139.7.10.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 139–7. The patterns used for the received conformance signal are specified in Table 139–10. The optical test signal is conditioned (stressed) using the stressed receiver methodology defined in 139.7.10.2 and has sinusoidal jitter applied as specified in 121.8.10.4. A suitable test set is needed to characterize the signal used to test the receiver. Stressed receiver conformance test signal verification is described in 139.7.10.3.

The low-pass filter is used to create ISI. The sinusoidal amplitude interferer causes additional eye closure, but in conjunction with the finite edge rates, also causes some jitter.

The sinusoidally jittered clock represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter. The sinusoidal amplitude interferer may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid harmonic relationships between the sinusoidal interferer, the sinusoidal jitter, the signaling rate, and the pattern repetition rate. The Gaussian noise generator, the amplitude of the sinusoidal interferer, and the low-pass filter are adjusted so that the SECQ specified in Table 139–7 is met, according to the methods specified in 139.7.10.2.

For improved visibility for calibration, all elements in the signal path (cables, DC blocks, E/O converter, etc.) should have wide and smooth frequency response, and linear phase response, throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be negligible.

139.7.10.2 Stressed receiver conformance test signal characteristics and calibration

The stressed receiver conformance test signal characteristics and calibration methods are as described in 121.8.10.2 with the following exceptions:

- The SECQ of the stressed receiver conformance test signal is measured according to 139.7.5, except that the test fiber is not used. The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 139–6.
- With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_{17.1}OMA$, $RIN_{15.6}OMA$, and $RIN_{15}OMA$ of the SRS test source for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER, respectively, should be no greater than the values specified in Table 139–6.
- An example stressed receiver conformance test setup is shown in Figure 139–7; however, alternative test setups that generate equivalent stress conditions may be used.
- The signaling rate of the test pattern generator and the extinction ratio of the E/O converter are as given in Table 139–6 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER.
- The required values of the “Stressed receiver sensitivity (OMA_{outer}) (max)”, “Stressed eye closure for PAM4 (SECQ)”, and “SECQ – $10\log_{10}(C_{eq})$ (max)” are as given in Table 139–7 for 50GBASE-FR and 50GBASE-LR.

139.7.10.3 Stressed receiver conformance test signal verification

The SECQ of the stressed receiver conformance test signal is measured according to 139.7.5, except that the test fiber is not used. The clock output from the clock source in Figure 139–7 is modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye jitter that includes the sinusoidal

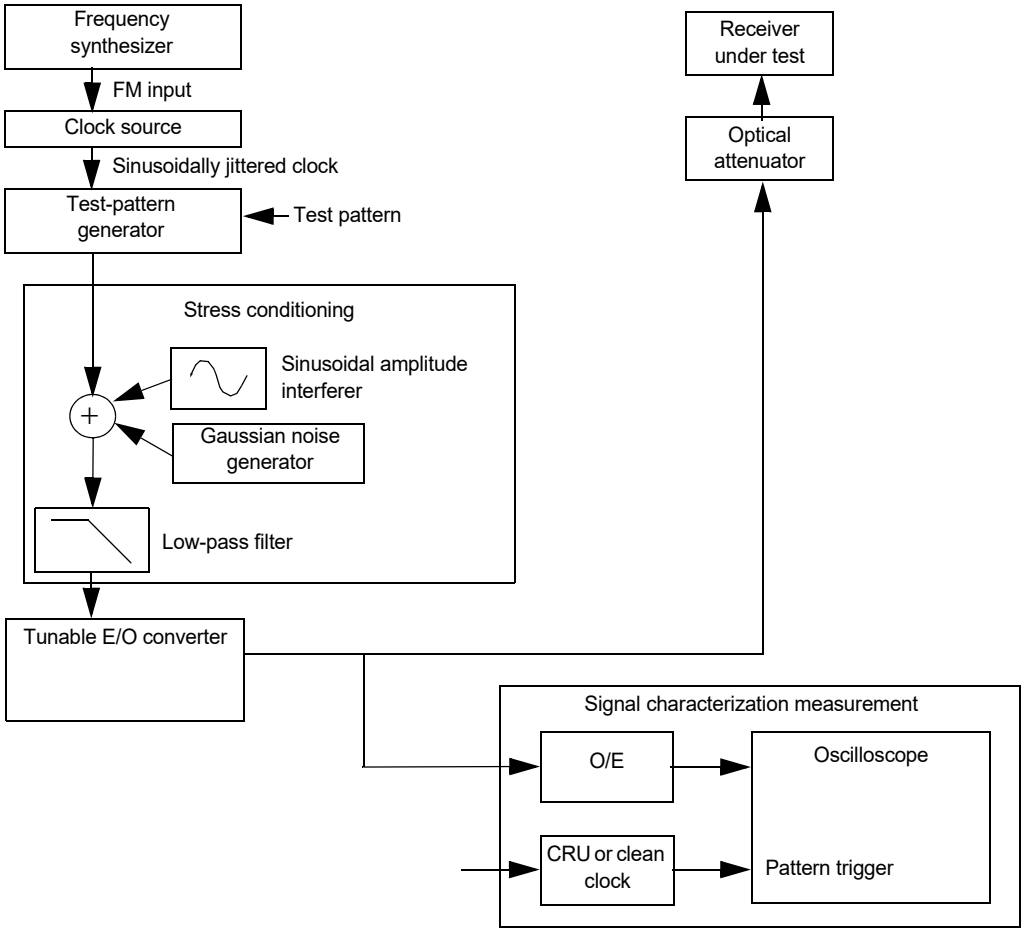

Figure 139–7—Stressed receiver conformance test block diagram

jitter component, a separate clock source (clean clock of Figure 139–7) is required that is synchronized to the source clock, but not modulated with the jitter source.

Care should be taken when characterizing the test signal because excessive noise/jitter in the measurement system would result in an input signal that does not fully stress the receiver under test. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. The noise/jitter introduced by the O/E, filters, and oscilloscope should be negligible or the results should be corrected for its effects. While the details of test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands to ensure that the stressed receiver conformance input signal meets the stress and sinusoidal jitter specified in 139.7.10.2 and 121.8.10.4.

139.8 Safety, installation, environment, and labeling

139.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

139.8.2 Laser safety

50GBASE-FR, 50GBASE-LR, and 50GBASE-ER optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[231]

139.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

139.8.4 Environment

Normative specifications in this clause shall be met by a system integrating a 50GBASE-FR, 50GBASE-LR, or 50GBASE-ER PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

139.8.5 Electromagnetic emission

A system integrating a 50GBASE-FR, 50GBASE-LR, or 50GBASE-ER PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

139.8.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

139.8.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 50GBASE-FR).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 139.8.2.

[231] A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

139.9 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 139–8.

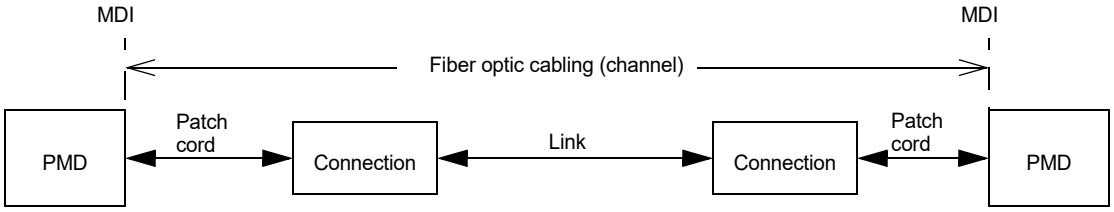

Figure 139–8—Fiber optic cabling model

The channel insertion loss is given in Table 139–12. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 139–12—Fiber optic cabling (channel) characteristics

Description	50GBASE-FR	50GBASE-LR	50GBASE-ER		Unit
Operating distance (max)	2	10	30	40	km
Channel insertion loss[a, b] (max)	4	6.3	18		dB
Channel insertion loss (min)	0	0	10[c]		dB
Positive dispersion[b] (max)	3.2	16	48	64	ps/nm
Negative dispersion[b] (min)	–3.7	–18.6	–56	–74	ps/nm
DGD_max[d]	3	8	10.3		ps
Optical return loss (min)	25	22	19		dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1304.5 nm to 1317.5 nm for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER.
[c] Channel insertion loss (min) may be implemented with an optical attenuator.
[d] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

139.10 Characteristics of the fiber optic cabling (channel)

The 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER fiber optic cabling shall meet the specifications defined in Table 139–12. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

139.10.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion unshifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 139–13 where they differ.

Table 139–13—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.43[a] or 0.5[b]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a]The 0.43 dB/km at 1304.5 nm attenuation for optical fiber cables is derived from Appendix I of ITU-T G.695.
[b]The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3. Using 0.5 dB/km may not support operation 10 km for 50GBASE-LR or 40 km for 50GBASE-ER.

139.10.2 Optical fiber connection

An optical fiber connection, as shown in Figure 139–8, consists of a mated pair of optical connectors.

139.10.2.1 Connection insertion loss

The maximum link distance for 50GBASE-LR and 50GBASE-ER is based on an allocation of 2 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. The maximum link distance for 50GBASE-FR is based on an allocation of 3 dB total connection and splice loss. Connections with different loss characteristics may be used provided the requirements of Table 139–12 are met.

139.10.2.2 Maximum discrete reflectance

The maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 139–14 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

139.10.3 Medium Dependent Interface (MDI) requirements

The 50GBASE-FR, 50GBASE-LR, or 50GBASE-ER PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” (as shown in Figure 139–8). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 139.5.1, not at the MDI.

Table 139–14—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance		
	50GBASE-FR	50GBASE-LR	50GBASE-ER
1	–25 dB	–22 dB	–19 dB
2	–31 dB	–29 dB	–27 dB
4	–35 dB	–33 dB	–32 dB
6	–38 dB	–35 dB	–35 dB
8	–40 dB	–37 dB	–37 dB
10	–41 dB	–39 dB	–39 dB

139.11 Requirements for interoperation between 50GBASE-ER and 50GBASE-FR

The 50GBASE-ER and 50GBASE-FR PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 50GBASE-FR are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 139–15 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 139–15—Channel insertion loss requirements for interoperation between 50GBASE-ER and 50GBASE-FR

Direction	Min loss	Max loss	Unit
50GBASE-ER transmitter to 50GBASE-FR receiver	4.6	8.5	dB
50GBASE-FR transmitter to 50GBASE-ER receiver	6.4	12.2	dB

139.12 Requirements for interoperation between 50GBASE-ER and 50GBASE-LR

The 50GBASE-ER and 50GBASE-LR PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 50GBASE-LR are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 139–16 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 139–16—Channel insertion loss requirements for interoperation between 50GBASE-ER and 50GBASE-LR

Direction	Min loss	Max loss	Unit
50GBASE-ER transmitter to 50GBASE-LR receiver	3.4	11.2	dB
50GBASE-LR transmitter to 50GBASE-ER receiver	7.6	13	dB

139.13 Protocol implementation conformance statement (PICS) proforma for Clause 139, Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER[232]

139.13.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 139, Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

139.13.2 Identification

139.13.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

139.13.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 139, Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[232]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

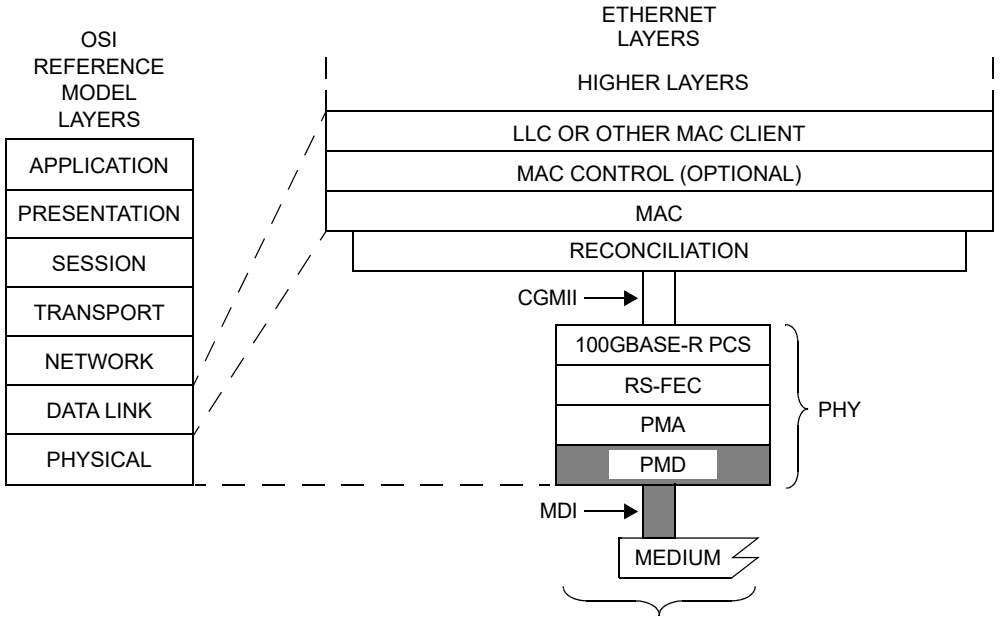
140. Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1

140.1 Overview

This clause specifies the 100GBASE-DR, 100GBASE-FR1, and the 100GBASE-LR1 PMDs together with the single-mode fiber medium. The optical signals generated by these PMD types are modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 140–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 140–1—Physical Layer clauses associated with the 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PMDs



Associated clause	100GBASE-DR, 100GBASE-FR1, 100GBASE-LR1
81—RS	Required
81—CGMII[a]	Optional
82—PCS	Required
83—100GBASE-R PMA	Optional
91—RS-FEC	Required
83A—CAUI-10 C2C	Optional
83B—CAUI-10 C2M	Optional
83D—CAUI-4 C2C	Optional
83E—CAUI-4 C2M	Optional
135—100GBASE-P PMA	Required
135D—100GAUI-4 C2C	Optional
135E—100GAUI-4 C2M	Optional
135F—100GAUI-2 C2C	Optional
135G—100GAUI-2 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.

Figure 140–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 100 Gigabit Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2.

100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

DR = PMD FOR SINGLE-MODE FIBER — 500 m
FR1 = PMD FOR SINGLE-MODE FIBER — 2 km
LR1 = PMD FOR SINGLE-MODE FIBER — 10 km

Figure 140–1—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

140.1.1 Bit error ratio

The bit error ratio (BER) when processed by the PMA (Clause 135) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap when additionally processed by the FEC (Clause 91) and PCS (Clause 82). For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-10} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap.

140.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with a single symbol stream (n = 1).

The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_0.request
PMD:IS_UNITDATA_0.indication
PMD:IS_SIGNAL.indication

In the transmit direction, the PMA continuously sends one stream of PAM4 symbols to the PMD using the PMD:IS_UNITDATA_*i*.request primitive, at a nominal signaling rate of 53.125 GBd. The PMD converts these streams of symbols into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends one stream of PAM4 symbols to the PMA, corresponding to the signals received from the MDI, using the PMD:IS_UNITDATA_*i*.indication primitive, at a nominal signaling rate of 53.125 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable SIGNAL_DETECT parameter as defined in 140.5.4. The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 140.1.1.

140.3 Delay and Skew

140.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD including 2 m of fiber in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

140.3.2 Skew constraints

The Skew (relative delay) between the FEC lanes is kept within limits so that the information on the FEC lanes can be reassembled by the FEC. The Skew Variation is also limited to ensure that a given FEC lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP0 to SP7 shown in Figure 80–9.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 83.5.3.4. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For more information on Skew and Skew Variation, see 80.5. The measurements of Skew and Skew Variation are defined in 89.7.2 with the exception that the measurement clock and data recovery unit high-frequency corner bandwidth is 4 MHz.

140.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 140–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 140–3.

Table 140–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable

Table 140–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

140.5 PMD functional specifications

The 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

140.5.1 PMD block diagram

The PMD block diagram is shown in Figure 140–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 140.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 140.10.3). Unless specified otherwise, all receiver measurements and tests defined in 140.7 are made at TP3.

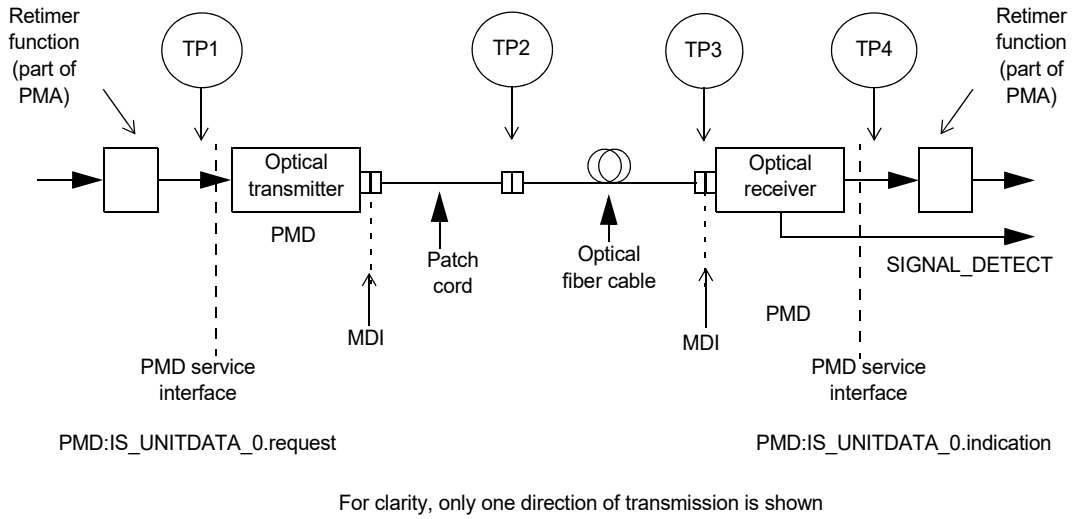

Figure 140–2—Block diagram for 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 transmit/receive paths

140.5.2 PMD transmit function

The PMD Transmit function shall convert the symbol stream requested by the PMD service interface messages PMD:IS_UNITDATA_0.request into an optical signal. The optical signal shall then be delivered to the MDI, according to the transmit optical specifications in this clause. The four optical power levels in the signal in order from lowest to highest shall correspond to tx_symbol values zero, one, two, and three, respectively.

140.5.3 PMD receive function

The PMD receive function shall convert the optical signal received from the MDI into a symbol stream for delivery to the PMD service interface using the message PMD:IS_UNITDATA_0.indication, all according to the receive optical specifications in this clause. The four optical power levels in each signal in order from lowest to highest shall correspond to rx_symbol values zero, one, two, and three, respectively.

140.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 131.3.

SIGNAL_DETECT shall be a global indicator of the presence of the optical signal. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 140–4. The PMD receiver is not required to verify whether a compliant 100GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Table 140–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –15 dBm	FAIL
[(Optical power at TP3 ≥ average receive power (min) Table 140–7) AND (compliant 100GBASE–R signal input)]	OK
All other conditions	Unspecified

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

140.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

140.5.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows the optical transmitter to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of the OFF transmitter in Table 140–6.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

140.5.7 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

140.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

140.5.9 PMD receive fault function (optional)

If the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

140.6 PMD to MDI optical specifications for 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1

The operating ranges for the 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PMDs are defined in Table 140–5. A 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 140–14. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 100GBASE-DR PMD operating at 600 m meets the operating range requirement of 2 m to 500 m).

The 100GBASE-FR1 PMD interoperates with the 100GBASE-DR PMD provided that the channel and power guidelines in 140.11.1 are met.

The 100GBASE-LR1 PMD interoperates with the 100GBASE-DR PMD provided that the channel guidelines in 140.11.2 are met.

The 100GBASE-LR1 PMD interoperates with the 100GBASE-FR1 PMD provided that the channel guidelines in 140.11.3 are met.

Table 140–5—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 operating ranges

PMD type	Required operating range
100GBASE-DR	2 m to 500 m
100GBASE-FR1	2 m to 2 km
100GBASE-LR1	2 m to 10 km

140.6.1 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 transmitter optical specifications

The 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 transmitter shall meet the specifications defined in Table 140–6 per the definitions in 140.7.

Table 140–6—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 transmit characteristics

Description	100GBASE-DR	100GBASE-FR1	100GBASE-LR1	Unit
Signaling rate (range)	53.125 ± 100 ppm			GBd
Modulation format	PAM4			—
Wavelength (range)	1304.5 to 1317.5			nm
Side-mode suppression ratio (SMSR), (min)	30			dB
Average launch power (max)	4	4	4.8	dBm
Average launch power[a] (min)	–2.9	–3.1	–1.9	dBm
Outer Optical Modulation Amplitude (OMA_{outer}) (max)	4.2	4.2	5	dBm

Table 140–6—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 transmit characteristics *(continued)*

Description	100GBASE-DR	100GBASE-FR1	100GBASE-LR1	Unit
Outer Optical Modulation Amplitude (OMA_{outer}) (min)[b]	–0.8	—	—	dBm
for TDECQ < 1.4 dB	—	–0.1	1.1	dBm
for 1.4 dB ≤ TDECQ ≤ 3.4 dB	—	–1.5 + TDECQ	–0.3 + TDECQ	dBm
Launch power in OMA_{outer} minus TDECQ (min):				
for extinction ratio ≥ 5 dB	–2.2	—	—	dBm
for extinction ratio < 5 dB	–1.9	—	—	dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ) (max)	3.4	3.4	3.4	dB
TDECQ – $10\log_{10}(C_{eq})$[c] (max)	3.4	—	—	dB
Transmitter eye closure for PAM4 (TECQ) (max)	—	3.4	3.4	dB
| TDECQ – TECQ | (max)	—	2.5	2.5	dB
Over/under-shoot (max)	—	22	22	%
Transmitter power excursion (max)	—	2	2.8	dBm
Extinction ratio (min)	3.5	3.5	3.5	dB
Transmitter transition time (max)	17	17	17	ps
Average launch power of OFF transmitter (max)	–15	–15	–15	dBm
RIN_xOMA (max), where *x* is the optical return loss tolerance (max)	–136	–136	–136	dB/Hz
Optical return loss tolerance (max)	15.5	17.1	15.6	dB
Transmitter reflectance[d] (max)	–26	–26	–26	dB

[a] Average launch power (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] For 100GBASE-DR, the requirement on the OMA_{outer} (min) applies even in the cases where TDECQ < 1.4 dB for an extinction ratio of ≥ 5 dB or where TDECQ < 1.1 dB for an extinction ratio of < 5 dB.
[c] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d] Transmitter reflectance is defined looking into the transmitter.

The values for OMA_{outer} (min) in Table 140–6 vary with TDECQ. Figure 140–3 illustrates this for 100GBASE-FR1 and 100GBASE-LR1, along with the values for OMA_{outer} (max).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

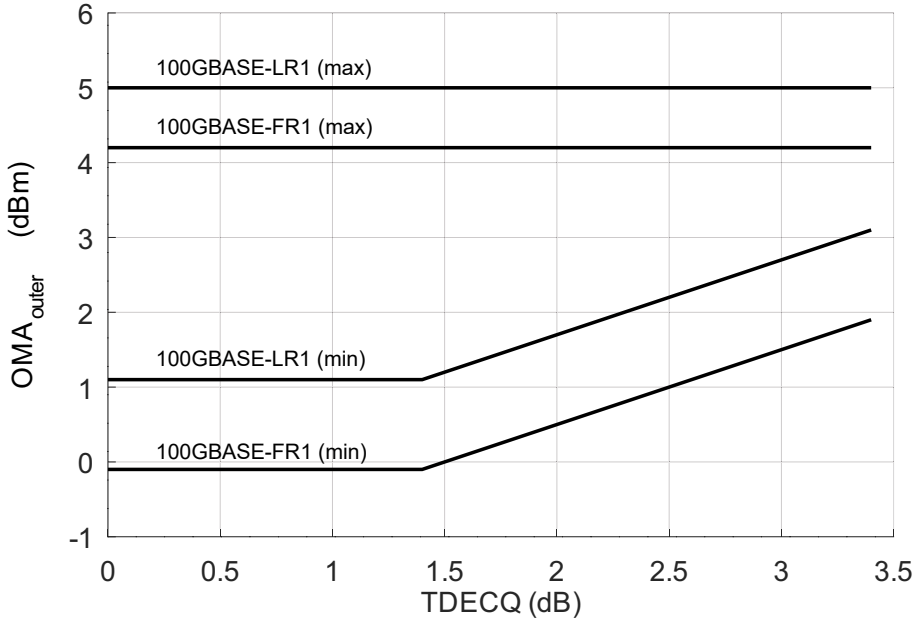

Figure 140–3—OMAouter (max) and OMAouter (min) versus TDECQ for 100GBASE-FR1 and 100GBASE-LR1

140.6.2 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 receive optical specifications

The 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 receiver shall meet the specifications defined in Table 140–7 per the definitions in 140.7.

Table 140–7—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 receive characteristics

Description	100GBASE-DR	100GBASE-FR1	100GBASE-LR1	Unit
Signaling rate (range)	53.125 ± 100 ppm			GBd
Modulation format	PAM4			—
Wavelengths (range)	1304.5 to 1317.5			nm
Damage threshold[a]	5	5	5.8	dBm
Average receive power (max)	4	4	4.8	dBm
Average receive power[b] (min)	–5.9	–7.1	–8.2	dBm
Receive power (OMA_{outer}) (max)	4.2	4.2	5	dBm
Receiver reflectance (max)	–26	–26	–26	dB
Receiver sensitivity (OMA_{outer}) (max) for TECQ < 1.4 dB for 1.4 dB ≤ TECQ ≤ 3.4 dB	Equation (140–1)[c] — —	— –4.5 –5.9 + TECQ	— –6.1 –7.5 + TECQ	dBm dBm dBm

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 140–7—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 receive characteristics *(continued)*

Description	100GBASE-DR	100GBASE-FR1	100GBASE-LR1	Unit
Stressed receiver sensitivity (OMA_{outer})[d] (max)	–1.9	–2.5	–4.1	dBm
Conditions of stressed receiver sensitivity test:[e]				
Stressed eye closure for PAM4 (SECQ)	3.4	3.4	3.4	dB
SECQ – $10\log_{10}(C_{eq})$[f] (max)	3.4	—	—	dB

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level. The receiver does not have to operate correctly at this input power.
[b] Average receive power (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity (OMA_{outer}) (max) for 100GBASE-DR is optional and is defined for a transmitter with a value of SECQ up to 3.4 dB.
[d] Measured with conformance test signal at TP3 (see 140.7.13) for the BER specified in 140.1.1.
[e] These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.
[f] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.

The values for receiver sensitivity (OMAouter) (max) in Table 140–7 vary depending on the value of TECQ of the test source used for measurement. Figure 140–4 illustrates this for 100GBASE-FR1 and 100GBASE-LR1.

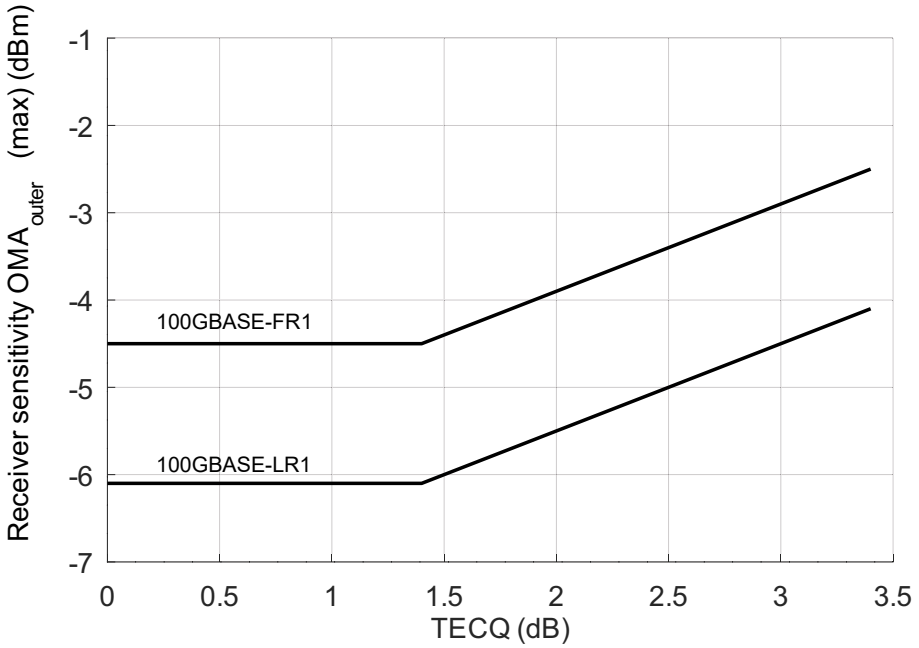

Figure 140–4—Receiver sensitivity (OMA_{outer}) (max) for 100GBASE-FR1 and 100GBASE-LR1

140.6.3 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 illustrative link power budgets

Illustrative power budgets and penalties for 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 channels are shown in Table 140–8.

Table 140–8—100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 illustrative link power budgets

Parameter	100GBASE-DR	100GBASE-FR1	100GBASE-LR1	Unit
Power budget (for max TDECQ): for extinction ratio ≥ 5 dB for extinction ratio < 5 dB	— 6.5 6.8	7.8 — —	10.6 — —	dB dB dB
Operating distance	500	2 000	10 000	m
Channel insertion loss	See 140.9[a]	4[a]	6.3[b]	dB
Maximum discrete reflectance	–35	–35[c, d]	–35[c, e]	dB
Allocation for penalties[f] (for max TDECQ): for extinction ratio ≥ 5 dB for extinction ratio < 5 dB	— 6.5 minus max channel insertion loss per Table 140–13 6.8 minus max channel insertion loss per Table 140–13	3.8 — —	4.3 — —	dB dB dB
Additional insertion loss allowed	0	0	0	dB

[a] The channel insertion losses for 100GBASE-DR and 100GBASE-FR1 are calculated using the maximum distances specified in Table 140–5 and cabled optical fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 140.10.2.1.
[b] The channel insertion loss for 100GBASE-LR1 is calculated using the maximum distance specified in Table 140–5 and fiber attenuation of 0.43 dB/km plus an allocation for connection and splice loss given in 140.10.2.1.
[c] See 140.10.2.2 for details and specifications as a function of the number of discrete reflectances within the channel.
[d] Maximum value for each discrete reflectance with 4 discrete reflectances above –55 dB within the channel.
[e] Maximum value for each discrete reflectance with 6 discrete reflectances above –55 dB within the channel.
[f] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

The values of transmitter OMA_{outer} (max), transmitter OMA_{outer} (min) versus TDECQ, and receiver sensitivity (OMA_{outer}) (max) versus TECQ are illustrated in Figure 140–5 for 100GBASE-FR1 and in Figure 140–6 for 100GBASE-LR1.

140.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

140.7.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 140–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 140–10 may be used to perform that test. The test patterns used in this clause are shown in Table 140–9.

Table 140–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle encoded by RS-FEC	82.2.11, 91
6	SSPRQ	120.5.11.2.3

Table 140–10—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 100GBASE-R signal	140.7.2
Side-mode suppression ratio	3, 5, 6 or valid 100GBASE-R signal	140.7.2
Average optical power	3, 5, 6 or valid 100GBASE-R signal	140.7.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	140.7.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	140.7.5
Transmitter eye closure for PAM4 (TECQ)	6	140.7.6
Over/under-shoot	6	140.7.7
Transmitter power excursion	6	140.7.8
Extinction ratio	4 or 6	140.7.9
Transmitter transition time	Square wave or 6	140.7.10
$RIN_x OMA$	Square wave	140.7.11
Receiver sensitivity	3 or 5	140.7.12
Stressed receiver conformance test signal calibration	6	140.7.13
Stressed receiver sensitivity	3 or 5	140.7.13

140.7.2 Wavelength and side-mode suppression ratio (SMSR)

The wavelength and SMSR shall be within the range given in Table 140–6 if measured per IEC 61280-1-3. The transmitter is modulated using the test pattern defined in Table 140–10.

140.7.3 Average optical power

The average optical power shall be within the limits given in Table 140–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern defined in Table 140–10, per the test setup in Figure 53–6.

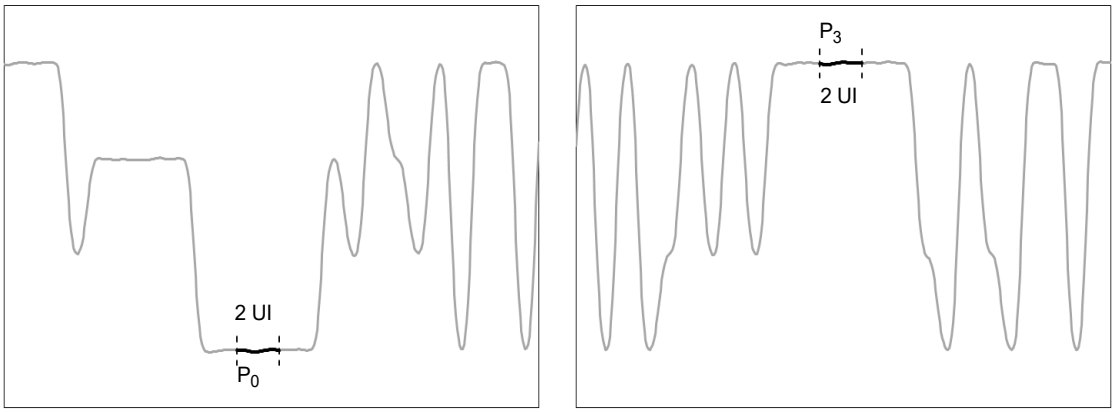

Figure 140–7—Example power levels P_0 and P_3 from PRBS13Q test pattern

140.7.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} shall be within the limits given in Table 140–6. The OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 140–10 as the difference between the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 140–7.

140.7.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

TDECQ, and for 100GBASE-DR only, TDECQ – $10\log_{10}(C_{eq})$ shall be within the limits given in Table 140–6 if measured using the test setup specified in 121.8.5.1, with an optical channel specified in 140.7.5.2, using the measurement method specified in 121.8.5.3, and using a reference equalizer as described in 140.7.5.1, with the following exceptions:

- The signaling rate of the test pattern generator is as given in Table 140–6 and uses a test pattern specified for TDECQ in Table 140–10.
- There are no interfering optical lanes and therefore the delay requirement of at least 31 UI between test pattern on one lane and any other lane, as specified in 121.8.5.1, is redundant.
- The combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 26.5625 GHz with a fourth-order Bessel-Thomson response to at least 1.3 × 53.125 GHz and at frequencies above 1.3 × 53.125 GHz the response should not exceed –20 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.
- The normalized noise power density spectrum, $N(f)$ in Equation (121–9), is equivalent to white noise filtered by a fourth-order Bessel-Thomson response filter with a 3 dB bandwidth of 26.5625 GHz.

140.7.5.1 TDECQ reference equalizer

The reference equalizer is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 140–8. The sum of the equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3 has the largest magnitude tap coefficient, which is constrained to be at least 0.8.

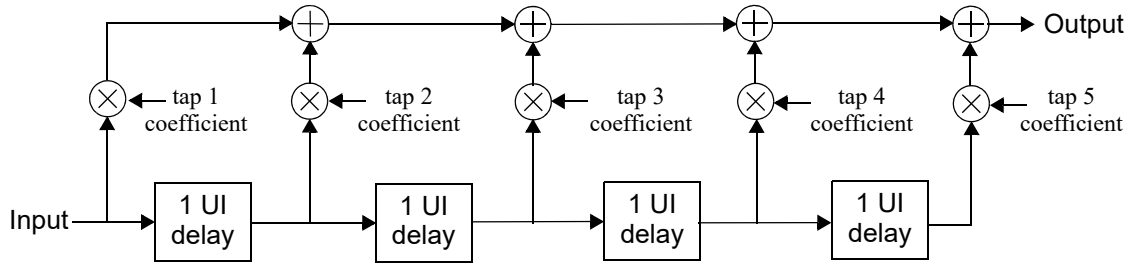

Figure 140–8—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver implementation.

140.7.5.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements in Table 140–11.

Table 140–11—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
100GBASE-DR	$0.011625\times\lambda\times[1-(1324 / \lambda)^4]$	$0.011625\times\lambda\times[1-(1300 / \lambda)^4]$	Minimum	15.5 dB	0.5 ps
100GBASE-FR1	$0.046\times\lambda\times[1-(1324 / \lambda)^4]$	$0.046\times\lambda\times[1-(1300 / \lambda)^4]$	Minimum	17.1 dB	0.8 ps
100GBASE-LR1	$0.230\times\lambda\times[1-(1324 / \lambda)^4]$	$0.230\times\lambda\times[1-(1300 / \lambda)^4]$	Minimum	15.6 dB	0.8 ps

[a] The dispersion is measured for the wavelength of the transmitter under test (λ in nm). The coefficient assumes 500 m for 100GBASE-DR, 2 km for 100GBASE-FR1, and 10 km for 100GBASE-LR1.
[b] There is no intent to stress the sensitivity of the O/E converter associated with the oscilloscope.
[c] The optical return loss is applied at TP2.

A 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 140–11 for the wavelength of the transmitter under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 140–11. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 140–11.

140.7.6 Transmitter eye closure for PAM4 (TECQ)

The transmitter eye closure for PAM4 (TECQ) is a measure of the optical transmitter's eye closure at TP2. TECQ shall be within the limits given in Table 140–6 for 100GBASE-FR1 and 100GBASE-LR1 if measured using a test pattern specified for TECQ in Table 140–10. TECQ is measured using the methods specified for TDECQ in 140.7.5, except that the test fiber is not used.

140.7.7 Over/under-shoot

The over/under-shoot shall be within the limits given in Table 140–6 for 100GBASE-FR1 and 100GBASE-LR1 if measured using a test pattern specified for over/under-shoot in Table 140–10.

Over/under-shoot is measured using the waveforms captured for the TDECQ test (see 140.7.5) and the waveform captured for the TECQ test (see 140.7.6), but without the reference equalizer being applied in either case.

Overshoot is defined as the maximum power above the level three power and relative to the OMA_{outer} according to:

$$\text{Overshoot} = (P_{max} - P_3) / (OMA_{outer}) \times 100$$

Undershoot is defined as the minimum power from the transmitter (P_{min}) below the level zero power and relative to the OMA_{outer} according to:

$$\text{Undershoot} = (P_0 - P_{min}) / (OMA_{outer}) \times 100$$

where

P_{max}	is based on a 10^{-2} hit ratio, where P_{max} is the smallest power level that results in the number of samples above that level not exceeding the product of hit ratio and total number of observed samples, with all samples acquired in a single unit interval eye diagram.
P_{min}	is based on a 10^{-2} hit ratio, where P_{min} is the largest power level that results in the number of samples below that level not exceeding the product of hit ratio and total number of observed samples, with all samples acquired in a single unit interval eye diagram.
P_3	is the power of the PAM4 level three defined in 122.8.4.
P_0	is the power of the PAM4 level zero defined in 122.8.4.
OMA_{outer}	is the outer optical modulation amplitude defined in 122.8.4.

140.7.8 Transmitter power excursion

The transmitter power excursion shall be within the limits given in Table 140–6 for 100GBASE-FR1 and 100GBASE-LR1 if measured using a test pattern specified for transmitter power excursion in Table 140–10.

Transmitter power excursion is measured using the waveforms captured for the TECQ test (see 140.7.6), but without the reference equalizer being applied. Transmitter power excursion is defined as:

$$\text{Transmitter power excursion} = \max (P_{max} - P_{average} , P_{average} - P_{min})$$

where

P_{max} and P_{min}	are defined in 140.7.7
$P_{average}$	is the average optical power defined in 140.7.3

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

140.7.9 Extinction ratio

The extinction ratio shall be within the limits given in Table 140–6 if measured using a test pattern specified for extinction ratio in Table 140–10. The extinction ratio of a PAM4 optical signal is defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 140–7.

140.7.10 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 140–6 if measured using a test pattern specified for transmitter transition time in Table 140–10.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with a combined 3 dB bandwidth of approximately 26.5625 GHz with a fourth-order Bessel-Thomson response to at least 1.3 × 53.125 GHz and at frequencies above 1.3 × 53.125 GHz the response should not exceed –20 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 140.7.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence and the falling edge is that within the 33333000000 symbol sequence.

140.7.11 Relative intensity noise ($RIN_x OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is *x* dB, where *x* is the optical return loss tolerance (max) in Table 140–6.

b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 53.2 GHz).

140.7.12 Receiver sensitivity

140.7.12.1 Receiver sensitivity for 100GBASE-DR

The receiver sensitivity for 100GBASE-DR is optional and is defined for a transmitter with a value of SECQ up to 3.4 dB. Receiver sensitivity for 100GBASE-DR should meet Equation (140–1), which is illustrated in Figure 140–9. The normative requirement for the 100GBASE-DR receiver is stressed receiver sensitivity.

$$RS = \max(-3.9, SECQ - 5.3) \quad \text{(dBm)} \tag{140–1}$$

where

RS	is the receiver sensitivity
SECQ	is the SECQ of the transmitter used to measure the receiver sensitivity

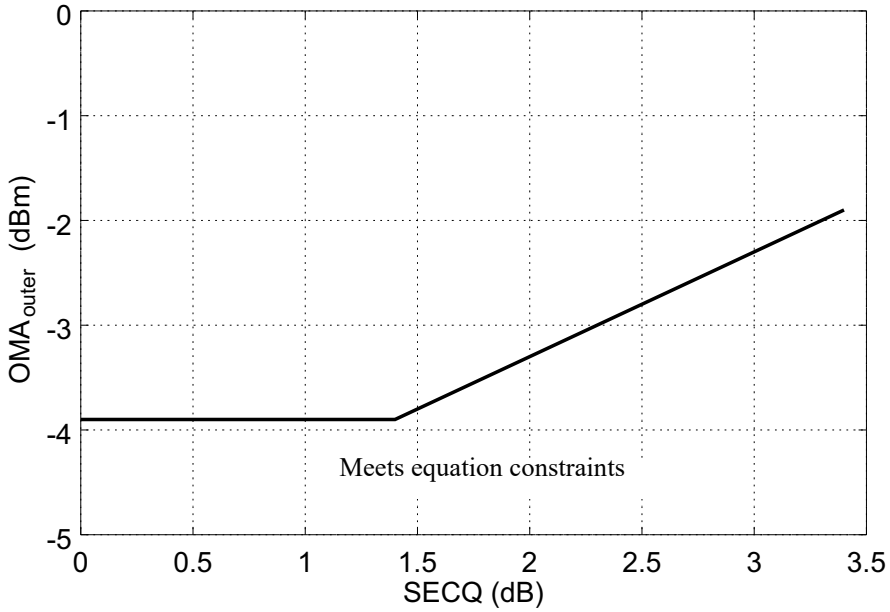

Figure 140–9—Illustration of receiver sensitivity

140.7.12.2 Receiver sensitivity for 100GBASE-FR1 and 100GBASE-LR1

The receiver sensitivity (OMA_{outer}) for 100GBASE-FR1 and 100GBASE-LR1 shall be within the limits given in Table 140–7 if measured using a test pattern for receiver sensitivity in Table 140–10.

The conformance test signal at TP3 meets the requirements for a 100GBASE-FR1 or 100GBASE-LR1 transmitter followed by an attenuator.

The TECQ of the conformance test signal is measured according to 140.7.5, except that the test fiber is not used. The measured value of TECQ is then used to calculate the limit for receiver sensitivity (OMA_{outer}) as specified in Table 140–7.

140.7.13 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 140–7 if measured using the method defined in 121.8.10, using the test pattern specified for SRS in Table 140–10, with the following exceptions:

— The SECQ of the stressed receiver conformance test signal is measured according to 140.7.5, except that the test fiber is not used. The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 140–6.

— With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the RIN_xOMA of the SRS test source (where x is the value for optical return loss tolerance from Table 140–6) should be no greater than the value specified in Table 140–6.

— An example stressed receiver conformance test setup is shown in Figure 139–7; however, alternative test setups that generate equivalent stress conditions may be used.

— The signaling rate of the test pattern generator and the extinction ratio of the E/O converter are as given in Table 140–6 using test patterns specified in Table 140–10.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— For 100GBASE-FR1 and 100GBASE-LR1 the values of over/under-shoot and transmitter power excursion of the stressed receiver conformance test signal are within the limits specified in Table 140–6.

— The required values of the "Stressed receiver sensitivity (OMA_{outer}) (max)", "Stressed eye closure for PAM4 (SECQ)", and for 100GBASE-DR only, "SECQ – $10\log_{10}(C_{eq})$ (max)" are as given in Table 140–7.

140.8 Safety, installation, environment, and labeling

140.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

140.8.2 Laser safety

100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[233]

140.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

140.8.4 Environment

Normative specifications in this clause shall be met by a system integrating a 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

140.8.5 Electromagnetic emission

A system integrating a 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

[233]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

140.8.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

140.8.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 100GBASE-DR).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 140.8.2.

140.9 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 140–10.

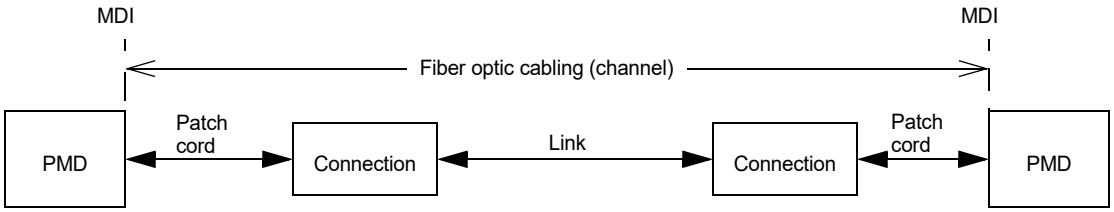

Figure 140–10—Fiber optic cabling model

The channel insertion loss is given in Table 140–12. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. The maximum value of channel insertion loss is dependent on the number and maximum value of the discrete reflectances within the channel as given in Table 140–13. Discrete reflectances below –55 dB may be ignored when determining the supported channel insertion loss. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 140–12—Fiber optic cabling (channel) characteristics

Description	100GBASE-DR	100GBASE-FR1	100GBASE-LR1	Unit
Operating distance (max)	500	2 000	10 000	m
Channel insertion loss[a, b] (max)	See Table 140–13	4	6.3	dB
Channel insertion loss (min)	0	0	0	dB
Positive dispersion[b] (max)	0.8	3.2	16	ps/nm
Negative dispersion[b] (min)	–0.93	–3.7	–18.6	ps/nm
DGD_max[c]	2.24	2.3	5	ps
Optical return loss (min)	27	25	22	dB

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1304.5 nm to 1317.5 nm
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

Table 140–13—100GBASE-DR maximum channel insertion loss versus number of discrete reflectances

Maximum channel insertion loss (dB)		Number of discrete reflectances > –55 dB and ≤ –45 dB								
		0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**
Number of discrete reflectances > –45 dB and ≤ –35 dB	**0**	3	3	3	3	3	3	3	3	3
	1	3	3	3	3	3	3	3	3	3
	2	3	3	3	2.9	2.9	2.9	2.9	2.9	2.9
	3	2.9	2.9	2.9	2.9	2.9	2.8	2.8	2.8	—[a]
	4	2.8	2.8	2.8	2.8	2.7	2.7	2.7	—[a]	—[a]
	5	2.8	2.8	2.7	2.7	2.7	2.6	—[a]	—[a]	—[a]
	6	2.6	2.6	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]

[a]The indicated combination of reflectances does not provide a supported maximum channel insertion loss.

140.10 Characteristics of the fiber optic cabling (channel)

The 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 fiber optic cabling shall meet the specifications defined in Table 140–14. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

140.10.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion unshifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 140–14 where they differ.

Table 140–14—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.43[a] or 0.5[b]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a] The 0.43 dB/km at 1304.5 nm attenuation for optical fiber cables is derived from Appendix I of ITU-T G.695.
[b]The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3. Using 0.5 dB/km may not support operation over 10 km for 100GBASE-LR1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

140.10.2 Optical fiber connection

An optical fiber connection, as shown in Figure 140–10, consists of a mated pair of optical connectors.

140.10.2.1 Connection insertion loss

For 100GBASE-DR, the maximum link distance is based on an allocation of 2.75 dB total connection and splice loss. For example, this allocation supports five connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 140–12 are met.

For 100GBASE-FR1, the maximum link distance is based on an allocation of 3 dB total connection and splice loss. For example, this allocation supports six connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 140–12 are met.

For 100GBASE-LR1, the maximum link distance is based on an allocation of 2 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 140–12 are met.

140.10.2.2 Maximum discrete reflectance

For 100GBASE-DR, the maximum discrete reflectance shall be less or equal than –35 dB. The number of maximum discrete reflectances in the ranges, > –45 dB and ≤ –35 dB, and, > –55 dB and ≤ –45 dB, is limited to the numbers given in Table 140–13 in relation to the maximum channel insertion loss.

For 100GBASE-FR1 and 100GBASE-LR1, the maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 140–15 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

Table 140–15—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance		Unit
	100GBASE-FR1	100GBASE-LR1	
1	–25	–22	dB
2	–31	–29	dB
4	–35	–33	dB
6	–38	–35	dB
8	–40	–37	dB
10	–41	–39	dB

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

140.10.3 Medium Dependent Interface (MDI)

The 100GBASE-DR, 100GBASE-FR1, or 100GBASE-LR1 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 140–10). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

For 100GBASE-DR, when the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2. For 100GBASE-FR1 and 100GBASE-LR1, when the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 140.5.1, not at the MDI.

140.11 Interoperation between 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1

The 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1 PMDs can interoperate with each other as described here.

140.11.1 Interoperation between 100GBASE-FR1 and 100GBASE-DR

The 100GBASE-FR1 and 100GBASE-DR PMDs can interoperate with each other provided that the fiber optic cabling (channel) characteristics for 100GBASE-DR (see 140.10 and Table 140–13) are met and the 100GBASE-FR1 transmitter average power is greater than or equal to the value for average launch power (min) for 100GBASE-DR in Table 140–6.

140.11.2 Interoperation between 100GBASE-LR1 and 100GBASE-DR

The 100GBASE-LR1 and 100GBASE-DR PMDs can interoperate with each other provided that the fiber optic cabling (channel) characteristics for 100GBASE-DR (see 140.10 and Table 140–13) are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 140–16 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 140–16—Channel insertion loss for interoperation between 100GBASE-LR1 and 100GBASE-DR

Direction	Min loss	Max loss	Unit
100GBASE-LR1 transmitter to 100GBASE-DR receiver	0.8	4	dB
100GBASE-DR transmitter to 100GBASE-LR1 receiver	0	5.2	dB

140.11.3 Interoperation between 100GBASE-LR1 and 100GBASE-FR1

The 100GBASE-LR1 and 100GBASE-FR1 PMDs can interoperate with each other provided that the fiber optic cabling (channel) characteristics for 100GBASE-FR1 (see 140.10) are met, with the exception of the

Copyright © 2022 IEEE. All rights reserved.

140.12 Protocol implementation conformance statement (PICS) proforma for Clause 140, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1, 100GBASE-FR1, and 100GBASE-LR1[234]

140.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 140, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1, 100GBASE-FR1, and 100GBASE-LR1, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

140.12.2 Identification

140.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

140.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 140, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1, 100GBASE-FR1, and 100GBASE-LR1
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

141. Physical Medium Dependent (PMD) sublayer and medium for Nx25G-EPON passive optical networks

141.1 Overview

This clause describes the Physical Medium Dependent (PMD) sublayer for Nx25G Ethernet passive optical networks (Nx25G-EPON) operating at a MAC data rate of 25 Gb/s or 50 Gb/s in the downstream direction and a MAC data rate of 10 Gb/s, 25 Gb/s, or 50 Gb/s in the upstream direction. These PMDs are collectively referred to by the term Nx25G-EPON. All Nx25G-EPON PMDs supporting the downstream MAC data rate of 50 Gb/s are collectively referred to as 50G-EPON PMDs while Nx25G-EPON PMDs supporting the downstream MAC data rate of 25 Gb/s are collectively referred to as 25G-EPON PMDs.

141.1.1 Terminology

Nx25G-EPON operates over a point-to-multipoint (P2MP) topology, also called a tree or trunk-and-branch topology. The device connected at the root of the tree is called an optical line terminal (OLT) and the devices connected as the leaves are referred to as optical network units (ONUs). The direction of transmission from the OLT to ONUs is referred to as the downstream direction, while the direction of transmission from the ONU to the OLT is referred to as the upstream direction.

141.1.2 Positioning of the PMD sublayer within the IEEE 802.3 architecture

Figure 141–1 depicts the relationships of Nx25G-EPON PMD sublayers (shown hatched) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

141.1.3 PHY link types

Characteristics of Nx25G-EPON PHY link types are summarized in Table 141–1 through Table 141–5. The indicated characteristics of PHY link types are the results of specific pairings of an OLT PMD and an ONU PMD. The supported PMD pairs are specified in Table 141–8 and Table 141–9. Nx25G-EPON PHY link types supporting 50 Gb/s use wavelength division multiplexing on two wavelengths and hence two wavelengths are listed for these links in Table 141–1 through Table 141–5.

Table 141–1—PHY links supporting 25 Gb/s downstream and 10 Gb/s upstream

Description	25/10-PQ20G	25/10-PQ20X	25/10-PQ30G	25/10-PQ30X	Units
Number of fibers	1				—
Nominal downstream line rate	25.78125				GBd

141.2 PMD nomenclature

141.2.1 Introduction

Nx25G-EPON PMDs are classified based on transmit and receive rate, coexistence type, transmission direction, and power level.

141.2.2 PMD rate classes

Nx25G-EPON PMDs defined in this clause fall into several rate classes depending on the upstream and downstream aggregate rate supported. Possible downstream rates are either 25 Gb/s or 50 Gb/s. Possible upstream rates are 10 Gb/s, 25 Gb/s, or 50 Gb/s. The rate(s) at which a PMD operates is indicated in the PMD name.

141.2.3 PMD coexistence classes

Nx25G-EPON PMDs defined in this clause support WDM coexistence with 10G-EPON or GPON. PMDs coexisting with 10G-EPON are denoted with the letter X in the PMD name while PMDs coexisting with GPON are denoted with the letter G.

141.2.4 PMD transmission direction classes

Nx25G-EPON PMDs defined in this clause are defined for either the OLT and face the downstream direction or for the ONU and face the upstream direction. OLT PMDs are denoted with the letter D in the PMD name while ONU PMDs are denoted with the letter U.

141.2.5 PMD power classes

Nx25G-EPON PMDs defined in this clause are defined as being in one of two power classes (a power class is a differentiator for PMD specifications based of their launch powers and sensitivities); the medium or the high power budget class:

— The medium PMD power class supports a P2MP media channel insertion loss of ≤ 24 dB e.g., a PON with a split ratio of 1:16 and the distance of 20 km or a PON with a split ratio of 1:32 and the distance of 10 km.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— The high PMD power class supports a P2MP media channel insertion loss of ≤ 29 dB e.g., a PON with a split ratio of 1:32 and the distance of 20 km.

The medium PMD power class is indicated in the PMD name with the numeral 2 while the high PMD power class is indicated with the numeral 3.

141.2.6 PMD naming

Nx25G-EPON PMD naming conforms to Table 141–6.

Table 141–6—PMD naming

Naming template	r_1/r_2GBASE-PQc-db	
Naming element	**Description**	**Allowed values**
r_1	PMD downstream rate class (see 141.2.2)	25, 50
r_2[a]	PMD upstream rate class (see 141.2.2)	10, 25, 50
G	PMDs operate at Gb/s rates	
BASE		
P	PMD for PON (P2MP media)	
Q	256B/257B line code	
c	Coexistence class (see 141.2.3)	G, X
d	Transmission direction class (see 141.2.4)	D, U
b	Power class (see 141.2.5)	2, 3

[a]If r_1 is equal to r_2 (i.e., symmetric-data rate PMDs), r_2 is omitted.

141.2.7 Supported combinations of OLT and ONU PMDs

The PHY link power budget (a power budget is a characteristic of a link type and depends on the paired PMDs' transmitter launch powers and receiver sensitivities) is determined by the PMDs located at the ends of the physical media. This subclause describes how OLT (D type) and ONU (U type) PMDs may be combined to achieve the power budgets listed in Table 141–1 through Table 141–5. Table 141–7 shows the list of all supported PMD types. Connection between G and X coexistence type PMDs is not supported, e.g., 25/10GBASE-PQG-D2 OLT PMD is not interoperable with 25/10GBASE-PQX-U2 due to non-overlapping OLT receiver sensitivity window and ONU transmitter wavelength range.

Table 141–7—List of supported PMD types

Upstream/ Downstream MAC data rate	**Downstream wavelengths[a]**	**Upstream wavelengths[b]**	**OLT PMDs**	**ONU PMDs**
25G/10G	DW0	UW0	25/10GBASE-PQG-D2 25/10GBASE-PQG-D3	25/10GBASE-PQG-U2 25/10GBASE-PQG-U3
	DW0	UW1	25/10GBASE-PQX-D2 25/10GBASE-PQX-D3	25/10GBASE-PQX-U2 25/10GBASE-PQX-U3
25G/25G	DW0	UW0	25GBASE-PQG-D2 25GBASE-PQG-D3	25GBASE-PQG-U2 25GBASE-PQG-U3

[a](*) - On an ODN, OLT and ONU PMDs support the same coexistence mode, either X or G.

141.3 PMD functional specifications

The Nx25G-EPON PMDs perform the transmit and receive functions that convey data between the PMD service interface and the MDI.

141.3.1 PMD service interface

The following specifies the services provided by Nx25G-EPON PMDs. These PMD sublayer service interfaces are described in an abstract manner and do not imply any particular implementation.

The PMD service interface supports the exchange of a continuous stream of bits between the PMA[*i*] and PMD entities. The PMD translates the serialized data received from the compatible PMA to and from signals suitable for the specified medium. The following primitives are defined:

— PMD_UNITDATA[*i*].request
— PMD_UNITDATA[*i*].indication
— PMD_SIGNAL[*i*].request
— PMD_SIGNAL[*i*].indication

where "[*i*]" represents the PMA Channel: 0 or 1.

141.3.1.1 Channel-to-wavelength mapping

An Nx25G-EPON PMD provides multiple instances of the PMD service interface that connect to multiple PMA channels (see 142.4.1). Within the PMD sublayer, each instance of the PMD service interface maps to a specific pair of wavelengths. This mapping is different for the two coexistence classes, and shall be as defined in Table 141–10 for the OLT and in Table 141–11 for the ONU.

Table 141–10—OLT Channel-to-wavelength mapping

PMA channel	PMD service primitives	Wavelength (coexistence class G)	Wavelength (coexistence class X)
0	PMD_UNITDATA[0].request PMD_SIGNAL[0].request	DW0	DW0
	PMD_UNITDATA[0].indication PMD_SIGNAL[0].indication	UW0	UW1
1	PMD_UNITDATA[1].request PMD_SIGNAL[1].request	DW1	DW1
	PMD_UNITDATA[1].indication PMD_SIGNAL[1].indication	UW1	UW2

Table 141–11—ONU Channel-to-wavelength mapping

PMA channel	PMD service primitives	Wavelength (coexistence class G)	Wavelength (coexistence class X)
0	PMD_UNITDATA[0].request PMD_SIGNAL[0].request	UW0	UW1
	PMD_UNITDATA[0].indication PMD_SIGNAL[0].indication	DW0	DW0
1	PMD_UNITDATA[1].request PMD_SIGNAL[1].request	UW1	UW2
	PMD_UNITDATA[1].indication PMD_SIGNAL[1].indication	DW1	DW1

141.3.1.2 Delay constraints

The Nx25G-EPON PMD delay variation within the PMD shall be less than 0.25 EQT (see 1.4.313).

141.3.1.3 PMD_UNITDATA[*i*].request

This primitive defines the transfer of a serial data stream from the PMA defined in 142.4 to the PMD.

The semantics of the service primitive are PMD_UNITDATA[*i*].request(tx_bit) (where $i = 0$ or 1). The data conveyed by PMD_UNITDATA[*i*].request is a continuous stream of bits. The tx_bit parameter can take one of two values: ONE or ZERO. The PMA defined in 142.4 continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal signaling rate of 25.78125 GBd in the case of Nx25G-EPON OLT and ONU PMDs. The PMA defined in 142.4 continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal signaling rate of 10.3125 GBd in the case of 25/10G-EPON and 50/10G–EPON ONU PMDs. Upon the receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals at the MDI.

141.3.1.4 PMD_UNITDATA[*i*].indication

This primitive defines the transfer of data from the PMD to the PMA defined in 142.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The semantics of the service primitive are PMD_UNITDATA[*i*].indication(rx_bit) (where *i* = 0 or 1). The data conveyed by PMD_UNITDATA[*i*].indication is a continuous stream of bits. The rx_bit parameter can take one of two values: ONE or ZERO. The PMD continuously sends a stream of bits to the PMA defined in 142.4 corresponding to the signals received from the MDI, at the nominal signaling rate of 25.78125 GBd in the case of Nx25G–EPON OLT and ONU PMDs or to the PMA defined in 142.4 at the nominal signaling rate of 10.3125 GBd in the case of 25/10G–EPON and 50/10G-EPON OLT PMDs.

141.3.1.5 PMD_SIGNAL[*i*].request

In the upstream direction, this primitive is generated by the PMA defined in 142.4 to turn on and off the transmitter according to the granted time. A signal for laser control is generated as described in 142.2.5.4.3 for the PCS defined in 142.2.

The semantics of the service primitive are PMD_SIGNAL[*i*].request(tx_enable) (where *i* = 0 or 1). The tx_enable parameter can take on one of two values: ENABLE or DISABLE, determining whether the PMD transmitter is on (enabled) or off (disabled). The PMA defined in 142.4 generates this primitive to indicate a change in the value of tx_enable. Upon the receipt of this primitive, the PMD turns the transmitter on or off as appropriate.

141.3.1.6 PMD_SIGNAL[*i*].indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI. The semantics of the service primitive are PMD_SIGNAL[*i*].indication(SIGNAL_DETECT) (where *i* = 0 or 1). The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting light at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA[*i*].indication(rx_bit) is undefined. The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT. If the MDIO interface is implemented, then PMD_global_signal_detect shall be continuously set to the value of SIGNAL_DETECT.

NOTE—SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA[*i*].indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the specified bit error ratio. PMD_SIGNAL[*i*].indication(SIGNAL_DETECT) has different characteristics for upstream and downstream links, see 141.3.5.

141.3.2 PMD block diagram

The PMD sublayer is defined at the reference points shown in Figure 141–2 for Nx25G-EPON PMDs. For any indexed test point (e.g., TP1[*i*]), [*i*] indicates the channel index, where *i* = 0 or 1.

For Nx25G-EPON PMDs, test points TP1[*i*], TP2, TP3, and TP4[*i*] refer to the downstream channel, while test points TP5[*i*], TP6, TP7, and TP8[*i*] refer to the upstream channel. In the downstream channel, TP2 and TP3 are compliance points, while in the upstream channel TP6 and TP7 are compliance points. TP1[*i*], TP4[*i*], TP5[*i*], and TP8[*i*] are reference points for use by implementers, defined on a per-channel basis. The optical transmit signal is defined at the output end of a patch cord (TP2 for the downstream channel and TP6 for the upstream channel), between 2 m and 5 m in length, of a fiber type consistent with the link type connected to the transmitter. Unless specified otherwise, all transmitter measurements and tests defined in 141.7 are made at TP2 or TP6. The optical receive signal is defined at the output of the fiber optic cabling (TP3 for the downstream channel and TP7 for the upstream channel) connected to the receiver. Unless specified otherwise, all receiver measurements and tests defined in 141.7 are made at TP3 or TP7.

The electrical specifications of the PMD service interface (TP1[*i*] and TP4[*i*] for the downstream channel and TP5[*i*] and TP8[*i*] for the upstream channel) are not system compliance points (these are not readily testable in a system implementation).

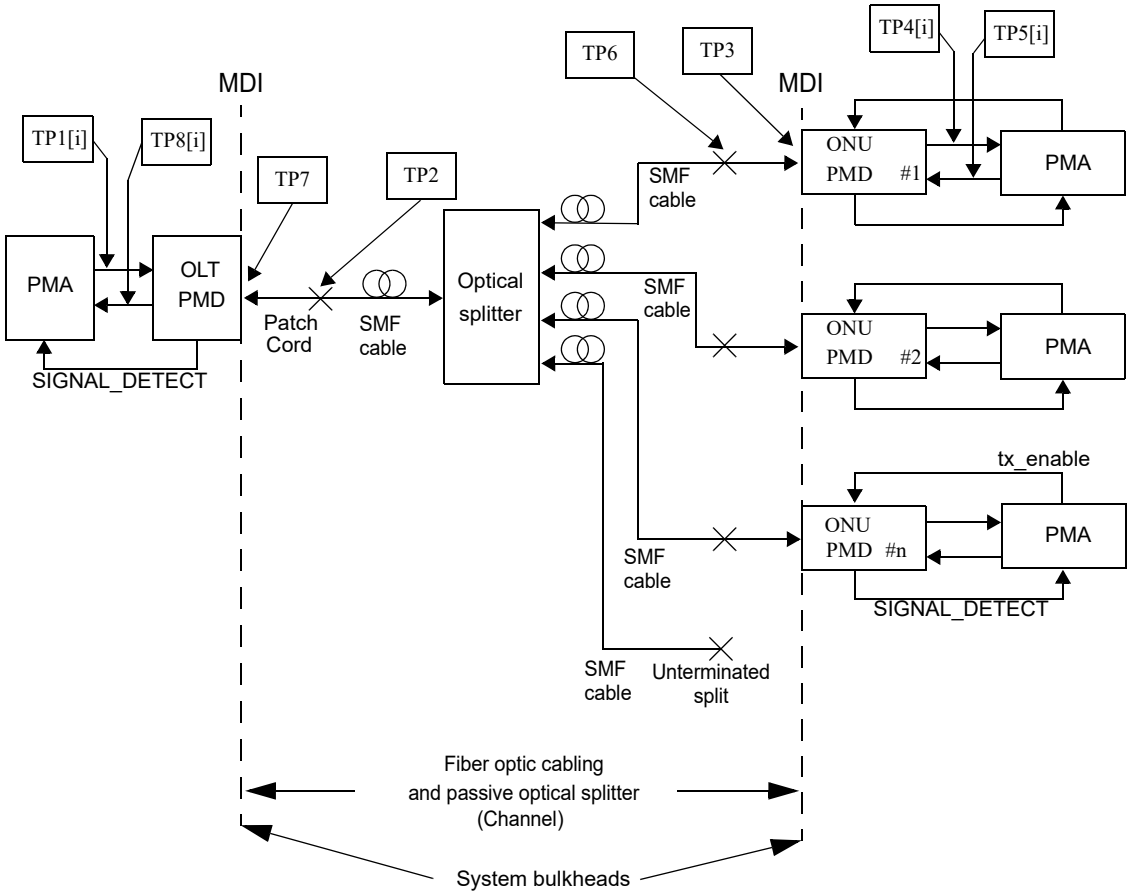

Figure 141–2—Nx25G-EPON PMD test points

141.3.3 PMD transmit function

The PMD transmit function shall convey the bits requested by the PMD service interface primitive PMD_UNITDATA[*i*].request(tx_bit) to the MDI according to the optical specifications in this clause. In the upstream direction, the flow of bits is interrupted according to PMD_SIGNAL[*i*].request(tx_enable). This implies three optical levels, 1, 0, and dark, the latter corresponding to the transmitter being in the OFF state. The highest optical power level shall correspond to tx_bit = ONE.

141.3.4 PMD receive function

The PMD receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the primitive PMD_UNITDATA[*i*].indication(rx_bit). The higher optical power level shall correspond to rx_bit = ONE.

141.3.5 PMD signal detect function

141.3.5.1 ONU PMD signal detect

The PMD signal detect function for the continuous mode downstream signal shall report to the PMD service interface, using the primitive PMD_SIGNAL[*i*].indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL[*i*].indication is intended to be an indicator of the presence of the optical

signal. The ONU PMD receiver is not required to verify whether a compliant Nx25G-EPON signal is being received.

141.3.5.2 OLT PMD signal detect

The response time for the PMD signal detect function for the burst mode upstream signal may be longer or shorter than a burst length; thus, it may not fulfill the traditional requirements placed on signal detect. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence. The signal detect function in the OLT may be realized in the PMD or the PMA defined in 142.4. The OLT PMD receiver is not required to verify whether a compliant Nx25G-EPON signal is being received.

141.3.5.3 Nx25G-EPON signal detect functions

The value of the SIGNAL_DETECT parameter for Nx25G–EPON PMDs shall be generated according to the conditions defined in Table 141–12.

Table 141–12—SIGNAL_DETECT value definitions for Nx25G-EPON PMDs

PMD type	Receive conditions	SIGNAL_DETECT value
Nx25G-EPON PMD	Average input optical power ≤ Signal detect threshold (min) in Table 141–17 or Table 141–18 at the specified receiver wavelength, as applicable	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 141–17 or Table 141–18 with a compliant signal input at the specified receiver wavelength, as applicable	OK
	All other conditions	Unspecified

141.4 Wavelength allocation

Downstream wavelength assignments are defined in Table 141–13. Upstream wavelength assignments are defined in Table 141–14.

Table 141–13—Downstream wavelength assignments

Wavelength name	Center wavelength (nm)	Wavelength range (nm)
DW0	1358	± 2
DW1	1342	± 2

Table 141–14—Upstream wavelength assignments

Wavelength name	Center wavelength (nm)	Wavelength range (nm)
UW0	1270	± 10
UW1	1300	± 10
UW2	1320	± 2

141.5 PMD to MDI optical specifications for OLT PMDs

This subclause details the PMD to MDI optical specifications for OLT PMDs. Specifically, 141.5.1 defines the OLT transmit parameters, while 141.5.2 defines the OLT receive parameters.

The operating parameters for Nx25G-EPON PHY link types are defined in Table 141–1 through Table 141–5. An Nx25G-EPON compliant transceiver operates over the media meeting the dispersion shown in Table 141–23 according to the specifications described in 141.9. A transceiver that exceeds the maximum reach requirement while meeting all other optical specifications is considered compliant.

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

141.5.1 Transmitter optical specifications

A medium power class Nx25G-EPON OLT PMD transmitter shall comply with the parameters shown in Table 141–15. A high power class Nx25G-EPON OLT PMD transmitter shall comply with the parameters shown in Table 141–16.

141.5.2 Receiver optical specifications

A medium power class Nx25G-EPON OLT PMD receiver shall comply with the parameters shown in Table 141–17. A high power class Nx25G-EPON OLT PMD receiver shall comply with the parameters shown in Table 141–18.

141.6 PMD to MDI optical specifications for ONU PMDs

This subclause details the PMD to MDI optical specifications for ONU PMDs. Specifically, 141.6.1 defines the ONU transmit parameters, while 141.6.2 defines the ONU receive parameters.

The operating parameters for Nx25G-EPON PHY link types are defined in Table 141–1 through Table 141–5. An Nx25G-EPON compliant transceiver operates over the media meeting the dispersion shown in Table 141–23 according to the specifications described in 141.9. A transceiver that exceeds the maximum reach requirement while meeting all other optical specifications is considered compliant.

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

141.6.1 Transmitter optical specifications

A medium power class Nx25G-EPON ONU PMD transmitter shall comply with the parameters shown in Table 141–19. A high power class Nx25G-EPON ONU PMD transmitter shall comply with the parameters shown in Table 141–20.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 141–19—ONU transmit characteristics, medium power class

Parameter	25GBASE-PQG-U2 50/25GBASE-PQG-U2	25GBASE-PQX-U2 50/25GBASE-PQX-U2	50GBASE-PQG-U2	50GBASE-PQX-U2	25/10GBASE-PQG-U2 50/10GBASE-PQG-U2 25/10GBASE-PQX-U2 50/10GBASE-PQX-U2	Unit
Signaling rate (range)	25.78125 ± 100 ppm				See Table 75–8	GBd
Channel wavelengths (range)	1260 to 1280	1290 to 1310	1260 to 1280 1290 to 1310	1290 to 1310 1318 to 1322		nm
Side-mode suppression ratio (SMSR) (min)	30					dB
Total average launch power (max)	—		10			dBm
Average launch power, each channel (max)	7					dBm
Optical Modulation Amplitude (OMA), each channel (min)[a]	1.3					dBm
Difference in launch power between any two channels (OMA) (max)	—		3			dB
Launch power in OMA minus TDP, each channel (min)(see note) for extinction ratio ≥ 5.5 dB for extinction ratio ≥ 4.5 dB for extinction ratio < 4.5 dB	0.2 0.5 0.8					dBm
Transmitter and dispersion penalty (TDP), each channel (max)	2					dB
Average launch power of OFF transmitter, each channel (max)	–45					dBm
Extinction ratio (min)	3.5					dB
$RIN_{15}OMA$ (max)	–128					dB/Hz
Optical return loss tolerance (max)	15					dB
Transmitter reflectance[b] (max)	–10					dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}[c]	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}					UI
Turn-on time (max)	128					ns
Turn-off time (max)	128					ns
NOTE—For reference, this implies that the minimum average launch power per channel at minimum extinction ratio and maximum TDP is 4 dBm. This minimum average launch power value is informative only.						

[a] Even if the TDP < 0.5 dB, the OMA (min) exceeds this value.
[b] Transmitter reflectance is defined looking into the transmitter.
[c] As defined in Figure 86–4.

Optical Modulation Amplitude (OMA), each channel (min)[a]	4.7				dBm
Difference in launch power between any two channels (OMA) (max)	—		3		dB
Launch power in OMA minus TDP, each channel (min)(see note) for extinction ratio ≥ 6 dB for extinction ratio < 6 dB	4 4.2				dBm
Transmitter and dispersion penalty (TDP), each channel (max)	2				dB
Average launch power of OFF transmitter, each channel (max)	–45				dBm
Extinction ratio (min)	5				dB
$RIN_{15}OMA$ (max)	–128				dB/Hz
Optical return loss tolerance (max)	15				dB
Transmitter reflectance[b] (max)	–10				dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}[c]	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}				UI
Turn-on time (max)	128				ns
Turn-off time (max)	128				ns
NOTE—For reference, this implies that the minimum average launch power per channel at minimum extinction ratio and maximum TDP is 6 dBm. This minimum average launch power value is informative only.					

[a] Even if the TDP < 0.5 dB, the OMA (min) exceeds this value.
[b] Transmitter reflectance is defined looking into the transmitter.
[c] As defined in Figure 86–4.

141.6.2 Receiver optical specifications

A medium power class Nx25G-EPON ONU PMD receiver shall comply with the parameters shown in Table 141–21. A high power class Nx25G-EPON ONU PMD receiver shall comply with the parameters shown in Table 141–22.

Table 141–21—ONU receive characteristics, medium power class

Parameter	25/10GBASE-PQG-U2 25/10GBASE-PQX-U2 25GBASE-PQG-U2 25GBASE-PQX-U2	50/10GBASE-PQG-U2 50/10GBASE-PQX-U2 50/25GBASE-PQG-U2 50/25GBASE-PQX-U2 50GBASE-PQX-U2 50GBASE-PQG-U2	Unit
Signaling rate (range)	25.78125 ± 100 ppm		GBd
Channel wavelengths (range)	1356 to 1360	1356 to 1360 1340 to 1344	nm
Bit error ratio (max)[a]	10^{-2}		—
Damage threshold[b]	–4		dBm
Average receive power, each channel (max)	–5		dBm
Receiver reflectance (max)	–12		dB
Receiver sensitivity (OMA), each channel[c] (max)(see note)	–21.4		dBm
Detect threshold, each channel (min)	–40		dBm
Stressed receiver sensitivity (OMA), each channel[d] (max)	–20.4		dBm
Conditions of stressed receiver sensitivity test			
Vertical eye closure penalty,[e] each channel	1.5		dB
Stressed eye J2 Jitter,[e] each channel	0.3		UI
Stressed eye J9 Jitter,[e] each channel	0.47		UI
NOTE—For reference, this implies that the maximum average power unstressed receiver sensitivity measured with an ideal transmitter signal at minimum extinction ratio is –23.5 dBm. This value is informative only.			

