For a set of *k* equal cost forwarding Ports, let P be an ordered list of the forwarding Ports sorted from greatest to least neighbor SPB System Identifier and Pi be the ith Port in P. Thus P0 is the Port whose neighbor has the greatest SPB System Identifier and Pk–1 is the Port whose neighbor has the least SPB System Identifier. The following algorithm is used to select a value for i for the individual MAC address, thus selecting Port Pi to be the forwarding port:

a) Set a 32-bit variable *bestHash32* to 0xFFFFFFFF.
b) Set *i* to 0 (zero).

c) For each *n* in 0..*k*–1, (in order) perform the following steps:
   1) Set a 32-bit variable *hash32* to 0x811C9DC5.
   2) For each octet O_j (extended to 32 bits with leading 0's) in the Bridge's SPB System Identifier (8.13.8), starting with the least significant octet (octet 5) and progressing to the most significant octet (octet 0), set *hash32* to ((*hash32* XOR O_j) × 0x01000193).
   3) For each octet O_j (extended to 32 bits with leading 0's) in the neighbor SPB System Identifier for Port P_n, starting with the least significant octet (octet 5) and progressing to the most significant octet (octet 0), set *hash32* to ((*hash32* XOR O_j) × 0x01000193).
   4) For each octet O_j (extended to 32 bits with leading 0's) in the individual MAC address, starting with the least significant octet (octet 5) and progressing to the most significant octet (octet 0), set *hash32* to ((*hash32* XOR O_j) × 0x01000193).
   5) If *hash32* < *bestHash32*, set *i* to *n* and set *bestHash32* to *hash32*.

If flow filtering (44.2) is supported and the ECT-ALGORITHM value indicates flow filtering (Table 44-1), ISIS-SPB configures the Flow Filtering Control Table (44.2.2) for each port on which the ECMP SPBM VID is registered (27.13). For CBPs the Base VID is configured with both Flow Filtering and Flow Hash Generation enabled. For PNPs the Base VID is configured with Flow Filtering enabled and Flow Hash Generation disabled. For each individual address the ECMP ECT Algorithm calculates a Port Map specifying forwarding for a set of equal cost hops to that address and creates a corresponding Dynamic Filtering Entry (8.8.3). These Dynamic Filtering Entries are used in the dynamic selection of forwarding ports by the flow filtering process (44.2.3).

For each I-SID on a CBP transmitting multicast frames, the ECMP ECT Algorithm may calculate a source rooted SPT. If equal cost paths are found to any node on the tree, the path whose parent node (neighbor node toward the root) has the least Bridge Identifier is selected. A group MAC Address Registration Entry (8.8.4) is created for the I-SID's source rooted tree SPBM group MAC address (Figure 27-3) if the node performing the calculation is located between the source node and any multicast receiver(s) for the I-SID. The group MAC Registration Entry indicates forwarding for each port that leads to at least one multicast receiver for the I-SID on the calculated SPT (except the port from the source).

The ECMP ECT Algorithm supports two additional parameters that control multicast forwarding state calculation. First, a Tie-Break Mask value may be specified for an I-SID on a CBP [item i) in 28.12.10 and item h) in 12.25.6.1.2]. When a nonzero Tie-Break Mask is advertised, a 64-bit mask (formed by repeating the 4-bit Tie-Break Mask value in each nibble) is applied to (XORed with) each Bridge Identifier before selecting the lowest value as described in the SPT calculation in the paragraph above. Thus the default behavior described above is equivalent to using a Tie-Break Mask of zero. This parameter enables up to 16 different SPTs to be calculated from a given source node. Each I-SID on a CBP may be assigned independently to one of these 16 source trees.

The second parameter controlling multicast forwarding state calculation is the shared tree indicator. An I-SID on a CBP may be configured to use a shared tree instead of a source-specific SPT [item h) in 28.12.10 and item g) in 12.25.6.1.2]. There may be up to 16 shared trees, corresponding to the 16 Tie-Break Mask values. Each shared tree is calculated by selecting a root Bridge using the least masked Bridge Identifier. If a node advertises a Bridge Priority for the given Tie-Break Mask (28.12.6.1) the advertised value is used instead of the normal Bridge Priority in forming its Bridge Identifier (before masking). In calculating the SPT from the selected root, the same Tie-Break Mask is used to form masked Bridge Identifiers (using the normal Bridge Priority), and the least value of masked Bridge Identifier is used to choose between equal cost parents for any node. If an I-SID on a CBP is configured to use a shared tree, the group address used in the group MAC Address Registration Entry is constructed using the Tie-Break Mask and the I-SID (27.15, Figure 27-6). In this case the ECMP ECT Algorithm creates a group MAC Address Registration Entry if the node performing the calculation is between the CBP and any multicast receivers on the SPT calculated from the selected root node. The Port Map indicates forwarding for all Ports that lead from a multicast transmitter to at least one multicast receiver for the I-SID.

If an I-SID on a CBP does not indicate transmission of multicast frames (e.g., head-end replication is to be used instead), then no group MAC Address Registration Entry is configured for multicast from that CBP for that I-SID.

Table 44-1 shows the ECT-ALGORITHM values for the ECMP ECT Algorithm.

Table 44-1—ECMP ECT-ALGORITHM values

ECT-ALGORITHM	ECMP behavior
00-80-C2-11	ECMP without flow filtering
00-80-C2-12	ECMP with flow filtering

44.1.3 Loop prevention for ECMP

Loop prevention for unicast ECMP operates as specified in Clause 13 with the extension of allowing multiple Root Ports in case of multiple equal cost paths in order to support the per frame tie-breaking of ECMP. The ECMP connectivity to a destination bridge comprises the shortest paths destined to that bridge when the topology is Agreed in the meaning of the Agreement Protocol. If a bridge is not the destination bridge, then the one or more ports that ISIS-SPB has calculated as respectively providing a shortest path to the destination is a Root Port in the ECMP connectivity. Each port, other than a Root Port, is a Designated Port if ISIS-SPB has calculated that the port provides a shortest path for frames forwarded from the attached bridge to the destination in the ECMP connectivity. With these extensions to the definitions of Port Roles, Clause 13 specifications apply to ECMP as well.

NOTE 1—Despite allowing more than one Root Port for an SPT Bridge, a single Root Port is enforced on a per-frame basis as ECMP operation ensures that a frame is forwarded through only one of the Root Ports towards the destination.

Loop prevention for the shared trees used for ECMP multicast operates as specified by Clause 13 for shared spanning trees except for that instead of a Spanning Tree Protocol Entity (STPE), it is ISIS-SPB that configures the per-tree Port States and Roles based on its calculations and the operation of the Agreement Protocol; furthermore, the Learning Process (8.7) neither creates nor deletes Dynamic Filtering Entries.

NOTE 2—The per-tree Port States and Roles do not belong to an MSTI having a distinct MSTID because an ECMP B-VID is assigned to the SPBM MSTI. The Port States and Roles are associated with a single SPT used as a shared spanning tree supporting bidirectional forwarding (not as a unidirectional tree as for SPB).

44.2 Support for Flow Filtering

Flow filtering support enables Bridges to distinguish frames belonging to different client flows and to use this information in the forwarding process. Information related to client flows may be used at the boundary of an SPT Domain to generate a flow hash value. The flow hash, carried in an F-TAG, serves to distinguish frames belonging to different flows and can be used in the forwarding process to distribute frames over equal cost paths. This provides for finer granularity load spreading while maintaining frame order for each client flow.

Flow filtering behavior is controlled by ISIS-SPB. To allow Bridges that support flow filtering to be used alongside Bridges that do not support flow filtering, ISIS-SPB requires that all Bridges at the SPT Domain boundary that advertise I-SIDs for an ECMP Base VID using flow filtering support F-TAG processing. Bridges that do not advertise I-SIDs for that Base VID are not required to support flow filtering. Therefore,

network operators are able to upgrade selected bridges to support flow filtering and use flow filtering for selected VIDs without requiring the simultaneous upgrade of all bridges in the SPT Domain.

NOTE—Support for F-TAG processing is indicated in I-SID advertisements and so is only available via ISIS-SPB once I-SIDs are assigned to the Base-VID. A "dummy" ISID configuration can be used to discover via ISIS-SPB whether F-TAG processing is supported on a Bridge.

This clause specifies the following:

a) A flow filtering tag (F-TAG) that carries a flow hash value (44.2.1).
b) F-TAG processing on Bridge Ports (44.2.2).
c) A forwarding process using the flow hash to select one forwarding port from a set of equal cost options (44.2.3).
d) TTL loop mitigation (44.2.4).
e) CFM for ECMP with flow filtering (44.2.5).
f) Operation of bridged LANs with selective support for flow filtering (44.2.6).

44.2.1 Flow filtering tag (F-TAG)

An F-TAG is specified to carry additional information in support of flow filtering functions. The F-TAG comprises a Tag Protocol Identifier (TPID) (EtherType) and Tag Control Information (TCI).

Table 44-2—F-TAG EtherType

Tag Type	Name	Value
Flow Filtering Tag	IEEE 802.1Q Flow Filtering Tag EtherType	89-4B

The F-TAG TCI field (Figure 44-1) is 4 octets in length and encodes priority, drop_eligible, TTL, and flow hash information for a service primitive.

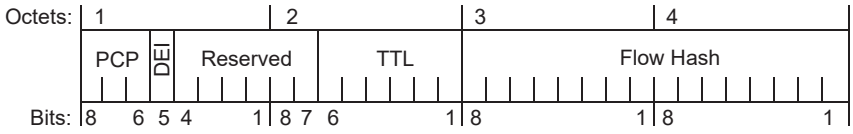

Figure 44-1—Flow Filtering TCI format

The F-TAG TCI contains the following fields:

a) *PCP (Priority Code Point)*—This 3-bit field encodes the priority and drop_eligible parameters of the service request primitive associated with this frame using the same encoding as specified for VLAN tags in 6.9.3.
b) *DEI (Drop Eligible Indicator*)—This 1-bit field carries the drop_eligible parameter of the service request primitive associated with this frame.
c) *Reserved*—This 6-bit field may be used for future format variations. The Reserved field contains a value of zero when the tag is encoded and is ignored when the tag is decoded.
d) *TTL (Time To Live)*—This 6-bit field holds a counter value that is decremented each time the F-TAG is read (44.2.2.1) and provides a mechanism to limit the number of network hops a frame may take.
e) *Flow Hash*—This 16-bit field carries a flow hash value used in the dynamic port selection process for ECMP (8.8.3).

44.2.2 F-TAG processing

This standard specifies flow filtering behavior for SPBM ECMP (44.2). To support this behavior, a flow hash may be conveyed in a mac_service_data_unit using an F-TAG (44.2.1). This clause specifies a Support for Flow Filtering shim that produces and processes F-TAG information. The shim has two EISS SAPs—a lower EISS toward a LAN and an upper EISS toward the MAC Relay Entity.

At the boundary of a flow filtering SPT Domain, for example, at CBPs, the flow hash is generated for EM_UNITDATA.indication primitives. At intermediate ports, for example, PNPs, the F-TAG is generated using the flow hash in EM_UNITDATA.request primitives or processed to retrieve the flow hash value from EM_UNITDATA.indication primitives. The F-TAG also includes a TTL field, used for loop mitigation, and PCP and DEI fields that are processed by this shim.

Flow filtering support is governed by a Flow Filtering Control Table for each port containing an entry for each VID with the following fields:

a) Flow Filtering (enabled/disabled). This field indicates whether flow filtering behavior is enabled on the port for the VID. The default value is disabled.
b) Flow Hash Generation (enabled/disabled). This field indicates whether flow hash generation is enabled on the port for the VID. The default value is disabled.
c) TTL Value (1..63). This field is the initial TTL value for frames entering the flow filtering SPT Domain [item d) in 12.16.5.5.2]. The default value is 8.

The Flow Filtering Control Table is provisioned by ISIS-SPB (44.1.2). For flow filtering, a CBP will have both the Flow Filtering field and the Flow Hash Generation field set to enabled and the TTL Value field set to provide the initial time_to_live value for indication primitives. For flow filtering, a PNP will have the Flow Filtering field set to enabled and the Flow Hash Generation field set to disabled. The TTL Value field (initial TTL value) is not used on a PNP.

NOTE—Based on the description above, for flow filtering, the condition “Flow Hash Generation field indicates enabled” is equivalent to indicating a CBP, and the condition “Flow Hash Generation field indicates disabled” is equivalent to indicating a PNP.

44.2.2.1 Data indications

On receipt of an EM_UNITDATA.indication primitive from the lower EISS on a PNP, the received frame shall be discarded if:

a) For the vlan_identifier in the Flow Filtering Control Table, the Flow Filtering field indicates enabled, and the initial octets of the mac_service_data_unit do not contain a valid F-TAG; or
b) The value in the TTL field in the F-TAG is 0.

NOTE 1—A frame received with a TTL value of 0 will be discarded, i.e., not relayed, even if it is addressed to another port on the receiving Bridge.

Otherwise, an EM_UNITDATA.indication primitive is invoked at the upper EISS with parameter values determined from the received primitive based on the Flow Filtering Control Table for the received vlan_identifier as follows:

c) If the Flow Filtering field indicates disabled, the invoked primitive is identical to the received primitive.
d) If the Flow Filtering field indicates enabled, the **destination_address**, **source_address**, **vlan_identifier**, and **connection_identifier** in the invoked primitive are identical to those parameters in the received primitive.
e) If the Flow Filtering field indicates enabled and the Flow Hash Generation field indicates disabled, the **mac_service_data_unit** in the invoked primitive is created by removing the F-TAG from the

received **mac_service_data_unit**; otherwise, the **mac_service_data_unit** in the invoked primitive is identical to the received primitive.

The value of the **flow_hash** and **time_to_live** parameters are determined as follows:

f) If the Flow Hash Generation field indicates enabled, the value of flow_hash is generated from the received primitive (using a process selected by the implementation). time_to_live is set to the TTL Value from the Flow Filtering Control Table for the received vlan_identifier.

NOTE 2—Procedures for calculating the flow hash are not covered by this standard. The procedure is typically a protocol-dependent hash of the client protocol header being carried within the mac_service_data_unit.

NOTE 3—There is often a compromise between the speed of a hash calculation and the quality of value spreading. This standard makes no assurances regarding the quality of the distribution of flow_hash values.

g) If the Flow Hash Generation field indicates disabled, the value of flow_hash is taken from the Flow Hash field in the received F-TAG, and time_to_live is set to the TTL value in the received F-TAG decremented by 1.

The value of the **drop_eligible** and **priority** parameters are determined as follows:

h) If the **mac_service_data_unit** was tagged with an F-TAG, the value of the drop_eligible parameter and the received priority value are decoded as described in 6.9.3, using the PCP and DEI values from the F-TAG. Otherwise,

i) The received priority value and the drop_eligible parameter value are the values in the EM_UNITDATA.indication.

j) The value of the priority parameter is then regenerated from the received priority, as specified in 6.9.4.

44.2.2.2 Data requests

On invocation of an EM_UNITDATA.request primitive at the upper EISS, an EM_UNITDATA.request primitive is invoked at the lower EISS, with parameter values determined based on the Flow Filtering Control Table for the received vlan_identifier.

If the Flow Filtering field indicates disabled or the Flow Hash Generation field indicates enabled, the invoked primitive is identical to the received primitive.

If the Flow Filtering field indicates enabled and the Flow Hash Generation field indicates disabled, all parameters in the invoked primitive match those in the received primitive except the mac_service_data_unit. The mac_service_data_unit in the invoked primitive is formed by inserting an F-TAG as the initial octets to the received mac_service_data_unit. The values of the **flow_hash**, **time_to_live**, **priority**, and **drop_eligible** parameters are used to determine the contents of the F-TAG, in accordance with 44.2.1.

44.2.3 Forwarding process extension for flow filtering

Frame filtering (8.6.3) reduces the set of potential transmission ports in accordance with applicable FDB entries. When flow filtering is enabled, the ISIS-SPB control plane creates Dynamic Filtering Entries with multiple forwarding Ports in the Port Map when there are multiple equal cost hops to a given individual address. Frame filtering must select only one of these forwarding ports on which to transmit each frame with a matching destination_address and VID.

Selection of one Port from a set indicated by the Port Map shall be performed using a form of the FNV non-cryptographic hash algorithm as follows:

For a Port Map specifying k potential forwarding Ports, let **P** be an ordered list of potential forwarding Ports sorted from greatest to least neighbor SPB System Identifier and P_i be the ith Port in **P**. Thus P_0 is the Port

whose neighbor has the greatest SPB System Identifier, and P_{k-1} is the Port whose neighbor has the least SPB System Identifier. The following dynamic port selection process is used to select a value for *i*, thus selecting Port P_i to be the transmission port:

a) Set a 32-bit variable *hash32* to 0x811C9DC.
b) For each octet O_j (extended to 32 bits with leading 0's) in the Bridge's SPB System Identifier (8.13.8), starting with the least significant octet (octet 5) and progressing to the most significant octet (octet 0), set *hash32* to ((*hash32* XOR O_j) × 0x01000193).
c) For each octet O_j (extended to 32 bits with leading 0's) in the flow_hash parameter, starting with the least significant octet (octet 4 of Figure 44-1) and progressing to the most significant octet (octet 3 of Figure 44-1), set *hash32* to ((*hash32* XOR O_j) × 0x01000193).
d) Set a 16-bit variable *hash16* to ((*hash32* and 0x0000FFFF) XOR (*hash32* / 0x00010000)).
e) Set *i* to (*hash16* mod *k*), selecting Port P_i.

44.2.4 TTL Loop mitigation

The F-TAG contains a TTL field whose value is decremented each time a frame is forwarded by an SPT Bridge supporting flow filtering [item g) in 44.2.2]. A frame is filtered (discarded) if it is received with a TTL value of 0. This mechanism mitigates the impact of looping frames by limiting the number of hops these frames may travel in the network. This method of loop mitigation protects network resources by ensuring frames are forwarded at most a fixed number of times.

NOTE—The TTL carried in the F-TAG is decremented for all frames; however, the Flow Hash is applicable only to unicast frames. The Flow Hash has no effect on the filtering of group addressed frames.

44.2.5 CFM for ECMP with flow filtering

CFM as specified in Clause 18 through Clause 22 provides capabilities useful in detecting, isolating, and reporting connectivity faults. SPBM MAs (27.18) can be used with an ECMP VID and provide most of the necessary CFM functionality. One additional MA type is specified for ECMP, the ECMP path MA, because an SPBM path MA can test only one path between a pair of endpoints.

An ECMP path MA is used to continuously test multiple paths between two endpoints. This type of MA has only two MEPs at two SPT Region boundary ports. The MA is identified by a TE-SID comprising an ESP in each direction between the two endpoints. An ECMP path MEP cycles through a set of flow hash values intended to direct the CCM frames along (and thus test) different paths to the other MEP in the MA. Each flow hash is used in multiple consecutive CCM frames so that a fault on a particular path will be detected and reported back via an RDI signal. This standard does not specify the mechanisms that would be necessary to support Loopback and Linktrace on an ECMP path MA since full Loopback and Linktrace coverage can be provided by an SPBM VID MA. Therefore, there are no MHFs associated with an ECMP path MA.

44.2.5.1 ECMP path MEP placement in a Bridge Port

Since ECMP path MEPs must only see traffic from one other endpoint, these MEPs need to be further differentiated by the TESI Multiplex Entity (6.19). This locates an ECMP path MEP so that it receives CCMs only from the other MEP in its MA. Figure 44-2 shows an example of ECMP path MEPs on a CBP.

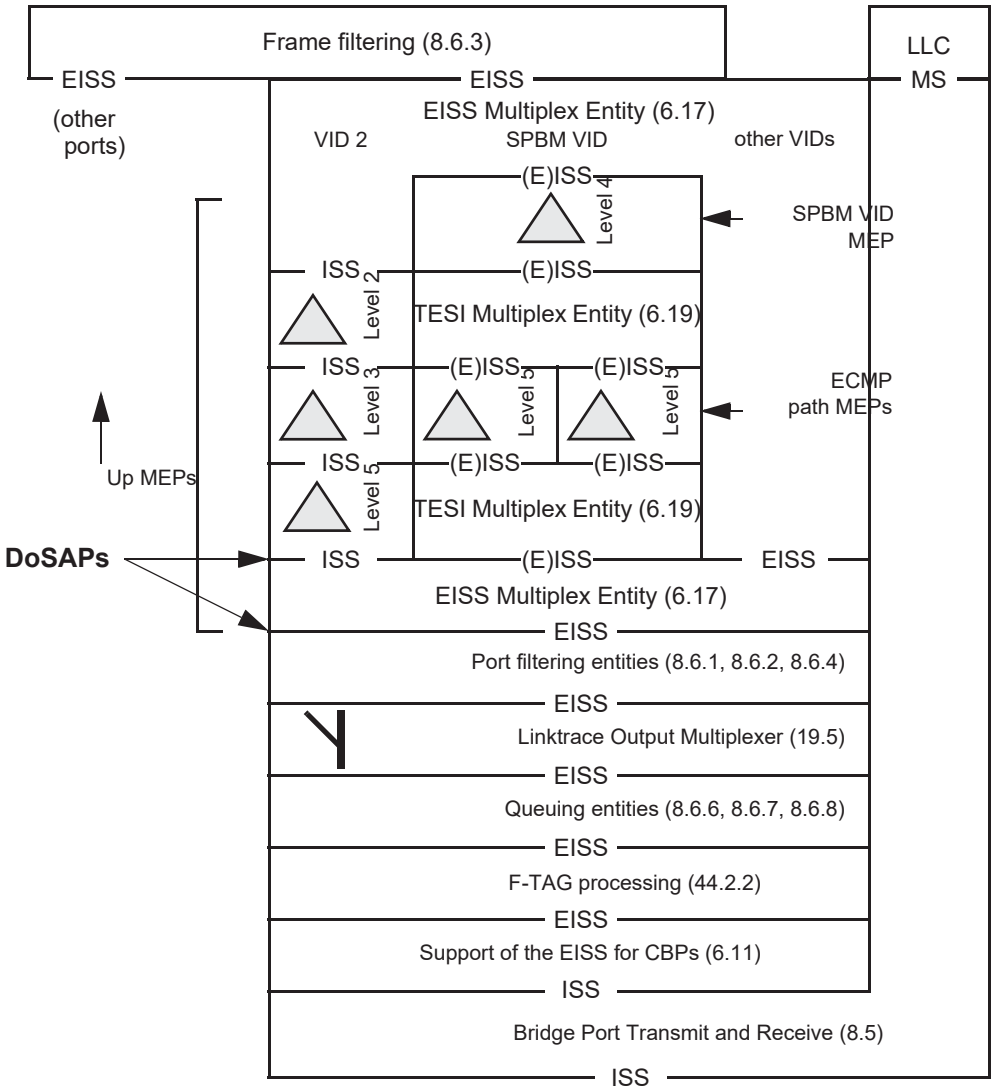

Figure 44-2—SPBM VID MEP and ECMP path MEP placement in a CBP

44.2.5.2 Continuity Check protocol in an ECMP path MA

The Continuity Check protocol is described in 20.1 and the corresponding state machines in Clause 20. The modifications required to realize ECMP path MAs include the following:

a) The MEP Continuity Check Initiator state machine adds three variables for controlling ECMP path testing (20.10.4, 20.10.5, 20.10.6) and shares two of these with the Remote MEP state machine (Figure 20-1).

b) The destination_address parameter is set to the individual MAC address of the other MEP in the MA [item a) in 20.11.1].

c) The flow_hash parameter is set to one of the values to be tested, and the time_to_live parameter is set as specified in item e) in 20.11.1.

d) The MEP Continuity Check initiator state machine is modified to support a cycle of path tests for an ECMP path MEP (20.12).

e) The Remote MEP state machine is modified to track a cycle of path test RDI values and report rMEPlastRDI as set if any RDI has been seen in the last path test cycle for an ECMP path MEP (20.19.2, 20.20).

NOTE—In an ECMP path MEP testing a set of paths, the RDI signal reflects back the state of far end CCM reception. Using the current CCM sending cycle position (pathN), the CCM sending rate, and the path round trip delay, one can calculate roughly the position in the sending cycle corresponding to a received RDI. This approach makes minimal changes to the CCM state machines at the CCM sending MEP and no changes at the CCM receiving MEP. It is subject to some ambiguity based on differences in path delay, the sending rate, and cycle length. In the case of ambiguous results, further testing would be required to identify a faulty path.

SPBM MAs may also implement the following enhancements to the Continuity Check protocol:

f) The procedure MEPprocessEqualCCM() on ECMP path MEPs does not include the check of the MAID on received CCMs [item b) in 20.17.1].

All other Continuity Check processes are the same as those for a VID-based MA.

44.2.6 Operation with selective support for flow filtering

When adding new capabilities to a network, it is desirable to make changes incrementally rather than perform a wholesale upgrade (e.g., incur a “flag day” event). Flow filtering is optional functionality that can be used with selected Base-VIDs while not adversely affecting other services in the network. However, flow filtering changes frame encoding (i.e., adds new header information in an F-TAG) and therefore requires that a Base-VID using ECMP with flow filtering have all its boundary points capable of processing the F-TAG. To enable incremental incorporation of flow filtering, ISIS-SPB requires F-TAG support for any Bridges with a CBP associated with a Base VID using ECMP with flow filtering while allowing other Bridges in the SPT region to operate without flow filtering support.

When the ECMP ECT-ALGORITHM value indicates support for flow filtering (Table 28-1), an I-SID cannot be configured to use a Base VID using ECMP with flow filtering unless the Bridge supports flow filtering (12.16.5.2). Requiring all Bridges advertising service instances using ECMP with flow filtering to support F-TAG processing provides for proper handling of F-tagged frames at the boundary of the SPT Domain.

Within the SPT Domain, it is possible to use Bridges that support the ECMP ECT Algorithm but do not support flow filtering (i.e., do not recognize F-TAGs). In this case, the ECMP ECT Algorithm (28.9) selects one port from the set of equal cost forwarding ports for each individual address and creates a Dynamic Filtering Entry for the address indicating the selected port.

NOTE—Bridges that do not support flow filtering should not change PCP and DEI values for frames carrying F-TAGs as this may not provide the desired behavior. If the PCP and DEI values are changed in the VLAN tag only, the PCP and DEI values carried in the F-TAG will be reasserted when the F-TAG is next processed.

These ECMP behaviors enable incremental upgrade of edge bridges to support flow filtering and selective use of this capability with I-SIDs registered only at these upgraded edge bridges. ECMP operation with selective support for flow filtering enables incremental introduction of flow filtering capabilities into an existing network and earlier introduction of flow filtering support for selected services.

45. Path Control and Reservation (PCR)

This clause specifies IS-IS extensions to provide the following:

a) Establishment of explicit trees for frame forwarding in an SPT Region (45.1),
b) Use of IS-IS to communicate bandwidth assignments made by the Path Computation Element (PCE) (45.2), and
c) Redundancy with the establishment of the corresponding trees (45.3).

The Path Control and Reservation (PCR) IS-IS extensions specified in this clause are compatible with ISIS-SPB specified in Clause 27 and Clause 28. Furthermore, IS-IS with PCR extensions (ISIS-PCR) relies on the SPB architecture and terminology; and ISIS-PCR also leverages some of the ISIS-SPB sub-TLVs (see, e.g., 5.5) as specified by this clause. This specification considers only point-to-point links for PCR although IS-IS also supports shared media LANs.

NOTE 1—ISIS-PCR does not require the implementation of the full ISIS-SPB protocol; but in addition to IS-IS, ISIS-PCR requires the support of the ISIS-SPB sub-TLVs listed in 5.5 (also listed as PCR-2–PCR-5 in A.43), whose use is specified by this clause. Nonetheless, if an SPT Bridge supports both ISIS-SPB and ISIS-PCR, then both of them are implemented by the same IS-IS Higher Layer Entity.

A VID can be associated with an explicit tree, i.e., with an explicit active topology within an SPT Region. The Base VID of the VLAN is then associated with explicit path control mode of IS-IS operation, i.e., ISIS-PCR. A VID can be associated with multiple explicit trees if the considerations explained in 45.1.4 are taken into account. VIDs controlled by ISIS-PCR do not participate in ECMP operation (Clause 44).

NOTE 2—A VLAN can provide a point-to-point, point-to-multipoint, or multipoint-to-point service using the multipoint-to-multipoint connectivity provided by an active topology. Similarly the Transmit and Receive IS-IS sub-TLV flags (28.12.10) of Edge Bridges allow an I-SID to use a multipoint-to-multipoint VLAN to provide point-to-point, point-to-multipoint, or multipoint-to-point service.

Path Computation Element (PCE) entities are external to the IS-IS protocol and fully or partially determine and describe each explicit tree to be established by ISIS-PCR throughout an SPT Region. There can be multiple PCEs in a region; nevertheless, any given explicit tree is under the control of one PCE. Explicit trees can be used, for example, for placing selected traffic on a precisely defined route, usually off the shortest path tree.

ISIS-PCR is able to record and communicate bandwidth assignments if instructed to do so by a PCE. ISIS-PCR can be used for bandwidth assignments only if MSRP is not used in the SPT Region. If ISIS-PCR communicates bandwidth assignments, then the tree descriptor assembled by the PCE also includes the details of the bandwidth assignment to be recorded by the Bridges. This mode of operation is expected to be used to divert traffic aggregates off their shortest path route, in order to avoid potential congestion on the default shortest path.

The redundancy provided by a physical topology can be leveraged by various resiliency schemes. A PCE can be used for the computation, and ISIS-PCR can be used for the establishment of the trees required for a given resiliency solution.

45.1 Explicit trees

This subclause specifies IS-IS extensions that provide explicit forwarding trees for data frames. An explicit tree is determined by a Path Computation Element (PCE) and is not required to follow the shortest path. PCE is defined by IETF RFC 4655 [B34]. A PCE is an entity that is capable of computing a topology for forwarding based on a network topology, its corresponding attributes, and potential constraints. A PCE explicitly describes a forwarding tree as specified in 45.1.9. Either a single PCE or multiple PCEs determine explicit trees for a region. Even if there are multiple PCEs in a region, each explicit tree is determined by only one PCE, which is referred to as the owner PCE of the tree. PCEs and ISIS-PCR can be used in combination with ISIS-SPB shortest path routing.

A PCE is a higher layer entity in an SPT Bridge or an end station. The PCE interacts with the active topology control protocol, i.e., with ISIS-PCR. The collaboration with ISIS-PCR can be provided by a Path Control Agent (PCA) on behalf of a PCE. Either the PCE or the corresponding PCA is part of the IS-IS Domain. If the PCE is not part of the IS-IS Domain, then the PCE has to be associated with a PCA that resides either in an SPT Bridge or in an end station directly connected to at least one Bridge of the SPT Region. The PCE or its PCA establishes IS-IS adjacency (45.1.7) in order to receive all the LSPs transmitted by the Bridges in the region. The PCE, either on its own or via its PCA, can control the establishment of explicit trees in that region by injecting an LSP conveying an explicit tree and thus instruct ISIS-PCR to set up the explicit tree determined by the PCE. Each PCE, whether located in a Bridge or end station, has access to the link state topology and resource information common throughout the region. If instructed to do so by a PCE, ISIS-PCR can also record and communicate bandwidth assignments, which can be applied only if MSRP is not used in the region. Different PCE and PCA locations are illustrated in Figure 45-1 and Figure 45-2.

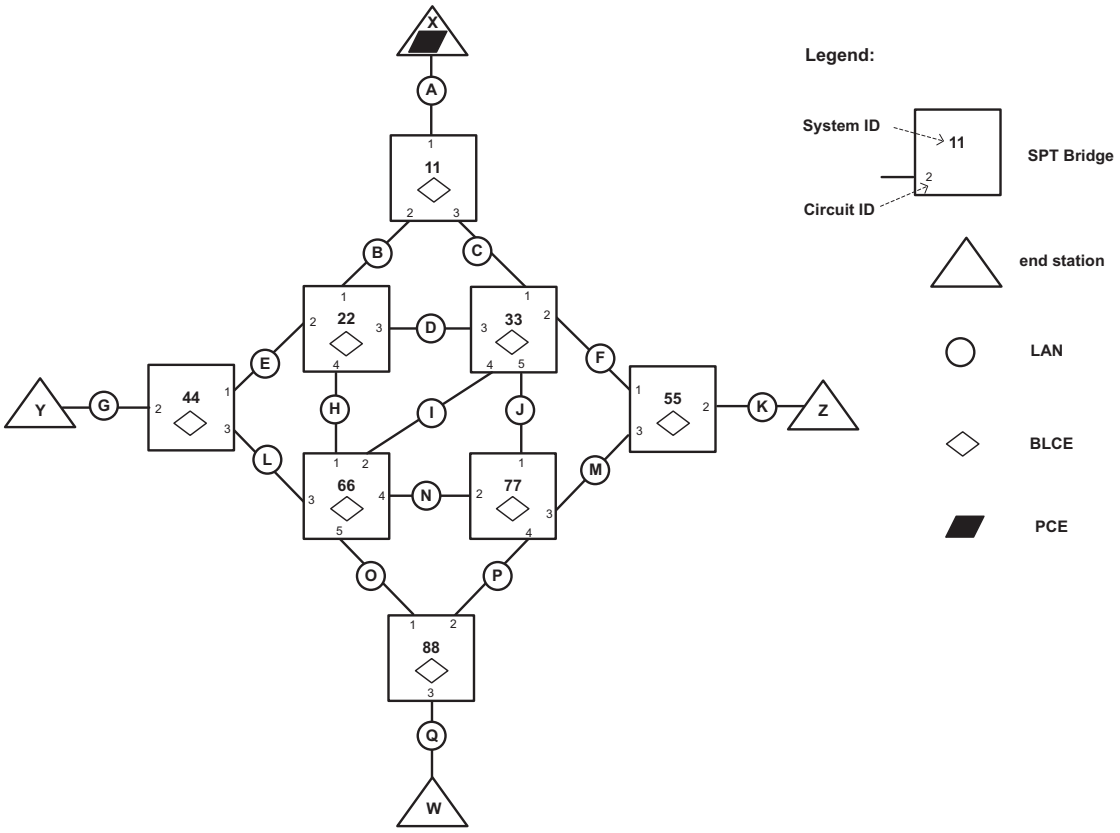

Figure 45-1—An SPT Region controlled by a single PCE

NOTE 1—The operation details of the PCE are not specified by this standard. If the PCE is part of the IS-IS Domain, then the PCE uses IS-IS PDUs to communicate with the IS-IS Domain, and the PCE has a live IS-IS LSDB (i.e., the PCE implements the PCA functions, too). A PCE can instead communicate with the IS-IS Domain via a PCA, e.g., to retrieve the Link State Database (LSDB) or instruct the creation of an explicit tree. However, the means of communication between the PCE and the PCA is not specified by this standard. A PCE could operate on a network topology retrieved by other means, e.g., configuration, instead of retrieving it from a live IS-IS LSDB; which operation mode is not specified by this standard. Having no live LSDB, the PCE instructs its PCA to flood the LSP conveying the appropriate Topology sub-TLV.

ISIS-PCR implements Software Defined Networking (SDN) through hosting the PCE in an external agent, e.g., an SDN Controller. In this case IS-IS is the protocol used to control the Bridges by the SDN Controller; the explicit trees are programmed in the Bridges via IS-IS.

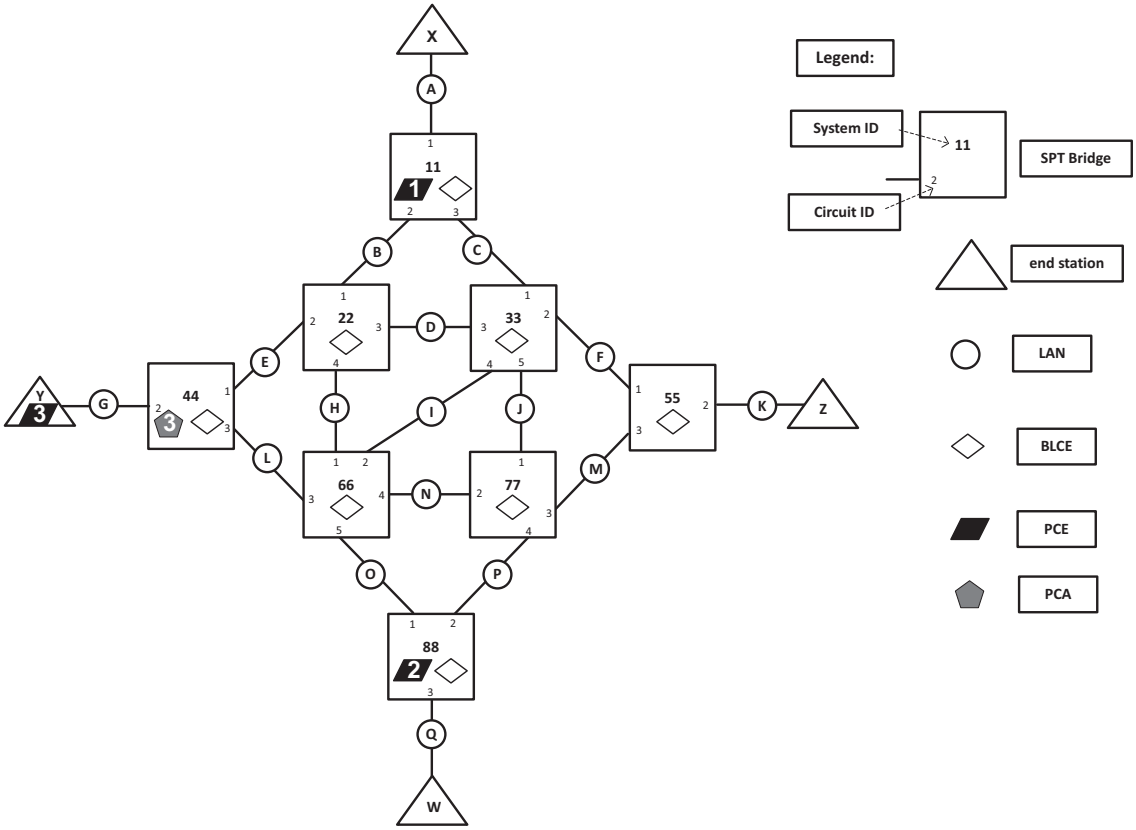

Figure 45-2—An SPT Region controlled by multiple PCEs

Figure 45-1 shows a region controlled by a single PCE residing in end station X connected to SPT Bridge 11. The PCE has IS-IS adjacency established with SPT Bridge 11, i.e., the PCE is part of the IS-IS Domain.

The IS-IS Domain coincides with the SPT Region in Figure 45-1 and Figure 45-2; they comprise SPT Bridges 11, 44, 55, and 88 (Edge Bridges) and SPT Bridges 22, 33, 66, and 77 (Core Bridges). As shown in the figures, each SPT Bridge implements a Bridge Local Computation Engine (BLCE).

Figure 45-2 shows a region controlled by multiple PCEs. Some of the SPT Bridges implement a PCE in addition to their BLCE; PCE 1 and PCE 2 reside in SPT Bridge 11 and SPT Bridge 88, respectively. PCE 3 resides in End Station Y. PCE 3 is not part of the IS-IS Domain; PCE 3 uses PCA 3 to instruct ISIS-PCR for the establishment of explicit trees and to retrieve link state data from the domain.

An Explicit Tree (ET) is an undirected loop-free topology, whose use is under the control of the owner PCE by means of associating VIDs and MAC addresses with it. As it is undirected, the ET contains no assumptions about the direction of any flows that use it; it can be used in either direction as specified by the VIDs and MAC addresses associated with it. It is the responsibility of the PCE to ensure reverse path congruency (3.213) and unicast multicast congruency (3.285) if that is required, e.g., making an explicit tree symmetric (3.264) by setting it up so that it is used in both directions between a pair of Bridges.

An explicit tree is either strict or loose. A strict explicit tree specifies all Bridges and paths it comprises. A loose tree specifies only the Bridges that have a special role in the tree, e.g., an Edge Bridge, and no path or path segment is specified between the Bridges, which are therefore loose hops even if Edge Bridges are adjacent neighbors. The special role of a hop can be an Edge Bridge, a root, a leaf, a Bridge to be avoided, or

a transit hop in the case of a tree with a single leaf. The path for a loose hop is determined by the BLCE of the SPT Bridges. The shortest path is used for a loose hop unless specified otherwise by the descriptor (45.1.9) of the tree or by the corresponding ECT Algorithm (45.1.2).

NOTE 2—PCE and BLCE are architecturally different entities. A BLCE is implemented in each SPT Bridge, where the BLCE implements the SPF algorithm at the minimum and can also implement more complex path computation algorithms, e.g., for determining constrained or redundant trees. For instance, the BLCE of SPT Bridges supporting ISIS-SPB at least implements an all pairs shortest path algorithm in addition to SPF. Forwarding trees are computed by the BLCEs unless they are explicitly given. Conversely, a PCE can implement more complex computation algorithms, and its main task is to determine explicit trees even if the PCE resides in a Bridge.

NOTE 3—If shortest paths are used for loose hops, then there is no need for any computation in addition to SPB as ISIS-SPB performs all pairs shortest path computation.

A loose explicit tree is constrained if the tree descriptor includes one or more constraints, e.g., the administrative group to which the links of the tree have to belong. The BLCE of the SPT Bridges then performs constrained routing (CR) to determine a loose hop instead of shortest path routing. CR relies on distributed link state operation similarly to shortest path routing. CR essentially performs shortest path routing on the topology that contains only the links meeting the constraint(s); therefore, the applied path computation algorithm is also referred to as Constrained Shortest Path First (CSPF).

NOTE 4—If a tree is a strict explicit tree, then it is fully specified; therefore, no constraint is included in the tree descriptor (45.1.9) as no further computation is needed.

An explicit tree is specified by a Topology sub-TLV (45.1.9). The Topology sub-TLV associates one or more VIDs with an explicit tree. The Topology sub-TLV includes two or more Hop sub-TLVs (45.1.10), and a hop is specified by an IS-IS System ID. A strict tree is decomposed to branches, and each branch is specified by an ordered list of Hop sub-TLVs. A loose tree is not fully specified, but the Topology sub-TLV conveys some of its hops. The Hop sub-TLV of a loose hop can include a delay constraint [item h) in 45.1.10]. A Topology sub-TLV can also include further sub-TLVs to constrain (45.1.11, 45.1.12) loose hops. The Bridges involved in an explicit tree store the corresponding Topology sub-TLVs in their Explicit Tree Database (ETDB).

Explicit trees are propagated and set up by ISIS-PCR in an SPT Region. The PCE or its PCA assembles the Topology sub-TLVs (45.1.9) and then instructs ISIS-PCR to establish the tree. If the PCE resides in an SPT Bridge, then the PCE entity passes the Topology sub-TLV (45.1.9) to the ISIS-PCR entity, which shall then flood an LSP including the Topology sub-TLV throughout the SPT Domain. If the PCE resides in an end station, then either the PCE or its PCA adds the Topology sub-TLV (45.1.9) into an LSP, which is flooded throughout the SPT Domain. The Topology sub-TLV is flooded by the same techniques used for the SPB LSPs. The SPT Bridges then shall process the Topology sub-TLV (45.1.9) upon reception. If the Topology sub-TLV specifies one or more loose trees, then the path for the loose hops is determined by the BLCE of the SPT Bridges. The SPT Bridges then install the appropriate FDB entries (45.1.6) for frame forwarding along the tree described by the Topology sub-TLV (45.1.9) or the trees computed based on the Topology sub-TLV. Dynamic Filtering Entries are maintained by ISIS-PCR for the VID, MAC address tuples associated with an ET.

NOTE 5—Due to the LSP aging of IS-IS, the Topology sub-TLVs (45.1.9) have to be refreshed similar to other IS-IS TLVs in order to keep the integrity of the LSDB. The corresponding Dynamic Filtering Entries are also refreshed when a Topology sub-TLV is refreshed. Refreshing Topology sub-TLVs is the task of the entity being part of the IS-IS Domain, i.e., either the PCE or the PCA.

The owner PCE can withdraw an explicit tree by sending an updated LSP that does not include the Topology sub-TLV. If a Topology sub-TLV is removed from an LSP (or has been changed), so that (previous) Topology sub-TLV is no longer present (or has been changed) in the LSDB, then that (previous) Topology sub-TLV is implicitly withdrawn. ISIS-PCR then removes (or updates) the explicit tree.

ISIS-PCR provides precedence order among Topology sub-TLVs as specified in 45.2.3 if it is needed in a region with multiple PCEs.

45.1.1 Tree structures

Two types of tree structures can be used for explicit trees, as follows:

— Ad-hoc trees
— Template trees

Ad-hoc explicit trees do not follow any template; they can comprise any path. A particular explicit tree is defined, and a VID is assigned to the explicit tree. The administratively straightforward way to do this is to use a bidirectional VID for the explicit tree. This approach constructs a shared bidirectional (*,G) tree joining all members of a group.

NOTE 1—A single common (*,G) spanning tree can be constructed this way.

Alternatively, explicit trees can follow templates. It can be helpful to define a tree rooted on every Bridge, where each tree spans every Bridge of a domain and the complete set of trees, one rooted on each Bridge of a domain, are constructed consistently, so that collectively they form a single forwarding plane offering any-to-any connectivity within that domain. Such trees are used as a source rooted tree for multicast traffic emitted from a Bridge, and they are also used as a destination rooted tree for unicast traffic being sent to their Bridge. There is a fundamental constraint that has to be obeyed for all such structures individually in that plane. They have to be simply connected trees, with only one path from any point in the network domain to the root of the tree. If paths to the root cross at any point, or merge and subsequently diverge, a unicast forwarding inconsistency or an unwanted multicast frame replication point is created.

This connectivity style (i.e., a tree per Bridge per plane) is, for example, enforced by construction by Shortest Path Bridging. In SPB, a Base VID is associated with one of the standard symmetric ECT Algorithms (28.8), which identifies a plane. In SPBM, the individual trees within each Base VID are defined by the MAC address of the root Bridge; in SPBV each Bridge is allocated an individual SPVID to define its tree.

Any preferred algorithm can be used when performing explicit routing, and the required constraint can be replicated by maintaining the simply connected tree construct. Thus the template-tree-based approach constructs one or more explicitly routed forwarding planes with tree sets, one tree rooted on each Bridge within each plane.

In the case of a learning VLAN, a unidirectional VID can be assigned to each tree (similarly to the unidirectional SPVID model), so that each tree is independent and identifies its root Bridge. Shared VLAN Learning (3.238) takes place among the VIDs associated with the same explicit tree set, where reverse congruence (3.213) has to be enforced by the function that computes the explicit trees on a particular forwarding plane (Base VID).

In the case of a non-learning VLAN, the MAC of the root Bridge identifies the tree, and a single Base VID identifies the entire forwarding plane.

Care has to be taken when constructing multicast trees with multiple sources if the template tree approach is used. Source-specific multicast (S,G) has to be applied if multiple sources participate in a single multicast group. A separate source rooted tree is constructed for every source of the group, and the complete multicast structure is the superposition of all these separate source rooted trees. The multicast traffic of the different sources has to be distinguished either by a VID (as in SPBV) or by a source-specific Group MAC address (as in SPBM, see 27.15).

NOTE 2—There is no requirement here that the initial template construction actually generates spanning trees. If Bridges only initially require connectivity to a subset of the SPT Bridges of a region, only the relevant part of the template need initially be constructed. This leaves freedom to add hitherto unconnected Bridges by extension of trees using a preferred route at a later stage.

45.1.2 Explicit ECT Algorithms

Five explicit path control modes are specified by this standard; each of them is identified by a distinct ECT-ALGORITHM. Table 45-1 summarizes the ECT Algorithms that can be used for explicit trees. The ECT-ALGORITHMs specified by this standard for explicit trees are formed using OUI=00-80-C2 and Index values 0x17, 0x18, 0x19, and the range from 0x21 to 0x40. SPT Bridges that support PCR shall support the Strict Tree ECT Algorithm (00-80-C2-17) and may support the other ECT Algorithms of Table 45-1. VLANs under explicit path control are associated with one of the ECT Algorithms as specified by 45.1.3.

NOTE 1—The ECT-ALGORITHM is in fact the identifier of the method and the algorithm used to determine the active topology. Although the active topology specified by this clause is not an Equal Cost Tree, the terminology and the ECT Algorithm framework of Clause 27 and Clause 28 is kept. The Opaque ECT concept (28.6) is also supported for explicit path control, which can be used for further algorithms.

Table 45-1—ECT-ALGORITHM values for explicit trees

ECT-ALGORITHM	Algorithm Name	Behavior
00-80-C2-17	Strict Tree (ST ECT Algorithm)	A single strict explicit tree. No restoration or update is performed by IS-IS on its own; only the PCE can initiate the update of a strict ET.
00-80-C2-21 ... 00-80-C2-30	Loose Tree (LT ECT Algorithm)	A single loose explicit tree. The loose hops are computed by the BLCE of SPT Bridges applying constrained or shortest path routing. The loose hops are restored by IS-IS upon a topology change if loop-free paths are available. The Bridge Priority Mask to be used in the case of constrained or shortest paths is specified by Table 45-2.
00-80-C2-31 ... 00-80-C2-40	Loose Tree Set (LTS ECT Algorithm)	A set of loose explicit trees. The set comprises an individual tree for each Edge Bridge included in the descriptor of the explicit tree, i.e., they are template trees. Each tree is computed by the BLCE of SPT Bridges applying constrained routing. These trees are restored by IS-IS upon a topology change. The Bridge Priority Mask to be used in the case of constrained or shortest paths is specified by Table 45-2.
00-80-C2-18	Maximally Redundant Trees (MRT ECT Algorithm)	Maximally Redundant Trees (MRTs) are loose trees for each MRT Root, which are computed together with the corresponding GADAG by the BLCE of SPT Bridges and cautiously restored by ISIS-PCR. If the topology view is identical throughout the SPT Domain, then IS-IS restores these trees one by one, only one of each redundant set at a time (45.3.3).
00-80-C2-19	Maximally Redundant Trees with GADAG (MRTG ECT Algorithm)	Maximally Redundant Trees (MRTs) are loose trees for each MRT Root, which are computed by the BLCE of SPT Bridges based on the GADAG received from the single GADAG Computer. MRTs are cautiously restored by ISIS-PCR upon reception of a new GADAG from the GADAG Computer. IS-IS restores these trees one by one, only one of each redundant set at a time (45.3.4).

The Strict Tree (ST) ECT Algorithm is used for a strict explicit tree. A strict ET is static as no other entity can update it but the tree owner PCE. In the case of a topology change, it is the task of the owner PCE to detect the topology change, e.g., based on the changes in the LSDB, and to update the strict trees if needed. In other words, the owner PCE computes the new tree, assembles its descriptor, and then instructs ISIS-PCR to install it. The use of VIDs for strict trees is described in 45.1.4, and redundant strict trees are explained in 45.3.2.

The Loose Tree (LT) ECT Algorithm is used for a single loose explicit tree. The path for loose hops is determined by the BLCE of the SPT Bridges; therefore, the Topology sub-TLV (45.1.9) specifying the tree

has to indicate which hop is the root of the tree. The loose hops are maintained by IS-IS, i.e., restored upon a topology change if a loop-free path is available. If the tree computed by the BLCE visits the same Bridge twice (implying that a loop or hairpin has been created), then that loop or hairpin has to be pruned from the tree even if it contains a hop specified by the Topology sub-TLV. Constrained routing can be applied for the loose hops based on the attributes listed in 45.1.8. If a Bridge is not to be included is also a constraint, which can be specified by the Exclude flag [item c6) in 45.1.10] of a Hop sub-TLV (45.1.10) conveyed by the Topology sub-TLV specifying the tree.

The Loose Tree Set (LTS) ECT Algorithm is used if connectivity among the Edge Bridges specified by the Topology sub-TLV (45.1.9) is to be provided by a set of loose trees so that one tree is rooted at each Edge Bridge, i.e., the loose trees are template trees (45.1.1). The BLCEs of the SPT Bridges compute the loose trees, which are maintained by IS-IS, i.e., restored upon a topology change. Avoiding some bridges in these trees is a constraint, which can be specified by the Exclude flag [item c6) in 45.1.10]. Further constraints can be specified by the Topology sub-TLV based on the attributes listed in 45.1.8.

NOTE 2—A Loose Tree Set is similar to a Shortest Path Tree Set with the following differences: The trees of an LTS span only the Edge Bridges specified by the Topology sub-TLV; they do not span the entire SPT Region. Furthermore, constrained routing is applied instead of shortest path routing.

Table 45-2—Bridge Priority Masking for the LT and LTS ECT Algorithms

ECT-ALGORITHM (LT ECT Algorithm)	ECT-ALGORITHM (LTS ECT Algorithm)	Algorithm MASK
00-80-C2-21	00-80-C2-31	0x00
00-80-C2-22	00-80-C2-32	0xFF
00-80-C2-23	00-80-C2-33	0x88
00-80-C2-24	00-80-C2-34	0x77
00-80-C2-25	00-80-C2-35	0x44
00-80-C2-26	00-80-C2-36	0x33
00-80-C2-27	00-80-C2-37	0xCC
00-80-C2-28	00-80-C2-38	0xBB
00-80-C2-29	00-80-C2-39	0x22
00-80-C2-2A	00-80-C2-3A	0x11
00-80-C2-2B	00-80-C2-3B	0x66
00-80-C2-2C	00-80-C2-3C	0x55
00-80-C2-2D	00-80-C2-3D	0xAA
00-80-C2-2E	00-80-C2-3E	0x99
00-80-C2-2F	00-80-C2-3F	0xDD
00-80-C2-30	00-80-C2-40	0xEE

In the case of the LT and LTS ECT Algorithms, the symmetric shortest path tie-breaking specified in 28.5, 28.6, 28.7, and 28.8 is used during shortest path computation to manipulate the lexicographic ordering of hops on a path after pruning the topology according to the constraints. The Bridge Priority Masks for the LT and LTS ECT Algorithms are shown in Table 45-2. The mask identification method specified for the

Symmetric ECT Algorithms is used. The IEEE 802.1 OUI (00-80-C2) is used, Index values 0x21 through 0x30 are used for the LT ECT Algorithm, and Index values 0x31 through 0x40 are used for the LTS ECT Algorithm as shown in Table 45-2.

The Maximally Redundant Trees (MRT) ECT Algorithm or the Maximally Redundant Trees with Generalized Almost Directed Acyclic Graph (GADAG) (MRTG) ECT Algorithm is used if maximally redundant loose explicit trees have to be maintained together. The use of the MRT ECT Algorithm and the MRTG ECT Algorithm is described in 45.3.3 and 45.3.4, respectively.

ISIS-PCR uses the link metrics specified by the SPB Link Metric sub-TLVs (28.12.7) if the LT, the LTS, the MRT, or the MRTG ECT Algorithm is used. The SPB Link Metric sub-TLV is used as specified in 28.12.7; therefore, the maximum metric value is used in cases where the metrics advertised by adjacent Bridges for a given link are different.

A topology change can cause the need for recomputing and updating multiple loose trees. If constrained routing based on available bandwidth (45.1.12) is used for multiple loose trees, then there can be a race hazard for the same resources if they are updated at the same time. Furthermore, the computation order can influence the trees. Therefore, ISIS-PCR applies the tie-breaking method specified in 45.2.3 in order to determine the computation order among the loose trees based on their descriptor Topology sub-TLV. If a Topology sub-TLV specifies multiple loose trees, e.g., LTS or MRTs, then the computation order of these trees follows the ascending order of the IS-IS System ID of the Bridges rooting the trees.

45.1.3 ISIS-PCR VLAN configuration

A VLAN provided by an explicit tree controlled by IS-IS is associated with IS-IS by means of allocating the VLAN's Base VID to the appropriate MSTID, i.e., either to the SPBM-MSTID or to the SPBV-MSTID. The explicit path control mode is then selected by associating the Base VID with the corresponding explicit ECT Algorithm.

The Base VID of VLANs controlled by IS-IS is allocated either to the SPBM-MSTID (0xFFC) or to the SPBV-MSTID (0xFFD) as specified in 27.4, which also applies to VLANs under explicit path control via IS-IS. If multiple VIDs belong to a VLAN under explicit path control, then each VID has to be allocated to the same MSTID; otherwise, the explicit trees do not get installed for the VLAN.

The exact active topology enforcement method applied for the VLAN is determined by the ECT Algorithm (28.8) with which the VLAN is associated. Explicit path control mode is configured by means of associating the Base VID with one of the ECT Algorithms specified in 45.1.2. The association of the VLAN with the ECT Algorithm shall be provided by the SPB Base VLAN-Identifiers sub-TLV (28.12.4).

Each VID belongs only to one PCE, which is the owner PCE that has full control on the use of the VID. The VIDs of a PCE are to be configured at the PCE. If multiple PCEs try to use the same VID, then ISIS-PCR provides the precedence as specified in 45.2.3.

An IS-IS controlled VLAN is a non-learning VLAN if the VLAN's Base VID is allocated to the SPBM-MSTID (0xFFC). MAC addresses are distributed explicitly for non-learning VIDs by IS-IS. The M flag is set in the SPB Instance sub-TLV (28.12.5) for non-learning VLANs. If a non-learning VLAN is associated with a symmetric ECT Algorithm (28.8), then the VLAN is under SPBM control as specified by Clause 27 and Clause 28 even if the VLAN is not a B-VLAN. If a non-learning VLAN is associated with one of the explicit ECT Algorithms (45.1.2), then it is under explicit path control as specified by this clause.

An IS-IS controlled VLAN is a learning VLAN if the VLAN's Base VID is allocated to the SPBV-MSTID (0xFFD). If a learning VLAN is supported by multiple VIDs, then Shared VLAN Learning (3.238) takes place among the VLAN's VIDs associated with the same shortest path or explicit tree set. The M flag is cleared in the SPB Instance sub-TLV (28.12.5) for learning VLANs. If a learning VLAN is associated with a

symmetric ECT Algorithm (28.8), then the VLAN is under SPBV control as specified by Clause 27 and Clause 28; correspondingly, SPVIDs can be auto-allocated to SPTs from the pool of SPVIDs, i.e., from the VIDs allocated to the SPVID-Pool-MSTID (0xFFF) as specified by 27.4. If a learning VLAN is associated with one of the explicit ECT Algorithms (45.1.2), then it is under explicit path control as specified by this clause; and each VID of the VLAN is allocated to the SPBV-MSTID (0xFFD), i.e., none of the VLAN's VIDs is allocated automatically. When a VLAN is under explicit path control, it is the responsibility of the PCE to provide reverse congruent paths (3.213) so that Shared VLAN Learning (3.238) operates correctly.

NOTE 1—The learning VIDs used for explicit trees are not allocated to the SPVID-Pool-MSTID. Therefore, they are not taken from the SPVID pool; they are not Shortest Path VIDs even if conveyed by an SPVID field of an IS-IS sub-TLV. To emphasize, a learning VID is an SPVID only if it is taken from the SPVID pool.

The Topology sub-TLV (45.1.9) conveys only the VLAN's Base-VID for each ECT Algorithm. Further VIDs, if any, are associated with the VLAN and its Base VID by ISIS-SPB sub-TLVs as specified below.

If the ST ECT Algorithm (Table 45-1) is used for either a learning or a non-learning VLAN, then the VLAN is supported only by its Base VID. The VLAN's Base VID shall be associated with the ST ECT Algorithm in the SPB Base VLAN-Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5).

If the LT ECT Algorithm (Table 45-1) is used for either a learning or a non-learning VLAN, then the VLAN is supported only by its Base VID, which is associated with the LT ECT Algorithm in the SPB Base VLAN-Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5).

If the LTS ECT Algorithm (Table 45-1) is used for a non-learning VLAN, then the VLAN is supported only by its Base VID, which is associated with the LTS ECT Algorithm in the SPB Base VLAN-Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5).

NOTE 2—The use of the LTS ECT Algorithm for a non-learning VLAN is similar to SPBM (Clause 27 and Clause 28) operations, but constrained trees are used instead of SPTs. One VID is sufficient for the support of a set of constrained trees, which is specified as a set of loose explicit trees.

However, if the LTS ECT Algorithm (Table 45-1) is used for a learning VLAN, then the VLAN is supported by multiple VIDs because each tree of an LTS is required to have its own VID. The VLAN's Base-VID is associated with the LTS ECT Algorithm in the SPB Base VLAN-Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5). In addition to the Base VID, as many VIDs are needed to support the VLAN as the number of transmitter Edge Bridges specified by the Topology sub-TLV (45.1.9). The individual VID of a transmitter Edge Bridge is configured to support the VLAN at the given SPT Bridge. The VID to be used for the loose tree of a transmitter Edge Bridge is conveyed by the SPVID field of the VLAN ID Tuple of the corresponding Base VID in the SPB Instance sub-TLV (28.12.5) of the given Edge Bridge. The A flag of the given VLAN ID Tuple is cleared to indicate that auto-allocation is not used for the SPVID parameter. If no VID is configured for the loose tree in the SPB Instance sub-TLV of a transmitter Edge Bridge, then ISIS-PCR does not install the loose tree for that Edge Bridge. If the same local VID value is configured at multiple Bridges, then ISIS-PCR does not install the loose tree for either Bridge, and the conflict has to be resolved by operator action. Although the field is called SPVID, the VID it conveys is not a Shortest Path VID but a loose tree VID as indicated by the ECT Algorithm field of the given VLAN ID Tuple and by the VID to MSTID allocation.

NOTE 3—The use of the LTS ECT Algorithm for a learning VLAN is similar to SPBV (Clause 27 and Clause 28) operations, but with loose trees, i.e., constrained trees are used instead of SPTs. Therefore, each Bridge rooting a loose tree has to have its own VID for the support of a learning VLAN on that tree. The SPB Instance sub-TLV is used to bind the VIDs of the individual root Bridges to the Base VID; the SPVID parameter conveys the VID to be used for the loose tree rooted at the given Bridge. The VID is not a Shortest Path VID because it is used for a loose explicit tree as indicated by the ECT Algorithm parameter and by the VID to MSTID allocation.

If the MRT ECT Algorithm (Table 45-1, 45.3.3) or the MRTG ECT Algorithm (Table 45-1, 45.3.4) is used for a VLAN, then a distinct VID is required for the two MRTs: MRT-Blue and MRT-Red. In the case of a non-learning VLAN, a single VID is used for MRT-Blue of all MRT Roots, and another VID is used for all MRT-Reds. Two VIDs support a non-learning VLAN if the MRTs protect each other, whereas the VID of

the SPT Set is also needed as the third VID if the MRTs protect SPTs. The MRT VIDs are also allocated to the SPBM-MSTID (0xFFC) in the case of a non-learning VLAN. However, each MRT Root has to be configured with its own unique VID-pair for its MRT-Blue and MRT-Red in the case of a learning VLAN, and all the MRT VIDs are allocated to the SPBV-MSTID (0xFFD). Independent VLAN Learning (3.95) is applied among the VIDs associated with MRTs. Twice as many MRT VIDs support a learning VLAN as MRT Roots, which are all the VIDs that are needed if the MRTs protect each other. The Shortest Path VIDs (real SPVIDs) of the SPTs are also needed in addition to the MRT VIDs for the support of a learning VLAN if the MRTs protect SPTs. As the two MRT algorithms differ only in GADAG handling, the VLAN configuration is the same for these two ECT Algorithms once the appropriate ECT-ALGORITHM value is used in the ECT Algorithm field of the IS-IS sub-TLVs. The VLAN's Base VID is associated with the MRT ECT Algorithm or with the MRTG ECT Algorithm in the SPB Base VLAN identifier sub-TLV (28.12.4).

The SPB Instance sub-TLV (28.12.5) provides the VIDs for MRT-Blue and MRT-Red and also associates them with the VLAN. The same VID values are used in the corresponding SPVID fields in the SPB Instance sub-TLV of all MRT Roots in the case of a non-learning VLAN; whereas the VID values in the SPVID fields are unique for each MRT Root in the case of a learning VLAN. The SPB Instance sub-TLV also specifies whether the MRTs are used to protect each other or whether they protect an SPT.

The SPB Instance sub-TLV (28.12.5) conveys three VLAN ID Tuples for the VLAN. The ECT Algorithm parameter of the second and the third VLAN ID Tuple is either the MRT ECT Algorithm or the MRTG ECT Algorithm, accordingly. If the MRTs are used to protect SPTs, then the ECT Algorithm parameter of the first VLAN ID Tuple specifies the ECT Algorithm to be used for shortest path computation, e.g., one of the standard symmetric ECT Algorithms (Table 45-1). The first VLAN ID Tuple also specifies the VID to be used for the shortest paths, which is the Base VID for a non-learning VLAN or the Shortest Path VID (allocated to the SPVID-Pool-MSTID) conveyed by the SPVID parameter for a learning VLAN. If the MRTs are used to protect each other, then the ECT Algorithm parameter of the first VLAN ID Tuple is the same as that of the second and the third VLAN ID Tuple. The second and the third VLAN ID Tuples associate the MRT VIDs with the Base VID. The SPVID parameter of the second VLAN ID Tuple provides the VID for MRT-Blue. The SPVID parameter of the third VLAN ID Tuple provides the VID for MRT-Red. In other words, the SPVID parameters of the second and third VLAN ID tuples convey the MRT VIDs, not Shortest Path VIDs. If ISIS-PCR detects that the same local MRT VID value is configured at multiple Bridges, then ISIS-PCR does not install the MRT for either Bridge, and the conflict has to be resolved by operator action.

If the MRTs are used to protect SPTs, then the MRT VIDs differ from the Base VID and also differ from Shortest Path VID conveyed by the SPVID parameter of a learning VLAN's first VLAN ID Tuple. In the case of non-learning VLANs, if the MRTs are used to protect each other, then the VLAN's Base VID is used as the VID for MRT-Blue; consequently, the SPVID parameter of the VLAN's second VLAN ID Tuple conveys the VLAN's Base VID. If the MRTs of a learning VLAN are used to protect each other, then no Shortest Path VID is required for the VLAN; therefore, the SPVID parameter of the VLAN's first VLAN ID Tuple is not used but ignored. The use of the SPB instance sub-TLV for the MRT and MRTG ECT Algorithms is illustrated in Figure 45-3.

NOTE 4—The SPVID parameter conveys only a Shortest Path VID if the ECT Algorithm parameter of the given VLAN ID Tuple identifies shortest path operations and the VID is allocated to the SPVID-Pool-MSTID. The SPVID parameter is not a Shortest Path VID if the ECT Algorithm parameter identifies explicit path control, i.e., taken from Table 45-1, which is also indicated by the fact that the VID is not allocated to the SPVID-Pool-MSTID.

An I-SID of a PBBN shall be associated with an explicit tree by the SPBM Service Identifier and Unicast Address sub-TLV (28.12.10) by means of associating the I-SID with a Base VID that is allocated to one of the explicit ECT Algorithms of Table 45-1.

	Parameter	Value

Figure 45-3—The use of the SPB Instance sub-TLV for MRT

45.1.4 Use of VIDs for strict explicit trees

The use of a distinct VID for each explicit tree does not scale in some cases. A more flexible and scalable method of VID assignment is available for explicit trees. This subclause explains the rules to be observed and suggests two schemes for the use of VIDs for strict explicit trees, i.e., for VIDs associated with the ST ECT Algorithm (Table 45-1). Nonetheless, ensuring that VIDs associated with strict explicit trees actually follow these rules in order to provide unambiguous and loop-free frame forwarding is the responsibility of the network administrator and the owner PCE controlling the VID; this standard provides no method for policing this. As each VID belongs to a single owner PCE, a VID can be used only for multiple explicit trees that are controlled by the same PCE.

NOTE 1—Use of VIDs associated with MRTs is explained in 45.3.3.

Ensuring unambiguous filtering entries and providing forwarding to the appropriate destination are the fundamental requirements to be met when assigning VIDs with explicit trees.

For unicast frames, there has to be a single egress port for each Individual MAC, VID tuple in each SPT Bridge. In other words, different explicit trees associated with the same bidirectional VID within an SPT Domain are not allowed to have any SPT Bridges in common when MAC learning is being used. Unidirectional VIDs or bidirectional non-learning VIDs associated with different explicit trees to a particular destination can have common SPT Bridges along the merged segments of those explicit trees as long as every such tree uses a single egress port for each unicast destination in every Bridge.

NOTE 2—A VID can be unidirectional by means of asymmetric use, e.g., as explained in F.1.3 or like an SPVID (3.248). Also, a bidirectional non-learning VID is in fact used in unidirectional fashion with respect to any given destination MAC address.

For multicast frames, it has to be ensured that each member of the multicast group receives only a single copy of a particular frame, even if there are multiple potential sources within a group.

Congruency (3.213), if required, has to be enforced by the PCE. In the case of unidirectional VIDs, the same path has to be used for both directions between a source and destination pair in order to provide reverse path congruency, essential when MAC learning is employed. Unicast and multicast traffic have to be placed on the same tree in order to provide unicast multicast congruency.

The tree structures explained in 45.1.1 can be applied for strict explicit trees, and VIDs can be used on top of these strict trees as follows.

An ad-hoc explicit tree (45.1.1) with a bidirectional VID provides a shared bidirectional (*,G) tree joining all members of a group. This structure minimizes VID consumption (as a local instance-by-instance optimization) compared to cases when each member has its own VID. On the other hand, there is the constraint that trees using the same VID are not allowed to touch or cross; hence the number of explicit trees is limited by the available VID space.

The template tree (45.1.1) approach constructs one or more explicitly routed forwarding planes with tree sets, one tree rooted on each Bridge within each plane. In the case of learning VIDs, each tree is associated with a unidirectional VID, and Shared VLAN Learning (3.238) takes place among the VIDs of a tree set. In the case of non-learning VIDs, the MAC of the root Bridge identifies the tree; therefore, one VID (the Base VID) is enough for an entire plane. Furthermore, source-specific multicast (S,G) has to be applied if multiple sources participate in a single multicast group as explained in 45.1.1. The desired connectivity can be then laid for VIDs associated with strict template trees with the complete assurance that the required simply connected tree constraint is obeyed.

The efficiency of the template trees approach can be improved substantially in terms of the usage of local VIDs if Edge Bridges “inherit” the tree and VID rooted at their directly connected Core Bridge. This is possible because a loop or forwarding ambiguity cannot be created in a single Ethernet hop; to guarantee this, multi-homed Edge Bridges have to be always configured as non-transit Bridges.

45.1.5 MAC addresses and ISIS-PCR

Propagation of MAC address information by IS-IS is required for explicit trees in order to create Dynamic Filtering Entries for VID, MAC tuples, except for learning VIDs. The SPBV MAC Address sub-TLV (28.12.9) shall be used for the advertisement of both Individual and Group MAC Addresses for S-VLANs and C-VLANs associated with explicit trees. The VLAN's VID is conveyed by Octets 3 and 4 of the SPBV MAC Address sub-TLV. This local VID (if required) and the VLAN's Base VID are allocated either to the SPBV-MSTID (for learning VIDs) or to the SPBM-MSTID (for non-learning VIDs); furthermore, the Base VID is allocated to one of the explicit ECT Algorithms (Table 45-1) as explained in 45.1.2 in more detail.

NOTE 1—Multiple SPBV MAC Address sub-TLVs are used if different MAC addresses are mapped to different VIDs at an SPT Bridge, i.e., MAC addresses associated with an SPT Bridge are not bound together.

The SPBM Service Identifier and Unicast Address sub-TLV (28.12.10) shall be used to associate Individual addresses with an I-SID; Octets 3 through 8 of the sub-TLV convey an Individual B-MAC address. Thus, the SPT Bridges populate their FDB with the Individual MAC addresses according to their T/R flags for the B-VLANs allocated to the SPBM-MSTID and associated with explicit path control.

Either a Group MAC address associated with an I-SID is source specific, or it is the Backbone Service Instance Group address (26.4). If Octets 3 through 8 of any SPBM Service Identifier and Unicast Address sub-TLV convey the null value throughout the SPT Domain, then the Backbone Service Instance Group address corresponding to the given I-SID is to be used for all multicast sources in (*,G) mode on one simple explicit tree. If no SPBM Service Identifier and Unicast Address sub-TLV with null value in its B-MAC address field is present in the SPT Domain, then the source-specific group addressing specified in 27.15 has to be applied, exactly as used for SPBM. In the source-specific case, the SPB Instance sub-TLV (28.12.5) shall be used to propagate the SPSourceID (27.10) of the Bridges that are Edge Bridges of the explicit tree and can be a source of the multicast traffic. In order to avoid forwarding anomalies, source-specific group addressing has to be used if there are multiple multicast sources for a given I-SID using the same B-VID and the template tree model (45.1.4) is followed, i.e., multiple trees are used.

NOTE 2—Multiple SPBM Service Identifier and Unicast Address sub-TLVs are used if different MAC addresses are mapped to different I-SIDs at an SPT Bridge, i.e., MAC addresses associated with an SPT Bridge are not bound together.

45.1.6 Filtering Database entries for explicit trees

The Topology sub-TLV (45.1.9) provides the information needed for ISIS-PCR to create the appropriate Dynamic VLAN Registration Entries, i.e., it provides the explicit tree, the VIDs associated with the tree, and the direction of the directed VIDs.

The per Bridge association of a MAC address with a VID is provided by the SPBV MAC Address sub-TLV (28.12.9) as described in 45.1.5. Based on the Topology sub-TLVs and SPBV MAC Address sub-TLVs, ISIS-PCR can create the VID, MAC tuple Dynamic Filtering Entries for VLANs associated with explicit trees.

The association of a B-VID with an explicit tree is provided by the Topology sub-TLV (45.1.9), and the per Bridge association of an I-SID to a B-VID is provided by the SPBM Service Identifier and Unicast Address sub-TLV (28.12.10), which also provides the association of a B-MAC to an I-SID as described in 45.1.5. The SPBM Service Identifier and Unicast Address sub-TLVs also make it clear whether source-specific group addressing is to be used. If that is the case, then the SPB Instance sub-TLVs (28.12.5) provide the SPSourceIDs (27.10) that are needed for the creation of the automatically generated Group MAC addresses of the I-SID as described in 45.1.5. Based on these sub-TLVs, ISIS-PCR can create the B-VID, B-MAC tuple Dynamic Filtering Entries for I-SIDs associated with explicit trees.

45.1.7 ISIS-PCR support

ISIS-PCR and PCEs are configured to use one of the Group addresses from Table 8-17 to establish adjacencies and exchange PDUs. ISIS-PCR running on C-VLAN components use the Customer Bridge address. ISIS-PCR running on S-VLAN components use the Provider Bridge address. ISIS-PCR running on B-VLAN components can use the Provider Bridge Address or one of the existing IS-IS addresses.

The use of the ISIS-PCR adjacency between Bridges is contingent on the Bridges inclusion within the same SPT Region and thus requires that they have an MCID and Auxiliary MCID (13.8, 28.12.2) where at least one matches on every adjacency in the Region (8.9.4, 13.8). MCID and Auxiliary MCID enable migration of the MCID definition allowing these Bridges to operate as one SPT Region under certain small changes. The operational set of Base VLANs has to be consistent during migration. The MCID and the Auxiliary MCID are exchanged in IS-IS Hello PDUs, which also include the SPB Base VLAN-Identifiers sub-TLV (28.12.4). ISIS-PCR adjacencies are formed and maintained as specified by 28.2, i.e., in exactly the same way as ISIS-SPB adjacencies. Either a PCE hosted by an end station has a PCA that is part of the IS-IS Domain, or the PCE forms and maintains an ISIS-PCR adjacency between the PCE and the SPT Bridge to which the end station is attached.

Management of explicit trees also requires the following:

a) Management of the PCR objects (12.26)
b) Administrative agreement on the MCID Configuration Name and Revision Level (Clause 28)

NOTE—The addresses used by IS-IS PDUs and the operations with respect to IS-IS adjacencies are the same for ISIS-PCR and ISIS-SPB. This subclause (45.1.7) simply reiterates provisions of Clause 27 and Clause 28 (see 27.2, 28.2).

45.1.8 Attributes for path computation

More attributes than the link metric are needed for PCEs or BLCEs in order to be able to determine paths that meet the requirements. Extended link attributes are specified by the Traffic Engineering (TE) extensions for IS-IS in IETF RFC 5305. The TE information is flooded in LSPs by IS-IS and it is stored in the Traffic Engineering Database (TED). The TED contains the topology and the resource information of the IS-IS Domain.

SPT Bridges may support the Extended IS Reachability TLV (type 22) specified in IETF RFC 5305, which provides the following link attribute IS-IS sub-TLVs:

a) Administrative Group (color, resource class) (sub-TLV type 3)
b) Maximum Link Bandwidth (sub-TLV type 9)
c) Maximum Reservable Link bandwidth (sub-TLV type 10)
d) Unreserved Bandwidth (sub-TLV type 11)
e) Traffic Engineering Default Metric (sub-TLV type 18)

SPT Bridges may support the following IS-IS TE Metric Extension link attribute sub-TLVs specified in IETF RFC 7810:

f) Unidirectional Link Delay (sub-TLV type 33)
g) Min/Max Unidirectional Link Delay (sub-TLV type 34)
h) Unidirectional Delay Variation (sub-TLV type 35)
i) Unidirectional Link Loss (sub-TLV type 36)
j) Unidirectional Residual Bandwidth (sub-TLV type 37)
k) Unidirectional Available Bandwidth (sub-TLV type 38)
l) Unidirectional Utilized Bandwidth (sub-TLV type 39)

The IS-IS TE Metric Extensions sub-TLVs are conveyed by IS-IS Extended IS Reachability TLV (type 22). The bandwidth already allocated determines the Residual Bandwidth and the Available Bandwidth. When they are used in a Bridged Network, reservations performed by MSRP or bandwidth assignments recorded by ISIS-PCR are taken into account to determine these sub-TLVs.

NOTE—The Residual Bandwidth and the Unreserved Bandwidth sub-TLVs can be used concurrently; see IETF RFC 7810.

If Shared Risk Link Group (SRLG) information is to be applied, then the SRLG TLV (type 138) of IETF RFC 5307 may be used as specified here. Figure 45-4 shows the format of the SRLG TLV.

		Octet	Length
	Type (138)	1	1
	Length	2	1
	System ID	3–8	6
	Pseudonode num	9	1
	Flag	10	1 bit
	reserved	10	7 bits
	Link Local Identifier	11–14	4
	Link Remote Identifier	15–18	4
SRLG *1*	Shared Risk Link Group Value	19–22	4
	...		
SRLG *n*	Shared Risk Link Group Value	(4*n*+15)–(4*n*+18)	4

Figure 45-4—Shared Risk Link Group (SRLG) TLV

The SRLG parameters are encoded as follows:

m) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 138.

n) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field, which is the number of SRLG Values multiplied by 4 plus 16 bytes.

o) System ID (48 bits). Octets 3 through 8 convey the 6-byte IS-IS System Identifier of the adjacent neighbor.

p) Pseudonode num (8 bits). Octet 9 conveys the pseudonode number if the neighbor is connected through a shared media.

q) Flag (1 bit). Octet 10 conveys a flag, which is encoded as a bit in a single octet. A flag is set if the bit takes the value 1; otherwise, it is reset. The Flag of Octet 10 indicates whether an IP address is used to identify the link. It is not an IP address in the case of ISIS-PCR, i.e., the link is unnumbered. Therefore, the flag is reset in an SPT Domain, i.e., each bit of Octet 10 takes value 0.

r) reserved (7 bits). Seven bits of Octet 10 are reserved for future use, transmitted as 0, and ignored on receipt.

s) Link Local Identifier (32 bits). Octets 11 through 14 convey the local identifier of the interface, which is an Extended Local Circuit ID as specified by IETF RFC 5303.

t) Link Remote Identifier (32 bits). Octets 15 through 18 convey the identifier of the remote interface, which is a Neighbor Extended Local Circuit ID as specified by IETF RFC 5303.

u) Shared Risk Link Group Value (32 bits). Octets 4*n*+15 through 4*n*+18 convey the value assigned to SRLG *n* to which the link belongs. The same SRLG value is used for all links that share a resource whose failure affects each link of the group. A link can belong to multiple SRLGs; therefore, multiple Shared Risk Link Group Values can be present in the same SRLG TLV.

45.1.9 Topology sub-TLV

The variable-length Topology sub-TLV shall be used to describe an explicit tree. The Topology sub-TLV may be also used for describing a Generalized Almost Directed Acyclic Graph (GADAG) as explained in 45.3.4 in detail. The Topology sub-TLV is carried in an MT-Capability TLV (type 144) in a Link State PDU. A Topology sub-TLV specifying an explicit tree conveys one or more Base VIDs and two or more Hop sub-TLVs (45.1.10) and can convey further sub-TLVs (45.1.11, 45.1.12) to constrain loose hops. The Topology sub-TLV also specifies the algorithm to be used for constrained routing. Figure 45-5 shows the format of the Topology sub-TLV.

		Octet	Length	
	Type (21)	1	1	
	Length	2	1	
	Number of Base VIDs	3	1	
Base VID Tuple *1*	reserved	4	4 bits	0 or 16 bits
	Base VID	4–5	12 bits	
	...			
Base VID Tuple *n*	reserved	(2*n*+2)	4 bits	0 or 16 bits
	Base VID	(2*n*+2)–(2*n*+3)	12 bits	
sub-TLV *1*	sub-TLV			
	...			
sub-TLV *m*	sub-TLV			

Figure 45-5—Topology sub-TLV

The parameters of explicit trees are encoded by the Topology sub-TLV as follows:

a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 21.

b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field.

c) Number of Base VIDs (8 bits). Octet 3 conveys the number of Base VIDs carried in the Topology sub-TLV. Its minimum value is 1 if the Topology sub-TLV specifies an active topology. Its value can be 0 if the Topology sub-TLV specifies only a GADAG.

d) reserved (4 bits). Four bits of Octet 2n+2 are reserved for future use, transmitted as 0, and ignored on receipt.

e) Base VID (12 bits). Octet 2n+2 and Octet 2n+3 convey the nth Base VID parameter. The Base VID parameter provides the Base VID of the VLAN that is associated with the explicit tree. Multiple Base VIDs can be associated with the same explicit tree.

   Some of the explicit ECT Algorithms (45.1.2) require further VIDs, in addition to the Base VID, which are associated with the VLAN by using the SPB Instance sub-TLV as specified in 45.1.3.

   By default, each Edge Bridge is both transmitter and receiver for all VIDs associated with an explicit tree. Different behavior can be specified in the Hop sub-TLV (45.1.10) of the Edge Bridge.

   If VIDs of a learning VLAN associated with the LTS ECT Algorithm (Table 45-1) are conveyed by the Topology sub-TLV, then the default behavior for each Edge Bridge is that it is the only transmitter on its own VID and a receiver on the VIDs of all the other Edge Bridges. For such a learning VLAN, a per Bridge local VID is announced by a transmitter Edge Bridge via the SPB Instance sub-TLV (28.12.5) as specified in 45.1.3. If no VID is allocated to the Edge Bridge, then it is not a transmitter but only a receiver.

   A Topology sub-TLV specifying a GADAG can have zero Base VID parameters. In this case, the given GADAG has to be applied for each VLAN associated with the MRTG ECT Algorithm.

f) sub TLVs. The rest of the octets convey further sub-TLVs that specify the hops of the topology and can also specify constraints, bandwidth assignment, and timestamp as specified in the following subclauses.

A topology is specified by a list of Hop sub-TLVs (45.1.10), and a hop is specified by an IS-IS System ID. An ill-formed Topology sub-TLV, e.g., specifying an invalid strict tree or having a conflict in its specification, is ignored; no tree is installed but a management report is generated.

The Topology sub-TLV specifies a strict tree by decomposing the tree to branches. Each branch is a point-to-point path specified by an ordered list of hops where the end of each branch is a leaf. Each element of a branch is the direct link between adjacent neighbor Bridges whose Hop sub-TLV is next to each other in the Topology sub-TLV. The first hop of the Topology sub-TLV is the root; hence, the first branch originates from the root. The rest of the branches fork from another branch. The first hop of a branch is a Bridge that is already part of a former branch, and the last hop is a leaf Bridge. Therefore, the hop after a leaf hop is the beginning of a new branch, if any. A hop of a branch is created if and only if the Bridge specified for that hop is directly connected to the preceding Bridge of the same branch. The order of the branches does not matter within the Topology sub-TLV, but the first branch begins with the root. Figure 45-6 shows an example for the specification of a strict tree.

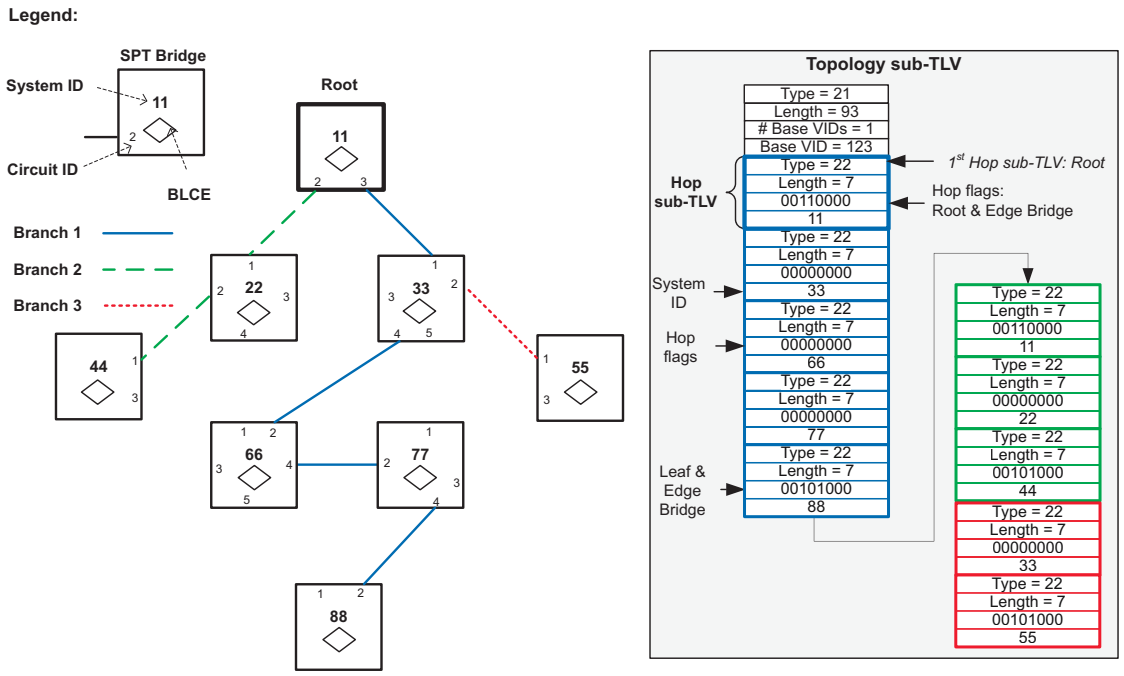

Figure 45-6—A strict tree and its descriptor Topology sub-TLV

The Topology sub-TLV of a loose tree does not provide any path or path segment, but the hops that are to participate. The root is the first hop. The leaves of a single loose tree are also specified. Hop sub-TLVs can be included in a Topology sub-TLV to specify Bridges that have to be avoided. If the Topology sub-TLV specifies only a single leaf, then one or more transit hops can be specified by the Topology sub-TLV to direct the path along a sequence of Bridges, specified by the order of hops. If Bridges whose respective Hop sub-TLVs are adjacent to each other in the Topology sub-TLV but are not topology neighbors, then it is a loose hop. If a Topology sub-TLV conveys one or more loose hops, then that sub-TLV defines a loose explicit tree, and each hop is considered as a loose hop. If a loose tree specified by a Topology sub-TLV would create a loop or hairpin, then the loop is pruned, and the remaining hops are installed. An example for the specification of a single loose tree is shown in Figure 45-7, where Bridge 77 is the root; Bridges 11, 44,

55, and 88 are leaves; and Bridge 22 is excluded from the tree. Bridges 11, 44, 55, and 88 are the Edge Bridges. Bridges 11, 44, 55, 77, and 88 are part of the tree because each of them has its special role as specified by the Topology sub-TLV. Conversely, the role of Bridges 33 and 66 is determined by the BLCE of the SPT Bridges only when the tree is computed after the reception of the Topology sub-TLV.

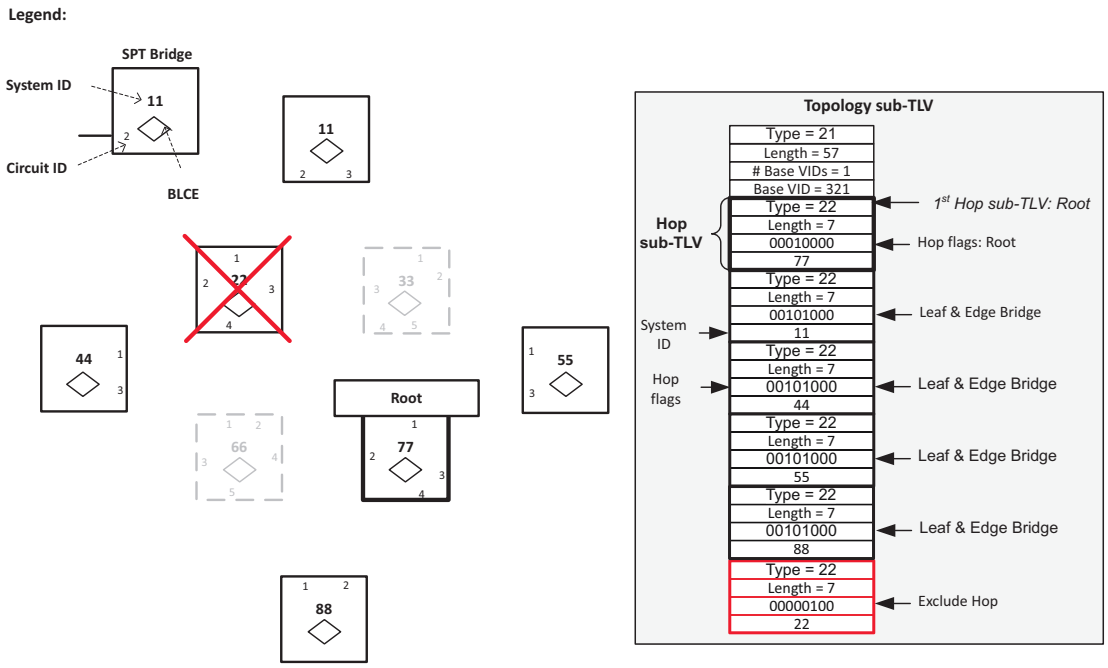

Figure 45-7—Topology sub-TLV of a loose tree

If the Base VIDs of the Topology sub-TLV are associated with the LTS ECT Algorithm or the MRT ECT Algorithm, then the Hop sub-TLVs conveyed by the Topology sub-TLV belong to Edge Bridges or Bridges to be excluded [item c6) in 45.1.10]. The BLCEs compute the loose trees, e.g., MRTs, so that they span the Edge Bridges and are rooted at an Edge Bridge.

The Topology sub-TLV specifies a GADAG if the Base VIDs conveyed by the Topology sub-TLV are associated with the MRTG ECT Algorithm (Table 45-1). The Topology sub-TLV specifies a GADAG by directed ear decomposition. A directed ear is a directed point-to-point path whose end points can coincide, but no other element of the path is repeated in the ear. Each ear is specified by an ordered list of hops, and that order of hops is according to the direction of the arcs in the GADAG. There are no leaves in a GADAG; hence, the Leaf flag is used to ease the parsing of the Topology sub-TLV and to mark the end of a topology block (3.272). The sequence of ears in the Topology sub-TLV is such that the end points of an ear belong to former ears. The GADAG Root is not marked by any flag, but the GADAG Root is the first hop in the Topology sub-TLV; correspondingly the first ear starts and ends with the GADAG Root. MRT Roots are marked by the Root flag, and all other Edge Bridges are leaves of the MRTs. If no MRT Root is specified, then each SPT Root is also an MRT Root. An example GADAG is shown in Figure 45-13 (in 45.3.4).

Each Edge Bridge of an explicit tree is always specified in the Topology sub-TLV by the inclusion of the Hop sub-TLVs corresponding to the Edge Bridges. The Edge Bridges of a tree are identified by setting the Edge Bridge flag [item c3) in 45.1.10] in the appropriate Hop sub-TLVs.

If the explicit tree is loose, then Administrative Group (45.1.11) and Bandwidth Constraint (45.1.12) sub-TLVs can be also conveyed by the Topology sub-TLV. In that case, each path of the tree has to meet the constraints specified by these sub-TLVs.

If ISIS-PCR is used for recording bandwidth assignment, then the Topology sub-TLV conveys the Bandwidth Assignment sub-TLV (45.2.1), and it can also convey a Timestamp sub-TLV (45.2.2). If the assignment of the bandwidth indicated by the Bandwidth Assignment sub-TLV of the Topology sub-TLV would result in overbooking any link of the explicit tree, then bandwidth assignment is not performed, and a management report is generated. If such a Topology sub-TLV describes a new valid explicit tree, then the paths of the tree are installed, but no bandwidth assignment is performed by ISIS-PCR.

NOTE 1—The LSP ID can be also considered as an identifier of an explicit tree if an LSP describes only a single tree, i.e., includes a single Topology sub-TLV.

NOTE 2—Allocation of VIDs to individual Aggregation Links between adjacent IS-IS Systems has to be done by the explicit configuration of conversations in that LAG at the two Systems in accordance with IEEE Std 802.1AX.

45.1.10 Hop sub-TLV

The Hop sub-TLV shall be used to specify a hop of a topology. Each Hop sub-TLV conveys an IS-IS System ID, which specifies a hop. A Hop sub-TLV is conveyed by a Topology sub-TLV (45.1.9). A strict explicit tree is decomposed to branches where each branch is a point-to-point path specified by an ordered list of Hop sub-TLVs as specified in 45.1.9 and illustrated in Figure 45-6. A hop of a branch is created if and only if the Bridge specified for that hop is directly connected to the preceding Bridge in the path. In other words, a point-to-point LAN is identified by the two Bridges it interconnects; and the LAN is part of the strict tree if and only if the Hop sub-TLVs of the two Bridges are next to each other in the Topology sub-TLV. A Hop sub-TLV can convey a Circuit ID in order to distinguish multiple links between adjacent neighbor Bridges. A Hop sub-TLV also specifies the role of a Bridge, e.g., if it is the root or an Edge Bridge. The Topology sub-TLV of a loose tree comprises only the Hop sub-TLVs of the Bridges that have special roles in the tree. The Hop sub-TLV may also specify a delay budget for a loose hop.

By default, the Edge Bridges both transmit and receive with respect to each VID associated with an explicit tree, except for an LTS associated with a learning VLAN [45.1.3, item e) in 45.1.9], which uses a unidirectional VID per Bridge. The Hop sub-TLV allows different configuration by means of the VID's Transmit (T) and Receive (R) flags conveyed in the sub-TLV. The VID and its T/R flags are present in the Hop sub-TLV only if the behavior of the Edge Bridges differs from the default [defined in item e) in 45.1.9]. The T/R flags of an I-SID associated with an explicit tree in a PBBN are set in the SPBM Service Identifier and Unicast Address sub-TLV (28.12.10), which also provides the association of the I-SID with the B-VID.

Figure 45-8 shows the format of the variable-length Hop sub-TLV, which shall be conveyed by a Topology sub-TLV (45.1.9).

		Octet	Length	
	Type (22)	1	1	
	Length	2	1	
Hop Flags	Circuit	3	1 bit	8 bits
	VID	3	1 bit	
	Edge Bridge	3	1 bit	
	Root	3	1 bit	
	Leaf	3	1 bit	
	Exclude	3	1 bit	
	reserved	3	2 bits	
	System ID	4–9	6	
	Extended Local Circuit ID	10–13	0 or 4	
	Number of VIDs	10 or 14	0 or 1	
VID Tuple *1*	T	11 or 15	1 bit	0 or 16 bits
	R	11 or 15	1 bit	
	reserved	11 or 15	2 bits	
	VID	11–12 or 15–16	12 bits	
	...			
VID Tuple *n*	T	(2*n*+9) or (2*n*+13)	1 bit	0 or 16 bits
	R	(2*n*+9) or (2*n*+13)	1 bit	
	reserved	(2*n*+9) or (2*n*+13)	2 bits	
	VID	(2*n*+9)–(2*n*+10) or (2*n*+13)–(2*n*+14)	12 bits	
	Delay Constraint	10–15 or 14–19 or (2*n*+13)–(2*n*+16) or (2*n*+17)–(2*n*+20)	0 or 6	

Figure 45-8—Hop sub-TLV

The parameters of a hop are encoded as follows:

a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 22.

b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field.

c) Hop Flags (8 bits). Octet 3 conveys the Hop flags. The Circuit and the VID flags influence the length of the Hop sub-TLV. Table 45-3 summarizes the use of the flags in the case of the different explicit ECT Algorithms.

   1) Circuit flag (1 bit). The Circuit flag indicates whether the Extended Local Circuit ID parameter is present. If the flag is set, then an Extended Local Circuit ID is also included in the Hop sub-TLV.

   2) VID flag (1 bit). The VID flag indicates whether one or more VIDs are conveyed by the Hop sub-TLV. If the flag is set, then the Number of VIDs parameter is present and indicates how many VIDs are conveyed by the Hop sub-TLV. If the VID flag is reset, then neither the Number of VIDs parameter nor VIDs are present in the Hop sub-TLV.

   3) Edge Bridge flag (1 bit). The Edge Bridge flag indicates whether the given System is an Edge Bridge, i.e., transmitter and/or receiver. If the System is an Edge Bridge, then the Edge Bridge flag is set. The Edge Bridge flag indicates that FDB entries have to be installed for the given hop as specified by its SPBV MAC address sub-TLV or SPBM Service Identifier and Unicast Address sub-TLV.

Table 45-3—Hop sub-TLV flags

		Flag			
		Edge Bridge	**Root**	**Leaf**	**Exclude**
ECT Algorithm	**Strict Tree**	The Bridge is an Edge Bridge.	The Bridge is the root of the tree. (first hop)	The Bridge is a leaf of the tree. (always an Edge Bridge)	—
	Loose Tree	The Bridge is an Edge Bridge. (set for every hop of multi-point trees except for exclude hops)	The Bridge is the root of the tree. (first hop)	The Bridge is a leaf of the tree. (always an Edge Bridge)	The Bridge has to be excluded from the tree.
	Loose Tree Set	The Bridge is an Edge Bridge. (set for every hop of multi-point trees except for exclude hops)	The Bridge roots a tree. (every Bridge that is Edge Bridge)	—	The Bridge has to be excluded from each tree.
	MRT	The Bridge is an Edge Bridge.	The Bridge is an MRT Root. (always an Edge Bridge)	—	The Bridge has to be excluded from the MRTs.
	MRT with GADAG	The Bridge is an Edge Bridge.	The Bridge is an MRT Root. (always an Edge Bridge)	The Bridge is the end of a topology block.	—

4) Root flag (1 bit). The Root flag indicates whether the given System is a root of the explicit tree specified by the Topology sub-TLV. If the System is a root of a tree, then the Root flag is set.

   If the Topology sub-TLV specifies a single tree, i.e., the Base VIDs conveyed by the Topology sub-TLV are associated with either the ST ECT Algorithm or the LT ECT Algorithm, then the Root flag is set only for one of the Systems conveyed by the Topology sub-TLV. Furthermore, the first Hop sub-TLV of the Topology sub-TLV conveys the System that is the root of the tree. If the Topology sub-TLV specifies a Loose Tree Set, i.e., the Base VIDs conveyed by the Topology sub-TLV are associated with the LTS ECT Algorithm (Table 45-1), then the Root flag is set for each Edge Bridge as each of them roots a tree. The first Hop sub-TLV of the Topology sub-TLV conveys a root.

   If the Topology sub-TLV is used for MRT operations, i.e., the Base VIDs conveyed by the Topology sub-TLV are associated with either the MRT ECT Algorithm or the MRTG ECT Algorithm (Table 45-1), then the Root flag is set for each MRT Root. If no MRT Root is specified by a Topology sub-TLV specifying a GADAG, then each SPT Root is an MRT Root as well.

   If the Base VIDs conveyed by the Topology sub-TLV are associated with the MRTG ECT Algorithm (Table 45-1), then the Topology sub-TLV specifies a GADAG, and the very first Hop sub-TLV specifies the GADAG Root. There is no flag for indicating the GADAG Root.

5) Leaf flag (1 bit). The Leaf flag indicates whether the given System is a leaf of the explicit tree specified by the Topology sub-TLV. If the System is a leaf, then the Leaf flag is set.

   The Leaf flag is used to mark a leaf of a tree only if the Topology sub-TLV specifies a single tree, i.e., the Base VIDs are associated with either the ST ECT Algorithm or the LT ECT Algorithm (Table 45-1).

   The Leaf flag is not used for marking leaves if the ECT Algorithm produces multiple trees because a Bridge that is leaf in one tree can be the root of another tree.

The Leaf flag is used to indicate the end of a topology block (3.272) if the Topology sub-TLV specifies a GADAG; see item f) in 45.1.9 and see 45.3.4.

6) Exclude flag (1 bit). The Exclude flag indicates whether the given System has to be excluded from the topology. The Exclude flag and the Root flag cannot be set for a given hop at the same time.
7) reserved (2 bits). Two bits of Octet 3 are reserved for future use, transmitted as 0, and ignored on receipt.

d) System ID (48 bits). Octets 4 through 9 convey the 6-byte IS-IS System Identifier of the Bridge to which the Hop sub-TLV refers.

e) Extended Local Circuit ID (32 bits). Octets 10 through 13 convey the Extended Local Circuit ID as specified by IETF RFC 5303 if Extended Local Circuit ID is present in the Hop sub-TLV, as indicated by the Circuit flag.

Parallel links corresponding to different IS-IS adjacencies between a pair of neighbor SPT Bridges can be distinguished by means of the Extended Local Circuit ID. The Extended Local Circuit ID is conveyed by the Hop sub-TLV specifying the Bridge nearer to the root of the tree and identifies a circuit that attaches the given Bridge to its neighbor cited by the next Hop sub-TLV of the Topology sub-TLV. The Extended Local Circuit ID can be used only in strict trees.

f) Number of VIDs (8 bits). A single octet conveys the Number of VIDs parameter, which is Octet 10 if the Extended Local Circuit ID parameter is absent whereas it is Octet 14 if the Extended Local Circuit ID parameter is present. If the Hop sub-TLV does not convey VIDs, then the Number of VIDs parameter is not present, as indicated by the VID flag.

g) VID and its T/R flags (14 bits). Two octets convey the VID and its T/R flags parameters. The first one is Octet 2n+9 and the second one is Octet 2n+10 if the Extended Local Circuit ID parameter is absent whereas the first one is Octet 2n+13 and the second one is Octet 2n+14 if the Extended Local Circuit ID parameter is present.

The VID and its T/R flags are present in the Hop sub-TLV only if the given Bridge is an Edge Bridge and it behaves differently from the default with respect to that particular VID. (The default behavior is defined in item e of the Topology sub-TLV (45.1.9).)

1) T flag (1 bit). This bit is the Transmit allowed flag for the VID following the flag.
2) R flag (1 bit). This bit is the Receive allowed flag, i.e., R flag for the VID following the flag.
3) reserved (2 bits). Two bits of the first Octet are reserved for future use, transmitted as 0, and ignored on receipt.
4) VID (12 bits). The VID can be a Base VID, an MRT VID, or a VID in support of a learning VLAN associated with the LTS ECT Algorithm.

h) Delay Constraint (48 bits). The last six octets specify a delay constraint if they convey a Unidirectional Link Delay sub-TLV [item f) in 45.1.8]. The delay constraint can be used in a Topology sub-TLV that specifies a single loose tree, i.e., the Base VIDs are associated with the LT ECT Algorithm (Table 45-1). If delay constraint is applied, then the loose hop has to fit in the delay budget specified by the Delay parameter of the Unidirectional Link Delay sub-TLV [item f) in 45.1.8] conveyed by the Hop sub-TLV. If the Topology sub-TLV specifies a single leaf, then the path between the preceding Hop sub-TLV and the current Hop sub-TLV has to meet the delay budget. If the Topology sub-TLV specifies multiple leaves, then the path between the root and the current Hop sub-TLV has to meet the delay budget. If the tree is used as a reverse congruent tree, then the delay constraint applies in both directions. If the tree is used as a directed tree, then the delay constraint applies in the direction of the tree.

NOTE 1—The T and R flags can be used to establish asymmetric VLANs, e.g., for rooted-multipoint connectivity.

NOTE 2—The Root and Leaf flags specify the role of the Bridges only in the explicit tree, i.e., the active topology. Roots and leaves with respect to data traffic are specified by the T/R flags of VIDs and MAC addresses associated with the Edge Bridges. Roots and leaves of the active topology and data flows do not necessarily coincide, e.g., see Figure 45-7.

45.1.11 Administrative Group sub-TLV

The Administrative Group sub-TLV may be included in a Topology sub-TLV (45.1.9) in order to put a constraint on loose hops. In this case, each LAN included in a loose hop has to be a member of the Administrative Group(s) indicated by the Administrative Group sub-TLV. The format of the Administrative Group sub-TLV is specified by IETF RFC 5305 as shown in Figure 45-9. In other words, the same format is used for the constraint as for the TE attribute; therefore, their comparison is easy.

	Octet	Length
Type (3)	1	1
Length (4)	2	1
Administrative Group	3–6	4

Figure 45-9—Administrative Group sub-TLV

The administrative groups are encoded as follows:

a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 3.
b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field. The value of the Length field is 4.
c) Administrative Group (32 bits). Octets 3 through 6 convey the Administrative Group parameter. It comprises 32 flags, and each flag belongs to a distinct group. Group membership is indicated by the flags set.

45.1.12 Bandwidth Constraint sub-TLV

The Bandwidth Constraint sub-TLV may be included in a Topology sub-TLV (45.1.9) in order to specify how much available bandwidth is to be provided by the tree. Each loose hop has to meet the bandwidth constraint. The bandwidth value of the constraint is a total value, or it refers only to a single PCP as specified by the sub-TLV. Figure 45-10 shows the format of the Bandwidth Constraint sub-TLV.

	Octet	Length
Type (23)	1	1
Length (5)	2	1
PCP	3	3 bits
DEI	3	1 bit
PCP flag	3	1 bit
reserved	3	3 bits
Available Bandwidth	4–7	4

Figure 45-10—Bandwidth Constraint sub-TLV

The parameters of the bandwidth constraint are encoded as follows:

a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 23.
b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field, The value of the Length field is 5 bytes.
c) PCP (3 bits). Octet 3 conveys the PCP parameter, which determines the traffic class to which the Available Bandwidth parameter refers.
d) DEI (1 bit). Octet 3 also conveys the DEI parameter.

   If the DEI parameter is clear, then the bandwidth constraint refers to committed information rate.
   If the DEI parameter is set, then the bandwidth constraint refers to peak information rate.

e) PCP flag (1 bit). Octet 3 also conveys the PCP flag. If it is set, then the PCP parameter is taken into account.

f) reserved (3 bits). Three bits of Octet 3 are reserved for future use, transmitted as 0, and ignored on receipt.

g) Available Bandwidth (32 bits). Octets 4 through 7 convey the Available Bandwidth. The Available Bandwidth is specific to the traffic class identified by the PCP parameter if the PCP flag is set; otherwise, it is total bandwidth. In line with the bandwidth parameters specified in IETF RFC 5305, the Available Bandwidth is encoded as a 32-bit IEEE floating point number, and the units are bytes (not bits!) per second. Thus, the Available Bandwidth constraint applied for a traffic class is easily comparable with the Unreserved Bandwidth stored in the TED for the given traffic class (see sub-TLV 11 specified by IETF RFC 5305).

   The bandwidth constraint applies for both directions in the case of symmetric (3.264) explicit trees. Nevertheless, a VID associated with an explicit tree can be made unidirectional by means of the T/R flags belonging to the VID in the Hop sub-TLV (45.1.10) of the Edge Bridges. If all the VIDs of the Topology sub-TLV (45.1.9) are unidirectional and all belong to the traffic class identified by the PCP parameter of the Bandwidth Constraint sub-TLV, then it is enough to meet the bandwidth constraint in the direction applied for those VIDs.

NOTE—The peak information rate is the committed information rate plus the excess information rate.

45.2 Reservation

ISIS-PCR may be used for recording bandwidth assignment for explicitly placed data traffic in an SPT Region if MSRP is not used within the region. If MSRP is used in an SPT Region, then only MSRP performs reservations and IS-IS does not.

45.2.1 Bandwidth Assignment sub-TLV

ISIS-PCR can record bandwidth assignment for explicitly placed data traffic. ISIS-PCR can be used for recording bandwidth assignment only within an SPT Region where MSRP is not used.

If precedence order has to be determined among bandwidth assignments in an SPT Region with multiple PCEs, then ISIS-PCR provides it as specified in 45.2.3.

The Bandwidth Assignment sub-TLV can be used to define the amount of bandwidth whose assignment is to be recorded by ISIS-PCR at each hop of the explicit tree described by the corresponding Topology sub-TLV (45.1.9). The Bandwidth Assignment sub-TLV is conveyed by a Topology sub-TLV (45.1.9).

The Bandwidth Assignment sub-TLV is used by ISIS-PCR for the recording of bandwidth assignment for a traffic class. Figure 45-11 shows the format of the Bandwidth Assignment sub-TLV.

	Octet	Length
Type (24)	1	1
Length (5)	2	1
PCP	3	3 bits
DEI	3	1 bit
Importance	3	3 bits
reserved	3	1 bit
Bandwidth	4–7	4

Figure 45-11—Bandwidth Assignment sub-TLV

The parameters for bandwidth assignment recorded by ISIS-PCR are encoded as follows:

a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 24.
b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field. The value of the Length field is 5.
c) PCP (3 bits). Octet 3 conveys the PCP parameter, which specifies the traffic class for which the bandwidth is to be assigned.
d) DEI (1 bit). Octet 3 also conveys the DEI parameter.

   If the DEI parameter is clear, then the bandwidth assignment is performed to provide committed information rate.

   If the DEI parameter is set, then the bandwidth assignment is performed to provide peak information rate.
e) Importance (3 bits). Octet 3 also conveys the Importance parameter for determining precedence order among bandwidth assignments within a PCP as specified in 45.2.3. A lower numerical value indicates a more important bandwidth assignment within a PCP. The default value of the Importance parameter is 7.
f) reserved (1 bit). One bit of Octet 3 is reserved for future use, transmitted as 0, and ignored on receipt.
g) Bandwidth (32 bits). Octets 4 through 7 convey the amount of bandwidth to be assigned for the traffic class identified by the PCP parameter. In line with the bandwidth values specified in IETF RFC 5305, the Bandwidth parameter is encoded as a 32-bit IEEE floating point number, and the units are bytes (not bits!) per second.

   The bandwidth assignment applies for both directions in the case of symmetric (3.264) explicit trees. Nevertheless, a VID associated with an explicit tree can be made unidirectional by means of the T/R flags belonging to the VID in the Hop sub-TLV (45.1.10) of the Edge Bridges. If all the VIDs having the same PCP in the Topology sub-TLV (45.1.9) are unidirectional, then the bandwidth is assigned only in the direction applied for those VIDs.

If bandwidth is to be assigned both for committed information rate and for peak information rate, then the Topology sub-TLV conveys two Bandwidth Assignment sub-TLVs: one with DEI cleared and another with DEI set.

45.2.2 Timestamp sub-TLV

The Timestamp sub-TLV may be included in a Topology sub-TLV (45.1.9) in order to provide precedence order among equally important bandwidth assignments within a PCP as specified in 45.2.3. Figure 45-12 shows the format of the Timestamp sub-TLV.

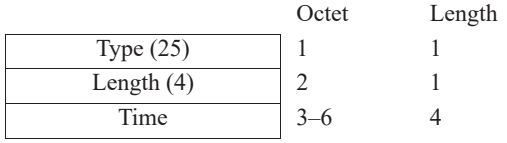

Figure 45-12—Timestamp sub-TLV

The timestamp represents a positive time with respect to the Precision Time Protocol (PTP) epoch, and it is encoded as follows:

a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 25.
b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field. The value of the Length field is 4.

c) Time (32 bits). Octets 3 through 6 convey the time in units of seconds with respect to the PTP epoch.

NOTE—The Timestamp sub-TLV carries the seconds portion of PTP as specified by IEEE Std 1588 [B15]. The epoch is 1970-01-01 00:00:00 TAI (i.e., the PTP time does not include leap seconds).

