
The mated test fixtures return loss is illustrated in Figure 85–17.

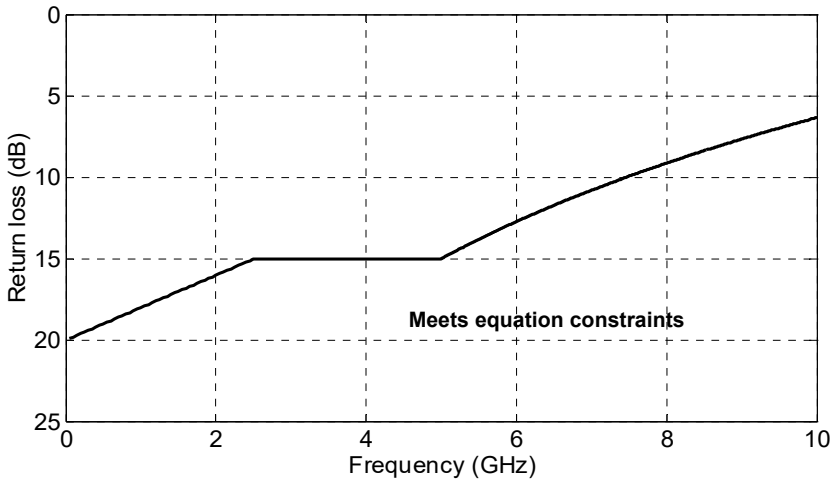

Figure 85–17—Mated test fixtures return loss

85.10.9.3 Mated test fixtures common-mode conversion loss

The common-mode conversion loss of the mated test fixtures measured at either test fixture test interface shall meet the values determined using Equation (85–38).

$$Conversion_loss(f) \geq \left\{ \begin{array}{ll} 30 - 2.91f & 0.01 \leq f < 5.5 \\ 14 & 5.5 \leq f \leq 10 \end{array} \right\} \text{ (dB)} \quad (85–38)$$

where

f is the frequency in GHz
$Conversion_loss(f)$ is the return loss at frequency f

The mated test fixtures common-mode conversion loss is illustrated in Figure 85–18.

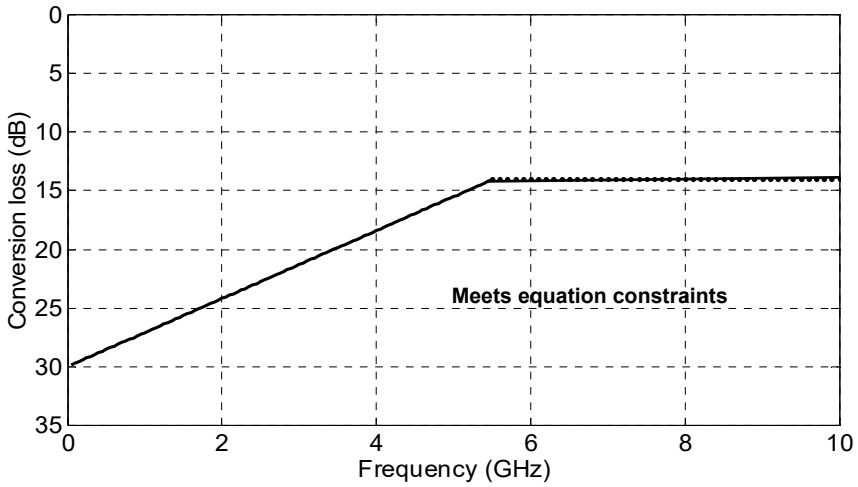

Figure 85–18—Common-mode conversion loss

85.10.9.4 Mated test fixtures integrated crosstalk noise

The mated test fixtures integrated crosstalk RMS noise voltages for the single-disturber near-end crosstalk loss and the single-disturber far-end crosstalk loss are determined using Equation (85–28) through Equation (85–32) by substituting the single disturber near-end for the multiple disturber near-end crosstalk loss and the single disturber far-end crosstalk loss for the multiple disturber far-end crosstalk loss. The values of the mated test fixtures integrated crosstalk RMS noise voltages determined using Equation (85–28) through Equation (85–32) for the single-disturber near-end crosstalk loss, the single-disturber far-end crosstalk loss, the multiple disturber near-end crosstalk loss, and the multiple disturber far-end crosstalk loss shall meet the specifications in Table 85–12.

Table 85–12—Mated test fixtures integrated crosstalk noise

Parameter	40GBASE-CR4	100GBASE-CR10	Units
Near-end integrated crosstalk noise voltage (max, RMS)	0.7	3	mV
Far-end integrated crosstalk noise voltage (max, RMS)	2.5	4	mV
MDNEXT integrated crosstalk noise voltage (max, RMS)	1	3	mV
MDFEXT integrated crosstalk noise voltage (max, RMS)	3.5	5	mV

85.10.10 Shielding

The cable assembly shall provide Class 2 or better shielding in accordance with IEC 61196-1.

85.10.11 Crossover function

The cable assembly shall be wired in a crossover fashion as illustrated in Figure 85–19, with each of the four or ten pairs being attached to the transmitter contacts at one end and the receiver contacts at the other end.

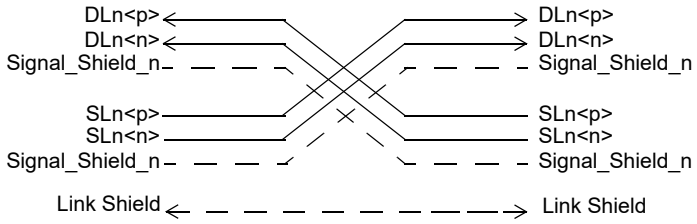

Figure 85–19—Cable assembly wiring

Note that the source lanes (SL) signals SLn<p> and SLn<n> are the positive and negative sides of the transmitters differential signal pairs and the destination lanes (DL) signals DLn<p> and DLn<n> are the positive and negative sides of the receivers differential signal pairs for lane n (n = 0, 1, 2, 3 or n = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9). Signal_Shield_n is the signal shield of the differential signal pair for Lane n.

85.11 MDI specification

This subclause defines the Media Dependent Interface (MDI). The 40GBASE-CR4 and 100GBASE-CR10 PMD, as per 85.7, is coupled to the cable assembly, as per 85.10, by the MDI.

85.11.1 40GBASE-CR4 MDI connectors

Connectors meeting the requirements of 85.11.1.1 (Style-1) or 85.11.1.2 (Style-2) shall be used as the mechanical interface between the PMD of 85.7 and the cable assembly of 85.10. The plug connector shall be used on the cable assembly and the receptacle on the PHY. Style-1 or Style-2 connectors may be used as the MDI interface.

85.11.1.1 Style-1 40GBASE-CR4 MDI connectors

The connector for each end of the cable assembly shall be the quad small form factor pluggable (QSFP+) with the mechanical mating interface defined by SFF-8436 and illustrated in Figure 85–20. The MDI connector shall be the quad small form factor pluggable (QSFP+) receptacle with the mechanical mating interface defined by SFF-8436 and illustrated in Figure 85–21. These connectors have contact assignments matching that in Table 85–13, and electrical performance consistent with the signal quality and electrical requirements of 85.8 and 85.9.

SL0<p>	S36	DL3<n>	S24
SL0<n>	S37	DL3<p>	S25
signal gnd	S38	signal gnd	S26

NOTE—Although the 40GBASE-CR4 Style-1 MDI supports 38 connections only the transmitter and receiver contact assignments are specified.

85.11.1.1.1 Style-1 AC-coupling

For Style-1 40GBASE-CR4 plug connectors the receive lanes are AC-coupled; the coupling capacitors are contained within the plug connectors as specified in 85.8.4.5.

85.11.1.2 Style-2 40GBASE-CR4 MDI connectors

The connector for each end of the cable assembly shall be the latch-type plug with the mechanical mating interface defined by SFF-8470 and illustrated in Figure 85–22. The MDI connector shall be the latch-type receptacle with the mechanical mating interface defined by SFF-8470 and illustrated in Figure 85–23. These connectors have a pinout matching that in Table 85–14, and electrical performance consistent with the signal quality and electrical requirements of 85.8 and 85.9. Note that support of compatibility with 10GBASE-CX4 is at the Style-2 40GBASE-CR4 MDI.

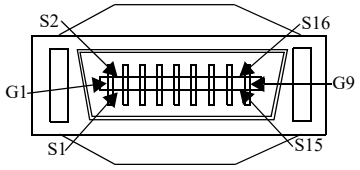

Figure 85–22—Example Style-2 cable assembly plug

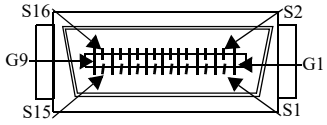

Figure 85–23—Example Style-2 MDI board receptacle

85.11.1.2.1 Style-2 40GBASE-CR4 Connector pin assignments

The MDI connector of the PMD comprises sixteen signal connections, eight signal shield connections, and one link shield connection. The 40GBASE-CR4 MDI connector pin assignments shall be as defined in Table 85–14.

85.11.2 100GBASE-CR10 MDI connectors

The connector for each end of the cable assembly shall be the plug with the mechanical mating interface defined in SFF-8642 and illustrated in Figure 85–24. The MDI connector shall be the receptacle with the mechanical mating interface defined by SFF-8642 and illustrated in Figure 85–25. These connectors have contact assignments matching that in Table 85–15, and electrical performance consistent with the signal quality and electrical requirements of 85.8 and 85.9.

NOTE—Although the 100GBASE-CR10 MDI supports 84 connections only the transmitter and receiver contact assignments are specified.

85.11.2.1 100GBASE-CR10 MDI AC-coupling

For 100GBASE-CR10 plug connectors, the receive lanes are AC-coupled; the coupling capacitors are contained within the plug connectors as specified in 85.8.4.5.

85.11.3 Electronic keying

Electronic keying can be used to enable the detection of Style-1 40GBASE-CR4 MDI connectors or 100GBASE-CR10 MDI cable assembly plugs versus fiber modules or no modules present. Specifications of electronic keying are beyond the scope of this standard.

85.12 Environmental specifications

All equipment subject to this clause shall conform to the applicable requirements of 14.7.

85.13 Protocol implementation conformance statement (PICS) proforma for Clause 85, Physical Medium Dependent (PMD) sublayer and baseband medium, type 40GBASE-CR4 and 100GBASE-CR10[150]

85.13.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 85 Physical Medium Dependent (PMD) sublayer and baseband medium, type 40GBASE-CR4 and 100GBASE-CR10, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

85.13.2 Identification

85.13.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

85.13.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 85, Physical Medium Dependent (PMD) sublayer and baseband medium, type 40GBASE-CR4 and 100GBASE-CR10
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[150] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

86. Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-SR4 and 100GBASE-SR10

86.1 Overview

This clause specifies the 40GBASE-SR4 PMD and the 100GBASE-SR10 PMD together with the multimode fiber medium. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 86–1, to the medium through the MDI, and optionally to the management functions that are accessible through the management interface defined in Clause 45, or equivalent.

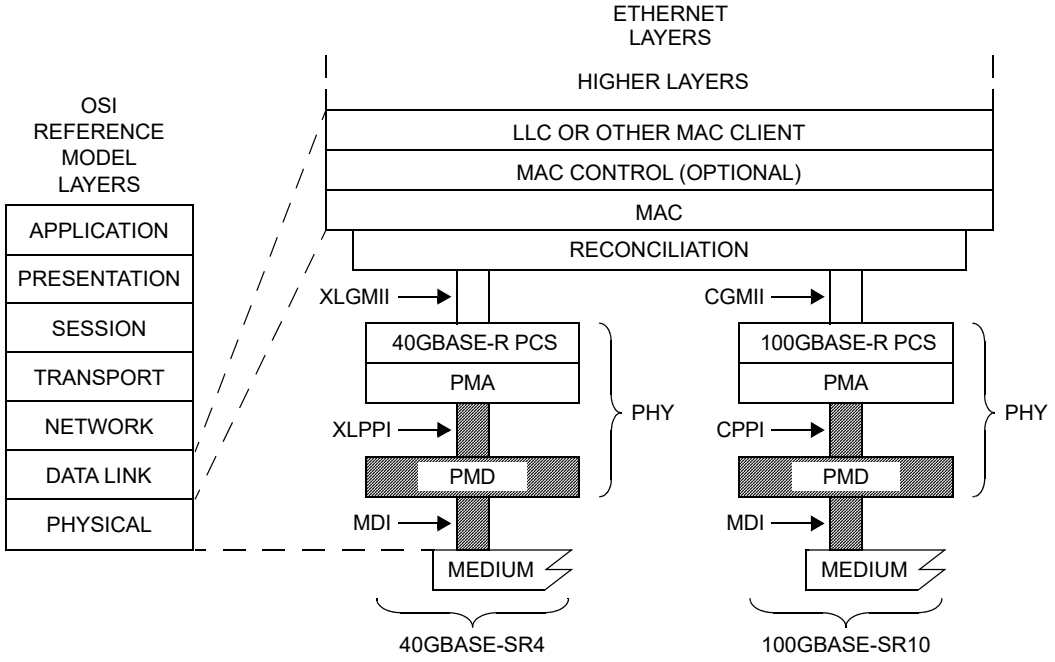

Table 86–1—Physical Layer clauses associated with the 40GBASE-SR4 and 100GBASE-SR10 PMDs

Associated clause	40GBASE-SR4	100GBASE-SR10
81—RS	Required	Required
81—XLGMII[a]	Optional	Not applicable
81—CGMII[a]	Not applicable	Optional
82—PCS for 40GBASE-R	Required	Not applicable
82—PCS for 100GBASE-R	Not applicable	Required
83—PMA for 40GBASE-R4	Required	Not applicable
83—PMA for 100GBASE-R10	Not applicable	Required
83A—XLAUI[b]	Optional	Not applicable
83A—CAUI-10[b]	Not applicable	Optional
83B—Chip to module XLAUI[b]	Optional	Not applicable
83B—Chip to module CAUI-10[b]	Not applicable	Optional
83D—CAUI-4	Not applicable	Optional
83E—Chip-to-module CAUI-4	Not applicable	Optional
86A—XLPPI	Optional	Not applicable
86A—CPPI	Not applicable	Optional
78—Energy Efficient Ethernet	Optional	Optional

[a] XLGMII and CGMII are optional interfaces. However, if the appropriate interface is not implemented, a conforming implementation behaves functionally as though the RS, and XLGMII or CGMII, were present.
[b] If XLAUI or CAUI-n is present, there is at least a PMA between the XLAUI or CAUI-n and the PMD.

Figure 86–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 40 Gb/s and 100 Gb/s Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2. Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions and abbreviations) and Annex A (bibliography, referenced as [B1], [B2], etc.).

CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
CPPI = 100 Gb/s PARALLEL PHYSICAL INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE
XLPPI = 40 Gb/s PARALLEL PHYSICAL INTERFACE
SR = PMD FOR MULTIMODE FIBER

Figure 86–1—40GBASE-SR4 and 100GBASE-SR10 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

The 40GBASE-SR4 and 100GBASE-SR10 PMD sublayers provide point-to-point 40 Gb/s and 100 Gb/s Ethernet links over four or ten pairs of multimode fiber, up to at least 100 m. Table 86–2 shows the primary attributes of each PMD type.

Table 86–2—Summary of 40GBASE–SR4 and 100GBASE–SR10

PMD Type	40GBASE–SR4	100GBASE–SR10	Unit
Fiber type	50/125 μm multimode, type A1a.2[a] (OM3) or A1a.3[b](OM4)		
Number of fiber pairs	4	10	
Nominal wavelength	850		nm
Required operating range	0.5 to 100 for OM3		m
	0.5 to 150 for OM4[c]		
Signaling rate, each lane	10.3125 ±100 ppm		GBd

[a] Type A1a.2 (OM3) specified in IEC 60793-2-10. See 86.10.2.1.
[b] Type A1a.3 (OM4) specified in IEC 60793-2-10. See 86.10.2.1.
[c] This is an engineered link with maximum 1 dB connection and splice loss.

40GBASE–SR4 uses four identical lanes, while 100GBASE–SR10 uses ten of the same lanes. In this clause, where there are four or ten items (depending on PMD type) such as lanes, the items are numbered from 0 to $n - 1$, and an example item is numbered i. Thus n is 4 or 10.

The connection to the PMA may use the optional physical instantiation of the PMD service interface called XLPPI (four lanes, for 40GBASE-SR4) or CPPI (ten lanes, for 100GBASE-SR10). The term "nPPI" is used to denote either XLPPI or CPPI, or both.

This clause is arranged as follows: following the overview and an abstract description of the PMD service interface, delay and Skew specifications, control and status variables and registers, a block diagram and high-level specification of the PMD functions, and lane assignments, 86.7 (four parts) contains the optical specifications for 40GBASE-SR4 and 100GBASE-SR10. 86.8 defines test points and optical and dual-use parameters. 86.9 addresses safety, installation, environment and labeling, 86.10 defines the optical channel, and 86.11 contains the PICS. Annex 86A contains the electrical specifications for XLPPI and CPPI, electrical compliance boards, definitions of electrical parameters, and a recommended PCB response for the host (PMA).

40GBASE-SR4 and 100GBASE-SR10 PHYs with the optional Energy Efficient Ethernet (EEE) capability may enter the fast wake Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

86.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 40GBASE-SR4 and 100GBASE-SR10 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation, although an optional implementation of the PMD service interface, the Parallel Physical Interface (nPPI), is specified in 86A.4.1 and 86A.4.2. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 40GBASE-SR4 PMD has four parallel bit streams, hence $i = 0$ to 3 for 40GBASE-SR4 and the 100GBASE-SR10 PMD has ten parallel bit streams, hence $i = 0$ to 9 for 100GBASE-SR10.

The PMA (or the PMD) continuously sends four or ten parallel bit streams to the PMD (or the PMA), one per lane, each at a nominal signaling rate of 10.3125 GBd (see 83.4).

Upon receipt of the PMD:IS_UNITDATA_*i*.request primitive, the PMD converts the specified streams of bits into the appropriate signals on the MDI.

The PMD:IS_UNITDATA_*i*.indication primitive corresponds to one of the signals received from the MDI. This primitive is received by the client (the PMA), as described in 83.4.

The PMD:IS_SIGNAL.indication(SIGNAL_DETECT) primitive is generated by the PMD to report the parameter SIGNAL_DETECT, which indicates the status of the signals being received from the MDI (see 86.5.4). There is one parameter and primitive, reporting on all the lanes as a group. This primitive is received by the client (the PMA) as PMD:IS_SIGNAL.indication(SIGNAL_OK), as described in 83.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_bit parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the 10^{-12} BER objective.

86.3 Delay and Skew

86.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 40GBASE-SR4 PMD including 2 m of fiber in one direction shall be no more than 1024 bit times (2 pause_quanta or 25.6 ns). The sum of the transmit and receive delays at one end of the link contributed by the 100GBASE-SR10 PMD including 2 m of fiber in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

86.3.2 Skew and Skew Variation constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–7 and Figure 80–8. Skew points as they relate to the nPPI are shown in Figure 86–3.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5. The measurements of Skew and Skew Variation are defined in 86.8.3.1.

86.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If MDIO is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 86–3, and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 86–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 86–3—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 9[a]	PMD transmit disable register	1.9.10	PMD_transmit_disable_9
PMD transmit disable 8[a] to PMD transmit disable 0	PMD transmit disable register	1.9.9 to 1.9.1	PMD_transmit_disable_8 to PMD_transmit_disable_0

[a]For 40GBASE-SR4, the highest-numbered six of the ten lane-by-lane transmit disables do not apply.

Table 86–4—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 9[a]	PMD receive signal detect register	1.10.10	PMD_signal_detect_9
PMD receive signal detect 8[a] to PMD receive signal detect 0	PMD receive signal detect register	1.10.9 to 1.10.1	PMD_signal_detect_8 to PMD_signal_detect_0

[a]For 40GBASE-SR4, the highest-numbered six of the ten lane-by-lane signal detects do not apply.

86.5 PMD functional specifications

The 40GBASE–SR4 and 100GBASE–SR10 PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

86.5.1 PMD block diagram

The PMD block diagram is shown in Figure 86–2. Figure 86–3 shows the test points. It is not required that the PMD service interface be exposed or measurable (nPPI as defined in Annex 86A with compliance points TP1, TP1a, TP4, TP4a). However, if it is not, a conforming implementation behaves as though the interface were compliant.

For purposes of system conformance, the PMD sublayer is standardized at the test points described in 86.8.1. The transmit side electrical signal (PMA output and PMD electrical input) is defined at TP1 and TP1a; see Annex 86A. The optical transmit signal is defined at the output end of a 50 μm multimode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all optical transmitter measurements and tests defined in 86.8 are made at TP2. The optical receive signal is defined at the output

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

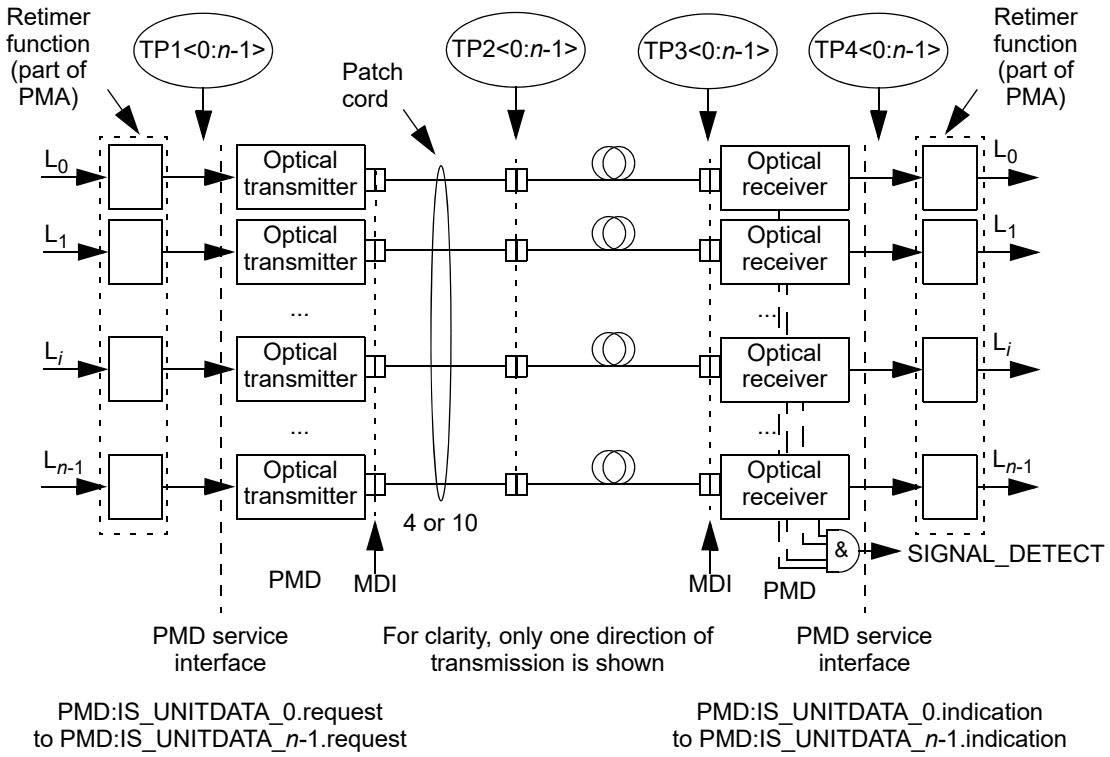

Figure 86–2—Block diagram for 40GBASE–SR4 and 100GBASE–SR10 transmit/receive paths

of the fiber optic cabling (TP3) at the MDI (see 86.10.3). Unless specified otherwise, all optical receiver measurements and tests defined in 86.8 are made at TP3. The receive side electrical signal (PMD electrical output and PMA input) is defined at TP4 and TP4a; see Annex 86A.

86.5.2 PMD transmit function

The PMD Transmit function shall convert the four or ten electronic bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_*n*-1.request into the same number of optical signals. The optical signals are delivered to the MDI, which contains four or ten parallel light paths for transmit, according to the transmit optical specifications in this clause. The higher optical power level in each signal shall correspond to tx_bit = one.

86.5.3 PMD receive function

The PMD Receive function shall convert the four or ten parallel optical signals received from the MDI into separate electronic bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_*n*-1.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_bit = one.

86.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 86–5. The PMD receiver is not required to verify whether a compliant 40GBASE-SR4 or 100GBASE-SR10 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 86–5—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ Minimum OMA, each lane, in Table 86–7) and (compliant 40GBASE–SR4 or 100GBASE–SR10 signal input as appropriate)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

86.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:*n*-1, shall be continuously set in response to the optical signal on its associated lane, according to the requirements of Table 86–5.

86.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

86.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 86–6.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

86.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitter in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:*n*-1) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 86–6.
b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane.

86.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one. If the MDIO interface is implemented, PMD_fault shall be mapped to the PMA/PMD fault bit as specified in 45.2.1.2.3.

86.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one. If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the PMA/PMD transmit fault bit as specified in 45.2.1.7.4.

86.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one. If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the PMA/PMD receive fault bit as specified in 45.2.1.7.5.

86.6 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for 40GBASE-SR4 or 100GBASE-SR10. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the physical ordering of the lanes, as the PCS is capable of receiving the lanes in any arrangement. The positioning of transmit and receive lanes at the MDI is specified in 86.10.3.

86.7 PMD to MDI specifications for 40GBASE-SR4 or 100GBASE-SR10

The required operating range for the 40GBASE–SR4 and 100GBASE–SR10 PMD is defined in Table 86–2. A compliant PMD operates on 50/125 μm multimode fibers according to the specifications of Table 86–14. A PMD which exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., operating at 125 m meets the operating range requirement of 0.5 m to 100 m). The signaling rate for a lane of a 40GBASE–SR4 or 100GBASE–SR10 PMD shall be as defined in Table 86–2. The optical signal at the transmit and receive side of the MDI is specified in 86.7.1 and 86.7.3. The range of optical signals within the optical medium is defined in 86.7.2, and an illustrative link power budget is provided in 86.7.4. Test points are defined in 86.8.1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

86.7.1 Transmitter optical specifications

Each lane of a 40GBASE–SR4 or 100GBASE–SR10 optical transmitter shall meet the specifications of Table 86–6 per the definitions in 86.8.

Table 86–6—40GBASE–SR4 or 100GBASE–SR10 optical transmit characteristics

Description	Type	Value	Unit
Center wavelength	Range	840 to 860	nm
RMS spectral width[a]	Max	0.65	nm
Average launch power, each lane	Max	2.4	dBm
Average launch power, each lane	Min	–7.6	dBm
Optical Modulation Amplitude (OMA), each lane	Max	3	dBm
Optical Modulation Amplitude (OMA), each lane	Min	–5.6[b]	dBm
Difference in launch power between any two lanes (OMA)	Max	4	dB
Peak power, each lane	Max	4	dBm
Launch power in OMA minus TDP, each lane	Min	–6.5	dBm
Transmitter and dispersion penalty (TDP), each lane	Max	3.5	dB
Extinction ratio	Min	3	dB
Optical return loss tolerance	Max	12	dB
Encircled flux[c]		≥ 86% at 19 μm, ≤ 30% at 4.5 μm	
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3} Hit ratio 5×10^{-5} hits per sample	Spec values	0.23, 0.34, 0.43, 0.27, 0.35, 0.4	
Average launch power of OFF transmitter, each lane	Max	–30	dBm

[a] RMS spectral width is the standard deviation of the spectrum.
[b] Even if the TDP < 0.9 dB, the OMA (min) has to exceed this value.
[c] If measured into type A1a.2 or type A1a.3 50 μm fiber in accordance with IEC 61280-1-4:2009.

86.7.2 Characteristics of signal within, and at the receiving end of, a compliant optical channel

Table 86–7 gives the characteristics of a signal within, and at the receiving end of, a lane of a compliant 40GBASE–SR4 or 100GBASE–SR10 optical channel, and the aggregate signal. A signal with power in OMA or average power not within the ranges given cannot be compliant. However, a signal with power values within the ranges is not necessarily compliant.

Table 86–7—Characteristics of signal within, and at the receiving end of, a compliant optical channel

Description	Minimum		Maximum	Unit
Fiber type	OM3	OM4		
Total average power for 40GBASE–SR4	–3.5	–3.1	+8.4	dBm
Total average power for 100GBASE–SR10	+0.5	+0.9	+12.4	dBm
Average power, each lane	–9.5	–9.1	+2.4	dBm
Optical Modulation Amplitude (OMA), each lane	–7.5	–7.1	+3	dBm

NOTE—Table 86–7 provides information for diagnostic purposes that is needed by network operators in maintenance. There is no need to assure compliance to it in normal circumstances.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

86.7.3 40GBASE-SR4 or 100GBASE-SR10 receiver optical specifications

Each lane of a 40GBASE–SR4 or 100GBASE–SR10 optical receiver shall meet the specifications defined in Table 86–8 per the definitions in 86.8.

Table 86–8—40GBASE-SR4 or 100GBASE-SR10 optical receiver characteristics

Description	Type	Value	Unit
Center wavelength, each lane	Range	840 to 860	nm
Damage threshold[a]	Min	+3.4	dBm
Average power at receiver input, each lane	Max	+2.4	dBm
	Min	–9.5	dBm
Receiver reflectance	Max	–12	dB
Optical Modulation Amplitude (OMA), each lane	Max	3	dBm
Stressed receiver sensitivity in OMA, each lane[b]	Max	–5.4	dBm
Peak power, each lane	Max	4	dBm
Conditions of stressed receiver sensitivity test:			
Vertical eye closure penalty (VECP)[c], each lane	—	1.9	dB
Stressed eye J2 Jitter[c], each lane	—	0.3	UI
Stressed eye J9 Jitter[c], each lane	—	0.47	UI
OMA of each aggressor lane	—	–0.4	dBm
Receiver jitter tolerance in OMA, each lane[d]	Max	–5.4	dBm
Conditions of receiver jitter tolerance test:			
Jitter frequency and peak-to-peak amplitude	—	(75, 5)	(kHz, UI)
Jitter frequency and peak-to-peak amplitude	—	(375, 1)	(kHz, UI)
OMA of each aggressor lane	—	–0.4	dBm

[a]The receiver shall be able to tolerate, without damage, continuous exposure to a modulated optical input signal having this power level on one lane. The receiver does not have to operate correctly at this input power.
[b]Measured with conformance test signal at TP3 (see 86.8.4.7).
[c]Vertical eye closure penalty and stressed eye jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver. The apparent discrepancy between VECP and TDP is because VECP is defined at eye center while TDP is defined with ±0.15 UI offsets of the sampling instant.
[d]This is a test of the optical receiver's ability to track low-frequency jitter and is inappropriate for any subsystem that does not include a CRU.

86.7.4 40GBASE-SR4 or 100GBASE-SR10 illustrative link power budget

Illustrative power budgets and penalties for 40GBASE–SR4 or 100GBASE–SR10 optical channels are shown in Table 86–9.

Table 86–9—40GBASE–SR4 or 100GBASE–SR10 illustrative link power budgets

Parameter	OM3	OM4	Unit
Effective modal bandwidth at 850 nm[a]	2000	4700	MHz•km
Power budget (for maximum TDP)	8.3		dB
Operating distance	0.5 to 100	0.5 to 150	m
Channel insertion loss[b]	1.9	1.5	dB
Allocation for penalties (for maximum TDP)[c]	6.4	6.5	dB
Unallocated margin	0	0.3[d]	dB
Additional insertion loss allowed	0		dB

[a]Per IEC 60793-2-10.
[b] The channel insertion loss is calculated using the maximum distances specified in Table 86–2 and cabled optical fiber attenuation of 3.5 dB/km at 850 nm plus an allocation for connection and splice loss given in 86.10.2.2.1.
[c] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.
[d] This unallocated margin is not available for use.

86.8 Definitions of optical and dual-use parameters and measurement methods

In this section, the test points and the parameters applicable to optical signals and for dual use (both optical and electrical) are defined. Test points are defined in 86.8.1, test patterns in 86.8.2, and parameters in 86.8.3 and 86.8.4. Further parameters for electrical use, and the use of electrical compliance boards, are defined in 86A.5.

86.8.1 Test points and compliance boards

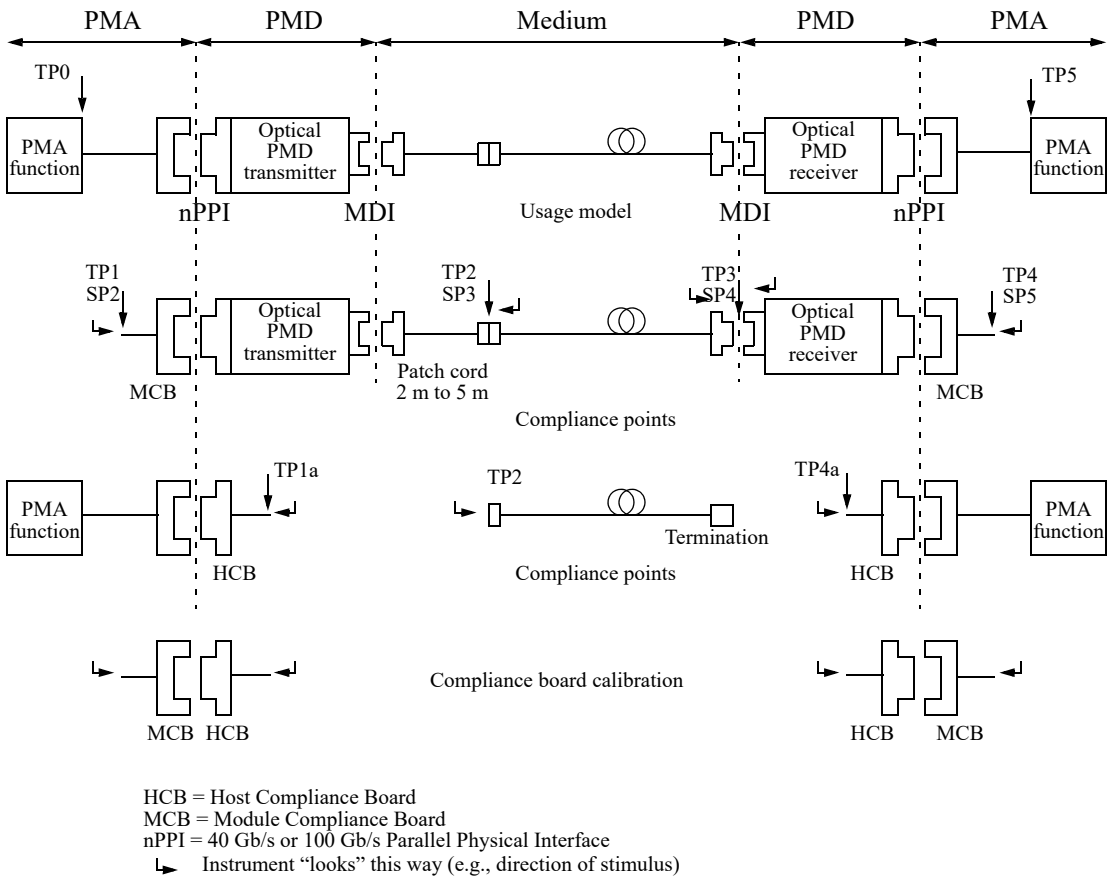

Figure 86–3 shows the six test points for 40GBASE-SR4 and 100GBASE-SR10. These are TP1, TP1a, TP2, TP3, TP4, and TP4a; four of these are Skew points SP2, SP3, SP4, and SP5 as shown. Figure 86–3 also shows the substitution of compliance boards for PMD or PMA. This is explained in Annex 86A. Table 86–10 shows the parameters or signals measured at each point, including the electrical compliance points.

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified. A patch cord that connects the MDI transmit side to 4 or 10 individual connectors may be suitable.

86.8.2 Test patterns and related subclauses

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 86–11 lists the defined test patterns, and Table 86–12 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. As Pattern 3 is more demanding than

Table 86–11—Test patterns

Pattern no.	Pattern	Pattern defined in
Square wave	Square wave (8 ones, 8 zeros)	83.5.10
3	PRBS31	83.5.10
4	PRBS9	83.5.10
5	Scrambled idle	82.2.11

Pattern 5 (which itself is the same or more demanding than other 40GBASE-R or 100GBASE-R bit streams) an item that is compliant using Pattern 5 is considered compliant even if it does not meet the required limit using Pattern 3. Test patterns for further electrical parameters are given in Table 86A–6.

Table 86–12—Test patterns and related subclauses

Parameter	Pattern	Related subclause
Wavelength, spectral width	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.4.1
Average optical power	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.4.2
Transmitter OMA (modulated optical power)	Square wave or 4	86.8.4.3
Extinction ratio	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.4.5
Transmitted optical waveform (eye mask)	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.3.2, 86.8.4.6
TDP (transmitter and dispersion penalty)	3 or 5	86.8.4.4
Stressed receiver sensitivity	3 or 5	86.8.4.7
Receiver jitter tolerance	3 or 5	86.8.4.8
Calibration of OMA for receiver tests	Square wave or 4	52.9.9
Vertical eye closure penalty calibration	3 or 5	52.9.9
J2 Jitter	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.3.3.1
J9 Jitter	3 or 5	86.8.3.3.2
Data Dependent Pulse Width Shrinkage (DDPWS)	4	86A.5.3.4

Table 86–12—Test patterns and related subclauses *(continued)*

Parameter	Pattern	Related subclause
AC common-mode voltage	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86A.5.3.1
Transition time	Square wave or 4	86A.5.3.3
Electrical waveform (eye mask)	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.3.2, 86A.5.3.6

86.8.2.1 Multi-lane testing considerations

TDP is defined for each lane, at a BER of 10^{-12} on that lane. Stressed receiver sensitivity, receiver jitter tolerance and host input signal tolerance (in Annex 86A) are defined for an interface BER of 10^{-12}. The interface BER is the average of the four or ten BERs of the receive lanes when they are stressed.

Measurements with Pattern 3 (PRBS31) allow lane-by-lane BER measurements. Measurements with Pattern 5 (scrambled idle) give the interface BER if all lanes are stressed at the same time. If each lane is stressed in turn, the BER is diluted by the three or nine unstressed lanes, and the BER for that stressed lane alone has to be found, e.g., by multiplying by 4 or 10 if the unstressed lanes have low BER. To allow TDP measurement with Pattern 5, unstressed lanes for the error detector may be created by setting the power at the reference receivers well above their sensitivities, or by copying the contents of the transmit lanes not under BER test to the error detector by other means. In stressed receiver sensitivity and receiver jitter tolerance measurements, unstressed lanes may be created by setting the power at the receiver under test well above its sensitivity and/or not stressing those lanes with ISI and jitter, or by other means. Each receive lane is stressed in turn while all are operated. All aggressor lanes are operated as specified. To find the interface BER, the BERs of all the lanes when stressed are averaged.

Where relevant, parameters are defined with all co-propagating and counter-propagating lanes operational so that crosstalk effects are included. Where not otherwise specified, the maximum amplitude (OMA or VMA) for a particular situation is used, and for counter-propagating lanes, the minimum transition time is used. Alternative test methods that generate equivalent results may be used. While the lanes in a particular direction may share a common clock, the Tx and Rx directions are not synchronous to each other. If Pattern 3 is used for the lanes not under test using a common clock, there is at least 31 UI delay between the PRBS31 patterns on one lane and any other lane.

86.8.3 Parameters applicable to both electrical and optical signals

86.8.3.1 Skew and Skew Variation

Skew and Skew Variation are defined in 80.5 and are required to remain within the limits given in 86.3.2 over the time that the link is in operation. Skew points as they relate to the nPPI are shown in Figure 86–3. The measurement of Skew and Skew Variation is made by acquiring the data on each lane using a clock and data recovery unit with a high-frequency corner bandwidth and slope as specified in 86.8.3.2. The arrival times of the one to zero transition of the alignment marker sync bits on each lane are then compared. This arrangement ensures that any high-frequency jitter that is present on the signals is not included in the Skew measurement.

86.8.3.2 Eye diagrams

Eye diagrams can be used to assess both electrical and optical signals. The measurement of the electrical eye is defined in 86A.5.3.6 and the measurement of the optical transmitter waveform is defined in 86.8.4.6. Whether electrical or optical eye diagrams, all co-propagating and counter-propagating lanes are active as crosstalk sources, using one of patterns 3, 5, or a valid 40GBASE-R or 100GBASE-R signal. The input lanes of the item under test are receiving signals that are asynchronous to those being output.

Normalized times of 0 and 1 on the unit interval scale are determined by the eye crossing means measured at the average value of the eye pattern. A clock recovery unit (CRU) is used to trigger the oscilloscope for mask measurements, as shown in Figure 52–9. It has a high-frequency corner bandwidth of 4 MHz and a slope of –20 dB/decade. The CRU tracks acceptable levels of low-frequency jitter and wander.

Consideration should be given as to whether a correction is needed for actual instrument properties.

86.8.3.2.1 Eye mask acceptable hit count examples

An example calculation relating hit count to hit ratio for an eye mask measurement using an oscilloscope is detailed below.

If an oscilloscope records 1350 samples/screen, and the time-base is set to 0.2 UI per division with 10 divisions across the screen, and the measurement is continued for 200 waveforms, then a signal that averages less than 6.75 hits is compliant to a hit ratio specification of 5×10^{-5}, i.e.,

$$\frac{5 \times 10^{-5} \times 200 \times 1350}{0.2 \times 10} = 6.75 \tag{86–1}$$

Likewise, if a measurement is continued for 1000 waveforms, then an average of less than 33.75 hits is compliant. An extended measurement is expected to give a more accurate result, and a single reading of 6 hits in 200 waveforms would not give a statistically significant pass or fail.

The hit ratio limit has been chosen to avoid misleading results due to signal and oscilloscope noise.

86.8.3.3 Jitter

J2 Jitter and J9 Jitter are specified with all co-propagating and counter-propagating lanes active as crosstalk sources, using one of patterns 3, 5, or a valid 40GBASE-R or 100GBASE-R signal. The input lanes of the item under test are receiving signals that are asynchronous to those being output.

86.8.3.3.1 J2 Jitter

J2 Jitter is defined as the time interval that includes all but 10^{-2} of the jitter distribution, which is the time interval from the 0.5th to the 99.5th percentile of the jitter histogram. This may be measured using an oscilloscope, or if measured by plotting BER vs. decision time, J2 is the time interval between the two points with a BER of 2.5×10^{-3}. Oscilloscope histograms should include at least 10 000 hits, and should be taken over about 1% of the signal amplitude. Test patterns are given in Table 86–12.

86.8.3.3.2 J9 Jitter

J9 Jitter is defined as the time interval that includes all but 10^{-9} of the jitter distribution. If measured by plotting BER vs. decision time, it is the time interval between the two points with a BER of 2.5×10^{-10}. Test patterns are given in Table 86–12.

86.8.4 Optical parameter definitions

86.8.4.1 Wavelength and spectral width

The wavelength and spectral width of each optical lane shall be within the range given in Table 86–6 if measured using the method given in the centroidal wavelength and RMS spectral width definitions in IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 86–12.

86.8.4.2 Average optical power

Average optical power is defined by the methods given in IEC 61280-1-1.

86.8.4.3 Optical Modulation Amplitude (OMA)

OMA shall be as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern, with the exception that each optical lane is tested individually. See 86.8.2 for test pattern information.

86.8.4.4 Transmitter and dispersion penalty (TDP)

Transmitter and dispersion penalty (TDP) shall be as defined for 10GBASE-S in 52.9.10 with the following exceptions:

a) Each optical lane is tested individually with all other lanes in operation.
b) The test pattern is as defined in Table 86–12.
c) The transmitter is tested using an optical channel with an optical return loss of 12 dB.
d) The reference receiver (including the effect of the decision circuit) has a fourth-order Bessel-Thomson filter response with a bandwidth of 6.1 GHz. The transversal filter of 52.9.10.3 is not used.
e) The reference sensitivity S and the measurement P_DUT are both measured with the sampling instant displaced from the eye center by ± 0.15 UI. For each of the two cases (early and late), if P_DUT(i) is larger than S(i), the TDP(i) for the transmitter under test is the difference between P_DUT(i) and S(i), TDP(i) = P_DUT(i) – S(i). Otherwise, TDP(i) = 0. The TDP is the larger of the two TDP(i).
f) The test setup illustrated in Figure 52–12 shows the reference method. Other measurement implementations may be used with suitable calibration.
g) The BER of 10^{-12} is for the lane under test on its own. See 86.8.2.1 for multi-lane pattern considerations.

NOTE—Because practical receivers and decision circuits have noise and timing impairments, the sampling instant offsets have to be calibrated. One method of doing this is via a jitter bathtub method using a known low-jitter signal.

86.8.4.5 Extinction ratio

Extinction ratio is defined by the methods of IEC 61280–2–2 using the test pattern defined in Table 86–12.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 86–12).

86.8.4.6 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram specified in Table 86–6 and shown in Figure 86–4. The transmitter optical waveform of a port transmitting the test pattern specified in Table 86–12 shall meet specifications according

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to the methods specified in 86.8.4.6.1 with the filter nominal reference frequency f_r of 7.5 GHz and filter tolerances as specified for STM-64 in ITU-T G.691.

86.8.4.6.1 Optical transmitter eye mask

The eye is measured with respect to the mask specified in Table 86–6 and shown in Figure 86–4 using a receiver with the fourth-order Bessel-Thomson response having a transfer function given by Equation (86–2) and Equation (86–3):

$$H(y) = \frac{105}{105 + 105y + 45y^2 + 10y^3 + y^4} \tag{86–2}$$

where:

$$y = 2.114p\ ; \quad p = \frac{j\omega}{\omega_r}\ ; \quad \omega_r = 2\pi f_r\ ; \quad f_r = \text{Reference frequency in GHz} \tag{86–3}$$

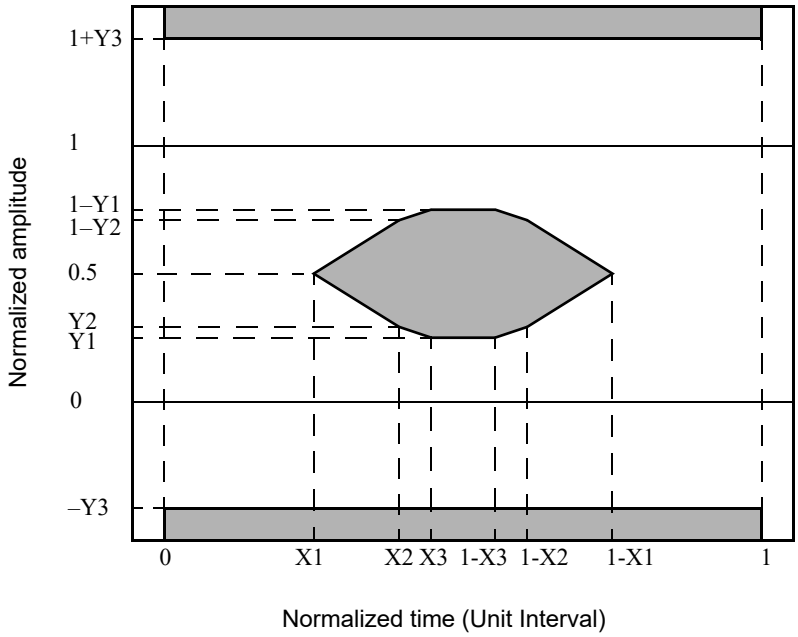

Figure 86–4—Transmitter eye mask definition

The Bessel-Thomson receiver is not intended to represent the noise filter used within a compliant optical receiver, but is intended to provide uniform measurement conditions at the transmitter. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response.

Normalized levels of 0 and 1 represent logic zero and one respectively. These are defined by the means of the lower and upper halves of the central 0.2 UI of the eye.

Further requirements are given in 86.8.3.2.

The transmitter shall achieve a hit ratio lower than the limit of hits per sample specified in the appropriate table or 5×10^{-5} hits per sample if not otherwise specified. “Hits” are the number of samples within the grey

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

areas of Figure 86–4, and the sample count is the total number of samples from 0 UI to 1 UI. Some illustrative examples are provided in 86.8.3.2.1.

Further information on optical eye pattern measurement procedures may be found in IEC 61280-2-2.

86.8.4.7 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 86–8 if measured using the method defined by 52.9.9 with the conformance test signal at TP3 and with the following exceptions:

a) The reference test procedure for a single lane is defined in 52.9.9. See 86.8.2.1 and below for multi-lane considerations.
b) The sinusoidal amplitude interferer is replaced by a Gaussian noise generator.
c) The fourth-order Bessel-Thomson filter is replaced by a low-pass filter followed by a limiter and a fourth-order Bessel-Thomson filter.
d) The sinusoidal jitter is at a fixed 80 MHz frequency and between 0 and 0.05 UI peak-to-peak amplitude.
e) The Gaussian noise generator, the amplitude of the sinusoidal jitter, and the Bessel-Thomson filter are adjusted so that the VECP, J2 Jitter and J9 Jitter specifications given in Table 86–8 are simultaneously met (the random noise effects such as RIN, random clock jitter do not need to be minimized).
f) The pattern for the received compliance signal is specified in Table 86–12.
g) The interface BER of the PMD receiver is the average of the BER of all receive lanes while stressed and at the specified receive OMA.
h) Where nPPI or XLAUI/CAUI-n is exposed, a PMD receiver is considered compliant if it meets the module electrical output specifications at TP4 given in Table 86A–3 for nPPI, or the requirements in Table 83B–3 for XLAUI/CAUI-10, or the requirements in Table 83E–3 for CAUI-4.

Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Each receive lane is tested in turn while all aggressor receive lanes are operated as specified in Table 86–8. Pattern 3 or Pattern 5, or a valid 40GBASE–R4 or 100GBASE–R10 signal is sent from the transmit section of the receiver under test. The signal being transmitted is asynchronous to the received signal. If Pattern 3 is used for the transmit and receive lanes not under test, there is at least 31 UI delay between the PRBS31 patterns generated on one lane and any other lane.

For 40GBASE-SR4 and 100GBASE-SR10, the relevant BER is the interface BER. The interface BER is the average of the four or ten BERs of the receive lanes when stressed: see 86.8.2.1.

86.8.4.8 Receiver jitter tolerance

Receiver jitter tolerance shall be as defined as in 68.6.11, with the following differences:

a) The reference test procedure for a single lane is defined in 68.6.11. See 86.8.2.1 for multi-lane considerations.
b) The pattern to be received is specified in Table 86–12.
c) The parameters of the signal are specified in Table 86–8 and the power in OMA at the receiver is set to the maximum for receiver jitter tolerance in OMA given in Table 86–8.
d) Each receive lane is tested in turn while all are operated. All aggressor lanes are operated as specified in Table 86–8.
e) The receive lanes not being tested are receiving Pattern 3, Pattern 5, or a valid 40GBASE-R4 or 100GBASE-R10 signal.
f) The transmitter is transmitting one of these signals using all lanes.
g) The transmitter and the receiver are not synchronous.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

h) The interface BER of the PMD receiver is the average of the BER of all receive lanes when stressed.
i) The mode-conditioning patch cord suitable for 62.5/125 μm fiber is not used.

86.9 Safety, installation, environment, and labeling

86.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

86.9.2 Laser safety

40GBASE–SR4 and 100GBASE–SR10 optical transceivers shall conform to Hazard Level 1M laser requirements as defined in IEC 60825–1 and IEC 60825–2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[151]

86.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

86.9.4 Environment

The 40GBASE–SR4 and 100GBASE–SR10 operating environment specifications are as defined in 52.11, as defined in 52.11.1 for electromagnetic emission, and as defined in 52.11.2 for temperature, humidity, and handling.

86.9.5 PMD labeling

The 40GBASE–SR4 and 100GBASE–SR10 labeling recommendations and requirements are as defined in 52.12.

86.10 Optical channel

The fiber optic cabling (channel) contains 4 or 10 optical fibers for each direction to support 40GBASE-SR4 or 100GBASE-SR10, respectively. The fiber optic cabling interconnects the transmitters at the MDI on one end of the channel to the receivers at the MDI on the other end of the channel. As defined in 86.10.3, the optical lanes appear in defined locations at the MDI but the locations are not assigned specific lane numbers within this standard because any transmitter lane may be connected to any receiver lane. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term *channel* is used here for consistency with generic cabling standards.

[151] A host system that fails to meet the manufacturers requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

86.10.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 86–5.

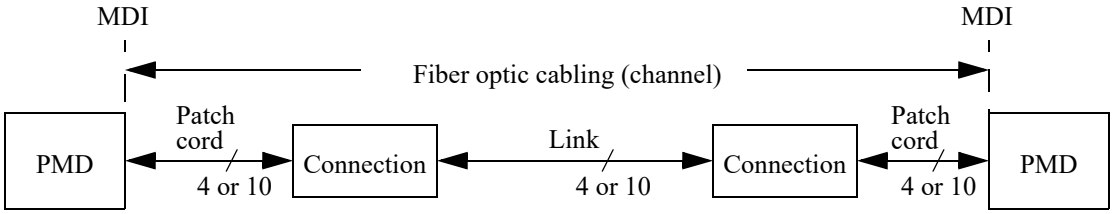

Figure 86–5—Fiber optic cabling model

The channel shall comply with the specifications in Table 86–13.

Table 86–13—Fiber optic cabling (channel) characteristics at 850 nm

Description	Type	OM3	OM4	Unit
Operating distance	Max	100	150	m
Cabling Skew	Max	79		ns
Cabling Skew Variation[a]	Max	2.2		ns
Channel insertion loss	Min	0		dB
Channel insertion loss[b]	Max	1.9[c]	1.5[d]	dB

[a] An additional 0.6 ns of Skew Variation could be caused by wavelength changes, which are attributable to the transmitter not the channel.
[b] These channel insertion loss values include cable, connectors, and splices.
[c] 1.5 dB allocated for connection and splice loss.
[d] 1 dB allocated for connection and splice loss.

A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, modal dispersion, reflections and losses of all connectors and splices meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method. As OM4 optical fiber meets the requirements for OM3, a channel compliant to the “OM3” column may use OM4 optical fiber, or a combination of OM3 and OM4.

86.10.2 Characteristics of the fiber optic cabling (channel)

86.10.2.1 Optical fiber cable

The fiber contained within the 40GBASE–SR4 or 100GBASE–SR10 fiber optic cabling shall comply with the specifications and parameters of Table 86–14. A variety of multimode cable types may satisfy these requirements, provided the resulting channel also meets the specifications of Table 86–13. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

Table 86–14—Optical fiber and cable characteristics

Description	OM3[a]	OM4[b]	Unit
Nominal core diameter	50		μm
Nominal fiber specification wavelength	850		nm
Effective modal bandwidth (min)[c]	2000	4700	MHz•km
Cabled optical fiber attenuation (max)	3.5		dB/km
Zero dispersion wavelength (λ_0)	$1295 \le \lambda_0 \le 1340$		nm
Chromatic dispersion slope (max) (S_0)	0.105 for $1295 \le \lambda_0 \le 1310$ and $0.000375\times(1590 - \lambda_0)$ for $1310 \le \lambda_0 \le 1340$		$ps/nm^2\ km$

[a]IEC 60793-2-10 type A1a.2.
[b] IEC 60793-2-10 type A1a.3.
[c] When measured with the launch conditions specified in Table 86–6.

86.10.2.2 Optical fiber connection

An optical fiber connection, as shown in Figure 86–5, consists of a mated pair of optical connectors.

86.10.2.2.1 Connection insertion loss

The maximum operating distances are based on an allocation of 1.5 dB or 1 dB total connection and splice loss. For example, these allocations support two connections, each with an insertion loss of 0.75 dB or 0.5 dB respectively. Connections with lower loss characteristics may be used provided the requirements of Table 86–13 are met. However, the loss of a single connection shall not exceed 0.75 dB.

86.10.2.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

86.10.3 Medium Dependent Interface (MDI)

The 40GBASE–SR4 or 100GBASE–SR10 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 86–5). The 40GBASE–SR4 PMD is coupled to the fiber optic cabling through one connector plug into the MDI optical receptacle as shown in Figure 86–6. The 100GBASE–SR10 PMD is coupled to the fiber optic cabling through one or two connector plugs into the MDI optical receptacle(s), depending on choice of implementation, as shown in Figure 86–7. Example constructions of the MDI include the following:

a) PMD with a connectorized fiber pigtail plugged into an adapter;
b) PMD receptacle.

86.10.3.1 Optical lane assignments for 40GBASE-SR4

The four transmit and four receive optical lanes of 40GBASE-SR4 shall occupy the positions depicted in Figure 86–6 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains eight active lanes within twelve total positions. The transmit optical lanes occupy the leftmost four positions. The receive optical lanes occupy the rightmost four positions. The four center positions are unused.

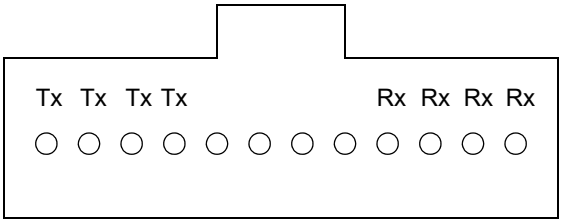

Figure 86–6—40GBASE-SR4 optical lane assignments

86.10.3.2 Optical lane assignments for 100GBASE-SR10

The ten transmit and ten receive optical lanes of 100GBASE-SR10 shall occupy the positions depicted in Figure 86–7 when looking into the MDI optical receptacle(s) with the connector keyway feature(s) on top. The single-receptacle Option A is recommended, the two-receptacle Option B and Option C are alternatives. The interface contains 20 active lanes within up to 24 total positions arranged in two rows of 10 or 12 positions. One row is dedicated to transmit optical lanes and the other row to receive optical lanes. For the depicted 12-position rows, the optical lanes occupy the center ten positions of each row with the outermost positions unused.

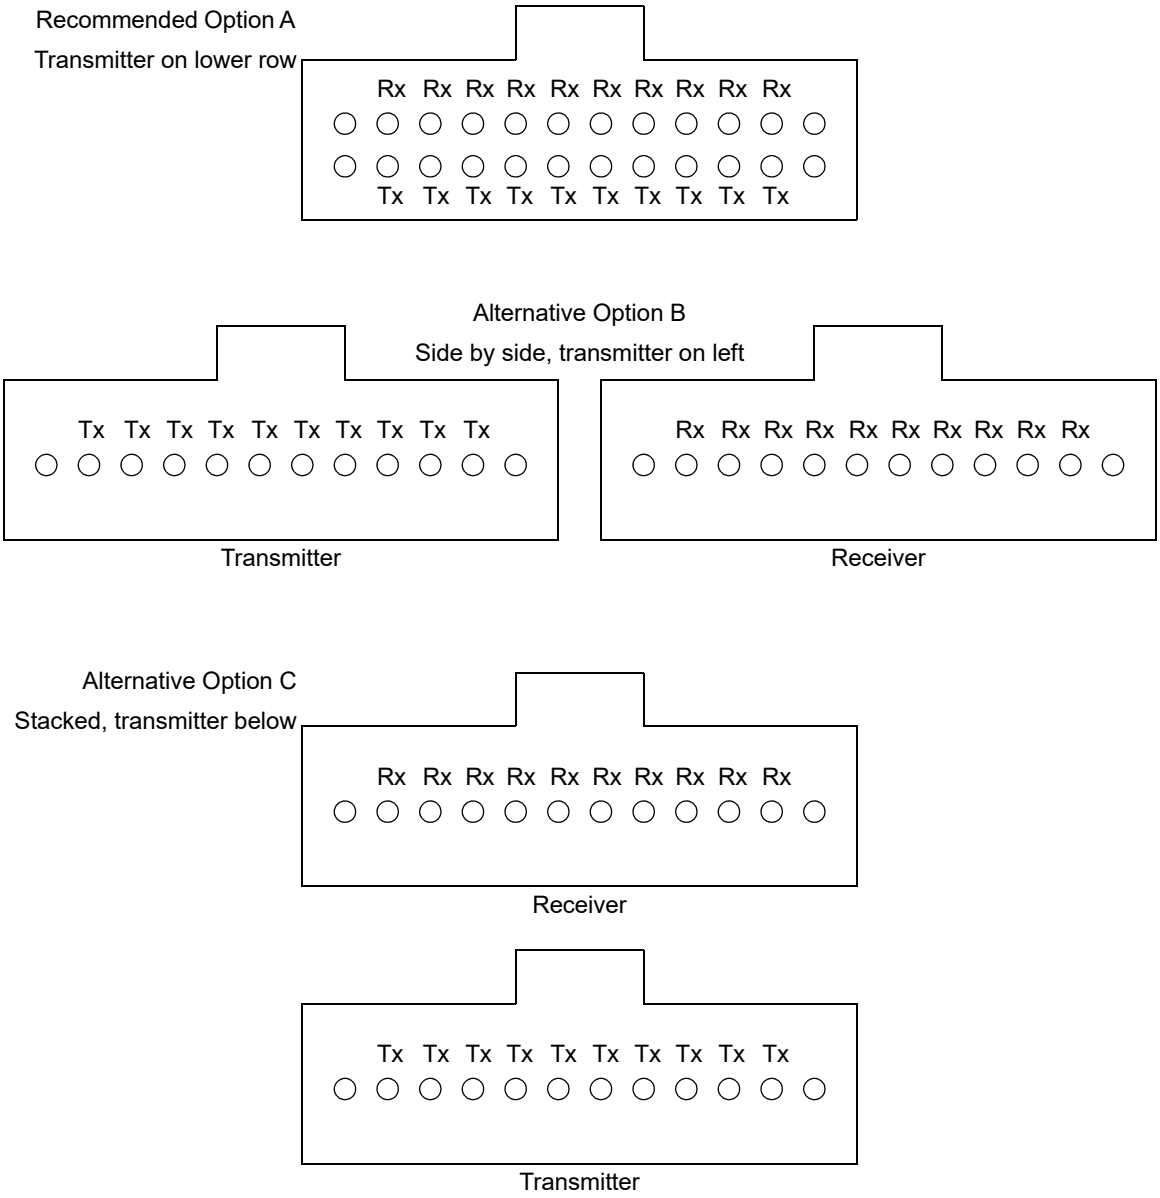

Figure 86–7—100GBASE-SR10 optical lane assignments

86.10.3.3 Medium Dependent Interface (MDI) requirements

The MDI adapter or receptacle shall meet the dimensional specifications of IEC 61754-7 interface 7-3, the MPO adapter interface. The plug terminating the optical fiber cabling shall meet the dimensional specifications of IEC 61754-7 interface 7-4, MPO female plug connector flat interface. The MDI shall optically mate with the plug on the optical fiber cabling. Figure 86–8 shows an MPO female plug connector with flat interface, and an MDI as a PMD receptacle using an MPO adapter interface.

The MDI shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-022-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 86.5.1, not at the MDI.

86.11 Protocol implementation conformance statement (PICS) proforma for Clause 86, Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-SR4 and 100GBASE-SR10[152]

86.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 86, Physical Medium Dependent sublayer and medium, type 40GBASE–SR4 and 100GBASE–SR10, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

86.11.2 Identification

86.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

86.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 86, Physical Medium Dependent sublayer and medium, type 40GBASE–SR4 and 100GBASE–SR10
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[152]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

87. Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-LR4 and 40GBASE-ER4

87.1 Overview

This clause specifies the 40GBASE-LR4 PMD and the 40GBASE-ER4 PMD together with the single-mode fiber medium. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 87–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 87–1—Physical Layer clauses associated with the 40GBASE-LR4 and 40GBASE-ER4 PMDs

Associated clause	40GBASE-LR4	40GBASE-ER4
81—RS	Required	Required
81—XLGMII[a]	Optional	Optional
82—PCS for 40GBASE-R	Required	Required
83—PMA for 40GBASE-R	Required	Required
83A—XLAUI	Optional	Optional
83B—Chip-to-module XLAUI	Optional	Optional
86A—XLPPI	Optional	Not applicable
78—Energy Efficient Ethernet	Optional	Optional

[a]The XLGMII is an optional interface. However, if the XLGMII is not implemented, a conforming implementation behaves functionally as though the RS and XLGMII were present.

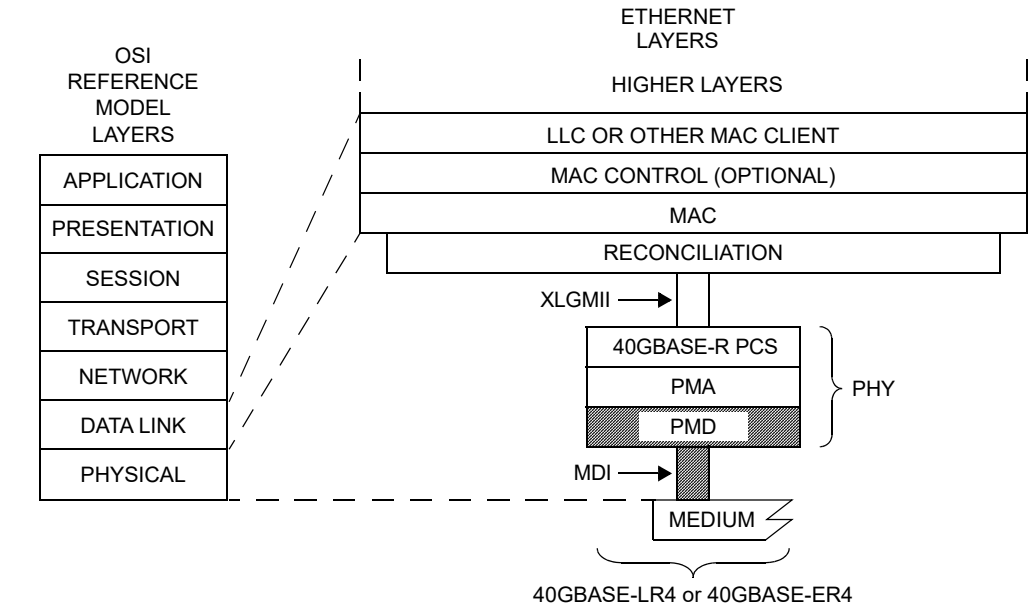

Figure 87–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 40 Gb/s and 100 Gb/s Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2.

40GBASE-LR4 and 40GBASE-ER4 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

87.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 40GBASE-LR4 and 40GBASE-ER4 PMDs. The service interface for these PMDs are described in an abstract manner and do not imply any particular implementation, although an optional implementation of the PMD service interface, the 40 Gb/s Parallel Physical Interface (XLPPI), is specified in Annex 86A. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

LR = PMD FOR SINGLE-MODE FIBER — 10 km
ER = PMD FOR SINGLE-MODE FIBER — 40 km

Figure 87–1—40GBASE-LR4 and 40GBASE-ER4 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 40GBASE-LR4 and 40GBASE-ER4 PMDs have four parallel bit streams, hence $i = 0$ to 3.

In the transmit direction, the PMA continuously sends four parallel bit streams to the PMD, one per lane, each at a nominal signaling rate of 10.3125 GBd. The PMD converts these streams of bits into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends four parallel bit streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 10.3125 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service primitive defined in 80.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_bit parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_bit parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the 10^{-12} BER objective.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

87.3 Delay and Skew

87.3.1 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the 40GBASE-LR4 or 40GBASE-ER4 PMD including 2 m of fiber in one direction shall be no more than 1024 bit times (2 pause_quanta or 25.6 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

87.3.2 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–7 and Figure 80–8.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5. The measurements of Skew and Skew Variation are defined in 87.8.2.

87.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 87–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 87–3.

87.5 PMD functional specifications

The 40GBASE-LR4 and 40GBASE-ER4 PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

87.5.1 PMD block diagram

The PMD block diagram is shown in Figure 87–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 87.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 87.11.3). Unless specified otherwise, all receiver measurements and tests defined in 87.8 are made at TP3.

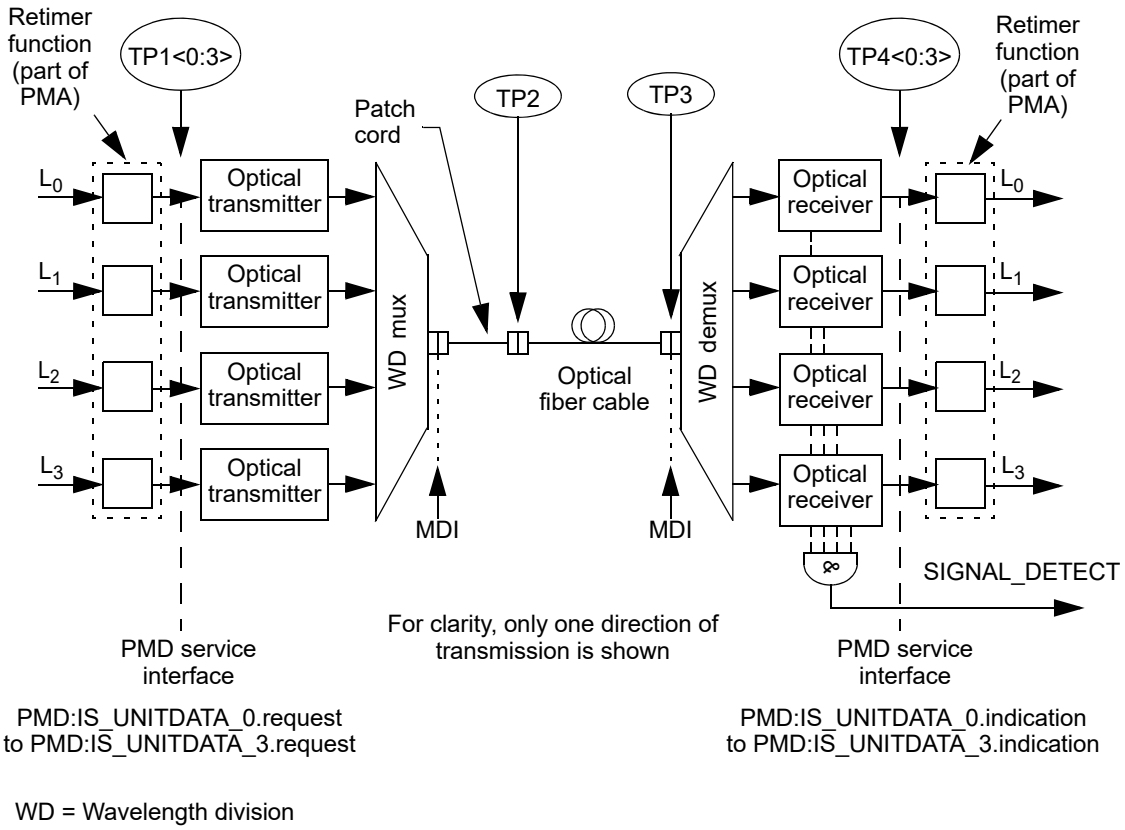
Table 87–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 3	PMD transmit disable register	1.9.4	PMD_transmit_disable_3
PMD transmit disable 2	PMD transmit disable register	1.9.3	PMD_transmit_disable_2
PMD transmit disable 1	PMD transmit disable register	1.9.2	PMD_transmit_disable_1
PMD transmit disable 0	PMD transmit disable register	1.9.1	PMD_transmit_disable_0

Table 87–3—MDIO/PMD status variable mapping



MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 3	PMD receive signal detect register	1.10.4	PMD_signal_detect_3
PMD receive signal detect 2	PMD receive signal detect register	1.10.3	PMD_signal_detect_2
PMD receive signal detect 1	PMD receive signal detect register	1.10.2	PMD_signal_detect_1
PMD receive signal detect 0	PMD receive signal detect register	1.10.1	PMD_signal_detect_0

TP1<0:3> and TP4<0:3> are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

87.5.2 PMD transmit function

The PMD Transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate optical signals. The four optical signals shall then be wavelength division multiplexed and delivered to the MDI, all according to the transmit optical specifications in this clause. The higher optical power level in each signal shall correspond to tx_bit = one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Specification of the retimer function is beyond the scope of this standard.

Figure 87–2—Block diagram for 40GBASE-LR4 and 40GBASE-ER4 transmit/receive paths

87.5.3 PMD receive function

The PMD Receive function shall demultiplex the composite optical signal received from the MDI into four separate optical signals. The four optical signals shall then be converted into four bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_bit = one.

87.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 80.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all four lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 87–4. The PMD receiver is not required to verify whether a compliant 40GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 87–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ receiver sensitivity (max) in OMA in Table 87–8) AND (compliant 40GBASE–R signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

87.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:3, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 87–4.

87.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

87.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 87–7.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

87.5.8 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitters in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 87–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method shall be provided to independently disable each transmit lane for testing purposes.

87.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one. If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

87.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one. If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

87.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one. If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

87.6 Wavelength-division-multiplexed lane assignments

The wavelength range for each lane of the 40GBASE-LR4 and 40GBASE-ER4 PMDs is defined in Table 87–5. The center wavelengths are members of the CWDM wavelength grid defined in ITU-T G.694.2 and are spaced at 20 nm.

Table 87–5—Wavelength-division-multiplexed lane assignments

Lane	Center wavelength	Wavelength range
L_0	1271 nm	1264.5 to 1277.5 nm
L_1	1291 nm	1284.5 to 1297.5 nm
L_2	1311 nm	1304.5 to 1317.5 nm
L_3	1331 nm	1324.5 to 1337.5 nm

NOTE—There is no requirement to associate a particular electrical lane with a particular optical lane, as the PCS is capable of receiving lanes in any arrangement.

87.7 PMD to MDI optical specifications for 40GBASE-LR4 and 40GBASE-ER4

The operating range for the 40GBASE-LR4 and 40GBASE-ER4 PMDs are defined in Table 87–6. A 40GBASE-LR4 or 40GBASE-ER4 compliant PMD operates on type B1.1, B1.3 or B6_a single-mode fibers according to the specifications defined in Table 87–14. A PMD that exceeds the required operating range

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

while meeting all other optical specifications is considered compliant (e.g., a 40GBASE-LR4 PMD operating at 12.5 km meets the operating range requirement of 2 m to 10 km).

The 40GBASE-ER4 PMD interoperates with the 40GBASE-LR4 PMD provided that the channel requirements defined in 87.12 are met.

Table 87–6—40GBASE-LR4 and 40GBASE-ER4 operating ranges

PMD type	Required operating range
40GBASE-LR4	2 m to 10 km
40GBASE-ER4	2 m to 30 km
	2 m to 40 km[a]

[a]Links longer than 30 km for the same link power budget are considered engineered links. Attenuation for such links needs to be less than the worst case specified for B1.1, B1.3, or B6_a single-mode fiber.

87.7.1 40GBASE-LR4 and 40GBASE-ER4 transmitter optical specifications

The 40GBASE-LR4 transmitter shall meet the specifications defined in Table 87–7 per the definitions in 87.8. The 40GBASE-ER4 transmitter shall meet the specifications defined in Table 87–7 per the definitions in 87.8.

Table 87–7—40GBASE-LR4 and 40GBASE-ER4 transmit characteristics

Description	40GBASE-LR4	40GBASE-ER4	Unit
Signaling rate, each lane (range)	10.3125 ± 100 ppm		GBd
Lane wavelengths (range)	1264.5 to 1277.5 1284.5 to 1297.5 1304.5 to 1317.5 1324.5 to 1337.5		nm
Side-mode suppression ratio (SMSR), (min)	30		dB
Total average launch power (max)	8.3	10.5	dBm
Average launch power, each lane (max)	2.3	4.5	dBm
Average launch power, each lane[a] (min)	–7	–2.7	dBm
Optical Modulation Amplitude (OMA), each lane (max)	3.5	5	dBm
Optical Modulation Amplitude (OMA), each lane (min)[b]	–4	0.3	dBm
Difference in launch power between any two lanes (OMA) (max)	6.5	4.7	dB
Launch power in OMA minus TDP, each lane (min)	–4.8	–0.5	dBm
Transmitter and dispersion penalty (TDP), each lane (max)	2.6		dB

Copyright © 2022 IEEE. All rights reserved.

Table 87–7—40GBASE-LR4 and 40GBASE-ER4 transmit characteristics *(continued)*

Description	40GBASE-LR4	40GBASE-ER4	Unit
Average launch power of OFF transmitter, each lane (max)	–30		dBm
Extinction ratio (min)	3.5	5.5	dB
$RIN_{20}OMA$ (max)	–128		dB/Hz
Optical return loss tolerance (max)	20		dB
Transmitter reflectance[c] (max)	–12		dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}	{0.25, 0.4, 0.45, 0.25, 0.28, 0.4}		

[a]Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b]Even if the TDP < 0.8 dB, the OMA (min) has to exceed this value.
[c]Transmitter reflectance is defined looking into the transmitter.

87.7.2 40GBASE-LR4 and 40GBASE-ER4 receive optical specifications

The 40GBASE-LR4 receiver shall meet the specifications defined in Table 87–8 per the definitions in 87.8.
The 40GBASE-ER4 receiver shall meet the specifications defined in Table 87–8 per the definitions in 87.8.

Table 87–8—40GBASE-LR4 and 40GBASE-ER4 receive characteristics

Description	40GBASE-LR4	40GBASE-ER4	Unit
Signaling rate, each lane (range)	10.3125 ± 100 ppm		GBd
Lane wavelengths (range)	1264.5 to 1277.5 1284.5 to 1297.5 1304.5 to 1317.5 1324.5 to 1337.5		nm
Damage threshold[a] (min)	3.3	3.8	dBm
Average receive power, each lane (max)	2.3	–4.5	dBm
Average receive power, each lane[b] (min)	–13.7	–21.2	dBm
Receive power, each lane (OMA) (max)	3.5	–4	dBm
Difference in receive power between any two lanes (OMA) (max)	7.5	7	dB
Receiver reflectance (max)	–26		dB
Receiver sensitivity (OMA), each lane[c] (max)	–11.5	–19	dBm
Receiver 3 dB electrical upper cutoff frequency, each lane (max)	12.3		GHz
Stressed receiver sensitivity (OMA), each lane[d] (max)	–9.6	–16.8	dBm

Table 87–8—40GBASE-LR4 and 40GBASE-ER4 receive characteristics *(continued)*

Description	40GBASE-LR4	40GBASE-ER4	Unit
Conditions of stressed receiver sensitivity test:			
Vertical eye closure penalty,[e] each lane	1.9	2.2	dB
Stressed eye J2 Jitter,[e] each lane	0.3		UI
Stressed eye J9 Jitter,[e] each lane	0.47		UI

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b]Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c]Receiver sensitivity (OMA), each lane (max) is optional.
[d]Measured with conformance test signal at TP3 (see 87.8.11) for BER = 10^{-12}.
[e]Vertical eye closure penalty, stressed eye J2 Jitter, and stressed eye J9 Jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

87.7.3 40GBASE-LR4 and 40GBASE-ER4 illustrative link power budgets

Illustrative power budgets and penalties for 40GBASE-LR4 and 40GBASE-ER4 channels are shown in Table 87–9.

Table 87–9—40GBASE-LR4 and 40GBASE-ER4 illustrative link power budgets

Parameter	40GBASE-LR4	40GBASE-ER4		Unit
Power budget (for max TDP)	9.3	21.1		dB
Operating distance	10	30	40[a]	km
Channel insertion loss	6.7[b]	16.5[b]	18.5[a]	dB
Maximum discrete reflectance	–26	–26		dB
Allocation for penalties[c] (for max TDP)	2.6	2.6		dB
Additional insertion loss allowed	0	2	0	dB

[a]Links longer than 30 km are considered engineered links. Attenuation for such links needs to be less than the worst case for B1.1, B1.3, or B6_a single-mode cabled optical fiber.
[b]The channel insertion loss is calculated using the maximum distance specified in Table 87–6 and cabled optical fiber attenuation of 0.47 dB/km at 1264.5 nm plus an allocation for connection and splice loss given in 87.11.2.1.
[c]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

87.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

87.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 87–11 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 87–11 may be used to perform that test. The test patterns used in this clause are shown in Table 87–10.

Table 87–10—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 ones, 8 zeros)	83.5.10
3	PRBS31	83.5.10
4	PRBS9	83.5.10
5	Scrambled idle	82.2.11

Table 87–11—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	3, 5 or valid 40GBASE-LR4 or 40GBASE-ER4 signal	87.8.3
Side mode suppression ratio	3, 5 or valid 40GBASE-LR4 or 40GBASE-ER4 signal	87.8.3
Average optical power	3, 5 or valid 40GBASE-LR4 or 40GBASE-ER4 signal	87.8.4
Optical modulation amplitude (OMA)	Square wave or 4	87.8.5
Transmitter and dispersion penalty (TDP)	3 or 5	87.8.6
Extinction ratio	3, 5 or valid 40GBASE-LR4 or 40GBASE-ER4 signal	87.8.7
$RIN_{20}OMA$	Square wave or 4	87.8.8
Transmitter optical waveform	3, 5 or valid 40GBASE-LR4 or 40GBASE-ER4 signal	87.8.9
Stressed receiver sensitivity	3 or 5	87.8.11
Calibration of OMA for receiver tests	Square wave or 4	87.8.11
Vertical eye closure penalty calibration	3 or 5	87.8.11
Receiver 3 dB electrical upper cutoff frequency	3, 5 or valid 40GBASE-LR4 or 40GBASE-ER4 signal	87.8.12

87.8.2 Skew and Skew Variation

Skew and Skew Variation are defined in 80.5 and are required to remain within the limits given in 87.3.2 over the time that the link is in operation. The measurement of Skew and Skew Variation is made by separating optical lanes with an optical demultiplexer and then acquiring the data on each lane using clock and data recovery units with high-frequency corner bandwidths as specified in 86.8.3.2 and a slope of –20 dB/decade. The arrival times of the one to zero transition of the alignment marker sync bits on each lane are then compared. This arrangement ensures that any high frequency jitter that is present on the signals is not included in the Skew measurement.

87.8.3 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR of each optical lane shall be within the ranges given in Table 87–5 if measured per IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 87–11.

87.8.4 Average optical power

The average optical power of each lane shall be within the limits given in Table 87–7 if measured using the methods given in IEC 61280-1-1, with the sum of the optical power from all of the lanes not under test below –30 dBm, per the test setup in Figure 53–6.

87.8.5 Optical Modulation Amplitude (OMA)

OMA shall be as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern, with the exception that each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.

87.8.6 Transmitter and dispersion penalty

Transmitter and dispersion penalty (TDP) shall be as defined in 52.9.10 with the exception that each optical lane is tested individually using an optical filter to separate the lane under test from the others. The measurement procedure for 40GBASE-LR4 and 40GBASE-ER4 is detailed in 87.8.6.1 to 87.8.6.4.

The optical filter passband ripple shall be limited to 0.5 dB peak-to-peak and the isolation is chosen such that the ratio of the power in the lane being measured to the sum of the powers of all of the other lanes is greater than 20 dB (see ITU-T G.959.1 Annex B). The lanes not under test shall be operating with PRBS31 or valid 40GBASE-R bit streams.

87.8.6.1 Reference transmitter requirements

The reference transmitter is a high-quality instrument-grade device that can be implemented by a CW laser modulated by a high-performance modulator. The basic requirements are as follows:

a) Rise/fall times of less than 25 ps at 20% to 80%.
b) The output optical eye is symmetric and passes the transmitter optical waveform test of 87.8.9.
c) In the center 20% region of the eye, the worst-case vertical eye closure penalty as defined in 52.9.9.2 is less than 0.5 dB.
d) Total Jitter less than 0.2 UI peak-to-peak.
e) RIN of less than –136 dB/Hz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

87.8.6.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 87–12.

Table 87–12—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]
	Minimum	Maximum		
40GBASE-LR4	$0.2325 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.2325 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	20 dB
40GBASE-ER4	$0.93 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.93 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	20 dB

[a]The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes 10 km for 40GBASE-LR4 and 40 km for 40GBASE-ER4.
[b]There is no intent to stress the sensitivity of the BERT's optical receiver.
[c]The optical return loss is applied at TP2.

A 40GBASE-LR4 or 40GBASE-ER4 transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 87–12 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 87–12. The state of polarization of the back reflection is adjusted to create the greatest RIN.

87.8.6.3 Reference receiver requirements

The reference receiver is required to have the bandwidth given in 87.8.9. The sensitivity of the reference receiver is limited by Gaussian noise. The receiver has minimal threshold offset, deadband, hysteresis, baseline wander, deterministic jitter, or other distortions. Decision sampling has minimal uncertainty and setup/hold times.

The nominal sensitivity of the reference receiver, S, is measured in OMA using the setup of Figure 52–12 without the test fiber and with the transversal filter removed. The sensitivity S has to be corrected for any significant reference transmitter impairments including any vertical eye closure. It is measured while sampling at the eye center or corrected for off-center sampling. It is calibrated at the wavelength of the transmitter under test.

For all transmitter and dispersion penalty measurements, determination of the center of the eye is required. Center of the eye is defined as the time halfway between the left and right sampling points within the eye where the measured BER is greater than or equal to 1×10^{-3}.

The clock recovery unit (CRU) used in the TDP measurement has a corner frequency of 4 MHz and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the data to the clock removes this low-frequency jitter from the measurement.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

87.8.6.4 Test procedure

The test procedure is as defined in 52.9.10.4 with the exception that all lanes are operational in both directions (transmit and receive), each lane is tested individually using an optical filter to separate the lane under test from the others, and the BER of 1×10^{-12} is for the lane under test on its own.

87.8.7 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 87–7 if measured using the methods specified in IEC 61280-2-2, with the sum of the optical power from all of the lanes not under test below –30 dBm. The extinction ratio is measured using the test pattern defined in Table 87–11.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 87–11).

87.8.8 Relative Intensity Noise ($RIN_{20}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 20 dB.
b) Each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.
c) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 10.3 GHz).

87.8.9 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4. The transmitter optical waveform of a port transmitting the test pattern specified in Table 87–11 shall meet specifications according to the methods specified in 86.8.4.6.1 with the filter nominal reference frequency f_r of 7.5 GHz and filter tolerances as specified for STM-64 in ITU-T G.691. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response.

87.8.10 Receiver sensitivity

Receiver sensitivity, which is defined for an ideal input signal, is optional and compliance is not required. If measured, the test signal should have negligible impairments such as intersymbol interference (ISI), rise/fall times, jitter, and RIN. Instead, the normative requirement for receivers is stressed receiver sensitivity.

87.8.11 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 87–8 if measured using the method described in 87.8.11.1 and 87.8.11.5 with the conformance test signal at TP3 as described in 87.8.11.2. The BER is required to be met for the lane under test on its own.

For each lane, the stressed receiver sensitivity is defined with the transmit section in operation on all four lanes and with the receive lanes not under test also in operation. Pattern 3 or Pattern 5, or a valid 40GBASE-R signal, is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.

87.8.11.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 87–3. The patterns used for testing the receiver are specified in Table 87–11. The optical test signal is conditioned (stressed) using the stressed receiver methodology defined in 87.8.11.2, and has sinusoidal jitter applied as specified in 87.8.11.4. A suitable test set is needed to characterize and verify that the signal used to test the receiver has the appropriate characteristics.

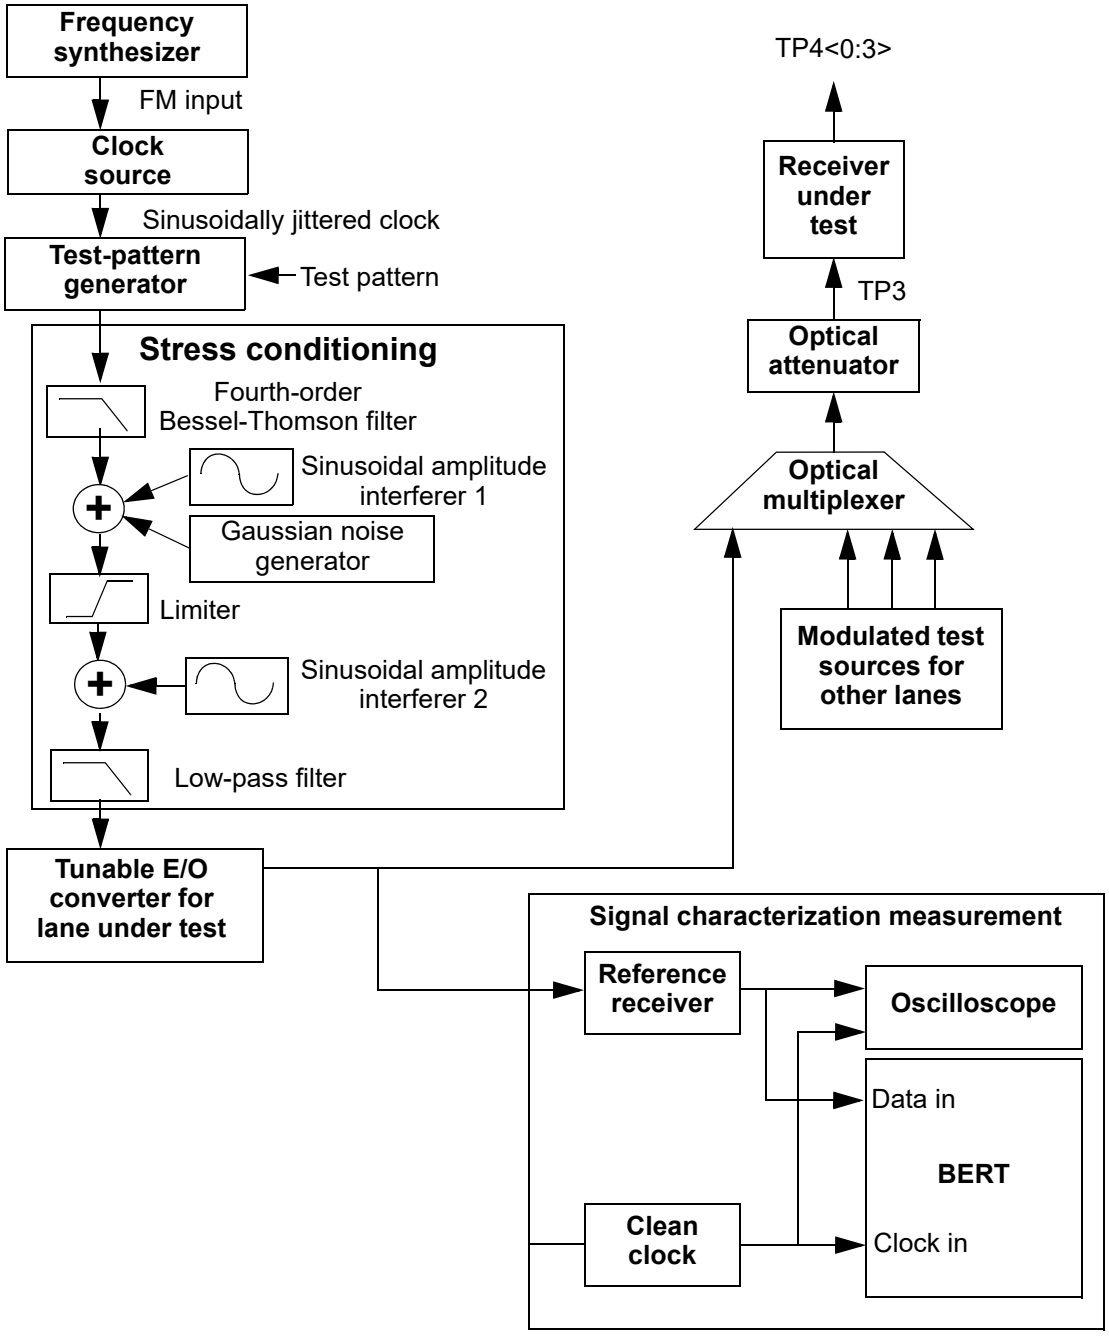

Figure 87–3—Stressed receiver conformance test block diagram

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The low-pass filter is used to create ISI-induced vertical eye closure penalty (VECP). The low-pass filter, when combined with the E/O converter, should have a frequency response that results in the appropriate level of initial vertical eye closure before the sinusoidal terms are added.

The sinusoidal amplitude interferer 1 causes jitter that is intended to emulate instantaneous bit shrinkage that can occur with DDJ. This type of jitter cannot be created by simple phase modulation. The sinusoidal amplitude interferer 2 causes additional eye closure, but in conjunction with the finite edge rates from the limiter, also causes some jitter. The sinusoidally jittered clock represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter. The sinusoidal amplitude interferers may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid harmonic relationships between the sinusoidal interferers, the sinusoidal jitter, the signaling rate, and the pattern repetition rate. The Gaussian noise generator, the amplitude of the sinusoidal interferers, and the low-pass filter are adjusted so that the VECP, stressed eye J2 Jitter, and stressed eye J9 Jitter specifications are met simultaneously.

For improved visibility for calibration, all elements in the signal path (cables, DC blocks, E/O converter, etc.) should have wide and smooth frequency response, and linear phase response, throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be minimized.

The stressed receiver conformance signal verification is described in 87.8.11.3.

87.8.11.2 Stressed receiver conformance test signal characteristics and calibration

The conformance test signal is used to validate that the PMD receiver of the lane under test meets BER requirements with near worst-case waveforms at TP3.

The primary parameters of the conformance test signal are vertical eye closure penalty (VECP), stressed eye J2 Jitter, and stressed eye J9 Jitter. VECP is measured at the time center of the eye (halfway between 0 and 1 on the unit interval scale as defined in 52.9.7). Stressed eye J2 Jitter is defined in 86.8.3.3.1 and stressed eye J9 Jitter is defined in 86.8.3.3.2. The values of these components are defined by their histogram results, as measured at the average optical power, which can be obtained with AC-coupling.

The vertical eye closure penalty is given by Equation (87–1).

$$\text{Vertical eye closure penalty} = 10\log_{10}\frac{OMA}{A_O} \quad \text{(dB)} \tag{87–1}$$

where

A_O is the amplitude of the eye opening from the 99.95th percentile of the lower histogram to the 0.05th percentile of the upper histogram

OMA is the optical modulation amplitude as defined in 87.8.5

An example stressed receiver conformance test setup is shown in Figure 87–3; however, any approach that modulates or creates the appropriate levels and frequencies of the VECP and jitter components is acceptable.

Residual low-probability noise and jitter should be minimized so that the outer slopes of the final amplitude histograms are as steep as possible.

The following steps describe a possible method for setting up and calibrating a stressed eye conformance signal when using a stressed receiver conformance test setup as shown in Figure 87–3:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

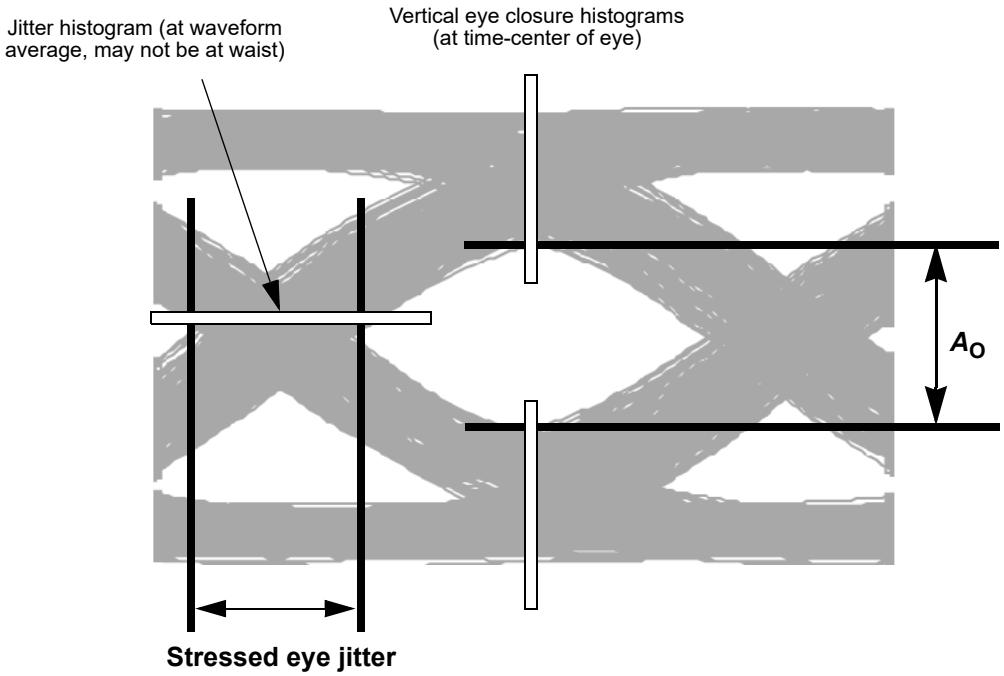

Figure 87–4—Required characteristics of the conformance test signal at TP3

1) Set the signaling rate of the test-pattern generator to meet the requirements in Table 87–8.
2) With sinusoidal interferers and sinusoidal jitter turned off, set the extinction ratio of the E/O to approximately the minimum specified in Table 87–7.
3) The required values of vertical eye closure penalty, stressed eye J2 Jitter, and stressed eye J9 Jitter of the stressed receiver conformance signal are given in Table 87–8.

   With the sinusoidal interferers and sinusoidal jitter turned off, greater than two thirds of the dB value of the VECP should be created by the selection of the appropriate bandwidth for the low-pass filter. Any remaining VECP has to be created with sinusoidal interferer 2 or sinusoidal jitter.

   The sinusoidal amplitude interferers may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid harmonic relationships between the sinusoidal interferers, the sinusoidal jitter, the signaling rate and the pattern repetition rate.

   Sinusoidal jitter is added as specified in Table 87–13. When calibrating the conformance signal, the sinusoidal jitter frequency should be well within the 4 MHz to 10 times LB as defined in Table 87–13 and illustrated in Figure 87–5.

   Iterate the adjustments of sinusoidal interferers and Gaussian noise generator until the values of VECP, stressed eye J2 Jitter and stressed eye J9 Jitter meet the requirements in Table 87–8, and sinusoidal jitter above 4 MHz is as specified in Table 87–13. The resulting stressed eye conformance signal is required to have at least 0.05 UI of pulse width shrinkage.

Figure 87–3 shows the stress conditioned signal being applied to a tunable E/O converter. However, any optical source may be used that can meet the OMA and wavelength requirements for the lane under test as described in 87.8.11.5. Similarly, the other test sources that supply modulated signals to the other lanes may use any tunable or fixed sources that meet the OMA and wavelength requirements described in 87.8.11.5.

Each receiver lane is conformance tested in turn. The source for the lane under test is adjusted to supply a signal at the input to the receiver under test at the stressed receiver sensitivity OMA specified in Table 87–8, and the test sources for the other lanes are set to the required OMA and wavelength as described in 87.8.11.5.

87.8.11.3 Stressed receiver conformance test signal verification

The stressed receiver conformance test signal can be verified using an optical reference receiver with an ideal fourth-order Bessel-Thomson response with a reference frequency f_r of 7.5 GHz. Use of G.691 tolerance filters may significantly degrade this calibration. The clock output from the clock source in Figure 87–3 will be modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye J2 Jitter and stressed eye J9 Jitter that includes the sinusoidal jitter component, a separate clock source (clean clock of Figure 87–3) is required that is synchronized to the source clock, but not modulated with the jitter source.

Care should be taken when characterizing the test signal because excessive noise/jitter in the measurement system will result in an input signal that does not fully stress the receiver under test. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. Care should be taken to minimize the noise/jitter introduced by the reference O/E, filters, and BERT and/or to correct for this noise. While the details of a BER scan measurement and test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands to ensure that the stressed receiver conformance input signal meets the stress and sinusoidal jitter specified in 87.8.11.2 and 87.8.11.4.

87.8.11.4 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. The amplitude of the applied sinusoidal jitter is dependent on frequency as specified in Table 87–13 and is illustrated in Figure 87–5.

Table 87–13—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 40$ kHz	Not specified
40 kHz $< f \leq 4$ MHz	2×10^5 Hz / f
4 MHz $< f <$ 10 LB[a]	0.05

[a] LB = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

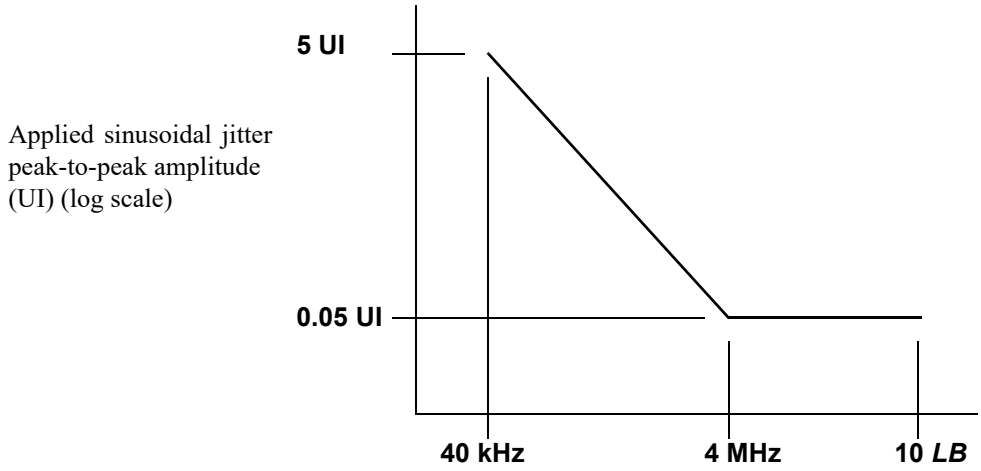

Figure 87–5—Illustration of the mask of the sinusoidal component of jitter tolerance

87.8.11.5 Stressed receiver conformance test procedure for WDM conformance testing

The receiver tests requiring the TP3 conformance test signal are performed on a per lane basis. For each lane, the stressed receiver sensitivity is defined with the transmit section in operation on all four lanes and with the receive lanes not under test also in operation. Pattern 3 or Pattern 5, or a valid 40GBASE-R signal is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal. All test sources are modulated simultaneously, using valid 40GBASE-R signals. The transmitter of the transceiver under test is operating with test patterns as defined in Table 87–11.

A rigorous method for testing WDM conformance using tunable test sources is described as follows:

a) The OMAs of the test sources in the lanes other than the lane under test are set to the highest OMA relative to the test source in the lane under test allowed by the “difference in receive power between any two lanes (OMA) (max)” parameter in Table 87–8.
b) The test sources in the lanes other than the lane under test are tuned to wavelengths within their wavelength range corresponding to the worst-case crosstalk to the lane under test.
c) The test source for the lane under test is tuned to the wavelength within its wavelength range corresponding to the worst-case sensitivity for the receiver under test.

It is recognized that a test setup that uses multiple tunable sources, while allowing rigorous worst-case measurements to be made, is likely to be onerous in practice.

A more practical, alternative method for testing WDM conformance is described below. The alternative WDM conformance test avoids the need for tunable sources but may result in some over-stressing of the receiver under test:

1) The test sources in each lane can be at any wavelength within each lane’s wavelength range.
2) The OMAs of the test sources in the lanes other than the lane under test are set to the highest OMA relative to the test source in the lane under test allowed by the “difference in receive power between any two lanes (OMA) (max)” parameter in Table 87–8, plus an increment corresponding to insertion loss variation within the lane under test (NOTE 1), plus an increment corresponding to the isolation variation of the lane in question (NOTE 2).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The increment corresponding to the variation of insertion loss with wavelength within the lane under test is equal to the dB variation of measured receiver sensitivity as the test source wavelength is swept across the wavelength range of the lane under test.

NOTE 2—For each of the test sources in the lanes not under test, an increment corresponding to the isolation variation is applied that is equal to the dB variation in optical crosstalk measured in the lane under test as the wavelength of each test source in the lanes not under test is swept across its respective wavelength range.

There are many ways to determine the size of the increments required, two example methods are given in the paragraphs that follow. Note that each lane will have one insertion loss variation value, and three values of optical crosstalk variation (one for each of the other lanes).

Example method 1: If a measure of the received signal strength is available for each lane, scan a tunable laser across the wavelength range of each lane while simultaneously recording the received signal in all lanes. As the laser sweeps across the wavelength range of a particular lane the dB variation in observed signal in that lane is equal to the insertion loss variation. The dB variation in signal observed in each of the other lanes is equal to the optical crosstalk variation.

Example method 2: If a discrete optical demultiplexer and discrete receivers are used, scan a tunable laser across the wavelength range of each channel while simultaneously recording the optical power of all four demultiplexer outputs. As the laser sweeps across the wavelength range of a particular channel, the dB variation in observed optical power in that lane's output is equal to the insertion loss variation. The dB variation in optical power observed in each of the other lanes outputs is equal to the optical crosstalk variation.

87.8.12 Receiver 3 dB electrical upper cutoff frequency

The receiver 3 dB electrical upper cutoff frequency shall be within the limits given in Table 87–8 if measured as described in 52.9.11. Each optical lane is measured using an optical signal or signals with its/their wavelength within the specified wavelength range of the lane to be tested. The test may use an electrical combiner and one optical source as in 53.9.13.

87.9 Safety, installation, environment, and labeling

87.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

87.9.2 Laser safety

40GBASE-LR4 and 40GBASE-ER4 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[153]

[153]A host system that fails to meet the manufacturers requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

87.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

87.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 40GBASE-LR4 or 40GBASE-ER4 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

87.9.4.1 Electromagnetic emission

A system integrating a 40GBASE-LR4 or 40GBASE-ER4 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

87.9.4.2 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

87.9.5 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 40GBASE-LR4).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 87.9.2.

87.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 87–6.

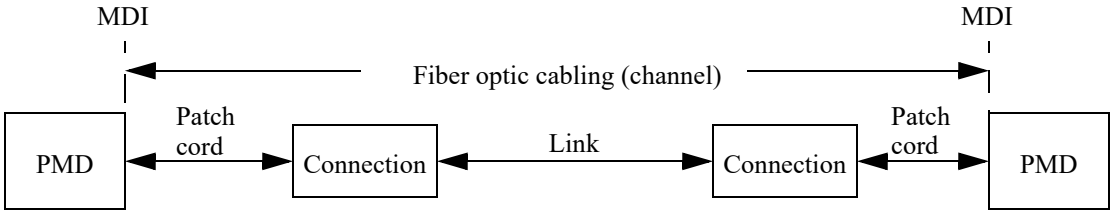

Figure 87–6—Fiber optic cabling model

The channel insertion loss is given in Table 87–14. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 87–14—Fiber optic cabling (channel) characteristics

Description	40GBASE-LR4	40GBASE-ER4		Unit
Operating distance (max)	10	30	40	km
Channel insertion loss[a, b](max)	6.7	18.5		dB
Channel insertion loss (min)	0	9		dB
Positive dispersion[b] (max)	33.5	100.5	134	ps/nm
Negative dispersion[b] (min)	–59.5	–178.5	–238	ps/nm
DGD_max[c]	10	12		ps
Optical return loss (min)	21	21		dB

[a]These channel insertion loss values include cable, connectors, and splices.
[b]Over the wavelength range 1264.5 nm to 1337.5 nm.
[c]Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

87.11 Characteristics of the fiber optic cabling (channel)

The 40GBASE-LR4 and 40GBASE-ER4 fiber optic cabling shall meet the specifications defined in Table 87–14. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

87.11.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion un-shifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 87–15 where they differ.

Table 87–15—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.47[a] or 0.5[b]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a]The 0.47 dB/km at 1264.5 nm attenuation for optical fiber cables is derived from Appendix I of ITU-T G.695.
[b]The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3. Using 0.5 dB/km may not support operation at 10 km for 40GBASE-LR4 or 40 km for 40GBASE-ER4.

87.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 87–6, consists of a mated pair of optical connectors.

87.11.2.1 Connection insertion loss

The maximum link distances for single-mode fiber are calculated based on an allocation of 2 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 87–14 are met.

87.11.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –26 dB.

87.11.3 Medium Dependent Interface (MDI) requirements

The 40GBASE-LR4 or 40GBASE-ER4 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 87–6). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 87.5.1, not at the MDI.

87.12 Requirements for interoperation between 40GBASE-LR4 and 40GBASE-ER4

The 40GBASE-LR4 and 40GBASE-ER4 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 40GBASE-LR4 given in Table 87–14 are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 87–16 for the two link directions separately.

Table 87–16—Channel insertion loss requirements for interoperation

Direction	Min loss	Max loss	Unit
40GBASE-LR4 Transmitter to 40GBASE-ER4 Receiver	7.5	14.2	dB
40GBASE-ER4 Transmitter to 40GBASE-LR4 Receiver	2.2	11	dB

87.13 Protocol implementation conformance statement (PICS) proforma for Clause 87, Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-LR4 and 40GBASE-ER4[154]

87.13.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 87, Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-LR4 and 40GBASE-ER4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

87.13.2 Identification

87.13.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

87.13.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 87, Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-LR4 and 40GBASE-ER4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[154]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

88. Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-LR4 and 100GBASE-ER4

88.1 Overview

This clause specifies the 100GBASE-LR4 PMD and the 100GBASE-ER4 PMD together with the single-mode fiber medium. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 88–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 88–1—Physical Layer clauses associated with the 100GBASE-LR4 and 100GBASE-ER4 PMDs

Associated clause	100GBASE-LR4	100GBASE-ER4
81—RS	Required	Required
81—CGMII[a]	Optional	Optional
82—PCS for 100GBASE-R	Required	Required
83—PMA for 100GBASE-R	Required	Required
83A—CAUI-10	Optional	Optional
83B—Chip to module CAUI-10	Optional	Optional
83D—CAUI-4	Optional	Optional
83E—Chip-to-module CAUI-4	Optional	Optional
78—Energy Efficient Ethernet	Optional	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.

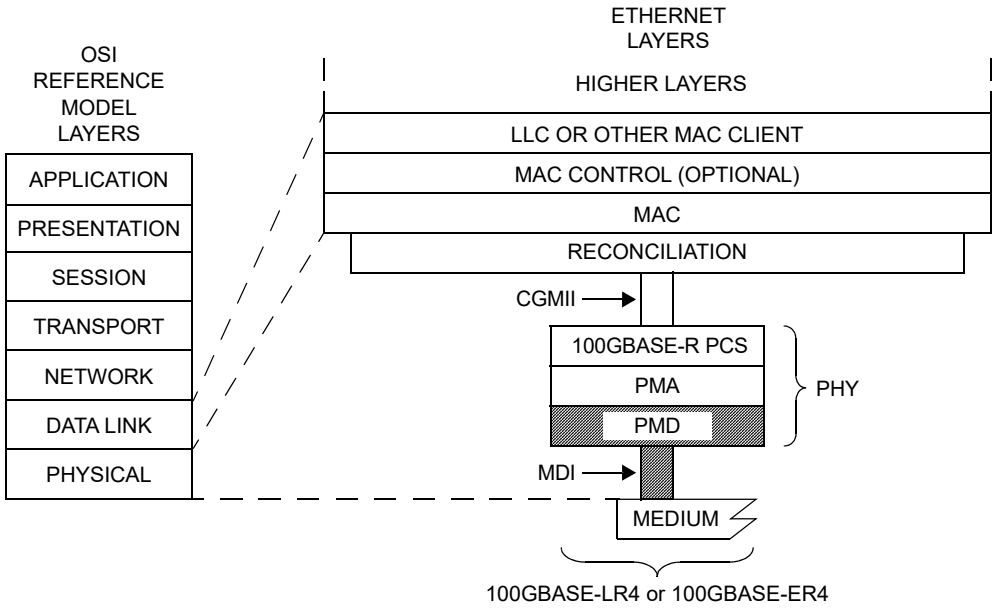

Figure 88–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 40 Gb/s and 100 Gb/s Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2.

100GBASE-LR4 and 100GBASE-ER4 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

88.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-LR4 and 100GBASE-ER4 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

LR = PMD FOR SINGLE-MODE FIBER — 10 km
ER = PMD FOR SINGLE-MODE FIBER — 40 km

Figure 88–1—100GBASE-LR4 and 100GBASE-ER4 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 100GBASE-LR4 and 100GBASE-ER4 PMDs have four parallel bit streams, hence $i = 0$ to 3.

In the transmit direction, the PMA continuously sends four parallel bit streams to the PMD, one per lane, each at a nominal signaling rate of 25.78125 GBd. The PMD then converts these streams of bits into the appropriate signals on the MDI.

In the receive direction, the PMD continuously sends four parallel bit streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service interface primitive defined in 80.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_bit parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_bit parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the 10^{-12} BER objective.

88.3 Delay and Skew

88.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 100GBASE-LR4 or 100GBASE-ER4 PMD including 2 m of fiber in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

88.3.2 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–7 and Figure 80–8.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

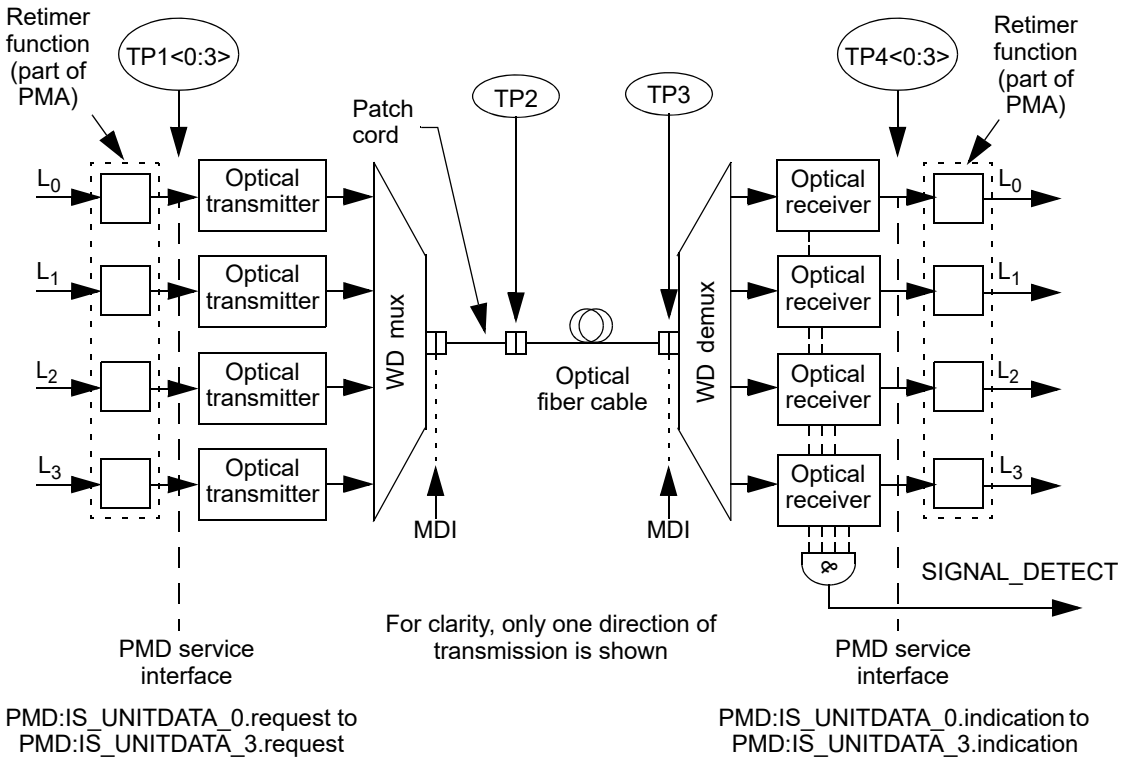
The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5. The measurements of Skew and Skew Variation are defined in 87.8.2 with the exception that the clock and data recovery units' high-frequency corner bandwidths are 10 MHz.

88.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 88–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 88–3.



88.5 PMD functional specifications

The 100GBASE-LR4 and 100GBASE-ER4 PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

88.5.1 PMD block diagram

The PMD block diagram is shown in Figure 88–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 88.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 88.11.3). Unless specified otherwise, all receiver measurements and tests defined in 88.8 are made at TP3.

NOTE—Specification of the retimer function and the electrical implementation of the PMD service interface is beyond the scope of this standard.

Figure 88–2—Block diagram for 100GBASE-LR4 and 100GBASE-ER4 transmit/receive paths

Table 88–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 3	PMD transmit disable register	1.9.4	PMD_transmit_disable_3
PMD transmit disable 2	PMD transmit disable register	1.9.3	PMD_transmit_disable_2
PMD transmit disable 1	PMD transmit disable register	1.9.2	PMD_transmit_disable_1
PMD transmit disable 0	PMD transmit disable register	1.9.1	PMD_transmit_disable_0

TP1<0:3> and TP4<0:3> are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

Table 88–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 3	PMD receive signal detect register	1.10.4	PMD_signal_detect_3
PMD receive signal detect 2	PMD receive signal detect register	1.10.3	PMD_signal_detect_2
PMD receive signal detect 1	PMD receive signal detect register	1.10.2	PMD_signal_detect_1
PMD receive signal detect 0	PMD receive signal detect register	1.10.1	PMD_signal_detect_0

88.5.2 PMD transmit function

The PMD Transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate optical signals. The four optical signals shall then be wavelength division multiplexed and delivered to the MDI, all according to the transmit optical specifications in this clause. The higher optical power level in each signal shall correspond to tx_bit = one.

88.5.3 PMD receive function

The PMD Receive function shall demultiplex the composite optical signal received from the MDI into four separate optical signals. The four optical signals shall then be converted into four bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_bit = one.

88.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 80.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all four lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 88–4. The PMD receiver is not required to verify whether a compliant 100GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 88–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ receiver sensitivity (max) in OMA in Table 88–8) AND (compliant 100GBASE–R signal input)]	OK
All other conditions	Unspecified

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

88.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:3, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 88–4.

88.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

88.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 88–7.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

88.5.8 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitters in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 88–7.
b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method shall be provided to independently disable each transmit lane for testing purposes.

88.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

88.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

88.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

88.6 Wavelength-division-multiplexed lane assignments

The wavelength range for each lane of the 100GBASE-LR4 and 100GBASE-ER4 PMDs is defined in Table 88–5. The center frequencies are members of the frequency grid for 100 GHz spacing and above defined in ITU-T G.694.1 and are spaced at 800 GHz.

Table 88–5—Wavelength-division-multiplexed lane assignments

Lane	Center frequency	Center wavelength	Wavelength range
L_0	231.4 THz	1295.56 nm	1294.53 to 1296.59 nm
L_1	230.6 THz	1300.05 nm	1299.02 to 1301.09 nm
L_2	229.8 THz	1304.58 nm	1303.54 to 1305.63 nm
L_3	229 THz	1309.14 nm	1308.09 to 1310.19 nm

NOTE—There is no requirement to associate a particular electrical lane with a particular optical lane, as the PCS is capable of receiving lanes in any arrangement.

88.7 PMD to MDI optical specifications for 100GBASE-LR4 and 100GBASE-ER4

The operating ranges for the 100GBASE-LR4 and 100GBASE-ER4 PMDs are defined in Table 88–6. A 100GBASE-LR4 or 100GBASE-ER4 compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 88–14. A PMD that exceeds the operating range

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

requirement while meeting all other optical specifications is considered compliant (e.g., a 100GBASE-LR4 PMD operating at 12.5 km meets the operating range requirement of 2 m to 10 km). The 100GBASE-ER4 PMD interoperates with the 100GBASE-LR4 PMD provided that the channel requirements for 100GBASE-LR4 are met.

Table 88–6—100GBASE-LR4 and 100GBASE-ER4 operating ranges

PMD type	Required operating range
100GBASE-LR4	2 m to 10 km
100GBASE-ER4	2 m to 30 km
	2 m to 40 km[a]

[a]Links longer than 30 km for the same link power budget are considered engineered links. Attenuation for such links needs to be less than the worst case specified for B1.1, B1.3, or B6_a single-mode fiber.

88.7.1 100GBASE-LR4 and 100GBASE-ER4 transmitter optical specifications

The 100GBASE-LR4 transmitter shall meet the specifications defined in Table 88–7 per the definitions in 88.8. The 100GBASE-ER4 transmitter shall meet the specifications defined in Table 88–7 per the definitions in 88.8.

Table 88–7—100GBASE-LR4 and 100GBASE-ER4 transmit characteristics

Description	100GBASE-LR4	100GBASE-ER4	Unit
Signaling rate, each lane (range)	25.78125 ± 100 ppm		GBd
Lane wavelengths (range)	1294.53 to 1296.59 1299.02 to 1301.09 1303.54 to 1305.63 1308.09 to 1310.19		nm
Side-mode suppression ratio (SMSR), (min)	30		dB
Total average launch power (max)	10.5	8.9	dBm
Average launch power, each lane (max)	4.5	2.9	dBm
Average launch power, each lane[a] (min)	–4.3	–2.9	dBm
Optical Modulation Amplitude (OMA), each lane (max)	4.5		dBm
Optical Modulation Amplitude (OMA), each lane (min)	–1.3[b]	0.1	dBm
Difference in launch power between any two lanes (OMA) (max)	5	—	dB
Difference in launch power between any two lanes (Average and OMA) (max)	—	3.6	
Launch power in OMA minus TDP, each lane (min)	–2.3	—	dBm
Transmitter and dispersion penalty (TDP), each lane (max)	2.2	2.5	dB
Average launch power of OFF transmitter, each lane (max)	–30		dBm
Extinction ratio (min)	4	8	dB
$RIN_{20}OMA$ (max)	–130		dB/Hz
Optical return loss tolerance (max)	20		dB
Transmitter reflectance[c] (max)	–12		dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}	{0.25, 0.4, 0.45, 0.25, 0.28, 0.4}		

[a]Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b]Even if the TDP < 1 dB, the OMA (min) has to exceed this value.
[c]Transmitter reflectance is defined looking into the transmitter.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

88.7.2 100GBASE-LR4 and 100GBASE-ER4 receive optical specifications

The 100GBASE-LR4 receiver shall meet the specifications defined in Table 88–8 per the definitions in 88.8.
The 100GBASE-ER4 receiver shall meet the specifications defined in Table 88–8 per the definitions in 88.8.

Table 88–8—100GBASE-LR4 and 100GBASE-ER4 receive characteristics

Description	100GBASE-LR4	100GBASE-ER4	Unit
Signaling rate, each lane (range)	25.78125 ± 100 ppm		GBd
Lane wavelengths (range)	1294.53 to 1296.59 1299.02 to 1301.09 1303.54 to 1305.63 1308.09 to 1310.19		nm
Damage threshold[a]	5.5		dBm
Average receive power, each lane (max)	4.5[b]		dBm
Average receive power, each lane[c] (min)	–10.6	–20.9	dBm
Receive power, each lane (OMA) (max)	4.5		dBm
Difference in receive power between any two lanes (OMA) (max)	5.5	—	dB
Difference in receive power between any two lanes (Average and OMA) (max)	—	4.5	
Receiver reflectance (max)	–26		dB
Receiver sensitivity (OMA), each lane[d] (max)	–8.6	–21.4	dBm
Receiver 3 dB electrical upper cutoff frequency, each lane (max)	31		GHz
Stressed receiver sensitivity (OMA), each lane[e] (max)	–6.8	–17.9	dBm
Conditions of stressed receiver sensitivity test			
Vertical eye closure penalty,[f] each lane	1.8	3.5	dB
Stressed eye J2 Jitter,[f] each lane	0.3		UI
Stressed eye J9 Jitter,[f] each lane	0.47		UI

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b]The average receive power, each lane (max) for 100GBASE-ER4 is larger than the 100GBASE-ER4 transmitter value to allow compatibility with 100GBASE-LR4 units at short distances.
[c]Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[d]Receiver sensitivity (OMA), each lane (max) is optional.
[e]Measured with conformance test signal at TP3 (see 88.8.10) for BER = 10^{-12}.
[f]Vertical eye closure penalty, stressed eye J2 Jitter, and stressed eye J9 Jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

88.7.3 100GBASE-LR4 and 100GBASE-ER4 illustrative link power budgets

Illustrative power budgets and penalties for 100GBASE-LR4 and 100GBASE-ER4 channels are shown in Table 88–9.

Table 88–9—100GBASE-LR4 and 100GBASE-ER4 illustrative link power budgets

Parameter	100GBASE-LR4	100GBASE-ER4		Unit
Power budget (for maximum TDP)	8.5	—		dB
Power budget	—	21.5		dB
Operating distance	10	30	40[a]	km
Channel insertion loss	6.3[b]	15	18	dB
Maximum discrete reflectance	–26	–26		dB
Allocation for penalties[c] (for maximum TDP)	2.2	—		dB
Allocation for penalties[c]	—	3.5		
Additional insertion loss allowed	0	3	0	dB

[a]Links longer than 30 km are considered engineered links. Attenuation for such links needs to be less than the worst case for B1.1, B1.3, or B6_a single-mode cabled optical fiber
[b]The channel insertion loss is calculated using the maximum distance specified in Table 88–6 for 100GBASE-LR4 and fiber attenuation of 0.43 dB/km at 1295 nm plus an allocation for connection and splice loss given in 88.11.2.1.
[c]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

88.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

88.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 88–11 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 88–11 may be used to perform that test. The test patterns used in this clause are shown in Table 88–10.

88.8.2 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR of each optical lane shall be within the ranges given in Table 88–5 if measured per IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 88–11.

88.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 88–7 if measured using the methods given in IEC 61280-1-1, with the sum of the optical power from all of the lanes not under test below –30 dBm, per the test setup in Figure 53–6.

Table 88–10—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 ones, 8 zeros)	83.5.10
3	PRBS31	83.5.10
4	PRBS9	83.5.10
5	Scrambled idle	82.2.11

Table 88–11—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	3, 5 or valid 100GBASE-R signal	88.8.2
Side mode suppression ratio	3, 5 or valid 100GBASE-R signal	88.8.2
Average optical power	3, 5 or valid 100GBASE-R signal	88.8.3
Optical modulation amplitude (OMA)	Square wave or 4	88.8.4
Transmitter and dispersion penalty (TDP)	3 or 5	88.8.5
Extinction ratio	3, 5 or valid 100GBASE-R signal	88.8.6
$RIN_{20}OMA$	Square wave or 4	88.8.7
Transmitter optical waveform	3, 5 or valid 100GBASE-R signal	88.8.8
Stressed receiver sensitivity	3 or 5	88.8.10
Calibration of OMA for receiver tests	Square wave or 4	87.8.11
Vertical eye closure penalty calibration	3 or 5	87.8.11
Receiver 3 dB electrical upper cutoff frequency	3, 5 or valid 100GBASE-R signal	88.8.11

88.8.4 Optical Modulation Amplitude (OMA)

OMA shall be as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern, with the exception that each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.

88.8.5 Transmitter and dispersion penalty (TDP)

Transmitter and dispersion penalty (TDP) shall be as defined in 52.9.10 with the exception that each optical lane is tested individually using an optical filter to separate the lane under test from the others. The measurement procedure for 100GBASE-LR4 and 100GBASE-ER4 is detailed in 88.8.5.1 to 88.8.5.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The optical filter passband ripple shall be limited to 0.5 dB peak-to-peak and the isolation is chosen such that the ratio of the power in the lane being measured to the sum of the powers of all of the other lanes is greater than 20 dB (see ITU-T G.959.1 Annex B). The lanes not under test shall be operating with PRBS31 or valid 100GBASE-R bit streams.

88.8.5.1 Reference transmitter requirements

The reference transmitter is a high-quality instrument-grade device, which can be implemented by a CW laser modulated by a high-performance modulator. The basic requirements are as follows:

a) Rise/fall times of less than 12 ps at 20% to 80%.
b) The output optical eye is symmetric and passes the transmitter optical waveform test of 88.8.8.
c) In the center 20% region of the eye, the worst-case vertical eye closure penalty as defined in 87.8.11.2 is less than 0.5 dB.
d) Total Jitter less than 0.2 UI peak-to-peak.
e) RIN of less than –138 dB/Hz.

88.8.5.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 88–12.

Table 88–12—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
100GBASE-LR4	$0.2325 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.2325 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	20 dB	0.8 ps
100GBASE-ER4	$0.93 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.93 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	20 dB	0.8 ps

[a]The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes 10 km for 100GBASE-LR4 and 40 km for 100GBASE-ER4.
[b]There is no intent to stress the sensitivity of the BERT's optical receiver.
[c]The optical return loss is applied at TP2.

A 100GBASE-LR4 or 100GBASE-ER4 transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 88–12 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 88–12. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 88–12.

88.8.5.3 Reference receiver requirements

The reference receiver is required to have the bandwidth given in 88.8.8. The sensitivity of the reference receiver is limited by Gaussian noise. The receiver has minimal threshold offset, deadband, hysteresis,

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

baseline wander, deterministic jitter, or other distortions. Decision sampling has minimal uncertainty and setup/hold times.

The nominal sensitivity of the reference receiver, S, is measured in OMA using the setup of Figure 52–12 without the test fiber and with the transversal filter removed. The sensitivity S has to be corrected for any significant reference transmitter impairments including any vertical eye closure. It is measured while sampling at the eye center or corrected for off-center sampling. It is calibrated at the wavelength of the transmitter under test.

For all transmitter and dispersion penalty measurements, determination of the center of the eye is required. Center of the eye is defined as the time halfway between the left and right sampling points within the eye where the measured BER is greater than or equal to 1×10^{-3}.

The clock recovery unit (CRU) used in the TDP measurement has a corner frequency of 10 MHz and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the data to the clock removes this low-frequency jitter from the measurement.

88.8.5.4 Test procedure

The test procedure is as defined in 52.9.10.4 with the exception that all lanes are operational in both directions (transmit and receive), each lane is tested individually using an optical filter to separate the lane under test from the others and the BER of 1×10^{-12} is for the lane under test on its own.

88.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 88–7 if measured using the methods specified in IEC 61280-2-2, with the sum of the optical power from all of the lanes not under test below –30 dBm. The extinction ratio is measured using the test pattern defined in Table 88–11.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 88–11).

88.8.7 Relative Intensity Noise ($RIN_{20}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 20 dB.
b) Each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.
c) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 25.8 GHz).

88.8.8 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4. The transmitter optical waveform of a port transmitting the test pattern specified in Table 88–11 shall meet specifications according to the methods specified in 86.8.4.6.1 with the exception that the clock recovery unit's high-frequency corner bandwidth is 10 MHz. The filter nominal reference frequency f_r is 19.34 GHz and the filter tolerances are as specified for STM-64 in ITU-T G.691. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

88.8.9 Receiver sensitivity

Receiver sensitivity, which is defined for an ideal input signal, is optional and compliance is not required. If measured, the test signal should have negligible impairments such as intersymbol interference (ISI), rise/fall times, jitter and RIN. Instead, the normative requirement for receivers is stressed receiver sensitivity.

88.8.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 88–8 if measured using the method defined in 87.8.11 with the following exceptions:

a) Added sinusoidal jitter is as specified in Table 88–13.
b) The stressed eye J2 Jitter, stressed eye J9 Jitter, and vertical eye closure penalty are as given in Table 88–8.
c) The test pattern is as given in Table 88–11.
d) The reference receiver used to verify the conformance test signal is required to have the bandwidth given in 88.8.8.

Table 88–13—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 100$ kHz	Not specified
100 kHz $< f \leq$ 10 MHz	5×10^5 Hz / f
10 MHz $< f <$ 10 LB[a]	0.05

[a]LB = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

88.8.11 Receiver 3 dB electrical upper cutoff frequency

The receiver 3 dB electrical upper cutoff frequency shall be within the limits given in Table 88–8 if measured as described in 52.9.11. Each optical lane is measured using an optical signal or signals with its/their wavelength within the specified wavelength range of the lane to be tested. The test may use an electrical combiner and one optical source as in 53.9.13.

88.9 Safety, installation, environment, and labeling

88.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

88.9.2 Laser safety

100GBASE-LR4 and 100GBASE-ER4 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[155]

88.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

88.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 100GBASE-LR4 or 100GBASE-ER4 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

88.9.5 Electromagnetic emission

A system integrating a 100GBASE-LR4 or 100GBASE-ER4 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

88.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

88.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 100GBASE-LR4).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 88.9.2.

[155]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

88.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 88–3.

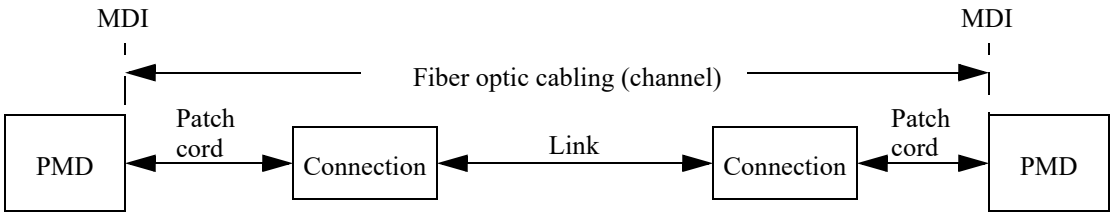

Figure 88–3—Fiber optic cabling model

The channel insertion loss is given in Table 88–14. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 88–14—Fiber optic cabling (channel) characteristics

Description	100GBASE-LR4	100GBASE-ER4		Unit
Operating distance (max)	10	30	40	km
Channel insertion loss[a, b] (max)	6.3	18	18	dB
Channel insertion loss (min)	0	0		dB
Positive dispersion[b] (max)	9.5	28	36	ps/nm
Negative dispersion[b] (min)	–28.5	–85	–114	ps/nm
DGD_max[c]	8	10.3	10.3	ps
Optical return loss (min)	21	21	21	dB

[a]These channel insertion loss values include cable, connectors, and splices.
[b]Over the wavelength range 1294.53 nm to 1310.19 nm.
[c]Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

88.11 Characteristics of the fiber optic cabling (channel)

The 100GBASE-LR4 and 100GBASE-ER4 fiber optic cabling shall meet the specifications defined in Table 88–14. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

88.11.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion un-shifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 88–15 where they differ.

Table 88–15—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.43[a] or 0.5[b]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a]The 0.43 dB/km at 1295 nm attenuation for optical fiber cables is derived from Appendix I of ITU-T G.695.
[b]The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3. Using 0.5 dB/km may not support operation at 10 km for 100GBASE-LR4 or 40 km for 100GBASE-ER4.

88.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 88–3, consists of a mated pair of optical connectors.

88.11.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 2 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 88–14 are met.

88.11.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –26 dB.

88.11.3 Medium Dependent Interface (MDI) requirements

The 100GBASE-LR4 or 100GBASE-ER4 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” (as shown in Figure 88–3). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 88.5.1, not at the MDI.

88.12 Protocol implementation conformance statement (PICS) proforma for Clause 88, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-LR4 and 100GBASE-ER4[156]

88.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 88, Physical Medium Dependent sublayer and medium, type 100GBASE-LR4 and 100GBASE-ER4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

88.12.2 Identification

88.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

88.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 88, Physical Medium Dependent sublayer and medium, type 100GBASE-LR4 and 100GBASE-ER4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[156]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

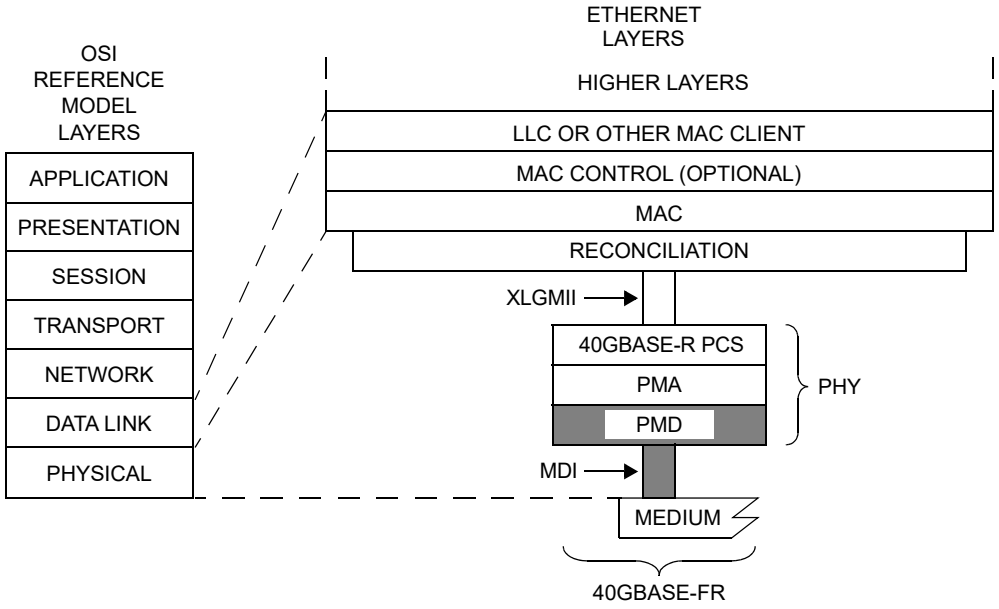
89. Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-FR

89.1 Overview

This clause specifies the 40GBASE-FR PMD together with the single-mode fiber medium. It is intended that devices compliant with this specification could be implemented to also be used for application VSR2000-3R2 as defined in ITU-T G.693 [B45] (but that is beyond the scope of this standard). The 40GBASE-FR PMD is defined using a specification and test methodology that is similar to that used in ITU-T G.693 [B45], which is different from the specification and test methodologies used for other optical PMDs at 1000 Mb/s and above in IEEE Std 802.3. For example, the transmitter specifications for 40GBASE-FR do not include OMA or TDP parameters but do include a dispersion penalty limit, and the receiver specifications for 40GBASE-FR do not include stressed receiver sensitivity parameters but do include a part-stressed sensitivity limit and a separate jitter tolerance limit. See 89.6.4.

When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 89–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 89–1—Physical Layer clauses associated with the 40GBASE-FR PMD



Associated clause	40GBASE-FR
81—RS	Required
81—XLGMII[a]	Optional
82—PCS for 40GBASE-R	Required
83—PMA for 40GBASE-R	Required
83A—XLAUI	Optional
83B—Chip to module XLAUI	Optional
78—Energy Efficient Ethernet	Optional

[a]The XLGMII is an optional interface. However, if the XLGMII is not implemented, a conforming implementation behaves functionally as though the RS and XLGMII were present.

Figure 89–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 40 Gb/s and 100 Gb/s Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2.

40GBASE-FR PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE
FR = PMD FOR SINGLE-MODE FIBER — 2 km

Figure 89–1—40GBASE-FR PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

89.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 40GBASE-FR PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_0.request
PMD:IS_UNITDATA_0.indication
PMD:IS_SIGNAL.indication

In the transmit direction, the PMA continuously sends a single serial stream of bits to the PMD at a nominal signaling rate of 41.25 GBd. The PMD converts this stream of bits into an appropriate signal on the MDI.

In the receive direction, the PMD continuously sends a single serial stream of bits to the PMA corresponding to the signal received from the MDI at a nominal signaling rate of 41.25 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service primitive defined in 80.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_bit parameter is undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_bit parameter is known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the 10^{-12} BER objective.

89.3 Delay and skew

89.3.1 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the 40GBASE-FR PMD including 2 m of fiber in one direction shall be no more than 1024 bit times (2 pause_quanta or 25.6 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

89.3.2 Skew constraints

The Skew (relative delay) between the PCS lanes is kept within limits so that the information on the lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–7 and Figure 80–8.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 83.5.3.4. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

For more information on Skew and Skew Variation, see 80.5. The measurements of Skew and Skew Variation are defined in 89.7.2.

89.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 89–2, and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 89–3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 89–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD Transmit disable register	1.9.0	PMD_global_transmit_disable

Table 89–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

89.5 PMD functional specifications

The 40GBASE-FR PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

89.5.1 PMD block diagram

The PMD block diagram is shown in Figure 89–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 89.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 89.10.3). Unless specified otherwise, all receiver measurements and tests defined in 89.7 are made at TP3.

89.5.2 PMD transmit function

The PMD Transmit function shall convert the bit stream requested by the PMD service interface message PMD:IS_UNITDATA_0.request into an optical signal and deliver it to the MDI, according to the transmit optical specifications in this clause. The higher optical power level in the signal shall correspond to tx_bit = one.

89.5.3 PMD receive function

The optical signal received from the MDI shall be converted into a bit stream for delivery to the PMD service interface using the message PMD:IS_UNITDATA_0.indication, according to the receive optical specifications in this clause. The higher optical power level in the signal shall correspond to rx_bit = one.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

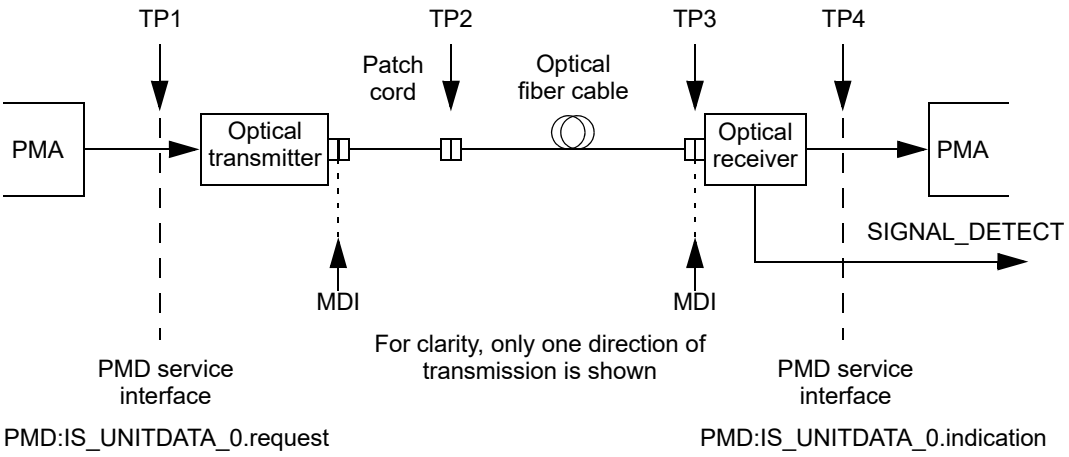

Figure 89–2—Block diagram for 40GBASE-FR transmit/receive paths

89.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 80.3.

SIGNAL_DETECT is an indicator of the presence of an optical signal. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 89–4. The PMD receiver is not required to verify whether a compliant 40GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 89–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –30 dBm	FAIL
(Optical power at TP3 ≥ receiver sensitivity (average power) (max) in Table 89–7) AND (compliant 40GBASE–R signal input)	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

89.5.5 PMD reset function

If the MDIO interface is implemented and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

89.5.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows the optical transmitter to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of the OFF transmitter in Table 89–6.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

If the MDIO interface is implemented, then this function shall map to the PMD_global_transmit_disable bit as specified in 45.2.1.8.7.

NOTE—The PMD lane-by-lane transmit disable function is not used for serial PMDs.

89.5.7 PMD fault function (optional)

If the PMD has detected a local fault on either the transmit or receive path, the PMD shall set PMD_fault to one. If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

89.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set the PMD_transmit_fault variable to one. If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

89.5.9 PMD receive fault function (optional)

If the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to one. If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

89.6 PMD to MDI optical specifications for 40GBASE-FR

The required operating range for the 40GBASE-FR PMD is defined in Table 89–5. A 40GBASE-FR compliant PMD operates on IEC 60793-2-50 type B1.1, B1.3 or B6_a single-mode fibers according to the specifications defined in Table 89–13. A PMD that exceeds the required operating range while meeting all other optical specifications is considered compliant (e.g., operating at 2.5 km meets the operating range requirement of 2 m to 2 km).

Table 89–5—40GBASE-FR required operating range

PMD type	Required operating range
40GBASE-FR	2 m to 2 km

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

89.6.1 40GBASE-FR transmitter optical specifications

The 40GBASE-FR transmitter shall meet the specifications defined in Table 89–6 per the definitions in 89.7.

Table 89–6—40GBASE-FR transmit characteristics

Description	Value	Unit
Signaling rate (range)	41.25 ± 100 ppm	GBd
Center wavelength (range)	1530 to 1565	nm
Side-mode suppression ratio (SMSR), (min)	35	dB
Average launch power (max)	3	dBm
Average launch power (min)	0	dBm
Dispersion penalty (max)	2	dB
Average launch power of OFF transmitter (max)	–30	dBm
Extinction ratio (min)	8.2	dB
$RIN_{20}OMA$ (max)	–132	dB/Hz
Optical return loss tolerance (max)	20	dB
Transmitter reflectance[a] (max)	–12	dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}	{0.25, 0.4, 0.45, 0.22, 0.25, 0.4}	

[a]Transmitter reflectance is defined looking into the transmitter.

89.6.2 40GBASE-FR receive optical specifications

The 40GBASE-FR receiver shall meet the specifications defined in Table 89–7 per the definitions in 89.7.

Table 89–7—40GBASE-FR receive characteristics

Description	Value	Unit
Signaling rate (range)	41.25 ± 100 ppm	GBd
Center wavelength (range)	1290 to 1330 and 1530 to 1565	nm
Damage threshold[a] (min)	4	dBm
Average receive power (max)	3	dBm
Receiver reflectance (max)	–26	dB
Receiver sensitivity (average power)[b] (max)	–6	dBm
Receiver jitter tolerance (max)	1	dB
Receiver 3 dB electrical upper cutoff frequency (max)	49	GHz

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.

[b]Receiver sensitivity (average power) is defined in 89.7.9 and is to be met with a transmitter with worst-case transmit eye, extinction ratio, transmitter reflectance, and $RIN_{20}OMA$. This is a different definition of receiver sensitivity from that used in other clauses (e.g., that in Clause 38). See 89.6.4 for a comparison.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

89.6.3 40GBASE-FR illustrative link power budget

An illustrative power budget and penalties for 40GBASE-FR channels are shown in Table 89–8.

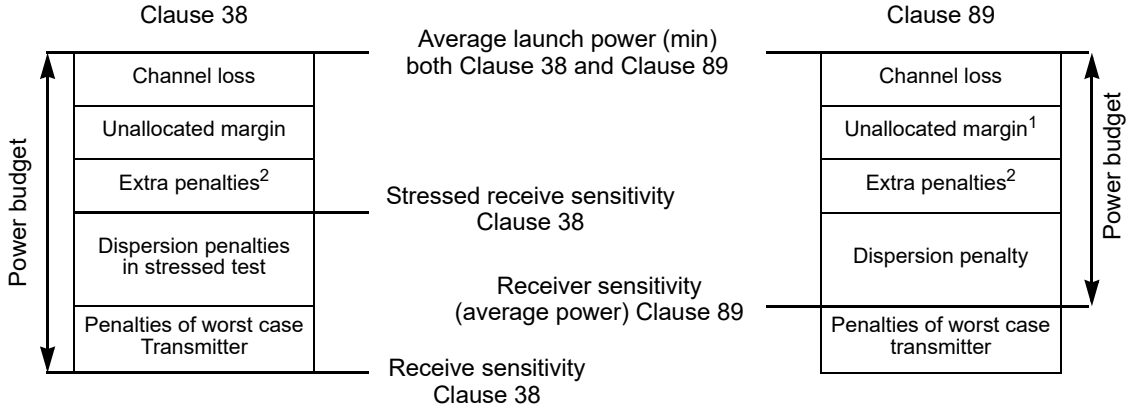

Table 89–8—40GBASE-FR illustrative power budget

Parameter	Value	Unit
Power budget[a]	6	dB
Operating distance	2	km
Channel insertion loss[b]	4	dB
Maximum discrete reflectance	–26	dB
Path penalty[a, c]	2	dB
Additional insertion loss allowed	0	dB

[a]This budget does not include the effect of a non-ideal transmitter waveform. See 89.6.4.
[b]The channel insertion loss is calculated using the maximum distance specified in Table 89–5 and cabled optical fiber attenuation of 0.5 dB/km at 1530 nm plus an allocation for connection and splice loss given in 89.10.2.1.
[c]Path penalty is the combined penalty caused by chromatic dispersion and polarization mode dispersion.

89.6.4 Comparison of power budget methodology

This clause uses the budgeting methodology that is used for application VSR2000-3R2 in ITU-T G.693 [B45], which is different from the methodology used in other clauses of this standard (e.g., Clause 38, Clause 52, Clause 86, Clause 87, Clause 88). Figure 89–3 compares the terminology used in this clause with Clause 38. Receiver sensitivity in this clause is specified with a worst-case transmitter input whereas in the other clauses it is specified with a perfect signal without penalties. Stressed receiver sensitivity is not specified in this clause but is specified as the key requirement in the other clauses with a signal that includes both transmitter and link penalties.

NOTE 1—For Clause 89 unallocated margin is zero and not mentioned in the rest of this clause.
NOTE 2—For Clause 38 extra penalties are any penalties that are not included in the stressed test while for Clause 89 extra penalties are any penalties that are not included in the dispersion penalty test.

Figure 89–3—Optical power budget methodology comparison with Clause 38

89.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

89.7.1 Test patterns for optical parameters

Compliance is to be achieved in normal operation. Table 89–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 89–10 may be used to perform that test. The test patterns used in this clause are shown in Table 89–9.

Table 89–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 ones, 8 zeros)	83.5.10
3	PRBS31	83.5.10
4	PRBS9	83.5.10
5	Scrambled idle	82.2.11

Table 89–10—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	3, 5 or valid 40GBASE-R signal	89.7.3
Side mode suppression ratio	3, 5 or valid 40GBASE-R signal	89.7.3
Average optical power	3, 5 or valid 40GBASE-R signal	89.7.4
Dispersion penalty	3 or 5	89.7.5
Extinction ratio	3, 5 or valid 40GBASE-R signal	89.7.6
$RIN_{20}OMA$	Square wave or 4	89.7.7
Transmitter optical waveform	3, 5 or valid 40GBASE-R signal	89.7.8
Receiver sensitivity	3 or 5	89.7.9
Receiver jitter tolerance	3 or 5	89.7.10
Receiver 3 dB electrical upper cutoff frequency	3, 5 or valid 40GBASE-R signal	89.7.11

Copyright © 2022 IEEE. All rights reserved.

89.7.2 Skew and Skew Variation

Skew and Skew Variation are defined in 80.5 and are required to remain within the limits given in 89.3.2 over the time that the link is in operation. Since the signal for this PMD is a serial bit stream at the PMD service interface and the MDI, there is no Skew Variation at skew points SP2, SP3, SP4, and SP5. The measurement of Skew is made by acquiring the data on the single lane using a clock and data recovery unit with high-frequency corner bandwidth of 16 MHz and a slope of –20 dB/decade. The arrival times of the one to zero transition of the alignment marker sync bits on each PCS lane are then compared. This arrangement ensures that any high-frequency jitter that is present on the signals is not included in the Skew measurement.

89.7.3 Wavelength and side mode suppression ratio (SMSR)

The center wavelength and SMSR shall be within the range given in Table 89–6 if measured per IEC 61280-1-3 using the test pattern referenced in Table 89–10.

89.7.4 Average optical power

The average optical power shall be within the limits given in Table 89–6 and Table 89–7 if measured using the methods given in IEC 61280-1-1 using the test pattern referenced in Table 89–10.

89.7.5 Dispersion penalty

The dispersion penalty of a transmitter is defined as the difference in sensitivity (at a BER of 10^{-12}) of a reference receiver as defined in 89.7.5.2 when receiving the signal from that transmitter via the channel defined in 89.7.5.1 compared to the sensitivity obtained when receiving the signal via an attenuator only.

89.7.5.1 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 89–11.

Table 89–11—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
40GBASE-FR	$0.0465 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.0465 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	20 dB	0.5 ps

[a]The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes a maximum operating distance of 2 km.
[b]There is no intent to stress the sensitivity of the BERT's optical receiver.
[c]The optical return loss is applied at TP2.

A 40GBASE-FR transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 89–11 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 89–11. The state of polarization of the back reflection is adjusted to create the greatest RIN.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The mean DGD of the channel is to be less than the value specified in Table 89–11.

89.7.5.2 Reference receiver requirements

The reference receiver is required to have the bandwidth given in 89.7.8. The sensitivity of the reference receiver is limited by Gaussian noise. The receiver has minimal threshold offset, deadband, hysteresis, baseline wander, deterministic jitter, or other distortions. Decision sampling has minimal uncertainty and setup/hold times.

The clock recovery unit (CRU) used in the dispersion penalty measurement has a corner frequency of 16 MHz and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the signal to the clock removes this low-frequency jitter from the measurement.

89.7.5.3 Test procedure

To measure the dispersion penalty, the following procedure shall be used:

a) Configure the test equipment as described above and illustrated in Figure 89–4.
b) With a short patch cable rather than the test fiber and with no reflection, adjust the attenuation of the optical attenuator to obtain a BER of 10^{-12}.
c) Record the optical power at the input to the reference receiver, P_ND, in dBm.
d) With the test fiber and reflection in place, adjust the attenuation of the optical attenuator to obtain a BER of 10^{-12}.
e) Record the optical power at the input to the reference receiver, P_D, in dBm.
f) If P_D is larger than P_ND, the dispersion penalty for the transmitter under test is P_D – P_ND. Otherwise, the dispersion penalty is zero.

It is to be ensured that the measurements are made in the linear power regime of the fiber.

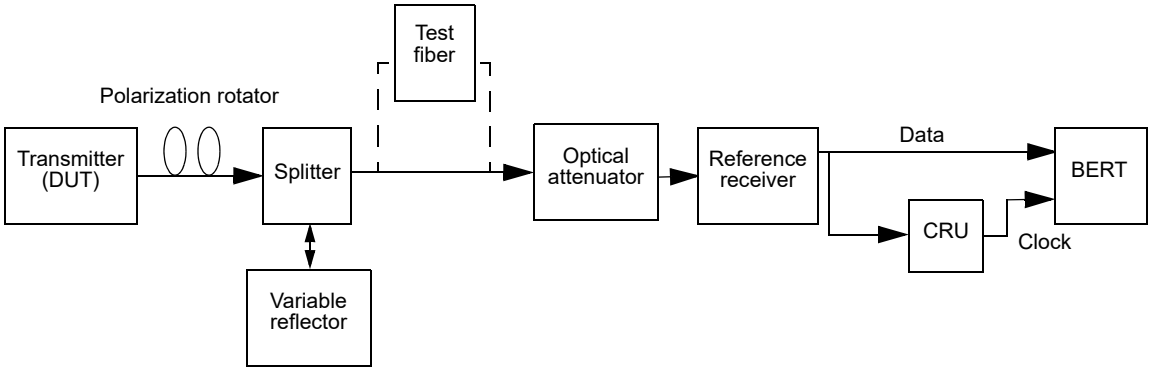

Figure 89–4—Test setup for measurement of dispersion penalty

89.7.6 Extinction ratio

The extinction ratio shall be within the limits given in Table 89–6 if measured using the methods specified in IEC 61280-2-2 using the test pattern referenced in Table 89–10.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 89–10).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

89.7.7 Relative Intensity Noise ($RIN_{20}OMA$)

The RIN measurement methodology shall be as defined in 52.9.6 with the following exceptions:

a) The optical return loss is 20 dB.
b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 41.25 GHz).

89.7.8 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4. The transmitter optical waveform of a port transmitting the test pattern specified in Table 89–10 shall meet specifications according to the methods specified in 86.8.4.6.1 with the filter nominal reference frequency f_r of 30.94 GHz and filter tolerances as specified for STM–64 in ITU–T G.691. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response.

89.7.9 Receiver sensitivity

Receiver sensitivity is defined as the minimum value of mean received power at TP3 to achieve a BER of 10^{-12}. This shall be met with a transmitter with worst-case transmit eye, extinction ratio, transmitter reflectance, and $RIN_{20}OMA$. The receiver sensitivity does not have to be met in the presence of dispersion, as this effect is specified separately as the dispersion penalty.

Receiver sensitivity is defined with the transmit section in operation. Pattern 3, or Pattern 5, or a valid 40GBASE–R signal is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.

89.7.10 Receiver jitter tolerance

Receiver jitter tolerance is defined as the largest increase in received optical power required to maintain a BER of 10^{-10} when the sinusoidal jitter defined in Table 89–12 is applied to the signal from a reference transmitter across the defined range of jitter frequencies.

The reference transmitter is a high-quality instrument-grade device, which can be implemented by a CW laser modulated by a high-performance modulator. The following basic requirements apply:

a) Rise/fall times are less than 10 ps at 20% to 80%.
b) The output optical eye is symmetric and passes the transmitter optical waveform test of 89.7.8.
c) In the center 20% region of the eye, the worst-case vertical eye closure penalty as defined in 52.9.9.2 is less than 0.5 dB.
d) Total Jitter is less than 0.2 UI peak-to-peak.

The receiver jitter tolerance shall be within the limits given in Table 89–7 if measured according to the above definition.

NOTE—Receiver jitter tolerance as defined here is made without additional amplitude stress.

89.7.11 Receiver 3 dB electrical upper cutoff frequency

The receiver 3dB electrical upper cutoff frequency shall be within the limits given in Table 89–7 if measured as described in 52.9.11 with the exception that the optical power level used in 52.9.11 b) is approximately equal to the receiver sensitivity level in Table 89–7.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 89–12—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 480$ kHz	Not specified
480 kHz $< f \leq$ 16 MHz	2.88×10^6 Hz / f
16 MHz $< f <$ 10 LB[a]	0.18

[a]LB = loop bandwidth; upper frequency bound for added sinusoidal jitter should be at least 10 times the loop bandwidth of the receiver being tested.

89.8 Safety, installation, environment, and labeling

89.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

89.8.2 Laser safety

40GBASE-FR optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single-fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[157]

89.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

89.8.4 Environment

Normative specifications in Clause 89 shall be met by a system integrating a 40GBASE-FR PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate, in the literature associated with the PHY, the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of Clause 89 will be met.

[157]A host system that fails to meet the manufacturers requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

89.8.4.1 Electromagnetic emission

A system integrating a 40GBASE-FR PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

89.8.4.2 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

89.8.5 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 40GBASE-FR).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 89.8.2.

89.9 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 89–5.

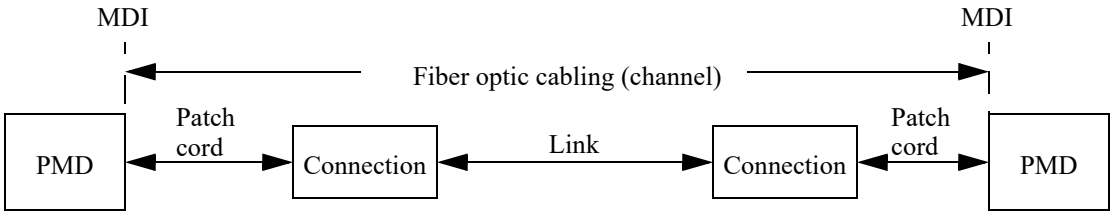

Figure 89–5—Fiber optic cabling model

The channel insertion loss is given in Table 89–13. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion, meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method, chromatic dispersion is measured in accordance with IEC 60793-1-42, and polarization mode dispersion is measured in accordance with IEC 60793-1-48. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term *channel* is used here for consistency with generic cabling standards.

89.10 Characteristics of the fiber optic cabling (channel)

The 40GBASE-FR fiber optic cabling shall meet the specifications defined in Table 89–13. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

89.10.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion un-shifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 89–14 where they differ.

Table 89–13—Fiber optic cabling (channel) characteristics for 40GBASE-FR

Description	Value	Unit
Operating distance (max)	2	km
Channel insertion loss[a, b] (max)	4	dB
Channel insertion loss (min)	0	dB
Dispersion[b] (max)	38	ps/nm
DGD_max[c]	3	ps
Optical return loss (min)	21	dB

[a]These channel insertion loss values include cable, connectors, and splices.
[b]Over the wavelength range 1530 nm to 1565 nm.
[c]Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

Table 89–14—Optical fiber and cable characteristics for 40GBASE-FR

Description	Value	Unit
Nominal fiber specification wavelength	1550	nm
Cabled optical fiber attenuation (max)	0.5[a]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a]The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA-568-C.3-2008.

89.10.2 Optical fiber connection

An optical fiber connection, as shown in Figure 89–5, consists of a mated pair of optical connectors.

89.10.2.1 Connection insertion loss

The maximum link distances for single-mode fiber are calculated based on an allocation of 3 dB total connection and splice loss. For example, this allocation supports six connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 89–13 are met.

89.10.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –26 dB.

89.10.3 Medium Dependent Interface (MDI) requirements

The 40GBASE-FR PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 89–5). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 89.5.1, not at the MDI.

89.11 Protocol implementation conformance statement (PICS) proforma for Clause 89, Physical Medium Dependent (PMD) sublayer and medium, type 40GBASE-FR[158]

89.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 89, Physical Medium Dependent sublayer and medium, type 40GBASE-FR, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

89.11.2 Identification

89.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

89.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 89, Physical Medium Dependent sublayer and medium, type 40GBASE-FR
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[158] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

90. Ethernet support for time synchronization protocols

90.1 Introduction

This clause specifies the optional Time Synchronization Service Interface (TSSI). The TSSI can be used to support protocols that require knowledge of packet egress and ingress time.

The TSSI is defined for the full-duplex mode of operation only. It supports MAC operation at various data rates. The MII (Clause 22), GMII (Clause 35), XGMII (Clause 46), 25GMII (Clause 106), XLGMII (Clause 81), CGMII (Clause 81), 50GMII (Clause 132), 200GMII (Clause 117), and 400GMII (Clause 117) specifications are all compatible with the generic Reconciliation Sublayer (gRS) defined in 90.5.

90.2 Overview

The goal of this clause is to provide an accurate indication of the transmission and reception initiation times of all packets, as required to support various time synchronization protocols, e.g., IEEE Std 1588-2008 [B41], and IEEE Std 802.1AS [B39].

The specific goals are to:

a) Define the Time Synchronization Service Interface (TSSI), with associated service primitives;

b) Add management registers to indicate the maximum and minimum data delays for estimation of link latency at the Time Synchronization Protocol (TimeSync) Client.

90.3 Relationship with other IEEE standards

Per 90.2, the TimeSync capability provides support for various time synchronization protocols, including e.g., IEEE Std 1588-2008 or IEEE Std 802.1AS. The definition of TimeSync Client, its capabilities and functions is outside the scope of IEEE Std 802.3.

90.4 Time Synchronization Service Interface (TSSI)

90.4.1 Introduction

This subclause specifies services provided by an extension to the Reconciliation Sublayers specified elsewhere in this standard.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

90.4.1.1 Interlayer service interfaces

Figure 90–1 depicts the TimeSync Client and the RS interlayer service interfaces.

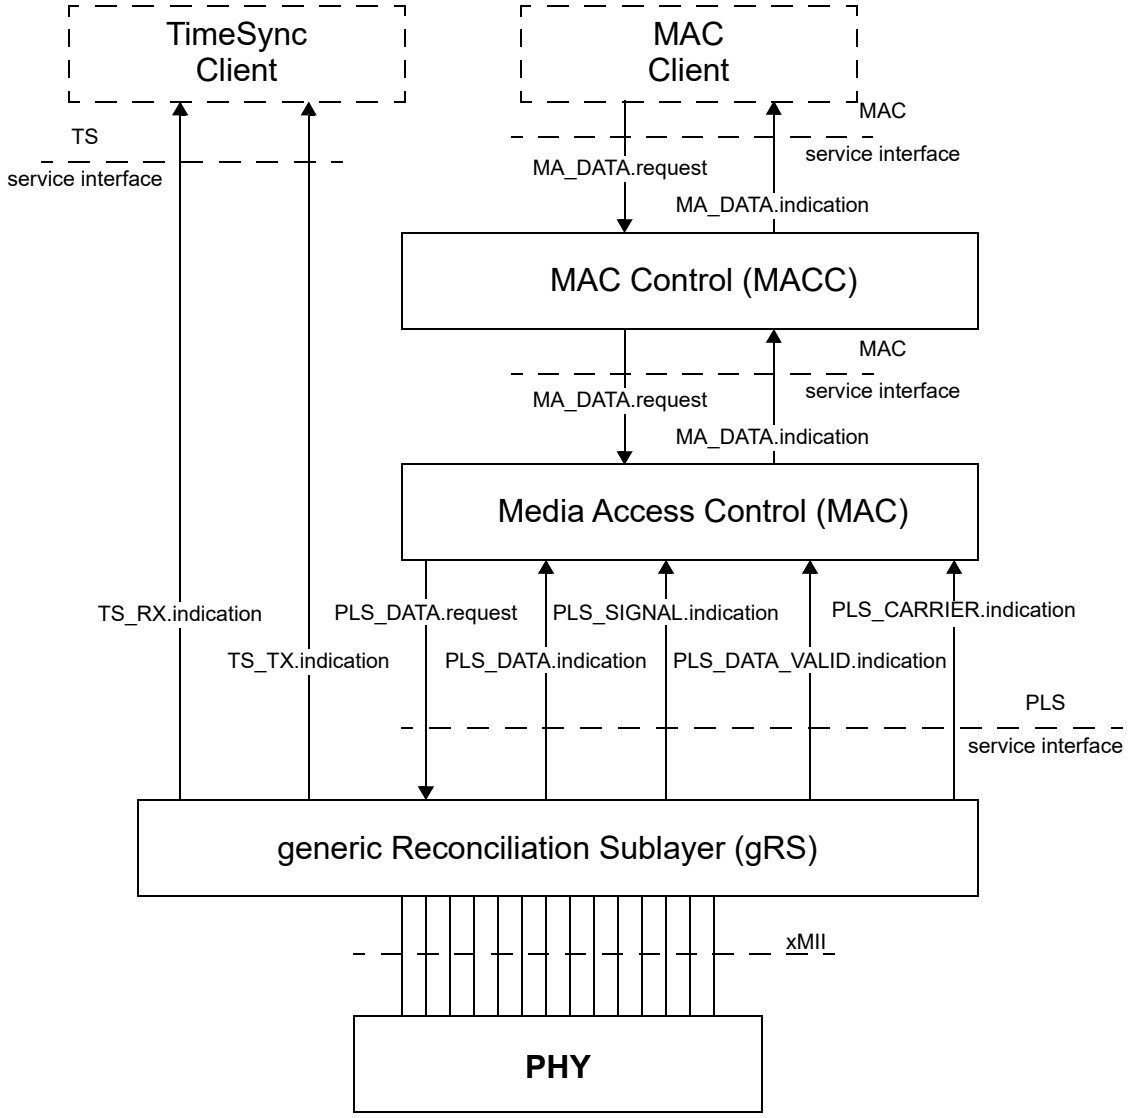

Figure 90–1—Relationship of the TimeSync Client, TSSI and gRS sublayer relative to MAC and MAC Client and associated interfaces

NOTE 1—In this figure, the xMII is used as a generic term for the Media Independent Interfaces for implementations of 10BASE-T1L, 10BASE-T1S, and 100 Mb/s and above. For example: for 100 Mb/s implementations this interface is called MII; for 1 Gb/s implementations, it is called GMII; for 10 Gb/s implementations, it is called XGMII; etc.

NOTE 2—Optional Low Power Idle (LPI) Client service interface not shown.

90.4.1.2 Responsibilities of TimeSync Client

The TimeSync Client can use the indication of the event corresponding to the egress and ingress of packets provided by the TSSI, combined with knowledge of the protocol frames, to select the egress and ingress times relevant to the protocol. Which frames are of interest to any particular protocol is beyond the scope of this standard.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The TimeSync Client can use the indication of the event corresponding to the egress and ingress of packets at the xMII provided by the TSSI, together with the information provided by the TimeSync PHY transmit data delay and TimeSync PHY receive data delay (see 30.13.1).

90.4.2 TSSI

The following specifies the service interface provided by the RS to the TimeSync Client. These services are described in an abstract manner and do not imply any particular implementation. The model used in this service specification is identical to that used in 1.2.2.

The following primitives are defined:

— TS_TX.indication
— TS_RX.indication

90.4.3 Detailed service specification

90.4.3.1 TS_TX.indication primitive

This primitive defines the transfer of the indication of an event between gRS and the TimeSync Client.

90.4.3.1.1 Semantics

The semantics of the primitive are as follows:

TS_TX.indication(SFD, MM)

The SFD parameter can take only one possible value, DETECTED. When asserted (SFD = DETECTED), the TimeSync Client is notified that a valid SFD was detected by the gRS sublayer TS_SFD_Detect_TX function (see 90.5.1) in the xMII transmit signals.

The MM parameter is mandatory when the MAC Merge sublayer (see Clause 99) is instantiated. The MM parameter, when present, can take one of two possible values, i.e., PMAC or EMAC. The value EMAC indicates the SMD-E (SFD) value has been detected at the xMII. The value PMAC indicates that an SMD-S value has been detected at the xMII (see Table 99–1). The MM parameter is not provided when MAC Merge sublayer is not instantiated.

90.4.3.1.2 Condition for generation

This primitive is generated by the gRS sublayer in response to detection of a valid SFD in the data stream transmitted across the xMII transmit signals. Specific conditions for generation of this primitive are described in 90.5.1.

90.4.3.1.3 Effect of receipt

The receipt of this primitive by the TimeSync Client is undefined.

90.4.3.2 TS_RX.indication primitive

This primitive defines the transfer of the indication of an event between gRS and the TimeSync Client.

90.4.3.2.1 Semantics

The semantics of the primitive are as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TS_RX.indication(SFD, MM)

The SFD parameter can take only one possible value, DETECTED. When asserted (SFD = DETECTED), the TimeSync Client is notified that a valid SFD was detected by the gRS sublayer TS_SFD_Detect_RX function (see 90.5.2) in the xMII receive signals.

The MM parameter is mandatory when the MAC Merge sublayer (see Clause 99) is instantiated. The MM parameter, when present, can take one of two possible values, i.e., PMAC or EMAC. The value EMAC indicates the SMD-E (SFD) value has been detected at the xMII. The value PMAC indicates that an SMD-S value has been detected at the xMII (see Table 99–1). The MM parameter is not provided when MAC Merge sublayer is not instantiated.

90.4.3.2.2 Condition for generation

This primitive is generated by the gRS sublayer in response to detection of a valid SFD in the data stream received across the xMII receive signals. Specific conditions for generation of this primitive are described in 90.5.2.

90.4.3.2.3 Effect of receipt

The receipt of this primitive by the TimeSync Client is undefined.

90.5 generic Reconciliation Sublayer (gRS)

Within the scope of this clause, the term generic Reconciliation Sublayer (gRS) is used to denote any IEEE 802.3 Reconciliation Sublayer (RS) used to interface a MAC with any PHY supporting the TimeSync capability through the xMII. The behavior of the gRS depends on whether a MAC Merge sublayer (see Clause 99) is instantiated above the gRS.

For the purpose of the TimeSync capabilities, two new functions are defined in this subclause, namely TS_SFD_Detect_TX (see 90.5.1) and TS_SFD_Detect_RX (see 90.5.2), which are responsible for generation of the TS_TX.indication and TS_RX.indication service primitives, as defined in 90.4. Figure 90–2 presents the TS_SFD_Detect_TX and TS_SFD_Detect_RX functions and their location within the RS sublayer.

90.5.1 TS_SFD_Detect_TX function

The TS_SFD_Detect_TX function observes the xMII transmit signals.

When the MAC Merge sublayer is not instantiated, the TS_SFD_Detect_TX function detects the occurrence of the Start Frame Delimiter (SFD, see 3.1.1 and 3.2.2) in compliance with the specifications of the given type of the instantiated xMII. The service primitive across the TSSI, i.e., TS_TX.indication shall be generated only when the SFD is detected on the transmit signals of the xMII (SFD=DETECTED).

When the MAC Merge sublayer is instantiated, the TS_SFD_Detect_TX function detects the occurrence of the Start mPacket Delimiter for an express packet or preemptable packet start (SMD-E or SMD-S, see 99.3.3) in compliance with the specifications of the given type of the instantiated xMII. The service primitive across the TSSI, i.e., TS_TX.indication, shall be generated only when the SMD-E or SMD-S is detected on the transmit signals of the xMII (SFD=DETECTED). The value of MM shall indicate whether an SMD-E (MM=EMAC) or an SMD-S (MM=PMAC) was detected.

90.5.2 TS_SFD_Detect_RX function

The TS_SFD_Detect_RX function observes the xMII receive signals.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the MAC Merge sublayer is not instantiated, the TS_SFD_Detect_RX function detects the occurrence of the Start Frame Delimiter (SFD, see 3.1.1 and 3.2.2) in compliance with the specifications of the given type of the instantiated xMII. The service primitive across the TSSI, i.e., TS_RX.indication, shall be generated only when the SFD is detected on the receive signals of the xMII (SFD=DETECTED).

When the MAC Merge sublayer is instantiated, the TS_SFD_Detect_RX function detects the occurrence of the Start mPacket Delimiter for an express packet or preemptable packet start (SMD-E or SMD-S, see 99.3.3) in compliance with the specifications of the given type of the instantiated xMII. The service primitive across the TSSI, i.e., TS_RX.indication, shall be generated only when the SMD-E or SMD-S is detected on the transmit signals of the xMII (SFD=DETECTED). The value of MM shall indicate whether an SMD-E (MM=EMAC) or an SMD-S (MM=PMAC) was detected.

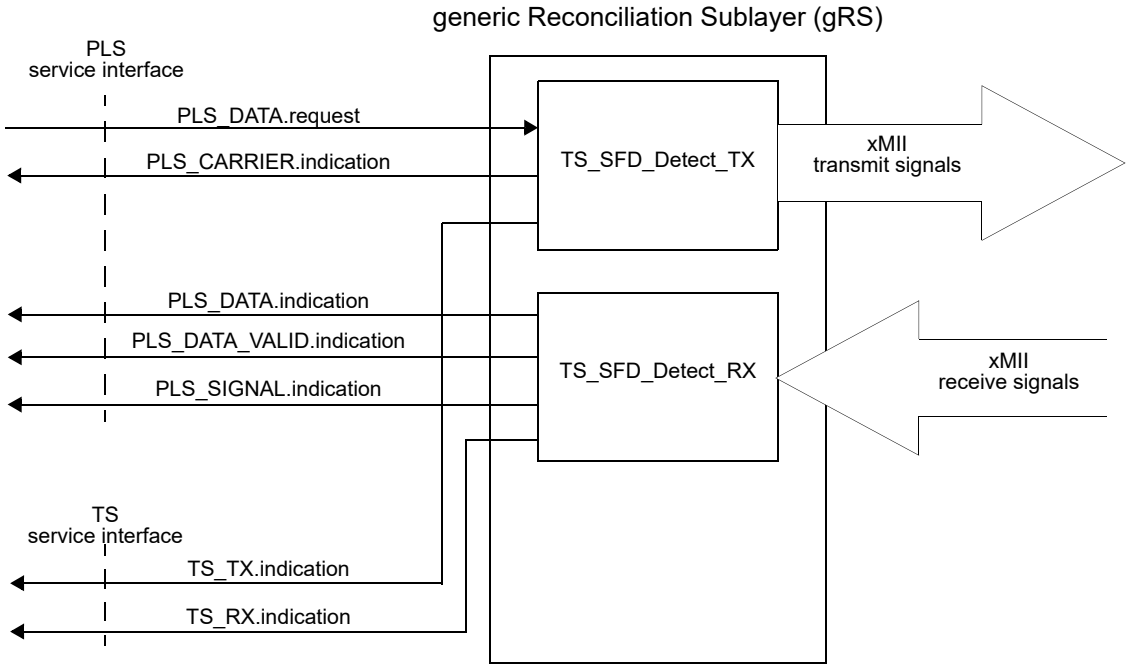

Figure 90–2—TS_SFD_Detect_TX and TS_SFD_Detect_RX functions within the generic Reconciliation Sublayer (gRS)

90.6 Overview of management features

Clause 30 describes the management functions for any of the IEEE Std 802.3 compliant PHYs. Objects defined in Clause 30 for the support of TimeSync capability are summarized below:

— oTimeSync managed object class, as defined in 30.13.1

— aTimeSyncCapabilityTX and aTimeSyncCapabilityRX managed objects, reflecting the status of a series of MDIO capability registers (1.1800, 2.1800, 3.1800, 4.1800, 5.1800, and 6.1800), as defined in 30.13.1.1 and 30.13.1.2, respectively

— aTimeSyncDelayTXmax and aTimeSyncDelayTXmin managed objects, representing the aggregate value of the series of transmit path data delay registers present in the instantiated MDIO registers (for each MMD, in case of multiple instances) 1.1801 through 1.1804, 2.1801 through 2.1804,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

3.1801 through 3.1804, 4.1801 through 4.1804, 5.1801 through 5.1804, and 6.1801 through 6.1804, as defined in 30.13.1.3 and 30.13.1.4, respectively

— aTimeSyncDelayRXmax and aTimeSyncDelayRXmin managed objects, representing the aggregate value of the series of receive path data delay registers present in the instantiated MDIO registers (for each MMD, in case of multiple instances) 1.1805 through 1.1808, 2.1805 through 2.1808, 3.1805 through 3.1808, 4.1805 through 4.1808, 5.1805 through 5.1808, and 6.1805 through 6.1808, as defined in 30.13.1.5 and 30.13.1.6, respectively

The Management Data Input/Output (MDIO) capability described in Clause 45 defines several variables that provide TimeSync status information for the PMD, as shown in Table 90–1:

Table 90–1—Summary of TimeSync features in Clause 45

Register	Name	Reference
1.1800	TimeSync PMA/PMD capability register	45.2.1.175
1.1801 through 1.1804	TimeSync PMA/PMD transmit path data delay	45.2.1.176
1.1805 through 1.1808	TimeSync PMA/PMD receive path data delay	45.2.1.177
2.1800	TimeSync WIS capability register	45.2.2.20
2.1801 through 2.1804	TimeSync WIS transmit path data delay	45.2.2.21
2.1805 through 2.1808	TimeSync WIS receive path data delay	45.2.2.22
3.1800	TimeSync PCS capability register	45.2.3.67
3.1801 through 3.1804	TimeSync PCS transmit path data delay	45.2.3.68
3.1805 through 3.1808	TimeSync PCS receive path data delay	45.2.3.69
4.1800	TimeSync PHY XS capability register	45.2.4.28
4.1801 through 4.1804	TimeSync PHY XS transmit path data delay	45.2.4.29
4.1805 through 4.1808	TimeSync PHY XS receive path data delay	45.2.4.30
5.1800	TimeSync DTE XS capability register	45.2.5.28
5.1801 through 5.1804	TimeSync DTE XS transmit path data delay	45.2.5.29
5.1805 through 5.1808	TimeSync DTE XS receive path data delay	45.2.5.30
6.1800	TimeSync TC capability register	45.2.6.14
6.1801 through 6.1804	TimeSync TC transmit path data delay	45.2.6.15
6.1805 through 6.1808	TimeSync TC receive path data delay	45.2.6.16

90.7 Data delay measurement

The TimeSync capability requires measurement of data delay in the transmit and receive paths, as shown in Figure 90–3. The transmit path data delay is measured from the beginning of the SFD at the xMII input to the beginning of the SFD at the MDI output. The receive path data delay is measured from the beginning of the SFD at the MDI input to the beginning of the SFD at the xMII output.

For a PHY that includes an FEC function, the transmit and receive path data delays may show significant variation depending upon the position of the SFD within the FEC block. However, since the variation due to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

this effect in the transmit path is expected to be compensated by the inverse variation in the receive path, it is recommended that the transmit and receive path data delays be reported as if the SFD is at the start of the FEC block.

The receiver of a multi-lane PHY is expected to include a buffer to compensate for skew between the lanes. This buffer selectively delays each lane such that the lanes are aligned at the buffer output. The earliest arriving lane experiences the most delay through the buffer and the latest arriving lane experiences the least delay through the buffer. The receive path data delay for a multi-lane PHY is reported as if the beginning of the SFD arrived at the MDI input on the lane with the smallest buffer delay.

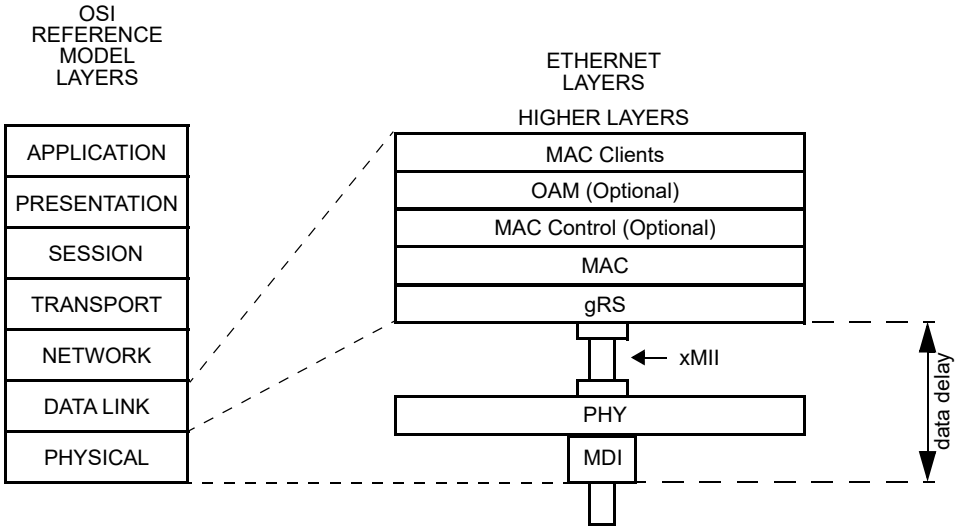

Figure 90–3—Data delay measurement

NOTE 1—The measured data delay in either the transmit or receive path should not include delay resulting from any length of the medium, regardless of the type of the medium used by the given PHY. It is observed that even if any medium-imposed delay is included in the measured data delay, it does not affect the operation of the TimeSync functions and only shifts the timing reference point farther from the MDI.

The obtained data delay measurement shall be reported in the form of a quartet of values; the maximum transmit data delay, the minimum transmit data delay, the maximum receive data delay, and the minimum receive data delay, as defined for the oTimeSync managed object class (30.13.1).

NOTE 2—The data delay values represent only the data delay in the PHY sublayers. The TimeSync Client may need to adjust for delays within the gRS. For example, the TimeSync Client may need to subtract the value of the delay associated with the TS_SFD_Detect_TX function from the sum of the minimum transmit data delay values reported by individual MMD(s). Likewise, the TimeSync Client may need to add the value of the delay associated with the TS_SFD_Detect_RX function to the sum of the maximum receive data delay values reported by individual MMD(s).

NOTE 3—For PHYs that are specified with an FEC sublayer separate from the PCS, the data delay for the FEC sublayer should be included in either the PCS delay registers or the PMA/PMD delay registers of the MMD in which the FEC sublayer is implemented, but not in both.

90.8 Protocol implementation conformance statement (PICS) proforma for Clause 90, Ethernet support for time synchronization protocols[159]

90.8.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 90 Ethernet support for time synchronization protocols, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

90.8.2 Identification

90.8.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

90.8.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 90, Ethernet support for time synchronization protocols
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022)	
Date of Statement	

[159] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

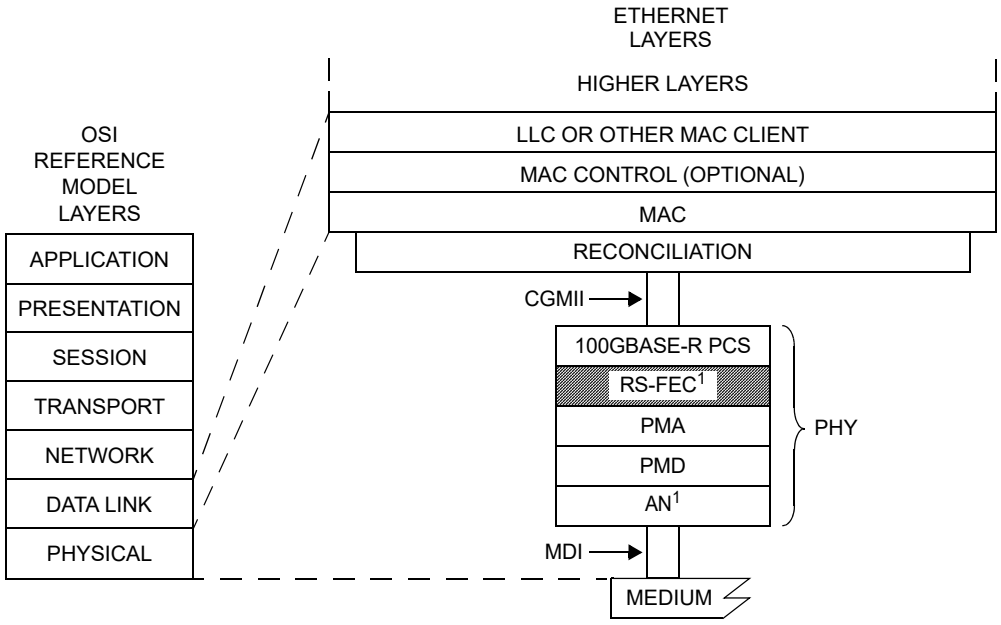
91. Reed-Solomon forward error correction (RS-FEC) sublayer for 100GBASE-R PHYs



91.1 Overview

91.1.1 Scope

This clause specifies a Reed-Solomon forward error correction (RS-FEC) sublayer for 100GBASE-R PHYs. Annex 91A provides examples of RS-FEC codewords constructed with the method specified in this clause.

91.1.2 Position of RS-FEC in the 100GBASE-R sublayers

Figure 91–1 shows the relationship of the RS-FEC sublayer to the ISO/IEC Open System Interconnection (OSI) reference model.

AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 91–1—RS-FEC relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

91.2 FEC service interface

This subclause specifies the services provided by the RS-FEC sublayer. The service interface is described in an abstract manner and does not imply any particular implementation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The FEC service interface is provided to allow the PCS to transfer information to and from the RS-FEC. The PCS may be connected to the RS-FEC using an optional instantiation of the PMA service interface (refer to Annex 83A or Annex 83D) in which case a PMA is the client of the FEC service interface.

The FEC service interface is an instance of the inter-sublayer service interface defined in 80.3. The FEC service interface primitives are summarized as follows:

FEC:IS_UNITDATA_*i*.request
FEC:IS_UNITDATA_*i*.indication
FEC:IS_SIGNAL.indication

The RS-FEC operates on 20 parallel bit streams, hence $i = 0$ to 19. The PCS (or PMA) continuously sends 20 parallel bit streams to the RS-FEC, one per lane, each at a nominal signaling rate of 5.15625 GBd. The RS-FEC continuously sends 20 parallel bit streams to the PCS (or PMA), one per lane, each at a nominal signaling rate of 5.15625 GBd.

The SIGNAL_OK parameter of the FEC:IS_SIGNAL.indication primitive can take one of two values: OK or FAIL. The value is set to OK when the FEC receive function has identified codeword boundaries as indicated by fec_align_status equal to true. That value is set to FAIL when the FEC receive function is unable to reliably establish codeword boundaries as indicated by fec_align_status equal to false. When SIGNAL_OK is FAIL, the rx_bit parameters of the FEC:IS_UNITDATA_*i*.indication primitives are undefined.

If the optional EEE deep sleep capability is supported, then the FEC service interface includes four additional primitives as follows:

FEC:IS_TX_MODE.request
FEC:IS_RX_MODE.request
FEC:IS_RX_TX_MODE.indication
FEC:IS_ENERGY_DETECT.indication

When the tx_mode parameter of the FEC:IS_TX_MODE.request primitive is QUIET or ALERT, the RS-FEC sublayer may disable transmit functional blocks to conserve energy. Otherwise the RS-FEC transmit function operates normally. The value of tx_mode is passed to the client sublayer via the PMA:IS_TX_MODE.request primitive.

When the rx_mode parameter of the FEC:IS_RX_MODE.request primitive is QUIET, the RS-FEC sublayer may disable receive functional blocks to conserve energy. Otherwise the RS-FEC receive function operates normally. The value of rx_mode is passed to the client sublayer via the PMA:IS_RX_MODE.request primitive.

The rx_tx_mode parameter of the FEC:IS_RX_TX_MODE.indication primitive is used to communicate the link partner's value of tx_mode as inferred by the PMA. It is assigned the value that is received via the PMA:IS_RX_TX_MODE.indication primitive.

The energy_detect parameter of the FEC:IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence. It is assigned the value that is received via the PMA:IS_ENERGY_DETECT.indication primitive.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

91.3 PMA compatibility

The RS-FEC sublayer requires that the PMA service interface consist of exactly four upstream lanes and exactly four downstream lanes. Therefore, the RS-FEC sublayer may be a client of the PMA sublayer defined in Clause 83 or Clause 135 when the PMA service interface width, *p*, is set to 4. The RS-FEC sublayer may also be a client of the PMA sublayer defined in Clause 94.

In addition, all PMA service interfaces between the RS-FEC sublayer and the PMD sublayer are required to consist of four or fewer upstream lanes and four or fewer downstream lanes. A consequence of this constraint is that a physical instantiation of the ten-lane PMA service interface (CAUI-10) may not be used below the RS-FEC sublayer.

91.4 Delay constraints

The maximum delay contributed by the RS-FEC sublayer (sum of transmit and receive delays at one end of the link) shall be no more than 40 960 bit times (80 pause_quanta or 409.6 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

91.5 Functions within the RS-FEC sublayer

91.5.1 Functional block diagram

A functional block diagram of the RS-FEC sublayer is shown in Figure 91–2.

91.5.2 Transmit function

91.5.2.1 Lane block synchronization

The RS-FEC transmit function forms 20 bit streams by concatenating the bits from each of the 20 FEC:IS_UNITDATA_*i*.request primitives in the order they are received. It obtains lock to the 66-bit blocks in each bit stream using the sync headers and outputs 66-bit blocks. Block lock is obtained as specified in the block lock state diagram shown in Figure 82–12.

91.5.2.2 Alignment lock and deskew

Once the RS-FEC transmit function achieves block lock on a PCS lane, it then begins obtaining alignment marker lock as specified by the alignment marker lock state diagram shown in Figure 82–13. This process identifies the PCS lane number received on a particular lane of the service interface. After alignment marker lock is achieved on all 20 lanes, all inter-lane Skew is removed as specified by the PCS deskew state diagram shown in Figure 82–14. The RS-FEC transmit function shall support a maximum Skew of 49 ns between PCS lanes and a maximum Skew Variation of 400 ps. Skew and Skew Variation are defined in 80.5.

91.5.2.3 Lane reorder

PCS lanes can be received on different lanes of the service interface from which they were originally transmitted due to Skew between lanes and multiplexing by the PMA. The RS-FEC transmit function shall order the PCS lanes according to the PCS lane number.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

91.5.2.4 Alignment marker removal

After all PCS lanes are aligned and deskewed, the PCS lanes are multiplexed together in the proper order to reconstruct the original stream of blocks and the alignment markers are removed from the data stream. Note that an alignment marker is always removed when am_lock is true for a given PCS lane even if it does not match the expected alignment marker value (due to a bit error for example). Repeated alignment marker errors result in am_lock being set to false for a given PCS lane, but until that happens it is sufficient to remove the block in the alignment marker position.

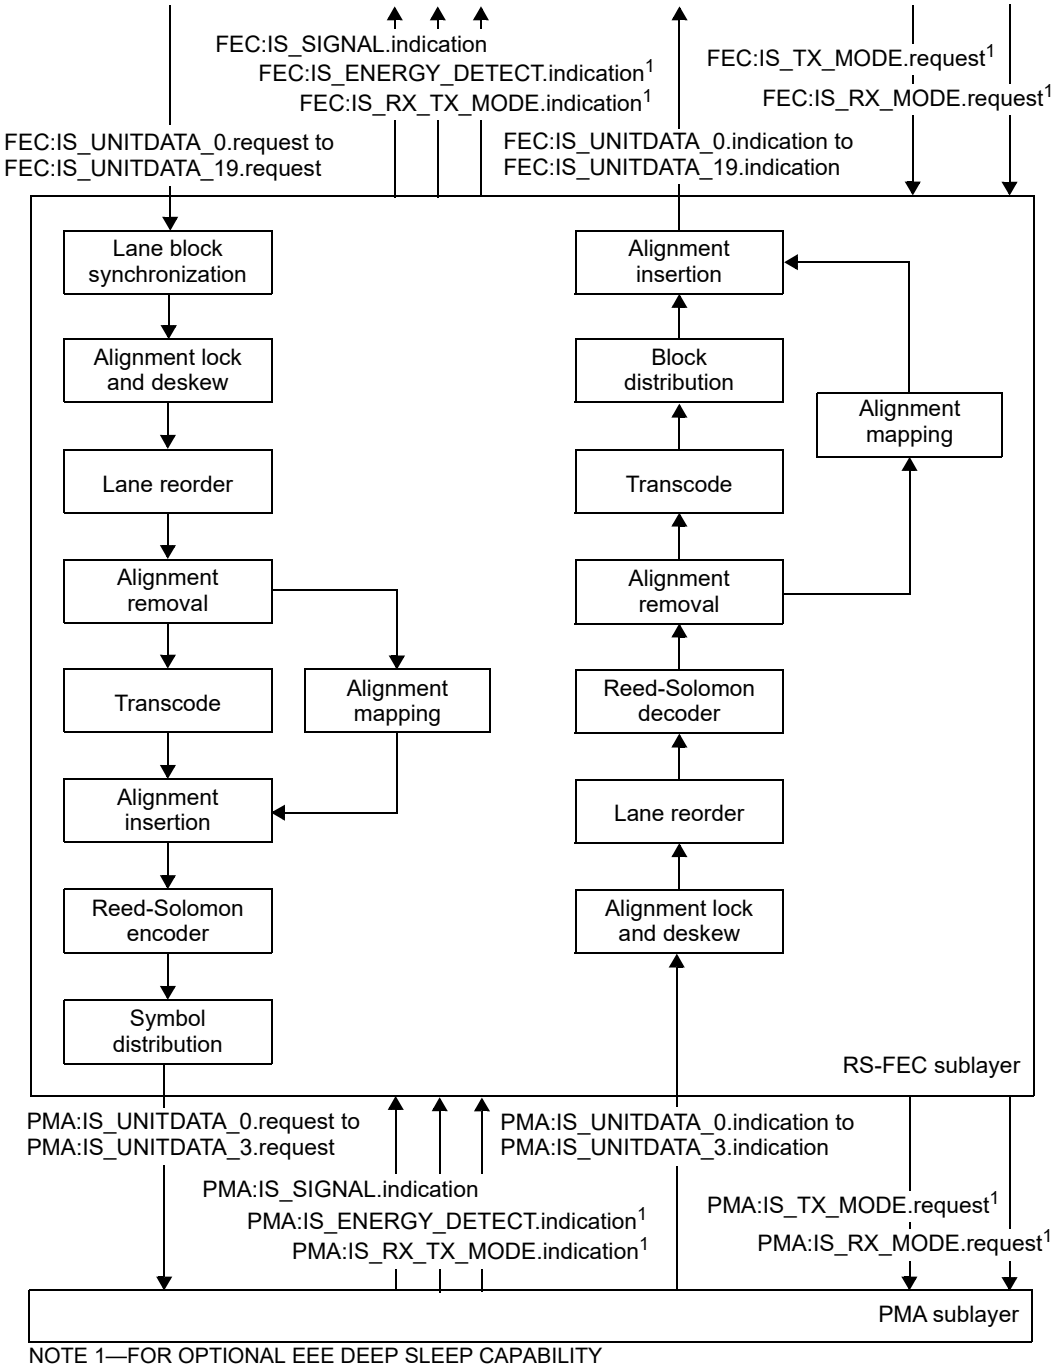

Figure 91–2—Functional block diagram

For the optional EEE deep sleep capability, transitions between normal alignment markers and Rapid Alignment Markers (RAMs) result in changes in relative position and frequency of alignment markers. These transitions are detected by the Transmit LPI state diagram (see Figure 91–10), and this information is used by the alignment marker removal function to determine which 66-bit blocks are to be removed.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

As part of the alignment marker removal process, the BIP_3 field is compared to the calculated Bit Interleaved Parity (BIP) value (see 82.2.8) for each PCS lane. If a Clause 45 MDIO is implemented, then the appropriate BIP error counter register (registers 1.230 to 1.249) is incremented by one each time the calculated BIP value does not equal the value received in the BIP_3 field. The bit error ratio in the data received from the local PCS can be estimated by dividing the BIP block error ratio by a factor of 1 081 344.

NOTE—The data received from the local PCS is processed by the RS-FEC transmit function without error correction.

91.5.2.5 64B/66B to 256B/257B transcoder

The transcoder constructs a 257-bit block, tx_scrambled<256:0>, from a group of four 66-bit blocks, tx_coded_*j*<65:0> where *j*=0 to 3. For each group of four 66-bit blocks, *j*=3 corresponds to the most recently received block. Bit 0 in each 66-bit block is the first bit received and corresponds to the first bit of the synchronization header.

If for all *j*=0 to 3, tx_coded_*j*<0>=0 and tx_coded_*j*<1>=1, tx_xcoded<256:0> shall be constructed as follows:

a) tx_xcoded<0> = 1
b) tx_xcoded<(64*j*+64):(64*j*+1)> = tx_coded_*j*<65:2> for *j*=0 to 3

If for all *j*=0 to 3, tx_coded_*j*<0> ≠ tx_coded_*j*<1> (valid synchronization header) and for any *j*=0 to 3, tx_coded_*j*<0>=1 and tx_coded_*j*<1>=0, tx_xcoded<256:0> shall be constructed as follows:

a1) tx_xcoded<0> = 0
b1) tx_xcoded<*j*+1> = tx_coded_*j*<1> for *j*=0 to 3
c1) Let *c* be the smallest value of *j* such that tx_coded_*c*<0>=1. In other words, tx_coded_*c* is the first 66-bit control block that was received in the current group of four blocks.
d1) Let tx_payloads<(64*j*+63):64*j*> = tx_coded_*j*<65:2> for *j*=0 to 3
e1) Omit tx_coded_*c*<9:6>, which is the second nibble (based on transmission order) of the block type field for tx_coded_*c,* from tx_xcoded per the following expressions.
tx_xcoded<(64*c*+8):5> = tx_payloads<(64*c*+3):0>
tx_xcoded<256:(64*c*+9)> = tx_payloads<255:(64*c*+8)>

If for any *j*=0 to 3, tx_coded_*j*<0> = tx_coded_*j*<1> (invalid synchronization header), tx_xcoded<256:0> shall be constructed as follows:

a2) tx_xcoded<0> = 0
b2) tx_xcoded<*j*+1> = 1 for *j*=0 to 3
c2) Let tx_payloads<(64*j*+63):64*j*> = tx_coded_*j*<65:2> for *j*=0 to 3
d2) Omit the second nibble (based on transmission order) of tx_coded_0 per the following expressions.
tx_xcoded<8:5> = tx_payloads<3:0>
tx_xcoded<256:9> = tx_payloads<255:8>

Several examples of the construction of tx_xcoded<256:0> are shown in Figure 91–3. In Figure 91–3, d_*j* indicates the *j*th 66-bit block contains only data octets, c_*j* indicates the *j*th 66-bit block contains one or more control characters, f_*j* denotes the first nibble of the block type field for 66-bit block *j*, and s_*j* denotes the second nibble of the block type field for 66-bit block *j*.

Finally, scramble the first 5 bits, based on transmission order, of tx_xcoded<256:0> to yield tx_scrambled<256:0> as follows:

a3) Set tx_scrambled<4:0> to the result of the bit-wise exclusive-OR of the tx_xcoded<4:0> and tx_xcoded<12:8>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b3) Set tx_scrambled<256:5> to tx_xcoded<256:5>

For each 257-bit block, bit 0 shall be the first bit transmitted.

91.5.2.6 Alignment marker mapping and insertion

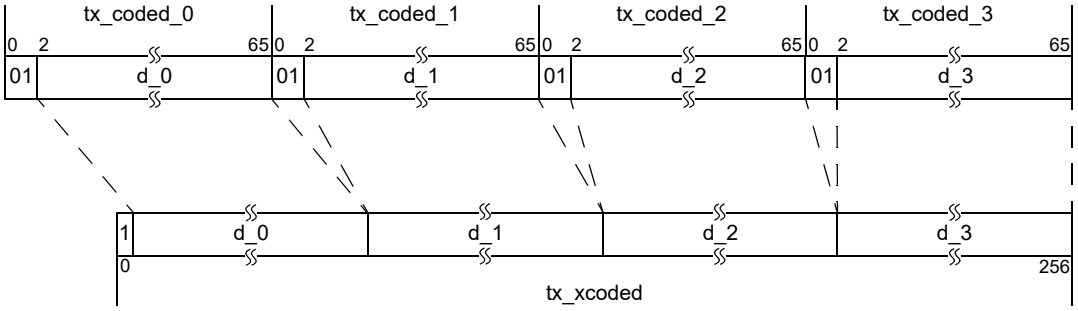
The alignment markers that were removed per 91.5.2.4 are re-inserted after being processed by the alignment marker mapping function. The alignment marker mapping function compensates for the operation of the symbol distribution function defined in 91.5.2.8 and rearranges the alignment marker bits so that they appear on the FEC lanes intact and in the desired sequence. This preserves the properties of the alignment markers (e.g., DC balance, transition density) and provides a deterministic pattern for the purpose of synchronization. The RS-FEC receive function uses knowledge of this mapping to determine the FEC lane that is received on a given lane of the PMA service interface, to compensate for skew between FEC lanes, and to identify RS-FEC codeword boundaries.

The alignment marker mapping function operates on a group of 20 aligned and reordered alignment markers. Let am_tx_x<65:0> be the alignment marker for PCS lane x, x=0 to 19, where bit 0 is the first bit transmitted. The alignment markers shall be mapped to am_txmapped<1284:0> in a manner that yields the same result as the following process.

For x=0 to 19, amp_tx_x<63:0> is constructed as follows:

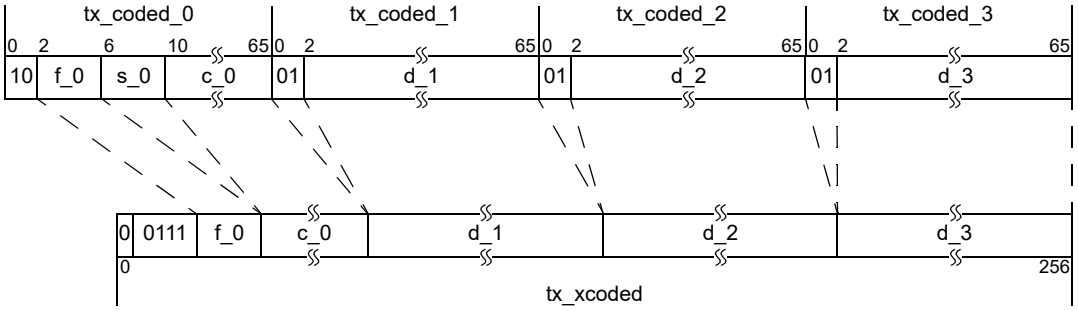
a) Set y = 0 when $x \le 3$, set y = 16 when $x \ge 16$ and four_lane_pmd, otherwise set $y = x$.
b) amp_tx_x<23:0> is set to M_0, M_1, and M_2 as shown in Figure 82–9 (bits 25 to 2) using the values in Table 82–2 for PCS lane number y. If am_tx_x corresponds to a Rapid Alignment marker, then the M_4, M_5, and M_6 values are used instead (see Figure 82–11).
c) amp_tx_x<31:24> = am_tx_x<33:26>
d) amp_tx_x<55:32> is set to M_4, M_5, and M_6 as shown in Figure 82–9 (bits 57 to 34) using the values in Table 82–2 for PCS lane number y. If am_tx_x corresponds to a Rapid Alignment marker, then the M_0, M_1, and M_2 values are used instead (see Figure 82–11).
e) amp_tx_x<63:56> = am_tx_x<65:58>

This process replaces the fixed bytes of the alignment markers received, possibly with errors, with the values from Table 82–2. In addition it substitutes the fixed bytes of the alignment markers corresponding to PCS lanes 1, 2, and 3 with the fixed bytes for the alignment marker corresponding to PCS lane 0. Similarly when used with a four-lane PMD, it substitutes the fixed bytes of the alignment markers corresponding to PCS lanes 17, 18, and 19 with the fixed bytes for the alignment marker corresponding to PCS lane 16. The variable bytes BIP or CD are unchanged. This process simplifies receiver synchronization since the receiver only needs to search for the fixed bytes corresponding to PCS lane 0 on each FEC lane. When the optional EEE deep sleep capability is supported, the receiver only needs to search for the fixed bytes corresponding to PCS lanes 0 and 16.



Construct a matrix of 4 rows and 320 columns, am_txpayloads, as shown in Figure 91–4. Given i=0 to 3, j=0 to 4, and x=i+4j, the matrix is derived per the following expression:

am_txpayloads<i, (64j+63):64j> = amp_tx_x<63:0>



Given i=0 to 3, k=0 to 31, and y=i+4k, am_txmapped may then be derived from am_txpayloads per the following expression:

am_txmapped<(10y+9):10y> = am_txpayloads<i, (10k+9):10k>

A 5-bit pad is appended to the mapped alignment markers to yield the equivalent of five 257-bit blocks. The pad bits, am_txmapped<1284:1280>, shall be set to the binary values 00101 and 11010 (the leftmost bit is assigned to the highest bit index) in an alternating pattern. In other words, if a pad value of 00101 is used for the current iteration of the mapping function, a value of 11010 is used in the next iteration and vice versa.

The result of the alignment marker mapping function is the deterministic mapping between alignment marker payloads and FEC lanes shown in Figure 91–4.

As a result of this process, the BIP_3 and BIP_7 fields from normal alignment markers are carried across the link protected by FEC. These fields cannot be used to monitor errors on the link protected by FEC as 64B/66B to 256B/257B transcoding and Reed-Solomon encoding alters the bit sequence. However, these fields may again be used to monitor errors after the original bit sequence is restored, i.e., following Reed-Solomon decoding and 256B/257B to 64B/66B transcoding.

One group of aligned and reordered alignment markers are mapped every 20 × 16384 66-bit blocks. This corresponds to 4096 Reed-Solomon codewords (refer to 91.5.2.7). The mapped alignment markers, am_txmapped<1284:0> shall be inserted as the first 1285 message bits to be transmitted from every 4096th codeword.

For the optional EEE deep sleep capability, when tx_lpi_active is true, one group of Rapid Alignment Markers (see 82.2.9) are mapped every 20 × 8 66-bit blocks. This corresponds to 2 Reed-Solomon codewords. The mapped Rapid Alignment Markers, am_txmapped<1284:0> shall be inserted as the first 1285 message bits to be transmitted from every other codeword.

The first 257-bit block inserted after am_txmapped shall correspond to the four 66-bit blocks received on PCS lanes 0, 1, 2, and 3 that immediately followed the alignment marker on each respective lane.

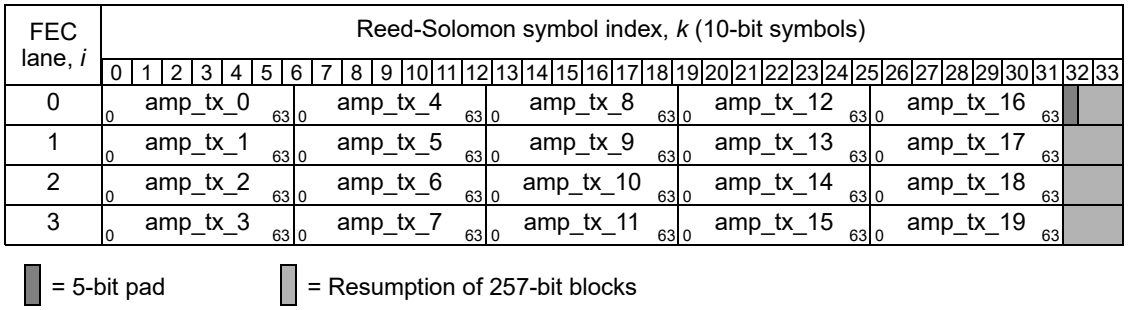

Figure 91–4—Alignment marker mapping to FEC lanes

91.5.2.7 Reed-Solomon encoder

The RS-FEC sublayer employs a Reed-Solomon code operating over the Galois Field GF(2^{10}) where the symbol size is 10 bits. The encoder processes k message symbols to generate $2t$ parity symbols, which are then appended to the message to produce a codeword of $n=k+2t$ symbols. For the purposes of this clause, a particular Reed-Solomon code is denoted RS(n,k).

When used to form a 100GBASE-CR4, 100GBASE-KR4, or 100GBASE-SR4 PHY, the RS-FEC sublayer shall implement RS(528,514). When used to form a 100GBASE-KP4, 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PHY, the RS-FEC sublayer shall implement RS(544,514). Each k-symbol message corresponds to 20 257-bit blocks produced by the transcoder. Each code is based on the generating polynomial given by Equation (91–1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$g(x) = \prod_{j=0}^{2t-1}(x-\alpha^j) = g_{2t}x^{2t} + g_{2t-1}x^{2t-1} + \ldots + g_1 x + g_0 \quad (91\text{–}1)$$

In Equation (91–1), α is a primitive element of the finite field defined by the polynomial $x^{10}+x^3+1$.

Equation (91–2) defines the message polynomial $m(x)$ whose coefficients are the message symbols m_{k-1} to m_0.

$$m(x) = m_{k-1}x^{n-1} + m_{k-2}x^{n-2} + \ldots + m_1 x^{2t+1} + m_0 x^{2t} \quad (91\text{–}2)$$

Each message symbol m_i is the bit vector $(m_{i,9}, m_{i,8}, \ldots, m_{i,1}, m_{i,0})$, which is identified with the element $m_{i,9}\alpha^9 + m_{i,8}\alpha^8 + \ldots + m_{i,1}\alpha + m_{i,0}$ of the finite field. The message symbols are composed of the bits of the transcoded blocks tx_scrambled (including a mapped group of alignment markers when appropriate) such that bit 0 of the first transcoded block in the message (or am_txmapped<0>) is bit 0 of m_{k-1} and bit 256 of the last transcoded block in the message is bit 9 of m_0. The first symbol input to the encoder is m_{k-1}.

Equation (91–3) defines the parity polynomial $p(x)$ whose coefficients are the parity symbols p_{2t-1} to p_0.

$$p(x) = p_{2t-1}x^{2t-1} + p_{2t-2}x^{2t-2} + \ldots + p_1 x + p_0 \quad (91\text{–}3)$$

The parity polynomial is the remainder from the division of $m(x)$ by $g(x)$. This may be computed using the shift register implementation illustrated in Figure 91–5. The outputs of the delay elements are initialized to zero prior to the computation of the parity for a given message. After the last message symbol, m_0, is processed by the encoder, the outputs of the delay elements are the parity symbols for that message.

The codeword polynomial $c(x)$ is then the sum of $m(x)$ and $p(x)$ where the coefficient of the highest power of x, $c_{n-1} = m_{k-1}$ is transmitted first and the coefficient of the lowest power of x, $c_0 = p_0$ is transmitted last. The first bit transmitted from each symbol is bit 0.

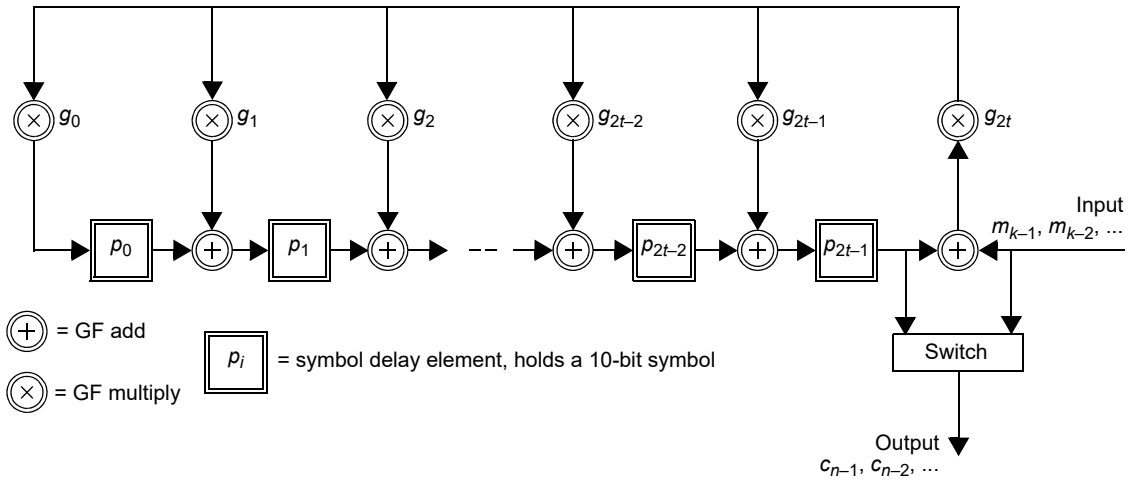

Figure 91–5—Reed-Solomon encoder functional model

The coefficients of the generator polynomial for each code are presented in Table 91–1. Example codewords for each code are provided in Annex 91A.

9	656	788	20		249			
10	32	361	21		282			

91.5.2.8 Symbol distribution

Once the data has been Reed-Solomon encoded, it shall be distributed to 4 FEC lanes, one 10-bit symbol at a time in a round robin distribution from the lowest to the highest numbered FEC lane. The distribution process is shown in Figure 91–6.

When used to form a 100GBASE-KP4 PHY, the PMA:IS_UNITDATA_*i*.request primitive is defined to include an additional parameter (refer to 94.2.1.1.1). At the beginning of an FEC codeword, the parameter start=TRUE is asserted for the first bit of the first four symbols of the codeword transferred across the four primitives. Otherwise the parameter start is set to FALSE.

91.5.2.9 Transmit bit ordering

The transmit bit ordering is illustrated in Figure 91–6.

91.5.3 Receive function

91.5.3.1 Alignment lock and deskew

The RS-FEC receive function forms 4 bit streams by concatenating the bits from each of the 4 PMA:IS_UNITDATA_*i*.indication primitives in the order they are received. It obtains lock to the alignment markers as specified by the FEC synchronization state diagram shown in Figure 91–8.

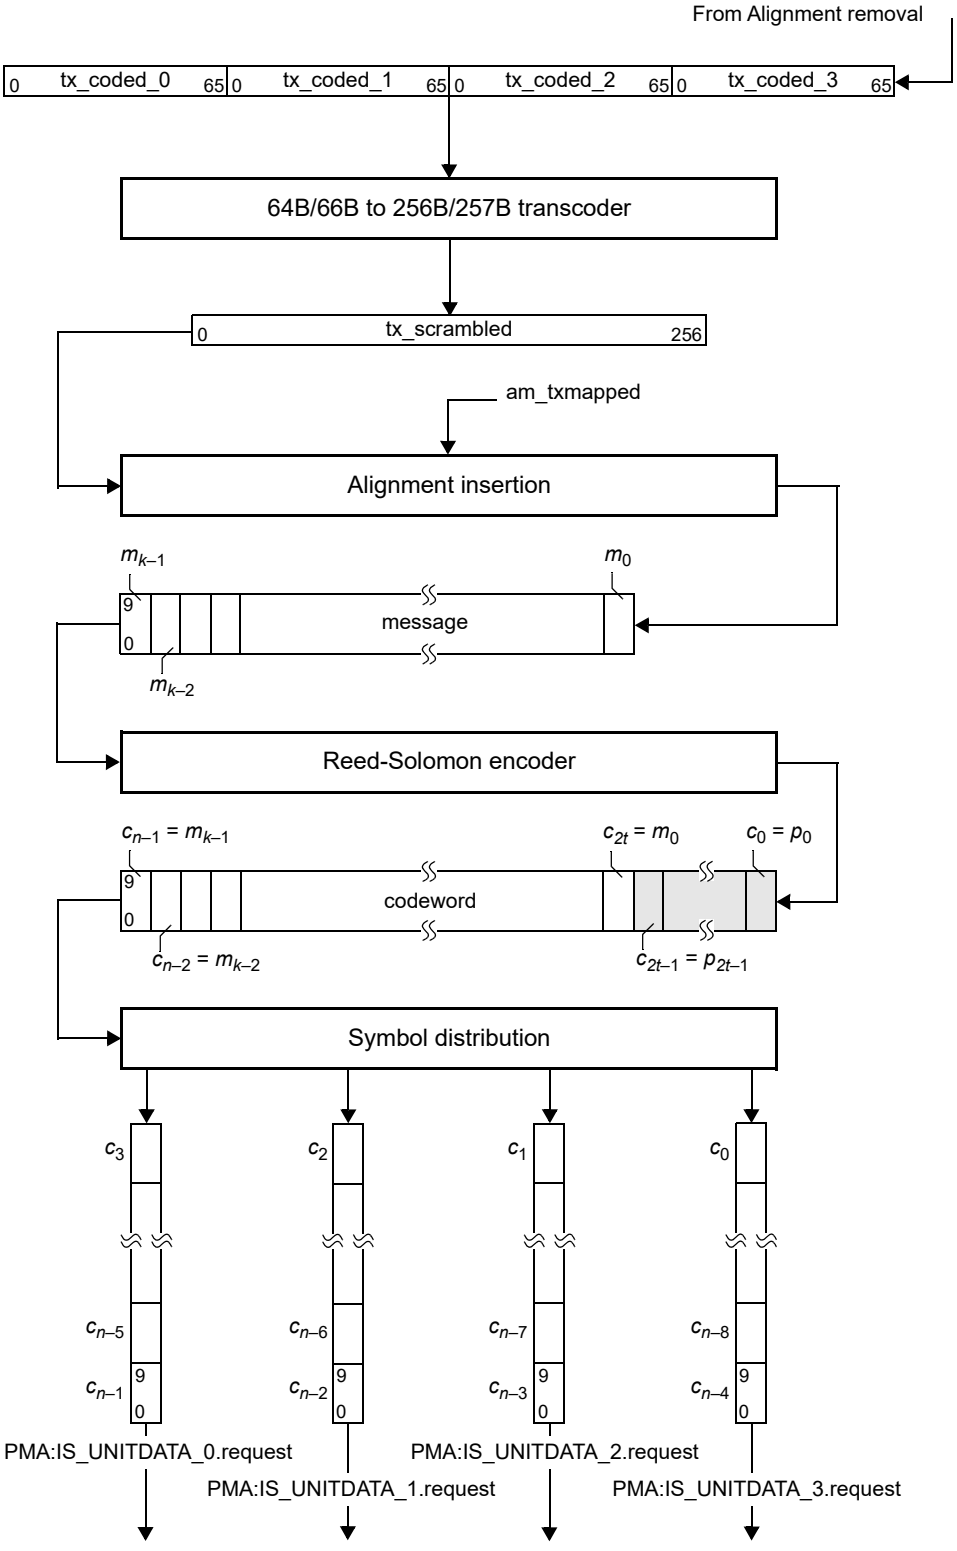

Figure 91–6—Transmit bit ordering

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

After alignment marker lock is achieved on all 4 lanes, all inter-lane Skew is removed as specified by the FEC alignment state diagram shown in Figure 91–9. The FEC receive function shall support a maximum Skew of 180 ns between FEC lanes and a maximum Skew Variation of 4 ns.