[a] The BER of 10^{-12} is achieved by the utilization of FEC as described in 142.2.4.1.
[b] The receiver tolerates, without damage, continuous exposure to an optical input signal having this average power level.
[c] Receiver sensitivity (OMA), each channel (max) is optional and is defined for a transmitter with VECP = 0.5 dB.
[d] Measured with conformance test signal at TP3 (see 141.7.11) for BER = 10^{-2}.
[e] Vertical eye closure penalty, stressed eye J2 Jitter, and stressed eye J9 Jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

141.7 Definitions of optical parameters and measurement methods

The following subclauses describe definitive patterns and test procedures for Nx25G-EPON PMDs. Implementers using alternative verification methods need to ensure adequate correlation and allow adequate margin such that specifications are met by reference to the definitive methods. All optical measurements, except TDP and $RIN_{15}OMA$ shall be made through a short patch cable between 2 m and 5 m in length.

141.7.1 Insertion loss

Insertion loss for SMF fiber optic cabling (channel) is defined at the wavelengths specified in Table 141–13 and Table 141–14, depending on the particular PMD. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280–4–2.

141.7.2 Test patterns

The test patterns used in this clause shall be the same as those used for 100GBASE-LR4, as described in 88.8.1 and shown in Table 88–10, with the exception of Pattern 5. Table 88–11 shows the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. A valid 25G-EPON signal is substituted for the 100GBASE-R signal specified in Table 88–11.

141.7.3 Wavelength and spectral width measurement

The center wavelength and spectral width (RMS) shall meet the specifications when measured according to the centroidal wavelength and RMS spectral width definitions in IEC 61280-1-3 under modulated conditions using an appropriate PRBS or a valid Nx25G-EPON signal, or another representative test pattern.

NOTE—The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.

141.7.4 Optical power measurements

Optical power shall meet specifications according to the methods specified in IEC 61280–1–1. A measurement may be made with the port transmitting any valid Nx25G-EPON signal.

141.7.5 Extinction ratio measurements

The extinction ratio shall meet the specifications when measured according to IEC 61280–2–2 with the port transmitting a valid Nx25G-EPON signal, and with minimal back reflections into the transmitter, lower than –20 dB. The test receiver has the frequency response as specified for the transmitter optical waveform measurement.

141.7.6 Optical Modulation Amplitude (OMA) test procedure

See 88.8.4.

141.7.7 Relative intensity noise optical modulation amplitude (RIN_xOMA) measuring procedure

See 88.8.7, with exception of the optical return loss value of 15 dB.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

141.7.8 Transmit optical waveform (transmit eye)

The required transmitter pulse shape characteristics for Nx25G-EPON PMDs are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4 and the test method shall be according to 88.8.8.

141.7.9 Transmitter and dispersion penalty (TDP) for 25G

TDP measurement tests transmitter impairments, including chromatic dispersion effects, due to signal propagation in SMF used in PON. Possible causes of impairment include intersymbol interference, jitter, and RIN. Meeting the separate requirements (e.g., eye mask, spectral characteristics) does not in itself guarantee the TDP. The TDP limit shall be met. TDP is measured as defined in 88.8.5 with the exceptions in 141.7.9.2 and 141.7.9.4.

141.7.9.1 Reference transmitter requirements

The reference transmitter shall meet the requirements listed in 88.8.5.1.

141.7.9.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed below.

An Nx25G-EPON OLT or ONU transmitter is to be compliant with a total dispersion at least as negative as the minimum dispersion given by Equation (141–1) and at least as positive as the maximum dispersion given by Equation (141–2) for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

$$D_{\min} = \min\left(0,\ 0.465 \times \lambda \times \left(1 - \left(\frac{1324}{\lambda}\right)^4\right)\right) \tag{141–1}$$

$$D_{\max} = \max\left(0,\ 0.465 \times \lambda \times \left(1 - \left(\frac{1300}{\lambda}\right)^4\right)\right) \tag{141–2}$$

where

λ is the wavelength of the device under test in nm

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss of 15 dB. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than 0.8 ps.

141.7.9.3 Reference receiver requirements

The reference receiver shall meet the requirements listed in 88.8.5.3.

141.7.9.4 Test procedure

The test procedure is as defined in 88.8.5.4, with the exception that a BER of 10^{-2} shall be used for the channel (wavelength) under test.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

141.7.10 Receive sensitivity

The test patterns in 75.7.3 (10G) and 141.7.2 (25G) are used to test receiver sensitivity.

The test signal is required to have negligible impairments such as intersymbol interference (ISI), rise/fall times, jitter, and RIN. The measurement procedure is described in 52.9.8 for 10 Gb/s PHYs and 88.8.9 for 25 Gb/s PHYs. The sensitivity shall be met for the bit error ratio defined in Table 141–17, Table 141–18, Table 141–21, or Table 141–22 as appropriate.

141.7.11 Stressed receiver conformance test

Compliance with stressed receiver sensitivity is mandatory for PMDs listed in Table 141–7. The stressed receiver conformance test is intended to screen against receivers with poor frequency response or timing characteristics that could cause errors when combined with a distorted but compliant signal. To be compliant with stressed receiver sensitivity, the receiver shall meet the specified bit error ratio at the power level and signal quality defined in Table 141–17, Table 141–18, Table 141–21, or Table 141–22 as appropriate, according to the measurement procedures of 52.9.9 for 10 Gb/s PHYs and 88.8.10 for 25 Gb/s PHYs.

141.7.12 Jitter measurements

When measuring jitter at TP1[*i*] and TP5[*i*], it is recommended that jitter contributions at frequencies below receiver corner frequencies (i.e., 10 MHz for 25.78125 GBd receiver and 4 MHz for 10.3125 GBd receiver) are filtered at the measurement unit.

141.7.13 Laser on/off timing measurement

T_{on} is defined in 141.7.13.1 and has the value of less than or equal to 128 ns (defined in Table 141–19 and Table 141–20).

T_{off} is defined in 141.7.13.1 and has the value of less than or equal to 128 ns (defined in Table 141–19 and Table 141–20).

141.7.13.1 Definitions

For each of the channels, T_{on} is denoted as the time beginning from the falling edge of the tx_enable line to the ONU PMD and ending at the time that the optical signal at TP2 of the ONU PMD is within 15% of its steady-state parameters (average launched power, wavelength, RMS spectral width, transmitter and dispersion penalty, optical return loss tolerance, jitter, $RIN_{15}OMA$, extinction ratio and eye mask opening) as defined in Table 141–19 and Table 141–20. T_{on} is presented in Figure 141–3. The data transmitted may be any valid 256B/257B symbols.

For each of the channels, T_{off} is denoted as the time beginning from the rising edge of the tx_enable line to the ONU PMD and ending at the time that the optical signal at TP2 of the ONU PMD reaches the specified maximum average launch power of OFF transmitter as defined in Table 141–19 and Table 141–20. T_{off} is presented in Figure 141–3. The data transmitted may be any of the patterns listed in Table 88–10.

141.7.13.2 Test specification

The test setup for measuring T_{on} and T_{off} is shown in Figure 141–4. An O/E converter is used to convert the optical signal at TP3 to an electrical signal at TP4[*i*] where it is assumed that the response time of the converter is considerably shorter that the T_{on} value under measurement. A scope, with a variable delay, is able to measure the time from the tx_enable trigger to the time the optical signal reaches all its specified conditions. The delay to the scope trigger is adjusted until the point that the received signal meets all its specified conditions. This is the T_{on} in question.

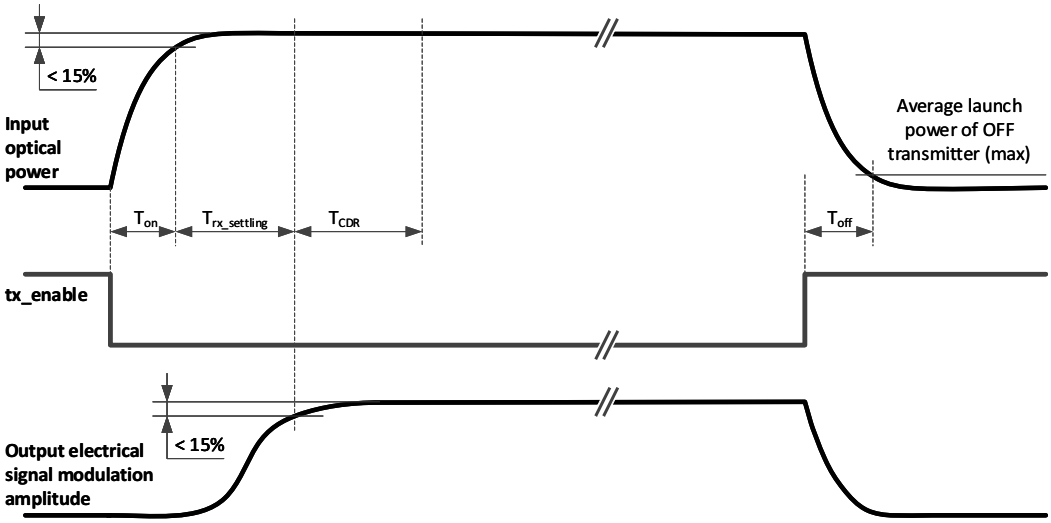

Figure 141–3—P2MP timing parameter definition, per channel

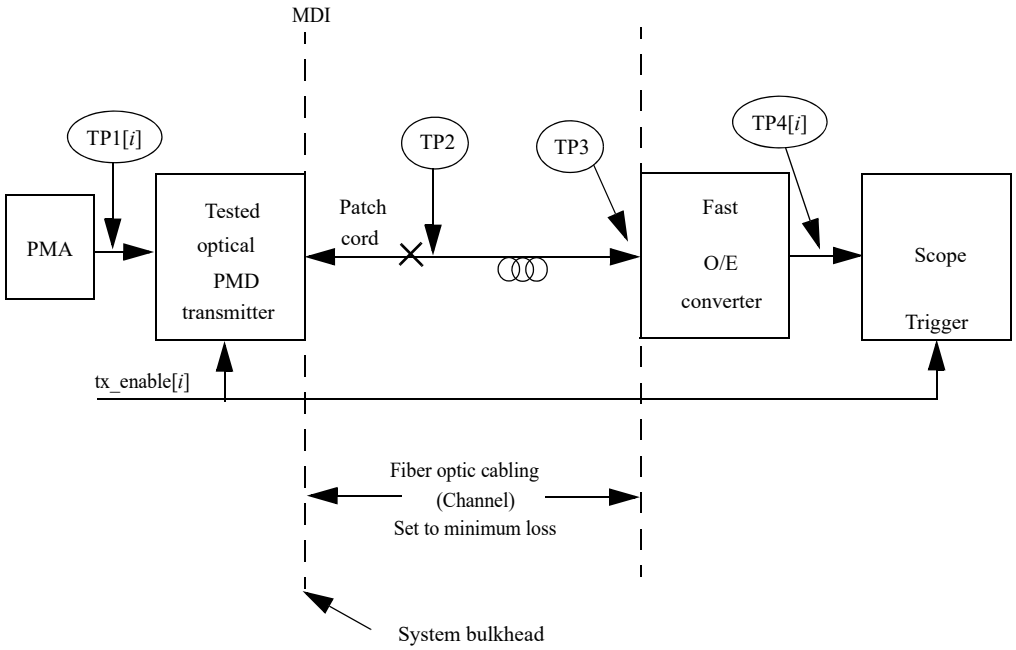

Figure 141–4—ONU PMD laser on/off time measurement setup

A non-rigorous way to describe this test setup would be: for a PMD with a declared T_{on} and T_{off}, measure all PMD optical parameters after T_{on} and T_{off} from the tx_enable trigger, confirming their conformance to being within 15% of the steady-state values. Notice that only the average launch power being below the average launch power of OFF transmitter is confirmed when measuring T_{off} time, since that is the only relevant parameter.

141.7.14 Receiver settling timing measurement

$T_{rx_settling}$ is defined in 141.7.14.1 and has a value of less than 800 ns (defined in Table 141–17 and Table 141–18). A method for measuring $T_{rx_settling}$ is illustrated in Figure 141–5.

141.7.14.1 Definitions

$T_{rx_settling}$ is defined to be the time between the moment when the optical power at TP7 reaches the conditions specified in 141.7.13.1 for T_{on} and the moment after which the electrical modulation (peak-to-peak) at TP8[*i*] remains within 15% of its steady-state amplitude and jitter (see Table 141–17 and Table 141–18). The $T_{rx_settling}$ time interval is illustrated in Figure 141–3. The data transmitted may be any valid 256B/257B symbols (or a specific power synchronization sequence). The optical signal at TP7, at the beginning of the locking, may have any valid 256B/257B pattern, optical power level, jitter, or frequency shift matching the standard specifications.

141.7.14.2 Test specification

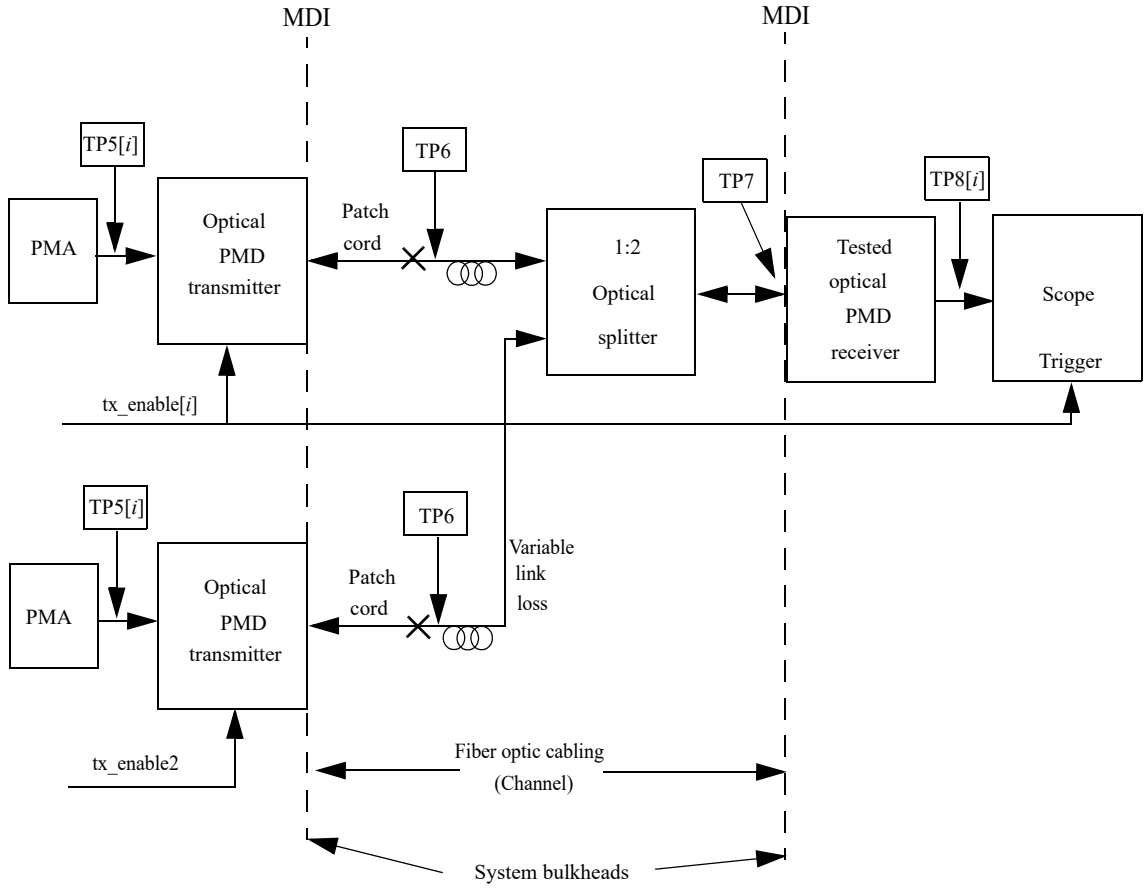

Figure 141–5—Receiver settling time measurement setup

Figure 141–5 illustrates the test setup for measuring the OLT PMD receiver (upstream) $T_{rx_settling}$ time. The optical PMD transmitter has well–known parameters, with a fixed known T_{on} time. After T_{on} time the parameters of the reference transmitter, at TP6 and therefore at TP7, reach within 15% of their steady-state values as specified in Table 141–19 and Table 141–20.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Define $T_{rx_settling}$ time as the time from the tx_enable assertion, minus the known T_{on} time, to the time the electrical signal at TP8 reaches within 15% of its steady-state conditions.

Conformance needs to be assured for an optical signal at TP7 with any level of its specified parameters before the tx_enable assertion. Especially, the $T_{rx_settling}$ time is expected to be met in the following scenarios:

— Switching from a 'weak' (minimal received power at TP7) ONU to a 'strong' (maximal received power at TP7) ONU, with minimal guard band between.
— Switching from a 'strong' ONU to a 'weak' ONU, with minimal guard band between.
— Switching from noise level, with maximal duration interval, to 'strong' ONU power level.

For a tested PMD receiver with a declared $T_{rx_settling}$ time, measure all PMD receiver electrical parameters at TP8[*i*] after $T_{rx_settling}$ from the tx_enable trigger minus the reference transmitter T_{on}, assuring conformance to within 15% of their specified steady-state values.

141.8 Environmental, safety, and labeling

141.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

141.8.2 Laser safety

Nx25G-EPON optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.

141.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

141.8.4 Environment

The Nx25G-EPON operating environment specifications are as defined in 52.11, as defined in 52.11.1 for electromagnetic emission, and as defined in 52.11.2 for temperature, humidity, and handling.

See Annex 67A for additional environmental information. Two optional temperature ranges are defined in Table 60–15. Implementations shall be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

141.8.5 PMD labeling

The Nx25G-EPON labeling recommendations and requirements are as defined in 52.12.

The list of all supported PMDs is shown in Table 141–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each field-pluggable component shall be clearly labeled with its operating temperature range over which compliance is ensured.

141.9 Characteristics of the fiber optic cabling

The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. It also includes a connector plug at each end to connect to the MDI. The fiber optic cabling spans from one MDI to another MDI, as shown in Figure 141–2.

141.9.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 141–2.

NOTE—The optical splitter presented in Figure 141–2 may be replaced by a number of smaller 1:n splitters such that a different topology may be implemented while preserving the link characteristics and power budget.

The maximum channel insertion losses shall meet the requirements specified in Table 141–1 through Table 141–5. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term *channel* is used here for consistency with generic cabling standards.

141.9.2 Optical fiber and cable

The fiber optic cabling shall meet the dispersion specifications defined in ITU-T G.652, Section 6.10. Maximum and minimum dispersion levels at the maximum 20 km reach at the nominal transmission wavelengths bands are summarized in Table 141–23.

Table 141–23—Optical fiber and cable characteristics

Parameter	UW0	UW1	UW2	DW0	DW1	Unit
Nominal wavelength	1270	1300	1320	1358	1342	nm
Max Dispersion (at 20 km) [a,b]	–45.4	0	36	100.1	73.7	ps/nm
Min Dispersion (at 20 km) [a,b]	–105.9	–45.4	–7.4	47.8	25.8	ps/nm

[a] These dispersion values were calculated using inequalities specified in ITU-T G.652, section 6.10
[b] These dispersion requirements are satisfied by G.652.D fibers specified in ITU-T G.652 (low water peak, dispersion unshifted SMF) and G.657.A fibers specified in ITU-T G.657 (bend–insensitive SMF).

141.9.3 Optical fiber connection

An optical fiber connection consists of a mated pair of optical connectors or an optical splice point. The number of splices/connectors is not predefined; the number of individual fiber sections between the OLT MDI and the ONU MDI is not defined. The only requirements are that the resulting channel insertion loss at all specified transmission wavelengths is within the limits specified in Table 141–1 through Table 141–5. Other fiber arrangements (e.g., increasing the split ratio while decreasing the fiber length) are supported as long as the limits for the channel insertion loss specified in Table 141–1 through Table 141–5 are observed.

The maximum discrete reflectance for single-mode connections shall be less than –26 dB.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

141.9.4 Medium Dependent Interface (MDI)

The Nx25G-EPON PMD is coupled to the fiber cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" as shown in Figure 141–2. Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a remateable connection, it shall meet the interface performance specifications of IEC 61753-1. The MDI carries the signal in both directions for Nx25G-EPON PMDs and couples to a single fiber.

NOTE—Transmitter compliance testing is performed at TP2 or TP6 as defined in 141.3.2, not at the MDI.

141.10 Protocol implementation conformance statement (PICS) proforma for Clause 141, Physical Medium Dependent (PMD) sublayer and medium for Nx25G-EPON passive optical networks[235]

141.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 141, Physical Medium Dependent (PMD) sublayer and medium for Nx25G-EPON passive optical networks, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

141.10.2 Identification

141.10.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

141.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 141, Physical Medium Dependent (PMD) sublayer and medium for Nx25G-EPON passive optical networks
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[235] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

141.10.4 PICS proforma tables for Physical Medium Dependent (PMD) sublayer and medium for passive optical networks, type 25/10GBASE-PQ, 25GBASE-PQ, 50/10GBASE-PQ, 50/25GBASE-PQ, and 50GBASE-PQ

141.10.4.1 PMD functional specifications

Item	Feature	Subclause	Value/Comment	Status	Support
FN1	Transmit function	141.3.3	Conveys bits from PMD service interface to MDI	M	Yes [ ]
FN2	Transmitter optical signal	141.3.3	Highest optical power transmitted is a logic one	M	Yes [ ]
FN3	Receive function	141.3.4	Conveys bits from MDI to PMD service interface	M	Yes [ ]
FN4	Receiver optical signal	141.3.4	Higher optical power received is a logic one	M	Yes [ ]
FN5	ONU signal detect function	141.3.5.1	Mapping to PMD service interface	M	Yes [ ]
FN6	ONU signal detect parameter	141.3.5.1	Generated according to Table 141–12	M	Yes [ ]
FN7	OLT signal detect function	141.3.5.2	Mapping to PMD service interface	O/3	Yes [ ] No [ ]
FN8	OLT signal detect function	141.3.5.2	Provided by higher layer	O/3	Yes [ ] No [ ]
FN9	OLT signal detect parameter	141.3.5.2	Generated according to Table 141–12	O	Yes [ ] No [ ]
FN10	Delay variation	141.3.1.2	Less than 0.25 EQT	M	Yes [ ]
FN11	Receiver sensitivity	141.7.10	The sensitivity is met for the bit error ratio defined in Table 141–17, Table 141–18, Table 141–21, or Table 141–22 as appropriate	M	Yes [ ]

142. Physical Coding Sublayer and Physical Media Attachment for Nx25G-EPON

142.1 Overview

This clause describes the Physical Coding Sublayer (PCS) with forward error correction (FEC) and Physical Medium Attachment (PMA) used with Nx25G-EPON point-to-multipoint (P2MP) networks. P2MP networks are passive optical networks (PONs) that connect multiple DTEs using a single shared fiber. The architecture is asymmetric, based on a tree and branch topology utilizing passive optical splitters. This type of network requires that the Multipoint MAC Control sublayer exists above the MACs, as described in Clause 144 (see Figure 142–1).

In this clause the term xMII is used to refer to both the 25GMII and the XGMII interfaces.

Figure 142–2 illustrates the functional block diagram of the Nx25G-EPON PHY with emphasis placed on the PCS. The Nx25G-EPON PCS is specified to support Nx25G-EPON PMDs, where:

— Both the receive and transmit paths operate at 25.78125 GBd rate (25/25G-EPON, 50/25G-EPON, and 50/50G-EPON), or
— The receive path operates at 25.78125 GBd rate and the transmit path operates at 10.3125 GBd (25/10G-EPON and 50/10G-EPON ONU), or
— The transmit path operates at 25.78125 GBd rate and the receive path operates at 10.3125 GBd (25/10G-EPON and 50/10G-EPON OLT).

See 143.3.1.1 for definition of TXD, TXC, TX_CLK, RXD, RXD, and RX_CLK.

142.1.1 Conventions

142.1.1.1 State diagrams

The body of this clause includes state diagrams and the associated definitions of variables, constants, and functions. The notation used in the state diagrams follows the conventions in 21.5, with extensions listed in the following subclauses. In case of any discrepancies between a state diagram and descriptive text, the state diagram prevails.

142.1.1.2 Hexadecimal notation

In addition to the rules for hexadecimal notation described in 1.2.5, the following conventions are used:

— Individual octets of a hexadecimal number are separated by hyphens, e.g., 0x1E-EE-80-23-CA.
— A part of a hexadecimal number enclosed in parenthesis followed by a subscripted decimal number *n* indicates that the parenthetical portion is to be repeated *n* times. For example, $0x12\text{-}34\text{-}56\text{-}(AB\text{-}CD)_6\text{-}EF$ is equivalent to the following expanded representation of a 128-bit number: 0x12-34-56-AB-CD-AB-CD-AB-CD-AB-CD-AB-CD-EF.

a) PCS transmit path **b) PCS receive path**

NOTE—All clock frequencies in this figure are shown for the nominal MAC data rate of 25 Gb/s. For PCS devices supporting the nominal MAC data rate of 10 Gb/s, all clock frequencies are scaled down by a multiplicative coefficient of 0.4.

142.1.1.3 Timers

Some state diagrams may utilize timers. Timers follow the conventions of 14.2.3.2 augmented as follows:

a) [start x_timer, *y*] sets expiration of *y* to timer x_timer.
b) Upon expiration of timer x_timer, a Boolean variable x_timer_done gets asserted automatically. Restarting the timer x_timer deasserts the value of x_timer_done.
c) [stop x_timer] aborts the timer operation for x_timer deasserting x_timer_done indefinitely.

142.1.1.4 Operations on variables

The operators used in state diagrams and in associated definitions of variables, constants, and functions are defined in Table 142–1. The operators are listed in decreasing order of precedence.

Table 142–1—Operators used in state diagrams and functions

Operator	Meaning
(…)	Indicates precedence or a set of function arguments
[…]	Array subscript
++	Unary operator placed after a variable; increments the variable by 1
– –	Unary operator placed after a variable; decrements the variable by 1
!	Boolean NOT
*	Multiplication
/	Division
+	Addition
–	Subtraction
<	Less than (see 142.1.1.5)
>	More than (see 142.1.1.5)
≤	Less than or equal to (see 142.1.1.5)
≥	More than or equal to (see 142.1.1.5)
= =	Equals (a test of equality)
!=	Not equals
AND	Logical or bitwise AND. If one or both operands are defined as Boolean values, the operation is logical AND. Otherwise, the operation is considered the bitwise AND (each bit of the first operand is logically AND-ed with the corresponding bit of the second operand).
XOR	Logical or bitwise exclusive OR. If one or both operands are defined as Boolean values, the operation is logical XOR. Otherwise, the operation is considered the bitwise XOR (each bit of the first operand is logically XOR-ed with the corresponding bit of the second operand).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 142–1—Operators used in state diagrams and functions *(continued)*

Operator	Meaning
OR	Logical or bitwise OR. If one or both operands are defined as Boolean values, the operation is logical OR. Otherwise, the operation is considered the bitwise OR (each bit of the first operand is logically OR-ed with the corresponding bit of the second operand).
|	Concatenation operation that combines several subfields or parameters into a single aggregated field or parameter
∈	Is a member of
∉	Is not a member of
⇐ =	Assignment operator (in state diagrams) Assignment operator (in function code)
+=	Increments left operand value by the value of the operand on the right (x += y is equivalent to x ⇐ x + y)
–=	Decrements left operand value by the value of the operand on the right (x –= y is equivalent to x ⇐ x – y)

Variables that allow access to individual bits are called vectors. The vector notations use 0 to mark the first received bit. Individual bits are accessed using the following notation:

a) data_vector<*k*> accesses the *k*th bit of the vector.
b) data_vector<*m*:*n*> accesses bits *n* through *m* inclusively. The *n*th bit is received earlier than the *m*th bit. Refer to 3.1.1 for the conventions on bit ordering.

142.1.1.5 Operations on wrap-around variables

Various integer variables/counters defined in this clause wrap around on overflow, i.e., reset to zero when incremented by one after reaching the maximum value. A subtraction operation ($a - b$) on such variables is straightforward and may be replaced by addition of the first operand a and two's complement of the second operand b. Unless explicitly stated, the result of such subtraction is a signed integer of the same size (bit width) as the largest of the two operands. In other words, the subtraction operation assumes that the maximum absolute difference between the two operands does not exceed half of their maximum range.

A function $a < b$ is used to compare two wrap-around values. Returned value is true when b is larger than a allowing for wrap-around of a and b. The comparison is made by subtracting b from a and testing the MSB. If MSB($a - b$) = 1 (i.e., if the result of $a - b$ is negative) the value true is returned, else false is returned. In addition, the following functions are defined in terms of $a < b$:

a) $a > b$ is equivalent to !*(a < b or a = b)*
b) $a \geq b$ is equivalent to !*(a < b)*
c) $a \leq b$ is equivalent to !*(a > b)*

142.1.1.6 FIFO access operations

State diagrams make extensive use of first-in, first-out (FIFO) buffers. These buffers support a common set of operations, defined as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Buf.Append(*e*) adds the element *e* to the input of FIFO buffer Buf.
b) Buf.Clear() removes all elements from the FIFO buffer Buf.
c) Buf.Fill(*e*) writes element/value *e* into each position of FIFO buffer Buf.
d) Buf.GetHead() returns the oldest (head) element in the FIFO buffer Buf, and removes that element from the FIFO, decreasing its length by one.
e) Buf.IsEmpty() returns true if the FIFO buffer is empty (has no elements), otherwise the function returns false.
f) Buf.IsFull() returns true if the FIFO buffer Buf is full (i.e., Buf has no unoccupied positions), otherwise the function returns false.
g) Buf.PeekHead() returns the oldest (head) element in the FIFO buffer Buf without removing that element from the FIFO.

All of the FIFO access operations are assumed to be non-blocking and to take zero time to complete the execution.

142.1.2 Delay constraints

The combined delay variation through the transmit path of the Nx25G-EPON PCS and PMA is expected to be less than 6 EQTs (see 1.4.313) for channels operating at 25.78125 GBd and less than 15 EQTs for channels operating at 10.3125 GBd.

The combined delay variation through the receive path of the Nx25G-EPON PCS and PMA is expected to be less than 2 EQTs for channels operating at 25.78125 GBd and less than 5 EQTs for channels operating at 10.3125 GBd.

The aforementioned delay variation limits are applicable only for the data units (either EQ or the corresponding 257-bit block) located at the fixed offset within the FEC codeword.

142.1.3 Burst transmission

Figure 142–3 presents the details of the ONU burst transmission, in particular, details of the FEC-unprotected and the FEC-protected areas of the upstream burst with three distinct synchronization pattern zones.

The upstream burst begins with a synchronization pattern, which is not FEC protected. The synchronization pattern comprises: SP1 zone, optimized for laser on (T_{on}) and automatic gain control (AGC, $T_{rx_settling}$); SP2 zone, optimized for clock and data recovery (CDR, T_{CDR}); and SP3 zone, optimized for the start-of-burst delimiter (SBD) pattern. Each SP zone is a multiple of 257 bits, aligning with the PCS (defined in 142.2 and 142.3) line code of 256B/257B.

Bit patterns transmitted within each SP zone are configured by the OLT using three SYNC_PATTERN MPCPDUs (see 144.3.6.7).

In the bursts transmitted during the discovery operation, the SBD is followed by a single (shortened) FEC codeword carrying a single REGISTER_REQ MPCPDU. In normal operation the SBD is followed by a number of FEC codewords, where the last codeword may be shortened to reduce the unused QC-LDPC codeword payload at the end of the burst (see 142.2.4). Each FEC codeword comprises a series of 256B/257B encoded and scrambled data blocks, followed by a series of 257-bit long parity blocks. Within a non-shortened FEC codeword, the FEC payload portion includes 56 of these 257-bit data blocks and 10 257-bit blocks carrying QC-LDPC parity and codeword delimiter. Within a shortened FEC codeword, the FEC payload portion may be truncated to a number of data blocks smaller than 56, while the size of the FEC parity portion remains unchanged.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

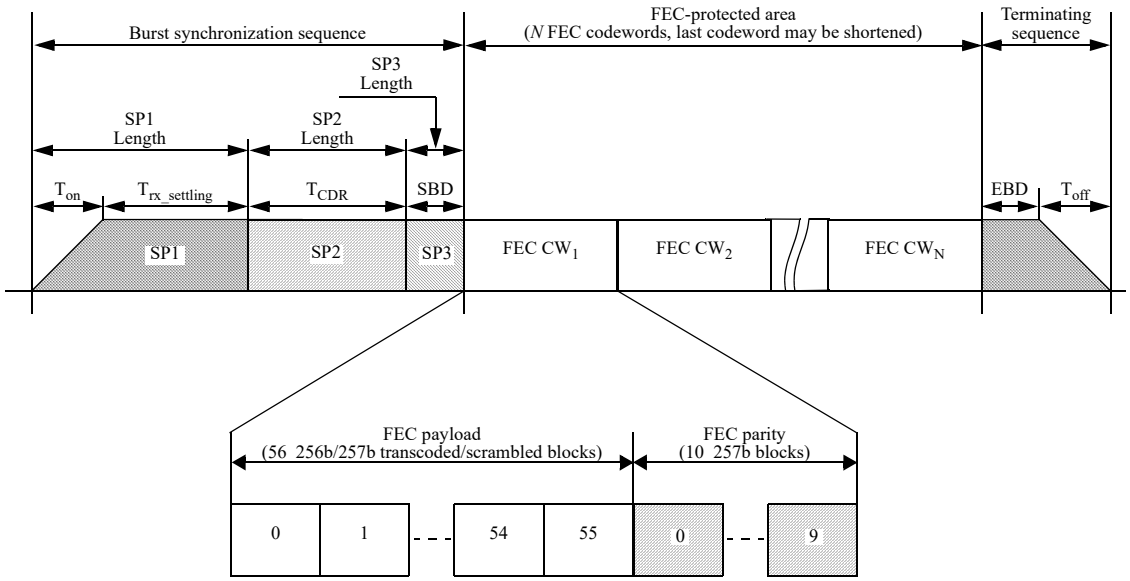

Figure 142–3—ONU burst structure, 3 zones

The upstream burst ends with an end-of-burst delimiter (EBD). When received at the OLT, the EBD pattern allows for the rapid reset of the OLT FEC synchronizer, preparing the OLT for the next incoming upstream burst. The EBD pattern is not part of the last FEC codeword.

142.1.3.1 Default synchronization pattern parameters

To assist the device development, testing/verification, and interoperability efforts, this subclause provides a set of default synchronization pattern parameters.

SP1 and SP2 synchronization patterns have the value of 0x1-$(AA)_{32}$ and are transmitted in a balanced form, i.e., every 257-bit block starting with the second one is an inversion of the previous block. The transmission bit sequence consists of 257 bits of alternating 1s and 0s, starting with 1.