45.2.3 Precedence ordering

The PCEs are collectively responsible for making a consistent set of bandwidth assignments when ISIS-PCR is used for recording bandwidth allocations. Despite that responsibility, if precedence ordering is required among bandwidth assignments, then ordering based on the following parameters has to be applied:

1) PCP parameter of Bandwidth Assignment Sub-TLV
2) Importance parameter of Bandwidth Assignment Sub-TLV
3) Timestamp sub-TLV (if present in the Topology sub-TLV)

A bandwidth assignment takes precedence if it has higher PCP, or higher Importance within a PCP, or earlier timestamp in the case of equal Importance within a PCP. A bandwidth assignment associated with a timestamp takes precedence over a bandwidth assignment without timestamp when PCP and Importance of different bandwidth assignments are both equal.

If resolution is not possible based on the above parameters or they are not available, e.g., each bandwidth assignment lacks timestamp or the precedence order has to be determined for the use of a VID, then the item is granted to the PCE whose LSP has the numerically least LSP ID.

45.3 Redundancy

This subclause specifies IS-IS extensions in support of redundancy schemes, i.e., protection and restoration for data flows.

Local protection for unicast data flows based on loop-free alternates is described in 45.3.1.

Protection schemes are often based on two or more redundant trees, or if that is not possible, then on maximally redundant trees. Maximally Redundant Trees (MRTs) can be used either in a static fashion or with cautious restoration for ISIS-PCR. This subclause specifies how MRTs are installed and maintained leveraging the tools provided by 45.1. The use of static MRTs is described in 45.3.2. Setting up and maintaining MRTs with cautious restoration is described in 45.3.3 and 45.3.4.

45.3.1 Loop-free alternates for unicast data flows

Downstream Loop-Free Alternates (LFAs) provide a simple redundancy scheme, which may be supported by ISIS-SPB for unicast flows of an SPBM VLAN and for SPBV VLANs. A path toward an individual destination MAC address is downstream if it is ensured that the distance to the destination decreases at each hop along the path. Downstream paths are always loop-free alternates to each other with respect to an individual destination MAC address. Therefore, a downstream alternate path can be safely used for local protection as a loop-free backup path.

NOTE—The Alternate Ports of RSTP and MSTP leverage the loop-free alternate paths provided by the physical topology to the Root Bridge. In the case of spanning trees, ‘up’ or ‘upward’ to the Root is used to refer to the same direction as ‘downstream’ for destination rooted trees.

LFA can be provided for SPBV by SPTs (13.17, Clause 27, Clause 28). The LFA mechanism is the same for an SPT as for an MSTI where Alternate Ports leverage LFA paths.

Loop mitigation (6.5.4.2) may be relaxed in order to allow LFAs for unicast SPBM traffic. Ingress checking is modified and relaxed in order to allow the reception of a unicast frame from any SPT Bridge that is upstream with respect to the given individual destination MAC address. Thus, relaxed ingress checking

implements a split horizon for loop mitigation by ensuring that a frame is admitted only if it is received from an SPT Bridge that is farther from the destination than the receiving SPT Bridge, which determines the valid set of ingress ports.

In the case of a failure at an SPT Bridge's Port or LAN on the shortest path toward individual MAC addresses, the SPT Bridge acts as a Point of Local Repair (PLR) and forwards frames through ports providing downstream LFA paths toward the given individual MAC addresses, if any.

An SPT Bridge updates its relaxed ingress checking after detecting a mismatch in the Agreement Digest. An ingress port is removed from the valid set of ingress ports with respect to a particular individual destination MAC address if a formerly upstream SPT Bridge is no longer farther from the destination than the given SPT Bridge. An LFA path is removed if the corresponding formerly downstream neighbor is not closer any more to the destination than the given SPT Bridge.

An SPT Bridge updates its LFA paths and relaxed ingress checking after finishing the updates of multicast states. If LFA paths with respect to an individual MAC address have been changed, then the new LFA paths are added. The valid set of ingress ports is extended with the new upstream Bridges with respect to an individual MAC address, if any.

45.3.2 Static redundant trees

The trees associated with the ST ECT Algorithm (00-80-C2-17, Table 45-1) are static in the sense that no entity other than the owner PCE can update them. In other words, ISIS-PCR only installs the strict trees and does not take any further action on them; i.e., ISIS-PCR neither restores them nor maintains them. In the case of a topology change, it is the task of the owner PCE to detect the topology change, e.g., based on the changes in its LSDB, and also update the strict trees if needed. This requires the owner PCE to compute the new tree and to assemble the corresponding new Topology sub-TLV (45.1.9). The PCE then sends the updated LSP conveying the new Topology sub-TLV, and ISIS-PCR updates the strict explicit tree. The owner PCE can withdraw an explicit tree by sending an updated LSP that does not include the Topology sub-TLV. If a Topology sub-TLV is removed from an LSP (or has been changed), so that (previous) Topology sub-TLV is no longer present (or has been changed) in the LSDB, then that (previous) Topology sub-TLV is implicitly withdrawn. ISIS-PCR then removes (or updates) the explicit tree.

NOTE 1—The PCE preferably does not initiate the update of explicit trees if there is any reason to suspect that the SPT Bridges of the SPT Region do not share a common view on network topology.

NOTE 2—The PCE can have a hot standby backup PCE in order to avoid a single point of failure.

Strict explicit trees can be used for Maximally Redundant Trees (MRTs), especially if more than two redundant trees are needed. Each tree is described by a distinct Topology sub-TLV (45.1.9). The VLAN configuration of strict trees is specified in 45.1.3.

The PCE or its PCA assembles and floods the corresponding Topology sub-TLVs (45.1.9); thus ISIS-PCR installs the explicit trees throughout the SPT Region as specified in 45.1. All of the maximally redundant trees are installed independently of each other, i.e., ISIS-PCR is not aware of any relationship between them. Maintaining the association among the redundant strict trees is not the responsibility of ISIS-PCR, but the entity that requests and uses them, e.g., the owner PCE and the management entity responsible for configuring the protection scheme in use. Therefore, no parameters for association of static explicit trees are present in the ISIS-PCR sub-TLVs.

NOTE 3—For instance, two static redundant trees can be used for CFM-based protection switching as specified in 26.10, where the association and the use of the paths are provided. Static redundant trees can be also used for 1+1 types of protection schemes, where a copy of each data frame is forwarded on each of the redundant paths.

The algorithm used by the owner PCE for the computation of static redundant trees is not specified by this standard. Number *K*, the number of trees to be computed, is an input for the owner PCE. The Topology sub-TLVs (45.1.9) are the output of the owner PCE. Other outputs can include the number of common links and their identity.

45.3.3 Maximally Redundant Trees (MRTs)

SPT Bridges may support MRTs. The BLCE of SPT Bridges is also involved in the computation of MRTs. The MRTs can be, for example, used for point-to-multipoint protection if the MRTs are source rooted or for multipoint-to-point protection if the MRTs are destination rooted. The MRTs can be used to protect an SPT rooted at the MRT Root. The MRTs can be also used so that they protect each other, e.g., in a 1+1 type of protection scheme where data frames are sent on both MRTs. An MRT provides an undirected active topology just like an SPT or a spanning tree instance (which is also a shortest path tree rooted at the spanning tree root). Correspondingly, MRTs can be used for bidirectional or unidirectional traffic, as determined by the T/R parameters of the data traffic carried on the tree.

The MRT ECT Algorithm (00-80-C2-18, Table 45-1) is used for the establishment and maintenance of MRTs in a distributed fashion as specified by this subclause. The MRT Lowpoint Algorithm specified by IETF RFC 7811 has to be used for the computation of MRTs that span more than two Edge Bridges. If only two Edge Bridges are to be connected, then the algorithm specified in this subclause has to be used for path computation. The MRT Lowpoint Algorithm produces two MRTs for an MRT Root: MRT-Blue and MRT-Red. If the MRTs are used in a primary and backup fashion, then MRT-Blue is the primary and MRT-Red is the backup. The MRTs are cautiously restored after a topology change as described in this subclause.

NOTE 1—If more than two maximally redundant trees are required, then static redundant trees (45.3.2) have to be used.

When the MRT Lowpoint Algorithm is used by ISIS-PCR, then the input parameters of the Interface_Compare function are as follows: The Interface_compare_metric is the SPB Link Metric (28.12.7), and the maximum metric value is used in cases where the metrics advertised by adjacent Bridges for a given link are different. The Interface_compare_unique_node_identifier is the 8-byte Bridge Identifier, which comprises a 6-byte IS-IS System Identifier and a 2-byte Bridge Priority.

The MRT Lowpoint Algorithm first computes the GADAG, and the computation requires the selection of the GADAG Root. The Bridge with the best Bridge Identifier is selected as the GADAG Root, where the numerically lower value indicates the better identifier. The manageable Bridge Priority component of the Bridge Identifier allows the configuration of the GADAG Root. The Bridge Priority is conveyed by Octets 15 and 16 of the SPB Instance sub-TLV (28.12.5). Based on its LSDB, each SPT Bridge can locally determine which Bridge is the GADAG Root and then compute the GADAG. The MRTs are then computed based on the GADAG. Examples for a GADAG and two corresponding MRTs are shown in Figure 45-13 and Figure 45-14, respectively. If tie-breaking is required among equal cost paths while the MRTs are computed, then the tie-breaking specified by the LowPATHID algorithm (28.7) has to be used. If MRTs support a VLAN having multiple multicast sources, then the BLCEs of the Bridges have to compute the MRTs of other Bridges in addition to their own MRTs due to the need to apply source-specific (S,G) multicast. This is similar to the application of All Pairs Shortest Path computation in ISIS-SPB. (See 45.1.1 for further details on source-specific (S,G) multicast.)

The MRT Lowpoint Algorithm is specified in terms of determining next hop FDB entries toward a particular unicast destination. This generates a tree directed to the root, which is the destination. By inverting the direction of this destination rooted tree, a source rooted tree can be retrieved.

If MRTs are required for a VLAN so that each Bridge performs all the MRT computation steps on its own including GADAG computation, i.e., the MRT computation is fully distributed, then the VLAN has to be associated with the MRT ECT Algorithm (Table 45-1) as specified in 45.1.3.

Just using the MRT ECT Algorithm creates MRT-Blue and MRT-Red for each SPT Root, i.e., each SPT Root is also an MRT Root, and IS-IS maintains all the MRTs. Furthermore, the MRTs are spanning trees in this case, i.e., each Bridge of the SPT Region is included in both MRT-Blue and MRT-Red. This operation mode is selected by providing the VLAN configuration in the SPB Base VLAN Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5) as specified in 45.1.3. The Topology sub-TLV (45.1.9) is not used in this case, i.e., only ISIS-SPB sub-TLVs are used.

If the level of redundancy provided by each SPT Root also being an MRT Root is not required, then the MRT Roots can be specified by a Topology sub-TLV (45.1.9); this approach can be also applied when MRTs protect each other and SPTs are not used. The Topology sub-TLV describes loose explicit trees in this case, i.e., it specifies only the Edge Bridges that the MRTs are to span, and each Edge Bridge is a loose hop. An MRT Root is specified by setting the Root flag [item c4) in 45.1.10] in the corresponding Hop sub-TLV (45.1.10). An MRT Root is typically an Edge Bridge too. MRTs provide a path from each Edge Bridge to the MRT Root, i.e., each Edge Bridge is a leaf except for the MRT Root. If a Topology sub-TLV specifies multiple MRT Roots, then an Edge Bridge has different roles in the MRTs rooted at different Bridges. Therefore, the Leaf flag [item c5) in 45.1.10] is not used to mark leaves of MRTs. The Topology sub-TLV can include a hop with the Exclude flag [item c6) in 45.1.10] set for a Bridge that is to be avoided by the MRTs, in which case the Bridge is excluded from the GADAG, too. The Topology sub-TLV can convey one or more Base VIDs that are associated with the MRT ECT Algorithm. Whether the MRTs are unidirectional or bidirectional is determined by the T/R flags corresponding to the VIDs, I-SIDs, and MAC addresses associated with the given MRTs.

NOTE 2—For instance, if a VLAN is supported by ISIS-SPB in SPBM mode (Clause 27, Clause 28) and MRTs are used for the protection of SPTs, then only three VIDs are required to support the VLAN. The Base VID is used for all the SPTs. Another VID is used for all MRT-Blues, and a third VID is used for all MRT-Reds. The MRTs are then used as destination rooted trees for unicast traffic and as source rooted trees for multicast traffic just like the SPTs. The T/R parameters for the MRT VIDs are exactly the same as for the Base VID; therefore, IS-IS populates the FDBs for the MRTs the same way as for the SPTs, i.e., just uses the corresponding MRT VID instead of the Base VID.

If the Topology sub-TLV specifies only two Edge Bridges, then the following algorithm is used for the computation of the two maximally redundant paths instead of the MRT Lowpoint Algorithm. As they interconnect only two Edge Bridges, the MRTs are reverse path congruent maximally redundant paths in this case. According to the algorithm below, one of the two maximally redundant paths is the shortest path. The two paths are used to protect each other. A VLAN associated with maximally redundant paths has to be configured as specified in 45.1.3 for the MRT ECT Algorithm. The VID of MRT-Blue is used for the shortest path, and the VID of MRT-Red is used for the other path. The establishment of the redundant paths is initiated by the flooding of a Topology sub-TLV (45.1.9). The paths are then determined by the BLCE of the SPT Bridges and then installed by ISIS-PCR. The Topology sub-TLV can convey constraint sub-TLVs, which have to be also taken into account when determining the paths. The BLCEs perform the following path computation algorithm:

1) Prune the topology according to the constraints of the Topology sub-TLV (45.1.9), if any. The rest of the computation steps are performed on the pruned topology. If pruning splits the SPT Region, then the outcome can be that no path is available.
2) Run Dijkstra to get the (constrained) shortest path, which is the primary path.
3) Install the FDB entries corresponding to the VID of MRT-Blue along the primary path.
4) Update th network graph by the appropriate method as follows:
   a) Prune the links of the primary path if that does not partition the SPT Region.
   b) Otherwise, multiply by 1000 the link metric of the links taking part in the primary path.
5) Run Dijkstra to get the backup path.
6) Install the FDB entries corresponding to the VID of MRT-Red along the backup path.

It is recommended to use distinct VIDs for MRT-Blue and MRT-Red, which are loose trees and therefore computed by multiple entities. As a strict tree is controlled by a single PCE, it is easier to ensure unambiguous forwarding and allow the use of the same VID for different strict trees as described in 45.1.4 than to do so for loose trees.

MRTs have to be restored cautiously after a topology change. The restoration should not be initiated if there is any reason to suspect that the SPT Bridges of the SPT Region do not share a common view on the network topology. BLCEs then perform path computation, and MRTs are updated as follows.

If MRTs are used for SPT protection, then MRTs are restored only after the restoration of the SPTs. Upon a failure event, Point of Local Repair (PLR) Bridges redirect data traffic to the MRT that is not affected by the failure, if any. As the topology change is announced by the corresponding LSPs, the SPT Bridges compute and install the new SPTs. If each SPT Bridge has installed the new SPT, then data traffic is directed back to the SPTs. After that, the new MRTs are computed and installed by the Bridges.

If MRTs support a non-learning VLAN, then the PLRs can redirect traffic by replacing the FDB entry belonging to the tree of normal operation (i.e., the SPT or an MRT) with the FDB entry belonging the protection tree (i.e., with MRT-Blue or MRT-Red) upon a failure event. If MRTs support a learning VLAN, then the PLRs can redirect traffic by updating VID translation at the Ingress Port from the VID of normal operation to the VID of the protection tree (i.e., to MRT-Blue or MRT-Red) upon a failure event.

If MRTs protect each other, then only one of the MRTs is restored at a time. Upon a failure event, PLR Bridges direct all data traffic to the MRT (e.g., MRT-Red) that is not affected by the failure. If a 1+1 type of protection scheme is used, then there is no need to react to a failure event as data frames are forwarded on both MRTs, i.e., there are no PLRs. When each SPT Bridge has the same view on the network topology again, then the SPT Bridges compute the new MRTs. The broken MRT (e.g., MRT-Blue) then is restored while the other MRT (e.g., MRT-Red) is not touched. If each SPT Bridge has installed the new MRT (e.g., the new MRT-Blue), then data traffic is directed to this newly restored MRT. The SPT Bridges then install the other MRT (e.g., the new MRT-Red). The same restoration procedure is followed if both MRTs are affected by the failure so that MRT-Blue is restored first.

Loop prevention (6.5.4.1, 27.9) has to be applied for MRTs during the period when they are being restored by ISIS-PCR.

There is a non-zero probability of out-of-order frame delivery while ISIS-PCR restores loose explicit trees, e.g., MRTs. This probability is similar to the probability of out-of-order frame delivery while ISIS-SPB restores SPTs.

If there are two maximally redundant paths between a pair of Edge Bridges and only the backup path went down, then just Steps 4–6 of the above algorithm are performed again. If only the primary path went down, then data traffic takes the backup path, i.e., only the backup path is in use by the applied protection mechanism. The primary path is then updated according to Steps 1–3. No further steps are taken until the primary path is up again. The protection scheme can then revert to the primary path, and the backup path can be updated according to Steps 4–6. If both paths went down, then Steps 1–6 are performed again.

NOTE 3—The method to be used for verifying whether the SPT Bridges have a common view on the topology and whether SPTs and MRTs have been restored is left to the implementer and the network operator. A common method is to wait some time after the reception of the last LSP indicating a topology change. Alternatively, OAM can be used for instance.

45.3.4 MRTs with centralized GADAG computation

The GADAG is identical for all the MRTs within a network domain, as a consequence of the use of the MRT Lowpoint Algorithm (IETF RFC 7811). The GADAG is computed by a single entity for VLANs associated with the MRTG ECT Algorithm (Table 45-1). This entity is referred to as the GADAG Computer and is either a PCE or the BLCE of the GADAG Root.

SPT Bridges may support the MRTG ECT Algorithm (00-80-C2-19, Table 45-1). MRTs are then computed by the SPT Bridges based on the GADAG provided by the GADAG Computer in a Topology sub-TLV (45.1.9). The GADAG and the MRTs are computed as specified by the MRT Lowpoint Algorithm (IETF RFC 7811). The MRTs produced by the MRTG ECT Algorithm are cautiously restored after a failure event as described in this subclause. A VLAN is associated with the MRTG ECT Algorithm as specified in 45.1.3 if MRTs with central GADAG computation are to be used for that VLAN.

The GADAG Root is determined based on the Bridge Identifier as described in 45.3.4, which also determines the sole SPT Bridge computing the GADAG if the GADAG Root is the GADAG Computer. Otherwise, the GADAG Computer PCE determines the GADAG Root, which also allows direct configuration of the GADAG Root.

The GADAG Computer performs the GADAG computation as specified by the MRT Lowpoint Algorithm (IETF RFC 7811). The GADAG Computer then encodes the GADAG in a Topology sub-TLV (45.1.9), which is then flooded throughout the domain. A GADAG is encoded in a Topology sub-TLV by means of directed ear decomposition as follows: A directed ear is a directed point-to-point path whose end points can coincide, but no other element of the path is repeated in the ear. Each ear is specified by an ordered list of hops, and that order of hops is according to the direction of the arcs in the GADAG. There are no leaves in a GADAG; hence, the Leaf flag [item c5) in 45.1.10] is used to ease the parsing of the Topology sub-TLV and to mark the end of a topology block (3.272). The sequence of ears in the Topology sub-TLV is such that the end points of an ear belong to former ears. The GADAG Root is not marked by any flag, but the GADAG Root is the first hop in the Topology sub-TLV; correspondingly the first ear starts and ends with the GADAG Root. MRT Roots are marked by the Root flag [item c4) in 45.1.10], and all other Edge Bridges are leaves of the given MRTs. If no MRT Root is specified, then each SPT Root is also an MRT Root. If a Bridge has to be excluded from the MRTs, then it is not part of the GADAG.

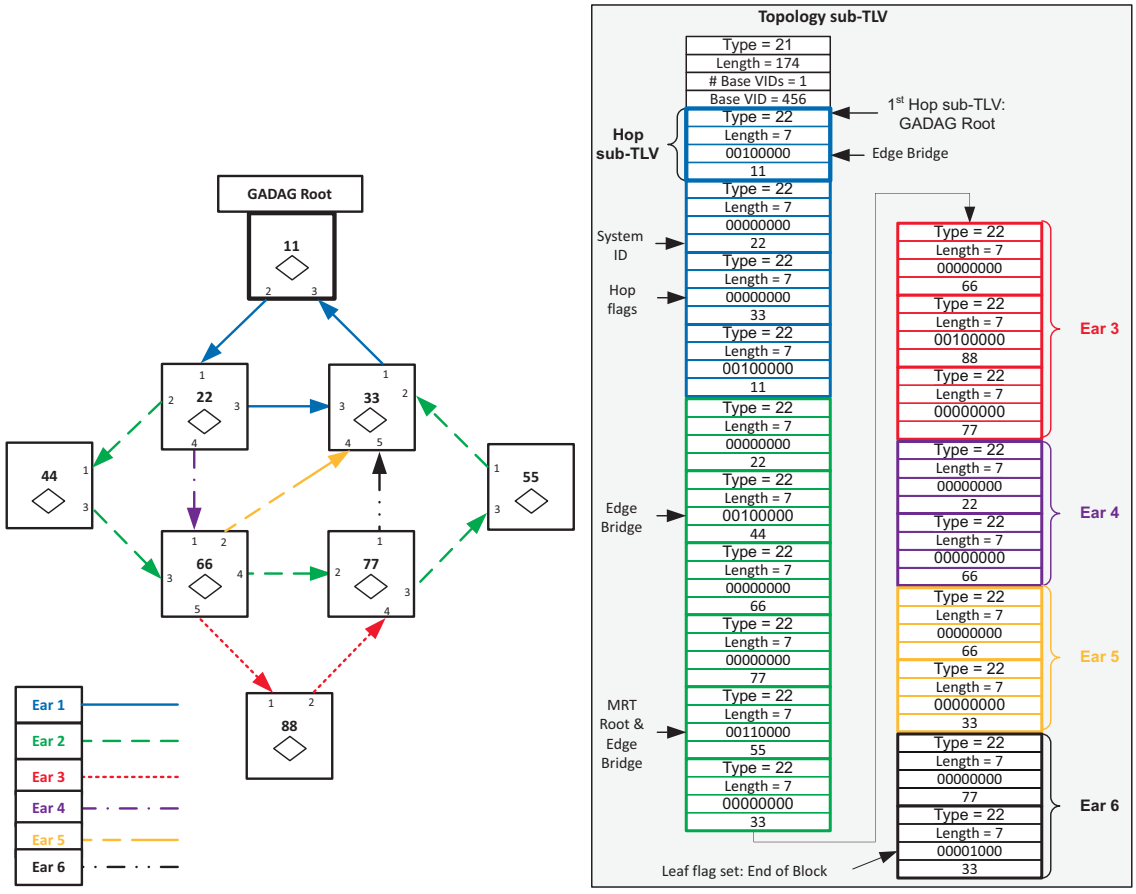

Figure 45-13—A GADAG and its descriptor Topology sub-TLV

Figure 45-13 shows the GADAG for the network topology depicted in Figure 45-1 and Figure 45-2 when SPT Bridge 11 is the GADAG Root. The graph shown in Figure 45-13 is in fact an ADAG, and removing the arc going from Bridge 33 to Bridge 11 (the GADAG Root) makes it a DAG. Figure 45-13 also shows the

Topology sub-TLV that specifies the GADAG. The first directed ear starts and ends at the GADAG Root, i.e., Bridge 11. The second ear (Ear 2) starts at Bridge 22 and ends at Bridge 33. The third ear (Ear 3) comprises Bridges 66, 88, and 77. Each of the remaining arcs is an individual ear added by a pair of Hop sub-TLVs according to the direction of the arc. Bridges 11, 44, 55, and 88 are Edge Bridges. Bridge 55 is the only MRT Root.

The MRTs are then computed by the SPT Bridges as specified by the MRT Lowpoint Algorithm (IETF RFC 7811) based on the GADAG descriptor received from the GADAG Computer. Whether the MRTs are unidirectional or bidirectional is determined by the T/R flags corresponding to the VIDs, I-SIDs, and MAC addresses associated with the given MRTs. Figure 45-14 shows MRT-Blue and MRT-Red if the GADAG descriptor Topology sub-TLV of Figure 45-13 is used for MRT computation, i.e., SPT Bridge 55 is the only MRT Root. Figure 45-14 also shows that an Edge Bridge is not necessarily a leaf; see Bridge 11.

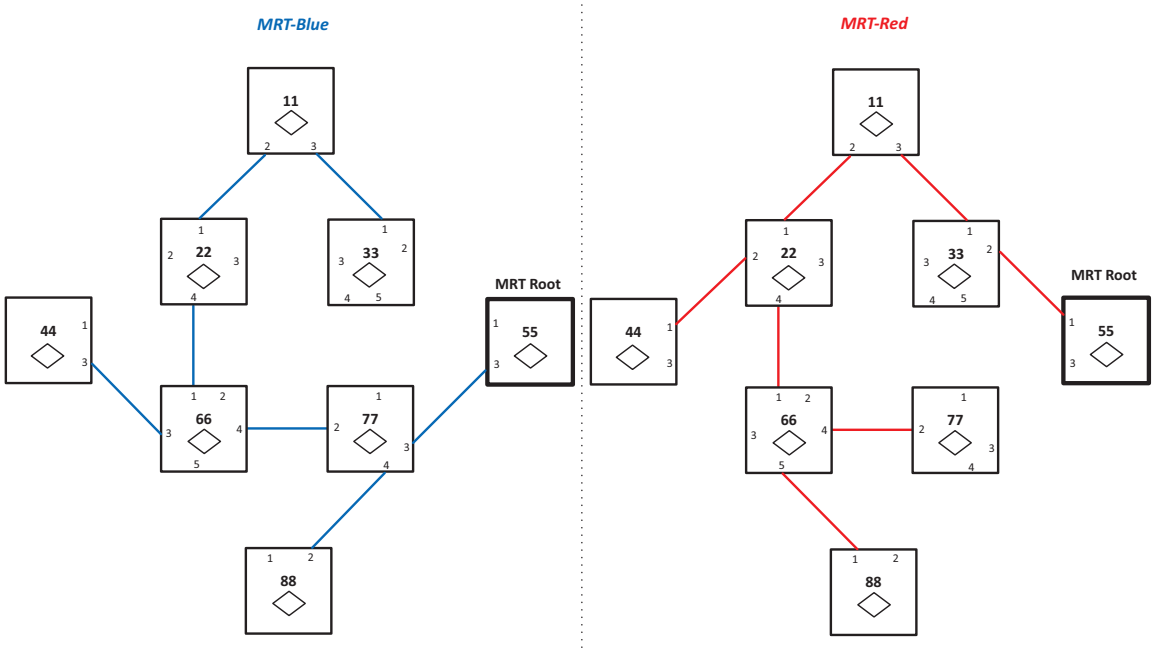

Figure 45-14—MRT-Blue and MRT-Red for MRT Root 55

The Topology sub-TLV specifying the GADAG can convey Base VIDs associated with the MRTG ECT Algorithm, which specifies the VLANs for which the GADAG is relevant. If there is no Base VID parameter in the Topology sub-TLV specifying a GADAG, then the given GADAG has to be used for all VLANs whose Base VID is associated with the MRTG ECT Algorithm.

A network topology can comprise multiple topology blocks (3.272), like the one illustrated in Figure 45-15, which comprises four blocks because each cut-link with the two Bridges at either end is a block. A GADAG is also shown in Figure 45-15. Note that two arcs with opposite direction represent a cut-link in a GADAG, e.g., see the cut-link between Bridges 75 and 77. The encoding starts with the block (ADAG) involving the GADAG Root as illustrated in Figure 45-15. The first hop in the Topology sub-TLV is the GADAG Root (Bridge 11 in this example). The ADAG of the first block is then described using the ear decomposition, as described above. In this example, the first block has been completely traversed at the second occurrence of Bridge 11 in the GADAG descriptor. The end of a block is indicated by setting the Leaf flag for the last hop of the block, e.g., for the second occurrence of Bridge 11 in the example GADAG descriptor. The next Bridge that appears in the GADAG descriptor (Bridge 44 in this case) is the localroot for the Bridges in the

next block. Continuing this process, the Leaf flag is set for the third occurrence of Bridge 44, the third occurrence of Bridge 75, and the third occurrence of Bridge 77, each indicating the end of a block.

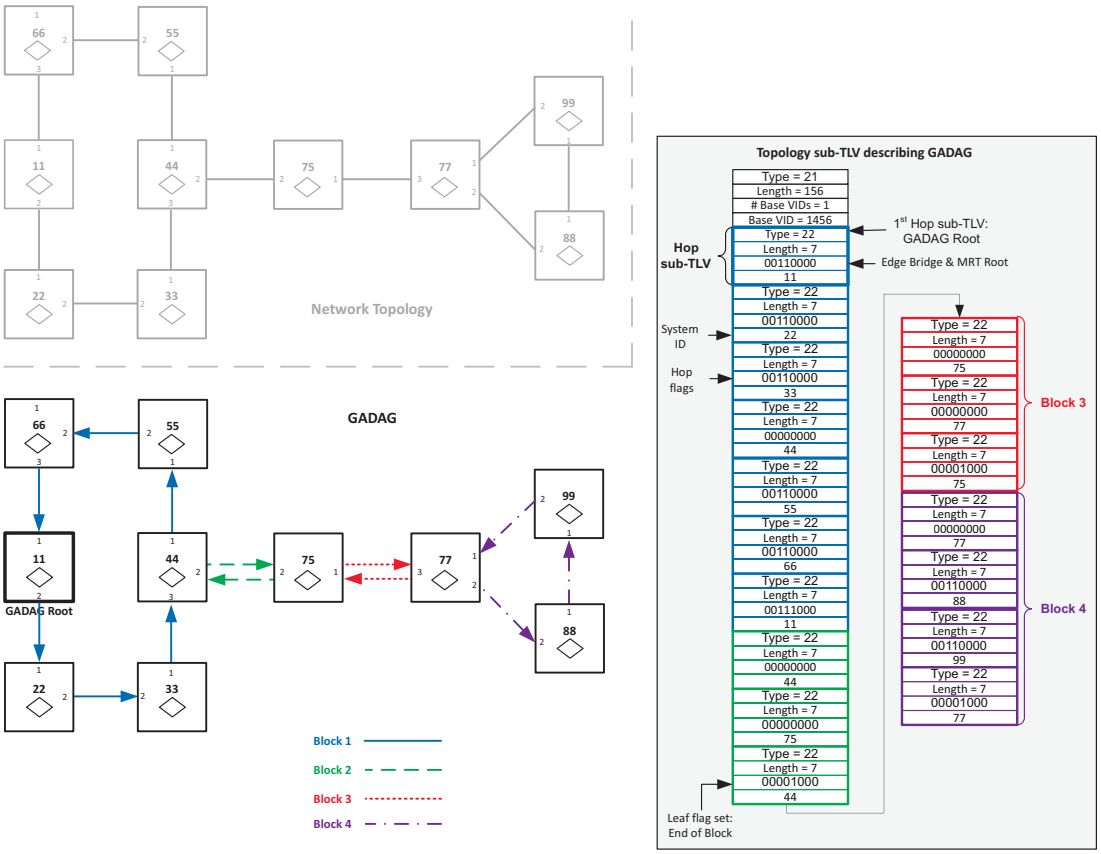

Figure 45-15—A GADAG for a topology with multiple blocks

The first hop of the first block is the GADAG Root; the first hop in the rest of the blocks is the localroot. The position of the set Leaf flags helps to determine the localroot, which is the next hop. In the example GADAG descriptor, one can determine that Bridge 11 is the localroot for Bridges 22, 33, 44, 55, and 66 (and Bridge 11 is the GADAG Root). Bridge 44 is the localroot for Bridge 75. Bridge 75 is the localroot for Bridge 77. Bridge 77 is the localroot for Bridges 88 and 99. The GADAG Root is assigned a localroot of None.

Block IDs are reconstructed while parsing a Topology sub-TLV specifying a GADAG. The current Block ID starts at 0 and is assigned to the GADAG Root. A Bridge appearing in the GADAG descriptor without a previously assigned Block ID value is assigned the current Block ID. The current Block ID is incremented by 1 after processing the localroot of a block. Note that the localroot of a block will keep the Block ID of the firsts block in which it is assigned a Block ID. In the example shown in Figure 45-15, Bridge 11 has Block ID=0. Bridges 22, 33, 44, 55, and 66 have Block ID=1. Bridge 75 has Block ID=2. Bridge 77 has Block ID=3. Bridges 88 and 99 have Block ID=4.

MRTs have to be restored cautiously after a topology change. The restoration should not be initiated if there is any reason to suspect that the SPT Bridges of the SPT Region do not share a common view on the network topology.

If MRTs are used for SPT protection, then MRTs are restored only after the restoration of the SPTs. Upon a failure event, PLR Bridges redirect data traffic to the MRT that is not affected by the failure, if any. As the topology change is announced by the corresponding LSPs, SPT Bridges and the GADAG Computer become aware of the change. The SPT Bridges then compute and install the new SPTs. When each SPT Bridge has installed the new SPT, then data traffic is directed back to the SPTs. The GADAG Computer then computes the new GADAG and floods its descriptor. The SPT Bridges then compute and install the new MRTs if each SPT Bridge has already directed traffic back to the SPTs.

If MRTs protect each other, then only one of the MRTs is restored at a time. Upon a failure event, PLR Bridges direct all data traffic to the MRT that is not affected by the failure (e.g., MRT-Red). If a 1+1 type of protection scheme is used, then there is no need to react to a failure event as data frames are forwarded on both MRTs, i.e., there are no PLRs. When the GADAG Computer and the SPT Bridges have the same view on the network topology again, then the GADAG Computer computes the new GADAG and floods its descriptor. Upon reception of the Topology sub-TLV describing the new GADAG, the SPT Bridges compute the new MRTs. The broken MRT (e.g., MRT-Blue) then is restored while the other MRT (e.g., MRT-Red) is not touched. If each SPT Bridge has installed the new MRT (e.g., the new MRT-Blue), then data traffic is directed to this newly restored MRT. The SPT Bridges then install the other MRT (e.g., the new MRT-Red). The same restoration procedure is followed if both MRTs are affected by the failure so that MRT-Blue is restored first.

NOTE—The method to be used for verifying whether the SPT Bridges have a common view on the topology and whether SPTs and MRTs have been restored is left to the implementer and the network operator. A common method is to wait some time after the reception of the last LSP indicating a topology change. Alternatively, OAM can be used, for instance.

46. Time-Sensitive Networking (TSN) configuration

Time-Sensitive Networking (TSN) is a collection of features in IEEE 802.1 standards that provide the following:

— Time synchronization among Bridges and end stations
— Significant reduction in frame loss due to faults in network equipment
— Significant reduction in, or the elimination of, frame loss due to egress Port congestion
— Bounded latency

This clause provides specifications for the configuration of TSN features in a network. The configuration process begins when Talkers and Listeners pass their requirements to the network and proceeds with the configuration of TSN features in Bridges along a tree from each Talker to its Listener(s).

46.1 Overview of TSN configuration

46.1.1 User/Network Interface (UNI)

TSN configuration uses the concept of a Stream that is transmitted by a Talker to one or more Listeners. The Talkers and Listeners are located within end stations.

This clause specifies configuration information that is exchanged over a User/Network Interface (UNI). The user side of the interface represents Talkers and Listeners. The network side of the interface represents the Bridges that transfer frames of the Stream from each Talker to its Listeners. Each user specifies requirements for its data, but without detailed knowledge of the network. The network obtains requirements from users, analyzes the topology and TSN capabilities of Bridges, and configures the Bridges to meet user requirements. The network returns the success or failure of each Stream's configuration to the user.

46.1.2 Modeling of user/network configuration information

A variety of protocols can be used for the exchange of configuration information over the TSN UNI (e.g., signaling protocols, remote network management protocols). These protocols can exchange the configuration information as text or as binary fields. To enable flexible integration of TSN configuration into a variety of protocols, 46.2 specifies the TSN user/network configuration information in a manner that is independent of schema, encoding, or protocol.

Specific TSN-capable products list the user/network protocol that is supported as part of their conformance [e.g., 5.18.3, item c) in 5.29]. Each user/network protocol will specify a specific schema and/or encoding for the configuration information in 46.2. Examples of these protocols are described for each of the TSN configuration models in 46.1.3.

46.1.3 TSN configuration models

This subclause describes three models for TSN user/network configuration. These models provide an architectural context for subsequent specifications. Each model specification shows the logical flow of user/network configuration information between various entities in the network.

46.1.3.1 Fully distributed model

In the fully distributed model, the end stations that contain users of Streams (i.e., Talkers and Listeners) communicate the user requirements directly over the TSN user/network protocol. The network is configured in a fully distributed manner, without a centralized network configuration entity. The distributed network configuration is performed using a protocol that propagates TSN user/network configuration information along the active topology for the Stream (i.e., Bridges in the tree from Talker to Listeners).

As user requirements propagate through each Bridge, management of the Bridge's resources is effectively performed locally. This local management is limited to the information that the Bridge has knowledge of and does not necessarily include knowledge of the entire network.

Figure 46-1 provides a graphical representation of the fully distributed model.

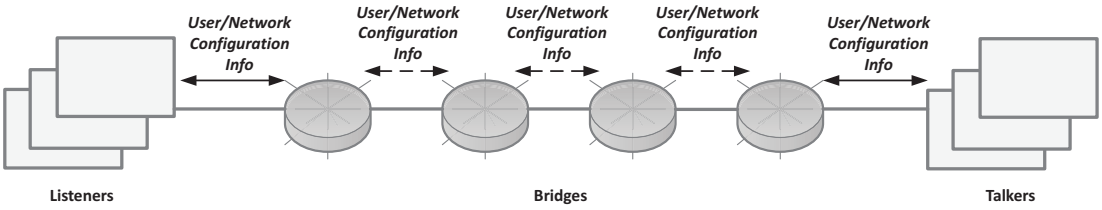

Figure 46-1—Fully distributed model

In the figure, the solid arrows represent the protocol that is used as the UNI for exchange of configuration information between Talkers/Listeners (users) and Bridges (network). This configuration information is specified in 46.2.

In the figure, the dashed arrows represent the protocol that propagates configuration information within the network. This protocol carries the TSN user/network configuration information (46.2) as well as additional information that is specific to network configuration.

The following TSN features can be configured by Bridges using this model:

a) Credit-based shaper algorithm (8.6.8.2) and its configuration (Clause 34)

The Stream Reservation Protocol (SRP) of Clause 35 can be used as the UNI and to propagate configuration information throughout the network of Bridges. SRP exchanges configuration information as binary fields using the Type-Length-Value (TLV) technique. Using this technique, the protocol's top-level message contains a list of one or more TLVs. Each TLV consists of a Type field that specifies what the Value field contains, a Length field that specifies the number of octets in the Value field, and the Value field. In SRP specifications, each TLV Type identifies one of the groups specified in 46.2, and the TLV Value contains a binary representation of the elements in that group.

46.1.3.2 Centralized network/distributed user model

Some TSN use cases are computationally complex. For example, for scheduled traffic (8.6.8.4), computation of the gate control list of each Port can take significant time. For such use cases, it is helpful to centralize the computation in a single entity (Bridge or end station), rather than perform the computation in all Bridges.

Some TSN use cases can benefit from a complete knowledge of all Streams in the network. For example, if the bandwidth for multiple Streams is greater than the available bandwidth along the shortest path between Talkers and Listeners, it is helpful to forward a subset of those Streams along a path other than the shortest.

For these use cases, a centralized entity can gather information for the entire network in order to find the best configuration.

The centralized network/distributed user model is similar to the fully distributed model in that end stations communicate their Talker/Listener requirements directly over the TSN UNI. In contrast, in the centralized network/distributed user model, the configuration information is directed to/from a Centralized Network Configuration (CNC) entity. All configuration of Bridges for TSN Streams is performed by this CNC using a remote network management protocol.

The CNC has a complete view of the physical topology of the network as well as the capabilities of each Bridge. This enables the CNC to centralize complex computations. The CNC can exist in either an end station or a Bridge.

The CNC knows the address of all Bridges at the edge of the network (those with an end station connected). The CNC configures those edge Bridges to act as a proxy, transferring Talker/Listener information directly between the edge Bridge and the CNC, rather than propagate the information to the interior of the network.

Figure 46-2 provides a graphical representation of the centralized network/distributed user model.

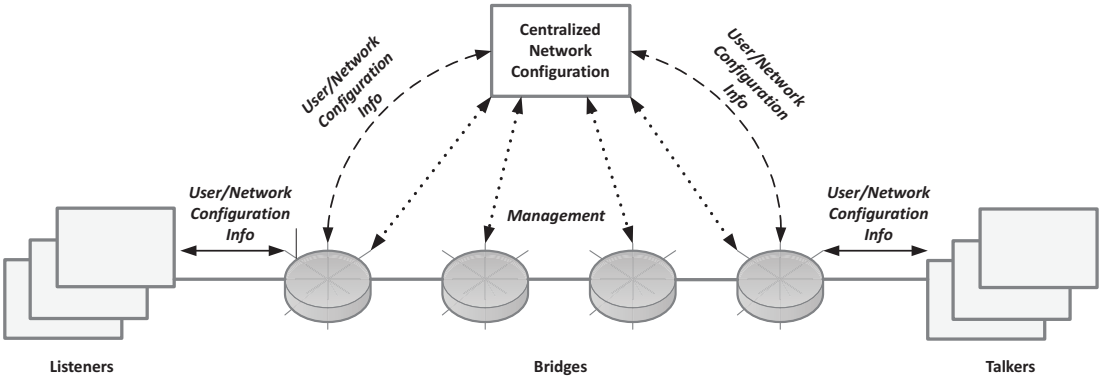

Figure 46-2—Centralized network/distributed user model

In the figure, the solid arrows represent the protocol that is used as the UNI for exchange of configuration information between Talkers/Listeners (users) and Bridges (network). This configuration information is specified in 46.2.

In the figure, the dashed arrows represent the protocol that transfers configuration information between edge Bridges and the CNC. This configuration information is specified in 46.2.

In the figure, dotted arrows represent the remote network management protocol. The CNC acts as the management client, and each Bridge acts as the management server. The CNC uses remote management to discover physical topology, retrieve Bridge capabilities, and configure TSN features in each Bridge. Talkers and Listeners are not required to participate in this remote network management protocol. The information carried by the remote network management protocol is specified in Clause 12.

NOTE 1—If the Talker/Listener protocol of the fully distributed model is selected to be the same as the Talker/Listener protocol of the centralized network/distributed user model, end stations can support both models without explicit knowledge of how the network is configured.

The following TSN features can be configured by the CNC using this model:

a) Credit-based shaper algorithm (8.6.8.2) and its configuration (Clause 34)
b) Frame preemption (6.7.2)
c) Scheduled traffic (8.6.8.4, 8.6.9)
d) Frame Replication and Elimination for Reliability (IEEE Std 802.1CB)
e) Per-Stream Filtering and Policing (8.6.5.1)
f) Cyclic queuing and forwarding (Annex T)

SRP (Clause 35) can be used as the UNI (solid arrows of Figure 46-2). SRP's MRP External Control (12.32.4) feature can be used to exchange configuration information with the CNC component (dashed arrows of Figure 46-2). SRP exchanges configuration information using the TLV technique to reference elements in 46.2 (see 46.1.3.1). Examples of a remote network management protocol (dotted arrows of Figure 46-2) include Simple Network Management Protocol (SNMP), NETCONF (IETF RFC 6241 [B39]), and RESTCONF (IETF RFC 8040 [B45]).

NOTE 2—NETCONF and RESTCONF specify a startup datastore: nonvolatile configuration that is applied when the Bridge powers on. The startup datastore feature enables a TSN CNC to configure Bridges and then remove itself from the network. SNMP does not specify a startup datastore feature. If SNMP is used by a TSN CNC, this can be mitigated by a) using a proprietary (Bridge-specific) startup datastore feature or b) ensuring that the TSN CNC is always active in the network in order to reconfigure Bridges that cycle power.

46.1.3.3 Fully centralized model

Many TSN use cases require significant user configuration in the end stations that act as Talkers and Listeners. For example, in many automotive and industrial control applications, the timing of physical inputs and outputs (I/Os) is determined by the physical environment under control, and the timing requirements for TSN Streams are derived from that I/O timing. In some use cases, these I/O timing requirements can be computationally complex and involve detailed knowledge of the application software/hardware within each end station.

In order to accommodate this sort of TSN use case, the fully centralized model enables a Centralized User Configuration (CUC) entity to discover end stations, retrieve end station capabilities and user requirements, and configure TSN features in end stations. The protocols that the CUC uses for this purpose are specific to the user application and outside the scope of this standard.

From a network perspective, the primary difference between the fully centralized model and the centralized network/distributed user model is that all user requirements are exchanged between the CNC and CUC. Therefore, the TSN UNI exists between the CNC and CUC.

Figure 46-3 provides a graphical representation of the fully centralized model.

In the figure, the solid arrows represent the protocol that is used as the UNI for exchange of configuration information between the CUC and the CNC. This configuration information is specified in 46.2.

In the figure, the dotted arrows represent the remote network management protocol. The CNC acts as the management client, and each Bridge acts as the management server. The CNC uses remote management to discover physical topology, retrieve Bridge capabilities, and configure TSN features in each Bridge. Talkers and Listeners are not required to participate in this remote network management protocol. The information carried by the remote network management protocol is specified in Clause 12.

In this fully centralized model, a protocol is used between the CUC and end stations (Talkers and Listeners) to retrieve end station capabilities and requirements and to configure the end stations. Since that protocol is user-to-user, its configuration information is considered to be outside the scope of this standard, and it is not shown in Figure 46-3.

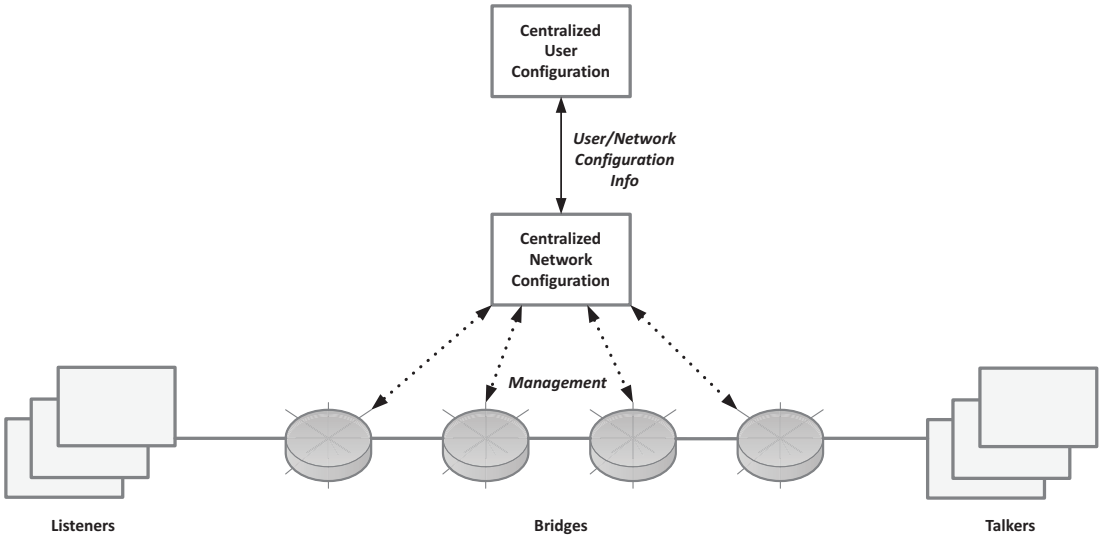

Figure 46-3—Fully centralized model

The following TSN features can be configured by the CNC using this model:

a) Credit-based shaper algorithm (8.6.8.2) and its configuration (Clause 34)
b) Frame preemption (6.7.2)
c) Scheduled traffic (8.6.8.4, 8.6.9)
d) Frame Replication and Elimination for Reliability (IEEE Std 802.1CB)
e) Per-Stream Filtering and Policing (8.6.5.1)
f) Cyclic queuing and forwarding (Annex T)

YANG (IETF RFC 7950) is a data modeling language used to model configuration data and state data for remote network management protocols. The remote network management protocol uses a specific encoding such as XML or JSON. For a particular feature, a YANG module specifies the organization and rules for the feature's management data, and a mapping from YANG to the specific encoding enables the data to be understood correctly by both client (e.g., network manager) and server (e.g., Bridge). Technically speaking, the TSN user/network configuration is not network management, in that information is exchanged between user and network, and not between a network manager and the network's Bridges (Clause 12). Nevertheless, the concepts are sufficiently similar that YANG is useful for modeling the configuration and state data for the TSN user/network configuration information.

In order to support the use of YANG-based protocols for the fully centralized model, 46.3 specifies a YANG module. The YANG module specifies a YANG typedef/grouping for each group of information in 46.2.

NOTE—At the time that this clause was developed, specific protocol implementations for the fully centralized model were a work in progress. One protocol explored for the UNI between CUC and CNC is RESTCONF (IETF RFC 8040 [B45]). A complete YANG module for the TSN UNI can be specified in a document other than IEEE Std 802.1Q. In order to conform with this clause, the complete TSN UNI YANG module imports the YANG module of 46.3 for use within its containers and lists. The complete TSN UNI YANG module will presumably specify features outside the scope of this clause, such as operations to control the deployment of Stream configuration to the network. The JSON encoding can be used with RESTCONF. Although the TSN UNI is technically not network management, use of RESTCONF provides a simple and effective application programming interface (API) for TSN configuration.

For an informative example workflow using the fully centralized model, refer to U.2.

46.1.4 Stream transformation

TSN configuration uses the concept of a Stream of data that is transmitted by a Talker to one or more Listeners. The Talkers and Listeners are end stations.

In order to apply TSN behavior to Streams (e.g., reserved bandwidth guarantees), the network must be able to distinguish one Stream from another Stream and distinguish Streams from non-TSN traffic (e.g., best-effort). Therefore, each frame of the Stream must contain fields in its header that uniquely identify the Stream.

The goal of TSN configuration is to allow Talkers and Listeners to use their existing transport layer and application layer protocols for data, rather than requiring a TSN-specific frame format. TSN achieves this goal by identifying each Stream using fields from well-established frame formats such as Transmission Control Protocol (TCP), User Datagram Protocol (UDP), and IEEE 802.1 (i.e., MAC addresses and VLAN identifier).

As the frames of each Stream cross the user/network boundary, the identification of the Stream in its frames can be different between the network and the user. For example, the user can use UDP without an awareness of VLAN IDs, but the network can require a specific VLAN ID in order to apply TSN features. In order to support this sort of difference in frame format, the TSN user/network configuration information (46.2) provides features to enable transformation of the Stream's identification at the user/network boundary. The user identification translates to/from the network identification at the boundary, either within the end station or a nearest Bridge. This transformation has the benefit of allowing the user's identification to match its higher layer application protocol and the network's identification to match the bridging technology.

Stream transformation can be accomplished using the functions specified in IEEE Std 802.1CB. The functions of IEEE Std 802.1CB can be implemented in the end station (Talker/Listener) or within the nearest Bridge. The descriptions in this clause focus on Stream transformation in the end station and use features of the TSN user/network configuration information (46.2).

NOTE 1—In this clause, Stream transformation refers to changes to the fields of a frame that identify the Stream. IEEE Std 802.1CB specifies Stream transformation for identification as well as for frame replication and elimination (redundancy).

NOTE 2—Stream transformation is an optional capability of end stations and Bridges. If stream transformation is not supported, the user's identification of the Stream must be the same as the network's identification, and the user must use an identification that is consistent with bridging as specified for TSN features in this standard (e.g., VLAN tag and group destination MAC address).

Figure 46-4 provides an example of Stream transformation in the Talker end station. Stream transformation in the Listener end station is similar. The example of Figure 46-4 assumes use of the centralized network/ distributed user model (46.1.3.2). Use of the fully centralized model (46.1.3.3) is similar.

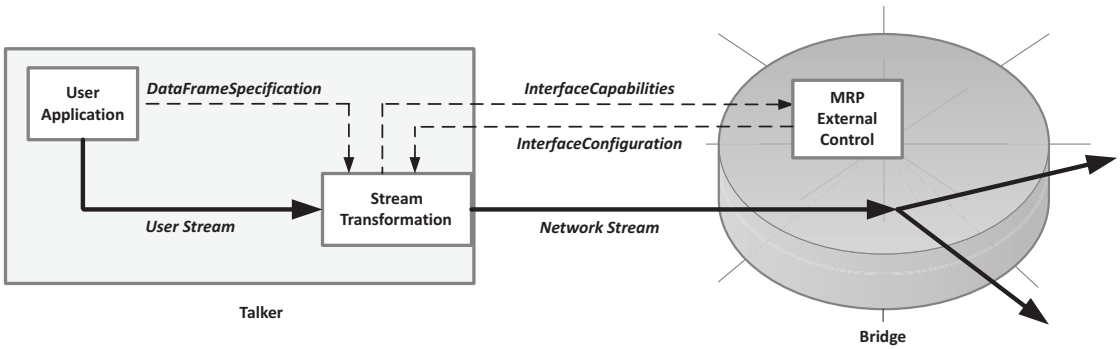

Figure 46-4—Example of Stream transformation in Talker end station

For Stream transformation in the end station, the end station's interface to the network can provide the transformation capability, acting as a network entity within the user's end station.

The identification of the Stream in the user originates from the User Application block, specified by the Talker as the DataFrameSpecification (46.2.3.4). The end station knows this user identification, but not the identification that the network requires. To negotiate the network identification, the Talker uses SRP to transmit InterfaceCapabilities (46.2.3.7) that describe its Stream transformation capabilities to the nearest Bridge. The Bridge uses MRP External Control (12.32.4) to send the InterfaceCapabilities to a CNC. The CNC consults its configuration of network identification and uses MRP External Control to send InterfaceConfiguration (46.2.5.3) along with successful Status (46.2.5) back to the Bridge. When the Bridge receives this information, it propagates back to the Talker using SRP. The InterfaceConfiguration provides the network identification, which the end station uses to perform Stream transformation for data frames.

NOTE 3—The network identification typically entails allocation of a group MAC address for the Stream. If a CNC is used, the CNC can allocate a group MAC address from a pool that it maintains.

Figure 46-5 provides an example of IEEE 802.1CB functions within the Stream Transformation block in the Talker end station. The example assumes that the user identification uses an Internet Protocol (IP) packet for identification and that the frame conveying the IP packet does not use the appropriate MAC address and VLAN tag for TSN features in Bridges (e.g., IP packet unicast destination MAC address, untagged). The IEEE 802.1CB function for IP Stream identification uses fields of the IP packet to identify the packet as a specific TSN stream. That stream identification is then applied to the IEEE 802.1CB function for Active Destination MAC and VLAN Stream identification to replace the destination MAC address and add a VLAN tag for TSN Bridge features. The IP fields of the packet are not changed. The IEEE 802.1CB functions can be implemented in software (e.g., operating system driver) or in hardware.

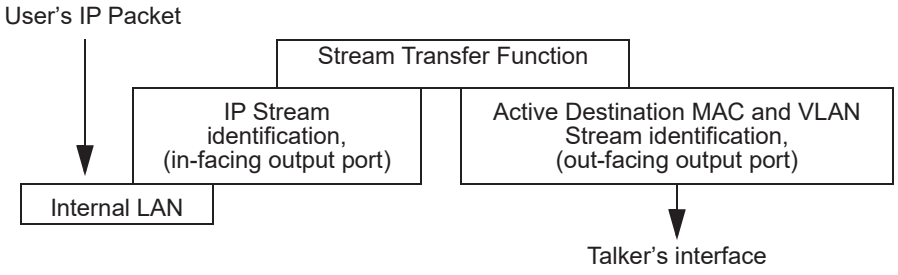

Figure 46-5—Example of IEEE 802.1CB functions in Talker end station

Figure 46-6 provides a corresponding example of IEEE 802.1CB functions within the Stream Transformation block in the Listener end station. In this direction, the IEEE 802.1CB function for Active Destination MAC and VLAN Stream identification provides both functions. The IEEE 802.1CB function uses the group destination MAC address and VLAN tag of the received frame to identify a specific Stream. The IEEE 802.1CB function then transforms the destination MAC address and VLAN tag to restore the Stream's frame to its original format (as transmitted by the Talker).

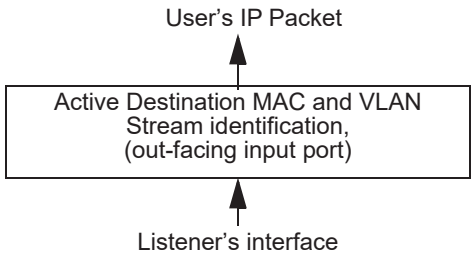

Figure 46-6—Example of IEEE 802.1CB functions in Listener end station

46.2 User/network configuration information

This subclause specifies the user/network configuration information that is used for the three TSN configuration models (46.1.3). The semantics for the TSN user/network configuration information is specified independent of schema, encoding, or protocol.

A schema or encoding of a protocol for the TSN user/network configuration information will reference 46.2 as part of its normative specifications. For the two distributed models, SRP specifies TLVs in 35.2.2.10 that reference information in 46.2. For the fully centralized model, the YANG module in 46.3 references information in 46.2.

Within this subclause, the word element refers to a single item of information used for TSN configuration. The word group refers to a collection of related elements. Groups are organized hierarchically, such that a group can be contained within another group. A single low-level group can be contained within multiple higher level groups. The dot-separated notation is used to refer to a specific element in text. For example, “Talker.StreamID.UniqueId” refers to the UniqueId element of the StreamID group that is contained within the Talker group.

This subclause specifies each group in a table. Each row of the table specifies an element of the group. Each element’s row specifies its name, data type, and a reference to normative text that specifies its semantics (i.e., meaning). The data type of each element uses one of the values from 46.2.1. Other specifications such as conformance (i.e., required or optional), direction of transfer (i.e., user to network or network to user), default value, and range limitations are specified with normative text instead of with the table.

Each element name uses a camel-case naming convention (e.g., “MacAddress”) to align with naming conventions used in other clauses of IEEE Std 802.1Q. A specific protocol can use a different naming convention (e.g., 46.3) as long as the protocol’s name for the element can be associated with the element’s specification in 46.2.

46.2.1 Data types

The data type of each element is limited to semantics, independent of a specific encoding or protocol. Data types in the tables include the following:

a) Boolean
b) int8, for a signed 8-bit integer
c) int16, for a signed 16-bit integer
d) int32, for a signed 32-bit integer
e) uint8, for an unsigned 8-bit integer
f) uint16, for an unsigned 16-bit integer
g) uint32, for an unsigned 32-bit integer
h) string
i) enumeration, for a collection of named values
j) rational, for a rational number consisting of a uint32 numerator and uint32 denominator
k) mac-address-type, for an IEEE 802 MAC address
l) ipv4-address-type, for an IPv4 address (IETF RFC 791 [B18])
m) ipv6-address-type, for an IPv6 address (IETF RFC 8200 [B46])
n) sequence of <X>, for a list of zero or more instances of data type <X> (e.g., sequence of uint32)

If the data type shown in the table is not from the preceding list, then the data type is specified in the normative text for the element.

46.2.2 Protocol integration

The TSN user/network configuration information consists of three high-level groups:

— **Talker:** Elements from user to network that specify the Talker for a single Stream.
— **Listener:** Elements from user to network that specify the Listener for a single Stream.
— **Status:** Elements from network to user that specify the status of the Stream's network configuration for a Talker or Listener. This group notifies the user when the Stream is ready for use (or a failure occurred).

A protocol that supports TSN user/network configuration information shall integrate the three groups using the specifications in this clause. The integration is provided in each protocol's specifications (not in this clause). For examples of such protocol integration, see Clause 35 and 46.3.

Each TSN configuration protocol shall use the StreamID of this clause (46.2.3.1) as the unique identifier of each Stream's configuration. The StreamID identifies configuration, not data, so it has no formal relation to the data frame encoding for the Stream.

TSN configuration can be viewed conceptually as a request/response exchange:

— Request: End station or CUC transmits a protocol message that contains a Talker or Listener group.
— Response: Bridge or CNC transmits a protocol message that contains a Status group.

The StreamID of each group correlates each request to its corresponding response, such that configuration of multiple Streams can overlap in time. For example, a possible sequence of messages is Talker request for StreamID 1, Talker request for StreamID 2, Listener request for StreamID 2, Status to Talker for StreamID 2, Status to Listener for StreamID 2, Listener request for StreamID 1, and so on.

For the fully distributed model (46.1.3.1), the Status response to a Talker is communicated in a message along with the Listener request(s). When there is more than one Listener per Stream, the Listener and Status groups must be merged as they propagate through Bridges to the Talker. The methodology for this merger is specified in the TSN configuration protocol (not in this clause).

For the fully centralized model (46.1.3.3), the CUC combines multiple Talker groups and Listener groups into a single transfer from CUC to CNC for computation together in the CNC. After the CNC computation is complete, a single transfer from CNC to CUC combines multiple Status groups. Each Status group can provide sub-groups for each Talker/Listener and merged groups for the entire Stream. The methodology for these combinations and mergers is specified in the TSN configuration protocol (not in this clause).

In addition to the request/response exchange, end stations can transmit Talker/Listener messages as advertisement (e.g., for a Talker to notify potential Listeners of its presence). The methodology for this advertisement is specified in the TSN configuration protocol (not in this clause).

For each Talker group and Listener group, there are two operations for each Stream:

— **Join:** Talker/Listener request to join the Stream and to configure network resources for this Stream's data transfer.
— **Leave:** Talker/Listener request to leave the Stream and to release the network resources for this Stream.

The groups in this clause specify requirements for the join and leave operation, but the encoding of the operation is not specified in this clause. Each TSN configuration protocol shall specify the encoding of the join/leave operation as part of its integration. For example, SRP specifications of this standard (Clause 35) encode the join/leave operation within the Multiple Registration Protocol (MRP) (Clause 10) that serves as its foundation.

The protocol message(s) that invoke the join or leave operation are not required to coincide with the protocol message(s) that contain the associated groups (Talker, Listener, or Status). Nevertheless, the groups specify elements that are required for a subsequent join or leave operation to be valid. For example, for the fully centralized model (46.1.3.3), the CUC can transfer a list of Talker/Listener groups to the CNC, followed by a separate protocol message with a join request that applies to the entire list. For the join request to succeed, each of the Talker/Listener groups must contain the required elements. At a later time, the CUC can read the resulting list of Status groups from the CNC, which provides the response to the join.

46.2.3 Talker

The Talker group specifies the following:

— Talker's behavior for Stream (how/when transmitted)
— Talker's requirements from the network
— TSN capabilities of the Talker's interface(s)

In the fully distributed model and the centralized network/distributed user model, this group originates from the Talker's end station. In the fully centralized model, this group originates from the CUC.

The Talker group contains the following groups:

— StreamID (46.2.3.1)
— StreamRank (46.2.3.2)
— EndStationInterfaces (46.2.3.3)
— DataFrameSpecification (46.2.3.4)
— TrafficSpecification (46.2.3.5)
— UserToNetworkRequirements (46.2.3.6)
— InterfaceCapabilities (46.2.3.7)

For the join operation, the StreamRank and TrafficSpecification groups shall be included within the Talker group.

For the join operation, the UserToNetworkRequirements and InterfaceCapabilities groups may be included within the Talker group. If a group is omitted, the network uses the default values specified for elements of that group.

For the join operation, the DataFrameSpecification shall be included within the Talker group unless all of the following conditions apply:

a) The InterfaceCapabilities group is included.
b) InterfaceCapabilities.CB-StreamIdenTypeList includes the type for Active Destination MAC and VLAN Stream identification.

The preceding conditions enable the Talker and Listener to perform Stream transformation (46.1.4), and therefore the network does not need the user's data frame identification in DataFrameSpecification. The absence of the DataFrameSpecification group notifies the network that Stream transformation is performed in the end stations for this Stream.

For the join and leave operation, the StreamID group shall be included in the TSN user/network protocol in a location associated with the Stream (e.g., Talker group).

For the join and leave operation, EndStationInterfaces shall be included within the Talker group for the fully centralized model (46.1.3.3). For the join and leave operation, EndStationInterfaces should be included within the Talker group for the fully distributed model (46.1.3.1) or centralized network/distributed user model (46.1.3.2).

46.2.3.1 StreamID

The StreamID group provides a unique identifier of the Stream's configuration and is used by protocols in the network to associate the user's Stream with TSN resources. The StreamID group is used by Talker, Listener, and Status groups.

The elements of the StreamID group are listed in Table 46-1.

Table 46-1—StreamID elements

Name	Data type	Reference
MacAddress	mac-address-type	46.2.3.1.1
UniqueID	uint16	46.2.3.1.2

46.2.3.1.1 MacAddress

MacAddress is a 48-bit IEEE 802 MAC address associated with the Talker sourcing the Stream to the bridged network. The entire range of MAC addresses are acceptable.

NOTE 1—The MAC address component of the StreamID can, but does not necessarily, have the same value as the source_address parameter of any frame in the actual data Stream. For example, the StreamID can be assigned by a TSN CUC (see 46.1.3.3), using a pool of MAC addresses that the TSN CUC maintains.

NOTE 2—If the MAC addresses used to construct StreamIDs are not unique within the network, duplicate StreamIDs can be generated, with unpredictable results.

46.2.3.1.2 UniqueID

UniqueID is used to distinguish between multiple Streams within the end station identified by MacAddress.

46.2.3.2 StreamRank

The StreamRank group provides the rank of this Stream relative to other Streams in the network. This rank is used to determine success/failure of Stream resource configuration and is unrelated to the Stream's data.

The elements of the StreamRank group are listed in Table 46-2.

Table 46-2—StreamRank elements

Name	Data type	Reference
Rank	uint8	46.2.3.2.1

46.2.3.2.1 Rank

The Rank is used by the network to decide which Streams can and cannot exist when TSN resources reach their limit. If a Bridge's Port becomes oversubscribed (e.g., network reconfiguration, IEEE 802.11 bandwidth reduction), the Rank is used to help determine which Streams can be dropped (i.e., removed from Bridge configuration).

The only valid values for Rank shall be zero and one. The configuration of a Stream with Rank zero is more important than the configuration of a Stream with Rank one. The Rank value of zero is intended for emergency traffic, and the Rank value of one is intended for non-emergency traffic.

NOTE—It is expected that higher layer applications and protocols can use the Rank to indicate the relative importance of Streams based on user preferences. Those user preferences are expressed by means beyond the scope of this standard. When multiple applications exist in a network (e.g., audio/video along with industrial control), it can be challenging for the varied applications and vendors to agree on multiple Rank values. To mitigate such challenges, this Rank uses a simple concept of emergency (zero) and non-emergency (one) that can be applied over all applications. For example, in a network that carries audio Streams for fire safety announcements, all applications are likely to agree that those Streams use Rank of zero.

46.2.3.3 EndStationInterfaces

The EndStationInterfaces group provides a list of one or more InterfaceID groups. Each InterfaceID group identifies a physical interface (distinct point of attachment) in the end station acting as a Talker/Listener.

Although many end stations contain a single interface, this list allows for multiple interfaces. Some TSN features allow a single Stream to span multiple interfaces (e.g., seamless redundancy).

In centralized network models, EndStationInterfaces is used by the CNC to locate the interfaces of the Talker/Listener in the topology.

The InterfaceID group is used to identify a distinct point of attachment in EndStationInterfaces, InterfaceConfiguration (46.2.5.3), and FailedInterfaces (46.2.5.4). In the context of EndStationInterfaces and InterfaceConfiguration, each interface is located in an end station only. In the context of FailedInterfaces, each interface can be located within an end station or a Bridge.

The elements of the InterfaceID group are listed in Table 46-3.

Table 46-3—InterfaceID elements

Name	Data type	Reference
MacAddress	mac-address-type	46.2.3.3.1
InterfaceName	string	46.2.3.3.2

46.2.3.3.1 MacAddress

MacAddress is the MAC address (IEEE Std 802) of the interface in the station (end station or Bridge). This MAC address uniquely identifies the station within the local network.

MacAddress shall be included in the InterfaceID group.

NOTE—This MAC address can be discovered in the physical topology using protocols such as IEEE Std 802.1AB (LLDP). LLDP supports MAC address as a subtype for the station's Chassis ID and Port ID. If the station does not use MAC address for its LLDP IDs, remote management can be used to associate this MacAddress to the values provided in the LLDP IDs.

46.2.3.3.2 InterfaceName

InterfaceName is the name of the interface that is assigned locally by the station (end station or Bridge).

InterfaceName may be included in the InterfaceID group.

IEEE Std 802 recommends that each distinct point of attachment to an IEEE 802 network have its own universal MAC address. If the identified station follows this IEEE 802 recommendation, the MacAddress element uniquely identifies the interface as well as the station, and InterfaceName is not needed.

If the MacAddress applies to more than one interface (distinct point of attachment) within the station, InterfaceName provides a locally assigned name that can help to identify the interface.

When YANG is used for management of the station, InterfaceName is the interface name that serves as the key for the station's interface list (IETF RFC 7223 [B43]).

NOTE 1—The TSN CNC is typically located in a different physical product than the station identified by this InterfaceID. Since the InterfaceName is assigned locally by the identified station, it is possible that the station's product will change InterfaceName in a manner that the TSN CNC cannot detect. For example, IETF RFC 7223 [B43] mentions that the YANG interface name can change when a physical attachment point is inserted or removed.

NOTE 2—This interface name can be discovered in the physical topology using protocols such as IEEE Std 802.1AB (LLDP). LLDP supports interface name as a subtype for its Port ID. If the station does not use interface name for its LLDP Port ID, remote management can be used to associate this InterfaceName to the values provided in the LLDP Port ID.

46.2.3.4 DataFrameSpecification

The DataFrameSpecification group specifies the frame that carries the Talker's Stream data. The network uses the specification to identify this Stream's frames as TSN in order to apply the required TSN configuration.

The DataFrameSpecification is based on the user's knowledge of the frame, without any network specifics. In other words, this specifies the frame that the Talker would use in the absence of TSN.

The DataFrameSpecification is provided as a list of fields that the user knows. Each field is provided as one of the following groups:

- IEEE802-MacAddresses (46.2.3.4.1)
- IEEE802-VlanTag (46.2.3.4.2)
- IPv4-tuple (46.2.3.4.3)
- IPv6-tuple (46.2.3.4.4)

The list of fields is ordered from start of frame to end of header. For example, if the Talker uses a VLAN-tagged Ethernet frame (not IP), the list consists of IEEE802-MacAddresses followed by IEEE802-VlanTag. For example, if the Talker uses a UDP/IPv4 packet without knowledge of the Ethernet header, the list consists of IPv4-tuple only.

This group is optional, and its absence indicates that Stream transformation is performed in the Talker and Listeners of this Stream (46.2.3).

46.2.3.4.1 IEEE802-MacAddresses

The IEEE802-MacAddresses group specifies a pair of IEEE 802 MAC addresses for Stream identification.

The use of these fields for Stream identification corresponds to the managed objects for Stream identification in IEEE Std 802.1CB. If inconsistency arises between this specification and IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.

The elements of the IEEE802-MacAddresses group are listed in Table 46-4.

Table 46-4—IEEE802-MacAddresses elements

Name	Data type	Reference
DestinationMacAddress	mac-address-type	46.2.3.4.1 item a)
SourceMacAddress	mac-address-type	46.2.3.4.1 item b)

The elements of the IEEE802-MacAddresses group:

a) **DestinationMacAddress**—This field specifies a destination MAC address. An address of all 1's specifies that the destination MAC address is ignored for purposes of Stream identification.

b) **SourceMacAddress**—This field specifies a source MAC address. An address of all 1's specifies that the source MAC address is ignored for purposes of Stream identification.

46.2.3.4.2 IEEE802-VlanTag

The IEEE802-VlanTag group specifies a customer VLAN Tag (C-TAG of Clause 9) for Stream identification.

The Drop Eligible Indicator (DEI) field is not relevant from the perspective of a TSN Talker/Listener.

The use of these fields for Stream identification corresponds to the managed objects for Stream identification in IEEE Std 802.1CB. If inconsistency arises between this specification and IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.

The elements of the IEEE802-VlanTag group are listed in Table 46-5.

Table 46-5—IEEE802-VlanTag elements

Name	Data type	Reference
PriorityCodePoint	uint8	46.2.3.4.2 item a)
VlanId	uint16	46.2.3.4.2 item b)

The elements of the IEEE802-VlanTag group:

a) **PriorityCodePoint**—This field specifies the Priority Code Point (PCP) field of the VLAN tag. The value range is 0 to 7 inclusive. The PriorityCodePoint is not used to identify the Stream, but it does identify a traffic class (queue) in Bridges.

b) **VlanId**—This field specifies the VLAN ID (VID) field of the VLAN tag. The value range is 0 to 4095 inclusive. If only the PriorityCodePoint is known, the VlanId is specified as 0.

46.2.3.4.3 IPv4-tuple

The IPv4-tuple group specifies fields to identify an IPv4 (RFC791) Stream.

The use of these fields for Stream identification corresponds to the managed objects for Stream identification in IEEE Std 802.1CB. If inconsistency arises between this specification and IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.

The elements of the IPv4-tuple group are listed in Table 46-6.

Table 46-6—IPv4-tuple elements

Name	Data type	Reference
SourceIpAddress	ipv4-address-type	46.2.3.4.3 item a)
DestinationIpAddress	ipv4-address-type	46.2.3.4.3 item b)
Dscp	uint8	46.2.3.4.3 item c)
Protocol	uint16	46.2.3.4.3 item d)
SourcePort	uint16	46.2.3.4.3 item e)
DestinationPort	uint16	46.2.3.4.3 item f)

The elements of the IPv4-tuple group:

a) **SourceIpAddress**—This field specifies the source IPv4 address. An address of all 0's specifies that the IP source address is ignored for purposes of Stream identification.

b) **DestinationIpAddress**—This field specifies the destination IPv4 address.

c) **Dscp**—This field specifies the Differentiated Services Code Point (DSCP) (IETF RFC 2474). A value of 64 decimal specifies that the DSCP is ignored for purposes of Stream identification.

d) **Protocol**—This field specifies the IPv4 Protocol (e.g., UDP). The special value of all 1's (FFFF hex) represents 'None', i.e., Protocol, SourcePort, and DestinationPort are ignored for purposes of Stream identification. For any value other than all 1's, the lower octet is used to match IPv4 Protocol.

e) **SourcePort**—This field specifies the source port of the Protocol.

f) **DestinationPort**—This field specifies the destination port of the Protocol.

46.2.3.4.4 IPv6-tuple

The IPv6-tuple group specifies fields to identify an IPv6 (RFC 8200 [B46]) Stream.

The use of these fields for Stream identification corresponds to the managed objects for Stream identification in IEEE Std 802.1CB. If inconsistency arises between this specification and IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.

The elements of the IPv6-tuple group are listed in Table 46-7.

Table 46-7—IPv6-tuple elements

Name	Data type	Reference
SourceIpAddress	ipv6-address-type	46.2.3.4.3 item a)
DestinationIpAddress	ipv6-address-type	46.2.3.4.3 item b)
Dscp	uint8	46.2.3.4.3 item c)
Protocol	uint16	46.2.3.4.3 item d)
SourcePort	uint16	46.2.3.4.3 item e)
DestinationPort	uint16	46.2.3.4.3 item f)

The elements of the IPv6-tuple group:

a) **SourceIpAddress**—This field specifies the source IPv6 address. An address of all 0's specifies that the IP source address is ignored for purposes of Stream identification.

b) **DestinationIpAddress**—This field specifies the destination IPv6 address.

c) **Dscp**—This field specifies the DSCP (IETF RFC 2474). A value of 64 decimal specifies that the DSCP is ignored for purposes of Stream identification.

d) **Protocol**—This field specifies the IPv6 Next Header (e.g., UDP). The special value of all 1's (FFFF hex) represents 'None', i.e., Protocol, SourcePort, and DestinationPort are ignored for purposes of Stream identification. For any value other than all 1's, the lower octet is used to match IPv6 Next Header.

e) **SourcePort**—This field specifies the source port of the Protocol.

f) **DestinationPort**—This field specifies the destination port of the Protocol.

46.2.3.5 TrafficSpecification

The TrafficSpecification group specifies how the Talker transmits frames for the Stream. This is effectively the Talker's promise to the network. The network uses this traffic specification to allocate resources and adjust queue parameters in Bridges.

The TrafficSpecification group consists of the following:

a) Its required elements, listed in Table 46-8.

Table 46-8—TrafficSpecification elements

Name	Data type	Reference
Interval	rational	46.2.3.5.1
MaxFramesPerInterval	uint16	46.2.3.5.2
MaxFrameSize	uint16	46.2.3.5.3
TransmissionSelection	uint8	46.2.3.5.4

b) An optional TSpecTimeAware group, whose elements are listed in Table 46-9.

Table 46-9—TSpecTimeAware elements

Name	Data type	Reference
EarliestTransmitOffset	uint32	46.2.3.5.5
LatestTransmitOffset	uint32	46.2.3.5.6
Jitter	uint32	46.2.3.5.7

The presence of TSpecTimeAware specifies that the Talker's traffic is synchronized to a known time on the network (e.g., using IEEE Std 802.1AS). The TSpecTimeAware group provides elements to specify the Talker's time-aware transmit to the network. The Talker and Listeners of a Stream are assumed to coordinate using user (application) mechanisms, such that each Listener is aware that its Talker transmits in a time-aware manner. If MaxFramesPerInterval is greater than one, the time-aware Talker shall transmit multiple frames as a burst within the Interval, with the minimum inter-frame gap allowed by the media.

NOTE—Although scheduled traffic (8.6.8.4) specifies a valid implementation of a time-aware Talker, the TSpecTimeAware group is intended to support alternate implementations of scheduling.

For informative examples using the TSpecTimeAware group of TrafficSpecification, refer to U.1.

46.2.3.5.1 Interval

Interval specifies the period of time in which the traffic specification cannot be exceeded. The traffic specification is specified by MaxFramesPerInterval and MaxFrameSize.

The Interval is a rational number of seconds, defined by an unsigned 32-bit integer numerator and an unsigned 32-bit integer denominator.

If the TSpecTimeAware group is not present, the Interval specifies a sliding window of time. The Talker's transmission is not synchronized to a time on the network, and therefore the traffic specification cannot be exceeded during any Interval in time.

If the TSpecTimeAware group is present, the Interval specifies a window of time that is aligned with the time epoch that is synchronized on the network. For example, if IEEE Std 802.1AS is used with the PTP timescale, the first Interval begins at 1 January 00:00:00 TAI. If CurrentTime represents the current time, then the start of the next Interval (StartOfNextInterval) is:

$$\text{StartOfNextInterval} = N \times \text{Interval}$$

where N is the smallest integer for which the relation:

$$\text{StartOfNextInterval} \geq \text{CurrentTime}$$

would be TRUE.

46.2.3.5.2 MaxFramesPerInterval

MaxFramesPerInterval specifies the maximum number of frames that the Talker can transmit in one Interval.

46.2.3.5.3 MaxFrameSize

MaxFrameSize specifies maximum frame size that the Talker will transmit, excluding any overhead for media-specific framing (e.g., preamble, IEEE 802.3 header, Priority/VID tag, CRC, interframe gap). As the Talker or Bridge determines the amount of bandwidth to reserve on the egress Port (interface), it will calculate the media-specific framing overhead on that Port and add it to the number specified in the MaxFrameSize element.

46.2.3.5.4 TransmissionSelection

TransmissionSelection specifies the algorithm that the Talker uses to transmit this Stream's traffic class. This algorithm is often referred to as the shaper for the traffic class.

The value for this element uses Table 8-6 (in 8.6.8). If no algorithm is known, the value zero (strict priority) can be used.

The Talker's shaping and scheduling of the Stream is considered to be on the user side of the user/network boundary, and this specifies the Talker's behavior to the network. In the fully distributed model, this value can be ignored by a Bridge, and it is not changed during propagation through the Bridge.

46.2.3.5.5 EarliestTransmitOffset

EarliestTransmitOffset specifies the earliest offset within each Interval at which the Talker is capable of starting transmit of its frames. As part of the Status group, the network will return a specific TimeAwareOffset to the Talker (within the earliest/latest range), which the Talker uses to schedule its transmit.

EarliestTransmitOffset is specified as an integer number of nanoseconds.

The Talker's transmit offsets include EarliestTransmitOffset, LatestTransmitOffset, and the TimeAwareOffset returned to the Talker in the Status group. Each of the Talker's offsets is specified at the point when the message timestamp point of the first frame of the Stream in each Interval passes the reference plane marking the boundary between the network media and PHY. The message timestamp point is specified by IEEE Std 802.1AS for various media.

46.2.3.5.6 LatestTransmitOffset

LatestTransmitOffset specifies the latest offset within the Interval at which the Talker is capable of starting transmit of its frames. As part of the Status group, the network will return a specific TimeAwareOffset to the Talker (within the earliest/latest range), which the Talker uses to schedule its transmit.

LatestTransmitOffset is specified as an integer number of nanoseconds.

46.2.3.5.7 Jitter

Jitter specifies the maximum difference in time between the Talker's transmit offsets and the ideal synchronized network time (e.g., IEEE 802.1AS time). Jitter is specified as an unsigned integer number of nanoseconds.

The maximum difference means sooner or later than the ideal (e.g., transmit ± 500 ns relative to IEEE 802.1AS time results in Jitter of 500).

The ideal synchronized network time refers to time at the source (e.g., IEEE 802.1AS grandmaster). The Jitter does not include inaccuracies as time is propagated from the time source to the Talker because those inaccuracies are assumed to be known by the network and time synchronization is a network technology. The Jitter element is intended to specify inaccuracies in the Talker's implementation. For example, if the Talker's IEEE 802.1AS time is ± 812 ns relative to the grandmaster and the Talker schedules using a 100 µs timer tick driven by IEEE 802.1AS time, Jitter is 50 000 (not 50 812).

The Talker's transmit offsets include EarliestTransmitOffset, LatestTransmitOffset, and the TimeAwareOffset returned to the Talker in the Status group.

46.2.3.6 UserToNetworkRequirements

The UserToNetworkRequirements group specifies user requirements for the Stream, such as latency and redundancy.

The network (e.g., CNC) will merge all UserToNetworkRequirements for a Stream to ensure that all requirements are met.

The elements of the UserToNetworkRequirements group are listed in Table 46-10.

Table 46-10—UserToNetworkRequirements elements

Name	Data type	Reference
NumSeamlessTrees	uint8	46.2.3.6.1
MaxLatency	uint32	46.2.3.6.2

46.2.3.6.1 NumSeamlessTrees

NumSeamlessTrees specifies the number of trees that the network will configure to deliver seamless redundancy for the Stream.

The value zero is interpreted as one (i.e., no seamless redundancy).

This requirement is provided from the Talker only. Listeners shall set this element to one.

From each Talker to a single Listener, the network configures a path that relays Stream data through Bridges. If the Talker has more than one Listener, the network configures a tree of multiple paths.

NumSeamlessTrees specifies the number of maximally disjoint trees that the network shall configure from the Talker to all Listeners. Each tree is disjoint from other trees, in that the network evaluates the physical topology to avoid sharing the same Bridge and links in each tree's paths. This computation of disjoint trees is maximal, in that shared Bridges and links are avoided to the maximum extent allowed by the physical topology. For example, if a single link exists from a Bridge to a Listener and NumSeamlessTrees is three, then all three trees will share that link to the Listener.

When NumSeamlessTrees is greater than one, the transfer of the Stream's data frames shall use a seamless redundancy standard, such as IEEE Std 802.1CB. When a link shared by multiple trees diverges to multiple disjoint links, the seamless redundancy standard replicates (i.e., forwards a distinct copy of each data frame to the disjoint trees). When disjoint trees converge to a single link, the seamless redundancy standard eliminates the duplicate copies of each data frame. Assuming that other sources of frame loss are mitigated (e.g., congestion), failure of a link or Bridge in one disjoint tree does not result in frame loss as long as at least one remaining disjoint tree is operational.

If the Talker sets this element to one, the network may make use of redundancy standards that are not seamless (i.e., failure of link results in lost frames), such as MSTP and IS-IS.

If the Talker sets this element to greater than one and seamless redundancy is not possible in the current network (no disjoint paths or no seamless redundancy standard in Bridges), the Status group returns a nonzero FailureCode (46.2.5.1).

If the UserToNetworkRequirements group is not provided within the Talker or Listener group, the network shall use the default value of one for this element.

46.2.3.6.2 MaxLatency

MaxLatency specifies the maximum latency from Talker to Listener(s) for a single frame of the Stream.

MaxLatency is specified as an integer number of nanoseconds.

Latency shall use the definition of 3.119, with additional context as follows: The "known reference point in the frame" is the message timestamp point specified in IEEE Std 802.1AS for various media (i.e., start of the frame). The "first point" is in the Talker at the reference plane marking the boundary between the network media and PHY (see IEEE Std 802.1AS). The "second point" is in the Listener at the reference plane marking the boundary between the network media and PHY.

When this requirement is specified by the Talker, it must be satisfied for all Listeners.

When this requirement is specified by the Listener, it must be satisfied for this Listener only.

If the UserToNetworkRequirements group is not provided within the Talker or Listener group, the network shall use the default value zero for this element.

The special value of zero represents usage of the initial value of Status.AccumulatedLatency as the maximum latency requirement. This effectively locks down the initial latency that the network calculates after successful configuration of the Stream, such that any subsequent increase in latency beyond that value causes the Stream to fail.

The assumption for when the “first point” occurs in the Talker depends on the presence of the TSpecTimeAware group in the Talker’s TrafficSpecification.

a) When TSpecTimeAware is not present:
   1) The Talker is assumed to transmit at an arbitrary time (not scheduled).
b) When TSpecTimeAware is present:
   1) The ‘first point’ is assumed to occur at the start of the Interval as if the Talker’s offsets (EarliestTransmitOffset and LatestTransmitOffset of 46.2.3.5) are both zero. The Talker’s offsets are not typically zero, but use of the start of Interval for purposes of MaxLatency allows the Listener(s) to schedule their application independently from the Talker’s offset configuration.
   2) The Listener determines MaxLatency based on its scheduling of a read function in the application. Nevertheless, the time from frame reception (i.e., “second point”) to execution of the read function is in the user’s scope and therefore not included in MaxLatency.
   3) MaxLatency can be set to a value greater than the Talker’s Interval in order to specify a longer latency requirement. For example, if the Talker’s Interval is 500 μs and MaxLatency is 700 μs, the Listener receives the frame no later than 200 μs into the interval that follows the Talker’s Interval.

46.2.3.7 InterfaceCapabilities

The InterfaceCapabilities group specifies the network capabilities of all interfaces (Ports) contained in the EndStationInterfaces group.

The network may provide configuration of these capabilities in the InterfaceConfiguration group of the Status group.

NOTE—If an end station contains multiple interfaces with different network capabilities, each interface should be specified in a distinct Talker or Listener group (i.e., one interface in EndStationInterfaces). Use of multiple interface in EndStationInterfaces is intended for network capabilities that span multiple interfaces (e.g., seamless redundancy).

The elements of the InterfaceCapabilities group are listed in Table 46-11.

Table 46-11—InterfaceCapabilities elements

Name	Data type	Reference
VlanTagCapable	Boolean	46.2.3.7.1
CB-StreamIdenTypeList	sequence of uint32	46.2.3.7.2
CB-SequenceTypeList	sequence of uint32	46.2.3.7.3

46.2.3.7.1 VlanTagCapable

When VlanTagCapable is true, the interface supports the ability to tag/untag frames using a Customer VLAN Tag (C-TAG of Clause 9) provided by the network.

For a Talker, the network’s tag replaces the tag specified by the DataFrameSpecification. If the DataFrameSpecification is untagged (no IEEE802-VlanTag group), the network’s tag is inserted in the frame as it passes through the interface.

For a Listener, the user's tag from the DataFrameSpecification replaces the network's tag as the frame passes through the interface. If the DataFrameSpecification is untagged (no IEEE802-VlanTag group), the network's tag is removed from the frame as it passes through the interface.

If the end station supports more than one interface (i.e., more than one entry in EndStationInterfaces), VlanTagCapable of true means that a distinct VLAN tag can be applied to each interface. The list of VLAN tags (one for each interface) can be provided by the network in InterfaceConfiguration.InterfaceList (IEEE802-VlanTag choice).

When VlanTagCapable is false, the interface does not support the capability to tag/untag frames using a Customer VLAN Tag (C-TAG of Clause 9) provided by the network.

If the InterfaceCapabilities group is not provided within the Talker or Listener group, the network shall use the default value of false for this element.

46.2.3.7.2 CB-StreamIdenTypeList

CB-StreamIdenTypeList provides a list of the supported Stream Identification types as specified in IEEE Std 802.1CB.

Each Stream Identification type is provided as a 32-bit unsigned integer. The upper 3 octets contain the OUI/CID, and the lowest octet contains the type number.

NOTE—If the Talker/Listener end system supports IEEE Std 802.1CB, Null Stream identification is required, and that Stream Identification type is included in this list. If the Talker/Listener end system does not support IEEE Std 802.1CB, this list is empty.

If the end station supports more than one interface (i.e., more than one InterfaceID in EndStationInterfaces), an empty CB-StreamIdenTypeList means that the end station is capable of transferring the Stream on any one of its interfaces (not all). When this is specified, the network shall decide which interface is best used for TSN purposes and communicate that decision by returning a single interface in InterfaceConfiguration.InterfaceList. The Talker/Listener uses this interface alone for the Stream.

If the InterfaceCapabilities group is not provided within the Talker or Listener group, the network shall use an empty list as the default value for this element.

46.2.3.7.3 CB-SequenceTypeList

CB-SequenceTypeList provides a list of the supported Sequence Encode/Decode types as specified in IEEE Std 802.1CB.

Each sequence type is provided as a 32-bit unsigned integer. The upper 3 octets contain the OUI/CID, and the lowest octet contains the type number.

If the InterfaceCapabilities group is not provided within the Talker or Listener group, the network shall use an empty list as the default value for this element.

46.2.4 Listener

The Listener group specifies the following:

— Listener's requirements from the network
— TSN capabilities of the Listener's interface(s)

In the fully distributed model and the centralized network/distributed user model, this group originates from the Listener's end station. In the fully centralized model, this group originates from the CUC.

The Listener group contains the following groups:

— StreamID (46.2.3.1)
— EndStationInterfaces (46.2.3.3)
— UserToNetworkRequirements (46.2.3.6)
— InterfaceCapabilities (46.2.3.7)

For the join operation, the UserToNetworkRequirements and InterfaceCapabilities groups may be included within the Listener group. If a group is omitted, the network uses the default values specified for elements of that group.

For the join and leave operation, the StreamID group shall be included in the TSN user/network protocol in a location associated with the Stream (e.g., Listener group).

For the join and leave operation, EndStationInterfaces shall be included within the Listener group for the fully centralized model (46.1.3.3). For the join and leave operation, EndStationInterfaces should be included within the Listener group for the fully distributed model (46.1.3.1) or centralized network/distributed user model (46.1.3.2).

46.2.5 Status

The Status group provides the status of a Stream's configuration from the network to each user (Talker or Listener).

In the fully distributed model and the centralized network/distributed user model, this group is delivered to each Talker end station and Listener end station of the Stream. In the fully centralized mode, this group is delivered to the CUC.

The Status group contains the following groups:

— StreamID (46.2.3.1)
— StatusInfo (46.2.5.1)
— AccumulatedLatency (46.2.5.2)
— InterfaceConfiguration (46.2.5.3)
— FailedInterfaces (46.2.5.4)

The AccumulatedLatency and InterfaceConfiguration groups are distinct for each Talker or Listener, and therefore Status is distinct.

The protocol for TSN configuration shall specify that one Status group is received in response to the transmit of a Talker group or Listener group. This provides at least one response to each join or leave request.

StreamID (46.2.3.1) identifies the Stream for which status is provided.

StatusInfo (46.2.5.1) provides the status of the Stream's configuration in the network.

For the join and leave operation, the StreamID and StatusInfo groups shall be included in the TSN user/network protocol in a location associated with the Stream (e.g., Status group).

For the join operation, the AccumulatedLatency group shall be included within the Status group that is sent to a Listener. For the join operation, the AccumulatedLatency group may be included within the Status group that is sent to a Talker.

For the join operation, the InterfaceConfiguration group may be included within the Status group. InterfaceConfiguration provides configuration of the interfaces in a specific end station.

If a group is omitted, the network uses the default values specified for elements of that group.

When a failure occurs in network configuration, FailedInterfaces identifies one or more interfaces (Ports) on which the failure occurred. If the FailureCode of the StatusInfo group (46.2.5.1) is zero, the FailedInterfaces group shall not be included within the Status group. If the FailureCode is nonzero, the FailedInterfaces group may be included within the Status group.

When a Talker and at least one Listener have joined the stream and network resources are configured for the Stream (success or failure), the network shall transmit Status to the Talker and Listener(s). After the initial Status, upon any change in the status of the network configuration (e.g., new Listeners, change in FailureCode), the network shall transmit Status to the Talker and Listener(s). When the Stream does not have a Talker or a Listener, the network configuration is removed, and the network shall transmit a final Status to the remaining Talker and/or Listener(s). Beyond these requirements, additional transmit of Status is specified by the protocol that carries the Status group.

46.2.5.1 StatusInfo

The StatusInfo group provides information regarding the status of a Stream's configuration in the network.

The elements of the StatusInfo group are listed in Table 46-12.

Table 46-12—StatusInfo elements

Name	Data type	Reference
TalkerStatus	enumeration	46.2.5.1.1
ListenerStatus	enumeration	46.2.5.1.2
FailureCode	uint8	46.2.5.1.3

46.2.5.1.1 TalkerStatus

TalkerStatus provides the status of the network configuration for the Stream's Talker.

TalkerStatus uses the enumeration specified in Table 46-13.

Table 46-13—TalkerStatus enumeration

Name	Value	Description
None	0	No Talker detected.
Ready	1	Talker ready (configured).
Failed	2	Talker failed.

46.2.5.1.2 ListenerStatus

ListenerStatus provides the status of the network configuration for the Stream's Listener(s). If there is more than one Listener for the Stream, ListenerStatus provides the status of all Listeners.

ListenerStatus uses the enumeration specified in Table 46-14.

Table 46-14—ListenerStatus enumeration

Name	Value	Description
None	0	No Listener detected.
Ready	1	All Listeners ready (configured).
PartialFailed	2	One or more Listeners ready, and one or more Listeners failed. If Talker is ready, Stream can be used.
Failed	3	All Listeners failed.

46.2.5.1.3 FailureCode

If the Stream encounters a failure (TalkerStatus is Failed, or ListenerStatus is Failed, or ListenerStatus is PartialFailed), FailureCode provides a nonzero code that specifies the problem. If the Stream is configured without a failure, FailureCode is zero.

Table 46-15 specifies the nonzero values for FailureCode.

46.2.5.2 AccumulatedLatency

The AccumulatedLatency group provides the worst-case latency that a single frame of the Stream can encounter along its current path(s).

The elements of the AccumulatedLatency group are listed in Table 46-16.

Table 46-15—TSN Failure Codes

Failure Code	Description of cause
1	Insufficient bandwidth
2	Insufficient Bridge resources
3	Insufficient bandwidth for traffic class
4	StreamID in use by another Talker
5	Stream destination_address already in use
6	Stream preempted by higher rank
7	Reported latency has changed
8	Egress Port is not AVB capable [a]
9	Use a different destination_address (i.e., MAC DA hash table full)
10	Out of MSRP resources
11	Out of MMRP resources
12	Cannot store destination_address (i.e., Bridge is out of MAC DA resources)
13	Requested priority is not an SR Class (3.262) priority
14	MaxFrameSize [item a) in 35.2.2.8.4] is too large for media
15	msrpMaxFanInPorts [item f) in 35.2.1.4] limit has been reached
16	Changes in FirstValue, other than AccumulatedLatency, for a registered StreamID
17	VLAN is blocked or filtered on this egress Port [b]
18	VLAN tagging is disabled on this egress Port (untagged set)
19	SR class priority mismatch
20	Enhanced feature cannot be propagated to original Port
21	MaxLatency exceeded
22	Nearest Bridge cannot provide network identification for stream transformation
23	Stream transformation not supported
24	Stream identification type not supported for stream transformation
25	Enhanced feature cannot be supported without a CNC

[a] A device can use the IEEE Std 802.1AS asCapable variable to help determine if its neighboring device is AVB capable. If the asCapable variable is FALSE for a particular Port, then the neighboring device is not a time-aware system and therefore not AVB capable.

[b] This Failure Code is never declared in a Talker Failed message since Talker attributes are not propagated on egress Ports that have the associated VLAN blocked in the VLAN spanning tree (7.3) or filtered in VLAN Registration Entries (8.8). The Bridge can still be queried by other means to learn why the Talker attribute was not declared.

46.2.5.2.1 AccumulatedLatency

Table 46-16—AccumulatedLatency elements

Name	Data type	Reference
AccumulatedLatency	uint32	46.2.5.2.1

The AccumulatedLatency element provides the worst-case maximum latency that a single frame of the Stream can encounter along its current path(s).

AccumulatedLatency is distinct for each Talker or Listener of the Stream.

When provided to a Listener, AccumulatedLatency is the worst-case maximum latency for that Listener only.

When provided to a Talker, AccumulatedLatency is the worst-case maximum latency for all Listeners (worst path).

AccumulatedLatency is specified as an integer number of nanoseconds.

AccumulatedLatency uses the same definition for latency as UserToNetworkRequirements.MaxLatency (46.2.3.6).

For a successful StatusInfo (46.2.5.1), the network returns a value less than or equal to UserToNetworkRequirements.MaxLatency.

If the TSpecTimeAware group is present in the TrafficSpecification group (46.2.3.5) of the Talker, the value is expressed as nanoseconds after the start of the Talker's Interval.

If the TSpecTimeAware group is not present in the TrafficSpecification group of the Talker, the value is expressed as nanoseconds after the Talker's transmit of any frame in the Stream, at any arbitrary time.

If UserToNetworkRequirements.NumSeamlessTrees is one, AccumulatedLatency shall provide the worst-case maximum latency for the current path from Talker to each Listener. If the path is changed (e.g., by a spanning tree protocol), AccumulatedLatency changes accordingly.

If UserToNetworkRequirements.NumSeamlessTrees is greater than one, AccumulatedLatency shall provide the worst-case maximum latency for all paths in use from the Talker to each Listener.

46.2.5.3 InterfaceConfiguration

The InterfaceConfiguration group provides configuration of interfaces in the Talker/Listener. This configuration assists the network in meeting the Stream's requirements. The InterfaceConfiguration meets the capabilities of the interface as provided in the InterfaceCapabilities group.

The InterfaceConfiguration group is distinct for each Talker or Listener of the Stream.

A distinct configuration is provided for each interface in the Talker/Listener (even if multiple interfaces use the same configuration). Each interface configuration consists of a single InterfaceID (46.2.3.3) group, followed by a list of configuration values for that interface.

The values in InterfaceID shall match one of the InterfaceID entries in the Talker/Listener EndStationInterfaces group.

The list of configuration values uses zero or more of the following groups:

— IEEE802-MacAddresses (46.2.5.3.1)
— IEEE802-VlanTag (46.2.5.3.2)
— IPv4-tuple (46.2.5.3.3)
— IPv6-tuple (46.2.5.3.4)
— TimeAwareOffset (46.2.5.3.5)

If the InterfaceConfiguration group is not provided within the Status group, the network shall assume zero configuration values as the default (no interface configuration).

46.2.5.3.1 IEEE802-MacAddresses

The IEEE802-MacAddresses group provides the source and destination MAC addresses that apply to the network side of the user/network boundary.

NOTE 1—On the user side, the MAC addresses are in DataFrameSpecification.IEEE802-MacAddresses.

NOTE 2—The source MAC address of the network is typically the same as the user. The destination MAC address can be different. For example, the user can use an individual address, but the network can use a group (multicast) address.

This group uses the specifications from DataFrameSpecification.IEEE802-MacAddresses (46.2.3.4.1).

This configuration value is not provided unless IEEE Std 802.1CB is supported and a value for Active Destination MAC and VLAN Stream identification is provided in CB-StreamIdenTypeList of InterfaceCapabilities.

46.2.5.3.2 IEEE802-VlanTag

The IEEE802-VlanTag group provides the Customer VLAN Tag (C-TAG of Clause 9) that applies to the network side of the user/network boundary.

NOTE—On the user side, the VLAN tag is in DataFrameSpecification.IEEE802-VlanTag (including untagged if that field is not provided).

This group uses the specifications from DataFrameSpecification.IEEE802-VlanTag (46.2.3.4.2).

If the user provides a VLAN ID in the IEEE802-VlanTag of DataFrameSpecification, the Stream's data frames are assumed to be limited to the active topology for that VLAN ID. Therefore, if the network uses a different VLAN ID in this configuration value, the network shall ensure that the replacement VLAN ID is limited to the equivalent active topology.

This configuration value is not provided unless VlanTagCapable of InterfaceCapabilities is true.

46.2.5.3.3 IPv4-tuple

The IPv4-tuple group provides the IPv4 identification that applies to the network side of the user/network boundary.

This group uses the specifications from DataFrameSpecification.IPv4-tuple (46.2.3.4.3).

This configuration value is not provided unless IEEE Std 802.1CB is supported and a value for IP Stream identification is provided in CB-StreamIdenTypeList of InterfaceCapabilities.

46.2.5.3.4 IPv6-tuple

The IPv6-tuple group provides the IPv6 identification that applies to the network side of the user/network boundary.

This group uses the specifications from DataFrameSpecification.IPv6-tuple (46.2.3.4.4).

This configuration value is not provided unless IEEE Std 802.1CB is supported and a value for IP Stream identification is provided in CB-StreamIdenTypeList of InterfaceCapabilities.

46.2.5.3.5 TimeAwareOffset

If the TSpecTimeAware group is present in the TrafficSpecification group (46.2.3.5) of the Talker, this configuration value shall be provided by the network to the Talker.

If the TSpecTimeAware group is not present in the TrafficSpecification group (46.2.3.5) of the Talker, this configuration value shall not be provided by the network.

This configuration value shall not be provided to Listeners as it is not applicable.

TimeAwareOffset specifies the offset that the Talker shall use for transmit. The network returns a value between EarliestTransmitOffset and LatestTransmitOffset of the Talker's TrafficSpecification. The value is expressed as nanoseconds after the start of the Talker's Interval. The data type is uint32.

46.2.5.4 FailedInterfaces

When a failure occurs in network configuration (i.e., nonzero FailureCode in StatusInfo group), FailedInterfaces provides a list of one or more physical interfaces (distinct points of attachment) in the failed end station or Bridge. Each identifier is sufficient to locate the interfaces in the physical topology.

The FailedInterfaces group is optional.

FailedInterfaces consists of a sequence of zero or more entries, each entry using the InterfaceID group specified in 46.2.3.3.

46.3 YANG for TSN user/network configuration

In order to support the use of YANG-based protocols for the fully centralized model (46.1.3.3), 48.6.3 specifies a YANG module.

If a YANG-based protocol is specified by another standard for the TSN user/network configuration information (46.2), that specification shall use the YANG module specified in 48.6.3 [see item d) in 5.29].

The YANG module of 48.6.3 provides YANG text for each group of elements in 46.2. Each element is specified using a YANG `leaf`. Each group is specified as a YANG `typedef` or `grouping`. The YANG module for user/network configuration imports the YANG module of 48.6.3 and uses the `typedef` and `grouping` nodes in order to specify the schema tree used for communication between CUC and CNC.

YANG identifiers use a naming convention of hyphens between lowercase names (e.g., "mac-address"). Identifiers for elements and groups in 46.2 use a naming convention of camel case (e.g., "MacAddress"). The specifications for an identifier in 48.6.3 shall be interpreted as applying to the corresponding identifier in 46.2 regardless of differences in naming convention (e.g., requirements for "MacAddress" in 46.2 apply to "mac-address" in 48.6.3).

In the YANG module definitions of 48.6.3, if any discrepancy between the "description" text and the corresponding specifications in 46.2 occurs, the specifications in 46.2 take precedence.

47. Asynchronous Traffic Shaping (ATS) in end stations

47.1 Talker transmission behavior

The operation of ATS traffic classes in Bridges is specified as a combination of per-stream classification and metering for ATS (8.6.5.2.2) and the ATS transmission selection algorithm (8.6.8.5). In order for end station originated data streams to make use of ATS traffic classes in Bridges, it is required that Talkers emit data streams in a compliant manner, and that the parameters of ATS scheduler state machines and ATS scheduler groups in Bridges are consistently set.

47.1.1 ATS traffic class model in Talkers

End stations that are Talkers have to emit streams consistent with the operation of the ATS scheduler state machines in Bridges (8.6.11). This subclause specifies a model of ATS traffic classes that satisfies this purpose. End stations shall exhibit the transmission behavior of this model at the egress ports.

In this model, Talker ports are composed by ATS scheduler instances, which assign eligibility times to the frames of all emitted streams at the egress port, followed by a queue per traffic class, for which the ATS transmission selection algorithm is executed. The relationship between ATS scheduler instances and streams is one-to-one, and each scheduler state machine is associated with a dedicated scheduler group. This effectively eliminates the association of multiple streams to an ATS scheduler instance, as well as the coupling of multiple ATS scheduler instances by ATS scheduler groups.

47.1.2 Simplified ProcessFrame(frame) procedure

Due to the one-to-one relationship between streams and ATS scheduler instances, as well as ATS scheduler instances and scheduler groups, the ProcessFrame(frame) procedure of ATS scheduler state machines, as specified in 8.6.11.3, can be simplified. The simplified procedure is described by the following pseudo-code.

```
ProcessFrame(frame) {
       lengthRecoveryDuration     = length(frame)/
                                    CommittedInformationRate;
       emptyToFullDuration        = CommittedBurstSize/
                                    CommittedInformationRate;
       schedulerEligibilityTime   = BucketEmptyTime +
                                    lengthRecoveryDuration;
       bucketFullTime             = BucketEmptyTime +
                                    emptyToFullDuration;
       eligibilityTime            = max(arrivalTime(frame),
                                        schedulerEligibilityTime);

       BucketEmptyTime      = (eligibilityTime < bucketFullTime) ?
              schedulerEligibilityTime :
              schedulerEligibilityTime + eligibilityTime – bucketFullTime;
       AssignAndProceed(frame,eligibilityTime);
}
```

47.1.3 System clock functions and processing delays

This model has a single implementation specific local system clock function, which is used as:

a) ATS scheduler clock (8.6.11.1) for all ATS scheduler instances and
b) Transmission selection clock (8.6.8.5) of all ATS traffic classes.

The processing delay from the ATS scheduler instances to the transmission selection is zero in this model (8.6.11.3.2):

$$0 = \text{ProcessingDelayMin} = \text{ProcessingDelayMax}$$

47.2 Scheduler parameter consistency

The ATS scheduler parameters CommittedBurstSize (8.6.11.3.5) and CommittedInformationRate (8.6.11.3.6) of Talker streams have to be consistently set to the respective parameters in the Bridge component connected to the Talker. In the Bridge component, a single ATS scheduler instance can be associated with multiple streams of this Talker.

For *n* streams associated with a single ATS scheduler instance in Bridge component, Equation (47-1) and Equation (47-2) can be used for scheduler parameter consistency.

$$CBS_{Bridge} \geq \sum_{i=1}^{n} CBS_i \tag{47-1}$$

$$CIR_{Bridge} \geq \left(\frac{1 + 10^{-6} ClkDev_{Talker}}{1 - 10^{-6} ClkDev_{Bridge}} \right) \sum_{i=1}^{n} CIR_i \tag{47-2}$$

where

CIR_{Bridge} is the CommittedInformationRate parameter of the scheduler instance in the Bridge

CIR_i is the CommittedInformationRate parameter of the *i*th stream in the Talker

CBS_{Bridge} is the CommittedBurstSize parameter of the scheduler instance in the Bridge

CBS_i is the CommittedBurstSize parameter of the *i*th stream in the Talker

$ClkDev_{Bridge}$ is the maximum deviation of the associated ATS scheduler clock (8.6.11.1) in the Bridge from its nominal frequency, in ppm

$ClkDev_{Talker}$ is the maximum deviation of the transmission selection clock (8.6.8.5 and 47.1.3) in the Talker from its nominal frequency, in ppm

48. YANG Data Models

This clause specifies YANG data models that provide control and status monitoring of systems and system components that implement functionality specified in this standard. These data models are based on the set of managed objects and their functionality specified in Clause 12.

This clause:

a) Introduces the YANG framework that governs the naming and hierarchy of configuration and operational data structures in the data models, and the modeling of network interfaces (48.1)

b) Describes each of the data models and its relationship to the operational processes and managed objects specified in the other clauses of this standard, and provides a UML representation of each data model (48.2)

c) Describes the structure of the data models, each of which comprises or makes use of one or more YANG modules (48.3)

d) Reviews security considerations applicable to each of the data models, with specific reference to data nodes in the YANG modules that compose the model (48.4)

e) Includes a schema tree for each of the YANG modules (48.5)

f) Includes each of the YANG modules (48.6)

NOTE 1—The MIB modules specified in Clause 17 were also derived from Clause 12. Consequently, the capabilities and structure of the YANG data models align closely with the MIBs. However the YANG data model has not been derived from the MIB, and there has been no attempt to include data or modeling constructs that might appear in the MIB but not in the information model.

NOTE 2—OMG UML 2.5 [B58] conventions together with C++ language constructs are used in this clause as a representation to convey model structure and relationships.

The YANG data models specified in this clause include the following:

— A VLAN Bridge components data model (48.2.1) that allows control and status monitoring of one or more C-VLAN or S-VLAN Bridge components (8.2) that compose all or part of a system's functionality, and the Bridge Port interfaces that support those components.

— A Two-Port MAC Relay data model (48.2.2) that both subsets and augments the VLAN Bridge components model to model a VLAN-unaware TPMR (3.282)

— A Customer VLAN Bridge model (48.2.3) that comprises a single VLAN Bridge component from the VLAN Bridge components model.

— A Provider Bridges model that uses one or multiple components from the VLAN Bridge components model to compose an S-VLAN component Provider Bridge or a Provider Edge Bridge.

— Connectivity Fault Management (CFM) models (48.2.3) for use with the VLAN Bridge components and related models in systems that provide CFM functionality.

— A Stream filters and stream gates model (48.2.6) that augments the VLAN Bridge components model.

— An Asynchronous Traffic Shaping (ATS) model that augments the VLAN Bridge components model and the Stream filters and stream gates model.

48.1 YANG Framework

This clause has been developed according to the YANG guidelines published in IETF RFC 6087 [B38] as applicable to IEEE standards.

The YANG framework applies hierarchy in the following areas:

1) The uniform resource name (URN), as specified in IEEE Std 802d–2017. The structure of the URN is such that ieee is the root (i.e., name-space identifier), followed by the standard, then the working group developing the standard.
2) The YANG objects form a hierarchy of configuration and operational data structures that define the YANG model. These hierarchical relationships are described in 48.3.

The general YANG framework hierarchy is illustrated in Figure 48-1.

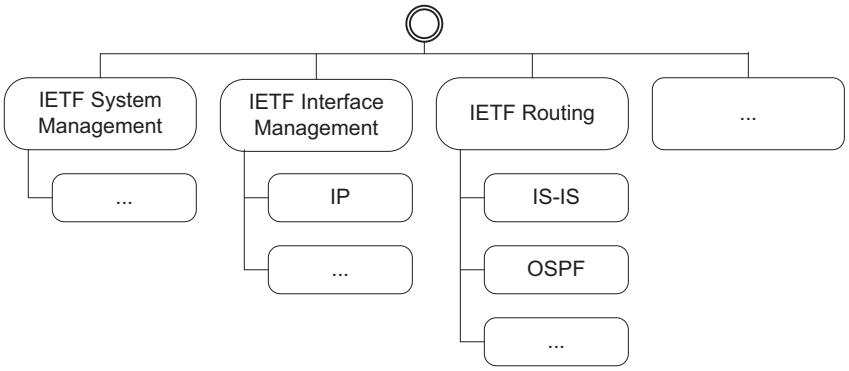

Figure 48-1—General YANG hierarchy

The YANG hierarchical structure that incorporates the IEEE 802.1Q YANG models supported by this standard is represented in Figure 48-2.