The 100GBASE-KP4 PMA transmit function (refer to 94.2.2) inserts PMA-specific overhead that is aligned with the start of a Reed-Solomon codeword. The 100GBASE-KP4 PMA receive function (refer to 94.2.3) synchronizes to this overhead and indicates the first bit of each of the first four symbols in a codeword by setting the PMA:IS_UNITDATA_*i*.indication parameter start=TRUE (see 94.2.1.2).

91.5.3.2 Lane reorder

FEC lanes can be received on different lanes of the service interface from which they were originally transmitted. The FEC receive function shall order the FEC lanes according to the FEC lane number (see 91.5.2.6). The FEC lane number is defined by the sequence of alignment markers that are mapped to each FEC lane.

After all FEC lanes are aligned, deskewed, and reordered, the FEC lanes are multiplexed together in the proper order to reconstruct the original stream of FEC codewords.

91.5.3.3 Reed-Solomon decoder

The Reed-Solomon decoder extracts the message symbols from the codeword, corrects them as necessary, and discards the parity symbols. The message symbols correspond to 20 transcoded blocks rx_scrambled.

When used to form a 100GBASE-CR4, 100GBASE-KR4, or 100GBASE-SR4 PHY, the RS-FEC sublayer shall be capable of correcting any combination of up to t=7 symbol errors in a codeword. When used to form a 100GBASE-KP4, 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PHY, the RS-FEC sublayer shall be capable of correcting any combination of up to t=15 symbol errors in a codeword. The RS-FEC sublayer shall also be capable of indicating when an errored codeword was not corrected. The probability that the decoder fails to indicate a codeword with t+1 errors as uncorrected is not expected to exceed 10^{-6}. This limit is also expected to apply for t+2 errors, t+3 errors, and so on.

The Reed-Solomon decoder may provide the option to perform error detection without error correction to reduce the delay contributed by the RS-FEC sublayer. The presence of this option is indicated by the assertion of the FEC_bypass_correction_ability variable (see 91.6.8). When the option is provided, it is enabled by the assertion of the FEC_bypass_correction_enable variable (see 91.6.1). This option shall not be used when the RS-FEC sublayer is used to form part of a 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-SR4, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PHY.

NOTE—The PHY may rely on the error correction capability of the RS-FEC sublayer to achieve its performance objectives. It is recommended that acceptable performance of the underlying link is verified before error correction is bypassed.

The Reed-Solomon decoder indicates errors to the PCS sublayer by intentionally corrupting 66-bit block synchronization headers. When the decoder determines that a codeword contains errors (when the bypass correction feature is enabled) or contains errors that were not corrected (when the bypass correction feature is not supported or not enabled), it shall ensure that, for every other 257-bit block within the codeword starting with the first (1st, 3rd, 5th, etc.), the synchronization header for the first 66-bit block at the output of the 256B/257B to 64B/66B transcoder, rx_coded_0<1:0>, is set to 11. In addition, it shall ensure rx_coded_0<1:0> corresponding to the 6th 257-bit block and rx_coded_3<1:0> corresponding to the last (20th) 257-bit block in the codeword are set to 11. This causes the PCS to discard all frames 64 bytes and larger that are fully or partially within the codeword.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Reed-Solomon decoder may optionally provide the ability to bypass the error indication feature to reduce the delay contributed by the RS-FEC sublayer. The presence of this option is indicated by the assertion of the FEC_bypass_indication_ability variable (see 91.6.9). When the option is provided it is enabled by the assertion of the FEC_bypass_indication_enable variable (see 91.6.2).

When FEC_bypass_correction_enable is asserted, the decoder shall not bypass error indication and the value of FEC_bypass_indication_enable has no effect.

When FEC_bypass_indication_enable is asserted, additional error monitoring is performed by the RS-FEC sublayer to reduce the likelihood that errors in a packet are not detected. The Reed-Solomon decoder counts the number of symbol errors detected on all four FEC lanes in consecutive non-overlapping blocks of 8192 codewords. When the number of symbol errors in a block of 8192 codewords exceeds *K*, the Reed-Solomon decoder shall cause synchronization header rx_coded<1:0> of each subsequent 66-bit block that is delivered to the PCS to be assigned a value of 00 or 11 for a period of 60 ms to 75 ms. As a result, the PCS sets hi_ber=true, which inhibits the processing of received packets. When Auto-Negotiation is supported and enabled, assertion of hi_ber causes Auto-Negotiation to restart.

For the optional EEE deep sleep capability, the error monitor employed when FEC_bypass_indication_enable is asserted shall be disabled when rx_lpi_active=true. The next block of 8192 codewords considered by the error monitor shall begin on the codeword boundary following the transition of rx_lpi_active from true to false.

When the RS-FEC sublayer is used to form a 100GBASE-CR4, 100GBASE-KR4, or 100GBASE-SR4 PHY, the symbol error threshold shall be *K*=417. When the RS-FEC sublayer is used to form a 100GBASE-KP4, 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PHY, the symbol error threshold shall be *K*=6380.

91.5.3.3.1 FEC Degraded SER (optional)

For 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PHYs an optional FEC degraded symbol error ratio function is available.

The Reed-Solomon decoder may optionally provide the ability to indicate a degradation of the received signal. The presence of this option is indicated by the assertion of the FEC_degraded_SER_ability variable (see 91.6.11). When the option is provided it is enabled by the assertion of the FEC_degraded_SER_enable variable (see 91.6.4).

When FEC_degraded_SER_enable is asserted, additional error monitoring is performed by the FEC. The Reed-Solomon decoder counts the total number of symbol errors detected in consecutive non-overlapping blocks of FEC_degraded_SER_interval codewords (see 91.6.7). If the decoder determines that a codeword is uncorrectable, the number of symbol errors detected is increased by 16. When the number of symbol errors exceeds the threshold set in FEC_degraded_SER_activate_threshold (see 91.6.5), the FEC_degraded_SER bit (see 91.6.12) is set. At the end of each interval, if the number of symbol errors is less than the threshold set in FEC_degraded_SER_deactivate_threshold (see 91.6.6), the FEC_degraded_SER bit is cleared. The value of the FEC_degraded_SER bit is unspecified if the value of FEC_degraded_SER_activate_threshold is less than the value of FEC_degraded_SER_deactivate_threshold.

If either FEC_degraded_SER_ability or FEC_degraded_SER_enable is deasserted then the FEC_degraded_SER bit is cleared.

91.5.3.4 Alignment marker removal

The first 1285 message bits in every 4096th codeword is the vector am_rxmapped<1284:0> where bit 0 is the first bit received. The specific codewords that include this vector are indicated by the alignment lock and deskew function (refer to 91.5.3.1).

For the optional EEE deep sleep capability, transitions between normal alignment markers and Rapid Alignment Markers result in changes in the relative position and frequency of am_rxmapped<1284:0>. These transitions are detected by the Receive LPI state diagram (see Figure 91–11) and this information is used by the alignment marker removal function to determine which bits are to be removed. When rx_lpi_active is true, the first 1285 message bits in every other codeword is the vector am_rxmapped<1284:0>.

The vector am_rxmapped shall be removed prior to transcoding.

91.5.3.5 256B/257B to 64B/66B transcoder

The transcoder extracts a group of four 66-bit blocks, rx_coded_*j*<65:0> where *j*=0 to 3, from each 257-bit block rx_scrambled<256:0>. Bit 0 of the 257-bit block is the first bit received.

First, descramble the first 5 bits, based on reception order, of rx_scrambled<256:0> to yield rx_xcoded<256:0> as follows.

a) Set rx_xcoded<4:0> to the result of the bit-wise exclusive-OR of the rx_scrambled<4:0> and rx_scrambled<12:8>.
b) Set rx_xcoded<256:5> to rx_scrambled<256:5>.

If rx_xcoded<0> is 1, rx_coded_*j*<65:0> for *j*=0 to 3 shall be derived as follows.

a1) rx_coded_*j*<65:2> = rx_xcoded<(64*j*+64):(64*j*+1)> for *j*=0 to 3
b1) rx_coded_*j*<0>=0 and rx_coded_*j*<1>=1 for all *j*=0 to 3

If rx_xcoded<0> is 0 and any rx_xcoded<*j*+1>=0 for *j*=0 to 3, rx_coded_*j*<65:0> for *j*=0 to 3 shall be derived as follows.

a2) Let *c* be the smallest value of *j* such that rx_xcoded<*j*+1>=0. In other words, rx_coded_*c* is the first 66-bit control block in the resulting group of four blocks.
b2) Let rx_payloads be a vector representing the payloads of the four 66-bit blocks. It is derived using the following expressions:
rx_payloads<(64*c*+3):0> = rx_xcoded<(64*c*+8):5>
rx_payloads<(64*c*+7):(64*c*+4)> = 0000 (an arbitrary value that is later replaced by s_*c*)
rx_payloads<255:(64*c*+8)> = rx_xcoded<256:(64*c*+9)>
c2) rx_coded_*j*<65:2> = rx_payloads<(64*j*+63):64*j*> for *j*=0 to 3
d2) Let f_*c*<3:0> = rx_coded_*c*<5:2> be the scrambled first nibble (based on transmission order) of the block type field for rx_coded_*c*.
e2) Descramble f_*c*<3:0> to yield g<3:0> per the following expression where "^" denotes the exclusive-OR operation. When *c*=0, rx_coded_(*c*–1) corresponds to rx_coded_3 from the previous 257-bit block.
g<*i*> = f_*c*<*i*> ^ rx_coded_(*c*–1)<*i*+8> ^ rx_coded_(*c*–1)<*i*+27> for *i*=0 to 3
f2) The block type field may be uniquely identified by either its most or least significant nibble. Since g<3:0> is the least significant nibble of the block type field (per the transmission order), derive h<3:0> by cross-referencing to g<3:0> using Figure 82–5. For example, if g<3:0> is 0xE then h<3:0> is 0x1. If no match to g<3:0> is found, h<3:0> is set to 0000.
g2) If rx_xcoded<*j*+1>=0, rx_coded_*j*<0>=1 and rx_coded_*j*<1>=0 for *j*=0 to 3

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

h2) If rx_xcoded<*j*+1>=1, rx_coded_*j*<0>=0 and rx_coded_*j*<1>=1 for *j*=0 to 3
i2) If h<3:0> = 0000, rx_coded_*c*<1>=1 (invalidate synchronization header)

If rx_xcoded<0> is 0 and all rx_xcoded<*j*+1>=1 for *j*=0 to 3, rx_coded_*j*<65:0> for *j*=0 to 3 shall be derived as follows.

a3) Set *c* = 0 and h<3:0> = 0000.
b3) Let rx_payloads be a vector representing the payloads of the four 66-bit blocks. It is derived using the following expressions.
rx_payloads<(64*c*+3):0> = rx_xcoded<(64*c*+8):5>
rx_payloads<(64*c*+7):(64*c*+4)> = 0000 (an arbitrary value that is later replaced by s_*c*)
rx_payloads<255:(64*c*+8)> = rx_xcoded<256:(64*c*+9)>
c3) rx_coded_*j*<65:2> = rx_payloads<(64*j*+63):(64*j*)> for *j*=0 to 3
d3) rx_coded_*j*<0>=0 and rx_coded_*j*<1>=0 for *j*=0 and 2
e3) rx_coded_*j*<0>=1 and rx_coded_*j*<1>=1 for *j*=1 and 3

If rx_xcoded<0> is 0, scramble h<3:0> to yield s_*c*<3:0> and assign it to rx_coded_*c* per the following expressions.

a4) s_*c*<*i*> = h<*i*> ^ rx_coded_(*c*–1)<*i*+12> ^ rx_coded_(*c*–1)<*i*+31> for *i*=0 to 3
b4) rx_coded_*c*<9:6> = s_*c*<3:0>

The 66-bit blocks are transmitted in order from *j*=0 to 3. Bit 0 of each block is the first bit transmitted.

91.5.3.6 Block distribution

After the data has been transcoded, it shall be distributed to multiple PCS lanes, one 66-bit block at a time in a round robin distribution from the lowest to the highest numbered PCS lanes. The distribution process is shown in Figure 82–6.

91.5.3.7 Alignment marker mapping and insertion

The alignment marker mapping function compensates for operation of lane reorder function (refer to 91.5.3.2) to derive the PCS lane alignment markers, am_rx_*x*<65:0> for *x*=0 to 19, from am_rxmapped<1284:0> (refer to 91.5.3.4).

The alignment markers shall be derived from am_rxmapped<1284:0> in a manner that yields the same result as the following process.

Given *i*=0 to 3, *k*=0 to 31, and *y*=*i*+4*k*, am_rxpayloads may be derived from am_rxmapped per the following expression:

am_rxpayloads<*i*, (10*k*+9):10*k*> = am_rxmapped<(10*y*+9):10*y*>

The 5-bit pad am_rxmapped<1284:1280> is ignored. Given *i*=0 to 3, *j*=0 to 4, and *x*=*i*+4*j*, amp_rx_*x* may be derived from am_rxpayloads by the following expression:

amp_rx_*x*<63:0> = am_rxpayloads<*i*, (64*j*+63):64*j*>

For *x*=0 to 19, am_rx_*x*<65:0> is constructed as follows:

a) am_rx_*x*<0>=1 and am_rx_*x*<1>=0.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) am_rx_*x*<25:2> is set to M_0, M_1, and M_2 as shown in Figure 82–9 using the values in Table 82–2 for PCS lane number *x*. If amp_rx_*x* corresponds to a Rapid Alignment marker, then the M_4, M_5, and M_6 values are used instead (see Figure 82–11).
c) am_rx_*x*<33:26> = amp_rx_*x*<31:24>.
d) am_rx_*x*<57:34> is set to M_4, M_5, and M_6 as shown in Figure 82–9 using the values in Table 82–2 for PCS lane number *x*. If amp_rx_*x* corresponds to a Rapid Alignment marker, then the M_0, M_1, and M_2 values are used instead (see Figure 82–11).
e) am_rx_*x*<65:58> = amp_rx_*x*<63:56>.

One vector is mapped to 20 alignment markers every 4096 Reed-Solomon codewords (see 91.5.3.4). The alignment markers are simultaneously transmitted on the 20 PCS lanes after every 16383rd column of 20 66-bit blocks.

For the optional EEE deep sleep capability, when rx_lpi_active is true, one vector is mapped to 20 Rapid Alignment Markers every 2 Reed-Solomon codewords. The Rapid Alignment Markers are simultaneously transmitted on the 20 PCS lanes after every 7th column of 20 66-bit blocks.

The alignment markers am_rx_0 to am_rx_3 shall be inserted so that they are immediately followed by rx_coded_0 to rx_coded_3, respectively, as derived from the first 257-bit block following am_rxmapped. Similarly am_rx_4 to am_rx_7 are followed by the 66-bit blocks corresponding to the second 257-bit block following am_rxmapped, and so on.

91.5.3.8 Receive bit ordering

The receive bit ordering is illustrated in Figure 91–7. This illustration shows the case where the FEC lanes appear across the PMA:IS_UNITDATA_*i*.indication primitives in the correct order.

91.5.4 Detailed functions and state diagrams

91.5.4.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, functions, and counters. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

91.5.4.2 State variables

91.5.4.2.1 Variables

all_locked
: A Boolean variable that is set to true when amps_lock<*x*> is true for all *x* and is set to false when amps_lock<*x*> is false for any *x*.

amp_counter_done
: Boolean variable that indicates that amp_counter has reached its terminal count.

amp_match
: Boolean variable that holds the output of the function AMP_COMPARE.

amp_valid
: Boolean variable that is set to true if the received 64-bit block is a valid alignment marker payload. The alignment marker payload, mapped to an FEC lane according to the process described in 91.5.2.6, consists of 48 known bits and 16 variable bits (the BIP_3 or CD_3 field and its complement BIP_7 or CD_7, see 82.2.7). The bits of the candidate block that are in the positions of the known bits in the alignment marker payload are compared on a nibble-wise basis (12 comparisons). If no more than 3 nibbles in the candidate block fail to match the corresponding known nibbles in the alignment marker payload, the candidate block is considered a valid alignment marker payload. For the normal mode of operation, each FEC lane compares the candidate block to the alignment marker payload for PCS lane 0. For the optional EEE deep sleep capability, each FEC lane also compares the candidate block to the alignment marker payload for PCS lane 16 when rx_lpi_active is true.

amps_lock<*x*>
: Boolean variable that is set to true when the receiver has detected the location of the alignment marker payload sequence for a given lane on the PMA service interface, where *x* = 0:3.

current_pcsl
: A variable that holds the PCS lane number corresponding to the current alignment marker payload that is recognized on a given lane of the PMA service interface. It is compared to the variable first_pcsl to confirm that the location of the alignment marker payload sequence has been detected.

cw_bad
: A Boolean variable that is set to true if the Reed-Solomon decoder (see 91.5.3.3) fails to correct the current FEC codeword and is set to false otherwise.

deskew_done
: A Boolean variable that is set to true when fec_enable_deskew is set to true and the deskew process is completed. Otherwise, this variable is set to false.

fec_align_status
: A variable set by the FEC alignment process to reflect the status of FEC lane-to-lane alignment. Set to true when all lanes are synchronized and aligned and set to false when the deskew process is not complete.

fec_alignment_valid
: Boolean variable that is set to true if all FEC lanes are aligned. FEC lanes are considered to be aligned when amps_lock<*x*> is true for all *x*, each FEC lane is locked to a unique alignment marker payload sequence (see 91.5.2.6), and the FEC lanes are deskewed. Otherwise, this variable is set to false.

fec_enable_deskew
: A Boolean variable that enables and disables the deskew process. Received bits may be discarded whenever deskew is enabled. It is set to true when deskew is enabled and set to false when deskew is disabled.

fec_lane
: A variable that holds the FEC lane number (0 to 3) received on lane *x* of the PMA service interface when amps_lock<*x*>=true. The FEC lane number is determined by the alignment marker payloads in the 2nd, 3rd, or 4th positions of the sequence based on the mapping defined in 91.5.2.6. The 48 bits that are in the positions of the known bits in the received alignment marker payload are

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

compared to the expected values for a given payload position and FEC lane on a nibble-wise basis (12 comparisons). If no more than 3 nibbles in the candidate block fail to match the corresponding known nibbles for any payload position on a given FEC lane, then the FEC lane number is assigned accordingly.

fec_lane_mapping<*x*>
: See 91.6.18.

fec_optional_states
: Boolean variable that is true if the optional states are implemented and false otherwise.

first_pcsl
: A variable that holds the PCS lane number that corresponds to the first alignment marker payload that is recognized on a given lane of the PMA service interface. It is compared to the PCS lane number corresponding to the second alignment marker payload that is tested.

reset
: Boolean variable that controls the resetting of the RS-FEC sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the RS-FEC sublayer into low-power mode.

restart_lock
: Boolean variable that is set by the FEC alignment process to reset the synchronization process on all FEC lanes. It is set to true after 3 consecutive uncorrected codewords are received (3_BAD state) and set to false upon entry into the LOSS_OF_ALIGNMENT state. It is also set to true when 5 Alignment Markers in a row fail to match (5_BAD state) if the optional states are supported in the FEC synchronization process.

rx_align_status
: Boolean variable that is set by the alignment lock and deskew function (see 91.5.2.2).

signal_ok
: Boolean variable that is set based on the most recently received value of PMA:IS_SIGNAL.indication(SIGNAL_OK). It is true if the value was OK and false if the value was FAIL.

slip_done
: Boolean variable that is set to true when the SLIP requested by the synchronization state diagram has been completed indicating that the next candidate 64-bit block position can be tested.

test_amp
: Boolean variable that is set to true when a candidate block position is available for testing and false when the FIND_1ST state is entered.

test_cw
: Boolean variable that is set to true when a new FEC codeword is available for decoding and is set to false when the TEST_CW state is entered.

The following variables are only used for the optional EEE deep sleep capability. If this capability is not supported, the values of tx_lpi_active and rx_lpi_active are set to false.

1st_ram_counter_done
: Boolean variable that indicates that 1st_ram_counter has reached its terminal count.

1st_ramps_counter_done
: Boolean variable that indicates that 1st_ramps_counter has reached its terminal count.

fec_lpi_fw
: Boolean variable that controls the behavior of the Transmit LPI and Receive LPI state diagrams. This variable is set to true when the local PCS is configured to use the fast wake mechanism and set to false otherwise.

ram_counter_done
: Boolean variable that indicates that ram_counter has reached its terminal count.

ram_valid
: Boolean variable that is set to true when the 66-bit blocks concurrently received on at least 2 PCS lanes are valid Rapid Alignment Markers with identical values for rx_down_count and is set to false otherwise.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ram_valid_prev
: Boolean variable that holds the value of ram_valid from the previous expected Rapid Alignment Marker position.

ramps_counter_done
: Boolean variable that indicates that ramps_counter has reached its terminal count.

ramps_valid
: Boolean variable that is set to true when the 64-bit block payloads concurrently received on at least 2 FEC lanes are valid Rapid Alignment Marker payloads with identical values for rx_down_count and is set to false otherwise.

ramps_valid_prev
: Boolean variable that holds that value of ramps_valid from the previous expected Rapid Alignment Marker payload position.

rx_down_count
: The value that results from the bit-wise exclusive-OR of the Count Down (CD_3) byte and the M_0 byte of the current Rapid Alignment Marker payload (see 82.2.9).

rx_lpi_active
: A Boolean variable that is set to true when the RS-FEC sublayer infers that the Low Power Idle is being received from the link partner and is set to false otherwise.

rx_quiet_timer_done
: A Boolean variable that indicates that rx_quiet_timer has reached its terminal count.

tx_down_count
: The value that results from the bit-wise exclusive-OR of the Count Down (CD_3) byte and the M_0 byte of the current Rapid Alignment Marker (see 82.2.9).

tx_lpi_active
: A Boolean variable that is set to true when the RS-FEC sublayer infers that the local PCS is transmitting Low Power Idle and is set to false otherwise.

tx_quiet_timer_done
: Boolean variable that indicates that tx_quiet_timer has reached its terminal count.

91.5.4.2.2 Functions

AMP_COMPARE
: This function compares the values of first_pcsl and current_pcsl to determine if a valid alignment marker payload sequence has been detected and returns the result of the comparison using the variable amp_match. When rx_lpi_active is false, if current_pcsl and first_pcsl are 0, amp_match is set to true. When rx_lpi_active is true, the comparison is performed as follows. If first_pcsl is 0 then amp_match is set to true if current_pcsl is 16. If first_pcsl is 16 then amp_match is set to true if current_pcsl is 0. Otherwise, amp_match is set to false.

SLIP
: Causes the next candidate block position to be tested. The precise method for determining the next candidate block position is not specified and is implementation dependent. However, an implementation shall ensure that all possible block positions are evaluated.

91.5.4.2.3 Counters

amp_bad_count
: Counts the number of consecutive alignment markers that don't match the expected values for a given FEC lane if the optional states are supported in the FEC synchronization process.

amp_counter
: When rx_lpi_active is false, this counter counts the 4096 FEC codewords that separate the ends of two consecutive normal alignment marker payload sequences. An FEC codeword is 1320 bits per FEC lane for 100GBASE-KR4 and 1360 bits per FEC lane for 100GBASE-KP4. When rx_lpi_active is true, then amp_counter is defined as follows. If first_pcsl corresponds to PCS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

lane 0, it counts the 256 bits to the end of the expected location of the Rapid Alignment Marker payload corresponding to PCS lane 16. If first_pcsl corresponds to PCS lane 16, this counter counts the 2 FEC codewords minus 256 bits to the end of the expected location of the next Rapid Alignment Marker payload corresponding to PCS lane 0.

cw_bad_count
: Counts the number of consecutive uncorrected FEC codewords. This counter is set to zero when an FEC codeword is received and cw_bad is false for that codeword.

The following counters are only used for the optional EEE deep sleep capability.

1st_ram_counter
: This counter counts 4 66-bit blocks from the end of one candidate RAM position to the end of the next candidate RAM position. The first instance of the counter counts from the end of the last normal alignment marker received.

1st_ramps_counter
: This counter counts one FEC codeword from the end of one candidate RAM payload to the end of the next RAM payload position. An FEC codeword is 1320 bits per FEC lane for 100GBASE-KR4 and 1360 bits per FEC lane for 100GBASE-KP4

ram_counter
: This counter counts 8 66-bit blocks from the end of the current RAM to the end of the next expected RAM position.

ramps_counter
: This counter counts 2 FEC codewords from the end of the current RAM payload to the end of the next expected RAM payload position.

rx_quiet_timer
: This timer limits the maximum time fec_align_status may be deasserted before the Transmit LPI state diagram concludes that the link has failed. The value of this timer is between 2 ms and 2.8 ms.

tx_quiet_timer
: This timer limits the maximum time rx_align_status may be deasserted before the Transmit LPI state diagram concludes that the link has failed. The value of this timer is between 1.8 ms and 2 ms.

91.5.4.3 State diagrams

The FEC shall implement four synchronization processes as shown in Figure 91–8. The synchronization process operates independently on each lane. The synchronization state diagram determines when the FEC has detected the location of the alignment marker payload sequence in the received bit stream for a given lane of the service interface.

The FEC shall implement the alignment process as shown in Figure 91–9.

When the optional EEE deep sleep capability is supported, the FEC shall also implement the Transmit LPI process as shown in Figure 91–10 and the Receive LPI process as shown in Figure 91–11. The Transmit LPI state diagram infers when Low Power Idle is being transmitted by the local PCS by checking for the presence of Rapid Alignment Markers. The Receive LPI state diagram infers when Low Power Idle is being received from the link partner using a similar mechanism. Monitoring the position and frequency of alignment markers is also critical to the operation of the alignment marker removal function (see 91.5.2.4 and 91.5.3.4).

91.6 RS-FEC MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the RS-FEC. If MDIO is implemented, it shall map MDIO control bits to RS-FEC control variables as shown in Table 91–2, and MDIO status bits to RS-FEC status variables as

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

shown in Table 91–3, and if a separated PMA (see 45.2.1) is connected to the FEC service interface it shall map additional MDIO status bits to additional RS-FEC status variables as shown in Table 91–4.

Table 91–2—MDIO/RS-FEC control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
FEC bypass correction enable	RS-FEC control register	1.200.0	FEC_bypass_correction_enable
FEC bypass indication enable	RS-FEC control register	1.200.1	FEC_bypass_indication_enable
Four lane PMD	RS-FEC control register	1.200.3	four_lane_pmd
FEC degraded SER enable	RS-FEC control register	1.200.4	FEC_degraded_SER_enable
FEC degraded SER activate threshold	RS-FEC degraded SER activate threshold register	1.650, 1.651	FEC_degraded_SER_activate_threshold
FEC degraded SER deactivate threshold	RS-FEC degraded SER deactivate threshold register	1.652, 1.653	FEC_degraded_SER_deactivate_threshold
FEC degraded SER interval	RS-FEC degraded SER interval register	1.654, 1.655	FEC_degraded_SER_interval

Table 91–3—MDIO/RS-FEC status variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
FEC bypass correction ability	RS-FEC status register	1.201.0	FEC_bypass_correction_ability
FEC bypass indication ability	RS-FEC status register	1.201.1	FEC_bypass_indication_ability
RS-FEC high SER	RS-FEC status register	1.201.2	hi_ser
FEC degraded SER ability	RS-FEC status register	1.201.3	FEC_degraded_SER_ability
FEC degraded SER	RS-FEC status register	1.201.4	FEC_degraded_SER
FEC optional states supported	RS-FEC status register	1.201.7	fec_optional_states
FEC AM lock *x*, *x*=0 to 3	RS-FEC status register	1.201.8:11	amps_lock<*x*>
RS-FEC align status	RS-FEC status register	1.201.14	fec_align_status
FEC corrected codewords	RS-FEC corrected codewords counter register	1.202, 1.203	FEC_corrected_cw_counter
FEC uncorrected codewords	RS-FEC uncorrected codewords counter register	1.204, 1.205	FEC_uncorrected_cw_counter
FEC lane *x* mapping	RS-FEC lane mapping register	1.206	FEC_lane_mapping<*x*>
FEC symbol errors, FEC lanes 0 to 3	RS-FEC symbol error counter register, FEC lanes 0 to 3	1.210 to 1.217	FEC_symbol_error_counter_*i*

The following subclauses define variables that are not otherwise defined, e.g., for use by state diagrams.

Table 91–4—MDIO/RS-FEC status variable mapping for separated PMA

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
PCS align status	RS-FEC status register	1.201.15	align_status
BIP errors, PCS lanes 0 to 19	RS-FEC BIP error counter register, PCS lanes 0 to 19	1.230 to 1.249	BIP_error_counter_*i*
PCS lane *x* mapping	PCS lane *x* mapping register	1.250 to 1.269	lane_mapping<*x*>
Block lock *x*	RS-FEC PCS alignment status 1 and 2 registers	1.280 to 1.281	block_lock<*x*>
Lane *x* aligned	RS-FEC PCS alignment status 3 and 4 registers	1.282 to 1.283	am_lock<*x*>

91.6.1 FEC_bypass_correction_enable

When this variable is set to one, the Reed-Solomon decoder performs error detection without error correction (see 91.5.3.3). When this variable is set to zero, the decoder also performs error correction. The default value of the variable is zero. This variable is mapped to the bit defined in 45.2.1.116 (1.200.0).

91.6.2 FEC_bypass_indication_enable

This variable is set to one to bypass the error indication function (see 91.5.3.3) when this ability is supported. When this variable is set to zero, the decoder indicates errors to the PCS sublayer. This variable has no effect (the decoder does not bypass error indication) if FEC bypass correction enable (1.200.0) is set to one. The default value of this variable is zero. This variable is mapped to the bit defined in 45.2.1.116 (1.200.1).

91.6.3 four_lane_pmd

When this variable is set to one, the alignment marker mapping function substitutes the fixed bytes of the alignment markers corresponding to PCS lanes 17, 18, and 19 with the fixed bytes for the alignment marker corresponding to PCS lane 16 (see 91.5.2.6). When this variable is set to zero, the alignment markers corresponding to PCS lanes 17, 18, and 19 are passed through unmodified. The default value of the variable is one which is the value required by the 100GBASE-CR4, 100GBASE-KR4, 100GBASE-KP4, and 100GBASE-SR4 PMDs. This variable is set to zero for the 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PMDs. This variable is mapped to the bit defined in 45.2.1.116 (1.200.3).

91.6.4 FEC_degraded_SER_enable

This variable enables the FEC decoder to indicate the presence of a degraded SER when the ability is supported (see 91.5.3.3.1). When set to a one, this variable enables degraded SER detection. When set to a zero, degraded SER detection is disabled. Writes to this bit are ignored and reads return a zero if the FEC does not have the ability to signal the presence of a degraded SER. This variable is mapped to the bit defined in 45.2.1.116 (1.200.4).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

91.6.5 FEC_degraded_SER_activate_threshold

This variable controls the threshold used to set the FEC_degraded_SER bit as defined in 91.5.3.3.1. It is mapped to the registers defined in 45.2.1.146 (1.650, 1.651).

91.6.6 FEC_degraded_SER_deactivate_threshold

This variable controls the threshold used to clear the FEC_degraded_SER bit as defined in 91.5.3.3.1. It is mapped to the registers defined in 45.2.1.147 (1.652, 1.653).

91.6.7 FEC_degraded_SER_interval

This variable controls the interval used to set and clear the FEC_degraded_SER bit as defined in 91.5.3.3.1. It is mapped to the registers defined in 45.2.1.148 (1.654, 1.655).

91.6.8 FEC_bypass_correction_ability

The Reed-Solomon decoder may have the option to perform error detection without error correction (see 91.5.3.3) to reduce the delay contributed by the RS-FEC sublayer. This variable is set to one to indicate that the decoder has the ability to bypass error correction. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.117 (1.201.0).

91.6.9 FEC_bypass_indication_ability

The Reed-Solomon decoder may have the option to bypass the error indication function (see 91.5.3.3) to reduce the delay contributed by the RS-FEC sublayer. This variable is set to one to indicate that the decoder has the ability to bypass error indication. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.117 (1.201.1).

91.6.10 hi_ser

This variable is defined when the FEC_bypass_indication_ability variable is set to one. When FEC_bypass_indication_enable is set to one, this bit is set to one if the number of RS-FEC symbol errors in a window of 8192 codewords exceeds the threshold (see 91.5.3.3) and is set to zero otherwise. This variable is mapped to the bit defined in 45.2.1.117 (1.201.2).

91.6.11 FEC_degraded_SER_ability

The FEC decoder may have the option to indicate the presence of a degraded SER (see 91.5.3.3.1). This variable is set to one to indicate that the FEC decoder has the ability to indicate the presence of a degraded SER. This variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.117 (1.201.3).

91.6.12 FEC_degraded_SER

When FEC_degraded_SER_enable is asserted, this variable indicates the presence of a degraded SER as defined in 91.5.3.3.1. This variable is mapped to the bit defined in 45.2.1.117 (1.201.4).

91.6.13 FEC_optional_states

This variable is set to true when the optional states in the FEC synchronization state diagram are implemented. This variable is mapped to the bit defined in 45.2.1.117 (1.201.7).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

91.6.14 amps_lock<*x*>

These variables are assigned by the FEC alignment state diagram shown in Figure 91–9 (see 91.5.4.3). They are mapped to the bits defined in 45.2.1.117 (1.201.8 to 1.201.11 for FEC lanes 0 to 3, respectively).

91.6.15 fec_align_status

This variable assigned by the FEC alignment state diagram shown in Figure 91–9 (see 91.5.4.3). It is mapped to the bit defined in 45.2.1.117 (1.201.14).

91.6.16 FEC_corrected_cw_counter

A corrected FEC codeword is a codeword that contains errors and was corrected.

FEC_corrected_cw_counter is a 32-bit counter that counts once for each corrected FEC codeword processed when fec_align_status is true. This variable is mapped to the registers defined in 45.2.1.118 (1.202, 1.203).

91.6.17 FEC_uncorrected_cw_counter

An uncorrected FEC codeword is a codeword that contains errors (when the bypass correction feature is supported and enabled) or contains errors that were not corrected (when the bypass correction feature is not supported or not enabled).

FEC_uncorrected_cw_counter is a 32-bit counter that counts once for each uncorrected FEC codeword processed when fec_align_status is true. This variable is mapped to the registers defined in 45.2.1.119 (1.204, 1.205).

91.6.18 FEC_lane_mapping<*x*>

When the RS-FEC receive function detects and locks to an alignment marker payload on PMA service interface lane *x*, the FEC lane number corresponding to the detected alignment marker payload is assigned to the variable FEC_lane_mapping<*x*>. These variables are mapped to the register defined in 45.2.1.120 (1.206).

91.6.19 FEC_symbol_error_counter_*i*

FEC_symbol_error_counter_*i*, where *i*=0 to 3, is a 32-bit counter that counts once for each 10-bit symbol corrected on FEC lane *i* when fec_align_status is true. These variables are mapped to the registers defined in 45.2.1.121 and 45.2.1.122 (1.210 to 1.217).

91.6.20 align_status

This variable is assigned the value of rx_align_status as defined by the PCS deskew state diagram shown in Figure 82–14 (see 91.5.2.2). It is mapped to the bit defined in 45.2.1.117 (1.201.15).

91.6.21 BIP_error_counter_*i*

BIP_error_counter_*i*, where *i*=0 to 19, is a 16-bit counter that holds the BIP error count for PCS lane *i* as calculated by the RS-FEC transmit function (see 91.5.2.4). These variables are mapped to the registers defined in 45.2.1.123 and 45.2.1.124 (1.230 to 1.249).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

91.6.22 lane_mapping<*x*>

When the RS-FEC transmit function detects and locks to an alignment marker on FEC service interface lane *x*, the PCS lane number corresponding to the detected alignment marker is assigned to the variable lane_mapping<*x*>. These variables are mapped to the registers defined in 45.2.1.125 and 45.2.1.126 (1.250 to 1.269).

91.6.23 block_lock<*x*>

These variables are assigned by the block lock state diagram shown in Figure 82–12 (see 91.5.2.1). They are mapped to the registers defined in 45.2.1.127 and 45.2.1.128 (1.280 to 1.281).

91.6.24 am_lock<*x*>

These variables are assigned by the alignment marker lock state diagram shown in Figure 82–13 (see 91.5.2.2). They are mapped to the registers defined in 45.2.1.129 and 45.2.1.130 (1.282 to 1.283).

91.7 Protocol implementation conformance statement (PICS) proforma for Clause 91, Reed-Solomon forward error correction (RS-FEC) sublayer for 100GBASE-R PHYs[160]

91.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 91, Reed-Solomon forward error correction (RS-FEC) sublayer for 100GBASE-R PHYs, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

91.7.2 Identification

91.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

91.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 91, Reed-Solomon forward error correction (RS-FEC) sublayer for 100GBASE-R PHYs
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[160] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

91.7.4.1 Transmit function

Item	Feature	Subclause	Value/Comment	Status	Support
TF1	Skew tolerance	91.5.2.2	Maximum Skew of 49 ns between PCS lanes and a maximum Skew Variation of 400 ps	M	Yes [ ]
TF2	Lane reorder	91.5.2.3	Order the PCS lanes according to the PCS lane number	M	Yes [ ]
TF3	64B/66B to 256B/257B transcoder	91.5.2.5	tx_xcoded<256:0> constructed per 91.5.2.5	M	Yes [ ]
TF4	257-bit block transmission order	91.5.2.5	First bit transmitted is bit 0	M	Yes [ ]
TF5	Alignment maker mapping	91.5.2.6	Map to am_txmapped<1284:0> per 91.5.2.6	M	Yes [ ]
TF6	Pad value	91.5.2.6	Binary values 00101 and 11010 (the leftmost bit is assigned to the highest bit index) in an alternating pattern	M	Yes [ ]
TF7	Alignment marker insertion	91.5.2.6	First 1285 message bits to be transmitted from every 4096th codeword	M	Yes [ ]
TF8	Alignment marker insertion when tx_lpi_active is true	91.5.2.6	First 1285 message bits to be transmitted from every other codeword	EEE:M	Yes [ ] N/A [ ]
TF9	Alignment marker insertion point	91.5.2.6	First 257-bit block inserted after am_txmapped corresponds to the four 66-bit blocks received on PCS lanes 0, 1, 2, and 3 that immediately followed the alignment marker on each respective lane	M	Yes [ ]
TF10	Reed-Solomon encoder for 100GBASE-CR4 or 100GBASE-KR4 or 100GBASE-SR4	91.5.2.7	RS(528,514)	KR4:M or SR4:M	Yes [ ] N/A [ ]
TF11	Reed-Solomon encoder for 100GBASE-KP4, 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1	91.5.2.7	RS(544,514)	KP4:M	Yes [ ] N/A [ ]
TF12	Symbol distribution	91.5.2.8	Distributed to 4 FEC lanes, one 10-bit symbol at a time in a round robin distribution from the lowest to the highest numbered FEC lane	M	Yes [ ]

91.7.4.2 Receive function

Item	Feature	Subclause	Value/Comment	Status	Support
RF1	Skew tolerance	91.5.3.1	Maximum Skew of 180 ns between FEC lanes and a maximum Skew Variation of 4 ns	M	Yes [ ]
RF2	Lane reorder	91.5.3.2	Order the FEC lanes according to the FEC lane number	M	Yes [ ]
RF3	Reed-Solomon decoder for 100GBASE-CR4 or 100GBASE-KR4	91.5.3.3	Corrects any combination of up to t=7 symbol errors in a codeword unless error correction bypassed	KR4:M	Yes [ ] N/A [ ]
RF4	Reed-Solomon decoder for 100GBASE-KP4, 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1	91.5.3.3	Corrects any combination of up to t=15 symbol errors in a codeword unless error correction bypassed	KP4:M	Yes [ ] N/A [ ]
RF5	Reed-Solomon decoder for 100GBASE-SR4	91.5.3.3	Corrects any combination of up to t=7 symbol errors in a codeword	SR4:M	Yes [ ] N/A [ ]
RF6	Error correction bypass for 100GBASE-CR2, 100GBASE-KR2, 100GBASE-SR2, 100GBASE-SR4, 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1	91.5.3.3	Error correction is not bypassed	SR4:M or FDDP:M	Yes [ ] N/A [ ]
RF7	Reed-Solomon decoder	91.5.3.3	Capable of indicating when a codeword was not corrected.	M	Yes [ ]
RF8	Error indication function	91.5.3.3	Corrupts 66-bit block synchronization headers for uncorrected errored codewords (or errored codewords when correction is bypassed)	M	Yes [ ]
RF9	Error indication when error correction is bypassed	91.5.3.3	Error indication is not bypassed	BEI:M	Yes [ ] N/A [ ]
RF10	Error monitoring while error indication is bypassed	91.5.3.3	When the number of symbols errors in a block of 8192 codewords exceeds K, corrupt 66-bit block synchronization headers	BEI:M	Yes [ ] N/A [ ]
RF11	Symbol error threshold for 100GBASE-CR4, 100GBASE-KR4, and 100GBASE-SR4	91.5.3.3	K=417	BEI* KR4:M or BEI* SR4:M	Yes [ ] N/A [ ]

92. Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-CR4

92.1 Overview

This clause specifies the 100GBASE-CR4 PMD and baseband medium. Annex 92A, an associated annex, provides information on parameters with test points that may not be testable in an implemented system.

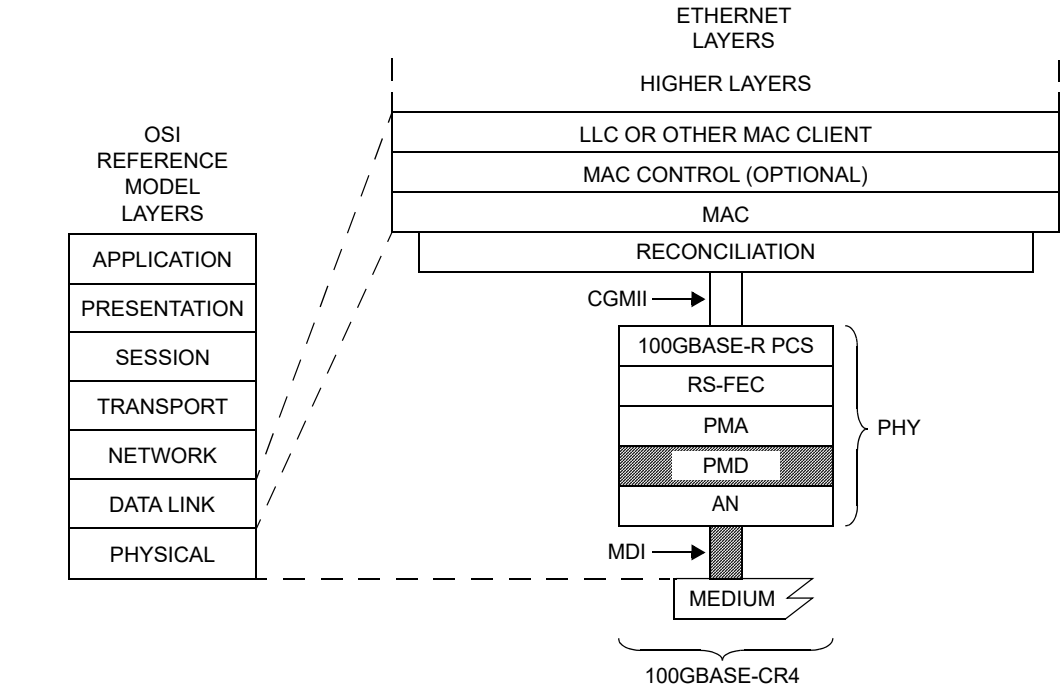
When forming a complete Physical Layer, a PMD shall be connected as illustrated in Figure 92–1, to the appropriate PMA as shown in Table 92–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 92–1—Physical Layer clauses associated with the 100GBASE-CR4 PMD

Associated clause	100GBASE-CR4
81—RS	Required
81—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
91—RS-FEC	Required
83—PMA for 100GBASE-R[b]	Required
83A—CAUI-10	Optional
83D—CAUI-4	Optional
73—Auto-Negotiation	Required
78—Energy Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]There are limitations on the number of PMA lanes that may be used between sublayers, see 83.

When forming a complete 100GBASE-CR4 Physical Layer, the following guidelines apply.



Differential signals received at the MDI from a transmitter that meets the requirements of 92.8.3 and have passed through the cable assembly specified in 92.10 are received with a BER less than 10^{-5}.

For a complete Physical Layer, this specification is considered to be satisfied by a frame loss ratio (see 1.4.344) less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

A 100GBASE-CR4 PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

Figure 92–1 shows the relationship of the 100GBASE-CR4 PMD sublayer and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 92–1—100GBASE-CR4 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

92.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-CR4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data. The PMD translates the encoded data to and from signals suitable for the medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 100GBASE-CR4 PMD has four parallel bit streams, hence i = 0 to 3. The PMA (or the PMD) continuously sends four parallel bit streams to the PMD (or the PMA), one per lane, each at a nominal signaling rate of 25.78125 GBd.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable Global_PMD_signal_detect as defined in 92.7.4. When Global_PMD_signal_detect is one, SIGNAL_OK shall be assigned the value OK. When Global_PMD_signal_detect is zero, SIGNAL_OK shall be assigned the value FAIL. When SIGNAL_OK is FAIL, the PMD:IS_UNITDATA_i.indication parameters are undefined.

If the optional EEE deep sleep capability is supported, then the PMD service interface includes two additional primitives as follows:

PMD:IS_TX_MODE.request
PMD:IS_RX_MODE.request

92.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 82.6.)

The 100GBASE-CR4 PHY may be extended using CAUI-n as a physical instantiation of the inter-sublayer service interface between devices. If CAUI-n is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

92.4 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the 100GBASE-CR4 PMD and AN shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). It is assumed that the one way delay through the medium is no more than 6000 bit times (60 ns).

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

92.5 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the RS-FEC sublayer. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–9.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5.

92.6 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control bits to PMD control variables as shown in Table 92–2, and MDIO status bits to PMD status variables as shown in Table 92–3.

Table 92–2—100GBASE-CR4 MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable	1.9.0	Global_PMD_transmit_disable

92.7 PMD functional specifications

92.7.1 Link block diagram

A 100GBASE-CR4 link in one direction is illustrated in Figure 92–2. For purposes of system conformance, the PMD sublayer is standardized at the test points described in this subclause. The electrical transmit signal is defined at TP2. Unless specified otherwise, all transmitter measurements and tests defined in 92.8.3 are made at TP2 utilizing the test fixture specified in 92.11.1. Unless specified otherwise, all receiver measurements and tests defined in 92.8.4 are performed at TP3 utilizing the test fixture specified in 92.11.1. A mated connector pair has been included in both the transmitter and receiver specifications defined in 92.8.3 and 92.8.4. The recommended maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is specified in 92.8.3.6.

The 100GBASE-CR4 channel is defined between the transmitter (TP0) and receiver (TP5) blocks to include the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss, as illustrated in Figure 92–2. Annex 92A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system. All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 92–2. The cable assembly test fixture of Figure 92–17, or its equivalent, is required for measuring the cable assembly specifications in 92.10 at TP1 and TP4. Two mated connector pairs and the cable assembly test fixture have been included in the cable assembly specifications defined in 92.10. Transmitter and receiver differential controlled impedance printed circuit board insertion losses defined between TP0–TP1 and TP4–TP5, respectively, are provided informatively in Annex 92A.

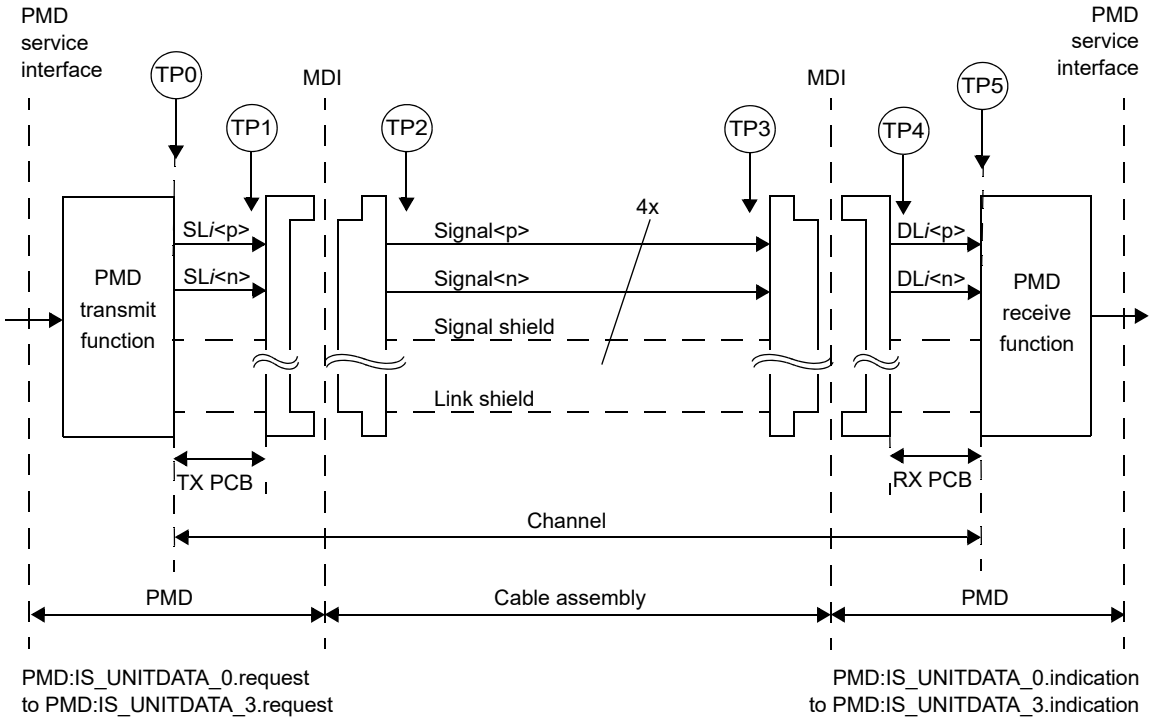

Figure 92–2—100GBASE-CR4 link (one direction is illustrated)

Note that the source lanes (SL), signals SL*i*<p>, and SL*i*<n> are the positive and negative sides of the transmitters differential signal pairs and the destination lanes (DL) signals, DL*i*<p>, and DL*i*<n> are the positive and negative sides of the receivers differential signal pairs for lane *i* (*i* = 0, 1, 2, 3).

Table 92–4 describes the defined test points illustrated in Figure 92–2.

Table 92–4—100GBASE-CR4 test points

Test points	Description
TP0 to TP5	The 100GBASE-CR4 channel including the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss.
TP1 to TP4	All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 92–2. The cable assembly test fixture of Figure 92–17 or its equivalent, is required for measuring the cable assembly specifications in 92.10 at TP1 and TP4.
TP0 to TP2 TP3 to TP5	A mated connector pair has been included in both the transmitter and receiver specifications defined in 92.8.3 and 92.8.4. The recommended maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is specified in 92.8.3.6.
TP2	Unless specified otherwise, all transmitter measurements defined in Table 92–6 are made at TP2 utilizing the test fixture specified in 92.11.1.
TP3	Unless specified otherwise, all receiver measurements and tests defined in 92.8.4 are made at TP3 utilizing the test fixture specified in 92.11.1.

92.7.2 PMD Transmit function

The PMD transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_*i*.request (*i*=0 to 3) into four separate electrical signals. The four electrical signals shall then be delivered to the MDI, all according to the transmit electrical specifications in 92.8.3. A positive differential output voltage (SL*i*<p> minus SL*i*<n>) shall correspond to tx_bit = one.

If the optional EEE deep sleep capability is supported, the following requirements apply. When tx_mode is set to ALERT, the PMD transmit function shall transmit a periodic sequence, where each period of the sequence consists of 8 ones followed by 8 zeros, on each lane, with the transmit equalizer coefficients set to the preset values (see 72.6.10.2.3.1). This sequence is transmitted regardless of the value of tx_bit presented by the PMD:IS_UNITDATA_*i*.request primitive. When tx_mode is not set to ALERT, the transmit equalizer coefficients are set to the values determined via the startup protocol (see 92.7.12).

92.7.3 PMD Receive function

The PMD receive function shall convert the four electrical signals from the MDI into four bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_*i*.indication (*i*=0 to 3). A positive differential input voltage (DL*i*<p> minus DL*i*<n>) shall correspond to rx_bit = one.

92.7.4 Global PMD signal detect function

The variable Global_PMD_signal_detect is the logical AND of the values of PMD_signal_detect_*i* for *i*=0 to 3.

When the MDIO is implemented, this function maps the variable Global_PMD_signal_detect to the register and bit defined in 92.6.

92.7.5 PMD lane-by-lane signal detect function

The PMD lane-by-lane signal detect function is used by the 100GBASE-CR4 PMD to indicate the successful completion of the startup protocol by the PMD control function (see 92.7.12). PMD_signal_detect_*i* (where *i* represents the lane number in the range 0 to 3) is set to zero when the value of the variable signal_detect is set to false by the Training state diagram for lane *i* (see Figure 72–5). PMD_signal_detect_*i* is set to one when the value of signal_detect for lane *i* is set to true.

If training is disabled by the management variable mr_training_enable (see 92.6), PMD_signal_detect_*i* shall be set to one for *i*=0 to 3.

If the optional EEE deep sleep capability is supported, the following requirements apply. The value of PMD_signal_detect_*i* (for *i*=0 to 3) is set to zero when rx_mode is first set to QUIET. While rx_mode is set to QUIET, PMD_signal_detect_*i* shall be set to one within 500 ns of the application of the ALERT pattern defined in 92.7.2, with peak-to-peak differential voltage of 720 mV measured at TP2, to the differential pair at the input of the cable assembly that connects the transmitter to the receiver of lane *i*. While rx_mode is set to QUIET, PMD_signal_detect_*i* shall not be set to one when the voltage input to the differential pair of the cable assembly that connects the transmitter to the receiver of lane *i* is less than or equal to 70 mV peak-to-peak differential.

When the MDIO is implemented, this function maps the variables to registers and bits as defined in 92.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

92.7.6 Global PMD transmit disable function

The Global PMD transmit disable function is mandatory if EEE deep sleep capability is supported and is otherwise optional. When implemented, it allows all of the transmitters to be disabled with a single variable.

a) When Global_PMD_transmit_disable variable is set to one, this function shall turn off all of the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage in Table 92–6.
b) If a PMD fault (92.7.9) is detected, then the PMD may set Global_PMD_transmit_disable to one.
c) Loopback, as defined in 92.7.8, shall not be affected by Global_PMD_transmit_disable.
d) The following additional requirements apply when the optional EEE deep sleep capability is supported. The Global PMD transmit disable function shall turn off all of the transmitters as specified in 92.8.3.1 when tx_mode transitions to QUIET from any other value. The Global PMD transmit disable function shall turn on all of the transmitters as specified in 92.8.3.1 when tx_mode transitions from QUIET to any other value.

92.7.7 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function is optional and allows the electrical transmitter in each lane to be selectively disabled. When this function is supported, it shall meet the following requirements:

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0 to 3) is set to one, this function shall turn off the transmitter associated with that variable such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 92–6.
b) If a PMD fault (92.7.9) is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the electrical transmitter in each lane.
c) Loopback, as defined in 92.7.8, shall not be affected by PMD_transmit_disable_*i*.

92.7.8 Loopback mode

Local loopback mode is provided by the adjacent PMA (see 83.5.8) as a test function. When loopback mode is enabled, transmission requests passed to each transmitter are sent directly to the corresponding receiver, overriding any signal detected by each receiver on its attached link. Note that loopback mode does not affect the state of the transmitter, which continues to send data (unless disabled).

Control of the loopback function is specified in 83.5.8.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

92.7.9 PMD fault function

If the MDIO is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3. PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault.

92.7.10 PMD transmit fault function

The PMD transmit fault function is optional. The faults detected by this function are implementation specific, but the assertion of Global_PMD_transmit_disable is not considered a transmit fault.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If PMD_transmit_fault is set to one, then Global_PMD_transmit_disable should also be set to one.

If the MDIO interface is implemented, then this function shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

92.7.11 PMD receive fault function

The PMD receive fault function is optional. The faults detected by this function are implementation specific. A fault is indicated by setting the variable PMD_receive_fault to one.

If the MDIO interface is implemented, then PMD_receive_fault shall be mapped to the Receive fault bit as specified in 45.2.1.7.5.

92.7.12 PMD control function

Each lane of the 100GBASE-CR4 PMD shall use the same control function as 10GBASE-KR, as defined in 72.6.10, with the following differences:

a) The training frame structure used by the 100GBASE-CR4 PMD control function shall be as defined in 72.6.10 with the exception that 25.78125 GBd symbols replace 10.3125 GBd symbols and 100GBASE-CR4 UI replace 10GBASE-KR UI.
b) In addition to the coefficient update process specified in 72.6.10.2.5, the period from receiving a new request to responding to that request shall be less than 2 ms, except during the first 50 ms following the beginning of the startup protocol. The beginning of the startup protocol is defined to be entry into the AN_GOOD_CHECK state in Figure 73–10. The start of the period is the frame marker of the training frame with the new request and the end of the period is the frame marker of the training frame with the corresponding response. A new request occurs when the coefficient update field is different from the coefficient field in the preceding frame. The response occurs when the coefficient status report field is updated to indicate that the corresponding action is complete.
c) In addition, the training pattern defined in 72.6.10.2.6 is replaced with a set of training patterns designed to minimize the correlation between physical lanes. The training pattern for each lane shall consist of 4094 bits from the output of a pseudo-random bit sequence (PRBS) generator followed by two zeros. The PRBS generator for each lane shall implement each of the four generator polynomials (polynomial_*n* where *n* goes from 0 to 3) given in Table 92–5, selectable by identifier_*i* (where *i* is the lane number). By default identifier_*i* is set to lane number *i* (i.e., identifier_0 = 0; identifier_1 = 1, etc.). At the start of the training pattern, the state of the generator shall be set to the value in seed_*i* (where *i* is the lane number), with the default values given in Table 92–5. Note that a seed value of 0x000 is invalid. An example implementation of the PRBS generator for *n* = 0 with default settings is given in Figure 92–3. The first 32 bits of the training pattern for each polynomial is also provided in Table 92–5.

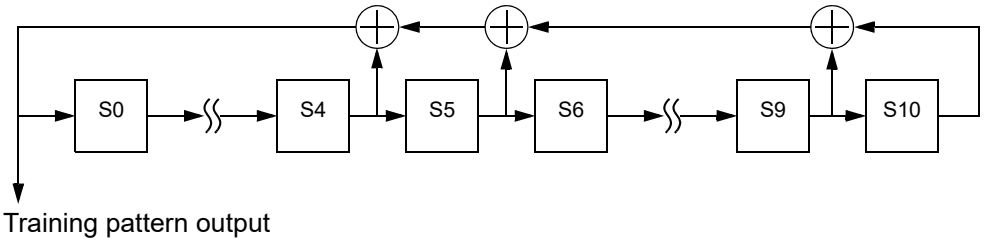

Figure 92–3—PRBS generator for polynomial_0

Table 92–5—PRBS parameters for each physical lane

n	Polynomial_*n*, *G*(*x*)	Default seed bits, S0 is the left most bit	Initial output[a]
0	$1 + x^5 + x^6 + x^{10} + x^{11}$	10101111110	FBF1CB3E
1	$1 + x^5 + x^6 + x^9 + x^{11}$	11001000101	FBB1E665
2	$1 + x^4 + x^6 + x^8 + x^{11}$	11100101101	F3FDAE46
3	$1 + x^4 + x^6 + x^7 + x^{11}$	11110110110	F2FFA46B

[a]The first 32 bits of the training pattern are presented in a hexadecimal representation where the hex symbols are transmitted from left to right and the most significant bit of each hex symbol is transmitted first

The variables rx_trained_*i*, frame_lock_*i*, training_*i,* and training_failure_*i* (where *i* goes from 0 to 3) report status for each lane and are equivalent to rx_trained, frame_lock, training, and training_failure as defined in 72.6.10.3.1.

If the MDIO interface is implemented, then this function shall map the variables polynomial_*i*, seed_*i*, rx_trained_*i*, frame_lock_*i*, training_*i,* and training_failure_*i* to the registers and bits defined in 92.6.

92.8 100GBASE-CR4 electrical characteristics

92.8.1 Signal levels

The 100GBASE-CR4 MDI is a low-swing AC-coupled differential interface. AC-coupling within the plug connectors, as defined in 92.12.1, allows for interoperability between components operating from different supply voltages.

92.8.2 Signal paths

The 100GBASE-CR4 MDI signal paths are point-to-point connections. Each path corresponds to a 100GBASE-CR4 MDI lane and comprises two complementary signals, which form a balanced differential pair. For 100GBASE-CR4, there are four differential paths in each direction for a total of eight pairs, or sixteen connections. The signal paths are intended to operate on twinaxial cable assemblies ranging from 0.5 m to 5 m in length, as described in 92.10.

92.8.3 Transmitter characteristics

Transmitter characteristics are summarized in Table 92–6. Unless specified otherwise, all transmitter measurements defined in Table 92–6 are made at TP2 utilizing the test fixtures specified in 92.11.1. A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all transmitter signal measurements, unless otherwise specified. The transmitter specifications at TP0 are provided informatively in Annex 92A.

92.8.3.1 Signal levels

The differential output voltage v_{di} is defined to be SL*i*<p> minus SL*i*<n>. The common-mode output voltage v_{cmi} is defined to be one half of the sum of SL*i*<p> and SL*i*<n>. These definitions are illustrated by Figure 92–4.

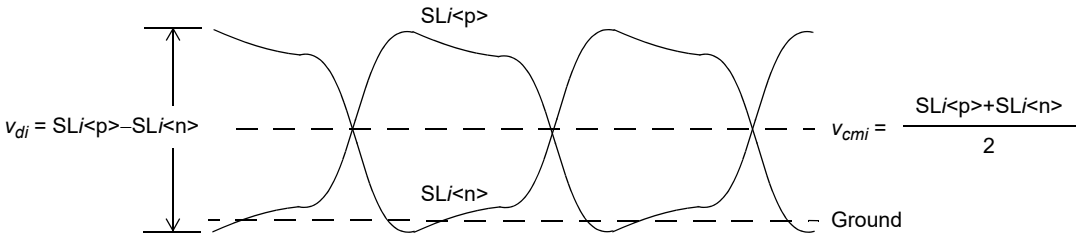

Figure 92–4—Transmitter output voltage definitions

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The peak-to-peak differential output voltage shall be less than or equal to 1200 mV regardless of the transmit equalizer setting. The peak-to-peak differential output voltage shall be less than or equal to 35 mV while the transmitter is disabled (refer to 92.7.6 and 92.7.7).

The 100GBASE-CR4 Style-1 connector may support 100GBASE-CR4 or XLPPI interfaces. For implementations that support both interfaces, the transmitter should not exceed the XLPPI voltage maximum until a 100GBASE-CR4 cable assembly has been identified.

The DC common-mode output voltage shall be between 0 V and 1.9 V with respect to signal ground. The AC common-mode output voltage shall be less than or equal to 30 mV RMS with respect to signal ground. Common-mode output voltage requirements shall be met regardless of the transmit equalizer setting.

If the optional EEE deep sleep capability is supported the following requirements also apply. The peak-to-peak differential output voltage shall be less than 35 mV within 500 ns of the transmitter being disabled. The peak-to-peak differential output voltage shall be greater than 720 mV within 500 ns of the transmitter being enabled. The transmitter is enabled by the assertion of tx_mode=ALERT, and the preceding requirement applies when the transmitted symbols are the periodic pattern defined in 92.8.1 and the transmitter equalizer coefficients are assigned their preset values. The transmitter shall meet the requirements of 92.8.3 within 1 μs of the transmitter being enabled. While the transmitter is disabled, the DC common-mode output voltage shall be maintained to within ±150 mV of the value for the enabled transmitter.

Differential and common-mode signal levels are measured with a PRBS9 test pattern.

92.8.3.2 Transmitter differential output return loss

The differential output return loss, in dB, of the transmitter shall meet Equation (92–1). This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$Return_loss(f) \geq \begin{cases} 9.5 - 0.37f & 0.01 \leq f < 8 \\ 4.75 - 7.4\log_{10}(f/14) & 8 \leq f \leq 19 \end{cases} \quad \text{(dB)} \tag{92–1}$$

where

f is the frequency in GHz

$Return_loss(f)$ is the differential output return loss at frequency f

The transmitter differential output return loss is illustrated in Figure 92–5.

92.8.3.3 Common-mode to differential mode output return loss

The common-mode to differential mode output return loss, in dB, of the transmitter shall meet Equation (92–2).

$$Return_loss(f) \geq \begin{cases} 22 - (20/25.78)f & 0.01 \leq f < 12.89 \\ 15 - (6/25.78)f & 12.89 \leq f \leq 19 \end{cases} \quad \text{(dB)} \tag{92–2}$$

where

f is the frequency in GHz

$Return_loss(f)$ is the common-mode to differential mode output return loss at frequency f

The common-mode to differential mode output return loss is illustrated in Figure 92–6.

$$Return_loss(f) \geq 2 \quad \text{(dB)} \tag{92–3}$$

for $0.2 \leq f \leq 19$ GHz

where

f is the frequency in GHz

$Return_loss(f)$ is the common-mode to common-mode return loss at frequency f

92.8.3.5 Transmitter output waveform

The 100GBASE-CR4 transmit function includes programmable equalization to compensate for the frequency-dependent loss of the channel and facilitate data recovery at the receiver. The functional model for the transmit equalizer is the three tap transversal filter shown in Figure 92–7.

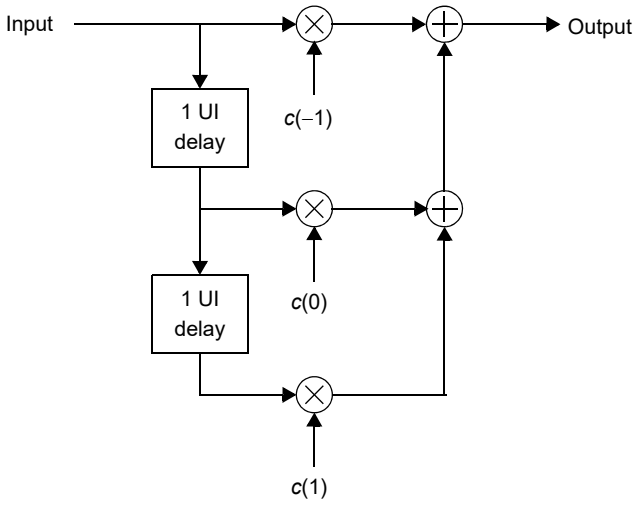

Figure 92–7—Transmit equalizer functional model

The state of the transmit equalizer and hence the transmitted output waveform may be manipulated via the PMD control function defined in 92.7.12 or via the management interface. The transmit function responds to a set of commands issued by the link partner's receive function and conveyed by a back-channel communications path.

This command set includes instructions to

a) Increment coefficient $c(i)$.
b) Decrement coefficient $c(i)$.
c) Hold coefficient $c(i)$ at its current value.
d) Set the coefficients to a predefined value (preset or initialize).

In response, the transmit function relays status information to the link partner's receive function. The status messages indicate that

a1) The requested update to coefficient $c(i)$ has completed (updated).
b1) Coefficient $c(i)$ is at its minimum value.
c1) Coefficient $c(i)$ is at its maximum value.
d1) Coefficient $c(i)$ is ready for the next update request (not_updated).

92.8.3.5.1 Linear fit to the measured waveform

For each configuration of the transmit equalizer, capture at least one complete cycle of the test pattern PRBS9 as specified in 83.5.10 at TP2 per 85.8.3.3.4. In the following calculation, M should be an integer not less than 32. Interpolation of the captured waveform may be used to achieve this. Compute the linear fit pulse response $p(k)$ from the captured waveform per 85.8.3.3.5 using $N_p = 14$ and $D_p = 2$. Define $r(k)$ to be the linear fit pulse response when transmit equalizer coefficients have been set to the "preset" values. The coefficients for any configuration of the transmit equalizer are computed using the following method.

Define an MN_p-by-3 matrix R_m. The elements of R_m are assigned values per Equation (92–4) where $i = -1$ to 1, $j = 1$ to MN_p, and $m = -M/2$ to $M/2-1$ when M is even and $-(M-1)/2$ to $(M-1)/2$ when M is odd.

$$R_m(j, i+2) = \left\{ \begin{array}{cc} r(m+j-iM) & 1 \le m+j-iM \le MN_p \\ 0 & otherwise \end{array} \right\} \tag{92–4}$$

The coefficients of the transmit equalizer are computed using Equation (92–5).

$$\begin{bmatrix} c_m(-1) \\ c_m(0) \\ c_m(1) \end{bmatrix} = (R_m^T R_m)^{-1} R_m^T \begin{bmatrix} p(1) \\ \dots \\ p(MN_p) \end{bmatrix} \tag{92–5}$$

The linear fit pulse response is reconstructed from the matrix R_m and the coefficients using Equation (92–6).

$$\begin{bmatrix} p_m(1) \\ \dots \\ p_m(MN_p) \end{bmatrix} = R_m \begin{bmatrix} c_m(-1) \\ c_m(0) \\ c_m(1) \end{bmatrix} \tag{92–6}$$

The sum of the squared error between $p(k)$ and $p_m(k)$ is computed using Equation (92–7). The transmit equalizer coefficients $c(i)$ for a given linear fit pulse $p(k)$ are the values $c_m(i)$ for the value of m that minimizes $\varepsilon^2(m)$.

$$\varepsilon^2(m) = \sum_{k=1}^{MN_p} (p(k) - p_m(k))^2 \tag{92–7}$$

92.8.3.5.2 Steady-state voltage and linear fit pulse peak

The steady-state voltage v_f is defined to be the sum of the linear fit pulse $p(k)$ divided by M (refer to 85.8.3.3 step 3). The steady-state voltage shall be greater than or equal to 0.34 V and less than or equal to 0.6 V after the transmit equalizer coefficients have been set to the "preset" values.

The peak value of $p(k)$ shall be greater than $0.45 \times v_f$ after the transmit equalizer coefficients have been set to the "preset" values.

92.8.3.5.3 Coefficient initialization

When the PMD enters the INITIALIZE state of the Training state diagram (Figure 72–5) or receives a valid request to "initialize" from the link partner, the coefficients of the transmit equalizer shall be configured such that the ratio $(c(0)+c(1)-c(-1))/(c(0)+c(1)+c(-1))$ is $1.29 \pm 10\%$ and the ratio

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$(c(0)–c(1)+c(–1))/(c(0)+c(1)+c(–1))$ is $2.57 \pm 10\%$. These requirements apply upon the assertion of a coefficient status report of "updated" for all coefficients.

92.8.3.5.4 Coefficient step size

The change in $c(i)$ corresponding to a request to "increment" that coefficient shall be between 0.0083 and 0.05. The change in $c(i)$ corresponding to a request to "decrement" that coefficient shall be between –0.0083 and –0.05.

The change in the coefficient is defined to be the difference in the value measured prior to the assertion of the "increment" or "decrement" request (e.g., the coefficient update request for all coefficients is "hold") and the value upon the assertion of a coefficient status report of "updated" for that coefficient.

92.8.3.5.5 Coefficient range

When sufficient "increment" or "decrement" requests have been received for a given coefficient, the coefficient will reach a lower or upper bound based on the range of that coefficient or the combination of coefficients.

With $c(–1)$ set to zero and both $c(0)$ and $c(1)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0) – c(1))/(c(0) + c(1))$ shall be greater than or equal to 4.

With $c(1)$ set to zero and both $c(–1)$ and $c(0)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0) – c(–1))/(c(0) + c(–1))$ shall be greater than or equal to 1.54.

Note that a coefficient may be set to zero by first asserting a coefficient preset request and then manipulating the other coefficients as required by the test.

92.8.3.6 Insertion loss TP0 to TP2 or TP3 to TP5

The recommended maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is given by Equation (92–8). Note that the recommended maximum insertion loss from TP0 to TP2 or from TP3 to TP5 is 9.85 dB at 12.8906 GHz.

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.08 + 0.57\sqrt{f} + 0.599f & 0.01 \le f < 14 \\ -19.067 + 2.119f & 14 \le f \le 19 \end{array} \right\} \text{ (dB)} \qquad (92–8)$$

where

f is the frequency in GHz

$Insertion_loss(f)$ is the insertion loss at frequency f

The maximum insertion loss of TP0 to TP2 or TP3 to TP5 is illustrated in Figure 92–8.

92.8.3.7 Transmitter signal-to-noise-and-distortion ratio (SNDR)

Signal-to-noise-and-distortion ratio (SNDR) is measured at the transmitter output using the following method, with transmitters on all PMD lanes enabled and transmitting the same pattern with identical transmit equalizer settings.

Given a configuration of the transmit equalizer, capture at least one complete cycle of the test pattern PRBS9 as specified in 83.5.10 at TP0a per 85.8.3.3.4. Compute the linear fit pulse response $p(k)$ and the linear fit

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

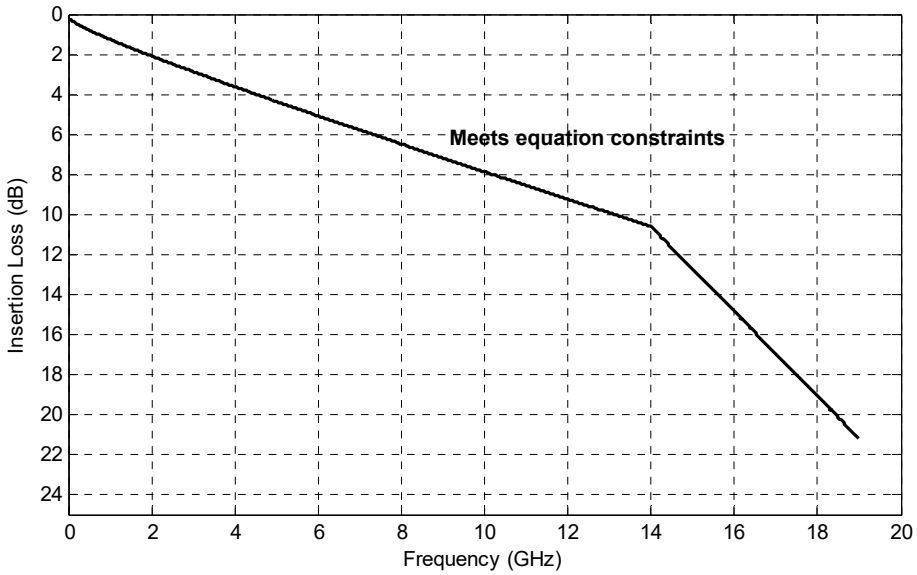

Figure 92–8—Maximum insertion loss TP0 to TP2 or TP3 to TP5

error waveform $e(k)$ from the captured waveform per 85.8.3.3.5 using $N_p = 14$ and $D_p = 2$. Denote the standard deviation of $e(k)$ as σ_e.

Given the same configuration of the transmit equalizer, measure the RMS deviation from the mean voltage at a fixed point in a run of at least 8 consecutive identical bits in a suitable pattern. PRBS9 is an example of a pattern that includes runs suitable to perform the measurement. It is recommended that the deviation is measured within the flattest portion of the waveform at a point where the slope is closest to zero. The RMS deviation is measured for a run of zeros and also a run of ones. The average of the two measurements is denoted as σ_n.

SNDR is defined by Equation (92–9) where $p_{\max}$ is the maximum value of $p(k)$.

$$SNDR = 10\log_{10}\left(\frac{p_{\max}^2}{\sigma_e^2 + \sigma_n^2}\right) \text{ dB} \tag{92–9}$$

SNDR shall be greater than 26 dB regardless of the transmit equalizer setting.

92.8.3.8 Transmitter output jitter

Three components of the transmitter output jitter are specified in this subclause: even-odd jitter, effective bounded uncorrelated jitter, and effective total uncorrelated jitter.

The effect of a single-pole high-pass filter with a 3 dB frequency of 10 MHz is applied to the jitter. The voltage threshold for the measurement of BER or crossing times is the mid-point (0 V) of the AC-coupled differential signal.

Jitter measurements are performed with transmitters on all PMD lanes enabled and transmitting the same pattern with identical transmit equalizer settings.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

92.8.3.8.1 Even-odd jitter

Even-odd jitter is measured using two repetitions of a PRBS9 pattern. The deviation of the time of each transition from an ideal clock at the signaling rate is measured. Even-odd jitter is defined as the magnitude of the difference between the average deviation of all even-numbered transitions and the average deviation of all odd-numbered transitions, where determining if a transition is even or odd is based on possible transitions but only actual transitions are measured and averaged.

Even-odd jitter shall be less than or equal to 0.035 UI regardless of the transmit equalization setting.

NOTE—Even-odd jitter has been referred to as *duty cycle distortion* by other Physical Layer specifications for operation over electrical backplane or twinaxial copper cable assemblies (see 72.7.1.9). The term *even-odd jitter* is used here to distinguish it from the duty cycle distortion referred to by Physical Layer specifications for operation over fiber optic cabling.

92.8.3.8.2 Effective bounded uncorrelated jitter and effective random jitter

Effective bounded uncorrelated jitter and effective random jitter are measured on each of two specific transitions in a PRBS9 pattern (see 83.5.10). The two transitions occur in the sequence of five zeros and four ones and nine ones and five zeros, respectively. The sequences are located at bits 10 to 18 and 1 to 14, respectively, where bits 1 to 9 are the run of nine ones.

a) The jitter components are determined according to the following method. Acquire a horizontal histogram of a transition around the zero-crossing point. The number of acquired samples should be sufficiently large to yield consistent measurement results. Designate the total number of samples as *NS*, the number of bins as *NB*, the number of samples in each bin as N_i where i is the bin number from 1 to *NB*, and the sample time corresponding with the center of each bin as t_i.
b) Create two cumulative distribution curves $CDFL_i$ and $CDFR_i$ according to Equation (92–10) and Equation (92–11) and two corresponding curves QR_i and QL_i according to Equation (92–12) and Equation (92–13), where $\text{erfc}^{-1}(x)$ is the inverse of the complementary error function $\text{erfc}(x)$ defined by Equation (92–14).
c) Determine the parameters m_{left} and b_{left} of Equation (92–15) that best fit QL_i as a function of t_i for bins with $CDFL_i$ in the range of 10^{-3} to 2.5×10^{-2}. Similarly determine the parameters of m_{right} and b_{right} that best fit QR_i as a function of t_i for bins with $CDFR_i$ in the range of 10^{-3} to 2.5×10^{-2}.
d) Calculate the values of effective bounded uncorrelated jitter and effective total uncorrelated jitter according to Equation (92–17) and Equation (92–19), respectively. The peak-to-peak contribution of the effective random jitter in the effective total uncorrelated jitter is related to a bit error ratio of 10^{-5}.

$$CDFL_i = \sum_{k=1}^{i} \frac{N_k}{NS} \tag{92–10}$$

$$CDFR_i = \sum_{k=i}^{NB} \frac{N_k}{NS} \tag{92–11}$$

$$QL_i = \sqrt{2} \times \text{erfc}^{-1}(2 \times CDFL_i) \tag{92–12}$$

$$QR_i = \sqrt{2} \times \text{erfc}^{-1}(2 \times CDFR_i) \tag{92–13}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{erfc}(x) = \frac{2}{\sqrt{\pi}} \times \int_{x}^{\infty} e^{-t^2} dt \quad (92\text{–}14)$$

$$Q_{left} = m_{\text{left}} \times t + b_{\text{left}} \quad (92\text{–}15)$$

$$Q_{right} = m_{\text{right}} \times t + b_{\text{right}} \quad (92\text{–}16)$$

$$\text{effective bounded uncorrelated jitter} = EBUJ = b_{\text{left}} / m_{\text{left}} - b_{\text{right}} / m_{\text{right}} \quad (92\text{–}17)$$

$$\text{effective random jitter} = ERJ = \frac{m_{\text{left}} - m_{\text{right}}}{2 \times m_{\text{right}} \times m_{\text{left}}} \quad (92\text{–}18)$$

$$\text{effective total uncorrelated jitter} = 7.9 \times ERJ + EBUJ \quad (92\text{–}19)$$

Effective bounded uncorrelated jitter shall be less than or equal to 0.1 UI peak-to-peak regardless of the transmit equalization setting.

The effective total uncorrelated jitter shall be less than or equal to 0.18 UI peak-to-peak regardless of the transmit equalization setting.

92.8.3.9 Signaling rate range

The 100GBASE-CR4 MDI signaling rate shall be 25.78125 GBd ±100 ppm per lane. The corresponding unit interval is approximately 38.787879 ps.

92.8.4 Receiver characteristics

The receiver characteristics are summarized in Table 92–7. Unless specified otherwise, all receiver measurements defined in Table 92–7 are made at TP3 utilizing the test fixtures specified in 92.11.1. Unless otherwise specified, a test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all receiver input signal measurements. The receiver specifications at TP5 are provided informatively in Annex 92A.

Table 92–7—Receiver characteristics at TP3 summary

Parameter	Subclause reference	Value	Units
Receiver input amplitude tolerance	92.8.4.1	1200 mV as measured at TP2	mV
Differential input return loss (min)	92.8.4.2	Equation (92–20)	dB

92.8.4.1 Receiver input amplitude tolerance

100GBASE-CR4 receiver shall operate at a BER better than 10^{-5} when connected to a compliant transmitter whose peak-to-peak differential output voltage, as defined by 92.8.3.1 using preset equalizer coefficients, is 1200 mV using a compliant cable assembly with the minimum insertion loss defined in 92.10.2. The receiver is allowed to control the transmitter equalizer coefficients, using the protocol defined in 92.7.12 or an equivalent process, to meet this requirement.

92.8.4.2 Receiver differential input return loss

The differential input return loss, in dB, of the receiver shall meet Equation (92–20). The reference impedance for differential return loss measurements shall be 100 Ω.

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 9.5 - 0.37f & 0.01 \leq f < 8 \\ 4.75 - 7.4\log_{10}(f/14) & 8 \leq f \leq 19 \end{array} \right\} \quad \text{(dB)} \tag{92–20}$$

where

f is the frequency in GHz

$Return_loss(f)$ is the differential input return loss at frequency f

92.8.4.3 Differential to common-mode input return loss

The differential to common-mode input return loss, in dB, of the receiver shall meet Equation (92–21).

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 22 - (20/25.78)f & 0.01 \leq f < 12.89 \\ 15 - (6/25.78)f & 12.89 \leq f \leq 19 \end{array} \right\} \quad \text{(dB)} \tag{92–21}$$

where

f is the frequency in GHz

$Return_loss(f)$ is the differential to common-mode input return loss at frequency f

92.8.4.4 Receiver interference tolerance test

The receiver interference tolerance of each lane shall comply with both test 1 and test 2 using the parameters of Table 92–8 when measured according to the requirements of 92.8.4.4.1 to 92.8.4.4.5. The cable assembly used in the test channel specified in 92.8.4.4.2 shall meet the cable assembly Channel Operating Margin (COM) specified in 92.10.7.

Table 92–8—100GBASE-CR4 interference tolerance parameters

Parameter	Test 1 values	Test 2 values	Units
RS-FEC symbol error ratio[a] (max)	10^{-4}	10^{-4}	
Fitted insertion loss coefficients	$a_1 = 1.7$ $a_2 = 0.546$ $a_4 = 0.01$	$a_1 = 4.3$ $a_2 = 0.571$ $a_4 = 0.04$	dB/√GHz dB/GHz dB/GHz^2
Applied SJ[b] (peak-to-peak)	0.1	0.1	UI
Applied RJ (RMS)	0.01	0.01	UI
Even-odd jitter	0.035	0.035	UI
COM[c]	3	3	dB

[a]The FEC symbol error ratio is measured in step 10 of the receiver interference tolerance method defined in 93C.2.
[b]Applied SJ frequency >100 MHz, specified at TP0.
[c]The COM value is the target for the far-end aggressor amplitude calibration defined in 92.8.4.4.3 step d). The far-end aggressor amplitude should be as close as practical to the value needed to produce the target COM. If higher amplitude values are used, this would demonstrate margin to the specification but this is not required for compliance.

92.8.4.4.1 Test setup

The interference tolerance test is performed with the setup shown in Figure 92–9. The requirements of this subclause are verified at the pattern generator connection (PGC) or test references in Figure 92–9 and Figure 92–10. The lanes under test (LUT) are illustrated in Figure 92–9 and Figure 92–10. The cable assembly single-ended receive lanes are terminated in 50 Ω to provide 100 Ω differential termination.

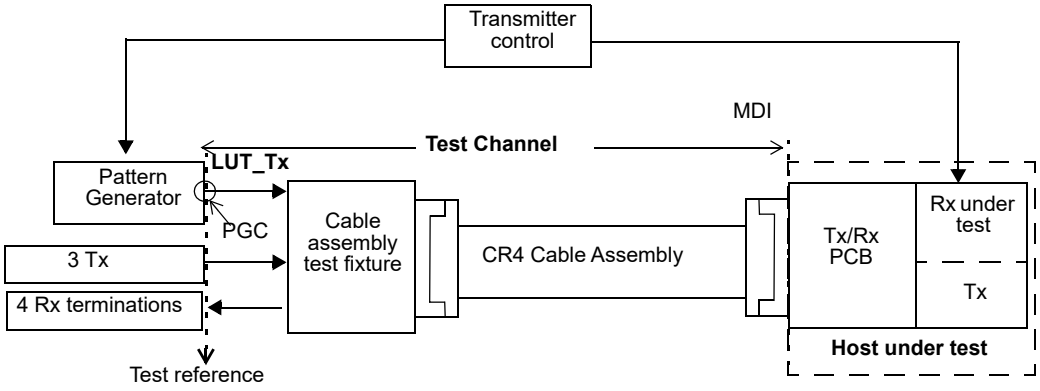

Figure 92–9—Interference tolerance test setup

92.8.4.4.2 Test channel

The test channel consists of the following:

a) A cable assembly that meets the cable assembly COM specified in 92.10.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) A cable assembly test fixture
c) A connecting path from the pattern generator to the cable assembly test fixture

92.8.4.4.3 Test channel calibration

The scattering parameters of the test channels are characterized at the test references as illustrated in Figure 92–10 using the cable assembly test fixtures specified in 92.11.2.

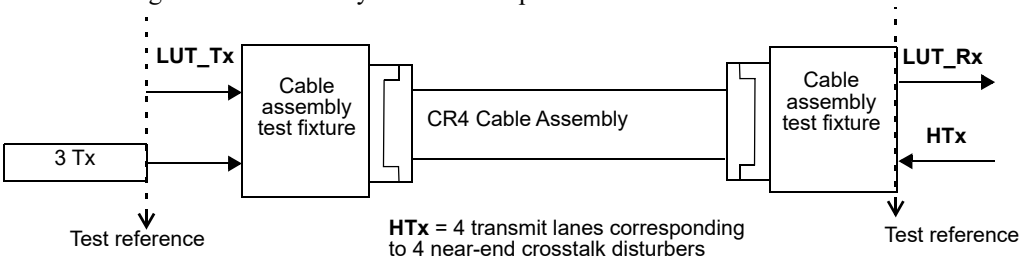

Figure 92–10—Test channel calibration

The fitted insertion loss coefficients of the lane under test (LUT), derived using the fitting procedure in 92.10.2, shall meet the test values in Table 92–8. It is recommended that the deviation between the insertion loss and the fitted insertion loss be as small as practical and that the fitting parameters be as close as practical to the values given in Table 92–8.

The far-end crosstalk disturbers consist of 100GBASE-CR4 transmitters. It is recommended that the transition time, equalization setting, and path from the far-end crosstalk disturbers to the cable assembly test fixture emulate the pattern generator as much as practical. For 100GBASE-CR4 test channels, the crosstalk that is coupled into a receive lane is from three transmitters. The disturber transmitters send scrambled idle encoded by RS-FEC. The amplitudes of each of the disturbers should be set to the value that results in the COM value given in Table 92–8 when calculated by the method given below.

The COM shall be calculated using the method and parameters of 92.10.7 with the following exceptions:

a) The channel signal path is $SCHS_p^{(k)} = \text{cascade}(\text{cascade}(S^{(CTSP)}, S^{(HOSP)}))$, where $S^{(CTSP)}$ is the measured channel between the test references for the LUT in Figure 92–10.
b) The channel far-end crosstalk path is $SCHNXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(CTFXTk)}, S^{(HOSP)}))$, where $S^{(CTFXTk)}$ is the measured FEXT channel between the test references [3 Tx] and LUT_Rx in Figure 92–10.
c) The value of the far-end aggressor amplitude A_{fe} is adjusted until the required COM is achieved. The far end aggressors ([3 Tx] in Figure 92–9) peak-to-peak amplitude is set to twice the resulting value for the test.
d) If the test transmitter presents a high-quality termination, e.g., it is a piece of test equipment, the transmitter device package model $S^{(tp)}$ is omitted from the calculation of $S_p^{(k)}$. Instead, the voltage transfer function is multiplied by the filter $H_t(f)$ defined by Equation (92–22) where T_r is the 20% to 80% transition time in ns (see 86A.5.3.3) of the signal as measured at TP0a and f is frequency in GHz.

$$H_t(f) = \exp(-2(\pi f T_r / 1.6832)^2) \quad (92–22)$$

92.8.4.4.4 Pattern generator

The pattern generator transmits data to the device under test. At the start of transmitter training, the pattern generator output amplitude shall be 800 mV peak-to-peak differential when measured on an alternating one-

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

zero pattern. The output amplitude, measured on an alternating one zero pattern, is not permitted to exceed 800 mV peak-to-peak differential during transmitter training. The pattern generator shall be set to match the jitter specification in Table 92–8. The output waveform of the pattern generator shall comply to 93.8.1.

92.8.4.4.5 Test procedure

For 100GBASE-CR4 testing, the pattern generator is first configured to transmit the training pattern defined in 92.7.12. During this initialization period, the device under test (DUT) configures the pattern generator equalizer, via transmitter control, to the coefficient settings it would select using the protocol described in 72.6.10 and the receiver is tuned using its optimization method.

After the pattern generator equalizer has been configured and the receiver tuned, the pattern generator is set to generate scrambled idle encoded by RS-FEC. The receiver under test shall meet the target RS-FEC symbol error ratio listed in Table 92–8. During the tests, the disturbers transmit at their calibrated level and all of the transmitters in the device under test transmit scrambled idle encoded by RS-FEC, with the maximum compliant amplitude and equalization turned off (preset condition).

92.8.4.5 Receiver jitter tolerance

Receiver jitter tolerance is defined by the procedure in this subclause. When measured using the test setup shown in Figure 92–9, or its equivalent, the RS-FEC symbol error ratio for each lane of the receiver shall be less than or equal to 10^{-4} for each case listed in Table 92–9. The pattern generator meets the requirements of 92.8.4.4.4. The test channel meets the requirements of the interference tolerance test channel using Test 2 values listed in Table 92–8.

The test procedure is as described in 92.8.4.4.5 except that during the test the disturber transmitters are off and the pattern generator jitter is set to the frequency and peak-to-peak amplitude specified in Table 92–9.

Table 92–9—Receiver jitter tolerance parameters

Parameter	Case A values	Case B values	Units
Jitter frequency	190	940	kHz
Peak-to-peak jitter amplitude	5	1	UI

92.8.4.6 Signaling rate range

A 100GBASE-CR4 receiver shall comply with the requirements of 92.8.4.4 for any signaling rate in the range 25.78125 GBd ± 100 ppm. The corresponding unit interval is approximately 38.787879 ps.

92.9 Channel characteristics

The 100GBASE-CR4 channel is defined between TP0 and TP5 to include the transmitter and receiver differential controlled impedance printed circuit board and the cable assembly as illustrated in Figure 92–2. The channel parameters insertion loss, return loss, COM and the transmitter and receiver differential controlled impedance printed circuit board parameters for each differential lane are provided informatively in 92A.4 through 92A.7.

92.10 Cable assembly characteristics

The 100GBASE-CR4 cable assembly contains insulated conductors terminated in a connector at each end for use as a link segment between MDIs. This cable assembly is primarily intended as a point-to-point interface of up to 5 m between network ports using controlled impedance cables. All cable assembly measurements are to be made between TP1 and TP4 with cable assembly test fixtures as specified in 92.11.2 and illustrated in Figure 92–17. These cable assembly specifications are based upon twinaxial cable characteristics, but other cable types are acceptable if the specifications of 92.10 are met.

The cable assembly COM is specified in 92.10.7.

Table 92–10 provides a summary of the cable assembly characteristics and references to the subclauses addressing each parameter; reported values are at 12.8906 GHz.

Table 92–10—Cable assembly differential characteristics summary

Description	Reference	Value	Unit
Maximum insertion loss at 12.8906 GHz	92.10.2	22.48	dB
Minimum insertion loss at 12.8906 GHz	92.10.2	8	dB
Minimum return loss at 12.8906 GHz	92.10.3	6	dB
Differential to common-mode return loss	92.10.4	Equation (92–28)	dB
Differential to common-mode conversion loss	92.10.5	Equation (92–29)	dB
Common-mode to common-mode return loss	92.10.6	Equation (92–30)	dB

92.10.1 Characteristic impedance and reference impedance

The nominal differential characteristic impedance of the cable assembly is 100 Ω. The differential reference impedance for cable assembly specifications shall be 100 Ω.

92.10.2 Cable assembly insertion loss

The fitted cable assembly insertion loss $IL_{fitted}(f)$ as a function of frequency f is defined in Equation (92–23).

$$IL_{\text{fitted}}(f) = a_1\sqrt{f} + a_2 f + a_4 f^2 \quad \text{(dB)} \tag{92–23}$$

where

f is the frequency in GHz

$IL_{\text{fitted}}(f)$ is the fitted cable assembly insertion loss at frequency f

Given the cable assembly insertion loss measured between TP1 and TP4 is at N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 19 000 MHz with a maximum frequency spacing of 10 MHz, the coefficients of the fitted insertion loss are determined using Equation (92–24) and Equation (92–25).

Define the frequency matrix F as shown in Equation (92–24).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$F = \begin{bmatrix} \sqrt{f_1} & f_1 & f_1^2 \\ \sqrt{f_2} & f_2 & f_2^2 \\ \cdots & \cdots & \cdots \\ \sqrt{f_N} & f_N & f_N^2 \end{bmatrix} \tag{92–24}$$

The polynomial coefficients a_1, a_2, and a_4 are determined using Equation (92–25). In Equation (92–25), T denotes the matrix transpose operator and IL is a column vector of the measured insertion loss values, IL_n at each frequency f_n.

$$\begin{bmatrix} a_1 \\ a_2 \\ a_4 \end{bmatrix} = (F^T F)^{-1} F^T IL \tag{92–25}$$

The fitted insertion loss corresponding to one example of the maximum insertion loss at 12.8906 GHz is illustrated in Figure 92–11.

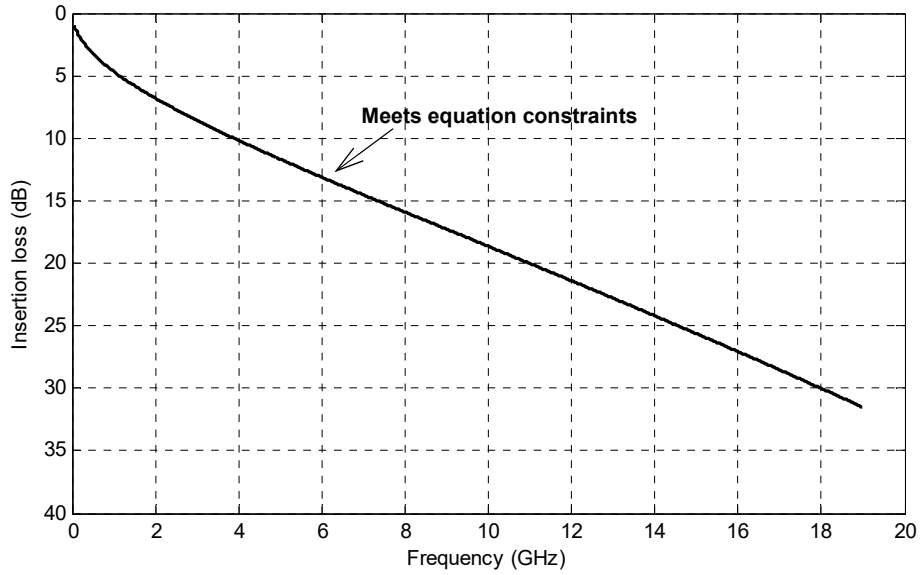

Figure 92–11—Example maximum cable assembly insertion loss

The measured insertion loss of the cable assembly shall be greater than or equal to the minimum cable assembly insertion loss given in Equation (92–26) and illustrated in Figure 92–12. The measured insertion loss of the cable assembly shall be less than or equal to the maximum cable insertion loss of 22.48 dB at 12.8906 GHz.

$$IL_{Cabmin}(f) = 0.7\sqrt{f} + 0.3f + 0.01f^2 \quad \text{(dB)} \tag{92–26}$$

where

f is the frequency in GHz

$IL_{\text{Cabmin}}(f)$ is the minimum cable assembly insertion loss at frequency f

Table 92–11—Maximum and minimum cable assembly insertion loss characteristics

Description	Value	Unit
Maximum insertion loss at 12.8906 GHz	22.48	dB
Minimum insertion loss at 12.8906 GHz	8	dB

92.10.3 Cable assembly differential return loss

The differential return loss of each pair of the 100GBASE-CR4 cable assembly shall meet the values determined using Equation (92–27).

$$Return_loss(f) \geq \begin{cases} 16.5 - 2\sqrt{f} & 0.05 \leq f < 4.1 \\ 10.66 - 14\log_{10}(f/5.5) & 4.1 \leq f \leq 19 \end{cases} \text{ (dB)} \qquad (92\text{–}27)$$

where

f is the frequency in GHz

$Return_loss(f)$ is the return loss at frequency f

The minimum cable assembly return loss is illustrated in Figure 92–13.

92.10.4 Differential to common-mode return loss

The differential to common-mode return loss, in dB, of the cable assembly shall meet Equation (92–28).

92.10.5 Differential to common-mode conversion loss

The difference between the cable assembly differential to common-mode conversion loss and the cable assembly insertion loss shall meet Equation (92–29).

$$Conversion_loss\ (f) - IL(f) \geq \left\{ \begin{array}{ll} 10 & 0.01 \leq f < 12.89 \\ 27 - (29/22)f & 12.89 \leq f < 15.7 \\ 6.3 & 15.7 \leq f \leq 19 \end{array} \right\} \quad (92–29)$$

where

f	is the frequency in GHz
$Conversion_loss(f)$	is the cable assembly differential to common-mode conversion loss
$IL(f)$	is the cable assembly insertion loss

92.10.6 Common-mode to common-mode return loss

The common-mode to common-mode return loss, in dB, of the cable assembly shall meet Equation (92–30).

$$Return_loss(f) \geq 2 \quad (\text{dB}) \quad (92–30)$$

for $0.2 \leq f \leq 19$ GHz

where

f	is the frequency in GHz
$Return_loss(f)$	is the common-mode to common-mode return loss at frequency f

92.10.7 Cable assembly Channel Operating Margin

The cable assembly Channel Operating Margin (COM) for each victim signal path (receive lane) is derived from measurements of the cable assembly victim signal path, the four individual near-end crosstalk paths, and the three far-end crosstalk paths that can couple into a victim signal path. COM is computed using the procedure in 93A.1 with the Test 1 and Test 2 values in Table 93–8 and the signal paths defined in 92.10.7.1 and 92.10.7.2. Test 1 and Test 2 differ in the value of the device package model transmission line length z_p.

NOTE—For cable lengths greater than 4 m a frequency step (Δf) no larger than 5 MHz is recommended.

The cable assembly COM shall be greater than or equal to 3 dB for each test. This minimum value allocates margin for practical limitations on the receiver implementation as well as the largest step size allowed for transmitter equalizer coefficients.

92.10.7.1 Channel signal path

The channel signal path between TP0 and TP5 for the cable assembly COM consists of the measured cable assembly signal path (TP1 and TP4), a representative transmitter PCB signal path (TP0 to TP1), and a representative receiver PCB signal path (TP4 to TP5). The signal path definitions include the function cascade() defined in 93A.1.2.1.

The channel signal path to be used in COM (93A.1.2) is the concatenation of the cable assembly signal path measurement, the transmitter PCB signal path, and the receiver PCB signal path using Equation (92–31) (see 93A.1.2.1). The transmitter and receiver PCB signal paths are calculated according to 92.10.7.1.1.

$$SCHS_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOSP)}, S^{(CASP)}), S^{(HOSP)}) \quad (92–31)$$

where

$SCHS_p^{(k)}$ is the channel signal path

$S^{(HOSP)}$ is the signal path calculated according to 92.10.7.1.1

$S^{(CASP)}$ is the cable assembly signal path

k is equal to zero

92.10.7.1.1 TP0 to TP1 and TP4 to TP5 signal paths

The additional transmitter and receiver PCB signal paths are calculated using the method defined in 93A.1.2.3. The scattering parameters for a PCB of length z_p are defined by Equation (93A–13), Equation (93A–14), and the parameter values given in Table 92–12.

For the channel signal path defined in 92.10.7.1 and calculated using Equation (92–31), the transmitter and receiver PCB model are each z_p = 151 mm in length representing an insertion loss of 6.26 dB at 12.89 GHz and are each denoted as $S^{(HOSP)}$.

For the channel crosstalk paths defined in 92.10.7.2 and calculated using Equation (92–32) and Equation (92–33), the receiver PCB model is $S^{(HOSP)}$. The transmitter PCB model is z_p = 72 mm in length representing an insertion loss of 3 dB at 12.89 GHz and is denoted as $S^{(HOTxSP)}$. The transmitter PCB insertion loss for the crosstalk channel is less than that for the signal channel to allow for a reasonable worst-case crosstalk in the COM calculation.

Table 92–12—Transmission line model parameters

Parameter	Value	Units
γ_0	0	1/mm
a_1	4.114×10^{-4}	$ns^{1/2}$/mm
a_2	2.547×10^{-4}	ns/mm
τ	6.191×10^{-3}	ns/mm
Z_c	109.8	Ω

92.10.7.2 Channel crosstalk paths

The channel structure includes three far-end and four near-end crosstalk paths. The MDI is the significant contributor to the channel crosstalk and is included in and characterized by the cable assembly crosstalk measurements. The cable assembly crosstalk signal paths to be used in COM are the four individual near-end crosstalk paths and the three far-end crosstalk paths that can couple into a victim signal path using the cascaded function defined in 93A.1.2.1 given in Equation (92–32) and Equation (92–33).

$$SCHNXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOTxSP)}, S^{(CANXTk)}), S^{(HOSP)}) \quad (92–32)$$

where

$SCHNXT_p^{(k)}$	is the channel near-end crosstalk path
$S^{(HOSP)}$	is the signal path calculated according to 92.10.7.1.1
$S^{(HOTxSP)}$	is the signal path calculated according to 92.10.7.1.1
$S^{(CANXTk)}$	is the cable assembly near-end crosstalk path k
k	is 1 to 4 near-end crosstalk paths

$$SCHFXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOTxSP)}, S^{(CASFXTk)}), S^{(HOSP)}) \quad (92–33)$$

where

$SCHFXT_p^{(k)}$	is the channel far-end crosstalk path
$S^{(HOSP)}$	is the signal path calculated according to 92.10.7.1.1
$S^{(HOTxSP)}$	is the signal path calculated according to 92.10.7.1.1
$S^{(CAFXTk)}$	is the cable assembly far-end crosstalk path k
k	is 1 to 3 far-end crosstalk paths

92.11 Test fixtures

Transmitter and receiver measurements are made at TP2 or TP3 utilizing the test fixture specified in 92.11.1. and illustrated in Figure 92–15. All cable assembly measurements are to be made between TP1 and TP4 with cable assembly test fixtures as specified in 92.11.2 and illustrated in Figure 92–17. The test fixtures of Figure 92–15 and Figure 92–17 are specified in a mated state, illustrated in Figure 92–18, to enable connections to measurement equipment. The requirements in this subclause are not MDI connector specifications for an implemented design.

92.11.1 TP2 or TP3 test fixture

The test fixture (also known as Host Compliance Board) of Figure 92–15, or its equivalent, is required for measuring the transmitter specifications in 92.8.3 at TP2 and the receiver return loss at TP3. The TP2 and TP3 test points are illustrated in Figure 92–2. Figure 92–15 illustrates the test fixture attached to TP2 or TP3.

92.11.1.1 Test fixture return loss

The differential return loss, in dB, of the test fixture is specified in a mated state and shall meet the requirements of 92.11.3.2.

92.11.1.2 Test fixture insertion loss

The test fixture printed circuit board insertion loss values determined using Equation (92–34) shall be used as the reference test fixture insertion loss. The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements.

92.11.2 Cable assembly test fixture

The test fixture of Figure 92–17 (also known as Module Compliance Board) or its equivalent, is required for measuring the cable assembly specifications in 92.10 at TP1 and TP4. The TP1 and TP4 test points are illustrated in Figure 92–2 and Figure 92–17. The test fixture return loss is equivalent to the test fixture return loss specified in 92.11.3.2. The test fixture printed circuit board insertion loss values determined using Equation (92–35) shall be used as the reference test fixture insertion loss. The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements.

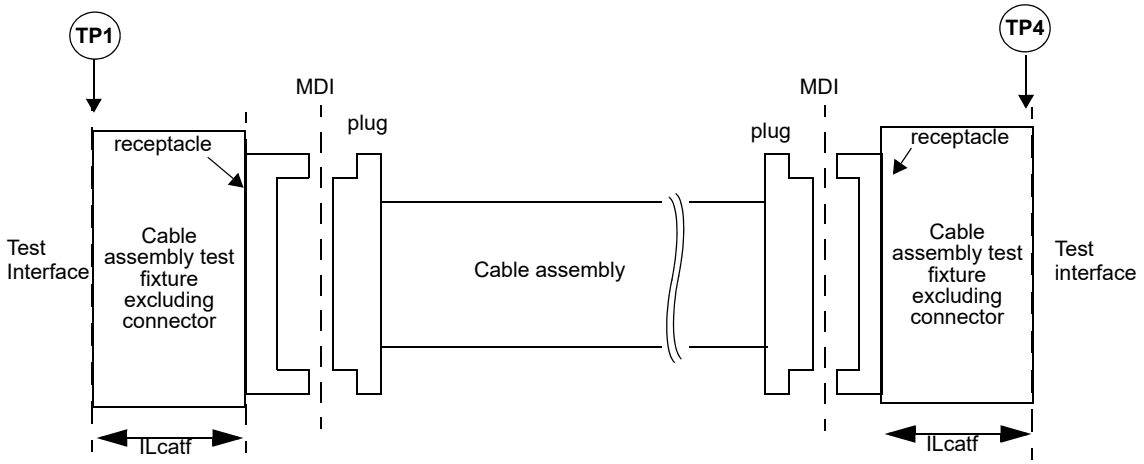

Figure 92–17—Cable assembly test fixtures

for $0.01\ \text{GHz} \le f \le 25\ \text{GHz}$

where

f is the frequency in GHz

$IL_{\mathrm{catf}}(f)$ is the reference test fixture printed circuit board insertion loss at frequency f

92.11.3 Mated test fixtures

The test fixtures of Figure 92–15 and Figure 92–17 are specified in a mated state illustrated in Figure 92–18. The mated test fixtures specifications shall be verified in both directions indicated by the arrows illustrated in Figure 92–18 except insertion loss, which shall be verified at either test interface illustrated in Figure 92–18.

92.11.3.1 Mated test fixtures insertion loss

The insertion loss of the mated test fixtures shall meet the values determined using Equation (92–36) and Equation (92–37).

$\mathrm{FOM_{ILD}}$ is calculated according to 93A.4 with f_b=25.78125 GHz, T_t=9.6 ps, and f_r=0.75 × f_b. The fitted insertion loss and insertion loss deviation are computed over the range $f_{\min}$=0.01 GHz to $f_{\max}$=25 GHz. $\mathrm{FOM_{ILD}}$ shall be less than 0.13 dB.

$$IL(f) \le IL_{\mathrm{MTFmax}}(f) = \left\{ \begin{array}{ll} 0.12 + 0.475\sqrt{f} + 0.221f & 0.01 \le f \le 14 \\ -4.25 + 0.66f & 14 < f \le 25 \end{array} \right\} \quad \text{(dB)} \tag{92–36}$$

92.11.3.5 Mated test fixtures common-mode to differential mode return loss

The common-mode to differential mode return loss of the mated test fixtures measured at each test fixture test interface shall meet the values determined using Equation (92–41).

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 30 - (30/25.78)f & 0.01 \leq f < 12.89 \\ 18 - (6/25.78)f & 12.89 \leq f \leq 25 \end{array} \right\} \text{ (dB)} \quad (92–41)$$

where

f is the frequency in GHz

$Return_loss(f)$ is the common-mode to differential mode return loss at frequency f

The mated test fixtures common-mode to differential mode return loss is illustrated in Figure 92–23.

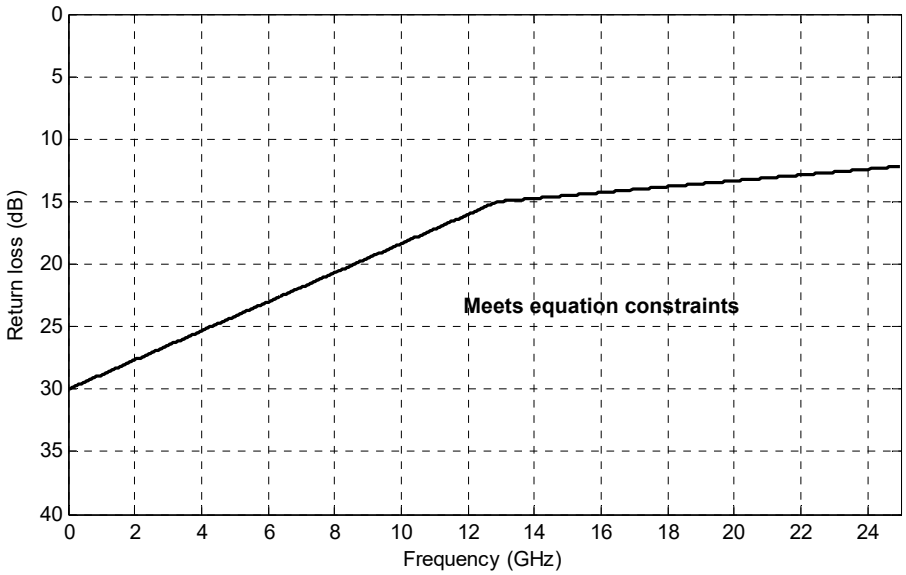

Figure 92–23—Common-mode to differential return loss

92.11.3.6 Mated test fixtures integrated crosstalk noise

The values of the mated test fixtures integrated crosstalk RMS noise voltages determined using Equation (92–44) through Equation (92–48) for the multiple disturber near-end crosstalk loss, and the multiple disturber far-end crosstalk loss shall meet the specifications in Table 92–13.

Table 92–13—Mated test fixtures integrated crosstalk noise

Parameter	100GBASE-CR4	Units
MDNEXT integrated crosstalk noise voltage	Less than 1.8	mV
MDFEXT integrated crosstalk noise voltage	Less than 4.8	mV

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

92.11.3.6.1 Mated test fixture multiple disturber near-end crosstalk (MDNEXT) loss

Since four lanes are used to transfer data between PMDs, the NEXT that is coupled into a receive lane is from the four transmit lanes. Multiple Disturber Near-End Crosstalk (MDNEXT) loss is determined using the individual NEXT losses.

MDNEXT loss is determined from the four individual pair-to-pair differential NEXT loss values using Equation (92–42).

$$MDNEXT_loss(f) = -10\log_{10}\left(\sum_{i=0}^{i=3} 10^{-NLi(f)/10}\right) \quad \text{(dB)} \tag{92–42}$$

for 0.05 GHz ≤ f ≤ 19 GHz

where

$MDNEXT_loss(f)$	is the MDNEXT loss at frequency f
$NL_i(f)$	is the NEXT loss at frequency f of pair combination i, in dB
f	is the frequency in GHz
i	is the 0 to 3 (pair-to-pair combination)

92.11.3.6.2 Mated test fixture multiple disturber far-end crosstalk (MDFEXT) loss

Since four lanes are used to transfer data between PMDs, the FEXT that is coupled into a data carrying lane is from the three other lanes in the same direction. MDFEXT loss is specified using the individual FEXT losses. MDFEXT loss is determined from the three individual pair-to-pair differential FEXT loss values using Equation (92–43).

$$MDFEXT_loss(f) = -10\log_{10}\left(\sum_{i=0}^{i=2} 10^{-NLi(f)/10}\right) \quad \text{(dB)} \tag{92–43}$$

for 0.05 GHz ≤ f ≤ 19 GHz

where

$MDFEXT_loss(f)$	is the MDFEXT loss at frequency f
$NL_i(f)$	is the FEXT loss at frequency f of pair combination i, in dB
f	is the frequency in GHz
i	is the 0 to 2 (pair-to-pair combination)

92.11.3.6.3 Mated test fixture integrated crosstalk noise (ICN)

ICN is calculated from the MDFEXT and MDNEXT. Given the multiple disturber near-end crosstalk loss $MDNEXT_loss(f)$ and multiple disturber far-end crosstalk loss $MDFEXT_loss(f)$ measured over N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 19 000 MHz with a maximum frequency spacing of 10 MHz, the RMS value of the integrated crosstalk noise is determined using Equation (92–44) through Equation (92–48). The RMS crosstalk noise is characterized at the output of a specified receive filter utilizing a specified transmitter waveform and the measured multiple disturber crosstalk transfer functions. The transmitter and receiver filters are defined in Equation (92–44) and Equation (92–45) as weighting functions to the multiple disturber crosstalk in Equation (92–46) and Equation (92–47). The sinc function is defined by $\text{sinc}(x) = \sin(\pi x)/(\pi x)$.

Define the weight at each frequency f_n using Equation (92–44) and Equation (92–45).

$$W_{nt}(f_n) = (A_{nt}^2/f_b)\mathrm{sinc}^2(f_n/f_b)\left[\frac{1}{1+(f_n/f_{nt})^4}\right]\left[\frac{1}{1+(f_n/f_r)^8}\right] \quad (92–44)$$

$$W_{ft}(f_n) = (A_{ft}^2/f_b)\mathrm{sinc}^2(f_n/f_b)\left[\frac{1}{1+(f_n/f_{ft})^4}\right]\left[\frac{1}{1+(f_n/f_r)^8}\right] \quad (92–45)$$

where the equation parameters are given in Table 92–14.

Note that the 3 dB transmit filter bandwidths f_{nt} and f_{ft} are inversely proportional to the 20% to 80% rise and fall times T_{nt} and T_{ft} respectively. The constant of proportionality is 0.2365 (e.g., $T_{nt}f_{nt} = 0.2365$; with f_{nt} in hertz and T_{nt} in seconds). In addition, f_r is the 3 dB reference receiver bandwidth, which is set to 18.75 GHz.

The near-end integrated crosstalk noise σ_{nx} is calculated using Equation (92–46).

$$\sigma_{nx} = \left[2\Delta f\sum_n W_{nt}(f_n)10^{-MDNEXT_{loss}(f_n)/10}\right]^{1/2} \quad (92–46)$$

The far-end integrated crosstalk noise σ_{fx} is calculated using Equation (92–47).

$$\sigma_{fx} = \left[2\Delta f\sum_n W_{ft}(f_n)10^{-MDFEXT_{loss}(f_n)/10}\right]^{1/2} \quad (92–47)$$

where Δf is the uniform frequency step of f_n.

The total integrated crosstalk noise σ_x is calculated using Equation (92–48).

$$\sigma_x = \sqrt{\sigma_{nx}^2 + \sigma_{fx}^2} \quad (92–48)$$

The total integrated crosstalk noise for the mated test fixture is computed using the parameters shown in Table 92–14.

Table 92–14—Mated test fixture integrated crosstalk noise parameters

Description	Symbol	Value	Units
Symbol rate	f_b	25.78125	GBd
Near-end disturber peak differential output amplitude	A_{nt}	600	mV
Far-end disturber peak differential output amplitude	A_{ft}	600	mV
Near-end disturber 20% to 80% rise and fall times	T_{nt}	9.6	ps
Far-end disturber 20% to 80% rise and fall times	T_{ft}	9.6	ps

92.12 MDI specification

This subclause defines the Media Dependent Interface (MDI). The 100GBASE-CR4 PMD, as per 92.7, is coupled to the cable assembly, as per 92.10, by the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

92.12.1 100GBASE-CR4 MDI connectors

Connectors meeting the requirements of 92.12.1.1 (Style-1) or 92.12.1.2 (Style-2) are used as the mechanical interface between the PMD of 92.7 and the cable assembly of 92.10. The plug connector is used on the cable assembly and the receptacle on the PHY. Style-1 or Style-2 connectors may be used as the MDI.

For Style-1 and Style-2 100GBASE-CR4 plug connectors, the receive lanes are AC-coupled; the AC-coupling shall be within the plug connectors. It should be noted that there may be various methods for AC-coupling in actual implementations. The low-frequency 3 dB cutoff of the AC-coupling shall be less than 50 kHz. It is recommended that the value of the coupling capacitors be 100 nF. The capacitor limits the inrush charge and baseline wander.

92.12.1.1 Style-1 100GBASE-CR4 MDI connectors

The plug connector for each end of the cable assembly shall be the QSFP+ 28 Gb/s 4X Pluggable (QSFP28) plugs defined in SFF-8665 and illustrated in Figure 92–24. The MDI connector shall be the QSFP+ 28 Gb/s 4X Pluggable (QSFP28) receptacle with the mechanical mating interface defined in SFF-8665 and illustrated in Figure 92–25. These connectors have contact assignments that are listed in Table 92–15 and electrical performance consistent with the signal quality and electrical requirements of 92.8 and 92.9.

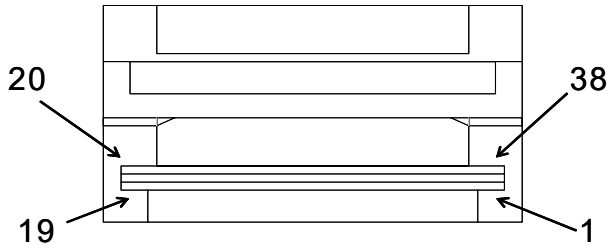

Figure 92–24—Style-1 example cable assembly

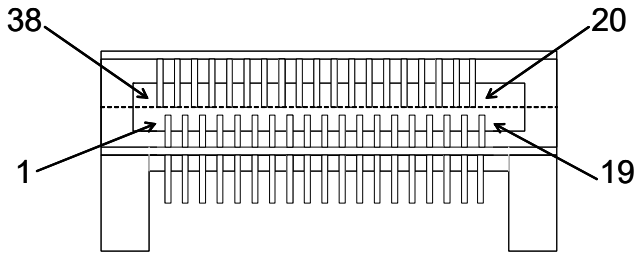

Figure 92–25—Style-1 example MDI board receptacle

The Style-1 MDI connector of the 100GBASE-CR4 PMD comprises 38 signal connections. The Style-1 100GBASE-CR4 MDI connector contact assignments shall be as defined in Table 92–15.

92.12.1.2 Style-2 100GBASE-CR4 MDI connectors

The connector for each end of the cable assembly shall be the 100G Form Factor Pluggable 4 (CFP4) with the mechanical mating interface defined in CFP4 MSA HW Specification and illustrated in Figure 92–26. The MDI connector shall be the 100G Form Factor Pluggable (CFP4) receptacle with the mechanical mating interface defined by CFP4 MSA HW Specification and illustrated in Figure 92–27. These connectors have contact assignments that are listed in Table 92–16, and electrical performance consistent with the signal quality and electrical requirements of 92.8 and 92.9.

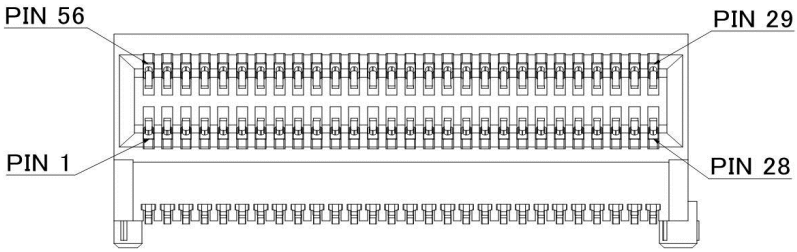

Figure 92–27—Style-2 example MDI board receptacle

The Style-2 MDI connector of the 100GBASE-CR4 PMD comprises 56 signal connections. The Style-2 100GBASE-CR4 MDI connector contact assignments shall be as defined in Table 92–16. Note that the source lanes (SL), signals SLi<p>, and SLi<n> are the positive and negative sides of the transmitters differential signal pairs and the destination lanes (DL) signals, DLi<p>, and DLi<n> are the positive and negative sides of the receivers differential signal pairs for lane i (i = 0, 1, 2, 3).

92.14 Protocol implementation conformance statement (PICS) proforma for Clause 92, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-CR4[161]

92.14.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 92, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-CR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

92.14.2 Identification

92.14.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

92.14.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 92, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-CR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[161] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

93. Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-KR4

93.1 Overview

This clause specifies the 100GBASE-KR4 PMD and baseband medium. There are three associated annexes. Annex 93A defines characteristics of electrical backplanes, Annex 93B extends the electrical backplane reference model with additional informative test points, and Annex 93C defines the test method for receiver interference tolerance.

When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 93–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 93–1—Physical Layer clauses associated with the 100GBASE-KR4 PMD

Associated clause	100GBASE-KR4
81—RS	Required
81—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
91—RS-FEC	Required
83—PMA for 100GBASE-R[b]	Required
83A—CAUI-10	Optional
83D—CAUI-4	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]There are limitations on the number of PMA lanes that may be used between sublayers, see 83.3.

A 100GBASE-KR4 PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

Figure 93–1 shows the relationship of the 100GBASE-KR4 PMD sublayer and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

The receive path of the RS-FEC sublayer may have the option to perform error detection without correction to reduce the data delay (see 91.5.3.3). When the receive path of the RS-FEC sublayer performs error correction, the link is required to operate with a BER of 10^{-5} or better. When the RS-FEC sublayer is configured to bypass error correction, the link is required to operate with a BER of 10^{-12} or better. In this context, a link consists of a compliant PMD transmitter, a compliant PMD receiver, and a channel meeting the requirements of 93.9.1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

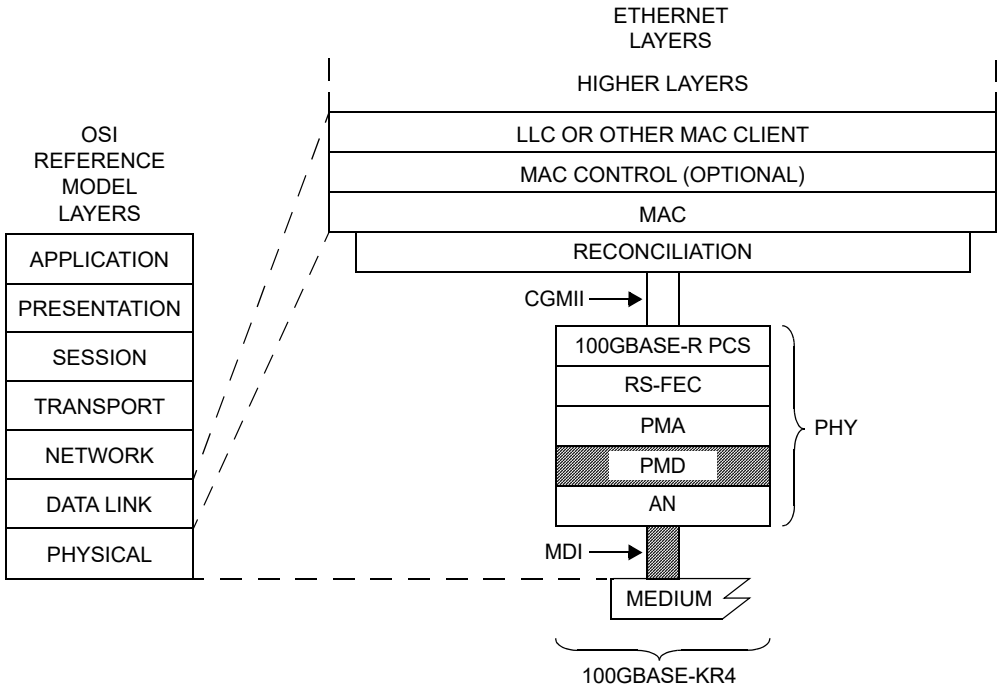

Figure 93–1—100GBASE-KR4 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

For a complete Physical Layer, this specification is considered to be satisfied by a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

93.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-KR4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data. The PMD translates the encoded data to and from signals suitable for the medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 100GBASE-KR4 PMD has four parallel bit streams, hence *i* = 0 to 3. The PMA (or the PMD) continuously sends four parallel bit streams to the PMD (or the PMA), one per lane, each at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable Global_PMD_signal_detect as defined in 93.7.4. When Global_PMD_signal_detect is one, SIGNAL_OK shall be assigned the value OK. When Global_PMD_signal_detect is zero, SIGNAL_OK shall be assigned the value FAIL. When SIGNAL_OK is FAIL, the PMD:IS_UNITDATA_*i*.indication parameters are undefined.

If the optional EEE deep sleep capability is supported, then the PMD service interface includes two additional primitives as follows:

PMD:IS_TX_MODE.request
PMD:IS_RX_MODE.request

93.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 82.6.)

The 100GBASE-KR4 PHY may be extended using CAUI-n as a physical instantiation of the inter-sublayer service interface between devices. If CAUI-n is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

93.4 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the 100GBASE-KR4 PMD, AN, and the medium in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). It is assumed that the one way delay through the medium is no more than 800 bit times (8 ns).

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

93.5 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the RS-FEC sublayer. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–9.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5.

93.6 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control bits to PMD control variables as shown in Table 93–2, and MDIO status bits to PMD status variables as shown in Table 93–3.

Table 93–2—100GBASE-KR4 MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable	1.9.0	Global_PMD_transmit_disable
PMD transmit disable 3 to PMD transmit disable 0	PMD transmit disable	1.9.4 to 1.9.1	PMD_transmit_disable_3 to PMD_transmit_disable_0

93.7 PMD functional specifications

93.7.1 Link block diagram

One direction for one lane of a 100GBASE-KR4 link is shown in Figure 93–2.

93.7.2 PMD Transmit function

The PMD transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_*i*.request (*i*=0 to 3) into four separate electrical signals. The four electrical signals shall then be delivered to the MDI, all according to the transmit electrical specifications in 93.8.1. A positive differential output voltage (SL*i*<p> minus SL*i*<n>) shall correspond to tx_bit = one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

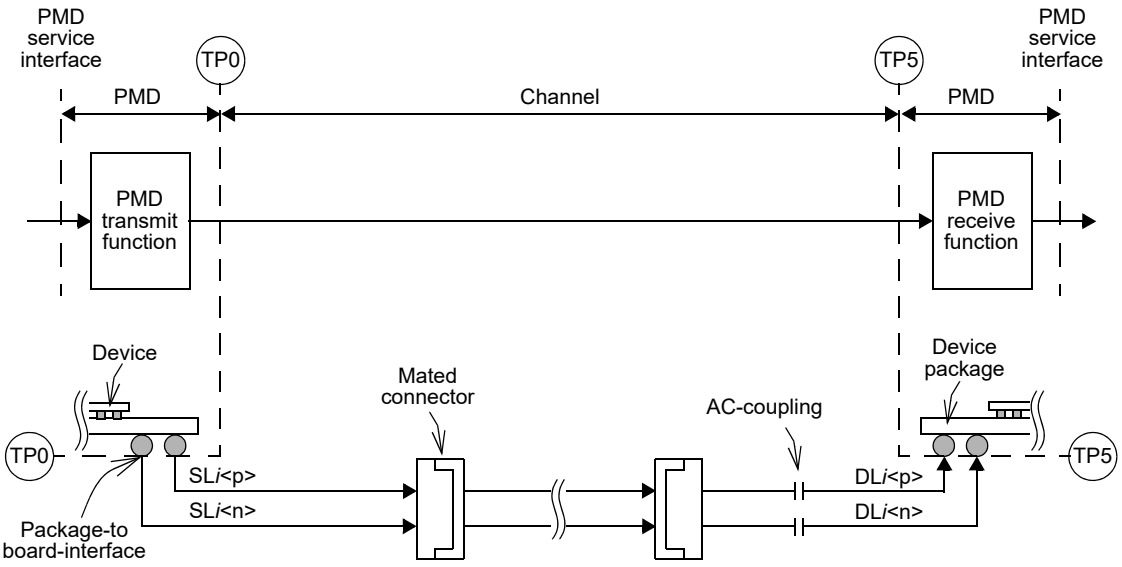

Figure 93–2—100GBASE-KR4 link (one direction for one lane is illustrated)

If the optional EEE deep sleep capability is supported, the following requirements apply. When tx_mode is set to ALERT, the PMD transmit function shall transmit a periodic sequence, where each period of the sequence consists of 8 ones followed by 8 zeros, on each lane, with the transmit equalizer coefficients set to the preset values (see 72.6.10.2.3.1). This sequence is transmitted regardless of the value of tx_bit presented by the PMD:IS_UNITDATA_*i*.request primitive.When tx_mode is not set to ALERT, the transmit equalizer coefficients are set to the values determined via the startup protocol (see 93.7.12).

93.7.3 PMD Receive function

The PMD receive function shall convert the four electrical signals from the MDI into four bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_*i*.indication (*i*=0 to 3). A positive differential input voltage (DL*i*<p> minus DL*i*<n>) shall correspond to rx_bit = one.

93.7.4 Global PMD signal detect function

The variable Global_PMD_signal_detect is the logical AND of the values of PMD_signal_detect_*i* for *i*=0 to 3.

When the MDIO is implemented, this function maps the variable Global_PMD_signal_detect to the register and bit defined in 93.6.

93.7.5 PMD lane-by-lane signal detect function

The PMD lane-by-lane signal detect function is used by the 100GBASE-KR4 PMD to indicate the successful completion of the startup protocol by the PMD control function (see 93.7.12). PMD_signal_detect_*i* (where *i* represents the lane number in the range 0 to 3) is set to zero when the value of the variable signal_detect is set to false by the Training state diagram for lane *i* (see Figure 72–5). PMD_signal_detect_*i* is set to one when the value of signal_detect for lane *i* is set to true.

If training is disabled by the management variable mr_training_enable (see 93.6), PMD_signal_detect_*i* shall be set to one for *i*=0 to 3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the optional EEE deep sleep capability is supported, the following requirements apply. The value of PMD_signal_detect_*i* (for *i*=0 to 3) is set to zero when rx_mode is first set to QUIET. While rx_mode is set to QUIET, PMD_signal_detect_*i* shall be set to one within 500 ns of the application of the ALERT pattern defined in 93.7.2, with peak-to-peak differential voltage of 720 mV as measured at TP0a, to the differential pair at the input of the channel that connects the transmitter to the receiver of lane *i*. While rx_mode is set to QUIET, PMD_signal_detect_*i* shall not be set to one when the voltage applied to the input of the differential pair of the channel that connects the transmitter to the receiver of lane *i* is less than or equal to 60 mV peak-to-peak differential.

When the MDIO is implemented, this function maps the variables to registers and bits as defined in 93.6.

93.7.6 Global PMD transmit disable function

The Global PMD transmit disable function is mandatory if the EEE deep sleep capability is supported and is otherwise optional. When implemented, it allows all of the transmitters to be disabled with a single variable.

a) When Global_PMD_transmit_disable variable is set to one, this function shall turn off all of the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage in Table 93–4.
b) If a PMD fault (93.7.9) is detected, then the PMD may set Global_PMD_transmit_disable to one.
c) Loopback, as defined in 93.7.8, shall not be affected by Global_PMD_transmit_disable.
d) The following additional requirements apply when the optional EEE deep sleep capability is supported. The Global PMD transmit disable function shall turn off all of the transmitters as specified in 93.8.1.3 when tx_mode transitions to QUIET from any other value. The Global PMD transmit disable function shall turn on all of the transmitters as specified in 93.8.1.3 when tx_mode transitions from QUIET to any other value.

93.7.7 PMD lane-by-lane transmit disable function

The PMD transmit disable function is optional and allows the electrical transmitter in each lane to be selectively disabled. When this function is supported, it shall meet the following requirements:

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0 to 3) is set to one, this function shall turn off the transmitter associated with that variable such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 93–4.
b) If a PMD fault (93.7.9) is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the electrical transmitter in each lane.
c) Loopback, as defined in 93.7.8, shall not be affected by PMD_transmit_disable_*i.*

93.7.8 Loopback mode

Local loopback mode is provided by the adjacent PMA (see 83.5.8) as a test function to the device. When loopback mode is enabled, transmission requests passed to each transmitter are sent directly to the corresponding receiver, overriding any signal detected by each receiver on its attached link. Note that loopback mode does not affect the state of the transmitter, which continues to send data (unless disabled).

Control of the loopback function is specified in 83.5.8.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

93.7.9 PMD fault function

PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault. If the MDIO is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

93.7.10 PMD transmit fault function

The PMD transmit fault function is optional. The faults detected by this function are implementation specific, but the assertion of Global_PMD_transmit_disable is not considered a transmit fault.

If PMD_transmit_fault is set to one, then Global_PMD_transmit_disable should also be set to one.

If the MDIO interface is implemented, then PMD_transmit_fault shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

93.7.11 PMD receive fault function

The PMD receive fault function is optional. The faults detected by this function are implementation specific. A fault is indicated by setting the variable PMD_receive_fault to one.

If the MDIO interface is implemented, then PMD_receive_fault shall be mapped to the Receive fault bit specified in 45.2.1.7.5.

93.7.12 PMD control function

Each lane of the 100GBASE-KR4 PMD shall use the same control function as 10GBASE-KR, as defined in 72.6.10, with the following differences:

a) The training frame structure used by the 100GBASE-KR4 PMD control function shall be as defined in 72.6.10 with the exception that 25.78125 GBd symbols replace 10.3125 GBd symbols and 100GBASE-KR4 UI replace 10GBASE-KR UI.
b) In addition to the coefficient update process specified in 72.6.10.2.5, the period from receiving a new request to responding to that request shall be less than 2 ms, except during the first 50 ms following the beginning of the startup protocol. The beginning of the startup protocol is defined to be entry into the AN_GOOD_CHECK state in Figure 73–10. The start of the period is the frame marker of the training frame with the new request and the end of the period is the frame marker of the training frame with the corresponding response. A new request occurs when the coefficient update field is different from the coefficient field in the preceding frame. The response occurs when the coefficient status report field is updated to indicate that the corresponding action is complete.
c) The training pattern defined in 72.6.10.2.6 shall be replaced with the set of training patterns defined in 92.7.12, which are designed to minimize the correlation between physical lanes.

The variables rx_trained_*i*, frame_lock_*i*, training_*i,* and training_failure_*i* (where *i* goes from 0 to 3) report status for each lane and are equivalent to rx_trained, frame_lock, training, and training_failure as defined in 72.6.10.3.1.

If the MDIO interface is implemented, then this function shall map these variables to the appropriate bits in the BASE-R PMD status register (register 1.151) as specified in 45.2.1.96.

93.8.1.1 Transmitter test fixture

Unless otherwise noted, measurements of the transmitter are made at the output of a test fixture (TP0a) as shown in Figure 93–5. The connection from TP0a to the test equipment is AC-coupled.

The insertion loss of the test fixture shall be between 1.2 dB and 1.6 dB at 12.89 GHz. The magnitude of the insertion loss deviation of the test fixture shall be less than or equal to 0.1 dB from 0.05 to 13 GHz.

The reference insertion loss of the test fixture is defined by Equation (93–1) where f is the frequency in GHz.

$$IL_{ref}(f) = -0.0015 + 0.144\sqrt{f} + 0.069f \text{ dB} \qquad 0.05 \le f \le 25 \tag{93–1}$$

The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements. The reference insertion loss is illustrated in Figure 93–3.

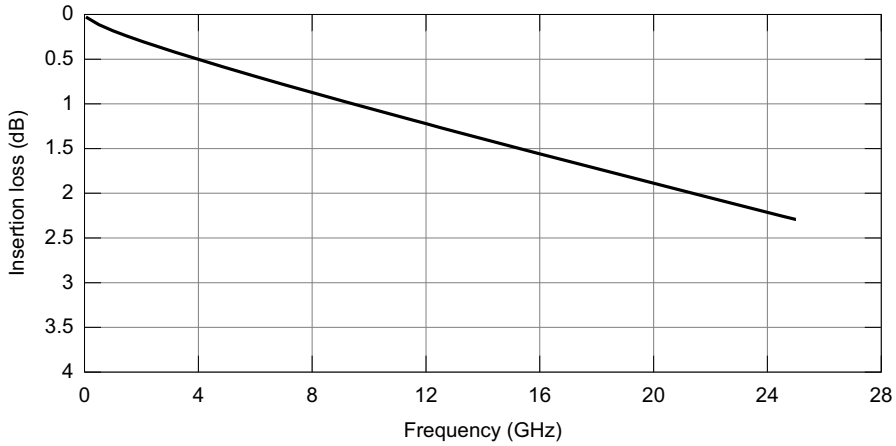

Figure 93–3—Test fixture reference insertion loss

The differential return loss of the test fixture, in dB, shall meet Equation (93–2) where f is the frequency in GHz.

$$RL_d(f) \geq \left\{ \begin{array}{ll} 20 - f & 0.05 \leq f \leq 5 \\ 15 & 5 < f \leq 13 \\ 20.57 - 0.4286f & 13 < f \leq 25 \end{array} \right\} \quad \text{dB} \tag{93–2}$$

The return loss limit is illustrated by Figure 93–4.

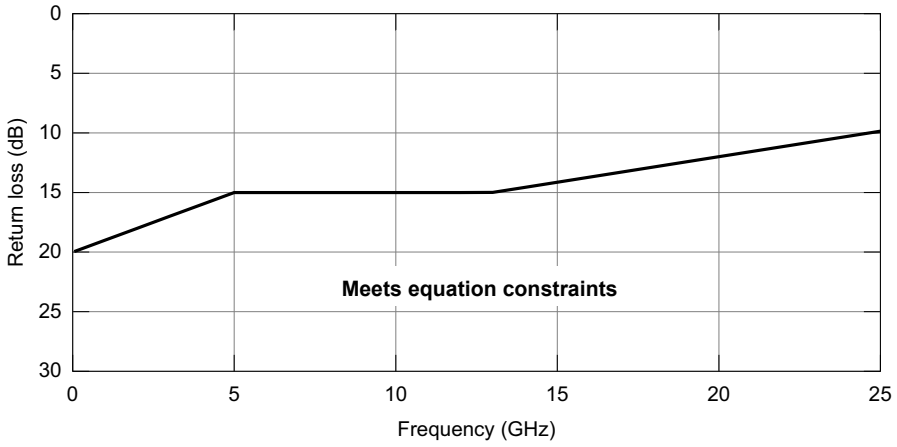

Figure 93–4—Test fixture differential return loss limit

The common-mode return loss of the test fixture shall be greater than or equal to 10 dB from 0.05 to 13 GHz.

A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all transmitter signal measurements, unless otherwise specified.

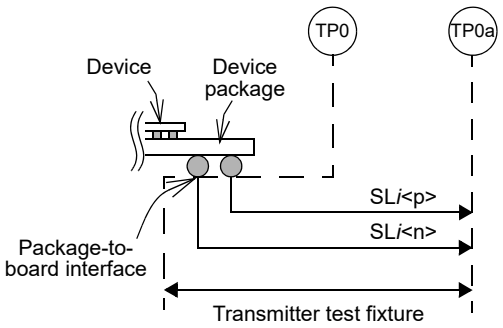

Figure 93–5—Transmitter test fixture and test points

93.8.1.2 Signaling rate and range

The 100GBASE-KR4 signaling rate shall be 25.78125 GBd ± 100 ppm per lane.

93.8.1.3 Signal levels

The differential output voltage v_{di} is defined to be SL*i*<p> minus SL*i*<n>. The common-mode output voltage v_{cmi} is defined to be one half of the sum of SL*i*<p> and SL*i*<n>. These definitions are illustrated by Figure 93–6.

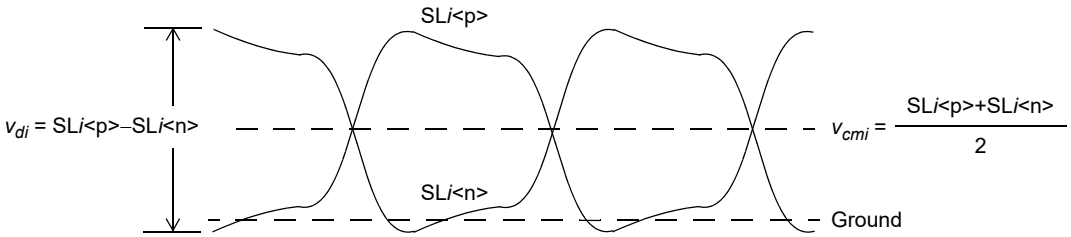

Figure 93–6—Transmitter output voltage definitions

Measurement of the DC common-mode voltage is made with a high-impedance connection to TP0a where each conductor of the differential pair is AC-coupled to a 50 Ω termination.

The peak-to-peak differential output voltage shall be less than or equal to 1200 mV regardless of the transmit equalizer setting. The peak-to-peak differential output voltage shall be less than or equal to 30 mV while the transmitter is disabled (refer to 93.7.6 and 93.7.7).

The DC common-mode output voltage shall be between 0 V and 1.9 V with respect to signal ground. The AC common-mode output voltage shall be less than or equal to 12 mV RMS with respect to signal ground. Common-mode output voltage requirements shall be met regardless of the transmit equalizer setting.

If the optional EEE deep sleep capability is supported the following requirements also apply. The peak-to-peak differential output voltage shall be less than 30 mV within 500 ns of the transmitter being disabled. The peak-to-peak differential output voltage shall be greater than 720 mV within 500 ns of the transmitter being enabled. The transmitter is enabled by the assertion of tx_mode=ALERT and the preceding requirement applies when the transmitted symbols are the periodic pattern defined in 93.7.2 and the transmitter equalizer coefficients are assigned their preset values. The transmitter shall meet the requirements of 93.8.1 within

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1 μs of the transmitter being enabled. While the transmitter is disabled, the DC common-mode output voltage shall be maintained to within ±150 mV of the value for the enabled transmitter.

Unless otherwise noted, differential and common-mode signal levels are measured with a PRBS9 test pattern.

93.8.1.4 Transmitter output return loss

The differential output return loss, in dB, of the transmitter shall meet Equation (93–3) where *f* is the frequency in GHz. This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$RL_d(f) \geq \left\{ \begin{array}{ll} 12.05 - f & 0.05 \leq f \leq 6 \\ 6.5 - 0.075f & 6 < f \leq 19 \end{array} \right\} \quad \text{dB} \tag{93–3}$$

The differential return loss limit is illustrated by Figure 93–7.

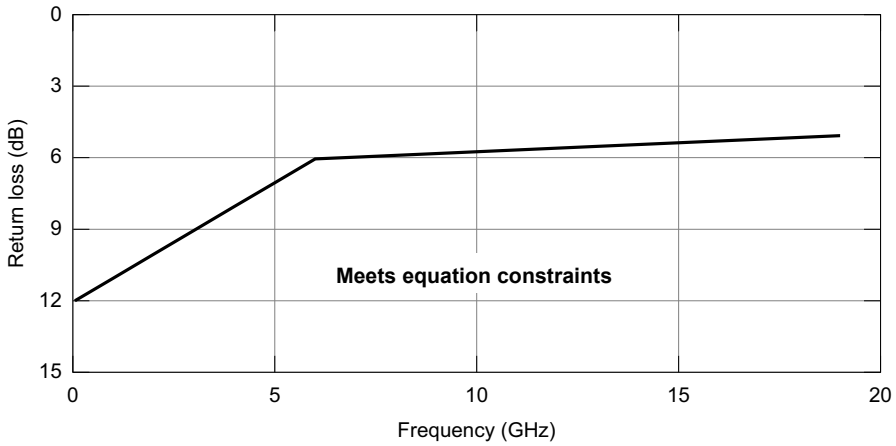

Figure 93–7—Differential return loss limit

The common-mode output return loss, in dB, of the transmitter shall meet Equation (93–4) where *f* is the frequency in GHz. This output impedance requirement applies to all valid output levels. The reference impedance for common-mode return loss measurements shall be 25 Ω.

$$RL_{cm}(f) \geq \left\{ \begin{array}{ll} 9.05 - f & 0.05 \leq f \leq 6 \\ 3.5 - 0.075f & 6 < f \leq 19 \end{array} \right\} \quad \text{dB} \tag{93–4}$$

The common-mode return loss limit is illustrated by Figure 93–8.

93.8.1.5 Transmitter output waveform

The 100GBASE-KR4 transmit function includes programmable equalization to compensate for the frequency-dependent loss of the channel and facilitate data recovery at the receiver. The functional model for the transmit equalizer is the three tap transversal filter shown in Figure 93–9.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

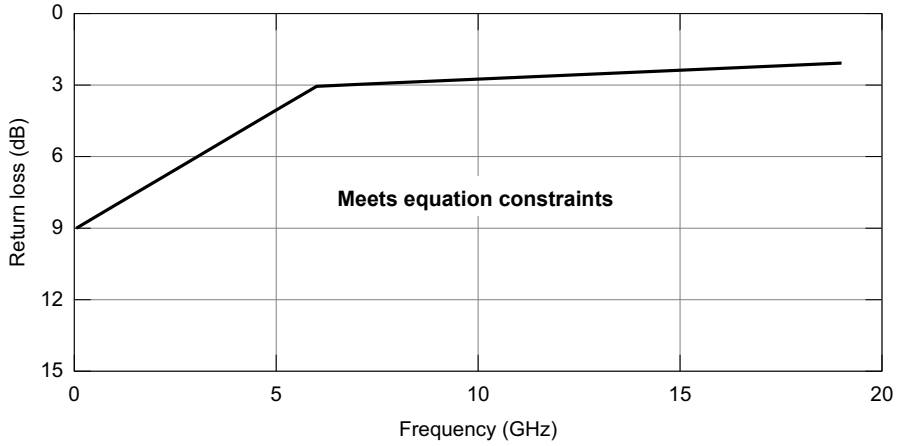

Figure 93–8—Common-mode return loss limit

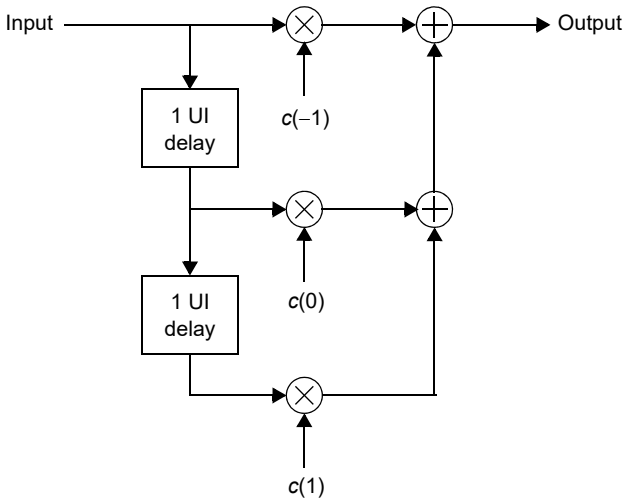

Figure 93–9—Transmit equalizer functional model

The state of the transmit equalizer and hence the transmitted output waveform may be manipulated via the PMD control function defined in 93.7.12 or via the management interface. The transmit function responds to a set of commands issued by the link partner's receive function and conveyed by a back-channel communications path.

This command set includes instructions to:

Increment coefficient $c(i)$.
Decrement coefficient $c(i)$.
Hold coefficient $c(i)$ at its current value.
Set the coefficients to a predefined value (preset or initialize).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In response, the transmit function relays status information to the link partner's receive function. The status messages indicate that:

The requested update to coefficient $c(i)$ has completed (updated).
Coefficient $c(i)$ is at its minimum value.
Coefficient $c(i)$ is at its maximum value.
Coefficient $c(i)$ is ready for the next update request (not_updated).

93.8.1.5.1 Linear fit to the measured waveform

The transmitter output waveform is characterized using the procedure described in 92.8.3.5.1 with the exception that the measurement is performed at TP0a rather than TP2.

93.8.1.5.2 Steady-state voltage and linear fit pulse peak

The steady-state voltage v_f is defined to be the sum of the linear fit pulse $p(k)$ divided by M (refer to 85.8.3.3 step 3). The steady-state voltage shall be greater than or equal to 0.4 V and less than or equal to 0.6 V after the transmit equalizer coefficients have been set to the "preset" values.

The peak value of $p(k)$ shall be greater than $0.71 \times v_f$ after the transmit equalizer coefficients have been set to the "preset" values.

93.8.1.5.3 Coefficient initialization

When the PMD enters the INITIALIZE state of the Training state diagram (Figure 72–5) or receives a valid request to "initialize" from the link partner, the coefficients of the transmit equalizer shall be configured such that the ratio $(c(0)+c(1)-c(-1))/(c(0)+c(1)+c(-1))$ is 1.29±10% and the ratio $(c(0)-c(1)+c(-1))/(c(0)+c(1)+c(-1))$ is 2.57±10%. These requirements apply upon the assertion a coefficient status report of "updated" for all coefficients.

93.8.1.5.4 Coefficient step size

The change in the normalized amplitude of coefficient $c(i)$ corresponding to a request to "increment" that coefficient shall be between 0.0083 and 0.05. The change in the normalized amplitude of coefficient $c(i)$ corresponding to a request to "decrement" that coefficient shall be between −0.05 and −0.0083.

The change in the normalized amplitude of the coefficient is defined to be the difference in the value measured prior to the assertion of the "increment" or "decrement" request (e.g., the coefficient update request for all coefficients is "hold") and the value upon the assertion of a coefficient status report of "updated" for that coefficient.

93.8.1.5.5 Coefficient range

When sufficient "increment" or "decrement" requests have been received for a given coefficient, the coefficient will reach a lower or upper bound based on the range of that coefficient or the combination of coefficients.

With $c(-1)$ set to zero and both $c(0)$ and $c(1)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0)-c(1))/(c(0)+c(1))$ shall be greater than or equal to 4.

With $c(1)$ set to zero and both $c(-1)$ and $c(0)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0)-c(-1))/(c(0)+c(-1))$ shall be greater than or equal to 1.54.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Note that a coefficient may be set to zero by first asserting the preset control and then manipulating the other coefficients as required by the test.

93.8.1.6 Transmitter signal-to-noise-and-distortion ratio (SNDR)

Signal-to-noise-and-distortion ratio (SNDR) measured at the transmitter output using the method described in 92.8.3.7 shall be greater than 27 dB regardless of the transmit equalizer setting.

93.8.1.7 Transmitter output jitter

The conditions for the measurement of transmitter output jitter (jitter filter, test pattern, etc.) are defined in 92.8.3.8.

Even-odd jitter is defined in 92.8.3.8.1. Even-odd jitter shall be less than or equal to 0.035 UI regardless of the transmit equalization setting.

Effective bounded uncorrelated jitter and effective total uncorrelated jitter are defined in 92.8.3.8.2. The effective bounded uncorrelated jitter shall be less than or equal to 0.1 UI peak-to-peak regardless of the transmit equalization setting. The effective total uncorrelated jitter shall be less than or equal to 0.18 UI peak-to-peak regardless of the transmit equalization setting.

93.8.2 Receiver characteristics

Receiver characteristics measured at TP5a are summarized in Table 93–5.

Table 93–5—Summary of receiver characteristics at TP5a

Parameter	Subclause reference	Value	Units
Differential input return loss (min.)	93.8.2.2	Equation (93–3)	dB
Differential to common-mode return loss (min.)	93.8.2.2	Equation (93–5)	dB
Interference tolerance	93.8.2.3	Table 93–6	—
Jitter tolerance	93.8.2.4	Table 93–7	—

93.8.2.1 Receiver test fixture

Unless otherwise noted, measurements of the receiver are made at the input to a test fixture (TP5a) as shown in Figure 93–10. The connection from the test equipment to TP5a is AC-coupled.

Unless otherwise noted, measurements of the receiver are made at the input to a test fixture as shown in Figure 93–10.

The insertion loss of the test fixture shall be between 1.2 dB and 1.6 dB at 12.89 GHz. The magnitude of the insertion loss deviation of the test fixture shall be less than or equal to 0.1 dB from 0.05 GHz to 13 GHz.

The reference insertion loss of the test fixture is defined by Equation (93–1) where f is the frequency in GHz. The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements. The reference insertion loss is illustrated in Figure 93–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The differential return loss of the test fixture, in dB, shall meet Equation (93–2) where *f* is the frequency in GHz. The return loss limit is illustrated by Figure 93–4.

The common-mode return loss of the test fixture shall be greater than or equal to 10 dB from 0.05 GHz to 13 GHz.

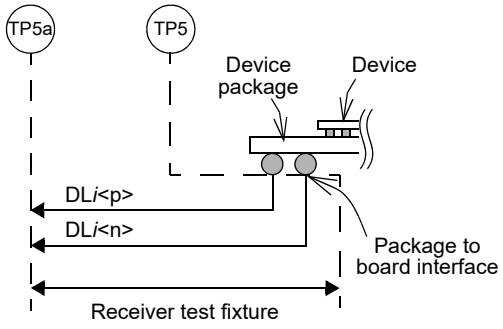

Figure 93–10—Receiver test fixture and test points

93.8.2.2 Receiver input return loss

The differential input return loss, in dB, of the receiver shall meet Equation (93–3) where *f* is the frequency in GHz. The reference impedance for differential return loss measurements shall be 100 Ω. The differential input return loss limit is illustrated by Figure 93–7.

The differential to common-mode return loss, in dB, of the receiver shall meet Equation (93–5).

$$RL_{cd}(f) = \left\{ \begin{array}{ll} 25 - 1.44f & 0.05 \le f \le 6.95 \\ 15 & 6.95 < f \le 19 \end{array} \right\} \quad \text{dB} \tag{93–5}$$

The differential to common-mode return loss limit is illustrated by Figure 93–11.

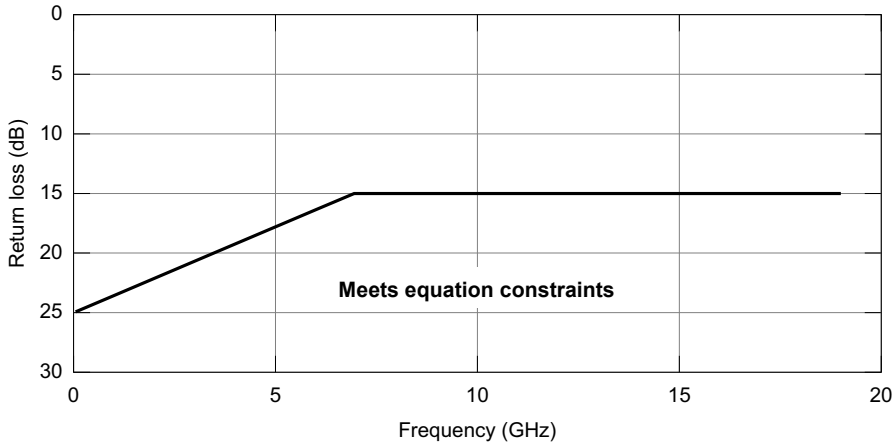

Figure 93–11—Receiver differential to common-mode return loss limit

93.8.2.3 Receiver interference tolerance

The receiver interference tolerance test setup and method are defined in Annex 93C. The receiver on each lane shall meet the RS-FEC symbol error ratio requirement with the channel defined for each test listed in Table 93–6. The parameter RSS_DFE4 is a figure of merit for the test channel that is defined in 93A.2.

The following considerations apply to the interference tolerance test. The test transmitter meets the specifications in 93.8.1 as measured at TP0a (see Figure 93C–3). The test transmitter is constrained such that for any transmit equalizer setting the differential peak-to-peak voltage (see 93.8.1.3) is less than or equal to 800 mV and the pre- and post-cursor equalization ratios (see 93.8.1.5.5) are less than or equal to 1.54 and 4, respectively. The lowest frequency f_{NSD1} for constraints on the noise spectral density is 1 GHz. The return loss of the test setup in Figure 93C–4 measured at TP5 replica meets the requirements of Equation (93–2).

The values of the parameters required for the calculation of Channel Operating Margin (COM) are given in Table 93–8 with the following exceptions. The COM parameter σ_{RJ} is set to the measured value of effective random jitter (see 92.8.3.8.2), the COM parameter A_{DD} is set to half the measured value of effective bounded uncorrelated jitter (see 93.8.1.7), and the COM parameter SNR_{TX} is set to the value of SNDR measured at TP0a (see 93.8.1.6). Tests 1 and 2 are for the case when error correction is bypassed in the RS-FEC sublayer (see 91.5.3.3) and for these cases COM is computed with a DER_0 value of 10^{-12}. The test pattern to be used is any valid PCS output (such as scrambled idle), which is subsequently encoded by the RS-FEC sublayer.

A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for measurement of the signal applied by the pattern generator and for measurements of the broadband noise.

Table 93–6—Receiver interference tolerance parameters

Parameter	Test 1 values		Test 2 values		Test 3 values		Test 4 values		Units
	Min	Max	Min	Max	Min	Max	Min	Max	
RS-FEC symbol error ratio[a]	—	10^{-11}	—	10^{-11}	—	10^{-4}	—	10^{-4}	—
Insertion loss at 12.89 GHz[b]	—	16	30	—	—	30	35	—	dB
Coefficients of fitted insertion loss[c]									
a_0	–0.9	0.9	–0.9	0.9	–0.9	0.9	–0.9	0.9	dB
a_1	0	3.3	0	3.3	0	3.3	0	3.3	dB/GHz$^{1/2}$
a_2	0	—	0	—	0	—	0	—	dB/GHz
a_4	0	0.022	0	0.03	0	0.03	0	0.043	dB/GHz^2
RSS_DFE4	0.05	—	0.05	—	0.05	—	0.05	—	—
COM, including effects of broadband noise[d]	3		3		3		3		dB

[a]The FEC symbol error ratio is measured in step 10 of the receiver interference tolerance method defined in 93C.2.
[b]Measured between TPt and TP5 (see Figure 93C–4).
[c]Coefficients are calculated from the insertion loss measured between TPt and TP5 (see Figure 93C–4) using the method in 93A.3 with f_{min} = 0.05 GHz, f_{max} = 25.78125 GHz, and maximum Δf = 0.01 GHz.
[d]The COM value is the target for the receiver noise level calibration defined in 93C.2 step 7. The channel noise voltage applied in 93C.2 step 8 should be as close as practical to the value needed to produce the target COM. If higher channel noise voltage values are used, this would demonstrate margin to the specification but this is not required for compliance.

93.8.2.4 Receiver jitter tolerance

Receiver jitter tolerance is measured using the test setup shown in Figure 93–12, or its equivalent, for the receiver of each lane.

The test transmitter meets the specifications of 93.8.1. It is constrained so that its differential peak-to-peak output voltage does not exceed 800 mV at TP0a regardless of the transmitter equalizer setting (see 93.8.1.3). It is further constrained so that its maximum pre-cursor equalization ratio is 1.54 and its maximum post-cursor equalization ratio is 4 (see 93.8.1.5.5).

The test channel meets the requirements of the interference tolerance test channel using Test 4 values (see 93.8.2.3). No broadband noise is added for this test.

Receiver jitter tolerance is verified for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 93–7. The synthesizer frequency is set to the specified jitter frequency and the synthesizer output amplitude is adjusted until the specified peak-to-peak jitter amplitude for that frequency is measured at TP0a. The output of the ISI channel is connected to the input of the receiver under test at TP5a. The link is initialized and the PMD startup protocol is allowed to complete, thereby optimizing the test transmitter equalizer. The test transmitter then transmits any valid PCS output (such as scrambled idle), which is subsequently encoded by the RS-FEC sublayer. The RS-FEC symbol error ratio is measured using the errored symbol counter FEC_symbol_error_counter_*i* where *i* is the lane number of the receiver under test.

The RS-FEC symbol error ratio shall be less than or equal to 10^{-4} for each case listed in Table 93–7.

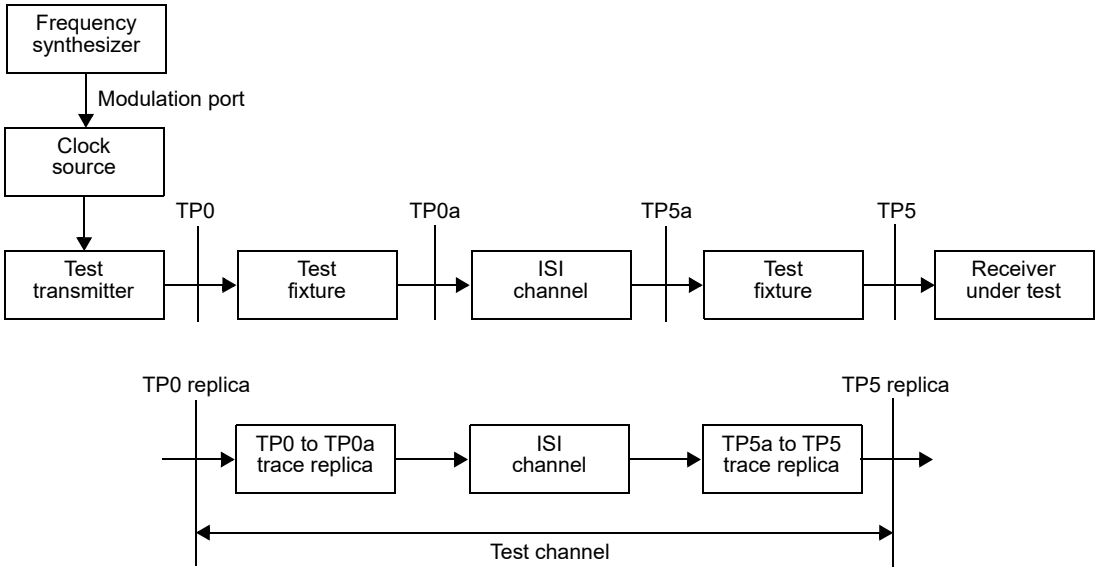

Figure 93–12—Jitter tolerance test setup

Table 93–7—Receiver jitter tolerance parameters

Parameter	Case A values	Case B values	Units
Jitter frequency	190	940	kHz
Peak-to-peak jitter amplitude	5	1	UI

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

93.9 Channel characteristics

93.9.1 Channel Operating Margin

The Channel Operating Margin (COM) is computed using the procedure in 93A.1 with the Test 1 and Test 2 values in Table 93–8. Test 1 and Test 2 differ in the value of the device package model transmission line length z_p.

COM shall be greater than or equal to 3 dB for each test. This minimum value allocates margin for practical limitations on the receiver implementation as well as the largest step size allowed for transmitter equalizer coefficients.

The receive path of the RS-FEC sublayer may have the option to perform error detection without correction to reduce the data delay (see 91.5.3.3). Channels that are compatible with this mode of operation shall meet this COM requirement with the value of DER_0 set to 10^{-12}.

93.9.2 Insertion loss

The insertion loss, in dB, of the channel is recommended to meet Equation (93–6).

$$IL(f) \le \left\{ \begin{array}{ll} 1.5 + 4.6\sqrt{f} + 1.318f & 0.05 \le f \le f_b/2 \\ -12.71 + 3.7f & f_b/2 < f \le f_b \end{array} \right\} \text{ (dB)} \qquad (93\text{–}6)$$

where

f is the frequency in GHz
f_b is the signaling rate (25.78125) in GHz
$IL(f)$ is the insertion loss at frequency f

The insertion loss limit is illustrated by Figure 93–13.

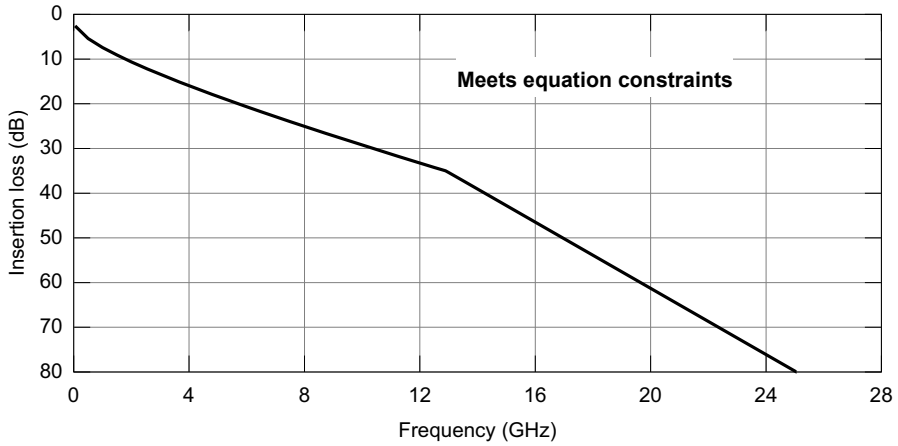

Figure 93–13—Insertion loss limit

93.9.3 Return loss

The return loss, in dB, of the channel is recommended to meet Equation (93–7).

$$RL_d(f) \geq \left\{ \begin{array}{ll} 12 & 0.05 \leq f \leq f_b/4 \\ 12 - 15\log_{10}(4f/f_b) & f_b/4 < f \leq f_b \end{array} \right\} \quad \text{dB} \qquad (93\text{–}7)$$

where

f is the frequency in GHz
f_b is the signaling rate (25.78125) in GHz
$RL(f)$ is the return loss at frequency f

The differential return loss limit is illustrated by Figure 93–14.

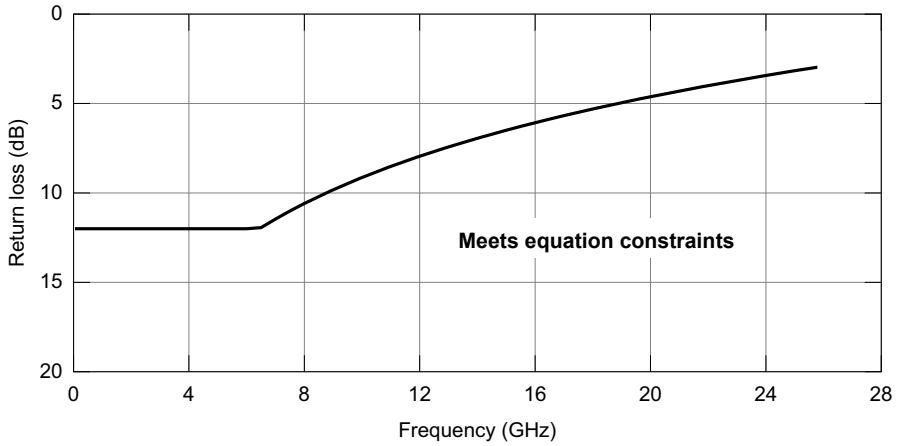

Figure 93–14—Differential return loss limit

93.9.4 AC-coupling

The 100GBASE-KR4 transmitter shall be AC-coupled to the receiver. Common-mode specifications are defined as if the DC-blocking capacitor is implemented between TP0 and TP5. Should the capacitor be implemented outside TP0 and TP5, the common-mode specifications in Table 93–4 may not be appropriate.

The impact of a DC-blocking capacitor implemented between TP0 and TP5 is accounted for within the channel specifications. Should the capacitor be implemented outside TP0 and TP5, it is the responsibility of implementers to consider any necessary modifications to common-mode and channel specifications required for interoperability as well as any impact on the verification of transmitter and receiver compliance.

The low-frequency 3 dB cutoff of the AC-coupling shall be less than 50 kHz.

93.10 Environmental specifications

93.10.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

93.10.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

93.10.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

93.10.4 Electromagnetic compatibility

A system integrating the 100GBASE-KR4 PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

93.10.5 Temperature and humidity

A system integrating the 100GBASE-KR4 PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

93.11 Protocol implementation conformance statement (PICS) proforma for Clause 93, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-KR4[162]

93.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 93, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-KR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

93.11.2 Identification

93.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

93.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 93, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-KR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[162] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

93.11.4 PICS proforma tables for Physical Medium Dependent (PMD) sublayer and baseband medium, type 100GBASE-KR4

93.11.4.1 Functional specifications

Item	Feature	Subclause	Value/Comment	Status	Support
FS1	PMD transmit function	93.7.2	Converts four logical bit streams from the PMD service interface into four electrical signals and delivers them to the MDI	M	Yes [ ]
FS2	Mapping of logical signals to electrical signals	93.7.2	Positive differential output voltage corresponds to tx_bit=one	M	Yes [ ]
FS3	ALERT signal	93.7.2	Transmit a periodic sequence, where each period of the sequence consists of 8 ones followed by 8 zeros, on each lane when tx_mode is set to ALERT	EEE:M	Yes [ ] N/A [ ]
FS4	PMD receive function	93.7.3	Converts four electrical signals from the MDI into four logical bit streams delivers them to the PMD service interface	M	Yes [ ]
FS5	Mapping of electrical signals to logical signals	93.7.3	Positive differential input voltage corresponds to rx-_bit=one	M	Yes [ ]
FS6	SIGNAL_OK mapping	93.2	Set to OK when Global_PM-D_signal_detect is one and set to FAIL when Global_P-MD_signal_detect is zero	M	Yes [ ]
FS7	Training disabled by variable mr_training_enable	93.7.5	PMD_signal_detect_*i* set to one for *i*=0 to 3	M	Yes [ ]
FS8	PMD_signal_detect_*i* asserted, rx_mode=QUIET	93.7.5	Set to one within 500 ns following the application of the signal defined in 93.7.5 to the input of the channel corresponding to the receiver of lane *i*	EEE:M	Yes [ ] N/A [ ]
FS9	PMD_signal_detect_*i* not asserted, rx_mode=QUIET	93.7.5	Not set to one when the signal applied to the input of the channel corresponding to the receiver of lane *i* is less than or equal to 60 mV peak-to-peak differential	EEE:M	Yes [ ] N/A [ ]
FS10	Global_PMD_transmit_disable variable	93.7.6	When set to one, all transmitters satisfy the requirements of 93.7.6	GTD:M	Yes [ ] N/A [ ]
FS11	Global PMD transmit disable function affect on loopback	93.7.6	No effect	GTD:M	Yes [ ] N/A [ ]
FS12	Global PMD transmit disable function, tx_mode transition to QUIET	93.7.6	Turn off all transmitters when tx_mode transitions to QUIET from any other value	EEE:M	Yes [ ] N/A [ ]

94. Physical Medium Attachment (PMA) sublayer, Physical Medium Dependent (PMD) sublayer, and baseband medium, type 100GBASE-KP4

94.1 Overview

This clause specifies the Physical Medium Attachment (PMA) sublayers, Physical Medium Dependent (PMD) sublayer, and medium for the 100GBASE-KP4 PHY.

When forming a complete Physical Layer, the PMA shall be connected to the RS-FEC, the PMD shall be connected to the medium through the MDI as shown in Figure 94–1, and the PMA and PMD shall be connected to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 94–1—Physical Layer clauses associated with the 100GBASE-KP4 PMD

Associated clause	100GBASE-KP4
81—RS	Required
81—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
83—PMA for 100GBASE-R	Optional
83A—CAUI-10	Optional
83D—CAUI-4	Optional
91—RS-FEC	Required
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.

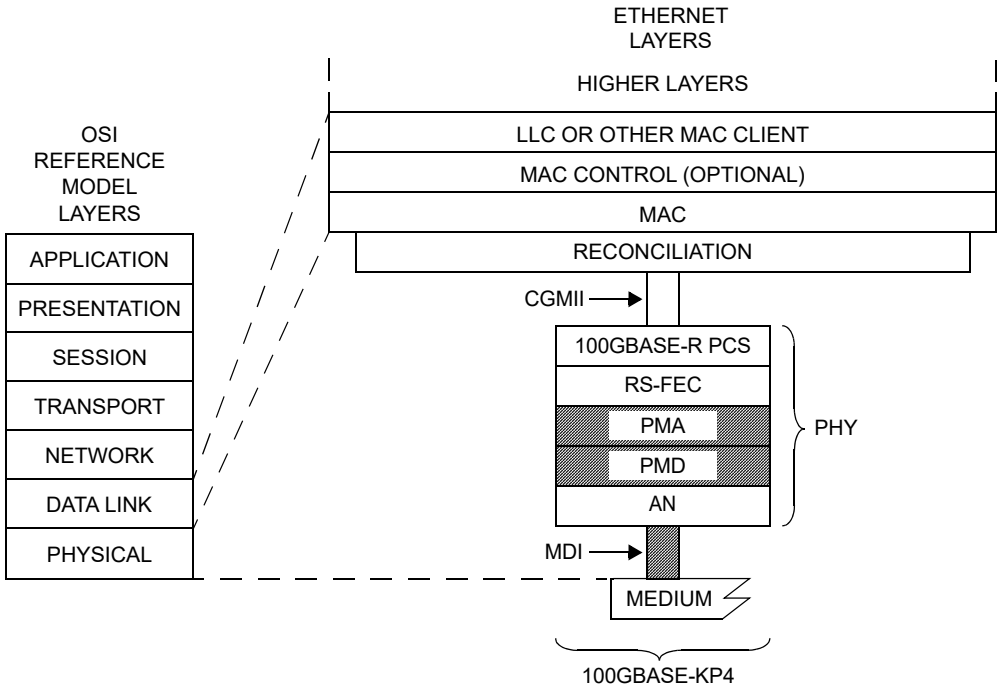

Figure 94–1 shows the relationship of the 100GBASE-KP4 PMA and PMD sublayers and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

Differential signals received at the MDI from a transmitter that meets the requirements of 94.2.2 and 94.3.12 and have passed through the channel specified in 94.4 are received with a BER less than 10^{-5} as measured at the PMA service interface.

For a complete Physical Layer, this specification is considered to be satisfied by a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

A 100GBASE-KP4 PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 94–1—100GBASE-KP4 PMA and PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

94.2 Physical Medium Attachment (PMA) Sublayer

94.2.1 PMA Service Interface

The PMA service interface for 100GBASE-KP4 PMA is based on the inter-sublayer service interface defined in 80.3. This interface is defined in an abstract manner and does not imply any particular implementation.

The PMA service interface primitives are summarized as follows:

PMA:IS_UNITDATA_*i*.request
PMA:IS_UNITDATA_*i*.indication
PMA:IS_SIGNAL.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the optional EEE deep sleep capability is supported (see Clause 78, 78.1.3.3.1), then the PMA service interface includes four additional primitives as follows:

PMA:IS_TX_MODE.request
PMA:IS_RX_MODE.request
PMA:IS_ENERGY_DETECT.indication
PMA:IS_RX_TX_MODE.indication

94.2.1.1 PMA:IS_UNITDATA_i.request

The PMA:IS_UNITDATA_*i*.request (where *i*=0 to 3) primitive is used to define the transfer of four streams of data units from the PMA client to the PMA.

94.2.1.1.1 Semantics of the service primitive

PMA:IS_UNITDATA_0.request(tx_bit,start)
PMA:IS_UNITDATA_1.request(tx_bit,start)
PMA:IS_UNITDATA_2.request(tx_bit,start)
PMA:IS_UNITDATA_3.request(tx_bit,start)

The data conveyed by PMA:IS_UNITDATA_0.request to IS_UNITDATA_3.request consists of four parallel continuous streams of encoded bits, one stream for each lane. Each of the tx_bit parameters can take one of two values: one or zero. The start parameter is TRUE to indicate that the concurrent tx_bit is the first bit of the first, second, third, or fourth FEC symbol in an FEC codeword and is otherwise FALSE.

94.2.1.1.2 When generated

The PMA client continuously sends four parallel bit streams PMA:IS_UNITDATA_*i*.request(tx_bit,start) to the PMA, each at a nominal signaling rate of 26.5625 Gb/s.

94.2.1.1.3 Effect of receipt

Upon receiving each instance of PMA:IS_UNITDATA_*i*.request, the tx_bit and start parameters are passed to the PMA framing process corresponding to each stream.

94.2.1.2 PMA:IS_UNITDATA_i.indication

The PMA:IS_UNITDATA_*i*.indication (where *i* = 0 to 3) primitive is used to define the transfer of four streams of data units from the PMA to the PMA client.

94.2.1.2.1 Semantics of the service primitive

PMA:IS_UNITDATA_0.indication(rx_bit, start)
PMA:IS_UNITDATA_1.indication(rx_bit, start)
PMA:IS_UNITDATA_2.indication(rx_bit, start)
PMA:IS_UNITDATA_3.indication(rx_bit, start)

The data conveyed by PMA:IS_UNITDATA_0.indication to PMA:IS_UNITDATA_3.indication consists of four parallel continuous streams of encoded bits, one stream for each lane. Each of the rx_bit parameters can take one of two values: one or zero. The start parameter is TRUE to indicate that the concurrent rx_bit is the first bit of the first, second, third, or fourth FEC symbol in the FEC codeword and is otherwise FALSE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.2.1.2.2 When generated

The PMA continuously sends four parallel bit streams PMA:IS_UNITDATA_*i*.indication(rx_bit,start) to the PMA client, each at a nominal signaling rate of 26.5625 Gb/s.

94.2.1.2.3 Effect of receipt

The effect of receipt of this primitive is defined by the PMA client.

94.2.1.3 PMA:IS_SIGNAL.indication

The PMA:IS_SIGNAL.indication primitive is generated by the PMA to the PMA client to indicate the status of the receive process. This primitive is generated by the receive process to propagate the detection of severe error conditions (e.g., loss of synchronization) to the PMA client.

94.2.1.3.1 Semantics of the service primitive

PMA:IS_SIGNAL.indication(SIGNAL_OK)

The SIGNAL_OK parameter can take on one of two values: OK or FAIL. A value of FAIL denotes that invalid data is being presented (rx_bit parameters undefined) by the PMA to the PMA client. A value of OK does not guarantee valid data is being presented by the PMA to the PMA client.

94.2.1.3.2 When generated

The PMA generates the PMA:IS_SIGNAL.indication primitive to the PMA client whenever there is a change in the value of the SIGNAL_OK parameter.

94.2.1.3.3 Effect of receipt

The effect of receipt of this primitive is defined by the PMA client.

94.2.1.4 PMA:IS_TX_MODE.request

The PMA:IS_TX_MODE.request primitive communicates the tx_mode parameter generated by the PCS LPI transmit process to invoke the appropriate PMA, FEC, and PMD transmit EEE states. Without EEE deep sleep capability, this primitive is never invoked and the sublayers behave as if tx_mode = DATA.

94.2.1.4.1 Semantics of the service primitive

PMA:IS_TX_MODE.request(tx_mode)

The tx_mode parameter takes on one of up to three values: DATA, QUIET, or ALERT.

94.2.1.4.2 When generated

This primitive is generated to indicate the state of the PCS LPI transmit function.

94.2.1.4.3 Effect of receipt

When this primitive is received, PMD:IS_TX_MODE.request(tx_mode) is generated with the value received in PMA:IS_TX_MODE.request(tx_mode).

If the value is DATA or ALERT, the PMA operates normally.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the value is QUIET, the PMA may go into a low power mode.

94.2.1.5 PMA:IS_RX_MODE.request

The PMA:IS_RX_MODE.request primitive communicates the rx_mode parameter generated by the PCS LPI receive process. Without EEE deep sleep capability, this primitive is never invoked and the sublayers behave as if rx_mode = DATA.

94.2.1.5.1 Semantics of the service primitive

PMA:IS_RX_MODE.request(rx_mode)

The rx_mode parameter takes on one of two values: DATA or QUIET.

94.2.1.5.2 When generated

This primitive is generated to indicate the state of the PCS LPI receive function.

94.2.1.5.3 Effect of receipt

When this primitive is received, PMD:IS_RX_MODE.request(rx_mode) is generated with the value received in PMA:IS_RX_MODE.request(rx_mode).

If the value is DATA, the PMA operates normally.

If the value is QUIET, the PMA may be go into a low power mode.

94.2.1.6 PMA:IS_ENERGY_DETECT.indication

The PMA:IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the presence of energy on the interface following a period of quiescence. Without EEE deep sleep capability, this primitive is never invoked and has no effect.

94.2.1.6.1 Semantics of the service primitive

PMA:IS_ENERGY_DETECT.indication(energy_detect)

The parameter energy_detect is Boolean.

94.2.1.6.2 When generated

This primitive is generated by the PMA, reflecting the state of PMD:IS_SIGNAL.indication(SIGNAL_OK) received from the PMD (see 94.3.1.3). When SIGNAL_OK indicates OK, energy detect indicates TRUE. When SIGNAL_OK indicates FAIL, energy_detect indicates FALSE.

94.2.1.6.3 Effect of receipt

The effect of receipt of this primitive is defined by the PMA client sublayers that receive it.

94.2.1.7 PMA:IS_RX_TX_MODE.indication

The PMA:IS_RX_TX_MODE.indication primitive communicates the value of the rx_tx_mode parameter. This parameter indicates the value of tx_mode that the PMA sublayer has inferred from the received signal.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Without EEE deep sleep capability, the primitive is never generated and the sublayers behave as if rx_tx_mode=DATA.

94.2.1.7.1 Semantics of the service primitive

PMA:IS_RX_TX_MODE.indication(rx_tx_mode)

The parameter rx_tx_mode is assigned one of the following values: DATA, QUIET, or ALERT. DATA is assigned when the PMA is reset or when PMA frames are being received. QUIET is assigned if PMA frame reception ceases. ALERT is assigned if rx_tx_mode = QUIET and PMD:IS_SIGNAL.indication(SIGNAL_OK) transitions from FAIL to OK.

94.2.1.7.2 When generated

This primitive is generated whenever there is change in the value of the rx_tx_mode parameter.

94.2.1.7.3 Effect of receipt

The RS-FEC sublayer passes this primitive through to the PMA sublayer that may exist above.

94.2.2 PMA Transmit Functional Specifications

In the transmit direction, the role of the 100GBASE-KP4 PMA is to adapt the signal from the FEC (the PMA client) to a PAM4 encoded signal to be passed to the PMD for transfer over the attached medium. The adaptation processes shown in Figure 94–2 include insert overhead, insert termination bits, apply Gray coding, apply 1/(1+D) mod 4 precoding, and apply PAM4 encoding.

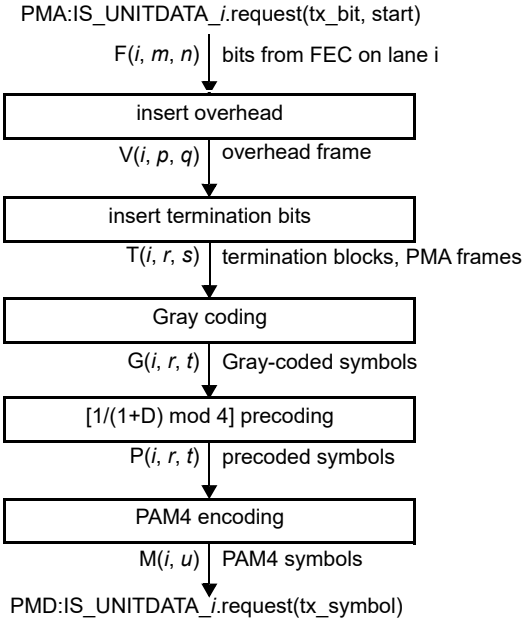

Figure 94–2—Transmit adaptation process diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.2.2.1 FEC Interface

The PMA transmit process receives FEC bits via the PMA:IS_UNITDATA_*i*(tx_bit, start) primitive (see 94.2.1.1). The index *i* indicates the PMA lane number: 0, 1, 2, or 3.

On each transaction, tx_bit is assigned to F(*i*, *m*, *n*), where

i is the lane number
m is an index indicating the FEC codeword number and increments at the start of each codeword
n is an index indicating the bit number within a codeword with a range 1 to 1360

The start of a codeword is determined by the start parameter associated with the tx_bit parameter being equal to TRUE.

94.2.2.2 Overhead Frame

The PMA transmit process shall create a sequence of overhead frames by inserting 40 overhead bits for every 31280 FEC bits as specified in this subclause.

The FEC bits, F(*i*, *m*, *n*), are mapped into a continuous sequence of overhead frames. The overhead frame is 31320 bits in length.

Each bit in the overhead frame is denoted V(*i*, *p*, *q*), where:

i is the lane number
p is an index that indicates the frame number and increments at the start of each frame
q is an index that indicates the bit number within a frame with a range 1 to 31320

The first 40 bits of the frame, V(*i*, *p*, 1) to V(*i*, *p*, 40), are the overhead bits (see 94.2.2.3). The next 31280 bits, V(*i*, *p*, 41) to V(*i*, *p*, 31320), are composed of the bits from 23 consecutive FEC codewords.

The overhead bits are inserted in the frame as follows:

V(*i*, *p*, 1) = H(*i*, *p*, 1)
V(*i*, *p*, 2) = H(*i*, *p*, 2)
V(*i*, *p*, ...) = H(*i*, *p*, ...)
V(*i*, *p*, 40) = H(*i*, *p*, 40)

The FEC codeword bits are aligned such that V(*i*, *p*, 41) is the first bit of a codeword, e.g., V(*i*, *p*, 41) = F(*i*, *m*, 1). The FEC bits are inserted into the frame in the order in which they were received from the FEC, e.g., V(*i*, *p*, 42) = F(*i*, *m*, 2), V(*i*, *p*, 43) = F(*i*, *m*, 3), and so on. The method for aligning the FEC codeword with the start of the overhead frame is outside the scope of this standard.

94.2.2.3 Overhead

The PMA transmit process shall form the overhead bits in each overhead frame as specified in this subclause.

The overhead bits are denoted H(*i*, *p*, *k*), where

i is the lane number
p is an index that indicates the frame number and increments at the start of each frame
k is an index that indicates the header bit number with a range 1 to 40

Bits are mapped to the overhead in a sequence of five groups of 8 bits each. Each 8-bit group takes on the value A or An. The values of the 8 bits in A are such that A(7:0) = TX_OH_pattern(7:0). The values of the 8 bits in An are such that each bit is the inverse of the corresponding bit in A. For each lane i, the sequence

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

of 8-bit groups is according to the bits in TX_OH_sequence_i(4:0) such that H(*i*,*p*,((*a*+1)*8):(*a**8+1)) is equal to A(7:0) or An(7:0) if TX_OH_sequence_i(*a*) is equal to 0 or 1, respectively, where a ∈ {0,1,2,3,4}.

If the optional Clause 45 MDIO is implemented, the overhead function maps the TX_OH_pattern and TX_OH_sequence_i status variables to the registers and bits defined in 94.2.10. The default values for each of the variables are summarized in Table 94–2.

Table 94–2—Default overhead configuration values

Parameter	Values (binary)
TX_OH_pattern(7:0)	01100110
TX_OH_sequence_0(4:0)	00110
TX_OH_sequence_1(4:0)	01010
TX_OH_sequence_2(4:0)	10101
TX_OH_sequence_3(4:0)	11001

94.2.2.4 Termination Blocks

The PMA transmit process shall create a sequence of termination blocks by inserting two termination bits for every 90 overhead frame bits as specified in this subclause. The termination block is 92 bits in length. The overhead frame mapped into 348 consecutive termination blocks forms a PMA frame.

Each bit in a termination block is denoted T(*i*, *r*, *s*), where:

i is the lane number
r is an index indicating block number and increments at the start of each block
s is an index indicating the bit number within a termination block with a range 1 to 92

The first two bits in each termination block, T(*i*, *r*, 1) and T(*i*, *r*, 2), are populated with the output of a PRBS13 generator of the form specified in 94.3.10.8. For each termination block, the PRBS13 generator generates a block of 92 pseudo-random bits, R(*i*,1:92). The first two bits are used for the termination bits such that T(*i, r,* 1)=R(*i*, 1) and T(*i, r*, 2)=R(*i*, 2). The PRBS13 generator is initialized during training (94.3.10.8). Upon the transition from the last training frame to the first PMA frame the PRBS13 generator used during training advances without reseeding (see 94.3.10.7.2) and without inversion, and the output is used to generate the termination bits. The PRBS13 generator continues to advance without reseeding and without inversion.

The remaining 90 bits of each termination block, T(*i*, *r*, 3) to T(*i*, *r*, 92), are overhead frame bits (see 94.2.2.2). The overhead frame bits are aligned with the termination blocks such that the first overhead bit, V(*i*, *p*, 1), corresponds to the third bit of a termination block, T(*i*, *r*, 3).

Overhead frame bits are mapped to the termination blocks in order of location within the overhead frame, e.g., T(*i*, *r*, 4) = V(*i*, *p*, 2), T(*i*, *r*, 5) = V(*i*, *p*, 3), and so on.

The termination bit PRBS13 generator is initialized during the training process. When training is complete the state of the termination bit PRBS13 generator is retained and the resulting output is used for the termination bits in the PMA frame.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.2.2.5 Gray Mapping

The PMA transmit process shall map consecutive pairs of bits to one of four Gray-coded symbols as specified in this subclause.

Each pair of bits, {A, B}, of each termination block are converted to a Gray-coded symbol with one of the four Gray-coded levels as follows:

{0, 0} maps to 0,
{0, 1} maps to 1,
{1, 1} maps to 2, and
{1, 0} maps to 3.

Gray-coded symbols corresponding to each termination block are denoted G(i, r, t), where:

i is the lane number
r is an index indicating the termination block number
t is an index indicating the symbol number within a termination block with a range 1 to 46

Pairing of bits is such that the first two bits of each termination block, T(i, r, 1) and T(i, r, 2), form a pair. Each bit pair {T(i, r, 2t–1), T(i, r, 2t)} maps to {A, B} and the Gray-coded result is assigned to G(i, r, t). The Gray-coded symbol G(i, r, 1) is formed from the first two bits of a termination block, the termination bits, thus forming a termination symbol.

94.2.2.6 Precoding

The PMA transmit process shall precode the Gray-coded symbols as specified in this subclause.

The precoder output symbols are denoted, P(i, r, t), where:

i is the lane number
r is an index indicating the termination block number
t is an index indicating the symbol number within a termination block with a range 1 to 46.

For each Gray-coded symbol G(i, r, t), a precoded symbol, P(i, r, t) is determined by the following algorithm:

If t = 1 then
    P(i, r, t) = G(i, r, t)
Else
    P(i, r, t) = (G(i, r, t) – P(i, r, t–1)) mod 4
End If

The bits contributing to the Gray-coded termination symbol, G(i, r, 1), are the termination bits. The precoding algorithm applies this symbol directly to the output rather than combining it with the previous non-deterministic symbols and thus this termination symbol is always deterministic.

94.2.2.7 PAM4 encoding

The PMA transmit process shall encode each precoder output symbol to one of four PAM4 levels as specified in this subclause.

The PAM4 encoded symbols are denoted M(i, u), where

i is the lane number
u is an index indicating the symbol number

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each consecutive precoder output symbol, P(*i*, *r*, *t*), is mapped to one of four PAM4 levels and assigned to the PAM4 encoder output M(*i*, u).

Mapping from the precoder output symbol P(*i*, *r*, *t*) to a PAM4 encoded symbol M(*i*, *u*) is as follows:

0 maps to –1,
1 maps to –1/3,
2 maps to +1/3, and
3 maps to +1.

94.2.2.8 PMD Interface

The PMA transmit process shall transmit each PAM4 encoded symbol, M(*i*, *u*) to the PMD via the PMD:IS_UNITDATA_*i*(tx_symbol) primitive at a symbol transfer rate of 13.59375 GBd.

94.2.3 PMA Receive Functional Specifications

The receive process shall recover the data encoded by the transmit process meeting the performance requirements specified in 94.1 after the overhead and termination bits have been removed.

The process by which the receiver recovers the data to meet this requirement is outside the scope of this standard. The signal structure encoded by the transmitter process including the overhead bits, Gray coding, and termination symbols may be leveraged by the receiver implementation at the discretion of the implementer. The remainder of this subclause specifies the receiver processes to reverse the transmitter encoding and report status.

In the received direction, the role of the 100GBASE-KP4 PMA is to adapt the PAM4 encoded signal from the PMD to an FEC encoded signal to be passed to the FEC for further processing. The adaptation processes shown in Figure 94–3 include PAM4 decoding, (1+D) mod 4 decoding, inverse Gray coding, remove termination bits, and remove overhead.

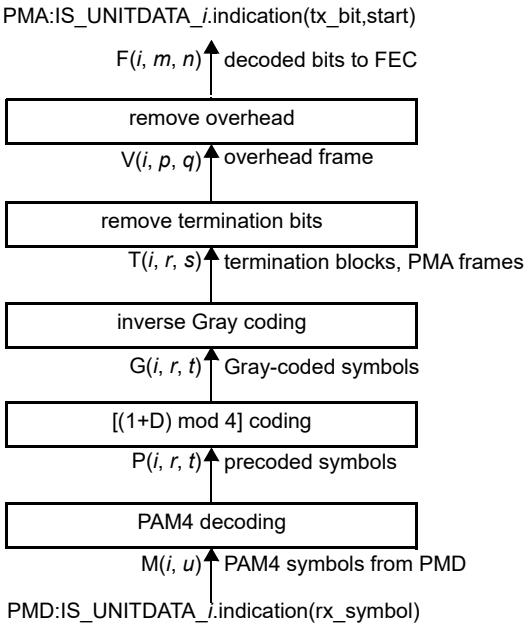

Figure 94–3—Receive adaptation process diagram

94.2.3.1 Overhead

The PMA receive process shall decode the overhead bits in each overhead frame as specified in this subclause. The format of the overhead bits is specified in 94.2.2.3.

The receive process decodes the received overhead bits in a sequence of five groups of 8 bits each into a sequence of 5 bits. Each group of 8 bits is compared with A and An, where A(7:0) = RX_OH_pattern(7:0) and the values of the 8 bits in An are such that each bit is the inverse of the corresponding bit in A. A match of each 8-bit group with A or An results in a decoded value of 0 or 1, respectively. The decoded value when the 8-bit group matches neither A or An is not specified. The decoded values from H(*i*,*p*,((*a*+1)*8):(*a**8+1)) are assigned to RX_OH_sequence_i(*a*), where $a \in \{0,1,2,3,4\}$. If all of the 8-bit groups match either A or An, the RX_OH_sequence_i(5) is set to 1 and is otherwise set to 0.

If the optional Clause 45 MDIO is implemented, the PMA receive process maps the RX_OH_pattern and RX_OH_sequence_i variables to the registers and bits defined in 94.2.10. The default values for each of the control variables are summarized in Table 94–3.

Table 94–3—Default overhead control values

Parameter	Values (binary)
RX_OH_pattern(7:0)	01100110

94.2.4 Skew constraints

Skew considerations for the 100GBASE-KP4 PMA, PMD, and AN are specified in 94.3.4.

94.2.5 Delay constraints

Delay considerations for the 100GBASE-KP4 PMA, PMD, AN, and medium are specified in 94.3.3.

94.2.6 Link status

The PMA shall provide link status information to the PMA client using the PMA:IS_SIGNAL.indication primitive (see 94.2.1.3). The PMA continuously monitors the link status reported by the PMD from the PMD:IS_SIGNAL.indication primitive, and uses this as input to Signal Indication Logic (SIL) to determine the link status to report to the PMA client. Other inputs to the SIL may include status of clock and data recovery on the lanes from the PMD and frame synchronization.

94.2.7 PMA local loopback mode

PMA local loopback shall be provided. This function involves looping back each input lane from the PMA service interface to the corresponding output lane on the PMA service interface. Each received instance of the PMA:IS_UNITDATA_*i*.request(tx_bit,start) primitive is looped back in the direction of the PMA client using the PMA:IS_UNITDATA_*i*.indication(rx_bit,start) primitive.

During local loopback, the PMA performs normal framing and precoding onto the lanes in the Tx direction toward the PMD service interface.

Ability to perform this function is indicated by the Local_loopback_ability status variable. The Local_loopback_ability status variable is always set to 1. If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.8.0 (45.2.1.7.15). A device is placed in local loopback mode when the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Local_loopback_enable control variable is set to one, and removed from local loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD control 1 register (bit 1.0.0, see 45.2.1.1.5).

94.2.8 PMA remote loopback mode (optional)

PMA remote loopback mode is optional. If implemented, it shall be as described in this subclause.

Remote loopback, if provided, should be implemented close enough to the PMD to maintain the bit sequence on each individual PMD lane. When remote loopback is enabled, each bit received over a lane of the service interface below the PMA via PMD:IS_UNITDATA_*i*.indication is looped back to the corresponding output lane toward the PMD via PMD:IS_UNITDATA_*i*.request.

During remote loopback, the PMA performs normal bit processing operation in the Rx direction towards the PMA client.

The ability to perform this function is indicated by the Remote_loopback_ability status variable. If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.13.15 (Clause 45.2.1.2.3). A device is placed in remote loopback mode when the Remote_loopback_enable control variable is set to one, and removed from remote loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD Control register 1 (bit 1.0.1, see Clause 45.2.1.1.4).

94.2.9 PMA test patterns

94.2.9.1 JP03A test pattern

A 100GBASE-KP4 PMA shall include a JP03A test pattern generator as specified in this subclause.

The JP03A test pattern is generated prior to PAM4 encoding. When the JP03A test pattern is enabled, it replaces the signal from the precoder. The JP03A test pattern is a repeating {0,3} sequence.

The JP03A test pattern is enabled by the test_pattern_enable and JP03A_enable control variables. If the optional Clause 45 MDIO is implemented, the control variables map to the registers and bits defined in 94.2.10.

94.2.9.2 JP03B test pattern

A 100GBASE-KP4 PMA shall include a JP03B test pattern generator as specified in this subclause.

The JP03B test pattern is generated prior to PAM4 encoding. When the JP03B test pattern is enabled, it replaces the signal from the precoder. The JP03B test pattern is a repeating sequence of {0,3} repeated 15 times followed by {3,0} repeated 16 times. The entire 62-symbol pattern is shown in Equation (94–1).

$$03030303030303030303030303033030303030303030303030303030303030 \quad (94–1)$$

The JP03B test pattern is enabled by the test_pattern_enable and JP03B_enable control variables. If the optional Clause 45 MDIO is implemented, the control variables map to the registers and bits defined in 94.2.10.

94.2.9.3 Quaternary PRBS13 test pattern

A 100GBASE-KP4 PMA shall include a quaternary PRBS13 (QPRBS13) pattern generator as specified in this subclause.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The QPRBS13 test pattern is a repeating 15548-symbol (338 training frame words) sequence equivalent to the training pattern specified in 94.3.10.8.

The PRBS13 pattern generator is re-initialized for each repetition of QPRBS13 with the same seeds specified in Table 94–11.

The QPRBS13 test pattern is enabled by the test_pattern_enable and QPRBS13_enable control variables. If the optional Clause 45 MDIO is implemented, the control variables map to the registers and bits defined in 94.2.10.

94.2.9.4 Transmitter linearity test pattern

A 100GBASE-KP4 PMA shall include a transmitter linearity test pattern generator as specified in this subclause.

The transmitter linearity test pattern is a repeating 160-symbol pattern with a sequence of 10 symbol values each 16 UI in duration. The 10 values correspond to the set of PAM4 symbols shown in Equation (94–2).

$$\{-1,-1/3,+1/3,+1,-1,+1,-1,+1,+1/3,-1/3\} \quad (94–2)$$

The transmitter linearity test pattern is enabled by the test_pattern_enable and TX_linearity_enable control variables. If the optional Clause 45 MDIO is implemented, the control variables map to the registers and bits defined in 94.2.10.

94.2.10 PMA MDIO function mapping

Clause 45 specifies the optional MDIO capability that describes several registers that provide control and status information for and about the PMA. 45.2.1 describes the Management Data Input/Output (MDIO) Manageable Device (MMD) addresses. If MDIO is implemented, it shall map MDIO control bits to PMA control variables as shown in Table 94–4, and MDIO status bits to PMA status variables as shown in Table 94–5.

Table 94–4—100GBASE-KP4 MDIO/PMA control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMA control variable
PMA local loopback	PMA/PMD control 1	1.0.0	Local_loopback_enable
PMA remote loopback	PMA/PMD status 2	1.0.1	Remote_loopback_enable
PMA Tx generator enable	PRBS pattern testing control	1.1501.3	test_pattern_enable

PMA receive overhead sequence 3	PMA overhead status 2	1.166.11:6	RX_OH_sequence_3

94.3 Physical Medium Dependent (PMD) Sublayer

94.3.1 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-KP4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data. The PMD translates the encoded data to and from signals suitable for the medium.

The PMD service interface is based on the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

If the optional EEE deep sleep capability is supported, then the PMD service interface includes two additional primitives as follows:

PMD:IS_TX_MODE.request
PMD:IS_RX_MODE.request

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.1.1 PMD:IS_UNITDATA_i.request

The PMD:IS_UNITDATA_*i*.request (where *i*=0 to 3) primitive is used to define the transfer of four streams of data units from the PMA to the PMD.

94.3.1.1.1 Semantics of the service primitive

PMD:IS_UNITDATA_0.request(tx_symbol)
PMD:IS_UNITDATA_1.request(tx_symbol)
PMD:IS_UNITDATA_2.request(tx_symbol)
PMD:IS_UNITDATA_3.request(tx_symbol)

The data conveyed by PMD:IS_UNITDATA_i.request consists of four parallel continuous streams of encoded symbols, tx_symbol, one stream for each lane. Each of the tx_symbol parameters can take one of four values: –1, –1/3, +1/3, or +1.

94.3.1.1.2 When generated

The PMA continuously sends four parallel symbol streams PMD:IS_UNITDATA_*i*.request(tx_symbol) to the PMD, each at a nominal signaling rate of 13.59375 GBd.

94.3.1.1.3 Effect of receipt

Upon receiving each instance of PMD:IS_UNITDATA_*i*.request, the tx_symbol parameter is passed to the PMD transmit process corresponding to each stream.

94.3.1.2 PMD:IS_UNITDATA_i.indication

The PMD:IS_UNITDATA_*i*.indication (where *i*=0 to 3) primitive is used to define the transfer of four streams of data units from the PMD to the PMA.

94.3.1.2.1 Semantics of the service primitive

PMD:IS_UNITDATA_0.indication(rx_symbol)
PMD:IS_UNITDATA_1.indication(rx_symbol)
PMD:IS_UNITDATA_2.indication(rx_symbol)
PMD:IS_UNITDATA_3.indication(rx_symbol)

The data conveyed by PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication consists of four parallel continuous streams of encoded symbols, one stream for each lane. Each of the rx_symbol parameters can take one of four values: –1, –1/3, +1/3, or +1.

94.3.1.2.2 When generated

The PMD continuously sends four parallel encoded symbol streams PMD:IS_UNITDATA_*i*.indication(rx_symbol) to the PMD client, each at a nominal signaling rate of 13.59375 GBd.

94.3.1.2.3 Effect of receipt

The effect of receipt of this primitive is undefined by the PMD.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.1.3 PMD:IS_SIGNAL.indication

The PMD:IS_SIGNAL.indication primitive is generated by the PMD to the PMA to indicate the status of the PMD receive process. This primitive is generated by the PMD receive process to propagate the detection of severe error conditions (e.g., loss of synchronization) to the PMA.

94.3.1.3.1 Semantics of the service primitive

PMD:IS_SIGNAL.indication(SIGNAL_OK).

The SIGNAL_OK parameter corresponds to the variable Global_PMD_signal_detect as defined in 94.3.6.4. When Global_PMD_signal_detect is one, SIGNAL_OK shall be assigned the value OK. When Global_PMD_signal_detect is zero, SIGNAL_OK shall be assigned the value FAIL. When SIGNAL_DETECT = FAIL, the PMD:IS_UNITDATA_*i*.indication parameters are undefined.

94.3.1.3.2 When generated

The PMD generates the PMD:IS_SIGNAL.indication primitive to the PMD client whenever there is change in the value of the Global_PMD_signal_detect parameter.

94.3.1.3.3 Effect of receipt

The effect of receipt of this primitive is undefined by the PMD.

94.3.2 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 82.6.)

The 100GBASE-KP4 PHY may be extended using CAUI-n as a physical instantiation of the inter-sublayer service interface between devices. If CAUI-n is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

94.3.3 Delay constraints

The sum of the transmit and the receive delays contributed by the 100GBASE-KP4 PMA, PMD, AN, and the medium in one direction shall be no more than 8192 bit times (16 pause_quanta or 81.92 ns). It is assumed that the one way delay through the medium is no more than 800 bit times (8 ns).

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

94.3.4 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the RS-FEC sublayer. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–9.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 0.4 ns.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 0.6 ns.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5.

94.3.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control bits to PMD control variables as shown in Table 94–6, and MDIO status bits to PMD status variables as shown in Table 94–7.

Table 94–6—100GBASE-KP4 MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable	1.9.0	Global_PMD_transmit_disable
PMD transmit disable 3 to PMD transmit disable 0	PMD transmit disable	1.9.4 to 1.9.1	PMD_transmit_disable_3 to PMD_transmit_disable_0
Restart training	BASE-R PMD control	1.150.0	mr_restart_training
Training enable	BASE-R PMD control	1.150.1	mr_training_enable

94.3.6 PMD functional specifications

94.3.6.1 Link block diagram

One direction for one lane of a 100GBASE-KP4 link is shown in Figure 94–4.

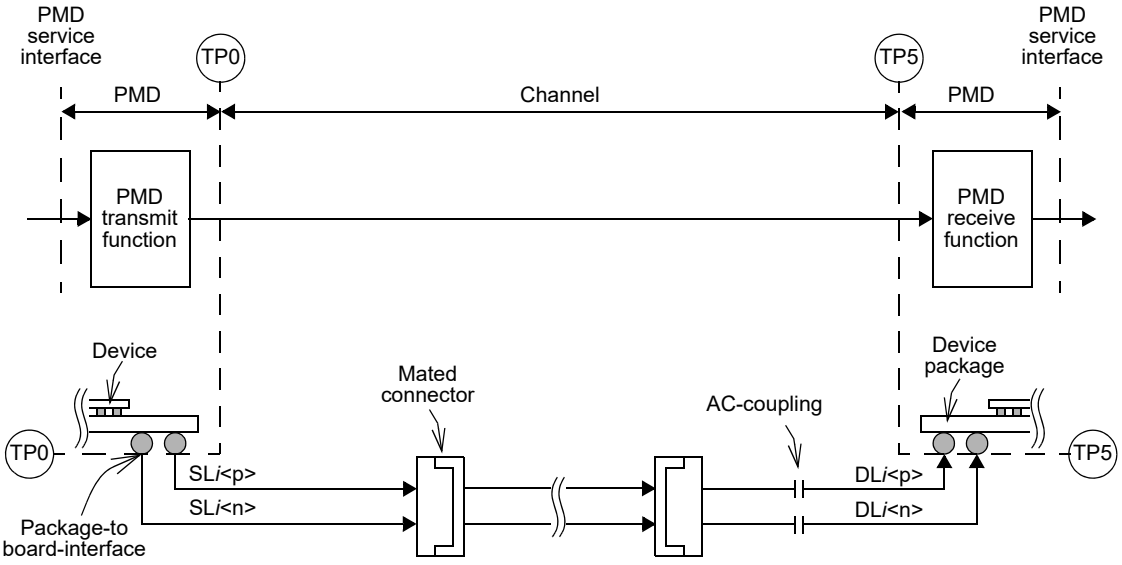

Figure 94–4—100GBASE-KP4 link (one direction for one lane is illustrated)

Copyright © 2022 IEEE. All rights reserved.

94.3.6.2 PMD Transmit function

The PMD transmit function shall convert the four encoded symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_i.request (i=0 to 3) into four separate electrical signals. The four electrical signals shall then be delivered to the MDI, all according to the transmit electrical specifications in 94.3.12. A positive differential output voltage (SL*i*<p> minus SL*i*<n>) shall correspond to a positive tx_symbol value.

If the optional EEE deep sleep capability is supported, the PMD transmit function shall transmit a periodic sequence, where each period of the sequence is an ALERT frame (see 94.3.11.1) when tx_mode is set to ALERT. Regardless of tx_mode, the transmit equalizer coefficients shall be set to the values determined via the startup protocol (see 94.3.10).

94.3.6.3 PMD Receive function

The PMD receive function shall convert the four electrical signals from the MDI into four encoded symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_i.indication (i=0 to 3). A positive differential input voltage of (DL*i*<p> minus DL*i*<n>) shall correspond to a positive rx_symbol value.

94.3.6.4 Global PMD signal detect function

The variable Global_PMD_signal_detect is the logical AND of the values of PMD_signal_detect_i for i=0 to 3.

When the MDIO is implemented, this function maps the variable Global_PMD_signal_detect to the register and bit specified in 94.3.5.

94.3.6.5 PMD lane-by-lane signal detect function

The PMD lane-by-lane signal detect function is used by the 100GBASE-KP4 PMD to indicate the successful completion of the startup protocol by the PMD control function (see 94.3.10). PMD_signal_detect_i (where i represents the lane number in the range 0 to 3) is set to zero when the value of the variable signal_detect is set to false by the Training state diagram for lane i (see Figure 72–5). PMD_signal_detect_i is set to one when the value of signal_detect for lane i is set to true.

If training is disabled by the management variable mr_training_enable (see 94.3.5), PMD_signal_detect_i shall be set to one for i=0 to 3.

If the optional EEE deep sleep capability is supported, the following requirements apply. The value of PMD_signal_detect_i (for i=0 to 3) is set to zero when rx_mode is first set to QUIET. While rx_mode is set to QUIET, PMD_signal_detect_*i* shall be set to one within 500 ns of the application of the ALERT pattern defined in 94.3.6.2 and meeting the EEE transmit-enabled amplitude requirement of 94.3.12.3. While rx_mode is set to QUIET, PMD_signal_detect_*i* shall not be set to one when the output of the transmitter on the same lane meets the EEE transmit-disabled amplitude requirement of 94.3.12.3.

When the MDIO is implemented, this function maps the variables to registers and bits as defined in 94.3.5.

94.3.6.6 Global PMD transmit disable function

The Global PMD transmit disable function is mandatory if EEE deep sleep capability is supported and is otherwise optional. When implemented, it allows all of the transmitters to be disabled with a single variable.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) When Global_PMD_transmit_disable variable is set to one, this function shall turn off all of the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage in Table 94–13.

b) If a PMD fault (94.3.7) is detected, then the PMD may set Global_PMD_transmit_disable to one.

c) Loopback, as defined in 94.3.6.8, shall not be affected by Global_PMD_transmit_disable.

d) The following additional requirements apply when the optional EEE deep sleep capability is supported. The Global PMD transmit disable function shall turn off all of the transmitters as specified in 94.3.12.3 when tx_mode transitions to QUIET from any other value. The Global PMD transmit disable function shall turn on all of the transmitters as specified in 94.3.12.3 when tx_mode transitions from QUIET to any other value.

94.3.6.7 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function is optional and allows the electrical transmitter in each lane to be selectively disabled. When this function is supported, it shall meet the following requirements:

a) When a PMD_transmit_disable_*i* variable (where i represents the lane number in the range 0 to 3) is set to one, this function shall turn off the transmitter associated with that variable such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 94–13.

b) If a PMD_fault (94.3.7) is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the electrical transmitter in each lane.

c) Loopback, as defined in 94.3.6.8, shall not be affected by PMD_transmit_disable_*i.*

94.3.6.8 Loopback mode

Local loopback mode is provided by the PMA (94.2.7). Loopback shall not affect the state of the transmitter, which continues to send data unless disabled (94.3.6.7).

NOTE—Placing a network port into loopback mode can be disruptive to a network.

94.3.7 PMD fault function

PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault.

If the MDIO is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

94.3.8 PMD transmit fault function

The PMD transmit fault function is optional. The faults detected by this function are implementation specific, but the assertion of Global_PMD_transmit_disable is not considered a transmit fault. A fault is indicated by setting the variable PMD_transmit_fault to one.

If PMD_transmit_fault is asserted, then Global_PMD_transmit_disable should also be asserted.

If the MDIO interface is implemented, then this function shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.9 PMD receive fault function

The PMD receive fault function is optional. The faults detected by this function are implementation specific. A fault is indicated by setting the variable PMD_receive_fault to one.

If the MDIO interface is implemented, then PMD_receive_fault shall contribute to the Receive fault bit as specified in 45.2.1.7.5.

94.3.10 PMD control function

94.3.10.1 Overview

The PMD control function generates the control actions required to bring the PMD from initialization to a mode in which data may be exchanged with the link partner.

The PMD control function is based upon the 10GBASE-KR startup protocol. This protocol facilitates timing recovery and equalization while also providing a mechanism through which the receiver can tune the transmit equalizer to optimize performance over the backplane interconnect. The protocol supports these mechanisms through the continuous exchange of fixed-length training frames.

Each lane of the 100GBASE-KP4 PMD shall have an independent control function as defined in this subclause.

The variables rx_trained_*i*, frame_lock_*i*, training_*i,* and training_failure_*i* (where *i* goes from 0 to 3) report status for each lane and are equivalent to rx_trained, frame_lock, training, and training_failure as defined in 72.6.10.3.1. If the MDIO interface is implemented, then this function shall map these variables to the appropriate bits in the BASE-R PMD status register (register 1.151) as specified in 45.2.1.96.

94.3.10.2 Training frame structure

The training frame is a fixed length structure that is sent continuously during training. The training frame, shown in Figure 94–5, is 348 training frame words (94.3.10.3) in length and contains a frame marker, a control channel, and training pattern. The frame marker delimits the beginning of a training frame. The control channel provides a means for the each receiver to control the taps on the link partner transmitter and communicate status. The training pattern provides content rich pattern for receiver convergence.

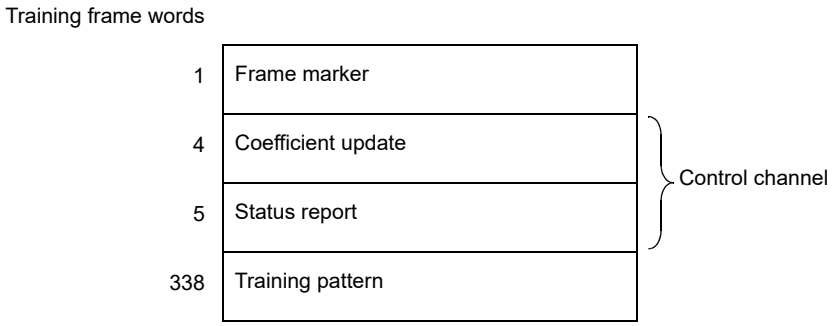

Figure 94–5—Training frame structure

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.10.3 Training frame words

Each training frame is composed of a series of 348 training frame words. Each training frame word is 46 symbols in length, equivalent in size to a termination block described in 94.2.2.4.

94.3.10.4 Frame marker

Each training frame shall be delimited by a frame marker as described in this subclause. The frame marker is a training frame word composed of a 46-symbol pattern of 23 +1 symbols followed by 23 –1 symbols. This pattern does not appear in the control channel or the training pattern and therefore serves as a unique indicator of the start of a training frame.

94.3.10.5 Control channel encoding

94.3.10.5.1 Differential Manchester encoding

The control channel shall be transmitted using differential Manchester encoding (DME). DME guarantees transition density and DC balance while the reduced rate of transmission facilitates reception over non-optimally equalized channels.