The SP3 synchronization pattern zone represents the start-of-burst delimiter (SBD). It has the length of one block (257 bits) and the value of 0x1-BF-40-18-E5-C5-49-BB-59-6B-F8-D8-12-D8-58-E4-AB-40-BF-E7 -1A-3A-B6-44-A6-94-07-27-ED-27-A7-1B-54. The transmission bit sequence is:

```
(first bit)   1  1111 1101 0000 0010 0001 1000 1010 0111

This combination of SP2 and SP3 synchronization pattern values is characterized by the Hamming distance of 110 or higher between the SP3 and any preceding 257-bit long pattern, i.e., concatenation of x bits of SP2 and y bits of SP3, where x is between 1 and 257, and $x + y = 257$.

142.2 PCS transmit data path

This subclause defines the transmit direction of the Nx25G-EPON PCS. In the OLT, the PCS transmit function operates in a continuous mode at 25.78125 GBd rate.

In the ONU, the PCS transmit function operates in burst mode at 25.78125 GBd rate (25/25G-EPON, 50/25G-EPON, and 50/50G-EPON) or at 10.3125 GBd rate (25/10G-EPON and 50/10G-EPON).

The PCS transmit function includes a mandatory QC-LDPC FEC encoder. The functional block diagram for the PCS transmit function is shown in Figure 142–2. The PCS transmit function consists of the following functional blocks:

— PCS Input process (see 142.2.5.4.1),
— PCS Framer process (see 142.2.5.4.2), and
— PCS Transmit process (see 142.2.5.4.3).

As shown in Figure 142–4, the PCS transmitter first inputs two transfers from the xMII and consolidates these into a single 72-bit block that is then encoded into a 66-bit block. Four 66-bit blocks are accumulated, scrambled, and transcoded into a 257-bit block that is transferred to the InputFifo and also copied to the FEC encoder. Data is transferred to the TxFifo, along with framing information (see 142.2.5.4.2) by the PCS Framer process. The PCS Transmit process transfers 257-bit blocks containing framing, information, and parity bits to the PMA. The PCS shall transmit bits in the order shown in Figure 142–4.

NOTE—Figure 142–4 only shows the bits that are being transmitted and does not show the bit that is added and removed within PCS for control purposes.

142.2.1 64B/66B line encoder

The Nx25G PCS encodes a 72-bit block into a 64B/66B block structure as defined in 49.2.4, using all the block type fields in Figure 49–7 except block type field values of: 0x2D, 0x33, 0x66, 0x55, and 0x4B.

The control characters and their mappings to Nx25G-EPON control codes are specified in Table 142–2. The representations of the control characters are the control codes. Control characters are transferred over the xMII as 7-bit values. The Nx25G-EPON PCS encodes the start and terminate control characters implicitly using the block type field. The Nx25G-EPON PCS does not support ordered set control codes. All control code values that do not appear in Table 142–2 shall not be transmitted and are treated as an error if received.

Start	/S/	0xFB	Encoded by block type field
Terminate	/T/	0xFD	Encoded by block type field
Error	/E/	0xFE	0x1E

142.2.2 Scrambler

The Nx25G PCS scrambles the payload of each 66-bit block. It then accumulates 66-bit blocks into groups of four and transcodes each group into a single 257-bit block. The payload of each 66-bit block is scrambled using the scrambling function defined in 49.2.6.

In the ONU, at the beginning of each burst, the scrambler is reset to a known initialization value (see the definition of ResetScrambler() function in 142.2.5.3).

142.2.3 64B/66B to 256B/257B transcoder

The 64B/66B to 256B/257B transcoder converts four consecutive scrambled 64B/66B blocks into one scrambled 256B/257B block as described in 91.5.2.5.

142.2.4 FEC encoder

The Nx25G-EPON PCS shall encode the transmitted data stream using a quasi-cyclic QC-LDPC FEC, defined in 142.2.4.1. FEC encoder test vectors are provided in Annex 142A.

142.2.4.1 Low-density parity-check coding

The full QC-LDPC code is defined by a $(M + P) \times (K + S + M + P) = 3\,072 \times 17\,664$ size parity-check matrix H composed of a 12×69 array of 256×256 sub-matrices $A_{i,j}$:

$$H = \begin{bmatrix} A_{1,1} & \cdots & A_{1,69} \\ \cdots & & \cdots \\ A_{12,1} & \cdots & A_{12,69} \end{bmatrix}$$

The sub-matrices $A_{i,j}$ are either a cyclic shifted version of identity matrix or a zero matrix, and have a size of 256×256. The parity-check matrix is described in its compact form:

$$H_C = \begin{bmatrix} a_{1,1} & \cdots & a_{1,69} \\ \cdots & & \cdots \\ a_{12,1} & \cdots & a_{12,69} \end{bmatrix}$$

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where $a_{i,j} = -1$ for a zero sub-matrix in position (i, j), and a positive integer number $a_{i,j}$ defines the number of right column shifts of the identity matrix.

The compact form of parity-check matrix H_c is shown in Table 142–3.

142.2.4.2 FEC encoding process

The FEC encoder is shown in Figure 142–5. The encoder consists of a systematic QC–LDPC encoding engine followed by a shortening and puncturing mechanism and the addition of a 10-bit delimiter. The parameters of the FEC encoder are as follows:

- The QC-LDPC parity-check matrix is a 12×69 array of circulant sub-matrices (see 142.2.4.1) with circulant size $Z = 256$; QC-LDPC user bit length before shortening is $57 \times 256 = 14\,592$, the parity bit length before puncturing is $12 \times 256 = 3072$; the codeword length before any shortening and puncturing is 17 664.
- The number of transmitted information bits, K (with maximum user length $K_{max} = 14\,392$).
- The number of shortened information bits, S ($S = 14\,592 - K$).
- The number of punctured parity-check bits, P ($P = 512$).
- The number of parity-check bits after puncturing, M ($M = 3072 - P = 2560$).
- The length of the FEC encoder output + delimiter is N where $N = K + M + 10$ bits and $N_{max} = K_{max} + M + 10$ bits = 16 962.
- The code rate, $R = K / N$, defined as the code rate after puncturing and after shortening.

The encoder supports a highest code rate $R_{max} = K_{max} / N_{max} = 0.848$. Codes with lower code rates/shorter block length shall be obtained through shortening. The puncturing length and location are fixed for all scenarios.

The encoding process therefore shall be as follows:

— A group of K information bits $u = [u_1, u_2, \ldots, u_K]$ are collected and copied to the output of the encoder to form a block of systematic code bits. They are also the input to the zero-padding block.
— A total of S zero padding bits are appended at the end of u to form the full-length information bit block $u^* = [u \mid 0, \ldots, 0]$, which is then sent to the information bit de-interleaver module, which in turn produces the bit-de-interleaved sequence $u'' = \pi^{-1}_{\text{info}}(u^*)$. π^{-1}_{info} represents the de-interleaver mapping of information bits that permutes u^* to u''.
— The de-interleaved QC-LDPC information bits u'' are sent to the QC-LDPC encoding engine, and used to compute parity-check bits p'' with the parity-check matrix H.
— $M + P$ parity bits $p'' = [p_1, p_2, \ldots, p_M \mid p_{M+1}, \ldots, p_{M+P}]$ are sent to the puncturing block. The last P bits of p'' are truncated, and M parity bits $p = [p_1, p_2, \ldots, p_M]$ are passed to the interleaver module.
— M parity bits p'' are interleaved to get $p^* = \pi_{\text{parity}}(\text{p''})$. π_{parity} represents the interleaver mapping of parity bits that permutes p'' to p^*.
— M interleaved parity bits $p^* = [p_1, p_2, \ldots, p_M]$ are copied to the output of the encoder to form the parity-check bits p.
— The FEC codeword without delimiter is $c = [u \mid p] = [u_1, u_2, \ldots, u_K \mid p_1, p_2, \ldots, p_M]$, such that $[u'' \mid p''] H^T = 0$.

The QC-LDPC encoder in Figure 142–5 places M bits of FEC parity into the parity staging buffer (TxParBuf) for use by the PCS Transmit process (see 142.2.5.4.3) and the FecParity() function. The buffer comprises 2560 bits of calculated parity along with the 10-bit codeword delimiter (FEC_CW_DELIM). This results in the parity bits assigned to TxParBuf<2559:0> and the 10-bit FEC_CW_DELIM value to TxParBuf<2569:2560>. The transmission order starts with bit 0 and ends with bit 2569.

142.2.4.3 Interleaver

The interleaver and de-interleaver are realized by using Omega networks and reverse Omega networks. An Omega network is a multi-stage interconnection network that uses multiple stages of switches. At each stage, the switches may be controlled independently to “pass-through” or “cross”.

The outputs from each stage are connected to the inputs of the next stage using an interconnection system. The details of interconnection and switch programming are shown in Figure 142–8.

“De-interleaver” refers to the mapping from transmitted sequence to encoding/decoding sequence (including user and parity). This is implemented using “reverse Omega (R→L)” (i.e., data input from the right side and output from the left). “Interleaver” refers to the mapping from encoding/decoding sequence to transmitted sequence. This is implemented as “Omega (L→R)” (i.e., data input from the left side and output from the right).

The information bit de-interleaver consists of 57 independent reverse Omega (R→L) networks of size 256 × 256 as illustrated in Figure 142–6. The information bits after zero padding are divided into 57 data chunks, and each data chunk has 256 bits, which is sent to one of the 256 × 256 reverse Omega (R→L) networks.

The parity bit interleaver consists of 10 independent Omega (L→R) networks (see Figure 142–7). Each 256-bit parity-check bit segment is sent to one of the 256 × 256 Omega (L→R) networks. Because the puncturing length is fixed (512) and 512 bits make up two whole data chunks, the last two parity Omega networks [B51] are bypassed. In implementation, the parity bit interleaver consists of 10 Omega networks.

Note that the interleaver (Omega L→R) and de-interleaver (reverse Omega R→L) are just reverse permutations of each other. To clarify, with the Omega (L→R) network architecture data is input from the

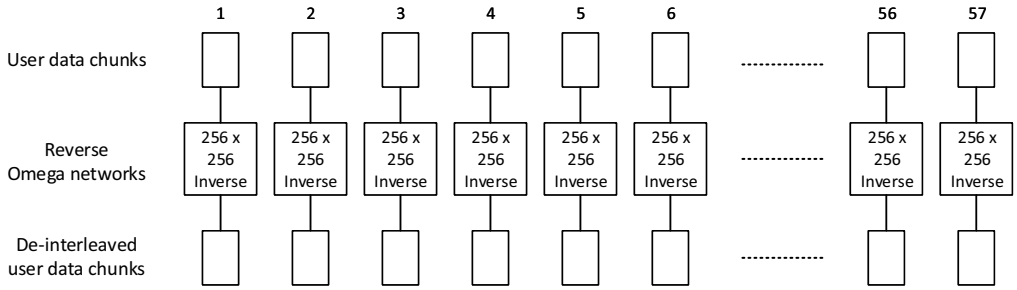

Figure 142–6—Information bit de-interleaver

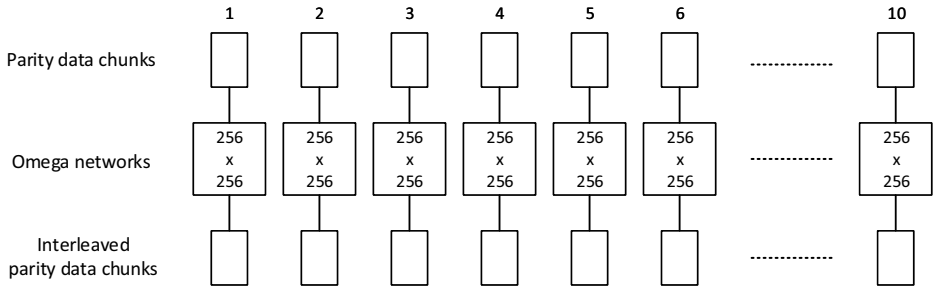

Figure 142–7—Parity bit interleaver

left side and output from the right; while the reverse Omega (R→L) network are obtained just by feeding the data to the right side and output from the left side. This is illustrated in Figure 142–8 where each Omega network is made of an interconnection network with 8 stages of switches, each stage has 128 switches, and each switch has two inputs and two outputs as shown. The inputs and outputs of switch i (i = 0...127) are connected to bits $i \times 2$ and $i \times 2 + 1$ of a 256-bit data chunk.

Each switch is individually programmed. If the switch is programmed to be 1, then this switch performs a swap of the input bits, otherwise, the input will be pass-through.

The interconnection between each stage of switches is deterministic and is described as follows. Denote the two output ports of switch i in stage k as $S^k_{i,0}$ and $S^k_{i,1}$, k = 0, …, 7 and i = 0, …, 127:

— Switch output port at stage k, $S^k_{i,0}$ is connected to switch input port at stage $k + 1$:

$$S^{k+1}_{\left\lfloor \frac{i}{2} \right\rfloor, \bmod(i,2)}$$

NOTE—The notation $\lfloor x \rfloor$ represents a floor function, which returns the value of its argument x rounded down to the nearest integer.

— Switch output port at stage k, $S^k_{i,1}$ is connected to switch input port at stage $k + 1$:

$$S^{k+1}_{\left\lfloor \frac{i}{2} \right\rfloor + 64, \bmod(i,2)}$$

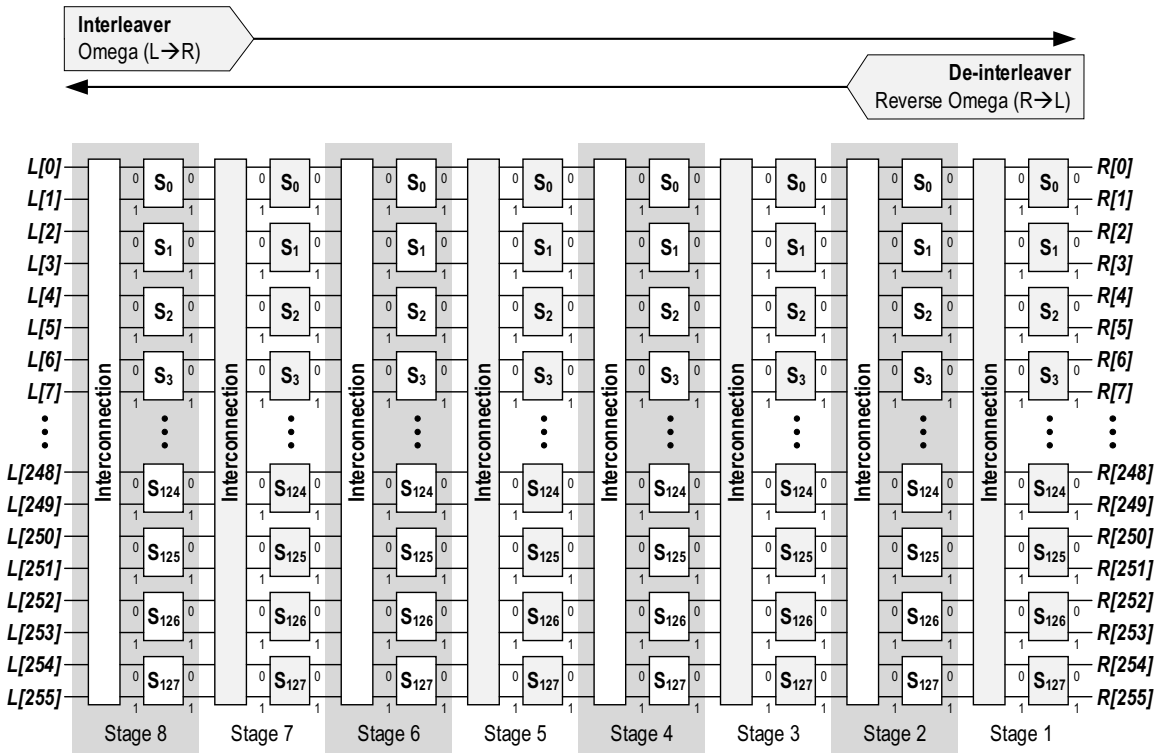

Figure 142–8—Omega network 256 interconnection network

In implementation one 256 × 256 Omega network of 8 × 128 switches is programmed based on a 128-bit control seed (see Table 142–5 and Table 142–6). The 128-bit switch programming sequence is derived by a circular bit shift of the control seed by *x* positions where *x* is given in Table 142–4 for each of the 8 stages.

Table 142–4—Control seed circular bit shift for stage 1 through 8

142.2.5 Transmit data path state diagrams

Various variables and buffers in the PCS are structured as 258-bit wide blocks. Bits 0 through 256 of each 258-bit block hold one line-coding unit (a 257-bit block) and bit 257 indicates the 257-bit block has been scrambled and transcoded (bit 257 is equal to 1) or that the block has not been scrambled and transcoded (bit 257 is equal to 0). The value of bit 257 also implies the origin of the block as being either the PCS Input process (bit 257 is equal to 1) or the PCS Framer process (bit 257 is equal to 0).

142.2.5.1 Constants

EBD258
Type: 258-bit block
Description: The EBD258 constant holds the value of the end-of-burst delimiter.
Value: EBD257 (see 142.3.5.1) with a bit having value 0 appended as MSB

FEC_CW_DELIM
Type: 10-bit block
Description: The codeword delimiter bit pattern found at the end of each FEC parity block.
Value: 0x3-CA

FEC_PARITY_SIZE
Type: Integer
Description: The FEC_PARITY_SIZE constant indicates the size of the parity portion of an FEC codeword.
Value: 10
Unit: 257-bit block

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FEC_PAYLOAD_SIZE
Type: Integer
Description: The FEC_PAYLOAD_SIZE constant indicates the size of the payload portion of an FEC codeword.
Value: 56
Unit: 257-bit block

IBI258
Type: 258-bit block
Description: The IBI258 constant represents an inter-burst idle block that is generated by the PCS Framer process in the absence of any burst framing blocks, data blocks, or FEC parity blocks.
Value: $0x0\text{-}(0A)_{32}$

IBI_EQ
See 143.3.3.3

PAR_PLACEHLDR
Type: 258-bit block
Description: The PAR_PLACEHLDR constant represents the value of a 258-bit block inserted into the data stream by the PCS Framer process in order to reserve the location where FEC parity and the 10-bit FEC codeword delimiter is to be inserted into the data stream by the PCS Transmit process.
Value: $0x0\text{-}(09)_{32}$

RATE_ADJ_EQ
See 143.3.3.3

SCRAMBLED
Type: binary
Description: This constant indicates that the contents of the 257-bit block are scrambled. When the bit TxInput<257> or TxOutput<257> is set to 1, then bits TxInput<256:0> or TxOutput<256:0> in the same block carry scrambled data.
Value: 1

142.2.5.2 Variables

BEGIN
TYPE: Boolean
Description: This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset, and it is reset to false on read.

ClkIn
Type: Boolean
Description: The clear-on-read variable ClkIn is set to true on each rising edge of the xMII clock.

ClkOut
Type: Boolean
Description: The clear-on-read variable ClkOut is set to true once for each 257-bit block output by the PMA, i.e., the ClkOut tracks the transmit clock of the corresponding PMA channel (see 142.4.4).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ClkXfr

Type: Boolean

Description: The clear-on-read variable ClkXfr is set to true once for each 257-bit block output by the PMA, i.e., the ClkXfr tracks the transmit clock of the corresponding PMA channel (see 142.4.4).

InputFifo[]

Type: array of 258-bit blocks

Description: The InputFifo receives data from the PCS Input process and hands it off to the PCS Framer process. Its primary function is to absorb data while the PCS is transmitting burst overhead or FEC parity. This FIFO holds SpLength elements and supports FIFO access operations as defined in 142.1.1.6.

TxParBuf

Type: 2570-bit block

Description: This variable holds the 2560-bit calculated parity value along with the 10-bit FEC_CW_DELIM value (see 142.2.5.1). The total size of 2570 bits represents the same size as ten 257-bit line encoding blocks.

TxFifo[]

Type: array of 258-bit blocks

Description: The TxFifo holds information queued by the Framer process for output by the PCS and enforces a fixed delay that is implementation dependent. The fixed delay ensures the PHY has sufficient time to generate FEC parity given that the Framer process inserts SpLength 257-bit blocks at the beginning of the burst. This FIFO holds either (FEC_DELAY – SpLength) or two elements, whichever is greater. The TxFifo supports FIFO access operations as defined in 142.1.1.6.

ParityLeft

Type: Integer

Description: The ParityLeft variable indicates the number of 257-bit parity blocks needed to complete the current FEC codeword being processed by the PCS Framer process.

PayloadLeft

Type: Integer

Description: The PayloadLeft variable indicates the number of 257-bit payload blocks needed to complete the current FEC codeword being processed by the PCS Framer process.

SyncPattern[]

Type: array of 258-bit blocks

Description: The SyncPattern array is set to the provisioned value of the synchronization pattern as determined by the most recent settings of SP1, SP2, SP3, and their corresponding length parameters by the MPCP. The MSB of each cell is set to zero, indicating the 257-bit block has not been scrambled and transcoded.

SpLength

Type: unsigned integer

Description: The SpLength variable represents the length of the synchronization pattern as determined by the sum of the most recent settings of SP1Length, SP2Length, and SP3Length provisioned in an ONU (see 144.3.6.4 and 144.3.6.6).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SpIndex
: Type: integer
Description: The SpIndex variable is a pointer into the SyncPattern array that indicates which 258-bit block from the array is sent to the TxFifo.

Transmitting
: Type: Boolean
Description: The Transmitting variable indicates whether the device is transmitting or not.

TxInput
: Type: 258-bit block
Description: This variable holds one transcoded 257-bit block prepended with a binary 1 indicating the 257-bit block has been scrambled and transcoded.

TxNext
: Type: 72-bit block
Description: The next 72-bit block to be processed by the PCS Input process.

TxLast
: Type: 258-bit block
Description: This variable holds the 258-bit that was read from TxFifo in the previous ClkOut cycle.

TxOutput
: Type: 258-bit block
Description: This variable holds one 258-bit block retrieved from the TxFifo.

TxPrev
: Type: 72-bit block
Description: This variable holds one 72-bit block received by the PCS Input process from the xMII in the previous ClkIn cycle.

xBuffer[]
: Type: array of 66-bit blocks
Description: This buffer holds four 66-bit blocks of 64B/66B encoded data to be transcoded into one 257-bit block.

xIndex
: Type: Integer
Description: An index into the xBuffer indicating the number of encoded blocks contained in the buffer that are ready to be transcoded.

142.2.5.3 Functions

FecParity()
: Upon initiation, the first call to this function returns a block containing the first 257 bits from the TxParBuf, i.e., TxParBuf<256:0>. Each subsequent call returns the subsequent 257 bits from the buffer. On the 10th call, the last 257 bits are returned, i.e., TxParBuf<2569:2312>, and the function resets to return TxParBuf<256:0> on the next call. This emulates a circular buffer of size 10 × 257 bits.

Encode(v)
: This function performs 64B/66B encoding of a 72-bit block v per 49.2.13.2.3 and returns the result.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PassToFecEncoder(v)

This function passes a 257-bit block v to the FEC engine for calculating the LDPC code parity.

NextTxVector()

This function returns a 72-bit block carrying a single EQ as shown in Figure 142–2. The block is constructed from the data received from the xMII over two subsequent 36-bit transfers: the first transfer is on rising TX_CLK edge and the second transfer is on the falling TX_CLK edge.

PassToPMA(v)

This function passes a 257-bit block v to the PMA using PMA_UNITDATA[*i*].request(v) (see 142.4.1.1).

ResetScrambler()

Description: This function resets the scrambler to the value of $0x3\text{-}(FF)_7$, i.e., each of the bits S0 through S57 of the scrambler shift register is set to 1 (see Figure 49–8).

Scramble(blk)

This function accepts one 66-bit block blk and performs the scrambling operation on the 64-bit payload of the block, as described in 49.2.6. The returned value is a scrambled 66-bit block.

Transcode(a[4])

This function transcodes four 64B/66B-encoded blocks into a single 256B/257B encoded block per 91.5.2.5 and returns the result. It takes four 64B/66B encoded blocks a[4] as an argument and returns a 257-bit block.

142.2.5.4 State diagrams

142.2.5.4.1 PCS Input process

The PCS Input process accepts two consecutive 36-bit transfers from the xMII interface and converts them into a single 72-bit block. The Input process discards all RATE_ADJ_EQs to allow for insertion of FEC parity blocks by the PCS Transmit process (see 142.2.5.4.3). IBI_EQs not required to complete a 256B/257B block at the end of an upstream burst are also discarded by the Input process. All other 72-bit blocks are encoded into 64B/66B blocks. Four 64B/66B blocks are accumulated, scrambled, and transcoded into a single 256B/257B block and copied to the FEC encoder. A single bit indicating the accompanying 256B/257B block has been scrambled and transcoded is appended to the block that is then stored in the InputFifo.

The PCS Input process shall implement the state diagram as depicted in Figure 142–9.

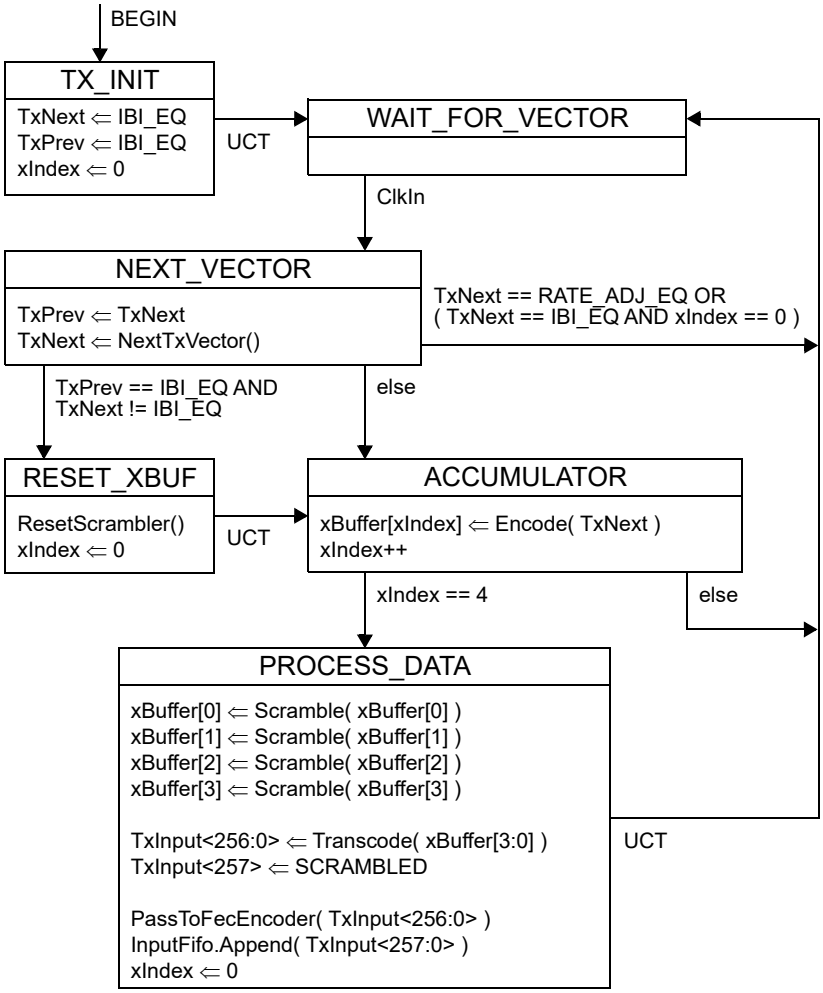

Figure 142–9—PCS Input process state diagram

142.2.5.4.2 PCS Framer process

The PCS Framer process monitors data from the InputFifo and transfers it to the TxFifo, inserting inter-burst idle blocks (IBI258), SyncPattern, parity placeholders (PAR_PLACEHLDR), and EBD258 as appropriate. While the InputFifo is empty, the PCS Framer process appends IBI258 to the TxFifo. When the InputFifo first becomes not empty, indicating the beginning of a burst, the SyncPattern is appended to the TxFifo. Once the complete SyncPattern is appended to the TxFifo, the Framer process begins transferring data from the InputFifo to the TxFifo. When sufficient data for a full FEC payload has been transferred to the TxFifo, or the end of the burst is detected as indicated by an empty InputFifo, the PCS Framer process appends sufficient PAR_PLACEHLDR blocks to the TxFifo to allow insertion of the contents of TxParBuf (FEC codeword parity and FEC codeword delimiter) into the data stream by the PCS Transmit process. Additional FEC codewords are allowed for until the end of the transmission is indicated by an empty InputFifo, at which point the Framer process appends the EBD258 to the TxFifo followed by IBI258.

The PCS Framer process shall implement the state diagram as depicted in Figure 142–10.

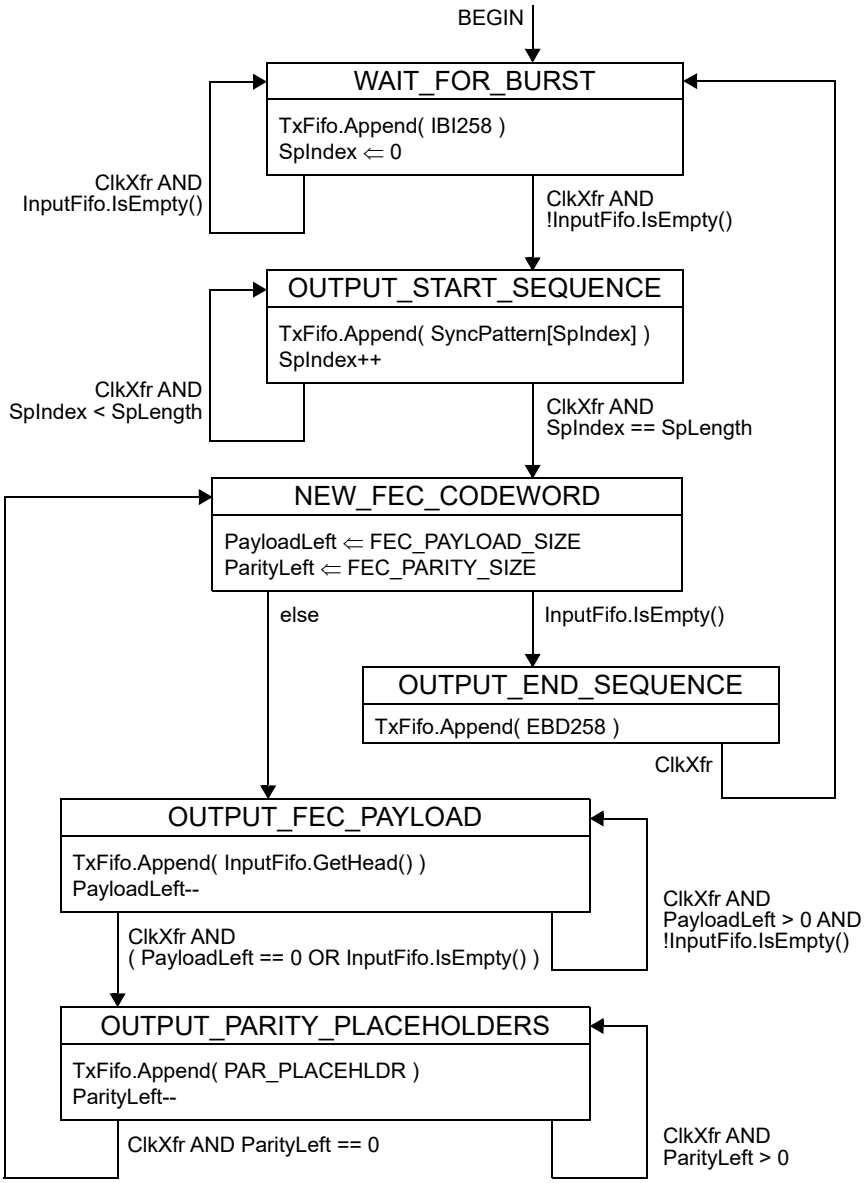

Figure 142–10—PCS Framer process state diagram

142.2.5.4.3 PCS Transmit process

The PCS Transmit process transfers data from the TxFifo or FEC encoder to the PMA. On each transition of the ClkOut to true the Transmit process retrieves one 258-bit block of data from the TxFifo. If the retrieved 258-bit block indicates the start of the burst and the ONU is currently not transmitting, the laser is turned on and data is sent towards the PMA for transmission. If the retrieved 258-bit block indicates the end of the burst and the ONU is currently transmitting, the laser is turned off and end of the burst delimiter is sent towards the PMA for transmission. If the retrieved 258-bit block indicates the FEC parity placeholder, the calculated FEC parity and 10 bits of FEC codeword delimiter are sent towards the PMA for transmission. Otherwise, data from the TxFifo is sent towards the PMA for transmission.

The PCS Transmit process shall implement the state diagram as depicted in Figure 142–11.

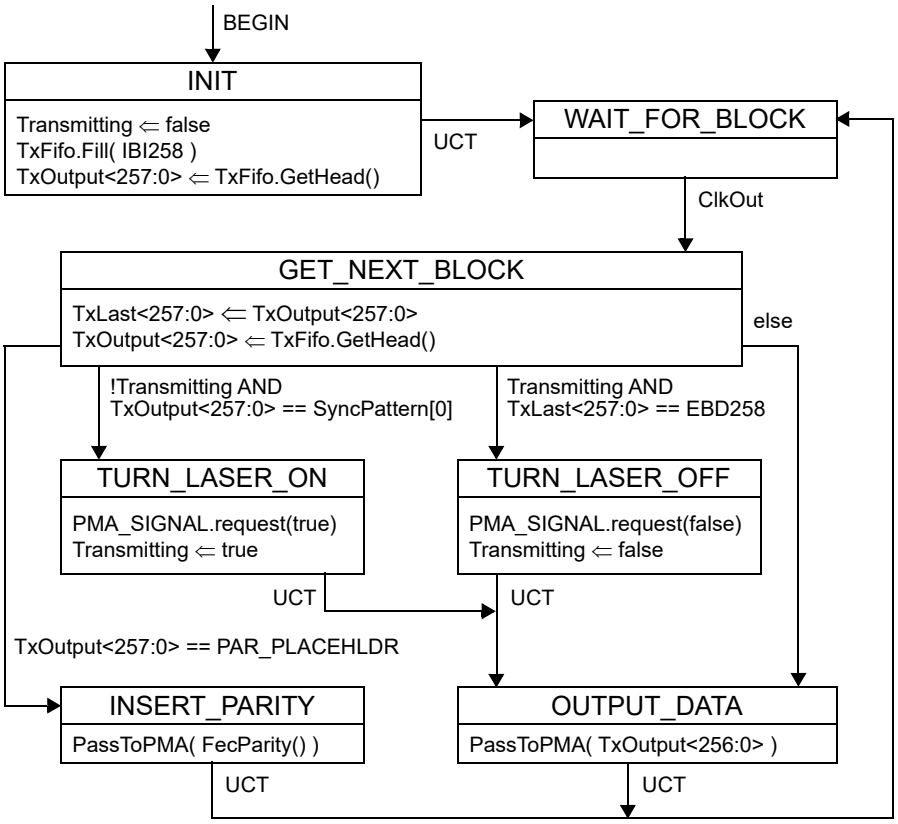

Figure 142–11—PCS Transmit state diagram

142.3 PCS receive data path

This subclause defines the PCS receive data path. In the ONU, the PCS receive data path operates in a continuous mode at a 25.78125 GBd rate. In the OLT, the PCS receive data path operates in burst mode at a 25.78125 GBd rate (25/25G-EPON, 50/25G-EPON, and 50/50G-EPON) or at a 10.3125 GBd rate (25/10G-EPON and 50/10G-EPON). The PCS receive data path includes a mandatory QC-LDPC FEC decoder (see 142.3.1.1).

The functional block diagram for the PCS receive data path is shown in Figure 142–2 and consists of the following processes:

— PCS Synchronizer process (see 142.3.5.4 and 142.3.5.5)
— PCS BER Monitor process (see 142.3.5.6)
— PCS Output process (see 142.3.5.7)

142.3.1 FEC decoder

Figure 142–12 illustrates the receiver QC-LDPC decoder with shortening/puncturing, interleaver/de-interleaver data path.

142.3.1.1 Receive interleaving

See 142.2.4.3.

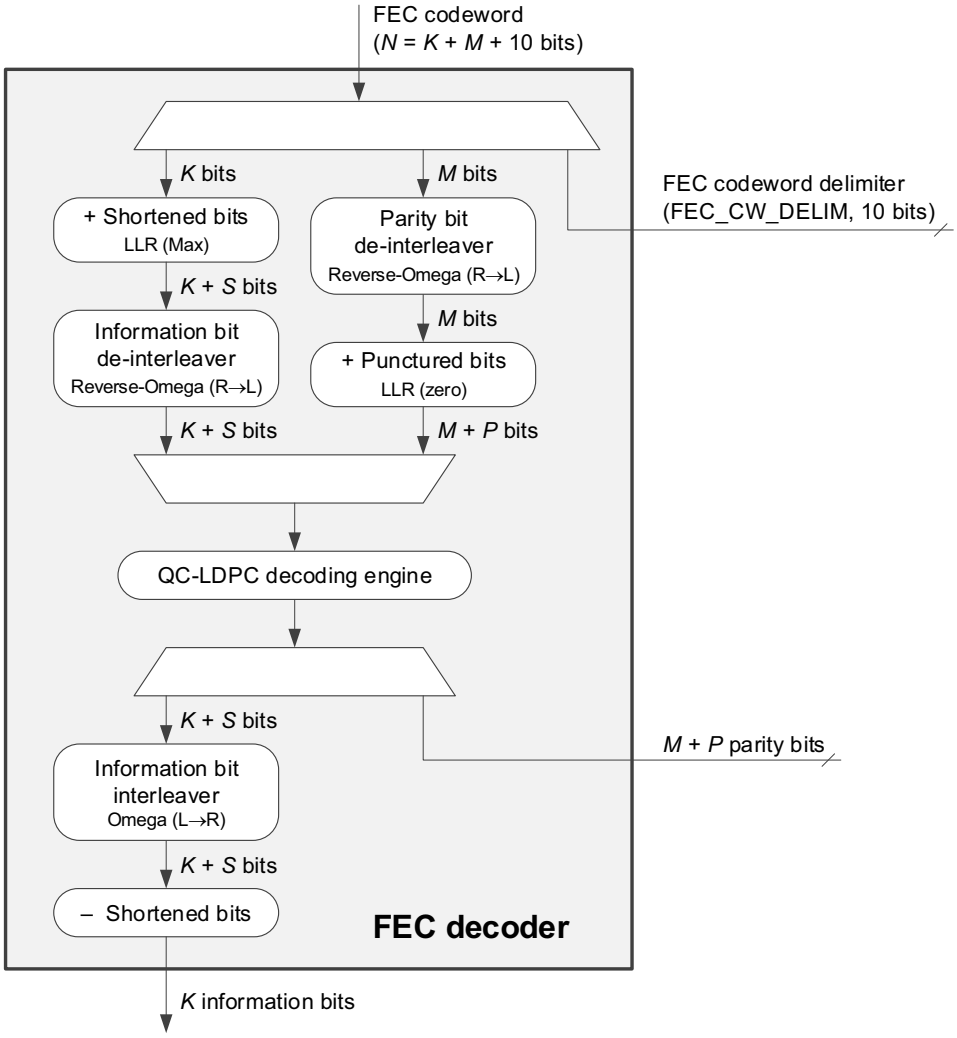

Figure 142–12—FEC decoder

142.3.2 256B/257B to 64B/66B transcoder

The 256B/257B to 64B/66B transcoder converts one scrambled 257-bit block received from the FEC decoder into four consecutive scrambled 66-bit blocks as described in 91.5.3.5 and returns the result to the PCS Output process.

142.3.3 Descrambler

The PCS uses the descrambler specified in 49.2.10.

In the OLT, at the beginning of each burst, the descrambler is reset to a known initialization value (see the definition of ResetDescrambler() function in 142.3.5.3).

142.3.5 Receive data path state diagrams

142.3.5.1 Constants

EBD257
Type: 257-bit block
Description: The EBD257 constant holds the value of the end-of-burst delimiter.
Value: A single 0 bit followed by 0x0F–10–$(01–EE–E8–02–D3–CA)_3$–$(EB–D2–57)_4$

NOTE—The transmission bit order is as defined in SBD257 (see 142.1.3.1).

EBD_TH
Type: Integer
Description: The EBD_TH constant holds the value of the Hamming threshold required to match the end-of-burst delimiter.
Value: 36

FEC_CW_DELIM
See 142.2.5.1

FEC_PAYLOAD_SIZE
See 142.2.5.1

FEC_CW_BIT_SZ
Type: Integer
Description: This constant represents the size of a full-length FEC codeword in bits.
Value: 16 962 (i.e., 257 × 66)

IBI_EQ
See 143.3.3.3.

MATCH_TARGET
Type: Integer
Description: The number of FEC codeword delimiters required to match in order to declare the block alignment in the ONU (i.e., in the continuous reception mode).
Value: 4

PCS_BLK_SZ
Type: Unsigned integer
Description: The PCS_BLK_SZ constant holds the size of the PCS data block.
Value: 257
Unit: bits

RATE_ADJ_EQ
See 143.3.3.3

RATE_ADJ_SIZE
See 143.3.3.3

SBD_TH
Type: Integer
Description: The SBD_TH constant holds the value of the Hamming threshold required to match

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the start-of-burst delimiter.
Value: 60

142.3.5.2 Variables

All variable definitions in this section assume an independent instance of the variable per each enabled receive channel.

BadCwCount
: Counts the number of invalid QC-LDPC codewords within the current BER monitoring interval period.

BEGIN
: See 142.2.5.2

BerMonitorInterval
: Indicates the length of the interval window period associated with the QC-LDPC BER Monitor in units of QC-LDPC codewords (see 45.2.3.43). This value is reflected in MDIO register 3.80.

BerThreshold
: Indicates the threshold value of invalid QC-LDPC codeword errors within the QC-LDPC BER Monitor function. At the end of each monitor interval period, HiBer is updated. The value of BerThreshold is reflected in MDIO register 3.82

Block257b
: Type: 257-bit block
Description: The Block257b variable temporarily holds one 257-bit block removed from the head of OutputFifo.

Block66b
: Type: 66-bit block
Description: The Block66b variable temporarily holds one descrambled 66-bit block.

Block72b
: Type: 72-bit block
Description: The Block72b variable temporarily holds the value being passed to the xMII.

CwAvailable
: Boolean variable that is set true when a new QC-LDPC codeword is available for testing by the BER Monitor process and set to false when the WAIT_FOR_CODEWORD state is entered. A new QC-LDPC codeword is available for testing by the BER Monitor process when the ONU Synchronizer process has accumulated enough blocks from the PMA to evaluate the next QC-LDPC codeword (see Figure 142–15).

CwLeft
: Counts the remaining number of QC-LDPC codewords within the current BER monitoring interval.

CwValid
: Boolean indication that is set true if a received QC-LDPC codeword is valid. As an example, a QC-LDPC codeword is valid if and only if all parity checks of the QC-LDPC code are satisfied thereby terminating iterations without exceeding the maximum count (e.g., 15). The specific method for evaluating codeword validity is implementation dependent within the QC-LDPC decoder and outside the scope of this standard.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

HiBer

Boolean variable that is asserted true if BadCwCount reaches or exceeds BerThreshold QC-LDPC codeword errors within one BER monitor interval period, otherwise set to false. The value of HiBer is reflected in MDIO register 3.81.

MatchCount

Type: Integer

Description: This counter tracks the number of consecutive successful detections of FEC codeword delimiters (FEC_CW_DELIM) while the ONU is not synchronized to the proper 257-bit block boundary.

OutputFifo[]

Type: Array of 257-bit blocks

Description: The OutputFifo buffer holds one FEC codeword payload after it has been processed by the FEC decoder. The OutputFifo supports FIFO access operations as defined in 142.1.1.6.

PayloadLeft

Type: Integer

Description: This variable holds the number of EQs remaining until one maximum-length FEC codeword payload has been sent to the xMII.

PersistentFecFail

Type: Boolean

Description: This variable is set to true if the FEC decoder is unable to correct all errors in the three FEC codewords most recently received on a given channel. Otherwise, this variable is set to false. In the OLT, the PersistentFecFail value is reset when SignalFail becomes true, or the EBD is detected, i.e., the uncorrectable FEC codewords from the previous burst do not result in PersistentFecFail becoming true during the next burst.

RateAdjLeft

Type: Integer

Description: This variable holds the number of EQs remaining to be generated in the PCS Output process to fill the gap left by the removal of FEC codeword parity data from the current FEC codeword.

RxCwBuf[]

Type: An array of 257-bit blocks

Description: The RxCwBuf is a buffer capable of storing one full FEC codeword. The RxCwBuf supports FIFO access operations as defined in 142.1.1.6.

RxInput

Type: 257-bit block

Description: The RxInput is a buffer containing the 257 bits most recently received from the PMA sublayer on a given channel.

RxXcBuf[3:0]

Type: Array of four 66-bit blocks

Description: This buffer holds four 66-bit blocks resulting from the decoding of a 257-bit block.

SBD257

Type: 257-bit block

Description: The SBD257 variable represents the start-of-burst delimiter, and its value is equal to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SP3 for the most recently provisioned synchronization pattern (see 142.1.3.1).
Value: see 142.1.3.1

SignalFail
Type: Boolean
Description: This Boolean variable is set based on the most recently received value of PMA_SIGNAL.indication(SIGNAL_OK) received on a given channel. It is true if the value of SIGNAL_OK was FAIL and false if the value was OK.

XcIndex
Type: Integer
Description: The XcIndex variable is an index to the RxXcBuf array and has a value ranging between 0 and 3, inclusive.

142.3.5.3 Functions

Decode257b(blk)
Description: This function accepts one 256B/257B encoded block blk and transcodes it into four 64B/66B encoded blocks. The result is returned as an array of four 66-bit blocks.

Decode66b(blk)
Description: This function accepts one 64B/66B encoded block blk and performs the decoding operation as described in 49.2.11 and Figure 49–17. The returned value is a 72-bit block.

Descramble(blk)
Description: This function accepts one 66-bit block blk and performs the descrambling operation on the 64-bit payload of the block, as described in 49.2.10. The returned value is a descrambled 66-bit block.

PassToFecDecoder(cw)
Description: The PassToFecDecoder function passes one complete FEC codeword cw to the FEC decoder. The FEC codeword may be full-length or shortened. The codeword length is intrinsic to the parameter cw.

MatchFound(value1, value2, threshold)
Description: This function compares bit by bit its arguments value1 and value2 and returns a Boolean true if the number of bits that are different is less or equal to the threshold, otherwise the function returns false.

OutputBlock(eq)
Description: This function accepts one 72-bit block eq and outputs two 36-bit blocks over the xMII. This is a blocking function and the control is not returned to the calling state until after the second 36-bit block is sent.

ResetDescrambler()
Description: This function resets the descrambler to the value of $0x3\text{-}(FF)_7$, i.e., each of the bits S0 through S57 of the descrambler shift register is set to 1 (see Figure 49–10).

Shift(buffer, *n*)
Description: This function receives 257-bit blocks from the PMA via the PMA_UNITDATA.indication(rx_code_group<256:0>) primitive and inserts *n* new bits at the end of the FIFO buffer, while removing the same number of old bits at the head of the buffer. The Shift() function is blocking and its execution takes exactly *n* bit times at the given receiving line rate.

142.3.5.4 OLT Synchronizer process state diagram

The OLT Synchronizer process is responsible for receiving unaligned 257-bit blocks from the PMA sublayer and aligning these blocks to the correct 257-bit block boundary. This process hunts for SBD257 and EBD257 values, allowing for a certain Hamming distance (see SBD_TH and EBD_TH). The 257-bit blocks that are received between the SBD and the EBD are accumulated in the RxCwBuf buffer. When a complete full-length or shortened FEC codeword is stored in the RxCwBuf, the buffer content is passed to the FEC decoder function (see 142.3.1).

The OLT shall implement an instance of the Synchronizer process as depicted in Figure 142–14 for every enabled receive channel.

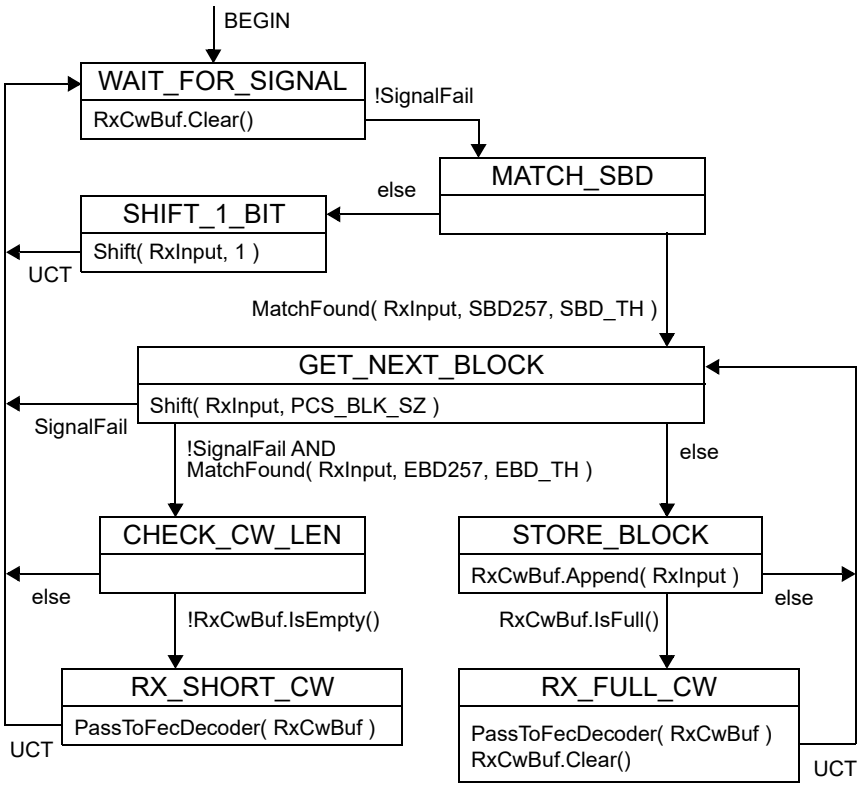

Figure 142–14—OLT Synchronizer process state diagram

142.3.5.5 ONU Synchronizer process state diagram

The ONU Synchronizer process is responsible for receiving unaligned 257-bit blocks from the PMA sublayer and aligning these blocks to the correct 257-bit block boundary. This process hunts for 10-bit FEC codeword delimiters FEC_CW_DELIM. The delimiter is expected to have the exact match and the block alignment is declared when the FEC_CW_DELIM values are matched MATCH_TARGET times and are exactly one FEC codeword size apart.

The received blocks are accumulated in the RxCwBuf buffer. When a complete full-length FEC codeword is stored in the RxCwBuf, the buffer content is passed to the FEC decoder function (see 142.3.1). In the ONU receive path, shortened FEC codewords are disallowed.

The ONU shall implement an instance of the Synchronizer process as depicted in Figure 142–15 for every enabled receive channel.

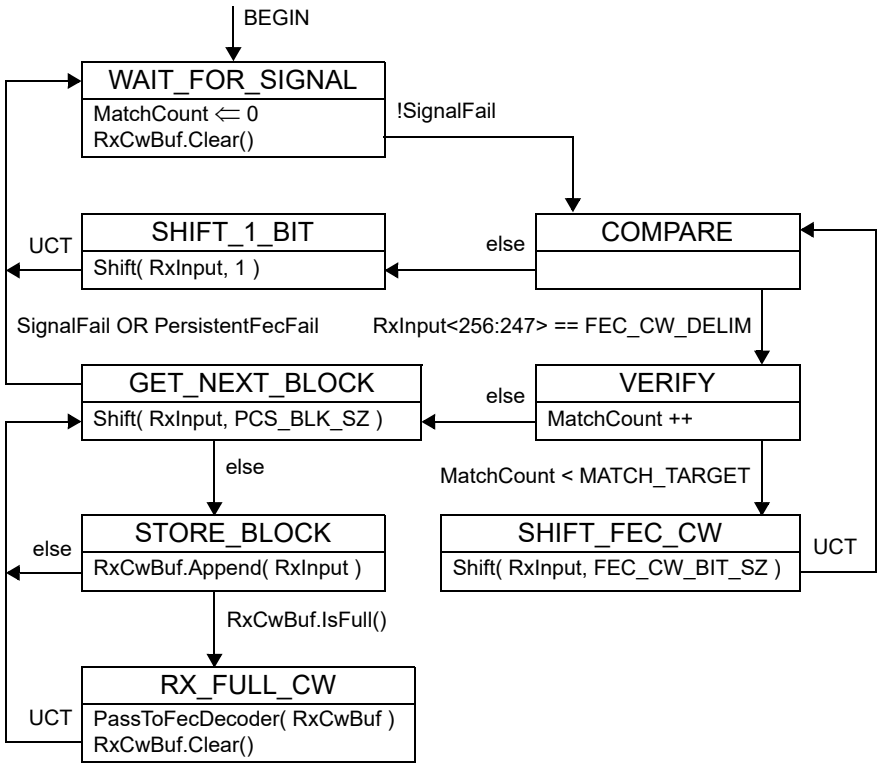

Figure 142–15—ONU Synchronizer process state diagram

142.3.5.6 PCS ONU BER Monitor process

When the ONU Synchronizer process has obtained block synchronization, the QC-LDPC BER Monitor process monitors the signal quality, asserting HiBer if a count of QC-LDPC parity errors reaches BerThreshold within the timer interval. The ONU shall implement an instance of the QC-LDPC BER Monitor shown in Figure 142–16 for each active downstream channel.

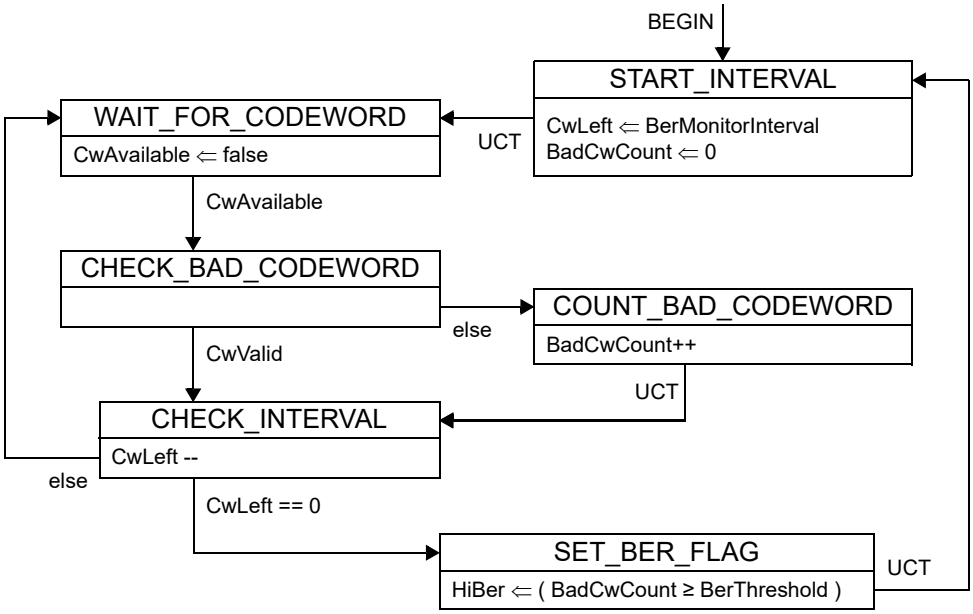

Figure 142–16—QC-LDPC BER Monitor state diagram (ONU only)

142.3.5.7 PCS Output process

The PCS Output process receives corrected information bits from the FEC decoder. The FEC decoder outputs an entire payload of an FEC codeword into the OutputFifo buffer. The FEC codeword payload consists of 56 257-bit blocks, however, in the OLT, the payload of a last codeword in a burst may contain fewer than 56 blocks.

The PCS Output process converts the 257-bit blocks into EQs by first transcoding each 257-bit block into four 66-bit blocks, then descrambling each block, and finally, decoding each 66-bit block into a 72-bit block. The 72-bit blocks are passed to xMII for transfer to the MCRS.

The PCS shall implement an instance of the Output process as depicted in Figure 142–17 for every enabled receive channel.

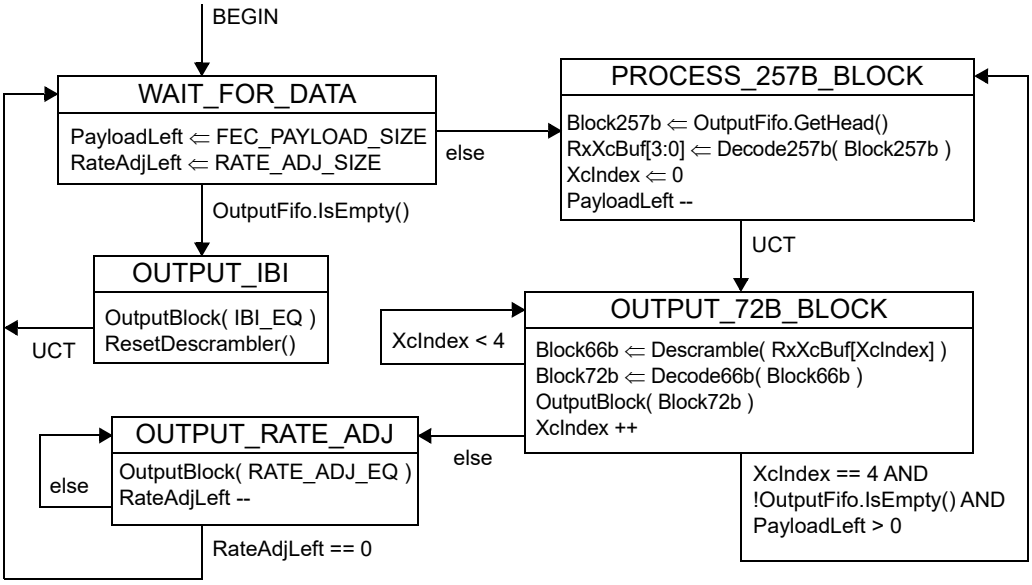

Figure 142–17—PCS Output process state diagram

142.4 Nx25G-EPON PMA

The PMA adapts the serial PMD service interface (PMD_UNITDATA, see 141.3.3 and 141.3.4) to the 257-bit wide interface of the PCS (PMA_UNITDATA, see 142.4.1). Where Nx25G-EPON operates over multiple channels, the PMA sublayer includes multiple identical instances of the transmit data path and/or the receive data path.

In the downstream direction (from the OLT to the ONUs), the PMA includes a differential encoding option (see 142.4.2 and 142.4.3). This encoding technique facilitates the use of lower bandwidth receivers at the ONUs.

142.4.1 Service Interface

The PMA provides a service interface to the PCS. These services are described in an abstract manner and do not imply any particular implementation. The PMA service interface supports the exchange of 257-bit single data-unit vectors between PCS entities. The PMA converts 257-bit single data-unit vectors into bits and passes these to the PMD, and vice versa.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following primitives are defined:

— PMA_UNITDATA[*i*].request(tx_code_group<256:0>)
— PMA_UNITDATA[*i*].indication(rx_code_group<256:0>)
— PMA_SIGNAL[*i*].request(tx_enable)
— PMA_SIGNAL[*i*].indication(SIGNAL_OK)

where "[*i*]" represents the PMA Channel: 0 or 1.

142.4.1.1 PMA_UNITDATA[*i*].request

This primitive defines the transfer of data (in the form of 257-bit single data-unit vectors) from the PCS to the PMA by the PCS Transmit process, see 142.2.

142.4.1.1.1 Semantics of the service primitive

PMA_UNITDATA[*i*].request(tx_code_group<256:0>)

Data is conveyed to PMA_UNITDATA[*i*].request() as described in the PCS Transmit state diagram via the PassToPMA function, see Figure 142–11.

142.4.1.1.2 When generated

The PCS continuously sends tx_code_group<256:0> single data-unit vectors to the PMA according to the PMA transmit clock at either (25.78125 / 257) GHz or (10.3125 / 257) GHz as defined in 142.4.4.

142.4.1.1.3 Effect of receipt

Upon receipt of this primitive, the PMA generates a serial bit stream for conveying data to the PMD using PMD_UNITDATA[*i*].request(tx_bit), see 141.3.1.2.

142.4.1.2 PMA_UNITDATA[*i*].indication

This primitive defines the transfer of data (in the form of 257-bit single data-unit vectors) from the PMA to the PCS. PMA_UNITDATA[*i*].indication is used by the PCS receive path processes, see 142.3.5.

142.4.1.2.1 Semantics of the service primitive

PMA_UNITDATA[*i*].indication(rx_code_group<256:0>)

The data conveyed by PMA_UNITDATA[*i*].indication is the rx_code_group<256:0> parameter that is used in the Shift() function (see 142.3.5.3). Shift() is used in the OLT Synchronizer process, see Figure 142–14, and in the ONU Synchronizer process, see Figure 142–15.

142.4.1.2.2 When generated

The PMA continuously sends rx_code_group<256:0> single data-unit vectors to the PCS according to the PMA transmit clock at either (25.78125 / 257) GHz or (10.3125 / 257) GHz as defined in 142.4.4.

142.4.1.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

142.4.1.3 PMA_SIGNAL[*i*].request

This primitive is used to turn the laser on and off at the PMD sublayer. In the OLT, this primitive shall always take the value ON. In the ONU, the value of this variable is controlled by the PCS Transmit function, see Figure 142–11.

142.4.1.4 PMA_SIGNAL[*i*].indication

PMA_SIGNAL[*i*].indication is generated by the PMA receive process to propagate the loss of optical signal from the PMD sublayer to the PMA client.

142.4.1.4.1 Semantics of the service primitive

PMA_SIGNAL[*i*].indication (SIGNAL_OK)

The SIGNAL_OK parameter can take one of two values: OK or FAIL. A value of FAIL denotes that invalid data is being presented to the PMA client. A value of OK does not guarantee valid data is being presented to the PMA client.

142.4.1.4.2 When generated

The PMA generates a PMA_SIGNAL[*i*].indication primitive to the PMA client whenever there is change in the value of the SIGNAL_OK parameter.

142.4.1.4.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

142.4.2 Differential encoder

Differential encoding as shown in Figure 142–18 shall be implemented in the transmit path of the OLT PMA. The use of differential encoding is optional. Setting the MDIO control bit 1.29.15 (see 45.2.1.27.1) to a one enables the differential encoding.

X_i = Input serial bit stream from OLT PCS FEC encoder
Y_i = Output serial bit stream to OLT PMD

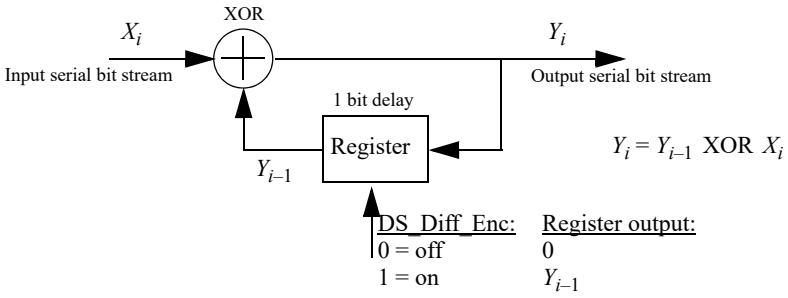

Figure 142–18—Differential encoding

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

142.4.3 Differential decoder

Differential decoding shall be implemented in the receive path of the ONU PMA as shown in Figure 142–19. The ONU shall implement automatic detection of receive path differential encoding, and switch in the decoder as appropriate. The DS_Diff_Enc bit is mapped to Clause 45 bit 1.29.15 (see 45.2.1.27.1). This bit is controlled by a local differential encoding detection function (outside the scope of this standard).

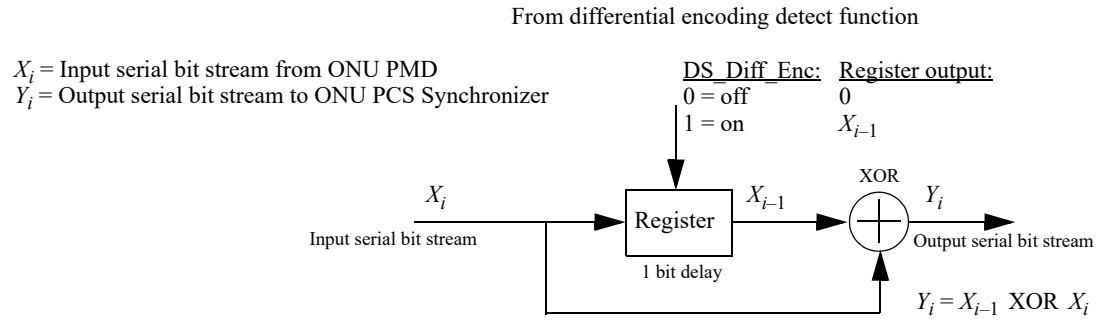

Figure 142–19—Differential decoding

142.4.4 PMA transmit clock

The data conveyed by PMA_UNITDATA.request() is a 257-bit vector representing a single data unit, which has been prepared for transmission by the PMA client. For the PMA devices transmitting at 25.78125 GBd, the PMA transmit clock is equal to (25.78125 / 257) GHz. For the PMA devices transmitting at 10.3125 GBd, the PMA transmit clock is equal to (10.3125 / 257) GHz. In PMA devices supporting multiple transmit channels, the transmit clocks for all channels are phase aligned.

142.4.4.1 Loop-timing specifications for ONUs

ONUs shall operate at the same time basis as the OLT, i.e., the ONU PMA transmit clock tracks the ONU PMA receive clock. Jitter transfer masks are defined in 141.6.2. For the ONUs supporting 10G transmission (i.e., 25/10G-EPON and 50/10G-EPON ONUs), the PMA transmit clock is derived from the PMA receive clock by dividing the latter by 2.5. In the ONUs supporting multiple receive channels, the PMA transmit clock tracks the received clock of the active (enabled) receive channel with the lowest index.

142.4.5 T_{CDR} measurement

142.4.5.1 Definitions

Clock and data recovery (CDR) lock time (denoted T_{CDR}) is defined as a time interval required by the receiver to acquire phase lock on the incoming data stream. T_{CDR} is measured as the time elapsed from the moment when the electrical signal after the PMD at TP8, as illustrated in Figure 141–3, reaches the conditions specified in 141.7.14 for receiver settling time to the moment when the signal phase is recovered and jitter is maintained for an input signal with BER of no worse than 10^{-2}.

A PMA instantiated in an OLT shall become synchronized at the bit level within 400 ns (T_{CDR}) after the appearance of a valid synchronization pattern (as defined in 142.1.3) at TP8.

142.4.5.2 Test specification

The test of the OLT PMA receiver T_{CDR} time assumes that there is an optical PMD transmitter at the ONU with a well-known T_{on} time as defined in 141.7.13, and an optical PMD receiver at the OLT with a

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

well-known $T_{rx_settling}$ time as defined in 141.7.14. After the T_{on} + $T_{rx_settling}$ time, the parameters at TP8 reach within 15 % of their steady-state values.

Set up the test ONU/OLT test system for 10^{-2} BER. Assuming a 3-zone SP1, SP2, and SP3 upstream ONU burst structure as shown in Figure 142–3, program the ONU SP1 TX pattern length so that the SP1 pattern ends at the precise end of the well-known OLT receiver settling time (within one 257-bit block of SP1, or ~10 ns granularity). Starting with the SP2 pattern of zero length (zero 257-bit blocks), test for SP3 detection. If the detection fails, increase the SP2 length by one and repeat the test until SP3 pattern is detected reliably. The number of 257-bit SP2 blocks times the length of each block is the T_{CDR} time, with a margin of error of one 257-bit block time. To reduce hysteresis, increase the number of 257-bit SP2 blocks several hundred nanoseconds beyond this point (20 to 30 additional 257-bit SP2 blocks), and then start decrementing the number of 257-bit SP2 blocks, testing for the SP3 detection at each decrement, until the SP3 SBD is not detected at the OLT. If the SP2 block time counting both forward and backward is less than the specified T_{CDR} maximum time of 400 ns, then the CDR performance meets the requirement.

142.5 Protocol implementation conformance statement (PICS) proforma for Clause 142, Physical Coding Sublayer and Physical Media Attachment for Nx25G-EPON[236]

142.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 142, Physical Coding Sublayer and Physical Media Attachment for Nx25G-EPON, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

142.5.2 Identification

142.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

142.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 142, Physical Coding Sublayer and Physical Media Attachment for Nx25G-EPON
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[236]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

143. Multi-Channel Reconciliation Sublayer

143.1 Overview

This clause describes the Multi-Channel Reconciliation Sublayer (MCRS) which enables multiple MACs to interface with multiple xMIIs. Figure 143–1 shows the relationship between this MCRS and the ISO/IEC OSI reference model. Generally, single-channel RS specifications enabled a single MAC to interface to a single PHY in point-to-point (P2P) links, or multiple MACs to interface to a single PHY in P2MP links (e.g., EPON architectures). This concept is expanded in this clause to allow single or multiple MACs to interface with multiple PHYs in either P2P or P2MP applications.

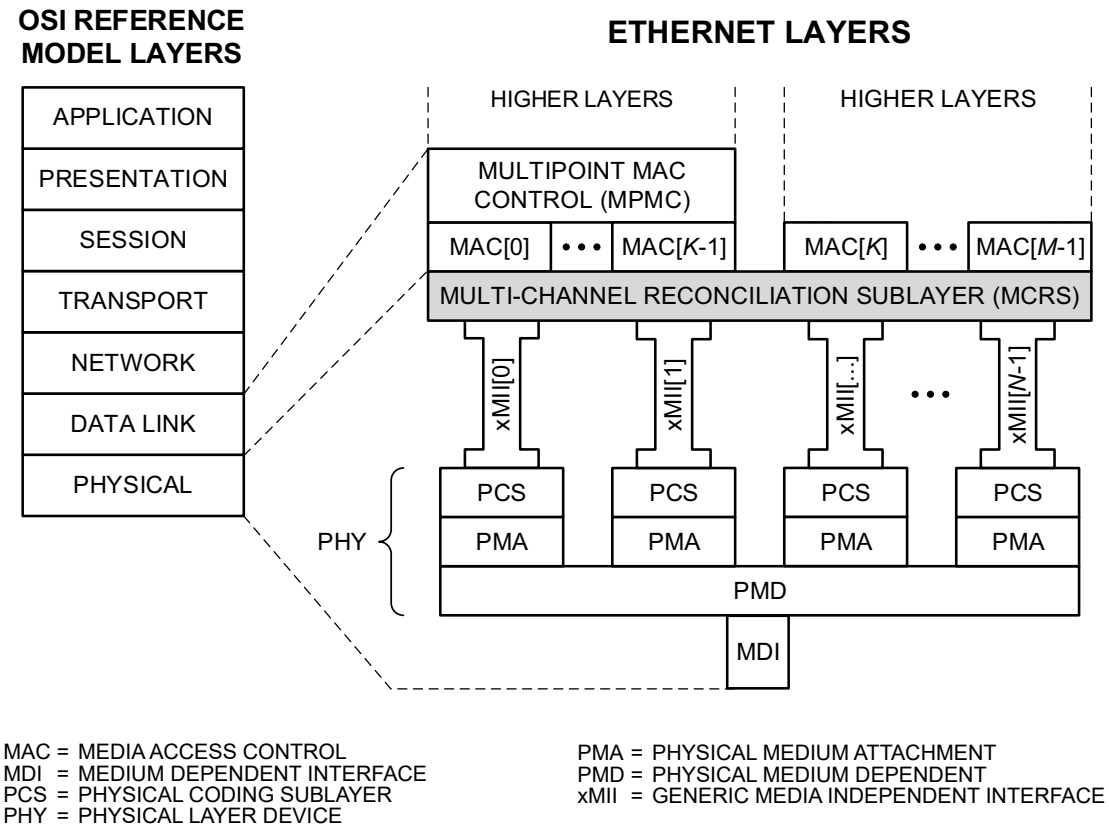

Figure 143–1—Relationship of MCRS to the OSI reference model

The MCRS adapts the bit-serial protocols of the MAC to the parallel format of the Physical Coding Sublayer (PCS) service interface. This clause defines an MCRS as an interface between the MAC sublayer and one or more xMIIs. In this clause, xMII is used as a generic term for the Media Independent Interfaces for implementations of 10 Gb/s and above. For example: for 10 Gb/s implementations, it is called XGMII; for 25 Gb/s implementations, it is called 25GMII. Though the xMII is an optional logical interface between the MAC sublayers and the Physical Layer devices, it is used extensively in this clause as a basis for specification.

143.2 Summary of major concepts

The following are the major concepts of the MCRS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) The MCRS transmission is controlled by a higher layer (e.g., Multipoint MAC Control sublayer defined in Clause 144) via the use of MCRS_CTRL primitives, which indicate envelope start time, durations, and transmission channels.
b) The MCRS establishes a temporary binding of a single MAC instance to one or more xMII instances with all xMIIs operating at the same rate.
c) In the transmit direction, the MCRS converts the MAC serial data stream into the parallel data paths of multiple xMIIs servicing separate PHYs.
d) In the receive direction, the MCRS maps the signal sets provided by the xMIIs to the PLS service primitives of individual MACs.
e) Each direction of data transfer is independent and serviced by data, control, and clock signals.
f) The MCRS generates continuous data or control characters in the transmit path and expects continuous data or control characters in the receive path.

143.2.1 Concept of a logical link and LLID

In point-to-multipoint architectures, such as EPON, the transmitting and receiving stations may include multiple MAC instances. Such architectures are best viewed as a collection of logical point-to-point and/or point-to-multipoint links. A point-to-point logical link connects a single MAC instance at the transmitting station to a single MAC instance at the receiving station. A point-to-multipoint logical link takes advantage of the P2MP topology and connects a single MAC instance at the transmitting station to multiple MAC instances at multiple receiving stations. The transmitting and receiving stations may be logically connected with each other via multiple logical links.

A logical link is created in the MCRS (below the MAC) by tagging each frame (or frame fragment) with a logical link identifier (LLID) value. The MCRS transmit function inserts a specific LLID value depending on which instance of MAC has sourced the frame. The MCRS receive function directs the received frame (or frame fragment) to the specific MAC instance mapped to this LLID value, or to multiple MAC instances, in case of a point-to-multipoint logical link. The concept of a logical link is further defined in 144.1.1.2.

143.2.2 Concept of an MCRS channel

An MCRS channel is a single unidirectional transmission path through the MCRS. The number of channels contained within an MCRS generally corresponds to the number of xMII instances connected to the MCRS. Thus, an MCRS implementation that connects to *N* xMII instances contains *N* transmit MCRS channels and *N* receive MCRS channels. Some architectures (e.g., EPON) allow an xMII interface to only implement either receive or a transmit data path. In such architectures, the number of receive and transmit MCRS channels may be different. For example, in a 50/10G-EPON OLT, there are two transmit MCRS channels attached to two 25GMIIs and one receive MCRS channel attached to one XGMII.

143.2.3 Binding of multiple MACs to multiple xMII instances

The key function of the MCRS is the dynamic binding of a PLS_DATA[*m*] interface to one or more MCRS channels (*m* represents the index of the MAC instance). The dynamic nature of the binding means that such a binding exists only for a predetermined interval of time during which a given MAC instance is expected to transmit or receive data. After that time, the binding no longer exists, and a different MAC instance may bind to the same MCRS channels.

The dynamic binding of MAC instances to MCRS transmit channels is controlled by the MCRS_CTRL.request() primitive described in 143.3.1.2.1. The dynamic binding of MAC instances to receive MCRS channels is determined by the LLID value of the incoming data.

143.2.4 Transmission and reception over multiple MCRS channels

143.2.4.1 Transmission unit

Within the MCRS, the basic unit of transmission is the envelope quantum (EQ). One EQ is represented by a 72-bit block consisting of 64 data bits and eight control bits. For 36-bit wide xMIIs, such as 25GMII, an EQ is mapped to two successive xMII transfers as shown in Figure 143–2.

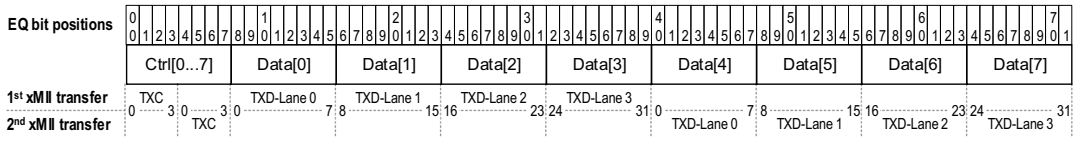

Figure 143–2—Envelope quantum (EQ) format

143.2.4.2 Transmission envelopes

The MCRS encapsulates data transmitted by a MAC instance in transmission envelopes. A transmission envelope represents a continuous transmission by a specific MAC instance (LLID) on a specific MCRS channel. A transmission envelope is transmitted on a single MCRS channel. In a system with a single channel an envelope includes one or more data frames and may contain at most two partial frames (one at the beginning and one at the end of the envelope) and any number of non-fragmented frames. In systems with multiple channels, envelopes may overlap (see 143.2.5) and a frame may be striped over multiple channels with each channel transporting parts of this frame. However, at the conclusion of the overlapped transmission, only a single frame may remain fragmented.

143.2.4.3 Envelope headers

Each transmission envelope begins with an envelope header (see Figure 143–3). The envelope header consists of multiple fields, such as LLID, Envelope Length, EnvType flag, and other fields defined in 143.3.2.

The LLID field identifies a specific logical link.

The size of the envelope header is exactly one EQ. The envelope header includes the Envelope Length field that shows the length of the entire envelope in units of EQ. The envelope header itself is counted as part of the envelope, therefore the minimum value of the Envelope Length field is one.

There are two distinct types of envelope headers; an envelope start header (ESH) and an envelope continuation header (ECH).

The ESH is inserted into the transmission stream at the beginning of every envelope, while no data is being taken from the corresponding MAC instance. At the receiving end, the ESH is processed by the MCRS and then discarded and no bits are passed to the corresponding MAC instance.

The ECH is inserted into the transmission stream in place of a data frame preamble. The length field of the ECH shows the residual length of the envelope. At the receiving end, the ECH is replaced with a normal frame preamble, which is passed to the corresponding MAC instance.

To distinguish the ESH and ECH, the envelope header includes a field called the EnvType flag. In ESH, the EnvType flag carries the value of 1 and in ECH, the flag carries the value of 0. Figure 143–3 illustrates a

transmission sequence for a single LLID *L* transmitting three frames (the first and the last frames are fragments). The format of the envelope header and field definitions are specified in 143.3.2.

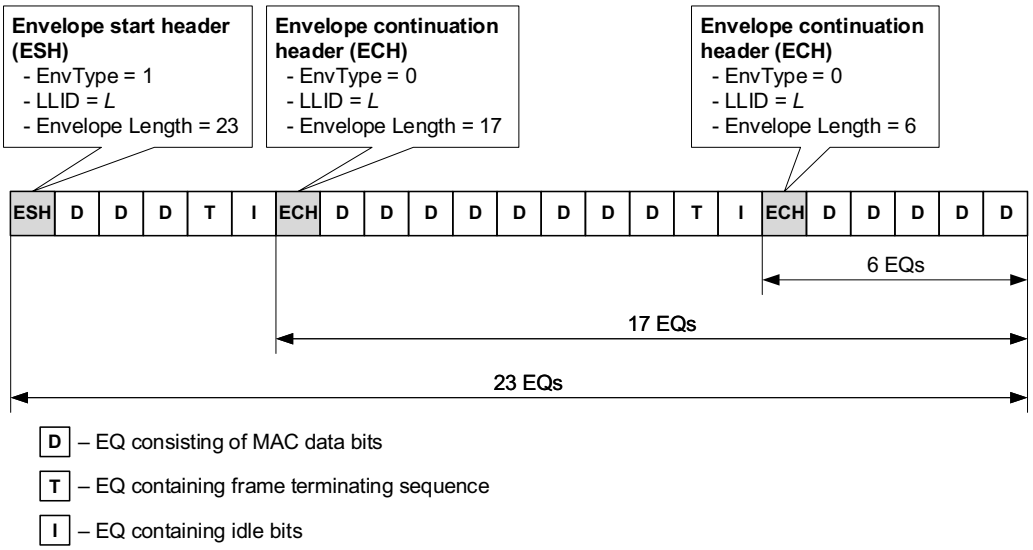

Figure 143–3—An illustration of transmission sequence consisting of three frames

143.2.4.4 Interpacket gap adjustment

Multi-lane xMIIs, such as 25GMII, require the alignment of the Start control character (first octet of preamble) to lane 0. Generally, a technique called Deficit Idle Count is used to accomplish this task (see 46.3.1.4).

However, because the MCRS replaces the frame preamble with an ECH, there is an additional requirement for the Start control character to be aligned to octet 0 of an EQ, such that the entire preamble occupies exactly one EQ and is not split across two consecutive EQs. To achieve such alignment, rather than maintaining a deficit idle count, the interpacket gap (IPG) is either unchanged or reduced, but is not expanded. The IPG may be reduced by up to seven octets from its default size of 96 bits. For back-to-back data frames, the minimum guaranteed IPG is five octets.

The exact size of the IPG depends on the length of the previous data frame (for the case of back-to-back frames). Figure 143–4 illustrates the IPG reduction for all possible positions of the end of frame character. The default IPG generated by the MAC and the reduced IPG are highlighted.

The minimum IPG of five octets is consistent with the requirements of 46.2.1 for XGMII (and hence applicable to 25GMII). Since the IPG either remains unchanged or is reduced, in order to prevent the MAC data rate from exceeding the specified maximum limit, the MCRS provides a rate adjustment mechanism, whereby a MAC is paused for a predefined duration of time at a predefined repeating interval.

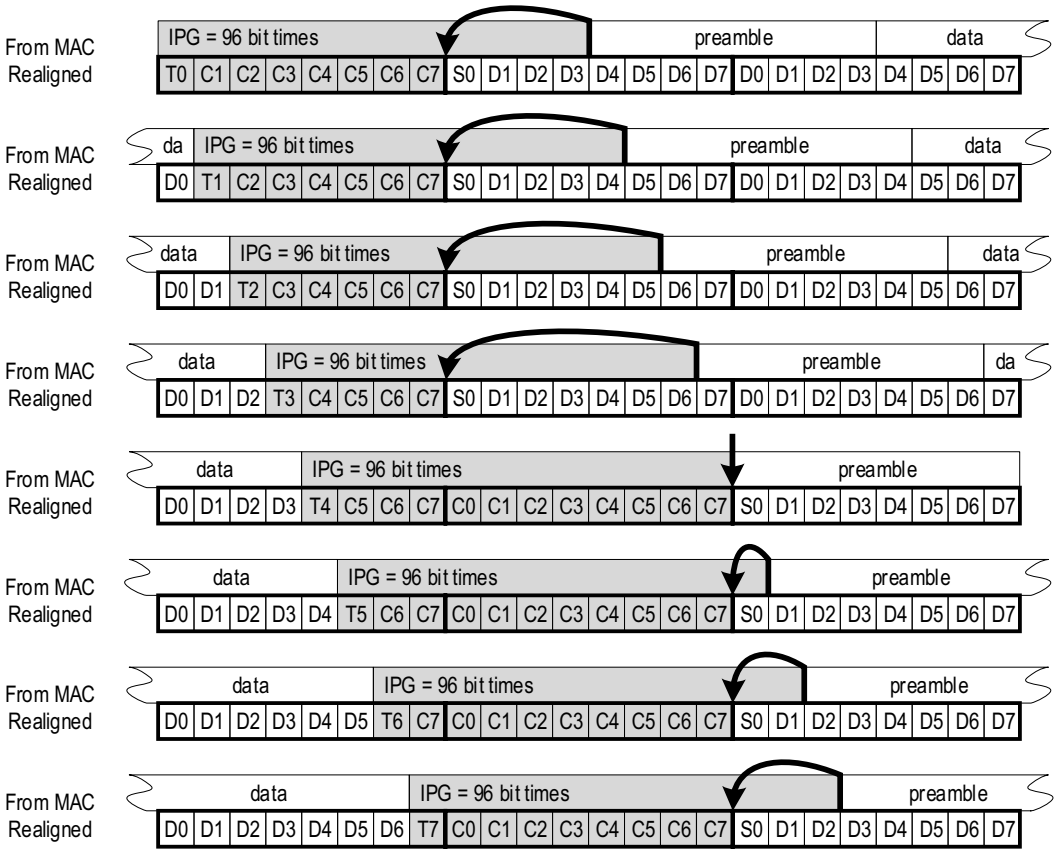

Figure 143–4—An illustration of Start control character alignment to octet 0

143.2.5 Dynamic channel bonding

If the PLS_DATA[*m*] interface is bound to a single MCRS channel that is connected to an xMII instance, the corresponding MAC instance is able to transmit and receive at a data rate corresponding to that xMII data rate. For example, if the MCRS sublayer is connected to a 25GMII, that MAC instance is able to transmit and receive at 25 Gb/s.

However, in a system that supports multiple MCRS channels (i.e., MCRS is connected to multiple xMII instances), a single PLS_DATA[*m*] interface may be simultaneously bound to N_{TX} MCRS transmit channels and N_{RX} MCRS receive channels, where N_{TX} may not equal N_{RX}. In this case, again assuming the 25GMII, the corresponding MAC instance supports the transmit data rate of $N_{TX} \times 25$ Gb/s and the receive data rate of $N_{RX} \times 25$ Gb/s.

The channel bonding takes place when an LLID is assigned transmission envelopes on more than one channel. Such envelopes may happen to activate at the same time and to have the same duration, as illustrated in Figure 143–5 for LLID A. But most often the envelopes are not mutually aligned and just partially overlap as shown for LLID B.

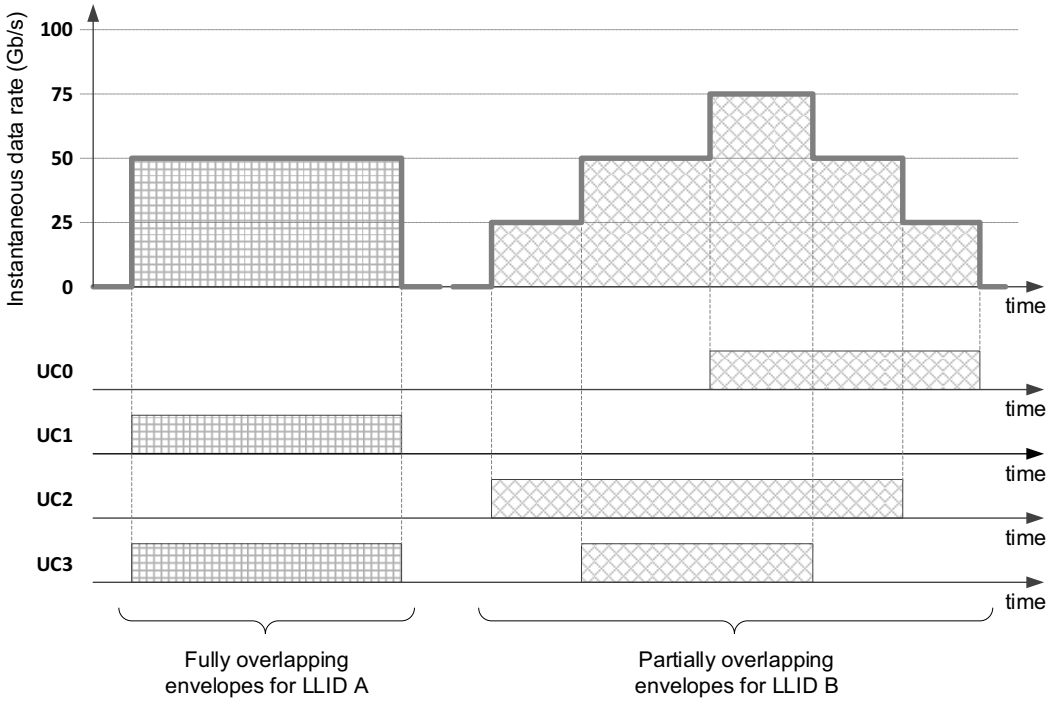

Figure 143–5—Full or partial envelope overlap and the resulting instantaneous data rate

An LLID (i.e., a MAC instance) that is given two or more overlapping envelopes on several MCRS channels is able to seamlessly increase its transmission data rate to the aggregated data rate of all the MCRS channels with the overlapping envelopes. This is referred to as dynamic channel bonding and it gives the system an ability to achieve a higher instantaneous transmission or reception rate than is available for any single MCRS channel. For example, a MAC instance connected to an MCRS with four channels of 25 Gb/s each can achieve an instantaneous transmission rate of 25 Gb/s, 50 Gb/s, 75 Gb/s, or 100 Gb/s by varying, in real time, the number of channels that are bonded to send data from a single LLID.

143.2.5.1 LLID transmission over multiple MCRS channels

The dynamic channel bonding is achieved by interleaving data belonging to a single LLID (i.e., data from a single MAC instance) over multiple envelopes on multiple MCRS channels. Figure 143–6 illustrates a dynamic channel bonding example based on the partially overlapping envelopes scenario in Figure 143–5. Each EQ is transmitted on the channel that has the earliest transmission availability. If there are multiple such channels, the one with the lowest channel index is selected. In other words, the overlapping envelopes are filled with EQs in the increasing order of MCRS channel index.

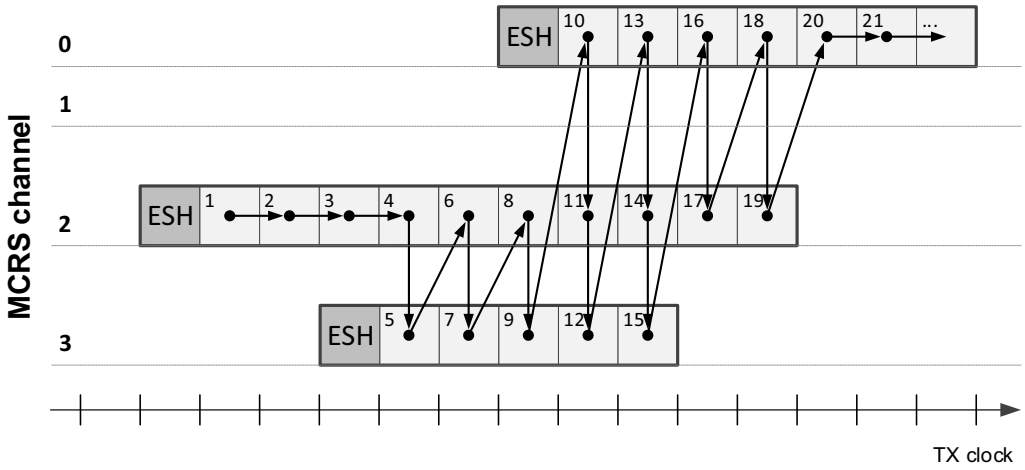

Figure 143–6—Fill order of overlapping envelopes

143.2.5.2 MCRS channel skew remediation mechanism

In a multi-channel system that uses multiple wavelengths to carry different MCRS channels, the channels have unequal propagation delays. This variable propagation delay results in a timing skew between signals received on separate MCRS channels. Other timing variability may accumulate in the sublayers below the MCRS, exacerbating this timing skew.

To properly restore the order of data transmitted over multiple bonded MCRS channels, the skew between the channels has to be eliminated at the receiver. The skew remediation mechanism is based on two buffers: an envelope transmission buffer (EnvTx) in the transmitting MCRS and an envelope reception buffer (EnvRx) in the receiving MCRS. As envelopes traverse the EnvTx buffer (before the skew has impacted any of the MCRS channels), their relative position in the EnvTx buffer is recorded and transmitted to the EnvRx buffer. At the receiving station, the envelopes received on multiple channels are aligned in the EnvRx buffer using the position information received from the transmitting device. The relative alignment of envelopes in EnvRx becomes identical to their relative alignment that existed in EnvTx. This envelope alignment method results in the complete elimination of any skew between the channels, as well as any timing variability that may accumulate in the sublayers below MCRS.

143.2.5.3 EnvTx and EnvRx buffers

The EnvTx and EnvRx buffers are two-dimensional buffers organized into rows and columns. The number of columns is equal to the number of channels supported by the device. If the number of rows is set to 32, this provides sufficient buffering to mitigate approximately 80 ns of skew between any two channels (assuming a 25GMII). If an application requires additional skew mitigation, up to ±81.92 ns of skew may be accommodated by increasing the number of buffer rows.

The EQs are written into the EnvTx and read from EnvRx buffers first by row, then by column, as shown in Figure 143–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

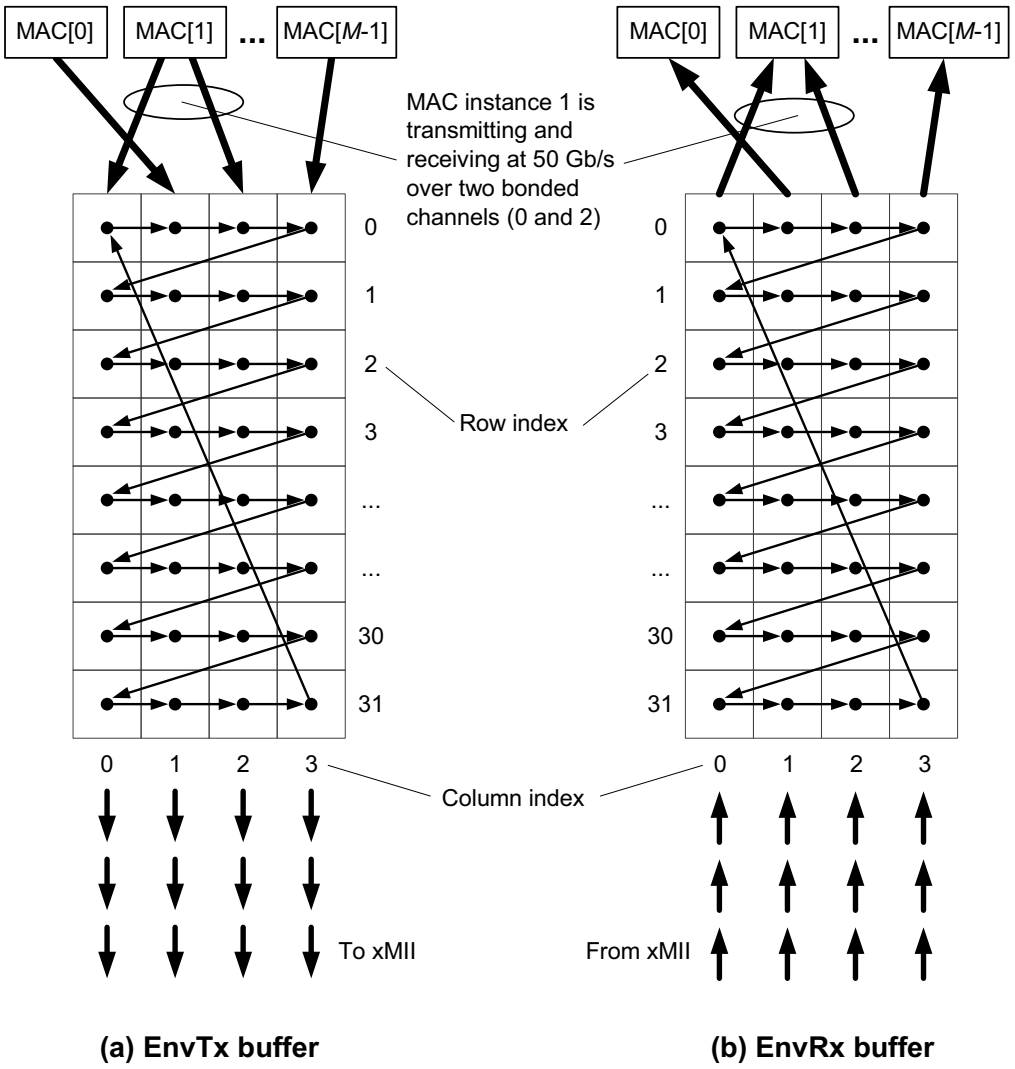

Figure 143–7—Internal structure of EnvTx and EnvRx buffers

In the EnvTx buffer all columns of a row are written before the write pointer shifts to the next row. The EQs written into each column may be sourced by different MAC instances, if the envelopes on different channels belonged to different LLIDs, or from the same MAC instance, in case of multiple channels bonded to serve the same LLID (see Figure 143–7).

Similarly, in the receiving device, the EQs read from different columns may be passed to different MAC instances, if the envelope headers on different channels carried different LLID values, or the EQs may be passed to the same MAC instance, if the envelope headers carried the same LLID value. In case of EQs from different columns being passed to the same MAC instance, the EQ from a column with the lower index is passed before an EQ from a column with the higher index.

EnvTx and EnvRx are circular buffers – after reading the last row, the read pointer shifts back to row 0. In EnvTx, the read and write pointers advance synchronously with the xMII transmit clock (TX_CLK). In

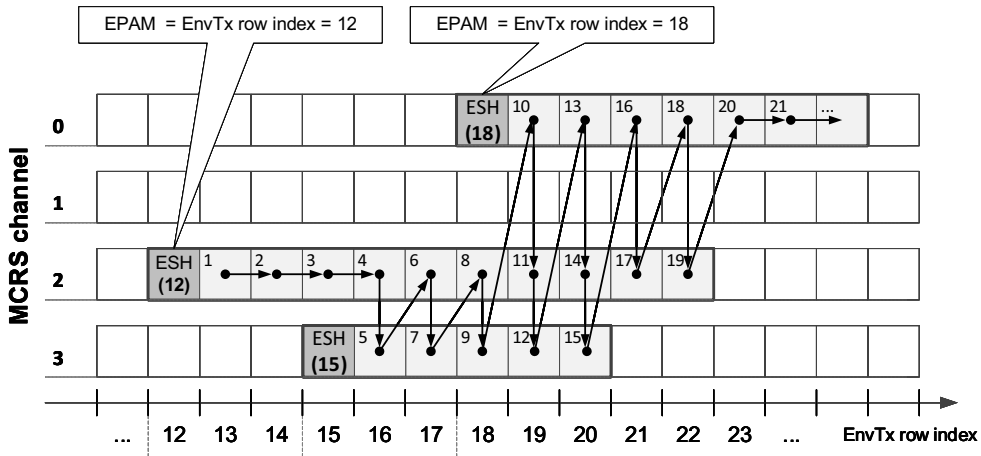
EnvRx, the read and write pointers advance synchronously with the xMII receive clock (RX_CLK). However, the value of the receive channel write pointer is updated whenever an envelope header is received.

143.2.5.4 Envelope position alignment marker

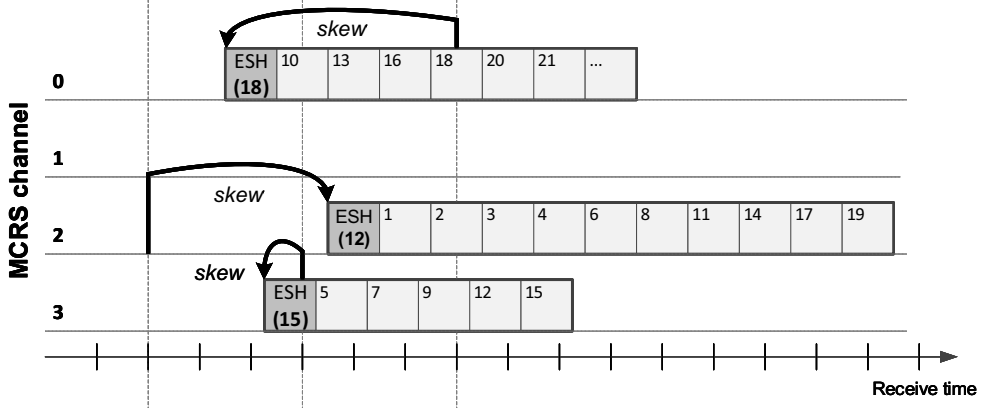
The relative envelope position recorded in an envelope header by the MCRS transmit function is simply the logical equivalent of the EnvTx buffer row index into which the given envelope header was written. This information is placed in an envelope header field called the envelope position alignment marker (EPAM). When an envelope header is received by the MCRS receive function, the EPAM field is extracted and its value is used to update the write pointer (row index) into which this envelope header is to be written. The remainder of the envelope is then written sequentially into the same column following the envelope header.

Figure 143–8 illustrates (a) the initial envelope positions in the EnvTx buffer, (b) the accumulated channel-dependent skew of the received channels at the EnvRx buffer, and (c) the restored alignment based on EPAM value carried in each envelope header. As the true relative positions of the envelopes are restored, reading the data in the same order as shown in Figure 143–8 properly serializes the data received over the multiple bonded channels.



At the receiving station, regardless of the amount of accumulated skew, EQs transmitted at the same time from the same MCRS are placed in the same row of the EnvRx. As the EnvRx is read out in a row-by-row order over all channels the receiver effectively realigns the EQs to the same order they were transmitted in.

143.2.6 MDIO addressing model for multi-channel architecture



The MDIO addressing model for multi-channel architecture is defined as follows:

— Separate physical ports on the OLT are managed by separate Station Management entities (STAs, see 45.1.2).
— Within each physical port, separate channels are addressed via port address (PRTAD, see 45.3.5).
— Within each channel, separate layers (PMA, PCS, etc.) are addressed via device address (DEVAD, see 45.3.6) as shown in Table 45–1.
— A common PMD that spans multiple channels is addressed via the numerically-lowest PRTAD associated with that PMD.

143.3 MCRS functional specifications

143.3.1 MCRS interfaces

Interfaces to the MCRS are illustrated in Figure 143–9. In addition to the *M* instances of the PLS service interface (one per MAC) and *N* xMII instances, there is an MCRS_CTRL interface that connects to the higher layers (see Figure 143–1).

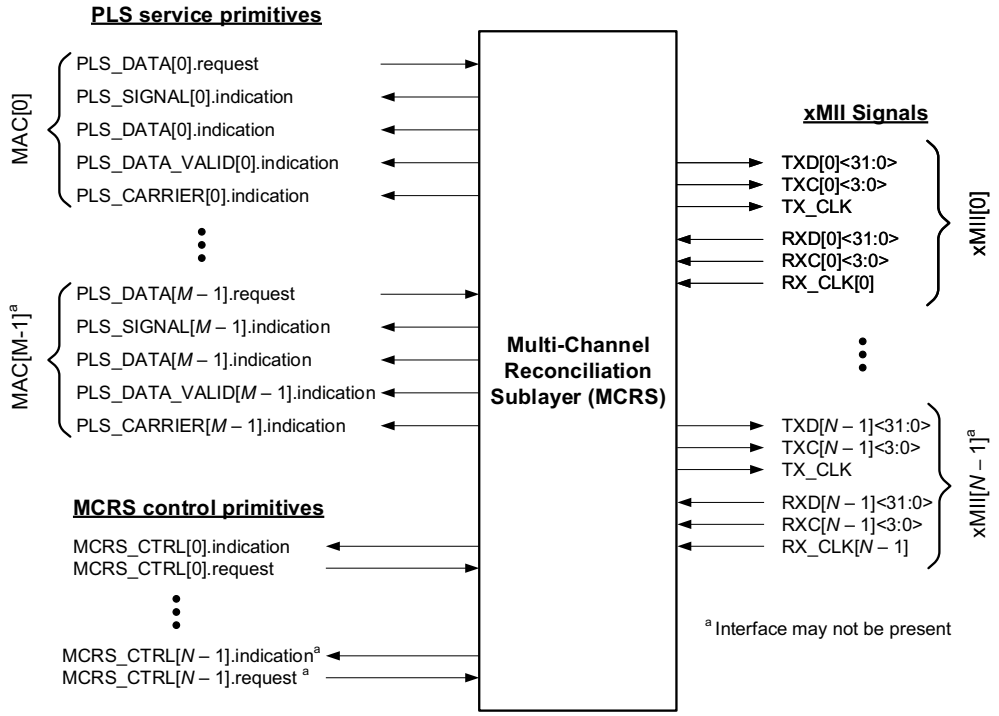

Figure 143–9—Multi-Channel Reconciliation Sublayer (MCRS) inputs and outputs

143.3.1.1 PLS service primitives

In all single-channel RS definitions, only one PLS service interface is active at any given moment; this is still true for systems with only one active MCRS channel. However, for systems with more than one MCRS channel there may be multiple PLS service interfaces active at any given time.

The mapping of the PLS service primitives to xMII signals are shown in 143.3.1.1.1 for PLS_DATA[].request primitives and in 143.3.1.1.3 for PLS_DATA[].indication primitives. These are similar to the mappings described in 46.1.7. However, in systems with multiple MCRS channels there are multiple xMIIs and therefore an index is added to the xMII signals to indicate which of the xMIIs to use.

Depending on the MAC operating speed, the PLS_DATA.request primitive maps to one or multiple xMII transmit interfaces (see Table 143–1).

Depending on the MAC operating speed, the PLS_DATA.indication primitive maps to one or multiple xMII receive interfaces (see Table 143–2).

Table 143–1—Mapping of PLS_DATA.request primitives

MAC operating speed	MCRS channels	Transmit interface	Signals
10 Gb/s	1	XGMII[0]	TXD[0]<31:0>, TXC[0]<3:0> and TX_CLK
25 Gb/s	1	25GMII[0]	TXD[0]<31:0>, TXC[0]<3:0> and TX_CLK
50 Gb/s	2	25GMII[0] 25GMII[1]	TXD[0]<31:0>, TXC[0]<3:0> and TX_CLK[a] TXD[1]<31:0>, TXC[1]<3:0>
N × 25 Gb/s	*N*	25GMII[0] 25GMII[1] 25GMII[2] … 25GMII[*N* – 1]	TXD[0]<31:0>, TXC[0]<3:0> and TX_CLK[a] TXD[1]<31:0>, TXC[1]<3:0> TXD[2]<31:0>, TXC[2]<3:0> … TXD[*N* – 1]<31:0>, TXC[*N* – 1]<3:0>

[a] All transmit 25GMII interfaces share a common clock.

Table 143–2—Mapping of PLS_DATA.indication primitives

MAC operating speed	MCRS channels	Receive interface	Signals
10 Gb/s	1	XGMII[0]	RXD[0]<31:0>, RXC[0]<3:0> and RX_CLK[0]
25 Gb/s	1	25GMII[0]	RXD[0]<31:0>, RXC[0]<3:0> and RX_CLK[0]
50 Gb/s	2	25GMII[0] 25GMII[1]	RXD[0]<31:0>, RXC[0]<3:0> and RX_CLK[0] RXD[1]<31:0>, RXC[1]<3:0> and RX_CLK[1]
N × 25 Gb/s	*N*	25GMII[0] 25GMII[1] 25GMII[2] … 25GMII[*N* – 1]	RXD[0]<31:0>, RXC[0]<3:0> and RX_CLK[0] RXD[1]<31:0>, RXC[1]<3:0> and RX_CLK[1] RXD[2]<31:0>, RXC[2]<3:0> and RX_CLK[2] … RXD[*N* – 1]<31:0>, RXC[*N* – 1]<3:0> and RX_CLK[*N* – 1]

143.3.1.1.1 Mapping of PLS_DATA[*ch*].request primitive

The MCRS maps the primitive PLS_DATA.request to the xMII signals TXD[*ch*]<31:0>, TXC[*ch*]<3:0>, and TX_CLK in the same way as for the XGMII as specified in 46.1.7.1.

143.3.1.1.2 Mapping of PLS_SIGNAL[*ch*].indication primitive

The MCRS support full duplex operation only and does not generate the PLS_SIGNAL.indication primitive.

143.3.1.1.3 Mapping of PLS_DATA[*ch*].indication primitive

The MCRS maps the primitive PLS_DATA.indication to the xMII signals RXD[*ch*]<31:0>, RXC[*ch*]<3:0> and RX_CLK[*ch*] in the same way as for the XGMII as specified in 46.1.7.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

143.3.1.1.4 Mapping of PLS_DATA_VALID[*ch*].indication primitive

The MCRS maps the primitive PLS_DATA_VALID.indication to the xMII signals RXC[*ch*]<3:0> and RXD[*ch*]<31:0> in the same way as for the XGMII as specified in 46.1.7.5.

143.3.1.1.5 Mapping of PLS_CARRIER[*ch*].indication primitive

The MCRS supports full duplex operation only and does not generate the PLS_CARRIER.indication primitive.

143.3.1.2 MCRS control primitives

The MCRS inputs the MCRS_CTRL[*ch*].request primitives from the Multipoint Control Protocol (MPCP) and outputs to the MPCP the MCRS_CTRL[*ch*].indication primitives.

143.3.1.2.1 MCRS_CTRL[*ch*].request(link_id, epam, env_length) primitive

The MPCP requests the MCRS to transmit the next envelope using the MCRS_CTRL[*ch*].request(link_id, epam, env_length) primitive. This opens an envelope on channel *ch* for the LLID specified by link_id with a length (in EQs) of env_length. If all channels are idle, the EnvPam variable (see 143.3.3.4) is set to the value of epam (see EnvStartHeader() function definition in 143.3.3.5).

143.3.1.2.2 MCRS_CTRL[*ch*].indication() primitive

The Input process (see Figure 143–12) requests the next envelope from the MPCP after the completion of the previous envelope using the MCRS_CTRL[*ch*].indication() primitive. This primitive indicates to the MPCP that the MCRS is available for the next envelope in a given channel. In the absence of an active envelope, the MCRS_CTRL[*ch*].indication() primitive is generated continuously on every InClk transition (see 143.3.3.4). The MPCP may decide whether to issue a new envelope immediately adjacent to the previous envelope for envelopes that are expected to be packed in the same transmission burst. If the MPCP has determined that a transmission opportunity has ended, it signals that condition by issuing an envelope with link_id set to ESC_LLID (see Table 144–1).

143.3.1.2.3 MCRS_ECH[*ch*].indication(Llid) primitive

The Output process (see Figure 143–16) generates the MCRS_ECH[*ch*].indication(Llid) primitive every time an ESH EQ is read from the EnvRx buffer. This primitive causes the MPMC Control Parser process (see 144.2.1) to generate a local timestamp (i.e., to latch the local MPCP time) representing the arrival time of the ESH EQ.

143.3.1.3 XGMII interfaces

The XGMII is specified to support 10 Gb/s operation. The structure of each of the XGMII interfaces in an MCRS system is as specified in 46.1.6.

For mapping between the XGMII signals and the PLS service interface, see 143.3.1.1.1 and 143.3.1.1.3.

For multi-channel MCRS systems the transmit XGMIIs are synchronous and only one TX_CLK is required.

143.3.1.4 25GMII interfaces

The 25GMII is specified to support 25 Gb/s operation. The structure of each of the 25GMII interfaces in an MCRS system is identical to the XGMII structure specified in 46.1.6. The 25GMII data stream has the same

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

characteristics as the XGMII data stream described in 46.2 with the exception of the clock rate, which is 390.625 MHz for the 25GMII.

For mapping between the 25GMII signals and the PLS service interface, see 143.3.1.1.1 and 143.3.1.1.3.

For multi-channel MCRS systems the transmit 25GMIIs are synchronous and only one TX_CLK is required.

143.3.2 Envelope header format

Each envelope initiated by the MCRS begins with a 72-bit envelope header. The envelope header shall be as shown in Figure 143–10. The envelope header includes a Start control code, an EnvType flag bit, a 22-bit Envelope Length field, an envelope position alignment marker (EPAM) field, two bits (E and K) reserved for encryption purposes, an LLID field, and an 8-bit cyclic redundancy check (CRC8).

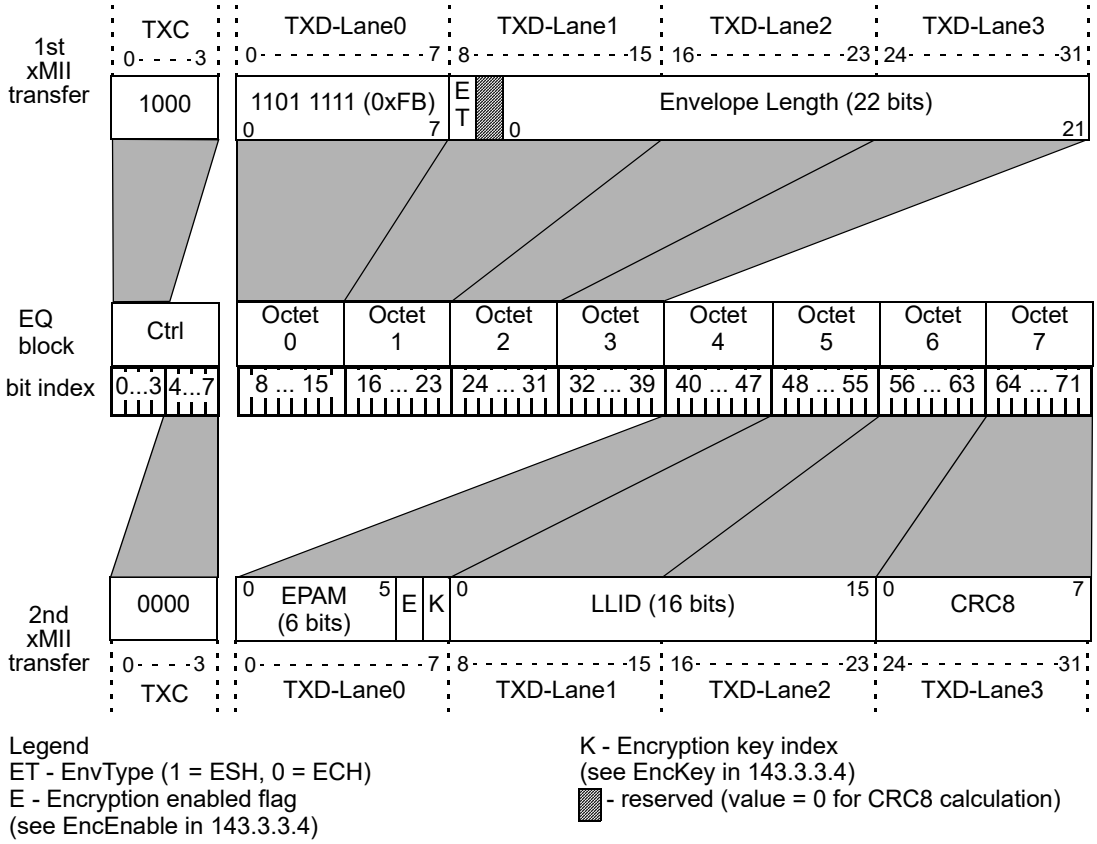

Figure 143–10—Mapping of envelope header fields into two xMII transfers

When the xMII is 36 bits wide, the transmission envelope header includes two successive transfers over the xMII, as illustrated in Figure 143–10. Each 36-bit transfer includes four control bits followed by 32 information bits. Octets within each envelope header field are transmitted from least significant to most significant. Bits within each octet are transmitted from LSB to MSB. An EQ contains eight octets of information so the length of the envelope header equals one EQ.

The envelope header is identified by a Start control code (Block type 0xFB, see Table 142–2).

The ESH has the EnvType flag set to one whereas the ECH has the EnvType flag set to zero. The ESH is used to indicate the beginning of a transmission from a specific LLID.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Following the EnvType flag, there is one reserved bit (EQ<17>) and it is set to zero at the transmitter and its value is ignored at the receiver except for the purposes of calculating the CRC8.

The Envelope Length field represents the number of EQs in the envelope, including the envelope header itself (1 EQ).

The EPAM is used by the receiving MCRS to remove any timing skew that may have occurred during the transmission of the envelope from the source MCRS to the destination MCRS.

The LLID field is set to the value of the LLID (MAC instance) associated with the data in the envelope.

The CRC8 field is used for error detection within the header. CRC8 uses the same generating polynomial as described in 65.1.3.2.3. The CRC8 checksum is calculated over EQ bits 8 through 63. The envelope header bits are processed by the CRC8 calculating function in the same order they are transmitted, i.e., for each field the bits are processed starting with the LSB and ending with the MSB.

143.3.2.1 CRC8 calculation test sequences

The test sequences in Table 143–3, Table 143–4, and Table 143–5 show several example envelope header field values and the resulting CRC8 value computed by a compliant implementation.

Table 143–3—CRC8 computation example #1[a]

Envelope header fields	Start control code	EnvType	Reserved	Envelope Length	EPAM	E	K	LLID
Envelope header fields	0xFB	1	0	64	15	0	0	0xAB-CD
Envelope header with CRC8 (hex)	E5-AB-CD-0F-00-01-01-FB (transmitted LSB first)							
Envelope header with CRC8 (bin)	(last bit) | 1110-0101-1010-1011-1100-1101-0000-1111-0000-0000-0000-0001-0000-0001-1111-1011 | (first bit)							

[a]Gray highlight indicates location and calculated value of CRC8 field

Table 143–4—CRC8 computation example #2[a]

Envelope header fields	Start control code	EnvType	Reserved	Envelope Length	EPAM	E	K	LLID
Envelope header fields	0xFB	0	0	960	5	1	0	0x00-01
Envelope header with CRC8 (hex)	23-00-01-45-00-0F-00-FB (transmitted LSB first)							
Envelope header with CRC8 (bin)	(last bit) | 0010-0011-0000-0000-0000-0001-0100-0101-0000-0000-0000-1111-0000-0000-1111-1011 | (first bit)

143.3.3 Transmit functional specifications

A functional block diagram of the MCRS transmit path is illustrated in Figure 143–11. The MCRS interfaces are described in 143.3.1. The MCRS transmit path is composed of two processes and one buffer.

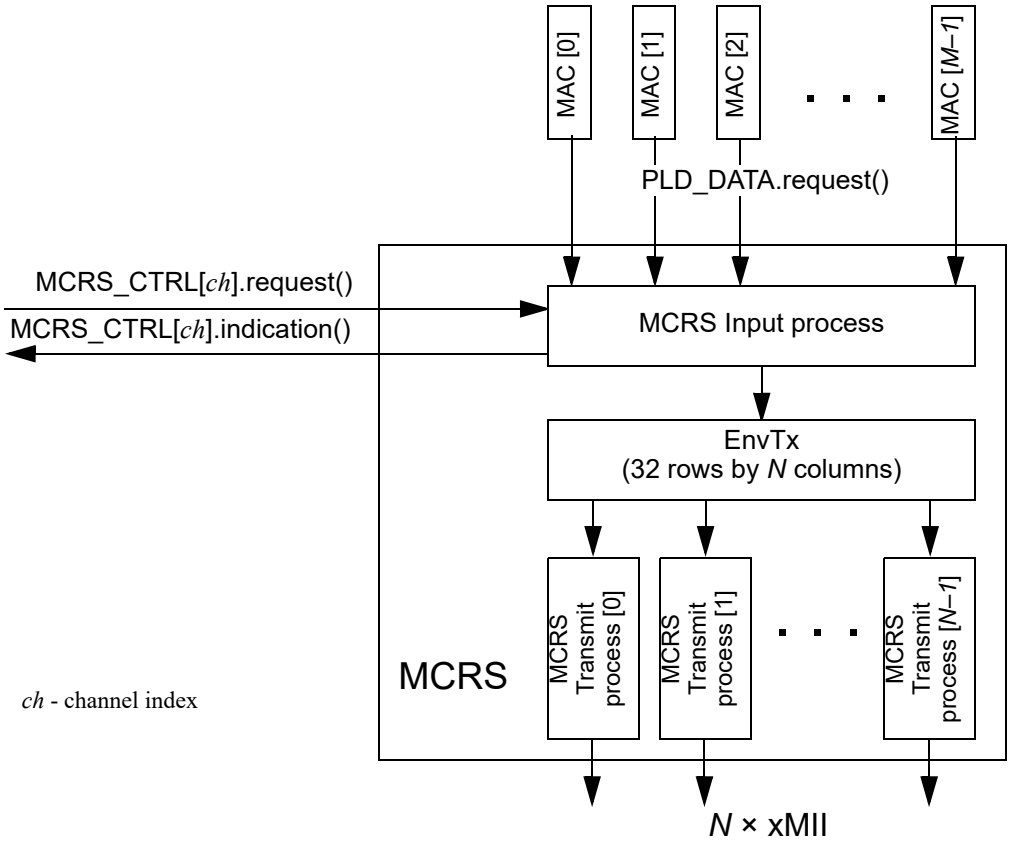

Figure 143–11—MCRS transmit functional block diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Input process, described in 143.3.3.6.1, accepts MAC data, formats it into EQs and stores these EQs in the EnvTx buffer. The Transmit process, described in 143.3.3.6.2, pulls EQs from the EnvTx buffer and feeds them to two successive transfers on the appropriate xMII.

143.3.3.1 Conventions

See 142.1.1.

143.3.3.2 Application-specific parameter definitions

Some constants and variables in this sub-clause have characteristics that are application-specific. For Nx25G-EPON specific parameter definitions refer to 143.4.1.3.

NOTE—References to future application-specific parameters are to be added only to this subclause.

143.3.3.3 Constants

ADJ_BLOCK_SIZE
: Type: integer
Description: The ADJ_BLOCK_SIZE constant represents the block size (in EQs) that is used to adjust the rate between the MAC and the PHY in the MCRS-based device.
Value: application-specific (see 143.3.3.2)

ESC_LLID
: See Table 144–1

IBI_EQ
: Type: 72-bit block
Description: The IBI_EQ constant indicates to the PCS that the burst is terminated.
Value: 0x0A-0A-0A-0A-0A-0A-0A-FF

IEI_EQ
: Type: 72-bit block
Description: The IEI_EQ represents an EQ value transmitted between envelopes.
Value: 0x08-08-08-08-08-08-08-FF

NUM_CH
: Type: unsigned integer
Description: The NUM_CH constant represents the number of channels supported by an MCRS-based device.
Value: application-specific (see 143.3.3.2)

PREAMBLE_EQ
: Type: 72-bit block
Description: The value of an EQ returned by the GetMacBlock() function that represents a preamble.
Value: 0x5D-55-55-55-55-55-55-FB-01

RATE_ADJ_EQ
: Type 72-bit block
Description: The value of an EQ that is used as a placeholder to allow for rate differences between the MAC and the PHY layers.
Value: 0x09-09-09-09-09-09-09-FF

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RATE_ADJ_SIZE

Type: integer

Description: The RATE_ADJ_SIZE constant represents the number of EQs within the ADJ_BLOCK_SIZE block during which the MAC transmission is deferred. The effective MAC rate (per channel) is equal to (nominal MAC rate) × (1 – RATE_ADJ_SIZE / ADJ_BLOCK_SIZE).

Value: application-specific (see 143.3.3.2)

143.3.3.4 Variables

ch

Type: integer

Description: The ch variable represents the index of a specific xMII channel bound to an instance of the MCRS Transmit or MCRS Receive process. The values of ch range from 0 to (NUM_CH – 1). Within each instance of the MCRS Transmit or MCRS Receive process, the value of ch remains constant.

BEGIN

See 142.2.5.2

BlkLeft[ch]

Type: integer

Description: The BlkLeft variable represents the number of EQs remaining in the envelope currently being processed by the MCRS.

EncEnable

Type: Boolean

Description: Encryption enabled flag, not for use by IEEE Std 802.3.

EncKey

Type: one-bit integer

Description: Encryption key index, not for use by IEEE Std 802.3.

EnvTx

Type: array of 72-bit blocks

Description: The EnvTx buffer is used to transfer information between the MCRS Input process and the MCRS Transmit process. In this buffer, each cell, represented by the variables EnvTx[ch][r], stores one EQ (a 72-bit block) of information. The number of columns in the EnvTx buffer is NUM_CH (see 143.3.3.3). The number of rows is 64, as determined by the size of the EPAM field in the envelope header (see 143.3.3.2). The buffer is filled sequentially by the MCRS Input process and is emptied in parallel by NUM_CH instances of the MCRS Transmit process. For additional details, refer to 143.2.5.3.

EnvLeft[ch]

Type: 23-bit signed integer

Description: The EnvLeft variable represents the length remaining in the current envelope for channel ch.

EnvPam

Type: 6-bit integer

Description: The EnvPam variable is used to remove delay variability (including skew) accumulated during transport between two or more channels from a single transmitter. EnvPam is also used as the row index for the EnvRx buffer into which the received data is to be written (see 143.3.4).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

InClk

Type: Boolean

Description: The InClk clear-on-read variable is set to true on each rising edge of the TX_CLK signal.

InEQ

Type: 72-bit binary array

Description: A temporary holding variable for one EQ used in the Input process.

LinkId[ch]

Type: 16-bit integer

Description: The LinkId[ch] variables represent the MAC (LLID) being transferred by the Input process or Output process for channel ch.

rCol

Type: integer

Description: The rCol variable represents the EnvTx buffer column currently being read by the MCRS Transmit process. Each column corresponds to a separate transmission channel, i.e., a separate xMII interface.

rRow

Type: 6-bit integer

Description: The rRow variable represents the row in the EnvTx buffer currently being read by the MCRS Transmit process. The value of this variable is synchronized to wRow and is equal to wRow – 1.

TxClk[ch]

Type: Boolean

Description: Description: The TxClk[ch] variable represents the MCRS transmit clock for channel ch. Each TxClk[ch] clear-on-read variable is set to true on each edge, rising and falling, of the TX_CLK signal (see Table 143–1).

TxActive[ch]

Type: Boolean

Description: When set to true, the TxActive[ch] variable indicates that channel ch is currently enabled for transmission. The channel transmits the envelopes or inter-envelope idle EQs (IEI_EQ values) in the absence of envelopes. When set to false, transmission on channel ch is prohibited and this channel generates only inter-burst idle EQs (IBI_EQ values) towards the xMII.

wCol

Type: integer

Description: The wCol variable represents the EnvTx buffer column currently being written by the MCRS Input process. Each column corresponds to a separate transmission channel, i.e., a separate xMII interface.

wRow

Type: 6-bit integer

Description: The variable wRow represents the EnvTx buffer row index currently being written by the MCRS Input process. The value of rRow is synchronized to this variable and is equal to wRow – 1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

143.3.3.5 Functions

EnvContHeader(wCol)

The EnvContHeader() function returns a new envelope header with the EnvType flag equal to 0, indicating that it is a continuation of the current envelope.