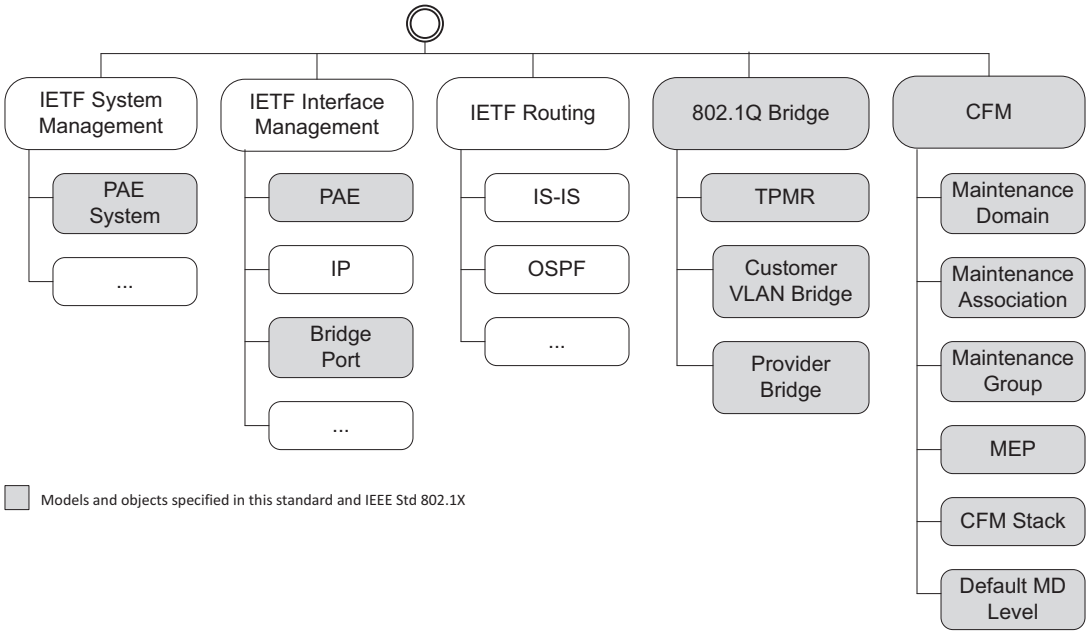

Figure 48-2—YANG root hierarchy with IEEE 802.1Q YANG modules

48.1.1 Interface Management (IETF RFC 8343) Model

Network interfaces are central to the management of protocols. Thus, it is important to establish a common data model for how interfaces are identified, configured, and monitored. The IETF Interface Management model (IETF RFC 8343) defines a generic YANG data model for the management of network interfaces.The Interface Management YANG model is augmented by the IEEE 802.1Q YANG models, and specifically the Bridge Port. A UML representation of the Interface Management model is illustrated in Figure 48-3.[50]

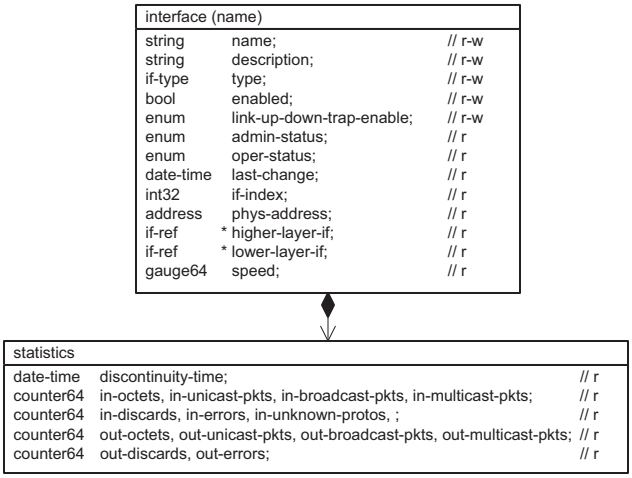

Figure 48-3— Interface YANG model

[50] The representation of the Interface YANG model is derived from IETF RFC 8343.

48.2 IEEE 802.1Q YANG models

The YANG data models are based on the management model outline in Clause 12. UML representations of the models are provided in the following subclauses.

48.2.1 VLAN Bridge components model

A network system can include one or more VLAN Bridge components.

Each VLAN Bridge component (5.4–5.6) comprises a single VLAN-aware MAC Relay Entity and its associated functionality (8.2, Figure 48-4), and is supported by a number of Bridge Ports (3.26, Figure 48-5). Each Bridge Port is associated with a single MAC Relay Entity, presents a single interface (a service access point) to that MAC Relay Entity, and comprises the interface stack that supports that service access point (6.1, 7.4 of IEEE Std 802.1AC-2016). In the 802.1Q YANG models, that interface is represented by the Interface Management (IETF RFC 8343) model augmented as shown in Figure 48-5.

Each MAC Relay Entity has a bridge-type attribute (e.g., customer-vlan-bridge), and the manageable attributes for the component can reflect that type: TPMR components (48.2.2), for example, are VLAN unaware.

A Bridge Port and the attributes associated with a media access method specific MAC entity (e.g, as specified by IEEE Std 802.3) supporting that Bridge Port can both be represented by augmentations of the same IETF_RFC_8343 Interface and identified by the same Interface index (if-index). In other cases *higher-layer-if* and *lower-layer-if* attributes define the interface stacking relationships within the Bridge Port. For example, an Aggregator (as defined by IEEE Std 802.1AX) Interface could be a Bridge Port. The *lower-layer-if* attributes associated with the Aggregator would point to the Aggregation Ports.

Each Bridge Port is uniquely identified, amongst those Bridge Ports supporting a given VLAN Bridge component, by a Port Number (*port-number*). A port number has no mandatory relationship to an Interface index (if-index).

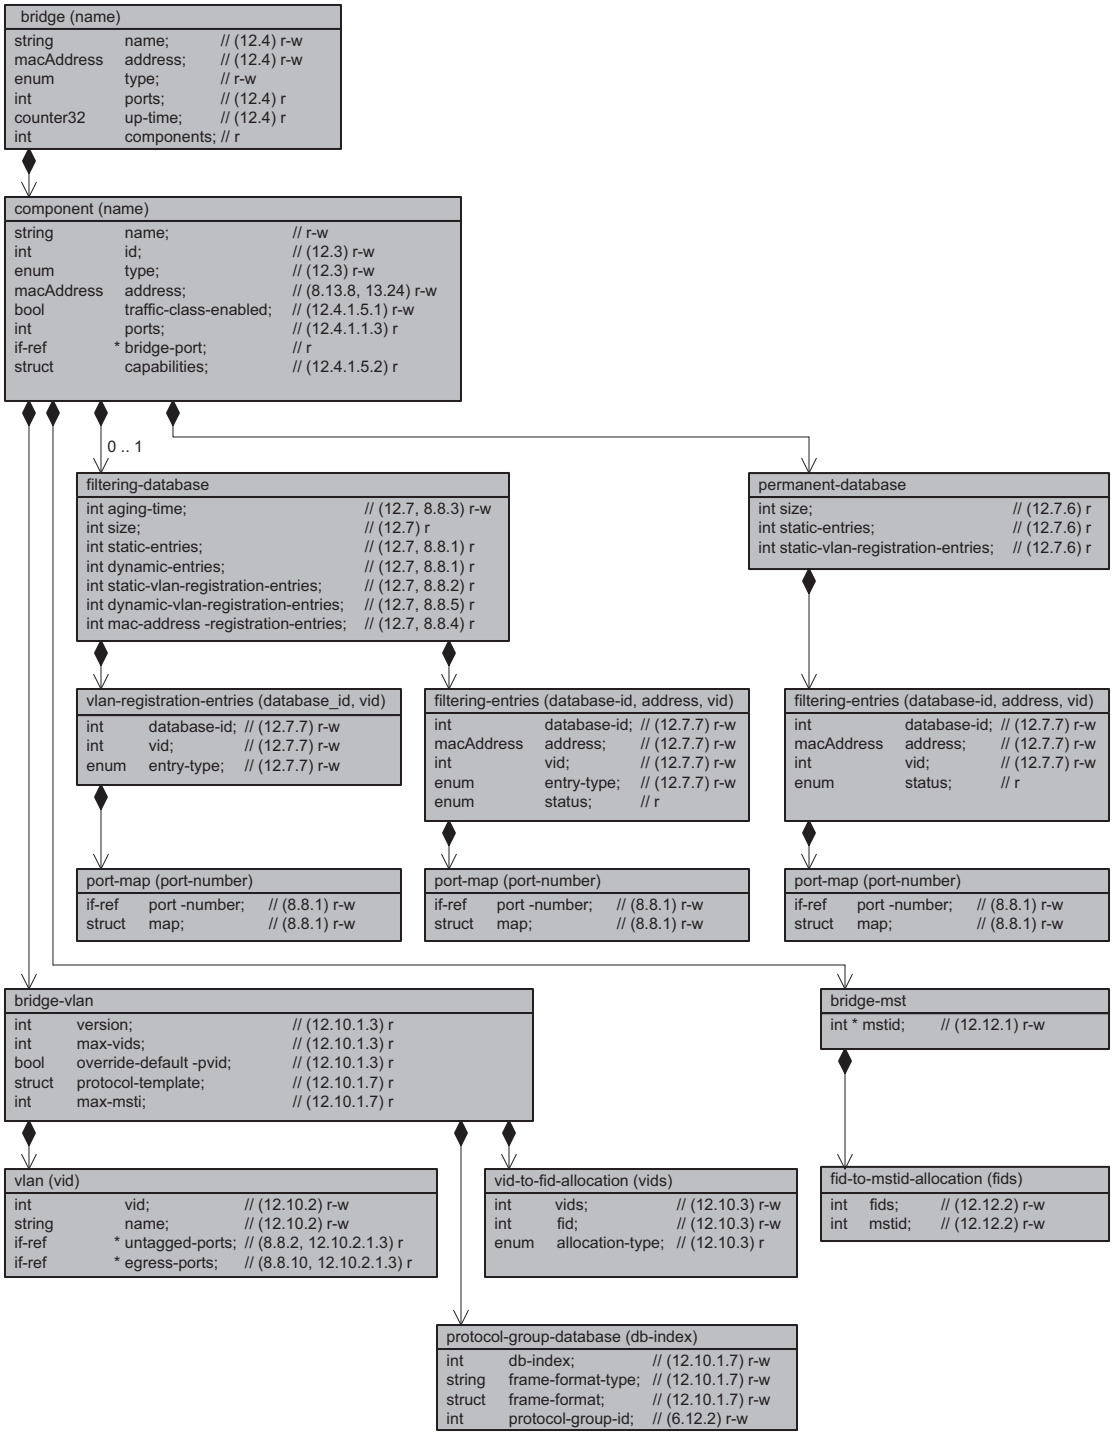

Figure 48-4—VLAN Bridge components model (MAC Relay Entities)

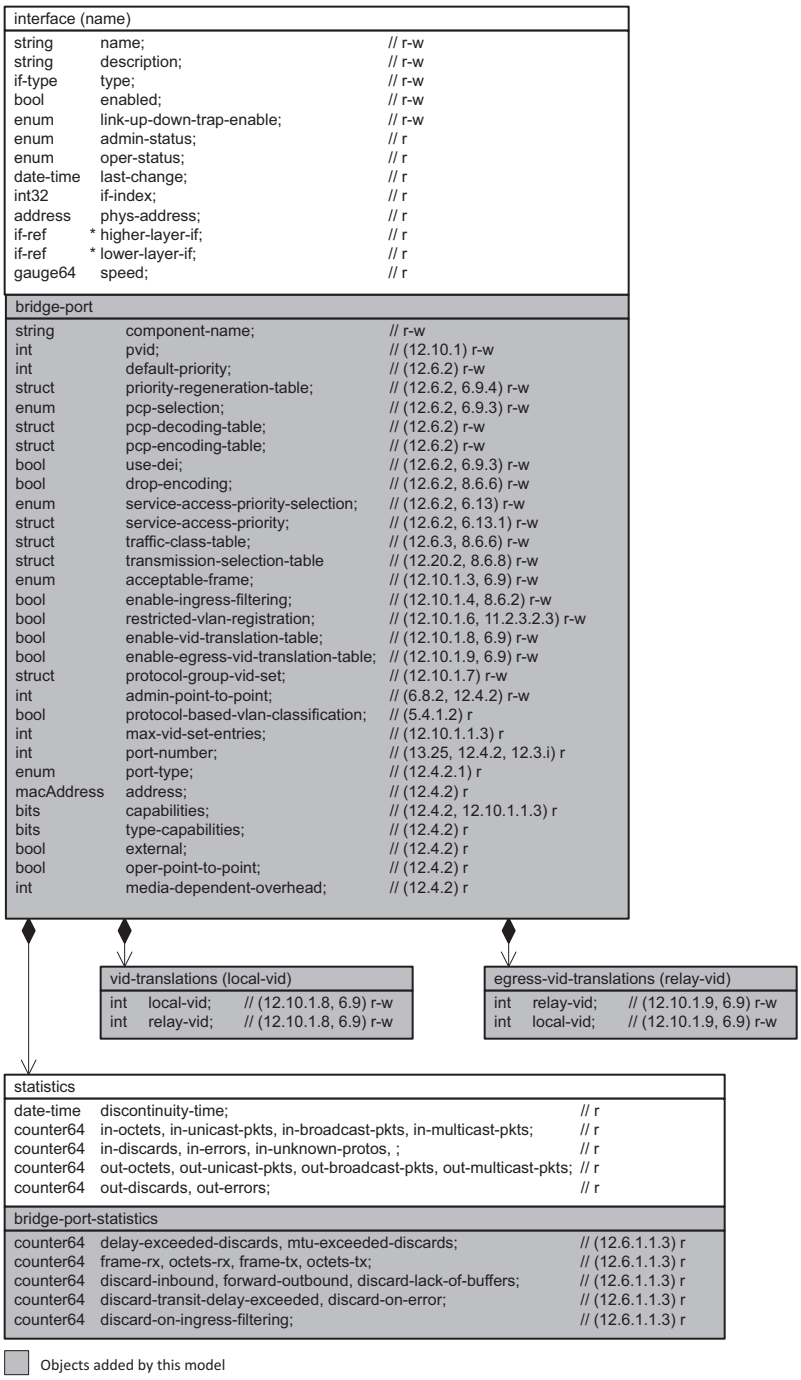

Figure 48-5—Bridge Port model

48.2.2 Two-Port MAC Relay (TPMR) model

A TPMR (5.15, 5.16) comprises a single VLAN-unaware MAC Bridge component supported by only two TPMR Ports (Clause 8, 8.5.2). The TPMR's VLAN-unaware MAC Relay Entity is modeled (Figure 48-6) as a subset of a VLAN Bridge component's MAC Relay Entity (Figure 48-4). This subset does not include the bridge-vlan, bridge-mst, and filtering-database nodes.

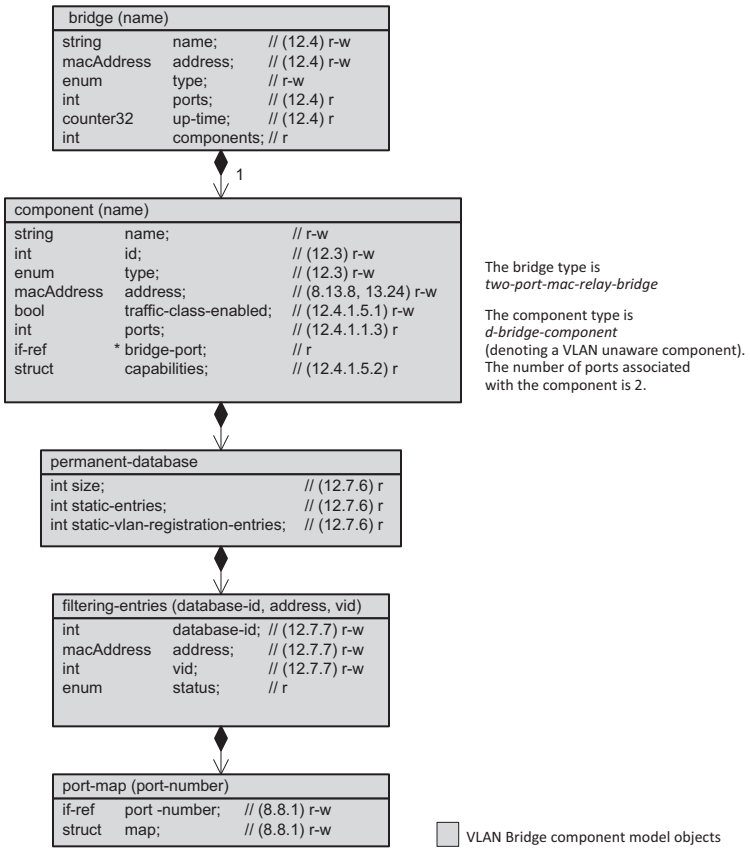

Figure 48-6—TPMR model (MAC Relay Entity)

The TPMR model extends the VLAN Bridge component's Bridge Port model as illustrated in Figure 48-7.

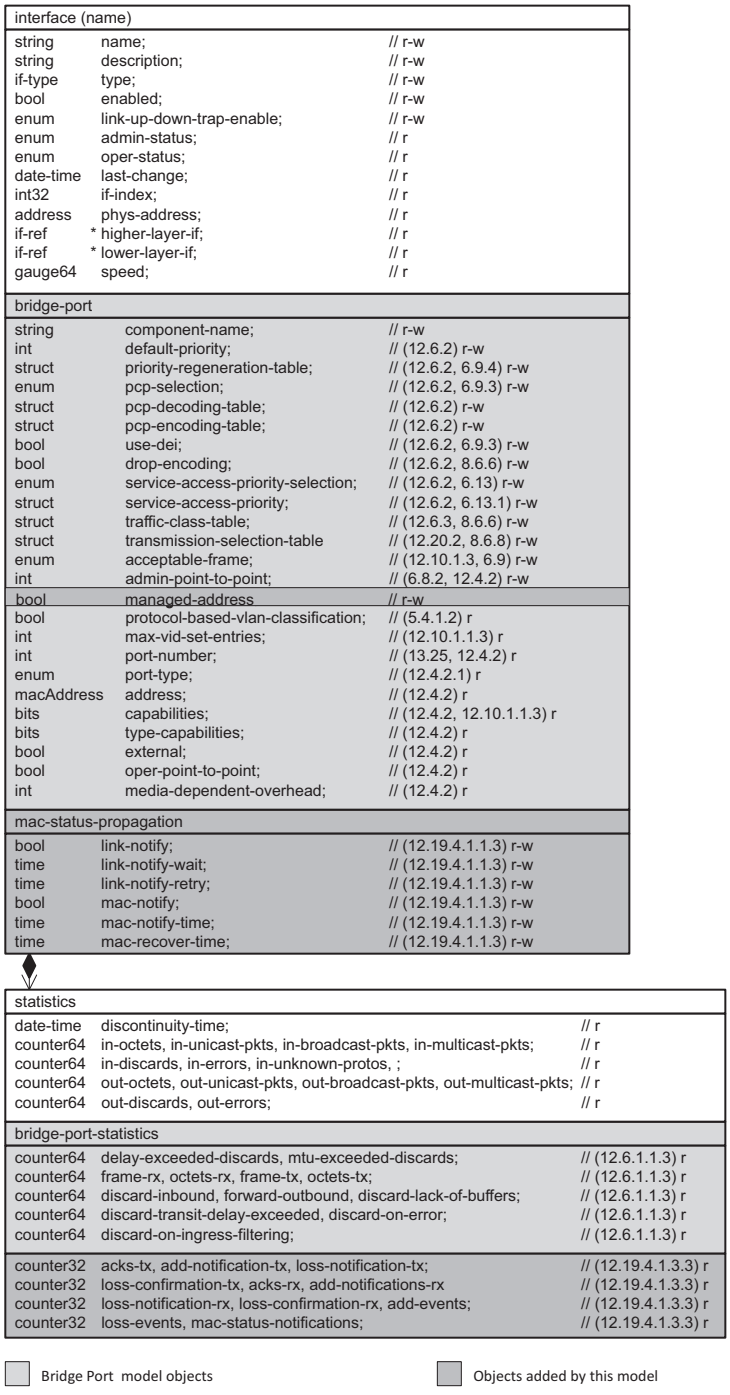

Figure 48-7—TPMR Port model

48.2.3 Customer VLAN Bridge model

A Customer VLAN Bridge (5.5) comprises a single C-VLAN Bridge component (Clause 8). The C-VLAN Bridge component's MAC Relay Entity and its Bridge Ports are modeled by the VLAN Bridge components model (48.2.1), with a single bridge component node with a type-of-bridge of customer-vlan-bridge (48.6.4) [a ComponentType of cVlanComponent in 12.3].

48.2.4 Provider Bridge model

A Provider Bridge (5.10, Clause 16) can be an S-VLAN Bridge with a single S-VLAN component or a Provider Edge Bridge with an S-VLAN component and multiple C-VLAN components. A Provider Bridge's MAC Relay Entities and its Bridge Ports (S-VLAN and C-VLAN Interfaces) are modeled (Figure 48-8, Figure 48-9, Figure 48-10) by extending the VLAN Bridge components model (48.2.1).

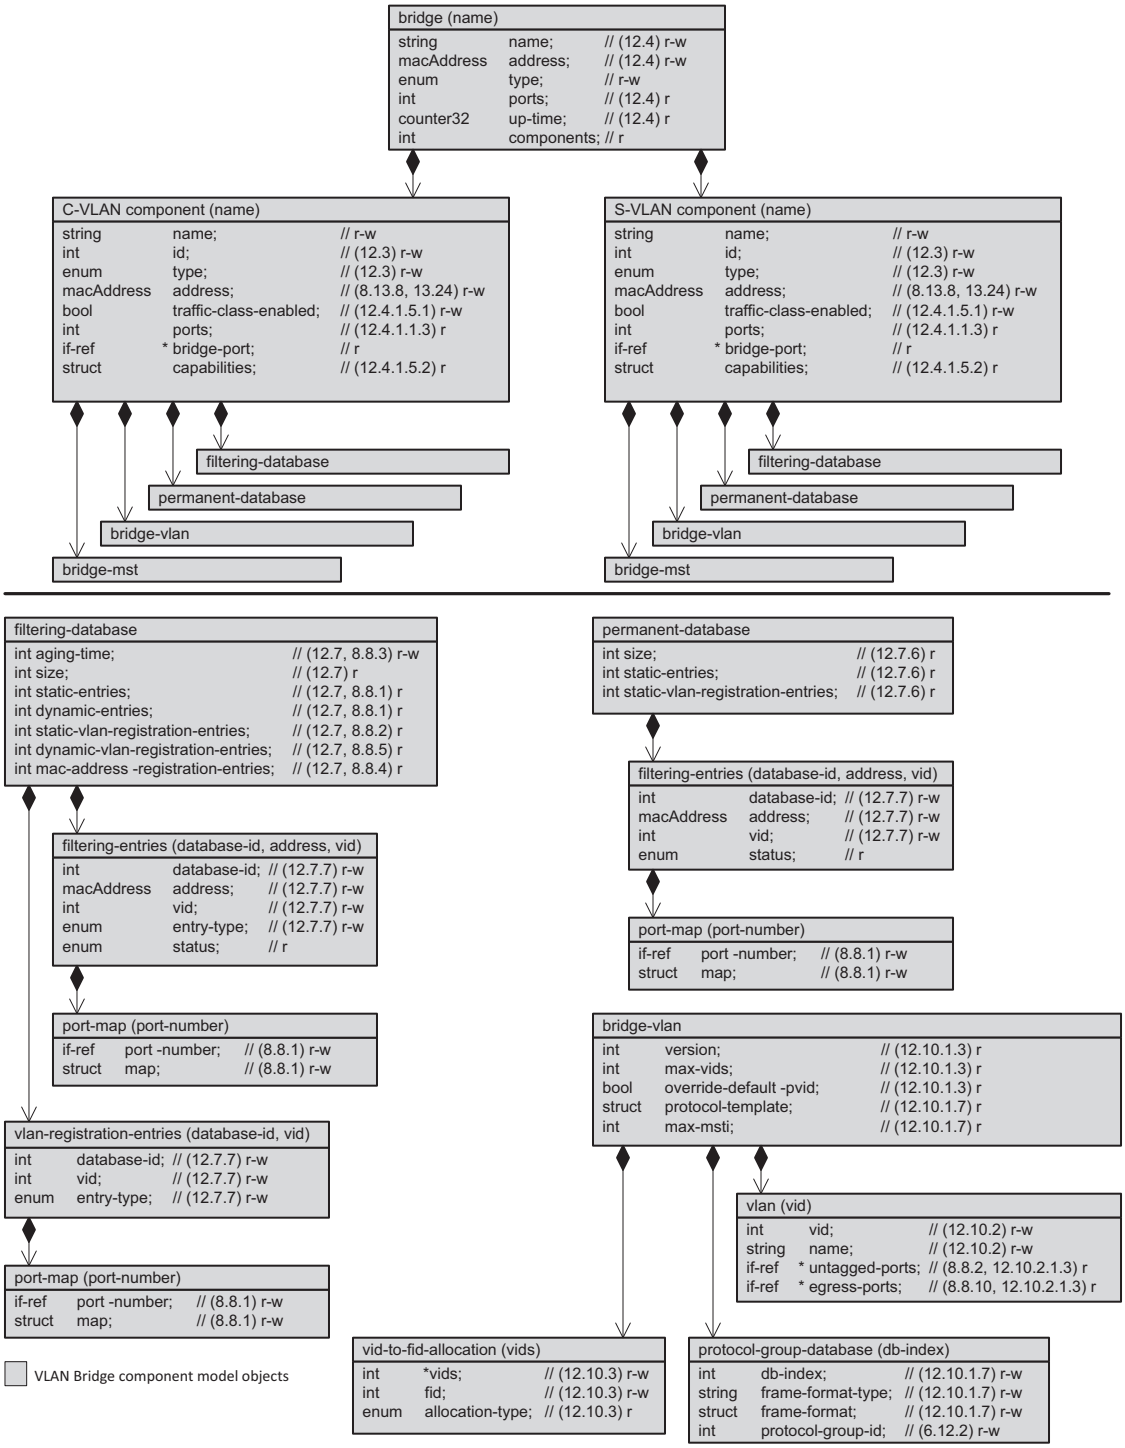

Figure 48-8—Provider Bridge model (MAC Relay Entities)

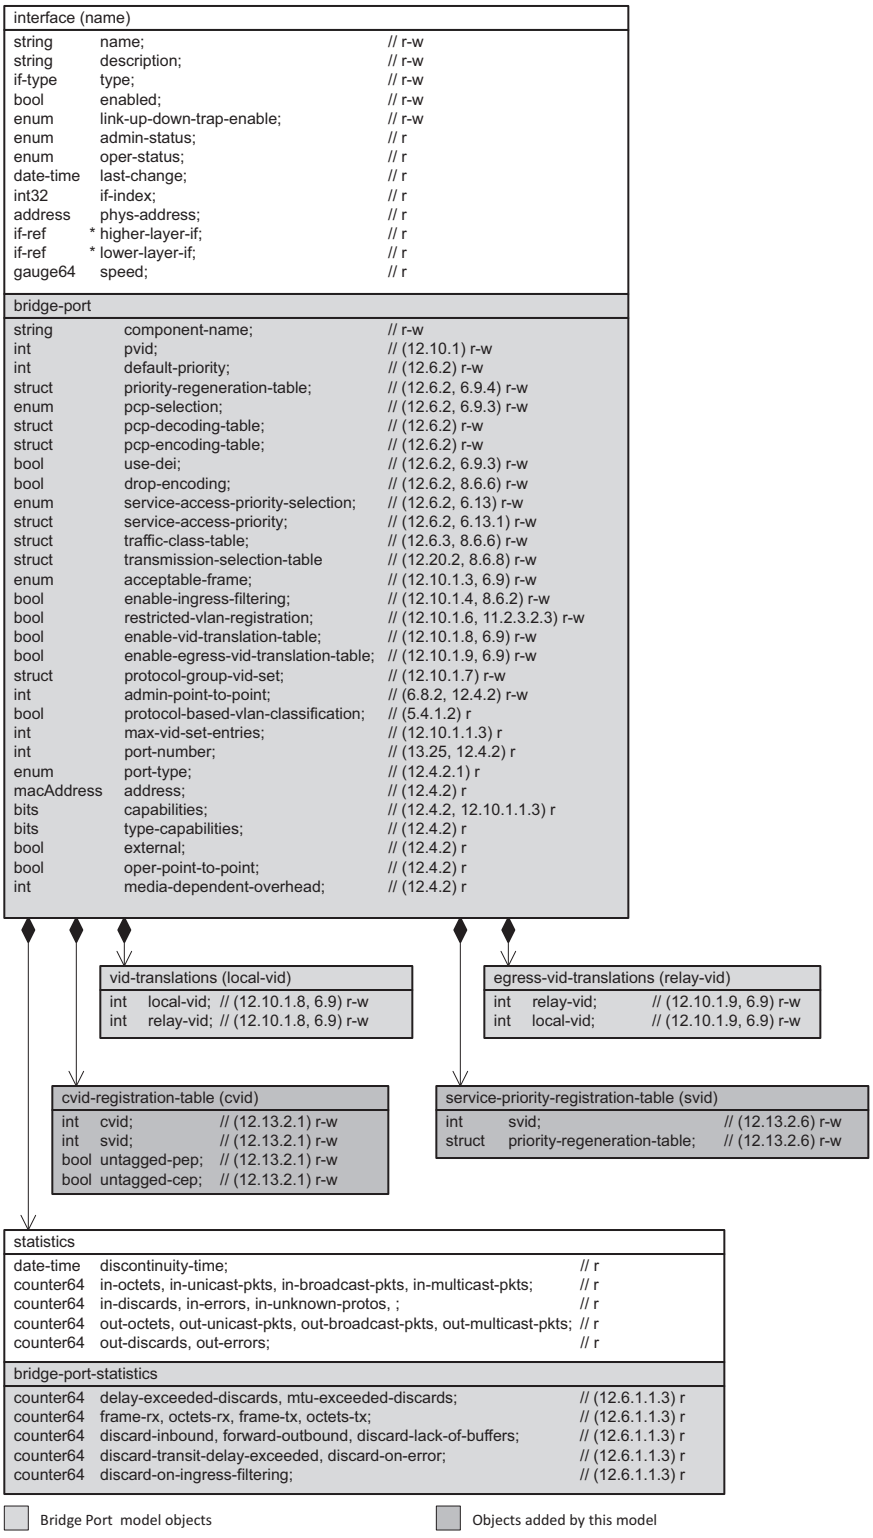

Figure 48-9—Provider Edge Bridge C-VLAN Interface model

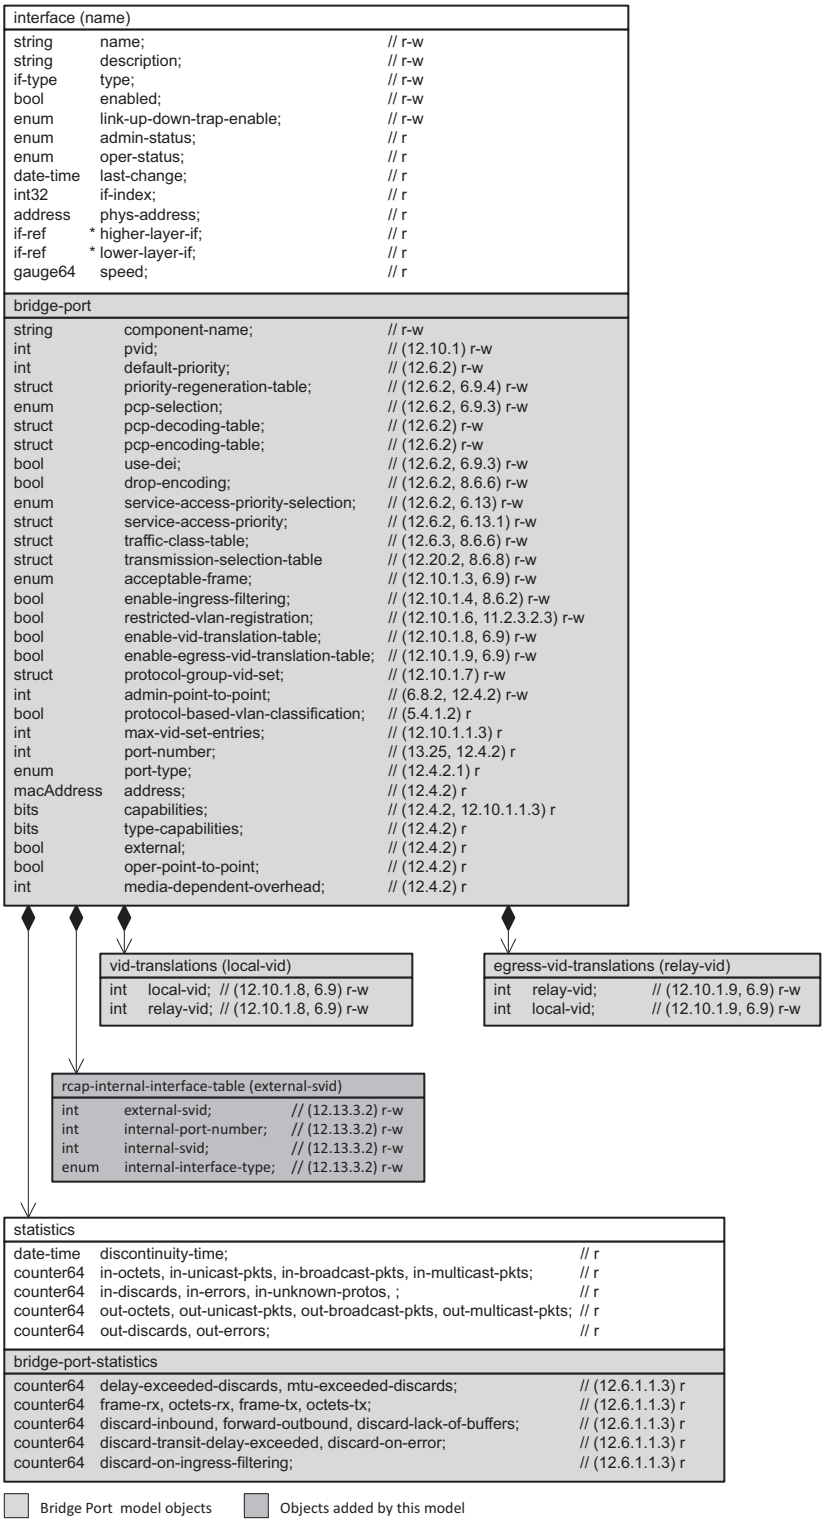

Figure 48-10—Provider Edge Bridge S-VLAN Interface model

48.2.5 CFM Model

The CFM UML data model is composed of the following set of major objects:

— The **Maintenance Domain** object is associated with a device (e.g., Bridge). It contains information used to identify the maintenance domain used to bind/contain Maintenance Association objects.

— The **Maintenance Association** objects are contained within a Maintenance Domain object. They contain maintenance point information related to the service instance being monitored.

— The **Maintenance Group** objects provide a convenient binding of a Maintenance Association object with a Maintenance Domain object.

— The **Maintenance association Endpoint** (MEP) object is associated with an Interface (e.g., Bridge Port) and a Maintenance Association Group object. It contains all information to manage a CFM entity, associated with a specific DoSAP of a service instance, which can generate and receive CFM PDUs and track any responses.

— The **Maintenance domain Intermediate Point** (MIP) object is associated with an Interface (e.g., Bridge Port) and a service (e.g., VID) to allow the explicit creation of an MHF.

— The **CFM Stack** object is associated with a device (e.g., Bridge). It contains information about maintenance points on a particular device Interface (e.g., Bridge Port or Aggregation Port).

— The **Default MD Level** object is associated with a device (e.g., Bridge) component. It contains MHF information needed for the creation of these functions on the services (e.g., VIDs) that are not attached to any Maintenance Association.

The **Configuration Error List** is associated with a device (e.g., Bridge). It contains configuration error information that is identifiable on a per-Interface (e.g., Bridge Port) and per-service (e.g., VID) basis.

The UML model representing the relationship between relevant Bridge objects to CFM objects is illustrated in Figure 48-11.

The CFM objects (e.g., cfm-stack, configuration-error-list, default-md-level, maintenance-domain) reference the device (i.e., Bridge and/or Bridge Component) to which they belong. This reference allows CFM objects to be associated with other types of devices (e.g., non-Bridges, end stations) where appropriate.

The Maintenance Group is modeled as a list that contains a convenient reference to a Maintenance Association object and its corresponding Maintenance Domain object. The identification of this collection of objects allows other CFM objects to more easily attach to a maintenance group and, in turn, simplifies configuration and operation retrieval procedures supported by the data model.

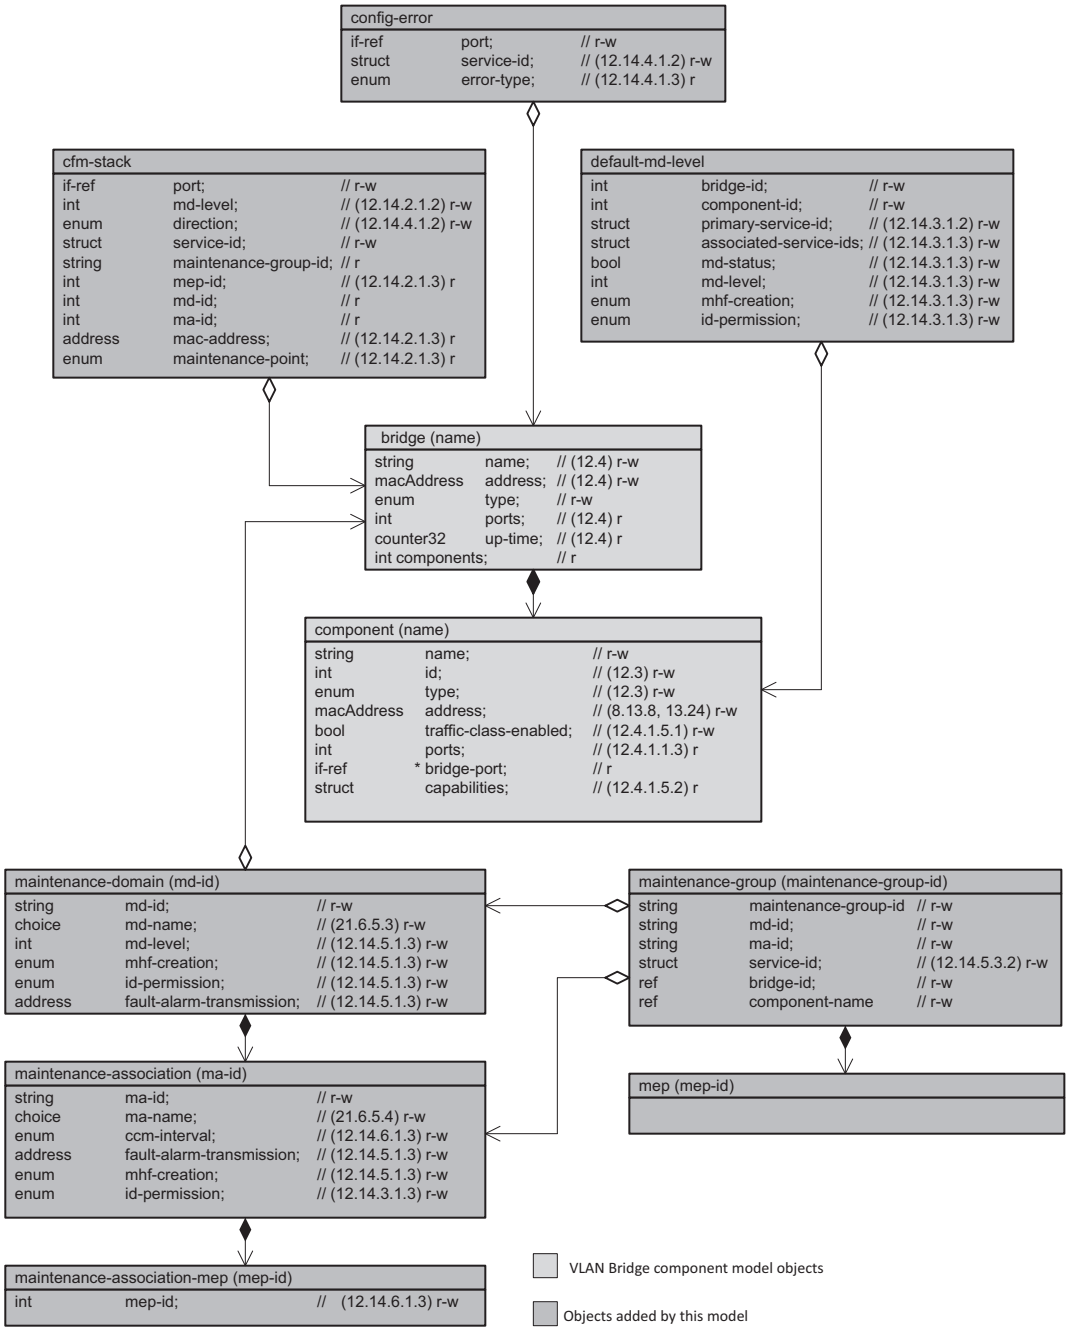

Figure 48-11—Bridge to CFM YANG model

As illustrated in Figure 48-12, MEP objects reference an Interface and are associated with a Maintenance Group. The interface relationship allows a MEP to be associated with a Bridge Port, as specified by this standard. This model also allows MEPs to be associated with other Interface types (for other devices).

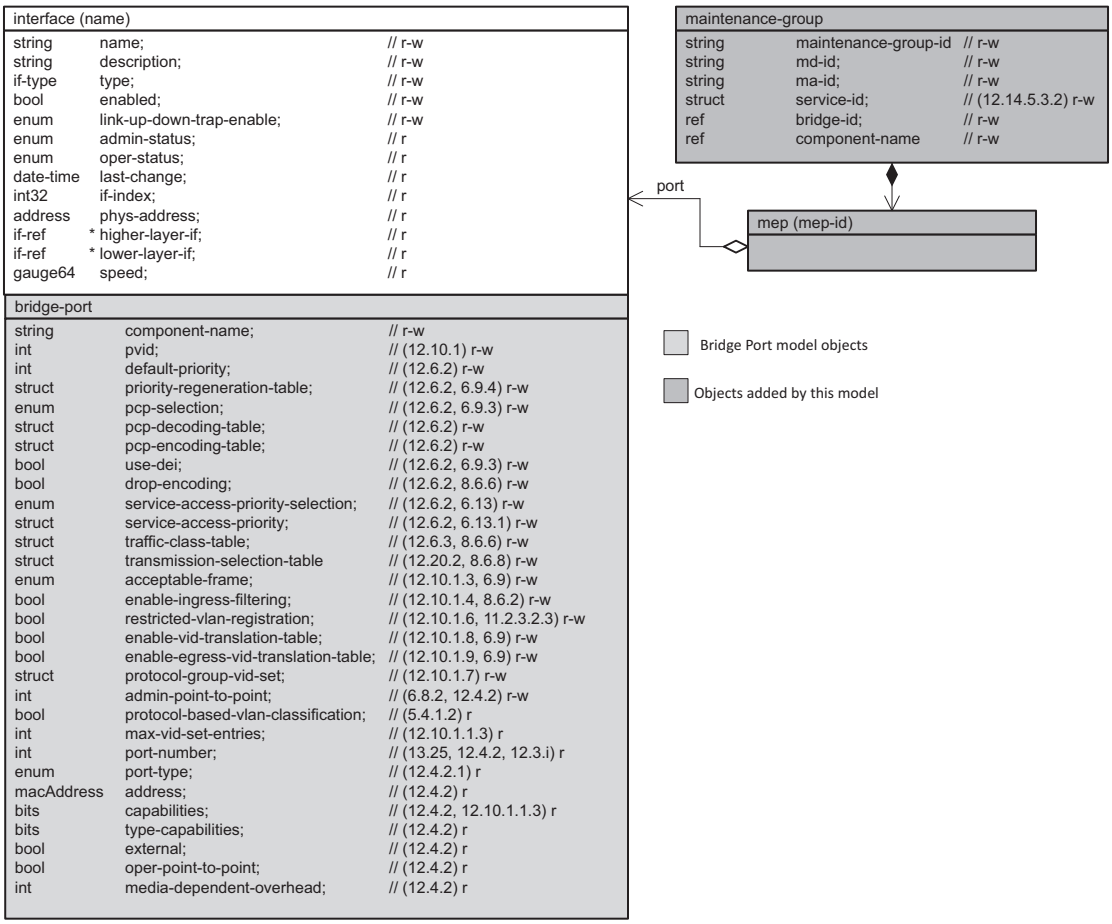

Figure 48-12—CFM MEP model relationships

The MEP object has relationships with other MEP-related objects. As illustrated in Figure 48-13, the CFM continuity check protocol suite-specific data needed to initiate protocol-specific sessions or maintain protocol-specific state information are grouped together. In addition, the MEP object will also reference the MEP CCM database and Stats objects.

48.2.5.1 CFM model support of CFM Operations

The CFM model also supports the initiation of Continuity Check, Loopback, and Linktrace protocol sessions. The general structure of the CFM session action data model is illustrated in Figure 48-14.

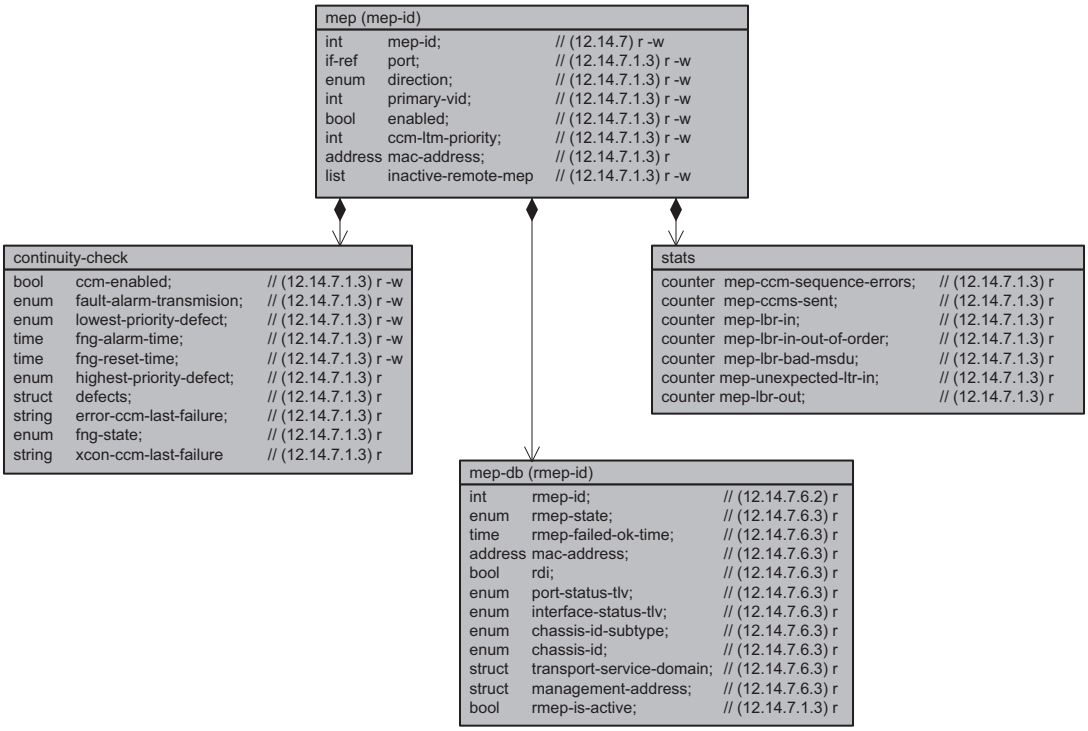

Figure 48-13—CFM MEP model

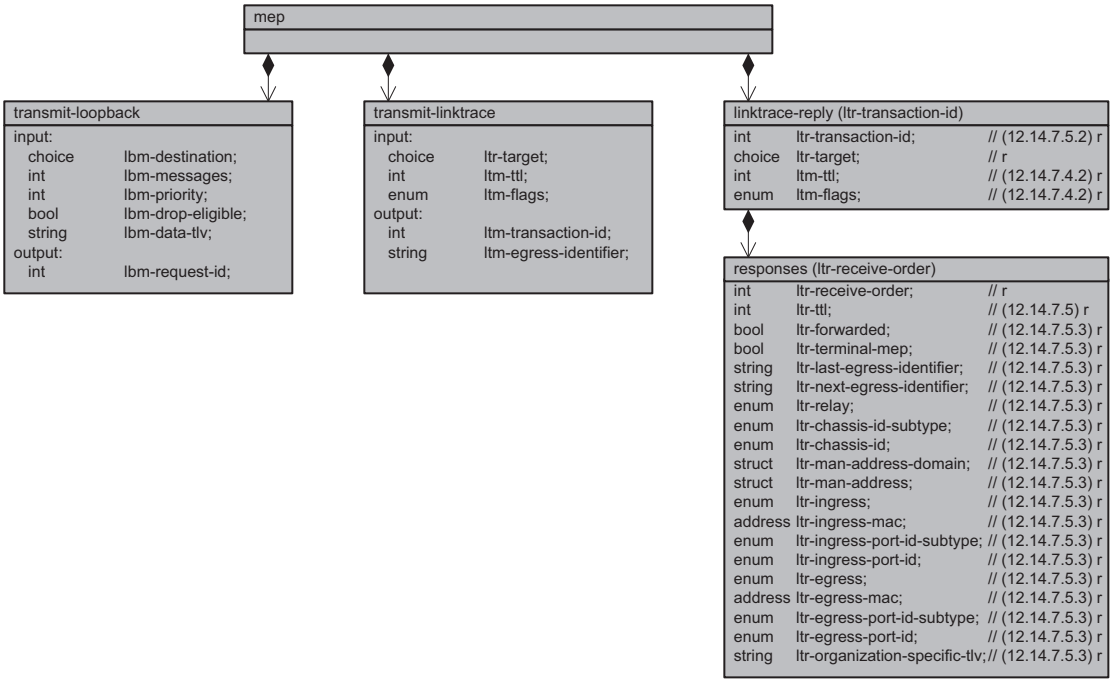

Figure 48-14—CFM operations structure

48.2.6 Stream filters and stream gates model

The stream filters and stream gates model augments the Bridge component model (48.3.1) by nodes that represent the following managed objects:

a) Stream Filter Instance Table (12.31.2)
b) Stream Gate Instance Table (12.31.3)

The UML representation of the stream filters and stream gates model is illustrated in Figure 48-15.

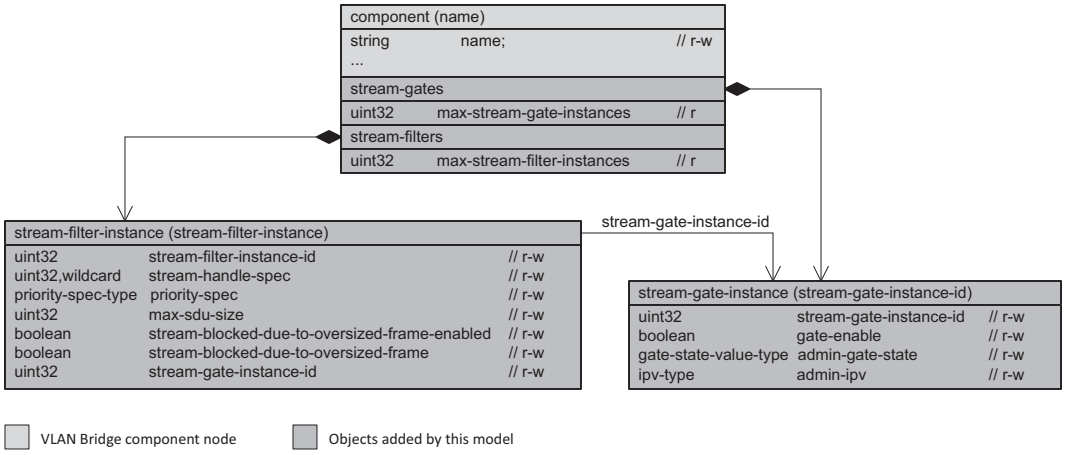

Figure 48-15—Stream filters and stream gates model

48.2.7 Asynchronous Traffic Shaping (ATS) model

The ATS model augments the Bridge component model (48.3.1) and the stream filters and stream gates model (48.3.6) by nodes that represent to following managed objects:

a) The Scheduler Instance Table (12.31.5)
b) The Scheduler Group Instance Table (12.31.6)
c) The Scheduler Port Parameter Table (12.31.7)
d) The Scheduler Timing Characteristics Table (12.31.8)
e) A Stream Filter specification type representing an ATS scheduler instance identifier (12.31.2.5)

The UML representation of the ATS model is illustrated in Figure 48-16.

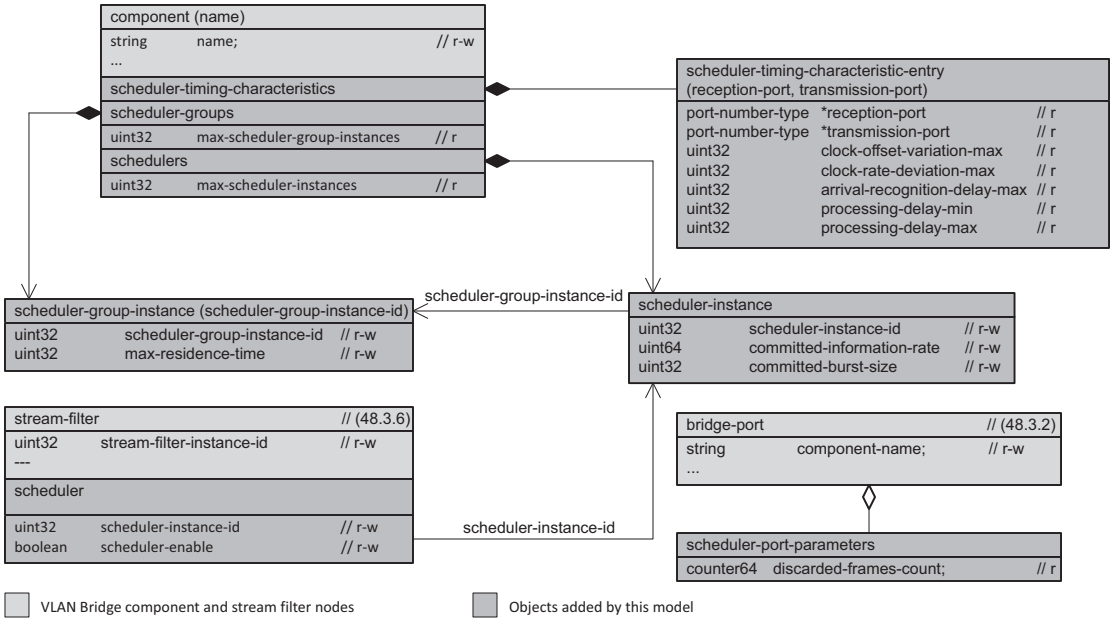

Figure 48-16—Asynchronous Traffic Shaping model

48.3 Structure of the YANG models

The YANG models specified by this standard use the YANG modules summarized in Table 48-1.[51]

In the YANG module definitions, if any discrepancy between the DESCRIPTION text and the corresponding definition in any other part of this standard occur, the definitions outside this clause (Clause 48) take precedence.

Table 48-1—Summary of the YANG modules

Module	References	Managed functionality	Initial YANG specification Notes
ieee802-types	48.6.1	Type definitions	IEEE Std 802.1Qcp General type definitions for IEEE 802 standards.
ieee802-dot1q-types	48.6.2	Type definitions	IEEE Std 802.1Qcp General type definitions used by IEEE Std 802.1Q.
ieee-802-dot1q-tsn-types	48.6.3	Type definitions	IEEE Std 802.1Qcp Type definitions and groupings for TSN user/network components.
ieee802-dot1q-bridge	48.5.4, 48.6.4	Clause 8	IEEE Std 802.1Qcp VLAN bridge component capabilities.
ieee802-dot1q-tpmr	48.5.5, 48.6.5	5.13, 5.15	IEEE Std 802.1Qcp TPMR augmentation of ieee802-dot1q-bridge.
ieee802-dot1q-pb	48.5.6, 48.6.6	Clause 20	IEEE Std 802.1Qcp Provider Bridge augmentation of ieee802-dot1q-bridge.
ieee802-dot1q-cfm-types	48.5.7, 48.6.7	Clause 20	IEEE Std 802.1Qcx General type definitions for CFM modules.
ieee802-dot1q-cfm	48.5.8, 48.6.8	Clause 20	IEEE Std 802.1Qcx Base CFM module defining Maintenance Domains, Maintenance Associations, Maintenance Groups, MEPs, and CFM session actions.
ieee802-dot1q-cfm-bridge	48.5.9, 48.6.9	Clause 20	IEEE Std 802.1Qcx Bridge and Bridge Port extension/ augmentation of ieee802-dot1q-cfm including CFM Stack, Default MD Levels, and Configuration Error Lists.
ieee802-dot1q-cfm-alarm	48.5.10, 48.6.10	Clause 20	IEEE Std 802.1Qcx Common CFM alarms, also supports alarms based on different frameworks (e.g., ietf-alarms).
ieee802-dot1q-stream-filters-gates	48.5.11, 48.6.11	8.6, 8.6.5.3, 8.6.5.4	IEEE Std 802.1Qcr Basic stream filtering and stream gating capabilities.
ieee802-dot1q-ats	48.5.12, 48.6.12	8.6	IEEE Std 802.1Qcr ATS extensions to ieee802-dot1q-stream-filters-gates and ieee802-dot1q-bridge modules.

The relationship between the models listed in 48.3 and the YANG modules listed in Table 48-1 is described in 48.4.1 through 48.4.5.

[51] An amendment's designation is often used to refer to functionality in an IEEE standard after the amendment has been incorporated in a revision of the standard, even if the functionality has been revised. The amendment that added each YANG module is identified to help locate the relevant provisions of this standard.

48.3.1 VLAN Bridge components model

This model provides basic bridging capabilities and allows for augmentation by specific YANG models (e.g., Two-Port MAC Relay model, Customer VLAN Bridge model, Provider Bridge model).

A system implementing the VLAN Bridge components model implements the YANG modules listed in Table 48-2.

48.3.2 Two-Port MAC Relay model

A system implementing the TPMR YANG model (48.3.2) implements the YANG modules listed in Table 48-3.

48.3.3 Customer VLAN Bridge model

A system implementing the Customer VLAN Bridge model (48.3.3) implements the YANG modules listed in Table 48-4.

48.3.4 Provider Bridge model

A system implementing the Provider Bridge model (48.3.4) implements the YANG modules listed in Table 48-5.

48.4 Security considerations

The YANG modules defined in this clause are designed to be accessed via a network configuration protocol, e.g., NETCONF protocol (IETF RFC 6241 [B39]). In the case of NETCONF, the lowest NETCONF layer is the secure transport layer and the mandatory to implement secure transport is SSH (IETF RFC 6242 [B40]). The NETCONF access control model (IETF RFC 6536 [B41]) provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

It is the responsibility of a system's implementor and administrator to ensure that the protocol entities in the system that support NETCONF, and any other remote configuration protocols that make use of these YANG modules, are properly configured to allow access only to those principals (users) that have legitimate rights to read or write data nodes. This standard does not specify how the credentials of those users are to be stored or validated.

48.4.1 Security considerations of the VLAN Bridge components model

There are a number of management objects defined in the ieee802-dot1q-bridge YANG module that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive or vulnerable in some network environments. A network configuration protocol, such as NETCONF, can support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure environment without proper protection, then negative effects on the network operation are possible.

The following objects in the ieee802-dot1q-bridge YANG module can be manipulated to interfere with the operation of VLANs and priority classes. This could, for example, be used to force a reinitialization of state machines, thus causing network instability, or to change the forwarding and filtering policies. Another possibility would be for an attacker to override established policy on Port priorities, thus giving a user (or an attacker) unauthorized preferential treatment.

interfaces/interface/bridge-port

interfaces/interface/bridge-port/priority-regeneration

interfaces/interface/bridge-port/transmission-selection-table

bridges/bridge/component/traffic-class-enabled

bridges/bridge/component/bridge-vlan/protocol-group-database

interfaces/interface/bridge-port/traffic-class

interfaces/interface/bridge-port/protocol-group-vid-set

a) The configurable object bridges/bridge/component/filtering-database/aging-time controls how fast dynamically learned forwarding information is aged out. Setting this object to a large value may simplify FDB overflow attacks. Setting this object to too small a value may compromise the throughput of the network by causing excessive flooding.
b) The configurable object bridges/bridge/component/filtering-database/filtering-entries/entry-type provides a filtering mechanism controlling which Ports frames originating from a specific source may be forwarded to. Write access to this table can be used to turn provisioned filtering off or to add filters to prevent rightful use of the network.

Some of the readable data in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control all types of access (e.g., including NETCONF get, get-config operations) to these objects and possibly to even encrypt the values of these objects when sending them over the network. These tables and objects and their sensitivity/vulnerability are described as follows:

— The object bridges/bridge/component/capabilities could be used by an attacker to determine which attacks might be useful to attempt against a given device.

— The readable objects defined in the ieee802-dot1q-bridge module provide information about the topology of a bridged network and the attached active stations. The addresses listed in the bridges/bridge/component/filtering-database/filtering-entries usually reveal information about the manufacturer of the MAC hardware, which can be useful information for mounting other specific attacks. In some networks, information about attached active stations can be considered personal identifying information about the user of the station. Unauthorized use of these objects can be considered a privacy threat.

48.4.2 Security considerations of the Two-Port MAC Relay model

There are a number of management objects defined in the ieee802-dot1q-tpmr YANG module that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive or vulnerable in some network environments. A network configuration protocol, such as NETCONF (IETF RFC 6241 [B39]), can support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure environment without proper protection, then negative effects on the network operation are possible.

The following objects in the ieee802-dot1q-tpmr YANG module could be manipulated to interfere with the operation of MAC status propagation on a TPMR port and, for example, be used to cause network instability:

interfaces/interface/bridge-port/mac-status-propagation/link-notify

interfaces/interface/bridge-port/mac-status-propagation/link-notify-wait

interfaces/interface/bridge-port/mac-status-propagation/link-notify-retry

interfaces/interface/bridge-port/mac-status-propagation/mac-notify

interfaces/interface/bridge-port/mac-status-propagation/mac-notify-time

interfaces/interface/bridge-port/mac-status-propagation/mac-recover-time

48.4.3 Security considerations of the Customer VLAN Bridge model

The Customer VLAN Bridge YANG model is based on, and has the same security considerations as, the VLAN Bridge components model. See 48.4.1.

48.4.4 Security considerations of the Provider Bridge model

There are a number of management objects defined in the ieee802-dot1q-pb YANG module that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive or vulnerable in some network environments. A network configuration protocol, such as NETCONF (IETF RFC 6241 [B39]), can support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure environment without proper protection, then negative effects on the network operation are possible.

The following objects in the ieee802-dot1q-pb YANG module can be manipulated to interfere with the operation of VLANs. This could, for example, be used to force a reinitialization of state machines, thus causing network instability, or to change the forwarding and filtering policies.

interfaces/interface/bridge-port

interfaces/interface/bridge-port/cvid-registration

interfaces/interface/bridge-port/service-priority-regeneration

48.4.5 Security considerations of the CFM model

There are a number of management objects defined in the ieee802-dot1q-cfm, ieee802-dot1q-cfm-bridge, and ieee802-dot1q-cfm-alarm YANG modules that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive or vulnerable in some network environments. A network configuration protocol, such as NETCONF (IETF RFC 6241 [B39]), can support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure environment without proper protection, then negative effects on the network operation are possible.

The following objects in the ieee802-dot1q-cfm YANG module could be manipulated to interfere with the operation of a CFM port. This could, for example, be used to force a reinitialization of CFM state machines, thus causing network instability, or to change the management policies.

cfm/maintenance-domain

cfm/maintenance-group

See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

48.4.6 Security considerations of the Stream filters and stream gates model

There are a number of management objects defined in the ieee802-dot1q-stream-filters-gates YANG module that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive or vulnerable in some network environments. A network configuration protocol, such as NETCONF (IETF RFC 6241 [B39]), can support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure environment without proper protection, then negative effects on the network operation are possible.

The following objects in the ieee802-dot1q-stream-filters-gates YANG module could be manipulated to interfere with the operation of stream filtering and gating. This could, for example, be used to force a reinitialization of PSFP or ATS state machines, thus causing network instability.

bridges/bridge/component/stream-filters

bridges/bridge/component/stream-gates

See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

48.4.7 Security considerations of the Asynchronous Traffic Shaping model

.There are a number of management objects defined in the ieee802-dot1q-ats YANG module that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive or vulnerable in some network environments. A network configuration protocol, such as NETCONF (IETF RFC 6241 [B39]), can support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure environment without proper protection, then negative effects on the network operation is possible.

The following objects in the ieee802-dot1q-ats YANG module could be manipulated to interfere with the operation of stream filtering. This could, for example, be used to force a reinitialization of ATS state machines, thus causing network instability.

48.5 YANG schema tree definitions

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

— Brackets “[“ and “]” enclose list keys.
— Abbreviations before data node names: “rw” means configuration (read-write), and “ro” means state data (read-only).
— Symbols after data node names: “?” means an optional node, “!” means a presence container, and “*” denotes a list and leaf-list.
— Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (“:”).
— Ellipsis (“...”) stands for contents of subtrees that are not shown.

48.5.1 Schema for the ieee802-types YANG module

This YANG module does not have a YANG schema tree.

48.5.2 Schema for the ieee802-dot1q-types YANG module

This YANG module does not have a YANG schema tree.

48.5.3 Schema for the ieee802-dot1q-tsn-types YANG module

  typedef chassis-id-type {
    type string {
      length "1..255";
    }
    description
```

```
    "The format of a chassis identifier string. Objects of this type
    are always used with an associated lldp-chassis-is-subtype object,
    which identifies the format of the particular lldp-chassis-id
    object instance.

    If the associated lldp-chassis-id-subtype object has a value of
    chassis-component, then the octet string identifies a particular
    instance of the entPhysicalAlias object (defined in IETF RFC 2737)
    for a chassis component (i.e., an entPhysicalClass value of
    chassis(3)).

    If the associated lldp-chassis-id-subtype object has a value of
    interface-alias, then the octet string identifies a particular
    instance of the ifAlias object (defined in IETF RFC 2863) for an
    interface on the containing chassis. If the particular ifAlias
    object does not contain any values, another chassis identifier
    type should be used.

    If the associated lldp-chassis-id-subtype object has a value of
    port-component, then the octet string identifies a particular
    instance of the entPhysicalAlias object (defined in IETF RFC 2737)
    for a port or backplane component within the containing chassis.

    If the associated lldp-chassis-id-subtype object has a value of
    mac-address, then this string identifies a particular unicast
    source address (encoded in network byte order and IEEE 802.3
    canonical bit order), of a port on the containing chassis as
    defined in IEEE Std 802-2001.

    If the associated lldp-chassis-id-subtype object has a value of
    network-address, then this string identifies a particular network
    address, encoded in network byte order, associated with one or
    more ports on the containing chassis. The first octet contains the
    IANA Address Family Numbers enumeration value for the specific
    address type, and octets 2 through N contain the network address
    value in network byte order.

    If the associated lldp-chassis-id-subtype object has a value of
    interface-name, then the octet string identifies a particular
    instance of the ifName object (defined in IETF RFC 2863) for an
    interface on the containing chassis. If the particular ifName
    object does not contain any values, another chassis identifier
    type should be used.

    If the associated lldp-chassis-id-subtype object has a value of
    local, then this string identifies a locally assigned Chassis ID.";

  typedef stream-id-type {
    type string {
      pattern
        "[0-9a-fA-F]{2}"+
        "(-[0-9a-fA-F]{2}){5}"+
        ":"+
        "[0-9a-fA-F]{2}"+
        "-"+
        "[0-9a-fA-F]{2}";
    }
    description
      "This typedef specifies a Stream ID, a unique identifier of the
      Stream's configuration, used by protocols in the network to
      associate the user's Stream with TSN resources.

      The Stream ID is a string that represents two fields:

      MAC Address:

      A 48-bit IEEE 802 MAC address associated with the Talker sourcing
      the Stream to the bridged network. The entire range of MAC
      addresses are acceptable.

      NOTE 1The MAC address component of the StreamID can, but does not
      necessarily, have the same value as the source_address parameter
      of any frame in the actual data Stream. For example, the Stream ID
      can be assigned by a TSN CUC (see 46.1.3.3 of IEEE Std
```

```
    802.1Q-2022), using a pool of MAC addresses that the TSN CUC
    maintains.

    NOTE 2If the MAC addresses used to construct Stream IDs are not
    unique within the network, duplicate Stream IDs can be generated,
    with unpredictable results.

    Unique ID:

    A 16-bit unique ID that is used to distinguish between multiple
    Streams within the station identified by MAC Address.

    The string specifies eight octets, with each octet represented as
    two hexadecimal characters. The first six octets specify the MAC
    Address, using the canonical format of IEEE Std 802, with a dash
    separating each octet. The last two octets specify the Unique ID,
    with the high-order octet, a dash, and then the low-order octet.
    The MAC Address and Unique ID are separated by colon.

    stream-id-type is intended for use by other modules as the type
    for a key to a list of Stream configurations (using group-talker
    and group-listener) and a list of Stream status (using
    group-status-stream and group-status-talker-listener).";

  leaf mac-address {
    type string {
      pattern "[0-9a-fA-F]{2}(-[0-9a-fA-F]{2}){5}";
    }
    description
      "mac-address is the unique individual MAC address (IEEE Std 802) of
      the interface in the station (end station or Bridge). This MAC
      address uniquely identifies the station within the local
      network.

      mac-address shall be included in an instance of a container
      using group-interface-id.

      NOTEThis MAC address can be discovered in the physical topology
      using protocols such as IEEE Std 802.1AB (LLDP). LLDP supports
      MAC address as a subtype for the stations Chassis ID and Port
      ID. If the station does not use MAC address for its LLDP IDs,
      remote management can be used to associate this mac-address to
      the values provided in the LLDP IDs.

      The string uses the hexadecimal representation specified in IEEE
      Std 802 (i.e. canonical format).";
  }
  leaf interface-name {
    type string;
    description
      "interface-name is the name of the interface that is assigned
      locally by the station (end station or Bridge).

      interface-name may be included in an instance of a container
      using group-interface-id.

      IEEE Std 802 recommends that each distinct point of attachment
      to an IEEE 802 network have its own EUI MAC address. If the
      identified station follows this IEEE 802 recommendation, the
      mac-address leaf uniquely identifies the interface as well as
      the station, and interface-name is not needed.

      If the mac-address applies to more than one interface (distinct
```

```
      point of attachment) within the station, interface-name provides
      a locally assigned name that can help to identify the interface.

      When YANG is used for management of the station, interface-name
      is the interface name that serves as the key for the stations
      interface list (RFC7223).

      NOTE 1The TSN CNC is typically located in a different physical
      product than the station identified by this group-interface-id.
      Since the interface-name is assigned locally by the identified
      station, it is possible that the stations product will change
      interface-name in a manner that the TSN CNC cannot detect. For
      example, RFC7223 mentions that the YANG interface name can
      change when a physical attachment point is inserted or removed.

      NOTE 2This interface name can be discovered in the physical
      topology using protocols such as IEEE Std 802.1AB (LLDP). LLDP
      supports interface name as a subtype for its Port ID. If the
      station does not use interface name for its LLDP Port ID, remote
      management can be used to associate this interface-name to the
      values provided in the LLDP Port ID.";

    leaf num-seamless-trees {
```

```
    type uint8;
    default "1";
    description
      "num-seamless-trees specifies the number of trees that the
      network will configure to deliver seamless redundancy for the
      Stream.

      The value zero is interpreted as one (i.e. no seamless
      redundancy).

      This requirement is provided from the Talker only. Listeners
      shall set this leaf to one.

      From each Talker to a single Listener, the network configures a
      path that relays Stream data through Bridges. If the Talker has
      more than one Listener, the network configures a tree of
      multiple paths.

      num-seamless-trees specifies the number of maximally disjoint
      trees that the network shall configure from the Talker to all
      Listeners. Each tree is disjoint from other trees, in that the
      network evaluates the physical topology to avoid sharing the
      same Bridge and links in each trees paths. This computation of
      disjoint trees is maximal, in that shared Bridges and links are
      avoided to the maximum extent allowed by the physical topology.
      For example, if a single link exists from a Bridge to a
      Listener, and num-seamless-trees is 3, then all 3 trees will
      share that link to the Listener.

      When num-seamless-trees is greater than one, the transfer of the
      Streams data frames shall use a seamless redundancy standard,
      such as IEEE Std 802.1CB. When a link shared by multiple trees
      diverges to multiple disjoint links, the seamless redundancy
      standard replicates (i.e. forwards a distinct copy of each data
      frame to the disjoint trees). When disjoint trees converge to a
      single link, the seamless redundancy standard eliminates the
      duplicate copies of each data frame. Assuming that other sources
      of frame loss are mitigated (e.g. congestion), failure of a link
      or Bridge in one disjoint tree does not result in frame loss as
      long as at least one remaining disjoint tree is operational.

      If the Talker sets this leaf to one, the network may make use of
      redundancy standards that are not seamless (i.e. failure of link
      results in lost frames), such as MSTP and IS-IS.

      If the Talker sets this leaf to greater than one, and seamless
      redundancy is not possible in the current network (no disjoint
      paths, or no seamless redundancy standard in Bridges),
      group-status-stream.status-info.failure-code is non-zero
      (46.2.4.1 of IEEE Std 802.1Q-2022).

      If group-user-to-network-requirements is not provided by the
      Talker or Listener, the network shall use the default value of
      one for this leaf.";
    reference
      "46.2.3.6.1 of IEEE Std 802.1Q-2022";
  }
  leaf max-latency {
    type uint32;
    default "0";
    description
      "Maximum latency from Talker to Listener(s) for a single frame
      of the Stream.

      max-latency is specified as an integer number of nanoseconds.

      Latency shall use the definition of 3.102, with additional
      context as follows: The Known reference point in the frame is
      the message timestamp point specified in IEEE Std 802.1AS for
      various media (i.e. start of the frame). The first point is in
      the Talker, at the reference plane marking the boundary between
      the network media and PHY (see IEEE Std 802.1AS). The second
```

```
        point is in the Listener, at the reference plane marking the
        boundary between the network media and PHY.

        When this requirement is specified by the Talker, it must be
        satisfied for all Listeners.

        When this requirement is specified by the Listener, it must be
        satisfied for this Listener only.

        If group-user-to-network-requirements is not provided by the
        Talker or Listener, the network shall use the default value of
        zero for this leaf.

        The special value of zero represents usage of the initial value
        of group-status-talker-listener.accumulated-latency as the
        maximum latency requirement. This effectively locks-down the
        initial latency that the network calculates after successful
        configuration of the Stream, such that any subsequent increase
        in latency beyond that value causes the Stream to fail.

        The assumption for when the first point occurs in the Talker
        depends on the presence of the time-aware container in the
        Talkers traffic-specification.

        When time-aware is not present:

        The Talker is assumed to transmit at an arbitrary time (not
        scheduled).

        When time-aware is present:

        The first point is assumed to occur at the start of each
        traffic-specification.interval, as if the Talkers offsets
        (earliest-transmit-offset and latest-transmit-offset) are both
        zero. The Talkers offsets are not typically zero, but use of the
        start of interval for purposes of max-latency allows the
        Listener(s) to schedule their application independently from the
        Talkers offset configuration.

        The Listener determines max-latency based on its scheduling of a
        read function in the application. Nevertheless, the time from
        frame reception (i.e. second point) to execution of the read
        function is in the user scope, and therefore not included in
        max-latency.

        max-latency can be set to a value greater than the Talkers
        interval, in order to specify a longer latency requirement. For
        example, if the Talkers interval is 500 microsec, and
        max-latency is 700 microsec, the Listener receives the frame no
        later than 200 microsec into the interval that follows the
        Talkers interval.";

    leaf vlan-tag-capable {
```

```
    type boolean;
    default "false";
    description
      "When vlan-tag-capable is true, the interface supports the
      ability to tag/untag frames using a Customer VLAN Tag (C-TAG of
      clause 9) provided by the network.

      For a Talker, the networks tag replaces the tag specified by the
      data-frame-specification. If the data-frame-specification is
      untagged (no group-ieee802-vlan-tag), the networks tag is
      inserted in the frame as it passes through the interface.

      For a Listener, the users tag from the data-frame-specification
      replaces the networks tag as the frame passes through the
      interface. If the data-frame-specification is untagged (no
      group-ieee802-vlan-tag), the networks tag is removed from the
      frame as it passes through the interface.

      If the end station supports more than one interface (i.e. more
      than one entry in end-station-interfaces), vlan-tag-capable of
      true means that a distinct VLAN tag can be applied to each
      interface. The list of VLAN tag (one for each interface) can be
      provided by the network in
      interface-configuration.interface-list (ieee802-vlan-tag
      choice).

      When vlan-tag-capable is false, the interface does not support
      the capability to tag/untag frames using a Customer VLAN Tag
      (C-TAG of clause 9) provided by the network.

      If interface-capabilities is not provided by the Talker or
      Listener, the network shall use the default value of false for
      this leaf.";

      "Rank of this Stream's configuration relative to other Streams
      in the network. This rank is used to determine success/failure
      of Stream resource configuration, and it is unrelated to the
      Streams data.";
    reference
      "46.2.3.2 of IEEE Std 802.1Q-2022";
    leaf rank {
      type uint8;
      description
        "The Rank is used by the network to decide which Streams can
        and cannot exist when TSN resources reach their limit. If a
        Bridges Port becomes oversubscribed (e.g. network
        reconfiguration, IEEE 802.11 bandwidth reduction), the Rank is
        used to help determine which Streams can be dropped (i.e.
        removed from Bridge configuration).

        The only valid values for Rank shall be zero and one. The
        configuration of a Stream with Rank zero is more important
        than the configuration of a Stream with Rank one. The Rank
        value of zero is intended for emergency traffic, and the Rank
        value of one is intended for non-emergency traffic.