DME cells shall be encoded using the following rules:

a) Each DME cell represents one bit of information.
b) The upper value is represented by a series of PAM4 +1 symbols.
c) The lower value is represented by a series of PAM4 –1 symbols.
d) A data transition occurs at each cell boundary.
e) A mid-cell data transition is used to signal a logical one.
f) The absence of a mid-cell data transition is used to signal a logical zero.

If a coding violation is detected within the bounds of the control channel in a given training frame, the contents of the control channel for that frame shall be ignored.

94.3.10.5.2 Control channel structure

The control channel shall be constructed of a series of DME cells as described in this subclause.

The control channel is composed of a series of 9 training frame words. Each training frame word is composed of four 10-symbol control channel DME cells and a 6-symbol control overhead DME cell.

The control overhead cell is always transmitted as a one following the DME rules. In other words, the control overhead cell is transmitted as either three +1 symbols followed by three –1 symbols or vice versa depending on the previously transmitted control channel cell.

The coefficient update field is transmitted in the first 16 control channel DME cells. The status report field is transmitted in the next 24 control channel DME cells. The structure of the frame marker and control channel are shown in Table 94–8.

94.3.10.6 Coefficient update field

The coefficient update field carries correction information from the local receiver to the link partner transmit equalizer. The field consists of preset controls, initialization controls, coefficient updates for three transmit equalizer taps, and parity. The coefficient update field is mapped into the first 16 control channel DME

8	cell 7	cell 6	cell 5	cell 4	overhead	
9	cell 3	cell 2	cell 1	cell 0	overhead	

The format of the coefficient update field shall be as shown in Table 94–9. Cell 15 of the coefficient update field shall be transmitted first. The preset, initialize, and coefficient update fields are set by the receiver adaptation process. The algorithm employed by the receiver adaptation process is beyond the scope of this standard.

Table 94–9—Coefficient update field

Cell(s)	Name	Description
15:14	Reserved	Transmitted as 0, ignored on reception.
13	Preset	1 = Preset coefficients 0 = Normal operation
12	Initialize	1 = Initialize coefficients 0 = Normal operation
11:7	Reserved	Transmitted as 0, ignored on reception.
6	Parity	Even parity of all other coefficient update cells.
5:4	Coefficient (+1) update	5 4 1 1 = reserved 0 1 = increment 1 0 = decrement 0 0 = hold
3:2	Coefficient (0) update	3 2 1 1 = reserved 0 1 = increment 1 0 = decrement 0 0 = hold
1:0	Coefficient (–1) update	1 0 1 1 = reserved 0 1 = increment 1 0 = decrement 0 0 = hold

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.10.6.1 Preset

The behavior in response to the preset field shall be as specified in 72.6.10.2.3.1.

94.3.10.6.2 Initialize

The behavior in response to the initialize field shall be as specified in 72.6.10.2.3.2, except that the conditions for the INITIALIZE state are specified in 94.3.12.5.4 instead of 72.6.10.4.2.

94.3.10.6.3 Parity

The parity bit shall be set so that all bits in the coefficient update field including the parity bit exhibit even parity. The parity bit protects against acceptance of errored control messages and preserves DC balance. If a parity violation is detected within a received coefficient update field, that field shall not be used to update the transmitter coefficients.

94.3.10.6.4 Coefficient (*k*) update

The coefficient update fields shall be encoded as described in this subclause.

Each coefficient, identified by the index k, is assigned a 2-bit field describing a requested update, where $k \in \{-1, 0, 1\}$ denoting the pre-cursor, main, and post-cursor taps, respectively. The encoding of the coefficient update fields are as shown in Table 94–9.

Three request encodings are defined: increment, decrement, and hold. The default state of each tap is hold, which corresponds to no change in the coefficient. The increment or decrement encodings are transmitted to request that the corresponding coefficient be increased or decreased. The amount of change implemented by the transmitter in response to the coefficient update request meets the requirements of 94.3.12.5.5. An increment or decrement request is transmitted continuously until the update status (94.3.10.7.4) for that tap indicates updated, maximum, or minimum. At that point, the outgoing requests for that tap may be set to hold. The hold setting has to be maintained until the incoming status message for that tap reverts to not_updated. A new request to increment or decrement a tap may be sent only when the incoming status message for that tap is not_updated.

Coefficient increment and decrement update requests are not sent in combination with initialize or preset.

94.3.10.7 Status report field

The status report field is used to signal state information from the local PMD to the link partner. The format of the status report field of training frames shall be as shown in Table 94–10. Cell 19 of the status report field shall be transmitted first.

Table 94–10—Status report field for training and alert frames

Cell(s)	Name	Description
19	Parity	Set to achieve even parity for status report field.
18	Mode	0: Training 1: EEE
17:16	Frame countdown	Number of frames remaining before transition to data mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 94–10—Status report field for training and alert frames *(continued)*

Cell(s)	Name	Description
15:13	PMA alignment offset	Relative location of the next alert frame within the PMA frame (set to zero for training frames).
12:7	Reserved	Transmitted as zeros.
6	Receiver ready	1 = The local receiver has determined that training is complete and is prepared to receive data. 0 = The local receiver is requesting that training continue.
5:4	Coefficient (+1) status	5 4 1 1 = maximum 1 0 = minimum 0 1 = updated 0 0 = not_updated (and for EEE alert frames)
3:2	Coefficient (0) status	3 2 1 1 = maximum 1 0 = minimum 0 1 = updated 0 0 = not_updated (and for EEE alert frames)
1:0	Coefficient (–1) status	1 0 1 1 = maximum 1 0 = minimum 0 1 = updated 0 0 = not_updated (and for EEE alert frames)

94.3.10.7.1 Parity

The parity cell shall be set so that all bits in the status report field including the parity bit exhibit even parity. The parity bit protects against acceptance of errored status messages and preserves DC balance. If a parity violation is detected within a received status field, that field shall not be used to determine the link partner status.

94.3.10.7.2 Training frame countdown

The training frame countdown cell shall signal the transition from training to data mode as described in this subclause. When training begins, countdown is set to the value 3 and remains so until all receivers have completed training. When the received status report receiver ready is 1 in all four received lanes and the transmitted status report receiver ready is 1 in all four transmitted lanes, the transmitter on each transmitted lane decrements the countdown in three successive frames. The countdown values are equal in all four lanes. In other words, in the last three training frames countdown contains 2, 1, and 0, respectively. Immediately after the last training frame word of the last training frame is sent, transmission of the PMA frame begins starting with the termination block containing the PMA overhead (see 94.3.10.9).

94.3.10.7.3 Receiver ready

The receiver ready bit shall signal the local receiver state to the link partner as described in this subclause. When training begins the receiver ready bit is deasserted and remains so until the receiver has concluded training. The receiver ready bit is asserted to indicate that the local receiver has concluded training and is prepared to receive data. The encoding of the receiver ready bit is as shown in Table 94–10.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.10.7.4 Coefficient (*k*) status

The behavior of the coefficient (*k*) status fields shall be as specified in 72.6.10.2.4.5.

94.3.10.7.5 Coefficient update process

The coefficient update process shall behave as specified in 72.6.10.2.5.

In addition, the period from receiving a new request to responding to that request shall be less than 2 ms, except during the first 50 ms following the beginning of the startup protocol. The beginning of the startup protocol is defined to be entry into the AN_GOOD_CHECK state in Figure 73–10. The start of the period is the frame marker of the training frame with the new request and the end of the period is the frame marker of the training frame with the corresponding response. A new request occurs when the coefficient update field is different from the coefficient field in the preceding frame. The response occurs when the coefficient status report field is updated to indicate that the corresponding action is complete.

94.3.10.8 Training pattern

The training pattern shall be encoded as specified in this subclause.

The training pattern is mapped into a series of 338 training frame words. Each training frame words is encoded as a PMA signal as specified in 94.2.2 with the exception that the input is from a PRBS13 generator rather than from the PMA service interface and no PMA overhead (94.2.2.2) is inserted.

For each training frame, the PRBS13 generator is used to produce 31096 bits. Three full cycles of 8191 bits and one truncated cycle of 6523 bits are concatenated to form the 31096 bit sequence, R(1:31096). Bits in the first and third cycle, R(1:8191) and R(16383:24573), are not inverted and bits in the second and fourth cycles, R(8192:16382) and R(24574:31096), are inverted.

The PRBS13 pattern generator produces the same result as the implementation shown in Figure 94–6, which implements the generator polynomial shown in Equation (94–3). The PRBS13 pattern generator is initialized for each frame using a unique seed for each lane. The 13-bit seed and the initial 16 bits for each lane are annotated in Table 94–11.

$$G(x) = 1 + x + x^2 + x^{12} + x^{13} \tag{94–3}$$

The PRBS13 pattern is mapped into the 92 bits of each training frame word. The first 2 bits of each training frame word form the termination bits (94.2.2.4) and each training frame word in the training pattern is equivalent to a termination block (94.2.2.4). The resulting termination blocks are Gray-mapped (94.2.2.5), precoded (94.2.2.6), and mapped to PAM4 levels (94.2.2.7).

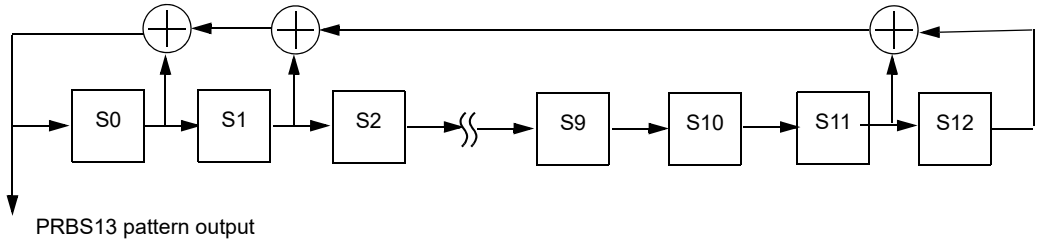

Figure 94–6—PRBS13 pattern generator

The outputs of PRBS13 generator, Gray mapper, and precoder for the first two training frame words are provided in Table 94–12.

94.3.10.9 Transition from training to data

The transmitted signal shall transition from the training signal to normal data as described in this subclause.

The transition from the training signal to normal data occurs when the training countdown is complete, as indicated by the training frame countdown being equal to 0 (94.3.10.7.2). Immediately after the last bit of the last training frame, transmission of the first PMA frame (94.2.2.4) begins with the termination block containing the overhead, T(i,1,1:92). The PRBS13 generator used during training to generate the training pattern is used to generate the termination bits in data mode. The state of the training PRBS13 generator is retained and 92 new bits are generated without reseeding or inverting. Termination bits are assigned and the PRBS13 generator continues to operate as specified in 94.2.2.4. The transition from training to data mode and mapping of the PRBS13 to training frame and termination bits is depicted in Figure 94–7.

94.3.10.10 Frame lock state diagram

The 10GBASE-KP4 PMD shall implement the frame lock state diagram as depicted in Figure 72–4 including compliance with the associated state variables, timers, counters, and functions specified in 72.6.10.3. The frame lock state diagram determines when the PMD control function has detected the frame boundaries in the received data stream.

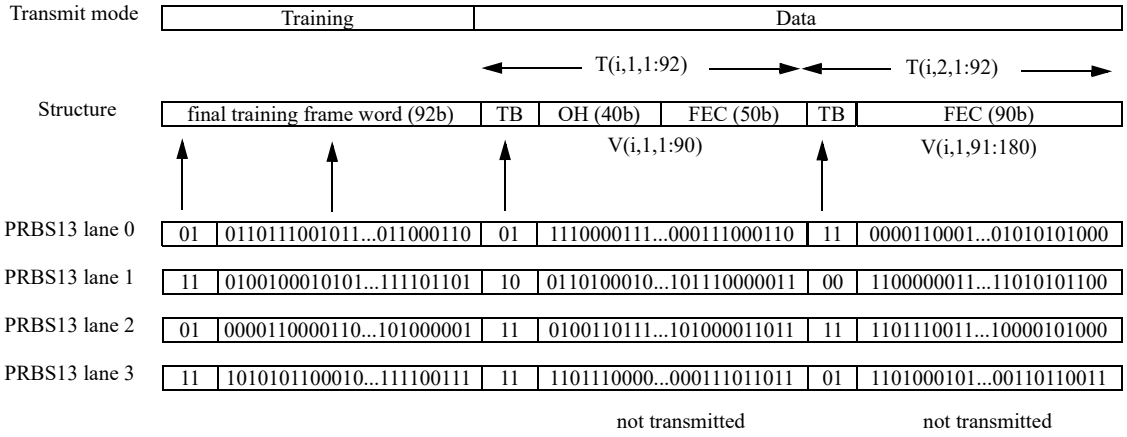

Figure 94–7—Transition from training to data mode

94.3.10.11 Training state diagram

The 10GBASE-KP4 PMD shall implement the training state diagram as depicted in Figure 72–5 including compliance with the associated state variables specified in 72.6.10.3. The training state diagram defines the operation of the 100GBASE-KP4 startup protocol.

When the training state diagram enters the INITIALIZE state, the transmitter equalizer shall be configured such that the output meets the requirements of 94.3.12.5.4.

94.3.10.12 Coefficient update state diagram

For each tap, the 100GBASE-KP4 PMD shall implement an instance of the coefficient update state diagram in Figure 72–6 including compliance with the associated state variables as specified in 72.6.10.3. The coefficient update state diagram defines the process for updating transmit equalizer coefficients in response to requests from the link partner and also defines the coefficient update status to be reported in outgoing training frames.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.11 PMD LPI function

The PMD LPI function responds to the transitions between Active, Sleep, Quiet, Refresh, and Wake states via the PMD:IS_TX_MODE.request and PMD:IS_RX_MODE.request. Implementation of the function is optional. EEE capabilities and parameters are advertised during the Backplane Auto-negotiation, as described in 45.2.7.14. The transmitter on the local device informs the link partner's receiver when to sleep, refresh, and wake. The local receiver transitions are controlled by the link partner's transmitter and can change independent of the local transmitter states and transitions.

94.3.11.1 Alert Signal

During refresh and wake, to enable effective detection and quick receiver synchronization, an alert frame is sent prior to sending normal PMA frames. The alert signal is a series of repeating alert frames.

The alert frame shall be composed of a frame marker, control channel, and training pattern as depicted in Figure 94–8. The alert frame is based on the training frame specified in 94.3.10.2. The distinguishing differences are that the training pattern is truncated to 48 training frame words (4416 bits) and the coefficient update and status report fields are encoded differently. The alert frame is a total of 58 training frame words in length.

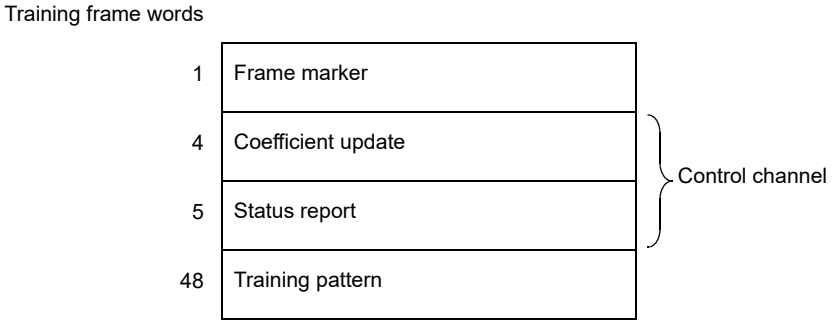

Figure 94–8—Alert frame structure

94.3.11.1.1 Frame marker

The frame marker shall be implemented as specified in 94.3.10.4.

94.3.11.1.2 Coefficient update field

The coefficient update field is unused in the alert frame. All bits in the coefficient update field are reserved and shall be transmitted as zeros.

94.3.11.1.3 Status report field

The status report field is used to signal state information from the local PMD to the link partner. The format of the status report field of alert frames shall be as shown in Table 94–10. Cell 19 of the status report field shall be transmitted first.

94.3.11.1.4 Parity

The parity field shall have the same behavior and purpose as specified for the training frame in 94.3.10.7.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.3.11.1.5 Mode

The mode field indicates whether the frame is a training frame (mode = 0) or an alert frame (mode = 1). This field differentiates the alert frame from a training frame. The mode field in the alert frame shall always indicate 1.

94.3.11.1.6 Alert frame countdown

The alert frame countdown field shall be updated as specified for the training frame in 94.3.10.7.2. The alert frame countdown may be used by the receiver to determine when the signal transitions from the alert frame to the PMA frame (see 94.3.11.1.9).

94.3.11.1.7 PMA alignment offset

The PMA alignment offset (PAO) shall indicate the relative position in the PMA frame in relation to the beginning of the next alert frame as described in this subclause. The PMA alignment offset may be used by the receiver to synchronize to the PMA frame without an additional frame synchronization process (see 94.3.11.1.9). The beginning of the PMA frame is defined as the termination block containing the PMA overhead (94.2.2.2).

The PMA frame length is exactly 6 times the alert frame length. The PMA alignment offset field indicates one of six offsets for the next alert frame within the PMA frame. The offset in number of training frame words of the next alert frame is determined by multiplying PMA alignment offset by 32. As a reference point, a PMA alignment offset of zero indicates that the start of the next alert frame is aligned with the start of a PMA frame. Valid values for the PMA alignment offset are {0,1,2,3,4,5}. The values {6,7} are not valid.

94.3.11.1.8 Receiver ready

The receiver ready cell shall always be set to 1 to indicate training is complete and the link is up.

94.3.11.1.9 Transition from alert to data

The transmitted signal shall transition from the alert signal to normal data as described in this subclause.

The transition from the alert signal to normal data occurs when the alert countdown is complete, as indicated by the alert frame countdown being equal to 0 (94.3.11.1.6). Immediately after the last bit of the last alert frame, transmission of the first PMA frame (94.2.2.4) begins with the termination block indicated by the PMA alignment offset, T(i,32*PAO,1:92). The PRBS13 generator used during alert to generate the training pattern is used to generate the termination bits in data mode. The state of the training PRBS13 generator is retained and 92 new bits are generated without reseeding or inverting. Termination bits are assigned and the PRBS13 generator continues to operate as specified in 94.2.2.4. The transition from alert to data mode and mapping of the PRBS13 to alert frame and termination bits is depicted in Figure 94–9. The values for the PRBS13 in Figure 94–9 are specific to a transition with a PAO of zero. The values are different for other PAO values.

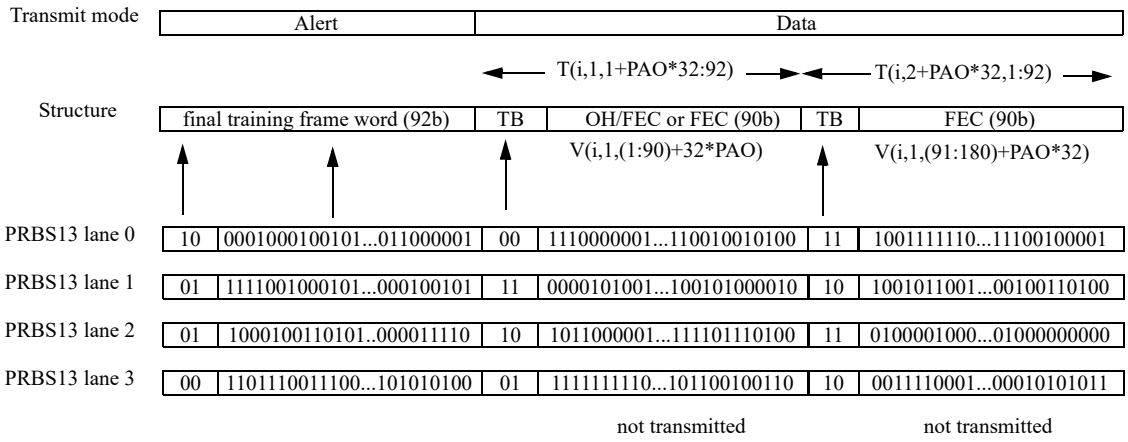

Figure 94–9—Transition from alert to data mode

94.3.12 PMD Transmitter electrical characteristics

Transmitter characteristics measured at TP0a are summarized in Table 94–13.

94.3.12.1 Test fixture

The test fixture of Figure 94–10 or its equivalent is required for measuring the transmitter specifications described in 94.3.12.

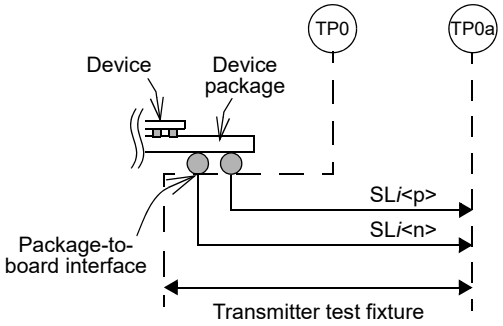

Figure 94–10—Transmitter test fixture and test points

94.3.12.1.1 Test fixture impedance

The differential load impedance applied to the transmitter output by the test fixture depicted in Figure 94–10 shall be 100 Ω.

The differential return loss, in dB with f in GHz, of the test fixture shall meet the requirement of Equation (94–4). The return loss limit $RL_{\min}(f)$ is shown Figure 94–11.

$$RL(f) \geq RL_{\min}(f) = \left\{ \begin{array}{ll} 20 - f & 0.05 \leq f \leq 5 \\ 15 & 5 < f \leq 13 \\ 20.57 - 0.4286f & 13 < f \leq 14 \end{array} \right\} \text{ (dB)} \qquad (94\text{–}4)$$

The common-mode return loss, in dB, with f in GHz, of the test fixture shall meet the requirement of Equation (94–5). The return loss limit $RL_{\min}(f)$ is shown Figure 94–12.

$$RL(f) \geq RL_{\min}(f) = 10 \text{ (dB)} \qquad 0.05 \leq f \leq 14 \qquad (94\text{–}5)$$

94.3.12.1.2 Test fixture insertion loss

The insertion loss of the test fixture measured at 12.89 GHz shall be between 1.2 dB and 1.6 dB.

The insertion loss deviation of the test fixture from 0.05 GHz to 10 GHz shall be less than 0.1 dB.

The reference insertion loss of the test fixture is defined by Equation (94–6), where f is the frequency in GHz, and is shown in Figure 94–13.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

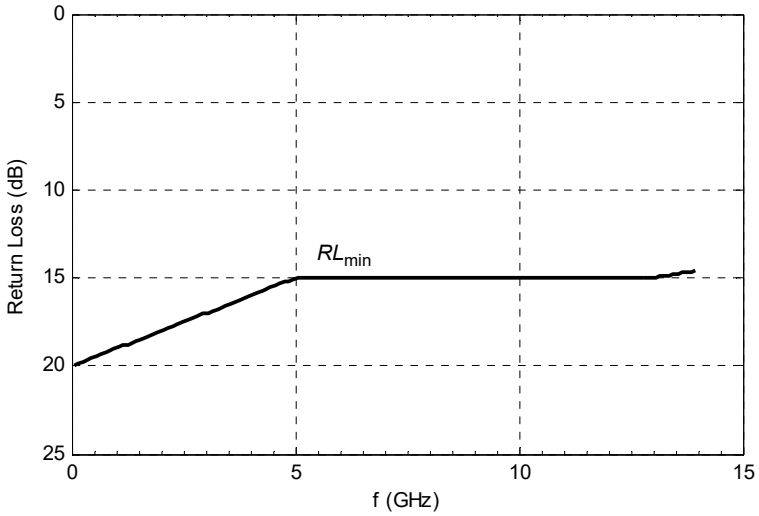

Figure 94–11—Test fixture differential return loss limit

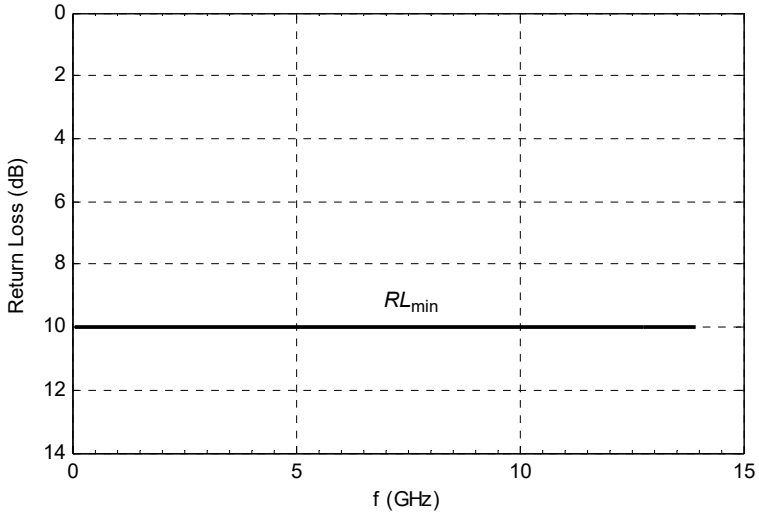

Figure 94–12—Test fixture common-mode return loss limit

$$IL_{ref}(f) = -0.0015 + 0.144\sqrt{f} + 0.069f \ \text{(dB)} \qquad 0.05 \le f \le 14 \tag{94–6}$$

The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements.

A test system with a fourth-order Bessel-Thomson low-pass response with 17 GHz 3 dB bandwidth is to be used for all transmitter signal measurements, unless otherwise specified.

94.3.12.2 Signaling rate and range

The 100GBASE-KP4 signaling rate shall be 13.59375 GBd ± 100 ppm per lane.

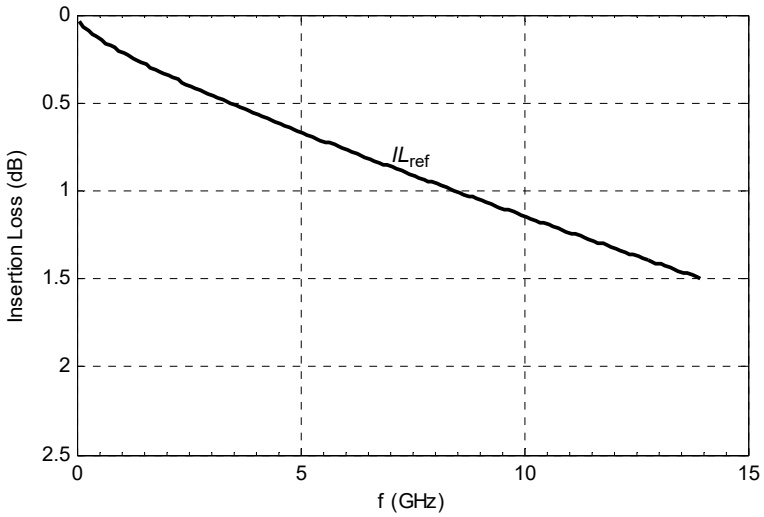

Figure 94–13—Test fixture reference insertion loss

94.3.12.3 Signal levels

The differential output voltage v_{di} is defined to be SL*i*<p> minus SL*i*<n>. The common-mode output voltage v_{cmi} is defined to be one half of the sum of SL*i*<p> and SL*i*<n>. These definitions are illustrated by Figure 94–14.

For a QPRBS13 test pattern (94.2.9.3), the peak-to-peak differential output voltage shall be less than or equal to 1200 mV regardless of the transmit equalizer setting. The peak-to-peak differential output voltage shall be less than or equal to 30 mV while the transmitter is disabled (refer to 94.3.6.6 and 94.3.6.7).

The DC common-mode output voltage shall be between 0 V and 1.9 V with respect to signal ground. The AC common-mode output voltage shall be less than or equal to 30 mV RMS with respect to signal ground. Common-mode output voltage requirements shall be met regardless of the transmit equalizer setting.

If the optional EEE deep sleep capability is supported, the following requirements also apply. The peak-to-peak differential output voltage shall be less than 30 mV within 500 ns of the transmitter being disabled.

When the transmitter transitions from disabled to enabled: (a) The amplitude of the frame marker of the third complete alert frame (see 94.3.11.1) after the transmitter is enabled shall be greater than 90% of the steady-state value (see 94.3.12.5.3), and (b) the transmitter output shall meet the requirements of 94.3.12 within 1 μs of the transmitter being enabled.

While the transmitter is disabled, the DC common-mode output voltage shall be maintained to within ±150 mV of the value for the enabled transmitter.

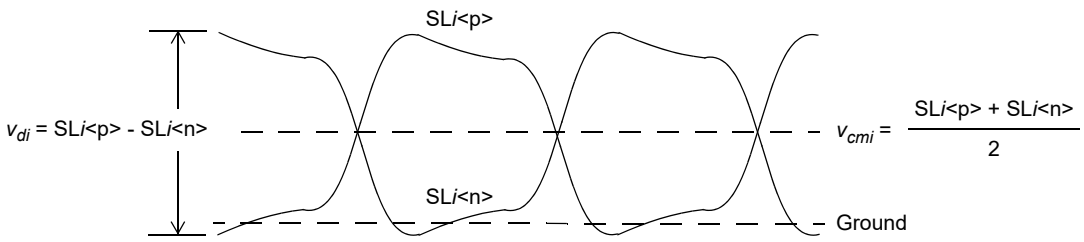

Figure 94–14—Transmitter output voltage definitions

94.3.12.4 Transmitter output return loss

The differential output return loss, in dB, of the transmitter shall meet Equation (94–7), where *f* is the frequency in GHz. The return loss limit $RL_{\min}(f)$ is shown Figure 94–15. This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$RL(f) \geq RL_{\min}(f) = \left\{ \begin{array}{cc} 12.05 - f & 0.05 \leq f \leq 6 \\ 6.5 - 0.075f & 6 < f \leq 10 \end{array} \right\} \quad \text{(dB)} \tag{94–7}$$

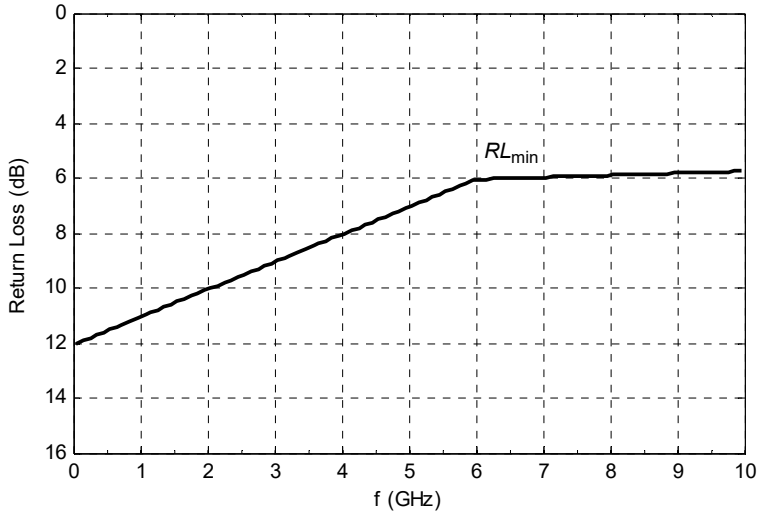

Figure 94–15—Transmitter differential return loss limit

The common-mode output return loss, in dB, of the transmitter shall meet Equation (94–8), where *f* is the frequency in GHz. The return loss limit $RL_{\min}(f)$ is shown Figure 94–16. This output impedance requirement applies to all valid output levels. The reference impedance for common-mode return loss measurements shall be 25 Ω.

$$RL(f) \geq RL_{\min}(f) = \left\{ \begin{array}{cc} 9.05 - f & 0.05 \leq f \leq 6 \\ 3.5 - 0.075f & 6 < f \leq 10 \end{array} \right\} \quad \text{(dB)} \tag{94–8}$$

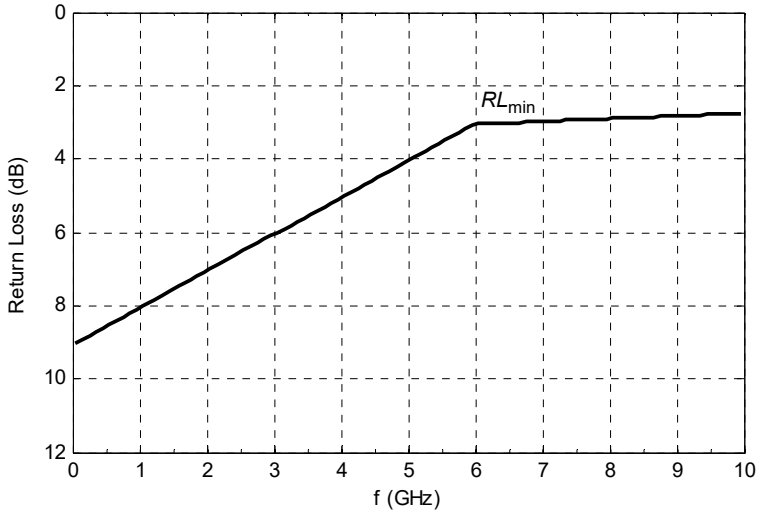

Figure 94–16—Transmitter common-mode return loss limit

94.3.12.5 Transmitter output waveform

The 100GBASE-KP4 transmit function includes programmable equalization to compensate for the frequency-dependent loss of the channel and facilitate data recovery at the receiver. The functional model for the transmit equalizer is the three tap transversal filter shown in Figure 94–17.

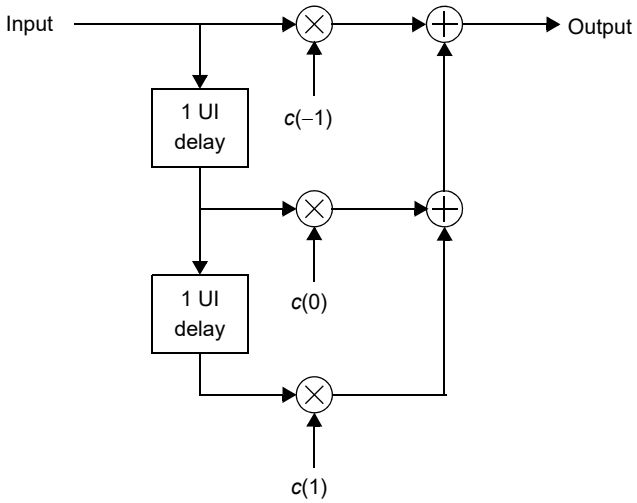

Figure 94–17—Transmit equalizer functional model

The state of the transmit equalizer and hence the transmitted output waveform may be manipulated via the PMD control function defined in 94.3.10 or via the management interface. The transmit function responds to a set of commands issued by the link partner's receive function and conveyed by a back-channel communications path.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This command set includes instructions to:

Increment coefficient $c(i)$.
Decrement coefficient $c(i)$.
Hold coefficient $c(i)$ at its current value.
Set the coefficients to a predefined value (preset or initialize).

In response, the transmit function relays status information to the link partner's receive function. The status messages indicate that:

The requested update to coefficient $c(i)$ has completed (updated).
Coefficient $c(i)$ is at its minimum value.
Coefficient $c(i)$ is at its maximum value.
Coefficient $c(i)$ is ready for the next update request (not_updated).

94.3.12.5.1 Transmitter linearity

Transmitter linearity is measured using the transmitter linearity test pattern (see 94.2.9.4).

The resulting waveform is shown in Figure 94–18. Each measured level, V_A, V_B, V_C, and V_D, is measured within a 2 UI period starting 7 UI after the last level transition time. The minimum signal level, S_{min}, effective symbol levels ES_1 and ES_2, and level separation mismatch ratio, R_{LM}, are calculated based on Equation (94–9), Equation (94–10), Equation (94–11), Equation (94–12), and Equation (94–13), respectively.

The level separation mismatch ratio shall be greater than 0.92.

$$S_{\text{min}} = \frac{\min(V_D - V_C, V_C - V_B, V_B - V_A)}{2} \tag{94–9}$$

$$V_{\text{avg}} = \frac{V_A + V_B + V_C + V_D}{4} \tag{94–10}$$

$$ES_1 = \frac{V_B - V_{\text{avg}}}{V_A - V_{\text{avg}}} \tag{94–11}$$

$$ES_2 = \frac{V_C - V_{\text{avg}}}{V_D - V_{\text{avg}}} \tag{94–12}$$

$$R_{\text{LM}} = \frac{6 \cdot S_{\text{min}}}{V_D - V_A} \tag{94–13}$$

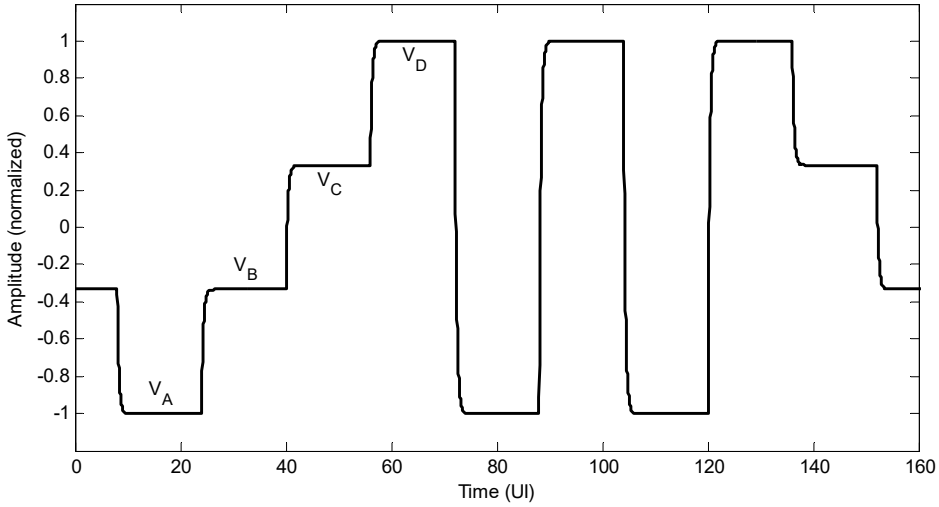

Figure 94–18—Transmitter linearity test pattern

94.3.12.5.2 Linear fit to the measured waveform

The following test procedure shall be followed to determine the linear fit pulse response, linear fit error, and normalized transmitter coefficient values.

For each configuration of the transmit equalizer, capture at least one complete cycle of the QPRBS13 test pattern (94.2.9.3) at TP0a per 85.8.3.3.4.

Compute the linear fit pulse response $p(k)$ from the captured waveform per 85.8.3.3.5 using $N_p = 16$ and $D_p = 2$. For aligned symbol values x(n) use –1, $-ES_1$, ES_2, and 1 to represent symbol values of 0, 1, 2, and 3, respectively, and where ES_1 and ES_2 are the effective symbol levels determined in 94.3.12.5.1.

Define $r(k)$ to be the linear fit pulse response when transmit equalizer coefficients have been set to the "preset" values (72.6.10.2.3.1).

For each configuration of the transmit equalizer, compute the normalized transmit equalizer coefficients, *c(i)*, according to 92.8.3.5.1.

94.3.12.5.3 Steady-state voltage and linear fit pulse peak

The linear fit pulse, $p(k)$, is determined according to the linear fit procedure in 94.3.12.5.2. The steady-state voltage v_f is defined to be the sum of the linear fit pulse $p(k)$ divided by M, determined in step 3 of the linear fit procedure.

The steady-state voltage shall be greater than or equal to 0.4 V and less than or equal to 0.6 V.

The peak value of $p(k)$ shall be greater than $0.85 \times v_f$.

94.3.12.5.4 Coefficient initialization

When the PMD enters the INITIALIZE state of the Training state diagram (Figure 72–5) or receives a valid request to "initialize" from the link partner, the coefficients of the transmit equalizer shall be configured such that the ratio (c(0)+c(1)–c(–1))/(c(0)+c(1)+c(–1)) is 1.29 ±10%, the ratio

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

(c(0)–c(1)+c(–1))/(c(0)+c(1)+c(–1)) is 2.57 ±10%, and the steady-state voltage, v_f, (see 94.3.12.5) is greater than or equal to 140 mV. These requirements apply upon the assertion of a coefficient status report of "updated" for all coefficients.

94.3.12.5.5 Coefficient step size

The normalized amplitude of each coefficient $c(i)$ is determined according to the linear fit procedure in 94.3.12.5.2.

The change in the normalized amplitude of coefficient $c(i)$ corresponding to a request to "increment" that coefficient shall be between 0.0083 and 0.05. The change in the normalized amplitude of coefficient $c(i)$ corresponding to a request to "decrement" that coefficient shall be between –0.05 and –0.0083.

The change in the normalized amplitude of the coefficient is defined to be the difference in the value measured prior to the assertion of the "increment" or "decrement" request (e.g., the coefficient update request for all coefficients is "hold") and the value upon the assertion of a coefficient status report of "updated" for that coefficient.

94.3.12.5.6 Coefficient range

When sufficient "increment" or "decrement" requests have been received for a given coefficient, the coefficient reaches a lower or upper bound based on the coefficient range or restrictions placed on the minimum steady-state differential output voltage or the maximum peak-to-peak differential output voltage.

With $c(-1)$ set to zero and both $c(0)$ and $c(1)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0)–c(1))/(c(0)+c(1))$ shall be greater than or equal to 4.

With $c(1)$ set to zero and both $c(-1)$ and $c(0)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0)–c(-1))/(c(0)+c(-1))$ shall be greater than or equal to 1.54.

Note that a coefficient may be set to zero by first asserting the preset control and then manipulating the other coefficients as required by the test.

94.3.12.6 Transmitter output jitter

Jitter measurements in this subclause are performed with transmitters on all PMD lanes enabled and transmitting the same pattern with identical transmit equalizer settings.

94.3.12.6.1 Clock random jitter and clock deterministic jitter

Clock random jitter (CRJrms) measured at the transmitter output using the methodology described in this subclause shall be less than 0.005 UI RMS regardless of transmit equalization setting.

Clock deterministic jitter (CDJ) measured at the transmitter output using the methodology described in this subclause shall be less than 0.05 UI peak-to-peak regardless of transmit equalization setting.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

CRJrms and CDJ are determined using the following procedure:

1) CRJrms and CDJ are measured using the JP03A test pattern (94.2.9.1).
2) Using appropriate test equipment and procedure, capture the zero-crossing times, $T_{ZC}(i)$, of a pattern of length, N, of 10^7 symbols or greater.
3) Determine the average pulse width ΔT_{Avg} using Equation (94–14).
4) Determine the jitter series, $\tau(k)$, using Equation (94–15).
5) Apply the effect of a high-pass filter with the response given by Equation (94–16) to the jitter samples to obtain $\tau_{HPF}(k)$, where f is the frequency in MHz, f_n is 2.12 MHz, T is 0.0286 μs, and $j = \sqrt{-1}$.
6) Create a CDF as a function of $\tau_{HPF}(k)$.
7) From the CDF, determine J_5 as the difference between τ_{HPF} at the $(1–0.5 \times 10^{-5})$ and 0.5×10^{-5} probabilities, respectively, and J_6 as the difference between τ_{HPF} at the $(1–0.5 \times 10^{-6})$ and 0.5×10^{-6} probabilities, respectively.
8) Calculate CRJrms and CDJ using the relationship in Equation (94–17).

$$\Delta T_{Avg} = \frac{T_{ZC}(N) - T_{ZC}(1)}{N-1} \tag{94–14}$$

$$\tau(k) = T_{ZC}(k) - (k-1)\cdot\Delta T_{Avg} - T_{ZC}(1) \qquad k = 2, 3, \ldots N \tag{94–15}$$

$$G(f) = \frac{f}{f - j \times f_n e^{(-j2\pi fT)}} \tag{94–16}$$

$$\begin{bmatrix} CRJrms \\ CDJ \end{bmatrix} = \begin{bmatrix} 1.0538 & -1.0538 \\ -9.3098 & 10.3098 \end{bmatrix} \begin{bmatrix} J_6 \\ J_5 \end{bmatrix} \tag{94–17}$$

94.3.12.6.2 Even-odd jitter

Even-odd jitter (EOJ) measured at the transmitter output using the methodology described in this subclause shall be less than 0.019 UI peak-to-peak regardless of transmit equalization setting.

EOJ is determined using the following procedure:

1) EOJ is measured using the JP03B test pattern (94.2.9.2).
2) Using appropriate test equipment and procedure, capture the time for each of the 60 transitions.
3) Averaging of the vertical waveform or of each zero-crossing time is recommended to mitigate the contribution of uncorrelated noise and jitter.
4) Denote the averaged zero-crossing times as $T_{ZC}(i)$, where i = {1,2,...60} and where i = 1 designates the transition from 3 to 0 after the consecutive pair of symbols {3,3}.
5) The set of 40 pulse widths, $\Delta T(j)$, isolated from the double-width pulses are determined using the relationship in Equation (94–18).
6) EOJ is calculated using the relationship in Equation (94–19).

$$\Delta T(j) = \left\{ \begin{array}{ll} T_{ZC}(j+10) - T_{ZC}(j+9) & 1 \le j \le 20 \\ T_{ZC}(j+19) - T_{ZC}(j+18) & 21 \le j \le 40 \end{array} \right\} \tag{94–18}$$

$$EOJ = \frac{\left| \sum_{j=1}^{20} \Delta T(2 \cdot j) - \sum_{j=1}^{20} \Delta T(2 \cdot j - 1) \right|}{40} \quad (94\text{–}19)$$

94.3.12.7 Transmitter signal-to-noise-and-distortion ratio (SNDR)

Signal-to-noise-and-distortion ratio (SNDR) is measured at the transmitter output using the following method, with transmitters on all PMD lanes enabled and transmitting the same pattern with identical transmit equalizer settings.

Compute the linear fit to the captured waveform and the linear fit pulse response, $p(k)$, and error, $e(k)$, according to 94.3.12.5.2. Denote the standard deviation of $e(k)$ as σ_e.

Given the same configuration of the transmit equalizer, measure the RMS deviation from the mean voltage at a fixed point in a run of at least 8 consecutive identical levels. The transmitter linearity test pattern as specified in 94.3.12.5.1 is an example of a pattern that includes runs suitable to perform the measurement. The RMS deviation is measured for a run of each of the four levels. The average of the four measurements is denoted as σ_n.

SNDR is defined by Equation (94–20) where $p_{\max}$ is the maximum value of $p(k)$.

$$SNDR = 10\log_{10}\left(\frac{p_{\max}^2}{\sigma_e^2 + \sigma_n^2}\right) \text{ (dB)} \quad (94\text{–}20)$$

SNDR shall be greater than 31 dB for any allowable transmit equalizer setting.

94.3.13 PMD Receiver electrical characteristics

Receiver characteristics measured at TP5a are summarized in Table 94–14.

Table 94–14—Summary of receiver characteristics at TP5a

Parameter	Subclause reference	Value	Units
Differential input return loss (min.)	94.3.13.2	Equation (94–7)	dB
Differential to common-mode return loss (min.)	94.3.13.2	Equation (94–21)	dB
Interference tolerance	94.3.13.3	Table 94–15	—
Jitter tolerance	94.3.13.4	Table 94–16	—

94.3.13.1 Test fixture

The test fixture of Figure 94–19 or its equivalent is required for measuring the receiver specifications described in 94.3.13. The test fixture shall meet the requirements for insertion loss, insertion loss deviation, differential return loss, and common-mode return loss in 94.3.12.1.

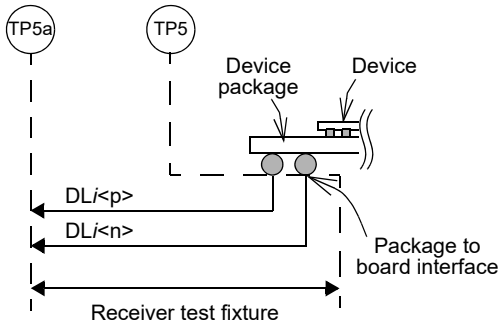

Figure 94–19—Receiver test fixture and test points

94.3.13.2 Receiver input return loss

The differential input return loss, in dB, of the receiver shall meet Equation (94–7). The reference impedance for differential return loss measurements shall be 100 Ω.

The differential to common-mode return loss, in dB, of the receiver shall meet Equation (94–21). The return loss limit $RL_{\min}(f)$ is shown Figure 94–20.

$$RL(f) \geq RL_{\min}(f) = \left\{ \begin{array}{cc} 25 - 1.44f & 0.05 \leq f \leq 6.95\text{GHz} \\ 15 & 6.95 \leq f \leq 10\text{GHz} \end{array} \right\} \text{ (dB)} \quad (94\text{–}21)$$

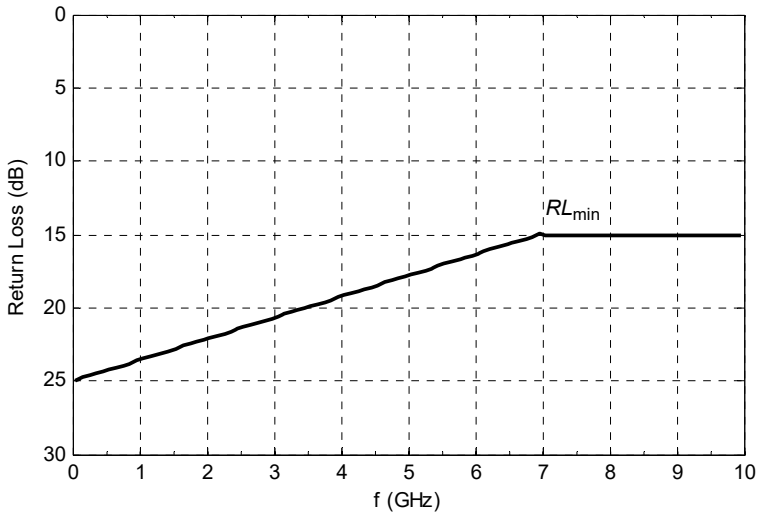

Figure 94–20—Receiver differential to common-mode return loss limit

94.3.13.3 Receiver interference tolerance

Receiver interference tolerance is defined by the procedure in Annex 93C. The receiver on each lane shall meet the FEC symbol error ratio requirement with channels matching the Channel Operating Margin (COM) and loss parameters for Test 1 and Test 2 in Table 94–15. Example fitted-insertion-loss curves for Test 1 and Test 2, as well as bounds resulting from the constraints on the fitted-insertion-loss coefficients with insertion loss at the limit specified for each test, are shown in Figure 94–21 and Figure 94–22, respectively. The

parameter RSS_DFE4 in Table 94–15 is a figure of merit for the test channel that is defined by Equation (93A–50) (see 93A.2).

The following considerations apply to the interference tolerance test. The transmitter noise parameter is SNDR (see 94.3.12.7). The transmitter output levels are set such that R_{LM} is equal to 0.92. The test transmitter meets the specifications in 94.3.12. The test transmitter is constrained such that for any transmitter equalizer setting the differential peak-to-peak voltage (see 94.3.12.3) is less than 800 mV, the pre-cursor peaking ratio (see 94.3.12.5.6) is less than 1.54, and the post-cursor peaking ratio (see 94.3.12.5.6) is less than 4. The lower frequency bound for the noise spectral density constraints, f_{NSD1}, is 1 GHz. The jitter parameters to be measured are CRJrms and CDJ (see 94.3.12.6.1). The return loss of the test setup in Figure 93C–4 measured at TP5 replica meets the requirements of Equation (94–4). The COM parameter σ_{RJ} is set to the measured value of CRJrms and the COM parameter A_{DD} is set to half the measured value of CDJ. Other COM parameters are set according to the values in Table 94–17. The test pattern to be used is the scrambled idles test pattern. A test system with a fourth-order Bessel-Thomson low-pass response with 17 GHz 3 dB bandwidth is to be used for measurement of the signal applied by the pattern generator and for measurements of the broadband noise.

Table 94–15—Receiver interference tolerance parameters

Parameter	Test 1 values		Test 2 values		Units
	Min	Max	Min	Max	
FEC symbol error ratio[a]	—	3.3×10^{-3}	—	3.3×10^{-3}	
COM, including effects of broadband noise[b]	3		3		dB
Insertion loss at 7 GHz[c]	—	14.4	33	—	dB
Fitted insertion loss coefficients[d]: a_0 a_1 a_2 a_4	 –1.5 0 0 0	 1 1.6 1.6 0.03	 –1.5 0 0 0	 2 3.8 4.2 0.065	 dB dB/√GHz dB/GHz dB/GHz^2
RSS_DFE4	0.05	—	0.05	—	—

[a]The FEC symbol error ratio is measured in step 10 of the interference tolerance test method in 93C.2.
[b]The COM value is the target for the receiver noise level calibration defined in 93C.2 step 7. The channel noise voltage applied in 93C.2 step 8 should be as close as practical to the value needed to produce the target COM. If higher channel noise voltage values are used, this would demonstrate margin to the specification but this is not required for compliance.
[c]Measured between TPt and TP5 (see Figure 93C–4).
[d]Coefficients are determined from insertion loss measured between TPt and TP5 (see Figure 93C–4) using the methodology in 93A.3 with f_{min} of 0.05 GHz, f_{max} of 13.59375 GHz, and maximum Δf of 0.01 GHz.

94.3.13.4 Receiver jitter tolerance

Receiver jitter tolerance is defined by the procedure defined in 94.3.13.4.2. The receiver FEC symbol error ratio shall be less than the maximum value for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 94–16.

Table 94–16—Receiver jitter tolerance parameters

Parameter	Case A values	Case B values	Units
Maximum FEC symbol error ratio[a]	3.3×10^{-3}	3.3×10^{-3}	
Jitter frequency	16	160	kHz
Jitter amplitude	5	0.5	UI

[a]The FEC symbol error ratio is measured in step 3 of the jitter tolerance test method in 94.3.13.4.2.

94.3.13.4.1 Test setup

Jitter tolerance is measured using the test setup in Figure 93C–2 on each lane. The transmitter output is constrained as described in 93C.1. The Tx and channel noise sources are disabled. The test channel (TPt to TP5 replica) meets the requirements for the channel used for Test 2 in 94.3.13.3. The low-frequency jitter specified in Table 94–16 is applied to the output of the transmitter and is measured at TP0a.

94.3.13.4.2 Test method

The following jitter tolerance test method is repeated for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 94–16.

1) Configure the transmitter with the corresponding jitter frequency and amplitude from Table 94–16.
2) Initiate training on the receiver under test and allow training to complete.
3) Measure the FEC symbol error ratio on each lane using the errored symbol counter, FEC_symbol_error_counter_*i*, where *i* is the lane under test.

94.4 Channel characteristics

94.4.1 Channel Operating Margin

The Channel Operating Margin (COM) is computed using the procedure in 93A.1 with the Test 1 and Test 2 values in Table 94–17. Test 1 and Test 2 differ in the value of the device package model transmission line length z_p.

COM shall be greater than or equal to 3 dB for each test. This minimum value allocates margin for practical limitations on the receiver implementation as well as the largest step size allowed for transmitter equalizer coefficients.

94.4.2 Channel insertion loss

The insertion loss, in dB, of the channel is recommended to meet Equation (94–22). The insertion loss limit is shown Figure 94–23.

where

$RL(f)$ is the return loss at frequency f in dB
$RL_{min}(f)$ is the minimum allowable return loss in dB
f is the measurement frequency in GHz
f_b is the signaling rate (13.59375) in GHz

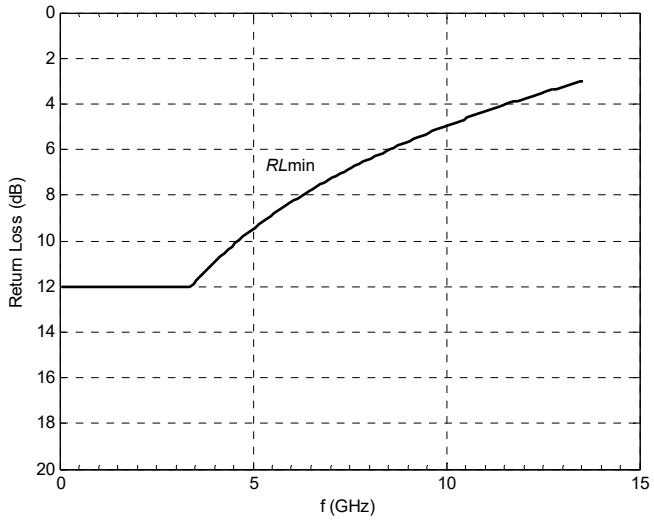

Figure 94–24—Channel return loss limit

94.4.4 Channel AC-coupling

The 100GBASE-KP4 transmitter shall be AC-coupled to the receiver. Common-mode specifications are defined as if the DC-blocking capacitor is implemented between TP0 and TP5. Should the capacitor be implemented outside TP0 and TP5, the common-mode specifications in Table 94–13 may not be appropriate.

The impact of a DC-blocking capacitor implemented between TP0 and TP5 is accounted for within the channel specifications. Should the capacitor be implemented outside TP0 and TP5, it is the responsibility of implementers to consider any necessary modifications to common-mode and channel specifications required for interoperability as well as any impact on the verification of transmitter and receiver compliance.

The low-frequency 3 dB cutoff of the AC-coupling shall be less than 50 kHz.

94.5 Environmental specifications

94.5.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

94.5.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

94.5.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

94.5.4 Electromagnetic compatibility

A system integrating the 100GBASE-KP4 PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

94.5.5 Temperature and humidity

A system integrating the 100GBASE-KP4 PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

94.6 Protocol implementation conformance statement (PICS) proforma for Clause 94, Physical Medium Attachment (PMA) sublayer, Physical Medium Dependent (PMD) sublayer, and baseband medium, type 100GBASE-KP4[163]

94.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 94, Physical Medium Attachment (PMA) sublayer, Physical Medium Dependent (PMD) sublayer, and baseband medium, type 100GBASE-KP4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

94.6.2 Identification

94.6.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

94.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 94, Physical Medium Attachment (PMA) sublayer, Physical Medium Dependent (PMD) sublayer, and baseband medium, type 100GBASE-KP4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[163] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

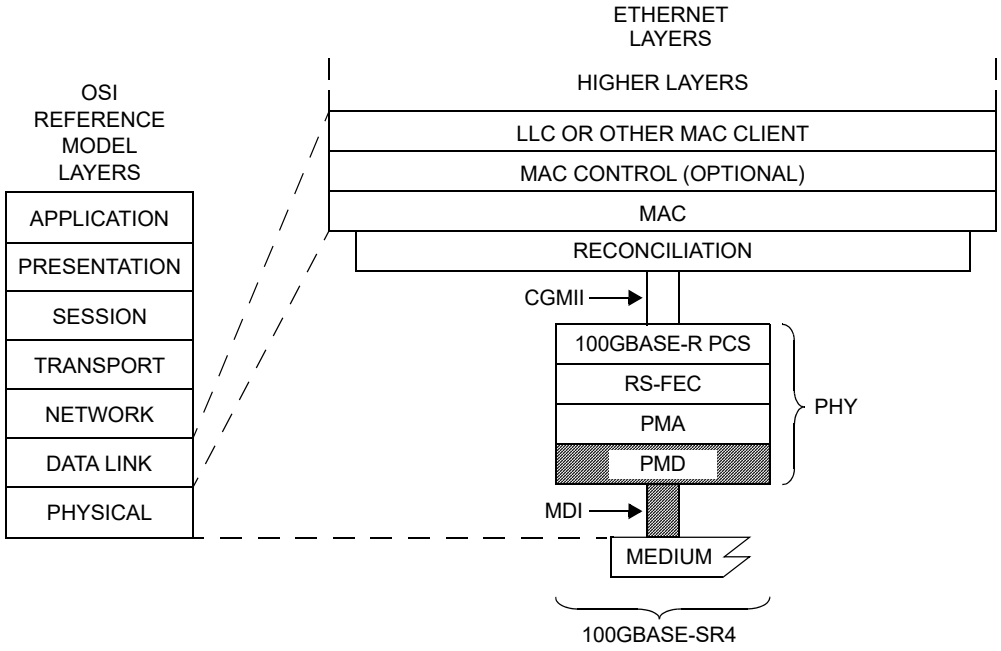
95. Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-SR4

95.1 Overview

This clause specifies the 100GBASE-SR4 PMD together with the multimode fiber medium. The PMD sublayer provides a point-to-point 100 Gb/s Ethernet link over four pairs of multimode fiber, up to at least 100 m. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 95–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 95–1—Physical Layer clauses associated with the 100GBASE-SR4 PMD

Associated clause	100GBASE-SR4
81—RS	Required
81—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
83—PMA for 100GBASE-R	Required
91—RS-FEC[b]	Required
83A—CAUI-10	Optional
83B—Chip-to-module CAUI-10[c]	Optional
83D—CAUI-4	Optional
83E—Chip-to-module CAUI-4	Optional
78—Energy Efficient Ethernet	Optional



[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]The option to bypass the Clause 91 RS-FEC correction function is not supported.
[c]This option requires the RS-FEC sublayer to be within the module. See 91.3.

Figure 95–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 40 Gb/s and 100 Gb/s Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2.

100GBASE-SR4 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions and abbreviations) and Annex A (bibliography, referenced as [B1], [B2], etc.).

CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION
SR = PMD FOR MULTIMODE FIBER

Figure 95–1—100GBASE-SR4 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

95.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 5×10^{-5} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 91.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 91.

95.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-SR4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 100GBASE-SR4 PMD has four parallel bit streams, hence i = 0 to 3.

In the transmit direction, the PMA continuously sends four parallel bit streams to the PMD, one per lane, each at a nominal signaling rate of 25.78125 GBd. The PMD converts these streams of bits into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends four parallel bit streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service primitive defined in 80.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_bit parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_bit parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 95.1.1.

95.3 Delay and Skew

95.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 100GBASE-SR4 PMD including 2 m of fiber in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

95.3.2 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the RS-FEC sublayer. Skew and Skew Variation are defined in 80.5 and specified at the points SP0 to SP7 shown in Figure 80–9.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5. The measurements of Skew and Skew Variation are defined in 86.8.3.1 with the exception that the clock and data recovery units' high-frequency corner bandwidths are 10 MHz.

95.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 95–2, and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 95–3.

Table 95–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 3	PMD transmit disable register	1.9.4	PMD_transmit_disable_3
PMD transmit disable 2	PMD transmit disable register	1.9.3	PMD_transmit_disable_2
PMD transmit disable 1	PMD transmit disable register	1.9.2	PMD_transmit_disable_1
PMD transmit disable 0	PMD transmit disable register	1.9.1	PMD_transmit_disable_0

Table 95–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 3	PMD receive signal detect register	1.10.4	PMD_signal_detect_3
PMD receive signal detect 2	PMD receive signal detect register	1.10.3	PMD_signal_detect_2
PMD receive signal detect 1	PMD receive signal detect register	1.10.2	PMD_signal_detect_1
PMD receive signal detect 0	PMD receive signal detect register	1.10.1	PMD_signal_detect_0

95.5 PMD functional specifications

The 100GBASE-SR4 PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

95.5.1 PMD block diagram

The PMD block diagram is shown in Figure 95–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a multimode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 95.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 95.11.3). Unless specified otherwise, all receiver measurements and tests defined in 95.8 are made at TP3.

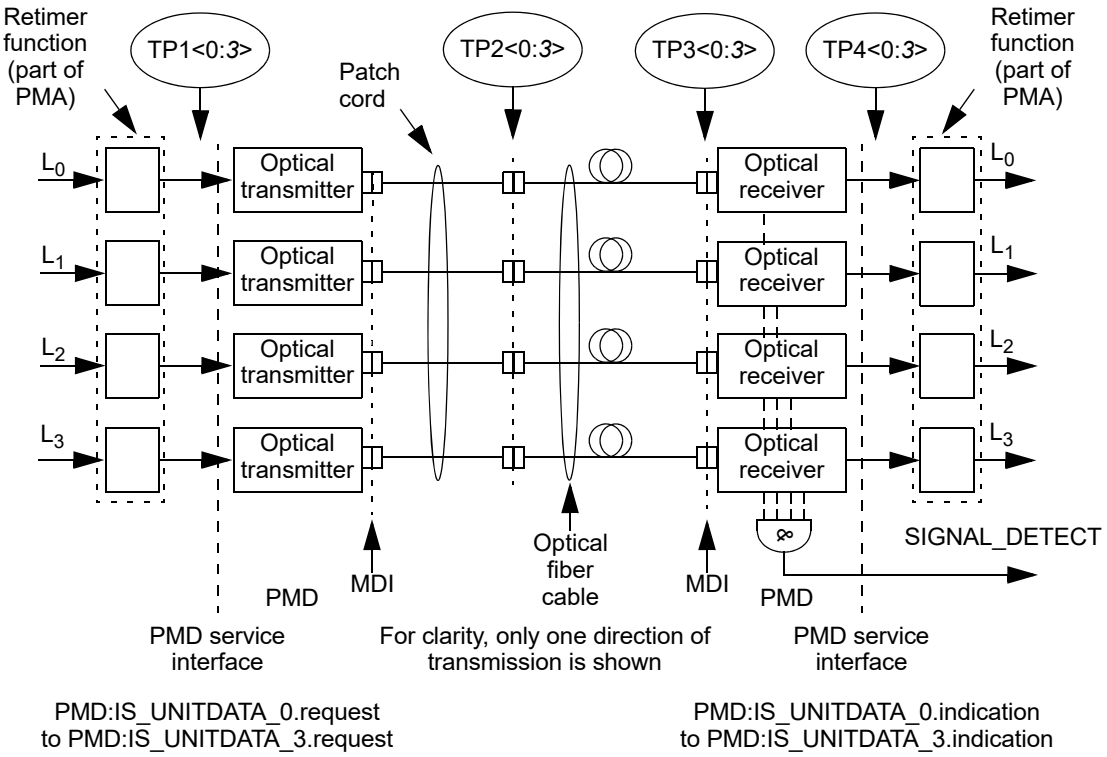

Figure 95–2—Block diagram for 100GBASE-SR4 transmit/receive paths

TP1<0:3> and TP4<0:3> are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

95.5.2 PMD transmit function

The PMD Transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate optical signals. The four optical signals shall then be delivered to the MDI, which contains four parallel light paths for transmit, according to the transmit optical specifications in this clause. The higher optical power level in each signal shall correspond to tx_bit = one.

95.5.3 PMD receive function

The PMD Receive function shall convert the four parallel optical signals received from the MDI into separate bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_bit = one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

95.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 80.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all four lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 95–4. The PMD receiver is not required to verify whether a compliant 100GBASE-SR4 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 95–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 95–7) AND (compliant 100GBASE-SR4 signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

95.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:3, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 95–4.

95.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

95.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 95–6.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

95.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitter in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 95–6.
b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane.

95.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

95.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set PMD_transmit_fault to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

95.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

95.6 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for 100GBASE-SR4. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the

physical ordering of the lanes, as the RS-FEC sublayer is capable of receiving the lanes in any arrangement. The positioning of transmit and receive lanes at the MDI is specified in 95.11.3.1.

95.7 PMD to MDI optical specifications for 100GBASE-SR4

The operating range for the 100GBASE-SR4 PMD is defined in Table 95–5. A 100GBASE-SR4 compliant PMD operates on 50/125 μm multimode fibers, type A1a.2 (OM3) or type A1a.3 (OM4), according to the specifications defined in Table 95–12. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 100GBASE-SR4 PMD operating at 120 m meets the operating range requirement of 0.5 m to 100 m).

Table 95–5—100GBASE-SR4 operating range

PMD type	Required operating range[a]
100GBASE-SR4	0.5 m to 70 m for OM3
	0.5 m to 100 m for OM4

[a]The RS-FEC correction function may not be bypassed for any operating distance.

95.7.1 100GBASE-SR4 transmitter optical specifications

Each lane of a 100GBASE-SR4 transmitter shall meet the specifications in Table 95–6 per the definitions in 95.8.

Table 95–6—100GBASE-SR4 transmit characteristics

Description	Value	Unit
Signaling rate, each lane (range)	25.78125 ± 100 ppm	GBd
Center wavelength (range)	840 to 860	nm
RMS spectral width[a] (max)	0.6	nm
Average launch power, each lane (max)	2.4	dBm
Average launch power, each lane (min)	–8.4	dBm
Optical Modulation Amplitude (OMA), each lane (max)	3	dBm
Optical Modulation Amplitude (OMA), each lane (min)[b]	–6.4	dBm
Launch power in OMA minus TDEC (min)	–7.3	dBm
Transmitter and dispersion eye closure (TDEC), each lane (max)	4.3	dB
Average launch power of OFF transmitter, each lane (max)	–30	dBm
Extinction ratio (min)	2	dB
Optical return loss tolerance (max)	12	dB

Table 95–6—100GBASE-SR4 transmit characteristics *(continued)*

Description	Value	Unit
Encircled flux[c]	≥ 86% at 19 μm ≤ 30% at 4.5 μm	
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3} Hit ratio 1.5×10^{-3} hits per sample	{0.3, 0.38, 0.45, 0.35, 0.41, 0.5}	

[a]RMS spectral width is the standard deviation of the spectrum.
[b]Even if the TDEC < 0.9 dB, the OMA (min) has to exceed this value.
[c]If measured into type A1a.2 or type A1a.3 50 μm fiber in accordance with IEC 61280-1-4:2009.

95.7.2 100GBASE-SR4 receive optical specifications

Each lane of a 100GBASE-SR4 receiver shall meet the specifications in Table 95–7 per the definitions in 95.8.

Table 95–7—100GBASE-SR4 receive characteristics

Description	Value	Unit
Signaling rate, each lane (range)	25.78125 ± 100 ppm	GBd
Center wavelength (range)	840 to 860	nm
Damage threshold[a] (min)	3.4	dBm
Average receive power, each lane (max)	2.4	dBm
Average receive power, each lane[b] (min)	–10.3	dBm
Receive power, each lane (OMA) (max)	3	dBm
Receiver reflectance (max)	–12	dB
Stressed receiver sensitivity (OMA), each lane[c] (max)	–5.2	dBm
Conditions of stressed receiver sensitivity test:[d]		
Stressed eye closure (SEC), lane under test	4.3	dB
Stressed eye J2 Jitter, lane under test	0.39	UI
Stressed eye J4 Jitter, lane under test (max)	0.53	UI
OMA of each aggressor lane	3	dBm
Stressed receiver eye mask definition {X1, X2, X3, Y1, Y2, Y3} Hit ratio 5×10^{-5} hits per sample	{0.28, 0.5, 0.5, 0.33, 0.33, 0.4}	

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level on one lane. The receiver does not have to operate correctly at this input power.
[b]Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c]Measured with conformance test signal at TP3 (see 95.8.8) for the BER specified in 95.1.1.
[d]These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

95.7.3 100GBASE-SR4 illustrative link power budget

An illustrative power budget and penalties for 100GBASE-SR4 channels are shown in Table 95–8.

Table 95–8—100GBASE-SR4 illustrative link power budget

Parameter	OM3	OM4	Unit
Effective modal bandwidth at 850 nm[a]	2000	4700	MHz.km
Power budget (for max TDEC)	8.2		dB
Operating distance	0.5 to 70	0.5 to 100	m
Channel insertion loss[b]	1.8	1.9	dB
Allocation for penalties[c] (for max TDEC)	6.3		dB
Additional insertion loss allowed	0.1	0	dB

[a]Per IEC 60793-2-10.
[b]The channel insertion loss is calculated using the maximum distance specified in Table 95–5 and cabled optical fiber attenuation of 3.5 dB/km at 850 nm plus an allocation for connection and splice loss given in 95.11.2.1.
[c]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

95.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

95.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 95–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 95–10 may be used to perform that test. As Pattern 3 is more demanding than Pattern 5 (which itself is the same or more demanding than other 100GBASE-R bit streams) an item that is compliant using Pattern 5 is considered compliant even if it does not meet the required limit using Pattern 3. The test patterns used in this clause are shown in Table 95–9.

Table 95–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 ones, 8 zeros)	83.5.10
3	PRBS31	83.5.10
4	PRBS9	83.5.10
5[a]	RS-FEC encoded scrambled idle	82.2.11[a]

[a]The pattern defined in 82.2.11 as encoded by Clause 91 RS-FEC for 100GBASE-SR4.

Table 95–10—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength, spectral width	3, 5 or valid 100GBASE-SR4 signal	95.8.2
Average optical power	3, 5 or valid 100GBASE-SR4 signal	95.8.3
Optical modulation amplitude (OMA)	Square wave or 4	95.8.4
Transmitter and dispersion eye closure (TDEC)	3, 5 or valid 100GBASE-SR4 signal	95.8.5
Extinction ratio	3, 5 or valid 100GBASE-SR4 signal	95.8.6
Transmitter optical waveform	3, 5 or valid 100GBASE-SR4 signal	95.8.7
Stressed receiver sensitivity	3, 5 or valid 100GBASE-SR4 signal	95.8.8
Stressed eye closure (SEC), calibration	3, 5 or valid 100GBASE-SR4 signal	95.8.8

95.8.1.1 Multi-lane testing considerations

Stressed receiver sensitivity is defined for an interface at the BER specified in 95.1.1. The interface BER is the average of the four BERs of the receive lanes when they are stressed.

Measurements with Pattern 3 (PRBS31) allow lane-by-lane BER measurements. Measurements with Pattern 5 (RS-FEC encoded scrambled idle) give the interface BER if all lanes are stressed at the same time. If each lane is stressed in turn, the BER is diluted by the three unstressed lanes, and the BER for that stressed lane alone has to be found, e.g., by multiplying by four if the unstressed lanes have low BER. In stressed receiver sensitivity measurements, unstressed lanes may be created by setting the power at the receiver under test well above its sensitivity and/or not stressing those lanes with ISI and jitter, or by other means. Each receive lane is stressed in turn while all are operated. All aggressor lanes are operated as specified. To find the interface BER, the BERs of all the lanes when stressed are averaged.

Where relevant, parameters are defined with all co-propagating and counter-propagating lanes operational so that crosstalk effects are included. Where not otherwise specified, the maximum amplitude (OMA or VMA) for a particular situation is used, and for counter-propagating lanes, the minimum transition time is used. Alternative test methods that generate equivalent results may be used. While the lanes in a particular direction may share a common clock, the Tx and Rx directions are not synchronous to each other. If Pattern 3 is used for the lanes not under test using a common clock, there is at least 31 UI delay between the PRBS31 patterns on one lane and any other lane.

95.8.2 Center wavelength and spectral width

The center wavelength and RMS spectral width of each optical lane shall be within the range given in Table 95–6 if measured per IEC 61280-1-3. The lane under test is modulated using one of the test patterns specified in Table 95–10.

95.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 95–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern defined in Table 95–10.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

95.8.4 Optical Modulation Amplitude (OMA)

OMA shall be within the limits given in Table 95–6 if measured as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or as defined in 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern, with the exception that each optical lane is tested individually. See 95.8.1 for test pattern information.

95.8.5 Transmitter and dispersion eye closure (TDEC)

TDEC of each lane shall be within the limits given in Table 95–6 if measured using the methods specified in 95.8.5.1 and 95.8.5.2.

TDEC is a measure of each optical transmitter's vertical eye closure; it is based upon vertical histogram data from an eye diagram measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a combined reference receiver and worst case optical channel. Table 95–10 specifies the test patterns to be used for measurement of TDEC.

95.8.5.1 TDEC conformance test setup

A block diagram for the TDEC conformance test is shown in Figure 95–3. Other measurement implementations may be used with suitable calibration.

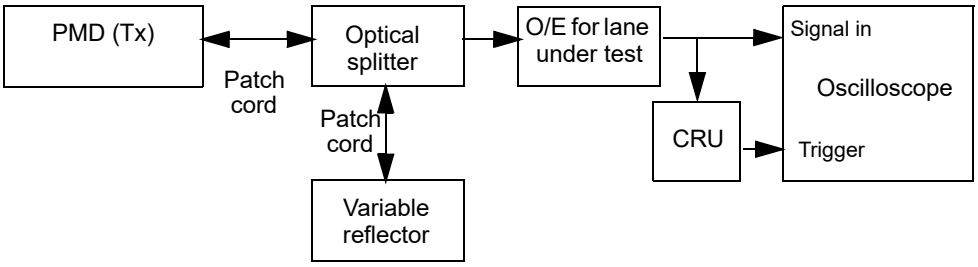

Figure 95–3—TDEC conformance test block diagram

Each optical lane is tested individually with all other lanes in operation. The optical splitter and variable reflector are adjusted so that each transmitter is tested with an optical return loss of 12 dB.

The combination of the O/E and the oscilloscope used to measure the optical waveform has a fourth-order Bessel-Thomson filter response with a bandwidth of 12.6 GHz. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The clock recovery unit (CRU) has a corner frequency of 10 MHz and a slope of 20 dB/decade.

95.8.5.2 TDEC measurement method

The oscilloscope is set up to accumulate samples of the optical eye diagram for the transmitter under test, as illustrated in Figure 95–4.

OMA is measured according to 95.8.4.

The standard deviation of the noise of the O/E and oscilloscope combination, *S*, is determined with no optical input signal and the same settings as used to capture the histograms described below.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The average optical power (P_{ave}), the crossing points of the eye diagram, and the four vertical histograms used to calculate TDEC, are all measured using the same test pattern selected from those identified for TDEC in Table 95–10. The 0 UI and 1 UI crossing points are determined by the average of the eye diagram crossing times, as measured at P_{ave}, as illustrated in Figure 95–4.

Four vertical histograms are measured through the eye diagram, centered at 0.4 UI and 0.6 UI, and above and below P_{ave}, as illustrated in Figure 95–4.

Each histogram window has a width of 0.04 UI. Each histogram window has an inner height boundary, which is set close to P_{ave} (so that no further samples would be captured by moving it closer to P_{ave}), and an outer height boundary, which is set beyond the outer-most samples of the eye diagram (so that no further samples would be captured by increasing the outer boundary of the histogram window).

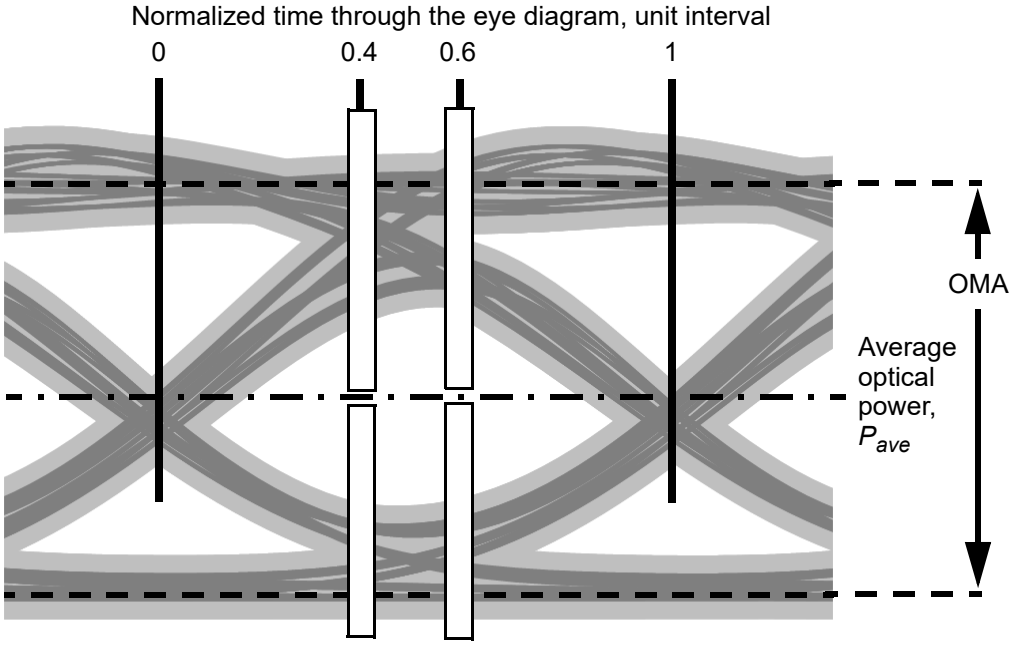

Figure 95–4—Illustration of the TDEC measurement

The distributions of the two histograms on the left are each multiplied by Q functions, which represent an estimate of the probability of errors caused by each part of the distribution for the greatest tolerable noise that could be added by an optical channel and a receiver. The resulting distributions are integrated and each integral is divided by the integral of the distribution it was derived from, giving two bit error probabilities. The Q function uses a standard deviation, σ_L, chosen so that the average of these two bit error probabilities is 5×10^{-5}. Similarly, for the two histograms on the right, a standard deviation, σ_R, is found.

Q(x) is the area under a Normal curve for values larger than *x* (the tail probability, related to the "complementary error function"), as shown in Equation (95–1):

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$Q(x) = \int_{x}^{\infty} \frac{e^{(-z^2/2)}}{\sqrt{2\pi}} dz \tag{95–1}$$

where

x	is $(y–P_{ave})/\sigma_G$ or $(P_{ave}–y)/\sigma_G$, as in Equation (95–2)

This procedure finds a value of σ_G such that Equation (95–2) is satisfied:

$$\frac{1}{2}\left(\frac{\int fu(y)Q\left(\frac{y-P_{ave}}{\sigma_G}\right)dy}{\int fu(y)dy}\right) + \frac{1}{2}\left(\frac{\int fl(y)Q\left(\frac{P_{ave}-y}{\sigma_G}\right)dy}{\int fl(y)dy}\right) = 5\times10^{-5} \tag{95–2}$$

where

$fu(y), fl(y)$	are the upper and lower distributions
σ_G	is the left or right standard deviation, σ_L or σ_R

The lesser of σ_L and σ_R is N.

The noise, R, that could be added by a receiver is given by Equation (95–3).

$$R = (1 - M_1)\sqrt{N^2 + S^2 - M_2^2} \tag{95–3}$$

where

M_1, M_2	defined in Equation (95–4) and Equation (95–5), account for mode partition noise and modal noise that could be added by the optical channel
S	is the standard deviation of the noise of the O/E and oscilloscope combination

$$M_1 = 0.04 \tag{95–4}$$

$$M_2 = 0.0175P_{ave} \tag{95–5}$$

where

P_{ave}	is the average optical power of the eye diagram.

TDEC is given by Equation (95–6).

$$TDEC = 10\log_{10}\left(\frac{OMA}{2} \times \frac{1}{3.8906R}\right) \tag{95–6}$$

where

OMA	is the optical modulation amplitude as defined in 95.8.4

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The factor 3.8906 is chosen for consistency with the BER of 5×10^{-5} given in 95.1.1.

The method described in 95.8.5.1 and 95.8.5.2 is the reference measurement method. Other equivalent measurement methods may be used with suitable calibration.

95.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 95–6 if measured using the methods specified in IEC 61280-2-2. The extinction ratio is measured using one of the test patterns specified for extinction ratio in Table 95–10.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 95–10).

95.8.7 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4 with the transmitter eye mask coordinates and hit ratio in Table 95–6. The transmitter optical waveform of a port transmitting the test pattern specified in Table 95–10 shall meet specifications according to the methods specified in 86.8.4.6.1 with the following exceptions:

— The clock recovery unit's high-frequency corner bandwidth is 10 MHz.
— The filter nominal reference frequency f_r is 19.34 GHz and the filter tolerances are as specified for STM-64 in ITU-T G.691.

Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response and for any excess reference receiver noise.

95.8.8 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 95–7 if measured using the method defined by 95.8.8.1 and 95.8.8.5, with the conformance test signal at TP3 as described in 95.8.8.2.

Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Pattern 3 or Pattern 5, or a valid 100GBASE-SR4 signal is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal. The interface BER of the PMD receiver is the average of the BER of all receive lanes while stressed and at the specified receive OMA.

95.8.8.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 95–5. The patterns used for the received conformance signal are specified in Table 95–10. The optical test signal is conditioned (stressed) using the stressed receiver methodology defined in 95.8.8.2 and has sinusoidal jitter applied as specified in 95.8.8.5. A suitable test set is needed to characterize and verify that the signal used to test the receiver has the appropriate characteristics. The fourth-order Bessel-Thomson filter has a 3 dB bandwidth of approximately 19 GHz. The low-pass filter is used to create ISI. The combination of the low-pass filter and the E/O converter should have a frequency response that results in the level of stressed eye closure (SEC) before the sinusoidal and Gaussian noise terms are added, as described in 95.8.8.2.

The sinusoidal amplitude interferer 1 causes jitter that is intended to emulate instantaneous bit shrinkage that can occur with DDJ. This type of jitter cannot be created by simple phase modulation. The sinusoidal amplitude interferer 2 causes additional eye closure, but in conjunction with the finite edge rates from the limiter, also causes some jitter. The sinusoidally jittered clock represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter. The sinusoidal amplitude interferers may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid harmonic

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

relationships between the sinusoidal interferers, the sinusoidal jitter, the signaling rate, and the pattern repetition rate. The Gaussian noise generator, the amplitude of the sinusoidal interferers, and the low-pass filter are adjusted so that the SEC and stressed eye J2 Jitter specifications given in Table 95–7 are met simultaneously, while the maximum stressed eye J4 Jitter specified in Table 95–7 is not exceeded, and while also passing the stressed receiver eye mask in Table 95–7 according to the methods specified in 95.8.7 (the random noise effects such as RIN, or random clock jitter, do not need to be minimized).

For improved visibility for calibration, all elements in the signal path (cables, DC blocks, E/O converter, etc.) should have wide and smooth frequency response, and linear phase response, throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be minimized.

The stressed receiver conformance test signal verification is described in 95.8.8.4.

Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Each receive lane is tested in turn while all aggressor receive lanes are operated as specified in Table 95–7. Pattern 3, Pattern 5, or a valid 100GBASE–SR4 signal is sent from the transmit section of the receiver under test. The signal being transmitted is asynchronous to the received signal. If Pattern 3 is used with a common clock for the transmit or receive lanes not under test, there is at least 31 UI delay between the PRBS31 patterns generated on one lane and any other lane.

For 100GBASE-SR4 the relevant BER is the interface BER at the PMD service interface. The interface BER is the average of the four BER of the receive lanes when stressed: see 95.8.1.1. If present, the RS-FEC sublayer can measure the lane symbol error ratio at its input. The lane BER can be assumed to be one tenth of the lane symbol error ratio. If each lane is stressed in turn, the PMD interface BER is the average of the BERs of all the lanes when stressed: see 95.8.1.1.

95.8.8.2 Stressed receiver conformance test signal characteristics and calibration

The conformance test signal is used to validate that each lane of the PMD receiver meets BER requirements with near worst-case waveforms at TP3.

The primary parameters of the stressed receiver conformance test signal are its stressed eye closure (SEC), stressed eye J2 Jitter, and stressed eye J4 Jitter. The SEC of the stressed receiver conformance test signal is measured according to 95.8.5, except that the combination of the O/E and the oscilloscope used to measure the waveform has a fourth-order Bessel-Thomson filter response with a bandwidth of 19.34 GHz, and the values of M_1 and M_2 in Equation (95–3) are set to zero. Stressed eye J2 Jitter and stressed eye J4 Jitter are defined in 95.8.8.3.

An example stressed receiver conformance test setup is shown in Figure 95–5; however, alternative test setups that generate equivalent stress conditions may be used.

The following steps describe a possible method for setting up and calibrating a stressed receiver conformance test signal when using a stressed receiver conformance test setup as shown in Figure 95–5:

1) Set the signaling rate of the test pattern generator to meet the requirements in Table 95–7.
2) With the sinusoidal jitter, sinusoidal interferers, and the Gaussian noise generator turned off, set the extinction ratio of the E/O to approximately the minimum specified in Table 95–6.
3) The required values of SEC and J2 Jitter, and the maximum value of J4 Jitter of the stressed receiver conformance test signal are given in Table 95–7. A valid stressed receiver conformance test signal may have a lower value of J4 jitter than the maximum specified in Table 95–7, provided it meets the required values of SEC and J2 Jitter.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

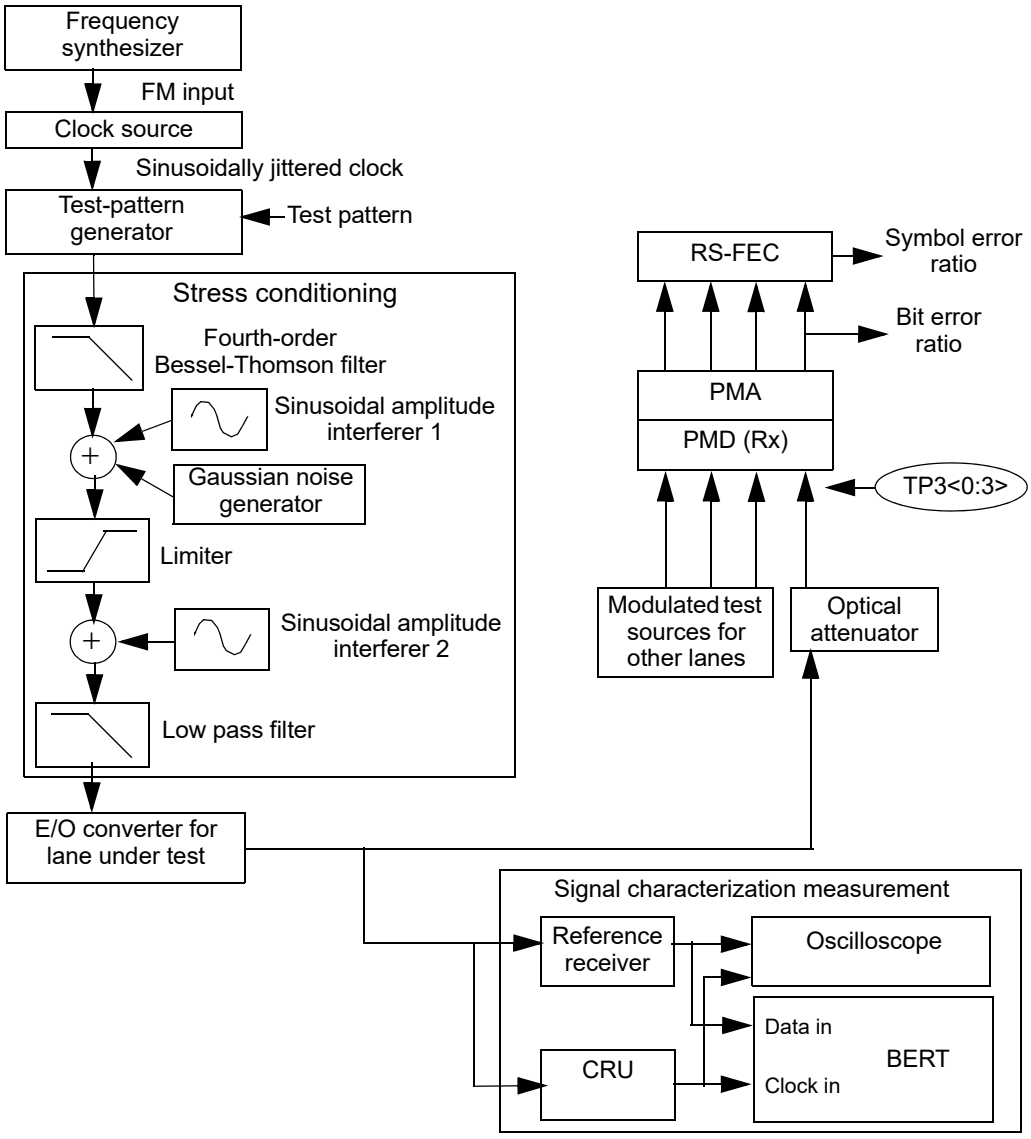

Figure 95–5—Stressed receiver conformance test block diagram

With the sinusoidal jitter, sinusoidal interferer 1, sinusoidal interferer 2, and the Gaussian noise generator turned off, at least 2.5 dB of SEC should be created by the selection of the appropriate bandwidth for the combination of the low-pass filter and the E/O converter. Any remaining SEC has to be created with a combination of sinusoidal jitter, sinusoidal interference, and Gaussian noise.

Sinusoidal jitter is added as specified in Table 95–11. When calibrating the conformance signal, the sinusoidal jitter frequency should be between 50 MHz and 10 times LB as defined in Table 95–11. Sinusoidal jitter amplitude may be calibrated by measuring the jitter on the oscilloscope, while transmitting the square wave pattern, and using a clean clock in place of the CRU to trigger the oscilloscope.

Iterate the adjustments of sinusoidal interferers and Gaussian noise generator and extinction ratio until the values of SEC and stressed eye J2 Jitter are met, while also meeting the following conditions: the maximum value of stressed eye J4 Jitter, as specified in Table 95–7, is not exceeded; the extinction ratio is approximately the minimum specified in Table 95–6; and sinusoidal jitter is as specified in Table 95–11.

Each receiver lane is conformance tested in turn. The source for the lane under test is adjusted to supply a signal at the input to the receiver under test at the "Stressed receiver sensitivity (OMA), each lane (max)" specified in Table 95–7, and the test sources for the other lanes are set to the "OMA of each aggressor lane" specified in Table 95–7.

95.8.8.3 J2 and J4 Jitter

J2 Jitter is defined as the time interval at the average optical power level that includes all but 10^{-2} of the jitter distribution, which is the time interval from the 0.5th to the 99.5th percentile of the jitter histogram. J2 Jitter is defined using a clock recovery unit as in 95.8.7. If measured using an oscilloscope, the histogram should include at least 10 000 hits and should be taken over about 1% of the signal amplitude. If measured by plotting BER vs. decision time, J2 is the time interval between the two points with a BER of 2.5×10^{-3}.

J4 Jitter is defined as the time interval at the average optical power level that includes all but 10^{-4} of the jitter distribution. J4 Jitter is defined using a clock recovery unit as in 95.8.7. If measured using an oscilloscope, the histogram should include at least 1 000 000 hits and should be taken over about 1% of the signal amplitude. If measured by plotting BER vs. decision time, J4 is the time interval between the two points with a BER of 2.5×10^{-5}.

95.8.8.4 Stressed receiver conformance test signal verification

The stressed receiver conformance test signal can be verified using an optical reference receiver with an ideal fourth-order Bessel-Thomson response with a reference frequency f_r of 19.34 GHz. Use of G.691 tolerance filters may significantly degrade this calibration. The clock output from the clock source in Figure 95–5 is modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye J2 Jitter and stressed eye J4 Jitter that includes the sinusoidal jitter component, a clock recovery unit (CRU of Figure 95–5) is required.

Care should be taken when characterizing the test signal because excessive noise/jitter in the measurement system would result in an input signal that does not fully stress the receiver under test. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. Care should be taken to minimize the noise/jitter introduced by the reference O/E, filters, and BERT and/or to correct for this noise. While the details of a BER scan measurement and test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands to ensure that the stressed receiver conformance input signal meets the stress and sinusoidal jitter specified in 95.8.8.2 and 95.8.8.5.

95.8.8.5 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. The amplitude of the applied sinusoidal jitter is dependent on frequency as specified in Table 95–11.

Table 95–11—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter peak-to-peak (UI)
$f < 100$ kHz	Not specified
100 kHz $< f \leq$ 10 MHz	5×10^5 Hz / f
10 MHz $< f \leq 10\ LB$[a]	0.05

[a] LB = loop bandwidth; upper frequency bound for added sinusoidal jitter should be at least 10 times the loop bandwidth of the receiver being tested.

95.9 Safety, installation, environment, and labeling

95.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

95.9.2 Laser safety

100GBASE-SR4 optical transceivers shall conform to Hazard Level 1M laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[164]

95.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

95.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 100GBASE-SR4 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate, in the literature associated with the PHY, the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

95.9.5 Electromagnetic emission

A system integrating a 100GBASE-SR4 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

95.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

[164]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

95.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 100GBASE-SR4).

Labeling requirements for Hazard Level 1M lasers are given in the laser safety standards referenced in 95.9.2.

95.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 95–6.

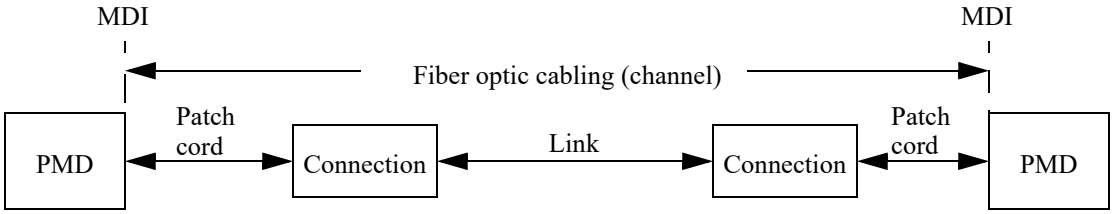

Figure 95–6—Fiber optic cabling model

The channel insertion loss is given in Table 95–12. A channel may contain additional connectors as long as the optical characteristics of the channel (such as attenuation, modal dispersion, reflections and losses of all connectors and splices) meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method. As OM4 optical fiber meets the requirements for OM3, a channel compliant to the "OM3" column may use OM4 optical fiber, or a combination of OM3 and OM4. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term *channel* is used here for consistency with generic cabling standards.

Table 95–12—Fiber optic cabling (channel) characteristics for 100GBASE-SR4

Description	OM3	OM4	Unit
Operating distance (max)	70	100	m
Cabling Skew (max)	79		ns
Cabling Skew Variation[a] (max)	2.4		ns
Channel insertion loss[b] (max)	1.8	1.9	dB
Channel insertion loss (min)	0		dB

[a]An additional 400 ps of Skew Variation could be caused by wavelength changes, which are attributable to the transmitter not the channel.
[b]These channel insertion loss values include cable loss plus 1.5 dB allocated for connection and splice loss, over the wavelength range 840 nm to 860 nm.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

95.11 Characteristics of the fiber optic cabling (channel)

The 100GBASE-SR4 fiber optic cabling shall meet the specifications defined in Table 95–12. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

95.11.1 Optical fiber cable

The fiber contained within the 100GBASE-SR4 fiber optic cabling shall comply with the specifications and parameters of Table 95–13. A variety of multimode cable types may satisfy these requirements, provided the resulting channel also meets the specifications of Table 95–12.

Table 95–13—Optical fiber and cable characteristics

Description	OM3[a]	OM4[b]	Unit
Nominal core diameter	50		μm
Nominal fiber specification wavelength	850		nm
Effective modal bandwidth (min)[c]	2000	4700	MHz.km
Cabled optical fiber attenuation (max)	3.5		dB/km
Zero dispersion wavelength (λ_0)	$1295 \le \lambda_0 \le 1340$		nm
Chromatic dispersion slope (max) (S_0)	0.105 for $1295 \le \lambda_0 \le 1310$ and $0.000375 \times (1590 - \lambda_0)$ for $1310 \le \lambda_0 \le 1340$		ps/nm^2 km

[a]IEC 60793-2-10 type A1a.2
[b]IEC 60793-2-10 type A1a.3
[c]When measured with the launch conditions specified in Table 95–6

95.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 95–6, consists of a mated pair of optical connectors.

95.11.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 1.5 dB total connection and splice loss. For example, this allocation supports three connections with an average insertion loss per connection of 0.5 dB. Connections with lower loss characteristics may be used provided the requirements of Table 95–12 are met. However, the loss of a single connection shall not exceed 0.75 dB.

95.11.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

95.11.3 Medium Dependent Interface (MDI)

The 100GBASE-SR4 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” (as shown in Figure 95–6). The 100GBASE-SR4 PMD is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

coupled to the fiber optic cabling through one connector plug into the MDI optical receptacle as shown in Figure 95–7. Example constructions of the MDI include the following:

a) PMD with a connectorized fiber pigtail plugged into an adapter;
b) PMD receptacle.

95.11.3.1 Optical lane assignments

The four transmit and four receive optical lanes of 100GBASE-SR4 shall occupy the positions depicted in Figure 95–7 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains eight active lanes within twelve total positions. The transmit optical lanes occupy the left-most four positions. The receive optical lanes occupy the right-most four positions. The four center positions are unused.

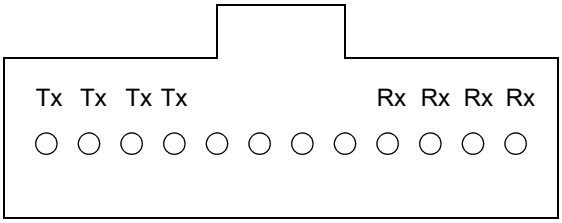

Figure 95–7—100GBASE-SR4 optical lane assignments

95.11.3.2 Medium Dependent Interface (MDI) requirements

The MDI adapter or receptacle shall meet the dimensional specifications for interface 7-1-3: *MPO adapter interface – opposed keyway configuration*, or interface 7-1-10: *MPO active device receptacle, flat interface*, as defined in IEC 61754-7-1. The plug terminating the optical fiber cabling shall meet the dimensional specifications of interface 7-1-4: *MPO female plug connector, flat interface for 2 to 12 fibres*, as defined in IEC 61754-7-1. The MDI shall optically mate with the plug on the optical fiber cabling. Figure 95–8 shows an MPO female plug connector with flat interface, and an MDI.

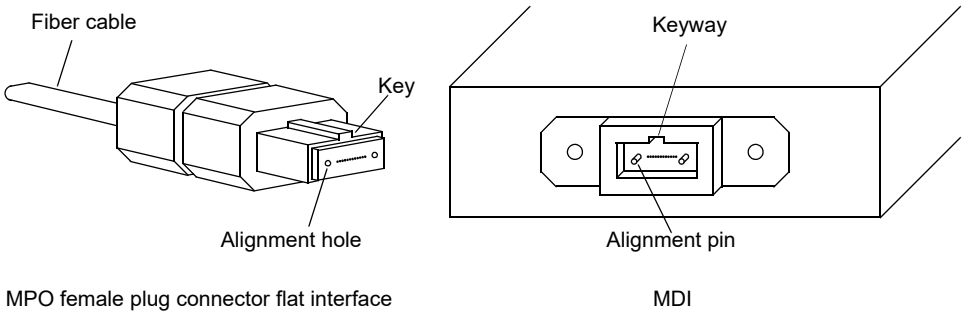

Figure 95–8—MPO female plug with flat interface and MDI

The MDI shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 95.5.1, not at the MDI.

95.12 Protocol implementation conformance statement (PICS) proforma for Clause 95, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-SR4[165]

95.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 95, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-SR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

95.12.2 Identification

95.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

95.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 95, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-SR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[165]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

96. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T1

96.1 Overview

The 100BASE-T1 Physical Layer supports standard media access controller (MAC) interfaces via the MII defined in Clause 22 with the exception of the MII Management interface defined in 22.2.4. The 100BASE-T1 management functions are optionally accessible through the management interface defined in Clause 45. Each copper port supports a single balanced twisted-pair link segment connection up to 15 m in length. 100BASE-T1 provides data rate of 100 Mb/s at the MAC interface over a single balanced twisted-pair cable as defined in 96.7. The architectural positioning of the 100BASE-T1 Physical Layer is depicted in Figure 96–1.

MDI = MEDIUM DEPENDENT INTERFACE
MII = MEDIA INDEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
PMD = PHYSICAL MEDIUM DEPENDENT

* Physical instantiation of MII is optional.
** Auto-Negotiation is optional

Figure 96–1—Architectural positioning of 100BASE-T1

This clause defines the PCS and PMA sublayers of the 100BASE-T1 PHY. A functional block diagram of the 100BASE-T1 PHY is provided in Figure 96–3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

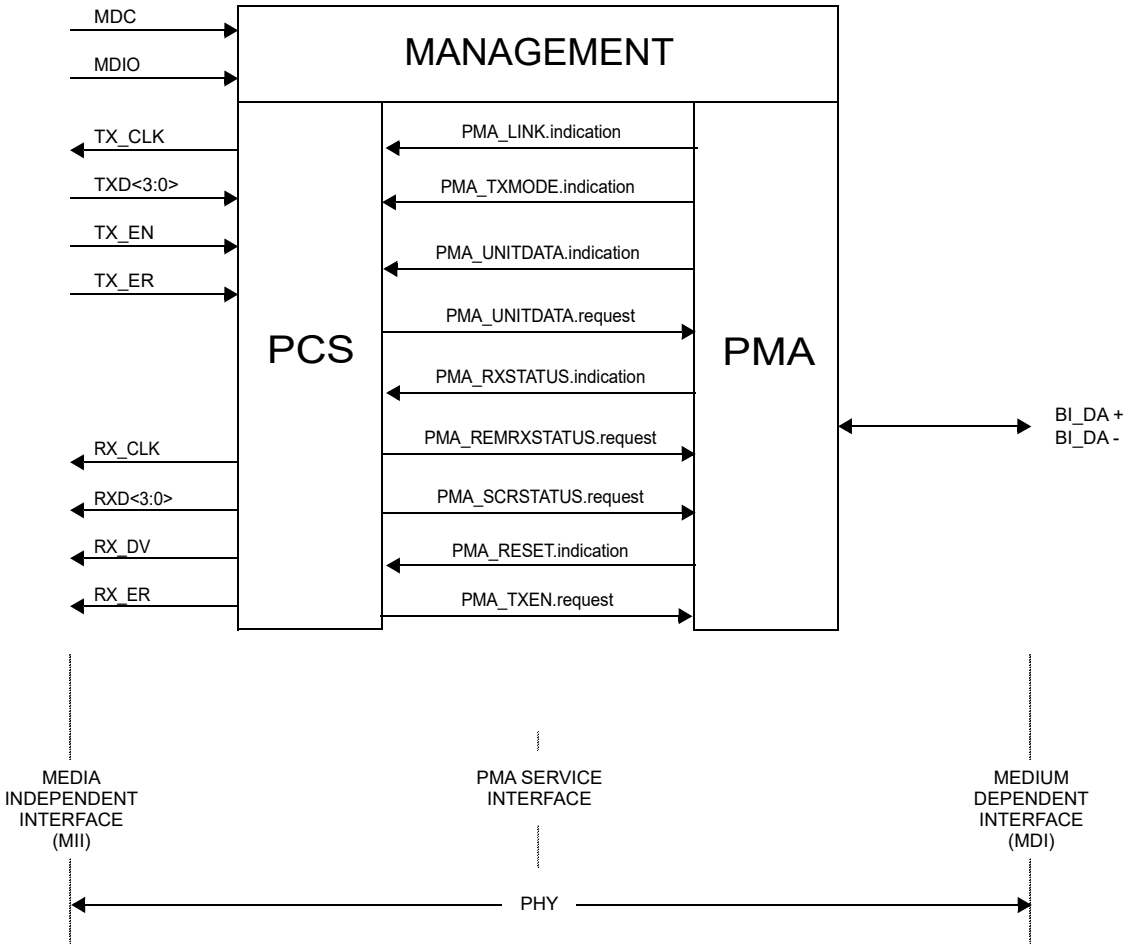

Figure 96–2—100BASE-T1 PHY interfaces

96.1.1 100BASE-T1 architecture

The 100BASE-T1 PHY operates using full-duplex communications (using echo cancellation) over a single balanced twisted-pair. This PHY uses ternary signaling and interfaces to the Clause 22 MII.

The 100BASE-T1 PHY interfaces to a Clause 22 MII. The PMA is similar to Clause 40. The PCS (specified in 96.3) is different from the PCS defined in Clause 40.

PMA functionality is defined in 96.4 with reference to Clause 40. The PMA functions are illustrated in Figure 96–3.

The 100BASE-T1 PHY leverages 1000BASE-T and 100BASE-TX PHY technologies in operation at 100 Mb/s, and introduces new PCS, PMA, and other modifications in support of the 100BASE-T1 PHY.

The specification features that enable operation over a single balanced twisted-pair are as follows:

a) Full-duplex communication with Ethernet MAC compatibility.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Adopt Pulse Amplitude Modulation 3 (PAM3) to provide trade-off between bandwidth and EMI performance.

Auto-Negotiation (Clause 98) may optionally be used by 100BASE-T1 devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for normal operation. Auto-Negotiation is performed upon link startup through the use of half-duplex differential Manchester encoding. The implementation of the Auto-Negotiation function is optional. If Auto-Negotiation is implemented, it shall meet the requirements of Clause 98.

96.1.1.1 Physical Coding Sublayer (PCS)

The 100BASE-T1 PCS transmits/receives signals to/from a Media Independent Interface (MII) as described in Clause 22, to/from signals on a 100BASE-T1 PMA, which supports a single balanced twisted-pair medium.

96.1.1.2 Physical Medium Attachment (PMA) sublayer

The 100BASE-T1 PMA transmits/receives signals to/from the PCS onto the single balanced twisted-pair cable medium and supports the link management and the 100BASE-T1 PHY Control function. The PMA provides full duplex communications at $66.66\overline{6}$ MBd over a single balanced twisted-pair cable up to 15 m in length.

96.1.1.3 Signaling

100BASE-T1 signaling is performed by the PCS generating continuous code-group sequences that the PMA transmits over the single balanced twisted-pair. The signaling scheme achieves a number of objectives including the following:

a) Algorithm mapping and inverse mapping from nibble data to ternary symbols and back.
b) Uncorrelated symbols in the transmitted symbol stream.
c) No correlation between symbol streams traveling both directions.
d) Ability to rapidly or immediately determine if a symbol stream represents data or idle.
e) Robust delimiters for Start-of-Stream delimiter (SSD), End-of-Stream delimiter (ESD), and other control signals.
f) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining.

96.1.2 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and a descriptive text, the state diagram prevails.

96.1.2.1 State diagram notation

The notation used in the state diagrams follows the conventions of 21.5.

96.1.2.2 State diagram timer specifications

All timers operate in the manner described in 40.4.5.2.

96.1.2.3 Service specifications

The method and notation used in the service specification follows the conventions of 1.2.2.

96.2 100BASE-T1 service primitives and interfaces

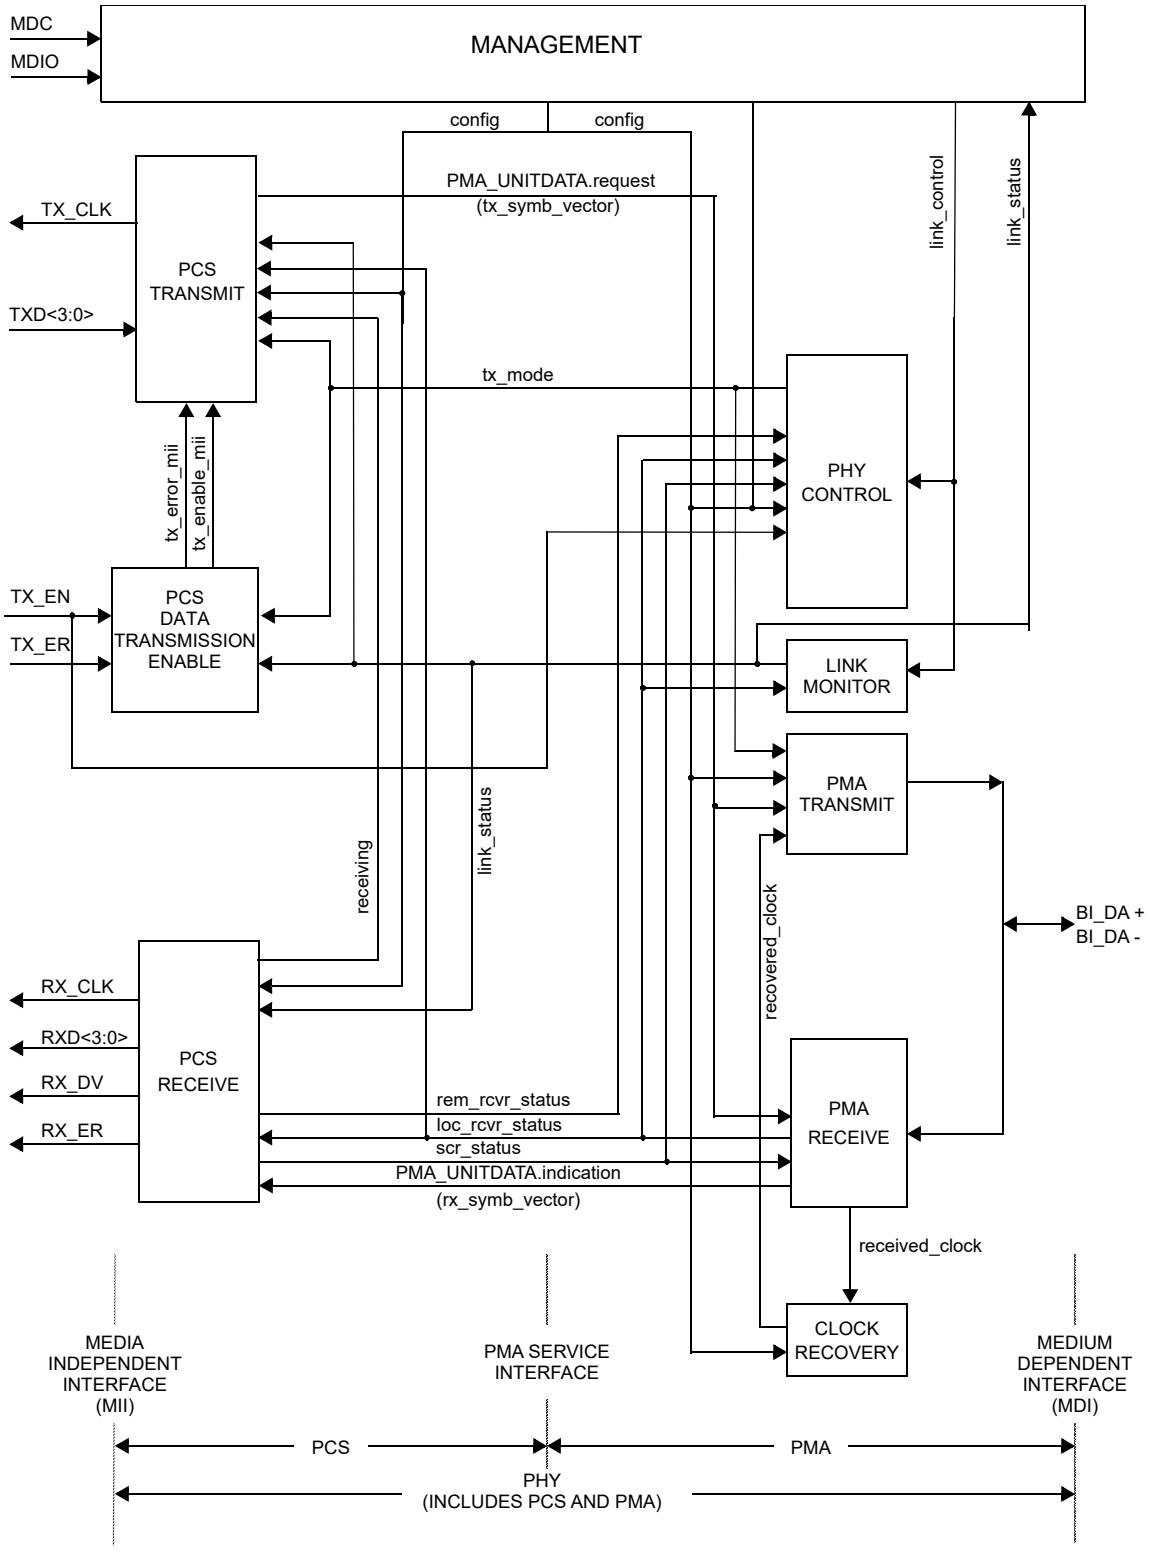
The 100BASE-T1 PHY shall use the service primitives and interfaces in 40.2, with exception of the following clarifications and differences noted in this section, in support of 100 Mb/s operations over a single balanced twisted-pair channel. Figure 96–2 shows the relationship of the service primitives and interfaces used by the 100BASE-T1 PHY.

Differences from the 40.2 service interface are as follows:

a) The 100BASE-T1 PHY uses the Media Independent Interface (MII) as specified in Clause 22.

b) The 100BASE-T1 PHY does not use 40.2 support of LPI (Low Power Idle) related functions.

c) The 100BASE-T1 PHY MASTER-SLAVE relationship is established by management (see 96.4.4).



NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

96.2.1 PMA service interface

As shown in Figure 96–2, 100BASE-T1 uses the following service primitives to exchange symbol vectors, status indications, and control signals across the PMA service interface:

PMA_LINK.indications (link_status)
PMA_TXMODE.indication (tx_mode)
PMA_UNITDATA.request (tx_symb_vector)
PMA_UNITDATA.indication (rx_symb_vector)
PMA_SCRSTATUS.request (scr_status)
PMA_RXSTATUS.indication (loc_rcvr_status)
PMA_REMRXSTATUS.request (rem_rcvr_status)
PMA_TXEN.request (TX_EN)

96.2.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 96.4.5. This primitive informs the PCS about the status of the underlying link.

96.2.2.1 Semantics of the primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on one of the following two values: FAIL or OK

FAIL	No valid link established
OK	The Link Monitor function indicates that a valid 100BASE-T1 link is established. Reliable reception of signals transmitted from the remote PHY is possible.

96.2.2.2 When generated

The PMA generates this primitive continuously to indicate the value of the link_status in compliance with the state diagram given in 96.4.5.

96.2.2.3 Effect of receipt

The effect of receipt of this primitive is specified in 96.4.5.

96.2.3 PMA_TXMODE.indication

The 100BASE-T1 transmitter sends code-groups that represent an MII data stream, control information, idles, or zeros.

96.2.3.1 Semantics of the primitive

PMA_TXMODE.indication (tx_mode)

PMA_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of code-groups the PCS should be transmitting. The parameter tx_mode can take on one of the following three values:

SEND_N	This value is continuously asserted when transmission of sequences of code-groups representing a MII data stream (data mode), control mode or idle mode is to take place.
SEND_I	This value is continuously asserted in case transmission of sequences of code-groups representing the idle mode is to take place.
SEND_Z	This value is continuously asserted in case transmission of zeros is required.

96.2.3.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages continuously.

96.2.3.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its Transmit function as described in 96.3.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.2.4 PMA_UNITDATA.request

This primitive defines the transfer of code-groups in the form of the tx_symb_vector parameter from the PCS to the PMA. The code-groups are obtained in the PCS Transmit function using the encoding rules defined in 96.3.3 to represent MII data streams, an idle mode, or other sequences.

96.2.4.1 Semantics of the primitive

PMA_UNITDATA.request (tx_symb_vector)

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb_vector the value of the symbols to be sent over the transmit pair BI_DA. The tx_symb_vector parameter takes on the following form:

SYMB_1D: A vector of one ternary symbol for a single transmit pair BI_DA. Each ternary symbol may take on one of the values {–1, 0, or +1}.

The ternary symbols that are elements of tx_symb_vector are called tx_symb_vector[BI_DA].

96.2.4.2 When generated

The PCS continuously generates PMA_UNITDATA.request (SYMB_1D) synchronously with every TX_TCLK cycle.

96.2.4.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated ternary symbols. The parameter tx_symb_vector is also used by the PMA Receive function to process the signals received on pair BI_DA.

96.2.5 PMA_UNITDATA.indication

This primitive defines the transfer of code-groups in the form of the rx_symb_vector parameter from the PMA to the PCS.

96.2.5.1 Semantics of the primitive

PMA_UNITDATA.indication (rx_symb_vector)

During reception, the PMA_UNITDATA.indication simultaneously conveys to the PCS via the parameter rx_symb_vector the values of the symbols detected on the receive pair BI_DA. The rx_symb_vector parameter takes on the following form:

SYMB_1D A vector of ternary symbols for the receive pair BI_DA. Each ternary symbol may take on one of the values {–1, 0, or +1}.

The ternary symbols that are elements of rx_symb_vector are called rx_symb_vector[BI_DA].

96.2.5.2 When generated

The PMA generates PMA_UNITDATA.indication (SYMB_1D) messages synchronously with signals received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is $66.66\overline{6}$ MHz, as governed by the recovered clock.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.2.5.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

96.2.6 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the descrambler has achieved synchronization.

96.2.6.1 Semantics of the primitive

PMA_SCRSTATUS.request (scr_status)

The scr_status parameter can take on one of the following two values:

OK	The descrambler has achieved synchronization.
NOT_OK	The descrambler is not synchronized.

96.2.6.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages continuously.

96.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 96.4.3 and 96.4.4.

96.2.7 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Transmit, PCS Receive, PMA PHY Control function, and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by the PCS Receive decoding functions. The criterion for setting the parameter loc_rcvr_status is left to the implementor. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting errors during reception of symbol streams that represent the idle mode.

96.2.7.1 Semantics of the primitive

PMA_RXSTATUS.indication (loc_rcvr_status)

The loc_rcvr_status parameter can take on one of the following two values:

OK	This value is asserted and remains true during reliable operation of the receive link for the local PHY.
NOT_OK	This value is asserted whenever operation of the link for the local PHY is unreliable.

96.2.7.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages continuously on the basis of signals received at the MDI.

96.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 96–18, 96.4.4, and 96.4.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.2.8 PMA_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The criterion for setting the parameter rem_rcvr_status is left to the implementor. It can be based, for example, on asserting rem_rcvr_status is NOT_OK until loc_rcvr_status is OK and then asserting the detected value of rem_rcvr_status after proper PCS receive decoding is achieved.

96.2.8.1 Semantics of the primitive

PMA_REMRXSTATUS.request (rem_rcvr_status)

The rem_rcvr_status parameter can take on one of the following two values:

OK	The receive link for the remote PHY is operating reliably.
NOT_OK	Reliable operation of the receive link for the remote PHY is not detected.

96.2.8.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages continuously on the basis of signals received at the MDI.

96.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 96–18.

96.2.9 PMA_RESET.indication

This primitive is used to pass the PMA Reset function to the PCS (pcs_reset=ON) when reset is enabled.

The PMA_RESET.indication primitive can take on one of the following two values:

TRUE	Reset is enabled.
FALSE	Reset is not enabled.

96.2.9.1 When generated

This primitive is generated under the conditions described in 40.4.2.1.

96.2.9.2 Effect of receipt

The effect of receipt of this primitive is specified in 40.4.2.1.

96.2.10 PMA_TXEN.request

This primitive indicates the presence of data on MII for transmission.

96.2.10.1 Semantic of the primitive

PMA_TXEN.request

The TX_EN parameter can take on one of the following two values:

TRUE	The data transmission on MII is enabled.
FALSE	The data transmission on MII is not enabled.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.2.10.2 When generated

PCS generates the PMA_TXEN.request messages continuously based on TX_EN signal received from MII.

96.2.10.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 96–18.

96.3 100BASE-T1 Physical Coding Sublayer (PCS) functions

The Physical Coding Sublayer (PCS) consists of PCS Reset, the PCS Data Transmission Enable, PCS Transmit, and PCS Receive functions as shown in Figure 96–4. The PCS Transmit function is explained in 96.3.3, and the PCS Receive function is explained in 96.3.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

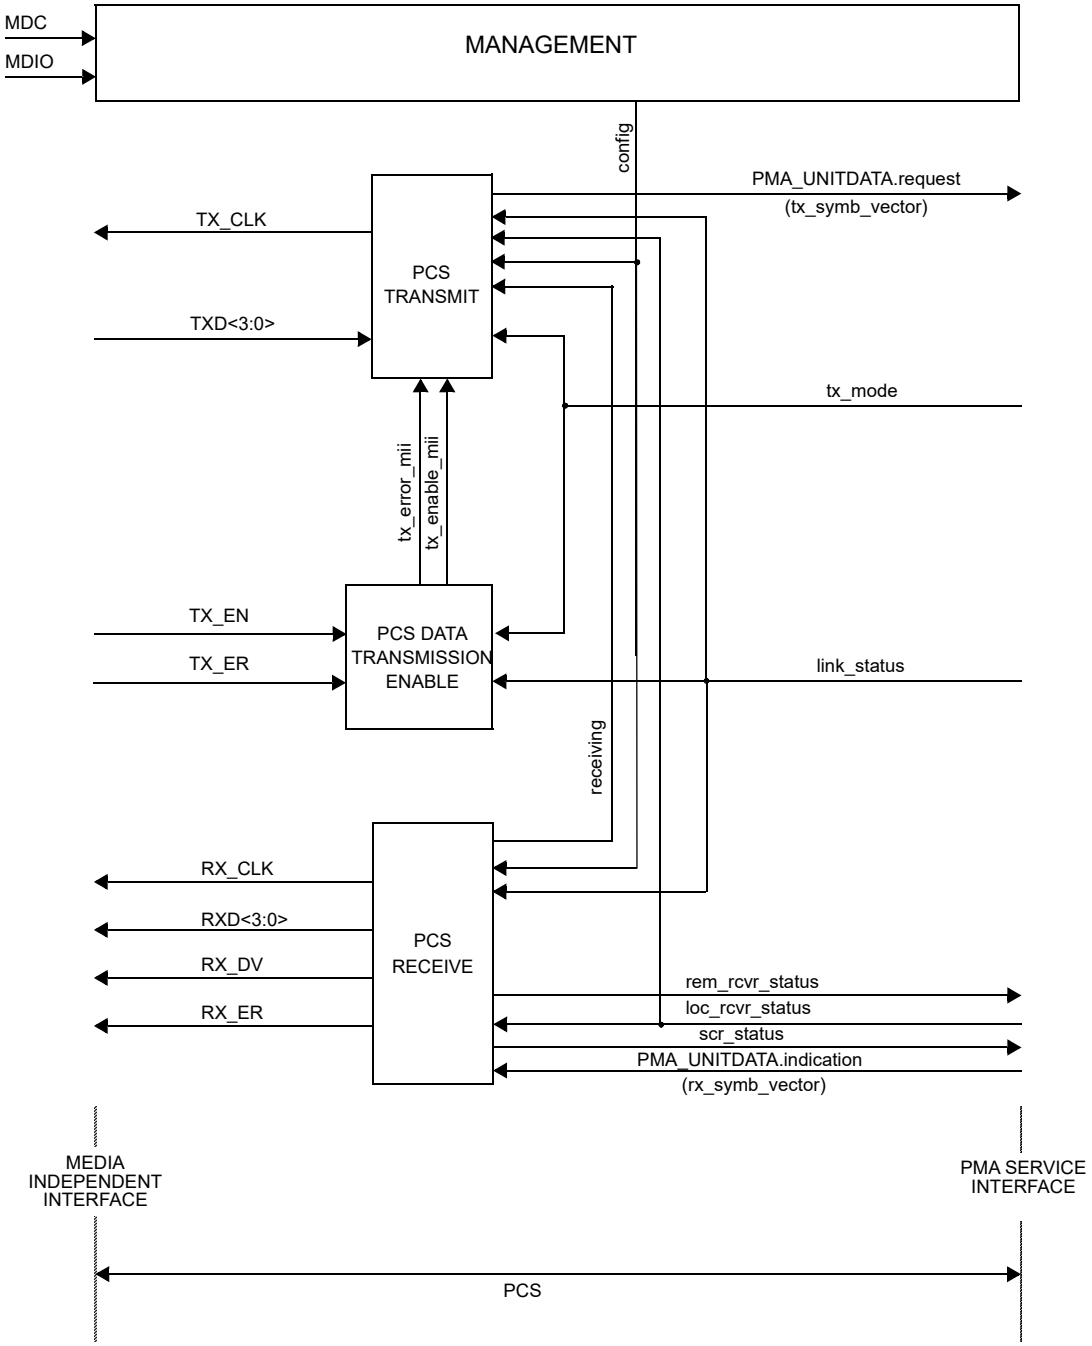

Figure 96–4—PCS reference diagram

96.3.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

a) Power on (see 36.2.5.1.3).
b) The receipt of a request for reset from the management entity.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PCS Reset sets pcs_reset=ON while any of the above reset conditions hold true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

96.3.2 PCS data transmission enabling

The PCS data transmission enabling function shall conform to the PCS data transmission enabling state diagram in Figure 96–5. When tx_mode is equal to SEND_N, the signals tx_enable_mii and tx_error_mii are equal to the value of the MII signals TX_EN and TX_ER respectively, otherwise tx_enable_mii and tx_error_mii are set to the value FALSE.

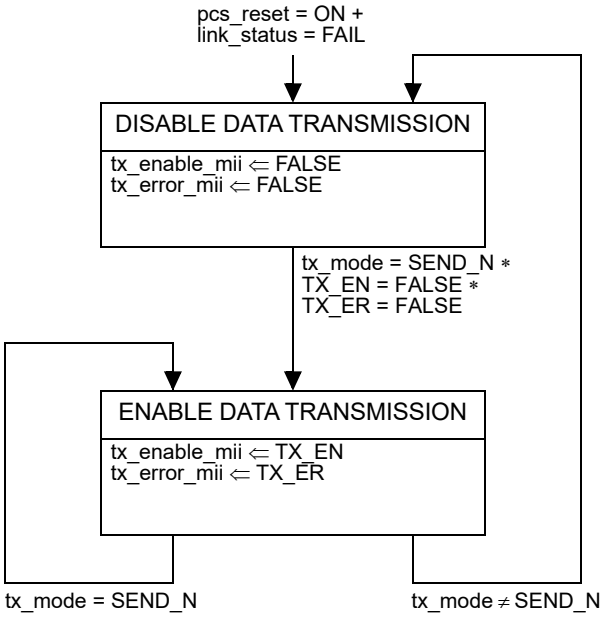

Figure 96–5—PCS data transmission enabling state diagram

96.3.2.1 Variables

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: ON or OFF

tx_enable_mii
: The tx_enable_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 96–5. When set to FALSE transmission is disabled, when set to TRUE transmission is enabled.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_error_mii
: The tx_error_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 96–5.When this variable is set to FALSE it indicates a non-errored transmission, when set to TRUE it indicates an errored transmission.
Values: TRUE or FALSE

TX_EN
: The TX_EN signal of the MII as specified in 22.2.2.3.

TX_ER
: The TX_ER signal of the MII as specified in 22.2.2.5.

tx_mode
: The tx_mode parameter set by the PMA PHY Control function and passed to the PCS via the PMA_TXMODE.indication primitive.
Values: SEND_Z, SEND_N, or SEND_I

96.3.3 PCS Transmit

96.3.3.1 4B/3B conversion

The PCS performs a 4B/3B conversion of the nibbles received at the MII, creates the ternary symbols, and then sends the symbols to the PMA for further processing. It receives 4 bits at the MII using TX_CLK, and converts the stream of 4-bit words at 25 MBd to a stream of 3-bit words at $33.33\overline{3}$ MBd. The bits are then scrambled and converted through PCS encoding to a stream of code-groups (pairs of ternary symbols). These ternary symbol pairs are then multiplexed to a serialized stream of ternary symbols at $66.66\overline{6}$ MBd

96.3.3.1.1 Control signals in 4B/3B conversion

Signals tx_enable_mii, tx_error_mii and TXD<3:0>, synchronized to MII TX_CLK are the input of 4B/3B conversion. After 4B/3B conversion, the transmit signals tx_data<2:0>, tx_enable and tx_error shall be synchronized with PCS transmit clock pcs_txclk. The frequencies of MII TX_CLK and pcs_txclk are 25 MHz and $33.33\overline{3}$ MHz respectively to keep the same bitwise throughput with 4B/3B conversion. TX_TCLK shall be derived from a local source in MASTER mode. TX_TCLK shall be derived from the recovered clock in SLAVE mode. The pcs_txclk is derived from the same clock source as TX_TCLK, with the proper clock division factor to get to the required frequency.

96.3.3.1.2 4B/3B conversion for MII data

The transmit data (TXD<3:0>) at the MII shall first be converted into 3 bits as a group (tx_data<2:0>). As shown in Figure 96–6b and Figure 96–6c, when the number of bits of a packet is not a multiple of three, the 4B/3B conversion shall append stuff bits to the end of a packet (1 or 2 bits), and correspondingly, the tx_enable signal remains TRUE until all the bits in a packet (appended with stuff bits if applicable) are rate converted. Note, a packet includes preamble, SFD, and a MAC Frame as specified in 1.4.447. Those stuff bits may be padded randomly, which is left to implementer, and will be discarded at the receiver upon the boundary of the last nibble at the MII RX domain. The minimum 12 byte IPG period between packets enables flushing the extra stuff bits to prevent FIFO overflow.

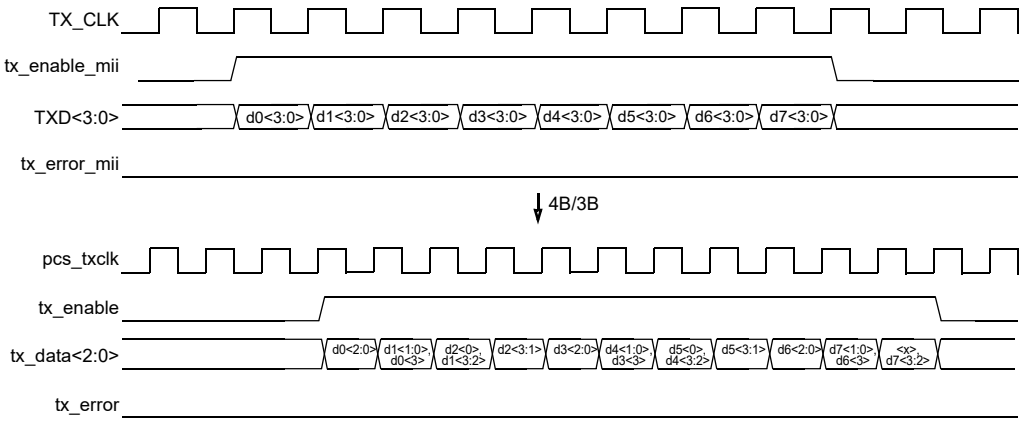

Figure 96–6c—4B/3B MII signal conversion ((3*n*+2)-bit data, 1 stuff bit appended)

96.3.3.2 PCS Transmit state diagram

The PCS Transmit function shall conform to the PCS Transmit state diagram in Figure 96–7, and the associated state variables, functions, timers and messages.

In each symbol period, PCS Transmit generates a sequence of symbols A_n to the PMA, operating in one of three different modes (tx_mode), where symbol A_n is a ternary code that can take values of {–1, 0, or +1}. The PMA transmits symbol A_n over the wire pair BI_DA. The integer, n, is a time index, introduced to establish a temporal relationship between different symbol periods. A symbol period, T, is nominally equal to 15 ns. In the normal mode of operation, the PCS Transmit generates sequences of vectors using the encoding rules defined for SEND_N in 96.3.3.3.7 and 96.3.3.3.8, according to the value of tx_enable. Upon the assertion of tx_enable, the PCS Transmit function passes an SSD of 6 consecutive symbols to the PMA, which replaces the first 9 bits of preamble. Following SSD, tx_data<2:0> is encoded into ternary symbols as specified in 96.3.3.3, until tx_enable is de-asserted. Following the de-assertion of tx_enable, a special code ESD (or ERR_ESD when transmit error is encountered) of 6 consecutive symbols is generated, after which the transmission of idle mode is resumed. As shown in Figure 96–6a and Figure 96–6b, if tx_error_mii is ever asserted (due to MII TX_ER assertion) during the data frame period, tx_error is set as TRUE and stays TRUE till the end of frame to record such an occurrence. 100BASE-T1 only has one special symbol pair (0, 0) that is not used by Idle or Data symbols. Therefore, at the end of a frame, tx_error is examined to determine whether ESD3 or ERR_ESD3 are to be transmitted following ESD1 and ESD2, as shown in Figure 96–7.

The 100BASE-T1 PHY supports normal operation and link training operation. In training operation, the PCS ignores signals from MII and sends only the idle signals to the PMA until training process is complete (signaled by the link partner). The training process usually includes descrambler lock, timing acquisition, echo cancellation and equalizer convergence, etc.

If tx_mode has the value SEND_Z, PCS Transmit passes a vector of zeros at each symbol period to the PMA.

If tx_mode has the value SEND_I, PCS Transmit generates sequences of symbols according to the encoding rule in training mode as described in 96.3.3.3.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If tx_mode has the value SEND_N, PCS Transmit generates symbols A_n at each symbol period representing data, special control symbols like SSD/ESD or IDLE symbols as defined in 96.3.3.3.5. The transition from idle to data is signaled by an SSD, and the end of transmission of data is signaled by an ESD.

During training operation (when tx_mode is SEND_I), knowledge of the transmitted symbols may be used at receiver side to perform any signal conditioning neccesary for meeting the required performance during normal operation. When the link is up, the PHY enters SEND_N mode and the transmitted PAM3 symbols are used at receiver PHY for continued clock frequency/phase tracking.

96.3.3.2.1 Variables

DATA
: A vector of two ternary symbols corresponding to the code-group indicating valid data, as specified in 96.3.

ERR_ESD3
: A vector of two ternary symbols in the third code-group of ESD in case of tx_error (–1, –1) as specified in 96.3.3.3.5.

ESD1
: A vector of two ternary symbols in the first code-group of ESD (0, 0) as specified in 96.3.3.3.5.

ESD2
: A vector of two ternary symbols in the second code-group of ESD (0, 0) as specified in 96.3.3.3.5.

ESD3
: A vector of two ternary symbols in the third code-group of ESD (1, 1) as specified in 96.3.3.3.5.

IDLE
: A sequence of vectors of ternary symbols representing the special code-group generated in Idle mode, as specified in 96.3.3.3.6 and 96.3.3.3.8.

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

loc_rcvr_status
: The loc_rcvr_status parameter set by the PMA Receive function and passed to the PCS via the PMA_RXSTATUS.indication primitive.
Values: OK or NOT_OK

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: ON or OFF

SSD1
: A vector of two ternary symbols in the first code-group of SSD (0, 0) as specified in 96.3.3.3.5.

SSD2
: A vector of two ternary symbols in the second code-group of SSD (0, 0) as specified in 96.3.3.3.5.

SSD3
: A vector of two ternary symbols in the third code-group of SSD (0, 0) as specified in 96.3.3.3.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TXD<3:0>
The TXD<3:0> signal of the MII as specified in 22.2.2.4.

tx_enable
The tx_enable parameter generated by PCS Transmit as specified in Figure 96–7.
Values: TRUE or FALSE

tx_data<2:0>
Generated by PCS Transmit, transmit data is synchronous to pcs_txclk (33.33$\overline{3}$ MHz clock).

tx_error
The tx_error parameter generated by PCS Transmit as specified in Figure 96–7.
Values: TRUE or FALSE

TX_EN
The TX_EN signal of the MII as specified in 22.2.2.3.

TX_ER
The TX_ER signal of the MII as specified in 22.2.2.5.

tx_mode
The tx_mode parameter set by the PMA PHY Control function and passed to the PCS via the PMA_TXMODE.indication primitive.
Values: SEND_Z, SEND_N, or SEND_I

Tx_n
Alias for tx_symb_vector at time *n*.

tx_symb_pair
A pair of ternary symbols generated by the PCS Transmit function after ternary pair encoding.
Value: A pair of ternary transmit symbols. Each of the ternary symbols may take on one of the values {–1, 0, or +1}

96.3.3.2.2 Functions

ENCODE	In the PCS Transmit process, this function takes as its argument tx_data<2:0> and returns the corresponding tx_symb_pair. ENCODE follows the rules defined in 96.3.3.3.

96.3.3.2.3 Timers

symb_timer	The symb_timer shall be generated synchronously with TX_TCLK. In the PCS Transmit state diagram, the message PMA_UNITDATA.request is issued concurrently with symb_timer_done.	
	Continuous timer:	The condition symb_timer_done becomes true upon timer expiration.
	Restart time:	Immediately after expiration; timer restart resets the condition symb_timer_done.
	Duration:	15 ns nominal. (See clock tolerance in 96.5.4.5.)
symb_pair_timer	The symb_pair_timer shall be generated synchronously with PCS transmit clock pcs_txclk.	
	Continuous timer:	The condition symb_pair_timer_done becomes true upon timer expiration.

Restart time:	Immediately after expiration; timer restart resets the condition symb_pair_timer_done.
Duration:	30 ns nominal.

96.3.3.2.4 Messages

STD	Alias for symb_pair_timer_done.

96.3.3.3 PCS transmit symbol generation

The reference diagram of PCS transmit symbol generation is indicated in Figure 96–8. The tx_symb_pair is the ternary pair (TA_n, TB_n).

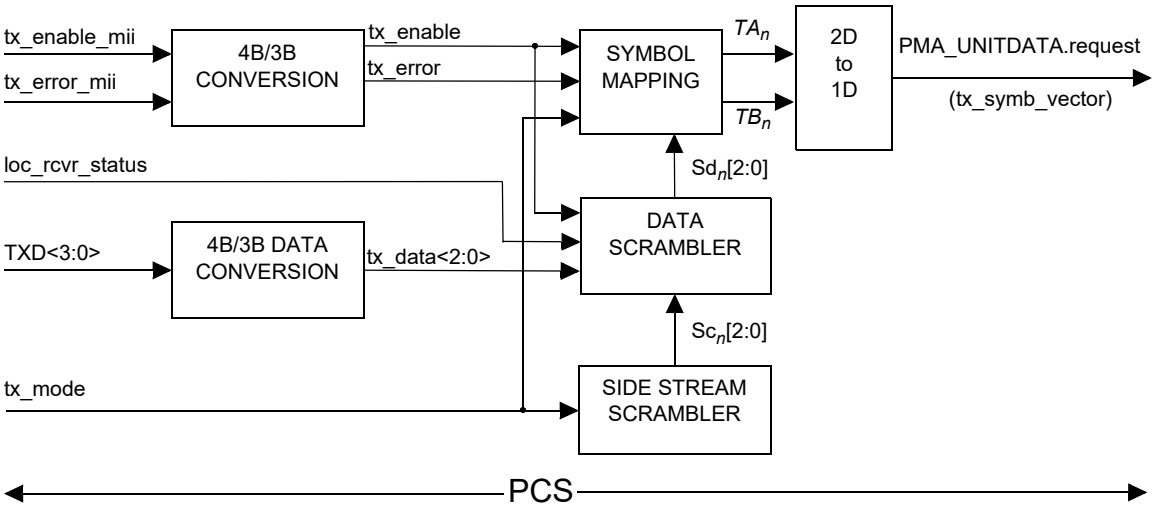

Figure 96–8—PCS transmit symbol generation

96.3.3.3.1 Side-stream scrambler polynomial

The scrambler function shall conform to 40.3.1.3.1 and associated Figure 40–6 without any exceptions.

96.3.3.3.2 Generation of Sy_n[2:0]

Generation of Sy_n[2:0] and Sc_n[2:0] shall conform to and be generated in accordance with the encoding rules in 40.3.1.3.2 and 40.3.1.3.3. Sy_n[2:0] vector in this specification is three bits, while the 40.3.1.3.2 vector is four bits.The PCS Transmit encoding of Sy_n[2:0] and then Sc_n[2:0] are performed, at time n, and used to eliminate the correlation of transmit data tx_data<2:0> and to generate idle and training symbols. Sy_n[3] is not used by definition.

96.3.3.3.3 Generation of Sc_n[2:0]

Bits Sc_n[2:0] shall be generated as follows:

$$Sc_n[2:0] = \begin{cases} [0\ 0\ 0] & \text{if (tx_mode = SEND_Z)} \\ Sy_n[2:0] & \text{else} \end{cases}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.3.3.3.4 Generation of scrambled bits $Sd_n[2:0]$

The $tx_data_n<2:0>$ is a three bit vector after 4B/3B conversion.

From scrambler bits $Sc_n[2:0]$ and $tx_data_n<2:0>$, bits $Sd_n[2:0]$ shall be generated as follows:

$$Sd_n[2] = \begin{cases} Sc_n[2] \wedge tx_data_n<2> & \text{if } (tx_enable_{n-3} = 1) \\ Sc_n[2] \wedge 1 & \text{else if } (loc_rcvr_status = OK) \\ Sc_n[2] & \text{else} \end{cases}$$

$$Sd_n[1:0] = \begin{cases} Sc_n[1:0] \wedge tx_data_n<1:0> & \text{if } (tx_enable_{n-3} = 1) \\ Sc_n[1:0] & \text{else} \end{cases}$$

where ^ denotes the XOR logic operator.

96.3.3.3.5 Generation of ternary pair (TA_n, TB_n)

The bits $Sd_n[2:0]$ are used to generate ternary pair (TA_n, TB_n). The ternary symbol pair (0, 0) is used in the special codes of SSD, ESD, and ESD with tx_error. Sequences of (0, 0), (0, 0), (0, 0) represent SSD, (0, 0), (0, 0), (1, 1) represent ESD and (0, 0), (0, 0), (–1, –1) represent ESD with tx_error.

96.3.3.3.6 Generation of (TA_n, TB_n) when tx_mode = SEND_I

Among the nine possible values for the ternary pair (TA_n, TB_n) only six values are used in the training sequence as indicated in Table 96–1. The ternary pairs used to encode SSD and ESD are not used during training.

Table 96–1—Idle symbol mapping in training

$Sd_n[2:0]$	TA_n	TB_n
000	–1	0
001	0	1
010	–1	1
011	0	1
100	1	0
101	0	–1
110	1	–1
111	0	–1

96.3.3.3.7 Generation of (TA_n, TB_n) when tx_mode = SEND_N, tx_enable = 1

The mapping from $Sd_n[2:0]$ to ternary pairs in data mode is indicated in Table 96–2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 96–2—Data symbols when tx_mode=SEND_N

$Sd_n[2:0]$	TA_n	TB_n
000	–1	–1
001	–1	0
010	–1	1
011	0	–1
Used for SSD/ESD	0	0
100	0	1
101	1	–1
110	1	0
111	1	1

96.3.3.3.8 Generation of (TA_n, TB_n) for idle sequence when tx_mode=SEND_N

The extra scrambling bit Sx_n is introduced to balance the power density for ternary pair (TA_n, TB_n). Sx_n shall be generated as follows:

$$Sx_n = Scr_n[7] \wedge Scr_n[9] \wedge Scr_n[12] \wedge Scr_n[14]$$

where ^ denotes the XOR logic operator. The ternary pair (TA_n, TB_n) is generated according to Table 96–3.

Table 96–3—Idle symbols when tx_mode=SEND_N

	tx_mode = SEND_N			
	$Sx_n = 0$		$Sx_n = 1$	
$Sd_n[2:0]$	TA_n	TB_n	TA_n	TB_n
000	–1	0	–1	0
001	0	1	1	1
010	–1	1	–1	1
011	0	1	1	1
100	1	0	1	0
101	0	–1	–1	–1
110	1	–1	1	–1
111	0	–1	–1	–1

96.3.3.3.9 Generation of (TA_n, TB_n) when tx_mode=SEND_Z

The ternary pair (TA_n, TB_n) simply shows as zero vector (0, 0) when tx_mode=SEND_Z.

96.3.3.3.10 Generation of symbol sequence

The generation of one-dimensional symbol sequence from ternary pair (TA_n, TB_n) is illustrated in Figure 96–9.

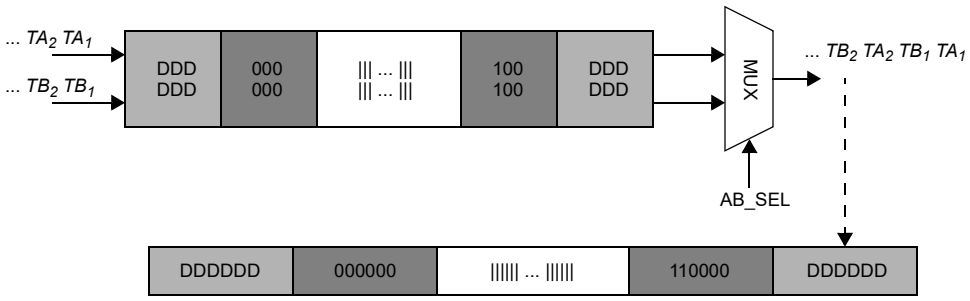

Figure 96–9—2-D symbol to 1-D symbol conversion

The symbol is sent to one sequence in the form of interleave in the order from right to left. AB_SEL signal defines the interleave selection for code-groups. The serial stream is created by interleaving either (TA_n, TB_n) with TA_n followed by TB_n or (TB_n, TA_n) with TB_n followed by TA_n. The ESD (after a packet) is followed by IDLE symbols, then SSD, and then by DATA. The symbol rate is twice as fast as pcs_txclk.

96.3.4 PCS Receive

96.3.4.1 PCS Receive overview

The PCS Receive function shall conform to the PCS Receive state diagram in Figure 96–10a and Figure 96–10b, and associated state variables.

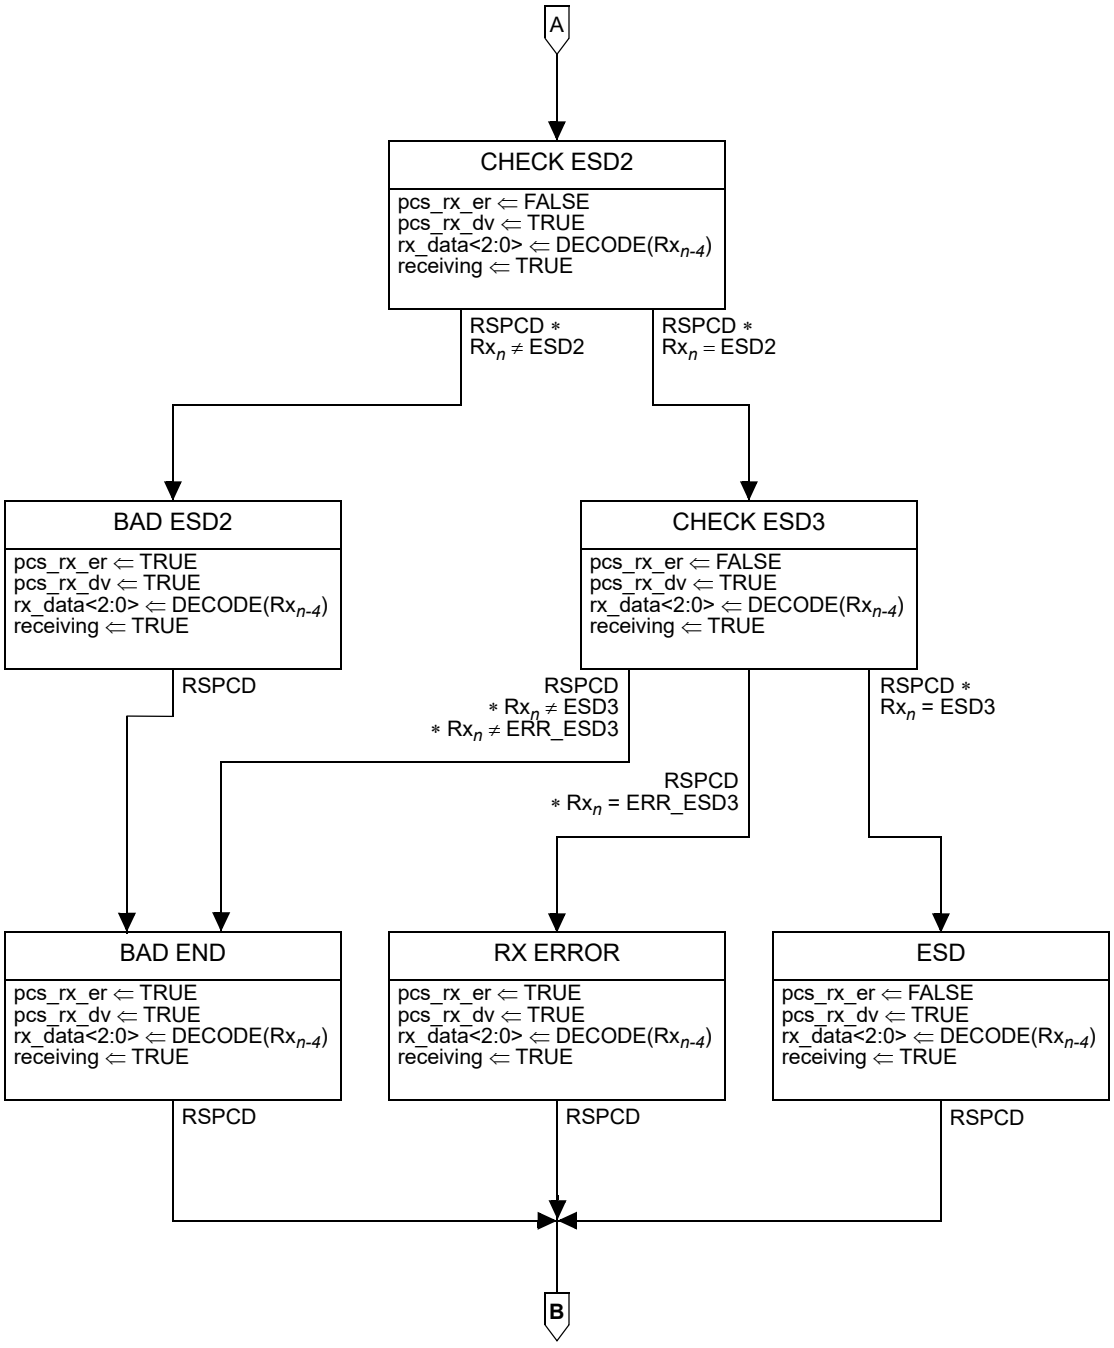

Figure 96–10b—PCS Receive state diagram (continued)

A JAB state machine as shown in Figure 96–11, is implemented to prevent any mis-detection of ESD1 and ESD2 that would make the PCS Receive state machine lock up in the DATA state. The maximum dwelling time in DATA state shall be less than the period specified for rcv_max_timer. When rcv_max_timer expires, the PCS Receive state machine is reset and transition to IDLE state is forced.

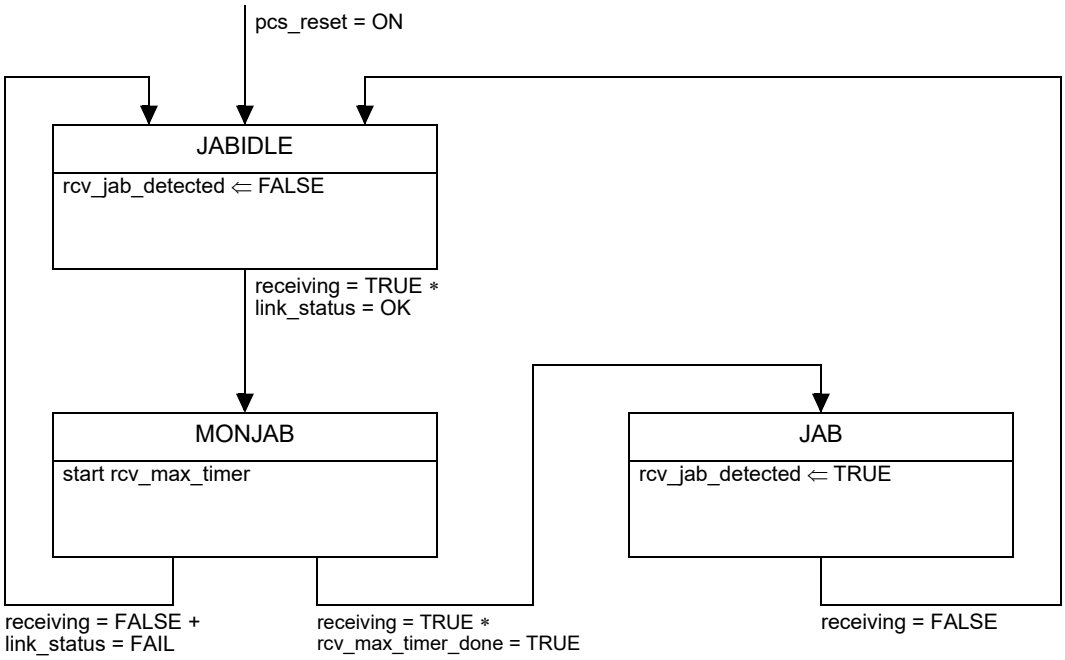

Figure 96–11—JAB state diagram

In Figure 96–10a, there are a total of four states after SSD3 detection before the DATA state; meanwhile, there are also four states before the IDLE state (including the DATA state) that perform DATA decoding. As a result, the depth of data flush-in delay line is the same as the flush-out delay line ensuring correct packet reception at the MII.

The variables, functions, and timers used in Figure 96–10a, Figure 96–10b, and Figure 96–11 are defined as below. For the definition of IDLE, SSD1, SSD2, SSD3, ESD1, ESD2, ESD3 and ERR_ESD3, see 96.3.3.2.1.

96.3.4.1.1 Variables

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

loc_rcvr_status
: The loc_rcvr_status parameter set by the PMA Receive function and passed to the PCS via the PMA_RXSTATUS.indication primitive.
Values: OK or NOT_OK

mii_fc_err
: Indicates that a false carrier error has occurred.
Values: TRUE or FALSE

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: ON or OFF

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pcs_rx_er
: PCS receive error indication signal synchronous to pcs_rxclk.
Values: TRUE or FALSE

pcs_rx_dv
: PCS receive data link indication signal synchronous to pcs_rxclk.
Values: TRUE or FALSE

receiving
: Generated by the PCS Receive function; if set as TRUE, it indicates that the PCS is in Data mode.
Values: TRUE or FALSE

rcv_jab_detected
: Variable set as TRUE when in JAB state as shown in JAB state diagram in Figure 96–11 else it is set FALSE.
Values: TRUE or FALSE

Rx_n
: Received symbol pair generated by PCS Receive at time *n*.

rx_data<2:0>
: PCS decoded data synchronous to pcs_rxclk.

rx_symb_pair
: A pair of ternary symbols generated by the PCS Receive function before ternary pair decoding.
Value: A pair of ternary receive symbols. Each of the ternary symbols may take on one of the values {–1, 0, or +1}.

rx_symb_vector
: A vector of ternary symbols received by the PMA and passed to the PCS via the PMA_UNITDATA.indication primitive.
Value: SYMB_1D

96.3.4.1.2 Functions

check_idle	A function used by the PCS Receive process to detect the reception of valid idle code-groups after an error condition during the process. The check_idle function operates on six consecutive code-groups after de-interleaving rx_symb_vectors. The check_idle function then returns a Boolean value indicating whether or not all six consecutive code-groups after de-interleaving rx_symb_vectors are valid in idle mode encoding, as specified in 96.3.3.3.5.
DECODE	In the PCS Receive process, this function takes as its argument the value of rx_symb_pair and returns the corresponding rx_data<2:0>. DECODE follows the rules outlined in 96.3.4.2.

96.3.4.1.3 Timer

RSPCD	Receive Symbol Pair Converted Done, synchronized with PCS receive clock pcs_rxclk of frequency 33.33$\overline{3}$ MHz.
rcv_max_timer	A timer used to determine the maximum amount of time the PHY Receive state machine stays in DATA state. The timer shall expire 1.08 ms ± 54 μs after being started. The condition rcv_max_timer_done becomes true upon timer expiration.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.3.4.2 PCS Receive symbol decoding

When PMA Receive indicates normal operation and sets loc_rcvr_status = OK, the PCS Receive function checks the symbol sequences and searches for SSD or receive error indicator. The receiver de-interleaves the sequences of rx_symb_vector to rx_symb_pair accordingly.

The received symbols, rx_symb_vector, are de-interleaved to generate rx_symb_pair (RA_n, RB_n). To achieve correct operation, PCS Receive uses the knowledge of the encoding rules that are employed in the idle mode. PCS Receive generates the sequence of symbols and indicates the reliable acquisition of the descrambler state by setting the parameter scr_status to OK. The received ternary pairs (RA_n, RB_n) are decoded to generate signals rx_data<2:0>, pcs_rx_dv, and pcs_rx_error. These signals are processed through 3B/4B conversion to generate signals RXD<3:0>, RX_DV and RX_ER at the MII.

PCS Receive sets pcs_rx_dv=TRUE when it receives SSD, and sets pcs_rx_dv=FALSE when it receives ESD or ESD with error. The number of bits received in a packet is always a multiple of 3 that shall go through the process of 3B/4B conversion, discarding the residual 1 bit or 2 bits of data.

PCS Receive shall set pcs_rx_er = TRUE when it receives bad ESDs, ERR_ESD, or bad SSDs. When the state machine reaches the IDLE state, pcs_rx_er gets reset to FALSE.

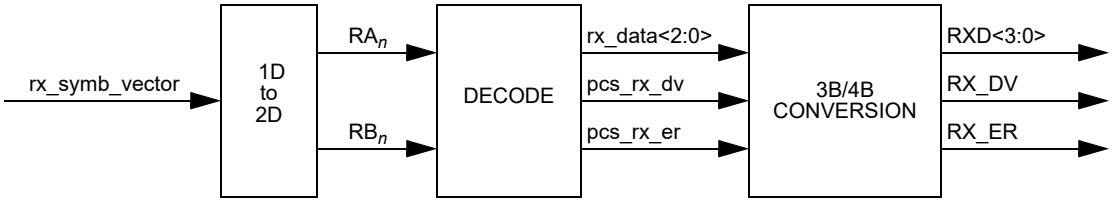

Figure 96–12—PCS Data receive symbol decoding

96.3.4.3 PCS Receive descrambler polynomial

This function shall conform to 40.3.1.4.2, with the exception that it applies to rx_data<2:0>.

96.3.4.4 PCS Receive automatic polarity detection (Optional)

During training, automatic polarity detection may be done in PCS Receive with proper decoding procedures. In the IDLE mode, $Sd_n[2:0]$ are generated by side-stream scrambler with $Sd_n[0]=Scr_n[0]$. According to Table 96–1, when $Sd_n[0]$ is 0, TA_n is either +1 or –1; otherwise, TA_n is 0. Based on this rule, $Scr_n[0]$ should be decoded solely depending on the value of RA_n, then fed back to the shift registers of side-stream descrambler to achieve reliable state acquisition. After that, in every symbol cycle, $Scr_n[0]$ should be compared with the processed RA_n value. Continuous consistency within a certain period means the scrambler has been successfully locked. Polarity can also be automatically detected with similar techniques in a recursive process: one assumption of polarity is made first and the descrambler synchronization is monitored within a certain period to determine whether such an assumption is correct; if not, the same procedure is repeated with a different polarity assumption.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Polarity detection and correction can be done simultaneously at the earliest link up stages. Link up starts with the MASTER PHY sending symbols to the SLAVE PHY. During this initial stage, all hand-shaking signal status, such as rem_rcvr_status, are known as FALSE. With this a priori knowledge, polarity should be accurately detected by the SLAVE side. If a polarity flip is detected, the SLAVE changes the sign of its received signals (RA_n, RB_n) to correct the polarity. Furthermore, it shall invert its transmitted signals (TA_n, TB_n). Since polarity correction has been taken care of by the SLAVE PHY, the polarity would always be observed as correct by the MASTER PHY.

96.3.4.5 PCS Receive MII signal 3B/4B conversion

The MII receive signals RXD<3:0>, RX_DV and RX_ER are synchronized with clock RX_CLK ; while PCS Receive generated signals rx_data<2:0>, rx_dv, and rx_error shall be synchronized with pcs_rxclk to keep the same bitwise throughput after 3B/4B conversion. Generation of pcs_rxclk is implementation dependent. RX_CLK may be derived from the same clock source as TX_CLK if the PHY is in MASTER mode or from the recovered clock if the PHY is in SLAVE mode. The pcs_rxclk is derived from the same clock source as RX_CLK, with the proper clock division factor to get to the required frequency.

The conversion from pcs_rxclk domain signals to MII signals is shown in Figure 96–13. If the number of bits from the received data packet in pcs_rxclk domain is not a multiple of four, the residual bits are actually the stuff bits appended during 4B/3B conversion at the transmitter side. With 3B/4B conversion, those bits shall be discarded. RX_DV shall be deasserted right after the last nibble is converted.

If the BAD SSD state occurred in Figure 96–10a PCS Receive state diagram, the false carrier error shall be indicated on the MII after conversion.

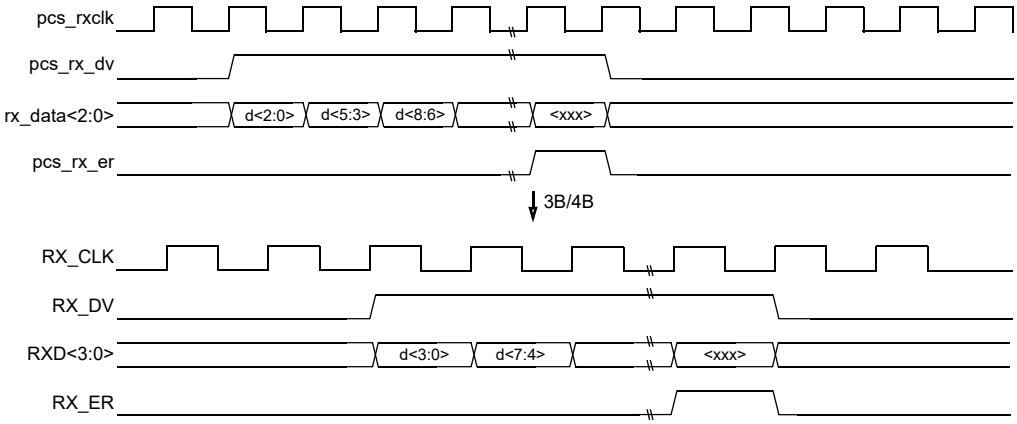

Figure 96–13—PCS Receive 3B/4B conversion reference diagram

96.3.5 PCS Loopback

The PCS shall be placed in loopback mode when the loopback bit in MDIO register 3.0.14, defined in 45.2.3.1.2, is set to a one. In this mode, the PCS shall accept data on the transmit path from the MII and return it on the receive path to the MII. Additionally, the PHY receive circuitry shall be isolated from the network medium, and the assertion of TX_EN at the MII shall not result in the transmission of data on the network medium. The PCS loopback data flow is illustrated in Figure 96–14.

.

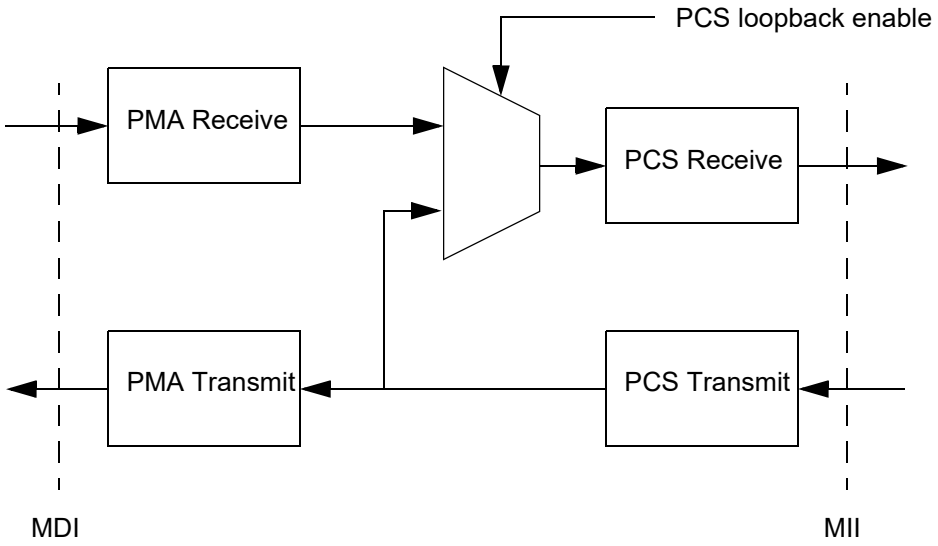

Figure 96–14—PCS loopback data flow

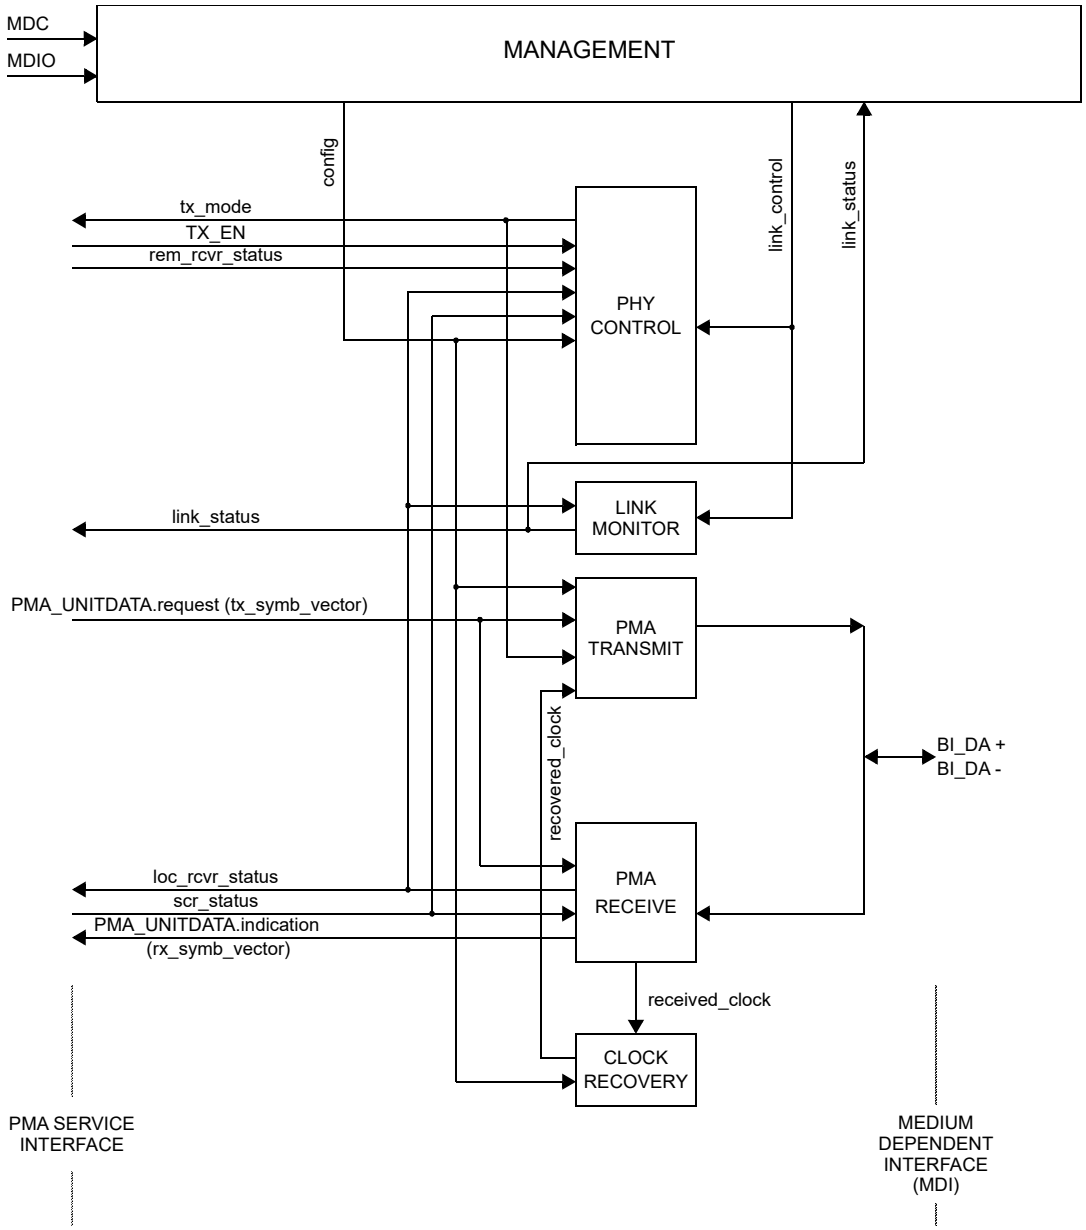
The MAC compares the packets sent through the MII Transmit function to the packets received from the MII Receive function to validate the functionality of 100BASE-T1 PCS functions.

96.4 Physical Medium Attachment (PMA) Sublayer



The PMA couples messages from the PMA service interface specified in 96.2.1 onto the 100BASE-T1 physical medium, and provides the link management and PHY Control functions. The PMA provides full duplex communications to and from medium employing 3-level Pulse Amplitude Modulation (PAM3). The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 96.8.

PMA functions are illustrated in Figure 96–15.

96.4.1 PMA Reset function

This function shall conform to 40.4.2.1 The optional low power mode referenced in 36.2.5.1.3 is not supported.

NOTE: The recovered_clock arc shown indicates delivery of the recovered clock back to PMA TRANSMIT for loop timing.

Figure 96–15—PMA functional block diagram

96.4.2 PMA Transmit function

Figure 96–16 illustrates the signal flow of the 100BASE-T1 PMA Transmit function. During transmission, PMA_UNITDATA.request conveys to the PMA using tx_symb_vector the value of the symbols to be sent over the single transmit pair.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

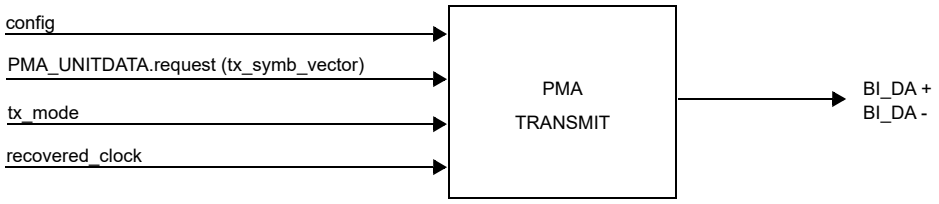

Figure 96–16—PMA Transmit

A single transmitter is used to generate the PAM3 signal BI_DA on the wire, using the transmit clock, TX_TCLK of 66.6$\overline{6}$ MHz, that is the reference clock for the MASTER. When the config parameter is set to MASTER, the PMA Transmit Function derives the TX_TCLK from a local clock source. When the config parameter is set to SLAVE, the PMA Transmit Function derives the TX_TCLK from the recovered clock.

The PMA Transmit fault function is optional. The faults detected by this function are implementation specific. If the MDIO interface is implemented, then this function shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

96.4.3 PMA Receive function

Figure 96–17 illustrates the signal flow of the 100BASE-T1 PMA Receive function. There are three primary PMA Receive characteristics: Receivers, Abilities, and Sub-Functions.

The 100BASE-T1 PMA Receive function comprises a single receiver (PMA Receive) for PAM3 modulated signals on a single balanced twisted-pair, BI_DA. PMA Receive has the ability to translate the received signals on the single pair into the PMA_UNITDATA.indication parameter rx_symb_vector. It detects ternary symbol sequences from the signals received at the MDI over one channel and presents these sequences to the PCS Receive function. PMA Receive has Signal Equalization and Echo Cancellation sub-functions. These sub-functions are used to determine the receiver performance and generate loc_rcvr_status. The parameter loc_rcvr_status is generated by PMA Receive to indicate the status of the receive link at the local PHY. This variable indicates to the PCS Transmitter, PCS Receiver, PMA PHY Control function and Link Monitor whether the status of the overall received link is ok or not. scr_status is generated by the PCS Receiver to indicate the status of the descrambler to the local PHY. It conveys the information on whether the scrambler has achieved synchronization or not to the PMA receive function.

The PMA Receive fault function is optional. The PMA Receive fault function is the logical OR of the link_status = Fail and any implementation specific fault. If the MDIO interface is implemented, then this function shall contribute to the receive fault bit specified in 45.2.1.7.5.

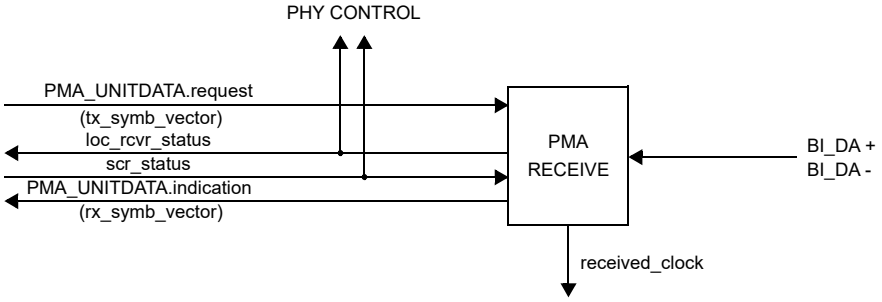

Figure 96–17—PMA Receive

96.4.4 PHY Control function

If the Auto-Negotiation process is not implemented or not enabled, PMA_CONFIG MASTER-SLAVE configuration is predetermined to be MASTER or SLAVE via management control during initialization or via default hardware setup. It governs the control actions needed to bring the PHY into the 100BASE-T1 mode of operation so that frames can be exchanged with the link partner. PMA PHY Control also generates the signals that control PCS and PMA sublayer operations. It determines whether the PHY operates in the normal mode, enabling data transmission over the link segment, or whether the PHY sends special code-groups that represent the idle mode. PHY Control shall comply with the state diagram shown in Figure 96–18. PHY Control sets tx_mode to SEND_N (transmission of normal MII Data Stream, Control Information, or idle), SEND_I (transmission of IDLE code-groups), or SEND_Z (transmission of zero code-groups).

96.4.5 Link Monitor function

Link Monitor operation, as shown in state diagram of Figure 96–19, shall be provided to support PHY Control. The link_control variable is controlled by management during the PHY initialization. In all cases, the time from power_on = FALSE, transitioning to power_on = TRUE, to link_status=OK shall be less than 100 ms.

96.4.6 PMA clock recovery

This PMA function recovers the clock from the received stream. It is coupled to the receiver in order to provide the clock for optimum sampling of the channel. PMA clock recovery outputs are also used as input variables for other PMA functions.

96.4.7 State variables

96.4.7.1 State diagram variables

config
: The config parameter is set by management and passed to the PMA and PCS.
Values: MASTER or SLAVE.

link_control
: This variable is generated by management or set by default.
Values: ENABLE or DISABLE.

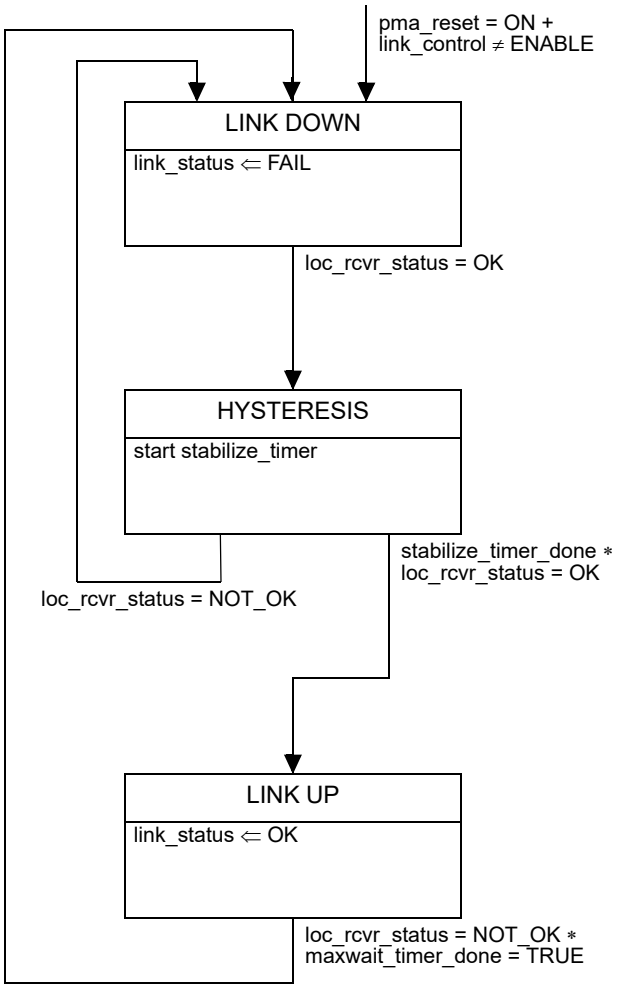

Figure 96–19—Link Monitor state diagram

link_status

This variable is generated by the PMA to indicate the status of the link.

Values: OK or FAIL.

loc_rcvr_status

Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive function for the local PHY.

Values: OK: The receive function for the local PHY is operating reliably.
NOT_OK: Operation of the receive function for the local PHY is unreliable.

pma_reset

Allows reset of all PMA functions.

Values: ON or OFF

Set by: PMA Reset

rem_rcvr_status

Variable set by the PCS Receive function to indicate whether correct operation of the receive function for the remote PHY is detected or not.

Values: OK: The receive function for the remote PHY is operating reliably.
NOT_OK: Reliable operation of the receive function for the remote PHY is not detected.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

scr_status
: The scr_status parameter as communicated by the PMA_SCRSTATUS.request primitive.
Values: OK: The descrambler has achieved synchronization.
NOT_OK: The descrambler is not synchronized.

tx_mode
: PCS Transmit sends code-groups according to the value assumed by this variable.
Values: SEND_N: This value is continuously asserted when code-group sequences representing a PCS code-group in PCS Transmit function, control information, or idle mode are transmitted.
SEND_I: This value is continuously asserted when transmission of sequences of code-groups representing the idle mode is to take place.
SEND_Z: This value is asserted when transmission of zero code-groups is to take place.

tx_enable
: The tx_enable parameter generated by PCS Transmit as specified in Figure 96–8.
Values: TRUE or FALSE.

96.4.7.2 Timers

maxwait_timer	A timer used to limit the amount of time during which a receiver dwells in the SLAVE SILENT and TRAINING states. The timer shall expire 200 ms ± 2 ms. This timer is used jointly in the PHY Control and Link Monitor state diagrams. The maxwait_timer is tested by the Link Monitor to force link_status to be set to FAIL if the timer expires and loc_rcvr_status is NOT_OK. See Figure 96–18.
minwait_timer	A timer used to determine the minimum amount of time the PHY Control stays in the TRAINING, SEND IDLE, or DATA states. The timer shall expire 1.8 µs ± 0.18 µs after being started.
stabilize_timer	A timer used to control the minimum time that loc_rcvr_status has to be OK before a transition to Link Up can occur. The timer shall expire 1.8 µs ± 0.18 µs after being started.

96.5 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA for a 100BASE-T1 Ethernet PHY.

96.5.1 EMC tests

Direct Power Injection (DPI) and 150 Ω emission tests for noise immunity and emission as per 96.5.1.1 and 96.5.1.2 may be used to establish a baseline for PHY EMC performance. These tests provide a high degree of repeatability and a good correlation to immunity and emission measurements. Additional tests may be needed to verify EMC performance in various configurations, applications, and conditions.

96.5.1.1 Immunity—DPI test

In a real application radio frequency (RF) common-mode (CM) noise at the PHY is the result of electromagnetic interference coupling to the cabling system. Additional differential-mode (DM) noise at the PHY is generated from the CM noise by mode conversion of all parts of the cabling system and the MDI. The sensitivity of the PMA's receiver to RF CM noise may be tested according to the DPI method of IEC 62132-4, and may need to comply with more stringent requirements as agreed upon between customer and supplier.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.5.1.2 Emission—Conducted emission test

The emission of the PMA transmitter to its electrical environment may be tested according to the 150 Ω direct coupling method of IEC 61967-4, and may need to comply with more stringent requirements as agreed upon between customer and supplier.

96.5.2 Test modes

The test modes described in this subclause shall be provided to allow testing of the transmitter waveform, transmitter distortion, transmitter jitter, and transmitter droop. The test modes can be enabled by setting bits 1.2102.15:13 (100BASE-T1 PMA/PMD test control register) of the PHY Management register set as described in 45.2.1.215. These test modes shall only change the data symbols provided to the transmitter circuitry and shall not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation.

a) Test mode 1—Transmit droop test mode
b) Test mode 2—Transmit jitter test in MASTER mode
c) Test mode 4—Transmit distortion test
d) Test mode 5—Normal operation at full power (for the PSD mask)

When test mode 1 is enabled, the PHY shall transmit N "+1" symbols followed by N "–1" symbols. The value of N shall be a minimum of 34 symbol periods to achieve a symbol period greater than 500 ns. This sequence is repeated continually. For example, a PHY with test mode 1 enabled and N = 40 symbols (symbol period of 600 ns) would transmit a pattern sufficiently long enough for a 500 ns droop measurement.

When test mode 2 is enabled, the PHY shall transmit the data symbol sequence {+1, –1} repeatedly on its channel. The transmitter shall time the transmitted symbols from a 66.66$\overline{6}$ MHz ± 100 ppm clock in the MASTER timing mode.

When test mode 4 is enabled, the PHY shall transmit the sequence of symbols generated by the following scrambler generator polynomial, bit generation, and level mappings:

$$g(x) = 1 + x^{9} + x^{11} \tag{96–1}$$

The maximum-length shift register used to generate the sequences defined by this polynomial shall be updated once per symbol interval (15 ns). The bits stored in the shift register delay line at a particular time *n* are denoted by $Scr_n[10:0]$. At each symbol period the shift register is advanced by one bit and one new bit represented by $Scr_n[0]$ is generated. Bits $Scr_n[8]$ and $Scr_n[10]$ are exclusive OR'd together to generate the next $Scr_n[0]$ bit. The bit sequences, $x0_n$, and $x1_n$, generated from combinations of the scrambler bits as shown in the following equations, shall be used to generate the ternary symbols, s_n, as shown in Table 96–4. The transmitter shall time the transmitted symbols from a 66.66$\overline{6}$ MHz ± 100 ppm clock in the MASTER timing mode.

$$x0_n = Scr_n[0] \tag{96–2}$$

$$x1_n = Scr_n[1] \wedge Scr_n[4] \tag{96–3}$$

Table 96–4—Transmitter test mode 4 symbol mapping

$x1_n$	$x0_n$	Transmit PAM3 symbol
0	0	0
0	1	1
1	0	0
1	1	–1

Test mode 5 is for checking whether the transmitter is compliant with the transmit PSD mask. When test mode 5 is enabled, the PHY shall transmit a pseudo-random sequence of PAM3 symbols, generated by the scrambling function described in 96.3.3.3.1.

96.5.3 Test fixtures

The fixtures shown in Figure 96–20, Figure 96–21, and Figure 96–22, or their equivalents, are used in the stated respective tests for measuring the transmitter specifications. The tolerance of resistors shall be ± 0.1%. All the transmitter tests are defined at the MDI.

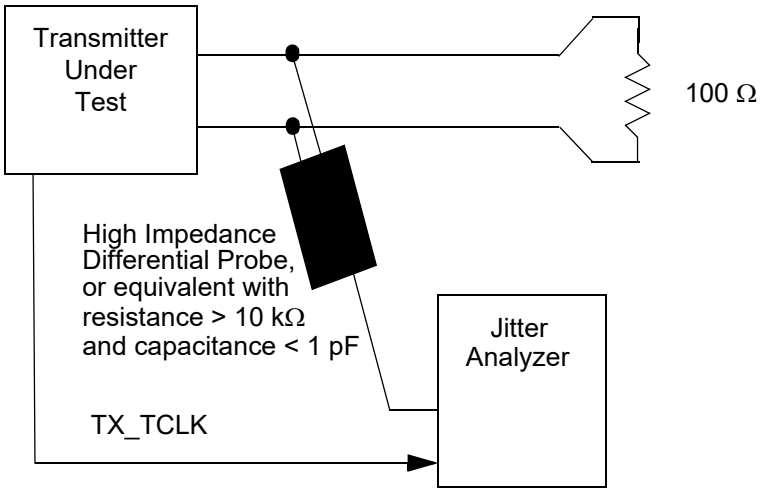

Figure 96–20—Transmitter test fixture 1: Droop, Jitter

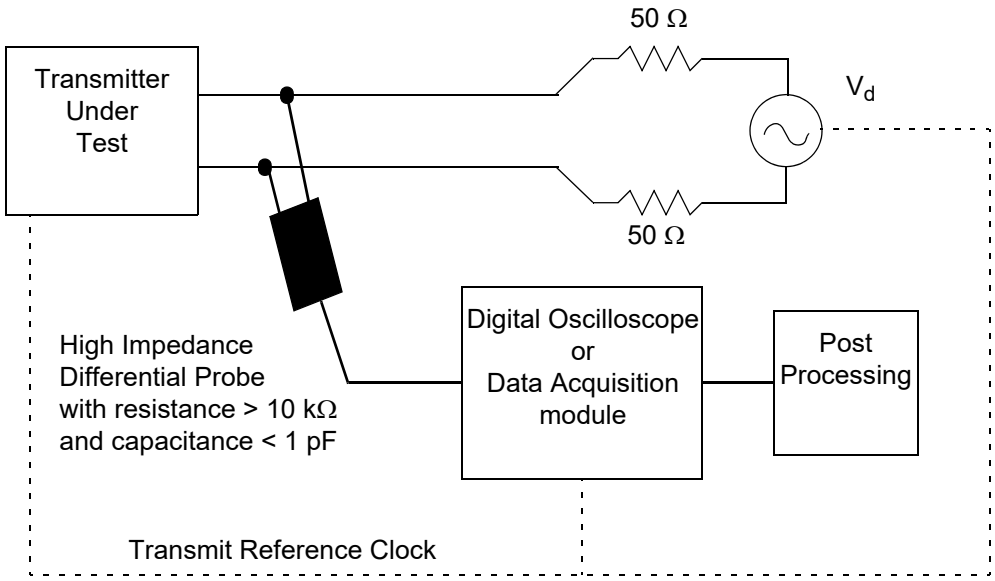

Figure 96–21—Transmitter test fixture 2: Distortion

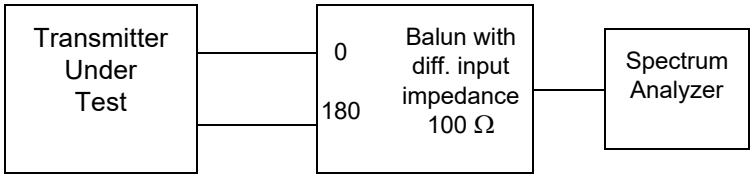

Figure 96–22—Transmitter test fixture 3: PSD mask

To allow for measurement of transmitted jitter in SLAVE modes, the PHY shall provide access to the symbol rate clock, TX_TCLK of 66.66$\overline{6}$ MHz, that times the transmitted symbols. The PHY shall provide a means to enable this clock output if it is not normally enabled.

In Figure 96–21, the disturbing signal, V_d, shall be a sine wave, synchronous with the transmit reference clock, with frequency given by one-sixth of the symbol rate and differential peak-to-peak voltage of 5.4 V.

The generator of the disturbing signal should have sufficient linearity and range that it does not introduce any appreciable distortion when connected to the transmitter output.

96.5.4 Transmitter electrical specifications

The PMA shall operate with AC coupling to the MDI. Where a load is not specified, the transmitter shall meet the requirements of this section with a 100 Ω (the value can vary within ±1% range) resistive differential load connected to the transmitter output.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.5.4.1 Transmitter output droop

The test mode 1 output droop is illustrated in Figure 96–23. With the transmitter in test mode 1 and using the transmitter test fixture 1, the magnitude of both the positive and negative droop measured with respect to an initial peak value after the zero crossing and the value 500 ns after the initial peak, shall be less than 45%.

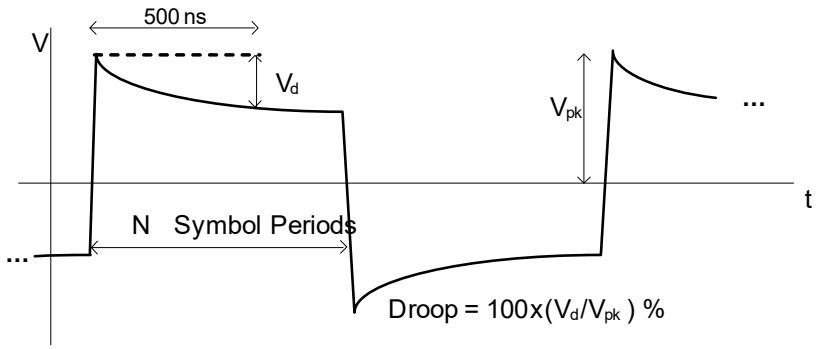

Figure 96–23—Test mode 1 output (not to scale)

When a Clause 104 Type A or Type C PI is encompassed within the MDI, the magnitude of both the positive and negative droop measured with respect to an initial peak value after the zero crossing and the value 500 ns after the initial peak, shall be less than 60%.

96.5.4.2 Transmitter distortion

The transmitter distortion is measured by capturing the test mode 4 waveform using transmitter test fixture 2. The peak distortion is determined by sampling the differential signal output with the symbol rate clock at an arbitrary phase and processing a block of consecutive samples with the code given below.[166, 167] The peak distortion values, measured at a minimum of 10 equally-spaced phases of a single symbol period, shall be less than 15 mV.

The code removes the disturbing signal from the measured data and computes the peak distortion. The code assumes the disturber signal and the data acquisition clock are frequency locked to the DUT transmit clock.

96.5.4.3 Transmitter timing jitter

When in test mode 2, the RMS (Root Mean Square) value of the MDI output jitter, J_{TXOUT}, relative to an unjittered reference shall be less than 50 ps. No high-pass filter is defined here for jitter measurement. The very low frequency components are expected to be filtered out in the setup via the memory size of the oscilloscope. For example, a digital sampling oscilloscope with 20 GSample/s with a 20 Mbytes sample memory size can only capture down to 1 kHz frequency.

When in the normal mode of operation as the SLAVE, jitter on the received signal reflects jitter on the TX_TCLK for SLAVE. Receiving valid signals from a compliant PHY operating as the MASTER with test port connected to the SLAVE, the RMS value of the SLAVE TX_TCLK jitter relative to an unjittered reference shall be less than 0.01 UI (Unit Interval) after the receiver is properly receiving the data. The test setup is shown in Figure 96–24.

For all jitter measurements, the RMS value is defined over an interval of not less than 1 ms and unjittered reference is a constant clock frequency extracted from each record of captured periodic wave. It is based on linear regression of frequency and phase that produces minimum Time Interval Error.

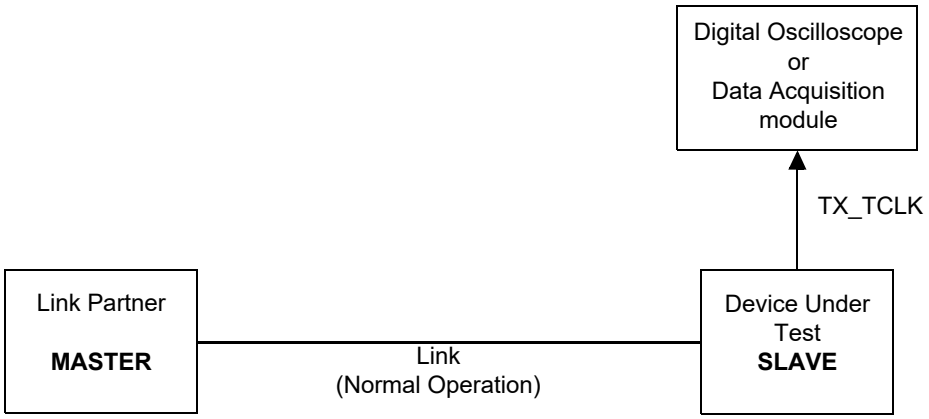

Figure 96–24—Setup for slave transmit timing jitter in normal mode

96.5.4.4 Transmitter power spectral density (PSD)

When test mode 5 is enabled, the PHY is forced to MASTER mode. In this mode, a pseudo-random sequence of ternary codes {–1, 0, +1}, which are mapped to 3 discrete differential signal levels, is transmitted.

In test mode 5, the power spectral density (PSD) of the transmitter, using the test fixture shown in Figure 96–22, shall be between the upper and lower bounds specified in the table below. The upper and lower limits are given in Equation (96–4) and Equation (96–5), and shown in Figure 96–25. The spectrum analyzer settings used for the PSD measurement should be: resolution bandwidth = 10 kHz, video bandwidth = 30 kHz, sweep time > 60 s, and RMS detector.

$$\text{Upper PSD}\ (f)\ = \begin{cases} -63.3 - 1.5 \times \dfrac{f-1}{19}\ \text{dBm/Hz} & \text{for}\ \ 1\ \text{MHz}\ \ \le f < 20\ \text{MHz} \\ -64.8 - 3.7 \times \dfrac{f-20}{20}\ \text{dBm/Hz} & \text{for}\ \ 20\ \text{MHz}\ \le f < 40\ \text{MHz} \\ -68.5 - 8.0 \times \dfrac{f-40}{17}\ \text{dBm/Hz} & \text{for}\ \ 40\ \text{MHz}\ \le f < 57\ \text{MHz} \\ -76.5\ \text{dBm/Hz} & \text{for}\ \ 57\ \text{MHz}\ \le f \le 200\ \text{MHz} \end{cases} \tag{96–4}$$

$$\text{Lower PSD}\ (f)\ = \begin{cases} -70.9 - 4.9 \times \dfrac{f-1}{19}\ \text{dBm/Hz} & \text{for}\ \ 1\ \text{MHz}\ \ \le f < 20\ \text{MHz} \\ -75.8 - 13.4 \times \dfrac{f-20}{20}\ \text{dBm/Hz} & \text{for}\ \ 20\ \text{MHz}\ \le f < 40\ \text{MHz} \end{cases} \tag{96–5}$$

where

Upper PSD(f)	is the upper limit of the PSD of the transmitted signal frequency f
Lower PSD(f)	is the lower limit of the PSD of the transmitted signal frequency f
f	is the frequency in MHz

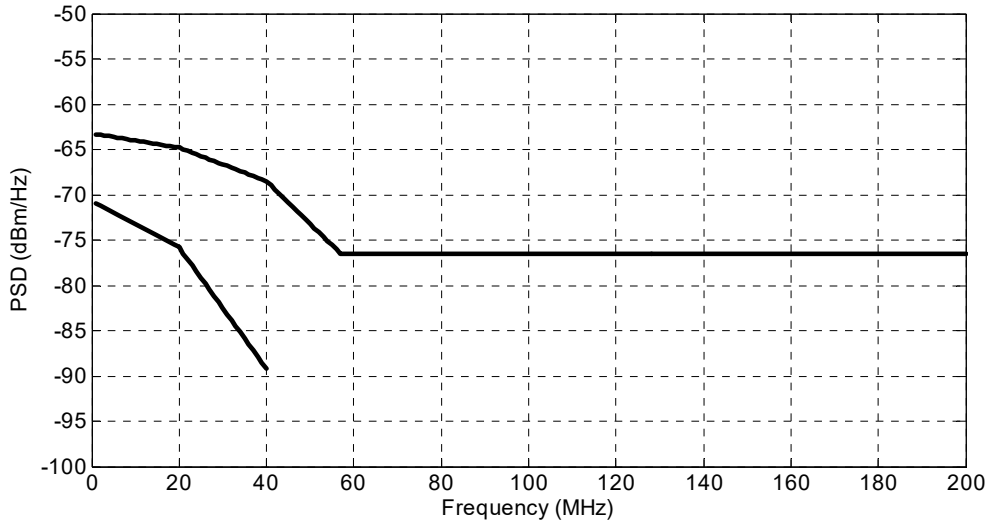

Figure 96–25—PSD upper and lower limits

96.5.4.5 Transmit clock frequency

The symbol transmission rate of the MASTER PHY shall be within the range 66.66$\overline{6}$ MBd ±100 ppm.

96.5.5 Receiver electrical specifications

The PMA shall meet the Receive function specified in PMA Receive function and the electrical specifications of this section. The single balanced twisted-pair cabling system used in test configurations shall be within the limits specified in 96.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.5.5.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of Transmitter Electrical Specifications and have passed through a link specified in 96.7, shall be received with a bit error ratio less than 10^{-10}.

96.5.5.2 Receiver frequency tolerance

The receiver feature shall properly receive incoming data with a symbol rate within the range 66.66$\overline{6}$ MBd ±100 ppm.

96.5.5.3 Alien crosstalk noise rejection

This specification is provided to verify the DUT's tolerance to alien crosstalk noise using two separate tests. The first test is performed with a noise source consisting of a 100BASE-T1 compliant transmitter sending idle symbols. The level of the noise at the MDI is nominally 100 mV peak-to-peak. The second test is performed with a noise source consisting of a signal generator with Gaussian distribution, bandwith of 50 MHz and magnitude of –85 dBm/Hz. The receive DUT is connected to these noise sources through a resistive network, as shown in Figure 96–26, with a link segment as defined in 96.7. The noise is added at the MDI of the DUT. The BER shall be less than 10^{-10}, and to satisfy this specification the frame error ratio is less than 10^{-7} for 125 octet packets measured at MAC/PLS service interface.

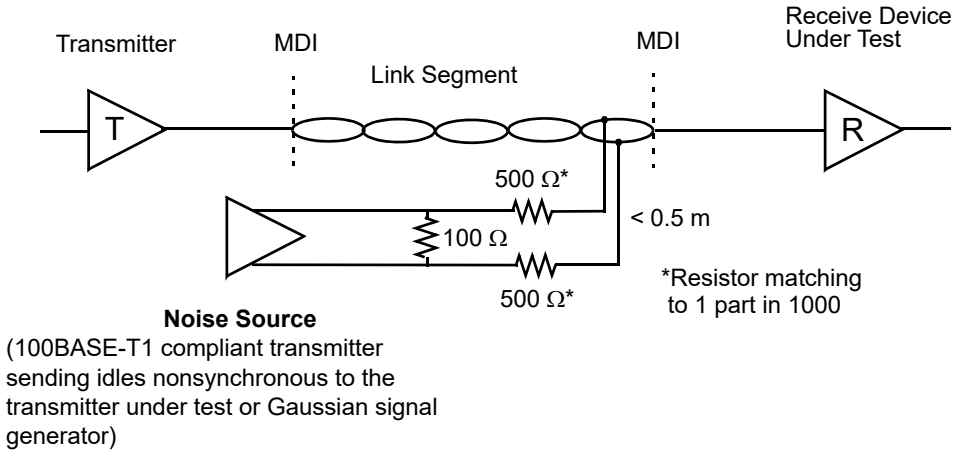

Figure 96–26—Alien crosstalk noise rejection test setup

96.5.6 Transmitter peak differential output

When measured with 100 Ω termination, transmit differential signal at MDI shall be less than 2.2 V peak-to-peak. This limit applies to all transmit modes including SEND_I and SEND_N modes.

96.5.7 PMA Local Loopback

The PMA local loopback function is optional. If supported, the PMA shall be placed in local loopback mode when the PMA local loopback bit in MDIO register 1.0.0, defined in 45.2.1.1, is set to a one. When the PHY is in the PMA local loopback mode the PMA Receive function utilizes the echo signals from the untermina-

ted MDI and decodes these signals to pass the data back to the MII Receive interface. The data flow of the external loopback is shown in Figure 96–27.

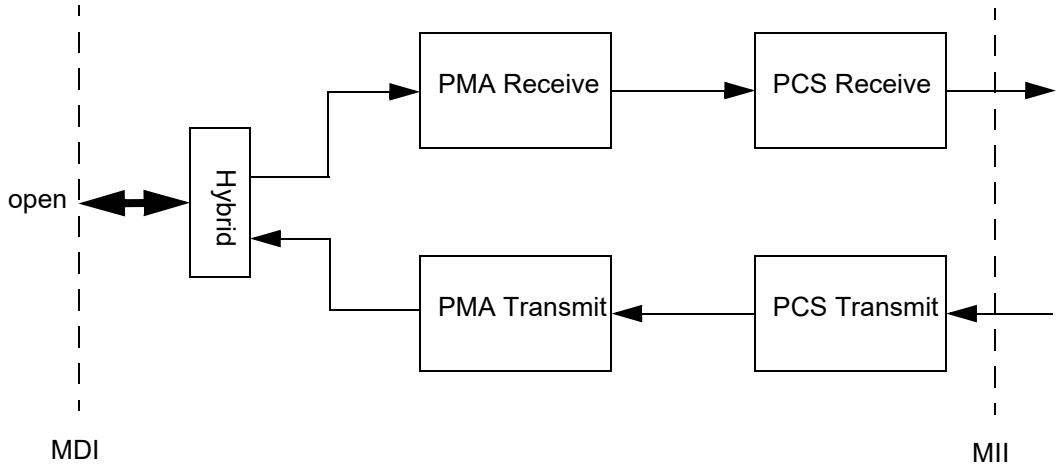

Figure 96–27—PMA loopback data flow

A MAC Client may compare the packets sent through the MII Transmit function to the packets received from the MII Receive function to validate the 100BASE-T1 PCS and PMA functions.

96.6 Management interface

100BASE-T1 uses the management interface as specified in Clause 45. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the registers is recommended.

96.6.1 MASTER-SLAVE configuration

MASTER-SLAVE assignment for each link configuration is necessary for establishing the timing control of each PHY. In 100BASE-T1, one PHY shall be configured as MASTER and one PHY shall be configured as SLAVE to operate. In the case where both PHYs are configured to be MASTER or both to be SLAVE, operation is undefined.

96.6.2 PHY-initialization

Both PHYs sharing a link segment are capable of being MASTER or SLAVE. A forced assignment scheme is employed depending on the physical deployment of the PHY within the application (e.g., at a multi-port bridge versus an end point). This process is conducted at the power-up or reset condition. The station management system manually configures the 100BASE-T1 PHY to be MASTER (before the link acquisition process starts) while the link partner defaults to SLAVE (un-managed).

96.6.3 PMA and PCS MDIO function mapping

The MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMA and PCS. Mapping of MDIO register bits to PMA and PCS control/status variables is shown in Table 96–5.

Table 96–5—MDIO register bit mapping reset and loopback control and link status variables

Register name	Register/bit number	Controls/status variable
PMA/PMD control 1	1.0.15	pma_reset
PMA/PMD control 1	1.0.0	PMA loopback
PCS control 1	3.0.15	pcs_reset
PCS control 1	3.0.14	PCS loopback
PMA/PMD status 1	1.1.2	link_status

96.7 Link segment characteristics

The 100BASE-T1 PHY is designed to operate over a single balanced twisted-pair cabling system. The single balanced twisted-pair cable supports an effective data rate of 100 Mb/s in each direction simultaneously. The link segment for a 100BASE-T1 PHY system is defined as in Figure 96–28, which consists of up to 15 m of single balanced twisted-pair cabling, with up to four in-line connectors and two mating connectors.

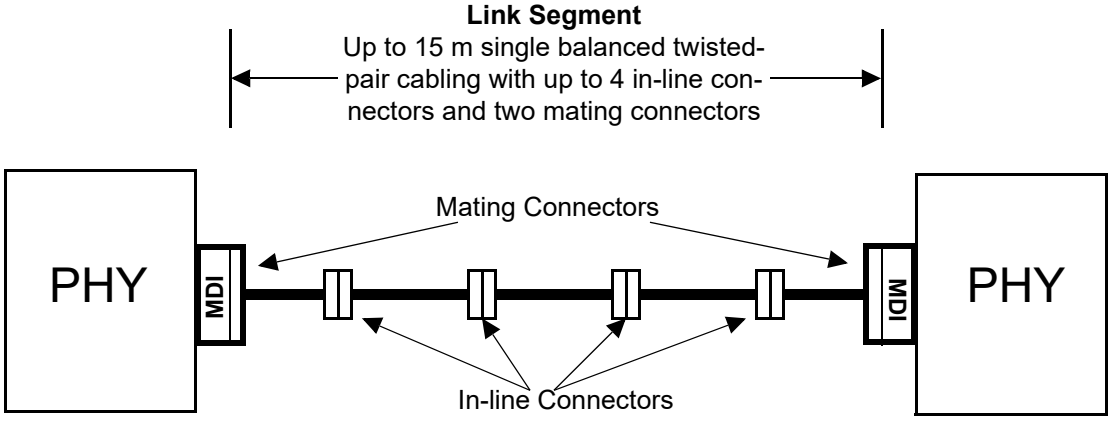

Figure 96–28—Link segment definition

96.7.1 Cabling system characteristics

The cabling system used in Figure 96–28 to support the 100BASE-T1 PHY is composed of a single balanced twisted-pair cable up to 15 m in length with associated connectors, and with impedance in the range of 90 Ω to 110 Ω (nominal 100 Ω) to support a data rate of 100 Mb/s in each direction simultaneously.

The transmission parameters contained in this specification are chosen to enable reliable operation over a single balanced twisted-pair cable link segment. The transmission parameters of the link segment include insertion loss, return loss, mode conversion loss, characteristic impedance, power sum alien near-end crosstalk, and power sum alien attenuation to crosstalk ratio far-end.

96.7.1.1 Characteristic impedance

The characteristic impedance of the cable and any mated MDI connector shall be 100 Ω ±10% measured with TDR and rise-time set not slower than 700 ps.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

96.7.1.2 Insertion loss

The insertion loss of the link segment shown in Figure 96–28 when measured with a 100 Ω termination shall be less than that contained in Equation (96–6).

$$\text{Insertion loss}\,(f) < \begin{cases} 1.0 + 1.6 \times \sqrt{\frac{f-1}{9}} \ \text{dB} & \text{for} \ \ 1\ \text{MHz} \le f < 10\ \text{MHz} \\ 2.6 + 2.3 \times \sqrt{\frac{f-10}{23}} \ \text{dB} & \text{for} \ \ 10\ \text{MHz} \le f < 33\ \text{MHz} \\ 4.9 + 2.3 \times \sqrt{\frac{f-33}{33}} \ \text{dB} & \text{for} \ \ 33\ \text{MHz} \le f \le 66\ \text{MHz} \end{cases} \tag{96–6}$$

where

Insertion loss(f)	is the Insertion loss of the link segment at frequency f
f	is the frequency in MHz

96.7.1.3 Return loss

The return loss of the link segment in Figure 96–28 shall meet or exceed Equation (96–7) for all frequencies from 1 MHz to 66 MHz (with 100 Ω reference impedance).

$$\text{Return loss}\,(f) \ge \begin{cases} 18 \ \text{dB} & \text{for} \ \ 1\ \text{MHz} \le f \le 20\ \text{MHz} \\ 18 - 10 \times \log_{10}\left(\frac{f}{20}\right) \ \text{dB} & \text{for} \ \ 20\ \text{MHz} \le f \le 66\ \text{MHz} \end{cases} \tag{96–7}$$

where

Return loss(f)	is the return loss of the link segment at frequency f
f	is the frequency in MHz

96.7.1.4 Mode conversion loss

Mode conversion LCL and LCTL (Sdc11, Sdc22 and Sdc21, Sdc12) of the link segment defined in 96.7 shall meet or exceed the limit defined in Equation (96–8) for all frequencies from 1 MHz to 200 MHz.

$$\text{Mode conversion loss}(f) \ge \begin{cases} 43 \ \text{dB} & \text{for} \ \ 1\ \text{MHz} \le f \le 33\ \text{MHz} \\ 43 - 20 \times \log_{10}\left(\frac{f}{33}\right) \ \text{dB} & \text{for} \ \ 33\ \text{MHz} \le f \le 200\ \text{MHz} \end{cases} \tag{96–8}$$

where

Mode conversion loss(f)	is the common-to-differential-mode conversion at frequency f
f	is the frequency in MHz

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Alternatively, TCL and TCTL (Scd11, Scd22 and Scd21, Scd12) may be measured to pass the limit line.

96.7.1.5 Power sum alien near-end crosstalk (PSANEXT)

There is no FEXT or NEXT as 100BASE-T1 is a single pair solution. When multiple cable pairs are bundled, the alien XTALK (ANEXT and AFEXT) become interference sources. Since the transmitted symbols from the alien noise source in one cable are not available to another cable, cancellation cannot be done. When there are multiple pairs of cables bundled together, where all pairs carry 100 Mb/s links, then each duplex link is disturbed by neighboring links, degrading the signal quality on the victim pair. In order to limit the near-end crosstalk noise for a 5-around-1 cable bundle (up to 15 m length and up to four in-line connectors, equally spaced), the Power sum alien near-end crosstalk (PSANEXT) loss shall meet Equation (96–9).

$$\text{PSANEXT}(f) \geq 31.5 - 10 \times \log_{10}\left(\frac{f}{100}\right) \quad \text{dB} \qquad \text{for} \quad 1\ \text{MHz} \leq f \leq 100\ \text{MHz} \qquad (96\text{–}9)$$

where

PSANEXT(f) is the power sum alien near-end crosstalk loss at frequency f
f is the frequency in MHz

96.7.1.6 Power sum alien attenuation to crosstalk ratio far-end (PSAACRF)

The Power sum alien attenuation to crosstalk ratio far-end (PSAACRF) for a 5-around-1 cable bundle (up to 15 m length and up to four in-line connectors, equally spaced) shall meet Equation (96–10).

$$\text{PSAACRF}(f) \geq 16.5 - 20 \times \log_{10}\left(\frac{f}{100}\right) \quad \text{dB} \qquad \text{for} \quad 1\ \text{MHz} \leq f \leq 100\ \text{MHz} \qquad (96\text{–}10)$$

where

PSAACRF(f) is the power sum alien attenuation to crosstalk ratio far-end at frequency f
f is the frequency in MHz

96.7.2 Noise environment

In the 100BASE-T1 automotive environment, there are several types of noise sources:

a) Echo from the local transmitter on the same cable pair is caused by the hybrid function for bidirectional data transmission in the 100BASE-T1 duplex channel and by the impedance discontinuities in the link segment. Echo cancellation techniques, up to each PHY implementer, are generally used to achieve the objective BER level.

b) The typical background noise is mainly due to thermal noise. Thermal noise, with level roughly at –140 dBm/Hz, is not a critical contributor that would impact performance. 100BASE-T1 signaling allows a robust margin over a 15 m single balanced twisted-pair cabling channel to combat thermal noise.

c) PSANEXT as described in 96.7.1.5.

d) PSAACRF as described in 96.7.1.6.

96.8 MDI specification

This section defines the MDI for 100BASE-T1.

96.8.1 MDI connectors

The mechanical interface to the balanced cabling is a 2-pin connector or 2 pins of a multi-pin connector.

96.8.2 MDI electrical specification

The MDI connector mated with a specified single balanced twisted-pair cable connector shall meet the electrical requirements specified in 96.7.1, except for return loss, and 96.7.2.

96.8.2.1 MDI return loss

The MDI return loss (RL) shall meet or exceed Equation (96–11) for all frequencies from 1 MHz to 66 MHz (with 100 Ω reference impedance) at all times when the PHY is transmitting data or control symbols.

When a Clause 104 Type A or Type C PI is encompassed within the MDI, the MDI return loss (RL) shall meet or exceed Equation (96–12) for all frequencies from 1 MHz to 66 MHz (with 100 Ω reference impedance) at all times when the PHY is transmitting data or control symbols.

$$\text{MDI return loss}\ (f) \geq \begin{cases} 20\ \text{dB} & \text{for}\ \ 1\ \text{MHz} \leq f \leq 30\ \text{MHz} \\ 20 - 20 \times \log_{10}\left(\frac{f}{30}\right)\ \text{dB} & \text{for}\ \ 30\ \text{MHz} \leq f \leq 66\ \text{MHz} \end{cases} \tag{96–11}$$

$$\text{MDI return loss}(f) \geq \left\{ \begin{array}{ll} 20 - 20 \times \log_{10}\left(\frac{2}{f}\right) & 1 \leq f < 2 \\ 20 & 2 \leq f < 30 \\ 20 - 20 \times \log_{10}\left(\frac{f}{30}\right) & 30 \leq f < 66 \end{array} \right\} \text{dB} \tag{96–12}$$

where

MDI return loss(f) is the MDI return loss at frequency f
f is the frequency in MHz

96.8.2.2 MDI mode conversion loss

Mode conversion LCL (Sdc11) of the PHY measured at MDI shall meet or exceed the limit defined in Equation (96–13) for all frequencies from 1 MHz to 200 MHz.

$$\text{MDI mode conversion loss}(f) \geq \begin{cases} 50\ \text{dB} & \text{for}\ \ 1\ \text{MHz} \leq f \leq 33\ \text{MHz} \\ 50 - 20 \times \log_{10}\left(\frac{f}{33}\right)\ \text{dB} & \text{for}\ \ 33\ \text{MHz} \leq f \leq 200\ \text{MHz} \end{cases} \tag{96–13}$$

where

MDI mode conversion loss(f) is the MDI mode conversion loss at frequency f

f is the frequency in MHz

Alternatively, TCL (Scd11) may be measured to pass the limit line.

96.8.3 MDI fault tolerance

The wire pair of the MDI shall, under all operating conditions, withstand without damage the application of short circuits of any wire to the other wire of the same pair or ground potential or positive voltages of up to 50 V dc with the source current limited to 150 mA, as per Table 96–6, for an indefinite period of time. Normal operation shall resume after the short circuit(s) is (are) removed.

The wire pair of the MDI shall also withstand without damage high-voltage transient noises and ESD per application requirements.

Table 96–6—Connection fault

BI_DA+	BI_DA-
No fault	No fault
BI_DA–	BI_DA+
Ground	No fault
No fault	Ground
+50 V dc	No fault
No fault	+50 V dc
Ground	+50 V dc
+50 V dc	Ground

96.9 Environmental specifications

96.9.1 General safety

All equipment subject to this clause is expected to conform to all applicable local, state, national, and application-specific standards.

96.9.2 Network safety

All cabling and equipment subject to this clause is expected to be mechanically and electrically secure in a professional manner. In automotive applications, all 100BASE-T1 cabling shall be routed in way to provide maximum protection by the motor vehicle sheet metal and structural components, following SAE J1292, ISO 14229, and ISO 15764.