```
EQ EnvContHeader(int col)
{
   EQ hdr;
   hdr<7:0> = 0x01;                 // Control bits
   hdr<15:8> = 0xFB;                // S character
   hdr<16> = 0;                     // EnvType identifies ECH
   hdr<17> = 0;                     // Reserved
   hdr<39:18> = EnvLeft[col];       // EnvLength
   hdr<45:40> = EnvPam;             // EPAM
   hdr<46> = EncEnable;             // Encryption enabled flag
   hdr<47> = EncKey;                // Encryption key index
   hdr<63:48> = LinkId[col];        // LLID
   hdr<71:64> = CRC8(hdr<63:8>);    // Calculate CRC8
   return hdr;
}
```

EnvStartHeader(wCol, epam)

The EnvStartHeader() function returns a new envelope header with the EnvType flag equal to 1, indicating that it is a start of a new envelope. If this envelope starts a new burst (i.e., all channels are idle) it updates EnvPam to the value of the epam variable provided in the MCRS_CTRL[].request primitive.

```
EQ EnvStartHeader(int col, int6 epam)
{
   EQ hdr;

   // Use provided 'epam' value if this envelope starts a new burst
   if(!TxActive[0] AND !TxActive[1] AND … AND !TxActive[NUM_CH-1])
      EnvPam = epam;

   hdr<7:0> = 0x01;                 // Control bits
   hdr<15:8> = 0xFB;                // S character
   hdr<16> = 1;                     // EnvType identifies ESH
   hdr<17> = 0;                     // Reserved
   hdr<39:18> = EnvLeft[col];       // EnvLength
   hdr<45:40> = EnvPam;             // EPAM
   hdr<46> = EncEnable;             // Encryption enabled flag
   hdr<47> = EncKey;                // Encryption key index
   hdr<63:48> = LinkId[col];        // LLID
   hdr<71:64> = CRC8(hdr<63:8>);    // Calculate CRC8
   return hdr;
}
```

GetFillerEQ(int col)

The GetFillerEQ() function returns an EQ value used to fill the transmit channel when no active envelopes are available. If this function is called when the transmission channel is active, it returns an inter-envelope idle EQ (IEI_EQ). Otherwise, it returns an inter-burst idle EQ (IBI_EQ).

```
EQ GetFillerEQ( int col)
{
   if( TxActive[col] )
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
        return IEI_EQ; //Inter-Envelope Idle
    else
        return IBI_EQ; //Inter-Burst Idle
}
```

GetMacBlock(link_id)

The GetMacBlock() function retrieves eight octets (64 bits) of data from a MAC identified by the link_id parameter and returns an EQ (72 bits) that contains both the data and the corresponding eight control bits. If the retrieved bits contain a partial frame preamble, the preamble is shifted forward such that the entire preamble is returned in one EQ in which case the function invokes the PLS_DATA.request() primitive up to 127 times. If no data is available from the MAC for a particular byte, the function returns an IDLE control code for that octet. This is a blocking function that returns control to the calling routine after 64 or more successive invocations of the PLS_DATA.request() primitive.

```
IdleFlag[.] = {true};
// Previous octet from a MAC (link_id)
// was an Idle. Global array of Booleans
// that retain their values between successive
// calls to GetMacBlock()
EQ GetMacBlock(int16 link_id)
{
    EQ eq; // Consists of 8 bits of control (Ctrl[0…7])
           // and 8 octets of data (Data[0…7]), as shown in Figure 143–2
    if( link_id == ESC_LLID )
        return IBI_EQ; // Inter-burst Idle
    for( octet_index = 0; octet_index < 8; octet_index++ )
    {
        tx_data = GetMacOctet( link_id ); // Get 8 bits from MAC
        if( IsIdle(tx_data) AND !IdleFlag[link_id] ) // 1st Idle after Data
        {
            IdleFlag[link_id] = true;
            eq.Ctrl[octet_index] = 1; // Store /T/ character
            eq.Data[octet_index] = 0xFD;
        }
        else if( IsIdle(tx_data) ) // Idle after Idle
        {
            eq.Ctrl[octet_index] = 1; // Store /I/ character
            eq.Data[octet_index] = 0x07;
        }
        else if( IdleFlag[link_id] ) // 1st Data after Idle
        {
            IdleFlag[link_id] = false;
            octet_index = 0; // Shift to octet 0
            eq.Ctrl[octet_index] = 1; // Store /S/ character
            eq.Data[octet_index] = 0xFB;
        }
        else // Data after Data
        {
            eq.Ctrl[octet_index] = 0; // Store Data octet
            eq.Data[octet_index] = tx_data;
        }
    }
    return eq;
}
```

GetMacOctet(link_id)

This function returns an eight-bit vector from a MAC identified by the link_id parameter. When the MAC sublayer has data available, the return value is composed of eight OUTPUT_UNIT values (see 46.1.7.1.2) delivered by eight consecutive invocations of the PLS_DATA[link_id].request(OUTPUT_UNIT) primitive (see Figure 143–9). When the MAC sublayer has no data available (i.e., if the last seen OUTPUT_UNIT value was equal to DATA_COMPLETE), the return value is composed of eight DATA_COMPLETE values.

IsIdle(octet)

This function returns a Boolean value indicating whether the parameter octet represents a data octet or an idle octet. This function returns true if any bit in octet has a value of DATA_COMPLETE (see 46.1.7.1.2), otherwise, false is returned. Note that since MAC data output is aligned to octet boundaries, all bits in the parameter octet are either equal to DATA_COMPLETE or all bits are not equal to DATA_COMPLETE.

143.3.3.6 State diagrams

143.3.3.6.1 Input process

The MCRS shall implement the Input process as depicted in Figure 143–12.

The Input process accepts data from a MAC interface and transfers that data to the EnvTx buffer one EQ at a time. The process prepends an ESH to each envelope and overwrites each preamble with an ECH. Only one instance of the process is needed. The Input process fills one full row (all columns) of the EnvTx buffer on each cycle of InClk (InClk is half the effective rate of TX_CLK). In case of overlapping envelopes, blocks in multiple columns are retrieved from the same MAC.

The process keeps track of the envelope sizes for each LLID and does not exceed the allowed number of EQs for a given envelope. The process adjusts the MAC rate to account for FEC parity insertion in the PCS.

143.3.3.6.2 Transmit process

The MCRS shall implement the Transmit process as depicted in Figure 143–13.

The Transmit process outputs one 36-bit block (TXD[*ch*]<31:0> + TXC[*ch*]<3:0>) to its associated xMII interface on each edge of the TX_CLK signal. There is one instantiation of the Transmit process for each channel implemented in the device. The main function of the process is to transmit a column of one row from the EnvTx buffer on an existing channel. The Transmit process is synchronized to TX_CLK.

143.3.4 Receive functional specifications

A functional block diagram of the MCRS receive path is illustrated in Figure 143–14. The MCRS interfaces are described in 143.3.1. The MCRS receive path is composed of two processes and one buffer. The Receive process, described in greater detail in 143.3.4.5.1, accepts two successive transfers from the associated xMII and consolidates them into an EQ, which is stored in the appropriate row of the EnvRx buffer. The Output process, described in greater detail in 143.3.4.5.2, pulls EQs from the EnvRx buffer and feeds them to the appropriate MAC as specified by the current LLID for that receive channel.

143.3.4.3 Variables

BEGIN
See 142.2.5.2

ch
See 143.3.3.4

EnvRx
Type: array of 72-bit blocks
Description: The EnvRx buffer is used to transfer information between the MCRS Receive process and the MCRS Output process. In this buffer, each cell, represented by the variable EnvRx stores one EQ (a 72-bit block) of information. The number of columns in EnvRx buffer is NUM_CH (see 143.3.3.3). The maximum number of rows is 64, as determined by the size of EPAM field in the envelope header (see 143.3.2). For some applications, fewer rows may be sufficient. The buffer is filled in parallel by NUM_CH instances of MCRS Receive process and is emptied sequentially by the MCRS Output process. For additional details, refer to 143.2.5.3.

EnvLeft[ch]
See 143.3.3.4

LinkId[ch]
See 143.3.3.4

OutClk
Type: Boolean
Description: The OutClk clear-on-read variable is set to true on each rising edge of TX_CLK.

OutEQ
Type: 72-bit binary array
Description: A temporary holding variable for one EQ used in the Output process.

rCol
Type: Integer
Description: The rCol variable represents the EnvRx buffer column currently being read by the MCRS Output process. Each column corresponds to a separate reception channel, i.e., a separate xMII interface.

rRow
Type: 6-bit integer
Description: The rRow variable represents the EnvRx buffer row index currently being read by the MCRS Output process.

RxClk[ch]
Type: Boolean
Description: The RxClk[ch] clear-on-read variables are set to true on each edge of the RX_CLK[ch] signals and represent the continuous clock that provides the timing reference for the transfer of the RXC[ch]<3:0> and RXD[ch]<31:0> signals received on the xMII channel ch.

RxEQ
Type: 72-bit binary
Description: The RxEQ variable represents the most recent EQ received from an xMII interface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

wCol

Type: Integer

Description: The wCol variable represents the EnvRx buffer column currently being written by the MCRS Receive process. Each column corresponds to a separate reception channel, i.e., a separate xMII interface.

wRow

Type: 6-bit integer

Description: The wRow variable represents the EnvRx buffer row index currently being written by the MCRS Receive process.

143.3.4.4 Functions

IsHeader(eq)

The IsHeader(eq) function returns true if the parameter eq represents an envelope header. An envelope header begins with a /S/ Start control character.

```
bool IsHeader(EQ eq)
{
   return(   eq<7:0> == 0x01 AND              // Control bits
             eq<15:8> == 0xFB AND             // Start Control Code /S/
             eq<71:64> == CRC8(eq<63:8>));    // Matching CRC8
}
```

IsMisaligned(eq)

The IsMisaligned(eq) function returns true if the parameter eq is misaligned, i.e., shifted by a half EQ.

```
bool IsMisaligned(EQ eq)
{
   return (  eq<7:0> == 0x1F AND           // Control bits
             eq<39:8> == IBI_EQ<71:40> AND // 1st Transfer: IBI_EQ
             eq<47:40> == 0xFB );          // 2nd Transfer: Env. Header
}
```

OutputToMac(LinkId[rCol], OutEQ)

The OutputToMac(LinkId[rCol], OutEQ) function transfers the eight information bytes in the OutEQ parameter to the MAC associated with the LLID value of LinkId[rCol] per the eight control bits in the OutEQ parameter.

```
OutputToMac(int16 link_id, EQ eq)
{
   for( octet_index = 0; octet_index < 8; octet_index++ )
   {
      if ( eq.Ctrl[octet_index] == 0 ) // Receive data octet
      {
         data_valid = true;
         rx_data = eq.Data[octet_index];
      }
      else if ( eq.Data[octet_index] == 0xFB ) // Rx /S/ character
      {
         data_valid = true;
         rx_data = 0x55; // Replace /S/ with preamble
      }
      else // Rx other ctrl. character, including /T/ (value 0xFD)
      {
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
            data_valid = false;
            rx_data = 0x07; // Replace with /I/
        }
        SetMacOctet( link_id, rx_data, data_valid ); // Set 8 bits to MAC
    }
}
```

SetMacOctet(link_id, rx_data, data_valid)

This function passes eight bits of rx_data vector to the MAC instance identified by the link_id parameter. The rx_data value is passed to the MAC using eight consecutive invocations of the PLS_DATA[link_id].indication(INPUT_UNIT) primitive (see 46.1.7.2), along with eight invocations of the PLS_DATA_VALID[link_id].indication(DATA_VALID_STATUS) primitive (see 46.1.7.5). When the parameter data_valid is equal to true, the DATA_VALID_STATUS has the value of DATA_VALID. When the parameter data_valid is equal to false, the DATA_VALID_STATUS has the value of DATA_NOT_VALID.

143.3.4.5 State diagrams

143.3.4.5.1 Receive process

The ONU and OLT MCRS shall implement the Receive process as depicted in Figure 143–15.

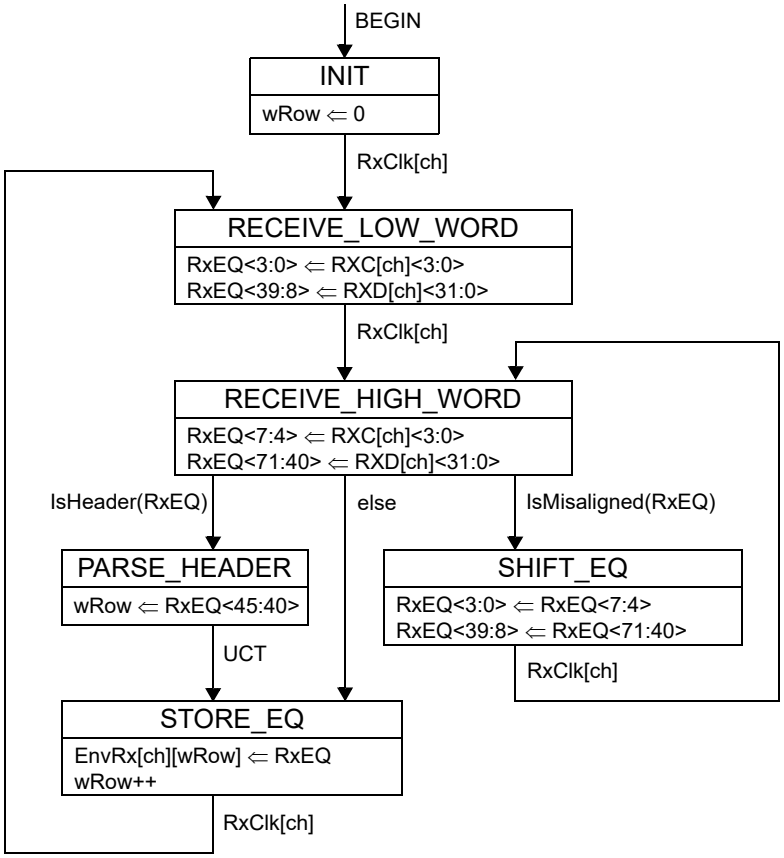

Figure 143–15—MCRS receive function, Receive process state diagram

This process forms an EQ from two successive xMII transfers. The process first verifies proper alignment of the EQ and, if misaligned, shifts the input by half of an EQ (four bytes). No other error checking is performed by this process. When an envelope header is received, the EPAM field is extracted and used as a

write position into the EnvRx buffer. Because the phase of the receive clock (RX_CLK[ch]) in every channel is different, due to different delay and transport skew, a separate instance of the Receive process is required for each channel implemented.

143.3.4.5.2 Output process

The ONU and OLT MCRS shall implement the MCRS Output process as depicted in Figure 143–16.

The Output process outputs EQs to the proper MAC. In the case of overlapping envelopes from the same LLID, data from multiple channels is properly serialized. A corrupted header may lead to loss of a frame, but no subsequent frames are lost due to the error since the next ECH resynchronizes the process for the following frame.

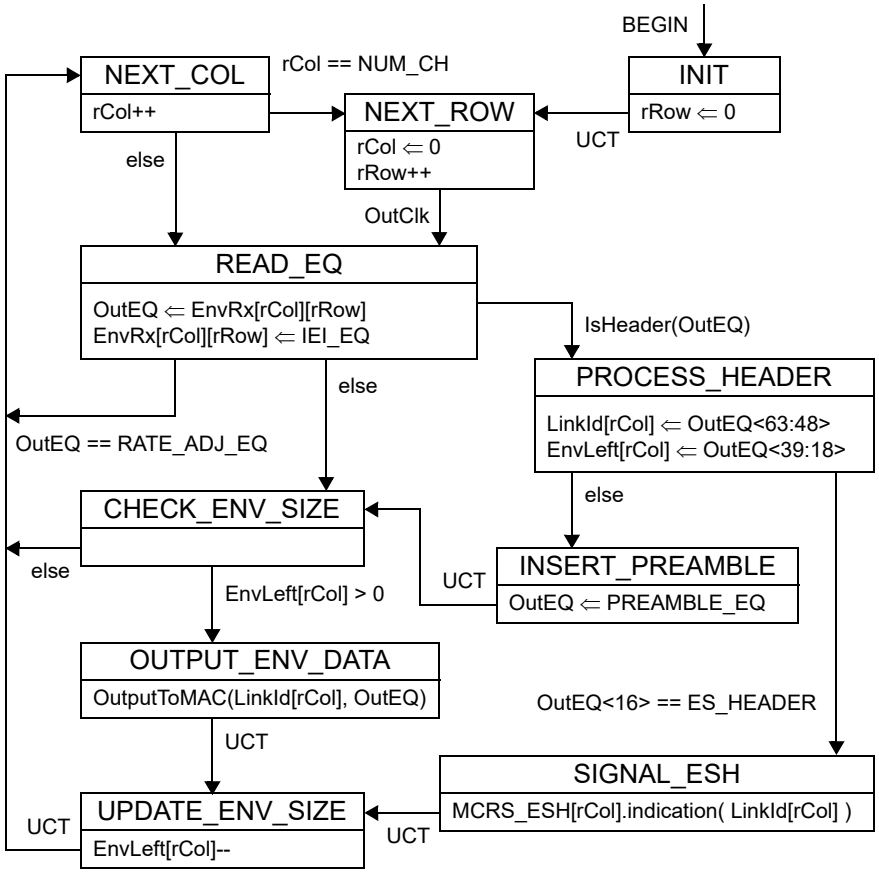

Figure 143–16—MCRS receive function, Output process state diagram

143.4 Nx25G-EPON MCRS requirements

143.4.1 Nx25G-EPON architecture

This subclause describes the MCRS requirements for Nx25G-EPON point-to-multipoint (P2MP) networks. P2MP networks are passive optical networks (PONs) that connect multiple optical network units (ONUs) to a single optical line terminal (OLT). The architecture is asymmetric, based on a tree and branch topology utilizing passive optical splitters.

A transmission direction from the OLT towards the ONUs is referred as the downstream direction and transmission direction from an ONU toward the OLT is referred as the upstream direction.

The MCRS is used with Nx25G-EPON point-to-multipoint (P2MP) networks in order to interface multiple MAC instances with one or two 25GMII channels in each direction. Figure 143–17 illustrates the relationship of the MCRS and the OSI protocol stack for Nx25G–EPON.

Nx25G-EPON OLT and ONU PMDs are defined in Clause 141, with the respective Nx25G-EPON PCS defined in 142.2 and 142.3.

The MCRS in Nx25G-EPON architecture serves as an interfaces sublayer between the MAC sublayer and 25GMII. The 25GMII interface is defined in Clause 106.

143.4.1.1 MCRS channels

An MCRS channel that carries information from the OLT to the ONU is referred to as the downstream channel, and the channel that carries information from an ONU to the OLT is referred to as the upstream channel.

The 25/10G-EPON and 25G/25G-EPON architectures shall implement a single MCRS channel in each direction.

The 50/10G-EPON and 50/25G-EPON architectures shall implement two MCRS channels in the downstream direction and a single channel in the upstream direction.

The 50/50G-EPON architecture shall implement two channels in each direction.

When two channels are implemented in the same direction, channel bonding of these two channels shall be supported. Table 143–6 summarizes MCRS channels for Nx25G-EPON.

Each MCRS channel is bound to a separate PCS instance via a separate xMII instance. Channels operating at 25 Gb/s are bound to 25GMII, whereas the channel operating at 10 Gb/s is bound to an XGMII instance. Thus, for any given system, there is a one-to-one correspondence between the MCRS channel count and the number of xMII instances supported.

Table 143–6—MCRS channel designation and capabilities

Designation	MCRS channel	MCRS channel function
DC0	Downstream channel 0	All ONUs receive this MCRS channel, broadcast.
DC1	Downstream channel 1	Only ONUs capable of receiving at 50 Gb/s support this MCRS channel.
UC0	Upstream channel 0	All ONUs transmit on this MCRS channel.
UC1	Upstream channel 1	Only ONUs capable of transmitting at 50 Gb/s support this MCRS channel.

143.4.1.2 Symmetric and asymmetric data rates

The Nx25G-EPON architecture supports symmetric and asymmetric data rates. The symmetric data rate systems include 25/25G-EPON or 50/50G-EPON. The asymmetric rate systems include 25/10G-EPON, 50/10G-EPON, and 50/25G-EPON.

A distinction is made regarding the underlying mechanisms of achieving the asymmetric data rates. In 25/10G-EPON systems, the asymmetric data rate is achieved via the MCRS channel rate asymmetry, where a single downstream MCRS channel DC0 operates at 25 Gb/s and a single upstream MCRS channel UC0 operates at 10 Gb/s. Additional details for MCRS implementations supporting the channel rate asymmetry are provided in 143.4.4. In 50/25G-EPON systems, the asymmetric data rate is achieved via the MCRS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

channel number asymmetry, where two MCRS channels are active in the downstream direction (DC0 and DC1), but only a single MCRS channel UC0 is active in the upstream direction. In 50/25G-EPON systems, upstream and downstream MCRS channels operate at the data rate of 25 Gb/s.

Both the channel rate asymmetry and the channel number asymmetry mechanisms may be combined, as is the case in 50/10G-EPON systems, where there are two downstream MCRS channels operating at 25 Gb/s and a single upstream MCRS channel operating at 10 Gb/s.

An Nx25G-EPON system may serve ONUs that support different numbers of MCRS channels (see 143.4.1). Therefore, some ONUs are only able to receive and transmit data on MCRS channels DC0 and UC0, some are able to receive on DC0 and DC1 and transmit on UC0 and UC1 or just on UC0.

143.4.1.3 Nx25G-EPON application-specific parameters

For definitions of constants, variables, and functions, see 143.3.3 (transmit direction) and 143.3.4 (receive direction).

143.4.1.3.1 Constants

ADJ_BLOCK_SIZE
: Value: 257

NUM_CH
: Value: 1 for devices supporting only 10 Gb/s or 25 Gb/s operation over a single channel; 2 for devices supporting 50 Gb/s operation over two channels.

RATE_ADJ_SIZE
: Value: 33

143.4.1.3.2 Transmit variables

EnvTx
: Description: Since there is no timing jitter or channel skew to be removed at the transmitting device, the size of the EnvTx buffer may be reduced to only two rows. If this optimization is implemented, the variables rRow and wRow are represented by 1-bit unsigned integers.

143.4.2 MCRS time synchronization

For MCRS to provide the intended skew and jitter remediation capabilities, a sufficient delay margin has to be built into the MCRS buffering at the ONU and the OLT. Such delay margin is established at the ONU registration time by proper setting of MCRS EnvRx read and write pointers at the OLT and the ONU.

Upon power-up or reset, an unregistered ONU synchronizes to the received clock and aligns to 257-bit block and FEC codeword boundaries on each of its active (enabled) receive channels (see ONU Synchronizer process, 142.3.5.5). After that, the received data is passed to FEC decoder, which introduces a near-constant delay. Corrected data from the FEC decoder is passed to xMII and is received into the ONU MCRS EnvRx buffer.

The following are the ONU rules for setting the EnvRx write and read pointers:

a) Write pointer
   1) The ONU MCRS always sets the write pointer for the EnvRx buffer to equal the EPAM value in any envelope header it receives, regardless of the LLID value in that envelope header.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

2) If multiple receive channels are active, the write pointers are set independently for each channel based on EPAM values in envelope headers received on each channel.

b) Read Pointer
   1) The read pointer increments synchronously with the LocalTime counter, which is locked to the xMII receive clock of the active (enabled) receive channel with the lowest index.
   2) In an unregistered ONU, upon every update of a write pointer associated with the receive channel with the lowest index, the read pointer is also updated according to the following equation:

$$ReadPointer = WritePointer \text{ XOR } 0x20 \quad (143–1)$$

In the OLT, the PCS receiver synchronizes on start-of-burst delimiter (see OLT Synchronizer process, 142.3.5.5) independently on each active (enabled) receive channel. After that, the received data is passed to the FEC decoder, which introduces a near-constant delay. Corrected data from the FEC decoder is passed to the xMII and is received into the OLT MCRS EnvRx buffer. The following are the OLT rules for setting the EnvRx write and read pointers:

a) Write pointer
   1) When receiving an envelope from a registered ONU, the OLT MCRS sets the write pointer for the EnvRx buffer to equal the EPAM value in the envelope header.
   2) When receiving an envelope from an unregistered ONU, the OLT MCRS sets the write pointer according to the following equation:

$$WritePointer = ReadPointer \text{ XOR } 0x20 \quad (143–2)$$

NOTE—The OLT MCRS determines that an envelope is from an unregistered ONU by either checking the LLID value in the envelope header (DISC_PLID) or by checking that an envelope header is received during the discovery window (see 144.1.1.3). Otherwise, the envelope is assumed to be received from a registered ONU.

b) Read Pointer
   1) The read pointer increments synchronously with the LocalTime counter, which is locked to the xMII transmit clock.
   2) If the OLT implements multiple transmit channels, all these channels share the same xMII transmit clock. Correspondingly, the read pointers for all channels increment synchronously and maintain equal values.

The above set of rules produces a delay of 32 EQT that is built into the ONU MCRS receive path and a similar delay of 32 EQT that is built into the OLT MCRS receive path. Therefore, the total round-trip delay measured by the MPCP (see 144.3.1.1) during an ONU discovery and registration includes a built-in margin of 64 EQT that is used to eliminate skew between different channels or the timing jitter within a channel.

143.4.3 Delay variability constraints

The MPCP relies on strict timing based on the distribution of timestamps. The MCRS is designed to allow a delay variability of up to 64 EQTs. During the normal operation of a registered ONU, the delay any EQ experiences in the EnvRx buffer is complementary to the accumulated skew and jitter that this EQ encounters after leaving the EnvTx buffer in the transmitting MCRS, such that the sum of the two delays remains constant.

143.4.4 Asymmetric rate operation

The 25/10G-EPON and 50/10G-EPON systems are characterized by channel rate asymmetry. In such systems, downstream transmission uses one or two channels operating at 25 Gb/s, while the upstream transmission uses a single channel operating at 10 Gb/s.

Figure 143–18 illustrates the layering diagram of a 25/10G-EPON OLT and ONU. In the OLT, the MCRS sublayer serves MAC entities supporting the transmit data rate of 25 Gb/s and the receive data rate of 10 Gb/s. In turn, the MCRS sublayer is connected to the transmit path of a 25GMII and the receive path of an XGMII. In the ONU, the MCRS sublayer serves MAC entities supporting the transmit data rate of 10 Gb/s and the receive data rate of 25 Gb/s. The MCRS sublayer is connected to the transmit path of an XGMII and the receive path of a 25GMII.

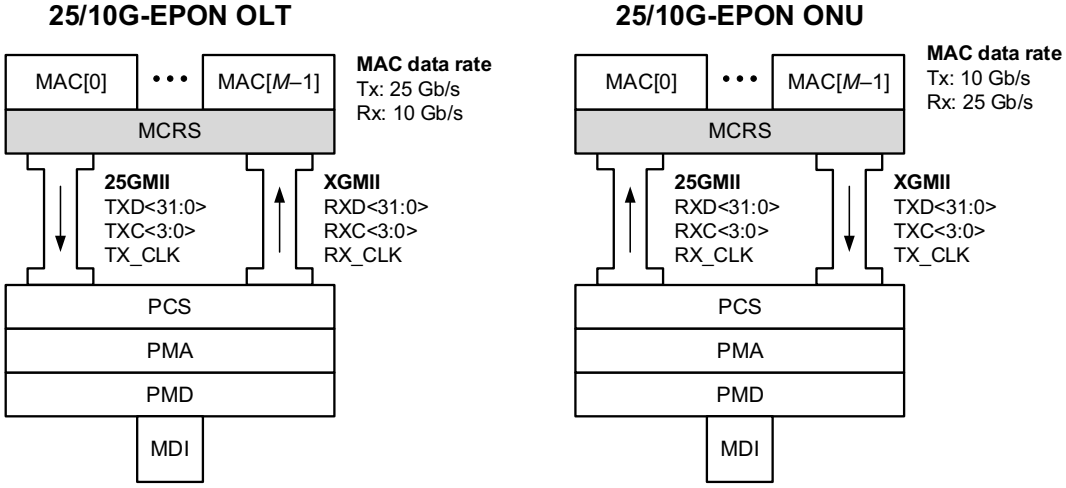

Figure 143–18—25G/10G-EPON OLT and ONU layering diagram

Because of the required close coupling between the MCRS clock (InClk, see 143.3.3.4 and OutClk, see 143.3.4.3) and MPCP clock (LocalTime, see 144.2.1.2), the MCRS buffer read pointers advance by one every EQT, i.e., both downstream and upstream channels within MCRS operate at a nominal data rate of 25 Gb/s. To adapt the MCRS channel rate to the MAC data rate of 10 Gb/s, the MCRS channel is throttled by inserting a padding EQ at the rate of 3 padding EQs per every 5 EQTs. The transfer of information through the 10 Gb/s MCRS channel is illustrated in Figure 143–19.

The padding EQs are interleaved with information EQs using the following pattern:

<information EQ> <padding EQ> <padding EQ> <information EQ> <padding EQ>

The usage of the padding EQs is entirely confined to the MCRS sublayer and does not affect the definition of interfaces to either of the adjacent sublayers. Therefore the definition of the padding EQ format and values are left to implementations.

143.5 Protocol implementation conformance statement (PICS) proforma for Clause 143, Multi-Channel Reconciliation Sublayer[237]

143.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 143, Multi-Channel Reconciliation Sublayer, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

143.5.2 Identification

143.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

143.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 143, Multi-Channel Reconciliation Sublayer
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[237] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

144. Multipoint MAC Control for Nx25G-EPON

144.1 Overview

This clause defines the mechanisms and control protocols required in order to reconcile the 25 Gb/s or 50 Gb/s passive optical network (PON) into the Ethernet framework. A PON is an optical network with no active elements in the signal's path from source to destination. The only interior elements used in a PON are passive optical components, such as optical fiber, splices, and splitters. When combined with the Ethernet protocol, such a network is referred to as an Ethernet passive optical network (EPON).

Topics covered in this clause include allocation of transmission resources in EPON, discovery and registration of EPON devices, and reporting queue occupancy to higher layers to facilitate dynamic bandwidth allocation schemes and statistical multiplexing across the PON.

This clause does not address specific bandwidth allocation strategies, authentication of end devices, quality-of-service definitions, provisioning, or management.

The Multipoint MAC Control (MPMC) sublayer defined in this clause includes two protocols:

— Multipoint Control Protocol (MPCP) responsible for arbitration of TDM-based access to the P2MP medium
— Channel Control Protocol (CCP) responsible for querying and control of multiple channels within the Nx25G-EPON PHY

The MPMC functionality shall be implemented for subscriber access devices containing point-to-multipoint (P2MP) Physical Layer devices defined in Clause 141 and Clause 142.

144.1.1 Principles of point-to-multipoint operation

A P2MP medium is an asymmetric medium based on a tree (or trunk-and-branch) topology. The DTE connected to the trunk of the tree is called an optical line terminal (OLT) and the DTEs connected at the branches of the tree are called optical network units (ONUs). The OLT typically resides at the service provider's facility, while the ONUs are located at the subscriber premises. A simplified P2MP topology example is depicted in Figure 144–1. Clause 67 provides additional examples of P2MP topologies.

144.1.1.1 Transmission arbitration

In the downstream direction (from the OLT to an ONU), signals transmitted by the OLT pass through a 1:*N* passive splitter (or cascade of splitters) and reach each ONU.

In the upstream direction (from the ONUs to the OLT), the signal transmitted by an ONU would only reach the OLT, but not other ONUs. To avoid upstream data collisions, transmission windows (grants) for all ONUs are controlled in such a way that only a single ONU's transmission reaches the OLT at any given time. The MPCP (see 144.3) is responsible for timing and arbitrating the ONU transmissions. This arbitration is achieved by allocating transmission windows (grants) to ONUs. An ONU defers its transmission until the start of its transmission window. When the transmission window starts, the ONU transmits its queued frames at full line rate for the duration of this transmission window.

Reporting of a queue occupancy state or congestion by different ONUs assists in optimal allocation of the transmission windows across the PON.

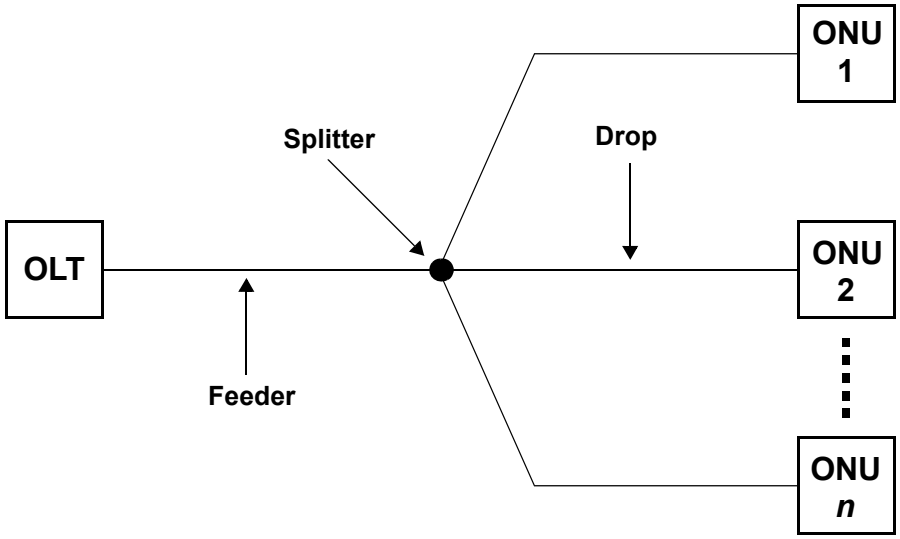

Figure 144–1—PON topology example

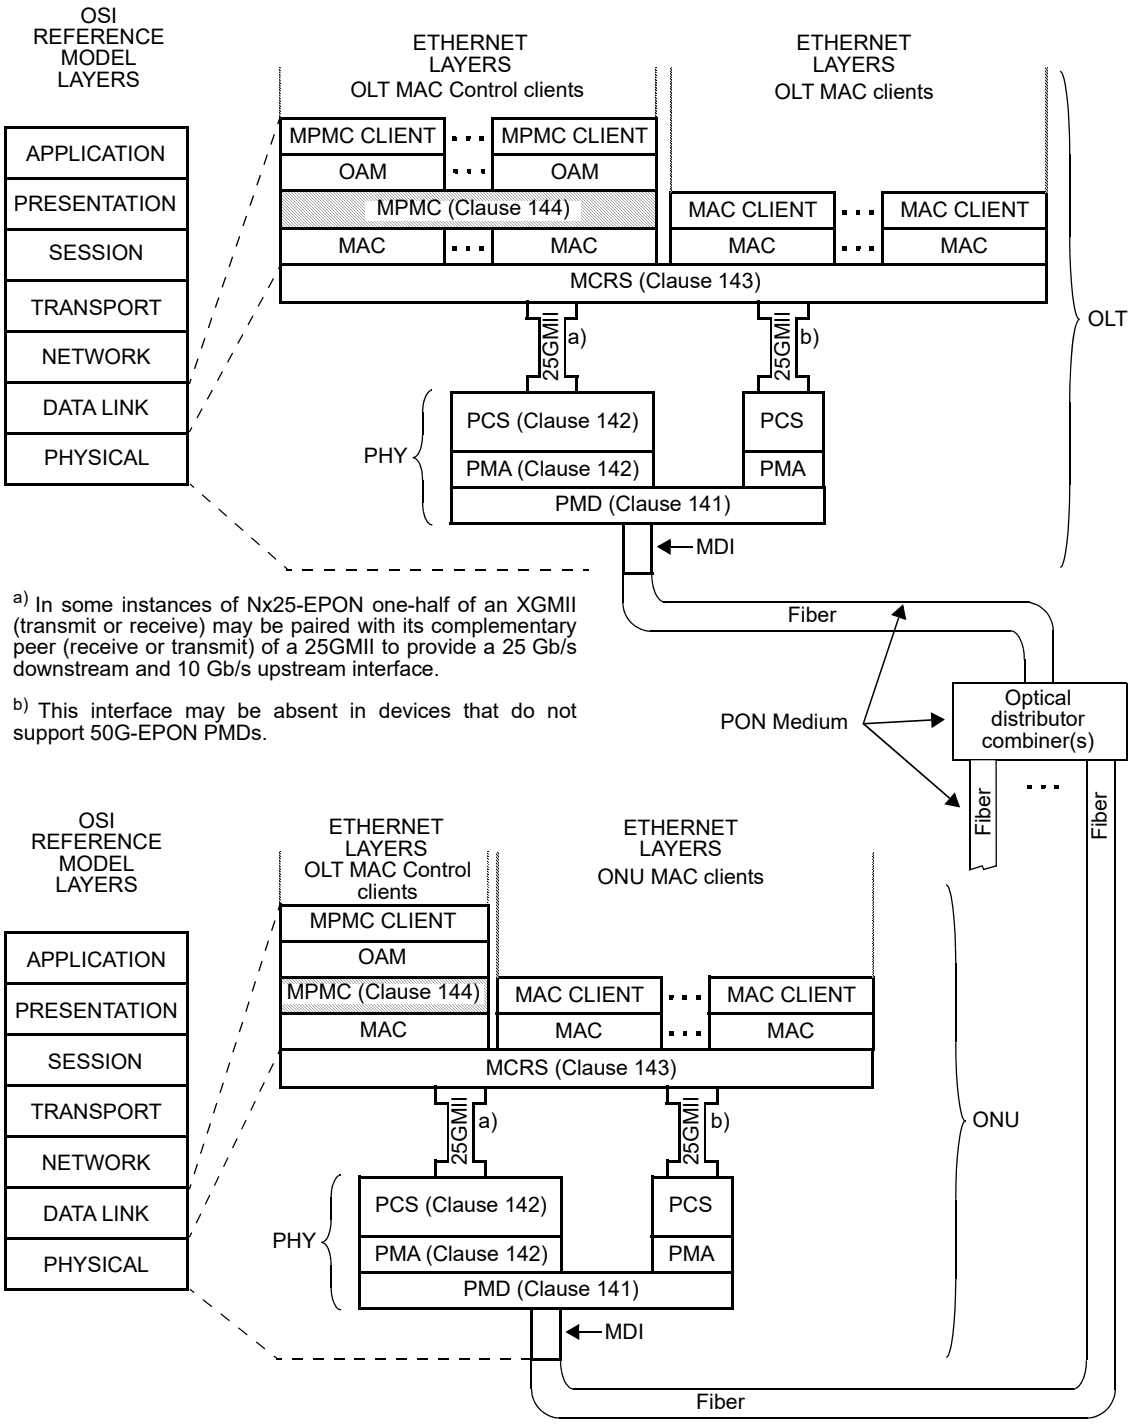
144.1.1.2 Concept of logical links

OLT and ONU devices instantiate multiple MAC instances (see Figure 144–2). P2MP architectures are best viewed as a collection of logical point-to-point and/or P2MP links. A logical link is created in the Multi-Channel Reconciliation Sublayer (MCRS), below the MAC by tagging each frame (or frame fragment) with a logical link identification (LLID) value and binding each instance of a MAC to a specific LLID value. See 143.2.1 for explanation of the mechanism of logical link operation.

A logical connection is formed when a MAC instance at the OLT and a MAC instance at the ONU are bound to the same LLID value. A point-to-point logical link connects a single MAC instance at the OLT to a single MAC instance at the ONU. A P2MP logical link takes advantage of the broadcasting nature of the P2MP topology and connects a single MAC instance at the OLT to multiple MAC instances in different ONUs. In a P2MP logical link, MAC instances in multiple ONUs are bound to the same LLID value.



By default, the OLT is connected to each ONU via two point-to-point logical links: one link is used for MPMC traffic, such as MPCPDUs (see 144.3) and the other link is used for management traffic, such as OAMPDUs (see Clause 57). These two connections per each ONU are established during the Discovery process (see 144.3.5).

Several single-copy broadcast logical links are pre-defined for specific purposes (see Table 144–1).

Additional point-to-point and/or P2MP links between the OLT and ONUs may be provisioned by network management based on specific access network configuration and service requirements. Provisioning of such additional logical links is outside the scope of this standard. Different types of logical links are described in 144.3.4.

Although the OLT and ONUs instantiate multiple MAC entities, each device may use a single MAC address. Within the EPON Network, MAC instances are uniquely identified by their LLID.

144.1.1.3 ONU discovery and registration

As was explained in 144.1.1.1, the upstream transmissions in an EPON are arbitrated by the OLT. Before any newly connected ONU can be scheduled for the upstream transmission, it needs to be discovered by the OLT. The Discovery process is used to detect the newly-connected ONUs.

At a high level, the Discovery process schedules a periodic discovery window – a timeslot during which only the unregistered ONUs are allowed to transmit their registration request. These registration request messages allow the OLT to learn the MAC address and to measure the round-trip propagation time of each new ONU. As part of the Discovery process, the new ONU is assigned its initial LLID values (see 144.1.1.2) and that allows this ONU to receive downstream traffic and also be scheduled for the upstream transmission.

The Discovery process is described in more detail in 144.3.7.

144.1.2 Position of Multipoint MAC Control (MPMC) within the IEEE 802.3 hierarchy

Figure 144–2 depicts the architectural positioning of the MPMC sublayer with respect to the MAC and the MPMC client. The MPMC sublayer extends the MAC Control sublayer to support multiple clients and additional MAC control functionality.

144.1.3 Functional block diagram

Figure 144–3 and Figure 144–4 provide a functional block diagram of the MPMC architecture for the OLT and the ONU, respectively.

144.1.4 Service interfaces

The MAC clients communicate directly with dedicated MAC instances using the standard service interface specified in 2.3. The MPMC does not interface with any MAC Clients.

The MPMC clients communicate with MPMC instances using the service interface defined in this clause. Each MPMC instance communicates with the underlying MAC sublayer using the standard service interface specified in 4A.3.2. Similarly, MPMC communicates internally using primitives and interfaces consistent with definitions in Clause 31.

144.1.4.1 MAC Control service (MCS) interface

The MCS interface is an interface between the MAC Control sublayer and the MPMC client above it (see Figure 144–3 and Figure 144–4). The definition and behavior of the MPMC client is outside the scope of this standard.

The MAC Control sublayer and the MPMC client communicate via MCS:MA_CONTROL.indication and MCS:MA_CONTROL.request primitives. In the state diagrams used in this clause, the following abbreviations are used:

- MCSI(indication_operand_list) is equivalent to:
  MCS:MA_CONTROL.indication(opcode, indication_operand_list), as defined in 31.3.2.
- MCSR(request_operand_list) is equivalent to:
  MCS:MA_CONTROL.request(destination_address, opcode, request_operand_list), as defined in 31.3.1.

144.1.4.2 MAC Control interconnect (MCI)

MCI is an internal interface between the Control Parser/Control Multiplexer and other opcode-specific functions of the MAC Control sublayer (see Figure 144–3 and Figure 144–4).

The Control Parser and Control Multiplexer communicate with opcode-specific functions via MCI:MA_CONTROL.indication and MCI:MA_CONTROL.request primitives. In the state diagrams used in this clause, the following abbreviations are used:

— MCII(indication_operand_list) is equivalent to:
MCI:MA_CONTROL.indication(opcode, indication_operand_list), as defined in 31.3.2.
— MCIR(request_operand_list) is equivalent to:
MCI:MA_CONTROL.request(destination_address, opcode, request_operand_list), as defined in 31.3.1.

144.1.4.3 MAC service Interface

The MAC service interface is an interface between the MAC sublayer and the MAC Control sublayer above it (see Figure 144–3 and Figure 144–4).

The MAC sublayer and MAC Control sublayer communicate via MAC:MA_DATA.indication and MAC:MA_DATA.request primitives. The following abbreviations are used in this clause:

— MADI(destination_address, source_address, mac_service_data_unit) is equivalent to:
MAC:MA_DATA.indication(destination_address, source_address, mac_service_data_unit, frame_check_sequence, reception_status), as defined in 2.3.2.
— MADR(destination_address, source_address, mac_service_data_unit) is equivalent to:
MAC:MA_DATA.request(destination_address, source_address, mac_service_data_unit, frame_check_sequence), as defined in 2.3.1.

144.1.4.4 MCRS Control interface

The MCRS Control interface is an interface between the MAC Control sublayer and the Multi-Channel Reconciliation Sublayer (see Clause 143). The MCRS Control interface is used to control the timing of envelope transmission over a multi-channel P2MP media.

The MAC Control sublayer and the MCRS communicate via the MCRS_CTRL.indication and MCRS_CTRL.request primitives.

144.1.5 Conventions

See 142.1.1

144.2 Protocol-independent operation

As depicted in Figure 144–3 and Figure 144–4, the MPMC comprises the following functional blocks:

a) Control Parser. This block is responsible for parsing MAC Control frames, as well as interfacing with Clause 31 entities, and opcode-specific blocks.
b) Control Multiplexer. This block is responsible for selecting the source of the frames to be transmitted.

144.2.1 Control Parser and Control Multiplexer

The Control Parser (see Figure 144–5) is responsible for opcode-independent parsing of MAC frames and forwarding these frames to other processes for opcode-specific operations. The Control Parser also extracts the value of the Timestamp field from all MPCPDUs that contain this field and checks whether the timestamp drift value is within the acceptable range. There are no interfaces connecting the Control Parser to MAC Clients.

The Control Multiplexer (see Figure 144–6) is responsible for forwarding frames received from multiple opcode-specific processes to the underlying MAC sublayer. The Control Multiplexer inserts the timestamp value into all MPCPDUs that carry the Timestamp field. There are no interfaces connecting the Control Multiplexer to MAC Clients.

144.2.1.1 Constants

DRIFT_THOLD
: Type: Integer
Description: This constant holds the maximum amount of drift allowed before a timestamp drift error is declared. Exceeding this drift causes ONU deregistration (either self-deregistration or deregistration by the OLT).
Value: 2 (for the receive channels operating at 25 Gb/s) or 3 (for the receive channels operating at 10 Gb/s)
Unit: EQT

144.2.1.2 Counters

LocalTime
: Type: 32-bit unsigned
Description: This variable holds the value of the local timer used to control MPCP operation. This variable is advanced by a timer at 390.625 MHz, and is equivalent to one EQT. At the OLT the counter shall track the 25GMII transmit clock, while at the ONU the counter shall track the 25GMII receive clock. For accuracy of the receive clock, see 142.4.4.1. In the ONU, this variable is updated with the received timestamp value by the Control Parser process (see 144.2.1.5).

144.2.1.3 Variables

BEGIN
: See 142.2.5.2

FirstTimestamp[Plid]
: Type: Boolean
Description: This variable indicates whether any MPCPDU with the given Physical Layer ID (PLID) value has been seen before or not. The FirstTimestamp[Plid] variable is initialized to true for any PLID value. After an MPCPDU is received from the MAC instance corresponding to the given PLID, the FirstTimestamp[Plid] is reset to false and does not change for the given PLID anymore.

msdu
: See the definition of mac_service_data_unit in 2.3.1.2.

opcode
: Type: 16-bit unsigned integer
Description: This variable represents the opcode value of the outgoing (in the Control Multiplexer) or incoming (in the Control Parser) MPCPDU.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

LatchedTime[]

Type: An array of 32-bit unsigned integers

Description: Each element of this array represents the value of the LocalTime counter (see 144.2.1.2) latched at the moment when the MCRS_ESH.indication(Llid) primitive was generated. The elements of the array are indexed by the Llid values.

Rtt[Plid]

Type: 24-bit unsigned integer

Description: This variable holds the measured round-trip time to the ONU. At the OLT, Rtt[DISC_PLID] is zero. At the ONU, Rtt[PLID] is zero.

Unit: EQT

SupportedOpcodes

Type: list of 16-bit unsigned integers

Description: A list of all supported opcodes (see Table 31A–1).

Timestamp

Type: 32-bit unsigned integer

Description: In the Control Multiplexer state diagram, this variable holds the PLID-specific value of timestamp to be inserted into an outgoing MPCPDU. In the Control Parser state diagram this variable represents the value of the Timestamp field of the received MPCPDU.

TsDelta

Type: 32-bit signed integer

Description: This variable represents the difference between the time that ESH was read from the MCRS EnvRx buffer (i.e., the LatchedTime[Plid]) and the Timestamp value in an MPCPDU that followed that ESH. In the ONU, the TsDelta is used to adjust the LocalTime value, while in the OLT it is used as the measurement of the round-trip time to the ONU that sourced the given MPCPDU.

TimestampOpcodes

Type: list of 16-bit unsigned integers

Description: A list of all MPCPDU opcodes that contain the Timestamp field (see Table 31A–1).

TimestampDrift

Type: Boolean

Description: This variable is used to indicate whether an uncorrectable timestamp drift was detected (when set to true) or not (when set to false). An uncorrectable timestamp drift causes an immediate PLID deregistration (see DeregistrationTrigger in 144.3.7.3, Figure 144–21, and Figure 144–22).

144.2.1.4 Functions

ProcessTimestamp (Plid, TsDelta)

This function takes the PLID and a parameter TsDelta, which represents the difference between the local time and the timestamp value in a received MPCPDU. This function checks whether the timestamp drift has exceeded the predefined device-specific threshold DRIFT_THOLD. In the ONU, this function sets the LocalTime counter based on the value of the received Timestamp field (see 144.3.1.1). In the OLT, this function measures the RTT value when the first timestamped MPCPDU is received on a given PLID link. Note that in the ONU, the RTT value is always zero. The ProcessTimestamp function is defined as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
ProcessTimestamp( Plid, TsDelta )
{
   if( FirstTimestamp[Plid] )
   {
      // The following line is executed only in the ONU
      LocalTime -= TsDelta;

      // The following line is executed only in the OLT
      Rtt[Plid] = TsDelta;

      TimestampDrift[Plid] = false;
      FirstTimestamp[Plid] = false;
   }
   else
      TimestampDrift[Plid] = abs(TsDelta) > DRIFT_THOLD
}
```

144.2.1.5 Control Parser state diagram

The OLT and ONU shall implement the Control Parser state diagram shown in Figure 144–5.

144.2.1.6 Control Multiplexer state diagram

The OLT and ONU shall implement the Control Multiplexer state diagram shown in Figure 144–6.

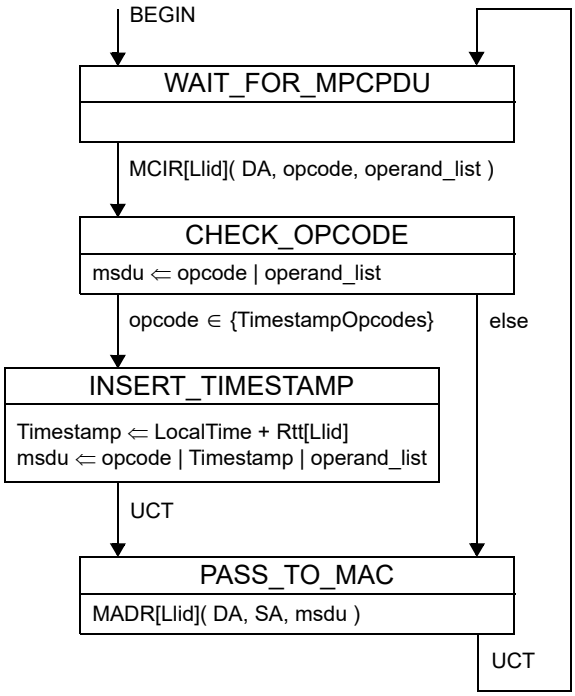

Figure 144–6—Control Multiplexer state diagram

144.3 Multipoint Control Protocol (MPCP)

144.3.1 Principles of Multipoint Control Protocol (MPCP)

In a TDM-based PON, the access to the shared physical medium needs to be arbitrated (see 144.1.1.1). The main purpose of the MPCP described in this subclause is to arbitrate transmissions in Nx25G-EPON. To achieve this goal, the MPCP includes processes that measure the range (i.e., round-trip propagation time) and maintain time synchronization between the OLT and ONUs (see 144.3.1.1) and processes that allow the OLT to assign transmission windows to individual logical links (see 144.3.3).

144.3.1.1 Ranging measurement and time synchronization

Both the OLT and the ONU have 32-bit counters (LocalTime) that increment by one every EQT. In the OLT, the LocalTime counter is synchronized with the OLT 25GMII transmit clock and increments synchronously with InClk (see 143.3.3.4). In the ONU, the LocalTime counter is synchronized with the 25GMII receive clock and increments synchronously with OutClk (see 143.3.3.4). In the ONUs supporting multiple downstream (receive) channels, the LocalTime counter is synchronized with the 25GMII receive clock of the active (enabled) channel with the lowest index.

The LocalTime counters supply the timestamp value for MPCPDUs transmitted by either device. The time reference point for the timestamp value is the transmission time of the envelope start header (ESH) of the envelope that includes the MPCPDU (see 143.3.2). In situations where multiple MPCPDUs are transmitted within a single envelope, all these MPCPDUs shall have the same timestamp value, referencing the transmission time of the ESH.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Note that the actual arrival times of MPCPDUs to the MAC Control sublayer do not affect the timing synchronization mechanism. MPCPDUs may get delayed in the transmitting MAC if, for example, the MAC is paused to allow for the MCRS rate adjustment or FEC parity insertion between the ESH and the MPCPDU.

The ONU ranging (i.e., round-trip propagation time) is measured during the ONU initial discovery and registration. The measured range value also includes the nominal delays of 32 EQT through the ONU MCRS receive data path and 32 EQT through the OLT MCRS receive data path (see 143.4.2).

The method of ranging measurement is illustrated in Figure 144–7. It consists of the following steps:

1) The OLT Discovery process transmits a DISCOVERY MPCPDU with a timestamp value equal to the LocalTime counter at the time when the MCRS_CTRL.request primitive is generated by the Envelope Activation process. This is also the time when the ESH is written into the EnvTx FIFO (see 143.3.1.2.1). Accordingly, the EPAM field of the ESH header matches the six least-significant bits of the LocalTime (LocalTime<5:0>).
2) When an unregistered ONU receives the DISCOVERY MPCPDUs, it sets its LocalTime counter based on the value in the Timestamp field in the received MPCPDU. From this moment, the LocalTime counter continues to increment synchronously with the 25GMII receive clock.
3) After the ONU's LocalTime counter reaches the value of GrantStartTime and an additional random delay, the ONU Registration process transmits the REGISTER_REQ MPCPDU with Timestamp field value equal to the LocalTime counter at the time when the MCRS_CTRL.request primitive is generated by the Envelope Activation process. This is also the time when the ESH is written into the EnvTx FIFO (see 143.3.1.2.1). Accordingly, the EPAM field of the ESH header matches the six least-significant bits of the LocalTime (LocalTime<5:0>).
4) When the OLT receives MPCPDUs, it uses the received Timestamp field value to calculate the round-trip time between the OLT and the ONU. The round-trip time (RTT) is equal to the difference between the OLT's LocalTime counter at the moment when the ESH is read from the MCRS EnvRx buffer and the Timestamp field value in the REGISTER_REQ MPCPDU.

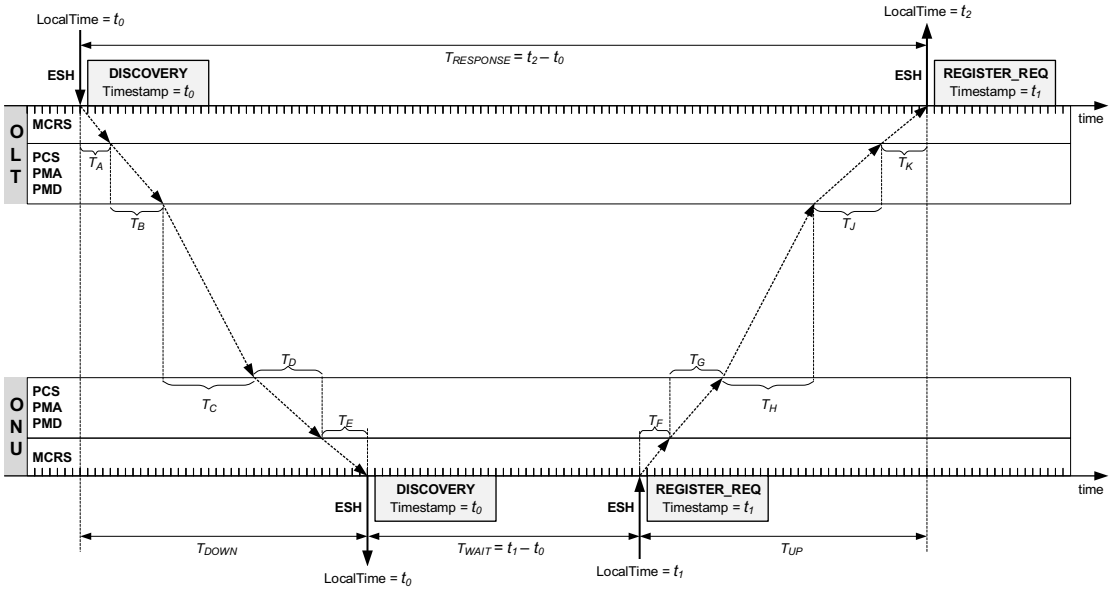

Figure 144–7—Ranging measurement

In the downstream direction, the combined delay T_{DOWN} includes the following delay components:

— T_A – delay through the transmit data path of the OLT MCRS sublayer.
— T_B – delay through the transmit data path of the OLT PCS, PMA, and PMD sublayers. This delay also includes FEC encoding delay.
— T_C – downstream optical signal propagation delay in fiber. In EPON systems supporting multiple downstream channels, this delay may be different on different channels.
— T_D – delay through the receive data path of the ONU PCS, PMA, and PMD sublayers. This delay also includes FEC decoding (correction) delay.
— T_E – delay through the receive data path of the ONU MCRS sublayer. During initial ranging, this delay is equal to 32 EQT (see 143.4.2). After the initial ranging, the delay T_E becomes inversely-correlated with the sum of delays T_A, T_B, T_C, and T_D, such that T_{DOWN} remains nearly-constant with only ± 1 EQT of variability.

In the upstream direction, the combined delay T_{UP} includes the following delay components:

— T_F – Delay through the transmit data path of the ONU MCRS sublayer.
— T_G – Delay through the transmit data path of the ONU PCS, PMA, and PMD sublayers. This delay also includes FEC encoding delay.
— T_H – Upstream optical signal propagation delay in fiber. In EPON systems supporting multiple upstream channels, this delay may be different on different channels.
— T_J – Delay through the receive data path of the OLT PCS, PMA, and PMD sublayers. This delay also includes FEC decoding (correction) delay.
— T_K – Delay through the receive data path of the OLT MCRS sublayer. During initial ranging, this delay is equal to 32 EQT (see 143.4.2). After the initial ranging, the delay T_K becomes inversely-correlated with the sum of delays T_F, T_G, T_H, and T_J, such that T_{UP} remains nearly-constant with only ± 1 EQT of variability.

As was stated above, the RTT value is equal to the difference between t_2 (the OLT's LocalTime counter at the moment when the ESH is received) and t_1 (the Timestamp field value in the REGISTER_REQ MPCPDU). Below is the derivation of this RTT value:

a) From the illustration in Figure 144–7, the total response time $T_{RESPONSE}$ (an interval of time from sending ESH with the DISCOVERY MPCPDU to the ONU and receiving ESH with the REGISTER_REQ MPCPDU from the ONU) is: $T_{RESPONSE} = t_2 - t_0$.
b) On the other hand, $T_{RESPONSE} = T_{DOWN} + T_{WAIT} + T_{UP}$, where $T_{WAIT} = t_1 - t_0$.
c) Thus, $t_2 - t_0 = T_{DOWN} + t_1 - t_0 + T_{UP}$.
d) RTT = $T_{DOWN} + T_{UP} = t_2 - t_1$.

Once the RTT is measured, the GATE Generation process for the new PLID is instantiated. That process is responsible for generating the GATE MPCPDUs to the registered ONU (PLID). All MPCPDUs sent by the OLT on unicast PLIDs have the Timestamp field value pre-compensated by the RTT associated with this PLID:

Timestamp[LLID] = LocalTime + RTT[LLID]

The effect of such pre-compensation is that the first ESH in any burst from an ONU arrives to the OLT MCRS EnvRx buffer approximately 32 EQT before their GrantStartTime values and this ESH is read from the EnvRx buffer into the associated MAC instance at the time when the OLT's LocalTime counter value is equal to GrantStartTime (see Figure 144–8).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

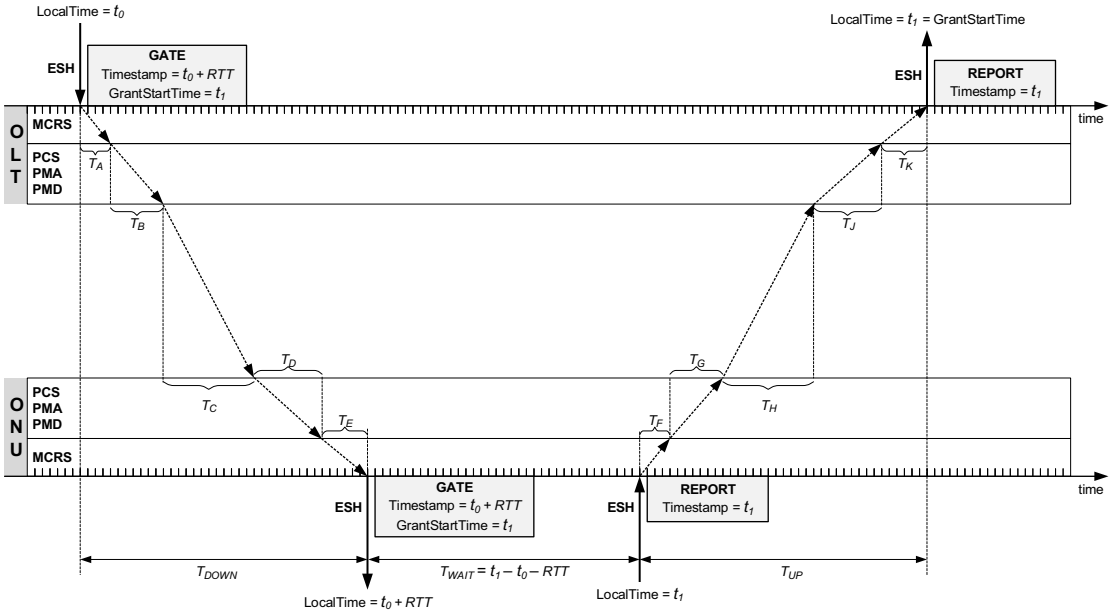

Figure 144–8—Illustration of GrantStartTime alignment

Another effect of the timestamp pre-compensation is that the Timestamp field value in a received MPCPDU is expected to match the LocalTime value at the time the MPCPDU is received. (As stated above, the timestamp reference point is the time the ESH is read from the EnvRx buffer).

A condition of timestamp drift error occurs if the OLT's and ONU's LocalTime counters lose their synchronization or mutual alignment. This condition can be independently detected by the OLT or an ONU. This condition is detected when an absolute difference between the Timestamp value received in an MPCPDU and the LocalTime counter exceeds the timestamp drift threshold limit DRIFT_THOLD (see 144.2.1.4). The timestamp drift error causes an immediate ONU deregistration.

After the ONU receives the REGISTER MPCPDU with its assigned PLID and management link ID (MLID), it stops processing any MPCPDUs received in envelopes with DISC_PLID. At this time, the ONU is ready to accept its first GATE received on the newly-assigned unicast PLID. The timestamp in this GATE MPCPDU is pre-compensated with ONU's RTT, and therefore, the ONU is expected to measure a large difference between the received Timestamp value and its LocalTime counter. This large difference that is detected immediately after registration is expected and the ONU does not recognize it as a timestamp drift error (see ProcessTimestamp in 144.2.1.4).

144.3.1.2 Granting access to the PON media by the OLT

To allow ONUs' access to the PON media, the OLT issues GATE MPCPDUs (see 144.3.6.1). A GATE MPCPDU contains a transmission start time (StartTime field) and transmission allocations (EnvAlloc[i] field) for up to seven LLIDs. The OLT may grant more than seven LLIDs by issuing multiple GATE MPCPDUs with the same StartTime value.

A GATE MPCPDU may be transmitted on any downstream channel and it may allocate upstream transmission windows on any or all upstream channels. An ONU ignores all the transmission allocations for the upstream channels that are not enabled in that ONU.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The ONU processes the GATE MPCPDUs in the order they are received and generates the upstream envelopes following the order of EnvAlloc[i] fields in each GATE MPCPDU. Therefore, it is possible for an LLID to be allocated multiple disjoint envelopes within the same grant.

As is explained in 143.3.1.2.3 and in 144.3.1.1, the value of the Timestamp field in MPCPDUs references the transmission (and reception) time of the ESH preceding these MPCPDUs. For that reason, the OLT shall never allocate overlapping envelopes to the PLID, except the fully-overlapping envelopes (see Figure 143–5).

In the case that the ONU is given partially overlapping PLID envelope allocations, it shall choose only one of these envelopes for MPCPDU transmission, and only if the envelope length is enough for at least one complete MPCPDU. The ONU ignores the rest of the overlapping PLID envelope allocations.

144.3.2 MPCP block diagram

Figure 144–9 illustrates a functional block diagram of the MPCP for the OLT. The MPCP in the OLT includes the following processes:

— GATE Generation process (see 144.3.8.7)
— Discovery Initiation process (see 144.3.7.6)
— Registration Completion process (see 144.3.7.7)
— Envelope Commitment process (see 144.3.8.9)
— Envelope Activation process (see 144.3.8.11)

In the OLT, a separate instance of the GATE Generation process and a separate instance of the Registration Completion process are created for each registered ONU (PLID, see 144.3.4).