        NOTEIt is expected that higher layer applications and
        protocols can use the Rank to indicate the relative importance
        of Streams based on user preferences. Those user preferences
        are expressed by means beyond the scope of this standard. When
        multiple applications exist in a network (e.g. audio/video
        along with industrial control), it can be challenging for the
        varied applications and vendors to agree on multiple Rank
        values. To mitigate such challenges, this Rank uses a simple
        concept of emergency (zero) and non-emergency (one) that can
        be applied over all applications. For example, in a network
        that carries audio Streams for fire safety announcements, all
        applications are likely to agree that those Streams use Rank
        of zero.";

```
      }
      leaf jitter {
        type uint32;
        description
          "The jitter leaf specifies the maximum difference in time
          between the Talkers transmit offsets, and the ideal
          synchronized network time (e.g. IEEE 802.1AS time). Jitter
          is specified as an unsigned integer number of nanoseconds.

          The maximum difference means sooner or later than the ideal
          (e.g. transmit +/- 500 nanoseconds relative to IEEE 802.1AS
          time results in jitter of 500).

          The ideal synchronized network time refers to time at the
          source (e.g. IEEE 802.1AS grandmaster). The jitter does not
          include inaccuracies as time is propagated from the time
          source to the Talker, because those inaccuracies are assumed
          to be known by the network, and time synchronization is a
          network technology. The jitter leaf is intended to specify
          inaccuracies in the Talkers implementation. For example, if
          the Talkers IEEE 802.1AS time is +/- 812 nanoseconds
          relative to the grandmaster, and the Talker schedules using
          a 100 microsecond timer tick driven by IEEE 802.1AS time,
          Jitter is 50000 (not 50812).

          The Talkers transmit offsets include
          earliest-transmit-offset, latest-transmit-offset, and the
          time-aware-offset returned to the Talker in
          group-status-talker-listener.interface-configuration.";

        "accumulated-latency provides the worst-case maximum latency
        that a single frame of the Stream can encounter along its
        current path(s).

        When provided to a Listener, accumulated-latency is the
        worst-case maximum latency for that Listener only.

        When provided to a Talker, accumulated-latency is the worst-case
        maximum latency for all Listeners (worst path).

        accumulated-latency is specified as an integer number of
        nanoseconds.

        accumulated-latency uses the same definition for latency as
        user-to-network-requirements.max-latency.

        For successful status-info, the network returns a value less
        than or equal to user-to-network-requirements.max-latency.

        If the time-aware container is present in the
        traffic-specification of the Talker, the value is expressed as
        nanoseconds after the start of the Talkers
        traffic-specification.interval.

        If the time-aware container is not present in the
        traffic-specification of the Talker, the value is expressed as
        nanoseconds after the Talkers transmit of any frame in the
        Stream, at any arbitrary time.

        If user-to-network-requirements.num-seamless-trees is one,
        accumulated-latency shall provide the worst-case maximum latency
        for the current path from Talker to each Listener. If the path
        is changed (e.g. by a spanning tree protocol),
        accumulated-latency changes accordingly.

        If user-to-network-requirements.num-seamless-trees is greater
        than one, accumulated-latency shall provide the worst-case
        maximum latency for all paths configured from the Talker to each

        "Identifies the MEP Linktrace Initiator that is
        originating this LTM.

        The low-order six octets contain a 48-bit IEEE MAC
        address unique to the system in which the MEP Linktrace
        Initiator or Linktrace Responder resides. The high-order
```

```
                two octets contain a value sufficient to uniquely
                identify the MEP Linktrace Initiator or Linktrace
                Responder within that system.

                For most Bridges, the address of any MAC attached to the
                Bridge will suffice for the low-order six octets, and 0
                for the high-order octets. In some situations, e.g., if
                multiple virtual Bridges utilizing emulated LANs are
                implemented in a single physical system, the high-order
                two octets can be used to differentiate among the
                transmitting entities.

                The value returned is undefined if the
                transmit-linktrace input action was not accepted.";

Annex A

(normative)

PICS proforma—Bridge implementations[55]

A.1 Introduction

The supplier of a protocol implementation that is claimed to conform to this standard shall complete the following Protocol Implementation Conformance Statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. The PICS can have a number of uses, including use:

a) By the protocol implementer, as a checklist to reduce the risk of failure to conform to the standard through oversight.
b) By the supplier and acquirer—or potential acquirer—of the implementation, as a detailed indication of the capabilities of the implementation, stated relative to the common basis for understanding provided by the standard PICS proforma.
c) By the user—or potential user—of the implementation, as a basis for initially checking the possibility of interworking with another implementation (note that, while interworking can never be guaranteed, failure to interwork can often be predicted from incompatible PICSs).
d) By a protocol tester, as the basis for selecting appropriate tests against which to assess the claim for conformance of the implementation.

A.2 Abbreviations and special symbols

A.2.1 Status symbols

M	mandatory
O	optional
O.n	optional, but support of at least one of the group of options labeled by the same numeral n is required
X	prohibited
pred:	conditional-item symbol, including predicate identification: see A.3.4
¬	logical negation, applied to a conditional item’s predicate

A.2.2 General abbreviations

N/A	not applicable
PICS	Protocol Implementation Conformance Statement

[55] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

A.3 Instructions for completing the PICS proforma

A.3.1 General structure of the PICS proforma

The first part of the PICS proforma, implementation identification and protocol summary, is to be completed as indicated with the information necessary to identify fully both the supplier and the implementation.

The main part of the PICS proforma is a fixed-format questionnaire, divided into several subclauses, each containing a number of individual items. Answers to the questionnaire items are to be provided in the rightmost column, either by simply marking an answer to indicate a restricted choice (usually Yes or No) or by entering a value or a set or range of values. (Note that there are some items where two or more choices from a set of possible answers can apply; all relevant choices are to be marked.)

Each item is identified by an item reference in the first column. The second column contains the question to be answered; the third column records the status of the item—whether support is mandatory, optional, or conditional: see also A.3.4. The fourth column contains the reference or references to the material that specifies the item in the main body of this standard, and the fifth column provides the space for the answers.

A supplier may also provide (or be required to provide) further information, categorized as either Additional Information or Exception Information. When present, each kind of further information is to be provided in a further subclause of items labeled Ai or Xi, respectively, for cross-referencing purposes, where i is any unambiguous identification for the item (e.g., simply a numeral). There are no other restrictions on its format and presentation.

A completed PICS proforma, including any Additional Information and Exception Information, is the Protocol Implementation Conformation Statement for the implementation in question.

NOTE—Where an implementation is capable of being configured in more than one way, a single PICS may be able to describe all such configurations. However, the supplier has the choice of providing more than one PICS, each covering some subset of the implementation's configuration capabilities, in case that makes for easier and clearer presentation of the information.

A.3.2 Additional information

Items of Additional Information allow a supplier to provide further information intended to assist the interpretation of the PICS. It is not intended or expected that a large quantity will be supplied, and a PICS can be considered complete without any such information. Examples might be an outline of the ways in which a (single) implementation can be set up to operate in a variety of environments and configurations, or information about aspects of the implementation that are outside the scope of this standard but that have a bearing on the answers to some items.

References to items of Additional Information may be entered next to any answer in the questionnaire and may be included in items of Exception Information.

A.3.3 Exception information

It may occasionally happen that a supplier will wish to answer an item with mandatory status (after any conditions have been applied) in a way that conflicts with the indicated requirement. No preprinted answer will be found in the Support column for this item. Instead, the supplier shall write the missing answer into the Support column, together with an *Xi* reference to an item of Exception Information, and shall provide the appropriate rationale in the Exception item itself.

An implementation for which an Exception item is required in this way does not conform to this standard.

NOTE—A possible reason for the situation described previously is that a defect in this standard has been reported, a correction for which is expected to change the requirement not met by the implementation.

A.3.4 Conditional status

A.3.4.1 Conditional items

The PICS proforma contains a number of conditional items. These are items for which both the applicability of the item itself, and its status if it does apply—mandatory or optional—are dependent on whether certain other items are supported.

Where a group of items is subject to the same condition for applicability, a separate preliminary question about the condition appears at the head of the group, with an instruction to skip to a later point in the questionnaire if the "Not Applicable" answer is selected. Otherwise, individual conditional items are indicated by a conditional symbol in the Status column.

A conditional symbol is of the form "**pred:** S" where **pred** is a predicate as described in A.3.4.2 below, and S is a status symbol, M or O.

If the value of the predicate is true (see A.3.4.2), the conditional item is applicable, and its status is indicated by the status symbol following the predicate: The answer column is to be marked in the usual way. If the value of the predicate is false, the "Not Applicable" (N/A) answer is to be marked.

A.3.4.2 Predicates

A predicate is one of the following:

a) An item-reference for an item in the PICS proforma: The value of the predicate is true if the item is marked as supported and is false otherwise.
b) A predicate-name, for a predicate defined as a boolean expression constructed by combining item-references using the boolean operator OR: The value of the predicate is true if one or more of the items is marked as supported.
c) The logical negation symbol "¬" prefixed to an item-reference or predicate-name: The value of the predicate is true if the value of the predicate formed by omitting the "¬" symbol is false, and vice versa.

Each item whose reference is used in a predicate or predicate definition, or in a preliminary question for grouped conditional items, is indicated by an asterisk in the Item column.

A.4 PICS proforma for IEEE Std 802.1Q—Bridge implementations

A.4.1 Implementation identification

Supplier	
Contact point for queries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification, e.g., name(s) and version(s) of machines and/or operating system names	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirement for full identification. NOTE 2—The terms “Name” and “Version” should be interpreted appropriately to correspond with a supplier’s terminology (e.g., Type, Series, Model).	

A.4.2 Protocol summary, IEEE Std 802.1Q

Identification of protocol specification	IEEE Std 802.1Q-2022, IEEE Standard for Local and metropolitan area networks—Bridges and Bridged Networks
Identification of amendments and corrigenda to the PICS proforma that have been completed as part of the PICS	Amd. : Corr. : Amd. : Corr. :
Have any Exception items been required? (See A.3.3: the answer “Yes” means that the implementation does not conform to IEEE Std 802.1Q)	No [ ] Yes [ ]

Date of Statement	

A.5 Major capabilities

Item	Feature	Status	References	Support
	If the implementation is an end station implementation, mark "N/A" and continue at Annex B.			N/A [ ]
MAC	Do the implementations of MAC technologies and support of the MAC Internal Sublayer Service (ISS) conform to MAC standards as specified in IEEE Std 802.1AC? (If support of a specific MAC technology is claimed, any PICS proforma(s) required by the standard specifying that technology shall also be completed.)	M	A.6, IEEE Std 802.1AC	Yes [ ]
LLC	Is a class of LLC supporting Type 1 operations supported on all Bridge Ports in conformance with ISO/IEC 8802-2? (The PICS proforma required by ISO/IEC 8802-2 shall also be completed.)	M	8.2, 8.3, 8.1.3, ISO/IEC 8802-2	Yes [ ]
RLY	Does the implementation relay and filter frames as specified?	M	8.5, 8.6, 8.7, 6.12, 8.8, A.7	Yes [ ]
BFS	Does the implementation maintain the information required to make frame filtering decisions and support Basic Filtering Services?	M	8.1, 8.5, 8.7, 8.8, A.8	Yes [ ]
ADDR	Does the implementation conform to the provisions for addressing?	M	8.13, A.9	Yes [ ]
MBRIDGE	Can the Bridge be configured to operate as a VLAN-unaware MAC Bridge	O.2	5.14	Yes [ ] No [ ]
TPMR	Can the Bridge be configured to operate as a Two Port MAC Relay?	O.2	5.16	Yes [ ] No [ ]
MSP	Is the operation of the MAC Status Propagation Entity (MSPE) supported?	TPMR: M	Clause 23	Yes [ ] N/A [ ]
RSTP	Is RSTP implemented?	¬TPMR:O.1 TPMR:X	Clause 5, Clause 13, Clause 14, A.10	Yes [ ] No [ ]
BPDU	Are transmitted Bridge Protocol Data Units (BPDUs) encoded and received BPDUs validated as specified?	¬TPMR:M TPMR:X	A.11, 13.29.27, 13.29.28, 13.29.29, Clause 14	Yes [ ] No [ ]
IMP	Are the required implementation parameters included in this completed PICS?	M	8.8, A.12	Yes [ ]
PERF	Are the required performance parameters included in this completed PICS? (Operation of the Bridge within the specified parameters shall not violate any of the other conformance provisions of this standard.)	M	8.5, A.13	Yes [ ]
MGT	Is management of the Bridge supported?	O PBBTE OR TPMR OR SRRM:M	Clause 5, A.14	Yes [ ] No [ ]

A.5 Major capabilities *(continued)*

Item	Feature	Status	References	Support
RMGT	Is a remote management protocol supported?	MGT:O PBBTE OR TPMR OR SRRM:M	Clause 5, A.15	Yes [ ] No [ ]
MIB	Does the system implementation support management operations using SMIv2 MIB modules?	MGT:O	8.12, Clause 17	Yes [ ] No [ ] N/A [ ]
TC	Are multiple traffic classes supported for relaying frames?	O	8.6.6, 8.6.7, 8.6.8, A.16	Yes [ ] No [ ]
EFS	Are Extended Filtering Services supported for relaying and filtering frames?	¬TPMR:O TPMR:X	A.17, 6.12	Yes [ ] No [ ]
MMRP	Is the operation of the Multiple MAC Registration Protocol supported?	EFS:M	5.4.1, A.20	Yes [ ] N/A [ ]
VLAN	Does the implementation support the ability to insert tag headers into, modify tag headers in, and remove tag headers from relayed frames?	¬(MBRIDGE OR TPMR):M (MBRIDGE OR TPMR):X	5.4, 6.3, 6.8, 6.9, 8.6, 6.12, Clause 9	Yes [ ] No [ ]
VTR	Does the implementation support a VLAN Identifier (VID) translation table?	¬(TPMR OR MBRIDGE):O (MBRIDGE OR TPMR):X	6.9	Yes [ ] No [ ]
MVRP	Is automatic configuration and management of VLAN topology using MVRP supported?	¬(TPMR OR MBRIDGE):M TPMR:X	5.4, A.21	Yes [ ] No [ ]
MRP	Is the Multiple Registration Protocol (MRP) implemented in support of MRP Applications?	MMRP:M MVRP:M	Clause 10, A.20, A.21, A.22	Yes [ ] N/A [ ]
MRP1	Does the MRP implementation support operation of the Full Participant?	MRP:O.4	Clause 10, A.22	Yes [ ] No [ ] N/A [ ]
MRP2	Does the MRP implementation support operation of the Full Participant, point-to-point subset?	MRP:O.4	Clause 10, A.22	Yes [ ] No [ ] N/A [ ]
MSTP	Is MSTP implemented?	¬TPMR:O.1 TPMR:X	Clause 5, Clause 7, 8.4, 8.6.1, 8.8.8, 8.9, 8.10, 8.13.7, 11.2.3.1.2, Clause 13, Clause 14, A.18	Yes [ ] No [ ]
VMGT	Does the implementation support VLAN management operations?	¬(TPMR OR MBRIDGE) AND MGT:O (MBRIDGE OR TPMR):X	5.4.1, 12.10.2, 12.10.3	Yes [ ] No [ ] N/A [ ]
CB	Can the Bridge be configured to operate as a C-VLAN Bridge, recognizing and using C-TAGs?	O.2	5.9	Yes [ ] No [ ]
PB	Can the Bridge be configured to operate as a Provider Bridge, recognizing and using S-TAGs?	O.2	5.10	Yes [ ] No [ ]

A.5 Major capabilities *(continued)*

Item	Feature	Status	References	Support
PEB	Can the Bridge be configured to operate as a Provider Edge Bridge with one or more Ports operating as Customer Edge Ports (CEPs)?	PB:O	5.10.2	Yes [ ] No [ ] N/A [ ]
RCSI	Can the Bridge be configured to operate as a Provider Edge Bridge with one or more Ports operating as Remote Customer Access Ports (RCAPs)?	PEB:O	5.10.2	Yes [ ] No [ ] N/A [ ]
PB-2	State which Ports support the following values for the Provider Bridge Port Type: — PNP — CNP — CEP — RCAP	PB:M	5.10	Ports: _____ Ports: _____ Ports: _____ Ports: _____
CFM	Is Connectivity Fault Management (CFM) implemented?	O PBBTE: M	5.4.1.4, Clause 19, Clause 20, Clause 21, Clause 22	Yes [ ] No [ ]
CFM-T	Does the implementation support a CFM MD-level zero MIP on each Port?	TPMR:M	5.15, Clause 18–Clause 22	Yes [ ] N/A [ ] N/A [ ]
BRG	Is this system a Bridge, and not a Station, for the purposes of CFM?	CFM: O	22.4	Yes [ ] No [ ]
BEB	Can the Bridge be configured to operate as a Backbone Edge Bridge, recognizing and using I-TAGs?	O.2	5.12	Yes [ ] No [ ] N/A [ ]
BEB-B	Can the Bridge be configured to operate as a Backbone Edge Bridge with one or more Ports operating as a Customer Backbone Ports (CBPs)?	BEB: O.3	5.12	Yes [ ] No [ ] N/A [ ]
BEB-I	Can the Bridge be configured to operate as a Backbone Edge Bridge with one or more Ports operating as a Provider Instance Port (PIP)?	BEB: O.3	5.12	Yes [ ] No [ ] N/A [ ]
BEB-1	State which Ports support the following values for the Backbone Edge Bridge Port Type: — PIP — CNP — PNP — CBP — CEP — RCAP	BEB: M	5.11	PIP: _____ CNP: _____ PNP: _____ CBP: _____ CEP: _____ RCAP: _____
DDCFM	Is management of data-driven and data-dependent connectivity faults implemented?	O	Clause 19, Clause 29	Yes [ ] No [ ]
PBBTE	Can the Bridge be configured by an external agent to provide TESIs?	O	8.4, 8.9, 25.10	Yes [ ] No [ ]
EXAG	Is the active topology, learning and forwarding of the TESIs under the control of an external agent?	PBBTE: O.1	8.4, 8.9	Yes [ ] No [ ] N/A [ ]

A.5 Major capabilities *(continued)*

Item	Feature	Status	References	Support
ESPVID	Are the VIDs associated with ESPs, the ESP-VIDs, allocated to the TE-MSTID?	PBBTE: M	8.9	Yes [ ] N/A [ ]
ESPFID	Is every ESP-VID allocated to a distinct FID?	PBBTE: M	25.10	Yes [ ] N/A [ ]
BCBTE	Can the Bridge be configured to operate as a Backbone Core Bridge (BCB) that provides TESIs?	PB AND PBBTE: O.5	5.10, 5.6.2	Yes [ ] N/A [ ] N/A [ ]
BEBTE	Can the Bridge be configured to operate as a Backbone Edge Bridge that provides TESIs?	BEB AND PBBTE: O.5	5.8.2, 5.12.1	Yes [ ] No[ ] N/A [ ]
PS	Is protection switching supported?	BEBTE: M	5.8.2, 26.10.3	Yes [ ] N/A [ ]
FQTSS	Does the implementation support Forwarding and Queuing Enhancements for time-sensitive streams?	O	5.4.1.5, Clause 34	Yes [ ] No [ ]
CN	Is congestion notification implemented?	O	5.4.3, Clause 30, Clause 31, Clause 32, Clause 33	Yes [ ] No [ ]
BRG1	Is this system a Bridge, and not an end station, for the purposes of congestion notification?	CN: O		Yes [ ] No [ ] N/A [ ]
SRP	Does the implementation support the Stream Reservation Protocol?	O	Clause 35	Yes [ ] No [ ]
MIRP	Is the Multiple I-SID Registration Protocol supported?	BEB-I OR BEB-B: O	5.7.1 item e), 5.8.1 item e)	Yes [ ] No [ ] N/A [ ]
PFC	Is Priority-based Flow Control implemented?	O	5.11, Clause 36	Yes [ ] No [ ]
ETS	Does the implementation support bandwidth management using ETS?	O	Clause 37	Yes [ ] No [ ]
DCBX	Does the implementation support configuration management via DCBX?	O	Clause 38	Yes [ ] No [ ]
IPS	Is Infrastructure Protection Switching supported?	PBBTE: O	5.6.2, 5.8.2, 26.11	Yes [ ] No [ ] N/A [ ]
SPB	Is Shortest Path Bridging supported?	O.1	5.4.5, Clause 27	Yes [ ] No [ ]
EVB-B	Does the implementation support the functionality of an EVB Bridge?	O	5.23	Yes [ ] No [ ]
EVB-S	Does the implementation support the functionality of an EVB station?	O	5.24	Yes [ ] No [ ]
ECMP	Is Equal Cost Multiple Paths supported?	SPBM:O	5.4.5.1, 44.1	Yes [ ] No [ ] N/A [ ]
FF	Is flow filtering supported, including inserting, modifying, and removing F-TAGs from relayed frames?	ECMP:O	5.4.5.2, 44.2	Yes [ ] No [ ]
FF-S	Does the S-VLAN component support F-TAG processing on each PNP?	PB AND FF:M	5.6.4, 44.2.2	Yes [ ] N/A [ ]
FF-B	Does the B-component support F-TAG processing on each CBP and PNP?	BEB AND FF:M	5.8.4, 44.2.2	Yes [ ] N/A [ ]
PCR	Is Path Control and Reservation supported?	O	Clause 45	Yes [ ] No [ ]

A.5 Major capabilities *(continued)*

Item	Feature	Status	References	Support
SCHED	Does the implementation support scheduled traffic?	O	5.4.1, 5.13.1, 8.6.8, 8.6.9, 12.29, 17.7.22	Yes [ ] No [ ]
PRE	Does the implementation support frame preemption?	O	5.4.1, 5.13.1, 6.7.2, 8.6.8, 12.30, 17.7.23	Yes [ ] No [ ]
PSFP	Does the implementation support PSFP?	O	8.6.5.2.1, 8.6.6 items d) and e), 8.6.10, 12.31	Yes [ ] No [ ]
ATS	Does the implementation support Asynchronous Traffic Shaping?	O	5.4.1.10, 5.13.1.3, 8.6.5.2.2, 8.6.6 items d) and e), 8.6.8, 8.6.8.5, 8.6.11, 12.31	Yes [ ] No [ ]
CQF	Does the implementation support cyclic queuing and forwarding?	O	5.4.1.9, 5.13.1.2	Yes [ ] No [ ]
YANG	Does the implementation support management operations using the YANG modules?	MGMT:O	8.12, 48	Yes [ ] No [ ] N/A [ ]
SRRM	Does the implementation support Stream reservation remote management?	O	5.4.1.10, 12.32, A.48	Yes [ ] No [ ]
CNC-S	Does the implementation support the functionality of a Centralized Network Configuration (CNC) station?	O	5.29, 46.2, A.17	Yes [ ] No [ ]
VDPnNVE	Does the implementation support the VDP NVO3 functionality of an nNVE?	O	5.30.1	Yes [ ] No [ ]
VDPtNVE	Does the implementation support the VDP NVO3 functionality of a tNVE?	O	5.30.2	Yes [ ] No [ ]

A.6 Media access control methods

Item	Feature	Status	References	Support
	Which media access control methods are implemented in conformance with the relevant MAC Standards?		5.4, IEEE Std 802.1AC	
MAC-802.3	Ethernet, IEEE Std 802.3	O.2	IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-802.11-PORT	IEEE 802.11 LAN Portal, IEEE Std 802.11	O.2	G.4.1, IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-PMPN-N	PMPN multiple port, IEEE Std 802.1AC	O.2	G.4.1, IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-PMPN-1	PMPN single port, IEEE Std 802.1AC	O.2	G.4.1, IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-802.20-WB	IEEE 802.20™ Wideband Mode	O.2	IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-802.20-625	IEEE 802.20 625k-MC Mode	O.2	IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-1	Has a PICS been completed for each of the media access control methods implemented as required by the relevant MAC standards?	M		Yes [ ]
MAC-2	Do all the media access control methods implemented support the MAC ISS as specified?	M	IEEE Std 802.1AC	Yes [ ]
MAC-3	Are the adminPointToPointMAC and operPointToPointMAC parameters implemented on all Ports?	M	IEEE Std 802.1AC	Yes [ ]
MAC-4	Does the implementation support the use of the adminEdgePort and operEdgePort parameters on any Ports?	O	13.27.1, 13.27.44	Yes [ ] No [ ]
MAC-4a	State which Bridge Ports support the adminEdgePort and operEdgePort parameters.			Ports_____
MAC-5	Is the priority of received frames set to the Default Priority where specified for the MAC?	M	IEEE Std 802.1AC	Yes [ ]
MAC-6	Can the Default Priority be set for each Port?	O	IEEE Std 802.1AC	Yes [ ] No [ ]
MAC-7	Can the Default Priority be set to any of 0–7?	MAC-6:M	IEEE Std 802.1AC	Yes [ ] N/A [ ]
MAC-12	Is the minimum tagged frame length that can be transmitted on IEEE 802.3 Ports less than 68 (but 64 or more) octets?	MAC-802.3:O	IEEE Std 802.1AC	Yes [ ] No [ ] N/A [ ]

A.7 Relay and filtering of frames

Item	Feature	Status	References	Support
RLY-1	Are received frames with MAC method errors discarded?	M	6.3, 8.5	Yes [ ]
RLY-2	Are user data frames the only type of frame relayed?	M	8.5	Yes [ ]
RLY-3	Is the priority of each frame relayed regenerated as specified?	¬TPMR: M TPMR: O	IEEE Std 802.1AC, 6.9.4, 8.5, 6.20	Yes [ ] No [ ]
RLY-4	Are the default values of the Priority Regeneration Table as specified for each Port?	M	6.9.4, Table 6-4	Yes [ ]
RLY-5	Can the Priority Regeneration Table be modified?	O	6.9.4, Table 6-4	Yes [ ] No [ ]
RLY-6	Can the entries in the Priority Regeneration Table be set independently for each priority and Port and to any of the full range of values?	RLY-5: M	6.9.4, Table 6-4	Yes [ ] N/A [ ]
RLY-7	Are frames transmitted by an LLC User attached at a Bridge Port also submitted for relay?	¬TPMR: M TPMR: X	8.5	Yes [ ] No [ ]
RLY-8	Are correctly received user data frames relayed subject to the conditions imposed by the Forwarding Process?	M	8.6, 8.6.2, 8.6.2, 8.6.3, 8.6.5, 8.6.4, 8.8, Table 8-10, Table 8-11, Table 8-12	Yes [ ]
RLY-9	Is the order of relayed frames preserved as required by the forwarding process?	M	8.6.6	Yes [ ]
RLY-10	Is a relayed frame submitted to a MAC Entity for transmission only once?	M	8.6.7	Yes [ ]
RLY-11	Is a maximum Bridge transit delay enforced for relayed frames?	M	8.6.7	Yes [ ]
RLY-12	Are queued frames discarded if a Port leaves the Forwarding State?	M	8.6.7	Yes [ ]
RLY-13	Is the default algorithm for selecting frames for transmission supported?	M	8.6.8	Yes [ ]
RLY-14	Is the access priority of each transmitted frame as specified for each media access method?	M	6.5.9	Yes [ ]
RLY-15	Is the Frame Check Sequence (FCS) of frames relayed between Ports of the same MAC type preserved?	O	6.9	Yes [ ] No [ ]
RLY-16	Is the undetected frame error rate greater than that achievable by preserving the FCS?	¬RLY-15:X	6.5.7, 6.9	No [ ] N/A [ ]
RLY-17	Are CFM frames discarded if they enter the queue subsequent to the Port leaving the Forwarding state?	CFM: X	8.6.7	No [ ] N/A [ ]

A.7 Relay and filtering of frames *(continued)*

Item	Feature	Status	References	Support
RLY-18	Are CFM frames discarded when the Port leaves the Forwarding state?	CFM: O	8.6.7	Yes [ ] No [ ]
RLY-19	Are received frames discarded (or not discarded) in accordance with the specification of a PIP, CBP, or Backbone Service Instance Multiplex Entity?	BEB: M	6.10.1, 6.11.1, 6.18.1	Yes [ ] N/A [ ]
RLY-20	Is the forwarding process for flow filtering supported?	FF:M	5.4.5.2, 44.2.3	Yes [ ] N/A [ ]

A.8 Basic Filtering Services

Item	Feature	Status	References	Support
BFS-1	Are correctly received user data frames submitted to the Learning Process if the learning variable is set?	¬TPMR: M TPMR: X	8.6, 8.7, 5.15	Yes [ ] No [ ]
BFS-2	Are correctly received frames of types other than user data frames submitted to the Learning Process?	¬TPMR: O TPMR: X	8.6, 8.7, 5.15	Yes [ ] No [ ]
BFS-3	Does the Filtering Database (FDB) support creation and update of Dynamic Filtering Entries by the Learning Process?	¬TPMR: M TPMR: X	8.7, 8.8, 8.8.3, 5.15	Yes [ ] No [ ]
BFS-4	Are Dynamic Filtering Entries created and updated if and only if the Port State permits?	M	8.7, 8.8.3	Yes [ ]
BFS-5	Are Dynamic Filtering Entries created on receipt of frames with a group source address?	X	8.7, 8.8.3	No [ ]
BFS-6	Can a Dynamic Filtering Entry be created that conflicts with an existing Static Filtering Entry?	X	8.7, 8.8, 8.8.2. 8.8.3	No [ ]
BFS-7	Are existing Dynamic Filtering Entries removed to allow creation of a new entry if the FDB is full?	¬TPMR: O TPMR: X	8.7, 8.8.3, 5.15	Yes [ ] No [ ]
BFS-8	Does the FDB contain Static Filtering Entries?	M	8.8.2	Yes [ ]
BFS-9	Are Static Filtering Entries aged out?	X	8.8	No [ ]
BFS-10	Can Static Filtering Entries be created, modified, and deleted by management?	¬(TPMR OR PBBTE): O PBBTE: M TPMR: X	8.8, 5.15	Yes [ ] No [ ]
BFS-11	Can Static Filtering Entries be made for individual and group MAC addresses?	BFS-10:M	8.8.2	Yes [ ] N/A [ ]
BFS-12	Can a Static Filtering Entry be made for the broadcast MAC address?	BFS-10:M	8.8.2	Yes [ ] N/A[ ]
BFS-13	Can a Static Filtering Entry specify a forwarding Port Map?	BFS-10:M	8.8.2	Yes [ ] N/A [ ]

A.8 Basic Filtering Services

Item	Feature	Status	References	Support
BFS-14	Can a Static Filtering Entry specify a filtering Port Map?	BFS-10:M	8.8.2	Yes [ ] N/A [ ]
BFS-15	Does the creation of a Static Filtering Entry remove any conflicting information in a Dynamic Filtering Entry for the same address?	M	8.8.2, 8.8.3	Yes [ ]
BFS-16	Can a separate Static Filtering Entry with a Port Map be created for each inbound Port?	¬TPMR: O TPMR: X	8.8.2, 5.15	Yes [ ] No [ ]
BFS-17	Are Dynamic Filtering Entries aged out of the FDB if not updated?	M	8.8.3	Yes [ ]
BFS-18	Can more than one Dynamic Filtering Entry be created for the same MAC address?	X	8.8.3	No [ ]
BFS-19	Can the Bridge be configured to use the recommended default Ageing Time?	¬TPMR: O TPMR: X	8.8.3, Table 8-9, 5.15	Yes [ ] No [ ]
BFS-20	Can the Bridge be configured to use any value in the range specified for Ageing Time?	¬TPMR: O TPMR: X	8.8.3, Table 8-9, 5.15	Yes [ ] No [ ]
BFS-21	Is the FDB initialized with the entries contained in the Permanent Database?	M	8.8.11	Yes [ ]
BFS-22	Are correctly received user data frames submitted to the Learning Process if they are associated with an ESP-VID?	PBBTE: X	8.4, 8.6.1	No [ ] N/A [ ]
BFS-23	Are correctly received user data frames that are associated with an ESP-VID discarded if their destination MAC address is unknown?	PBBTE: M	8.8.1	Yes [ ] N/A [ ]

A.9 Addressing

Item	Feature	Status	References	Support
ADDR-1	Does each Port have a separate MAC address?	M	8.13.2	Yes [ ]
ADDR-2	Are frames addressed to a MAC address for a Port and received from or relayed to the attached LAN submitted to LLC Service User for the destination LLC Address?	M	8.5, 8.13.2	Yes [ ]
ADDR-3	Are all BPDUs and MRP PDUs transmitted using the Bridge Spanning Tree Protocol LLC Address?	M	8.13.3, Table 8-15	Yes [ ]
ADDR-4	Are PDUs addressed to the Bridge Spanning Tree Protocol Address with an unknown Protocol Identifier (PID) discarded on receipt?	M	14.5	Yes [ ]
ADDR-5	Are all BPDUs generated by a Spanning Tree Protocol Entity associated with a C-VLAN component transmitted to the Bridge Group Address?	CB OR PEB: M	8.13.3, Table 8-1, Table 8-2	Yes [ ] N/A [ ]

A.9 Addressing

Item	Feature	Status	References	Support
ADDR-6	Are all BPDUs generated by a Spanning Tree Protocol Entity associated with an S-VLAN component, I-component, or B-component transmitted to the Provider Bridge Group Address?	PB: M BEB:M	Table 8-1	Yes [ ] N/A [ ]
ADDR-7	Are all MRPDUs transmitted to the group address assigned for the MRP Application?	M	8.13.3, Table 8-1	Yes [ ]
ADDR-8	Is it possible to create entries in the Permanent Database or FDB for unsupported MRP application addresses or delete or modify entries for supported application addresses?	X	8.13.3	No [ ]
ADDR-9	Is the source MAC address of BPDUs and MRPDUs for MRP Applications supported by the Bridge address of the transmitting Port?	M	8.13.3	Yes [ ]
ADDR-10	Is the source MAC address of BPDUs generated by a Spanning Tree Protocol Entity associated with a C-VLAN component of a Provider Edge Bridge the address of the associated CEP?	PEB:M	12.13	Yes [ ] N/A [ ]
ADDR-11	Is Bridge Management accessible through a Port using the MAC address of the Port?	MGT:O	8.13.7	Yes [ ] No [ ] N/A [ ]
ADDR-12	Is an EUI-48 universally administered MAC Address assigned to each Bridge as its Bridge Address?	M	8.13.8	Yes [ ]
ADDR-13	Is the Bridge Address the Address of a Port?	O	8.13.8	Yes [ ] No [ ]
ADDR-14	Is the Bridge Address the Address of Port 1?	ADDR-13: O	8.13.8	Yes [ ] No [ ] N/A [ ]
ADDR-15	Are frames addressed to any of the C-VLAN component Reserved Addresses relayed by a C-VLAN component?	CB or PB:X	8.13.4, Table 8-1	No [ ] N/A [ ]
ADDR-16	Are frames addressed to any of the S-VLAN component Reserved Addresses relayed by an S-VLAN component, I-component, or B-component?	PB:X BEB:X	Table 8-2	No [ ] N/A [ ]
ADDR-17	Is it possible to delete or modify entries in the Permanent Database and FDB for the Reserved Addresses?	X	8.13.4	No [ ]
ADDR-18	Are PIPs capable of filtering frames received with a B-SA matching the PIP MAC address?	BEB-I: O	5.7.1	Yes [ ] No [ ] N/A [ ]
ADDR-19	Is the address of an internal PIP on Backbone Edge Bridge (BEB) supporting a TESI configured to take the value of the MAC address of the connected CBP?	BEBTE:M	25.10	Yes [ ] N/A [ ]

A.10 Rapid Spanning Tree Protocol (RSTP)

Item	Feature	Status	References	Support
	If item RSTP is not supported, mark "N/A" and continue at A.11			N/A [ ]
RSTP-1	Does each Bridge have a unique identifier based on the Bridge Address, and a unique identifier for each Port?	RSTP:M	13.2	Yes [ ]
RSTP-2	Can each Port be configured as an edge port by setting the adminEdgePort parameter?	RSTP:O	13.4	Yes [ ] No [ ]
RSTP-3	Can each Port be configured to automatically determine if it is an edge port by setting the autoEdgePort parameter?	RSTP:O	13.4	Yes [ ] No [ ]
RSTP-4	Are learned MAC addresses transferred from a retiring Root Port to a new Root Port?	RSTP:O	13.19	Yes [ ] No [ ]
RSTP-5	Is the Spanning Tree Protocol Entity reinitialized if the Force Protocol Version parameter is modified?	RSTP:M	13.26	Yes [ ]
RSTP-6	Are spanning tree priority vectors and Port Role assignments recomputed if the Bridge Identifier Priority, Port Identifier Priority, or Port Path Costs change?	RSTP:M	13.26	Yes [ ]
RSTP-7	Is the txCount variable for a Port set to zero if the Port's Transmit Hold Count is modified?	RSTP:M	13.26	Yes [ ]
RSTP-8	Are the recommended default values of Migrate Time, Bridge Hello Time, Bridge Max Age, Bridge Forward Delay, and Transmit Hold Count used?	RSTP:O	13.25	Yes [ ] No [ ]
RSTP-9	Can the Bridge Max Age, Bridge Forward Delay, and Transmit Hold Count parameters be set?	RSTP:O	13.25, 13.26	Yes [ ] No [ ]
RSTP-10	Can Bridge Max Age, Bridge Forward Delay, Transmit Hold Count be set to any value in the permitted range?	RSTP-9: M	13.25, 13.30, Table 13-5	Yes [ ] N/A [ ]
RSTP-11	Are the relationships between Bridge Hello Time, Bridge Max Age, and Bridge Forward Delay enforced?	RSTP-9: M	13.25	Yes [ ] N/A [ ]
RSTP-12	Are the recommended values of Bridge Identifier Priority, Port Path Costs, and Port Identifier Priorities used?	RSTP:O	13.18	Yes [ ] No [ ]
RSTP-13	Can the Bridge Identifier Priority, Port Path Costs, and Port Identifier Priorities be set?	RSTP:O	13.1, 13.4.1, 13.18, 13.25, 13.26, 13.27	Yes [ ] No [ ]
RSTP-14	Can the Bridge Identifier Priority and Port Identifier Priorities be set to any of the values in the ranges specified?	RSTP-13: M	13.18	Yes [ ] N/A [ ]
RSTP-15	Can the Port Path Cost for each Port be set to any of the values in the specified range?	RSTP-13: M	13.18	Yes [ ] N/A[ ]
RSTP-16	Are Port Path Costs changed automatically by default if port speeds change?	RSTP:X	13.18	No [ ]

A.10 Rapid Spanning Tree Protocol (RSTP)

Item	Feature	Status	References	Support
RSTP-17	Is one instance of the Port Role Selection state machine implemented for the Bridge; is one instance of each of the Port Timers, Port Receive, Port Protocol Migration, Bridge Detection, Port Transmit, Port Information, Port Role Transition, Port State Transition, and Topology Change state machines implemented per Port; and are the referenced definitions and declarations followed for all machines?	RSTP:M	13.5.2, 13.24, 13.36, 13.30, 13.31, 13.32, 13.33, 13.34, 13.35, 13.37, 13.38, 13.38.2	Yes [ ] N/A [ ]
RSTP-18	Is it possible to set each Port Protocol Migration state machine's mcheck variable?	RSTP:O	13.27.38	Yes [ ] No [ ]
RSTP-19	Is a single instance of each of the timer variables implemented per Port?	RSTP:M	13.30	Yes [ ]
RSTP-20	Are the values for maximum RSTP processing delay and maximum BPDU transmission delay ever exceeded for any of the specified external events, actions, internal events, or transmissions?	RSTP:X	24.3, Table 24-1	No [ ]
RSTP-21	Does each C-VLAN component of a Provider Edge Bridge operate an instance of Rapid Spanning Tree (RST) as modified for CEPs?	RSTP AND PEB:M	13.41	Yes [ ] N/A [ ]
RSTP-22	Does each I-component of a BEB operate an instance of RST as modified for Virtual Instance Ports (VIPs)?	RSTP AND BEB:M	13.42	Yes [ ] N/A [ ]
RSTP-23	Can each Port be configured to support detection of fragile Bridges by setting the autoIsolatePort parameter?	RSTP:O	13.23, 13.27.19	Yes [ ] No [ ]
RSTP-24	Can a port be configured as an L2 Gateway Port by setting the isL2gp parameter?	RSTP:O	13.20, 13.27.26	Yes [ ] No [ ]
RSTP-25	Can the pseudoRootId parameter be set for an L2 Gateway Port?	RSTP-24:M	13.20, 13.27.51	Yes [ ] N/A [ ]
RSTP-26	Is one instance of the L2 Gateway Port state machine implemented for each L2GP port?	RSTP-24:M	13.40	Yes [ ] N/A [ ]

A.11 BPDU encoding

Item	Feature	Status	References	Support
BPDU-1	Do all BPDUs contain an integral number of octets?	M	Clause 14	Yes [ ]
BPDU-2	Are all the following BPDU parameter types encoded as specified?	M	Clause 14	Yes [ ]
	Protocol Identifiers		Clause 14	
	Protocol Version Identifiers		Clause 14	
	BPDU Types		Clause 14	
	Flags		Clause 14	
	Bridge Identifiers		Clause 14	
	Root Path Cost		Clause 14	
	Port Identifiers		Clause 14	
	Timer Values		Clause 14	
BPDU-3	Do Configuration BPDUs have the format, parameters, and parameter values specified?	M	Clause 14	Yes [ ]
BPDU-4	Do Topology Change Notification BPDUs have the format, parameters, and parameter values specified?	M	Clause 14	Yes [ ]
BPDU-5	Do RST BPDUs have the format, parameters, and parameter values specified?	M	Clause 14	Yes [ ]
BPDU-6	Are received BPDUs validated as and only as specified?	M	Clause 14	Yes [ ]
BPDU-7	Does the implementation process BPDUs of prior and possible later protocol versions as specified?	M	Clause 14	Yes [ ]
BPDU-8	Do MST BPDUs have the format, parameters, and parameter values specified?	MSTP:M	14.1	Yes [ ] N/A [ ]

A.12 Implementation parameters

Item	Feature	Status	References	Support
IMP-1	State the Filtering Database Size.	M	8.8	____ entries
IMP-2	State the Permanent Database Size.	M	8.8	____ entries
IMP-3	State the maximum number of VIDs supported by the implementation.	M	5.4, 8.8	_____ VIDs
IMP-4	State the range of VID values supported by the implementation.	M	5.4, 8.8	0 through _____
IMP-5	State the maximum number of FIDs that can be supported by the implementation.	M	8.8.8	____ FIDs
IMP-6	State the maximum number of VIDs that can be allocated to each FID.	M	8.8.8	____ VIDs
IMP-7	State the number of MSTIs supported.	MSTP:M	5.4.1, 8.8.8, 13.14	____ MSTIs N/A [ ]

A.13 Performance

Item	Feature	Status	References	Support
PERF-1	Specify a Guaranteed Port Filtering Rate, and the associated measurement interval *TF*, for each Bridge Port in the format specified below.	M	24.1	
PERF-2	Specify a Guaranteed Bridge Relaying Rate, and the associated measurement interval *TR*, in the format specified below. Supplementary information shall clearly identify the Ports.	M	24.2	

Guaranteed Bridge Relaying Rate	TR
_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)

Port number(s) or other identification	Guaranteed port filtering rate (specify for all ports)	T_F (specify for all ports)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)
	_ _ _ _ _ _ _ _ _ _ _ frames per second	_ _ _ _ _ _ second(s)

A.14 Bridge management

Item	Feature	Status	References	Support
	If item MGT is not supported, or if item TPMR is supported, mark N/A and continue at A.15.			N/A [ ]
MGT-1	Discover Bridge	MGT:M	12.4.1.1	Yes [ ]
MGT-2	Read Bridge	MGT:M	12.4.1.2	Yes [ ]

MGT-247	Read PCR Topology ECT Table managed object	PCR:O	12.28.2.1	Yes [ ] No [ ] N/A [ ]
MGT-248	Does the implementation support the management entities defined in 12.29?	SCHED OR CQF: M	5.4.1 item ad), 5.4.1.9 item c), 5.13.1.2 item c), 12.29	Yes [ ] N/A [ ]
MGT-249	Does the implementation support the management entities defined in 12.30?	PRE: M	5.4.1 item ae), 12.30	Yes [ ] N/A [ ]
MGT-250	Does the implementation support the management entities defined in 12.31 for PSFP?	PSFP OR CQF: M	5.4.1.9 item e), 5.13.1.2 item e), 8.6.5.2.1, 8.6.10, 12.31	Yes [ ] N/A [ ]
MGT-251	Does the implementation support the management entities defined in 12.31 for ATS?	ATS:M	5.4.1.10 item e), 5.13.1.2 item e), 8.6.5.2.1, 8.6.10, 12.31	Yes [ ] N/A [ ]

A.15 Remote management

Item	Feature	Status	References	Support
	If item RMGT is not supported, mark N/A and continue at A.16.			N/A [ ]
RMGT-1	What Management Protocol standard(s) or specification(s) are supported?	RMGT:M	5.4.1	
RMGT-2	What standard(s) or specifications for Managed Objects and Encodings are supported?	RMGT:M	5.4.1	

A.16 Expedited traffic classes

Item	Feature	Status	References	Support
TC-1	Does the implementation provide more than one transmission queue for (a) Bridge Port(s)?	TC: M	8.6.6	Yes [ ] N/A [ ]
TC-2	Is the recommended mapping of priority to traffic classes supported for each Port?	TC: O	8.6.6	Yes [ ] No [ ] N/A [ ]
TC-3	Can the traffic class tables be managed?	TC: O	8.6.6, Table 8-5	Yes [ ] No [ ] N/A [ ]
TC-4	Is the default algorithm for selecting frames for transmission supported?	M	8.6.8	Yes [ ]
TC-5	Are additional algorithms for selecting frames for transmission supported?	O	8.6.8	Yes [ ] No [ ]

A.17 Extended Filtering Services

Item	Feature	Status	References	Support
EFS-1	Can MAC Address Registration Entries be created, updated, and removed from the FDB by MMRP?	EFS:M	8.8, 8.8.4, Clause 10	Yes [ ] N/A [ ]
EFS-2	Can a Static Filtering Entry be created with an address specification that represents a group address, or All Group Addresses, or All Unregistered Group Addresses, and with a control element for each Port that specifies unconditional forwarding, or unconditional filtering, or the use of dynamic or default group filtering information?	EFS:M	8.8.1	Yes [ ] N/A [ ]
EFS-3	Can a Static Filtering Entry be created with an address specification that represents an individual address and with a control element for each Port that specifies unconditional forwarding, or unconditional filtering?	M	8.8.1	Yes [ ]
EFS-4	Can a Static Filtering Entry be created with an address specification that represents an individual address and with a control element for each Port that specifies unconditional forwarding, or unconditional filtering, or the use of dynamic filtering information?	EFS:O	8.8.1	Yes [ ] No [ ] N/A [ ]

A.18 Multiple Spanning Tree Protocol (MSTP)

Item	Feature	Status	References	Support
	If item MSTP is not supported, mark N/A and continue at the start of A.19.			N/A [ ]
MSTP-1	Support the CIST plus a stated maximum number of MSTIs, where that number is at least 2 and at most 64	MSTP:M	5.4.1, 8.8.8, 13.14	Yes [ ]
MSTP-2	Support at least as many FIDs as MSTIs	MSTP:M	5.4, 5.4.1, 8.8.8	Yes [ ]
MSTP-3	Associate each FID to a spanning tree	MSTP:M	5.4, 8.9.3	Yes [ ]
MSTP-4	Transmit and receive MST Configuration Identifier (MCID) information	MSTP:M	5.4, 8.9.2	Yes [ ]
MSTP-5	Support a set of port state information per spanning tree per port	MSTP:M	5.4, 8.4, 13.38	Yes [ ]
MSTP-6	Support an instance of spanning tree protocol per spanning tree per port	MSTP:M	5.4, 8.10, Clause 13	Yes [ ]
MSTP-7	Use the Bridge Group Address as specified	MSTP:M	5.4, 8.13.2	Yes [ ]
MSTP-8	Support default Bridge Forward Delay and Bridge Priority parameter values as specified	MSTP:M	5.4, 13.26	Yes [ ]
MSTP-9	Provision of identifiers for Bridge and Ports	MSTP:M	13.2	Yes [ ]
MSTP-10	Not exceed the values in 24.3 for max BPDU transmission delay	MSTP:M	24.3, Table 24-1	Yes [ ]
MSTP-11	Inclusion of active Ports in computation of the active topology for a given spanning tree	MSTP:M	13.9	Yes [ ]
MSTP-12	Processing of BPDUs received on Ports included in the computation of the active topology for a given spanning tree	MSTP:M	13.9	Yes [ ]
MSTP-13	Discarding received frames in the Discarding state for a given spanning tree	MSTP:M	13.9	Yes [ ]
MSTP-14	Incorporating station location information to the FDB in the Learning and Forwarding states for a given spanning tree	MSTP:M	13.9	Yes [ ]
MSTP-15	Not incorporating station location information to the FDB in the Discarding state for a given spanning tree	MSTP:M	13.9	Yes [ ]
MSTP-16	Transfer learned MAC addresses from a retiring Root Port to a new Root Port for a given spanning tree	MSTP:O	13.16	Yes [ ] No [ ]
MSTP-17	Instances of state machines per Bridge, per Port, and per spanning tree instance, as specified	MSTP:M	13.24	Yes [ ]
MSTP-18	Port Timers state machine support	MSTP:M	13.25, 13.30	Yes [ ]
MSTP-19	Port Receive state machine support	MSTP:M	13.25, 13.31	Yes [ ]
MSTP-20	Port Protocol Migration state machine support	MSTP:M	13.25, 13.32	Yes [ ]
MSTP-21	Port Transmit state machine support	MSTP:M	13.25, 13.34	Yes [ ]

A.18 Multiple Spanning Tree Protocol (MSTP) *(continued)*

Item	Feature	Status	References	Support
MSTP-22	Port Information state machine support	MSTP:M	13.25, 13.35	Yes [ ]
MSTP-23	Port Role Selection state machine support	MSTP:M	13.25, 13.36	Yes [ ]
MSTP-24	Port Role Transitions state machine support	MSTP:M	13.25, 13.37	Yes [ ]
MSTP-25	Port State Transition state machine support	MSTP:M	13.25, 13.38	Yes [ ]
MSTP-26	Topology Change state machine support	MSTP:M	13.25, 13.39	Yes [ ]
MSTP-27	Are the values of Migrate Time, Bridge Hello Time, Bridge Max Age, Bridge Forward Delay, Transmit Hold Count, and Max Hops within the permitted range?	MSTP:M	13.25, Table 13-5	Yes [ ]
MSTP-28	Enforcement of parameter relationships	MSTP:M	13.25, Table 13-5	Yes [ ]
MSTP-29	Range and granularity of priority values	MSTP:M	13.18	Yes [ ]
MSTP-30	Range and granularity of path cost values	MSTP:M	13.18	Yes [ ]
MSTP-31	Are all PNPs capable of supporting the L2GP spanning tree protocol?	PB: O	13.40	Yes [ ] N/A [ ] No [ ]
MSTP-32	Are PIPs capable of supporting the encapsulation/decapsulation of BPDUs?	BEB-I: O	5.7.1	Yes [ ] N/A [ ] No [ ]
MSTP-33	Can each Port be configured to support detection of fragile Bridges by setting the autoIsolatePort parameter?	MSTP:O	13.23, 13.27.19	Yes [ ] No [ ]
MSTP-34	Can a port be configured as an L2 Gateway Port by setting the isL2gp parameter?	MSTP:O	13.20, 13.27.26	Yes [ ] No [ ]
MSTP-35	Can the pseudoRootId parameter be set for an L2 Gateway Port for the CIST and for each MSTI?	MSTP-34:M	13.20, 13.27.51	Yes [ ] N/A [ ]
MSTP-36	Is one instance of the L2 Gateway Port state machine implemented for each L2GP port?	MSTP-34:M	13.40	Yes [ ] N/A [ ]

A.19 VLAN support

Item	Feature	Status	References	Support
VLAN-1	Does the implementation support, on each Port, one or more of the permissible combinations of values for the Acceptable Frame Types parameter?	M	5.4, 6.9	Yes [ ]
VLAN-2	Does the implementation support, on each Provider Bridge Port, the *Admit All Frames* value for the Acceptable Frame Types Parameter?	PB:M	5.6, 6.9	Yes [ ] N/A [ ]
VLAN-3	State which Ports support the following values for the Acceptable Frame Types parameter: — *Admit Only VLAN-tagged frames* — *Admit Only Untagged and Priority Tagged frames* — *Admit All frames*	M	5.4, 6.9	Ports: _____ Ports: _____ Ports: _____
VLAN-4	On Ports that support both values for the Acceptable Frame Types parameter, is the parameter configurable via management?	M	5.4, 6.9, 12.10	Yes [ ] N/A [ ]
VLAN-5	Does the implementation support the ability for the FDB to contain static and dynamic configuration information for at least one VID, by means of Static and Dynamic VLAN Registration Entries?	M	5.4, 8.8	Yes [ ]
VLAN-6	Does the implementation support at least one FID?	M	5.4, 8.8.3, 8.8.8, 8.8.9	Yes [ ]
VLAN-7	Can the implementation allocate at least one VID to each FID supported?	M	5.4, 8.8.3, 8.8.8, 8.8.9	Yes [ ]
VLAN-8	Does the implementation take account of the allocation of VIDs to FIDs when making forwarding decisions relative to group MAC addresses?	O	8.8.9	Yes [ ] No [ ]
VLAN-9	On Ports that support untagged and priority-tagged frames, does the implementation support:		5.4, 6.9, 8.8.2,	
VLAN-9.1	— A PVID value?	M	12.10	Yes [ ] N/A [ ]
VLAN-9.2	— The ability to configure one VID whose untagged set includes that Port?	M		Yes [ ] N/A [ ]
VLAN-9.3	— Configuration of the PVID value via management operations?	M		Yes [ ] N/A [ ]
VLAN-9.4	— Configuration of Static Filtering Entries via management operations?	M		Yes [ ] N/A [ ]
VLAN-9.5	— The ability to configure more than one VID whose untagged set includes that Port?	O		Yes [ ] No [ ] N/A [ ]
VLAN-10	Does the implementation support the ability to enable and disable Ingress Filtering?	CB:O PB:M BEB:M	5.4.1, 5.6, 8.6.3	Yes [ ] No [ ] N/A [ ]
VLAN-11	Can the PVID or the VID in any member of the VID Set for any Port be assigned the value of the null VID?	X	6.9, Table 9-2	No [ ]
VLAN-12	Are frames discarded (or not discarded) in accordance with the settings of the Acceptable Frame Types parameters?	M	6.9	Yes [ ]
VLAN-13	Are all frames received classified as belonging to exactly one VID, as defined in the ingress rules?	M	6.9	Yes [ ]
VLAN-14	Is Ingress Filtering performed in accordance with the value of the Enable Ingress Filtering parameter?	M	8.6.2	Yes [ ]

A.19 VLAN support *(continued)*

Item	Feature	Status	References	Support
VLAN-15	Are all frames that are not discarded as a result of the application of the ingress rules submitted to the Forwarding Process and to the Learning Process?	M	8.6.2	Yes [ ]
VLAN-16	Does the implementation support Port-and-Protocol-based classification of frames on any or all Ports?	O	6.12	Yes [ ] No [ ]
VLAN-16.1	State which Ports support Port-and-Protocol- based classification rules.	VLAN-16:M	6.12	Ports: _____
VLAN-16.2	For each Port that supports Port-and-Protocol-based classification rules, is a VID Set supported?	VLAN-16:M	6.12	Port: _____ Yes [ ] N/A [ ]
VLAN-16.3	For each Port that supports Port-and-Protocol-based classification rules, state how many entries are supported in the VID Set.	VLAN-16:M	6.12	Port: _____ _____ Entries
VLAN-16.4	For each Port that supports Port-and-Protocol-based classification rules, is the VID Set configurable via management?	VLAN-16:M	12.10.1.2	Port: _____ Yes [ ] N/A [ ]
VLAN-17	Does the implementation support a Protocol Group Database?	VLAN-16:M	6.12.3	Yes [ ] N/A [ ]
VLAN-17.1	State how many entries are supported in the Protocol Group Database.	VLAN-17:M	6.12.3	Entries _____
VLAN-17.2	Is the Protocol Group Database configurable via management?	VLAN-17:O	12.10.2.1	Yes [ ] No [ ] N/A [ ]
VLAN-17.3	Does the Protocol Group Database support entries of format Ethernet?	VLAN-17:O	6.12.3	Yes [ ] No [ ] N/A [ ]
VLAN-17.4	Does the Protocol Group Database support entries of format RFC_1042?	VLAN-17:O	6.12.3	Yes [ ] No [ ] N/A [ ]
VLAN-17.5	Does the Protocol Group Database support entries of format SNAP_8021H?	VLAN-17:O	6.12.3	Yes [ ] No [ ] N/A [ ]
VLAN-17.6	Does the Protocol Group Database support entries of format SNAP_Other?	VLAN-17:O	6.12.3	Yes [ ] No [ ] N/A [ ]
VLAN-17.7	Does the Protocol Group Database support entries of format LLC_Other?	VLAN-17:O	6.12.3	Yes [ ] No [ ] N/A [ ]
VLAN-17.8	Does the Protocol Group Database support entries of at least one of the following formats: Ethernet, RFC_1042, SNAP_8021H, SNAP_Other, LLC_Other?	VLAN-17: M	6.12.3	Yes [ ] N/A [ ]
VLAN-18	Are frames discarded if the transmission Port is not present in the member set for the frame's VID?	M	6.9.2, 8.8.10	Yes [ ]
VLAN-19	Are frames transmitted as VLAN-tagged frames or as untagged frames in accordance with the value of the untagged set for the frame's VID?	M	8.8.2	Yes [ ]
VLAN-20	Does the implementation support Static VLAN Registration Entries as defined in 8.8.2?	M	8.8.2	Yes [ ]
VLAN-21	Does the implementation support the creation of a separate Static VLAN Registration Entry with a distinct Port Map for each VID from which frames are received by the Forwarding Process?	O	8.8.2	Yes [ ] No [ ]

A.19 VLAN support *(continued)*

Item	Feature	Status	References	Support
VLAN-22	Does the implementation support Dynamic VLAN Registration Entries as defined in 8.8.5?	M	8.8.5	Yes [ ]
VLAN-23	Does the implementation support the creation of a separate Dynamic VLAN Registration Entry with a distinct Port Map for each VID from which frames are received by the Forwarding Process?	O	8.8.5	Yes [ ] No [ ]
VLAN-24	Does the implementation allocate VIDs to FIDs in accordance with the specification in 8.8.8?	M	8.8.8	Yes [ ]
VLAN-25	Does the implementation correctly detect Learning Constraint violations?	M	8.8.8	Yes [ ]
VLAN-26	Is determination of the member set and the untagged set for a given VID achieved as defined in 8.8.10?	M	8.8.10	Yes [ ]
VLAN-27	Do VLAN-tagged frames transmitted by the Bridge conform to the format defined in Clause 9 for the MAC type on which they are transmitted?	M	Clause 9	Yes [ ]
VLAN-28	Are all BPDUs transmitted untagged?	M	8.13.9	Yes [ ]
VLAN-29	Is encoding of the drop_eligible parameter in the PCP field of the VLAN tag supported?	CB:O PB:M BEB:M	5.5.1, 5.6, 6.9.3, 9.6	Yes [ ] No [ ] N/A [ ]
VLAN-30	Is Service Access Priority Selection supported?	CB:O PB:X BEB:X	5.5.1, 5.6, 6.13	Yes [ ] No [ ] N/A [ ]
VLAN-31	Is the VID translation table supported?	¬SPBV:O SPBV:M	5.4.1, 5.4.5, 6.9	Yes [ ] No [ ]
VLAN-32	Is the Egress VID translation table supported?	¬VLAN-31:X ¬SPBV AND VLAN-31:O SPBV:M	5.4.1, 5.4.5, 6.9	Yes [ ] No [ ] N/A [ ]
VLAN-33	Is the VIP-ISID parameter supported?	BEB-I: M	6.10	Yes [ ] N/A [ ]
VLAN-34	Is the default Backbone Destination supported?	BEB-I: M BEBTE: M	6.10	Yes [ ] N/A [ ]
VLAN-35	Is the adminPointToPointMAC supported?	BEB-I: O	6.10	Yes [ ] No [] N/A [ ]
VLAN-36	Is the Backbone-SID field in the Backbone Service Instance table supported?	BEB-B: M	6.11	Yes [ ] N/A [ ]
VLAN-37	Is the B-VID field in the Backbone Service Instance table supported?	BEB-B: O BEBTE: M	6.11	Yes [ ] No [ ] N/A [ ]
VLAN-38	Is the Local-SID field in the Backbone Service Instance table supported?	BEB-B: O	6.11	Yes [ ] No [ ] N/A [ ]
VLAN-39	Is the Default Backbone Destination field in the Backbone Service Instance table supported?	BEB-B: O BEBTE: M	6.11	Yes [ ] No [ ] N/A [ ]
VLAN-40	Is many-to-one S-VID to I-SID mapping supported?	BEB-I: O	5.7.1	Yes [ ] No [ ] N/A [ ]

A.20 Multiple MAC Registration Protocol (MMRP)

Item	Feature	Status	References	Support
	If MMRP is not supported, mark N/A and continue at A.21			N/A [ ]
MMRP1	Does the implementation support the exchange of Multiple MAC Registration Protocol Data Units (MMRPDUs), using the generic MRPDU format defined in 10.8 to exchange MMRP-specific information, as defined in 10.12?	M	5.4.1.3, 10.8, 10.12	Yes [ ]
MMRP2	Is the MMRP Application supported as defined in 10.12?	M	5.4.1.3, 10.12	Yes [ ]
MMRP3	Does the implementation propagate registration information in accordance with the operation of MAP for the Base Spanning Tree Context, as specified in 10.3.1?	M	5.4.1.3, 10.3.1	Yes [ ]
MMRP4	Does the implementation forward, filter, or discard MAC frames carrying any MRP Application address as the destination MAC address in accordance with the requirements of 8.13.6?	M	5.4.1.3, 8.13.6	Yes [ ]
MMRP5	Is the MAP Context Identifier used to identify a VLAN Context equal to the VID used to identify the corresponding VLAN?	M	10.12.1.1	Yes [ ]
MMRP6	Is the set of Ports of a Bridge defined to be part of the active topology for a given VLAN Context as specified in 10.12.1.1?	M	10.12.1.1	Yes [ ]
MMRP7	Is the group MAC address used as the destination address for MRPDUs destined for MMRP Participants the group MAC address identified in Table 10-1 as “Customer and Provider Bridge MMRP address”?	M	10.12.1.3	Yes [ ]
MMRP8	Is the EtherType used for MRPDUs destined for MMRP Participants the MMRP EtherType identified in Table 10-2?	M	10.12.1.4, Table 10-2	Yes [ ]
MMRP9	Does the ProtocolVersion used for the implementation of MMRP take the hexadecimal value 0x00?	M	10.12.1.5	Yes [ ]
MMRP10	Are the Attribute Type values used in the implementation as specified in 10.12.1.6?	M	10.12.1.6	Yes [ ]
MMRP11	Does the implementation encode the values in FirstValue fields in accordance with the definition in 10.12.1.7?	M	10.12.1.7	Yes [ ]
MMRP12	Is management of the Restricted_MAC_Address_Registration control parameter supported?	O	10.12.2	Yes [ ] No [ ]
MMRP13	If management of the Restricted_MAC_Address_Registration control parameter is not supported, is the value of this parameter FALSE for all Ports?	¬MMRP12:M	10.12.2	Yes [ ] N/A [ ]

A.20 Multiple MAC Registration Protocol (MMRP) *(continued)*

Item	Feature	Status	References	Support
MMRP14	Does the implementations maintain state information for all attribute values that support the Group service requirement registration?	M	10.10.2	Yes [ ]
MMRP15	Is the implementation capable of supporting any attribute value in the range of possible values that can be registered using Group membership and individual MAC address registration?	M	10.12.4	Yes [ ]
MMRP16	State the number of Group membership and individual MAC address state values that can be supported on each Port.	M	10.12.4	Number_____

A.21 Multiple VLAN Registration Protocol (MVRP)

Item	Feature	Status	References	Support
	If MVRP is not supported, mark N/A and continue at A.22			N/A [ ]
MVRP1	Does the implementation support the exchange of MVRPDUs, using the generic MRPDU format defined in 10.8 to exchange MVRP-specific information, as defined in 11.2?	M	5.4.2, 10.8, 11.2	Yes [ ]
MVRP2	Is the MVRP Application supported as defined in 11.2?	M	5.4.2, 11.2	Yes [ ]
MVRP3	Does the implementation propagate registration information in an MST Bridge, in accordance with the operation of MAP for multiple spanning tree contexts, as specified in 11.2.3.1.2?	MSTP:M	5.4.2, 11.2.3.1.2	Yes [ ] N/A [ ]
MVRP4	Does the implementation propagate registration information in an SST Bridge, in accordance with the operation of MAP for the Base Spanning Tree Context, as specified in 10.3.1?	¬MSTP:M	5.4.2, 10.3.1	Yes [ ] N/A [ ]
MVRP5	Does the implementation forward, filter, or discard MAC frames carrying any MRP Application address as the destination MAC address in accordance with the requirements of 8.13.6?	M	5.4.2, 8.13.6	Yes [ ]
MVRP6	If a VID translation table is in use, does the implementation translate VIDs in MVRPDUs as specified in 11.2.4?	VTR:M	11.2.4	Yes [ ]
MVRP7	Is the group MAC address used as the destination address for MRPDUs destined for MVRP Participants as defined in 11.2.3.1.3?	M	11.2.3.1.3	Yes [ ]
MVRP8	Is the EtherType used for MRPDUs destined for MVRP Participants the MVRP EtherType identified in Table 10-2?	M	11.2.3.1.4, Table 10-2	Yes [ ]
MVRP9	Does the ProtocolVersion used for the implementation of MVRP take the hexadecimal value 0x00?	M	11.2.3.1.5	Yes [ ]
MVRP10	Are the Attribute Type values used in the implementation as specified in 11.2.3.1.6?	M	11.2.3.1.6	Yes [ ]

A.21 Multiple VLAN Registration Protocol (MVRP) *(continued)*

Item	Feature	Status	References	Support
MVRP11	Does the implementation encode the values in FirstValue fields in accordance with the definition in 11.2.3.1.7?	M	11.2.3.1.7	Yes [ ]
MVRP12	Is the implementation of MVRP capable of supporting all attribute values in the range of possible values that can be registered using MVRP?	M	11.2.7	Yes [ ]
MVRP13	Is the implementation capable of maintaining current state information for all attributes in the range of possible values?	M	11.2.7	Yes [ ]
MVRP14	Does the Bridge support an MVRP New-Only Participant?	O	11.2.6	Yes [ ] No [ ]
MVRP15	Does the MVRP Participant transmit the Attribute value 0 as specified in 11.2.3.1.7?	MVRP14: M	11.2.3.1.7	Yes [ ]
MVRP16	Does the Bridge interpret the Attribute value 0 in an MVRP message as the PVID for the Port?	M	11.2.3.1.7	Yes [ ]
MVRP17	Does MVRP ignore New messages in MVRPDUs for VLANs not Registration Fixed (New propagated) when configured for New propagated?	MVRP14: M	11.2.6	Yes [ ]

A.22 Multiple Registration Protocol (MRP)

Item	Feature	Status	References	Support
MRP1	Does the implementation of MRP meet all of the requirements for interoperability stated in 10.5 that apply to Bridge operation?	M	10.5	Yes [ ]
MRP2	Does the implementation support the operation of the complete Applicant state machine?	MRP1:M	10.7, 10.7.7	Yes [ ] N/A [ ]
MRP3	Does the implementation support the operation of the point-to-point subset of the Applicant state machine?	MRP2:M	10.7, 10.7.7	Yes [ ] N/A [ ]
MRP4	Does the implementation support the operation of the Registrar state machine?	M	10.7, 10.7.8	Yes [ ]
MRP5	Does the implementation support the operation of the LeaveAll state machine?	M	10.7, 10.7.9	Yes [ ]
MRP6	Does the implementation support the operation of the PeriodicTransmission state machine?	M	10.7, 10.7.10	Yes [ ]

A.23 Connectivity Fault Management (CFM)

Item	Feature	Status	References	Support
CFM-1	Does the Bridge support the creation of Maintenance Domains at eight MD Levels, with multiple Maintenance Domains at each MD Level?	BRG AND CFM: M	5.4.1.4 item a)	Yes [ ] N/A [ ]
CFM-2	Does the Bridge support the creation of a Maintenance Association (MA) on each VID supported by the Bridge for each MD Level?	BRG AND CFM: M	5.4.1.4 item b)	Yes [ ] N/A [ ]
CFM-3	Does the Bridge support the creation of a single MIP for each Maintenance Domain on each Port, all MIPs being at the same MD Level?	BRG AND CFM: M	5.4.1.4 item c)	Yes [ ] N/A [ ]
CFM-4	Does the Bridge support the creation of eight Up MEPs on each VID on each Port, each MEP at a different MD Level?	BRG AND CFM: M	5.4.1.4 item d)	Yes [ ] N/A [ ]
CFM-5	Does the Bridge support the creation of eight Down MEPs on each VID on each Port, each MEP at a different MD Level?	BRG AND CFM: M	5.4.1.4 item e)	Yes [ ] N/A [ ]
CFM-6	Does the Bridge support the creation of eight Down MEPs associated with no VID on each Port, each MEP at a different MD Level?	BRG AND CFM: M	5.4.1.4 item f)	Yes [ ] N/A [ ]
CFM-7	Does the Bridge support the maintenance of a MEP CCM Database?	BRG AND CFM: M	5.4.1.4 item g)	Yes [ ] N/A [ ]
CFM-8	Does the Bridge conform to the state machines and procedures in Clause 20?	BRG AND CFM: M	5.4.1.4 item i), Clause 20	Yes [ ] N/A [ ]
CFM-9	Does the Bridge transmit and accept frames in the formats specified in Clause 21?	BRG AND CFM: M	5.4.1.4 item j)	Yes [ ] N/A [ ]
CFM-10	Does the Bridge support the creation of MIPs at different MD Levels on a single Port?	BRG AND CFM: O	5.4.1.4 item k), 22.3	Yes [ ] No [ ] N/A [ ]
CFM-11	Does the Bridge support the creation of MEPs at MD Levels equal to or higher than the MD Levels of MIPs on other VIDs on the same Port?	BRG AND CFM: O	5.4.1.4 item l), 22.3	Yes [ ] No [ ] N/A [ ]
CFM-12	Does the Bridge support the maintenance of a MIP CCM Database in MIPs and MEPs?	BRG AND CFM: O	5.4.1.4 item m), 19.3, 19.2.8	Yes [ ] No [ ] N/A [ ]
CFM-13	Does the Bridge support the creation of MAs that are associated with more than one VID?	BRG AND CFM: O	5.4.1.4 item o)	Yes [ ] No [ ] N/A [ ]
CFM-14	Does the Station support the creation of Maintenance Domains at eight MD Levels, with multiple Maintenance Domains at each MD Level?	¬BRG AND CFM: M	5.4.5 item a), 5.19	Yes [ ] N/A [ ]
CFM-15	Does the Station support the creation of an MA on each VID supported by the Bridge for each MD Level?	¬BRG AND CFM: M	5.4.5 item b), 5.19	Yes [ ] N/A [ ]
CFM-16	Does the Station support the creation of MIPs?	¬BRG AND CFM: X	22.4 item b)	No [ ] N/A [ ]
CFM-17	Does the Station support the creation of Up MEPs?	¬BRG AND CFM: X	22.4 item b)	No [ ] N/A [ ]
CFM-18	Does the Station support the creation of eight Down MEPs on each VID on each Port, each MEP at a different MD Level?	¬BRG AND CFM: M	5.4.5 item c), 5.19	Yes [ ] N/A [ ]

A.23 Connectivity Fault Management (CFM) *(continued)*

Item	Feature	Status	References	Support
CFM-19	Does the Station support the creation of eight Down MEPs associated with no VID on each Port, each MEP at a different MD Level?	¬BRG AND CFM: M	5.4.5 item d), 5.19	Yes [ ] N/A [ ]
CFM-20	Does the Station support the maintenance of a MEP CCM Database?	¬BRG AND CFM: M	5.4.5 item e), 5.19	Yes [ ] N/A [ ]
CFM-21	Does the Station conform to the state machines and procedures in Clause 20?	¬BRG AND CFM: M	5.4.5 item g), 5.19, Clause 20	Yes [ ] N/A [ ]
CFM-22	Does the Station transmit and accept frames in the formats specified in Clause 21?	¬BRG AND CFM: M	5.4.5 item h), 5.19	Yes [ ] N/A [ ]
CFM-23	Does the Station support the creation of MAs that are associated with more than one VID?	¬BRG AND CFM: O	5.4.5 item k), 5.19	Yes [ ] No [ ] N/A [ ]
CFM-24	Does the MP Level Demultiplexer discard frames that are too short to contain an MD Level header field?	CFM: M	19.2.6, 20.51.4.1	Yes [ ] N/A [ ]
CFM-25	Is an LBM always discarded, and not replied to, if its source_address is a Group address?	CFM: M	20.2.2	Yes [ ] N/A [ ]
CFM-26	Are the contents of an LBM, except for the source_address and OpCode, ignored and not interpreted by a non-PBB-TE receiver?	¬CFM-93 AND CFM: M	20.2.2	Yes [ ] N/A [ ]
CFM-27	Is the LTFwhile timer implemented?	CFM:M	20.5, 20.5.1	Yes [ ] N/A [ ]
CFM-28	Are the per-MEP timers CCIwhile, errorCCMwhile, xconCCMwhile, LBIwhile, and FNGwhile implemented?	CFM:M	20.5, 20.5.2, 20.5.3, 20.5.4, 20.5.5, 20.5.6	Yes [ ] N/A [ ]
CFM-29	Is the per-MEP per-remote MEP timer rMEPwhile implemented?	CFM:M	20.5, 20.5.10	Yes [ ] N/A [ ]
CFM-30	Can a MEP set rMEPCCMdefect within (3.25 × CCMtime(CCMinterval)) seconds of the receipt of a CCM?	X	20.5.10	No [ ]
CFM-31	Can a MEP take longer to set rMEPCCMdefect than (3.5 × CCMtime(CCMinterval)) seconds of the receipt of the last CCM?	CFM: X	20.5.10	No [ ] N/A [ ]
CFM-32	Does the system transmit a nonzero value for the CCM Interval in CCMs?	CFM: M	20.8.1, 20.11.1 item g)	Yes [ ] N/A [ ]
CFM-33	Does the Bridge transmit all CFM PDU fixed header fields in conformance with this standard?	CFM: M	20.51.2	Yes [ ] N/A [ ]
CFM-34	Does the Bridge transmit all reserved bits and fields in CFM PDUs as 0?	CFM: M	20.51.2	Yes [ ] N/A [ ]
CFM-35	Does the Bridge transmit additional fixed header fields not defined in this standard in CFM PDUs?	X	20.51.2	No [ ]
CFM-36	Does the Bridge transmit code points in any field that are reserved, either by this standard or by ITU-T G.8013/Y.1731?	X	20.51.2	No [ ]
CFM-37	Does the Bridge transmit additional fields in any CFM PDU in any TLV defined by this standard?	X	20.51.2	No [ ]

A.23 Connectivity Fault Management (CFM) *(continued)*

Item	Feature	Status	References	Support
CFM-38	Does the Bridge determine the validity of those CFM PDUs that are validated, in a manner indistinguishable, by external observation of the Bridge, from the procedures described in this standard?	CFM: M	20.51.3	Yes [ ] N/A [ ]
CFM-39	Is the version by which each PDU is processed selected correctly, and are the prohibited validation criteria not applied, by the System?	CFM: M	20.17.1, 20.17.2, 20.28.1, 20.33.1, 20.51.4.2	Yes [ ] N/A [ ]
CFM-40	Does the System determine the validity of a CFM PDU in the manner defined by this standard?	CFM: M	20.17.1, 20.17.2, 20.28.1, 20.33.1, 20.51.4.1, 20.51.4.3	Yes [ ] N/A [ ]
CFM-41	Are all CFM PDUs transmitted with an integral number of octets?	CFM: M	21.1	Yes [ ] N/A [ ]
CFM-42	Does the Bridge transmit Organization-Specific TLVs?	CFM: O	20.51.2, 21.5.2	Yes [ ] No [ ]
CFM-43	Does the Bridge transmit an Organization-Specific TLV that requires it or the receiver to violate any requirement of this standard?	X	21.5.2	No [ ]
CFM-44	Is the information transmitted in an Organization-Specific TLV independent from information in a TLV received from any other port?	CFM-42: M	21.5.2	Yes [ ] N/A [ ]
CFM-45	Do Organization-Specific TLV(s) transmitted by the Bridge provide a means for sending messages that are larger than would fit within a single CFM PDU?	X	21.5.2	No [ ]
CFM-46	Do the Organization-Specific TLV(s) transmitted by the Bridge conform to the validation and versioning rules of 20.51?	CFM-42: M	21.5.2	Yes [ ] N/A [ ]
CFM-47	Does the Management Address Domain field in the Sender ID TLV(s) transmitted by the Bridge (if any) conform to section 8.19 of ITU-T X.690 (2002)?	CFM: M	21.5.3.5	Yes [ ] N/A [ ]
CFM-48	Can a MEP in a multiple spanning tree environment not statically restricted to a single MSTI generate a Port Status TLV?	X	21.5.4	No [ ]
CFM-49	Does the Bridge, in any case except when receiving an LBR, interpret the contents of the Data TLV?	X	21.5.6	No [ ]
CFM-50	Can the Bridge transmit the Data TLV in an LBM?	CFM: O	21.5.6	Yes [ ] No [ ] N/A [ ]
CFM-51	Is the Bridge able to receive and process all valid CCM PDUs that are 128 octets or less in length (from MD Level through End TLV)?	CFM: M	21.6	Yes [ ] N/A [ ]
CFM-52	Does the Bridge discard, as invalid, CCM PDUs that exceed 128 octets in length?	CFM: O	21.6	Yes [ ] No [ ] N/A [ ]
CFM-53	Can the Bridge transmit a CCM PDU that is longer than 128 octets in length?	X	21.6	No [ ]

A.23 Connectivity Fault Management (CFM) *(continued)*

Item	Feature	Status	References	Support
CFM-54	Is the length of the Maintenance Association Identifier (MAID) transmitted in a CCM exactly 48 octets?	CFM: M	21.6.5	Yes [ ] N/A [ ]
CFM-55	Is the field Defined by ITU-T G.8013/Y.1731 always transmitted as 0?	CFM: M	21.6.6	Yes [ ] N/A [ ]
CFM-56	Does the First TLV Offset field contain the value as specified for the OpCode for each CFM message transmitted?	CFM: M	21.4.5, 21.6.2, 21.7.2, 21.8.2, 21.9.2	Yes [ ] N/A [ ]
CFM-57	Does every transmitted LTM contain an LTM Egress Identifier TLV?	CFM: M	21.8.7	Yes [ ] N/A [ ]
CFM-58	Does every transmitted LTR contain an LTR Egress Identifier TLV?	CFM: M	21.9.6	Yes [ ] N/A [ ]
CFM-59	Does the receiving Bridge behave differently if the order of TLVs in a CFM PDU, other than the End TLV, or TLVs in an LBR, is altered?	X	21.6.7, 21.9.6	No [ ]
CFM-60	Does the Bridge support the creation of MPs at one or more MD Level on every Port?	CFM: M	22.3	Yes [ ] N/A [ ]
CFM-61	Is every Down MEP on a Bridge Port assigned a MAC address different than any Down MEP on any other Bridge Port?	CFM: M	19.4	Yes [ ] N/A [ ]
CFM-62	Does the Provider Edge Bridge support the creation of a Down MEP on the interface corresponding to a CEP?	PEB AND BRG AND CFM: M	22.6.1	Yes [ ] N/A [ ]
CFM-63	Does the Provider Edge Bridge support the creation of a Down MEP on the interface corresponding to a RCAP?	RCSI AND BRG AND CFM: M	22.6.4	Yes [ ] No [ ]
CFM-64	Does the Provider Edge Bridge support the creation of a Down MEP on the interface corresponding to a CEP connected to a Provider Access Port (PAP)?	RCSI AND BRG AND CFM: M	22.6.4	Yes [ ] No [ ]
CFM-65	If the MIP CCM Database has insufficient resources to record a new entry, does it preferentially remove the oldest entry to make room for the new one?	BRG AND CFM-12: O	20.1.3	Yes [ ] No [ ] N/A [ ]
CFM-66	Does the Bridge transmit successive integer values in the Sequence Number field of a CCM?	CFM: O	20.1, 20.11.1 item i)	Yes [ ] No [ ] N/A [ ]
CFM-67	Does the Bridge transmit neither successive integer values nor 0 in the Sequence Number field of a CCM?	X	20.1, 20.11.1	No [ ]
CFM-68	Does the Bridge keep track of received CCMs' Sequence Number fields in the MEP CCM Database, and count out-of-sequence CCMs in CCMsequenceErrors?	CFM: O	20.1, 20.17.1	Yes [ ] N/A [ ] N/A [ ]
CFM-69	Does the Bridge check the validity of every received LTM, and LTR?	CFM: M	20.33.1, 20.44.1, 20.47.1	Yes [ ] N/A [ ]
CFM-70	Does the Bridge check the validity of every received CCM?	CFM: O	20.17.1, 20.17.2	Yes [ ] No [ ] N/A [ ]
CFM-71	Does the Bridge check the validity of every received LBM?	CFM: O	20.2.2, 20.28.1	Yes [ ] No [ ] N/A [ ]

A.23 Connectivity Fault Management (CFM) *(continued)*

Item	Feature	Status	References	Support
CFM-72	Does the Bridge check the validity of every received LBR?	CFM: O	20.2.2, 20.33.1	Yes [ ] No [ ] N/A [ ]
CFM-73	Does the Bridge compare the received LBR bit-by-bit against the original LBM?	CFM: O	20.2.3, 20.33.1	Yes [ ] No [ ] N/A [ ]
CFM-74	Can the Bridge transmit LBMs at a rate fast enough to overflow output queues in the absence of other data traffic?	X	20.2.1	No [ ]
CFM-75	Can a high rate of incoming CFM PDUs increase the probability that the Bridge fails to protect the network against forwarding loops?	BRG: X	20.51.5	No [ ] N/A [ ]
CFM-76	Are the Optional CCM TLVs included in every CCM?	CFM: O	21.6.7	Yes [ ] No [ ] N/A [ ]
CFM-77	Are Organization-Specific TLVs included in CCMs?	CFM: O	21.6.7	Yes [ ] No [ ] N/A [ ]
CFM-78	Is the Sender ID TLV included in every LBM?	CFM:O	21.5.3, 21.7.4	Yes [ ] N/A [ ] N/A [ ]
CFM-79	Is the Management Address included in the Sender ID TLV?	CFM-78: O	21.5.3	Yes [ ] No [ ] N/A [ ]
CFM-80	Are Organization-Specific TLVs included in LBMs?	CFM: O	21.7.4	Yes [ ] No [ ] N/A [ ]
CFM-81	Does the Station discard, and not process, all CFM PDUs not discarded or processed by its MEPs?	¬BRG AND CFM: M	22.4 item c)	Yes [ ] N/A [ ]
CFM-82	Does the Station create entries in the Configuration Error List managed object other than CFMleak errors?	X	22.4 item d), 12.14.4	No [ ]
CFM-83	Can CFM monitor backbone service instances using Backbone Service Instance Multiplex Entities placed back-to-back?	BEB: O	5.7.1, 5.8.1	Yes [ ] No [ ] N/A [ ]
CFM-84	Does the Bridge support the creation of an MA on each TESI supported by the Bridge for each MD Level?	BEBTE: M	5.8.2, 26.9	Yes [ ] N/A [ ]
CFM-85	Does the Bridge support the creation of an Up MEP on each TESI on each CBP?	BEBTE: M	5.8.2, 6.19, 26.9.3	Yes [ ] N/A [ ]
CFM-86	Does the Bridge support the creation of eight Up MEPs on each TESI on each CBP, each MEP at a different MD Level?	BEBTE: O	5.8.2	Yes [ ] No [ ] N/A [ ]
CFM-87	Does the Bridge support the creation of MIPs on TESIs?	PBBTE: O	5.6.2, 5.8.2	Yes [ ] No [ ] N/A [ ]
CFM-88	Is the PBB-TE MIP TLV included in every LBM that is targeting a PBB-TE MIP?	BEBTE: M	20.2, 21.7.5	Yes [ ] N/A [ ]
CFM-89	Is the PBB-TE MIP TLV included in every LTM that is associated with a PBB-TE MA?	BEBTE: M	20.3, 21.7.5	Yes [ ] N/A [ ]
CFM-90	Is the PBB-TE MIP TLV included in LBMs that are targeting a PBB-TE MEP?	BEBTE: X	20.2, 21.7.5	No [ ] N/A [ ]
CFM-91	Is the PBB-TE MIP TLV the first TLV in an LBM targeting a PBB-TE MIP?	CFM-88: M	20.2, 21.7.5	Yes [ ] N/A [ ]

A.23 Connectivity Fault Management (CFM) *(continued)*

Item	Feature	Status	References	Support
CFM-92	Is the Reverse MAC field included in the PBB-TE MIP TLVs required by LBMs/LTMs that are associated with Point-to- Multipoint PBB-TE MAs?	CFM-88 OR CFM-89: M	20.2, 20.3, 21.7.5	Yes [ ] N/A [ ]
CFM-93	Does the PBB-TE MEP check the MAID in received CCMs?	BEBTE: O	20.1.3, 20.17.1	Yes [ ] No [ ] N/A [ ]
CFM-94	Does the PBB-TE MEP set the Traffic field bit in the transmitted CCMs and process it in the received CCMs	PS-5: M	20.11.1, 20.17.1, 21.6.1.4	Yes [ ] N/A [ ]
CFM-95	Does the Bridge keep track of the Traffic field bit in received CCMs?	PS-5: M	20.16.3, 20.17.1, 21.6.1.4	Yes [ ] N/A [ ]
CFM-96	Are the per-PBB MEP timers mmCCMwhile, mmLocwhile, and mmFNGwhile implemented?	PS-5: M	20.5.7	Yes [ ] N/A [ ]
CFM-97	Are the per-PBB MEP mismatch defect related, MEP Traffic Field Mismatch state machine, MEP Local Mismatch state machine and MEP Mismatch Fault Notification Generator state machine implemented?	PS-5: M	20.24, 20.40	Yes [ ] N/A [ ]
CFM-98	Are SPBM VID MAs supported?	SPBM:O	27.18, Clause 20	Yes [ ] No [ ] N/A [ ]
CFM-99	Are SPBM group MAs supported?	SPBM:O	27.18, Clause 20	Yes [ ] No [ ] N/A [ ]
CFM-100	Are SPBM path MAs supported?	SPBM:O	27.18, Clause 20	Yes [ ] No [ ] N/A [ ]
CFM-101	Are ECMP path MAs supported?	FF:O	44.2.5, Clause 20	Yes [ ] No [ ] N/A [ ]

MIB-39	Are the IEEE8021-ECMP-MIB module objects ieee8021EcmpEctStaticTable and ieee8021EcmpTopSrvTable supported?	MIB AND ECMP:O	5.4.5.1, 17.7.10	Yes [ ] No [ ] N/A [ ]
MIB-40	Is the IEEE8021-ECMP-MIB module fully supported (per its MODULE-COMPLIANCE)?	MIB AND FF:O	5.4.5.2, 17.7.21	Yes [ ] No [ ] N/A [ ]
MIB-41	Are PCR objects in the IEEE8021-SPB-MIB supported per ieee8021PcrCompliance ?	MIB AND PCR:O	5.5, 17.7.19	Yes [ ] No [ ] N/A [ ]
MIB-42	Is the IEEE8021-ST-MIB module fully supported (per its MODULE-COMPLIANCE)?	MIB AND (SCHED OR CQF): O	5.4.1 item ad), 5.4.1.9 item c), 5.13.1.2 item c), 12.29, 17.7.22	Yes [ ] No [ ] N/A [ ]
MIB-43	Is the IEEE8021-Preemption-MIB module fully supported (per its MODULE-COMPLIANCE)?	PRE: O	5.4.1 item ae), 12.30, 17.7.23	Yes [ ] No [ ] N/A [ ]
MIB-44	Is the IEEE8021-PSFP-MIB module fully supported (per its MODULE-COMPLIANCE)?	PSFP OR CQF: O	5.4.1.9 item e), 5.13.1.2 item e), 8.6.5.2, 8.6.10, 12.31, 17.7.24	Yes [ ] No [ ] N/A [ ]

A.25 Protection Switching (PS)

Item	Feature	Status	References	Support
	If item PS is not supported, mark N/A and continue at the subsequent subclause.			N/A [ ]
PS-1	Is 1:1 protection switching supported?	PS: M	5.8.2, 26.10.3	Yes [ ]
PS-2	Are the operator commands Forced Switch (FS), Lockout of Protection (LoP), Manual Switch to Working, and Manual Switch to Protection implemented?	PS-1: M	26.10.3.3	Yes [ ]
PS-3	Is the hold-off timer implemented?	PS-1: O	26.10.3.2.2	Yes [ ] No [ ]
PS-4	Is protection switching with load sharing supported?	PS: O	5.8.2, 12.14.1.2	Yes [ ] No [ ]
PS-5	Is the detection of mismatch defects supported?	PS: O	26.12	Yes [ ] No [ ]

A.26 Data-driven and data-dependent connectivity fault management (DDCFM)

Item	Feature	Status	References	Support
DDCFM-1	Does the Bridge support the Reflection Responder (RR) function?	DDCFM:M	29.2.2	Yes [ ] N/A [ ]
DDCFM-2	Does the Bridge support the RFM Receiver function?	DDCFM:M	29.2.4	Yes [ ] N/A [ ]
DDCFM-3	Does the Bridge support the Decapsulator Responder (DR) function?	DDCFM:M	29.2.6	Yes [ ] N/A [ ]
DDCFM-4	Does the Bridge support the SFM Originator function?	DDCFM:M	29.2.7	Yes [ ] N/A [ ]

A.27 Two-Port MAC Relay (TPMR)

Item	Feature	Status	References	Support
	If TPMR is not supported, mark N/A and continue at A.28.			N/A [ ]
TPMR-1	Does the TPMR comprise a single TPMR component?	TPMR:M	5.15	Yes [ ]
TPMR-2	Is each TPMR Port capable of attaching directly to an IEEE 802 LAN?	TPMR:M	5.16	Yes [ ]
TPMR-3	Does the implementation support exactly two externally-accessible Bridge Ports?	TPMR:M	5.15	Yes [ ]
TPMR-4	Does the implementation support the operation of the Bridge Port Transmit and Receive process, using the TPMR Port connectivity rules?	TPMR:M	5.15, 8.5, 8.5.2	Yes [ ]
TPMR-5	Does the Forwarding Process support frame filtering, queuing frames, queue management, and transmission selection?	TPMR:M	5.15, 8.6.3, 8.6.6, 8.6.7, 8.6.8	Yes [ ]
TPMR-6	Does the implementation support at least one traffic class on each externally accessible Port?	TPMR:M	5.15	Yes [ ]

A.27 Two-Port MAC Relay (TPMR) *(continued)*

Item	Feature	Status	References	Support
TPMR-7	Does the implementation support the management functionality specified in 12.19?	TPMR:M	12.19	Yes [ ]
TPMR-8	Does the implementation support remote management via one of the externally accessible Ports?	TPMR:M	5.15, 8.13.7	Yes [ ]
TPMR-9	Does the implementation support Static Filtering Entries in accordance with the requirements stated in 5.15:f?	TPMR:M	5.15, 8.13.7, Table 8-3	Yes [ ]
TPMR-10	Does the implementation support multiple traffic classes on each externally accessible Port?	TPMR:O	5.15	Yes [ ] No [ ]
TPMR-11	Does the implementation support remote management via one or both of the externally accessible Ports, using IETF RFC 4789, and the TPMR MIB module?	TPMR:O	5.15, IETF RFC 4789, 8.13.7, 17.7.11	Yes [ ] No [ ]
TPMR-12	Does the implementation support signaled priority?	TPMR: O	6.20	Yes [ ] No [ ]

A.28 MAC Status Protocol (MSP)

Item	Feature	Status	References	Support
	If MSP is not supported, mark N/A.			N/A [ ]
MSP-1	Does the implementation support the operation of the Status Transmission state machine (STM)?	MSP:M	23.8	Yes [ ]
MSP-2	Does the implementation support the operation of the Status Notification state machine (SNM)?	MSP:M	23.9	Yes [ ]
MSP-3	Does the Receive Process receive and validate MSPDUs as specified?	MSP:M	23.10, 23.16	Yes [ ]
MSP-4	Does the Transmit Process identify, address, structure, encode, and transmit MSPDUs as specified?	MSP:M	23.11, 23.13, 23.14, 23.15	Yes [ ]
MSP-5	Does the implementation allow performance parameters to be read by management?	MSP:O	23.12	Yes [ ] No [ ]
MSP-6	Does the implementation allow performance parameters to be modified by management?	MSP:O	23.12	Yes [ ] No [ ]
MSP-7	Does the implementation maintain the specified counts for at least one Port of the TPMR?	MSP:O	23.12	Yes [ ] No [ ]
MSP-8	Does the implementation maintain the specified counts for both ports of the TPMR?	MSP:O	23.12	Yes [ ] No [ ]

A.29 Forwarding and Queuing Enhancements for time-sensitive streams (FQTSS)

Item	Feature	Status	References	Support
	If forwarding and queuing for time-sensitive streams (FQTSS in A.6) is not supported, mark N/A and ignore the remainder of this table.		5.4.1.5, Clause 34	N/A [ ]
FQTSSE1	Support a minimum of two traffic classes, of which one supports the strict priority algorithm and the other is an SR class.	FQTSS:M	5.4.1.5, 8.6.8.1, Clause 34	Yes [ ] N/A [ ]
FQTSSE2	Support the operation of the credit-based shaper algorithm on all Ports as the transmission selection algorithm used for the SR class.	FQTSS:M	5.4.1.5, 8.6.8.2, Clause 34	Yes [ ] N/A [ ]
FQTSSE3	Support SRP domain boundary port priority regeneration override as defined in 6.9.4, and the default priority regeneration override value defined in Table 6-5, for SR class “B.”	FQTSS:M	5.4.1.5, 6.9.4, Table 6-5, Clause 34	Yes [ ] N/A [ ]
FQTSSE4	Support the tables and procedures for mapping priorities to traffic classes as defined in 34.5.	FQTSS:M	5.4.1.5, Clause 34, 34.5	Yes [ ] N/A [ ]
FQTSSE5	Support two or more SR classes (a maximum of seven), and support the operation of the credit-based shaper algorithm on all Ports as the transmission selection algorithm used for those SR classes. The number of SR classes supported shall be stated in the PICS.	FQTSS:O	5.4.1.5, 8.6.8.2, 34.6	Yes [ ] No [ ] Number____
FQTSSE6	Support SRP domain boundary port priority regeneration override as defined in 6.9.4, and the default priority regeneration override value defined in Table 6-5, for SR class “A.” If more than two SR classes are supported, the default priority regeneration override values used for the additional SR classes shall be stated in the PICS.	FQTSS:O	5.4.1.5, 6.9.4, Table 6-5, 34.6	Yes [ ] No [ ] Priority override values_____

A.30 Congestion notification

Item	Feature	Status	References	Support
CN-1	Does the system conform to the required provisions of IEEE Std 802.1AB?	CN: M	5.4.3 item e), 5.21 item f)	Yes [ ] N/A [ ]
CN-2	Does the system support the use of the Congestion Notification TLV in LLDP?	CN: M	5.4.3 item f), 5.21 item g)	Yes [ ] N/A [ ]
CN-3	Does the system transmit more than one Congestion Notification TLV in a single LLDPDU?	CN: M	D.2.7	No [ ] N/A [ ]
CN-4	Does the system transmit a Congestion Notification TLV with 0 in all of the Per-priority CNPV indicators?	CN: M	D.2.7	No [ ] N/A [ ]
CN-5	Does the system implement the Congestion Notification Domain (CND) defense variables, procedures, and state machine?	CN: M	32.4, 32.5, 32.6	Yes [ ] N/A [ ]
CN-6	Does the Bridge support the creation of at least one CP on at least one Port?	BRG1 AND CN: M	5.4.3 item a)	Yes [ ] N/A [ ]

A.30 Congestion notification *(continued)*

Item	Feature	Status	References	Support
CN-7	Does the Bridge support the creation of more than one CP on at least one Port?	BRG1 AND CN: O	5.4.3 item i)	Yes [ ] No [ ] N/A [ ]
CN-8	Does the Bridge support the creation of more than seven CPs on any Port?	BRG1 AND CN: M	5.4.3 item i)	No [ ] N/A [ ]
CN-9	Does every CP on the Bridge support all four defense modes separately on each CNPV?	BRG1 AND CN: M	5.4.3 item d), 31.1.1, 32.2.1	Yes [ ] N/A [ ]
CN-10	Is each CP on the Bridge able to remove CN-TAGs?	BRG1 AND CN: M	5.4.3 item b)	Yes [ ] N/A [ ]
CN-11	Does the PIP perform CNM translation on the return path?	BEB-I AND CN:M	5.4.3 item g)	Yes [ ] N/A [ ]
CN-12	Does the Provider Edge Port (PEP) perform CNM translation on the return path?	PEB AND CN:M	5.4.3 item h)	Yes [ ] N/A [ ]
CN-13	Is each CP on the system able to generate CNMs?	BRG1 AND CN: M	5.4.3 item b)	Yes [ ] N/A [ ]
CN-14	Does the Bridge override the priority of a frame entering a port on a CNPV when in mode cptEdge?	BRG1 AND CN: M	32.2.1	Yes [ ] N/A [ ]
CN-15	Does the Bridge allow any other priority to be remapped to a CNPV when in any mode other than cptDisabled?	BRG1 AND CN: M	32.2.1	No [ ] N/A [ ]
CN-16	Do the system's CPs implement the specified variables and procedures?	BRG1 AND CN: M	32.7 item a), 32.8, 32.9	Yes [ ] N/A [ ]
CN-17	Is the CP's Random() function initialized to a different value each time the system is reset?	BRG1 AND CN: M	32.9.1	Yes [ ] N/A [ ]
CN-18	Does a system's CP interpret a CN-TAG to any degree beyond simply copying it to the CNM?	BRG1 AND CN: M	33.2.1	No [ ] N/A [ ]
CN-19	Does the CP transmit a 0 in the CNM's Version field?	BRG1 AND CN: M	33.4.1	Yes [ ] N/A [ ]
CN-20	Does the CP transmit a 0 in the CNM's ReservedV field?	BRG1 AND CN: M	33.4.2	Yes [ ] N/A [ ]

A.31 Stream Reservation Protocol (SRP)

Item	Feature	Status	References	Support
	If SRP (in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
SRP-1	Does the implementation support the exchange of Multiple Stream Registration Protocol Data Units (MSRPDUs), using the generic Multiple Registration Protocol Data Unit (MRPDU) format defined in 10.8 to exchange MSRP-specific information, as defined in 35.2.2.8.1, 35.2.2.9.1, and 35.2.2.10.1?	M	10.8, 35.2.2.8.1, 35.2.2.9.1, 35.2.2.10.1	Yes [ ]

A.31 Stream Reservation Protocol (SRP) *(continued)*

Item	Feature	Status	References	Support
SRP-2	Is the MSRP Application supported as defined in Clause 35?	M	Clause 35	Yes [ ]
SRP-3	Does the implementation propagate registration information in accordance with the operation of MAP for the Base Spanning Tree Context, as specified in 35.2.4?	M	35.2.4	Yes [ ]
SRP-4	Does the implementation forward, filter, or discard MAC frames carrying any MRP Application address as the destination MAC address in accordance with the requirements of 8.13.6?	M	8.13.6	Yes [ ]
SRP-5	Is the group MAC address used as the destination address for MRPDUs destined for MSRP Participants the group MAC address identified in Table 8-1, Table 8-2, and Table 8-3 as “Individual LAN Scope group address, Nearest Bridge group address”?	M	35.2.2.1, Table 8-1, Table 8-2, Table 8-3	Yes [ ]
SRP-6	Is the EtherType used for MRPDUs destined for MSRP Participants the MSRP EtherType identified in Table 10-2?	M	35.2.2.2, Table 10-2	Yes [ ]
SRP-7	Does the ProtocolVersion used for the implementation of MSRP take the hexadecimal value 0x01?	M	35.2.2.3	Yes [ ]
SRP-8	Are the Attribute Type values used in the implementation as specified in 35.2.2.4 and Table 35-1?	M	35.2.2.4, Table 35-1	Yes [ ]
SRP-9	Are the Attribute Length values used in the implementation as specified in 35.2.2.5 and Table 35-2?	M	35.2.2.5, Table 35-2	Yes [ ]
SRP-10	Are the MSRP Vector FourPackedEvents values used in the implementation as specified in 35.2.2.7.2 and Table 35-3?	M	35.2.2.7.2, Table 35-3	Yes [ ]
SRP-11	Does the implementation encode the values in FirstValue fields in accordance with the definition in 35.2.2.8, 35.2.2.9, and 35.2.2.10?	M	35.2.2.8, 35.2.2.9, 35.2.2.10	Yes [ ]
SRP-12	Does the implementation update Accumulated Latency as the Talker attributes propagate through the Bridge?	M	35.2.2.8.6, 35.2.2.10.10	Yes [ ]
SRP-13	Does the implementation update failure information in the event of insufficient bandwidth or resources through a Bridge?	M	35.2.2.8.7, 35.2.2.10.9, 35.2.2.10.12	Yes [ ]

A.31 Stream Reservation Protocol (SRP) *(continued)*

Item	Feature	Status	References	Support
SRP-14	Does the implementation propagate a Talker Advertise as a Talker Failed in the event of insufficient bandwidth or resources through a Bridge?	M	35.2.4.3, Table 35-9	Yes [ ]
SRP-15	Is talkerPruning and MMRP supported?	O	35.2.4.3.2	Yes [ ] No [ ]
SRP-16	Are Listener attributes merged and propagated as described in 35.2.4.4?	M	35.2.4.4, Table 35-12, Table 35-15	Yes [ ]
SRP-17	Does the implementation support updates to the Dynamic Reservation Entries as described in 35.2.4.4.2?	M	8.8 item k), 35.2.4.4.2, Table 35-13	Yes [ ]
SRP-18	Does the implementation support updates to operIdleSlope as defined in 35.2.4.4.2?	M	35.2.4.4.2, Table 35-14	Yes [ ]
SRP-19	Does the implementation support the automatic modifications to stream reservations as described in 35.2.6?	M	35.2.6	Yes [ ] No [ ]
SRP-20	Are MSRPDUs transmitted on all ports?	M	35.2	Yes [ ]
SRP-21	State the number of Talker registrations values that can be supported on each Port.	M	35.2.7	Number _____
SRP-22	State the number of Listener registrations values that can be supported on each Port.	M	35.2.7	Number _____
SRP-23	Can the SR_PVID for any Port be assigned the value of the null VID or VID FFF (hexadecimal)?	X	35.2.1.4 item i), Table 9-2	No [ ]
SRP-24	Does the device support changing the SR_PVID value from the default value shown in Table 9-2?	O	35.2.1.4 item i), Table 9-2	Yes [ ] No [ ]
SRP-25	Does the implementation support both original and enhanced attribute types?	M	35.1	Yes [ ]
SRP-26	Does the implementation detect domain boundaries?	M	35.2.4.3	Yes [ ]
SRP-27	Does the implementation support Stream transformation in Bridge?	O	35.2.2.10.5	Yes [ ] No [ ]
SRP-28	Does the implementation support protocol version translation for Talker attributes?	M	35.2.4.3.1	Yes [ ]
SRP-29	Does the implementation support protocol version translation for Listener attributes?	M	35.2.4.4.4	Yes [ ]
SRP-30	Does the implementation declare the Domain attribute prior to Talker/Listener attributes?	M	35.2.2.9	Yes [ ]
SRP-31	Is talker pruning per Port supported?	O	35.2.4.3.3	Yes [ ] No [ ]

A.31 Stream Reservation Protocol (SRP) *(continued)*

Item	Feature	Status	References	Support
SRP-32	Is talker VLAN pruning supported?	O	35.2.4.3.4	Yes [ ] No [ ]
SRPMDCSN	Does this device support media-dependent Coordinated Shared Networking (CSN) functionality on one or more ports?	SRPMDMOCA:M OR: SRPMDDOT11:M	Annex C	Yes [ ] No [ ]
SRPMDMOCA	Does this device support media-dependent Multimedia over Coax Alliance (MoCA) functionality on one or more ports?	O:1	C.2	Yes [ ] No [ ]
SRPMDDOT11	Does this device support media-dependent IEEE 802.11 Access Point (AP) functionality on one or more ports?	O:1	C.3	Yes [ ] No [ ]
SRPMDCSN-1	Does this device support a single Designated MSRP Node (DMN)?	SRPMDCSN:M	35.1.1	Yes [ ] N/A [ ]
SRPMDMOCA-1	Does this device support DMN Device Attribute Information Element to L2ME message?	SRPMDMOCA:M	C.2.1.2	Yes [ ] N/A [ ]
SRPMDMOCA-2	Does this device support DMN selection?	SRPMDMOCA:M	C.2.1.3	Yes [ ] N/A [ ]
SRPMDMOCA-3	Does this device support MSRP Attribute Declaration as specified in Table C-1	SRPMDMOCA:M	C.2.2, Table C-1	Yes [ ] N/A [ ]
SRPMDDOT11-1	Does this device support EDCA-AC?	SRPMDDOT11:M	Table C-5	Yes [ ] N/A [ ]
SRPMDDOT11-2	Is the DMN and the QAP of the IEEE 802.11 BSS co-located in the same device?	SRPMDDOT11:M	C.3.2	Yes [ ] N/A [ ]
SRPMDDOT11-3	Does the device support MLME primitives specified in Table C-4?	SRPMDDOT11:M	C.3.3, Table C-4	Yes [ ] N/A [ ]
SRPMDDOT11-4	Does the device support VLAN tag encapsulation/de-encapsulation on the IEEE 802.11 interface?	SRPMDDOT11:M	C.3.3.1	Yes [ ] N/A [ ]
SRPMDDOT11-5	Is the reservation process an atomic operation?	SRPMDDOT11:M	C.3.1, Figure C-11, Figure C-12, Figure C-13	Yes [ ] N/A [ ]

A.32 Multiple I-SID Registration Protocol (MIRP)

Item	Feature	Status	References	Support
MIRP-1	Does the Bridge allow both MIRP and MVRP to be enabled on the same VIP?	MIRP AND BEB-I: X	12.9.2.2.2	No [ ] N/A [ ]
MIRP-2	Does the I-component implement MIRP as specified in Table 39.2?	MIRP AND BEB-I: M	39.1.1 item a)	Yes [ ] N/A [ ]
MIRP-3	Does the I-component propagate attributes freely between MVRP and MIRP Participants?	MIRP AND BEB-I AND MVRP: M	39.1.1 item b)	Yes [ ] N/A [ ]
MIRP-4	Does the I-component support operation as an MRP New-Only Participant?	MIRP AND BEB-I: M	39.1.1 item c)	Yes [ ] N/A [ ]
MIRP-5	Does the B-component implement the MIRP application as specified?	MIRP AND BEB-I: M	39.1.2 item a)	Yes [ ] N/A [ ]
MIRP-6	Does the B-component support operation as an MRP New-Only Participant?	MIRP AND BEB-I: M	39.1.2 item b)	Yes [ ] N/A [ ]
MIRP-7	Does the B-component translate I-SIDs in MIRPDUs as required?	MIRP AND BEB-I: M	39.2.1.2	Yes [ ] N/A [ ]
MIRP-8	Does the I-component transmit every MIRPDU with the Nearest Customer Bridge group address?	MIRP AND BEB-I: M	39.2.1.5	Yes [ ] N/A [ ]
MIRP-9	Does the I-component or B-component transmit MIRPDUs with the MIRP EtherType from Table 10-2?	MIRP: M	39.2.1.7	Yes [ ] N/A [ ]
MIRP-10	Does the I-component or B-component use 1 as the attribute type in MIRPDUs?	MIRP: M	39.2.1.9	Yes [ ] N/A [ ]
MIRP-11	Does the I-component or B-component encode the I-SIDs in the MIRPDU as 3-octet binary values?	MIRP: M	39.2.1.10	Yes [ ] N/A [ ]
MIRP-12	Does the I-component or B-component support the full range of attribute values in MIRPDUs?	MIRP: M	39.2.4	Yes [ ] N/A [ ]
MIRP-13	Does the I-component support at least 4094 attribute values?	MIRP AND BEB-I: M	39.2.4	Yes [ ] N/A [ ]
MIRP-14	Does the B-component support at least as many attribute values as supported by its Backbone Service Instance table?	MIRP AND BEB-B: M	39.2.4	Yes [ ] N/A [ ]
MIRP-15	Does the B-component transmit at least one MIRPDU for each distinct pair of destination MAC address and VID identified by the managed variables?	MIRP AND BEB-B: M	39.2.1.6	Yes [ ] N/A [ ]

A.33 Priority-based Flow Control (PFC)

Item	Feature	Status	References	Support
PFC-1	Enabling PFC on at least one priority	PFC: M	36.1.2	Yes [ ] N/A [ ]
PFC-2	Processing PFC Requests	PFC: M	36.1.3.1	Yes [ ] N/A [ ]
PFC-3	Processing PFC Indications	PFC: M	36.1.3.2	Yes [ ] N/A [ ]
PFC-4	PFC delay constraints	PFC: M	36.1.3.3	Yes [ ] N/A [ ]
PFC-5	PFC-aware system queue functions	PFC: M	36.2	Yes [ ] N/A [ ]
PFC-6	DCBX	PFC: M	5.11	Yes [ ] N/A [ ]
PFC-7	Enabling PFC on up to eight priorities	PFC: O	36.1.2	Yes [ ] No [ ] N/A [ ]
PFC-8	PFC not enabled for traffic classes using the credit-based shaper algorithm	PFC: M	8.6.8.2	Yes [ ] N/A [ ]

A.34 Enhanced Transmission Selection (ETS)

Item	Feature	Status	References	Support
ETS-1	Support at least 3 traffic classes	ETS:M	37.3	Yes [ ] N/A [ ]
ETS-2	Support bandwidth configuration with a granularity of 1% or finer	ETS:M	37.3	Yes [ ] N/A [ ]
ETS-3	Support bandwidth allocation with a precision of 10%	ETS:M	37.3	Yes [ ] N/A [ ]
ETS-4	Support allocation of a portion of available bandwidth to each traffic class	ETS:M	37.3	Yes [ ] N/A [ ]
ETS-5	Support DCBX.	ETS:M	Clause 38	Yes [ ] N/A [ ]

A.35 Data Center Bridging eXchange protocol (DCBX)

Item	Feature	Status	References	Support
DCBX-1	Support LLDP	DCBX:M	IEEE Std 802.1AB	Yes [ ] N/A [ ]
DCBX-2	Support the DCBX ETS Configuration TLV	DCBX:M	D.2.8	Yes [ ] N/A [ ]
DCBX-3	Support the ETS Recommendation TLV	DCBX:M	D.2.9	Yes [ ] N/A [ ]
DCBX-4	Support the Priority-based Flow Control Configuration TLV	DCBX:M	D.2.10	Yes [ ] N/A [ ]
DCBX-5	Support the Application Priority TLV	DCBX:M	D.2.11	Yes [ ] N/A [ ]
DCBX-6	Support the DCBX asymmetric state machine	DCBX:M	38.4.1	Yes [ ] N/A [ ]
DCBX-7	Support the DCBX symmetric state machine	DCBX:M	38.4.2	Yes [ ] N/A [ ]
DCBX-8	Support the Application VLAN TLV	DCBX:M	D.2.14	Yes [ ] N/A [ ]

A.36 Infrastructure Protection Switching (IPS)

Item	Feature	Status	References	Support
	If IPS is not supported, mark N/A and continue at A.37.			N/A [ ]
IPS-1	Is 1:1 IPS supported?	IPS: M	26.11.2	Yes [ ]
IPS-2	Is M:1 IPS supported?	IPS: O	26.11.5	Yes [ ] No [ ] N/A [ ]
IPS-3	Are the operator commands Forced Switch (FS), Lockout of Protection (LoP), Manual Switch to Working, and Manual Switch to Protection implemented?	IPS: M	26.11.2.5	Yes [ ]
IPS-4	Is the hold-off timer implemented?	IPS: O	26.11.2.3	Yes [ ] No [ ]
IPS-5	Is the M:1 wait-to-restore (MWTR) timer implemented?	IPS-2: O	26.11.5.4.7	Yes [ ] No [ ] N/A [ ]

A.37 Shortest Path Bridging (SPB)

Item	Feature	Status	References	Support
SPB-1	Does the Bridge support IS-IS Link State Protocol with procedures to ensure Loop Prevention?	SPB:M	5.4.5, Clause 28	Yes [ ] N/A [ ]
SPB-2	Encode, decode, and validate IS-IS Hello PDUs or SPT BPDUs for the Agreement Protocol (AP) and support AP logic in IS-IS?	SPB:M	5.4.5, Clause 28	Yes [ ] N/A [ ]
SPB-3	State the maximum number of FIDs supported. Minimum is three for SPB	SPB:M	5.4.5	_____FIDs
SPB-4	Support VLAN Registration and filtering of frames with unregistered VIDs	SPB:O	5.4.5	Yes [ ] No [ ] N/A [ ]
SPBV	Is Shortest Path Bridging VID mode supported?	SPB: O.6	5.4.5	Yes [ ] No [ ] N/A [ ]
SPBM	Is Shortest Path Bridging MAC mode supported?	SPB: O.6	5.4.5	Yes [ ] No [ ] N/A [ ]

A.38 EVB Bridge

Item	Feature	Status	References	Support
	If EVB Bridge functionality (EVB-B in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
EVB-B-1	Does the implementation comprise a single conformant C-VLAN component?	EVB-B:M	5.5, 5.6, 5.23	Yes [ ]
EVB-B-2	Is each externally accessible port capable of being configured as either a C-VLAN Bridge Port or a Station Facing Bridge Port (SBP)?	EVB-B:M	5.23, Clause 40	Yes [ ]
EVB-B-3	Does the implementation support the functionality of a C-VLAN component?	EVB-B:M	5.5, 5.23	Yes [ ]
EVB-B-4	Does the implementation support at least one SBP on the C-VLAN component?	EVB-B:M	5.23, Clause 40	Yes [ ]
EVB-B-5	Does the implementation support the EVB status parameters for EVBMode = EVB Bridge?	EVB-B:M	5.23, 40.4	Yes [ ]
EVB-B-6	Does the implementation support an LLDP nearest Customer Bridge database including the EVB TLV on each SBP?	EVB-B:M	5.23, D.2.12	Yes [ ]
EVB-B-7	Does the implementation support ECP on each SBP?	EVB-B:M	5.23, Clause 43	Yes [ ]
EVB-B-8	Does the implementation support the Bridge role of VDP on each SBP?	EVB-B:M	5.23, Clause 41	Yes [ ]
EVB-B-9	Does the implementation support at least one Port-mapping S-VLAN component and associated UAP configured as specified in 40.22 (a)–(d)?	EVB-B:O	5.23, 22.6.4, 40.2 items a)–d)	Yes [ ] No [ ]
EVB-B-10	Is each externally accessible port capable of being configured as an Uplink Access Port (UAP)?	EVB-B:O	5.23, Clause 40	Yes [ ] No [ ]
EVB-B-11	Does the implementation support CDCP, as specified in Clause 42, operating in Bridge mode?	EVB-B-9: M	Clause 42, 42.3	Yes [ ] N/A [ ]

A.38 EVB Bridge *(continued)*

Item	Feature	Status	References	Support
EVB-B-12	Does the implementation support the enhanced filtering utility criteria and not support the default filtering utility criteria (8.7)?	EVB-B-9: M	8.7	Yes [ ] N/A [ ]
EVB-B-13	Does the implementation support configuration of reflective relay on each SBP of the C-VLAN component?	EVB-B:O	5.23, 40.4, 8.6.1	Yes [ ] No [ ]
EVB-B-14	Does the implementation support management for the EVB components?	EVB-B:O	5.23, 12.4–12.12,12.26	Yes [ ] No [ ]
EVB-B-15	Does the implementation support an Simple Network Management Protocol (SNMP) management MIB module?	EVB-B:O	5.23, 17.7.20	Yes [ ] No [ ]
EVB-B-16	Does the implementation support assignment of VIDs to GroupIDs?	EVB-B:O	5.23, 41.2.9	Yes [ ] No [ ]
EVB-B-17	Does the implementation support the use of the M and S bits in VDP?	EVB-B:O	5.23, 41.2.3	Yes [ ] No [ ]
EVB-B-18	Does the Bridge reserve the S-channel Identifier (SCID) value 1 and S-VID value 1 for the exclusive use as the un-S-tagged default S-channel?	EVB-B:M	42.1	Yes [ ]

A.39 EVB station

Item	Feature	Status	References	Support
	If EVB station functionality (EVB-S in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
EVB-S-1	Does the EVB station comprise one or more conformant ER components?	EVB-S:M	5.6, 5.24.1	Yes [ ]
EVB-S-2	Is each externally accessible port capable of being configured as at least one of – A UAP – An uplink relay port (URP)?	EVB-S:M	5.24, Clause 40	Yes [ ]
EVB-S-3	Is each DRP capable of attaching its ER to one or more VSIs?	EVB-S:M	5.24, Clause 40	Yes [ ]
EVB-S-4	Is each URP capable of attaching its ER to a point-to-point LAN connecting the URP to a CAP, or to the LAN connecting to an EVB Bridge in the case where no Port-mapping S-VLAN component is present?	EVB-S:M	5.24, Clause 40	Yes [ ]
EVB-S-5	Does the implementation support at least one ER?	EVB-S:M	5.24, Clause 40	Yes [ ]
EVB-S-6	Does the implementation support at least one accessible URP?	EVB-S:M	5.24, Clause 40	Yes [ ]
EVB-S-7	Does the implementation support the EVB status parametersEVB-S: for EVBMode = EVB station on each URP?	EVB-S:M	5.24, 40.4	Yes [ ]
EVB-S-8	Does the implementation support an LLDP Nearest Customer Bridge database including the EVB TLV on each URP of each ER?	EVB-S:M	5.24, D.2.12	Yes [ ]
EVB-S-9	Does the implementation support ECP on each URP of each ER?	EVB-S:M	5.24, Clause 43	Yes [ ]

A.39 EVB station *(continued)*

Item	Feature	Status	References	Support
EVB-S-10	Does the implementation support the station role of VDP for each URP of each ER?	EVB-S:M	5.24, Clause 41	Yes [ ]
EVB-S-11	Does the implementation support a Port-mapping S-VLAN component on each Port configured as a UAP, configured as specified in 40.2 (a)–(d)?	EVB-S:O	5.24, 22.6.4, 40.2 items a)–d)	Yes [ ] No [ ]
EVB-S-12	Does the implementation support CDCP, as specified in Clause 42, operating in Station mode?	EVB-S-11: M	Clause 42, 42.3	Yes [ ] N/A [ ]
EVB-S-13	Does the implementation support the enhanced filtering utility criteria (8.7.2) and not support the default filtering utility criteria (8.7.1)?	EVB-S-11: M	8.7.1, 8.7.2	Yes [ ] N/A [ ]
EVB-S-14	Does the implementation support multiple ERs?	EVB-S:O	5.24, Clause 40	Yes [ ] No [ ]
EVB-S-15	Does the implementation support management for the EVB components?	EVB-S:O	5.24, 12.26	Yes [ ] No [ ]
EVB-S-16	Does the implementation support an EVB station SNMP management MIB module?	EVB-S:O	5.24, 17.7.20	Yes [ ] No [ ]
EVB-S-17	Does the implementation support assignment of VIDs to GroupIDs?	EVB-S:O	5.24, 41.2.9	Yes [ ] No [ ]
EVB-S-18	Does the implementation support Support the use of the M and S bits in VDP?	EVB-S:O	5.24, 41.2.3	Yes [ ] No [ ]

A.40 Edge relay (ER)

Item	Feature	Status	References	Support
	If EVB station functionality (EVB-S in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
ERC-1	Does the ER conform to the relevant standard for the MAC technology implemented at each Port in support of the MAC ISS, as specified in IEEE Std 802.1AC, and 6.14?	EVB-S:M	IEEE Std 802.1AC , 6.14	Yes [ ]
ERC-2	Does the ER support the MAC Enhanced Internal Sublayer Service (EISS) at each Port, as specified in 6.8 and 6.9?	EVB-S:M	6.8, 6.9	Yes [ ]
ERC-3	Does the ER recognize and use C-TAGs?	EVB-S:M	6.9	Yes [ ]
ERC-4	Does the ER relay and filter frames as described in 8.1 and specified in 8.5, 8.6, 8.7, and 8.8?	EVB-S:M	8.5, 8.6, 8.8	Yes [ ]
ERC-5	Does the ER support a PVID value, and configuration of at least one VID whose untagged set includes that Port, on each DRP that supports untagged and priority-tagged frames?	EVB-S:M	6.9, 8.8.2	Yes [ ]
ERC-6	Does the ER support setting the Acceptable Frame Types parameter to *Admit Only VLAN-tagged Frames* on the URP?	EVB-S:M	5.24.1, 6.9	Yes [ ]

A.40 Edge relay (ER) *(continued)*

Item	Feature	Status	References	Support
ERC-7	Does the ER allow tag headers to be inserted, modified, and removed from relayed frames, as specified in 8.2 and Clause 9, as required by the value(s) of the Acceptable Frame Types parameter supported on each Port, and by the ability of each Port to transmit VLAN-tagged and/or untagged frames?	EVB-S:M	8.1, Clause 9	Yes [ ]
ERC-8	Does the ER support at least one FID?	EVB-S:M	IEEE Std 802.1AC, 8.8.3, 8.8.8, 8.8.9	Yes [ ]
ERC-9	Does the ER allow allocation of at least one VID to each FID that is supported?	EVB-S:M	IEEE Std 802.1AC, 8.8.3, 8.8.8, 8.8.9	Yes [ ]
ERC-10	Does the ER support exactly one URP supporting the parameters of 40.4 for EVBMode = EVB station?	EVB-S:M	5.24.1, 40.4, Clause 40	Yes [ ]
ERC-11	Does the ER support one or more DRPs each supporting access to VSIs?	EVB-S:M	5.24.1, Clause 40	Yes [ ]
ERC-12	Does the ER filter the reserved MAC addresses?	EVB-S:M	5.24.1, Table 8-1	Yes [ ]
ERC-13	Does the ER support more than one DRP?	EVB-S:O	5.24.1	Yes [ ] No [ ]
ERC-14	Does the ER support setting the Enable Ingress Filtering parameter (8.6.2) on each DRP?	ERC-13:M	5.24.1, 8.6.2	Yes [ ] N/A [ ]
ERC-15	Does the ER support setting the Enable Ingress Filtering parameter (8.6.2) on each URP?	ERC-13:M	5.24.1, 8.6.2	Yes [ ] N/A [ ]
ERC-16	Does the ER support the requirements of either a VEB ER or a VEPA ER?	ERC-13:M	5.24.1, 5.24.1.1, 5.24.1.2	Yes [ ]
ERC-17	Does the ER support a PVID value, and configuration of at least one VID whose untagged set includes that Port, if the URP supports untagged and priority-tagged frames?	EVB-S:O	6.9, 8.8.2	Yes [ ]
ERC-18	Does the ER comprise a single conformant C-VLAN component?	EVB-S:O	5.4	Yes [ ] No [ ]
ERC-19	Does the ER support disabling of learning on each DRP?	EVB-S:O	5.24.1, 8.6.1	Yes [ ] No [ ]
ERC-20	Does the ER support discarding frames with unregistered source addresses at each DRP?	EVB-S:O	5.24.1, 8.8.1	Yes [ ] No [ ]
ERC-21	Does the ER support the operation of the learning process?	EVB-S:O	8.7	Yes [ ] No [ ]

A.41 VEB and VEPA ER components

Item	Feature	Status	References	Support
	If EVB station functionality (EVB-S in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
VERC-1	Does the ER component support VEB functionality?	EVB-S:O.6	5.24.1.1	Yes [ ] No [ ]
VERC-2	Does the ER component support VEPA functionality?	EVB-S:O.6	5.24.1.2	Yes [ ] No [ ]
VERC-3	Does the ER component request that reflective relay service not be provided by setting adminReflectiveRelayRequest to FALSE?	VERC-1:M	5.24.1.1	Yes [ ] N/A [ ]
VERC-4	Does the VEPA ER disable learning on the URP?	VERC-2:M	5.24.1.2, 8.6.1	Yes [ ] N/A [ ]
VERC-5	Does the VEPA ER filter frames received at each URP that are destined to a DRP that originated the frame?	VERC-2:M	5.24.1.2, 8.6.1	Yes [ ] N/A [ ]
VERC-6	Does the VEPA ER request reflective relay service by setting adminReflectiveRelayRequest to True?	VERC-2:O	5.24.1.2, 40.4	Yes [ ] N/A [ ]
VERC-7	Does the ER filter frames received at each DRP that are destined for the URP until reflective relay is enabled?	VERC-2:O	5.24.1.2, 8.6.1.1	Yes [ ] No [ ] N/A [ ]
VERC-8	Does the ER forward frames as specified in 8.6.3.1?	VERC-2:M	5.24.1.2, 8.6.3.1	Yes [ ] N/A [ ]

A.42 VDP, CDCP, and ECP

Item	Feature	Status	References	Support
	If neither EVB station functionality (EVB-S in A.5) nor EVB Bridge functionality (EVB-B in A.5) is supported, mark N/A and ignore the remainder of this table.			N/A [ ]
VDP-1	Does the implementation support the Bridge VDP state machine as specified in Clause 41?	EVB-B:M	Clause 41, 41.5.2	Yes [ ]
VDP-2	Does the implementation support the Station VDP state machine as specified in Clause 41?	EVB-S:M	Clause 41, 41.5.3	Yes [ ]
CDCP-1	Does the implementation support the CDCP configuration state machine for the Bridge role, as specified in Clause 42?	EVB-B AND EVB-B-9: M	Clause 42, 42.3	Yes [ ] N/A [ ]
CDCP-2	Does the implementation support the CDCP configuration state machine for the station role, as specified in Clause 42?	EVB-S AND EVB-S-11: M	Clause 42, 42.3	Yes [ ] N/A [ ]
ECP-1	Does the implementation support the ECP transmit state machine as specified in Clause 43?	EVB-S AND EVB-B:M	Clause 43, 43.3.4	Yes [ ]
ECP-2	Does the implementation support the ECP receive state machine as specified in Clause 43?	EVB-S AND EVB-B:M	Clause 43, 43.3.5	Yes [ ]

A.43 Path Control and Reservation

Item	Feature	Status	References	Support
	If Path Control and Reservation (PCR in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
PCR-1	Does the Bridge support the ISIS-PCR protocol?	PCR:M	Clause 45	Yes [ ]
PCR-2	Does the Bridge support the SPB Link Metric sub-TLV?	PCR:M	28.12.7	Yes [ ]
PCR-3	Does the Bridge support the SPB Base VLAN-Identifiers sub TLV?	PCR:M	28.12.4	Yes [ ]
PCR-4	Does the Bridge support the SPB Instance sub-TLV?	PCR:M	28.12.5	Yes [ ]
PCR-5	Does the Bridge support the SPBV MAC address sub-TLV?	PCR:M	28.12.9	Yes [ ]
PCR-6	Does the Bridge support the SPBM Service Identifier and Unicast Address sub-TLV?	BEB AND PCR:M	28.12.10	Yes [ ] N/A [ ]
PCR-7	Does the Bridge support the Topology sub-TLV?	PCR:M	45.1.9	Yes [ ]
PCR-8	Does the Bridge support the Hop sub-TLV?	PCR:M	45.1.10	Yes [ ]
PCR-9	Does the Bridge support the ST ECT Algorithm?	PCR:M	45.1.2	Yes [ ]
PCR-10	Does the Bridge support the LT ECT Algorithm?	PCR:O	45.1.2	Yes [ ] No [ ]
PCR-11	Does the Bridge support the LTS ECT Algorithm?	PCR:O	45.1.2	Yes [ ] No [ ]
PCR-12	Does the Bridge support the MRT ECT Algorithm?	PCR:O	45.1.2, 45.3.3	Yes [ ] No [ ]
PCR-13	Does the Bridge support the MRTG ECT Algorithm?	PCR:O	45.1.2, 45.3.4	Yes [ ] No [ ]
PCR-14	Does the Bridge support the Extended IS Reachability TLV?	PCR:O	45.1.8, IETF RFC 5305	Yes [ ] No [ ]
PCR-15	Does the Bridge support the Unidirectional Link Delay sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]
PCR-16	Does the Bridge support the Min/Max Unidirectional Link Delay sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]
PCR-17	Does the Bridge support the Unidirectional Delay Variation sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]
PCR-18	Does the Bridge support the Unidirectional Link Loss sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]
PCR-19	Does the Bridge support the Unidirectional Residual Bandwidth sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]
PCR-20	Does the Bridge support the Unidirectional Available Bandwidth sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]
PCR-21	Does the Bridge support the Unidirectional Utilized Bandwidth sub-TLV?	PCR:O	45.1.8, IETF RFC 7810	Yes [ ] No [ ]

A.43 Path Control and Reservation *(continued)*

Item	Feature	Status	References	Support
PCR-22	Does the Bridge support the Shared Risk Link Group TLV?	PCR:O	45.1.8, IETF RFC 5307	Yes [ ] No [ ]
PCR-23	Does the Bridge support the Administrative Group sub-TLV?	PCR:O	45.1.11	Yes [ ] No [ ]
PCR-24	Does the Bridge support the Bandwidth Constraint sub-TLV?	PCR:O	45.1.12	Yes [ ] No [ ]
PCR-25	Does the Bridge support the Bandwidth Assignment sub-TLV?	PCR:O	45.2.1	Yes [ ] No [ ]
PCR-26	Does the Bridge support the Timestamp sub-TLV?	PCR:O	45.2.2	Yes [ ] No [ ]
PCR-27	Does the Bridge support Loop-Free Alternates for unicast data flows supported by SPBM?	SPBM:O PCR:O	45.3.1	Yes [ ] No [ ] N/A [ ]
PCR-28	Does the Bridge support relaxed ingress checking?	SPBM:O PCR:O	8.4, 8.6.1, 8.8.3, 45.3.1	Yes [ ] No [ ] N/A [ ]

A.44 Scheduled traffic

Item	Feature	Status	References	Support
	If neither scheduled traffic (SCHED in A.5) nor cyclic queuing and forwarding (CQF in A.5) are supported, mark N/A and ignore the remainder of this table.		5.4.1, 5.13.1, 8.6.8, 8.6.9, 12.29, 17.7.22	N/A [ ]
SCHED1	Does the implementation support the state machines and associated definitions specified in 8.6.9	SCHED OR CQF:M	5.4.1, 5.13.1, 8.6.8, 8.6.9	Yes [ ] N/A [ ]
SCHED2	Does the implementation support the management entities defined in 12.29?	SCHED OR CQF:M	5.4.1 item ad), 5.4.1.9 item c), 5.13.1.2 item c), 12.29	Yes [ ] N/A [ ]
SCHED3	Is the IEEE8021-ST-MIB module fully supported (per its MODULE-COMPLIANCE)?	MIB AND (SCHED OR CQF):O	5.4.1 item ad), 5.4.1.9 item c), 5.13.1.2 item c), 12.29, 17.7.22	Yes [ ] N/A [ ] No [ ]

A.45 Frame preemption

Item	Feature	Status	References	Support
	If frame preemption (PRE in A.5) is not supported, mark N/A and ignore the remainder of this table.		5.4.1, 5.13.1, 6.7.2, 8.6.8, 12.30, 17.7.23	N/A [ ]
PRE1	Does the implementation support the functionality of frame preemption as specified in 6.7.2 and 8.6.8?	PRE: M	5.4.1, 5.13.1, 6.7.2, 8.6.8	Yes [ ] N/A [ ]

A.46 Per-Stream Filtering and Policing

Item	Feature	Status	References	Support
	If neither Per-Stream Filtering and Policing (PSFP in A.5) nor cyclic queuing and forwarding (CQF in A.5) are supported, mark N/A and ignore the remainder of this table.		5.4.1.9, 5.13.1.2, 8.6.5.2, 8.6.10, 12.31, 17.7.24	N/A[ ]
PSFP1	Does the implementation support the state machines and associated definitions as specified in 8.6.10?	PSFP OR CQF:M	5.4.1.9 item b), 5.13.1.2 item b), 8.6.5, 8.6.10	Yes [ ] N/A [ ]
PSFP2	Does the implementation support the management entities defined in 12.31?	PSFP OR CQF:M	5.4.1.9 item e), 5.13.1.2 item e), 8.6.5.2, 8.6.10, 12.31	Yes [ ] N/A [ ]
PSFP3	Is the IEEE8021-PSFP-MIB module fully supported (per its MODULE-COMPLIANCE)?	MIB AND (PSFP OR CQF):O	5.4.1.9 item e), 5.13.1.2 item e), 12.31, 17.7.24	Yes [ ] N/A [ ] No [ ]

A.47 YANG

Item	Feature	Status	References	Support
	If item YANG is not supported, mark N/A			N/A [ ]
YANG-802-TYPES	Is the *ieee802-types* module supported?	M	48.6.1	Yes [ ]
YANG-Q-TYPES	Is the *ieee802-dot1q-types* module supported?	M	48.6.2	Yes [ ]
YANG-TSN-TYPES	Is the *ieee802-dot1q-tsn-types* module supported?	O	48.6.3	Yes [ ] No [ ]
YANG-QBRIDGE	Is the *ieee802-dot1q-bridge* module supported?	M	48.6.4	Yes [ ] N/A [ ]
YANG-TPMR	Is the *ieee802-dot1q-tpmr* module supported?	TPMR:O	48.6.5	Yes [ ] No [ ] N/A [ ]
YANG-PB	Is the *ieee802-dot1q-pb* module supported?	PB:O	48.6.6	Yes [ ] No [ ] N/A [ ]
YANG-CFM-TYPES	Is the *ieee802-dot1q-cfm-types* module supported?	CFM:O	48.6.7	Yes [ ] No [ ] N/A [ ]
YANG-CFM	Is the *ieee802-dot1q-cfm* module supported?	CFM:O	48.6.8	Yes [ ] No [ ] N/A [ ]
YANG-CFM-BRIDGE	Is the *ieee802-dot1q-cfm-bridge* module supported?	CFM:O	48.6.9	Yes [ ] No [ ] N/A [ ]
YANG-CFM-ALARM	Is the *ieee802-dot1q-cfm-alarm* module supported?	CFM:O	48.6.10	Yes [ ] No [ ] N/A [ ]
YANG-STREAMS	Is the *ieee802-dot1q-stream-filters-gates* module supported?	ATS:O	48.6.11	Yes [ ] No [ ] N/A [ ]
YANG-ATS	Is the *ieee802-dot1q-ats* module supported?	ATS:O	48.6.12	Yes [ ] No [ ] N/A [ ]

A.48 Stream reservation remote management (SRRM)