96.9.2.1 Environmental safety

In automotive applications, all equipment subject to this clause shall conform to the potential environmental stresses with respect to their mounting location, as defined in the following specifications:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) General loads: ISO 16750-1
b) Electrical loads: ISO 16750-2, ISO 7637-2:2008, and ISO 8820-1
c) Mechanical loads: ISO 16750-3, ASTM D4728, and ISO 12103-1
d) Climatic loads: ISO 16750-4 , IEC 60068-2-1, IEC 60068-2-27, IEC 60068-2-30, IEC 60068-2-38, IEC 60068-2-52, IEC 60068-2-64, and IEC 60068-2-78
e) Chemical loads: ISO 16750-5 and ISO 20653

Automotive environmental conditions are generally more severe than those found in many commercial environments. The targeted application environment(s) require careful analysis prior to implementation.

96.9.2.2 Electromagnetic compatibility

A system integrating the 100BASE-T1 PHY shall comply with all applicable local and national codes. In addition, the system may need to comply with more stringent requirements as agreed upon between customer and supplier, for the limitation of electromagnetic interference. In automotive applications, a 100BASE-T1 PHY shall be tested according to CISPR 25 test methods, and shall meet the following motor vehicle EMC requirements:

a) Radiated/Conducted Emissions: CISPR 25, IEC 61967-1/4, and IEC 61000-4-21
b) Radiated/Conducted Immunity: ISO 11452, IEC 62132-1/4, and IEC 61000-4-21
c) Electrostatic Discharge: ISO 10605 and IEC 61000-4-2/3
d) Electrical Disturbances: IEC 62215-3 and ISO 7637-2/3

Exact test setup and test limit values may be adapted to each specific application, subject to agreement between the customer and the supplier.

96.10 Delay constraints

Every 100BASE-T1 PHY associated with MII shall comply with the bit delay constraints for full duplex operation. The delay for the transmit path, from the MII input to the MDI, shall be less than 360 ns. The delay for the receive path, from the MDI to the MII output, shall be less than 960 ns.

96.11 Protocol implementation conformance statement (PICS) proforma for Clause 96, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T1[168]

96.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 96, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) and baseband medium, type 100BASE-T1, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

96.11.2 Identification

96.11.2.1 Implementation identification

Supplier[1]	
Contact point for enquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

96.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 96, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T1
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

96.11.4.5 PMA electrical specifications

Item	Feature	Subclause	Value/Comment	Status	Support
PME1	Test modes	96.5.2	Provided to allow testing of the transmitter waveform, transmitter distortion, transmitter jitter, and transmitter droop	M	Yes [ ]
PME2	These test modes shall only change the data symbols provided to the transmitter circuitry and shall not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation.	96.5.2		M	Yes [ ]
PME3	When test mode 1 is enabled, the PHY shall	96.5.2	Transmit N "+1" symbols followed by N "–1" symbols. The value of N (minimum of 34) shall be chosen such that N symbol period is greater than 500 ns	M	Yes [ ]
PME4	When test mode 2 is enabled, the PHY shall	96.5.2	Transmit the data symbol sequence {+1, –1} repeatedly on its channel. The transmitter shall time the transmitted symbols from a $66.66\overline{6}$ MHz ± 100 ppm clock in the MASTER timing mode	M	Yes [ ]
PME5	When test mode 4 is enabled, the PHY shall	96.5.2	Transmit the sequence of symbols generated by the scrambler generator polynomial, bit generation, and level mappings as defined in 96.5.2	M	Yes [ ]
PME6	The maximum-length shift register used to generate the sequences defined by this polynomial shall	96.5.2	Be updated once per symbol interval (15 ns)	M	Yes [ ]
PME7	The transmitter shall	96.5.2	Time the transmitted symbols from a $66.66\overline{6}$ MHz ± 100 ppm clock in the MASTER timing mode	M	Yes [ ]
PME8	When test mode 5 is enabled, the PHY shall	96.5.2	Transmit a pseudo-random sequence of PAM3 symbols, generated by the scrambling function described in 96.3.3.3	M	Yes [ ]
PME9	The tolerance of resistors shall be ± 0.1%.	96.5.3		M	Yes [ ]
PME10	The PHY shall provide access to the symbol rate clock, TX_TCLK of $66.66\overline{6}$ MHz, that times the transmitted symbols.	96.5.3		M	Yes [ ]

96.11.4.7 Characteristics of the Link Segment

Item	Feature	Subclause	Value/Comment	Status	Support
LKS1	The characteristic impedance of the cable and any mated MDI connector	96.7.1.1	Be 100 Ω ±10% measured with TDR and rise-time set not slower than 700 ps	M	Yes [ ]
LKS2	The insertion loss when measured with a 100 Ω termination	96.7.1.2	Be less than that contained in Equation (96–6)	M	Yes [ ]
LKS3	The return loss (with 100 Ω reference impedance)	96.7.1.3	Meet or exceed Equation (96–7) for all frequencies from 1 MHz to 66 MHz	M	Yes [ ]
LKS4	Mode conversion LCL and LCTL	96.7.1.4	Meet or exceed the limit defined in Equation (96–8) for all frequencies from 1 MHz to 200 MHz	M	Yes [ ]
LKS5	The PSANEXT defined in 96.7.1.5	96.7.1.5	Meet Equation (96–9)	M	Yes [ ]
LKS6	The PSAACRF defined in 96.7.1.6	96.7.1.6	Meet Equation (96–10)	M	Yes [ ]

96.11.4.8 MDI Requirements

Item	Feature	Subclause	Value/Comment	Status	Support
MDI1	The MDI connector mated with a specified single balanced twisted-pair cable connector	96.8.2	Meet the electrical requirements specified in 96.7.1, except for return loss, and 96.7.2	M	Yes [ ]
MDI2	The MDI return loss without Clause 104 power	96.8.2.1	Meet or exceed Equation (96–11) for all frequencies from 1 MHz to 66 MHz (with 100 Ω reference impedance) at all times when the PHY is transmitting data or control symbols	!POWER :M	Yes [ ] N/A [ ]
MDI3	The MDI return loss with Clause 104 power	96.8.2.1	Meet or exceed Equation (96–12) for all frequencies from 1 MHz to 66 MHz (with 100 Ω reference impedance) at all times when PHY is transmitting data or control symbols.	POWER: M	Yes [ ] N/A [ ]
MDI4	Mode conversion LCL	96.8.2.2	Meet or exceed the limit defined in Equation (96–13) for all frequencies from 1 MHz to 200 MHz	M	Yes [ ]

97. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 1000BASE-T1

97.1 Overview

This clause defines the type 1000BASE-T1 Physical Coding Sublayer (PCS) and type 1000BASE-T1 Physical Medium Attachment (PMA) sublayer. Together, the PCS and PMA sublayers comprise a 1000BASE-T1 Physical Layer device (PHY). Provided in this clause are fully functional and electrical specifications for the type 1000BASE-T1 PCS and PMA.

The 1000BASE-T1 PHY is one of the Gigabit Ethernet family of high-speed full-duplex PHY specifications, capable of operating at 1000 Mb/s. The 1000BASE-T1 PHY is intended to be operated over a single twisted-pair copper cable, referred to as an *automotive link segment* (Type A) or *optional link segment* (Type B), defined in 97.6. The automotive link segment specifications defined in 97.6 may also be used for other applications that have similar link segment requirements. The cabling supporting the operation of the 1000BASE-T1 PHY is defined in terms of performance requirements between the attachment points [Medium Dependent Interface (MDI)], allowing implementers to provide their own cabling to operate the 1000BASE-T1 PHY as long as the normative requirements included in this clause are met.

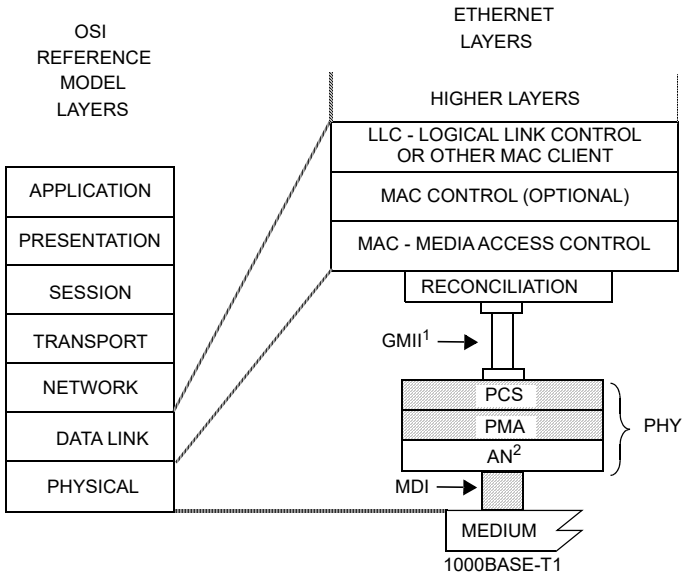
This clause also specifies an optional Energy-Efficient Ethernet (EEE) capability. A 1000BASE-T1 PHY that supports this capability may enter a Low Power Idle (LPI) mode of operation during periods of low link utilization as described in Clause 78.

97.1.1 Relationship of 1000BASE-T1 to other standards

The relationship between the 1000BASE-T1 PHY, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 Ethernet Model are shown in Figure 97–1. The PHY sublayers (shown shaded) in Figure 97–1 connect one Clause 4 Media Access Control (MAC) layer to the medium. Auto-Negotiation for 1000BASE-T1 is defined in Clause 98. GMII is defined in Clause 35.

97.1.2 Operation of 1000BASE-T1

The 1000BASE-T1 PHY operates using full-duplex communications over a single twisted-pair copper cable with an effective rate of 1 Gb/s in each direction simultaneously while meeting the requirements (EMC, temperature, etc.) of automotive and industrial environments. The PHY supports operation on two types of link segments:



a) An automotive link segment supporting up to four in-line connectors using a single twisted-pair copper cable for up to at least 15 m (referred to as *link segment type A*)

b) An optional link segment supporting up to four in-line connectors using a single twisted-pair copper cable for up to at least 40 m to support applications requiring extended physical reach, such as industrial and automation controls and transportation (aircraft, railway, bus and heavy trucks). This link segment is referred to as *link segment type B*.

The 1000BASE-T1 PHY utilizes 3 level Pulse Amplitude Modulation (PAM3) transmitted at a 750 MBd rate. A 15-bit scrambler is used to improve the EMC performance. GMII TX_D, TX_EN, and TX_ER are encoded together using 80B/81B encoding, where 10 cycles of GMII data and control are encoded together in 81 bits to reduce the overhead. To maintain a bit error ratio (BER) of less than or equal to 10^{-10}, the 1000BASE-T1 PHY adds 396 bits of Reed-Solomon forward error correction (RS-FEC) parity to each

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

group of 45 80B/81B blocks (containing 450 octets of GMII data). The PAM3 mapping, scrambler, RS-FEC, and 80B/81B encoder/decoder are all contained in the PCS (see 97.3).

MDI = MEDIUM DEPENDENT INTERFACE
GMII = TEN GIGABIT MEDIA INDEPENDENT INTERFACE

NOTE 1—GMII is optional
NOTE 2—Auto-Negotiation is optional

PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
AN = AUTO-NEGOTIATION

Figure 97–1—Relationship of 1000BASE-T1 PHY to the ISO/IEC OSI reference model and the IEEE 802.3 Ethernet Model

Auto-Negotiation (Clause 98) may optionally be used by 1000BASE-T1 devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for normal operation. Auto-Negotiation is performed upon link startup through the use of half-duplex differential Manchester encoding. The implementation of the Auto-Negotiation function is optional. If Auto-Negotiation is implemented, it shall meet the requirements of Clause 98.

A 1000BASE-T1 PHY shall be capable of operating as MASTER or SLAVE, per runtime configuration. A MASTER PHY uses a local clock to determine the timing of transmitter operations. A SLAVE PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations. When Auto-Negotiation is used, the MASTER-SLAVE relationship between two devices sharing a link segment is established during Auto-Negotiation (see Clause 98). If Auto-Negotiation is not used, a MASTER-SLAVE relationship shall be established by management or hardware configuration of the PHYs. The MASTER and SLAVE are synchronized by a PHY Link Synchronization function in the PHY (see 97.4.2.6).

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

A 1000BASE-T1 PHY may optionally support Energy-Efficient Ethernet (see Clause 78) and advertise the EEE capability as described in 97.4.2.4.5. The EEE capability is a mechanism by which 1000BASE-T1 PHYs are able to reduce power consumption during periods of low link utilization.

The 1000BASE-T1 PHY may optionally support the 1000BASE-T1 PCS-based Operations, Administration, and Maintenance (OAM). The 1000BASE-T1 OAM is useful for monitoring link operation by exchanging PHY link health status and messages. The 1000BASE-T1 OAM information is exchanged between two

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1000BASE-T1 PHYs out of band. The 1000BASE-T1 OAM is specified in 97.3.8, and the 1000BASE-T1 PHY advertises its 1000BASE-T1 OAM capability as described in 97.4.2.4.5.

The 1000BASE-T1 PMA couples messages from the PCS to the MDI and provides clock recovery, link management, and PHY Control functions. The PMA provides full duplex communications at 750 MBd over the single twisted-pair copper cable. PMA functionality is described in 97.4. The MDI is specified in 97.7.

97.1.2.1 Physical Coding Sublayer (PCS)

The 1000BASE-T1 PCS couples a Gigabit Media Independent Interface (GMII), as described in Clause 35, to a Physical Medium Attachment (PMA) sublayer, described in 97.4, which supports communication over a single twisted-pair copper cable.

The PCS comprises the PCS Reset function, PCS Transmit, and PCS Receive. After completion of the Reset function, the Transmit and Receive functions start immediately and run simultaneously.

The PCS operates in two modes: the data mode and the training mode. In the data mode, the PCS Transmit function data path starts with the GMII interface, where TXD, TX_EN, and TX_ER input data to the PCS every 8 ns (as clocked by GTX_CLK). Data and control from ten GTX_CLK cycles are 80B/81B encoded into an 81-bit “81B block” that encodes every possible combination of data and control (control signals include transmit error propagation, receive error, assert low power idle, and inter-frame signaling, as defined in 35.2.1.6). Each set of 45 80B/81B blocks along with 9 bits of 1000BASE-T1 OAM data (see 97.3.8) is processed by an RS-FEC encoder. The RS-FEC encoder adds 396 RS-FEC parity bits and the resulting 4050 bits (45 80B/81B blocks = 3645 bits, 9 bits of 1000BASE-T1 OAM, and 396 bits of FEC parity bits) are scrambled using a 15-bit side-stream scrambler. The 4050 bits are referred to interchangeably as a *PHY frame* or as a *Reed-Solomon frame*. Each group of 3 bits of the scrambled data is converted to 2 PAM3 symbols by the 3B2T mapper (the 4050 bits in the PHY frame become 2700 PAM3 symbols) and passed to the PMA. PCS transmit functions are described in 97.3.2.2.

In the data mode, the PCS Receive function data path operates in the opposite order as the transmit path. The incoming PAM3 symbols are synchronized to PHY frame boundaries. Within each PHY frame, each two PAM3 symbols are demapped to 3 bits by the 3B2T demapper (the 2700 PAM3 symbols are converted to 4050 bits). The data is then descrambled and passed to the RS-FEC decoder for data validation and correction. Finally, each of the 45 80B/81B blocks is 80B/81B decoded into GMII data or control. The PCS data mode receive is described in 97.3.2.3.

In the training mode (see 97.4.2.4), the PCS transmits and receives PAM2 training sequences to synchronize to the PHY frame, learns the data mode scrambler seed, and exchanges EEE and 1000BASE-T1 OAM capabilities. The training mode uses PAM2 encoding.

97.1.2.2 Physical Medium Attachment (PMA) sublayer

The 1000BASE-T1 PMA transmits/receives symbol streams to/from the PCS onto the single balanced twisted-pair and provides the clock recovery, link monitor, and the 1000BASE-T1 PHY Control function. The PMA provides full duplex communications at 750 MBd.

The PMA PHY Control function generates signals that control the PCS and PMA sublayer operations. PHY Control is enabled following the completion of Auto-Negotiation or PHY Link Synchronization and provides the startup functions required for successful 1000BASE-T1 operation. It determines whether the PHY operates in a disabled state, a training state, or a data state where MAC frames can be exchanged between the link partners.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Link Monitor determines the status of the underlying link channel and communicates this status to other functional blocks. A failure of the receive channel causes the data mode operation to stop and Auto-Negotiation or Link Synchronization to restart.

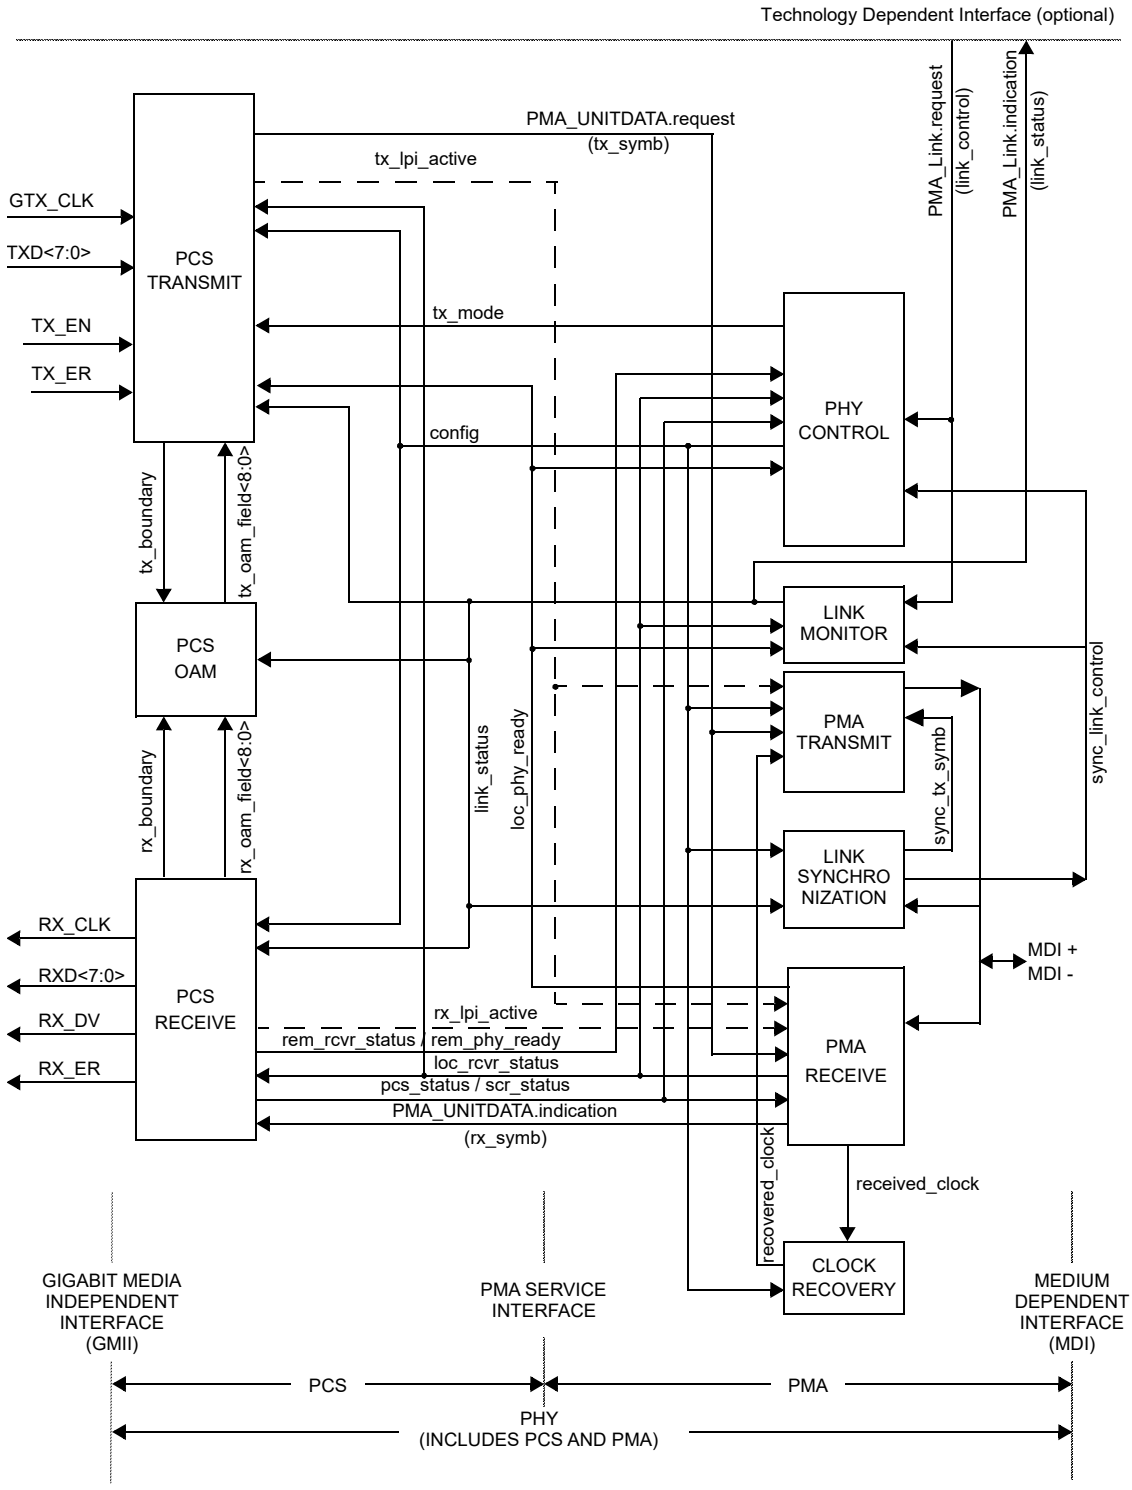
The minimum link segment characteristics, EMC requirements, and test modes are specified in 97.5.

97.1.2.3 EEE capability

A 1000BASE-T1 PHY may optionally support the EEE capability, as described in 78.3. The EEE capability is a mechanism by which 1000BASE-T1 PHYs are able to reduce power consumption during periods of low link utilization. PHYs can enter the LPI mode of operation after completing training. Each direction of the full duplex link is able to enter and exit the LPI mode independently, supporting symmetric and asymmetric LPI operation. This allows power savings when only one side of the full duplex link is in a period of low utilization. The transition to or from LPI mode shall not cause any MAC frames to be lost or corrupted.

In the transmit direction the transition to the LPI transmit mode begins when the PCS transmit function detects an “Assert Low Power Idle” condition on the GMII in the last 80B/81B block of a PHY frame. At the next PHY frame aligned to the wake window the PCS transmits a sleep signal composed of an entire PHY frame containing only LP_IDLE. The sleep signal indicates to the link partner that the transmit function of the PHY is entering the LPI transmit mode. Immediately after the transmission of the sleep frame, the transmit function of the local PHY enters the LPI transmit mode. While the transmit function is in the LPI mode the PHY may disable data path and control logic to save additional power. Periodically the transmit function of the local PHY transmits refresh frames that may be used by the link partner to update adaptive filters and timing circuits. LPI mode may begin with quiet signaling, a full refresh period, or a wake frame. The quiet-refresh cycle continues until the PCS function detects a condition that is not Assert Low Power Idle on the GMII. This condition signals to the PHY that the LPI transmit mode should end. At the next PHY frame the PCS transmits a wake frame composed of an entire PHY frame containing only Idle. On the next PHY frame normal power mode shall resume.

Support for EEE capability is advertised during Training. See 97.4.2.4.5 for details. Transitions to and from the LPI transmit mode are controlled via GMII signaling. Transitions to and from the LPI receive mode are controlled by the link partner using sleep and wake signaling.



When the 1000BASE-T1 OAM SNR settings indicate that LPI is insufficient to maintain PHY SNR, the PHY may temporarily be forced to exit LPI mode and send idles.

The PCS 80B/81B Transmit state diagram in Figure 97–14 includes additional states for EEE. The PCS 80B/81B Receive state diagram in Figure 97–12 includes additional states for EEE.

97.1.2.4 Link Synchronization

The Link Synchronization function is used when Auto-Negotiation is disabled to synchronize between the MASTER PHY and SLAVE PHY before training starts. Link Synchronization provides a fast and reliable mechanism for the link partner to detect the presence of the other, validate link, and start the timers used by the link monitor. Link Synchronization operates in a half-duplex fashion. Based on timers, the MASTER PHY sends a synchronization sequence for 1 µs. If there is no response from the SLAVE, the MASTER repeats by sending a synchronization sequence every 5 µs. If the slave detects the sequence, it responds with a synchronization sequence for 1 µs (after the MASTER has stopped transmitting). If no other detection happens after the SLAVE response for 4 µs then Link Synchronization is successfully complete, link monitor timers are started, and the PHY Control state machine starts Training. Link synchronization is defined in 97.4.2.6.

97.1.3 Signaling

1000BASE-T1 signaling is performed by the PCS generating continuous symbol sequences that the PMA transmits over the single twisted-pair copper cable. The signaling scheme achieves a number of objectives including the following:

a) Algorithmic mapping from TXD<7:0> to PAM3 symbols in the transmit path
b) Algorithmic mapping from PAM3 symbols to RXD<7:0> in the receive path
c) Adding FEC coded data to transmit and validating data using FEC on receive
d) Uncorrelated symbols in the transmitted symbol stream
e) No correlation between symbol streams traveling both directions
f) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining
g) Optionally, ability to signal to the remote PHY that the transmitting PHY is entering the LPI mode or exiting the LPI mode and returning to normal power operation

The PHY may operate in three basic modes: the normal data mode, the training mode, or an optional LPI mode.

In the normal data mode, PCS generates symbols that represent data, control, or idles for transmission by the PMA.

In the training mode, the PCS generates only a PAM2 pattern with periodic embedded data that enables the receiver at the other end to train and synchronize timing, scrambler seeds, and capabilities. The LPI mode is enabled separately in each direction (see LPI signaling in 97.3.5). When transmitting in LPI mode, the PCS generates zero symbols and periodically send a REFRESH pattern to keep the two PHYs synchronized (see 97.3.2.2.15).

97.1.4 Interfaces

All 1000BASE-T1 PHY implementations are compatible at the MDI and at a physically exposed GMII, if made available. Physical implementation of the GMII is optional. Designers are free to implement circuitry within the PCS and PMA in an application-dependent manner provided that the MDI and GMII (if the GMII is implemented) specifications are met. System operation from the perspective of signals at the MDI and management objects are identical whether the GMII is implemented or not.

97.1.5 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5.

The values of all components in test circuits shall be accurate to within ± 1% unless otherwise stated.

Default initializations, unless specified, are left to the implementer.

97.2 1000BASE-T1 Service Primitives and Interfaces

1000BASE-T1 transfers data and control information across the following four service interfaces:

a) Gigabit Media Independent Interface (GMII)
b) Technology Dependent Interface

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) PMA service interface

d) Medium dependent interface (MDI)

The GMII is specified in Clause 35; the Technology Dependent Interface is specified in 98.4. The PMA service interface is defined in 97.2.2, and the MDI is defined in 97.7.3.

97.2.1 Technology Dependent Interface

1000BASE-T1 uses the following service primitives to exchange status indications and control signals across the Technology Dependent Interface as specified in 98.4:

PMA_LINK.request(link_control)

PMA_LINK.indication(link_status)

97.2.1.1 PMA_LINK.request

This primitive allows the Auto-Negotiation or the PHY Link Synchronization algorithm to enable and disable operation of the PMA, as specified in 98.4.2, respectively.

97.2.1.1.1 Semantics of the primitive

PMA_LINK.request(link_control)

The link_control parameter can take on one of the following two values: DISABLE, or ENABLE.

DISABLE	Used by the Auto-Negotiation function to disable the PHY
ENABLE	Used by the Auto-Negotiation to enable the PHY

97.2.1.1.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in 98.4.

97.2.1.1.3 Effect of receipt

This primitive affects the operation of the PMA Link Monitor function as defined in 97.4.2.5, the PMA PHY Control function as defined in 97.4.2.4, and the PMA Receive function defined in 97.4.2.3.

97.2.1.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 98.4.1. This primitive informs the PCS, PMA PHY Control function, and the Auto-Negotiation functions about the status of the underlying link.

97.2.1.2.1 Semantics of the primitive

PMA_LINK.indication(link_status)

The link_status parameter can take on one of the following two values: FAIL or OK.

FAIL	No valid link established.
OK	The Link Monitor function indicates that a valid 1000BASE-T1 link is established. Reliable reception of signals transmitted from the remote PHY is possible.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.2.1.2.2 When generated

The PMA generates this primitive to indicate a change in link_status in compliance with the state diagram given in Figure 97–27.

97.2.1.2.3 Effect of receipt

The effect of receipt of this primitive is specified in 98.4.1.

97.2.2 PMA service interface

1000BASE-T1 uses the following service primitives to exchange symbol vectors, status indications, and control signals across the service interfaces:

PMA_TXMODE.indication(tx_mode)
PMA_CONFIG.indication(config)
PMA_UNITDATA.request(tx_symb)
PMA_UNITDATA.indication(rx_symb)
PMA_SCRSTATUS.request(scr_status)
PMA_PCSSTATUS.request(pcs_status)
PMA_RXSTATUS.indication(loc_rcvr_status)
PMA_PHYREADY.indication(loc_phy_ready)
PMA_REMRXSTATUS.request(rem_rcvr_status)
PMA_REMPHYREADY.request(rem_phy_ready)

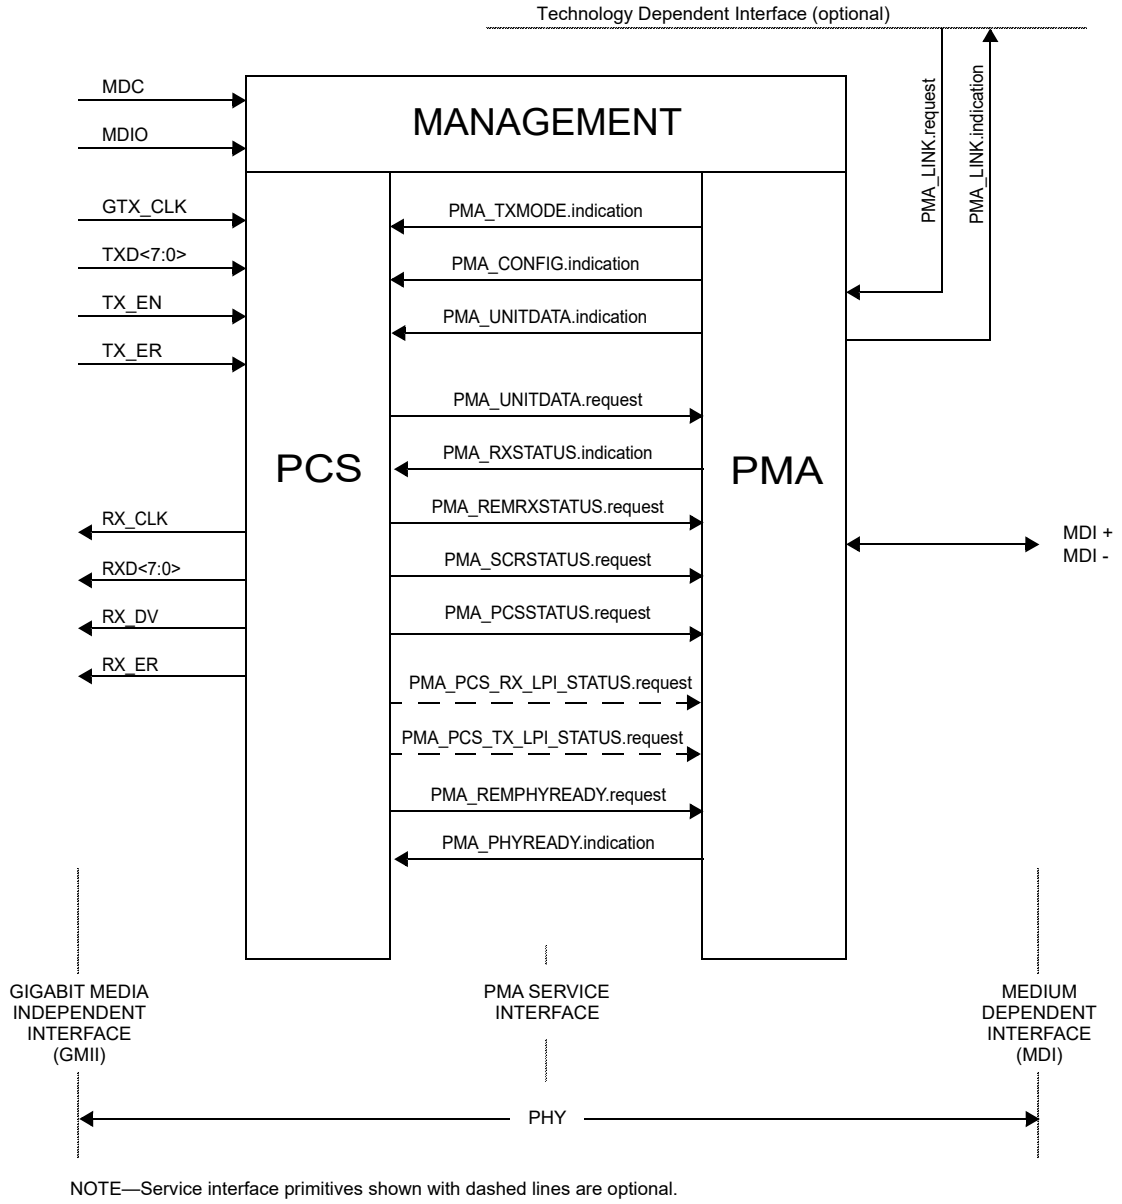
The use of these primitives is illustrated in Figure 97–3. Connections from the management interface (signals MDC and MDIO) to the sublayers are pervasive and are not shown in Figure 97–3.

EEE-capable PHYs additionally support the following service primitives:

PMA_PCS_RX_LPI_STATUS.request(rx_lpi_active)
PMA_PCS_TX_LPI_STATUS.request(tx_lpi_active)

97.2.2.1 PMA_TXMODE.indication

The transmitter in a 1000BASE-T1 link normally sends over the MDI symbols that represent a GMII data stream with framing, scrambling and encoding of data, control information, or idles.



97.2.2.1.1 Semantics of the primitive

PMA_TXMODE.indication(tx_mode)

PMA_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of symbols the PCS should be transmitting. The parameter tx_mode can take on one of the following four values of the form:

SEND_NThis value is continuously asserted during transmission of sequences of symbols representing a GMII data stream in the data mode
SEND_IThis value is continuously asserted when transmission of sequences of idle symbols is to take place
SEND_TThis value is continuously asserted in case transmission of sequences of symbols representing the training mode is to take place
SEND_ZThis value is continuously asserted in case transmission of zeros is required

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Service interface primitives shown with dashed lines are optional.

Figure 97–3—1000BASE-T1 service interfaces

97.2.2.1.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages to indicate a change in tx_mode.

97.2.2.1.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 97.3.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.2.2.2 PMA_CONFIG.indication

Each PHY in a 1000BASE-T1 link is capable of operating as a MASTER PHY and as a SLAVE PHY. If the Auto-Negotiation process is enabled, PMA_CONFIG MASTER-SLAVE configuration is determined during Auto-Negotiation (Clause 98) and the result is provided to the PMA. If the Auto-Negotiation process is not implemented or not enabled, PMA_CONFIG MASTER-SLAVE configuration is predetermined to be MASTER or SLAVE via management control during initialization or via default hardware setup.

97.2.2.2.1 Semantics of the primitive

PMA_CONFIG.indication(config)

PMA_CONFIG.indication specifies to PCS and PMA Transmit via the parameter config whether the PHY operates as a MASTER PHY or as a SLAVE PHY. The parameter config can take on one of the following two values of the form:

MASTER	This value is continuously asserted when the PHY operates as a MASTER PHY
SLAVE	This value is continuously asserted when the PHY operates as a SLAVE PHY

97.2.2.2.2 When generated

PMA generates PMA_CONFIG.indication messages to indicate a change in configuration.

97.2.2.2.3 Effect of receipt

PCS and PMA Clock Recovery perform their functions in MASTER or SLAVE configuration according to the value assumed by the parameter configuration.

97.2.2.3 PMA_UNITDATA.request

This primitive defines the transfer of symbols in the form of the tx_symb parameter from the PCS to the PMA. The symbols are obtained in the PCS Transmit function using the encoding rules defined in 97.3.2.2 to represent GMII data and control streams or other sequences.

97.2.2.3.1 Semantics of the primitive

PMA_UNITDATA.request(tx_symb)

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb the value of the symbols to be sent over the MDI. The tx_symb may take on one of the values in the set { –1, 0, 1 }

97.2.2.3.2 When generated

The PCS generates PMA_UNITDATA.request(tx_symb) synchronously with every transmit clock cycle.

97.2.2.3.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated symbols after processing with optional transmit filtering and other specified PMA Transmit processing.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.2.2.4 PMA_UNITDATA.indication

This primitive defines the transfer of symbols in the form of the rx_symb parameter from the PMA to the PCS.

97.2.2.4.1 Semantics of the primitive

PMA_UNITDATA.indication(rx_symb)

During reception the PMA_UNITDATA.indication conveys to the PCS via the parameter rx_symb the value of symbols detected on the MDI during each cycle of the recovered clock.

97.2.2.4.2 When generated

The PMA generates PMA_UNITDATA.indication(rx_symb) messages synchronously for every symbol received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is 750 MHz, as governed by the recovered clock.

97.2.2.4.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

97.2.2.5 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the training mode descrambler has achieved synchronization.

97.2.2.5.1 Semantics of the primitive

PMA_SCRSTATUS.request(scr_status)

The scr_status parameter can take on one of the following two values of the form:

OK	The training mode descrambler has achieved synchronization
NOT_OK	The training mode descrambler is not synchronized

97.2.2.5.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages to indicate a change in scr_status.

97.2.2.5.3 Effect of receipt

The effect of receipt of this primitive is specified in 97.4.2.3 and 97.4.2.4.

97.2.2.6 PMA_PCSSTATUS.request

This primitive is generated by PCS Receive to indicate the fully operational state of the PCS for the local PHY. The parameter pcs_status conveys to the PMA Receive function the information that the PCS is operating reliably in the data mode.

97.2.2.6.1 Semantics of the primitive

PMA_PCSSTATUS.request(pcs_status)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The pcs_status parameter can take on one of the following two values of the form:

OK	The PCS is operating reliably in the data mode
NOT_OK	The PCS is not operating reliably in the data mode

97.2.2.6.2 When generated

PCS Receive generates PMA_PCSSTATUS.request messages to indicate a change in pcs_status.

97.2.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 97.4.4.1.

97.2.2.7 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Transmit, PCS Receive, PMA PHY Control function, and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by the PCS Receive decoding functions. The criterion for setting the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting errors during reception of symbol stream.

97.2.2.7.1 Semantics of the primitive

PMA_RXSTATUS.indication(loc_rcvr_status)

The loc_rcvr_status parameter can take on one of the following two values of the form:

OK	This value is asserted and remains true during reliable operation of the receive link for the local PHY
NOT_OK	This value is asserted whenever operation of the link for the local PHY is unreliable

97.2.2.7.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages to indicate a change in loc_rcvr_status on the basis of signals received at the MDI.

97.2.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 97–26, 97.3.2.3, 97.4.2.4, and 97.4.5.

97.2.2.8 PMA_PHYREADY.indication

This primitive is generated by PMA Receive to indicate the local PHY is ready or not ready to receive data. The parameter loc_phy_ready is conveyed to the link partner by the PCS as defined in Table 97–1.

97.2.2.8.1 Semantics of the primitive

PMA_PHYREADY.indication(loc_phy_ready)

The loc_phy_ready parameter can take on one of the following two values of the form:

OK	The local PHY is ready to receive data
NOT_OK	The local PHY is not ready to receive data

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.2.2.8.2 When generated

PMA Receive generates PMA_PHYREADY.indication messages to indicate a change in loc_phy_ready based on loc_rcvr_status and pcs_status values.

97.2.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 97–26 and Figure 97–27.

97.2.2.9 PMA_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The parameter rem_rcvr_status is set to the value received in the loc_rcvr_status bit in the InfoField from the remote PHY. The rem_rcvr_status is set to NOT_OK if the PCS has not decoded a valid InfoField from the remote PHY.

97.2.2.9.1 Semantics of the primitive

PMA_REMRXSTATUS.request(rem_rcvr_status)

The rem_rcvr_status parameter can take on one of the following two values of the form:

OK	The receive link for the remote PHY is operating reliably
NOT_OK	Reliable operation of the receive link for the remote PHY is not detected

97.2.2.9.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages to indicate a change in rem_rcvr_status based on the PCS decoding the loc_rcvr_status bit in InfoField messages received from the remote PHY during training.

97.2.2.9.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 97–26.

97.2.2.10 PMA_REMPHYREADY.request

This primitive is generated by PCS Receive to indicate whether the remote PHY is ready or not ready to receive data. Its value is received from the link partner by the PCS as defined in Table 97–1.

97.2.2.10.1 Semantics of the primitive

PMA_REMPHYREADY.request(rem_phy_ready)

The rem_phy_ready parameter can take on one of the following two values of the form:

OK	The remote PHY is ready to receive data
NOT_OK	The remote PHY is not ready to receive data

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.2.2.10.2 When generated

The PCS generates PMA_REMPHYREADY.request messages to indicate a change in rem_phy_ready based on the PCS decoding the control words in Table 97–1 received from the remote PHY.

97.2.2.10.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 97–26.

97.2.2.11 PMA_PCS_RX_LPI_STATUS.request

When the PHY supports the EEE capability this primitive is generated by the PCS receive function to indicate the status of the receive link at the local PHY. The parameter PMA_PCS_RX_LPI_STATUS.request conveys to the PCS transmit and PMA receive functions information regarding whether the receive function is in the LPI receive mode.

97.2.2.11.1 Semantics of the primitive

PMA_PCS_RX_LPI_STATUS.request(rx_lpi_active)

The rx_lpi_active parameter can take on one of the following two values of the form:

true	The receive function is in the LPI receive mode
false	The receive function is not in the LPI receive mode

97.2.2.11.2 When generated

The PCS generates PMA_PCS_RX_LPI_STATUS.request messages to indicate a change in the rx_lpi_active variable as described in 97.3.2.3 and 97.3.6.2.2.

97.2.2.11.3 Effect of receipt

The effect of receipt of this primitive is specified in 97.3.6.4.

97.2.2.12 PMA_PCS_TX_LPI_STATUS.request

When the PHY supports the EEE capability this primitive is generated by the PCS transmit function to indicate the status of the transmit link at the local PHY. The parameter PMA_PCS_TX_LPI_STATUS.request conveys to the PCS transmit and PMA receive functions information regarding whether the transmit function is in the LPI transmit mode.

97.2.2.12.1 Semantics of the primitive

PMA_PCS_TX_LPI_STATUS.request(tx_lpi_active)

The tx_lpi_active parameter can take on one of the following two values of the form:

true	The transmit function is in the LPI transmit mode
false	The transmit function is not in the LPI transmit mode

97.2.2.12.2 When generated

The PCS generates PMA_PCS_TX_LPI_STATUS.request messages to indicate a change in the tx_lpi_active variable as described in 97.3.5 and 97.3.6.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.2.2.12.3 Effect of receipt

The effect of receipt of this primitive is specified in 97.3.6.4.

97.3 Physical Coding Sublayer (PCS)

97.3.1 PCS service interface (GMII)

The PCS service interface allows the 1000BASE-T1 PCS to transfer information to and from a PCS client. The PCS Interface is defined as the Gigabit Media Independent Interface (GMII) in Clause 35.

97.3.2 PCS functions

The PCS comprises one PCS Reset function and two simultaneous and asynchronous operating functions. The PCS operating functions are: PCS Transmit and PCS Receive. All operating functions start immediately after the successful completion of the PCS Reset function.

The PCS reference diagram, Figure 97–4, shows how the two operating functions relate to the messages of the PCS-PMA interface. Connections from the management interface (signals MDC and MDIO) to other layers are pervasive and are not shown in Figure 97–4.

97.3.2.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

a) Power for the device containing the PMA has not reached the operating state
b) The receipt of a request for reset from the management entity

PCS Reset sets pcs_reset = ON while any of the above reset conditions hold true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

The control and management interface shall be restored to operation within 10 ms from the setting of bit 3.2304.15.

97.3.2.2 PCS Transmit function

The PCS Transmit function shall conform to the PCS 80B/81B Transmit state diagram in Figure 97–14 and the PCS Transmit bit ordering in Figure 97–5 and Figure 97–7.

When communicating with the GMII, the PCS uses an octet-wide, synchronous data path, with packet delimiting being provided by transmit control signals and receive control signals. Alignment to 80B/81B blocks is performed in the PCS. The PMA sublayer operates independently of block and packet boundaries. The PCS provides the functions necessary to map packets between the GMII format and the PMA service interface format.

When the transmit channel is in the data mode, the PCS Transmit process continuously generates 80B/81B blocks based upon the TXD <7:0>, TX_EN and TX_ER signals on the GMII. The subsequent functions of the PCS Transmit process then pack the resulting blocks plus one 1000BASE-T1 OAM symbol, both of which are then processed by a Reed-Solomon (RS-FEC) encoder and subsequently 3B2T mapped into a transmit PHY frame of PAM3 symbols. Transmit data-units are sent to the PMA service interface via the PMA_UNITDATA.request primitive. A symbol period, T, is 4/3 ns.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

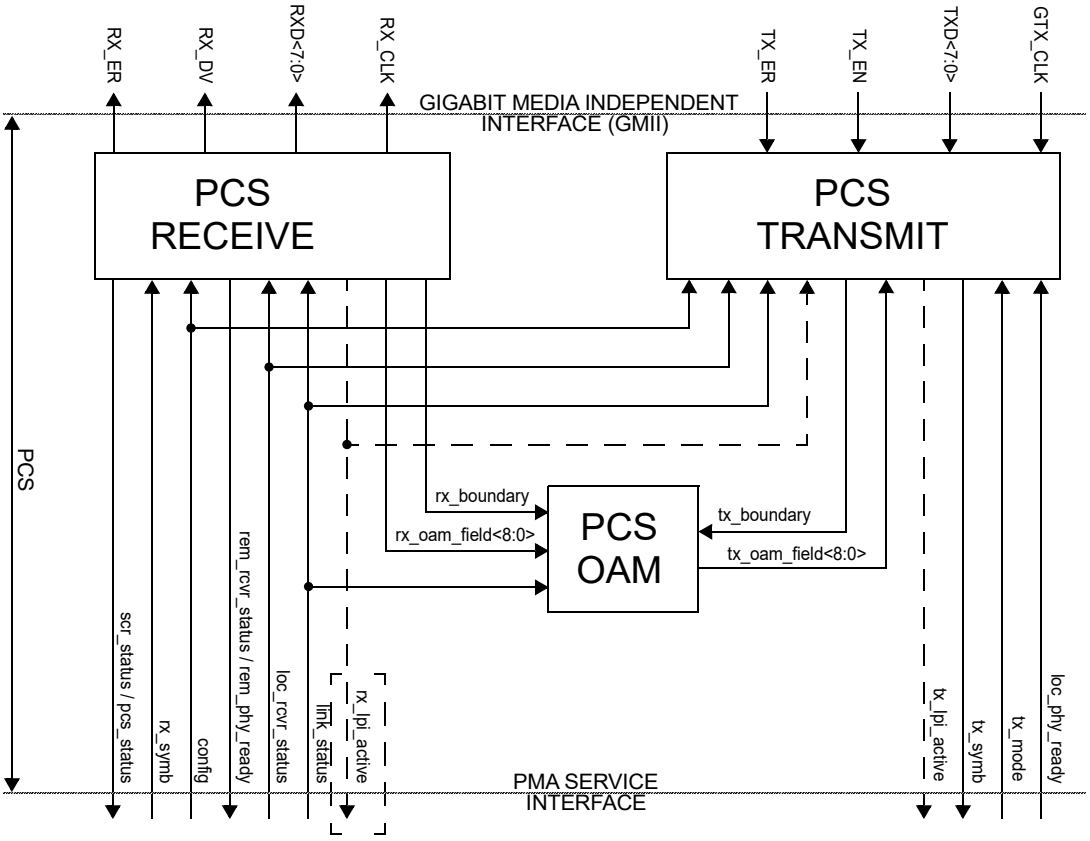

Figure 97–4—PCS reference diagram

If a PMA_TXMODE.indication message has the value SEND_T, PCS Transmit generates sequences of codes defined in 97.3.4.2 to the PMA via the PMA_UNITDATA.request primitive. These codes are used for training mode and only transmit the values {–1, +1}.

During training mode an InfoField is transmitted at regular intervals containing messages for startup operation. By this mechanism, a PHY indicates the status of its own receiver to the link partner. (See 97.4.2.4.)

In the data mode of operation, the PMA_TXMODE.indication message has the value SEND_N, and the PCS Transmit function uses an 81B-RS coding technique to generate at each symbol period symbols that represent data or control. During transmission, 45 80B/81B blocks shall be aggregated, encoded by a PHY frame encoder, and then scrambled by a PCS scrambler. During data encoding PCS Transmit frames shall be encoded into a sequence of PAM3 symbols and transferred to the PMA.

Dashed rectangles in Figure 97–14 indicate states and state transitions in the transmit process state diagram that are supported by PHYs with the EEE capability. PHYs without the EEE capability do not support these transitions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

After reaching the data mode of operation, EEE-capable PHYs may enter the LPI transmit mode under the control of the MAC via the GMII. The EEE Transmit state diagram is contained within the PCS Transmit function. The EEE capability is described in 97.3.2.2.15.

97.3.2.2.1 Use of blocks

The PCS maps GMII signals into 81-bit blocks inserted into a PHY frame, and vice versa, using an 81B-RS coding scheme. The PAM2 PMA training frame synchronization allows establishment of PHY frame and 81B boundaries by the PCS Synchronization process. Blocks and PHY frames are unobservable and have no meaning outside the PCS. The PCS functions ENCODE and DECODE generate, manipulate, and interpret blocks and PHY frames as provided by the rules in 97.3.2.2.2.

97.3.2.2.2 81B-RS transmission code

The PCS uses a transmission code to improve the transmission characteristics of information to be transferred across the link and to support transmission of control and data characters. The encoding defined by the transmission code ensures that sufficient information is present in the PHY bit stream to make clock recovery possible at the receiver. The encoding also preserves the likelihood of detecting any PHY frame errors that may occur during transmission and reception of information. In addition, the code enables the receiver to achieve PCS synchronization alignment on the incoming PHY bit stream.

The relationship of block bit positions to GMII, PMA, and other PCS constructs is illustrated in Figure 97–5 for transmit and Figure 97–6 for receive. These figures illustrate the processing of a multiplicity of blocks containing 10 data octets. See 97.3.2.2.5 for information on how blocks containing control characters are mapped.

97.3.2.2.3 Notation conventions

For values shown as binary, the leftmost bit is the first transmitted bit.

97.3.2.2.4 Transmission order

The PCS Transmit bit ordering shall conform to Figure 97–5 and Figure 97–7. Note that these figures show the mapping from GMII to 80B/81B block for a block containing ten data characters. The LSB of the 1000BASE-T1 OAM symbol is transmitted first.

97.3.2.2.5 Block structure

Blocks consist of 81 bits. The first bit of a block is the data/ctrl header. Blocks are either data blocks or control blocks. The data/ctrl header is 0 for data blocks and 1 for control blocks. The remainder of the block contains the payload.

Data blocks contain 10 data octets. Control blocks begin with a 5-bit pointer field that indicates the location of the first control code within the block. Bits 0 to 3 of the pointer field points to the next octet that is a control symbol. Bit 4 of the pointer field indicates whether the next control symbol is the final control symbol of the block: 0 = final, 1 = more control symbols. If the first octet in the block is a control character, the pointer field is followed by a 3-bit control code. Otherwise the pointer field is followed by one or more data octets until the position of the first control code. Then the 3-bit control code indicates type of control character. The control code is followed by a 5-bit pointer field to the next control character if the prior pointer field value was greater than 15 (i.e., bit 4 = 1). The pointer field may be followed by a data octet or control code depending on the value of the pointer field. In this way any combination of ten data octets and control characters may be encapsulated within an 80B/81B block.

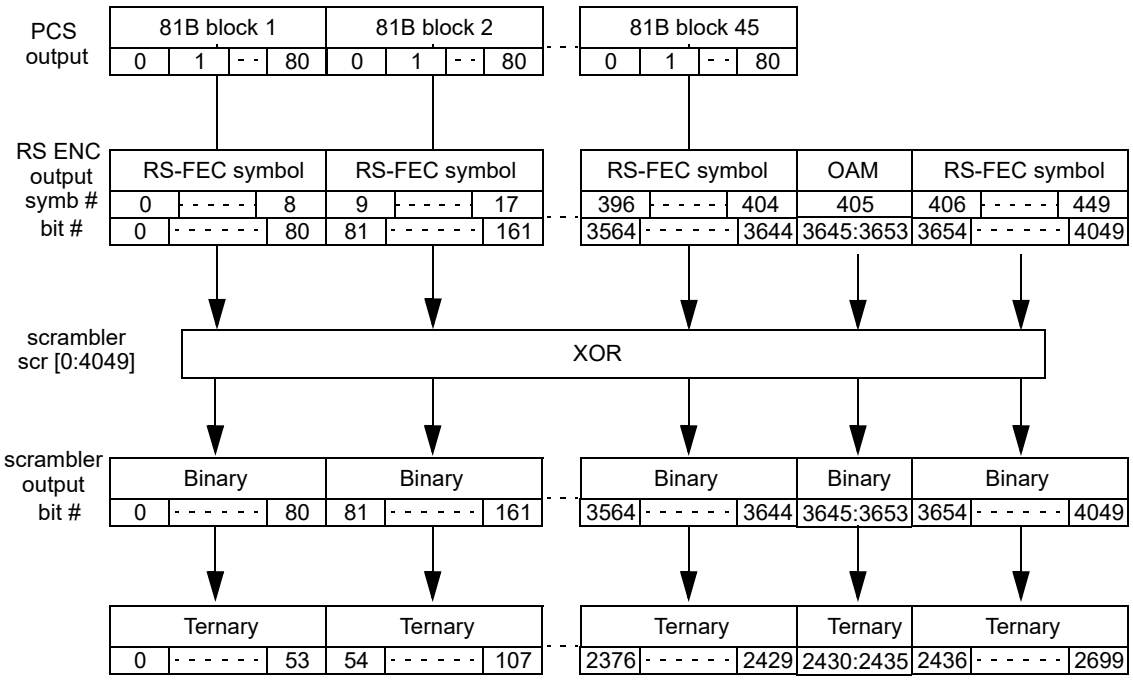

Figure 97–7—PCS detailed transmit bit ordering

The 80B/81B block encoding is defined by the following pseudo-code, where N = 10.

```
N = number of GMII octets encoded into block. Octets numbered n = 0,1,2,…,N-1.
octet 0 is the first one presented on GMII.
TC[n] = 0 if octet n is data octet on GMII, 1 if octet n is control octet on GMII
TC[-1] = 1 by definition
TD[n][0:7] = GMII octet n TXD[0:7] if TC[n] = 0
TD[n][5:7] = 010 – IPG (loc_phy_ready = OK), 101 – LPI, 001 – TX Error, 000 – IPG
(loc_phy_ready = NOT_OK) if TC[n] = 1. TD[n][0:4] is undefined.
B[0:8N] is the 8N+1 block. Bit 0 transmitted first.
OR(n) = Bitwise OR of TC[n:N-1]
NEXT(n)[0:3] = bit position of lowest bit in TC[n:N-1] that is a 1. Bit 3 is MSB.
NEXT(n)[4] = 0 if Bitwise SUM of TC[n:N-1] = 1, else 1

B[0] =              OR(0)
B[8n+1:8n+4] =      TD[n][0:3] – if OR(n) = 0
                    NEXT(n)[0:3] – if OR(n) = 1 AND TC[n-1] = 1
                    TD[n-1][3:6] – if OR(n) = 1 AND TC[n-1] = 0
B[8n+5] =           TD[n][4] – if OR(n) = 0
                    NEXT(n)[4] – if OR(n) = 1 AND TC[n-1] = 1
                    TD[n-1][7] – if OR(n) = 1 AND TC[n-1] = 0
B[8n+6:8n+8] =      TD[n][5:7] – if OR(n) = 0
                    TD[n][5:7] – if OR(n) = 1 AND TC[n] = 1
                    TD[n][0:2] – if OR(n) = 1 AND TC[n] = 0
```

97.3.2.2.6 Control codes

A subset of control characters defined at the GMII are supported by the 1000BASE-T1 PCS. When TX_ER and TX_EN are both asserted, the 1000BASE-T1 PCS conveys an Error symbol in the 80B/81B block code. When TX_EN is not asserted and no other supported control code is present at the GMII, the 1000BASE-T1 PCS conveys a Normal Inter-Frame control code in the 80B/81B block code.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The control characters and their mappings to 1000BASE-T1 control code and GMII control code are specified in Table 97–1. All GMII and 1000BASE-T1 control code values that do not appear in the table shall not be transmitted and shall be treated as an error if received.

Table 97–1—GMII control code mapping

Control Code[0:2]	GMII Transmit	GMII Receive
000	Normal Inter-Frame with loc_phy_ready = NOT_OK	Normal Inter-Frame with rem_phy_ready = NOT_OK
001	Transmit Error Propagation	Data Reception Error
010	Normal Inter-Frame with loc_phy_ready = OK	Normal Inter-Frame with rem_phy_ready = OK
101	Assert Low Power Idle	Assert Low Power Idle

The Carrier Extend and Carrier Extend Error, and Reserved transactions, if any occurred, are assigned to Normal inter-frame in the PCS 80B/81B Encoder.

97.3.2.2.7 Idle

Idle (Normal Inter-frame) control characters are transmitted when TX_EN is not asserted and no other supported control code is present at the GMII. Idle characters may be added or deleted by the PCS to adapt between clock rates. Idle characters shall not be added within a MAC frame.

97.3.2.2.8 LP_IDLE

The low power idle control characters (LP_IDLEs) are transmitted when TX_EN is not asserted, TX_ER is asserted, and TXD<7:0> = 0x1. A continuous stream of LPI control characters is used to maintain a link in the LPI transmit mode. Idle control characters are used to transition from the LPI transmit mode to the normal power mode. EEE compliant PHYs respond to the Assert Low Power Idle condition on the GMII using the procedure outlined in 97.1.2.3. LP_IDLE characters may be added or deleted by the PCS to adapt between clock rates. LP_IDLE characters shall not be added within a MAC frame.

Where the GMII and PMA sublayer data rates are not synchronized, the transmit process needs to insert LPI_IDLEs, or delete LPI_IDLEs to adapt between the rates.

If EEE is not supported, then LP_IDLE shall be converted to IDLE.

97.3.2.2.9 Error

The Error control code is sent when TX_ER and TX_EN are both asserted. Error allows physical sublayers such as the PCS to propagate received errors.

97.3.2.2.10 Transmit process

The transmit process generates blocks based upon the TXD<7:0>, TX_EN, and TX_ER signals received from the GMII. Ten GMII data transfers are encoded into each block. It takes 2700 PMA_UNITDATA transfers to send a PHY frame of data. Where the GMII and PMA sublayer data rates are not synchronized to that ratio, the transmit process needs to insert idles, or delete idles to adapt between the rates.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The transmit process generates blocks as specified in the transmit process state diagram. The contents of each block are contained in a vector tx_coded<80:0>, which is aggregated with 45 80B/81B blocks and 1000BASE-T1 OAM, then passed to the RS-FEC Encoder and then finally passed to the scrambler. tx_coded<0> contains the data/ctrl header and the remainder of the bits contain the block payload.

97.3.2.2.11 RS-FEC encoder

The 1000BASE-T1 PCS shall encode the transmitted data stream using Reed-Solomon code (450,406). The RS-FEC encoder shall follow the bit order described in 97.3.2.2.3 where the LSB is the first bit into the RS-FEC encoder and the first transmitted bit.

The FEC code used for 1000BASE-T1 links is a shortened Reed-Solomon (450,406) code over the Galois Field of GF(2^9)—a code operating on 9-bit symbols, as shown in Figure 97–8. The code encodes 406 information symbols and adds 44 parity symbols, enabling correction of up to 22 symbol errors. The code is systematic, meaning that the information symbols are not disturbed in any way in the encoder and the parity symbols are added separately to each block.

The code is based on the generating polynomial shown in Equation (97–1).

$$G(Z) = \prod_{i=0}^{43} (Z - \alpha^i) = A_{44}Z^{44} + A_{43}Z^{43} + \ldots + A_0Z^0 \quad (97–1)$$

where

α is a root of the binary primitive polynomial $x^9 + x^4 + 1$ and is represented as 0x002
A is a series representing the resulting polynomial coefficients of $G(Z)$, (A_{44} is equal to 0x001)
Z corresponds to an 9-bit GF(2^9) symbol
x corresponds to a bit position in a GF(2^9) symbol

The parity calculation shall produce the same result as the shift register implementation shown in Figure 97–8. Before calculation begins, the shift register shall be initialized to zero. The contents of the shift register are transmitted without inversion.

An FEC parity vector is represented by Equation (97–2).

$$P(Z) = D(Z) \bmod G(Z) \quad (97–2)$$

where

$D(Z)$ is the data vector $D(Z) = D_{405}Z^{449} + D_{404}Z^{448} + \ldots + D_0Z^{44}$. D_{405} is the first 9-bit data symbol and D_0 is the last

$P(Z)$ is the parity vector $P(Z) = P_{43}Z^{43} + P_{42}Z^{42} \ldots + P_0Z^0$. P_{43} is the first 9-bit parity symbol and P_0 is the last

A data symbol (d_8, d_7, ..., d_1, d_0) is identified with the element: $d_8\alpha^8 + d_7\alpha^7 + ... + d_1\alpha^1 + d_0$ in GF(2^9), the finite field with 2^9 elements.

The d_0 is identified as the LSB and d_8 is identified as the MSB for all symbols.

The resulting payload of scrambled 45 80B/81B blocks, followed by the 1000BASE-T1 OAM symbol results in a total payload of 3654 bits. The resulting PHY frame size is 450 9-bit symbols, a total of 4050 bits. Figure 97–7 shows the bit mapping between PCS and FEC.

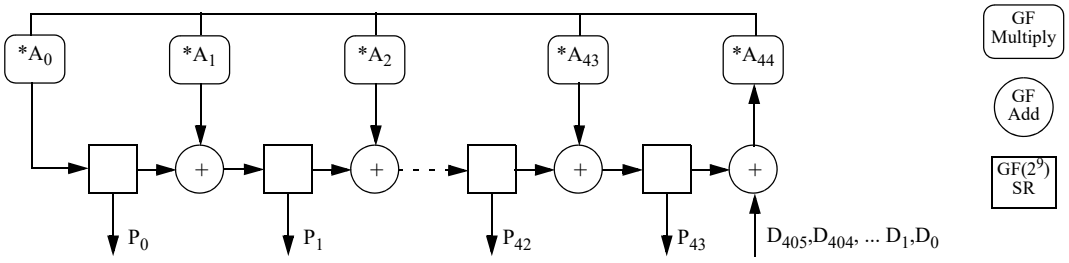

Figure 97–8—Circuit for generating FEC parity vector

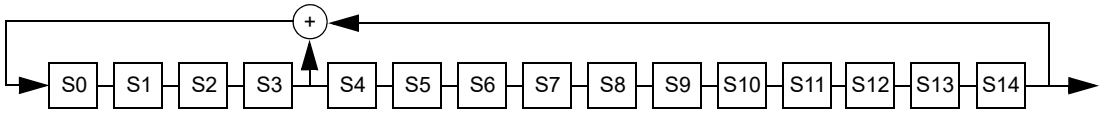
97.3.2.2.12 PCS scrambler

The PCS Transmit function employs side-stream scrambling. The scrambler for the MASTER shall produce the same result as the implementation shown in Figure 97–9. This implements the scrambler polynomial as shown in Equation (97–3):[169]



$$G(x) = 1 + x^4 + x^{15} \tag{97–3}$$

The scrambler for the SLAVE shall produce the same result as the implementation shown in Figure 97–9. This implements the scrambler polynomial as shown in Equation (97–4):

$$G(x) = 1 + x^{11} + x^{15} \tag{97–4}$$

The initial seed values for the MASTER and SLAVE scramblers are left to the implementer. The seed values shall be non-zero and transmitted during the InfoField exchange. (See 97.4.2.4.5). The scrambler is run continuously on all PHY frame output bits.

PCS scrambler employed by the MASTER

PCS scrambler employed by the SLAVE

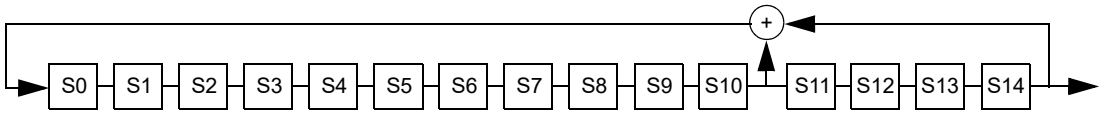


Figure 97–9—MASTER and SLAVE PCS scramblers

97.3.2.2.13 3B2T to PAM3

The 3B2T mapper generates 2700 PAM3 symbols per PHY frame that are sent to the PMA via PMA_UNITDATA.request. Every 9-bit symbol is divided into three 3-bit groups with the LSB bits as the first group. Each 3-bit group is then mapped by the 3B2T into 2 PAM3 symbols. The mapping of 3B2T to PAM3 is illustrated in Table 97–2. B[0] is the LSB and T[0] is the first PAM3 symbol transmitted..

[169]The convention here, which considers the most recent bit into the scrambler to be the lowest order term, is consistent with most references and with other scramblers shown in this standard. Some references consider the most recent bit into the scrambler to be the highest order term and would therefore identify this as the inverse of the polynomial in Equation (97–3). In case of doubt, note that the conformance requirement is based on the representation of the scrambler in the figure rather than the polynomial equation.

Table 97–2—3B2T Mapping to PAM3

B[2], B[1], B[0]	T[1], T[0]
000	–1,–1
001	0,–1
010	–1,0
011	–1,+1
100	+1,0
101	+1,–1
110	+1,+1
111	0,+1

97.3.2.2.14 81B-RS framer

The 81B-RS framer adapts between the 81-bit width of the 80B/81B blocks and the PAM3 input to the PMA. When the transmit channel is operating in the data mode, the 81B-RS sends one PAM3 symbol of transmit data at a time via PMA_UNITDATA.request primitives. The PMA_UNITDATA.request primitives are fully packed with bits.

97.3.2.2.15 EEE capability

The optional 1000BASE-T1 EEE capability allows compliant PHYs to transition to an LPI mode of operation when link utilization is low. EEE compliant PHYs shall implement the transmit state diagram including the EEE portion, noted by dotted lines in Figure 97–14, within the PCS.

When there is an Assert Low Power Idle while in the SEND_DATA state the PHY transmits the sleep signal to indicate to the link partner that it is transitioning to the SEND_LPI state. The sleep signal is one PHY frame composed entirely of LP_IDLE characters. If the LP_IDLE character fills the entire last 80B/81B block then the sleep signal is the next PHY frame. The PHY shall transmit no PHY frames partially filled with LP_IDLES.

Following the transmission of the sleep signal, quiet-refresh signaling begins, as described in 97.3.5.

While the PMA asserts SEND_N, the lpi_tx_mode variable shall control the transmit signal through the PMA_UNITDATA.request primitive described as follows:

- When the PMA_TXMODE.indication message does not have the value of SEND_N, the lpi_tx_mode variable is ignored
- When the lpi_tx_mode variable takes the value NORMAL the PCS passes coded data to the PMA via the PMA_UNITDATA.request primitive
- When the lpi_tx_mode variable takes the value QUIET the PCS passes zeros to the PMA through the PMA_UNITDATA.request primitive
- When the lpi_tx_mode variable takes the value REFRESH, the PCS passes zero data encoded through PCS data path to the PMA via the PMA_UNITDATA.request primitive

The quiet-refresh cycle is repeated until Assert Low Power Idle is not detected at the GMII (indicating that the local system is requesting a transition back to the normal power mode) or until an 1000BASE-T1 OAM

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

message with SNR<1:0> set to 01 is transmitted to or received from the link partner (indicating that the LPI refresh is insufficient to maintain the SNR). At the next wake frame window the PCS transmits a wake frame composed of an entire PHY frame containing only Idle. The wake frame shall be sent only during alternating PHY frame counts.

The wake signal occurs at the beginning of every second PHY frame boundary, and the maximum duration of the PHY wake time is 10.8 μs (lpi_wake_timer = T_{w_phy} as defined by Clause 78).

97.3.2.3 PCS Receive function

The PCS Receive function shall conform to the PCS 80B/81B receive state diagram in Figure 97–12 and the PCS Receive bit ordering in Figure 97–6 including compliance with the associated state variables as specified in 97.3.6.

The PCS Receive function accepts received symbols provided by the PMA Receive function via the parameter rx_symb. The PCS receiver uses knowledge of the PMA training alignment to correctly align the 81B-RS frames. The received 81B-RS frames are decoded with error correction; the framing is checked; and the 80B/81B blocks are converted to 10 data octets to obtain the signals RXD<7:0>, RX_DV, and RX_ER for transmission to the GMII.

During PMA training mode, PCS Receive checks the received PAM2 framing and signals the reliable acquisition of the descrambler state by setting the parameter scr_status to OK.

When the PCS Synchronization process has obtained synchronization, the PHY frame error rate (RFER) monitor process monitors the signal quality asserting hi_rfer if excessive PHY frame errors are detected (RS parity error). If 40 consecutive PHY frame errors are detected, the block_lock flag is de-asserted. When block_lock is asserted and hi_rfer is de-asserted, the PCS Receive process continuously accepts blocks. The PCS Receive process monitors these blocks and generates RXD<7:0>, RX_DV and RX_ER for transmission to the GMII.

When the receive channel is in training mode, the PCS Synchronization process continuously monitors PMA_RXSTATUS.indication(loc_rcvr_status). When loc_rcvr_status indicates OK, then the PCS Synchronization process accepts data-units via the PMA_UNITDATA.request primitive. It attains PHY frame and block synchronization based on the PMA training frames and conveys received blocks to the PCS Receive process. The PCS Synchronization process sets the block_lock flag to indicate whether the PCS has obtained synchronization. The PMA training sequence includes 1 bit pattern every 180 PAM2 symbols, which is aligned with the PCS partial PHY frame boundary, as well as an InfoField, which is inserted in the 15th PCS partial PHY frame. When the PCS Synchronization process is synchronized to the PHY frame boundary using this pattern, block_lock is asserted. One partial PHY frame codeword is defined to be 1/15 of a PHY frame. Fifteen partial PHY frames concatenated back to back form one PHY frame. The start of the first partial PHY frame coincides with the start of the PHY frame.

PHYs with the EEE capability support transition to the LPI mode when the PHY has successfully completed training. Transitions to and from the LPI mode are allowed to occur independently in the transmit and receive functions. The PCS receive function is responsible for detecting transitions to and from the LPI receive mode and indicating these transitions using signals defined in 97.3.6.

The link partner signals a transition to the LPI mode of operation by transmitting one PHY frame composed entirely of 80B/81B blocks of LP_IDLES. When blocks of LP_IDLES are detected at the output of the 80B/81B decoder, rx_lpi_active is asserted by the PCS receive function and the LPI character is continuously asserted at the receive GMII. After the sleep frame the link partner begins transmitting zeros, and it is recommended that the receiver power down receive circuits to reduce power consumption. The receive function uses PHY frame counters to maintain synchronization with the remote PHY and receives periodic refresh signals that are used to update coefficients, so that the integrity of adaptive filters and timing

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

loops in the PMA is maintained. LPI signaling is defined in 97.3.5. The quiet-refresh cycle continues until the PHY detects the wake frame. The PHY receive function sends Idles to the GMII for the remainder of the wake frame and then resumes normal power mode operation.

97.3.2.3.1 Frame and block synchronization

When operating in the data mode, the receiving PCS shall form a PAM3 stream from the PMA_UNITDATA.indication primitive by concatenating requests in order from rx_data<0> to rx_data<2699> (see Figure 97–6). It obtains block lock to the PHY frames during the PAM2 training pattern using synchronization bits provided in the training sequence.

97.3.2.3.2 PCS descrambler

The descrambler processes the payload to reverse the effect of the scrambler using the same polynomial. The PCS descrambles the data stream and returns the proper sequence of symbols to the decoding process for generation of RXD<7:0> to the GMII. For side-stream descrambling, the MASTER PHY shall employ the receiver descrambler generator polynomial per Equation (97–4) and the SLAVE PHY shall employ the receiver descrambler generator polynomial per Equation (97–3).

97.3.2.3.3 Valid and invalid blocks

An 80B/81B block is invalid if any of the following conditions exists:

a) The block contains an invalid pointer
b) Any control character contains a value not in Table 97–1
c) The PHY frame containing this 80B/81B block is uncorrectable

Invalid blocks are replaced with Error.

97.3.3 Test-pattern generators

The test-pattern generator mode is provided for enabling joint testing of the local transmitter, the channel and remote receiver. When the transmit PCS is operating in test-pattern mode it shall transmit continuously as illustrated in Figure 97–5, with the input to the RS-FEC encoder set to zero and the initial condition of the scrambler set to any non-zero value. This has the same effect as setting the input to the scrambler to zero. When the receiver PCS is operating in test-pattern mode it shall receive continuously as illustrated in Figure 97–6. The output of the received descrambled values should be zero. Any nonzero values correspond to receiver bit errors. The output of the RS-FEC decoder should also be zero, however there is the possibility that the RS-FEC decoder may have corrected some errors. This mode is further described as test mode 7 in 97.5.2.

97.3.4 PMA training side-stream scrambler polynomials

The PCS Transmit function employs side-stream scrambling. If the parameter config provided to the PCS by the PMA PHY Control function via the PMA_CONFIG.indication message assumes the value MASTER, PCS Transmit shall employ Equation (97–5)

$$g_M(x) = 1 + x^{13} + x^{33} \quad (97–5)$$

as transmitter side-stream scrambler generator polynomial. If the PMA_CONFIG.indication message assumes the value of SLAVE, PCS Transmit shall employ Equation (97–6)

$$g_S(x) = 1 + x^{20} + x^{33} \quad (97–6)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

as transmitter side-stream scrambler generator polynomial. An implementation of MASTER and SLAVE PHY side-stream scramblers by linear-feedback shift registers is shown in Figure 97–9. The bits stored in the shift register delay line at time n are denoted by $Scr_n[32:0]$. At each symbol period, the shift register is advanced by one bit, and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. In no case shall the scrambler state be initialized to all zeros.

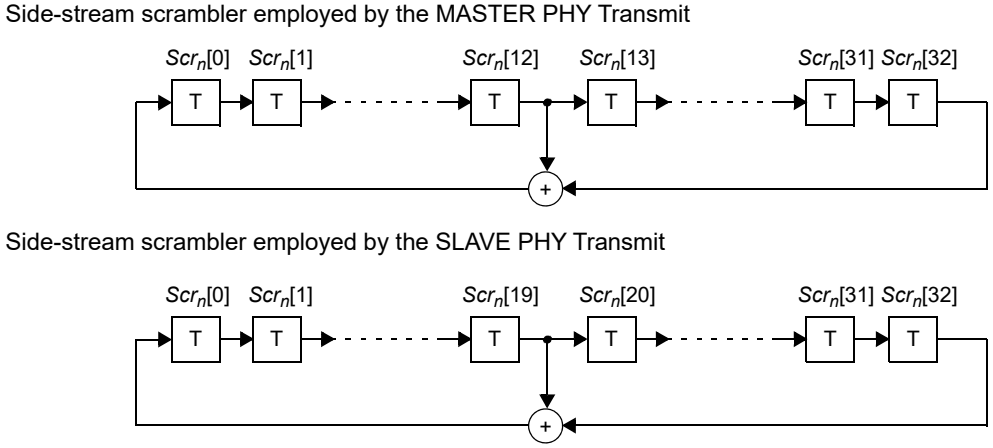

Figure 97–10—Realization of side-stream scramblers by linear feedback shift registers

97.3.4.1 Generation of S_n

During PMA training, the training pattern is embedded with indicators to establish alignment to the RS-FEC block and the 15 partial PHY frames that comprise the block. The last partial PHY frame is embedded with an information field used to exchange messages between link partners. PMA training signal encoding is based on the generation, at time n, of the bit S_n. The first bit is inverted in the first 14 partial PHY frames of each RS-FEC block. The first 96 bits of the 15th partial PHY frame is XORed with the contents of the InfoField. Each partial PHY frame is 180 bits long, beginning at S_n where (n mod 180) = 0. See Equation (97–7).

$$S_n = \begin{cases} Scr_n[0] \oplus InfoField_{(n \bmod 180)} & 2520 \le (n \bmod 2700) \le 2615 \\ Scr_n[0] \oplus 1 & \text{else if } (n \bmod 180) = 0 \\ Scr_n[0] & \text{otherwise} \end{cases} \quad (97\text{–}7)$$

97.3.4.2 Generation of symbol T_n

The bit S_n is mapped to the transmit symbol T_n as follows: if $S_n = 0$ then $T_n = +1$, if $S_n = 1$ then $T_n = -1$.

97.3.4.3 PMA training mode descrambler polynomials

The PHY shall acquire descrambler state synchronization to the PAM2 training sequence and report success through scr_status. For side-stream descrambling, the MASTER PHY employs the receiver descrambler generator polynomial per Equation (97–6) and the SLAVE PHY employs the receiver descrambler generator polynomial per Equation (97–5).

97.3.5 LPI signaling

PHYs with EEE capability have transmit and receive functions that can enter and leave the LPI mode independently. The PHY can transition to the LPI mode when the PHY has successfully completed training. The transmit function of the PHY initiates a transition to the LPI transmit mode when it generates a sleep signal composed of 80B/81B blocks containing only LPI control characters, as described in 97.3.2.2.15. When the transmitter begins to send the sleep signal, it asserts tx_lpi_active and the transmit function enters the LPI transmit mode.

Within the LPI mode PHYs use a repeating quiet-refresh cycle (see Figure 97–11). The first part of this cycle is known as the *quiet period* and lasts for a time lpi_quiet_time equal to 354 partial PHY frame periods. The quiet period is defined in 97.3.5.2. The second part of this cycle is known as the *refresh period* and lasts for a time lpi_refresh_time equal to 6 partial PHY frame periods. The refresh period is defined in 97.3.5.3. A cycle composed of one quiet period and one refresh period is known as an LPI cycle and lasts for an lpi_qr_time equal to 24 × 15 = 360 partial PHY frame periods.

lpi_offset, lpi_quiet_time, lpi_refresh_time, and lpi_qr_time are timing parameters that are integer multiples of the partial PHY frame period. lpi_offset is a fixed value equal to lpi_qr_time/2 + 15. It is used to ensure refresh signals and wake start times are appropriately offset by the link partners.

PHYs begin the transition from the LPI receive mode when they detect the wake frame.

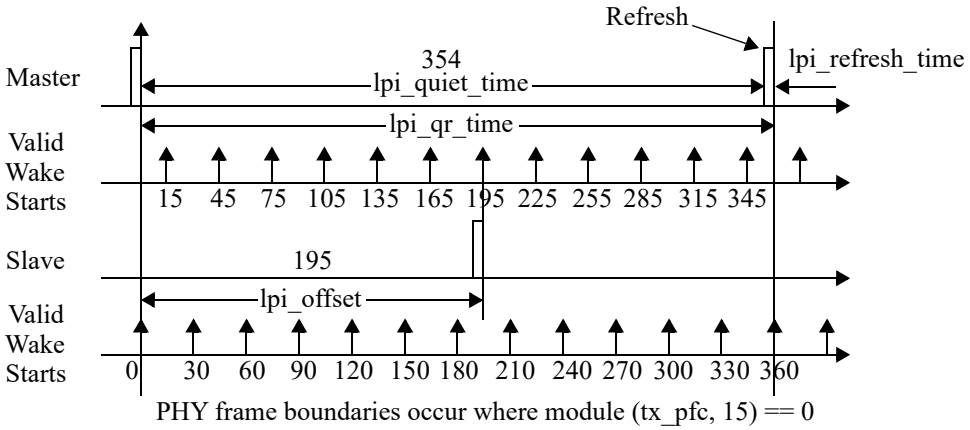

Figure 97–11—LPI signal timing

97.3.5.1 LPI Synchronization

To maximize power savings, maintain link integrity, and ensure interoperability, EEE-capable PHYs shall synchronize refresh intervals during the LPI mode. The quiet-refresh cycle is established from the Master partial PHY frame Count (PFC24) during PMA Training. At the MASTER, partial PHY frame zero and all multiples of 360 partial PHY frames thereafter denote the start of the cycle.

An EEE-capable PHY in SLAVE mode is responsible for synchronizing its partial PHY frame count to the MASTER's partial PHY frame count during link up. The SLAVE shall ensure that its partial PHY frame count is synchronized to the MASTER's partial PHY frames within 1 partial PHY frame. The start of the SLAVE quiet-refresh cycle is delayed from the MASTER by 13 PHY frames (195 partial PHY frames). This offset ensures that the MASTER and SLAVE wake/sense windows are offset from each other and that the refresh periods are nearly a half cycle offset.

Following the transition to PAM3, the PCS continues to count transmitted partial PHY frames (tx_pfc), and uses the counter to generate refresh and wake control signals for the transmit functions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Wake frames may be sent at the beginning of every second PHY frame boundary starting at the beginning of the refresh PHY frame. This sets wake_period to 30 partial PHY frames. The MASTER and SLAVE allowable wake positions do not overlap. The wake frame may start in the same PHY frame as a planned refresh and obviate this refresh.

The MASTER and SLAVE shall derive the tx_refresh_active and tx_wake_start signals from the transmitted partial PHY frames (tx_pfc) as shown in Table 97–3 and Table 97–4.

Table 97–3—Synchronization logic derived from SLAVE signal partial PHY frame count

Slave-side Variable	u = tx_pfc
tx_refresh_active=true	lpi_offset – lpi_refresh_time ≤ mod(u, lpi_qr_time) < lpi_offset
tx_wake_start=true	mod(u, wake_period) = 0

Table 97–4—Synchronization logic derived from MASTER signal partial PHY frame count

Master-side variable	v = tx_pfc
tx_refresh_active=true	mod(v, lpi_qr_time) ≥ lpi_quiet_time
tx_wake_start=true	mod(v, wake_period) = wake_period/2

97.3.5.2 Quiet period signaling

During the quiet period the transmitter shall put PAM3 symbol zero on to the MDI. During the quiet period the transmitter may be turned off to save power.

97.3.5.3 Refresh period signaling

During the LPI mode 1000BASE-T1 PHYs use staggered, out-of-phase refresh signaling to maximize power savings. PAM3 refresh symbols are generated from the output of the data mode PCS side-stream scrambler polynomials described in 97.3.2.2.12 with PCS transmit data masked to zero. The scramblers run continuously regardless of the transmit mode. The refresh occupies the last 6 partial PHY frames of where the PHY frame would occur if it were transmitted.

The 1000BASE-T1 OAM symbols and the RS parity symbols are XORed with the scrambler stream at the same relative position to the RS boundaries as they occupy during normal mode. The parity is generated using Equation (97–2) with D_{405} ... $D_1 = 0$ and D_0 = OAM.

97.3.6 Detailed functions and state diagrams

97.3.6.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of constants, variables, functions, counters, and messages. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

97.3.6.2 State diagram parameters

97.3.6.2.1 Constants

EBLOCK_R<99:0>
TYPE: bit vector
100-bit vector to be sent to the GMII containing symbol errors in all 10 character locations.

IBLOCK_R<99:0>
TYPE: bit vector
100-bit vector to be sent to the GMII containing idles in all 10 character locations.

IBLOCK_T<99:0>
TYPE: bit vector
100-bit vector to be sent to the encoder containing idles in all 10 character locations.

LPBLOCK_R<99:0>
TYPE: bit vector
100-bit vector to be sent to the GMII containing LP_IDLEs in all 10 character locations.

LPBLOCK_T<99:0>
TYPE: bit vector
100-bit vector to be sent to the encoder containing LP_IDLEs in all 10 character locations.

RFER_CNT_LIMIT
TYPE: Integer
VALUE: 16
Number of Reed-Solomon frames with uncorrectable errors.

RFRX_CNT_LIMIT
TYPE: Integer
VALUE: 88
Number of Reed-Solomon frames received over bit error rate interval.

ZBLOCK_T<80:0>
TYPE: bit vector
81-bit vector containing all zero bits.

97.3.6.2.2 Variables

block_lock
Boolean variable that is set true when receiver acquires block delineation.

hi_rfer
Boolean variable that is asserted true when the rfer_cnt reaches RFER_CNT_LIMIT indicating a bit error ratio > 4×10^{-4}.

pcs_reset
When this variable is set to ON, all PCS functions are reset. Otherwise, this variable holds the value of OFF. This variable is set by the PCS Reset function.

rx_coded<81:0>
Vector containing the input to the 80B/81B decoder including a block valid flag. The format for

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_coded<80:0> is shown in Figure 97–6. The leftmost bit in the figure is rx_coded<0> and the rightmost bit is rx_coded<80>. rx_coded<81> (not shown in the figure) is set to 1 if all parity checks of the Reed-Solomon frame are satisfied, otherwise it is set to 0.

rf_valid

Boolean indication that is set true if received Reed-Solomon frame is valid. The frame is valid if all parity checks of the coded bits are satisfied.

rx_lpi_active

This variable is set true upon detection of LP_IDLE. Set false upon detection of a wake frame.

rx_raw<99:0>

Vector containing 10 successive GMII output transfers. Each transfer is numbered from 0 to 9 with the first transfer numbered as the 0th transfer. The nth GMII transfer is labeled as RX_DV[n], RX_ER[n], RXD[n]<7:0>.
For n = 0 to 9, RX_DV[n] = rx_raw<10n>, RX_ER[n] = rx_raw<10n+1>,
RXD[n]<7:0> = rx_raw<10n+9:10n+2>

rx_wake_frame_complete

This variable is set true at end of WAKE PHY frame, otherwise false.

tx_coded<80:0>

Vector containing the output from the 80B/81B encoder. The format for this vector is shown in Figure 97–5. The leftmost bit in the figure is tx_coded<0> and the rightmost bit is tx_coded<80>.

tx_data_mode

Set true when tx_mode = SEND_N, otherwise false.

tx_lpi_active

This variable is set false at the next wake frame window if any of the following conditions is true:

— a non-LP_IDLE is detected on GMII in any block

— the PHY receives SNR<1:0> set to 01 by its link partner

— the PHY transmits SNR<1:0> set to 01 to its link partner as defined in 97.3.8.2.14

This variable is set true on next PHY frame if all of the following conditions are true:

— an LP_IDLE detected on GMII during the entire last 80B/81B block

— the PHY does not receive SNR<1:0> set to 01 by its link partner

— the PHY does not transmit SNR<1:0> set to 01 to its link partner as defined in 97.3.8.2.14

tx_raw<99:0>

Vector containing 10 successive GMII transfers. Each transfer is numbered from 0 to 9 with the first transfer numbered as the 0th transfer. The nth GMII transfer is labeled as TX_EN[n], TX_ER[n], TXD[n]<7:0>.
For n = 0 to 9, tx_raw<10n> = TX_EN[n], tx_raw<10n+1> = TX_ER[n], tx_raw<10n+9:10n+2> = TXD[n]<7:0>

tx_sleep_frame_complete

This variable is set to true when PHY is transitioning to the LPI mode and the sleep signal transmission is completed. This variable is set to false when the PHY is transitioning out of the LPI mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_wake_frame_complete
: This variable is set to true at the end of a complete wake frame. This variable is set to false otherwise.

lpi_tx_mode
: A variable indicating the signaling to be used from the PCS to the PMA across the PMA_UNITDATA.request(tx_symb) interface.
lpi_tx_mode controls tx_symb only when tx_mode is set to SEND_N.
The variable is set to NORMAL when !tx_lpi_active, indicating that the PCS is in the normal power mode of operation.
The variable is set to REFRESH when (tx_lpi_active * tx_refresh active).
The variable is set to QUIET when (tx_lpi_active * !tx_refresh active).

rx_aggregate
: This variable is set to true when nine aligned 9-bit Reed-Solomon symbols are aggregated in rx_coded. This variable is asserted even when the receiver is in low power idle mode at the time when the nine 9-bit RS-FEC symbols would be aggregated in rx_coded if the receiver was operating in non-lpi mode. This variable is set to false otherwise.

rx_frame
: This variable is set to true when a full Reed-Solomon frame has been decoded and the variable rf_valid is updated. This variable is set to false otherwise.

tx_aggregate
: This variable is set to true when 10 GMII transfers are aggregated in tx_raw<99:0>. This variable is set to false otherwise.

97.3.6.2.3 Functions

DECODE(rx_coded<81:0>)
: In the PCS Receive process, this function takes as its argument 82-bit rx_coded<81:0> from the Reed-Solomon decoder and descrambler. If rx_coded<81> = 1 then the decoder decodes the 81B-Reed-Solomon bit vector rx_coded<80:0> returning a vector rx_raw<99:0>, which is sent to the GMII. The DECODE function shall decode the block based on code specified in 97.3.2.2.2. If rx_coded<81> = 0 then the decoder returns EBLOCK_R.

ENCODE(tx_raw<99:0>)
: Encodes the 100-bit vector received from the GMII, returning 81-bit vector tx_coded. The ENCODE function shall encode the block as specified in 97.3.2.2.2. The ENCODE function shall only encode LPI_IDLE while in the SEND_LPI state. Otherwise LPI_IDLE is converted to Idle in the ENCODE function.

97.3.6.2.4 Counters

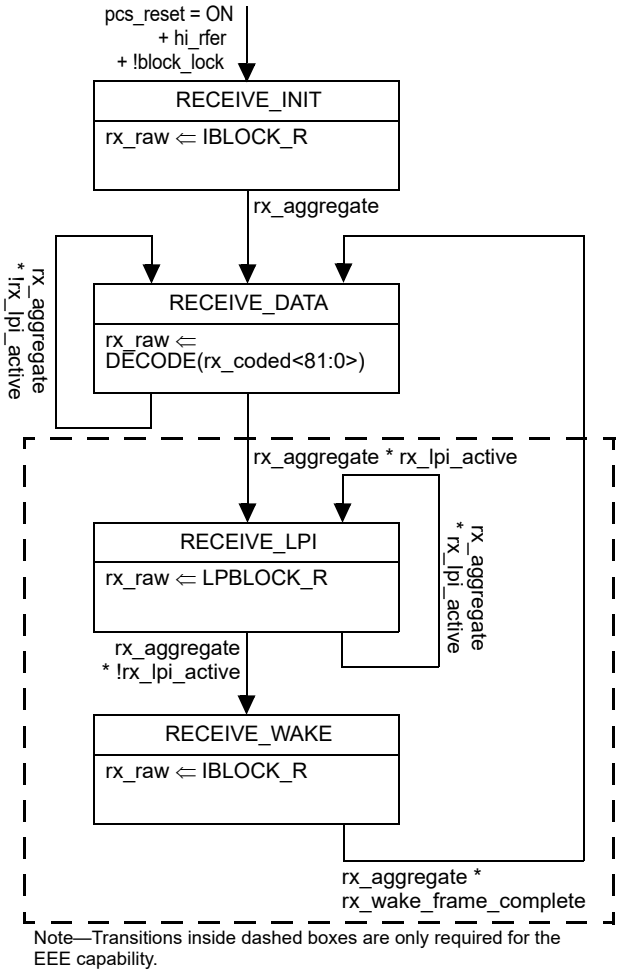
rfer_cnt
: Count up to a maximum of RFER_CNT_LIMIT of the number of invalid Reed-Solomon frames within the current RFRX_CNT_LIMIT Reed-Solomon frame period.

rfrx_cnt
: Count number Reed-Solomon frames received during current period.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.3.6.3 Messages

PCS_status
: Indicates whether the PCS is in a fully operational state. (See 97.3.7.1.)



PMA_UNITDATA.indication(rx_symb)
: A signal sent by PMA Receive indicating that a PAM3 symbol is available in rx_symb.

PMA_UNITDATA.request(tx_symb)
: A signal sent to PMA Transmit indicating that a PAM3 symbol is available in tx_symb.

97.3.6.4 State diagrams

The RFER Monitor state diagram shown in Figure 97–13 monitors the received signal for high PHY frame error ratio. The 80B/81B Transmit state diagram shown in Figure 97–14 controls the encoding of 81B transmitted blocks. It makes exactly one transition for each 81B transmit block processed. The 80B/81B Receive state diagram shown in Figure 97–12 controls the decoding of 81B received blocks. It makes exactly one transition for each receive block processed. The PCS shall perform the functions of PCS Receive, RFER monitor, and PCS Transmit, as specified in Figure 97–12, Figure 97–13, and Figure 97–14, respectively.

97.3.7 PCS management

The following objects apply to PCS management. If an MDIO Interface is provided (see Clause 45), they are accessed via that interface. If not, it is recommended that an equivalent access be provided.

97.3.7.1 Status

PCS_status:
: Indicates whether the PCS is in a fully operational state. It is only true if block_lock is true and hi_rfer is false. This status is reflected in MDIO register 3.2306.10. A latch low view of this status is reflected in MDIO register 3.2305.2 and the inverse of this status is reflected in MDIO register 3.2305.7.

block_lock:
: Indicates the state of the block_lock variable. This status is reflected in MDIO register 3.2306.8. A latch low view of this status is reflected in MDIO register 3.2306.6.

hi_rfer:
: Indicates the state of the hi_rfer variable. This status is reflected in MDIO register 3.2306.9. A latch high view of this status is reflected in MDIO register 3.2306.7.

Rx LPI indication:
: For EEE capability, this variable indicates the current state of the receive LPI function. This flag is set to true (register bit set to one) when the PCS Receive state diagram (Figure 97–12) is in the RECEIVE_LPI or RECEIVE_WAKE states. This status is reflected in MDIO register 3.2305.8. A latch high view of this status is reflected in MDIO register 3.2305.10 (Rx LPI received).

Tx LPI indication:
: For EEE capability, this variable indicates the current state of the transmit LPI function. This flag is set to true (register bit set to one) when the PCS Transmit state diagram (Figure 97–14) is in the SEND_LPI or SEND_WAKE states. This status is reflected in MDIO register 3.2305.9. A latch high view of this status is reflected in MDIO register 3.2305.11 (Tx LPI received).

97.3.7.2 Counter

The following counter is reset to zero upon read and upon reset of the PCS. When it reaches all ones, it stops counting. Its purpose is to help monitor the quality of the link.

RFER_count:
: 6-bit counter that counts each time RFER_BAD_RF of the RFER monitor state diagram (see Figure 97–13) is entered. This counter is reflected in MDIO register bits 3.2306.5:0. The counter is reset when register 3.2306 is read by management. Note that this counter counts a maximum of RFER_CNT_LIMIT counts per RFRX_CNT_LIMIT period since the RFER_BAD_RF state can be entered a maximum of RFER_CNT_LIMIT times per RFRX_CNT_LIMIT window.

97.3.7.3 Loopback

The PCS shall be placed in loopback mode when the loopback bit in MDIO register 3.2304.14 is set to a one. In this mode, the PCS shall accept data on the transmit path from the GMII and return it on the receive path to the GMII. In addition, the PCS shall transmit a continuous stream of GMII data to the 81B encoder and on further to the PMA sublayer and shall ignore all data presented to it by the PMA sublayer.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.3.8 BASE-T1 Operations, Administration, and Maintenance (OAM)

The 1000BASE-T1 PCS level Operations, Administration, and Maintenance (OAM) provides an optional mechanism useful for monitoring link operation such as exchanging PHY link health status and message exchange. When OAM is implemented, behavior shall conform to the state diagrams in Figure 97–17 and Figure 97–18. The 1000BASE-T1 OAM information is exchanged out of band between two PHYs using excess bandwidth available on the link. The 1000BASE-T1 OAM is strictly between two 1000BASE-T1 PHYs on the physical layer and their associated management entities if present. Passing 1000BASE-T1 OAM information to other layers is outside the scope of this standard.

1000BASE-T1 OAM is operational as long as both PHYs implement this mechanism and link is up. It continues to be operational during low power idle albeit the information is transferred at a slower rate during the refresh cycle.

The 1000BASE-T1 OAM frame data is carried in the OAM9 field described in 97.3.2.2.4 for the normal power data mode and 97.3.5.3 for low power mode. This 9-bit field is used to exchange 1000BASE-T1 OAM frames. The implementation of 1000BASE-T1 OAM frame exchange function is optional. However, if 1000BASE-T1 EEE is implemented, then the 1000BASE-T1 OAM frame exchange function is implemented to exchange, at a minimum, the link partner health status.

For the remainder of this subclause, the term 1000BASE-T1 OAM is specific to the 1000BASE-T1 PCS level OAM.

97.3.8.1 Definitions

1000BASE-T1 OAM frame: A frame consisting of 12 octets of data with 12 parity bits.

1000BASE-T1 OAM symbol: A 9-bit symbol consisting of one data octet plus a parity bit. Twelve 1000BASE-T1 OAM symbols make up an 1000BASE-T1 OAM frame.

1000BASE-T1 OAM field: The OAM9 field in each PHY frame as described in 97.3.2.2.11 or in each refresh cycle as described in 97.3.5.3.

1000BASE-T1 OAM message: A message contains a 4-bit message number plus 8 octets of message data embedded in an 1000BASE-T1 OAM frame. The same 1000BASE-T1 OAM message can be repeated on multiple 1000BASE-T1 OAM frames.

97.3.8.2 Functional specifications

97.3.8.2.1 1000BASE-T1 OAM Frame Structure

Each 1000BASE-T1 OAM frame is made up of 12 octets of data and 12 parity bits. Each symbol consists of 8 bits of data and one parity bit. The parity bit value for symbol 0 should be such that the sum of the number of 1s in the nine bits is even. The parity bit value for symbols 1 to 11 should be such that the sum of the number of 1s in the nine bits is odd.

Figure 97–15—OAM Frame

One 1000BASE-T1 OAM symbol is placed in the 9-bit 1000BASE-T1 OAM field in each PHY frame during normal power operation in the data mode. One 1000BASE-T1 OAM symbol is placed in the 9-bit 1000BASE-T1 OAM field in each refresh cycle during low power idle. The 12 1000BASE-T1 OAM symbols are consecutively inserted into 12 consecutive PHY frames and/or refresh cycles. Once the 12 symbols of the current 1000BASE-T1 OAM frame are inserted, the 12 symbols of the next 1000BASE-T1 OAM frame are inserted. This process is continuous without any break in the insertion of 1000BASE-T1 OAM symbols.

Bit 0 of each 1000BASE-T1 OAM symbol is the first bit transmitted in the 9-bit 1000BASE-T1 OAM field. Symbol 0 is the first symbol transmitted in each 1000BASE-T1 OAM frame.

The 1000BASE-T1 OAM frame boundary can be found at the receiver by determining the symbol parity. Symbol 0 has even parity while all other symbols have odd parity.

If 1000BASE-T1 OAM is not implemented then the 9-bit 1000BASE-T1 OAM field shall be set to all 0s. If the link partner does not implement 1000BASE-T1 OAM, the 9-bit 1000BASE-T1 OAM field will remain static and the symbol parity will not change.

97.3.8.2.2 1000BASE-T1 OAM Frame Data

The 1000BASE-T1 OAM frame data is shown in Figure 97–15. OAM<x><y> refers to symbol x, bit y of the 1000BASE-T1 OAM frame. Reserved fields shall be set to 0.

97.3.8.2.3 Ping RX

The Ping RX is indicated in OAM<0><3>.

This bit is set by the PHY to the same value as the Ping TX bit received from the link partner.

97.3.8.2.4 Ping TX

The Ping TX is indicated in OAM<0><2>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This bit is set by the PHY to for the link partner to echo on Ping RX.

97.3.8.2.5 PHY Health

The PHY Health (SNR<1:0>) is indicated in OAM<0><1:0>.

This status is set by the PHY to indicate the status of the receiver. The definitions of good, marginal, when to request idles, and when to request retrain are implementation dependent.

- 00: PHY link is failing and will drop link and relink within 2 ms to 4 ms after the end of the current 1000BASE-T1 OAM frame
- 01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled)
- 10: PHY SNR is marginal
- 11: PHY SNR is good

97.3.8.2.6 1000BASE-T1 OAM Message Valid

The 1000BASE-T1 OAM message valid (Valid) is indicated in OAM<1><7>.

- 0: Current 1000BASE-T1 OAM frame does not contain a valid 1000BASE-T1 OAM message
- 1: Current 1000BASE-T1 OAM frame contains a valid 1000BASE-T1 OAM message

97.3.8.2.7 1000BASE-T1 OAM Message Toggle

The 1000BASE-T1 OAM message toggle (Toggle) is indicated in OAM<1><6>.

The toggle bit is used to ensure proper 1000BASE-T1 OAM message synchronization between the PHY and the link partner. The toggle bit in the current 1000BASE-T1 OAM message is set to the opposite value of the toggle bit in the previous 1000BASE-T1 OAM message only if link partner acknowledge the 1000BASE-T1 OAM message is received. This allows one 1000BASE-T1 OAM message to be delineated from a second 1000BASE-T1 OAM message since the same 1000BASE-T1 OAM message may be repeated over multiple 1000BASE-T1 OAM frames. This bit is valid only if Valid is set to 1.

97.3.8.2.8 1000BASE-T1 OAM Message Acknowledge

The 1000BASE-T1 OAM message Acknowledge (Ack) is indicated in OAM<1><5>.

Ack is set by the PHY to let the link partner know that the 1000BASE-T1 OAM message sent by the link partner was successfully received as defined in 97.3.8.2.13 and the PHY is ready to accept a new 1000BASE-T1 OAM message. An 1000BASE-T1 OAM message is defined to be Message_Number<3:0> and Message<7:0><7:0>.

- 0: No Acknowledge
- 1: Acknowledge

97.3.8.2.9 1000BASE-T1 OAM Message Toggle Acknowledge

The 1000BASE-T1 OAM message Toggle Acknowledge (TogAck) is indicated in OAM<1><4>.

TogAck is set by the PHY to let the link partner know which the 1000BASE-T1 OAM message is being acknowledged. TogAck takes the value of Toggle bit of the 1000BASE-T1 OAM message being acknowledged. This bit is valid only if Ack is set to 1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.3.8.2.10 1000BASE-T1 OAM Message Number

The 1000BASE-T1 OAM message number is indicated in OAM<1><3:0>.

This field is user-defined but is recommended that it be used to indicate the meaning of the 8-octet message that follows. If used this way, up to 16 different 8-octet messages can be exchanged.

The message number is user-defined and its definition is outside the scope of this standard.

97.3.8.2.11 1000BASE-T1 OAM Message Data

The 1000BASE-T1 OAM message data is indicated in OAM<9:2><7:0>.

The 8-octet message data is user-defined and its definition is outside the scope of this standard.

Ack is set by the PHY to let the link partner know that the 1000BASE-T1 OAM frame sent by the link partner is successfully received as defined The 1000BASE-T1 OAM frame octet is the lower 8 bits of the 9-bit 1000BASE-T1 OAM symbol. Twelve octets form the 1000BASE-T1 OAM data.

97.3.8.2.12 CRC16

The CRC16 is indicated in OAM<11:10><7:0>.

The CRC16 implements the polynomial $(x+1)(x^{15}+x+1)$ of the previous 10 octets. The CRC16 shall produce the same result as the implementation shown in Figure 97–16. The 16 delay elements S0,..., S15, shall be initialized to zero. Afterwards OEM<9:0><7:0> presented in their transmitted order as described in 97.3.8.2.1 are used to compute the CRC16 with the switch connected, which is setting CRC gen in Figure 97–16. Note that the parity bit is not used in the CRC16 calculation. After all the 10 octets have been processed, the switch is disconnected (setting CRC out) and the 16 values stored in the delay elements are transmitted in the order illustrated, first S15, followed by S14, and so on, until the final value S0. S15 is indicated in OAM<10><0> and S0 is indicated in OAM<11><7>.

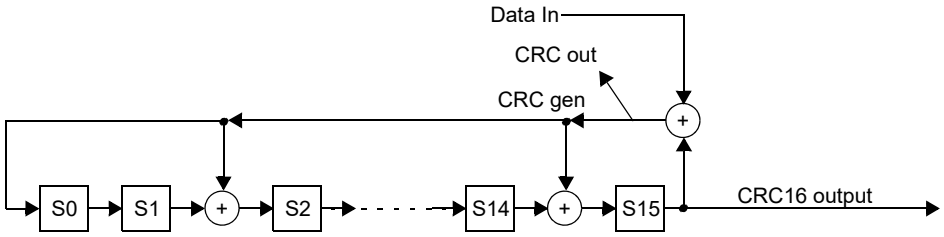

Figure 97–16—1000BASE-T1 OAM CRC16

97.3.8.2.13 1000BASE-T1 OAM Frame Acceptance Criteria

All fields of the 1000BASE-T1 OAM frame shall be accepted and updated, unless any of the following occurs:

a) Incorrect parity on any of the 12 symbols

b) Incorrect CRC16

c) Uncorrectable PHY frame on any of the 12 symbols

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.3.8.2.14 PHY Health Indicator

The PHY current health is sent to the link partner on a per 1000BASE-T1 OAM frame basis using the SNR<1:0> bits as described in 97.3.8.2.5. It lets the link partner have an early indication of potential problems that may cause the PHY to drop link or have high error rates.

If EEE is implemented, there may be a case where a PHY's receiver can no longer maintain good SNR based on quiet/refresh cycles. Instead of dropping the link, the PHY can attempt to recover the link by forcing the link partner to exit LPI in its egress direction so that the PHY can use normal power mode to recover. This is done by transmitting SNR<1:0> with a value of 01.

If a PHY receives SNR<1:0> set to 01 by its link partner, then it cannot enter into LPI in the egress direction. If the PHY is already in LPI then the PHY shall immediately exit LPI.

97.3.8.2.15 Ping

The PingTx bit is set based on the value in mr_tx_ping. The PingRx bit is set based on the latest PingTx received from the link partner. The value in mr_rx_ping is set based on the received PingRx from the link partner. The user can determine that the link partner 1000BASE-T1 OAM is operating properly by togging mr_tx_ping and observing mr_rx_ping matches after a short delay.

The Ping bits are updated on a per 1000BASE-T1 OAM frame basis.

97.3.8.2.16 1000BASE-T1 OAM Message Exchange

Unlike the PHY health indicator and the ping function that operate on a per 1000BASE-T1 OAM frame basis, the 1000BASE-T1 OAM message exchange operates on a per 1000BASE-T1 OAM message basis that will occur over many 1000BASE-T1 OAM frames. The 1000BASE-T1 OAM message exchange mechanism allows a management entity attached to a PHY and its peer attached to the link partner to asynchronously pass 1000BASE-T1 OAM messages and verify their delivery.

The 1000BASE-T1 OAM message is first written into the 1000BASE-T1 OAM transmit registers in the PHY. The 1000BASE-T1 OAM message is then read out of the 1000BASE-T1 OAM transmit registers and transmitted to the link partner. After the link partner receives the 1000BASE-T1 OAM message it transfers it into the link partner's 1000BASE-T1 OAM receive registers and also sends an acknowledge back to the PHY indicating that the next 1000BASE-T1 OAM message can be transmitted. One 1000BASE-T1 OAM message can be loaded into the 1000BASE-T1 OAM transmit registers while another 1000BASE-T1 OAM message is being transmitted by the PHY to the link partner while yet another 1000BASE-T1 OAM message is being read out at the link partner's 1000BASE-T1 OAM receive registers. The exchange of 1000BASE-T1 OAM messages are occurring concurrently and bi-directionally.The transfers between the management entities can be done asynchronously. On the transmit side mr_tx_valid = 0 indicates that the next 1000BASE-T1 OAM message can be written into the 1000BASE-T1 OAM transmit registers. Once the registers are written the management entity sets mr_tx_valid to 1 to indicate that the 1000BASE-T1 OAM transmit registers contains a valid 1000BASE-T1 OAM message. Once the message is read out atomically, the state machine clears the mr_tx_valid to 0 to indicate that the registers are ready to accept the next 1000BASE-T1 OAM message.

On the receive side mr_rx_lp_valid indicates that valid 1000BASE-T1 OAM message can be read from the 1000BASE-T1 OAM receive registers. Once these registers are read, the mr_rx_lp_valid should be cleared to 0 to indicate that the registers are ready to receive the next 1000BASE-T1 OAM message. If mr_rx_lp_valid is not cleared then the 1000BASE-T1 OAM message transfer will eventually stall since the sender cannot send new 1000BASE-T1 OAM messages if the receiver does not acknowledge that an 1000BASE-T1 OAM message has been transferred into the 1000BASE-T1 OAM receive registers.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The management entities can asynchronously read mr_tx_valid and mr_rx_lp_valid to know when 1000BASE-T1 OAM messages can be transferred in and out of the 1000BASE-T1 OAM registers.

The toggle bit alternates between 0 and 1, which lets the management entity determine which 1000BASE-T1 OAM message is being referred to. The toggle bit transitioning rules between one 1000BASE-T1 OAM frame to the next 1000BASE-T1 OAM frame are shown in Table 97–5.

Table 97–5—Toggle bit transition rules

Previous Valid	Previous Toggle	Current Valid	Current Toggle	Description
0	0	0	0	No valid 1000BASE-T1 OAM message
0	0	0	1	Illegal transition (Error)
0	0	1	0	New 1000BASE-T1 OAM message starting
0	0	1	1	Illegal transition (Error)
0	1	0	0	Illegal transition (Error)
0	1	0	1	No valid 1000BASE-T1 OAM message
0	1	1	0	Illegal transition (Error)
0	1	1	1	New 1000BASE-T1 OAM message starting
1	0	0	0	Illegal transition (Error)
1	0	0	1	Received acknowledge, no new 1000BASE-T1 OAM message to send
1	0	1	0	Repeating current 1000BASE-T1 OAM message, waiting for link partner's acknowledge
1	0	1	1	Previous 1000BASE-T1 OAM message ending, new 1000BASE-T1 OAM message starting
1	1	0	0	Received acknowledge, no new 1000BASE-T1 OAM message to send
1	1	0	1	Illegal transition (Error)
1	1	1	0	Previous 1000BASE-T1 OAM message ending, new 1000BASE-T1 OAM message starting
1	1	1	1	Repeating current 1000BASE-T1 OAM message, waiting for link partner's acknowledge

97.3.8.3 State diagram variable to BASE-T1 OAM register mapping

The state diagrams of Figure 97–18 and Figure 97–17 generate and accept variables of the form "mr_x," where x is an individual signal name. These variables comprise a management interface to communicate the 1000BASE-T1 OAM information to and from the management entity. Clause 45 MDIO registers are defined in MMD3 to support the 1000BASE-T1 OAM. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the information is recommended. Table 97–6 describes the MDIO register to the state diagrams variable mapping.

97.3.8.4 Detailed functions and state diagrams

97.3.8.4.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, counters, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5.

97.3.8.4.2 State diagram parameters

97.3.8.4.3 Variables

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive. This variable takes the values of OK or FAIL.

mr_rx_lp_message[63:0]
: Eight octet 1000BASE-T1 OAM message from the link partner. The value in this variable is valid only when mr_rx_lp_valid is 1.

mr_rx_lp_message_num[3:0]
: Four bit message number from the link partner. The value in this variable is valid only when mr_rx_lp_valid is 1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mr_rx_lp_SNR[1:0]

Link partner health status.

Values:

00: PHY link is failing and will drop link and relink within 2 ms to 4 ms after the end of the current 1000BASE-T1 OAM frame

01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled).

10: PHY SNR is marginal

11: PHY SNR is good

The threshold for the status is implementation dependent.

mr_rx_lp_toggle

The toggle bit value associated with the eight octet 1000BASE-T1 OAM message from the link partner.

Values:

The toggle bit alternates between 0 and 1.

mr_rx_lp_valid

Indicates whether 1000BASE-T1 OAM message in mr_rx_lp_message[63:0], mr_rx_lp_message_num[3:0] and the toggle bit in mr_rx_lp_toggle is valid or not. This variable should be cleared when mr_rx_lp_message[63:48] is read and is not explicitly shown in the state machine. The clearing of this variable indicates to the state machine that the 1000BASE-T1 OAM message is read by the user and the state machine can proceed to load in the next 1000BASE-T1 OAM message.

Values:

0: invalid

1: valid

mr_rx_ping

Echoed ping value from the link partner.

Values:

The value can be 0 or 1.

mr_tx_message[63:0]

Eight octet 1000BASE-T1 OAM message transmitted by the local PHY. The value in this variable is valid only when mr_tx_valid is 1.

mr_tx_message_num[3:0]

Four bit message number transmitted by the local PHY. The value in this variable is valid only when mr_tx_valid is 1.

mr_tx_ping

Ping value transmitted by the local PHY.

Values:

The value can be 0 or 1.

mr_tx_received

Indicates whether the most recently transmitted 1000BASE-T1 OAM message with a toggle bit value of mr_tx_received_toggle was received, read, and acknowledged by the link partner. This variable shall clear on read.

Values:

0: 1000BASE-T1 OAM message not received and read by the link partner

1: 1000BASE-T1 OAM message received by the link partner

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mr_tx_received_toggle

Toggle bit value of the 1000BASE-T1 OAM message that was received, read, and most recently acknowledged by the link partner. This bit is valid only if mr_tx_received is 1.

Values:

The value can be 0 or 1.

mr_tx_SNR[1:0]

Status register indicating PHY health status.

Values:

00: PHY link is failing and will drop link and relink within 2 to 4 ms after the end of the current 1000BASE-T1 OAM frame
01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled)
10: PHY SNR is marginal
11: PHY SNR is good

The threshold for the status is implementation dependent.

mr_tx_toggle

The toggle bit value associated with the eight octet 1000BASE-T1 OAM message transmitted by the PHY. The value is automatically set by the state machine and cannot be set by the user. This bit should be read and recorded prior to setting mr_tx_valid to 1.

Values:

The toggle bit alternates between 0 and 1.

mr_tx_valid

Indicates whether 1000BASE-T1 OAM message in mr_tx_message[63:0] and mr_rx_lp_message_num[3:0] is valid or not. This register will be cleared by the state machine to indicate whether the next 1000BASE-T1 OAM message can be written into the registers.

Values:

0: invalid
1: valid

reset

Reset

Values:

false: 1000BASE-T1 OAM circuit not in reset
true: 1000BASE-T1 OAM circuit is in reset

rx_ack

Acknowledge from link partner in response to PHY's 1000BASE-T1 OAM message.

Values:

0: no acknowledge
1: acknowledge

rx_ack_toggle

The toggle value corresponding to the PHY's 1000BASE-T1 OAM message that the link partner is acknowledging. This value is valid only if the rx_ack is set to 1.

Values:

The toggle bit can take on values of 0 or 1.

rx_boundary

This variable is set to true whenever the receive data stream reaches the end of a Reed-Solomon frames during normal power operation in the data mode, or at the end of a received refresh cycle

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

during low power idle operation. This variable is set to false at other times.
Values:
false: receive stream not at a boundary end
true: receive stream at a boundary end

rx_exp_toggle
This variable holds the expected toggle value of the next 1000BASE-T1 OAM message. This is normally the opposite value of the current toggle value, but is reset on error conditions where two back to back 1000BASE-T1 OAM messages separated by 1000BASE-T1 OAM frames without a valid message have the same toggle value.
Values:
The toggle bit can take on values of 0 or 1.

rx_lp_ack
Acknowledge from PHY in response to link partner's 1000BASE-T1 OAM message. Indicates whether valid 1000BASE-T1 OAM message from the link partner has been sampled into the PHY's registers.
Values:
0: no acknowledge / not sampled
1: acknowledge / sampled

rx_lp_ping
Ping value received from the link partner that should be looped back.
Values:
The value can be 0 or 1.

rx_lp_toggle
The toggle bit value in the previous 1000BASE-T1 OAM frame received from the link partner.
Values:
The toggle bit alternates between 0 and 1.

rx_lp_valid
Indicates whether 1000BASE-T1 OAM message in previous 1000BASE-T1 OAM frame received from the link partner is valid or not.
Values:
0: invalid
1: valid

rx_oam_field<8:0>
Nine bit 1000BASE-T1 OAM symbol extracted from a received Reed-Solomon frame during normal power operation in the data mode, or from a received refresh cycle during low power idle operation.

rx_oam<11 to 0><8:0>
Raw 12 symbol 1000BASE-T1 OAM frame received from the link partner.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SNR[1:0]

PHY health status.

Values:

00: PHY link is failing and will drop link and relink within 2 ms to 4 ms after the end of the current 1000BASE-T1 OAM frame

01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled)

10: PHY SNR is marginal

11: PHY SNR is good

Both the status threshold and condition for generating this status are implementation dependent.

tx_boundary

This variable is set to true whenever the transmit data stream reaches the start of a PHY frame during normal power operation in the data mode, or at the start of a transmit refresh cycle during low power idle operation. This variable is set to false at other times.

Values:

false: transmit stream not at a boundary end

true: transmit stream at a boundary end

tx_oam_field<8:0>

Nine bit 1000BASE-T1 OAM symbol inserted into a transmitted Reed-Solomon frame during normal power operation in the data mode, or into a transmitted refresh cycle during low power idle operation.

tx_oam<11 to 0><8:0>

Raw 12 symbol 1000BASE-T1 OAM frame transmitted from the PHY.

tx_lp_ready

Indicates whether the link partner is ready to receive the next 1000BASE-T1 OAM message from the PHY. If ready, then the PHY will load the next 1000BASE-T1 OAM message from the registers and begin transmitting them.

Values:

0: not ready

1: ready

tx_toggle

The toggle bit value being send in the current 1000BASE-T1 OAM frame transmitted by the PHY.

Values:

The value can be 0 or 1.

97.3.8.4.4 Counters

rx_cnt

A count of received 1000BASE-T1 OAM frames.

Values:

The value can be any integer from 0 to 12, inclusive.

tx_cnt

1000BASE-T1 OAM frame transmit symbol count.

Values:

The value can be any integer from 0 to 12, inclusive.

97.3.8.4.5 Functions

CRC16(10 octets)

This function outputs a 16-bit CRC value using 10-octet input as defined in 97.3.8.2.12.

CRC16_Check(12 octets)

This function checks whether the 12-octet frame has the correct CRC16 as defined in 97.3.8.2.12.

Values:

BAD: CRC16 check is bad

GOOD: CRC16 check is good

Parity(12 octets)

This function outputs 12 parity bits, one for each of the 12 input octets. An even parity bit is output for the first octet, and odd parity bits are output for each of the remaining 11 octets.

Parity_Check(9-bit symbol)

This function calculates the bit parity of the 9-bit symbol.

Values:

Even: symbol has even parity

Odd: symbol has odd parity

97.4 Physical Medium Attachment (PMA) sublayer

97.4.1 PMA functional specifications

The PMA couples messages from a PMA service interface specified in 97.2.2 to the 1000BASE-T1 baseband medium, specified in 97.5.

The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 97.7.

NOTE—The recovered_clock arc is shown to indicate delivery of the recovered clock signal back to PMA TRANSMIT for loop timing.

Figure 97–19—PMA reference diagram

97.4.2 PMA functions

The PMA sublayer comprises one PMA Reset function and five simultaneous and asynchronous operating functions. The PMA operating functions are PHY Control, PMA Transmit, PMA Receive, Link Monitor, and Clock Recovery. All operating functions are started immediately after the successful completion of the PMA Reset function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA reference diagram, Figure 97–19, shows how the operating functions relate to the messages of the PMA Service interface and the signals of the MDI. Connections from the management interface, comprising the signals MDC and MDIO, to other layers are pervasive and are not shown in Figure 97–19.

97.4.2.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

a) Power for the device containing the PMA has not reached the operating state
b) The receipt of a request for reset from the management entity

PMA Reset sets pma_reset = ON while any of the above reset conditions hold true. All state diagrams take the open-ended pma_reset branch upon execution of PMA Reset. The reference diagrams do not explicitly show the PMA Reset function.

The 1000BASE-T1 PMA takes no longer than 100 ms to enter the PCS_DATA state after exiting from reset or low power mode (see Figure 97–26).

97.4.2.2 PMA Transmit function

The PMA Transmit function comprises a transmitter to generate a three level modulated signal on the single twisted-pair copper cable. PMA Transmit shall continuously transmit onto the MDI pulses modulated by the symbols given by tx_symb when sync_link_control = ENABLE, or the sync_tx_symb output by the PHY Link Synchronization function when sync_link_control = DISABLE, after processing with optional transmit filtering, digital-to-analog conversion (DAC) and subsequent analog filtering. The signals generated by PMA Transmit shall comply with the electrical specifications given in 97.5.

When the PMA_CONFIG.indication parameter config is MASTER, the PMA Transmit function shall source TX_TCLK from a local clock source while meeting the transmit jitter requirements of 97.5.3.3. The MASTER-SLAVE relationship shall include loop timing. If the PMA_CONFIG.indication parameter config is SLAVE, the PMA Transmit function shall source TX_TCLK from the recovered clock of 97.4.2.8 while meeting the jitter requirements of 97.5.3.3.

97.4.2.2.1 Global PMA transmit disable

When the PMA_transmit_disable variable is set to true, this function shall turn off the transmitter so that the transmitter Average Launch Power of the Transmitter is less than –53 dBm.

97.4.2.3 PMA Receive function

The PMA Receive function comprises a receiver for PAM3 signals on the twisted-pair. PMA Receive contains the circuits necessary to both detect symbol sequences from the signals received at the MDI over receive pair and to present these sequences to the PCS Receive function. The PMA translates the signals received on the twisted-pair into the PMA_UNITDATA.indication parameter rx_symb. The quality of these symbols shall allow RFER of less than 3.6×10^{-7} after RS-FEC decoding, over a channel meeting the requirements of 97.6.

To achieve the indicated performance, it is highly recommended that PMA Receive include the functions of signal equalization and echo cancellation. The sequence of symbols assigned to tx_symb is needed to perform echo cancellation.

The PMA Receive function uses the scr_status parameter and the state of the equalization, cancellation, and estimation functions to determine the quality of the receiver performance, and generates the loc_rcvr_status variable accordingly. The loc_rcvr_status variable is expected to become NOT_OK when the link partner's

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_mode changes to SEND_Z from any other values (see PHY Control state diagram in Figure 97–26). The precise algorithm for generation of loc_rcvr_status is implementation dependent.

The receiver uses the sequence of symbols during the training sequence to detect and correct for pair polarity swaps.

The PMA Receive fault function is optional. The PMA Receive fault function is the logical OR of the link_status = FAIL and any implementation specific fault. If the MDIO interface is implemented, then this function shall contribute to the receive fault bit specified in 45.2.1.238.6.

97.4.2.4 PHY Control function

PHY Control generates the control actions that are needed to bring the PHY into a mode of operation during which frames can be exchanged with the link partner. PHY Control shall comply with the state diagram description given in Figure 97–26.

During PMA training (TRAINING and COUNTDOWN states in Figure 97–26), PHY Control information is exchanged between link partners with a 12-octet InfoField, which is XORed with the first 96 bits of the 15th partial PHY frame (bits 2520 to 2615) of the PHY frame. The InfoField is also denoted IF. The link partner is not required to decode every IF transmitted but is required to decode IFs at a rate that enables the correct actions prior to the PAM2 to PAM3 transition.

The 12-octet InfoField shall include the fields in 97.4.2.4.2 through 97.4.2.4.8, also shown in the overview Figure 97–20, and the more detailed Figure 97–21 and Figure 97–22. Each InfoField shall be transmitted at least 256 times to ensure detection at link partner.

97.4.2.4.1 InfoField notation

For all the InfoField notations in the following subclauses, Reserved<bit location> represents any unused values and shall be set to zero on transmit and ignored when received by the link partner. The InfoField is transmitted following the notation described in 97.3.2.2.3 where the LSB of each octet is sent first and the octets are sent in increasing number order (that is, the LSB of Oct1 is sent first).

97.4.2.4.2 Start of Frame Delimiter

The start of Frame Delimiter consists of 3 octets [Oct1<7:0>, Oct2<7:0>, Oct3<7:0>] and shall use the hexadecimal value 0xBBA700. 0xBB corresponds to Oct1<7:0> and so forth.

97.4.2.4.3 Partial PHY frame Count (PFC24)

The start of partial PHY frame Count consists of 3 octets [Oct4<7:0>, Oct5<7:0>, Oct6<7:0>] and indicates the running count of partial PHY frames sent LSB first. There are 15 partial PHY frames per PHY frame and the InfoField is embedded within the 15th partial PHY frame. The first partial PHY frame is zero, thus the first partial PHY frame count field after a reset is 14.

97.4.2.4.4 Message Field

Message Field (1 octet). For the MASTER, this field is represented by Oct7{PMA_state<7:6>, loc_rcvr_status<5>, en_slave_tx<4>, reserved<3:0>}. For the SLAVE, this field is represented by Oct7{PMA_state<7:6>, loc_rcvr_status<5>, timing_lock_OK<4>, reserved<3:0>}.

The two state-indicator bits PMA_state<7:6> shall communicate the state of the transmitting transceiver to the link partner. PMA_state<7:6> = 00 indicates TRAINING, and PMA_state<7:6> = 01 indicates COUNTDOWN.

All possible Message Field settings are listed in Table 97–7 for the MASTER and Table 97–8 for the SLAVE. Any other value shall not be transmitted and shall be ignored at the receiver. The Message Field setting for the first transmitted PMA frame shall be the first row of Table 97–7 for the MASTER and the first or second row of Table 97–8 for the SLAVE. Moreover, for a given Message Field setting, the next Message Field setting shall be the same Message Field setting or the Message Field setting corresponding to a row below the current setting. When loc_rcvr_status = OK the InfoField variable is set to loc_rcvr_status<5> = 1 and set to 0 otherwise.

Table 97–7—InfoField message field valid MASTER settings

PMA_state<7:6>	loc_rcvr_status	en_slave_tx	reserved	reserved	reserved	reserved
00	0	0	0	0	0	0
00	0	1	0	0	0	0
00	1	1	0	0	0	0
01	1	1	0	0	0	0

Table 97–8—InfoField message field valid SLAVE settings

PMA_state<7:6>	loc_rcvr_status	timing_lock_OK	reserved	reserved	reserved	reserved
00	0	0	0	0	0	0
00	0	1	0	0	0	0
00	1	1	0	0	0	0
01	1	1	0	0	0	0

97.4.2.4.5 PHY Capability Bits, User Configurable Register, and Data Mode Scrambler Seed

When PMA_state<7:6> = 00, then [0ct8<7:0>, 0ct9<7:0>, 0ct10<7:0>] contains the two PHY capability bits, the user configurable register bits, and the 15-bit data mode scrambler seed (Seed). Each octet is sent LSB first.

The format of PHY capability bits is Oct9<7> = EEEen and Oct10<0> = OAMen, indicating EEE and 1000BASE-T1 OAM capability enable, respectively. The PHY shall indicate the support of optional capabilities by setting the corresponding capability bits.

The data mode scrambler seed contains bits S14 (sent first) to S0 (sent last) to indicate the initial state of the data mode transmit scrambler of the local device upon reaching the data switch partial PHY frame count. The state of the scrambler in Figure 97–9 shall be S14:S0 at the first bit of the first PHY frame when the partial PHY frame counter equals to the DataSwPFC24 value, see 97.4.2.4.6. The format of Seed is Oct8<7:0> = S<7:14> and Oct9<6:0> = S<0:6>. Seed S<14:0> shall not be all zeros.

The remaining 7-bit Oct10<7:1> form a user-configurable register. See 97.4.2.4.11 for details.

97.4.2.4.6 Data Switch partial PHY frame Count

When PMA_state<7:6> = 01, then [Oct8<7:0>, Oct9<7:0>, Oct10<7:0>] contains the data switch partial PHY frame count (DataSwPFC24) sent LSB first. DataSwPFC24 indicates the partial PHY frame count when the transmitter switches from PAM2 to PAM3, which occurs at the start of an RS-FEC block. The last value of PFC24 prior to the transition is DataSwPFC24 - 1. DataSwPFC24 shall be set to an integer multiple of 15. This value of DataSwPFC24 guarantees that the switch from PAM2 to PAM3 occurs on a PHY frame boundary.

97.4.2.4.7 Reserved Fields

When PMA_state<7:6> is greater than 01, then [Oct8<1:0>, Oct9<1:0>, Oct10<7:0>] contains a reserved field. All InfoField fields denoted Reserved are reserved for future use.

97.4.2.4.8 CRC16

CRC16 (2 octets) shall implement the CRC16 polynomial $(x+1)(x^{15}+x+1)$ of the previous 7 octets, Oct4<7:0>, Oct5<7:0>, Oct6<7:0>, Oct7<7:0>, Oct8<7:0>, Oct9<7:0>, and Oct10<7:0>. The CRC16 shall produce the same result as the implementation shown in Figure 97–23. In Figure 97–23 the 16 delay elements S0,..., S15, shall be initialized to zero. Afterwards Oct4 through Oct10 are used to compute the CRC16 with the switch connected, which is setting CRCgen in Figure 97–23. After all the 7 octets have

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

been processed, the switch is disconnected (setting CRCout) and the 16 values stored in the delay elements are transmitted in the order illustrated, first S15, followed by S14, and so on, until the final value S0.

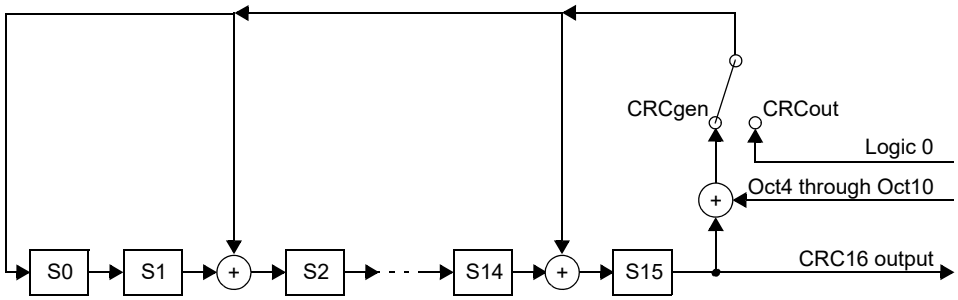

Figure 97–23—CRC16

97.4.2.4.9 PMA MDIO function mapping

The MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMA. Mapping of MDIO control variables to PMA control variables is shown in Table 97–9. Mapping of MDIO status variables to PMA status variables is shown in Table 97–10.

Table 97–9—MDIO/PMA control variable mapping

MDIO control variable	PMA register name	Register/bit number	PMA control variable
Reset	Control register 1 / 1000BASE-T1 PMA control register	1.0.15 / 1.2304.15	pma_reset
Transmit disable	1000BASE-T1 PMA control register	1.2304.14	PMA_transmit_disable

Table 97–10—MDIO/PMA status variable mapping

MDIO status variable	PMA register name	Register/bit number	PMA status variable
Receive fault	1000BASE-T1 PMA status register	1.2305.1	PMA_receive_fault

97.4.2.4.10 Startup sequence

The startup sequence shall comply with the state diagram description given in Figure 97–26. If the Auto-Negotiation function is not implemented, or mr_autoneg_en = false, PMA_CONFIG is predetermined to be MASTER or SLAVE via management control during initialization or via default hardware setup.

The Auto-Negotiation function is optional for 1000BASE-T1 PHYs. If the Auto-Negotiation function is used, during the Auto-Negotiation process PHY Control is in the DISABLE_TRANSMITTER state and the transmitter is disabled. If the Auto-Negotiation function is not used, during the PHY Link Synchronization stage the PHY Control remains in the DISABLE_TRANSMITTER state and the Link Synchronization function (see 97.4.2.6) is the data source for the PMA Transmit function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the Auto-Negotiation asserts link_control = ENABLE, or PHY Link Synchronization process asserts sync_link_control = ENABLE, PHY Control enters the INIT_MAXWAIT_TIMER state. Upon entering the INIT_MAXWAIT_TIMER state, the maxwait_timer is started. PHY Control then transitions to the SILENT state where the minwait_timer is started and the PHY transmits zeros (tx_mode = SEND_Z).

In MASTER mode PHY Control transitions to the TRAINING state once the minwait_timer expires.

Upon entering the TRAINING state, the minwait_timer is started and the PHY Control asserts tx_mode = SEND_T sending PAM2 together with InfoFields. The PHY Control also sets PMA_state = 00 and sends the PHY capability bits, the user configurable register bits, and the Seed value used by the local device for the data mode scrambler initialization, see 97.4.2.4.5.

The optional EEE capability shall be enabled only if both PHYs set the capability bit EEEen = 1. The optional 1000BASE-T1 OAM capability shall be enabled only if both PHYs set the capability bit OAMen = 1.

Initially the MASTER is not ready for the SLAVE to respond and sets en_slave_tx = 0, which is communicated to the link partner via the InfoField. After the MASTER has sufficiently converged the necessary circuitry, the MASTER shall set en_slave_tx = 1 to allow the SLAVE to transition to TRAINING.

In SLAVE mode PHY Control transitions to the TRAINING state only after the SLAVE PHY acquires timing, converges its equalizers, acquires its descrambler state and sets loc_SNR_margin = OK. The SLAVE shall align its transmit 81B-RS frame to within +0/–1 partial PHY frames of the MASTER as seen at the SLAVE MDI. The SLAVE InfoField partial PHY frame Count shall match the MASTER InfoField partial PHY frame Count for the aligned frame.

Upon entering TRAINING state the SLAVE initially sets timing_lock_OK = 0 until it has acquired timing lock at which point the SLAVE sets timing_lock_OK = 1.

After the PHY completes successful training and establishes proper receiver operations, PCS Transmit conveys this information to the link partner via transmission of the parameter InfoField value loc_rcvr_status. The link partner's value for loc_rcvr_status is stored in the local device parameter rem_rcvr_status. Upon expiration of the minwait_timer and when the condition loc_rcvr_status = OK and rem_rcvr_status = OK is satisfied, PHY control transitions to the COUNTDOWN state.

Upon entering the COUNTDOWN state, PHY Control sets PMA_state = 01 and DataSwPFC24 to the value of the partial PHY frame count when the transmitter switches from PAM2 to PAM3.

Upon reaching DataSwPFC24 partial PHY frame count PHY Control transitions to the SEND_IDLE1 state and forces transmission into the idle mode by asserting tx_mode = SEND_I.

Once the link partner has transitioned from PAM2 to PAM3, PHY Control transitions to the SEND_IDLE2 state and starts the minwait_timer.

Upon expiration of the minwait_timer and when the condition loc_phy_ready = OK and rem_phy_ready = OK is satisfied, PHY control transitions to the SEND_DATA state.

Upon entering the SEND_DATA state, PHY Control starts the minwait_timer and enables frame transmission to the link partner by asserting tx_mode = SEND_N.

The operation of the maxwait_timer requires that the PHY complete the startup sequence from state INIT_MAXWAIT_TIMER to SEND_DATA in the PHY Control state diagram state diagram (Figure 97–26) in less than 97.5 ms to avoid link_status being changed to FAIL by the Link Monitor state diagram (Figure 97–27).

97.4.2.4.11 PHY Control Registers

The PHY control registers are shown in Table 97–11.

Table 97–11—PHY Control Registers

MDIO control/status variable	PMA register name	Register/bit number	PMA control/status variable
MASTER-SLAVE	BASE-T1 PMA/PMD control register	1.2100.14	force_config (see 97.4.2.6.1)
Type selection	BASE-T1 PMA/PMD control register	1.2100.3:0	force_PHY_type (see 97.4.2.6.1)
1000BASE-T1 OAM Ability	1000BASE-T1 PMA status register	1.2305.11	
EEE Ability	1000BASE-T1 PMA status register	1.2305.10	
User Field	1000BASE-T1 training register	1.2306.10:4	PMA_state<7:6> = 00, Oct10<7:1>
1000BASE-T1 OAM Advertisement	1000BASE-T1 training register	1.2306.1	PMA_state<7:6> = 00, Oct10<0>
EEE Advertisement	1000BASE-T1 training register	1.2306.0	PMA_state<7:6> = 00, Oct9<7>
Link Partner User Field	1000BASE-T1 link partner training register	1.2307.10:4	LP PMA_state<7:6> = 00, Oct10<7:1>
Link Partner 1000BASE-T1 OAM Advertisement	1000BASE-T1 link partner training register	1.2307.1	LP PMA_state<7:6> = 00, Oct10<0>
Link Partner EEE Advertisement	1000BASE-T1 link partner training register	1.2307.0	LP PMA_state<7:6> = 00, Oct9<7>

97.4.2.5 Link Monitor function

Link Monitor determines the status of the underlying receive channel and communicates it via the variable link_status. Failure of the underlying receive channel causes the PMA to set link_status to FAIL, which in turn causes the PMA's clients to stop exchanging frames and restart the auto-negotiation (if enabled) or synchronization (if auto-negotiation is not enabled) process.

The Link Monitor function shall comply with the state diagram of Figure 97–27.

Upon power on, reset, or release from power down, the Auto-Negotiation function set link_control = DISABLE, or PHY Link Synchronization algorithms set sync_link_control = DISABLE. During this period, link_status = FAIL is asserted. When the Auto-Negotiation function establishes the presence of a remote 1000BASE-T1 PHY, link_control is set to ENABLE, or when the PHY Link Synchronization finishes the synchronization function, sync_link_control is set to ENABLE, and the Link Monitor state machines begins monitoring the PCS and receiver lock status. As soon as reliable transmission is achieved, the variable link_status = OK is asserted, upon which further PHY operations can take place.

97.4.2.6 PHY Link Synchronization

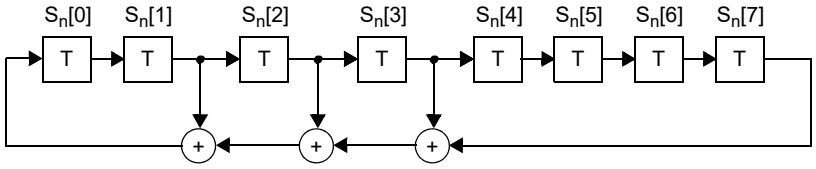
If the optional Clause 98 Auto-Negotiation function is disabled or not implemented, then the Link Synchronization function is responsible for establishing the start of PHY PMA training as defined in 97.4.2.4.

When operating, the Link Synchronization function is the data source for the PMA Transmit function (see 97.4.2.2) and generates a signal, SEND_S, used by the MASTER and SLAVE to discover the link partner and synchronize the start of PMA training.

Link Synchronization employs the SEND_S signal to achieve synchronization prior to link training. If the PHY is configured as MASTER, Link Synchronization shall employ Equation (97–8) as the PN sequence generator.

$$p_M(x) = x^8 + x^4 + x^3 + x^2 + 1 \quad (97–8)$$

If the PHY is configured as SLAVE, Link Synchronization shall employ Equation (97–9) as PN sequence generator.



$$p_{MS}(x) = x^8 + x^6 + x^5 + x^4 + 1 \quad (97–9)$$

The period of both PN sequences is 255.

An implementation of MASTER and SLAVE PHY SEND_S PN sequence generators by linear-feedback shift registers is shown in Figure 97–24. The bits stored in the shift register delay line at time n are denoted by Sn[7:0]. At each symbol period, the shift register is advanced by one bit, and one new bit represented by Sn[0] is generated. The PN sequence generator shift registers shall be reset to a non-zero value upon entering into the TRANSMIT_DISABLE state (see Figure 97–25). The receiver may not necessarily receive a continuous PN sequence between separate periods of SEND_S.

The bit $S_n[0]$ is mapped to the transmit symbol Tn as follows: if $S_n[0] = 0$ then Tn = +1, if $S_n[0] = 1$ then Tn = –1.

MASTER PHY SEND_S PN sequence generator

SLAVE PHY SEND_S PN sequence generator

The synchronization state diagram in Figure 97–25 shall be used to synchronize 1000BASE-T1 PHYs prior to the 1000BASE-T1 link training. If Clause 98 Auto-Negotiation function is enabled, then the Auto-Negotiation function shall be used as the mechanism for PHY synchronization and the synchronization state diagram in Figure 97–25 remains in the SYNC_DISABLE state.

97.4.2.6.1 State diagram variables

force_config
: This variable indicates whether the PHY operates as a MASTER or as a SLAVE. The variable takes on one of the following values:
  - MASTER: this value is continuously asserted when the PHY operates as a MASTER
  - SLAVE: this value is continuously asserted when the PHY operates as a SLAVE

force_phy_type
: This variable indicates what speed the PHY is to operate when Auto-Negotiation is disabled or not implemented. The variable takes on one of the following values:
  - 1000-T1: if Auto-Negotiation is disabled or not implemented and 1000BASE-T1 is selected
  - 100-T1: if Auto-Negotiation is disabled or not implemented and 100BASE-T1 is selected
  - None: else

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive. This variable takes the values of OK or FAIL.

mr_autoneg_enable
: See 98.5.1.

mr_main_reset
: See 98.5.1.

power_on
: See 98.5.1.

send_s_sigdet
: This variable indicates whether the SEND_S pattern was detected. This variable shall be set false no later than 1 μs after the signal goes quiet on the MDI.
  Values:
  - true: SEND_S pattern detected
  - false: SEND_S pattern not detected

sync_link_control
: This variable indicates the data source for the PMA Transmit function.
  Values:
  - DISABLE: The data source is the PHY Link Synchronization function (sync_tx_symb)
  - ENABLE: The data source is PMA_UNITDATA.request (tx_symb)

sync_tx_mode
: This variable indicates what symbols are sent by the PHY Link Synchronization process.
  Values:
  - SEND_S: this value is continuously asserted to enable transmission of the PN sequence defined in 97.4.2.6
  - SEND_Z: this value is asserted to disable transmission

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.4.2.6.2 State diagram timers

break_link_timer
: See 98.5.2.

link_fail_inhibit_timer
: See 98.5.2.

send_s_timer
: This timer is used to control the duration SEND_S is transmitted. The timer shall expire 1.0 μs ± 0.04 μs after being started.

sigdet_wait_timer
: This timer is used to control the wait time after transmitting or detecting the end of SEND_S. The timer shall expire 4 μs ± 0.1 μs after being started.

97.4.2.6.3 Messages

sync_tx_symb
: A signal sent from Link Synchronization block to PMA Transmit indicating that a PAM2 (SEND_S) or zero (SEND_Z) symbol is available. The Link Synchronization block generates sync_tx_symb synchronously with every transmit clock cycle.

Copyright © 2022 IEEE. All rights reserved.

97.4.2.7 Refresh Monitor function

A 1000BASE-T1 PHY supporting the EEE capability shall implement the Refresh monitor function. The Refresh monitor operates when the PHY is in the LPI receive mode. If Refresh is not reliably detected within a moving window of 50 Q/R cycles (4.32 ms), the refresh monitor shall set PMA_refresh_status to FAIL, which sets link_status to FAIL. Subsequently the PHY restarts auto-negotiation (if auto-negotiation is enabled) or synchronization (if auto-negotiation is disabled). PMA_refresh_status shall be set to OK when the Link Monitor state diagram (Figure 97–27) enters the LINK_UP state.

97.4.2.8 Clock Recovery function

The Clock Recovery function shall provide a clock suitable for signal sampling so that the RS FER indicated in 97.4.2.3 is achieved. The received clock signal is expected to be stable and ready for use when training has been completed. The received clock signal is supplied to the PMA Transmit function by received_clock.

97.4.3 MDI

Communication through the MDI is summarized in 97.4.3.1 and 97.4.3.2.

97.4.3.1 MDI signals transmitted by the PHY

The symbols to be transmitted by the PMA are denoted by tx_symb. The modulation scheme used over each pair is PAM3. PMA Transmit generates a pulse-amplitude modulated signal on each pair in the following form:

$$s(t) = \sum_{n=0}^{\infty} a_n h_T(t - nT) \tag{97–10}$$

In Equation (97–10), a_n is the PAM3 modulation symbol from the set {–1, 0, 1} to be transmitted at time nT, and $h_T(t)$ denotes the system symbol response at the MDI. This symbol response shall comply with the electrical specifications given in 97.5.

97.4.3.2 Signals received at the MDI

Signals received at the MDI can be expressed for each pair as pulse-amplitude modulated signals that are corrupted by noise as follows:

$$r(t) = \sum_{n=0}^{\infty} a_n h_R(t - nT) + w(t) \tag{97–11}$$

In Equation (97–11) $h_R(t)$ denotes the symbol response of the overall channel impulse response between the transmit symbol source and the receive MDI and $w(t)$ represents the contribution of various noise sources including uncancelled echo. The receive signal is processed within the PMA Receive function to yield the received symbols rx_symb.

97.4.4 State variables

97.4.4.1 State diagram variables

auto_neg_imp
: This variable indicates if an optional Auto-Negotiation sublayer is associated with the PMA.
Values:
- true: An optional Auto-Negotiation sublayer is associated with the PMA
- false: An optional Auto-Negotiation sublayer is not associated with the PMA

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

config

The PMA generates this variable continuously and passes it to the PCS via the PMA_CONFIG.indication primitive.

Values:

MASTER
SLAVE

en_slave_tx

The en_slave_tx variable in the InfoField received by the SLAVE.

Values:

0: Master is not ready for the SLAVE to transmit
1: Master is ready for the SLAVE to transmit

infofield_complete

This variable indicates that a complete set of InfoField messages has been sent (see 97.4.2.4).

Values:

false: a complete set of InfoField messages has not been sent
true: a complete set of InfoField messages has been sent

link_control

This variable is defined in 97.2.1.1.1.

link_status

The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive. This variable takes the values of OK or FAIL.

loc_phy_ready

This variable is set by the PMA Receive function to indicate the local PHY is ready or not ready to receive data. The value of loc_phy_ready is equal to OK only if loc_rcvr_status = OK and pcs_status = OK. Otherwise its value is NOT_OK. This variable is conveyed to the link partner by the PCS as defined in Table 97–1.

Values:

OK: the local PHY is ready to receive data
NOT_OK: the local PHY is not ready to receive data

loc_countdown_done

This variable is set to false when the PHY Control state diagram is in the DISABLE_TRANSMITTER state and is set to true immediately after transmitting the last bit of the DataSwPFC24–1 partial PHY frame.

loc_rcvr_status

Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive link for the local PHY. This variable is transmitted in the loc_rcvr_status bit of the InfoField by the local PHY.

Values:

OK: the receive link for the local PHY is operating reliably
NOT_OK: operation of the receive link for the local PHY is unreliable

loc_SNR_margin

This variable reports whether the local device has sufficient SNR margin to continue to the next state. The criterion for setting the parameter loc_SNR_margin is left to the implementer.

Values:

OK: the local device has sufficient SNR margin
NOT_OK: the local device does not have sufficient SNR margin

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_refresh_status

This variable indicates the status of the Refresh Monitor as described in 97.4.3.

Values:

OK: refresh is detected reliably

FAIL: refresh is not detected reliably

pma_reset

Allows reset of all PMA functions. It is set by PMA Reset.

Values:

ON

OFF

PMA_state

Variable for the value transmitted in the PMA_state<7:6> of the InfoField by the local PHY.

Values:

00: TRAINING state

01: COUNTDOWN state

PMA_watchdog_status

Variable indicating the status of the PAM3 monitor.

Values:

OK: the local device has received sufficient PAM3 transitions

NOT_OK: the local device has not received sufficient PAM3 transitions

During normal operation NOT_OK is assigned when:

— PAM3 symbol 0 consecutively seen on the line for longer than 2 μs ± 0.1 μs

— PAM3 symbol +1 consecutively seen on the line for longer than 3.9 μs ± 0.1 μs

— PAM3 symbol –1 consecutively seen on the line for longer than 3.9 μs ± 0.1 μs

During Low Power Idle operation NOT_OK is assigned when:

— PAM3 symbol not toggling on the line during one full refresh window

rem_countdown_done

This variable is set to false when the PHY Control state diagram is in the DISABLE_TRANSMITTER state or SILENT state and is set to true once the receiver has transitioned from PAM2 to PAM3 mode and has received a valid PHY frame containing all IDLEs.

rem_phy_ready

This variable is set by the PCS Receive function to indicate whether the remote PHY is ready or not ready to receive data. This variable is received from the link partner by the PCS as defined in Table 97–1. The variable retains its value until the next normal Inter-Frame idle is received.

Values:

OK: the remote PHY is ready to receive data

NOT_OK: the remote PHY is not ready to receive data

rem_rcvr_status

Variable set by the PCS Receive function to indicate whether correct operation of the receive link for the remote PHY is detected or not. This variable is received in the loc_rcvr_status bit in the InfoField from the remote PHY. This variable is set to NOT_OK if the PCS has not decoded a valid InfoField from the remote PHY.

Values:

OK: the receive link for the remote PHY is operating reliably

NOT_OK: reliable operation of the receive link for the remote PHY is not detected

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

sync_link_control
This variable is defined in 97.4.2.6.1.

tx_mode
The PMA generates this variable continuously and passes it to the PCS via the PMA_TX-MODE.indication primitive.
Values:
SEND_N: this value is continuously asserted when transmission of sequences of symbols representing a GMII data stream take place
SEND_I: this value is continuously asserted when transmission of sequences of symbols representing an idle stream takes place
SEND_T: this value is continuously asserted when transmission of sequences of symbols representing the training sequences of symbols is to take place
SEND_Z: this value is asserted when transmission of zero symbols is to take place

97.4.4.2 Timers

All timers operate in the manner described in 14.2.3.2.

maxwait_timer
A timer used to limit the amount of time during which a receiver dwells in the SILENT and TRAINING states. The timer shall expire 97.5 ms ± 0.5 ms after being started.
This timer is used jointly in the PHY Control and Link Monitor state diagrams. The maxwait_timer is tested by the Link Monitor to force link_status to be set to FAIL if either of the following conditions is true:

— the PMA_watchdog_status is NOT_OK
— the timer expires and loc_phy_ready is NOT_OK
— the PMA_refresh_status is FAIL

See Figure 97–26 and Figure 97–27.

minwait_timer
A timer used to determine the minimum amount of time the PHY Control stays in the SILENT, TRAINING, SEND IDLE2, and SEND DATA states. The timer shall expire 975 µs ± 50 µs after being started.

97.5 PMA electrical specifications

This subclause specifies the electrical characteristics of the PMA for a 1000BASE-T1 Ethernet PHY.

97.5.1 EMC Requirements

See 96.5.1.

97.5.1.1 Immunity—DPI test

See 96.5.1.1.

97.5.1.2 Emission—150 Ω conducted emission test

See 96.5.1.2.

97.5.2 Test modes

The test modes described as follows shall be provided to allow for testing of the transmitter jitter, transmitter distortion, transmitter PSD, transmitter droop, and BER testing.

These test modes shall be enabled by setting a control register 1.2308.15:13 as shown in Table 97–12. The test modes shall only change the data symbols provided to the transmitter circuitry and do not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 97–12—MDIO management registers settings for test modes

Register value	Register description
000	Normal (non-test mode) operation.
001	Test mode 1—Setting MASTER and SLAVE PHYs for transmit clock jitter test in linked mode.
010	Test mode 2—Transmit MDI jitter test in MASTER mode.
011	Reserved.
100	Test mode 4—Transmit distortion test.
101	Test mode 5—Normal operation in Idle mode. This is for the PSD Mask test.
110	Test mode 6—Transmitter droop test mode.
111	Test mode 7—Normal operation with zero data pattern. This is for BER monitoring.

Test mode 1 enables testing of timing jitter on MASTER and SLAVE transmitters. MASTER and SLAVE 1000BASE-T1 PHYs are connected over a link segment defined in 97.6. When in this mode, the 1000BASE-T1 PHY shall provide access to a frequency reduced version of the transmit symbol clock or TX_TCLK125. This 125 MHz test clock is one sixth frequency divided version of TX_TCLK that times the transmitted symbols.

Test mode 2 is for transmitter jitter testing on MDI when transmitter is in MASTER timing mode. When test mode 2 is enabled, the 1000BASE-T1 PHY shall transmit a continuous pattern of three {+1} symbols followed by three {–1} symbols with the transmitted symbols timed from its local clock source of 750 MHz. The transmitter output is a 125 MHz signal.

Test mode 3 is not defined and the corresponding register is reserved for future use.

Test mode 4 is for transmitter linearity testing. When test mode 4 is enabled, 1000BASE-T1 PHY shall transmit the sequence of symbols generated by the scrambler generator polynomial per Equation (97–12).

$$g(x) = 1 + x^{9} + x^{11} \tag{97–12}$$

The maximum-length shift register used to generate the sequences defined by this polynomial shall be updated once per symbol interval (2/750 MHz). The bits stored in the shift register delay line at a particular time n are denoted by $Scr_n[10:0]$. At each symbol period the shift register is advanced by one bit and one new bit represented by $Scr_n[0]$ is generated. Bits $Scr_n[8]$ and $Scr_n[10]$ are exclusive ORed together to generate the next $Scr_n[0]$ bit. The bit sequences $x0_n$, $x1_n$, and $x2_n$ generated from combinations of the scrambler bits, as shown in Equation (97–13), shall be used to generate the ternary symbols, $T0_n$ and $T1_n$, as shown in Table 97–13. The transmitter shall time the transmitted symbols from a 750 MHz ± 0.01% clock in the MASTER timing mode. The transmit signal level and spectral shaping in this mode shall be same as normal (non-test) mode. A typical transmitter output for transmitter test mode 4 is shown in Figure 97–28.

$$\begin{aligned} x0_n &= Scr_n[0] \\ x1_n &= Scr_n[1] \wedge Scr_n[4] \\ x2_n &= Scr_n[1] \wedge Scr_n[5] \end{aligned} \tag{97–13}$$

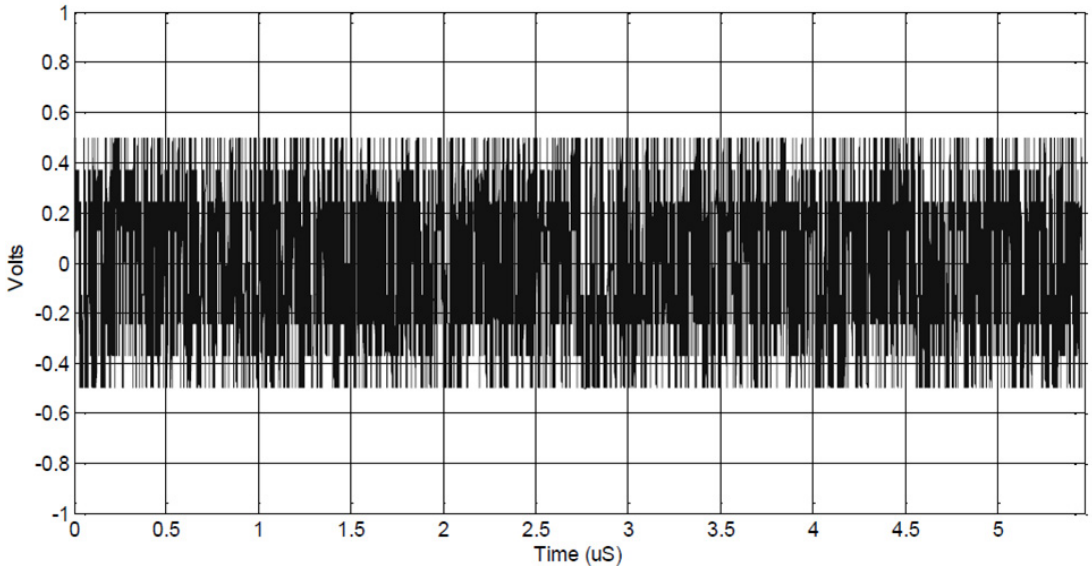

Figure 97–28—Typical transmitter output for transmitter test mode 4

Table 97–13—Transmit test mode 4 symbol mapping

$x2_n$	$x1_n$	$x0_n$	$T1_n$	$T0_n$
0	0	0	–1	–1
0	0	1	0	–1
0	1	0	–1	0
0	1	1	–1	+1
1	0	0	+1	0
1	0	1	+1	–1
1	1	0	+1	+1
1	1	1	0	+1

Test mode 5 is for checking whether the transmitter is compliant with the transmit PSD mask and the transmit power level. When test mode 5 is enabled, 1000BASE-T1 PHY shall transmit as in non-test operation and in the MASTER data mode with data set to normal Inter-Frame idle signals.

When test mode 6 is enabled, 1000BASE-T1 PHY shall transmit a continuous pattern of fifteen {+1} symbols followed by fifteen {–1} symbols with the transmitted symbols timed from its local clock source of 750 MHz. The transmitter output is a 25 MHz signal.

Test mode 7 is for enabling measurement of the bit error ratio of the link including the RS-FEC encoder / decoder, transmit and receive analog front ends of 1000BASE-T1 PHY, and a cable connecting two 1000BASE-T1 PHYs. This mode reuses the 1000BASE-T1 normal (non-test) mode with zero data pattern. Instead of encoding received data from MAC, continuous zero data pattern is encoded. In the receive side,

after FEC and 80B/81B decoding, zero data sequence is expected with no error. Any non-zero data bit received is counted as error and calculated in BER.

97.5.2.1 Test fixtures

The following fixtures, or their equivalents, as shown in Figure 97–29, Figure 97–30, Figure 97–31, Figure 97–32, and Figure 97–33, in stated respective tests, shall be used for measuring the transmitter specifications for data communication only. The tolerance of resistors shall be ± 0.1%.

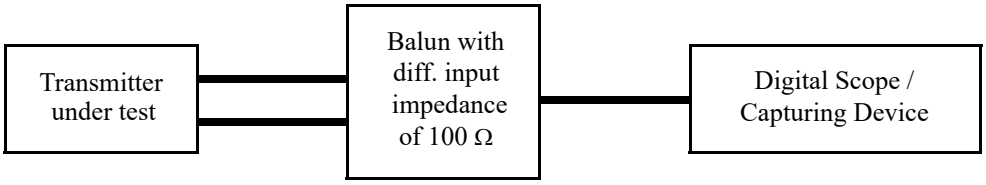

Figure 97–32—Transmitter test fixture 4 for MDI jitter measurement

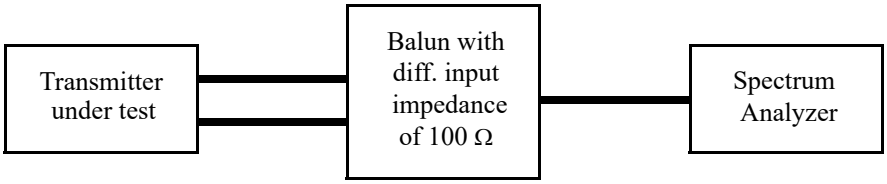

Figure 97–33—Transmitter test fixture 5 for power spectral density measurement and transmit power level measurement

97.5.3 Transmitter electrical specifications

The PMA provides the Transmit function specified in 97.4.2.2 in accordance with the electrical specifications of this clause. The PMA shall operate with AC coupling to the MDI. Where a load is not specified, the transmitter shall meet the requirements of this clause with a 100 Ω resistive differential load connected to the transmitter output.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.5.3.1 Maximum output droop

With the transmitter in test mode 6 and using the transmitter test fixture 1, the magnitude of both the positive and negative droop shall be less than 10%, measured with respect to an initial value at 4 ns after the zero crossing and a final value at 16 ns after the zero crossing (12 ns period).

97.5.3.2 Transmitter distortion

In Figure 97–30, the sinusoidal disturbing signal Vd, shall have amplitude of 3.6 V peak-to-peak differential, and frequency given by one-sixth of the symbol rate (125 MHz) synchronous with the test pattern. The generator of the disturbing signal shall have sufficient linearity and range so it does not introduce any appreciable distortion when connected to the transmitter output.

Transmitter distortion is measured by capturing the test mode 4 waveform using transmitter test fixture 2. The peak distortion is determined by sampling the differential signal output with the symbol rate clock at an arbitrary phase and processing a block of consecutive samples with pseudo-code given below or an equivalent. The captured block of signal shall be at least 40 μs long and be sampled with the minimum sampling rate of 7.5 Gs/s (10 times the transmit symbol rate of 750 Ms/s).

The peak distortion values, measured at a minimum of 10 equally spaced phases of a single symbol period, shall be less than 15 mV. Notice the peak signal level is normalized to 1 V in the processing code. The pseudo-code removes the sinusoidal disturbing signal from the measured data and computes the peak distortion. The code assumes the disturber signal and the data acquisition clock are frequency locked to the DUT transmit clock.

97.5.3.3 Transmitter timing jitter

The transmitter timing jitter is measured by capturing the TX_TCLK125 waveform in both MASTER and SLAVE configurations while in test mode 1 using the transmitter test fixture 3 shown in Figure 97–31.

When in test mode 1 and the link is up and the two PHYs have established link (link_status is set to OK), the RMS value of the MASTER TX_TCLK125 jitter relative to an unjittered reference shall be less than 5 ps. The peak-to-peak value of the MASTER TX_TCLK125 jitter relative to an unjittered reference shall be less than 50 ps.

When in test mode 1 and the link is up and the two PHYs have established link (link_status is set to OK), the RMS value of the SLAVE TX_TCLK125 jitter relative to an unjittered reference shall be less than 10 ps. The peak-to-peak value of the SLAVE TX_TCLK125 jitter relative to an unjittered reference shall be less than 100 ps.

TX_TCLK125 jitter shall be measured over an interval of 1 ms ± 10%. The band-pass bandwidth of the capturing device shall be larger than 2 MHz. The unjittered reference is a constant clock frequency extracted from each record of captured TX_TCLK125. The unjittered reference is based on linear regression of frequency and phase that produces minimum Time Interval Error.

For PHYs supporting LPI mode, in order for the transmit jitter to be similar to normal power mode operation, the clock reference used to clock transmit-symbols shall be continuous going from normal power mode into and out of LPI mode.

In addition to jitter measurement for transmit clock, MDI jitter is measured when in test mode 2 and using test fixture 4 as shown in Figure 97–32. The RMS value of the MDI output jitter relative to an unjittered

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

reference shall be less than 5 ps. The peak-to-peak value of the MDI output jitter relative to an unjittered reference shall be less than 50 ps. Jitter shall be measured over an interval of 1 ms ± 10%. The band-pass bandwidth of the measurement device shall be larger than 2 MHz. Unjittered reference is a constant clock frequency extracted from each record of captured differential output on MDI. The unjittered reference is based on linear regression of frequency and phase that produces minimum Time Interval Error.

$$UpperPSD(f) = \begin{cases} -80 & \text{dBm/Hz} \quad 0 < f \le 100 \\ -76 - \frac{f}{25} & \text{dBm/Hz} \quad 100 < f \le 400 \\ -85.6 - \frac{f}{62.5} & \text{dBm/Hz} \quad 400 < f \le 600 \end{cases} \tag{97–14}$$

$$LowerPSD(f) = \begin{cases} -86 & \text{dBm/Hz} \quad 40 < f \le 100 \\ -82 - \frac{f}{25} & \text{dBm/Hz} \quad 100 < f \le 400 \end{cases} \tag{97–15}$$

where

f is the frequency in MHz

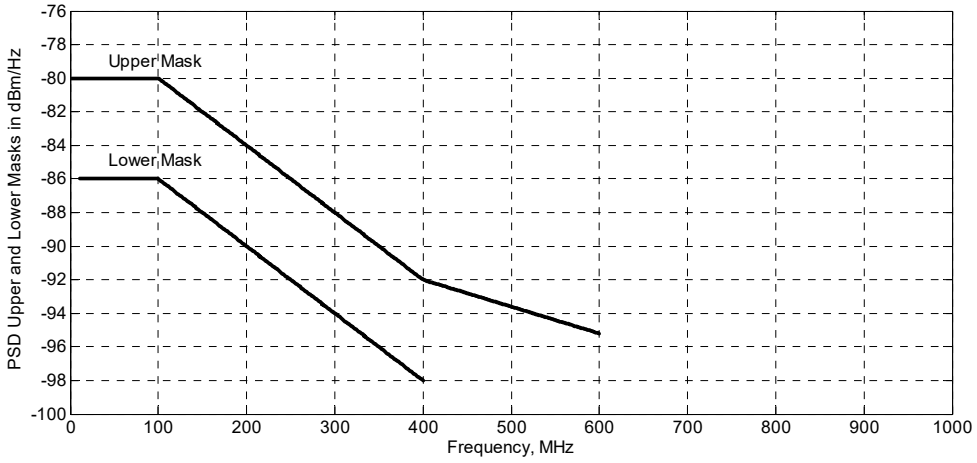

Figure 97–34—Transmitter Power Spectral Density, upper and lower masks

97.5.3.4 Transmitter Power Spectral Density (PSD) and power level

In test mode 5 (normal operation), the transmit power shall be less than 5 dBm and the power spectral density of the transmitter, measured into a 100 Ω load using the test fixture 5 shown in Figure 97–33 shall be between the upper and lower masks specified in Equation (97–14) and Equation (97–15). The masks are shown in Figure 97–34. The measurements need to be calibrated for insertion loss of the differential Balun used in the test. The resolution bandwidth of 100 kHz and sweep time of larger than 1 second are considered in PSD measurement.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.5.3.5 Transmitter peak differential output

When measured with 100 Ω termination, transmit differential signal at MDI shall be less than 1.30 V peak-to-peak. This limit applies to all transmit modes including SEND_S, SEND_T, SEND_I, and SEND_N modes.

97.5.3.6 Transmitter clock frequency

The symbol transmission rate of the MASTER PHY shall be within the range 750 MHz ± 100 ppm.

For a MASTER PHY, when the transmitter is in the LPI transmit mode, the transmitter clock short-term rate of frequency variation shall be less than 0.1 ppm/second. The short-term frequency variation limit shall also apply when switching to and from the LPI mode.

97.5.4 Receiver electrical specifications

97.5.4.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of 97.5.3 and have passed through a link segment type A (specified in 97.6.1 and 97.6.3) are received with a BER less than 10^{-10} and sent to the PCS after link reset completion. This BER specification shall be satisfied by a frame loss ratio less than 10^{-7} for 125-octet frames. Operation on link segment type B is optional. If supported, the frame loss ratio shall also be met for link segments specified at 97.6.2 and 97.6.4.

97.5.4.2 Alien crosstalk noise rejection

This specification is provided to verify the receiver's tolerance to alien crosstalk noise. The test is performed with a noise source consisting of a signal generator with Gaussian distribution, bandwidth of 550 MHz and magnitude of –100 dBm/Hz for devices supporting type A link segments and –110 dBm/Hz for devices supporting type B link segments. The receive DUT is connected to these noise sources through a resistive network, as shown in Figure 97–35, with a link segment as defined in 97.6. The noise is added at the MDI of the DUT. The BER is expected to be less than 10^{-10}, and to satisfy this specification the frame loss ratio is less than 10^{-7} for 125-octet packets measured at MAC/PLS service interface.

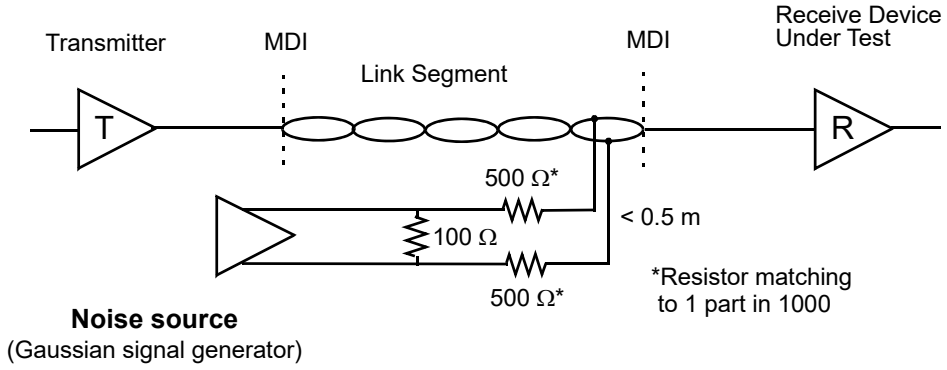

Figure 97–35—Alien crosstalk noise rejection test setup

97.6 Link segment characteristics

1000BASE-T1 is designed to operate over a single twisted-pair copper cable that meets the requirements specified in this subclause. The single twisted-pair copper cable supports an effective data rate of 1 Gb/s in

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

each direction simultaneously. The term *link segment* used in this clause refers to a single twisted-pair copper cable operating in full duplex.

The following two link segments are specified:

a) A link segment optimized for use in automotive applications that supports up to four in-line connectors using a single twisted-pair copper cable for up to at least 15 m. This link segment is referred to as *link segment type A*.

b) An optional link segment supporting up to four in-line connectors using a single twisted-pair copper cable for up to at least 40 m to support applications requiring additional physical reach, such as industrial and automation controls and transportation (aircraft, railway, bus, and heavy trucks). This link segment is referred to as *link segment type B*.

97.6.1 Link transmission parameters for link segment type A

The transmission characteristics for type A link segment are specified to support operation over automotive temperature and electromagnetic conditions.

97.6.1.1 Insertion loss

The insertion loss of each type A link segment shall meet the values determined using Equation (97–16).

$$\text{InsertionLoss}(f) \le 0.0023f + 0.5907\sqrt{f} + 0.0639/\sqrt{f} \quad \text{dB} \tag{97–16}$$

where

f is the frequency in MHz; $1 \le f \le 600$

The insertion loss for the link segment calculated using Equation (97–16) accounts for the insertion loss of a single twisted-pair copper cable and four in-line connectors within each link segment. The insertion loss is illustrated in Figure 97–36.

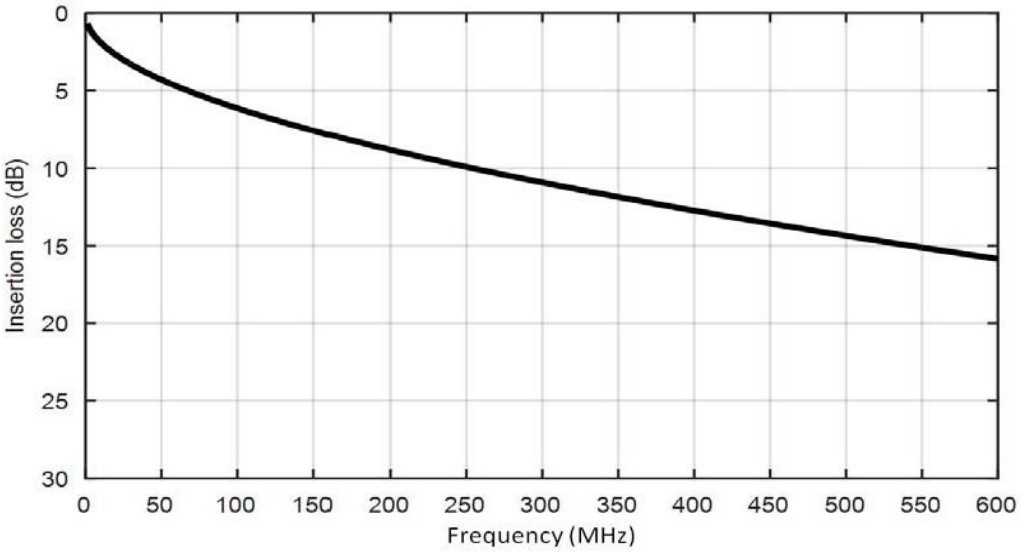

Figure 97–36—Insertion loss calculated using Equation (97–16)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.6.1.2 Differential characteristic impedance

The nominal differential characteristic impedance of each type A link segment is 100 Ω for all frequencies between 1 MHz and 600 MHz.

97.6.1.3 Return loss

In order to limit the noise at the receiver due to impedance mismatches each type A link segment shall meet the values determined using Equation (97–17) at all frequencies from 1 MHz to 600 MHz. The reference impedance for the return loss specification is 100 Ω.

$$\text{Return Loss} \geq \begin{cases} 19 & 1 \leq f < 10 \\ 24 - 5\log_{10} f & 10 \leq f < 40 \\ 16 & 40 \leq f < 130 \\ 37 - 10\log_{10} f & 130 \leq f < 400 \\ 11 & 400 \leq f \leq 600 \end{cases} \text{ dB} \qquad (97\text{–}17)$$

where

f is the frequency in MHz; $1 \leq f \leq 600$

The return loss is illustrated in Figure 97–37.

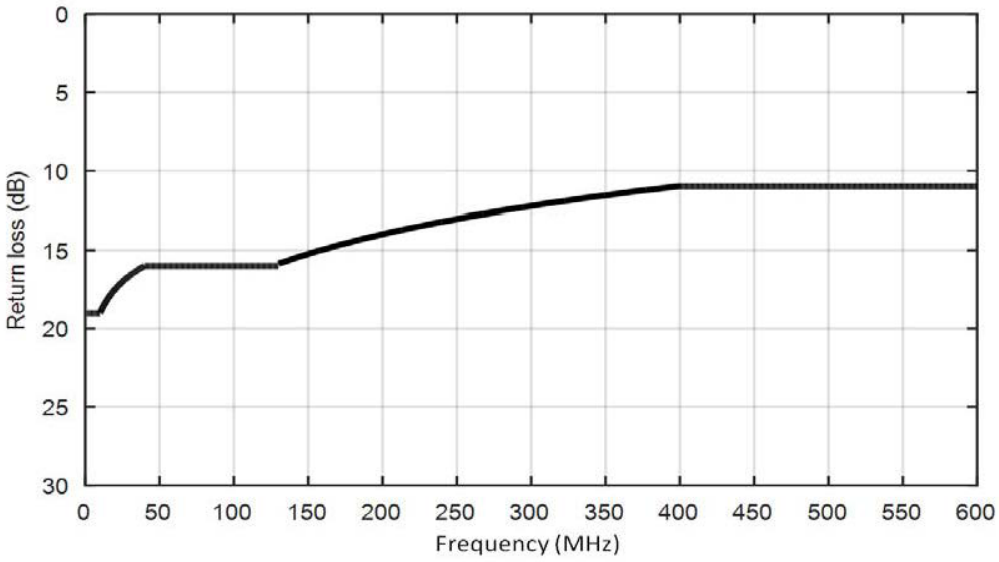

Figure 97–37—Return loss calculated using Equation (97–17)

97.6.1.4 Differential-to-common-mode conversion

The balance of the type A link segment is characterized by the differential-to-common-mode conversion. Each type A link segment shall meet the values determined using Equation (97–18) at all frequencies from 10 MHz to 600 MHz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{ConversionLoss}(f) \geq \left\{ \begin{array}{ll} 50 & 10 \leq f \leq 80 \\ 72 - 11.51\log_{10} f & 80 < f \leq 600 \end{array} \right\} \text{ dB} \quad (97\text{–}18)$$

where

f is the frequency in MHz; $10 \leq f \leq 600$

The function ConversionLoss(f) represents the mode conversion loss at frequency f. The conversion loss is illustrated in Figure 97–38.

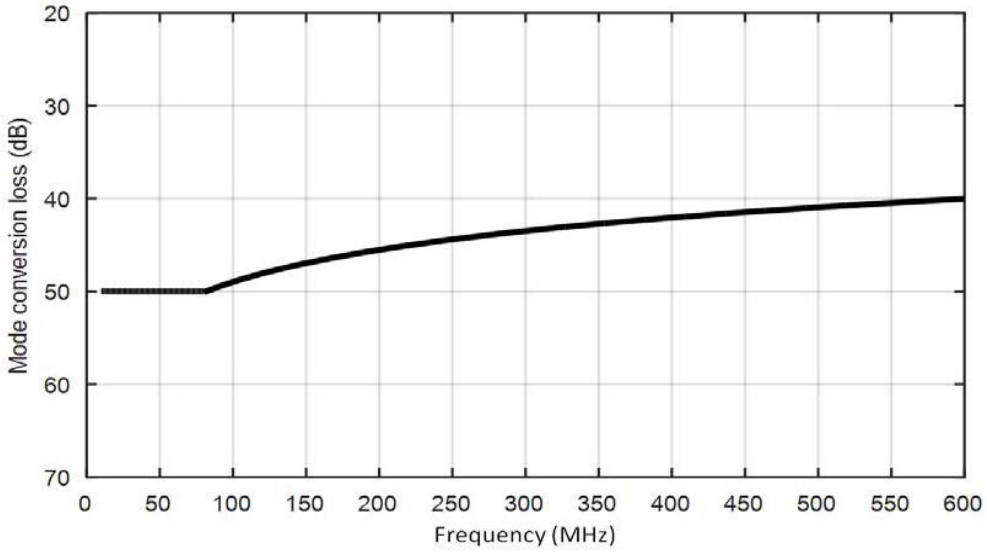

Figure 97–38—Conversion loss calculated using Equation (97–18)

The mode conversion specification applies to the following:

- Longitudinal conversion loss (LCL) with s-parameter SDC11/SDC22 and description common-to-differential-mode return loss
- Transverse conversion loss (TCL) with s-parameter SCD11/SCD22 and description differential-to-common-mode return loss
- Longitudinal conversion transmission loss (LCTL) with s-parameter SDC12/SDC21 and description common-to-differential-mode insertion loss
- Transverse conversion transmission loss (TCTL) with s-parameter SCD12/SCD21 and description differential-to-common-mode insertion loss

For compliance to the specification measurements of LCL and LCTL are sufficient as LCL and TCL are considered reciprocal and LCTL and TCTL are considered reciprocal. The differential-to-common-mode conversion loss test methodologies are specified in Annex 97A.

97.6.1.5 Maximum link delay

The propagation delay of a type A link segment shall not exceed 94 ns at all frequencies between 2 MHz and 600 MHz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.6.2 Link transmission parameters for link segment type B

The transmission characteristics for type B link segment are specified to support applications requiring additional reach such as industrial and automation controls and transportation (aircraft, railway, bus, and heavy trucks) for up to at least 40 m. Type B link segment may be shielded or screened, consistent with the specification in 97.6.2.5 and 97.6.4.

97.6.2.1 Insertion loss

The insertion loss of each type B link segment shall meet the values determined using Equation (97–19).

$$\text{InsertionLoss}(f) \le 0.7131\sqrt{f} + 0.0040f + (0.1100/\sqrt{f}) + 0.08\sqrt{f} + 0.018\sqrt{f} \quad \text{dB} \qquad (97\text{–}19)$$

where

f is the frequency in MHz; $1 \le f \le 600$

The insertion loss is illustrated in Figure 97–39.

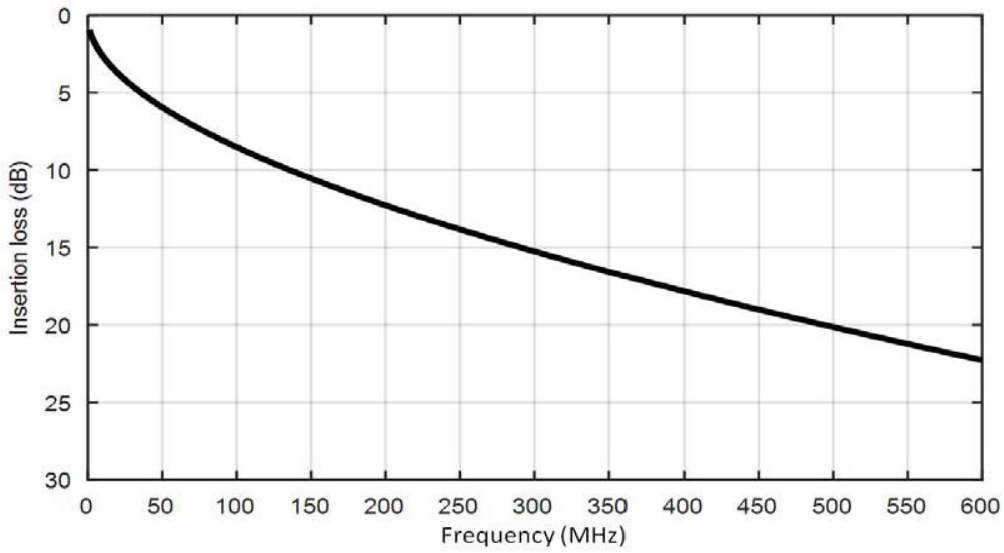

Figure 97–39—Insertion loss calculated using Equation (97–19)

The insertion loss for the link segment calculated using Equation (97–19) accounts for the insertion loss of a single twisted-pair copper cable and four in-line connectors within each link segment.

97.6.2.2 Differential characteristic impedance

The nominal differential characteristic impedance of each type B link segment is 100 Ω for all frequencies between 1 MHz and 600 MHz.

97.6.2.3 Return loss

In order to limit the noise at the receiver due to impedance mismatches each type B link segment shall meet the values determined using Equation (97–20) at all frequencies from 1 MHz to 600 MHz. The reference impedance for the return loss specification is 100 Ω.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{Return Loss} \geq \left\{ \begin{array}{cc} 19 & 1 \leq f < 10 \\ 24 - 5\log_{10}(f) & 10 \leq f < 40 \\ 16 & 40 \leq f < 130 \\ 37 - 10\log_{10}(f) & 130 \leq f < 400 \\ 11 & 400 \leq f \leq 600 \end{array} \right\} \text{ dB} \qquad (97\text{–}20)$$

where

f is the frequency in MHz; $1 \leq f \leq 600$

The return loss is illustrated in Figure 97–40.

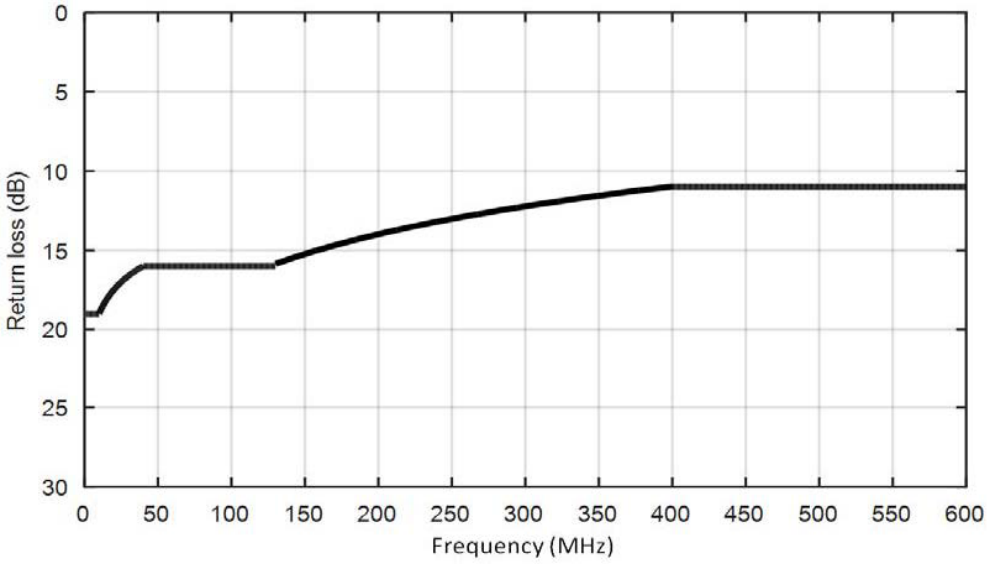

Figure 97–40—Return loss calculated using Equation (97–20)

97.6.2.4 Maximum link delay

The propagation delay of a type B link segment shall not exceed 234 ns at all frequencies between 2 MHz and 600 MHz.

97.6.2.5 Coupling attenuation

The coupling attenuation requirements of the type B link segment depend on the electromagnetic noise environment. The requirements in Table 97–14 shall be met based on the local environment as described by the electromagnetic classifications given in Table 97–15, E_1, E_2, or E_3. The coupling attenuation is tested as specified in IEC 62153-4–14.

Electromagnetic	Minimum (dB)		
	E_1	E_2	E_3
Radiated RF – AM	3 V/m at (80 MHz to 1000 MHz) 3 V/m at (1400 MHz to 2000 MHz) 1 V/m at (2000 MHz to 2700 MHz)	3 V/m at (80 MHz to 1000 MHz) 3 V/m at (1400 MHz to 2000 MHz) 1 V/m at (2000 MHz to 2700 MHz)	10 V/m at (80 MHz to 1000 MHz) 3 V/m at (1400 MHz to 2000 MHz) 1 V/m at (2000 MHz to 2700 MHz)
Conducted RF	3 V at 150 kHz to 80 MHz	3 V at 150 kHz to 80 MHz	10 V at 150 kHz to 80 MHz

97.6.3 Coupling parameters between type A link segments

Noise coupled between the disturbed type A link segment and the disturbing type A link segment is referred to as *alien crosstalk noise*. To ensure the total alien NEXT loss and alien FEXT loss coupled between type A link segments is limited, multiple disturber alien near-end crosstalk (MDANEXT) loss and multiple disturber alien FEXT (MDAFEXT) loss is specified. The test methodologies are specified in Annex 97A and Annex 97B.

97.6.3.1 Multiple disturber alien near-end crosstalk (MDANEXT) loss

In order to limit the alien crosstalk at the near end of a type A link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between the disturbed type A link segment and the disturbing type A link segment is specified to meet the bit error ratio objective. To ensure the total alien NEXT coupled into a type A link segment is limited, multiple disturber alien NEXT loss is specified as the power sum of the individual alien NEXT disturbers.

97.6.3.2 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

PSANEXT loss is determined by summing the power of the individual pair-to-pair differential alien NEXT loss values over the frequency range 1 MHz to 600 MHz as follows in Equation (97–21).

$$\mathrm{PSANEXTloss}_N(f) \ge -10\log_{10}\left(\sum_{j=1}^{m} 10^{\frac{-\mathrm{AN}(f)_{j,N}}{10}}\right) \mathrm{dB} \qquad (97\text{–}21)$$

Copyright © 2022 IEEE. All rights reserved.

where the function $AN(f)_{j,N}$ represents the magnitude (expressed in dB) of the alien NEXT loss at frequency f of the disturbing type A link segment j (1 to m) for the disturbed type A link segment N.

The power sum ANEXT loss between a disturbed type A link segment and the disturbing type A link segment shall meet the values determined using Equation (97–22).

$$\text{PSANEXT}loss(f) \geq \left\{ \begin{array}{ll} 54 - 10\log_{10}\left(\frac{f}{100}\right) & 1 \leq f \leq 100 \\ 54 - 15\log_{10}\left(\frac{f}{100}\right) - 6\left(\frac{f-100}{400}\right) & 100 < f \leq 600 \end{array} \right\} \text{ dB} \quad (97\text{–}22)$$

where

f is the frequency in MHz

PSANEXT is illustrated in Figure 97–41.

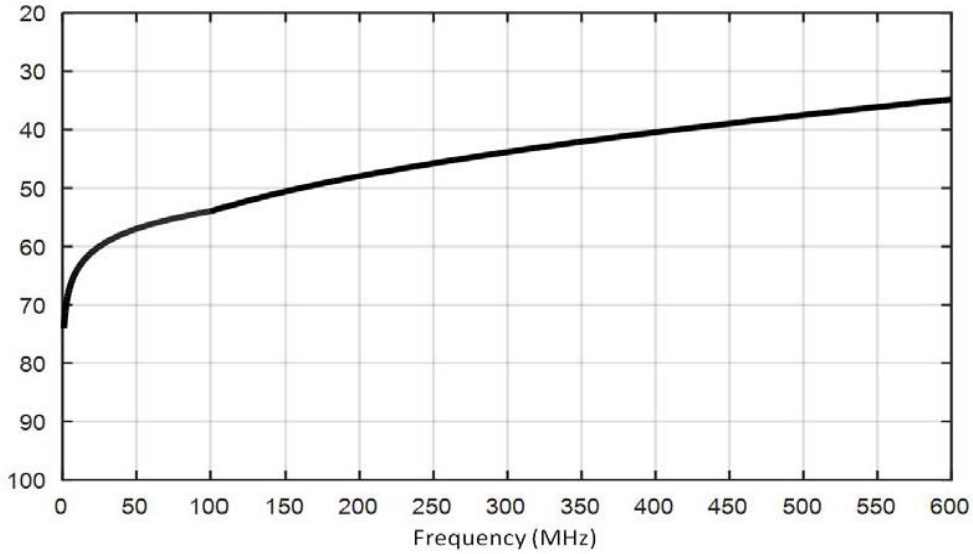

Figure 97–41—PSANEXT calculated using Equation (97–22)

97.6.3.3 Multiple disturber alien far-end crosstalk (MDAFEXT) loss

In order to limit the alien crosstalk at the far-end of a type A link segment, the differential pair-to-pair alien far-end crosstalk (FEXT) loss between the disturbed type A link segment and the disturbing type A link segment is specified to meet the bit error ratio objective. To ensure the total alien FEXT coupled into a type A link segment, multiple disturber attenuation to crosstalk ratio far-end ACRF is specified as the power sum of the individual alien ACRF disturbers.

97.6.3.4 Multiple disturber power sum alien attenuation crosstalk ratio far-end (PSAACRF)

PSAACRF is determined by summing the power of the individual pair-to-pair differential alien ACRF values over the frequency range 1 MHz to 600 MHz as follows in Equation (97–23).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\mathrm{PSAACRF}_N(f) \geq -10\log_{10}\left(\sum_{j=1}^{m} 10^{\frac{-\mathrm{AF}(f)_{j,N}}{10}}\right) \text{ dB} \qquad (97\text{–}23)$$

where the function $\mathrm{AF}(f)_{j,N}$ represents the magnitude (expressed in dB) of the alien ACRF of the disturbing type A link segment j (1 to m) for disturbed type A link segment N.

The power sum AACRF between a disturbed type A link segment and the disturbing type A link segment shall meet the values determined using Equation (97–24).

$$\mathrm{PSAACRF}(f) \geq -20\log_{10}\left(10^{\frac{(-10)\log_{10}0.15 + 38.2 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}} + 4 \times 10^{\frac{67 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right) \text{ dB} \qquad (97\text{–}24)$$

where

f is the frequency in MHz

PSAACRF is illustrated in Figure 97–42.

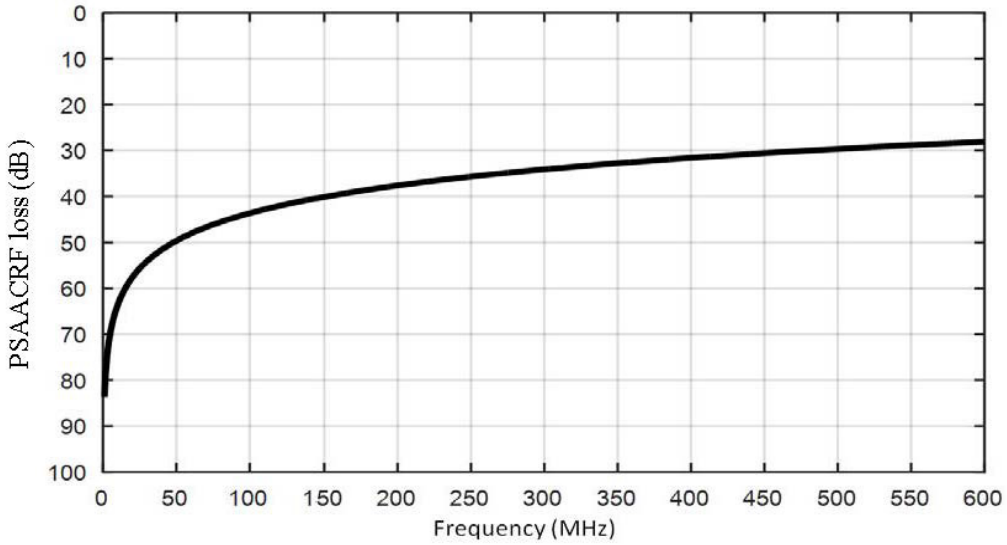

Figure 97–42—PSAACRF calculated using Equation (97–24)

97.6.4 Coupling parameters between type B link segments

Noise coupled between the disturbed type B link segment and the disturbing type B link segment is referred to as alien crosstalk noise. To ensure the total alien NEXT loss and alien FEXT loss coupled between type B link segments is limited, multiple disturber alien near-end crosstalk (MDANEXT) loss and multiple disturber alien FEXT (MDAFEXT) loss is specified.

97.6.4.1 Multiple disturber alien near-end crosstalk (MDANEXT) loss

In order to limit the alien crosstalk at the near end of a type B link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between the disturbed type B link segment and the disturbing type B link segment is specified to meet the bit error ratio objective. To ensure the total alien NEXT coupled into a type B link segment is limited, multiple disturber alien NEXT loss is specified as the power sum of the individual alien NEXT disturbers.

97.6.4.2 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

PSANEXT loss is determined by summing the power of the individual pair-to-pair differential alien NEXT loss values over the frequency range 1 MHz to 600 MHz as follows in Equation (97–25).

$$\mathrm{PSANEXT}_N(f) \geq -10\log_{10}\sum_{j=1}^{m} 10^{\frac{-\mathrm{AN}(f)_{j,N}}{10}} \ \mathrm{dB} \qquad (97–25)$$

where the function $\mathrm{AN}(f)_{j,N}$ represents the magnitude (expressed in dB) of the alien NEXT loss at frequency f of the disturbing type B link segment j (1 to m) for the disturbed type B link segment N.

The power sum ANEXT loss between a disturbed type B link segment and the disturbing type B link segment shall meet the values determined using Equation (97–26).

$$\mathrm{PSANEXT}(f) \geq 65 \ \mathrm{dB} \qquad (97–26)$$

where

f is the frequency in MHz; $1 \leq f \leq 600$

97.6.4.3 Multiple disturber alien far-end crosstalk (MDAFEXT) loss

In order to limit the alien crosstalk at the far-end of a type B link segment, the differential pair-to-pair alien far-end crosstalk (FEXT) loss between the disturbed type B link segment and the disturbing type B link segment is specified to meet the bit error ratio objective. To ensure the total alien FEXT coupled into a type B link segment, multiple disturber attenuation to crosstalk ratio far-end ACRF is specified as the power sum of the individual alien ACRF disturbers.

97.6.4.4 Multiple disturber power sum alien attenuation crosstalk ratio far-end (PSAACRF)

PSAACRF is determined by summing the power of the individual pair-to-pair differential alien ACRF values over the frequency range 1 MHz to 600 MHz as follows in Equation (97–27).

$$\mathrm{PSAACRF}_N(f) \geq -10\log_{10}\sum_{j=1}^{m} 10^{\frac{-\mathrm{AF}(f)_{j,N}}{10}} \ \mathrm{dB} \qquad (97–27)$$

where the function $\mathrm{AF}(f)_{j,N}$ represents the magnitude (expressed in dB) of the alien ACRF of the disturbing type B link segment j (1 to m) for disturbed type B link segment N.

The power sum AACRF between a disturbed type B link segment and the disturbing type B link segment shall meet the values determined using Equation (97–28) or 70 dB, whichever is less.

$$\mathrm{PSAACRF}(f) \geq 61 - 20\log_{10}(f/100) \ \mathrm{dB} \qquad (97–28)$$

where

f is the frequency in MHz; $1 \leq f \leq 600$

97.7 Media Dependent Interface (MDI)

97.7.1 MDI connectors

The mechanical interface to the balanced cabling is a 2-pin connector or 2 pins of a multi-pin connector. Further specification of the mechanical interface is beyond the scope of this standard.

97.7.2 MDI electrical specification

The electrical requirements specified in 97.5.3 and 97.5.4 shall be met when the PHY is connected to the MDI connector mated with a specified balanced twisted-pair cable connector.

97.7.2.1 MDI return loss

The differential impedance at the MDI (see Figure 97–43) for each transmit/receive channel shall be such that any reflection (due to differential signals incident upon the MDI with a test port having a differential impedance of 100 Ω) is attenuated relative to the incident signal per Equation (97–29).

$$\text{Return Loss}(f) \geq \begin{cases} 18 - 18\log_{10}\frac{20}{f} & 2 \leq f < 20 \\ 18 & 20 \leq f < 100 \\ 18 - 16.7\log_{10}\frac{f}{100} & 100 \leq f \leq 600 \end{cases} \text{ dB} \qquad (97\text{–}29)$$

where f is the frequency in MHz.

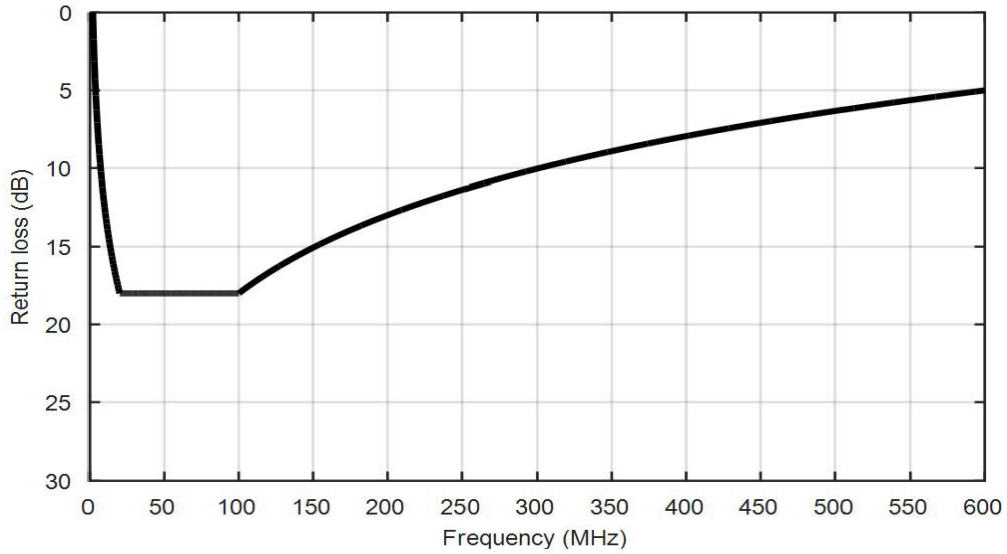

Figure 97–43—Return loss calculated using Equation (97–29)

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

97.7.2.2 MDI mode conversion loss

Mode conversion LCL (Sdc11) or TCL (Scd11) of the PHY measured at MDI shall meet the values determined using Equation (97–30) at all frequencies from 10 MHz to 600 MHz.

$$\text{ConversionLoss}(f) \geq \left\{ \begin{array}{cc} 55 & 10 \leq f \leq 80 \\ 77 - 11.51\log_{10} f & 80 < f \leq 600 \end{array} \right\} \text{dB} \quad (97–30)$$

where

f is the frequency in MHz; $10 \leq f \leq 600$

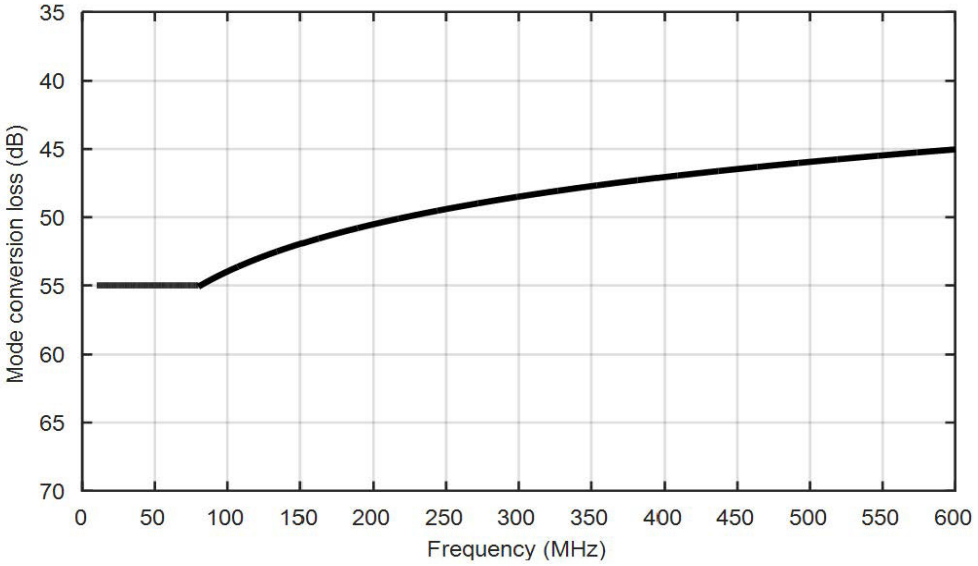

Figure 97–44—MDI mode conversion loss calculated using Equation (97–30)

97.7.3 MDI fault tolerance

See 96.8.3.

97.8 Management Interfaces

1000BASE-T1 makes extensive use of the management functions that may be provided by the MDIO (Clause 45), and the communication and self-configuration functions provided by the optional Auto-Negotiation (Clause 98).

97.8.1 Optional Support for Auto-Negotiation

If Auto-Negotiation is supported and enabled the mechanism described in Clause 98 shall be used.

Auto-Negotiation is performed as part of the initial setup of the link, and allows the PHYs at each end to advertise their capabilities and to automatically select the operating mode for communication on the link. Auto-Negotiation signaling is used for the following primary purposes for 1000BASE-T1:

a) To negotiate that the PHY is capable of supporting 1000BASE-T1 transmission

b) To determine the MASTER-SLAVE relationship between the PHYs at each end of the link

97.9 Environmental specifications

97.9.1 General safety

All equipment subject to this clause is expected to conform to all applicable local, state, national, and application-specific standards.

97.9.2 Network safety

All cabling and equipment subject to this clause is expected to be mechanically and electrically secure in a professional manner. In automotive applications, all 1000BASE-T1 cabling is routed in way to provide maximum protection by the motor vehicle sheet metal and structural components, following SAE J1292, ISO 14229, and ISO 15764.

97.9.2.1 Environmental safety

All equipment subject to this clause, when used in the automotive environment, shall conform to the potential environmental stresses with respect to their mounting location, as defined in the following specifications:

a) General loads: ISO 16750–1
b) Electrical loads: ISO 16750-2, ISO 7637-2:2008, and ISO 8820–1
c) Mechanical loads: ISO 16750-3, ASTM D4728, and ISO 12103–1
d) Climatic loads: ISO 16750-4, IEC 60068-2-1, IEC 60068-2-27, IEC 60068-2-30, IEC 60068-2-38, IEC 60068-2-52, IEC 60068-2-64, and IEC 60068-2-78
e) Chemical loads: ISO 16750-5 and ISO 20653

Automotive environmental conditions are generally more severe than those found in many commercial and industrial environments. The target automotive, industrial, or commercial environment(s) require careful analysis prior to implementation.

97.9.2.2 Electromagnetic compatibility

A system integrating the 1000BASE-T1 PHY shall comply with all applicable local and national codes. In addition, the system may need to comply with more stringent requirements as agreed upon between customer and supplier, for the limitation of electromagnetic interference. A 1000BASE-T1 PHY shall be tested according to CISPR 25 test methods defined to measure the PHY's EMC performance in terms of radio frequency (RF) immunity and RF emissions. When used in an automotive environment, a 1000BASE-T1 PHY is expected to meet the following motor vehicle EMC requirements:

a) Radiated/conducted emissions: CISPR 25, IEC 61967–1/4, and IEC 61000-4-21
b) Radiated/conducted immunity: ISO 11452, IEC 62132–1/4, and IEC 61000-4-21
c) Electrostatic discharge: ISO 10605 and IEC 61000-4-2/3
d) Electrical disturbances: IEC 62215-3 and ISO 7637-2/3

Exact test setup and test limit values may be adapted to each specific application, subject to agreement between the customer and the supplier.

97.10 Delay constraints

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The sum of the transmit and receive data delays for an implementation of a 1000BASE-T1 PHY shall not exceed 7168 bit times (14 pause_quanta or 7168 ns). Transmit data delay is measured from the input of a given unit of data at the GMII to the presentation of the same unit of data by the PHY to the MDI. Receive data delay is measured from the input of a given unit of data at the MDI to the presentation of the same unit of data by the PHY to the GMII.

NOTE—The physical medium interconnecting two PHYs introduces additional delay in a link.

97.11 Protocol implementation conformance statement (PICS) proforma for Clause 97, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 1000BASE-T1[170]

97.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 97, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 1000BASE-T1, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

97.11.2 Identification

97.11.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

97.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 97, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 1000BASE-T1
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[170] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

97.11.9 Physical Medium Attachment (PMA)

Item	Feature	Subclause	Value/Comment	Status	Support
PMF1	PMA Reset function	97.4.2.1	Described in 97.4.2.1	M	Yes [ ]
PMF2	PMA Transmit function	97.4.2.2	Continuously transmit onto the MDI pulses modulated by the symbols given by tx_symb after processing with optional transmit filtering.	M	Yes [ ]
PMF3	Signals generated by PMA transmit	97.4.2.2	Comply with 97.5	M	Yes [ ]
PMF4	MASTER TX_TCLK source	97.4.2.2	Local clock source while meeting the transmit jitter requirements of 97.5.3.3	M	Yes [ ]
PMF5	The MASTER-SLAVE relationship	97.4.2.2	Include loop timing	M	Yes [ ]
PMF6	SLAVE TX_TCLK source	97.4.2.2	Recovered clock of 97.4.2.8 while meeting the jitter requirements of 97.5.3.3.	M	Yes [ ]
PMF7	PMA_transmit_disable variable	97.4.2.2.1	When set to true, turn off the transmitter so that the transmitter Average Launch Power of the Transmitter is less than –53 dBm	M	Yes [ ]
PMF8	Quality of rx_symb symbols	97.4.2.3	Allow RFER of less than 3.6×10^{-7} after RS-FEC decoding, over a channel meeting the requirements of 97.6	M	Yes [ ]
PMF9	PMA receive fault function	97.4.2.3	Contribute to the receive fault bit specified in 45.2.1.238.6	MDIO:O	Yes [ ] N/A [ ]
PMF10	PHY Control	97.4.2.4	Comply with Figure 97–26	M	Yes [ ]
PMF11	12-octet InfoField	97.4.2.4	Include the fields in 97.4.2.4.2 through 97.4.2.4.8	M	Yes [ ]
PMF12	Each unique InfoField	97.4.2.4	Transmitted at least 256 times	M	Yes [ ]
PMF13	InfoField Reserved bits	97.4.2.4.1	Set to zero on transmit and ignored when received by the link partner	M	Yes [ ]
PMF14	Start of Frame Delimiter	97.4.2.4.2	Hexadecimal value 0xBBA700	M	Yes [ ]
PMF15	PMA_state<7:6>	97.4.2.4.4	Communicate the state of the transmitting transceiver to the link partner	M	Yes [ ]
PMF16	Any Message Field value not listed in Table 97–7 or Table 97–8	97.4.2.4.4	Not be transmitted and ignored at the receiver	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PMF17	The Message Field setting for the first transmitted PMA frame	97.4.2.4.4	First row of Table 97–7 for the MASTER and the first or second row of Table 97–8 for the SLAVE	M	Yes [ ]
PMF18	Indicate support of optional capabilities	97.4.2.4.5	Set the corresponding capability bits	M	Yes [ ]
PMF19	State of the scrambler	97.4.2.4.5	S14:S0 at the first bit of the first PHY frame when the partial PHY frame counter equals to the DataSwPFC24 value	M	Yes [ ]
PMF20	Seed S<14:0>	97.4.2.4.5	Not all zeros	M	Yes [ ]
PMF21	DataSwPFC24	97.4.2.4.6	Set to an integer multiple of 15	M	Yes [ ]
PMF22	CRC16 (2 octets)	97.4.2.4.8	Implement the CRC16 polynomial $(x+1)(x^{15}+x+1)$ of the previous 7 octets	M	Yes [ ]
PMF23	CRC16	97.4.2.4.8	Figure 97–23	M	Yes [ ]
PMF24	CRC16 delay elements	97.4.2.4.8	Initialized to zero	M	Yes [ ]
PMF25	Startup sequence	97.4.2.4.10	Comply with Figure 97–26	M	Yes [ ]
PMF26	Enable EEE capability	97.4.2.4.10	Enabled if both PHYs set EEEen = 1	EEE:M	Yes [ ] N/A [ ]
PMF27	Set en_slave_tx = 1	97.4.2.4.10	After the MASTER has sufficiently converged the necessary circuitry, allowing the SLAVE to transition to TRAINING	M	Yes [ ]
PMF28	Enable 1000BASE-T1 OAM capability	97.4.2.4.10	Enabled only if both PHYs set OAMen = 1	M	Yes [ ]
PMF29	SLAVE PHY TRAINING	97.4.2.4.10	Align transmit 81B-RS frame within +0/–1 partial PHY frames of the MASTER	M	Yes [ ]
PMF30	SLAVE InfoField partial PHY frame Count	97.4.2.4.10	Match MASTER InfoField partial PHY frame Count for the aligned frame	M	Yes [ ]
PMF31	Link Monitor function	97.4.2.5	Comply with Figure 97–27	M	Yes [ ]
PMF32	Refresh monitor function	97.4.3		EEE:M	Yes [ ] N/A [ ]
PMF33	Set PMA_refresh_status to FAIL	97.4.3	When Refresh is not detected within a moving window of 50 Q/R cycles	EEE:M	Yes [ ] N/A [ ]
PMF34	Set PMA_refresh_status to OK	97.4.3	When Link Monitor state diagram enters LINK_UP state	EEE:M	Yes [ ] N/A [ ]
PMF35	Clock Recovery function	97.4.2.8	Provide a clock suitable for signal sampling so that RS FER is achieved	M	Yes [ ]

98. Auto-Negotiation for single differential-pair media

98.1 Overview

98.1.1 Scope

Clause 98 describes the single twisted-pair Auto-Negotiation function that allows a device to advertise enhanced modes of operation it possesses to a device at the remote end of a link segment and to detect corresponding enhanced operational modes that the other device may be advertising. Annex 98A describes the Selector Field that is used by Auto-Negotiation to identify the type of message being sent.

The objective of the single twisted-pair Auto-Negotiation function is to provide the means to exchange information between two devices that share a link segment and to automatically configure both devices to take maximum advantage of their abilities. It has the additional objective of providing a common synchronization time between two devices prior to link training.

Single twisted-pair Auto-Negotiation is performed using differential Manchester encoding (DME) pages. DME provides a DC balanced signal. DME does not add packet or upper layer overhead to the network devices. DME is transferred in a half-duplex manner over the single twisted-pair copper cable.

Single twisted-pair Auto-Negotiation does not test the link segment characteristics.

The function allows the devices at both ends of a link segment to advertise abilities, acknowledge receipt and understanding of the common mode(s) of operation that both devices share, and to reject the use of operational modes that are not shared by both devices. Where more than one common mode exists between the two devices, a mechanism is provided to allow the devices to resolve to a single mode of operation using a predetermined priority resolution function. The single twisted-pair Auto-Negotiation function allows the identification of the operational mode of the link partner. Should multiple modes be present, management may select between the various offered modes. How such selection is done is beyond the scope of this standard.

98.1.2 Relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model

The single twisted-pair Auto-Negotiation function is provided at the Physical Layer of the ISO/IEC OSI reference model as shown in Figure 98–2. A device that supports multiple modes of operation may advertise its capabilities using the single twisted-pair Auto-Negotiation function. The actual transfer of information is observed only at the MDI.

98.2 Functional specifications

The single twisted-pair Auto-Negotiation function provides a mechanism to control connection of a single MDI to a single PHY type, where more than one PHY type may exist. A management interface provides control and status of single twisted-pair Auto-Negotiation, but the presence of a management agent is not required.

Auto-Negotiation shall provide the following functions (as shown in Figure 98–1):

a) Transmit
b) Receive
c) Half duplex
d) Arbitration

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

These functions shall comply with the state diagrams from Figure 98–7 through Figure 98–10. The single twisted-pair Auto-Negotiation functions shall interact with the technology-dependent PHYs through the Technology Dependent Interface (see 98.4).

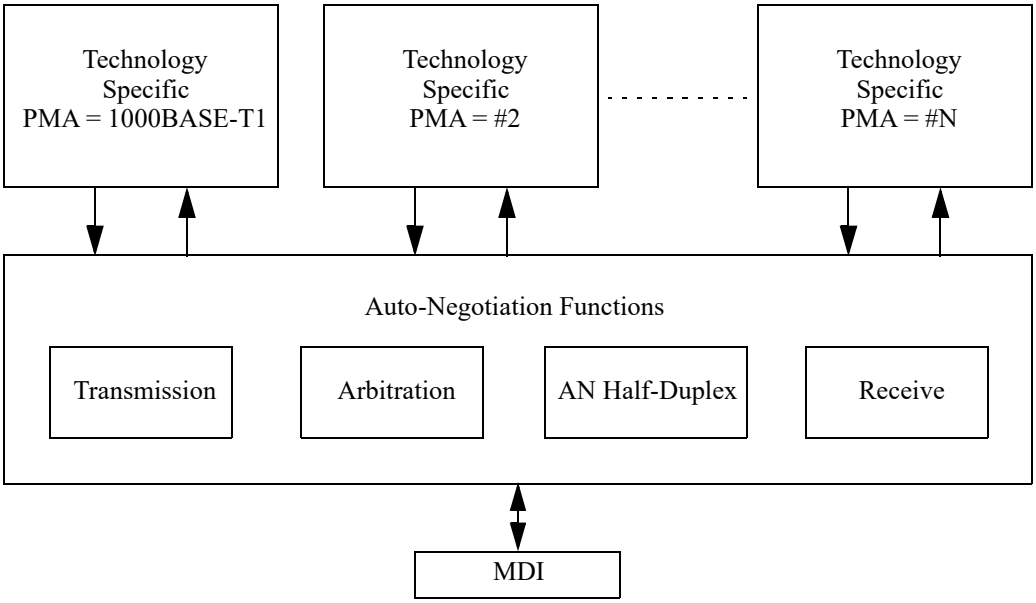

Figure 98–1—High-level model

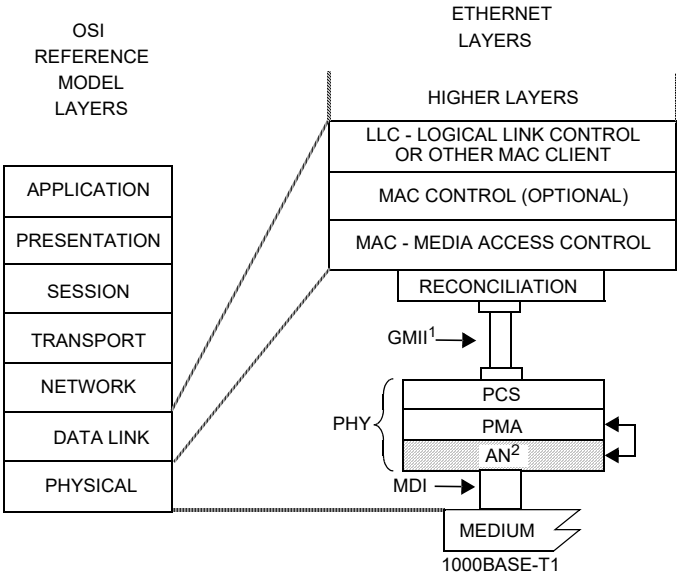
98.2.1 Transmit function requirements

The Transmit function provides the ability to transmit pages. The first pages exchanged by the local device and its link partner after Power-On, link restart, or renegotiation contain the base link codeword defined in Table 98–2. The local device may modify the link codeword to disable an ability it possesses, but will not transmit an ability it does not possess. This makes possible the distinction between local abilities and advertised abilities so that multi-ability devices may Auto-Negotiate to a mode lower in priority than the highest common ability.

Two different Auto-Negotiation speeds are defined in this subclause. A PHY shall support at least one of these Auto-Negotiation speeds. The two speeds are referred to as *high-speed mode*, or HSM, and *low-speed mode*, or LSM. If Auto-Negotiation is implemented, 1000BASE-T1, 100BASE-T1, and 10BASE-T1S PHYs shall support HSM and may optionally support LSM. For link segments with high insertion loss and those requiring 10BASE-T1L, LSM is provided to enable the full reach capability. If Auto-Negotiation is implemented, 10BASE-T1L PHYs shall support LSM and may optionally support HSM. When performing Auto-Negotiation in high-speed mode, DME pages are transmitted at a nominal rate of 16.667 Mb/s. In low-speed mode, DME pages are transmitted at a nominal rate of 625 kb/s. Subclause 98.5.6 describes the behavior to automatically choose between the different Auto-Negotiation speeds when a PHY supports both.



98.2.1.1 DME transmission

Auto-Negotiation's method of communication builds upon the encoding mechanism known as differential Manchester encoding (DME). The DME page encodes the data that is used to control the Auto-Negotiation function. DME pages shall not be transmitted when Auto-Negotiation is complete and the highest common denominator PHY has been enabled.

98.2.1.1.1 DME page encoding

A DME page carries a 48-bit Auto-Negotiation page. It consists of 157 evenly spaced transition positions starting from the initial transition from silent to active in the preamble. The page contains a Start Delimiter, the 48-bit page, 16-bit CRC, and an end delimiter (see Figure 98–6). The odd-numbered transition positions represent clock information. The even numbered transition positions represent data information. DME pages are alternately transmitted between the two devices with quiet period separating the DME pages. When the DME page is active, the PHY shall transmit either +1 or –1 level with the voltage levels as specified in 98.2.1.1.4.