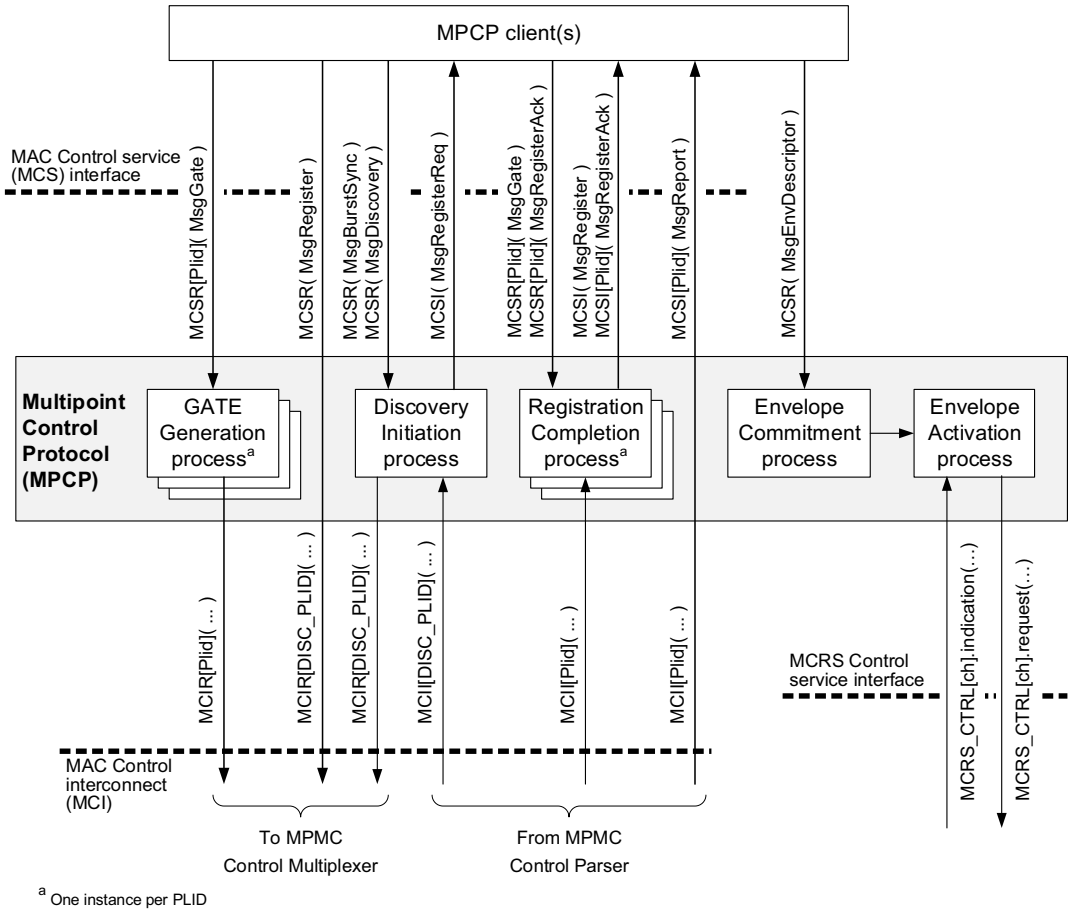

Figure 144–9—OLT Multipoint Control Protocol (MPCP) functional block diagram

Figure 144–10 illustrates a functional block diagram of the MPCP for the ONU. The MPCP in the ONU includes the following processes:

— ONU Registration process (see 144.3.7.8)
— GATE Reception process (see 144.3.8.8)
— Envelope Commitment process (see 144.3.8.10)
— Envelope Activation process (see 144.3.8.11)

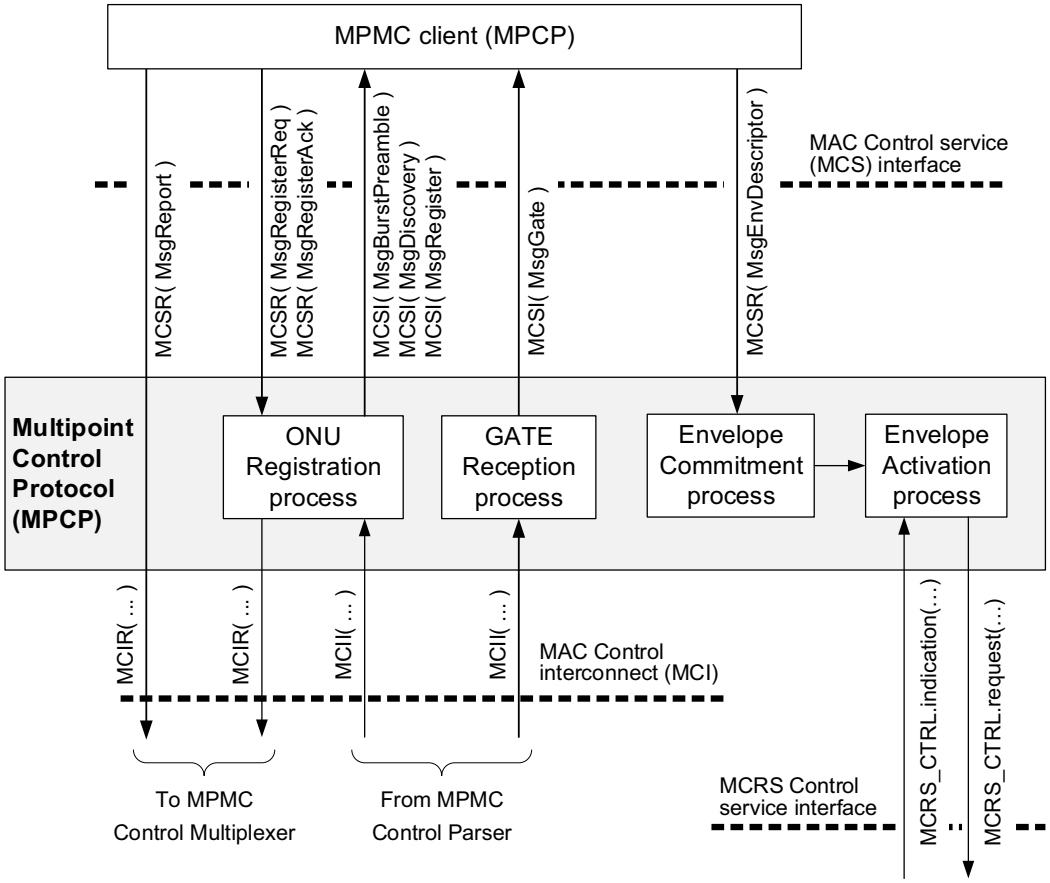

Figure 144–10—ONU Multipoint Control Protocol (MPCP) functional block diagram

144.3.3 Delay variability requirements

The MPCP protocol relies on strict timing based on distribution of timestamps. A compliant implementation needs to guarantee a constant delay through the MAC and PHY in order to maintain the correctness of the timestamping mechanism. The actual delay is implementation dependent; however, a complying implementation shall maintain the combined delay variation through the MAC and PHY of less than one EQT for channels operating at 25.78125 GBd and less than two EQTs for channels operating at 10.3125 GBd.

144.3.4 Logical link identifier (LLID) types

144.3.4.1 Physical Layer ID (PLID)

The PLID carries messages used to control critical Nx25G-EPON operations, such as ONU registrations and arbitration of ONUs' access to the PON medium. All Multipoint Control Protocol data units (MPCPDUs) are transported using the PLID. A successful ONU Discovery and Registration process, described in 144.3.7.8, results in the assignment of a single unique PLID value to the ONU.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

144.3.4.2 Management link ID (MLID)

The MLID carries management traffic flows, such as OAMPDUs (see 57.4) and CCPDUs (see 144.4). Each ONU is assigned a single unique MLID value as part of the ONU Discovery and Registration process, described in 144.3.7.8.

144.3.4.3 User link ID (ULID)

User link IDs (ULIDs) carry subscriber traffic. It is expected that a single subscriber may be assigned one or more ULIDs to allow for separation of traffic classes and types. ULID values are assigned (provisioned) to an ONU using an appropriate management protocol outside the scope of this standard. ULID values need not have a one-to-one binding of an OLT MAC to an ONU MAC. A ULID that binds a single OLT MAC to multiple MACs in different ONUs represents a multicast ULID.

144.3.4.4 Group link ID (GLID)

To assist in traffic management the Nx25G-EPON system supports consolidation of several LLIDs into arbitrary groups using the group link ID (GLID). For example, all LLIDs for a specific subscriber hosted on an ONU servicing numerous subscribers could be grouped together into a single GLID; in another example all LLIDs supporting a specific traffic class (e.g., best-effort traffic) on a multi-subscriber ONU could be grouped together. GLID values are used only for the purposes of bandwidth granting by the OLT and reporting by the ONU. The GLID report contains the sum of all queue lengths of member LLIDs from that ONU. The bandwidth granted to a GLID is distributed among its member LLIDs. The method by which the granted bandwidth is distributed among the member LLIDs is outside the scope of this standard. The actual envelope transmission is identified by a PLID, an MLID, or a ULID value, associated with a specific MAC instance that sourced the data (i.e., the LLID field in the envelope headers may only contain a PLID, MLID, or ULID, but never a GLID).

144.3.5 Allocation of LLID values

Table 144–1 shows the allocation of LLID values.

Table 144–1—Allocation of LLID values

LLID value	Designation	Description
0x00-00	ESC_LLID	The ESC_LLID is used in the GATE MPCPDU to indicate an empty EnvAlloc[n] field or in the REPORT MPCPDU to indicate an empty LlidStatus field. The ESC_LLID is also used in the MCRS_CTRL.request primitive to mark the end of an upstream burst.
0x00-01	DISC_PLID	PLID value used for discovery of unregistered ONUs.
0x00-02	BCAST_PLID	PLID value reserved for MPCPDU broadcast.
0x00-03	BCAST_MLID	MLID value reserved for broadcast of management frames (OAMPDUs).
0x00-04 to 0x0F-FF	N/A	Reserved.
0x10-00 to 0xFF-FF	N/A	The range of LLID values available for allocation to PLID, MLID, ULID, or GLID. The values may be allocated to form unicast, multicast, or broadcast connections. LLID allocation policy is outside the scope of this standard.

The OLT and the ONUs shall not transmit envelopes with ESC_LLID or a reserved value in the LLID field, and they shall ignore the received envelopes with any of these LLID values.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

An unregistered ONU shall accept only the envelopes containing the DISC_PLID value in the LLID field. The envelopes with other LLID values shall be ignored.

Upon successful registration, an ONU shall no longer accept envelopes with DISC_PLID. Instead, a registered ONU shall accept all envelopes containing any of the following LLID values:

— The specific PLID value assigned to this ONU during registration
— The specific MLID value assigned to this ONU during registration
— Broadcast PLID (BCAST_PLID)
— Broadcast MLID (BCAST_MLID)
— Any ULID or GLID assigned to this ONU by management[238]

144.3.6 MPCPDU structure and encoding

The MPCPDU structure is shown in Figure 144–11, and is further defined as follows:

— DestinationAddress:
In MPCPDUs, the DestinationAddress is the MAC Control Multicast address as specified in the annexes to Clause 31, or the individual MAC address associated with the PLID to which the MPCPDU is destined.

— SourceAddress:
In MPCPDUs, the SourceAddress is the individual MAC address associated with the PLID through which the MPCPDU is transmitted. For MPCPDUs originating at the OLT, this may be the address of any individual MAC. These MACs may all share a single unicast address, as explained in 144.1.1.2.

— Length/Type:
In MPCPDUs this field carries the MAC_Control_type field value as specified in 31.4.1.3.

— Opcode:
This field identifies the specific MPCPDU being encapsulated. Opcode field values are defined in Table 31A–1.

— OperandList:
A set of opcode-specific fields as defined in 144.3.6.1 through 144.3.6.7.

— Pad:
This field is present only when the total length of the OperandList is below 44 octets. The Pad field is added to bring the MPCPDU length up to the minimum frame size (see 4A.2.3.2.4). This field is filled with zeros on transmission, and is ignored on reception.

— FCS:
This is the frame check sequence, typically generated by the MAC.

[238]After registration, an ONU may be configured to use multiple ULID or GLID values via management. The method of provisioning of these additional ULID or GLID values is outside the scope of this standard.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

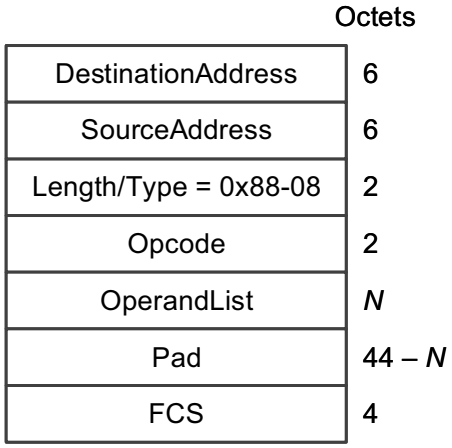

Figure 144–11—Generic MPCPDU

Fields within a frame are transmitted from top to bottom. When consecutive octets are used to represent a single numerical value, the most significant octet is transmitted first, followed by successively less significant octets. Bits within each octet are transmitted from LSB to MSB.

144.3.6.1 GATE description

The purpose of the GATE message is to grant transmission windows to ONUs for upstream transmission on the shared medium. A single grant to an ONU may consist of multiple GATE MPCPDUs, all having the same StartTime value. Up to seven envelope allocations can be carried in a single GATE MPCPDU. Only envelope allocations with a non-zero value for the LLID field are processed by the ONU. A GATE MPCPDU with no EnvAlloc (i.e., all LLID fields equal to zero) is valid and may be used as an MPCP keep alive from the OLT to the ONU.

The GATE MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–12.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

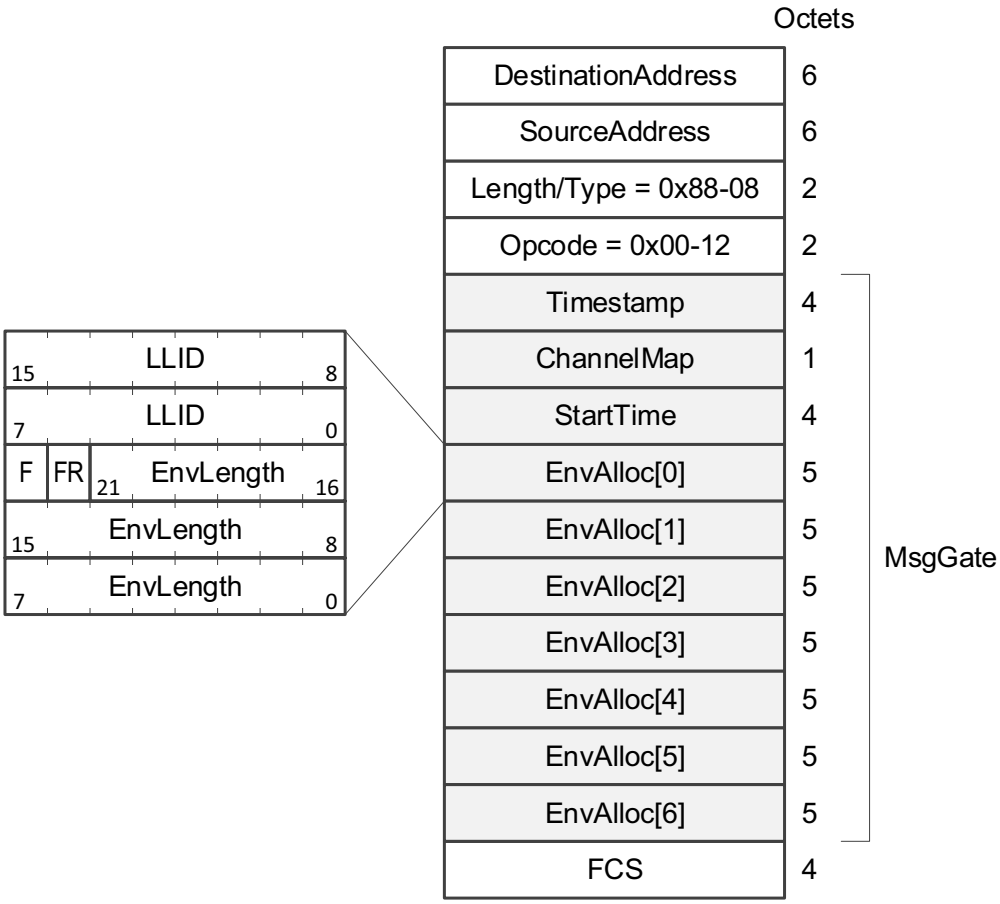

Figure 144–12—GATE MPCPDU

The GATE MPCPDU is identified by the Opcode field value of 0x00-12. The MsgGate structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the OLT's MPCP local time counter (see LocalTime counter in 144.2.1.2) compensated for the RTT of the PLID to which the GATE MPCPDU is sent. This field is used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

— ChannelMap:
This 8-bit field identifies the upstream channel(s) granted to the ONU in a given GATE MPCPDU. Table 144–2 shows the mapping between individual bits and upstream channels. When multiple channels are allowed in a single GATE MPCPDU, the transmission on each channel shall start at the ONU's local time equal to the StartTime value and have the length as necessary to transmit all allocated envelopes (the sum of all EnvLength fields) together with the associated optical and FEC overhead.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 144–2—ChannelMap bit assignment

Bit	Channel field	Values
0	Upstream channel 0	0 – do not use upstream channel 0 for transmission 1 – use upstream channel 0 for transmission
1	Upstream channel 1	0 – do not use upstream channel 1 for transmission 1 – use upstream channel 1 for transmission
7:2	Reserved	set to 0

— StartTime:
This 32-bit unsigned integer value represents the start time of the transmission window (burst), expressed in the units of EQT. The start time is compared to the LocalTime to correlate the start of the grant.

— EnvAlloc:
This is a 40-bit structure that describes the transmission window assigned to a specific LLID. Up to seven EnvAlloc elements can be carried by a single GATE MPCPDU. The EnvAlloc structure consists of the following sub-fields:

  — LLID:
  This 16-bit unsigned integer value represents the logical link that is being allocated a transmission slot. When this field is set to the value of ESC_LLID (see Table 144–1) then it signifies an empty EnvAlloc structure.

  — EnvLength:
  This 22-bit unsigned value represents the length of the envelope assigned to this specific LLID. The length of the envelope is expressed in units of EQ. The EnvLength represents the number of EQs to be sourced from a corresponding (virtual) MAC, less one EQ reserved for the ESH. The EnvLength does not include any transmission overhead components (FEC overhead or optical burst-mode overhead).

  — Fragmentation (F):
  When set to 1, this flag informs the ONU that it is allowed to fragment new frames transmitted on the given LLID. When this flag set to 0, the ONU shall not fragment new frames. If a frame fragment remains queued in this LLID since the previous envelope transmission, this old fragment is transmitted first, regardless of the value of the Fragmentation flag. The ONU shall not fragment MPCPDU frames, regardless of the value of the Fragmentation flag in the EnvAlloc structure that allocates a PLID envelope.

  — ForceReport (FR):
  When this flag is set to 1, the ONU shall report the total length of the frames (including IPG and preamble), queued for transmission on this specific LLID. When the respective bit is set to 0, the ONU is not required to report the length of the given queue.

144.3.6.2 REPORT description

The purpose of the REPORT message is to report to the OLT the amount of data queued per individual LLID in an ONU. Up to seven LLIDs can be reported by a single REPORT MPCPDU. REPORT MPCPDUs also carry the Timestamp field. The value of this field is used by the OLT to check for the timestamp drift error (see 144.3.1.1).

The REPORT MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–13.

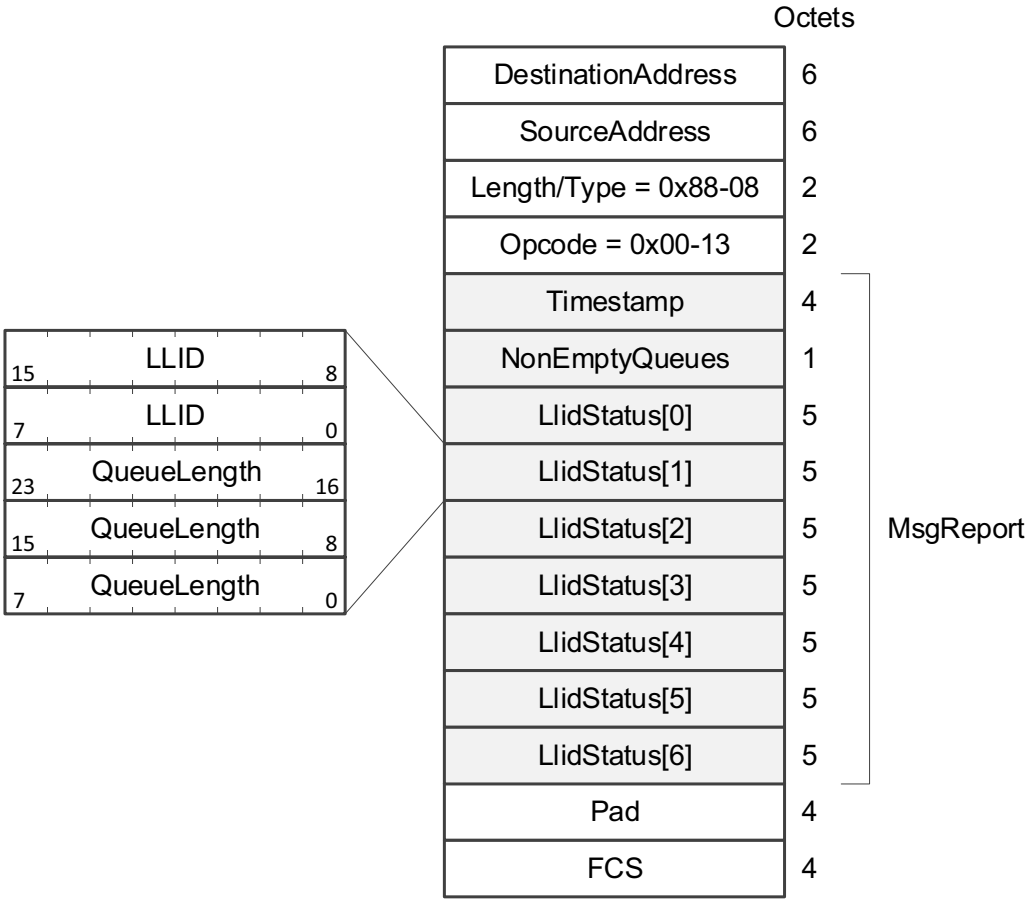

Figure 144–13—REPORT MPCPDU

The REPORT MPCPDU is identified by the Opcode field value of 0x00-13. The MsgReport structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the ONU's MPCP local time counter (see LocalTime counter in 144.2.1.2) used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

— NonEmptyQueues:
The number of LLIDs in the ONU with queues that were non-empty at the time of the REPORT MPCPDU transmission.

— LlidStatus:
This is a 40-bit structure that describes the occupancy of the queue assigned to a specific LLID. The occupancy reports for up to seven queues may be included into a single REPORT MPCPDU. The LlidStatus structure consists of the following sub-fields:

  — LLID:
  This 16-bit unsigned integer value represents the logical link that is being reported. When this

field is set to the value of ESC_LLID (see Table 144–1) then it signifies an empty LlidStatus structure.

— QueueLength:
This 24-bit value represents the length of the queue assigned to the given logical link (as indicated by the value of LLID sub-field), including the associated framing overhead (IPG and preamble). The QueueLength value is expressed in the units of EQ.

144.3.6.3 REGISTER_REQ description

The purpose of the REGISTER_REQ message is to inform the OLT of an ONU's attempt to register or unregister. When multiple ONUs attempt registration, the REGISTER_REQ MPCPDUs are transmitted in the shared discovery window and may collide. The REGISTER_REQ MPCPDUs are transmitted in envelopes with the LLID equal to DISC_PLID (see 144.3.3). The REGISTER_REQ MPCPDUs carry the Timestamp field. The value of this field is used by the OLT to measure the round-trip time of that ONU (see 144.3.1.1).

The REGISTER_REQ MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–14.

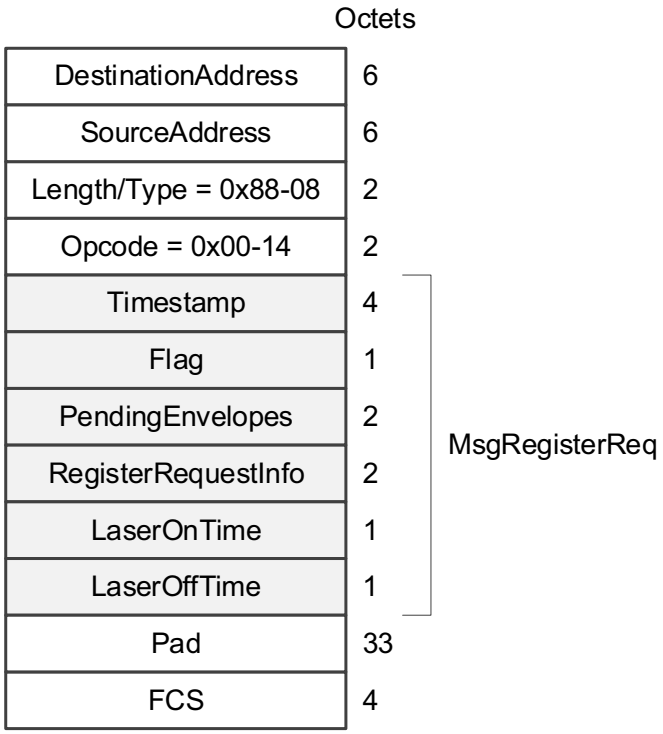

Figure 144–14—REGISTER_REQ MPCPDU

The REGISTER_REQ MPCPDU is identified by the Opcode field value of 0x00-14. The MsgRegisterReq structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the ONU's MPCP local time counter (see LocalTime counter in 144.2.1.2) used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Flag:
This is an 8-bit field that indicates special requirements for the registration, as presented in Table 144–3.

Table 144–3—REGISTER_REQ MPCPDU Flag field

Value	Indication	Comment
0	ACK	ONU is requesting registration by the OLT
1	NACK	ONU is requesting deregistration by the OLT
2 to 255	Reserved	Ignored on reception

— PendingEnvelopes:
This is an unsigned 16-bit value signifying the maximum number of envelope allocations the ONU is capable of buffering. The OLT should not grant the ONU more than this maximum number of envelope allocations into the future.

— RegisterRequestInfo:
This is a 16-bit flag register that informs the OLT about the ONU's supported transmission rate on the channel on which this MPCPDU is transmitted. Table 144–4 presents the structure of the RegisterRequestInfo field.

Table 144–4—RegisterRequestInfo field

Bit	Flag field	Values
0	Reserved	Ignored on reception
1	ONU is 10G upstream capable	0 – ONU transmitter is not capable of 10 Gb/s 1 – ONU transmitter is capable of 10 Gb/s
2	ONU is 25G upstream capable	0 – ONU transmitter is not capable of 25 Gb/s 1 – ONU transmitter is capable of 25 Gb/s
4:3	Reserved	Ignored on reception
5	10G registration attempt	0 – 10 Gb/s registration is not attempted 1 – 10 Gb/s registration is attempted
6	25G registration attempt	0 – 25 Gb/s registration is not attempted 1 – 25 Gb/s registration is attempted
15:7	Reserved	Ignored on reception

— LaserOnTime:
This field is one octet long and carries the time required to turn the ONU transmitter on. The value of LaserOnTime is expressed in the units of EQT.

— LaserOffTime:
This field is one octet long and carries the time required to turn the ONU transmitter off. The value of LaserOffTime is expressed in the units of EQT.

144.3.6.4 REGISTER description

The REGISTER message is used to convey to the registering ONU the assigned PLID and MLID values. As the ONU is not yet aware of its assigned PLID value, the REGISTER MPCPDUs are transmitted in envelopes with the LLID equal to DISC_PLID (see 144.3.5); however, they use the ONU's MAC address as the REGISTER MPCPDU DestinationAddress.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The OLT also may send the REGISTER MPCPDU to an already-registered ONU to request it to de-register or re-register. Such REQUEST MPCPDUs are sent in the envelopes with the unicast PLID assigned to the given ONU.

The REGISTER MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–15.

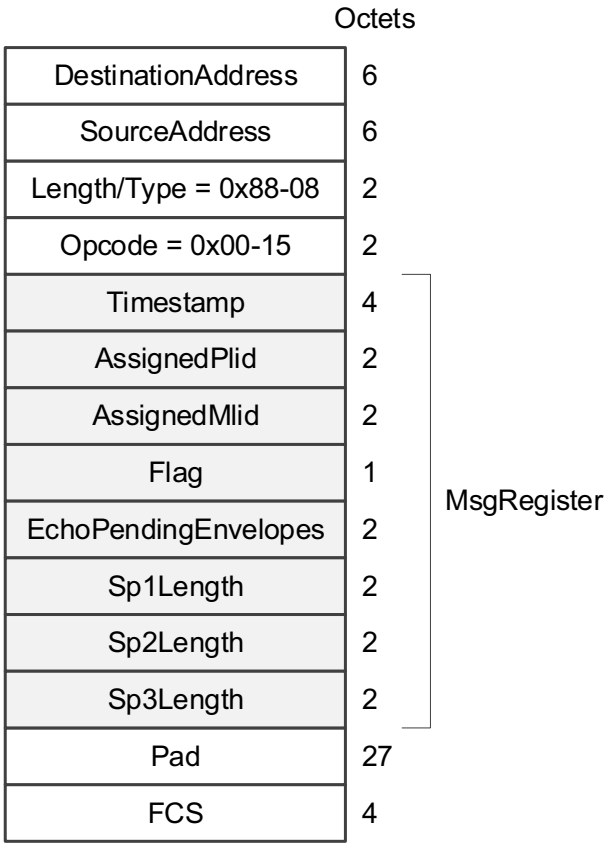

Figure 144–15—REGISTER MPCPDU

The REGISTER MPCPDU is identified by the Opcode field value of 0x00-15. The MsgRegister structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the OLT's MPCP local time counter (see LocalTime counter in 144.2.1.2) used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

— AssignedPlid:
This field holds a 16-bit unsigned value reflecting the PLID (see 144.3.4.1) assigned to the ONU during the registration.

— AssignedMlid:
This field holds a 16-bit unsigned value reflecting the MLID (see 144.3.4.2) assigned to the ONU during the registration.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Flag:
This is an 8-bit flag register that indicates special requirements for the registration, as presented in Table 144–5.

Table 144–5—REGISTER MPCPDU Flag field

Value	Indication	Comment
0	ACK	The ONU's requested registration is successful or a registered ONU is asked to re-register
1	NACK	The registration request is denied or a registered ONU is asked to deregister
2 to 255	Reserved	Ignored on reception

— EchoPendingEnvelopes:
This is an unsigned 16-bit value holding the number of envelope descriptors the ONU is able to buffer for a future activation. This is a confirmation of the PendingEnvelopes value received in the REGISTER_REQ MPCPDU.

— SP1Length:
This is a 16-bit field indicating the number of times SP1 is to be repeated at the beginning of a burst (see 142.1.3).

— SP2Length:
This is a 16-bit field indicating the number of times SP2 is to be repeated at the beginning of a burst (see 142.1.3).

— SP3Length:
This is a 16-bit field indicating the number of times SP3 is to be repeated at the beginning of a burst (see 142.1.3).

144.3.6.5 REGISTER_ACK description

The REGISTER_ACK message is transmitted by the ONU to acknowledge the completion of the Registration process. This is the first MPCPDU that the ONU transmits on its unique assigned PLID.

The REGISTER_ACK MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–16.

Copyright © 2022 IEEE. All rights reserved.

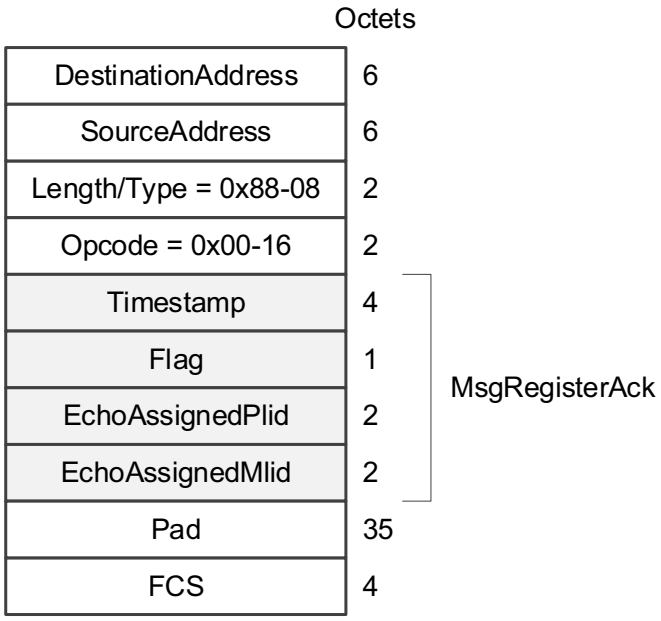

Figure 144–16—REGISTER_ACK MPCPDU

The REGISTER_ACK MPCPDU is identified by the Opcode field value of 0x00-16. The MsgRegisterAck structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the ONU's MPCP local time counter (see LocalTime counter in 144.2.1.2) used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

— Flag:
This is an 8-bit flag register that indicates special requirements for the registration, as presented in Table 144–6.

Table 144–6—REGISTER_ACK MPCPDU Flag field

Value	Indication	Comment
0	ACK	The Registration process is successfully acknowledged
1	NACK	The requested registration attempt is denied by the MPMC client
2 to 255	Reserved	Ignored on reception

— EchoAssignedPlid:
This field holds a 16-bit unsigned value of the PLID (see 144.3.4.1) assigned to the ONU in the process of registration (see 144.3.4.1).

— EchoAssignedMlid:
This field holds a 16-bit unsigned value of the MLID (see 144.3.4.1) assigned to the ONU in the process of registration (see 144.3.4.1).

144.3.6.6 DISCOVERY description

The DISCOVERY message is used by the OLT to announce a discovery grant to all unregistered ONUs. The DISCOVERY MPCPDUs are transmitted in envelopes with the LLID equal to DISC_PLID (see 144.3.5). All registered ONUs ignore the DISC_PLID, and therefore do not respond to the DISCOVERY MPCPDUs.

The DISCOVERY MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–17.

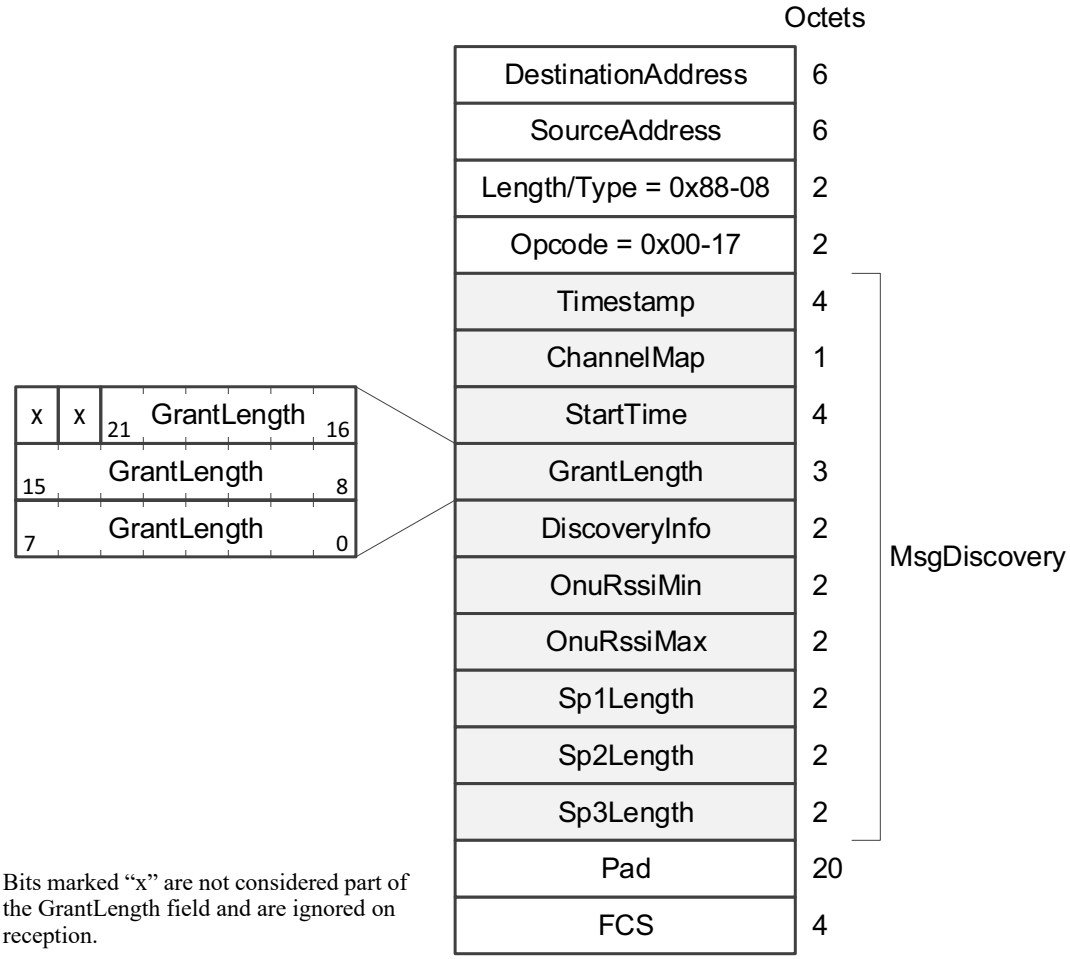

Figure 144–17—DISCOVERY MPCPDU

The DISCOVERY MPCPDU is identified by the Opcode field value of 0x00-17. The MsgDiscovery structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the OLT's MPCP local time counter (see LocalTime counter in 144.2.1.2) used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

— ChannelMap:
This 8-bit field identifies the upstream channel(s) granted to the ONU in a given DISCOVERY MPCPDU. Table 144–2 shows the mapping between individual bits and upstream channels. When

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

multiple channels are allowed in a single DISCOVERY MPCPDU, an unregistered ONU shall attempt to register on a single channel only. The choice of the channel is implementation-specific.

— StartTime:
This 32-bit unsigned integer value represents the start time of the discovery window (burst), expressed in the units of EQT. The start time is compared to LocalTime, to correlate the start of the grant. The ONU's burst typically does not start at the advertised discovery grant StartTime, but is delayed by a random time interval to avoid persistent collisions of REGISTER_REQ messages from multiple unregistered ONUs (see 144.3.7).

— GrantLength:
This 22-bit unsigned value represents the length of the discovery grant expressed in the units of EQ. The GrantLength does not include any transmission overhead components (FEC overhead or optical burst-mode overhead).

— DiscoveryInfo:
This is a 16-bit flag register. Table 144–7 presents the internal structure of the DiscoveryInfo field.

Table 144–7—DiscoveryInfo field

Bit	Flag field	Values
0	Reserved	Ignored on reception
1	OLT is 10G upstream capable	0 – OLT does not support 10 Gb/s reception 1 – OLT supports 10 Gb/s reception
2	OLT is 25G upstream capable	0 – OLT does not support 25 Gb/s reception 1 – OLT supports 25 Gb/s reception
4:3	Reserved	Ignored on reception
5	OLT is opening 10G discovery window	0 – OLT is not capable of receiving 10 Gb/s data in this window 1 – OLT is capable of receiving 10 Gb/s data in this window
6	OLT is opening 25G discovery window	0 – OLT is not capable of receiving 25 Gb/s data in this window 1 – OLT is capable of receiving 25 Gb/s data in this window
13:7	Reserved	Ignored on reception
14	Coexistence class G	0 – ONUs supporting PMDs coexistence class G are not allowed to register 1 – ONUs supporting PMDs coexistence class G are allowed to register
15	Coexistence class X	0 – ONUs supporting PMDs coexistence class X are not allowed to register 1 – ONUs supporting PMDs coexistence class X are allowed to register

The flags in the DiscoveryInfo field allow the OLT to exercise discovery admission control over the unregistered ONUs. Specifically, the following ONU behavior is defined:

— The ONU shall not generate/transmit a REGISTER_REQ MPCPDU using the 10 Gb/s upstream channel if the OLT did not open the 10 Gb/s discovery window, i.e., if bit 5 was set to 0.

— The ONU shall not generate/transmit a REGISTER_REQ MPCPDU using the 25 Gb/s upstream channel if the OLT did not open the 25 Gb/s discovery window, i.e., if bit 6 was set to 0.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— An ONU supporting PMD coexistence class G (see 141.2.3 and Table 141–7) shall not generate/transmit a REGISTER_REQ MPCPDU if the OLT does not allow the G-type coexistence, i.e., if bit 14 was set to 0.

— An ONU supporting PMD coexistence class X (see 141.2.3 and Table 141–7) shall not generate/transmit a REGISTER_REQ MPCPDU if the OLT does not allow the X-type coexistence, i.e., if bit 15 was set to 0.

The values of the DiscoveryInfo field flags are set by the OLT MPMC client and may change from one discovery attempt to the next. The OLT MPMC client may allow a concurrent registration of ONUs with different rates by setting both bits 5 and 6 to 1. The processing of DiscoveryInfo flags by the ONU and the ONU behavior in dual-rate systems is further specified in 144.3.9. The OLT MPMC client may also allow a concurrent registration of ONUs with different coexistence options by setting both bits 14 and 15 to 1. For ONUs that support both coexistence types, the choice of which type to attempt to register is implementation-dependent.

— OnuRssiMin:
This is a 16-bit unsigned integer field, representing the minimum received signal strength indicator (RSSI) threshold for the given discovery attempt. Only the ONUs with measured RSSI greater or equal to OnuRssiMin shall generate a REGISTER_REQ message in the given discovery window. The unit of OnuRssiMin value is 0.1 μW, allowing the entire field to cover the range of 0 to 6.5535 mW (~ –40 dBm to +8.2 dBm).

— OnuRssiMax:
This is a 16-bit unsigned integer field, representing the maximum RSSI threshold for the given discovery attempt. Only the ONUs with measured RSSI lower or equal to OnuRssiMax shall generate a REGISTER_REQ message in the given discovery window. The unit of OnuRssiMax value is 0.1 μW, allowing the entire field to cover the range of 0 to 6.5535 mW (~ –40 dBm to +8.2 dBm).

— SP1Length:
This is a 16-bit unsigned integer field indicating the number of times SP1 is to be repeated at the beginning of a burst carrying the REGISTER_REQ MPCPDU (see 142.1.3).

— SP2Length:
This is a 16-bit unsigned integer field indicating the number of times SP2 is to be repeated at the beginning of a burst carrying the REGISTER_REQ MPCPDU (see 142.1.3).

— SP3Length:
This is a 16-bit unsigned integer field indicating the number of times SP3 is to be repeated at the beginning of a burst carrying the REGISTER_REQ MPCPDU (see 142.1.3).

144.3.6.7 SYNC_PATTERN description

The SYNC_PATTERN message is transmitted by the OLT to announce a synchronization pattern (257-bit sequence) to be used by ONUs at the beginning of each upstream burst (i.e., as a burst preamble). The OLT announces three distinct patterns to be used at the beginning of every burst (see 142.1.3). An unregistered ONU does not respond to a DISCOVERY message if it did not receive all three SYNC_PATTERN MPCPDUs before it received the DISCOVERY MPCPDU. As part of the Discovery process, the SYNC_PATTERN MPCPDUs are transmitted in envelopes with the LLID equal to DISC_PLID (see 144.3.5) to allow unregistered ONUs to obtain the synchronization pattern. An ONU that received three synchronization patterns and subsequently registered with the OLT, continues to use the same synchronization patterns after the registration.

The SYNC_PATTERN MPCPDU is an instantiation of the Generic MPCPDU and shall be as shown in Figure 144–18.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

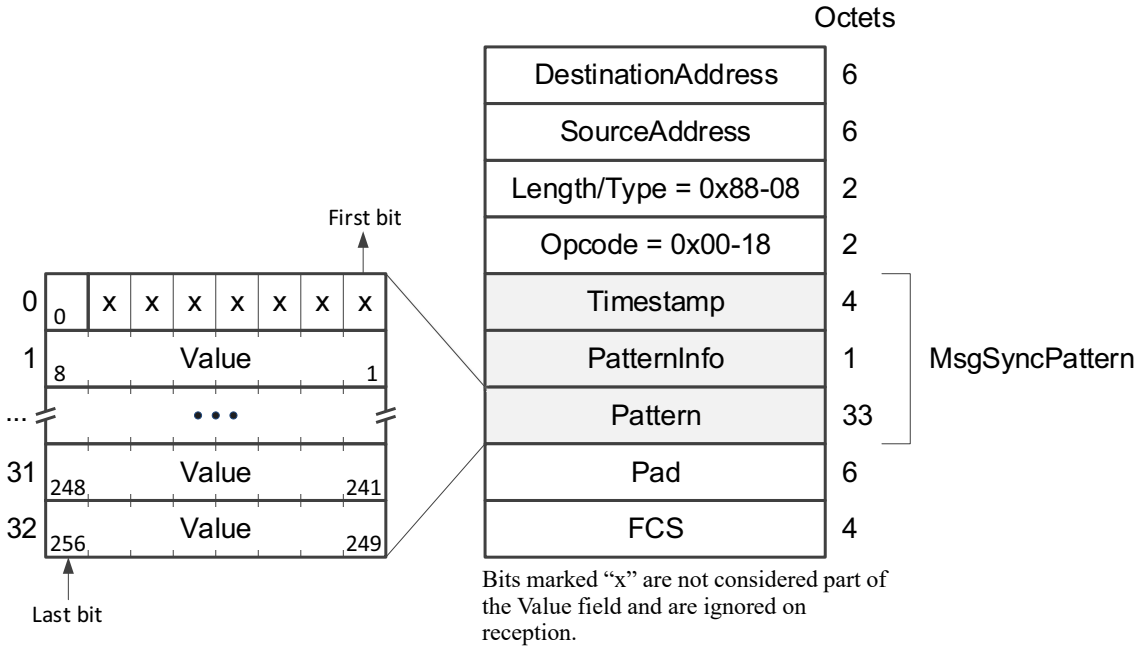

Figure 144–18—SYNC_PATTERN MPCPDU

The SYNC_PATTERN MPCPDU is identified by the Opcode field value of 0x00-18. The MsgSyncPattern structure represents a set of opcode-specific fields, defined as follows:

— Timestamp:
This field conveys the content of the OLT's MPCP local time counter (see LocalTime counter in 144.2.1.2) used for MPCP time synchronization (see 144.3.1.1). This field carries a 32-bit unsigned integer value that represents time in the units of EQT.

— PatternInfo:
This is an 8-bit field, with individual bits defined per Table 144–8.

Table 144–8—PatternInfo field value

Bit(s)	Field Name	Meaning
1:0	Index	Indicates the index of the synchronization pattern element being configured by the OLT. Valid values for index are 0, 1, or 2.
6:2	Reserved	Ignored on reception
7	Balanced	Indicates whether the given synchronization pattern element is to be balanced or not: 0 – synchronization pattern is to remain unbalanced, i.e., synchronization pattern value is repeated unchanged 1 – synchronization pattern is to be balanced, i.e., each 257-bit block of synchronization pattern element (starting with the second block) is an inversion of its preceding block

— Pattern:
This is a 33-octet field, containing a 257-bit synchronization pattern element (sub-field Value). The ONU transmits the corresponding burst synchronization pattern matching the exact bit sequence that it received in the Value sub-field.

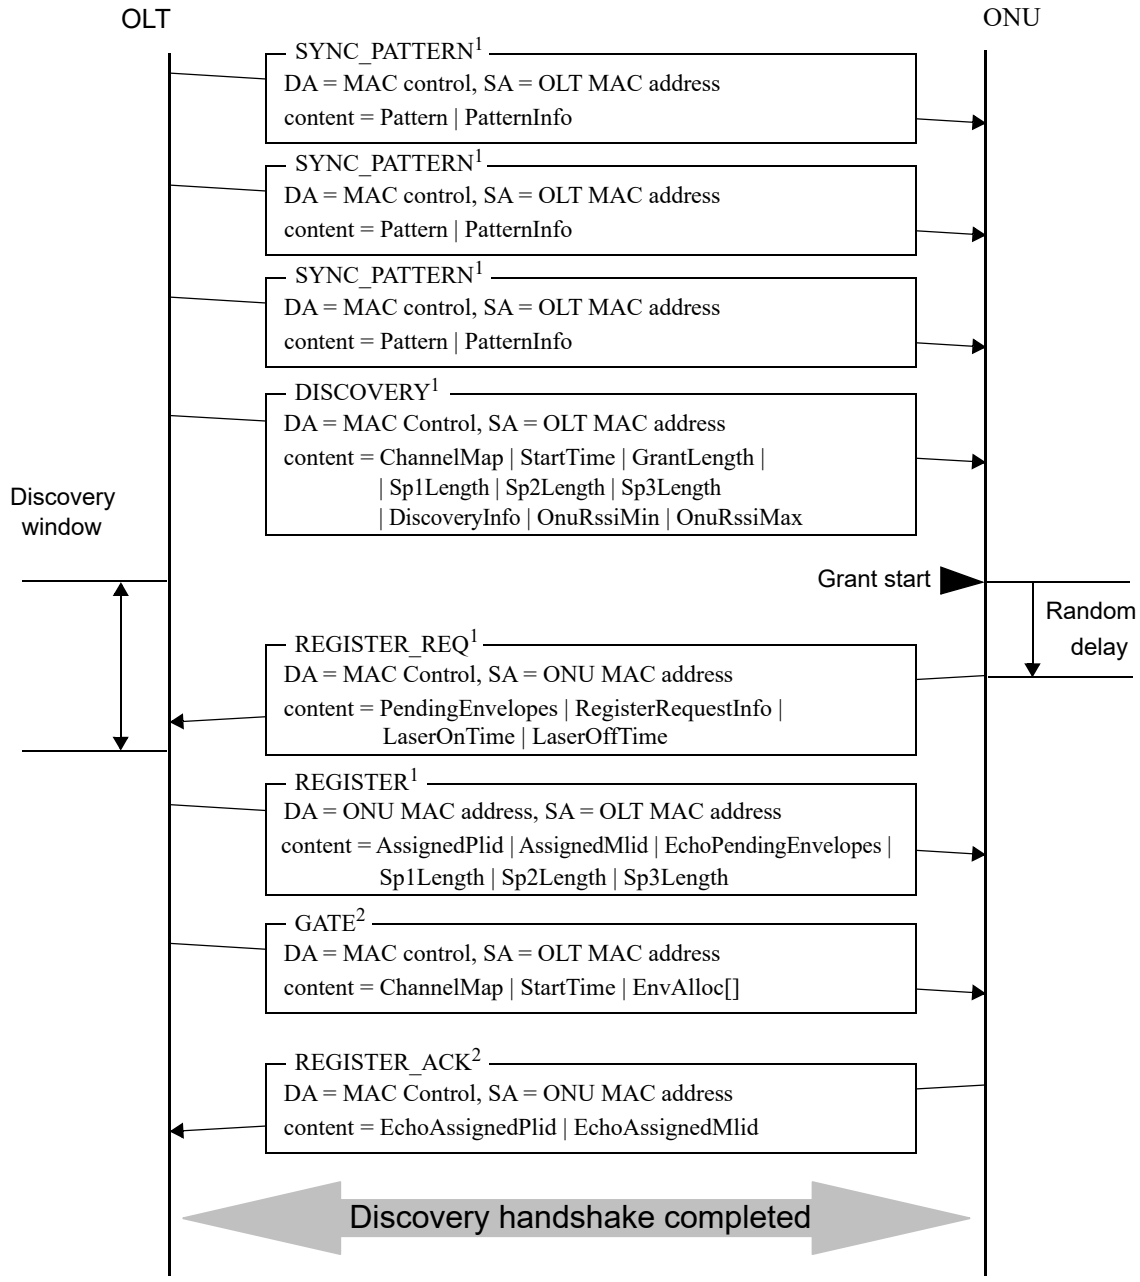
144.3.7 Discovery process

Discovery is the process whereby newly connected or unregistered ONUs are provided access to the PON. The process is driven by the OLT, which periodically makes available discovery windows during which unregistered ONUs are given the opportunity to make themselves known to the OLT. The periodicity of these windows is unspecified.

The Discovery process begins with the announcement of the MsgSyncPattern structure using the SYNC_PATTERN MPCPDU exchange between the OLT and the ONU. Three separate SYNC_PATTERN MPCPDUs are sent by the OLT, announcing the value of SP1, SP2, and SP3 portions of the FEC unprotected area in the head of the upstream burst (see 142.1.3). Repeat counts for SP1, SP2, and SP3 during the discovery window are announced within the DISCOVERY MPCPDU. Repeat counts for SP1, SP2, and SP3 outside of the discovery window (normal granting operation) are announced within the REGISTER MPCPDU. Combined, this allows the OLT to effectively configure the synchronization pattern structure and optimize it for the specific OLT receiver implementation. If a SYNC_PATTERN MPCPDU is received prior to the transmission of a REGISTER_REQ MPCPDU of an ONU responding to a previous discovery window (see Figure 144–22) that registration is aborted and the ONU waits for a subsequent MsgSyncPattern announcement and the discovery window to register.

Upon completion of the MsgSyncPattern announcement, the OLT signals that a discovery period is occurring by broadcasting a DISCOVERY MPCPDU, which includes the starting time and length of the discovery window, along with the DiscoveryInfo field, as defined in 144.3.6.6. With the appropriate settings of individual flags contained in this 16-bit wide field, the OLT notifies all the ONUs about its upstream and downstream channel transmission capabilities. Note that the OLT may simultaneously support more than one data rate in the given transmission direction.

Unregistered ONUs, upon receiving a DISCOVERY MPCPDU, wait for the period to begin and then transmit a REGISTER_REQ MPCPDU to the OLT. Discovery windows are unique in that they are the only times when multiple ONUs are allowed to access the same upstream channel simultaneously, and transmission overlap may occur. In order to reduce transmission overlaps, a contention algorithm is used by all ONUs. Measures are taken to reduce the probability for overlaps by artificially simulating a random distribution of distances from the OLT. Each ONU waits a random amount of time before transmitting the REGISTER_REQ MPCPDU. The wait time together with the REGISTER_REQ MPCPDU transmission time (including optical overhead, burst synchronization sequence, and FEC parity data) does not exceed the length of the discovery window. Note that multiple valid REGISTER_REQ MPCPDUs may be received by the OLT during a single discovery window. Included in the REGISTER_REQ MPCPDU is the ONU's MAC address and number of maximum pending envelopes. Additionally, a registering ONU notifies the OLT of its transmission capabilities in the current upstream channel by setting appropriately the flags in the RegisterRequestInfo field, as specified in 144.3.6.3.



Note that even though a compliant ONU may be capable of supporting more than one data rate in any transmission channel, it is expected that an ONU only attempts to register at a single rate as indicated in the RegisterRequestInfo field bits 5 and 6. Moreover, in order to improve the upstream channel utilization and to decrease the required size of the guard band between individual data bursts, the registering ONU notifies the OLT of the laser on/off times, by setting appropriate values in the LaserOnTime and LaserOffTime fields.

Upon receipt of a valid REGISTER_REQ MPCPDU, the OLT registers the ONU, allocating and assigning two new port identities (PLID and MLID), and binding them to corresponding MACs in the OLT.

The next step in the process is for the OLT to transmit a REGISTER MPCPDU containing the PLID and MLID to the newly discovered ONU. The REGISTER MPCPDU also contains the OLT's required synchronization time. Moreover, the OLT echoes the maximum number of pending envelopes.

After processing the REGISTER_REQ MPCPDU received from a given ONU, the OLT has enough information to schedule that ONU for access to the PON. The OLT transmits a GATE MPCPDU allowing the ONU to transmit a REGISTER_ACK MPCPDU. Upon receipt of the REGISTER_ACK MPCPDU, the Discovery process for that ONU is complete, the ONU is registered and normal message traffic may begin. It is the responsibility of Layer Management to perform the MAC binding, and start transmission from/to the newly registered ONU. The discovery message exchange is illustrated in Figure 144–19.

[1] Messages sent on discovery PLID (DISC_PLID)
[2] Messages sent on unicast PLID

Figure 144–19—Discovery handshake message exchange

There may exist situations when the OLT requires an ONU to re-register. The OLT initiates such reregistration by transmitting a REGISTER MPCPDU to the ONU. This MPCPDU is transmitted in an envelope with unicast PLID assigned to this ONU.

If the Flag field in the REGISTER MPCPDU has the value of ACK, the ONU performs a fast registration sequence where it simply responds with the REGISTER_ACK MPCPDU, while remaining registered at all times. If the Flag field in the REGISTER MPCPDU has the value of NACK, the ONU deregisters and goes through a complete discovery sequence, as outlined above.

There may also be situations when the MPMC client (MPCP) in the ONU determines that this ONU needs to deregister. The ONU transmits a REGISTER_REQ MPCPDU with the Flag field equal to NACK before unconditionally deregistering itself. Depending on the causes for such a deregistration, the MPMC client (MPCP) determines whether the ONU is allowed to participate in a new discovery sequence or not; the criteria for such a determination is outside the scope of this standard.

144.3.7.1 Constants

ACK_GATE_LIMIT
Type: Integer
Description: The maximum number of GATE MPCPDUs that the OLT issues to a registering ONU to provide an opportunity for REGISTER_ACK MPCPDU transmission.
Value: 8

DISCOVERY_MARGIN
Type: Integer
Description: This constant holds the extra margin reserved at the end of a discovery grant to accommodate the largest possible round-trip time on a given ODN. The round-trip time also includes any internal delays in the OLT and ONU, such as FEC encoding and decoding delays.
Value: 80 078 (205 μs for ODN with 20 km reach)
Unit: EQT

MISSED_REPORT_LIMIT
Type: Integer
Description: This constant represents the number of missed REPORT MPCPDUs that cause the OLT to deregister the given ONU.
Value: 8

REQ_LENGTH
Type: Integer
Description: This constant holds the envelope length sufficient to carry a single REGISTER_REQ MPCPDU.
Value: 10
Unit: EQT

SP_COUNT
Type: Integer
Description: The number of synchronization patterns used at the beginning of each burst.
Value: 3

144.3.7.2 Counters

GateCount

Description: This counter counts the number of remaining GATE MPCPDUs to be issued to a registering ONU before the registration attempt is deemed to have failed due to a lack of acknowledgment (i.e., missing REGISTER_ACK MPCPDU).

LocalTime

See 144.2.1.2

144.3.7.3 Variables

BEGIN

See 142.2.5.2

ChState

Type: Array of eight Boolean values

Description: The value of this variable represents a binary-encoded status of upstream channels at the ONU. Bit 0 corresponds to channel 0 and bit 1 corresponds to channel 1. Bits 2 through 7 are set to 0. The value of each bit has the following meaning:

1 = channel is enabled

0 = channel is disabled

DeregistrationTrigger

Type: Boolean

Description: This variable is set to true when at least one of multiple conditions for ONU deregistration becomes true. Otherwise, the variable is set to false. The DeregistrationTrigger is an alias for the following code:

```
DeregistrationTrigger =
   // 1) ONU MPCP is unresponsive
   MissedReportCount == MISSED_REPORT_LIMIT OR

   // 2) Timestamp drift exceeded the safe margin
   TimestampDrift == true OR

   // 3) ONU requested deregistration
   ( MCII(MsgRegisterReq) AND MsgRegisterReq.Flag == NACK )
```

GrantEndTime

Type: 32-bit unsigned integer

Description: This variable holds the time at which the ONU grant ends. Failure of a REGISTER_ACK message from an ONU to arrive at the OLT before GrantEndTime for more than ACK_GATE_LIMIT times is a fatal error in the Discovery process, and causes registration to fail for the specified ONU.

Unit: EQT

GrantMargin

Type: 22-bit unsigned integer

Description: This variable represents the total time required for an ONU to terminate one burst and immediately initiate another burst. The variable includes the following burst overhead components:

a) The length of end-of-burst delimiter (EBD)
b) The length of SP1 synchronization pattern (SP1Length)
c) The length of SP2 synchronization pattern (SP2Length)
d) The length of SP3 synchronization pattern (SP3Length).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

e) The FEC Parity overhead (2560 parity bits + 10 bits of FEC codeword delimiter)

All the above overhead components are represented in terms of 257-bit line coding blocks. The sum of these values S is converted into units of EQ as S × 4.

Value: GrantMargin is calculated the first time when the ONU receives DISCOVERY MPCPDU with Sp1Length, Sp2Length, and Sp3Length. Then, it is recalculated when the ONU receives REGISTER MPCPDU, which may have the same Sp1Length, Sp2Length, and Sp3Length values or different.

NOTE—If an ONU receives a grant with a StartTime within the GrantMargin from the end of the previous grant, then the ONU ignores such a grant.

MaxDelay

Type: 32-bit unsigned integer

Description: This variable indicates the maximum delay the ONU may apply to REGISTER_REQ MPCPDU transmission while remaining within the allocated discovery grant.

Unit: EQT

MissedReportCount

Type: 8-bit unsigned integer

Description: This variable counts the number of missed REPORT MPCPDUs from a given PLID. A REPORT MPCPDU is considered missing if the OLT has allocated an envelope for the PLID and has not received any REPORT MPDCPDUs in the corresponding PLID envelope. The MissedReportCount counter is incremented by one per each PLID envelope that did not contain any REPORT MPCPDUs, regardless of the length of that envelope. If a REPORT MPCPDU is received from a given PLID, the value of MissedReportCount is reset to zero.

Onu10GCapable

Type: Boolean

Description: This variable is set to true if the ONU is capable of transmitting at a line rate of 10.3125 GBd. Otherwise, it is set to false

Onu25GCapable

Type: Boolean

Description: Description: This variable is set to true if the ONU is capable of transmitting at a line rate of 25.78125 GBd. Otherwise, it is set to false.

OnuCoexType

Type: 2-bit integer

Description: This variable represents the coexistence types supported by the ONU transceiver (see 141.2.3). Bit 0 represents G-type coexistence and bit 1 represents X-type coexistence. Therefore, this variable takes the following values:

0x1: The ONU transceiver supports G-type coexistence

0x2: The ONU transceiver supports X-type coexistence

0x3: The ONU transceiver supports both G-type and X-type coexistence

OnuRssiLocal

Type: 16-bit unsigned integer

Description: This variable holds the RSSI value measured by the ONU receiver. Only the ONUs whose OnuRssiLocal value is within the RSSI limits advertised in the DISCOVERY MPCPDU are allowed to register in the given discovery window. Refer to definitions of OnuRssiMin and OnuRssiMax in 144.3.6.6.

Unit: 0.1 μW

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RegAllowed

Type: Boolean

Description: This variable is set to true if upon the verification of the various fields of the DISCOVERY MPCPDU, the ONU has determined that it is allowed to transmit a REGISTER_REQ in the current discovery window. The RegAllowed is an alias for the following code:

```
RegAllowed =

      // 1) Upstream channel is available
      ((MsgDiscovery.ChannelMap AND ChState) != 0) AND

      // 2) RSSI is within the allowed limits
      OnuRssiLocal ≥ MsgDiscovery.OnuRssiMin AND
      OnuRssiLocal ≤ MsgDiscovery.OnuRssiMax AND

      // 3) OLT and ONU support the same coexistence mode (G or X)
      ((MsgDiscovery.DiscoveryInfo[15:14] AND OnuCoexType) != 0) AND

      // 4) 25G discovery is open and ONU is 25G-capable,
      // OR (10G discovery is open and ONU is 10G-capable
      // AND the OLT and/or the ONU are not 25G-capable)
      // (see Discovery in dual-rate systems, 144.3.7)
      ((MsgDiscovery.DiscoveryInfo[6] == 1 AND Onu25GCapable) OR
      ((MsgDiscovery.DiscoveryInfo[5] == 1 AND Onu10GCapable) AND
      (MsgDiscovery.DiscoveryInfo[2] == 0 OR !Onu25GCapable)));
```

Registered

Type: Boolean

Description: This variable holds the current registration status of a PLID. It is set to true once the Discovery process is complete and registration is acknowledged.

RegStart

Type: 32-bit unsigned integer

Description: This variable indicates the local time at which the REGISTER_REQ MPCPDU is to be transmitted by the ONU. The RegStart is delayed from the discovery grant start time by a random amount to prevent persistent collisions of REGISTER_REQ MPCPDUs from multiple registering ONUs.

Unit: EQT

SpSeq

Type: 2-bit unsigned integer

Description: This variable indicates the index of the synchronization pattern announced by the OLT in the SYNC_PATTERN MPCPDU. The SpSeq variable takes values 0, 1, or 2. Details about individual synchronization pattern elements are covered in 142.1.3.

144.3.7.4 Functions

BurstLength(env_length)

This function takes the envelope length (or a total of multiple envelope lengths) and calculates the total length of the upstream burst, including the following overhead components:

a) The length of SP1 synchronization pattern (SP1Length)
b) The length of SP2 synchronization pattern (SP2Length)
c) The length of SP3 synchronization pattern (SP3Length)
d) Rounding overhead due to 256B/257B line coding

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

e) The FEC Parity overhead, including the 10-bit FEC codeword delimiter
f) The length of burst terminating sequence, including the EBD and laser off time

The result is converted into EQT and is rounded up to the next integer value.

Random(min_value, max_value)

This function returns a random value uniformly distributed in the range from min_value to max_value, inclusive.

144.3.7.5 Messages

MsgBurstSync

A set of parameters (operand_list) carried in multiple SYNC_PATTERN MPCPDUs. Within the OLT Discovery Initiation process (see 144.3.7.6), the MsgBurstSync set is received from the MPMC client and is transmitted in three SYNC_PATTERN MPCPDUs. Within the ONU Registration process (see 144.3.7.8), the parameters received in multiple SYNC_PATTERN MPCPDUs are combined and passed to the MPMC client as a single MsgBurstSync set. The MsgBurstSync set includes the following parameters:

Balanced[SP_COUNT]: An array of SP_COUNT Boolean values, where the *n*th element of the array indicates whether the *n*th synchronization pattern is balanced or not.

Value[SP_COUNT]: An array of SP_COUNT 257-bit values, where the *n*th element of the array represents the *n*th synchronization pattern.

MsgDiscovery

A set of parameters (operand_list) carried in the DISCOVERY MPCPDU, as defined in 144.3.6.6.

MsgGate

A set of parameters (operand_list) carried in the GATE MPCPDU, as defined in 144.3.6.1.

MsgRegister

A set of parameters (operand_list) carried in the REGISTER MPCPDU, as defined in 144.3.6.4.

MsgRegisterAck

A set of parameters (operand_list) carried in the REGISTER_ACK MPCPDU, as defined in 144.3.6.5.

MsgRegisterReq

A set of parameters (operand_list) carried in the REGISTER_REQ MPCPDU, as defined in 144.3.6.3.

MsgSyncPattern

A set of parameters (operand_list) carried in the SYNC_PATTERN MPCPDU, as defined in 144.3.6.7.

144.3.7.6 Discovery Initiation state diagram

The OLT MPCP shall implement a single instance of the OLT Discovery Initiation process shown in Figure 144–20. This instance shall be associated with the DISC_PLID value, i.e., it only receives and generates MPCPDUs that are carried in envelopes with the DISC_PLID value.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

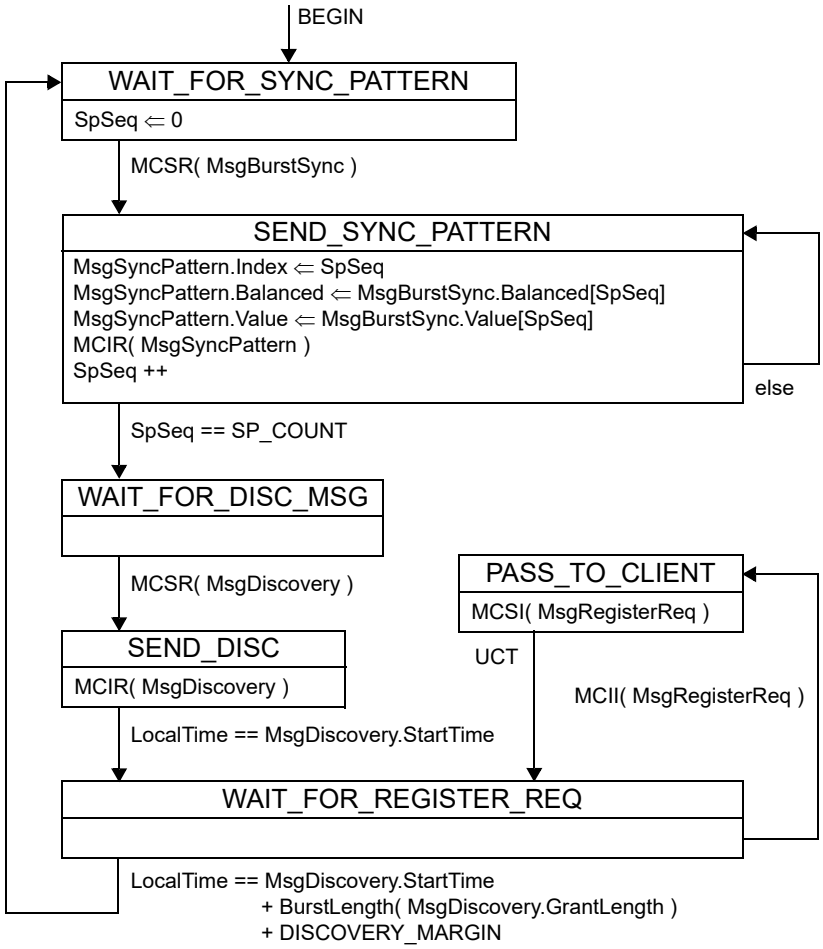

Figure 144–20—OLT Discovery Initiation state diagram

144.3.7.7 Registration Completion state diagram

The OLT MPCP shall implement multiple instances of the OLT Registration Completion state diagram shown in Figure 144–21 where each instance is associated with a unicast PLID being registered.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

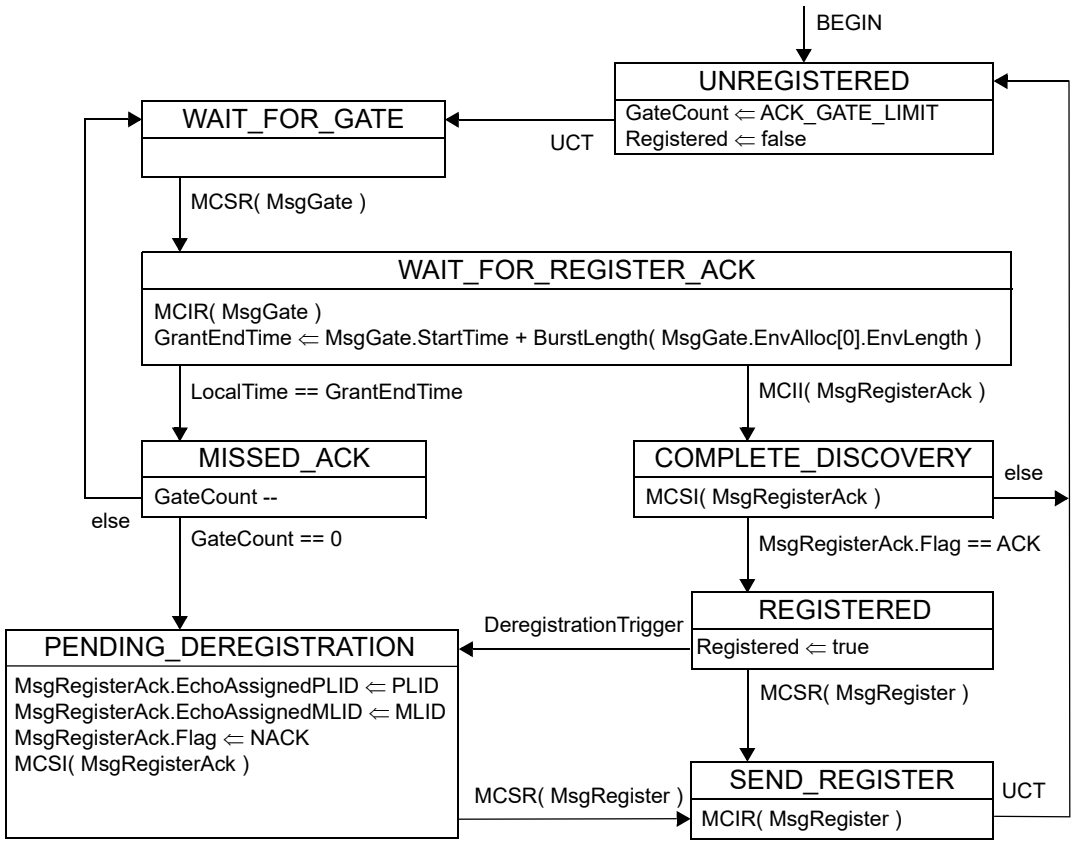

Figure 144–21—OLT Registration Completion state diagram

144.3.7.8 ONU Registration state diagram

The ONU MPCP shall implement a single instance of the ONU Registration state diagram as shown in Figure 144–22. This instance is associated with the DISC_PLID value when the Registered variable is equal to false, and it is associated with unicast PLID and BCAST_PLID values, when the Registered variable is equal to true.

144.3.8 Granting process

As noted in 144.1.1.1, upstream transmissions in a PON network are arbitrated by the OLT. The OLT sends an ONU a grant (see 1.4.348) to allow an upstream transmission by that ONU to begin at a specific time and have a specific duration. A grant is defined by the envelope allocations in one or more GATE messages (see 144.3.6.1). Multiple envelope allocations apply to a single grant if they have the same start time and apply to the same ONU. How the OLT MPMC client determines the start time and duration of grants is out of scope for this standard, but may be based on REPORT messages (see 144.3.6.2) received from an ONU. The following description of the granting process makes use of the interfaces and functional blocks found in Figure 144–3 and Figure 144–4.

The upstream granting process begins when the OLT MPMC client defines a transmission opportunity for an ONU and compiles a GATE message using the MsgGate structure (see 144.3.6.1), which is sent to the MPMC sublayer via the MCSR interface. This generates a GATE MPCPDU using the process defined in the GATE Generation state diagram (see 144.3.8.7). The GATE MPCPDU is transmitted to an ONU.

Upon receiving the GATE message, the ONU processes the message as defined in the GATE Reception state diagram (see 144.3.8.8) and passes the included information to the MPMC client via the MCSI using the MsgGate message. The ONUs MPMC client determines when its next transmission opportunity is and generates an appropriate envelope descriptor, which may be grouped with other envelope descriptors, and is sent to the ONU's MPMC in a MsgEnvGroup message (see 144.3.8.3) over the MCSR interface. The MsgEnvGroup message is processed using the ONU Envelope Commitment state diagram (see 144.3.8.10). This results in an envelope being added to the EnvList[] (see 144.3.8.3).

The EnvList[] is processed by the ONU Envelope Commitment state diagram (see 144.3.8.10), which results in an MCRS_CTRL[*ch*].request being generated in the Envelope Activation state diagram (see 144.3.8.11) for the indicated channel or channels at the start of the next burst.

Since the OLT transmits continuously, grants are not explicitly used by the OLT in the downstream direction. However, the OLT does use the envelope descriptors, OLT Envelope Commitment process (see 144.3.8.9), and Envelope Activation process (see 144.3.8.11) in a manner similar to how these processes are used in the ONUs. In the case of the OLT, the transition from inter-envelope idle to data transmission begins with the issuing of an envelope descriptor by the OLT MPMC client (MPCP). The envelope descriptor is processed by the OLT Envelope Commitment state diagram and Envelope Activation state diagram as described for the ONU.