Item	Feature	Status	References	Support
	If Stream reservation remote management functionality (SRRM of A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
SRRM-1	What management protocol standard(s) or specification(s) are supported (server side)?	M	5.4.1.10(b)	_____ _____ _____
SRRM-2	Does the implementation report delay through the Bridge?	M	12.32.1	Yes [ ]
SRRM-3	Does the implementation report propagation delay?	M	12.32.2	Yes [ ]
SRRM-4	Does the implementation support Static Trees for static configuration of spanning trees?	M	5.4.1.10 item c), 12.32.3	Yes [ ]
SRRM-5	Does the implementation support MRP External Control for the MSRP application?	O SRP: M	12.32.4	Yes [ ] No [ ] N/A [ ]
SRRM-6	Does the implementation support MRP External Control for the MVRP application?	O MVRP: M	12.32.4	Yes [ ] No [ ] N/A [ ]
SRRM-7	Does the implementation support MRP External Control for the MMRP application?	O MMRP: M	12.32.4	Yes [ ] No [ ] N/A [ ]
SRRM-8	Does the implementation support queue reservation for traffic classes using the strict priority algorithm, through configuration of adminIdleSlope?	M	5.4.1.10 item e), 12.20.1, 34.3	Yes [ ]

A.49 TSN Centralized Network Configuration (CNC) station

Item	Feature	Status	References	Support
	If the functionality of a Centralized Network Configuration station (CNC-S of A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
CNC-S-1	What management protocol standard(s) or specification(s) are supported (client side)?	M	5.29 item a)	_____ _____ _____
CNC-S-2	Does the implementation support the managed object definitions and encodings for Stream reservation remote management?	M	5.29 item b), 12.32	Yes [ ]
CNC-S-3	Does the implementation support the managed object definitions and encodings for scheduled traffic?	O	12.29	Yes [ ] No [ ]
CNC-S-4	Does the implementation support the managed object definitions and encodings for frame preemption?	O	12.30	Yes [ ] No [ ]
CNC-S-5	Does the implementation support the managed object definitions and encodings for IEEE Std 802.1AS?	O	IEEE Std 802.1AS	Yes [ ] No [ ]
CNC-S-6	Does the implementation support the managed object definitions and encodings for IEEE Std 802.1CB?	O	IEEE Std 802.1CB	Yes [ ] No [ ]
CNC-S-7	Does the implementation support MRP External Control for the MSRP application?	O	12.32.4	Yes [ ] No [ ]
CNC-S-8	Does the implementation support MRP External Control for the MVRP application?	O	12.32.4	Yes [ ] No [ ]
CNC-S-9	Does the implementation support MRP External Control for the MMRP application?	O	12.32.4	Yes [ ] No [ ]
CNC-S-10	What user/network configuration protocol standard(s) or specification(s) are supported?	M	5.29 item c), 46.2.2	_____ _____ _____
CNC-S-11	Does the implementation conform to the conditional requirements for use of a YANG-based protocol?	M	5.29 item d), 46.2, 46.3	Yes [ ]
CNC-S-13	Does the implementation conform to the conditional requirements for use of SRP?	M	5.29 item e), 46.2, 12.32.4	Yes [ ]

A.50 VDP for NVO3 nNVE Devices

Item	Feature	Status	References	Support
	If VDP-NVO3 nNVE functionality (VDP-NVO3-nNVE in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
VDP-nNVE-1	Does the implementation support the Bridge role of VDP on each SBP?	M	5.30.1, Clause 41	Yes [ ]
VDP-nNVE-2	Does the implementation support the Bridge VDP state machine as specified in Clause 41?	M	Clause 41, 41.5.2	Yes [ ]
VDP-nNVE-3	Does the implementation support assignment of VIDs to GroupIDs?	M	5.30.1, 41.2.9	Yes [ ]
VDP-nNVE-4	Does the implementation support at least one SBP on the nNVE?	M	5.30.1, Clause 40	Yes [ ]
VDP-nNVE-5	Does the implementation support an LLDP nearest Customer Bridge database including the EVB TLV on each SBP?	O	5.30.1, D.2.12	Yes [ ] No [ ]
VDP-nNVE-6	Does the implementation support the EVB status parameters for EVBMode = NVO3 and NVERole = nNVE for the nNVE role?	O	5.30.1, 40.4, 40.5	Yes [ ] No [ ]
VDP-nNVE-7	Does the implementation support the EVB Bridge status parameters for IPv4 address capability?	VDP-nNVE-6:M	D.2.12.3.5	Yes [ ] No [ ]
VDP-nNVE-8	Does the implementation support the EVB Bridge status parameters for IPv6 address capability?	VDP-nNVE-6:M	D.2.12.3.4	Yes [ ] No [ ]
VDP-nNVE-9	Does the implementation support ECP on each SBP?	O	5.30.1, Clause 43	Yes [ ] No [ ]
VDP-nNVE-10	Does the implementation support the use of M, S, and N bits in VDP?	O	5.30.1, 41.2.3	Yes [ ] No [ ]
VDP-nNVE-11	Does the implementation support the use of IPv4 addresses in VDP filter info format?	O	5.30.1, 41.2.9	Yes [ ] No [ ]
VDP-nNVE-12	Does the implementation support the use of IPv6 addresses in VDP filter info format?	O	5.30.1, 41.2.9	Yes [ ] No [ ]
VDP-nNVE-13	Does the implementation support an LLDP database addressed by a unicast MAC address including the EVB TLV on each SBP?	O	5.30.1, D.2.12	Yes [ ] No [ ]

A.51 VDP for NVO3 tNVE Devices

Item	Feature	Status	References	Support
	If VDP-NVO3 tNVE functionality (VDP-NVO3-tNVE in A.5) is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
VDP-tNVE-1	Does the implementation support the Station role of VDP on each URP?	M	5.30.1, Clause 41	Yes [ ]
VDP-tNVE-2	Does the implementation support the Station VDP state machine as specified in Clause 41?	M	Clause 41, 41.5.3	Yes [ ]
VDP-tNVE-3	Does the implementation support an LLDP nearest Customer Bridge database including the EVB TLV on each URP?	O	5.30.2, D.2.12	Yes [ ] No [ ]
VDP-tNVE-4	Does the implementation support the EVB status parameters for EVBMode = NVO3 and NVERole = tNVE for the tNVE role?	O	5.30.2, 40.4, 40.5	Yes [ ] No [ ]
VDP-tNVE-5	Does the implementation support the EVB Bridge status parameters for IPv4 address capability?	VDP-tNVE-4:M	D.2.12.4.5	Yes [ ] No [ ]
VDP-tNVE-6	Does the implementation support the EVB Bridge status parameters for IPv6 address capability?	VDP-tNVE-4:M	D.2.12.4.4	Yes [ ] No [ ]
VDP-tNVE-7	Does the implementation support ECP on each URP?	O	5.30.2, Clause 43	Yes [ ] No [ ]
VDP-tNVE-8	Does the implementation support the use of M, S, and N bits in VDP?	O	5.30.2, 41.2.3	Yes [ ] No [ ]
VDP-tNVE-9	Does the implementation support the use of IPv4 addresses in VDP filter info format?	O	5.30.2, 41.2.9	Yes [ ] No [ ]

VDP-tNVE-11	Does the implementation support an LLDP database addressed by a unicast MAC address including the EVB TLV on each URP?	O	5.30.2, D.2.12	Yes [ ] No [ ]
VDP-tNVE-12	Does the RRREQ in EVB station status parameters set to FALSE to make reflective relay always disabled?	VDP-tNVE-4:M	D.2.12.4	Yes [ ] No [ ]

A.52 Asynchronous Traffic Shaping

Item	Feature	Status	References	Support
	If Asynchronous Traffic Shaping (ATS in Table A.5) is not supported, mark N/A and ignore the remainder of this table.		5.4.1.10, 5.13.1.3, 8.6.5.2.2, 8.6.6 items d) and e), 8.6.8.5, 8.6.8, 8.6.8.5, 8.6.11, 12.31	N/A [ ]
ATS-1	Does the implementation support the ATS per-stream classification and metering for ATS as specified in 8.6.5.2.2?	ATS:M	5.4.1.10, 5.13.1.3, 8.6.5.2.2	Yes [ ]
ATS-2	Does the implementation support the ATS transmission selection algorithm as specified in 8.6.8.5?	ATS:M	5.4.1.10, 5.13.1.3, 8.6.8.5	Yes [ ]
ATS-3	Does the implementation support the ATS scheduler state machines as specified in 8.6.11?	ATS:M	5.4.1.10, 5.13.1.3, 8.6.11	Yes [ ]
ATS-4	Does the implementation support the management entities defined in 12.31 for ATS?	ATS:M	5.4.1.10, 5.13.1.3, 12.31	Yes [ ]

Annex B

(normative)

PICS proforma—End station implementations[56]

B.1 Introduction

The supplier of a protocol implementation that is claimed to conform to this standard shall complete the following Protocol Implementation Conformance Statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. The PICS can have a number of uses, including use:

a) By the protocol implementor, as a checklist to reduce the risk of failure to conform to the standard through oversight.
b) By the supplier and acquirer—or potential acquirer—of the implementation, as a detailed indication of the capabilities of the implementation, stated relative to the common basis for understanding provided by the standard PICS proforma.
c) By the user—or potential user—of the implementation, as a basis for initially checking the possibility of interworking with another implementation (note that, while interworking can never be guaranteed, failure to interwork can often be predicted from incompatible PICSs).
d) By a protocol tester, as the basis for selecting appropriate tests against which to assess the claim for conformance of the implementation.

B.2 Abbreviations and special symbols

B.2.1 Status symbols

M	mandatory
O	optional
O.n	optional, but support of at least one of the group of options labeled by the same numeral n is required
X	prohibited
pred:	conditional-item symbol, including predicate identification: see B.3.4
¬	logical negation, applied to a conditional item’s predicate

B.2.2 General abbreviations

N/A	not applicable
PICS	Protocol Implementation Conformance Statement

[56] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

B.3 Instructions for completing the PICS proforma

B.3.1 General structure of the PICS proforma

The first part of the PICS proforma, implementation identification and protocol summary, is to be completed as indicated with the information necessary to identify fully both the supplier and the implementation.

The main part of the PICS proforma is a fixed-format questionnaire, divided into several subclauses, each containing a number of individual items. Answers to the questionnaire items are to be provided in the rightmost column, either by simply marking an answer to indicate a restricted choice (usually Yes or No), or by entering a value or a set or range of values. (Note that there are some items where two or more choices from a set of possible answers can apply; all relevant choices are to be marked.)

Each item is identified by an item reference in the first column. The second column contains the question to be answered; the third column records the status of the item—whether support is mandatory, optional, or conditional: see also B.3.4 below. The fourth column contains the reference or references to the material that specifies the item in the main body of this standard, and the fifth column provides the space for the answers.

A supplier may also provide (or be required to provide) further information, categorized as either Additional Information or Exception Information. When present, each kind of further information is to be provided in a further subclause of items labeled Ai or Xi, respectively, for cross-referencing purposes, where i is any unambiguous identification for the item (e.g., simply a numeral). There are no other restrictions on its format and presentation.

A completed PICS proforma, including any Additional Information and Exception Information, is the Protocol Implementation Conformation Statement for the implementation in question.

NOTE—Where an implementation is capable of being configured in more than one way, a single PICS may be able to describe all such configurations. However, the supplier has the choice of providing more than one PICS, each covering some subset of the implementation's configuration capabilities, in case that makes for easier and clearer presentation of the information.

B.3.2 Additional information

Items of Additional Information allow a supplier to provide further information intended to assist the interpretation of the PICS. It is not intended or expected that a large quantity will be supplied, and a PICS can be considered complete without any such information. Examples might be an outline of the ways in which a (single) implementation can be set up to operate in a variety of environments and configurations, or information about aspects of the implementation that are outside the scope of this standard but that have a bearing upon the answers to some items.

References to items of Additional Information may be entered next to any answer in the questionnaire, and may be included in items of Exception Information.

B.3.3 Exception information

It may occasionally happen that a supplier will wish to answer an item with mandatory status (after any conditions have been applied) in a way that conflicts with the indicated requirement. No preprinted answer will be found in the Support column for this: instead, the supplier shall write the missing answer into the Support column, together with an *Xi* reference to an item of Exception Information, and shall provide the appropriate rationale in the Exception item itself.

An implementation for which an Exception item is required in this way does not conform to this standard.

NOTE—A possible reason for the situation described previously is that a defect in this standard has been reported, a correction for which is expected to change the requirement not met by the implementation.

B.3.4 Conditional status

B.3.4.1 Conditional items

The PICS proforma contains a number of conditional items. These are items for which both the applicability of the item itself, and its status if it does apply—mandatory or optional—are dependent upon whether certain other items are supported.

Where a group of items is subject to the same condition for applicability, a separate preliminary question about the condition appears at the head of the group, with an instruction to skip to a later point in the questionnaire if the "Not Applicable" answer is selected. Otherwise, individual conditional items are indicated by a conditional symbol in the Status column.

A conditional symbol is of the form "**pred:** S" where **pred** is a predicate as described in B.3.4.2 below, and S is a status symbol, M or O.

If the value of the predicate is true (see B.3.4.2), the conditional item is applicable, and its status is indicated by the status symbol following the predicate: the answer column is to be marked in the usual way. If the value of the predicate is false, the "Not Applicable" (N/A) answer is to be marked.

B.3.4.2 Predicates

A predicate is one of the following:

a) An item-reference for an item in the PICS proforma: the value of the predicate is true if the item is marked as supported, and is false otherwise.
b) A predicate-name, for a predicate defined as a Boolean expression constructed by combining item-references using the Boolean operator OR: the value of the predicate is true if one or more of the items is marked as supported.
c) The logical negation symbol "¬" prefixed to an item-reference or predicate-name: the value of the predicate is true if the value of the predicate formed by omitting the "¬" symbol is false, and vice versa.

Each item whose reference is used in a predicate or predicate definition, or in a preliminary question for grouped conditional items, is indicated by an asterisk in the Item column.

B.4 PICS proforma for IEEE Std 802.1Q—End station implementations

B.4.1 Implementation identification

Supplier	
Contact point for queries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) of machines and/or operating system names	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirement for full identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

B.4.2 Protocol summary, IEEE Std 802.1Q

Identification of protocol specification	IEEE Std 802.1Q-2022, IEEE Standard for Local and metropolitan area networks—Bridges and Bridged Networks
Identification of amendments and corrigenda to the PICS proforma that have been completed as part of the PICS	Amd. : Corr. : Amd. : Corr. :
Have any Exception items been required? (See A.3.3: the answer Yes means that the implementation does not conform to IEEE Std 802.1Q)	No [ ] Yes [ ]

Date of Statement	

B.5 Major capabilities

Item	Feature	Status	References	Support
MRPAP	Does the implementation support any MRP applications? If “No” is marked, continue at FQTSSE.	O	5.18.1	Yes [ ] No [ ]
MMRP	Is the operation of MMRP supported?	O.1	5.18.1, B.6	Yes [ ] No [ ]
MVRP	Is automatic configuration and management of VLAN topology using MVRP supported?	O.1	5.18.1, B.7	Yes [ ] No [ ]
MSRP	Is the operation of MSRP supported?	O.1	5.18.3, B.10	Yes [ ] No [ ]
MRP	Is the Multiple Registration Protocol implemented in support of MRP Applications?	M	Clause 10, B.6, B.7, B.8	Yes [ ]
SPRU	Does the implementation support Source Pruning?	O	5.18, 10.10.3, 11.2.1.1	Yes [ ] No [ ]
MRP1	Does the MRP implementation support operation of the Full Participant?	SPRU:O.2 ¬SPRU:O.3	Clause 10, B.8	Yes [ ] No [ ]
MRP2	Does the MRP implementation support operation of the Full Participant, point-to-point subset?	SPRU:O.2 ¬SPRU:O.3	Clause 10, B.8	Yes [ ] No [ ]
MRP3	Does the MRP implementation support operation of the Applicant-Only Participant?	¬SPRU:O.3	Clause 10, B.8	Yes [ ] No [ ]
MRP4	Does the MRP implementation support operation of the Simple-Applicant Participant, point-to-point subset?	¬SPRU:O.3	Clause 10, B.8	Yes [ ] No [ ]
FQTSSE	Does the implementation support forwarding and queuing for time-sensitive streams?	O	5.20, 34.6, B.9	Yes [ ] No [ ]
CN	Is congestion notification implemented?	O	5.21, Clauses 30, 31, 32, 33, B.11	Yes [ ] No [ ]
PFC	Is Priority-based Flow Control implemented?	O	5.11, Clause 36, B.12	Yes [ ] No [ ]
ETS	Does the implementation support bandwidth management using ETS?	O	Clause 37, B.13	Yes [ ] No [ ]
DCBX	Does the implementation support configuration management via DCBX?	O	Clause 38, B.14	Yes [ ] No [ ]
EVB-S	Does the implementation support EVB Station functionality?	O	5.24, A.39	Yes [ ] No [ ]
SCHED	Does the implementation support scheduled traffic?	O	5.4.1, 5.13.1, 8.6.8, 8.6.9, 12.29, 17.7.22	Yes [ ] No [ ]
PRE	Does the implementation support frame preemption?	O	5.4.1, 5.13.1, 6.7.2, 8.6.8, 12.30, 17.7.23	Yes [ ] No [ ]
PSFP	Does the implementation support PSFP?	O	8.6.5.2.1, 8.6.10, 12.31	Yes [ ] No [ ]
ATS	Does the implementation support Asynchronous Traffic Shaping?	O	8.6.5.2.2, 8.6.8, 8.6.8.5, 8.6.11, 12.31	Yes [ ] No [ ]
CQF	Does the implementation support cyclic queuing and forwarding?	O	5.25, 5.28	Yes [ ] No [ ]
CNC-S	Does the implementation support Centralized Network Configuration (CNC) station functionality?	O	5.29, 46.2, A.17	Yes [ ] No [ ]

B.6 Multiple MAC Registration Protocol (MMRP)

Item	Feature	Status	References	Support
	If MMRP is not supported, mark N/A and continue at B.7.			N/A [ ]
MMRP1	Does the implementation support the exchange of MMRPDUs, using the generic MRPDU format defined in 10.8 to exchange MMRP-specific information, as defined in 10.12?	M	5.4.1.3, 10.8, 10.12	Yes [ ]
MMRP2	Is the MMRP Application supported as defined in 10.12?	M	5.4.1.3, 10.12	Yes [ ]
MMRP5	Is the MAP Context Identifier used to identify a VLAN Context equal to the VID used to identify the corresponding VLAN?	M	10.12.1.1	Yes [ ]
MMRP7	Is the group MAC address used as the destination address for MRPDUs destined for MMRP Participants the group MAC address identified in Table 10-1 as “Customer and Provider Bridge MMRP address”?	M	10.12.1.3	Yes [ ]
MMRP8	Is the EtherType used for MRPDUs destined for MMRP Participants the MMRP EtherType identified in Table 10-2?	M	10.12.1.4, Table 10-2	Yes [ ]
MMRP9	Does the ProtocolVersion used for the implementation of MMRP take the hexadecimal value 0x00?	M	10.12.1.5	Yes [ ]
MMRP10	Are the Attribute Type values used in the implementation as specified in 10.12.1.6?	M	10.12.1.6	Yes [ ]
MMRP11	Does the implementation encode the values in FirstValue fields in accordance with the definition in 10.12.1.7?	M	10.12.1.7	Yes []
MMRP12	Is management of the Restricted_MAC_Address_Registration control parameter supported?	O	10.12.2	Yes [ ] No [ ]
MMRP13	If management of the Restricted_MAC_Address_Registration control parameter is not supported, is the value of this parameter FALSE for all Ports?	¬MMRP12:M	10.12.2	Yes [ ] N/A [ ]
MMRP14	Does the implementations maintain state information for all attribute values that support the Group service requirement registration?	SPRU:M	10.10.2	Yes [ ] N/A [ ]
MMRP15	Is the implementation capable of supporting any attribute value in the range of possible values that can be registered using Group membership and individual MAC address registration?	M	10.12.4	Yes [ ]
MMRP16	State the number of Group membership and individual MAC address state values that can be supported on each Port.	M	10.12.4	Number_____

B.7 Multiple VLAN Registration Protocol (MVRP)

Item	Feature	Status	References	Support
	If MVRP is not supported, mark N/A and continue at B.8.			N/A [ ]
MVRP1	Does the implementation support the exchange of MMRPDUs, using the generic MRPDU format defined in 11.2 to exchange MMRP-specific information, as defined in 10.12?	M	5.4.2, 10.8, 11.2	Yes [ ]
MVRP2	Is the MMRP Application supported as defined in 11.2?	M	5.4.2, 11.2	Yes [ ]
MVRP7	Is the group MAC address used as the destination address for MRPDUs destined for MVRP Participants as defined in 11.2.3.1.3?	M	11.2.3.1.3	Yes [ ]
MVRP8	Is the EtherType used for MRPDUs destined for MVRP Participants the MVRP EtherType identified in Table 10-2?	M	11.2.3.1.4, Table 10-2	Yes [ ]
MVRP9	Does the ProtocolVersion used for the implementation of MVRP take the hexadecimal value 0x00?	M	11.2.3.1.5	Yes [ ]
MVRP10	Are the Attribute Type values used in the implementation as specified in 11.2.3.1.6?	M	11.2.3.1.6	Yes [ ]
MVRP11	Does the implementation encode the values in FirstValue fields in accordance with the definition in 11.2.3.1.7?	M	11.2.3.1.7	Yes [ ]
MVRP12	Is the implementation of MVRP capable of supporting all attribute values in the range of possible values that can be registered using MVRP?	SPRU:M	11.2.7	Yes [ ] N/A [ ]
MVRP13	Is the implementation capable of maintaining current state information for all attributes in the range of possible values?	SPRU:M	11.2.7	Yes [ ] N/A [ ]

B.8 Multiple Registration Protocol (MRP)

Item	Feature	Status	References	Support
MRP5	Does the implementation of MRP meet all of the requirements for interoperability stated in 10.5 that apply to end station operation?	M	10.5	Yes [ ]
MRP6	Does the implementation support the operation of the complete Applicant state machine?	MRP1:M	10.7, 10.7.7	Yes [ ] N/A [ ]
MRP7	Does the implementation support the operation of the point-to-point subset of the Applicant state machine?	MRP2:M	10.7, 10.7.7	Yes [ ] N/A [ ]
MRP8	Does the implementation support the operation of the Applicant-Only subset of the Applicant state machine?	MRP3:M	10.7, 10.7.7	Yes [ ] N/A [ ]
MRP9	Does the implementation support the operation of the Simple-Applicant subset of the Applicant state machine?	MRP4:M	10.7, 10.7.7	Yes [ ] N/A [ ]
MRP10	Does the implementation support the operation of the Registrar state machine?	MRP1:M MRP2:M	10.7, 10.7.8	Yes [ ] N/A [ ]
MRP11	Does the implementation support the operation of the LeaveAll state machine?	MRP1:M MRP2:M	10.7, 10.7.9	Yes [ ] N/A [ ]
MRP12	Does the implementation support the operation of the PeriodicTransmission state machine?	M	10.7, 10.7.10	Yes [ ]

B.9 Forwarding and Queuing Enhancements for time-sensitive streams (FQTSS)

Item	Feature	Status	References	Support
FQTSSE1	Support a minimum of two traffic classes, of which one supports the strict priority algorithm and the other is an SR class?	FQTSSE:M	5.20, 8.6.8.1, 34.6	Yes [ ] N/A [ ]
FQTSSE2	Support the credit-based shaper algorithm as the transmission selection algorithm for frames transmitted for each stream associated with the SR class.	FQTSSE:M	5.20, 8.6.8.2, 34.6	Yes [ ] N/A [ ]
FQTSSE3	Support the operation of the credit-based shaper algorithm on all Ports as the transmission selection algorithm used for the SR class.	FQTSSE:M	5.20, 8.6.8.2, 34.6	Yes [ ] N/A [ ]
FQTSSE4	Use the default priority associated with SR class “B” as shown in Table 6-5 as the priority value carried in transmitted SR class “B” data frames.	FQTSSE:M	5.20, Table 6-5, 34.6	Yes [ ] N/A [ ]
FQTSSE5	Support two or more SR classes (a maximum of seven), and support the operation of the credit-based shaper algorithm on all Ports as the transmission selection algorithm used for those SR classes. The number of SR classes supported shall be stated in the PICS.	FQTSSE:O	5.20, 8.6.8.2, 34.6	Yes [ ] No [ ] Number____
FQTSSE6	Use the default priority associated with SR class “A” as shown in Table 6-5 as the priority value carried in transmitted SR class “A” data frames. If more than two SR classes are supported, the priority value carried in transmitted data frames for the additional SR classes shall be stated in the PICS.	FQTSSE:O	5.20, Table 6-5, 34.6	Yes [ ] No [ ] Priority override values_____

B.10 Stream Reservation Protocol (SRP)

Item	Feature	Status	Reference	Support
	If SRP is not supported, mark N/A and ignore the remainder of this table.			N/A [ ]
SRP-1	Does the implementation support the exchange of Multiple Stream Registration Protocol Data Units (MSRPDUs), using the generic Multiple Registration Protocol Data Unit (MRPDU) format defined in 10.8 to exchange MSRP-specific information, as defined in 35.2.2.8.1, 35.2.2.9.1, and 35.2.2.10.1?	M	5.4.4, 10.8, 35.2.2.8.1, 35.2.2.9.1, 35.2.2.10.1	Yes [ ]
SRP-2	Is the MSRP Application supported as defined in Clause 35?	M	5.4.4, Clause 35	Yes [ ]
SRP-3	Is the group MAC address used as the destination address for MRPDUs destined for MSRP Participants the group MAC address identified in Table 8-1, Table 8-2, Table 8-3 as “Individual LAN Scope group address, Nearest Bridge group address”?	M	35.2.2.1, Table 8-1, Table 8-2, Table 8-3	Yes [ ]
SRP-4	Is the EtherType used for MRPDUs destined for MSRP Participants the MSRP EtherType identified in Table 10-2?	M	35.2.2.2, Table 10-2	Yes [ ]
SRP-5	Does the ProtocolVersion used for the implementation of MSRP take the hexadecimal value 0x01?	M	35.2.2.3	Yes [ ]
SRP-6	Are the Attribute Type values used in the implementation as specified in 35.2.2.4 and Table 35-1?	M	35.2.2.4, Table 35-1	Yes [ ]
SRP-7	Are the Attribute Length values used in the implementation as specified in 35.2.2.5 and Table 35-2?	M	35.2.2.5, Table 35-2	Yes [ ]
SRP-8	Are the MSRP Vector FourPackedEvents values used in the implementation as specified in 35.2.2.7.2 and Table 35-3?	M	35.2.2.7.2, Table 35-3	Yes [ ]
SRP-9	Does the implementation encode the values in FirstValue fields in accordance with the definition in 35.2.2.8, 35.2.2.9, and 35.2.2.10?	M	35.2.2.8, 35.2.2.9, 35.2.2.10	Yes [ ]
SRP-10	Does the Talker implementation populate the Accumulated Latency with a reasonable, nonzero value?	M	35.2.2.8.6, 35.2.2.10.10	Yes [ ]
SRP-11	Does the implementation update the Failure Information end station MAC address and Code when a Talker Failed is declared?	M	35.2.2.8.7, 35.2.2.10.9, 35.2.2.10.12	Yes [ ]

B.10 Stream Reservation Protocol (SRP) *(continued)*

Item	Feature	Status	Reference	Support
SRP-12	Does the implementation create a Talker Failed in the event of insufficient bandwidth or resources?	O	35.1.2.1	Yes [ ] No [ ]
SRP-13	Is talkerPruning and MMRP supported?	O	35.2.4.3.2	Yes [ ] No [ ]
SRP-14	Are MSRPDUs transmitted on all ports?	M	35.2	Yes [ ]
SRP-15	State the number of Talker registration values that can be supported on each Port.	M	35.2.7	Number _____
SRP-16	State the number of Listener registration values that can be supported on each Port.	M	35.2.7	Number _____
SRP-17	Does the Listener issue an appropriate MVRP VLAN membership request before attaching to a Stream?	M	35.1.2.2	Yes [ ]
SRP-18	When MAC_Operational transitions to TRUE does the device declare the default SR class priority value as the SRclassPriority prior to receiving an SRclassPriority declaration from its neighbor?	M	IEEE Std 802.1AC, 35.2.2.9.3, Table 6-5	Yes [ ]
SRP-19	Does the device set SRclassPriority to the value declared by the neighboring device?	M	35.2.2.9.3	Yes [ ]
SRP-20	When MAC_Operational transitions to TRUE does the device declare the default SR_PVID value as the SRclassVID prior to receiving an SRclassVID declaration from its neighbor?	M	IEEE Std 802.1AC, 35.2.2.9.4, Table 9-2	Yes [ ]
SRP-21	Does the device set SRclassVID to the value declared by the neighboring device?	M	35.2.2.9.4	Yes [ ]
SRP-22	Does the implementation support Stream transformation in end station?	O	35.2.2.10.5	Yes [ ] No [ ]
SRP-23	Does the implementation declare the Domain attribute prior to Talker/ Listener attributes?	M	35.2.2.9	Yes [ ]
SRPMDCSN	Does this device support media-dependent CSN functionality on one or more ports?	SRPMDMOCA:M OR: SRPMDDOT11:M	Annex C	Yes [ ] No [ ]
SRPMDMOCA	Does this device support media-dependent MoCA functionality on one or more ports?	O:1	C.2	Yes [ ] No [ ]
SRPMDDOT11	Does this device support media-dependent IEEE 802.11 AP functionality on one or more ports?	O:1	C.3	Yes [ ] No [ ]

B.10 Stream Reservation Protocol (SRP) *(continued)*

Item	Feature	Status	Reference	Support
SRPMDCSN-1	Does this device support a single Designated MSRP Node (DMN)?	SRPMDCSN:M	35.1.1	Yes [ ]
SRPMDMOCA-1	Does this device support DMN Device Attribute Information Element to L2ME message?	SRPMDMOCA:M	C.2.1.2	Yes [ ]
SRPMDMOCA-2	Does this device support DMN selection?	SRPMDMOCA:M	C.2.1.3	Yes [ ]
SRPMDMOCA-3	Does this device support MSRP Attribute Declaration as specified in Table C-1?	SRPMDMOCA:M	C.2.2 Table C-1	Yes [ ]
SRPMDDOT11-1	Does this device support EDCA-AC?	SRPMDDOT11:M	Table C-5	Yes [ ]
SRPMDDOT11-2	Is the DMN and the QAP of the IEEE 802.11 BSS co-located in the same device?	SRPMDDOT11:M	C.3.2	Yes [ ]
SRPMDDOT11-3	Does the device support MLME primitives specified in Table C-4?	SRPMDDOT11:M	C.3.3, Table C-4	Yes [ ]
SRPMDDOT11-4	Does the device support VLAN tag encapsulation/de-encapsulation on the IEEE 802.11 interface?	SRPMDDOT11:M	C.3.3.1	Yes [ ]
SRPMDDOT11-5	Is the reservation process an atomic operation?	SRPMDDOT11:M	C.3.1, Figure C-11, Figure C-12, Figure C-13	Yes [ ]

B.11 Congestion notification

Item	Feature	Status	References	Support
CN-1	Does the system conform to the required provisions of IEEE Std 802.1AB?	CN: M	5.21	Yes [ ]
CN-2	Does the system support the use of the Congestion Notification TLV in LLDP?	CN: M	5.21	Yes [ ]
CN-3	Does the system transmit more than one Congestion Notification TLV in a single LLDPDU?	CN: M		No [ ]
CN-4	Does the system transmit a Congestion Notification TLV with 0 in all of the Per-priority CNPV indicators?	CN: M		No [ ]
CN-5	Does the system implement the Congestion Notification Domain (CND) defense variables, procedures, and state machine?	CN: M	32.4, 32.5, 32.6	Yes [ ]
CN-6	Does the end station support the creation of at least one RP?	CN: M	5.21	Yes [ ]
CN-7	Does the end station allow more than rpppMaxRps RPs to be created on one port and priority?	CN: M	32.10.1	No [ ]
CN-8	Does the end station support at least the cptDisabled and cptInterior defense modes separately on each CNPV?	CN: M	5.21, 32.1.1	Yes [ ]
CN-9	Does the end station add a tag to frames transmitted from CCFs?	CN: O	30.5, 31.2.2.5	Yes [ ] No [ ]
CN-10	Does the end station support both the cptInterior, and cptInteriorReady defense modes separately on each CNPV?	CN: O	5.21, 31.2.2.5 , 32.14.3	Yes [ ] No [ ]
CN-11	Does the end station support the cptEdge defense mode on any CNPV?	CN: O	5.21, 32.4.9	Yes [ ] No [ ]
CN-12	Does the end station accept CN-TAGs in data frames on any CNPV?	CN: O	5.21, 32.4.10	Yes [ ] No [ ]
CN-13	Does the end station support the creation of more than one RP?	CN: O	5.21, 31.2.1	Yes [ ] No [ ]
CN-14	Reserved			
CN-15	Do the end station’s RP(s) limit the output frame rate in response to CNMs received?	CN: M	5.21	Yes [ ]
CN-16	Does the end station distinguish correctly to which RP a given CNM is directed?	CN-13: M	5.21	Yes [ ]
CN-17	Does the end station support the creation of at least one CP?	CN: O	5.21	Yes [ ] No [ ]
CN-18	Does the end station’s have a single flow queue as its default configuration?	CN: M	31.2.1	Yes [ ]
CN-19	Does the end station change its method for assigning frames to Flow queues in a manner that impairs the ability of compliant CPs to throttle its flows?	CN: M	31.2.1	No [ ]

B.11 Congestion notification *(continued)*

Item	Feature	Status	References	Support
CN-20	Does the end station change its method for assigning frames to Flow queues in a manner that significantly increases the likelihood of frame misordering, and thus impacts higher layer functions?	CN: M	31.2.1	No [ ]
CN-21	Does the end station's Rate Limiters always meet the specified formula for L_T?	CN: M	31.2.2.4, Equation (31-1)	Yes [ ]
CN-22	Can the end station's Flow Selection functions drop frames between the Flow queue and the Flow multiplexer?	CN: M	31.2.2.5	No [ ]
CN-23	Does the end station output frames with CN-TAGs on a priority operating in mode cptEdge or cptInterior?	CN: M	32.1.1	No [ ]
CN-24	Do the end station's RPs implement the specified timers, variables. procedures, and state machines?	CN: M	32.7 item b), 32.12, 32.13, 32.14, 32.15	Yes [ ]
CN-25	Does the end station insert the CN-TAG and VLAN-TAG in the correct order (addresses, VLAN-TAG, CN-TAG)?	CN: M	33.2	Yes [ ]
CN-26	Does the end station ignore the CNM's Version field?	CN: M	33.4.1	Yes [ ]
CN-27	Does the end station ignore the CNM's ReservedV field?	CN: M	33.4.2	Yes [ ]
CN-28	Does the end station assign meaning to subfields within a received CNM's Congestion Point Identifier field?	CN: M	33.4.4	No [ ]
CN-29	Does the end station ignore received CNMs that are too short?	CN: M	33.4.11 item a)	Yes [ ]
CN-30	Does the end station ignore received CNMs that have no CN-TAG?	CN: O	33.4.11 item b)	Yes [ ] No [ ]
CN-31	Does the end station ignore received CNMs that have nonzero values in the Version or ReservedV fields?	CN: M	33.4.11 item c)	No [ ]
CN-32	Does the end station support all of the objects required to manage its RP(s)?	CN: M	5.21, 12.21.1, 12.21.6	Yes [ ]
CN-33	Does the end station use the same Reaction Point group managed object to manage RPs serving more than one CNPV?	CN: M	32.11	No [ ]
CN-34	Does the end station support all of the objects in the CN component managed object?	CN-17: M	5.21, 12.21.1	Yes [ ]
CN-35	Does the end station support all of the objects in the CN component priority managed object?	CN-17: M	5.21, 12.21.2	Yes [ ]
CN-36	Does the end station support all of the objects in the CN Port priority managed object?	CN-17: M	5.21, 12.21.3	Yes [ ]
CN-37	Does the end station support all of the objects in the Congestion Point managed object?	CN-17: M	5.21, 12.21.4	Yes [ ]

B.12 Priority-based Flow Control (PFC)

Item	Feature	Status	References	Support
PFC-1	Enabling PFC on at least one priority	PFC: M	36.1.2	Yes [ ]
PFC-2	Processing PFC Requests	PFC: M	36.1.3.1	Yes [ ]
PFC-3	Processing PFC Indications	PFC: M	36.1.3.2	Yes [ ]
PFC-4	PFC delay constraints	PFC: M	36.1.3.3	Yes [ ]
PFC-5	PFC-aware system queue functions	PFC: M	36.2	Yes [ ]
PFC-6	DCBX	PFC: M	5.11	Yes [ ]
PFC-7	Enabling PFC on up to eight priorities	PFC: O	36.1.2	Yes [ ]No [ ]
PFC-8	PFC not enabled for traffic classes using the credit-based shaper algorithm	PFC: M	8.6.8.2	Yes [ ]

B.13 Enhanced Transmission Selection (ETS)

Item	Feature	Status	References	Support
ETS-1	Support at least 3 traffic classes	ETS:M	37.3	Yes [ ]
ETS-2	Support bandwidth configuration with a granularity of 1% or finer	ETS:M	37.3	Yes [ ]
ETS-3	Support bandwidth allocation with a precision of 10%	ETS:M	37.3	Yes [ ]
ETS-4	Support allocation of a portion of available bandwidth to each traffic class	ETS:M	37.3	Yes [ ]
ETS-5	Support DCBX	ETS:M	Clause 38	Yes [ ]

B.14 Data Center Bridging eXchange protocol (DCBX)

Item	Feature	Status	References	Support
DCBX-1	Support LLDP	DCBX:M	IEEE Std 802.1AB	Yes [ ]
DCBX-2	Support the DCBX ETS Configuration TLV	DCBX:M	D.2.8	Yes [ ]
DCBX-3	Support the ETS Recommendation TLV	DCBX:M	D.2.9	Yes [ ]
DCBX-4	Support the Priority-based Flow Control Configuration TLV	DCBX:M	D.2.10	Yes [ ]
DCBX-5	Support the Application Priority TLV	DCBX:M	D.2.11	Yes [ ]
DCBX-6	Support the DCBX asymmetric state machine	DCBX:M	38.4.1	Yes [ ]
DCBX-7	Support the DCBX symmetric state machine	DCBX:M	38.4.2	Yes [ ]
DCBX-8	Support the Application VLAN TLV	DCBX:M	D.2.14	Yes [ ]

B.15 Scheduled traffic

Item	Feature	Status	References	Support
	If neither scheduled traffic (SCHED in B.5) nor cyclic queuing and forwarding (CQF in B.5) are supported, mark N/A and ignore the remainder of this table.		5.25, 5.28, 8.6.8, 8.6.9, 12.29, 17.7.22	N/A [ ]
SCHED1	Does the implementation support the state machines and associated definitions specified in 8.6.9	SCHED OR CQF:M	5.28 item b), 8.6.8, 8.6.9	Yes [ ] N/A [ ]
SCHED2	Does the implementation support the management entities defined in 12.29?	SCHED OR CQF:M	5.28 item c), 12.29	Yes [ ] N/A [ ]
SCHED3	Is the IEEE8021-ST-MIB module fully supported (per its MODULE-COMPLIANCE)?	MIB AND (SCHED OR CQF):O	5.28 item c), 12.29, 17.7.22	Yes [ ] N/A [ ] No [ ]

B.16 Frame Preemption

Item	Feature	Status	References	Support
	If frame preemption (PRE in B.5) is not supported, mark N/A and ignore the remainder of this table.		5.4.1, 5.13.1, 6.7.2, 8.6.8, 12.30, 17.7.23	N/A [ ]
PRE1	Does the implementation support the functionality of frame preemption as specified in 6.7.2 and 8.6.8?	PRE: M	5.4.1, 5.13.1, 6.7.2, 8.6.8	Yes [ ] N/A [ ]
PRE2	Does the implementation support the management entities defined in 12.30?	PRE: M	5.4.1 item ae), 12.30	Yes [ ] N/A [ ]
PRE3	Is the IEEE8021-Preemption-MIB module fully supported (per its MODULE-COMPLIANCE)?	PRE: O	5.4.1 item ae), 12.30, 17.7.23	Yes [ ] N/A [ ]

B.17 Per-Stream Filtering and Policing

Item	Feature	Status	References	Support
	If neither Per-Stream Filtering and Policing (PSFP in B.5) nor cyclic queuing and forwarding (CQF in B.5) are supported, mark N/A and ignore the remainder of this table.		5.28 items d) and e), 8.6.5.2.1, 8.6.10, 12.31, 17.7.24	N/A[ ]
PSFP1	Does the implementation support the state machines and associated definitions as specified in 8.6.10?	PSFP OR CQF:M	5.28 items b) and d), 8.6.5.4, 8.6.10,	Yes [ ] N/A [ ]
PSFP2	Does the implementation support the management entities defined in 12.31 for PSFP?	PSFP OR CQF:M	5.28 item e), 8.6.5.2, 8.6.10, 12.31	Yes [ ] N/A [ ]
PSFP3	Is the IEEE8021-PSFP-MIB module fully supported (per its MODULE-COMPLIANCE)?	MIB AND (PSFP OR CQF):O	12.31, 17.7.24	Yes [ ] N/A [ ] No [ ]

B.18 Asynchronous Traffic Shaping

Item	Feature	Status	References	Support	
	If Asynchronous Traffic Shaping (ATS in Table B.5) is not supported, mark N/A and ignore the remainder of this table.		5.31, 8.6.5.2.2, 8.6.8, 8.6.8.5, 8.6.11, 47.1.2	N/A[ ]	
ATS1	Does the implementation support at least one traffic class that supports the strict priority transmission selection algorithm (8.6.8.1) and another traffic class that supports the ATS transmission selection algorithm (8.6.8.5)?	ATS:M	5.31, 8.6.8, 8.6.8.5,	Yes [ ]	N/A [ ]
ATS2	Does the implementation support ATS schedulers as specified in 8.6.5.6?	ATS:M	5.31, 8.6.5.6, 47.1	Yes [ ]	N/A [ ]
ATS3	Does the implementation support the ATS scheduler state machines as specified in 47.1?	ATS:M	5.31, 47.1	Yes [ ]	N/A [ ]

Annex C

(normative)

Designated MSRP Node (DMN) Implementations

This annex describes the DMN implementation on an IEEE 802.11 Network and Coordinated Shared Networks (CSNs).

C.1 DMNs on CSNs

A CSN is a contention-free, time-division multiplexed-access network, supporting reserved bandwidth based on priority or flow (QoS). One of the nodes of the CSN acts as the Network Coordinator (NC) node, granting transmission opportunities to the other nodes of the network. The NC node also acts as the bandwidth resource manager of the network.

C.1.1 CSN characteristics

CSNs support two types of transmissions: unicast transmission for node-to-node transmission and multicast/broadcast transmission for one-node-to-other/all-nodes transmission. Each node-to-node link has its own bandwidth characteristics that could change over time due to the periodic ranging of the link. The multicast/broadcast transmission characteristics are the lowest common characteristics of multiple/all the links of the network.

A CSN network is physically a shared network, in that a CSN node has a single physical port connected to the half-duplex medium, but is also a logically fully-connected one-hop mesh network, in that every node could transmit to every other node using its own profile over the shared medium.

Figure C-1 illustrates a CSN network acting as a backbone interconnecting AV systems.

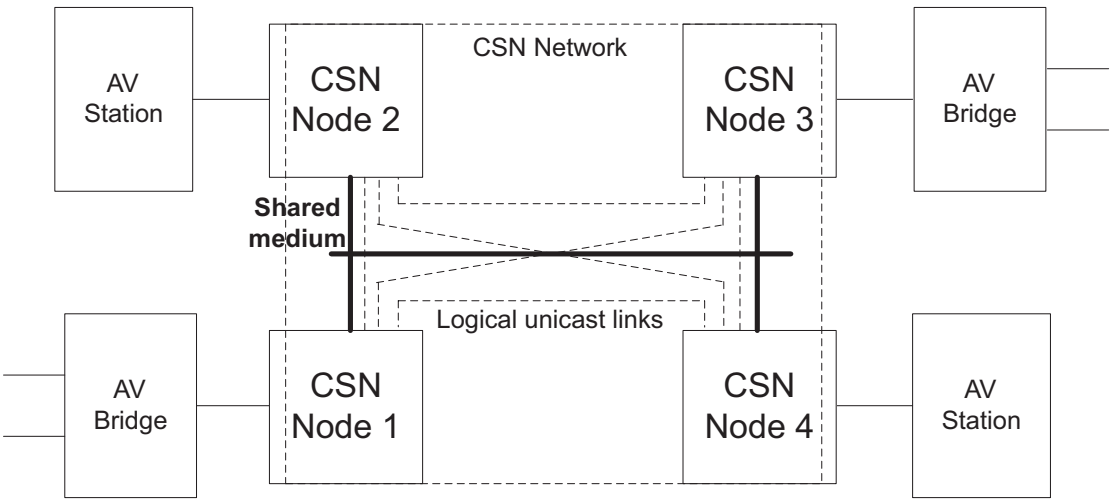

Figure C-1—CSN backbone

Depending on the CSN technology, the Network Coordinator node either may be a fixed node or may be dynamically selected during normal operation.

C.1.2 DMN handling on CSN

From the bandwidth reservation standpoint a CSN network is modeled as a Bridge as illustrated by Figure C-2. Each node-to-node link is equivalent to a Bridge's path from an ingress port to an egress port.

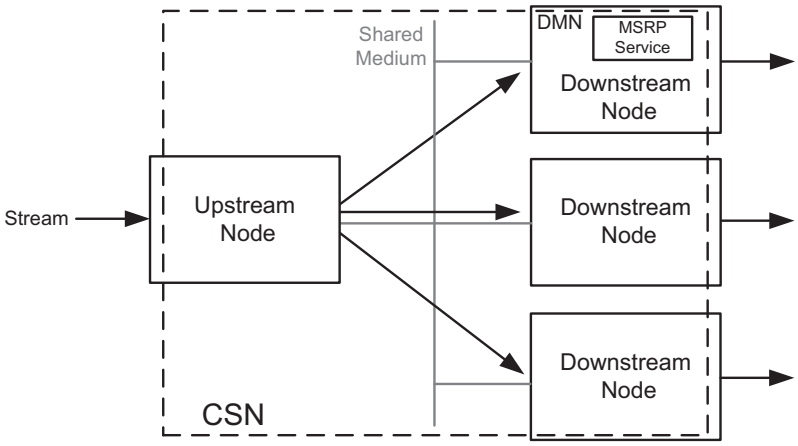

Figure C-2—Bridge's CSN model for bandwidth reservation

A CSN shall provide a single entity called the Designated MSRP Node (DMN) (35.1.1), which communicates with the MSRP Service to manage the CSN bandwidth resources for the MSRP streams.

NOTE 1—The MSRP Service supplies both MSRP Attribute Propagation (MAP) for the CSN and MSRP Attribute Declaration (MAD) for each MSRP-aware CSN node.

NOTE 2—An end station node provides an end station MSRP implementation as outlined in 5.18.3. This MSRP implementation is logically on the upper layer side of this interface. This standard expects that an MSRP-aware CSN node will have a single non-CSN interface. If more interfaces are present, they are expected to be connected through a Bridge function. If this node happens to be the DMN, then this end station MSRP implementation is separate and distinct from the DMN's MSRP Service.

C.1.2.1 DMN selection and migration

Depending on the CSN technology, the DMN might correspond to a static node or dynamically migrate between nodes during normal operation. The DMN selection is network specific and described in C.2.1 and C.3.2.

Over time the DMN constructs its database by handling the MSRP Talker and Listener Declarations generated by the nodes of the CSN. If the DMN migrates, the new DMN broadcasts an MRP LeaveAll message to all the nodes of the CSN, which will force its neighbors to redeclare their attributes. The MSRP Participant nodes answer the MRP LeaveAll message by sending an MRP JoinIn message consumed by the DMN as an MRP Re-Declare! message. These redeclarations permit the new DMN to immediately build its database.

C.1.3 MSRPDU handling on a CSN

Figure C-3 and Figure C-4 illustrate the flow and handling of MSRPDU messages on a CSN.

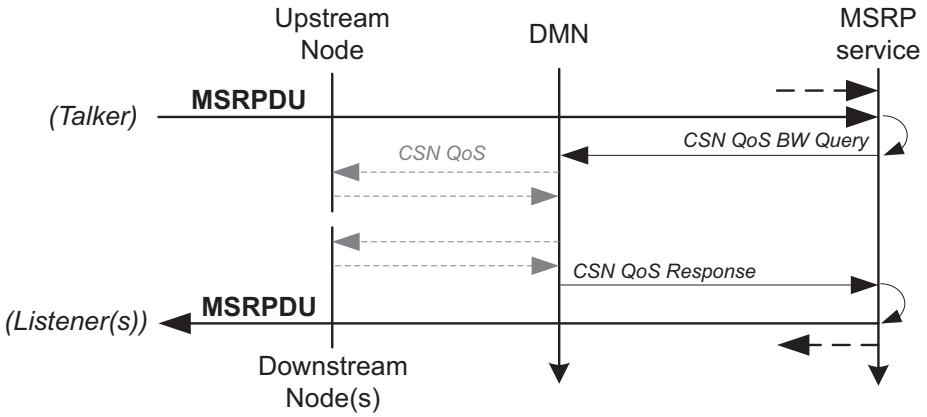

Figure C-3—Talker MSRPDU flow

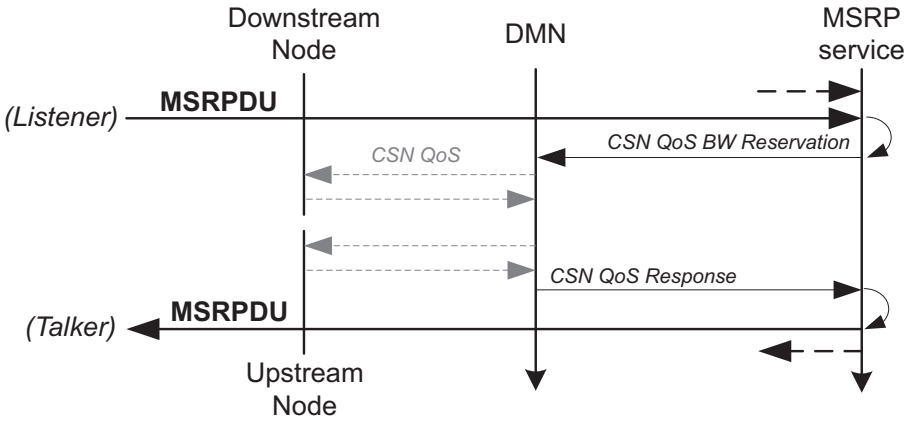

Figure C-4—Listener MSRPDU flow

a) A MSRP-aware CSN node identifies MSRPDUs received on its non-CSN interface (the interface either to another network media or to upper layers of the node) by their destination MAC address (35.2.2.1) and EtherType (35.2.2.2).

b) Non-DMN nodes send MSRPDUs to the DMN over the CSN.

c) The DMN delivers MSRPDUs, along with information about the originating interface, to the MSRP Service.

d) The DMN translates the MSRP TSpec parameters into CSN QoS parameters and invokes the CSN's Protocol Specific QoS transactions with the CSN Network Coordinator (C.2.2, C.3.3) as follows:

   1) When the DMN receives a Talker Advertise message originated from an upstream CSN node, the DMN invokes a bandwidth query transaction with the CSN Network Coordinator to check whether the bandwidth advertised in the message's TSpec is available on each upstream to downstream node link of the CSN network. In addition the DMN associates the MSRP attributes with the CSN's native QoS records via the StreamID (which is included in the CSN frames).

2) When the DMN receives a Listener Ready message originated from a downstream CSN node, the DMN invokes a bandwidth reservation transaction with the CSN QoS manager to reserve the bandwidth associated with the message's StreamID on the downstream to upstream CSN node link.

e) After the DMN completes the CSN QoS transactions, the DMN behaves as an MSRP application on a Bridge and propagates (MAP) and distributes (MAD) MSRP attributes (35.2).

NOTE—When the MAD function of the MSRP Service distributes attributes, it will deliver MSRPDUs to the DMN's non-CSN interface and/or send them to the appropriate MSRP-aware CSN nodes.

C.1.4 CSN bandwidth fluctuations

Bandwidth on a CSN may fluctuate depending on interference experienced by the media. The MSRP Attribute Propagation (35.2.4) supports a *bandwidthAvailabilityChanged* notification when bandwidth increases or decreases across the media. When a bandwidth changed is encountered, MAP will reassess reservation requests to maintain appropriate bandwidth utilization.

C.2 DMN on MoCA

NOTE—The discussion that follows is based on terminology found in the MoCA MAC/PHY Specifications v1.1 and v2.0 [B55] and [B56].

C.2.1 DMN Selection on MoCA Network

C.2.1.1 DMN-capable node discovery

A DMN-capable node shall append the *IEEE DMN Device Attribute Information Element* (C.2.1.2) to the L2ME payload of the Device Discovery Protocol SUBMIT L2ME transaction message specified in the MoCA MAC/PHY Specification v2.0 [B56].

Upon completion of the L2ME Device Discovery transaction, all the DMN-capable nodes of the MoCA network share the same information as follows:

a) Which MoCA nodes are DMN capable
b) Which MoCA node is selected as the DMN

If no DMN is selected, the DMN selection shall be performed (C.2.1.3).

C.2.1.2 IEEE DMN Device Attribute IE

C.2.1.2.1 General

The fields of the IEEE DMN Device Attribute IE are specified in Figure C-5 and C.2.1.2.2 through C.2.1.2.7. The general format of the Device Attribute Information Element is described in the MoCA MAC/PHY Specification v2.0 [B56].

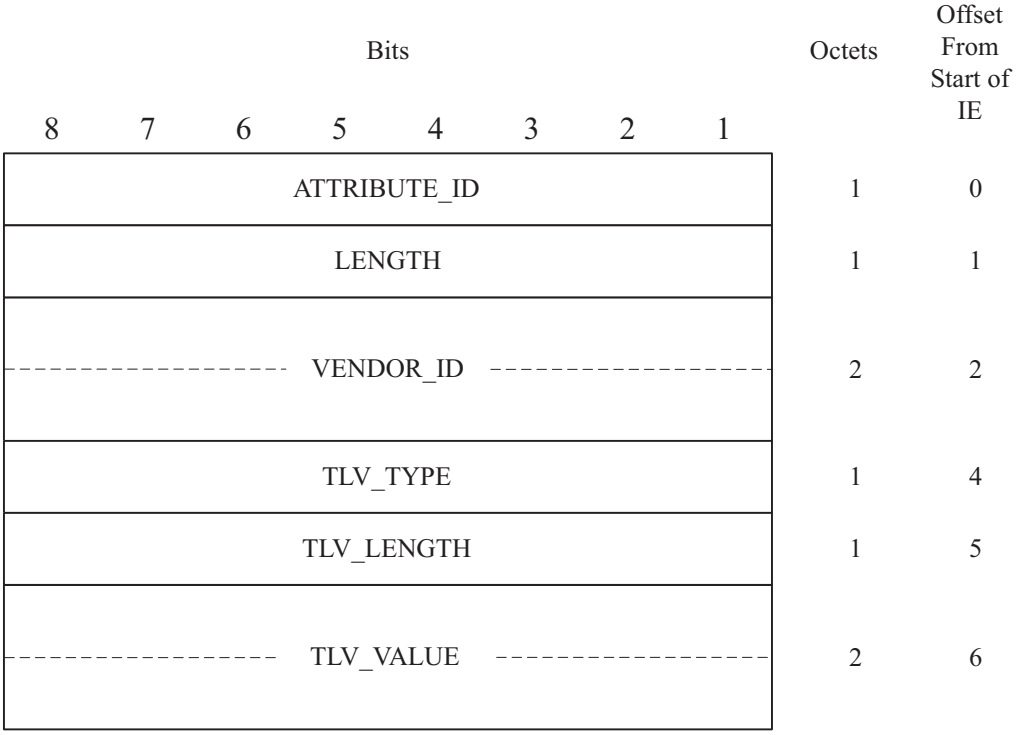

Figure C-5—IEEE DMN Device Attribute IE

C.2.1.2.2 ATTRIBUTE_ID (Enumeration8)

The value of the ATTRIBUTE_ID is 0xFF.

C.2.1.2.3 LENGTH (UInteger8)

The value of the LENGTH is 1.

NOTE—The actual length of the Attribute IE in bits is (LENGTH + 1) × 32.

C.2.1.2.4 VENDOR_ID (Enumeration16)

The value of VENDOR_ID is 0x0090 (IEEE 802.1 AVB).

C.2.1.2.5 TLV_TYPE (Enumeration16)

The value of the TLV_TYPE is 1 (SRP).

C.2.1.2.6 TLV_LENGTH (UInteger8)

The length of the TLV in octets is 4.

C.2.1.2.7 TLV_VALUE (Octet2)

The meaning of the field of the TLV_VALUE are specified as described in C.2.1.2.7.1 through C.2.1.2.7.3.

C.2.1.2.7.1 DMNcapable (Bit 0 - Boolean)

A value of 1 indicates the node is capable of acting as the DMN of the network. A value of 0 indicates the node is not capable to act as a DMN.

C.2.1.2.7.2 DMNselected (Bit 1 - Boolean)

A value of 1 indicates the node has been selected as the DMN of the network. A value of 0 indicates the node is not the selected DMN.

C.2.1.2.7.3 Reserved (Bit 2..15)

These bits are reserved for future use.

C.2.1.3 DMN selection and confirmation

If either 1) the *NODE_BITMASK* field into MAP frames indicates that the selected DMN has been removed from the network (due to failure, power state/down, etc.) or 2) the DMN node discovery (C.2.1.1) does not indicate a DMN selected node, the DMN-capable node with the lowest node ID will start acting as the DMN and confirm the selection to the other DMN-capable nodes by generating a L2ME DMN Confirmation Transaction (C.2.1.3.1).

NOTE—"MAP frame" is defined in the MoCA MAC/PHY Specification v1.1 [B55].

C.2.1.3.1 L2ME DMN Confirmation Transaction

C.2.1.3.1.1 Overview of DMN Confirmation Transaction

Figure C-6 provides an overview of the signals exchanged among the nodes during an L2ME DMN Confirmation Transaction. As shown in the figure, the NC node starts the transaction either when it receives a Submit L2ME Frame from a node (called the DMN Selected Entry Node for that Transaction) or on its own. The transaction includes two L2ME Waves. The details of each message exchanged during the DMN Confirmation Transaction are provided below.

C.2.1.3.1.2 DMN Confirmation Submit

The DMN Confirmation Transaction starts when the DMN Selected Entry Node sends a Submit L2ME Frame to the NC.

The general fields of the Submit L2ME frame are as specified in section 2.2.3.1 of the MoCA MAC/PHY Specification v1.1 [B55]. The parameters in the Submit L2ME Frame are set as follows:

a) VENDOR_ID (see C.2.1.2.4)
b) TRANS_TYPE = 0x1 (SRP)
c) TRANS_SUBTYPE = 0x1 (DMN Confirmation)
d) WAVE0_NODEMASK = (DMN-capable nodes)
e) MSG_PRIORITY = 0xF0
f) TXN_LAST_WAVE_NUM = 0x1
g) L2ME_PAYLOAD = 0 bytes

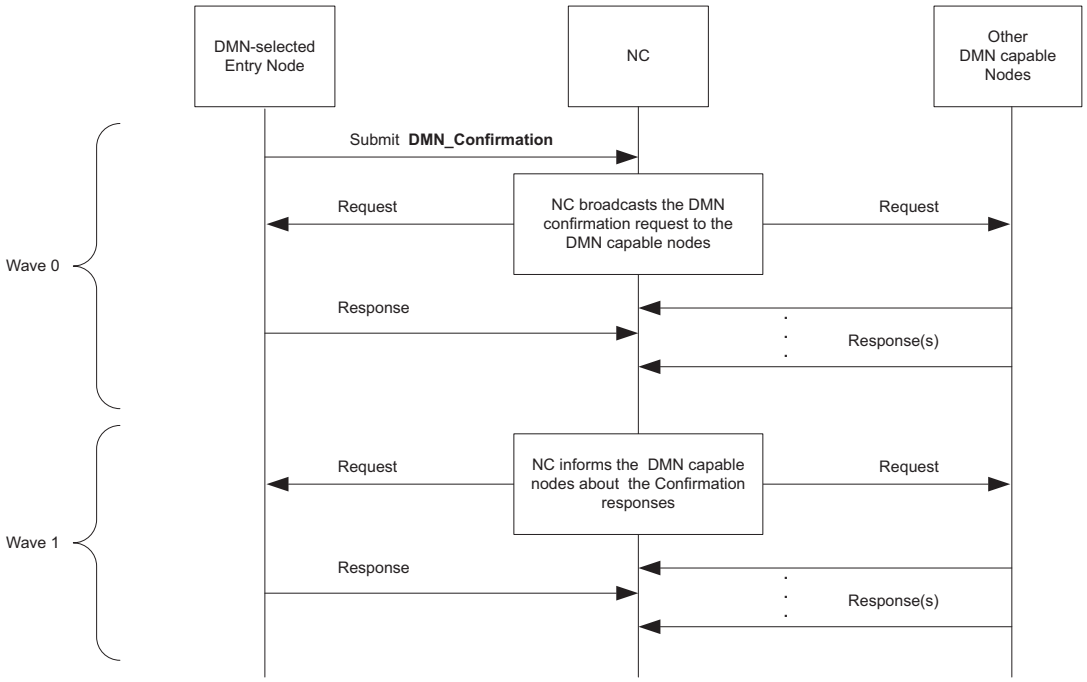

Figure C-6—DMN Confirmation Transaction

C.2.1.3.1.3 Request L2ME Frame of Wave 0 of DMN Confirmation Transaction

In the Wave 0 that follows the DMN Confirmation Submit message, the NC node initiates a Request L2ME Frame based on the Submit L2ME Frame.

The general fields of the Request L2ME frame are as specified in section 2.2.3.2 of the MoCA MAC/PHY Specification v1.1 [B55].

C.2.1.3.1.4 Response L2ME Frame of Wave 0 of DMN Confirmation Transaction

Each of the requested DMN-capable nodes sends a Response L2ME Frame to acknowledge the confirmation request.

The general fields of the Response L2ME frame are as specified in 2.2.3.3 of the MoCA MAC/PHY Specification v1.1 [B55]. The parameters in the Response L2ME Frame are set as follows:

a) RESP_STATUS <INTERPRETED> = ’1’
b) RESP_STATUS <IN_NEXT_WAVE> = ’1’
c) L2ME_PAYLOAD = 0 bytes

C.2.1.3.1.5 Request L2ME Frame of Wave 1 of DMN Confirmation Transaction

In Wave 1, the NC node informs the DMN-capable nodes about the acknowledgment results from Wave 0. The NC node initiates Wave 1 using a Request L2ME Frame with the “concatenated” type of L2ME_PAYLOAD.

The general fields of the Request L2ME frame are as specified in section 2.2.3.1 of the MoCA MAC/PHY Specification v1.1 [B55]. The “concatenated“ L2ME_Payload is as specified in Table 2-4 of the MoCA MAC/PHY Specification v1.1 [B55].

C.2.1.3.1.6 Response L2ME Frame of Wave 1 of DMN Confirmation Transaction

The DMN Confirmation Transaction is completed when the DMN Selected Entry node and the other DMN-capable nodes send their final Response L2ME Frame to the NC node.

The general fields of the Response L2ME frame are as specified in section 2.2.3.3 of the MoCA MAC/PHY Specification v1.1 [B55]. The parameters in the Response L2ME Frame are set as follows:

a) RESP_STATUS <INTERPRETED> = ’1’
b) RESP_STATUS <IN_NEXT_WAVE> = ’0’
c) L2ME_PAYLOAD = 0 bytes

C.2.2 MoCA network bandwidth management

The MSRP service within the MoCA network manages the MoCA bandwidth for the MSRP streams by invoking the MoCA native PQoS transactions. The DMN shall map the MSRP Attribute Declaration and the resultant MAD declarations as described in Table C-1.

Table C-1—SRP to MoCA PQoS Transaction mapping

MSRP Attribute	MAD Primitive	MoCA PQoS Transactions	Description
Talker Advertise	MAD_Join.request(new)	Create PQoS Flow	Query bandwidth without reservation (see NOTE)
Listener Ready or Listener Ready Failed	MAD_Join.request(new)	Create PQoS Flow	Reserve bandwidth for a stream
Listener Ready or Listener Ready Failed	MAD_Join.request()	Update PQoS Flow	Renew the bandwidth reservation (leased time) for a stream
Talker or Listener Leave	MAD_Leave.request()	Delete PQoS Flow	Free bandwidth associated with a stream
NOTE—MoCA PQoS APIs do not include a Bandwidth Query-specific API. Therefore, bandwidth is queried by invoking a CreatePQoSFlow reservation for more bandwidth than the network could provide. The request will fail and CreatePQoSFlow will then return a failure status that includes the bandwidth available for reservations.			

Table C-2 describes the mapping between SRP TSpec components and MoCA PQoS TSPEC parameters.

Table C-2—SRP TSpec to MoCA TSPEC mapping

SRP TSpec	MoCA PQoS TSPEC
MaxFrameSize	Max Packet Size
MaxFrameSize × MaxIntervalFrames	Peak Data Rate
MaxFrameSize × MaxIntervalFrames × Class B class measurement interval (34.4)	(Max) Burst Size

Table C-3 describes the mapping of the SRP StreamID to MoCA PQoS Flow transactions. The MoCA Flow parameters includes a 32-bit field that allows an application, like SRP, to store application-specific information. SRP will use this field (FLOW_TAG) to store the 16-bit unique ID portion of the StreamID.

Table C-3—SRP StreamID to MoCA PQoS Flow transaction mapping

SRP StreamID	MoCA PQoS Flow Transaction		
	Transaction	L2ME Payload	Field
MAC Address	Create PQoS Flow Update PQoS Flow	Submit	PACKET_DA
	Query PQoS Flow	Response	
16-bit Unique ID	Create PQoS Flow Update PQoS Flow	Submit	FLOW_TAG
	Query PQoS Flow	Response	

C.3 DMNs on IEEE 802.11 media

NOTE—Even though IEEE Std 802.11 is not a CSN, it uses the same DMN concepts described below.

From the bandwidth reservation standpoint an IEEE 802.11 BSS network is modeled as a Bridge as illustrated by Figure C-7, Figure C-8, and Figure C-9. Each STA-AP link, STA-AP-STA link and optional STA-STA DLS direct link is equivalent to the path from an input to an output Bridge's port.

An IEEE 802.11 BSS provides a single entity called the Designated MSRP Node (DMN) (35.1.1) to manage the BSS bandwidth resources for the MSRP streams.

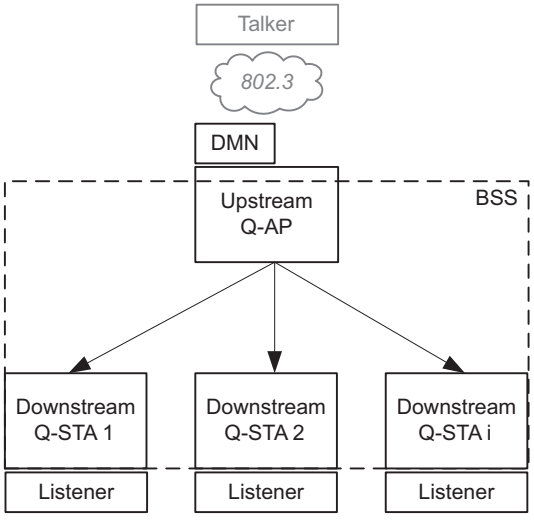

Figure C-7—Bandwidth reservation—bridge model for IEEE 802.11 BSS (STA downstream Port)

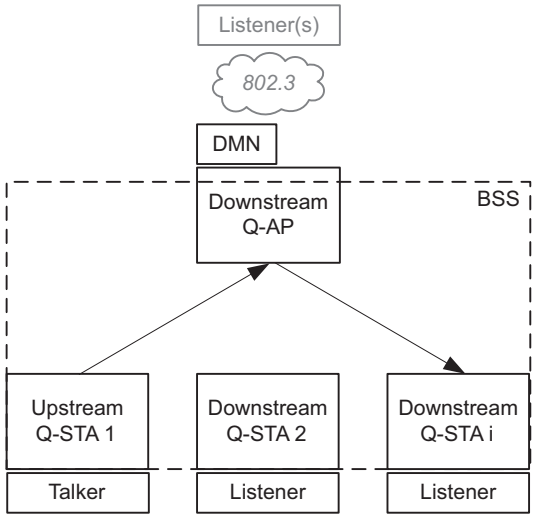

Figure C-8—Bandwidth reservation—bridge model for IEEE 802.11 BSS (STA upstream Port)

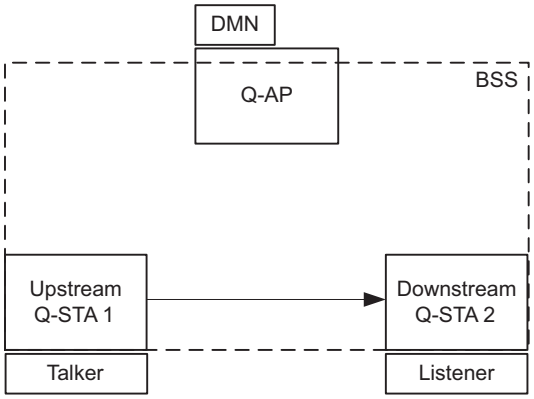

Figure C-9—Bandwidth reservation—bridge model for IEEE 802.11 BSS (direct link setup)

C.3.1 MSRP handling

MSRPDUs are transparently transported by the IEEE 802.11 BSS network and delivered to the DMN.

The DMN maps the MSRP commands into IEEE 802.11 MLME TS commands and interacts with the AP through the AP's MLME SAP.

Figure C-10 through Figure C-13 describe the flow of information between the MSRP and IEEE 802.11 entities, and corresponding over the air IEEE 802.11 frames. Figure C-10 is an example of the IEEE 802.11 bandwidth query process associated with an MSRP Talker Advertise.

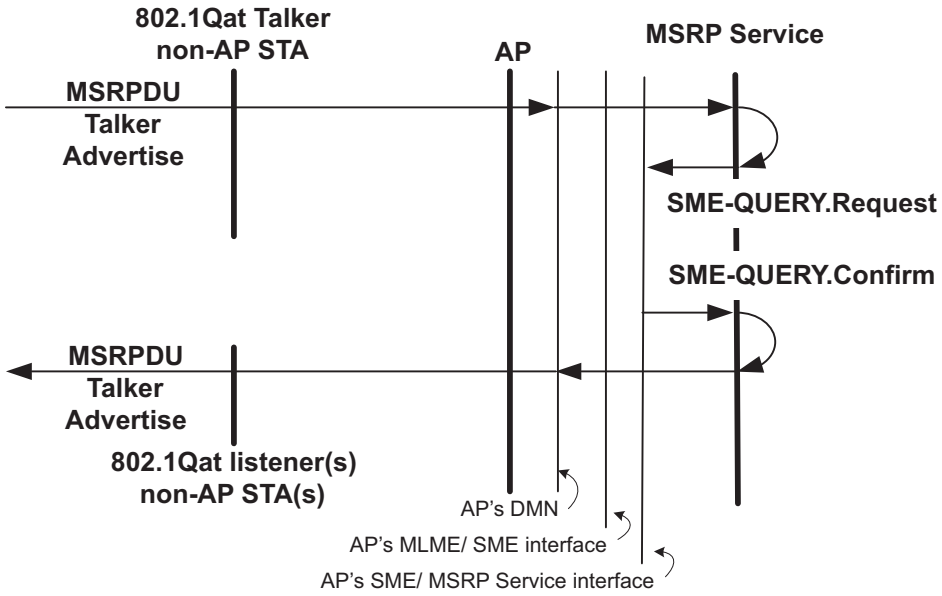

Figure C-10—MSRP/IEEE 802.11 query flows

Figure C-10 is an example of the reservation process associated with a Listener non-AP STA requesting a Stream from the Talker non-AP STA. The diagram at the left of the figure shows the Listener non-AP STA sending a Listener Ready (A) through the AP's MSRP Service, which then propagates that Listener Ready (B) to the Talker non-AP STA. The message flow on the right of the figure shows the corresponding IEEE 802.11 message exchanges associated with the two Listener Readys (A & B).

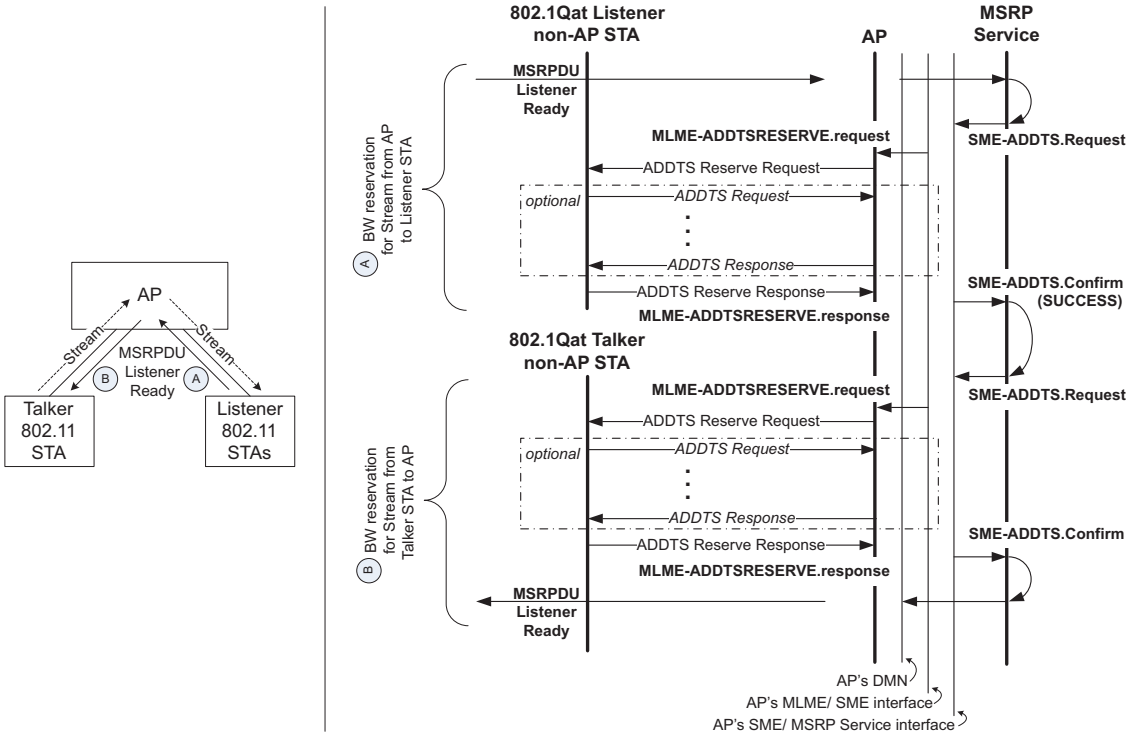

Figure C-11—MSRP/802.11 Talker STA to Listener STA reservation flows

There are two reservations (A & B) required to allow the Stream to flow from Talker to Listener. In Figure C-11, Figure C-12, and Figure C-13, the reservation process must be an atomic operation so, if either reservation fails, then both reservations shall be removed and the MSRP attributes updated accordingly.

Figure C-12 is an example of the reservation process associated with a "Bridged" Listener requesting a Stream from a Talker non-AP STA. The Listener sends a Listener Ready (A) from the "Bridged" side of the network and bandwidth is reserved as explained in SRP (Clause 35). The IEEE 802.11 message exchanges associated with the Listener Ready (B) propagating to the Talker non-AP STA are also shown.

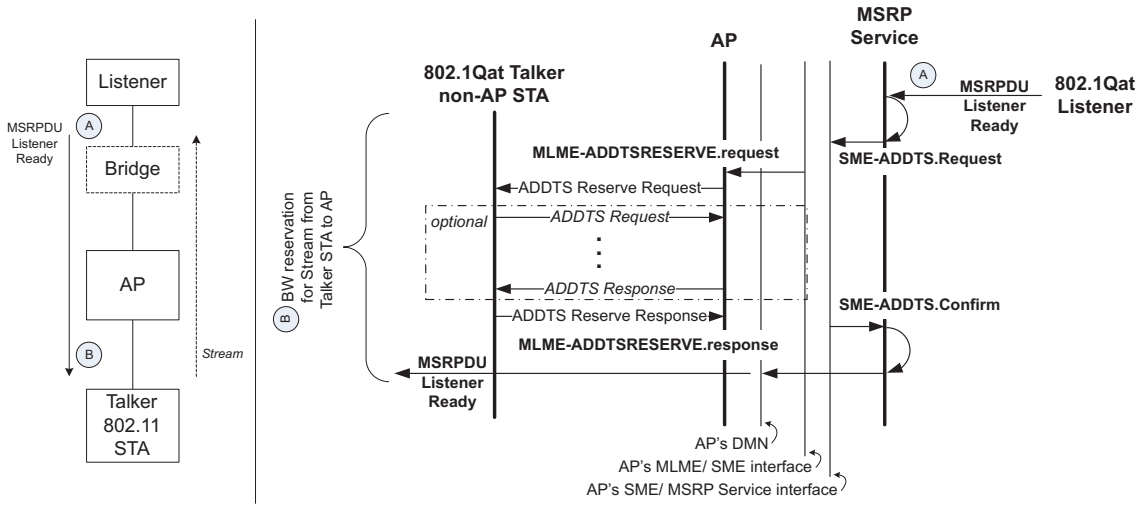

Figure C-12—MSRP/802.11 "Bridged" Listener to Talker STA reservation flows

Figure C-13 is an example of the reservation process associated with a Listener non-AP STA requesting a Stream from a "Bridged" Talker. The Listener non-AP STA sends a Listener Ready (A) through the AP's MSRP Service, resulting in the IEEE 802.11 message exchanges shown. The reservation process associated with the Listener Ready (B) sent to the "Bridged" Talker is explained in SRP (Clause 35).

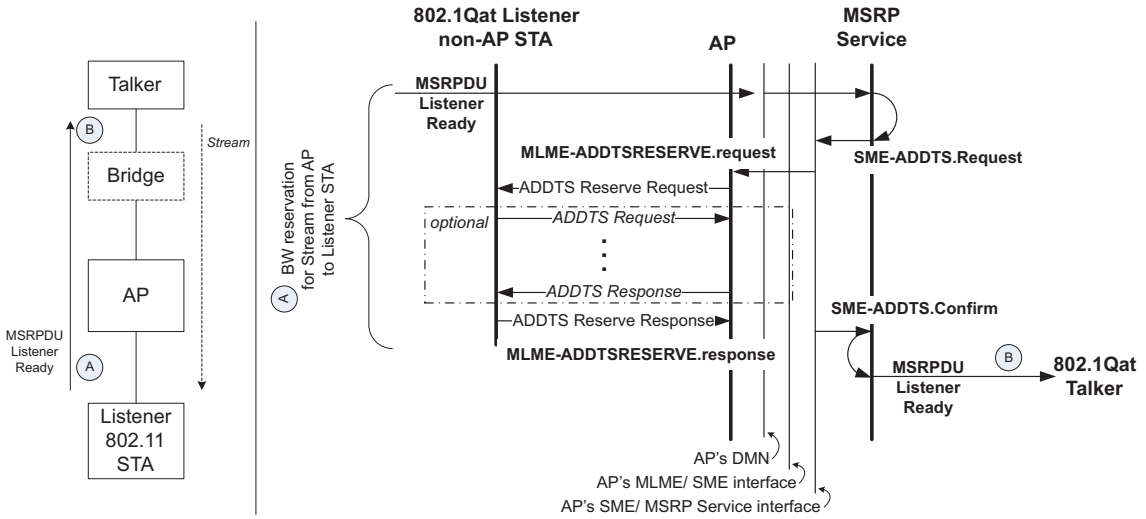

Figure C-13—MSRP/802.11 Listener STA to "Bridged" Talker reservation flows

The IEEE 802.11 message exchanges shown in the preceding three figures are explained in more detail as follows:

a) BBS nodes identify MSRPDUs by their Group Destination Address (35.2.2.1) and EtherType (35.2.2.2) and send these PDUs to the AP.
b) The AP forwards the MSRPDUs to the MSRP service on the DMN.
c) The DMN translates the MSRP TSpec parameters into an equivalent IEEE 802.11 TSPEC and invokes DMN-SME interface primitives with the AP as follows:
    1) When the DMN receives a Talker Advertise message that originated from an upstream BSS node, the DMN invokes QoS Query transactions (SME-QUERY.Request) with the BSS QoS AP (i.e., HC where dot11RobustAVStreamingImplemented is true) to check whether the bandwidth advertised in the message's TSpec is available on each upstream to downstream node link of the BSS. In addition the DMN maps the MSRPDU's TSpec with the message's StreamID.
    2) When the DMN receives a Listener Ready message originated from a downstream BSS node, the DMN invokes a QoS Reservation transaction (SME-ADDTS.Request) with the BSS QoS manager to reserve the bandwidth associated with the message's StreamID on the downstream to upstream BSS node link.

       The IEEE 802.11 BSS QoS AP on receipt of a SME-ADDTS.Request from the DMN shall make a determination about whether to accept the request or deny the request. The algorithm to be used by the BSS QoS AP to make this determination is an implementation detail.

       If the BSS QoS AP decides to accept the request, the AP shall derive a medium time value from the parameters specified in the SME-ADDTS.Request. The BSS QoS AP shall then generate an ADDTS Reserve Request frame in which the medium time value is included and transmit it to the appropriate SRP Talker (BSS upstream) and Listener (BSS downstream) nodes. The appropriate SRP Talker or Listener node replies to this ADDTS Reserve Request frame with an ADDTS Reserve Response frame indicating if the node accepts the reservation request. One or more ADDTS Request and ADDTS Response frames might be exchanged prior to the ADDTS Reserve Response frame.

       If the BSS QoS AP or Listener/Talker node decides to reject the request, it shall respond to the DMN with SME-ADDTS.confirm with a ResultCode of Rejected. The confirm primitive may also include a TSPEC, which the BSS QoS AP can accept, if specified in a subsequent SME-ADDTS.request.

NOTE—The TSPEC included in the SME-ADDTS.confirm is based on the result of the negotiations (labeled optional in Figure C-11 through Figure C-13) with the upstream BSS node. As a result the TSPEC included in the SME-ADDTS.confirm may be different from the one in the SME-ADDTS.request from the DMN.

d) After the DMN completes the BSS QoS transactions (SME-QUERY.Confirm or SME-ADDTS.Confirm as appropriate), the DMN behaves as an MSRP application on a Bridge and propagates MSRP attributes (35.2).

C.3.2 BSS DMN selection

The DMN shall be co-located with the device that supports the QoS AP function in the BSS.

C.3.3 BSS network bandwidth management

The MSRP service within the IEEE 802.11 network manages the BSS bandwidth for the MSRP streams by invoking the MLME QoS services. The DMN shall map the MLME services as described in Table C-4.

Table C-4—SRP to MLME QoS Services mapping

MSRP Attribute	MAD Primitive	SME QoS Services	Description
Talker Advertise	MAD_Join.request(new)	SME-QUERY	Query bandwidth without reservation
Listener Ready or Listener Ready Failed	MAD_Join.request(new)	SME-ADDTS	Reserve bandwidth for a stream
Listener Ready or Listener Ready Failed	MAD_Join.request()	SME-ADDTS[a]	Renew the bandwidth reservation (leased time) for a stream
Talker or Listener Leave	MAD_Leave.request()	SME-DELTS	Free bandwidth associated with a stream

[a] Bandwidth renewal is not required as long as the reservation is already established.

C.3.3.1 MSRPDU Encapsulation/De-encapsulation

In order to preserve the priority of an MSRPDU when traversing through an IEEE 802.11 network not using a Length/Type field in the MSDU, the priority shall be encapsulated while the MSRPDU is in the IEEE 802.11 network and shall be de-encapsulated as it exits. See IEEE Std 802.11 for additional information.

NOTE—For example if the priority of the MSRPDU is 4, DEI=0 and VID = 1893 the equivalent VLAN tag field (32 bits) is 81-00-87-65. When the frame enters the IEEE 802.11 network, the encapsulated 802.11 LLC header is AA-AA-03-00-00-00-81-00-87-65-08-00, where AA-AA-03-00-00-00-81-00-87-65 is the SNAP encoded VLAN header. When the frame exits the IEEE 802.11 network a de-encapsulation operation is performed and the resulting VLAN tag field is 81-00-87-65.

C.3.3.2 QoS Maintenance Report

An SRP DMN may obtain QoS Maintenance Report using IEEE 802.11 Transmit Stream/Category Measurement Requests and processing the corresponding Transmit Stream/Category Measurement Reports. The Transmit Stream/Category Measurement Request is sent to both the SRP Talker (BSS upstream) and the SRP Listener (BSS downstream) nodes. Triggers are set on appropriate conditions such that Transmit Stream/Category Measurement Reports are generated only when predefined thresholds are breached. See 9.4.2.21.11 of IEEE Std 802.11-2016 [B14] for details.

NOTE—This provides an indication to SRP (35.2.4) that bandwidth has changed.

C.3.3.3 SRP TSpec to IEEE 802.11 TSPEC mapping

SR Class B traffic has three parameters associated with it, namely delay budget per IEEE 802.11 hop (20 ms), **MaxFrameSize** (?1500 bytes) and **MaxIntervalFrames** (units of 4000 frames per second). IEEE 802.11 TSPECs include a Minimum PHY rate that is derived from the SR Class B parameters as described below:

a) Overhead = 10-byte VLAN tag + 8 byte Protocol definition = 18 bytes.
b) Mean Data Rate = (SRP TSpec **MaxFrameSize** + overhead) × 4000 × SRP TSpec **MaxIntervalFrames** bytes/second.
c) The Mean Data Rate is also the Max Data Rate (since it is assumed that MSDU size is fixed).
d) Assuming 70% × efficiency between the MAC and the PHY this translates into
(10/7) × (SRP TSpec **MaxFrameSize** + overhead) × 4000 × SRP TSpec **MaxIntervalFrames** bytes/second, or
(10/7) × 8 × (SRP TSpec **MaxFrameSize** + overhead) × 4000 × SRP TSpec **MaxIntervalFrames** bits/second.
e) Minimum PHY Rate is therefore
(10/7) × 8 × (SRP TSpec **MaxFrameSize** + overhead) × 4000 × SRP TSpec **MaxIntervalFrames** bits/second.

NOTE—For example, with 1500 and 1 for **MaxFrameSize** the above turns into 69.394285 Mb/s. Or, with 64 and 1 for **MaxFrameSize** and **MaxIntervalFrames** the above turns into 3.748571 Mb/s.

Table C-5 describes the mapping between SRP TSpec components and IEEE 802.11 QoS TSPEC parameters for the mandatory EDCA-AC mode.

Table C-5—EDCA-AC for AV Streams

TSPEC parameter		SR Class B
TSINFO	TID	5
	Direction	Up, Down
	Access Policy	10 (EDCA)
	ACK Policy	10 (No Ack) / 11 (Block Ack)
	APSD	0
	Aggregation	Yes
	Priority	**5**
Nominal MSDU Size[a]		**SRP TSpec MaxFrameSize+ 18 (also set bit 15 to a 1)**
Maximum MSDU Size		**SRP TSpec MaxFrameSize + 18**
Peak Data Rate		**(SRP TSpec MaxFrameSize + 18) × 4000 × SRP TSpec MaxIntervalFrames**
Minimum PHY Rate[b]		**(10/7) × 8 × (SRP TSpec MaxFrameSize + 18) × 4000 × SRP TSpec MaxIntervalFrames**
Delay Bound		**20 ms**
Surplus Bandwidth Allowance[c]		1.2

[a] bit15 set to indicate that the MSDU size is fixed.
[b] Assuming 70% efficiency between the MAC and the PHY.
[c] 20% surplus allocation.

Table C-6 describes the mapping between SRP **TSpec** components and IEEE 802.11 QoS TSPEC parameters for the optional HCCA mode.

Table C-6—HCCA for AV Streams

TSPEC parameter		SR Class B
TSINFO	TID	5
	Direction	Up, Down
	Access Policy	01 (HCCA)
	ACK Policy	10 (No Ack) / 11 (Block Ack)
	APSD	0
	Aggregation	Yes
	Priority	**5**
Nominal MSDU Size[a]		**0**
Maximum MSDU Size		**SRP TSpec MaxFrameSize+ 18**
Minimum Service Interval		10 ms
Maximum Service Interval		10 ms
Inactivity Interval		0
Minimum Data Rate		0
Mean Data Rate		**0**
Maximum Burst Size		**(SRP TSpec MaxFrameSize + 18) × 4000 × SRP TSpec MaxIntervalFrames × 10^{-2}**
Minimum PHY Rate[b]		**(10/7) × 8 × (SRP TSpec MaxFrameSize+ 18) × 4000 × SRP TSpec MaxIntervalFrames**
Peak Data Rate		**(SRP TSpec MaxFrameSize + 18) × 4000 × SRP TSpec MaxIntervalFrames**
Delay Bound		20 ms
Surplus Bandwidth Allowance[c]		1.2

[a] Bit 15 set to indicate that the MSDU size is fixed.
[b] Assuming 70% efficiency between the MAC and the PHY.
[c] 20% surplus allocation.

Annex D

(normative)

IEEE 802.1 Organizationally Specific TLVs

D.1 Requirements of the IEEE 802.1 Organizationally Specific TLV sets

The IEEE 802.1 Organizationally Specific TLVs may be supported in conjunction with any of the destination MAC addresses identified by IEEE Std 802.1AB for LLDPDU transmission.

If any IEEE 802.1 Organizationally Specific TLV set is supported, all IEEE 802.1 Organizationally Specific TLVs that are identified as members of that TLV set shall be supported. All IEEE 802.1 Organizationally Specific TLVs shall conform to the LLDPDU bit and octet ordering conventions of IEEE Std 802.1AB.

The IEEE 802.1 Organizationally Specific TLVs specified in this standard are listed in Table D-1. Other standards can also define IEEE 802.1 Organizationally Specific TLVs. The “TLV set name” column identifies the TLV set to which each TLV belongs. Any additions or changes to these TLVs will be included in this annex.

Table D-1—IEEE 802.1 Organizationally Specific TLVs

IEEE 802.1 subtype	TLV name	TLV set name	TLV reference	Feature clause reference
01	Port VLAN ID	basicSet	D.2.1	6.9
02	Port And Protocol VLAN ID	basicSet	D.2.2	6.12
03	VLAN Name	basicSet	D.2.3	12.10.2.1.3
04	Protocol Identity	basicSet	D.2.4	D.2.4
05	VID Usage Digest	basicSet	D.2.5	D.2.5
06	Management VID	basicSet	D.2.6	D.2.6
07	Link Aggregation TLV	basicSet	IEEE Std 802.1AX	IEEE Std 802.1AX
08	Congestion Notification	cnSet	D.2.7	Clause 33
09	ETS Configuration TLV	dcbxSet	D.2.8	Clause 38
0A	ETS Recommendation TLV	dcbxSet	D.2.9	Clause 38
0B	Priority-based Flow Control Configuration TLV	dcbxSet	D.2.10	Clause 38
0C	Application Priority TLV	dcbxSet	D.2.11	Clause 38
0D	EVB TLV	evbSet	D.2.12	D.2.12
0E	CDCP TLV	evbSet	D.2.13	D.2.13
10	Application VLAN TLV	dcbxSet	D.2.14	Clause 38

D.2 Organizationally Specific TLV definitions

In the TLV definitions that follow, any fields that are labeled as "Reserved" are transmitted as zero and ignored on receipt.

NOTE—In the case of a Port supported by Link Aggregation (IEEE Std 802.1AX), these TLVs apply to the aggregation, not the individual links. Since sending multiple copies is allowed, an implementation can send these TLVs with the same values on each individual link, but a TLV received on any individual link applies to the aggregation.

D.2.1 Port VLAN ID TLV

The Port VLAN ID TLV is an optional fixed length TLV that allows a VLAN Bridge Port to advertise the port VLAN identifier (PVID) that is associated with untagged or priority tagged frames (see 6.9).

Figure D-1 shows the Port VLAN ID TLV format.

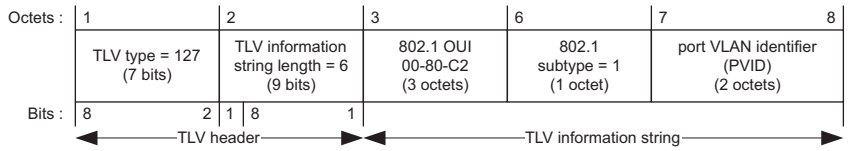

Figure D-1—Port VLAN ID TLV format

D.2.1.1 port VLAN identifier (PVID)

The PVID field shall contain the VID for the Bridge Port as defined in 6.9. A value of zero shall be used if the system either does not know the PVID or does not support Port-based VLAN operation.

D.2.1.2 Port VLAN ID TLV usage rules

An LLDPDU should contain no more than one Port VLAN ID TLV.

D.2.2 Port And Protocol VLAN ID TLV

The Port And Protocol VLAN ID TLV is an optional TLV that allows a Bridge Port to advertise a port and protocol VLAN identifier (PPVID). Figure D-2 shows the Port And Protocol VLAN ID TLV format.

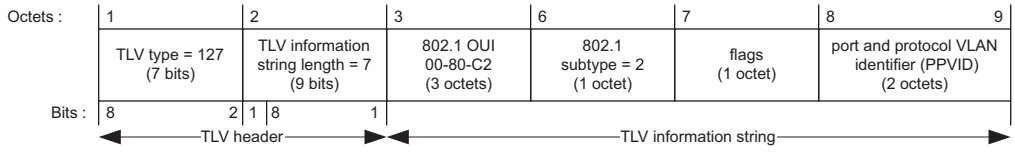

Figure D-2—Port And Protocol VLAN ID TLV format

D.2.2.1 flags

The flags field shall contain a bit map indicating the port and protocol VLAN capability and status as defined in Table D-2.

Table D-2—Port and protocol capability/status

Bit	Function	Value/meaning
0	Reserved for future standardization	—
1	Port and protocol VLAN supported	1 = supported 0 = not supported
2	Port and protocol VLAN enabled	1 = enabled 0 = not enabled
3–7	Reserved for future standardization	(set to zero)

D.2.2.2 port and protocol VLAN identifier (PPVID)

The PPVID field shall contain the PPVID number for this IEEE 802 LAN station. If the port is not capable of supporting port and protocol VLANs and/or the port is not enabled with any port and protocol VLAN, the PPVID number should be zero.

D.2.2.3 Port And Protocol VLAN ID TLV usage rules

Port And Protocol VLAN ID TLVs are subject to the following rules:

a) If more than one Port And Protocol VLAN ID TLV is defined for a port, the PPVID value shall be different from any other PPVID defined for the port.
b) If the support bit (bit 1) of the flag field indicates that the port is not capable of supporting port and protocol VLANs but the enabled bit (bit 2) indicates that the port is enabled with one or more port and protocol VLANs, the Port And Protocol VLAN ID TLV is interpreted as containing an error and will be discarded.
c) If the PPVID reference number is greater than 4094, the Port And Protocol VLAN ID TLV is interpreted as containing an error and is discarded.

D.2.3 VLAN Name TLV

The VLAN Name TLV is an optional TLV that allows an IEEE 802.1Q-compatible IEEE 802 LAN station to advertise the assigned name of any VLAN with which it is configured.

Figure D-3 shows the VLAN Name TLV format.

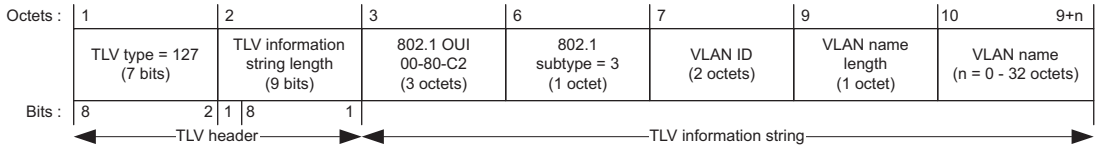

Figure D-3—VLAN Name TLV format

D.2.3.1 TLV information string length

The TLV information string length field shall contain the length, in octets, of the (VLAN name + 7).

D.2.3.2 VLAN ID (VID)

The VLAN ID field shall contain the VID number associated with the VLAN name.

D.2.3.3 VLAN name length

The VLAN name length field shall contain the length, in octets, of the VLAN name. A VLAN name length of zero indicates that there is no VLAN name associated with this VLAN.

D.2.3.4 VLAN name

If present, the VLAN name field shall contain the VLAN's name. If implementations support IETF RFC 4363, the dot1QVLANStaticName object should be used for this field.

D.2.3.5 VLAN Name TLV usage rules

If more than one VLAN Name TLV is defined for a port, the VID and the associated VLAN name combination shall be different from any other VID and VLAN name combination defined for the port.

D.2.4 Protocol Identity TLV

The Protocol Identity TLV is an optional TLV that allows an IEEE 802 LAN station to advertise particular protocols that are accessible through the port. Figure D-4 shows the protocol identity TLV format.

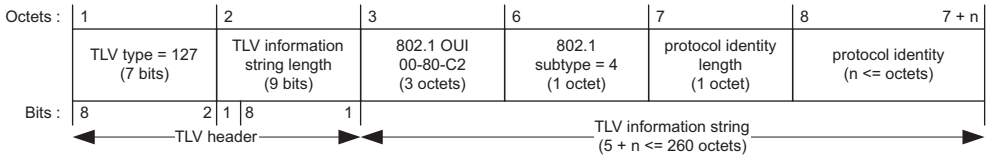

Figure D-4—Protocol Identity TLV format

D.2.4.1 TLV information string length

The TLV information string length field shall contain the length, in octets, of the (protocol identity + 5).

D.2.4.2 protocol identity length

The protocol identity length field shall contain the length, in octets, of the protocol identity.

D.2.4.3 protocol identity

The protocol identity field shall contain the first n octets of the protocol after the layer 2 addresses (i.e., for example, starting with the EtherType field) that the sender would like to advertise. The value of *n* is determined by the need for the protocol to disambiguate itself. The protocol information string shall include enough octets to allow the receiver to correctly identify the protocol and its version. To advertise spanning tree protocols, for example, the protocol identity field would need to include at least eight octets: IEEE 802.3 length (two octets), LLC addresses (two octets), IEEE 802.3 control (one octet), Protocol ID (two octets), and the protocol version (one octet).

D.2.4.4 Protocol Identity TLV usage rules

If more than one Protocol Identity TLV is defined for a port, the protocol identity field value shall be different from any other Protocol Identity TLV defined for the port.

D.2.5 VID Usage Digest TLV

The VID Usage Digest TLV is an optional TLV that allows an IEEE Std 802.1Q-compatible IEEE 802 LAN station to advertise the value of a VID Usage Digest associated with the system. The value of the VID Usage Digest is obtained by applying the CRC32 function (see IEEE Std 802.3) to a VID Usage Table having a fixed length of 512 octets. A bit of the VID Usage Table contains the value PBB-TE-USAGE (binary 1) if the corresponding element of the MST Configuration Table (8.9.1) contains the value PBB-TE MSTID (hex FFE) and otherwise contains the value NON-PBB-TE-USAGE (binary 0).

Figure D-5 shows the VID Usage Digest TLV format.

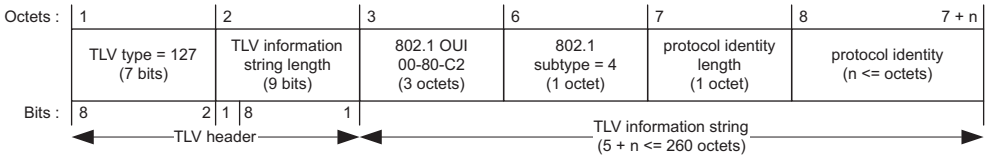

Figure D-5—VID Usage Digest TLV format

D.2.5.1 VID Usage Digest

The VID Usage Digest field shall contain a VID Usage Digest value obtained by applying the CRC32 function to the 512-octet VID Usage Table. A bit of the VID Usage Table contains the value PBB-TE-USAGE (binary 1) if the corresponding element of the MST Configuration Table (8.9.1) contains the value PBB-TE MSTID (hex FFE) and otherwise contains the value NON-PBB-TE-USAGE (binary 0).

D.2.6 Management VID TLV

The Management VID TLV is an optional TLV that allows an IEEE 802.1Q-compatible IEEE 802 LAN station to advertise the value of a Management VID associated with the system.

Figure D-6 shows the Management VID TLV format.

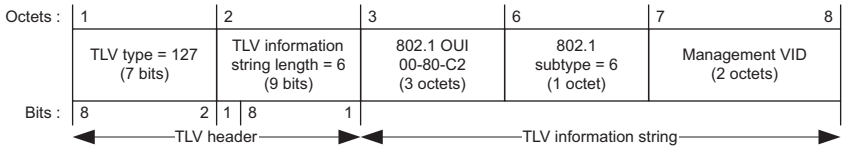

Figure D-6—Management VID TLV format

D.2.6.1 Management VID

The Management VID field shall contain the value configured for the Management VID, or the value 0 if a Management VID has not been provisioned.

D.2.7 Congestion Notification TLV

The TLV illustrated in Figure D-7 is encoded into each LLDP message transmitted by a system that is configured to support congestion notification on one or more priority values.

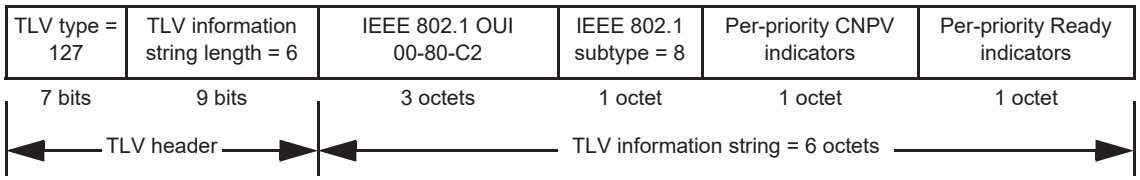

Figure D-7—Congestion Notification TLV format

A system shall transmit no more than one Congestion Notification TLV in a single LLDPDU. If a system receives an LLDPDU with more than one Congestion Notification TLV, the behavior of the receiving system is unspecified. A system shall not transmit a Congestion Notification TLV with all of the Per-priority CNPV indicators (D.2.7.3) clear (0).

D.2.7.1 TLV type

A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the value 127.

D.2.7.2 TLV information string length

A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information string length) and the entire second octet of the TLV, containing the total number of octets in the TLV information string of the Congestion Notification TLV. This does not count the TLV type and TLV information string length fields. It is equal to 6.

D.2.7.3 Per-priority CNPV indicators

A bit vector, one per priority value, containing all eight of the cnpdXmitCnpvCapable variables (32.4.7) for this port. The LSB of the octet carries priority 0's cnpdXmitCnpvCapable variable, and the MSB that of priority 7.

D.2.7.4 Per-priority Ready indicators

A bit vector, one per priority value, containing all eight of the cnpdXmitReady variables (32.4.8) for this port. The LSB of the octet carries priority 0's cnpdXmitReady variable, and the MSB that of priority 7.

D.2.8 ETS Configuration TLV

The TLV illustrated in Figure D-8 is encoded into each LLDP message and may be transmitted by a system in order to indicate the ETS configuration. Shall be sent using Asymmetric attribute passing (38.4.1).

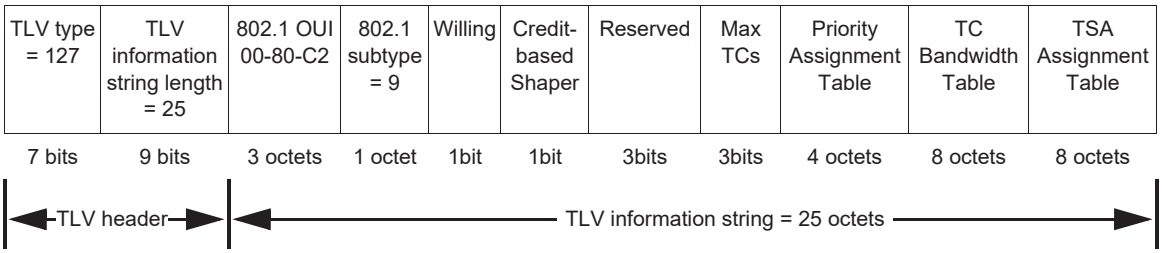

Figure D-8—ETS Configuration TLV format

D.2.8.1 TLV type

A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the value 127.

D.2.8.2 TLV information string length

A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information string length) and the entire second octet of the TLV, containing the total number of octets in the TLV information string of the ETS Configuration TLV. This does not count the TLV type and TLV information string length fields. It is equal to 25.

D.2.8.3 Willing

The Willing bit. A value of one indicates that the station is willing to accept configurations from the remote station.

D.2.8.4 Credit-based Shaper

The Credit-based Shaper bit. A value of one indicates that the station supports the Credit-based Shaper transmission selection algorithm (see Table 8-6 and Clause 34).

D.2.8.5 Max TCs

A 3-bit unsigned integer where the value of the integer is the maximum number of traffic classes that the implementation can support with the value 0 used when a device supports 8.

D.2.8.6 Priority Assignment Table

Table D-3 shows the layout of the priority assignment table.

Table D-3—Priority assignment table

Octets:	1		2		3		4	
	Priority 0	Priority 1	Priority 2	Priority 3	Priority 4	Priority 5	Priority 6	Priority 7
Bits:	7 4	3 0	7 4	3 0	7 4	3 0	7 4	3 0

The table consists of one 4-bit entry per Priority, where:

a) 0–7 indicate the Priority is mapped to the corresponding traffic class; and
b) All other values are Reserved.

D.2.8.7 TC Bandwidth Table

Table D-4 shows the layout of the traffic class bandwidth table.

Table D-4—Traffic class bandwidth assignment table

Octets:	1	2	3	4	5	6	7	8
	TC% 0	TC% 1	TC% 2	TC% 3	TC% 4	TC% 5	TC% 6	TC% 7

The table consists of one 8-bit entry per traffic class, and always contains 8 entries. Each entry:

a) Indicates the current TCBandwidth percentage configured for each traffic class N where N is 0 to 7.
b) Total shall equal 100 (implies valid range is 0–100 for each entry).

NOTE—While it is intended that only TCs configured for ETS will have a bandwidth value associated with them, it is possible, during configuration changes, to have situations where a TC is not configured for ETS but has a nonzero TCBandwidth percentage. In this case, the sum of all the TCBandwidth percentages is still equal to 100, but the TC bandwidth percentages of the non-ETS TCs would be unused bandwidth and reallocated to the ETS TCs.

D.2.8.8 TSA Assignment Table

Table D-5 shows the layout of the Transmission Selection Algorithm (TSA) Assignment Table.

Table D-5—TSA Assignment Table

Octets:	1	2	3	4	5	6	7	8
	Traffic Class 0	Traffic Class 1	Traffic Class 2	Traffic Class 3	Traffic Class 4	Traffic Class 5	Traffic Class 6	Traffic Class 7

The table consists of one 8-bit entry per traffic class. Each entry indicates the Transmission selection algorithm to be used for that traffic class as defined in Table 8-6. A value of 255 indicates a Vendor-specific Transmission selection algorithm.

D.2.9 ETS Recommendation TLV

The TLV illustrated in Figure D-9 is encoded into each LLDP message and may be transmitted by a system in order to indicate a recommendation on how ETS should be configured. A Willing system may receive a recommendation TLV that utilizes more Traffic Classes than the receiving system supports. In this case the receiving system may assign the received recommendations to match its capabilities. Shall be sent using Asymmetric attribute passing (38.4.1).

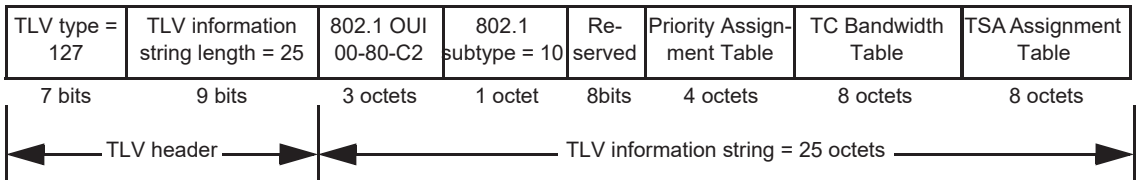

Figure D-9—ETS Recommendation TLV format

D.2.9.1 TLV type

A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the value 127.

D.2.9.2 TLV information string length

A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information string length) and the entire second octet of the TLV, containing the total number of octets in the TLV information string of the ETS Recommendation TLV. This does not count the TLV type and TLV information string length fields. It is equal to 25.

D.2.9.3 Priority Assignment Table

Table D-3 shows the layout of the priority assignment table.

See D.2.8.6 for description of table entries.

D.2.9.4 TC Bandwidth Table

Table D-4 shows the layout of the Traffic Class bandwidth assignment table.

See D.2.8.7 for description of table entries.

D.2.9.5 TSA Assignment Table

Table D-5 shows the layout of the TSA Assignment Table.

See D.2.8.8 for description of table entries.

D.2.10 Priority-based Flow Control Configuration TLV

The TLV illustrated in Figure D-10 is encoded into each LLDP message and may be transmitted by a system in order to indicate how PFC should be configured. Shall be sent using Symmetric attribute passing.

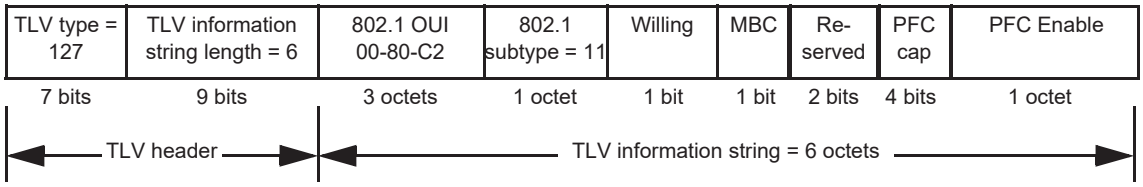

Figure D-10—Priority-based Flow Control Configuration TLV format

D.2.10.1 TLV type

A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the value 127.

D.2.10.2 TLV information string length

A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information string length) and the entire second octet of the TLV, containing the total number of octets in the TLV information string of the Priority-based Flow Control Configuration TLV. This does not count the TLV type and TLV information string length fields. It is equal to 6.

D.2.10.3 Willing

The Willing bit. A value of one indicates that the station is willing to accept configurations from the remote station.

D.2.10.4 MBC

The MACsec Bypass Capability Bit. If set to zero, the sending station is capable of bypassing MACsec processing when MACsec is disabled. If set to one, the sending station is not capable of bypassing MACsec processing when MACsec is disabled (see Clause 36).

D.2.10.5 PFC cap

A 4-bit unsigned integer, PFC cap (PFC capability) indicates the device's limitation of how many traffic classes may simultaneously support PFC.

NOTE 1—PFC may be enabled on up to eight traffic classes allowing each priority to be independently paused.

NOTE 2—In a DCB environment at least one priority would generally have PFC enabled.

D.2.10.6 PFC Enable

Table D-6 shows the layout of the PFC Enable bit vector.

Table D-6—PFC Enable bit vector

Octet:	1							
	Priority 7	Priority 6	Priority 5	Priority 4	Priority 3	Priority 2	Priority 1	Priority 0
Bits:	7	6	5	4	3	2	1	0

A bit vector of 8 bits, one per priority:

a) A one indicates PFC is enabled on the priority.
b) A zero indicates that PFC is disabled on the priority.
c) Local policy in each end of the link decides whether to use the priority if the configuration does not match.

D.2.11 Application Priority TLV

The TLV illustrated in Figure D-11 is encoded into each LLDP message and may be transmitted by a system in order to indicate the application priority table. This TLV is informational and used to indicate to a peer station the local configuration.

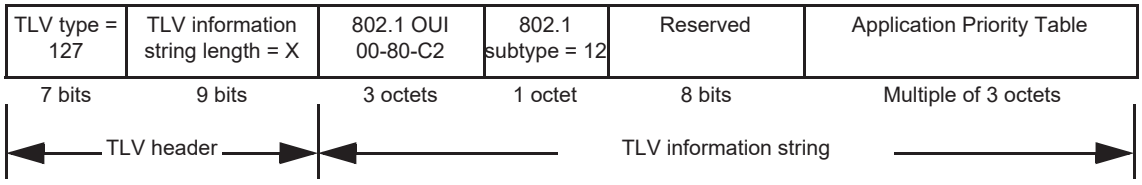

Figure D-11—Application Priority TLV format

D.2.11.1 TLV type

A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the value 127.

D.2.11.2 TLV information string length

A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information string length) and the entire second octet of the TLV, containing the total number of octets in the TLV information string of the Application Priority TLV. This does not count the TLV type and TLV information string length fields. The length for the Application Priority TLV is variable depending on the number of Application Priorities specified. The length shall be 5 plus a multiple of 3 octets.

D.2.11.3 Application Priority Table

Table D-7 shows the layout of a 3-octet entry in the Application Priority Table field.

Table D-7—Application Priority Table Entry format

Octets:	1			2	3
	Priority	Reserved	Sel	Protocol ID	
Bits:	8 6	5 4	3 1	8 1	8 1

The priority field is a 3-bit unsigned integer indicating the priority for which the Protocol ID is being used.

The meaning of the Protocol ID field is determined by the Sel field. Allowed values for the Sel field are shown in Table D-8.

Table D-8—Sel field values

Sel value	Protocol ID value
0	Reserved
1	0: Default application priority. For use when application priority is not otherwise specified. 1–1535: Reserved. 1536–65 535: An EtherType
2	Well Known Port number over TCP, or Stream Control Transmission Protocol (SCTP) [B36].
3	Well Known Port number over UDP, or Datagram Congestion Control Protocol (DCCP).
4	Well Known Port number over TCP, SCTP, UDP, or DCCP.
5	Differentiated Services Code Point (DSCP) value. The 6-bit DSCP value is stored in bits 1–6 of the low order octet of the Protocol ID field (octet 3 of the Application Priority Table Entry). Bits 7 and 8 and the high order octet of the Protocol ID field are set to zero. (See IETF RFC 2474 for the definition of the DSCP value.)
6–7	Reserved

NOTE—The port numbers shown are for identification (i.e., as assigned by IANA) instead of the actual port numbers being used in a particular deployment.

D.2.12 EVB TLV

The EVB TLV is used to:

a) Advertise a station or Bridge’s EVB capabilities.
b) Negotiate and activate common capabilities.

The EVB TLV is exchanged via LLDP and conforms to the LLDP TLV specification. The LLDP database carrying the EVB TLV is addressed using the Nearest Customer Bridge address. One LLDP database is built at the URP of each ER. If the EVB TLV is used for VDP NVO3 support, the LLDP database carrying the EVB TLV can also be accessed using a unicast MAC address.

The EVB TLV allows setting the EVB Bridge's C-VLAN component Port to operate in reflective relay. Reflective relay is implemented by changing the active topology enforcement rules described in 8.6.1 to allow forwarding on the reception Bridge Port. When reflective relay is enabled on a given Bridge Port, that port is a potential transmission port for frames received on that port.

The EVB TLV structure is illustrated in Figure D-12.

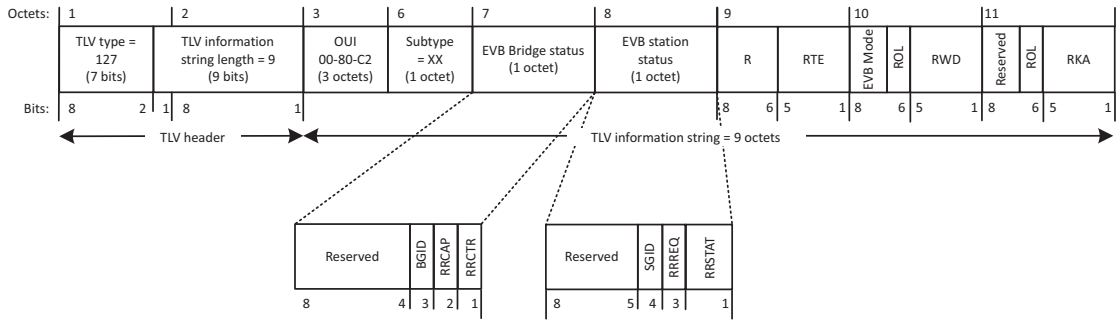

Figure D-12—EVB TLV format

The EVB TLV information string fields are as defined in D.2.12.1 through D.2.12.10.

D.2.12.1 OUI

The OUI used to identify the EVB TLV is the 802.1 OUI 00-80-C2.

D.2.12.2 Subtype

The subtype used to identify the EVB TLV is as shown in Table D-1.

D.2.12.3 EVB Bridge status

The EVB Bridge status field describes EVB capabilities that are supported by the EVB Bridge. If the sender of the TLV is an EVB Bridge (EVB Mode = EVB Bridge—see D.2.12.7), then the field reflects its own capabilities; if the sender of the TLV is an EVB station (EVB Mode = EVB station), then the field reflects the capabilities received from an attached EVB Bridge, or a value of zero if no TLV has been received from an attached EVB Bridge.

If the sender of the TLV is an nNVE (EVB Mode = NVO3 and NVE Role = nNVE—see D.2.12.7 and D.2.12.10), then the field reflects its own capabilities; if the sender of the TLV is a tNVE (EVB Mode = NVO3 and NVE Role = tNVE), then the field reflects the capabilities received from an attached nNVE, or a value of zero if no TLV has been received from an attached nNVE.

Each capability is represented by a single bit flag; a value of TRUE (1) indicates that the capability is supported, a value of FALSE (0) indicates that the capability is not supported.The capabilities are as defined in D.2.12.3.1 through D.2.12.3.5.

D.2.12.3.1 BGID

A value of TRUE indicates that the EVB Bridge wishes to control VID assignments and use the GroupID in VDP exchanges. A value of FALSE indicates that the EVB Bridge does not wish to make use of the Group ID in VDP exchanges.

If the EVB station sets SGID = TRUE, and the EVB Bridge also sets BGID = TRUE, then the EVB Bridge can control VID assignments and use the GroupID in VDP exchanges.

If the EVB station does not set SGID = TRUE, or the EVB Bridge does not set BGID = TRUE, then the EVB Bridge cannot control VID assignments or use the GroupID in VDP exchanges.

In an NVO3 Split-NVE scenario, BGID should always be set to TRUE by nNVE.

D.2.12.3.2 RRCAP

The RRCAP flag indicates the state of the EVB Bridge's reflectiveRelayCapable parameter (40.4.2).

If the EVB Bridge's reflectiveRelayCapable parameter is TRUE, and a TLV has been received by the EVB Bridge from an attached EVB station in which the value of RRREQ (D.2.12.4.2) is also TRUE, then the value of the EVB Bridge's operReflectiveRelayControl parameter (40.4.2) shall be set to TRUE. Otherwise, the value of the EVB Bridge's operReflectiveRelayControl parameter (40.4.2) shall be set to FALSE.

In an NVO3 Split-NVE scenario, RRCAP should be FALSE since reflective relay is not a required capability of nNVE.

D.2.12.3.3 RRCTR

The RRCTR flag indicates the state of the EVB Bridge's operReflectiveRelayControl parameter (40.4.2).

In an NVO3 Split-NVE scenario, RRCTR should be FALSE since RRREQ (D.2.12.4.2) received by nNVE is always FALSE.

D.2.12.3.4 V6CAP

This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the nNVE supports the use of IPv6 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates that the nNVE does not support the use of IPv6 addresses in that field. When both nNVE and tNVE set V6CAP = TRUE, then IPv6 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv6 addresses cannot be used in the Filter Info field in VDP exchanges.

D.2.12.3.5 V4CAP

This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the nNVE supports the use of IPv4 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates that the nNVE does not support the use of IPv4 addresses in that field. When both nNVE and tNVE set V4CAP = TRUE, then IPv4 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv4 addresses cannot be used in the Filter Info field in VDP exchanges.

D.2.12.4 EVB station status

The EVB station status field describes EVB capabilities that are supported by the EVB station. If the sender of the TLV is an EVB station (EVB Mode = EVB station—see D.2.12.7), then the field reflects its own capabilities; if the sender of the TLV is an EVB Bridge (EVB Mode = EVB Bridge), then the field reflects the capabilities received from an attached EVB station, or a value of zero if no TLV has been received from an attached EVB station.

If the sender of the TLV is a tNVE (EVB Mode = NVO3 and NVE Role = tNVE—see D.2.12.7 and D.2.12.10), then the field reflects its own capabilities; if the sender of the TLV is an nNVE (EVB Mode = NVO3 and NVE Role = nNVE), then the field reflects the capabilities received from an attached tNVE, or a value of zero if no TLV has been received from an attached tNVE.

Each capability is represented by a single bit flag; a value of TRUE (1) indicates that the capability is supported, a value of FALSE (0) indicates that the capability is not supported. The capabilities are as defined in D.2.12.4.1 through D.2.12.4.5.

D.2.12.4.1 SGID

A value of TRUE indicates that the EVB station can support the use of the GroupID.

If the EVB station sets SGID = TRUE, and the EVB Bridge also sets BGID = TRUE, then the EVB Bridge can control VID assignments and use the GroupID in VDP exchanges.

If the EVB station does not set SGID = TRUE, or the EVB Bridge does not set BGID = TRUE, then the EVB Bridge cannot control VID assignments or use the GroupID in VDP exchanges.

In an NVO3 Split-NVE scenario, SGID should always be set to TRUE by tNVE.

D.2.12.4.2 RRREQ

The RRREQ flag indicates the state of the EVB station's adminReflectiveRelayRequest parameter (40.4.3).

In an NVO3 Split-NVE scenario, RRREQ should always be set to FALSE in order to make sure reflective relay is not enabled.

D.2.12.4.3 RRSTAT

RRSTAT is a composite flag that indicates the state of the EVB station's operReflectiveRelayStatus parameter (40.4.3) as shown in Table D-9.

Table D-9—RRSAT flag values and meanings

Bit 1	Bit 2	Meaning
TRUE	FALSE	operReflectiveRelayStatus is TRUE
FALSE	FALSE	operReflectiveRelayStatus is FALSE
TRUE	TRUE	operReflectiveRelayStatus is Unknown
FALSE	TRUE	operReflectiveRelayStatus is Unknown

If a TLV has been received by the EVB station from an attached EVB Bridge in which the value of RRCTR (D.2.12.3.3) is TRUE, then the value of the EVB station's operReflectiveRelayStatus parameter (40.4.3) shall be set to TRUE. If a TLV has been received by the EVB station from an attached EVB Bridge in which the value of RRCTR (D.2.12.3.3) is FALSE, then the value of the EVB station's operReflectiveRelayStatus parameter (40.4.3) shall be set to FALSE. If no TLV has been received by the EVB station from an attached EVB Bridge, then the value of the EVB station's operReflectiveRelayStatus parameter (40.4.3) shall be set to Unknown.

In an NVO3 Split-NVE scenario, RRSTAT is always FALSE as RRCTR (D.2.12.3.3) received from nNVE is FALSE.

D.2.12.4.4 V6CAP

This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the tNVE supports the use of IPv6 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates that the tNVE does not support the use of IPv6 addresses in that field. When both nNVE and tNVE set V6CAP = TRUE, then IPv6 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv6 addresses cannot be used in the Filter Info field in VDP exchanges.

D.2.12.4.5 V4CAP

This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the tNVE supports the use of IPv4 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates that the tNVE does not support the use of IPv4 addresses in that field. When both nNVE and tNVE set V4CAP = TRUE, then IPv4 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv4 addresses cannot be used in the Filter Info field in VDP exchanges.

D.2.12.5 R

This field carries the maxRetries value for the ECP state machine (43.3.7.4). Both sides transmit the local value, and use the largest of the two values of R. If no remote value is available, then the local value is used.

D.2.12.6 RTE (retransmission exponent)

RTE is an EVB link or S-channel attribute used to calculate the minimum ECPDU retransmission time, ackTimerInit. The value of ackTimerInit, in ECP timer tics of 10 usec, is calculated as:

2^{RTE} ECP timer tics

Both sides transmit the local value, and use the largest of the two values of RTE for this calculation. If no remote value is available, then the greater of 2 ms and local value is used.

D.2.12.7 EVB Mode

The EVB Mode field represents the value of the EVBMode parameter (40.4) for the sender of the TLV, as shown in Table D-10.

Table D-10—EVB Mode values

EVBMode (40.4)	Field value
Not Supported	0
EVB Bridge	1
EVB station	2
NVO3	3

D.2.12.8 ROL (remote or local) and RWD (resource wait delay)

The RWD value transmitted by the EVB Bridge indicates the exponent value in use by the EVB Bridge for determining the value of the resourceWaitDelay variable (41.5.5.7). The value of resourceWaitDelay, in VDP timer tics of 10 usec, is calculated as:

2^{RWD} VDP timer tics

Both sides transmit the local value, and use the largest of the local and remote values of RWD in calculation of resourceWaitDelay or respWaitDelay variable (41.5.5.9); if there is no remote value available, the local (proposed) value is used. The Remote or Local (ROL) flag indicates whether the remote RWD value is in use (TRUE) or the local value is in use (FALSE) at the sending node.

D.2.12.9 ROL (remote or local) and RKA (reinit keep alive)

The RKA value transmitted by the EVB station indicates the exponent value in use by the EVB station for determining the value of the reinitKeepAlive variable (41.5.5.5). The value of reinitKeepAlive, in VDP timer tics of 10 usec, is calculated as:

2^{RKA} VDP timer tics

Both sides transmit the local value, and use the largest of the local and remote values of RKA in calculation of reinitKeepAlive or toutKeepAlive variable (41.5.5.13); if there is no remote value available, the local (proposed) value is used. The Remote or Local (ROL) flag indicates whether the remote RKA value is in use (TRUE) or the local value is in use (FALSE) at the sending node.

D.2.12.10 NVE Role

NVE Role field represents the value of the NVERole parameter (40.5) for the sender of the TLV, as shown in Table D-11. This field is useful only when EVBMode = NVO3.

Table D-11—NVE Role values

NVERole (40.5)	Field values
nNVE	00
tNVE	01
Reserved	10, 11

D.2.13 CDCP TLV

The EVB station and Bridge both use the same LLDP TLV to configure S-channels (see Figure D-13). This TLV is in LLDP Organizationally Specific TLV format (see IEEE Std 802.1AB). The S-channel's capabilities, requests, and running configuration is encoded in the information string of this TLV as defined in D.2.13.1D.2.13.1 through D.2.13.8.

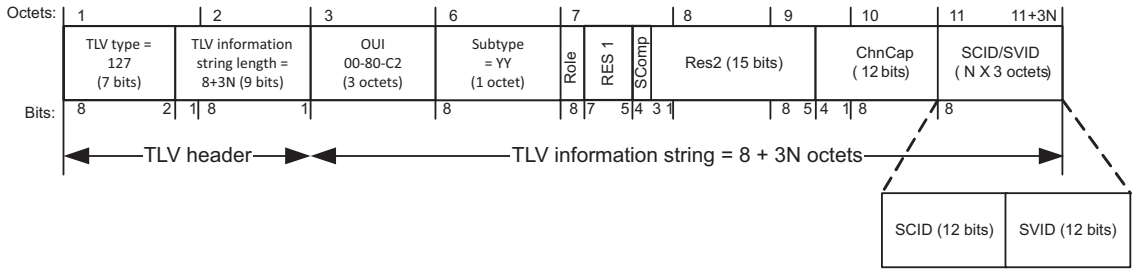

Figure D-13—CDCP TLV structure

D.2.13.1 OUI

The OUI used to identify the CDCP TLV is the 802.1 OUI 00-80-C2.

D.2.13.2 Subtype

The subtype used to identify the CDCP TLV is as shown in Table D-1.

D.2.13.3 Role

Role is a 1-bit field, defined as follows:

a) S(1)—Indicates the sender is operating in the station role, assigns channels numbers and a default SVID for the default channel 1, and requests SVID assignments from the neighboring 'B'.
b) B(0)—Indicates the sender is operating in the Bridge role, accepts S-channel configuration requests from its neighboring 'S' and that the sender will do the best it can to fill the SVID assignment requests from the neighboring 'S'.

D.2.13.4 RES1

RES1 is a 3-bit field, reserved for future standardization. This field is transmitted as zero and ignored on receipt.

D.2.13.5 SComp

SComp is a 1-bit field that indicates the presence or absence of an S-VLAN component for S-channel support. A value of 1 indicates TRUE, zero indicates FALSE.

NOTE—If this bit is zero, then the sender does not have a CDCP state machine, and the other fields in the TLV are not valid.

D.2.13.6 Res2

RES2 is a 15-bit field, reserved for future standardization. This field is transmitted as zero and ignored on receipt.

D.2.13.7 ChnCap

Channel capacity. Identifies the total number of S-channels, both assigned and available to be assigned, that the sender has.

D.2.13.8 SCID/SVID

An SCID/SVID pair exists for each S-channel that is currently supported by the sender. Each SCID/SVID pair consists of two 12-bit values, as follows:

a) SCID—indicates the index number of the S-channel. The station assigns S-channel numbers in the range 0–167. Zero is reserved. The S-channel index should be between 1 and the maximum number of S-channels supported by the port.
b) SVID—The VID assigned to the S-channel. The Bridge assigns SVIDs to channels in the range 1–0xffe. A station uses the 0 SVID to request an SVID assignment from the Bridge.

After the station receives the SVID assignment from the Bridge, it uses the SVID assigned value in all subsequent exchanges for that specific SCID (SCID/SVID pair).

NOTE 1—The first entry in the list of SCID/SVID pairs contains the default S-channel. (i.e., the first channel pair is <1,1>).

NOTE 2—A maximum of 167 S-channels can be supported. Other formats (assuming sequential SVIDs) could be defined to allow support for 4K+ S-channels.

NOTE 3—This listing can be sparse (in order to indicate arrival and removal of S-channels). The S-channel going away is indicated by removing the SCID/SVID pair.

NOTE 4—The order of the list determines the priority of SVID assignments. If the Bridge does not have resources for all channels, it assigns the first channels in the list.

D.2.14 Application VLAN TLV

The TLV illustrated in Figure D-14 is encoded into each LLDP message and may be transmitted by a system in order to indicate the application VLAN table. This TLV is informational and used to indicate to a peer station the local configuration.

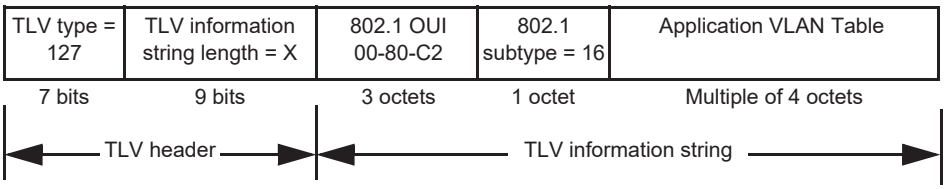

Figure D-14—Application VLAN TLV format

D.2.14.1 TLV type

A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the value 127.

D.2.14.2 TLV information string length

A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information string length) and the entire second octet of the TLV, containing the total number of octets in the TLV information string of the Application VLAN TLV. This does not count the TLV type and TLV information string length fields. The length for the Application VLAN TLV is variable depending on the number of Application VLANs specified. The length shall be 4 plus a multiple of 4 octets.

D.2.14.3 Application VLAN Table

Table D-12 shows the layout of a 4 octet entry in the Application VLAN Table.

Table D-12—Application VLAN Table Entry format

Octets:	1		2			3		4	
Field:	VID			Reserved	Sel	Protocol ID			
Bits:	8	1	8	5	4	3	1	8	1	8	1

The VID field is a 12-bit unsigned integer indicating the VID of the VLAN for which the Protocol ID is being used.

The meaning of the Protocol ID field is determined by the Sel field. Allowed values for the Sel field are shown in Table D-13.

Table D-13—Sel field values

Sel value	Protocol ID value
0	Reserved
1	0: PVID. For use when an application VLAN is not otherwise specified. 1–1535: Reserved 1536–65 535: An EtherType.
2	Well Known Port number over TCP, or SCTP.
3	Well Known Port number over UDP, or DCCP.
4	Well Known Port number over TCP, SCTP, UDP, or DCCP.
5	Differentiated Services Code Point (DSCP) value. The 6-bit DSCP value is stored in bits 1–6 of the low order octet of the Protocol ID field (octet 4 of the Application VLAN Table Entry). Bits 7 and 8 and the high order octet of the Protocol ID field are set to zero. (See IETF RFC 2474 for the definition of the DSCP value.)
6–7	Reserved

The Application VLAN TLV may be exchanged between EVB station ERs (5.24.1) and EVB Bridges (5.23) with LLDP using the Nearest Customer Bridge address. This allows ERs sharing a LAN using S-channels (40.2) to use different VLANs for the same application.

NOTE 1—The Application VLAN TLV allows multiple VLANs to be associated with an application on a port. Issues involved with using multiple VLANs for an application on a port, such as resolving which IP subnetwork corresponds to which VLAN, are beyond the scope of this standard.

NOTE 2—Selection of different IEEE 802.1 paths may use different VLANs, which could be associated with different quality of service levels. This TLV may not apply to deployment cases where the VID is implied by other attributes of the frame, for example, by the IP subnet of the source IP address.

D.3 IEEE 802.1 Organizationally Specific TLV management

D.3.1 IEEE 802.1 Organizationally Specific TLV selection management

TLV selection management consists of providing the network manager with the means to select which specific IEEE 802.1 Organizationally Specific TLVs are enabled for inclusion in an LLDPDU. The following LLDP variables cross reference to LLDP local systems configuration MIB tables indicate which specific TLVs are enabled for the particular port(s) on the system. The specific port(s) through which each TLV is enabled for transmission may be set (or reset) by the network manager:

a) **mibXdot1PortVlanTxEnable:** This variable lists the VID of the port through which the referenced TLV is enabled for transmission.

b) **mibXdot1VlanNameConfigTxEnable:** This variable lists the different VLAN name/PPVID TLVs that are defined for the system, each with a bit map indicating the system ports through which the particular VLAN name TLV is enabled for transmission.

c) **mibXdot1ProtoVlanConfigTxEnable:** This variable lists the Port And Protocol VLAN TLVs that are defined for the system, each with a bit map indicating the system ports through which the particular Port And Protocol VLAN TLV is enabled for transmission.

d) **mibXdot1ProtocolConfigTxEnable:** This variable lists the protocol identity TLVs that are defined for the system, each with a bit map indicating the system ports through which the particular protocol TLV is enabled for transmission.

D.3.2 IEEE 802.1 managed objects—TLV variables

D.3.2.1 Port VLAN ID TLV managed objects

a) **PVID:** The port VLAN identifier (see D.2.1.1).

D.3.2.2 Port And Protocol VLAN ID TLV managed objects

a) **Port and protocol VLAN supported:** A flag indicating whether port and protocol VLANs are supported (see D.2.2.1).
b) **Port and protocol VLAN enabled:** A flag indicating whether port and protocol VLANs are enabled (see D.2.2.1).
c) **PPVID:** The advertised port and protocol VLAN identifier (see D.2.2.2).

D.3.2.3 VLAN Name TLV managed objects

a) **VID:** The VLAN identifier associated with the VLAN name (see D.2.3.2).
b) **VLAN name length:** The length of the VLAN name (see D.2.3.3).
c) **VLAN name:** The VLAN's name (see D.2.3.4).

D.3.2.4 Protocol Identity TLV managed objects

a) **protocol identity length:** The length of the protocol identity (see D.2.4.2).
b) **protocol identity:** The protocol's identity (see D.2.4.3).

D.3.2.5 VID Usage Digest TLV managed objects

a) **VID Usage Digest:** The VID Usage Digest value (see D.2.5.1)

D.3.2.6 Management VID TLV managed objects

a) **Management VID:** The Management VID value (see D.2.6.1)

D.3.2.7 Link Aggregation TLV managed objects

a) **aggregation status:** The capability and current aggregation status of the link (see IEEE Std 802.1AX).
b) **aggregated port ID:** The aggregated port identifier (see IEEE Std 802.1AX).

D.3.2.8 Congestion Notification TLV managed objects

a) **CNPV indicators:** A per-priority CNPV indicator vector (see D.2.7.3).
b) **CN ready indicators:** A per-priority ready indicator vector (see D.2.7.4).

D.3.2.9 EVB TLV managed objects

a) **EVB TLV:** see D.2.12.

D.3.2.10 CDCP TLV managed objects

a) **CDCP TLV:** see D.2.13.

D.4 PICS proforma for IEEE 802.1 Organizationally Specific TLV extensions[57] [58]

D.4.1 Implementation identification

Supplier	
Contact point for queries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) of machines and/or operating system names	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirement for full identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

D.4.2 Protocol summary, IEEE Std 802.1Q

Identification of protocol specification	IEEE Std 802.1Q-2022, IEEE Standard for Local and metropolitan area networks—Bridges and Bridged Networks
Identification of amendments and corrigenda to the PICS proforma that have been completed as part of the PICS	Amd. : Corr. : Amd. : Corr. :
Have any Exception items been required? (See A.3.3: The answer Yes means that the implementation does not conform to IEEE Std 802.1Q.)	No [ ] Yes [ ]

Date of Statement	

[57] Instructions for completing the PICS proforma are given in A.3.

[58] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

D.4.3 Major capabilities and options

Item	Feature	Status	References	Support
dot1basicSet	Is the IEEE 802.1 Organizationally Specific TLV basicSet implemented?	O.1	D.1, Table D-1	Yes [ ] No [ ]
dot1basictlv	Is each TLV in the IEEE 802.1 Organizationally Specific TLV basicSet implemented?			
	Port VLAN ID TLV	dot1basicSet:M	D.2.1	Yes [ ]

lldpmib	Which type of MIB is implemented (one is mandatory)?			
	SNMP is supported (if yes, answer item **snmpmib** and skip **equivstor**)	O.2	D.5	Yes [ ] No [ ]
	SNMP is not supported (if yes, answer **equivstor** and skip **snmpmib**)	O.2	D.5	Yes [ ] No [ ]
snmpmib	If the SNMP MIB is implemented, is the MIB module in conformance with the MIB groups indicated in Table D-14 for the operating mode being implemented?	M	D.5	Yes [ ]

D.4.3 Major capabilities and options *(continued)*

Item	Feature	Status	References	Support
equivstor	If the SNMP is not supported, is the provided storage and retrieval capability functionally equivalent with the indicated specifications of this clause for the operating mode being implemented?	M	D.2.1. D.2.2, D.2.3, D.2.4, and IEEE Std 802.1AX	Yes [ ]
dcbxSet	Is the IEEE 802.1 DCBX TLV set implemented?	O.1	Annex D	Yes [ ] No [ ]
dcbxtlv	Is each TLV in the IEEE 802.1 DCBX TLV set implemented?			
	ETS Configuration TLV	dcbxSet:M	D.2.8	Yes [ ]
	ETS Recommendation TLV	dcbxSet:M	D.2.9	Yes [ ]
	Priority-based Flow Control Configuration TLV	dcbxSet:M	D.2.10	Yes [ ]
	Application Priority TLV	dcbxSet:M	D.2.11	Yes [ ]
	Application VLAN TLV	dcbxSet:M	D.2.14	Yes [ ]

D.5 IEEE 802.1/LLDP extension MIB

D.5.1 Internet Standard Management Framework

LLDP MIBs are designed to operate in a manner consistent with the principles of the Internet Standard Management Framework, which describes the separation of a data modeling language (for example, SMIv2) from content-specific data models (for example, the LLDP remote systems MIB), and from messages and protocol operations used to manipulate the data (for example, SNMPv3).

For a detailed overview of the documents that describe the current Internet Standard Management Framework, refer to section 7 of IETF RFC 3410 (2002).

Managed objects are accessed via a virtual information store, termed the *Management Information Base* or *MIB*. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This clause specifies a MIB module that is compliant to the SMIv2, which is described in IETF STD 58, IETF RFC 2578, IETF RFC 2579, and IETF RFC 2580.

D.5.2 Structure of the IEEE 802.1/LLDP extension MIB

Table D-14 summarizes the particular object groups that are required for each operating mode. The implemented MIB shall comply with the MIB conformance section for the particular operating mode being supported.

Table D-14—IEEE 802.1 extension MIB object group conformance requirements

MIB group	Rx mode	Tx mode	Tx/Rx mode
lldpV2Xdot1ConfigGroup	M[a]	M	M
lldpV2Xdot1LocSysGroup	M	—	M
lldpV2Xdot1RemSysGroup	—	M	M
ifGeneralInformationGroup	M	M	M
lldpXdot1dcbxETSGroup	DCBX:M	DCBX:M	DCBX:M
lldpXdot1dcbxPFCGroup	DCBX:M	DCBX:M	DCBX:M
lldpXdot1dcbxApplicationPriorityGroup	DCBX:M	DCBX:M	DCBX:M
lldpXdot1dcbxApplicationVlanGroup	DCBX:M	DCBX:M	DCBX:M

[a]M=Mandatory.

Table D-15 shows the structure of the MIB and the relationship of the MIB objects to the LLDP operational status/control variables, LLDP statistics variables, and TLV variables.

[a] The term Extension Group is used here to be consistent with LLDP (see IEEE Std 802.1AB).

D.5.3 Relationship to other MIBs

Version 2 of the IEEE 802.1 LLDP extension MIB module appears in D.5.5. Version 1 of the MIB module that was published in IEEE Std 802.1AB-2005 [B6] has been superseded by version 2 of the MIB module, and support of the version 2 module is a requirement for conformance to the required or optional capabilities (Clause 5 of IEEE Std 802.1AB-2009 [B7]) in IEEE Std 802.1AB-2009. The version 2 MIB module reflects

changes in indexation of the MIB objects that support the use of LLDP with multiple destination MAC addresses, as discussed in Clause 6 of IEEE Std 802.1AB-2009 [B7].

The relationship of the IEEE 802.1 LLDP extension MIB module to other MIBs, and coexistence between version 1 and version 2 implementations, is further discussed in 11.3 of IEEE Std 802.1AB-2009 [B7].

D.5.4 Security considerations for IEEE 802.1 LLDP extension MIB module

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write.[59] Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a nonsecure environment without proper protection can have a negative effect on network operations.

Setting the following objects to incorrect values can result in improper operation of LLDP when in the transmit mode:

a) lldpV2Xdot1ConfigPortVlanTxEnableV2
b) lldpV2Xdot1ConfigVlanNameTxEnable
c) lldpV2Xdot1ConfigProtoVlanTxEnable
d) lldpV2Xdot1ConfigProtocolTxEnable
e) lldpV2Xdot1ConfigVidUsageDigestTxEnable
f) lldpV2Xdot1ConfigManVidTxEnable

The following readable objects in this MIB module may be considered to be sensitive or vulnerable in some network environments:

g) MIB objects that are related to the transmit mode:
    1) lldpV2Xdot1LocPortVlanId
    2) lldpV2Xdot1LocProtoVlanSupported
    3) lldpV2Xdot1LocProtoVlanEnabled
    4) lldpV2Xdot1LocVlanName
    5) lldpV2Xdot1LocProtocolId
    6) lldpV2Xdot1LocVidUsageDigest
    7) lldpV2Xdot1LocManVidTxEnable
    8) lldpV2Xdot1LocLinkAggStatus
    9) lldpV2Xdot1LocLinkAggPortId
    10) lldpXdot1dcbxConfigETSConfigurationEntry
    11) lldpXdot1dcbxConfigPFCTable
    12) lldpXdot1dcbxLocETSBasicConfigurationTable
    13) lldpXdot1dcbxLocETSConPriorityAssignmentTable
    14) lldpXdot1dcbxLocETSRecoTrafficSelectionAlgorithmTable
    15) lldpXdot1dcbxLocPFCBasicTable
    16) lldpXdot1dcbxLocPFCEnableTable
    17) lldpXdot1dcbxAdminETSBasicConfigurationTable
    18) lldpXdot1dcbxAdminETSConPriorityAssignmentTable
    19) lldpXdot1dcbxAdminETSRecoTrafficSelectionAlgorithmTable
    20) lldpXdot1dcbxAdminPFCBasicTable
    21) lldpXdot1dcbxAdminPFCEnableTable
    22) lldpXdot1dcbxLocApplicationPriorityAppTable
    23) lldpXdot1dcbxLocApplicationVlanAppTable
    24) lldpXdot1dcbxAdminApplicationPriorityAppTable

[59] In IETF MIB definitions, the MAX-ACCESS clause defines the type of access that is allowed for particular data elements in the MIB. An explanation of the MAX-ACCESS mappings is given in section 7.3 of IETF RFC 2578 (1999).

25) lldpXdot1dcbxAdminApplicationVlanAppTable

h) MIB objects that are related to the receive mode:
   1) lldpV2Xdot1RemPortVlanId
   2) lldpV2Xdot1RemProtoVlanSupported
   3) lldpV2Xdot1RemProtoVlanEnabled
   4) lldpV2Xdot1RemVlanName
   5) lldpV2Xdot1RemProtocolId
   6) lldpV2Xdot1RemVidUsageDigest
   7) lldpV2Xdot1RemManVidTxEnable
   8) lldpV2Xdot1RemLinkAggStatus
   9) lldpV2Xdot1RemLinkAggPortId
   10) lldpXdot1dcbxConfigETSConfigurationEntry
   11) lldpXdot1dcbxConfigPFCTable
   12) lldpXdot1dcbxRemETSBasicConfigurationTable
   13) lldpXdot1dcbxRemETSConPriorityAssignmentTable
   14) lldpXdot1dcbxRemETSRecoTrafficSelectionAlgorithmTable
   15) lldpXdot1dcbxRemPFCBasicTable
   16) lldpXdot1dcbxRemPFCEnableTable
   17) lldpXdot1dcbxAdminETSBasicConfigurationTable
   18) lldpXdot1dcbxAdminETSConPriorityAssignmentTable
   19) lldpXdot1dcbxAdminETSRecoTrafficSelectionAlgorithmTable
   20) lldpXdot1dcbxAdminPFCBasicTable
   21) lldpXdot1dcbxAdminPFCEnableTable
   22) lldpXdot1dcbxRemApplicationPriorityAppTable
   23) lldpXdot1dcbxRemApplicationVlanAppTable
   24) lldpXdot1dcbxAdminApplicationPriorityAppTable
   25) lldpXdot1dcbxAdminApplicationVlanAppTable

This concern applies both to objects that describe the configuration of the local host, as well as for objects that describe information from the remote hosts, acquired via LLDP and displayed by the objects in this MIB module. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example, by using IPSec), there is no control about who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

Implementers should consider the security features as provided by the SNMPv3 framework (see IETF RFC 3410 (2002), section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, implementers should not deploy SNMP versions prior to SNMPv3. Instead**,** implementers should deploy SNMPv3 to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

D.5.5 IEEE 802.1 LLDP extension MIB module—version 2[60] [61]

In the following MIB definition, should any discrepancy between the DESCRIPTION text and the corresponding definition in D.2.1 through D.5 occur, the definition in D.2.1 through D.5 shall take precedence.

    DESCRIPTION
            "The LLDP Management Information Base extension module for
            IEEE 802.1 organizationally defined discovery information.

            In order to ensure the uniqueness of the LLDP-V2-MIB,
            lldpV2Xdot1MIB is branched from lldpV2Extensions using an
            Organizationally Unique Identifier (OUI) value as the node.
            An OUI is a 24 bit globally unique number assigned by the
            IEEE Registration Authority - see:

            http://standards.ieee.org/develop/regauth/oui/index.html

        Unless otherwise indicated, the references in this MIB
        module are to IEEE Std 802.1Q-2022.
```