MDI = MEDIUM DEPENDENT INTERFACE
GMII = TEN GIGABIT MEDIA INDEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
AN = AUTO-NEGOTIATION

NOTE 1—GMII is optional.
NOTE 2—Auto-Negotiation is optional. Auto-Negotiation communicates with the PMA sublayer through the PMA service interface messages PMA_LINK.request and PMA_LINK.indication.

Figure 98–2—Location of Auto-Negotiation function within the ISO/IEC OSI reference model

The first 26 transition positions contain the Start Delimiter, which marks the beginning of the page. The Start Delimiter contains a transition from quiet to active at position 1. For HSM Auto-Negotiation, this transition is followed by transitions at positions 2, 3, 5, 7, 8, 12, 13, 14, 15, 19, 21, 24, 25, 26 and no transitions at the remaining positions. For LSM Auto-Negotiation, this transition is followed by transitions at positions 2, 3, 4, 5, 6, 7, 8, 9, 11, 13, 15, 16, 18, 19, 20, 22, 23, 24, 26 and no transitions at the remaining positions.

The final 2 transition positions contain the ending delimiter, which marks the end of the page. The ending delimiter contains a transition at position 155 and no transitions at the remaining positions. Position 157 contains a transition from active to quiet.

Each of the remaining 64 odd-numbered transition positions between the starting and ending delimiters shall contain a transition. The remaining 64 even-numbered transition positions shall represent data information as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— A transition present in an even-numbered transition position represents a logical one.
— A transition absent from an even-numbered transition position represents a logical zero.

The first 48 of these positions shall carry the data of the Auto-Negotiation page. The final 16 positions carry the 16-bit CRC.

The CRC16 polynomial is $x^{16} + x^{15} + x^2 + 1$. The CRC16 shall produce the same result as the implementation shown in Figure 98–3. The 16 delay elements S0,..., S15, shall be initialized to zero. Afterwards the 48 data bits are used to compute the CRC16 with the switch connected (setting CRCgen). After all the 48 bits have been processed, the switch is disconnected (setting CRCout) and the 16 values stored in the delay elements are transmitted in the order illustrated, first S15, followed by S14, and so on, until the final value S0.

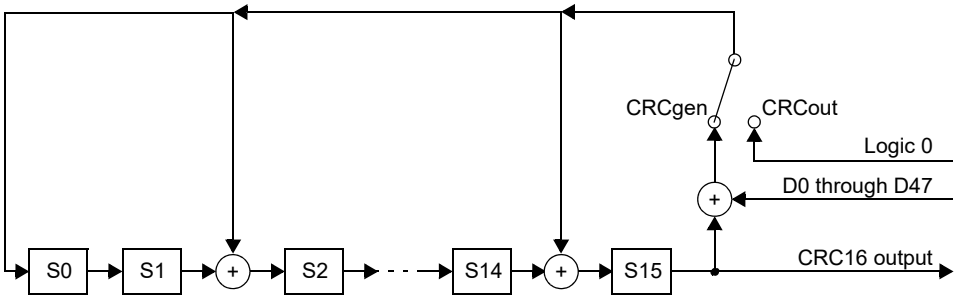

Figure 98–3—CRC16

The polarity at position 0 is randomly determined in an implementation specific manner.

The purpose of randomizing the starting polarity is to remove the spectral peaks that would otherwise occur when sending the same DME page repeatedly. Randomly choosing the starting polarity results in randomly inverting or not inverting the encoded page so that repetitions of the same page no longer produce a periodic signal.

Clock transition positions are differentiated from data transition positions by the spacing between them, as shown in Figure 98–4 and enumerated in Table 98–1.

The encoding of data using DME bits in a DME page is illustrated in Figure 98–4.

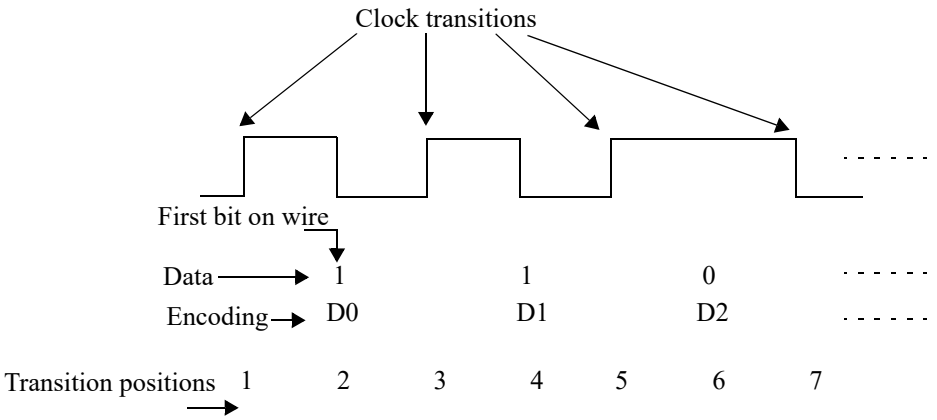

Figure 98–4—Data bit encoding within DME pages

98.2.1.1.2 DME page timing

The timing parameters for DME pages shall be followed as in Table 98–1. The transition positions within a DME page are spaced with a period of T1. T2 is the separation between clock transitions. T3 is the time from a clock transition to a data transition representing a one. When operating in high-speed mode, transitions shall occur within ± 0.8 ns of their ideal positions. When operating in low-speed mode, transitions shall occur within ± 10 ns of their ideal positions.

T5 specifies the duration of a DME page. The minimum number of transitions and maximum number of transitions in a page is represented by T4a. T4b indicates that the start of a DME page begins with a transition from 0 to ±1 and the end of the DME page is a transition from ±1 to 0.

Table 98–1 summarizes the timing parameters. The transition timing parameters are illustrated in Figure 98–5 and Figure 98–6.

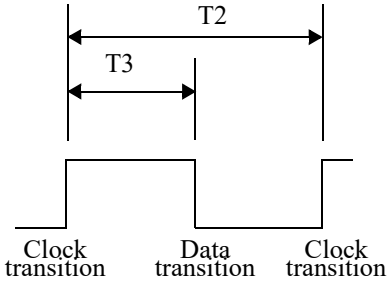

Figure 98–5—DME page transition timing

Table 98–1—DME page timing summary

	Parameters	Mode	Min	Typ	Max	Units
T1	Transmit position spacing (period)	high-speed	29.997	30	30.003	ns
		low-speed	799.96	800	800.04	
T2	Clock transition to clock transition	high-speed	59.8	60	60.2	ns
		low-speed	1590	1600	1610	
T3	Clock transition to data transition (data = 1)	high-speed	29.9	30	30.1	ns
		low-speed	795	800	805	
T4a	+1 to –1 or –1 to +1 transitions in a DME page	high-speed	79	—	143	—
		low-speed	84	—	148	
T4b	0 to ±1 or ±1 to 0 transitions in a DME page	high-speed	2	2	2	—
		low-speed	2	2	2	
T5	DME page width	high-speed	4679	4680	4681	ns
		low-speed	124 793	124 800	124 807	

98.2.1.1.3 DME page Delimiters

The page is preceded by a unique Start Delimiter consisting of a 26 × T1 sequence that includes multiple DME transition violations. For a Start Delimiter starting with a 0 to +1 transition, the bit sequence for high-speed Auto-Negotiation mode is:

+1 –1 +1 +1 –1 –1 +1 –1 –1 –1 –1 +1 –1 +1 –1 –1 –1 –1 +1 +1 –1 –1 –1 +1 –1 +1.

For a Start Delimiter starting with a 0 to +1 transition, the bit sequence for low-speed Auto-Negotiation mode is:

+1 –1 +1 –1 +1 –1 +1 –1 +1 +1 –1 –1 +1 +1 –1 +1 +1 –1 +1 –1 –1 +1 –1 +1 +1 –1.

The DME page ends with an end delimiter that consists of an electrical 0. An example of the delimiters is shown in Figure 98–6.

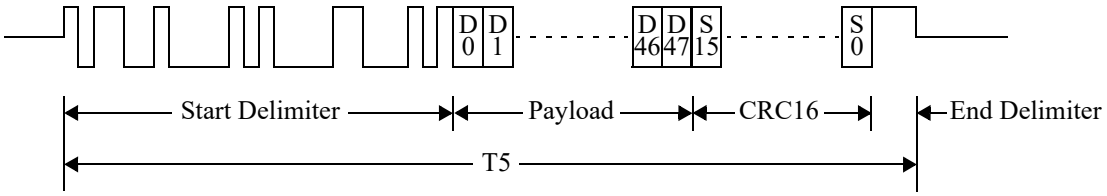

Figure 98–6—DME Page

NOTE—The Start Delimiter may begin with a 0 to +1 or 0 to –1 transition depending upon the DME page starting polarity randomizer.

98.2.1.1.4 Transmitter peak differential output

When measured with 100 Ω termination, transmit differential signal at MDI shall be within range of 1 V ± 30% peak-to-peak.

98.2.1.2 Link codeword encoding

The base link codeword (Base Page) transmitted within a DME page shall convey the encoding shown in Table 98–2. The Auto-Negotiation function supports additional pages using the Next Page function.

Encoding for the link codeword(s) used in the Next Page exchange are defined in 98.2.4.3. In a DME page, D0 shall be the first bit transmitted.

Table 98–2—Link codeword Base Page

D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12	D13	D14	D15
S0	S1	S2	S3	S4	E0	E1	E2	E3	E4	C0	C1	M/S	RF	Ack	NP
D16	D17	D18	D19	D20	D21	D22	D23	D24	D25	D26	D27	D28	D29	D30	D31

D32	D33	D34	D35	D36	D37	D38	D39	D40	D41	D42	D43	D44	D45	D46	D47
A11	A12	A13	A14	A15	A16	A17	A18	A19	A20	A21	A22	A23	A24	A25	A26

D[4:0] contains the Selector Field. D[9:5] contains the Echoed Nonce field. D[11:10] contains capability bits to advertise capabilities not related to the PHY. C[1:0] is used to advertise pause capability. D[12] is the force MASTER-SLAVE bit (see 98.2.1.2.5). D[15:13] contains the RF, Ack, and NP bits. The RF, Ack, and NP bits shall function as specified in 98.2.1.2.7, 98.2.1.2.8, and 98.2.1.2.9, respectively. D[20:16] contains the Transmitted Nonce field. D[47:21] contains the Technology Ability Field.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

98.2.1.2.1 Selector Field

Selector Field (S[4:0]) is a 5-bit wide field, encoding 32 possible messages. Selector Field encoding definitions are shown in Annex 98A. Combinations not specified are reserved. Reserved combinations of the Selector Field shall not be transmitted.

The Selector Field for IEEE Std 802.3 is shown in Table 98–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 98–3—Selector Field Encoding

S4	S3	S2	S1	S0	Selector description
0	0	0	0	1	IEEE Std 802.3

98.2.1.2.2 Echoed Nonce Field

Echoed Nonce Field (E[4:0]) is a 5-bit wide field containing the nonce received from the link partner. If the device has not received a DME page with good CRC16, the bits in this field shall contain logical zeros. If the device has received a DME page with good CRC16, the bits in this field shall contain the value received in the Transmitted Nonce Field from the link partner at the same time as the Acknowledge bit is set.

98.2.1.2.3 Transmitted Nonce Field

Transmitted Nonce Field (T[4:0]) is a 5-bit wide field whose lower 4 bits contains a random or pseudo-random number. A new value shall be generated for each entry to the Ability Detect state. The method of generating the nonce is left to the implementer. The lower 4 bits of the transmitted nonce should have a uniform distribution in the range from 0 to $2^4 – 1$. The method used to generate the value should be designed to minimize correlation to the values generated by other devices.

Bit T[4] should be set to 1 if the device prefers or is forced to be MASTER and 0 if the device prefers or is forced to be SLAVE.

If the device has received a DME page with good CRC16 and the link partner has a Transmitted Nonce Field (T[4:0]) that matches the devices generated T[4:0], the device shall invert its T[0] bit and regenerate a new random value for T[3:1] and use that as its new T[4:0] value. Since the DME pages are exchanged in a half-duplex manner, it is possible to swap to a new T[4:0] value prior to transmitting the DME page. One device will always see a DME page with good CRC16 before the other device hence this swapping will guarantee that nonce_match will never be true.

98.2.1.2.4 Technology Ability Field

Technology Ability Field (A[26:0]) is a 27-bit wide field containing information indicating supported technologies specific to the selector field value when used with the single twisted-pair Auto-Negotiation Ethernet. These bits are mapped to individual technologies such that abilities are advertised in parallel for a single selector field value. The Technology Ability Field encoding for the IEEE 802.3 selector with single twisted-pair Auto-Negotiation Ethernet is described in 98B.3.

Multiple technologies may be advertised in the link codeword. A device shall support the data service ability for a technology it advertises. It is the responsibility of the Arbitration function to determine the common mode of operation shared by a link partner and to resolve multiple common modes.

98.2.1.2.5 Force MASTER-SLAVE

The force MASTER-SLAVE bit, D12, allows a device to force its MASTER-SLAVE configuration. If this bit is set to 0 then the device is in preferred mode, otherwise it is in the forced mode. The MASTER-SLAVE resolution is shown in Table 98–4.

98.2.1.2.6 Pause Ability

Pause (C0:C1) is encoded in bits D11:D10 of the base link codeword. The 2-bit Pause is encoded as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 98–4—MASTER-SLAVE Configuration

Local Device		Remote Device		Local Device Resolution	Remote Device Resolution
M/S	T[4]	M/S	T[4]		
0	X	0	X	Device with higher T[4:0] is MASTER, otherwise SLAVE	Device with higher T[4:0] is MASTER, otherwise SLAVE
0	X	1	0	MASTER	SLAVE
0	X	1	1	SLAVE	MASTER
1	0	0	X	SLAVE	MASTER
1	1	0	X	MASTER	SLAVE
1	0	1	0	Configuration Fault	Configuration Fault
1	0	1	1	SLAVE	MASTER
1	1	1	0	MASTER	SLAVE
1	1	1	1	Configuration Fault	Configuration Fault

a) C0 is the same as PAUSE as defined in Annex 28B

b) C1 is the same as ASM_DIR as defined in Annex 28B

The Pause encoding is defined in 28B.2, Table 28B–2. The PAUSE bit indicates that the device is capable of providing the symmetric PAUSE functions as defined in Annex 31B. The ASM_DIR bit indicates that asymmetric PAUSE is supported. The value of the PAUSE bit when the ASM_DIR bit is set indicates the direction the PAUSE frames are supported for flow across the link. Asymmetric PAUSE configuration results in independent enabling of the PAUSE receive and PAUSE transmit functions as defined by Annex 31B. See 28B.3 regarding PAUSE configuration resolution.

98.2.1.2.7 Remote Fault

Remote Fault (RF) is encoded in bit D13 of the base link codeword. The default value is logical zero. The Remote Fault bit provides a standard transport mechanism for the transmission of simple fault information. When the RF bit in the BASE-T1 AN advertisement register (register 7.514.13) is set to logical one, the RF bit in the transmitted base link codeword is set to logical one. When the RF bit in the received base link codeword is set to logical one, the Remote Fault bit in the BASE-T1 AN LP Base Page ability register (register 7.517.13) will be set to logical one, if the management function is present.

98.2.1.2.8 Acknowledge

Acknowledge (Ack) is used by the Auto-Negotiation function to indicate that a device has successfully received its link partner's link codeword. The Acknowledge Bit is encoded in bit D14 of link codeword. If no Next Page information is to be sent, this bit shall be set to logical one in the link codeword after the reception of at least one DME page with a correct CRC. If Next Page information is to be sent, this bit shall be set to logical one after the device has successfully received at least one DME page with correct CRC, and will remain set until the Next Page information has been loaded into the BASE-T1 AN NEXT PAGE transmit register (Registers 7.520, 7.521, 7.522). In order to save the current received link codeword, it shall be read from the BASE-T1 AN LP NEXT PAGE ability register (register 7.523, 7.524, 7.525) before the Next Page of transmit information is loaded into the BASE-T1 AN NEXT PAGE transmit register. After the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

COMPLETE ACKNOWLEDGE state has been entered, the link codeword will be transmitted at least three times.

98.2.1.2.9 Next Page

Next Page (NP) is encoded in bit D15 of link codeword. Support of Next Pages is mandatory. If the device does not have any Next Pages to send, the NP bit shall be set to logical zero. If a device wishes to engage in Next Page exchange, it shall set the NP bit to logical one. If a device has no Next Pages to send and its link partner has set the NP bit to logical one, it shall transmit Next Pages with Null message codes and the NP bit set to logical zero while its link partner transmits valid Next Pages. Next page exchanges will occur if either the device or its link partner sets the Next Page bit to logical one. The Next Page function is defined in 98.2.4.3.

98.2.1.3 Transmit Switch function

The Transmit Switch function shall enable the transmit path from a single technology-dependent PHY to the MDI once a highest common denominator choice has been made and Auto-Negotiation has completed. During Auto-Negotiation, the Transmit Switch function shall connect only the DME page generator controlled by the Transmit state diagram to the MDI. When a PHY is connected to the MDI through the Transmit Switch function, the signals at the MDI shall conform to all of the PHY's specifications.

98.2.2 Receive function requirements

The Receive function detects the DME page sequence, decodes the information contained within, and stores the data in rx_link_code_word[64:1]. The receive function incorporates a receive switch to control connection to the various PMAs.

98.2.2.1 DME page reception

To be able to detect the DME bits, the receiver should have the capability to receive DME signals sent with the electrical specifications of the PHY. The DME transmit signal level is specified in 98.2.1.1.4.

98.2.2.2 Receive Switch function

The Receive Switch function shall enable the receive path from the MDI to a single technology-dependent PHY once a highest common denominator choice has been made and Auto-Negotiation has completed.

During Auto-Negotiation, the Receive Switch function shall connect the DME page receiver controlled by the Receive state diagram to the MDI and the Receive Switch function shall also connect the appropriate receivers to the MDI.

98.2.2.3 Link codeword matching

The Receive function shall generate ability_match, acknowledge_match, and consistency_match variables as defined in Arbitration state diagram Figure 98–7.

98.2.3 AN half-duplex function requirements

The AN half-duplex function is defined by Figure 98–10 and ensures that only one of the link partners is transmitting a DME page at each step during the DME page exchange process. The AN half-duplex function uses a blind timer to ensure that the receiver ignores signals reflected from the channel following the end of the device's transmitted DME page. A silent timer is used to ensure that the device does not begin transmitting the DME page until after the link partner has exited from the blind timer. The half-duplex

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

backoff timer resolves concurrent transmissions by using a random wait time to listen for a DME page to arrive from the link partner before the local device transmits a DME page.

98.2.4 Arbitration function requirements

The Arbitration function is defined by Figure 98–7 and ensures proper sequencing of the Auto-Negotiation function using the Transmit function, Receive function, and AN half-duplex function. The Arbitration function enables the Transmit function to advertise and acknowledge abilities. Upon indication of acknowledgment, the Arbitration function determines the highest common denominator using the priority resolution function and enables the appropriate technology-dependent PHY via the Technology Dependent Interface (see 98.4).

98.2.4.1 Renegotiation function

A Renegotiation request from any entity, such as a management agent, shall cause the Arbitration function to disable all technology-dependent PHYs and halt any transmit data and link transition activity until the break_link_timer expires. Consequently, the link partner will go into link fail and normal Auto-Negotiation resumes. The local device shall resume Auto-Negotiation after the break_link_timer has expired by issuing DME pages with the Base Page valid in tx_link_code_word[64:1]. Once Auto-Negotiation has completed, renegotiation will take place if the Highest Common Denominator technology that receives link_control = ENABLE returns link_status = FAIL. To allow the PHY an opportunity to determine link integrity using its own link integrity test function, the link_fail_inhibit_timer qualifies the link_status = FAIL indication such that renegotiation takes place if the link_fail_inhibit_timer has expired and the PHY still indicates link_status = FAIL.

98.2.4.2 Priority Resolution function

Since a local device and a link partner may have multiple common abilities, a mechanism to resolve which mode to configure is required. The mechanism used by Auto-Negotiation is a Priority Resolution function that predefines the hierarchy of supported technologies. The single PHY enabled to connect to the MDI by Auto-Negotiation shall be the technology corresponding to the bit in the Technology Ability Field common to the local device and link partner that has the highest priority as defined in 98B.4 (listed from highest priority to lowest priority).

The common technology is referred to as the *highest common denominator*, or HCD, technology. If the local device receives a Technology Ability Field with a bit set that is reserved, the local device shall ignore that bit for priority resolution. Determination of the HCD technology occurs on entrance to the AN GOOD CHECK state. In the event that there is no common technology, HCD shall have a value of “NULL,” indicating that no PHY receives link_control = ENABLE and link_status[HCD] = FAIL.

98.2.4.3 Next Page function

The Next Page function uses the Auto-Negotiation arbitration mechanisms to allow exchange of Next Pages of information, which may follow the transmission and acknowledgment procedures used for the base link codeword. The Next Page has both Message Code Field and Unformatted Code Fields.

A dual acknowledgment system is used. Acknowledge (Ack) is used to acknowledge receipt of the information; Acknowledge 2 (Ack2) is used to indicate that the receiver is able to act on the information (or perform the task) defined in the message.

The Toggle (T) bit is used to ensure proper synchronization between the local device and the link partner.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Next page exchange occurs after the base link codewords have been exchanged if either end of the link segment set the Next Page bit to logical one indicating that it had at least one Next Page to send. Next page exchange consists of using the normal Auto-Negotiation arbitration process to send Next Page messages.

The Next Page contains two message encodings. The message encodings are defined as follows: message code, which contains predefined 11-bit codes, and unformatted code, which contains 32-bit codes. Multiple Next Pages with appropriate message codes and unformatted codes can be transmitted to send extended messages. Each series of Next Pages shall have a Message code that defines how the Unformatted codes will be interpreted. Any number of Next Pages may be sent in any order; however, it is recommended that the total number of Next Pages sent be kept small to minimize the link startup time.

Next Page transmission ends when both ends of a link segment set their Next Page bits to logical zero, indicating that neither has anything additional to transmit. It is possible for one device to have more pages to transmit than the other device. Once a device has completed transmission of its Next Page information, it shall transmit Next Pages with Null message codes and the NP bit set to logical zero while its link partner continues to transmit valid Next Pages. An Auto-Negotiation able device shall recognize reception of Message Pages with Null message codes as the end of its link partner's Next Page information.

98.2.4.3.1 Next page encodings

The Next Page shall use the encoding shown in Table 98–5 and Table 98–6 for the NP, Ack, MP, Ack2, and T bits. These bits shall function as specified in 98.2.1.2.9, 98.2.1.2.8, 28.2.3.4.5, 28.2.3.4.6, and 28.2.3.4.7 respectively. There are two types of Next Page encodings: message and unformatted. For message Next Pages, the MP bit shall be set to logical one, the 11-bit field D[10:0] shall be encoded as a Message Code Field and D[47:16] shall be encoded as Unformatted Code Field. For Unformatted Next Pages, the MP bit shall be set to logical ZERO: D[10:0] and D[47:16] shall be encoded as the Unformatted Code Field.

98.2.4.3.2 Use of Next Pages

Next page exchange shall commence after the Base Page exchange if either device requests it by setting the NP bit to logical one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Next page exchange shall continue until neither device on a link has more pages to transmit as indicated by the NP bit. A Next Page with a Null Message Code Field value shall be sent if the device has no other information to transmit.

A message code can carry either a specific message or information that defines how the corresponding unformatted codes should be interpreted.

98.3 State diagram variable to Auto-Negotiation register mapping

The state diagrams of Figure 98–7 to Figure 98–10 generate and accept variables of the form "mr_x," where x is an individual signal name. These variables comprise a management interface to communicate Auto-Negotiation information to and from the management entity. Clause 45 MDIO registers are defined in MMD7 to support Auto-Negotiation. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the information is recommended.

Table 98–7 describes the MDIO register to the state diagrams variable mapping.

Table 98–7—State diagram variable to Single twisted-pair Auto-Negotiation MDIO register mapping

State diagram variable	Description / MDIO register mapping
mr_adv_ability[48:1]	{7.516.15:0, 7.515.15:0, 7.514.15:0} BASE-T1 AN advertisement registers
mr_autoneg_complete	7.513.5 Auto-Negotiation complete
mr_autoneg_enable	7.512.12 Auto-Negotiation enable
mr_lp_adv_ability[48:1]	For Base Page: {7.519.15:0, 7.518.15:0, 7.517.15:0} BASE-T1 AN LP Base Page ability registers For Next Page(s): {7.525.15:0, 7.524.15:0, 7.523.15:0} BASE-T1 AN LP NEXT PAGE ability register
mr_main_reset	7.512.15 AN reset
mr_next_page_loaded	Set on write to BASE-T1 AN NEXT PAGE transmit register; cleared by Arbitration state diagram
mr_np_tx[48:1]	{7.522.15:0, 7.521.15:0, 7.520.15:0} BASE-T1 AN NEXT PAGE transmit register
mr_page_rx	7.513.6 Page received
mr_restart_negotiation	7.512.9 Restart Auto-Negotiation
set to 1	7.513.3 Auto-Negotiation ability

98.4 Technology-Dependent Interface

The Technology-Dependent Interface is the communication mechanism between each technology's PMA and the Auto-Negotiation function. Auto-Negotiation can support multiple technologies, all of which need not be implemented in a given device. Each of these technologies may utilize its own technology-dependent link integrity test function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

98.4.1 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium. The purpose of this primitive is to give the Auto-Negotiation function a means of determining the validity of received code elements.

98.4.1.1 Semantics of the service primitive

PMA_LINK.indication(link_status)

The link_status parameter shall assume one of two values: OK or FAIL, indicating whether the underlying receive channel is intact and enabled (OK) or not intact (FAIL).

98.4.1.2 When generated

A technology-dependent PMA generates this primitive to indicate a change in the value of link_status.

98.4.1.3 Effect of receipt

The effect of receipt of this primitive shall be governed by the state diagram of Figure 98–7.

98.4.2 PMA_LINK.request

This primitive is generated by Auto-Negotiation to allow it to enable and disable operation of the PMA.

98.4.2.1 Semantics of the service primitive

PMA_LINK.request(link_control)

The link_control parameter shall assume one of two values: DISABLE or ENABLE.

The link_control=DISABLE mode shall be used by the Auto-Negotiation function to disable PMA processing.

The link_control=ENABLE mode shall be used by Auto-Negotiation to turn control over to a single PMA for all normal processing functions.

98.4.2.2 When generated

The Auto-Negotiation function shall generate this primitive to indicate to the PHY how to respond, in accordance with the state diagram of Figure 98–7. Upon power-on or reset, if the Auto-Negotiation function is enabled (mr_autoneg_enable=true) the PMA_LINK.request(DISABLE) message shall be issued to all technology-dependent PMAs.

98.4.2.3 Effect of receipt

This primitive affects operation of the underlying PMA.

98.5 Detailed functions and state diagrams

The notation used in state diagrams follows the conventions in Clause 28. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Auto-Negotiation shall implement the Transmit state diagram, Receive state diagram, half-duplex state diagram, and Arbitration state diagram. Additional requirements to these state diagrams are made in the respective functional requirements sections. Options to these state diagrams clearly stated as such in the functional requirements sections or state diagrams shall be allowed. In the case of any ambiguity between stated requirements and the state diagrams, the state diagrams shall take precedence.

98.5.1 State diagram variables

A variable with "_[x]" appended to the end of the variable name indicates a variable or set of variables as defined by "x". "x" may be as follows:

— all; represents all specific technology-dependent PMAs supported in the local device.
— HCD; represents the single technology-dependent PMA chosen by Auto-Negotiation as the highest common denominator technology through the Priority Resolution.
— notHCD; represents all technology-dependent PMAs not chosen by Auto-Negotiation as the highest common denominator technology through the Priority Resolution.
— 1GigT1; represents that the 1000BASE-T1 PMA is the signal source.
— 2.5GigT1; represents that the 2.5GBASE-T1 PMA is the signal source.
— 5GigT1; represents that the 5GBASE-T1 PMA is the signal source.
— 10GigT1; represents that the 10GBASE-T1 PMA is the signal source.

Variables with [48:1] appended to the end of the variable name indicate arrays that can be directly mapped to 48-bit registers. For these variables, "[x]" indexes an element or set of elements in the array, where "[x]" may be as follows:

a) Any integer
b) Any range of integers
c) Any variable that takes on integer values
d) NP; represents the index of the Next Page bit
e) ACK; represents the index of the Acknowledge bit
f) RF; represents the index of the Remote Fault bit

Variables of the form "mr_x", where x is a label, comprise a management interface that is intended to be connected to the Management function. However, an implementation-specific management interface may provide the control and status function of these bits. The mapping between state diagram variables and Single twisted-pair Auto-Negotiation MDIO registers is shown in Table 98–7.

ability_match
Indicates that at least one link codeword with good CRC16 was received.
Values:
false: at least one link codeword with good CRC16 has not been received (default)
true: at least one link codeword with good CRC16 has been received

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

ability_match_word [48:1]
A 48-bit array that is loaded upon transition to Acknowledge Detect state with the value of the link codeword that caused ability_match = true for that transition. For each element in the array transmitted.
Values:
ZERO: data bit is logical zero
ONE: data bit is logical one

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ack_finished

Status indicating that the final remaining_ack_cnt link codewords with the Ack bit set have been transmitted.

Values:

- false: more link codewords with the Ack bit set to logical one is transmitted
- true: all remaining link codewords with the Ack bit set to logical one have been transmitted

ack_nonce_match

Indicates whether the echoed nonce received from the link partner matches the transmitted nonce field sent by the local device. The echoed nonce value from the DME page that caused acknowledge_match to be set is used for this test.

Values:

- false: link partner echoed nonce does not equal local device transmitted nonce
- true: link partner echoed nonce equals local device transmitted nonce

acknowledge_match

Indicates that at least one link codeword with the Acknowledge bit set and with good CRC16 was received. The link codeword that initially set the ability_match variable should not be used to set this variable.

Values:

- false: at least one link codeword with the Acknowledge bit set and with good CRC16 has not been received (default)
- true: at least one link codeword with the Acknowledge bit set and with good CRC16 has been received

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

an_link_good

Indicates that Auto-Negotiation has completed.

Values:

- false: negotiation is in progress (default)
- true: negotiation is complete, forcing the Transmit and Receive functions to IDLE

an_receive_idle

Indicates that the Receive state diagram is in the IDLE state.

Values:

- false: the Receive state diagram is not in the IDLE state (default)
- true: the Receive state diagram is in the IDLE state

ANSP

This variable contains the type of the selected Auto-Negotiation speed.

Values:

- HSM: high-speed mode
- LSM: low-speed mode

base_page

Status indicating that the page currently being transmitted by Auto-Negotiation is the initial link codeword encoding used to communicate the device's abilities.

Values:

- false: a page other than base link codeword is being transmitted
- true: the base link codeword is being transmitted

code_sel

A random or pseudo-random value uniformly distributed. A new value is generated each time the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

variable code_sel is used.
Values:
ZERO: a zero has been assigned
ONE: a one has been assigned

complete_ack
Controls the counting of transmitted link codewords that have their Acknowledge bit set.
Values:
false: transmitted link codewords with the Acknowledge bit set are not counted (default)
true: transmitted link codewords with the Acknowledge bit set are counted

consistency_match
Indicates that the ability_match_word is the same as the link codeword that caused acknowledge_match to be set.
Values:
false: the link codeword that caused ability_match to be set is not the same as the link codeword that caused acknowledge_match to be set, ignoring the Acknowledge bit value and the echoed nonce value
true: the link codeword that caused ability_match to be set is the same as the link codeword that caused acknowledge_match to be set, ignoring the Acknowledge bit value and the echoed nonce value

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

detect_mv_end
Status indicating that the receiver has detected the end delimiter.
Values:
false: set to false after any Receive State Diagram state transition (default)
true: end delimiter has been detected

detect_mv_start
Status indicating that the receiver has detected a Start Delimiter as defined in 98.2.1.1.1.
Values:
false: set to false after any Receive State Diagram state transition (default)
true: Start Delimiter has been detected

detect_transition
Status indicating that the receiver has detected a transition.
Values:
false: set to false after any Receive State Diagram state transition (default)
true: set to true when a transition is received

incompatible_link
Parameter used following Priority Resolution to indicate the resolved link is incompatible with the local device settings. A device's ability to set this variable to true is optional.
Values:
false: a compatible link exists between the local device and link partner (default)
true: optional indication that Priority Resolution has determined no highest common denominator exists following the most recent negotiation

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

link_control_[x]
Controls the connection of each PMD to the MDI. When all PMD transmitters are isolated from the MDI, the AN transmitter is connected to the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values:
DISABLE: isolates the PMD from the MDI
ENABLE: connects the PMD (both transmit and receive) to the MDI

link_status_[x]
The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive. This variable takes the values of OK or FAIL.

mr_autoneg_complete
Status indicating whether Auto-Negotiation has completed or not.
Values:
false: Auto-Negotiation has not completed
true: Auto-Negotiation has completed

mr_autoneg_enable
Controls the enabling and disabling of the Auto-Negotiation function.
Values:
false: Auto-Negotiation is disabled
true: Auto-Negotiation is enabled

mr_adv_ability[48:1]
A 48-bit array that contains the Advertised Abilities link codeword. For each element within the array:
Values:
ZERO: data bit is logical zero
ONE: data bit is logical one

mr_lp_adv_ability[48:1]
A 48-bit array that contains the link partner's Advertised Abilities link codeword. For each element within the array:
Values:
ZERO: data bit is logical zero
ONE: data bit is logical one

mr_main_reset
Controls the resetting of the Auto-Negotiation state diagrams.
Values:
false: do not reset the Auto-Negotiation state diagrams
true: reset the Auto-Negotiation state diagrams

mr_next_page_loaded
Status indicating whether a new page has been loaded into the BASE-T1 AN NEXT PAGE transmit register (see 45.2.7.24).
Values:
false: a New Page has not been loaded
true: a New Page has been loaded

mr_np_tx[48:1]
A 48-bit array that contains the new Next Page to transmit. For each element within the array:
Values:
ZERO: data bit is logical zero
ONE: data bit is logical one

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mr_page_rx

Status indicating whether a New Page has been received. A New Page has been successfully received when acknowledge_match = true and consistency_match = true and the link codeword has been written to mr_lp_adv_ability[48:1].

Values:

false: a New Page has not been received
true: a New Page has been received

mr_restart_negotiation

Controls the entrance to the TRANSMIT DISABLE state to break the link before Auto-Negotiation is allowed to renegotiate via management control.

Values:

false: renegotiation is not taking place
true: renegotiation is started

multispeed_autoneg_reset

See 98.5.6.1.

nonce_match

Indicates whether the transmitted nonce received from the link partner matches the transmitted nonce field sent by the local device.

Values:

false: link partner transmitted nonce does not equal local device transmitted nonce
true: link partner transmitted nonce equals local device transmitted nonce

np_rx

Flag to hold the value of rx_link_code_word[NP] upon entry to the COMPLETE ACKNOWLEDGE state. This value is associated with the value of rx_link_code_word[NP] when acknowledge_match was last set.

Values:

ZERO: local device np_rx bit equals a logical zero
ONE: local device np_rx bit equals a logical one

page_polarity

Starting polarity of the page.

Values:

ZERO: starting polarity of page is negative
ONE: starting polarity of page is positive

power_on

Condition that is true until such time as the power supply for the device that contains the Auto-Negotiation state diagrams has reached the operating region or the device has low-power mode set via 1000BASE-T1 PMA control register bit 1.2304.11 or via 10BASE-T1L PMA control register bit 1.2294.11.

Values:

false: the device is completely powered (default)
true: the device has not been completely powered

receive_blind

Controls whether the receiver should ignore activity on the line.

Values:

true: ignore received DME transitions
false: accept received DME transitions

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

receive_DME_active

Status indicating whether or not a DME page reception is in progress.

Values:

- true: DME page reception in progress
- false: DME page reception completed

rx_link_code_word[64:1]

A 64-bit array that contains the data bits to be received from a DME page. For each element within the array:

Values:

- ZERO: data bit is a logical zero
- ONE: data bit is a logical one

rx_nonce[4:0]

A 5-bit array that contains the transmitted nonce received from the DME page that caused ability_match = true. For each element within the array:

Values:

- ZERO: data bit is a logical zero
- ONE: data bit is a logical one

TD_AUTONEG

Controls the signal sent by Auto-Negotiation on the TD_AUTONEG circuit.

Values:

- disable: transmission of Auto-Negotiation signals is disabled
- idle: Auto-Negotiation maintains the current signal level on the MDI
- mv_end_delimiter: Auto-Negotiation causes the transmission of the end delimiter on the MDI
- mv_start_delimiter: Auto-Negotiation causes the transmission of the Start Delimiter on the MDI as defined in 98.2.1.1.1
- transition: Auto-Negotiation causes a transition in the level on the MDI

toggle_rx

Flag to keep track of the state of the link partner's Toggle bit.

Values:

- ZERO: link partner's Toggle bit equals logical zero
- ONE: link partner's Toggle bit equals logical one

toggle_tx

Flag to keep track of the state of the local device's Toggle bit.

Values:

- ZERO: local device's Toggle bit equals logical zero
- ONE: local device's Toggle bit equals logical one

transmit_ability

Controls the transmission of the link codeword containing tx_link_code_word[64:1].

Values:

- false: any transmission of tx_link_code_word[64:1] is halted (default)
- true: the transmit state diagram begins sending tx_link_code_word[64:1]

transmit_ack

Controls the setting of the Acknowledge bit in the tx_link_code_word[64:1] to be transmitted.

Values:

- false: sets the Acknowledge bit in the transmitted tx_link_code_word[64:1] to a logical zero (default)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

true: sets the Acknowledge bit in the transmitted tx_link_code_word[64:1] to a logical one

transmit_disable

Controls the transmission of tx_link_code_word[64:1].

Values:

false: tx_link_code_word[64:1] transmission is allowed (default)

true: tx_link_code_word[64:1]transmission is halted

transmit_DME_done

Status indicating the DME page transmission completed.

Values:

true: DME page transmission completed

false: DME page transmission in progress

transmit_DME_wait

Control indication whether a DME page can be transmitted.

Values:

true: pause DME page transmission

false: continue DME page transmission

transmit_mv_end_done

Status indicating that the transmission of the end delimiter has completed.

Values:

false: transmission of the end delimiter is in progress

true: transmission of the end delimiter has completed

transmit_mv_start_done

Status indicating that the transmission of the Start Delimiter defined in 98.2.1.1.1 has been completed.

Values:

false: transmission of the Start Delimiter is in progress

true: transmission of the Start Delimiter has been completed

tx_link_code_word[64:1]

A 64-bit array that contains the data bits to be transmitted in an DME page. tx_link_code_word[48:1] contains the Auto-Negotiation page to be transmitted. tx_link_code_word[64:49] contains the CRC16. This array may be loaded from mr_adv_ability or mr_np_tx. For each element within the array:

Values:

ZERO: data bit is logical zero

ONE: data bit is logical one.

98.5.2 State diagram timers

All timers operate in the manner described in 40.4.5.2.

When operating in high-speed mode, the following timer value definitions shall apply:

backoff_timer_[HSM]

Timer for the random amount of time to wait for a page to arrive from the link partner before transmitting a page. The timer shall expire according to the formula below after being started. If T[4] bit is 1, the timer duration is (6805 ns to 6925 ns) + (random integer from 0 to 15) × (2120 ns to 2240 ns).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If T[4] bit is 0, the timer duration is (7895 ns to 8015 ns) + (random integer from 0 to 15) × (2120 ns to 2240 ns).

A new random integer from 0 to 15 inclusive is generated every time the backoff_timer_[HSM] is started. The random value should be uniformly distributed.

blind_timer_[HSM]

Timer for the amount of time to blind the receiver after end of transmission to prevent the device from seeing its own echo. The timer shall expire 2000 ns to 2120 ns after being started.

break_link_timer_[HSM]

Timer for the amount of time to wait in TRANSMIT DISABLE to assure that the link partner will exit from either ACKNOWLEDGE DETECT or NEXT PAGE WAIT; effect on the link partner in other states is not defined. The timer shall expire 300 µs to 305 µs after being started.

clock_detect_max_timer_[HSM]

Timer for the maximum time between detection of differential Manchester clock transitions. The clock_detect_max_timer_[HSM] shall expire 63 ns to 75 ns after being started or restarted.

clock_detect_min_timer_[HSM]

Timer for the minimum time between detection of differential Manchester clock transitions. The clock_detect_min_timer_[HSM] shall expire 45 ns to 57 ns after being started or restarted.

data_detect_max_timer_[HSM]

Timer for the maximum time between a clock transition and the following data transition. This timer is used in conjunction with the data_detect_min_timer_[HSM] to detect whether the data bit between two clock transitions is a logical zero or a logical one. The data_detect_max_timer_[HSM] shall expire 33 ns to 45 ns from the last clock transition.

data_detect_min_timer_[HSM]

Timer for the minimum time between a clock transition and the following data transition. This timer is used in conjunction with the data_detect_max_timer_[HSM] to detect whether the data bit between two clock transitions is a logical zero or a logical one. The data_detect_min_timer_[HSM] shall expire 15 ns to 27 ns from the last clock transition.

interval_timer_[HSM]

Timer for the separation of a transmitted clock pulse from a data bit. The interval_timer_[HSM] shall expire 30 ns ± 0.01% from each clock pulse and data bit.

page_test_max_timer_[HSM]

Timer for the maximum time between detection of start and end delimiters. The page_test_max_timer_[HSM] shall expire 4800 ns to 4920 ns after being started or restarted.

receive_DME_timer_[HSM]

Timer for the maximum amount of time to receive a complete page before timeout. The timer shall expire 6805 ns to 6925 ns after being started.

rx_wait_timer_[HSM]

Timer for the maximum time between detection of DME pages. This timer is used to detect whether the link partner is transmitting DME pages. The rx_wait_timer_[HSM] shall expire 15 µs to 17 µs after being started or restarted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

silent_timer_[HSM]

Timer for the amount of time to wait after receiving a page before transmitting a page. The timer shall expire 2120 ns to 2240 ns after being started.#

When operating in low-speed mode, the following timer value definitions shall apply:

backoff_timer_[LSM]

Timer for the random amount of time to wait for a page to arrive from the link partner before transmitting a page. The timer shall expire according to the formula below after being started.
If T[4] bit is 1, the timer duration is (156 300 ns to 159 500 ns) + (random integer from 0 to 15) × (31 400 ns to 34 600 ns).
If T[4] bit is 0, the timer duration is (172 800 ns to 176 000 ns) + (random integer from 0 to 15) × (31 400 ns to 34 600 ns).
A new random integer from 0 to 15 inclusive is generated every time the backoff_timer_[LSM] is started. The random value should be uniformly distributed.

blind_timer_[LSM]

Timer for the amount of time to blind the receiver after end of transmission to prevent the device from seeing its own echo. The timer shall expire 28 200 ns to 31 400 ns after being started.

break_link_timer_[LSM]

Timer for the amount of time to wait in TRANSMIT DISABLE to assure that the link partner will exit from either ACKNOWLEDGE DETECT or NEXT PAGE WAIT; effect on the link partner in other states is not defined. The timer shall expire 8000 µs to 8133 µs after being started.

clock_detect_max_timer_[LSM]

Timer for the maximum time between detection of differential Manchester clock transitions. The clock_detect_max_timer_[LSM] shall expire 1680 ns to 2000 ns after being started or restarted.

clock_detect_min_timer_[LSM]

Timer for the minimum time between detection of differential Manchester clock transitions. The clock_detect_min_timer_[LSM] shall expire 1200 ns to 1520 ns after being started or restarted.

data_detect_max_timer_[LSM]

Timer for the maximum time between a clock transition and the following data transition. This timer is used in conjunction with the data_detect_min_timer_[LSM] to detect whether the data bit between two clock transitions is a logical zero or a logical one. The data_detect_max_timer_[LSM] shall expire 880 ns to 1200 ns from the last clock transition.

data_detect_min_timer_[LSM]

Timer for the minimum time between a clock transition and the following data transition. This timer is used in conjunction with the data_detect_max_timer_[LSM] to detect whether the data bit between two clock transitions is a logical zero or a logical one. The data_detect_min_timer_[LSM] shall expire 400 ns to 720 ns from the last clock transition.

interval_timer_[LSM]

Timer for the separation of a transmitted clock pulse from a data bit. The interval_timer_[LSM] shall expire 800 ns ± 0.005% from each clock pulse and data bit.

page_test_max_timer_[LSM]

Timer for the maximum time between detection of start and end delimiters. The page_test_max_timer_[LSM] shall expire 128 000 ns to 131 200 ns after being started or restarted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

receive_DME_timer_[LSM]
: Timer for the maximum amount of time to receive a complete page before timeout. The timer shall expire 156 300 ns to 159 500 ns after being started.

rx_wait_timer_[LSM]
: Timer for the maximum time between detection of DME pages. This timer is used to detect whether the link partner is transmitting DME pages. The rx_wait_timer_[LSM] shall expire 330 μs to 370 μs after being started or restarted.

silent_timer_[LSM]
: Timer for the amount of time to wait after receiving a page before transmitting a page. The timer shall expire 31 400 ns to 34 600 ns after being started.

Depending on the selected PHY type, done by Auto-Negotiation, the following timer values shall be used:

link_fail_inhibit_timer_[HCD]
: Timer for qualifying a link_status=FAIL indication or a link_status=OK indication when a specific technology link is first being established. A link will be considered "failed" only if the link_fail_inhibit_timer_[HCD] has expired and the link has still not gone into the link_status=OK state. The expiration time of the link_fail_inhibit_timer_[HCD] shall be dependent on the selected PHY type. For all PHY types, except 10BASE-T1L and 10BASE-T1S, this timer shall expire 97 ms to 98 ms after entering the AN GOOD CHECK state. For a 10BASE-T1L PHY, this timer shall expire 3030 ms to 3090 ms after entering the AN GOOD CHECK state. For a 10BASE-T1S PHY, this timer shall expire 400 ms to 405 ms after entering the AN GOOD CHECK state.

NOTE—The link_fail_inhibit_timer_[HCD] expiration value is greater than the time required for the link partner to complete Auto-Negotiation after the local device has completed Auto-Negotiation plus the time required for the specific technology to enter the link_status=OK state.

98.5.3 State diagram counters

remaining_ack_cnt
: A counter that may take on integer values from 0 to 3. The number of additional link codewords with the Acknowledge Bit set to logical one to be sent to ensure that the link partner receives the acknowledgment.
Values:
not_done: positive integers between 0 and 2 inclusive
done: positive integer 3
init: counter is reset to zero

rx_bit_cnt
: A counter that may take on integer values from 0 to 64. This counter is used to keep a count of data bits received from a DME page and to ensure that when erroneous extra transitions are received, the first 48 bits are kept while the next 16 bits are used for CRC16 check and any additional bits are ignored. When this counter reaches 64, enough data bits have been received. This counter does not increment beyond 64 and does not return to 0 until it is reinitialized.

tx_bit_cnt
: A counter that may take on integer values from 1 to 64. This counter is used to keep a count of data bits sent within a DME page. When this counter reaches 64, all data bits have been sent.

98.5.4 Function

CRC16(x[48:1])

Returns the output of the CRC16 generator described in 98.2.1.1.1 after processing the 48-bit input x.

98.5.5 State diagrams

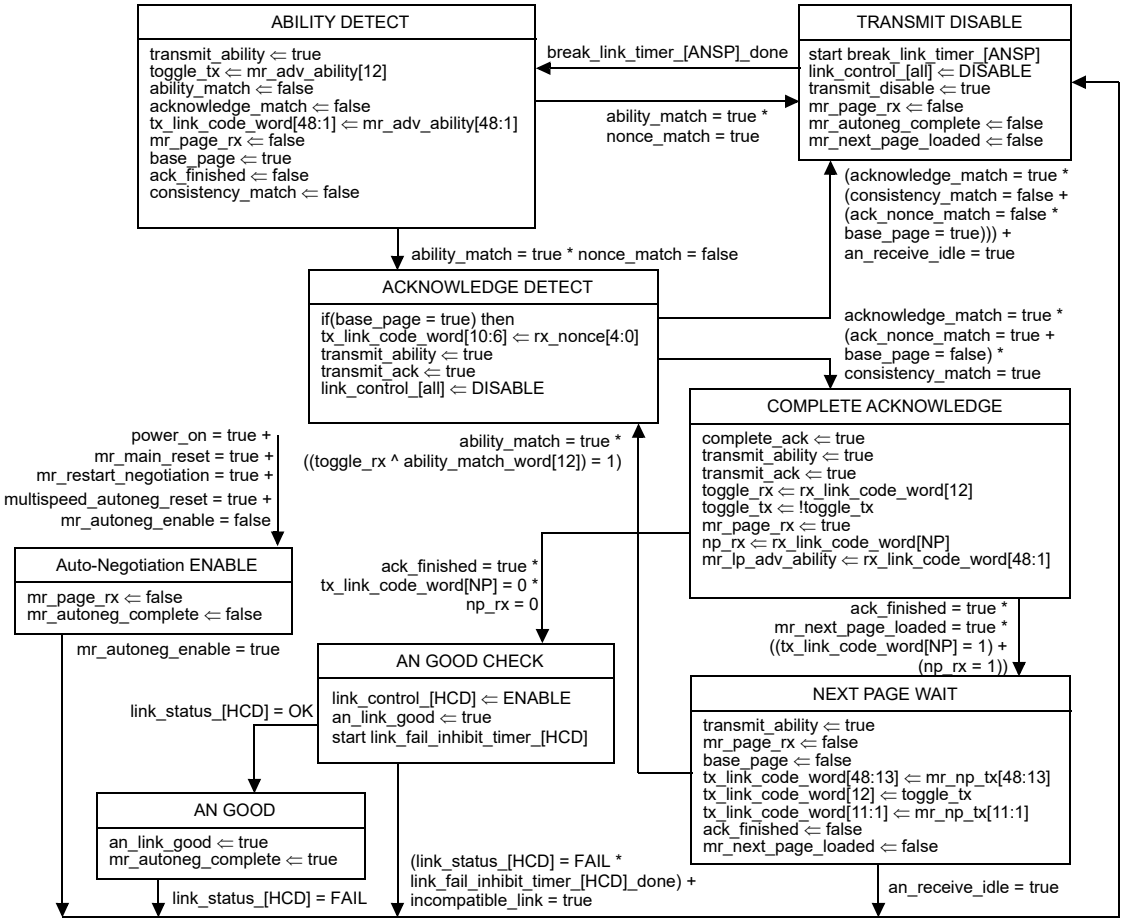

Figure 98–7—Arbitration state diagram

98.5.6 High-speed and low-speed Auto-Negotiation modes

A PHY supporting two different Auto-Negotiation speeds, as described in 98.2.1.1.2, shall implement the behavior shown in Figure 98–11. Figure 98–11 determines the mode used for the timers in Figure 98–7, Figure 98–8, Figure 98–9, Figure 98–10, and Figure 98–11 through the variable ANSP and synchronizes them through the variable multispeed_autoneg_reset.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A PHY supporting only one Auto-Negotiation speed shall implement the behavior as shown in Figure 98–7, Figure 98–8, Figure 98–9, and Figure 98–10, using the associated timer values for high-speed mode (HSM) or low-speed mode (LSM) Auto-Negotiation as described in 98.5.2.

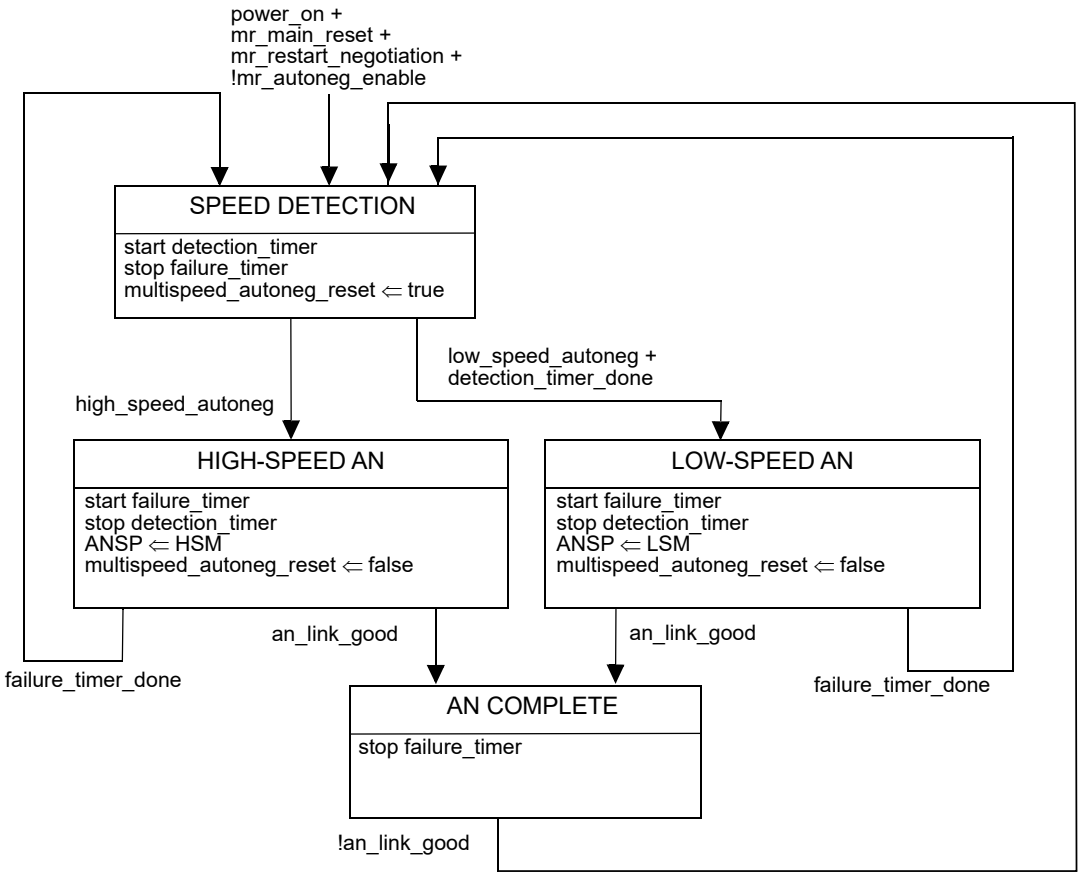

Figure 98–11—Auto-Negotiation—high-speed mode and low-speed mode selection

98.5.6.1 Variables

an_link_good
: See 98.5.1.

ANSP
: See 98.5.1.

mr_autoneg_enable
: See 98.5.1.

mr_main_reset
: See 98.5.1.

mr_restart_negotiation
: See 98.5.1.

multispeed_autoneg_reset
: If two different Auto-Negotiation speeds are implemented and this variable is set to true by the state diagram in Figure 98–11, then the state diagrams in Figure 98–7, Figure 98–8,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Figure 98–9, and Figure 98–10 are restarted. If only single speed Auto-Negotiation is implemented, then this variable remains set to false.
Values: true: Auto-Negotiation state diagrams are restarted
false: Auto-Negotiation state diagrams are in normal operation

power_on
See 98.5.1.

98.5.6.2 Functions

high_speed_autoneg
This function returns true if at least the last 12 received DME pulses are within the allowed range for the high-speed Auto-Negotiation communication (15 ns to 135 ns pulse width) including the violations of the DME encoding within the start delimiter; otherwise, this function returns false.
Values: true or false

low_speed_autoneg
This function returns true if at least the last 12 received DME pulses are within the allowed range for the low-speed Auto-Negotiation communication (400 ns to 2000 ns pulse width) including the violations of the DME encoding within the start delimiter; otherwise, this function returns false.
Values: true or false

98.5.6.3 Timers

All timers operate in the manner described in 40.4.5.2.

detection_timer
This timer limits the maximum time for detection of Auto-Negotiation frames sent by the far end PHY, before starting to send its own Auto-Negotiation frames at low-speed. This timer is not automatically restarted after expiration. A new random integer from 0 to 15 inclusive is generated every time the detection_timer is started. The random value should be uniformly distributed.
Timer value: (10 ms ± 0.1 ms) + (random integer from 0 to 15) × (0.5 ms ± 0.05 ms)

failure_timer
This timer limits the maximum time for the underlying Auto-Negotiation state diagrams to complete the Auto-Negotiation process before restarting the Auto-Negotiation process. This timer is not automatically restarted after expiration.
Timer value: 250 ms ± 1 ms

98.6 Protocol implementation conformance statement (PICS) proforma for Clause 98, Auto-Negotiation for Single Differential-Pair Media[171]

98.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 98, Auto-Negotiation for Single Differential-Pair Media, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

98.6.2 Identification

98.6.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

98.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 98, Auto-Negotiation for Single Differential-Pair Media
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[171] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

98.6.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
*ANSM	Auto-Negotiation Speed Mode	98.5.6		O	Yes [ ] No [ ]
*HSM	High-Speed Mode	98.5.2, 98.5.6		O	Yes [ ] No [ ]
*LSM	Low-Speed Mode	98.5.2, 98.5.6		O	Yes [ ] No [ ]
*10T1L	10BASE-T1L PHY type	98.5.2		O	Yes [ ] No [ ]
*10T1S	10BASE-T1S PHY type	98.5.2		O	Yes [ ] No [ ]

98.6.4 General

Item	Feature	Subclause	Value/Comment	Status	Support
G1	Single twisted-pair Auto-Negotiation function	98.2	Provide Auto-Negotiation transmit, Auto-Negotiation receive, Auto-Negotiation half-duplex, and Auto-Negotiation arbitration	M	Yes [ ]
G2	Auto-Negotiation functions	98.2		M	Yes [ ]
G3	PHY support for High-Speed Mode	98.2.1, 98.5.6		ANSM: O.1	Yes [ ] No [ ] N/A [ ]
G4	PHY support for Low-Speed Mode	98.2.1, 98.5.2, 98.5.6		ANSM: O.1	Yes [ ] No [ ] N/A [ ]

98.6.5 DME transmission

Item	Feature	Subclause	Value/Comment	Status	Support
DME1	DME pages	98.2.1.1	Not be transmitted when Auto-Negotiation is complete and the highest common denominator PHY has been enabled.	M	Yes [ ]
DME2	DME page encoding levels	98.2.1.1.1	Transmit either a +1 or –1 level	M	Yes [ ]
DME3	DME Page 64 odd-numbered transmission positions	98.2.1.1.1	Contain a transition	M	Yes [ ]
DME4	DME Page 64 even-numbered transmission positions	98.2.1.1.1	Represent data	M	Yes [ ]
DME5	DME Page first 48 even-numbered positions	98.2.1.1.1	Carry the data of the Auto-Negotiation page	M	Yes [ ]

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
DME6	CRC16	98.2.1.1.1	Comply with Figure 98–3 and initialize 16 delay elements to zero	M	Yes [ ]
DME7	Timing parameters for DME pages	98.2.1.1.2	Table 98–1	M	Yes [ ]
DME8	DME page transitions in high-speed mode	98.2.1.1.2	Occur within ± 0.8 ns of their ideal position	HSM: M	Yes [ ] N/A [ ]
DME9	DME page transitions in low-speed mode	98.2.1.1.2	Occur within ± 10 ns of their ideal position	LSM: M	Yes [ ] N/A [ ]
DME10	Transmit differential signal at the MDI	98.2.1.1.4	Within range of 1 V ± 30% peak-to-peak when measured in reference to a 100 Ω termination	M	Yes [ ]

98.6.6 Link codeword encoding

Item	Feature	Subclause	Value/Comment	Status	Support
DT1	Base Page transmitted within a DME page	98.2.1.2	Convey the encoding shown in Table 98–2	M	Yes [ ]
DT2	Encoding for link codeword(s) used inside a Next Page exchange	98.2.1.2	In a DME page, D0 is the first bit transmitted	M	Yes [ ]
DT3	RF, ACK, NP bits	98.2.1.2	Function as specified in 98.2.1.2.7, 98.2.1.2.8, and 98.2.1.2.9, respectively	M	Yes [ ]
DT4	Reserved combinations of the Selector Field	98.2.1.2.1	Not be transmitted	M	Yes [ ]
DT5	Echoes Nonce Field bad	98.2.1.2.2	Contain logical zeros when the device does not receive a DME page with good CRC16	M	Yes [ ]
DT6	Echoed Nonce Field good	98.2.1.2.2	Contain the value received in the Transmitted Nonce Field from the link partner when the device has received a DME page with good CRC16	M	Yes [ ]
DT7	Generate a new Transmitted Nonce Field value for each entry to the Ability Detect state	98.2.1.2.3		M	Yes [ ]
DT8	Matching T[4:0]	98.2.1.2.3	Invert T[0] bit and regenerate a new random value for T[3:1]	M	Yes [ ]
DT9	Support the data service ability for a technology it advertises	98.2.1.2.4		M	Yes [ ]
DT10	Acknowledge bit with no Next Page	98.2.1.2.8	Set to 1 after the reception of at least one DME page with correct CRC	M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
DT11	Acknowledge bit with Next Page	98.2.1.2.8	Set to 1 after the device successfully receives reception of at least one DME page with correct CRC and remain set until Next Page information has been loaded	M	Yes [ ]
DT12	No Next Page to send	98.2.1.2.9	Set Next Page to 0	M	Yes [ ]
DT13	Next Page to send	98.2.1.2.9	Set Next Page to 1	M	Yes [ ]
DT14	No Next Page to send and link partner Next Page is set to 1	98.2.1.2.9	Transmit Next Pages with Null message codes and the Next Page set to 0	M	Yes [ ]
DT15	Transmit Switch function	98.2.1.3	Enable the transmit path from a single technology-dependent PHY to the MDI once Auto-Negotiation has completed	M	Yes [ ]
DT16	Transmit Switch function during Auto-Negotiation	98.2.1.3	Connect only the DME page generator controlled by the Transmit state diagram to the MDI	M	Yes [ ]
DT17	Signal at the MDI	98.2.1.3	Conform to all the PHY's specifications when a PHY is connected to the MDI through the Transmit Switch function	M	Yes [ ]

98.6.7 Arbitration function requirements

Item	Feature	Subclause	Value/Comment	Status	Support
AF1	Regeneration request	98.2.4.1	Cause Arbitration function to disable all technology-dependent PHYs and halt any transmit data and link transition activity until the break_link_timer expires	M	Yes [ ]
AF2	break_link_timer expires	98.2.4.1	Resume Auto-Negotiation	M	Yes [ ]
AF3	Priority Resolution function	98.2.4.2	Highest priority is assigned to the single PHY enabled to connect to the MDI by Auto-Negotiation	M	Yes [ ]
AF4	Receipt of a Technology Ability Field with a bit that is reserved	98.2.4.2	Ignore the bit for priority resolution	M	Yes [ ]
AF5	No common technology	98.2.4.2	Value "NULL" is assigned to HCD	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
AF6	Next Pages message encodings	98.2.4.3	Have a Message code that defines how the Unformatted code will be interpreted for each series of Next Pages	M	Yes [ ]
AF7	Completed transmission of Next Page information	98.2.4.3	Transmit Next Pages with Null message codes and the NP bit set to 0	M	Yes [ ]
AF8	Receipt of Message Pages with Null message codes	98.2.4.3	End of its link partner's Next Page information	M	Yes [ ]
AF9	Next Page encoding	98.2.4.3.1	Shown in Table 98–5 and Table 98–6	M	Yes [ ]
AF10	NP, Ack, MP, Ack2 and T bits	98.2.4.3.1	Function as specified in 98.2.1.2.9, 98.2.1.2.8, 28.2.3.4.5, 28.2.3.4.6, and 28.2.3.4.7, respectively	M	Yes [ ]
AF11	Message Next Pages	98.2.4.3.1	MP bit set to 1, D[10:0] encoded as a Message Code Field, and D[47:16] encoded as Unformatted Code Field	M	Yes [ ]
AF12	Unformatted Next Pages	98.2.4.3.1	MP bit set to 0, D[10:0] and D[47:16] encoded as the Unformatted Code Field	M	Yes [ ]
AF13	Next Page exchange	98.2.4.3.1	Continue until neither device on a link has more pages to transmit	M	Yes [ ]
AF14	Next Page with Null Message Code Field value	98.2.4.3.1	Sent if the device has no other information to transmit	M	Yes [ ]

98.6.8 Service primitives

Item	Feature	Subclause	Value/Comment	Status	Support
TDI1	link_status parameter	98.4.1.1	OK, FAIL	MDIO:M	Yes [ ]
TDI2	Receipt of link_status primitive	98.4.1.3	Comply with Figure 98–7	M	Yes [ ]
TDI3	link_control parameter	98.4.2.1	DISABLE, ENABLE	M	Yes [ ]
TDI4	link_control=DISABLE	98.4.2.1	Used by Auto-Negotiation to disable PMA processing	M	Yes [ ]
TDI5	link_control=ENABLE	98.4.2.1	Used by Auto-Negotiation to turn control over to a single PMA for all normal processing functions	M	Yes [ ]

99. MAC Merge sublayer

99.1 Introduction

This clause specifies an optional MAC Merge sublayer for use with a pair of full-duplex MACs and a single PHY operating at 100 Mb/s or higher on a point-to-point link. The two MACs are as follows:

— A preemptable MAC (pMAC), which carries the preemptable traffic, and

— An express MAC (eMAC), which carries the express traffic.

The MAC Merge sublayer supports interspersing express traffic with preemptable traffic. This is achieved by using a MAC Merge sublayer to attach an express Media Access Control (MAC) and a preemptable MAC to a single Reconciliation Sublayer (RS) service. The MAC Merge sublayer supports two ways to hold transmission of preemptable traffic in the presence of express traffic:

— The MAC Merge sublayer may preempt (interrupt) preemptable traffic being currently transmitted, and

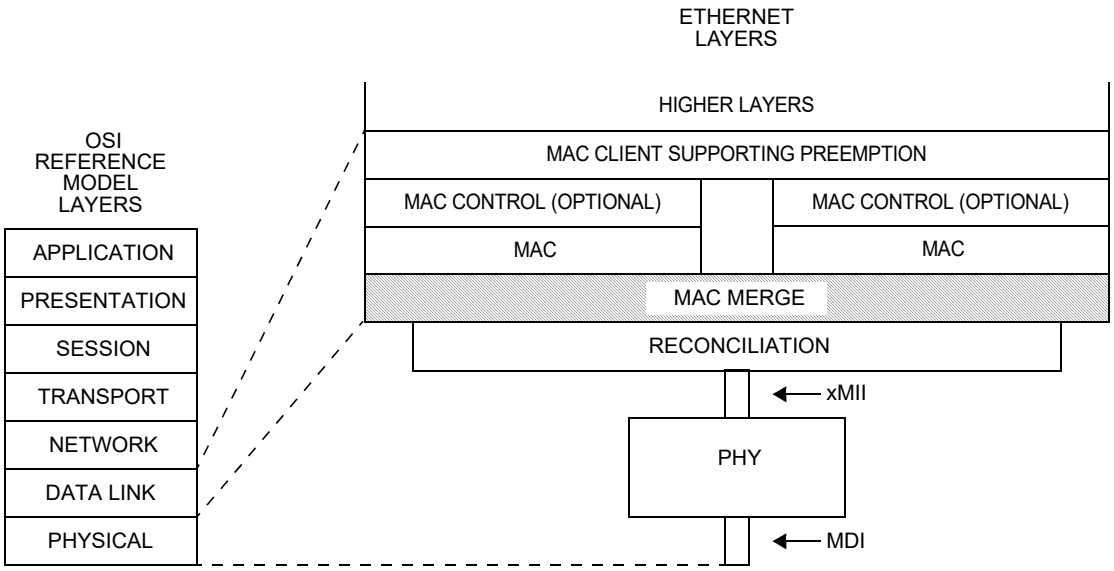
— The MAC Merge sublayer may prevent starting the transmission of preemptable traffic.

This clause also specifies a MAC Merge Service Interface (MMSI) providing a primitive that causes the transmission of preemptable traffic to be held or released, minimizing the latency for express traffic. For example, when the MAC Client supports scheduled traffic as defined in IEEE Std 802.1Q, transmission of preemptable packets can be held before express traffic is scheduled to be transmitted.

When the preemption capability is active, the MAC Merge sublayer allows frames provided over the express MAC service interface (express traffic) or the MMSI service primitive to interrupt transmission of a frame provided over the preemptable MAC service interface.

When the preemption capability is inactive, the MAC Merge sublayer does not allow express traffic or the MMSI service primitive to interrupt transmission of a frame provided over the preemptable MAC service interface.

Regardless of whether the preemption capability is active, the MAC Merge sublayer allows express traffic or the MMSI service primitive to prevent the start of transmission of frames provided over the preemptable MAC service interface (preemptable traffic).



The preemption capability is most useful at lower operating speeds. For example, the duration of a 2000 octet packet on a 100 Mb/s link is 160 µs and on a 1 Gb/s link is 16 µs. The time to transmit a maximum length packet is an upper bound on the additional delay before a MAC Client can send an Express frame when the preemption capability is not used. At higher operating speeds this additional delay gets smaller in proportion to the speed, reducing the advantage of the preemption mechanism.

Figure 99–1 shows the relationship of MAC Merge sublayer to the other sublayers and the ISO/IEC Open Systems Interconnection (OSI) reference model. The MAC Merge sublayer has two clients that are MAC sublayer instances: the eMAC and the pMAC.

Figure 99–2 shows the service interfaces of the MAC Merge sublayer and its associated MACs and Reconciliation Sublayer.

When attached to an eMAC or a pMAC, the MAC Control Sublayer shall not generate PAUSE (see Annex 31B).

NOTE—In this figure, the xMII is used as a generic term for the Media Independent Interfaces for implementations of 10BASE-T1L, 10BASE-T1S, and 100 Mb/s and above. For example: for 100 Mb/s implementations this interface is called MII; for 1 Gb/s implementations, it is called GMII; for 10 Gb/s implementations, it is called XGMII; etc.

MAC = MEDIA ACCESS CONTROL
xMII = MEDIA INDEPENDENT INTERFACE
MDI = MEDIUM DEPENDENT INTERFACE
PHY = PHYSICAL LAYER DEVICE

Figure 99–1—Relationship of MAC Merge sublayer to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

Devices that implement the MAC Merge sublayer interoperate with devices that do not implement the MAC Merge sublayer. The preemption capability is enabled only after it has been determined that the link partner supports it (see 99.4.2).

99.1.1 Relationship to other IEEE standards

MAC Merge sublayer and its MACs provide support for Frame Preemption as defined in IEEE Std 802.1Q.

99.1.2 Functional Block Diagram

Figure 99–3 provides a functional block diagram of the MAC Merge sublayer.

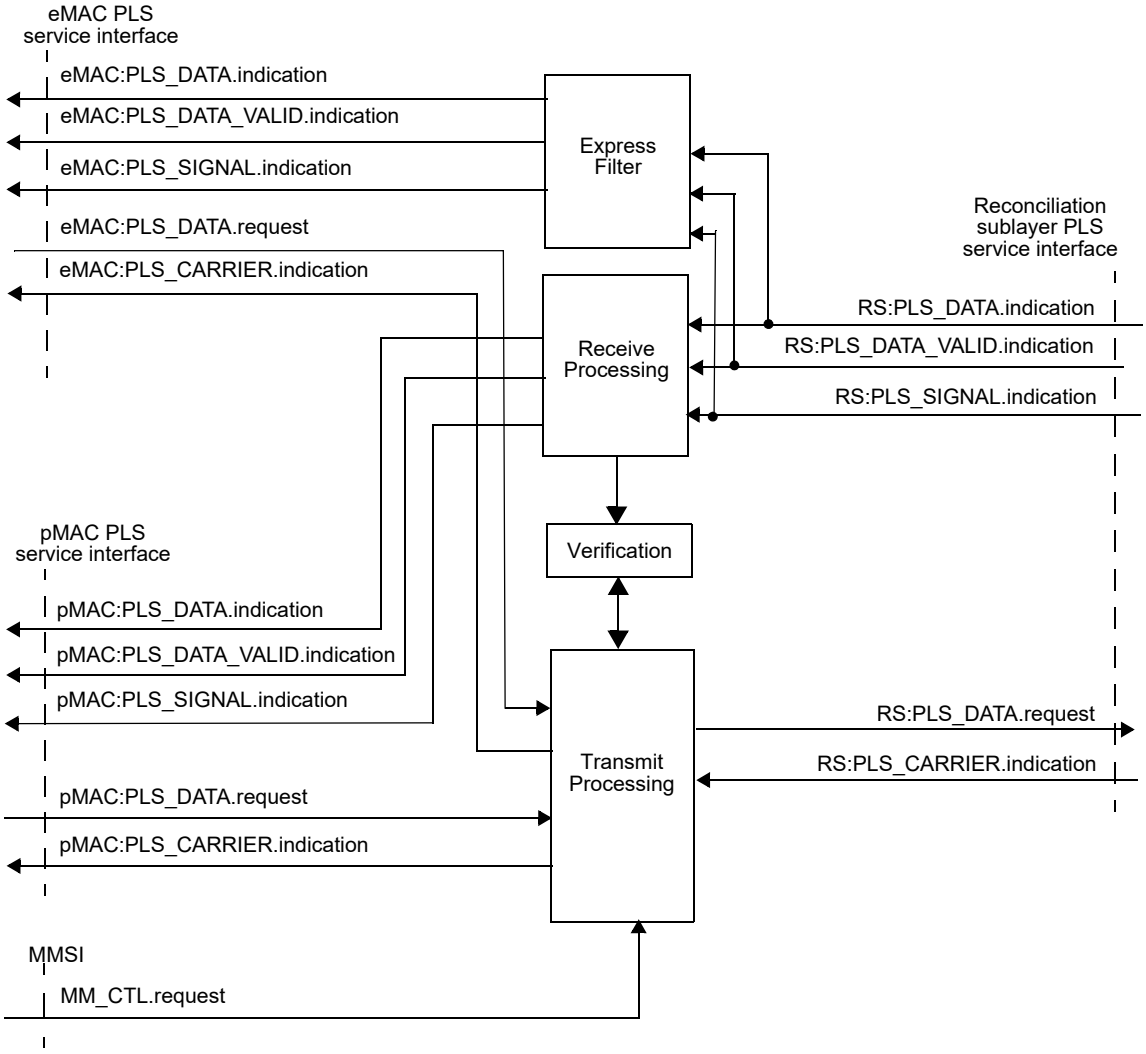

Figure 99–3—MAC Merge sublayer Functional Block Diagram

99.2 MAC Merge Service Interface (MMSI)

This subclause specifies the services provided by the MAC Merge sublayer to a MAC Client. The service interface is described in an abstract manner and does not imply any particular implementation. The model used in this service specification is identical to that used in 1.2.2.

The following primitive is defined:

— MM_CTL.request

99.2.1 MM_CTL.request

This primitive defines a request from a MAC Client to MAC Merge sublayer to hold or release transmission of preemptable traffic.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

99.2.1.1 Semantics

The semantics of the primitive are as follows:

MM_CTL.request (hold_req)

The hold_req parameter takes one of two values, HOLD or RELEASE. The value of HOLD causes the MAC Merge sublayer to hold transmission of preemptable traffic. The value of RELEASE causes the MAC Merge sublayer to release transmission of preemptable traffic.

99.2.1.2 When generated

The generation of this primitive is out of scope of this standard.

99.2.1.3 Effect of receipt

Receipt of the primitive with the hold_req parameter set to the value HOLD causes preemption when the conditions allow preemption and prevents starting transmission of pMAC packets until this primitive is received with the value RELEASE.

Receipt of the primitive with the hold_req parameter set to the value RELEASE allows MAC Merge sublayer to transmit packets from the pMAC when the eMAC does not have a packet to transmit.

99.3 MAC Merge Packet (mPacket)

When the preemption capability is active, MAC Merge sublayer sends mPackets to the Reconciliation sublayer (RS). An mPacket contains one of the following:

— a complete express packet,
— a complete preemptable packet
— an initial fragment of a preemptable packet, or
— a continuation fragment of a preemptable packet.

99.3.1 mPacket format

Part (a) of Figure 99–4 shows the format of an mPacket containing an express packet, a complete preemptable packet, or the initial fragment of a preemptable packet. Part (b) of Figure 99–4 shows the format of an mPacket containing a continuation fragment of a packet.

The mPacket format is indicated by the value of the SMD (see 99.3.3).

99.3.2 Preamble

The preamble in the mPacket shown in part (a) of Figure 99–4 contains seven octets. The preamble in the mPacket shown in part (b) of Figure 99–4 contains six octets. Each octet contains the value of 0x55 (transmitted in order from left to right 10101010).

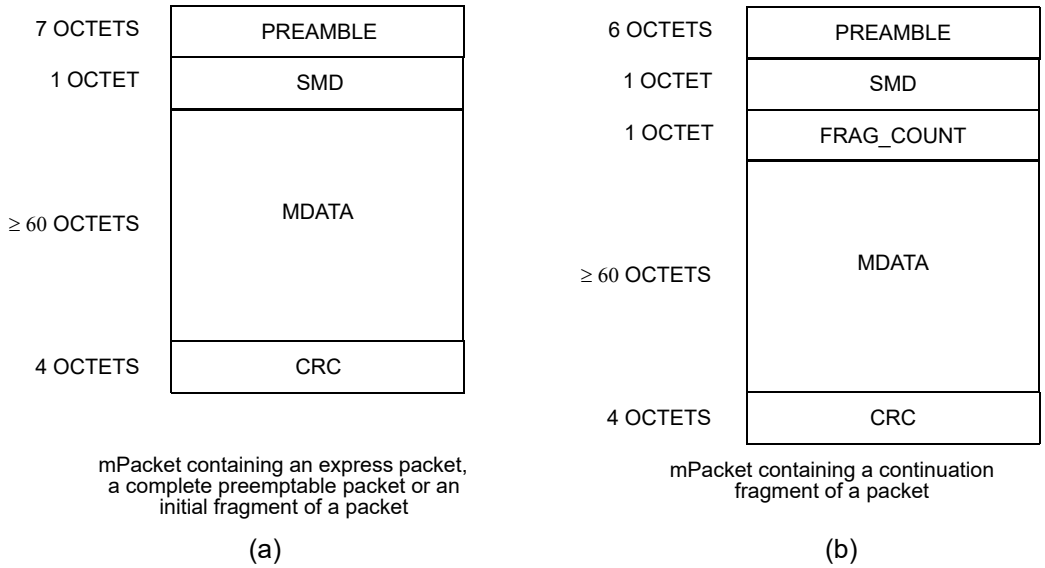

Figure 99–4—mPacket format

99.3.3 Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. All valid SMD values are defined in Table 99–1.

An mPacket carrying an express packet (transmitted by eMAC) has the same format as the express packet, because SMD-E (i.e., SMD value for an express packet) is same as the SFD value. An mPacket carrying a complete (non-fragmented) preemptable packet or the initial fragment of a preempted preemptable packet (transmitted by pMAC) has the SFD octet replaced with the appropriate SMD value. An mPacket carrying any of the continuation fragments of a preempted preemptable packet (transmitted by pMAC) has a continuation fragment SMD value, and includes an additional fragment counter octet (frag_count) following the SMD.

The SMD in an mPacket carrying a complete (non-fragmented) preemptable packet or any of the fragments of a preemptable packet also indicates the frame count. Information about the frame count prevents reassembling an invalid packet if the final mPacket of one preemptable packet and the initial fragment of the next preemptable packet are lost. The frame count is a modulo-4 count.

The term “SMD-S” refers to any of the four SMD values (SMD-S0, SMD-S1, SMD-S2, and SMD-S3) in an mPacket carrying the start of a preemptable packet. The term “SMD-C” refers to any of the four SMD values (SMD-C0, SMD-C1, SMD-C2, and SMD-C3) in an mPacket carrying a continuation fragment of a preemptable packet.

Two additional SMD values, SMD-V and SMD-R, identify mPackets used to verify that a link can support the preemption capability.

99.3.4 frag_count

The frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 99–1—SMD values

mPacket type	Notation	Frame count	Value
verify packet	SMD-V	—	0x07
respond packet	SMD-R	—	0x19
express packet	SMD-E	—	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

The frag_count field is present only in mPackets with SMD-C. The frag_count is zero in the first continuation fragment of each preemptable packet.

The valid frag_count values are shown in Table 99–2.

Table 99–2—Frag_count values

Frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

99.3.5 mData

The contents of the frame from the MAC from the first octet after the SFD to the last octet before the FCS are sent in the mData fields of the one or more mPackets for that frame. The minimum size of the mData field is 60 octets.

NOTE—The Transmit Processing state diagram ensures that the minimum mData field size is met. There is no pad field.

99.3.6 CRC

The CRC field contains a cyclic redundancy check (CRC) and an indication of whether this is the final mPacket of a frame.

In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For other mPackets, the CRC field contains an mCRC value. This includes mPackets used to verify that a link can support the preemption capability. The mCRC shall be calculated on the octets of the frame from the first octet of the frame (i.e., the octet following the SFD sent by the pMAC) to the last octet of the frame transmitted in that mPacket by:

— performing steps a) through d) in 3.2.9, and then
— XORing the calculated 32 bits with 0x0000FFFF.

NOTE—0x0000 is XORed with two octets that contain the higher order coefficients of the CRC, and 0xFFFF is XORed with the two octets that contain the lower order coefficients of the CRC.

99.4 MAC Merge sublayer operation

The MAC Merge sublayer receiver always operates the same way regardless of whether preemption is active. This allows MAC Merge sublayers to enable and use preemption once the link partner has indicated support for it, without sychronizing the transition between the two ends of the link.

The express mPacket format is the same as the MAC packet format. As a result, any packet received from a device that does not implement the MAC Merge sublayer or that has preemption disabled is received through the eMAC.

99.4.1 MAC Merge sublayer transmit behavior when preemption is disabled

When preemption is disabled, the packets presented by the pMAC and eMAC pass through the MAC Merge sublayer without alteration, i.e., the MAC Merge sublayer transmits packets rather than mPackets. If both the eMAC and pMAC have packets ready to transmit and no packet is being transmitted, the eMAC packet is transmitted. If a pMAC packet is being transmitted and the eMAC has a packet to transmit, the packet from the eMAC is transmitted after transmission of the pMAC packet completes.

99.4.2 Determining that the link partner supports preemption

The preemption capability is enabled in the transmit direction only if it is determined that the link partner supports the preemption capability.

The process of discovering the support for the preemption capability on the link partner relies on the exchange of the Additional Ethernet Capabilities TLV (see 79.3.7).

The preemption capability shall be enabled only if the link partner announces its support for the preemption capability via an Additional Ethernet Capabilities TLV in an LLDPDU addressed to the Nearest Bridge group address (see IEEE Std 802.1Q). The preemption capability shall be disabled if the MAC Merge sublayer receives indication of link failure.

NOTE—Indication of link failure to the MAC Merge sublayer is implementation dependent.

99.4.3 Verifying preemption operation

Verification (see Figure 99–3) checks that the link can support the preemption capability.

If verification is enabled, the preemption capability shall be active only after verification has completed successfully.

If the preemption capability is enabled but has not been verified yet, the MAC Merge sublayer initiates verification. Verification relies on the transmission of a verify mPacket and receipt of a respond mPacket to confirm that the remote station supports the preemption capability. The format of a verify mPacket and a

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

respond mPacket is as shown in part (a) of Figure 99–4, with the SMD values defined in Table 99–1 and an mData field containing 60 octets of 0x00.

When an mPacket with an SMD-V and a correct mCRC is received, a respond mPacket is sent. A respond mPacket has 7 octets of preamble (0x55), an SMD-R, 60 octets of 0x00, and an mCRC.

When an mPacket with an SMD-R and a correct mCRC is received, the preemption capability is verified.

Verification may be disabled. Verification disable is intended for engineered closed networks (i.e., where it is ensured by design that links can support preemption capability).

If verification is enabled, it shall be performed as specified in part (a) of Figure 99–8.

Respond shall be performed as in part (b) of Figure 99–8.

99.4.4 Transmit processing

Transmit processing (see Figure 99–3) receives packets from the eMAC and pMAC. Transmit processing preempts a preemptable packet when a MM_CTL.request primitive is received with a hold_req parameter value of HOLD or the eMAC has a packet to transmit if that can be done while meeting minimum mPacket mData field size. Therefore, preemption occurs only if at least 60 octets of the preemptable frame have been transmitted and at least 64 octets (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the addFragSize variable. Preemption does not occur until at least 64 × (1+ addFragSize) – 4 octets of the preemptable frame have been sent. The addFragSize variable is set to the value of the addFragSize field in the received Additional Ethernet Capabilities TLV (see 79.3.7).

Transmit processing includes a CRC generator to calculate an mCRC as specified in 99.3.6.

When the preemption capability is active, transmit processing replaces the SFD of a pMAC packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value. The SMD-E value is the same as the SFD value so the SFD of an eMAC packet does not need to be replaced.

When a packet is preempted, transmit processing appends the mCRC to the non-final mPackets. For the final mPacket of a preempted frame, the CRC field contains the CRC of the preempted MAC frame (the FCS field).

Transmit processing resumes transmission of the remainder of a preempted packet by sending preamble followed by an SMD-C and frag_count before continuing transmission of the packet. The SMD-C encodes the same frame count value as the SMD-S of the initial fragment.

Transmit processing shall be performed as specified in Figure 99–5.

If a PLS_CARRIER.indication is received from the PLS, PLS_CARRIER.indications with the same CARRIER_STATUS shall be sent to the pMAC and the eMAC.

99.4.5 Receive processing

Receive processing (see Figure 99–3) checks the SMD of each received mPacket. If an mPacket contains an SMD-E, Receive processing ignores the mPacket.

An SMD containing an SMD-S indicates the initial mPacket of a preemptable packet.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If an mPacket containing an SMD-S is received when Receive processing has not completed receiving the previous preempted packet, Receive processing shall ensure that the MAC detects a FrameCheckError in the partially received frame. This requirement may be met by producing a received frame data sequence delivered to the MAC sublayer that is guaranteed to not yield a valid CRC result, as specified by the frame check sequence algorithm (see 3.2.8). This data sequence may be produced by substituting data delivered to the MAC. It can do this by checking that the prior four octets sent to the MAC did not match the CRC of the data sent before them or by sending eight additional PLS_DATA.indication primitives to the pMAC or by implementation dependent means. Other techniques may be employed to respond to an incomplete packet provided that the result is that the MAC sublayer behaves as though a FrameCheckError occurred in the received frame.

When an SMD-S is detected, receive processing records the frame count indicated by the SMD. Receive processing sends an SFD to the pMAC in place of the SMD and then begins sending PLS_DATA.indication primitives to the pMAC.

Receive processing checks whether the last four octets of the mPacket match the mCRC. If the last four octets of the mPacket do not match, that indicates the end of the packet. The PLS_DATA.indications for the last four octets are sent to the pMAC followed by PLS_DATA_VALID.indication(DATA_NOT_VALID). If the last for octets of the mPacket match, that indicates that the packet was preempted and the PLS_DATA.indications for the last four octets are not sent to the pMAC. No further primitives are sent to the pMAC until the next mPacket of the packet is received.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet.

Upon receiving an SMD value of SMD-C, Receive processing checks that:

a) There is a preempted packet in progress,
b) The frame count indicated by the SMD matches the frame count of the packet in progress, and
c) The frag_count value indicates the next fragment count.

If any of the checks fail, the mPacket is discarded and Receive processing ensures that the pMAC detects a FrameCheckError as previously described. Then PLS_DATA_VALID.indication(DATA_NOT_VALID) is sent to the pMAC.

If all the checks pass, the next fragment count is incremented modulo 4 and the PLS_DATA.indications after the frag_count field are sent to the pMAC.

Receive processing handles the last four octets of the mPacket as previously described.

Receive processing shall be performed as specified in Figure 99–6.

PLS_SIGNAL.indication is never produced by Receive processing since it does not apply to full duplex PHYs.

99.4.6 Express filter

The Express filter (see Figure 99–3) checks the SMD of each received mPacket. If an mPacket contains an SMD-E, the Express filter passes the RS PLS_DATA.indication to the eMAC. If the SMD contains any other value, Express filter ignores the mPacket.

Express processing shall be performed as specified in Figure 99–7.

PLS_SIGNAL.indication is never produced by Express filter since it does not apply to full duplex PHYs.

99.4.7 Detailed functions and state diagrams

99.4.7.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

PLS service interface primitives are prefixed by a letter to designate the PLS service interface as follows:

— e PLS service interface between the eMAC and MAC Merge sublayer
— p PLS service interface between the pMAC and MAC Merge sublayer
— r PLS service interface between MAC Merge sublayer and RS

For example, ePLS_DATA.request is a PLS_DATA.request primitive from the eMAC.

99.4.7.2 Constants

minFrag
: the integer 64, the number of octets required for a minimum size fragment.

PREAMBLE
: 0x55

SFD
: 0xD5

verifyLimit
: the integer 3, the number of verification attempts

99.4.7.3 Variables

addFragSize
: An integer in the range 0:3 that controls the minimum non-final mPacket length, as specified in 99.4.4. Set to the value of the addFragSize field in the received Additional Ethernet Capabilities TLV (see 79.3.7).

begin
: Boolean variable that is set TRUE by implementation dependent means to initialize the state machines.

cFrameCnt
: An integer in the range 0:3 set by the SMD_DECODE function invoked on the SMD-C of a continuation packet that indicates the frame count of the continuation mPacket.

disableVerify
: Boolean variable that is set by management to control verification of preemption operation (see 99.4.3). TRUE disables verification and FALSE enables verification.

eTx
: Boolean variable that is TRUE when an ePLS_DATA.request has been received and a corresponding rPLS_DATA.request has not yet been generated. FALSE otherwise.

eTxCplt
: Boolean variable that is set TRUE when ePLS_DATA.request with the value DATA_COMPLETE is received and set FALSE when the end of frame has been processed.

keepSafterD
: Boolean variable that indicates whether an implementation is able to process the start of a

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

packet while discarding an errored packet. When an SMD-S is received while Receive processing is waiting for the next mPacket of a preempted packet, the preempted packet is discarded. The value TRUE indicates that an implementation is able to process the new packet when this occurs.

hold

Boolean variable that is set TRUE when MM_CTL.request is received with a hold_req parameter value of HOLD and FALSE when MM_CTL.request is received with a hold_req parameter value of RELEASE.

link_fail

Boolean variable that is TRUE when the MAC Merge sublayer receives indication of link failure. FALSE otherwise.

NOTE—Indication of link failure to the MAC Merge sublayer is implementation dependent.

rRxDv

Boolean variable that is set TRUE when rPLS_DATA_VALID.indication is received with the value DATA_VALID and set FALSE when rPLS_DATA_VALID.indication is received with the value DATA_NOT_VALID.

pActive

Boolean variable that is TRUE when the preemption capability is active and FALSE otherwise. The value of pActive is pEnable ∗ (verified + disableVerify).

pAllow

Boolean variable that is set to the value of pActive when SEND_SMD_S state is entered.

pEnable

Boolean variable that is set TRUE to enable the preemption capability and set FALSE to disable the preemption capability.

preempt

Boolean that is TRUE when a preemptable packet is to be preempted. The value of preempt is: pAllow ∗ (eTx + hold) ∗ preemptableFragSize ∗ MIN_REMAIN.

preemptableFragSize

Boolean variable that is TRUE when a enough bits of the current preemptable packet have been transmitted to allow it to be preempted. The value of preemptableFragSize is: fragSize ≥ (minFrag × (1 + addFragSize) – 4).

pTX

Boolean variable that is TRUE when a pPLS_DATA.request has been received and a corresponding rPLS_DATA.request has not yet been generated. FALSE otherwise.

pTxCplt

Boolean variable that is set TRUE when pPLS_DATA.request with the value DATA_COMPLETE is received and set FALSE when the end of packet has been processed.

rcv_r

Boolean that is set TRUE when an mPacket with SMD-R and a correct mCRC is received and set FALSE when the INIT_VERIFICATION state of the VERIFY state diagram is entered.

rcv_v

Boolean that is set TRUE when an mPacket with SMD-V and a correct mCRC is received and set FALSE when the INIT_VERIFICATION state of the VERIFY state diagram or the SEND_RESPOND state of the Respond state diagram is entered.

resumeTx

Boolean variable that is TRUE if a preemptable packet is waiting to resume transmission.

rxFragCnt

An integer in the range 0:4 set by the FRAG_DECODE function invoked on the frag_count of a continuation packet that indicates the fragment count of the continuation mPacket.

rxFrameCnt

An integer in the range 0:3 set by the SMD_DECODE function invoked on the SMD-S of a continuation packet that indicates the frame count of the initial mPacket.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

send_r
: Boolean that is set TRUE to initiate sending a respond mPacket and set FALSE when a respond mPacket is sent.

send_v
: Boolean that is set TRUE to initiate sending a verification mPacket and set FALSE when a verify mPacket is sent.

verified
: Boolean that is set TRUE when the ability of the link to support the preemption capability has been verified and FALSE when the INIT_VERIFICATION state of the VERIFY state diagram is entered.

verify_fail
: Boolean that is set TRUE when verification attempts have failed and FALSE when the INIT_VERIFICATION state of the VERIFY state diagram is entered.

verifyTime
: An integer in the range 1:128 used to configure the number of ms after which the verify_timer expires (see 99.4.7.6). The default value of verifyTime is 10.

99.4.7.4 Functions

For functions that produce primitives based on an 8-bit vector, a primitive value is ONE if the corresponding bit is 1 and ZERO if the corresponding bit is 0. The primitives are produced from bit 0 to bit 7 in sequence.

For functions that produce an 8-bit vector based on eight primitives, a bit is 1 if the corresponding primitive value is ONE and 0 if the corresponding primitive is ZERO. The primitives are mapped to bit 0 to bit 7 in sequence.

When the value of a vector is expressed as a hexadecimal number, the LSB corresponds to bit 0 and the MSB corresponds to bit 7.

DISCARD
: Ensures that the MAC detects a FrameCheckError in that frame (see 99.4.5) and then invokes pRX_DV(FALSE). Used when Receive processing detects that the packet cannot be continued after it was preempted.

eRX_DATA(data<7:0>)
: Produces eight ePLS_DATA.indication primitives based on the 8-bit vector data<7:0>.

eRX_DV(data_valid)
: Produces an ePLS_DATA_VALID.indication. If the Boolean parameter data_valid is TRUE, the primitive value is DATA_VALID. If data_valid is FALSE, the primitive value is DATA_NOT_VALID.

eTX_DATA
: Returns an 8-bit vector based on eight ePLS_DATA.request primitives.

FRAG_ENCODE(frag_cnt)
: Creates an 8-bit vector with the frag_count encoding for a fragment count of frag_cnt (see Table 99–2). Produces eight rPLS_DATA.request primitives based on the 8-bit vector.

FRAG_DECODE
: Decodes eight rPLS_DATA.indication primitives by producing an 8-bit vector and comparing it to encoded frag_count values (see Table 99–2). If frag_count contains a valid value, places the fragment count decoded in rxFragCnt. Otherwise, it sets rxFragCnt to 4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

MIN_REMAIN

Prescient function to check if enough octets of the current pMAC packet remain meet the minimum fragment requirement after preemption. Produces a Boolean value as follows:

TRUE ≥ minFrag octets are left to transmit
FALSE Otherwise

rRX_DATA

Returns an 8-bit vector based on eight rPLS_DATA.indication primitives.

rTX_CPLT

Produces an rPLS_DATA.request primitive with the value DATA_COMPLETE.

rTX_DATA(data<7:0>)

Produces eight rPLS_DATA.request primitives based on the 8-bit vector data<7:0>.

pRX_DATA(data<7:0>)

Produces eight pPLS_DATA.indication primitives based on the 8-bit vector data<7:0>.

pRX_DV(data_valid)

Produces a pPLS_DATA_VALID.indication. If the Boolean parameter data_valid is TRUE, the primitive value is DATA_VALID. If data_valid is FALSE, the primitive value is DATA_NOT_VALID.

pTX_DATA

Returns an 8-bit vector based on eight pPLS_DATA.request primitives.

RX_MCRC_CK

Prescient function returning a Boolean value. The value is TRUE if rPLS_DATA_VALID.indication with a value of DATA_NOT_VALID will be received after the next 32 rPLS_DATA.indication primitives and the next 32 rPLS_DATA.indications equal the computed mCRC result for the preemptable packet being received. It is FALSE otherwise.

SFD_DET

Prescient function returning a Boolean value. The value is TRUE if an 8-bit vector produced from the next eight pPLS_DATA.request primitives contains an SFD.

SMD_DECODE

Decodes the value of 8 rPLS_DATA.indication primitives by producing an 8-bit vector and returning one of the following values based on the value of the vector (see Table 99–1):

Preamble 0x55
E SMD-E encoding
S SMD-S encoding
C SMD-C encoding
V SMD-V encoding
R SMD-R encoding
ERR Any other value - error.

If S is returned, the function sets rxFrameCnt equal to the frame count indicated by the SMD-S. If C is returned, the function sets cFrameCnt equal to the frame count indicated by the SMD-C.

SMDC_ENCODE(frame_cnt)

Creates an 8-bit vector with the SMD encoding for an SMD-C with frame count of frame_cnt. Produces eight rPLS_DATA.request primitives based on the 8-bit vector.

SMDS_ENCODE(frame_cnt)

Returns an 8-bit vector with the SMD encoding for an SMD-S with frame count of frame_cnt if pAllow is TRUE. Otherwise it returns a vector containing 0xD5 (i.e., SFD). Consumes 8 pPLS_DATA.request primitives containing the SFD.

TX_MCRC

Produces 32 rPLS_DATA.requests that transmit the mCRC computation for the mPacket.

TX_R

Produces 576 rPLS_DATA.requests to send a respond mPacket: 7 octets of 0x55, 1 octet SMD-R, 60 octets of 0x00, mCRC followed by an rPLS_DATA.request with the value DATA_COMPLETE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TX_V
: Produces 576 rPLS_DATA.requests to send a verify mPacket: 7 octets of 0x55, 1 octet SMD-V, 60 octets of 0x00, mCRC followed by an rPLS_DATA.request with the value DATA_COMPLETE.

99.4.7.5 Counters

fragSize
: a count of the number of octets of mData transmitted in the current preemptable mPacket.

nxtRxFrag
: a modulo-4 counter containing the next expected fragment count for the next incoming continuation packet.

preambleCnt
: a count of the number of preamble octets sent for a continuation fragment.

txFrag
: a modulo-4 counter containing the fragment count for the next outgoing continuation mPacket.

txFrame
: a modulo-4 counter containing the frame count for the next outgoing preemptable packet.

verifyCnt
: a count of the number of verification attempts that have completed.

99.4.7.6 Timers

ipg_timer
: A timer counting bit times since the end of the prior packet. The timer expires 96 bit times after being started.

verify_timer
: A timer of time from when a verification mPacket was sent to initiating the next attempt. The timer expires verifyTime ms ± 20% after being started.

99.4.7.7 State diagrams

The Transmit Processing state diagram is shown in Figure 99–5. The Receive Processing state diagram is shown in Figure 99–6. The Express Filter state diagram is shown in Figure 99–7. The Verify state diagram and Respond state diagram are shown in Figure 99–8.

99.4.8 Delay Constraints

Predictable operation for time sensitive traffic (e.g., IEEE Std 802.1Q, Clause 31, Annex 31D PFC operation) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

If the preemption capability is active, transmission of preemptable traffic shall be preempted within the hold response time (HRT) after the MAC Client sends MM_CTL.request with a hold_req parameter value of HOLD. HRT is (1240 + 512 × addFragSize) bit times.

When preemptable traffic is held by an MM_CTL.request with a hold_req parameter value of HOLD sent by the MAC Client at least HRT before the MA_DATA.request, the maximum cumulative MAC Control, MAC, MAC Merge sublayer and RS delay for an express packet shall meet the delay specified for a MAC Control, MAC and RS delay based on the MAC operating speed.

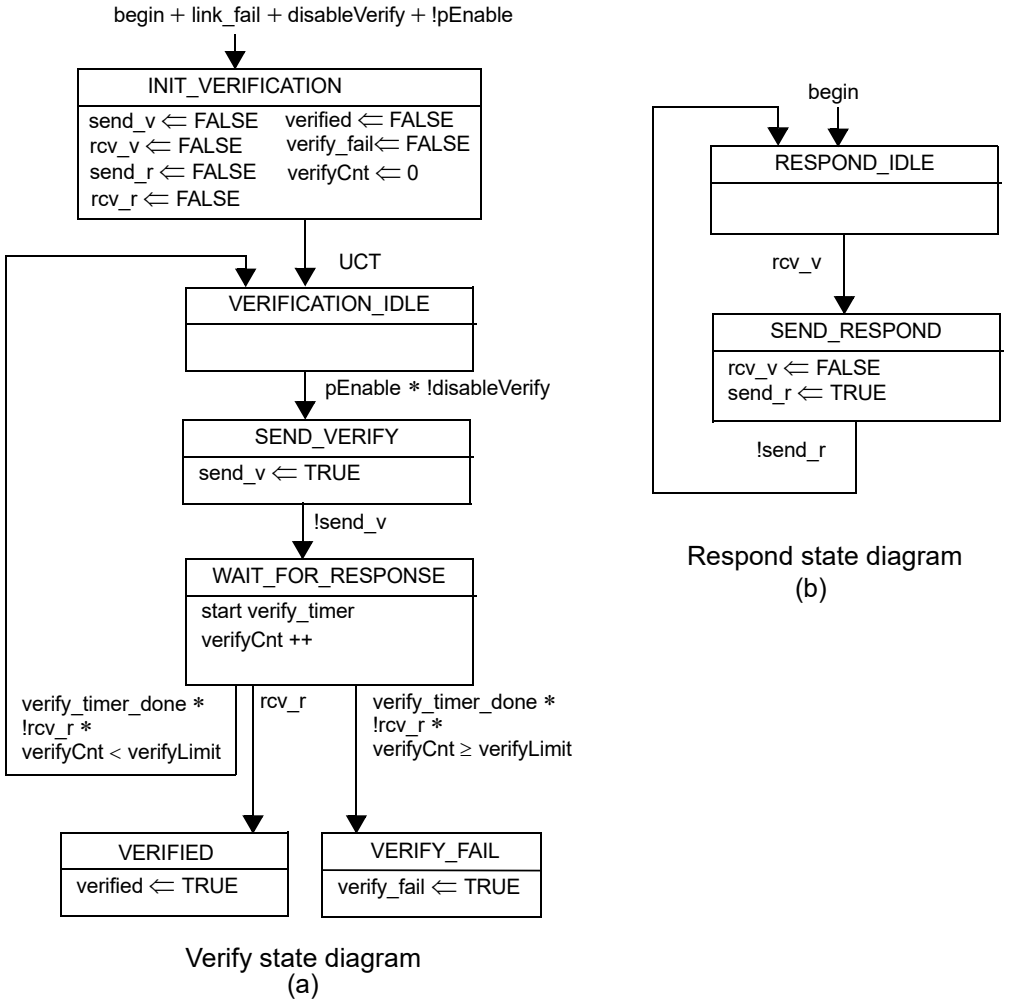

Figure 99–8—Verify state diagram (a) and Respond state diagram (b)

When preemption is active and preemptable traffic is not held by an MM_CTL.request with a hold_req parameter value of HOLD sent by the MAC Client at least HRT before the MA_DATA.request, the maximum cumulative MAC Control, MAC, MAC Merge sublayer, and RS delay for an express packet shall meet the delay specified for a MAC Control, MAC and RS delay based on the MAC operating speed delay plus HRT.

When preemptable traffic is released by an MM_CTL.request with a hold_req parameter value of RELEASE sent by the MAC Client at least 96 bit times before the MA_DATA.request and no express packets are being sent, the maximum cumulative MAC Control, MAC, MAC Merge sublayer, and RS delay for a preemptable packets shall meet the delay specified for a MAC Control, MAC and RS delay based on the MAC operating speed.

99.5 Protocol implementation conformance statement (PICS) proforma for Clause 99, MAC Merge sublayer[172]

99.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 99, MAC Merge sublayer, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

99.5.2 Identification

99.5.2.1 Implementation identification

Supplier[1]	
Contact point for enquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

99.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 99, MAC Merge sublayer
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[172]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

100. Physical Medium Dependent (PMD) sublayer, and medium for coaxial distribution networks, type 10GPASS-XR

100.1 Overview

This clause describes the Physical Medium Dependent (PMD) sublayer for EPON Protocol over Coax (EPoC) PHYs operating at the line rate of up to 10 Gb/s in the downstream direction and up to 1.6 Gb/s in the upstream direction.

100.1.1 Terminology and conventions

EPoC operates over a point-to-multipoint (P2MP) topology composed of passive segments of coaxial media and passive taps/couplers, optionally interconnected with active coaxial amplifiers, and/or analog optical links creating a tree-and-branch topology.

The device connected at the root of the tree is called a Coaxial Line Terminal (CLT) and the devices connected as the leaves are referred to as Coaxial Network Units (CNUs). The direction of transmission from the CLT to CNUs is referred to as the *downstream direction*, while the direction of transmission from CNUs to the CLT is referred to as the *upstream direction*.

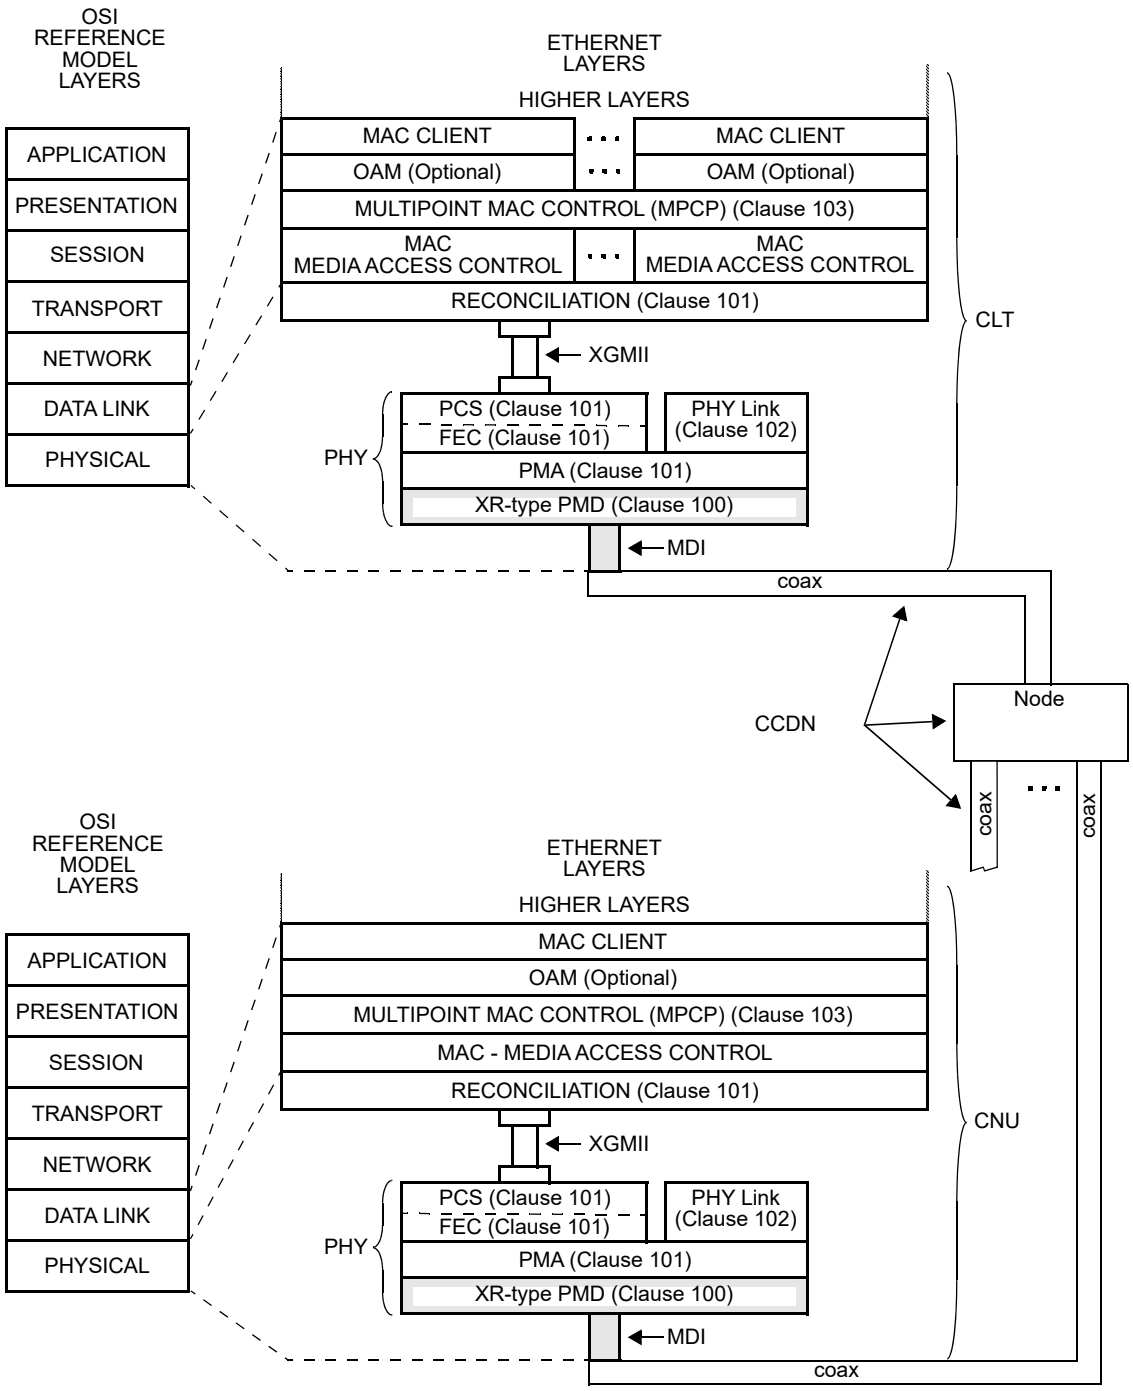
Unless otherwise noted, the notation $\lceil x \rceil$ represents a *ceiling* function, which returns the value of its argument x rounded up to the nearest integer.

The notation $\lfloor x \rfloor$ represents a *floor* function, which returns the value of its argument x rounded down to the nearest integer.

100.1.2 Positioning of the PMD sublayer within the IEEE 802.3 architecture

Figure 100–1 depicts the relationships of the asymmetric-rate EPoC PMD sublayer (shown hatched) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

100.1.3 PMD types



In the downstream direction, the signal transmitted by the 10GPASS-XR-D type PMD is received by all 10GPASS-XR-U type PMDs. In the upstream direction, the 10GPASS-XR-D type PMD receives data bursts from each of the 10GPASS-XR-U type PMDs. The 10GPASS-XR-D and 10GPASS-XR-U PMDs both have a variable rate that is determined when configured. See Equation (100–1) and Equation (100–2) for additional information on the 10GPASS-XR-D and 10GPASS-XR-U data rates, respectively. See 102.4.3 for "reset on change" events that may affect rate calculations.

The asymmetric-rate 10GPASS-XR-D type PMD, transmitting in continuous mode and receiving in burst mode, is defined in this clause, with downstream data rate calculation in 100.3.2.1. The asymmetric-rate 10GPASS-XR-U type PMD, transmitting in burst mode and receiving in continuous mode, is defined in this clause, with upstream data rate calculation in 100.3.2.2. The data rate of a 10GPASS-XR PHY is dependent on network configuration.

100.1.4 Mapping of PMD variables

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the 10GPASS-XR PHY or are communicated between the CLT and the CNU via the PHY Link. The mapping of MDIO control and status variables to PMD variables is shown in Table 100–1. The least significant bit in each variable is mapped to the lowest numbered bit in the lowest numbered register for Clause 45 registers. These variables are used by the PHY Link for PHY management.

100.2 PMD functional specification

The 10GPASS-XR type PMDs perform the transmit and receive functions that convey data between the PMD service interface and the MDI. PMD functions are implementation-dependent and include digital-to-analog conversion, analog-to-digital conversion, interpolation, analog filtering, frequency conversion, and/or RF power amplification.

100.2.1 PMD service interface

The following specifies the services provided by Clause 100 PMDs. The service interface is described in an abstract manner and does not imply any particular implementation.

The PMD service interface supports the exchange of a continuous stream of OFDM/OFDMA time domain sampled waveform between the PMA and PMD entities. The samples are encoded as complex numbers, i.e., I/Q value pairs.

The PMD translates data received from the compatible PMA to and from signals suitable for the specified coaxial medium. The following primitives are defined:

— PMD_UNITDATA.request
— PMD_UNITDATA.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— PMD_SIGNAL.request

100.2.1.1 PMD_UNITDATA.request

This primitive defines the transfer of one modulated symbol encoded as an I/Q value pair from the Clause 101 PMA to the Clause 100 PMD.

The semantics of the service primitive are PMD_UNITDATA.request(*I_value*, *Q_value*, *ChNum*). The data conveyed by PMD_UNITDATA.request is a continuous stream of I/Q value pairs and target OFDM channel. Both *I_value* and *Q_value* are encoded as 32-bit signed integers. *ChNum* indicates the applicable channel.

The Clause 101 PMA continuously sends the stream of I/Q value pairs and OFDM channel number to the Clause 100 PMD for transmission on the medium, at the nominal rate of 204.8 million samples per second (Msps). Upon the receipt of this primitive, the PMD converts the received appropriately formatted I/Q value pairs into the appropriate signals at the MDI, effectively sending data across the coaxial media.

100.2.1.2 PMD_UNITDATA.indication

This primitive defines the transfer of I/Q value pair data from the Clause 100 PMD to the Clause 101 PMA.

The semantics of the service primitive are PMD_UNITDATA.indication(*I_value*, *Q_value, ChNum*). The data conveyed by PMD_UNITDATA.indication is a continuous stream of I/Q value pairs and received OFDM channel. Both *I_value* and *Q_value* are encoded as 32-bit signed integers. *ChNum* indicates the applicable channel.

The Clause 100 PMD continuously sends an appropriately formatted stream of I/Q value pairs and OFDM channel number to the Clause 101 PMA corresponding to the signals received from the MDI, at the nominal rate of 204.8 Msps.

100.2.1.3 PMD_SIGNAL.request

The semantics of the service primitive are PMD_SIGNAL.request(*Tx_Enable*). The *Tx_Enable* parameter can take on one of the following two values: ON or OFF, determining whether the PMD transmitter is on (enabled) or off (disabled). The Clause 101 PCS generates this primitive to indicate a change in the value of *Tx_Enable* parameter. Upon the receipt of this primitive, the Clause 100 PMD turns the transmitter on or off as appropriate.

As input to the PMD, PMD_SIGNAL.request is the OR product of the signal from PCS data detector (see 101.3.2.5.1) with that from the PHY Link (see 102.3.1.3) signaling RF power amplifier turn on to the PMD; either the PCS data detector or the PHY Link may signal ON. When both the PCS and the PHY Link set the value to OFF, this signals RF power amplifier turn off to the PMD.

100.2.2 Delay constraints

The PMD shall introduce a transmit delay variation of no more than 0.5 time_quanta, and a receive delay variation of no more than 0.5 time_quanta. A description for the time_quantum can be found in 77.2.2.1.

100.2.3 PMD transmit function

The PMD Transmit function conveys the I/Q value pairs requested by the PMD service interface message PMD_UNITDATA.request(*I_value, Q_value, ChNum*) to the MDI according to the PMD to MDI RF specifications in 100.3.3 and 100.3.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the upstream direction, the flow of appropriately formatted stream of I/Q value pairs is interrupted according to PMD_SIGNAL.request(*Tx_Enable*).

100.2.4 PMD receive function

The PMD Receive function conveys the bits received from the MDI to the PMD service interface using the message PMD_UNITDATA.indication(*I_value, Q_value*), creating appropriately formatted stream of I/Q value pairs and OFDM channel information.

100.2.5 PMD transmit enable function

The PMD_SIGNAL.request(*Tx_Enable*) message is defined for the CNU PMD specified in this clause. The PMD_SIGNAL.request(*Tx_Enable*) message is asserted prior to data transmission by the CNU PMDs. Note PMD_SIGNAL.request(*Tx_Enable*) message is not defined for the CLT; CLT PMD data transmission is always enabled.

100.3 PMD operational requirements

100.3.1 CLT and CNU modulation formats

The CLT and CNU transmitters and receivers shall support the mandatory modulation formats as specified in Table 100–2.

Table 100–2—Modulation formats

Modulation format[a]	MAC data path		PHY Link data path	
	CLT Tx CNU Rx	CNU Tx CLT Rx	CLT Tx CNU Rx	CNU Tx CLT Rx
BPSK[b]	M	M	M	M
QPSK	N/S	M[c]	N/S	N/S
8-QAM	O	M[c]	N/S	N/S
16-QAM	O	M	M	M
32-QAM	O	M	N/S	M
64-QAM	M	M	N/S	M
128-QAM	M	M	N/S	M
256-QAM	M	M	N/S	N/S
512-QAM	M	M	N/S	N/S
1024-QAM	M	M	N/S	N/S
2048-QAM	M	O	N/S	N/S
4096-QAM	M	O	N/S	N/S
8192-QAM	O	N/S	N/S	N/S
16384-QAM	O	N/S	N/S	N/S

[a] M = mandatory, O = optional, N/S = not supported.
[b] Used for pilots, burst markers, preambles, and probes.
[c] This modulation format is required only for low density pilots.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

See 102.2.1.2 and 102.3.1.2, respectively, for a description of downstream and upstream PHY Link modulation.

The CNU reports supported optional modulations to the CLT via *US_ModAbility* variable see 101.4.4.4.4.

100.3.2 Data rates

In baseline channel conditions, as defined in Annex 100A, a 192 MHz OFDM channel supports a data rate of at least 1.6 Gb/s at the MAC/PLS interface. The MAC date rate scales linearly with the number of OFDM channels, for the same baseline channel conditions in the upstream OFDMA channel and each downstream OFDM channel.

100.3.2.1 Downstream PHY data rate

The CLT calculates the downstream PMA data rate after any configuration update that changes the downstream profile descriptor variables *DS_ModTypeSC(n)* or for any change to the cyclic prefix size *DSNcp*. See 101.4.3.4.5 and 101.4.3.12.1. Specifically after any configuration change and after the continuous and scattered pilot map has been updated (see 101.4.3.6), the CLT shall update the value of the variable *DS_DataRate*.

The downstream PMA OFDM superframe repeats every 128 symbols. The superframe length is determined using the *DS_Extended_OFDM_Symbol* based on size of the selected cyclic prefix.

$$DS_Frame_Length = 128 \times DS_Extended\ OFDM\ Symbol\ (\mu s)$$

$$DS_Extended_OFDM_Symbol = 20 + DSNcp\ (\text{downstream})\ (\mu s)$$

The downstream OFDM frame data load (bits) is a summation over all active downstream OFDM channels, as defined by *DS_ChCnt*, over 128 symbols, the summation of bit per subcarrier for all active subcarriers (subcarriers that are not configured as excluded are active subcarriers).

$$DS_Frame_Data_Load = \sum_{c=1}^{DS_ChCnt} \text{active channel}_c \left(\sum_{s=1}^{128} \text{symbol}_s \left(\sum_{sc=0}^{4095} \text{bits per symbol}_{sc} \right) \right)$$

PHY Link, excluded, and unused subcarriers and continuous and scattered pilots are skipped. Note that in the definition of *DS_ModTypeSC(n)* the values binary 0011 (3 decimal) through 1110 (14 decimal) directly represent the number of data bits per active subcarrier (see 101.4.3.4.5).

DS_Frame_Data_Load has the same value every downstream OFDM frame, therefore *DS_DataRate* remains the same for any given downstream profile descriptor configuration as shown in Equation (100–1):

$$DS_DataRate = DS_Frame_Data_Load / DS_Frame_Length\ (\text{b/s}) \qquad (100\text{–}1)$$

Equation (100–1) establishes nominal data rate for CLT PMA_UNITDATA.request service interface.

Based on the current profile, the CLT calculates *DS_DateRate* and communicates this to the CNU. The CNU also calculates *DS_DataRate* based on the configured profile. If the CNU calculation differs from the CLT value by more than 10 b/s, the CNU sets *DS_RateMatchFail* to TRUE indicating mismatch; otherwise it is set to FALSE.

100.3.2.2 Upstream PHY data rate

The CLT calculates the upstream PMA data rate after any configuration update that changes the upstream profile descriptor variables *US_ModTypeSC(n)* or for any change to the cyclic prefix size *USNcp*. See 101.4.4.4.4 and 101.4.4.10.1. Specifically after any configuration change and after the Type I and Type II pilot map has been updated (see 101.4.4.6), the CLT shall update the value of the variable *US_DataRate*.

The upstream PMA RB Superframe repeats every 256 + 6 symbols, where the Probe region is 6 symbols in length. The superframe length is determined using the *US_Extended_OFDM_Symbol* based on size of the selected cyclic prefix size (μs).

$$US_Frame_Length = (256 + 6) \times US_Extended\ OFDM\ Symbol \ (\mu s)$$

$$US_Extended_OFDM_Symbol = 20 + USNcp \ (\mu s)$$

The upstream OFDM frame data load (bits) is a summation over the 256 symbols, the summation of bits per Resource Element. For a low density type "L" pilot Resource Element, the value is the *US_ModTypeSC(n)* value minus 4 (decimal) or 1, whichever is higher. The probe region symbols are not included in this summation.

$$US_Frame_Data_Load = \sum_{s=1}^{256} \text{symbol}_s \left(\sum_{RE=0}^{4095} \text{resource element}_{RE} \right)$$

PHY Link, excluded, and unused subcarriers and type "P" pilot Resource Elements are skipped. Note that in the definition of *US_ModTypeSC(n)* the values binary 0011 (3 decimal) through 1110 (14 decimal) directly represent the number of data bits per active subcarrier (see 101.4.4.4.4).

A Resource Element is a single subcarrier over the duration of a single symbol. A Resource Block is a group of 8 or 16 adjacent Resource Elements in the same subcarrier as defined by the variable *RBsize* (see 101.4.4.3.1).

US_Frame_Data_Load has the same value every upstream RB Superframe; therefore, *US_DataRate* remains the same for any given upstream profile descriptor configuration as shown in Equation (100–2):

$$US_DataRate = US_Frame_Data_Load / US_Frame_Length \ (\text{b/s}) \qquad (100–2)$$

Note that *US_DataRate* does not include PCS or burst marker overheads.

This establishes nominal data rate for CLT PMA_UNITDATA.request service interface and also serves as the negotiated upstream PHY data rate for each CNU.

Based on the current profile, the CLT calculates *US_DateRate* and communicates this to the CNU. The CNU also calculates *US_DataRate* based on the configured profile. If the CNU calculation differs from the CLT value by more than 10 b/s, the CNU sets *US_RateMatchFail* to TRUE indicating mismatch; otherwise it is set to FALSE.

100.3.2.3 PHY Link managed variables

DS_ChCnt

TYPE: 3-bit unsigned integer

This variable indicates the number of downstream OFDM channels in use. The value of *DS_ChCnt* is between 1 and 5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

DS_DataRate

TYPE: UQ34.3 format

This variable indicates the downstream data rate in units of b/s and is calculated as shown in Equation (100–1).

DS_FreqCh(n)

TYPE: 16-bit unsigned integer

This variable specifies the center frequency, in units of 50 kHz, of subcarrier 0 for the downstream OFDM channel n ($1 \le n \le 5$). Subcarriers are numbered from 0 to 4095 with subcarrier 0 at the lowest frequency. This definition equates to a subcarrier 0 center frequency of 54 MHz to 3276.75 MHz. The minimum value for this register is 1080. See Table 100–3 for additional details.

DS_RateMatchFail

TYPE: Boolean

This variable is set to TRUE if the CNU calculation of *DS_DataRate* differs from the *DS_DataRate* calculation communicated from the CLT by more than 10 b/s; otherwise, the variable is set to FALSE.

US_DataRate

TYPE: UQ34.3 format

This variable indicates the upstream data rate in units of b/s and is calculated as shown in Equation (100–2).

US_FreqCh1

TYPE: 16-bit unsigned integer

This variable specifies the center frequency, in units of 50 kHz, of subcarrier 0 for the upstream OFDMA channel. Subcarriers are numbered from 0 to 4095 with subcarrier 0 at the lowest frequency. This definition equates to a subcarrier 0 center frequency of 0 MHz to 3276.75 MHz. The minimum value for this register is 148 to accommodate starting at 7.4 MHz. See Table 100–11 for additional details.

US_RateMatchFail

TYPE: Boolean

This variable is set to TRUE if the CNU calculation of *US_DataRate* differs from the *US_DataRate* calculation communicated from the CLT by more than 10 b/s; otherwise, the variable is set to FALSE.

100.3.3 CLT transmitter requirements

100.3.3.1 OFDM channel power definitions

This subclause defines the terms and concepts used when specifying the CLT RF output requirements. For an OFDM channel there is a) the number of equivalent 6 MHz channels (*Neq*), b) the encompassed spectrum, c) the modulated spectrum, and d) the number of active equivalent 6 MHz channels (*Neq*').

The number of equivalent 6 MHz channels, *Neq*, is constant and calculated for a single OFDM channel size of 192 MHz as follows: 192/6 = 32.

Neqport at the MDI is the sum of the individual *Neq* of each OFDM channel.

The total number of OFDM channels, *NOFDM* is 5. Thus, *Neqport* is 5 × 32 = 160.

The encompassed spectrum is the difference between a) the center frequency of the highest frequency active subcarrier of the highest frequency OFDM channel and b) the center frequency of the lowest frequency active subcarrier of the lowest frequency OFDM channel, plus the subcarrier spacing of 0.05 MHz (all

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

expressed in MHz). The encompassed spectrum of a single OFDM channel is the difference between the center frequency of the highest frequency active subcarrier and the center frequency of the lowest frequency active subcarrier in the OFDM channel, plus the subcarrier spacing.

Occupied spectrum (*Occupiedspectrum*) as shown in Equation (100–3) is the accumulation of the bandwidth (RF spectrum) in all channel frequency allocations (e.g., 6 MHz *channelsize*) that are occupied by the OFDM channel (*OFDMchannelbandwidth*).

$$Occupiedspectrum = channelsize \times \lceil OFDMchannelbandwidth / channelsize \rceil \quad (100–3)$$

The occupied spectrum is a multiple of 6 MHz and consists of all 6 MHz channels that are included in the encompassed spectrum, plus the taper region shaped by the OFDM channels' transmit windowing; the out-of-band spurious emissions requirements in 100.3.3.5 (except for interior exclusion band spurious emissions requirements) apply outside the occupied spectrum. With a 1 MHz taper region on each band edge of the OFDM channel, shaped by the transmit windowing function, an encompassed spectrum of 190 MHz of active subcarriers has 192 MHz of occupied spectrum.

An exclusion band is a contiguous block of excluded spectrum that is 1 MHz wide or greater. An individually excluded subcarrier is any excluded subcarrier in a contiguous block of excluded spectrum less than 1 MHz.

The modulated spectrum of a single OFDM channel is the encompassed spectrum minus the total spectrum in the internal excluded subbands of the OFDM channel, where the total spectrum in the internal excluded subbands is equal to the number of subcarriers in all of the internal excluded subbands of the OFDM channel multiplied by the subcarrier spacing of the OFDM channel. For example, with 190 MHz encompassed spectrum, if there are 188 subcarriers total in three internal exclusion subbands, then the total spectrum in the internal excluded subbands (in MHz) is $188 \times 0.05 = 9.4$ MHz, and the modulated spectrum is 190 MHz – 9.4 MHz = 180.6 MHz.

The modulated spectrum at the MDI (TP1, see 100.4) is the sum of the modulated spectrum of each OFDM channel.

The number of active equivalent 6 MHz channels, *Neq'*, for an OFDM channel is a function of the modulated spectrum (MHz) of a channel as calculated in Equation (100–4).

$$Neq' = \lceil modulated\ spectrum\ of\ a\ single\ channel / channelsize \rceil \quad (100–4)$$

Neqport' at the MDI is the sum of the *Neq*' of each OFDM channel.

The CLT shall comply with all CLT transmitter requirements (see 100.3.3) operating with all *Neqport* channels on the MDI and with all requirements for the device operating with *Neqport*' active channels on the MDI for all values of *Neqport*' less than *Neqport*.

100.3.3.2 CLT output electrical requirements

For OFDM, all modulated subcarriers in an OFDM channel are set to the same average power (except pilots that are boosted by 6 dB). For the purposes of meeting spurious emissions requirements, for each OFDM channel:

— Configure the OFDM channel power using the commanded average power of an equivalent 6 MHz channel for the first OFDM channel, which is *DS_PowerCh*(1) (see Table 100–5) as follows:

  —CLT calculates power for data subcarrier and pilots using the subcarriers in the 6 MHz band centered on the PHY Link.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The configured average power of an equivalent 6 MHz channel for the first OFDM channel is defined as the power for the 6 MHz band centered on the PHY Link.

— For the second OFDM channel, let X dB be the commanded average power of an equivalent 6 MHz channel for the second OFDM channel minus commanded average power of an equivalent 6 MHz channel for the first OFDM channel; i.e., $X \text{ dB} = DS_PowerCh(2) - DS_PowerCh(1)$. Then set the data subcarrier power for the second channel equal to data subcarrier power for the first channel plus X dB.

— Data subcarrier power for the third, fourth, and fifth OFDM channels are computed relative to the first OFDM channel in the same fashion.

A CLT shall output an OFDM RF modulated signal with the characteristics defined in Table 100–3, Table 100–5, and Table 100–6. These requirements are to be met under the conditions where the configured average power of an equivalent 6 MHz channel is the same for each OFDM channel, with the exception of the following: single channel active phase noise, diagnostic carrier suppression, OFDM phase noise, OFDM diagnostic suppression, and power difference requirements, and as described for out-of-band noise and spurious requirements.

Table 100–3—CLT RF output requirements

Parameter	Value	Units
Downstream 10.24 MHz Master Clock frequency	10.24	MHz
Frequency band	258 to 1218	MHz
OFDM channel bandwidth (*OFDMchannelbandwidth*)	24 to 192	MHz
Encompassed spectrum	22 to 190	MHz
Subcarrier spacing	50	kHz
OFDM symbol rate FFT duration	20	μs
FFT size	4096	FFT bins
Maximum number of active subcarriers per FFT	3800	subcarriers
Level	See Table 100–5	
Modulation format	See Table 100–2	
Transmit MUTE when TRUE.[a] See 100.4.1.	≥ 73	dBc
Inband spurious, distortion, and noise[d]		
For measurements below 600 MHz[a]	≤ –50	dBr
For measurements from 600 MHz to 1002 MHz[a]	≤ –47	dBr
For measurements 1002 MHz to 1218 MHz[b]	≤ –45	dBr
MER in 192 MHz OFDM channel occupied spectrum 528 MHz total occupied spectrum, 88 equivalent 6 MHz channels[c, d, e, f, g]		
For measurements below 600 MHz:		
Any single subcarrier	≥ 48	dB
Average over the complete OFDM channel[h]	≥ 50	dB
For measurements from 600 MHz to 1002 MHz:

Table 100–3—CLT RF output requirements *(continued)*

Parameter	Value	Units
Any single subcarrier	≥ 45	dB
Average over the complete OFDM channel[g]	≥ 47	dB
For measurements 1002 MHz to 1218 MHz:		
Any single subcarrier	≥ 43	dB
Average over the complete OFDM channel[g]	≥ 45	dB
MER in 24 MHz OFDM channel occupied spectrum, single OFDM channel only, 24 MHz total occupied spectrum.[b, c, d, i] Average over the complete OFDM channel:		
For measurements below 600 MHz	≥ 48	dB
For measurements from 600 MHz to 1002 MHz	≥ 45	dB
For measurements 1002 MHz to 1218 MHz	≥ 43	dB
Output impedance	75	Ω
Output return loss. Specified for within an active output OFDM channel or in every inactive OFDM channel as noted.		
88 MHz to 750 MHz; active	> 14	dB
750 MHz to 870 MHz; active	> 13	dB
870 MHz to 1218 MHz; active	> 12	dB
54 MHz to 870 MHz; inactive	> 12	dB
870 MHz to 1218 MHz; inactive	> 10	dB
MDI Connector	F connector per ISO/IEC-61169-24 or SCTE 02	

[a]RF output power below the operationally configured aggregate power of the RF modulated signal, in every 6 MHz channel from 258 MHz to 1218 MHz.
[b]Average over center 400 kHz subcarriers within gap.
[c]Receiver OFDM channel estimation is applied in the test receiver; test receiver does best estimation possible. Transmit windowing is applied to potentially interfering channel and selected to be sufficient to suppress cross channel interference.
[d]Modulation error ratio (MER) is determined by the cluster variance caused by the transmit waveform at the output of the ideal receive matched filter. MER includes all discrete spurious, noise, subcarrier leakage, clock lines, synthesizer products, distortion, and other undesired transmitter products. Phase noise up to ± 50 kHz of the subcarrier's center frequencies is excluded from inband specification, to separate the phase noise and inband spurious requirements as much as possible. In measuring MER, record length or carrier tracking loop bandwidth may be adjusted to exclude low-frequency phase noise from the measurement. MER requirements assume measuring with a calibrated test instrument with its residual MER contribution removed.
[e]Phase noise up to 10 MHz offset is mitigated in test receiver processing or by test equipment (latter using hardline carrier from modulator, which requires special modulator test port and functionality).
[f] Up to five subcarriers in one OFDM channel can be excluded from this requirement.
[g] When the estimated channel impulse response used by the test receiver is limited to half of length of smallest transmit cyclic prefix then there is a 2 dB relief for above requirements (e.g., MER > 48 dB becomes MER > 46 dB).
[h]See 100.4.2 for average MER calculation method.
[i]A single subcarrier in the OFDM channel can be excluded from this requirement, no windowing is applied and minimum CP is selected.

100.3.3.2.1 PHY Link managed variables

DS_PowerCh(n)

TYPE: 9-bit unsigned integer.
This variable specifies the downstream CLT transmit power, in units of 0.2 dBmV/6 MHz, for OFDM channel n ($1 \le n \le 5$). The value is set according to the requirements in Table 100–5.

100.3.3.3 Phase noise requirements

The CLT transmitted signal for each OFDM channel shall meet the phase noise requirements as per Table 100–4.

Table 100–4—Downstream phase noise requirements

Parameter	Value	Units
Phase noise, integrated double-sided maximum, 1002 MHz or lower:		
1 kHz to 10 kHz	–48	dBc
10 kHz to 100 kHz	–56	dBc
100 kHz to 1 MHz	–60	dBc
1 MHz to 10 MHz	–54	dBc
10 MHz to 100 MHz	–60	dBc

100.3.3.4 Power per OFDM channel for CLT

The CLT shall adjust the RF transmit power per Table 100–5. In Table 100–5 the value for N^*, the adjusted number of active channels combined per MDI, is calculated using Equation (100–5).

$$\text{If } \left(Neqport' < \frac{Neqport}{4}\right) \text{ then } \left(N^* = \text{minimum}\left(4Neqport', \left\lceil \frac{Neqport}{4} \right\rceil\right)\right)$$
$$\text{If } \left(Neqport' \ge \frac{Neqport}{4}\right) \text{ then } (N^* = Neqport') \quad (100\text{–}5)$$

The applicable maximum power per OFDM channel and spurious emissions requirements are defined for the CLT using the value of N^* per Equation (100–5).

Table 100–5—CLT RF output power requirements

Parameter	Value[a,b,c]	Units
Maximum value of OFDM channel power in the OFDM channel occupied spectrum normalized to 6 MHz ((OFDM signal power/occupied spectrum) × 6 MHz:		
Neqport' OFDM channels combined onto a single MDI for *Neqport*' ≥ *Neqport*/4	$60 - \lceil 3.6 \times \log_2(N^*) \rceil$ [d]	dBmV/6 MHz
Neqport' OFDM channels combined onto a single MDI for 4 ≤ *Neqport*' < *Neqport*/4[c]	$60 - \lceil 3.6 \times \log_2(N^*) \rceil$ [d]	dBmV/6 MHz

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 100–5—CLT RF output power requirements *(continued)*

Parameter	Value[a,b,c]	Units
Range of commanded transmit power for each OFDM channel, at least 8 dB below the required power level specified above, maintaining full fidelity over the range	≥ 8	dB
Commanded power per OFDM channel step size. Strictly monotonic.	≤ 0.2	dB
Power difference between any two adjacent OFDM channels in the 108 MHz to 1218 MHz downstream spectrum[e]	≤ 0.5	dB
Power difference (normalized for bandwidth) between any two channels' OFDM channel blocks in the 108 MHz to 1218 MHz downstream spectrum[e]	≤ 2	dB
Power per channel absolute accuracy	± 2	dB

[a]Add 3 dB relaxation to the values specified above for noise and spurious emissions requirements in all channels with 603 MHz ≤ center frequency ≤ 999 MHz. For example –73 dBc becomes –70 dBc. Also see 100.3.3.5.
[b]Add 1 dB relaxation to the values specified above for noise and spurious emissions requirements in gap channels with center frequency below 600 MHz. For example –73 dBc becomes –72 dBc. Also see 100.3.3.5.
[c]Add 5 dB relaxation to the values specified above for noise and spurious emissions requirements in all channel with 999 MHz < center frequency of the noise measurement ≤ 1215 MHz. For example –73 dBc becomes –68 dBc. Also see 100.3.3.5.
[d]These ceiling functions round to the nearest 0.5.
[e]The power difference in this context is the accuracy of measured differential power between two channels of interest as compared to the configured differential power between those two channels.

100.3.3.5 Out-of-band noise and spurious requirements for the CLT

Table 100–6 lists the out-of-band spurious requirements. In cases where the configured average power of an equivalent 6 MHz channel is not the same for each OFDM channel, 0 dBc for the spurious emissions requirements corresponds to the largest configured average power of an equivalent 6 MHz channel among all the active OFDM channels. When the configured average power of an equivalent 6 MHz channel is the same for each OFDM channel, 0 dBc should be interpreted as the measured power of the 6 MHz band centered on the PHY Link contained in OFDM channel 1.

The 10GPASS-XR-D PMD shall satisfy the out-of-band spurious emissions requirements of Table 100–6 in measurements below 600 MHz and outside the encompassed spectrum when the active OFDM channels are contiguous or when the ratio of modulated spectrum to gap spectrum within the encompassed spectrum is 4:1 or greater. Gap spectrum is spectrum between active OFDM channel's occupied spectrum and excluded bands within OFDM channel's occupied spectrum.

The 10GPASS-XR-D PMD shall satisfy the out-of-band spurious emissions requirements of Table 100–6 in gap spectrum between OFDM channels of at least 6 MHz and within exclusion bands within OFDM channels of at least 8 MHz, except for the 1 MHz of excluded subcarriers on each edge of any exclusion band, with relaxations as described in the following paragraphs when applicable.

The 10GPASS-XR-D PMD shall satisfy the out-of-band spurious emissions requirements of Table 100–6, with 1 dB relaxation, in measurements within gap spectrum in modulated spectrum below 600 MHz and within the encompassed spectrum when the ratio of modulated spectrum to gap spectrum within the encompassed spectrum is 4:1 or greater.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 10GPASS-XR-D PMD shall satisfy the out-of-band spurious emissions requirements of Table 100–6, with 3 dB relaxation, when the ratio of modulated spectrum to gap spectrum within the encompassed spectrum is 4:1 or greater, in measurements from 603 MHz to 999 MHz inclusive, outside the encompassed spectrum or in gap spectrum within the encompassed spectrum.

The 10GPASS-XR-D PMD shall satisfy the out-of-band spurious emissions requirements of Table 100–6, with 5 dB relaxation, when the ratio of modulated spectrum to gap spectrum within the encompassed spectrum is 4:1 or greater, in measurements from 999 MHz to 1209 MHz inclusive, outside the encompassed spectrum or in gap spectrum within the encompassed spectrum.

The 10GPASS-XR-D PMD shall satisfy the out-of-band spurious emissions requirements of Table 100–6, in addition to contributions from theoretical transmit windowing, with permissible configurations of lower edge and upper edge subband exclusions of at least 1 MHz each, cyclic prefix length (*DSNcp*) and windowing roll-off period (*DSNrp*) values. The test limit for determining compliance to the spurious emissions requirements is the power sum of the spurious emissions requirements, taken in accordance with Table 100–6 and the contributions from the theoretical transmit windowing for the configured transmissions.

The full set of *Neqport*' active equivalent 6 MHz channels is referred to throughout this specification as the modulated OFDM channels or the active OFDM channels. However, for purposes of determining the spurious emissions requirements for non-contiguous transmitted OFDM channels, each separate contiguous sub-block of channels within the active OFDM channels is identified, and the number of OFDM channels in each contiguous sub-block is denoted as *Neqi*, for $i = 1$ to K, where K is the number of contiguous blocks. Therefore,

$$Neqport' \leq \sum_{i=1}^{K} Neqi \tag{100–6}$$

Because exclusion subbands may be as small as 1 MHz with two or more contiguous sub-blocks within an OFDM channel, the number of active equivalent 6 MHz channels in each contiguous sub-block may add to more than the number of active equivalent 6 MHz channels in the full OFDM channel. Any double-counting of active subcarriers near small exclusion bands is acceptable in calculating the spurious emissions requirements; the equipment has to meet spurious emissions requirements in cases where Equation (100–6) is met with equality and the small relaxation in requirements which results from inequality is thus not compelling.

Note that $K = 1$ when and only when the entire set of active OFDM channels is contiguous. Also note that an isolated transmit OFDM channel, i.e., a transmit channel with empty adjacent OFDM channels, is described by $Neqi = 1$ and constitutes a block of one contiguous OFDM channel. Any number of the contiguous blocks may have such an isolated transmit OFDM channel; if each active OFDM channel was an isolated channel, then $K = Neq'$.

When the *Neqport*' combined active OFDM channels are not contiguous and the ratio of modulated spectrum to gap spectrum within the encompassed spectrum is 4:1 or greater, the spurious emissions requirements are determined by summing the spurious emissions power allowed in a given *Measurement Bandwidth* by each of the contiguous blocks among the occupied spectrum. In the gap spectrum within the encompassed spectrum and below 600 MHz there is a 1 dB relaxation in the spurious emissions requirements, so that within the encompassed spectrum the spurious emissions requirements (in absolute power) are 26% higher power in the measurement band determined by the summing of the contiguous blocks spurious emissions requirements. In all OFDM channels above 600 MHz there is a 3 dB relaxation in the spurious emissions requirements, so that the spurious emissions requirements (in absolute power) are double the power in the measurement band determined by the summing of the contiguous blocks spurious emissions requirements.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The details of the spurious emissions requirements for non-contiguous OFDM channel operation outside the encompassed spectrum are as follows. Note that within the encompassed spectrum the same details apply, except there is an additional 1 dB allowance below 600 MHz and a 3 dB allowance is applied above 600 MHz for all OFDM channels.

— The noise and spurious power requirements for all contiguous blocks of transmitted channels are determined from Table 100–6, even if the block contains fewer than *Neqport*/4 active OFDM channels. The noise and spurious power requirements for the *i*th contiguous block of transmitted channels is determined from Table 100–6 using the value *Neqi* for the number of active OFDM channels combined per MDI, and using dBc relative to the highest commanded power level of a 6 MHz equivalent channel among all the active OFDM channels, and not just the highest commanded power level in the *i*th contiguous block, in cases where the *Neqport'* combined OFDM channels are not commanded to the same power. The noise and spurious emissions power in each measurement band, including harmonics, from all *K* contiguous blocks, is summed (absolute power, NOT in dB) to determine the composite noise floor for the non-contiguous channel transmission condition. For the measurement OFDM channels adjacent to a contiguous block of channels, the spurious emissions requirements from the non-adjacent blocks are divided on an equal per Hz basis for the narrow and wide adjacent measurement bands.

— For a measurement channel positioned between two contiguous blocks, adjacent to each, the measurement channel is divided into three measurement bands: one wider in the middle and two narrower bands each abutting one of the adjacent transmit channels. The wideband spurious and noise requirement is split into two parts, on an equal per Hz basis, to generate the allowed contribution of power to the middle band and to the farthest narrowband.

In Table 100–6 the value for N^* is calculated using Equation (100–5). Item 1 through item 4 list the requirements in channels adjacent to the active channels. Item 5 lists the requirements in all other channels further from the active channels. Some of these "other" channels are allowed to be excluded from meeting the item 5 specification. All the exclusions, such as 2nd and 3rd harmonics of the modulated channel, are fully identified in the table. Item 6 lists the requirements on the 2*Neqport'* 2nd harmonic channels and the 3*Neqport'* 3rd harmonic channels.

Table 100–6—CLT output out-of-band noise and spurious emissions requirements

Item	Band	Requirement (in dBc)[a,b,c]
1	Adjacent channel up to 750 kHz from channel block edge	For $N^* = 1$: ≤ -58 For $N^* = 2$: ≤ -58 For $N^* = 3$: ≤ -58 For $N^* = 4$: ≤ -58 For $N^* \geq 5$: $\leq 10 \times \log_{10} [10^{-58/10} + (0.75/6) \times (10^{-65/10} + (N^* - 2) \times 10^{-73/10})]$
2	Adjacent channel (750 kHz from channel block edge to 6 MHz from channel block edge)	For $N^* = 1$: ≤ -62 For $N^* \geq 2$: $\leq 10 \times \log_{10} [10^{-62/10} + (5.25/6) \times (10^{-65/10} + (N^* - 2) \times 10^{-73/10})]$
3	Next-adjacent channel (6 MHz from channel block edge to 12 MHz from channel block edge)	$\leq 10 \times \log_{10} [10^{-65/10} + (N^* - 1) \times 10^{-73/10}]$

Table 100–6—CLT output out-of-band noise and spurious emissions requirements *(continued)*

Item	Band	Requirement (in dBc)[a,b,c]
4	Third-adjacent channel (12 MHz from channel block edge to 18 MHz from channel block edge)	For $N^* = 1$: ≤ -73 For $N^* = 2$: ≤ -70 For $N^* = 3$: ≤ -67 For $N^* = 4$: ≤ -65 For $N^* = 5$: ≤ -64.5 For $N^* = 6$: ≤ -64 For $N^* = 7$: ≤ -64 For $N^* \geq 8$: $\leq -73 + 10 \times \log_{10}(N^*)$
5	Noise in other channels (47 MHz to 1218 MHz) measured in each 6 MHz channel excluding the following: a) Desired channel(s) b) 1st, 2nd, and 3rd adjacent channels (see items 1, 2, 3, 4 in this table) c) Channels coinciding with 2nd and 3rd harmonics (see item 6 in this table)	For $N^* = 1$: ≤ -73; For $N^* = 2$: ≤ -70; For $N^* = 3$: ≤ -68; For $N^* = 4$: ≤ -67; For $N^* \geq 5$: $\leq -73 + 10 \times \log_{10}(N^*)$
6	In each of 2*Neqport*' contiguous 6 MHz channels or in each of 3*Neqport*' contiguous 6 MHz channels coinciding with 2nd harmonic and with 3rd harmonic components, respectively (up to 1218 MHz)	$\leq -73 + 10 \times \log_{10}(N^*)$ or –63, whichever is greater
7	Lower out of band noise in the band of 5 MHz to 47 MHz, measured in 6 MHz channel bandwidth	$\leq -50 + 10 \times \log_{10}(N^*)$
8	Higher out of band noise in the band of 1218 MHz to 3000 MHz, measured in 6 MHz channel bandwidth	For $N^* \leq 8$: $\leq -55 + 10 \times \log_{10}(N^*)$ For $N^* > 8$: $\leq -60 + 10 \times \log_{10}(N^*)$

[a]Add 3 dB relaxation to the values specified above for noise and spurious emissions requirements in all channels with 603 MHz ≤ center frequency ≤ 999 MHz. For example –73 dBc becomes –70 dBc.
[b]Add 5 dB relaxation to the values specified above for noise and spurious emissions requirements in all channels with 999 MHz < center frequency ≤ 1209 MHz. For example –73 dBc becomes –68 dBc.
[c]Add 1 dB relaxation to the values specified above for noise and spurious emissions requirements in gap channels with center frequency below 600 MHz. For example –73 dBc becomes –72 dBc.

100.3.3.6 CLT transmitter output requirements

The CLT shall provide for independent selection of center frequency with the ratio of modulated spectrum to gap spectrum in the encompassed spectrum being at least 2:1.

The CLT shall disable transmitter output when *PD_Enable* is equal to FALSE and continue in normal transmitter operation when *PD_Enable* is equal to TRUE.

100.3.4 CNU transmitter requirements

100.3.4.1 Burst timing convention

The start time of an OFDMA transmission by a CNU is referenced to an upstream Superframe boundary that begins with a Probe region (6 OFDMA symbols) followed by 256 OFDMA symbols. The 256 OFDMA symbols are divided into 32 8-symbol Resource Blocks, or 16 16-symbol Resource Blocks, as configured by *RBsize* (see 101.4.4.3.1).

The upstream time reference is defined as the first sample of the first symbol of an upstream Superframe, pointed to by the dashed arrow of Figure 100–2. The parameter N_{FFT} refers to the length of the FFT duration of 4096, and the parameter *USNcp* is the length of the configurable cyclic prefix. The sample rate is 204.8 Msps.

The upstream time reference for construction of each OFDMA symbol is defined as the first sample of each FFT duration of each OFDMA symbol, as illustrated in Figure 100–2.

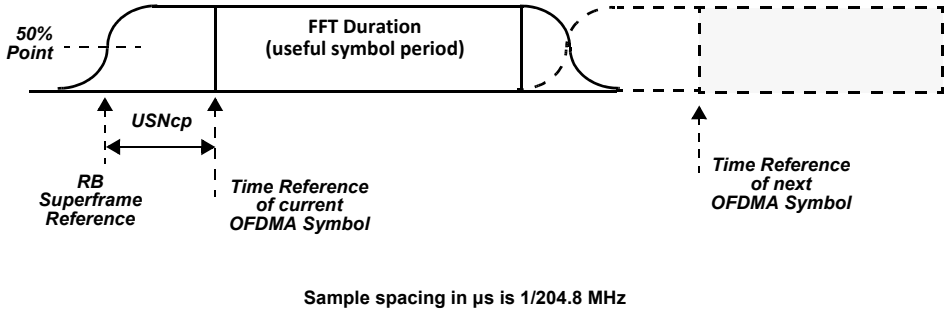

Figure 100–2—Time references for OFDMA symbol and RB Superframe

100.3.4.2 Transmit power requirements

The OFDMA channel power is defined as the average power when all active subcarriers in an OFDMA symbol are granted to the CNU. The normalized channel power of an OFDMA channel is the average power of the OFDMA subcarriers in 1.6 MHz bandwidth with no exclusions. This normalized channel power of an OFDMA channel is denoted as $P_{1.6}$. The transmit power requirements are a function of the occupied spectrum of the OFDMA channel.

The maximum value of the total power output of the CNU P_{Max} is at least 65 dBmV.

For the upstream OFDMA channel, N_{eq} is calculated per Equation (100–7).

$$N_{eq} = \lceil (BW_{OFDMA}) / 1.6 \rceil \quad (100\text{–}7)$$

BW_{OFDMA} (MHz) is the sum of the bandwidth of the modulated spectrum of the OFDMA channel.

Maximum equivalent channel power ($P_{1.6Max}$) is calculated as shown in Equation (100–8).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$P_{1.6Max} = P_{Max} - 10 \times \log_{10}(N_{eq}) \quad (100–8)$$

The CLT shall limit the configured $P_{1.6Max}$ to no more than 53.2 + (P_{Max} – 65) dBmV if the bandwidth of the modulated spectrum is ≤ 24 MHz. This enforces a maximum power spectral density of P_{Max} dBmV per 24 MHz.

The minimum equivalent channel power ($P_{1.6Min}$) for OFDMA channels is 17 dBmV.

During PHY Discovery ranging a CNU shall initiate communications starting from lowest power, which is set by the CLT using *PdRespInitPwr* (see 102.4.1.4). Therefore it should be noted that transmissions may use power per subcarrier that is as much as 9 dB lower than indicated by $P_{1.6Min}$ during PHY Discovery.

100.3.4.3 OFDMA transmit power calculations

The CNU determines individual subcarrier transmit power and maintains reported power level $P_{1.6r}$ in dBmV.

The CNU updates its reported power, *ReportedPwr*, by the following steps:

a) $1.P_{1.6r} = P_{1.6r} + \Delta P$ (add power level adjustment to reported power level).
b) The CNU shall report its transmit power using the variable *ReportedPwr* when requested by the CLT.

The value for $P_{1.6r}$ has the following limits:

— $P_{1.6r} \leq P_{1.6Max}$ (clip at max power limit).
— $P_{1.6r} \geq P_{1.6Min}$ (clip at min power limit per channel).

The CNU shall then transmit each data subcarrier with target power as calculated by Equation (100–9).

$$P_{t_sc_i} = P_{1.6r} + Pre\text{-}Eq_i - 10 \times \log_{10}(32) \quad (100–9)$$

where

$Pre\text{-}Eq_i$ is the magnitude of the ith subcarrier pre-equalizer coefficient (dB)

32 is the number of subcarriers in 1.6 MHz

That is, the reported power, normalized to 1.6 MHz, minus compensation for the pre-equalization for the subcarrier, less a factor taking into account the number of subcarriers in 1.6 MHz.

The CNU transmit power, P_t, in an upstream RB Frame is the sum of the individual transmit powers $P_{t_sc_i}$ of each subcarrier where the sum is performed using absolute power quantities in the non-dB domain.

The transmitted power level varies dynamically as the number and type of allocated subcarriers varies.

100.3.4.3.1 PHY Link managed variables

ReportedPwr

TYPE: 9-bit unsigned integer

This variable reports the CNU transmit power, in units of 0.25 dBmV, for the upstream OFDMA channel.

100.3.4.4 OFDMA fidelity requirements

100.3.4.4.1 Spurious emissions

The noise and spurious power generated by the CNU shall not exceed the levels given in Table 100–7, Table 100–8, and Table 100–9. Up to five discrete spurs[173] can be excluded from the emissions requirements listed in Table 100–7, Table 100–8, and Table 100–9 and have to be less than –42 dBc relative to a single subcarrier power level.

The parameter *SpurFloor* is related to the ratio of the number of subcarriers being modulated by a CNU in an OFDMA symbol to the maximum number of subcarriers available (3840) including guard bands and is calculated in dBc per Equation (100–10).

$$SpurFloor = \max\{-57 + 10\times\log_{10}(N_{S_Max}/3840), -60\} \quad (100–10)$$

where N_{S_Max} is the number of modulated subcarriers in an OFDMA symbol.

Maximum number of simultaneous transmitters is defined as shown in Equation (100–11).

$$N_{T_Max} = \left\lfloor 0.2 + 10^{((-44 - SpurFloor)/10)} \right\rfloor \quad (100–11)$$

The parameter *Under-grant Subcarriers* (number of subcarriers) is defined as shown in Equation (100–12).

$$Under\text{-}grant\ Subcarriers = N_{S_Max}/N_{T_MAX} \quad (100–12)$$

When a CNU is transmitting with fewer subcarriers than the *Under-grant Subcarriers* the spurious emissions requirement limit is the power value (in dBmV), corresponding to the specifications for the power level associated with a grant number of subcarriers equal to *Under-grant Subcarriers*. In addition, when a CNU is transmitting such that the total power of the CNU, P_t, is less than 17 dBmV, but other requirements are met, then the CNU spurious emissions requirements limit is the power value (in dBmV) computed with all conditions and relaxations factored in, plus an amount X dB where:

$$X\ \text{dB} = 17\ \text{dBmV} - P_t$$

In Table 100–7, inband spurious emissions includes noise, carrier leakage, clock lines, synthesizer spurious products, and other undesired transmitter products. It does not include ISI. The *Measurement Bandwidth* for inband spurious for OFDM is equal to the Subcarrier Clock frequency (50 kHz) and is not a synchronous measurement. The signal reference power for OFDMA inband spurious emissions is the total transmit power measured and adjusted (if applicable), and then apportioned to a single active subcarrier (see Table 100–8 and Table 100–9).

The *Measurement Bandwidth* is 160 kHz for Between Bursts specifications of Table 100–6, except where called out as 4 MHz or 250 kHz.

The signal reference power for Between Bursts transmissions is the reported power as in 100.3.4.3.

The Transmitting Burst specifications apply during the transmission of Resource Blocks and for 20 µs before the first symbol of the OFDMA transmission and for 20 µs after the last symbol of an OFDMA transmission. The Between Bursts specifications apply except during transmission of Resource Blocks and for

[173]Discrete (narrowband) spurious emissions, such as a continuous wave (CW) sinusoid or other signal with significant power concentrated in small bandwidth.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

20 µs before the first symbol of the OFDMA transmission and for 20 µs after the last symbol of an OFDMA transmission. The signal reference power for Transmitting Burst transmissions, other than inband, is the total transmit power measured and adjusted (if applicable) as described in this subclause.

For the purpose of spurious emissions definitions, a burst refers to a burst of Resource Blocks to be transmitted at the same time from the same CNU.

For PHY Discover Ranging spurious emissions requirements use Table 100–7, Table 100–8, and Table 100–9, with *100% Grant Spectrum* equal to the bandwidth of the *modulated spectrum* of the transmission.

The spurious emissions requirements over the entire upstream spectrum given in Table 100–7 for transmission of $N_{S_Max}/10$ or fewer subcarriers may be relaxed by 2 dB in an amount of spectrum equal to the following equation:

$$Measurement\ Bandwidth \times \lceil (100\%\ Grant\ Spectrum/10\ )/Measurement\ Bandwidth \rceil$$

where the *Measurement Bandwidth* value is defined in Table 100–8 and Table 100–9.

The 2 dB relaxation applies in the *Measurement Bandwidth*. This relaxation does not apply to between bursts emission requirements. The relaxation is added to the spurious emissions power limits calculated for the *Measurement Bandwidths* of Table 100–8 and Table 100–9 for *Measurement Bandwidth* values comprising roughly 10% of the upstream spectrum when the granted spectrum is less than 10% of the *100% Grant Spectrum*.

Table 100–7—Spurious emissions

Parameter	Transmitting	Between bursts
Inband	–45 dBc OFDMA 100% grant [a, b] –51 dBc OFDMA 5% grant [a, b]	N/S
Adjacent band	See Table 100–9	N/S
Within the upstream operating range 5 MHz to 204 MHz (excluding modulated spectrum and adjacent spectrum)	See Table 100–8	5 MHz to 20 MHz: –69 dBc[c] 20 MHz to 204 MHz: –72 dBc[c]
CNU integrated spurious emissions limits (all in 4 MHz, includes discrete spurs)[d]		
204 MHz to 258 MHz	–50 dBc	–72 dBc
258 MHz to 1218 MHz	–45 dBmV	max(–45 dBmV, –40 dB reference downstream)[d]
CNU discrete spurious emissions limits[e]		
204 MHz to 258 MHz	–50 dBc	–36 dBmV
258 MHz to 1218 MHz	–50 dBmV	–50 dBmV

[a]Up to five subcarriers within the entire upstream bandwidth with discrete spurs may be excluded from the MER calculation if they fall within transmitted bursts. These five spurs are the same spurs that may be excluded for spurious emissions and not an additional or different set.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

[b]Receive equalization is allowed if an MER test approach is used, to take ISI out of the measurement; measurements other than MER-based to find spurs or other unwanted power may be applied to this requirement.
[c]The signal reference power, 0 dBc, is the total transmit power defined in 100.3.4.4.1.
[d]"dB reference downstream" is relative to the received downstream signal level. Some spurious outputs are proportional to the receive signal level.
[e]These spec limits exclude a single discrete spur related to the tuned received channel; this single discrete spur is to be no greater than –40 dBmV.

100.3.4.4.2 Spurious emissions in the upstream frequency range

Table 100–8 lists the allowed spurious emissions for *Under-grant Hold Bandwidth* conditions. The initial measurement interval at which to start measuring the spurious emissions (from the transmitted burst's modulation edge) is 400 kHz from the edge of the transmission's modulation spectrum. Measurements should start at the initial distance and be repeated at increasing distance from the carrier until the upstream band edge or spectrum adjacent to other modulated spectrum is reached.

For OFDMA transmissions with non-zero transmit windowing, the CNU shall meet the required performance measured within the 2 MHz adjacent to the modulated spectrum using slicer values from a CLT burst receiver or equivalent, synchronized to the downstream transmission provided to the CNU.

In the remainder of the upstream spectrum, the CNU shall meet the required performance measured with a bandpass filter (e.g., an unsynchronized measurement).

For OFDMA transmissions with zero transmit windowing, CNU shall meet the required performance using synchronized measurements across the complete upstream spectrum.

The calculation for far out spurious emissions for specification in the interval values in Table 100–8 is shown in Equation (100–13).

$$\text{Round}(\textit{SpurFloor} + 10 \times \log_{10}(\textit{Measurement Bandwidth}/\textit{Under-grant Hold Bandwidth}) \quad (100\text{–}13)$$

The notation Round(x) as used in Equation (100–13), represents a rounding function that returns the value of its argument x rounded to the nearest 0.1.

The calculation for *SpurFloor* values in Table 100–8 and Table 100–9 is shown in Equation (100–14).

$$\textit{SpurFloor} = \max\{-57 + 10 \times \log_{10}(\textit{100\% Grant Spectrum}/192), -60\} \quad (100\text{–}14)$$

The calculation for *Under-grant Hold #Users* in Table 100–8 and Table 100–9 is shown in Equation (100–15).

$$\textit{Under-grant Hold \#Users} = \left\lfloor 0.2 + 10^{((-44 - \textit{SpurFloor})/10)} \right\rfloor \quad (100\text{–}15)$$

Grant Spectrum is the spectrum of the grant (number of Resource Blocks multiplied by the bandwidth of a single Resource Block) allocated to a CNU in a given upstream RB Frame (see 101.4.4.3.1). *Grant Spectrum* may vary from one RB Frame to another. *100% Grant Spectrum* is the bandwidth of the entire upstream transmission resource, which occurs with probes, that incorporate all Resource Blocks and unused subcarriers (see 101.4.4.3.1).

Under-grant Hold Bandwidth in Table 100–8 and Table 100–9 is shown in Equation (100–16).

$$\textit{Under-grant Hold Bandwidth} = \textit{100\% Grant Spectrum}/\textit{Under-grant Hold \#Users} \quad (100\text{–}16)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For transmission bursts with modulation spectrum less than the *Under-grant Hold Bandwidth*, the spurious power requirement is calculated as in Equation (100–16), but increased by $10 \times \log_{10}$ (*Under-grant Hold Bandwidth*/*Grant Spectrum*).

Table 100–8—Spurious emissions requirements in the upstream frequency range for grants of Under-grant Hold Bandwidth and larger[a]

100% Grant Spectrum (MHz)	*SpurFloor* (dBc[b])	*Under-grant Hold #Users*	*Under-grant Hold Bandwidth* (MHz)	*Measurement Bandwidth* (MHz)[c]	Specification in the Interval (dBc[b])
Up to 64 [e.g., 22 MHz] (see note) [e.g., 46 MHz]	–60	40	100% Grant Spectrum/40 [0.55 MHz](see note) [1.15 MHz]	1.6	Eq (100–13) [–55.4](see note) [–58.6]
Greater than 64, up to 96 [e.g., 94 MHz]	–60	40	100% Grant Spectrum/40 [2.35 MHz]	3.2	Eq (100–13) [–58.7]
Greater than 96, up to 192 [e.g., 142 MHz] [e.g., 190 MHz]	Eq (100–14) [–58.3] [–57]	Eq (100–15) [27] [20]	Eq (100–16) [5.3] [9.5]	9.6	Eq (100–13) [–55.47 [–57]
Greater than 192 [e.g., 200 MHz]	Eq (100–14) [–56.8]	Eq (100–15) [19]	Eq (100–16) [10.5]	12.8	Eq (100–13) [–58.7]
NOTE— Each row of bracketed values represent a set of calculated examples. The value in the first column is an example value for 100% Grant Spectrum (MHz). The remaining columns are the result of the calculations for that column.					

[a]Spurious emissions requirements in the upstream frequency range relative to the per channel transmitted burst power level for each channel for grants of *Under-grant Hold Bandwidth* and larger.
[b]The signal reference power, 0 dBc, is the total transmit power defined in 100.3.4.4.1.
[c]The *Measurement Bandwidth* is a contiguous sliding measurement window.

The CNU shall control transmissions such that (within the *Measurement Bandwidth* of Table 100–8) spurious emissions measured for individual subcarriers contain no more than +3 dB power larger than the required average power of the spurious emissions in the full *Measurement Bandwidth*. When non synchronous measurements are made, only 25 kHz *Measurement Bandwidth* is used.

100.3.4.4.3 Adjacent channel spurious emissions

Table 100–9 lists the required adjacent channel spurious emission levels when there is a transmitted burst with bandwidth at the *Under-grant Hold Bandwidth*. The measurement is performed in an adjacent channel interval of 400 kHz adjacent to the transmitted burst modulation spectrum. For OFDMA transmissions, the measurement is performed starting on an adjacent subcarrier of the transmitted spectrum (both above and below), using the slicer values from a CLT burst receiver or equivalent synchronized to the downstream transmission provided to the CNU.

Note that the *Measurement Bandwidth* for Table 100–9 is less than the *Measurement Bandwidth* values in Table 100–8. Thus comparing the two tables in terms of the specification "dBc" values requires appropriate scaling. Table 100–9 provides specification "dBc" only for grants of a specific amount for each row, while Table 100–8 provides "dBc" specification for grants of all sizes from the *Under-grant Hold Bandwidth* to 100%.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For transmission bursts with the *Grant Spectrum* less than the *Under-grant Hold Bandwidth*, the spurious power requirement is calculated as above, but increased by $10 \times \log_{10}$ (*Under-grant Hold Bandwidth*/*Grant Spectrum*).

For transmission bursts with modulation spectrum greater than the *Under-grant Hold Bandwidth*, the spurious power requirement in the adjacent 400 kHz is calculated by converting the requirement to absolute power "dBmV" for a grant of precisely *Under-grant Hold Bandwidth* from Table 100–9, and similarly computing the absolute power "dBmV" from Table 100–8 for a grant equal to the following:

Grant Spectrum – Under-grant Hold Bandwidth

Then the absolute power calculated from Table 100–8 is scaled back in exact proportion of 400 kHz compared to the *Measurement Bandwidth* in Table 100–8. Then the power from Table 100–9 is added to the scaled apportioned power from Table 100–8 to produce the requirement for the adjacent 400 kHz measurement with a larger grant than the *Under-grant Hold Bandwidth*. The requirement for adjacent spurious power in adjacent 400 kHz is as follows:

P1 (*Grant Spectrum-Under-grant Hold Bandwidth*) = absolute power derived from Table 100–8 dBmV

P2 (*Under-grant Hold Bandwidth*) = absolute power derived from Table 100–9 dBmV

$P1_{scaled} = P1 \times (0.4)/($*Measurement Bandwidth* used in Table 100–8) dBmV

$P_{spec_limit} = P1_{scaled} + P2$ dBmV

Equation (100–17) is used in Table 100–9 for calculating the table column: "Specification in Adjacent 400 kHz with Grant of *Under-grant Hold Bandwidth* (dBc)."

$$\text{Round}(10 \times \log_{10}((10^{(SpurFloor/10)} + (10^{(-57/10)})) \times (0.4/\textit{Under-grant Hold Bandwidth}))) \quad (100–17)$$

The notation Round(x) as used in Equation (100–17), represents a rounding function that returns the value of its argument x rounded to the nearest 0.1.

Greater than 64, up to 96 [e.g., 94 MHz]	–60	40	100% Grant Spectrum/40 [2.35 MHz]	0.4 MHz	Eq (100–17) [–62.9]
Greater than 96 [e.g., 142 MHz] [e.g., 190 MHz] [e.g., 200 MHz]	Eq (100–14) Round nearest 0.1 dB [–58.3] [–57] [–56.8]	Eq (100–15) [27] [20] [19]	Eq (100–16) [5.3] [9.5] [10.5]	0.4 MHz	Eq (100–17) [–65.8] [–67.7] [–68.1]
NOTE—Each row of bracketed values represent a set of calculated examples. The value in the first column is an example value for 100% Grant Spectrum (MHz). The remaining columns are the result of the calculations for that column.					

[a]The signal reference power, 0 dBc, is the total transmit power defined in 100.3.4.4.1.

100.3.4.4.4 Spurious emissions during burst on/off transients

The CNU shall control spurious emissions prior to and during RF power amplifier turn on, during and following turn off, and before and after a burst. See 100.3.4.7.

The CNU's on/off spurious emissions, such as the change in voltage at the upstream transmitter output, due to enabling or disabling transmission, shall be no more than 50 mV.

The CNU's voltage step at the MDI (TP2, see 100.4) shall be dissipated no faster than 4 μs of constant slewing when the CNU is transmitting at +55 dBmV or more.

At transmit levels below +55 dBmV, the CNU's maximum change in voltage shall decrease by a factor of 2 for each 6 dB decrease of power level, from +55 dBmV down to a maximum change of 3.5 mV at 31 dBmV and below. The amplifier turn on and turn off transients of this subclause (100.3.4.4.4) are not applicable when the entire CNU is being powered on or off.

100.3.4.5 Transmit MER requirements

Transmit MER measures the cluster variance caused by the CNU during upstream transmission due to transmitter imperfections. The terms "equalized MER" and "unequalized MER" refer to a measurement with linear distortions equalized or not equalized, respectively, by the test equipment receive equalizer. The requirements in this subclause refer only to unequalized MER, as described for each requirement. MER is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

measured on each modulated data subcarrier and pilot (MER is computed based on the pilot power) in a Resource Block of a burst and averaged for all the subcarriers in each Resource Block. MER includes the effects of Inter-Carrier Interference, spurious emissions, phase noise, noise, distortion, and all other undesired transmitter degradations with an exception for a select number of discrete spurs impacting a select number of subcarriers. Compliance with MER requirements is verified with the use of a calibrated test instrument that synchronizes to the OFDMA signal, applies a receive equalizer in the test instrument that removes MER contributions from nominal channel imperfections related to the measurement equipment, and calculates the value. The equalizer in the test instrument is calculated, applied and frozen for the CNU testing. Receiver equalization of CNU linear distortion is not provided; hence this is considered to be a measurement of unequalized MER, even though the test equipment contains a fixed equalizer setting.

100.3.4.5.1 Definitions

The transmitted RF waveform at the F connector of the CNU (after appropriate down conversion) is filtered, converted to baseband, sampled, and processed using standard OFDMA receiver methods, with the exception that receiver equalization is not provided. The processed values are used in Equation (100–18) and Equation (100–19). No external noise (AWGN) is added to the signal.

The carrier frequency offset, carrier amplitude, carrier phase offset, and timing are adjusted during each burst to maximize MER as follows:

a) One carrier amplitude adjustment common for all subcarriers and OFDM symbols in burst.
b) One carrier frequency offset common for all subcarriers resulting in phase offset ramping across OFDM symbols in bursts.
c) One timing adjustment resulting in phase ramp across subcarriers.
d) One carrier phase offset common to all subcarriers per OFDM symbol in addition to the phase ramp.

MER per Resource Block (RB_{MER} in dB) is computed as shown in Equation (100–18).

$$RB_{MER} = 10 \times \log_{10}\left(\frac{E_{avg}}{\left(\frac{1}{RBlen}\left(\sum_{k=1}^{RBlen} |e_{j,k}|^2\right)\right)}\right) \quad (100–18)$$

where

E_{avg} is the average constellation energy for equally likely symbols
$RBlen$ is a value of 8 when *RBsize* is FALSE and a value of 16 when *RBsize* is TRUE
$e_{j,k}$ is the error vector from the *j*th subcarrier in the burst and *k*th received symbol to the ideal transmitted QAM symbol of the appropriate modulation order

MER per burst ($BURST_{MER}$ in dB) is computed as shown in Equation (100–19).

$$BURST_{MER} = \frac{1}{N}\sum_{j=1}^{N} (RB_{MER}\, j) \quad (100–19)$$

where

j is the *j*th subbcarrier in the burst
E_{avg} is the average constellation energy for equally likely symbols
N is the number of Resource Blocks in a burst

A sufficient number of OFDMA symbols should be included in the time average so that the measurement uncertainty from the number of symbols is less than other limitations of the test equipment.

MER with a 100% grant is defined as the condition when all OFDMA subcarriers are granted to the CNU.

MER with a 5% grant is defined as the condition when less than or equal to 5% of the available OFDMA subcarriers have been granted to the CNU.

100.3.4.5.2 Requirements

Unless otherwise stated, the CNU shall meet or exceed the following MER limits in Table 100–10 over the full transmit power range, all modulation orders, all grant configurations and over the full upstream frequency range.

The measurements indicated in Table 100–10 are made with flat channel (as nearly flat as practical in a laboratory test environment), after the pre-equalization coefficients have been set to their optimum values. The receiver uses best effort synchronization to optimize the MER measurement.

Table 100–10—Upstream MER requirements (with pre-equalization)

Parameter	Value	Units
MER (100% grant), each burst	≥ 44[a]	dB
MER (5% grant), each burst	≥ 50[a]	dB
Pre-equalizer constraints	Pre-equalization not used	

[a]Up to five subcarriers within the entire upstream bandwidth with discrete spurs may be excluded from the MER calculation if they fall within transmitted bursts. These five spurs are the same spurs that may be excluded for spurious emissions and not an additional or different set.

100.3.4.6 CNU Transmitter output requirements

The CNU shall output an RF Modulated signal with characteristics defined in Table 100–11.

Table 100–11—CNU RF output requirements

Parameter	Value	Units
Frequency band Equipment may be adapted to all or part of this frequency band to suit regional requirements. See 100.5.4.1.2.	7.4 to 204	MHz
OFDMA channel bandwidth	10 to 192	MHz
Subcarrier channel spacing	50	kHz
OFDM symbol rate FFT duration	20	µs
FFT size	4096	FFT bins
Maximum number of data subcarriers	3800	subcarriers
Total average transmit output power	up to 65	dBmV
Modulation format	See Table 100–2

Table 100–11—CNU RF output requirements *(continued)*

Parameter	Value	Units
R_{on} max (see 100.3.4.7)	100	μs
R_{off} max (see 100.3.4.7)	100	μs
Output impedance	75	Ω
Output return loss 7.4 MHz to f_{max} MHz (42/65/85/117/204 MHz)	> 6	dB
MDI Connector	F connector per ISO/IEC 61169-24 or SCTE 02	

100.3.4.7 CNU RF power amplifier requirements

In EPoC, the upstream CNU PMD RF power amplifier (PA) may be turned off between bursts as shown in Figure 100–3. PMD_SIGNAL.request(ON) is asserted when the first bit of the burst is conveyed from the PCS to the PMA via PMA_UNITDATA.request() (see 101.4.2.1). The delay time through the EPoC PMA (T_{PMA}) is no less than the sum of the *RBframe* size multiplied by the OFDM symbol time *RBlen*(*RBsize)* of 8 times or 16 times 20 μs, see 100.3.4.1) plus the implementation specific processing time of the IDFT (nominal range 10 μs to 40 μs). For any given implementation and upstream profile configuration, T_{PMA} is fixed and the CNU is required to meet the PMD delay variance requirements in 100.2.2. The time to turn on and stabilize the PA for meeting burst transmission fidelity requirements (see 100.3.4.2) is represented by R_{on}. The time from PMD_SIGNAL.request(ON) to initiate PA turn on is implementation specific. PMD_SIGNAL.request(OFF) is asserted when the last bit of the burst is conveyed from the PCS to the PMA. PA turn off is initiated after the T_{PMA} delay and after the last OFDM symbol of the burst. The time for the PA to turn off is represented by R_{off}.

The RF transmission of burst energy begins at the beginning of the grant after R_{on}. The R_{on} time period of one CNU may overlap completely with the R_{off} time period of another CNU. Turning the PA off achieves two purposes: to meet the energy efficiency requirements of 100.6 and to minimize the cumulative impact on CLT receiver SNR by avoiding all CNU PAs powered on 100% of the time.

R_{on} and R_{off} times are not included in burst overhead calculations (see 103.3.5). T_{PMA} in either *RBsize* configuration is longer than R_{on} maximum (see Table 100–11) and does not impact adjusting grant lead time (see 103.3.5).

The CNU shall disable transmitter output when *PD_Enable* is equal to FALSE and continue in normal transmitter operation when *PD_Enable* is equal to TRUE. This requirement has precedence over the requirements in this subclause.

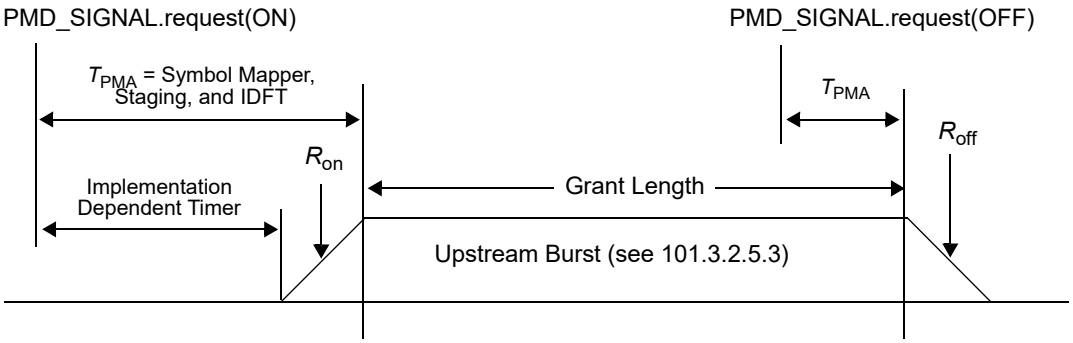

Figure 100–3—Details of RF power amplifier turn on and turn off timing

100.3.5 CLT receiver requirements

100.3.5.1 CLT receiver input power requirements

The CLT Upstream Demodulator shall operate with an average input signal level, including ingress and noise to the upstream demodulator, up to 31 dBmV. Operation above this level is not specified.

The CLT shall be configured according to Table 100–12 for intended received power normalized to 6.4 MHz of bandwidth.

When using the modulation formats and power set points shown, the CLT upstream demodulator shall operate within its defined performance specifications when received bursts are within the ranges specified in Table 100–12.

Table 100–12—Upstream OFDMA channel demodulator input power characteristics

Modulation	Minimum set point[a] (dBmV)	Maximum set point[a] (dBmV)	Range (dB)
QPSK	–4	10	–9 to +3
8-QAM	–4	10	–9 to +3
16-QAM	–4	10	–9 to +3
32-QAM	–4	10	–9 to +3
64-QAM	–4	10	–9 to +3
128-QAM	0	10	–9 to +3
256-QAM	0	10	–9 to +3
512-QAM	0	10	–3 to +3

The CLT shall provide upstream power measurements with a standard deviation of 0.33 dB or better under the test conditions given in 100.4.3.

100.3.5.1.1 PHY Link managed variables

CLT_TargetReceivePower

TYPE: signed 10-bit integer

This variable specifies the CLT receive power, in units of 0.1 dBmV/6.4 MHz. The value is set according to the requirements in Table 100–12.

100.3.5.2 CLT receiver error performance in AWGN channel

This subclause describes the conditions at which the CLT PMD when connected to a compliant PMA and PCS is required to meet the error performance in an AWGN channel.

The CLT shall achieve a received frame loss ratio of less than or equal to 10^{-6} when all of the following input load and channel conditions are met:

- A single transmitter, pre-equalized and ranged.
- A single OFDMA 192 MHz channel, using all 3800 subcarriers.
- Ranging with same CNR and input level to CLT as with data bursts, and with 6-symbol probes.
- Any valid transmit combination (frequency, transmit window, cyclic prefix, upstream OFDMA Superframe length, Resource Block size pilot patterns, etc.) as defined in this specification.
- Input power level per constellation is the minimum set point as defined in Table 100–12.
- Received signal having a CNR greater than or equal to that shown in Table 100–13.
- OFDMA phase noise and frequency offset are at the max limits as defined for the CLT transmission specification.
- Ideal AWGN channel with no other artifacts (reflections, burst noise, tilt, etc.).
- Large bursts consisting of frames of any allowed sizes, including bursts consisting only of minimum size frames (4A.2.3.2.4) and bursts consisting only of maximum size frames (4A.2.4.2).

Table 100–13—CLT minimum CNR performance in AWGN channel

Modulation	CNR[a,b] (dB)	Set point[c] (dBmV)	Offset (dB)
QPSK	11	–4	0
8-QAM	14	–4	0
16-QAM	17	–4	0
32-QAM	20	–4	0
64-QAM	23	–4	0
128-QAM	26	0	0
256-QAM	29	0	0
512-QAM	32.5	0	0
1024-QAM	35.5	0	0

Table 100–13—CLT minimum CNR performance in AWGN channel *(continued)*

Modulation	CNR[a,b] (dB)	Set point[c] (dBmV)	Offset (dB)
2048-QAM	39	7	0
4096-QAM	43	10	0

[a]CNR is defined here as the ratio of average signal power in occupied spectrum to the average noise power in the occupied spectrum given by the noise power spectral density integrated over the same occupied spectrum.
[b]Channel CNR is adjusted to the required level by measuring the source inband noise including phase noise component and adding the required delta noise from an external AWGN generator.
[c] With respect to 6.4 MHz.

100.3.5.3 CLT upstream receive modulation error ratio requirements

This subclause provides measurements of the upstream receive modulation error ratio (RxMER) for each subcarrier. The CLT measures the RxMER using an upstream probe. For the purposes of RxMER measurement at the CLT, RxMER is defined as the ratio of the average power of the ideal BPSK constellation to the average error-vector power. The error vector is the difference between the equalized received probe value and the known correct probe value.

The CLT shall be capable of providing measurements of RxMER for all active subcarriers for any single specified CNU in the upstream OFDMA channel, using probe symbols. The CLT can use a sufficient number of upstream probe symbols for a reliable estimate of RxMER.

100.3.5.3.1 PHY Link managed variables

RxMER_ChID
: TYPE: 3-bit integer
This variable is a pointer to one of the five possible OFDM channels in the EPoC network. When set in the CNU the values in *RxMER_SC(n)* reflect the measurements of OFDM channel number *RxMER_ChID* when *RxMER_Valid* goes TRUE. In the CNU this register may have a value of between 1 and 5 inclusive. In the CLT this variable is read only and will always have a value of one.

RxMER_CNU_ID
: TYPE: unsigned 14-bit integer
This variable identifies for the CLT the CNU for which the CLT is to measure the upstream RxMER. When set in the CLT the values in *RxMER_SC(n)* reflect the measurements of the CNU whose *CNU_ID* matches *RxMER_CNU_ID* when *RxMER_Valid* goes TRUE. In the CNU this variable is read only and will always have a value of one.

RxMER_SC(n)
: TYPE: array of 8-bit unsigned integer
This variable represents the measured receive modulation error ratio (RxMER) for subcarrier index *n* for an OFDM channel in increments of 0.25 dB with a value range from 0 dB (0x00) to 63.5 dB (0xFE). Subcarriers (such as exclusion bands) that cannot be measured indicate a value of 0xFF. The default (initial) value of RxMER is 0xFF for all subcarriers.

RxMER_Valid
: TYPE: Boolean
When TRUE this variable indicates that the values *RxMER_SC(n)* for the CNU indicated by *RxMER_CNU_ID* for the OFDM channel indicated by *RxMER_ChID* are valid. When FALSE this variable indicates the some values in *RxMER_SC(n)* may be invalid.

100.3.6 CNU receiver requirements

100.3.6.1 Input signal characteristics at CNU receiver

The CNU shall meet electrical parameters and all performance specifications when receiving a signal conformant to the parameters shown in Table 100-14.

Table 100–14—Electrical input to CNU

Parameter	Value	Units
Total input power, 54 MHz to 1.794 GHz	< 40	dBmV
OFDM channel input level range (24 MHz min occupied spectrum) Note that level range does not imply anything about BER performance or capability vs. QAM. CNU BER performance is separately described.	–9 to +21	dBmV/24 MHz
Maximum average power per MHz input to the CNU from 54 MHz to 1.794 GHz For additional Demodulated Bandwidth, B_{demod} :[a] For additional Non-Demodulated Bandwidth, $B_{no\text{-}demod}$[b] and for up to 12 MHz of occupied spectrum (analog, out of band (OOB), QAM, OFDM): For all remaining spectrum:[c]	 ≤ Min [$X - 10\times\log_{10}(24) + 10$; $21 - 10\times\log_{10}(24)$] ≤ Min [$X - 10\times\log_{10}(24) + 10$; $26 - 10\times\log_{10}(24)$] ≤ Min [$X - 10\times\log_{10}(24) + 10$; $21 - 10\times\log_{10}(24)$] where X = Average power of lowest power 24 MHz of modulated spectrum for demodulation	dBmV/MHz
Input impedance	75	Ω
Input return loss 258 MHz to 1218 MHz	> 6	dB

[a]Additional Demodulated Bandwidth represented by B_{demod} is any 1 MHz of spectrum defined by the downstream profile (see 101.4.2) for the CNU that is outside the 24 MHz of the downstream profile that has the lowest average power.
[b]Additional Non-Demodulated Bandwidth represented by $B_{no\text{-}demod}$ is any 1 MHz of spectrum outside the downstream profile (101.4.2) see for the CNU.
[c]Remaining bandwidth in 54 MHz to 1.794 GHz, excluding both the Additional Demodulated Bandwidth and the Additional Non-Demodulated Bandwidth.

100.3.6.2 CNU error performance in AWGN channel

This subclause describes the conditions at which the CNU PMD when connected to a compliant PMA and PCS is required to meet the error performance in an AWGN channel.

The CNU shall achieve a received frame loss ratio of less than or equal to 10^{-6} under the following input load and channel conditions:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Any valid transmit combination (frequency, Subcarrier Clock frequency, transmit window, cyclic prefix, pilot, PHY Link, subcarrier exclusions, interleaving depth, modulation profile configuration, etc.) as defined in this standard.

— P_{6AVG} (the measured OFDM channel power divided by number of occupied 6 MHz channels) ≤ 15 dBmV.

— Up to fully loaded spectrum. Note that the frame loss ratio requirements are levied on all active OFDM channels. Those requirements are to be met with a single channel operating in isolation and up to and including all of the other OFDM channels being operated. This is what is meant by "Up to fully loaded spectrum".

— Power in (both above and below) four adjacent 6 MHz channels ≤ P_{6AVG} + 3 dB.

— Power in any 6 MHz channel over the modulated spectrum ≤ P_{6AVG} + 6 dB.

— Peak envelope power in any analog channel over the modulated spectrum ≤ P_{6AVG} + 6 dB.

— Average power per channel across modulated spectrum ≤ P_{6AVG} + 3 dB.

— Received signal having a CNR greater than or equal to that shown in Table 100–15.

— OFDM channel phase noise as per Table 100–3 and Table 100–6.

— Large bursts consisting of frames of any allowed sizes, including bursts consisting only of minimum size frames (4A.2.3.2.4) and bursts consisting only of maximum size frames (4A.2.4.2).

— No other artifacts (reflections, burst noise, tilt, etc.).

Table 100–15—CNU minimum CNR performance in AWGN channel

Constellation	CNR[a] (dB) Up to 1 GHz	CNR[a] (dB) 1 GHz to 1.2 GHz	Min P_{6AVG} dBmV
4096	41	41.5	–6
2048	37	37.5	–9
1024	34	34	–12
512	30.5	30.5	–12
256	27	27	–15
128	24	24	–15
64	21	21	–15
16	15	15	–15

[a]CNR is defined here as total signal power in occupied spectrum divided by total noise in occupied spectrum. OFDM channel CNR is adjusted to the required level by measuring the source inband noise including phase noise component and adding the required delta noise from an external AWGN generator. Applicable to an OFDM channel with 192 MHz of occupied spectrum.

100.3.6.3 Receive modulation error ratio requirements

The CNU provides measurements of downstream receive modulation error ratio (RxMER) for all active subcarrier locations for each OFDM downstream channel, using pilots and PHY Link preamble symbols.

The CNU measures the RxMER using scattered pilots and PHY Link preamble symbols. Note that if a scattered pilot falls on top of a continuous pilot, it is still considered as a scattered pilot for these measurements. For the purposes of RxMER measurement at the CNU, RxMER is defined as the ratio of the average power of the ideal QAM constellation to the average error-vector power. The error vector is the difference between the equalized received pilot or preamble value and the known correct pilot value or preamble value. As a defining test case, for an ideal AWGN channel, an OFDM channel containing a mix of QAM constellations, with data-subcarrier CNR = 35 dB CNR on the QAM subcarriers, yielding an RxMER measurement of nominally 35 dB averaged over all subcarrier locations. If some subcarriers (such as exclusion bands) cannot

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

be measured by the CNU, the CNU indicates that condition in the measurement data for those subcarriers as a value of 0xFF.

RxMER may be more clearly defined in mathematical notation in accordance with Figure 100–4, which shows an ideal transmit and receive model, with no intent to imply an implementation. Let *p* represent the pilot or PHY Link preamble symbol before transmit IDFT, *H* represents the channel coefficient for a given subcarrier frequency, *n* represents noise, and *y* is the unequalized received symbol after receive FFT:

$$y = (H \times p) + n$$

The receiver computes *G* as an estimate of *H*, and computes the equalized received symbol *r* as follows:

$$r = y / G$$

Using the known modulation value of the pilot or preamble symbol *p*, the receiver computes the equalized error vector *e* as follows:

$$e = r - p$$

All the above quantities are complex numbers for a given subcarrier. To compute RxMER, the receiver computes *E* as the time average of $|e|^2$ (squared absolute value) over many visits of the pilot to the given subcarrier (or PHY Link preamble symbol as applicable), and $E_dB = 10 \times \log_{10}(E)$. Let *S_dB* be the average power of the ideal QAM data subcarrier constellation (not including pilots) expressed in dB. The CNU reports *RxMER_dB* = *S_dB* – *E_dB*.

The CNU shall provide RxMER measurements with *RxMER_std* ≤ 0.5 dB under conditions specified in 100.4.2.

Define *delta_RxMER* = (*RxMER_mean* at CNR_data_subcarrier = 35 dB) – (*RxMER_mean* at CNR_data_-subcarrier = 30 dB). The CNU shall provide RxMER measurements such that 4 dB ≤ *delta_RxMER* ≤ 6 dB under the above specified condition.

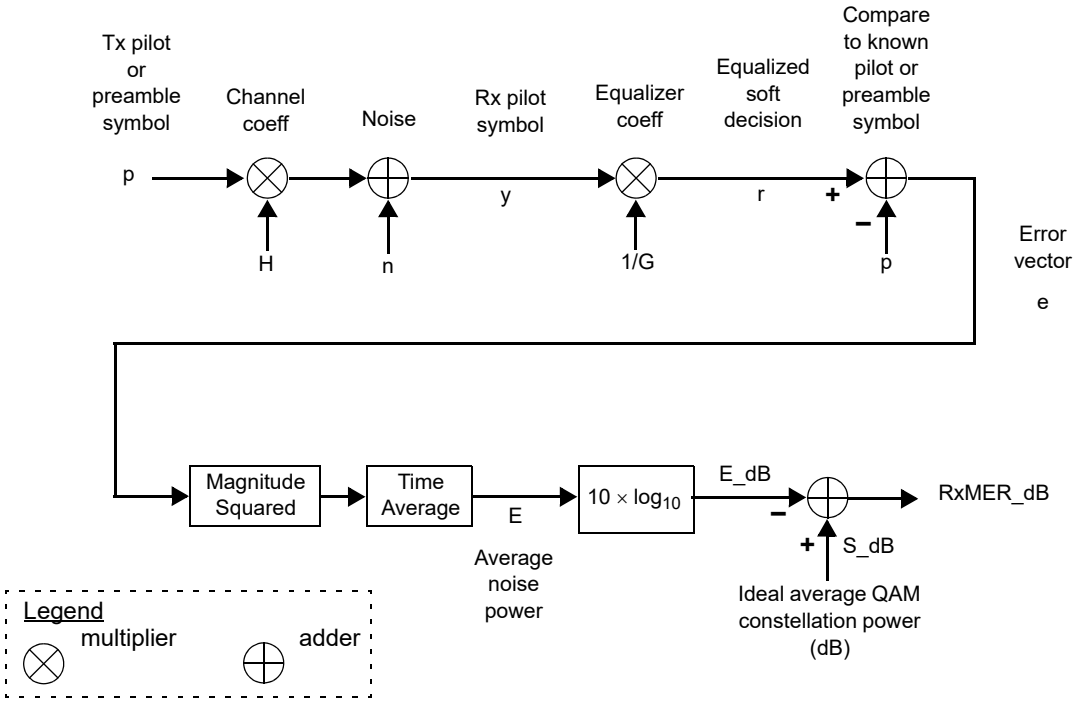

Figure 100–4—Computation of received modulation error ratio (RxMER) for a given subcarrier

100.3.7 Channel band rules

During OFDM and OFDMA channel planning, the following rules are to be observed to ensure proper operation of the CLT and CNU.

100.3.7.1 Downstream channel bandwidth rules

The encompassed spectrum of each 192 MHz downstream OFDM channel cannot exceed 190 MHz and does not exceed 3800 active subcarriers (see Table 100–3). The CLT uses the subcarriers in the range specified for IDFT Equation (101–25).

At least 1 MHz of exclusion band between the spectral edge any non-OFDM channel and the center frequency of the nearest OFDM subcarrier is required. This non-OFDM channel may be external to the OFDM channel or may be embedded within the OFDM channel.

100.3.7.2 Downstream exclusion band rules

The downstream exclusion band rules listed below apply to each OFDM channel and the composite downstream channel inclusive of OFDM and other signals using downstream spectrum concurrently with EPoC, e.g., video channels. The CLT and CNU are not expected to meet performance and fidelity requirements when the system configuration does not comply with the following downstream exclusion band rules:

— There has to be at least one contiguous modulated OFDM bandwidth of 22 MHz or greater.
— Exclusion bands may separate contiguous modulation bands.
— All contiguous modulation bands are to be 2 MHz or greater.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— The only exception to the above is for exclusion bands that are allowed to occupy 405.925 MHz to 406.176 MHz in alignment with FCC regulations as per CFR 76. Unique FCC egress requirements exist for these bands separate from the general exclusion bands requirements.
— Exclusion bands plus individually excluded subcarriers are limited to 20% or less of the encompassed spectrum of any individual OFDM channel and modulated spectrum is to be at least 80% of the encompassed spectrum of all active channels.
— The number of individually excluded subcarriers is limited by the following:
  — The total spectrum of individually excluded subcarriers cannot exceed 5% of any contiguous modulation spectrum.
  — The total spectrum of individually excluded subcarriers cannot exceed 5% of a 6 MHz moving window across the contiguous modulation spectrum.
  — The total spectrum of individually excluded subcarriers cannot exceed 20% of a 1 MHz moving window across the contiguous modulation spectrum.
— The 6 MHz of contiguous spectrum used for the PHY Link cannot have any exclusion bands or excluded subcarriers.

100.3.7.3 Upstream channel bandwidth rules

The encompassed spectrum of the upstream OFDMA channel cannot exceed 190 MHz and does not exceed 3800 active subcarriers (see Table 100–11). The CLT uses the subcarriers in the range specified for IDFT Equation (101–25).

100.3.7.4 Upstream exclusions and unused subcarriers rules

The CLT and CNU are not expected to meet performance and fidelity requirements when the system configuration does not comply with the following downstream exclusion band rules:

— Subcarriers that lie outside the Encompassed Spectrum are excluded.
— Upstream exclusion bands may include one or more subcarriers.
— There is no restriction on the number or placement of excluded and unused subcarriers between Resource Blocks (see 101.4.4.3.1).

100.4 Test requirements and measurement methods

All testing and measurement is performed in a coax cable distribution network that conforms to Annex 100A. The test point for the CLT is located at the MDI and labeled TP1 as shown in Figure 101–1 and Figure 101–4. The test point for the CNU is located at the MDI and labeled TP2 as shown in Figure 101–2 and Figure 101–3.

100.4.1 CLT RF output muting requirement

The specified limit of 73 dB below the operationally configured aggregate power (see *CLT_TxMute* below and Table 100–3) applies with all active OFDM channels commanded to the same transmit power level. Starting with all channels commanded to the same power level, then commanding a reduction in the transmit level of any, or all but one, of the active OFDM channels does not change the specified limit for measured muted power in 6 MHz. The output return loss at TP1/MDI of the muted device complies with the Output Return Loss requirements for inactive OFDM channels given in Table 100–3.

CLT_TxMute
TYPE: Boolean
When this variable is set to TRUE the CLT sets the RF output power = 73 dBc (see Table 100–3)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

below the operationally configured aggregate power of the RF modulated signal, in every 6 MHz channel from 258 MHz to 1218 MHz. When set to FALSE the CLT is in its normal operating state.

100.4.2 CNU receive modulation error ratio testing

Performance requirements for downstream RxMER measurements are defined under the following list of specified conditions:

- Channel loading consists of a single OFDM channel with no other signals.
- The OFDM channel being measured has a fixed configuration with a 192 MHz channel bandwidth with 190 MHz modulated spectrum and no excluded subcarriers other than at band edges.
- The channel is flat without impairments other than AWGN.
- AWGN level is set to two values giving data-subcarrier CNR = 30 dB and 35 dB at the MDI (F connector) of the CNU across all data subcarriers in the OFDM channel.
- Signal level is fixed at a nominal receive level of 6 dBmV per 6 MHz.
- A minimum warm-up time of 30 min occurs before measurements are made.
- Each measurement consists of the frequency average across all subcarriers of the reported time-averaged individual subcarrier RxMER values as defined above. Frequency averaging is performed by external computation.
- An ensemble of M frequency-averaged RxMER measurements (M large enough for reliable statistics, i.e., such that the result lies within a given confidence interval) are taken in succession (e.g., over a period of up to 10 min) at both CNR values. The mean, *RxMER_mean* in dB, and standard deviation, *RxMER_std* in dB, are computed over the M measurements at both CNR values. The statistical computations are performed directly on the dB values.

The CNU shall provide RxMER measurements with *RxMER_std* ≤ 0.5 dB under the specified conditions in the previous list.

Define *delta_RxMER* = (*RxMER_mean* at CNR_data_subcarrier = 35 dB) – (*RxMER_mean* at CNR_data_subcarrier = 30 dB). The CNU shall provide RxMER measurements such that 4 dB ≤ *delta_RxMER* ≤ 6 dB under the above specified condition.

100.4.3 Upstream channel power

The purpose of the upstream OFDMA channel power metric is to provide an estimate of the total received power at the F connector input of the CLT (see “TP1 / MDI” Figure 101–4) for a single specified upstream CNU. The measurement is based on upstream probes. While digital power measurements are inherently accurate, the measurement referred to the analog input depends on available calibration accuracy.

NOTE—It is recommended that the CLT provide configurable averaging over a range at least including 1 to 32 probes.

The CLT provides upstream power measurements with a standard deviation of 0.33 dB or better under the following test conditions:

- Center frequency is fixed.
- Probe being measured has a fixed configuration containing at least 256 active subcarriers.
- Channel is without impairments other than AWGN at 25 dB CNR.
- Signal level is fixed at a value within ± 6 dB relative to a nominal receive level of 0 dBmV.
- A minimum warm up time of 5 min occurs before power measurements are made.
- Averaging is set to $N = 8$ probes per measurement.
- M measurements (M large enough for reliable statistics) are taken in succession (e.g,. over a period of up to 10 min). The standard deviation is computed over the M measurements, where each measurement is the average of N probes.

100.4.3.1 PHY Link managed variables

RxPwr

TYPE: 9-bit signed integer
This variable is used to report the received power for the CNU indicated by *RxPwr_CNU_ID* in units of 0.1 dBmV.

RxPwr_CNU_ID

TYPE: 14-bit integer
When set to a CNU_ID this variable indicates which CNU is to be measured for receive power reporting using *RxPwr*.

RxPwrValid

TYPE: Boolean
When TRUE this flag indicates that the value of *RxPwr* is valid for the CNU indicated by *RxPwr_CNU_ID*. Any write to *RxPwr_CNU_ID* sets this variable to FALSE.

100.4.4 Guidelines for verifying compliance with downstream phase noise requirements

The CLT transmitted signal for each OFDM channel shall meet the test phase noise requirements as per Table 100–16. These are transmitter requirements only.

Table 100–16—Downstream phase noise test requirements

Parameter	Value	Units
Phase noise, integrated double sided maximum, full power CW signal 1002 MHz or lower:		
1 kHz to 10 kHz	–48	dBc
10 kHz to 100 kHz	–56	dBc
100 kHz to 1 MHz	–60	dBc
1 MHz to 10 MHz	–54	dBc
10 MHz to 100 MHz	–60	dBc
Full power 192 MHz OFDM channel block with 6 MHz in center as internal exclusion subband + 0 dBc CW signal in center, with block not extending beyond 1002 MHz.		
1 kHz to 10 kHz	–48	dBc
10 kHz to 100 kHz	–56	dBc
Full power 192 MHz OFDM channel block with 24 MHz in center as internal exclusion subband + 0 dBc CW signal in center, with block not extending beyond 1002 MHz.		
100 kHz to 1 MHz	–60	dBc
Full power 192 MHz OFDM channel block with 30 MHz in center as internal exclusion subband + 7 dBc CW signal in center, with block not extending beyond 1002 MHz.		
1 MHz to 10 MHz	–53	dBc

A CW signal can be generated via an FFT, where the CW signal is constructed as a continuous pilot selected to be on a subcarrier in proper coordination with the cyclic prefix; so there are no phase glitches on the

subcarrier in transitioning from one OFDM symbol to another. In this configuration the EPoC OFDM continuous pilot is in fact phase continuous in the time domain; in general the continuous pilots are not phase continuous in the time domain. Continuous pilot means that subcarrier is continuously used as a pilot and in general does not mean that the phase is continuous. Placing a continuous pilot using a subcarrier where the continuous pilot does in fact have continuous phase in the time domain serves as the CW signal in the phase noise tests and allow the full FFT processing associated with compliant OFDM transmissions to be engaged (compliant except for a single active subcarrier with large power in the middle of a large exclusion subband). This is the preference for verifying phase noise requirements.

If a continuous pilot is not used (as above), the OFDM channel has real data in the non-excluded subcarriers, FFT processing is occurring for those data subcarriers. The OFDM transmitter needs to generate a time continuous phase signal on the CW signal subcarrier that is synchronous with the data subcarriers RF and OFDM Clock. The OFDM test receiver need to be functionally equivalent to: 1) phase/noise test equipment that filters out data subcarriers and 2) a modified compliant receiver that validates the data subcarriers are operating properly. This latter step can be done non-real time.

100.4.4.1 Test mode 1

A CLT shall provide a test mode of operation, for out-of-service testing, configured for *N* channels but generating one CW signal per channel, one channel at a time at the center frequency of the selected channel; all other combined channels are suppressed. One purpose of this test mode is to support one method for testing the phase noise requirements of Table 100–4 and Table 100–16. As such, the CLT generation of a CW signal test tone should exercise the signal generation chain to the fullest extent practicable, in such a manner as to exhibit phase noise characteristics typical of actual operational performance; for example, repeated selection of a constellation symbol with power close to the constellation RMS level would seemingly exercise much of the modulation and up-conversion chain in a realistic manner. The CLT test mode shall be capable of generating the CW signal tone over the full range of Center Frequency in Table 100–16. In addition, the CLT shall be configurable in either one or both of the following conditions:

— Two CW signals on a single out-of-service downstream OFDM channel, at selectable valid subcarrier center frequencies 20 MHz to 100 MHz apart within the selected channel. All other subcarriers within the selected out-of-service downstream OFDM channel are suppressed.

— One CW signal on each of two separate but synchronized downstream OFDM channels at selectable valid subcarrier center frequencies 20 MHz to 100 MHz apart within the selected channels. All other subcarriers within the selected out-of-service downstream OFDM channel are suppressed.

The purpose of this test mode is to support the ability to measure the downstream OFDM Clock jitter requirements of Table 101–7, whereby the two CW signals are mixed to create a difference product CW signal at frequency ($f_2 - f_1$), for which the jitter is measure directly and compared to the requirements stated in that section.

100.4.4.2 Test mode 2

A CLT shall provide a test mode of operation, for out-of-service testing, generating one-CW-per-channel, at the center frequency of the selected channel, with all other N – 1 of the combined channels active and containing valid data modulation at operational power levels. One purpose for this test mode is to support one method for testing the phase noise requirements of Table 100–16. As such, the generation of the CW test tone should exercise the signal generation chain to the fullest extent practicable, in such manner as to exhibit phase noise characteristics typical of actual operational performance. For example, a repeated selection of a constellation symbol, with power close to the constellation RMS level, would seemingly exercise much of the modulation and up-conversion chain in a realistic manner. For this test mode, it is acceptable that all channels operate at the same average power, including each of the N – 1 channels in valid operation, and the single channel with a CW tone at its center frequency.

100.5 Environmental, safety, and labeling

100.5.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

100.5.2 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

100.5.3 Environment

Normative specifications in this clause should be designed to be met by a system integrating 10GPASS-XR over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the RF link, the distance and operating environmental conditions over which the specifications of this clause will be met.

100.5.4 PMD labeling

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 10GPASS-XR).

100.5.4.1 Frequency plan

Equipment conforming to this standard shall be clearly labeled with information about the supported downstream and upstream frequency ranges.

100.5.4.1.1 Downstream frequency plan

The CLT transmitter and CNU receiver are expected to support a frequency range from 258 MHz to 1218 MHz as defined in Table 100–3. Equipment may be adapted to all or part of this frequency band to suit regional requirements.

100.5.4.1.2 Upstream frequency plan

The CNU transmitter and CLT receiver are expected to support a frequency range from 7.4 MHz to 204 MHz as defined in Table 100–11. Equipment may be adapted to all or part of this frequency band to suit regional requirements.

100.6 EEE capability

For the 10GPASS-XR-U PHY the CNU shall enable Energy-Efficient Ethernet (EEE) capability to conserve energy by deactivating power-consuming PMD Functions (e.g., RF power amplifier) between bursts using PMD_SIGNAL.request (see 100.2.1.3).

100.7 Protocol implementation conformance statement (PICS) proforma for Clause 100, Physical Medium Dependent (PMD) sublayer and medium for coaxial cable distribution networks, type 10GPASS-XR[174]

The supplier of a protocol implementation that is claimed to conform to Clause 100, Physical Medium Dependent (PMD) sublayer and medium for passive optical networks type 10GPASS-XR shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

100.7.1 Identification

100.7.1.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

100.7.1.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 100, Physical Medium Dependent (PMD) Sublayer for 10GPASS-XR
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[174] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

101. Reconciliation Sublayer, Physical Coding Sublayer, and Physical Media Attachment for EPoC

101.1 Overview

This clause describes the Reconciliation Sublayer (RS), Physical Coding Sublayer (PCS) with FEC, and Physical Medium Attachment (PMA) used with 10GPASS-XR point-to-multipoint (P2MP) networks. These are multipoint coaxial cable distribution networks (CCDN) that connect multiple DTEs using a single shared coaxial link. The architecture is asymmetric, based on a tree and branch topology utilizing coaxial taps and splitters. This type of network requires that the Multipoint MAC Control sublayer exists above MAC instances, as described in Clause 103.

101.1.1 Conventions

The notation used in the state diagrams in this clause follows the conventions in 21.5. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation "++" after a counter indicates it is to be incremented by 1. The notation "––" after a counter indicates it is to be decremented by 1. Code examples given in this clause adhere to the style of the "C" programming language.

For equations used in this clause the symbol $\lceil x \rceil$ represents a ceiling function that rounds up its argument x to the next highest integer. The notation $\lfloor x \rfloor$ represents a *floor* function, which returns the value of its argument x rounded down to the nearest integer.

101.1.2 Constraints for delay through RS, PCS, and PMA

The operation of EPoC Multipoint Control Protocol (MPCP), as defined in Clause 103, relies on strict timing based on the distribution of timestamps. The actual delay is implementation-dependent but an implementation shall maintain a combined delay variation through RS, PCS, and PMA sublayers of no more than 1 time_quantum (see 64.2.2.1) so as not to interfere with the MPCP timing and operation.

101.1.3 Mapping of PCS, and PMA variables

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the 10GPASS-XR PHY or are communicated between the CLT and the CNU via the PHY Link. The mapping of MDIO control and status variables to PCS/PMA variables is shown in Table 101–1. The least significant bit in each variable is mapped to the lowest numbered bit in the lowest numbered register for Clause 45 registers. These variables are used by the PHY Link for PHY management.

101.1.4 Functional blocks supporting 10GPASS-XR PCS, PMA, and PMD sublayers

Figure 101–1 and Figure 101–4 illustrate functional blocks within the CLT PCS, PMA, and PMD sublayers, and interactions between them in the transmit direction and in the receive direction, respectively. Figure 101–2 and Figure 101–3 illustrate functional blocks within the CNU PCS, PMA, and PMD sublayers, and interactions between them in the transmit direction and in the receive direction, respectively. Clause 100 focuses on functions of the PMD sublayer, Clause 101 focuses on PCS and PMA, and Clause 102 focuses on PHY Link.

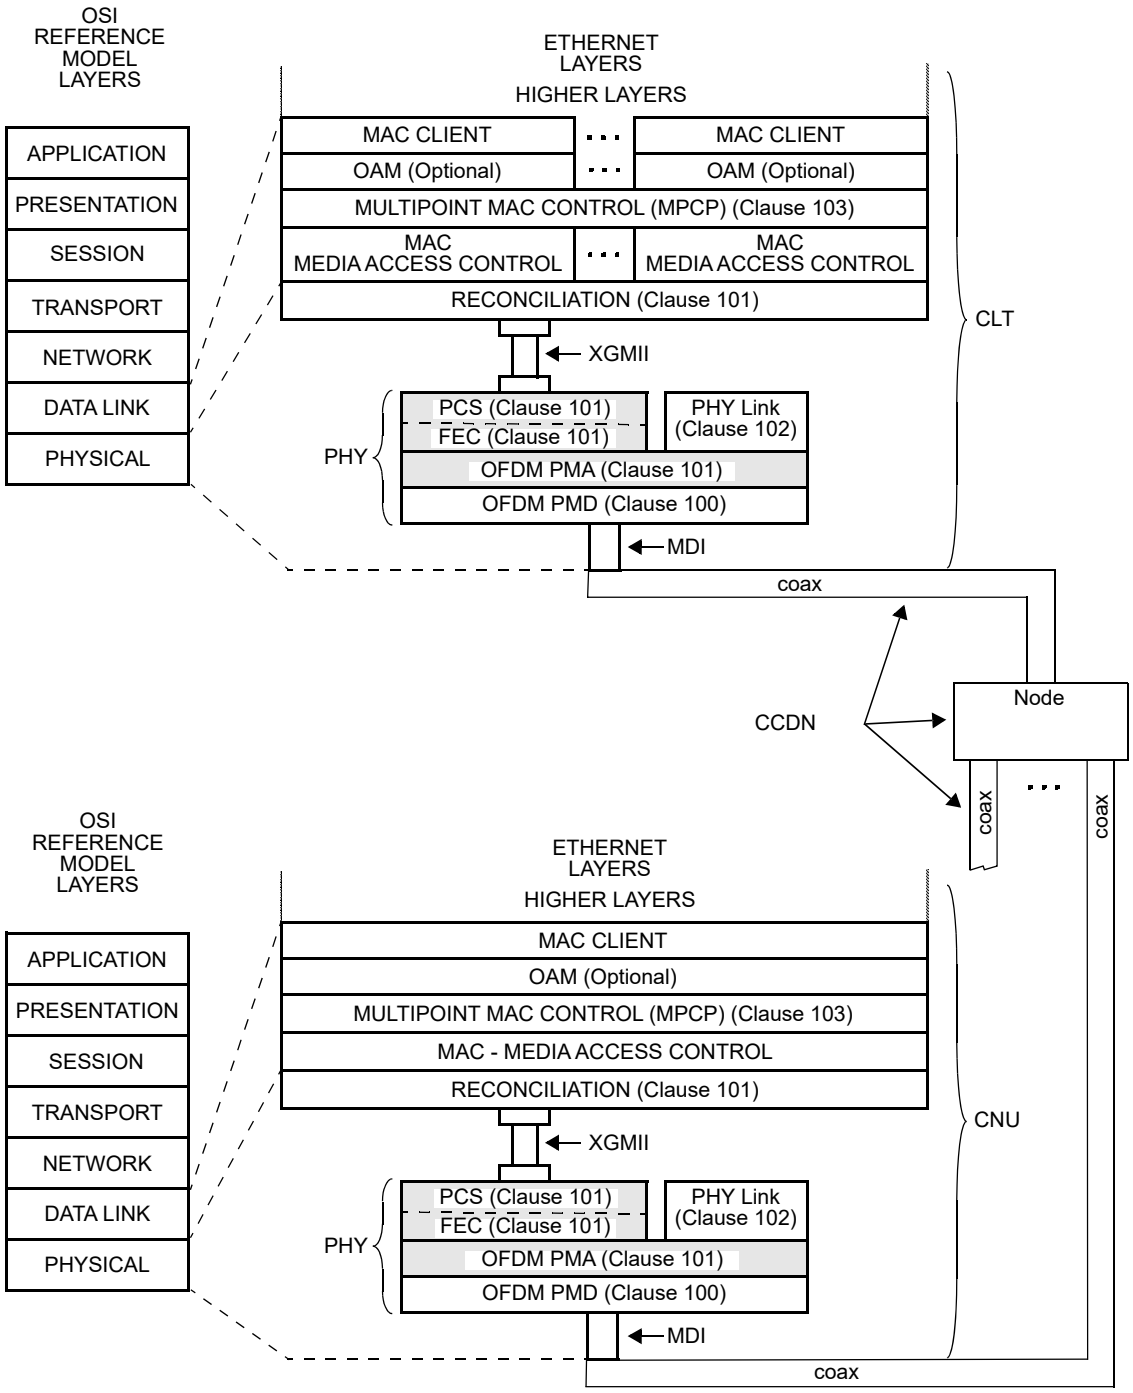
101.2 Reconciliation Sublayer (RS) for EPoC

The Reconciliation sublayer used for 10GPASS-XR is identical to that described in 76.2.

101.3 Physical Coding Sublayer (PCS) for EPoC



101.3.1 Overview

This subclause defines the Physical Coding Sublayer (PCS) for 10GPASS-XR, supporting operation over the point-to-multipoint coaxial cable distribution network. The EPoC PCS is specified to support the operation of up to 10 Gb/s in the downstream direction and up to 1.6 Gb/s in the upstream direction, where the upstream and downstream data rates are configured independently.

This subclause also specifies a forward error correction (FEC) as well as Idle control character insertion and deletion mechanisms. The FEC mechanism increases the available link budget. The FEC codeword additionally includes a CRC40 to ensure that mean time to false frame acceptance of 4.4×10^{17} seconds is met. The Idle control character insertion and deletion mechanisms accommodates rate adaptation between the MAC and MAC Control Clients operating at 10 Gb/s and the EPoC PCS and PMD sublayers operating at data rates below 10 Gb/s.

Figure 101–5 shows the relationship between the EPoC PCS sublayer and the ISO/IEC OSI reference model. Figure 101–1 illustrates the CLT transmitter functional block diagram, including the PCS, while Figure 101–2 illustrates the CNU transmitter functional block diagram. Figure 101–3 and Figure 101–4 illustrate the functional block diagram of the receive path in the CLT PCS and CNU PCS, respectively.

101.3.2 PCS transmit function

In the CLT, the PCS transmit function operates in a continuous fashion at the data rate of up to 10 Gb/s. In the CNU, the PCS transmit function operates in a burst mode at the data rate of up to 1.6 Gb/s. Figure 101–1 illustrates the CLT transmitter functional block diagram, while Figure 101–2 illustrates the CNU transmitter functional block diagram.

In the transmit direction, the EPoC PCS includes an Idle Deletion function that performs data rate adaptation and FEC overhead compensation, followed by a 64B/66B Encoder, and an FEC Encoder/Data Detector.

101.3.2.1 Idle deletion process

In the transmitting PCS, the Idle deletion process is responsible for deleting excess Idle control characters inserted between individual frames to adjust the data rate enforced by the MAC Control (as defined in Clause 103) to the effective data rate supported by the PCS and PMD. The gaps created within the data stream by the operation of the Idle deletion process are used in one of the following ways:

— Some gaps created by the removal of Idle control characters are filled with FEC parity data (FEC overhead compensation sub-process); or

— Other gaps created by the removal of Idle control characters are discarded in order to decrease the effective data rate between the MAC and PHY (data rate adaptation sub-process).