144.3.8.1 Constants

MPCP_PROCESS_DLY
: Type: 32-bit unsigned integer
Description: This constant represents the maximum time allowed for the ONU to complete MPCPDU processing.
Value: 6400 (16.384 μs)
Unit: EQT

GATE_TIMEOUT
: Type: 32-bit unsigned integer
Description: This constant represents the maximum allowed interval of time between two GATE messages generated by the OLT to the same ONU.
Value: 19 531 250 (50 ms)
Unit: EQT

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

144.3.8.2 Counters

LocalTime
See 144.2.1.2

144.3.8.3 Variables

Back2BackEnv[]
Type: 2-element array of Boolean values
Description: Each element of this array is associated with the respective MCRS channel and represents whether the next envelope is to be transmitted immediately upon completion of the previous envelope (if both envelopes belong to the same grant). The value is set to true upon activation of the first envelope in a grant and it is reset to false upon activation of the grant-terminating envelope (i.e., an envelope with LLID = ESC_LLID).

BEGIN
See 142.2.5.2

ChIndex
Type: 1-bit unsigned integer
Description: The value of this variable indicates the channel the envelope descriptor is intended for, where the value of 0 corresponds to channel 0, and the value of 1 corresponds to channel 1.

ChState
See 144.3.7.3

Env
Type: structure
Description: Env is a structure representing a single envelope descriptor. It includes the following fields:
LLID: the 16-bit LLID value of an envelope descriptor
StartTime: the 32-bit start time of the given envelope. Within a single burst, all envelope descriptions have the same StartTime value. The StartTime is expressed in units of EQT.
Length: the 22-bit length of the envelope, including the envelope header. The Length value is expressed in units of EQ.

EnvIndex
Type: 16-bit unsigned integer
Description: The value of this variable indicates the index of the envelope descriptor in the MsgEnvGroup message.

EnvList[]
Type: an array of lists (FIFO) containing envelope descriptors (see Env variable).
Description: Each element of the array is associated with the respective MCRS channel. Each EnvList[ch] list supports FIFO access operations as defined in 142.1.1.6.

GrantMargin
See 144.3.7.3

NextEnv
See Env variable.

Registered
See 144.3.7.3

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

144.3.8.4 Functions

IsValid(llid)

This function returns true if the LLID value llid is active (i.e., is registered and is eligible to transmit data). Otherwise, false is returned.

144.3.8.5 Timers

GateTxTimer

Each instance of the OLT Gate Generation state diagram generates GATE MPCPDUs with a periodicity of less than GATE_TIMEOUT. This timer counts down the time remaining before a forced generation of a GATE MPCPDU by the given instance of this state diagram.

144.3.8.6 Messages

MsgEnvGroup

A set of parameters (operand_list) representing multiple envelope descriptors for a given channel. In the OLT, the MsgEnvGroup is generated by the MPMC client based on local traffic queue status and downstream frame scheduling policies. In the ONU, the MsgEnvGroup is generated by the MPMC client based on envelope allocations (EnvAlloc[n]) received in GATE MPCPDUs. The MsgEnvGroup set includes the following parameters:

ChIndex: A 1-bit integer indicating whether the following envelope descriptors are intended for channel 0 or channel 1.

StartTime: A 32-bit unsigned integer representing the start time of an envelope. This value is expressed in units of EQT.

EnvCount: A 16-bit unsigned integer representing the number of envelope descriptors carried in the message.

EnvLLID[EnvCount]: An array of 16-bit elements, where the *n*th element of the array represents the LLID value for the *n*th envelope descriptor.

EnvLength[EnvCount]: An array of 22-bit elements, where the *n*th element of the array represents the envelope length for the *n*th envelope descriptor.

MsgGate

A set of parameters (operand_list) carried in the GATE MPCPDU, as defined in 144.3.6.1.

144.3.8.7 GATE Generation state diagram

The OLT shall implement an instance of the GATE Generation state diagram, as shown in Figure 144–23, per each registered ONU (PLID).

144.3.8.11 Envelope Activation state diagram

The OLT and the ONU shall implement a single instance of the Envelope Activation state diagram, as depicted in Figure 144–27.

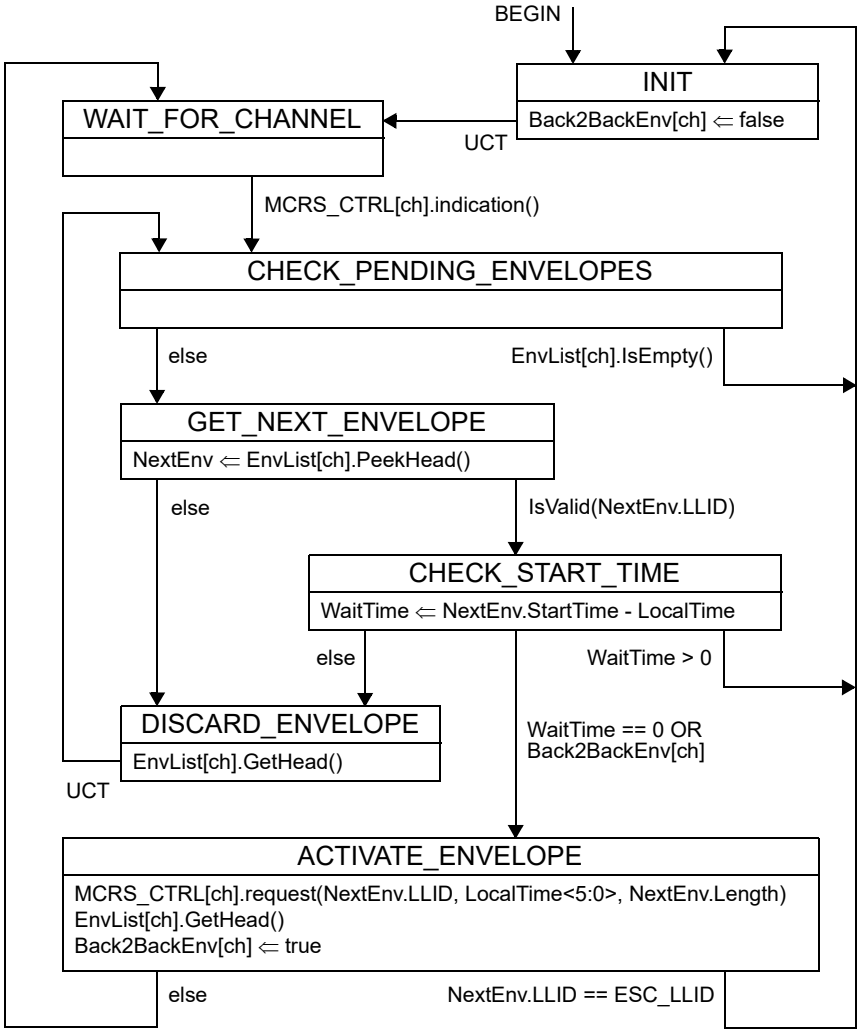

Figure 144–27—Envelope Activation state diagram

144.3.9 Discovery process in dual-rate systems

The MPCP Discovery process (see 144.3.7) facilitates the coexistence of different types of Nx25G-EPON ONUs on the same PON. The coexistence mode allows, for example, 25/10G-EPON, 50/10G-EPON, and 50/25G-EPON ONUs to be deployed on the same ODN and to be connected to the same Nx25G-EPON OLT.

144.3.9.1 OLT rate-specific discovery

The DISCOVERY MPCPDU (see 144.3.6.6) includes the DiscoveryInfo field, which gives the Nx25G-EPON OLT control over the types of ONUs allowed to participate in the given discovery window. Using the DiscoveryInfo field, the OLT indicates its receive line rate capabilities (10 Gb/s and/or 25 Gb/s) as

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

well as the specific line rate(s) allowed in the given discovery window. The OLT may open separate (non-overlapping) discovery windows for 10 Gb/s and 25 Gb/s transmission using two separate DISCOVERY MPCPDUs or it may open a single discovery window for both 10 Gb/s and 25 Gb/s line rates using a single DISCOVERY MPCPDU.

Table 144–9 illustrates the different types of ONUs that may respond to a DISCOVERY MPCPDU with the given settings of the DiscoveryInfo sub-fields.

Table 144–9—DISCOVERY MPCPDUs for various Nx25G-EPON ONU types

ONU types targeted by DISCOVERY MPCPDU					DiscoveryInfo field value			
					Upstream capable		Discovery window	
25/10G-EPON	25G-EPON	50/10G-EPON	50/25G-EPON	50G-EPON	10G	25G	10G	25G
X		X			1	0/1	1	0
	X		X	X	0/1	1	0	1
X	X	X	X	X	1	1	1	1

144.3.9.2 ONU rate-specific registration

An unregistered Nx25G-EPON ONU is capable of receiving a DISCOVERY MPCPDU transmitted by the OLT on the DISC_PLID. When received by a 25/10G-EPON or 50/10G-EPON ONU, the DISCOVERY MPCPDU is parsed, and if a 10 Gb/s discovery window is opened, the ONU may attempt to register in the EPON, if other conditions are also satisfied (see definition of the RegAllowed variable in 144.3.7.3). When received by a 25/25G-EPON, 50/25G-EPON, or 50/50G-EPON ONU, the DISCOVERY MPCPDU is parsed, and if a 25 Gb/s discovery window is opened, the ONU may attempt to register in the EPON.

In general, the ONUs attempt to register using the highest upstream transmission rate supported by both the OLT and the ONU. If the OLT advertised itself as 25G capable, but in the current DISCOVERY MPCPDU it has not enabled the 25 Gb/s discovery window, the 25G-capable ONU skips such discovery attempts and waits for a future discovery window in which 25 Gb/s transmission is enabled.

Table 144–10 shows the action the ONU shall take based on the ONU transmit capabilities and the received discovery information.

Table 144–10—ONU action during discovery window

DiscoveryInfo field				ONU upstream capability		ONU action
Upstream capability		Discovery window				
10G	25G	10G	25G	10G	25G	
1	0	1	0	1	0/1	Attempt 10G registration
1	0/1	1	0/1	1	0	Attempt 10G registration
0/1	1	0/1	1	0/1	1	Attempt 25G registration
1	1	0	1	1	0	Wait for 10G discovery window
1	1	1	0	0/1	1	Wait for 25G discovery window

The ONU transmits the REGISTER_REQ MPCPDU in envelopes with the discovery PLID (DISC_PLID, see 144.3.5).

144.4 Channel Control Protocol (CCP)

The CCP allows the OLT to query and control the state of individual channels (see Table 143–6) through the exchange of CC_REQUEST and CC_RESPONSE CCPDUs, as defined in 144.4.3. Individual channels on the ONU and/or OLT may need to be disabled in a controlled manner for a variety of operational reasons, including power saving, scheduled diagnostic/maintenance activities, optical protection, and others. Any of the channels on the ONU and/or OLT may also fail, requiring a timely notification of the peer station of this fact.

144.4.1 CCP block diagram

Figure 144–28 illustrates a functional block diagram of the CCP for the OLT. The CCP in the OLT includes the CCPDU processing state diagram (see 144.4.4.5).

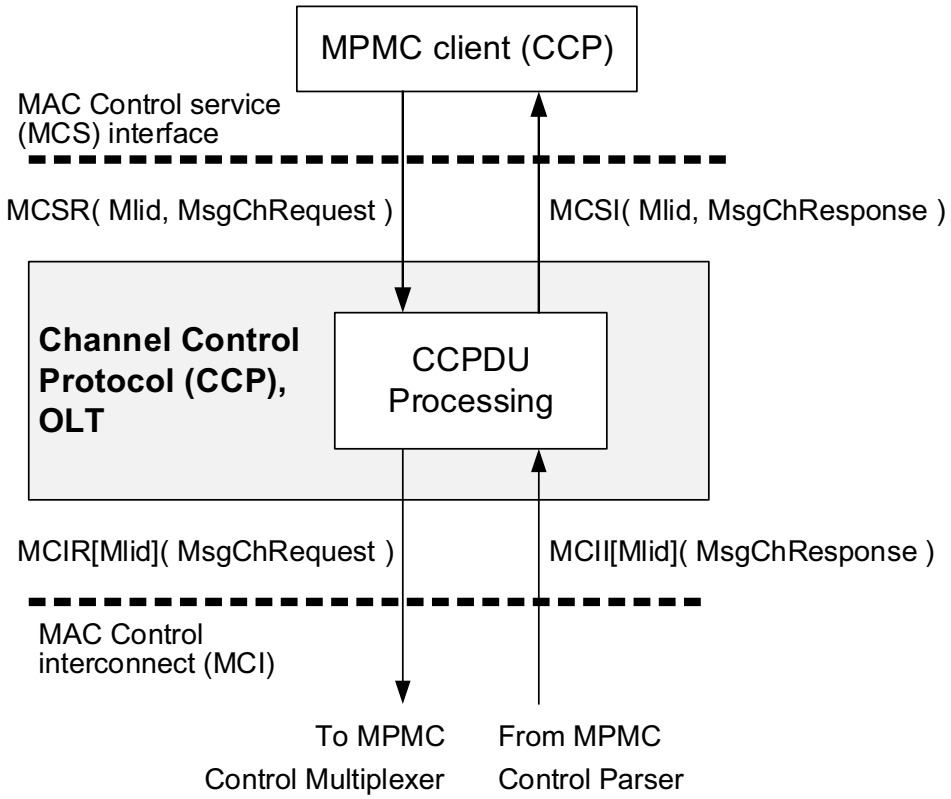

Figure 144–28—OLT CCP functional block diagram

Figure 144–29 illustrates a functional block diagram of the CCP for the ONU. The CCP in the ONU includes the CCPDU processing state diagram (see 144.4.4.6).

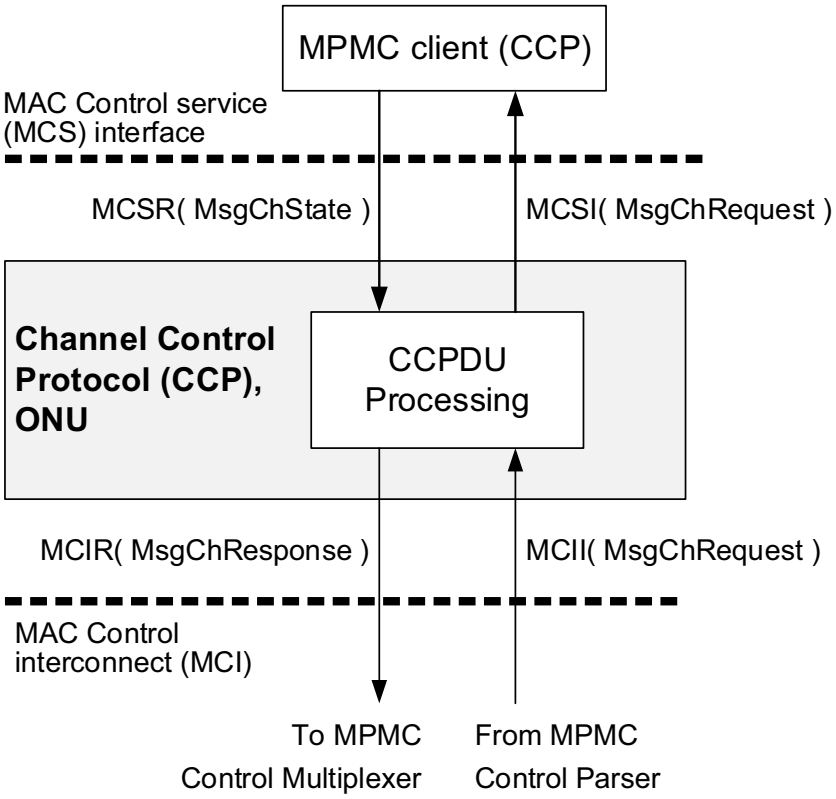

Figure 144–29—ONU CCP functional block diagram

144.4.2 Principles of Channel Control Protocol

The ONU channel status discovery is accomplished via an exchange of a CC_REQUEST and CC_RESPONSE Channel Control PDUs (CCPDUs). Using the CC_REQUEST CCPDU, the OLT polls the state of all downstream and upstream channels, without altering the state of any channels.

The ONU channel status discovery process may be initiated by the OLT MPMC client at any time.

Furthermore, the ONU may send an unsolicited CC_RESPONSE CCPDU to notify the OLT about any local changes in the channel status, including imminent transceiver element (transmitter and/or receive) failure, local channel disabling, power failure and resulting channel shutdown.

Once the CC_RESPONSE CCPDU from the ONU is received, the OLT saves the channel status information associated with the given ONU in the local MPMC client.

Once the ONU channel status discovery has been completed, the OLT MPMC client may change the state of any of the channels on the ONU by requesting the transmission of a CC_REQUEST CCPDU, with specific action encoded for each and every downstream and upstream channel for the given ONU. The OLT may enable a channel, disable a channel, or poll the current channel status.

The OLT may request the ONU to implement changes for the given channel in a persistent or non-persistent manner. Any persistent changes are preserved across ONU reset events. Any non-persistent changes are reverted upon ONU reset and re-registration.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The ONU receives the CC_REQUEST CCPDU, saves the request information in the local MPMC client, and attempts to implement the requested changes to the channel status. The CC_RESPONSE CCPDU is transmitted back to the OLT with the outcome of the configuration changes for each and every supported channel as well as the current channel state after the change. The ONU updates the ChState variable to match the new upstream channel status (see 144.3.8.3) and purges any pending transmission envelopes for disabled upstream channels.

The sequence of events on the OLT and ONU, when enabling/disabling one of the downstream or upstream channels, is outlined in the following subclauses.

144.4.2.1 Disabling a downstream channel at an ONU

Disabling a downstream channel at an ONU results in the ONU receiver for the given channel being powered down. It is an ONU implementation choice to also shut down the associated receive path through the PCS and MCRS sublayers. If the receive path associated with a disabled channel remains active, it does not result in any accumulation of statistics or increment of error counters on this channel, such as invalid receive blocks or uncorrectable FEC codewords. Disabling a downstream channel at an ONU does not result in the given channel also being disabled at the OLT.

To disable a downstream channel (DC_n) at an ONU, the CCP performs the following sequence of steps:

1) The OLT MPMC client stops transmitting any data to the target ONU on the channel being disabled. The said ONU shortly thereafter stops receiving any data on this downstream channel.
2) The MPMC client initiates transmission of a CC_REQUEST CCPDU to the target ONU, requesting the ONU to disable the downstream channel DC_n.
3) Once the ONU has completed the request, the ONU sends a CC_RESPONSE CCPDU to the OLT, indicating the outcome of the requested configuration changes and the new state of all of its downstream and upstream channels.

144.4.2.2 Enabling a downstream channel at an ONU

Enabling a downstream channel at an ONU results in the ONU receiver for the given channel being powered up. Depending on the ONU implementation, the associated receive path through PCS and MCRS sublayers in the ONU may also need to be powered up.

To enable a downstream channel (DC_n) at an ONU, the CCP performs the following sequence of steps:

1) The MPMC client initiates transmission of a CC_REQUEST CCPDU to the target ONU, requesting the ONU to enable the downstream channel DC_n.
2) Once the ONU has completed the request, the ONU sends a CC_RESPONSE CCPDU to the OLT, indicating the outcome of the requested configuration changes and the new state of all of its downstream and upstream channels.
3) The OLT MPMC client starts transmitting data to the target ONU on the channel being enabled only when the given downstream channel is confirmed to have been enabled on the ONU. The said ONU shortly thereafter starts receiving data on this downstream channel.

144.4.2.3 Disabling an upstream channel at an ONU

Disabling an upstream channel at an ONU results in the ONU transmitter for the given channel being powered down. It is an ONU implementation choice to also shut down the associated transmit path through the PCS and MCRS sublayers. If the transmit path associated with a disabled channel remains active, it does not result in any accumulation of statistics or increment of error counters on this channel, such as packets or

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

octets transmitted. Disabling an upstream channel at an ONU does not result in the given channel also being disabled at the OLT.

To disable an upstream channel (UC_n) at an ONU, the CCP performs the following sequence of steps:

1) The MPMC client initiates transmission of a CC_REQUEST CCPDU to the target ONU, requesting the ONU to disable the upstream channel UC_n.
2) The OLT MPMC client continues to grant the upstream channel UC_n on the target ONU.
3) Once the ONU has completed the request, the ONU sends a CC_RESPONSE CCPDU to the OLT, indicating the outcome of the requested configuration changes and the new state of all of its downstream and upstream channels. ONU also purges any pending upstream transmission envelopes scheduled for the now disabled upstream channel.
4) The OLT MPMC client stops granting the upstream channel UC_n on the target ONU only when the given upstream channel is confirmed to have been disabled on the ONU.

144.4.2.4 Enabling an upstream channel at an ONU

Enabling an upstream channel at an ONU results in the ONU transmitter for the given channel being powered up. Depending on the ONU implementation, the associated transmit path through PCS and MCRS sublayers in the ONU may also need to be powered up.

To enable an upstream channel (UC_n) at an ONU, the CCP performs the following sequence of steps:

1) The MPMC client initiates transmission of a CC_REQUEST CCPDU to the target ONU, requesting the ONU to enable the upstream channel UC_n.
2) Once the ONU has completed the request, the ONU sends a CC_RESPONSE CCPDU to the OLT, indicating the outcome of the requested configuration changes and the new state of all of its downstream and upstream channels.
3) The OLT MPMC client starts granting the upstream channel UC_n on the target ONU only when the given upstream channel is confirmed to have been enabled on the ONU.

144.4.2.5 Local channel state changes at an ONU

The MPMC client may monitor and react to the changes in the state of the downstream and/or upstream channels, allowing the ONU to notify the OLT of observed or expected channel state changes. For example, the MPMC client may have ability to detect a failure of one of the channel receivers.

To notify the MPMC client at the OLT about a local channel state change, the CCP performs the following sequence of steps:

1) When a channel state change is identified, the MPMC client at the ONU sends an unsolicited CC_RESPONSE CCPDU to the OLT, indicating the new state of all of its downstream and upstream channels.
2) If a state change for an upstream channel is being reported, the OLT MPMC client may adjust granting for the affected upstream channel. Similarly, if a state change for a downstream channel is being reported, the OLT MPMC client may adjust downstream transmission on the affected downstream channel.

144.4.3 CCPDU structure and encoding

The CCPDU structure is shown in Figure 144–30, and is further defined as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— DestinationAddress:
In CCPDUs, the DestinationAddress is the MAC Control Multicast address as specified in the annexes to Clause 31.

— SourceAddress:
In CCPDUs, the SourceAddress is the individual MAC address associated with the MLID through which the CCPDU is transmitted. For CCPDUs originating at the OLT, this may be the address of any individual MAC. These MACs may all share a single unicast address, as explained in 144.1.1.2.

— Length/Type:
In CCPDUs, this field carries the MAC_Control_type field value as specified in 31.4.1.3.

— Opcode:
This field identifies the specific CCPDU being encapsulated. Opcode field values are defined in Table 31A–1.

— OperandList:
A set of opcode-specific fields as defined in 144.4.3.1 and 144.4.3.2.

— Pad:
This field is present only when the total length of the OperandList is below 44 octets. The Pad field is added to bring the CCPDU length up to the minimum frame size (see 4A.2.3.2.4). This field is filled with zeros on transmission, and is ignored on reception.

— FCS:
This is the frame check sequence, typically generated by the MAC.

Fields within a frame are transmitted from top to bottom. When consecutive octets are used to represent a single numerical value, the most significant octet is transmitted first, followed by successively less significant octets. Bits within each octet are transmitted from LSB to MSB.

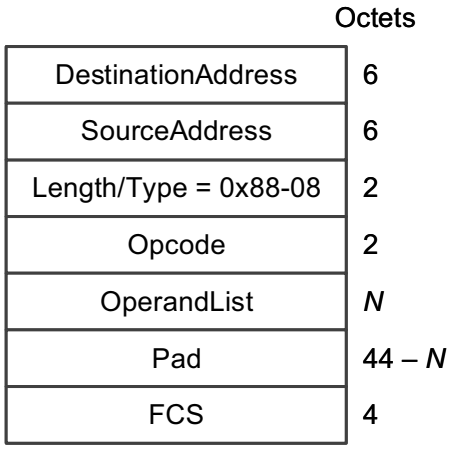

Figure 144–30—Generic CCPDU

144.4.3.1 CC_REQUEST description

The CC_REQUEST CCPDU is used by the OLT to query the state of ONU's channel(s) or change the state of ONU's channel(s), depending on the specific action code carried in the action field associated with the given upstream or downstream channel.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CC_REQUEST CCPDU is an instantiation of the Generic CCPDU and shall be as shown in Figure 144–31.

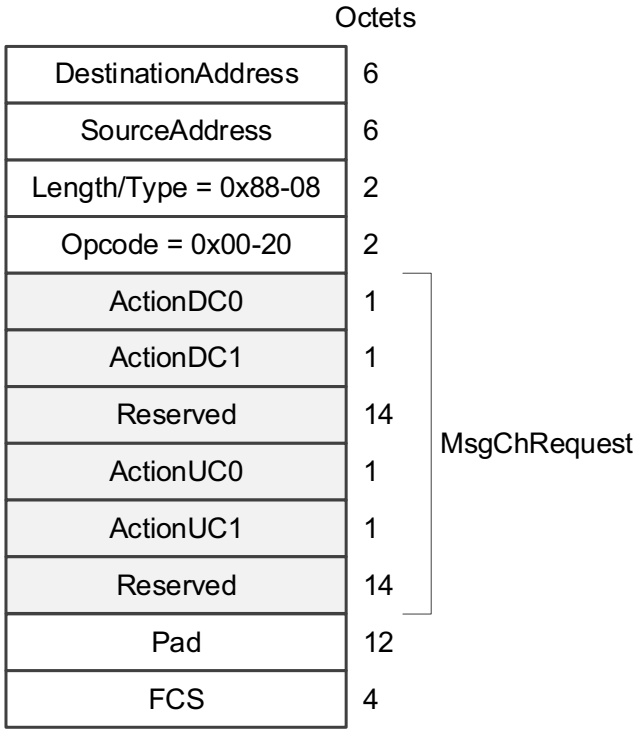

Figure 144–31—CC_REQUEST CCPDU

The CC_REQUEST CCPDU is identified by the Opcode field value of 0x00-20. The MsgChRequest structure represents a set of opcode-specific fields, defined as follows:

— ActionDC0:
This 8-bit field conveys the action requested for the downstream channel 0 (DC0). The encoding of this field is defined in Table 144–11.

— ActionDC1:
This 8-bit field conveys the action requested for the downstream channel 1 (DC1). The encoding of this field is defined in Table 144–11.

— ActionUC0:
This 8-bit field conveys the action requested for the upstream channel 0 (UC0). The encoding of this field is defined in Table 144–11.

— ActionUC1:
This 8-bit field conveys the action requested for the upstream channel 1 (UC1). The encoding of this field is defined in Table 144–11.

Table 144–11—Channel Action field [a]

Bit	Field name	Value	Description
3:0	ActionCode	0x0	No action
		0x1	Disable channel
		0x2	Enable channel
		0x3–0xF	Reserved, ignored on reception
6:4	Reserved, ignored on reception		
7	PersistenceFlag	0	The channel action is non-persistent, i.e., the requested channel state is not preserved across the reset event. Upon reset, the channel reverts to its previous persistent state.
		1	The channel action is persistent, i.e., the requested channel state is to preserved across the reset event.

[a] Persistently disabling all downstream and/or all upstream channels in an ONU makes that ONU non-operational.

144.4.3.2 CC_RESPONSE description

The CC_RESPONSE CCPDU is generated by the ONU to report its current channel(s) state and/or convey to the OLT the result code for the last requested action (CC_REQUEST CCPDU).

The CC_RESPONSE CCPDU is an instantiation of the Generic CCPDU and shall be as shown in Figure 144–32.

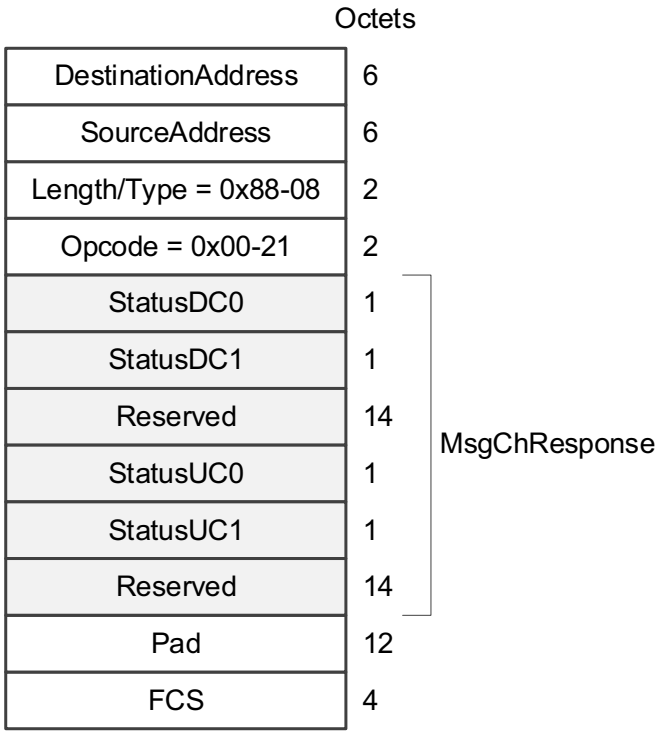

Figure 144–32—CC_RESPONSE CCPDU

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CC_RESPONSE CCPDU is identified by the Opcode field value of 0x00-21. The MsgChResponse structure represents a set of opcode-specific fields, defined as follows:

— StatusDC0:
This 8-bit field carries the channel state and the action response code for the downstream channel 0 (DC0). The encoding of this field is defined in Table 144–12.

— StatusDC1:
This 8-bit field carries the channel state and the action response code for the downstream channel 1 (DC1). The encoding of this field is defined in Table 144–12.

— StatusUC0:
This 8-bit field carries the channel state and the action response code for the upstream channel 0 (UC0). The encoding of this field is defined in Table 144–12.

— StatusUC1:
This 8-bit field carries the channel state and the action response code for the upstream channel 1 (UC1). The encoding of this field is defined in Table 144–12.

Table 144–12—Encoding of the channel status

Bit	Field name	Value	Description
3:0	ChannelState	0x0	Channel absent
		0x1	Channel enabled
		0x2	Channel disabled remotely (by the OLT)
		0x3	Channel disabled locally (by the ONU)
		0x4	Channel failure (PMD failure)
		0x5–0xF	Reserved, ignored on reception
7:4	ActionResultCode	0x0	No action requested
		0x1	Action succeeded
		0x2	Action failed
		0x3	No change required, i.e., the channel is already in the requested state
		0x4	Invalid command, i.e., the operation was requested for a non-existing channel
		0x5–0xF	Reserved, ignored on reception

144.4.4 Channel Control operation

144.4.4.1 Constants

ACTION_FAILED
Description: This constant represents the value of ActionResultCode corresponding to “Action failed”, per Table 144–12.
Value: 0x2

ACTION_SUCCEEDED
Description: This constant represents the value of ActionResultCode corresponding to “Action succeeded”, per Table 144–12.
Value: 0x1

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ACT_DISABLE
Description: This constant represents the value of ActionCode corresponding to “Disable channel”, per Table 144–11.
Value: 0x1

ACT_ENABLE
Description: This constant represents the value of ActionCode corresponding to “Enable channel”, per Table 144–11.
Value: 0x2

ACT_NONE
Description: This constant represents the value of ActionCode corresponding to “No action”, per Table 144–11.
Value: 0x0

CH_STATE_ABSENT
Description: This constant represents the value of ChannelState corresponding to “Channel absent”, per Table 144–12.
Value: 0x0

CH_STATE_DISABLED_REMOTE
Description: This constant represents the value of ChannelState corresponding to “Channel disabled remotely (by the OLT)”, per Table 144–12.
Value: 0x2

CH_STATE_ENABLED
Description: This constant represents the value of ChannelState corresponding to “Channel enabled”, per Table 144–12.
Value: 0x1

INVALID_COMMAND.
Description: This constant represents the value of ActionResultCode corresponding to “Invalid command”, per Table 144–12.
Value: 0x4.

NO_ACTION_REQUESTED
Description: This constant represents the value of ActionResultCode corresponding to “No action requested”, per Table 144–12.
Value: 0x0

NO_CHANGE_REQUIRED
Description: This constant represents the value of ActionResultCode corresponding to “No change required”, per Table 144–12.
Value: 0x3

144.4.4.2 Variables

ActionCode[]
Type: 4-element array of 4-bit unsigned integers
Description: Each element of this array stores a copy of the action request for the given channel, as received in the CC_REQUEST CCPDU, with individual admissible values per Table 144–11, ActionCode field. This array is indexed with the channel designator, i.e., DC0, DC1, UC0, and UC1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEGIN
See 142.2.5.2

ChState
See 144.3.7.3

PrevChState[]
Type: 4-element array of 4-bit unsigned integers
Description: Each element of this array indicates the previous (old) status of the given upstream or downstream channel, with individual admissible values per Table 144–12, ChannelState field. This array is indexed with the channel designator, i.e., DC0, DC1, UC0, and UC1.

144.4.4.3 Functions

GetResponseCode(chIndex)
This function generates an action response code for a channel identified by chIndex. The response code is determined by the channel state before the action was requested (OldState), the type of the requested action (ActionCode), and the channel state after the action was implemented (NewState).

```
int4 GetResponseCode( int chIndex )
{
    OldState = PrevChState[ chIndex ];
    NewState = MsgChState[ chIndex ];
    Action = ActionCode[ chIndex ];

    if( Action == ACT_NONE )
        return NO_ACTION_REQUESTED;

    if( NewState == CH_STATE_ABSENT )
        return INVALID_COMMAND;

    if( Action == ACT_ENABLE )
    {
        if( NewState != CH_STATE_ENABLED )
            return ACTION_FAILED;
        else if( NewState == OldState )
            return NO_CHANGE_REQUIRED;
        else
            return ACTION_SUCCEEDED;
    }

    if( Action == ACT_DISABLE )
    {
        if( NewState != CH_STATE_DISABLED_REMOTE )
            return ACTION_FAILED;
        else if( NewState == OldState )
            return NO_CHANGE_REQUIRED;
        else
            return ACTION_SUCCEEDED;
    }

return INVALID_COMMAND;
}
```

UpdateChState (chIndex, NewState)

This function updates the state record (ChState) for the given upstream channel chIndex, in the function of the new channel state NewState. When an upstream channel is disabled, this function purges the list of envelope descriptors for the given channel, stored in the EnvList array (see 144.3.8.3).

```
UpdateChState( int chIndex, int NewState )
{
    if (NewState == CH_STATE_ENABLED )
         ChState<chIndex> = 1;
    else
    {
         ChState<chIndex> = 0;
         EnvList[chIndex].Clear();
    }
}
```

144.4.4.4 Messages

MsgChRequest

A set of parameters (operand_list) carried in a CC_REQUEST CCPDU, as defined in 144.4.3.1.

MsgChResponse

A set of parameters (operand_list) carried in a CC_RESPONSE CCPDU, as defined in 144.4.3.2.

MsgChState

A set of parameters (operand_list) representing the current states of ONU's downstream and upstream channels. The operand_list is treated as an array, such that an individual channel state (array element) may be accessed using one of the channel index designators: DC0, DC1, UC0, and UC1 (see Table 143–6). Each channel state is represented by a 4-bit integer with permissible values as defined for the field ChannelState per Table 144–12. The MsgChState is generated by the MPMC client and is processed (consumed) by the CCPDU processing state diagram in the ONU.

144.4.4.5 OLT CCPDU processing state diagram

The OLT CCP shall implement a single instance of the CCPDU processing state diagram shown in Figure 144–33.

144.5 Protocol implementation conformance statement (PICS) proforma for Clause 144, Multipoint MAC Control for Nx25G-EPON[239]

144.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 144, Multipoint MAC Control for Nx25G-EPON, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

144.5.2 Identification

144.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

144.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 144, Multipoint MAC Control for Nx25G-EPON
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[239]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

145. Power over Ethernet

145.1 Overview

This clause defines the functional and electrical characteristics of an enhanced Power over Ethernet (PoE) system. The original PoE system is defined in Clause 33. Clause 145 includes the capability to provide power over 4 pairs while maintaining compatibility with equipment designed in accordance with Clause 33.

A PoE system consists of three separately specified major elements. They are the power supply, a non-data entity which is called the Power Sourcing Equipment (PSE), the powered load, another non-data entity which is called the Powered Device (PD), and the standards based, balanced, twisted-pair cabling connecting the two.

The cabling portion of the system is defined as the link section. The link section shares use of the cabling with the link segment used for data transmission. The PSE is normally an element of the powering DTE but may, instead, be located within the cabling portion of the system. PSEs located within the cabling portion of the system are called Midspan PSEs, or simply Midspans. The PD is an element of the powered DTE.

The system specified here is for use with IEEE 802.3 MAUs connected by 4-pair twisted pair cabling that have been qualified as being compatible with this clause. Those MAUs are defined in Clause 14 and the PHYs are defined in Clause 25, Clause 40, Clause 55, and Clause 126. Use in other environments is outside the scope of this standard. Power over Ethernet allows devices to supply / use power using the same generic cabling as is used for data transmission.

PSEs and PDs are categorized by Type. This clause specifies Type 3 and Type 4 devices as well as their interaction with Type 1 and Type 2 devices. References in this clause to PSEs and PDs without a Type qualifier refer exclusively to Type 3 and Type 4 devices. See Clause 33 for the specification of Type 1 and Type 2 devices.

Power over Ethernet is intended to provide a 10BASE-T, 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, or 10GBASE-T device with a single cabling interface for both data and power. This clause specifies the following:

a) A PSE to add power to the 100 Ω balanced cabling system
b) The characteristics of a PD's load on the PSE and the structured cabling
c) A protocol allowing the detection of a PD that requests power from a PSE
d) Methods to classify a PD based on its power needs
e) A method for a connected PSE and PD to dynamically negotiate power
f) A method for scaling supplied power back to the detect level when power is no longer requested or required

The importance of item c) above should not be overlooked. Given the large number of legacy devices (both IEEE 802.3 and other types of devices) that could be connected to a 100 Ω balanced cabling system, and the possible consequences of applying power to such devices, the protocol to distinguish compatible devices and non-compatible devices is important to prevent damage to non-compatible devices.

The detection and powering algorithms are likely to be compromised by cabling that is not point-to-point, resulting in unpredictable performance and possibly damaged equipment.

This clause differentiates between the two ends of the powered portion of the link, i.e. the link section, defining the PSE and the PD as separate but related devices.

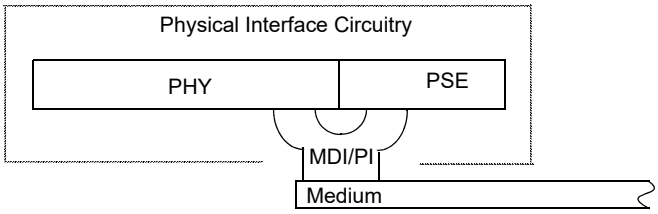
145.1.1 Compatibility considerations

The requirements in this Clause are designed such that PSEs and PDs that meet these requirements are compatible at their respective Power Interfaces (PIs). Designers are free to implement circuitry within the PD and PSE in an application-dependent manner provided that the respective PI specifications are satisfied.

145.1.2 Relationship of Power over Ethernet to the IEEE 802.3 Architecture



Power over Ethernet comprises an optional non-data entity. As a non-data entity, it does not appear in a depiction of the OSI Reference Model. Figure 145–1 depicts the positioning of PoE in the case of the PD.

MDI = Medium Dependent Interface
PD = Powered Device
PHY = Physical Layer Device
PI = Power Interface

Figure 145–1—Power over Ethernet powered device relationship to the physical interface circuitry and the IEEE 802.3 Ethernet LAN model

Figure 145–2 and Figure 145–3 depict the positioning of PoE in the cases of the Endpoint PSE and the Midspan PSE, respectively.

MDI = Medium Dependent Interface
PHY = Physical Layer Device
PI = Power Interface
PSE = Power Sourcing Equipment

Figure 145–2—Power over Ethernet Endpoint power sourcing equipment relationship to the physical interface circuitry and the IEEE 802.3 Ethernet LAN model

The Power Interface (PI) is the mechanical and electrical interface between the PSE or PD and the transmission medium as defined in 1.4.484.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In an Endpoint PSE and in a PD, the PI is the MDI as defined in 1.4.395.

In the case of a Midspan PSE, the PI is physically separate from the MDI and is contained within the cabling portion of the data transmission system.

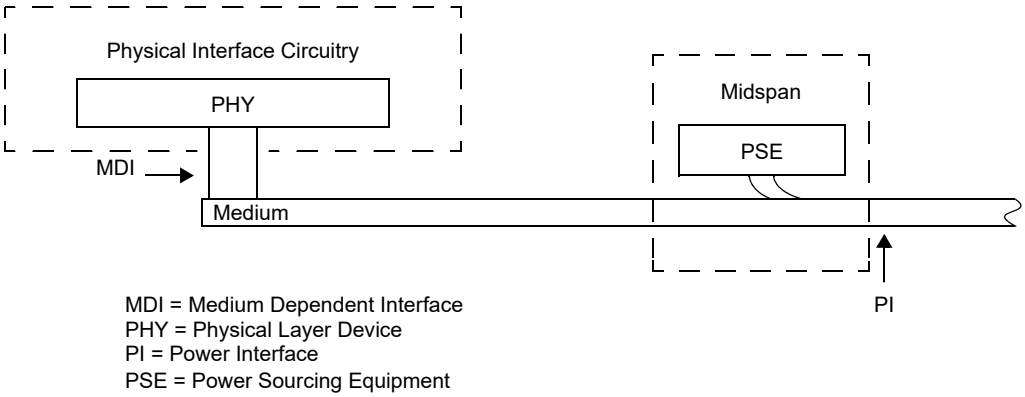


Figure 145–3—Power over Ethernet Midspan power sourcing equipment relationship to the physical interface circuitry and the IEEE 802.3 Ethernet LAN model

145.1.3 System parameters

A valid power system consists only of a single PSE sourcing power, a single PD, and the link section connecting them. The PSE and PD can each be of a Type defined in Clause 33 or Clause 145, in any combination. The power system has certain basic parameters defined according to Table 145–1. See 33.1.4 for these parameters as applicable to Type 1 and Type 2 devices. These parameters define not only certain performance characteristics of the system, but are also used in calculating the various electrical characteristics of PSEs and PDs as described in 145.2 and 145.3.

Table 145–1—System parameters

PSE Type	Nominal highest current per pair (I_{Cable}, A)	Number of powered pairs	Channel pairset maximum DC loop resistance (R_{Ch}, Ω)	Minimum cabling type
Type 3	0.6	2 or 4	12.5	Class D (ISO/IEC11801:1995) or Category 5 (ANSI/EIA/TIA-568-A:1995)
Type 4	0.6	2	12.5	
	0.96	4	12.5	
NOTE—The current on the pairs may be impacted by pair-to-pair system resistance unbalance. See 145.2.10.6.1. For additional information on pair-to-pair resistance unbalance in structured cabling systems, see TIA TSB-184-A [B66] and ISO/IEC TS 29125.				

I_{Cable}, specified in Table 145–1, is the current on one twisted pair in the balanced twisted-pair cable. When power is delivered over 2 pairs, two twisted pairs are required to source I_{Cable}, one carrying (+ I_{Cable}) and one carrying (– I_{Cable}), from the perspective of the PI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When power is delivered over 4 pairs, four twisted pairs are required to source 2 × I_{Cable}, two each carrying a nominal current (+ I_{Cable}) and two each carrying a nominal current (– I_{Cable}), from the perspective of the PI. Greater than Class 4 power delivery requires 4 pairs.

I_{Cable} is the highest nominal current on a pair for a system without pair-to-pair current unbalance. When power is provided over 4 pairs, the current may be unbalanced, causing one pair to have a higher current than I_{Cable}, while the other pair of the same polarity carries a corresponding lower current than I_{Cable}. The maximum nominal total 4-pair current is twice the value of I_{Cable}. See TIA TSB-184-A [B66] and ISO/IEC TS 29125 for additional information on pair-to-pair resistance unbalance.

The cable references use "DC loop resistance," which refers to two single conductors in series. This clause uses "pairset DC loop resistance" (R_{Ch}), which refers to two pairs in series. Therefore, R_{Ch} is related to, but not equivalent to, the "DC loop resistance" called out in the cable references. In addition to I_{Cable}, the requirements of this clause reference the total current and the per pairset current, which are described here.

I_{Port} is the total current on both pairs with the same polarity and is defined in Equation (145–7).

$I_{Port\text{-}2P}$ is the current on the negative pair of a pairset and is derived from $I_{Port\text{-}2P\text{-}pri}$ and $I_{Port\text{-}2P\text{-}sec}$ in Equation (145–5).

Pairset current is the current on the negative pair associated with a given pairset. Note that the positive pair and the negative pair of a pairset may carry a different amount of current, caused by the independent pair-to-pair current unbalance in the positive pairs, and in the negative pairs, when the system is providing power over more than 2 pairs.

2-pair mode refers to power delivery using either one pair at positive V_{PSE} and one at negative V_{PSE}, or to using two pairs at positive V_{PSE} and one at negative V_{PSE}.

4-pair mode refers to power delivery using two pairs at positive V_{PSE} and two at negative V_{PSE}.

R_{Ch} is the maximum pairset DC loop resistance, as defined in Table 145–1.

R_{Chan} is the actual DC resistance from the PSE PI to the PD PI and back. R_{Chan} has a maximum value of R_{Ch} / 2 when operating in 4-pair mode. R_{Chan} has a maximum value of R_{Ch} when operating in 2-pair mode.

$R_{Chan\text{-}2P}$ is the actual pairset DC resistance from the PSE PI to the PD PI and back. $R_{Chan\text{-}2P}$ has a maximum value of R_{Ch}.

V_{PD} is the voltage at the PD PI. For a single-signature PD, V_{PD} is measured between any positive conductor of a pairset and any negative conductor of the corresponding pairset, for the pairset with the highest voltage. For a dual-signature PD, V_{PD} is measured between any positive conductor of a pairset and any negative conductor of the corresponding pairset, for the given Mode.

V_{PSE} is the voltage at the PSE PI. When connected to a single-signature PD and operating in 4-pair mode, V_{PSE} is measured between any positive conductor and any negative conductor. When connected to a dual-signature PD, when operating in 2-pair mode, or when the PD signature configuration has not yet been identified, V_{PSE} is measured between any positive conductor of the pairset and any negative conductor of the corresponding pairset, for the given Alternative.

145.1.4 Cabling requirements

Class D or better cabling as specified in ISO/IEC 11801:1995, with the additional requirement that the channel DC loop resistance is 25 Ω or less, is required to support operation as specified in this Clause. These requirements are also met by Class D or better cabling as specified by ISO/IEC 11801:2002, Category 5e or

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

better cable and components as specified in ANSI/TIA-568-C.2, or Category 5 cable and components as specified in ANSI/TIA/EIA-568-A-1995.

Cable ambient operating temperature guidelines for Type 3 and Type 4 operation are provided in ISO/IEC TR 29125 [B44][240] and TIA TSB-184A [B66]. For Type 3 and Type 4 PoE systems, managing the temperature rise can require a reduction in the maximum number of cables bundled. See ISO/IEC TS 29125, TIA TSB-184-A, as well as applicable local codes and regulations, e.g., the National Electrical Code® (NEC®) (NFPA 70®, 2017 Edition) [B56], for more information.

Planning considerations for PoE systems are provided in ISO/IEC CD 14763-2 supported by the information in ISO/IEC TS 29125 and TIA TSB-184-A, as well as applicable local codes and regulations.

Within Clause 145 and its annexes, the term link section refers to the point-to-point medium connection between two and only two active Power Interfaces (PIs). Type 3 and Type 4 operation requires link sections to comply with the intra-pair resistance unbalance requirements for twisted-pair cabling as specified in ISO/IEC 11801:2002 and ANSI/TIA-568-C.2. Refer to Annex 145A for more information including the requirements for pair-to-pair resistance unbalance when operating over 4 pairs.

145.2 Power sourcing equipment (PSE)

The PSE is the portion of the end station or midspan equipment that provides the power to a single PD. The PSE's main functions are as follows:

— To search the link section for a PD
— To supply power to the detected PD through the link section
— To monitor the power on the link section
— To remove power when no longer requested or required, returning to the searching state

An unplugged link section is one instance when power is no longer required.

In addition, power classification mechanisms exist to provide the PSE with detailed information regarding the power needs of the PD.

A PSE is electrically specified at the point of the physical connection to the cabling.

Additional electrical specifications that apply to the PSE are specified in 145.4.

145.2.1 PSE Type descriptions

A PSE can be categorized as either a Type 1, Type 2, Type 3 or Type 4 PSE. See 33.2 for the specification of Type 1 and Type 2 PSEs.

Type 1, Type 2, Type 3, and Type 4 PSEs interoperate with Type 1, Type 2, Type 3, and Type 4 PDs, subject to power limitations. See 145.2.8.

Table 145–2 summarizes the supported parameters of Type 3 and Type 4 PSEs. The PSE Type can only change when the PSE state diagram (Figure 145–13) is in IDLE.

[240]The numbers in brackets correspond to those of the bibliography in Annex A.

Table 145–2—PSE supported parameters

PSE Type	Supports 4-pair power	Highest Class supported[a]	Short MPS support[b]	Physical Layer classification[a]	Data Link Layer classification[a]	Autoclass[c]
Type 3	No / Yes	1 to 4	Yes	Multiple-Event	Optional	Optional
	Yes	1 to 6				
Type 4	Yes	7 to 8				

[a] See 145.2.8, Table 145–11 and Table 145–12.
[b] See 145.2.12.
[c] See 145.2.8.2 and 145.3.6.2.

145.2.2 PSE location

PSEs may be placed in two locations with respect to the link segment, either coincident with the DTE/Repeater or midspan. A PSE that is coincident with the DTE/Repeater is an “Endpoint PSE”. A PSE that is located within a link segment that is distinctly separate from and between the MDIs is a “Midspan PSE”. The requirements of this document apply equally to Endpoint and Midspan PSEs unless the requirement contains an explicit statement that it applies to only one implementation. The location of various Endpoint and Midspan PSEs are illustrated in Figure 145–4 to Figure 145–11.

PSEs can be compatible with any of the following: 10BASE-T, 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, 10GBASE-T.

145.2.3 Midspan PSE variants

There are several variants of Midspan PSEs defined.

10BASE-T/100BASE-TX Midspan PSE:
A Midspan PSE that results in a link that can support only 10BASE-T and 100BASE-TX operation (see Figure 145–8 and Figure 145–10). Note that this limitation is due to the presence of the Midspan PSE whether it is supplying power or not.

1000BASE-T Midspan PSE:
A Midspan PSE that results in a link that can support 10BASE-T, 100BASE-TX, and 1000BASE-T operation (see Figure 145–9 and Figure 145–11).

2.5GBASE-T Midspan PSE:
A Midspan PSE that results in a link that can support 1000BASE-T and 2.5GBASE-T operation, and optionally support 10BASE-T and 100BASE-TX operation (see Figure 145–9 and Figure 145–11).

5GBASE-T Midspan PSE:
A Midspan PSE that results in a link that can support 1000BASE-T, 2.5GBASE-T, and 5GBASE-T operation, and optionally support 10BASE-T and 100BASE-TX operation (see Figure 145–9 and Figure 145–11).

10GBASE-T Midspan PSE:
A Midspan PSE that results in a link that can support 1000BASE-T, 2.5GBASE-T, 5GBASE-T,

and 10GBASE-T operation, and optionally support 10BASE-T and 100BASE-TX operation (see Figure 145–9 and Figure 145–11).

NOTE—See 145.4.9.3 for Alternative A Midspan PSEs.

145.2.4 PSE PI

A PSE device may provide power via one or both of the two valid four-conductor connections, named pairsets. A pairset consists of a pair at the positive V_{PSE} and a pair at the negative V_{PSE}. The two conductors associated with a pair each carry the same nominal current in both magnitude and polarity. Figure 145–12, in conjunction with Table 145–3, illustrates the pairsets, which for PSEs are named Alternative A and Alternative B.

PSEs are required to switch the negative pairs, and may switch the positive pairs as defined in 145.4.1.1. This may lead to both positive pairs providing current in 2-pair mode.

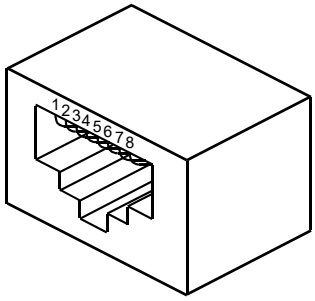

Figure 145–12—PD and PSE eight-pin modular jack

Table 145–3—PSE Pinout Alternatives

Conductor	Alternative A (MDI-X)	Alternative A (MDI)	Alternative B(X)	Alternative B(S)
1	Negative V_{PSE}	Positive V_{PSE}	—	—
2	Negative V_{PSE}	Positive V_{PSE}	—	—
3	Positive V_{PSE}	Negative V_{PSE}	—	—
4	—	—	Negative V_{PSE}	Positive V_{PSE}
5	—	—	Negative V_{PSE}	Positive V_{PSE}
6	Positive V_{PSE}	Negative V_{PSE}	—	—
7	—	—	Positive V_{PSE}	Negative V_{PSE}
8	—	—	Positive V_{PSE}	Negative V_{PSE}

PSEs shall use only the permitted polarity configurations associated with Alternative A and Alternative B listed in Table 145–4 corresponding with their Type. For further information on the placement of MDI vs. MDI-X, see 14.5.2.

Table 145–4—Permitted Pinout Alternatives per Type

PSE Type	Alternative A (MDI-X)	Alternative A (MDI)	Alternative B(X)	Alternative B(S)
Type 3	Yes	Yes	Yes	Yes
Type 4	Yes	No	No	Yes

Type 3 PSEs shall implement Alternative A, Alternative B, or both. Type 3 PSEs providing Class 5 or Class 6 power levels and Type 4 PSEs shall implement Alternative A and Alternative B. PSEs may operate simultaneously on both Alternatives, when the requirements of 145.2.9 are met.

The PSE specifications related to current apply on the negative pair or pairs unless otherwise noted.

145.2.5 PSE state diagrams

PSEs shall provide the behavior of the state diagrams shown in Figure 145–13 to Figure 145–18.

145.2.5.1 State diagram overview and timing

If power is to be applied, the PSE turns on power after a valid detection in less than T_{pon} as defined in Table 145–16. If the PSE cannot supply power within T_{pon}, it initiates and successfully completes a new detection cycle before applying power. See 145.2.10.14 for details.

It is possible that two separate PSEs, one that implements Alternative A and one that implements Alternative B (see 145.2.2), may be attached to the same link segment. In such a configuration, and without the required backoff algorithm, the PSEs could prevent each other from ever detecting a PD by interfering with the detection process of the other.

A PSE performing detection using only Alternative B may fail to detect a valid PD detection signature. When this occurs, the PSE shall not apply a voltage greater than V_{Off} to the PI until after at least T_{dbo}, as defined in Table 145–16, has passed before attempting another detection, except in the case of an open circuit as defined in 145.2.6.5. See 145.2.6.5 for more information on Alternative B detection backoff requirements.

If a PSE performing detection using Alternative A detects an invalid detection signature, it should complete a second detection in less than T_{dbo} after the beginning of the first detection attempt. This allows an Alternative A PSE to complete a successful detection cycle prior to an Alternative B PSE present on the same link section that may have caused the invalid detection signature.

Connection check timing requirements are specified in Table 145–10. Detection and power turn-on timing requirements are specified in Table 145–16. Classification timing requirements are specified in Table 145–14. Autoclass timing requirements are specified in Table 145–15.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the state diagram, each Alternative serves a distinct role during 4-pair operation. In any implementation, the roles of the Alternatives shall be established in IDLE and be maintained in every other state. In the state diagram, the roles of the Alternatives are named Primary Alternative and Secondary Alternative.

NOTE—During 4-pair operation, it may be necessary to swap the roles of Alternative A and Alternative B in IDLE in order to detect a PD.

The state diagram consists of multiple state diagrams that operate concurrently. Depending on the connected PD being identified as single-signature or dual-signature, the state diagram operates in a different manner. The top level state diagram consists of Figure 145–13.

If the connected PD is identified as dual-signature, the top level state diagram will proceed to SISM_START and remain in that state, at which point the semi-independent state diagrams for the Primary and Secondary Alternative become active. The dual-signature semi-independent state diagram is defined in Figure 145–15 and Figure 145–16 for the Primary and Secondary Alternative respectively.

Monitoring of MPS is described by the state diagrams in Figure 145–17 and Figure 145–18.

145.2.5.2 Conventions

The notation used in the state diagrams follows the conventions of state diagrams as described in 21.5. In addition a precedence order for operators is established in Table 145–5. Operators of equal precedence are evaluated left-to-right. Operator precedence in qualifiers is a local convention for this clause.

Table 145–5—State diagram operators in order of precedence (highest to lowest)

Operator	Meaning
( )	Indicates precedence
<, ≤ , >, ≥, =, ≠	Less than, less than or equal to, greater than, greater than or equal to, equals, not equals
!	Boolean NOT
*	Boolean AND
^	Boolean XOR
+	Boolean OR
⇐	Assignment operator

Some states in the state diagrams use an IF-THEN-ELSE-END construct to condition which actions are taken within the state. If the logical expression associated with the IF evaluates TRUE all the actions listed between THEN and ELSE will be executed. In the case where ELSE is omitted, the actions listed between THEN and END will be executed. If the logical expression associated with the IF evaluates FALSE the actions listed between ELSE and END will be executed. After executing the actions listed between THEN and ELSE, between THEN and END, or between ELSE and END, the actions following the END, if any, will be executed.

State diagrams may span over multiple pages. Arcs between states located on a different page within the same state diagram are drawn using a label containing the destination state's name at the originating state. An empty label is used at the destination state to indicate that there exists an entry, or entries, from another state.

145.2.5.2.1 Alternative designation

Alternative information is obtained by replacing the X in the desired variable or function with the letter of the Alternative of interest. The Alternative is referred to in general as follows:

X
: Generic Alternative designator. When X is used in a state diagram, its value is local to that state diagram and not global to the set of state diagrams.
Values:
A: Alternative A
B: Alternative B

NOTE—The variables alt_pri and alt_sec map Alternatives to Primary and Secondary.

145.2.5.3 Constants

CC_DET_SEQ
: A constant indicating the sequence in which the PSE performs connection check and detection. See Annex 145B for timing diagrams.
Values:
0: Connection check is followed by staggered detection for a single-signature PD and parallel or staggered detection for a dual-signature PD.
1: Detection on a pairset is followed by connection check and then detection on the other pairset for a single-signature PD and parallel or staggered (starting with first pairset) detection for a dual-signature PD.
2: Connection check and detection on both pairsets are performed within a single T_{det} window.
3: Connection check is followed by staggered detection.

Parallel detection refers to detection on both pairsets being performed in the same T_{det} time period. Staggered detection refers to detection on both pairsets being performed in a different T_{det} cycle.

145.2.5.4 Variables

ac_measurement_completed
: A variable that indicates that an Autoclass measurement has been completed. This variable is set by the state diagram.
Values:
FALSE: The Autoclass measurement has not completed.
TRUE: An Autoclass measurement has been completed.

alt_done_pri
: A variable used to coordinate the main single-signature state diagram with the semi-independent dual-signature state diagram for the Primary Alternative.
Values:
FALSE: The semi-independent state diagram is not ready to return to IDLE within the single-signature state diagram.
TRUE: The semi-independent state diagram is ready to return to IDLE within the single-signature state diagram.

alt_done_sec
: A variable used to coordinate the main single-signature state diagram with the semi-independent dual-signature state diagram for the Secondary Alternative.
Values:
FALSE: The semi-independent state diagram is not ready to return to IDLE within the single-signature state diagram.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TRUE: The semi-independent state diagram is ready to return to IDLE within the single-signature state diagram.

alt_pri

A variable used to select which Alternative assumes the role of Primary Alternative in the state diagram.

Values:

a: Alternative A assumes the role of Primary Alternative. When operating over 4 pairs, Alternative B assumes the role of Secondary Alternative.

b: Alternative B assumes the role of Primary Alternative. When operating over 4 pairs, Alternative A assumes the role of Secondary Alternative.

alt_pwrd_pri

A variable that controls the circuitry that the PSE uses to power the PD over the Alternative that has been assigned as Primary.

Values:

FALSE: The circuitry that applies operating voltage to the Primary Alternative is disabled.

TRUE: The circuitry that applies operating voltage to the Primary Alternative is enabled.

alt_pwrd_sec

A variable that controls the circuitry that the PSE uses to power the PD over the Alternative that has been assigned as Secondary.

Values:

FALSE: The circuitry that applies operating voltage to the Secondary Alternative is disabled.

TRUE: The circuitry that applies operating voltage to the Secondary Alternative is enabled.

autoclass_enable

A variable indicating that the PSE is enabled to check if the PD is requesting Autoclass via Physical Layer classification; see 145.2.8.2 and 145.3.6.2.

Values:

FALSE: Autoclass is disabled in the PSE.

TRUE: Autoclass is enabled in the PSE.

class_4PID_mult_events_pri

A variable indicating if the PSE generates 3 class events on the Primary Alternative to determine if a dual-signature PD is a candidate for 4-pair power.

Values:

FALSE: The PSE does not need to generate 3 class events to determine if the PD is a candidate for 4-pair power.

TRUE: The PSE generates at least 3 class events to determine if the PD is a candidate for 4-pair power.

class_4PID_mult_events_sec

A variable indicating if the PSE generates 3 class events on the Secondary Alternative to determine if a dual-signature PD is a candidate for 4-pair power.

Values:

FALSE: The PSE does not need to generate 3 class events to determine if the PD is a candidate for 4-pair power.

TRUE: The PSE generates at least 3 class events to determine if the PD is a candidate for 4-pair power.

det_once_sec

This variable indicates if the PSE has probed the Secondary Alternative at least once following exit from ENTRY_SEC.

Values:

FALSE: The PSE has not probed the Secondary Alternative since entering the Secondary Alternative state diagram.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TRUE: The PSE has probed the Secondary Alternative at least once since entering the Secondary Alternative state diagram.

det_start_pri

A variable that indicates to the Secondary Alternative that the Primary Alternative is between START_DETECT and POWER_UP.

Values:

FALSE: The Primary Alternative is not between START_DETECT and POWER_UP.
TRUE: The Primary Alternative is between START_DETECT and POWER_UP.

det_start_sec

A variable that indicates to the Primary Alternative that the Secondary Alternative is between START_DETECT and POWER_UP.

Values:

FALSE: The Secondary Alternative is not between START_DETECT and POWER_UP.
TRUE: The Secondary Alternative is between START_DETECT and POWER_UP.

det_temp

A variable that indicates whether a 4-pair PSE has completed detection on one and only one Alternative or if the PSE has completed detection on neither or both Alternatives.

Values:

both_neither: The PSE has completed detection on both Alternatives or neither Alternatives.
only_one: The PSE has completed detection on only one Alternative.

error_condition

A variable indicating the status of implementation-specific fault conditions or optionally other system faults that prevent the PSE from meeting the specifications in Table 145–16 and that require the PSE not to source power. This variable may be set by the PSE at any time.

Values:

FALSE: No fault indication.
TRUE: A fault indication exists.

error_condition_pri

A variable indicating the status of implementation-specific fault conditions or optionally other system faults that prevent the PSE from meeting the specifications in Table 145–16 and that require the PSE not to source power over the Primary Alternative. This variable may be set by the PSE at any time.

Values:

FALSE: No fault indication.
TRUE: A fault indication exists.

error_condition_sec

A variable indicating the status of implementation-specific fault conditions or optionally other system faults that prevent the PSE from meeting the specifications in Table 145–16 and that require the PSE not to source power over the Secondary Alternative. This variable may be set by the PSE at any time.

Values:

FALSE: No fault indication.
TRUE: A fault indication exists.

error_pri

Alias for the following terms: short_det_pri + ovld_det_pri + option_vport_lim_pri.

error_sec

Alias for the following terms: short_det_sec + ovld_det_sec + option_vport_lim_sec.

iclass_lim_det

A variable indicating if any I_{Class} measured by the PSE during do_classification is invalid or equal to or greater than I_{Class_LIM} min as defined in Table 145–14. This variable is set per this description.

Values:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FALSE: Measured I_{Class} is not invalid or is less than I_{Class_LIM} min during do_classification or this function is not active.

TRUE: Measured I_{Class} is invalid or equal to or greater than I_{Class_LIM} min during do_classification.

iclass_lim_det_pri

A variable indicating if any I_{Class} measured by the PSE over the Primary Alternative during do_classification_pri is invalid or equal to or greater than I_{Class_LIM} min as defined in Table 145–14. This variable is set per this description.

Values:

FALSE: Measured I_{Class} over the Primary Alternative is not invalid or is less than I_{Class_LIM} min during do_classification_pri or this function is not active.

TRUE: Measured I_{Class} over the Primary Alternative is invalid or equal to or greater than I_{Class_LIM} min during do_classification_pri.

iclass_lim_det_sec

A variable indicating if any I_{Class} measured by the PSE over the Secondary Alternative during do_classification_sec is invalid or equal to or greater than I_{Class_LIM} min as defined in Table 145–14. This variable is set per this description.

Values:

FALSE: Measured I_{Class} over the Secondary Alternative is not invalid or is less than I_{Class_LIM} min during do_classification_sec or this function is not active.

TRUE: Measured I_{Class} over the Secondary Alternative is invalid or equal to or greater than I_{Class_LIM} min during do_classification_sec.

MirroredPDAutoclassRequest

The copy of the ‘PD Autoclass request’ field in the Power via MDI TLV that the PSE receives from the remote system. This variable is mapped from aLldpXdot3RemAutoclassRequest (30.12.3.1.35) and assigned through Table 145–38.

Values:

FALSE: The PSE has not received an Autoclass measurement request from PD.

TRUE: The PSE has received an Autoclass measurement request from PD.

mps_valid

The PSE monitors the Maintain Power Signature (MPS, see 145.2.12). This variable indicates the presence or absence of a valid MPS, when the connected PD is a single-signature PD, or the PSE is operating in 2-pair mode. This variable is set per this description.

Values:

FALSE: MPS is absent.

TRUE: MPS is present.

mps_valid_pri

The PSE monitors the Maintain Power Signature (MPS, see 145.2.12) on the Primary Alternative. This variable indicates the presence or absence of a valid MPS on the Primary Alternative, when the connected PD is a dual-signature PD. This variable is set per this description.

Values:

FALSE: MPS is absent.

TRUE: MPS is present.

mps_valid_sec

The PSE monitors the Maintain Power Signature (MPS, see 145.2.12) on the Secondary Alternative. This variable indicates the presence or absence of a valid MPS on the Secondary Alternative, when the connected PD is a dual-signature PD. This variable is set per this description.

Values:

FALSE: MPS is absent.

TRUE: MPS is present.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

option_2ev

This variable indicates if PSE will generate 2 or 3 class events when pse_avail_pwr is 4.

Values:

FALSE: The PSE is not restricted to 2 class events when pse_avail_pwr is 4.

TRUE: The PSE is restricted to 2 class events when pse_avail_pwr is 4.

option_class_probe

This variable indicates if the PSE should determine the PD requested Class via the do_class_probe function. When set to TRUE, the PSE will issue 3 class events to determine the PD requested Class, perform a classification reset by applying V_{Reset} for at least T_{Reset} to the PI (see Table 145–14), followed by a normal classification procedure.

Values:

FALSE: The PSE will not probe for the PD requested Class.

TRUE: The PSE probes for the PD requested Class.

option_class_probe_pri

This variable indicates if the PSE should determine the PD requested Class on the Primary Alternative via the do_class_probe_pri function. When set to TRUE, the PSE will issue 3 class events to determine the PD requested Class, perform a classification reset by applying V_{Reset} for at least T_{Reset} to the Primary Alternative (see Table 145–14).

Values:

FALSE: The PSE will not probe for the PD requested Class.

TRUE: The PSE probes for the PD requested Class.

option_class_probe_sec

This variable indicates if the PSE should determine the PD requested Class on the Secondary Alternative via the do_class_probe_sec function. When set to TRUE, the PSE will issue 3 class events to determine the PD requested Class, perform a classification reset by applying V_{Reset} for at least T_{Reset} to the Secondary Alternative (see Table 145–14).

Values:

FALSE: The PSE will not probe for the PD requested Class.

TRUE: The PSE probes for the PD requested Class.

option_detect_ted

This variable indicates if detection can be performed by the PSE during the ted_timer interval.

Values:

FALSE: Do not perform detection during ted_timer interval.

TRUE: Perform detection during ted_timer interval.

option_detect_ted_pri

This variable indicates if detection can be performed by the PSE on the Primary Alternative during the ted_timer_pri interval.

Values:

FALSE: Do not perform detection during ted_timer_pri interval.

TRUE: Perform detection during ted_timer_pri interval.

option_detect_ted_sec

This variable indicates if detection can be performed by the PSE on the Secondary Alternative during the ted_timer_sec interval.

Values:

FALSE: Do not perform detection during ted_timer_sec interval.

TRUE: Perform detection during ted_timer_sec interval.

option_MEC_after_probe

This variable indicates if Multiple-Event classification is allowed after a class probe in the dual-signature state diagrams.

Values:

FALSE: Only allow Single-Event classification after class probe.

TRUE: Allow Multiple-Event classification after class probe.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

option_probe_alt_sec

This variable indicates if the PSE will continue to detect and conditionally perform Physical Layer classification on the Secondary Alternative in the event power is not applied to the Primary Alternative.

Values:

FALSE: PSE does not probe the Secondary Alternative if power is not applied to the Primary Alternative.

TRUE: PSE does probe the Secondary Alternative if power is not applied to the Primary Alternative.

option_vport_lim_pri

This variable indicates if V_{PSE} on the Primary Alternative is out of the operating range during normal operating state. This variable is set per this description.

Values:

FALSE: V_{PSE} on the Primary Alternative is within the $V_{Port_PSE\text{-}2P}$ operating range as defined in Table 145–16 or the PSE does not implement this option.

TRUE: V_{PSE} on the Primary Alternative is outside of the $V_{Port_PSE\text{-}2P}$ operating range as defined in Table 145–16.

option_vport_lim_sec

This variable indicates if V_{PSE} on the Secondary Alternative is out of the operating range during normal operating state. This variable is set per this description.

Values:

FALSE: V_{PSE} on the Secondary Alternative is within the $V_{Port_PSE\text{-}2P}$ operating range as defined in Table 145–16 or the PSE does not implement this option.

TRUE: V_{PSE} on the Secondary Alternative is outside of the $V_{Port_PSE\text{-}2P}$ operating range as defined in Table 145–16.

ovld_det_pri

A variable indicating if the PSE output current has been in an overload condition on the Primary Alternative; see 145.2.10.8. This variable is set per this description.

Values:

FALSE: The PSE has not detected an overload condition on the Primary Alternative.

TRUE: The PSE has detected an overload condition on the Primary Alternative.

ovld_det_sec

A variable indicating if the PSE output current has been in an overload condition on the Secondary Alternative; see 145.2.10.8. This variable is set per this description.

Values:

FALSE: The PSE has not detected an overload condition on the Secondary Alternative.

TRUE: The PSE has detected an overload condition on the Secondary Alternative.

pd_4pair_cand

This variable is used by the PSE to indicate that a connected PD is a candidate to receive power on both Modes. This variable is a function of the results of detection, connection check, Physical Layer classification, and PD 4PID; see 145.2.9.

Values:

FALSE: The PD is not a candidate to receive power on both Modes.

TRUE: The PD is a candidate to receive power on both Modes.

pd_autoclass_cancelled

A variable that indicates whether the PD cancelled Autoclass by drawing less than Class 1 power during the Autoclass measurement period.

Values:

FALSE: The PD did not cancel Autoclass or did not request Autoclass.

TRUE: The PD requested Physical Layer Autoclass and cancelled.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_cls_4PID_pri

This variable indicates that the Type of the dual-signature PD has been established on the Primary Alternative by Physical Layer classification.

Values:

FALSE: The PD is not a candidate for 4-pair power or the PSE has not used Physical Layer classification to determine the PD Type.

TRUE: The PD is a candidate for 4-pair power and has been identified as a Type 3 or Type 4 PD, see Table 145–27.

pd_cls_4PID_sec

This variable indicates that the Type of the dual-signature PD has been established on the Secondary Alternative by Physical Layer classification.

Values:

FALSE: The PD is not a candidate for 4-pair power or the PSE has not used Physical Layer classification to determine the PD Type.

TRUE: The PD is a candidate for 4-pair power and has been identified as a Type 3 or Type 4 PD, see Table 145–27.

pd_req_pwr

The variable indicates the PD requested Class. When a PD requests a higher Class than a PSE can support, the PSE assigns the PD to Class 3, Class 4, or Class 6, whichever is the highest Class it can support. If pse_avail_pwr is less than 4 and option_class_probe is FALSE, this variable may not contain the PD requested Class; do_class_probe also returns this variable.

Values:

0: Class 0
1: Class 1
2: Class 2
3: Class 3
4: Class 4
5: Class 5
6: Class 6
7: Class 7
8: Class 8

power_available

Variable that is asserted in an implementation-dependent manner when the PSE is no longer capable of sourcing sufficient power to support the attached PD. Sufficient power is defined by classification; see 145.2.8. This variable may be set by the PSE at any time.

Values:

FALSE: PSE is no longer capable of sourcing power to a PD.

TRUE: PSE is capable to continue to source power to a PD.

power_available_pri

Variable that is asserted in an implementation-dependent manner when the PSE is no longer capable of sourcing sufficient power on the Primary Alternative to support the attached PD. Sufficient power is defined by classification; see 145.2.8. This variable may be set by the PSE at any time.

Values:

FALSE: PSE is no longer capable of sourcing power on the Primary Alternative.

TRUE: PSE is capable to continue to source power on the Primary Alternative.

power_available_sec

Variable that is asserted in an implementation-dependent manner when the PSE is no longer capable of sourcing sufficient power on the Secondary Alternative to support the attached PD. Sufficient power is defined by classification; see 145.2.8. This variable may be set by the PSE at any time.

Values:

FALSE: PSE is no longer capable of sourcing power on the Secondary Alternative.

TRUE: PSE is capable to continue to source power on the Secondary Alternative.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pse_allocated_pwr

A variable that indicates the Class that has been assigned to the PD.

Values:

- 0: No power has been assigned to the PD
- 1: Class 1
- 2: Class 2
- 3: Class 3
- 4: Class 4
- 5: Class 5
- 6: Class 6
- 7: Class 7
- 8: Class 8

pse_alternative

This variable indicates which Pinout Alternative the PSE uses to apply power to the PI (see Table 145–3).

Values:

- a: The PSE uses PSE pinout Alternative A.
- b: The PSE uses PSE pinout Alternative B.
- both: The PSE uses both Alternative A and Alternative B.

pse_avail_pwr

This variable indicates the highest Class the PSE may assign to the PD by Physical Layer classification. The value is restricted to the allowed range defined in Table 145–6 and set in an implementation-specific manner.

Values:

- 1: Class 1
- 2: Class 2
- 3: Class 3
- 4: Class 4
- 5: Class 5
- 6: Class 6
- 7: Class 7
- 8: Class 8

pse_avail_pwr_pri

This variable indicates the highest Class the PSE may assign to the PD by Physical Layer classification on the Primary Alternative. The value is restricted to the allowed range defined in Table 145–6 and set in an implementation-specific manner.

Values:

- 1: Class 1
- 2: Class 2
- 3: Class 3
- 4: Class 4
- 5: Class 5

pse_avail_pwr_sec

This variable indicates the highest Class the PSE may assign to the PD by Physical Layer classification on the Secondary Alternative. The value is restricted to the allowed range defined in Table 145–6 and set in an implementation-specific manner.