    REVISION "202211080000Z" -- November 8, 2022
    DESCRIPTION
            "Published as part of IEEE Std 802.1Q-2022.
            Cross references and contact information updated."

    REVISION "201807010000Z" -- July 1, 2018
    DESCRIPTION
            "Published as part of IEEE Std 802.1Q 2018 revision.
            Cross references updated and corrected.
            Changes introduced by IEEE Std 802.1Qcd-2015 and
            IEEE Std 802.1Q-2014 Cor 1-2015 merged. "

    REVISION "201502160000Z" -- February 16, 2015
    DESCRIPTION
            "Published as part of IEEE Std 802.1Q 2014 Cor-1.
            Updated as a result of maintenance items #0132 and #0152"

    REVISION "201502160000Z" -- February 16, 2015
    DESCRIPTION
            "Published as part of IEEE Std 802.1Qcd.
            Adds Application VLAN TLV objects to the DCBX groups of
            the MIB module."

    REVISION "201412150000Z" -- December 15, 2014
    DESCRIPTION
            "Published as part of IEEE Std 802.1Q 2014 revision.
            Cross references updated and corrected.
            New tables lldpV2Xdot1RemVidUsageDigestV2Table
            and lldpV2Xdot1RemManVidV2Table inserted; old
            versions deprecated. New versions add an index for
            lldpV2RemIndex. "

    REVISION "201103250000Z" -- March 25, 2011
    DESCRIPTION
            "Published as part of IEEE Std 802.1Qaz-2011. Adds the DCBX
            objects to the MIB module"

    REVISION "201103230000Z" -- March 23, 2011
    DESCRIPTION
            "Published as part of IEEE Std 802.1Q-2011 revision.
            This revision contains changes associated with
            relocating the extension MIB from IEEE Std 802.1AB to
            IEEE Std 802.1Q, minor tweaks to the text of the
            DESCRIPTION statement above to fix references to
            IEEE Std 802.1Q, updating of references to refer to
            Annex D, and addition of object definitions for
            Congestion Notification TLVs and corresponding
            compliance statements."

    REVISION "200906080000Z" -- June 08, 2009
    DESCRIPTION
            "Published as part of IEEE Std 802.1AB-2009 revision.
            This revision incorporated changes to the MIB to
            support the use of LLDP with multiple destination MAC
            addresses, and to import the Link Aggregation TLV
            from the IEEE 802.3 extension MIB"

    STATUS      current
    DESCRIPTION
            "This TC describes the link aggregation status.

            The bit 'aggCapable(0)' indicates the link is capable of being
            aggregated if 1, not capable if 0.

            The bit 'aggEnabled(1)' indicates the link is currently in
            an aggregation if 1, not in an aggregation if 0.

            The bits 'portTypeLS(1)' and portTypeMS(2)' form the LS
            and MS bits of a Port Type value respectively:
            00 = no port type specified
            01 = transmitted from Aggregation Port
            10 = transmitted from Aggregator
            11 = transmitted from an Aggregator with a single
                 Aggregation Port.

            The remaining bits are reserved for future standardization."

    STATUS      current
    DESCRIPTION
            "This TC describes a bit vector used in the Congestion
            Notification objects. Each bit represents a Boolean status
            associated with a priority code point. A bit value of 0
            represents FALSE, 1 represents TRUE.

            The bit 'pri0status(0)' indicates the status for priority 0
            The bit 'pri1status(1)' indicates the status for priority 1
            The bit 'pri2status(2)' indicates the status for priority 2
            The bit 'pri3status(3)' indicates the status for priority 3
            The bit 'pri4status(4)' indicates the status for priority 4
            The bit 'pri5status(5)' indicates the status for priority 5
            The bit 'pri6status(6)' indicates the status for priority 6
            The bit 'pri7status(7)' indicates the status for priority 7"

        "Indicates the bandwidth assigned to this traffic class.
        The sum of the bandwidths assigned to a given port is
        required at all times to equal 100.  An operation that
        attempts to change this table such that the bandwidth
        entires do not total 100 shall be rejected. An implication
        of this is that modification of this table requires that
        multiple set operations be included in a single SNMP PDU,
        commonly referred to as an MSET operation, to perform
        simultaneous set operations to keep the sum at 100.  Any
        attempt to change a single entry in this table will result
        in the operation being rejected since entries in the
        table referring to the given port will no longer
        sum to 100."

        required at all times to equal 100.  An operation that
        attempts to change this table such that the bandwidth
        entires do not total 100 shall be rejected. An implication
        of this is that modification of this table requires that
        multiple set operations be included in a single SNMP PDU,
        commonly referred to as an MSET operation, to perform
        simultaneous set operations to keep the sum at 100.  Any
        attempt to change a single entry in this table will result
        in the operation being rejected since entries in the
        table referring to the given port will no longer
        sum to 100."

Annex E

(normative)

Notational conventions used in state diagrams

State diagrams are used to represent the operation of the protocol by a number of cooperating state machines each comprising a group of connected, mutually exclusive states. Only one state of each machine can be active at any given time.

Each state is represented in the state diagram as a rectangular box, divided into two parts by a horizontal line. The upper part contains the state identifier, written in upper case letters. The lower part contains any procedures that are executed on entry to the state.

All permissible transitions between states are represented by arrows, the arrowhead denoting the direction of the possible transition. Labels attached to arrows denote the condition(s) that must be met in order for the transition to take place. All conditions are expressions that evaluate to TRUE or FALSE; if a condition evaluates to TRUE, then the condition is met. The label UCT denotes an unconditional transition (i.e., UCT always evaluates to TRUE). A transition that is global in nature (i.e., a transition that occurs from any of the possible states if the condition attached to the arrow is met) is denoted by an open arrow, i.e., no specific state is identified as the origin of the transition. When the condition associated with a global transition is met, it supersedes all other exit conditions including UCT. The special global condition BEGIN supersedes all other global conditions, and once asserted remains asserted until all state blocks have executed to the point that variable assignments and other consequences of their execution remain unchanged.

On entry to a state, the procedures defined for the state (if any) are executed exactly once, in the order that they appear on the page. Each action is deemed to be atomic, i.e., execution of a procedure completes before the next sequential procedure starts to execute. No procedures execute outside of a state block. The procedures in only one state block execute at a time, even if the conditions for execution of state blocks in different state machines are satisfied. All procedures in an executing state block complete execution before the transition to and execution of any other state block occurs, i.e., the execution of any state block appears to be atomic with respect to the execution of any other state block and the transition condition to that state from the previous state is TRUE when execution commences. The order of execution of state blocks in different state machines is undefined except as constrained by their transition conditions. A variable that is set to a particular value in a state block retains this value until a subsequent state block executes a procedure that modifies the value.

On completion of all of the procedures within a state, all exit conditions for the state (including all conditions associated with global transitions) are evaluated continuously until one of the conditions is met. The label ELSE denotes a transition that occurs if none of the other conditions for transitions from the state are met (i.e., ELSE evaluates to TRUE if all other possible exit conditions from the state evaluate to FALSE). Where two or more exit conditions with the same level of precedence become TRUE simultaneously, the choice about which exit condition causes the state transition to take place is arbitrary.

Where it is necessary to split a state machine description across more than one diagram, a transition between two states that appear on different diagrams is represented by an exit arrow drawn with dashed lines, plus a reference to the diagram that contains the destination state. Similarly, dashed arrows and a dashed state box are used on the destination diagram to show the transition to the destination state. In a state machine that has been split in this way, any global transitions that can cause entry to states defined in one of the diagrams are deemed to be potential exit conditions for all of the states of the state machine, regardless of which diagram the state boxes appear in.

Should a conflict exist between a state diagram and either the corresponding global transition tables or the textual description associated with the state machine, the state diagram takes precedence. The interpretation of the special symbols and operators used in the state diagrams is as defined in Table E-1; these symbols and operators are derived from the notation of the "C++" programming language, ISO/IEC 14882. If a Boolean variable is described in this clause as being set it has or is assigned the value TRUE, if reset or clear the value FALSE.

Table E-1—State machine symbols

Symbol	Interpretation
( )	Used to force the precedence of operators in Boolean expressions and to delimit the argument(s) of actions and conditional actions within state boxes.
{}	Used to group multiple actions.
;	Used as a terminating delimiter for actions within state boxes. Where a state box contains multiple actions, the order of execution follows the normal English language conventions for reading text.
=	Assignment action. The value of the expression to the right of the operator is assigned to the variable to the left of the operator. Where this operator is used to define multiple assignments, e.g., a = b = X the action causes the value of the expression following the right-most assignment operator to be assigned to all of the variables that appear to the left of the right-most assignment operator.
!	Logical NOT operator.
&&	Logical AND operator.
||	Logical OR operator.
if <expr> <action>	Conditional action. If the Boolean expression, <expr>, evaluates to TRUE, then the <action> following the expression is executed. If multiple actions are to be executed, they are grouped together by means of {}.
!=	Inequality. Evaluates to TRUE if the expression to the left of the operator is not equal in value to the expression to the right.
==	Equality. Evaluates to TRUE if the expression to the left of the operator is equal in value to the expression to the right.
*	Arithmetic multiplication operator.
-	Arithmetic subtraction operator.

Annex F

(informative)

Shared and Independent VLAN Learning (SVL and IVL)

This standard provides for a variety of approaches to the implementation of Bridges from the point of view of the way that individual MAC addresses are learned, and how that learned information is used in subsequent forwarding/filtering decisions. Two mechanisms are used as a basis for these variants:

a) Making use of address information learned across a number of VIDs in order to make learning decisions relative to any one of those VIDs. This is referred to as Shared VLAN Learning (SVL, 3.238).
b) Making use of address information learned in association with one VID only in order to make learning decisions relative to that VID, and ensuring that it is not used in learning decisions relative to any other VID. This is referred to as *Independent VLAN Learning* (IVL, 3.111).

These mechanisms lead to the SVL/IVL model for how a Bridge implements learning and filtering for MAC addresses. Using the terminology of 8.8.8, an SVL/IVL Bridge supports multiple FIDs (which effectively equates to supporting multiple FDBs), and multiple VIDs can use each FID. By varying the number of FIDs supported, and the number of VIDs that can share each FID, the following simplifications of the SVL/IVL model can be created:

c) *SVL only*. The implementation supports only one FID, so all VIDs share the same learned MAC address information, regardless of which VID the information was learned in.
d) *IVL only*. Multiple FIDs are supported, but each FID can support only one VID, so each VID makes use only of MAC address information learned within the context of that VID.

All three approaches are permitted by this standard, and each has advantages in particular circumstances. The remainder of this annex discusses the following:

e) The requirements for IVL, SVL, or both.
f) How Bridges are made aware of the requirement for particular VLANs to be “shared” or “independent.”
g) How Bridges based on one of these models can interoperate with Bridges based on a different model, in the same network.

F.1 Requirements for Shared and Independent Learning

Under most circumstances, the SVL and IVL approaches work equally well, and Bridges adopting either approach can be freely intermixed within a network. There are, however, a small number of configuration cases where, in order to prevent undue flooding of unicast frames, and in some cases, to make communication between the affected end systems possible, it is necessary to make specific choices about how Bridges that adopt these different learning models are deployed in a network. The following subclauses give examples of some of these configurations and provide a generic statement of the requirements that must be met in order for each learning model to be successfully deployed.

F.1.1 Connecting independent VLANs

Figure F-1 illustrates how a device that connects two VLANs together, and which therefore itself shares learning between those VLANs, creates a need for those VLANs to be independent in other Bridges.

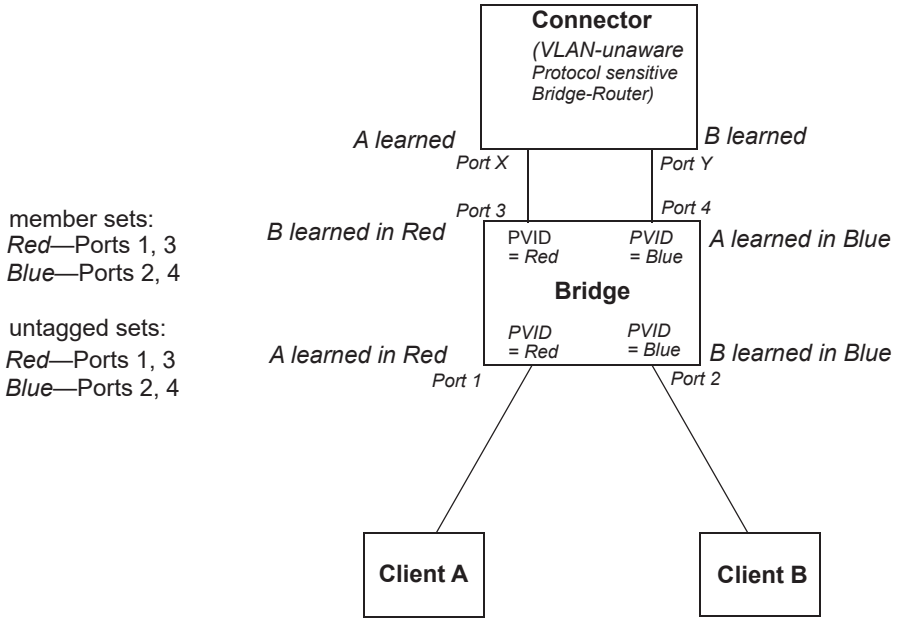

Figure F-1—Connecting independent VLANs—1

Clients A and B are connected via the protocol sensitive Bridge-Router (Connector), with an intervening VLAN Bridge. The fact that all Ports of the Bridge carry untagged traffic neatly conceals the fact that the Connector has the effect of connecting VLANs Red and Blue together with regard to bridged traffic. The Connector learns A and B in the same database, as it has no knowledge of VLANs Red and Blue. This prevents any traffic transmitted on the Red VLAN (Port X of the Connector) that is destined for A, from being bridged to Port Y and transmitted on the Blue VLAN.

The VLAN Bridge must keep its learning separate for Red and Blue; otherwise, the addresses of the two clients would be alternately learned on diagonally opposite Ports as, for example, traffic sourced by A reenters the Bridge on Port 4 having previously been seen on Port 1.

NOTE—This example assumes that the spanning tree protocol is disabled in the Connector, so that the VLAN Bridge does not attempt to suppress the loop that apparently exists if VLANs are not taken into account.

A simpler example can be constructed, with a single Port connecting the Connector and the VLAN Bridge, if the Connector is itself VLAN aware and transmits and receives only VLAN-tagged traffic. In this case, the Connector would allocate a single FID for use by Red and Blue. This is shown in Figure F-2.

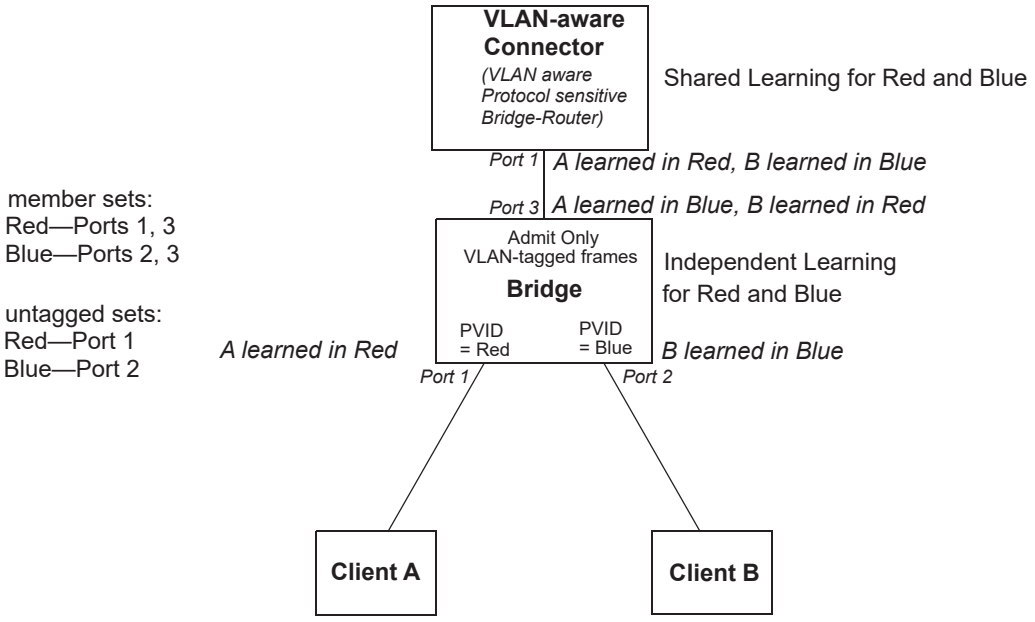

Figure F-2—Connecting independent VLANs—2

F.1.2 Duplicate MAC addresses

The simplest example of a need for IVL occurs where two (or more) distinct devices in different parts of the network reuse the same individual MAC address, or where a single device is connected to multiple LANs, and all of its LAN interfaces use the same individual MAC address. This is shown in Figure F-3.

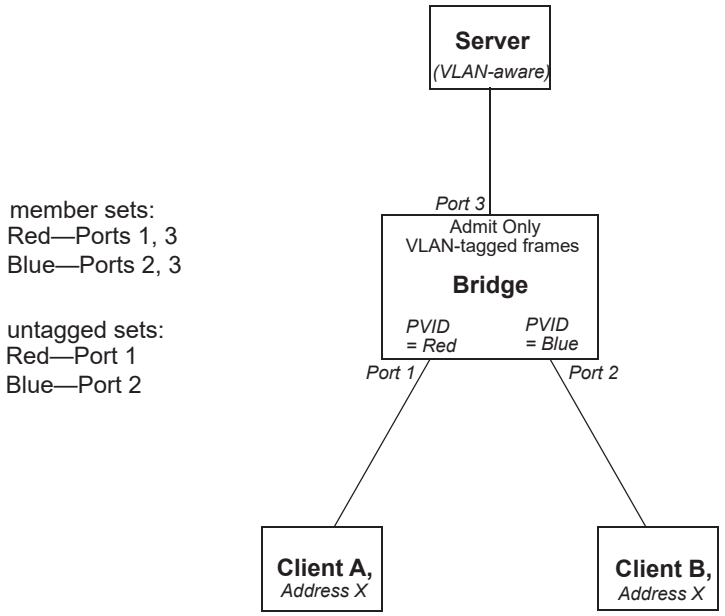

Figure F-3—Duplicate MAC addresses

The example shows two clients with access to the same server; both clients are using the same individual MAC address, X. If the Bridge shares learning between VLAN Red (which serves Client A) and VLAN Blue (which serves Client B), i.e., the Bridge uses the same FID for both VIDs, then Address X will appear to move between Ports 1 and 2 of the Bridge, depending on which client has most recently transmitted a frame. Communication between these Clients and the server will therefore be seriously disrupted. Assignment of distinct FIDs for Red and Blue ensures that communication can take place correctly.

Hence, in order to construct this particular VLAN configuration, either an IVL Bridge or an SVL/IVL Bridge would be required.

F.1.3 Asymmetric VLANs and Rooted-Multipoint connectivity

A primary example of the requirement for SVL is found in “asymmetric” uses of VLANs. Under normal circumstances, a pair of devices communicating in a VLAN environment will both send and receive using the same VID; however, there are some circumstances in which it is convenient to make use of two distinct VIDs, one used for A to transmit to B and the other used for B to transmit to A. Examples of such applications include configuring multi-netted servers, and configuring rooted-multipoint services.

F.1.3.1 Multi-netted Server

An example of Multi-netted Server application of asymmetric VLANs is shown in Figure F-4. Note that:

a) In the example, the server and both clients are assumed to be VLAN-unaware devices, i.e., they transmit and receive untagged frames only.
b) The ingress classification rules assumed by the example are as defined in this standard, i.e., Port-based classification only.
c) The configuration shown can only be achieved by management configuration of appropriate values in Static VLAN Registration Entries (8.8.10) in order to configure the indicated member sets and untagged sets.

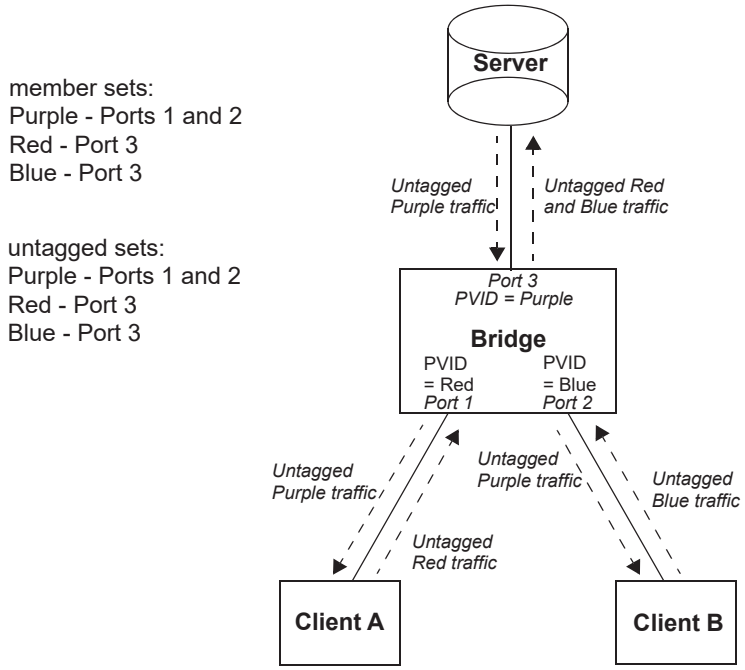

Figure F-4—Asymmetric VID use: “multi-netted server”

In the example, Port-based tagging and an asymmetric VLAN configuration is used in order to permit Clients A and B access to a common server, but to prohibit Clients A and B from talking to each other. Examples of where this type of configuration might be required are if the clients are on distinct IP subnets, or if there is some confidentiality-related need to segregate traffic between the clients.

Client A transmits to the server via Port 1, which will classify this traffic as belonging to VLAN Red; the Bridge therefore learns Client A's MAC address on Port 1 in association with VLAN Red's VID. The Server transmits its responses to Client A via Port 3, which classifies the return traffic as belonging to VLAN Purple. If individual MAC address learning is configured in the Bridge such that learning is independent between Red and Purple (the VIDs for Red and Purple are allocated to distinct FIDs), then the Bridge will have no knowledge of A in VLAN Purple and will therefore flood the server's responses to Client A on both Port 1 and Port 2. Conversely, if the VIDs for Red and Purple are defined to share the same FID, then the address information learned in Red will be available for use in forwarding the Purple traffic, and the responses to Client A are forwarded only through Port 1.

Similarly, there is a need in this configuration for Blue and Purple to share learning information; hence, in order for this configuration to achieve its objectives, the Red, Blue, and Purple VIDs must be allocated to the same FID in the Bridge.

Hence, in order to construct this particular VLAN configuration, either an SVL Bridge or an SVL/IVL Bridge would be required.

NOTE—The example has been deliberately simplified; in practical applications, the central Bridge would likely be replaced by a number of VLAN Bridges, interconnected with links that would carry the traffic between clients and server as VLAN-tagged frames, with VLAN-tagging and untagging occurring only at the "edge" Ports of the network. An alternative approach to the one described here could also be achieved either by using a VLAN-aware server or by use of more sophisticated ingress classification rules.

F.1.3.2 Rooted-Multipoint

An example of a rooted-multipoint application of asymmetric VLANs is shown in Figure F-5. The defining characteristic of a rooted-multipoint service is that all Bridge Ports that provide access points to the service are designated as either a Root Port or a Leaf Port, and that the Root Ports can communicate with all other Root Ports and all Leaf Ports, whereas the Leaf Ports can communicate with all Root Ports but not with any other Leaf Ports. Services based on rooted-multipoint connectivity are also known as "Rooted-Multipoint EVC" services as defined in MEF 10.3. Rooted-multipoint connectivity would typically be used by an Internet access provider or a video content provider, where the provider of the service connects to Root Ports, and the subscribers of the service connect to Leaf Ports. This connectivity can be achieved with the "multi-netted server" configuration shown in Figure F-4, but it consumes one VID per subscriber. Figure F-5 shows an alternative that uses just two VIDs: a "Trunk" VID for traffic from Root Ports to Leaf Ports (and to other Root Ports) and a "Branch" VID for traffic from Leaf Ports to Root Ports.

To allow the servers to communicate with all other servers and all subscribers, and to allow the subscribers to communicate with all servers but not with other subscribers, the rooted-multipoint connectivity requires the following configuration:

a) The server(s) and all subscribers transmit and receive untagged frames only. Note that for a rooted-multipoint service on a PBN, this means the frames do not contain S-TAGs at the customer service interface (in other words, the User Network Interface (UNI)). Therefore, rooted-multipoint can be supported at Port-based service interfaces (15.3) and C-tagged service interfaces (15.4).
b) The ingress C-VLAN classification may be Port-based or Port-and-Protocol-based for rooted-multipoint on CBNs. The ingress S-VLAN classification may be Port-based or C-TAG-based for rooted-multipoint on PBNs.
c) In Customer Bridges and S-VLAN Bridges, the indicated values of the member sets and untagged sets (8.8.10) are achieved by management configuration of Static VLAN Registration Entries

(8.8.2). In Provider Edge Bridges the Trunk and Branch VIDs are also mapped to the appropriate CNP/PEP pair by management configuration of the PEP Table (12.13.2.4, ieee8021PbEdgePortTable 17.6.1.2). Note that connectivity between Leaf Ports is blocked by not including Leaf Ports in the member set associated with the Branch VID.

d) In Customer Bridges and S-VLAN Bridges the indicated values of the PVID parameters are configured by management. In Provider Edge Bridges the equivalent configuration is achieved by management configuration of the C-VID Registration Table (12.13.2.2, ieee8021PbCVidRegistrationTable 17.6.1.2).

e) The Enable Ingress Filtering parameter (8.6.2) is reset, i.e., ingress VLAN filtering is disabled, on Leaf Ports.

f) The Trunk and Branch VIDs share the same FID (to enable SVL).

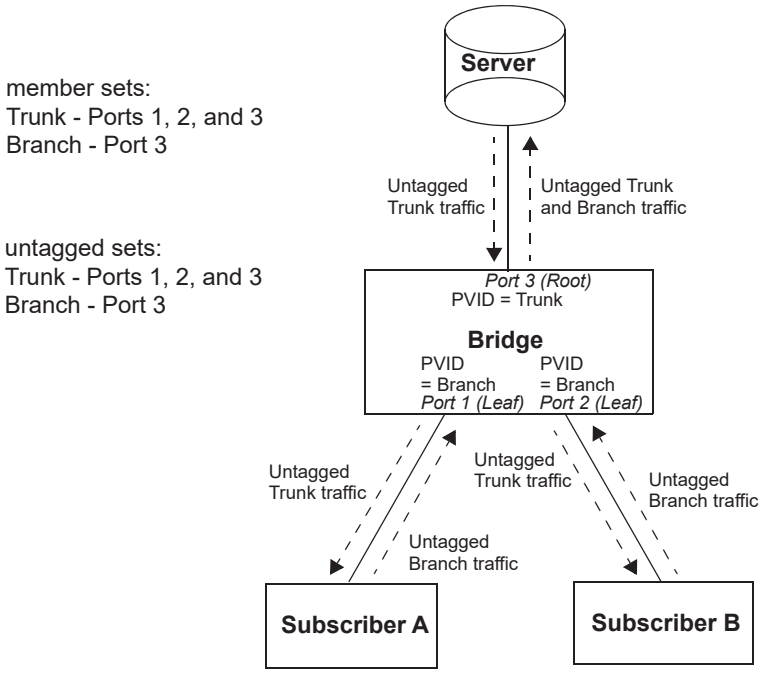

Figure F-5—Asymmetric VLAN use: "Rooted-Multipoint"

NOTE 1—The example has been deliberately simplified; in practical applications, the central Bridge would likely be replaced by a number of VLAN Bridges, interconnected with links that would carry the traffic between subscribers and servers as VLAN-tagged frames, with only the Root and Leaf Ports of the network carrying untagged frames.

Rooted-multipoint services can be carried on PBBNs by configuring Trunk and Branch S-VIDs as described above, with the Root and Leaf Ports at CNPs either at an I-component of a BEB, or at a Provider Edge Bridge of a PBN that then connects to the PBBN. The I-component of a BEB can then either map the Trunk and Branch S-VIDs to separate backbone service instances (i.e., mapped to separate I-SIDs) or bundle them into a single backbone service instance.

Rooted-multipoint connectivity can also be created on a PBBN by configuring Trunk and Branch B-VIDs as described above, with the Root and Leaf Ports at CBPs of a B-component in a BEB. One or more backbone service instances can then be mapped to the Trunk and Branch B-VIDs to take advantage of the rooted-multipoint connectivity.

As noted in item a) above, the configurations described above apply to scenarios where the ingress and egress frames at a Root or Leaf Port on a Customer Bridge or S-VLAN Bridge are untagged. Customer Bridges and S-VLAN Bridges that support both the VID Translation Table and Egress VID Translation Table (6.9) can support tagged ingress and egress frames at a Root or Leaf Port. Figure F-6 shows the configuration where the server(s) and subscribers transmit and receive tagged frames. The server uses VID R for frames associated with the rooted-multipoint service, and the subscribers use VIDs L1 and L2. The values of R, L1, and L2 could be, but are not necessarily, the same. The configuration of the Bridge(s) with Root and Leaf Ports are shown in the diagram. All Root and Leaf Ports are included in the member set of the Trunk and Branch VIDs, but not in the untagged set (including the Leaf Ports in the member set of the Branch VID allows ingress VLAN filtering to be enabled at these ports if desired). The VID translation at a Root Port ensures that ingress frames go to the Trunk VID, and egress frames come from both the Trunk and Branch VIDs. The VID translation at a Leaf Port ensures that ingress frames go to the Branch VID, and egress frames come from the Trunk VID (translating the Branch VID to 0xFFF on egress frames at Leaf Ports causes these frames to be discarded).

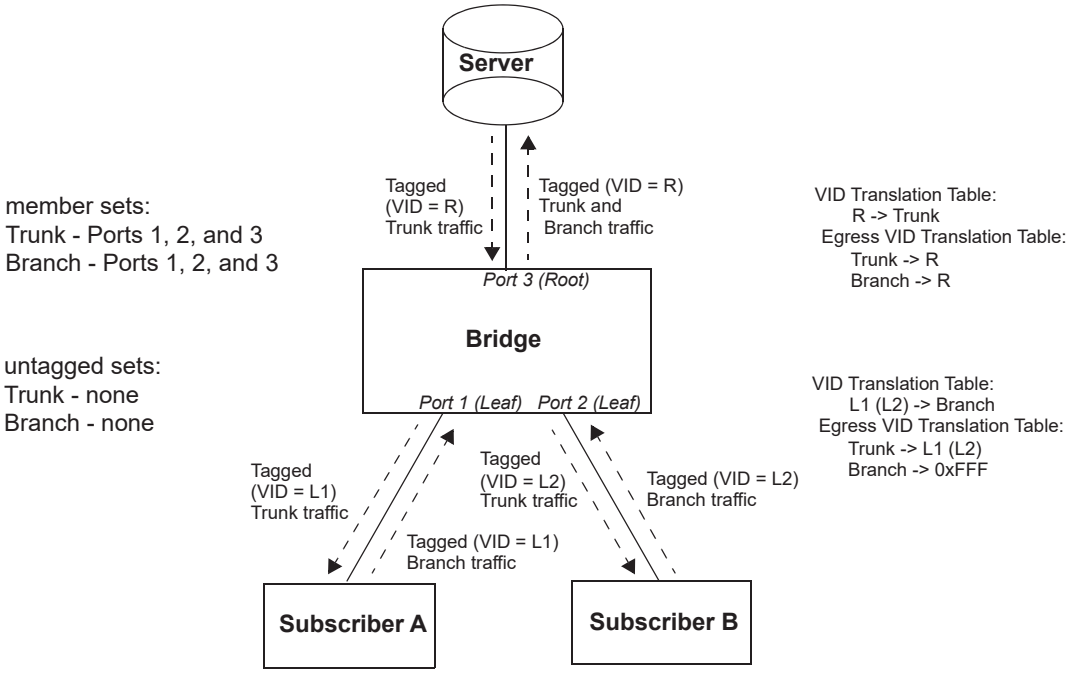

Figure F-6—Rooted-Multipoint with tagged interfaces

NOTE 2—The example has been deliberately simplified; in practical applications, the central Bridge would likely be replaced by a number of VLAN Bridges, interconnected with links that would carry the traffic between subscribers and servers as frames tagged with either the Trunk or Branch VID. VLAN translation occurs only at the Root and Leaf Ports of the network.

F.1.4 Shared learning and Shortest Path Bridging VID (SPBV) mode

SPBV mode uses shared learning among the set of SPVIDs that support a given SPBV VLAN. Each SPT Bridge supporting an SPBV VLAN is assigned a unique VID (SPVID) for transmitting VLAN frames into the SPT Region. This SPVID is registered by the ISIS-SPB control plane along an SPT rooted at the SPT Bridge to which it is assigned. The SPTs determined by ISIS-SPB provide symmetric bidirectional paths (i.e., congruent paths) between any pair of SPT Bridges within an SPT Region. The congruency of the paths is essential to allow shared learning. Shared learning is required because frames forwarded from a given SPT Bridge will contain a different SPVID from frames being forwarded to that SPT Bridge.

Figure F-7 shows an example of a simple SPBV VLAN operating in an SPT Region comprising three Bridges A, B, and C. Each of the Bridges is assigned an SPVID, in this example using the same letter designation as the Bridge to which it is assigned. ISIS-SPB maintains the VID member sets such that the SPVID of an SPT Bridge follows an SPT rooted at that particular SPT Bridge. The SPT includes all boundary ports participating in the SPBV VLAN (in this example the ports connected to stations A, B, and C).

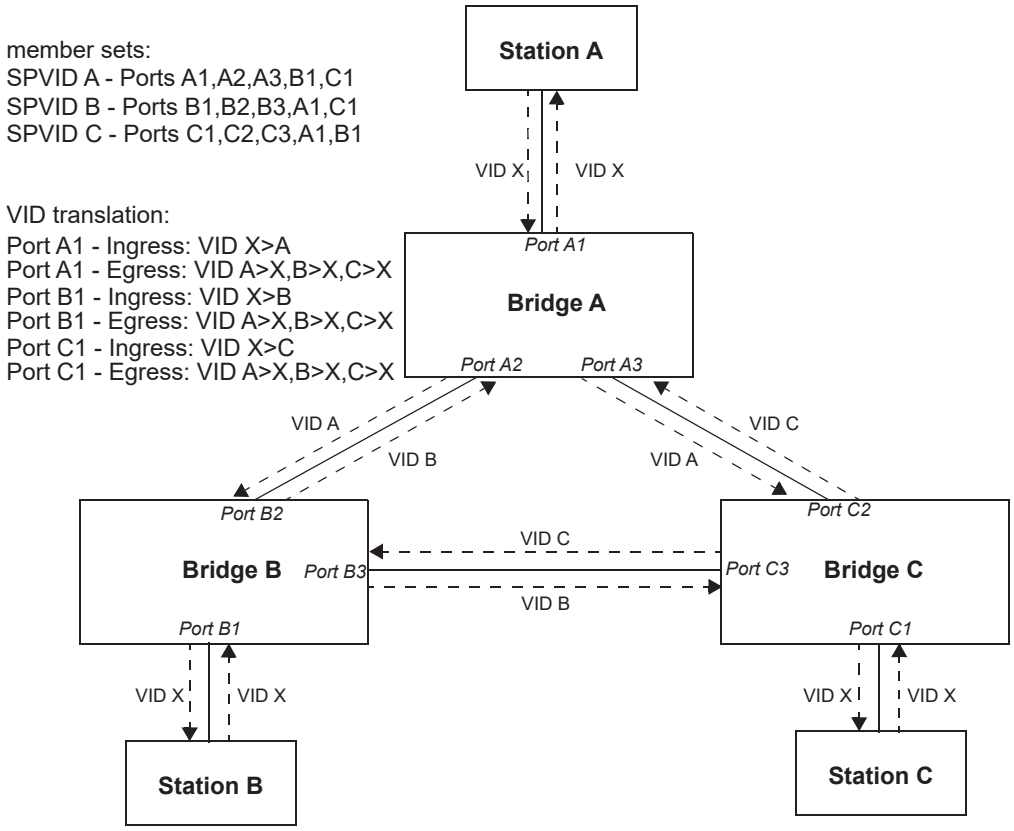

Figure F-7—SPBV VLAN Shared Learning and VID Translation

Shared learning is used among all the SPVIDs belonging to the SPBV VLAN. This enables the filtering information learned from frames transmitted from a Bridge (with that Bridge's SPVID) to be applied to frames being transmitted to that Bridge from other Bridges using the other Bridges' SPVIDs. For example, a frame sent from station A to station B will be transmitted by Bridge A using SPVID A. At Bridge B the frame's source address will be learned at port B2. When station B later sends a frame to station A, Bridge B will assign the frame SPVID B. Shared learning enables Bridge B to use the MAC address previously learned from the frame with SPVID A to filter the frame with SPVID B to transmit only on port B2.

Enhanced VID translation capabilities allow a single VID to be used for VLANs on boundary ports connected to an SPT Region even though many SPVIDs with shared learning are used within the SPT Region. In this example stations A, B, and C all use VID X. At each boundary port ingress translation is set to translate the external VID (usually the Base VID) to the SPVID for the Bridge on which the boundary port resides. Egress VID translation is set to translate all the SPVIDs belonging to the SPBV VLAN to the external VID.

F.1.5 Generic constraints on SVL and IVL use

This subclause describes the general constraints on the mapping of VIDs to FIDs, from the point of view of a given Bridge that learns from or forwards frames on a set of VIDs (the Bridge's "active set" of VIDs). If:

a) The individual MAC addresses associated with each point of attachment to the active set of VIDs are unique (i.e., the "Duplicate MAC Address problem" is not present), and
b) There is no Bridge or Bridge-like device that takes frames from one VID in the active set and subsequently transmits them on another VID in the active set, then

every VID in the active set may share the same FID; in other words, individual MAC address information learned in the context of any one VID may be used in forwarding decisions taken relative to any of the others, so the SVL approach can be used in that Bridge.

Furthermore, if:

c) Each bidirectional, individual MAC-Addressed, conversation between pairs of end stations makes use of the same VID in both directions, then

every VID in the active set may be allocated a distinct FID (with the possibility of a little extra flooding as learning of addresses in the context of one VID does not contribute to forwarding decisions for that address relative to any other VID). Under these circumstances, rule b) may also be relaxed and restated as follows:

d) Frames associated with one VID in the active set may be received by (up to) one Bridge and transmitted using another VID in the active set, provided that there is no loop in such VLAN to VLAN forwarding, e.g., for a set of VIDs Red, Blue, and Green, there is no logical loop in copying frames between VIDs, such as copying from Red to Green by one Bridge, Green to Blue by another, and Blue back to Red by a third.

So:

e) If rules a), b), and c) are true, and d) is false, for all VIDs in the active set, then either an SVL or an IVL Bridge can be deployed;
f) If rules a) and b) are true, and c) and d) are false for all VIDs in the active set, then only an SVL Bridge can be deployed;
g) If rules a) or b) or d) are false, and c) is true for all VIDs in the active set, then only an IVL Bridge can be deployed.

These conditions are all on the basis that they apply "for all VIDs in the active set." Clearly, in more complex scenarios, some VIDs in the active set will have requirements that dictate SVL behavior on the part of a given Bridge, while others will have requirements that dictate IVL behavior. Under such circumstances, an SVL/IVL Bridge is required, allowing those VIDs that need to be shared to be mapped to a single FID, while those that need to be independent are mapped to distinct FIDs. Needless to say, wherever an SVL or IVL Bridge can be deployed, it can successfully be replaced by an appropriately configured SVL/IVL Bridge.

Annex G

(informative)

MAC method-dependent aspects of VLAN support

G.1 Example tagged IEEE 802.3 EtherType-encoded frame format

Figure G-1 provides an illustrative example of a single tagged EtherType-encoded frame format as used in an Ethernet to Ethernet Bridge. This illustration is only of the simplest case, that is, a single-level, fixed-size tagging between identical MACs.[62]

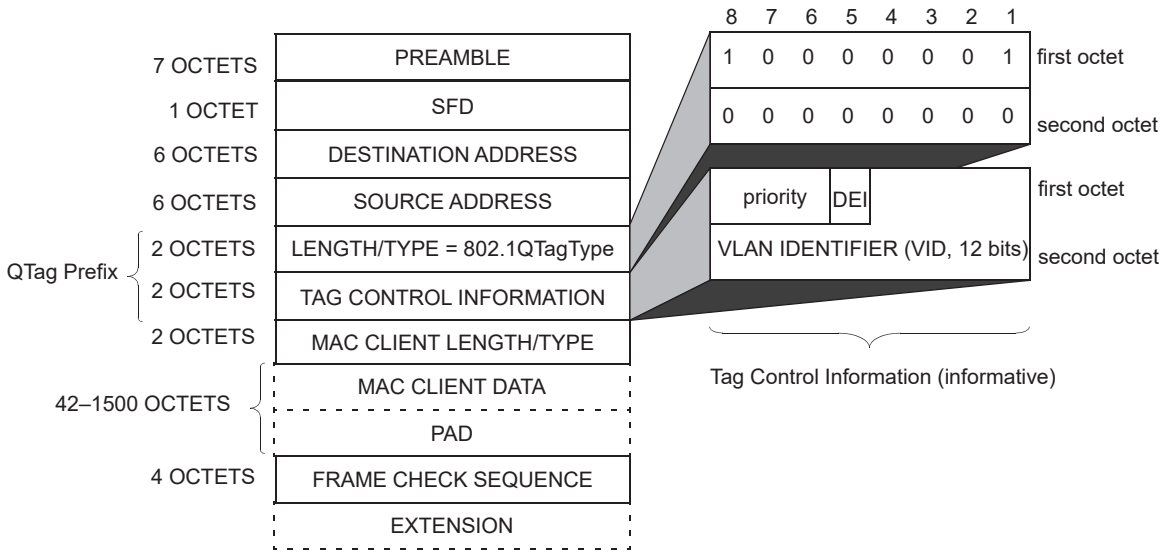

Figure G-1—Example of IEEE 802.3 MAC frame format

G.2 Padding and frame size considerations

G.2.1 Treatment of PAD fields in IEEE 802.3 frames

The minimum frame size constraint placed on IEEE 802.3/Ethernet frames requires frames to carry zero or more pad octets following the MAC client data, in order to ensure that no frame of total length less than 64 octets is transmitted on the medium. This requirement means that frames whose overall length would otherwise be less than 64 octets in length have (64-len) octets of padding added after the MAC client data, where len is the size of the frame before padding.

[62] Figure G-1 was part of Clause 3 of IEEE Std 802.3-2005.

When tagged frames are transmitted by a Bridge on an IEEE 802.3 MAC, there are two permissible approaches, as follows:

a) Keep the minimum frame size generated by the Bridge equal to 64 octets. This implies that the number of pad octets in a received untagged IEEE 802.3 frame would be reduced by up to 4 octets when that frame was tagged.
b) Adopt a minimum tagged frame length of 68 octets. This implies that the number of pad octets in a received untagged IEEE 802.3 frame would not be adjusted when tagging such frames; equally, if subsequently untagged, no pad adjustment would be necessary before transmission on IEEE 802.3/ Ethernet.

There is a similar choice to be made in end stations that generate tagged frames:

c) In some existing implementations, the decision about whether pad octets are needed will be made at a point where it is impractical to distinguish between tagged and untagged frames. In these cases, the end station will use a minimum frame size of 64 octets for all frames.
d) In other cases, the padding decision will be taken at a point before it is known whether the frame will be transmitted tagged or untagged. In these cases, the end station will use a minimum tagged frame size of 68 octets and a minimum of 64 octets for untagged frames.

These approaches are all consistent with the IEEE 802.3 frame specification.

The implication is that, for correct operation on IEEE 802.3/Ethernet, all devices have to be capable of correctly handling tagged frames of less than 68 octets in length (G.2.3).

G.2.2 Maximum PDU size

VLAN tagging of an untagged frame, or relaying frames in tagged frame format, can result in an increase in the length of the original frame. If transmission of a given frame in tagged frame format through a given destination Port would result in violation of the maximum PDU size for the destination MAC method, the Bridge discards the frame for that destination Port.

NOTE—Violation of the maximum PDU sizes for destination MAC methods can produce undefined results in networks that contain devices that adhere strictly to these maxima, or in MAC methods where these maxima are inherently constrained by the operation of the MAC method itself (e.g., constrained by timing considerations in the MAC state machines).

IEEE Std 802.3 defines an extension to the normal IEEE 802.3 maximum frame size for the specific purpose of accommodating the additional octets of the VLAN tag header. The example frame translations in this annex make use of this extension to the IEEE 802.3 frame size.

G.2.3 Minimum PDU size

VLAN untagging of a tagged frame results in the original frame decreasing in length.

Where the destination MAC is Ethernet:

a) If untagging a given frame would result in violation of the minimum frame length requirements of Ethernet, the Bridge is required to adjust the PAD field to ensure that the frame length equals the minimum length of 64 octets (G.2.1).
b) If a frame is transmitted in tagged frame format, the Bridge may adopt a minimum tagged frame length of either 64 or 68 octets, as an implementation option. If the latter is chosen, the Bridge adjusts the size of the PAD field on transmission for any tagged frame that is less than 68 octets in length (G.2.1).

G.3 Tag insertion and removal for LLC media

In IEEE Std 802.1Q-2014 and all previous revisions of IEEE Std 802.1Q, the method of inserting and deleting tags was independent of whether a Length/Type field is used for protocol type encoding. The tag was inserted into or deleted from the first octets of the mac_service_data_unit and the remainder of the mac_service_data_unit was unchanged.

That deletion/insertion method did not provide for interoperability between VLAN-aware end stations where only one used a Length/Type field to encode protocol identifiers. It specified that the station on the LLC media used a SNAP-encoded VLAN tag followed by a SNAP-encoded data unit, whereas on the station using Length/Type, the VLAN tag was followed by an EtherType protocol identifier. These multiple encodings required a bridge to translate both the VLAN tag and the following protocol identifier, along with any other tags defined previously or subsequently. Translation of the second and any subsequent protocol identifiers is impossible if the contents of the frame are protected against modification or rendered confidential, as in the case of a frame protected by MAC Security (IEEE Std 802.1AE).

To avoid this problem, revisions of IEEE Std 802.1Q subsequent to 2014, and IEEE Std 802.1AC subsequent to 2012, specify that following the first protocol identifier, all subsequent protocol identifiers (if any) use Length/Type encoding.

The net result was that the expected format for a tagged frame changed. For example, on LLC media, the first 18 octets of a VLAN-tagged SNAP-encoded MSDU carrying an EtherType of 08-00 (hexadecimal) for the user data, priority 0, VLAN 123, was, in revisions prior to IEEE Std 802.1Q-2018:

AA-AA-03-00-00-00-81-00-01-23-AA-AA-03-00-00-00-08-00

and subsequently, is:

AA-AA-03-00-00-00-81-00-01-23-08-00

The underlined octets are no longer present. That is, on LLC media, all tags and protocol identifiers after the first are Length/Type encoded.

G.4 IEEE 802.11 and PMPN media

Figure G-2 illustrates an example of a five-port Bridge that uses three of the methods defined by IEEE Std 802.1AC whereby a Bridge can connect to an IEEE 802.11 medium, or to a Point-to-Multipoint Network (PMPN). The following subclauses describe these methods.

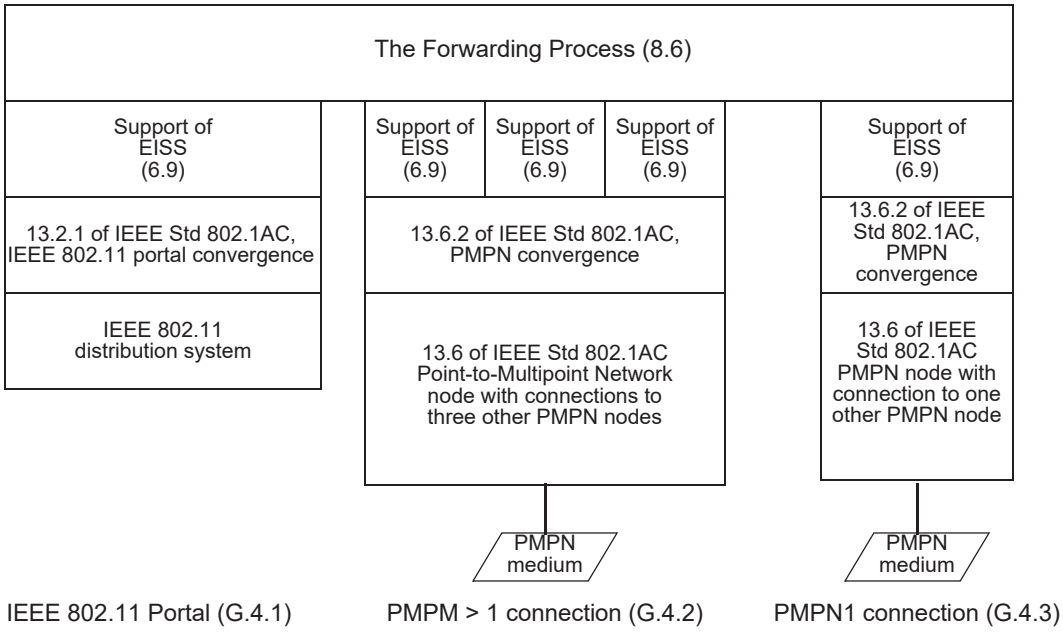

Figure G-2—Methods for Bridge access to IEEE 802.11 and PMPN media: example

G.4.1 IEEE 802.11 Portal convergence

A Bridge, along with the portal convergence function defined in 13.2.1 of IEEE Std 802.1AC-2016 [B8], together constitute an example of an IEEE 802.11 Portal.

G.4.2 Point-to-Multipoint Network convergence: multiple connections

The PMPN convergence function, defined in 13.6.2 of IEEE Std 802.1AC-2016 [B8], provides a set of virtual point-to-point instances of the ISS, one to each PMPN node to which an underlying PMPN node is associated. The convergence function maps this set of ISS instances to a single instance of the service defined for the PMPN node. This interface supports PMPN media interior to a Bridged Network or Virtual Bridged Network. In Figure G-2, the center block in the diagram has three Bridge Ports connecting to three of these instances.

G.4.3 Point-to-Multipoint Network convergence: single connection

The PMPN convergence function, defined in 13.6.2 of IEEE Std 802.1AC-2016 [B8], is also used between the ISS and the MAC service interface defined for a PMPN node that has, or is capable of, only a single connection.

Annex H

(informative)

Interoperability considerations

VLAN Bridges are able to interoperate in networks with other VLAN Bridges. However, the VLAN-based filtering service defined in this standard, as provided in the context of a single spanning tree for the network, involves some constraints on the network topology and individual device configurations that differ from the set of constraints that apply to the building and configuration of networks based only on MAC Bridges.

In addition, VLAN Bridges are able to interoperate with MAC Bridges, as well as with both priority-aware and VLAN-aware end systems. Both the VLAN-based filtering service and the tag insertion and removal service specified in this standard cause constraints on intermixed network topologies and device configurations that again differ from the building and configuration of networks containing MAC Bridges.

The implications of certain device configurations may not be immediately apparent from the technical detail of this standard. In order to clarify the nature of the additional constraints, H.1 through H.4

a) Describe the basic requirements for interoperability.
b) Discuss those requirements in the context of homogeneous and heterogeneous configurations, with examples of some of the problems that can occur if these requirements are not adhered to.

H.1 Requirements for interoperability

Two primary aspects of the configuration of a network are of concern from the point of view of interoperability:

a) Establishing a consistent view of the static filtering configuration of Bridges in the network.
b) Ensuring that untagged frames are VLAN-tagged (and that the tag is subsequently removed) consistently regardless of spanning tree reconfigurations.

H.1.1 Static filtering requirements

Static filtering controls allow the network administrator to impose a level of control over the permitted connectivity in the network, by setting static MAC address filters in the FDBs of Bridges, and by controlling the extent of particular VLANs by manipulation of Static VLAN Registration Entries (8.8.2).

In order to ensure that end station-to-end station connectivity (or the lack of it) is consistent in all possible spanning tree configurations, any static filters need to be established taking account of the full mesh topology of the physical interconnections between Bridges in the network, not just the “normal” spanning tree topology to which the network is configured when all Bridges and LANs are operating correctly. An example of the consequences of failure to establish consistent controls for static VLAN filtering is given in H.2.1.

H.1.2 Configuration requirements for VLAN-tagging

VLAN Bridges classify incoming untagged frames by applying either a Port-based tagging rule on ingress that uses the PVID for the reception Port as the VLAN classification for such frames or a Port-and-Protocol-based rule that uses the frame’s ULP to select one of a port’s VIDs. Maintaining

consistent connectivity between any pair of end stations that are on the same VLAN, and where one or both of those end stations is VLAN-unaware, requires that:

a) All VLAN Bridge Ports that are connected to the same LAN apply a consistent set of ingress rules (8.6).
b) All VLAN Bridge Ports that are connected to the same *legacy region* of a network apply a consistent set of ingress rules.
c) All VLAN Bridge Ports that serve LANs to which members of the same VLAN are (or can be) attached apply a consistent set of ingress rules.

A legacy region of a network consists of any set of LANs that are physically interconnected via MAC Bridges. A legacy region has the property that, by appropriate configuration of the spanning tree, a spanning tree path could be created between any pair of LANs in the region such that the path would pass only through MAC Bridges.

NOTE—In case b), spanning tree reconfiguration within the legacy region can change the logical connectivity between the VLAN Bridge Ports and the LANs that they (directly or indirectly) serve. Hence, a spanning tree reconfiguration could result in any end stations connected to the legacy region being serviced via any VLAN Bridge Port. In effect, such a reconfiguration reduces case b) to case a). Figure H-2 and Figure H-3 give examples of this type of configuration. In Figure H-2, the legacy region consists of all three LANs and both MAC Bridges. In Figure H-3, the legacy region consists of the MAC Bridge and both LANs to which it is attached. An example of case c) is where an end station attached to a leaf LAN is in the same VLAN as a server that is attached to a distinct LAN, i.e., all possible spanning tree paths between the two stations pass through a VLAN-aware region of the network.

The essence of what these rules express is that if a given untagged frame belongs on a given VLAN, then the classification and tagging behavior of any VLAN Bridges that are required to tag that frame needs to be the same, regardless of the logical connectivity that is created by the spanning tree configuration of the network. Examples of the consequences of failure to apply these rules appear in H.3 and H.4.

H.2 Homogeneous VLAN-aware networks

This standard requires new considerations in building a network in which all Bridges are VLAN Bridges. The arbitrary plug-and-play capability of MAC Bridges in creating a network topology is restricted when making use of the VLAN extensions defined in this standard.

H.2.1 Consistency of static VLAN filtering

In order for stations that are members of a given VLAN to be able to reach other members of the same VLAN elsewhere in the network, all Bridge Ports that are part of the spanning tree active topology (i.e., all Bridge Ports that are in a forwarding state) connecting the stations must be included in the member set (8.8.10) for the VID that identifies that VLAN. In order for this connectivity to be independent of any reconfiguration of the spanning tree topology, all paths among those stations, both forwarding and blocked, must have this characteristic. Use of management controls to manipulate the member set (e.g., filters for security) must be applied in a manner consistent with requirements of the full mesh topology of the network.

An inconsistency occurs, for example, if a VID is restricted from an active path, but not from a redundant path currently blocked by the operation of spanning tree. Should a spanning tree reconfiguration enable the previously blocked path, the restriction will no longer be in place. In the reverse, a spanning tree reconfiguration may suddenly impose a restriction that had not existed. A common use of such management restriction will likely arise from managers who make use of an “access” port construct. An access port may be a port that is absent from the member set (8.8.10) for all VIDs but the untagged, default VID. Should such an access port become the active connection between two portions of the network as a result of a spanning tree reconfiguration, all VLANs but the one identified by the default VID will be partitioned at that point in the topology.

In Figure H-1, the trunk style link and access style link cause a loop through the left and right portions of the network. STP will block one or the other. Should the spanning tree block at point #1, all 2000 users may communicate on any of the 50 VLANs. However, should the spanning tree block at point #2, the left and right portions of the network will be partitioned on all VLANs excepting VLAN 3 (the VLAN carried via the access style link.)

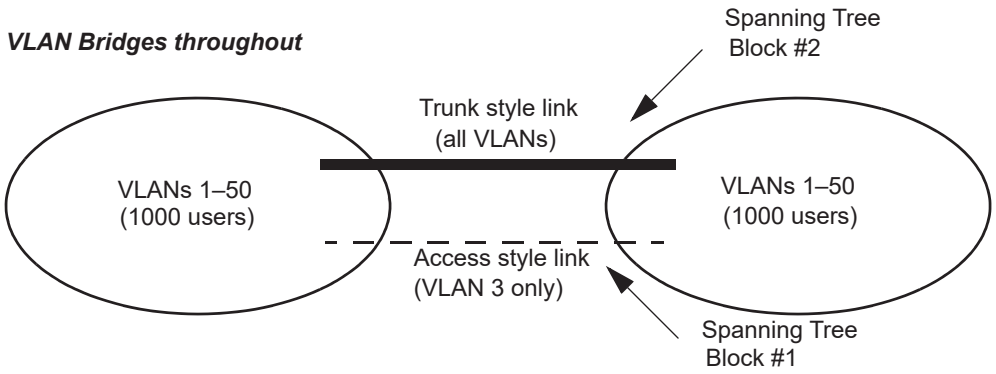

Figure H-1—Static filtering inconsistency

H.2.2 Consistent view of the “untagged VLAN(s)” on a given LAN

In the Port-based VLAN model defined in this standard, the PVID for a Bridge Port provides the VLAN classification for all frames on the attached LAN that are received in untagged form. Any LAN with more than one VLAN Bridge attached has such an “untagged VLAN” for each VLAN Bridge. No explicit requirement that PVID be consistent for all VLAN Bridges on the same LAN, nor mechanism to ensure such, has been included in this standard.

Similarly, in the Port-and-Protocol-based VLAN model defined in this standard, one member of the VID Set for a Bridge Port provides the VLAN classification for all frames on the attached LAN that are received in untagged form with a particular ULP. Any LAN with more than one such VLAN Bridge attached has such a set of “untagged VLANs” for each VLAN Bridge. No explicit requirement that these be consistent for all VLAN Bridges on the same LAN, nor mechanism to ensure such, has been included in this standard.

Consider the case of a LAN to which are attached three VLAN Bridges, each of which is using Port-based classification and is capable of transmission of untagged frames onto the LAN. An untagged frame placed on that LAN by any one of the VLAN Bridges will be associated by each of the other two VLAN Bridges with its own configured PVID for its reception Port on that LAN. The VLAN model requires that each frame have a unique VLAN association, and that association is represented by a single, global VID value. Therefore, it follows that all VLAN Bridges on that LAN must make use of the same classification rules (in this case, the same PVID) for their ports connected to that LAN.

It has been suggested that in the special case of a direct point-to-point connection between two VLAN Bridges or other VLAN-aware devices, other rules might apply. No mechanism for identifying such links has yet been suggested.

This creates a configuration challenge for installers of VLAN Bridges that conform to this standard. Initial management configuration of the VLAN Bridges (the setting of PVIDs, VID Sets, and Protocol Group Databases) must be made consistent among the VLAN Bridges, in a manner that takes into account the actual physical topology. Changes to the physical topology may require specific changes to the configuration of all affected switches. These requirements effectively disallow a plug-and-play installation as supported by MAC Bridges, unless all VLAN Bridges are left with their default Port-based classification rules and with each PVID = 1.

H.3 Heterogeneous networks: Intermixing MAC Bridges (M) and VLAN Bridges (V)

This subclause discusses networks in which VLAN Bridges are intermixed with MAC Bridges.

A principal limitation in intermixing VLAN Bridges with MAC Bridges is that the VLAN filtering services are not universally available throughout the network. Also, services for the insertion and removal of tags are not universally available. Furthermore, spanning tree reconfigurations may cause filtering services, as well as tag insertion and removal services, to become available or become unavailable independent of actions of affected users.

H.3.1 Example: Adding a VLAN Bridge to provide filtering to a MAC Bridged Network

Example problems can be shown with the following topology diagrams. Figure H-2 includes one V Bridge and two M Bridges.

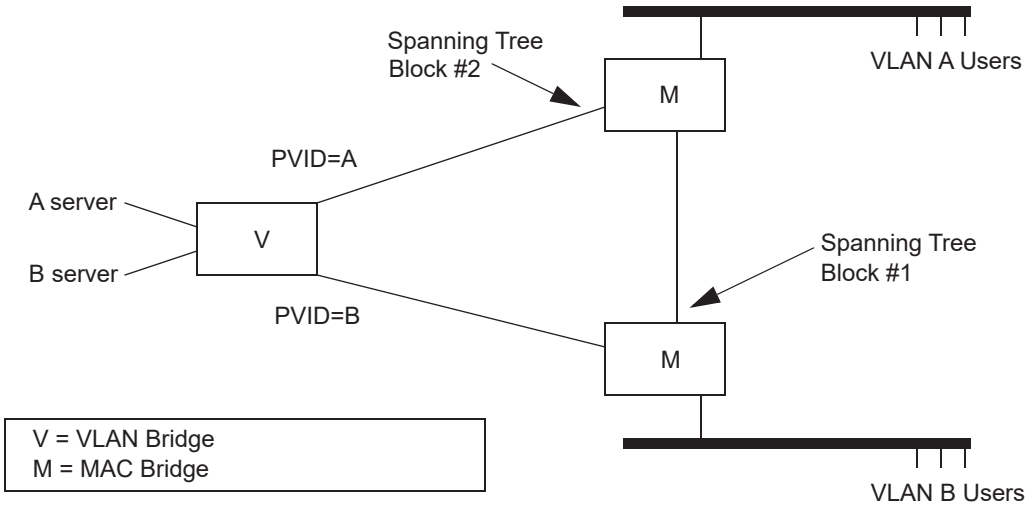

Figure H-2—Interoperability with MAC Bridges: example 1

If the spanning tree protocol determines to break the loop among the three Bridges by blocking at point #1, connectivity within each VLAN is as desired. However, should the block occur at point #2, traffic from VLAN A users will pass through both M Bridges and be treated as VLAN B traffic upon arrival in the V Bridge. Connectivity to the A server will be lost for the A users.

H.3.2 Example: Adding a MAC Bridge to a (previously) Homogeneous VLAN Bridged Network

A similar problem, demonstrating the impact of placing an M Bridge within an otherwise homogeneous V topology, can be shown by the configuration in Figure H-3. This figure includes two V Bridges and adds a single redundant M Bridge.

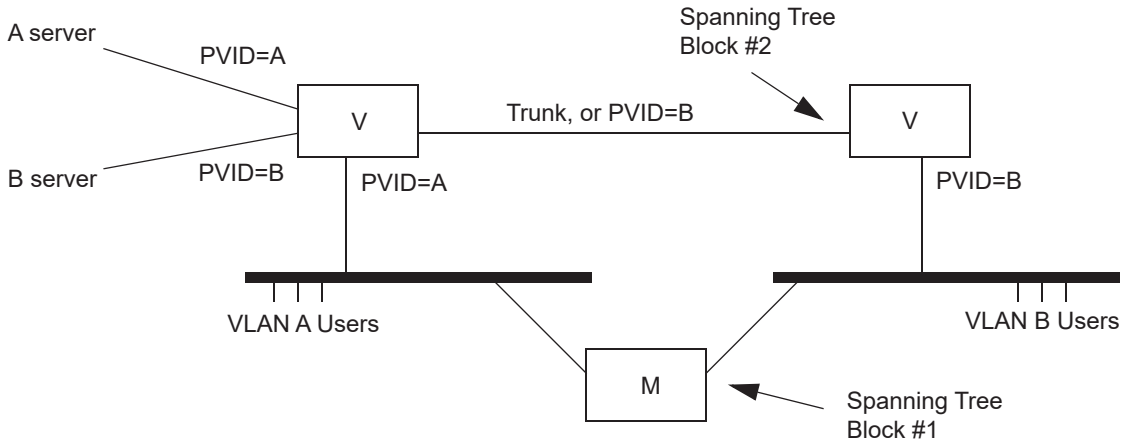

Figure H-3—Interoperability with MAC Bridges: example 2

If STP determines to break the loop among the three Bridges by blocking at point #1, connectivity within each VLAN is as desired. The two V switches operate as expected. A and B VLAN frames are VLAN-tagged on arrival in either V Bridge and forwarded only to the appropriate servers. Now suppose an STP reconfiguration results in a block at point #2, but not at #1. This redirects VLAN B user traffic through the M Bridge. VLAN B users no longer have their traffic identifiably distinct from VLAN A. An immediate consequence is that the VLAN B users will no longer have access to the "B server."

H.4 Intermixing Port-based classification and Port-and-Protocol-based classification or future enhancements in VLAN Bridges

Intermixing V Bridges with M Bridges has a direct analogue in the mixing of Bridges implementing only Port-based and Port-and-Protocol-based classification of frames in VLAN Bridged networks. This revision and potential subsequent editions of this standard extend the VLAN classification capabilities to support more sophisticated ingress rules for frame classification.

In VLAN configurations that use both Port-based and Port-and-Protocol-based VLAN classification, a Bridge that supports only Port-based VLAN classification will merge VLANs that would otherwise be classified separately by a Bridge that supports Port-and-Protocol-based VLAN classification. To get around this problem, it may be possible to dedicate specific Ports to specific protocols in Bridges that support only Port-based VLAN classification, as in the example shown in Figure H-4. However, such solutions may not be possible where there are multiprotocol end stations in the network.

H.4.1 Example: Intermixing Protocol-based ingress rules

Consider the case where Bridges implement a configuration mechanism to select between Port-based classification rules (a "V-Port Bridge") and Port-and-Protocol-based rules (a "V-Port/Protocol Bridge"). This case would allow, for example, for support for IP and IPX as distinct VLANs. The topology shown in Figure H-4 might apply when a V-Port/Protocol Bridge is added to a topology; otherwise, using only V-Port Bridges allows users of two protocols to participate in two separate VLANs.

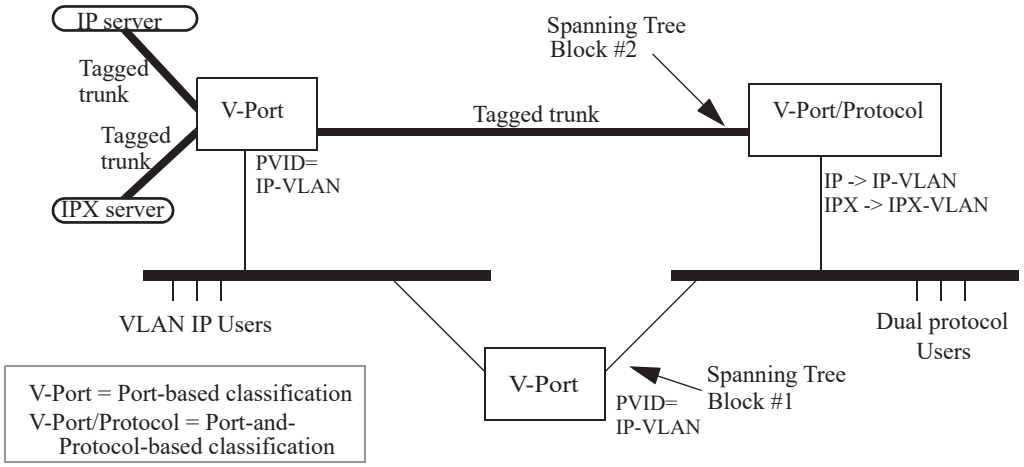

Figure H-4—Interoperability between Port-based and Port-and-Protocol-based classification

Consider this network, when STP has blocked at point #1, and not at #2. The upper V-Port Bridge operates as expected, and the V-Port/Protocol Bridge provides Port-and-Protocol-based classification for the frames received from the dual protocol users on the right-hand LAN. IP-VLAN and IPX-VLAN frames are VLAN-tagged on the trunks to and from the uppermost Bridges and servers. But if a STP reconfiguration should result in a block at point #2, but not at #1, activating traffic through the lower V-Port Bridge, dual protocol users will have all their traffic treated as part of the IP-VLAN. An immediate consequence is that the uppermost Bridge will no longer provide them access to the "IPX server." It is the fact that the lower V-Port Bridge must have just one of the two VLANs configured for all untagged traffic, regardless of its protocol, that leads to this lack of connectivity.

H.4.2 Differing views of untagged traffic on a given LAN

Further challenges arise when one considers the case where several V Bridges, some implementing Port-based and some implementing Port-and-Protocol-based classification, all attach to the same LAN. Again, the rule that any given frame exists in exactly one VLAN requires that all of these Bridges be configured with consistent ingress rules. In this case, the V-Port Bridges will provide a least common capability, and this further requires common configuration of the PVID in the V-Port and V-Port/Protocol Bridges.

Annex I

(informative)

Priority and drop precedence

This standard allows management of priorities, flow metering, queue assignment, and queue servicing. This annex documents the rationale for the recommended and default priority to traffic class mappings in Table 8-5 and the encoding of priority and drop eligibility in Table 6-2 and Table 6-3.

Classification of user data frames into a small number of behavior aggregates, together with aggregate dependent forwarding behavior in each Bridge, allows signaling of application requirements to the network. Frame classification, aggregate bandwidth metering, policing, and drop precedence marking also facilitate network scaling and provision of services to independent customers through allocation of those functions to appropriate Bridges in the network.

While there are many possible ways to classify frames and to specify forwarding behaviors, it is widely appreciated that a set of well-known and easily understood defaults can facilitate interoperability and the deployment of services. The defaults described in this annex and supported by this standard were chosen to support integrated and differentiated services, to minimize the burden of management, to reduce the possibility of misconfiguration and out-of-order frame delivery, and to provide useful service without management in many networks.

This standard mandates support for strict priority frame transmission (8.6.6) but permits the use of additional traffic class-based transmission selection algorithms. The default assignments of frames to traffic classes on the basis of frame priority, as described in this annex, also support the use of frame priority to select general traffic class-based forwarding behavior.

NOTE—Annex W provides references to the IETF work on integrated and differentiated services ([B21] through [B25] and [B26] through [B33]).

I.1 Traffic types

A full description of the QoS needs of applications and network services is too complex to be represented by a simple number 0 through 7. The pragmatic aim of traffic classification is to simplify requirements to preserve the high-speed, low-cost characteristics of Bridges. At the margin, potential bandwidth efficiency is traded for simplicity and higher speed operation—historically a good decision in the LAN.

The following list of traffic types, each of which can benefit from simple segregation from the others, are of general interest:

a) Network Control—characterized by a guaranteed delivery requirement to support configuration an maintenance of the network infrastructure.
b) Internetwork Control—in large networks comprising separate administrative domains there is typically a requirement to distinguish traffic supporting the network as a concatenation of those domains from the Network Control of the immediate domain.
c) Voice—characterized by less than 10 ms delay and, hence, maximum jitter (one way transmission through the LAN infrastructure of a single campus).
d) Video—characterized by less than 100 ms delay, or other applications with low latency as the primary QoS requirement.
e) Critical Applications—characterized by having a guaranteed minimum bandwidth as their primary QoS requirement and subject to some form of admission control to ensure that one system or application does not consume bandwidth at the expense of others. The admission control mechanism

can range from preplanning of the network requirement at one extreme to bandwidth reservation per flow at the time the flow is started at the other.

f) Excellent Effort—or "CEO's best effort," the best-effort type services that an information services organization would deliver to its most important customers.

g) Best Effort—for default use by unprioritized applications with fairness only regulated by the effects of TCP's dynamic windowing and retransmission strategy.

h) Background—bulk transfers and other activities that are permitted on the network but that should not impact the use of the network by other users and applications.

I.2 Managing latency and throughput

Use of priorities and queuing by traffic classes, each class encompassing one or more priorities, facilitates improvement and management of latency and throughput, allowing QoS goals to be supported at higher levels of network loading than would otherwise be possible.

Congestion, resulting in QoS degradation, is not equally likely at all Bridges in a network. Transient traffic patterns are likely to result in congestion in only a few Bridges at a time, while over an extended period, momentary congestion is more likely to occur in the network core than at Bridge Ports attached to one or a relatively small number of end stations. Use of fewer traffic classes for those Ports can lower the cost of implementation and management, and this standard facilitates the use of Bridges supporting differing numbers of classes within a single network that delivers a consistent set of QoS parameters for each frame priority level. Although the number of traffic classes supported by each Bridge Port along the path taken by a given flow of data can vary, the default mappings of priorities to classes ensures that frame ordering is preserved as required by 8.6.6.

With few classes, the focus is on meeting latency requirements—the bandwidth surplus required in a bursty data environment to guarantee sub-10 ms delays without a distinct traffic classification is uneconomically large. As the number of traffic classes that can be used increases, the focus shifts to managing throughput.

The simple default queue servicing policy defined in this standard, strict priority, supports latency management. Active management of bandwidth sharing necessarily requires some management.

I.3 Traffic type to traffic class mapping

Table I-1 is an example of how traffic types can be grouped to match the number of traffic class queues supported by a Bridge Port. Each grouping of types is shown as {*Distinguishing type*, Type, Type, . . .}. The "distinguishing type" is not treated in any way differently in a Bridge but is italicized here to illustrate, for any given number of queues, which traffic types have driven the allocation of types to classes.

The step-by-step breaking out of traffic types as more classes are available proceeds as follows:

a) With a single queue, there are no choices. All traffic is Best Effort.

b) To support integrated services in the presence of bursty best effort data, it is necessary to segregate all time-critical traffic. The amount of high-priority traffic will be restricted by the need to support low latency for Voice, which becomes the defining type for the additional queue.

c) Two queues may be adequate for Bridge Ports attaching to end stations. The stability of the network as a whole may be unaffected by the performance of configuration protocols on those Ports, and in-band management of the Bridge is likely to occur through another Port. For Bridges within the network infrastructure, a further queue is used to isolate Network Control from the user data traffic.

d) Traffic for business Critical Applications is separated from Best Effort to allow a bandwidth guarantee to be provided.

e) The queue separation so far provided can support a large network. The next queue is allocated to distinguishing Internetwork Control traffic from local Network Control.

f) Background is separated from Best Effort to minimize the effect of bulk transfers on ordinary network use.

g) Excellent Effort is separated from Critical Applications, either to provide a simple superior service based on policy controlled access or to provide an additional segregated bandwidth guarantee.

h) The final provides increased network utilization as the higher bandwidth traffic associated with Video is no longer given the same latency guarantee as Voice.This description is illustrative rather than definitive of the logic of allocating traffic types to classes. The mappings in Table 8-5 support the assignment of other semantics to each traffic type identified by priority values, e.g., the identification of all three illustrative types “Video,” “Critical Applications,” and “Excellent Effort” with ensured forwarding classes that provide segregated bandwidth guarantees. However, alternate semantics should take into account the service provided by Bridges with limited traffic class queuing; e.g., of the foregoing, only “Video” would receive priority treatment by default at a Bridge Port supporting queuing for only two classes.

Table I-1—Traffic type to traffic class mapping

Number of queues	Traffic types
1	{*Best Effort*, Background, Excellent effort, Critical Applications, Voice, Video, Internetwork Control, Network Control}
2	{*Best Effort*, Background, Excellent effort, Critical Applications} {*Voice,* Video, Internetwork Control, Network Control}
3	{*Best Effort,* Background, Excellent effort, Critical Applications} {*Voice,* Video} {*Network Control,* Internetwork Control}
4	{*Best Effort,* Background} {*Critical Applications,* Excellent effort} {*Voice,* Video} {*Network Control,* Internetwork Control}
5	{*Best Effort,* Background} {*Critical Applications,* Excellent effort} {*Voice,* Video} {*Internetwork Control*} {*Network Control*}
6	{*Background*} {*Best Effort*} {*Critical Applications,* Excellent effort} {*Voice,* Video} {*Internetwork Control*} {*Network Control*}
7	{*Background*} {*Best Effort*} {*Excellent effort*} {*Critical Applications*} {*Voice,* Video} {*Internetwork Control*} {*Network Control*}
8	{*Background*} {*Best Effort*} {*Excellent effort*} {*Critical Applications*} {*Video*} {*Voice*} {*Internetwork Control*} {*Network Control*}

I.4 Traffic types and priority values

Table I-2 shows the correspondence between traffic types and priority values used to select the defaults in Table 8-5. The default priority used for transmission by end stations is 0. Changing this default would result in confusion and likely in interoperability problems. At the same time, the default traffic type is definitely Best Effort. 0 is thus used both for default priority and for Best Effort, and Background is associated with a priority value of 1. This means that the value 1 effectively communicates a lower priority than 0.

Table I-2—Traffic type acronyms

Priority	Acronym	Traffic type
1	BK	Background
0 (Default)	BE	Best Effort
2	EE	Excellent Effort
3	CA	Critical Applications
4	VI	“Video,” < 100 ms latency and jitter
5	VO	“Voice,” < 10 ms latency and jitter
6	IC	Internetwork Control
7	NC	Network Control

Table I-3 summarizes Table I-1, showing just the defining traffic types. By maintaining the groupings of types established for a given number of queues for all less numbers, the table preserves the order of frames of any given type, independent of the number of queues.

Table I-3—Defining traffic types

Number of queues	Defining traffic type							
1	BE							
2	VO				BE			
3	NC		VO		BE			
4	NC		VO		CA		BE	
5	NC	IC	VO		CA		BE	
6	NC	IC	VO		CA		BE	BK
7	NC	IC	VO		CA	EE	BE	BK
8	NC	IC	VO	VI	CA	EE	BE	BK

This discussion of traffic types, and the suggested association of each with a priority value, differs from the similar discussion in Annex G of IEEE Std 802.1D-2004 [B12] and prior revisions of that standard. The latter was developed contemporaneously with IETF Intserv and predates Diffserv. The discussion in this

annex better aligns with current practice; in particular, Voice is associated with priority 5, matching the setting of the relevant bits for Expedited Forwarding (EF) in the DSCP (Differentiated Services Code Point) for IP and in the common use of the EXP bits for MPLS. Standards for DSCPs are believed to be the prime reference for use of priority by end stations, and there is no direct change to the behavior of Bridge implementations conforming to this standard as a result of this change.

The priority to traffic class mappings in Table 8-5 differ in one minor respect from those specified in prior revisions of this standard and in IEEE Std 802.1D-2004 [B12] and its prior revisions. Priority value 2 was previously described as ‘Spare’ and positioned lower than 0 (Best Effort) in priority order. This change may result in networks, including Bridges, conformant to prior revisions of this standard, and implementing four or more traffic classes, providing less-than-expected priority to traffic described in this annex as Excellent Effort, and misordering drop eligible traffic for Critical Applications. The change allows better use of the available traffic classes, given the low demand for two distinct priorities of lesser importance than Best Effort, and the best use of Priority Code Point when encoding drop eligibility.

I.5 Supporting the credit-based shaper algorithm

Table 34-1 and Table 34-2 define a set of recommended priority to traffic class mappings where the credit-based shaper algorithm (8.6.8.1) is supported by one or two of the available traffic classes; the recommended mappings shown are intended for use where priority 3 is used to support SR class A and priority 2 is used to support SR class B.

In order for the credit-based shaper algorithm to operate in the way it is intended, it is necessary to ensure that the shaper algorithm is supported on the numerically highest traffic class(es). Hence, if two traffic classes are used to support the shaper algorithm, it follows that the minimum useful number of traffic classes that a Port could support is three.

Table I-4 redraws Table I-3 for the case where only SR class B (SR-B) is supported. The defining traffic type for the numerically highest traffic class is SR-B in all cases. VI does not appear in this table since SR-B is used for the video traffic.

Table I-4—Defining traffic types—Credit-based shaper support of SR class B only

Number of queues	Defining traffic type							
2	SR-B	BE						
3	SR-B	NC		BE				
4	SR-B	NC		CA		BE		
5	SR-B	NC	IC		CA		BE	
6	SR-B	NC	IC		CA		BE	BK
7	SR-B	NC	IC		CA	EE	BE	BK
8	SR-B	NC	IC	VO	CA	EE	BE	BK

NOTE—When one or more SR classes are supported, the primary distinction being made is between traffic that requires bandwidth reservation and latency guarantees on the one hand, and different types of “best effort” traffic on the other. The audio and video traffic types identified in Table I-1 are therefore not applicable.

Table I-5 redraws Table I-3 for the case where SR classes A (SR-A) and B (SR-B) are supported in place of VO and VI. The defining traffic types for the two numerically highest traffic classes are SR-A and SR-B in all cases; for 4 through 8 traffic classes, the remaining traffic types are broken out in the same order as in Table I-3.

Table I-5—Defining traffic types—Credit-based shaper support of SR classes A and B

Number of queues	Defining traffic type							
3	SR-A	SR-B	BE					
4	SR-A	SR-B	NC		BE			
5	SR-A	SR-B	NC		CA		BE	
6	SR-A	SR-B	NC	IC	CA		BE	
7	SR-A	SR-B	NC	IC	CA		BE	BK
8	SR-A	SR-B	NC	IC	CA	EE	BE	BK

I.6 Supporting drop precedence

It is often desirable to meter traffic from different users to ensure fairness or to meet bandwidth guarantees; however, dropping all traffic in excess of a committed rate is likely to result in severe under-utilization of the networks, because most traffic sources are bursty in nature. At the same time, it is burdensome to meter traffic at all points in the network where bandwidth contention occurs. One solution is to mark those frames in excess of the committed rate as drop eligible on admission to the network.

This standard allows drop eligibility to be conveyed separately from priority in VLAN tags so that all previously introduced traffic types can be marked as drop eligible. To provide compatibility with previous revisions of this standard while allowing drop eligibility to be conveyed in C-TAGs, this standard also allows a subset of the priorities to be conveyed along with drop eligibility marking for some of those priorities within the PCP field of both S-TAGs and C-TAGs.

I.7 Priority Code Point allocation

The Priority Code Point of VLAN tags allows encoding of five, six, seven, or eight distinct priorities, with a single level of drop eligibility on three, two, one, or zero of those priorities, respectively. Table 6-2 and Table 6-3 specify encoding and decoding for five through eight priorities. The tables are consistent with the following step-by-step reduction in the number of distinct priorities to provide drop eligibility for certain traffic types:

a) If eight distinct priorities are required, drop eligibility cannot be encoded in the Priority Code Point (but may be encoded in VLAN tags using the DEI).
b) Drop eligibility in support of QoS maintenance for traffic conforming to a committed rate is most effective when used to support time-critical traffic. If seven priorities, one of which can be marked as drop eligible, are required, then the traffic class queuing distinction between Voice and Video is sacrificed to providing drop eligibility for the combined traffic types. This does not preclude marking all Video traffic as drop eligible upon ingress to a network to provide the same guarantee to Voice as a distinct priority.

c) The distinctions between Critical Applications and Excellent Effort, and between Best Effort and Background traffic types, is removed to provide drop eligibility for Critical Applications and for Best Effort.
d) Although the use of four priorities, each with drop eligibility, is possible, it is not recommended. Combining Network Control with Internetwork Control could only serve to increase the guarantees provided to the latter at the expense of the former, which if not delivered threatens the stability of the overall network in any case. Moreover, both traffic types should be supportable with guaranteed bandwidth if the network is to be operated successfully.

Choosing first to combine Video and Voice, and then Critical Applications with Excellent Effort (for six queues), provides consistency with the allocation of priorities to traffic classes in the absence of drop eligibility. Bridges that do not implement drop eligibility, but are configured to use the same number or fewer traffic classes, will not misorder frames. If such a Bridge is configured to use only five traffic classes, and in accordance with Table 8-5, it will not misorder frames with a Priority Code Point encoded using any of the alternatives provided by Table 6-2.

I.8 Interoperability

Encoding of drop eligibility within the Priority Code Point, as opposed to explicitly with the DEI, provides interoperability with Bridges that are not capable of supporting the DEI. It also provides compatibility with the use of the MPLS EXP bits to convey priority and drop eligibility.

However, the requirement to provide different combinations of priorities with drop eligibility within the confines of the Priority Code Point means that priority and drop eligibility information can be lost for frames traversing a network if the combinations used on individual LANs differ. Use of the DEI does not suffer from this problem. In some cases, loss of drop eligibility information at the boundary between administrative domains risks impacting profile conformant traffic from some users with out-of-profile drop eligible traffic from others; in other cases, the drop eligible marking has already done its job (the next LAN, for example, might deliver traffic to a single customer). Without explicit management, a Bridge Port cannot decide, so the Require Drop Encoding parameter (8.6.7) has been provided.

If Bridges attached to the same LAN encode and decode the Priority Code Point differently, then incorrect priority values can be attributed and subsequent misordering of frames can occur. Misordering will not occur, with the recommended priority to traffic class mappings of Table 8-5 and the recommended Priority Code Point encoding and decoding in Table 6-2 and Table 6-3, if the Bridge performing the incorrect decoding assumes fewer priorities than are actually encoded or if all Bridges subsequently transited by the frame use the same number or fewer traffic classes than those used for the encoding. However, incorrect decoding will in all probability affect other service guarantees that the network is intended to support. If a Bridge can be used in a network that encodes drop eligibility in the Priority Code Point, and there is any likelihood of the Bridge being brought into service prior to the network-dependent service-level configuration, then five priorities, three with drop eligibility (5P3D encoding and decoding), should be used. Bridges that do not support drop precedence should be configured to support five or fewer traffic classes in the same circumstances.

The use of separate Priority Code Point Encoding and Priority Code Point Decoding Tables for each Bridge Port allows adaptation between the encoding scheme in one domain of the network and the encoding scheme used in another to be accomplished in only one of any pair of Bridges, each serving as a boundary of its domain, connected by a point-to-point LAN. However, if more than two Bridges are attached to a LAN, all need to use the same encoding so that each of its recipients can assign the correct priority to the frame.

The default Priority Code Point encoding and decoding, as documented in Table 6-2 and Table 6-3, are reproduced in Table I-6 and Table I-7, with the addition of the default allocation of priorities to traffic classes to the latter.

NOTE—The sequence of the columns for the priority values of 0 and 1 in Table I-6 and Table I-7 are reversed from the sequence in Table 6-2 and Table 6-3 in order to show the alignment with the traffic classes in Table I-3.

Table I-6—Priority Code Point encoding

priority drop_eligible		7	7DE	6	6DE	5	5DE	4	4DE	3	3DE	2	2DE	0	0DE	1	1DE

Annex J

(informative)

CFM protocol design and use

J.1 Origin of CFM

Operations, Administration, and Maintenance (OAM) functions are a product of the world of telephony. As Ethernet, which has traditionally been an Enterprise network technology, expands into the realm of service providers, such useful notions as OAM become important. The OAM work conducted in various standards bodies and in various vendors' products can be classified into five groups:

a) Provider Edge OAM, as defined by IEEE Std 802.3.
b) Ethernet Local Management Interface (E-LMI), as defined by MEF 16 [B52].
c) Underlying layers of OAM, such as MPLS OAM [B57] or ATM OAM [B2], used on various sorts of emulated Ethernet links, carrying Ethernet frames as a higher layer.
d) Ethernet frames carrying End-to-End CFM PDUs, defined by this standard and by ITU-T G.8013/Y.1731.
e) Network performance measurement, defined by the MEF Forum in MEF 35.1 [B54] and ITU-T, including ITU-T G.8013/Y.1731.

CFM is one part of the whole OAM picture. It defines group in item d), Ethernet frames carrying End-to-End CFM PDUs, defined by this standard and by ITU-T G.8013/Y.1731. This standard does not explicitly address the subject of the configuration or provisioning of MEF services, but it does generate significant requirements on configuration and provisioning. Certain CFM PDU formats are also useful for network performance measurement [item e)] and are defined in this standard. Additional PDUs for these operations are defined in ITU-T G.8013/Y.1731.

Finally, unlike OAM in the telephony world, CFM does not address recovery from a loss of connectivity. That is the function of the various Layer 2 control protocols such as spanning tree (see Clause 13).

J.2 Deployment of CFM

It is critical to the early deployment of CFM that no hardware changes be required to achieve a significant level of CFM functionality. However, if the MEPs in a large number of large MAs issue Continuity Check Messages (CCMs) at the highest allowed rates, a Provider Bridge's ability to generate and/or absorb these CCMs could be overwhelmed. To achieve its full potential, CFM could require hardware modifications to existing Provider Bridges.

a) The CFM shims shown in Figure 22-4 are an abstract concept. They have been defined so that it should be possible to emulate their functions on most existing platforms, though perhaps not at high rates of CFM PDU transmission and reception. Hardware assistance can enable higher CFM PDU rates and can enable the implementation of the Shared MP address model of operation instead of the Individual MP address model (J.6).
b) Directing CFM PDUs to the appropriate ports of a Provider Bridge could necessitate a separate MAC Address Registration Entry for each VID in the FDB. Some means whereby this large number of entries could be abstracted would reduce the load on the FDB and enable the use of a larger number of MD Levels.
c) The reception of an LBM and generation of the corresponding LBR have been defined in a manner that is amenable to implementation in hardware. If so implemented, then the providers' ability to support a particular requirement for bandwidth in a service instance can easily be tested.

J.3 MD Level allocation alternative

There are eight Maintenance Domain Levels (MD Levels) as shown in Table J-1. In order to allow administrations to configure different Maintenance Domains in the same Bridge without having to resort to detailed inter-organizational agreements about which MD Levels are available for use, an administrator of a Maintenance Domain can decide which of three roles that Maintenance Domain will play: the “customer” role, the “service provider” role, or the “operator” role. The administrator would then be free to assign an MD Level to a Maintenance Domain within the range shown in Table J-1 according to the Maintenance Domain’s role. If two administrations can operate Maintenance Domains using the same role in one Bridge at different MD Levels.