The Idle deletion process deletes a specific number of 72-bit vectors containing Idle control characters from the data stream composed of a series of 72-bit vectors received from the XGMII. The number of deleted 72-bit vectors containing Idle control characters depends on the EPoC PMD data rate, PMD overhead (including, for example, cyclic prefix), and the size of FEC parity data. The Idle deletion process performs the following two functions:

— Create gaps by Idle removal to allow for FEC parity/CRC40.

— Rate adaptation by Idle removal to adjust from the XGMII rate to the PMD rate.

The operation of the EPoC MPCP defined in Clause 103 ensures that a sufficient number of Idle control characters are present in the data stream, so that the minimum IPG between two adjacent frames is preserved once all excess Idle control characters are removed through the operation of the data rate adaptation and the FEC overhead compensation sub-processes.

101.3.2.1.1 Constants

DS_FEC_OSize
: TYPE: U5.3 format
The number of 72-bit vectors constituting the overhead (parity and CRC40) portion of a downstream FEC codeword. To normalize the downstream pre-FEC data rate, the Idle deletion process removes *DS_FEC_OSize* vectors per every *DS_PHY_DSize* vectors transferred to the 64B/66B Encoder.
Value: (1800+40)/65

DS_PHY_DSize
: TYPE: 16-bit unsigned integer
The number of 72-bit vectors constituting the payload portion of a downstream FEC codeword. To normalize the effective downstream PCS data rate, the Idle deletion process removes DS_*PHY_OSize* vectors per every DS_*PHY_DSize* vectors to compensate for FEC overhead and PMD derating processes.
Value: 220

US_FEC_OSize
: TYPE: U5.3 format

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The number of 72-bit vectors constituting the parity (overhead) portion of a upstream FEC codeword. To normalize the upstream pre-FEC data rate, the Idle deletion process removes *US_FEC_OSize* vectors per every *US_PHY_DSize* vectors transferred to the 64B/66B Encoder.
Value: (280+40)/65

US_PHY_DSize
TYPE: 16-bit unsigned integer
The number of 72-bit vectors constituting the payload portion of a upstream FEC codeword. To normalize the effective upstream PCS data rate, the Idle deletion process removes *US_PHY_OSize* vectors per every *US_PHY_DSize* vectors to the compensation of FEC overhead and PMD derating process.
Value: 12

XGMII_Rate
TYPE: unsigned integer
The data transfer rate of the XGMII interface.
Value: 10 Gb/s

101.3.2.1.2 Variables

accResidue
TYPE: U1.3 format
The variable *accResidue* tracks the accumulation of *PHY_OSizeFrac*.

BEGIN
TYPE: Boolean
This variable is used when initiating operation of the state diagram. It is set to TRUE following initialization and every reset.

DelayBound
TYPE: 16-bit unsigned integer
This value represents the number of consecutive 65-bit blocks containing Idles used by the Data Detector input and CNU output process to determine end of burst. This value represents the delay sufficient to initiate the transmitter at the CNU and to accommodate timing jitter caused by PMA overhead, such as burst markers, and pilots. This variable is used only by the CNU. By default, the value should be set the same as that for length of the *FIFO_FEC_TX* buffer.

DS_DataRate
See 100.3.2.1.

DS_PHY_OSize
TYPE: 16-bit unsigned integer
To normalize the effective PCS data rate, the Idle deletion process removes *DS_PHY_OSize* vectors per every *DS_PHY_DSize* vectors to compensate for FEC overhead and PMD derating process. *DS_PHY_OSize* is defined in Equation (101–1).

$$DS_PHY_OSize = \left\lfloor \frac{XGMII_Rate - PCS_DS_Rate}{PCS_DS_Rate} \times (DS_PHY_DSize + DS_FEC_OSize) + DS_FEC_OSize \right\rfloor \quad (101–1)$$

PCS_DS_Rate:
TYPE: UQ34.3 format
The transmission rate of PCS data, excluding the 64B/65B sync header bit in the 64/65B line encoder, as defined in Equation (101–2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$PCS_DS_Rate = DS_DataRate \times \frac{64}{65} \quad (101–2)$$

PHY_OSizeFrac:

TYPE: U0.3 format

The fractional part of *DS_PHY_OSize* due to the floor operation in Equation (101–1). The *PHY_OSizeFrac* is defined in Equation (101–3).

$$PHY_OSizeFrac = \frac{XGMII_Rate - PCS_DS_Rate}{PCS_DS_Rate} \times (DS_PHY_DSize + DS_FEC_OSize) + DS_FEC_OSize - DS_PHY_OSize \quad (101–3)$$

tx_raw<71:0>

This variable is defined in 49.2.13.2.2.

tx_raw_out<71:0>

72-bit vector sent from the output of the Idle deletion process to the 64B/66B Encoder. This vector contains two XGMII transfers mapped as shown for *tx_raw*<71:0>.

101.3.2.1.3 Counters

countDelete

TYPE: 16-bit unsigned integer

Counts the number of 72-bit vectors that need to be deleted from the received data stream as part of the data rate adaptation and FEC overhead compensation.

countVector

TYPE: 16-bit unsigned integer

Counts the number of 72-bit vectors transmitted after the removal of Idle characters as part of data rate adaptation and FEC overhead compensation.

101.3.2.1.4 Functions

T_TYPE(*tx_raw*<71:0>)

This function is defined in 49.2.13.2.3.

101.3.2.1.5 State diagrams

The CLT PCS shall perform the Idle deletion process as shown in Figure 101–6. The CNU PCS shall perform the Idle deletion process as shown in Figure 101–7.

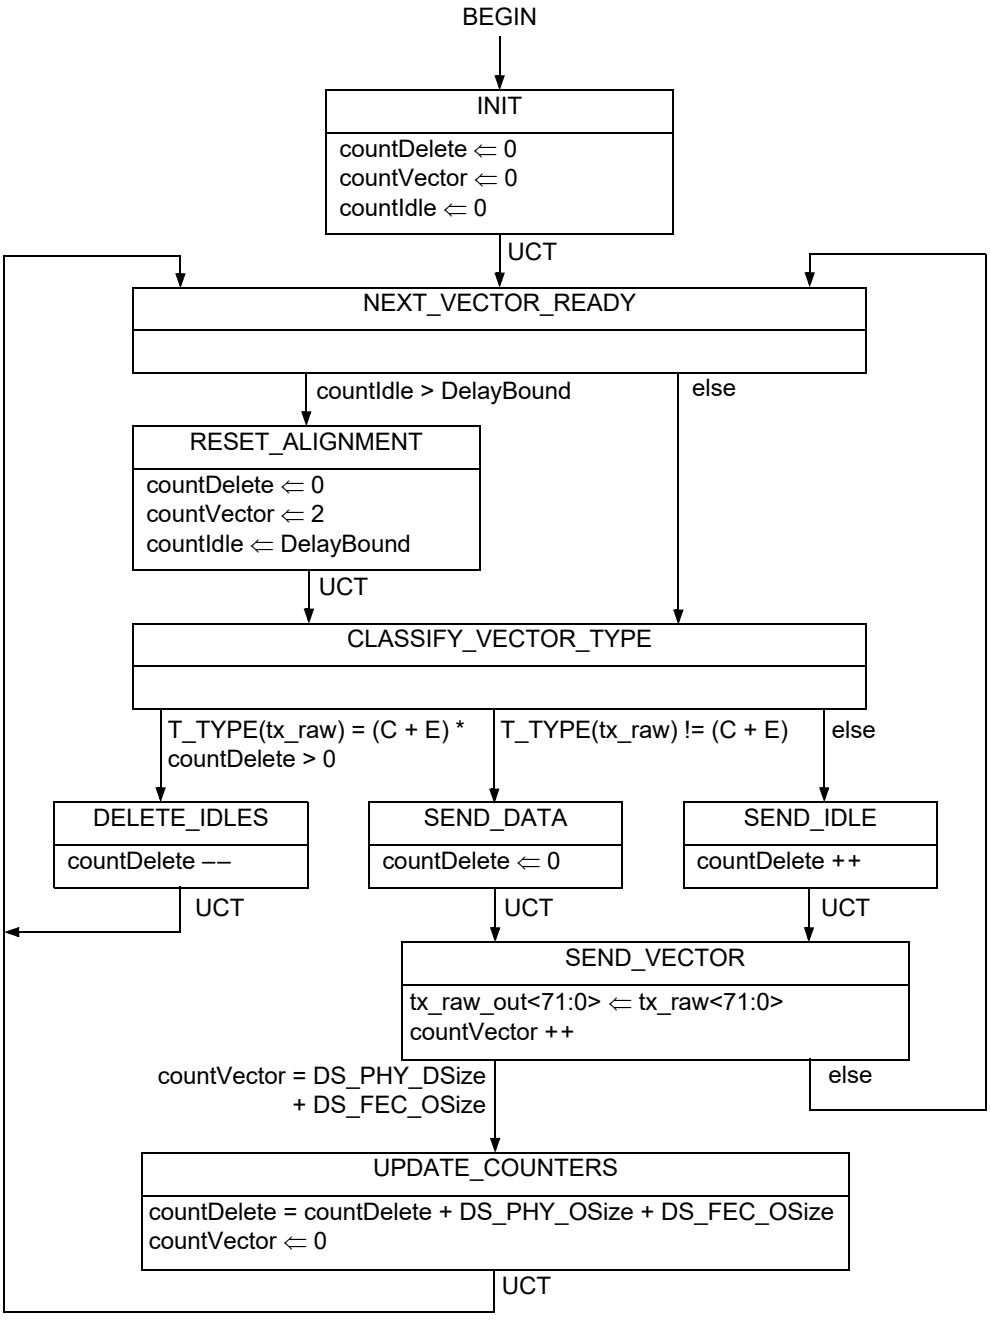

Figure 101–7—CNU Idle deletion process state diagram

101.3.2.2 64B/66B Encoder

The EPoC PHY utilizes a 64B/66B Encoder based on that described in 49.2.4 with several important differences. The EPoC 64B/66B Encoder does not include a scrambler function as described in 49.2.6 and the output is a 65B block with a single synch header bit. The state diagram found in Figure 49–16 is followed after which the sync header bit <0> is removed as illustrated in Figure 101–9.

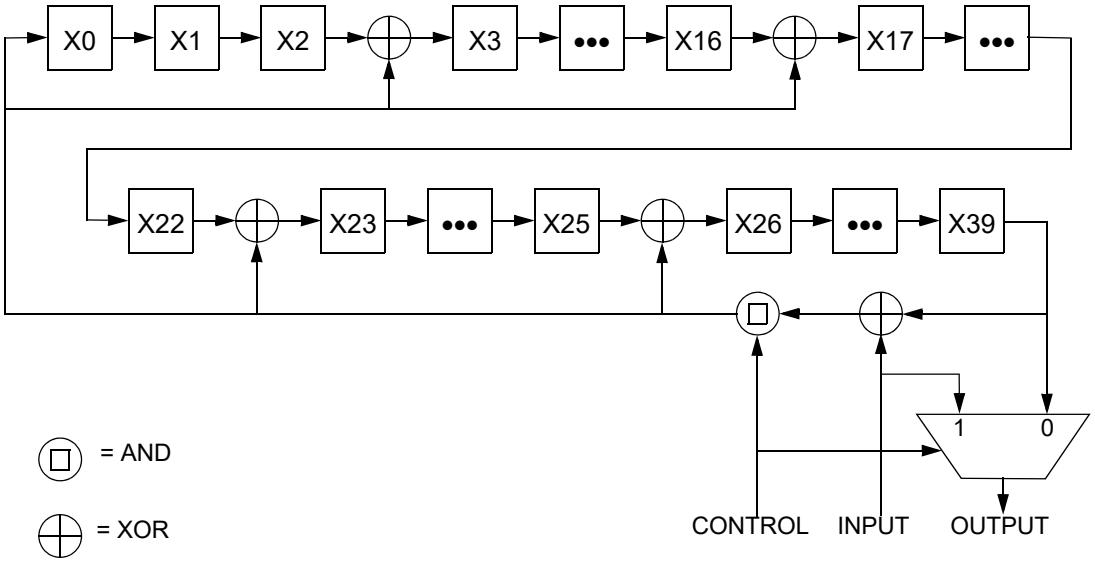
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



101.3.2.3 CRC40

The CRC40 field contains a 40-bit cyclic redundancy check value. This value is computed as a function of the contents of the B_Q 65-bit blocks (see Table 101–2), forming the payload portion of the FEC codeword.

The encoding is defined by the CRC40 generating polynomial shown in Equation (101–4):

$$x^{40} + x^{26} + x^{23} + x^{17} + x^3 + 1 \quad (101–4)$$

This CRC40 calculation shall produce the same result as the serial implementation shown in Figure 101–8. At the beginning of each FEC codeword (before the calculation of CRC40 begins), the shift register shall be initialized to the value zero. The content of the shift register is transmitted without inversion.

CONTROL = 1 when shifting the payload portion of FEC codeword calculation CRC40

CONTROL = 0 when transmitting the CRC40 field

Figure 101–8—CRC40 generation

101.3.2.4 Low Density Parity Check (LDPC) forward error correction (FEC) codes

The 10GPASS-XR PHY encodes the transmitted data using a systematic Low-Density Parity-Check (LDPC) (F_C, F_P) code. A LDPC Encoder encodes F_P information bits $i_{0 \ldots} i_{F_P - 1}$ into a codeword

$$cFc = (i_0, \ldots, i_{F_P - 1}, p_{F_P}, \ldots, p_{F_C - 1}) \quad (101–5)$$

by adding F_R parity bits $p_{F_p \ldots} p_{F_C - 1}$ obtained so that

$$Hc^T = 0$$

where H is an $F_R \times F_C$ binary matrix containing mostly '0' and relatively few '1', called low-density parity-check matrix (see Gallagher [B26]). The detailed description of such parity check matrices is given in 101.3.2.4.1.

The CLT 10GPASS-XR PCS operating on a CCDN shall encode the transmitted data using the LDPC (16200, 14400) code per Table 101–2. The CNU 10GPASS-XR PCS operating on CCDN shall encode the transmitted data using one of the LDPC (F_C, F_P) codes per Table 101–2.

Table 101–2—LDPC codes used in EPoC

Upstream (US) Downstream (DS)	Codeword F_C [bits]	Payload F_P [bits]	Parity F_R [bits]	US filling threshold F_T		Payload		
				bits	65-bit blocks	65-bit blocks B_Q	CRC bits	Padding bits B_P
US/DS	16200	14400	1800	6601	101	220	40	60
US	5940	5040	900	1601	25	76	40	60
US	1120	840	280	1	1	12	40	20

101.3.2.4.1 LDPC matrix definition

The low-density parity check matrix H for LDPC (F_C, F_P) encoder can be divided into blocks of L^2 sub-matrices. Its compact circulant form is represented by an $m \times n$ block matrix:

$$H = \begin{bmatrix} H_{1,1} & H_{1,2} & H_{1,3} & \dots & H_{1,n} \\ H_{2,1} & H_{2,2} & H_{2,3} & \dots & H_{2,n} \\ H_{3,1} & H_{3,2} & H_{3,3} & \dots & H_{3,n} \\ \dots & \dots & \dots & & \dots \\ H_{m,1} & H_{m,2} & H_{m,3} & \dots & H_{m,n} \end{bmatrix}$$

where the submatrix $H_{i,j}$ is an $L \times L$ all-zero submatrix or a cyclic right-shifted identity submatrix. The last $n–m$ submatrix columns represent the parity portion of the matrix. Moreover, $nL = F_C$, $mL = F_P$ and the code rate is $(n – m)/n = (F_C – F_P)/F_C$. The submatrix size L is called the lifting factor.

The submatrix $H_{i,j}$ is represented by a value in {–1, 0,…, L–1}, where a '–1' value represents an all-zero submatrix, and the remaining values represent an $L \times L$ identity submatrix cyclically right-shifted by the specified value. Such representation of the parity-check matrix is called a base matrix.

Table 101–3 presents a 5×45 base matrix of the low-density parity-check matrix H for LDPC (16200, 14400) code listed in Table 101–2 for downstream and upstream. The lifting factor of the matrix is $L = 360$.

101.3.2.5 FEC Encoder and Data Detector processes

101.3.2.5.1 Data Detector process

The 10GPASS-XR PCS transmit path includes the Data Detector process. This process contains a delay line (represented by the *FIFO_FEC_TX* buffer) that stores 65-bit blocks received from the output of the 64B/66B Encoder to allow insertion of the FEC parity data into the transmitted data stream. The length of the *FIFO_FEC_TX* buffer is selected in such a way that it is large enough to compensate for the FEC overhead and PHY overhead, as discussed in 101.3.2.3 and 101.3.2.5.2.

101.3.2.5.2 LDPC encode process

The process of padding FEC codewords and appending FEC parity octets in the 10GPASS-XR PCS transmit path is illustrated in Figure 101–9. For the CLT, the FEC Encoder uses a single FEC LDPC codeword size of 16200 bits indicated by "DS" in Table 101–2 represented by constant FEC_DS_CodeWordSize (see 101.3.2.5.2). For the CNU, the FEC Encoder performs an algorithm as described in 101.3.2.5.4 for selecting the use of one or more "long" codewords (upstream size 16200 bits), a "medium" codeword (upstream size 5940), or one or more "short" codewords (upstream size 1120 bits) as detailed in Table 101–2.

The 64B/66B Encoder, as described in 101.3.2.2 and shown in Figure 101–9, delivers a stream of 65-bit blocks to the FEC Encoder and Data Detector. In the CNU only, a 65-bit Burst Time Header is added as the first 65-bit block at the start of a burst (see Figure 101–13).

Next, the FEC Encoder calculates CRC40 (see 101.3.3) over the aggregated B_Q (see Table 101–2) 65-bit blocks, placing the resulting 40 bits of CRC40 code immediately after the B_Q 65-bit blocks, forming the payload portion of the FEC codeword. Finally, based on the codeword size the FEC Encoder appends B_P (see Table 101–2) padding bits (with the binary value of "0") to the payload of the FEC codeword as shown in Figure 101–9.

The resulting F_P bits of data are then passed to the LDPC Encoder operating on a payload length of $F_P - B_P$ bits. The LDPC Encoder generates F_R bits of parity. After encoding, the encoder deletes the B_P bits of padding and constructs the output codeword with a length of $(F_P - B_P) + F_R$ bits.

101.3.2.5.3 LDPC codeword transmission order

Once the process of calculating FEC parity is complete, the payload portion of the FEC codeword and the parity portion of the FEC codeword are then transferred to the transmit PMA Client.

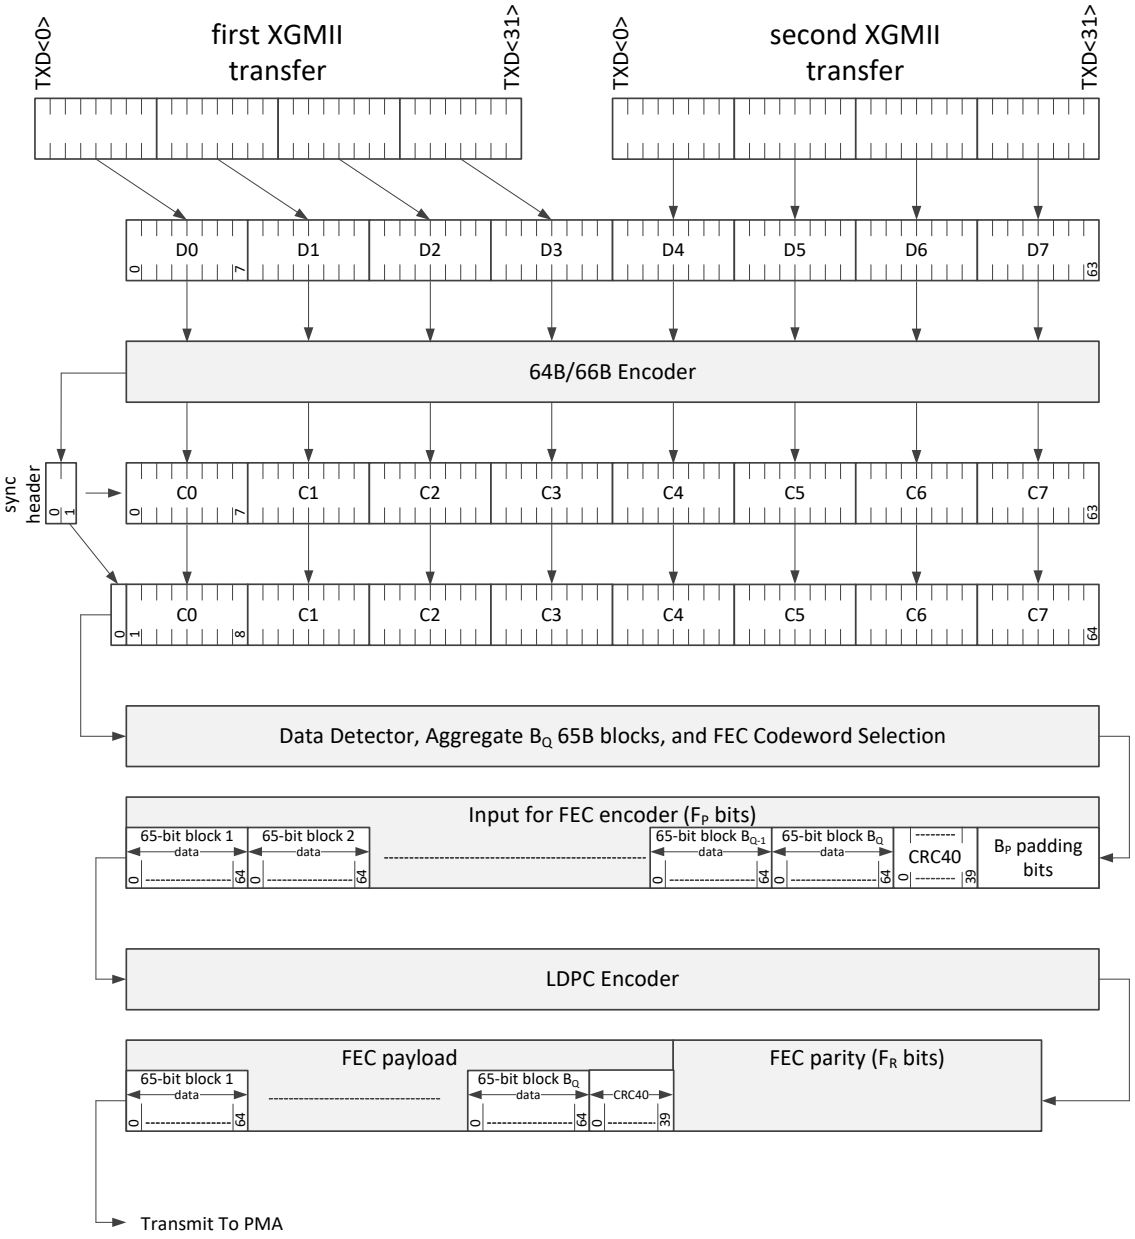

Figure 101–9—10GPASS-XR PCS transmit path processing

Figure 101–10 illustrates the details of the 10GPASS-XR CNU burst structure. In particular, this figure shows the details of the necessary burst elements and the FEC protected portions of the burst transmission, explicitly showing each FEC codeword.

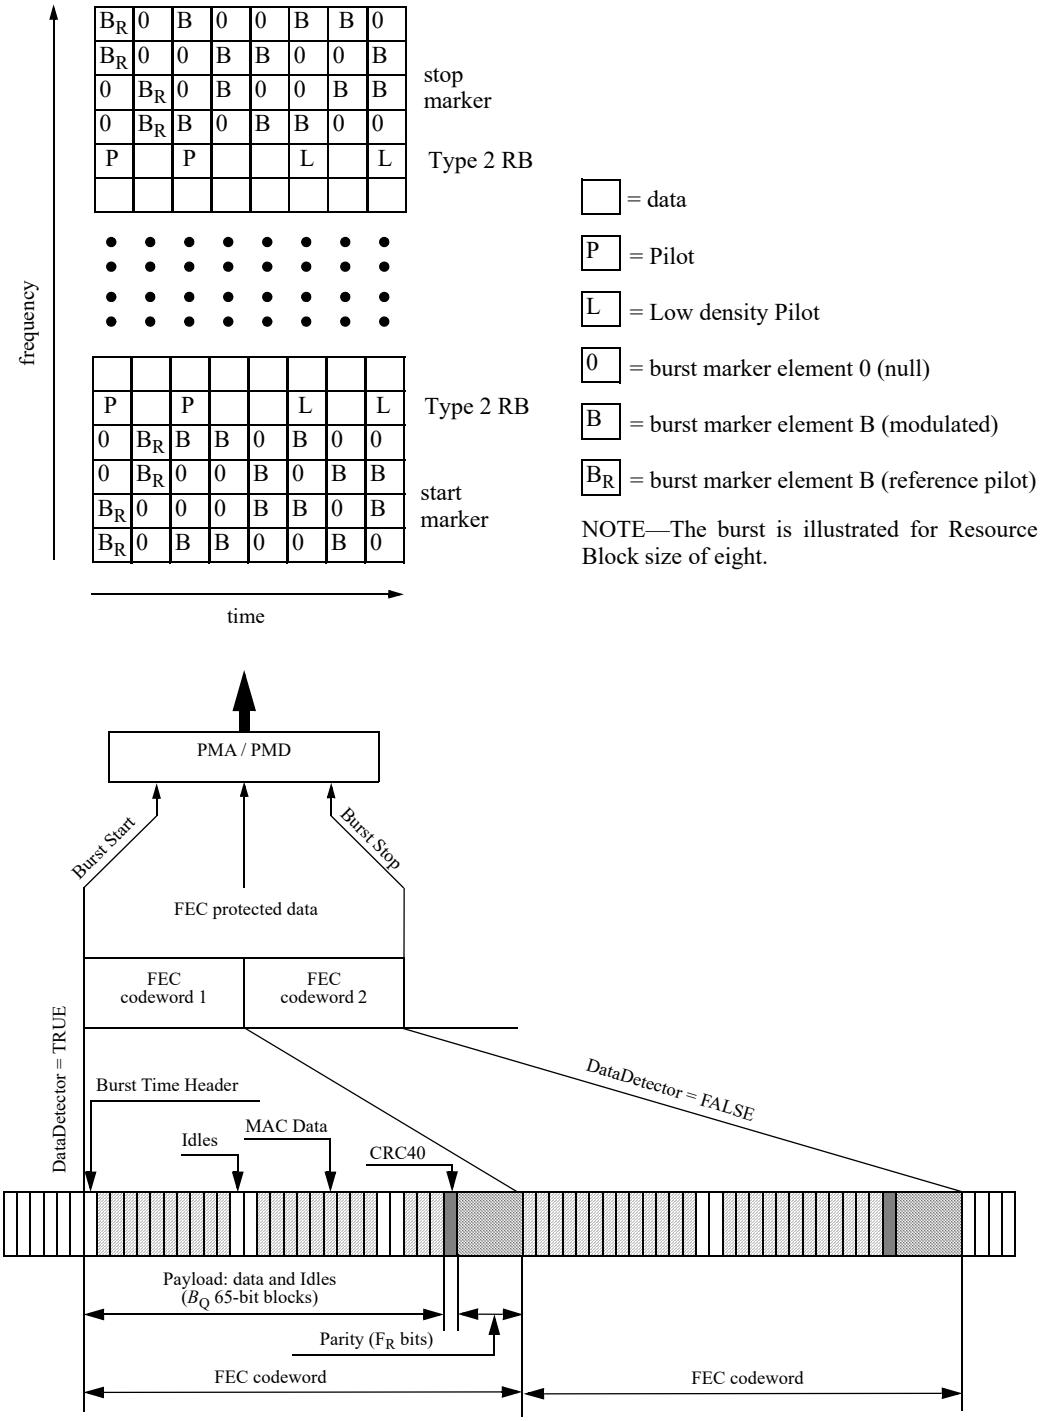

Figure 101–10—Details of burst composition

The CNU burst transmission begins with a start burst marker (see 101.4.4.8), which facilitates the detection of the start of an incoming data burst. When received at the CLT, the start burst marker enables FEC codeword alignment to the incoming data stream, even in the presence of bit errors. The start burst marker is not part of the first FEC codeword but is added by the PMA.

The CNU burst ends with the end burst marker (see 101.4.4.8), which facilitates the detection of the end of the current data burst. When received at the CLT, the end burst marker allows for the rapid reset of the CLT FEC synchronizer, so that it can search for the next burst. The end burst marker is not part of the last FEC codeword but is added by the PMA.

101.3.2.5.4 Upstream FEC encoding

Upstream bursts in EPoC are variable in length and may contain more than one MAC frame. The upstream makes use of three different LDPC codeword sizes as described Table 101–2. Each codeword size has a specific, associated US filling threshold F_T.

Starting with a 16200 (long) codeword:

1) If the number of available 65-bit blocks (Bin) is sufficient to fill a long FEC codeword ($B_Q \geq 220$), create a long FEC codeword. If Bin ≥ 220, is true repeat step 1).
2) If 220 > Bin ≥ 101, create a shortened long FEC codeword.
3) If 101 > Bin ≥ 76, create a medium FEC codeword.
4) If 76 > Bin ≥ 25, create a shortened medium FEC codeword.
5) If 25 > Bin ≥ 12, create a shortened FEC codeword. If Bin ≥ 12, is true repeat step 5).
6) If 12 > Bin ≥ 1, create a shortened short FEC codeword.

101.3.2.5.5 Constants

FEC_DS_CodeWordSize
: TYPE: 16-bit integer
The fixed size, in bits, of the downstream FEC codeword.
Value: 16140

SH_CTRL
: See 76.3.2.5.2.

SH_DATA
: See 76.3.2.5.2.

101.3.2.5.6 Variables

blockCount
: TYPE: 16-bit unsigned integer
This variable represents the number of 65-bit blocks input to the FEC Encoder.

B_P
: TYPE: 16-bit unsigned integer
VALUE: see Table 101–2
This variable represents the number of padding bits within the payload portion of the FEC codeword.

B_Q
: TYPE: 16-bit unsigned integer
VALUE: see Table 101–2
This variable represents the number of 65-bit blocks within the payload portion of the FEC codeword.

burstEnd
: TYPE: Boolean
When TRUE this flag signals the end of burst.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

burstStart

TYPE: Boolean
When TRUE this flag signals the start of a burst.

CLK

TYPE: Boolean
This variable is TRUE on every negative edge of *TX_CLK* (see 46.3.1) and represents instances of time at which a 66-bit block is passed from the output of the 64B/66B Encoder into the FEC Encoder. This variable is reset to FALSE upon read.

dataPayload<F_P–1:0>

TYPE: Bit array
This array represents the payload portion of the FEC codeword, accounting for the necessary padding. It is initialized to the size of F_P bits and filled with the binary value of "0".

dataParity<F_R–1+B_P:0>

TYPE: Bit array
This array represents the parity portion of the FEC codeword, accounting for the necessary padding. It is initialized to the size of F_R bits and filled with the binary value of "0".

DelayBound

See 101.3.2.1.2.

DS_DataRate

See 100.3.2.1.

FIFO_FEC_TX

TYPE: Array of 65-bit blocks
A FIFO array used to store 65-bit blocks, inserted by the input process and retrieved by the output process in the FEC Encoder (see Figure 101–11, Figure 101–12, and Figure 101–13). The size of FIFO_FEC_TX buffer in the 10GPASS-XR PCS is set to 29 = ceil((1800+40)/65).

firstcodeword

TYPE: Boolean
When TRUE this flag signals the first codeword of a burst.

F_P

TYPE: 16-bit unsigned integer
VALUE: see Table 101–2
This variable represents the number of bits within the payload portion of the FEC codeword.

F_R

TYPE: 16-bit unsigned integer
VALUE: see Table 101–2
This variable represents the number of bits within the parity portion of the FEC codeword.

IdleBlockCount

TYPE: 32-bit signed integer
The number of consecutive non-data 65-bit blocks ending with the most recently received block. The non-data 65-bit blocks are represented by sync header 0 (binary).

lastcodeword

TYPE: Boolean
When TRUE this flag signals the last codeword of a burst.

loc

TYPE: 16-bit unsigned integer
This variable represents the position within the given bit array.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Short2Payload<F_C–1:0>
TYPE: bit array
This bit array is used as a temporary buffer for the second short codeword in the Check_datapayload() function.

Short2blockCount
TYPE: 16-bit unsigned integer
This variable is used as a temporary to hold the *blockCount* of *Short2Payload<>*.

sizeFifo
TYPE: 16-bit unsigned integer
This variable represents the number of 65-bit blocks stored in the FIFO.

Transmitting
TYPE: Boolean
When TRUE this variable indicates the device is transmitting. At the CNU, the default value of *Transmitting* is FALSE. At the CLT, this variable is always set to TRUE except when *PD_Enable* is FALSE (see 102.2.7.3).

tx_coded<65:0>
TYPE: 66-bit block
This 66-bit block contains 64B/66B encoded data from the output of the 64B/66B Encoder. The format for this data block is shown in Figure 49–7. The left-most bit in the figure is *tx_coded<0>* and the right-most bit is *tx_coded<65>*.

tx_coded_out<F_C–1:0>
TYPE: bit array
This bit array contains the output of the FEC Encoder being passed to the Data Detector. The left-most bit is *tx_coded_out<0>* and the right-most bit is *tx_coded_out<F_C–1>*.

txCount
TYPE: 16-bit unsigned integer
This variable is used for counting bits in the Transfer to PMA process.

US_DataRate
See 100.3.2.2.

xfrSize
TYPE: integer
This variable is set as input to the transferToPMA process and indicates the number of bits in the ARRAY_IN.

101.3.2.5.7 Functions

BurstTimeHeader()
The BurstTimeHeader() function returns a 65-bit vector with the following values:
bit <0> = binary 1
bits<1:32> = the current PHY Link timestamp
bits<33:64> = a fixed value of 0xD858E4AB.
This 65-bit vector is transmitted as the first 65-bit block of an upstream burst.

Calculate_CRC40_and_3Parity(paritySize)
This function takes an argument of “LONG”, “MEDIUM”, or “SHORT” and then processes *dataPayload* and *tx_coded_out* to add CRC40 and appropriate LDPC parity. The *tx_coded_out* array is then passed to transferToPMA() with indicated length and *lastcodeword* status.

```
Function Calculate_CRC40_and_3Parity( paritySize ) {

    IF (paritySize == LONG)
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
        parityLength = 1800;
    IF (paritySize == MEDIUM)
        parityLength = 900;
    IF (paritySize == SHORT)
        parityLength = 280;

    dataPayload<loc+39:loc> = calculateCrc(dataPayload<loc-1:0>);
    tx_coded_out<loc+39:loc> = dataPayload<loc+39:loc>;
    loc += 40;
    dataParity<parityLength-1:0> =
        calculateParity(dataPayload<loc-1:0>, loc, paritySize);
    tx_coded_out<loc+parityLength-1:loc> = dataParity<parityLength-1:0>;
    xfrSize += parityLength;
    transferToPMA(tx_coded_out, xfrSize, lastcodeword);

    // Setup for next codeword in burst if more data
    firstcodeword = FALSE;
    loc = 0;
    resetArray(dataPayload);
    resetArray(dataParity);
}
```

calculateCrc (ARRAY_IN)

This function calculates a CRC40 value for data included in ARRAY_IN (see 101.3.2.3).

calculateParity(ARRAY_IN , Length, paritySize)

This function calculates the LDPC parity (for the code per Table 101–2) for data included in ARRAY_IN up to the specified Length (bits). For any Length less than F_P, any remaining bits in ARRAY_IN after Length are considered padding bits (of length B_P bits) and will not be included in the encoder output producing a shortened codeword; i.e., codeword length will be $F_P - B_P + F_R$. When paritySize is "LONG", the values for the downstream or upstream codeword size of 16200 are used; for "MEDIUM" the values for the upstream codeword size of 5940 are used; and for "SHORT" the values for the upstream codeword size of 1120 are used.

Check_dataPayload(firstcodeword, lastcodeword)

This function performs the upstream codeword filling algorithm examining accumulated *blockCount* as per 101.3.2.5.4. This function calls Calculate_CRC40_and_3Parity() indicating the appropriate codeword size to use, as appropriate.

```
Function Check_dataPayload( firstcodeword, lastcodeword ) {

    IF (lastblock == FALSE) {
        IF (blockCount == 220 )
            Calculate_CRC40_and_3Parity(LONG);
    } ELSE {
        IF (blockCount < 200 && blockCount >= 101)
            Calculate_CRC40_and_3Parity(LONG);
        IF (blockCount < 101 && blockCount >= 76)
            Calculate_CRC40_and_3Parity(MEDIUM);
        IF (blockCount < 76 && blockCount >= 25)
            Calculate_CRC40_and_3Parity(MEDIUM);
        IF (blockCount < 24 && blockCount > 12) {
            // dataPayload<> contains two short codewords
            // first is 12 blocks, second is remainder
            Short2blockCount = blockCount - 12;
            Short2Payload<Short2loc:0> = dataPayload<loc:12*65>;
            loc = (12*65) - 1;
            blockCount = 12;
            Calculate_CRC40_and_3Parity(SHORT);
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
            dataPayload<Short2loc:0> = Short2Payload<Short2loc:0>;
            tx_coded_out<Short2loc:0> = Short2Payload<Short2loc:0>;
            loc = (Short2blockCount * 65) – 1;
            blockCount = Short2blockCount;
            Calculate_CRC40_and_3Parity(SHORT);
         } ELSE IF ( blockCount >= 1 ) {
            Calculate_CRC40_and_3Parity(SHORT);
         }
      return();
   };
```

resetArray(ARRAY_IN)

This function resets the content of ARRAY_IN, removing all the elements within ARRAY_IN and setting its size to 0.

removeFifoHead(ARRAY_IN)

This function removes the first block in ARRAY_IN and decrements its size by 1.

```
   Function removeFifoHead( ARRAY_IN ){
            ARRAY_IN[0] = ARRAY_IN[1];
            ARRAY_IN[1] = ARRAY_IN[2;]
            ...
            ARRAY_IN[sizeFifo-2] = ARRAY_IN[sizeFifo-1];
            sizeFifo --;
   }
```

transferToPMA(ARRAY_IN, xfrSize, lastcodeword)

This function serially transfers a PCS FEC output codeword that is represented as bits in ARRAY_IN to the PMA using the PMA_UNITDATA.request() service primitive. Rate clocking is provided by the PMA service primitive. In the downstream direction, the PCS continuously provides codewords for transfer. For the first bit of the downstream codeword transfer, *burstStart* is set to TRUE and set to FALSE otherwise; for the last bit, *burstEnd* is set to TRUE, and set to FALSE otherwise. In the upstream direction, the PCS builds an upstream burst that consists of one or more concatenated codewords, where the length of each burst is based on MPCP scheduling. For the first bit of the first codeword of the upstream transfer, *burstStart* is set to TRUE and set to FALSE otherwise; for the last bit of the last codeword of the burst, *burstEnd* is set to TRUE and set to FALSE otherwise. The *burstStart* and *burstEnd* flags are used by the respective PMA symbol mapping functions (see 101.4.3.8 and 101.4.4.5). In the CLT the lastcodeword argument to this function is always TRUE (see Figure 101–12). This function is represented by the following pseudo code:

```
   Function transferToPMA( ARRAY_IN, xfrSize, lastcodeword) {
   burstStart = FALSE;
   burstEnd   = FALSE;
      for ( txCount = 0; txCount < xfrSize; txCount++) {
         if (txCount == 0)
            burstStart = TRUE;
         if ((txCount == (xfrSize-1)) && (lastcodeword == TRUE))
            burstEnd = TRUE;
         PMA_UNITDATA.request(ARRAY_IN[txCount], burstStart, burstEnd)
      }
   }
```

direction functional block diagrams for the CLT and CNU are illustrated in Figure 101–3 and Figure 101–4, respectively.

In the receive direction, the EPoC PCS includes a mandatory FEC Decoder, followed by a 64B/66B Decoder and an Idle control character insertion function performing the function of data rate adaptation and an FEC overhead compensation.

101.3.3.1 FEC Decoder

The 10GPASS-XR PHY decodes the received data using LDPC (F_C, F_P) code. The CLT 10GPASS-XR PCS operating on a CCDN shall decode the received data using one of the LDPC (F_C, F_P) codes per Table 101–2. The CNU 10GPASS-XR PCS operating on CCDN shall decode the received data using LDPC (16200, 14400) code per Table 101–2.

101.3.3.1.1 Upstream FEC decoding

The CLT receives an upstream burst with a length of R bits from a CNU via the PMA Client.

Start with B_Q = 220, CRC = 40, and F_R = 1800 for long codewords:

1) If $R \geq B_Q * 65 + 40 + F_R$ bits, decode a long codeword.
   Repeat and decode using long codewords if remaining bits $\geq B_Q * 65 + 40 + F_R$ bits.
   End processing burst if remaining bits ≤ 0.
2) If remaining bits < (B_Q = 220) * 65 + 40 + (F_R = 1800) and ≥ (B_Q = 101) * 65 + 40 + (F_R = 1800), decode a shortened long codeword.
   End processing burst if remaining bits ≤ 0.
3) If remaining bits ≥ (B_Q = 76) * 65 + 40 + (F_R = 900), decode a medium codeword.
   End processing burst if remaining bits ≤ 0.
4) If remaining bits < (B_Q = 76) * 65 + 40 + (F_R = 900) and ≥ (B_Q = 25) * 65) + 40 + (F_R = 900), decode a shortened medium codeword.
   End processing burst if remaining bits ≤ 0.
5) If remaining bits ≥ (B_Q = 12) * 65 + 40 + (F_R = 280), decode a short codeword.
   Repeat and decode using short codewords if remaining bits ≥ (B_Q = 12) * 65 + 40 + (F_R = 280) bits.
   End processing burst if remaining bits ≤ 0.
6) If remaining bits ≥ 65 + 40 + 280, decode a shortened short codeword.
7) If remaining bits, declare receiver burst error.

All codeword decoding follows the same procedures as the downstream with the following differences:

— The appropriate values from Table 101–2 are used for the corresponding codeword size being decoded.
— The *burstStart* indication in the PMA_UNITDATA.indication() corresponds to the first bit in the concatenated burst received from a CNU.
— The *burstEnd* indication in the PMA_UNITDATA.indication() corresponds to the last bit of the concatenated burst received from a CNU.
— The nominal data rate of the PMA_UNITDATA_request() is *US_DataRate* calculated by the CLT (see 100.3.2.2).

101.3.3.1.2 LDPC decoding process within CNU (downstream)

The process of decoding FEC codewords in the 10GPASS-XR CNU receiver is illustrated in Figure 101–14.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

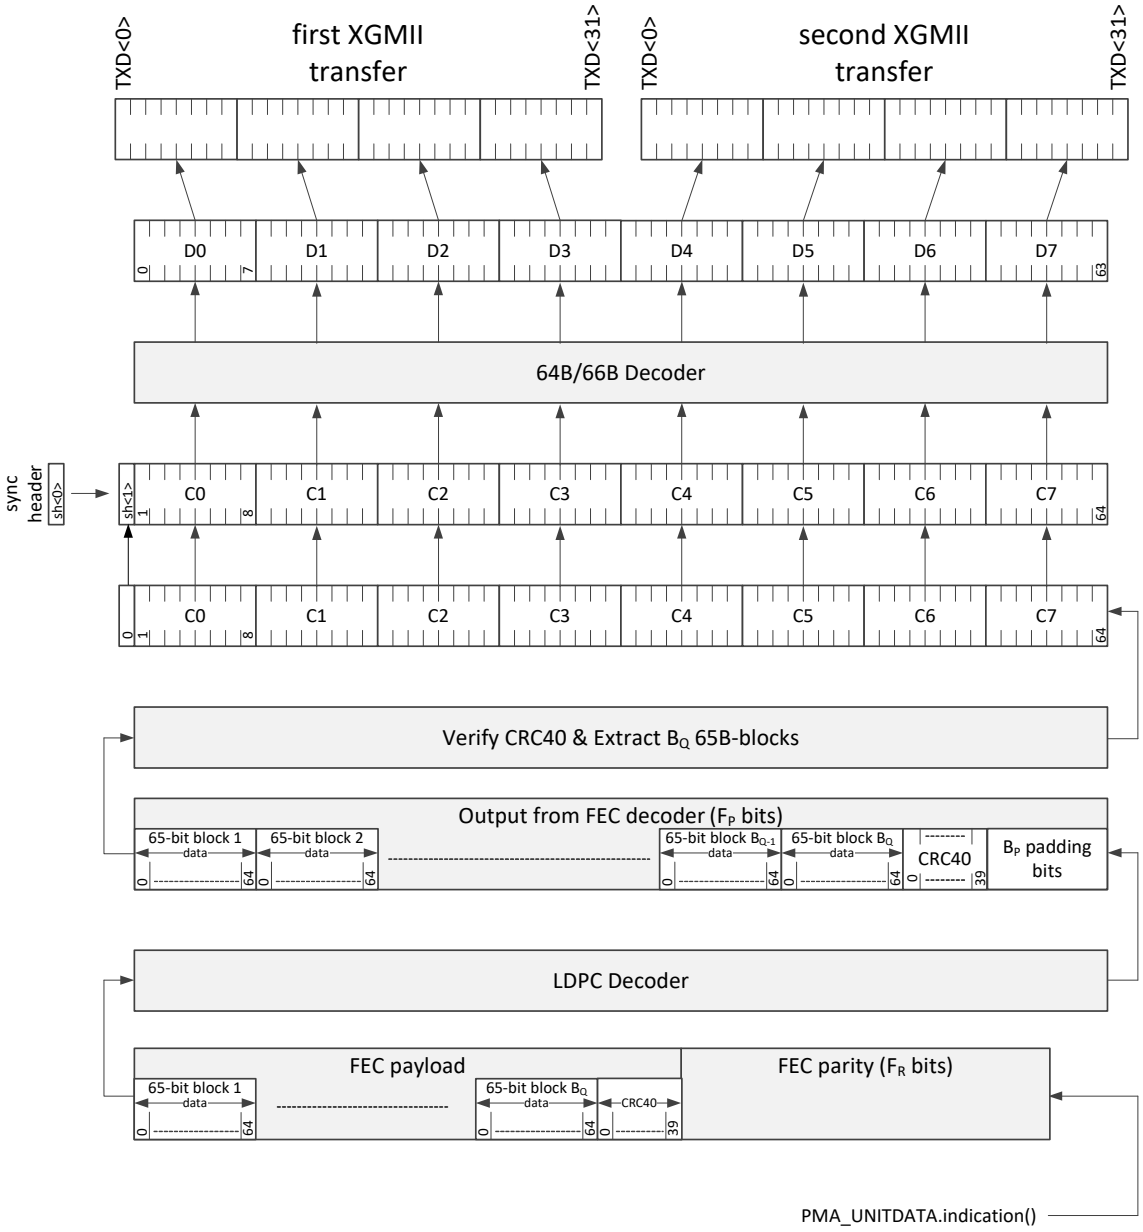

Figure 101–14—PCS receive path processing

Once the alignment to the FEC codeword is found, the 10GPASS-XR CNU receiver aggregates a total of FEC_DS_CodeWordSize bits received from the descrambler as input to the FEC Decoder. The output of the FEC Decoder contains the full FEC Payload consisting of 65-bit blocks number 1 to B_Q, the CRC40 data, and B_P padding bits with all bits set to the binary value of "0".

The FEC Decoder produces the FEC payload portion of the codeword with the size of F_P (in bits), where bits $<F_P - B_P - 1>$ ... $<F_P - 1>$ contain padding (with the binary value of "0"). Next, the CRC40 is calculated over the remaining 65-bit blocks 1 through B_Q and then compared with the value of CRC40 retrieved from the received FEC codeword. If both CRC40 codes match, the decoded FEC codeword is treated as error-free. Otherwise, the decoded FEC codeword is treated as errored.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Finally, the FEC Decoder prepends each of the B_Q 65-bit blocks with bit <0> of the sync header containing the binary inverse of the value carried in bit <1> of the sync header, producing 66-bit blocks. This also guarantees that properly decoded blocks meet the requirements of 49.2.4.3.

The FEC Decoder maintains error monitors to detect FEC codeword successes and failures. See 101.3.3.1.4 for details.

Each resulting 66-bit block is then fed into the 64B/66B Decoder, removing the sync header information (bit <0> and bit <1>), which is used to generate control signaling for the XGMII. Finally, the resulting 64-bit block is then separated into two 32-bit portions, which are transmitted across the XGMII on two consecutive transfers, with the proper control signaling retrieved from the sync header information retrieved in the 64B/66B Decoder.

101.3.3.1.3 LDPC decoding process within CLT upstream

In the Verify CRC40 and Extract B_Q 65B Blocks function of the upstream receiver, the CLT will remove the first 65-bit block of a burst containing the Burst Time Header, the remainder of the 65-bit blocks will be passed to the 64B/66B Decoder. The 32-bit PHY Link timestamp value will be extracted. The use of this timestamp in the upstream receiver processing is implementation specific and beyond the scope of this standard. This timestamp is provided as a mechanism to minimize any jitter introduced by OFDMA framing and the 1D to 2D insertion and extraction mechanisms. For example, an implementation may implement a timestamp-based burst play out buffer prior to passing any frames contained within a burst to the XGMII.

101.3.3.1.4 Codeword error monitor

The FEC Decoder shall provide a user-configurable option (variable *CRC40ErrCtrl*) to indicate an uncorrectable FEC codeword to higher layers. If *CRC40ErrCtrl* is TRUE and the calculated value of CRC40 does not match the value of CRC40 retrieved from the received FEC codeword, the FEC Decoder replaces bit <0> and <1> in the sync headers in the first 64B/66B block and every eighth 64B/66B block, (1st, 9th, 17th, 25th, etc.) as well as the last 64B/66B block from the errored FEC codeword with the binary value of "11". The state table for replacing the sync header bits is shown in Table 101–6. For EPoC, the BER monitor state machine as defined in Clause 49 is disabled.

Table 101–6—Sync header decoding state table

		CRC40ErrCtrl	
		FALSE	**TRUE**
CRC40	matches	Pass SH as received	Pass SH as received
	does not match	Pass SH as received	Replace SH with "11"

101.3.3.1.5 Constants

IDLE

TYPE: 66-bit vector
This constant represents /I/ character with 64B/66B encoding, as defined in 49.2.4.7.

XGMII_Rate

See 101.3.2.1.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.3.3.1.6 Variables

blockCount
: See 101.3.2.5.5.

B_P
: See 101.3.2.5.5.

B_Q
: See 101.3.2.5.5.

CLK
: See 101.3.2.5.5.

CRC40ErrCtrl
: TYPE: Boolean
This variable controls the processing of codewords that fail the CRC40 checksum test. See 101.3.3.1.4.

dataInSize
: TYPE: 16-bit unsigned integer
VALUE: $(B_Q + 1) \times 65 + 40 + B_P$
This variable represents the size of the *dataIn* array in bits, containing the combination of the payload portion of the FEC codeword ($(B_Q + 1) \times 65$), the CRC40 (40), and the parity portion of the FEC codeword (B_P).

dataCrcA<39:0>
: TYPE: Bit array
This array represents the CRC40 recovered from the payload portion of the FEC codeword prior to the FEC decoding process. This array is initialized to the size of 40 bits and filled with the binary value of "0".

dataCrcB<39:0>
: TYPE: Bit array
This array represents the CRC40 calculated over B_Q 65-bit blocks in the payload portion of the FEC codeword after the FEC decoding process. This array is initialized to the size of 40 bits and filled with the binary value of "0".

dataIn<dataInSize–1:0>
: TYPE: Bit array
This array represents the combination of the payload portion of the FEC codeword, the parity portion of the FEC codeword, CRC40, and all the necessary padding. It is initialized to the size of *dataInSize* bits and filled with the binary value of "0".

dataOut<F_P–1:0>
: TYPE: Bit array
This array represents the combination of the payload portion of the FEC codeword, CRC40, and all the necessary padding. It is initialized to the size of F_P bits and filled with the binary value of "0".

FecCodeWordCount
: TYPE: 32-bit unsigned integer
This variable is incremented for every received FEC codeword. After reaching 0xFF-FF-FF-FF, this variable is set to 0x00-00-00-00.

FecCodeWordFail
: TYPE: 32-bit unsigned integer
This variable is incremented for every received FEC codeword for which the decoding process failed. After reaching 0xFF-FF-FF-FF, this variable is set to 0x00-00-00-00.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FecCodeWordSuccess
TYPE: 32-bit unsigned integer
This variable is incremented for every received FEC codeword for which the decoding process completes successfully. After reaching 0xFF-FF-FF-FF, this variable is set to 0x00-00-00-00.

FIFO_FEC_RX
TYPE: Array of 66-bit blocks
A FIFO array used to store tx_coded<65:0> blocks, inserted by the input process in the FEC Decoder, while encoded data is then sent to 64B/66B Decoder for processing and transmission towards the XGMII.

loc
See 101.3.2.5.5.

PMA_CLK
TYPE: Boolean
This variable is to TRUE on every negative edge of a clock that is synchronized to the PMA_UNITDATA.indication data rate of *DS_DataRate* (see 101.4.2.1). This variable is set to FALSE upon read. This variable is set to FALSE upon read.

rx_coded_in<64:0>
TYPE: 65-bit block
This 65-bit block contains the input into the FEC Decoder being passed from PMA. The left-most bit is *rx_coded_in<0>* and the right-most bit is *rx_coded_in<64>*.

rx_coded_in<F_C–1:0>
TYPE: bit array
This array contains the input into the FEC Decoder being passed from PMA. The left-most bit is *rx_coded_in<0>* and the right-most bit is *rx_coded_out<F_C–1>*.

rxCount
TYPE: 16-bit unsigned integer
This variable is used for counting bits in the Transfer from PMA process.

sizeFifoRx
TYPE: 16-bit unsigned integer
This variable represents the number of 65-bit blocks stored in the FIFO.

syncFec
TYPE: Boolean
This variable indicates whether the FEC codeword alignment was found (value equal to TRUE) or not (value equal to FALSE).

tx_coded<65:0>
See 101.3.2.5.5.

101.3.3.1.7 Functions

calculateCrc (ARRAY_IN)
See 101.3.2.5.5.

decodeFec(ARRAY_IN, Length)
This function performs FEC decoding (for the codeword per Table 101–2) for data included in ARRAY_IN, comprising the combination of the FEC payload portion, CRC40, and FEC Parity (F_R). Since the FEC Parity and CRC are of constant size, if Length < F_C, the FEC payload will be shortened by F_C – Length bits (considered as padding bits B_P). The output of the decoder will be of length F_P bits composed of the received FEC payload, the received CRC40, and the added B_P padding bits. The padding bits will be set to a binary value of 0.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

resetArray(ARRAY_IN)
See 101.3.2.5.5.

transferFromPMA(ARRAY_OUT)
This function invokes the Transfer From PMA process to transfer a downstream burst (codeword) from the PMA to the FEC Decoder.

101.3.3.1.8 State diagrams

The CLT PCS shall implement the transfer from PMA process as shown in Figure 101–15.

The CNU PCS shall implement the LDPC decoding process input process, and LDPC decoding output process as shown in Figure 101–16 and Figure 101–17, respectively.

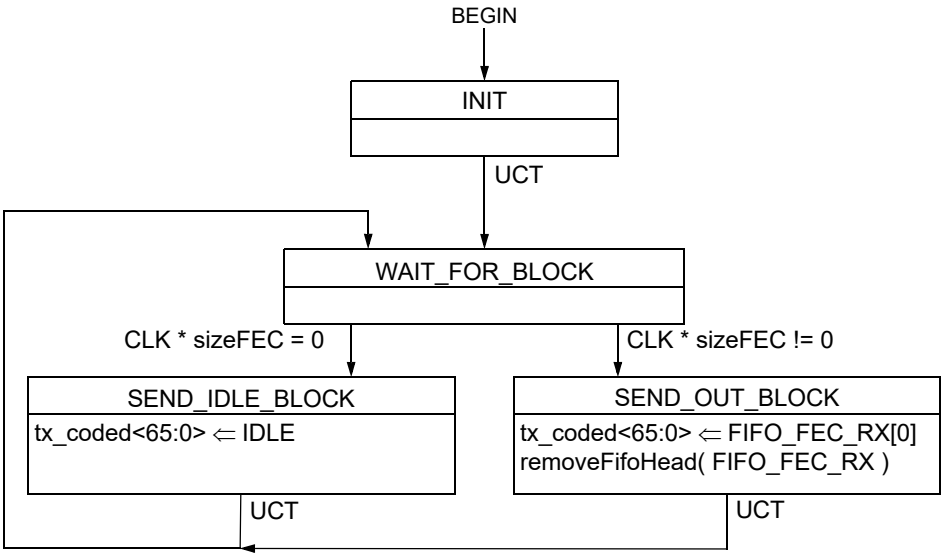

Figure 101–17—FEC Decoder, output process state diagram (CNU)

101.3.3.2 64B/66B Decoder

The EPoC PHY utilizes a 64B/66B Decoder based on that described in 49.2.11 with several important differences. The EPoC 64B/66B Decoder does not include a descrambler function as described in 49.2.10 and the input is a 65B block with a single sync header bit. The state diagram found in Figure 49–17 is followed after the addition of sync header bit <0> as illustrated in Figure 101–14.

101.3.3.3 Idle control character insertion process

In the receiving PCS, the Idle control character insertion process inserts Idle control characters into the data stream with gaps as received from the FEC Decoder and 64B/66B Decoder, adjusting the effective PCS and PMD data rate to the data rate expected by the MAC Control (as defined in Clause 103). Effectively, the Idle control character insertion process fills in the gaps created after the removal of FEC parity data, as well as compensates for the derating of the EPoC PMD relative to the EPoC MAC.

The Idle control character insertion process (see Figure 101–18) is composed of the following:

a) A receive process, receiving 72-bit vectors from the 64B/66B Decoder and writing them into the Idle Insertion FIFO (called FIFO_II); and

b) A transmit process, reading 72-bit vectors from FIFO_II and transferring them to the XGMII.

The receive process receives 72-bit vectors from the 64B/66B Decoder at a slower data rate than the nominal XGMII data rate for the following two reasons:

1) The FEC parity data is removed within the FEC Decoder, leaving behind gaps in the data stream; and

2) The data rate supported by EPoC PCS and PMD is lower than the data rate expected by MAC Control Client, requiring data rate adaptation between the PCS and MAC.

The transmit process outputs 72-bit vectors at the nominal XGMII data rate.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

To match the difference in data rates between the receive process and the transmit process, the Idle control character insertion process inserts additional 72-bit vectors containing Idle control characters. The additional blocks are inserted between frames and not necessarily at the same locations where FEC parity data was removed within the FEC Decoder.

101.3.3.3.1 Constants

IDLE_VECTOR
: TYPE: 72-bit binary array
This constant represents a 72-bit vector containing Idle control characters.

LBLOCK_R
: This constant is defined in 49.2.13.2.1.

101.3.3.3.2 Variables

BEGIN
: TYPE: Boolean
This variable is used when initiating operation of the state diagram. It is set to TRUE following initialization and every reset.

FIFO_II
: TYPE: Array of 72-bit vectors
The FIFO_II buffer is used to perform data rate adaptation between XGMII data rate and the EPoC PMD data rate. Upon initialization, all elements of this array are filled with instances of IDLE_VECTOR. The FIFO_II buffer has the size of *FIFO_II_SIZE* (see 101.3.3.3.1).

FIFO_II_SIZE
: TYPE: 16-bit unsigned integer
This variable represents the size of Idle Insertion FIFO buffer. The size of this buffer is selected in such a way that it is able to accommodate the number of 66-bit vectors sufficient to fill the gap introduced by removing the FEC parity data for a maximum size MAC frame, and compensate for the maximum supported difference between the MAC rate and PMD rate. *FIFO_II_SIZE* is dependent on the line rate the PHY is operating at and may need to be adjusted whenever the profile is changed.

RX_CLK
: TYPE: Boolean
This variable represents the *RX_CLK* signal defined in 46.3.2.1.

rx_raw_in<71:0>
: TYPE: 72-bit binary array
This variable represents a 72-bit vector received from the output of the 64B/66B Decoder. *RXD*<0> through *RXD*<31> for the second transfer are placed in *rx_raw*<40> through *rx_raw*<71>, respectively.

rx_raw_out<71:0>
: TYPE: 72-bit binary array
This variable represents a 72-bit vector passed from the Idle control character insertion process to XGMII. The vector is mapped to two consecutive XGMII transfers as follows:
Bits *rx_raw*<3:0> are mapped to *RXC*<3:0> for the first transfer.
Bits *rx_raw*<7:4> are mapped to *RXC*<3:0> for the second transfer.
Bits *rx_raw*<39:8> are mapped to *RXD*<31:0> for the first transfer.
Bits *rx_raw*<71:40> are mapped to *RXD*<31:0> for the second transfer.

countVector
: TYPE: 16-bit unsigned integer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable represents the number of 72-bit vectors stored in the *FIFO_II* at the given moment of time.

101.3.3.3.3 Functions

T_TYPE(*rx_raw*<71:0>)
This function is defined in 49.2.13.2.3.

101.3.3.3.4 Messages

DECODER_UNITDATA.indicate(*rx_raw*_in<71:0>)
A signal sent by the EPoC PCS Receive process, conveying the next received 72-bit vector.

DUDI
Alias for DECODER_UNITDATA.indicate(*rx_raw*_in<71:0>).

101.3.3.3.5 State diagrams

The CLT and CNU PCS shall perform the Idle control character insertion process as shown in Figure 101–18.

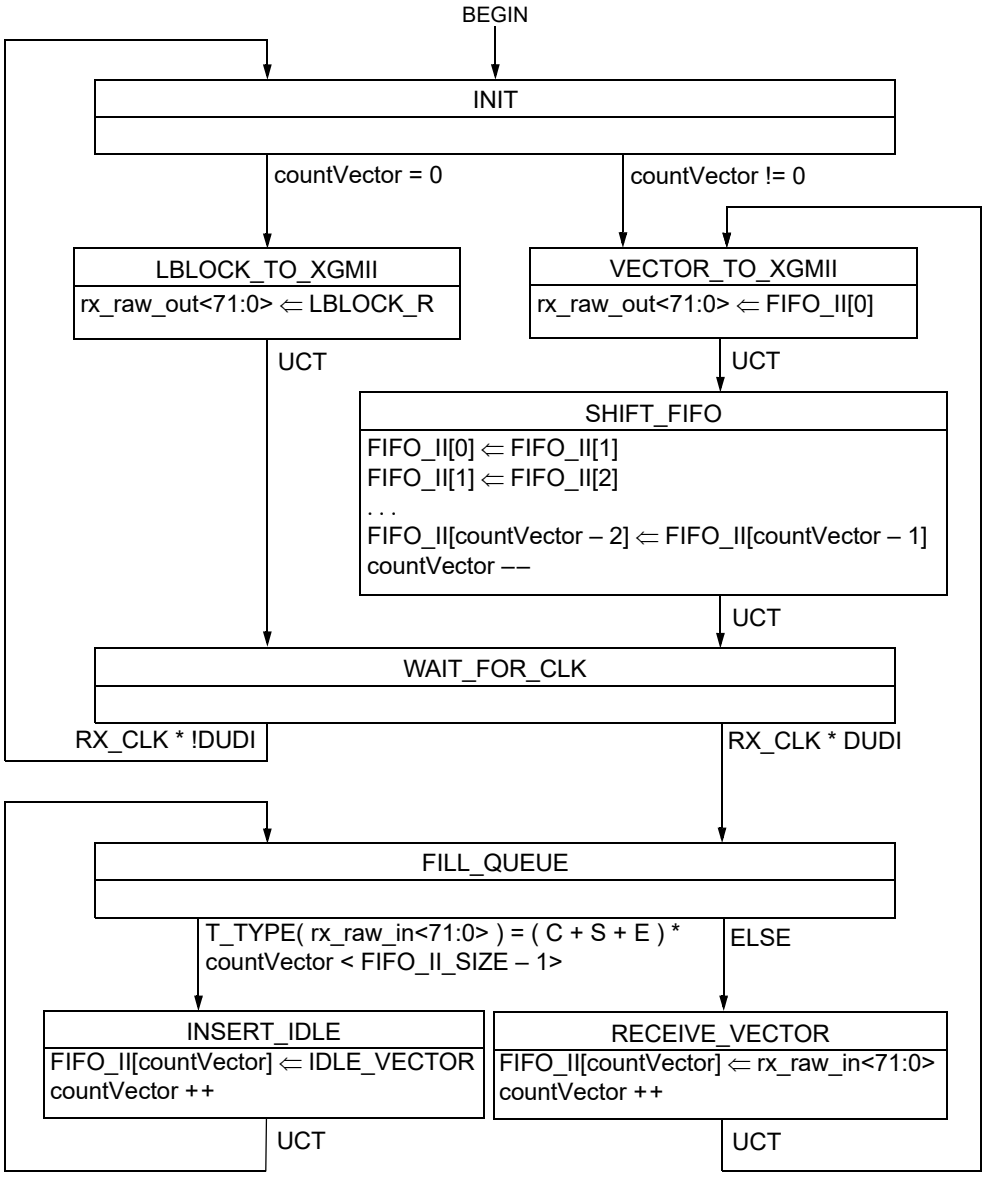

Figure 101–18—Idle control character insertion process state diagram

101.4 10GPASS-XR PMA

101.4.1 Overview

This subclause defines the Physical Media Attachment (PMA) for 10GPASS-XR, supporting operation over the point-to-multipoint coaxial cable distribution networks. The 10GPASS-XR PMA is specified to support the operation of up to 10 Gb/s in the downstream direction and up to 1.6 Gb/s in the upstream direction, where the upstream and downstream data rates are configured independently.

Figure 101–5 shows the relationship between the 10GPASS-XR PMA sublayer and the ISO/IEC OSI reference model. Figure 101–1 illustrates the CLT transmitter functional block diagram, including the PMA,

Copyright © 2022 IEEE. All rights reserved.

while Figure 101–2 illustrates the CNU transmitter functional block diagram. Figure 101–3 and Figure 101–4 illustrate the functional block diagram of the receive path in the CLT and CNU, respectively in the 10GPASS-XR PMA.

The transmit PMA sublayer translates a serial data stream into a stream of I/Q value pair and channel number using the following functions: data scrambler, symbol mapper, interleaver (CLT only), Pilot Insertion, Inverse Discrete Fourier Transform (IDFT), and Cyclic Prefix insertion. The receive PMA sublayer translates a stream of I/Q value pair and channel number into a serial data stream using the following functions: Fast Fourier Transform (FFT), equalization, Pilot processing, de-interleaver (CNU only), symbol de-mapper, and data descrambler.

101.4.2 PMA Service Interface

The EPoC PMA provides a Service Interface to the 10GPASS-XR PCS sublayer, i.e., the PMA client. These services are described in an abstract manner and do not imply any particular implementation. The PMA Service Interface shall support the exchange of data between the PMA and the PMA client.

The PMA inputs serial data from the PCS and, after processing, passes serial data to the PMD and vice versa. It also generates an additional status indication for use by its client.

The following primitives are defined:
PMA_UNITDATA.request(tx_data_bit<bit>, *burstStart*, *burstEnd*)
PMA_UNITDATA.indication(rx_data_bit<bit>, *burstStart*, *burstEnd*)

101.4.2.1 PMA_UNITDATA.request

This primitive defines the transfer of data (in the form of data bits) from the PMA client to the PMA and notifies the PMA of the start and the end of the data burst.

PMA_UNITDATA.request is generated by the PMA client's transmit process.

101.4.2.1.1 Semantics of the service primitive

PMA_UNITDATA.request(tx_data_bit<bit>, *burstStart*, *burstEnd*)

The data conveyed by PMA_UNITDATA.request is a single data bit which has been prepared for transmission by the PMA client. The Boolean variable *burstStart* is set to TRUE when the data bit is the first bit at the start of transmission burst, and is set to FALSE otherwise. The Boolean variable *burstEnd* is set to TRUE when the data bit is the last bit of a transmission burst, and is set to FALSE otherwise. In the downstream direction, the CLT transmission burst is composed of a single FEC codeword; whereas, in the CNU upstream, the burst may include one or more concatenated FEC codewords (see 101.3.2.5.3).

101.4.2.1.2 When generated

The PMA client continuously sends data bits to the PMA at a nominal rate of *DS_DataRate* in the downstream direction. In the upstream direction, the nominal rate is *US_DataRate* during a burst. Refer to 100.3.2.2.

NOTE 1—*DS_DataRate* is calculated by the PMA after the downstream PHY has been configured. It is based on the sum of the available data bits per subcarrier over the timespan of a downstream OFDM frame consisting of 128 modulation symbols. *DS_DataRate* is a constant during the span of the PHY configuration. If re-configured, *DS_DataRate* is re-calculated.

NOTE 2—*US_DataRate* is calculated by the PMA after the upstream PHY has been configured. It is based on the sum of the available data bits per Resource Element over the timespan of the upstream superframe consisting of 256 symbols

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

plus 6 Probe Period symbols. *US_DataRate* is a constant during the span of the PHY configuration. If reconfigured, *US_DataRate* is recalculated.

101.4.2.1.3 Effect of receipt

Upon receipt of this primitive, the PMA Symbol Mapper transfers the data bit into the OFDM frame.

In the CLT and upon the start of a downstream OFDM frame and when *burstStart* is TRUE, the PMA Symbol Mapper updates the FEC Codeword Pointer (FCP) in the downstream PHY Link. See 101.4.3.8.

In the CNU, both *burstStart* and *burstEnd* parameters are used by the upstream Symbol Mapper for placing start and end burst markers, respectively, into the appropriate Resource Elements. See 101.4.4.8.

101.4.2.2 PMA_UNITDATA.indication

This primitive defines the transfer of data in the form of bits from the PMA to its client. PMA_UNITDATA.indication is used by the client's receive path process.

101.4.2.2.1 Semantics of the service primitive

PMA_UNITDATA.indication(rx_data_bit<bit>, *burstStart*, *burstEnd*)

The data conveyed by PMA_UNITDATA.indication is single data bit that has been prepared by the PMA receive process to the PMA client. The Boolean variable *burstStart* is set to TRUE when the data bit is the first bit at the start of received burst, and is set to FALSE otherwise. The Boolean variable *burstEnd* is set to TRUE when the data bit is the last bit of a received burst, and is set to FALSE otherwise.

101.4.2.2.2 When generated

The PMA sends one rx_data_bit <bit> to the PMA client corresponding to the receipt of each bit of received from the receiver Symbol De-Mapper.

In the CNU, the PMA continuously sends data bits to the PMA client at a nominal rate of *DS_DataRate* in the downstream direction. In the upstream direction, the nominal rate is *US_DataRate* during a burst. Refer to 100.3.2.1 and 100.3.2.2.

101.4.2.2.3 Effect of receipt

The effect of receipt of this primitive by the client is specified in 101.3.3.

101.4.3 Downstream PMA transmit function

101.4.3.1 Overview

The downstream PMA transmit functional diagram is shown in Figure 101–2. The PMA supports five 190 MHz wide OFDM channels; each containing 3800 active subcarriers. Each OFDM channel is associated with the following processing functions: Time and Frequency Interleaver (see 101.4.3.9), Pilot Insertion (see 101.4.3.10), IDFT (see 101.4.3.11), and cyclic prefix and Windowing (see 101.4.3.12). The outputs of each OFDM channel are digitally combined. All OFDM channels follow the same frame timing and use the same OFDM Clock (see 100.4.4), cyclic prefix size, and window size.

OFDM channel 1 shall always be enabled but is muted during RxMER testing (see 100.4.2). Optional OFDM channels 2, 3, 4, and 5 are enabled when configured for operation via the *DS_ChCnt* variable. When enabled, each OFDM channel is configured for placement in the downstream RF frequency band of the coax

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

cable distribution network (see Figure 100–1). The encompassed spectrum of any OFDM channel does not overlap with that of any other OFDM channel. The tight time skew requirements (see Table 101–7) permit the active edge subcarrier of one OFDM channel to be placed immediately adjacent to that of the adjacent OFDM channel without any guard band. CLTs shall declare the number of downstream OFDM channels it supports via the *DS_OFDM_ChAbility* variable.

The Symbol Mapper distributes PCS data over all active subcarriers that are configured to carry data (subcarriers that are not configured as excluded are active subcarriers). See 101.4.3.8.

The PHY Link is processed by the OFDM channel 1 IDFT and cyclic prefix and Windowing functions.

101.4.3.2 Time and frequency synchronization

This subclause specifies the timing and frequency synchronization requirements for CLT transmitters and CNU receivers.

The purpose of this subclause is to help ensure that the CLT transmitter can provide proper timing and frequency references for EPoC downstream OFDM operation and that the CNU receiver can acquire the system timing and subcarrier from the downstream for proper EPoC operation.

The CLT downstream OFDM symbol and subcarrier frequency and timing relationship is defined in 101.4.3.3.

Tolerances for the downstream Subcarrier Clock frequency are specified in this subclause (Table 101–7). Downstream Subcarrier Clock frequency and downstream signal generation are detailed in 101.4.3.3. The Subcarrier Clock frequency tolerance performance is coupled to the phase noise requirements of Table 100–4 and the downstream OFDM Clock requirements as follows:

— Each cycle of the downstream Subcarrier Clock is 4096 cycles (50 kHz subcarrier spacing) of the downstream OFDM Clock frequency (which is nominally 204.8 MHz).
— The downstream Subcarrier Clock waveform is locked to the 10.24 MHz Master Clock frequency (see Table 100–3, 101.4.3.3, and Equation (101–6)).
— The downstream OFDM Clock jitter requirements in Table 101–7 shall apply equivalently to the downstream Subcarrier Clock and its harmonics.

NOTE—The requirements on the OFDM Clock are effectively measured on observables in the downstream waveform, which include the downstream Subcarrier Clock frequency (manifested in the subcarrier spacing) and downstream subcarrier frequencies.

CLT transmitters and CNU receivers shall conform to the requirements given in Table 101–7.

Table 101–7—Downstream time and frequency synchronization

Item	Requirement
OFDM Clock jitter	1) $< [-21 + 20\times\log_{10}(f_{DS}/204.8)]$ dBc (i.e., < 0.07 ns RMS) 10 Hz to 100 Hz 2) $< [-21 + 20\times\log_{10}(f_{DS}/204.8)]$ dBc (i.e., < 0.07 ns RMS) 100 Hz to 1 kHz where f_{DS} is the frequency of the measured downstream OFDM Clock in MHz.[a]
Inter-OFDM channel time skew	156.25 ns
CNU Timing Acquisition Accuracy	Better than 1 OFDM Clock period (1/204.8 MHz).
Acquisition time	< 60 seconds

[a] The CLT uses a value of f_{DS} that is an integral multiple or divisor of the downstream OFDM Clock frequency. For example, an f_{DS} = 409.6 MHz clock may be measured if there is no explicit 204.8 MHz clock available.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CLT shall lock the 204.8 MHz downstream OFDM Clock and downstream OFDM RF transmissions to the CLT 10.24 MHz Master Clock (Table 100–3).

Inter-OFDM channel time skew is defined as the maximum transmission time skew between any two OFDM channels.

The CNU timing acquisition accuracy for the downstream clock timing is defined with respect to downstream PHY Link frame. The CNU shall adjust its 10.24 MHz Master Clock to synchronize its own clock timing with PHY Link frame for proper operation. The CNU acquires downstream clock timing from the downstream signal (pilots, preambles, or mixed pilots, preambles, and data).

Downstream OFDM channel acquisition time for a CNU is defined as the time required for a single CNU with no previous network frequency plan knowledge to achieve downstream signal acquisition (frequency and time lock, see Table 101–7).

In addition to meeting the clock jitter requirements given previously, the CLT is required to meet the phase noise specifications defined in Table 100–4. In the event of a conflict between the clock jitter and the phase noise requirement, the CLT shall meet the more stringent requirement.

101.4.3.3 Subcarrier clocking

The synchronization of the Subcarrier Clock and subcarrier frequency are defined and characterized by the following rules:

— Each OFDM symbol is defined with an FFT duration (equal to Subcarrier Clock period) of 20 μs. For each OFDM symbol, the Subcarrier Clock period (μs) may vary from nominal with limits defined in Table 101–7.

— The number of OFDM Clock periods (1/204.8 MHz) of each subcarrier generated by the CLT during one period of the Subcarrier Clock is an integer number. The CLT Subcarrier Clock shall be synchronous with the 10.24 MHz Master Clock defined by the following:

$$SC_f = ((2 \times 10)/4096) \times MC_f \tag{101–6}$$

where
SC_f is the Subcarrier Clock frequency
MC_f is the 10.24 MHz Master Clock frequency (see Table 100–3)

— The limitation on the variation from nominal of the Subcarrier Clock frequency at the output connector is defined in 101.4.3.2.

— Each OFDM symbol has a cyclic prefix that is an integer multiple of 1/128th, of the Subcarrier Clock period.

— Each OFDM symbol duration is the sum of one Subcarrier Clock period and the cyclic prefix duration.

— The carrier frequency (i.e., the center frequency of the N-th subcarrier) is an integer multiple of the subcarrier spacing and may contain phase noise with limits defined in Table 100–4. The number of cycles for each subcarrier generated by the CLT during an OFDM symbol duration (Sym_T) shall be as given in Equation (101–7).

$$Sym_T = K + K \times L/128 \tag{101–7}$$

where
K is an integer equal to the nominal RF frequency of the subcarrier (Hz) divided by the nominal subcarrier spacing (Hz)
L is an integer related to the cyclic prefix as shown in Equation (101–8)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$L = 128 \times (DSNcp \times 10^{-6}) \times 50000 \quad (101–8)$$

101.4.3.4 Subcarrier configuration and bit loading

Each subcarrier in an OFDM channel is configured using the *DS_ModTypeSC(n)* variables (where $0 \le n \le 4095$) in conjunction with *DS_OFDM_ID*. The OFDM channel being configured is determined by *DS_OFDM_ID*. The *DS_ModTypeSC(n)* variables configure each subcarrier to be nulled, to be a continuous pilot, to have a specific bit loading (such as 512-QAM or 1024-QAM), or to be excluded. Subcarrier configuration in an EPoC OFDM channel of 192 MHz shall conform to the rules outlined in Table 101–8.

All CNUs and the CLT in an EPoC network share the same downstream subcarrier configuration and bit loading including nulled subcarriers, continuous pilots, bit loaded subcarriers, and excluded subcarriers.

An EPoC PHY shall declare which of the optional modulation types listed in Table 100–2 it supports via the *DS_ModAbility* and *US_ModAbility* variables.

Table 101–8—Downstream subcarrier configuration rules

Parameter	Limit	Unit
Minimum number of active subcarriers in a contiguous group	40	subcarriers
Minimum OFDM channel guard band	1	MHz
Maximum excluded spectrum in the encompassed spectrum	20	%

101.4.3.4.1 Nulled subcarriers

Nulled subcarriers do not carry MAC or PHY Link data but may be used as pilots. Nulled subcarriers are BPSK modulated using the pseudo-random sequence generated by the 13-bit linear feedback shift register, illustrated in Figure 101–28 except when being used as a scattered pilot in the downstream direction (see 101.4.3.6.1).

101.4.3.4.2 Continuous pilots

In the downstream direction continuous pilots are used to help delineate the downstream PHY Link (see 101.4.3.6.2).

101.4.3.4.3 Bit loaded subcarriers

When a subcarrier is used to carry MAC data it uses the modulation type of QPSK or 2^n-QAM, where the integer n is $4 \le n \le 12$, assigned via the *DS_ModTypeSC(n)* variable except when used as a downstream scattered Pilot (see 101.4.3.6.1).

There is at least one contiguous 22 MHz or greater band of active subcarriers with an assigned non-zero bit loading in any single 192 MHz OFDM channel. This 22 MHz band may include subcarriers intended as Pilots and PHY Link subcarriers. A 1 MHz guard band of excluded subcarriers above and below this 22 MHz creates a minimum width OFDM channel of 22 MHz encompassed spectrum.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.4.3.4.4 Excluded subcarriers

An EPoC PHY shall not transmit energy into a subcarrier that has been excluded from the OFDM channel (i.e., excluded subcarriers have zero amplitude). Typically there is a band edge Exclusion Band at both the top and bottom of the OFDM channel and there may be up to 14 exclusion bands internal to a single 192 MHz OFDM channel.

101.4.3.4.5 PHY Link managed variables

DS_ModAbility

TYPE: 5-bit binary

This bit mapped variable is used to declare which optional modulation types the PHY supports in the downstream direction for the MAC data path. When a bit read as TRUE it indicates that the PHY supports that modulation type.

Bit	Modulation type
0	8-QAM
1	16-QAM
2	32-QAM
3	8192-QAM
4	16384-QAM

DS_ModTypeSC(n)

TYPE: 4-bit binary

This set of variables determines the modulation parameters for each of the 4096 downstream OFDM subcarriers ($0 < n < 4095$). Each variable controls one of the 4096 subcarriers that are transmitted over an OFDM channel, with *DS_ModTypeSC(0)* controlling subcarrier zero, *DS_ModTypeSC(1)* controlling subcarrier 1, etc. The assignment of bits to each modulation type is shown below:

bit 3 2 1 0

1 1 1 1 = Excluded subcarrier
1 1 1 0 = 16384-QAM
1 1 0 1 = 8192-QAM
1 1 0 0 = 4096-QAM
1 0 1 1 = 2048-QAM
1 0 1 0 = 1024-QAM
1 0 0 1 = 512-QAM
1 0 0 0 = 256-QAM
0 1 1 1 = 128-QAM
0 1 1 0 = 64-QAM
0 1 0 1 = 32-QAM
0 1 0 0 = 16-QAM
0 0 1 1 = 8-QAM
0 0 1 0 = QPSK
0 0 0 1 = reserved (used by PHY for continuous pilots only, if set via MDIO to this value the PHY treats the subcarrier as null)
0 0 0 0 = null (carries no data but used for Wideband Probing)

DS_OFDM_ChAbility

TYPE: 3-bit integer

This variable indicates the number of OFDM channels the PHY is able to support in the downstream direction. The value of these bits is between 1 and 5 inclusive.

DS_OFDM_ID

TYPE: 3-bit integer

This variable is a pointer to one of the five possible OFDM channels in the downstream EPoC

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

network. Thus when *DS_OFDM_ID* is set to a value of one variables *DS_ModTypeSC(n)* reflect the OFDM descriptor for OFDM channel one. When *DS_OFDM_ID* is set to a value of two variables *DS_ModTypeSC(n)* reflect the OFDM descriptor for OFDM channel two, etc.

101.4.3.5 Framing

The downstream OFDM frame is synchronized to the downstream PHY Link frame and the downstream Timestamp (see 102.2). Each downstream OFDM frame is composed of 128 OFDM symbols as illustrated in Figure 101–19 and Figure 102–1. The first 8 symbols of the downstream OFDM frame coincide with the 8 downstream symbols of the downstream PHY Link preamble. The Timestamp marks the first subcarrier of the first symbol after the Preamble (see Figure 102–11).

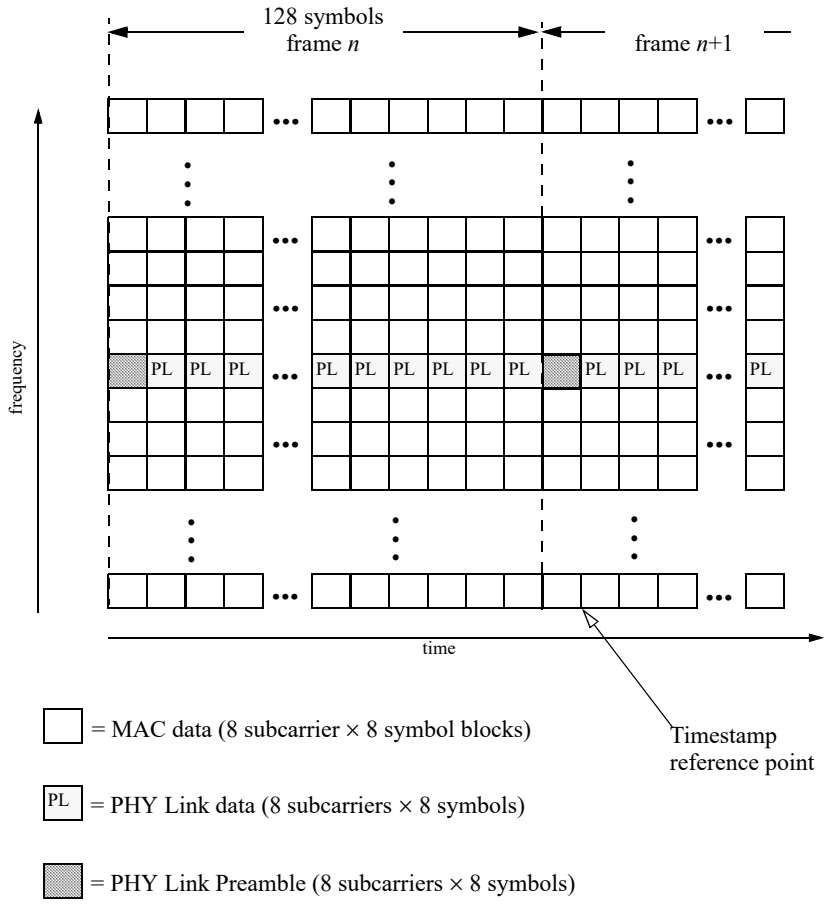

Figure 101–19—Downstream OFDM frame structure

101.4.3.6 Pilot map

Downstream pilots are composed of subcarriers modulated with a predefined data sequence known to all CNUs. The pilot data sequence is conveyed via the Pilot Insertion function (see 101.4.3.10 and Figure 101–1). Pilot Insertion follows time and frequency interleaving, before IDFT processing.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

There are two types of downstream pilots: continuous and scattered. Scattered pilots occur at different frequency locations in different symbols in a repeating cyclic pattern. Continuous pilots occur at fixed frequencies in every symbol.

101.4.3.6.1 Scattered pilots

The scattered pilot pattern is synchronized to the PHY Link as illustrated in Figure 101–20. The first OFDM symbol after the PHY Link preamble has a scattered pilot in the subcarrier just after the highest frequency subcarrier of the PHY Link.

The remainder of the scattered pilot pattern is placed so that in each symbol scattered pilots occur every 128 subcarriers. From symbol to symbol, scattered pilots are shifted by one subcarrier position in the direction of the increasing frequency. This will result in scattered pilots placed in the exclusion band and in the 400 kHz PHY Link band, such scattered pilots are not transmitted.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

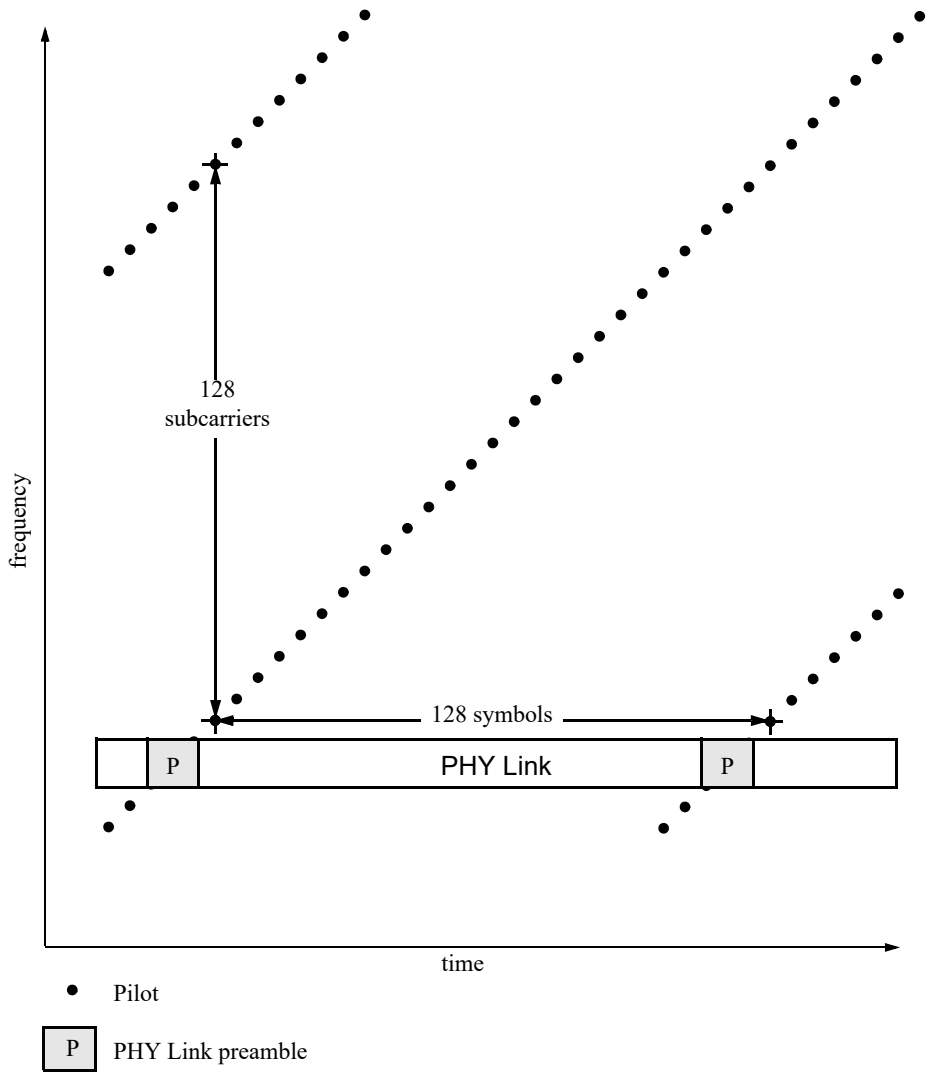

Figure 101–20—Downstream scattered pilot pattern

Mathematically, the scattered pilot pattern shall be defined as follows:

Let a subcarrier just after the PHY Link preamble be referred to as $x(m,n)$,

where

m is the frequency index
n is the time index (i.e., the OFDM symbol number)

The scattered pilots in the 128 symbols following (and including symbol n) are given by:

Symbol n:$x(n, m\pm128i)$, for all non-negative integers i
Symbol $(n+1)$:$x(n+1, m\pm128i + 1)$, for all non-negative integers i
Symbol $(n+2)$:$x(n+2, m\pm128i + 2)$, for all non-negative integers i
...
Symbol $(n+127)$:$x(n+127, m\pm128i + 127)$, for all non-negative integers i

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each of the above locations is a scattered pilot, provided that it does not fall on a continuous pilot, on the PHY Link, on an exclusion zone or on an excluded subcarrier. If the scattered pilot coincides with a continuous pilot it is treated as a continuous pilot and not as a scattered pilot.

This pattern repeats every 128 symbols. That is, symbol (*128+n*) has the same scattered pilot pattern as symbol *n*.

101.4.3.6.2 Continuous pilots

Continuous pilots occur at the same frequency location in all symbols and are used for receiver synchronization. Placement of continuous pilots is determined in one of the following two ways:

1) Predefined continuous pilot placement around the PHY Link (see Figure 102–7), or
2) Continuous pilot placement defined via PHY Link instructions.

Note that continuous and scattered pilots can overlap; the amount of overlap, in terms of number of carriers, changes from symbol to symbol. Overlapping pilots are treated as continuous pilots.

101.4.3.6.3 Predefined continuous pilots around the PHY Link

As discussed in 102.2, the PHY Link is placed at the center of a 6 MHz spectral region. Four pairs of predefined continuous pilots shall be placed symmetrically around the PHY Link as shown in Figure 102–7 at the distances indicated in Table 101–9. The spacing between each pilot pair and the PHY Link are different to prevent all pilots from being impacted at the same time by echo or interference.

The locations of the continuous pilots are defined with reference to the edges of the PHY Link band. Hence, once the PHY Link has been detected, these continuous pilots also become known to the receiver.

Table 101–9 provides the values of d_1, d_2, d_3, and d_4, measured in number of subcarriers from the PHY Link edge. That is, d_x is the absolute value of the difference between the index of the continuous pilot and the index of the PHY Link subcarrier at the PHY Link edge nearest to the continuous pilot. The index of a subcarrier is the integer k of the IDFT definition given in 101.4.3.11. For example, let the lowest frequency subcarrier of the PHY Link have the IDFT index k equal to 972. Then according to Table 101–9 the continuous pilot nearest to this lowest frequency PHY Link subcarrier will have the IDFT index k of (972 – 15) = 957. The index k of the highest frequency PHY Link subcarrier of this OFDM channel is 979. Hence continuous pilot that is nearest upper frequency edge of the PHY Link has an index k of 994.

For each distance (d_x) defined in Table 101–9, the CLT places two pilots: one d_x subcarriers above and one d_x subcarriers below the edge of the PHY Link band.

Table 101–9—Subcarrier distances for placement of predefined pilots

	d_1	d_2	d_3	d_4
PHY Link 8 subcarriers	15	24	35	47

101.4.3.6.4 Continuous pilot placement defined by PHY Link message

The CLT defines a set of continuous pilots distributed as uniformly as possible (see paragraphs that follow) over the entire OFDM spectrum in addition to the predefined continuous pilots described in 101.4.3.6.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CLT ensures that there are no isolated active OFDM spectral regions that are not covered by continuous pilots.

The CLT provides the continuous pilot placement definition via the 10GPASS-XR downstream profile descriptor variables *DS_ModTypeSC(n)* using the PHY Link EPoC message block format contained in 102.2.3.3.

The CLT shall place continuous pilots (excluding the eight continuous pilots around the PHY Link) per the following eight steps after calculating a value for N_{PC} using Equation (101–9). This calculation occurs as the first step of activating a downstream profile (see 102.2.3.1.1).

The CLT obtains the value of N_{PC} using Equation (101–9):

$$N_{PC} = min\left(max\left(8, \left\lceil CntPltSF \times \left(\frac{F_{max} - F_{min}}{190 \times 10^6}\right)\right\rceil\right), 120\right) \quad (101–9)$$

where

F_{max} refers to frequency in Hz of the highest frequency active subcarrier of the OFDM channel
F_{min} refers to frequency in Hz of the lowest frequency active subcarrier of the OFDM channel
CntPltSF is the continuous pilot scaling factor

The number of continuous pilots is between 16 and 128. This range includes the eight continuous pilots around the PHY Link channel.

The value of *CntPltSF* in Equation (101–9) is kept as a parameter that can be adjusted by the CLT.

NOTE—The typical value proposed for *CntPltSF* is 48.

Step 1:

Merge all the subcarriers between F_{max} and F_{min} eliminating the following:

1) Exclusion bands
2) 6 MHz band containing the PHY Link

Let the merged frequency band be defined as the frequency range [0, $F_{mergedmax}$].

Step 2:

Define a set of N_{PC} frequencies using the following equation:

$$F_i = \frac{F_{mergedmax}}{2N_{PC}} + \frac{i \times F_{mergedmax}}{N_{PC}}, \text{ for } i = 0, 1, \ldots, N_{PC} - 1 \quad (101–10)$$

This yields a set of uniformly spaced N_{PC} frequencies:

$$\left\{\frac{F_{mergedmax}}{2N_{PC}}, \frac{3F_{mergedmax}}{2N_{PC}}, \ldots, F_{mergedmax} - \frac{F_{mergedmax}}{2N_{PC}}\right\} \quad (101–11)$$

Step 3:

Map the set of frequencies given above to the nearest subcarrier locations in the merged spectrum. This will give a set of N_{PC} approximately uniformly spaced subcarriers in the merged domain.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Step 4:

De-merge the merged spectrum through the inverse of the operations through which the merged spectrum was obtained in step 1.

Step 5:

If any continuous pilot is within 1 MHz of a band edge, move this inwards (but avoiding subcarrier locations impacted by interferences like CSO/CTB) so that every continuous pilot is at least 1 MHz away from a band edge. This is to prevent continuous pilots from being impacted by external interferences. If the width of the spectral region does not allow the continuous pilot to be moved 1 MHz from the edge then the continuous pilot has to be placed at the center of the spectral region.

Step 6:

Identify any spectral regions containing active subcarriers (separated from other parts of the spectrum by exclusion bands on each side) that do not have any continuous pilots. Introduce an additional continuous pilot at the center of every such isolated active spectral region.

In the unlikely event that the inclusion of these extra pilots results in the total number of continuous pilots defined by PHY Link exceeding 120, return to step 1 and re-do the calculations after decrementing the value of N_{PC} by one.

Step 7:

Test for periodicity in the continuous pilot pattern and disturb periodicity, if any, through the perturbation of continuous pilot locations using a suitable algorithm. A simple procedure would be to introduce a random perturbation of up to ±5 subcarrier locations around each continuous pilot location, but avoiding subcarrier locations impacted by interferences like CSO/CTB.

Step 8:

The CLT transmits this continuous pilot pattern to the CNUs in the system and communicates the placement using the PHY Link.

101.4.3.6.5 PHY Link managed variables

CntPltSF

TYPE: 7-bit unsigned integer
This variable is used to determine the number of continuous pilots in the downstream OFDM channels.
$120 \geq CntPltSF \geq 48$.

101.4.3.7 Scrambler

The PHY shall scramble the output of the LDPC FEC encoding process using a linear feedback shift register mechanism as illustrated in Figure 101–21.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

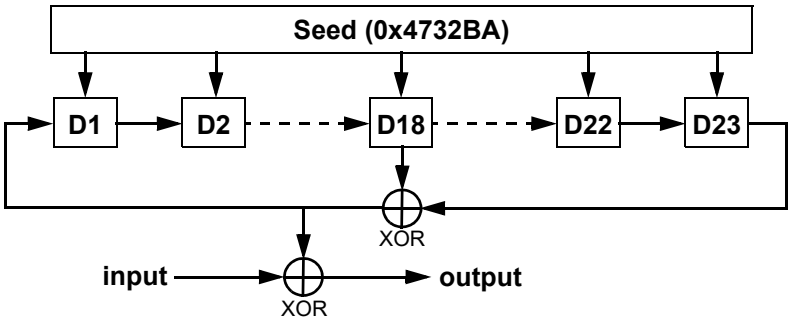

Figure 101–21—Scrambler

The scrambler is defined by the following polynomial.

$$x^{23} + x^{18} + 1$$

The scrambler is initialized to the hexadecimal value of 0x4732BA. The CLT shall initialize the scrambler at the first codeword of the downstream OFDM frame. The CNU shall initialize the scrambler with the hexadecimal value at the beginning of each grant.

101.4.3.8 Symbol mapper

101.4.3.8.1 Introduction

The Symbol Mapping function performs the following:

1) Initializes (resets) the scrambler function (see 101.4.3.7) and sets an *FCPbitCnt* to 1 (see 101.4.3.8.4), and initializes the mapping function with the lowest numbered active subcarrier.
2) Continually accepts a tx_unit (bit) from the Scrambler via the PMA_UNITDATA.request as well as monitors the Boolean state of *burstStart* and *burstEnd* (see 101.3.2.5.6) and the start of OFDM frame indication from the frame timing function. Also, the *FCPbitCnt* is incremented for each bit processed.
3) Per OFDM symbol, allocates scrambled tx_unit bits to all active OFDM data-carrying subcarriers (over all active channels) in ascending order based on a mapping configuration that anticipates frequency interleaving, staggered pilot placement and PHY Link signals per channel. While processing tx_unit bits, upon a start of frame indication, the bit counter is reset to one and the scrambler is reset before mapping the current bit to a subcarrier. Upon the next transition of *burstStart* = TRUE, the FCP update function calculates the next FCP value and updates the current PHY Link message (see 101.4.3.8.4).
4) Converts tx_unit bits to an array of QAM constellation points using a two-dimensional array with an I and Q "bin" value for each subcarrier and passes these values to the Interleaver.
5) When the last active subcarrier of the current symbol is completed, counter k is reset to 1 and processing of the next OFDM symbol begins.

The transmitter uses the number of bits per subcarrier as defined in Table 100–3 when bit mapping subcarrier (MAC) data to QAM constellations. Permissible modulation Types are listed in Table 100–2. QAM constellation mappings are described in 101.4.5.

101.4.3.8.2 Transmitter bit loading for symbol mapping

The excluded versus non-excluded (active) status, PHY Link use, continuous pilot placement, and bit loading pattern (profile) information for each subcarrier is provided by the Subcarrier Configuration and Bit Loading Function. This information is configured by management.

The notation $S^{(E)}$ is used here to define the non-empty set of excluded subcarriers.

The notation $S^{(C)}$ is used here to define the set of continuous pilots (see 101.4.3.6.2).

The notation $S^{(P)}$ is used here to define the set of PHY Link subcarriers (see 101.4.3.6.3).

For bit loading, continuous pilots and the PHY Link are treated in the same manner as excluded subcarriers; hence, the set of subcarriers that includes the PHY Link, continuous pilots and excluded subcarriers is defined as:

$$S^{(PCE)} = S^{(P)} \cup S^{(C)} \cup S^{(E)} \tag{101–12}$$

The subcarriers in the set $S^{(PCE)}$ do not carry MAC data (PHY Link carries signaling information).

Bit loading information includes the option for nulled subcarriers (i.e., subcarriers that are not use for data transport) and are BPSK modulated, as described in 101.4.5.2.

Scattered pilots do not occur at the same frequency in every symbol; in some cases scattered pilots will overlap with continuous pilots. If a scattered pilot overlaps with a continuous pilot, then that pilot is no longer considered to be a scattered pilot. It is treated as a continuous pilot.

Because the locations of scattered pilots change from one OFDM symbol to another, the number of overlapping continuous and scattered pilots changes from symbol to symbol. Since overlapping pilots are treated as continuous pilots, the number of scattered pilots changes from symbol to symbol.

The following notation is used here:

N:The total number of subcarriers in the OFDM symbol (4096 per OFDM channel)
N_C:The number of continuous pilots in an OFDM symbol
N_S:The number of scattered pilots in an OFDM symbol
N_E:The number of excluded subcarriers in an OFDM symbol
N_P:The number of PHY Link subcarriers in an OFDM symbol
N_D:The number of data subcarriers in an OFDM symbol
N_I:The number of scattered pilots and data subcarriers in the OFDM symbol

The values of N, N_C, N_E, and N_P do not change from symbol to symbol for a given OFDM template; the values of N_S and N_D change from symbol to symbol.

The following equations holds for all symbols:

$$N = N_C + N_S + N_E + N_P + N_D \tag{101–13}$$

$$N_I = N_S + N_D \tag{101–14}$$

Interleaving and de-interleaving are applied to the set of data subcarriers and scattered pilots of size N_I.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.4.3.8.3 Bit loading

The bit loading pattern defines the QAM constellations assigned to each of the 4096 (N) subcarriers per OFDM channel of the OFDM transmission. Let the bit loading pattern per OFDM channel for configuration i be defined as $A_i(k)$, where:

k is the subcarrier index that goes from 0 to 4095

$A_i(k) \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14\}$. A value of 0 indicates that the subcarrier k is nulled. Other values indicate that the modulation of subcarrier k is QAM with order shown in Equation (101–15). See variable *DS_ModTypeSC(n)* defined in 101.4.3.4.5.

$$QAM\ order = 2^{A_i(k)} \tag{101–15}$$

The function $A_i(k)$ and subsequent bit loading functions are defined per OFDM channel as the interleaver function is replicated with identical operation per OFDM channel. As up to five OFDM channels are accommodated (refer to Table 101–12) with a labeling of 1 to 5 (L), the bit loading processing ordering is $L = \{1, 2, 3, 4, 5\}$. OFDM channel 1 is always present and contains active data subcarriers.

Downstream RF spectrum availability as well as device implementation will determine OFDM channel presence and actual subcarrier use. The symbol mapping function therefore shall process all active subcarriers per symbol across all OFDM channels.

Let the sequence

$\{A_i(k), k = 0, 1, \ldots, (N-1), k \notin S^{(PCE)}\}$ be arranged as N_I consecutive values of another sequence:

$B_i(k), k = 0, 1, \ldots, (N_I - 1)$.

Given the locations of the excluded subcarriers, continuous pilots and the PHY Link in the OFDM configuration, it is possible to obtain the bit-loading pattern $B_i(k)$ that is applicable only to spectral locations without excluded subcarriers, continuous pilots, and PHY Link subcarriers. However, note that $B_i(k)$ does contain the spectral locations occupied by scattered pilots; these locations change from symbol to symbol.

The bit loading pattern is defined in the domain in which subcarriers are transmitted on the media, however bit loading is processed prior to interleaving. As such there is a permutation mapping of subcarriers, defined by the interleaving function, between the domain in which bit loading is applied to subcarriers and the domain in which subcarriers are transmitted.

The total number of subcarriers that pass through the interleaver and de-interleaver is given in Equation (101–14) and does not change from symbol to symbol. The frequency interleaver introduces a one-to-one permutation mapping P on the N_I subcarriers.

NOTE—The corresponding permutation mapping applied at the receiver de-interleaver is P^{-1}.

The bit loading pattern at the input to the interleaver. This is given by:

$$C_i(k) = P^{-1}(B_i(k)) \tag{101–16}$$

The sequence $C_i(k)$ is obtained by sending $\{B_i(k), k = 0, 1, \ldots, N-1\}$ through the frequency de-interleaver.

Note that $C_i(k)$ gives the bit-loading pattern for N_I subcarriers per OFDM channel. Scattered pilots are avoided in the bit-loading process and identified by a two-dimensional binary pattern $D(k, j)$ per OFDM

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

channel. The scattered pilot pattern has a periodicity of 128 in the time dimension, this binary pattern also has periodicity 128 in the column dimension *j*.

D(k, j) is defined for $k = 0, 1, ..., (N_I - 1)$ and for $j = 0, 1, ..., 127$.

The binary pattern *D(k, j)* begins with the transmitted scattered pilot pattern defined in 101.4.3.6.1.

The CLT executes the following steps to obtain the pattern *D(k, j)*:

1) Define a two-dimensional binary array *P(k, j)* per OFDM channel in the subcarrier transmitted domain that contains a one for each scattered pilot location and zero otherwise:
   P(k, j), for $k = 0, 1, ..., 4095$ and for $j = 0, 1, ...,127$
   The first column of this binary sequence corresponds to the first OFDM symbol following the preamble of the PHY Link.
2) Exclude the rows corresponding to excluded subcarriers, continuous pilots, and PHY Link from the two-dimensional array *P(k, j)* to give an array *Q(k, j)*. The number of rows of the resulting array is N_I and the number of columns is 128.
3) Pass this two-dimensional binary array *Q(k, j)* through the frequency de-interleaver and then the time de-interleaver, with each column treated as an OFDM symbol. After the 128 columns of the pattern have been input into the interleaver, re-insert the first *DS_TmIntrlv* columns, where *DS_TmIntrlv* is the depth of the time interleaver. This is equivalent to periodically extending *Q(k, j)* along the dimension *j* and passing (128 + *DS_TmIntrlv*) columns of this extended sequence through the frequency de-interleaver and the time de-interleaver.
4) Discard the first *DS_TmIntrlv* symbols coming out of the time de-interleaver and collect the remaining 128 columns into an array to give the binary two-dimensional array *D(k, j)* of size $(N_I \times 128)$.

For bit loading the CLT accesses the appropriate column *j* of the binary pattern bit *D(k, j)* together with the appropriate bit loading profile $C_i(k, j)$. If the value of the bit *D(k, j)* is 1, the CLT skips this subcarrier *k* and moves to the next subcarrier. This subcarrier is included as a placeholder for a scattered pilot that will be inserted in this subcarrier location after interleaving. After each symbol the column index *j* has to be incremented modulo 128.

The CLT uses this binary two-dimensional array *D(k, j)* of size $(N_I \times 128)$ in order to do bit-loading of OFDM subcarriers, as described earlier in this subclause.

The corresponding operation in the CNU is de-mapping the QAM subcarriers to get log-likelihood ratios corresponding to the transmitted bits. This operation, described below, is much simpler than the mapping operation in the transmitter.

The scattered pilots and data subcarriers of every received symbol are subjected to frequency and time de-interleaving. The scattered pilots have to be tagged so that these can be discarded at the output of the time and frequency de-interleavers. This gives N_I subcarriers for every OFDM symbol. The CNU accesses theses N_I de-interleaved subcarriers together with the bit-loading pattern $C_i(k)$ to implement the de-mapping of the QAM subcarriers into log-likelihood ratios. If the subcarrier *k* happens to be a scattered pilot, then this subcarrier, as well as the corresponding value $C_i(k)$, is skipped and the CNU moves to the next subcarrier $(k+1)$.

101.4.3.8.4 FCP calculation

The FCP calculation is supplied by the Symbol Mapper via a function call UpdateFCP. The Symbol Mapper resets the bit counter, FCPbitCnt, to zero at the start of each downstream OFDM frame and increments it for every bit processed in the frame. On the first transition of *burstStart* to TRUE from the PMA_UNITDATA.request after the start of a new frame the Symbol Mapper calls the UpdateFCP function with the counter value. The UpdateFCP function calculates the next (new) FCP value based on the supplied value, the *DS_Frame_Data_Load* (see 100.3.2.1) and *FEC_DS_CodeWordSize* (see 101.3.2.5.2) per

Equation (101–17). The UpdateFCP function shall complete and pass the new FCP value to the PHY Link with sufficient time for insertion in the PHY Link frame currently being processed.

$$FCP = (FCPbitCnt + DS_Frame_Data_Load) \bmod FEC_DS_CodeWordSize \quad (101–17)$$

where

FCPbitCnt is a counter reset to zero at the beginning of each downstream OFDM frame and is incremented for each bit that is transfered from the PMA service interface.

The downstream FEC Encoder is not aligned with the downstream OFDM frame, thus FEC codewords may straddle downstream OFDM frame boundaries. The CNU may use the FCP value in the received PHY Link messages to help locate the downstream FEC codewords. The FCP value indicates the starting bit position of the first full codeword in the next downstream OFDM frame. See 102.2.3.5.

101.4.3.9 Time and frequency interleaver

101.4.3.9.1 Overview

The CLT first applies a time interleaver to all N_I subcarriers of each OFDM symbol [see Equation (101–14)] across a group of *DS_TmIntrlv* OFDM symbols. The CLT then subjects each OFDM symbol containing these N_I time interleaved subcarriers to frequency interleaving. There is a single Time and Frequency interleaving function per OFDM channel for the MAC data path.

101.4.3.9.2 Time interleaving

The CLT shall time interleave after OFDM symbols have been mapped to QAM constellations and before they are frequency interleaved as described in this subclause.

The time interleaver is a convolutional interleaver that operates at the OFDM subcarrier level. If the depth of the interleaver is *DS_TmIntrlv*, then there are *DS_TmIntrlv* branches, as shown in Figure 101–22.

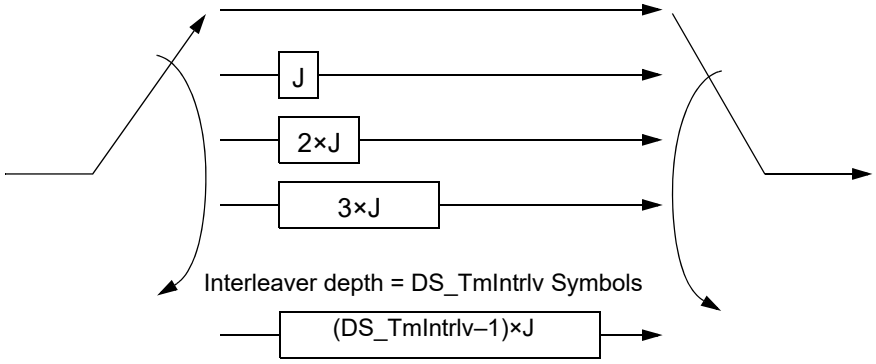

Figure 101–22—Time interleaver structure

The CLT shall support values of *DS_TmIntrlv* from 1 to 32 (see 101.4.3.9.5).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each branch is a delay line; the input and output will always be connected to the same delay line. This delay line will be clocked to insert a new subcarrier's data into the delay line and to extract a subcarrier's data from the delay line. Next, the commutator switches the input and the output to the next delay line in the direction shown by the arrows in Figure 101–22. After the delay line with the largest delay, the commutator will move to the delay line with zero delay.

The lowest frequency subcarrier of an OFDM symbol always goes through the branch with zero delay. Then the commutator switch at input and the corresponding commutator switch at output are rotated by one position for every new subcarrier.

The value of J is given by the following equation:

$$J = \left\lceil \frac{N_{\mathrm{I}}}{DS_\mathrm{TmIntrlv}} \right\rceil \tag{101–18}$$

Where, N_{I} [see Equation (101–14)] is the number of data subcarriers and scattered pilots in an OFDM symbol.

If N_{I} is not divisible by *DS_TmIntrlv*, all of the branches are not filled. Therefore, "dummy subcarriers" are added to the symbol to make the number of subcarriers equal to a multiple of *DS_TmIntrlv*. The number of dummy subcarriers is given by:

$$J \times DS_TmIntrlv - N_{\mathrm{I}} \tag{101–19}$$

The dummy subcarriers are added for definition purposes only; at the output of the interleaver these dummy subcarriers are discarded.

101.4.3.9.3 Frequency interleaving

The CLT shall perform frequency interleaving after time interleaving; subcarriers containing continuous pilots, excluded subcarriers, or PHY Link data are not frequency interleaved.

The frequency interleaver works on individual OFDM symbols. Each symbol to be interleaved consists of N_{I} subcarriers indexed from 0 to $N_{\mathrm{I}} - 1$ in ascending frequency order. These N_{I} subcarriers are made up of N_{D} data subcarriers and N_{S} scattered pilot placeholders. Although N_{D} and N_{S} are not the same for every symbol, the value of N_{I} is a constant for all OFDM symbols in the downstream OFDM frame for a given system configuration.

Conceptually, frequency interleaving of each individual OFDM symbol is performed using memory arranged in a 2D store comprising 2^{L} rows and K columns where L and K are chosen depending on the size of the FFT used for creating the OFDM symbols. If the number of data subcarriers and scattered pilots in the OFDM symbol is N_{I}, then the number of columns, K, is given by the following equation:

$$K = \left\lceil \frac{N_{\mathrm{I}}}{2^{L}} \right\rceil \tag{101–20}$$

If N_I is not an integer multiple of 2^L, then the last column will only be partially filled during the frequency interleaving process. The number of data subcarriers in the last column, C, is given by:

$$C = N_{\mathrm{I}} - 2^{L}(K - 1) \tag{101–21}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The frequency interleaver follows the following process; note that rows are numbered 0 to 2^L–1, and columns are numbered from 0 to *K–1*:

1) Write successive consecutive subcarriers into the 2D store in the row given by the *L*-bit CRC (cyclic redundancy check) value of each *L*-bit row address (Figure 101–25).
2) Rotate the subcarriers in each row written by the same *L*-bit CRC value of the row address modulo the number of columns in that row (either modulo *K* for a row below *C* or modulo *K*–1 for row *C* and higher) using a right circular shift (Figure 101–23a).
3) Rotate the subcarriers in each column by the *L*-bit CRC value of [*K*–1 minus the column address] using a downward circular shift (Figure 101–23b). Note that the last column *K*–1 with a CRC value of 0 is not rotated.
4) Read the subcarriers out of the 2D store column-wise from row 0, column 0 to row *C*–1, column *K*–1.

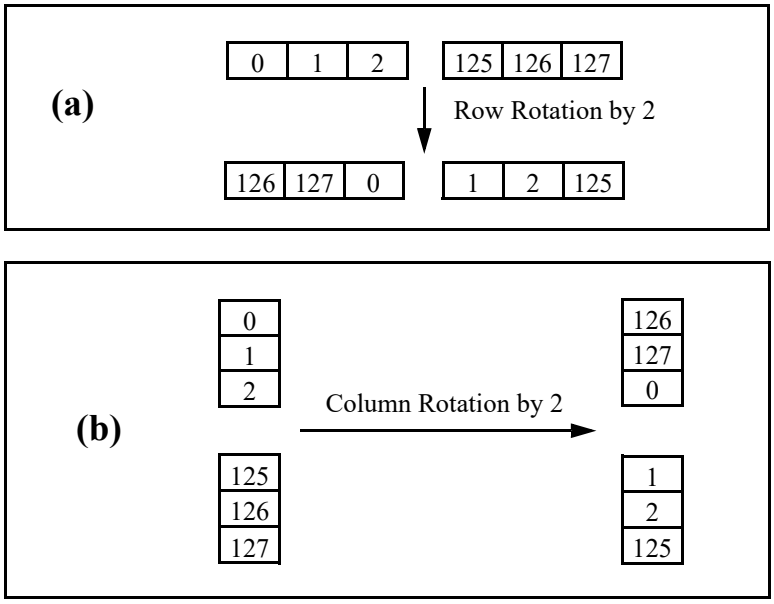

Figure 101–23—Rotation of subcarriers: a) Horizontal rows, b) Vertical columns

Assume that the input subcarriers of the OFDM symbol are initially arranged into the 2D store in sequential order column-wise from row 0, column 0 to row *C*–1, column *K*–1. The above procedure relocates each sequential input subcarrier number in row *r*, column *c* into a permuted output subcarrier number in the 2D store in that position in row *r*, column *c* as *sc(r,c)* given by Equation (101–22):

$$sc(r,c) = sc_0[(r - CRC(K-1-c))mod2^L] + (c - (r - CRC(K-1-c)mod2^L))modM \qquad (101\text{–}22)$$

where $M = K$, for $(r - CRC(K-1-c))mod2^L < C$

otherwise $M = K$–1

$sc(r,c) \in [0,1, \ldots, N_I - 1]$ and $sc_0[n]$ is defined as an array of 2^L elements where each element contains the cumulative number of subcarriers previously written into the 2D store prior to writing into the permuted output row *n*. Note that if the last column contains fewer subcarriers than 2^L, the cumulative value in $sc_0[n]$

takes into account those previously written permuted output rows that were shorter by one subcarrier (i.e., those prior row addresses that were greater than or equal to *C*, the number of subcarriers in the last column).

The structure of the two-dimensional store is shown in Figure 101–24.

.

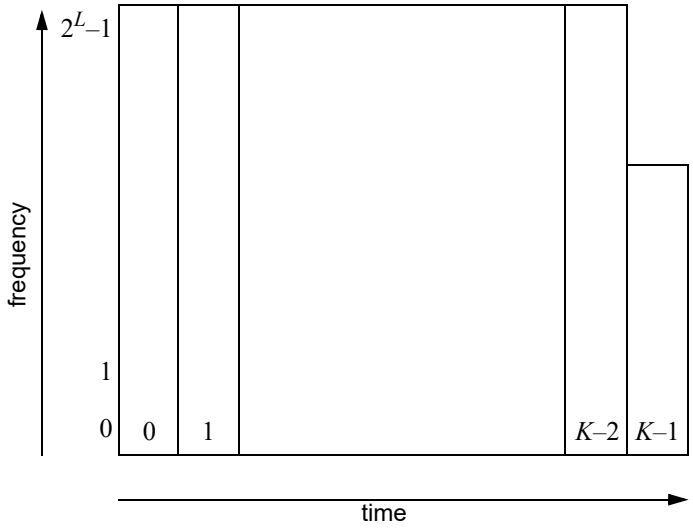

Figure 101–24—Two-dimensional store block structure

The m-stage linear feedback shift register for calculating the CRC of each row address is defined using a generator polynomial of degree $m = L$ in the finite (Galois) field GF[2]:

$$G(X) = g_m X^m + g_{m-1} X^{m-1} + g_{m-2} X^{m-2} + \ldots + g_2 X^2 + g_1 X^1 + g_0 \quad (101\text{–}23)$$

where the coefficients g_m corresponding to the feedback taps of the linear feedback shift register are chosen such that the resulting generator polynomial is primitive (i.e., if the polynomial is prime and cannot be factored, and if it is a factor that evenly divides X^N+1, where $N = 2^m–1$). This guarantees that each *L*-bit address for the 2^L rows is unique and the CRC values span the entire set of 2^L, *L*-bit addresses.

The linear feedback shift register implementing the generator polynomial is shown in Figure 101–25.

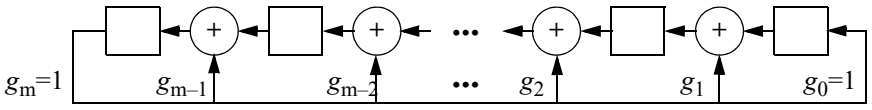

Figure 101–25—Row address linear feedback shift register

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Calculation of the CRC c_{m-1}, c_{m-2}, …, c_1, c_0 for each row address b_{m-1}, b_{m-2}, …, b_1, b_0 using this linear feedback shift register structure is shown in Figure 101–26.

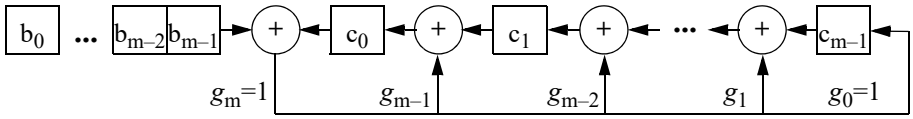

Figure 101–26—CRC calculation using a linear feedback shift register

The specific generator polynomial for the calculation of the CRC with $m = L = 6$ is given by:

$$G(X) = X^6 + X^1 + 1 \tag{101–24}$$

The corresponding linear feedback shift register is shown in Figure 101–27.

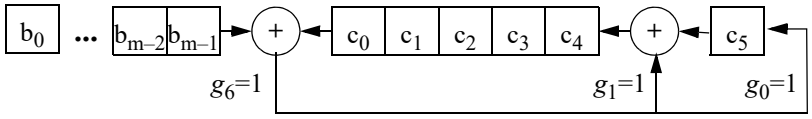

Figure 101–27—CRC calculation for $G(X) = X^6 + X^1 + 1$ with a linear feedback shift register

De-interleaving is accomplished by reversing the interleaving process described above. Each symbol to be de-interleaved consists of N_I subcarriers indexed from 0 to $N_I - 1$ in ascending frequency order. Assume that the input subcarriers of the interleaved OFDM symbol are arranged into the 2D store in sequential order column-wise from row 0, column 0 to row 2^L, column C.

The frequency de-interleaver performs the following process to reverse the interleaving process; note that rows are numbered from 0 to 2^L–1, and columns are numbered from 0 to K–1:

1) Write the subcarriers into the 2D store column-wise from column 0, row 0 to column K–1, row C.
2) Rotate the subcarriers in each column by the L-bit CRC value of [K–1 minus the column address] using an upward circular shift (reverse of Figure 101–25b). Note that the last column K–1 with a CRC value of 0 in not rotated.
3) Rotate the subcarriers in each row written by the same L-bit CRC value of the row address modulo the number of columns in that row (either modulo K for a row below C or modulo K–1 for row C and higher) using a left circular shift (reverse of Figure 101–25a).
4) Read the subcarriers out of the 2D store row-wise in the row order given by the L-bit CRC value of each L-bit row address skipping the last column at or beyond row C.

101.4.3.9.4 Interleaving impact on continuous pilots, scattered pilots, PHY Link and excluded spectral region

The CLT interleaves the subcarriers that are tagged to act as placeholders for scattered pilots. The actual BPSK modulation to these placeholder subcarriers is applied after interleaving as described in 101.4.3.9.2 and 101.4.3.9.3.

The CLT retains a reference pattern for inserting scattered pilot placeholders prior to interleaving. Since the scattered pilot pattern repeats every 128 symbols, this pattern is a ($N_I \times 128$) two-dimensional bit pattern. A

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

value of one in this bit-pattern indicates the location of a scattered pilot. The CLT inserts data subcarriers where this reference pattern has a zero and scattered pilot placeholders where this pattern has a one.

This reference pattern may be derived from the following procedure:

1) In the time-frequency plane, create a two-dimensional bit-pattern of zeros and ones from the transmitted "diagonal" scattered pilot patterns described in 101.4.3.6.1. This pattern has a periodicity of 128 symbols and has a value of one for a scattered pilot location and zero otherwise. Let the time axis be horizontal and the frequency axis vertical.
2) Delete all horizontal lines containing continuous pilots, excluded subcarriers, and PHY Link from the above mentioned two-dimensional bit pattern; note that some scattered pilots could coincide with continuous pilots. These locations are treated as continuous pilot locations.
3) Send the resulting bit-pattern through the frequency de-interleaver and the time de-interleaver in succession. This will give another two-dimensional bit pattern that has a periodicity of 128 symbols. The appropriate 128-symbol segment of this bit-pattern is chosen as the reference bit pattern referred to above.

The synchronization of the scattered pilot pattern to the PHY Link preamble, as described in Figure 101–20 uniquely defines the 128-symbol segment that is used as the reference pattern.

Note that the number of OFDM subcarriers that are interleaved does not change from symbol to symbol. The insertion of continuous pilots, PHY Link, and excluded regions happens after both time and frequency interleaving. Interleaving is independent of individual subcarrier modulation and the modulation pattern of these data subcarriers may change from symbol to symbol.

101.4.3.9.5 PHY Link managed variables

DS_TmIntrlv
: TYPE: 5-bit integer
This variable indicates the number of time interleaved OFDM symbols in the downstream direction. The value is between 1 and 32.

101.4.3.10 Pilot insertion

Continuous and scattered pilots shall be BPSK modulated using the pseudo-random sequence generated by the 13-bit linear feedback shift register, illustrated in Figure 101–28 with polynomial $(x^{13}+x^{12}+x^{11}+x^{8}+1)$ and described next.

This linear feedback shift register is initialized to all ones at the k=0 index of the discrete Fourier transform defining the OFDM signal (refer to 101.4.3.11). It is then clocked after every subcarrier of the IDFT. If the subcarrier is a pilot (scattered or continuous), then the BPSK modulation for that subcarrier is taken from the linear feedback shift register output.

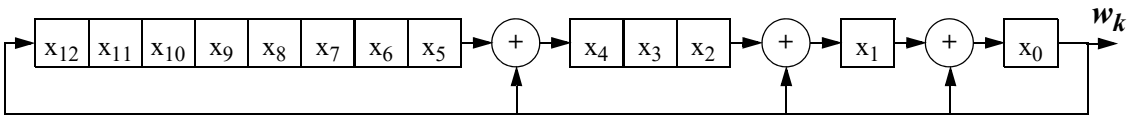

Figure 101–28—13-Bit Linear Feedback Shift Register for the pilot modulation Pseudo-Random Sequence

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Let the output of the linear feedback shift register be w_k then BPSK modulation used for the pilot is:

$w_k = 0$: BPSK constellation point = 1 + j0

$w_k = 1$: BPSK constellation point = –1 + j0

101.4.3.10.1 Pilot boosting

All active subcarriers, with the exception of pilots, are transmitted with the same average power. The CLT shall multiply the real and imaginary components of continuous and scattered pilots by a real-valued number such that the amplitude of the continuous and scattered pilots is twice the root-mean-square value of the amplitude of other subcarriers of the OFDM symbol. That is, continuous and scattered pilots are boosted by approximately 6 dB with reference to other subcarriers.

101.4.3.11 Inverse Discrete Fourier Transform (IDFT)

The CLT OFDM and CNU OFDMA signals are assembled in the frequency domain using 4096 subcarriers per OFDM/OFDMA channel. The signal is composed of: MAC data subcarriers, scattered pilots, continuous pilots, PHY Link subcarriers, zero-bit-value subcarriers, and excluded subcarriers (zero valued into the IDFT).These OFDM/OFDMA signals are described in IDFT Equation (101–25).

$$x(i) = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} X(k) \exp\left(j \frac{2\pi i \left(k - \frac{N}{2} \right)}{N} \right), \text{ for } i = 0, 1, \ldots, (N-1) \qquad (101\text{–}25)$$

where

N equals 4096
$X(0)$ is the lowest frequency component
$X(N–1)$ is the highest frequency component
k is the spectral index of the subcarrier

The resulting time domain discrete signal, *x(i)*, is a baseband complex-valued signal, sampled at 204.8 million samples per second resulting in a subcarrier spacing of 50 kHz.

Once the CNU detects the downstream PHY Link and receives the *DS_FreqCh(1)* variable (see Table 101–1), the CNU knows the location of $k = 0$.

The encompassed spectrum of a 192 MHz OFDM channel is 190 MHz (3800 active subcarriers, see Table 100–3 and Table 100–11). These 3800 maximum active subcarriers of a CLT or CNU OFDM transmitter channel shall occupy the range $148 \leq k \leq 3947$, where k is the spectral index of the subcarrier in Equation (101–25).

101.4.3.11.1 PHY Link managed variables

DS_FreqCh(n)
See 100.3.2.3.

101.4.3.12 Cyclic prefix and windowing

CLT and CNU cyclic prefix (CP) and windowing processing begins with the N-point output of the IDFT:

$\{x(0), x(1), \ldots, x(N-1)\}$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The variable *DSNcp* represents the provisioned duration, in OFDM Clock periods, of the downstream cyclic prefix parameter (see Table 101–10) for the CLT. The *DSNcp* samples at the end of this *N*-point IDFT are copied and prepended to the beginning of the IDFT output to give a sequence of length (*N* + *DSNcp*):

$$\{x(N - DSNcp), x(N - DSNcp + 1),\ldots, x(N - 1), x(0), x(1), \ldots, x(N - 1)\}$$

The variable *DSNrp* represents the provisioned duration, in OFDM Clock periods, of the downstream windowing parameter (see Table 101–11 for the CLT. The *DSNrp* samples at the start of the *N*-point IDFT are copied and appended to the end of the IDFT output to give a sequence of length (*N* + *DSNcp* + *DSNrp*):

$$\{x(N - DSNcp), x(N - DSNcp + 1), \ldots, x(N - 1), x(0), x(1), \ldots, x(N - 1), x(0), x(1), ..., x(DSNrp - 1)\}$$

Let this extended sequence of length (*N* + *DSNcp* + *DSNrp*) be defined as:

$$\{y(i),\ i=0, 1, ..., (N + DSNcp + DSNrp - 1)\} \tag{101–26}$$

DSNrp samples at both ends of this extended sequence are subject to tapering. This tapering is achieved using a raised-cosine window function; a window is defined to be applied to this entire extended sequence. This window has a flat top and raised-cosine tapering at the edges, as shown in Figure 101–29.

The window function *w(i)* is symmetric at the center; therefore, only the right half of the window is defined in the following equation:

$$w\left(i + \frac{N + DSNcp + DSNrp}{2}\right) = 1.0 \tag{101–27}$$

$$\text{for } i = 0, 1, \ldots, \frac{(N + DSNcp + DSNrp)}{2} - 1$$

$$w\left(i + \frac{N + DSNcp + DSNrp}{2}\right) = \frac{1}{2}\left(1 - \sin\left(\frac{\pi}{\alpha(N + DSNcp)}\left(i - \frac{N + DSNcp}{2} + \frac{1}{2}\right)\right)\right) \tag{101–28}$$

$$\text{for } i = \left(\left(\frac{N + DSNcp - DSNrp}{2}\right), \ldots, \left(\frac{N + DSNcp + DSNrp}{2} - 1\right)\right)$$

Here,

$$\alpha = \frac{DSNrp}{N + DSNcp} \tag{101–29}$$

defines the window function for (*N* + *DSNcp* + *DSNrp*)/2 samples. The complete window function of length (*N* + *DSNcp* + *DSNrp*) is defined using the symmetry property as:

$$w\left(\frac{N + DSNcp + DSNrp}{2} - i - 1\right) = w\left(\frac{N + DSNcp + DSNrp}{2} + 1\right), \tag{101–30}$$

$$\text{for } i = 0, 1, \ldots, \frac{(N + DSNcp + DSNrp)}{2} - 1$$

This yields a window function (or sequence): $\{w(i),\ i=0, 1, ..., (N + DSNcp + DSNrp - 1)\}$. The length of this sequence is an even-valued integer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The previous window function is applied to the sequence $\{y(i)\}$:

$$z(i) = y(i)\, w(i), \quad for\ i = 0, 1, \ldots, (N + DSNcp + DSNrp - 1) \tag{101–31}$$

Each successive set of N samples at the output of the IDFT yields a sequence $z(i)$ of length $(N + DSNcp + DSNrp)$. Each of these sequences is overlapped at each edge by *DSNrp* samples with the preceding and following sequences, as shown in the last stage of Figure 101–29. Overlapping regions are added together.

To define this "overlap and add" function mathematically, consider two successive sequences $z_1(i)$ and $z_2(i)$. The overlap and addition operations of these sequences are defined using the following equation:

$$z_1(N + DSNcp + i) + z_2(i), \quad for\ i=0, 1, \ldots, DSNrp - 1 \tag{101–32}$$

That is, the last *DSNrp* samples of sequence $z_1(i)$ are overlapped and added to the first *DSNrp* samples of sequence $z_2(i)$.

The length of the extended OFDM symbol is $(N + DSNcp + DSNrp)$ samples. Of this, ($DSNrp$/2) samples are within the preceding symbol, and ($DSNrp$/2) samples are within the following symbol. This yields a symbol period of ($N + DSNcp$) samples.

The process of cyclic prefix and windowing is illustrated in Figure 101–29. In the downstream direction the CLT shall use one of the permissible values for *DSNcp* and *DSNrp* given in Table 101–10 and Table 101–11, respectively, selected such that $DSNrp < DSNcp$.

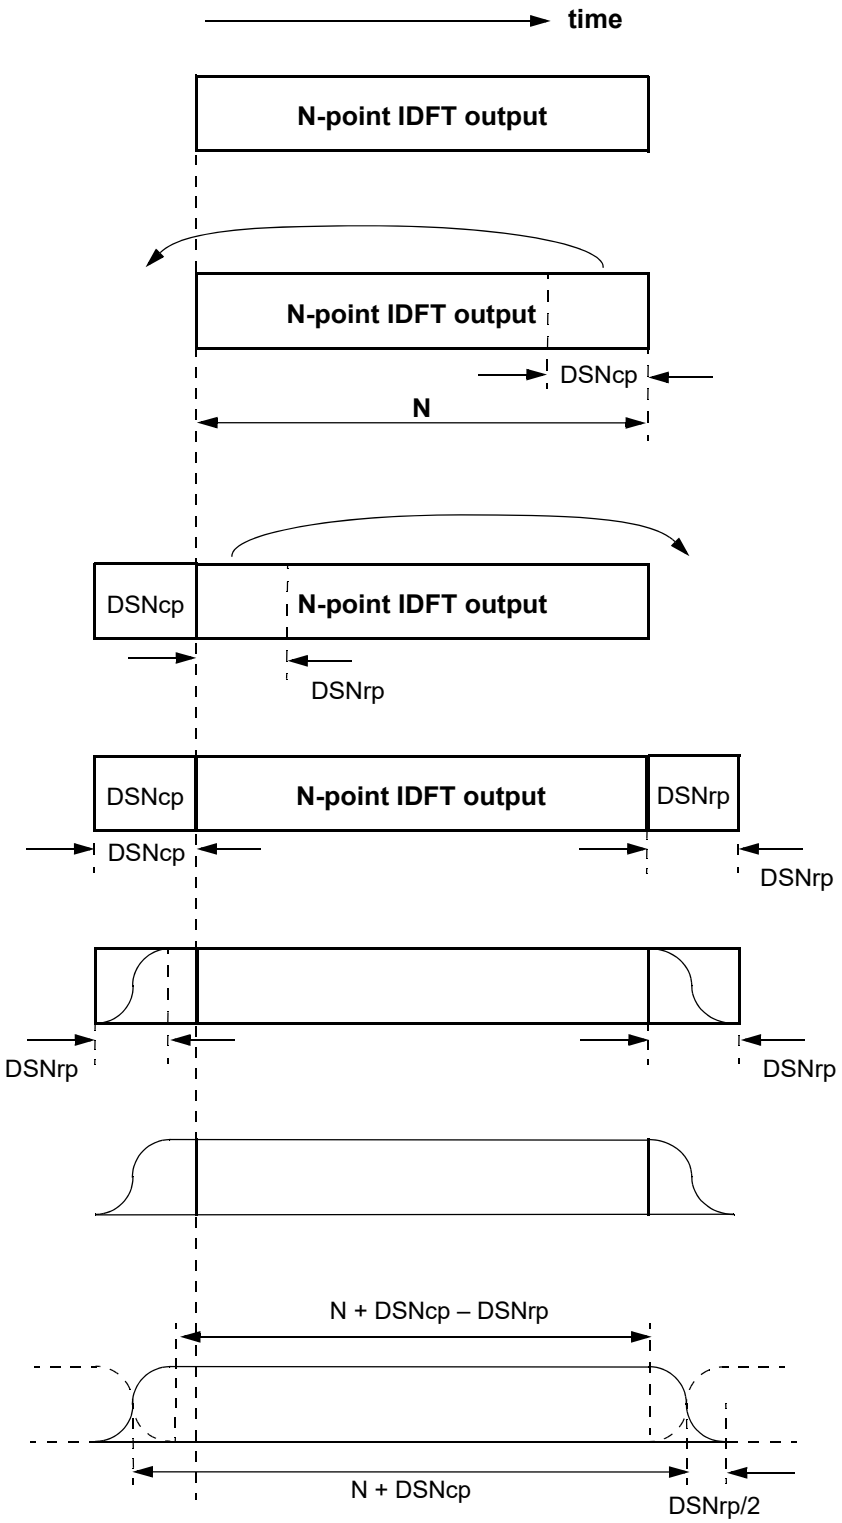

Table 101–10—Size of cyclic prefix (*DSNcp*), downstream direction

101.4.3.12.1 PHY Link managed variables

DSNcp

TYPE: 4-bit binary
This variable controls the size of the cyclic prefix in the downstream direction per the following enumeration:
bit 3 2 1 0
1 x x x = reserved
0 1 x x = reserved
0 0 1 1 = 768 OFDM Clock periods (1/204.8 MHz)
0 0 1 0 = 512 OFDM Clock periods (1/204.8 MHz)
0 0 0 1 = 256 OFDM Clock periods (1/204.8 MHz)
0 0 0 0 = reserved

DSNrp

TYPE: 3-bit binary
This variable controls the size of the windowing function in the downstream direction per the following enumeration:
bit 2 1 0
1 1 x = reserved
1 0 1 = 256 OFDM Clock periods (1/204.8 MHz)
1 0 0 = 192 OFDM Clock periods (1/204.8 MHz)
0 1 1 = 128 OFDM Clock periods (1/204.8 MHz)
0 1 0 = 64 OFDM Clock periods (1/204.8 MHz)
0 0 1 = reserved
0 0 0 = 0 samples (windowing disabled)

101.4.3.13 OFDM channel requirements

The 10GPASS-PX-D PHY shall comply with the OFDM channel operational requirements in Table 101–12.

Table 101–12—Multiple OFDM channel requirements

Item	Requirement
OFDM channel 1 configuration	OFDM channel 1 is always be enabled. OFDM channel 1 processes subcarriers for data as well as the PHY Link.
OFDM channel 2, 3, 4, 5 configuration	OFDM channels 2, 3, 4, or 5 may be enabled or disabled for operation. OFDM channels are enabled in ascending order: e.g., enable OFDM channel 2 before enabling OFDM channel 3, enable OFDM channel 3 before enabling OFDM channel 4, enable OFDM channel 4 before enabling OFDM channel 5.
OFDM channel frequency placement	An OFDM channel may be configured for operation in any portion of the downstream Frequency Band as per Table 100–3.
OFDM channel subcarrier indexing relation to RF frequency	OFDM channel 1: 0 to 4095 OFDM channel 2: 4096 to 8191 OFDM channel 3: 8192 to 12287 OFDM channel 4: 12288 to 16383 OFDM channel 5: 16384 to 20479

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 101–12—Multiple OFDM channel requirements *(continued)*

Item	Requirement
OFDM channel subcarrier frequency ordering	RF frequency correlates to subcarrier index; i.e., the lower the subcarrier index, the lower the RF frequency.
Minimum encompassed Spectrum	The minimum encompassed spectrum of any enabled OFDM channel is 22 MHz as per Table 100–3.
Encompassed spectrum overlap	The encompassed spectrum of any enabled OFDM channel does not overlap with that of any other enabled OFDM channel.
Adjacent OFDM channel placement	The CLT transmitter permits placement of the edge subcarrier of an OFDM channel's encompassed spectrum immediately adjacent to the edge subcarrier of another OFDM channel's encompassed spectrum without any frequency guard band.

101.4.4 Upstream PMA transmit function

101.4.4.1 Overview

101.4.4.2 Time and frequency synchronization

CNU upstream frequency and transmission timing is based on downstream channel tracking, and in the case of timing, also on receiving and applying timing adjustments commanded by the CLT using the PHY Link Channel.

This subclause describes the CNU upstream transmission performance requirements for frequency and timing that are based on tracking the downstream input to the CNU, and receiving and operating on commands from the CLT.

101.4.4.2.1 OFDM channel frequency accuracy

The CNU shall lock the frequency of the upstream Subcarrier Clock (50 kHz) and lock each upstream subcarrier frequency to the 10.24 MHz Master Clock derived from the downstream OFDM signal.

All upstream subcarrier frequency specifications assume a downstream input to the CNU per 101.4.3.2 and 101.4.3.3 and a downstream received signal per 100.3.6.3 but with a CNR of at least 32 dB and received signal level of at least –15 dBmV for 6 MHz averaged for OFDM downstream.

The frequency of the upstream Subcarrier Clock shall be accurate within 0.4 ppm. Each subcarrier frequency shall be accurate to within 30 Hz. Both of these requirements are relative to the 10.24 MHz Master Clock reference, and both for five sigma of the upstream OFDMA transmissions, for subcarrier frequencies up to 204.8 MHz.

101.4.4.2.2 OFDM channel timing accuracy

For OFDMA upstream the ranging time offset is described in 102.4.1.6. The CNU shall implement the OFDMA timing adjustment to within ± 10 ns.

101.4.4.2.3 Modulation timing jitter

CNU OFDM Clock timing error relative to the CLT 10.24 MHz Master Clock as measured at the CLT shall be within ± 10 ns in each burst measured within any 35 second measurement period. This applies to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

worst-case jitter and frequency drift specified for the CLT 10.24 MHz Master Clock and the CLT downstream OFDM Clock. The mean error is the result of the adjustment applied by the CNU as specified in 101.4.4.3.6.

101.4.4.3 Frame timing

The frame timing function is reset by the PHY Link during link auto-negotiation. The framing timing state machine (see Figure 101–31) implements the RB Superframe structure per 101.4.4.3.1.

101.4.4.3.1 RB Superframe configuration and burst transmission

The upstream Superframe shall be composed of the Probe Period followed by 256 OFDMA symbols. Each Probe Period is six OFDMA symbols in duration. An RB Frame is one Resource Block column (i.e., one column of Resource Blocks over the entire upstream spectrum). Each Resource Block is composed of one subcarrier and has a duration of either 8 or 16 symbols and is set using the *RBsize* variable. Changing the Resource Block duration results in a network restart. The superframe structure is illustrated in Figure 101–30.

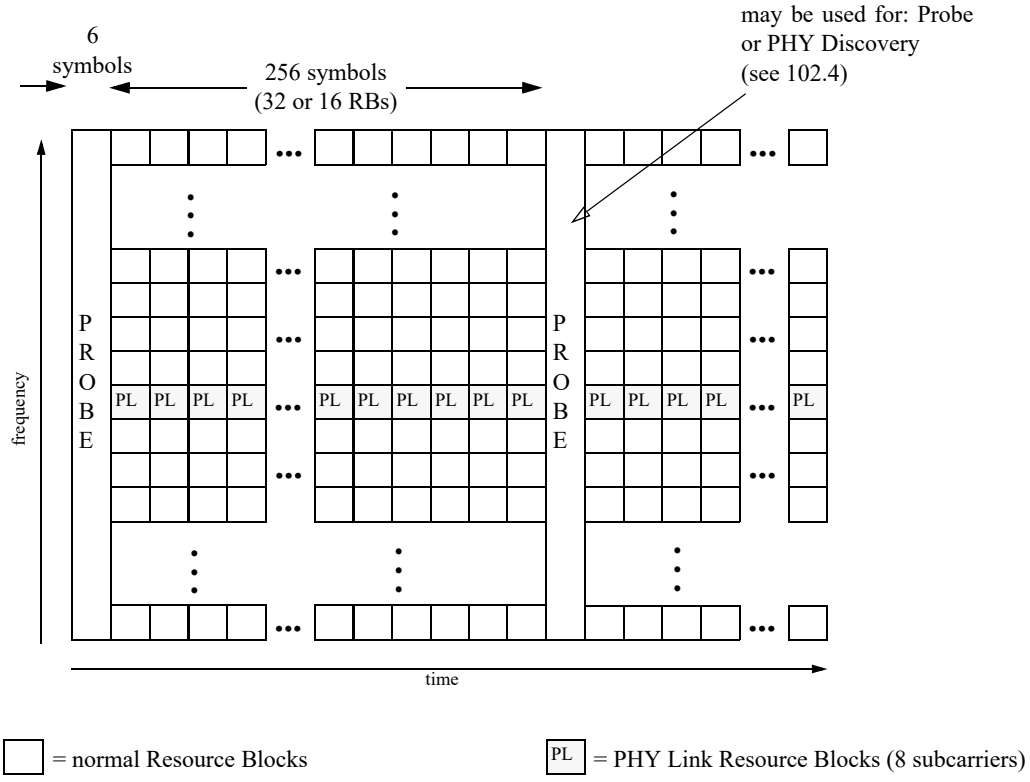

Figure 101–30—Upstream superframe structure

101.4.4.3.2 OFDMA transmission burst start

A CNU OFDMA transmission shall start with four contiguous subcarriers that include the start burst marker (see 101.4.4.8). No MAC data is transmitted during the burst marker.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.4.4.3.3 OFDMA transmission internal to a burst

In general Resource Blocks internal to a burst may be of Type 0, Type 1 or Type 2 as determined by the provisioned Pilot pattern (see 101.4.4.6). An OFDMA transmission may straddle excluded subcarriers, unused subcarriers, and the Probe Period. An example of this would be if the transmission burst start and stop markers straddle an exclusion band or if the burst start marker occurs in one RB Frame and the stop marker occurs in a subsequent RB Frame. In such cases, where the OFDMA transmission crosses a band edge (anywhere an excluded subcarrier is adjacent to an active subcarrier), the active subcarrier immediately adjacent to the band edge shall be of Type 2.

101.4.4.3.4 OFDMA transmission burst end

An OFDMA transmission shall end with four contiguous subcarriers that include the stop burst marker (see 101.4.4.8). No MAC data is transmitted during the burst marker.

101.4.4.3.5 Variables

RBsize

TYPE: Boolean
This variable determines the size of the upstream Resource Blocks. When *RBsize* is TRUE then Resource Block size is 16 symbols, When *RBsize* is FALSE then Resource Block size is 8 symbols.

RBlen(*RBsize*)

TYPE: integer
This integer represents the number of symbols for the configured Resource Block size. See Table 101–1.
Value: 8 when *RBsize* is FALSE, 16 when *RBsize* is TRUE.

SCLK

TYPE: Boolean
This clear on read variable is TRUE on every negative edge of a clock that is synchronized to the period of the Extended OFDM symbol time composed of the 20 μs useful symbol time plus the cyclic prefix time *USNcp*.

RBSF_reset

TYPE: Boolean
This variable is used to reset the frame timing state diagram (see Figure 101–31). A transition from FALSE to TRUE causes the state diagram to reset to the beginning of the RB_SUPERFRAME_RESET when *SCLK* goes TRUE. Upon being read this variable is reset to FALSE. The variable is set to TRUE on any reset or any Link-down condition (as defined in Table 102–14).

Probe_start

TYPE: Boolean
This variable transitions from the value of FALSE to TRUE for the first symbol of the Probe region. At the end of the first symbol of the probe region, the value transitions to FALSE until the first symbol of the next RB Superframe.

RB_Frame_start

TYPE: Boolean
This variable transitions from the value of FALSE to TRUE for the first symbol of each RB Frame in the RB Superframe as related to *RBsize*. The value is FALSE for all probe region symbols and for symbol 2 through *RBlen*(*RBsize)* for each RB Frame.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SYMcount

TYPE: unsigned integer
This is variable is used for counting the symbols of the RB Superframe.

RBmod

TYPE: unsigned integer
This variable is used to set the symbols per RB Frame upon reset.

101.4.4.3.6 State diagram

The CLT PMA shall implement the frame timing process as shown in Figure 101–31.

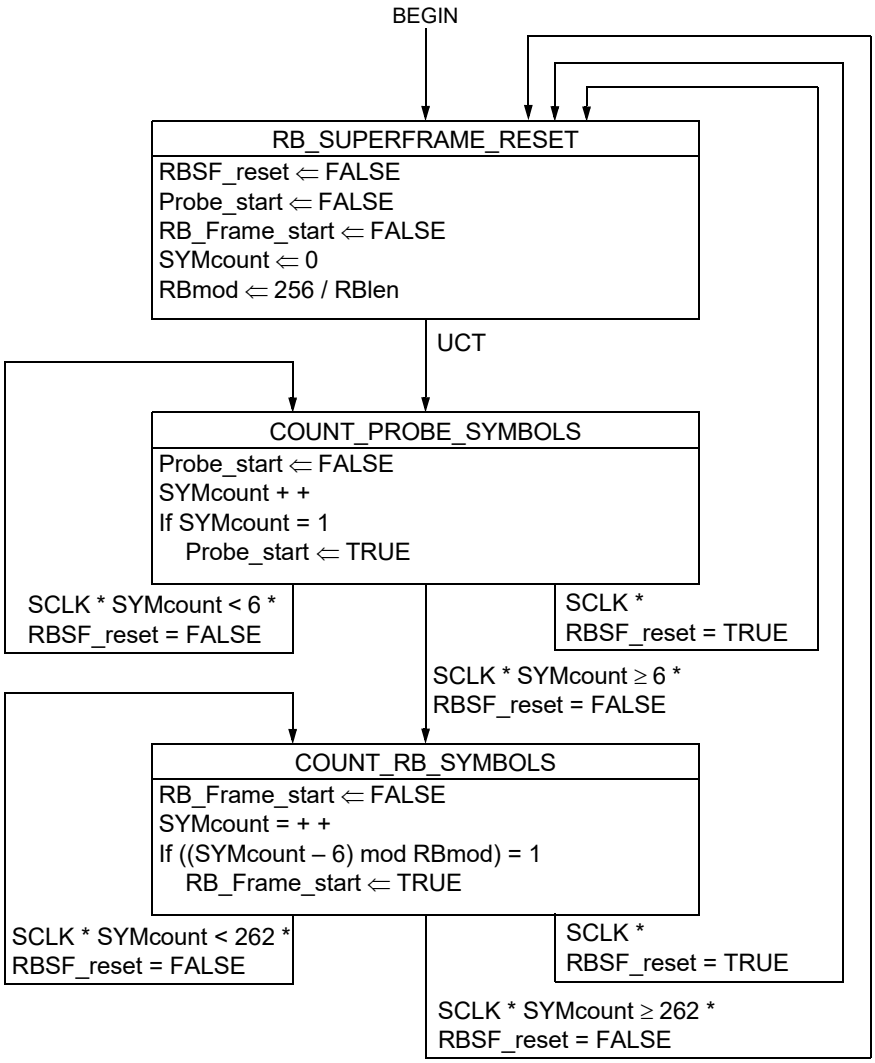

Figure 101–31—Framing timing state diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.4.4.4 Subcarrier configuration and bit loading

Each subcarrier in the OFDMA channel is configured using the *US_ModTypeSC(n)* (where $0 \le n \le 4095$) or *TypeN_Repeat/TypeN_Start* ($N = 1$ or 2) variables. These variables allow the PHY to configure each subcarrier to be nulled, to have a specific bit loading (such as 512-QAM or 1024-QAM), or to be excluded and to define the pilot pattern to be used in upstream transmissions. Subcarrier configuration in an EPoC OFDM channel of 192 MHz at the CNU shall conform to the rules outlined in Table 101–13.

All devices in an EPoC network share the same upstream subcarrier configuration and bit loading including nulled subcarriers, pilot pattern, bit loaded subcarriers, and excluded subcarriers.

Table 101–13—Upstream subcarrier configuration rules

Parameter	Limit	Unit
Minimum number of combined active and nulled subcarriers for Probe	180	Subcarriers
Minimum OFDMA channel guard band	1	MHz
Max OFDMA channel encompassed spectrum	190	MHz

101.4.4.4.1 Nulled subcarriers

Nulled subcarriers do not carry MAC or PHY Link data but may be used as probes. Nulled subcarriers are not modulated except when being used as a Probe Symbol in the upstream direction (see 102.4.2).

101.4.4.4.2 Bit loaded subcarriers

When a subcarrier is used to carry MAC data it uses the modulation type of QPSK or 2^n-QAM, where $4 \le n \le 16$, assigned via the *US_ModTypeSC(n)* variables except when used as an upstream pilot (see 101.4.4.6), Probe, PHY Discovery Response (see 102.4.1), or burst marker (see 101.4.4.8).

There is at least one contiguous 10 MHz or greater band of active subcarriers in the upstream 192 MHz OFDM channel (see Table 100–11). This may include subcarriers intended as Pilots and PHY Link subcarriers. A 1 MHz guard band of excluded subcarriers above and below this 10 MHz creates a minimum width OFDM channel of 10 MHz encompassed spectrum.

101.4.4.4.3 Excluded subcarriers

CNUs shall not transmit energy into a subcarrier that has been excluded from the OFDM channel (i.e., excluded subcarriers have zero amplitude). There is a band edge Exclusion Band at both the top and bottom of the OFDM channel.

101.4.4.4.4 PHY Link managed variables

US_ModAbility

TYPE: 2-bit binary

This bit mapped variable is used to declare which modulation types the PHY supports in the upstream direction for the MAC data path. When a bit read as TRUE it indicates that the PHY supports that modulation type.

Bit	Modulation type
0	2048-QAM
1	4096-QAM

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

US_ModTypeSC(n)

TYPE: 4-bit binary

This set of provisioned variables determine the modulation parameters for each of the 4096 upstream OFDM subcarriers. $0 < n < 4095$. Each variable controls one of the 4096 subcarriers that are transmitted over the OFDMA channel, with *US_ModTypeSC(0)* controlling subcarrier zero, *US_ModTypeSC(1)* controlling subcarrier 1, etc. The assignment of bits to each modulation type is shown below:

bit 3 2 1 0
1 1 1 1 = Excluded subcarrier
1 1 1 0 = reserved
1 1 0 1 = reserved
1 1 0 0 = 4096-QAM
1 0 1 1 = 2048-QAM
1 0 1 0 = 1024-QAM
1 0 0 1 = 512-QAM
1 0 0 0 = 256-QAM
0 1 1 1 = 128-QAM
0 1 1 0 = 64-QAM
0 1 0 1 = 32-QAM
0 1 0 0 = 16-QAM
0 0 1 1 = 8-QAM
0 0 1 0 = QPSK
0 0 0 1 = BPSK (Used for continuous pilots only)
0 0 0 0 = null (carries no data)

101.4.4.5 Upstream symbol mapper

The upstream symbol mapper consists of an idle loop process and a fill process. The idle loop process is initialized when the upstream profile is configured and set to align with the start of the RB Superframe. An RB Superframe is composed of a Probe Period (first six OFDMA symbols) followed by 32 (*RBsize* value FALSE) or 16 (*RBsize* value TRUE) RB Frames (see 101.4.3.5). The main task of the idle loop is to walk through all data bits in all data carrying Resource Elements (in each RB Frame) at the clock rate established by *US_DataRate* (see 100.3.2.2). The fill process, upon an assertion of the start of a burst from the PMA Client, starts filling at the Resource Block, Resource Element, and fill bit that is at the current walk point. This includes placing the start burst marker elements, filling bits in data Resource Elements and low density pilots as specified, creating the QAM map for the fill word bits, sensing the end of burst, padding to the end of the current Resource Block, encoding and placing the end burst marker elements and then terminating. Both processes are continuous loops. During the idle walk and fill processes, two-dimensional arrays (Resource Block size by total subcarriers) termed RB Frames are allocated and passed to the staging process when complete. RB Frames initially consist of null values that correspond to excluded subcarriers. Non-null values are inserted by the fill process when mapping burst markers and filling data Resource Elements, and when later processed by the Pilot Insert process fill “P” type pilots patterns (see 101.4.4.6). Null Resource Blocks are equivalent to excluded subcarriers and produce no energy on the corresponding OFDMA subcarrier after the IDFT process.

101.4.4.5.1 Variables

BITPOS

TYPE: integer

This is an integer used by the fill process to indicate the current bit position being filled in *FillWord*.

END

TYPE: enumerated type

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable that ends the end state processing of the fill process, where:
FALSE indicates a *burstStart* = TRUE has not been received from received PMA_UNITDATA.request() primitive,
PAD indicates *burstStart* = TRUE has been received and the fill process is padding bits to the end of the current RB,
TRUE indicates that the fill process has reached the end of the last RB while padding.

FillWord<16:1>

TYPE: bit array
This an array that stages the bits to fill a Resource Element prior to mapping to QAM symbols.

FIRST

TYPE: Boolean
This is used within the fill process to indicate status of placing the first bit passed in the function call. If TRUE, the passed first bit is used, otherwise the bit from the processed PMA_UNITDATA.request() is used.

FRB

TYPE: integer
This variable is used to determine the current Resource Block being processed in the fill process. The range of values is from 0 to 4095.

FRE

TYPE: integer
This variable is used to determine the current Resource Element being processed in the fill process. The range of values is from –1 to 16.

ICLK

TYPE: Boolean
This clear on read variable is set to TRUE on each positive transition of a clock running at the *US_DataRate* (see 100.3.2.2).

IDLEBITS

TYPE: integer
This variable is used by the idle loop to increment through the bit loading of the current data carrying Resource Element.

IRB

TYPE: integer
This variable is used to determine the current Resource Block being processed in the idle process. The range of values is from –1 to 4095.

IRE

TYPE: integer
This variable is used to determine the current Resource Element being processed in the idle process. The range of values is from 0 to *RBlen*.

LBIT

TYPE: integer
This variable records the last bit filled in the current data Resource Element (QAM symbol) before mapping. The value can be from 1 to 15, where 1 represents the LSB. The value is set to the bit loading for the data Resource Element and then decremented during the symbol mapper fill process for mapping data burst bits to the current data Resource Element. This value is reset for each new data Resource Element being filled. The value is incremented while filling bits and stops incrementing upon receiving an end of burst indication. This value is not incremented or reset when placing padding bits.

LRE

TYPE: integer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable records the last filled data Resource Element in the current Resource Block. The value can be from 1 to 16, where 1 represents the first Resource Element in the Resource Block (in time) and up to 8 or 16 (*RBlen*) representing the last Resource Element in the Resource Block (later in time). The value is reset for each new Resource Block being filled. The value is incremented to the current data Resource Element being filled and stops incrementing upon receiving an end of burst indication. This value is not incremented or reset when placing padding bits.

PILOT_MAP<4096>

TYPE: array of enumerated values

This array defines the pilot pattern use for Type 1 and Type 2 pilot patterns as defined in the upstream profile descriptor (see 101.4.4.6). The pilot pattern is fixed for the RB Superframe configuration and remains constant. The enumerated type values are as follows:

"EX": no Type 0, Type 1, or Type 2 pattern is configured for this subcarrier (i.e., nulled subcarriers and excluded)

"T0": this Resource Block, if used for data, contains a Type 0 pattern (see 101.4.4.6)

"T1": this Resource Block, if used for data, contains a Type 1 pattern (see 101.4.4.6)

"T2": this Resource Block, if used for data, contains a Type 2 pattern (see 101.4.4.6)

"PHYLINK": this Resource Block is reserved for use by the PHY Link

All other enumerated type values are reserved. For any used Resource Element containing data and not containing either a start or end burst marker, this value is used to set the *RB_Type* array element value for further processing by the pilot insertion and staging functions.

RB_Frame<4096, *RBlen*>

TYPE: Array of *I_value* and *Q_value* bin value pair.

This two-dimensional array holds the I and Q QAM symbol bin values that are passed from the symbol mapper to the staging function, then to the IDFT for transmission by the CNU. When first allocated, *RB_Frame* contains null values ("0") in all I and Q values. I and Q bin values are signed 16-bit integers. Index 4095:0 represents the total number of possible subcarriers in the upstream corresponding OFDMA channel, *RBlen* represents the number of Resource Elements in Resource Block. Subcarrier 0, RB number 1 (*RB_Frame*<0,1>) is reserved for special use in coordinating symbol mapper idle and fill processing: I_value of "0" indicates the *RB_Frame* has not transferred to the staging process, *I_value* of "1" indicates the *RB_Frame* has been passed to the staging process, *Q_value* is always "0".

RB_Type<4096>

TYPE: array of enumerated values

This array defines the use of each Resource Block, the values and descriptions are as follows:

"EX": the Resource Block is excluded (no energy output from IDFT), all Resource Elements contain null I and Q value pairs.

"T0": Resource Block in use, Type 0 pilot pattern (see 101.4.4.6)

"T1": Resource Block in use, Type 1 pilot pattern (see 101.4.4.6)

"T2": Resource Block in use, Type 2 pilot pattern (see 101.4.4.6)

"SM": Resource Block in use, contains a start marker pattern

"EM": Resource Block in use, contains an end marker pattern

All other enumerated type values are reserved. The use of this array indicates the availability and type of each used Resource Block to pilot insertion. A null (unused) Resource Block array element produces no energy output from the IDFT for the corresponding OFDMA subcarrier. (This is also true for excluded subcarriers).

RBlen(*RBsize*)

See 101.4.4.3.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.4.4.5.2 Functions

Allocate_RB_Frame(*RB_Frame*, *RB_Type*)

This function allocates a new *RB_Frame* array with all *I_value* and *Q_value* bin pairs set to null "0" and a new *RB_Type* array with all enumerations set to "EX".

BITLOAD(*resource_element*, *Resource Block*)

This function returns the current bit loading capacity of the current data carrying Resource Element or low density pilot. Bit loading is based on the setting of *US_ModTypeSC(n)* for this Resource Block (subcarrier) as well as Resource Elements containing low density pilots in Type 2 Resource Blocks (see 101.4.4.6).

Initialize_Pilot_Map()

This function initializes the *PILOT_MAP*<> array based on the descriptor information for indicating Type 0, Type 1, and Type 2 patterns. See 101.4.4.6.

Map_End_Marker (*RB_number*, *Last_Bit*, *Last_RE*)

This function starts at the current *RB_number*. This function then constructs the end burst marker by encoding the *Last_Bit* and *Last_RE* information. See 101.4.4.8.3 for end marker encoding. The value of *Last_Bit* directly indicates fill position in the current Resource Element. A values of *Last_RE* ranges from "0" which indicates the first Resource Element of the Resource Block up to *RBlen* – 1.This function then places end burst marker elements in the Resource Block according to the *RBlen* of the Superframe. This function continues to increment Resource Blocks (subcarriers) and places the remaining end burst marker elements in the next usable Resource Block as indicated in *US_ModTypeSC(n)* setting in the upstream profile descriptor. For each Resource Block used for an end burst marker element, the corresponding entry in the *RB_Type* array is set to "EM". Excluded subcarriers and null subcarriers are skipped. The next usable Resource Block is defined as an *US_ModTypeSC(n)* value from binary 0001 (BPSK) to binary 1110 (16384-QAM) and not being used by the PHY Link.

If at any time this function increments beyond the last usable Resource Block in the current *RB_Frame*<> (highest usable subcarrier configured in the profile descriptor), it examines the *I_value* of *RB_Frame*<0,1>. If "0", this function sets the value to "1" and passes the *RB_Frame*<> array and *RB_Type* array to the staging function and allocates a new *RB_Frame*<> array and *RB_Type* array use the Allocate_RB_Frame() function. If *I_value* of *RB_Frame*<0,1> is "1", the function skips passing to staging and allocations, assumes a new *RB_Frame*<> has been allocated, and increments to the first data carrying Resource Block and Resource Element in the new *RB_Frame*<>.

Map_Start_Marker (*RB_number*)

This function begins by placing the first Resource Block of a start burst marker in the current Resource Block *RB_number*, according to the *RBlen* of the Superframe (see 101.4.4.8). This function continues to increment Resource Blocks (subcarriers) and placing the remaining start burst marker elements in the next usable Resource Block(s) as indicated in *US_ModTypeSC(n)* setting in the upstream profile descriptor [defined as a *US_ModTypeSC(n)* value from binary 0001 (BPSK) to binary 1110 (16384-QAM) and not being used by the PHY Link]. Excluded subcarriers and null subcarriers are skipped. After placing the last start burst marker Resource Block, this function returns the value in *RB_number*.

For each Resource Block used for a start burst marker element, the corresponding entry in the *RB_Type*<*RB_number*> array is set to "SM". The next usable Resource Block is defined as a *US_ModTypeSC(n)* value from binary 0001 (BPSK) to binary 1110 (16384-QAM) and not being used by the PHY Link.

If at any time this function increments beyond the last usable Resource Block in the current *RB_Frame* (highest usable subcarrier configured in the profile descriptor), it examines the I_value of *RB_Frame*<0,1>. If "0", this function sets the value to "1" and passes the *RB_Frame* array and *RB_Type* array to the staging function and allocates a new *RB_Frame* array and *RB_Type* array use the Allocate_RB_Frame() function. If I_value of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RB_Frame<0,1> is "1", skips passing to staging and allocations, assume a new *RB_Frame* has been allocated, and increments to the first data carrying Resource Block and Resource Element in the new *RB_Frame*.

Map_to_QAM(*resource_block*, *resource_element* , *FillWord*, *FILLBITS*)

This function maps the bits in *FillWord*<> into the *I* and *Q* bin value pairs for the current Resource Element in the current *resource_block* (subcarrier) in *RB_Frame*<> (see 101.4.4.3). *Fillbits* represents the bitloading of the current data Resource Element or low density pilot, where *FillWord*<*Fillbits*> represents the MSB and *FillWord*<1> represents the LSB for the mapping.

If *RB_Type*<*resource_block*> is "EX", this function overrides the value and sets *RB_Type*<*resource_block*) to *PILOT_MAP*<*resource_block*> to indicate this Resource Block is in use and contains non-null values.

Next_RE(re*source_element*, *resource_block*)

This function increments to the next usable data carrying Resource Element starting from the passed resource_element number in the passed resource_block (subcarrier). This includes data carrying Resource Elements and low density pilots, pilot Resource Elements are skipped. See 101.4.4.6. The Resource Element is returned and may have a value from 1 to *RBlen*. If *resource_element* has a value of –1, this function increments to the next Resource Block and begins with the first useable Resource Element.

This function first increments to the next usable Resource Element in the current Resource Block. If necessary, this function increments to the next data carrying Resource Block (e.g., Type 0, 1, or 2). The Resource Block number (subcarrier) is from 0 to 4095.

When advancing to the next Resource Block and *FILL_STATE* = FILL, the value from *Pilot_Map*<*Resource Block*> sets the value of *RB_Type*<*Resource Block*>.

If at any time this function increments beyond the last usable Resource Block in the current *RB_Frame* (highest usable subcarrier configured in the profile descriptor), It examines the I_value of *RB_Frame*<0,1>. If "0", this function sets the value to "1" and passes the *RB_Frame* array and *RB_Type* array to the staging function and allocates a new *RB_Frame* array and *RB_Type* array using the allocate_RB_Frame() function. If I_value of *RB_Frame*<0,1> is "1", it skips passing to staging and allocations, and assumes a new *RB_Frame* has already been allocated, and increments to the first data carrying Resource Block and Resource Element in the new RB Frame.

Upon return, the updated Resource Element index is returned via *resource_element*, and the current Resource Block (subcarrier) index returned via *resource_block*.

Reset_Scrambler()

The upstream symbol mapper utilizes a separate instantiation of the scrambler as described in 101.4.3.7 with the same seed value of 0x4732BA. This function initializes the bit scrambler with the seed value.

Scramble(*bit*)

This function provides a bit scrambler, local to the upstream data symbol mapper function. The passed *bit* is used as input to the scrambler, the output is used as the return value. See 101.4.3.7.

101.4.4.5.3 State diagrams

The CNU PMA shall perform the symbol mapper idle process as shown in Figure 101–32.

The CNU PMA shall perform the symbol mapper fill process as shown in Figure 101–33.

101.4.4.5.4 Minimum gap time and burst marker overhead

The CLT ensures a minimum gap time between bursts from any CNU equal to the transmission time of one Resource Block expressed in units of *time_quantum*.

Let *Highestbitload* be the highest bit loading among all active subcarriers in any data carrying symbol (non-probe symbol) in an upstream RB frame, the number of *time_quantum* per Resource Block is calculated as per Equation (101–33):

$$RB_time_quanta = \lceil RBlen \times (Highestbitload) / (US_DataRate) / (time_quantum) \rceil \quad (101–33)$$

Start and end burst marker overhead is a multiple of *RB_time_quanta*. For *RBlen* of 8, total burst marker overhead is eight (8) times *RB_time_quanta*. For *RBlen* of 16, total burst marker overhead is four (4) times *RB_time_quanta*. See 101.4.4.8 for burst marker Resource Block use.

101.4.4.6 Pilot patterns

A Resource Block may be any one of three types as illustrated in Figure 101–34. Type 0 Resource Blocks contain only data Resource Elements modulated per the *ModTypeSC(n)* variable where *n* is the subcarrier index of the Resource Block. Type 1 Resource Blocks contain two pilots in the first and third Resource Element transmitted. Type 2 Resource Blocks contain a Low Density Pilot, in the last and third from last Resource Elements transmitted, in addition to the two pilots of the Type 1 Resource Block. The Low Density Pilot Resource Element is modulated using the higher modulation order of either BPSK or 4 bits lower than the bit loading specified in the *ModTypeSC(n)* variable for that subcarrier. Each RB type is configured via the variables *Type1_Start*, *Type1_Repeat*, *Type2_Start*, and *Type2_Repeat* as described next. The configuration of these variables determines the upstream transmission pilot pattern that all CNUs in the network use. However the pattern is defined over the entire 4095 subcarrier range with subcarrier 0 being the first subcarrier and subcarrier 4095 being the last subcarrier in the range. Excluded subcarrier settings override the pilot pattern definition, and Type 2 pilot definitions override Type 1 definitions. See 101.4.4.3.1 for additional rules on Pilot Type usage in burst transmissions.

The *TypeN_Start* variable determines on which subcarrier the repeating pattern for Type N pilot starts and the *TypeN_Repeat* variable determines the number of subcarriers between Type N pilots in the repeating pattern is encoded as shown in Table 101–14. *US_ModTypeSC(n)* excluded subcarriers override the repetitive pilot pattern and the Type 2 Pilot pattern overrides the Type 1 Pilot pattern.

Table 101–14—TypeN_Repeat[a] encoding

TypeN_Repeat value	Number of SC between TypeN Pilots
000	TypeN Pilot pattern disabled
001	0
010	1
011	3
100	7
101	15
11x	reserved

[a] $N = 1$ or 2

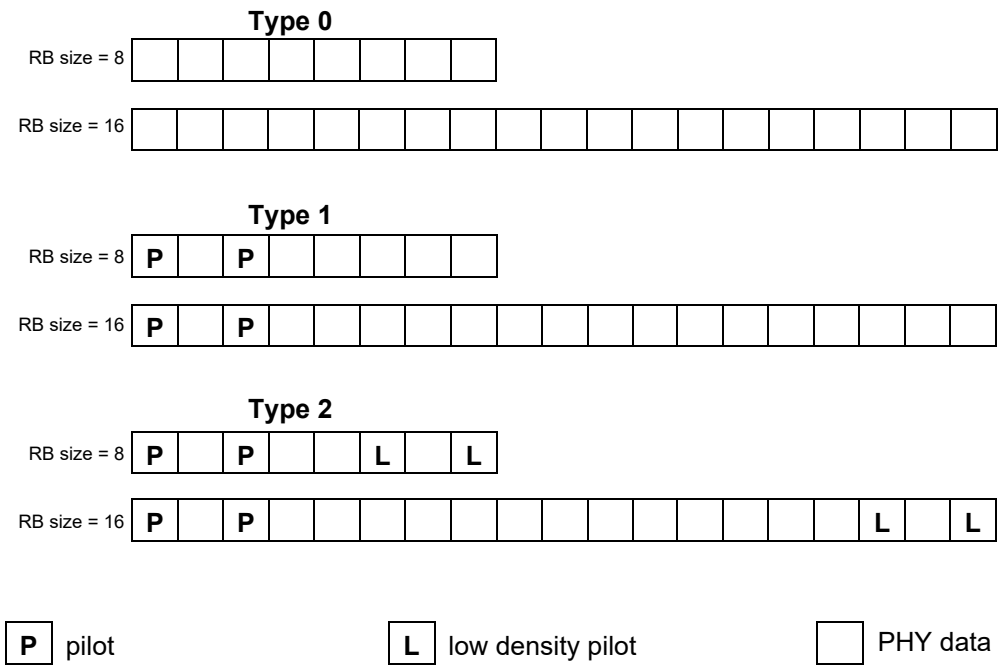

Figure 101–34—Resource Block types

101.4.4.6.1 variables

Type1_Repeat
: TYPE: 3-bit unsigned integer
This variable indicates the number of subcarriers, from 0 to 7, between repeating Type 1 Pilots.

Type1_Start
: TYPE: 4-bit unsigned integer
This variable indicates the number, between 0 and 15, of the first subcarrier designated as a Type 1 Pilot.

Type2_Repeat
: TYPE: 3-bit unsigned integer
This variable indicates the number of subcarriers, from 0 to 7, between repeating Type 2 Pilots.

Type2_Start
: TYPE: 4-bit unsigned integer
This variable indicates the number, between 0 and 15, of the first subcarrier designated as a Type 2 Pilot.

101.4.4.7 Staging and pilot insertion

101.4.4.7.1 Staging

The Staging function accepts an *RB_Frame* and *RB_Type* array from the Symbol Mapper when transferred from the Symbol Mapper. Staging then accumulates (copies) a PHY Link RB Frame (8 subcarriers by

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Resource Block size 8 or 16) if available for this *RB_Frame*. If a PHY Link RB Frame was copied, the *RB_Type* entries for the corresponding subcarriers are set to "T2" (see *RB_Type* array in 101.4.4.5.1).

Pilot insertion then proceeds as per the procedure in 101.4.4.7.2. Upon a positive transition of *RB_Frame_start* (value FALSE to value TRUE) as set by frame timing, the *RB_Frame* and *RB_Type* arrays are transferred to the IDFT process.

101.4.4.7.2 Pilot insertion

Upstream pilot insertion is performed using a BPSK mapped bit sequence generated by a pseudo-random sequence (PRBS) generator defined by the polynomial $x^{12} + x^9 + x^8 + x^5 + 1$ (illustrated in Figure 102–27). Pilots are inserted after the RB Frame is processed by the symbol mapper (see 101.4.3.8) and before the RB Frame is passed to the IDFT function.

The method for pilot insertion shall be as follows:

1) The PRBS generator is initialized with the seed value 0xBFF at the beginning of each RB Frame for the subcarrier with index k=0 of the IDFT Equation (101–25) (see 101.4.3.11).
2) the PRBS generator is clocked once for every subcarrier of the IDFT.
3) Pilots are inserted (mapped) into the "P" positions of PHY Link subcarriers in each subcarrier where a CNU is transmitting a PHY Link message (see 102.3.4) and in each Resource Block to be transmitted containing a data burst designated as Type 1 or Type 2 Resource Block (see 101.4.4.6).
4) "P" pilots are BPSK modulated with the output of the feedback shift register, with a value of 0 mapping to (1 + j0) and a value of 1 mapping to (–1 + j0).
5) The same BPSK value is used for each "P" location in a subcarrier.

When an RB Frame has been processed by this function, the RB Frame is passed to the IDFT function for further processing.

101.4.4.8 Burst markers

101.4.4.8.1 Introduction

Burst markers are used to indicate the start or end of a burst received via the PMA service interface. A burst marker is a predefined sequence of two types of burst marker elements: B's and 0's, where B's represent differential QPSK (D-QPSK) modulated symbols (see 101.4.4.8.3), and 0's represent nulls (i.e., no energy being transmitted). Each burst marker element is transmitted in one Resource Element. B burst marker elements are boosted by 3 dB. The first modulated B marker element on a subcarrier is encoded as a reference pilot. There are separate burst marker patterns for 8 and 16 symbol Resource Blocks.

Burst markers are placed by the upstream Symbol Mapper function (see 101.4.4.5).

101.4.4.8.2 Burst marker start and stop sequences

For the 8 symbol Resource Block, the start and stop burst marker sequences are defined in Figure 101–35. For the 16 symbol Resource Block, the start and stop marker sequences are defined in Figure 101–36.

101.4.4.8.3 Burst marker B element encoding

The first modulated D-QPSK symbol for each subcarrier of a start and end burst marker is a reference pilot and is modulated with value (11). This is indicated by the position of the B_R burst marker element in Figure 101–35, Figure 101–36, Figure 101–37, and Figure 101–38.

The remaining B burst marker elements are D-QPSK modulated with information value pairs and parity encoding value pairs. The parity encoding is a Reed-Solomon coding over GF(2^4) with $t = 2$. The Reed-Solomon code of RS(15,11) is shortened to length 6 of 7 depending on the Resource Block length. The RS generator is shown in equation Equation (101–34) where the primitive element alpha (a) is 0x2.

$$g(x) = (x + a^0)(x + a^1)(x + a^2)(x + a^3) \quad (101–34)$$

The RS primitive polynomial is shown in equation Equation (101–35).

$$p(x) = x^4 + x + 1 \quad (101–35)$$

For Resource Block size of 8, two information code symbols designated I2 and I1 contain 8 information bits and are encoded and shortened to a length of 6:

(0 0 0 0 0 0 0 0 I2 I1 P4 P3 P2 P1)

For Resource Block size of 16, three information code symbols designated I3, I2, and I1 contain 12 information bits and are encoded and shortened to a length of 7:

(0 0 0 0 0 0 0 0 I3 I2 I1 P4 P3 P2 P1)

Each information code symbol is represented by a pair of D-QPSK symbols. The high order pair is designated as $I_{\#H}$ and the low order pair by $I_{\#L}$, for # = 1, 2, or 3. For each parity code symbol high order pair is designated as $P_{\#H}$ and the low order pair by $P_{\#L}$, for # = 1, 2, 3, or 4.

For start burst markers and Resource Block size 8, the two information code symbols I2 and I1 are each set to 0xF (i.e., 0xFF, all ones in all information symbols) with the D-QPSK modulated symbol pair placement as per Figure 101–37.

For start burst markers and Resource Block size 16, the three information code symbols I3, I2, and I1 are each set to 0xF (i.e., 0xFFF, all ones in all information symbols) with the D-QPSK modulated symbol pair placement as per Figure 101–38.

The start burst marker setting of 0xFF and 0xFFF in RB Frames of size 8 and 16, respectively designates that the first bit of data for the burst starts in the MSB bit of the first usable data Resource Element in the Resource Block immediately following the start burst marker. All other values and designations are reserved.

For stop burst markers and Resource Block size 8, the two information code symbols are set as follows: L_2 encodes the last Resource Block value as designated by the symbol mapper (see 101.4.4.5) as per Table 101–15 and L_1 encodes the last fill bit position value as designated by the symbol mapper (see 101.4.4.5) as per Table 101–16 with the D-QPSK modulated symbol pair placement as per Figure 101–37.

For stop burst markers and Resource Block size 16, the three information code symbols are set as follows: L_3 encodes a pad value of 0x00 (i.e., not null), L_2 encodes the last Resource Block value as designated by the symbol mapper (see 101.4.4.5) as per Table 101–15, and L_1 encodes the last fill bit position value as desig-

Figure 101–38—Burst marker encoding in 16 symbol Resource Block

101.4.4.9 Pre-equalization and Inverse Discrete Fourier Transform (IDFT)

The CNU upstream IDFT uses the same definition as in the downstream. See 101.4.3.11.

101.4.4.9.1 Pre-equalization coefficients

Linear pre-equalization is performed in the digital domain before upstream IDFT processing. The CNU shall support a single complex coefficient (equalizer tap) per subcarrier that may be updated via the PHY Link. A CNU shall use a default value of 0 + j0 for all pre-equalizer coefficients. Changing a subcarrier from excluded to active or visa versa shall cause the pre-equalizer coefficients for that subcarrier to be automatically set to a value of 1 + j0 (for subcarriers set to active) or 0 + j0 (for subcarriers set to excluded).

On update, the PHY Link may either indicate a complex coefficient (initialization or reset) or may indicate a multiplication factor. Coefficients are updated only as part of a response to upstream probes received by the CLT. See 102.4.2.

Upon reception of a coefficient multiplication factor, the CNU processes the update per subcarrier as follows:

$$C(k) \Leftarrow C(k) \times A(k) \tag{101–36}$$

where

C(k)	is the pre-equalizer coefficient of the k-th subcarrier as used in the last probe transmission
A(k)	is the coefficient updates in variables *EQ_CoefR(k)* and *EQ_CoefI(k)* (see 101.4.4.9.2), received via the PHY Link
The symbol "×"	indicates a complex multiplication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CNU shall normalize the newly calculated coefficients by adjusting the mean of the absolute value of $(Ck)^2$ to be one. The summation is over all *k* active subcarriers. The CNU shall switch from the prior set of coefficients to the new set of coefficients between transmissions within 10 ms after receiving an update via a PHY Link message.

On transmissions, the CNU shall

1) Always pre-equalize all transmissions other than probe and PHY Discovery signals.
2) Transmit a probe signal with or without pre-equalization (all coefficients are reset to 1 + j0) as instructed by the CLT using the PHY Link probe instruction described in 102.4.2.

The CLT shall be able to calculate and distribute initial pre-equalizer coefficients to reduce the OFDMA channel amplitude variation, by 0.8 dB or more corresponding to a 3 dB increase in MER from 16 dB to 19 dB, given that the probe signal power into CLT burst receiver is +5.4 dBmV ± 1 dB and the upstream OFDMA channel has an encompassed spectrum of at least 22 MHz, where all subcarriers within the encompassed spectrum are active subcarriers.

Testing methodology for pre-equalizer can be found in 101.4.6.1.

101.4.4.9.2 PHY Link managed variables

EQ_CoefR(n)

TYPE: Q2.14 format signed fractional number
This set of variables determines the real and imaginary part of the pre-equalizer settings for the upstream transmitter. Each variable in the set controls one subcarrier of the 4096 subcarriers that are transmitted over the OFDMA channel, with *EQ_CoefR(0)* controlling the real number setting for subcarrier 0 and *EQ_CoefR(1)* controlling the real number setting for subcarrier 1 and so on. Thus *EQ_CoefR(4096)* controls the real settings for subcarrier 4095.

EQ_CoefI(n)

TYPE:Q2.14 format signed fractional number
This set of variables determines the real and imaginary part of the pre-equalizer settings for the upstream transmitter. Each variable in the set controls one subcarrier of the 4096 subcarriers that are transmitted over the OFDMA channel, with *EQ_CoefI(0)* controlling the imaginary number setting for subcarrier 0 and *EQ_CoefI(1)* controlling the imaginary number setting for subcarrier 1and so on. Thus *EQ_CoefI(4095)* controls the imaginary settings for subcarrier 4095.

101.4.4.10 Cyclic prefix and windowing

The CNU upstream cyclic prefix and windowing function uses the same definition as in the downstream. See 101.4.3.12. The CNU shall use one of the permissible values for *USNcp* and *USNrp* in the upstream direction given in Table 101–17 and Table 101–18, respectively. Cyclic prefix and windowing function sizes shall be selected such that the *USNrp* value is less than the *USNcp* value.

Table 101–17—Size of cyclic prefix (USNcp), upstream direction

[a]USNrp is in units of OFDM Clock periods (1/204.8 MHz).

101.4.4.10.1 PHY Link managed variables

USNcp

TYPE: 4-bit binary
This variable controls the size of the cyclic prefix in the upstream direction per the following enumeration:
bit 3 2 1 0
1 x x x = reserved
0 1 1 1 = 768 OFDM Clock periods (1/204.8 MHz)
0 1 1 0 = 640 OFDM Clock periods (1/204.8 MHz)
0 1 0 1 = reserved
0 1 0 0 = 512 OFDM Clock periods (1/204.8 MHz)
0 0 1 1 = reserved
0 0 1 0 = 384 OFDM Clock periods (1/204.8 MHz)
0 0 0 1 = reserved
0 0 0 0 = 256 OFDM Clock periods (1/204.8 MHz)

USNrp

TYPE: 3-bit binary
This variable controls the size of the windowing function in the upstream direction per the following enumeration:
2 1 0
1 1 1 = 256 OFDM Clock periods (1/204.8 MHz)
1 1 0 = 192 OFDM Clock periods (1/204.8 MHz)
1 0 1 = reserved
1 0 0 = 128 OFDM Clock periods (1/204.8 MHz)
0 1 1 = reserved
0 1 0 = 64 OFDM Clock periods (1/204.8 MHz)
0 0 1 = reserved
0 0 0 = 0 samples (windowing disabled)

101.4.5 Constellation structure and mapping

After LDPC encoding and scrambling for downstream and upstream transmissions, the output bit stream of the CLT and CNU Symbol Mapper shall be mapped to QAM symbols such that first bit is the least-significant bit of the first QAM subcarrier constellation m-tuple, see Figure 101–39.

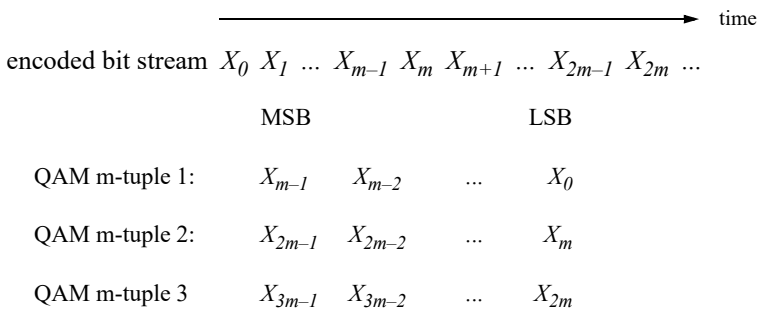

Figure 101–39—Bitstream to QAM m-tuple mapping

The m-tuples are modulated onto subcarriers using QAM constellation. As described in the following subclauses, the QAM constellation structure and mappings are defined inductively and use Gray mapping as their base.

101.4.5.1 One dimensional Gray mapping for m-tuple binary bits

1) When m=1, the Gray mapping is define to be $\text{Gray}_1(0) = 1$ and $\text{Gray}_1(1) = -1$
2) When m>1, the Gray mapping is defined inductively, i.e.,

$$\text{Gray}_m(x_{m-1} \cdot x_{m-2} \cdot \ldots \cdot x_0) = (1 - 2 \cdot x_0) \cdot \left(2^{m-1} + \text{Gray}_{m-1} \cdot (x_{m-1} \cdot x_{m-2} \cdot \ldots \cdot x_0)\right)$$

101.4.5.2 Constellation structure and mapping of BPSK

Let m = 1 and a binary bit is x. The BPSK mapping is as follows:

$$(I_1(x), Q_1(x)) = (\text{Gray}_1(x), 0) = \begin{cases} (1, 0) & (x = 0) \\ (-1, 0) & (x = 1) \end{cases}$$

Also, see Figure 101–40.

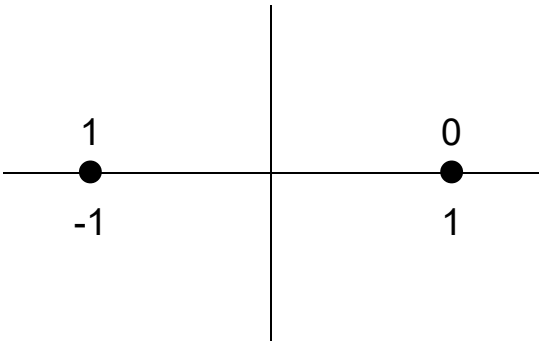

Figure 101–40—BPSK

101.4.5.3 Constellation structure and mapping of 2^{2n}–QAM

Let $m = 2 \cdot n$ and the m-tuple binary bits are $x_0, ..., x_{n-1}, x_n, ..., x_{2 \cdot n - 1}$. The mapping from that m-tuple to a 2^m–QAM is defined by

$$(I_{2n}(x_{2n-1}, ..., x_n, x_{n-1}, ..., x_0), Q_{2n}(x_{2n-1}, ..., x_n, x_{n-1}, ..., x_0)) = (\text{Gray}_n(x_{n-1}, ..., x_0), \text{Gray}_n(x_{n-1}, ..., x_0)) \quad (101–37)$$

where the Gray mapping is defined in 101.4.5.1. Some of the examples are given in the following figures.

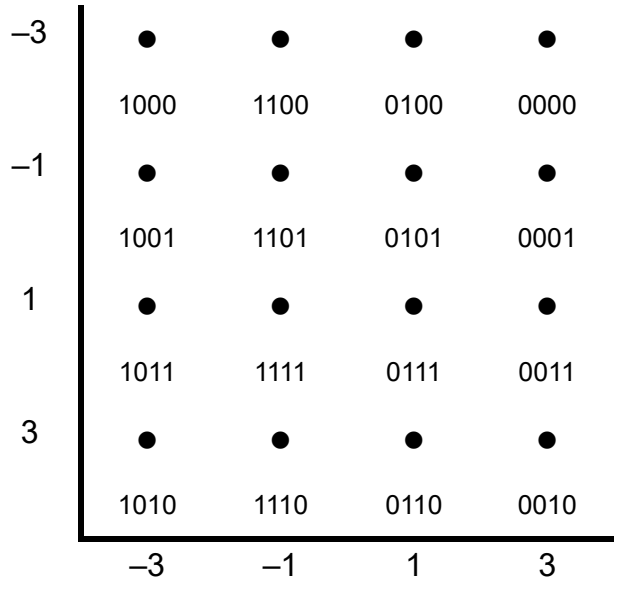

Figure 101–41—16-QAM

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

101.4.5.4 Constellation structure and mapping of 2^{2n+1}–QAM (n>0)

Let $m = 2n + 1$ and the m-tuple binary bits are $x_0, ..., x_{n-1}, x_n, ..., x_{2n}$. Firstly, map this m-tuple to a rectangular constellation defined by

$$(I_{rct}(x_{2n}, ..., x_n, x_{n-1}, ..., x_0), Q_{rct}(x_{2n}, ..., x_n, x_{n-1}, ..., x_0)) = (\text{Gray}_{n+1}(x_{2n}x_{2n-1}...x_n), \text{Gray}_n(x_{n-1}, x_{n-2}, ..., x_0)) \quad (101\text{–}38)$$

where the Gray mapping is defined in 101.4.5.1. Then the structures and mappings of cross-constellations are generated in the following subclauses.

101.4.5.4.1 Constellation structure and mapping of 8–QAM

Let the constellation signal and its mapping be denoted by $(I_3(x_2x_1x_0), Q_3(x_2x_1x_0))$ then

$$\begin{cases} \begin{cases} I_3(x_2x_1x_0) = I_{rct}(x_2x_1x_0) + 1 \\ Q_3(x_2x_1x_0) = Q_{rct}(x_2x_1x_0) \end{cases} & I_{rct}(x_2x_1x_0) < 3 \\ \begin{cases} I_3(x_2x_1x_0) = 3 - I_{rct}(x_2x_1x_0) \\ Q_3(x_2x_1x_0) = sign(Q_{rct}(x_2x_1x_0)) \times (\left|Q_{rct}(x_2x_1x_0)\right| + 2) \end{cases} & \text{otherwise} \end{cases}$$

where the sign function is defined by $sign(a) = \begin{cases} 1 & a \geq 0 \\ -1 & a < 0 \end{cases}$

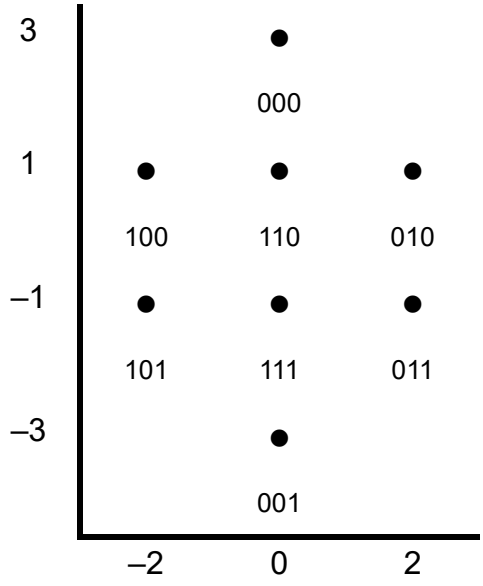

Figure 101–42—8-QAM

101.4.5.4.2 Constellation structure and mapping of 2^{2n+1}–QAM with $n > 1$

Let the mapping be denoted by $(I_{2n+1}(x_{2n}x_{2n-1}...x_0), Q_{2n+1}(x_{2n}x_{2n-1}...x_0))$ and let $s = 2^{n-1}$.

Then, when $\left|I_{rct}(x_{2n}x_{2n-1}...x_0)\right| < 3s$

$$\begin{cases} I_{2n+1}(x_{2n}x_{2n-1}...x_0) = I_{rct}(x_{2n}x_{2n-1}...x_0) \\ Q_{2n+1}(x_{2n}x_{2n-1}...x_0) = Q_{rct}(x_{2n}x_{2n-1}...x_0) \end{cases}$$

and when $\left|I_{rct}(x_{2n}x_{2n-1}...x_0)\right| \geq 3s$

$$\begin{cases} \begin{cases} I_{2n+1}(x_{2n}x_{2n-1}...x_0) = sign(I_{rec}(x_{2n}x_{2n-1}...x_0)) \times (\left|I_{rct}(x_{2n}x_{2n-1}...x_0)\right| - 2s) \\ Q_{2n+1}(x_{2n}x_{2n-1}...x_0) = sign(Q_{rct}(x_{2n}x_{2n-1}...x_0)) \times (4s - \left|Q_{rct}(x_{2n}x_{2n-1}...x_0)\right|) \end{cases} & \text{if } \left|Q_{rct}(x_{2n}x_{2n-1}...x_0)\right| > s \\ \begin{cases} I_{2n+1}(x_{2n}x_{2n-1}...x_0) = sign(I_{rec}(x_{2n}x_{2n-1}...x_0)) \times (4s - \left|I_{rct}(x_{2n}x_{2n-1}...x_0)\right|) \\ Q_{2n+1}(x_{2n}x_{2n-1}...x_0) = sign(Q_{rct}(x_{2n}x_{2n-1}...x_0)) \times (\left|Q_{rct}(x_{2n}x_{2n-1}...x_0)\right| + 2s) \end{cases} & \text{if } \left|Q_{rct}(x_{2n}x_{2n-1}...x_0)\right| \leq s \end{cases}$$

Figure 101–43 presents the 32-QAM structure and mapping.

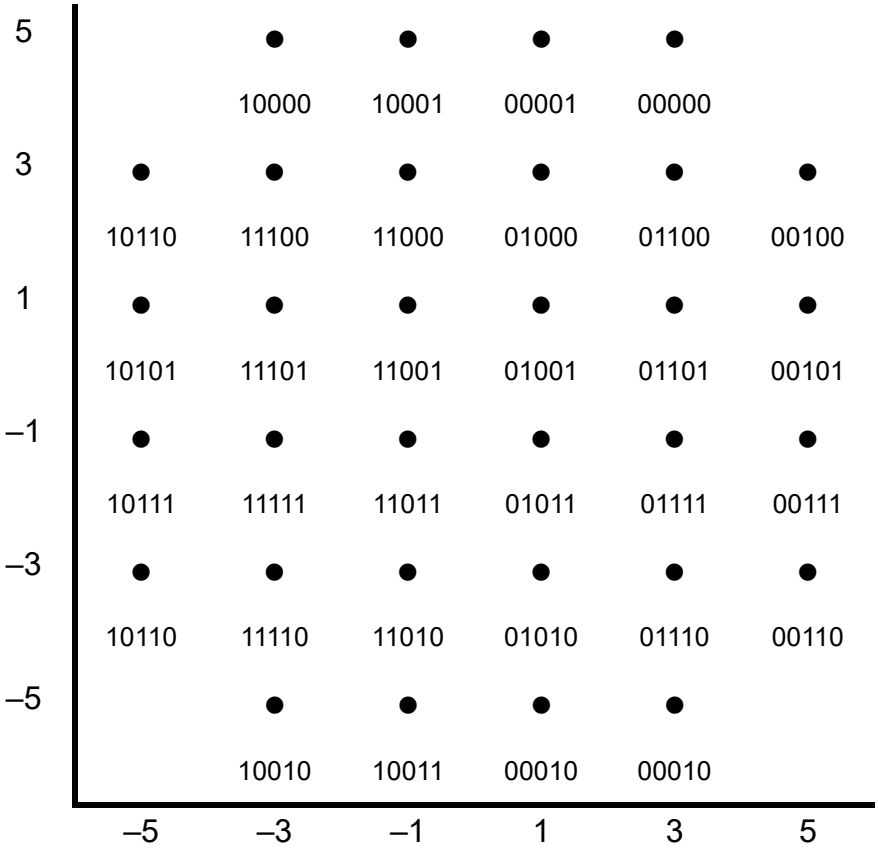

Figure 101–43—32-QAM

101.4.5.5 QAM constellation scaling

Both real and imaginary axis of a QAM constellation shall be scaled by the CLT or CNU transmitter using the scaling factors given in Table 101–19. These scaling factors ensure that the mean square value of all QAM constellations are equal to one.

Table 101–19—QAM constellation scaling factors

QAM constellation	*m* number of bits	Scaling factor
BPSK	1	1
QPSK	2	$1/(\sqrt{2})$
8-QAM	3	$1/(\sqrt{5})$
16-QAM	4	$1/(\sqrt{10})$
32-QAM	5	$1/(\sqrt{20})$
64-QAM	6	$1/(\sqrt{42})$

Table 101–19—QAM constellation scaling factors *(continued)*

QAM constellation	*m* number of bits	Scaling factor
128-QAM	7	$1/(\sqrt{82})$
256-QAM	8	$1/(\sqrt{170})$
512-QAM	9	$1/(\sqrt{330})$
1024-QAM	10	$1/(\sqrt{682})$
2048-QAM	11	$1/(\sqrt{1322})$
4096-QAM	12	$1/(\sqrt{2730})$
8192-QAM	13	$1/(\sqrt{5290})$
16384-QAM	14	$1/(\sqrt{10922})$

101.4.6 PMA testing

101.4.6.1 Pre-equalization testing

Pre-equalization operation is verified using the following method:

1) A test modulator generates the first transmission using a compliant probe. This transmission is input into a spectrum analyzer, with an initial "flat" test channel, achieving 0.3 dB peak-to-peak amplitude variation or less after calibration of the spectrum analyzer (corresponding to a residual MER of 35 dB).
2) A micro-reflection is added into the test channel with an amplitude of –16 dB ± 0.5 dB and a delay of 312.5 ± 0.5 ns compared to main path.
3) Verify the channel (except for the echo) changes by no more than 0.3 dB peak-to-peak, in addition to the 2.78 dB peak-to-peak signal amplitude variation induced by the micro-reflection (the 0.3 dB tolerance allows the maximum amplitude variation to increase to 3.08 dB peak-to-peak corresponding to total MER of 15.3 dB or a residual MER of 35 dB).
4) The test modulator generates a second transmission using a compliant probe sent to both the spectrum analyzer and the CLT receiver (unit under test) with a CNR > 35 dB.
5) Measure and record the amplitude variation over the spectrum of subcarriers (this is the "reference amplitude variation measurement" of the test) using the spectrum analyzer.
6) The CLT OFDMA receiver develops pre-equalizer coefficients.
7) The CLT formats and transmits compliant commands for the pre-equalizer coefficients.
8) The downstream test receiver validates reception of pre-equalization coefficients.
9) The received pre-equalization coefficients are implemented by the test modulator and used to generate a third transmission.
10) Measure and record the amplitude variation over the spectrum of subcarriers for this third transmission, pre-equalized, from the test modulator.
11) Compare the amplitude variation measurement taken in step 10) to the reference amplitude variation measurement. The difference observed should be less than the required minimum reduction in amplitude variation.

101.4.6.2 OFDM channel frequency accuracy test

The measurements of the frequency of the upstream Subcarrier Clock, and the subcarrier frequencies, are averaged over the duration of a single upstream burst. A constant temperature is maintained during the measurements within a range of 20 ºC ± 2 ºC. A minimum warm up time of 30 min occurs before the CNU frequency measurements are made.

NOTE—As an example, upstream Subcarrier Clock frequency is linked with upstream FFT duration (and subcarrier spacing in the frequency domain), and is at least one component in developing each upstream subcarrier frequency. Other components may also contribute to upstream subcarrier frequency, for example, an up conversion process from complex baseband or low intermediate frequency may contribute. All such components are locked to the derived 10.24 MHz Master Clock at the CNU. The accuracy requirements for the Subcarrier Clock frequency and for each individual subcarrier frequency necessary to support 4K-QAM upstream are not necessarily the same.

101.5 Applicability of Clause 90 and IEEE Std 802.1AS, Clause 13 for EPoC time transport

This subclause describes how the time synchronization functionality for EPON included in IEEE Std 802.1AS can also be used for EPoC time synchronization with minor adjustments to compensate for CLT and CNU PHY time delays described in Clause 90. CLTs and CNUs should use the methods described in 101.5.1 and 101.5.2.

101.5.1 CLT PHY asymmetry correction of future time transmitted by the CLT to CNU_i

In IEEE Std 802.1AS-2011 13.1.4, instead of sending a future time $ToD_{X,i}$ at a future MPCP frame X, for EPoC the following future time at the future MPCP frame is substituted for $ToD_{X,i}$:

$$ToD_EPOC_CLT_{X,i} = ToD_{X,i} + T_CORR_CLT \quad (101–39)$$

(i.e., future time sent by CLT to CNU_i = 802.1AS future time + CLT correction factor)

where

$ToD_EPOC_CLT_{X,i}$ is the time of day at the future MPCP counter value X being sent from the CLT to CNU_i, corrected for the EPoC CLT PHY time delay asymmetry

$ToD_{X,i}$ is the future time for CNU_i at future MPCP counter value X as defined in IEEE Std 802.1AS, 13.1.4

T_CORR_CLT is 1/2 of the CLTs differential delay as defined in Equation (101–40)

$$T_CORR_CLT = (MaxTxDly - MaxRxDly + MinTxDly - MinRxDly)/2 \quad (101–40)$$

where

MaxTxDly is the management variable equivalent to Clause 45 registers 1.1801 and 1.1802.

MaxRxDly is the management variable equivalent to Clause 45 registers 1.1803 and 1.1804.

MinRxDly is the management variable equivalent to Clause 45 registers 1.1805 and 1.1806.

MinRxDly is the management variable equivalent to Clause 45 registers 1.1807 and 1.1808.

101.5.2 CNU PHY asymmetry correction of future time received by CNU_i

Instead of using the $ToD_EPOC_CLT_{X,i}$ future time for CNU_i directly, each CNU_i is to correct the future time value received from the CLT for its own CNU PHY time delay asymmetry as follows:

$$ToD_EPOC_CNU_{X,i} = ToD_EPOC_CLT_{X,i} + T_CORR_CNU_i \quad (101–41)$$

(i.e., CNU time = CNU_i future time sent by CLT + CNU_i correction factor)

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where

$ToD_EPOC_CNU_{X,i}$ is the future time to be loaded in the time of day counter of CNU_i at the future MPCP counter value X

$ToD_EPOC_CLT_{X,i}$ is defined above in Equation (101–39)

$T_CORR_CNU_i$ is 1/2 of the CNUs differential delay as given in Equation (101–42)

$$T_CORR_CNU = (MaxTxDly - MaxRxDly + MinTxDly - MinRxDly)/2 \quad (101–42)$$

101.6 Protocol implementation conformance statement (PICS) proforma for Clause 101, Reconciliation Sublayer, Physical Coding Sublayer, and Physical Media Attachment for EPoC[175]

101.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 101, Reconciliation Sublayer, Physical Coding Sublayer, and Physical Media Attachment for EPoC, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

101.6.2 Identification

101.6.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

101.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 101, Reconciliation Sublayer, Physical Coding Sublayer, and Physical Media Attachment for EPoC
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[175] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

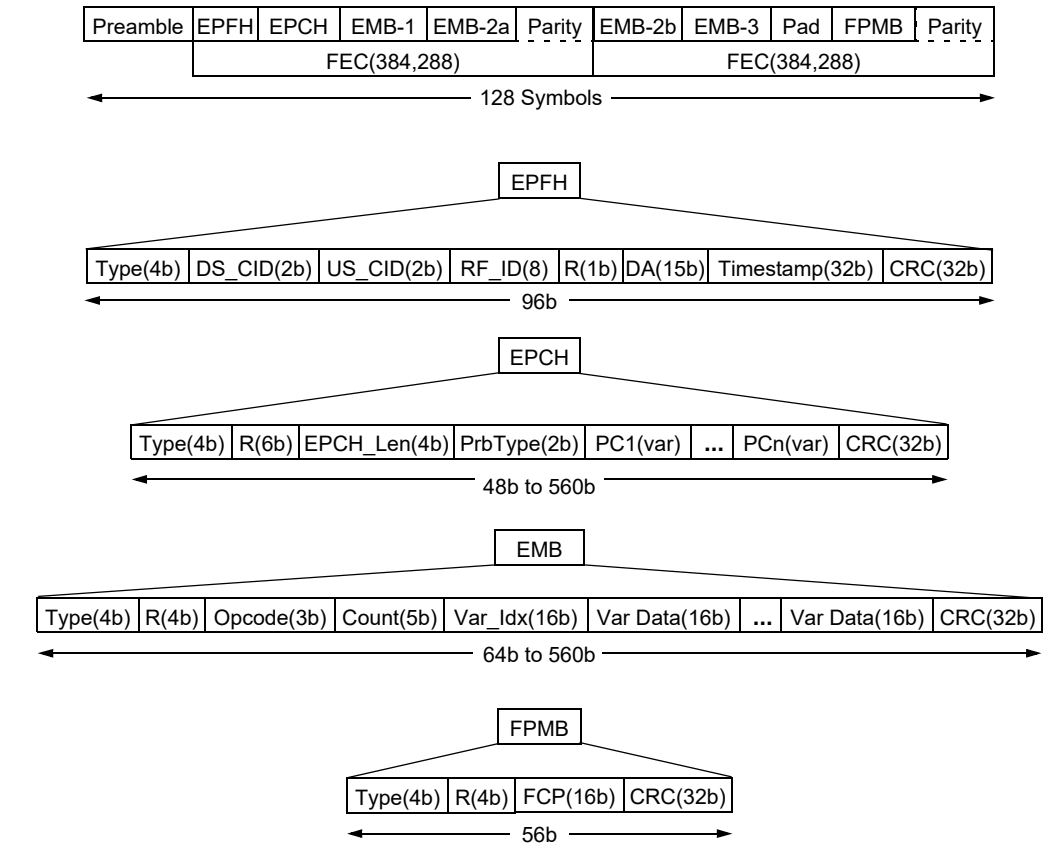
102. EPoC PHY Link

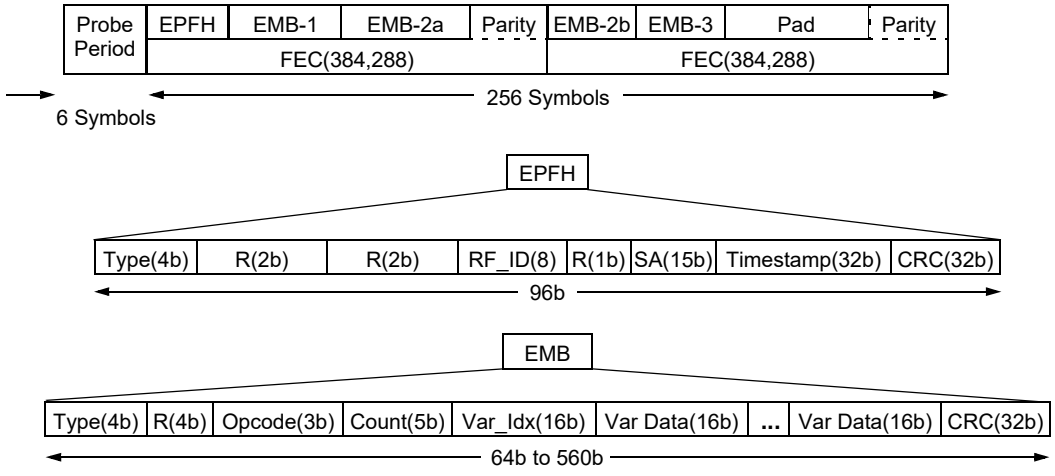
102.1 PHY Link overview and architecture



The PHY Link is a low level communications link used between the CLT PHY and its subordinated CNU PHYs. It is used to communicate PHY OFDM channel parameters and to negotiate initialization of CNUs that wish to join the EPoC network. A small amount of RF spectrum is dedicated to the PHY Link at network setup time for both the upstream (US) and the downstream (DS) directions (see 102.2.1 and 102.3.1). In a multi-OFDM channel PHY, only OFDM channel one has a PHY Link (see Figure 102–1 and Figure 102–3). The PHY Link uses a straightforward query response protocol with broadcast capability to transfer information in variables between the CLT and its subordinated CNUs and vice versa. Both the upstream and the downstream PHY Link include a frame structure. Each PHY Link frame is composed of message blocks containing timing, control information, status information, PHY Instructions, or PHY Responses. The frame is padded to achieve a fixed bit length and encoded in multiple FEC codewords.

The upstream superframe (see 101.4.4.3.1) begins with the Probe Period. CNU PHY Discovery Responses and probing are performed during the Probe Period. The PHY Discovery Response is used for initial CNU bring up and is fully described in 102.4.1.4. Probing is used to perform fine ranging and periodic link maintenance tasks and is described in 102.4.2.

102.1.1 PHY Link frame structure and protocol



The PHY Link frame is illustrated in Figure 102–1 and Figure 102–2.

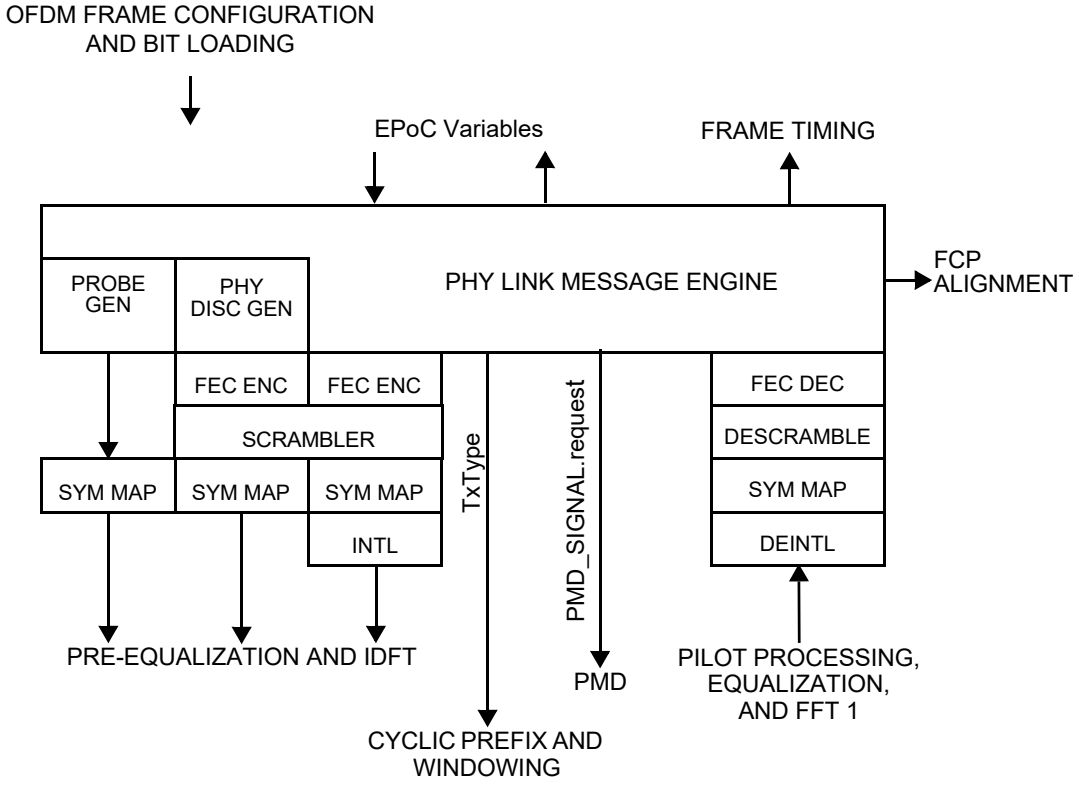
The PHY Link protocol is a query and response protocol where the CLT transmits one or more instructions enclosed in EPoC Message Blocks to a CNU or group of CNUs. Each instruction can perform a read, write or write/verify operation. Read and write/verify instructions cannot be addressed to a group of CNUs. The PHY Link frame length shall be fixed; the downstream length is 128 OFDM symbols long and the upstream length is 262 OFDM symbols long.

The CLT and the CNU shall support both an upstream and a downstream PHY Link channel.

102.1.2 PHY Link block diagram



The architecture of the PHY Link data path is illustrated in Figure 102–3 and Figure 102–4. The relationship between the PHY Link functional blocks and the rest of the 10GPASS-XR PHY is illustrated in Figure 101–1 and Figure 101–2.

102.1.3 PHY Link Message Engine

The PHY Link Message Engine block is responsible for the origination and termination of all messages passed over the PHY Link, as well as PHY to PHY signaling. In the downstream direction there are four message blocks—the EPoC PHY Frame Header (EPFH), the EPoC Probe Control Header (EPCH), the EPoC message block, and the FEC Parity message block. The upstream PHY Link Message Engine also has the two additional PHY to PHY signaling types—PHY Discovery Response and Probing.

The content of each message block is detailed in the following subclauses as is the characteristic of the two additional PHY signaling types. The details of the PHY Message Engine behavior is described in 102.2.3 and 102.3.2.

Once a PHY Link message block has been created the stream of bytes is converted into a stream of bits, MSB first.

102.1.4 PHY Link FEC encoder

The PHY Link uses several LDPC FEC encoders. These encoders are derived from mother encoders using either puncturing only or both shortening and puncturing. A general description of LDPC codes is given in 101.3.2.4.

102.1.4.1 LDPC (480, 288) mother code

The base matrix of a parity check matrix for the (480,288) mother code is listed in Table 102–1, where the submatrix size (lifting factor) is $L = 48$ (see 101.3.2.4 for the general definition of a base matrix).

Table 102–1—Base matrix of (480,288) LDPC code parity check matrix

Columns	Rows									
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
1	16	1	28	9	40	38	16	—	—	—

4	18	18	40	18	0	34	—	—	7	32

102.1.4.2 LDPC (160, 80) mother code

The base matrix of a parity check matrix for the (160,80) mother code is listed in Table 102–2, where the submatrix size (lifting factor) is $L = 16$ (see 101.3.2.4 for the general definition of a base matrix).

Table 102–2—Base matrix for (160, 80) DPC code parity check matrix

102.1.4.3 Shortening and puncturing encoders

Shortening encoder operationally includes the following three steps:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Pad zero bits to the payload bits to fit for the codeword size of the mother code, the entire bits are called mother code information bits and the coordinates corresponded to the padded zeros are called shortening coordinates.
b) Encode the information bits obtained in step a) using mother code encoder.
c) Delete the shortening coordinates: i.e., all the padded zero bits in step a).

Puncturing encoder operationally includes the following two steps:

1) Encode the payload (with or without padding) bits using mother encoder.
2) Delete the puncturing coordinates of encoded codeword of step 1), where the puncturing coordinates are given coordinates of the mother code codeword.

102.1.4.3.1 LDPC (384, 288) puncturing encoder

The LDPC (384, 288) encoder is operated on the (480, 288) LDPC mother code encoder with the puncturing.