Values:

- 1: Class 1
- 2: Class 2
- 3: Class 3
- 4: Class 4
- 5: Class 5

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pse_dll_capable

This variable indicates whether the PSE is capable of performing optional Data Link Layer classification. See 145.5 for a description of Data Link Layer functionality. A variable that is set in an implementation-dependent manner.

Values:

FALSE: The PSE's Data Link Layer classification capability is not enabled.
TRUE: The PSE's Data Link Layer classification capability is enabled.

pse_dll_enable

A variable indicating whether the Data Link Layer classification mechanism is enabled. See 145.5.

Values:

FALSE: Data Link Layer classification is not enabled.
TRUE: Data Link Layer classification is enabled.

pse_dll_ready

An implementation-specific variable that indicates that the PSE has initialized Data Link Layer classification. This variable maps into the aLldpXdot3LocReady attribute (30.12.2.1.61). This variable may be set by the PSE at any time.

Values:

FALSE: Data Link Layer classification has not completed initialization.
TRUE: Data Link Layer classification has completed initialization.

pse_enable

A variable that selects PSE operation. This variable may be set by the PSE at any time.

Values:

disable: All PSE functions disabled (behavior is as if there was no PSE functionality).
enable: Normal PSE operation.

pse_power_update

A variable that is set when the PSEAllocatedPowerValue in the DLL state diagram in Figure 145–40 has been updated. This variable may be set by the PSE at any time.

Values:

FALSE: The value of PSEAllocatedPowerValue has not changed.
TRUE: The value of PSEAllocatedPowerValue has changed.

pse_power_update_pri

A variable that is set when the PSEAllocatedPowerValue_alt(X) in the DLL state diagram in Figure 145–42 or Figure 145–43 has been updated, where X is the Primary Alternative. This variable may be set by the PSE at any time.

Values:

FALSE: The value of PSEAllocatedPowerValue_alt(X) has not changed.
TRUE: The value of PSEAllocatedPowerValue_alt(X) has changed.

pse_power_update_sec

A variable that is set when the PSEAllocatedPowerValue_alt(X) in the DLL state diagram in Figure 145–42 or Figure 145–43 has been updated, where X is the Secondary Alternative. This variable may be set by the PSE at any time.

Values:

FALSE: The value of PSEAllocatedPowerValue_alt(X) has not changed.
TRUE: The value of PSEAllocatedPowerValue_alt(X) has changed.

pse_ready

Variable that is asserted in an implementation-dependent manner to probe the link segment. This variable may be set by the PSE at any time.

Values:

FALSE: PSE is not ready to probe the link segment.
TRUE: PSE is ready to probe the link segment.

NOTE—Care should be taken when negating this variable in a PSE performing detection using Alternative A after an invalid detection signature is detected due to the delay it introduces between detection attempts (see 145.2.5.1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pse_ready_pri

Variable that is asserted in an implementation-dependent manner to probe the Primary Alternative. This variable may be set by the PSE at any time.

Values:

FALSE: PSE is not ready to probe the primary link segment.
TRUE: PSE is ready to probe the primary link segment.

pse_ready_sec

Variable that is asserted in an implementation-dependent manner to probe the Secondary Alternative. This variable may be set by the PSE at any time.

Values:

FALSE: PSE is not ready to probe the secondary link segment.
TRUE: PSE is ready to probe the secondary link segment.

pse_reset

Controls the resetting of the PSE state diagram. Condition that is TRUE until such time as the power supply for the device that contains the PSE overall state diagrams has reached the operating region. It is also TRUE when implementation-specific reasons require reset of PSE functionality. This variable is set per this description.

Values:

FALSE: Do not reset the PSE state diagram.
TRUE: Reset the PSE state diagram.

pse_reset_pri

Controls the resetting of the PSE state diagram on Primary Alternative. Condition that is TRUE until such time as the power supply for the device that contains the PSE overall state diagrams has reached the operating region. It is also TRUE when implementation-specific reasons require reset of PSE Primary Alternative functionality. This variable is set per this description.

Values:

FALSE: Do not reset the PSE state diagram.
TRUE: Reset the PSE state diagram.

pse_reset_sec

Controls the resetting of the PSE state diagram on Secondary Alternative. Condition that is TRUE until such time as the power supply for the device that contains the PSE overall state diagrams has reached the operating region. It is also TRUE when implementation-specific reasons require reset of PSE Secondary Alternative functionality. This variable is set per this description.

Values:

FALSE: Do not reset the PSE state diagram.
TRUE: Reset the PSE state diagram.

pse_ss_mode

A variable that controls whether the PSE provides power over 2 pair or 4 pair to a single-signature PD assigned to Class 1 through Class 4. This variable may be set by the PSE at any time.

0: Single-signature PD is powered over 2 pair.
1: Single-signature PD is powered over 4 pair.

pse_ss_mode_update

A variable that is used to cause the PSE to re-evaluate the value of pse_ss_mode when it is in POWER_ON. This variable may be set by the PSE at any time.

Values:

FALSE: pse_ss_mode is not re-evaluated.
TRUE: pse_ss_mode will be re-evaluated.

pwr_app_pri

A variable indicating that the PSE has begun steady state operation on the Primary Alternative by having asserted alt_pwrd_pri, completed the ramp up of voltage, is not in a current limiting mode, and is operating beyond the POWER_UP requirements of 145.2.10.7. This variable is set per this description.

Values:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FALSE: The PSE is either not applying power or has begun applying power but is still in POWER_UP on the Primary Alternative.
TRUE: The PSE has begun steady state operation on the Primary Alternative.

pwr_app_sec

A variable indicating that the PSE has begun steady state operation on the Secondary Alternative by having asserted alt_pwrd_sec, completed the ramp up of voltage, is not in a current limiting mode, and is operating beyond the POWER_UP requirements of 145.2.10.7. This variable is set per this description.

Values:

FALSE: The PSE is either not applying power or has begun applying power but is still in POWER_UP on the Secondary Alternative.
TRUE: The PSE has begun steady state operation on the Secondary Alternative.

semi_pwr_en

A variable indicating if, in the case of a single-signature PD, the PSE uses the method consisting of turning off only the pairset on which a short-circuit, overload or out of range V_{PSE} is detected.

Values:

TRUE: Only the pairset with the fault condition is turned off.
FALSE: Both pairsets are turned off if there is a fault on one pairset.

short_det_pri

A variable indicating if the PSE output current has been in a short circuit condition on the Primary Alternative. This variable is set per this description. See 145.2.10.9.

Values:

FALSE: The PSE has not detected a short circuit condition on the Primary Alternative.
TRUE: The PSE has detected a short circuit condition on the Primary Alternative.

short_det_sec

A variable indicating if the PSE output current has been in a short circuit condition on the Secondary Alternative. This variable is set per this description. See 145.2.10.9.

Values:

FALSE: The PSE has not detected a short circuit condition on the Secondary Alternative.
TRUE: The PSE has detected a short circuit condition on the Secondary Alternative.

sism

A variable used by the single-signature state diagram to initiate the semi-independent dual-signature state diagrams.

Values:

FALSE: Single-signature state diagram has control of the Alternatives.
TRUE: Single-signature state diagram has passed control of the Alternatives to the semi-independent dual-signature state diagrams.

temp_var

A variable used to store the previous value of the variable pd_class_sig.

temp_var_pri

A variable used to store the previous value of the variable pd_class_sig_pri for the Primary Alternative.

temp_var_sec

A variable used to store the previous value of the variable pd_class_sig_sec for the Secondary Alternative.

PSEs shall set pse_avail_pwr, pse_avail_pwr_pri, and pse_avail_pwr_sec from the range in Table 145–6.

145.2.5.5 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition: a timer is reset and stops counting upon entering a state where “stop *x*_timer” is asserted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 145–6—Allowed Type 3 and Type 4 PSE permutations for pse_avail_pwr

PSE Type	pse_avail_pwr	pse_avail_pwr_pri, pse_avail_pwr_sec
Type 3	1 to 6	1 to 4
Type 4	1 to 8	1 to 5

tauto_pse1_timer
: A timer used to delay Autoclass power measurement following transition into POWER_ON; see T_{AUTO_PSE1} in Table 145–15.

tauto_pse2_timer
: A timer used to limit Autoclass power measurement following transition into POWER_ON; see T_{AUTO_PSE2} in Table 145–15.

tcc2det_timer
: A timer used to limit the time between connection check and detection when CC_DET_SEQ = 0 or CC_DET_SEQ = 3. See T_{cc2det} in Table 145–10.

tcev_timer
: A timer used to limit the second through fifth class event time in Multiple-Event classification; see T_{CEV} in Table 145–14.

tcev_timer_pri
: A timer used to limit the second through fourth class event time in Multiple-Event classification on the Primary Alternative; see T_{CEV} in Table 145–14.

tcev_timer_sec
: A timer used to limit the second through fourth class event time in Multiple-Event classification on the Secondary Alternative; see T_{CEV} in Table 145–14.

tclass_acs_timer
: A timer used to indicate when the PSE may measure the class current during the first long class event, to check if the PD is requesting Autoclass. See T_{Class_ACS} in Table 145–14.

tclass_reset_timer
: A timer used to limit the classification reset time; See T_{Reset} in Table 145–14.

tclass_reset_timer_pri
: A timer used to limit the classification reset time on the Primary Alternative; see T_{Reset} in Table 145–14.

tclass_reset_timer_sec
: A timer used to limit the classification reset time on the Secondary Alternative; see T_{Reset} in Table 145–14.

tdbo_timer
: A timer used to regulate backoff upon detection of an invalid detection signature; see T_{dbo} in Table 145–16.

tdet_timer
: A timer used to limit an attempt to detect a PD; see T_{det} in Table 145–16.

tdet_timer_pri
: A timer used to limit an attempt to detect a PD on the Primary Alternative; see T_{det} in Table 145–16.

tdet_timer_sec
: A timer used to limit an attempt to detect a PD on the Secondary Alternative; see T_{det} in Table 145–16.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tdet2det_timer
: A timer used to limit the time between the completion of a detection on one pairset and the beginning of a detection on the other; see $T_{det2det}$ in Table 145–10.

ted_timer
: A timer used to regulate a subsequent attempt to power a PD after an error condition causes power removal; see T_{ed} in Table 145–16. The default state of this timer is ted_timer_done.

ted_timer_pri
: A timer used to regulate a subsequent attempt to power a PD after an error condition causes power removal from the Primary Alternative; see T_{ed} in Table 145–16. The default state of this timer is ted_timer_pri_done.

ted_timer_sec
: A timer used to regulate a subsequent attempt to power a PD after an error condition causes power removal from the Secondary Alternative; see T_{ed} in Table 145–16. The default state of this timer is ted_timer_sec_done.

tinrush_timer_pri
: A timer used to monitor the duration of the inrush event on the Primary Alternative; see T_{Inrush} in Table 145–16.

tinrush_timer_sec
: A timer used to monitor the duration of the inrush event on the Secondary Alternative; see T_{Inrush} in Table 145–16.

tlce_timer
: A timer used to limit the first class event time in Multiple-Event classification; see T_{LCE} in Table 145–14.

tlce_timer_pri
: A timer used to limit the first class event time in Multiple-Event classification on the Primary Alternative; see T_{LCE} in Table 145–14.

tlce_timer_sec
: A timer used to limit the first class event time in Multiple-Event classification on the Secondary Alternative; see T_{LCE} in Table 145–14.

tme1_timer
: A timer used to limit mark event times for all but the last mark event time during Multiple-Event classification; see T_{ME1} in Table 145–14.

tme1_timer_pri
: A timer used to limit mark event times for all but the last mark event time during Multiple-Event classification on the Primary Alternative; see T_{ME1} in Table 145–14.

tme1_timer_sec
: A timer used to limit mark event times for all but the last mark event time during Multiple-Event classification on the Secondary Alternative; see T_{ME1} in Table 145–14.

tme2_timer
: A timer used to limit the final mark event time in Multiple-Event classification; see T_{ME2} in Table 145–14.

tme2_timer_pri
: A timer used to limit the final mark event time in Multiple-Event classification on the Primary Alternative; see T_{ME2} in Table 145–14.

tme2_timer_sec
: A timer used to limit the final mark event time in Multiple-Event classification on the Secondary Alternative; see T_{ME2} in Table 145–14

tmpdo_timer
: A timer used to monitor the dropout of the MPS; see T_{MPDO} in Table 145–16.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tmpdo_timer_pri
: A timer used to monitor the dropout of the MPS on the Primary Alternative; see T_{MPDO} in Table 145–16.

tmpdo_timer_sec
: A timer used to monitor the dropout of the MPS on the Secondary Alternative; see T_{MPDO} in Table 145–16.

tpon_timer
: A timer used to limit the time for power turn-on; see T_{pon} in Table 145–16.

tpon_timer_pri
: A timer used to limit the time on the Primary Alternative for power turn-on; see T_{pon} in Table 145–16.

tpon_timer_sec
: A timer used to limit the time on the Secondary Alternative for power turn-on; see T_{pon} in Table 145–16.

145.2.5.6 Functions

The variable formed by the function name appended with "_done" is used to indicate when the function has completed. This variable is set to FALSE when the function is called and is set to TRUE once the function is complete and its output variables are valid.

do_autoclass_measure
: This function measures $P_{Autoclass}$ as defined in 145.2.8.2. This function returns the following variable:

  $P_{Autoclass}$: The power measured by the PSE during Physical Layer classification as defined in 145.2.8.2.

do_autoclassification
: This function returns the following variable:

  pd_autoclass: This variable indicates whether the PD requests Autoclass during Physical Layer classification. pd_autoclass is set to True when a class signature of '0' is detected during the T_{Class_ACS} window, as defined in Table 145–14, otherwise it is set to False.
  Values:
  FALSE: The PD does not request Autoclass.
  TRUE: The PD requests Autoclass.

do_class_probe
: This function discovers the PD requested Class by producing a number of class events. The class events produced are limited to CLASS_EV1_LCE to MARK_EV3. The tlce_timer in CLASS_EV1_LCE may be replaced with the tcev_timer to allow abbreviated class timing duration. This function returns the following variable:

  pd_req_pwr: See pd_req_pwr in 145.2.5.4.

do_class_probe_pri
: This function discovers the PD requested Class by producing a number of class events on the Primary Alternative. The class events produced are limited to CLASS_EV1_LCE_PRI to MARK_EV3_PRI. The tlce_timer_pri in CLASS_EV1_LCE_PRI may be replaced with the tcev_timer_pri to allow abbreviated class timing duration. This function returns the following variables:

  pd_req_pwr_pri: See do_classification_pri function.
  pd_cls_4PID_pri: See pd_cls_4PID_pri in 145.2.5.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

do_class_probe_sec

This function discovers the PD requested Class by producing a number of class events on the Secondary Alternative. The class events produced are limited to CLASS_EV1_LCE_SEC to MARK_EV3_SEC. The tlce_timer_sec in CLASS_EV1_LCE_SEC may be replaced with the tcev_timer_sec to allow abbreviated class timing duration. This function returns the following variables:

pd_req_pwr_sec: See do_classification_sec function.
pd_cls_4PID_sec: See pd_cls_4PID_sec in 145.2.5.4.

do_class_reset

This function produces the classification reset voltage; See V_{Reset} in Table 145–14. This function does not return any variables.

do_class_reset_pri

This function produces the classification reset voltage on the Primary Alternative; See V_{Reset} in Table 145–14. This function does not return any variables.

do_class_reset_sec

This function produces the classification reset voltage on the Secondary Alternative; See V_{Reset} in Table 145–14. This function does not return any variables.

do_classification

This function produces the classification event voltage and determines the PD's class signature. This function returns the following variable:

pd_class_sig: The PD class signature seen on the negative pair or pairs during the most recent class event; see Table 145–13 and 145.2.8.
Values:

0: class signature 0
1: class signature 1
2: class signature 2
3: class signature 3
4: class signature 4

do_classification_pri

This function produces the classification event voltage and determines the PD's class signature for the Primary Alternative. This function returns the following variables for the Primary Alternative:

pd_req_pwr_pri: This variable indicates the PD requested Class. When a PD requests a higher Class than a PSE can support, the PSE assigns the PD Class 3 or 4, whichever is the highest that it can support. See 145.2.8. The returned value is based on all previous do_classification_pri function calls since the last time in DETECT_EVAL_PRI or CLASS_RESET_PRI. See Table 145–27 for a determination of the PD requested Class.
Values:

1: Class 1
2: Class 2
3: Class 3
4: Class 4
5: Class 5

pse_allocated_pwr_pri: This variable indicates the Class assigned to the PD for the Primary Alternative. The returned value is based on all previous do_classification_pri function calls since the last time in DETECT_EVAL_PRI or CLASS_RESET_PRI. See Table 145–11 for a determination of the PSE assigned Class.
Values:

1: Class 1
2: Class 2
3: Class 3

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

4: Class 4
5: Class 5

pd_class_sig_pri: The PD class signature seen on the negative pair associated with the Primary Alternative during the most recent class event; see Table 145–13 and 145.2.8.
Values:
0: class signature 0
1: class signature 1
2: class signature 2
3: class signature 3
4: class signature 4

do_classification_sec

This function produces the classification event voltage and determines the PD's class signature for the Secondary Alternative. This function returns the following variables for the Secondary Alternative:

pd_req_pwr_sec: This variable indicates the PD requested Class. When a PD requests a higher Class than a PSE can support, the PSE assigns the PD Class 3 or 4, whichever is the highest that it can support. See 145.2.8. The returned value is based on all previous do_classification_sec function calls since the last time in DETECT_EVAL_SEC or CLASS_RESET_SEC. See Table 145–27 for a determination of the PD requested Class.
Values:
1: Class 1
2: Class 2
3: Class 3
4: Class 4
5: Class 5

pse_allocated_pwr_sec: This variable indicates the Class assigned to the PD for the Secondary Alternative. The returned value is based on all previous do_classification_sec function calls since the last time in DETECT_EVAL_SEC or CLASS_RESET_SEC. See Table 145–11 for a determination of the PSE assigned Class.
Values:
1: Class 1
2: Class 2
3: Class 3
4: Class 4
5: Class 5

pd_class_sig_sec: The PD class signature seen on the negative pair associated with the Secondary Alternative during the most recent class event; see Table 145–13 and 145.2.8.
Values:
0: class signature 0
1: class signature 1
2: class signature 2
3: class signature 3
4: class signature 4

do_cxn_chk

This function initiates the connection check as defined in 145.2.7. This function returns the following variable:

sig_type: This variable indicates the PD signature configuration connected to the PI, with respect to 4-pair operation.
Values:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

invalid: Neither a single-signature nor a dual-signature configuration has been found. This includes an open circuit condition on either pairset.
single: The PSE has determined there is a single-signature PD configuration connected to the PI.
dual: The PSE has determined there is a dual-signature PD configuration connected to the PI.

do_detect_pri

This function returns the following variables (see 145.2.6):

sig_pri: This variable indicates the presence or absence of a valid PD detection signature on the Primary Alternative.
Values:
open_circuit: The PSE has detected an open circuit.
valid: The PSE has detected a valid PD detection signature.
invalid: Neither an open circuit nor a valid PD detection signature has been found.

do_detect_sec

This function returns the following variables (see 145.2.6):

sig_sec: This variable indicates the presence or absence of a valid PD detection signature on the Secondary Alternative.
Values:
open_circuit: The PSE has detected an open circuit.
valid: The PSE has detected a valid PD detection signature.
invalid: Neither an open circuit nor a valid PD detection signature has been found.

do_initialize

This function returns the following variables (see 145.2.5.4):

alt_pri
autoclass_enable
class_4PID_mult_events_pri
class_4PID_mult_events_sec
option_2ev
option_class_probe
option_class_probe_pri
option_class_probe_sec
option_detect_ted
option_detect_ted_pri
option_detect_ted_sec
option_MEC_after_probe
option_probe_alt_sec
pse_alternative
pse_avail_pwr
pse_avail_pwr_pri
pse_avail_pwr_sec
pse_dll_capable
semi_pwr_en

do_mark

This function produces the classification mark event voltage. This function does not return any variables.

do_mark_pri

This function produces the classification mark event voltage on the Primary Alternative. This function does not return any variables.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

do_mark_sec

This function produces the classification mark event voltage on the Secondary Alternative. This function does not return any variables.

do_update_pse_allocated_pwr

A function that updates the pse_allocated_pwr based on the value of PSEAllocatedPowerValue as defined in Table 145–12. This function returns the following variable:

pse_allocated_pwr: See pse_allocated_pwr in 145.2.5.4.

do_update_pse_allocated_pwr_pri

A function that updates the pse_allocated_pwr_pri value based on the value of PSEAllocatedPowerValue_alt(X) as defined in Table 145–12. This function returns the following variable:

pse_allocated_pwr_pri: See do_classification_pri function.

do_update_pse_allocated_pwr_sec

A function that updates the pse_allocated_pwr_sec value based on the value of PSEAllocatedPowerValue_alt(X) as defined in Table 145–12. This function returns the following variable:

pse_allocated_pwr_sec: See pse_allocated_pwr_sec in 145.2.5.6.

145.2.6 PSE detection of PDs

The PSE shall not apply operating voltage to a pairset until the PSE has successfully detected a valid signature over that pairset. When a PSE is already in POWER_ON, it may transition between 2-pair and 4-pair power without redoing detection as described in 145.2.10.1.

The PSE PI is connected to a PD through a link section. The PSE probes the link section in order to detect a valid PD detection signature. In the following subclauses, the link is not called out to preserve clarity.

The PSE is not required to continuously probe to detect a PD detection signature. The period of time when a PSE is not attempting to detect a PD detection signature is implementation dependent. Also, a PSE may successfully detect a PD or detect and classify a PD, but then opt not to power the detected PD.

A PSE detecting an invalid PD signature on either Alternative may perform detection on the other Alternative, and if valid may perform classification on that pairset.

145.2.6.1 PSE detection validation circuit

The PSE shall detect the PD by probing via the PSE PI. The PSE shall present a non-valid PD detection signature as defined in Table 145–22 when probed in either polarity by another PSE. An illustrative embodiment of a detection circuit is shown in Figure 145–19.

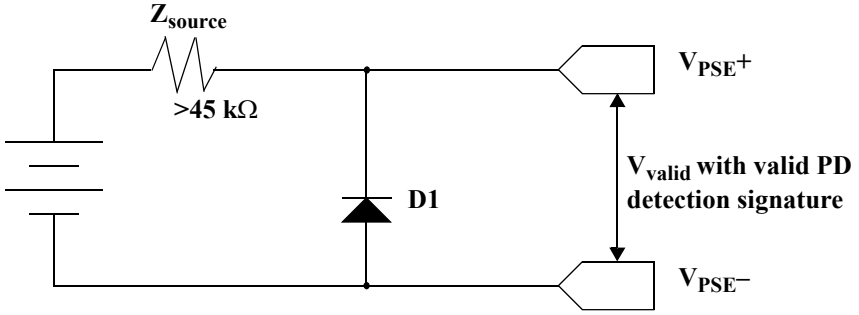

Figure 145–19—PSE detection source

A functional equivalent of the detection circuit that has no source impedance limitation but restricts the PSE detection circuit to the first quadrant is shown in Figure 145–20.

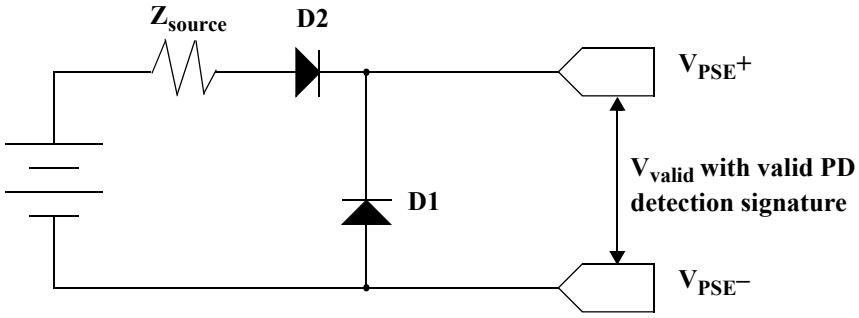

Figure 145–20—Alternative PSE detection source

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In Figure 145–19 and Figure 145–20, the diode D1 presents a non-valid PD detection signature for a reversed voltage PSE to PSE connection.

The open circuit voltage and short circuit current shall meet the specifications in Table 145–7. The PSE shall not be damaged by up to 5 mA backdriven current over the range of V_{oc} as defined in Table 145–7. Output capacitance shall be as defined in Table 145–7 when V_{PSE} is in the range of 0 V to V_{valid} max.

145.2.6.2 Detection probe requirements

The detection voltage at the PSE PI shall be within the V_{valid} voltage range, as defined in Table 145–7, with a valid PD detection signature connected, as defined in Table 145–21.

Table 145–7—PSE PI per pairset detection state electrical requirements

Item	Parameter	Symbol	Unit	Min	Max
1	Open circuit voltage	V_{oc}	V	0	30
2	Short circuit current	I_{sc}	mA	—	5
3	Valid test voltage	V_{valid}	V	2.8	10
4	Voltage difference between test points	ΔV_{test}	V	1	—
5	Slew rate	V_{slew}	V/µs	—	0.1
6	Pairset output capacitance	C_{out}	nF	—	520

In evaluating the presence of a valid PD, the PSE shall make at least two measurements with V_{PSE} values that create at least a ΔV_{test} difference as defined in Table 145–7. An effective resistance is calculated from two or more measurements made during the detection process.

The resistance is calculated with Equation (145–1):

$$R = \left\{ \frac{(V_2 - V_1)}{(I_2 - I_1)} \right\}_{\Omega} \tag{145–1}$$

where

V_1 and V_2 are the first and second voltage measurements made on the pairset, respectively
I_1 and I_2 are the first and second current measurements made on the negative pair of the pairset, respectively
R is the effective resistance

Attached PI capacitance may be determined using these measurements and the port RC time-constant charging characteristics.

NOTE—Settling time before voltage or current measurement: the voltage or current measurement should be taken after V_{PSE} has settled to within 1 % of its steady state condition with a valid PD detection signature connected (as defined in Table 145–21).

The PSE shall control the slew rate of the probing detection voltage when switching between detection voltages to be less than V_{slew} as defined in Table 145–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

145.2.6.3 Detection criteria

A PSE shall accept as a valid PD detection signature a pairset with all of the characteristics specified in Table 145–8.

Table 145–8—Valid PD detection signature electrical characteristics, as measured at the PSE PI

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Accept signature resistance	R_{good}	kΩ	19	26.5	—
2	Accept signature capacitance	C_{good}	µF	—	0.15	—
3	Signature offset voltage tolerance	V_{os}	V	0	2	—
4	Signature offset current tolerance	I_{os}	µA	0	12	—

145.2.6.4 Rejection criteria

The PSE shall reject as an invalid detection signature, a pairset which exhibits any of the following characteristics:

a) Resistance less than or equal to R_{bad} min, or
b) Resistance greater than or equal to R_{bad} max, or
c) Capacitance greater than or equal to C_{bad} min.

R_{bad} min, R_{bad} max, and C_{bad} min are defined in Table 145–9.

NOTE—Detection and rejection criteria for Clause 145 remain unchanged from Clause 33, for the purpose of maintaining interoperability with Clause 33 devices (see also 145.2.6.3).

A PSE may accept or reject a signature resistance in the band between R_{good} min and R_{bad} min, and in the band between R_{good} max and R_{bad} max. A PSE may accept or reject a parallel signature capacitance in the band between C_{good} max and C_{bad} min.

In instances where the resistance and capacitance meet the detection criteria, but one or both of the offsets are exceeded, the detection behavior of the PSE is undefined.

Table 145–9—Invalid PD detection signature electrical characteristics, as measured at the PSE PI

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Reject signature resistance	R_{bad}	kΩ	15	33	—
2	Reject signature capacitance	C_{bad}	µF	10	—	—
3	Open circuit resistance	R_{open}	MΩ	0.5	—	—

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

145.2.6.5 Open circuit criteria

If a PSE that is performing detection using Alternative B (see 145.2.4) determines that the impedance at the PI is greater than R_{open} as defined in Table 145–9, it may optionally consider the link to be open circuit and omit the tdbo_timer interval.

145.2.7 Connection check

PSEs that will source power on both pairsets shall complete a connection check prior to the classification of a PD as defined in 145.2.8 to determine if the PSE is connected to a single-signature PD configuration, a dual-signature PD configuration, or neither.

NOTE—When a link segment is connected to an MDI, not all contacts are made simultaneously. A link segment connection or removal may occur at any time during connection check. PSE implementations should take these considerations into account.

During connection check the PSE shall meet the specifications for open circuit voltage, V_{oc}, and short circuit current, I_{sc}, in Table 145–7. The connection check voltage at the PSE PI shall be within the V_{valid} voltage range, as defined in Table 145–7, when a single-signature PD or a dual-signature PD is connected.

The specification of T_{cc2det}, defined in Table 145–10, applies to the time between the end of connection check and the beginning of detection on at least one pairset. If the connection check takes place after the beginning of detection, this specification does not apply.

The specification of $T_{det2det}$, defined in Table 145–10, applies to the time between the end of detection on the first pairset to the beginning of detection on the other pairset when the second detection occurs before power up on the first pairset.

Table 145–10—Connection check timing requirements

Item	Parameter	Symbol	Unit	Min	Max	Additional Information
1	Connection check to detection time	T_{cc2det}	s	—	0.4	Applies only when connection check is performed before the start of detection.
2	Detection to detection time	$T_{det2det}$	s	—	0.4	—

The connection check is rerun before applying power if power up fails to meet the timing requirements in both Table 145–10 and 145.2.10.14 or if power is absent on both pairsets simultaneously.

If the voltage on either pairset rises above V_{valid} max, as defined in Table 145–7, during connection check, the PSE shall reset the PD by bringing the voltage at the PI below V_{off} max, as defined in Table 145–16, for at least T_{Reset}, as defined in Table 145–14, before performing classification.

145.2.8 PSE classification of PDs and mutual identification

The ability for the PSE to query the PD in order to determine the power requirements of that PD is called classification. The interrogation and power classification function is intended to establish mutual identification and is intended for use with advanced features such as power management.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Mutual identification is the mechanism that allows a PSE to differentiate between Type 1, Type 2, Type 3, and Type 4 PDs. Additionally, mutual identification allows PDs to differentiate between Type 1, Type 2, Type 3, and Type 4 PSEs.

There are two forms of classification: Multiple-Event Physical Layer classification and Data Link Layer (DLL) classification.

Physical Layer classification occurs after a valid detection and before a PSE supplies power to a PD, when the PSE asserts a voltage in the range of V_{Class} as defined in Table 145–14 onto one or both pairsets. This is called a class event. The PD responds to each class event with a current representing one of a limited number of class signatures. The class signatures generated by the PD indicate the PD requested Class. See Table 145–26 and Table 145–27 for a mapping of class signature to the PD requested Class.

NOTE—Requested Class 0 is not defined for Type 3 PDs. A Type 1 PD that does not implement Physical Layer classification requests Class 0, with a power level equivalent to Class 3. Such PDs are assigned to Class 3 by Type 3 and Type 4 PSEs.

The assigned Class is the result of the PD requested Class and the number of class events produced by the PSE as shown in Table 145–11. See 145.3.6 for PD classification behavior.

When a single-signature PD requests a higher Class than a PSE can support, the PSE assigns the PD Class 3, 4, or 6, whichever is the highest that it can support. When a dual-signature PD requests a higher Class than a PSE can support, the PSE assigns the PD Class 3 or 4, whichever is the highest that it can support. The minimum output power a PSE supports depends on the assigned Class.

The minimum output power a PSE supports when powering a single-signature PD, or supplying power in 2-pair mode, is defined by Equation (145–2). PSE implementations may use $V_{PSE} = V_{Port_PSE\text{-}2P}$ min and $R_{Chan\text{-}2P} = R_{Ch}$ when the assigned Class is 1 through 4, or $R_{Chan} = R_{Ch}/2$ when the assigned Class is 5 through 8 to arrive at over-margined values as shown in Table 145–11. P_{Class} may subsequently be adjusted using Data Link Layer classification.

$$P_{Class} = \left\{ \begin{array}{ll} V_{PSE} \times \left(\dfrac{V_{PSE} - \sqrt{V_{PSE}^2 - 4 \times R_{Chan\text{-}2P} \times P_{Class_PD}}}{2 \times R_{Chan\text{-}2P}} \right) & \text{for assigned Class 1 through 4} \\ V_{PSE} \times \left(\dfrac{V_{PSE} - \sqrt{V_{PSE}^2 - 4 \times R_{Chan} \times P_{Class_PD}}}{2 \times R_{Chan}} \right) & \text{for assigned Class 5 through 8} \end{array} \right\}_{W} \quad (145\text{–}2)$$

where

V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3
R_{Chan} is the link section DC loop resistance
$R_{Chan\text{-}2P}$ is the pairset DC loop resistance
P_{Class_PD} is the maximum power at the PD PI per the PDs assigned Class, as defined in Table 145–29

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When connected to a dual-signature PD, a PSE operating over 4 pairs treats the requested power over each pairset independently. The minimum output power a PSE supports on a pairset when powering a dual-signature PD is defined by Equation (145–3). PSE implementations may use $V_{PSE} = V_{Port_PSE\text{-}2P}$ min and $R_{Chan\text{-}2P} = R_{Ch}$ to arrive at over-margined values as shown in Table 145–11. $P_{Class\text{-}2P}$ may subsequently be adjusted using Data Link Layer classification or Autoclass.

$$P_{\text{Class-2P}} = \left\{ V_{\text{PSE}} \times \left(\frac{V_{\text{PSE}} - \sqrt{V_{\text{PSE}}^2 - 4 \times R_{\text{Chan-2P}} \times P_{\text{Class_PD-2P}}}}{2 \times R_{\text{Chan-2P}}} \right) \right\}_{\text{W}} \tag{145–3}$$

where

V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3

$R_{Chan\text{-}2P}$ is the pairset DC loop resistance

$P_{Class_PD\text{-}2P}$ is the maximum power at the PD PI for a pairset per the PDs assigned Class, as defined in Table 145–29

P_{Class} and $P_{Class\text{-}2P}$ are valid over the range of $V_{Port_PSE\text{-}2P}$ defined in Table 145–16.

If the PD connected to the PSE performs Autoclass (see 145.2.8.2 and 145.3.6.2), the PSE may set the minimum supported output power based on $P_{Autoclass}$, the power drawn during the Autoclass measurement window. $P_{Autoclass}$ shall be increased by at least P_{ac_margin}, as defined in Table 145–15, in order to account for potential increase in link section resistance due to temperature increase, up to the value defined in Table 145–11 of the Class assigned to the PD. If $P_{Autoclass}$ is less than or equal to 4 W then the minimum supported output power shall be P_{Class} per the assigned Class.

When the PSE assigns Class 5 through 8 prior to a fault and then transitions to PRIMARY_SEMI_PWRON or SECONDARY_SEMI_PWRON, it shall revert the allocation of power to Class 4 and assert local_system_change to update PSEAllocatedPowerValue.

A PSE that measured $P_{Autoclass}$ while providing power over 4 pairs, shall increase the power allocation by at least P_{ac_extra}, as defined in Equation (145–4), when it provides power over 2 pairs.

$$P_{\text{ac_extra}} = \left\{ \left(\frac{P_{\text{Autoclass}}}{V_{\text{Port_PSE-2P}}\text{min}} \right)^2 \times \frac{R_{\text{Ch}}}{2} \right\}_{\text{W}} \tag{145–4}$$

where

$P_{Autoclass}$ is the amount of power measured by the PSE during the Autoclass measurement

$V_{Port_PSE\text{-}2P}$ min is the minimum PSE operating voltage

R_{Ch} is the maximum pairset DC loop resistance, as defined in Table 145–1

Table 145–11—Physical Layer power classifications

PD Requested Class	Number of PSE class events	Assigned Class	P_{Class}	$P_{Class-2P}$
PSEs connected to a single-signature PD				
1	1	1	4 W	—
2	1	2	6.7 W	—
0, 3 to 8	1	3	14 W	—
4 to 8	2 or 3	4	30 W	—
5	4	5	45 W	—
6 to 8	4	6	60 W	—
7	5	7	75 W	—
8	5	8	90 W	—
PSEs connected to a dual-signature PD (classification per pairset)				
1	1, 2, or 3	1	—	4 W
2	1, 2, or 3	2	—	6.7 W
3	1, 2, or 3	3	—	14 W
4 or 5	1	3	—	14 W
4 or 5	2 or 3	4	—	30 W
5	4	5	—	45 W

NOTE 1—P_{Class} in Table 145–11 is the minimum required power at the PSE PI calculated using minimum $V_{Port\ PSE-2P}$ and maximum R_{Chan}. Use Equation (145–2) for other values of $V_{Port\ PSE-2P}$ and R_{Chan}. For PD requested power levels, see Table 145–26.

NOTE 2—$P_{Class-2P}$ in Table 145–11 is the minimum required power for a pairset calculated using minimum $V_{Port\ PSE-2P}$ and maximum $R_{Chan-2P}$. Use Equation (145–3) for other values of $V_{Port\ PSE-2P}$ and $R_{Chan-2P}$. For PD requested power levels, see Table 145–27.

NOTE 3—The number of PSE class events refers to the number of class events since the most recent PD reset.

NOTE 4—The values of P_{Class} and $P_{Class-2P}$ are calculated for the lowest Type PSE that is able to support that power level.

With Data Link Layer classification, the PSE and PD communicate using the Data Link Layer Protocol (see 145.5) after the data link is established. The Data Link Layer classification has finer power resolution and the ability for the PSE and PD to participate in dynamic power allocation wherein allocated power to the PD may change one or more times during PD operation. Data Link Layer classification takes precedence over Physical Layer classification.

After a successful DLL classification, the assigned Class changes depending on the value of the PSEAllocatedPowerValue or PSEAllocatedPowerValue_alt(X) variable, as defined in Table 145–12. The PSEAllocatedPowerValue or PSEAllocatedPowerValue_alt(X) values correspond with the maximum power a PD may draw, P_{Class_PD} or P_{Class_PD-2P} respectively; see Table 145–29 and 145.5.3.2.2.

Subsequent to successful detection, PSEs shall perform Multiple-Event Physical Layer classification and may perform Data Link Layer classification. PSEs that will source power over 4-pair to a dual-signature PD shall perform Physical Layer classification on each pairset.

Table 145–12—Relation of assigned Class and DLL

Single-signature		Dual-signature	
PSEAllocatedPowerValue	**Assigned Class**	**PSEAllocatedPowerValue_alt(X)**	**Assigned Class on Alternative X**
1 to 39	1	1 to 39	1
40 to 65	2	40 to 65	2
66 to 130	3	66 to 130	3
131 to 255	4	131 to 255	4
256 to 400	5	256 to 499	5
401 to 510	6		
511 to 620	7		
621 to 999	8		

A PSE shall be capable of assigning the highest Class it can support by means of Multiple-Event Physical Layer classification.

A PSE shall return to IDLE if it fails to complete classification after successfully completing detection of a single-signature PD. A PSE shall return to IDLE_PRI or IDLE_SEC, whichever corresponds to the appropriate Alternative, if it successfully completes detection on a pairset of a dual-signature PD but fails to complete classification on that pairset.

145.2.8.1 PSE Multiple-Event Physical Layer classification

Classification consists of a series of classification and mark events as defined in the state diagram in Figure 145–13, Figure 145–15, and Figure 145–16.

Voltages V_{Class}, V_{Mark}, and V_{Reset} and currents I_{Class_LIM} and I_{Mark_LIM} are specified in Table 145–14. PD class signature measurements of I_{Class} are specified in Table 145–13. Classification times, T_{LCE}, T_{CEV}, T_{ME1}, T_{ME2}, T_{Class}, and T_{Reset} are specified in Table 145–14. Autoclass timing, T_{Class_ACS} is specified in Table 145–14. See Annex 145B for more details and timing diagrams.

Type 3 PSEs:

— Shall provide a maximum of four class events and four mark events for single-signature PDs.
— Shall provide a maximum of three class events and three mark events on each pairset for dual-signature PDs.

Type 4 PSEs:

— Shall provide a maximum of five class events and five mark events for single-signature PDs.
— Shall provide a maximum of four class events and four mark events on each pairset for dual-signature PDs.

Table 145–13—Class signatures evaluated at the PSE PI

Measured I_{Class}	Class signature
0 mA to 5 mA	Class signature 0
> 5 mA and < 8 mA	Either class signature 0 or 1
8 mA to 13 mA	Class signature 1
> 13 mA and < 16 mA	Either class signature 1 or 2
16 mA to 21 mA	Class signature 2
> 21 mA and < 25 mA	Either class signature 2 or 3
25 mA to 31 mA	Class signature 3
> 31 mA and < 35 mA	Either class signature 3 or 4
35 mA to 45 mA	Class signature 4
> 45 mA and < 51 mA	Either class signature 4 or invalid class signature

Table 145–14—PSE Physical Layer classification electrical requirements

Item	Parameter	Symbol	Units	Min	Max
1	Class event voltage	V_{Class}	V	15.5	20.5
2	Mark event voltage	V_{Mark}	V	7	10
3	Classification reset voltage	V_{Reset}	V	0	2.8
4	Class event current limitation	I_{Class_LIM}	A	0.051	0.1
5	Mark event current limitation	I_{Mark_LIM}	A	0.005	0.1
6	Classification reset timing	T_{Reset}	ms	15	—
7	Class event I_{Class} measurement timing	T_{Class}	ms	6	—
8	LCE I_{Class} measurement timing	T_{Class_LCE}	ms	T_{Class}	75
9	Autoclass I_{Class} measurement timing	T_{Class_ACS}	ms	88	—
10	Long first class event timing	T_{LCE}	ms	88	105
11	Second through fifth class event timing	T_{CEV}	ms	6	20
12	Mark event timing (except last mark event)	T_{ME1}	ms	6	12
13	Last mark event timing[a]	T_{ME2}	ms	6	—

[a] The maximum value of T_{ME2} is limited by T_{pon}, as defined in 145.2.10.14

PSEs connected to a single-signature PD shall issue no more class events than the Class they are able to support and no more than

— One class event when the PD requests Class 0 through 3
— Three class events when the PD requests Class 4
— Four class events when the PD requests Class 5 or 6
— Five class events when the PD requests Class 7 or 8

between the most recent time V_{PSE} was at V_{Reset} for at least T_{Reset} and a transition to any of the power up states.

PSEs connected to a dual-signature PD shall issue, for a given pairset, no more class events than the Class they are able to support and no more than

— Three class events when the PD requests Class 1 through 4 on the given pairset
— Four class events when the PD requests Class 5 on the given pairset

between the most recent time V_{PSE} was at V_{Reset} for at least T_{Reset} and a transition to any of the power up states.

PSEs that issue more class events than the Class they are capable of supporting, in order to determine the PD requested Class, transition to CLASS_RESET to reset the PD's class event count.

When the PSE is in CLASS_EV1_LCE, CLASS_EV1_AUTO, CLASS_EV1_LCE_PRI, CLASS_EV1_LCE_SEC, CLASS_EV1_LCE_4PID_PRI, or CLASS_EV1_LCE_4PID_SEC, it shall provide to the PI or pairset V_{Class}, subject to T_{LCE} timing specification.

The PSE in CLASS_EV1_AUTO shall measure I_{Class} on the negative pair or pairs after T_{Class_ACS}, referenced from the application of the first class event, to determine if the PD will perform Autoclass. If the Autoclass enabled PSE in CLASS_EV1_AUTO measures I_{Class} in the range of class signature 0 this indicates the PD will perform Autoclass; see 145.2.8.2 and 145.3.6.2.

When the PSE is in CLASS_EV2, CLASS_EV2_PRI, CLASS_EV2_SEC, CLASS_EV3, CLASS_EV3_PRI, CLASS_EV3_SEC, CLASS_EV4, CLASS_EV4_PRI, CLASS_EV4_SEC, or CLASS_EV5, it shall provide to the PI or pairset V_{Class}, subject to the T_{CEV} timing specification.

In all CLASS states except CLASS_EV1_AUTO, the PSE shall measure I_{Class} on the negative pair or pairs after T_{Class}. This measurement is referenced from the application of V_{Class} min to ignore initial transients.

The timing specification for PSEs in a DO_CLASS_PROBE state may be reduced to T_{CEV} for all class events.

When the PSE is in MARK_EV1, MARK_EV1_PRI, MARK_EV1_SEC, MARK_EV2, MARK_EV2_PRI, MARK_EV2_SEC, MARK_EV3, MARK_EV3_PRI, MARK_EV3_SEC, or MARK_EV4, it shall provide to the PI or pairset V_{Mark}. The timing specification shall be as defined by T_{ME1}.

When a PSE is in MARK_EV_LAST, MARK_EV_LAST_PRI or MARK_EV_LAST_SEC, it shall provide to the PI or pairset V_{Mark}. The timing specification shall be as defined by T_{ME2}.

The V_{Mark} requirement is to be met with load currents in the range of I_{Mark} as defined in Table 145–25.

NOTE—In a properly operating system, the port may or may not discharge to the V_{Mark} range due to the combination of the overall channel and PD capacitance and PD current loading. This is normal and acceptable system operation. For compliance testing, it is necessary to discharge the port in order to observe the V_{Mark} voltage. Discharge can be accomplished with a 2 mA load for 3 ms, after which V_{Mark} can be observed with minimum and maximum load current.

If any measured I_{Class} is equal to or greater than I_{Class_LIM} min, a PSE returns to IDLE, IDLE_PRI, or IDLE_SEC as appropriate. The PSE shall limit class event currents to I_{Class_LIM} and shall limit mark event currents to I_{Mark_LIM}.

All class event voltages and mark event voltages shall have the same polarity as defined for V_{Port_PSE-2P} in 145.2.4. PSEs may issue class events on one or both pairsets, when connected to a single-signature PD and operating over 4 pairs. The PSE shall complete Multiple-Event Physical Layer classification and transition to POWER_ON, POWER_ON_PRI, or POWER_ON_SEC without allowing the voltage at the PI or pairset to go below V_{Mark} min, unless in CLASS_RESET, CLASS_RESET_PRI, or CLASS_RESET_SEC. If the PSE returns to IDLE, it shall maintain the PI voltage in the range of V_{Reset} for a period of at least T_{Reset} min before starting a new detection cycle. If the PSE returns to IDLE_PRI or IDLE_SEC, it shall maintain the PI voltage on the corresponding pairset in the range of V_{Reset} for a period of at least T_{Reset} min before starting a new detection cycle. If the PSE is in any of the CLASS_RESET states it shall maintain the PI or pairset voltage in the range of V_{Reset} for a period of at least T_{Reset} min.

A PSE that implements 4PID based on Physical Layer classification and is restricted to Class 3 power or less, when connected to a dual-signature PD, shall issue three initial class events to determine the Type of the connected PD, then transition to either CLASS_RESET_PRI or CLASS_RESET_SEC.

145.2.8.2 Autoclass (optional)

PSEs may implement an extension of Physical Layer classification known as Autoclass. The purpose of Autoclass is to allow the PSE to determine the actual maximum power draw of the connected PD. Autoclass is only defined for single-signature PDs. See Figure 145B–15 for Autoclass timing diagrams.

If the PSE implements Autoclass it shall measure $P_{Autoclass}$ when it reaches POWER_ON and pd_autoclass is TRUE. $P_{Autoclass}$ is the power provided by the PSE measured throughout the period bounded by T_{AUTO_PSE1} and T_{AUTO_PSE2}, defined in Table 145–15. P_{ac_margin}, defined in Table 145–15, is the minimum amount of power the PSE adds to $P_{Autoclass}$ in order to allocate enough power to cope with increases in the link section resistance due to temperature increase.

P_{ac_extra} is the minimum amount of additional power allocation (above $P_{Autoclass}$ and P_{ac_margin}) that a PSE allocates while providing power in 2-pair mode, when it performed the measurement of $P_{Autoclass}$ in 4-pair mode. This extra allocation covers the additional losses incurred by the increase in link section resistance in 2-pair mode. P_{ac_extra} does not apply for PSEs that performed the $P_{Autoclass}$ measurement in 2-pair mode.

T_{AUTO_PSE1} and T_{AUTO_PSE2} timing is referenced from the transition of POWER_UP to POWER_ON. The power consumption shall be defined as the highest average power measured throughout the period bounded by T_{AUTO_PSE1} and T_{AUTO_PSE2}. Average power is measured using a sliding window with a width in the range of T_{AUTO_Window} as defined in Table 145–15.

Table 145–15—Autoclass electrical requirements

Item	Parameter	Symbol	Units	Min	Max	Additional information
1	Autoclass power measurement start	T_{AUTO_PSE1}	ms	1400	1600	Measured from the transition of POWER_UP to POWER_ON
2	Autoclass power measurement end	T_{AUTO_PSE2}	ms	3100	3500	
3	Autoclass average power sliding window width	T_{AUTO_Window}	ms	150	300	—
4	Autoclass power margin per the assigned Class					—
	Class 1 to 4	P_{ac_margin}	W	0.5	—	
	Class 5 to 6			0.75	—	
	Class 7 to 8			1.5	—	

145.2.9 4PID requirements

PSEs determine whether an attached PD is a candidate to receive power on both pairsets prior to applying operating voltage to both pairsets. This determination is referred to as 4PID. 4PID is a logical function of the detection state of both pairsets, the result of connection check as described in 145.2.7, and mutual identification. The variable pd_4pair_cand, defined in 145.2.5.4, contains the result of this determination.

A PSE shall not apply 4-pair power unless the PSE has detected a valid detection signature on both pairsets and one or more of the following conditions are met:

a) The connected PD is a single-signature PD.
b) The PSE detects a valid detection signature on the unpowered pairset when power is provided in 2-pair mode.
c) The PSE has identified the PD as Type 3 or Type 4.

145.2.10 Power supply output

When the PSE provides power to the PI, it shall conform with Table 145–16. Table 145–16 values support worst-case operating conditions. These ranges may be narrowed when additional information is known and applied in accordance with this specification. Power may be removed from both pairsets any time power is removed from one pairset.

Table 145–16—PSE output PI electrical requirements for all PD Classes, unless otherwise specified *(continued)*

Item	Parameter	Symbol	Unit	Min	Max	PSE Type	Additional information
19	DC MPS current on at least one pairset, per the assigned Class						See 145.2.12.
	Single-signature PD, Class 1 to 4, 2-pair	$I_{Hold-2P}$	A	0.004	0.009	3, 4	
	Single-signature PD, Class 1 to 4, 4-pair			0.002	0.005		
	Single-signature PD, Class 5 to 8			0.002	0.007		
	DC MPS current on each pairset						
	Dual-signature PD	$I_{Hold-2P}$	A	0.002	0.007	3, 4	
20	DC MPS total current on both pairs of the same polarity, per the assigned Class						See 145.2.12.
	Single-signature PD, Class 1 to 4	I_{Hold}	A	0.004	0.009	3, 4	
	Single-signature PD, Class 5 to 8			0.004	0.014	3, 4	
21	PD MPS dropout time limit	T_{MPDO}	ms	320	400	3,4	See 145.2.12.
22	PD MPS time for validity	T_{MPS}	ms	6	—	3,4	See 145.2.12.
23	Alternative B detection backoff time	T_{dbo}	ms	2000	—	3, 4	—
24	Detection timing	T_{det}	ms	—	500	3, 4	Time to complete detection on a pairset.
25	Error delay timing	T_{ed}	ms	750	—	3, 4	See 145.2.10.15

[a] The $I_{Con-2P-unb}$ value is higher than the value for Class 5 as unbalance for Class 4 is not restricted.
[b] Unbalance at Class 4 is not restricted. The I_{LIM-2P} value is higher than the value for Class 5 for PSEs operating in 4-pair mode.

145.2.10.1 Output voltage in the power on states

The specification for $V_{Port_PSE\text{-}2P}$ in Table 145–16 shall be met with a load step of (I_{Hold} max × $V_{Port_PSE\text{-}2P}$ min) to the maximum power per the PSE's assigned Class at a rate of change of up to 15 mA/µs. The voltage transients as a result of load changes up to 35 mA/µs shall be limited to 3.5 V/µs.

A PSE that has assigned Class 1 to 4 to a single-signature PD and is in a power on state may transition between 2-pair and 4-pair power at any time, including after the expiration of T_{pon}. A PSE that has assigned Class 5 to 8 to a single-signature PD shall apply power to both pairsets while in POWER_ON.

T_{Rise}, as defined in Table 145–16, is referenced from 10% to 90% of the voltage difference between the positive and the negative conductors of a pairset in a power on state from the beginning of a power up state.

145.2.10.2 Output voltage pair-to-pair difference

$V_{Port_PSE_diff}$, as defined in Table 145–16, is the maximum voltage difference between pairs with the same polarity, at no load condition, when operating over 4 pairs, in a power on state.

145.2.10.3 Voltage transients

A PSE shall maintain an output voltage no less than $V_{Tran\text{-}2P}$ for transient conditions lasting more than 30 µs and less than 250 µs, and meet the requirements of 145.2.10.9. Transients less than 30 µs in duration may cause the voltage at the PI to fall below $V_{Tran\text{-}2P}$. See 145.3.8.6 for PD transient requirements. Transients lasting more than 250 µs shall meet the $V_{Port_PSE\text{-}2P}$ specification.

NOTE—The occurrence of voltage transients lasting more than 250 µs or voltage steps of significant amplitude (within the $V_{Port_PSE\text{-}2P}$ specification) should be limited to rare circumstances such as those involving switchover of backup power supplies or those involving significant change in current demand on the PSE power supply due to a large load step spread over multiple powered ports.

145.2.10.4 Reflected voltage

When a 4-pair capable PSE provides power in 2-pair mode, whereby two pairs are connected to the positive V_{PSE}, and one pair is connected to the negative V_{PSE}, a single-signature PD may reflect a voltage of up to V_{PSE} back onto the unpowered pairset. See 145.3.8.8. This can cause a reverse current, I_{rev} as defined in Table 145–16, to flow. Reverse current is current flowing out of the PSE on a negative pair.

The PSE shall not source a current higher than I_{rev}, as defined in Table 145–16, on a negative pair. This requirement holds only when no power is being sourced into the PSE.

145.2.10.5 Power feeding ripple and noise

V_{Noise}, the specification for power feeding ripple and noise in Table 145–16, shall be met for common-mode and pair-to-pair noise values at all static PSE output voltages. The limits are meant to preserve data integrity. To meet EMI standards, lower values may be needed. For higher frequencies, see 145.4.4, 145.4.5, and 145.4.6.

145.2.10.6 Continuous current capability in the power on states

$I_{Port\text{-}2P}$ and $I_{Port\text{-}2P\text{-}other}$ are the currents on the negative pairs and are defined in Equation (145–5) and in Equation (145–6).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$I_{\text{Port-2P}} = \left\{ \begin{array}{l} I_{\text{Port-2P-pri}} \text{ for the Primary Alternative} \\ I_{\text{Port-2P-sec}} \text{ for the Secondary Alternative} \end{array} \right\}_{\text{A}} \quad (145\text{–}5)$$

$$I_{\text{Port-2P-other}} = \left\{ \begin{array}{l} I_{\text{Port-2P-sec}} \text{ for the Primary Alternative} \\ I_{\text{Port-2P-pri}} \text{ for the Secondary Alternative} \end{array} \right\}_{\text{A}} \quad (145\text{–}6)$$

I_{Port} is the total current on both pairs with the same polarity and is defined in Equation (145–7).

$$I_{\text{Port}} = \{ I_{\text{Port-2P}} + I_{\text{Port-2P-other}} \}_{\text{A}} \quad (145\text{–}7)$$

where

$I_{\text{Port-2P-pri}}$ is the current supplied on the negative pair of the Primary Alternative
$I_{\text{Port-2P-sec}}$ is the current supplied on the negative pair of the Secondary Alternative

PSEs shall be able to supply $I_{\text{Con-2P}}$, the current the PSE supports on both pairs of each powered pairset, as defined in Equation (145–8). $I_{\text{Con-2P}}$ should be measured using a sliding window with a width of 1 second.

$$I_{\text{Con-2P}} = \left\{ \begin{array}{ll} P_{\text{Class}} / V_{\text{PSE}} & \text{when in 2-pair mode} \\ \min(I_{\text{Con}} - I_{\text{Port-2P-other}},\ I_{\text{Con-2P-unb}}) & \text{when 4-pair powering a single-signature PD} \\ P_{\text{Class-2P}} / V_{\text{PSE}} & \text{when 4-pair powering a dual-signature PD} \end{array} \right\}_{\text{A}} \quad (145\text{–}8)$$

where

P_{Class} is P_{Class} as defined in Equation (145–2)
$P_{\text{Class-2P}}$ is $P_{\text{Class-2P}}$ as defined in Equation (145–3)
V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3
I_{Con} is the total current a PSE is able to source as defined in Equation (145–9)
$I_{\text{Con-2P-unb}}$ is the current a PSE is able to supply on each pair to account for pair-to-pair unbalance as defined in Table 145–16
$I_{\text{Port-2P-other}}$ is the current on the other negative pair as defined in Equation (145–6)

When powering a single-signature PD over 4 pairs, a PSE supports both:

— A total current of I_{Con}, defined in Equation (145–9), over both pairs with the same polarity;
— A minimum current of $I_{\text{Con-2P-unb}}$ on both the positive pair and the negative pair with the highest current to account for pair-to-pair unbalance.

$$I_{\text{Con}} = \left\{ \frac{P_{\text{Class}}}{V_{\text{PSE}}} \right\}_{\text{A}} \quad (145\text{–}9)$$

where

P_{Class} is P_{Class} as defined in Equation (145–2)
V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PSE shall support the AC current waveform parameter $I_{Peak\text{-}2P}$, defined in Equation (145–10), on both pairs of each powered pairset, while within the operating voltage range of $V_{Port_PSE\text{-}2P}$, for a minimum of T_{CUT} and a duty cycle of at least 5%.

$$I_{Peak\text{-}2P} = \left\{ \begin{array}{ll} I_{Peak} & \text{when in 2-pair mode} \\ \min(I_{Peak} - I_{Port\text{-}2P\text{-}other},\ I_{Peak\text{-}2P\text{-}unb}) & \text{when 4-pair powering a single-signature PD} \\ \dfrac{V_{PSE} - \sqrt{V_{PSE}^2 - 4 \times R_{Chan\text{-}2P} \times P_{Peak_PD\text{-}2P}}}{2 \times R_{Chan\text{-}2P}} & \text{when 4-pair powering a dual-signature PD} \end{array} \right\}_A \quad (145\text{–}10)$$

where

I_{Peak} is the total peak current a PSE supports per Equation (145–11)
$I_{Port\text{-}2P\text{-}other}$ is the current on the other negative pair as defined in Equation (145–6)
$I_{Peak\text{-}2P\text{-}unb}$ is the minimum peak current supported to account for unbalance, defined in Equation (145–12)
V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3
$R_{Chan\text{-}2P}$ is the pairset loop resistance; this parameter has a worst-case value of R_{Ch} defined in 145.1.3 and Table 145–1
$P_{Peak_PD\text{-}2P}$ is the peak power a dual-signature PD may draw per its assigned Class on a pairset; see Table 145–29

I_{Peak}, defined in Equation (145–11), is the total current of the powered pairs with the same polarity that a PSE supports, when powering a PD over 2 pairs or powering a single-signature PD over 4 pairs.

$$I_{Peak} = \left\{ \frac{V_{PSE} - \sqrt{V_{PSE}^2 - 4 \times R_{Chan} \times P_{Peak_PD}}}{2 \times R_{Chan}} \right\}_A \quad (145\text{–}11)$$

where

V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3
R_{Chan} is the link section loop resistance as defined in 145.1.3
P_{Peak_PD} is the total peak power a PD may draw for its Class; see Table 145–29

$I_{Peak\text{-}2P\text{-}unb}$, defined in Equation (145–12), is the minimum current that a PSE is able to supply on both the positive pair and the negative pair with the highest current, when powering a single-signature PD over 4 pairs.

$$I_{Peak\text{-}2P\text{-}unb} = \{I_{LIM\text{-}2P} - 0.002\}_A \quad (145\text{–}12)$$

where

$I_{LIM\text{-}2P}$ is the $I_{LIM\text{-}2P}$ min value per pairset for the PSE, as defined in Table 145–16

Copyright © 2022 IEEE. All rights reserved.

145.2.10.6.1 PSE pair-to-pair current unbalance

When a PSE supplies power to a PD using all 4 pairs, the current may not equally divide between the pairs that are at the same polarity. This is referred to as pair-to-pair current unbalance. The degree to which the current is unbalanced depends on the specific combination of PSE, cabling, and PD.

The maximum pair current in a system depends on the assigned Class (see 145.2.8), and is defined in Table 145–17.

Table 145–17—Maximum pair-to-pair current unbalance

Parameter	Assigned Class	Unit	Value
$I_{Unbalance\text{-}2P}$	1 to 4	A	I_{Con} [a]
	5 to 8		$I_{Con\text{-}2P\text{-}unb} - 0.01$

[a] Unbalance current for these assigned Classes is not restricted.

PSEs that operate over 4 pairs are subject to unbalance requirements. The contribution of PSE PI pair-to-pair effective resistance unbalance to the system end-to-end effective resistance unbalance is specified by PSE maximum (R_{PSE_max}) and minimum (R_{PSE_min}) common-mode effective resistance in the powered pairs of same polarity, see Figure 145A–1. Effective resistances of R_{PSE_min} and R_{PSE_max} include the effects of $V_{Port_PSE_diff}$ as defined in Table 145–16 and the PSE PI resistive elements. See definition and measurements in Annex 145A.

The PSE PI pair-to-pair effective resistance unbalance determined by R_{PSE_max} and R_{PSE_min}, along with any other parts of the system, i.e., the cabling and the PD, bounds the current such that the pair with the highest current including unbalance does not exceed $I_{Unbalance\text{-}2P}$ as defined in Table 145–17 during normal operating conditions. $I_{Unbalance\text{-}2P}$ is the highest pair current in case of maximum unbalance and will be higher than $I_{Con} / 2$. $I_{Unbalance\text{-}2P}$ applies to link section common-mode pair resistances from 0.2 Ω to R_{Ch}, as defined in 145.1.3.

R_{PSE_max} and R_{PSE_min} are specified and measured under maximum P_{Class_PD} load conditions, measured at the PD PI, over the $V_{Port_PSE\text{-}2P}$ operating range. R_{PSE_max} and R_{PSE_min} for the positive pairs are not necessarily the same values as for the negative pairs.

PSEs that meet R_{PSE_min} and R_{PSE_max}, as defined by Equation (145–13) meet the unbalance requirements under worst case conditions of link section pair to pair unbalance and PD PI pair to pair unbalance. Equation (145–13) is only applicable for R_{PSE_min} up to a value of 1 Ω for Class 5 and Class 6, and 0.5 Ω for Class 7 and Class 8.

$$0 < R_{PSE_max} \leq \left\{ \begin{array}{ll} 2.182 \times R_{PSE_min} - 0.04 & \text{for Class 5} \\ 1.999 \times R_{PSE_min} - 0.04 & \text{for Class 6} \\ 1.904 \times R_{PSE_min} - 0.03 & \text{for Class 7} \\ 1.832 \times R_{PSE_min} - 0.03 & \text{for Class 8} \end{array} \right\}_{\Omega} \quad (145\text{–}13)$$

where

R_{PSE_max} is, given R_{PSE_min}, the highest supported common-mode effective resistance in the powered pairs of the same polarity

R_{PSE_min} is the lower PSE common-mode effective resistance in the powered pairs of the same polarity

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

R_{PSE_min} or R_{PSE_max} common-mode effective resistance is the resistance of the two internal conductors (including the internal components on each conductor) in a powered pair of the same polarity connected in parallel.

A PSE shall not source more than $I_{Unbalance\text{-}2P}$ on any pair when connected to a load as shown in Figure 145–21, using values of R_{load_min} and R_{load_max} as defined in Equation (145–14) and Equation (145–15). This unbalance current requirement applies at the PSE PI connector (jack) when mated with a specified balanced cabling connector (plug).

R_{load_min} and R_{load_max}, defined in Equation (145–14) and Equation (145–15), are respectively the minimum and maximum common-mode effective load resistances in the powered pairs of the same polarity.

Table 145–18 specifies the resistance values used to compute R_{load_min} and R_{load_max} according to Equation (145–14) and Equation (145–15). The load resistances R_{load_min} and R_{load_max} are split into two series resistances R_{load1_min} and R_{load2_min}, and R_{load1_max} and R_{load2_max} respectively, as shown in Figure 145–21, so the power sink can be set such that the power consumption inside the P_{load} box equals P_{Class_PD}.

$$R_{load_min} = R_{load1_min} + R_{load2_min} \quad (145\text{–}14)$$

$$R_{load_max} = R_{load1_max} + R_{load2_max} \quad (145\text{–}15)$$

where

R_{load1_max} is, given R_{load1_min}, the higher resistance value representing the link section resistance
R_{load1_min} is the lower resistance representing the link section resistance
R_{load2_max} is, given R_{load2_min}, the higher resistance value representing the PD contribution to unbalance
R_{load2_min} is the lower resistance representing the PD contribution to unbalance

Table 145–18—PSE unbalance test fixture resistances

PSE Class	R_{load1_min} (Ω)	R_{load1_max} (Ω)	R_{load2_min} (Ω)	R_{load2_max} (Ω)	Additional information
5	0.087	0.101	0.638	1.518	Low link section resistance conditions.
6			0.538	1.183	
7			0.483	1.017	
8			0.439	0.894	
5	5.41	6.25	0.704	1.026	High link section resistance conditions.
6			0.564	0.822	
7			0.491	0.717	
8			0.43	0.629

The values for $I_{Unbalance\text{-}2P}$ and the relation between R_{PSE_max} and R_{PSE_min}, as defined in Equation (145–13), are valid given that $R_{Chan\text{-}2P}$ (see 145.1.3) ranges from 0.2 Ω to 12.5 Ω. See 145A.4 for guidelines on how to support low resistance link sections.

Figure 145–21 shows a verification circuit for the PSE current unbalance requirements measurement. Other methods for measuring R_{PSE_min} and R_{PSE_max} are described in Annex 145A.

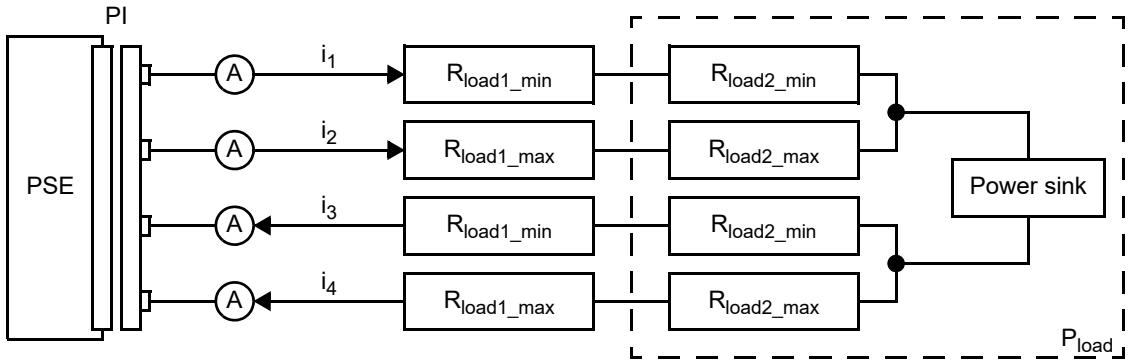

Figure 145–21—PSE current unbalance verification circuit

The evaluation method is as follows:

a) Use R_{load_min} and R_{load_max} from Equation (145–14) and Equation (145–15) for low channel resistance conditions.
b) Adjust the power sink such that P_{load} (the power consumed by the R_{load2} resistances and the power sink) equals P_{Class_PD} for the given Class.
c) Verify that currents i_1, i_2, i_3, and i_4 are lower than $I_{Unbalance\text{-}2P}$, as defined in Table 145–17.
d) Exchange R_{load_max} and R_{load_min}. Repeat steps b) and c).
e) Repeat steps b) through d) for R_{load_min} and R_{load_max} components from Equation (145–14) and Equation (145–15) for high channel resistance conditions.

145.2.10.7 Current during power up

Power up occurs on each pairset between the transition to a power up state on that pairset and the expiration of T_{Inrush}. A PSE that provides current on both pairsets during POWER_UP shall complete power up within T_{Inrush} max, starting when the first pairset exceeds a voltage of 30 V. PSEs that have assigned Class 1 through 6 to a single-signature PD may perform inrush over 2 pairs or over 4 pairs. PSEs that have assigned Class 5 or Class 6 to a single-signature PD transition to 4-pair mode by T_{Inrush}. PSEs that have assigned Class 7 or Class 8 to a single-signature PD perform inrush over 4 pairs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PSE shall limit the current on each powered negative pair to $I_{Inrush\text{-}2P}$ and the total current on the negative pairs to I_{Inrush} during power up per the requirements of Table 145–16, with the exception of the initial per pairset transient described in Equation (145–16).

$$I_{PSEIT\text{-}2P}(t) = \left\{ \begin{array}{ll} I_{Inrush\text{-}2P}\text{max} & \text{for } 0 \le t < t_0 \\ 50 & \text{for } t_0 \le t < (t_0 + 10\times10^{-6}) \\ I_{Inrush\text{-}2P}\text{max} + \dfrac{(50 - I_{Inrush\text{-}2P}\text{max}) \times (0.001 + t_0 - t)}{99\times10^{-5}} & \text{for } (t_0 + 10\times10^{-6}) \le t < (t_0 + 0.001) \\ I_{Inrush\text{-}2P}\text{max} & \text{for } (t_0 + 0.001) \le t < 0.075 \end{array} \right\}_A \quad (145\text{–}16)$$

where

t is the time in seconds

$I_{Inrush\text{-}2P}$ max is the maximum value of $I_{Inrush\text{-}2P}$ as defined in Table 145–16

t_0 is the time when $I_{Port\text{-}2P}$ exceeds $I_{Inrush\text{-}2P}$ max for the first time during the power up states. The range for t_0 is $0 \le t_0 \le 49$ ms.

The PSE inrush maximum limit, $I_{PSEIT\text{-}2P}$, shown in Figure 145–22, is defined by Equation (145–16).

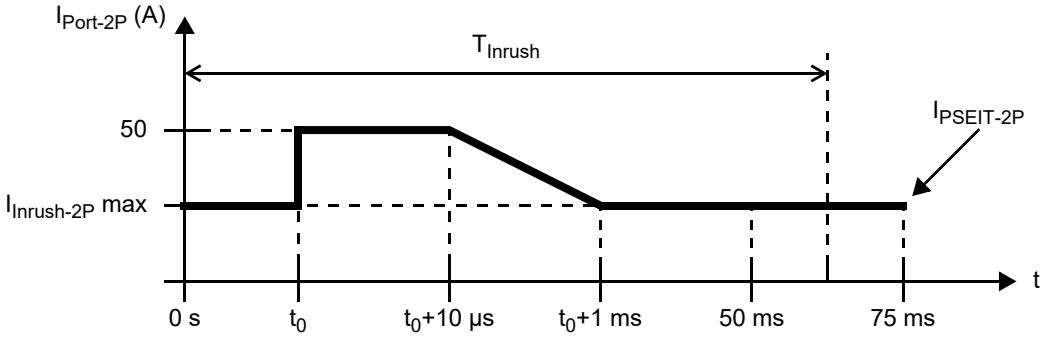

Figure 145–22—Per pairset PSE inrush maximum current

The minimum I_{Inrush} and $I_{Inrush\text{-}2P}$ current capability as defined in Table 145–16 applies when V_{PSE} exceeds 30 V. During a power up state, the PSE shall support the following:

— When powering a single-signature PD, a minimum I_{Inrush} of 5 mA when V_{PSE} is between 0 V and 10 V, and 60 mA when V_{PSE} is between 10 V and 30 V.

— When powering a dual-signature PD, a minimum $I_{Inrush\text{-}2P}$ of 5 mA when V_{PSE} is between 0 V and 10 V, and 60 mA when V_{PSE} is between 10 V and 30 V.

145.2.10.8 Overload current

If the current on either pair of a pairset exceeds $I_{CUT\text{-}2P}$ for longer than T_{CUT}, the PSE may remove power from that pairset. The cumulative duration of T_{CUT} is measured using a sliding window of at least 1 second width.

145.2.10.9 Short circuit current

The PSE shall limit the pairset current to $I_{LIM\text{-}2P}$ for a duration of at least T_{LIM} min, when V_{PSE} is in the range of $V_{Port_PSE\text{-}2P}$. The cumulative duration of the current limit event may be measured with a sliding window of at most 1 second width.

The maximum value of $I_{LIM\text{-}2P}$ is the PSE upperbound template described by Equation (145–17), Equation (145–18), Figure 145–23, and Figure 145–24. The $I_{LIM\text{-}2P}$ minimum value in Table 145–16 for Class 5 and above includes the effective system end-to-end resistance unbalance effect.

The PSE shall remove power from a pairset before a current limit event persists on that pairset continuously for T_{LIM} max as defined in Table 145–16.

A PSE in a power on state may remove power from a pairset without regard to T_{LIM} when the voltage on that pairset no longer meets the $V_{Port_PSE\text{-}2P}$ specification for longer than 250 μs or the voltage no longer meets the $V_{Tran\text{-}2P}$ specification.

If $I_{Port\text{-}2P}$ exceeds the PSE lowerbound template, the PSE output voltage may drop below $V_{Port_PSE\text{-}2P}$ min.

A PSE may remove power from the PI if the current on any pair exceeds the “PSE lowerbound template” in Figure 145–23 or Figure 145–24. Power shall be removed from a pairset of a PSE before the pairset current exceeds the “PSE upperbound template” in Figure 145–23 or Figure 145–24. When connected to a single-signature PD, the PSE should remove power from both pairsets before the current exceeds the “PSE upperbound template” on either pairset.

The right side vertical axis in Figure 145–23 and Figure 145–24 indicates the total current over both pairsets when the PSE supplies 4-pair power to a single-signature PD.

— For Type 3 PSEs, Figure 145–23, Equation (145–17) and Equation (145–19) apply.
— For Type 4 PSEs, Figure 145–24, Equation (145–18) and Equation (145–20) apply.