Table J-1—Provider MD Level allocation

MD Level	7	6	5	4	3	2	1	0
Use	customer			service provider		operator		
	Highest	<- Higher lower->						Lowest

This method of MD Level allocation attempts to minimize the likelihood of incompatibilities caused by MD Level selection among separate administrative organizations that interconnect in a manner such that their MD Levels are visible to each other. Due to the addition of encapsulations such as VLAN tags that can hide one organization’s MD Levels from another, it is considered unlikely that the allocation method shown in Table J-1 will be necessary and that the method described in 22.3 will be sufficient.

J.4 Relationship of IEEE Std 802.1Q CFM to other standards

ITU-T G.8013/Y.1731 is a compatible extension of CFM. Certain terminology is different between ITU-T G.8013/Y.1731 and this standard. These differences are summarized in Table J-2 .

Table J-2—IEEE / ITU-T terminology differences

IEEE Std 802.1Q	ITU-T G.8013/Y.1731
Maintenance Association (MA)	Maintenance Entity Group (MEG)
Maintenance Association Identifier (MAID)	Maintenance Entity Group Identifier (MEGID)
Maintenance Domain	(No such construct present)
Maintenance Domain Level (MD Level)	Maintenance Entity Group Level (MEG Level)

ITU-T G.8013/Y.1731 includes a number of OpCodes in addition to the CCM, LBM, LBR, LTM, and LTR defined in this standard. ITU-T G.8013/Y.1731 also specifies that the LBM can have a Group destination_address, in addition to the ability of using an Individual destination_address, as defined in this standard. It is for this reason that the MP Loopback Responder’s ProcessLBM() procedure (20.28.1) is required to respond to an LBM whose destination_address is the appropriate CCM Group address, even though this standard specifies no means for generating such a frame.

The MIP is defined as two MHFs in this standard, but not in ITU-T G.8013/Y.1731. This is because ITU-T G.8013/Y.1731 is not concerned with the details of the implementation.

ITU-T G.8013/Y.1731 does not include an LTM Egress Identifier TLV (21.8.8) or LTR Egress Identifier TLV (21.9.7). For compatibility with early implementations of ITU-T G.8013/Y.1731, this standard does not require that these TLVs be present on received LTMs or LTRs. However, this standard does require these TLVs to be transmitted in LTMs and LTRs.

ITU-T G.8013/Y.1731 specifies that, if an LTM passes through MPs on both the ingress and egress ports, the TTL field of the LTM will be decremented twice. This standard requires, in that case, that the Bridge decrement the TTL field only once, and return a single LTR. The ITU-T G.8013/Y.1731 behavior is compatible with the LTR analysis presented in J.5, as long as each of the MPs that decrement the LTM's TTL field also return an LTR. If a Bridge decremented the TTL twice, but returned only a single LTR, it would be impossible for the originating MEP to tell whether an LTR was lost in transit.

The Flags field (21.9.1) returned in the LTR contains two extra bits of information in this standard that are not in ITU-T G.8013/Y.1731.

J.5 Interpreting Linktrace results

The LTR entries are retrieved from the Linktrace Database in the order the LTRs were received by the MEP. There is no way to determine when the last LTR has been received, except to wait for some number of seconds (e.g., long enough for a worst-case delay through the Bridged Network plus a few seconds), after the successful completion of the Transmit Linktrace Message command, before assuming that no further LTRs are likely to be received.

Because of the timer used by the LTR Transmitter state machine (20.5.1), the order in which the LTRs are received (time order) is likely to be different from the order of the MPs reached by the LTM as it was forwarded, MP by MP (path order). It is possible for an LTM to take more than one path, so that the LTRs report a tree, rooted at the originating MEP, rather than a simple linear series of zero or more MHFs terminating at a MEP or an MHF. If there are no network topology changes during the Linktrace operation, and if all systems' behavior conforms to this standard, the following can be said about constructing this path tree from the list of LTR entries returned by the Read Linktrace Reply command:

a) Sort the returned LTR entries by decreasing value of ltrReplyTTL (20.41.2.2). The highest reported value is one less than the initial LTM TTL field value [item d) in 12.14.7.4.2] used in the Transmit Linktrace Message command, and corresponds to the first Linktrace Responder reached by the initial LTM. This Linktrace Responder resides in the same Bridge as the MEP, in the case of an LTM originated by an Up MEP. The next-lower value corresponds to the MHF(s) or MEP(s) reached by the first forwarded copy of that LTM, and so on. Any gaps in the sequence of Reply TTL values indicate lost LTRs.
b) The ltrNextEgressId variable (20.41.2.4) in every LTR entry returned from a given Transmit Linktrace Message command is unique among the LTR entries in a given LTM entry in the Linktrace database, since no Linktrace Responder transmits more than one copy of an LTM.
c) The ltrLastEgressId variable (20.41.2.3) in any LTR entry is unique only over those LTR entries with matching values of the ltrReplyTTL variable.
d) The ltrLastEgressId variable (20.41.2.3) in any LTR entry whose ltrReplyTTL variable is one less than the initial LTM TTL field also matches the original LTM's LTM Egress Identifier TLV value, as returned from the Transmit Linktrace Message command [item c) in 12.14.7.4.3].
e) In the absence of lost LTRs, the ltrLastEgressId variable of any LTR whose ltrReplyTTL variable contains x will match the ltrNextEgressId variable of one of the LTRs whose ltrReplyTTL variable contains $(x + 1)$. For LTR entry x, this match indicates which of the Linktrace Responders $(x + 1)$ forwarded the LTM that was received by the Linktrace Responder that returned LTR entry x, and thus turns the list of LTR entries at each ltrReplyTTL value into a tree.

f) Along any given path from the root of the reply tree, the last reply can report any of the following conditions that terminate the forwarding of the LTM:
   1) FwdYes bit of the ltrFlags variable is reset (false); or
   2) TerminalMEP of the ltrFlags variable is set (true); or
   3) ltrRelayAction variable contains the value, RlyHit; or
   4) ltrReplyTTL variable contains 0.

g) If any path does not terminate with one of the conditions 1) through 3) in the previous item f), then either the initial LTM TTL field was insufficiently large to trace the complete path (and the last ltrReplyTTL variable of the end MP in the path contains 0), or a data frame addressed to the target MAC address of the LTM would be flooded after being forwarded from the Bridge that returned the last LTR in the path.

h) If the first Bridge encountered by the original LTM (which is the Bridge on which the LTM was originated, if originated from an Up MEP) would have flooded a data frame addressed to the target MAC address of the LTM, no LTRs will be returned in response to the LTM.

i) A gap in the ltrReplyTTL value sequence indicates the loss of (or failure to transmit) one or more LTRs. Similarly, a gap in the chain of ltrNextEgressId and ltrLastEgressId variables can be caused by the loss of LTRs. These conditions can make the construction of a reply tree impossible, if multiple LTRs have been returned with the same ltrReplyTTL value. If the last LTR along the path is lost, there is no gap in the ltrReplyTTL sequence to indicate the loss.

j) The Transmit Linktrace Message command can be reissued, and the resultant LTRs correlated with the results of a previous LTM, to improve the reliability of the results.

Diagnosing whether an anomalous result from a Read Linktrace Reply command, i.e., one that violates any of the prior assertions, is the result of ordinary frame loss (caused, e.g., by congestion), transitory network behavior (e.g., the loss of a LAN during the Linktrace procedure), a permanent malfunction (e.g., a Bridge is behaving in a noncompliant manner due to a hardware or software malfunction), or some other reason, is beyond the scope of this standard.

J.6 MP addressing: Individual and Shared MP addresses

It is stated in 21.3.2 that the source MAC address for a frame carrying a CFM PDU is the MAC address of the MP transmitting the PDU. This does not necessarily mean that the MP's physical implementation is tied to a particular Bridge Port, and that the MAC addresses used in the frames carrying CFM PDUs are the MAC addresses of those Bridge Ports. While this method of MAC address assignment produces the best protection that this standard can provide for a network, it is not required that every MP use its Bridge Port's MAC address.

CFM does not require the MPs configured on a single Bridge Port, e.g., all of the MPs illustrated in Figure 22-4, to have MAC addresses that are different from each other, nor does CFM require that they be the same. If the MPs in Figure 22-4 all have the same MAC address, CFM frames can be directed to the different MPs on that Bridge Port based on VID and MD Level. Choices can be made, however, with regard to whether MPs on different Bridge Ports can share the same MAC address. Two models are presented in this subclause for the assignment of MAC addresses to MPs:

a) **Individual MP address model:** The individual MAC address assigned to an MP associated with a particular MA, and hence that MA's MD Level and set of VIDs, is unique over all service instances associated with that same set of VIDs, such that those service instances' CFM PDUs can be distinguished only by their MD Levels that can pass through that MP's Bridge Port.

b) **Shared MP address model:** The same as the Individual MP address model, except that Up MPs (but not Down) in the same MA and in the same Bridge can share a (i.e., can all have the same) MAC address.

Down MPs in different Bridge Ports have different MAC addresses. If two Bridge Ports are connected to the same LAN, but have the same MAC address, then both would respond to an LBM sent to that MAC address.[63] This is true, even though one of those two Bridge Ports would be Blocked (it would be either a Backup or an Alternate Port, see 13.12), because Down MEPs are between the LAN and the Port filtering entities (8.6.1, 8.6.2, 8.6.4) that enforce the blocking. This placement allows Down MEPs to test their service instances even when their Port is blocked, so that the system administrator knows that the failover links will be ready to carry data when a network event causes the Port to become Forwarding.

A Bridge can use the Shared MP address model, or the Individual MP address model, on any given Bridge Port. This is an implementation decision; no managed objects are provided to select one or the other model of operation.

A Bridge using either of these two models can also make use of a third scheme for configuring MPs:

c) **Management Port MEPs:** Up MEPs (not Up MHFs, not Down MPs) are configured on a Management Port, a Bridge Port that does not connect to any LAN exterior to the Bridge. (See 8.3 and Figure 8-8.) Typically, this would be the same MAC address, and the same Bridge Port, that used for the Bridge's Management Port (see Figure 8-8).

The Individual MP address model is described in J.6.1, Shared MP address model in J.6.2, and Management Port MEPs in 22.7.

J.6.1 Individual MP address model

The purpose of CFM is to detect and diagnose connectivity errors. If a Bridge implements its Up MPs as close to the physical layer hardware as possible, it maximizes the capability of CFM to detect connectivity errors caused by malfunctions in that Bridge. In particular, giving each Up MP a MAC address that is tied to its particular Bridge Port means that an LBM/LBR exchange tests the Frame filtering entity (8.6.3) at both ends of the path. Figure 22-5 illustrates this fact. Any LBMs or LBRs passing between the Up MEPs and MHFs at the ends of the grayed service instance traverse exactly the same path through the Frame filtering entity as ordinary data frames carried from the left-most LAN to the right-most LAN.

J.6.2 Shared MP address model and the CFM Port

Although the Individual MP address model (J.6.1) gives the best detection and diagnostic capabilities, not all Bridge implementations are capable of inserting and removing CFM PDUs at points close to the physical layer. For example, the reflection of a high-speed LTM/LTR test stream by an Up MEP configured on a Port that is also receiving normal traffic from its LAN implies the presence of prioritization, data path, queuing, and bandwidth resources not otherwise required by this standard. This does not mean that Bridges lacking those resources cannot support CFM. The Shared MP address model provides one way for these Bridges to maximize their CFM capabilities.

Consider Figure 20-16, case c), but assume that the PDU entering Port 5, instead of being an LTM, is an LBM addressed to the Up MEP on Port 3. One cannot discern, from observing the external behavior of a Bridge, whether that LBM was actually delivered to the Up MEP on Port 3 or to some other entity within the Bridge. The Shared MP address model takes advantage of this fact by allowing Up MPs in different Bridge Ports to share the same MAC address. The Up MPs are still configured on different Bridge Ports according to the managed objects in Clause 12. For the most part, they have distinct identities. They share their MAC addresses and, as discussed more fully in 20.53, certain state machines and variables.

[63] Bridge implementations are known that use the same source MAC address for different Bridge Ports. As long as the Bridge Port or Management Port to which higher layer entities (e.g., an IP/TCP stack) are attached has its own unique MAC address, and as long as those Bridge Ports that share an address transmit only frames, such as BPDUs that do not traverse other Bridges, and as long as those Ports are not running any protocols that expect unicast frames to pass through a Bridge to reach them, Bridges of this description can interoperate each other and can interoperate with Bridges that follow the requirement to have a different MAC address for every Port. However, CFM PDUs do traverse other Bridges, and the LBM protocol does utilize individual MAC addresses. Therefore, the CFM protocols do not meet the goals of Clause 18 in all network topologies if Bridge Ports' Down MPs share MAC addresses.

In a Bridge configured according to the Shared MP address model, whether an LBM (or other PDU) that enters Port 5 in Figure 20-16 is addressed to the Up MEP on Port 3, or the Up MHF on Port 2, it is delivered to the same physical Bridge Port, called a "CFM Port." This could be a normal Bridge Port, e.g., one with more capability than the Bridge Port on which the addressed MP is configured, or it could be a Port that is attached to no LAN, in the manner of a Management Port (8.3, 22.7). A Bridge can have more than one CFM Port, but within that Bridge, each CFM Port has a MAC address that is different from the other CFM Ports. In the limiting case, each CFM Port is also a Bridge Port, and is associated with only its own Up MPs; this is indistinguishable from the Individual MP address model. A CFM Port, for which the MPs of three different Bridge Ports are residing, is illustrated in Figure J-1.

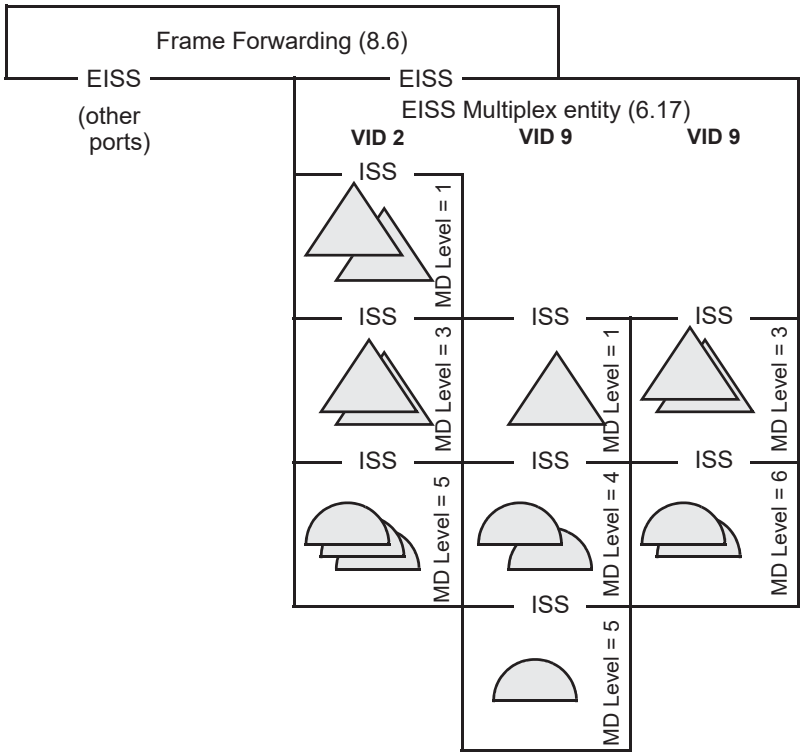

Figure J-1—Up MPs in a CFM Port

NOTE 1—Unlike normal Bridge Ports or a Management Port, multiple levels of MHFs can be present on a CFM Port for the same service instance, because they belong to different MAs on different Bridge Ports.

MPs on this CFM Port are distinguished by VID and by MD Level. However, those criteria are insufficient when Up MPs configured on different Bridge Ports are in the same MA, and thus in the same VID and at the same MD Level. There is no way of distinguishing, in that case, to which of those Up MPs a given CFM PDU is addressed. For the PDUs defined in this standard, this is not a problem.

Each MEP, even when multiple MEPs reside on a single CFM Port, has its own MEP Continuity Check Initiator state machine (20.12) and associated variables. Each MEP is responsible for transmitting its own CCMs, carrying information (e.g., the optional Sender ID TLV, 21.5.3) peculiar to its configured Bridge Port.

On the other hand, otherwise indistinguishable MEPs sharing a MAC address share a single LTR Transmitter state machine (20.50) and a single MEP Loopback Initiator transmit state machine (20.32), and their associated variables. The managed objects in 12.14.7.1.3 support this sharing.

When any CFM PDU arrives at the CFM Port, it is copied and delivered to each of the MPs that share the same MA. Each of these MPs responds to the CFM PDU separately and responds as if it resided in its configured Bridge Port. Since a multicast would be delivered to all of the MPs anyway, there is no harm in placing all of them in a single CFM Port, with a single MAC address.

Unicast CCMs, LTMs, LBRs, and LTRs present no issues. CCMs require no response. The LTMs all go to the Bridge's single Linktrace Responder. Even when an LTM is multicast, only one LTR and/or forward LTM is produced, so delivering a unicast LTM to multiple MPs causes no additional problems. Since the MEPs sharing a single CFM Port also share a single MEP Loopback Initiator transmit state machine (20.32) and a single MEP Loopback Initiator receive state machine (20.34), and since they all share a single set of variables, particularly those related to the LTM Transaction Identifier fields in these PDUs, there is no confusion about which MEP the LBR or LTR is directed.

The remaining PDU type is the LBM. Consider what would happen if the MEPs and their associated MP Loopback Responders (19.2.10) resided on separate Bridge Ports, but all shared the same MAC address. Assuming that the Frame filtering entity had learned that MAC address, the LBM would be forwarded to exactly one of those MEPs, namely the one that, by chance, last happened to transmit a frame, thus causing the Learning Process (8.7) to associate the shared MAC address with that transmitter's Bridge Port. Thus, exactly one LBR would be returned, not one per Bridge Port. The MEP receiving that LBR would not know from which MP the LBR was returned, because there is nothing in the LBR to indicate the identity of the responding MP. Therefore, only one response to a unicast LBM is returned from a CFM Port, no matter how many MPs on that LBM's MA reside on the CFM Port.

On the other hand, a multicast LBM could cause any number of Up MPs configured in the same MA, but on different Bridge Ports in a single Bridge, to respond. Thus, a high-speed stream of multicast LBMs could impose an arbitrarily large burden upon a single CFM Port that is supporting a large number of Bridge Ports' MPs, if each MP responded to that LBM. Therefore, among a set of MPs for a single MA that all share the same MAC address (i.e., reside on the same CFM Port), one or more, but not all, of their MP Loopback Responders (19.2.10) can be disabled by not configuring any group MAC address for them to recognize. This configuration is accomplished automatically by a Bridge that utilizes CFM Ports and is not controlled by any managed object.

The externally visible behaviors that can be discerned from outside a Bridge that uses the Shared MP address model are as follows:

a) An external MEP can regularly receive CFM PDUs other than LTRs, from two different MPs in the same MA that have the same source_address.
b) A multicast LBM can regularly receive only one reply from among a set of MPs that normally all respond to unicast LBMs, but all with the same source_address, without implying the presence of an intermittent network failure.
c) A system administrator can see unexpected advances in a MEP's managed objects that count LBMs and LBRs, apparently due to activity on another MEP.
d) If conceptual rows in the Interface MIB module of IETF RFC 2863 are instantiated for individual MPs, the packet and frame counts of those interfaces count both CFM PDUs and ordinary data frames passing through the Active and Passive SAPs, and thus can indicate whether an MP is instantiated on the Bridge Port on which it is configured, or on a separate CFM Port through which no ordinary data frames pass.

NOTE 2—None of these behaviors is impossible for a Bridge using the Individual MP address model; MAC addresses can change faster than CCMs time out, momentary congestion can cause frame loss, multiple administrators can access different MEPs' managed objects, and ordinary data frames can be absent. It is only the frequency of these behaviors that distinguishes the Individual MP address model from the Shared MP address model.

Annex K

(informative)

TPMR use cases

This material is intended to assist the reader of this standard in putting the operation of a TPMR in context with the operation of Bridged Networks as a whole, by illustrating some of the uses of a TPMR in conjunction with other types of Bridge. The set of cases is not, and is not intended to be, exhaustive in terms of all of the possible usage scenarios.

K.1 Use case 1—TPMR as User to Network Interface (UNI) demarcation device

Figure K-1 illustrates a use case where the TPMR performs the function of a UNI demarcation device between an customer network and a provider network. In this illustration, the user link between the customer Bridge and the TPMR, and the extension link between the TPMR and the provider Bridge, are both assumed to be IEEE 802.3 links, although, with the exception of the use of IEEE 802.3 EFM OAM on the extension link, these links could in principle be provided by use of any IEEE 802 LAN technology.

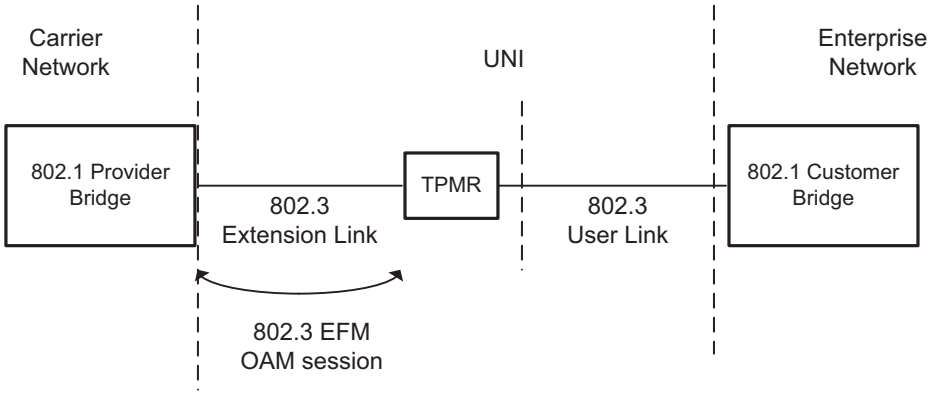

Figure K-1—TPMR as UNI demarcation device

The use of EFM OAM on the extension link allows the service provider to:

a) Put the TPMR into an intrusive loopback for out-of-service testing.
b) Query the IEEE 802.3 MIB in the TPMR.
c) Be notified of critical events (Link Fault, Dying Gasp, Critical Event).
d) Be notified of link performance events (Errored Symbol Period event, Errored Frame event, Errored Frame Period event, Errored Frame Seconds Summary event).

The potential exists with EFM OAM (on the extension link) to make use of extensions, via organization-specific OAMPDUs, to manage the Port of the TPMR that faces the user link.

Alternatively, the TPMR might be managed using SNMP over UDP/IP either in-band on the IEEE 802.3 extension link or out-of-band through separate management connector on the TPMR.

K.2 Use case 2—TPMRs with aggregated links

Figure K-2 illustrates a use case where two TPMRs are used within paired extension/user links that are aggregated at their endpoints (the Bridges). The TPMRs are transparent to the operation of the IEEE 802.1AX Link Aggregation Control Protocol (LACP), because the Provider Bridge and Customer Bridge are configured to use the "Nearest non-TPMR Bridge group address" as the destination address for LACP; from the point of view of Link Aggregation, each paired extension link and user link, with the TPMR joining them together, appears to be a single IEEE 802.3 LAN.

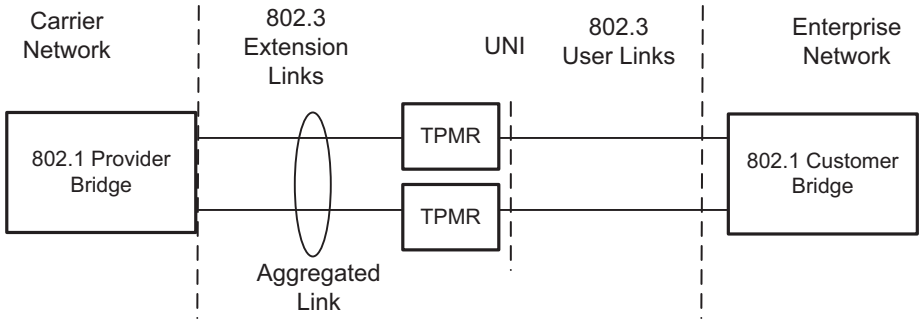

Figure K-2—TPMRs with aggregated links

The TPMRs would be managed separately, via EFM OAM, as in use case 1 (K.1). It should be noted that the use of SNMP to manage the TPMRs in this scenario is problematic, as the aggregated link appears to the higher layers to be a single link, but individual conversations are allocated by the frame distributor in the aggregator to the links in the aggregation in a nondeterministic manner.

K.3 Use case 3—Multiple TPMRs

Figure K-3 shows a variant of use case 1 (K.1) where two extension links and a user link are used, interconnected using two TPMRs.

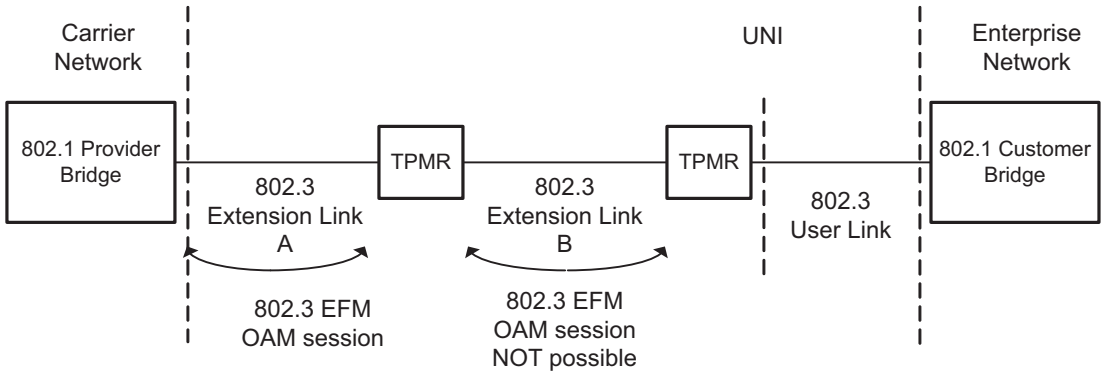

Figure K-3—Multiple TPMRs

Some commercial TPMRs used as demarcation devices power up in EFM OAM Passive mode, waiting to hear from the Active mode master device at the edge of the provider network. A passive-to-passive EFM OAM session, as would occur on extension link B, would never activate, making it impossible to manage the customer-facing TPMR by this means, unless significant changes were made to the capabilities of EFM OAM to allow some kind of relay capability. On the other hand, by using SNMP as the management protocol, this problem would be avoided.

K.4 Special cases

Figure K-4 (new connectivity) and Figure K-6 (connectivity failure) represent the target cases for the MAC status propagation design.

Figure K-4 shows recovery of the individual LAN at one end of at TPMR chain. The result is to "blip" the MAC_Operational status at the other end of the chain, delaying availability of the recovered link by slightly more than $T_{w+}T_d$. The figure also shows a possible effect of timing relationships between T_r and T_d, as the initiator of the change retries its Add message transmission just as the TPMR at the other end of the chain returns a confirm. The crossing of messages shown is unlikely, as the time sequence diagrams overemphasize the delay experienced by the Add and Confirm messages, but the effect is benign in any case.

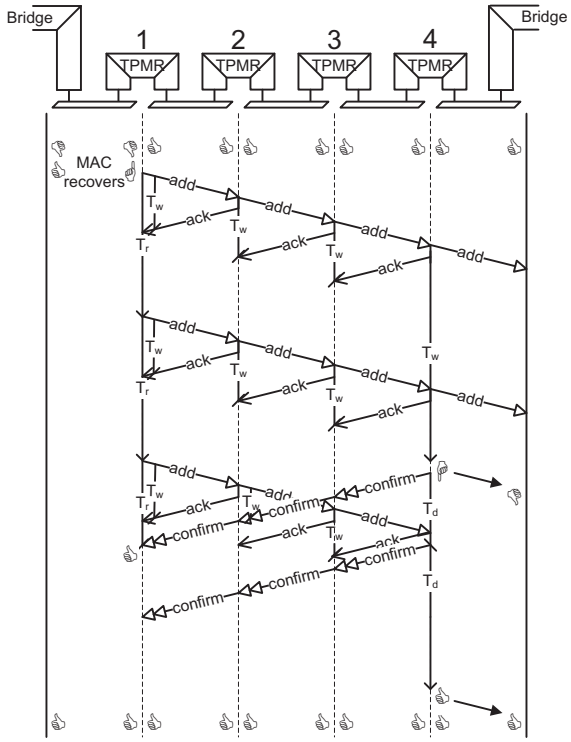

Figure K-4—Recovery at the end of a chain

If the LAN between the end system and the first TPMR in the chain (TPMR 1) had failed instead of recovering, the rest of Figure K-4 would have looked the same, with the exception of the final state of that first LAN. The net effect of the status notification protocol is to transfer the change in MAC_Operational to the other end of the chain so that both ends see the transition. For best effects the transfer should complete in a short enough time so that the end system protocols at the initiating end of the link are still executing their initial state.

Figure K-5 shows what happens if both ends of the link come up at the same time, the net effect is simply to delay the simultaneous start.

Figure K-6 shows simultaneous transitions of one LAN in the chain to OperUp and the other to OperDown, and illustrates a number of points about how the protocol or protocols do or should operate.

First, signaling of addition or loss can be somewhat arbitrary and depend on the relative timing of transitions on separate individual LANs. The same final connectivity can be represented by a loss followed by an

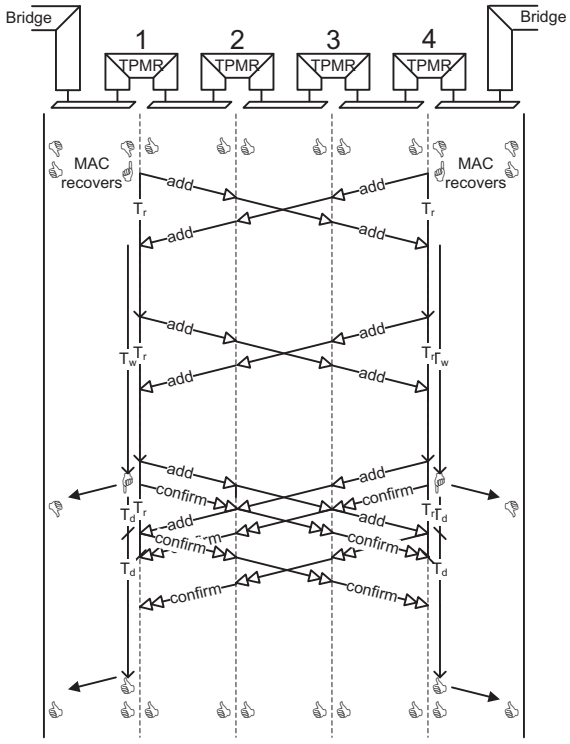

Figure K-5—Near simultaneous recoveries

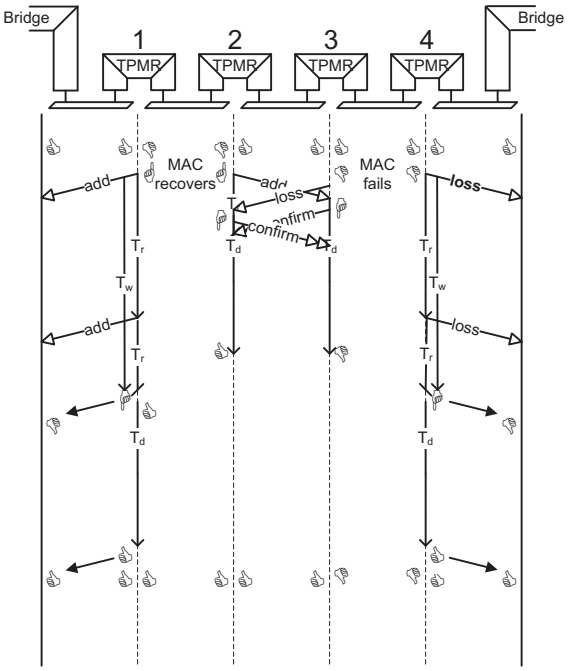

Figure K-6—Near simultaneous failure and recovery

addition, or an addition followed by a loss. If the implied resulting state is to mean anything then the information “connected as far as,” or “connected to and beyond” also needs to be communicated. However, while this is a candidate for inclusion in any new protocol, support by existing protocols is unlikely. However, this clause persists with distinguishing Add and Loss messages, and their confirmations, because that ensures that closely spaced transitions, which might otherwise disguise unusual loss of higher layer

protocol messages, are not missed by the systems connected to the TPMR chain. Figure K-7 shows a loss followed by recovery of the same LAN.

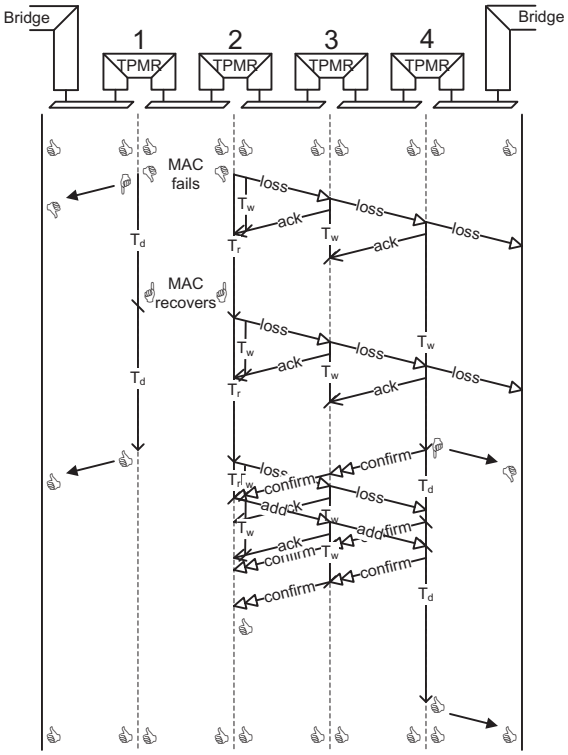

Figure K-7—Loss with quick recovery

Second, no message is sent across the LAN between TPMRs 1 and 2 when the MAC is OperDown from the protocol client's point of view. That allows support of the protocol to be architected such that a message that signals "add(ition)" or "loss" is forwarded through the normal bridged path so its speed of propagation does not depend on scheduling or notifying a status propagation process in each TPMR. Also, users have a free choice about what additional functionality can reside between the entities responsible for status propagation and the "real" MAC.

One last common case of simultaneous transitions is what happens when the two ports of a TPMR power up or are enabled at the same time. Each tries to send a link notification through the other, and each link notification is discarded as the Port is not yet available (mssOperUp FALSE). The result is to "blip" each LAN. The ends of the TPMR chain see an Add Loss Add sequence, if they are protocol capable, and a blip in MAC_Operational otherwise. If T_w is less than T_d, this will be a single blip.

Annex L

(informative)

Operation of the credit-based shaper algorithm

This annex contains a more detailed analysis of the way the credit-based shaper algorithm (8.6.8.2) operates, and how its operation affects the performance of the network, from the point of view of traffic that uses a credit-based shaped queue, and also from the point of view of other queues associated with the Port. The analysis and description in this annex does not take into account any interruption to bandwidth availability resulting from the operation of stream gates.

L.1 Overview of credit-based shaper operation

The credit-based shaper algorithm has a single externally determined parameter, *idleSlope* (see 8.6.8.2), that determines the maximum fraction of the *portTransmitRate* that is available to the queue associated with a traffic class (*bandwidthFraction*), as follows in Equation (L-1):

$$bandwidthFraction = idleSlope/portTransmitRate \quad \text{(L-1)}$$

where *portTransmitRate* is the maximum transmit data rate that the port supporting the outbound queue is able to deliver. The detailed derivation of Equation (L-1) can be seen in Equation (L-5) through Equation (L-8).

If a traffic class supported by the credit-based shaper algorithm uses less than the bandwidth allocated to it, then the unused bandwidth can be used by other traffic classes, in accordance with the relative priorities of the traffic classes and the transmission selection algorithms that are associated with them.

NOTE 1—It is a natural consequence of the way transmission selection operates that if a given traffic class does not have a frame available for transmission, then a lower priority traffic class that does have a frame available for transmission is able to transmit. Hence, if a given traffic class that uses the credit-based shaper algorithm has been allocated X% of the available bandwidth on a Port, but only uses (X-Y)%, then the unused portion of its allocation (Y%) is available for other traffic classes to use if they are in a position to do so. Whether this unused bandwidth can be used use by a traffic class depends upon the transmission selection algorithm that is associated with it. For example, a traffic class that has been allocated a specific bandwidth, such as one that uses the credit-based shaper algorithm, would be unable to use any bandwidth allocation not used by a higher priority traffic class, as that would result in it exceeding its bandwidth allocation; however, a traffic class that uses the strict priority algorithm, which is not associated with a bandwidth allocation, would be able to use bandwidth allocated to, but not used by, a higher priority traffic class.

The *idleSlope* parameter, in conjunction with the size of the frames that are being transmitted using the queue, and the maximum time delay that a queue can experience before it is able to transmit a queued frame, places an upper bound on the burst size that can be transmitted from queues that use the algorithm.

In order to describe the operation of the algorithm, it is useful to define the following values, in addition to the formal parameters of the algorithm described in 8.6.8.2:

a) ***maxFrameSize.*** The maximum sized frame that can be transmitted through the Port for the traffic class concerned. This value can be determined by admission control algorithms, or can be simply a function of the transmission behavior of the traffic source. Either way, the value can be smaller than would be allowed by the normal operation of the underlying MAC Service.
b) ***hiCredit.*** The maximum value that can be accumulated in the *credit* parameter. This parameter is a function of the operation of the algorithm, and cannot be controlled by management.

c) ***loCredit.*** The minimum value that can be accumulated in the *credit* parameter. The value of *loCredit* is a function of the values of *maxFrameSize*, *portTransmitRate*, and *sendSlope*, as follows in Equation (L-2).

$$loCredit = maxFrameSize \times (sendSlope/portTransmitRate) \quad \text{(L-2)}$$

d) ***maxInterferenceSize.*** The maximum size, in bits, of any burst of traffic that can delay the transmission of a frame that is available for transmission for this traffic class. For the numerically highest traffic class, *maxInterferenceSize* is exactly equal to the maximum sized frame that can be transmitted through the Port (the maximum frame size supported by the underlying MAC). For all other traffic classes, the derivation of *maxInterferenceSize* becomes more complex, owing to the possibility that any higher traffic classes that support the credit-based shaper algorithm can delay the transmission of a frame. *maxInterferenceSize* must also account for any media access delay, such as the recovery time in Energy Efficient Ethernet. A detailed analysis can be found in L.3.1.1.

NOTE 2—The definition of *maxInterferenceSize* assumes that any traffic classes that support the shaper algorithm are numerically higher than any traffic classes that support the default strict priority algorithm (8.6.8.1). If this is not true, then the value of *maxInterferenceSize* is infinite, and the operation of the credit-based shaper algorithm cannot provide the bandwidth that has been reserved for it. A detailed analysis of how *maxInterferenceSize* can be determined for a given traffic class is contained in L.3.

The value of *hiCredit* is determined by the worst-case interfering traffic, as follows in Equation (L-3).

$$hiCredit = maxInterferenceSize \times (idleSlope/portTransmitRate) \quad \text{(L-3)}$$

The value of *hiCredit* can therefore be considered as a “high water mark”; the operation of the algorithm is such that the value of the *credit* parameter will never exceed *hiCredit.*

The choice of value for *idleSlope,* and the calculated value of *hiCredit*, can be used to determine the maximum burst size that can be output from the queue, as follows in Equation (L-4).

$$maxBurstSize = (portTransmitRate \times ((hiCredit - loCredit)/(-sendSlope))) \quad \text{(L-4)}$$

NOTE 3—There is an interrelationship between the maximum burst size and the buffer size available to the traffic class. There is no point in accumulating more credit than the traffic class can handle in queued frames, as the limiting factor is the discarding of frames when the queue overflows. This means that the amount of bandwidth that can be reserved on a given Port for a given traffic class depends upon the amount of buffering available to that traffic class. This in turn, combined with the port’s transmission rate, will determine the maximum value of idle slope that can be supported for that traffic class on that Port.

The operation of the credit-based shaper algorithm is illustrated in the examples shown in Figure L-1 through Figure L-3. In Figure L-1, a frame is queued at a time when the *credit* value is zero, and there is no conflicting traffic (there is no higher priority traffic awaiting transmission, and there is no frame being transmitted on the Port). The frame is immediately selected for transmission, and *credit* decreases at the rate of *sendSlope* as the transmission proceeds. Once the frame transmission is complete, *credit* increases back to zero at the rate of *idleSlope*, at which point, a further frame can be selected for transmission.

If a continuous stream of frames is made available to the shaper algorithm, i.e., there is always one frame queued awaiting transmission when the *credit* value reaches zero, then the fraction of the *portTransmitRate* that is available to the queue (*bandwidthFraction*) is equal to the fraction of time that frames are being transmitted from the queue. Assuming that *credit* decreases to value *loCredit* at the end of each frame transmission, then the following shows the detailed derivation of Equation (L-1):

$$bandwidthFraction = (-loCredit/sendSlope)/[(-loCredit/sendSlope) + (loCredit/idleSlope)] \quad \text{(L-5)}$$

$$= (-1/sendSlope)/[(1/idleSlope) - (1/sendSlope)] \quad \text{(L-6)}$$

$$= (-idleSlope)/(sendSlope - idleSlope) \quad \text{(L-7)}$$

$$= idleSlope/portTransmitRate \quad \text{(L-8)}$$

This fraction of the bandwidth is available to the stream even in the presence of conflicting traffic, as illustrated in the following examples.

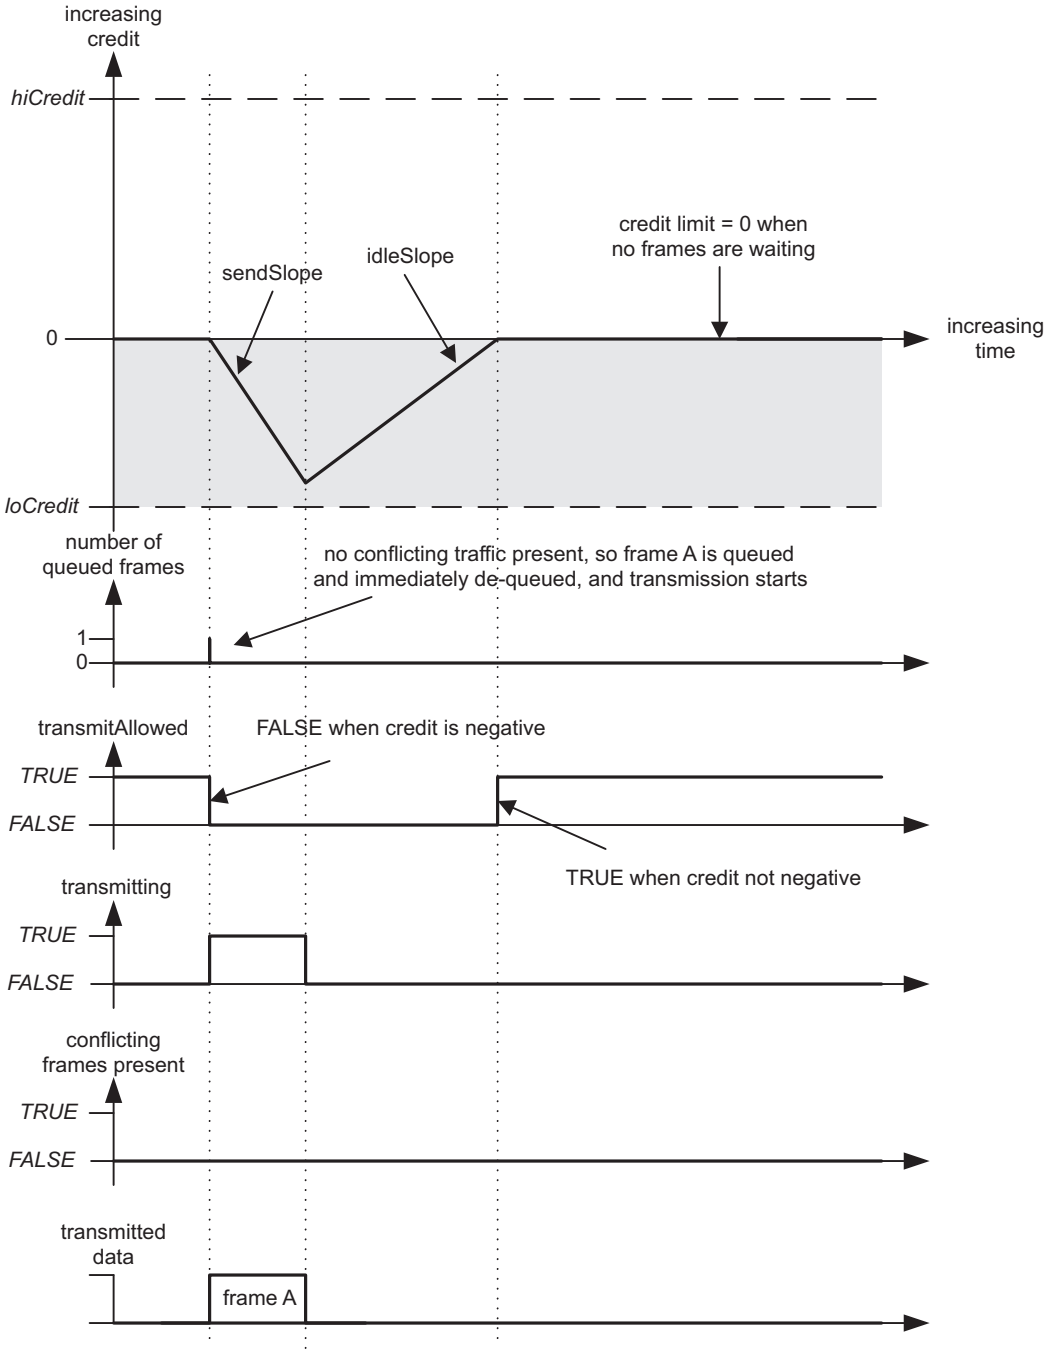

Figure L-1—Credit-based shaper operation—no conflicting traffic

In Figure L-2, a frame is queued at a time when the Port is transmitting conflicting traffic. The value of *credit* increases at the rate of *idleSlope* while the queued frame waits for the Port to become available. Transmission of the conflicting traffic completes before the value of *credit* is limited by *hiCredit*, and transmission of the queued frame starts. The value of *credit* starts to decrease at the rate of *sendSlope*; however, as the frame is not large enough to consume all of the available *credit*, and there are no further frames queued, *credit* is reduced to zero on completion of the transmission.

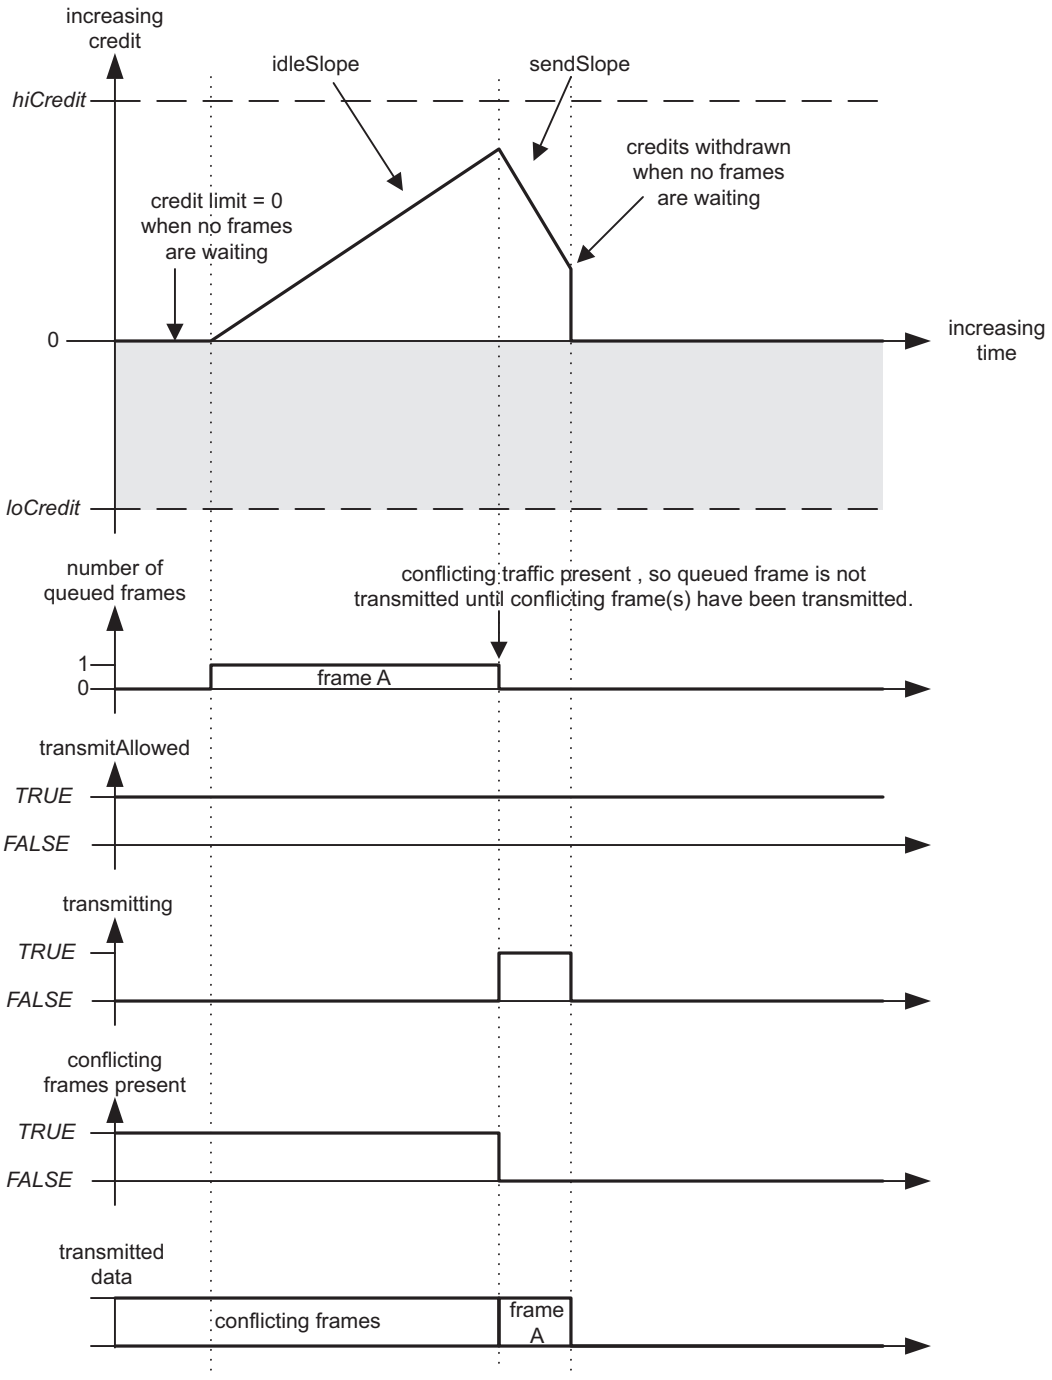

Figure L-2—Credit-based shaper operation–conflicting traffic

In Figure L-3, three frames are queued while the Port is transmitting conflicting traffic, and *credit* accumulates at the rate of *idleSlope*. Once the conflicting traffic has been transmitted, the first and second frames are transmitted back-to-back, because transmitting the first frame leaves *credit* ≥ 0. However, as transmitting the second frame causes credit to become negative, transmission of the third frame is delayed until *credit* returns to zero.

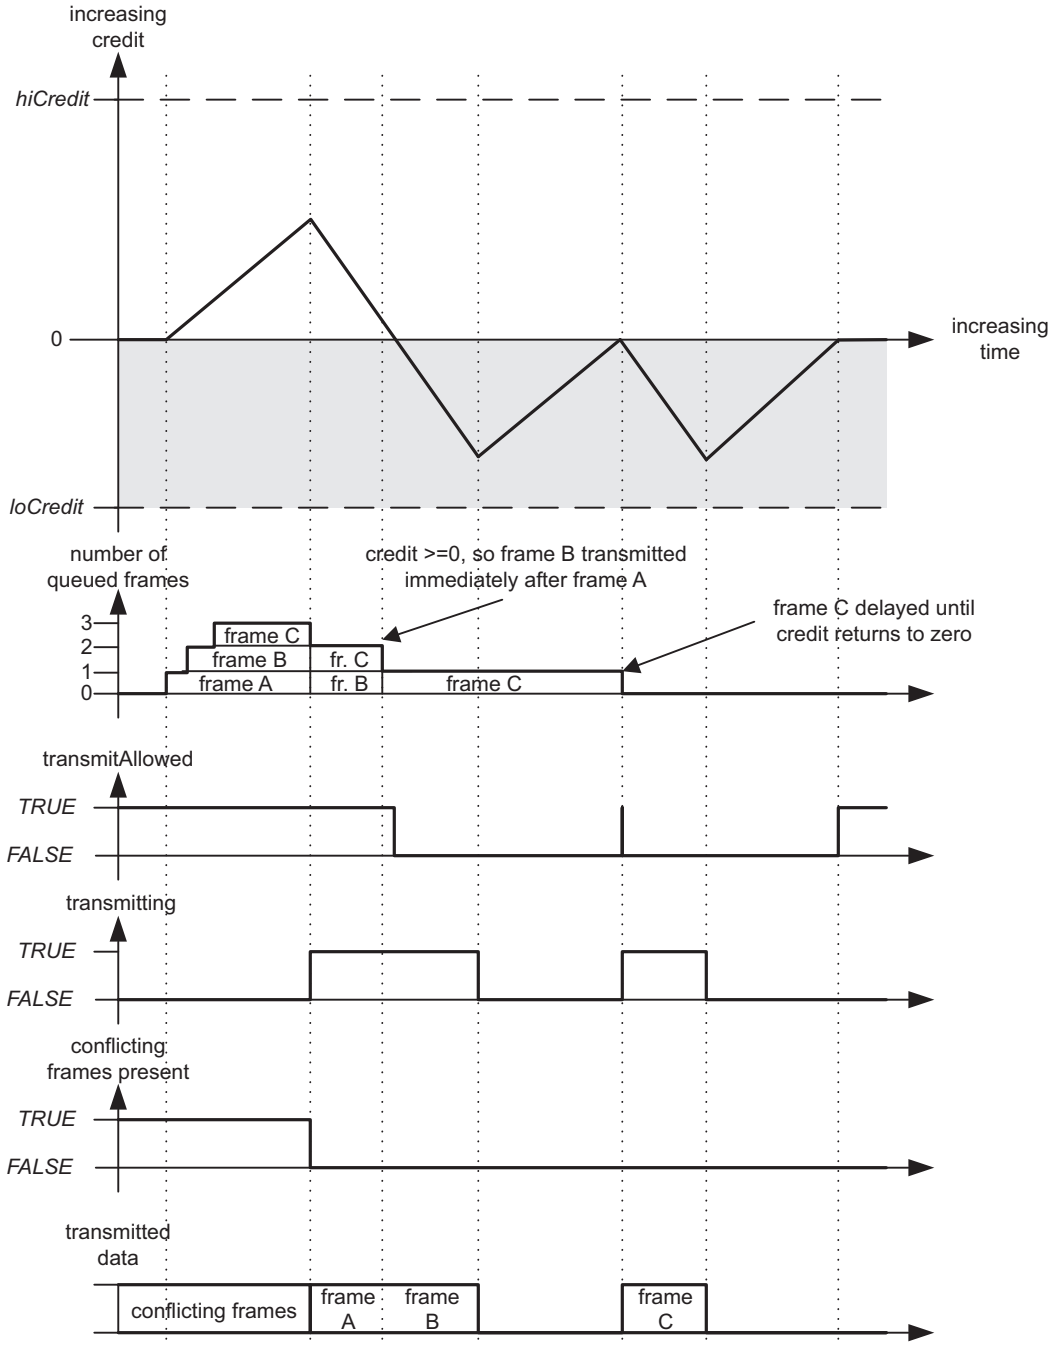

Figure L-3—Credit-based shaper operation—burst traffic

L.2 “Class measurement intervals” in Bridges

The “class measurement interval” defines acceptable Talker behavior with respect to per-stream transmission (see 34.6.1.1); however, it does not directly impact the operation of the credit-based shaper algorithm in Bridges.

The maximum fraction of the available bandwidth that a queue operating the credit-based shaper algorithm consumes is determined by *idleSlope*, as discussed in L.1; if *idleSlope* is 75% of the link transmission rate, then the algorithm gets a maximum of 75% of the link, averaged over some time period (the class measurement interval) at the Talker. For a Bridge, where transmission becomes bursty due to interfering transmission from other traffic classes, the minimum measurement interval that is meaningful (i.e., the minimum period over which it is still possible to observe that the 75% maximum bandwidth is not exceeded) is the time taken for the traffic class concerned to transmit a maximum sized burst, multiplied by 100/75. In the case of the 125 μs class measurement interval for SR class A traffic, on 100 Mb/s Ethernet, and with 75% reservation, the approximate calculation is (ignoring interframe gaps)

a) The maximum interference size (*maxInterferenceSize*) is one maximum sized Ethernet frame, which is 2000 octets, or 16 000 bits, so *hiCredit* would be 75% of that, or 12 000 bits.

NOTE 1—Media access delays, such as those imposed by Energy Efficient Ethernet, could be more significant than the interference created by a maximum sized frame.

NOTE 2—The figure of 2000 octets is a maximum for Ethernet and therefore a worst case for an interfering frame; in a specific implementation, the maximum frame size that is used could be smaller. In implementations where the maximum frame size is known to be less than 2000, the smaller value could be used.

b) The maximum frame size for this traffic class is 75% of the number of bits that can be transmitted in 125 μs, so 75% of 12 500 bits in the case of a 100 Mb/s LAN, or 9375 bits (including up to 500 or so possible “overhead” octets—used for, e.g.,Tag headers, physical layer overhead). As this is not an integral number of octets, this figure is rounded down to 9368. *loCredit* is 25% of that, or –2342.

c) The maximum burst size, for frames no greater than 9368 bits long, would occur if *credit* reached 12 000, then a series of frames were transmitted that exactly took credit to 0, followed by a final 9368 bit frame that would take credit down to –2342. This maximum burst is therefore calculated as (12 000 + 2342) • (*portTransmitRate/(-sendSlope))* or 57 368 bits.

d) The minimum measurement interval over which one can expect to be able to measure the bandwidth utilization for SR class A, and observe that it does not exceed its 75% allocation, is therefore 57 368 bit times multiplied by 100/75, which is 76 491 bit times, rounded up to the nearest integer, or 764.91 μs.

NOTE 3—The maximum sized burst will be preceded by a *maxInterferenceSize* event, and at the end of the burst, *credit* will have been reduced to –2342; it will therefore take 2342/*idleSlope* seconds, or nearly 3123 bit times, for *credit* to return to zero, and for SR Class A to be allowed to transmit again. In addition, the actual utilization for SR Class A is 57368/(57368+16000+ (2342/0.75)) = 75%.

For the SR class B traffic, all that really changes is the potential size of any interference, which increases from the SR class A *maxInterferenceSize* to the maximum burst size for SR class A plus the class A *maxInterferenceSize*.

So, the smallest possible measurement interval over which the ratio *idleSlope*/*portTransmitRate* will be seen to hold good is dependent on the maximum interference size for the SR class, the maximum frame size for the SR class, and the value of *idleSlope*.

L.3 Determining worst-case latency contribution and buffering requirements

From the point of view of the operation of AV Bridges, it is important to be able to assess the contribution that each Bridge makes to the worst-case latency that stream data frames can be subject to during their transmission along the path from Talker to Listener. Closely related to the latency contribution that a Bridge makes is the buffering requirement that is required in the Bridge in order for the delay not to result in frame discard; if a Bridge can potentially delay a frame of a given SR class for a given period of time, then it must be capable of buffering the worst-case number of frames of that same SR class that could be received for onward transmission on each Port. The following discussion looks at the factors that contribute to the delay that could be experienced by a frame as it passes through a Bridge, and how the delay can be accurately determined.

NOTE 1—This discussion is also useful to guide designers of Talker stations in determining the delay added by the Talker's network interface.

The worst-case latency for a single hop from Bridge to Bridge, measured from arrival of the last bit at Port *n* of Bridge A to the arrival of the last bit at Port *m* of Bridge B, can be broken out into the following components:

a) Input queuing delay. (There are no input queues in the IEEE 802.1 architecture, but if present, the implementation must account for them.)
b) Interference delay (L.3.1).
c) Frame transmission delay. (The time taken to transmit one maximum frame at *portTransmitRate*.)
d) LAN propagation delay. (A variable delay that depends on the length of the LAN connection to the next Bridge; this is measurable using the mechanisms defined in IEEE Std 802.1AS.)
e) Store-and-forward delay. This includes all other elements of forwarding delay that are a consequence of the internal processing of the Bridge, assuming that the input and output queues are empty, such as:
    1) The time needed to pass a frame from the input port to the output port, assuming empty queues.
    2) The time delay between a frame being available for transmission on a Port and the Port being ready to transmit the frame.

NOTE 2—For example, in the case where the MAC/PHY has entered a power saving mode, there may be a delay incurred in switching the Port back to normal operation.

    3) The difference, if any, in the delay incurred by a frame that bypasses an empty queue, vs. that incurred by a frame that must be enqueued.
    4) The time added (subtracted) by the lengthening (shortening) of the frame due to addition (removal) of frame headers such as Q-tags or MACSec-tags.
    5) The time needed to encrypt a MACSec frame.

In the remainder of this clause, the following abbreviations are used:

M_0 Maximum sized frame for non-SR classes
M_x Maximum sized frame for SR class x
R_0 portTransmitRate
R_x idleSlope for SR class x
T_{xy} Time interval between events x and y
W_x -sendSlope$_x$
variable$_{<x}$ The sum of the values of the named *variable* for all SR classes with a higher priority (and therefore earlier letter in the collating sequence) than x

L.3.1 Interference delay

The interference delay for frame X can be broken out into the following components:

a) **Queuing delay:** The delay caused by the frame that was selected for transmission an arbitrarily small time before frame X became eligible for transmission selection, plus the delay caused by queued-up frames from all stream frames with higher priority than frame X's class (i.e., the "*maxBurstSize*" for SR Classes with higher priority than X—see L.1). This is what is referred to as *maxInterferenceSize* in L.1. Queuing delay is analyzed in detail in L.3.1.1.

b) **Fan-in delay:** The delay caused by other frames in the same class as frame X that arrive at more-or-less the same time from different input Ports. Fan-in delay is analyzed in detail in L.3.1.2.

c) **Permanent delay:** The delay caused by frames that reside in a buffer for a long time, relative to the output queuing delay, because of the history of activity in the network. Permanent delay is analyzed in detail in L.3.1.3.

L.3.1.1 Queuing delay

The queuing delay for frame X can be broken out into the following components:

a) The delay, *maxInterferenceTime*, before a frame X queued for an SR class, and that is eligible for transmission, can actually be transmitted. This delay is experienced when a frame, of any priority, is selected for transmission an arbitrarily small time before frame X became eligible for transmission; it is also experienced in LAN media, such as Ethernet, where there can be a low energy consumption mode that is entered under idle conditions, and where there is a significant delay, *mediumAccessDelay,* before the LAN returns to normal operation and is able to transmit. The value of *maxInterferenceTime* is therefore equal to whichever is the greater of the following:
   1) The time taken to transmit the maximum frame size supported by the medium, i.e., $maxFrameSize_{(m)}$ / *portTransmitRate*.
   2) The *mediumAccessDelay* for the medium.

b) The delay caused by any queued-up frames associated with the next higher priority SR class than frame X's SR class (i.e., *maxBurstSize* for the next higher priority SR class), if frame X does not belong to the highest SR class.

For SR class A, only the first of these components applies, as there is no higher SR class.

Suppose that the queue for SR class A is full, and it has accumulated the maximum amount of *credit (hiCredit)*. Because SR class A frames have priority over all other traffic (even BPDUs), *hiCredit* for SR class A is merely the credit accumulated during the *maxInterferenceTime* required to transmit a lower-priority frame. Until that accumulated credit is exhausted, SR class B (C, D,...) frames cannot be transmitted.

If SR class A were permitted to use 100% of the LAN bandwidth, then the SR class A queue would never catch up, because it would use credit as fast as it was gained, and there would never be a chance for any other traffic class to transmit a frame. If SR class A were permitted to use 99% of the LAN bandwidth, then SR class A can transmit back-to-back frames and the accumulated *credit* would be drained at 1% of the LAN bandwidth until it goes negative; at that point, SR class A cannot transmit further frames until its *credit* returns to a non-negative value, which ensures that at least 1% of the bandwidth is available to other traffic classes.

NOTE—In general, if SR Class A is permitted to use X% of the bandwidth, then only (100-X)% remains available for use by lower priority traffic classes. In practice, as 75% is the default value for the highest percentage of *portTransmitRate* that can be used by all SR classes, there is always at least 25% of *portTransmitRate* available for use by the non-SR traffic classes.

Figure L-4 illustrates this burst transmission behavior, and the effect of *maxInterferenceTime* on the latency of SR class frames. At point *a* on the time line, the queues for SR classes A and B are empty, and a maximum sized frame (M_0 bits long) belonging to a non-SR traffic class starts transmission. An instant later, SR class A and B frames arrive that are all of the maximum size that the classes are currently experiencing (M_A and M_B bits long, respectively); however, as there is a frame already being transmitted, they are queued. At point *b*, transmission of the non-SR class frame completes, and the first of a burst of four SR class A frames are transmitted. By point *d*, SR class A's credit has been taken negative by the transmission of the last of its burst of frames, and therefore no further SR Class A frames can be transmitted until its credit is no longer negative; this allows SR Class B to transmit a frame. What happens at the end of the class B frame will depend on what frames are queued waiting for transmission, and whether the credit available to either of the SR classes is non-negative.

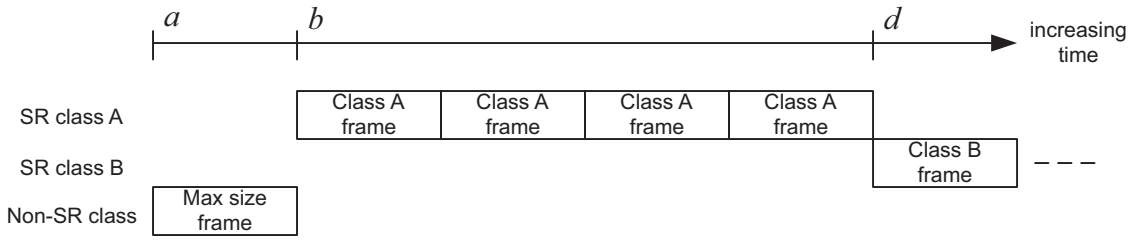

Figure L-4—Interference and latency

The queuing delay experienced by the first SR Class A frame is therefore the time interval between *a* and *b*, T_{ab}. If R_0 is the transmission rate (*portTransmitRate*), then:

$$T_{ab} = M_0 / R_0 = maxInterferenceTime \quad \text{(L-9)}$$

Figure L-5 shows how credit changes for SR Class A during this sequence.

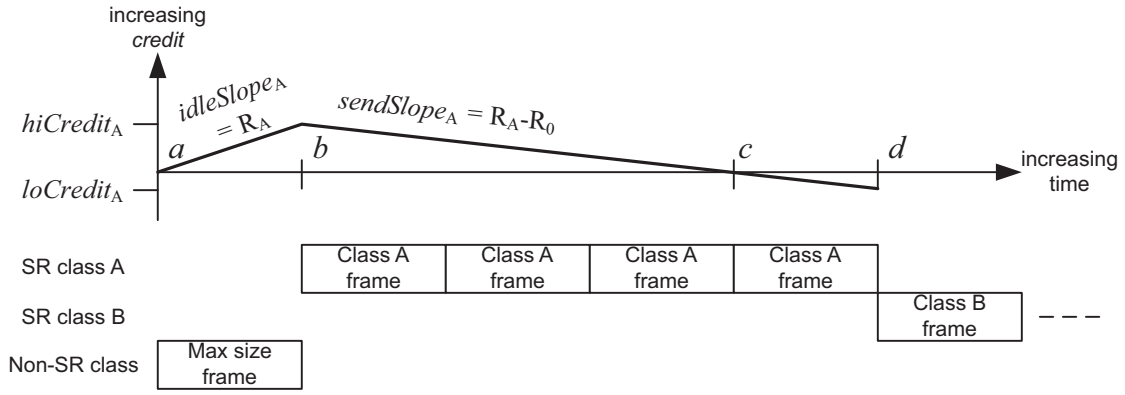

Figure L-5—Burst behavior and credit

R_A is the reserved data rate for SR Class A (which is the *idleSlope* for class A), R_B is the reserved data rate for SR Class B, and so on. The value of $credit_A$ accumulates up to $hiCredit_A$ during the transmission of the maximum sized non-SR frame so that:

$$hiCredit_A = R_A \times M_0 / R_0 = \text{idleSlope}_A \times maxInterferenceTime \quad \text{(L-10)}$$

credit is drained during the transmission of the SR Class A frames, at the rate $sendSlope_A$, as follows:

$$sendSlope_A = (R_A - R_0) \quad \text{(L-11)}$$

credit reaches zero at point *c* in Figure L-5, which, for the purposes of this discussion, is assumed to happen exactly at the point where transmission of the third class A frame finishes. Since a frame can be transmitted when *credit* = 0, Class A's credits continue to drain to the following value:

$$loCredit_A = (R_A - R_0) \times M_A / R_0 \quad \text{(L-12)}$$

during the transmission of the fourth class A frame (M_A bits long, transmitted in time M_A / R_0). At point *d*, transmission of the fourth frame completes; as $credit_A$ is now negative, no more class A frames can be transmitted, and transmission of a class B frame starts.

So, for class A, the maximum burst size is equal to the transmission rate, R_0, multiplied by the time interval between points *b* and *d* in Figure L-5:

$$\text{max Class A burst size} = R_0 \times (-(hiCredit_A - loCredit_A) / sendSlope_A) \quad \text{(L-13)}$$

Substituting $hiCredit_A$, $sendSlope_A$, and $loCredit_A$ from Equation (L-10), Equation (L-11), and Equation (L-12), respectively, results in the following:

$$\text{max Class A burst size} = R_0 \times (-(R_A \times M_0 / R_0 - (R_A - R_0) \times M_A / R_0) / (R_A - R_0)) \quad \text{(L-14)}$$

$$= R_0 \times (R_A \times M_0 / R_0) / (R_0 - R_A) + M_A / R_0 \quad \text{(L-15)}$$

$$= (R_A \times M_0) / (R_0 - R_A) + M_A \quad \text{(L-16)}$$

The queuing delay experienced by SR class B is the time interval between *a* and *d* in Figure L-5, T_{ad}:

$$T_{ad} = T_{ab} + T_{bc} + T_{cd} \quad \text{(L-17)}$$

$$= M_0 / R_0 + hiCredit_A / (-sendSlope_A) + M_A / R_0 \quad \text{(L-18)}$$

$$= M_0 / R_0 + (R_A \times M_0 / R_0) / (R_0 - R_A) + M_A / R_0 \quad \text{(L-19)}$$

$$= M_0 / (R_0 - R_A) + M_A / R_0 \quad \text{(L-20)}$$

This can be generalized to calculate the queuing delay experienced by any SR class, X, by using the sum of the credits available to all higher priority SR classes. In the following, the subscript "<X" is used to indicate the sum of the values for all SR classes with higher priority (and therefore, earlier letters in the collating sequence) than X.

The credit acquisition rate $idleSlope_{<X}$ for SR classes A through X – 1 is the sum of the data rates for all higher priority classes so that:

$$idleSlope_{<X} = \sum_{K<X} R_K \quad \text{(L-21)}$$

This is just the sum of the $idleSlope_K$ values for the higher classes. However, the combined classes accumulate credits only until the single interfering non-SR interfering frame stops transmitting, and then the credits start decreasing linearly. So, the upper limit for the combined credits is not the sum of the individual Class's credits; it is the number of bits divided by the slope, or:

$$hiCredit_{<X} = (\sum_{K<X} R_K) \times M_0 / R_0 \quad \text{(L-22)}$$

Similarly, the combined $sendSlope_{<X}$ is:

$$sendSlope_{<X} = -(R_0 - \sum_{K<X} R_K) \quad \text{(L-23)}$$

These combined rates hold true until some class's buffer empties and its credits are forced to 0. In the worst-case scenarios examined here, this does not happen.

Defining:

$$W_{<X} = -\mathit{sendSlope}_{<X} = R_0 - \sum_{K<X} R_K \quad \text{(L-24)}$$

leads to:

$$\mathit{sendSlope}_{<X} = -W_{<X} \quad \text{(L-25)}$$

and:

$$\mathit{hiCredit}_{<X} = (R_0 - W_{<X}) \times M_0 / R_0 \quad \text{(L-26)}$$

For all combined classes, T_{ab} is the same as for SR class A, the time for the non-SR frame to transmit:

$$T_{ab} = M_0 / R_0 \quad \text{(L-27)}$$

The combined classes A through X – 1 drain from $\mathit{hiCredit}_{<X}$ to 0 in time $\mathit{hiCredit}_{<X} / W_{<X}$ so that:

$$T_{bc} = ((R_0 - W_{<X}) \times M_0 / R_0) / W_{<X} \quad \text{(L-28)}$$

The worst-case value of $\mathit{loCredit}_{<X}$ for the combined <X classes is not the sum $\sum_{K<X} \mathit{loCredit}_K$ as this would overestimate the worst case. Only one of the <X classes can be transmitting a frame at a given time, so the end of the burst for the <X classes occurs when one of the <X classes, Q say, starts transmitting a frame at a point where all the other <X classes have negative credit, and their credit is therefore rising. If, by the time Q's frame transmission finishes, the other <X classes still have negative credit, then Q's frame is the last frame of the <X burst; but at that point, all the other <X classes must, by definition, have more credit than their respective *loCredit* values (i.e., for these other classes, *credit* > *loCredit*) because even if they were at their respective *loCredit* values when Q started transmitting, they have been gaining credit during the transmission of Q's frame.

It is also not possible to decide that $\mathit{loCredit}_{<X}$ is simply the time needed to transmit one copy of each Class's maximum-length frame; for some classes it could be possible transmit more than a single last frame after the total credits = 0, even if all Classes' credits reach 0 simultaneously. For example, classes A and B reach *credit* = 0 at the same time; A transmits a frame, then B transmits a frame. By the end of the B frame, A's *credit* has returned to zero, and so A can transmit a further "last" frame.

Some class must transmit the last frame, and for it to be the worst case, that last frame is a maximum length frame. If it were not, then either:

c) Extending it to the maximum length still leaves the other classes at negative *credit*; or
d) Extending it to the maximum length leaves one or more other class with 0 or positive *credit*, in which case they will transmit more frames.

So, for class Q to be the class that transmits the last frame of the <X burst, the following condition must be true for all other <X classes, P:

$$M_q \times R_P > (R_0 - R_P) \times M_p \quad \text{(L-29)}$$

Equation (L-29) follows from the fact that the increase in credits of class P during the transmission of M_q, which is equal to $(M_q/R_0) \times R_P$ is greater than the absolute value of the *loCredit* of P, which is equal to $(R_0 - R_P) \times M_p$. So,

$$(M_q/R_0) \times R_P > (R_0 - R_P) \times M_p / R_0 \quad \text{(L-30)}$$

This statement is true because the other classes P must have low enough *credit* that their *credit* cannot climb above 0 during the transmission of M_q.

The very lowest that $credit_{<X}$ might reach for three SR classes, Q, P, and S is shown in Equation (L-31).

$$loCredit_{<X} \geq loCredit_Q + loCredit_P + loCredit_S + R_S \times M_q/R_0 + R_P \times M_q/R_0 \quad \text{(L-31)}$$

However, even this is pessimistic, as it assumes that more than one class can be at their *loCredit* at the same time, which is not the case. What this shows, however, is that if R_K is small for all K<X (i.e., $R_K << R_0$), then the $R_K \times M_q/R_0$ terms all approach zero, and therefore $loCredit_{<X}$ approaches the sum $\sum_{K<X} loCredit_K$. So,

$$loCredit_{<X} = \sum_{K<X} loCredit_K \quad \text{(L-32)}$$

$$= \sum_{K<X} (R_K - R_0) \times M_K / R_0 \quad \text{(L-33)}$$

But in this worst case, $R_K << R_0$; therefore,

$$loCredit_{<X} = \sum_{K<X} (-M_K) \quad \text{(L-34)}$$

Putting together these various components, the queuing delay for SR Class X, $qDelay_X$, is as follows:

$$qDelay_X = M_0 / R_0 + (hiCredit_{<X} - loCredit_{<X}) / |sendSlope_{<X}| \quad \text{(L-35)}$$

$$= M_0 / R_0 + ((R_0 - W_{<X}) \times M_0 / R_0 + \sum_{K<X} M_K) / W_{<X} \quad \text{(L-36)}$$

$$qDelay_X = (M_0 + \sum_{K<X} M_K) / W_{<X} \quad \text{(L-37)}$$

For SR class A, this equation reduces to Equation (L-38):

$$qDelay_A = M_0/W_{<A} \quad \text{(L-38)}$$

As there is not a "<A" class, A being the highest priority class, $W_{<A}$ is simply R_0, so this reduces to Equation (L-39):

$$qDelay_A = M_0/R_0 \quad \text{(L-39)}$$

This agrees with the earlier discussion in L.1.

For SR class B, the equation reduces to Equation (L-40):

$$qDelay_B = (M_0 + M_A) / W_A \quad \text{(L-40)}$$

As W_A is $-sendSlope_A$, which is just $R_0 - R_A$, this can be rewritten as shown in Equation (L-41):

$$\mathbf{qDelay_B = (M_0 + M_A) / (R_0 - R_A)} \quad \text{(L-41)}$$

The maximum burst size for a given class, X, is the number of bits that can be transmitted in "back-to-back" frames by class X. The maximum burst occurs when that class has experienced the maximum queuing delay for that class, $qDelay_X$, and class X is then able to transmit frames, uninterrupted by any higher priority classes, until it reaches $loCredit_X$. The size of this burst, $maxBurst_X$, is equal to the number of bits that can be transmitted at line rate, R_0, in the time it takes for creditX to reduce from $hiCredit_X$ to $-loCredit_X$, as follows in Equation (L-42):

$$maxBurst_X = (hiCredit_X - loCredit_X) \times R_0 / W_X \quad \text{(L-42)}$$

From the earlier results, the worst case for $loCredit_X$ is just $(-M_X)$ so that:

$$= hiCredit_X \times R_0 / W_X + M_X \times R_0 / W_X \quad \text{(L-43)}$$

and $hiCredit_X$ is the amount of credit that can be accumulated during $qDelay_X$ seconds, which is $qDelay_X$ multiplied by the idle slope, R_X, so that:

$$maxBurst_X = (M_0 + \sum_{K<X} M_K) \times R_X \times R_0 / (W_{<X} \times W_X) + M_X \times R_0 / W_X \quad \text{(L-44)}$$

L.3.1.2 Fan-in delay

The delay caused by other frames in the same class as frame X that arrive at more-or-less the same time from different input Ports. Consider the scenario in Figure L-6, where a Bridge has a number of Ports on which it receives frames for a given SR Class and the frames will be queued on a single outbound Port. Imagine that the "upstream" Bridge Ports feeding every reception Port of the Bridge all encounter a maximum interference event for Class X at the same time. The output Port will be starved of data. Then, once the interference events complete, the "upstream" Bridges start to transmit frames and the input Ports all receive a frame at the same moment; all received frames are delivered to the output queue.

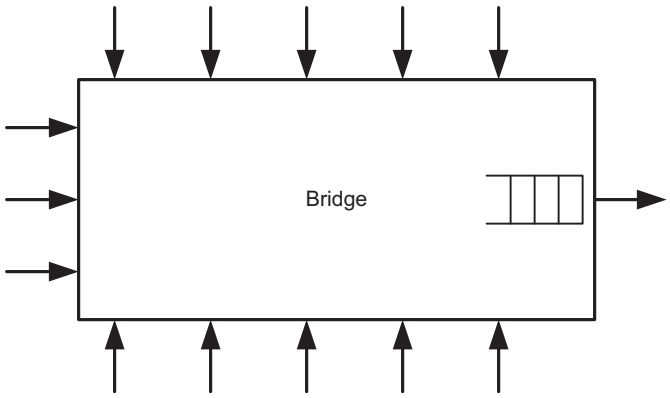

Figure L-6—Fan-in scenario

Assuming that all of the Ports of the Bridge support the same data rate, and the outbound queues of the upstream Bridges are all configured the same as the outbound queue of this Bridge, then the outbound Port would not be able to transmit frames from its queue at the desired, combined data rate of the incoming traffic, as this would require the outbound Port (in this example) to transmit at 20 times its reserved data rate, which would not be permitted by the Stream Reservation Protocol (SRP). It follows that whatever the reserved data rate is on the outbound Port, this must be the same as the sum of the reserved data rates being fed into the inbound Ports.

By allocating the majority of the reserved bandwidth to one of the inbound Ports (shown in gray in Figure L-6) and a very small amount of bandwidth to all of the other inbound Ports, the amount of fan-in data that will be received can be maximized; the gray Port will receive $maxBurst_X$ bits of burst data, and all other Ports will receive a single frame of length M_X. Hence, the data that the outbound queue has to handle in this scenario is $maxBurst_X + 12 \times M_X$ bits of fan-in data.

NOTE 1—The reason that this choice maximizes the fan-in data burst size is that regardless of how little bandwidth is allocated to the black Ports, they still get to burst a complete frame.

The following is a procedure (not a formula) for determining the maximum amount of fan-in data for a given SR class and output port:

a) Determine B_O, the maximum possible bandwidth for class X on the output port.
b) For each possible input port *i*, determine the maximum possible bandwidth B_i for Class X—it is assumed that this information is obtained, by some means, from the transmitting Bridge that is the source of the frames received by *i*.
c) For input port *i*, calculate $\text{maxBurst}_{X,i}$ using $\max(B_O, B_i)$ for the bandwidth. (In the maxBurst formula, use $W_X = R_0 - \max(B_O, B_i)$.)
d) Add $\max(\text{maxBurst}_{X,i})$ to the total fan-in data.
e) Set $B_O = B_O - B_i$ and repeat from step c) until $B_O = 0$.
f) For each remaining port, add $M_{X,i}$ to the total fan-in data.

The fan-in delay is then equal to the time taken for the total fan-in burst data, computed as shown above, to be output at the line rate of the output port.

NOTE 2—The definition of a measurement interval for stream TSpecs implies a minimum frame transmission rate (8000 frames per second for class A's 125 µs measurement interval). At this frame transmission rate, the frames are smaller and, due to the overhead in small frames, fewer streams are possible (no more than 13 through a 100 Mb port). These constraints should be given due consideration when determining the value to be used for M_X and for determining the maximum number of ports contributing to fan-in delay.

Example calculations of fan-in delay can be found in the paper "Calculating the Delay Added by Qav Stream Queue" [B3].

L.3.1.3 Permanent delay

Permanent delay reflects the fact that, if a path through the network is being used continuously at its full capacity for a particular SR class, interfering traffic can cause "permanent" buffer occupancy at the point of congestion. This is illustrated in Figure L-7 through Figure L-10 and the accompanying text.

In Figure L-7 a Talker station, T, has reserved the highest possible bandwidth, R_X, for an SR class X stream on the path through 3 Bridges to Listener L. For the purposes of the discussion, R_X is the maximum reservable data rate for class X on the outbound Ports of all three Bridges, and Talker T starts transmitting the stream, at the reserved data rate R_X. Assuming that the LANs are short and there is no interfering traffic (i.e., the only traffic being handled is this particular stream), the buffer occupancy in each Bridge will approach zero, as frames can be transmitted onwards as soon as they are received.

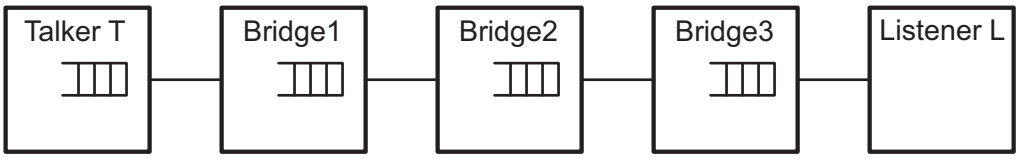

Figure L-7—Permanent delay scenario

In Figure L-8, a second transmission, Q, generates the maximum possible interference to class X (i.e., class X's next frame for transmission is delayed by qDelay_X). Talker T's class X queue fills, and its *credit* increases to $hiCredit_X$ (shown on the figure as $C=C_X$). Because T is no longer transmitting class X frames, the downstream Bridges are starved of frames to transmit, their buffers are empty, and their credit is zero ($C = 0$).

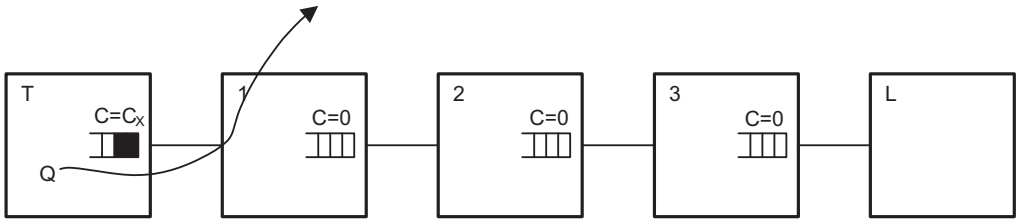

Figure L-8—Building up buffer occupancy—1

In Figure L-9, the interfering traffic goes away, and T is able to transmit a maximum sized class X burst of frames at line rate; once the burst has finished, T reverts to transmitting the stream at the reserved rate R_X. As Bridge 1 has no credit, it will have to buffer most of the burst of frames, and as T is sending frames as fast as Bridge 1 can get rid of them, its buffer occupancy will remain at that level unless something else affects that steady state. Bridge 1 ends up with a credit value that hovers around the *hiCredit* level; the credit in the other Bridges will have *credit* of 0 or some value between 0 and *loCredit* as the Bridges receive and transmit frames.

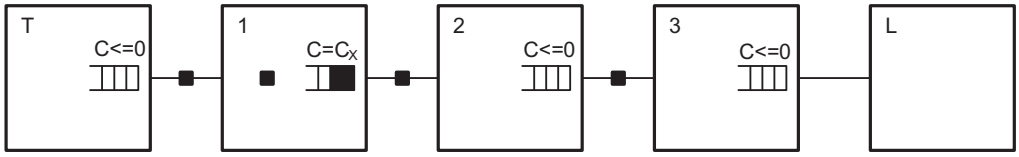

Figure L-9—Building up buffer occupancy—2

If the interfering traffic, Q, starts up again, Talker T's buffer occupancy will build up again; however, as Bridge 1 still has frames buffered, it can continue to transmit, and the downstream Bridges are not starved of frames, and Bridge 1's buffer occupancy and *credit* returns to around 0. When the interference stops, T transmits a burst at line rate, as before, which simply restores Bridge 1's queue to the state shown in Figure L-9.

If a new interfering frame source, S, starts up that affects class X in Bridge 1, then Bridges 2 and 3 could again be starved of traffic, and the buffer occupancy and credit in Bridge 1 could increase temporarily to $2C_X$ (see Figure L-10). When S stops transmitting, then Bridge 2 can create a line rate burst of traffic that will restore its buffer to the previous steady state (Figure L-9), but now Bridge 2 has a permanent buffer loading as shown in Figure L-10.

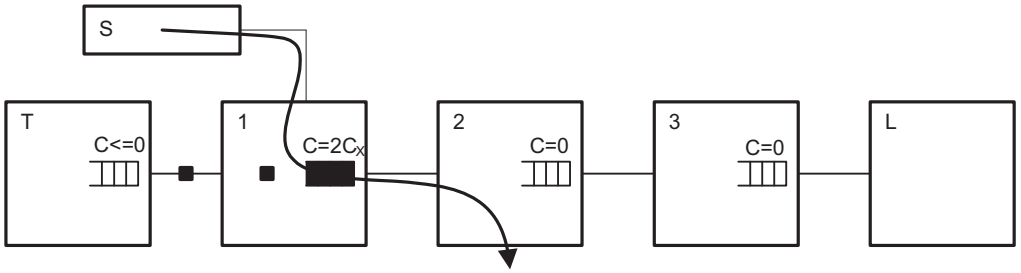

Figure L-10—Building up buffer occupancy—3

This can of course happen for other Bridges in the path, leading eventually to some level of permanent buffer occupancy in each Bridge (Table L-11). The problem does not get any worse from that point on, because no Bridge ever starves (i.e., no Bridge's credit is set to zero because it runs out of frames to send); starvation is a requirement in order for permanent partial occupancy to be created.

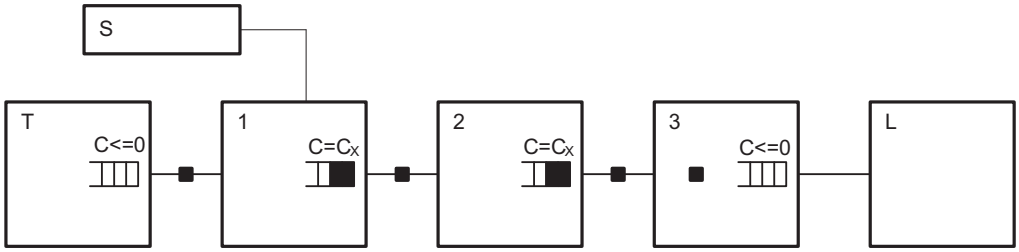

Figure L-11—Building up buffer occupancy—4

It may, therefore, be considered desirable for all Bridges to reserve a little bit more bandwidth than the actual total reserved by the Talkers, so that this "permanent" buffer build-up can drain away. However, this would not make the problem significantly better on the timescales of the output queuing delay, so it does not factor into those calculations, and, of course, this additional capacity would increase the queuing delay at each hop.

NOTE—Many applications have media clocks that are asynchronous to the free-running clock used to determine class measurement intervals. As the two clocks could be operating at the extremes of their permissible variation, it is necessary to reserve more bandwidth than is nominally needed in order to account for the potential difference in clock rate.

Since this kind of event could happen on multiple input ports at the same time, the "permanently buffered" data equals the worst-case fan-in data.

L.3.2 Maximum interference delay and maximum buffer requirement

As discussed in L.3.1, the worst-case interference delay for SR class X on a given Port is the sum of the following three parts:

a) $qDelay_X$ [see Equation (L-35) in L.3.1.1]
b) The fan-in delay (see L.3.1.2)
c) The "permanent" buffer contents contribution (see L.3.1.3), which is equal to the worst-case fan-in delay

The buffering requirements for SR class X consist of the following three components:

d) A contribution from the queuing delay, equal to $maxBurst_X$
e) The fan-in burst data size, computed as described in L.3.1.2
f) The "permanent" buffer contents, which is equal to the fan-in burst data size

The fan-in burst size and the permanent buffer contents do not count twice; if a fan-in burst happens, then it becomes the permanent buffer contents. If it happens a second time, it can only happen after a pause that has allowed the permanent buffer loading to drain. So the worst-case buffering requirement for SR class X is simply the sum of the first two elements, $maxBurst_X$ [Equation (L-42)] and fan-in burst data size; therefore,

$$maxBuffering_X = maxBurst_X + (\text{fan-in burst data size})_X \quad \text{(L-45)}$$

The worst-case total buffering requirement for all of the SR classes on a given Port is the sum of the following two parts:

g) The worst-case buffering requirement for the lowest priority SR class on that Port
h) One max-size frame $M_{i,Z}$ for each class Z of higher priority than Class X for each input port i

Since the worst-case buffer requirement for Class X is when it is taking almost all of the bandwidth from the higher-priority classes, the SR priority levels can share buffering space. The only additional requirement is for the fan-in from higher priorities on other Ports. Thus, the SR classes would do well to share their buffer space on each Port.

L.4 Operation of credit-based shaper in Coordinated Shared Network (CSN)

A CSN is a contention-free, QoS-capable, time division multiplexed access network. One of the nodes of the network acts as the Network Coordinator (NC) node granting transmission opportunities to the other nodes of the network. The NC node also acts as the QoS manager of the network.

From the perspective of the specification of the credit-based shaper, a CSN is equivalent to a distributed Bridge. Rather than shaping the AV traffic in the egress nodes, which could lack the buffering resources to do so, the shaping could instead be performed by the CSN's NC per Class of Service when it schedules transmissions opportunities from the CSN's ingress to the CSN egress nodes. The behavior of CSN's egress to another MAC technology should be consistent with the behavior specified in this standard, regardless of how the shaper is implemented.

Annex M

(normative)

Support for PFC in link layers without MAC Control

M.1 Overview

Priority-based Flow Control (PFC) is a function defined for only point-to-point full-duplex links in terms of the M_CONTROL primitives (11.4 of IEEE Std 802.1AC-2016 [B8]). For IEEE 802.3 link layers the M_CONTROL primitives are mapped into the MAC Control MA_CONTROL primitives (IEEE Std 802.1AC), that use the PDU format defined in IEEE Std 802.3. Other link layers supporting point-to-point full-duplex operations need to define their mapping of the M_CONTROL primitives. This annex describes a PDU format suitable to support PFC.

M.2 PFC PDU format

Figure M-1 shows a PDU format suitable to support PFC.

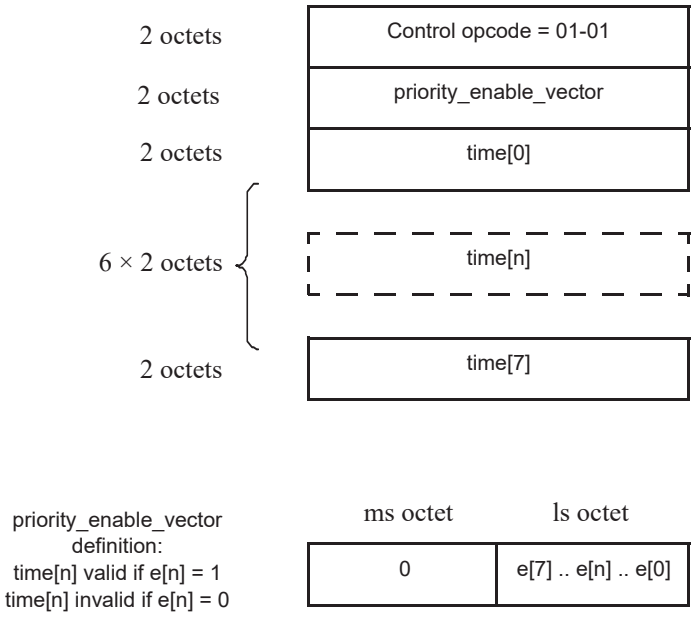

Figure M-1—PFC PDU format

The Control opcode field contains a 2-octet operation code indicating the Control function.

The remaining fields contain the parameters defined in 36.1.2.

Annex N

(informative)

Buffer requirements for PFC

N.1 Overview

To ensure that data frames are not lost due to lack of receive buffer space, receivers must ensure that a PFC M_CONTROL.request primitive is invoked while there is sufficient receive buffer to absorb the data that can continue to be received during the time needed by the remote system to react to the PFC operation. The precise calculation of this buffer requirement is highly implementation dependent. This annex provides an example of how it can be calculated based on a hypothetical delay model. Setting the PFCLinkDelayAllowance (see 12.22.6) to less than the round-trip delay value can result in frames loss.

Figure N-1 provides an high-level view of the various delays to consider:

a) Processing and queuing delay of the PFC request
b) Propagation delay of the PFC frame across the media
c) Response time to the PFC indication at the far end
d) Propagation delay across the media on the return path

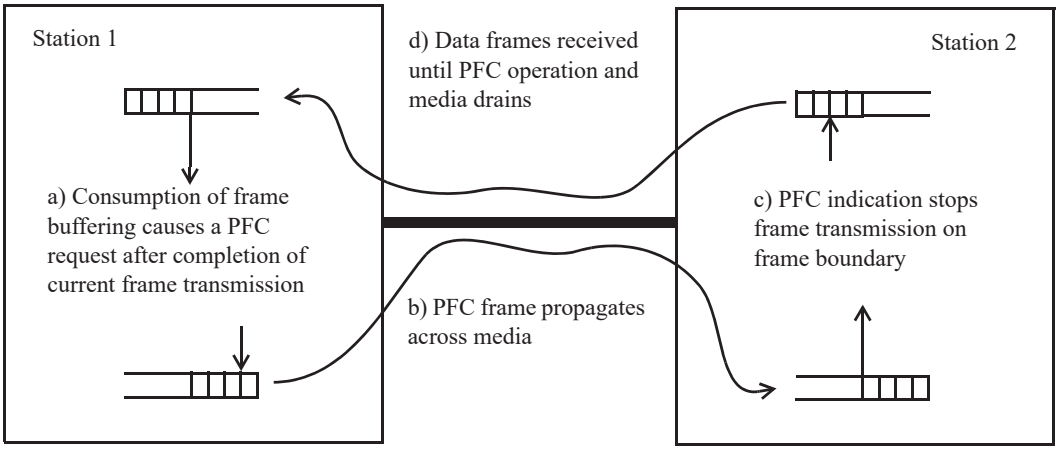

Figure N-1—PFC delays

N.2 Delay model

Figure N-2 shows how to model the various delays between two stations connected by a point-to-point full-duplex IEEE 802.3 link.

The main delay components shown in Figure N-2 are as follows:

a) **PFC transmission delay:** the time needed by a station to request transmission of a PFC frame after a PFC M_CONTROL.request has been invoked (e.g., because a maximum length data frame can be transmitted).
b) **Interface Delay (ID):** the sum of MAC Control, MAC/RS, PCS, PMA, and PMD delays. Interface Delay is dependent on the MAC and physical layer in use.

c) **Cable Delay:** the number of bits in flight stored in the transmission medium. This delay value is dependent on the selected technology and on the medium length.

d) **Higher Layer Delay (HD):** the time needed for a queue to go into paused state after the reception of a PFC M_CONTROL.indication that paused its priority. A substantial portion of this delay component is implementation specific.

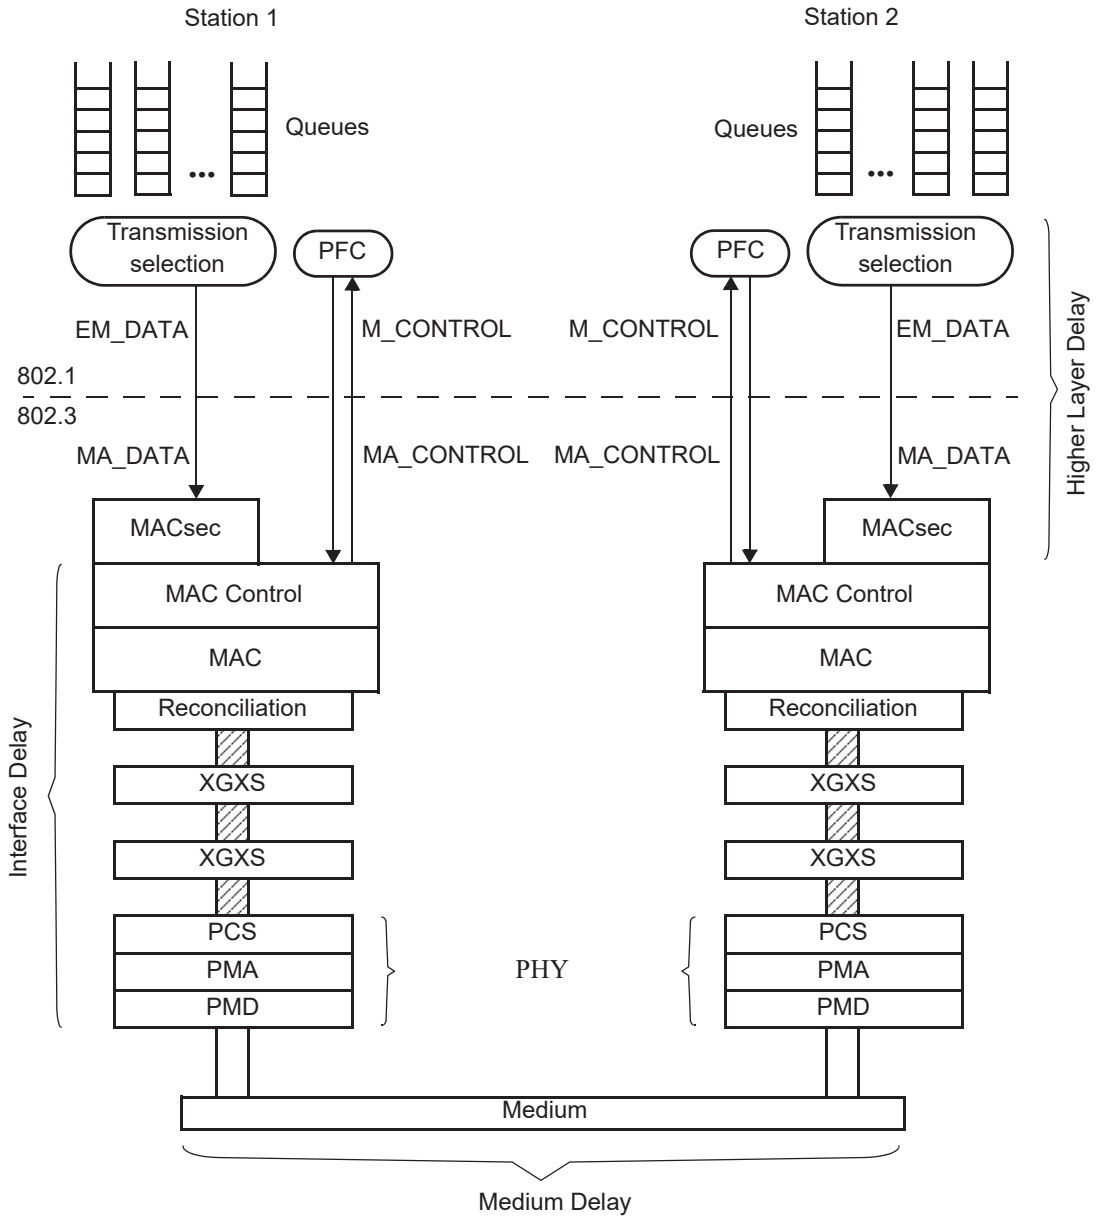

Figure N-2—Delay model

Figure N-3 shows a possible worst-case delay example.

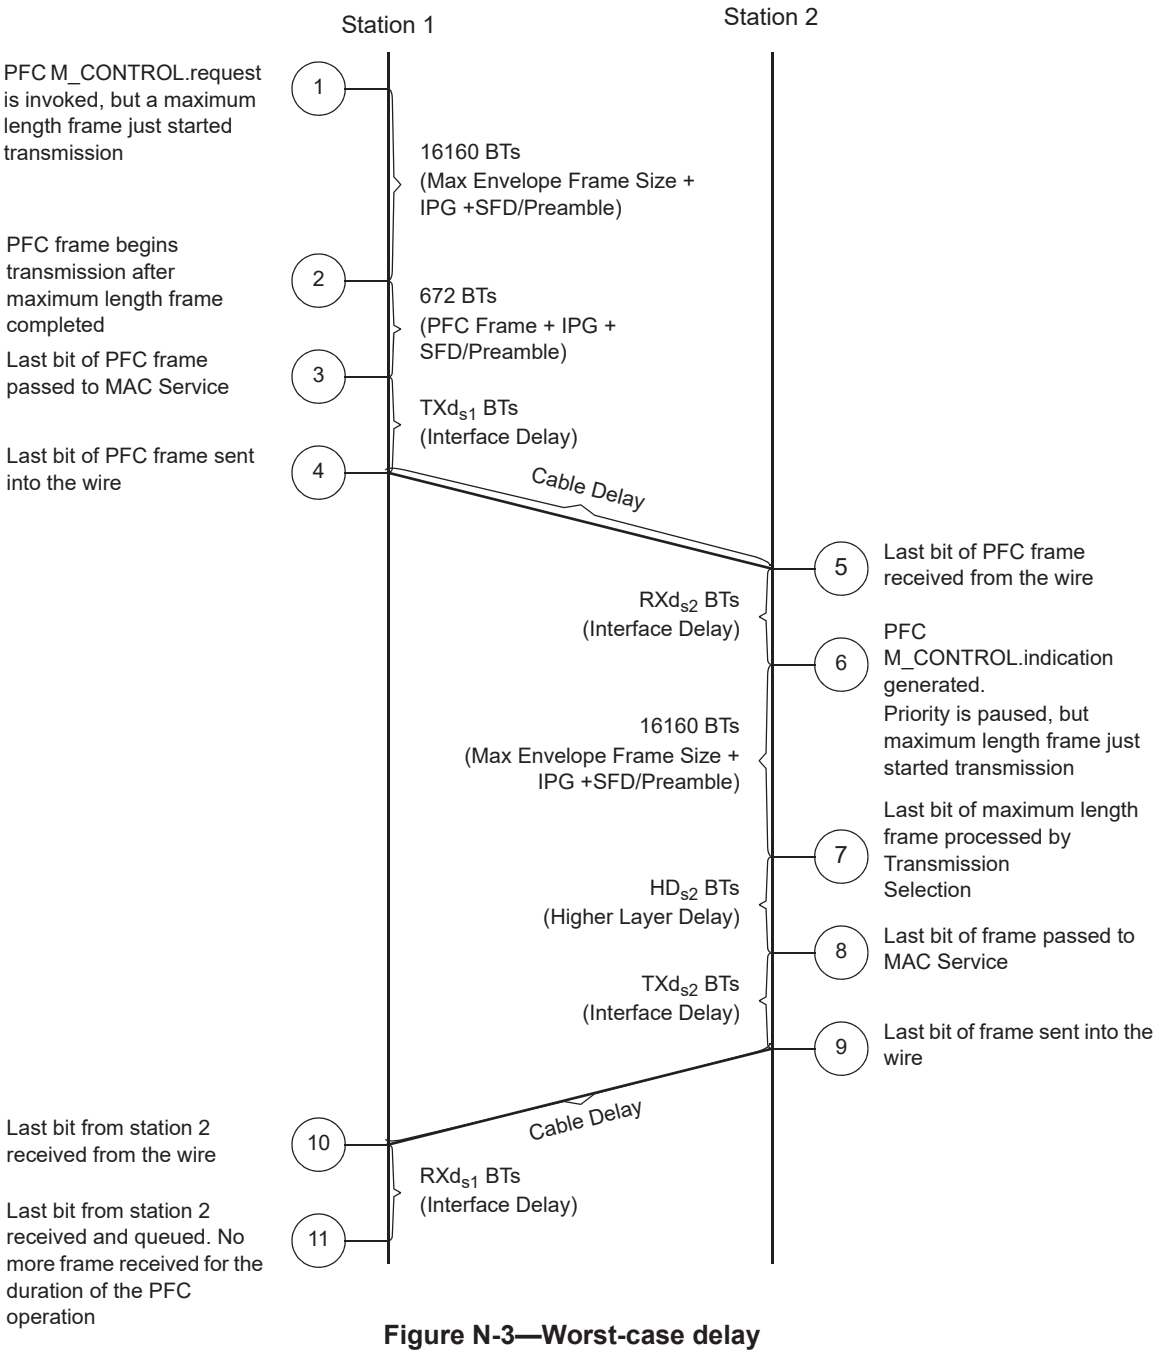

Figure N-3—Worst-case delay

The total Delay Value (DV) is the sum of all delays shown in Figure N-3:

$$DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + TXd_{s1} + RXd_{s2} + HD_{s2} + TXd_{s2} + RXd_{s1}$$

For any given station the Interface Delay includes both transmit and receive paths (i.e., ID = TXd + RXd). Therefore:

$$DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + ID_{s1} + ID_{s2} + HD_{s2}$$

Usually the peer stations connected by a point-to-point link use the same technology, therefore $ID_{s1} = ID_{s2}$:

$$DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + 2 \times ID + HD_{s2}$$

N.3 Interface Delay

The Interface Delay comprises all delay components below the MAC Control Client, excluding the cable delay. Table N-1 shows the Interface Delay constraints for some IEEE 802.3 interfaces.

Table N-1—IEEE 802.3 Interface Delays

Sublayer	Maximum RTT (bit times)	Maximum RTT (pause quanta)	Reference (subclause of IEEE Std 802.3-2018 [B13])
10G MAC Control, MAC, and RS	8192	16	46.1.4
XGXS and XAUI	2048	4	48.5
10GBASE-X PCS	2048	4	49.2.15
10GBASE-R PCS	3584	7	50.3.7
LX4 PMD	512	1	53.2
CX4 PMD	512	1	54.3
Serial PMA and PMD	512	1	52.2
10GBASE-T	25 600	50	55.11

N.4 Cable Delay

The Cable Delay is the propagation delay over the transmission medium and can be approximated by the following equation:

$$\text{Cable Delay} = \text{Medium Length} \times \frac{1}{BT \times \upsilon}$$

where υ is the signal propagation speed in the medium and *BT* is the bit time of the medium.

N.5 Higher Layer Delay

The Higher Layer Delay comprises the delay components between the MAC Control Client and the port Transmission Selection. Example of these delays are MACsec and implementation specific delays.

For link speeds of up to 10Gb/s, MACsec constrains each of the transmit delay and the receive delay to a maximum of 19 360 bit times (see 36.1.3.3).

This standard constrains the implementation specific delays to be less that 614.4 ns (see 36.1.3.3). This delay is equivalent to 6144 bit times at the speed of 10Gb/s.

N.6 Computation example

A station needs to be capable of buffering DV bit times of data to ensure no frame loss due to congestion. The worst case is with a 10GBASE-T PHY. Assuming MACsec is not supported, this results in the following:

— Maximum envelope frame size: 2000 octets, 16 160 bit times;
— PFC frame size: 64 octets, 672 bit times;
— XGMII MAC/RS and XAUI interface: 8192 + 2 × 2048 = 12 288 bit times;
— 10GBASE-T Delay: 25 600 bit times;
— 100 meters Cat6 cable: 5556 bit times (computed assuming $\upsilon = 0.6 \times c$, where c is the speed of the light in meters per second);
— HD = 6144.

The total Delay Value in this scenario results as follows:

$$DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + 2 \times ID + HD_{s2}$$

$$DV = 2 \times (16\,160) + (672) + 2 \times (5556) + 2 \times (25\,600) + 2 \times (12\,288) + 6144 = 126\,024 \text{ bit times}$$

For this case, the amount of buffering needed to ensure no frame loss due to congestion results to be 126 024 bit times, roughly equivalent to 15.5 kB.

If MACsec is used, the High Layer Delay is incremented by 19 360 bit times; therefore, the total Delay Value results as follows:

$$DV = 2 \times (16\,160) + (672) + 2 \times (5556) + 2 \times (25\,600) + 2 \times (12\,288) + 25\,504 = 145\,384 \text{ bit times}$$

For this case, the amount of buffering needed to ensure no frame loss due to congestion results to be 145 384 bit times, roughly equivalent to 18 kB.

Annex O

(informative)

Preserving the integrity of FCS fields in MAC Bridges

O.1 Background

When relaying frames between Ports of a MAC Bridge, one of the functions of the Bridge is to regenerate the FCS field in accordance with the MAC procedures that apply to the medium access method through which the frame will be relayed. One of the requirements of the MAC Bridge standard is that any such regeneration of the FCS shall not increase the level of undetected FCS errors that are experienced on the transmitting MAC over that which would be experienced by preserving the FCS. The point at issue here is only the *undetected* error rate; a conformant Bridge will discard frames that are received with an FCS error; however, there is a finite possibility of undetectable corruption taking place, i.e., the frame is corrupted, but the FCS algorithm does not reveal the error.

This annex looks at the various cases that apply to the operation of the MAC Bridge with respect to FCS regeneration and the alternative approaches that can be taken in order to address the cases. The following cases need to be considered:

a) The source and destination media access methods are identical from the point of view of the operation of the FCS algorithm.

NOTE—This is the case, for example, where the source and destination media access methods are identical. It could also happen with dissimilar media access methods if the FCS coverage, the FCS algorithm, the definitions of the fields covered by the FCS, and the bit/octet ordering are the same in both media access methods.

b) The source and destination media access methods differ from the point of view of the operation of the FCS algorithm.
c) The data covered by the FCS is not modified by the operation of the relay function of the Bridge.
d) The data covered by the FCS is modified by the operation of the relay function of the Bridge.