The mother code is defined in 102.1.4.1. The puncturing operation is as follows (also see Figure 102–5):

1) Denote the information bits sent to the mother code encoder by ($a_0, \ldots, a_{287}$)
2) Let the encoding output be ($a_0, \ldots, a_{287}, b_{288}, \ldots, b_{479}$), where ($b_{288}, \ldots, b_{479}$) are parity-check bits. The coordinates to be deleted by the puncturing step are as follows:
   — Period 1: 48 consecutive coordinates $a_{48}, \ldots, a_{95}$
   — Period 2: 48 consecutive coordinates $b_{384}, \ldots, b_{431}$

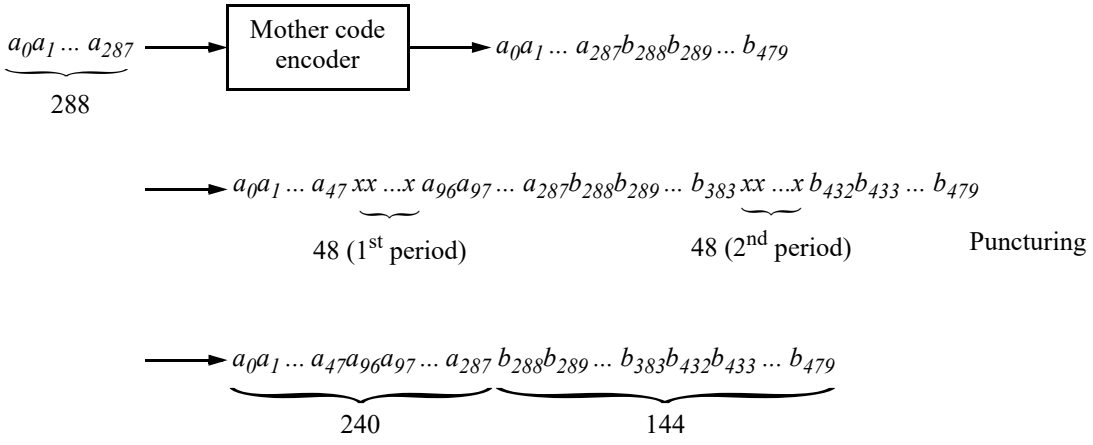

Figure 102–5—Puncturing encoder for LDPC (384,288) FEC

102.1.4.3.2 LDPC (128, 80) puncturing encoder

The LDPC (128, 80) encoder is operated on the (160, 80) LDPC mother code encoder with the puncturing.

The mother code is defined in 102.1.4.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The puncturing operation is as follows (also see Figure 102–6):

Denote the information bits sent to the mother code encoder by (a_0, ... , a_{79}) and let the encoding output be (a_0, ... , a_{79}, b_{80}, ... , b_{159}), where (b_{80}, ... , b_{159}) are parity-check bits. Then do puncturing on the puncturing coordinates given by the following:

— Period 1: 16 consecutive coordinates a_0, ... , a_{15}
— Period 2: 16 consecutive coordinates b_{144}, ... , b_{159}

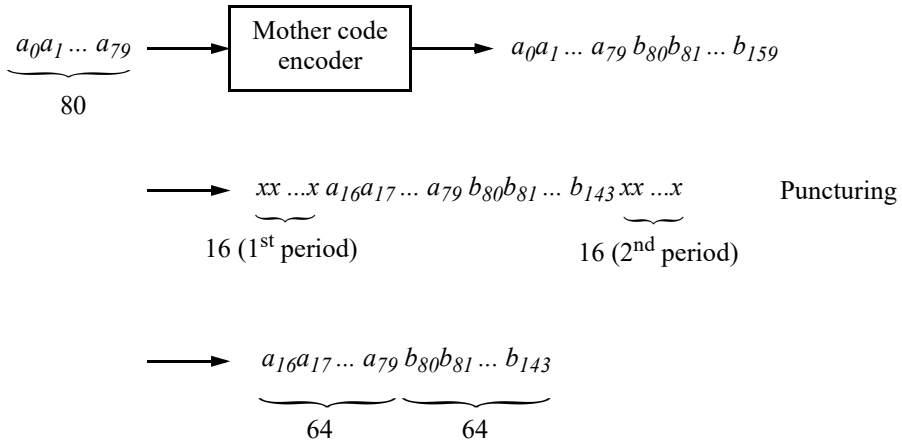

Figure 102–6—Puncturing encoder for the LDPC (128, 80) FEC

102.1.5 PHY Link scrambler

The CLT and CNU shall scramble the output of the PHY Link FEC encoding process using a linear feedback shift register mechanism as illustrated in Figure 101–21.

The scrambler is defined by the following polynomial:

$$x^{23} + x^{18} + 1$$

The scrambler is initialized to the hexadecimal value of 0x4732BA. The CLT shall initialize the scrambler with the hexadecimal value at the beginning of the first OFDM symbol following the PHY Link preamble in the downstream direction. In the upstream direction, the CNU shall initialize the scrambler at the beginning of an upstream PHY Link transmission.

The PHY shall not scramble the PHY Link preamble.

102.1.6 PHY Link symbol map and constellation mapping

The PHY maps the scrambled bit stream of normal PHY Link data into a complex number using the assigned modulation order. In the downstream direction, the assigned modulation order shall be 16-QAM and uses the mapping shown in 101.4.5. The upstream PHY Link shall be 16-QAM or a higher order modulation (see 101.4.5 for mapping structure). The PHY multiplies the real and imaginary parts by the appropriate factor in Table 101–19 to ensure that mean-square value of the QAM constellation is unity.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

102.1.7 Interleaving

Data in the PHY Link channel is time interleaved. For the downstream direction this time interleaving is described in 102.2.1.3.

Transmissions in the upstream direction for PHY Discovery Response are not time interleaved.

Control for the interleaving process is conveyed using the TxType in the CNU (see Figure 102–4) and RxType in the CLT (see Figure 102–3).

102.1.8 Mapping of PHY Link variables

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PHY Link or are communicated between CLT and CNU via the PHY Link. Mapping of MDIO control and status variables to PHY Link variables is shown in Table 102–3. The least significant bit in each variable is mapped to the lowest numbered bit in the lowest numbered register for Clause 45 registers. These variables are used by the PHY Link for PHY management.

NOTE—Most of the variables transferred via the PHY Link are reflected in Clause 45. The EPoC Index and bits are determined from Clause 45 register designations using the following rules:
If 1.1900 ≤ RegAdd ≤1.1999, then Index = (RegAdd – 1.1900) × 1000 (i.e., 0 to 99).
If 12.0000 ≤ RegAdd, then Index = (RegAdd – 12.0000) × 1000 + 1000 (i.e., 1000 +).
If variable is not in Clause 45, indexes between 500 and 999 are used and are given in the variable definition.

102.2 Downstream PHY Link

102.2.1 Downstream PHY Link Physical Layer

102.2.1.1 Resource allocation

During network setup the downstream PHY Link shall be allocated 400 kHz of spectrum. The allocated spectrum for the downstream PHY Link shall reside anywhere within a 24 MHz contiguous OFDM channel spectrum (i.e., 24 MHz with no internal exclusion bands) and have at least 3 MHz of contiguous spectrum above and below it for a total band of 6 MHz. This PHY Link band also includes eight pilot tone subcarriers placed symmetrically above and below the information subcarriers as illustrated in Figure 102–7; see 101.4.3.6.3 for exact placement of pilots. No additional continuous pilots are allowed within this 6 MHz band (see 101.4.3.6). However, scattered pilots are allowed in this spectrum in subcarriers that normally carry MAC data. The downstream PHY Link is located per the *DS_PhyLinkStrt* variable (see 102.2.6) that determines the lowest frequency subcarrier of the PHY Link. The downstream PHY Link shall use the same OFDM Symbol definition (cyclic prefix duration and windowing size) as the downstream MAC data OFDM channel.

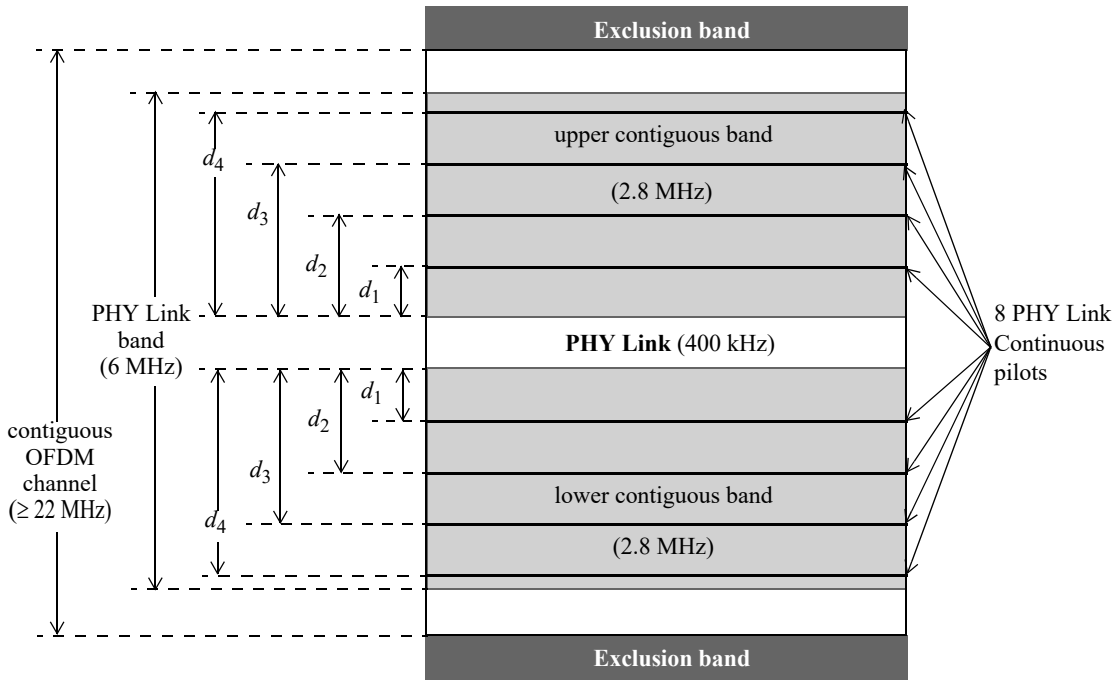

Figure 102–7—Downstream PHY Link spectrum placement

102.2.1.2 Downstream PHY Link modulation

The downstream PHY Link uses a 16-QAM constellation for all information subcarriers as specified under PHY Link CLT Tx/CNU Rx in Table 100–2.

102.2.1.3 Downstream PHY Link subcarrier block interleaving

Figure 102–5 shows 288 data bits entering the LDPC Encoder and 384 encoded bits exiting it. This sequence is in effect time-reverse ordered. The time-ordered sequence takes the form shown in Figure 102–8. The PHY shall map the 384 FEC encoded data bits, as processed by the scrambler, to 96 4-bit nibbles $\{u_i, i=0, 1, \ldots, 95\}$ as shown in Figure 102–8.

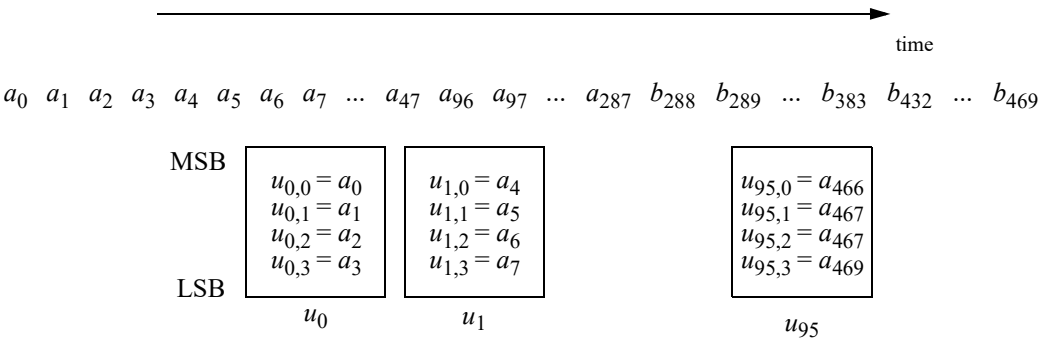

Figure 102–8—Downstream PHY Link mapping of FEC output to stream nibbles

The resulting 4-bit nibbles from this mapping operation are then time interleaved. The PHY shall interleave the 96-nibble sequence $\{u_0\ u_1\ u_2 \ldots\ u_{95}\}$ as illustrated in Figure 102–9.

Conceptually, the PHY uses an 8×2 array to perform interleaving. The PHY writes the values u_i along the rows of this two-dimensional array, as shown in Figure 102–9. The PHY reads this two-dimensional array along vertical columns to form the two-dimensional sequence $\{v_{t,f},\ t = 0,1,\ldots,11$ and $f = 0,1,\ldots,7\}$. This operation is mathematically represented as follows:

$$v_{t,f} = u_{t+12f} \tag{102–1}$$

The PHY maps each of the 8-point sequences given in Equation (102–2) to the eight successive PHY Link subcarriers of an OFDM symbol after scrambling as described in the 102.1.5.

$$V_t = \{v_{t,f}, f = 0,1,\ldots,7\} \text{ for 12 successive OFDM symbols } t = 0, 1, \ldots, 11 \tag{102–2}$$

Therefore, each FEC codeword will occupy the PHY Link segment of twelve successive OFDM symbols. There will be ten such codewords in a 128-symbol PHY Link frame, including the 8-symbol preamble.

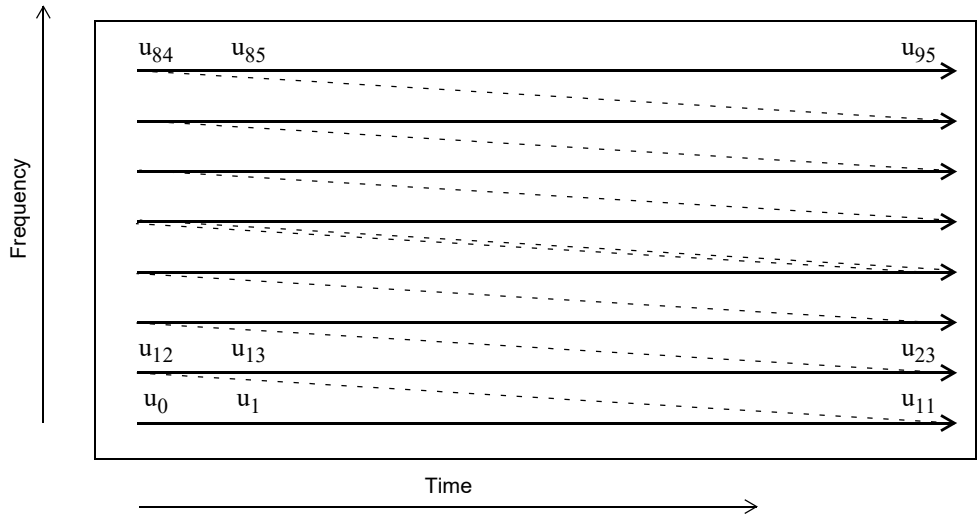

Figure 102–9—Downstream PHY Link subcarrier block interleaving

The PHY Link is time interleaved separately from the MAC data OFDM channel. The PHY Link preamble is not time interleaved.

102.2.2 Downstream preamble

The downstream Preamble shall be a fixed pattern of 64 bits as illustrated in Table 102–4, modulated using binary phase-shift keying (BPSK), that fill the first eight symbols of the PHY Link frame. The pattern is selected to enable the CNU to easily ascertain the PHY Link subcarriers without prior knowledge of the PHY Link's precise location in the RF spectrum range of an EPoC network. Detection of the PHY Link is the first action a CNU takes to join an EPoC network.

The CLT maps each of the binary bits shown in Table 102–4 to a BPSK constellation point in the complex plane using the following transformation:

$0 \rightarrow (1 + j0)$
$1 \rightarrow (-1 + j0)$

Table 102–5 is provided for information purposes and illustrates the receiver processing of the PHY Link preamble.

102.2.3 Downstream frame

The downstream PHY Link uses a frame format, illustrated in Figure 102–1, to which the 128 symbol staggered pilot pattern is aligned with as described in 101.4.3.6. The 128 symbol downstream PHY Link frame is composed of a Preamble (see 102.2.2), one 96-bit EPoC PHY Frame Header (EPFH), one variable length EPoC Probe Control Header (EPCH), some number of variable length EPoC message blocks (EMB), one 56-bit FEC Parity message block (FPMB), and padding. The message blocks within the frame are protected with an FEC mechanism. Each message block and its included fields is described next. The number of optional EPoC message blocks contained within the frame is limited only by the frame size.

Each message block contains a Type field used to identify the contents of the block. CLTs shall use the appropriate message Type fields listed in Table 102–6 in each message block. The contents of the each message block is protected by a CRC32. See 3.2.9 for a description of how this field is calculated. The CNU

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

shall calculate a CRC32 on the data fields within each message block received and, if the calculated CRC32 does not match the received CRC32 discard the message and take no action based on it.

Table 102–6—PHY Link message block Type values

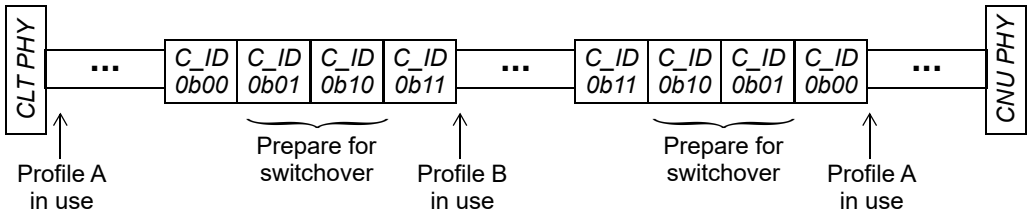
Type value	Message block
0x00 to 0x08	Reserved
0x09	EPoC PHY Frame Header
0x0A	EPoC Probe Control Header
0x0B	EPoC message block
0x0C	FEC Parity message block
0x0D to 0x0F	Reserved

102.2.3.1 Downstream EPoC PHY Frame Header

The downstream EPoC PHY Frame Header includes a Type field, the Configuration ID fields (*DS_CID* and *US_CID*), the Return Frame ID field (*RF_ID*), the PHY Link DA field, the PHY Timestamp field, and a CRC32 as illustrated in Figure 102–1.

102.2.3.1.1 Configuration ID and profile activation

The Configuration ID fields are 2-bit fields used to inform a CNU to switch from one modulation profile to another. There is one field for control of the downstream profile (*DS_CID*) and one field for the upstream profile (*US_CID*). Each CNU contains two profiles in each direction, copy "A" and copy "B"; only one of which is active at any given time. The CLT shall set an identical inactive profile in all CNUs prior to its activation. The CLT updates the unused profile then, using the PHY Configuration ID field, switches the CNU to the updated profile. Once the CLT begins the switchover, as indicated by Configuration ID field values 0b01 or 0b10 it shall complete the switchover. During a switchover the value of the Configuration ID field is either incremented or decremented by one in each successive frame. The switchover is completed and the CNU activates the new profile when the Configuration ID field reaches a value of 0b00 or 0b11; thus a switchover takes three PHY Link frame times. Table 102–7 summarizes the use and meaning of the PHY Configuration ID bits and their operation is illustrated in Figure 102–10.



102.2.3.1.2 Response Frame ID

In the downstream direction, the new profile is activated at the first symbol (i.e., the symbol containing the PHY Link Preamble) in the next PHY Link frame. In the upstream direction, the new profile is activated in the first symbol of the Probe Period following the frame identified by the Return Frame ID field.

Table 102–7—Configuration ID bits

PHY Configuration ID		Meaning
bit 1	bit 0	
0	0	Copy “A” in use
0	1	Prepare for switchover
1	0	
1	1	Copy “B” in use

C_ID = Configuration ID

Figure 102–10—Configuration ID bit usage

The Response Frame ID field is an 8-bit field that indicates to the receiving CNU which RB Frame to use for the response message to this frame. The CLT shall ensure that all CNUs have sufficient time (as determined by the variable PhyLnkRspTm) to respond to the downstream PHY Link frame.

102.2.3.1.3 PHY Link DA

The PHY Link DA is an address field that identifies the CNU for which any EPoC message blocks in that PHY frame are targeted. This field is 15 bits and may be a unicast address or a broadcast address (see Table 102–8). In the CNU if the DA does not match the assigned address (*CNU_ID*) or the broadcast address, then the EMBs in the frame are discarded and no response is made. The CLT shall only transmit the valid values of the PHY DA field as given in Table 102–8.

Table 102–8—PHY DA field values

Field Values	Use
0x7F00 .. 0x7FF0	Broadcast addresses
0x7EFF ..0x0001	Unicast CNU addresses
0x0000	CLT PHY DA address

102.2.3.1.4 PHY Timestamp

The PHY Timestamp is a 32-bit field that the EPoC PHY uses to synchronize the upstream PHY Link frame and OFDMA symbols. The *LocalTS*, from which this field is set, is clocked from the 204.8 MHz OFDM Clock. When a CNU PHY that has *PD_Enable* equal to FALSE receives a PHY Frame addressed to it or to the broadcast address, it shall reset its *LocalTS* to the value in the Timestamp. The reference point for the Timestamp shall be the first sample of the PHY Link symbol immediately following the Preamble (Figure 102–11). For additional information on the use of the Timestamp, see 101.3.3.1.3.

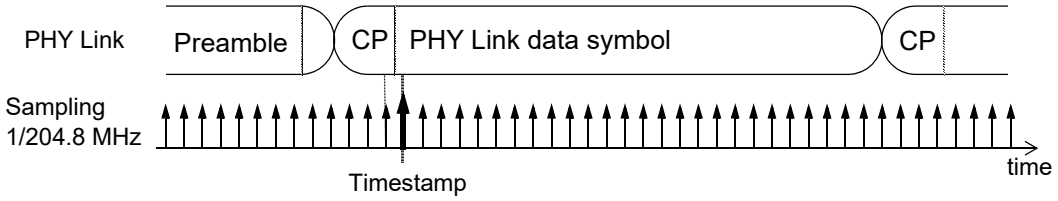

Figure 102–11—PHY Link Timestamp reference point

The CNU PHY Link receiver maintains counts of EPoC PHY Frame Headers received and those received that have CRC32 errors using the variables *EPFHcnt* and *EPFHerr*, respectively.

102.2.3.2 EPoC Probe Control Header message block

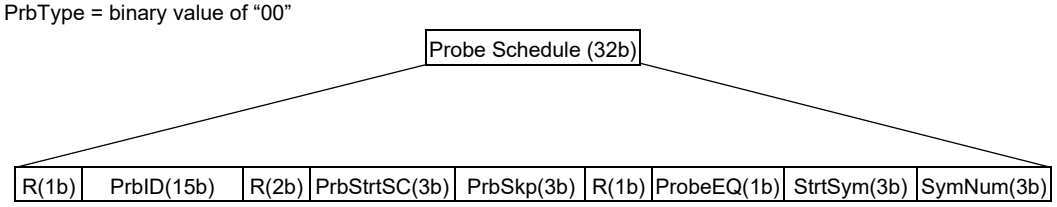
The EPoC Probe Control Header includes a Type field, the EPCH_Len field, the PrbType field, some number of Probe Control (PCn) fields, and a CRC32 as illustrated in Figure 102–1.

The EPCH_Len field is a 4-bit number that conveys the number of Probe Control fields contained in the message block. Each EPoC Probe Control Header may contain 0 to 15 Probe Control fields.

The PrbType field is a 2-bit field that conveys the type of Probe Control fields contained in the message block. There are three types of Probe Control fields; a Probe Scheduling type, a broadcast PHY Discovery type and a Unicast PHY Discovery type as shown in Table 102–9.

Table 102–9—PrbType values

PrbType value	Probe Control field	Probe Control length
0x00b	Probe Scheduling	32 bits
0x01b	Broadcast PHY Discovery	16 bits
0x10b	Unicast PHY Discovery	64 bits
0x11b	Reserved	n/a



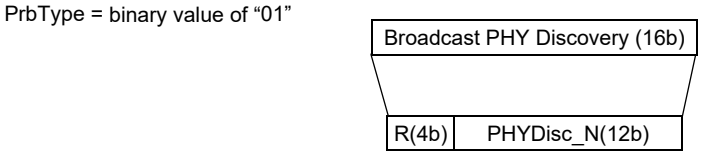
The CNU PHY Link receiver maintains counts of EPoC Probe Control Headers received and those received that have CRC32 errors using the variables *EPCHcnt* and *EPCHerr,* respectively.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CNU shall decode and be capable of acting on EPoC Probe Control Header instructions included in a downstream PHY Link frame within 2.5 ms after reception.

102.2.3.2.1 Probe Scheduling type Probe Control fields

The Probe Scheduling type Probe Control fields each enable one CNU to participate in the first Probe Period of the upstream PHY Link frame following the Response Frame ID. Each Probe Scheduling field contains a PrbID, PrbStrtSC, PrbSkip, PrbEQ, StrtSym, SymNum, and several reserved (R) subfields as illustrated in Figure 102–12. To enable a CNU to participate in a Probe Period the *CNU_ID* of the participating CNU is placed in PrbID subfield of the Probe Control. The remaining subfields set the corresponding variables in the designated CNU. A Probe Control field set to all zeros or any broadcast *CNU_ID* is ignored and does not enable any CNU. For additional information on use of the Probe Control fields, see 102.4.2.3.

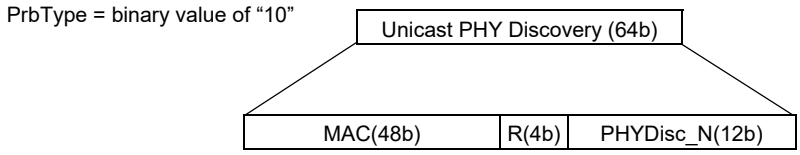


NOTE—The notation "(#b)" indicates the number of bits in the field.

Figure 102–12—Probe Scheduling type Probe Control field

102.2.3.2.2 Broadcast PHY Discovery type Probe Control fields

The Broadcast PHY Discovery type Probe Control fields each enable one PHY Discovery window within the Probe Period of the upstream PHY Link frame following the Response Frame ID. Each Broadcast PHY Discovery field contains a PHY Discovery window descriptor (PHYDisc_N), which designates the starting subcarrier of the PHY Discovery window as illustrated in Figure 102–13. For additional information on use of the Broadcast PHY Discovery type Probe Control fields, see 102.4.1.3.



NOTE—The notation "(#b)" indicates the number of bits in the field.

Figure 102–13—Broadcast PHY Discovery type Probe Control field

102.2.3.2.3 Unicast PHY Discovery type Probe Control fields

The Unicast PHY Discovery type Probe Control fields each enable a single CNU, as designated by a MAC address, to use a unique PHY Discovery window within the Probe Period of the upstream PHY Link frame following the Response Frame ID. Each Unicast PHY Discovery field contains a MAC address and a PHY Discovery window descriptor (PHYDisc_N), which designates the starting subcarrier of the PHY Discovery window as illustrated in Figure 102–13. For additional information on use of the Broadcast PHY Discovery type Probe Control fields, see 102.4.1.3.

NOTE—The notation "(#b)" indicates the number of bits in the field.

Figure 102–14—Unicast PHY Discovery type Probe Control field

102.2.3.2.4 PHY Link managed variables

DiscStrt

TYPE: 32-bit unsigned integer
This variable indicates when the next PHY Discovery window is open relative to the downstream Timestamp. Setting the PHY Discovery start parameter to zero disables the PHY Discovery window.

102.2.3.3 Downstream EPoC message block

The downstream EPoC message block contains a Type field (see Table 102–6) a PHY Instruction and a CRC32.

The CLT can perform read and write operations on the EPoC variables of subordinated CNUs via PHY Instructions. Each instruction contains an OPCODE, a Variable Group Count, a Variable Index, and up to 31 Variable Group Data fields.

The PHY Link OPCODE is a 3-bit field that conveys the operation of the PHY Instruction in which it resides. The CLT shall only transmit the valid OPCODE field values as given in Table 102–10.

Table 102–10—Valid OPCODE values

Value	Operation	Description
b000	NOP	No operation, the CNU acknowledges this instruction only
b001	Read	The CNU responds with the contents of variables starting at the index specified by the Variable Group Index field and subsequent variables as specified by the Variable Group Count field
b010	Write	The CNU stores the values given in the data field starting at the variable given in the Variable Group Index field and subsequent variables as specified by the Variable Group Count field
b011	Write/Verify	The CNU first writes the variables as specified by Variable Group Index and Variable Group Count field and then responds with the values contained in those same variables
b1xx	Reserved	No operation, the CNU ignores these instructions

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Variable Group Count field specifies the number of 16-bit EPoC Variable groups contained in a write or write/verify PHY Instruction or the number of 16-bit EPoC Variable groups that are to be returned in a read or write/verify PHY Instruction. The Variable Group Count field has a value of 0 to 31. The Variable Group Count field in a NOP instruction always has a value of 0. Whereas, for a read, write, or write/verify instruction, the Variable Group Count always has a value between 1 and 31.

The 16-bit EPoC Variable Index field specifies the variable group at which the CNU is to begin the read, write, or write/verify operation. The NOP instruction does not include an Index field.

The 16-bit Variable Group Data fields contain the data values to be written in consecutive variable groups starting with the group indicated by the Variable Index field and continuing for the number of groups indicated by Variable Group Count of the target CNU. The Variable Group Data fields are valid only for a write or write/verify PHY Instructions; or in the response to a read or write/verify PHY Instruction. In the event there is a discrepancy between the Variable Group Count field and the number of 16-bit Variable Group Data fields, the CNU shall write no data to its variables and returns a Nack indication (see 102.3.2.2).

The CNU PHY Link receiver maintains counts of EPoC message blocks received and those received that have CRC32 errors using the variables *EMBcnt* and *EMBerr,* respectively.

102.2.3.4 Downstream padding

The Pad field is used to fill the PHY frame in the event there are unused bits after the message blocks and FEC fields have been populated. The Pad field consists of all zeros and is ignored upon receipt.

102.2.3.5 Downstream FEC Parity message block

The FEC Parity message block includes a Type field, the FEC Codeword pointer (*FCP*), and a CRC32. The *FCP* is a 16-bit field used to identify the start of the first FEC codeword in the next PHY Link frame.

The CNU PHY Link receiver maintains counts of FEC Parity message blocks received and those received that have CRC32 errors using the variables *FPMEcnt* and *FPMEerr,* respectively.

102.2.4 Downstream PHY Link FEC

The downstream PHY Link shall use a binary punctured LDPC (384,288) code described in 102.1.4.1 and 102.1.4.3.1.

102.2.5 Downstream PHY Link response time.

The CNU shall decode and be capable of acting on EPoC message block instructions included in a downstream PHY Link frame within 4.8 ms. The CNU may indicate it is capable of a shorter response time to a downstream EPoC message block by setting the *PhyLinkRspTm* to a value of less than 61440 (4.8 ms).

102.2.6 PHY Link managed variables

DS_PhyLinkStrt

TYPE: 12-bit unsigned integer

This variable sets the starting subcarrier in OFDM Channel 1 of the downstream PHY Link. It specifies the lowest frequency subcarrier of the downstream PHY Link used to carry PHY Link information bits.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

102.2.7 Downstream state diagrams

102.2.7.1 Constants

EMB

TYPE: 4-bit unsigned integer
This constant represents the PHY Link message type for the EPoC message blocks.
VALUE: 0x0B

EPCHtp

TYPE: 4-bit unsigned integer
This constant represents the PHY Link message type for the EPoC Probe Control Header message block.
VALUE: 0x0A

EPFHtp

TYPE: 4-bit unsigned integer
This constant represents the PHY Link message type for the EPoC PHY Frame Header message block.
VALUE: 0x09

FPMBtp

TYPE: 4-bit unsigned integer
This value represents the PHY Link message type for the FEC Parity message block.
VALUE: 0x0C

MaxMBlen

TYPE: unsigned integer
This constant represents the maximum number of bits in the downstream PHY Link frame minus the length of the one CRC 32 and the FEC Pointer message block and excluding FEC Parity.
VALUE: 2824

102.2.7.2 Counters

EMBcnt

TYPE: 16-bit unsigned integer
This variable counts the number of EPoC message blocks received. The variable is cleared when read and does not roll over at maximum count.

EMBerr

TYPE: 16-bit unsigned integer
This variable counts the number of EPoC message blocks received with CRC32 errors. The variable is cleared when read and does not roll over at maximum count.

EPCHcnt

TYPE: 16-bit unsigned integer
This variable counts the number of EPoC Probe Control Headers received. The variable is cleared when read and does not roll over at maximum count.

EPCHerr

TYPE: 16-bit unsigned integer
This variable counts the number of EPoC Probe Control Headers received with CRC32 errors. The variable is cleared when read and does not roll over at maximum count.

EPFHcnt

TYPE: 16-bit unsigned integer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable counts the number of EPoC PHY Frame Headers received. The variable is cleared when read and does not roll over at maximum count.

EPFHerr

TYPE: 16-bit unsigned integer
This variable counts the number of EPoC PHY Frame Headers received with CRC32 errors. The variable is cleared when read and does not roll over at maximum count.

FPMEcnt

TYPE: 16-bit unsigned integer
This variable counts the number of FEC Parity message blocks received. The variable is cleared when read and does not roll over at maximum count.

FPMEerr

TYPE: 16-bit unsigned integer
This variable counts the number of FEC Parity message blocks received with CRC32 errors. The variable is cleared when read and does not roll over at maximum count.

LocalTS

TYPE: 32-bit unsigned integer
This counter holds the value of the local Timestamp. The counter is advanced by the OFDM Clock and rolls over to zero from 0xFF-FF-FF-FF. At the CLT the counter shall track the transmit clock, while at the CNU the counter shall track the receive clock. For accuracy of receive clock, see 101.4.4.2.

102.2.7.3 Variables

BEGIN

TYPE: Boolean
This variable is used when initiating operation of the functional block state diagram. It is set to TRUE following initialization and every reset.

DS_CID

TYPE: 2-bit unsigned integer
This variable represents the downstream Configuration ID value as described in 102.2.3.1.

FCP

TYPE: unsigned integer
This variable represents the beginning of the first MAC data FEC codeword in the current downstream PHY Link frame as described in 102.2.3.5.

FmLen

TYPE: unsigned integer
This variable represents the total number of bits transmitted in the current PHY Link frame.

PC_Fifo

TYPE: bit array
This variable holds the Probe Scheduling, Broadcast PHY Discovery, or Unicast PHY Discovery variables to be transmitted in the next EPCH message block.

PhyDA

TYPE: 15-bit unsigned integer
This variable represents the *CNU_ID* of the intended recipient of the PHY Link frame.

PhyDA_Fifo

TYPE: bit array
This variable holds the CNU_IDs to which the PHY Link frame and each PHY Link Instruction is to be sent. For any single PHY Link Frame there is one entry for the frame and one entry for each instruction.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PhyLinkRspTm

TYPE: 16-bit unsigned integer

This read only variable indicates the PHYs minimum response time to a downstream PHY Link instruction in units of 16/204.8 MHz. The maximum value for this variable is 61440 (4.8 ms), which is also the default value for this variable.

PhyTD

TYPE: bit array

This variable represents a bit array corresponding to data to be sent over the PHY Link.This variable is used to accumulate payload of outgoing PHY Link message blocks, for example to set the Timestamp Message Block.

PhyTxFifo

TYPE: bit array

This variable holds a series of PHY Instructions to be transmitted in the next PHY frame. Each entry in the fifo includes Opcode, Count, Variable Group Index, and Data fields for each instruction.

RF_ID

TYPE: 8-bit unsigned integer

This variable represents the Response Frame ID as described in 102.2.3.1.

RT

TYPE: Boolean

This variable represents the Response Type as described in 102.2.3.1.

PhyLnkRspTm

TYPE: 16-bit unsigned integer

The value of this variable defines the minimum time, in units of 78.125 ns (16 × 1/204.8 MHz), after receiving the last bit of the FEC, needed by the CNU to decode and prepare the response to a PHY Link Instruction.

PrbCtrl

TYPE: 32-bit binary

These variables represent the eight Probe control fields as described in 102.2.3.2.

StrtOfFm

TYPE: Boolean

When this variable transitions from FALSE to TRUE it indicates the beginning of an OFDM frame.

tmpDA

TYPE: 15-bit unsigned integer

This variable represents the *CNU_ID* of the intended recipient of the EPoC message blocks included in the PHY Link frame.

PD_Enable

TYPE: Boolean

This variable enables the device to respond to a PHY Discovery window and transmit onto the media when TRUE. It is set to FALSE following initialization and every reset. In the CNU it is set to TRUE after all elements required for PHY Discovery listed in Table 102–13 have been written by the CLT. In the CLT this variable, when set to FALSE, prevents transmissions from the CLT until it is fully configured and when TRUE permits transmissions.

TxPre

TYPE: Boolean

When TRUE, this variable indicates the PHY Link should be sending the preamble pattern as defined in 102.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

US_CID

TYPE: 2-bit binary
This variable represents the upstream Configuration ID value as described in 102.3.2.1.

102.2.7.4 Functions

CRC32(x)

This function returns a 32-bit CRC of the bit array *x* (see 3.2.9).

LEN(x)

This function returns the length of variable *x*.

PCnxt(x)

This function removes and returns the next *x* bits from the *PC_Fifo* bit array.

POP()

This function removes one record from the *PhyTxFifo*.

PUSH()

This function returns one record from the *PhyTxFifo*.

Send(x)

This function transfers the contents of variable *x* to the PHY Link FEC Encoder block. When the transfer is complete, the variable length is zero.

102.2.7.5 State diagrams

The CLT PHY Link transmit process shall conform to the state diagram shown in Figure 102–15.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

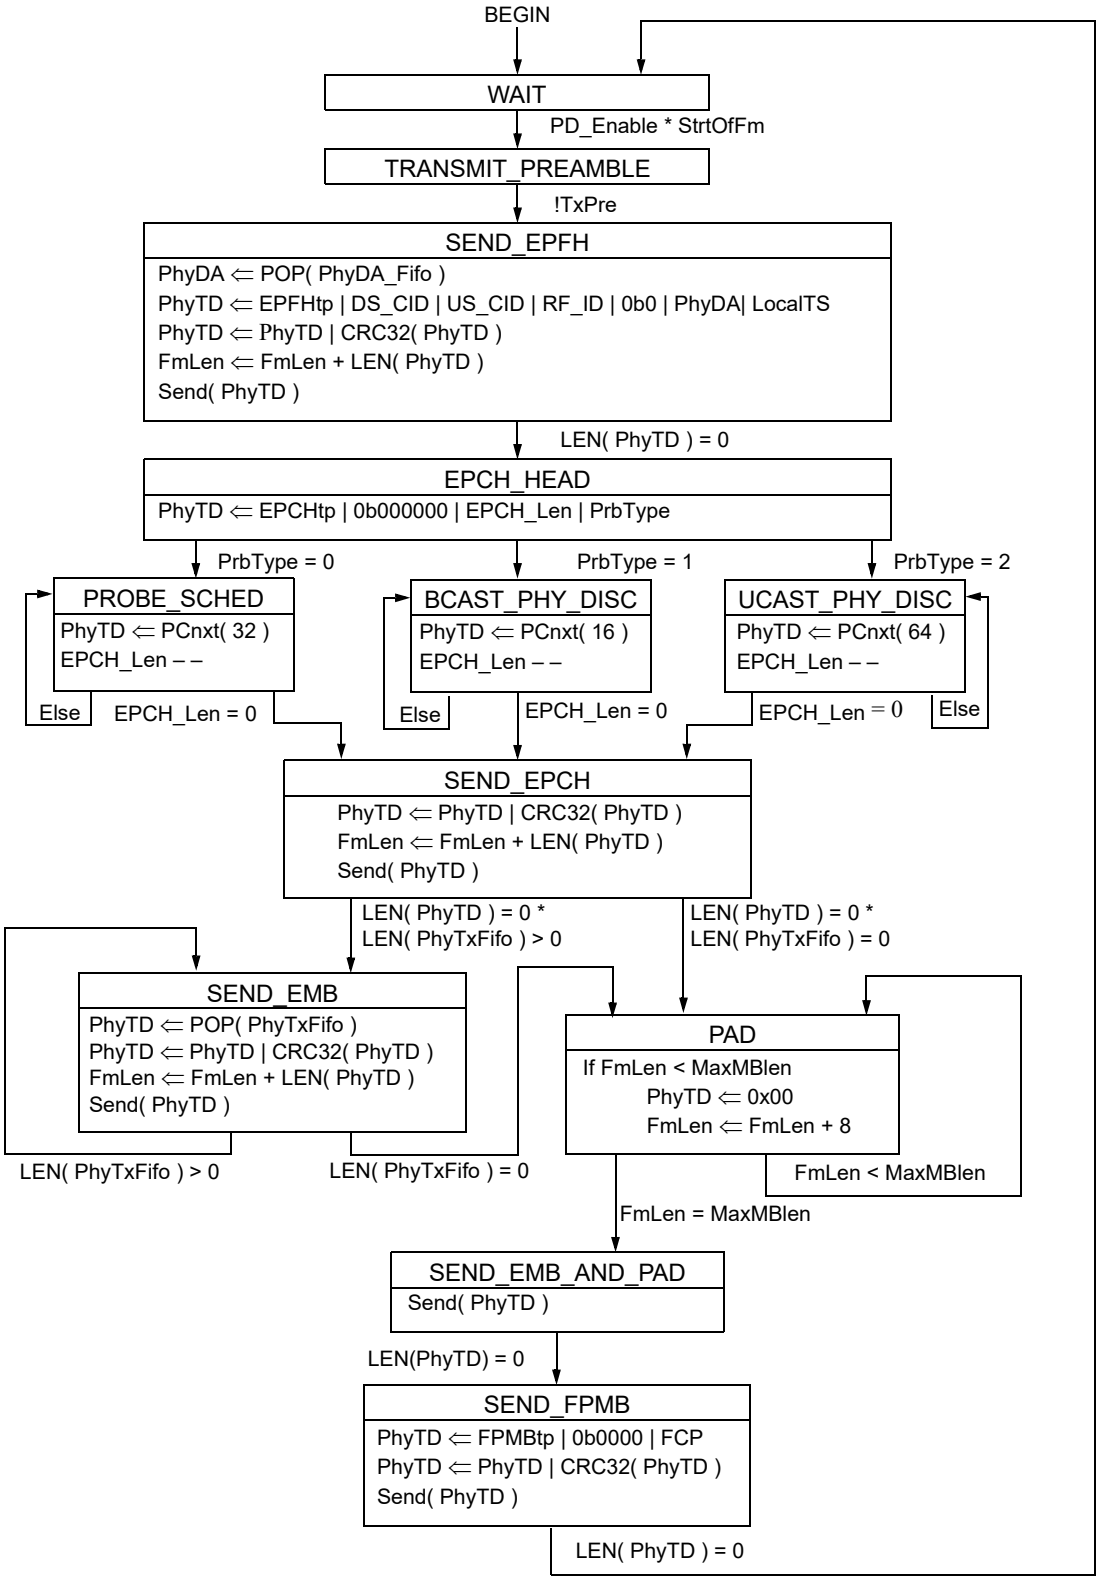

Figure 102–15—CLT PHY Link transmit process state diagram

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

102.3 Upstream PHY Link

102.3.1 Upstream PHY Link Physical Layer

102.3.1.1 Upstream resource allocation

During network setup the upstream PHY Link shall be allocated 400 kHz of spectrum. The upstream PHY Link is located per the *US_PhyLinkStrt* variable (see 102.3.5.3) that determines the lowest frequency subcarrier of the PHY Link. The upstream PHY Link shall use the same cyclic prefix duration and window size as the upstream MAC data OFDM channel.

102.3.1.2 Upstream PHY Link modulation

The upstream PHY Link shall use any of the modulation formats listed under PHY Link CNU Tx/CLT Rx in Table 100–2 and is set using the *US_PhyLinkMod* variable.

102.3.1.3 Upstream PHY Link transmission

CNU only operation: upon initialization of the CNU, the PMD_SIGNAL.request(*Tx_enable*) primitive is set to the value OFF in the PHY Link. When the first bit of a PHY Link message arrives at the PHY Link symbol mapper, the CNU sets the PMD_SIGNAL.request(*Tx_enable*) primitive to the value ON, which instructs the PMD sublayer to start the process of turning the RF power amplifier ON (see Figure 101–2 and 100.3.4.6). When the last bit of a PHY Link message arrives at the PHY Link symbol mapper, the CNU sets the PMD_SIGNAL.request(*Tx_enable*) primitive to the value OFF, which instructs the PMD sublayer to start the process of turning the RF power amplifier off.

102.3.2 Upstream PHY Link frame

The upstream PHY Link frame is composed of the EPoC PHY Frame Header, optional EPoC message blocks, and an FEC. These messages are described in the paragraphs that follow.

Each message block contains a Type field used to identify the contents of the block. CNUs shall use the appropriate message Type fields listed in Table 102–6 in each message block.

The contents of the each message block is protected by a CRC32. See 3.2.9 for a description of how this field is calculated. The CLT shall calculate a CRC32 on the data fields within each message block received and, if the calculated CRC32 does not match the received CRC32, discard the message and take no action based on it. The CLT PHY Link receiver maintains count of EPoC PHY Frame Headers received and those received that have CRC32 error using the variables *EPFHcnt* and *EPFHerr*, respectively.

102.3.2.1 Upstream EPoC PHY Frame Header

The upstream EPoC PHY Frame Header includes a Type field, the Return Frame ID field, the PHY SA, the PHY Timestamp field, and a CRC32 as illustrated in Figure 102–2. The Type field and Return Frame ID field are echoes of the same fields in the downstream message to which the CNU is responding. The PHY SA is an address field that identifies the CNU from which the PHY frame is transmitted. This field is 15 bits and is always the unicast address (*CNU_ID*) associated with the CNU transmitting in the PHY Link (see Table 102–8). The CNU SA is assigned during the PHY Discovery process (see 102.4.1). The PHY Timestamp is a 32-bit field set from the *LocalTS*.

102.3.2.2 Upstream EPoC message block

The EPoC message block contains a Type field (see Table 102–6), the PHY Response and a CRC32.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the downstream PHY Link EPoC PHY Frame Header contains the unicast *CNU_ID* for the CNU, the addressed CNU shall respond to PHY Link instructions using the PHY Response. Each Response contains an OPCODE, a Variable Group Count, an Variable Group Index, and up to 31 Variable Group Data fields.There is a one-to-one correspondence between PHY Instructions in the downstream PHY Link and PHY Responses in the upstream PHY Link.

The PHY Response OPCODE is a 3-bit value that conveys the acknowledge type for the PHY Instruction to which the CNU is responding and the success or failure of the PHY Instruction command. CNUs shall use the valid values of the acknowledgment type given in Table 102–11.

Table 102–11—OPCODE Acknowledgement values

Value	Operation	Description
b000	NOP ACK	NOP Instruction acknowledge returned in response to a successfully received NOP Instruction
b001	Read ACK	Read Instruction acknowledge returned in response to a successfully received and executed read Instruction along with the requested variables as specified in the Variable Group Index and Variable Group Count fields of the PHY Instruction
b010	Write ACK[a]	Write Instruction acknowledge returned in response to a successfully received and executed Write Instruction
b011	Write/Verify ACK[a]	Write/Verify Instruction acknowledge returned in response to a successfully received and executed Write/Verify Instruction along with the requested variables as specified in the Variable Group Index and Variable Group Count fields of the PHY Instruction
b100	NOP NACK	NOP Instruction negative acknowledge returned in response to a unsuccessfully received NOP Instruction
b101	Read NACK	Read Instruction negative acknowledge returned in response to an unsuccessfully received or executed Read Instruction
b110	Write NACK	Write Instruction negative acknowledge returned in response to an unsuccessfully received or executed Write Instruction
b111	Write/Verify NACK	Write/Verify Instruction negative acknowledge returned in response to an un successfully received or executed Write/Verify Instruction

[a]A write or write/verify PHY Instruction to an index that contains read-only bits is considered successful when all read/write bits in the index are written.

The Variable Group Count field specifies the number of 16-bit variable groups that are being returned in response to a read or write/verify PHY Instruction. In the event the CNU is returning a Nack response (Acknowledgment values 0b100 through 0b0111) the Variable Group Count field shall be set to zero and is ignored at the CLT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 16-bit Variable Group Index field specifies the first index for which the CNU is returning data due to a read or write/verify operation or the first index of the corresponding write Instruction.

The 16-bit Variable Group Data fields contain the data values read from the variables due to a read or write/verify PHY Instruction. In the event the CNU is responding to a write instruction this field is omitted. The Variable Group Data field should be omitted in Nack Responses (Acknowledgment values 0b100 to 0b111) and, if included, shall be ignored at the CLT.

The CLT PHY Link receiver maintains count of EPoC message blocks received and those received that have CRC32 error using the variables *EMBcnt* and *EMBerr,* respectively.

102.3.2.2.1 Padding

The Pad field is used to fill the PHY frame in the event there are unused bits after the message blocks and FEC fields have been accounted for.

102.3.3 Upstream PHY Link FEC

The upstream PHY Link shall use a (384,288) binary punctured LDPC code described in 102.1.4.1 and 102.1.4.3.1.

102.3.4 Upstream PHY Link pilot pattern

The upstream PHY Link utilizes a pilot pattern to assist the CLT receiver in capturing the bursting PHY Link transmissions. The PHY Link pilot pattern is illustrated in Figure 102–16. PHY Link pilots are BPSK encoded. The two edge subcarriers of the upstream PHY Link are Type 2 pilots; whereas, the six internal subcarriers are Type 1 Pilots.

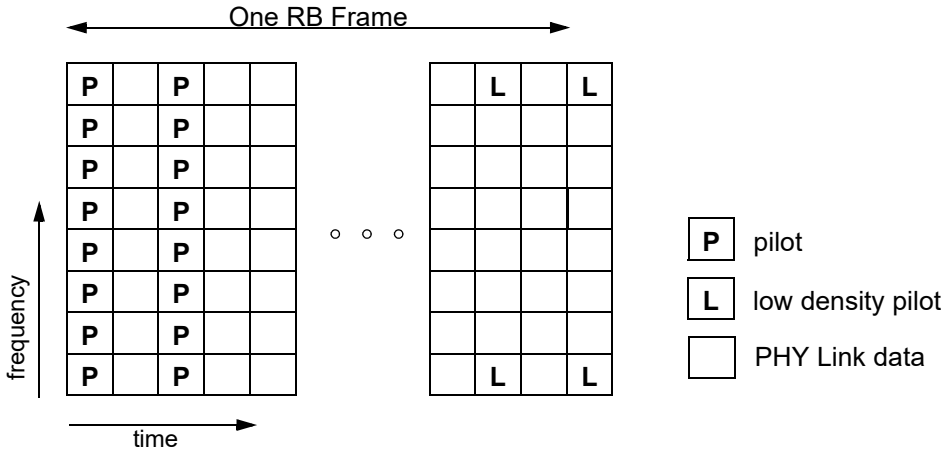

Figure 102–16—Upstream PHY Link pilot pattern

USPLfec

TYPE: Integer
This constant represents the upstream PHY Link FEC data length.
Value: 288

102.3.5.2 Counters

EMBcnt

See 102.2.7.2.

EMBerr

See 102.2.7.2.

EPFHcnt

See 102.2.7.2.

EPFHerr

See 102.2.7.2.

US_FmCnt

TYPE: 9-bit unsigned
This modulo 262 counter tracks the OFDMA symbols within the upstream superframe. Symbol zero is the first symbol in the Probe Period.

102.3.5.3 Variables

CNU_ID

TYPE: 15-bit integer that carries the value of the CNU_ID assigned by the CLT to the CNU during PHY Discovery process (see 102.4.1.6).

PhyDA

See 102.2.7.3.

PhyTD

See 102.2.7.3.

PhyTxFifo

See 102.2.7.3.

RF_ID

See 102.2.7.3.

RT

See 102.2.7.3.

PD_Enable

See 102.2.7.3.

PdCmplt

TYPE: Boolean
When TRUE this variable indicates the CNU has completed the PHY Discovery process and is allowed to transmit in the OFDMA MAC and PHY Link data paths.

US_PhyLinkMod

TYPE: 4-bit binary
This variable sets the type of modulation used for the upstream PHY Link. The assignment of bits to each modulation type is shown below.
bit 3 2 1 0
1 x x x = reserved
0 1 1 1 = 128-QAM

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

0 1 1 0 = 64-QAM
0 1 0 1 = 32-QAM
0 1 0 0 = 16-QAM
0 0 1 x = reserved
0 0 0 1 = BPSK

US_PhyLinkStrt

TYPE: 12-bit unsigned integer
This variable indicates the starting subcarrier of the upstream 10GPASS-XR PHY Link. It specifies the lowest frequency subcarrier of the upstream PHY Link used to carry PHY Link information bits.

102.3.5.4 Functions

CRC32()

See 102.2.7.4.

LEN()

See102.2.7.4.

Mod(x,y)

This function returns the remainder of *x/y*.

POP()

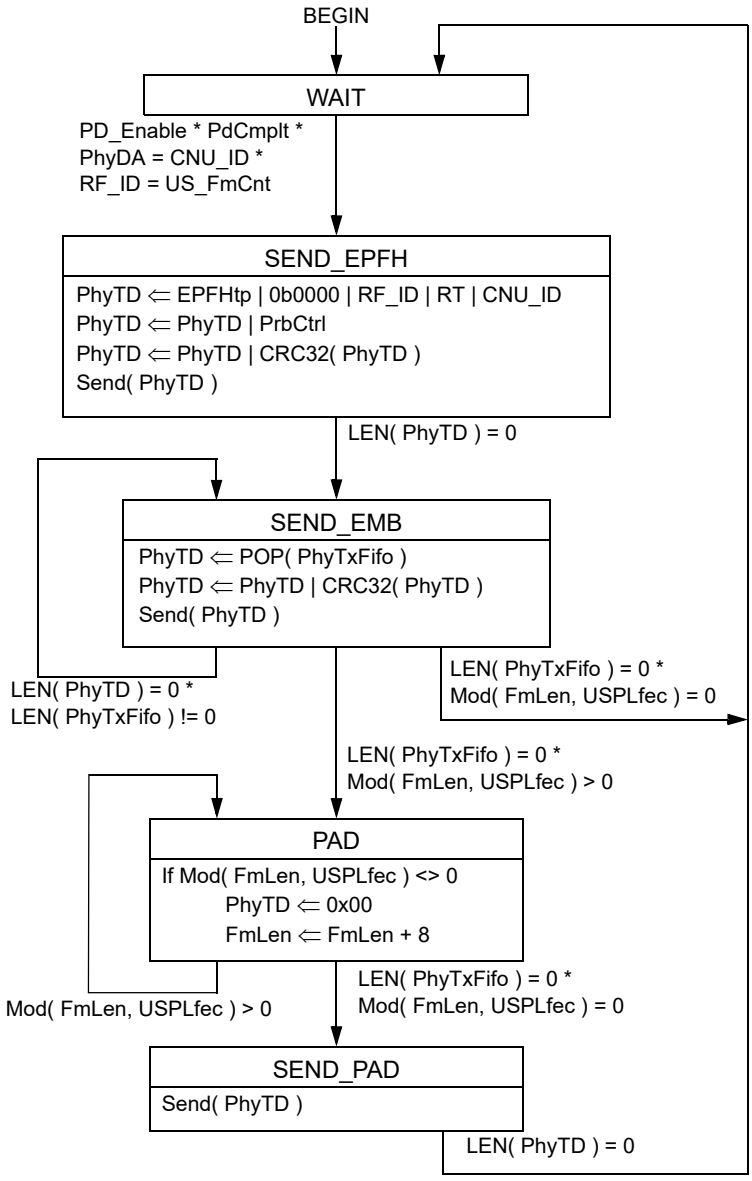

Figure 102–17—CNU PHY Link transmission control state diagram

102.4 PHY Link applications

When a CNU first joins the EPoC network it has no prior knowledge of the upstream RB Superframe configuration and timing necessary to produce transmissions that are orthogonal to the rest of the EPoC network when viewed from the perspective of the CLT receiver. PHY Discovery is the process whereby newly connected or off-line CNUs are provided timing and operating parameters necessary to function properly in the EPoC network.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

While an EPoC network is in operation, periodic verification of the CNUs OFDMA timing, transmission power, and pre-equalizer coefficients is needed to ensure orthogonality and proper reception. This is accomplished using Wideband Probing. Wideband Probing may also used during the PHY Discovery process to fine tune the timing of CNUs joining the network.

102.4.1 PHY Discovery

102.4.1.1 Overview of PHY Discovery

The PHY Discovery process is composed of PHY Link acquisition, PHY Discovery window opening, PHY Discovery Response, CNU_ID Allocation, and Wideband Probing. Each of these steps is described in detail in the following subclauses. The PHY Discovery message exchange is illustrated in Figure 102–18.

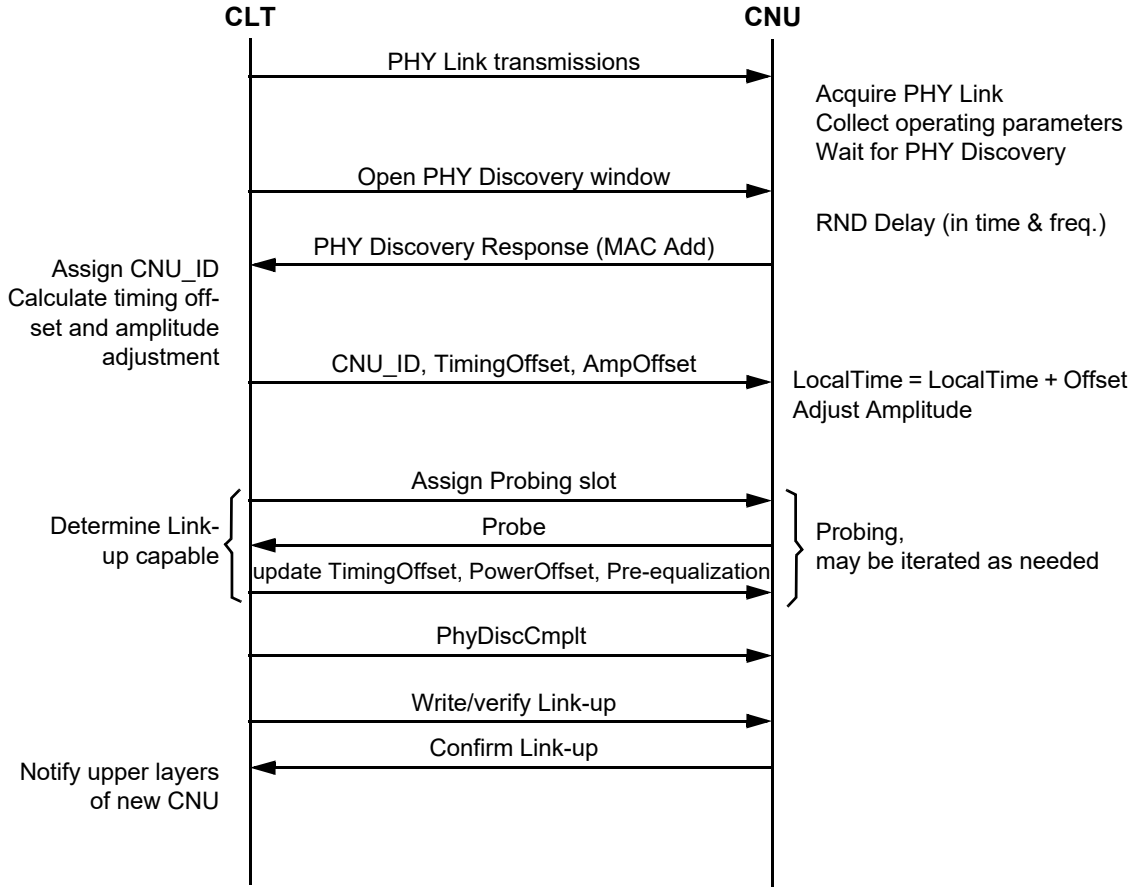

Figure 102–18—PHY Discovery message exchange

102.4.1.2 PHY Link acquisition

When a CNU joins an EPoC network it first locates the downstream PHY Link. This is typically done via a vendor specific correlation algorithm. Prior to any transmission in an EPoC network the CNU shall locate

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the downstream PHY Link, gather the required PHY Discovery operating parameters listed in Table 102–13 and synchronize its 10.24 MHz Master Clock to the downstream OFDM Clock. Once the CNU has completed the prerequisites for transmission it waits for the CLT to issue a PHY Discovery window.

102.4.1.3 PHY Discovery window opening

The CLT periodically makes available PHY Discovery windows during which off-line CNUs are given the opportunity to make themselves known to the CLT. The periodicity of these windows is unspecified. The CLT signifies that a PHY Discovery period is occurring by transmitting either a Broadcast PHY Discovery type or Unicast PHY Discovery type Probe Control message block.

The PHY Discovery window is coincident with the Probe symbols (see 101.4.3.10) but is only four symbols in duration to allow for timing ambiguity in the PHY Discovery Response.

102.4.1.4 PHY Link Discovery Response

Off-line CNUs, upon being notified of a PHY Discovery window, wait for the beginning of the PHY Discovery window and then transmit a PHY Discovery Response to the CLT. The CNU initially transmits a PHY Discovery Response using the power level indicated by *PdRespInitPwr*. If there is no acknowledgment from the CLT to the initial PHY Discovery Response the CNU increases the PHY Discovery Response transmit power by the value indicated by *PdRespPwrStep*. The CNU continues to increases the PHY Discovery Response transmit power by the value indicated by *PdRespPwrStep* until an acknowledgment is received from the CLT. If the CNU has transmitted four PHY Discovery Responses at maximum power without acknowledgment from the CLT it reverts to the power level indicated by *PdRespInitPwr* and begins incrementing its output power as described previously.

PHY Discovery windows are unique in that they are the only times when multiple CNUs can access the coax cable distribution network using the same RF spectrum simultaneously, and transmission overlap can occur in both time and frequency. In order to reduce transmission overlaps, a contention algorithm is used by all off-line CNUs. Measures are taken to reduce the probability for overlaps by artificially introducing a random distribution in the PHY Discovery window used by each CNU. Each CNU selects a random number of PHY Discovery windows it waits before transmitting the PHY Discovery Response. Multiple valid PHY Discovery Responses that overlap in time, but not frequency, may be received by the CLT during a single PHY Discovery window depending on the modulated spectrum of the upstream OFDM channel.

Included in the PHY Discovery Response is a preamble (see 102.4.1.5), the CNU's MAC address and a 32-bit CRC. See 3.2.9 for a description of how the 32-bit CRC is calculated. The data in the PHY Discovery Response shall be encoded using a (128,80) binary punctured LDPC code described in 102.1.4.3.2.

The PHY Discovery Response is composed of 128 subcarriers with a duration of four symbols and may include exclusions between these 128 subcarriers (see Figure 102–19). In a single Probe Period there may be up to 16 PHY Discovery windows. For the purposes of PHY Discovery Response contention mitigation, the broadcast PHY Discovery windows are numbered consecutively from lower starting frequency to higher starting frequency and increasing as time progresses as illustrated in Figure 102–20. Unicast PHY Discovery windows are not numbered for contention mitigation purposes.

In the event there is an analog fiber segment between the CLT and CNU, the CLT can delay the PHY Discovery Response by the amount of time specified in *PhyRngOffset*.

The CNU PHY Discovery Response is only allowed after a CNU has completed the PHY Discovery prerequisites (Table 102–13). In the PHY Discovery Response message, the preamble used is the special PHY Discovery Preamble (see 102.4.1.5) and the only data included is the CNU MAC address protected by a CRC32. The PHY duplicates symbols of the upstream PHY Discovery Response transmission. This duplication is accomplished by duplicating the time domain samples at the output of the iFFT in the upstream data path for these signals, and adding cyclic prefix and windowing (per variables *USNcp* and *USNrp*, respectively) as illustrated in Figure 102–21. Control for the duplication process is conveyed using the TxType in the CNU (see Figure 102–4).

The CLT calculates the range of the CNU based on the PHY Link Response and uses this to report the NewCNU_Rng when declaring the CNU link-up (see 102.4.3).

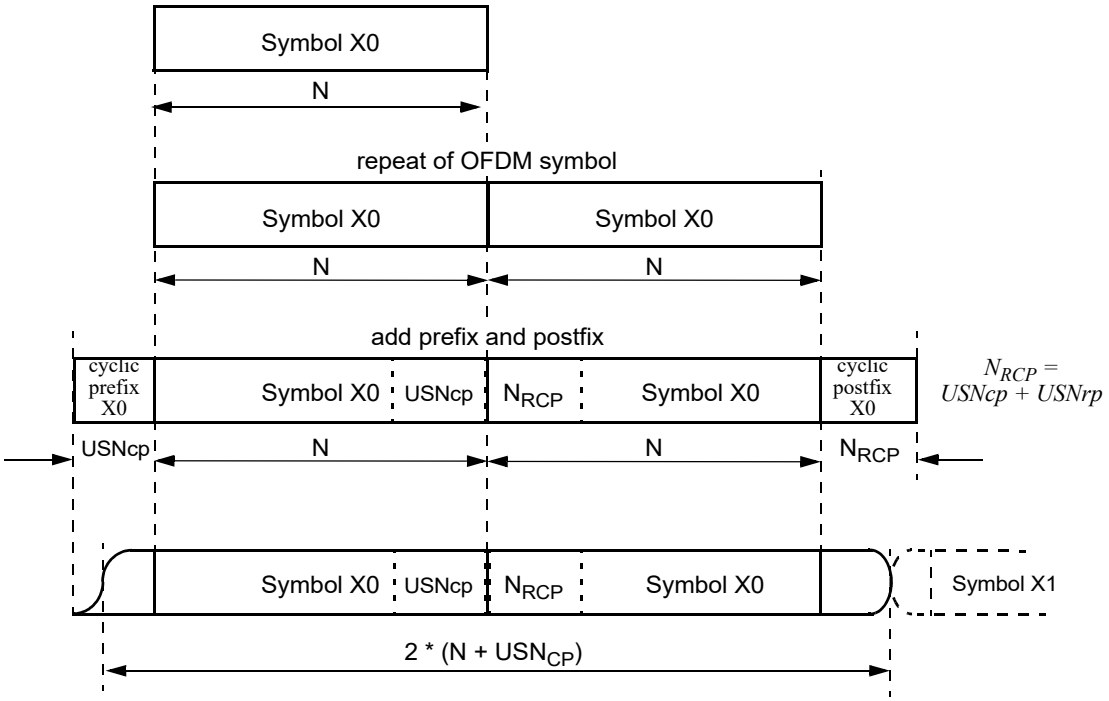

Figure 102–21—Symbol duplication, cyclic prefix, and windowing algorithm for PHY Discovery Response

102.4.1.5 PHY Discovery preamble

The PHY Discovery preamble is transmitted in the first two symbols of the PHY Discovery Response. The first symbol of the preamble shall be populated with a BPSK mapped 128-bit sequence generated by a pseudo-random sequence generator defined by the polynomial $x^7 + x^1 + 1$ seeded with a fixed bit pattern of 0x55 (see Figure 102–22) at the beginning of the PHY Discovery Response (see Figure 102–23). The output of the sequence generator is mapped using BPSK modulation (see 101.4.5.2) where a bit value of 0 is mapped to a BPSK value of plus 1 and a bit value of 1 is mapped to a BPSK value of minus 1. The second symbol of the PHY Discovery preamble shall be a duplicate copy of the first symbol as illustrated in Figure 102–21.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

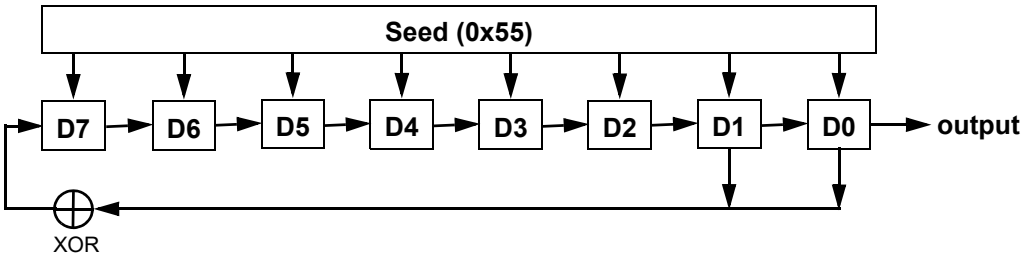

Figure 102–22—PHY Discovery Preamble generator

102.4.1.6 CNU_ID allocation

Upon receipt of a valid PHY Discovery Response, the CLT updates the CNU by allocating and assigning a new port identity (*CNU_ID*) using the *AssgndCNU_ID* and *AllwdCNU_ID* variables. To allocate the *CNU_ID* the CLT shall use the CNU_ID Allocation instruction as defined in Table 102–12. This instruction uses a broadcast DA.

The CLT calculates an OFDMA timing and power offsets and adjusts the CNU using the *PHYTimingOffset* and *PHYPowerOffset* variables, respectively. These parameters are transmitted to the CNU via the CNU_ID Allocation instruction. The first EMB of the CNU_ID Allocation instruction is a write of the *New_MACn* variables (note that this variable is read only so the actual variable value in the CNU will not change). The value written is the CNU MAC address received in the PHY Discovery Response.

The second EMB writes *AllwdCNU_ID* and sets *AssgndCNU_ID* to TRUE in the CNU. This causes the value of *AllwdCNU_ID* to be assigned in the CNU. Thereafter the CLT cannot use the same value of *AllwdCNU_ID* for another newly discovered CNU. See 102.4.3 for additional information on use of *AllwdCNU_ID* and *AssgndCNU_ID.*

Subsequent EMBs are used to write the CNU *PHYTimingOffset* and *PHYPowerOffset* variables.

Table 102–12—Special Instruction sequences

Special Instruction	EMB order	Read/Write	Variable
CNU_ID Allocation	1	Write	*New_MAC0* through *New_MAC2*
	2	Write	*AllwdCNU_ID*
	3	Write	*PHYTimingOffset* *PHYPowerOffset*

When the CNU receives the *PhyTimingOffset* variable, it shall add the new value of *PhyTimingOffset* to the *LocalTS* affecting the CNU transmit timing accordingly. When the CNU receives the *PhyPowerOffset* variable, it shall add the new value of *PhyPowerOffset* to the *PHYPowerOut* affecting the CNU transmit power accordingly.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

102.4.1.7 PHY Discovery completion

When the CLT determines [via Wideband Probing (see 102.4.2), updates to *PhyTimingOffset,* and updates to *PhyPowerOffset*] that the new CNU has successfully tuned its transmitter to be orthogonal to the rest of the CNUs on the coax cable distribution network, it sets *PhyDiscCmplt* TRUE. This signifies that the CNU has completed the process of PHY Discovery.

102.4.1.8 PHY Link managed variables

AllwdCNU_ID

TYPE: 15-bit unsigned integer

This variable is used to indicate to the 10GPASS-XR PHY a valid *CNU_ID* value. The value may be assigned to a new CNU when the associated *CNU_ID* assigned flag (*AssgndCNU_ID*) is set to zero, when the flag is set to one it is an indication that this value has already been assigned to a CNU and it should not be use for another CNU.

AssgndCNU_ID

TYPE: Boolean

The value of this variable is used to indicate if the associated *AllwdCNU_ID* value has been assigned to a CNU by the PHY. When the flag is set to TRUE the associated *AllwdCNU_ID* has been assigned to a new CNU whereas when the flag is set to FALSE the associated *AllwdCNU_ID* has not been assigned.

DS_OFDM_ID

See 101.4.3.4.5.

LinkUpRdy

TYPE: Boolean

This Boolean variable is set to TRUE by the CLT when it has verified all of the variables required for Link-Up state in Table 102–13. The variable is set to FALSE on reset or as described in 102.4.4.

NewCNU_Rng

TYPE: 16-bit unsigned integer

This variable indicates the range of the CNU corresponding to Allowed CNU_ID in units of OFDM Clock periods (1/204.8 MHz).

PhyDiscCmplt

TYPE: Boolean

When TRUE, this variable indicates that the CNU has completed PHY Discovery (see 102.4.1) on the coaxial cable distribution network. When FALSE, the variable indicates that the PHY has not completed PHY Discovery on the coaxial cable distribution network. This variable is defined in 10GPASS-XR-U PMA/PMD only. The variable is set to FALSE on any reset.

PdRespInitPwr

TYPE: 8-bit unsigned integer

This variable is used to set the initial transmit level, in units of 0.25 dBmV/1.6 MHz, for a CNUs PHY Discovery Response message. The range of this variable is from 0 to 64 dBmV/1.6 MHz.

PdRespPwrStep

TYPE: 8-bit unsigned integer

This variable is used to increase the transmit level, in units of 0.25 dB, for a CNUs PHY Discovery Response message in the event a PHY Discovery Response sent by the CNU is not acknowledged by the CLT.

PdRndDly

TYPE: unsigned integer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable indicates the random delay, in PHY Discovery windows, selected by the PHY to avoid contention during PHY Discovery.

PhyPowerOffset

TYPE: signed 8-bit integer
This variable is used to set the CNU upstream transmitter power by specifying the relative change in transmission power level the CNU is to make, in units of 0.25 dB, in order that transmissions arrive at the CLT at the desired power level. Changing the value of this variable while running using Management is highly undesirable and is unspecified.

PhyRngOffset

TYPE: 32-bit unsigned integer
This variable may be used to provision a delay in the ranging response, in units of 1/204.8 MHz, in the event there is an analog optical segment between the CLT and the CNUs as described in 102.4.1.4. This variable defaults to a value of 0 on reset.

PhyTimingOffset

TYPE: signed 32-bit integer
This variable is used to align the CNU to the upstream OFDM timing in units of 1/204.8 MHz. A negative value causes the timing of the CNU transmissions to be delayed. Changing the value of this variable while running using Management is highly undesirable and is unspecified.

102.4.1.9 PHY Discovery state diagrams

102.4.1.9.1 Constants

Pad96

TYPE: 96 bit binary
This constant holds 96 bits of padding.
Value: 0

102.4.1.9.2 Variables

New_MAC

TYPE: 48-bit hex
This vairable holds the MAC address of the CNU.

NxtWin

TYPE: unsigned integer
This variable holds the subcarrier index for the next PHY Discovery window.

PdData

TYPE: bit array
This variable holds the data to be transmitted in the PHY Discovery window.

PdWinFifo

TYPE: bit array
This fifo holds the list of 12-bit subcarrier indexes for each PHY Discover window from the most recent EPoC Probe 64B/65B sync header bit message block.

PdWinTp

TYPE: Boolean
This variable indicates if the list PHY Discover windows in *PdWinFifo* are unicast or broadcast windows. *PdWinTp* has the value of Ucast when the PHY Discovery window is unicast and Bcast when the window is broadcast.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Rnd

TYPE: 8-bit unsigned integer
This variable is used as a seed in the back-off algorithm for the PHY Discovery Response.

SoSF

TYPE: Boolean
This variable indicates the beginning of the upstream superframe and is set to TRUE for one OFDM Clock period at the beginning of the superframe.

PD_Enable

See 102.2.7.3.

102.4.1.9.3 Counters

SC_Cnt

TYPE: 12-bit
This counter tracks the subcarriers within each symbol and increments once for every subcarrier. Subcarrier zero is the first subcarrier while subcarrier 4095 is the last. The counter is reset at the beginning of every symbol.

102.4.1.9.4 Functions

CRC32()

See 102.2.7.4.

Len(x)

See 102.2.7.4.

PD_Pre

This function returns the PHY Discovery preamble as described in 102.4.1.5.

POP(x)

See 102.2.7.4.

rnd(r)

This function returns a random integer number uniformly distributed between 1 and *r*.

102.4.1.9.5 State diagrams

The CNU PHY Discovery Response transmission control shall conform to the state diagram shown in Figure 102–23.

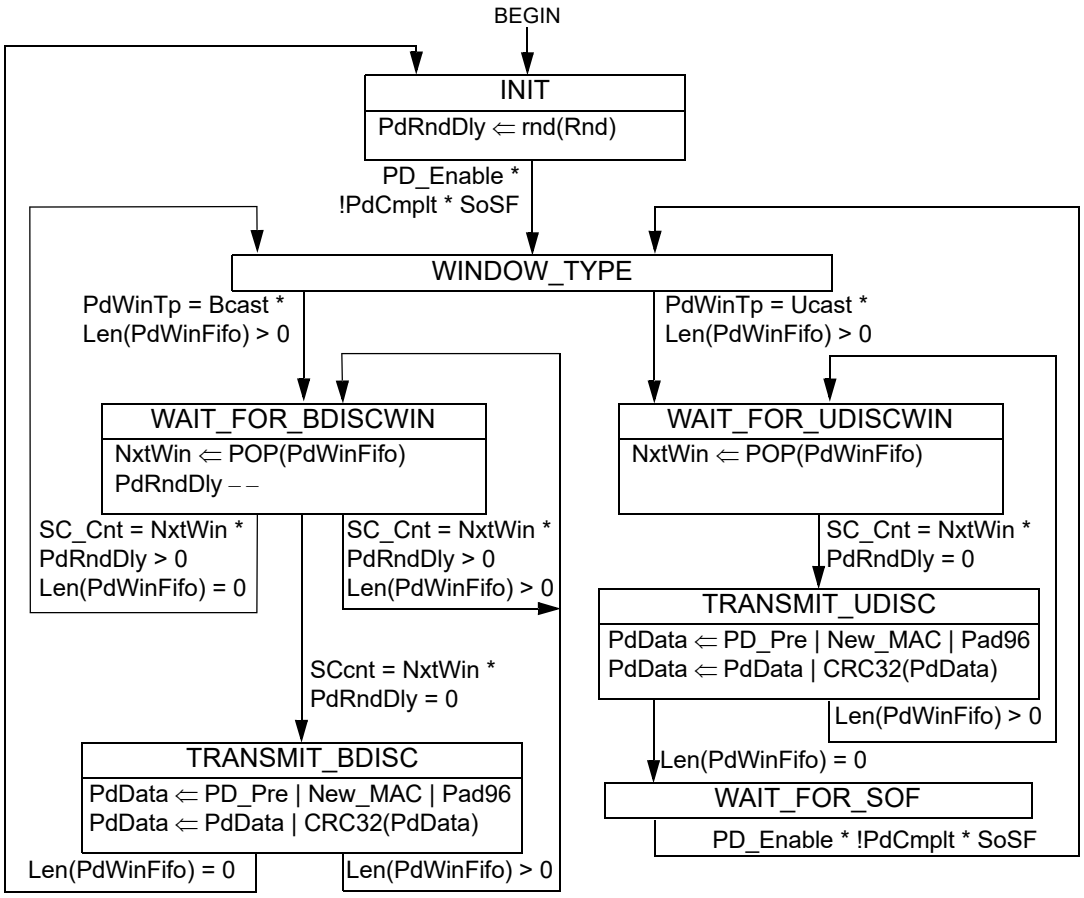

Figure 102–23—CNU PHY Discovery Response transmission control state diagram

102.4.2 Upstream Wideband Probing

102.4.2.1 Introduction

In upstream Wideband Probing a CNU transmits pilots spanning all active subcarriers. The CNU transmits one pilot per subcarrier. Each pilot is a predefined BPSK symbol. Each upstream superframe begins with six symbols, called the Probe Period, designated for probing and PHY Discovery. Each symbol within the Probe Period is referred to as a probing symbol. The CLT may use the received probing symbol for the following:

a) Upstream OFDM channel estimation. The CLT computes the coefficients of the upstream pre-equalizer for each CNU and sends them back to that CNU.
b) Upstream SNR measurement. The CLT measures the SNR per subcarrier and computes the upstream bit loading tables.
c) Upstream timing adjustment. During CNU bring up the CLT may use Wideband Probing to adjust the timing of the new CNU to the upstream RB Frame and superframe.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

102.4.2.2 Probing symbol pilots

Probing symbol pilots are BPSK symbols.

Probing symbol pilot *i* is always associated with the *i*-th subcarrier of the symbol, where:

$i = 0, 1, \ldots, 4095$

NOTE—Subcarriers are numbered in ascending order of frequency starting from 0.

102.4.2.3 Probing symbol scheduling

The CLT may allocate a one or more probing symbols to a CNU within the Probe Period and instruct the CNU to transmit the probing sequence in that symbol. CLT specifies the probing symbol within the Probe Period via the EPoC Probe Control Header message block in the downstream PHY Link frame. The CLT assigns a CNU either all the pilots of the assigned probing symbol, or a subset of (scattered) pilots of the assigned probing symbol.

The CLT allocates subcarriers within a probing symbol by sending five variables to the CNU: *PrbStrtSC*, *PrbSkp*, *PrbEQ*, *StrtSym,* and *SymNum* (see 102.4.2.6.2). Figure 102–24 and Figure 102–25 illustrate the use of *PrbStrtSC* and *PrbSkp*. The CNU uses the *PrbStrtSC* and *PrbSkp* variables to determine which subcarriers are to be used for probing transmission, as follows:

— The *PrbStrtSC* variable is the starting subcarrier number.
— The *PrbSkp* variable is the number of subcarriers to be skipped between successive pilots. *PrbSkp* = 0 implies no skipping of subcarriers (i.e., all subcarriers are used for probing).

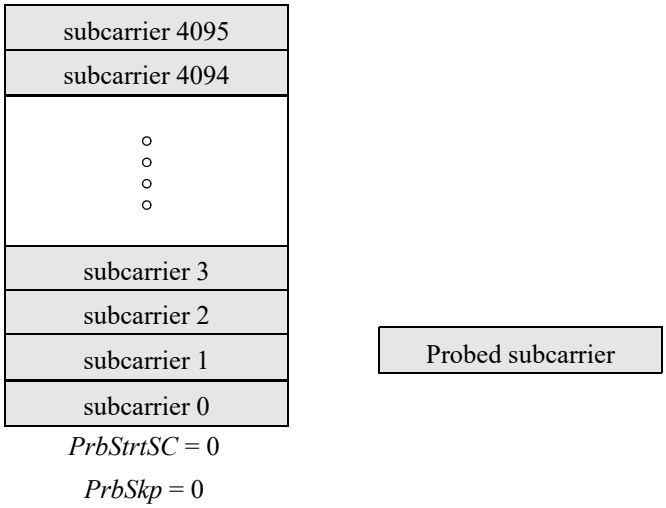

Figure 102–24—Example, all subcarriers used for probing, no skipping

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

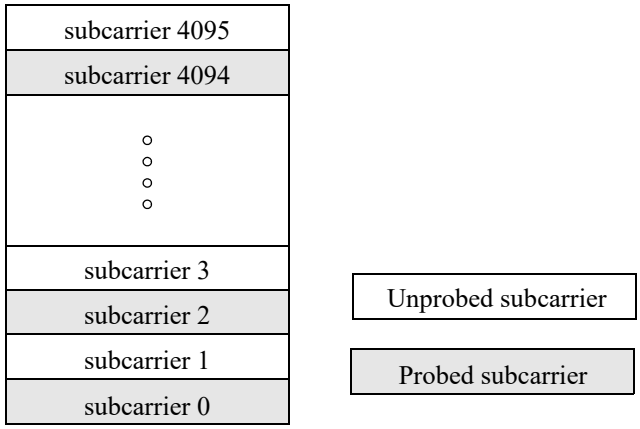

Figure 102–25—Example, alternate subcarriers used for probing

To schedule a single CNU in a probing symbol without skipping subcarriers, the CLT does the following:

- Allocate a specific probing symbol to a single CNU using *StrtSym* and *SymNum*.
- Set *PrbSkp* to zero.
- Set *PrbStrtSC* to the number of the first subcarrier.

To schedule a single CNU in a probing symbol with skipping subcarriers to create nulls (as illustrated in Figure 102–25), the CLT does the following:

- Allocate a specific probing symbol to a single CNU using *StrtSym* and *SymNum*.
- Set *PrbSkp* to a non-zero positive integer value.
- Set *PrbStrtSC* to the number of the first subcarrier.

To schedule multiple CNUs in a probing symbol (as illustrated in Figure 102–26), the CLT does the following:

- Allocate the same probing symbol at any given time to more than one CNU using *StrtSym* and *SymNum*.
- Assign a different *PrbStrtSC* number to each CNU.
- Assign the same *PrbSkp* value to every CNU within the probing symbol.

This method can be used with or without skipping subcarriers to create nulls. To create nulls, specify a *PrbSkp* value equal to, or greater than, the number of CNUs in the pattern.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

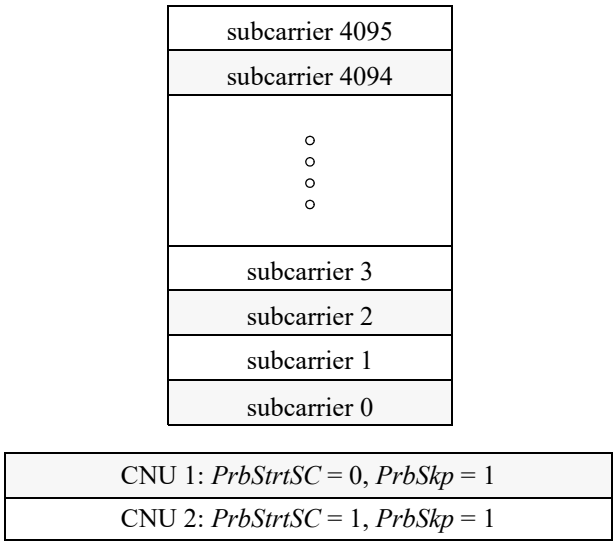

Figure 102–26—Scheduling two CNUs in the same probing symbol

The *PrbEQ* variable determines if the pilots transmitted are to be equalized (*PrbEQ* TRUE) or unequalized (*PrbEQ* FALSE).

StrtSym and *SymNum* variables determine which symbols within the Probe Period are to be used by the CNU. The value of *StrtSym* determines the first symbol within the Probe Period to begin probe transmissions and *SymNum* determines the number of adjacent symbols in which to send probe pilots. The CLT is responsible for properly setting the Probe Control fields so that the probe pilots are defined within the Probe Period. The CNU shall not transmit probe pilots in response to settings which define transmission outside the configured Probe Period. For example if *StrtSym* equals 4 and *SymNum* equals 3 the CNU does not transmit any probe pilots. The CNU is not responsible for crosschecking Probe Control settings to ensure that two CNUs are not assigned the same subcarriers for probing. Should the CLT make such an assignment it will receive a garbled response.

102.4.2.4 Probing sequence

The Probe symbol shall be populated with a BPSK mapped bit sequence generated by a pseudo-random sequence generator defined by the polynomial shown in Equation (102–3) seeded with a fixed bit pattern of 0xBFF at the beginning of each upstream superframe (illustrated in Figure 102–27). The output of the sequence generator is mapped using BPSK modulation (see 101.4.5.2) where a bit value of 0 is mapped to a BPSK value of plus 1 and a bit value of 1 is mapped to a BPSK value of minus 1.

$$x^{12} + x^{9} + x^{8} + x^{5} + 1 \tag{102–3}$$

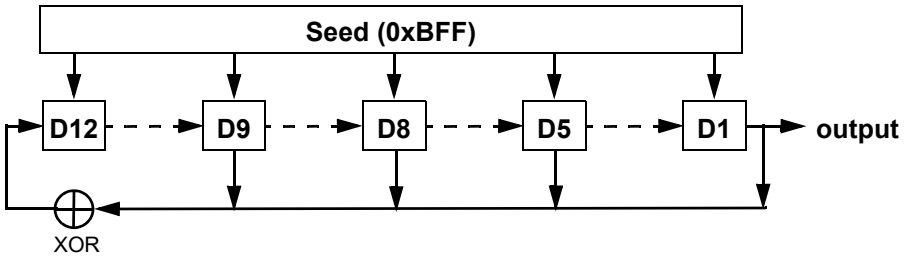

Figure 102–27—Probe sequence generator

102.4.2.5 Probe symbol repetition

Probes use all active subcarriers of a symbol. The first symbol in a Probe is generated as described in 102.4.2.4. The second symbol is a direct copy of the first symbol.

102.4.2.6 Wide Band Probing state diagrams

102.4.2.6.1 Constants

Exclude
: This constant informs the PMA that the subcarrier with which it is associated is not to be used for transmission.

102.4.2.6.2 Variables

ActPrbID
: TYPE: set of 15-bit Integers
When the *CNU_ID* of the CNU is contained in this set of variables the CNU is allowed to transmit a Probe Signal per the Probe Control variable *PrbEQ*, *PrbSkp*, *PrbStrtSC*, *StrtSym,* and *SymNum*. This set of variables is updated with each downstream PHY Link frame when *RF_ID = US_FmCnt* (see Figure 102–29). Each element in this set is one of the *PrbIDs* received in the most recent EPoC Probe Control Header.

CNU_ID
: See 102.3.5.3.

PhyDisc_N (N = 1, 2, ... 16)
: TYPE: 12-bit Integers
Each of these variables designates the starting subcarrier of a PHY Discovery window within the Probe Period.

PrbEQ
: TYPE: Boolean
When this provisioned variable is TRUE, the CNU transmits the probe symbol with equalization applied. When this variable is FALSE, the CNU transmits the probe symbol without equalization applied.

PrbSkp
: TYPE: unsigned integer
The value of this provisioned variable determines the number of subcarriers to be skipped in the probe symbol. The range of *PrbSkp* is from zero to seven.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PrbStrtSC

TYPE: unsigned integer
The value of this provisioned variable determines the starting subcarrier to be used in the probe symbol. The range of *PrbStrtSC* is from zero to seven.

RcvPrbID

TYPE: set of 15-bit Integers
This set of provisioned variables contains the received set of *PrbID* variables from the most recent downstream PHY Link frame, *PrbID*. When *US_FrmCnt = RF_ID* the values in this set replaces the values in the *ActPrbID* set (see Figure 102–2).

PrbData

TYPE: bit array
This variable holds the probe sequence bits to be transmitted during the Probe Period.

SC_clk

TYPE: Boolean
This clear on read variable goes TRUE at the beginning of each subcarrier.

StrtSym

TYPE: unsigned integer
The value of this variable determines the starting symbol within the Probe Period in which to begin transmitting probe pilots. The range of this variable is from one to six. The sum of *StrtSym* and *SymNum* is less than or equal to six.

SymNum

TYPE: unsigned integer
The value of this variable determines the number of consecutive symbols in which to transmit probe pilots. The range of this variable is from one to six. The sum of *StrtSym* and *SymNum* is less than or equal to six.

US_ModTypeSC(n)

See 101.4.4.4.4 for the definition of these variables.

102.4.2.7 Counters

SC_Cnt

See 102.4.1.9.3.

US_FmCnt

See 102.3.5.2.

102.4.2.8 Functions

Mod(x,y)

This function returns the remainder of *x* divided by *y*.

PrbSeq

This function returns one bit worth of probe data using the sequence generator described in 102.4.2.4. The function is reset at the beginning of the Probe Period.

SndPrbData(x)

This function transfers one symbols worth of Probe data (*PrbData*) from the Probe Symbol Mapper function to the PMA. If *x* = TRUE then the probe data is to be sent with equalization, if *x* = FALSE then probe data is sent without equalization.

102.4.2.9 State diagrams

The CNU probe transmit process shall conform to the state diagram shown in Figure 102–28.

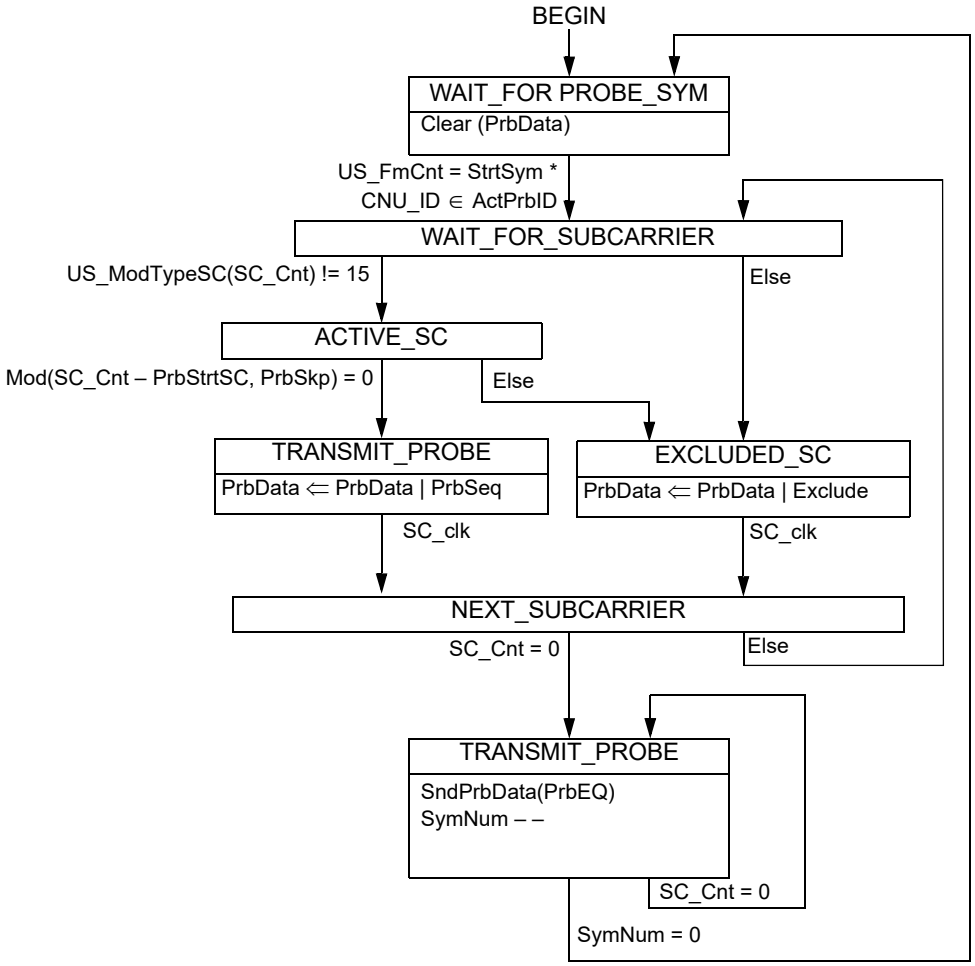

Figure 102–28—CNU Probe transmission control state diagram

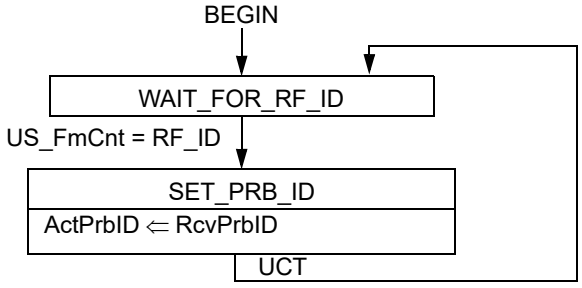

Figure 102–29—PrbID update state diagram

102.4.3 Link-up declaration

Before declaring a CNU is in the link-up state the CLT shall ensure that a CNU joining the EPoC network is properly aligned to the upstream OFDMA timing and is cognizant of all necessary provisioning parameters needed to properly operate in the OFDMA network without adverse impact to the EPoC network or other services operating in RF spectrum unused by the EPoC network. A list of required parameters is given in Table 102–13.

Once the CLT has verified the CNU is in the link-up status by reading the variables listed in the Link-Up column of Table 102–13 it shall set the *LinkUpRdy* variable to TRUE. Once the CLT has verified the CNU is in the link-up status by reading the *PD_Enable* variable as TRUE it may set the *AssgndCNU_ID* to TRUE to notify the upper layers that the associated CNU_ID has been assigned and a device has been added to the network (see 102.4.1.9.2).

There may exist situations when the CLT requires that a CNU go through the PHY Discovery sequence again. Similarly, there may be situations where a CNU needs to inform the CLT of its desire to leave the EPoC network. The CNU can then go through the PHY Discovery sequence again.

Table 102–13—Required variables for PHY Discovery Response and Link-Up

Variable/Variable Group	Reset on change[a]	Required for[b]	
		PHY Discovery	Link-Up
LinkUpRdy	N		T
PD_Enable	N	T	T
PhyDiscCmplt	N		T
DS_ChCnt	Y		Y
DS_TmIntrlv	Y		Y
DSNrp	Y		Y
DSNcp	Y		Y
DS_FreqCh(1) through *DS_FreqCh(5)* [a]	Y		Y
Rnd	N	Y	Y
RBsize	Y	Y	Y
USNrp	Y	Y	Y
USNcp	Y	Y	Y
US_FreqCh1	Y	Y	Y
Type2_Repeat	N		Y
Type2_Start	N		Y
Type1_Repeat	N		Y
Type1_Start	N		Y
DS_PhyLinkStrt	Y	Y	Y

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 102–13—Required variables for PHY Discovery Response and Link-Up *(continued)*

Variable/Variable Group	Reset on change[a]	Required for[b]	
		PHY Discovery	Link-Up
US_PhyLinkStrt	Y	Y	Y
AllwdCNU_ID [c]	Y		Y
PhyTimingOffset	N		Y
PhyPowerOffset	N		Y
PhyRngOffset	Y	Y	Y
DS_DataRate	N	Y	Y
US_DataRate	N	Y	Y
DS_ModAbility	N/A		Y
US_ModAbility	N/A		Y
DS_OFDM_ChAbility	N/A		Y
DS_OFDM_ID [d]	N		Y
PdRespInitPwr	N	Y	Y
PdRespPwrStep	N	Y	Y
DS_ModTypeSC(4) through *DS_ModTypeSC(4095)* [c]	N		Y
US_ModTypeSC(0) through *US_ModTypeSC(4095)*	N	Y	Y
EQ_CoefR(0) through *EQ_CoefR(4095)*	N		Y
EQ_CoefI(0) through E*Q_CoefI(4095)*	N		Y
OFDMA_ClkSync	Y [e]	T	T

[a]Y = a network reset is required before changing this variable, N = this variable can be changed without a network reset, N/A = not applicable.
[b]T = variable is TRUE, Y = variable has been written in the CNU via the PHY Link.
[c]*AllwdCNU_ID* is set using the CNU_ID Allocation special instruction (see 102.4.1.6).
[d]The downstream OFDM descriptor is written for each OFDM channel that contains active subcarriers.
[e]See Table 102–14.

In some instances the CNU may fail to achieve link-up status. This may happen for a number of reasons; for example the CNU may be unable to support the downstream or upstream Profile due to network conditions. In these circumstances the CLT may take mitigating action outside the scope of this standard and attempt to bring up the CNU at a later time.

102.4.4 Link-down declaration

There are three ways to declare a CNU in the Link-down state—CNU PHY self declared, CLT declared, CNU Upper layer declared. These are described in 102.4.4.1 through 102.4.4.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

102.4.4.1 CNU PHY self declared link-down

If any of the conditions listed in Table 102–14 become TRUE the CNU shall declare itself to be link-down and sets *LinkUpRdy*, *PhyDiscComplete,* and *PD_Enable* to FALSE. If subsequent analysis indicates the device is ready to re-join the EPoC network, as described in 102.4.1 it may do so by going through the normal discover process.

Table 102–14—Link-down causal conditions

Condition	Description
CNU OFDM Clock misaligned	|Received Timestamp – *LocalTS*| > 10
DS PHY Link loss of frame	Unable to decode the DS PHY Link frame for three or more consecutive frames
Change in DS OFDM channel count	Any provisioned change to *DS_ChCnt*
Change in DS time interleaver	Any provisioned change to *DS_TmrIntrlv*
Change of cyclic prefix length	Any provisioned change to *DSNcp* or *USNcp*
Change of OFDM channel frequency	Any provisioned change to *DS_FreqCh(1), DS_FreqCh(1), DS_FreqCh(2), DS_FreqCh(3), DS_FreqCh(4), DS_FreqCh(5) or US_FreqCh1*
Change of Resource Block size	Any provisioned change to RBsize
Change of Pilot structure	Any provisioned change to *Type2_Repeat, Type2_Start, Type1_Repeat* or *Type1_Start*
Change of PHY Link	Any provisioned change to *DS_PhyLinkStrt* or *US_PhyLnkStrt*
Change of PHY ranging offset	Any provisioned change to *PhyRngOffset*

102.4.4.2 CLT declared link-down

The CLT may declare a CNU to be in a link-down state by setting *PhyDiscComplete* to FALSE. It may further force the CNU to reassess its readiness for participation on the network by setting *PD_Enable* and *LinkUpRdy* to FALSE.

102.4.4.3 Upper layer declared link-down

The upper layers may declare a CNU to be in a link-down state by setting *PhyDiscComplete* to FALSE. It may further force the CNU to reassess its readiness for participation on the network by setting *PD_Enable* and *LinkUpRdy* to FALSE.

102.4.5 OFDM Profile descriptors

In the EPoC upstream and downstream link the OFDM profile is defined by the *DS_ModTypeSC(n)* and *US_ModTypeSC(n)* variables, respectively. Two copies of each profile variable set exist—an active copy and an inactive copy. During a profile switch (see 102.2.3.1) the network switches operation from the currently active profile to the inactive profile. Note that for the downstream profile there are five OFDM channels; the channel referred to by the *DS_ModTypeSC(n)* variable set is determined by the *DS_OFDM_ID* variable.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The currently active profile can be copied to the inactive profile via a profile copy. This is controlled via the *DS_PrflCpy*, *DS_CpyCh*, and *US_PrflCpy* variables. While the copy is in process, as indicated by the *DS_CpyInP* and *US_CpyInP* variables profile switches are prohibited and profile writes are ignored.

To update the entire downstream profile in an EPoC network that includes all five downstream OFDM channels the CLT first sets the *DS_OFDM_ID* variable to one then updates the changed *DS_ModTypeSC(n)* variables for the first OFDM channel. The CLT then proceeds to update the second OFDM channel by changing *DS_OFDM_ID* to two followed by any updates to the *DS_ModTypeSC(n)* variables for the second channel. This continues until all five OFDM channels have been updated. The final action the CLT takes is to update the *DS_CID* (see 102.2.3.1.1) to switch from the current active profile to the profile copy that was just updated by the above actions. The above description is an example only; the CLT need not update the downstream profile in its entirety nor in any particular order before the *DS_CID* switch.

102.4.5.1 PHY Link managed variables

DS_CpyCh

TYPE: 3-bit unsigned integer
This variable identifies which of the five downstream OFDM channel profiles (profile 1 to 5) is to be copied into the downstream profile variables.

DS_CpyInP

TYPE: Boolean
When set to a TRUE, this variable indicates that a copy of the currently active downstream profile to the inactive profile is in process. Note that while this variable has a value of TRUE writes to all downstream profile variables shall be ignored and switching between profiles is prohibited. This variable is set to FALSE by the PMA/PMD when the copy is completed.

DS_PrflCpy

TYPE: Boolean
When this variable is set to TRUE, a copy of the currently active downstream profile to the inactive profile is initiated. Once initiated this action continues to completion (i.e., it cannot be interrupted or aborted once initiated). This variable is set to FALSE by the PHY on or before completion of the profile copy.

US_CpyInP

TYPE: Boolean
When set to a TRUE, this variable indicates that a copy of the currently active upstream profile to the inactive profile is in process. Note that while this variable has a value of TRUE writes to all upstream profile variables shall be ignored and switching between profiles is prohibited. This variable is set to FALSE by the PMA/PMD when the copy is completed.

US_PrflCpy

TYPE: Boolean
When this variable is set to TRUE, a copy of the currently active upstream profile to the inactive profile is initiated. Once initiated this action continues to completion (i.e., it cannot be interrupted or aborted once initiated). This variable is set to FALSE by the PHY on or before completion of the profile copy.

102.5 Protocol implementation conformance statement (PICS) proforma for Clause 102, EPoC PHY Link[176]

102.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 102, EPoC PHY Link, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

102.5.2 Identification

102.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

102.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 102, EPoC PHY Link
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[176]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

103. Multipoint MAC Control for EPoC

103.1 Overview

This clause deals with the mechanism and control protocols required in order to reconcile the EPoC (EPON protocol over coax) into the Ethernet framework. The P2MP medium is a coax cable distribution network (CCDN) in which passive and active elements are present in the signal's path from source to destination. When combined with the EPON protocol, such a network is referred to as EPON protocol over coax network (EPoC).

P2MP is an asymmetric medium based on a tree (or tree-and-branch) topology. The DTE connected to the trunk of the tree is called cable line terminal (CLT) and the DTEs connected at the branches of the tree are called cable network units (CNU). The CLT typically resides at the service provider's facility, while the CNUs are located at the subscriber premises.

The EPoC topology is similar to the P2MP topology of EPON with the optical line terminal being replaced by a CLT, the optical network units replaced by CNU and operating over a coaxial network rather than an optical network.

A simplified P2MP topology example is depicted in Figure 103–1.

Topics dealt with in this clause include allocation of upstream transmission resources to different CNUs, discovery and registration of CNUs into the network, and reporting of congestion to higher layers to allow for dynamic bandwidth allocation schemes and statistical multiplexing across the CCDN.

This clause does not deal with topics including bandwidth allocation strategies, authentication of end-devices, quality-of-service definition, provisioning, or management.

This clause specifies the multipoint control protocol (MPCP) to operate a coax cable distribution network by defining a Multipoint MAC Control sublayer as an extension of the MAC Control sublayer defined in Clause 31, and supporting current and future operations as defined in Clause 31 and annexes.

Each CCDN consists of a node located at the root of the tree assuming the role of CLT, and multiple nodes located at the tree leaves assuming roles of CNUs. The network operates by allowing CNUs multiplexed in frequency and in time to share the upstream medium. The MPCP located at the CLT is responsible for timing the different transmissions. Reporting of congestion by the different CNUs may assist in optimally allocating the bandwidth across the CCDN.

Automatic discovery of end stations is performed, culminating in registration through binding of a CNU to a CLT port by allocation of a Logical Link ID (see LLID 76.2.6.1.3.2), and dynamic binding to a MAC connected to the CLT.

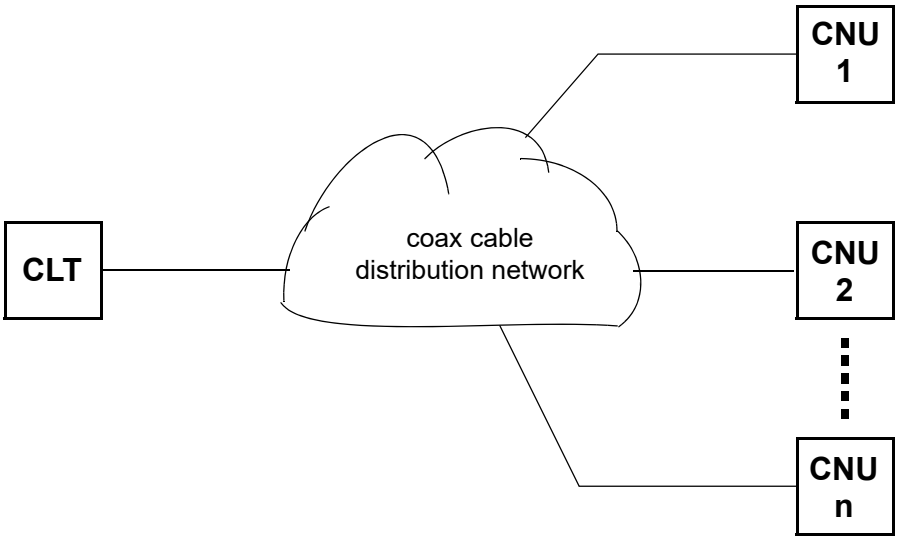

Figure 103–1—Coax cable distribution network topology example

The Multipoint MAC Control functionality shall be implemented for subscriber access devices containing point-to-multipoint Physical Layer devices defined in Clause 100, Clause 101, and Clause 102.

The EPoC Multipoint MAC Control shares much in common with the Multipoint MAC Control protocol defined in Clause 64 and Clause 77. There are a number of variables, constants and functions that are complementary to those defined for EPON Multipoint MAC Control but that are unique to EPoC. These are listed in Table 103–1.

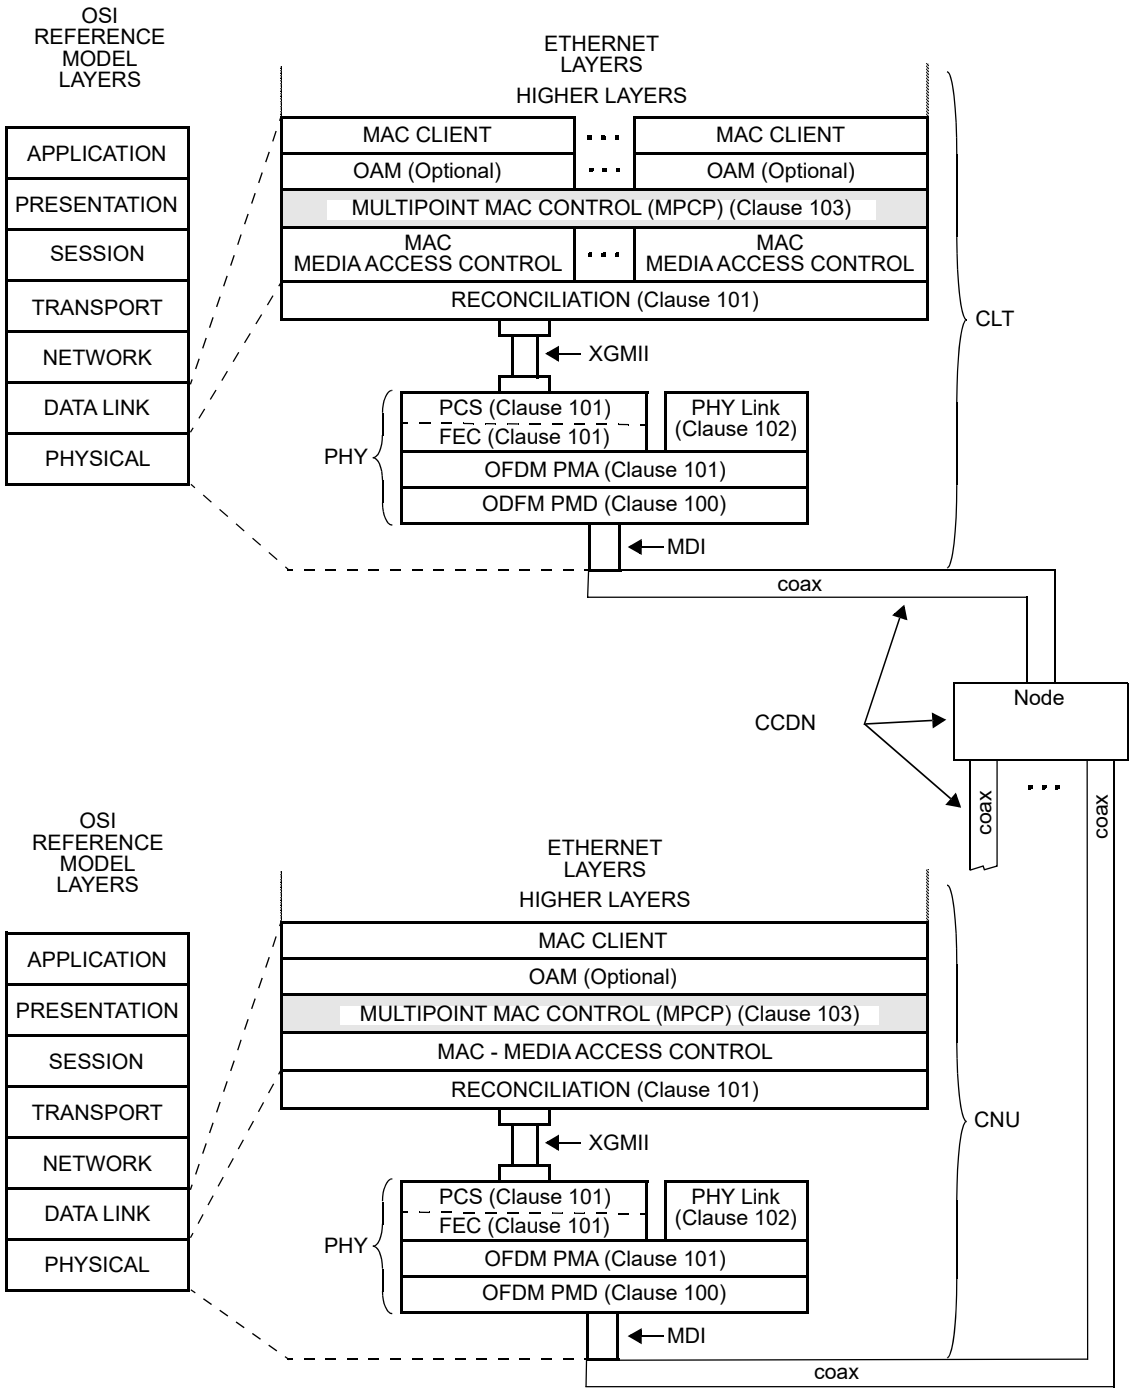
103.1.1 Position of Multipoint MAC Control within the IEEE 802.3 hierarchy

The Multipoint MAC Control in this clause defines the MAC control operation for point-to-multipoint networks over coaxial cable distribution networks. Figure 103–2 depicts the architectural positioning of the Multipoint MAC Control sublayer with respect to the MAC and the MAC Control client. The Multipoint MAC Control sublayer takes the place of the MAC Control sublayer to extend it to support multiple clients and additional MAC control functionality.

Multipoint MAC Control is defined using the mechanisms and precedents of the MAC Control sublayer. The MAC Control sublayer has extensive functionality designed to manage the real-time control and manipulation of MAC sublayer operation. This clause specifies the extension of the MAC Control mechanism to manipulate multiple underlying MACs simultaneously. This clause also specifies a specific protocol implementation for MAC Control.



The Multipoint MAC Control sublayer is specified such that it can support new functions to be implemented and added to this standard in the future. MultiPoint Control Protocol (MPCP), the management protocol for P2MP is one of these protocols. Non-real-time, or quasi-static control (e.g., configuration of MAC operational parameters) is provided by Layer Management. Operation of the Multipoint MAC Control sublayer is transparent to the MAC.

As depicted in Figure 103–2, the layered system instantiates multiple MAC entities, using a single Physical Layer. The individual MAC instances offer a point-to-point emulation service between the CLT and the CNU. An additional MAC is instantiated to communicate to all EPoC CNUs at once. This instance takes maximum advantage of the broadcast nature of the downstream channel by sending a single copy of a frame that is received by all EPoC CNUs. This MAC instance is referred to as Single Copy Broadcast (SCB).

The CNU only requires one MAC instance since frame filtering operations are done at the RS layer before reaching the MAC. Therefore, MAC and layers above are emulation-agnostic at the CNU.

Although Figure 103–2 and supporting text describe multiple MACs within the CLT, a single unicast MAC address may be used by the CLT. Within the EPoC Network, MACs are uniquely identified by their LLIDs, which are dynamically assigned by the registration process.

103.1.3 Service interfaces

See 77.1.4.

103.1.4 State diagram conventions

The body of this standard comprises state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2 augmented as follows:

a) [start x_timer, y] sets expiration of y to timer x_timer.

b) [stop x_timer] aborts the timer operation for x_timer asserting x_timer_not_done indefinitely.

The state diagrams use an abbreviation MACR as a shorthand form for MA_CONTROL.request and MACI as a shorthand form for MA_CONTROL.indication.

The vector notations used in the state diagrams for bit vector use 0 to mark the first received bit and so on (for example data[0:15]), following the conventions of 3.1 for bit ordering. When referring to an octet vector, 0 is used to mark the first received octet and so on (for example m_sdu[0..1]).

a < b: A function that is used to compare two (cyclic) time values. Returned value is TRUE when b is larger than a allowing for wrap around of a and b. The comparison is made by subtracting b from a and testing the MSB. When MSB(a – b) = 1 the value TRUE is returned, else FALSE is returned. In addition, the following functions are defined in terms of a < b:
a > b is equivalent to !(a < b or a = b)
a ≥ b is equivalent to !(a < b)
a ≤ b is equivalent to !(a > b)

103.1.5 Other conventions

For equations used in this clause the symbol $\lceil x \rceil$ represents a ceiling function that rounds up its argument x to the next highest integer; in pseudo code listing the term ceiling() is used for this function. The symbol $\lfloor x \rfloor$ represents a floor function that rounds down its argument x to the next lowest integer.

103.2 Multipoint MAC Control operation

As depicted in Figure 103–3, the Multipoint MAC Control functional block contains functions very similar to those found in Clause 77. In EPoC the CLT replaces the OLT and the CNU replaces the ONU. Significant differences are noted in 103.2.1 through 103.2.2.

103.2.1 Principles of Multipoint MAC Control

The principles of Multipoint MAC Control are the same as those described in 77.2.1 for EPON.

103.2.1.1 Ranging and timing process

The ranging and timing processes for EPoC are the same as those described in 77.2.1.1 for EPON.

103.2.2 Multipoint transmission control, Control Parser, and Control Multiplexer

The purpose and high level functionality of multipoint transmission control is similar to those described in 77.2.2 for EPON. Detailed differences are noted in the definitions below and in Figure 103–3 through Figure 103–13.

103.2.2.1 Constants

DS_FEC_CW_Sz
: TYPE: unsigned integer
This constant represents the integer number of octets in the FEC codeword and is equal to the sum of *DS_FEC_Pld_Sz* and *DS_FEC_Prty_Sz*.
VALUE: 1987

DS_FEC_CW_Sz_FRAC
: TYPE: real number
This constant represents the exact size of the FEC codeword expressed in units of octets.
VALUE: 1760 + 2944/13 or 1760 + (1840 × 64/65/8)

DS_FEC_Prty_Sz
: TYPE: unsigned integer
This constant represents the size of FEC codeword parity field in units of octets.
VALUE: 227

DS_FEC_Pld_Sz
: TYPE: unsigned integer
This constant represents the size of FEC codeword payload in units of octets.
VALUE: 1760 (220 block of 64 bits as seen from the MAC Table 101–2)

guardThresholdCLT
: TYPE: unsigned integer
This constant holds the maximum amount of drift allowed for a *timestamp* received at the CLT. This value is measured in units of *time_quantum*.
VALUE: 12

guardThresholdCNU
: TYPE: unsigned integer
This constant holds the maximum amount of drift allowed for a *timestamp* received at the CNU. This value is measured in units of *time_quantum*.
VALUE: 8

MAC_Control_type
: TYPE: unsigned integer
The value of the Length/Type field as defined in 31.4.1.3.
VALUE: 0x8808

tailGuard
: TYPE: unsigned integer
This constant holds the value used to reserve space at the end of the upstream transmission at the CNU in addition to the size of last MAC service data unit (m_sdu) in units of octets. Space is allocated for the MAC overheads including: preamble, SFD, DA, SA, Length/Type, FCS, and minimum interpacket gap. The sizes of the above listed MAC overhead items are described in 3.1.1. The size of the minimum IPG is described in 4A.4.2.
VALUE: 38

time_quantum
: This constant is defined in 64.2.2.1 and is 16 ns.

XGMII_Rate
: TYPE: unsigned integer
See 101.3.2.1.1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

103.2.2.2 Counters

localTime

TYPE: 32-bit unsigned integer
This counter is defined in 77.2.2.2 and holds the value of the local timer used to control MPCP operation.

103.2.2.3 Variables

BEGIN

TYPE: Boolean
This variable is used when initiating operation of the functional block state diagram. It is set to TRUE following initialization and every reset.

data_rx

TYPE: bit array
This variable is defined in 77.2.2.3 and represents a 0-based bit array corresponding to the payload of a received MPCPDU.

data_tx

TYPE: bit array
This variable is defined in 77.2.2.3 and represents a 0-based bit array corresponding to the payload of an MPCPDU being transmitted.

fecOffsetC

TYPE: 32-bit unsigned integer
A variable that advances by one after every octet time. In the CLT, after reaching the value of *DS_FEC_CW_Sz*, this variable is held for a period of time for PMD derating and then reset to zero as illustrated in Figure 103–8. In the CNU, this variable is assigned in Figure 103–13.

fecPldSz

TYPE: integer
fecPldSz is an alias for *DS_FEC_Pld_Sz.*

grantStart

TYPE: Boolean
This variable is defined in 77.2.2.3 and indicates beginning of a grant transmission.

IdleGapCount

TYPE: 32-bit unsigned integer
This variable defined in 77.2.2.3 represents length of gap between subsequent frames, expressed in the unit of octet time and advances by 1 after every 8-bit times.

initial_derating_delay

TYPE: 24 bit unsigned integer
This variable is used to set the time-out interval for *derating_timer* defined in 103.2.2.5 expressed in units of octets.

newRTT

TYPE: 16-bit unsigned integer
This variable is defined in 77.2.2.3 and temporarily holds a newly-measured Round Trip Time.

m_sdu_rx

TYPE: bit array
This varible is defined in 77.2.2.3 and is equal to the concatenation of the Length/Type and *data_rx* variables.

m_sdu_tx

TYPE: bit array

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable is defined in 77.2.2.3 and is equal to the concatenation of the Length/Type and *data_tx* variables.

m_sdu_ctl

TYPE: bit array
This varible is defined in 77.2.2.3 and is equal to the concatenation of the *MAC_Control_type* and *data_tx* variables.

Octet_CLK

TYPE: Boolean
This clear on read Boolean value is TRUE for every octet time period, i.e., the amount of time used to transmit one octet in 10Gb/s MAC data rate.

OctetsRemainingC

TYPE: 32-bit unsigned integer
This variable is an alias for the expression (((*stopTime* – *localTime*) × *tqSizeC*/128) – *tqOffset*). It denotes the number of octets that can be transmitted between the current time and the end of the grant.

OctetsRequired

TYPE: 16-bit unsigned integer
This variable is defined in 77.2.2.3 and represents a total transmission time of next packet and is used to check whether the next packet fits in the remainder of the transmission window. The value of *OctetsRequired* includes packet transmission time, *tailGuard* defined in 103.2.2.1, and FEC parity data overhead expressed in units of octets.

opcode_rx

TYPE: 16-bit unsigned integer
This variable is defined in 77.2.2.3 and holds an opcode of the last received MPCPDU.

opcode_tx

TYPE: 16-bit unsigned integer
This variable is defined in 77.2.2.3 and holds an opcode of an outgoing MPCPDU.

packet_initiate_delay

TYPE: 18-bit unsigned integer
This variable is defined in 77.2.2.3 and used to set the time-out interval for *packet_initiate_timerC* defined in 103.2.2.5 expressed in units of octets.

PCS_DS_Rate

See 101.3.2.1.2 and Equation (101–2).

ResetBoundC

TYPE: 32-bit unsigned integer
This variable represents the value of *DelayBound* (see 101.3.2.1.2) expressed in units of octet time (i.e., *ResetBoundC* = 8 × *DelayBound*).

RTT

TYPE: 16-bit unsigned integer
This variable is defined in 77.2.2.3 and holds the measured Round Trip Time to the CNU expressed in units of *time_quanta*.

stopTime

TYPE: 32-bit unsigned integer
This variable is defined in 77.2.2.3 and holds the value of the *localTime* counter corresponding to the end of the nearest grant.

timestamp

TYPE: 32-bit unsigned integer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable is defined in 77.2.2.3 and holds the value of *timestamp* of the last received MPCPDU frame.

timestampDrift

TYPE: Boolean
This variable is defined in 77.2.2.3 and used to indicate whether an error is signaled as a result of uncorrectable *timestamp* drift.

tqOffset

TYPE: 8-bit unsigned integer
This variable is defined in 77.2.2.3 and denotes the offset (in octet times) of the current actual time from the *localTime* variable.

tqSizeC

TYPE: unsigned integer
This variable represents the number of octets that can be transmitted in 128 *time_quantum* units, i.e., 2048 ns.

transmitAllowed

TYPE: Boolean
This variable is defined in 77.2.2.3 and used to control PDU transmission at the CNU.

transmitEnable

TYPE: Boolean array
This array is defined in 77.2.2.3 and used to control the transmit path in the Multipoint MAC Control instance at the CLT.

transmitInProgress

TYPE: Boolean array
This array is defined in 77.2.2.3 and indicates that the Multipoint MAC Control instance is in a process of transmitting a frame.

transmitPending

TYPE: Boolean array
This array is defined in 77.2.2.3 and indicates that a Multipoint MAC Control instance is ready to transmit a frame.

103.2.2.4 Functions

abs(n)

This function returns the absolute value of the parameter *n*.

Opcode–specific function(opcode)

These functions are defined in 77.2.2.4 and exported from *opcode* specific blocks that are invoked on the arrival of a MAC Control message of the appropriate *opcode*.

CheckGrantSizeC(length)

This function calculates the future time at which the transmission of the current frame (including the FEC parity overhead) is completed.

```
Function CheckGrantSizeC( length ){
   GntSize = 0;
   length += fecOffsetC;
   while (length > fecPldSz[0]) {      // Calc # of full Lg CW's
      length -= fecPldSz[0];
      GntSize += DS_FEC_CW_Sz_FRAC[0];
   }
   // Calc remaining 1 part Lg CW <OR> 2 Med CW
   // (2 full <OR> 1 full & 1 part) <OR> 1 Sm CW (full <OR> part)
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
    while (length > 0) {
       if (length > 6464) {
          GntSize += length + ceiling(length/64) + fecPrtySz[0];
       }
       else if (length >= fecPldSz[1]) {   // full Med CW
          GntSize += DS_FEC_CW_Sz_FRAC[1];
       }
       else if (length >= 1600) {          // partial Med CW
       GntSize += length + ceiling(length/64) + fecPrtySz[1];
       }
       else if (length >= fecPldSz[2]) {   // full Small CW
          GntSize += DS_FEC_CW_Sz_FRAC[2];
       }
       else {                              // partial Small CW
          GntSize += length + ceiling(length/64) + fecPrtySz[2];
       }
    }
    return GntSize - fecOffsetC;
}
```

PHY_Overhead(length)

This function calculates the additional amount of time (in octet times) that the MPCP control multiplexer waits following transmission of a frame of size *length* by the MAC. The additional time is added to allow the insertion of parity data into the frame by the PHY layer and to adjust the data rate to the effective data rate supported by the PCS and PMD. PHY_Overhead() returns the number of octets that the PHY inserts during transmission of a particular packet. Parameter *length* represents the size of an entire frame including preamble, SFD, DA, SA, Length/Type, FCS, and IPG, which are accounted for in *tailGuard*. The following formula is used to calculate the overhead:

$$PMD_Overhead(length) =$$

$$FEC_Overhead(length) + Derating_Overhead(length, \frac{XGMII_Rate}{PCS_DS_Rate})$$

$$FEC_Overhead(length) = 12 + DS_FEC_Prty_Sz \times \left\lfloor \frac{fecOffset + length}{DS_FEC_Pld_Sz} \right\rfloor$$

$$Derating_Overhead(length) =$$

$$\left\lceil \left(\frac{XGMII_Rate}{PCS_DS_Rate} - 1 \right) \times DS_FEC_CW_Sz_FRAC \times \left\lfloor \frac{fecOffset + length}{DS_FEC_Pld_Sz} \right\rfloor \right\rceil$$

select()

This function is defined in 77.2.2.4 and selects the next Multipoint MAC Control instance allowed to initiate transmission of a frame. The function returns an index to the *transmitPending* array for which the value is not FALSE. The selection criteria in the presence of multiple active elements in the list is implementation-dependent.

SelectFrame()

This function is defined in 77.2.2.4 and enables the interface that has a pending frame. If multiple interfaces have frames waiting at the same time, only one interface is enabled. The selection criteria is not specified, except for the case when some of the pending frames have

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Length/Type = MAC_Control. In this case, one of the interfaces with a pending MAC Control frame shall be enabled.

sizeof(sdu)
: This function is defined in 77.2.2.4 and returns the size of the *sdu* in octets.

transmissionPending()
: This function is defined in 77.2.2.4 and returns TRUE if any of the Multipoint MAC Control instances has a frame waiting to be transmitted.

103.2.2.5 Timers

derating_timer:
: This timer is used to suspend the advancing of *fecOffsetC* in order to derate the MAC frame transmission to be able to match the PMD rate.

packet_initiate_timerC
: This timer is used to delay frame transmission from MAC Control to avoid variable MAC delay while MAC enforces IPG after a previous frame. In addition, this timer increases inter-frame spacing just enough to accommodate the extra parity data to be added by the FEC encoder.

103.2.2.6 Messages

MAC:MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: The service primitive is defined in 31.3.

MCF:MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: The service primitive is defined in 31.3.

MAC:MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 31.3. The action invoked by this service primitive is not considered to end until the transmission of the frame by the MAC has concluded. The ability of the MAC control layer to determine this is implementation-dependent.

MCF:MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 31.3.

103.2.2.7 State diagrams

The Multipoint transmission control function in the CLT shall implement state diagrams shown in Figure 103–8 and Figure 103–9. Control parser function in the CLT shall implement the state diagram shown in Figure 103–10. Control parser function in the CNU shall implement the state diagram shown in Figure 103–11. Control multiplexer function in the CLT shall implement the state diagram shown in Figure 103–12. Control multiplexer function in the CNU shall implement the state diagram shown in Figure 103–13.

103.3 Multipoint Control Protocol (MPCP)

As depicted in Figure 103–3, the Multipoint MAC Control functional block comprises nearly the same functions and layering system as that described in 77.3. In EPoC the CLT replaces the OLT and the CNU replaces the ONU. All other significant differences are noted in 103.3.1 through 103.3.6.

103.3.1 Principles of Multipoint Control Protocol

The principles of the Multipoint Control Protocol are the same as those found in 77.3.1 except the EPoC system uses an Orthogonal Frequency Division Multiple Access (OFDMA) method in the upstream direction. In EPON the Multipoint Control Protocol, one and only one MAC is allowed to transmit at any given time. In EPoC the Multipoint Control Protocol allows multiple MACs to transmit in any given time but coincident transmitters are separated in frequency.

103.3.2 Compatibility considerations

103.3.2.1 PAUSE operation

See 77.3.2.1 and time constraints found at 103.3.2.4.

103.3.2.2 Optional Shared LAN emulation

Optional Shared LAN emulation for EPoC is the same as described in 77.3.2.2.

103.3.2.3 Multicast and single copy broadcast support

Multicast and single copy broadcast support in EPoC is the same as described in 77.3.2.3.

103.3.2.4 Delay requirements

The MPCP protocol relies on strict timing based on distribution of timestamps. A compliant implementation needs to guarantee a constant delay through the MAC and PHY in order to maintain the correctness of the timestamping mechanism. The actual delay is implementation-dependent; however, a complying implementation shall maintain a delay variation of no more than 1 *time_quantum* through the MAC.

The CLT shall not issue a gate message more than 1024 *time_quanta* into the future. The CNU shall process all messages in less than this period. The CLT shall not issue more than one message every 1024 *time_quanta* to a single CNU. The unit of *time_quantum* is defined in 64.2.2.1. The CLT shall ensure that a minimum gap time between bursts from any two CNUs equal to *RB_time_quanta* [see Equation (101–33)].

103.3.3 Discovery processing

Discovery processing in the EPoC is the same as described in 77.3.3 with the following exceptions. In EPoC, CNUs that have not completed PHY Discovery process (see 102.4.1) will not respond to Discovery GATE MPCPDUs. In the EPoC coax cable distribution network only one upstream data rate is allowed for a given configuration. The *laserOnTime* and *laserOffTime* parameters in 77.3.3 are replaced in EPoC with *rfOnTime* and *rfOffTime*, respectively.

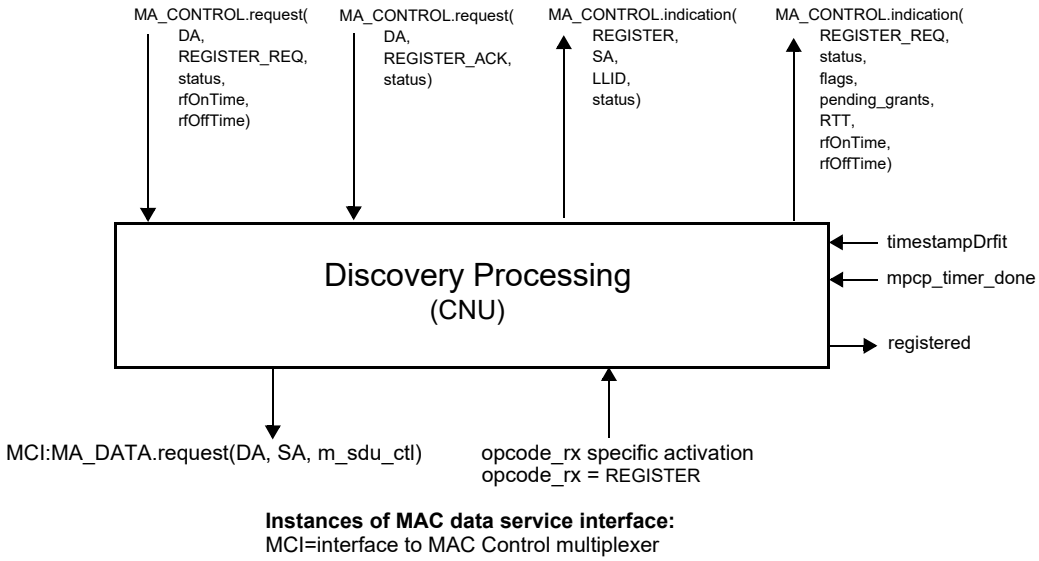

Figure 103–16—Discovery Processing service interfaces (CNU)

103.3.3.1 Constants

rfOffTime

TYPE: 8-bit unsigned integer
This variable holds the time required to terminate the RF and is included for consistency with Clause 77.
VALUE: zero

rfOnTime

TYPE: 8-bit unsigned integer
This variable holds the time required to initiate the PMD and is included for consistency with Clause 77.
VALUE: zero

103.3.3.2 Variables

BEGIN

This variable is defined in 103.2.2.3.

data_rx

This variable is defined in 103.2.2.3.

data_tx

This variable is defined in 103.2.2.3.

grantEndTime

TYPE: 32-bit unsigned integer
This variable is defined in 77.3.3.2 and holds the time at which the CLT expects the CNU grant to complete.

insideDiscoveryWindow

TYPE: Boolean
This variable is defined in 77.3.3.2 and holds the current status of the discovery window.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

localTime
: This variable is defined in 103.2.2.2.

m_sdu_ctl
: This variable is defined in 103.2.2.3.

opcode_rx
: This variable is defined in 103.2.2.3.

pendingGrants
: TYPE: 16-bit unsigned integer
This variable is defined in 77.3.3.2 and holds the maximum number of pending grants that a CNU is able to queue.

registered
: TYPE: Boolean
This variable is defined in 77.3.3.2 and holds the current result of the Discovery Process.

RB_time_quanta
: See Equation (101–33).

syncTime
: TYPE: 16-bit unsigned integer
This variable is defined in 77.3.3.2 and holds the time required to stabilize an EPON receiver at the OLT (see 76.3.2.5.3). The EPoC CLT OFDMA receiver is synchronized and stabilized during PHY Discovery and does not use a synchronization preamble as part of the upstream burst (see Figure 101–10). This variable is present to maintain compatibility with the EPON MPCP and always has a value of zero in EPoC PHYs.

timestampDrift
: This variable is defined in 103.2.2.3.

103.3.3.3 Timers

discovery_window_size_timer
: This timer is defined in 77.3.3.4 and used to wait for the event signaling the end of the discovery window.

mpcp_timer
: This timer is defined in 77.3.3.4 and used to measure the arrival rate of MPCP frames in the link.

103.3.3.4 Messages

MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: This service primitive is defined in 2.3.2.

MA_DATA.request (DA, SA, m_sdu)
: This service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, GATE, discovery, start, length, discovery_length, sync_time)
: This service primitive is used by the MAC Control client at the CLT to initiate the Discovery Process. This primitive takes the following parameters:

DA:	Multicast or unicast MAC address.
GATE:	Opcode for GATE MPCPDU as defined in Table 31A–1.
discovery:	Flag specifying that the given GATE message is to be used for discovery only.
start:	Start time of the discovery window.
length:	Length of the grant given for discovery.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

discovery_length: Length of the discovery window process.
sync_time: The time interval required to stabilize the receiver at the CLT.

MA_CONTROL.request(DA, GATE, grant_number, start[4], length[4], force_report[4])

This service primitive is used by the MAC Control client at the CLT to issue the GATE message to a CNU. This primitive takes the following parameters:

DA: Multicast MAC Control address as defined in Annex 31B.
GATE: Opcode for GATE MPCPDU as defined in Table 31A–1.
grant_number: Number of grants issued with this GATE message. The number of grants ranges from 0 to 4.
start[4]: Start times of the individual grants. Only the first grant_number elements of the array are used.
length[4]: Lengths of the individual grants. Only the first grant_number elements of the array are used.
force_report[4]: Flags indicating whether a REPORT message should be generated in the corresponding grant. Only the first grant_number elements of the array are used.

MA_CONTROL.request(DA,REGISTER_REQ,status,*rfOnTime*,*rfOffTime*)

This service primitive is used by a client at the CNU to request the Discovery Process to perform a registration. This primitive takes the following parameters:

DA: Multicast MAC Control address as defined in Annex 31B.
REGISTER_REQ: opcode for REGISTER_REQ MPCPDU as defined in Table 31A–1.
status: This parameter takes on the indication supplied by the flags field in the REGISTER_REQ MPCPDU as defined in Table 77–3.
rfOnTime: This parameter holds the *rfOnTime* value, expressed in units of *time_quanta*, as reported by MAC client and specified in 103.3.6.3.
rfOffTime: This parameter holds the *rfOffTime* value, expressed in units of *time_quanta,* as reported by MAC client and specified in 103.3.6.3.

MA_CONTROL.indication(REGISTER_REQ, status, flags, pending_grants, *RTT*, *rfOnTime*, *rfOffTime*)

The service primitive is issued by the Discovery Process to notify the client and Layer Management that the registration process is in progress. This primitive takes the following parameters:

REGISTER_REQ: Opcode for REGISTER_REQ MPCPDU as defined in Table 31A–1.
status: This parameter holds the values incoming or retry. Value incoming is used at the CLT to signal that a REGISTER_REQ message was received successfully. The value retry is used at the CNU to signal to the client that a registration attempt failed and needs to be repeated.
flags: This parameter holds the contents of the flags field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the CLT.
pending_grants: This parameter holds the contents of the pending_grants field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the CLT.
RTT: The measured round trip time to/from the CNU is returned in this parameter. *RTT* is stated in *time_quanta* units. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the CLT.
rfOnTime: This parameter holds the contents of the *rfOnTime* field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the CLT.
rfOffTime: This parameter holds the contents of the *rfOffTime* field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the CLT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

MA_CONTROL.request(DA, REGISTER, LLID, status, pending_grants, *rfOnTime*, *rfOffTime*)

The service primitive is used by the MAC Control client at the CLT to initiate acceptance of a CNU. This primitive takes the following parameters:

DA: Unicast MAC address or multicast MAC Control address as defined in Annex 31B.

REGISTER: Opcode for REGISTER MPCPDU as defined in Table 31A–1.

LLID: This parameter holds the logical link identification number assigned by the MAC Control client.

status: This parameter takes on the indication supplied by the flags field in the REGISTER MPCPDU as defined in Table 77–4.

pending_grants: This parameters echoes back the pending_grants field that was previously received in the REGISTER_REQ message.

rfOnTime: This parameter carries the target value of RF On Time for the given CNU transmitter. This value may be different than the *rfOnTime* value carried in the REGISTER_REQ MPCPDU received from the corresponding CNU MAC during Discovery stage.

rfOffTime: This parameter carries the target value of RF Off Time for the given CNU transmitter. This value may be different than the *rfOffTime* value carried in the REGISTER_REQ MPCPDU received from the corresponding CNU MAC during Discovery stage.

MA_CONTROL.indication(REGISTER, SA, LLID, status)

This service primitive is issued by the Discovery Process at the CLT or a CNU to notify the MAC Control client and Layer Management of the result of the change in registration status. This primitive takes the following parameters:

REGISTER: Opcode for REGISTER MPCPDU as defined in Table 31A–1.

SA: This parameter represents the MAC address of the CLT.

LLID: This parameter holds the logical link identification number assigned by the MAC Control client.

status: This parameter holds the value of accepted/denied/deregistered/reregistered.

MA_CONTROL.request(DA, REGISTER_ACK, status)

This service primitive is issued by the MAC Control clients at the CNU and the CLT to acknowledge the registration. This primitive takes the following parameters:

DA: Multicast MAC Control address as defined in Annex 31B.

REGISTER_ACK: Opcode for REGISTER_ACK MPCPDU as defined in Table 31A–1.

status: This parameter takes on the indication supplied by the flags field in the REGISTER MPCPDU as defined in Table 77–5.

MA_CONTROL.indication(REGISTER_ACK, SA, LLID, status, *RTT*)

This service primitive is issued by the Discovery Process at the CLT to notify the client and Layer Management that the registration process has completed. This primitive takes the following parameters:

REGISTER_ACK: Opcode for REGISTER_ACK MPCPDU as defined in Table 31A–1.

SA: This parameter represents the MAC address of the reciprocating device (CNU address at the CLT, and CLT address at the CNU).

LLID: This parameter holds the logical link identification number assigned by the MAC Control client.

status: This parameter holds the value of accepted/denied/reset/deregistered.

RTT: The measured round trip time to/from the CNU is returned in this parameter. *RTT* is stated in *time_quanta* units. This parameter holds a valid value only when the invoking Discovery Process in the CLT.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

103.3.3.5 State diagrams

The Discovery Process in the CLT shall implement the discovery window setup state diagram shown in Figure 103–17, request processing state diagram as shown in Figure 103–18, register processing state diagram as shown in Figure 103–19, and final registration state diagram as shown in Figure 103–20. The discovery process in the CNU shall implement the registration state diagram as shown in Figure 103–21.

Instantiation of state diagrams as described in Table 103–17, Table 103–18, and Table 103–19 is performed only at the Multipoint MAC Control instances attached to the broadcast LLID (0x7FFE). Instantiation of state diagrams as described in Table 103–20 and Table 103–21 is performed for every Multipoint MAC Control instance, except the instance attached to the broadcast channel.

103.3.4 Report Processing

Report processing in EPoC is as described in 77.3.4.

103.3.5 Gate Processing

Gate processing in EPoC is as described in 77.3.5 with the exception being that EPoC uses an RF transmitter rather than a laser.

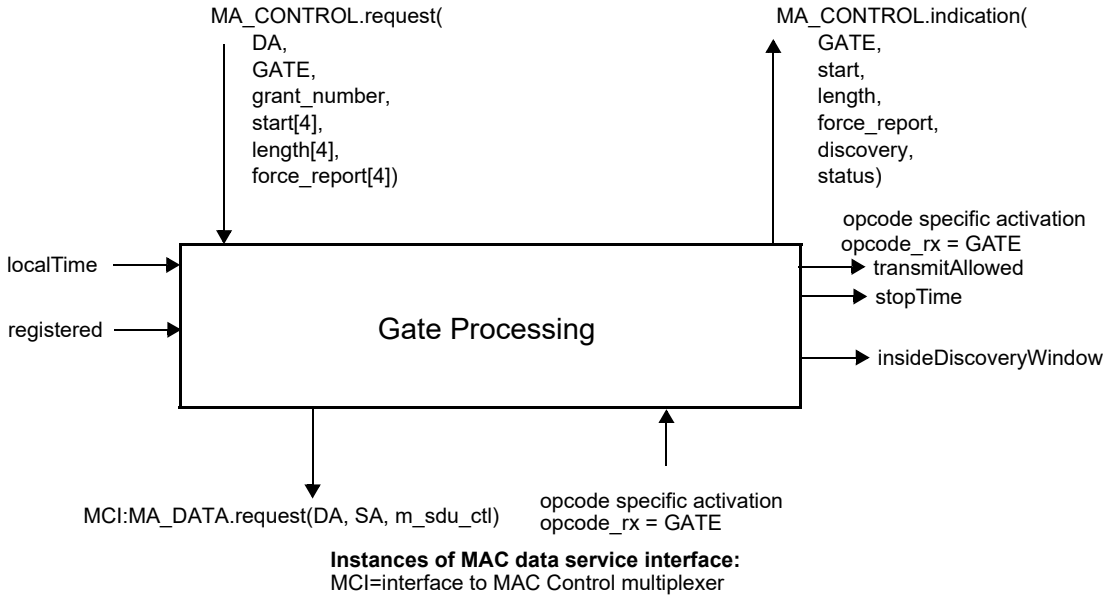

Figure 103–22—Gate Processing service interface

103.3.5.1 Constants

max_future_grant_time
: TYPE: 32-bit unsigned integer
This constant is defined in 77.3.5.1 and holds the time limiting the future time horizon for a valid incoming grant.
VALUE: 0x03-B9-AC-A0 (1 s)

min_processing_time
: TYPE: 32-bit unsigned integer
This constant is defined in 77.3.5.1and holds the time required for the CNU processing.
VALUE: 0x00-00-04-00 (16.384 μs)

103.3.5.2 Variables

BEGIN
: This variable is defined in 103.2.2.3.

BurstOverhead
: TYPE: integer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable represents the burst overhead and returned by the BurstTimeHeader() function (see 101.3.2.5.7).

counter

TYPE: integer
This variable is used as a loop iterator counting the number of incoming grants in a GATE message.

currentGrant

TYPE:

```
structure
{
    DA:             48-bit unsigned, a.k.a MAC address type
    start           32-bit unsigned
    length          16-bit unsigned
    force_report    Boolean
    discovery       Boolean
}
```

This variable is defined in 77.3.5.2 and used for local storage of a pending grant state during processing. It is dynamically set by the Gate Processing functional block and is not exposed. The state is a structure field composed of multiple subfields.

data_rx

This variable is defined in 103.2.2.3.

data_tx

This variable is defined in 103.2.2.3.

effectiveLengthC

TYPE: 32-bit unsigned integer
This variable is used for temporary storage of a normalized net time value. It holds the net effective length of a grant, normalized for elapsed time.

gate_timeout

TYPE: 32-bit unsigned integer
This variable is defined in 77.3.5.2 and represents the maximum allowed interval of time between two GATE messages generated by the CLT to the same CNU, expressed in units of time_quanta.
VALUE: 0x00-2F-AF-08 (50 ms, default value)

grantList

TYPE: list of elements having the structure define in *currentGrant*
This variable is defined in 77.3.5.2 and used for storage of the list of pending grants. It is dynamically set by the Gate Processing functional block and is not exposed. Each time a grant is received it is added to the list. The list elements are structure fields composed of multiple subfields. The list is indexed by the start subfield in each element for quick searches.

grantStart

This variable is defined in 103.2.2.3.

insideDiscoveryWindow

This variable is defined in 103.3.3.2.

m_sdu_ctl

This variable is defined in 103.2.2.3.

maxDelay

TYPE: 16-bit unsigned integer
This variable is defined in 77.3.5.2 and holds the maximum delay that can be applied by a

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

CNU before sending the REGISTER_REQ MPCPDU. This delay is calculated such that the CNU would have sufficient time to transmit the REGISTER_REQ message and its associated overhead (FEC parity data, end-of-frame sequence, etc.) and terminate the RF before the end of the discovery grant.

minGrantLengthC

TYPE: 32-bit unsigned integer
This variable represents the minimum data portion of a grant expressed in units of time_quanta. The *minGrantLengthC* is related to the minimum size Ethernet frame plus EPON overhead of 72 bytes (576 bits) processed as per 101.3.2.5.2 using a short codeword plus two IDLE blocks and one block for Burst Time Header. This results in a shortened codeword length of 1091 bits. The minimum grant length will include stop and end burst marker overhead based on *RBsize* and *RB_time_quanta* [see Equation (101–33)]:

Number_of_Burst_RBs is 8 for *RBsize* = FALSE or 4 for *RBsize* = TRUE

RB_total_time = *RB_time_quanta* × *Number_of_Burst_RBs*.

The value of *minGrantLengthC* is based on the *time_quanta* required for the number of Resource Blocks needed to transmit the 1091 data bits based on *US_DataRate* plus *RB_total_time*:

Data_TQ = 1091 / *US_DataRate*/*time_quantum*

minGrantLengthC = ceiling(*Data_TQ*/*RB_time_quanta*) × *RB_time_quanta* + *RB_total_time*

nextGrant

TYPE: element having same structure as defined in *currentGrant*
This variable is defined in 77.3.5.2 and used for local storage of a pending grant state during processing. It is dynamically set by the Gate Processing functional block and is not exposed. The content of the variable is the next grant to become active.

nextStopTime

TYPE: 32-bit unsigned integer
This variable is defined in 77.3.5.2 and holds the value of the *localTime* counter corresponding to the end of the next grant.

opcode_rx

This variable is defined in 103.2.2.3.

registered

This variable is defined in 103.3.3.2.

stopTime

This variable is defined in 103.2.2.3.

syncTime

This variable is defined in 103.3.3.2.

transmitAllowed

This variable is defined in 103.2.2.3.

103.3.5.3 Functions

empty(list)

This function is defined in 77.3.5.3 and used to check whether the list is empty. When there are no elements queued in the list, the function returns TRUE. Otherwise, a value of FALSE is returned.

InsertInOrder(sorted_list, inserted_element)

This function is defined in 77.3.5.2 and used to queue an element inside a sorted list. The queu-

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ing order is sorted. In the condition that the list is full the element may be discarded. The length of the list is dynamic and its maximum size equals the value advertised during registration as maximum number of pending grants.

IsBroadcast(grant)
: This function is defined in 77.3.5.3 and used to check whether its argument represents a broadcast grant, i.e., grant given to multiple CNUs. This is determined by the destination MAC address of the corresponding GATE message. The function returns the value TRUE when MAC address is a global assigned MAC Control address as defined in Annex 31B, and FALSE otherwise.

PeekHead(sorted_list)
: This function is defined in 77.3.5.3 and used to check the content of a sorted list. It returns the element at the head of the list without dequeuing the element.

Random(r)
: This function is defined in 77.3.5.3 and used to compute a random integer number uniformly distributed between 0 and *r*. The randomly generated number is then returned by the function.

RemoveHead(sorted_list)
: This function is defined in 77.3.5.3 and used to dequeue an element from the head of a sorted list. The return value of the function is the dequeued element.

103.3.5.4 Timers

gntWinTmr
: This timer is defined in 77.3.5.4 and used to wait for the event that signals the end of a grant window.
VALUE: The timer value is dynamically set according to the signaled grant length.

gate_periodic_timer
: This timer is defined in 77.3.5.4 and counts down time remaining before a forced generation of a GATE message in the CLT. The CLT is required to generate GATE MPCPDUs with a periodicity of less than *gate_timeout* value.

mpcp_timer
: This timer is defined in 103.3.3.3.

rndDlyTmrC
: This timer is used to measure a random delay inside the discovery window. The purpose of the delay is to a priori reduce the probability of transmission overlap during the registration process, and thus lowering the expectancy of registration time in the CCDN.
VALUE: A random value less than the net discovery window size less the REGISTER_REQ MPCPDU frame size less the idle period and RF turn on and off delays less the preamble size less the IFG size. The timer value is set dynamically based on the parameters passed from the client.

103.3.5.5 Messages

MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, GATE, grant_number, start[4], length[4], force_report[4])
: This service primitive is defined in 103.3.3.4.

MA_CONTROL.indication(GATE, start, length, force_report, discovery, status)
: This service primitive issued by the Gate Process at the CNU to notify the MAC Control client and higher layers that a grant is pending. This primitive is invoked multiple times when a sin-

Copyright © 2022 IEEE. All rights reserved.

gle GATE message arrives with multiple grants. It is also generated at the start and end of each grant as it becomes active. This primitive uses the following parameters:

GATE: Opcode for GATE MPCPDU as defined in Table 31A–1.

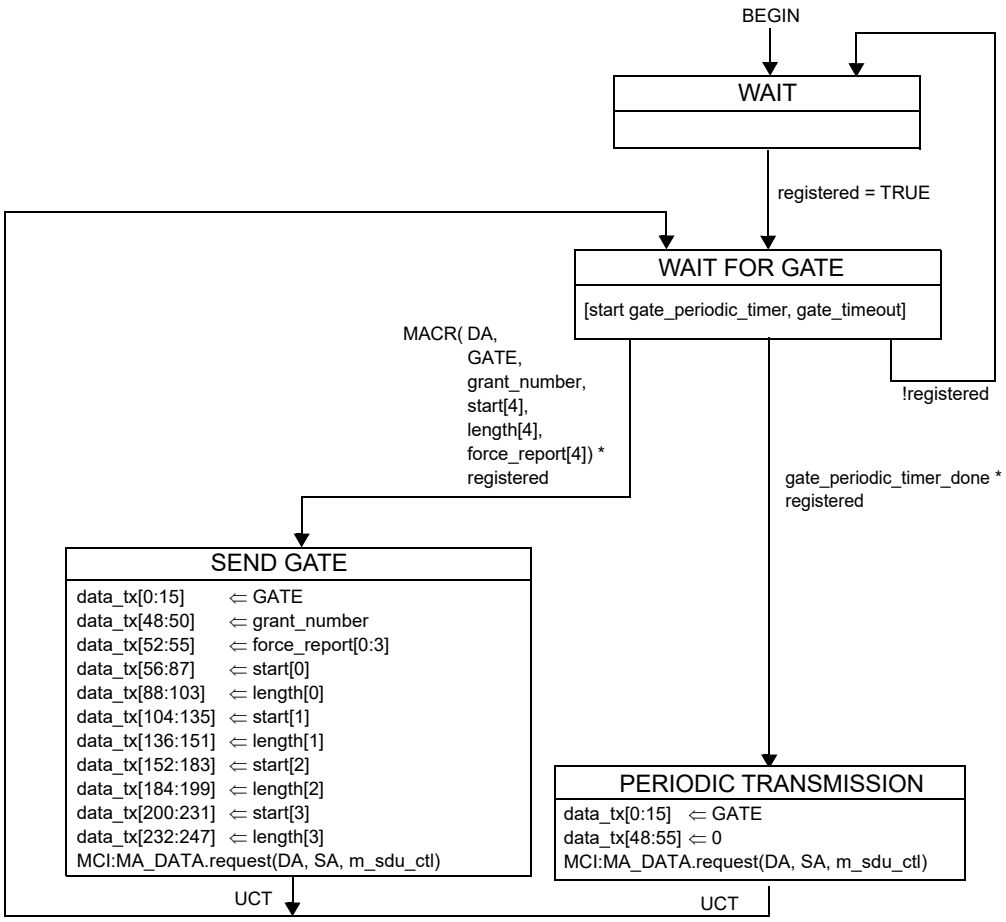
start: Start time of the grant. This parameter is not present when the parameter status value is equal to deactive.

length: Length of the grant. This parameter is not present when the parameter status value is equal to deactive.

force_report: Flags indicating whether a REPORT message should be transmitted in this grant. This parameter is not present when the parameter status value is equal to deactive.

discovery: This parameter holds the value TRUE when the grant is to be used for the discovery process, and FALSE otherwise. This parameter is not present when the parameter status value is equal to deactive.

status: This parameter takes the value arrive on grant reception, active when a grant becomes active, and deactive at the end of a grant.



Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

103.3.5.6 State diagrams

The gating process in the CLT shall implement the Gate processing state diagram as shown in Figure 103–23. The gating process in the CNU shall implement the Gate processing state diagram as shown in Figure 103–24 and Figure 103–25. Instantiation of state diagrams as described is performed for all Multipoint MAC Control instances.

103.3.6 MPCPDU structure and encoding

The generic MPCPDU structure and encoding in EPoC is as described in 77.3.6 The MPCPDU structure shall be as shown in Figure 77–31. Changes to specific MPCPDU messages are noted in 103.3.6.1 through 103.3.6.5.

103.3.6.1 GATE description

The GATE MPCPDU used in EPoC is the same as that described in 77.3.6.1 with the following exceptions. In EPoC *rfOnTime* and *rfOffTime* replace *laserOnTime* and *laserOffTime*, respectively. The Sync Time and Discovery Information fields described in 77.3.6.1 are not used in EPoC and shall be set to zero on transmit and ignored on reception.

103.3.6.2 REPORT description

The REPORT MPCPDU used in EPoC is the same as that described in 77.3.6.2.

103.3.6.3 REGISTER_REQ description

The REGISTER_REQ MPCPDU used in EPoC and illustrated in Figure 103–26 is the same as that described in 77.3.6.3 with the following exceptions. The Discovery Information field described in 77.3.6.3 is not used in EPoC and shall be set to zero on transmit and ignored on reception.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

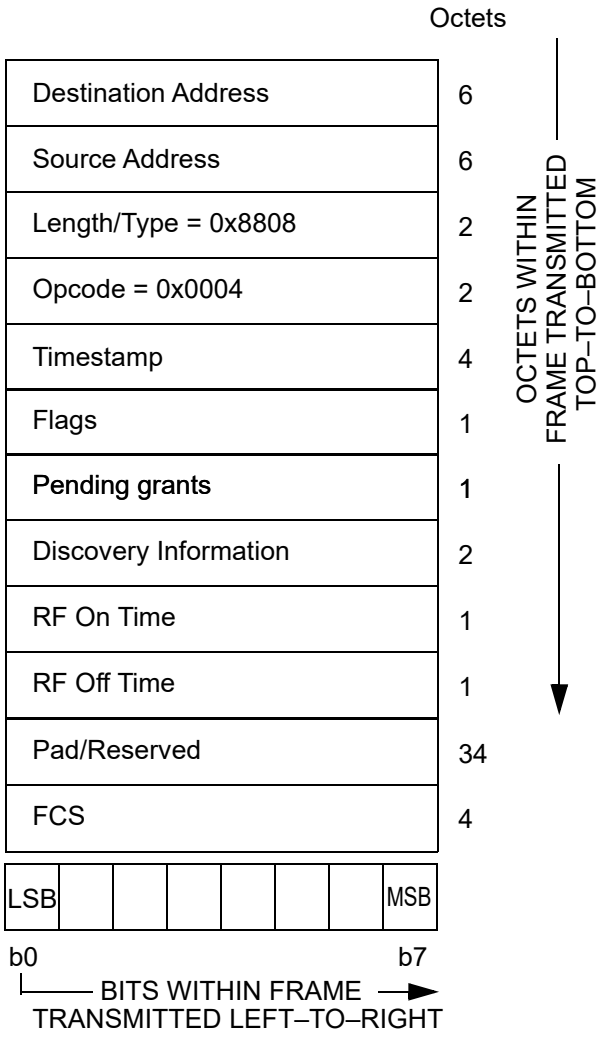

Figure 103–26—REGISTER_REQ MPCPDU

103.3.6.4 REGISTER description

The REGISTER MPCPDU used in EPoC and illustrated in Figure 103–27 is the same as that described in 77.3.6.4 with the following exceptions. In EPoC, the Sync Time field is calculated using *rfOnTime*, *rfOffTime* rather than the *laserOnTime* and *laserOffTime* used in 77.3.6.4.

103.4 Protocol implementation conformance statement (PICS) proforma for Clause 103, Multipoint MAC Control for EPoC[177]

103.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 103, Multipoint MAC Control for EPoC, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

103.4.2 Identification

103.4.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

103.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 103, Multipoint MAC Control for EPoC
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[177] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

104. Power over Data Lines (PoDL) of Single-Pair Ethernet

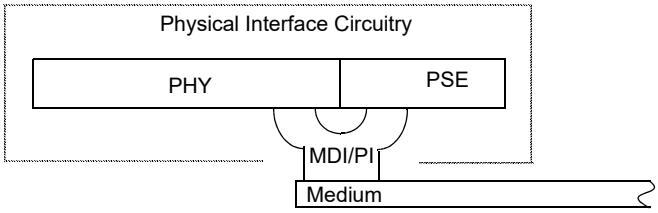
104.1 Overview

This clause defines the functional and electrical characteristics of two optional power entities, a PoDL Powered Device (PD) and PoDL Power Sourcing Equipment (PSE), for use with supported single balanced twisted-pair Ethernet Physical Layers. When used in this clause, the term PSE always means PoDL PSE, and the term PD always means PoDL PD. These entities allow devices to supply/draw power using the same cabling that may be used for data transmission. PoDL is intended to provide a single balanced twisted-pair Ethernet Physical Layer device with a single interface to both the data it requires and the power to process this data. This clause specifies the following:

a) The characteristics of a power source to add power to the 100 Ω single balanced twisted-pair cabling system.
b) The characteristics of a PD's load on the power source and the cabling.
c) Certain electrical parameters of each MDI/PI that may be different from that specified in the PHY clause when power is simultaneously transmitted with data.
d) Physical Layer protocols allowing the detection of a device that requests power from a PSE and classification of the device based on its power needs.
e) A method for Powered Devices and Power Sourcing Equipment to negotiate and allocate power.
f) A method for scaling supplied voltage back to the sleep level when full operating voltage is no longer requested or required.

This clause differentiates between the two ends of the link, defining the PSE and the PD as separate but related devices within a PoDL system.

104.1.1 Compatibility considerations



Compliant implementations of PD and PSE systems are defined as compatible at their respective Power Interfaces (PIs) when used in accordance with the restrictions of this clause. Designers are free to implement circuitry within the PD and PSE in an application-dependent manner provided that the respective PI specifications are satisfied. MDIs that incorporate compliant PoDL PIs are compatible with their respective Physical Layer standards. Such compatibility may require additional specifications found within this clause (see 104.6).

104.1.2 Relationship of PoDL to the IEEE 802.3 architecture

PoDL is an optional power entity to be used in conjunction with supported single-pair Ethernet Physical Layers. Data that is out of band to normal Ethernet traffic may be transmitted and received between the PSE and PD prior to the application of power and subsequent to the removal of full operating voltage via the MDI using the Serial Communication Classification Protocol (SCCP) which is described in 104.7.

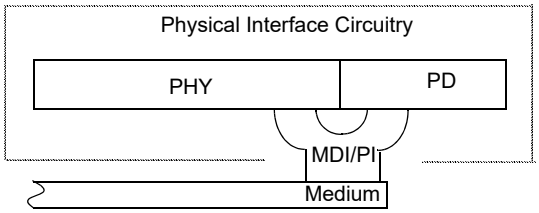


Figure 104–1 depicts the positioning of PoDL for the PSE. Figure 104–2 depicts the positioning of PoDL in the case of the PD.

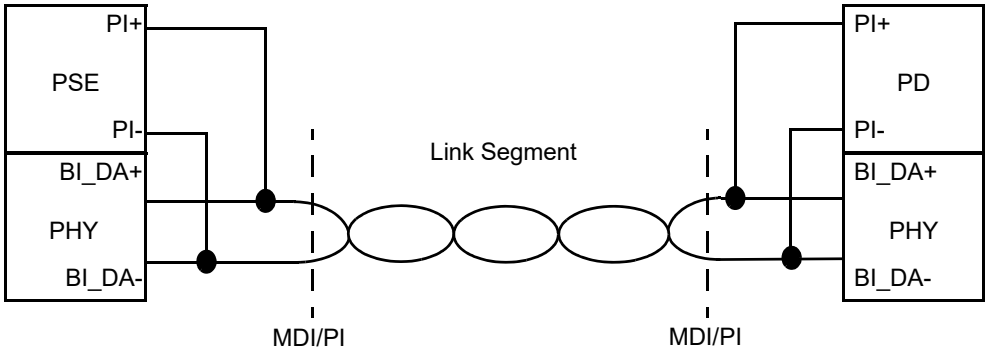
MDI = Medium Dependent Interface
PHY = Physical Layer Device
PI = Power Interface
PSE = Power Sourcing Equipment

Figure 104–1—PoDL Power Sourcing Equipment (PSE) relationship to the physical interface circuitry and the IEEE 802.3 Ethernet model

MDI = Medium Dependent Interface
PD = Powered Device
PHY = Physical Layer Device
PI = Power Interface

Figure 104–2—PoDL Powered Device (PD) relationship to the physical interface circuitry (PHY) and the IEEE 802.3 Ethernet model

The Power Interface (PI) is the generic term that refers to the mechanical and electrical interface between the PSE or PD and the transmission medium. The PI is encompassed within the MDI.



104.1.3 PoDL system types

A PoDL system consists of a PSE, a link segment, and a PD. PoDL systems are not specified for mixing segments.

A Type A or Type C PSE and Type A or Type C PD are compatible with 10BASE-T1S and 100BASE-T1 PHYs. A Type B or Type C PSE and Type B or Type C PD are compatible with 1000BASE-T1 PHYs. A Type C PSE and Type C PD are compatible with 10BASE-T1S, 100BASE-T1, and 1000BASE-T1 PHYs. Type D PSEs and Type D PDs may be incompatible with IEEE 802.3 PHYs and may lack a data entity. A Type E PSE and Type E PD are compatible with 10BASE-T1L PHYs. A Type F PSE and Type F PD are compatible with 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs.

Figure 104–3 illustrates the block diagram for a PoDL system.

NOTE—PI elements that prevent loading of the data signal by the PSE and PD are not shown. PHY elements that block dc are not shown.

Figure 104–3—PoDL system block diagram

104.2 Link segment

The dc loop resistance of the link segment shall be less than 6 Ω for classes 0 and 1. The dc loop resistance shall be less than 6.5 Ω for classes 2 through 9. The link segment dc loop resistance shall be less than 65 Ω for classes 10 and 13. The link segment dc loop resistance shall be less than 25 Ω for classes 11 and 14. The link segment dc loop resistance shall be less than 9.5 Ω for classes 12 and 15.

104.3 Class power requirements

PSEs and PDs are further categorized by their class. These classes and the relevant electrical specifications are shown in Table 104–1 and Table 104–2.

Table 104–1—Class power requirements matrix for PSE, PI, and PD for classes 0 through 9

	12 V unregulated PSE		12 V regulated PSE		24 V unregulated PSE		24 V regulated PSE		48 V regulated PSE	
Class	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
$V_{PSE(max)}$ (V)[a]	18	18	18	18	36	36	36	36	60	60
$V_{PSE_OC(min)}$ (V)[b]	6	6	14.4	14.4	12	12	26	26	48	48
$V_{PSE(min)}$ (V)	5.6	5.77	14.4	14.4	11.7	11.7	26	26	48	48
$I_{PI(max)}$ (mA)[c]	101	227	249	471	97	339	215	461	735	1 360
$P_{Class(min)}$ (W)[d]	0.566	1.31	3.59	6.79	1.14	3.97	5.59	12	35.3	65.3

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 104–1—Class power requirements matrix for PSE, PI, and PD for classes 0 through 9 *(continued)*

	12 V unregulated PSE		12 V regulated PSE		24 V unregulated PSE		24 V regulated PSE		48 V regulated PSE	
Class	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
$V_{PD(min)}$ (V)	4.94	4.41	12	10.6	10.3	8.86	23.3	21.7	40.8	36.7
$P_{PD(max)}$ (W)[e]	0.5	1	3	5	1	3	5	10	30	50

[a]$V_{PSE(max)}$ is the maximum allowed voltage at the PSE PI over the full range of operating conditions.
[b]$V_{PSE_OC(min)}$ is the minimum allowed open circuit voltage measured at the PSE PI.
[c]$I_{PI(max)}$ is the maximum current flowing at the PSE and PD PIs except during inrush or an overload condition. $I_{PI(max)}$ may be exceeded during inrush or an overload (see 104.4.7.2). Users are cautioned to be aware of the ampacity of cabling, as installed, and local codes and regulations (see 104.8.1).
[d]$P_{Class(min)}$ is the minimum average available output power at the PSE PI.
[e]$P_{PD(max)}$ is the maximum average available power at the PD PI.

Table 104–2—Class power requirements matrix for PSE, PI, and PD for classes 10 through 15

Class	**10**	**11**	**12**	**13**	**14**	**15**
$V_{PSE(max)}$ (V)	30	30	30	58	58	58
$V_{PSE_OC(min)}$ (V)	20	20	20	50	50	50
$V_{PSE(min)}$ (V)	20	20	20	50	50	50
$I_{PI(max)}$ (mA)	92	240	632	231	600	1579
$P_{class(min)}$ (W)	1.85	4.8	12.63	11.54	30	79
$V_{PD(min)}$ (V)	14	14	14	35	35	35
$P_{PD(max)}$ (W)	1.23	3.2	8.4	7.7	20	52

104.4 Power Sourcing Equipment (PSE)

The PSE provides power to the PD. The PSE's main functions are as follows:

a) To search the link segment for a PD
b) To supply power to a detected PD through the link segment
c) To monitor the power applied to a link segment
d) To remove the full operating voltage when no longer required, when transitioning to the SLEEP state, or when a short-circuit or other fault is detected

Voltage and power classification mechanisms exist via the Serial Communication Classification Protocol (SCCP) to provide the PSE with detailed information regarding the requirements of the PD and vice versa.

A PSE is specified by its electrical and logical behavior as seen at the PI.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

104.4.1 PSE types

For PoDL systems there are multiple types of PSEs—Type A, Type B, Type C, Type D, Type E, and Type F consistent with 104.1.3.

104.4.2 PI pin assignments

A PSE provides power via a single two-wire connection. Table 104–3 in conjunction with Figure 104–3 illustrates the PSE pinout.

Table 104–3—PSE pinout

Contact	PI
1	PI+
2	PI–

A PSE shall implement the PSE pinout in Table 104–3.

104.4.3 PSE classes

A PSE shall comply with the voltage and power requirements listed in Table 104–1 for the relevant class.

104.4.4 PSE state diagram

The PSE shall implement the behavior of the state diagrams shown in Figure 104–4, Figure 104–5, and Figure 104–6.

104.4.4.1 Overview

Prior to application of full operating voltage at the PI, the PSE performs detection in order to verify that a valid PD is present. A PSE may apply full operating voltage if it is able to successfully classify the PD using SCCP.

After full operating voltage has been applied, the PSE monitors the PI for a valid Maintain Full Voltage Signature (MFVS) from the PD. In the event a valid MFVS is not present, the PSE reduces the voltage at the PI to the range of V_{Sleep}. If an external wakeup request is received or if a valid wakeup current signature is detected at the PI, the PSE confirms that a valid PD is present by re-performing detection and, if enabled, classification before reapplying full operating voltage to the PI.

Additionally, while voltage is applied, the PSE monitors the current drawn and removes power if it detects an overload, short-circuit, or other fault.

104.4.4.2 Conventions

The notation used in the state diagrams follows the conventions of state diagrams as described in 21.5.

104.4.4.3 Variables

The PSE state diagrams use the following variables:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

detection_done
TRUE: the detection sequence has terminated since the last entry to the IDLE state either as a result of a valid or invalid signature being detected.
FALSE: the detection sequence has not terminated since the last entry to the IDLE state either as a result of a valid or invalid signature being detected.

do_classification_done
TRUE: following a detection sequence, the PSE has concluded serial communication after performing a read of the PD information and any additional implementation dependent read or write commands.
FALSE: following a detection sequence, the PSE has not concluded serial communication after performing a read of the PD information and any additional implementation dependent read or write commands.

external_wakeup
TRUE: while in the SLEEP state, the PSE has received an external wakeup request.
FALSE: while in the SLEEP state, the PSE has not received an external wakeup request.

iprebias_valid
TRUE: the PSE pre-bias output current is valid (see 104.4.7.2.3).
FALSE: the PSE pre-bias output current is invalid (see 104.4.7.2.3).

mfvs_timeout
TRUE: the MFVS dropout timer has timed out.
FALSE: the MFVS dropout timer has not timed out.

mfvs_valid
TRUE: MFVS is present (see 104.4.8.1).
FALSE: MFVS is absent (see 104.4.8.1).

mr_pse_enable
TRUE: enable operation of the PSE.
FALSE: disable operation of the PSE.

mr_sccp_enabled
TRUE: SCCP is enabled (see 104.7).
FALSE: SCCP is not enabled (see 104.7).

mr_invalid_signature
TRUE: an invalid signature has been detected during the detection cycle subsequent to the last idle sequence.
FALSE: an invalid signature has not been detected.

mr_valid_signature
TRUE: a valid PD signature has been detected during the detection cycle subsequent to the last idle sequence.
FALSE: a valid PD signature has not been detected.

overload_detected
TRUE: the PSE has detected an overload condition (see 104.4.7.2.1).
FALSE: the PSE has not detected an overload condition.

overload_held
TRUE: overload_detected has been TRUE since last entry to the IDLE state.
FALSE: overload_detected has been FALSE since last entry to the IDLE state.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_wakeup
TRUE: while in the SLEEP state, the PSE has detected a valid wakeup current signature.
FALSE: while in the SLEEP state, the PSE has not detected a valid wakeup current signature.

pi_classifying
TRUE: the PSE is performing classification at the PI (see 104.7).
FALSE: the PSE is not performing classification at the PI.

pi_detecting
TRUE: the circuitry that forces a voltage limited detection current and senses the voltage at the PI is enabled (see 104.4.5).
FALSE: the circuitry that forces a voltage limited detection current and senses the voltage at the PI is disabled.

pi_discharge_en
TRUE: the circuitry that discharges the PI to V_{Sleep} is enabled.
FALSE: the circuitry that discharges the PI to V_{Sleep} is disabled.

pi_powered
TRUE: the circuitry that applies full operating voltage to the PI is enabled.
FALSE: the circuitry that applies full operating voltage to the PI is disabled.

pi_prebiased
TRUE: the circuitry that applies V_{Sleep} at the PI during the RESTART, RESTART_DELAY, and IDLE states is enabled (see 104.4.7.1).
FALSE: the circuitry that applies V_{Sleep} at the PI is disabled.

pi_sleeping
TRUE: the circuitry that applies V_{Sleep} at the PI during the SETTLE_SLEEP and SLEEP states is enabled (see 104.4.7.1).
FALSE: the circuitry that applies V_{Sleep} at the PI is disabled.

power_stable
TRUE: following inrush, the PSE has begun steady-state operation.
FALSE: the PSE is either not applying full operating voltage or has begun applying full operating voltage but is still in the POWER_UP state.

power_available
TRUE: a compatible PSE class to PD class pairing exists as defined in Table 104–4 and Table 104–5, and the PSE is able to source the required voltage and power.
FALSE: a valid PSE class to PD class pairing does not exist as defined in Table 104–4 and Table 104–5, or the PSE is not able to source the required voltage and power.

pse_ready
TRUE: the PSE is ready to probe the link segment.
FALSE: the PSE is not ready to probe the link segment.

pse_reset
Controls the resetting of the PSE state diagram. Condition that is TRUE until such time as the power supply for the device that implements the PSE overall state diagrams has reached the operating region. It is also TRUE when implementation-specific reasons require reset of PSE functionality.

valid_class
TRUE: valid class information was received from the PD during SCCP.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FALSE: valid class information was not received from the PD during SCCP.

vsleep_valid

TRUE: V_{PSE} is in the range of V_{Sleep}.
FALSE: V_{PSE} is outside the range of V_{Sleep}.

vsig_valid

TRUE: a valid PD signature has been detected as defined in 104.4.5.2 and 104.4.5.3.
FALSE: an invalid PD signature has been detected as defined in 104.4.5.2 and 104.4.5.3.

Table 104–4—PSE power_available matrix for PSE and PD for classes 0 through 9

			PSE Class[a]									
			12V unreg		12V reg		24V unreg		24V reg		48V reg

104.4.4.4 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition: a timer is reset and stops counting upon entering a state where “stop x_timer” is asserted.

tclass_timer
: A timer used to limit the time allowed for classifying a PD (see T_{Class} in Table 104–7).

tdet_timer
: A timer used to limit the time allowed for attempting to detect a PD (see T_{det} in Table 104–6).

tod_timer
: A timer used to regulate a subsequent attempt to power a PD after an overload condition that causes a fault (see T_{od} in Table 104–7).

tinrush_timer
: A timer used to limit the duration of the inrush event (see T_{Inrush} in Table 104–7).

tmfvdo_timer
: A timer used to monitor the dropout of MFVS (see T_{MFVDO} in Table 104–7).

toff_timer
: A timer used to limit the time the PSE attempts to discharge the PI to the range of V_{Sleep} (see T_{OFF} in Table 104–7). If toff_timer expires during the SETTLE_SLEEP state, an overload condition exists, and the port state diagram enters the OVERLOAD state.

trestart_timer
: A timer used to regulate a subsequent attempt to power a PD after an error condition that does not result in a fault (see $T_{Restart}$ in Table 104–7).

vsig_hold_timer
: A timer used to de-glitch the PD signature voltage valid output in the detection state diagram (see T_{sig_hold} in Table 104–6).

104.4.4.5 Functions

do_classification

This function returns the following variables:

CLASS_TYPE_INFO register:
: Refer to Table 104–13 for a description of the contents.

VOLT_INFO register:
: PSEs that support cable resistance measurement also return the VOLT_INFO register. Refer to Table 104–14 for a description of the contents.

POWER_INFO register:
: PSEs that support cable resistance measurement also return the POWER_INFO register. Refer to Table 104–15 for a description of the contents.

POWER_ASSIGN register:
: PSEs that support cable resistance measurement also return the POWER_ASSIGN register. Refer to Table 104–16 for a description of the contents.

104.4.5 PSE detection of a PD

When in the DETECTION state, the PSE shall complete detection of a valid PD signature within T_{det} as specified in Table 104–6. If a valid signature is not detected and classification is not performed, the PSE shall wait at least $T_{Restart}$ before reattempting detection. If a valid signature is detected and classification is not performed, the PSE may proceed to the POWER_UP state. A PSE may successfully detect a PD but then opt not to power the detected PD.

104.4.5.1 Detection probe requirements

All detection currents at the PI shall be within the I_{valid} current range, as specified in Table 104–6, when connected to a valid PD detection signature as specified in Table 104–9. The detection probe shall conform to V_{OC}, I_{SC}, I_{slew}, and C_{out} as specified in Table 104–6.

Table 104–6—PSE PI detection state electrical output requirements

Item	Parameter	Symbol	Unit	Min	Max	Type	Additional information
1	Open circuit voltage	V_{OC}	V	4.75	5.5	All	
2	Short-circuit current	I_{SC}	mA	—	24	All	
3	Valid test probe current	I_{valid}	mA	9	16	All	
4	Slew rate	I_{slew}	A/ms	—	1	All	
5	Output capacitance during detection	C_{out}	µF	—	2.64	A, B, C, D	
					0.4	E	
6	Maximum detection time	T_{det}	ms	—	3.11	All	See 104.4.5
7	Valid PD detection signature range measured at PSE PI	V_{good_PSE}	V	4.05	4.7	All	See 104.4.5.2
8	Invalid PD detection signature high range measured at PSE PI	$V_{bad_hi_PSE}$	V	V_{oc}–0.05	—	All	See 104.4.5.3
9	Invalid PD detection signature low range measured at PSE PI	$V_{bad_lo_PSE}$	V	—	3.7	All	
10	Signature hold timer for validity	T_{sig_hold}	ms	1	—	All	See 104.4.5.2

104.4.5.2 Detection criteria

A PSE shall accept as a valid PD signature a link segment with a voltage in the range of V_{good_PSE} for at least T_{sig_hold} in response to a probing current in the range I_{valid} as specified in Table 104–6.

104.4.5.3 Rejection criteria

The PSE shall reject link segments as having an invalid PD signature when those link segments exhibit any of the following characteristics with a probe current, as specified in Table 104–6:

a) Voltage less than or equal to $V_{bad_lo_PSE}$ max
b) Voltage greater than or equal to $V_{bad_hi_PSE}$ min

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A PSE may accept or reject a voltage in the band between $V_{bad_lo_PSE}$ max and V_{good_PSE} min and in the band between V_{good_PSE} max and $V_{bad_hi_PSE}$ min. The values of these voltages are specified in Table 104–6.

104.4.6 PSE classification of a PD

The ability for the PSE to query the PD in order to determine the PD type and power class requirements of that PD is called classification.

Classification is optional, and is performed using SCCP. See 104.7.

A PSE with SCCP enabled shall complete classification after detection and prior to application of full operating voltage at the PI in a time less than T_{Class} as specified in Table 104–7. If classification is not completed before the T_{Class} timer expires, a new detection cycle shall be completed before any subsequent application of full operating voltage, the PSE shall transition to the RESTART state.

Valid class information is one that returns one of the defined bit patterns in Table 104–13 with a valid CRC8 result.

104.4.7 PSE output requirements

When the PSE provides power to the PSE PI, it shall conform to the electrical limits in Table 104–7.

Under all conditions, a PSE shall present an invalid PD signature with one of the attributes as specified in Table 104–10.

Table 104–7—PSE output requirements

Item	Parameter	Symbol	Unit	Min	Max	Class	Type	Additional information
1	DC output voltage during POWER_ON state	$V_{PSE(PON)}$	V	Class $V_{PSE(min)}$	Class $V_{PSE(max)}$	All	All	See 104.4.7.1 and Table 104–1

Table 104–7—PSE output requirements *(continued)*

Item	Parameter	Symbol	Unit	Min	Max	Class	Type	Additional information
16	Valid wakeup current signature range	I_{Wakeup}	mA	1.25	1.85	All	All	See 104.4.7.2.2
17	Wakeup current hold time required for validity	T_{Wakeup}	ms	0.1	—			
18	Invalid wakeup current signature high range	$I_{Wakeup_bad_hi}$	mA	2.5	—			
19	Invalid wakeup current signature low range	$I_{Wakeup_bad_lo}$	mA	—	0.5			
20	Output discharge current during SETTLE_SLEEP state	$I_{discharge}$	mA	1.2	24	All	All	See 104.4.7.2
21	DC output voltage during the DISABLED, OVERLOAD, and OVERLOAD_DELAY states	$V_{Disable}$	V	—	1	All	All	See 104.4.7.1
22	Disable time	$T_{Disable}$	ms	—	500	All	All	See 104.4.7.6

104.4.7.1 Output voltage

A PSE operating in the POWER_ON state shall apply a voltage in the range of $V_{PSE(PON)}$ at the PI. A PSE shall apply a voltage at the PI in the range of $V_{Disable}$ when in the OVERLOAD, OVERLOAD_DELAY, and DISABLED states (see 104.4.7.5).

The PSE shall apply a voltage at the PI in the range of V_{Sleep} while operating in the SLEEP, RESTART, RESTART_DELAY, and IDLE states (see Table 104–7).

A PSE operating in the SETTLE_SLEEP state shall discharge the PSE PI to the range of V_{Sleep} within a time less than T_{OFF} max.

104.4.7.2 Output current

A PSE operating in the POWER_ON state shall enter the SETTLE_SLEEP state if a valid MFVS is not present at the PI.

A PSE operating in the SETTLE_SLEEP state shall discharge the PI to the range of V_{Sleep} with a current in the range of $I_{discharge}$.

During the POWER_UP state, PSE output shall not exceed I_{LIM} max.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

104.4.7.2.1 Output current—at overload condition

During operation in the POWER_UP and POWER_ON states, the PSE shall limit the current to I_{LIM} for a duration of up to T_{LIM} in order to account for PSE dV/dt transients at the PI as specified in Table 104–7.

If I_{PSE} exceeds I_{LIM} min during the POWER_ON state, the PSE output voltage may drop below $V_{PSE(PON)}$ min.

During operation in any state other than POWER_UP or POWER_ON when the PSE is enabled, the PSE shall limit I_{PSE} to less than I_{SC} as specified in Table 104–6 for a duration of up to T_{LIM}.

If the PSE is limiting current in any state when pi_powered, pi_sleeping or pi_prebias are true, within T_{LIM} of the initiation of current limiting, overload_detected is set TRUE and power removal from the PI shall begin.

Measurements of I_{PSE} during a short-circuit condition shall be made 1 ms after the initial transient to allow for settling.

104.4.7.2.2 Wakeup current signature detection

A PSE shall transition from the SLEEP state to the DETECTION state when I_{PSE} is in the valid range of I_{Wakeup} for a minimum of T_{Wakeup} (see Table 104–7).

A PSE operating in the SLEEP state shall remain in the SLEEP state if I_{PSE} is greater than $I_{Wakeup_bad_hi}$ or less than $I_{Wakeup_bad_lo}$. A PSE may consider a PD wakeup request valid or invalid if I_{PSE} is in the band between $I_{Wakeup_bad_hi}$ and I_{Wakeup} max or the band between I_{Wakeup} min and $I_{Wakeup_bad_lo}$.

104.4.7.2.3 Output current requirement during idle

The PSE output current during the IDLE state shall be defined as valid if it less than I_{Wakeup} max for at least T_{Wakeup} min (see Table 104–7). A PSE may define its output current during the IDLE state as valid if the current is in the range between I_{Wakeup} max and $I_{Wakeup_bad_hi}$ for at least T_{Wakeup} min.

A PSE may define its output current during the IDLE state as invalid if the current is in the range between I_{Wakeup} max and $I_{Wakeup_bad_hi}$. A PSE shall consider its output current during the IDLE state to be invalid if the current is greater than $I_{Wakeup_bad_hi}$.

104.4.7.3 Power feeding ripple and transients

The ripple and transient limits specified in Table 104–7, items (4) and (3) respectively, are meant to preserve data integrity.

A digital oscilloscope or data acquisition module with a differential probe is used to observe the voltage at the MDI/PI of the PSE device under test (DUT) as shown in Figure 104–7. The input impedance, $Z_{in}(f)$, and transfer function, $H_1(f)$, of the differential probe are specified by Equation (104–1) and Equation (104–2), respectively. When measuring the ripple voltage for a Type A or Type C PSE as specified by Table 104–7 item (4a), f_1 = 31.8 kHz ± 1%. When measuring the ripple voltage for a Type B or Type F PSE as specified in Table 104–7 item (4a), f_1 = 318 kHz ± 1%. When measuring the ripple voltage for a Type E PSE as specified in Table 104–7 item (4a), f_1 = 3.18 kHz ± 1%.

$$Z_{in}(f) = \left(100 \pm 0.1\% \times \frac{\sqrt{f^2 + f_1^2}}{f}\right) \Omega \quad (104–1)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$H_1(f) = \frac{f}{\sqrt{f^2 + f_1^2}} \quad (104–2)$$

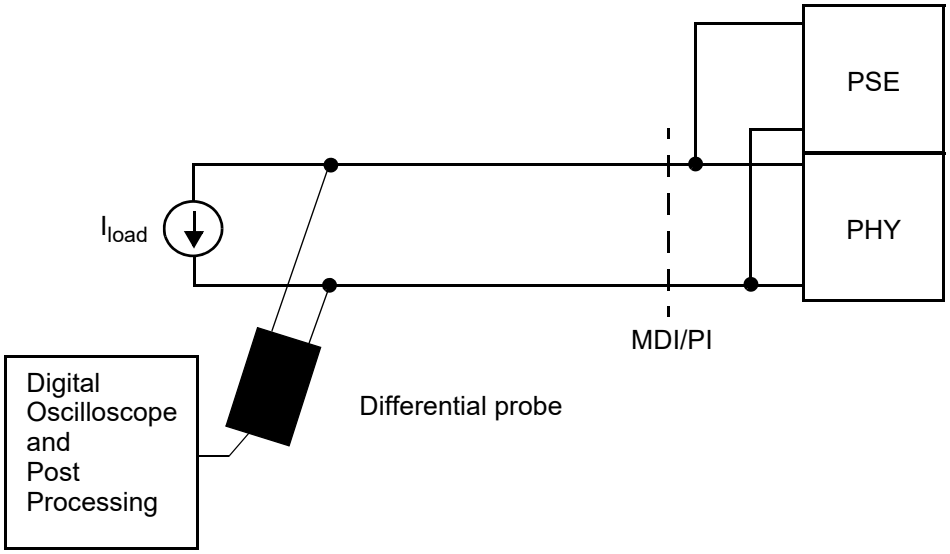

Figure 104–7—PSE ripple voltage test fixture

When measuring the ripple voltages for a Type A or Type C PSE as specified by Table 104–7 item (4b), the voltage observed at the MDI/PI with the differential probe where f_1 = 31.8 kHz ± 1% is post-processed with transfer function $H_2(f)$ specified in Equation (104–3) where f_2 = 1 MHz ± 1%.

When measuring the ripple voltages for a Type B or Type F PSE as specified by Table 104–7 item (4b), the voltage observed at the MDI/PI with the differential probe where f_1 = 318 kHz ± 1% is post-processed with transfer function $H_2(f)$ specified in Equation (104–3) where f_2 = 10 MHz ± 1%.

When measuring the ripple voltages for a Type E PSE as specified by Table 104–7 item (4b), the voltage observed at the MDI/PI with the differential probe where f_1 = 3.18 kHz ± 1% is post-processed with transfer function $H_2(f)$ specified in Equation (104–3) where f_2 = 0.1 MHz ± 1%.

$$H_2(f) = \frac{f}{\sqrt{f^2 + f_2^2}} \quad (104–3)$$

104.4.7.4 Inrush time

The specification for T_{Inrush} in Table 104–7 applies to the PSE power-up time allowed for a PD after completion of detection and optional classification. If full operating voltage is applied within T_{Inrush} min, the PSE shall enter the POWER_ON state. If full operating voltage is not applied within T_{Inrush} max, a new detection cycle shall be initiated after a delay of $T_{Restart}$ before any subsequent application of full operating voltage. If full operating voltage is applied within the range of T_{Inrush}, the PSE may enter the POWER_ON state or begin a new detection cycle after a delay of $T_{Restart}$.

104.4.7.5 Turn off time

The specification for T_{OFF} in Table 104–7 applies to the discharge time from V_{PSE} in the POWER_ON state to V_{Sleep}. In addition, it is recommended that the PI be discharged when the PSE is not enabled. T_{OFF} starts when V_{PSE} drops 1 V below the steady-state full operating voltage value after the pi_powered variable is set to FALSE. T_{OFF} ends when $V_{PSE} < V_{Sleep}$ max.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

104.4.7.6 Disable time

The specification for $T_{Disable}$ in Table 104–7 shall apply to the discharge time from V_{PSE} to $V_{Disable}$ with a test resistor of 320 kΩ attached to the PI. $T_{Disable}$ starts when V_{PSE} drops 1 V below the steady-state value after the pi_powered, pi_classifying, pi_detecting, pi_prebiased, and pi_sleeping variables are set to FALSE (see Figure 104–4). $T_{Disable}$ ends when V_{PSE} is less than or equal to $V_{Disable}$ max.

104.4.7.7 Continuous output power in POWER_ON state

P_{Class} is the minimum continuous class power that the PSE shall be capable of supplying, as defined in Table 104–1.

Measurement of P_{Class} shall be averaged using a uniform sliding window with a width of 1 s.

A PSE may remove power from the PI when more than P_{Class} is sourced.

104.4.8 PSE power removal

While the PSE is operating in the POWER_ON state, full operating voltage shall be removed from the PSE PI in the absence of the PD MFVS or if overload_detected is TRUE.

104.4.8.1 PSE MFVS requirements

MFVS shall be defined as being present in the POWER_ON state when I_{PSE} is greater than or equal to I_{Hold} max for a minimum of T_{MFVS}.

MFVS may be defined as present or absent in the POWER_ON state if I_{PSE} is in the range of I_{Hold}.

MFVS shall be defined as absent in the POWER_ON state if I_{PSE} is less than or equal to I_{Hold} min. The PSE-PI Voltage shall be reduced to the range of V_{Sleep} when MFVS has been absent for a duration greater than T_{MFVDO}.

104.5 Powered Device (PD)

A PD is the portion of a device that is either drawing power or requesting power by participating in the PD detection or classification algorithms. A device that is capable of becoming a PD may have the ability to draw power from an alternate power source. A PD requiring power from the PI may simultaneously draw power from an alternate power source.

A PD is specified at the point of the physical connection to the PI. Limits defined for a PD are specified at the PI, not at any point internal to the PD, unless specifically stated.

104.5.1 PD types

For PoDL systems there are six types of PDs—Type A, Type B, Type C, Type D, Type E, and Type F consistent with 104.1.3.

104.5.2 PD PI

A PD may receive power in two modes, Mode A and Mode B. Table 104–8 in conjunction with Figure 104–3 illustrates the PD pinout.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 104–8—PD pinout

Contact	Mode A	Mode B
1	PI+	PI–
2	PI–	PI+

Class 0 to class 9 PDs shall be able to operate per the Mode A column in Table 104–8. Class 10 to class 15 PDs shall be implemented to be insensitive to the polarity of the power supply and shall be able to operate per the Mode A column and the Mode B column in Table 104–8.

104.5.3 PD classes

A PD shall comply with the voltage and power requirements listed in Table 104–1 for the relevant class.

104.5.4 PD state diagram

The PD state diagram specifies the externally observable behavior of a PD. The PD shall provide the behavior of the state diagram shown in Figure 104–8.

104.5.4.1 Overview

A falling edge of the PD input voltage through V_{sig_enable} enables a voltage signature, as defined in 104.5.5. When the input voltage rises through the $V_{sig_disable}$ the PD disables its voltage signature.

A PD requests detection and wakeup while the voltage signature is enabled by presenting a valid wakeup current signature. SCCP may also be used for communication with the PD by the PSE when the voltage signature is enabled.

A rising edge through the V_{On} threshold causes the PD to enable MDI power to the load after a delay of T_{power_dly}. A falling edge through the V_{Off} threshold causes the PD to disable MDI power.

104.5.4.2 Conventions

The notation used in the state diagram follows the conventions of state diagrams as described in 21.5.

104.5.4.3 Variables

The PD state diagram uses the following variables:

disconnect_pd
: TRUE: the PD no longer requires full operating voltage from the PI and has reduced its port current below the MFVS threshold current.
: FALSE: the PD still requires full operating voltage from the PI.

enable_mdi_pwr
: TRUE: the PD is enabled and ready to consume full power from the PI.
: FALSE: the PD is disabled or not ready to consume full power from the PI.

fault_detected
: TRUE: the PD no longer requires power as the result of an implementation-specific error condition.
: FALSE: no fault has been detected.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_fault
TRUE: following the application of full operating voltage at the PI, the PD has gone offline as the result of an error condition.
FALSE: following the application of full operating voltage at the PI, no fault has been detected.

pd_sccp_enabled
TRUE: during detection, a PSE reset pulse has been detected by the PD and a SCCP serial transaction is pending.
FALSE: during detection, no PSE reset pulse has been detected by the PD.

pd_reset
An implementation-specific control variable that unconditionally resets the PD state diagram to the RESET state.
TRUE: the device is in reset.
FALSE: the device is not in reset (default).

present_det_sig
A variable that controls the PD detection signature as specified in 104.5.5.
TRUE: the detection signature is to be applied to the PD PI.
FALSE: the detection signature is not to be applied to the PD PI.

present_iwakeup
TRUE: the wakeup signature (I_{Wakeup_PD}) is to be applied to the PD PI.
FALSE: the wakeup signature (I_{Wakeup_PD}) is not to be applied to the PD PI.

present_mfvs
TRUE: the MFVS is to be applied to the PD PI.
FALSE: the MFVS is not to be applied to the PD PI.

sccp_reset_pulse
TRUE: during detection, a SCCP reset pulse per Figure 104–10 as described in 104.7.1.1 has been received by the PD.
FALSE: during detection, a SCCP reset pulse has not been received by the PD.

V_{Off}
PD turn off threshold voltage (see Table 104–11).

V_{On}
PD turn on threshold voltage (see Table 104–11).

V_{PD}
The voltage measured at the PI of the PD.

$V_{sig_disable}$
PD signature disable threshold voltage (see Table 104–9).

V_{sig_enable}
PD signature enable threshold voltage (see Table 104–9).

wakeup
TRUE: the PD requires the full operating voltage at the PI.
FALSE: the PD is ready to go to sleep.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

104.5.4.4 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where “stop x_timer” is asserted.

tpower_dly_timer
: A timer used to prevent a PD from drawing more than inrush current during the PSE’s POWER_UP state (see T_{power_dly} in Table 104–11).

sccp_watchdog_timer
: A timer used to limit the time in the DO_CLASSIFICATION state in the event serial communication between the PSE and PD is idle or stalled (see $T_{SCCP_watchdog}$ in Table 104–11).

104.5.4.5 Functions

do_sccp

This function returns the following variable to the PSE:

CLASS_TYPE_INFO register:
: Refer to Table 104–13 for a description of the contents.

VOLT_INFO register:
: PDs that support cable resistance measurement also return the VOLT_INFO register. Refer to Table 104–14 for a description of the contents.

POWER_INFO register:
: PDs that support cable resistance measurement also return the POWER_INFO register. Refer to Table 104–15 for a description of the contents.

POWER_ASSIGN register:
: PDs that support cable resistance measurement also return the POWER_ASSIGN register. Refer to Table 104–16 for a description of the contents.

104.5.4.6 State diagram

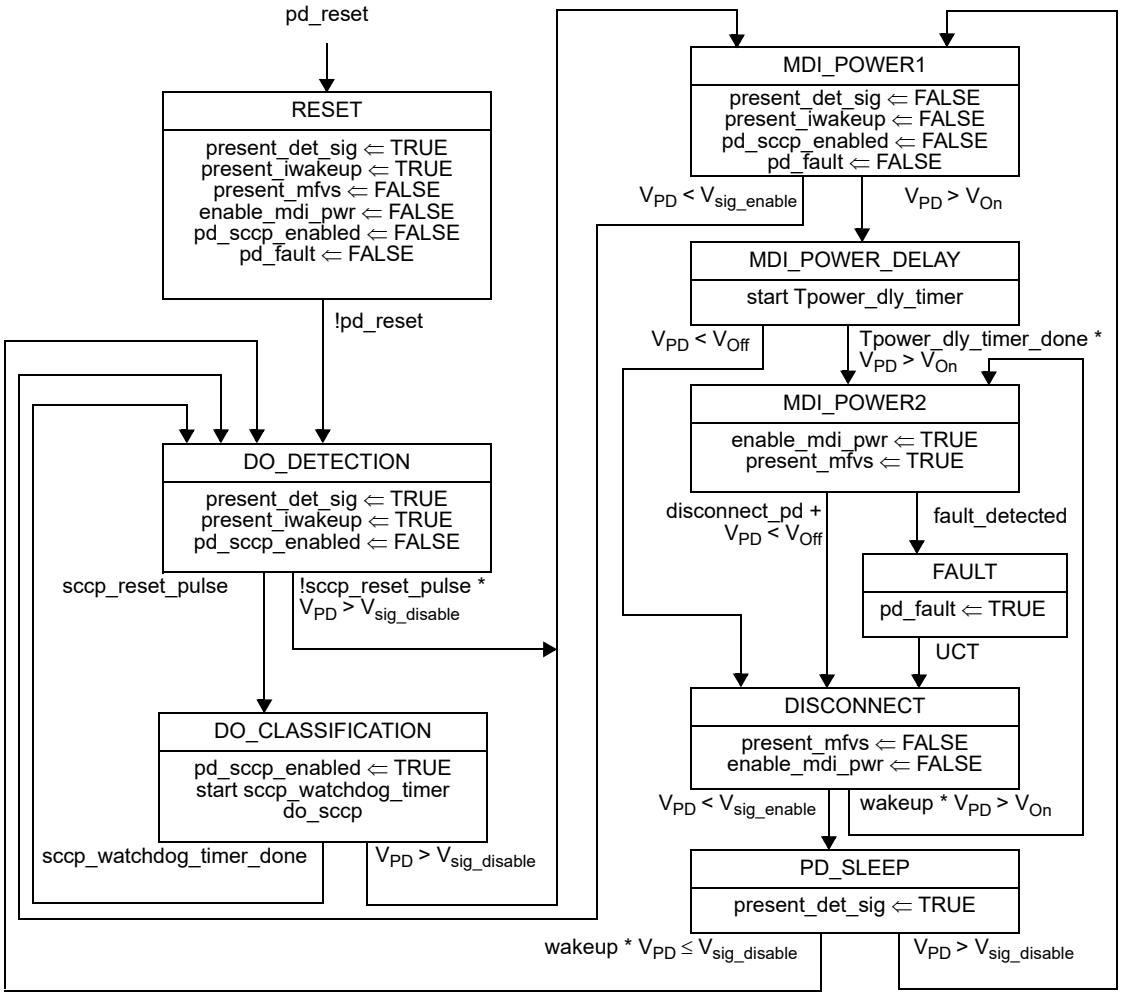

Figure 104–8—PD state diagram

104.5.5 PD signature

Class 0 and Class 1 PDs, or PDs that do not implement classification shall enable a valid detection signature when V_{PD} is less than V_{sig_enable} min and may enable a valid detection signature when V_{PD} is less than V_{sig_enable} max. A PD that presents an invalid detection signature greater than V_{bad_hi} max as specified in Table 104–10 shall implement classification as specified in 104.7.

When V_{PD} is greater than $V_{sig_disable}$ a PD shall remove the current draw of the detection signature.

The detection signature shall consist of a current limited voltage V_{good} per Table 104–9 when measured by the PSE.

A valid PD detection signature shall have all of the characteristics of Table 104–9.

A non-valid PD detection signature shall have one of the characteristics in Table 104–10.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A PD that presents a signature within the limits set out in Table 104–9 is assured to pass detection, while a PD that presents one of the signature characteristics of Table 104–10 is assured to fail detection.

Table 104–9—Valid PD detection signature characteristics, measured at PD PI

Parameter	Conditions	Min	Max	Unit
V_{good}	7 mA < I_{PD} < 17 mA, PD exiting RESET state	4.05	4.55	V
$I_{signature_limit}$	V_{PD} < $V_{sig_disable}$ max	—	24	mA
$V_{sig_disable}$	V_{PD} rising	4.6	5.75	V
V_{sig_enable}	V_{PD} falling	3.6	4.3	V

Table 104–10—Non-valid PD detection signature characteristics, measured at PD PI

Parameter	Conditions	Min	Max	Unit
V_{bad_hi}	7 mA < I_{PD} < 17 mA, PD exiting RESET state	5.15	—	V
V_{bad_lo}	7 mA < I_{PD} < 17 mA, PD exiting RESET state	—	3.7	V

104.5.6 PD classification and mutual identification between the PSE and PD

A PD may be classified by the PSE based on SCCP information provided by the PD. The intent of PD classification is to provide information about the voltage and power required by the PD during operation. SCCP classification may also be used to establish mutual identification between a PSE and a PD. See 104.7 for more information about SCCP.

104.5.7 PD power

The PD shall operate within the characteristics in Table 104–11.

104.5.7.1 PD discharge

At a delay of T_{OFF} max (see Table 104–7) after disconnection from the PSE, a PD shall not source greater than 410 μJ out of its PI until V_{PD} drops below V_{Sleep_PD} max.

104.5.7.2 PD input voltage

The PD shall turn on at a voltage less than or equal to V_{On} max and with a delay greater than T_{power_dly} min. After the PD turns on, the PD shall stay on over the range from V_{PD} min to V_{PSE} max. The PD shall turn off at a voltage in the range of V_{PD} min to V_{Off} min. Table 104–1 defines the values for V_{PD} min and V_{PSE} max. Table 104–11 defines the values for V_{On}, T_{power_dly}, and V_{Off}.

The PD shall turn on or off without startup oscillation and within the first trial when a voltage in the range of V_{PSE} (as defined in Table 104–1) is applied with a series resistance within the range of valid dc loop resistance (see 104.2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PD shall operate in the PD_SLEEP state with an input voltage greater than V_{Sleep_PD} min as specified in Table 104–11.

When the input voltage is greater than $V_{sig_disable}$, then the signature is disabled.

104.5.7.3 Input current

During operation in the DISCONNECT and PD_SLEEP states, the PD shall not draw current in excess of I_{Sleep_PD} as specified in Table 104–11.

A PD that requires detection and application of power shall draw current in the range of I_{Wakeup_PD} for at least T_{Wakeup_PD} when V_{PD} is within the range of V_{Sleep_PD} as specified in Table 104–11.

A PD shall draw less than I_{PD_pwr1} max of current for a constant PD input voltage between $V_{sig_disable}$ max and V_{On} min.

104.5.7.4 PD ripple and transients

The specifications for ripple and transients in Table 104–11 apply to the voltage or current at the PD PI generated by the PD circuitry. Ripple and transient limits are provided to preserve data integrity.

The PD DUT is connected to a power supply through a dc bias coupling network as shown in Figure 104–9. The ripple and transient specifications for a Type A or Type C PD shall be met for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Equation (96–12), and over the range of P_{PD}. The ripple and transient specifications for a Type B PD shall be met for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Clause 97, and over the range of P_{PD}. The ripple and transient specifications for a Type E PD shall be met for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Clause 146 and over the range of P_{PD}. The ripple and transient specifications for a Type F PD shall be met for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Clause 149, and over the range of P_{PD}.

A digital oscilloscope or data acquisition module with a differential probe is used to observe the voltage at the MDI/PI. The input impedance, $Z_{in}(f)$, and transfer function, $H_1(f)$, of the differential probe are specified by Equation (104–1) and Equation (104–2), respectively. When measuring the ripple voltage for a Type A or Type C PD as specified by Table 104–11 item (3a), $f_1 = 31.8$ kHz ± 1%. When measuring the ripple voltage for a Type B or Type F PD as specified by Table 104–11 item (3a), $f_1 = 318$ kHz ± 1%. When measuring the ripple voltage for a Type E PD as specified by Table 104–11 item (3a), $f_1 = 3.18$ kHz ± 1%.

When measuring the ripple voltages for a Type A or Type C PD as specified by Table 104–11 item (3b), the voltage observed at the MDI/PI with the differential probe where $f_1 = 31.8$ kHz ± 1% shall be post-processed with transfer function $H_2(f)$ specified in Equation (104–3) where $f_2 = 1$ MHz ± 1%. When measuring the ripple voltages for a Type B or Type F PD as specified by Table 104–11 item (3b), the voltage observed at the MDI/PI with the differential probe where $f_1 = 318$ kHz ± 1% shall be post-processed with transfer function $H_2(f)$ specified in Equation (104–3) where $f_2 = 10$ MHz ± 1%. When measuring the ripple voltages for a Type E PD as specified by Table 104–11 item (3b), the voltage observed at the MDI/PI with the differential probe where $f_1 = 3.18$ kHz ± 1% shall be post-processed with transfer function $H_2(f)$ specified in Equation (104–3) where $f_2 = 0.1$ MHz ± 1%.

104.5.7.5 Input average power

The maximum average power, $P_{PD(max)}$ in Table 104–1, shall be calculated using a uniform sliding window with a width of 1 s.

104.5.7.6 PD stability

When any voltage between V_{PSE} min and V_{PSE} max (with R_{Loop_max} in series) is applied to the PI of the PD, P_{PD} is defined as shown in Equation (104–4).

$$P_{PD} = (V_{PD} \times I_{PD}) \text{ (Watts)} \quad (104–4)$$

where

P_{PD} is the input power at the PD PI
V_{PD} is the input voltage at the PD PI
I_{PD} is the input current to the PD

NOTE—When connected together as a system, the PSE and PD might exhibit instability at the PSE side, the PD side, or both due to the presence of negative impedance at the PD input.

104.5.8 PD Maintain full voltage

In order to signal the PSE to maintain full operating voltage, the PD shall provide a valid MFVS at the PI. The MFVS shall consist of current draw equal to or greater than I_{hold_PD} for a minimum duration of T_{MFVS_PD} measured at the PD PI followed by an allowed MFVS dropout for no longer than T_{MFVDO} min. PDs that do not require full operating voltage at the PI shall remove the current draw of the MFVS from the PI.

104.6 Additional electrical specifications

104.6.1 Isolation

In order to prevent the formation of a ground loop, a PD shall provide at least 1 MΩ dc isolation between all accessible external conductors, including frame ground (if any), and all MDI leads, when measured using a 5 V ± 20% source voltage. Any equipment that can be connected to a PD through a non-MDI connector that is not isolated from the MDI leads needs to provide isolation between all accessible external conductors,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

including frame ground (if any), and the non-MDI connector, so as not to negate the dc isolation provided by the PD.

104.6.2 Fault tolerance

The PI for Type A, Type B, Type C, and Type F PSEs and PDs shall meet the fault tolerance requirements as specified in 96.8.3. The PI for Type E PSEs and PDs shall meet the fault tolerance requirements as specified in 146.8.6.

A PD shall not be damaged when connected to any PSE as defined in 104.4.

The PSE PI shall withstand without damage the application of short circuits between the wires within the cable for an indefinite period of time.

104.7 Serial communication classification protocol (SCCP)

Implementation of SCCP by PSEs and PDs that present a valid detection signature is optional. PDs that present an invalid detection signature as specified in Table 104–10 shall implement SCCP. The PSE acts as a master during the SCCP exchange, controlling the PD that acts as the slave device. SCCP is a current-sinking, wired-OR (e.g., open-drain or open-collector), half-duplex bidirectional serial data bus. The PSE sources the required pull-up current. PDs can derive power from the PSE's pull-up current during classification via the PD PI.

Measurement of initial cable resistance, $R_{Cable_initial}$, by PSEs and PDs that implement SCCP is optional. PSEs and PDs that implement cable resistance measurement support the VOLT_INFO, POWER_INFO, and POWER_ASSIGN registers (see Table 104–14, Table 104–15, and Table 104–16). PSEs that implement cable resistance measurement shall report assigned power through PoDL PSE Status 2 Register (see 45.2.9.3).

104.7.1 SCCP signaling

SCCP uses the following signal types in order to ensure data integrity: reset pulse, presence pulse, Write 0, Write 1, Read 0, and Read 1. The PSE initiates all of these signals.

104.7.1.1 Initialization procedure—reset and presence pulses

All SCCP communication with a PD shall begin with an initialization sequence that consists of a reset pulse from the PSE followed by a presence pulse from the PD. This is illustrated in Figure 104–10. See Table 104–12 for requirements on the timing relationships.

During the initialization sequence the PSE shall transmit the reset pulse by first driving V_{PSE} low and then releasing to the pull up at t_{RSTL}. The PSE shall then go into receive mode (RX). When the PD detects the rising edge at the PD PI, it shall wait t_{PDH} and then transmit a presence pulse by pulling V_{PD} low for t_{PDL}. Presence data from the PD shall be valid for the entire time window defined by t_{MSP} following the rising edge that terminated the reset pulse. Therefore, the PSE should sample the subsequent voltage within t_{MSP} from the completion of the preceding rising edge at its PI.

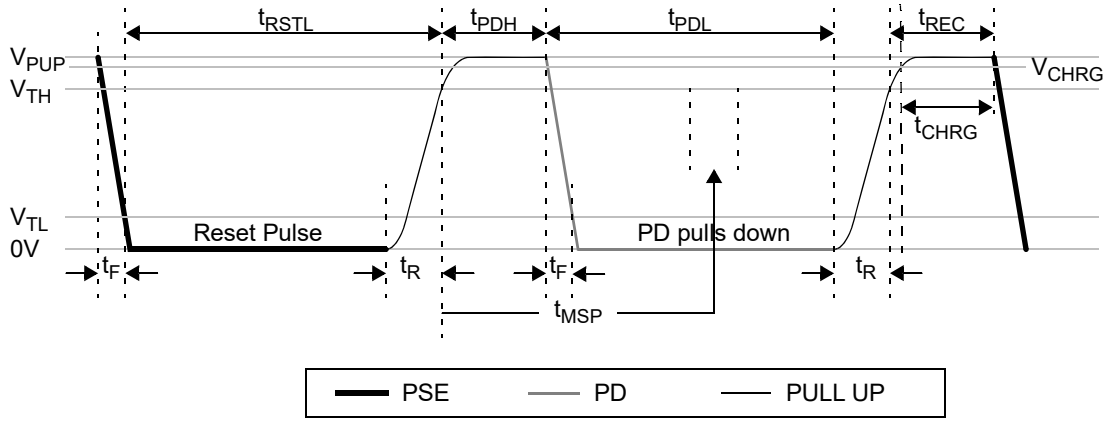

Figure 104–10—Reset command timing diagram

104.7.1.2 Write time slots

There are two types of write time slots: Write 1 and Write 0 time slots. Figure 104–11 illustrates Write 0/1 timing diagrams. The PSE shall use a Write 1 time slot to transmit a logic 1 to the PD and a Write 0 time slot to transmit a logic 0 to the PD. All write time slots shall be $t_{WRITESLOT}$ in duration. The PSE shall initiate both types of write time slots by pulling V_{PSE} low.

To generate a Write 1 time slot, after pulling V_{PSE} low, the PSE shall pull up V_{PSE} within the range of t_{W1L}. To generate a Write 0 time slot, after pulling the V_{PSE} low, the PSE shall pull up V_{PSE} within the range of t_{W0L}. The PD shall sample the V_{PD} within the range of t_{ssw} after the falling edge during a Write 1 or Write 0 operation.

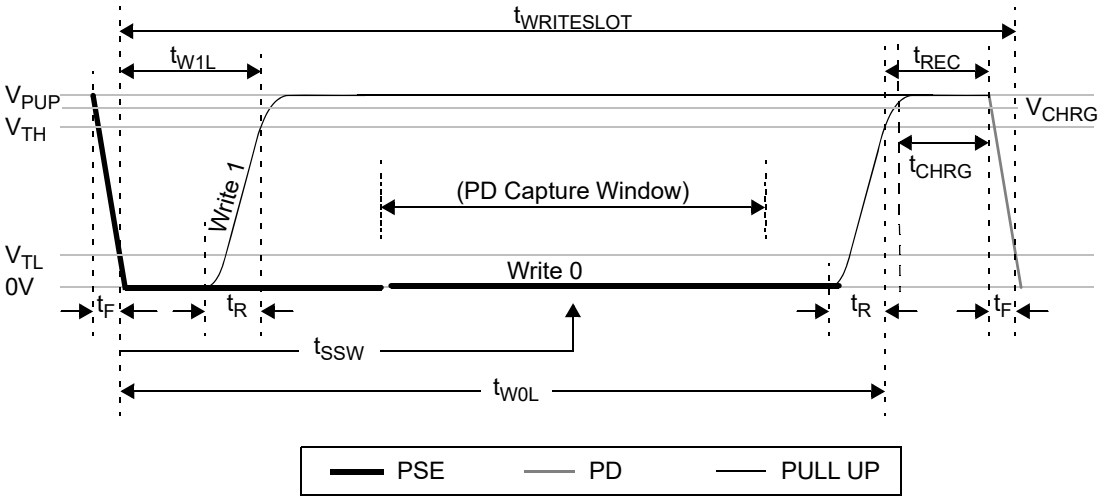

Figure 104–11—Write 0/1 slot timing diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

104.7.1.3 Read time slots

Figure 104–12 illustrates Read 0/1 timing diagrams. The PD can only transmit data to the PSE when the PSE issues read time slots. Therefore, the PSE shall generate read time slots immediately after issuing a function command, which requires data from the PD so that the PD can provide the requested data. In addition, the PSE can generate read time slots after issuing a manufacturer specific function command in order to determine the status of a commanded operation.

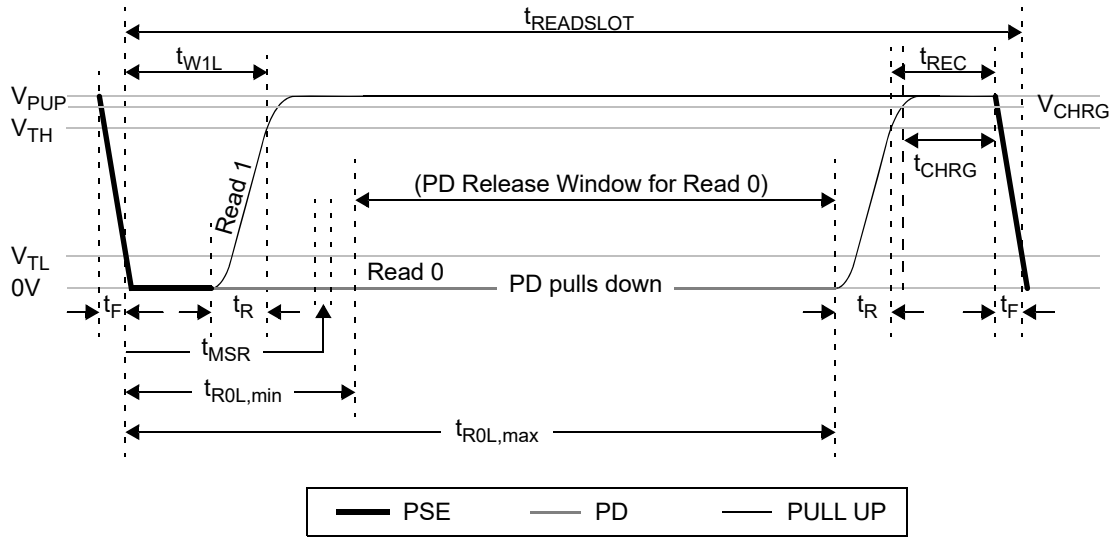

Figure 104–12—Read 0/1 slot timing diagram

All read time slots shall be $t_{READSLOT}$ in duration. The PSE shall initiate a read time slot by pulling V_{PSE} low and then pulling-up V_{PSE} within t_{W1L}. After the PSE initiates the read time slot, the PD shall begin transmitting a 1 or 0 at its PI. The PD shall transmit a 1 by leaving V_{PD} high and transmit a 0 by pulling V_{PD} low. When transmitting a 0, the PD shall hold V_{PD} low and then release V_{PD} within t_{R0L}. V_{PSE} and V_{PD} will be pulled back to the high idle state by the PSE's pull-up current. Output data from the PD is valid for t_{MSR} after the falling edge that initiated the read time slot. Therefore, the PSE shall release V_{PSE} and then sample the subsequent voltage within t_{MSR} from the start of the read time slot SCCP electrical requirements.

A PSE or PD implementing SCCP shall comply with the electrical and timing requirements in Table 104–12. All voltages are referenced to the PI, as shown in Figure 104–3. See Figure 104–10, Figure 104–11, and Figure 104–12 for timing definitions.

104.7.1.4 Calculations for cable resistance

A PSE that implements cable resistance measurement may calculate cable resistance (dc loop resistance of the link segment) using the voltage and current at the PSE PI during the presence pulse and the voltage at the PD PI as shown in Equation (104–5). The measurement tolerances in the voltage and current values should be included in the cable resistance measurement calculation. The initial calculated link segment cable resistance, $R_{Cable_initial}$, is defined in Equation (104–5).

$$R_{Cable_initial} = \left(\frac{V_{PSE} - V_{Report_PD}}{I_{PSE}} \right) \ \Omega \tag{104–5}$$

where

V_{Report_PD} is the voltage at PD's PI during the presence pulse as reported in b[7:0] of VOLT_INFO in Table 104–14

V_{PSE} is the voltage at PSE's PI during the presence pulse

I_{PSE} is the current at PSE's PI during the presence pulse

The initial cable resistance value calculated in Equation (104–5) is then margined by the Resistance Margin Factor, K_{RMF}, as shown in Equation (104–6). The margined link segment cable resistance, R_{Cable}, should not exceed the maximum allowable link segment dc loop resistance for the class as shown in Equation (104–6).

$$R_{Cable} = \min(R_{Cable_initial} \times K_{RMF}, R_{Loop(max)}) \ \Omega \tag{104–6}$$

where

$R_{Cable_initial}$ is the initial calculated link segment cable resistance

K_{RMF} is the Resistance Margin Factor per Table 104–12

$R_{Loop(max)}$ is the maximum allowable link segment dc loop resistance for the class per 104.2

104.7.1.5 Calculations for power allocation

A PD that supports cable resistance measurement may request a power allocation between 0.1 W and $P_{\text{Class(max)}}$ via the PD Requested Power, $P_{\text{PD_req}}$, field of the POWER_INFO register b[11:0]. The PD Requested Power may exceed $P_{\text{PD(max)}}$. A PSE that supports cable resistance measurement shall set PD Assigned Power ($P_{\text{PD_assign}}$) based on PD Requested Power, $P_{\text{PD_req}}$, and measured cable resistance as shown in Equation (104–7):

$$P_{\text{PD_assign}} = \left\{ \begin{array}{ll} \min(P_{\text{PD_req}}, P_{\text{Class(min)}} - {I_{\text{PI(max)}}}^2 \times R_{\text{Cable}}) & \text{for } P_{\text{PD_req}} > P_{\text{PD(max)}} \\ P_{\text{PD_req}} & \text{for } P_{\text{PD_req}} \le P_{\text{PD(max)}} \end{array} \right\} \text{W} \qquad (104\text{–}7)$$

where

$P_{\text{PD_req}}$ is the PD Requested Power as reported in b[11:0] of POWER_INFO in Table 104–15

$P_{\text{PD_assign}}$ is the PD Assigned Power by PSE as assigned in b[11:0] of POWER_ASSIGN in Table 104–16

$P_{\text{Class(min)}}$ see Table 104–1 for description

$I_{\text{PI(max)}}$ see Table 104–1 for description

$P_{\text{PD(max)}}$ see Table 104–1 for description

For systems that implement cable resistance measurement, the PSE determines $P_{\text{PD_assign}}$, as assigned in b[11:0] of POWER_ASSIGN in Table 104–16. Maximum average available power at the PD PI is $P_{\text{PD_assign}}$. $P_{\text{PD_assign}}$ may be greater or less than $P_{\text{PD(max)}}$.

104.7.2 Serial communication classification protocols

All data and commands shall be transmitted least significant bit first using SCCP. The PSE initiates all transactions.

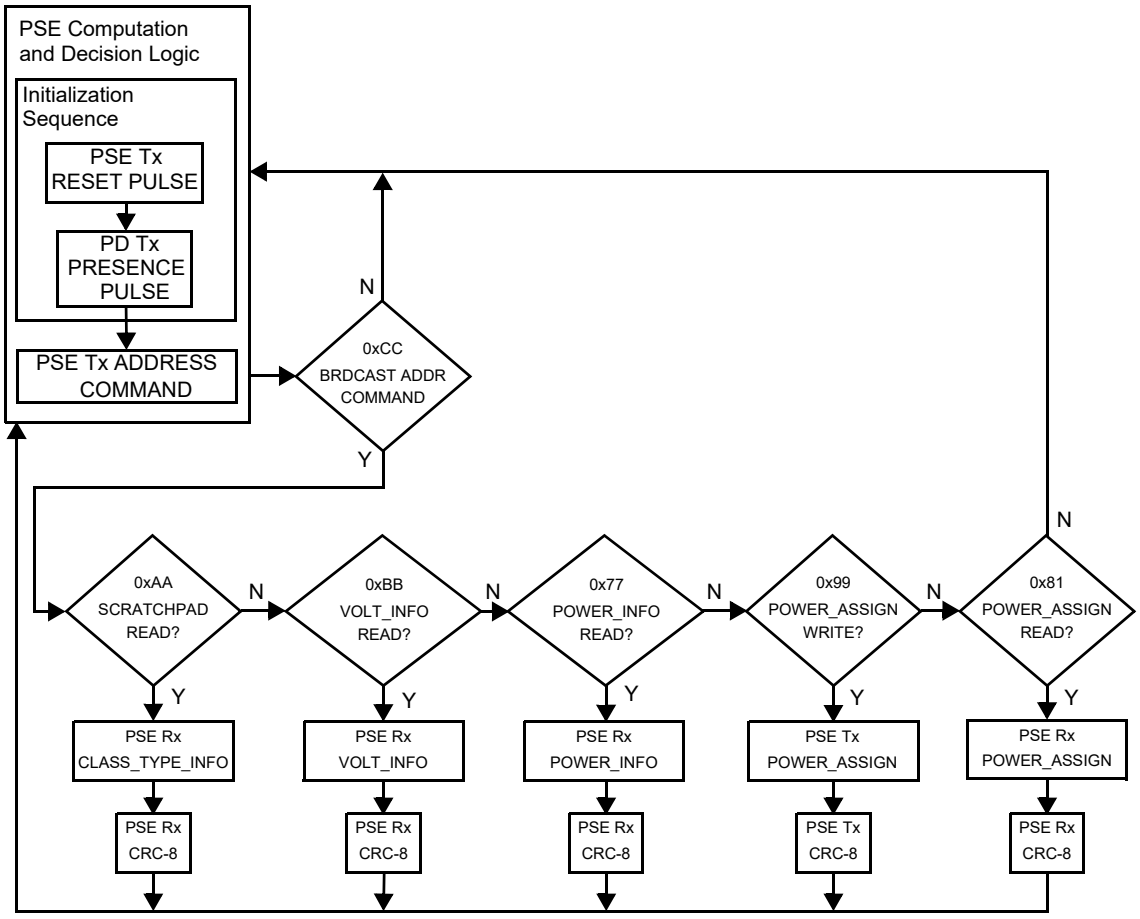

Figure 104–13—Address and Read_Scratchpad function command flowchart

104.7.2.1 SCCP transaction sequence

The transaction sequence for accessing a PD on SCCP is as follows:

a) Initialization
b) Address Command (followed by any required data exchange)
c) Function Command

104.7.2.2 Initialization

All communication with a PD shall begin with the initialization sequence that consists of a reset pulse from the PSE followed by a presence pulse from the PD.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

104.7.2.3 Address commands

All SCCP-capable PDs shall support the Broadcast Address command. The PSE shall issue an appropriate address command before issuing a function command.

104.7.2.3.1 Broadcast address [0xCC]

The PSE uses this command to address a PD on the bus without sending out unique address code information.

104.7.2.4 Read_Scratchpad function command [0xAA]

All SCCP-capable PDs shall support the 8-bit Read_Scratchpad command. After receiving a Read_Scratchpad function command the PD shall respond with a 16-bit CLASS_TYPE_INFO read payload followed by an 8-bit CRC8 field as specified in 104.7.2.5. A flowchart for operation of the address and the Read_Scratchpad function command is shown in Figure 104–13. Table 104–13 illustrates the contents of the CLASS_TYPE_INFO register.

Table 104–13—CLASS_TYPE_INFO register table

Bit(s)	Name	Description	R/W
b[15:12]	Type	15 14 13 12 1 1 1 0 = Type A 1 1 0 1 = Type B 1 0 1 1 = Type C 0 1 1 1 = Type D 1 1 0 0 = Type E 0 0 1 1 = Type F	RO
b[11]	pd_faulted	1—error condition has occurred that prevented the PD from receiving power at the PI. Set to 1 when the pd_fault variable transitions from FALSE to TRUE 0—no error condition detected	RO/ LH
b[10]	Cable resistance measurement	1 — Cable resistance measurement enabled 0 — Cable resistance measurement disabled	RO
b[9:0]	Class	9 8 7 6 5 4 3 2 1 0 1 1 1 1 1 1 1 1 1 0 = Class 0 1 1 1 1 1 1 1 1 0 1 = Class 1 1 1 1 1 1 1 1 0 1 1 = Class 2 1 1 1 1 1 1 0 1 1 1 = Class 3 1 1 1 1 1 1 0 1 1 1 = Class 4 1 1 1 1 0 1 1 1 1 1 = Class 5 1 1 1 0 1 1 1 1 1 1 = Class 6 1 1 0 1 1 1 1 1 1 1 = Class 7 1 0 1 1 1 1 1 1 1 1 = Class 8 0 1 1 1 1 1 1 1 1 1 = Class 9 0 0 0 0 0 0 0 0 0 1 =Class 10 0 0 0 0 0 0 0 0 1 0 =Class 11 0 0 0 0 0 0 0 0 1 1 =Class 12 0 0 0 0 0 0 0 1 0 0 =Class 13 0 0 0 0 0 0 0 1 0 1 =Class 14 0 0 0 0 0 0 0 1 1 0 =Class 15	RO

104.7.2.5 CRC8 field

The CRC8 field is an 8-bit cyclic redundancy check value. This value is computed as a function of the contents of the preceding Read/Write payload.

The encoding is defined by the generating polynomial shown in Equation (104–8):

$$G(x) = x^8 + x^5 + x^4 + 1 \quad (104–8)$$

This CRC8 calculation shall produce the same result as the serial implementation shown in Figure 104–14. Before calculation begins, the shift register shall be initialized to the value 0x00. The content of the shift register is transmitted without inversions.

CONTROL = 1 when shifting the contents of the register and calculating the CRC field
CONTROL = 0 when transmitting the CRC field

Figure 104–14—CRC8 field generation

104.7.2.6 Read_VOLT_INFO command [0xBB]

All PSEs and PDs that support cable resistance measurement shall support the 8-bit Read_VOLT_INFO command. After receiving a Read_VOLT_INFO command, the PD shall respond with a 16-bit VOLT_INFO read payload followed by an 8-bit CRC8 field as specified in 104.7.2.5. A flowchart for operation of the address and the Read_VOLT_INFO command is shown in Figure 104–13. Table 104–14 illustrates the contents of the VOLT_INFO register.

Table 104–14—VOLT_INFO register table

Bit(s)	Name	Description	R/W[a]
b[15:8]	Reserved	Value always 0	RO
b[7:0]	Voltage at PD PI during Presence Pulse	± 20 mV tolerance, 10 mV per LSB	RO

[a]RO = Read only

104.7.2.7 Read_POWER_INFO command [0x77]

All PSEs and PDs that support cable resistance measurement shall support the 8-bit Read_POWER_INFO command. After receiving a Read_POWER_INFO command, the PD shall respond with a 16-bit POWER_INFO read payload followed by an 8-bit CRC8 field as specified in 104.7.2.5. A flowchart for operation of the address and the Read_POWER_INFO command is shown in Figure 104–13. Table 104–15 illustrates the contents of the POWER_INFO register.

Table 104–15—POWER_INFO register table

Bit(s)	Name	Description	R/W[a]
b[15:12]	Reserved	Value always 0	RO
b[11:0]	P_{PD_req} PD Requested Power	Power requested by PD, 0.025 W per LSB	RO

[a]RO = Read only

104.7.2.8 Write_POWER_ASSIGN command [0x99]

All PSEs and PDs that support cable resistance measurement shall support the 8-bit Write_POWER_ASSIGN command. After transmitting a Write_POWER_ASSIGN command, the PSE shall transmit a 16-bit POWER_ASSIGN write payload followed by an 8-bit CRC8 field as specified in 104.7.2.5. A flowchart for operation of the address and the Write_POWER_ASSIGN command is shown in Figure 104–13. Table 104–16 illustrates the contents of the POWER_ASSIGN register.

Table 104–16—POWER_ASSIGN register table

Bit(s)	Name	Description	R/W[a]
b[15:12]	Reserved	Value always 0	RO
b[11:0]	P_{PD_assign} PD Assigned Power	PD assigned power, 0.025 W per LSB	R/W

[a]RO = Read only, R/W = Read/Write

104.7.2.9 Read_POWER_ASSIGN command [0x81]

All PSEs and PDs that support cable resistance measurement shall support the 8-bit Read_POWER_ASSIGN command. After receiving a Read_POWER_ASSIGN command, the PD shall respond with a 16-bit POWER_ASSIGN read payload followed by an 8-bit CRC8 field as specified in 104.7.2.5. A flowchart for operation of the address and the Read_POWER_ASSIGN command is shown in Figure 104–13. Table 104–16 illustrates the contents of the POWER_ASSIGN register.

104.8 Environmental

104.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2. In particular, the PSE shall be classified as a Limited Power Source in accordance with Annex Q of IEC 62368-1:2018, as applicable. For automotive applications, systems described in this clause may be subject to additional requirements; refer to ISO 26262.

All equipment subject to this clause may be additionally required to conform to any applicable local, state, or national standards, including national motor vehicle standards related to safety or as agreed to between the customer and supplier.

104.8.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns. The list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to verify compliance with the appropriate requirements. LAN cabling systems described in this clause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cabling and components.
c) High-energy transients coupled onto the LAN cabling system.
d) Voltage potential differences between safety grounds to which various LAN components are connected.

Such electrical safety hazards should be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures should be taken to verify that the intended safety features are not negated during installation of a new network or during modification of an existing network.

104.8.3 Installation and maintenance guidelines

It is a mandatory requirement that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

In particular, users are cautioned to be aware of the ampacity of cabling, as installed, and local codes and regulations, e.g., ANSI/NFPA 70—National Electric Code® (NEC®), relevant to the maximum class supported.

It is a mandatory requirement that, during installation of the cabling plant, care be taken to verify that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

All cabling and equipment subject to this clause is expected to be mechanically and electrically secure in a professional manner.

In automotive applications, all PoDL cabling should be routed in way to provide maximum protection by the motor vehicle sheet metal and structural components, following SAE J1292, ISO 14229, and ISO 15764.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Automotive environmental conditions are generally more severe than those found in many commercial and industrial environments. The target automotive, industrial, or commercial environment(s) require careful analysis prior to implementation.

104.8.4 Patch panel considerations

It is possible that the current carrying capability of a cabling cross-connect may be exceeded by a PSE. The designer should consult the manufacturers' specifications to verify compliance with the appropriate requirements.

104.8.5 Telephony voltages

The use of building wiring brings with it the possibility of wiring errors that may connect telephony voltages to a PSE or PD. Other than voice signals, the primary voltages that may be encountered are the "battery" and ringing voltages. Although there is no universal standard, the following maximums generally apply:

Battery voltage to a telephone line is generally 56 Vdc, applied to the line through a balanced 400 Ω source impedance. Ringing voltage is a composite signal consisting of an ac component and a dc component. The ac component is up to 175 Vp at 20 Hz to 60 Hz with a 100 Ω source resistance. The dc component is 56 Vdc with 300 Ω to 600 Ω source resistance. Large reactive transients can occur at the start and end of each ring interval.

Application of any of the above voltages to the PI of a PSE or a PD in non-automotive applications shall not preclude conformance with 104.8.1 and 104.8.2.

104.8.6 Electromagnetic emissions

The PD and PSE powered cabling link shall comply with applicable local and national codes for the limitation of electromagnetic interference.

In addition, the system may need to comply with more stringent requirements as agreed upon between customer and supplier, for the limitation of electromagnetic interference. In automotive applications, a PoDL system shall be tested according to CISPR 25 test methods, and shall meet the following motor vehicle EMC requirements:

a) Radiated/Conducted Emissions: CISPR 25, IEC 61967-1/4, and IEC 61000-4-21
b) Radiated/Conducted Immunity: ISO 11452, IEC 62132-1/4, and IEC 61000-4-21
c) Electrostatic Discharge: ISO 10605 and IEC 61000-4-2/3
d) Electrical Disturbances: IEC 62215-3 and ISO 7637-2/3

Exact test setup and test limit values may be adapted to each specific application, subject to agreement between the customer and the supplier.

104.8.7 Temperature and humidity

The PD and PSE powered cabling link segment is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling. Specific requirements and values for these parameters are beyond the scope of this standard.

104.9 Protocol implementation conformance statement (PICS) proforma for Clause 104, Power over Data Lines (PoDL) of Single-Pair Ethernet[178]

104.9.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 104, Power over Data Lines (PoDL) of Single-Pair Ethernet, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

104.9.2 Identification

104.9.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

104.9.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 104 Power over Data Lines (PoDL) of Single-Pair Ethernet
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022)	

Date of Statement	

[178] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

104.9.4 PICS proforma tables for Clause 104, Power over Data Lines (PoDL) of Single-Pair Ethernet

104.9.4.1 Link Segment

Item	Feature	Subclause	Value/Comment	Status	Support
LNK1	DC loop resistance	104.2	Less than 6 Ω for Classes 0 and 1, less than 6.5 Ω for Classes 2 through 9, less than 65 Ω for Classes 10 and 13, less than 25 Ω for Classes 11 and 14, less than 9.5 Ω for Classes 12 and 15	M	Yes [ ]

104.9.4.2 Power Sourcing Equipment (PSE)

Item	Feature	Subclause	Value/Comment	Status	Support
PSE1	PSE pinout	104.4.2	See Table 104–3	M	Yes [ ]
PSE2	Voltage and power requirements	104.4.3	As defined in Table 104–1 for each relevant class	M	Yes [ ]
PSE3	PSE behavior	104.4.4	In accordance with the state diagrams shown in Figure 104–4, Figure 104–5, and Figure 104–6	M	Yes [ ]
PSE4	Complete detection of a valid PD signature	104.4.5	Within T_{det} as specified in Table 104–6	M	Yes [ ]
PSE5	Valid signature not detected and classification not performed	104.4.5	Wait at least $T_{Restart}$ before reattempting detection	M	Yes [ ]
PSE6	Detection currents	104.4.5.1	Within I_{valid} current range, as specified in Table 104–6,when connected to a valid PD detection signature as specified in Table 104–9	M	Yes [ ]
PSE7	Detection Probe	104.4.5.1	To conform to V_{OC}, I_{SC}, I_{slew}, and C_{out} as specified in Table 104–6	M	Yes [ ]
PSE8	Accept valid PD signature	104.4.5.2	From link segment with a voltage in the range of V_{good_PSE} for at least T_{sig_hold} in response to a probing current in the range of I_{valid} as specified in Table 104–6	M	Yes[ ]
PSE9	Reject invalid PD signature	104.4.5.3	From link segment that exhibits the following characteristics outlined in Table 104–6: a) Voltage less than or equal to $V_{bad_lo_PSE}$max b) Voltage greater than or equal to $V_{bad_hi_PSE}$min	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PSE10	Applying full operating voltage at the PI with SCCP enabled	104.4.6	Only after detection and complete classification in a time less than T_{Class} as specified in Table 104–7	M	Yes [ ]
PSE11	T_{Class} timer expired before complete classification	104.4.6	Complete a new detection cycle before applying any subsequent full operating voltage and transition to the RESTART state	M	Yes [ ]
PSE12	Providing power to the PSE PI	104.4.7	To conform to electrical limits in Table 104–7	M	Yes [ ]
PSE13	Present invalid PD signature	104.4.7	With one of the attributes as specified in Table 104–10 under all conditions	M	Yes [ ]
PSE14	Applied voltage at the PI while in the POWER_ON state	104.4.7.1	In the range of $V_{PSE(PON)}$	M	Yes [ ]
PSE15	Applied voltage at the PI when in the OVERLOAD, OVERLOAD_DELAY, and DISABLED states	104.4.7.1	In the range of $V_{Disable}$	M	Yes [ ]
PSE16	Applied voltage at the PI while in the SLEEP, RESTART, RESTART_DELAY, and IDLE states	104.4.7.1	In the range of V_{Sleep}	M	Yes [ ]
PSE17	SETTLE_SLEEP state	104.4.7.1	Discharge the PSE PI to the range of V_{Sleep} within a time less than T_{OFF}max	M	Yes [ ]
PSE18	Enter SETTLE_SLEEP state	104.4.7.2	If a valid MFVS is not present at the PI while operating in the POWER_ON state	M	Yes [ ]
PSE19	PI discharge while in SETTLE_SLEEP state	104.4.7.2	To the range of V_{Sleep} with a current in the range of $I_{discharge}$	M	Yes [ ]
PSE20	PSE output during POWER_UP state	104.4.7.2	Not to exceed I_{LIM}max	M	Yes [ ]
PSE21	POWER_UP and POWER_ON state operation	104.4.7.2.1	Limit the current to I_{LIM} for a duration of up to T_{LIM} in order to account for PSE dV/dt transients at the PI as specified in Table 104–7	M	Yes [ ]
PSE22	PSE enabled while not in POWER_ON or POWER_UP states	104.4.7.2.1	Limit I_{PSE} to less than I_{SC} as specified in Table 104–6 for a duration of up to T_{LIM}	M	Yes [ ]
PSE23	Set overload_detected to TRUE and begin power removal from the PI within T_{LIM} of the initiation of current limiting	104.4.7.2.1	If the PSE is limiting current in any state when pi_powered, pi_sleeping, or pi_prebias are true	M	Yes [ ]
PSE24	Measuring I_{PSE} during short circuit	104.4.7.2.1	To be made 1 ms after the initial transient to allow for settling	M	Yes [ ]

104.9.4.3 Powered Device (PD)

Item	Feature	Subclause	Value/Comment	Status	Support
PD1	PD PI	104.5.2	Class 0 to 9 PDs operate per the Mode A column in Table 104–8. Class 10 to 15 PDs are polarity-insensitive and are able to operate per Mode A and Mode B of Table 104–8.	M	Yes [ ]
PD2	Voltage and power requirements	104.5.3	As defined in Table 104–1 for each relevant class	M	Yes [ ]
PD3	PD behavior	104.5.4	In accordance with the state diagram shown in Figure 104–8	M	Yes [ ]
PD4	Present valid detection signature when classification is not implemented or if a Class 0 or Class 1 PD	104.5.5	When V_{PD} is less than V_{sig_enable}	M	Yes [ ]
PD5	Classification implementation required	104.5.5	If PD presents an invalid detection signature greater than V_{bad_hi} max as specified in Table 104–10	M	Yes [ ]
PD6	Removal of current draw of detection signature	104.5.5	When V_{PD} is greater than $V_{sig_disable}$	M	Yes [ ]
PD7	PD detection signature	104.5.5	To consist of a current limited, voltage, V_{good} as specified in Table 104–9 when measured by the PSE	M	Yes [ ]
PD8	Valid detection signature	104.5.5	In accordance with all of the characteristics shown in Table 104–9	M	Yes [ ]
PD9	Non-valid detection signature	104.5.5	In accordance with one of the characteristics shown in Table 104–10	M	Yes [ ]
PD10	PD power	104.5.7	In accordance with the characteristics shown in Table 104–11	M	Yes [ ]
PD11	PD discharge	104.5.7.1	At a delay of T_{OFF} max after disconnection from the PSE, a PD shall not source greater than 410 μJ out of its PI until V_{PD} drops below V_{Sleep_PD} max	M	Yes [ ]
PD12	PD turn on	104.5.7.2	At a voltage less than or equal to V_{On} max and with a delay greater than T_{power_dly} min	M	Yes [ ]
PD13	PD on voltage	104.5.7.2	Over the range from V_{PD} min to V_{PSE} max	M	Yes [ ]
PD14	PD turn off	104.5.7.2	At a voltage in the range of V_{PD} min to V_{Off} min	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD15	PD turn on or off	104.5.7.2	Without startup oscillation and within the first trial when a voltage in the range of V_{PSE} (as defined in Table 104–1) is applied with a series resistance within the range of valid dc loop resistance (as defined in 104.2)	M	Yes [ ]
PD16	PD_SLEEP state input voltage	104.5.7.2	Greater than V_{Sleep_PD} min as specified in Table 104–11	M	Yes [ ]
PD17	Input current while in DISCONNECT and PD_SLEEP states	104.5.7.3	Current drawn is not in excess of I_{Sleep_PD} as specified in Table 104–11	M	Yes [ ]
PD18	PD requiring detection and application of power	104.5.7.3	Draw current in the range of I_{Wakeup_PD} for at least T_{Wakeup_PD} when V_{PD} is in the range of V_{Sleep_PD} as specified in Table 104–11	M	Yes [ ]
PD19	Constant PD input voltage between V_{sig_disble}max and V_{On} min	104.5.7.3	Draw current less than I_{PD_pwr1}max	M	Yes [ ]
PD20	Type A or Type C PD ripple and transients	104.5.7.4	In accordance with specifications shown in Table 104–11 for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Clause 96, and over the range of P_{PD}	PDTA:M or PDTC:M	Yes [ ] N/A [ ]
PD21	Type F PD ripple and transients	104.5.7.4	In accordance with specifications shown in Table 104–11 for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Clause 149, and over the range of P_{PD}	PDTF:M	Yes [ ] N/A [ ]
PD22	Type B PD ripple and transients	104.5.7.4	In accordance with specifications shown in Table 104–11 for all operating voltages in the range of V_{PD} sourced through a dc bias coupling network with MDI return loss as specified by Clause 97, and over the range of P_{PD}	PDTB:M	Yes [ ] N/A [ ]
PD23	Type A or Type C PD measured ripple voltage post-processing	104.5.7.4	With transfer function $H_2(f)$ specified in Equation (104–3) where f_2=1 MHz ±1%	PDTA:M or PDTC:M	Yes [ ] N/A [ ]
PD24	Type F PD measured ripple voltage post-processing	104.5.7.4	With transfer function $H_2(f)$ specified in Equation (104–3) where f_2 = 10 MHz ± 1%	PDTF:M	Yes [ ] N/A [ ]

104.9.4.6 PD Electrical

Item	Feature	Subclause	Value/Comment	Status	Support
PDEL1	DC isolation	104.6.1	Of at least 1 MΩ provided between all accessible external conductors, including frame ground (if any), and all MDI leads, when measured using a 5 V ± 20% source voltage	M	Yes [ ]
PDEL2	PD PI	104.6.2	A PD shall not be damaged when connected to any PSE as defined in 104.4	M	Yes [ ]

104.9.4.7 SCCP

Item	Feature	Subclause	Value/Comment	Status	Support
SCCP1	SCCP implementation mandatory	104.7	For PDs that present an invalid detection signature as specified in Table 104–10	SCCP:M	Yes [ ] N/A[ ]
SCCP2	SCCP communication	104.7.1.1	Begins with an initialization sequence consisting of a result pulse from the PSE followed by a presence pulse from the PD. See Figure 104–10	SCCP:M	Yes [ ] N/A[ ]
SCCP3	Initialization sequence	104.7.1.1	PSE transmits a reset pulse by first driving V_{PSE} low and then releasing to the pull up at t_{RSTL} before going into receive mode (RX)	SCCP:M	Yes [ ] N/A[ ]
SCCP4	PD presence pulse	104.7.1.1	Transmitted after detecting rising edge at PD PI and waiting t_{PDH}	SCCP:M	Yes [ ] N/A[ ]
SCCP5	Presence data from PD	104.7.1.1	To be valid for the entire time window defined by t_{MSP} following the rising edge that terminated the reset pulse	SCCP:M	Yes [ ] N/A[ ]
SCCP6	PSE write time slots	104.7.1.2	Write 1 time slot to transmit logic 1 to PD and write 0 time slot to transmit logic 0 to PD	SCCP:M	Yes [ ] N/A[ ]
SCCP7	Write time slot duration	104.7.1.2	Defined as t_{SLOT} shown in Table 104–12	SCCP:M	Yes [ ] N/A[ ]
SCCP8	Write time slot initiation	104.7.1.2	Initiated by pulling V_{PSE} low	SCCP:M	Yes [ ] N/A[ ]
SCCP9	Write 1 time slot generation	104.7.1.2	Pull up V_{PSE} within the range of t_{W1L} after pulling V_{PSE} low	SCCP:M	Yes [ ] N/A[ ]
SCCP10	Write 0 time slot generation	104.7.1.2	Pull up V_{PSE} within the range of t_{W0L} after pulling V_{PSE} low	SCCP:M	Yes [ ] N/A[ ]
SCCP11	PD sampling during a write 1 or write 0 operation	104.7.1.2	Sample V_{PD} within the range of t_{SSW} after falling edge.	SCCP:M	Yes [ ] N/A[ ]

Item	Feature	Subclause	Value/Comment	Status	Support
SCCP12	Read time slot generation	104.7.1.3	Generated by the PSE immediately after issuing a function command that requires data from the PD	SCCP:M	Yes [ ] N/A[ ]
SCCP13	Read time slot duration	104.7.1.3	Defined as t_{SLOT} shown in Table 104–12	SCCP:M	Yes [ ] N/A[ ]
SCCP14	Read time slot initiation	104.7.1.3	Initiate by pulling PI port voltage low and then pulling up the PI port voltage within t_{W1L}	SCCP:M	Yes [ ] N/A[ ]
SCCP15	PD transmit	104.7.1.3	Transmit a 1 or 0 at the PD PI after PSE initiates read time slot	SCCP:M	Yes [ ] N/A[ ]
SCCP16	PD transmit 1	104.7.1.3	Leave PI port voltage high	SCCP:M	Yes [ ] N/A[ ]
SCCP17	PD transmit 0	104.7.1.3	Pull PI port voltage low	SCCP:M	Yes [ ] N/A[ ]
SCCP18	PD transmit 0 duration	104.7.1.3	While transmitting 0, hold the PI low, and then release its PI within t_{R0L}	SCCP:M	Yes [ ] N/A[ ]
SCCP19	Read time slot sample	104.7.1.3	PSE releases PI and then samples subsequent voltage within t_{MSR} from the start of the read time slot	SCCP:M	Yes [ ] N/A[ ]
SCCP20	SCCP electrical requirements	104.7.1.3	To comply with the electrical and timing requirements in Table 104–12	SCCP:M	Yes [ ] N/A[ ]
SCCP21	SCCP data and commands	104.7.2	Transmitted least significant bit first	SCCP:M	Yes [ ] N/A[ ]
SCCP22	Communication with PD	104.7.2.2	Begins with the initialization sequence that consists of a reset pulse from the PSE followed by a presence pulse from the PD	SCCP:M	Yes [ ] N/A[ ]
SCCP23	SCCP-capable PDs	104.7.2.3	Support the Broadcast Address command	SCCP:M	Yes [ ] N/A[ ]
SCCP24	Issuing function command	104.7.2.3	Only after issuing an appropriate address command	SCCP:M	Yes [ ] N/A[ ]
SCCP25	8-bit Read Scratchpad command	104.7.2.4	Supported by all SCCP-enabled PDs	SCCP:M	Yes [ ] N/A[ ]
SCCP26	Reception of Read Scratchpad function command	104.7.2.4	PD shall respond with a 16-bit CLASS_TYPE_INFO read payload followed by an 8-bit CRC8 field	SCCP:M	Yes [ ] N/A[ ]
SCCP27	CRC8 calculation	104.7.2.5	Produces the same result as the serial implementation shown in Figure 104–14	SCCP:M	Yes [ ] N/A[ ]
SCCP28	Shift register	104.7.2.5	Initialized to the value 0x00 before CRC8 calculation begins	SCCP:M	Yes [ ] N/A[ ]

105. Introduction to 25 Gb/s networks

105.1 Overview

105.1.1 Scope

25 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer, connected through a 25 Gigabit Media Independent Interface (25GMII) to Physical Layer devices such as 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, 25GBASE-KR-S, 25GBASE-SR, 25GBASE-T, 25GBASE-LR, and 25GBASE-ER.

25 Gb/s Physical Layer devices, such as those specified in Table 105–1, provide a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

25 Gigabit Ethernet is defined for full duplex operation only.

105.1.2 Relationship of 25 Gigabit Ethernet to the ISO OSI reference model

25 Gigabit Ethernet couples the IEEE 802.3 MAC to a family of 25 Gb/s Physical Layers. The relationships among 25 Gigabit Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 105–1.

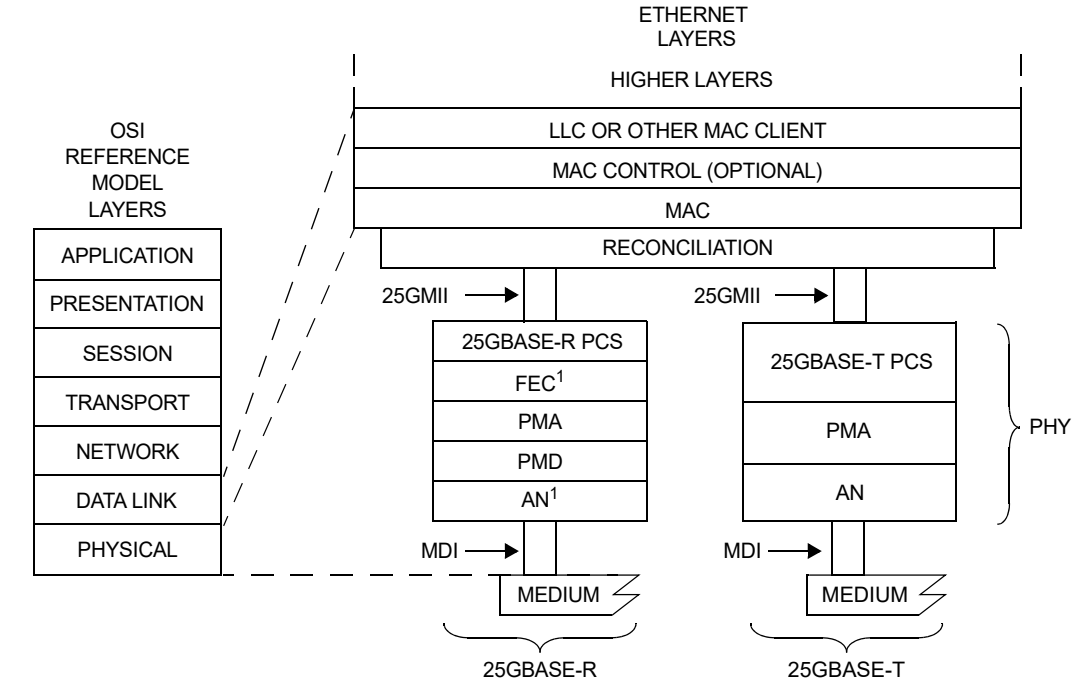

Figure 105–1—Architectural positioning of 25 Gigabit Ethernet

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience. The only exceptions are as follows:

a) The PMA service interface, which, when physically implemented as 25GAUI at an observable interconnection port, uses a single-lane data path as specified in Annex 109A or Annex 109B.

b) The management interface, which, when physically implemented as the MDIO/MDC (Management Data Input/Output and Management Data Clock) at an observable interconnection port, uses a bit-wide data path as specified in Clause 45.

c) The Media Dependent Interface (MDI) as specified in Clause 110 for 25GBASE-CR and 25GBASE-CR-S, in Clause 111 for 25GBASE-KR and 25GBASE-KR-S, in Clause 112 for 25GBASE-SR, or in Clause 114 for 25GBASE-LR and 25GBASE-ER uses a single-lane data path.

d) The MDI as specified in Clause 113 for 25GBASE-T uses a four-lane data path.

105.1.3 Nomenclature

The prefix 25GBASE in the port type (e.g., 25GBASE-R) represents a family of Physical Layer devices operating at a speed of 25 Gb/s.

The term 25GBASE-R refers to a specific family of Physical Layer implementations based upon the 64B/66B data coding method specified in Clause 107. The 25GBASE-R family is composed of 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, 25GBASE-KR-S, 25GBASE-SR, 25GBASE-LR, and 25GBASE-ER.

25GBASE-T represents Physical Layer devices using Clause 113 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, for data communication at 25 Gb/s over a point-to-point 4-pair balanced twisted-pair medium. 25GBASE-T uses a combination of Reed-Solomon-FEC (RS-FEC) and low density parity check (LDPC) FECs in its physical coding sublayer that is mapped to a 128 double-square (DSQ128) constellation for transmission on 4-pair, twisted-pair copper cabling.

Physical Layer devices listed in Table 105–1 are defined for operation at 25 Gb/s.

Table 105–1—25 Gb/s PHYs

Name	Description
25GBASE-KR-S	25 Gb/s PHY equivalent to 25GBASE-KR without support for the RS-FEC sublayer (see Clause 111).
25GBASE-KR	25 Gb/s PHY using 25GBASE-R encoding over one lane of an electrical backplane (see Clause 111).
25GBASE-CR-S	25 Gb/s PHY equivalent to 25GBASE-CR without support for the RS-FEC sublayer (see Clause 110).
25GBASE-CR	25 Gb/s PHY using 25GBASE-R encoding over one lane of twinaxial copper cable (see 1.4.559 and Clause 110).
25GBASE-T	25 Gb/s PHY using RS-FEC and LDPC encoding over balanced twisted-pair structured cabling systems (see Clause 113).
25GBASE-SR	25 Gb/s PHY using 25GBASE-R encoding over a duplex multimode fiber (see Clause 112).
25GBASE-LR	25 Gb/s PHY using 25GBASE-R encoding over a duplex single-mode fiber, with reach up to at least 10 km (see Clause 114).
25GBASE-ER	25 Gb/s PHY using 25GBASE-R encoding over a duplex single-mode fiber, with reach up to at least 40 km (see Clause 114).

105.2 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. The generic term 25 Gigabit Ethernet refers to any use of the 25 Gb/s IEEE 802.3 MAC (the 25 Gigabit Ethernet MAC) coupled with any IEEE 802.3 25GBASE Physical Layer implementation. Table 105–2 specifies the correlation between

nomenclature and clauses. Implementations conforming to one or more nomenclatures shall meet the requirements of the corresponding clauses.

Table 105–2—Nomenclature and clause correlation, 25 Gb/s Ethernet PHYs

Nomenclature	Clause/Annex

[a]O = Optional, M = Mandatory

105.3 Summary of 25 Gigabit Ethernet sublayers

105.3.1 Reconciliation Sublayer (RS) and 25 Gigabit Media Independent Interface (25GMII)

The 25GMII (Clause 106) provides a logical interconnection between the Media Access Control (MAC) sublayer and Physical Layer devices (PHYs). The 25GMII supports 25 Gb/s operation through its 32-bit-wide transmit and receive data paths.

The RS provides a mapping between the signals provided at the 25GMII and the MAC/PLS service definition.

While the 25GMII is an optional interface, it is used extensively in this standard as a basis for functional specification and provides a common service interface for a 25 Gb/s PHY.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

105.3.2 Physical Coding Sublayer (PCS)

25GBASE-R PHYs use the PCS specified in Clause 107. The 25GBASE-R PCS performs encoding of data from the 25GMII to 64B/66B code blocks and transfers the encoded data to the PMA and performs decoding of 64B/66B blocks from the PMA and transfers the decoded data to the 25GMII.

105.3.3 Forward error correction (FEC) sublayer

An FEC sublayer is available for all 25GBASE-R PHYs. The FEC sublayer can be placed in between the PCS and PMA sublayers or between two PMA sublayers.

The BASE-R FEC (see Clause 74) may be used by some 25GBASE-R PHYs.

The RS-FEC (see Clause 108) may be used by some 25GBASE-R PHYs.

The requirement to implement FEC for each Physical Layer implementation is summarized in 105.2.

105.3.4 Physical Medium Attachment (PMA) sublayer

The PMA sublayer provides a medium-independent means for the PCS to support the use of a range of physical media. The PMA performs the mapping of transmit and receive data streams between the PCS and PMA via the PMA service interface and mapping of transmit and receive data streams between the PMA and PMD via the PMD service interface.

The 25GBASE-R PMA (see Clause 109) performs retiming of the received data stream when appropriate, optionally provides data loopback at the PMA or PMD service interface, and optionally provides test-pattern generation and checking. The 25GBASE-R PMA also may provide the observable electrical interface for the 25GAUI chip-to-chip (C2C) or chip-to-module (C2M) (see Annex 109A and Annex 109B).

105.3.5 Physical Medium Dependent (PMD) sublayer

The PMD sublayer is responsible for interfacing to the transmission medium.

The MDI connects the PMD to the medium and is defined in the associated PMD clause.

The 25GBASE-R PMDs and their corresponding media are specified in Clause 110, Clause 111, Clause 112, and Clause 114.

105.3.6 Auto-Negotiation (AN)

AN provides a linked device with the capability to detect the abilities (modes of operation) supported by the device at the other end of the link, determine common abilities, and configure for joint operation.

Clause 28 AN is used by the 25GBASE-T PHY.

Clause 73 AN is used by the 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, and 25GBASE-KR-S PHYs.

105.3.7 Management interface (MDIO/MDC)

The MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMD) and Station Management (STA) entities.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

105.3.8 Management

Managed objects, attributes, and actions are defined for all 25 Gigabit Ethernet components. These items are defined in Clause 30.

105.4 Service interface specification method and notation

The service interface specification for 25GBASE-R Physical Layers is as per the definition in 1.2.2 and is based upon the service interface specification in 80.3, but redefined for a single lane.

105.4.1 Inter-sublayer service interface

The inter-sublayer service interface is described in an abstract manner and does not imply any particular implementation. The inter-sublayer service interface primitives are defined as follows:

IS_UNITDATA.request
IS_UNITDATA.indication
IS_SIGNAL.indication

The IS_UNITDATA.request primitive is used to define the transfer of a stream of data units from a sublayer to the next lower (closer to the medium) sublayer. The IS_UNITDATA.indication primitive is used to define the transfer of a stream of data units from a sublayer to the next higher (closer to the MAC) sublayer. The IS_SIGNAL.indication primitive is used to define the transfer of signal status from a sublayer to the next higher sublayer.

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see 78.1.3.3.1), then the inter-sublayer service interface includes some or all (depending on sublayer, see Figure 105–3) of five additional primitives defined as follows:

IS_TX_MODE.request
IS_RX_MODE.request
IS_ENERGY_DETECT.indication
IS_RX_LPI_ACTIVE.request
IS_RX_TX_MODE.indication

The IS_TX_MODE.request primitive is used to communicate the state of the PCS LPI transmit function to other sublayers in the PHY.

The IS_RX_MODE.request primitive is used to communicate the state of the PCS LPI receive function to other sublayers.

The IS_RX_TX_MODE.indication primitive is used to communicate the state of the rx_tx_mode parameter that reflects the inferred state of the link partner's tx_mode parameter from the PMA to other sublayers.

The IS_RX_LPI_ACTIVE.request primitive is used to communicate to the BASE-R FEC (see Clause 74) that the PCS has detected LPI signaling. This allows the FEC to use rapid block lock; the RS-FEC (see Clause 108) does not use this signal.

The IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence.

105.4.2 Instances of the Inter-sublayer service interface

The inter-sublayer interface can be instantiated between different sublayers, hence a prefix notation is defined to identify a specific instance of an inter-sublayer service interface. The following prefixes are defined:

a) PMD:—for primitives issued on the interface between the PMD sublayer and the PMA sublayer called the PMD service interface.
b) PMA:—for primitives issued on the interface between the PMA sublayer and the PCS (or the FEC) sublayer called the PMA service interface.
c) FEC:—for primitives issued on the interface between the FEC sublayer and the PCS (or the PMA) sublayer called the FEC service interface.

Examples of inter-sublayer service interfaces for 25GBASE-R with their corresponding instance names are illustrated in Figure 105–2 and Figure 105–3. For example, the primitives for one instance of the inter-sublayer service interface, named the PMD service interface are identified as follows:

PMD:IS_UNITDATA.request
PMD:IS_UNITDATA.indication
PMD:IS_SIGNAL.indication.

Primitives for other instances of inter-sublayer interfaces are represented in a similar manner as described above.

105.4.3 Semantics of inter-sublayer service interface primitives

The semantics of the inter-sublayer service interface primitives for the 25GBASE-R sublayers are described in 105.4.3.1 through 105.4.3.3.

105.4.3.1 IS_UNITDATA.request

The IS_UNITDATA.request primitive is used to define the transfer of a stream of data units from a sublayer to the next lower sublayer.

105.4.3.1.1 Semantics of the service primitive

IS_UNITDATA.request(tx_bit)

The data conveyed by IS_UNITDATA.request is a continuous stream of encoded bits. The tx_bit parameter can take one of two values: one or zero.

105.4.3.1.2 When generated

The sublayer continuously sends a bit stream IS_UNITDATA.request(tx_bit) to the next lower sublayer, at a nominal signaling rate of 25.78125 GBd.

105.4.3.1.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

105.4.3.2 IS_UNITDATA.indication

The IS_UNITDATA.indication primitive is used to define the transfer of a stream of data units from the sublayer to the next higher sublayer.

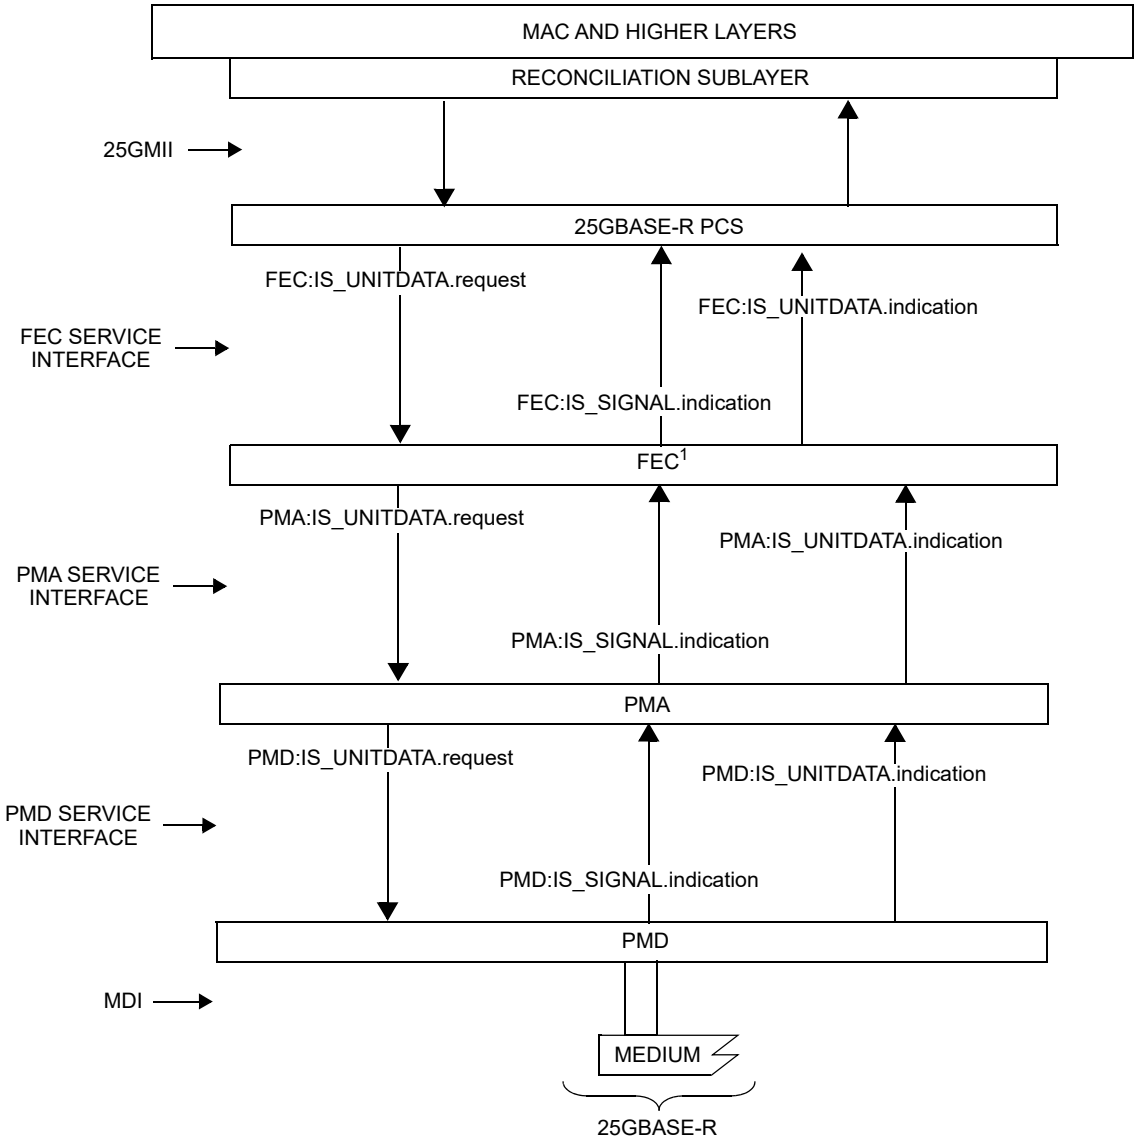

Figure 105–2—25GBASE-R inter-sublayer service interfaces

105.4.3.2.1 Semantics of the service primitive

IS_UNITDATA.indication(rx_bit)

The data conveyed by IS_UNITDATA.indication is a continuous stream of encoded bits. The rx_bit parameters can take one of two values: one or zero.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

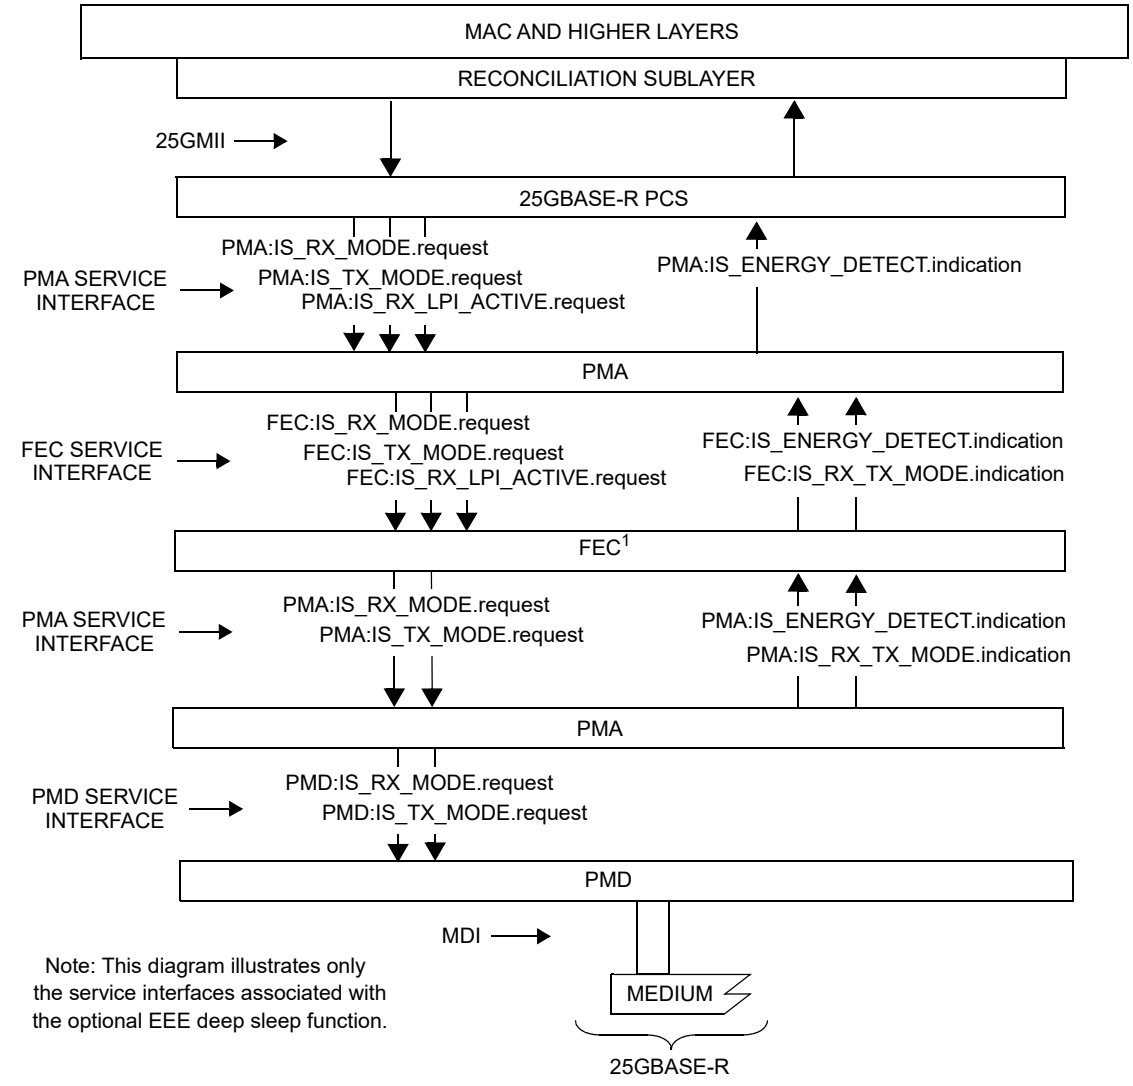

Figure 105–3—Optional inter-sublayer service interfaces for EEE deep sleep support

105.4.3.2.2 When generated

The sublayer continuously sends a bit stream IS_UNITDATA.indication(rx_bit) to the next higher sublayer, at a nominal signaling rate of 25.78125 GBd.

105.4.3.2.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

105.4.3.3 IS_SIGNAL.indication

The IS_SIGNAL.indication primitive is generated by the sublayer to the next higher sublayer to indicate the status of the receive process. This primitive is generated by the receive process to propagate the detection of severe error conditions (e.g., no valid signal being received by the sublayer that generates this primitive) to the next higher sublayer.

105.4.3.3.1 Semantics of the service primitive

IS_SIGNAL.indication(SIGNAL_OK)

The SIGNAL_OK parameter can take on one of the following two values: OK or FAIL. A value of FAIL denotes that invalid data is being presented (rx_bit parameters undefined) by the sublayer to the next higher sublayer. A value of OK does not guarantee valid data is being presented by the sublayer to the next higher sublayer.

105.4.3.3.2 When generated

The sublayer generates the IS_SIGNAL.indication primitive to the next higher sublayer whenever there is change in the value of the SIGNAL_OK parameter.

105.4.3.3.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

105.4.3.4 IS_TX_MODE.request

The IS_TX_MODE.request primitive communicates the tx_mode parameter generated by the PCS Transmit Process for EEE capability to invoke the appropriate PMA, FEC, and PMD transmit EEE states. Without EEE deep sleep mode capability, the primitive is never invoked and the sublayers behave as if tx_mode = DATA.

105.4.3.4.1 Semantics of the service primitive

IS_TX_MODE.request(tx_mode)

The tx_mode parameter takes on one of up to three values: DATA, QUIET, or ALERT.

105.4.3.4.2 When generated

This primitive is generated to indicate the low power mode of the transmit path.

105.4.3.4.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the sublayer that receives this primitive. In general, when tx_mode is DATA, the sublayer operates normally and when tx_mode is QUIET, the sublayer may go into a low power mode.

105.4.3.5 IS_RX_MODE.request

The IS_RX_MODE.request primitive communicates the rx_mode parameter generated by the PCS LPI receive function to other sublayers.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Without EEE deep sleep mode capability, the primitive is never invoked and the sublayers behave as if rx_mode = DATA.

105.4.3.5.1 Semantics of the service primitive

IS_RX_MODE.request(rx_mode)

The rx_mode parameter takes on one of two values: DATA or QUIET.

105.4.3.5.2 When generated

This primitive is generated to indicate the state of the PCS LPI receive function.

105.4.3.5.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the sublayer that receives this primitive. In general, when rx_mode is DATA, the sublayer operates normally and when rx_mode is QUIET, the sublayer may go into a low power mode.

105.4.3.6 IS_RX_LPI_ACTIVE.request

The IS_RX_LPI_ACTIVE.request primitive communicates to the FEC that the PCS LPI receive function is active. This primitive may be passed through a PMA sublayer but has no effect on that sublayer. This primitive is only used for a PMA sublayer that is between the PCS and a Clause 74 FEC sublayer; in all other cases the primitive is never invoked and has no effect. Without EEE deep sleep mode capability, the primitive is never invoked and has no effect.

105.4.3.6.1 Semantics of the service primitive

IS_RX_LPI_ACTIVE.request(rx_lpi_active)

The parameter rx_lpi_active is Boolean.

105.4.3.6.2 When generated

This primitive is generated to indicate the state of the PCS LPI receive function. It is FALSE when in the RX_ACTIVE state and TRUE in all other states.

105.4.3.6.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the FEC sublayer that receives this primitive. When rx_lpi_active is true, the FEC sublayer uses rapid block lock to reestablish FEC operation following a period of quiescence.

105.4.3.7 IS_ENERGY_DETECT.indication

The IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence. Without EEE deep sleep mode capability, the primitive is never invoked and has no effect.

105.4.3.7.1 Semantics of the service primitive

IS_ENERGY_DETECT.indication(energy_detect)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The parameter energy_detect is Boolean.

105.4.3.7.2 When generated

This primitive is generated by the PMA, reflecting the state of the signal_detect parameter received from the PMD.

105.4.3.7.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the PCS sublayer that receives this primitive.

This parameter is used to indicate that activity has returned on the interface following a period of quiescence.

105.4.3.8 IS_RX_TX_MODE.indication

The IS_RX_TX_MODE.indication primitive communicates the rx_tx_mode parameter. This parameter indicates the value of tx_mode that the PMA sublayer has inferred from the received signal. Without EEE deep sleep capability, the primitive is never generated and the sublayers behave as if rx_tx_mode = DATA.

105.4.3.8.1 Semantics of the service primitive

IS_RX_TX_MODE.indication(rx_tx_mode)

The parameter rx_tx_mode is assigned one of the following values: DATA, QUIET, or ALERT.

105.4.3.8.2 When generated

This primitive is generated whenever there is change in the value of the rx_tx_mode parameter.

105.4.3.8.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the sublayer that receives it.

105.5 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices. Table 105–3 contains the values of maximum sublayer delay (sum of transmit and receive delays at one end of the link) in bit times as specified in 1.4 and pause_quanta as specified in 31B.2. If a PHY contains an Auto-Negotiation sublayer, the delay of the Auto-Negotiation sublayer is included within the delay of the PMD and medium.

Equation (105–1) specifies the calculation of bit time per meter of fiber or electrical cable based upon the parameter *n*, which represents the ratio of the speed of electromagnetic propagation in the fiber or electrical cable to the speed of light in a vacuum. The value of *n* should be available from the fiber or electrical cable manufacturer, but if no value is known then a conservative delay estimate can be calculated using a default value of $n = 0.66$. The speed of light in a vacuum is $c = 3 \times 10^8$ m/s. Table 44–3 can be used to convert fiber or electrical cable delay values specified relative to the speed of light or in nanoseconds per meter.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{Cable delay} = \frac{25 \times 10^9}{nc} \text{ BT/m} \quad (105\text{–}1)$$

See 31B.3.7 for PAUSE reaction timing constraints for stations at operating speeds of 25 Gb/s.

Table 105–3—Sublayer delay constraints

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
25G RS, MAC, and MAC Control	8 192	16	327.68	See 106.1.4.
25GBASE-R PCS	3 584	7	143.36	See 107.4.
25G BASE-R FEC	6 144	12	245.76	See 74.6.
25GBASE-R RS-FEC	24 576	48	983.04	See 108.4.
25GBASE-R PMA[d]	4 096	8	163.84	See 109.5.
25GBASE-CR PMD	512	1	20.48	See 110.4.
25GBASE-CR-S PMD	512	1	20.48	See 110.4.
25GBASE-KR PMD	512	1	20.48	See 111.4.
25GBASE-KR-S PMD	512	1	20.48	See 111.4.
25GBASE-SR PMD	512	1	20.48	See 112.3.
25GBASE-LR PMD	512	1	20.48	See 114.3.
25GBASE-ER PMD	512	1	20.48	See 114.3.
25GBASE-T PHY	25 600	50	1024	See 113.11.
25GBASE-BR10 PMD	512	1	20.48	See 158.3.
25GBASE-BR20 PMD	512	1	20.48	See 158.3.
25GBASE-BR40 PMD	512	1	20.48	See 158.3.

[a]1 bit time (BT) is equal to 40 ps. (See 1.4.215 for the definition of bit time.)
[b]1 pause_quantum is equal to 20.48 ns. (See 31B.2 for the definition of pause_quanta.)
[c]Should there be a discrepancy between this table and the delay requirements of the relevant sublayer clause, the sublayer clause prevails.
[d]Cumulative round-trip delay contributed by up to four PMA stages in a PHY.

105.6 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

Multiple states of a function that have a transition to a common state utilizing different qualifiers (for example, multiple exit conditions to an IDLE or WAIT state) may be indicated by a shared arrow. An exit transition arrow connects to the shared arrow, and the qualifier is met prior to termination of the transition arrow on the shared arrow. The shared arrow has no qualifier.

105.7 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 45, Clause 73, Clause 74, Clause 106 through Clause 112, Clause 114, and related annexes demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the 25 Gigabit Ethernet PICS conforms to the same notation and conventions used in 21.6.

106. Reconciliation Sublayer (RS) and Media Independent Interface (25GMII) for 25 Gb/s operation

106.1 Overview

This clause defines the characteristics for the Reconciliation Sublayer (RS) and the 25 Gigabit Media Independent Interface (25GMII) between the Ethernet MAC and PHY. Figure 106–1 shows the relationship of the RS and 25GMII to the ISO/IEC (IEEE) OSI reference model. The 25 Gb/s RS has identical logical functionality to the 10 Gb/s RS defined in Clause 46. A physical implementation and associated electrical characteristics for the 25GMII are not defined.

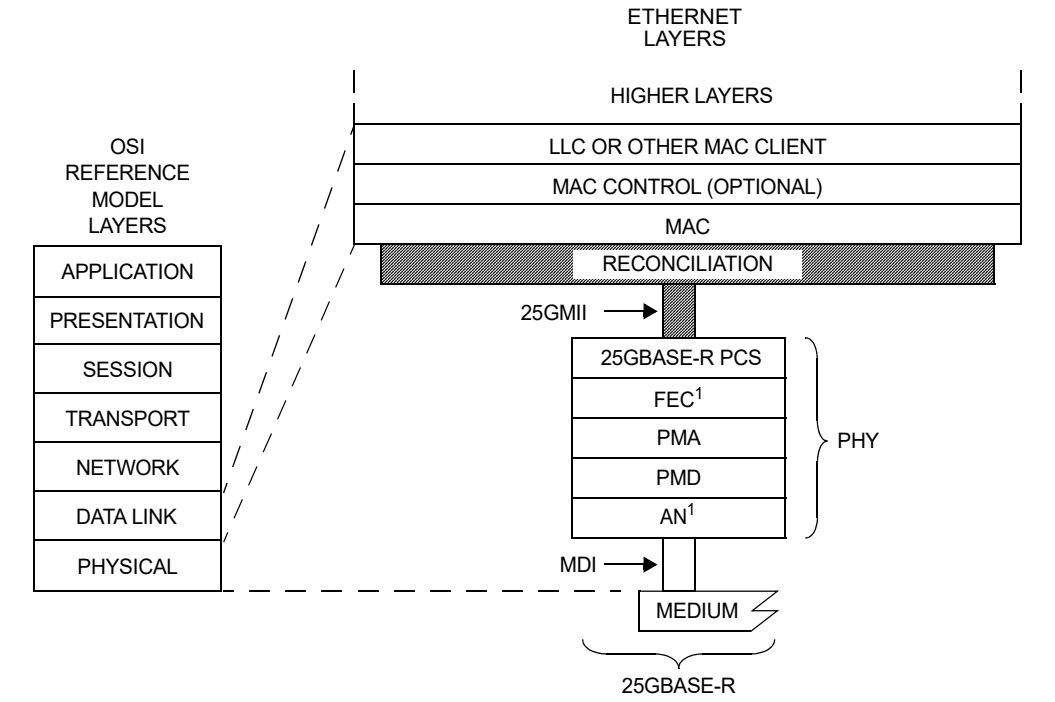

Figure 106–1—RS and 25GMII relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The 25GMII is an optional logical interface between the MAC sublayer and the Physical Layer device.

The RS adapts the bit serial protocols of the MAC to the parallel format of the PCS service interface. Though the 25GMII is an optional interface, it is used extensively in this standard as a basis for specification. The 25 Gb/s Physical Coding Sublayer (PCS) is specified to the 25GMII, so if not implemented, a conforming implementation behaves functionally as if the RS and 25GMII were implemented.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 25GMII has the following characteristics:

a) It is capable of supporting 25 Gb/s operation.
b) Data and delimiters are synchronous to clock reference.
c) It provides independent 32-bit-wide transmit and receive data paths.
d) It provides for full duplex operation only.

106.1.1 Summary of major concepts

The following are the major concepts of 25GMII:

a) The 25GMII is functionally similar to other media independent interfaces that have been defined for other speeds, as they all define an interface allowing independent development of MAC and PHY logic.
b) The RS converts between the MAC serial data stream and the parallel data paths of the 25GMII.
c) The RS maps the signal set provided at the 25GMII to the PLS service primitives provided at the MAC.
d) Each direction of data transfer is independent and serviced by data, control, and clock signals.
e) The RS generates continuous data or control characters on the transmit path and expects continuous data or control characters on the receive path.
f) The RS participates in link fault detection and reporting by monitoring the receive path for status reports that indicate an unreliable link and generating status reports on the transmit path to report detected link faults to the DTE on the remote end of the connecting link.
g) The 25GMII may also support Low Power Idle (LPI) signaling for PHY types supporting Energy-Efficient Ethernet (EEE) (see Clause 78).

106.1.2 Application

This logical interface is used to provide media independence so that an identical MAC may be used with all 25GBASE PHY types.

106.1.3 Rate of operation

The 25GMII is specified to support 25 Gb/s operation.

106.1.4 Delay constraints

The maximum cumulative MAC Control, MAC, and RS round-trip (sum of transmit and receive) delay shall meet the values specified in Table 106–1. Bit time is defined in 1.4, and pause_quanta is defined in 31B.2.

Table 106–1—Round-trip delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)
MAC, RS, and MAC Control	8192	16

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

106.1.5 Allocation of functions

The allocation of functions at the 25GMII balances the need for media independence with interface simplicity. The 25GMII maximizes media independence by separating the Data Link and Physical Layers of the OSI seven-layer reference model.

106.1.6 25GMII structure

The 25GMII structure is identical to the XGMII structure specified in 46.1.6.

106.1.7 Mapping of 25GMII signals to PLS service primitives

The Reconciliation Sublayer (RS) shall map the signals provided at the 25GMII to the PLS service primitives defined in Clause 6. The PLS service primitives provided by the RS and described here behave in exactly the same manner as defined in Clause 6. Full duplex operation only is implemented at 25 Gb/s; therefore, PLS service primitives supporting CSMA/CD operation are not mapped through the RS to the 25GMII. The mapping is changed if EEE capability is supported (see 78.3). This behavior and restrictions are the same as described in 22.7, with the details of the signaling described in 106.3. LPI_REQUEST shall not be set to ASSERT unless the attached link has been operational for at least one second (i.e., link_status = OK, according to the underlying PCS/PMA).

EEE capability requires the use of the MAC defined in Annex 4A for simplified full duplex operation (with carrier sense deferral). This provides full duplex operation but uses the carrier sense signal to defer transmission when the PHY is in its low power state.

Mappings for the following primitives are defined for 25 Gb/s operation:

PLS_DATA.request
PLS_DATA.indication
PLS_CARRIER.indication
PLS_SIGNAL.indication
PLS_DATA_VALID.indication

106.1.7.1 Mapping of PLS_DATA.request

The RS maps the primitive PLS_DATA.request to the 25GMII signals TXD<31:0>, TXC<3:0>, and TX_CLK in the same way as for the XGMII as specified in 46.1.7.1.

106.1.7.2 Mapping of PLS_DATA.indication

The RS maps the primitive PLS_DATA.indication to the 25GMII signals RXD<31:0>, RXC<3:0> and RX_CLK in the same way as for the XGMII as specified in 46.1.7.2.

106.1.7.3 Mapping of PLS_CARRIER.indication

25 Gb/s operation supports full duplex operation only. The RS never generates the PLS_CARRIER.indication primitive for PHYs that do not support EEE or Link Interruption.

For PHYs that support EEE capability, CARRIER_STATUS is set in the same way as specified in 46.1.7.3.

106.1.7.4 Mapping of PLS_SIGNAL.indication

25 Gb/s operation supports full duplex operation only. The RS never generates the PLS_SIGNAL.indication primitive.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

106.1.7.5 Mapping of PLS_DATA_VALID.indication

The RS maps the primitive PLS_DATA_VALID.indication to the 25GMII signals RXC<3:0> and RXD<31:0> in the same way as for the XGMII as specified in 46.1.7.5.

106.2 25GMII data stream

The 25GMII data stream has the same characteristics as the XGMII data stream described in 46.2.

106.3 25GMII functional specifications

The 25GMII functions identically to the XGMII specified in 46.3 with the exception that the TX_CLK and RX_CLK frequency shall be 390.625 MHz ±100 ppm (also one-sixty-fourth of the MAC transmit data rate).

106.4 LPI Assertion and Detection

25 Gb/s PHYs may support Clause 78 Energy-Efficient Ethernet (see Table 105–2).

LPI signaling by the 25 Gb/s RS is identical to that defined for XGMII in 46.4.

The operation of LPI in the PHY requires that the MAC does not send valid data for a time after LPI has been de-asserted as governed by resolved Transmit T_{w_sys} defined in 78.4.2.3.

This wake-up time is enforced by the transmit LPI state diagram using CARRIER_SENSE.indication in an identical manner to that defined in 46.4.

106.5 Protocol implementation conformance statement (PICS) proforma for Clause 106 Reconciliation Sublayer (RS) and Media Independent Interface (25GMII) for 25 Gb/s operation[179]

106.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 106, Reconciliation Sublayer (RS) and Media Independent Interface (25GMII) for 25 Gb/s operation, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

106.5.2 Identification

106.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

106.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 106, Reconciliation Sublayer (RS) and Media Independent Interface (25GMII) for 25 Gb/s operation
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[179]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

107. Physical Coding Sublayer (PCS) for 64B/66B, type 25GBASE-R

107.1 Overview

107.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) that is common to a family of 25 Gb/s Physical Layer implementations known as 25GBASE-R. The 25GBASE-R PCS is a sublayer of the 25 Gb/s PHYs listed in Table 105–1. The term 25GBASE-R is used when referring generally to Physical Layers using the PCS defined in this clause.

107.1.2 Relationship of 25GBASE-R to other standards

Figure 107–1 depicts the relationships among the 25GBASE-R sublayers, the Ethernet MAC and reconciliation layers, and the higher layers.

The 25GBASE-R PCS is identical to the 10GBASE-R PCS specified in Clause 49 with three exceptions:

1) It has a single-bit interface to the Physical Medium Attachment (PMA) sublayer rather than the 16-bit interface described in Clause 49.
2) It has the ability to generate the scrambled idle test pattern.
3) hi_ber is asserted if ber_cnt reaches 97 in a 2 ms period. This differs from the definition in 49.2.13.3, which defines hi_ber as occurring if ber_cnt reaches 16 in a 125 µs period.

107.1.3 Summary of 25GBASE-R sublayers

Figure 107–1 shows the relationship of the 25GBASE-R PCS sublayer with other sublayers to the ISO Open System Interconnection (OSI) reference model.

107.1.3.1 Physical Coding Sublayer (PCS)

The PCS service interface is the 25GMII, which is defined in Clause 106. The 25GMII is identical to the XGMII, which is the service interface of the 10GBASE-R PCS, but operates with 390.625 MHz clocks rather than 156.25 MHz clocks. The 25GMII provides a uniform interface to the Reconciliation Sublayer for all 25 Gb/s PHY implementations.

The 25GBASE-R PCS provides all services required by the 25GMII.

107.1.4 Inter-sublayer interfaces

The upper interface of the PCS may connect to the Reconciliation Sublayer through the 25GMII. The lower interface of the PCS connects to the PMA sublayer to support a PMD. If an FEC sublayer is implemented and the optional physical instantiation of 25GAUI is not implemented directly below the PCS sublayer, then the lower PCS interface connects to the FEC sublayer. The 25GBASE-R PCS has a nominal rate at the PMA (or FEC) service interface of 25.78125 Gb/s, which provides capacity for the MAC data rate of 25 Gb/s.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience.

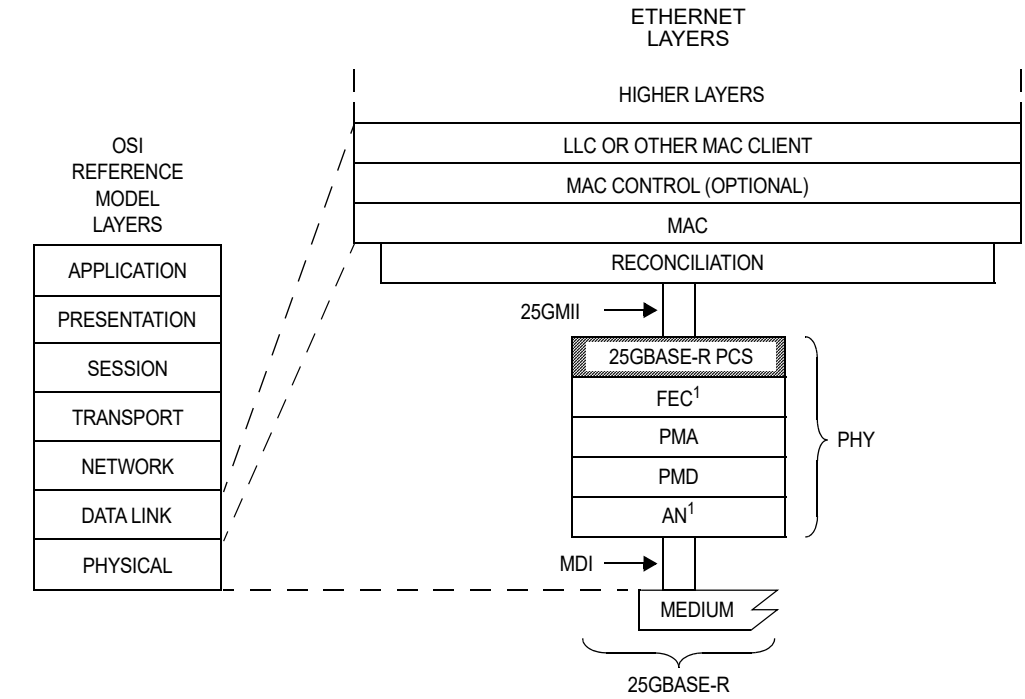

Figure 107–1—25GBASE-R PCS relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

107.1.4.1 PCS service interface (25GMII)

The PCS service interface allows the 25GBASE-R PCS to transfer information to and from a PCS client. The PCS client is the Reconciliation Sublayer. The PCS service interface is defined as the 25GMII in Clause 106.

107.1.4.2 Physical Medium Attachment (PMA) service interface

The PMA (or FEC) service interface for the PCS is described in an abstract manner and does not imply any particular implementation. The PMA (or FEC) Service Interface supports the exchange of encoded data between the PCS and PMA (or FEC) sublayer. The PMA (or FEC) service interface is single-bit and defined in 109.2 and is an instance of the inter-sublayer service interface definition in 105.4.

107.2 Functions within the PCS

The 25GBASE-R PCS shall have all the functionality of the 10GBASE-R PCS specified in Clause 49. In addition, the PCS has the ability to generate the scrambled idle test-pattern generator specified in 107.2.3.

The BER monitor state diagram shown in Figure 49–15 still applies but it shall use a 2 ms timer instead of a 125 µs timer and ber_cnt is tested for a value of 97 rather than 16 in the exit conditions from state BER_BAD_SH. So:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1) The definition of "125us_timer" in 49.2.13.2.5 is replaced with "Timer that is triggered every 2 ms +1%, –25%".
2) The definition of "ber_cnt" in 49.2.13.2.4 is replaced with "Count up to a maximum of 97 of the number of invalid sync headers within the current 2 ms period".
3) The definition of "hi_ber" in 49.2.13.2.2 is replaced with "Boolean variable that is asserted true when the ber_cnt reaches 97 indicating a bit error ratio $>10^{-4}$".

The PCS encodes data and control information into 66-bit blocks. The relationship of block bit positions to the 25GMII, PMA, and other PCS constructs is illustrated in Figure 107–2 for transmit and Figure 107–3 for receive.

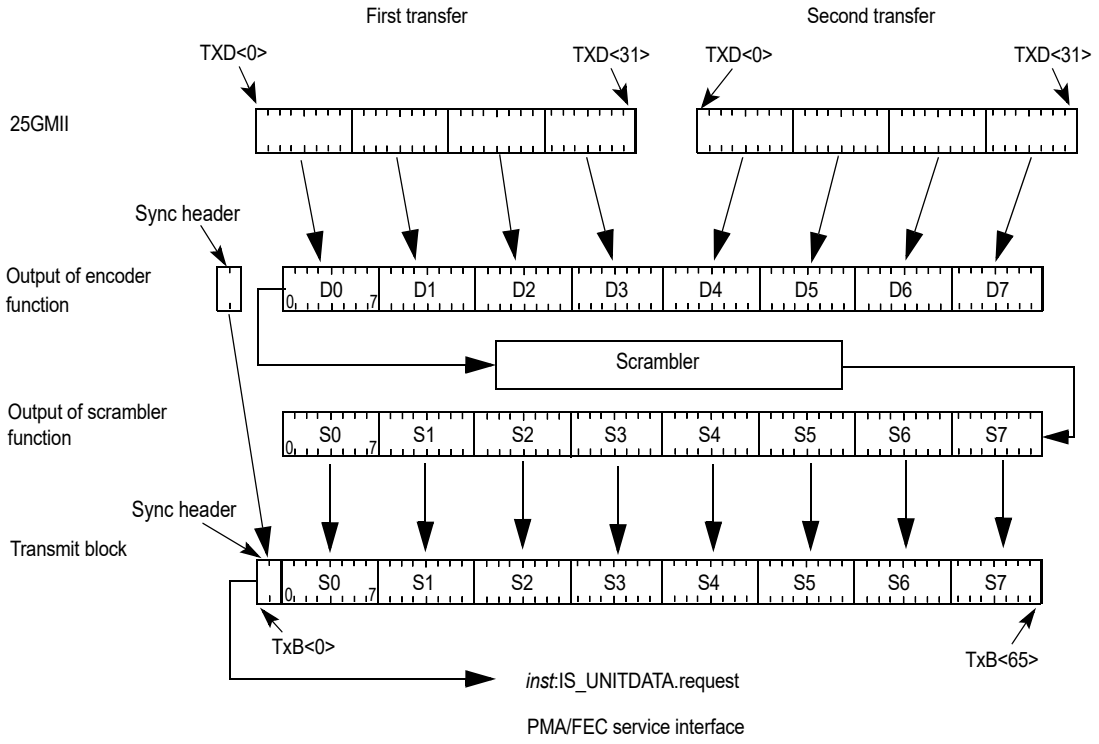

Figure 107–2—PCS Transmit bit ordering

107.2.1 Notation conventions

Values represented in binary are shown with the first transmitted bit (the LSB) on the left.

Two consecutive 25GMII transfers provide eight characters that are encoded into one 66-bit transmission block.

107.2.2 Transmission order

Block bit transmission order is illustrated in Figure 107–2 and Figure 107–3. Note that these figures show the mapping from 25GMII to 64B/66B block for a block containing eight data characters.

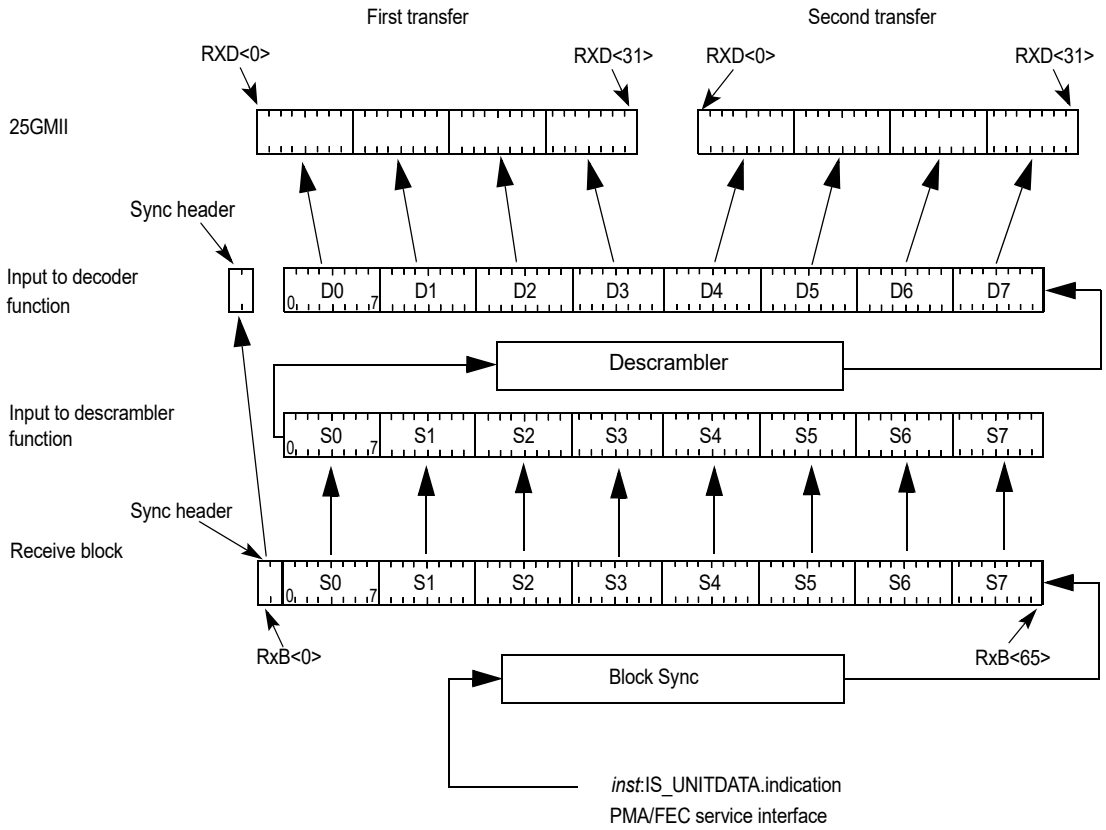

Figure 107–3—PCS Receive bit ordering

107.2.3 Test-pattern generator

In addition to those patterns specified in 49.2.8, the PCS shall have the ability to generate a scrambled idle test pattern. This test pattern is suitable for receiver tests and for certain transmitter tests.

When enabled, the scrambled idle test pattern is generated by the scrambler. The input to the scrambler is a control block (block type=0x1E) with all idles as defined in Figure 49–7. Sync headers are added to the scrambled data output.

If a Clause 45 MDIO is implemented, then control of the test-pattern generation is from the BASE-R PCS test-pattern control register (3.42).

107.3 LPI

If the 25GBASE-R PCS is part of a PHY configured for EEE deep sleep operation, the PCS shall follow the state diagrams specified in Figure 49–12 and Figure 49–13.

The LPI functions shall use the timer values in Table 107–1 and Table 107–2 for EEE deep sleep operation.

If the 25GBASE-R PCS is part of a PHY configured for EEE fast wake operation, the PCS shall encode and decode LPI when indicated but the state diagrams specified in Figure 49–12 and Figure 49–13 do not apply. Management functions may use MDIO register bit LPI_FW 3.20.0 to select fast wake operation (see 45.2.3.10.15).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 107–1—Transmitter LPI timing parameters

Parameter	Description	Min	Max	Units
T_{SL}	Local Sleep Time from entering the TX_SLEEP state to when tx_mode is set to QUIET	4.9	5.1	µs
T_{QL}	Local Quiet Time from when tx_mode is set to QUIET to entry into the TX_ALERT state	1.7	1.8	ms
T_{WL}	Time spent in the TX_WAKE state	10.9	11.1	µs
T_{1U}	Time spent in the TX_ALERT and TX_SCR_BYPASS states	1.1	1.3	µs

Table 107–2—Receiver LPI timing parameters

Parameter	Description	Min	Max	Units
T_{QR}	The time the receiver waits for energy_detect to be set to TRUE while in the RX_SLEEP and RX_QUIET states before asserting receive fault	2	3	ms
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault (when scr_bypass_enable = FALSE)	—	11.5	µs
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault (when scr_bypass_enable = TRUE)	—	13.7	µs
T_{WTF}	Wake time fault recovery time	—	10	ms

107.4 Delay constraints

The maximum delay contributed by the 25GBASE-R PCS (sum of transmit and receive delays at one end of the link) shall be no more than 3584 BT (7 pause_quanta or 143.36 ns). A description of overall system delay constraints can be found in 105.5.

107.5 Support for Auto-Negotiation

A PCS used with a 25GBASE-KR PMD, 25GBASE-KR-S PMD, 25GBASE-CR PMD, or 25GBASE-CR-S PMD has the same requirements to support auto-negotiation as a PCS used with a 10GBASE-KR PMD. These are specified in 49.2.16.

107.6 Protocol implementation conformance statement (PICS) proforma for Clause 107, Physical Coding Sublayer (PCS) for 64B/66B, type 25GBASE-R[180]

107.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 107, Physical Coding Sublayer (PCS) for 64B/66B, type 25GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

107.6.2 Identification

107.6.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

107.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 107, Physical Coding Sub-layer (PCS) for 64B/66B, type 25GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[180]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

108. Reed-Solomon forward error correction (RS-FEC) sublayer for 10GBASE-R and 25GBASE-R PHYs

108.1 Overview

108.1.1 Scope

This clause specifies a Reed-Solomon forward error correction (RS-FEC) sublayer for 10GBASE-R and 25GBASE-R PHYs. The specification is closely related to that of the RS-FEC sublayer for 100GBASE-R PHYs, specified in Clause 91. Annex 91A provides examples of RS-FEC codewords constructed with the method specified in this clause.

108.1.2 Position of RS-FEC in the 10GBASE-R and 25GBASE-R PHY sublayers

Figure 108–1 shows the relationship of the 10GBASE-R and 25GBASE-R RS-FEC sublayer to the ISO/IEC Open System Interconnection (OSI) reference model.

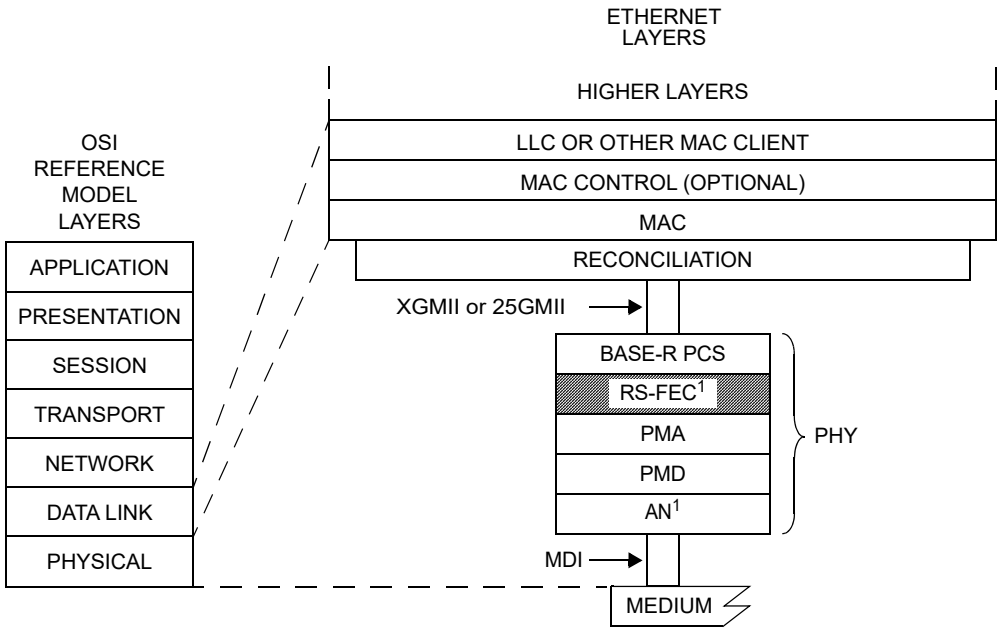

Figure 108–1—10GBASE-R and 25GBASE-R RS-FEC relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

108.1.3 Inter-sublayer interfaces

An FEC service interface is provided to allow the RS-FEC sublayer to transfer information to and from the PCS. An abstract service model is used to define the operation of this interface. For 10GBASE-R, the FEC service interface directly maps to the PMA service interface of the PCS defined in Clause 49 and the lower FEC sublayer interface maps to the service interface provided by the serial PMA sublayer defined in Clause 51. For 25GBASE-R, the FEC service interface is an instance of the inter-sublayer service interface defined in 105.4, as is the PMA service interface defined in 109.2.

This standard defines these interfaces in terms of bits, octets, data-group, data units, and signals; however, implementers may choose other data-path widths and other control mechanisms for implementation convenience, provided that the implementation adheres to the logical model of the service interface.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

108.1.3.2 Functional block diagram for 25GBASE-R PHYs

Figure 108–3 shows the functional block diagram of FEC for 25GBASE-R PHYs and the relationship between the PCS and PMA sublayers.

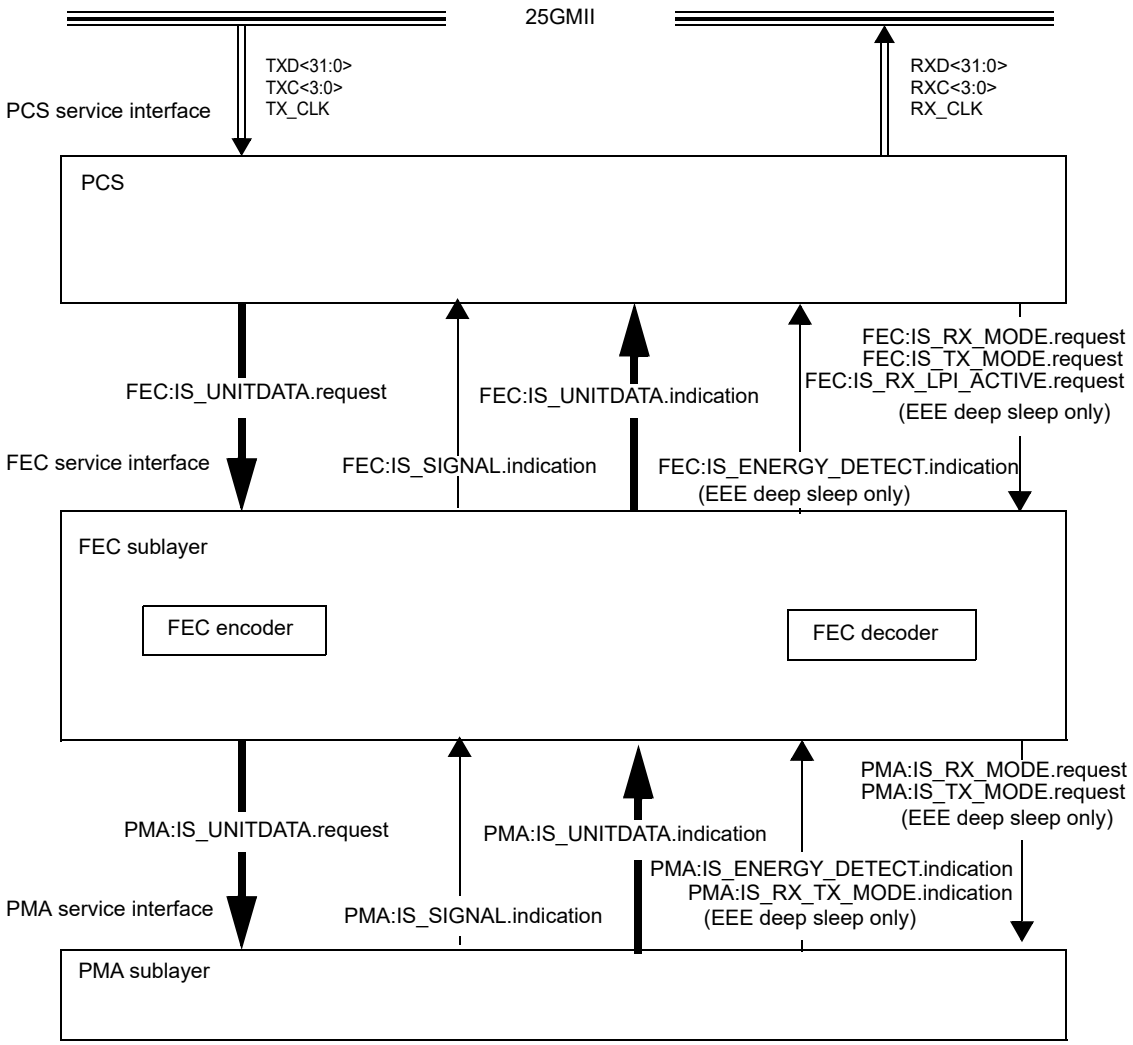

Figure 108–3—Functional block diagram for 25GBASE-R PHYs

108.2 FEC service interface

This subclause specifies the services provided by the 10GBASE-R and 25GBASE-R RS-FEC sublayer. The service interface is described in an abstract manner and does not imply any particular implementation.

The FEC service interface is provided to allow the PCS to transfer information to and from the RS-FEC. The FEC service interface is equivalent to the PMA service interface for 10GBASE-R PHYs and is an instance of the inter-sublayer service interface defined in 105.4 for 25GBASE-R PHYs.

The service primitives are defined differently for 10GBASE-R PHYs and for 25GBASE-R PHYs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PCS may be connected to the 10GBASE-R and 25GBASE-R RS-FEC using an optional physical instantiation of the PMA service interface (see Clause 51 and Annex 109A), in which case a PMA is the client of the FEC service interface.

108.2.1 10GBASE-R service primitives

The following primitives are defined within the FEC service interface for 10GBASE-R PHYs:

FEC_UNITDATA.request(tx_data-group<15:0>)
FEC_UNITDATA.indication(rx_data-group<15:0>)
FEC_SIGNAL.indication(SIGNAL_OK)

The FEC service interface directly maps to the PMA service interface of the 10GBASE-R PCS defined in Clause 49. The FEC_UNITDATA.request maps to the PMA_UNITDATA.request primitive, the FEC_UNITDATA.indication maps to the PMA_UNITDATA.indication primitive, and the FEC_SIGNAL.indication maps to the PMA_SIGNAL.indication primitive of the 10GBASE-R PCS.

108.2.1.1 FEC_UNITDATA.request

This primitive defines the transfer of data in the form of constant-width data units from the PCS to the RS-FEC. The data supplied via FEC_UNITDATA.request is mapped by the RS-FEC transmit process into the payload capacity of the outgoing FEC block stream.

108.2.1.1.1 Semantics of the service primitive

FEC_UNITDATA.request(tx_data-group<15:0>)

The data conveyed by FEC_UNITDATA.request is a 16-bit vector representing a single data unit that has been prepared for transmission by the 10GBASE-R PCS Transmit process.

108.2.1.1.2 When generated

The 10GBASE-R PCS sends tx_data-group<15:0> to the RS-FEC at a nominal rate of 644.53125 MHz, corresponding to the 10GBASE-R signaling rate of 10.3125 GBd.

108.2.1.1.3 Effect of receipt

Upon receipt of this primitive, the RS-FEC transmit process maps the data conveyed by the tx_data unit<15:0> parameter into the payload of the transmitted FEC block stream, adds FEC overhead as required, scrambles the data, and transfers the result to the PMA via the PMA_UNITDATA.request primitives.

108.2.1.2 FEC_UNITDATA.indication

This primitive defines the transfer of received data in the form of constant-width data units from the RS-FEC to the PCS. FEC_UNITDATA.indication is generated by the RS-FEC receive process in response to FEC block data received from the PMA.

108.2.1.2.1 Semantics of the service primitive

FEC_UNITDATA.indication(rx_data-group<15:0>)

The rx_data-group<15:0> parameter is a 16-bit vector that represents the data unit transferred by the RS-FEC to the 10GBASE-R PCS.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

108.2.1.2.2 When generated

The RS-FEC sends one rx_data-group<15:0> to the 10GBASE-R PCS for each 16 bits received from the PMA sublayer. The nominal rate of generation of the FEC_UNITDATA.indication primitive is 644.53125 Mtransfers/s.

108.2.1.2.3 Effect of receipt

The effect of receipt of this primitive by the RS-FEC client is unspecified by the RS-FEC sublayer. See 49.2.

108.2.1.3 FEC_SIGNAL.indication

This primitive is sent by the RS-FEC to the PCS to indicate the status of the receive process. FEC_SIGNAL.indication is generated by the RS-FEC receive process in order to propagate the detection of severe error conditions (e.g., no valid signal being received from the PMA sublayer) to the PCS.

108.2.1.3.1 Semantics of the service primitive

FEC_SIGNAL.indication(SIGNAL_OK)

The SIGNAL_OK parameter can take one of two values: OK or FAIL. A value of OK denotes that the RS-FEC receive process is successfully delineating valid payload information from the incoming data stream received from the PMA sublayer indicated by the fec_signal_ok variable equal to true, and this payload information is being presented to the PCS via the FEC_UNITDATA.indication primitive. A value of FAIL denotes that errors have been detected by the Receive process indicated by the fec_signal_ok variable equal to false, that prevent valid data from being presented to the PCS, in this case the FEC_UNITDATA.indication primitive and its associated rx_data-group<15:0> parameter are meaningless.

108.2.1.3.2 When generated

The RS-FEC generates the FEC_SIGNAL.indication primitive to the 10GBASE-R PCS whenever there is a change in the value of the SIGNAL_OK parameter and FEC block synchronization is achieved.

108.2.1.3.3 Effect of receipt

The effect of receipt of this primitive by the RS-FEC client is unspecified by the RS-FEC sublayer. See 49.2.

108.2.2 25GBASE-R service primitives

For 25GBASE-R PHYs the FEC service interface is an instance of the inter-sublayer service interface defined in 105.4. The FEC service interface primitives are summarized as follows:

FEC:IS_UNITDATA.request(tx_bit)
FEC:IS_UNITDATA.indication(rx_bit)
FEC:IS_SIGNAL.indication

The PCS (or PMA) continuously sends a bit stream to the RS-FEC using the FEC:IS_UNITDATA.request(tx_bit) primitive, at a nominal signaling rate of 25.78125 GBd.

The RS-FEC continuously sends a bit stream to the PCS (or PMA) using the FEC:IS_UNITDATA.indication(rx_bit) primitive, at a nominal signaling rate of 25.78125 GBd. The actual signaling rate is equal to the underlying PMD signaling rate.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The SIGNAL_OK parameter of the FEC:IS_SIGNAL.indication primitive can take one of two values: OK or FAIL. The value is set to OK when the RS-FEC receive function has identified codeword boundaries as indicated by FEC_align_status equal to true. That value is set to FAIL when the RS-FEC receive function is unable to reliably establish codeword boundaries as indicated by FEC_align_status equal to false.

If the optional EEE deep sleep capability is supported, then the FEC service interface includes four additional primitives as follows:

FEC:IS_TX_MODE.request
FEC:IS_RX_MODE.request
FEC:IS_RX_TX_MODE.indication
FEC:IS_ENERGY_DETECT.indication

When the tx_mode parameter of the FEC:IS_TX_MODE.request primitive is QUIET or ALERT, the RS-FEC sublayer may disable transmit functional blocks to conserve energy. Otherwise the RS-FEC transmit function operates normally. The value of tx_mode is passed to the client sublayer via the PMA:IS_TX_MODE.request primitive.

When the rx_mode parameter of the FEC:IS_RX_MODE.request primitive is QUIET, the RS-FEC sublayer may disable receive functional blocks to conserve energy. Otherwise the RS-FEC receive function operates normally. The value of rx_mode is passed to the client sublayer via the PMA:IS_RX_MODE.request primitive.

The rx_tx_mode parameter of the FEC:IS_RX_TX_MODE.indication primitive is used to communicate the link partner's value of tx_mode as inferred by the PMA. It is assigned the value that is received via the PMA:IS_RX_TX_MODE.indication primitive.

The energy_detect parameter of the FEC:IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence. It is assigned the value that is received via the PMA:IS_ENERGY_DETECT.indication primitive.

108.3 PMA compatibility

For 10GBASE-R PHYs, the 10GBASE-R and 25GBASE-R RS-FEC sublayer is a client of the 10GBASE-R PMA subylayer defined in Clause 51. For 25GBASE-R PHYs, the 10GBASE-R and 25GBASE-R RS-FEC sublayer is a client of the 25GBASE-R PMA sublayer defined in Clause 109.

When 25GAUI C2C is used between a device that includes a PCS and a device that includes the RS-FEC, the 25GBASE-R PMA sublayer is the client of the 10GBASE-R and 25GBASE-R RS-FEC sublayer.

108.4 Delay constraints

The maximum delay contributed by the 10GBASE-R and 25GBASE-R RS-FEC sublayer (sum of transmit and receive delays at one end of the link) shall be no more than 24 576 bit times (48 pause_quanta). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 44.3 and 105.5.

108.5 Functions within the RS-FEC sublayer

108.5.1 Functional block diagram

A functional block diagram of the RS-FEC sublayer is shown in Figure 108–4.

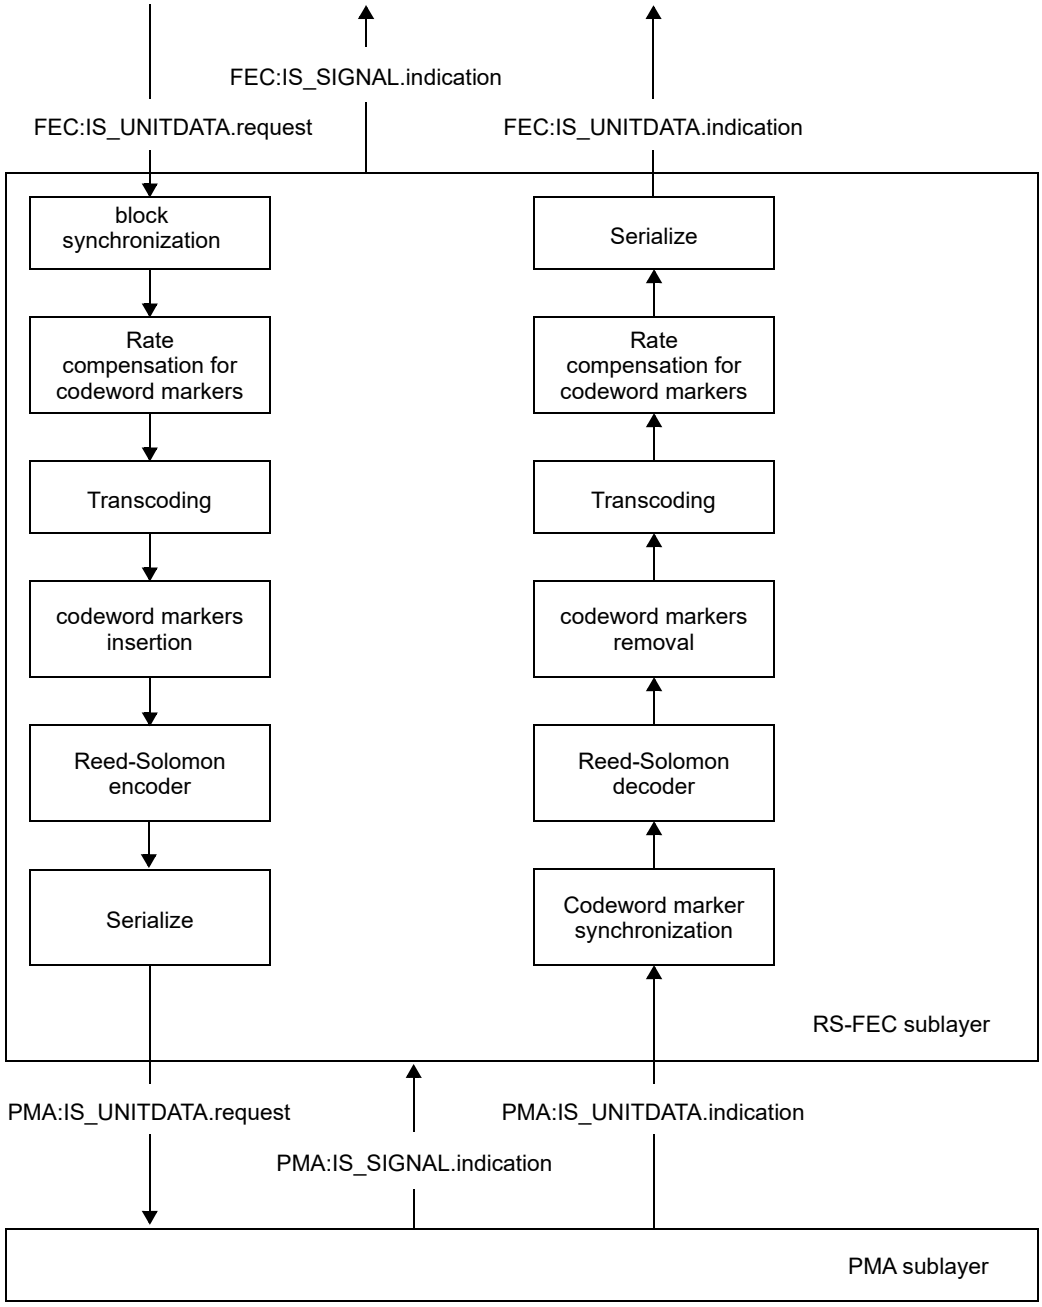

Figure 108–4—Functional block diagram

108.5.1.1 Reverse gearbox and gearbox functions for 10GBASE-R

The reverse gearbox function adapts between the 66-bit width of the 64B/66B blocks and the 16-bit width of the PCS interface. It receives the 16-bit stream from the PCS interface and converts it back to 66-bit encoded blocks for the RS-FEC encoder to process. The reverse gearbox function operates in the same manner as the block synchronization function defined in 49.2.9.

The reverse gearbox function receives data via 16-bit FEC_UNITDATA.request primitives. It forms a bit stream from the primitives by concatenating requests with the bits of each primitive in order to form tx_data-group<0> to tx_data-group<15> (see Figure 49–6). It obtains lock to the 66-bit blocks in the bit stream using the sync headers and outputs 66-bit blocks. Lock is obtained as specified in the lock state diagram shown in Figure 49–14.

NOTE—Figure 49–6 shows rx_data-group<0> to rx_data-group<15> because the processing depicted in that figure is in the receive function. However, the reverse gearbox in this subclause is part of the transmit function, so it uses tx_data-group<0> to tx_data-group<15>.

The reverse gearbox functionality is necessary only when the optional PMA compatibility interface named XSBI is implemented between the PCS and RS-FEC functions, since that interface passes data via a 16-bit wide path. When the XSBI is not implemented, the internal data-path width between the PCS and RS-FEC is an implementation choice. Depending on the path width, the reverse gearbox function may not be necessary.

The gearbox adapts between the 66-bit width of the blocks and the 16-bit width of the PMA interface. It receives the 66-bit blocks. When the transmit channel is operating in normal mode, the gearbox sends 16 bits of transmit data at a time via the PMA_UNITDATA.request primitive. The UNITDATA.request primitive is fully packed with bits. For example, if one block happened to start with the sync header on bits 0 and 1 of a PMA_UNITDATA.request, then the last two bits of that block would be on bits 0 and 1 of a PMA_UNITDATA.request and the next block would begin with a sync header on bits 2 and 3 of that PMA_UNITDATA.request. When a PMA_UNITDATA.request contains bits from two blocks, then the bits from the first block shall be placed in the lowest numbered bits of tx_data-group<15:0>. The bits shall be packed into the tx_data-group in sequence with the lowest numbered bit of the block going into the lowest numbered bit of the part of tx_data-group<15:0> bits containing bits from that block (see Figure 49–5).

The gearbox functionality is necessary when the optional PMA compatibility interface, XSBI, is implemented since that interface passes data over a 16-bit wide path. When the XSBI is not implemented, the internal data-path width between the PCS and PMA is an implementation choice. Depending on the path width, the gearbox functionality may not be necessary.

108.5.2 Transmit function

108.5.2.1 Block synchronization

The RS-FEC transmit function uses the bit stream provided by the FEC:IS_UNITDATA.request primitive. It obtains lock to the 66-bit blocks in the bit stream using the sync headers and outputs 66-bit blocks. Block lock is obtained as specified in the lock state diagram shown in Figure 49–14.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

108.5.2.2 Rate compensation for codeword markers in the transmit direction

The RS-FEC transmit process periodically inserts codeword markers into the transcoded block stream (see 108.5.2.4). In order to maintain the same bit rate after codeword marker insertion, the RS-FEC transmit process shall perform the rate compensation function described below, or its functional equivalent:

a) Decode the PCS blocks received by descrambling (see 49.2.10) and applying the PCS receive process (see 49.2.11) to obtain the XGMII or 25GMII character stream.
b) Delete Idle control characters (/I/), Low Power Idle control characters (/LI/), and ordered sets, according to the rules in 49.2.4.7 and 49.2.4.10, to create room as necessary for the periodically occurring codeword markers.
c) Re-encode the data stream obtained, by applying the PCS transmit process (see 49.2.5) and scrambler (see 49.2.6) to obtain 64B/66B blocks.

If the optional EEE deep sleep capability is supported, when rapid codeword markers are sent, characters are deleted more frequently in item b) as necessary to maintain a constant bit rate.

NOTE—When rapid codeword markers are sent, the PCS LPI transmit state diagram (Figure 49–12) is in the TX_WAKE state, so the data encoded by the PCS comprises one of two control characters, either /I/ or /LI/. Both types of control characters can be deleted for rate compensation. See 78.1.3.1 and 78.1.3.3.1 for more details about LPI wake cycles.

108.5.2.3 64B/66B to 256B/257B transcoder

The transcoder constructs a 257-bit block, tx_scrambled<256:0>, from a group of four 66-bit blocks, tx_coded_*j*<65:0> where *j*=0 to 3. For each group of four 66-bit blocks, *j*=3 corresponds to the most recently received block. Bit 0 in each 66-bit block is the first bit received and corresponds to the first bit of the synchronization header.

The construction of the transcoded block shall be according to the process described in 91.5.2.5. For each 257-bit block, bit 0 shall be the first bit transmitted.

108.5.2.4 Codeword marker insertion

In order to support codeword alignment in the receive direction, the RS-FEC shall periodically insert codeword markers into the stream of transcoded blocks as the first 257 bits of every 1024th RS-FEC codeword (see 108.5.2.5). The distance between the beginning of successive codeword markers is therefore 20480 257-bit transcoded blocks, equivalent to 81920 64B/66B blocks.

Room for codeword markers is created by the rate compensation for codeword markers in the transmit direction process (see 108.5.2.2) such that the bit rates at the input and the output of the RS-FEC sublayer are equal.

The transmitted codeword marker is a 257-bit block, tx_cwm, constructed of four alignment markers followed by a zero bit. Each alignment marker is built from eight octets M_0, M_1, M_2, BIP_3, M_4, M_5, M_6, and BIP_7 with the bit order shown in Figure 82–9. The BIP_3 field is set to the constant value 0x33 and the BIP_7 field is set to the constant value 0xCC.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_cwm is constructed as follows:

a) tx_cwm<63:0> are set to bits <65:2> of the alignment marker of PCS lane 0 defined in Table 82–2.
b) tx_cwm<127:64> are set to bits <65:2> of the alignment marker of PCS lane 1 defined in Table 82–3.
c) tx_cwm<191:128> are set to bits <65:2> of the alignment marker of PCS lane 2 defined in Table 82–3.
d) tx_cwm<255:192> are set to bits <65:2> of the alignment marker of PCS lane 3 defined in Table 82–3.
e) tx_cwm<256> is set to 0.

For the optional EEE deep sleep capability, a rapid method of codeword alignment is used following a transition of tx_mode from ALERT to DATA, by transmitting rapid codeword markers. When the value of tx_down_count is nonzero, rapid codeword markers are sent at the beginning of each codeword. Rapid codeword markers are identical to regular codeword markers, with the exception that BIP_3 is set to the value of tx_down_count instead of the constant 0x33 and BIP_7 is set to the bit-wise inversion of tx_down_count instead of the constant 0xCC.

108.5.2.5 Reed-Solomon encoder

The RS-FEC sublayer employs the Reed-Solomon code RS(528,514) operating over the Galois Field GF(2^{10}) where the symbol size is 10 bits. The encoder described in 91.5.2.7 shall be used.

108.5.2.6 Codeword serialization

Once the data has been Reed-Solomon encoded, it shall be serialized and sent to the PMA using the PMA:IS_UNITDATA.request primitive with the transmit bit ordering illustrated in Figure 108–5.

108.5.2.7 RS-FEC encoding for rapid codeword lock (EEE deep sleep)

If the optional EEE deep sleep capability is supported, the RS-FEC transmit function changes its signaling during LPI refresh and wake periods, as described in this subclause.

The transition of the PCS LPI transmit state diagram (Figure 49–12) to TX_WAKE state is detected by the change of the tx_mode parameter of the FEC:IS_TX_MODE.request primitive from ALERT to DATA. Following this transition, the transmit function behaves as follows:

a) Set tx_down_count to 40. This causes the codeword marker insertion function (108.5.2.4) to insert a rapid codeword marker in the beginning of each of the following 40 codewords. The value of tx_down_count is encoded in each rapid codeword marker and is decremented after the rapid codeword marker is sent.

b) The rapid codeword marker with down_count=1 sets the location of the subsequent regular codeword markers, such that a codeword marker is inserted at the beginning of the 1024th codeword after it. Figure 108–6 depicts the codeword marker locations during this transition.

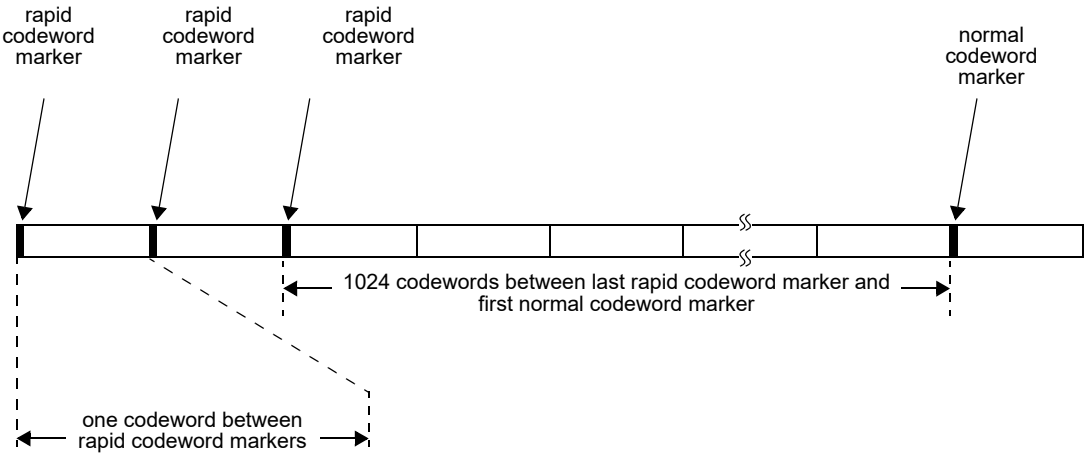

Figure 108–6—Transition from rapid to normal codeword markers

108.5.3 Receive function

108.5.3.1 Codeword marker lock

The RS-FEC shall implement the codeword marker lock process as described in this subclause.

The RS-FEC receive function forms a bit stream by concatenating the bits from the PMA:IS_UNITDATA.indication primitive in the order they are received. This process obtains lock to the codeword markers as shown in FEC synchronization state diagram (Figure 108–8). The status of the codeword marker lock process is reflected by the state variable FEC_align_status.

108.5.3.2 Reed-Solomon decoder

The Reed-Solomon decoder extracts the message symbols from the codeword, corrects them as necessary, and discards the parity symbols. The message symbols correspond to a codeword comprising 20 transcoded blocks rx_scrambled.

The RS-FEC sublayer shall be capable of correcting any combination of up to 7 symbol errors in a codeword. The RS-FEC sublayer shall also be capable of indicating when a codeword contains errors that were not corrected. The probability that the decoder fails to indicate a codeword with 8 or more symbol errors as uncorrected is expected to be lower than 10^{-6}.

The Reed-Solomon decoder may provide the option to perform error detection without error correction to reduce the delay contributed by the RS-FEC sublayer. The presence of this option is indicated by the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

assertion of the FEC_bypass_correction_ability variable (see 108.6.4). When the option is provided, it is enabled by the assertion of the FEC_bypass_correction_enable variable (see 108.6.1). This option shall not be used when the RS-FEC sublayer is used to form part of a 10GBASE-BR20, 25GBASE-SR, 25GBASE-LR, or 25GBASE-ER PHY.

NOTE 1—The PHY may rely on the error correction capability of the RS-FEC sublayer to achieve its performance objectives. It is recommended that acceptable performance of the underlying link is verified before error correction is bypassed.

The Reed-Solomon decoder shall indicate errors to the PCS sublayer by intentionally corrupting 66-bit block synchronization headers. When the decoder determines that a codeword contains errors (when the bypass correction feature is enabled) or contains errors that were not corrected (when the bypass correction feature is not supported or not enabled), it ensures that, for every other 257-bit block within the codeword starting with the first (1st, 3rd, 5th, etc.), the synchronization header for the first 66-bit block at the output of the 256B/257B to 64B/66B transcoder, rx_coded_0<1:0>, is set to 11. In addition, it ensures that rx_coded_0<1:0> corresponding to the second 257-bit block and rx_coded_3<1:0> corresponding to the last (20th) 257-bit block in the codeword are set to 11.

NOTE 2—Setting rx_coded_0<1:0> to 11 as described causes the PCS to assign R_BLOCK_TYPE=E to the block and decode its content as EBLOCK_R (see 49.2.13.2.1 and 49.2.13.2.3). This will cause all frames 64 bytes and larger that are fully or partially within the codeword to be discarded.

The Reed-Solomon decoder may optionally provide the ability to bypass the error indication feature to reduce the delay contributed by the RS-FEC sublayer. The presence of this option is indicated by the assertion of the FEC_bypass_indication_ability variable (see 108.6.5). When the option is provided it is enabled by the assertion of the FEC_bypass_indication_enable variable (see 108.6.2).

When FEC_bypass_correction_enable is asserted, the decoder shall not bypass error indication and the value of FEC_bypass_indication_enable has no effect.

When FEC_bypass_indication_enable is asserted, additional error monitoring is performed by the RS-FEC sublayer to reduce the likelihood that errors in a packet are not detected. The Reed-Solomon decoder counts the number of symbol errors detected in consecutive non-overlapping blocks of 8192 codewords. When the number of symbol errors in a block of 8192 codewords exceeds 417, the Reed-Solomon decoder shall cause synchronization header rx_coded<1:0> of each subsequent 66-bit block that is delivered to the PCS to be assigned a value of 00 or 11 for a period of 60 ms to 75 ms.

NOTE 3—This setting of rx_coded<1:0> marks the 64B/66B block as bad and inhibits processing of received packets by the PCS. The BER monitor state diagram (Figure 49–15) sets hi_ber to true and the PCS block_lock is set to false. When AN is supported and enabled, this event causes AN to restart.

For the optional EEE deep sleep capability, the error monitor employed when FEC_bypass_indication_enable is asserted shall be disabled when rx_lpi_active is true. The next block of 8192 codewords considered by the error monitor begins on the codeword boundary following the transition of rx_lpi_active from true to false.

108.5.3.3 Codeword monitor

After codeword marker lock has been achieved, this process continuously checks codeword validity as indicated by the codeword monitor state diagram (Figure 108–9). When three consecutive uncorrected codewords are detected, the codeword monitor shall restart the codeword marker lock process. In such event, it is likely that multiple blocks are marked as bad until codeword marker alignment is found.

NOTE—Marking multiple 64B/66B blocks as bad causes the PCS to assert hi_ber and lose its block lock. When AN is supported and enabled, this event causes AN to restart.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

108.5.3.4 Codeword marker removal

The first 257 message bits in every 1024th codeword is the vector rx_cwm<256:0> where bit 0 is the first bit received. The specific codewords that include this vector are indicated by the codeword marker lock function (108.5.3.1).

For the optional EEE deep sleep capability, when FEC_align_status is true and rx_down_count is nonzero, rx_cwm<256:0> is set to the first 257 message bits in every codeword.

The vector rx_cwm shall be removed prior to transcoding.

108.5.3.5 256B/257B to 64B/66B transcoder

The transcoder extracts a group of four 66-bit blocks, rx_coded_*j*<65:0> where *j*=0 to 3, from each 257-bit block rx_scrambled<256:0>. Bit 0 of the 257-bit block is the first bit received.

The transcoder described in 91.5.3.5 shall be used, with the exception that in step f2), h<3:0> is derived by cross-referencing to g<3:0> using Figure 49–7 instead of Figure 82–5, to account for the block types used by the PCS.

The transcoder creates a stream of 66-bit vectors rx_coded<65:0> from the groups of four blocks rx_coded_*j*<65:0> where *j*=0 to 3. rx_coded_0 is the first block transmitted out of each group.

108.5.3.6 Rate compensation for codeword markers in the receive direction

After the codeword markers have been discarded from transcoding and the stream of rx_coded<65:0> vectors has been obtained, to compensate for the deleted codeword markers, the RS-FEC receive process shall perform the rate compensation function described below, or its functional equivalent:

a) Decode the stream of rx_coded vectors by descrambling (see 49.2.10) and applying the PCS receive process (see 49.2.11) to obtain the XGMII or 25GMII character stream.
b) Insert /I/ or /LI/, according to the rules in 49.2.4.7, to fill in as necessary for any deleted codeword markers or rapid codeword markers.
c) Re-encode the data stream obtained, by applying the PCS transmit process (see 49.2.5) and scrambling (see 49.2.6) to obtain 64B/66B blocks rx_coded_out<65:0>.

If rx_coded<1:0> is either 00 or 11, the process in list item c) shall set rx_coded_out<1:0> to rx_coded<1:0> and the process in list item b) shall not insert idle characters at the next block after rx_coded_out.

If the optional EEE deep sleep capability is supported, this function sets rx_lpi_active according to the RX LPI state diagram (Figure 49–13).

108.5.3.7 Rapid codeword lock for EEE deep sleep

If the optional EEE deep sleep capability is supported, the RS-FEC receive function performs rapid codeword lock during LPI refresh and wake periods, as described in this subclause.

When rx_mode (or rx_tx_mode if appropriate) transitions from QUIET to DATA:

a) Start timer hold_off_timer.
b) Enable the RS-FEC rapid codeword lock mechanism, which attempts to detect rapid codeword markers sent by the remote RS-FEC transmit function (see 108.5.2.7). When two rapid codeword markers that are one codeword distance apart are detected (causing entry to state WAKE_GOOD in

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the FEC synchronization state diagram, Figure 108–8), the start location of the RS-FEC codeword is set to the start location of the rapid codeword markers. The next codeword marker position is set to 1024 codewords following the rapid codeword marker with down_count=1.

NOTE—The rapid codeword lock mechanism is implementation dependent and outside the scope of this standard.

When the start location is found, FEC_align_status is set to true and test_cw is asserted for each subsequent codeword, enabling aligned codeword decoding. Assuming the rapid codeword lock has determined the correct start of codeword location, the RS-FEC codeword monitor state diagram (Figure 108–9) reaches the CW_GOOD state, and then the decoding in item a) of 108.5.3.6 results in one of two deterministic blocks, composed of either /I/ or /LI/ control characters.

The RS-FEC sublayer shall hold off asserting SIGNAL_OK until one of the following two events occurs:

1) The RS-FEC codeword monitor state diagram (Figure 108–9) reaches the CW_GOOD state.
2) hold_off_timer_done = true.

108.5.3.8 Receive bit ordering

The receive bit ordering shall be as illustrated in Figure 108–7.

108.5.4 Detailed functions and state diagrams

108.5.4.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, functions, and counters. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

108.5.4.2 State variables

cw_bad
: Boolean variable that is set to true if the Reed-Solomon decoder (see 108.5.3.2) detects any errors in the current codeword and does not correct them, and is set to false otherwise.

cwm_counter_done
: Boolean variable that indicates that cwm_counter has reached its terminal count.

cwm_valid
: Boolean variable that is set to true if the received block rx_cwm<256:0> (as defined in 108.5.3.4) is a valid codeword marker. Codeword marker validity is tested by comparing bits 23:0 and 55:32 of rx_cwm<256:0>, on a nibble-wise basis (12 comparisons), against their respective values in tx_cwm<256:0> (as defined in 108.5.2.4). If nine or more nibbles in the candidate block match the corresponding known nibbles in the codeword marker, the candidate block is considered a valid codeword marker.

FEC_align_status
: Boolean variable that is set to true when the receiver has found the alignment of the codeword marker on the PMA service interface.

reset
: Boolean variable that controls the resetting of the RS-FEC sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the RS-FEC sublayer into low-power mode.

Copyright © 2022 IEEE. All rights reserved.

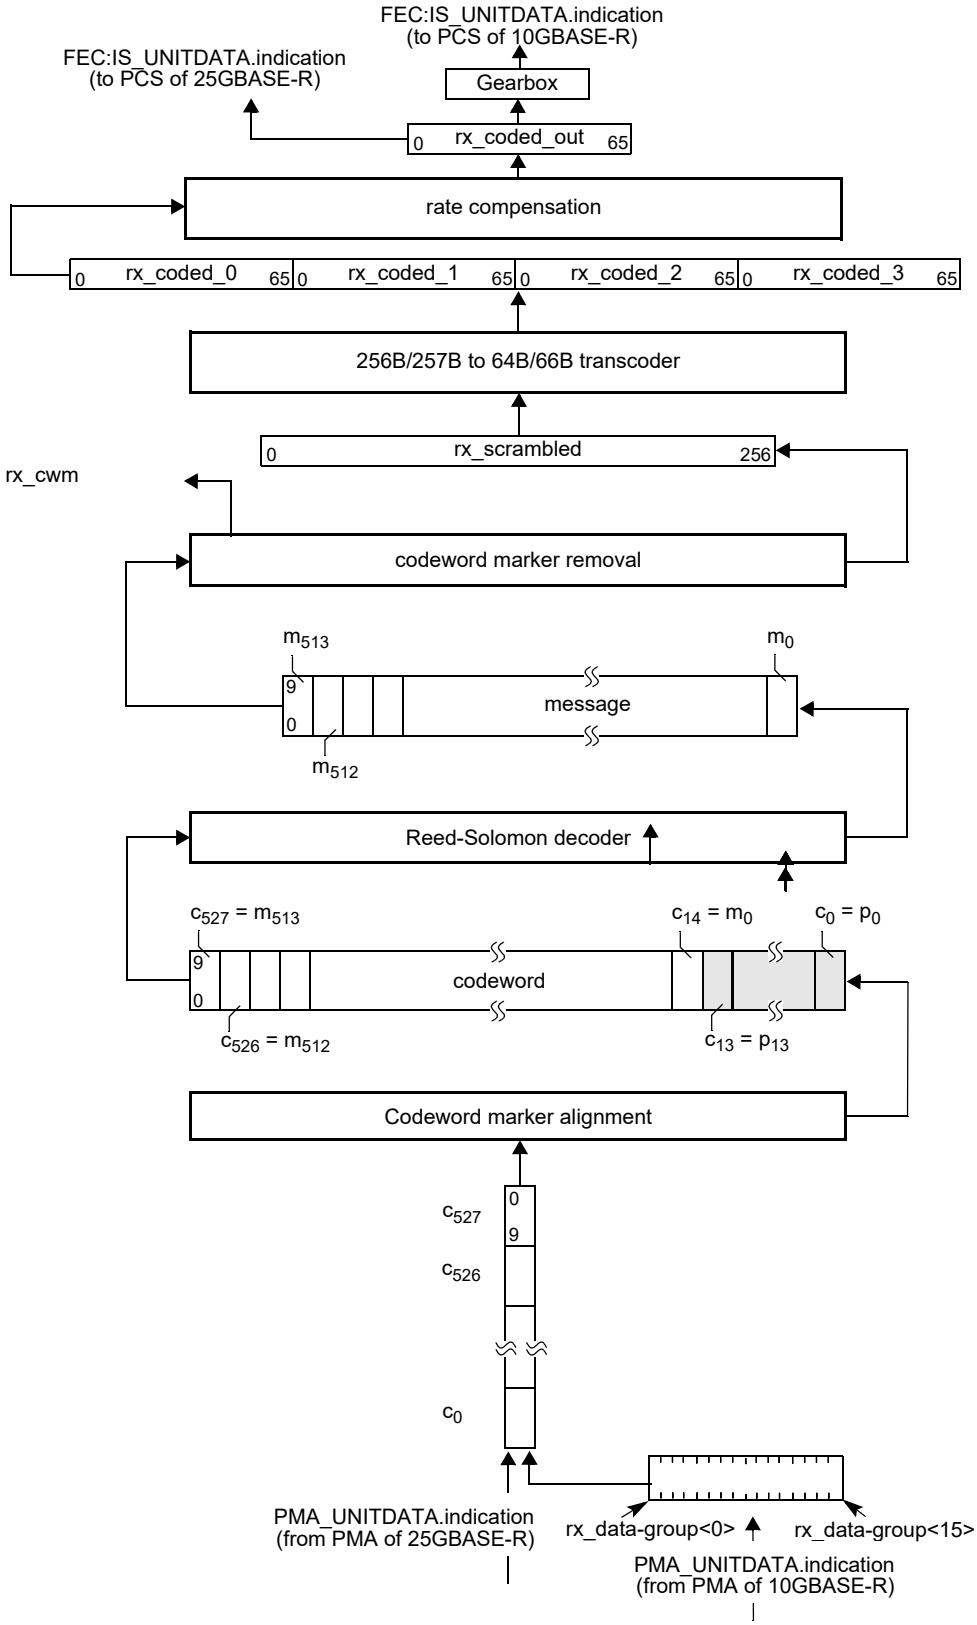

Figure 108–7—Receive bit ordering

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

restart_lock
: Boolean variable that is set by the codeword monitor process to reset the synchronization process. It is set to true after 3 consecutive uncorrected codewords are received (3_BAD state) and set to false upon entry into the LOSS_OF_ALIGNMENT state.

signal_ok
: Boolean variable that is set based on the most recently received value of PMA:IS_SIGNAL.indication(SIGNAL_OK). It is true if the value was OK and false if the value was FAIL.

slip_done
: Boolean variable that is set to true when the SLIP requested by the synchronization state diagram has been completed indicating that the next candidate 257-bit block position can be tested.

test_cwm
: Boolean variable that is set to true when a candidate block position is available for testing and is set to false according to the FEC synchronization state diagram in Figure 108–8.

test_cw
: Boolean variable that is set to true when a new FEC codeword is available for decoding and is set to false according to the codeword monitor state diagram in Figure 108–9.

The following variables are only used for the optional EEE deep sleep capability. If this capability is not supported, lpi_rapid_align, rx_lpi_active, and rcwm_counter_done are set to false, and rx_down_count is set to 0.

lpi_rapid_align
: Boolean variable that is set according to the FEC synchronization state diagram in Figure 108–8. Set to false when reset is true.

rx_lpi_active
: Boolean variable that is set to true when the rate compensation for codeword markers in the receive direction function (108.5.3.6) infers that the Low Power Idle is being received from the link partner, and is set to false otherwise.

rcwm_counter_done
: Boolean variable that indicates that rcwm_counter has reached its terminal count.

rx_down_count
: The countdown value of rapid codeword markers inferred by the receiver from rx_cwm. Transmitted rapid codeword markers contain four copies of tx_down_count and four copies of its bitwise-inverse, from which this value may be extracted.

108.5.4.3 Functions

SLIP
: Causes the next candidate block position to be tested. The precise method for determining the next candidate block position is not specified and is implementation dependent. However, an implementation shall ensure that all possible block positions are evaluated.

108.5.4.4 Counters

cwm_counter
: This counter counts the received codewords that separate the ends of two consecutive codeword markers. An RS-FEC codeword is 5280 bits. The terminal count of this counter is equal to the codeword offset between transmitted codeword markers, 1024.

cw_bad_count
: Counts the number of consecutive uncorrected codewords. This counter is set to zero when a codeword is received and cw_bad is false for that codeword.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following counters are only used for the optional EEE deep sleep capability:

tx_down_count
: A counter that is used when transmitting rapid codeword markers and is decremented each time a rapid codeword marker is sent. The counter initial value is set to 40 when the tx_mode parameter of the FEC:IS_TX_MODE.request primitive changes from ALERT to DATA. The terminal count is zero.

rcwm_counter
: This counter counts the received codewords that separate the ends of two consecutive rapid codeword markers. An RS-FEC codeword is 5280 bits. The terminal count of this counter is equal to one, which is the codeword offset between transmitted rapid codeword markers.

108.5.4.5 Timers

The following timer is only used for the optional EEE deep sleep capability.

hold_off_timer
: This timer is started when rx_mode (or rx_tx_mode if appropriate) transitions from QUIET to DATA. The timer terminal count is 11.5 μs. The timer is stopped when the terminal count is reached or when the FEC synchronization state diagram enters the 2_GOOD state. When the timer reaches the terminal count, it sets hold_off_timer_done = true.

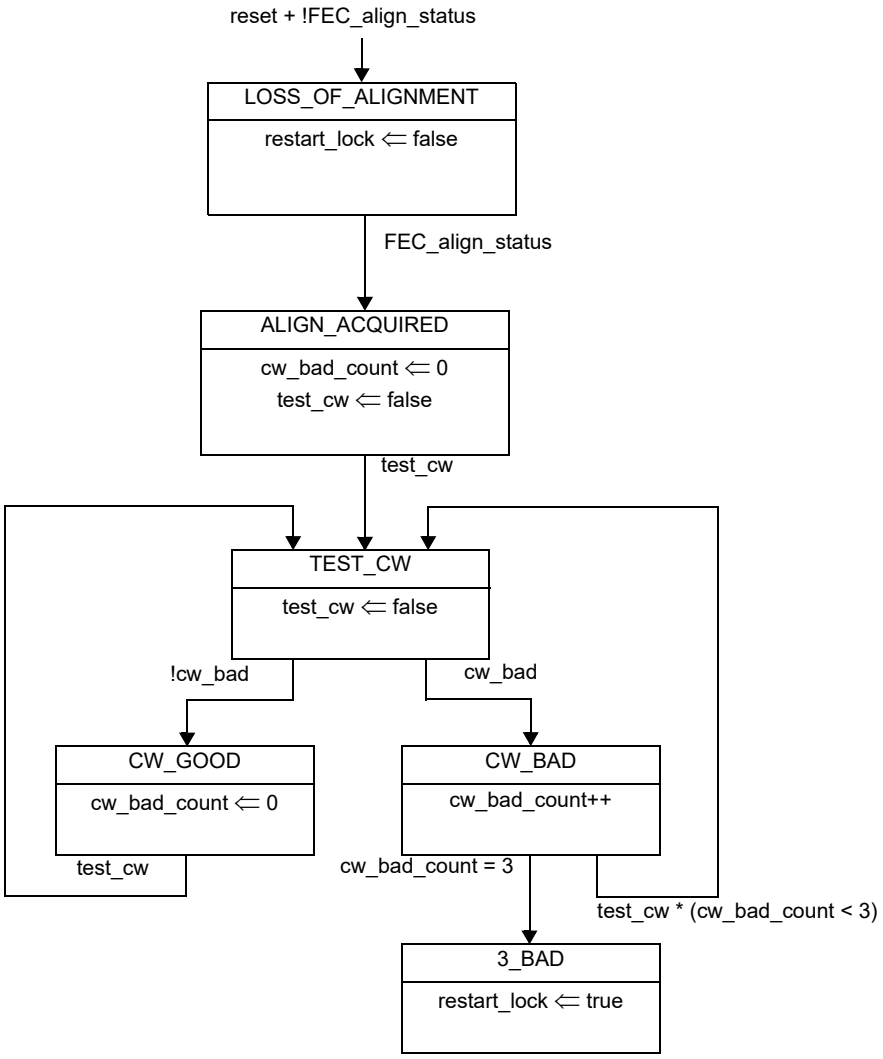

Figure 108–9—Codeword monitor state diagram

108.6 RS-FEC MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the RS-FEC. If MDIO is implemented, it shall map MDIO control bits to RS-FEC control variables as shown in Table 108–1 and MDIO status bits to RS-FEC status variables as shown in Table 108–2. If a separated PMA (see 45.2.1) is connected to the FEC service interface, the MDIO shall map additional MDIO status bits to additional RS-FEC status variables as shown in Table 108–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 108–1—MDIO/RS-FEC control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
FEC bypass correction enable	RS-FEC control register	1.200.0	FEC_bypass_correction_enable
FEC bypass indication enable	RS-FEC control register	1.200.1	FEC_bypass_indication_enable
RS-FEC enable	RS-FEC control register	1.200.2	FEC_Enable

Table 108–2—MDIO/RS-FEC status variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
FEC bypass correction ability	RS-FEC status register	1.201.0	FEC_bypass_correction_ability
FEC bypass indication ability	RS-FEC status register	1.201.1	FEC_bypass_indication_ability
RS-FEC high SER	RS-FEC status register	1.201.2	FEC_high_ser
RS-FEC align status	RS-FEC status register	1.201.14	FEC_align_status
RS-FEC corrected codewords counter	RS-FEC corrected codewords counter register	1.202, 1.203	FEC_corrected_cw_counter
RS-FEC uncorrected codewords counter	RS-FEC uncorrected codewords counter register	1.204, 1.205	FEC_uncorrected_cw_counter
RS-FEC symbol error counter, lane 0	RS-FEC symbol error counter lane 0 register	1.210, 1.211	FEC_symbol_error_counter_0

Table 108–3—MDIO/RS-FEC status variable mapping for separated PMA

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
PCS align status	RS-FEC status register	1.201.15	align_status

The following subclauses define variables that are not otherwise defined, e.g., for use by state diagrams.

108.6.1 FEC_bypass_correction_enable

When this variable is set to one, the Reed-Solomon decoder performs error detection without error correction (see 108.5.3.2). When this variable is set to zero, the decoder also performs error correction. The default value of the variable is zero. This variable is mapped to the bit defined in 45.2.1.116 (1.200.0).

108.6.2 FEC_bypass_indication_enable

This variable is set to one to bypass the error indication function (see 108.5.3.2) when this ability is supported. When this variable is set to zero, the decoder indicates errors to the PCS sublayer. This variable

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

has no effect (the decoder does not bypass error indication) if FEC bypass correction enable (1.200.0) is set to one. The default value of this variable is zero. This variable is mapped to the bit defined in 45.2.1.116 (1.200.1).

108.6.3 RS-FEC Enable

The RS-FEC sublayer may have capability to enable or disable the FEC function for some PHY types. For those PHY types, an MDIO interface or an equivalent management interface shall be provided to access the variable FEC_Enable for the RS-FEC sublayer. When FEC_Enable variable is set to a one, the RS-FEC performs the transmit function as specified in 108.5.2 and the receive function as specified in 108.5.3. When the variable is set to zero, the RS-FEC transmit and receive functions are disabled, and the RS-FEC sublayer is bypassed, effectively connecting its service interface to the service interface of its underlying sublayer. Implementation of this bypass function should cause a minimal delay in the transmit and receive paths. This variable is mapped to the bit defined in 45.2.1.116.3 (1.200.2).

108.6.4 FEC_bypass_correction_ability

The Reed-Solomon decoder may have the option to perform error detection without error correction (see 108.5.3.2) to reduce the delay contributed by the RS-FEC sublayer. This variable is set to one if the decoder has the ability to bypass error correction. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.117 (1.201.0).

108.6.5 FEC_bypass_indication_ability

The Reed-Solomon decoder may have the option to bypass the error indication function (see 108.5.3.2) to reduce the delay contributed by the RS-FEC sublayer. This variable is set to one to indicate that the decoder has the ability to bypass error indication. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.117 (1.201.1).

108.6.6 FEC_high_ser

This variable is defined when the FEC_bypass_indication_ability variable is set to one. When FEC_bypass_indication_enable is set to one, this variable is set to one if the number of RS-FEC symbol errors in a window of 8192 codewords exceeds the threshold 417 (see 108.5.3.2) and is set to zero otherwise. This variable is mapped to the bit defined in 45.2.1.117 (1.201.2).

108.6.7 FEC_corrected_cw_counter

A corrected FEC codeword is a codeword that contained errors that were corrected.

FEC_corrected_cw_counter is a 32-bit counter that counts once for each corrected FEC codeword processed when FEC_align_status is true. This variable is mapped to the registers defined in 45.2.1.118 (1.202, 1.203).

108.6.8 FEC_uncorrected_cw_counter

An uncorrected FEC codeword is a codeword that contains errors (when the bypass correction feature is supported and enabled) or contains errors that were not corrected (when the bypass correction feature is not supported or not enabled).

FEC_uncorrected_cw_counter is a 32-bit counter that counts once for each uncorrected FEC codeword processed when FEC_align_status is true. This variable is mapped to the registers defined in 45.2.1.119 (1.204, 1.205).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

108.6.9 FEC_symbol_error_counter_0

FEC_symbol_error_counter_0, as defined in 91.6.19, is a 32-bit counter that counts once for each 10-bit symbol corrected in lane 0 when FEC_align_status is true. This variable is mapped to the registers defined in 45.2.1.121 (1.210, 1.211). For the RS-FEC defined in this clause, all symbols are assigned to lane 0 and all symbol errors are counted by this counter.

108.6.10 align_status

This variable is assigned the value of rx_block_lock as defined by the PCS lock state diagram (Figure 49–14) used in the block synchronization function (108.5.2.1). This variable is mapped to the bit defined in 45.2.1.117.1 (1.201.15).

108.7 Protocol implementation conformance statement (PICS) proforma for Clause 108, Reed-Solomon forward error correction (RS-FEC) sublayer for 10GBASE-R and 25GBASE-R PHYs[181]

108.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 108, Reed-Solomon forward error correction (RS-FEC) sublayer for 10GBASE-R and 25GBASE-R PHYs, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

108.7.2 Identification

108.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

108.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 108, Reed-Solomon forward error correction (RS-FEC) sublayer for 10GBASE-R and 25GBASE-R PHYs
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[181] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

109. Physical Medium Attachment (PMA) sublayer, type 25GBASE-R

109.1 Overview

109.1.1 Scope

This clause specifies the Physical Medium Attachment sublayer (PMA) that is common to a family of 25 Gb/s Physical Layer implementations, known as 25GBASE-R. The PMA allows the PCS (specified in Clause 107) to connect in a media-independent way with a range of physical media. 25GBASE-R can be extended to support any full duplex medium requiring only that the PMD be compliant with the PMA interface.

The PMA service interface is defined in an abstract manner and does not imply any particular implementation. Electrical interfaces connecting PMA sublayers, known as 25GAUI, are defined in Annex 109A and Annex 109B.

109.1.2 Position of the PMA in the 25GBASE-R sublayers

Figure 109–1 shows the relationship of the PMA sublayer (shown shaded) with other sublayers to the ISO Open System Interconnection (OSI) reference model.

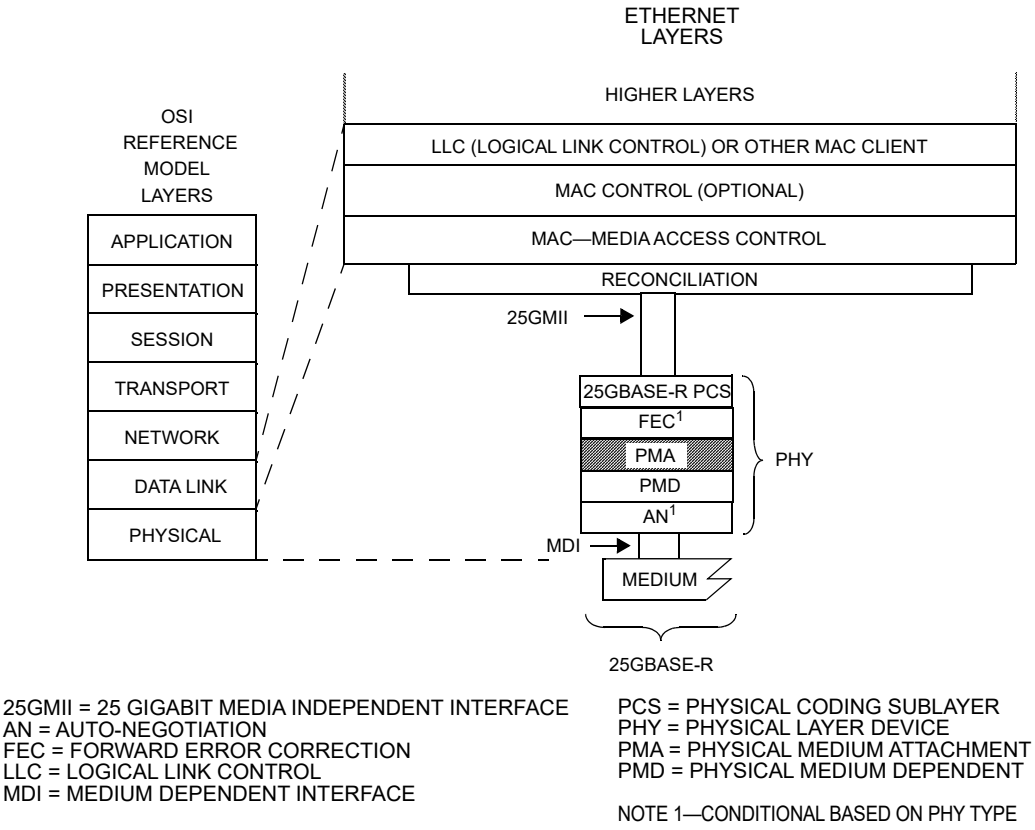

Figure 109–1—25GBASE-R PMA relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

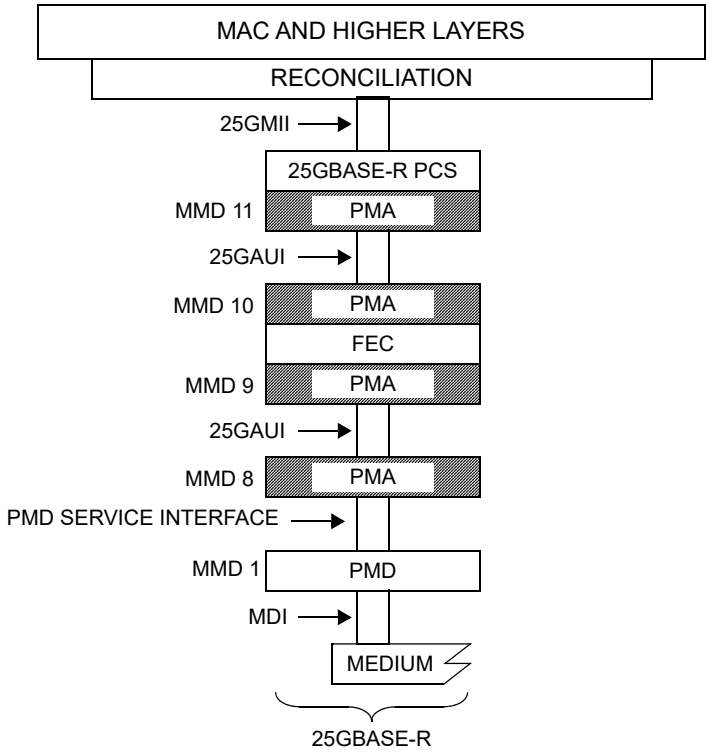
109.1.3 Summary of functions

The following is a summary of the principal functions implemented (when required) by the PMA in both the transmit and receive directions:

a) Provide clock and data recovery.
b) Provide signal drivers.
c) Optionally provide local loopback to/from the PMA service interface.
d) Optionally provide remote loopback to/from the PMD service interface.
e) Optionally provide test-pattern generation and detection.

The functional block diagram in Figure 109–2 shows the inputs, outputs, test-pattern checking and generation, loopbacks, and Signal Indication Logic (SIL, see 109.2).

inst = PMD, PMA, or FEC, depending on which sublayer is below this PMA
SIL = Signal Indication Logic



[a] If 25GAUI immediately above this PMA.
[b] If 25GAUI or PMD service interface immediately below this PMA.
[c] Optional.
[d] Conditional (see 109.4.2)

Figure 109–2—PMA Functional Block Diagram

109.1.4 PMA sublayer positioning

An implementation may use one or more PMA sublayers to provide an interface with a physical electrical interface, 25GAUI, between devices. The number of PMA sublayers required depends on the partitioning of functionality for a particular implementation. An example is illustrated in Figure 109–3. This example illustrates the partitioning that might arise from implementing an FEC sublayer in a device that is separate from the PCS. Additional examples are illustrated in Annex 109C.

25GAUI = 25 GIGABIT ATTACHMENT UNIT INTERFACE
25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 109–3—Example 25GBASE-R PMA layering

Management Data Input/Output (MDIO) Manageable Device (MMD) addresses 1, 8, 9, 10, and 11 are available for addressing multiple instances of PMA sublayers (see Table 45–1 for MMD device addresses). If the PMA sublayer that is closest to the PMD is packaged with the PMD, it shares MMD 1 with the PMD. More addressable instances of PMA sublayers, each one separated from lower addressable instances by chip-to-chip interfaces, may be implemented and addressed allocating MMD addresses to PMAs in increasing numerical order going from the PMD toward the PCS. The example shown in Figure 109–3 could be implemented with four addressable instances: MMD 8 addressing the lowest PMA sublayer (note that this cannot share MMD 1 with the PMD as they are not packaged together in this example), MMD 9 addressing the PMA sublayer above the 25GAUI below the FEC, MMD 10 addressing the PMA sublayer below the 25GAUI above the FEC, and MMD 11 addressing the PMA sublayer closest to the PCS.

The following guidelines apply to the partitioning of PMAs:

a) The inter-sublayer service interface, defined in 105.4, is used for the PMA, FEC, and PMD service interfaces supporting a flexible architecture with optional FEC and multiple PMA sublayers.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) 25GAUI is a 25.78125 GBd serial physical instantiation of the connection between two adjacent PMA sublayers. As a physical instantiation, it defines electrical and timing specification as well as requiring a receive re-timing function.

c) Opportunities for optional test-pattern generation, optional test-pattern detection, optional local loopback and optional remote loopback are dependent upon the location of the PMA sublayer in the implementation. See Figure 109–2.

d) A minimum of one PMA sublayer is required in a PHY.

e) A maximum of four PMA sublayers are addressable as MDIO MMDs.

109.2 PMA service interface

This subclause specifies the services provided by the 25GBASE-R PMA. The service interface for this PMA is described in an abstract manner and does not imply any particular implementation. The PMA service interface supports the exchange of encoded data. The PMA translates the encoded data to and from signals suitable for the medium.

The PMA service interface is an instance of the inter-sublayer service interface defined in 105.4. The PMA service interface primitives are summarized as follows:

PMA:IS_UNITDATA.request
PMA:IS_UNITDATA.indication
PMA:IS_SIGNAL.indication

The PMA continuously sends a bit stream to the PMA client (e.g., PCS) at a nominal signaling rate of 25.78125 GBd. Likewise the PMA client continuously sends a bit stream to the PMA.

In the Tx direction, if data from a PMA:IS_UNITDATA.request primitive is received over a 25GAUI, clock and data are recovered on the lane to recover data one bit at a time. Each recovered bit is sent to the sublayer below using the *inst*:IS_UNITDATA.request primitive.

In the Rx direction, when data is received from the sublayer below the PMA using the *inst*:IS_UNITDATA.request primitive, each received bit is sent to the PMA client using the PMA:IS_UNITDATA.indication primitive.

PMA:IS_SIGNAL.indication(SIGNAL_OK) is generated based on receipt of *inst*:IS_SIGNAL.indication(SIGNAL_OK) from the sublayer below and status of the input signal as determined by the signal detect function (see Figure 109–2). When *inst*:IS_SIGNAL.indication(SIGNAL_OK) has the value FAIL or the signal detect function detects an invalid signal, PMA:IS_SIGNAL.indication(SIGNAL_OK) shall have the value FAIL, otherwise PMA:IS_SIGNAL.indication(SIGNAL_OK) shall have the value OK. The operation of the signal detect function is beyond the scope of this standard.

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78, 78.1.3.3.1) then the inter-sublayer service interface includes four additional primitives defined as follows:

PMA:IS_TX_MODE.request
PMA:IS_RX_MODE.request
PMA:IS_ENERGY_DETECT.indication
PMA:IS_RX_TX_MODE.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A physically instantiated service interface with the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option (see 78.1.3.3.1) may enter a low power state to conserve energy during periods of low link utilization. The ability to support transition to a low power state in the ingress direction is indicated by register 1.1.9 (PMA Ingress AUI Stop Ability, PIASA). The ability to support transition to a low power state in the egress direction is indicated by register 1.1.8 (PMA Egress AUI Stop Ability, PEASA). Transition to the low power state in the ingress direction is enabled by register 1.7.9 (PMA Ingress AUI Stop Enable, PIASE). Transition to the low power state in the egress direction is enabled by register 1.7.8 (PMA Egress AUI Stop Enable, PEASE). The system shall not assert the enable bit for an interface unless the corresponding ability bit at the other side of the interface is also asserted. If the PIASE bit is TRUE, then the PMA may disable transmitters on the physical instantiation of the ingress AUI when aui_tx_mode is QUIET. If the PEASE bit is TRUE, then the PMA may disable transmitters on the physical instantiation of the egress AUI when tx_mode is QUIET.

109.3 Service interface below PMA

Since the architecture supports multiple PMA sublayers, there are several different sublayers that may appear below a PMA, including FEC, the PMD, or another PMA. The variable *inst* represents whichever sublayer appears below the PMA.

The sublayer below the PMA utilizes the inter-sublayer service interface defined in 105.4. The service interface primitives provided to the PMA are summarized as follows:

inst:IS_UNITDATA.request(tx_bit)
inst:IS_UNITDATA.indication(rx_bit)
inst:IS_SIGNAL.indication(SIGNAL_OK)

Note that electrical and timing specifications of the service interface are defined if the interface is physically instantiated (e.g., 25GAUI), otherwise the service interface is specified abstractly. The service interface below the PMA has an input and output for data transfer and a status input indicating a good signal sent by the sublayer below the PMA (see Figure 109–2).

In the Tx direction, data received via the PMA:IS_UNITDATA.request primitive from the PMA client at the PMA service interface is sent to the sublayer below the PMA via the *inst*:IS_UNITDATA.indication primitive.

In the Rx direction, if the bit is received over a physically instantiated interface (e.g., 25GAUI), clock and data are recovered on the lane receiving the bit. The bit is routed through the PMA to an output lane toward the PMA client, sending the bit to the PMA client using the PMA:IS_UNITDATA.indication primitive at the PMA service interface.

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78, 78.1.3.3.1) then inter-sublayer service interface for the sublayer below the PMA includes four additional primitives defined as follows:

inst:IS_TX_MODE.request
inst:IS_RX_MODE.request
inst:IS_ENERGY_DETECT.indication
inst:IS_RX_TX_MODE.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

109.4 Functions within the PMA

109.4.1 Signal drivers

For cases where the interface between the PMA client and the PMA, or between the PMA and the sublayer below the PMA represent a physically instantiated interface, the PMA provides electrical signal drivers for that interface.

The electrical and jitter/timing interface requirements for the 25GAUI chip-to-chip (C2C) are specified in Annex 109A.

The electrical and jitter/timing interface requirements for the 25GAUI chip-to-module (C2M) are specified in Annex 109B.

109.4.2 PMA local loopback mode

PMA local loopback shall be provided by the PMA adjacent to the PMD for 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, and 25GBASE-KR-S. PMA local loopback mode is optional for other PMDs or for PMAs not adjacent to the PMD. If it is implemented, it shall be as described in this subclause.

The PMA local loopback function involves looping back the input to the output. Each bit received from the PMA:IS_UNITDATA.request(tx_bit) primitive is looped back in the direction of the PCS using the PMA:IS_UNITDATA.indication(rx_bit) primitive.

Ability to perform the local loopback function is indicated by the Local_loopback_ability status variable. A device is placed in local loopback mode when the Local_loopback_enable control variable is set to one, and removed from local loopback mode when this variable is set to zero.

If the optional Clause 45 MDIO is implemented, the PMA receive process maps the Local_loopback_ability and Local_loopback_enable variables to the registers and bits defined in 109.6.

109.4.3 PMA remote loopback mode

PMA remote loopback mode is optional. If implemented, it shall be as described in this subclause.

When remote loopback is enabled, each bit from the service interface below the PMA via *inst*:IS_UNITDATA.indication is looped back toward the PMD via *inst*:IS_UNITDATA.request. Note that the service interface below the PMA can be provided by the FEC or PMD.

The ability to perform this function is indicated by the Remote_loopback_ability status variable. A device is placed in remote loopback mode when the Remote_loopback_enable control variable is set to one, and removed from remote loopback mode when this variable is set to zero.

If the optional Clause 45 MDIO is implemented, the PMA receive process maps the Remote_loopback_ability and Remote_loopback_enable variables to the registers and bits defined in 109.6.

109.4.4 PMA test patterns

Where the output of the PMA appears on a physically instantiated interface 25GAUI or the PMD service interface, the PMA may optionally generate and detect test patterns. These test patterns are used to test adjacent layer interfaces for an individual PMA sublayer or to perform testing between a physically instantiated interface of a PMA sublayer and external testing equipment.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

109.4.4.1 Transmit PRBS31 test-pattern generation

The ability to generate PRBS31 test patterns in the transmit direction is indicated by the PRBS31_Tx_generator_ability status variable. If supported, transmit PRBS31 test-pattern generation is enabled by the PRBS31_enable and PRBS_Tx_gen_enable control variables. When transmit PRBS31 test-pattern generation is enabled, the PMA shall generate a PRBS31 pattern as defined in 49.2.8 toward the service interface below the PMA via the *inst*:IS_UNITDATA.request primitive.

If the optional Clause 45 MDIO is implemented, the PMA transmit process maps the PRBS31_Tx_checker_ability, PRBS31_Rx_checker_ability, PRBS31_enable, and PRBS_Tx_gen_enable variables to the registers and bits defined in 109.6.

To avoid correlated crosstalk between this link and other locally implemented links, it is highly recommended that the PRBS31 patterns generated on each link use independent, random seeds or ensure a minimum offset of 20 000 UI between the PRBS31 sequence on any two links.

109.4.4.2 Receive PRBS31 test-pattern generation

The ability to generate PRBS31 test patterns in the receive direction is indicated by the PRBS31_Rx_generator_ability status variable. If supported, receive PRBS31 test-pattern generation is enabled by the PRBS31_enable and PRBS_Rx_gen_enable control variables. When receive PRBS31 test-pattern generation is enabled, the PMA shall generate a PRBS31 pattern as defined in 49.2.8 toward the PMA client via the PMA:IS_UNITDATA.indication primitive. While this test pattern is enabled, the PMA also generates PMA:IS_SIGNAL.indication(SIGNAL_OK) indicating a valid signal (SIGNAL_OK=OK) toward the PMA client independent of the status at the service interface below the PMA. When receive PRBS31 test-pattern generation is disabled, the PMA returns to normal operation.

If the optional Clause 45 MDIO is implemented, the PMA receive process maps the PRBS31_Rx_generator_ability, PRBS31_enable, and PRBS_Rx_gen_enable variables to the registers and bits defined in 109.6.

To avoid correlated crosstalk between this link and other locally implemented links, it is highly recommended that the PRBS31 patterns generated on each link use independent, random seeds or ensure a minimum offset of 20 000 UI between the PRBS31 sequence on any two links.

109.4.4.3 Transmit PRBS31 test-pattern checking

The ability to check PRBS31 test patterns in the transmit direction is indicated by the PRBS31_Tx_checker_ability status variable. If supported, the transmit PRBS31 test-pattern checking is enabled by the PRBS31_enable and PRBS_Tx_check_enable control variables. When transmit PRBS31 test-pattern checking is enabled, the PMA shall check for the PRBS31 pattern received from the PMA client via the PMA:IS_UNITDATA.request primitive. The checker shall increment the test-pattern error counter by one for each incoming bit error in the PRBS31 pattern for isolated single-bit errors. Implementations should be capable of counting at least one error whenever one or more errors occur in a sliding 1000-bit window. The transmit test-pattern error count is indicated by the Ln0_PRBS_Tx_test_err_counter status variable. When transmit PRBS31 test-pattern checking is disabled, the PMA returns to normal operation.

If the optional Clause 45 MDIO is implemented, the PMA transmit process maps the PRBS31_Tx_checker_ability, PRBS31_enable, PRBS_Tx_check_enable, and Ln0_PRBS_Tx_test_err_counter variables to the registers and bits defined in 109.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

109.4.4.4 Receive PRBS31 test-pattern checking

The ability to check PRBS31 test patterns in the receive direction is indicated by the PRBS31_Rx_checker_ability status variable. If supported, receive PRBS31 test-pattern checking is enabled by the PRBS31_enable and PRBS_Rx_check_enable control variables. When receive PRBS31 test-pattern checking is enabled, the PMA shall check for the PRBS31 pattern received from the service interface below the PMA via the *inst*:IS_UNITDATA.indication primitive. The receive test-pattern error count is indicated by the Ln0_PRBS_Rx_test_err_counter status variable. While the receive PRBS31 test-pattern mode is enabled, the PMA:IS_SIGNAL.indication(SIGNAL_OK) primitive does not indicate a valid signal (SIGNAL_OK=FAIL). When receive PRBS31 test-pattern checking is disabled, the PMA returns to normal operation.

If the optional Clause 45 MDIO is implemented, the PMA receive process maps the PRBS31_Rx_checker_ability, PRBS31_enable, PRBS_Rx_check_enable, and Ln0_PRBS_Rx_test_err_counter variables to the registers and bits defined in 109.6.

109.4.4.5 Transmit PRBS9 test-pattern generation

The ability to generate the PRBS9 test patterns in the transmit direction is indicated by the PRBS9_Tx_generator_ability status variable. If supported, transmit PRBS9 test-pattern generation is enabled by the PRBS9_enable and PRBS_Tx_gen_enable control variables. When transmit PRBS9 pattern generation is enabled, the PMA shall generate a PRBS9 pattern as defined in Table 68–6 toward the service interface below the PMA via the *inst*:IS_UNITDATA.request primitive. When transmit PRBS9 test-pattern generation is disabled, the PMA returns to normal operation.

If the optional Clause 45 MDIO is implemented, the PMA transmit process maps the PRBS9_Tx_generator_ability, PRBS9_enable, and PRBS_Tx_gen_enable variables to the registers and bits defined in 109.6.

Note that the transmit PRBS9 test pattern is intended to be checked by external test gear and no PRBS9 checking function is provided within the PMA.

109.4.4.6 Receive PRBS9 test-pattern generation

The ability to generate the PRBS9 test patterns in the receive direction is indicated by the PRBS9_Rx_generator_ability status variable. If supported, receive PRBS9 test-pattern generation is enabled by the PRBS9_enable and PRBS_Rx_gen_enable control variables. When receive PRBS9 test-pattern generation is enabled, the PMA shall generate a PRBS9 pattern as defined in Table 68–6 toward the PMA client via the PMA:IS_UNITDATA.indication primitive. The PMA will also generate PMA:IS_SIGNAL.indication(SIGNAL_OK) toward the PMA client independent of the status at the service interface below the PMA. When receive PRBS9 test-pattern generation is disabled, the PMA returns to normal operation.

If the optional Clause 45 MDIO is implemented, the PMA receive process maps the PRBS9_Rx_generator_ability, PRBS9_enable and PRBS_Rx_gen_enable variables to the registers and bits defined in 109.6.

Note that the receive PRBS9 test pattern is intended to be checked by external test gear and no PRBS9 checking function is provided within the PMA.

109.4.4.7 Transmit square wave test-pattern generation

The optional transmit square wave test-pattern generation applies to the PMA transmit direction towards a physically instantiated 25GAUI or towards the PMD service interface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The ability to generate the square wave test pattern in the transmit direction is indicated by the Square_wave_ability status variable. If supported, transmit square wave test-pattern generation is enabled by the Square_wave_enable_0 control variable. When transmit square wave test-pattern generation is enabled, the PMA shall generate a square wave test pattern composed of 8 ones followed by 8 zeros toward the service interface below the PMA via the *inst*:IS_UNITDATA.request primitive. When transmit square wave test-pattern generation is disabled, the PMA returns to normal operation.

If the optional Clause 45 MDIO is implemented, the PMA transmit process maps the Square_wave_ability and Square_wave_enable_0 variable to the registers and bits defined in 109.6.

109.4.5 Energy Efficient Ethernet for 25GAUI

When the optional Energy Efficient Ethernet (EEE) deep sleep capability is supported and the PMA service interface is physically instantiated as 25GAUI, the additional functions listed in 83.5.11 are required. These functions enable the communication of service interface parameters that are essential to the operation of the EEE deep sleep capability. The timing parameters for EEE operation are shown in Table 83–2.

PMA EEE operation for 25GAUI is specified in 83.5.11 with respect to lane 0 only. Considerations related to multiple lanes do not apply.

109.5 Delay constraints

The maximum cumulative delay contributed by up to four PMA stages in a PHY (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 109–1. A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 105.5.

Table 109–1—Delay constraints

Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
4096	8	163.84

109.6 PMA MDIO function mapping

The optional MDIO capability described in Clause 45 describes several variables that provide control and status information for and about the PMA. Since a given implementation may employ more than one PMA sublayer, the PMA control and status information is organized into multiple addressable instances, one for each possible PMA sublayer. See 45.2.1 and 109.1.4 for the allocation of MMD addresses to PMA sublayers. Control and status registers for MMD 8, 9, 10, and 11 will use the Extended PMA control and status registers at identical locations to those for MMD 1.

Mapping of MDIO control variables to PMA control variables is shown in Table 109–2. Mapping of MDIO status variables to PMA status variables is shown in Table 109–3. Mapping of MDIO counter to PMA counters is shown in Table 109–4. These tables provide the register and bit numbers for the PMA addressed as MMD 1. For implementations with multiple PMA sublayers, additional PMA sublayers use the corresponding register and bit numbers in MMDs 8, 9, 10, and 11 as necessary.

109.7 Protocol implementation conformance statement (PICS) proforma for Clause 109, Physical Medium Attachment (PMA) sublayer, type 25GBASE-R[182]

109.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 109, Physical Medium Attachment (PMA) sublayer, type 25GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

109.7.2 Identification

109.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

109.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 109, Physical Medium Attachment (PMA) sublayer, type 25GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[182]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

110. Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-CR and 25GBASE-CR-S

110.1 Overview

This clause specifies the 25GBASE-CR PMD, the 25GBASE-CR-S PMD, and the baseband medium. The specifications are closely related to those of 100GBASE-CR4 (Clause 92), but with a single lane instead of four lanes. There are three associated annexes. Annex 110A provides information on parameters with test points that may not be testable in an implemented system, Annex 110B specifies test fixtures, and Annex 110C describes 25GBASE-CR and 25GBASE-CR-S host and cable assembly form factors.

When forming a complete Physical Layer, the PMD shall be connected as illustrated in Figure 110–1, to the appropriate PMA as shown in Table 110–1, to the medium through the MDI, and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 110–1—Physical Layer clauses associated with the 25GBASE-CR and 25GBASE-CR-S PMDs

Associated clause	25GBASE-CR	25GBASE-CR-S
106—RS	Required	Required
106—25GMII[a]	Optional	Optional
107—PCS	Required	Required
74—BASE-R FEC[b]	Required	Required
108—RS-FEC[b]	Required	N/A
109—PMA	Required	Required
109A—25GAUI C2C	Optional	Optional
73—Auto-Negotiation	Required	Required
78—Energy Efficient Ethernet	Optional	Optional

[a]The 25GMII is an optional interface. However, if the 25GMII is not implemented, a conforming implementation behaves functionally as though the RS and 25GMII were present.
[b]FEC sublayers can be enabled or disabled according to the FEC mode (see 110.6).

A 25GBASE-CR PHY operates over cable assemblies of types CA-25G-N, CA-25G-S and CA-25G-L (see 110.10). A 25GBASE-CR-S PHY operates over cable assemblies of types CA-25G-N and CA-25G-S. A 25GBASE-CR-S PHY interoperates with a 25GBASE-CR PHY. Table 110–2 summarizes the cable assembly types supported by each of the PHY types.

Table 110–2—Cable assembly types supported by each PHY type

PHY type	CA-25G-N	CA-25G-S	CA-25G-L
25GBASE-CR	Yes	Yes	Yes
25GBASE-CR-S	Yes	Yes	No

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When forming a complete 25GBASE-CR or 25GBASE-CR-S Physical Layer, the link BER requirements depend on the FEC mode (see 110.6) according to the following guidelines:

a) If a PHY operates in the RS-FEC mode, and the RS-FEC decoder does not bypass error correction (see 108.5.3.2), the link is required to operate with a BER of 10^{-5} or better.
b) If a PHY operates in the BASE-R FEC mode, the link is required to operate with a BER of 10^{-8} or better.
c) If a PHY operates in the no-FEC mode, or in the RS-FEC mode with error correction bypassed, the link is required to operate with a BER of 10^{-12} or better.

In this context, a link consists of a compliant PMD transmitter, a compliant PMD receiver, and a compliant cable assembly.

For a complete Physical Layer, this specification is considered to be satisfied by a frame loss ratio (see 1.4.344) less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

25GBASE-CR and 25GBASE-CR-S PHYs with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

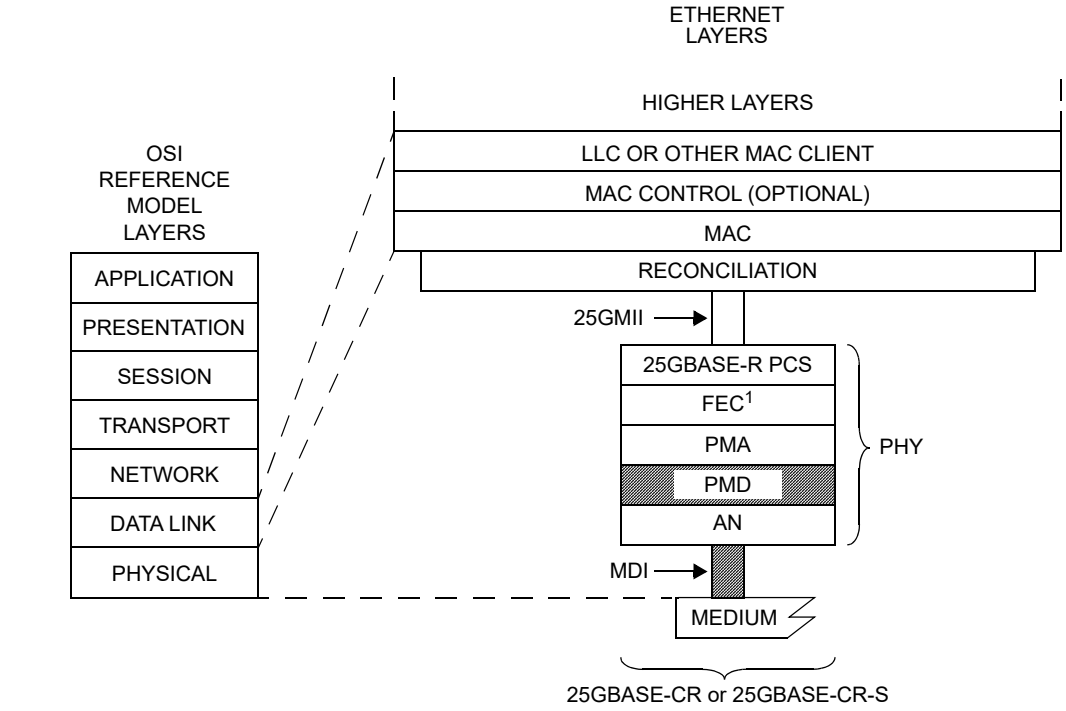
Figure 110–1 shows the relationship of the 25GBASE-CR and 25GBASE-CR-S PMD sublayers and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

110.2 PMD service interface

This subclause specifies the services provided by the 25GBASE-CR and 25GBASE-CR-S PMDs. The service interface for these PMDs is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data. The PMD translates the encoded data to and from signals suitable for the medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 105.4. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA.request
PMD:IS_UNITDATA.indication
PMD:IS_SIGNAL.indication



The PMA (or the PMD) continuously sends a bit stream to the PMD (or the PMA) at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable Global_PMD_signal_detect as defined in 110.7.4. When Global_PMD_signal_detect is one, SIGNAL_OK shall be assigned the value OK. When Global_PMD_signal_detect is zero, SIGNAL_OK shall be assigned the value FAIL. When SIGNAL_OK is FAIL, the PMD:IS_UNITDATA.indication parameter is undefined.

If the optional EEE deep sleep capability is supported, then the PMD service interface includes two additional primitives as follows:

PMD:IS_TX_MODE.request
PMD:IS_RX_MODE.request

25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
AN = AUTO-NEGOTIATION
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 110–1—25GBASE-CR and 25GBASE-CR-S relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

110.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 107.5.)

25GBASE-CR and 25GBASE-CR-S PHYs may be extended using a 25GAUI chip-to-chip (C2C) as a physical instantiation of the inter-sublayer service interface between devices. If 25GAUI C2C is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

110.4 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the PMD and AN shall be no more than 512 bit times (1 pause_quantum or 20.48 ns). It is assumed that the one way delay through the medium is no more than 1500 bit times (60 ns).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 105.5.

110.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control bits to PMD control variables as shown in Table 110–3, and MDIO status bits to PMD status variables as shown in Table 110–4.

Table 110–3—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable	1.9.0	Global_PMD_transmit_disable
Restart training	BASE-R PMD control	1.150.0	mr_restart_training
Training enable	BASE-R PMD control	1.150.1	mr_training_enable
Polynomial identifier 0	PMD training pattern lane 0	1.1450.12:11	identifier_0
Seed 0	PMD training pattern lane 0	1.1450.10:0	seed_0

Table 110–4—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/bit number	PMD status variable
Fault	PMA/PMD status 1	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect	1.10.0	Global_PMD_signal_detect
Receiver status 0	BASE-R PMD status	1.151.0	rx_trained
Frame lock 0	BASE-R PMD status	1.151.1	frame_lock
Startup protocol status 0	BASE-R PMD status	1.151.2	training
Training failure 0	BASE-R PMD status	1.151.3	training_failure

110.6 FEC modes

A 25GBASE-CR PHY implements the BASE-R FEC sublayer (Clause 74) and the 25GBASE-R RS-FEC sublayer (Clause 108). A 25GBASE-CR-S PHY implements the BASE-R FEC sublayer (Clause 74). Each FEC sublayer can be either enabled or disabled, according to AN resolution or management control.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Three FEC modes are supported:

a) When the 25GBASE-R RS-FEC sublayer is enabled, the PHY is defined to operate in the RS-FEC mode.
b) When the BASE-R FEC sublayer is enabled, the PHY is defined to operate in the BASE-R FEC mode.
c) When no FEC sublayer is enabled, the PHY is defined to operate in the no-FEC mode.

A 25GBASE-CR PHY can operate in RS-FEC, BASE-R FEC, or no-FEC mode. A 25GBASE-CR-S PHY can operate in either BASE-R FEC or no-FEC mode.

The cable assembly types (CA-25G-N, CA-25G-S, or CA-25G-L, see 110.10) that the PHY supports and the required PMD receiver characteristics (110.8.4) depend on the FEC mode.

The FEC mode is determined using AN (Clause 73) if AN is enabled, or by management control if AN is disabled, and is used in both transmit direction and receive direction. It is recommended to configure the AN FEC advertisement such that only modes that are compatible with the type of the cable assembly attached to the MDI are selected.

110.7 PMD functional specifications

110.7.1 Link block diagram

One direction of a 25GBASE-CR or 25GBASE-CR-S link is shown in Figure 110–2.

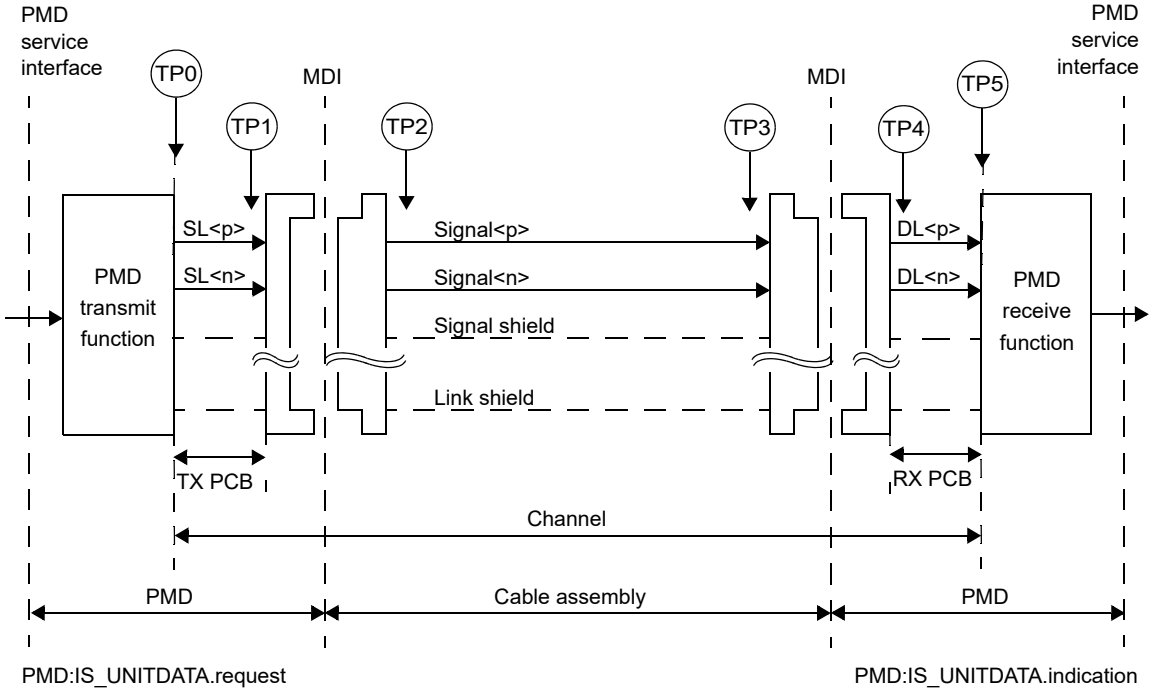

Figure 110–2—25GBASE-CR or 25GBASE-CR-S link (one direction is illustrated)

Note that the source lane (SL) signals SL<p> and SL<n> are the positive and negative sides of the transmitter's differential signal pair and the destination lane (DL) signals DL<p> and DL<n> are the positive and negative sides of the receiver's differential signal pair.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For purposes of system conformance, the PMD sublayer is standardized at the test points described in this subclause.

The electrical transmit signal is defined at TP2. Unless specified otherwise, all transmitter measurements and tests defined in 110.8.3 are made at TP2 utilizing the test fixture specified in 110B.1.1.

The electrical receive signal is defined at TP3. Unless specified otherwise, all receiver measurements and tests defined in 110.8.4 are performed at TP3 utilizing the test fixture specified in 110B.1.1.

A mated connector pair has been included in both the transmitter and receiver specifications defined in 110.8.3 and 110.8.4. The recommended maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is provided in 92.8.3.6. Annex 110A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system.

The channel (see 110.9) is defined between the transmitter (TP0) and receiver (TP5) blocks to include the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss, as illustrated in Figure 110–2. All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 110–2. The cable assembly test fixture of 110B.1.2, or its equivalent, is required for measuring the cable assembly specifications in 110.10 at TP1 and TP4. Two mated connector pairs and the cable assembly test fixture have been included in the cable assembly specifications defined in 110.10. Transmitter and receiver differential controlled impedance printed circuit board insertion losses defined between TP0 and the MDI and between the MDI and TP5, respectively, are provided informatively in 92A.4.

Table 110–5 describes the defined test points illustrated in Figure 110–2.

Table 110–5—Test points

Test points	Description
TP0 to TP5	The channel including the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss.
TP1 to TP4	All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 110–2. The cable assembly test fixture of 110B.1.2, or its equivalent, is required for measuring the cable assembly specifications in 110.10 at TP1 and TP4.
TP0 to TP2 TP3 to TP5	A mated connector pair has been included in both the transmitter and receiver specifications defined in 110.8.3 and 110.8.4. The recommended maximum insertion loss from TP0 to TP2 or from TP3 to TP5 including the test fixture is provided in 92.8.3.6.
TP2	Unless specified otherwise, all transmitter measurements defined in 110.8.3 are made at TP2 utilizing the test fixture specified in 110B.1.1.
TP3	Unless specified otherwise, all receiver measurements and tests defined in 110.8.4 are made at TP3 utilizing the test fixture specified in 110B.1.1.

110.7.2 PMD transmit function

The PMD transmit function shall convert the bit stream requested by the PMD service interface message PMD:IS_UNITDATA.request(tx_bit) into an electrical signal. The electrical signal shall then be delivered to the MDI, according to the transmit electrical specifications in 110.8.3. A positive differential output voltage (SL<p> minus SL<n>) shall correspond to tx_bit = one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the optional EEE deep sleep capability is supported, the following requirements apply. When the PMD service interface message PMD:IS_TX_MODE.request(tx_mode) is received with tx_mode = ALERT, the PMD transmit function shall transmit a periodic sequence, where each period of the sequence consists of 8 ones followed by 8 zeros, with the transmit equalizer coefficients set to the preset values (see 72.6.10.2.3.1). This sequence is transmitted regardless of the value of tx_bit presented by the PMD:IS_UNITDATA.request primitive. When tx_mode is not set to ALERT, the transmit equalizer coefficients are set to the values determined via the startup protocol (see 110.7.10).

110.7.3 PMD receive function

The PMD receive function shall convert the electrical signal from the MDI into a bit stream for delivery to the PMD service interface using the messages PMD:IS_UNITDATA.indication(rx_bit). A positive differential input voltage (DL<p> minus DL<n>) shall correspond to rx_bit = one.

110.7.4 Global PMD signal detect function

The Global PMD signal detect function is used by the PMD to indicate the successful completion of the startup protocol by the PMD control function (see 110.7.10). Global_PMD_signal_detect is set to zero when the value of the variable signal_detect is set to false by the Training state diagram (see Figure 72–5). Global_PMD_signal_detect is set to one when the value of signal_detect is set to true.

If training is disabled by the management variable mr_training_enable (see 110.5), Global_PMD_signal_detect shall be set to one.

If the optional EEE deep sleep capability is supported, the following requirements apply. The value of Global_PMD_signal_detect is set to zero when the PMD service interface message PMD:IS_RX_MODE.request(rx_mode) is initially received with rx_mode = QUIET. While rx_mode is set to QUIET, Global_PMD_signal_detect shall be set to one within 500 ns of the application of the ALERT pattern defined in 110.7.2, with peak-to-peak differential voltage of 720 mV measured at TP2, to the differential pair at the input of the cable assembly that connects the transmitter to the receiver. While rx_mode is set to QUIET, Global_PMD_signal_detect shall not be set to one when the voltage input to the differential pair of the cable assembly that connects the transmitter to the receiver is less than or equal to 70 mV peak-to-peak differential.

When the MDIO is implemented, this function maps the variables to registers and bits as defined in 110.5.

110.7.5 Global PMD transmit disable function

The Global PMD transmit disable function is mandatory if EEE deep sleep capability is supported and is otherwise optional.When Global_PMD_transmit_disable variable is set to one, this function shall turn off the transmitter such that it drives a constant level (i.e., no transitions) and does not exceed the differential peak-to-peak output voltage (max.) with Tx disabled in Table 92–6.

If a PMD fault (110.7.7) is detected, then the PMD may set Global_PMD_transmit_disable to one.

Loopback, as defined in 110.7.6, shall not be affected by Global_PMD_transmit_disable.

The following additional requirements apply when the optional EEE deep sleep capability is supported:

a) The Global PMD transmit disable function shall turn off the transmitter as specified in 92.8.3.1 when tx_mode transitions to QUIET from any other value.
b) The Global PMD transmit disable function shall turn on the transmitter as specified in 92.8.3.1 when tx_mode transitions from QUIET to any other value.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

110.7.6 Loopback mode

Local loopback mode is provided by the adjacent PMA (see Clause 109) as a test function. When loopback mode is enabled, transmission requests passed to the transmitter are sent directly to the receiver, overriding any signal detected by the receiver on its attached link. Note that loopback mode does not affect the state of the transmitter, which continues to send data (unless disabled).

Control of the loopback function is specified in 109.4.2.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

110.7.7 PMD fault function

PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault. If the MDIO interface is implemented, then PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

110.7.8 PMD transmit fault function

The PMD transmit fault function is optional. The faults detected by this function are implementation specific, but the assertion of Global_PMD_transmit_disable is not considered a transmit fault.

If PMD_transmit_fault is set to one, then Global_PMD_transmit_disable should also be set to one.

If the MDIO interface is implemented, then PMD_transmit_fault shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

110.7.9 PMD receive fault function

The PMD receive fault function is optional. The faults detected by this function are implementation specific. A fault is indicated by setting the variable PMD_receive_fault to one.

If the MDIO interface is implemented, then PMD_receive_fault shall be mapped to the Receive fault bit as specified in 45.2.1.7.5.

110.7.10 PMD control function

25GBASE-CR and 25GBASE-CR-S PMDs shall use the same control function as lane 0 of 100GBASE-CR4, as defined in 92.7.12.

The variables seed_0 and polynomial_0 control the training pattern. It is recommended that implementations with multiple PMDs use distinct values of polynomial_0 for PMDs that are coupled by crosstalk.

110.8 Electrical characteristics

110.8.1 Signal levels

The MDI (see 110.11) is a low-swing AC-coupled differential interface. AC-coupling within the plug connectors, as defined in 110.11.1, allows for interoperability between components operating from different supply voltages.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

110.8.2 Signal paths

The MDI transmit and receive paths are point-to-point connections. Each path comprises two complementary signals, which form a balanced differential pair. There is one differential path in each direction for a total of two pairs, or four connections.

110.8.3 Transmitter characteristics

Transmitter electrical characteristics at TP2 for 25GBASE-CR and 25GBASE-CR-S PHYs shall be the same as those of a single lane of 100GBASE-CR4, as summarized in Table 92–6 and detailed in 92.8.3.1 through 92.8.3.9, with the exception that the value of linear fit pulse peak (min.) is $0.49 \times v_f$. The transmitter specifications at TP0 are provided informatively in 110A.2.

110.8.4 Receiver characteristics

Receiver electrical characteristics are specified at TP3. The receiver shall meet the return loss requirements specified in 92.8.4.2 and 92.8.4.3. In addition, the requirements in 110.8.4.1, 110.8.4.2, 110.8.4.3 and 110.8.4.4 apply.

The receiver specifications at TP5 are provided informatively in 110A.3.

110.8.4.1 Receiver input amplitude tolerance

When a 25GBASE-CR or 25GBASE-CR-S PMD receiver is connected to a compliant transmitter whose peak-to-peak differential output voltage, as defined by 92.8.3.1 using preset equalizer coefficients, is 1200 mV, using a compliant cable assembly with the minimum insertion loss specified in 110.10.2, the following BER requirements apply.

a) When the RS-FEC mode is used, the PMD receiver shall operate at a BER better than 10^{-5}.
b) When the BASE-R FEC mode is used, the PMD receiver shall operate at a BER better than 10^{-8}.
c) When the no-FEC mode is used, the PMD receiver shall operate at a BER better than 10^{-12}.

The receiver is allowed to control the transmitter equalizer coefficients, using the protocol defined in 92.7.12 or an equivalent process, to meet these requirements.

110.8.4.2 Receiver interference tolerance test

Receiver interference tolerance is measured according to the requirements listed in 110.8.4.2.1 through 110.8.4.2.5.

A 25GBASE-CR PHY shall comply with the receiver interference tolerance test requirements for the RS-FEC, BASE-R FEC, and no-FEC modes. A 25GBASE-CR-S PHY shall comply with the receiver interference tolerance test requirements for the BASE-R FEC and no-FEC modes.

Two tests are defined for each FEC mode. Test 1 includes a low-loss channel, identical for all FEC modes. Test 2 includes a high-loss channel, which is different for each FEC mode. The cable assembly used in the test channel (see 110.8.4.2.2) shall meet the cable assembly Channel Operating Margin (COM) as specified in 110.10.7, with CA-25G-L COM parameter values being used for RS-FEC mode test, CA-25G-S COM parameter values being used for BASE-R FEC mode test, and CA-25G-N COM parameter values being used for no-FEC mode test.

The test requirements for the RS-FEC mode are provided in Table 110–6. The test requirements for the BASE-R FEC mode are provided in Table 110–7. The test requirements for the no-FEC mode are provided in Table 110–8.

Table 110–6—25GBASE-CR interference tolerance parameters, RS-FEC mode

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Test pattern	Scrambled idle encoded by RS-FEC				
RS-FEC symbol error ratio required[a]	$< 10^{-4}$				
Test channel insertion loss at 12.8906 GHz[b]	14.3	14.8	29.44	29.94	dB
Cable assembly insertion loss at 12.8906 GHz	8	10	20.48	22.48	dB
COM[c]	3		3		dB
b_{max} used in COM calculation	1				
DER_0 used in COM calculation	10^{-5}				

[a]The RS-FEC symbol error ratio is measured using the RS-FEC symbol error counter (see 108.6.9).
[b]Insertion loss between the two test references (see Figure 110–3b).
[c]The COM value is the target value for the SNR_TX calibration defined in 110.8.4.2.3 item f). The SNR_TX value measured at the Tx test reference should be as close as practical to the value needed to produce the target COM. If lower SNR_TX values are used, this would demonstrate margin to the specification but this is not required for compliance.

Table 110–7—25GBASE-CR and 25GBASE-CR-S interference tolerance parameters, BASE-R FEC mode

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Test pattern	Scrambled idle encoded by BASE-R FEC				
BASE-R FEC corrected block ratio required[a,b]	$< 2.1 \times 10^{-5}$				
Test channel insertion loss at 12.8906 GHz[c]	14.3	14.8	23.44	23.94	dB
Cable assembly insertion loss at 12.8906 GHz	8	10	14.48	16.48	dB
COM[d]	3		3		dB
b_{max} used in COM calculation	0.5				
DER_0 used in COM calculation	10^{-8}				

[a]The BASE-R FEC corrected block ratio is measured using the FEC corrected blocks counter (see 74.8.4.1).
[b]The FEC uncorrected blocks counter (see 74.8.4.2) is required to indicate zero errors during the test unless the test duration is such that the uncorrected block ratio can be verified to be less than 4.7×10^{-10}.
[c]Insertion loss between the two test references (see Figure 110–3b).
[d]The COM value is the target value for the SNR_TX calibration defined in 110.8.4.2.3 item f). The SNR_TX value measured at the Tx test reference should be as close as practical to the value needed to produce the target COM. If lower SNR_TX values are used, this would demonstrate margin to the specification but this is not required for compliance.

Table 110–8—25GBASE-CR and 25GBASE-CR-S interference tolerance parameters, no-FEC mode

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Test pattern	Scrambled idle or PRBS31				
Bit error ratio required[a]	$< 10^{-12}$				
Test channel insertion loss at 12.8906 GHz[b]	14.3	14.8	22.48	22.98	dB
Cable assembly insertion loss at 12.9806 GHz	8	10	13.5	15.5	dB
COM[c]	3		2.2		dB
b_{max} used in COM calculation	0.35				
DER_0 used in COM calculation	10^{-12}				

[a]The bit error ratio is measured using the PCS errored blocks counter (see 49.2.14.2) or the PMA PRBS31 error counter (see 109.4.4.4) as appropriate.
[b]Insertion loss between the two test references (see Figure 110–3b).
[c]The COM value is the target value for the SNR_TX calibration defined in 110.8.4.2.3 item f). The SNR_TX value measured at the Tx test reference should be as close as practical to the value needed to produce the target COM. If lower SNR_TX values are used, this would demonstrate margin to the specification but this is not required for compliance.

110.8.4.2.1 Test setup

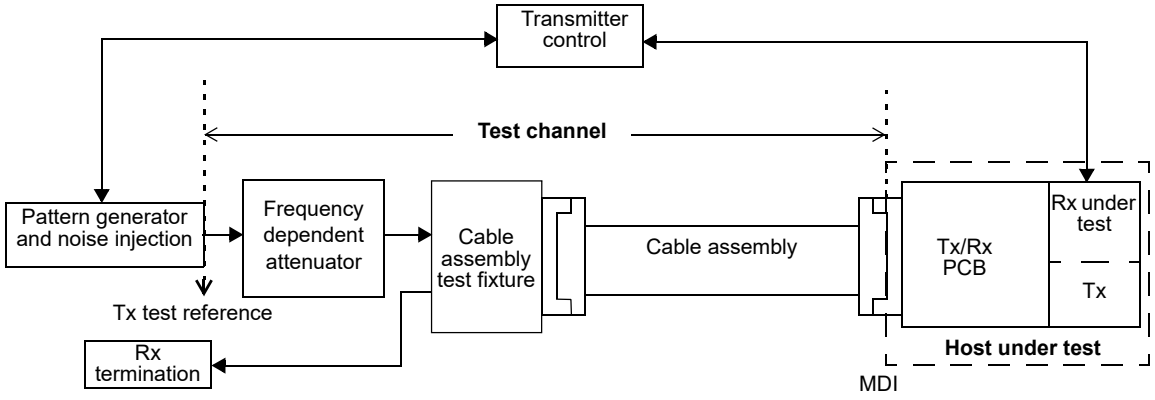
The interference tolerance test is performed with the setup shown in Figure 110–3a. The requirements of this subclause are verified at the test references in Figure 110–3a and Figure 110–3b. The cable assembly unused single-ended paths are terminated in 50 Ω to provide 100 Ω differential termination.

NOTE—The cable assembly provides AC-coupling as specified in 110.11.

110.8.4.2.2 Test channel

The test channel (as depicted in Figure 110–3a) consists of the following:

a) A cable assembly meeting the requirements of 110.10 and the insertion loss specified for the test being performed.
b) A cable assembly test fixture (see 110B.1.2 and 92.11.2).
c) A frequency-dependent attenuator.



NOTE—The frequency-dependent attenuator represents a Tx host channel and may be implemented with PCB traces and test cables.

110.8.4.2.3 Test channel calibration

The scattering parameters of the test channel are measured at the test references as illustrated in Figure 110–3b using the cable assembly test fixtures specified in 110B.1.

The insertion loss at 12.8906 GHz of the signal path between the test references in Figure 110–3b is within the limits in Table 110–6, Table 110–7, or Table 110–8, as appropriate for the test being performed.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The MDI of the host under test is not included in the test channel.

Figure 110–3a—Interference tolerance test setup

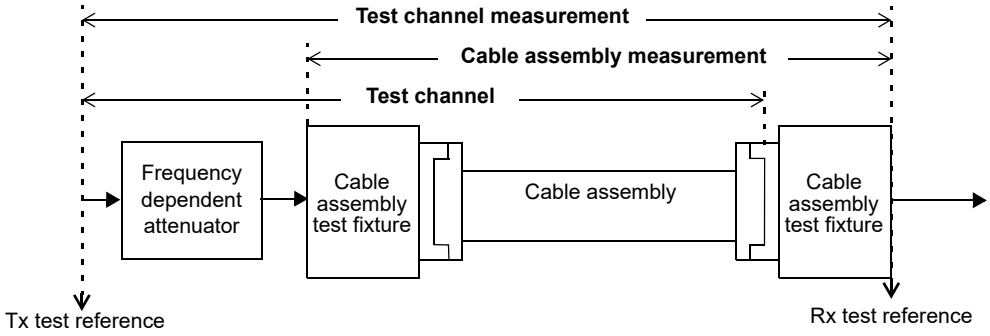


Figure 110–3b—Test channel calibration

The COM is calculated using the method and parameters of 110.10.7 with the following considerations:

a) The channel signal path is $SCHS_p$ = cascade($S^{(CTSP)}$, $S^{(HOSP)}$), where cascade() is defined in 93A.1.2.1, $S^{(HOSP)}$ is defined in 110.10.7.1.1, and $S^{(CTSP)}$ is the measured channel between the test references in Figure 110–3b.

b) The COM parameters are as modified by Table 110–6, Table 110–7, or Table 110–8, as appropriate for the test being performed.

c) COM is calculated using both Test 1 and Test 2 device package model transmission line lengths listed in Table 110–11 on the receiver side. The value of COM is taken as the lower of the two calculated values.

d) The augmented signal path in 93A.1.2 is replaced by S_p determined from Equation (110–1) (effectively omitting the transmitter device package model $S^{(tp)}$). The filtered voltage transfer function $H^{(k)}(f)$ calculated in Equation (93A–19) uses the filter $H_t(f)$ defined by Equation (93A–46), where T_r is the 20% to 80% transition time at the Tx test reference. T_r is measured using the method in 86A.5.3.3, with the exception that the observation filter bandwidth is 33 GHz instead of 12 GHz. T_r is measured with the transmit equalizer turned off (i.e., coefficients set to the preset values, see 72.6.10.2.3.1).

e) Even-odd jitter, effective bounded uncorrelated jitter and effective random jitter without noise injection (see 110.8.4.2.4) are measured at the Tx test reference and comply with the specification in 92.8.3.8.1 and 92.8.3.8.2. In the calculation of COM, A_{DD} is set to half of the value of $EBUJ$ and σ_{RJ}

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

is set to the value of *ERJ*, replacing the values in Table 110–11. It is recommended to adjust the pattern generator jitter such that the effective bounded uncorrelated jitter and the effective total uncorrelated jitter (see 92.8.3.8.2) are as close as practical to their limits in Table 92–6.

f) The SNR_{TX} value that results in the required COM value for the test is calculated. The injected noise (see 110.8.4.2.4) is set such that the SNDR, as measured at the Tx test reference using the procedure in 92.8.3.7, matches the calculated SNR_{TX} value.

$$S_p = \text{cascade}(SCHS_p, S^{(rp)}) \quad (110–1)$$

where

cascade()	is defined in 93A.1.2.1
$SCHS_p$	is defined in item a) above
$S^{(rp)}$	is defined in 93A.1.2.4

110.8.4.2.4 Pattern generator and noise injection

The pattern generator transmits data to the device under test. At the start of transmitter training, the pattern generator output amplitude shall be 800 mV peak-to-peak differential when measured on an alternating one-zero pattern. The output amplitude, measured on an alternating one-zero pattern, is not permitted to exceed 800 mV peak-to-peak differential during transmitter training. The output waveform of the pattern generator shall comply with 110.8.1.

Broadband noise is added to the signal before the Tx test reference, with noise level set according to step f in 110.8.4.2.3.

110.8.4.2.5 Test procedure

The pattern generator is first configured to transmit the training pattern defined in 110.7.10. During this initialization period, the device under test (DUT) configures the pattern generator transmit equalizer to the coefficient settings it would select using the protocol described in 72.6.10 and the receiver is tuned using its optimization method. The coefficient settings may be communicated via the startup protocol or by other means.

After the pattern generator equalizer has been configured and the receiver tuned, the pattern generator is set to generate the test pattern specified in Table 110–6, Table 110–7, or Table 110–8, as appropriate for the test being performed. During the test, the transmitter in the device under test transmits the same pattern type specified for the test, with equalization turned off (preset condition).

For 25GBASE-CR and 25GBASE-CR-S PHYs, the receiver under test meets the error requirements specified for the tests in Table 110–7 and Table 110–8. For a 25GBASE-CR PHY, the receiver under test meets the error requirement specified for the test in Table 110–6.

110.8.4.3 Receiver jitter tolerance

Jitter tolerance in RS-FEC mode is measured with a channel meeting the insertion loss of Test 2 and the RS-FEC symbol error ratio requirement specified in Table 110–6. Jitter tolerance in BASE-R FEC mode is measured with a channel meeting the insertion loss of Test 2 and the corrected block ratio requirement specified in Table 110–7. Jitter tolerance in no-FEC mode is measured with a channel meeting the insertion loss of Test 2 and the bit error ratio requirement specified in Table 110–8.

Receiver jitter tolerance is verified for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 110–9. The test setup and procedure of 110.8.4.2 are used, with the exception that no noise is injected (i.e., step f in 110.8.4.2.3 is not performed). In addition, jitter with the specified frequency is applied

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to the transmitter and the jitter amplitude is adjusted to obtain the specified peak-to-peak jitter for that frequency at the Tx test reference.

For a 25GBASE-CR-S PHY, the receiver under test shall meet the error requirements specified for the tests in Table 110–7 and Table 110–8, for each case listed in Table 110–9. For a 25GBASE-CR PHY, the receiver under test shall also meet the error requirement specified for the test in Table 110–6 for each case listed in Table 110–9.

Table 110–9—Receiver jitter tolerance parameters

Parameter	Case A values	Case B values	Units
Jitter frequency	190	940	kHz
Peak-to-peak jitter amplitude	5	1	UI

110.8.4.4 Signaling rate range

25GBASE-CR and 25GBASE-CR-S PHYs shall comply with the receiver requirements of 110.8.4.2 and 110.8.4.3 for any signaling rate in the range 25.78125 GBd ± 100 ppm. The corresponding unit interval is approximately 38.787879 ps.

110.9 Channel characteristics

The channel is defined between TP0 and TP5 to include the transmitter and receiver differential controlled impedance printed circuit board and the cable assembly as illustrated in Figure 110–2. The channel insertion loss, return loss, COM, and the transmitter and receiver differential controlled impedance printed circuit board parameters are provided informatively in 110A.4 through 110A.7.

Channel definitions apply for links between two PHYs that can each be either 25GBASE-CR or 25GBASE-CR-S.

110.10 Cable assembly characteristics

Cable assemblies defined in this subclause contain insulated conductors terminated in a connector at each end for use as link segments between MDIs. Cable assemblies are primarily intended as point-to-point links between 25GBASE-CR or 25GBASE-CR-S PHYs using controlled impedance cables. Since 25GBASE-CR and 25GBASE-CR-S PHYs have two specified MDI connectors, single-lane (SFP28, specified in 110.11.1) and multi-lane (QSFP28, specified in 92.12), there are three possible combinations of the connectors at each end. The possible cable assembly types are described in Annex 110C.

All cable assembly measurements are to be made between TP1 and TP4 with cable assembly test fixtures as specified in Annex 110B. These cable assembly specifications are based upon twinaxial cable characteristics, but other cable types are acceptable if the specifications of this subclause are met.

Three cable assembly types are specified, with different COM requirements:

a) Cable assembly long (CA-25G-L): Cable assembly that supports links between two PHYs that operate in RS-FEC mode with error correction enabled on both receivers, with achievable cable length of at least 5 m.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Cable assembly short (CA-25G-S): Cable assembly that supports links between two PHYs that operate in BASE-R FEC mode, with achievable cable length of at least 3 m.

c) Cable assembly no-FEC (CA-25G-N): Cable assembly that supports links between two PHYs that operate in no-FEC mode, with achievable cable length of at least 3 m.

NOTE—It may be possible to construct compliant cable assemblies longer than indicated. Length of a cable assembly does not imply compliance to specifications.

Table 110–10 provides a summary of the cable assembly characteristics for CA-25G-L, CA-25G-S, and CA-25G-N, and references to the subclauses addressing each parameter. Due to the improved error correction capability in RS-FEC mode, the specified maximum insertion loss for CA-25G-L is larger than that of CA-25G-S. Likewise, due to the error correction capability provided in BASE-R FEC mode, the specified maximum insertion loss for CA-25G-S is larger than that of CA-25G-N. All other parameters except for some of the input parameters for the COM calculation are identically specified.

Table 110–10—Cable assembly characteristics summary

Description	Reference	CA-25G-L	CA-25G-S	CA-25G-N	Unit
Maximum insertion loss at 12.8906 GHz	110.10.2	22.48	16.48	15.5	dB
Minimum insertion loss at 12.8906 GHz	110.10.2	8			dB
Minimum differential return loss at 12.8906 GHz	110.10.3	6			dB
Differential to common-mode return loss	110.10.4	Equation (92–28)			dB
Differential to common-mode conversion loss	110.10.5	Equation (92–29)			dB
Common-mode to common-mode return loss	110.10.6	Equation (92–30)			dB
COM	110.10.7	See Table 110–11			dB

110.10.1 Characteristic impedance and reference impedance

The nominal differential characteristic impedance of the cable assembly is 100 Ω. The differential reference impedance for cable assembly specifications shall be 100 Ω.

110.10.2 Cable assembly insertion loss

The measured insertion loss of the CA-25G-L, CA-25G-S, and CA-25G-N cable assembly shall be greater than or equal to the minimum cable assembly insertion loss given in Equation (92–26) and illustrated in Figure 92–12.

The measured insertion loss at 12.8906 GHz of the CA-25G-L cable assembly shall be less than or equal to 22.48 dB. The measured insertion loss at 12.8906 GHz of the CA-25G-S cable assembly shall be less than or equal to 16.48 dB. The measured insertion loss at 12.8906 GHz of the CA-25G-N cable assembly shall be less than or equal to 15.5 dB.

110.10.3 Cable assembly differential return loss

The cable assembly differential return loss shall meet the requirements of 92.10.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

110.10.4 Differential to common-mode return loss

The cable assembly differential to common-mode return loss shall meet the requirements of 92.10.4.

110.10.5 Differential to common-mode conversion loss

The cable assembly differential to common-mode conversion loss shall meet the requirements of 92.10.5.

110.10.6 Common-mode to common-mode return loss

The cable assembly common-mode to common-mode return loss shall meet the requirements of 92.10.6.

110.10.7 Cable assembly Channel Operating Margin

The cable assembly Channel Operating Margin (COM) for each lane is derived from measurements of the cable assembly signal, near-end crosstalk and far-end crosstalk paths. COM is computed using the path calculations defined in 110.10.7.1 and the procedure in 93A.1, where T_r is 8 ps for $H_t(f)$ as used in Equation (93A–19). The specific paths used depend on cable assembly form factor (see Annex 110C), as described in 110.10.7.2.

COM parameter values for the three cable assembly types, CA-25G-L, CA-25G-S, and CA-25G-N, are provided in Table 110–11.

Table 110–11—COM parameter values

Parameter	Symbol	CA-25G-N	CA-25G-S	CA-25G-L[a]	Units
Signaling rate	f_b	25.78125			GBd
Maximum start frequency	f_{min}	0.05			GHz
Maximum frequency step[b]	Δf	0.01			GHz
Device package model Single-ended device capacitance Transmission line length, Test 1 Transmission line length, Test 2 Single-ended package capacitance at package-to-board interface	 C_d z_p z_p C_p	 2.5×10^{-4} 12 30 1.8×10^{-4}			 nF mm mm nF
Single-ended reference resistance	R_0	50			Ω
Single-ended termination resistance	R_d	55			Ω
Receiver 3 dB bandwidth	f_r	$0.75 \times f_b$			GHz
Transmitter equalizer, minimum cursor coefficient	$c(0)$	0.62			—

Table 110–11—COM parameter values *(continued)*

Parameter	Symbol	CA-25G-N	CA-25G-S	CA-25G-L[a]	Units
Continuous time filter, DC gain Minimum value Maximum value Step size	g_{DC}	 –16 0 1	 –13 0 1	 –13 0 1	 dB dB dB
Continuous time filter, zero frequency for $g_{DC} = 0$	f_z	$f_b / 4$			GHz
Continuous time filter, pole frequencies	f_{p1} f_{p2}	$f_b / 4$ f_b			GHz
Transmitter differential peak output voltage Victim Far-end aggressor Near-end aggressor	 A_v A_{fe} A_{ne}	 0.4 0.6 0.6			 V V V
Number of signal levels	L	2			—
Level separation mismatch ratio	R_{LM}	1			—
Transmitter signal-to-noise ratio	SNR_{TX}	29	29	29	dB
Number of samples per unit interval	M	32			—
Decision feedback equalizer (DFE) length	N_b	14			—
Normalized DFE coefficient magnitude limit, for $n = 1$ to N_b	$b_{max}(n)$	0.35	0.5	1	—
Random jitter, RMS	σ_{RJ}	0.01			UI
Dual-Dirac jitter, peak	A_{DD}	0.05			UI
One-sided noise spectral density	η_0	5.2×10^{-8}			V^2/GHz
Target detector error ratio	DER_0	10^{-12}	10^{-8}	10^{-5}	—
Channel Operating Margin (min.)	COM	3[c]	3	3	dB

[a]The parameters for CA-25G-L are the same as those for 100GBASE-CR4 (Table 93–8), except for g_{DC}, A_{fe}, and SNR_{TX}.
[b]For cable lengths greater than 4 m, a frequency step (Δf) no larger than 5 MHz is recommended.
[c]For CA-25G-N cable assemblies with insertion loss at 12.8906 GHz greater than 12 dB, the minimum COM is relaxed to 2.2 dB.

Test 1 and Test 2 differ in the value of the device package model transmission line length z_p. COM for any channel within the cable assembly shall be greater than or equal to the Channel Operating Margin (min.) value specified in Table 110–11 for both Test 1 and Test 2.

110.10.7.1 Channel signal and crosstalk path calculations

The channel paths between TP0 and TP5 used for calculation of the cable assembly COM consist of measured cable assembly signal and crosstalk paths, representative transmitter PCB signal paths, and representative receiver PCB signal paths.

The transmitter and receiver PCB signal paths are calculated using the method defined in 93A.1.2.3. The scattering parameters for a PCB are defined by Equation (93A–13), Equation (93A–14), and the parameter

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

values given in Table 92–12. The PCB trace length parameter z_p has different value for each specific signal path, as specified in 110.10.7.1.1 and 110.10.7.1.2.

The channel path calculations use the function cascade() defined in 93A.1.2.1.

110.10.7.1.1 Channel signal path

The scattering parameters of the channel signal path from TP0 to TP5 are calculated using Equation (110–2). The transmitter and receiver PCB signal paths are both denoted as $S^{(HOSP)}$ and are calculated from Equation (93A–13) and Equation (93A–14) using the parameter values given in Table 92–12 and z_p = 151 mm, representing an insertion loss of 6.26 dB at 12.8906 GHz on each PCB.

$$SCHS_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOSP)}, S^{(CASP)}), S^{(HOSP)}) \quad (110–2)$$

where

$SCHS_p^{(k)}$ is the channel signal path

$S^{(HOSP)}$ is the host (transmitter or receiver) PCB signal path

$S^{(CASP)}$ is the cable assembly signal path (TP1 to TP4)

k is equal to zero

110.10.7.1.2 Channel crosstalk paths

The MDI is the significant contributor to crosstalk and is included in and characterized by the cable assembly crosstalk measurements. Crosstalk includes a near-end path where the aggressor is the PMD transmitter, and for specific form factors, near-end and alien far-end crosstalk paths where the aggressors are other PMD transmitters that are connected to the same cable assembly.

For the channel crosstalk paths, the receiver PCB model is $S^{(HOSP)}$ as defined in 110.10.7.1.1. The aggressor transmitter host PCB model is denoted as $S^{(HOTxSP)}$ and is calculated from Equation (93A–13) and Equation (93A–14) using the parameter values given in Table 92–12 and z_p = 72 mm, representing an insertion loss of 3 dB at 12.8906 GHz. The transmitter host PCB insertion loss is lower than that used for the signal path, to allow for a reasonable worst-case crosstalk in the COM calculation.

The scattering parameters of the channel near-end crosstalk paths are calculated using Equation (110–3). The scattering parameters of the channel alien far-end crosstalk paths are calculated using Equation (110–4).

$$SCHNXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOTxSP)}, S^{(CANXTk)}), S^{(HOSP)}) \quad (110–3)$$

where

$SCHNXT_p^{(k)}$ is the near-end crosstalk path

$S^{(HOSP)}$ is the host receiver PCB signal path defined in 110.10.7.1.1

$S^{(HOTxSP)}$ is the aggressor transmitter PCB signal path

$S^{(CANXTk)}$ is the cable assembly near-end crosstalk path k (TP1 to TP4)

k is the index of the near-end crosstalk path

$$SCHAFXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOTxSP)}, S^{(CAFXTk)}), S^{(HOSP)}) \quad (110–4)$$

where

$SCHAFXT_p^{(k)}$ is the alien far-end crosstalk path

$S^{(HOSP)}$ is the host receiver PCB signal path defined in 110.10.7.1.1

$S^{(HOTxSP)}$ is the aggressor transmitter PCB signal path

$S^{(CAFXTk)}$ is the cable assembly far-end crosstalk path k (TP1 to TP4)

k is the index of the alien far-end crosstalk path

110.10.7.2 Signal and crosstalk paths used in calculation of COM

Cable assemblies have several form factors, as described in Annex 110C. The choice of signal and crosstalk paths for calculation of COM is specific to each cable assembly form factor, as specified in 110.10.7.2.1 through 110.10.7.2.4.

110.10.7.2.1 SFP28 to SFP28

The SFP28 to SFP28 channel structure includes the signal path, one near-end crosstalk path and no alien far-end crosstalk. The signal and near-end crosstalk paths are used in calculation of COM.

The signal path is calculated using Equation (110–2).

The near-end crosstalk path is calculated using Equation (110–3).

110.10.7.2.2 QSFP28 to SFP28

The QSFP28 to SFP28 channel structure includes the signal path, three alien far-end and one near-end crosstalk path. These five paths are used in calculation of COM. Crosstalk from transmitters on other SFP28 connectors is assumed to be insignificant.

The signal path is calculated using Equation (110–2).

The near-end crosstalk path is calculated using Equation (110–3), with k equal to 1.

The three alien far-end crosstalk paths are calculated using Equation (110–4), with k values from 1 to 3.

110.10.7.2.3 SFP28 to QSFP28

The SFP28 to QSFP28 channel structure includes the signal path, three alien far-end and four near-end crosstalk paths. These eight paths are used in calculation of COM.

The signal path is calculated using Equation (110–2).

The near-end crosstalk paths are calculated using Equation (110–3), with k values from 1 to 4.

The three alien far-end crosstalk paths are calculated using Equation (110–4), with k values from 1 to 3.

110.10.7.2.4 QSFP28 to QSFP28

The QSFP28 to QSFP28 channel structure includes the same paths defined for the SFP28 to QSFP28 channel, and COM is calculated in the same way, as defined in 110.10.7.2.3.

110.11 MDI specification

This subclause defines the 25GBASE-CR Media Dependent Interface (MDI), used for both 25GBASE-CR and 25GBASE-CR-S Physical Layers. The MDI couples the PMD (110.7 and 110.8) to the cable assembly (110.10).

The mechanical interface between the PMD and the cable assembly may be either a mated pair of connectors meeting the requirements of 110.11.1 (single-lane MDI) or a mated pair of connectors meeting the requirements of 92.12.1.1 (multi-lane MDI). The plug connector is used on the cable assembly and the receptacle is used on the PMD.

For the multi-lane MDI, each of the paired transmit and receive lanes (SL1, DL1), (SL2, DL2), (SL3, DL3) or (SL4, DL4) may be used for the transmit and receive connections (SL and DL) of a 25GBASE-CR or 25GBASE-CR-S PHY.

For 25GBASE-CR plug connectors, the receive lanes are AC-coupled; the AC-coupling shall be within the plug connectors. It should be noted that there may be various methods for AC-coupling in actual implementations. The low-frequency 3 dB cutoff of the AC-coupling shall be less than 50 kHz. It is recommended that the value of the coupling capacitors be 100 nF. The capacitor limits the inrush charge and baseline wander.

110.11.1 Single-lane MDI connectors

The single-lane MDI uses the SFP+ 28 Gb/s 1X Pluggable (SFP28) plug and receptacle as defined in SFF-8402 and SFF-8432.

The cable assembly connector shall be the SFP28 plug as illustrated in Figure 110–4. The PMD connector shall be the SFP28 receptacle with the mechanical mating interface as illustrated in Figure 110–5. These connectors shall have data signal and signal ground contact assignments as specified in Table 110–12 and electrical performance consistent with the signal quality and electrical requirements of 110.8, 110.9, and 110.10.

110.13 Protocol implementation conformance statement (PICS) proforma for Clause 110, Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-CR and 25GBASE-CR-S[183]

110.13.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 110, Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-CR and 25GBASE-CR-S, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

110.13.2 Identification

110.13.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

110.13.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 110, Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-CR and 25GBASE-CR-S
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[183] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.