In each case, it is important to ensure that there is a low probability of additional undetected errors being generated by corruption of the data portion of the frame between removal of the old FCS and computation of the new one, which would result in the transmitted frame carrying invalid data and a valid FCS. Such corruption might occur, for example, as a result of the effect of environmental noise on the operation of the Bridge hardware.

If both item a) and item c) are true, then the FCS carried in the received frame is still valid, and the ideal approach would be to reuse this value as the FCS for the transmitted frame.

If either item b) or item d) are true, then it will be necessary for the Bridge to recalculate the FCS on transmission, and may therefore need to take additional precautions against in-memory corruption causing increased undetected FCS error levels.

O.2 Basic mathematical ideas behind CRC and FCS

The standard CRC algorithm is based on the following ideas:

a) An n-bit message is regarded as a polynomial, M(x), of degree n – 1.
b) In order to generate a CRC value of length r bits, a generator polynomial, G(x), is used, of degree r
c) The value of the last r bits of M(x) are chosen such that M(x) ÷ G(x) has a remainder of 0 [i.e., M(x) = 0 mod G(x)].

Messages can be added, in which each coefficient is 0 or 1:

d) M3(x) = M1(x) + M2(x). Messages are added together by bit-wise addition (XOR) of coefficients with the same bit position (i.e., coefficients with the same exponent).

Subtraction of messages:

e) Addition and subtraction are equivalent operations (as A = A XOR B XOR B); hence, using the messages in item d) above, M1(x) can be regenerated from M3(x) by adding M2(x).

Linearity:

f) If M(x) = 0 mod G(X), then (M(x) + E(x)) = 0 mod G(x) IFF E(x) = 0 mod G(x). In other words, if an error pattern, E(x), is added to a message, M(x), then the resultant message will give no remainder when divided by the generator polynomial if both M(x) and E(x) gave no remainder when divided by the generator polynomial.
g) x^mM(x) = 0 mod G(x) IFF M(x) = 0 mod G(x). A message can be shifted by adding zero padding without affecting the integrity of the CRC.
h) Thus, the CRC algorithm has the property that it will detect any burst error, of length r bits or less, applied to the message, as such an error must result in a nonzero remainder when the message is divided by the generator polynomial. Alternatively, adding two messages together, both of which have valid CRCs, results in a message with a valid CRC.

In Ethernet, the algorithm used differs from the standard CRC, and is known as an FCS. The FCS is based on the CRC but with the following differences:

— The first 32 bits of M(x) are complemented before the FCS value is calculated.
— A CRC value is calculated, as described above, by dividing the first n – 32 bits of M(x) by G(x) and taking the remainder as the CRC value.
— The CRC value is complemented and inserted as the last 32 bits of M(x).

By application of the addition and linearity rules, item d) and item f) above, the Ethernet frame with its FCS can be viewed as consisting of the following component messages, added together:

— An n-bit message, M(x), carrying a standard CRC as the last 32 bits.
— An n-bit “FCS adjustment factor,” An(x), which adjusts the CRC to form an FCS.

Figure O-1 illustrates the conversion of a message with a CRC to the equivalent message with an FCS, by the addition of the adjustment factor. The adjustment factor consists of the following two components:

— The first component, when added to M(x), contributes an adjustment to the CRC, which is equivalent to the effect of complementing the first 32 bits of M(x) before calculating the CRC bits, and complements the first 32 bits of M(x).
— The second component, when added to the partially adjusted M(x), restores the first 32 bits of M(x) to their original value, and complements the (adjusted) CRC to form the final FCS.

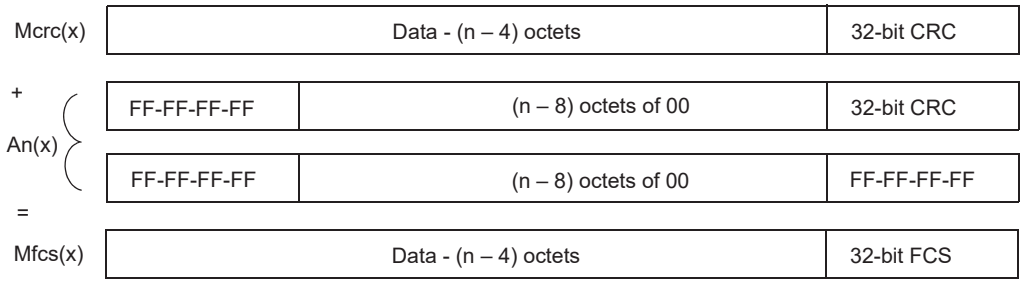

Figure O-1—Converting a CRC to an FCS

O.3 Detection Lossless Circuit approach

This approach is illustrated in Figure O-2. The basis of this approach is that the FCS used in the modified message is always recomputed from scratch using the normal FCS generation algorithm (Check Generator B); however, the original message data and FCS are also used as an input to an FCS checker (Checker A) in order to check that the inputs to the FCS generator were correct. Hence, if errors are introduced into the message while it is in memory in the Bridge in the time period since the message was received and FCS-checked, then Checker A will detect the error at the same time as the new FCS for the modified message is being generated.

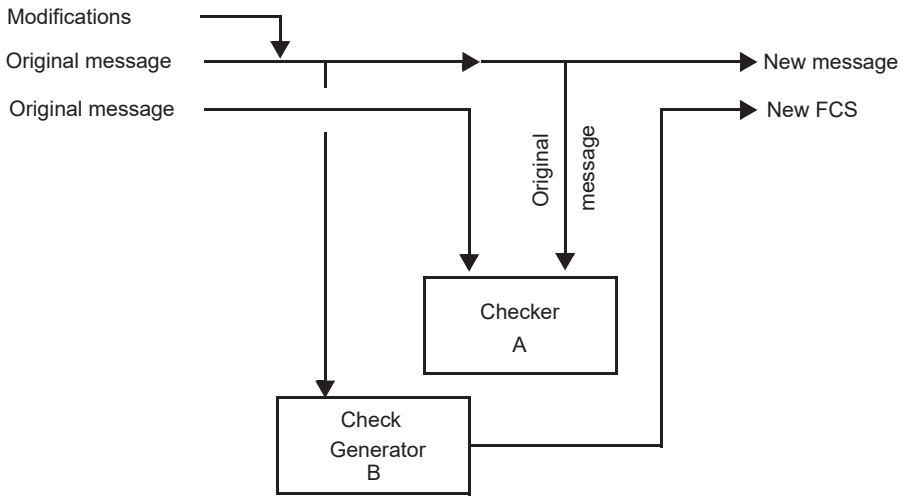

Figure O-2—Detection Lossless Circuit

Checker A is fed both with the original message in its unmodified form, and with the original message as used in the construction of the new message; this occurs after (or simultaneously with) the generation of the new FCS by Check Generator B. Any discrepancies detected by Checker A indicate that the information used to generate the new message and its FCS are suspect, and that the message should therefore be discarded.

O.4 Algorithmic modification of an FCS

In cases where the need to recalculate the FCS comes about as a result of changes to the data rather than by changes in the operation of the FCS algorithm, one option, rather than recalculating an FCS from scratch for a given message, is to examine the changes that have been made to the message and to calculate an FCS adjustment factor that reflects those changes. There are two cases, as follows:

a) The overall length of the message is unchanged, but the contents of one or more octets of data covered by the FCS have changed.
b) The overall length of the message has increased or decreased, as a result of the addition or removal of octets covered by the FCS, but the contents of the original octets is unchanged (although some may have been shifted in position as a result of the insertion/deletion).

O.4.1 Data changed, length unchanged

Adjustment of a message, $MF_1(x)$, in order to change the value of a field F from current value F_1 to new value F_2 consists of the following steps:

— Remove the FCS adjustment factor for a message of length n, An(x).
— Remove the contribution to the message and its FCS provided by the current value of the field, $F_1(x)$.
— Add the contribution to the message and its FCS provided by the new value of the field, $F_2(x)$.
— Add the FCS adjustment factor for a message of length n, An(x).

In other words,

$$MF_2(x) = MF_1(x) – An(x) – F_1(x) + F_2(x) + An(x)$$

The addition and subtraction of An(x) cancel each other out, so,

$$MF_2(x) = MF_1(x) – F_1(x) + F_2(x)$$

Also, the correction factors $F_1(x)$ and $F_2(x)$ can be replaced by a single factor, $F_3(x)$, which is the contribution to M(x) and its FCS that would be provided by the value of Field F that would be produced by F_1 XOR F_2. So,

$$MF_2(x) = MF_1(x) + F_3(x)$$

This is shown in Figure O-3.

Alternatively,

$$\text{FCS of } MF_2(x) = (\text{FCS of } MF_1(x)) + \text{adjustment}$$

where

$$\text{Adjustment} = (\text{FCS of } F_1(x)) + (\text{FCS of } F_2(x))$$

or equivalently,

$$\text{FCS of } MF_2(x) = (\text{FCS of } MF_1(x)) + (\text{FCS of } F_3(x))$$

The adjustment factor (FCS of $F_3(x)$) is incidentally the same factor that would be used if the value of F were to be changed back from F_2 to F_1.

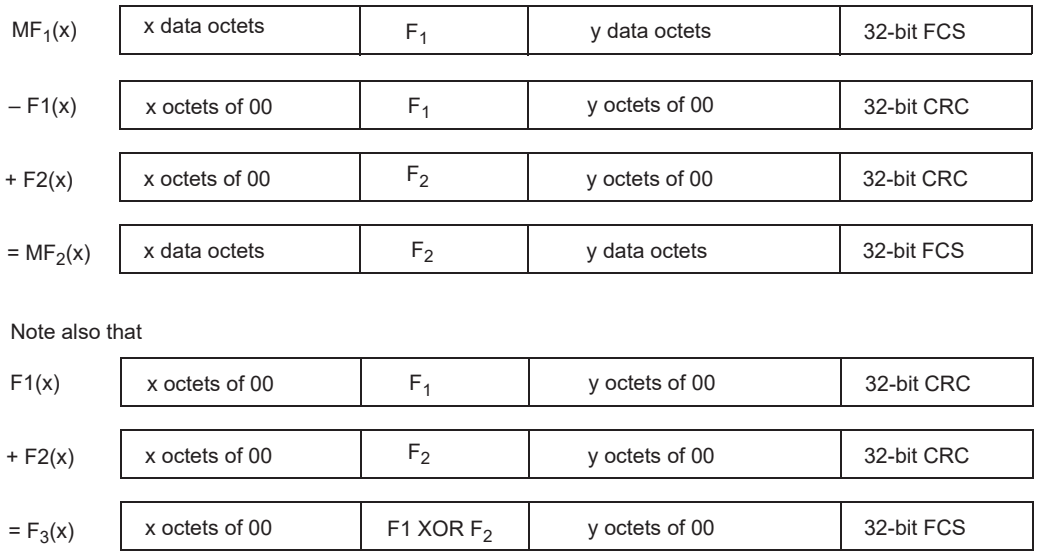

Figure O-3—Field change adjustment

The relative simplicity of this case (relative to the case where the length changes) is a consequence of linearity and the fact that the FCS adjustment factor, An(x), is constant for any given message length n, not a function of the data carried in the message.

O.4.2 Length changed, original data unchanged

Adjustment of a message M(x) of length n to cater for an inserted field, I, of length i involves the following steps:

- Remove the FCS adjustment factor for a message of length n, An(x);
- Remove the contribution to the message and FCS that is provided by the header portion of the message (the portion before the inserted field), H(x);
- Add the contribution to the message and FCS that is provided by the header plus the inserted field I, HI(x);
- Add the FCS adjustment factor for a message of length n+i, An+i(x).

So,

$$MI(x) = M(x) – An(x) – H(x) + HI(x) + An+i(x)$$

This is shown in Figure O-4.

Alternatively,

$$\text{FCS of } MI(x) = (\text{FCS of } M(x)) + \text{adjustment}$$

where

$$\text{adjustment} = (\text{CRC of } An(x)) + (\text{CRC of } H(x)) + (\text{CRC of } HI(x)) + (\text{CRC of } (An+i(x))$$

As with the field change example, the value of *adjustment* is the same adjustment factor that would be used to adjust the FCS of MI(x) if field I were to be removed from the message.

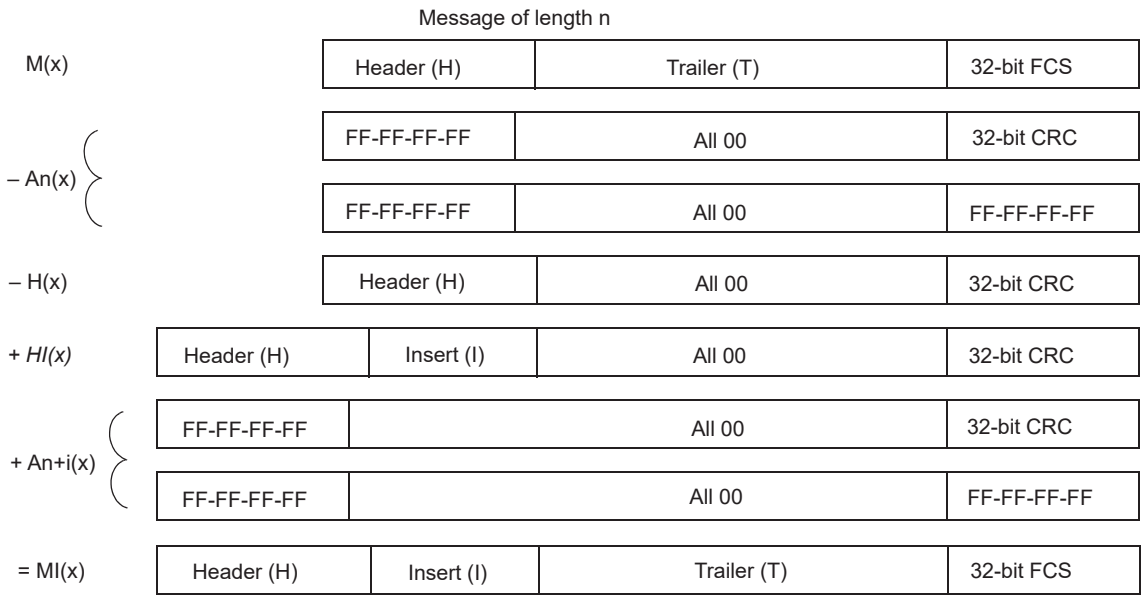

Figure O-4—Field insertion adjustment

O.4.3 Preservation of detectability

With either of the algorithmic adjustment methods described here, the important question is whether the ability of the FCS to detect errors in the message is preserved across these transformations; in other words, if a detectable error pattern, E(x), is added to the message M(x) before the modification, addition, or removal of a field, is that error still detectable after the message has been adjusted.

NOTE—The following analysis assumes that E(x) is a detectable error pattern, of length 32 bits or less. Analysis of the performance of this method with longer error patterns has not been attempted here.

In the cases where the error component is in those parts of the message that are not affected (changed or shifted) by the transformation, it is reasonably apparent that, as the transformation takes no account of the portion of the message that is in error, the detectability of that error is unchanged.

In the case of a field change, where field F_1 is to be replaced with F_2, and E(x) had been applied in some part of the message before changing the field, the new FCS value would be calculated as follows:

$$\text{FCS of } MF_2(x) = (\text{FCS of } MF_1(x)) + (\text{FCS of } F_1(x)) + (\text{FCS of } F_2(x))$$

However, the correction factor that is applied to the FCS contains components based only on F_1 and F_2, and no contribution related to the error pattern E(x). Therefore, after the value of the field has been changed to F_2, the new FCS value as calculated above will still be capable of detecting error pattern E(x), regardless of where the error pattern appears in the message.

In the case of a field insertion (or removal, as insertion and removal have already been shown to be equivalent), where E(x) has been applied to H(x), the correction factor that is applied to the FCS will contain two components related to E(x); the first based on E(x) in its original position, and the second based on E(x) shifted by i, the length of the inserted field, as follows:

$$\text{FCS of } MI(x) = (\text{FCS of } M(x)) + \text{adjustment}$$

where

adjustment = (CRC of An(x)) + (CRC of H(x)) + (CRC of HI(x)) + (CRC of (An+i(x))
+ (CRC of E(x)) + (CRC of (E(x) shifted by i))

The presence of the (CRC of E(x)) component ensures that the final message will still indicate an FCS error. (Note that, even if (CRC of E(x)) and (CRC of (E(x) shifted by i)) turn out to be the same value, the final message will still indicate an FCS error, as its FCS is now correct for the value of MI(x) without the error component.)

The above does not exhaustively analyze all the cases of field insertion and removal, and in particular, does not analyze the cases where the error pattern crosses the insertion/removal boundaries; however, it can be shown that the error detection characteristics of the FCS are preserved in these cases as well.

The conclusion from the above examples is that, as long as the field values used in the calculation of these FCS correction factors are the same as the field values present in the original and final messages (e.g., that the same value of H+E is used both in its original and shifted forms), then the properties of the FCS are preserved. However, if different values are used for calculation of the correction factor from those present in the messages (as could happen, for example, as a result of in-memory corruption), then the properties of the FCS are no longer preserved. Hence, if these algorithmic approaches are used, it is necessary to design the implementation in a manner that ensures that these conditions are met.

O.5 Conclusions

Where it is necessary to recalculate the FCS before transmission, then either the algorithmic FCS modification approaches or the Detection Lossless Circuit approach offer a basis for this to be achieved while still preserving the error detection coverage that was provided by the original FCS.

The Detection Lossless Circuit approach requires access to the entire contents of the original message, to compute the necessary FCS adjustments or to check the integrity of the data that is being used to create the new message and its FCS. In contrast, the algorithmic approach requires access only to the header, insert, and FCS of the original message.

With the algorithmic approach, care needs to be taken in the implementation in order to ensure that the inputs to the correction algorithms are consistent with the contents of the original and modified messages, whereas in the Detection Lossless Circuit, such consistency checking is inherent in the way that the original FCS is used to check the generation of the new FCS.

Annex P

(informative)

Frame duplication and misordering

Although RSTP provides a single loop-free path between communicating stations at any instant, RSTP can reconfigure the active topology of the Bridged Network in less time than it can take a frame to transit from its source to its destination(s). This annex explains how this can result in user data frame duplication and misordering and examines the possible QoS impact.

NOTE—The ForceVersion parameter provided by RSTP allows network administrators to choose slower reconfiguration, thereby trading off service availability against the risk of duplication and misordering.

P.1 Background

In a network of Bridges implementing STP, specified in the 1998 and earlier editions of IEEE Std 802.1D [B11], delays in transitioning Ports to Forwarding ensure that frames in transit prior to a network reconfiguration are delivered or discarded before being forwarded on the new active topology. In such a network, the only source of misordered or duplicated frames is a “magically healed” LAN between two Bridges, for example, as a result of accidental interconnections between shared media hubs.

RSTP, by design, can transition a Port to Forwarding very rapidly. A Root Port transition can occur as rapidly as the hardware can manage it, and a Designated Port transition in the time it takes to transmit two frames from separate stations on a single LAN. It is conceivable that a reconfiguration can take place, and a Port be made Forwarding as a result, while frames forwarded on the prior active topology are still in transit.

P.2 Frame duplication

A unicast frame whose destination address has been learned by the Bridges that can forward it, can only be buffered for transmission on one Port of one Bridge at any one time, and cannot be duplicated.

A unicast frame whose destination address has not been learned, can be flooded by some Bridges, and therefore buffered on multiple outbound Ports at the same time, and can be duplicated during network reconfiguration. Figure P-1 provides an example. In this network fragment, the Root Bridge is assumed to be somewhere to the left of Bridge A’s Port A1, and the Port Path Costs of the three Bridges result in the active topology shown, with Port B3 Discarding and the remaining Ports all Forwarding.

If the configuration is stable, a unicast frame arriving at A1 and destined for an unlearned unicast destination reachable through B2 is flooded by Bridge A to its Ports A2 and A3, and by Bridge C to its Ports C2 and C3. As B3 is Discarding, only the frame reaching B1 is transmitted through B2, and the destination receives a single copy of the frame.

During reconfiguration the following sequence of events can occur:

a) A receives the frame through A1 and transmits copies of it through A2 and A3.
b) B and C each receive a copy and queue them for transmission through B2, C2, and C3.
c) B2 transmits its copy of the frame to its destination.
d) B detects that LAN A2-B1 has failed, and immediately makes B3 Forwarding as its new Root Port.
e) C2 transmits its copy of the frame, B receives and transmits this second copy through B2.

The destination station, reachable through B2, receives the same frame twice. However, any subsequent response from the destination station would cause the address to be learned. While this reconfiguration will itself cause addresses to be flushed from the Bridge's FDBs of Bridges, the flushing commences after the Port becomes Forwarding, and will not increase frame duplication unless there are further changes in the active topology.

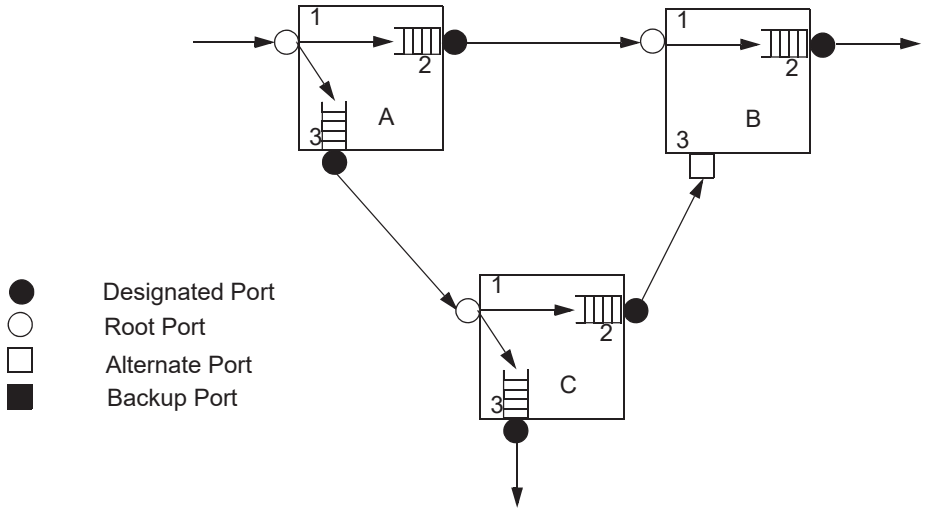

Figure P-1—Frame duplication scenario

Multicast frames are all potentially subject to duplication on reconfiguration events, as they can be buffered at multiple outbound Ports. Frame duplication does not cause problems in known multicast LAN protocols.

The risk of frame duplication depends upon network configuration, frequency of reconfiguration, equipment implementation details, and the characteristics of the network traffic that determine how long each frame is likely to be buffered in each Bridge, and therefore cannot be quantified without reference to the a particular network.

P.3 Frame misordering

A change in the active topology between two communicating end stations can result in frame misordering, as a frame sent after reconfiguration can experience a lower transit delay, being queued at fewer Bridge Ports or for less time. Figure P-2 provides an example. In this network fragment a station connected to A1 is communicating with a station connected to B2. Prior to reconfiguration, A2 is an Alternate Port and is Discarding; all traffic between the two stations is relayed by Bridge C. During reconfiguration the following sequence of events can occur:

a) Frame F1 is received through A1, buffered and transmitted through A3, received through C1 and buffered awaiting transmission through C2.
b) A detects that LAN A3-C1 has failed, and immediately makes A2 Forwarding as its new Root Port.
c) Frame F2 is received through A1, transmitted through A2 to B1, and then transmitted through B2.
d) F1 is transmitted through C2 to B3, and then transmitted through B2.

Clearly, the receiving station connected to B2 sees the frames in the reverse of the order in which the originating station transmitted them.

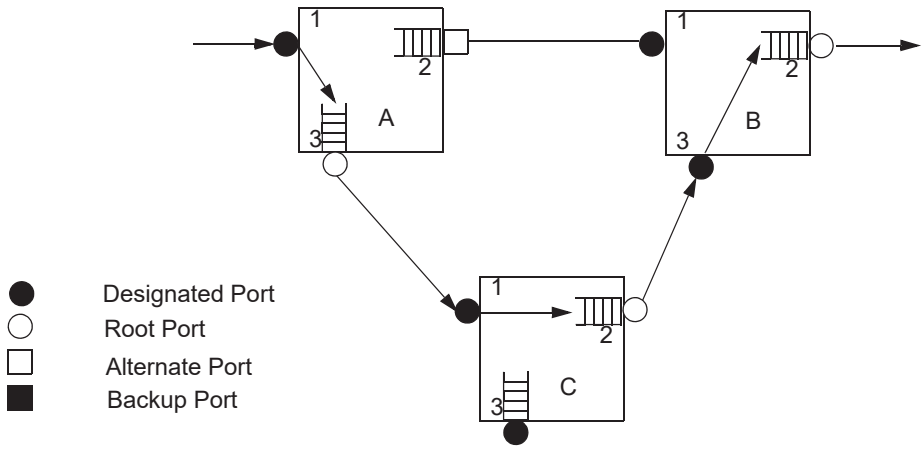

Figure P-2—Frame misordering scenario

As with frame duplication, the overall risk of frame misordering depends upon network configuration, frequency of reconfiguration, equipment implementation details, and the characteristics of the network traffic that determine how long each frame is likely to be buffered in each Bridge, and therefore cannot be quantified without reference to the a particular network.

Some LAN protocols, for example LAT, LLC2, and NETBEUI, are sensitive to misordering, so even a low incidence of misordering could result in perceived problems in networks that support these protocols.

P.4 Other considerations

The possibility that frames may be stored “in transit” on old routes after a reconfiguration has completed means that there is also a possibility that addresses will be mis-learned, leading to a risk of denial of service for the addresses concerned. Hence, it is necessary to run short aging timers for a period after a reconfiguration to allow such frames to be delivered or discarded.

The Bridge model described in this standard does not include the concept of queuing on input to a Port; however, practical Bridge designs generally include some input queuing. While this is not a solution to the effects described above, a Bridge should flush any input queue associated with a Port that becomes Disabled. This behavior is consistent with the Bridge model; if a frame is in an input queue, it has not been received as far as the Bridge Port is concerned, and therefore should not be received after the Port becomes Disabled.

Annex Q

(informative)

Traffic scheduling

This annex provides some background to the mechanisms provided in this standard for traffic scheduling, with the intent of providing some insight into the motivation for the provision of mechanisms for traffic scheduling and some of the ways that the mechanisms might be used.

Q.1 Motivation

Some applications have a need for frame delivery that is highly predictable in terms of the time at which frame transmission will occur, and the overall latency and jitter that will be experienced as the frame is propagated to its destination. Examples include industrial and automotive control applications, where data transmitted over the network is used to feed the parameters of control loops that are critical to the operation of the plant or machinery involved, and where frames carrying control data are transmitted on a repeating time schedule; late delivery of such frames can result in instability, inaccuracy, or failure of the operation of the control loops concerned. In some implementations, this need has been met by the provision of dedicated, highly engineered networks that are used solely for the transmission of time-critical control traffic; however, as the bandwidth occupied by such traffic is often low, and the cost of providing a dedicated control network can be high, it can be desirable to mix time-critical traffic with other classes of traffic in the same network, as long as such mixing can be achieved while still meeting the timing requirements of the time-critical traffic.

Prioritization alone is insufficient to address the needs of this kind of traffic; if a low priority frame is already being transmitted, then that transmission will complete before a higher priority frame can access the transmission medium, so there could be a delay of up to a maximum-sized frame before a high priority transmission can start. If such delays occur at every hop, then the accumulated latency could be unacceptably large.

Interfering traffic can itself be time-critical; for example, there could be multiple time-critical traffic streams related to different control systems. The ability to coordinate different time-critical traffic streams in such a way that they do not interfere with each other is also important.

One approach to meeting these objectives is to ensure that, at specific times, only one traffic class (or set of traffic classes) has access to the network; in effect to create a protected “channel” that is used by that traffic class alone. However, in order to ensure that the remaining unprotected traffic cannot affect the transmission of protected traffic, it is necessary to stop the transmission of unprotected traffic sufficiently far in advance of the protected time slot to be certain that the last unprotected transmission has completed before protected transmission starts. In the worst case, this would mean that the last unprotected transmission would start a maximum-sized frame transmission time before the start of the protected traffic “window.” In effect, a guard band is created before the time that the protected traffic transmission is due to start; transmission of unprotected traffic is not permitted between the start of the guard band and the start of the protected traffic window. The simplest approach is for the guard band to be as long as a maximum-sized frame transmission; however, the start of the guard band need not be fixed if the implementation is able to determine, from the size of the frames that it has queued, that there is sufficient time for a frame to be transmitted in its entirety before the start of the protected traffic window. This approach is illustrated in Figure Q-1. If the simple approach were taken, then the time difference between T0 and T1 would be equal to the transmission time of a maximum-sized frame on that port (Figure Q-1, part A); if the implementation is able to determine frame transmission times on the fly, then T0 could vary between a maximum frame transmission time before T1 and a minimum frame transmission time before T1, depending upon what unprotected frames were available for transmission on the Port (Figure Q-1, part B).

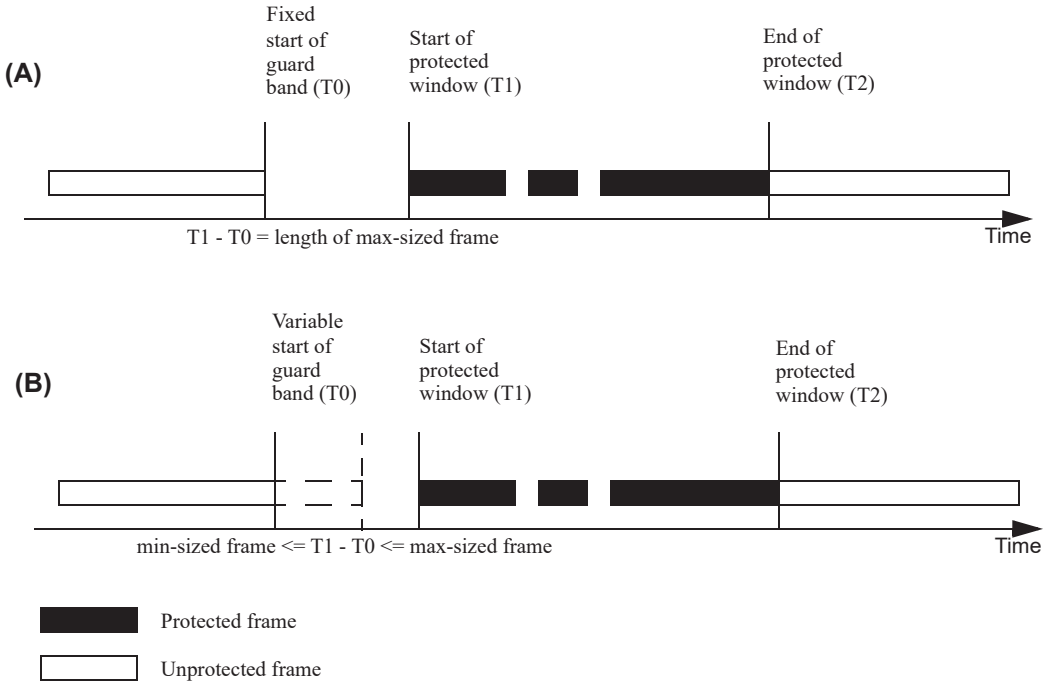

Figure Q-1—Establishing a guard band

Q.2 Using gate operations to create protected windows

The enhancements for scheduled traffic described in 8.6.8.4 allow transmission to be switched on and off on a timed basis for each traffic class that is implemented on a port. This switching is achieved by means of individual on/off transmission gates associated with each traffic class and a list of gate operations that control the gates; an individual SetGateStates operation has a time delay parameter that indicates the delay after the gate operation is executed until the next operation is to occur, and a GateState parameter that defines a vector of up to eight state values (open or closed) that is to be applied to each gate when the operation is executed. The gate operations allow any combination of open/closed states to be defined, and the mechanism makes no assumptions about which traffic classes are being "protected" and which are "unprotected"; any such assumptions are left to the designer of the sequence of gate operations. The sequence of gate operations terminates at the end of the list, and restarts when OperCycleTime (8.6.9.4.19) nanoseconds have elapsed since the start of the sequence, thus providing a repeating cycle of gate state changes. If OperCycleTime is shorter than the total execution time of the sequence of operations, the sequence is truncated and restarted at OperCycleTime.

There is no necessity to explicitly define the start of a guard band, as the specification of how the gates operate states that a frame for a given traffic class can only be transmitted if the gate associated with that traffic class is open and there is sufficient time for the whole of the frame to be transmitted before the gate is due to close. Figure Q-2 illustrates how gate operations could be used to create a protected window for traffic class 3 in order to achieve the result illustrated in Figure Q-1. A SetGateStates operation at time T1 sets the state of the gates for traffic classes 7, 6, 5, 4, 2, 1, and 0 to closed (C) and sets the state of the gate for traffic class 3 to open (o), so only traffic class 3 can transmit after T1. At time T2, the SetGateStates operation reverses the state for all eight traffic classes, so traffic class 3 can no longer transmit after T1, but all other traffic classes can.

There is no need to explicitly define the position of T0, because the "guard band" behavior is inherent in the defined behavior of the gates, as previously stated.

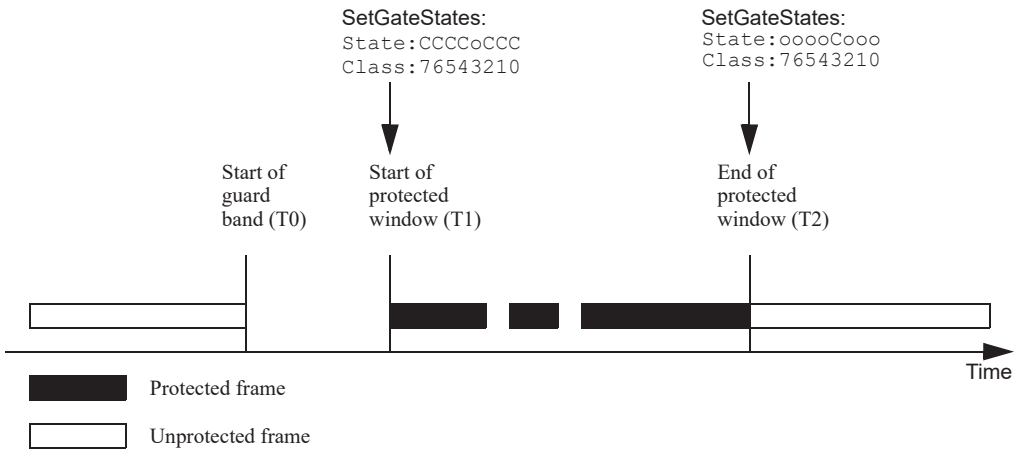

Figure Q-2—Using gate operations

Q.3 Availability of PTP

The timing of gate operations as specified in 8.6.8.4 assumes that PTP is operating and therefore PTP time is available to the Bridge or end station. However, that is clearly not the case on initial startup or when PTP communication is interrupted for some reason; particular implementations could also choose to use alternative (non-PTP) mechanisms for ensuring that a common view of time is available across a number of systems. The approach adopted in these circumstances will be heavily dependent on the application, and so is an implementation choice; the mechanisms described in 8.6.8.4 are not themselves affected by that choice.

Q.4 Scheduled traffic and end stations

It is possible for Bridges to support the enhancements for scheduled traffic while end stations connected to those Bridges do not. In general, the scheduling mechanism is not needed in end stations that are only recipients of scheduled traffic.

Q.5 CycleTimeExtension variables

The AdminCycleTimeExtension (8.6.9.4.4) and OperCycleTimeExtension (8.6.9.4.20) state machine variables provide a means for an operator to control how a new gating cycle is configured into a system that is already running an existing gating cycle.

If the choice of cycle time for the new gating cycle (AdminCycleTime) is unchanged from the cycle time for the old gating cycle (OperCycleTime), and if the base time chosen for the new gating cycle (AdminBaseTime) is an integer multiple of the OperCycleTime different to OperBaseTime, then the new gating cycle will exactly “line up” with the old gating cycle, i.e., the cycle start times for the new gating cycle will be the same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues.

However, if AdminCycleTime differs from OperCycleTime, and/or AdminBaseTime is in the future and is not an integer multiple of OperCycleTime different to OperBaseTime, then the old and new cycles do not line up, and when AdminBaseTime is reached (i.e., when the new configuration is installed and starts to execute), the last old cycle would normally be truncated in order to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The CycleTimeExtension variables allow this extension of the last old cycle to be done in a defined way; if the last complete old cycle would normally end less than OperCycleTimeExtension nanoseconds before the new base time, then the last complete cycle before AdminBaseTime is reached is extended so that it ends at AdminBaseTime.

Annex R

(informative)

Preemption and IEEE 802.1AE MAC Security

This annex answers questions about the use of MAC Security (MACsec) that arose in the development of the IEEE Std 802.1Qbu (Frame Preemption) amendment to this standard. It provides background for readers not familiar with MACsec. For the normative specification of MACsec and its supporting authentication and key management framework refer to IEEE Std 802.1AE and IEEE Std 802.1X.

NOTE—While these issues arose during development of preemption, they can also apply to other situations, such as a customer link running MACsec over a provider bridged network.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptible) frame, the preemptible frame transmission being resumed and completed once the express frame(s) have been transmitted. A preemptible frame can thus be broken into two or more fragments. A MACsec Cipher Suite implementation can protect each frame in its entirety before requesting its transmission, or can transmit the octets of the protected frame as soon as they are made available by the operation of the block by block symmetric cryptography. The latter is often preferred as it reduces the delay due to protection, and some implementations impose a constant delay in support of time-sensitive networking objectives. Similarly validation of a received frame can be delayed until its reception is complete, or can proceed as each block of octets becomes available. These implementation details lie outside the normative scope of IEEE Std 802.1AE, but naturally give rise to questions as to how frames should be protected when they are fragmented, particularly when the symmetric keys used to protect frames are being changed.

Each time a Cipher Suite's symmetric cryptography is used to protect a frame with a given key, a unique value, known as a 'nonce' or IV (initial value), has to be included in the computation. A PN (packet number) that is incremented for each frame transmitted forms part of the MACsec IV. A replayProtect control with a configurable replay window allows the receiver to use the PN to protect against misordered, replayed, and much delayed frames. A frame whose PN value is less than the highest received with a successfully validated frame (from the same source, protected by the same key) minus the replay window size is discarded. Setting the replay window size to zero and enabling replayProtect enforces strict replay protection, no out of order or replayed frames are accepted. The transmitter of each MACsec frame is identified by a Secure Channel Identifier (SCI), and the Secure Channel (SC) that allows it to communicate securely with its peers in a secure Connectivity Association (CA) is supported by a sequence of Secure Associations (SAs). Each SA is replaced by its successor when its associated secret Secure Association Key (SAK) can no longer be used, either because all or most of the PN space has been used with one of the SAs in the CA, or because the network administrator has a security policy that mandates regular key changes (often once a week). New SAs and SAKs are also required after reauthentication and reauthorization, when the (possibly changed) members of a CA acquire a fresh secure Connectivity Association Key (CAK), the shared secret key whose possession permits participation in the CA and that is used by the MAC Security Key Agreement protocol (MKA) to identify the CA members to each other and to distribute SAKs.

MACsec connectivity is not interrupted or delayed by SA and SAK changes. The SCI and the Association Number (AN), a two-bit circular sequence number that identifies the SA within the SC, are communicated by the MAC Security TAG (SecTAG) and form part of the IV. Their values thus have to be decided and encoded in the frame to be transmitted prior to encipherment. The MACsec operational and management models reflect the fact that, at any instant, the frame whose SecTAG is currently being encoded can be using a different SA and SAK than the frame currently being cryptographically processed. This accommodates implementations that buffer user transmit requests for performance or implementation reasons (e.g., to allow parallel processing). A transmit SA/SAK is not deleted until sometime after it has ceased to be used. Similarly an implementation that is enciphering a preemptible frame block by block can suspend its

cryptographic operation, encipher an express frame that has been assigned to a subsequent SA, and resume processing the preempted frame using the IV already encoded, the SAK identified by the SCI and AN for that IV, and the intermediate results produced by the Cipher Suite up to the point that the frame was preempted. The Integrity Check Value (ICV) generated, and appended to the MACsec protected frame, protects the entire frame. An attacker cannot omit a fragment or substitute one for another. The ICV also has exactly the same value that would be obtained by protecting the entire frame prior to transmitting any of its octets, which is important for reasons that go beyond facilitating interoperability between different styles of implementation. While MACsec protects communication between neighboring peer users of the MAC Service, those service instances can be supported by bridging at a lower layer. Communication between two C-VLAN Bridges can be supported by individual LANs connected by TPMRs, or by S-VLAN Bridges, for example. The receiving MAC Security Entity (SecY) that validates a preemptible frame can receive it in fragments that differ from those transmitted by the port and SecY that originally protected the frame, and is not necessarily aware that the received frame was fragmented en-route. The first of two TPMRs supporting a link between two C-VLAN Bridges (for example) might reassemble all received frames prior to forwarding, thus allowing express frames to overtake preemptible frames on the link connecting the TPMRs without fragmenting the latter.

Just as the use of an SA can be overlapped with the use of its successor on transmission, each receive SA and its successor are enabled for reception for 3 seconds after an MKA Key Server tells the other member(s) of the CA to start transmitting using a new SAK and SA(s). Thus the receipt of an express frame protected with a new SAK does not preclude the receipt and validation of a preempted frame, protected with the prior SAK, after its final fragment (including the protected frame's ICV) has been received.

IEEE Std 802.1AE describes the use of MACsec in a number of different systems, interface stacks, and interworking scenarios. When MACsec is used to secure connectivity across a provider network, the protected frame can be priority-tagged (6.13) so the provider can forward frames of different priorities appropriately, even if the contents of those frames is otherwise confidential, and they can be received and validated out of order just as they might be if some frames had been preempted en-route. The receiving SecY's replay window size can be managed to accommodate these frames, though it is not always easy to determine or predict an optimal value for the size of replay window that is needed. MACsec's strict replay protection can also be retained by assigning transmitted frames for different service access priorities (or for express and preemptible frames) to different SCs, each supported by its own sequence of SAs. From the point of view of a receiving SecY, the separate SCs behave just as if they had been transmitted by separate SecYs. IEEE Std 802.1AE allows the choice of SCI and access priority[64] to be determined by the frame's user priority.[65] (See Seaman [B59].)

[64] The priority value accompanying the service request made at the SecY's lower Common Port to transmit the protected frame.
[65] The priority value provided by the service request, to protect and transmit the frame, made at the SecY's upper Controlled Port.

Annex S

(informative)

Preemption and scheduled traffic

The enhancements for scheduled traffic specified in 8.6.8.4 and the support for frame preemption specified in 6.7.2 and 8.6.8 can be used individually or in combination in order to provide different degrees of protection to "time-sensitive traffic" from interference caused by traffic with less stringent timing requirements. The choice of which features to use, and in what combination, will depend upon the latency and jitter requirements of the application concerned. There are four permutations of interest. They are as follows:

a) Scheduling used in isolation (S.1)
b) Preemption used in isolation (S.2)
c) Scheduling and preemption used in combination, but without use of HOLD and RELEASE (S.3)
d) Scheduling and preemption used in combination, with use of HOLD and RELEASE (S.4)

NOTE—As the only MAC standard for preemption at the time this annex was developed was IEEE Std 802.3, it reflects constraints that exist in that particular approach to preemption.

S.1 Scheduling used in isolation

This subject is dealt with in Annex Q.

S.2 Preemption used in isolation

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame, the preemptable frame transmission being resumed and completed once the express frame(s) have been transmitted.

The ability to designate one or more priority as express (and the remaining priorities as preemptable) means that, when an express frame is ready for transmission and a preemptable frame is already in the process of being transmitted, the delay before the express frame transmission starts is at worst 123 octet times and will often be 64 octet times or less. Preemption, used without scheduling, is therefore a useful tool for reducing the jitter experienced by time-sensitive frames. These frames could be transmitted using any of the available transmission selection algorithms (Table 8-6), but the likely choice would be an algorithm that is intended for use with time-sensitive data, such as the credit-based shaper (8.6.8.2). In common use cases, it would be expected that express traffic would have a higher priority than preemptable traffic.

NOTE 1—IEEE Std 802.3 defines a minimum final fragment size of 64 octets and allows the receiver to request that any non-final fragments are larger than this by 0, 64, 128, or 192 octets. Therefore, the minimum non-final fragment size is 64, 128, 192, or 256 octets, depending upon the non-final fragment size stipulated by the receiving MAC. For the purposes of the discussion in this annex, it is assumed that the minimum non-final fragment size selected is 64 octets.

NOTE 2—The 123 octet times worst-case delay is because non-final fragments have to be 64 octets in length, including the mCRC that is added by the MAC Merge sublayer, so a fragment that is 124 (60 + 64) octets in length can be preempted, but a fragment that is 123 or fewer octets in length cannot be preempted. This occurs when transmission has just started for a fragment of a frame with less than 124 octets left to transmit, or for a preemptable frame of less than 124 octets in total. The more likely case is that the delay would be between 0 and 64 octet times. The actual delay experienced also has to take account of the extra overheads imposed by the need for preamble, start of frame delimiter (SFD), inter-frame gap (IFG), and the latency of the MAC itself.

It should be noted that, other things being equal, designating a priority as "express" effectively increases its priority above that of any priority designated as "preemptable". Also, in cases where the number of traffic

classes supported on a port is less than 8, all priority values that map to the same traffic class should have the same designation (all express or all preemptable).

If preemptable and express priorities are assigned to the same traffic class, an express frame might not be able to preempt a preemptable frame that is ahead of it in the queue.

S.3 Scheduling and preemption used in combination, no HOLD/RELEASE

The discussion of scheduling in Annex Q points out that there is no need for an explicitly scheduled "guard band" when using the scheduling mechanism in isolation, because the specification of the operation of the transmission gates is such that, in a conformant implementation, a frame cannot start transmission if the transmission gate for its traffic class is due to close before transmission of the frame would complete. However, the requirement not to transmit a frame if transmission cannot complete before the gate closes means that, depending upon the size of frames in the queue, there would be a significant length of time during which frames cannot be transmitted.

If the schedule that applies to the preemptable traffic classes was designed to allow preemptable traffic to be transmitted at any time (i.e., there is no "gate close" event for the preemptable traffic), then preemptable frame transmission can occur at any time up to the start of an express transmission, and depending upon the timings, can continue up to 123 octet times after the express traffic gate opens. This dramatically reduces the delay experienced by preemptable traffic, at the expense of increasing the delay experienced by express traffic. While that may be acceptable for some applications, it is clearly not acceptable for applications where it is desired to reduce or remove any delay experienced by express frames.

S.4 Scheduling and preemption used in combination with HOLD/RELEASE

The HOLD and RELEASE mechanism provided by preemption (6.7.2, 12.30.1) allows an explicit "guard band" to be implemented around a protected transmission window, but one that is rather smaller than would otherwise be needed. As with S.3, this scenario assumes that the preemptable traffic's gate is scheduled to be open at all times. If an MM_CTL.request(hold_req) primitive is scheduled 124 octet times before the express traffic window opens, then preemptable frame transmission can start up to 124 octet times before the start of the protected window, and can potentially continue up to (but not beyond) the start of the window.

The result of using scheduling, HOLD/RELEASE and preemption in combination is that the express traffic's protected window can be completely protected from interference from preemptable traffic, while at the same time reducing the impact of the protected window on the amount of bandwidth that is available to preemptable traffic.

A further reason to use HOLD and RELEASE is that a schedule will often be intended for a string of express frames to be sent within an open window. If HOLD/RELEASE is not used and there is a greater than IPG gap between transmitting express frames (e.g., because of minor jitter in there arrival time), a preemptable frame or fragment could be started between express frames and cause up to 124 octets of latency in the middle of the string of express frames. Using HOLD ensures that this will not happen.

S.5 Bandwidth allocation and express traffic

The implementation of preemption in an IEEE 802.3 MAC (see IEEE Std 802.3) does not enforce a limit on how long a preemptable frame can be preempted by express traffic. This is at odds with the following:

a) Transit delay requirements of a bridge, if there is any preempted traffic present.
b) The impossibility, as shown by queuing theory, of arranging express traffic to occupy exactly 100% of the available bandwidth in the absence of unbounded queues.

For effective use of preemption, system-wide mechanisms, such as bandwidth allocation, must operate so as to keep the bandwidth allocated to express traffic below 100% as judged on timescales comparable to the delays tolerated by time-sensitive traffic.

The fact that preemption can add delay that is invisible to transit delay protection could be addressed by schedules being set such that express traffic windows are short enough and gaps between them are short enough that the worst case time to send a preemptable frame is much less than transit delay requirements. For example, if transit delay is one second, the time between express windows is greater than the maximum transmission time for a single frame, and express window size is small compared to one second (e.g., <50 ms), then preemption will not add significantly to worst-case transit delay.

For preemption without scheduling, there is no guarantee on the added latency, but that alternative should be used when the volume of express traffic is expected to be small. If the express traffic is using a shaper, such as the credit-based shaper, that could put a similar reasonable bound on transit delay.

Annex T

(informative)

Cyclic queuing and forwarding[66]

T.1 Overview of CQF

Cyclic queuing and forwarding (CQF) is a method of traffic shaping that can deliver deterministic, and easily calculated, latency for time-sensitive traffic streams. As the name implies, the principle underlying CQF is that stream traffic is transmitted and queued for transmission along a network path in a cyclic manner. Time is divided into numbered time intervals *i*, *i*+1, *i*+2, ... *i*+*N*, each of duration *d*. Frames transmitted by a Bridge, *Alice*, during time interval *i* are received by a downstream Bridge, *Bob*, during time interval *i* and are transmitted onwards by *Bob* towards Bridge *Charlie* during time interval *i*+1, and so on. A starting assumption is that, for a given traffic class, all Bridges and all end stations connected to a given bridge have a common understanding (to a known accuracy) of the start time of cycle *i*, and the cycle duration, *d*.

Frames transmitted by *Alice* during interval *i* are transmitted by *Bob* in interval *i*+1; the maximum possible delay experienced by a given frame is from the beginning of *i* to the end of *i*+1, or twice *d*. Similarly, the minimum possible delay experienced is from the end of *i* to the beginning of *i*+1, which is zero. More generally, the maximum delay experienced by a given frame is:

$$(h+1) \times d$$

and the minimum delay experienced by a given frame is:

$$(h-1) \times d$$

where *h* is the number of hops.

This illustrates the attraction of CQF as a technique for handling time-sensitive traffic; the latency introduced as a frame transits the network is completely described by the cycle time and the number of hops, and is unaffected by any other topology considerations, including interference from other non time-sensitive traffic. This only holds, however, if frames are kept to their allotted cycles; if, for example, some of the frames that were expected to be received by *Bob* during cycle *i* do not appear until cycle *i*+1 has started, then the stated assumptions about maximum latency calculation no longer hold. Careful choice of cycle times, alignment of cycle times among the Bridges in the network, and the timing of first and last transmissions within a cycle are required in order to ensure that the desired latency bounds are achieved.

Any delays through a particular intermediate relay (for example, *Bob*) do not affect the end-to-end delay so long as *Bob's* performance does not affect the correct assignment of frames to time intervals.

Since one of the goals for the handling of time-sensitive streams is zero frame loss (assuming that no unrecognizable non-conformant traffic is present), it is prudent to assume that reception is continuous—a frame received by a downstream system will always be assigned to one interval or another. This places most of the burden of correct interval assignment on the transmitting system; frames should not be transmitted if incorrect interval assignment is possible upon reception. It is therefore necessary to define the anticipated (and accommodated) errors in reception assignment with respect to the point in interval time, *t,* where interval *i*–1 becomes interval *i*. A relay (such as *Bob*) can of course choose when to start reception assignment to *i* in relation to *t*; it is assumed that *Bob's* intent is that the earliest frame to be assigned to *i* is the first whose very last octet (or other frame transmission encoding symbol) is still on the transmission medium (or other definable external event to what is considered to be *Bob* reference point) at *t*, thus placing any accommodation of known implementation dependent delays within *Bob* under *Bob's* control.

[66] In early discussions, CQF was known as the "Peristaltic Shaper" [B64].

While *Bob* attempts to start *i* reception with a frame coming off the medium at *i*, and may factor known and repeatable internal delays into the way he goes about that intent, his actual start time depends on:

a) The error in *Bob's* time sync (i.e., the error in his determination as to when *t* actually occurs).
b) The maximum deviation (jitter) in *Bob's* use of that time.
c) Additional delays that *Bob* does not account for, such as delays in selecting the output queue to be used for *i.*

Alice has to stop transmitting frames for *i*–1 before *t*, by a time that is the sum of *Bob's* possible early start of *i* as a consequence of a) through c), and the following:

d) The error in *Alice's* time sync (i.e., the error in her determination as to when *t* occurs).
e) The maximum deviation (jitter) in *Alice's* use of that time.
f) The time between *Alice* deciding to commit a frame for transmission and the appearance of the last octet/symbol "on the medium" at *Alice's* end.
g) The length of "the medium" in transmission time, i.e., the time for the last octet/symbol to leave *Alice* and reach *Bob*, including any consideration of the effect of interfering frames or fragments.

The description of CQF in terms of a number of consecutive intervals (as opposed to their support by "odd/even" queues, as discussed in T.2 onwards) gives easy answers to what to do with traffic still queued when its selected transmission interval has expired—discard it, or mark it down (discard eligible or priority change) and generate an alarm. In an environment where the stream bandwidth is allocated appropriately (i.e., the bandwidth allocated per time interval is less than can be received/transmitted in the chosen interval duration), this will be a rare occurrence, the traffic that follows will be conformant, and the overall system performance will be recoverable.

The discussion so far has assumed that all link speeds are the same; however, the situation becomes more complicated when links of different speeds are considered. One typical arrangement might comprise low speed links at the start and end of the path (network periphery to periphery), another with the high speed towards one end (periphery to core or vice versa). Taking the first of these, and placing *Alice* at the first transition from slow to fast, *Bob* as her fast neighbor, *Charlie* as his fast neighbor, and *Donald* at the transition from fast to slow, the important thing (treating the fast core of the network as a CQF black box) is that all conformant traffic received by *Alice* in interval *i* (say) is transmitted by *Donald* in a later interval *i*+*n*. A number of internal arrangements might be made between *Alice*, *Bob*, *Charlie*, and *Donald* to make this happen and would be valid from an external CQF perspective. It is also possible to consider fractional *n*, where *n* is still > 1, as *Alice* may need to collect the entirety of any slow cycle before transmitting that in a more compressed burst into the rest of the fast network. More complex possibilities are equivalent to redefining the slow cycle time. Some of the less elaborate possibilities for the use of links of different speeds are discussed in T.5.

T.2 An approach to CQF implementation

In essence, the approach involves the use of two transmission queues and a cycle timer. During even numbered cycles (intervals), queue 1 accumulates received frames from the Bridge's reception Ports (and does not transmit them), while queue 2 transmits any queued frames from the previous odd-numbered cycle (and does not receive any frames). During odd-numbered cycles, queue 2 accumulates received frames from the Bridge's reception Ports (and does not transmit them), while queue 1 transmits any queued frames from the previous even-numbered cycle (and does not receive any frames). With appropriate choice of receive and transmit cycle times (see T.5), such that, for any given stream, the cycle is at least long enough to accommodate all of the time-sensitive traffic that will need to be transmitted on the Bridge Port during the class measurement interval for that stream (see 34.6.1.1, also known as the observation interval in IEEE Std 802.1BA™ [B9]), plus a maximum-sized interfering frame (or frame fragment, if preemption is supported), then all of the stream's traffic will be accumulated during the cycle time in queues that are in receive mode, and it will all be transmitted during the cycle time when the queues switch to transmit mode.

CQF is implemented by configuring a combination of the stream gate control mechanisms defined in 8.6.5.4 and the traffic scheduling mechanisms defined in 8.6.8.4 and 8.6.9. Per-stream filtering is used to direct received frames to one of a pair of outbound queues on a timed basis, determined by the cycle time of the per-stream filter, and traffic scheduling is used to ensure that frames are transmitted from the appropriate queue using the same cycle time, as described in the rest of this annex.

T.3 Use of Per-Stream Filtering and Policing for CQF

The first step in establishing the filtering and queuing structures needed for CQF is to set up one or more stream filters (8.6.5.3) and a stream gate instance (8.6.5.4) that will be receiving incoming time-sensitive frames. The stream filter(s) are configured so that all time-sensitive frames received on a given Port are directed to the same stream gate instance; in turn, the stream gate instance is configured so that the internal priority value (IPV) associated with the time-sensitive frames will direct them to one of two outbound queues on a timed basis. The use of the IPV allows this direction of frames to outbound queues to be independent of the received priority, and also does not affect the priority associated with the frame on transmission.

T.3.1 Stream filter configuration

The simplest stream filter configuration would be achieved where the same priority is used for all time-sensitive frames (and this priority is not used for any other frames); for example, the default priority assigned to SR class A (see Clause 34) could be used, in which case, the priority associated with the time-sensitive frames would be 3. The parameters that would define the stream filter for the time-sensitive frames would then be as follows:

a) The *stream_handle specification* would take the wild-card value.
b) The *priority specification* would take the priority value 3.
c) The *stream gate instance identifier* would take the value of the instance identifier for the stream gate (T.3.2).
d) In the simplest case, there would be no further per-stream classification and metering operations (8.6.5.2); however, these could be added as appropriate, for example if the maximum SDU size (8.6.5.3.1) for the time-sensitive traffic is bounded at a value less than the maximum SDU size for the medium.

This stream filter configuration results in all frames that carry a priority value of 3 being submitted to the stream gate. As the operation of stream filters is such that received frames that do not match a stream filter are handled as if subsequent per-stream classification and metering operations were not implemented, there is no need for further stream filter configuration to handle frames that carry priorities other than 3 unless there are other filtering or gating decisions that need to be taken for such frames.

T.3.2 Stream gate configuration

The *stream gate instance* (8.6.5.4) needed to support the stream filter described in T.3.1 has a *stream gate control list* that contains two entries, each containing a SetGateAndIPV operation, with parameters as follows:

1) StreamGateState = *open*, IPV = 7, TimeInterval = T
2) StreamGateState = *open*, IPV = 6, TimeInterval = T

This control list has the effect of directing any traffic that passes the stream filter specified in T.3.1 to one of two different outbound queues (assuming that the outbound Ports support 8 queues, and that the default assignments for priorities to traffic classes follows the recommendation shown in Table 34-1); in the first time interval T, traffic is directed to queue 7, in the second time interval T, to queue 6, in the third time

interval to queue 7, in the fourth time interval, to queue 6, and so on. The choice of time interval T is discussed in T.5; the cycle time (OperCycleTime, see 8.6.9.4.19) for the stream gate state machines would need to be set to 2T in order to accommodate the sum of the time intervals for the two gate operations. See Figure T-1.

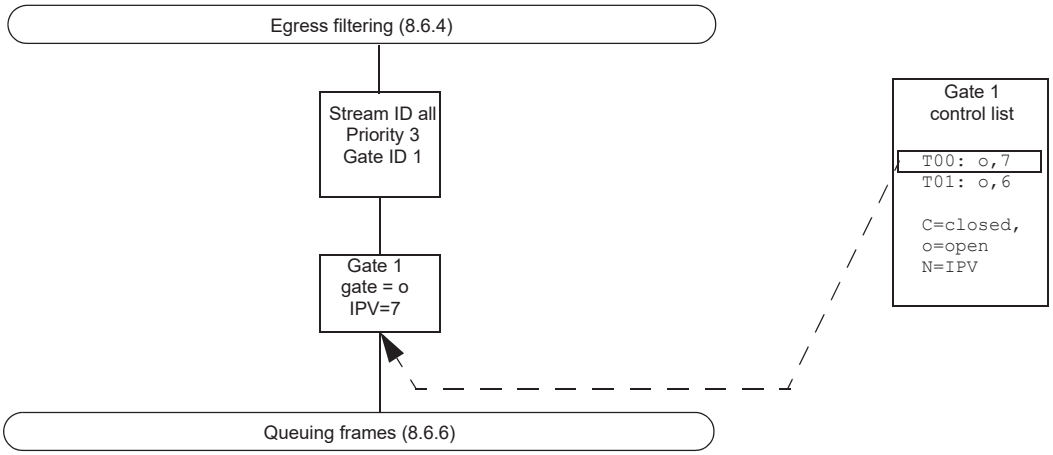

Figure T-1—Example Stream Filer and Stream Gate configuration for CQF

T.4 Use of traffic scheduling for CQF

The traffic scheduling support needed on each outbound Port in order to support the PSFP configuration described in T.3 is to execute a gate control list that will set the GateState to *open* for queue 6 and *closed* for queue 7 for a TimeInterval of T, and then set the GateState to *open* for queue 7 and *closed* for queue 6 for a TimeInterval of T, repeating ad infinitum. If there are no other traffic scheduling considerations, this can be achieved with a gate control list that contains just two SetGateStates gate operations, with parameters as follows:

1) GateState: 0, 1, 2, 3, 4, 5, 6 *open*, 7 *closed*, TimeInterval = T
2) GateState: 0, 1, 2, 3, 4, 5, 7 *open*, 6 *closed*, TimeInterval = T

This sequence of gate operations has the effect that during the initial time period T, the GateState for queue 7 is closed while queue 7 is being filled, and queue 6 is open to allow any queued frames to be transmitted; during the second time period T, the GateState for queue 6 is closed while queue 6 is being filled, and queue 7 is open to allow any queued frames to be transmitted. The gates for all other queues are open. The choice of time interval T is discussed in T.5; the cycle time (OperCycleTime; see 8.6.9.4.19) for the scheduled traffic state machines would be set to 2T in order to accommodate the sum of the time intervals for the two gate operations.

If there are traffic scheduling requirements for any of the other queues, then the gate control list could be extended to accommodate those requirements; however, the time interval between the changes of state of the gates for queues 6 and 7 has to be T, and consequently, OperCycleTime has to be a multiple of 2T, in order for the CQF requirements to be met. Figure T-2 illustrates the simplest possible traffic scheduling configuration for the case that traffic scheduling is only needed to support CQF.

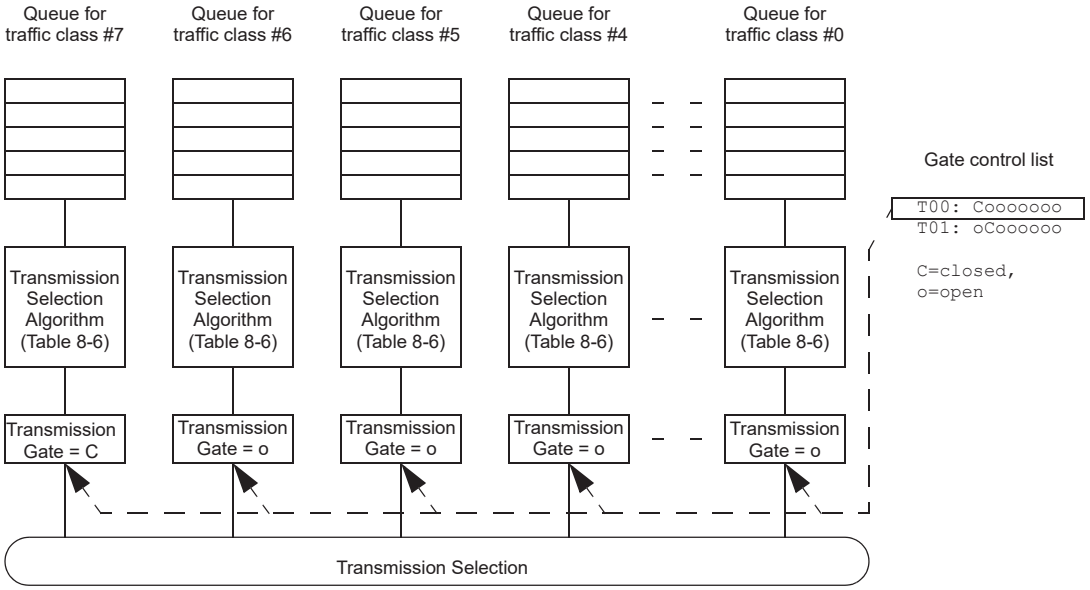

Figure T-2—Traffic scheduling example for CQF

T.5 Timing considerations

T.5.1 Choice of T

T should be chosen such that it is large enough to accommodate the stream data that can be received during the class measurement interval for the stream(s) concerned, plus at least one maximal interfering frame or frame fragment. This is important in order to ensure the key performance aspect associated with the class measurement interval; namely, that if a stream or set of streams is observed over time, the reserved data rate for that stream or set of streams will not be exceeded during any observed time period equal to the class measurement interval associated with those streams. This effectively places a lower bound on the choice of T, that it should not be smaller than the class measurement interval, and also places a restriction on larger values of T, that they should be integer multiples of the class measurement interval.

If streams associated with two different observation intervals are being handled, for example if streams that use SR classes A and B pass through the Bridge, then the OperCycleTime used for the transmit traffic scheduling has to be a common multiple of the two class measurement intervals that are in use in order to make it possible for the transmission cycles to properly match the two values of T that are chosen. Figure T-3 and Figure T-4 illustrate how the Stream Filters, Stream Gates, and traffic scheduling could be configured in the case where SR classes A and B are active; in Figure T-3, incoming frames that carry SR Class A (priority 3) are handled using Gate 1, and the cycle time for the stream gate control list is twice the class measurement interval for SR Class A, which is 2 × 125 μs. Gate 1 alternately tags these frames with an IPV of 7 or 6. Incoming frames that carry SR Class B (priority 2) are handled using Gate 2, and the cycle time for the stream gate control list is twice the class measurement interval for SR Class B, which is 2 × 250 μs. Gate 2 alternately tags these frames with an IPV of 5 or 4.

The traffic schedule is based on the smaller of the two class measurement intervals, 125 μs, but now has four entries in the gate control list (as opposed to 2 entries in Figure T-2), giving an overall cycle time of 500 μs. The gate control list switches the gate states for traffic classes 7 and 6 every 125 μs, and switches the gate states for traffic classes 5 and 4 every 250 μs.

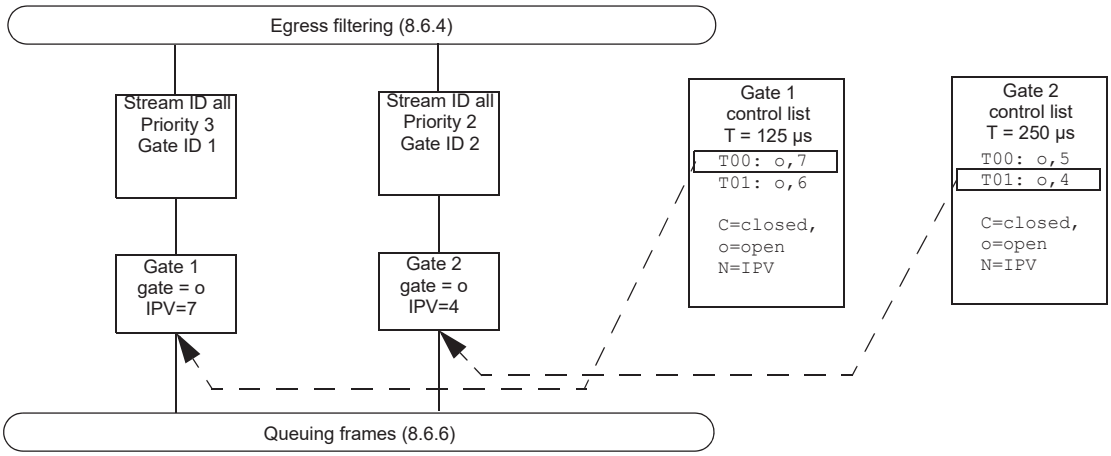

Figure T-3—Example Stream Filter and Stream Gate configuration with two values of T

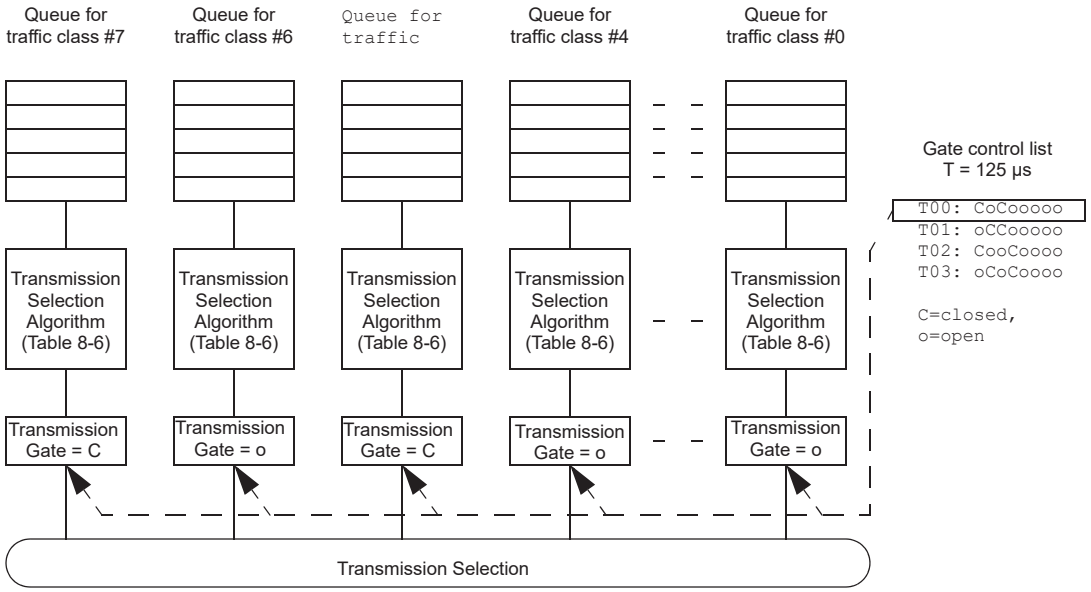

Figure T-4—Traffic scheduling example with two values of T

T.5.2 Cycle interleaving

In some circumstances, particularly where the data rates differ between reception and transmission Ports, it can be desirable to interleave cycles on the faster Port so that the best use is made of the higher bandwidth available, and also to reduce the latency that is added as a stream passes through faster parts of the transmission path. Because there is a delay imposed on the transmission of received frames, caused by the cyclic switching of reception and transmission between a pair of queues, when a queue is allowed to transmit, all of its received frames will have been enqueued, and all of them will therefore be transmitted in a burst, assuming that priorities permit, and that the transmission queue uses the strict priority transmission selection algorithm (8.6.8.1). Hence, if the received traffic from a given Port was spread out over the time interval T, and it is all sent to the same queue, the transmitted traffic will be compressed into a burst. If

the transmission data rate is, say, ten times the reception data rate, then the maximum length of that burst is T/10, so there is the potential to fit 9 more such bursts into the bandwidth available on that transmission Port. With appropriate timing on reception Ports and transmission Ports, the reception and transmission cycles can be interleaved such that those additional transmission bursts can occur. In the example illustrated in Figure T-5, it is assumed that:

a) There are two Ports on which stream data is being received, Rx1 and Rx2.
b) There is a single Port on which stream data is being transmitted, Tx1.
c) Rx1 and Rx2 operate at half of the data rate of Tx1 (or less).
d) All stream traffic is SR Class A, and is received with priority 3.

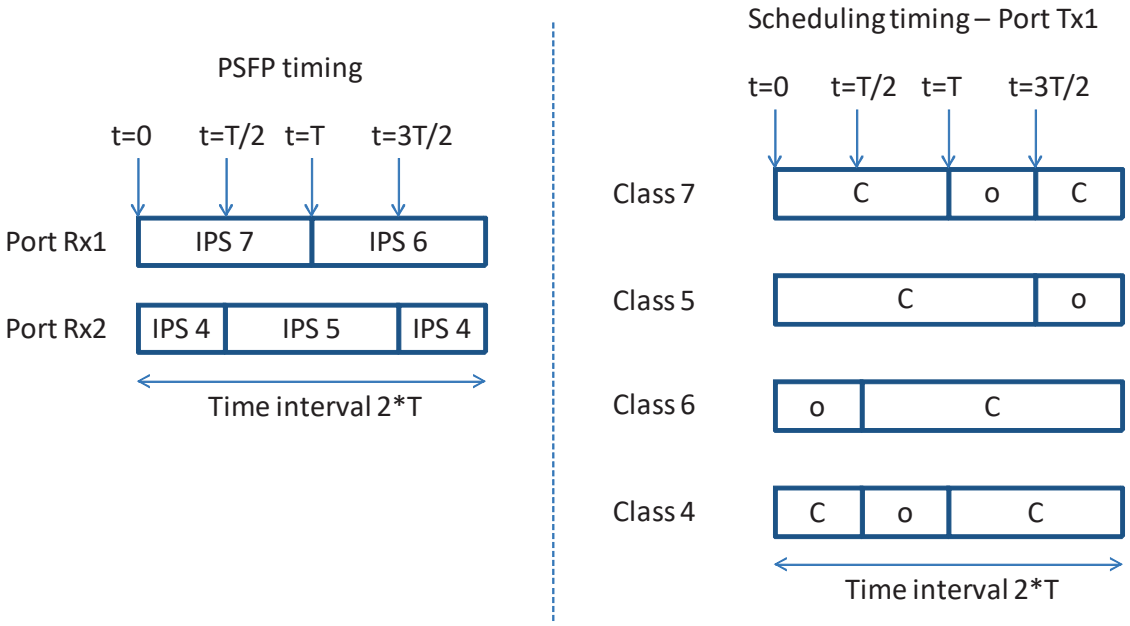

Figure T-5—Interleaving example—factor of 2

On the reception side, traffic received on Rx1 with priority 3 is sent to traffic class queue 7 during the odd cycles and to traffic class queue 6 during the even cycles. Similarly, traffic received on Rx2 with priority 3 is sent to traffic class queue 5 during the odd cycles and to traffic class queue 4 during the even cycles; however, these cycles are offset with respect to the cycles for Rx1 by T/2.

On the transmission side, each queue is in the open (transmitting) state for T/2, and in the closed (receiving) state for 3T/2. The timings of the gate open/gate closed events are arranged so that only one queue is transmitting at any one time.

It should be noted that with a scheme like this, although the transmit side appears to be operating on the basis of a value of T that is half that used on the Rx side, the effect from the point of view of the streams originating from a given reception Port is that the Rx and Tx timing is the same, as frames received on that Port are transmitted once in every time period T, and as assumed in the preceding point c), the transmit rate is twice the receive rate (or more), so the available transmit bandwidth is the same as or more than the receive bandwidth. The interleaving therefore meets the requirements stated in T.5.1. The reception Port of the Bridge downstream of Tx1 can operate using T/2, and if it is possible to carry this through to the transmission Ports as well, the contribution to the latency for streams passing through this Bridge will be T/2, rather than the T contributed by the first Bridge.

More complex schemes can be envisaged; for example, using more than two Rx Ports, and these can be made to work as long as the received bandwidth can be shared equally between the pairs of traffic classes that are used. Interleaving of this kind can also be defined for larger interleave factors; the only limitation is the number of available outbound queues. It is also possible to define interleaving schemes where the received bandwidth is not shared equally among the pairs of traffic classes, as long as the bandwidth allocated to a given pair of traffic classes does not exceed the bandwidth available during the time intervals when those traffic classes are able to transmit.

NOTE—Although the number of traffic classes described in this standard is limited to 8, the value of the IPV does not have such a limitation placed upon it. If a system supported more than 8 traffic classes, it would therefore be possible to define interleaving factors greater than 4.

T.5.3 Cycle alignment between adjacent Ports

The examples so far assume a perfect world where the transmission from transmission Port to reception Port is instantaneous and the internal timings of the transmitting and receiving systems are perfectly synchronized. In reality, transmission takes time, and synchronization is not perfect; therefore, it would be possible that a transmission Port launches the last frame(s) of one transmission burst just after the reception Port downstream has switched reception and transmission queues, which would mean that those last frames are placed in the wrong queue. Similarly, if the timing misalignment worked the other way, it would be possible for the transmission Port to finish transmitting its burst early, and switch to transmitting the next burst before the downstream Port had changed state.

In order to avoid this problem, the timings must be adjusted such that there is a very high degree of probability that when a reception Port changes the state of the stream filters to direct incoming frames to a different outbound queue, there are no frames still to be transmitted, or in flight, from the upstream transmission Port. This can be achieved by slightly delaying the start of the transmission window, and slightly advancing the end of the transmission window. The value of “slightly” depends on a number of factors, including the following:

a) Any error in the time synchronization between the adjacent systems.
b) Jitter in the propagation time of a frame from starting to leave the transmit queue in the upstream system to being presented to the downstream policing function.
c) Jitter in the propagation time of a frame between the downstream policing function and the appropriate transmission queue in the downstream system.
d) The size of any potential interfering frame or frame fragment.
e) Difference in the resolution of the clocks that are maintained by adjacent systems.

The effect of this adjustment factor, S, on the timings shown on the transmission Port in the earlier examples would be that the time slots where the gate is in the “open” state would be shorter by a factor of 2S, and would start S later. Hence, the transmission phase for traffic class 7 in Figure T-5 would start at T+S, and would end at (3T/2)–S. S should be set to the sum of the errors or jitter values from all sources given in the preceding list.

Annex U

(informative)

TSN configuration examples

This annex provides implementation examples for Time-Sensitive Networking (TSN) configuration (Clause 46).

The examples in this annex are not intended to be comprehensive, but to serve as informative background to assist in understanding of Clause 46.

U.1 Examples for time-aware talker

One of the goals of TSN configuration is avoid forcing the user's application to be subservient to the network's configuration. The user describes what it does (e.g., TrafficSpecification) and what it needs from the network (e.g., UserToNetworkRequirements). The user also describes the configuration that it is willing to accept from the network (e.g., InterfaceCapabilities), but the goals are to keep that configuration to a minimum and to avoid topics that change aspects of the user's application, such as the timing of the application's execution and interaction with the physical world (e.g., sensors, actuators).

Aligned with these goals, it is possible for the Talker to transmit frames in a manner that is not aware of time synchronization protocols like IEEE Std 802.1AS. Using the time-aware features of TrafficSpecification and InterfaceConfiguration, it is also possible for a Talker to use awareness of time synchronization for transmission of frames. Nevertheless, TSN configuration avoids assumptions of a specific implementation of time-aware transmit, and TSN configuration avoids changes to application timing.

In order to demonstrate these concepts, consider an example in which Talkers and Listeners use IEEE Std 802.1AS to execute synchronized application loops at an interval of 500 µs. The code for the application consists of two stages: a 250 µs computation stage that generates data and a 250 µs stage to transmit that data in TSN frames. The MaxLatency requirements can span one or more iterations of the application loop.

This example uses IEEE Std 802.1AS for time synchronization. The application begins execution on September 13, 2020, at 12:26:40 pm TAI, which corresponds to 1 600 000 000 000 000 µs in IEEE 802.1AS time.

The application loops begin in alignment with IEEE 802.1AS time; in other words, the 250 µs transmit stage begins at a base offset of 250 µs in IEEE 802.1AS time. For example, after the application has been running for 6 s, a sequence of transmit stages can execute at 1 600 000 006 000 750 µs, 1 600 000 006 001 250 µs, 1 600 000 006 001 750 µs, and so on.

This example focuses on a single Talker that transmits two Streams, J and K. The application generates a single frame of data for J and/or K at arbitrary times in the computation. In other words, during a single iteration data for K can follow J, and in the next iteration data for J can follow K, and in the next iteration data can be J only.

The frame for Stream J uses 120 µs in time. The frame for Stream K uses 80 µs in time. This implies a 100 Mb/s LAN technology.

U.1.1 Using enhancements for scheduled traffic

One option for implementation of this time-aware Talker is the enhancements for scheduled traffic (8.6.8.4). The Talker has two queues for transmit: one for TSN frames and another for non-TSN frames (e.g., best effort). The scheduled traffic enhancements use IEEE 802.1AS time to open and close gates for each queue (traffic class).

The enhancements of 8.6.8.4 schedule traffic per queue, and not per stream. Given the preceding application assumptions, therefore, the frame for Stream J can precede the frame for Stream K, and in the next cycle K can precede J.

For a time-aware Talker, the Jitter of TrafficSpecification (46.2.3.5) represents the variance in time for the single Stream. Since the enhancements of 8.6.8.4 are per queue, the Jitter must include the variance that is introduced by other Streams from this Talker.

Using the scheduled traffic enhancements of 8.6.8.4, the time-aware Talker needs an open TSN window of 120+80=200 µs for both J and K. The network (CNC) can locate that TSN window from 250 µs to 450 µs through 300 µs to 500 µs. The Talker uses the TimeAwareOffset returned in InterfaceConfiguration (46.2.5.3) to determine where to locate the TSN window.

For this implementation, the TrafficSpecifications are as follows:

- Stream J
  - MaxFrameSize = (120 µs in time)
  - MaxFramesPerInterval = 1
  - Interval = 500 µs
  - Jitter = 40 µs (Stream K can occur before J, such that J is 80 µs in window.
    Stream K can occur after J, such that J is 0 µs in window.
    Jitter represents the midpoint of this variance.
    Use the returned TimeAwareOffset-Jitter as the start of
    the TSN window.)
  - EarliestTransmitOffset = 250 µs + Jitter = 290 µs
  - LatestTransmitOffset = 500 µs – <MaxFrameSize in time> – Jitter = 340 µs
- Stream K
  - MaxFrameSize = (80 µs in time)
  - MaxFramesPerInterval = 1
  - Interval = 500 µs
  - Jitter = 60 µs (Stream J can occur before or after K)
    EarliestTransmitOffset = 250 µs + Jitter = 310 µs
  - LatestTransmitOffset = 500 µs – <MaxFrameSize in time> – Jitter = 360 µs

Assume that the CNC decides to use EarliestTransmitOffset, presumably because that can be aligned with the schedules in Bridges. This results in InterfaceConfigurations of:

- Stream J
  - TimeAwareOffset = 290 µs
- Stream K
  - TimeAwareOffset = 310 µs

The Talker subtracts the Jitter from these TimeAwareOffset values and uses the lower of the results to configure AdminBaseTime and OperBaseTime of 8.6.8.4. The resulting configuration of the scheduled traffic enhancements of 8.6.8.4 is shown in Figure U-1 along with example traffic.

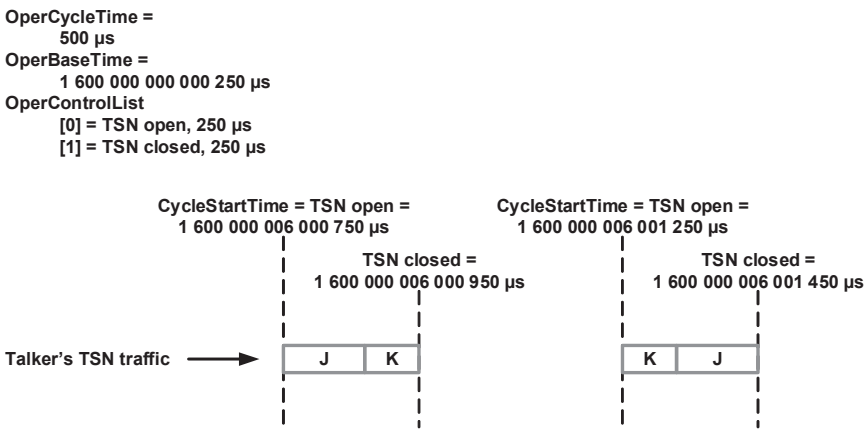

Figure U-1—Example of enhancements for scheduled traffic

NOTE—For this example, the Talker could also decide to use OperBaseTime of 0 µs and swap OperControlList elements 0 and 1 (i.e., 250 µs TSN closed followed by 250 µs TSN open). That configuration is equivalent from the network perspective.

U.1.2 Using strict priority

If the Talker has no hardware to assist in scheduling of traffic, it can take advantage of its application timing for TSN configuration of its Streams. This implementation assumes that the Talker has two queues for transmit, but each queue uses strict priority alone for transmission selection (8.6.8.1). The TSN queue uses a higher priority traffic class than the non-TSN queue.

For this implementation, assume that the Talker disables the TSN queue during its computation stage, but continues to place frames for J and K into the TSN queue. When the Talker transitions to its transmit stage (i.e., 250 µs base offset in IEEE 802.1AS time), it enables the TSN queue for transmit.

When the TSN queue is enabled, a non-TSN frame (e.g., best effort) can interfere such that it has just begun its transmit. For 100 Mb/s full-duplex IEEE Std 802.3 and a maximum frame size of 1522, this interference is 123.36 µs. This interference must be incorporated into the Jitter of TrafficSpecification, much like the Jitter of Streams J and K in U.1.1.

This implementation has no flexibility in the location of its TSN window, which always starts at a 250 µs offset.

For this implementation, the TrafficSpecifications are as follows:

- Stream J
  - MaxFrameSize = (120 µs in time)
  - MaxFramesPerInterval = 1
  - Interval = 500 µs
  - Jitter = (80 µs + 123.36 µs) / 2 = 101.68 µs
    (Stream K and max non-TSN can occur before J.)
  - EarliestTransmitOffset = 250 µs + Jitter = 351.68 µs
  - LatestTransmitOffset = 250 µs + Jitter = 351.68 µs
    (No flexibility. TSN window always starts at 250 µs.)

- Stream K
  - MaxFrameSize = (80 µs in time)
  - MaxFramesPerInterval = 1
  - Interval = 500 µs
  - Jitter = (120 µs + 123.36 µs) / 2 = 121.68 µs)
    EarliestTransmitOffset = 250 µs + Jitter = 371.68 µs
  - LatestTransmitOffset = 250 µs + Jitter = 371.68 µs

This results in the following InterfaceConfigurations (or a failure):

- Stream J
  - TimeAwareOffset = 351.68 µs
- Stream K
  - TimeAwareOffset = 371.68 µs

Due to the high Jitter and inflexibility of the scheduling window, this implementation has the potential for more Stream configuration failures as compared to the implementation described in U.1.1.

U.1.3 Using per-stream scheduling

Some Talker implementations provide additional hardware assistance for time-aware transmission, such that each individual Stream has its own scheduled gating (i.e., per stream).

One such implementation is similar to the scheduled traffic enhancements of 8.6.8.4, but each Stream has a dedicated transmit queue and gate control list. An alternative implementation has a single transmit queue for TSN traffic, but each frame has an associated timestamp to specify its time for transmit. A variety of implementations are possible. For this example, assume that scheduled transmit is per stream, but do not assume a specific hardware implementation.

Assume that the per-stream scheduling hardware uses IEEE 802.1AS time directly. Therefore, the time-aware transmit has no additional variance beyond what IEEE Std 802.1AS provides, and the Jitter of TrafficSpecification is zero.

Given the application requirements, the CNC can locate Stream J anywhere in the window from 250 µs to 500 µs. The CNC can also locate Stream K anywhere in the window from 250 µs to 500 µs, but it cannot overlap with Stream J.

For this implementation, the TrafficSpecifications are as follows:

- Stream J
  - MaxFrameSize = (120 µs in time)
  - MaxFramesPerInterval = 1
  - Interval = 500 µs
  - Jitter = 0 µs
  - EarliestTransmitOffset = 250 µs + Jitter = 250 µs
  - LatestTransmitOffset = 500 µs – <MaxFrameSize in time> – Jitter = 380 µs
- Stream K
  - MaxFrameSize = (80 µs in time)
  - MaxFramesPerInterval = 1
  - Interval = 500 µs
  - Jitter = 0 µs
    EarliestTransmitOffset = 250 µs + Jitter = 250 µs
  - LatestTransmitOffset = 500 µs – <MaxFrameSize in time> – Jitter = 420 µs

Assuming that the CNC can locate Stream J at 250 µs and Stream K immediately after, this results in the following InterfaceConfigurations:

- Stream J
  - TimeAwareOffset = 250 µs
- Stream K
  - TimeAwareOffset = 370 µs

Due to the zero Jitter and improved flexibility of the scheduling window, this implementation has the potential for more Stream configuration success as compared to the implementation described in U.1.1. In addition, given that each Stream has a distinct offset in time, this implementation enables the CNC to configure the scheduled traffic enhancements of 8.6.8.4 in Bridges such that multiple Streams do not overlap upon ingress from multiple Ports. In turn, the overall variance in latency is reduced.

U.2 Example of workflow for fully centralized models

This subclause provides an example workflow for the centralized TSN configuration models of Clause 46. The example is not intended to be comprehensive, but to help the reader understand how aspects of the configuration can be addressed (e.g., TSN domain detection and enforcement).

The example assumes the fully centralized model (46.1.3.3) with a single Centralized User Configuration (CUC) entity and a single Centralized Network Configuration (CNC) entity.

Many user-level protocol standards exist for the purpose of discovering and configuring end stations in order to design a distributed application. The application is usually specific to a particular market segment (e.g., industrial automation, professional audio/video). A centralized software entity is used for the application's design, possibly including programming of software in end stations (e.g., industrial Programmable Logic Controller). The centralized entity uses the user-level protocol to communicate with the relevant end stations for its application. When TSN configuration is applied to these existing standards, the goal is to integrate TSN functionality without significant changes. The existing application design software is represented by the CUC concept, and the end stations are represented by the Talker and Listener concepts. This example does not designate a specific user-level protocol, but it does assume the existence of a single CUC.

The CNC discovers capabilities of network infrastructure (e.g., Bridges) and configures those features.

The example provides a workflow as a framework for describing each step in the TSN configuration procedure. The steps do not necessarily need to occur sequentially. Although the example assumes a single CUC, its CNC workflow (i.e., step 4 through step 8 below) can be applied to other examples that assume multiple CUCs, such as the following:

a) Multiple application design tools are used (i.e., multiple user-level protocols), and therefore multiple CUCs are used with a single CNC.
b) No application design tool is used, and instead each CUC represents a single Talker or Listener that communicates directly with the CNC.
c) Each CUC represents a single Talker or Listener that uses the Nearest Bridge as a proxy to the CNC (i.e., centralized network/distributed user model).

The workflow for this example consists of the following steps:

1) **CUC discovers Talker and Listener end stations.**

   The protocol used by the CUC is outside the scope of this standard. When the communication between CUC and end stations uses IP, protocols such as mDNS (IETF RFC 6762 [B42]) are sometimes used.

2) CUC reads the capabilities of each end station.

This step includes TSN capabilities, but also many other capabilities that are not related to network technology. For example, if the end station is a sensor, the CUC reads the capabilities of the sensor as it applies to the physical world. The CUC also reads the frame size that is needed to transfer the sensor's measured value and associated diagnostics.

Although the communication between CUC and end station is not directly related to Clause 46, the CUC needs to obtain the following information:

— Number of Ports and MAC address of each Port
— InterfaceCapabilities: IEEE 802.1 capabilities of each Port
— TrafficSpecification.MaxFrameSize and MaxFramesPerInterval: Size of end station's data

The user-level protocol used by the CUC is outside the scope of this standard.

3) End-user designs the distributed application using the CUC.

The end user of the CUC decides which end stations communicate with one another as part of the distributed application. In other words, in terms of this standard, the CUC is used to design the Streams, including selection of the Talker and Listeners for each Stream. The CUC is also used to design the application's timing requirements.

The CUC creates the following information for each Stream, and its end stations are not directly aware of this information:

— StreamID: This identifier is primarily used between CUC and CNC.
— StreamRank: The importance of each Stream is related to its use in the application.
— UserToNetworkRequirements: MaxLatency is tied to application timing requirements.

The periodic execution of application code is designed using the CUC. This translates to the interval (i.e., period, rate) at which a Talker transmits its data. The CUC sends this interval to its end stations using the user-level protocol.

4) CNC discovers the physical network topology.

To discover the physical links between end stations and Bridges, the CNC uses IEEE Std 802.1AB (LLDP) along with a remote management protocol.

5) CNC reads the TSN capabilities of each Bridge.

The CNC uses a remote management protocol to read the TSN capabilities of each Bridge.

Whereas the previous step used the MIB/YANG of IEEE Std 802.1AB, this step uses the MIB/YANG of standards for TSN, such as IEEE Std 802.1Q, IEEE Std 802.1AS, and IEEE Std 802.1CB. The CNC uses the Chassis (Bridge) and Port identifications from the IEEE 802.1AB MIB/YANG to find the corresponding Port capabilities in the MIB/YANG of other IEEE 802.1 standards.

For example, the CNC will read the Bridge Delay (12.32.1) and Propagation Delay (12.32.2) from each Bridge in order to compute AccumulatedLatency (for step 9).

The CNC of this fully centralized model coexists with the fully distributed model (46.1.3.1). If the CNC finds a Bridge with msrpEnabledStatus TRUE (12.22.1) and MRP externalControl FALSE (12.32.4.1), the CNC avoids use of MSRP's VLAN ID (12.22.2, 12.22.4) for Streams configured by the CNC. The CNC also avoids use of MSRP's Priority (12.20.4) and associated traffic class. Although there might be methodologies for sharing the same resources (VLANs and traffic classes) between both models, this CNC takes the simpler approach of keeping the resources separate.

6) CUC sends Talker/Listener groups to the CNC.

The CUC requests configuration of Streams by sending Join requests (46.2.2) that specify the Talker group and Listener groups for each Stream.

The EndStationInterfaces group of each Talker and Listener identifies the associated end station in the physical topology, using the end station's MAC address. The MAC address is persistent (i.e., does not change due to software or protocols) and is assumed to be unique within the network, which serves as excellent identification in the physical topology. For this example, assume that end

stations use MAC address as their LLDP Chassis ID, such that the CNC can associate each Talker/Listener group to its neighboring Bridge Port.

7) CNC configures TSN domain(s).

Using the information learned in step 4 through step 6, the CNC knows the Bridges in the path(s) between each Talker and its Listeners. The CNC also knows the Bridge Ports that do not transmit frames for a Stream. This effectively defines the TSN domain for the collection of Streams.

The CNC uses destination MAC address and VLAN ID as tools to configure TSN features within the TSN domain. The InterfaceConfiguration group provides a mechanism for the CNC to allocate destination MAC addresses and VLAN IDs from its own pool and to provide the allocated values to the CUC (and the end stations). If end stations do not support InterfaceConfiguration, the CNC learns the destination MAC addresses and VLAN IDs from the DataFrameSpecification of each Stream.

i) Inside the TSN domain

When Bridges in the TSN domain are using spanning tree protocols (e.g., MSTP, ISIS-SPB) to forward Streams, the CNC uses management of the Static Filtering Entries (12.7) in order to avoid spanning tree protocols updating the active topology of the VLAN used by Streams.

When the CNC uses IEEE Std 802.1CB for redundant paths for Streams, the CNC uses management of Static Trees (12.32.3) and the associated TE-MSTID in order to avoid spanning tree operation on the VLAN ID used by Streams. The CNC uses management of IEEE Std 802.1CB to configure the redundant paths in Bridges between each Talker and its Listeners.

ii) Outside the TSN domain

The CNC uses management of Static Filtering Entries (12.7) to prevent transmit of TSN frames to Bridge Ports outside the TSN domain.

The CNC uses management of the Priority Regeneration Table (12.6) to prevent interference by non-TSN frames received on Bridge Ports outside the TSN domain, in that the priority of the non-TSN frame can be downgraded to zero. This is similar to the use of the Priority Regeneration Override Table (12.20.3) by SRP (6.9.4).

The accuracy/precision of IEEE Std 802.1AS degrades slightly for each Bridge that transfers time, so it makes sense for the CNC to limit the size of the IEEE 802.1AS domain as much as possible. As its default mode of operation, the CNC of this example uses management of IEEE Std 802.1AS to disable operation on Ports outside of the TSN domain. For example, assume that the CNC detects two distinct TSN domains G and H with respect to Talkers and Listeners (i.e., no Stream from G to H or vice versa). There is a Bridge between TSN domains G and H, and that Bridge supports IEEE Std 802.1AS. Rather than use a single IEEE 802.1AS domain that spans G and H, the CNC disables IEEE Std 802.1AS on the Ports between G and H; this action effectively creates two distinct IEEE 802.1AS domains, one for each TSN domain.

8) CNC configures TSN features for Streams.

The CNC uses the management of IEEE Std 802.1Q to configure TSN features in the path(s) from Talker to Listeners. Examples include enhancements for scheduled traffic (8.6.8.4), frame preemption (6.7.2), and the credit-based shaper (8.6.8.2).

9) CNC returns the Status of each Stream to the CUC.

This step includes the success/failure of each Stream's configuration, the AccumulatedLatency, and the InterfaceConfiguration for each end station.

10) CUC configures each end station.

If one or more Streams fail configuration, the CUC might decide to adjust its requirements and try again (i.e., return to step 3).

Assuming that the Stream status is sufficient to proceed, the CUC configures each end station to prepare it for application execution. Although the communication between CUC and end station is not directly related to Clause 46, the CUC provides the following information for each Stream:

— InterfaceConfiguration: Provides the destination MAC address and/or VLAN ID (if needed).

11) CUC executes the distributed application.

If there are other CUCs for other applications, the CNC can continue to configure Bridge resources for those while this application runs.

12) CUC stops the distributed application.

The CUC can send Leave requests (46.2.2) for Streams that are no longer needed.

If the application is changed, this workflow can return to step 1, step 2, or step 3.

Annex V

(informative)

Asynchronous Traffic Shaping delay analysis framework

The framework in this annex provides methods for worst-case delay analysis in static networks with static configurations. General assumptions of this framework are listed in V.1. The end-to-end delay modeling approach is described in V.2. An upper bound on buffering delays is described in V.3. Subsequent clauses (V.4 through V.8) cover additional sources of delays. The combined delay bounds are shown in V.9.

V.1 General assumptions

The following assumptions are made throughout the remainder of this framework:

a) The Transmission Selection Table (8.6.8) of all transmission Ports under consideration assigns the ATS Transmission Selection Algorithm (Table 8-6, 8.6.8.5) to one or more numerically highest traffic classes (i.e., no other algorithm than the ATS Transmission Selection Algorithm is assigned to a numerically higher traffic class than the traffic classes to which the ATS Transmission Selection Algorithm is assigned).
b) The transmission gates (8.6.8.4) associated with all traffic classes using the ATS Transmission Selection Algorithm of all transmission Ports under consideration reside permanently in state Open.
c) All streams are associated with ATS traffic classes in all transmission Ports.
d) If frame preemption (6.7.2) is supported by a transmission Port under consideration, it is assumed that the frame preemption status in the frame preemption status table associated with the transmission Port in the network is either express, or preemptable for all traffic classes using the ATS Transmission Selection Algorithm.
e) The underlying MAC Service of all transmission Ports under consideration transmits at a constant data rate.
f) The committed information rate parameters in Bridges under consideration are set consistently with the constraints in V.8.
g) The data rate of a Port under consideration is greater than the sum of associated committed information rates.
h) Frames at all transmission Ports have the same media-dependent overhead (12.4.2.2). Likewise, there is no variation in frame lengths (i.e., tag addition or removal along a path is not considered).

V.2 End-to-end delay modeling approach

The path from the Talker station to a single Listener station is subdivided into the contained *n* hops, where the *1*st hop is the hop from the Talker to the first Bridge on the path, and the *n*th hop is the hop from the last Bridge on the path to the Listener.

The end-to-end delay bound $d_{max}(f)$ of a stream of interest is given by per hop delay bounds $d_{max}(k, f)$ of the *n* subsequent hops along the path of stream *f* as shown in Equation (V-1).

$$d_{max}(f) = \sum_{k=1}^{n} d_{max}(k, f) \quad \text{(V-1)}$$

where

f	is the stream of interest
k	is the hop index at the path from the Talker to the Listener ($1 \le k \le n$)
$d_{max}(k, f)$	is the per hop delay bound of stream *f* at the *k*th hop

Figure V-1 illustrates the path of stream *f* across the relevant mechanisms and interfaces of two subsequent bridges along the path, and the associated delay bounds [e.g., $d_{AT, max}(k)$, introduced in V.5] described in the following subclauses.

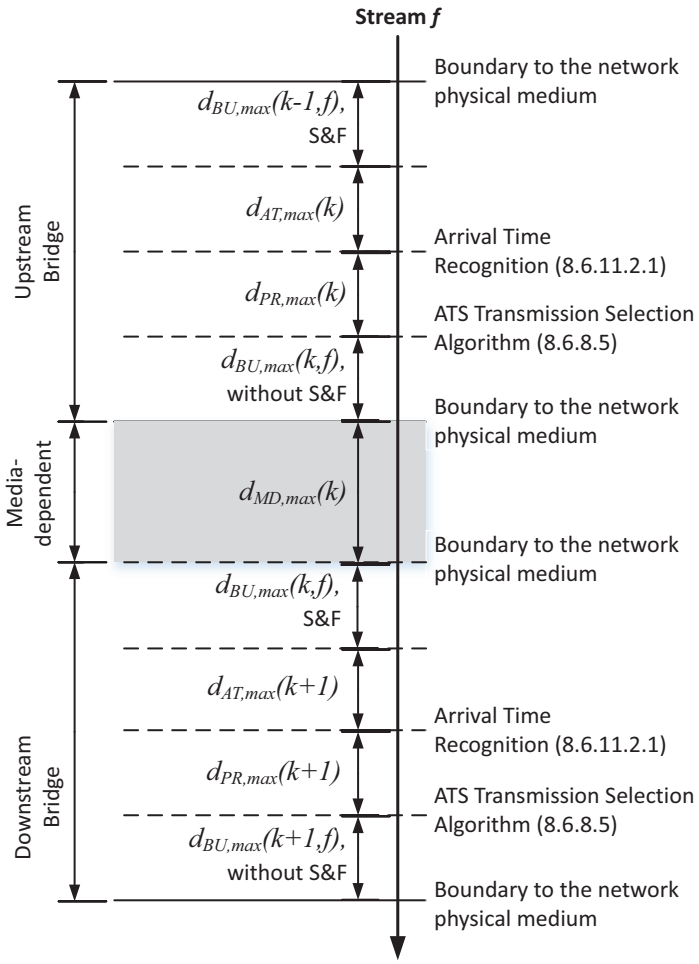

Figure V-1—Path of frames along a single hop with index *k* with two Bridges

V.3 Buffering delays

The buffering delays comprise all delays on frames of a stream *f* resulting from their residence in queues of associated traffic classes in the transmission Ports along the path. For a transmission Port on the path, these delays are caused by:

a) Competing frames in queues of traffic classes different than the traffic class of stream *f*.
b) Competing frames in the queue of the traffic class of stream *f* competing for transmission.
c) The enforcement of traffic envelopes by the operation of the ATS scheduler state machines (8.6.11).
d) Store and forward operation in reception Ports.

A delay bound $d_{BU,\,max}(k, f)$ on the buffering delay for a single hop in absence of the effects covered in subsequent clauses is known (see Specht and Samii [B63]). For $k < n$ (i.e., all but the last hop to the Listener), the delay bound $d_{BU,\,max}(k, f)$ is given by Equation (V-2).

$$d_{BU,\,max}(k, f) = \max_{h \in F_S(k, f)} \left\{ \frac{\sum_{g \in F_H(k, h) \cup F_S(k, h)} b_{max}(k, g) - l_{min}(h) + l_{LP,\,max}(k, h)}{R(k) - \sum_{g \in F_H(k, h)} r_{max}(k, g)} + \frac{l_{min}(h)}{R(k)} \right\} \quad \text{(V-2)}$$

For $k = n$ (i.e., the last hop to the Listener), this bound is given by Equation (V-3).

$$d_{BU,\,max}(n, f) = \frac{\sum_{g \in F_H(n, f) \cup F_S(n, f)} b_{max}(n, g) - l_{min}(f) + l_{LP,\,max}(n, f)}{R(n) - \sum_{g \in F_H(n, f)} r_{max}(n, g)} + \frac{l_{min}(f)}{R(n)} \quad \text{(V-3)}$$

where

$F_H(k, f)$ and $F_H(k, h)$	denote the set of streams transmitted in a numerically higher traffic class (8.6.8) than stream *f* and a stream *h*, respectively, at the upstream transmission Port of the *k*th hop
$F_S(k, f)$ and $F_S(k, h)$	denote the set of streams transmitted in the same traffic class as stream *f*, including stream *f* and stream *h*, respectively, at the upstream transmission Port of the *k*th hop
$l_{LP,\,max}(k, f)$ and $l_{LP,\,max}(k, h)$	denote the maximum interference length, in bits, by any numerically lower traffic class than the class of stream *f* and a stream *h*, respectively, at the upstream transmission Port of the *k*th hop
$l_{min}(f)$ and $l_{min}(h)$	denote the minimum frame length of stream *f* and a stream *h*, respectively, in bits, including all media-dependent overhead (8.6.11.3.11, 12.4.2.2)
$b_{max}(k, g)$	is the maximum burst size associated with a stream *g* at the *k*th hop, in bits
$r_{max}(k, g)$	is the committed information rate of stream *g* at the upstream device of the *k*th hop, in bits per second
$R(k)$	is the transmission rate, in bits per second, that the underlying MAC Service that supports transmission through the upstream transmission Port of the *k*th hop provides

NOTE 1—The relationship between $b_{max}(k, g)$ and the committed burst size at the Talker station is further discussed in V.7.

NOTE 2—The relationship between $r_{max}(k, g)$ and the committed information rate at the Talker station (47.2) is further discussed in V.8.

NOTE 3—If frame preemption is not supported, $l_{LP,\,max}(k, f)$ is at most one maximum frame length, including all media-dependent overhead, supported by the upstream transmission Port of the *k*th hop. If frame preemption is supported, and all classes with the ATS transmission selection algorithm can preempt all numerically lower traffic classes, $l_{LP,\,max}(k, f)$ is at most a maximum fragment length (S.2), including all media-dependent overhead.

V.4 Media-dependent delays

Frames of stream *f* experience a media-dependent delay between the upstream transmission Port of this hop and the downstream reception Port of a hop. This delay is measured between:

a) The time at which a particular octet of a frame passed the boundary from the upstream transmission Port to the network physical medium and
b) The time at which this particular octet passed the boundary from the network physical medium to the downstream Port.

The maximum media-dependent delay of the *k*th hop is denoted as $d_{MD,\,max}(k)$ and assumed to be known for analysis.

Variations in media-dependent delays do not affect the combined delay bounds in V.9. Such variations happen before the arrival time recognition by the associated ATS scheduler clock and the processing by the associated ATS scheduler instance. A frame that experiences a lower media-dependent delay than an earlier frame processed by the same scheduler instance would be delayed by scheduler, if required by envelope enforcement.

V.5 Bridge—Internal arrival time recognition delays

The maximum arrival time recognition delay in the upstream Bridge of the *k*th hop ($k > 1$) for any frame of a stream is given by the associated ArrivalRecognitionDelayMax parameter (8.6.11.3.1, 12.31.8.5). For compact representation and notational consistency, ArrivalRecognitionDelayMax is subsequently denoted as $d_{AT,\,max}(k)$.

Variations in arrival time recognition delays do not affect the combined delay bounds in V.9, similar to variations in media-dependent delays (V.4).

V.6 Bridge—Internal processing delays

The bounds on the processing delays in the upstream Bridge of the *k*th hop ($k > 1$) for any frame of a stream are given by the associated ProcessingDelayMin and ProcessingDelayMax parameters (8.6.11.3.2, 12.31.8.6, 12.31.8.7). The associated ProcessingDelayMin and ProcessingDelayMax parameters are subsequently denoted as $d_{PR,\,min}(k)$ and $d_{PR,\,max}(k)$, respectively.

Variations in Bridge-internal processing delays can increase the burst sizes in buffering delays (V.3). Based on the specified computation of the assigned eligibility time (8.6.11.3.2), these variations reside within the associated clock offset variations (V.7).

NOTE—The total of the maximum arrival time recognition delay and the maximum processing delay is different from the associated maximum independent delay found in the Bridge Delay attributes (12.32.1.1). This total can be larger.

V.7 Bridge—Internal clock offset variations

The maximum clock offset variation in the upstream Bridge of the *k*th hop ($k > 1$) for any frame of a stream is given by the associated ClockOffsetVariationMax parameter (8.6.11.2, 12.31.8.3). The associated ClockOffsetVariationMax is subsequently denoted as $\Delta_{CO,\,max}(k, g)$.

Clock offset variations of up to $d_{AT,\,max}(k)$ between ATS scheduler clock and transmission selection clock instances (8.6.11.2) associated with a stream *g* can increase the burst size of streams subsequently competing in the transmission Port.

This impact can be taken into account by definition of $b_{max}(k, g)$ for $k > 1$, as shown in Equation (V-4).

$$b_{max}(k, g) = r_{max}(k, g)\Delta_{CO,\,max}(k, g) + b_{max}(1, g) \tag{V-4}$$

where $b_{max}(1, g)$ is the committed burst size of stream *g* at the Talker station (47.2).

V.8 Inter-device clock rate deviations

The clock constraints in 8.6.11 limit ATS scheduler clock instances and transmission selection clock instances in a Bridge to effectively operate at the same rate, although differences within [ClockOffsetMin,ClockOffsetMax] are permitted (8.6.11.2). As a basic property of asynchronous mechanisms such as ATS, no such limitation exists between different devices (i.e., clocks in different devices are not synchronized).

Deviations of clocks from their nominal rates (e.g., within oscillator tolerances) affect the spacing between successive frames according to the assigned eligibility times (8.6.11.3.2, 8.6.8.5). If the upstream device at a hop runs faster than nominal (e.g., +100 ppm), and a connected downstream Bridge at this hop runs slower than nominal (e.g., –100 ppm), the backlog as well as the per hop delay in the downstream Bridge could grow under peak load conditions.

The situation can be prevented by management constraints (12.31.5) on $r_{max}(k, g)$ for $1 < k < n$, such that Equation (V-5) holds for any stream *g*.

$$r_{max}(k, g) \geq \frac{1 + 10^{-6}\Delta_{CR,\,max}(k-1)}{1 - 10^{-6}\Delta_{CR,\,max}(k)} r_{max}(k-1, g) \tag{V-5}$$

where

$\Delta_{CR,\,max}(k)$ is the upper bound over all absolute rate deviations of all ATS scheduler clocks and transmission selection clocks from their nominal rate in the upstream device of the *k*th hop available via the associated ClockRateDeviationMax parameter (12.31.8.4), in ppm (e.g., $\Delta_{CR,\,max}(k) = 100$)

$r_{max}(1, g)$ is the committed information rate of stream *g* at the Talker station (47.2)

V.9 Combined delay bounds

For a path from a Talker station to a Listener station with at least one Bridge ($n > 1$), a combined end-to-end delay bound $d_{max}(f)$ of a stream of interest *f* can be summarized by Equation (V-6)

$$d_{max}(f) = \sum_{k=1}^{n} d_{BU,\,max}(k, f) + \sum_{k=1}^{n} d_{MD,\,max}(k) + \sum_{k=2}^{n} d_{AT,\,max}(k) + \sum_{k=2}^{n} d_{PR,\,max}(k) \tag{V-6}$$

with Equation (V-7), Equation (V-8), and Equation (V-9) for $1 < k < n$.

$$d_{BU,\,max}(1, f) = \max_{h \in F_S(1,f)} \left\{ \frac{\sum_{g \in F_H(1,h) \cup F_S(1,h)} b_{max}(1, g) - l_{min}(h) + l_{LP,\,max}(1, h)}{R(1) - \sum_{g \in F_H(1,h)} r_{max}(1, g)} + \frac{l_{min}(h)}{R(1)} \right\} \tag{V-7}$$

$$d_{BU,\,max}(n, f) = \frac{\sum_{g \in F_H(n,f) \cup F_S(n,f)} (r_{max}(n, g)\Delta_{CO,\,max}(n, g) + b_{max}(1, g)) - l_{min}(f) + l_{LP,\,max}(n, f)}{R(n) - \sum_{g \in F_H(n,f)} r_{max}(n, g)} + \frac{l_{min}(f)}{R(n)} \tag{V-8}$$

$$d_{BU,\,max}(k, f) = \max_{h \in F_S(k,f)} \left\{ \frac{\sum_{g \in F_H(k,h) \cup F_S(k,h)} (r_{max}(k, g)\Delta_{CO,\,max}(k, g) + b_{max}(1, g)) - l_{min}(h) + l_{LP,\,max}(k, h)}{R(k) - \sum_{g \in F_H(k,h)} r_{max}(k, g)} + \frac{l_{min}(h)}{R(k)} \right\} \tag{V-9}$$

In absence of Bridges on the path from the Talker station to the Listener station (i.e., $n = 1$), the end-to-end delay bound can be summarized by Equation (V-10).

$$d_{max}(1, f) = \frac{\sum_{g \in F_H(1,f) \cup F_S(1,f)} b_{max}(1, g) - l_{min}(f) + l_{LP,\,max}(1, f)}{R(1) - \sum_{g \in F_H(1,f)} r_{max}(1, g)} + \frac{l_{min}(f)}{R(1)} + d_{MD,\,max}(1) \tag{V-10}$$