The PSE upperbound templates, $I_{PSEUT\text{-}Type3\text{-}2P}$ and $I_{PSEUT\text{-}Type4\text{-}2P}$, are defined by the following segments:

$$I_{PSEUT\text{-}Type3\text{-}2P}(t) = \left\{ \begin{array}{ll} 50 & \text{for } (0 \le t < 10\times10^{-6}) \\ \sqrt{\frac{K}{t}} & \text{for } (10\times10^{-6} \le t < 8.2\times10^{-3}) \\ 1.75 & \text{for } (8.2\times10^{-3} \le t < T_{CUT}\text{max}) \\ 0.85 & \text{for } (T_{CUT}\text{max} \le t) \end{array} \right\}_A \quad (145\text{–}17)$$

$$I_{PSEUT\text{-}Type4\text{-}2P}(t) = \left\{ \begin{array}{ll} 50 & \text{for } (0 \le t < 10\times10^{-6}) \\ \sqrt{\frac{K}{t}} & \text{for } (10\times10^{-6} \le t < 8.2\times10^{-3}) \\ 1.75 & \text{for } (8.2\times10^{-3} \le t < T_{CUT}\text{max}) \\ 1.3 & \text{for } (T_{CUT}\text{max} \le t < 4) \\ I_{LPS\text{-}2P} & \text{for } (4 \le t) \end{array} \right\}_A \quad (145\text{–}18)$$

where

t	is the duration in seconds that the PSE sources $I_{Port\text{-}2P}$
K	is 0.025 A^2s, an energy limitation constant for the pairset current when it is not in steady state normal operation
T_{CUT} max	is T_{CUT} max per pairset, as defined in Table 145–16
$I_{LPS\text{-}2P}$	is the current defined in 145.2.10.13

The PSE lowerbound templates, $I_{PSELT\text{-}Type3\text{-}2P}$ and $I_{PSELT\text{-}Type4\text{-}2P}$, are defined by the following segments:

$$I_{PSELT\text{-}Type3\text{-}2P}(t) = \left\{ \begin{array}{ll} I_{LIM\text{-}2P}\text{min} & \text{for } (0 \le t < T_{LIM}\text{min}) \\ I_{Peak\text{-}2P} & \text{for } (T_{LIM}\text{min} \le t < T_{CUT}\text{min}) \\ I_{Con\text{-}2P} & \text{for } (T_{CUT}\text{min} \le t) \end{array} \right\}_A \quad (145\text{–}19)$$

$$I_{PSELT\text{-}Type4\text{-}2P}(t) = \left\{ \begin{array}{ll} I_{LIM\text{-}2P}\text{min} & \text{for } (0 \le t < T_{LIM}\text{min}) \\ I_{Peak\text{-}2P} & \text{for } (T_{LIM}\text{min} \le t < T_{CUT}\text{min}) \\ I_{Con\text{-}2P} & \text{for } (T_{CUT}\text{min} \le t) \end{array} \right\}_A \quad (145\text{–}20)$$

where

t	is the duration that the PI sources $I_{Port\text{-}2P}$
$I_{LIM\text{-}2P}$ min	is the $I_{LIM\text{-}2P}$ min value per pairset for the PSE as defined in Table 145–16
T_{LIM} min	is T_{LIM} min per pairset as defined in Table 145–16
T_{CUT} min	is T_{CUT} min per pairset, as defined in Table 145–16
$I_{Peak\text{-}2P}$	is the minimum peak current supported on each powered pair, as defined in Equation (145–12)
$I_{Con\text{-}2P}$	is the minimum supported continuous current on each powered pair as defined in 145.2.10.6

145.2.10.10 Turn off time

The specification for T_{Off} in Table 145–16 shall apply to the discharge time from $V_{Port_PSE\text{-}2P}$ min to V_{Off} of a pairset with a test resistor of 320 kΩ attached to that pairset. In addition, it is recommended that the pairset be discharged when operating voltage is not applied. T_{Off} ends when $V_{PSE} \leq V_{Off}$.

145.2.10.11 Turn off voltage

The voltage at the PI shall be equal or less than V_{Off}, as defined in Table 145–16, when the PSE is in DISABLED, IDLE, BACKOFF, or ERROR_DELAY. The voltage at the corresponding pairset shall be equal or less than V_{Off}, as defined in Table 145–16, when the PSE is in IDLE_PRI, WAIT_PRI, ERROR_DELAY_PRI, IDLE_SEC, WAIT_SEC, or ERROR_DELAY_SEC.

145.2.10.12 Intra-pair current unbalance

The PSE shall support an intra-pair current unbalance of I_{unb}, as defined in Equation (145–21). The intra-pair current unbalance is the current unbalance between the two conductors of a power pair over the current load range.

$$I_{unb} = \{3\% \times I_{Peak\text{-}2P\text{-}unb_max}\}_A \quad (145\text{–}21)$$

A 100BASE-TX transmitter in a Type 3 or Type 4 Endpoint PSE shall meet the requirements of 25.4.5 in the presence of (I_{unb} / 2).

145.2.10.13 Type power

P_{Type} min is the minimum power a PSE is capable of sourcing.

Type 4 PSEs shall not source more power than P_{Type} max, as defined in Table 145–16, measured using a sliding window with a width up to 4 seconds. $I_{LPS\text{-}2P}$ is defined in Equation (145–22) and is the maximum current per pairset that results in less than P_{Type} max being sourced by the PSE.

$$I_{LPS\text{-}2P} = \left\{ \begin{array}{ll} 0.85 & \text{when in 2-pair mode} \\ \min\left(\frac{P_{Type}\text{max}}{V_{PSE}} - I_{Port\text{-}2P\text{-}other},\ 1.3 \right) & \text{when in 4-pair mode} \end{array} \right\}_A \quad (145\text{–}22)$$

where

P_{Type} max is the maximum power allowed for a given Type as defined in Table 145–16
V_{PSE} is the voltage across the pairset at the PSE PI as defined in 145.1.3
$I_{Port\text{-}2P\text{-}other}$ is the output current on the other pairset (see 145.2.10.6)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

145.2.10.14 Power turn on time

The specification for T_{pon} in Table 145–16 applies to the PSE power up time for a PD after completion of detection.

PSEs, when connected to a single-signature PD, shall reach POWER_ON within T_{pon} after completing detection on the last pairset. When connected to a dual-signature PD, PSEs shall reach the respective power on state for a pairset within T_{pon} after completing detection on the same pairset.

145.2.10.15 Error delay timing

T_{ed}, defined in Table 145–16, is the minimum delay time before a PSE may attempt subsequent powering of a pairset after power removal from that pairset because of an error condition.

145.2.10.16 PSE stability

When connected together as a system, the PSE and PD might exhibit instability at the PSE side or the PD side or both due to the presence of negative impedance at the PD input. See Annex 33A for PSE design guidelines for stable operation.

145.2.11 Power supply allocation

A PSE does not initiate power provision to one or both pairsets if the PSE has less than Class 3 power available and the connected PD requests more than the available power.

The PSE may manage the allocation of power based on additional information beyond the classification of the attached PD. Allocating power based on additional information about the attached PD, and the mechanism for obtaining that additional information, is beyond the scope of this standard with the exception that the allocation of power shall not be based solely on the historical data of the power consumption of the attached PD.

See 145.5 for a description of Data Link Layer classification.

If the system implements a power allocation algorithm, no additional behavioral requirement is placed on the system as it approaches or reaches its maximum power subscription. Specifically, the interaction between one PSE PI and another PSE PI in the same system is beyond the scope of this standard.

145.2.12 PSE Maintain Power Signature (MPS) requirements

A PSE removes power when a connected PD no longer draws a minimum amount of current. This is referred to as the "Maintain Power Signature." The PSE state diagrams in Figure 145–17 and Figure 145–18 monitor for the absence of MPS.

A PSE, depending on the PD assigned Class and PD signature configuration, shall use the applicable I_{Hold}, $I_{Hold\text{-}2P}$, T_{MPS} and T_{MPDO} values as defined in Table 145–16. The specification for T_{MPS} in Table 145–16 applies only to the DC MPS component.

A PSE powering a PD over a single pairset

- Shall consider the DC MPS component to be present if $I_{Port\text{-}2P}$ is greater than or equal to $I_{Hold\text{-}2P}$ max continuously for a minimum of T_{MPS}.
- Shall consider the DC MPS component to be absent if $I_{Port\text{-}2P}$ is less than or equal to $I_{Hold\text{-}2P}$ min.
- May consider the DC MPS component to be either present or absent if $I_{Port\text{-}2P}$ is in the range of $I_{Hold\text{-}2P}$.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Shall remove power from the PI when DC MPS has been absent for a duration greater than T_{MPDO}.
— Shall not remove power from the PI when DC MPS has been present within the $T_{MPS} + T_{MPDO}$ window. This allows a PD to minimize its power consumption.

A PSE powering a single-signature PD over both pairsets

— Shall consider the DC MPS component to be present if $I_{Port-2P}$ of the pairset with the highest current is greater than or equal to $I_{Hold-2P}$ max and I_{Port} is greater than or equal to I_{Hold} max continuously for a minimum of T_{MPS}.
— Shall consider the DC MPS component to be absent if $I_{Port-2P}$ of the pairset with the highest current is less than or equal to $I_{Hold-2P}$ min and I_{Port} is less than or equal to I_{Hold} min.
— May consider the DC MPS component to be either present or absent if $I_{Port-2P}$ of the pairset with the highest current is within the range of $I_{Hold-2P}$ or I_{Port} is within the range of I_{Hold}.
— Shall remove power from the PI when DC MPS has been absent for a duration greater than T_{MPDO}.
— Shall not remove power from the PI when DC MPS has been present within the $T_{MPS} + T_{MPDO}$ window. This allows a PD to minimize its power consumption.

NOTE—The DC MPS requirements for PSEs connected to a single-signature PD are such that the PSE may measure either the total current over both pairsets (I_{Hold}), the current on the pairset with the highest current ($I_{Hold-2P}$), or both.

A PSE powering a dual-signature PD over both pairsets

— Shall consider the DC MPS component to be present or absent on each pairset independently.
— Shall consider the DC MPS component to be present on a pairset if $I_{Port-2P}$ is greater than or equal to $I_{Hold-2P}$ max continuously for a minimum of T_{MPS}.
— Shall consider the DC MPS component to be absent on a pairset if $I_{Port-2P}$ is less than or equal to $I_{Hold-2P}$ min.
— May consider the DC MPS component on a pairset to be either present or absent if $I_{Port-2P}$ is within the range of $I_{Hold-2P}$.
— Shall remove power from a pairset when DC MPS has been absent on that pairset for a duration greater than T_{MPDO}.
— Shall not remove power from a pairset when DC MPS has been present on both pairsets within the $T_{MPS} + T_{MPDO}$ window.
— May maintain power on a pairset when DC MPS has been present on that pairset within the $T_{MPS} + T_{MPDO}$ window. This allows a PD to minimize its power consumption.

145.3 Powered devices (PDs)

A PD is the portion of a device that is either drawing power or requesting power by participating in the PD detection algorithm. A device that is capable of becoming a PD may have the ability to draw power from an alternate power source. A PD requiring power from the PI may simultaneously draw power from an alternate power source. PD capable devices that are neither drawing nor requesting power are also covered in this subclause.

A PD is specified at the point of the physical connection to the cabling. Characteristics such as the losses due to voltage correction circuits, power supply inefficiencies, separation of internal circuits from external ground or other characteristics induced by circuits after the PI connector are not specified. Limits defined for the PD are specified at the PI, not at any point internal to the PD, unless specifically stated.

Additional electrical specifications that apply to the PD are specified in 145.4.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

145.3.1 PD Type descriptions

PDs can be categorized as either Type 1, Type 2, Type 3, or Type 4. See 33.3 for the specification of Type 1 and Type 2 PDs. PDs can be implemented as either a single-signature configuration or a dual-signature configuration as defined in 1.4 and 145.3.5 and shown in Table 145–19. Table 145–19 shows the supported parameters of PDs.

Table 145–19—PD supported parameters

PD Type	Signature configuration	PD Class	Physical Layer classification	Data Link Layer classification	Optional Capabilities
Type 3	Single	1 to 3	Multiple-Event	Optional	Autoclass
		4 to 6	Multiple-Event	Mandatory	Autoclass
	Dual	1 to 3	Multiple-Event	Optional	—
		4	Multiple-Event	Mandatory	—
Type 4	Single	7 to 8	Multiple-Event	Mandatory	Autoclass
	Dual	5	Multiple-Event	Mandatory	—

NOTE 1—See Table 145–26 and Table 145–27 for the allowed PD power for each Type and Class.
NOTE 2—Data Link Layer classification for dual-signature PDs is optional only if the PD requested Class on both Modes is less than or equal to 3.
NOTE 3—Type 4 dual-signature PDs request Class 5 on at least one pairset

145.3.2 PD PI

The PD's PI consists of 8 conductors. The two conductors associated with a pair are at the same nominal voltage. A pairset consists of two pairs, as defined in 145.2.4. The two pairsets are named Mode A and Mode B, which correspond with Alternative A and Alternative B. Figure 145–12 in conjunction with Table 145–20 illustrate the two power modes.

PDs shall be capable of accepting power in any valid 2-pair configuration and any valid 4-pair configuration as defined in Table 145–20.

A PD shall meet the requirements of detection (145.3.4), PD signature configuration (145.3.5), and PD classification (145.3.6) in any valid 2-pair configuration, as defined in Table 145–20.

NOTE—This includes configurations with two pairs connected to the same positive potential and one pair connected to the negative potential.

A single-signature PD shall meet all specifications related to current by meeting the specified total current, where total current is the combined current of the two pairs at the same polarity, unless otherwise noted (see 145.3.8.9). A dual-signature PD shall meet all specifications related to current by meeting the specified current on the negative pair of a given Mode, unless otherwise noted (see 145.3.8.9).

The PD shall be insensitive to the polarity of the voltage applied on each Mode regardless of the polarity of the voltage applied on the other Mode. Single-signature PDs that request Class 4 or less shall be able to operate if power is supplied with any valid configuration defined in Table 145–20. All other PDs may require being supplied with a valid 4-pair configuration to operate at their nominal power level.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—PDs that support only Mode A or Mode B are specifically not allowed by this standard. PDs that are sensitive to polarity are specifically not allowed by this standard.

PDs interoperate with Type 1, Type 2, Type 3, and Type 4 PSEs, subject to power limitations. See 145.3.6.

The PD shall not source power on its PI.

The PD shall withstand any voltage from 0 V to 57 V applied to the PD PI per any of the valid configurations defined in Table 145–20 indefinitely without permanent damage.

Table 145–20—PD input power configurations

Pairsets	**Mode A**		**Mode B**	
Pairs	**Pair 1**	**Pair 2**	**Pair 3**	**Pair 4**
Conductor	**1 and 2**	**3 and 6**	**4 and 5**	**7 and 8**
	Valid 2-pair configurations			
	P	N	—	—
	N	P	—	—
	—	—	P	N
	—	—	N	P
	P	N	P	—
	P	N	—	P
	N	P	P	—
	N	P	—	P
	P	—	P	N
	—	P	P	N
	P	—	N	P
	—	P	N	P
	Valid 4-pair configurations			
	N	P	N	P
	N	P	P	N
	P	N	N	P
	P	N	P	N

N denotes a pair connected to negative potential
P denotes a pair connected to positive potential
— denotes a pair not connected to a supply rail
PSEs are required to switch the negative pairs, and may switch the positive pairs as defined in 145.4.1.1.1. This may lead to both positive pairs providing current in 2-pair mode.

145.3.3 PD state diagrams

The PD state diagrams specify the externally observable behavior of a PD.

145.3.3.1 Conventions

The notation used in the state diagram follows the conventions of state diagrams as described in 145.2.5.2.

145.3.3.2 Mode designation

Dual-signature PDs are implemented on Mode A and Mode B as defined in 145.3.2. Mode information is obtained by replacing the X in the desired variable or function with the letter of the Mode of interest. Modes are referred to in general as follows:

X
: Generic Mode designator. When X is used in a state diagram, its value is local to that state diagram and not global to the set of state diagrams.
Values:
A: Mode A
B: Mode B

145.3.3.3 Single-signature PD state diagrams

Single-signature PDs shall provide the behavior of the state diagram shown in Figure 145–25 and Figure 145–26.

145.3.3.3.1 Constants

$I_{Inrush_PD_max}$
: The maximum PD inrush current I_{Inrush_PD} max (see Table 145–29)

$V_{Off_PD_min}$
: The minimum PD off voltage V_{Off_PD} min (see Table 145–29)

$V_{Reset_PD_max}$
: The maximum PD reset voltage V_{Reset_PD} max (see Table 145–25)

145.3.3.3.2 Variables

I_{Port}
: is the total PD input current as defined in 145.1.3.

mdi_power_required
: A variable indicating the PD is enabled and should request power from the PSE by applying a PD detection signature to the PI, and when the PSE sources power to apply the MPS to keep the PSE sourcing power. This variable may be set by the PD at any time.
Values:
FALSE: PD functionality is disabled.
TRUE: PD functionality is enabled.

nopower
: A variable that indicates the PD has been in POWEROFF, which indicates V_{PD} was below V_{Off_PD} while being powered, since the last time V_{PD} was below V_{Reset} for at least T_{Reset}.
Values:
FALSE: The PD has not been in POWEROFF.
TRUE: The PD has been in POWEROFF.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_acs_cancel

This variable indicates that the PD is aborting the Autoclass procedure. See 145.3.6.2.

Values:

FALSE: The PD does not abort the Physical Layer Autoclass procedure.

TRUE: The PD aborts the Physical Layer Autoclass procedure.

pd_acs_full_power

This variable indicates whether the PD is required to draw maximum power, $P_{Autoclass_PD}$. See 145.3.6.2.

Values:

FALSE: The PD is not required to draw maximum power.

TRUE: The PD is required to draw maximum power for Autoclass measurement.

pd_acs_req

This variable indicates if a PD draws $P_{Autoclass_PD}$ in the Autoclass time window after reaching POWERED. See 145.3.6.2.

Values:

FALSE: The PD does not request Autoclass.

TRUE: The PD requests Autoclass.

pd_autoclass_enable

A variable indicating that the PD is enabled to perform Autoclass by changing its class signature to class signature 0 during the first class event (see 145.3.6.2).

Values:

FALSE: Autoclass is disabled.

TRUE: Autoclass is enabled.

pd_dll_capable

This variable indicates whether the PD implements Data Link Layer classification.

Values:

FALSE: The PD does not implement Data Link Layer classification.

TRUE: The PD does implement Data Link Layer classification.

pd_dll_enable

A variable indicating whether the Data Link Layer classification mechanism is enabled.

Values:

FALSE: Data Link Layer classification is not enabled.

TRUE: Data Link Layer classification is enabled.

pd_inrush_lim

A variable indicating that the PD limits the inrush current below I_{Inrush_PD} and $I_{Inrush_PD\text{-}2P}$ for the duration of the PD inrush time as defined in 145.3.8.3. This variable is set per this description.

Values:

FALSE: The PD does not limit the inrush current.

TRUE: The PD does limit the inrush current.

pd_max_power

A variable indicating the maximum power that the PD may draw from the PSE. See power classifications in Table 145–29.

Values:

inrush: There is no maximum power limit on the PD

0: The PD may draw up to 44 mA of current

1: PD may draw Class 1 power

2: PD may draw Class 2 power

3: PD may draw Class 3 power

4: PD may draw Class 4 power

5: PD may draw Class 5 power

6: PD may draw Class 6 power

7: PD may draw Class 7 power

8: PD may draw Class 8 power

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_overload

A variable that indicates if the PD is drawing peak power in excess of P_{Class_PD}, as defined in 145.3.8.4, or when the PD is exposed to a transient condition as defined in 145.3.8.6.

Values:

FALSE: The PD is not drawing peak power or is exposed to a transient condition.
TRUE: The PD is drawing peak power and is not exposed to a transient condition.

pd_power_update

A variable that is set when the PDMaxPowerValue in the DLL state diagram in Figure 145–44 has been updated.

Values:

FALSE: The value of PDMaxPowerValue has not changed.
TRUE: The value of PDMaxPowerValue has changed.

pd_req_class

A variable indicating the PD requested Class.

Values:

1: The PD requests Class 1.
2: The PD requests Class 2.
3: The PD requests Class 3.
4: The PD requests Class 4.
5: The PD requests Class 5.
6: The PD requests Class 6.
7: The PD requests Class 7.
8: The PD requests Class 8.

pd_reset

An implementation-specific variable that unconditionally resets the PD state diagram to OFFLINE. This variable may be set by the PD at any time.

Values:

FALSE: The device has not been reset.
TRUE: The device has been reset.

PDAutoclassRequest

A variable output by the PD power control state diagram indicating whether the PD requests Autoclass via the Data Link Layer. See 145.5.

Values:

FALSE: The PD does not request an Autoclass measurement to be performed.
TRUE: The PD requests an Autoclass measurement to be performed.

present_class_sig_0

Controls presenting the class signature '0' during T_{ACS} of the first class event (see 145.3.6.2).

Values:

FALSE: Class signature 0 is not to be applied to the PI.
TRUE: Class signature 0 is to be applied to the PI.

present_class_sig_A

Controls presenting the class signature that is used during first two class events (see 145.3.6) by the PD.

Values:

FALSE: The class signature corresponding with class_sig_A is not to be applied to the PI.
TRUE: The class signature corresponding with class_sig_A is to be applied to the PI.

present_class_sig_B

Controls presenting the class signature that is used during the third class event and all subsequent class events (see 145.3.6) by the PD.

Values:

FALSE: The class signature corresponding with class_sig_B is not to be applied to the PI.
TRUE: The class signature corresponding with class_sig_B is to be applied to the PI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

present_det_sig

Controls presenting the detection signature (see 145.3.4) by the PD.

Values:

invalid: A non-valid PD detection signature is to be applied to both pairsets.

valid: A valid PD detection signature is to be applied to both pairsets.

either: Either a valid or non-valid PD detection signature may be applied to each pairset.

present_mark_sig

Controls presenting the mark event current and impedance (see 145.3.6.1.1) by the PD.

Values:

FALSE: The PD does not present mark event behavior.

TRUE: The PD does present mark event behavior.

present_mps

Controls applying the Maintain Power Signature MPS (see 145.3.9) to the PI.

Values:

FALSE: The MPS is not to be applied to the PI.

TRUE: The MPS is to be applied to the PI.

pse_assigned_class

A variable that indicates the assigned Class. This variable is initially set by Physical Layer classification and may be updated through DLL classification.

Values:

1: Class 1
2: Class 2
3: Class 3
4: Class 4
5: Class 5
6: Class 6
7: Class 7
8: Class 8

pse_power_level

A variable that indicates to the PD the level of power the PSE is supplying.

Values:

3: The PSE has allocated the PD requested Class or Class 3 power, whichever is less.
4: The PSE has allocated Class 4 power.
6: The PSE has allocated the PD requested Class or Class 6 power, whichever is less.
8: The PSE has allocated the PD requested Class or Class 8 power, whichever is less.

V_{Mark_th}

Mark event voltage threshold (see Table 145–25)

V_{Off_PD}

PD power supply turn off voltage (see Table 145–29)

V_{On_PD}

PD power supply turn on voltage (see Table 145–29)

V_{PD}

Voltage at the PD PI as defined in 145.1.3.

V_{Reset_th}

Reset voltage threshold (see Table 145–25)

145.3.3.3.3 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where “stop x_timer” is asserted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tacspd_timer
: A timer used to change the classification current to class signature ‘0’ when a PD uses Autoclass; see T_{ACS} in Table 145–28.

tauto_pd1_timer
: A timer indicating maximum delay until start of Autoclass power draw. Applies to Autoclass requests by Physical Layer classification; see T_{AUTO_PD1} in 145.3.6.2.

tauto_pd2_timer
: A timer indicating minimum delay until end of Autoclass power draw. Applies to Autoclass requests by Physical Layer classification; see T_{AUTO_PD2} in 145.3.6.2.

tinrushpdmax_timer
: A timer used to determine when the PD exits INRUSH; see T_{Inrush_PD} max in Table 145–29.

tpowerdly_timer
: A timer used to limit the PD’s current and power draw from T_{Inrush_PD} to T_{delay}; see T_{delay} in Table 145–29.

145.3.3.3.4 Functions

do_class_timing
: This function is used to evaluate the Type of PSE connected to the PI by measuring the length of the first class event. PDs that do not measure the length of the first class event return FALSE. The class event timing requirements are defined in Table 145–25. This function returns the following variable:

  long_class_event: A variable that indicates to the PD the Type of PSE to which it is connected. This variable is used to indicate which MPS timing requirements (see 145.3.9) the PD should use. See 145.3.7.
  Values:
  - FALSE: The PSE is identified as a Type 1 or Type 2 PSE, or the PD has not measured the length of the first class event.
  - TRUE: The PSE is identified as a Type 3 or Type 4 PSE.

do_initialize
: This function returns the following variables (see 145.3.3.3.2):

  pd_autoclass_enable
  pd_req_class
  pd_dll_capable

do_update_pse_assigned_class
: A function that updates the pse_assigned_class based on the value of PDMaxPowerValue as defined in Table 145–23. This function returns the following variable:

  pse_assigned_class: See pse_assigned_class defined in 145.3.3.3.2.

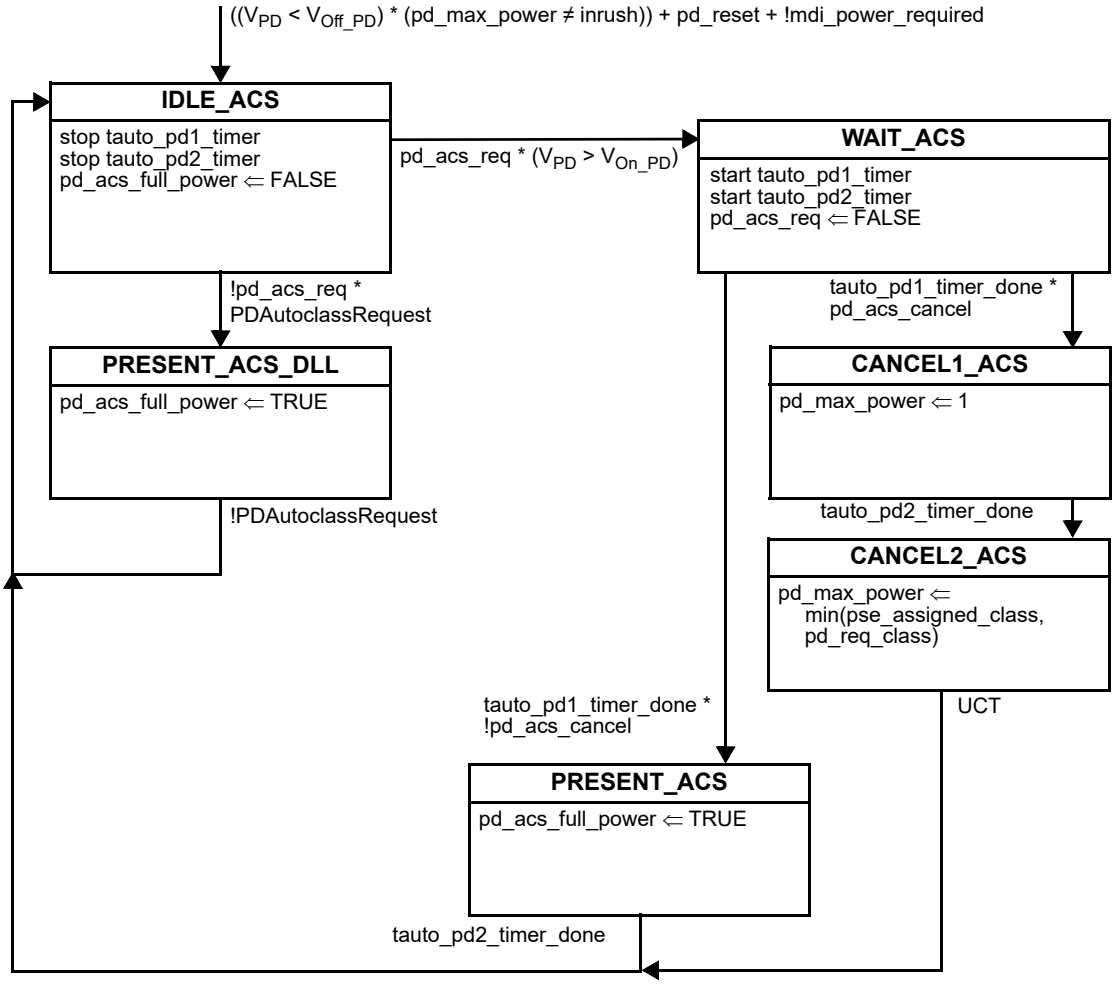

Figure 145–26—Single-signature PD Autoclass state diagram

NOTE 1—DO_CLASS_EVENT6 creates a defined behavior for a Type 3 or Type 4 PD that is brought into the classification range more than 5 times.

NOTE 2—In general, there is no requirement for a PD to respond with a valid class signature for any DO_CLASS_EVENT duration less than T_{Class_PD} as defined in Table 145–25.

145.3.3.4 Dual-signature PD state diagram

Dual-signature PDs shall provide the behavior of the state diagram shown in Figure 145–27 over each pairset independently unless otherwise specified. All the parameters that apply to Mode A and Mode B are denoted with the suffix "_mode(X)" where "X" can be "A" or "B". A parameter that ends with the suffix "_mode(X)" may have different values for Mode A and Mode B in the independent state diagrams.

145.3.3.4.1 Constants

$I_{Inrush_PD_2P_max}$
: The maximum inrush current per pairset $I_{Inrush_PD\text{-}2P}$ max (see Table 145–29)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$V_{Off_PD_min}$
: The minimum PD off voltage V_{Off_PD} min (see Table 145–29)

$V_{Reset_PD_max}$
: The maximum PD reset voltage V_{Reset_PD} max (see Table 145–25)

145.3.3.4.2 Variables

$I_{Port_2P_}$mode(X)
: Is the current on the negative pair ($I_{Port\text{-}2P}$) of the Mode X pairset; see 145.1.3.

mdi_power_required
: A variable indicating that the PD is enabled and should request power from the PSE by applying a PD detection signature, and when the PSE sources power to apply the MPS to keep the PSE sourcing power. This variable may be set by the PD at any time.
Values:
FALSE: PD functionality is disabled.
TRUE: PD functionality is enabled.

nopower_mode(X)
: A variable that indicates the PD has been in POWEROFF on Mode X, which indicates V_{PD} was below V_{Off_PD} while being powered, since the last time V_{PD} was below V_{Reset} for at least T_{Reset}.
Values:
FALSE: The PD has not been in POWEROFF.
TRUE: The PD has been in POWEROFF.

pd_dll_capable
: This variable indicates whether the PD implements Data Link Layer classification.
Values:
FALSE: The PD does not implement Data Link Layer classification.
TRUE: The PD does implement Data Link Layer classification.

pd_dll_enable
: A variable indicating whether the Data Link Layer classification mechanism is enabled.
Values:
FALSE: Data Link Layer classification is not enabled.
TRUE: Data Link Layer classification is enabled.

pd_inrush_lim_mode(X)
: A variable indicating that the PD limits the inrush current on Mode X below $I_{Inrush_PD\text{-}2P}$ for the duration of the PD inrush time as defined in 145.3.8.3. This variable is set per this description.
Values:
FALSE: The PD does not limit the inrush current on Mode X.
TRUE: The PD does limit the inrush current on Mode X.

pd_max_power_mode(X)
: A variable indicating the maximum power that the PD may draw from the PSE on Mode X. See power classifications in Table 145–29.
Values:
inrush: There is no maximum power limit
0: The PD may draw up to 44 mA of current
1: The PD may draw Class 1 power
2: The PD may draw Class 2 power
3: The PD may draw Class 3 power
4: The PD may draw Class 4 power
5: The PD may draw Class 5 power

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_overload_mode(X)

A variable that indicates if the PD is drawing peak power in excess of P_{Class_PD}, as defined in 145.3.8.4, or when the PD is exposed to a transient condition as defined in 145.3.8.6, on Mode X.

Values:

FALSE: The PD is not drawing peak power or is exposed to a transient condition.

TRUE: The PD is drawing peak power and is not exposed to a transient condition.

pd_power_update_mode(X)

A variable that is set when the PDMaxPowerValue_mode(X) in the DLL state diagram in Figure 145–46 or Figure 145–47 has been updated.

Values:

FALSE: The value of PDMaxPowerValue_mode(X) has not changed.

TRUE: The value of PDMaxPowerValue_mode(X) has changed.

pd_req_class_mode(X)

A constant indicating the PD requested Class on Mode X

Values:

1: The PD requests Class 1.

2: The PD requests Class 2.

3: The PD requests Class 3.

4: The PD requests Class 4.

5: The PD requests Class 5.

pd_reset_mode(X)

An implementation-specific variable that unconditionally resets the PD state diagram on Mode X to OFFLINE. This variable may be set by the PD at any time.

Values:

FALSE: The device has not been reset.

TRUE: The device has been reset.

present_class_sig_A_mode(X)

Controls presenting the class signature that is used during first two class events (see 145.3.6) by the PD on Mode X.

Values:

FALSE: The class signature corresponding with class_sig_A is not to be applied to the pairset.

TRUE: The class signature corresponding with class_sig_A is to be applied to the pairset.

present_class_sig_B_mode(X)

Controls presenting the class signature that is used during the third class event and all subsequent class events (see 145.3.6) by the PD on Mode X.

Values:

FALSE: The class signature corresponding with class_sig_B is not to be applied to the pairset.

TRUE: The class signature corresponding with class_sig_B is to be applied to the pairset.

present_det_sig_mode(X)

Controls presenting the detection signature (see 145.3.4) by the PD on Mode X.

Values:

invalid: A non-valid PD detection signature is to be applied to the pairset on Mode X.

valid: A valid PD detection signature is to be applied to the pairset on Mode X.

either: Either a valid or non-valid PD detection signature may be applied to the pairset.

present_mark_sig_mode(X)

Controls presenting the mark event current and impedance (see 145.3.6.1.1) by the PD on Mode X.

Values:

FALSE: The PD does not present mark event behavior.

TRUE: The PD does present mark event behavior.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

present_mps_mode(X)

Controls applying MPS (see 145.3.9) to the PD's PI on Mode X.

Values:

FALSE: The Maintain Power Signature (MPS) is not to be applied to the PD's PI.

TRUE: The MPS is to be applied to the PD's PI.

pse_assigned_class_mode(X)

A variable (generated by the PD) that indicates the PSE assigned Class on Mode X to the PD. This variable is initially set by Physical Layer classification and may be updated through DLL classification.

Values:

1: Class 1.

2: Class 2.

3: Class 3.

4: Class 4.

5: Class 5.

pse_power_level_mode(X)

A variable that indicates to the PD the level of power the PSE is supplying on Mode X.

Values:

3: The PSE has allocated the PD requested Class or Class 3 power, whichever is less.

4: The PSE has allocated Class 4 power.

5: The PSE has allocated Class 5 power.

V_{Mark_th}

Mark event voltage threshold (see Table 145–25)

V_{Off_PD}

PD power supply turn off voltage (see Table 145–29)

V_{On_PD}

PD power supply turn on voltage (see Table 145–29)

$V_{PD_}$mode(X)

V_{PD} of the Mode X pairset; see 145.1.3.

V_{Reset_th}

Reset voltage threshold (see Table 145–25)

145.3.3.4.3 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where "stop x_timer" is asserted.

tinrushpdmax_timer_mode(X)

A timer used to determine when the PD exits INRUSH on Mode X; see T_{Inrush_PD} max in Table 145–29.

tpowerdly_timer_mode(X)

A timer used to limit the PD's current and power draw on Mode X from T_{Inrush_PD} to T_{delay}; see T_{delay} in Table 145–29.

145.3.3.4.4 Functions

do_class_timing_mode(X)

This function is used by a PD to evaluate the Type of PSE connected to the pairset by measuring the length of the class event on Mode X. The class event timing requirements are defined in Table 145–25. This function returns the following variable:

long_class_event_mode(X): A variable that indicates to the PD the Type of PSE to which it is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

connected. This variable is used to indicate which MPS timing requirements (see 145.3.9) the PD should use. See 145.3.7.

Values:

FALSE: The PSE is identified as a Type 1 or Type 2 PSE.

TRUE: The PSE is identified as a Type 3 or Type 4 PSE.

do_initialize_mode(X)

This function returns the following variables (see 145.3.3.4.2):

pd_req_class_mode(X)

pd_dll_capable

do_update_pse_assigned_class_mode(X)

A function that updates the pse_assigned_class_mode(X) based on the value of PDMaxPowerValue_mode(X) as defined in Table 145–23. This function returns the following variable:

pse_assigned_class_mode(X): See pse_assigned_class_mode(X) defined in 145.3.3.4.2.

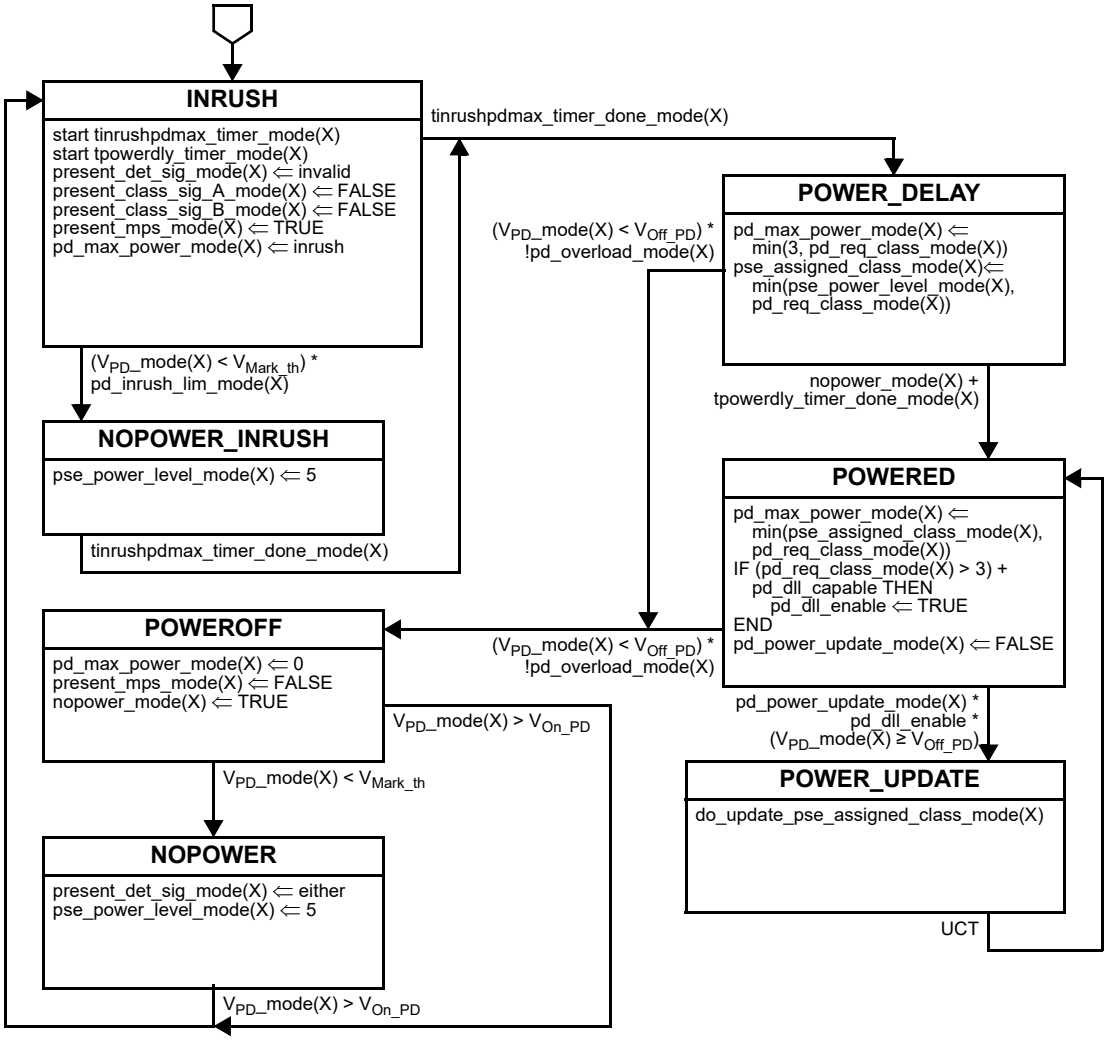

Figure 145–27—Dual-signature PD state diagram *(continued)*

145.3.4 PD valid and non-valid detection signatures

A PD presents a valid detection signature when it is in DO_DETECTION per Figure 145–25 or Figure 145–27. See 145.3.5.

A PD presents a non-valid detection signature on both pairsets while it is in a state where it does not accept power via the PI per Figure 145–25 or Figure 145–27.

A PD presents a non-valid detection signature when in a mark event state per Figure 145–25 or Figure 145–27.

When a PD presents a valid or non-valid detection signature, it shall present the detection signature at the PI between Positive V_{PD} and Negative V_{PD} of PD Mode A and PD Mode B as defined in 145.3.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

While a PD presents a valid detection signature on a given Mode, that detection signature shall be valid when presented under each of the following conditions (see Figure 145–28):

— With any resistance greater than 45 kΩ across the other Mode
— With any resistance greater than 45 kΩ across the other Mode and one pair of the other Mode connected to the positive potential of the given Mode

A single-signature PD that is powered over only one pairset shall present a non-valid detection signature on the unpowered pairset. A dual-signature PD that is powered over only one pairset shall present a valid detection signature on the unpowered pairset.

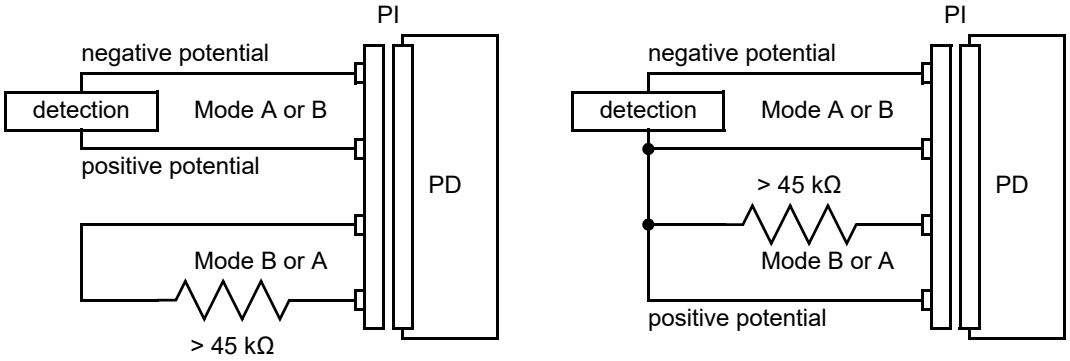

Figure 145–28—Detection signature requirements connection configurations

A PD may or may not present a valid detection signature when in IDLE.

The detection signature is a resistance calculated from two voltage/current measurements made during the detection process as defined in Equation (145–23).

$$R_{\text{detect}} = \left\{ \frac{(V_2 - V_1)}{(I_2 - I_1)} \right\}_{\Omega} \tag{145–23}$$

where

V_1 and V_2 are the first and second voltage measurements made at the PD PI, respectively
I_1 and I_2 are the first and second current measurements made at the PD PI, respectively
R_{detect} is the effective resistance

A valid PD detection signature shall have the characteristics of Table 145–21.

A non-valid detection signature shall have one or both of the characteristics in Table 145–22.

A PD that presents a detection signature outside of Table 145–21 is non-compliant, while a PD that presents the signature of Table 145–22 is assured to fail detection.

Table 145–21—Valid PD detection signature characteristics, measured at the PD PI

Parameter	Conditions	Min	Max	Unit	Additional information
R_{detect} (at any 1 V or greater chord within the voltage range conditions)	2.7 V to 10.1 V	23.7	26.3	kΩ	—
V_{offset}	—	0	1.9	V	See Figure 145–29
Voltage at the PI	$I_{Port-2P}$ = 124 μA	2.7	—	V	—
Input capacitance	2.7 V to 10.1 V	0.05	0.12	μF	—
Series input inductance	2.7 V to 10.1 V	—	100	μH	—

Table 145–22—Non-valid PD detection signature characteristics, measured at PD PI

Parameter	Conditions	Range of values	Unit
R_{detect}	V_{PD} < 10.1 V	Either greater than 45 or less than 12	kΩ
Input capacitance	V_{PD} < 10.1 V	Greater than 10	μF

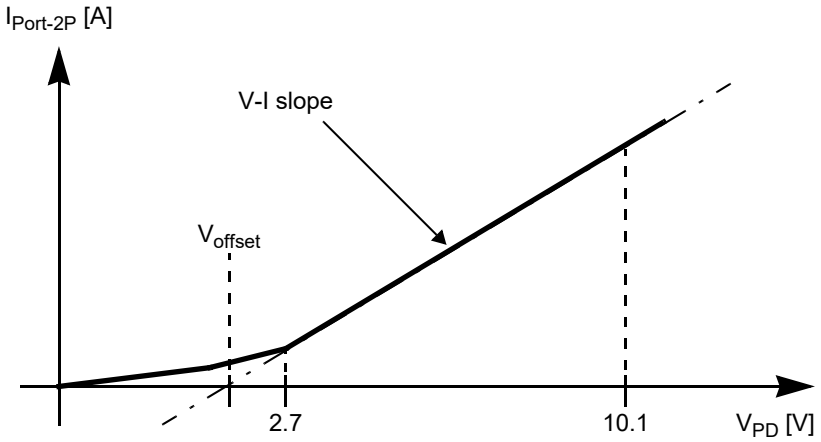

Figure 145–29—Valid PD detection signature offset

145.3.5 PD signature configurations

A single-signature PD shall present a valid detection signature, as defined in Table 145–21, on a given Mode when no voltage or current is applied across the other Mode, and shall not present a valid detection signature on the given Mode when any voltage in the range of 3.7 V to 57 V is applied across the other Mode or any current greater than 124 μA is drawn from the negative pair of the other Mode. These requirements apply to both Mode A and Mode B.

NOTE—A valid detection signature meets every requirement in Table 145–21 across all specified conditions. A failure under any allowed condition is considered “not a valid signature.”

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A dual-signature PD shall present a valid detection signature, as defined in Table 145–21, on a given Mode, regardless of any voltage between 0 V and 57 V applied to the other Mode. This requirement applies to both Mode A and Mode B.

These requirements allow the PD to be correctly identified by a PSE performing connection check as defined in 145.2.7.

145.3.6 PD classification

A PD may be classified by the PSE based on Physical Layer classification, Data Link Layer (DLL) classification, or a combination of both provided by the PD. The intent of PD classification is to provide information about the maximum power required by the PD during operation. Additionally, classification is used by the PSE and the PD to mutually identify the Type of the device to which they are connected.

See 145.2.8 for a general description of classification mechanisms. See 145.2.8.2 and 145.3.6.2 for a description of the optional Autoclass mechanism.

The requested Class of the PD is the Class the PD advertises during Physical Layer classification. It represents the amount of power the PD requires for operation. The PD shall draw no more power across any voltage in the range of $V_{Port_PD\text{-}2P}$ than defined for the requested Class in Table 145–26 and Table 145–27. Up to 3 class events may be required to discover the requested Class of the PD.

Depending on the number of class events produced by the PSE, the assigned Class is equal to or lower than the PD requested Class. The PD shall conform to the assigned Class, regardless of its requested Class. After a successful DLL classification, the assigned Class changes depending on the value of PDMaxPowerValue for single-signature PDs and PDMaxPowerValue_mode(X) for dual-signature PDs, as defined in Table 145–23.

Table 145–23—Relation of assigned Class and DLL

Single-signature		Dual-signature	
PDMaxPowerValue	**Assigned Class**	**PDMaxPowerValue_mode(X)**	**Assigned Class on Mode X**
1 to 39	1	1 to 39	1
40 to 65	2	40 to 65	2
66 to 130	3	66 to 130	3
131 to 255	4	131 to 255	4
256 to 400	5	256 to 499	5
401 to 510	6		
511 to 620	7		
621 to 999	8		

PDs shall provide Multiple-Event Physical Layer classification as defined in 145.3.6.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Single-signature PDs that request Class 1, 2, or 3 may provide Data Link Layer classification (see 145.5). Single-signature PDs that request Class 4 or higher and dual-signature PDs that request Class 4 or higher on at least one of its Modes shall provide DLL classification.

PD classification behavior shall conform to the state diagram in Figure 145–25 or Figure 145–27, and shall conform to the electrical specifications defined in Table 145–24 and Table 145–25.

A PD that is assigned to a Class lower than the Class it requested shall provide the user with an active indication if underpowered. The method of active indication is left to the implementer.

145.3.6.1 PD Multiple-Event class signature

The response of the PD to Multiple-Event Physical Layer classification consists of two class signatures, class_sig_A and class_sig_B as described by Table 145–26 or Table 145–27.

PDs shall present class_sig_A during DO_CLASS_EVENT1 and DO_CLASS_EVENT2 and class_sig_B during DO_CLASS_EVENT3, DO_CLASS_EVENT4, DO_CLASS_EVENT5, and DO_CLASS_-EVENT6, as shown in Figure 145–25 and Figure 145–27, with the corresponding classification signatures specified in Table 145–24. PDs implementing Autoclass shall present class signature 0, as defined in Table 145–24, during DO_CLASS_EVENT_AUTO as defined in 145.3.6.2.

After entering a DO_CLASS_EVENT state, the PD Physical Layer class signature shall be valid within T_{Class_PD} as defined in Table 145–25 and remain valid for the remainder of the class event.

V_{Reset_PD}, as defined in Table 145–25, is the voltage range in which the PD remains in IDLE.

Single-signature PDs shall advertise class signatures according to the PD Type and PD requested Class, as defined in Table 145–26. For single-signature PDs, the PD requested Class on either pairset is the maximum amount of power requested by the PD.

NOTE—Requested Class 0 is not defined for Type 3 PDs. A Type 1 PD that does not implement Physical Layer classification requests Class 0, with a power level equivalent to Class 3. Such PDs are assigned to Class 3 by Type 3 and Type 4 PSEs.

Dual-signature PDs shall advertise class signatures according to the PD Type and PD requested Class on each pairset, as defined in Table 145–27. For dual-signature PDs, the PD requested Class on a pairset is the maximum amount of power requested by the PD on that pairset. Dual-signature PDs may advertise different class signatures on each pairset. A dual-signature PD that is powered over only one pairset shall present a valid class signature on the unpowered pairset.

After a successful Multiple-Event Physical Layer classification has completed, a single-signature PD sets the pse_power_level variable to either 3, 4, 6 or 8. Based on the value of pse_power_level and the PD requested Class, pd_req_class, the assigned Class is derived in the variable pse_assigned_class.

After a successful Multiple-Event Physical Layer classification has completed, a dual-signature PD sets the pse_power_level_mode(X) variable to either 3, 4, or 5. Based on the value of pse_power_level_mode(X) and the PD requested Class, pd_req_class_mode(X), the assigned Class is derived in the variable pse_assigned_class_mode(X).

Table 145–24—Class signatures generated at the PD PI

Parameter	Conditions	Minimum	Maximum	Unit
Current for class signature 0	14.5 V to 20.5 V	1	4	mA
Current for class signature 1		9	12	
Current for class signature 2		17	20	
Current for class signature 3		26	30	
Current for class signature 4		36	44	

Table 145–25—Multiple-Event Physical Layer classification electrical requirements

Item	Parameter	Symbol	Units	Min	Max	Additional information
1	Class event voltage	V_{Class_PD}	V	14.5	20.5	—
2	Mark event voltage	V_{Mark_PD}	V	6.9	10.1	—
3	Mark event current	I_{Mark}	mA	0.25	4	See 145.3.6.1.1
4	Mark event threshold	V_{Mark_th}	V	10.1	14.5	See 145.3.6.1.1
5	Classification reset threshold	V_{Reset_th}	V	2.81	6.9	See 145.3.6.1.1
6	Classification reset voltage	V_{Reset_PD}	V	0	2.81	See 145.3.6.1
7	Long first class event timing	T_{LCE_PD}	ms	75.5	87.5	See 145.3.7
8	PD classification stability time	T_{Class_PD}	ms	—	5	See 145.3.6.1

Table 145–26—Physical Layer classifications and Multiple Event Responses for single-signature PDs

PD Type	Requested Class	class_sig_A class signature	class_sig_B class signature	Requested power (W)
3	1	1	1	3.84
	2	2	2	6.49
	3	3	3	13
	4	4	4	25.5
	5	4	0	40
	6	4	1	51
4	7	4	2	62
	8	4	3	71.3

NOTE 1—See Table 145–24 for definition of class signatures 0 to 4.
NOTE 2—PDs may be assigned to a lower Class than the PD requested Class, which results in a lower value of P_{Class_PD}.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 145–27—Physical Layer classifications and Multiple Event Responses for dual-signature PDs

PD Type	Requested Class per pairset	class_sig_A class signature	class_sig_B class signature	Requested power (W)
3	1	1	0	3.84
	2	2	0	6.49
	3	3	0	13
	4	4	0	25.5
4	5	4	3	35.6

NOTE 1—See Table 145–24 for definition of class signatures 0 to 4.
NOTE 2—PDs may be assigned to a lower Class than the PD requested Class, which results in a lower value of P_{Class_PD-2P}.

145.3.6.1.1 Mark Event behavior

When the PD is presenting a mark event signature in a DO_MARK_EVENT state, as shown in the state diagram of Figure 145–25 and Figure 145–27, the PD shall draw I_{Mark} as defined in Table 145–25 and present a non-valid detection signature as defined in Table 145–22.

The PD shall not exceed the I_{Mark} current limits when voltage at the PI enters the V_{Mark_PD} specification as defined in Table 145–25.

V_{Mark_th} is the PI voltage threshold at which the PD transitions into, and one of the voltage thresholds to transition out of, the DO_CLASS_EVENT states as shown in Figure 145–25 and Figure 145–27.

Implementations should employ appropriate methods (such as hysteresis in V_{Mark_th}) to avoid erroneous transitions between class and mark states when the PSE switches from a class voltage to a mark voltage or vice versa.

V_{Reset_th} is the PI voltage threshold at which the PD transitions from a DO_MARK_EVENT state to IDLE as shown in Figure 145–25 and Figure 145–27.

145.3.6.2 Autoclass (optional)

Single-signature PDs may choose to implement an extension of Physical Layer classification known as Autoclass. Autoclass is only defined for single-signature PDs. The purpose of Autoclass is to allow the PSE to determine the actual maximum power draw of the connected PD. See 145.2.8.2.

A PD that implements Autoclass shall change its current during the first class event to class signature 0 no earlier than T_{ACS} min and no later than T_{ACS} max, as defined in Table 145–28.

After power up, a PD that implements Autoclass shall draw its highest required power, $P_{Autoclass_PD}$, subject to the requirements on P_{Class_PD} in 145.3.8.2, throughout the period bounded by T_{AUTO_PD1} and T_{AUTO_PD2}, measured from when V_{PD} rises above V_{On_PD}. The PD is restricted to a maximum power draw of $P_{Autoclass_PD}$ until the PD successfully negotiates a higher power level through Data Link Layer classification as defined in 145.5. A PD that draws less than P_{Class_PD} max for Class 1 during the period bounded by T_{AUTO_PD1} and T_{AUTO_PD2} indicates to the PSE that the power allocation should be determined by the assigned Class. By doing this the PD can abort the Physical Layer Autoclass procedure.

Table 145–28—Autoclass PD timing requirements

Item	Parameter	Symbol	Units	Min	Max	Additional Information
1	Autoclass signature timing	T_{ACS}	ms	75.5	87.5	Measured from transition to DO_CLASS_EVENT1
2	Autoclass power draw start time	T_{AUTO_PD1}	ms	—	1350	Measured from when V_{PD} rises above V_{On_PD}
3	Autoclass power draw end time	T_{AUTO_PD2}	ms	3650	—	

145.3.7 PSE Type identification

PDs may determine the Type of the PSE they are connected to by measuring the duration of the first class event. Such a PD may set long_class_event to TRUE if the first class event is longer than T_{LCE_PD} min and shall set long_class_event to TRUE if the first class event is longer than T_{LCE_PD} max. If long_class_event is FALSE, this indicates the PSE is a Type 1 or Type 2 PSE. If long_class_event is TRUE this indicates the PSE is a Type 3 or Type 4 PSE. This determination allows the PD to make use of short MPS to reduce standby power.

145.3.8 PD power

The PD shall operate within the characteristics in Table 145–29.

The PD may be capable of drawing power from a local power source. When a local power source is provided, the PD may draw some, none, or all of its power from the PI.

Table 145–29—PD power supply limits

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Input DC voltage per pairset per the assigned Class					
	Class 1	V_{Port_PD-2P}	V	42.8	57	See 145.3.8.1, Table 145–1
	Class 2			42		
	Class 3			39.9		
	Class 4			42.5		
	Class 5, single-signature PD			44.3		
	Class 5, dual-signature PD			41.1		
	Class 6			42.5		
	Class 7			42.9		
	Class 8			41.1

145.3.8.1 Input voltage

The specification for $V_{Port_PD\text{-}2P}$ in Table 145–29 is for the input voltage range after startup (see 145.3.8.3), and accounts for loss in the cabling plant.

The PD shall turn on at a voltage in the range of V_{On_PD}. After the PD turns on, the PD shall stay on over the entire $V_{Port_PD\text{-}2P}$ range. After reaching POWER_DELAY, the PD shall turn off at a voltage in the range of V_{Off_PD}. For dual-signature PDs the requirements for V_{On_PD} and V_{Off_PD} apply to each pairset individually. A PD shall not turn off due to peak power draw, causing V_{PD} to go as low as $V_{Overload\text{-}2P}$, as specified in 145.3.8.4, or due to a voltage transient as defined in 145.3.8.6. This behavior is encoded in the variable pd_overload and pd_overload_mode(X).

The PD shall turn on or off without startup oscillation and within the first trial at any load value when fed by $V_{Port_PSE\text{-}2P}$ min to $V_{Port_PSE\text{-}2P}$ max (as defined in Table 145–16):

— With a series resistance less than or equal to R_{Ch} for assigned Class 1 through 4 to a single-signature PD.
— With a series resistance less than or equal to R_{Ch} / 2 for assigned Class 5 through 8 to a single-signature PD.
— With a series resistance less than or equal to R_{Ch} connected to a given Mode of a dual-signature PD.

V_{On_PD} min is set at 30 V to align with V_{Off_PD} min. It is recommended that a PD implements hysteresis between V_{On_PD} and V_{Off_PD}.

When the PD is in POWEROFF and V_{PD} falls below V_{Mark_th}, the PD transitions to NOPOWER and may show a valid or invalid detection signature, and may or may not draw mark current, draw any class current, and show MPS. Interoperability between PSE and PD is no longer guaranteed when the nopower variable is TRUE or the PD has entered NOPOWER_INRUSH since the last time V_{PD} was below V_{Reset_PD} max.

145.3.8.2 Input average power

P_{Port_PD} is the average power drawn by a single-signature PD, measured using a sliding window with a width of 1 second. $P_{Port_PD\text{-}2P}$ is the average power drawn by a given Mode of a dual-signature PD, measured using a sliding window with a width of 1 second.

For single-signature PDs, P_{Port_PD} shall not exceed P_{Class_PD} for the assigned Class. For dual-signature PDs, $P_{Port_PD\text{-}2P}$ shall not exceed $P_{Class_PD\text{-}2P}$ for the assigned Class.

A PD that has either enabled Autoclass during Physical Layer classification and drew a power higher than Class 1 power during the period bounded by T_{AUTO_PD1} and T_{AUTO_PD2} or has requested Autoclass through DLL, shall not draw more power than $P_{Autoclass_PD}$, unless the PD successfully negotiates a different power level, up to the PD requested Class, through Data Link Layer classification as defined in 145.5.

P_{Class_PD} and $P_{Class_PD\text{-}2P}$ defined in Table 145–29 are determined per the assigned Class. The assigned PSE Class is determined by the number of class events and the PD requested Class, as shown in Table 145–11. P_{Class_PD} is the maximum average PI power and applies to single-signature PDs. $P_{Class_PD\text{-}2P}$ is the maximum average power on a pairset and applies to dual-signature PDs.

PDs may dynamically adjust their maximum required operating power below P_{Class_PD} or $P_{Class_PD\text{-}2P}$ as described in 145.5. PDs may also adjust their maximum required operating power below P_{Class_PD} by using Autoclass (see 145.3.6.2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Single-signature PDs that have successfully completed DLL classification shall not exceed a power consumption of PDMaxPowerValue as defined in 145.5.3.3.1. Dual-signature PDs that have successfully completed DLL classification shall not exceed a power consumption of PDMaxPowerValue_mode(X) on Mode X as defined in 145.5.3.4.2.

145.3.8.2.1 Input average power exceptions

For single-signature PDs assigned to Class 8 and PDMaxPowerValue set to 713 or greater, when additional information is available to the PD regarding actual link section DC resistance between the PSE PI and the PD PI, the PD may consume greater than P_{Class_PD} but shall not consume greater than P_{Class} at the PSE PI and shall not draw a total 4-pair current in excess of $2 \times I_{Cable}$ as defined in Table 145–1.

For dual-signature PDs assigned to Class 5 and PDMaxPowerValue_mode(X) set to 356 or greater, when additional information is available to the PD regarding actual link section DC resistance between the PSE PI and the PD PI, the PD may consume greater than $P_{Class_PD\text{-}2P}$ but shall not consume greater than $P_{Class\text{-}2P}$ on the pairset at the PSE PI and shall not draw current in excess of I_{Cable} as defined in Table 145–1.

145.3.8.2.2 System stability test conditions during startup and steady state operation

When connected together as a system, the PSE and PD might exhibit instability at the PSE side, the PD side, or both due to the presence of negative impedance at the PD input. See Annex 33A for PD design guidelines for stable operation.

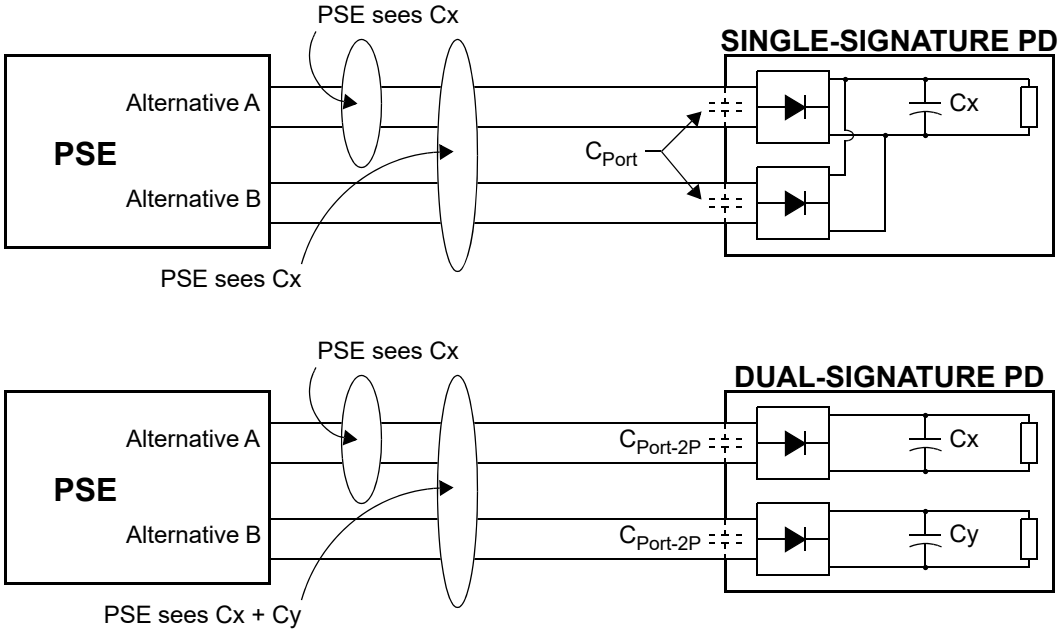
Stable operation may be verified by confirming that the PD meets V_{Noise_PD}, as defined in Table 145–29, when the PD is powered by a voltage source set in the range of $V_{Port_PSE\text{-}2P}$, as defined in Table 145–16, through a series resistance of R_{Ch}, as defined in Table 145–1, and the PD is operating at or below P_{Class_PD} or $P_{Class_PD\text{-}2P}$.

145.3.8.3 Input inrush current

The PD inrush time duration is defined as beginning with the application of input voltage at the PI when V_{PD} crosses the PD power supply turn on voltage, V_{On_PD} as defined in Table 145–29, and ends after T_{delay}.

The inrush current is the initial current drawn by the PD, which is used to charge C_{Port} or $C_{Port\text{-}2P}$. A PD may limit the inrush current below I_{Inrush_PD} and $I_{Inrush_PD\text{-}2P}$ to allow for large values of C_{Port} and $C_{Port\text{-}2P}$.

The PSE limits the inrush current to I_{Inrush} and $I_{Inrush\text{-}2P}$, for at least T_{Inrush_PD} max, as defined in Table 145–16 and Table 145–29.



PDs shall draw less than I_{Inrush_PD} and $I_{Inrush_PD\text{-}2P}$ from T_{Inrush_PD} max until T_{delay} min, when connected to a source that meets the requirements of 145.2.10.7. This delay is required so that the PD does not enter a high power state before the PSE has had time to change the available current from the POWER_UP to the POWER_ON limits. A PD can meet this requirement by either having C_{Port} or $C_{Port\text{-}2P}$ charged within T_{Inrush_PD} max or by limiting the input inrush current.

Single-signature PDs assigned to Class 1, 2, or 3 shall conform to P_{Class_PD} and P_{Peak_PD} within T_{Inrush_PD} max as defined in Table 145–29. Dual-signature PDs assigned to Class 1, 2, or 3 shall conform to $P_{Class_PD\text{-}2P}$ and $P_{Peak_PD\text{-}2P}$ within T_{Inrush_PD} max as defined in Table 145–29 on that pairset.

NOTE—PDs may be subjected to PSE POWER_ON current limits during inrush when the PD input voltage reaches 99% of steady state or after T_{Inrush_PD} max. PD requirements are impacted by PSE current limits. See 145.2.10.7 for details.

C_{Port} in Table 145–29 is the PD input capacitance during POWER_UP and POWER_ON that a PSE sees as load when operating one or both pairsets, when connected to a single-signature PD. $C_{Port\text{-}2P}$ in Table 145–29 is the PD input capacitance during POWER_UP_PRI, POWER_UP_SEC, POWER_ON_PRI, and POWER_ON_SEC that a PSE sees as load on each pairset independently, when connected to a dual-signature PD. See Figure for a simplified PSE-PD C_{Port} and $C_{Port\text{-}2P}$ interpretation model.

NOTE—The “dual-signature PD” in Figure represents a PD with two completely isolated circuits connected to Mode A and Mode B. The PSE will see a capacitance of Cx + Cy. A dual-signature PD can also be implemented with a single load, resulting in a lower than Cx + Cy capacitance value as seen by the PSE.

Figure 145–30—C_{Port} interpretation model

145.3.8.4 Peak operating power

$V_{Overload\text{-}2P}$ is the PD PI voltage when the PD is drawing the permissible P_{Peak_PD} for single-signature PDs, or $P_{Peak_PD\text{-}2P}$ for dual-signature PDs.

At any static voltage at the PI, and any PD operating condition, with the exception described in 145.3.8.4.1, the peak power for single-signature PDs shall not exceed P_{Class_PD} for more than T_{CUT} min, as defined in Table 145–16 and 5% duty cycle. P_{Peak_PD} is the maximum peak operating power and applies to single-signature PDs.

At any static voltage at the PI, and any PD operating condition, with the exception described in 145.3.8.4.1, the peak power for a dual-signature PD shall not exceed $P_{Class_PD\text{-}2P}$ for more than T_{CUT} min, as defined in Table 145–16 and 5% duty cycle. $P_{Peak_PD\text{-}2P}$ is the maximum peak operating power on a pairset and applies to dual-signature PDs.

NOTE—The duty cycle of the peak current is measured using a sliding window with a width of 1 second.

Peak power is defined in Table 145–29 and depends on the Class assigned by the PSE. Equation (145–24) and Equation (145–25) are used to approximate the ratiometric peak powers of Class 1 through Class 8. These equations may be used to calculate P_{Peak_PD} or $P_{Peak_PD\text{-}2P}$ after Data Link Layer classification and for Autoclass by substituting PDMaxPowerValue with the corresponding value of $P_{Autoclass_PD}$.

$$P_{Peak_PD} = \left\{ \begin{array}{l} 0.129 \times \text{PDMaxPowerValue for assigned Class 1 and 2} \\ 0.111 \times \text{PDMaxPowerValue for assigned Class 3 and 4} \\ 0.105 \times \text{PDMaxPowerValue for assigned Class 5 to 8} \end{array} \right\}_{W} \quad (145\text{–}24)$$

$$P_{Peak_PD\text{-}2P} = \left\{ \begin{array}{l} 0.129 \times \text{PDMaxPowerValue_mode(X) for assigned Class 1 and 2} \\ 0.111 \times \text{PDMaxPowerValue_mode(X) for assigned Class 3 and 4} \\ 0.105 \times \text{PDMaxPowerValue_mode(X) for assigned Class 5} \end{array} \right\}_{W} \quad (145\text{–}25)$$

where

PDMaxPowerValue	is the actual maximum input average the PD may draw under the current power allocation; see 145.5.3.3.1
PDMaxPowerValue_mode(X)	is the actual maximum input average the PD may draw under the current power allocation on Mode X; see 145.5.3.4.2

145.3.8.4.1 Peak operating power exceptions

For single-signature PDs assigned to Class 8 and for dual-signature PDs assigned to Class 5, when additional information is available to the PD regarding actual link section DC resistance between the PSE PI and the PD PI, in any operating condition with any static voltage at the PI, the peak power shall not exceed P_{Port_PD} max for single-signature PDs and $P_{Port_PD\text{-}2P}$ max for dual-signature PDs for more than T_{CUT} min, as defined in Table 145–16 and with 5% duty cycle. Peak operating power shall not exceed $1.05 \times P_{Port_PD}$ max for single-signature PDs and shall not exceed $1.05 \times P_{Port_PD\text{-}2P}$ max for dual-signature PDs on each pairset. P_{Port_PD} max and $P_{Port_PD\text{-}2P}$ max refer to the maximum power draw as permitted by 145.3.8.2.1.

145.3.8.5 Input current slew rate

When the input voltage at the PI is static and in the range of $V_{Port_PD\text{-}2P}$ defined by Table 145–29, the input current drawn by a single-signature PD shall not change faster than $I_{Slewrate}$ defined in Table 145–29, in either polarity. Each pairset current drawn by a dual-signature PD shall not change faster than $I_{Slewrate}$ defined in Table 145–29, in either polarity. This limitation applies after inrush has completed (see 145.3.8.3) and before the PD has disconnected.

145.3.8.6 PD behavior during transients at the PSE PI

A PD shall continue to operate without interruption in the presence of transients

- Lasting longer than 30 µs and less than 250 µs at the PSE PI as defined in 145.2.10.3, and causing the voltage at the PD PI to fall to no less than $V_{Tran_PD\text{-}2P}$, as defined in Table 145–29.
- Lasting less than 30 µs and causing the voltage at the PD PI to fall to not less than 34 V.

During a transient the input power of the PD may exceed P_{Peak_PD} or $P_{Peak_PD\text{-}2P}$. Table 145–30 defines three PSE output voltage transients.

Table 145–30—Transient conditions

Item	Assigned Class	2-pair/ 4-pair	$T_{Transient}$	Initial voltage	Final voltage	Source dv / dt	Source resistance	Source current[a]
TR1	1 to 4	2-pair	10 ms	50 V	56 V	2.25 V/ms	12.5 Ω	Limit to I_{LIM-2P} + 5 mA
	1 to 6	4-pair					6.25 Ω	
TR2	1 to 4	2-pair	6 ms	52 V			12.5 Ω	
	1 to 8	4-pair					6.25 Ω	
TR3	1 to 8	both	4 ms	52 V	54.5 V	3500 V/ms	1.5 Ω	> 5 A capability

[a] The source current for TR1 and TR2 is the current limit per powered pairset.

When transient TR1 or TR2 is applied, the PD shall meet the operating power limits within $T_{Transient}$, as defined in Table 145–30, referenced from when the 'final voltage' is reached at the source. When transient TR1 or TR2 is applied, the PD shall not cause the source to be in current limit for longer than T_{LIM} min.

When transient TR3 is applied, the PD shall meet the operating power limits within 4 ms, referenced from the beginning of the TR3 transient.

The TR1, TR2, and TR3 tests consists of a voltage source, with a current limit (for TR1 and TR2), driven from the 'initial voltage' to the 'final voltage' at the 'source dv/dt' rate. A source resistance, as defined in Table 145–30 is in series with this voltage source and the PD.

These requirements apply to each pairset individually for a dual-signature PD.

145.3.8.7 Ripple and noise

The PD shall meet V_{Noise_PD}, defined in Table 145–29, the common-mode or differential pair-to-pair noise at the PD PI generated by the PD circuitry. V_{Noise_PD} applies for all operating voltages in the range of V_{Port_PD-2P}, over the range of input power of the device, and when connected to any source resistance up to R_{Ch}.

The PD shall operate correctly in the presence of ripple and noise generated by the PSE that appears at the PD PI. These levels are specified in Table 145–16.

145.3.8.8 Reflected voltage

For a single-signature PD, when any voltage in the range of 0 V to V_{Port_PD-2P} max is applied per any of the valid 2-pair configurations, defined in Table 145–20, that have only a single pair connected to the positive potential (see Figure 145–31), the voltage on the Mode not connected to the voltage source, with a 100 kΩ resistor connected across that Mode, shall not exceed V_{refl} as defined in Table 145–29.

For a dual-signature PD, when any voltage in the range of 0 V to V_{Port_PD-2P} max is applied per any of the valid 2-pair configurations, defined in Table 145–20, including those with two pairs connected to the positive potential (see Figure 145–31), the voltage on the Mode with at least one pair not connected to the voltage source, with a 100 kΩ resistor connected across that Mode, shall not exceed V_{refl} as defined in Table 145–29.

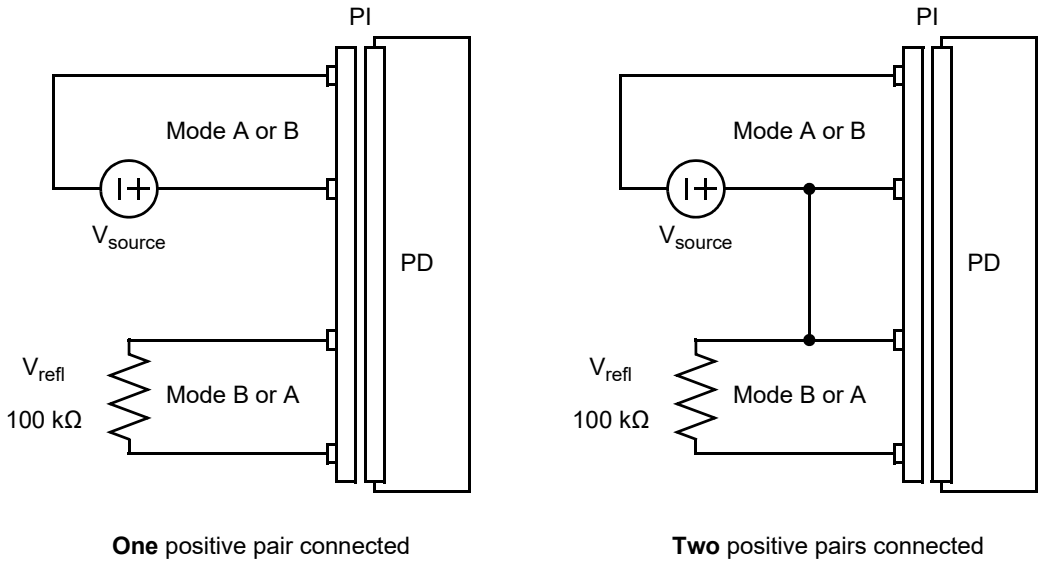

Figure 145–31—Reflected voltage requirements

145.3.8.9 PD pair-to-pair current unbalance

When a PSE supplies power to a PD using all 4 pairs, the current may not equally divide between the pairs that are at the same polarity. This is referred to as pair-to-pair current unbalance. The degree to which the current is unbalanced depends on the specific combination of PSE, cabling, and PD.

The maximum pair current in a system depends on the assigned Class (see 145.3.6), and is defined in Table 145–31.

Table 145–31—Maximum pair-to-pair current unbalance

Parameter	Assigned Class	Unit	Value
$I_{Unbalance_PD\text{-}2P}$	1 to 4[a]	A	P_{Class_PD} / V_{PD}
	5 to 8		$I_{Con\text{-}2P\text{-}unb} - 0.01$
$I_{Unbalance_peak\text{-}2P}$	1 to 4[a]	A	P_{Peak_PD} / V_{PD}
	5 to 8		$I_{LIM\text{-}2P} - 0.002$

[a] There is no maximum unbalance current requirement for these assigned Classes.

This subclause describes unbalance requirements for PDs that operate over 4 pairs. The contribution of PD PI pair-to-pair effective resistance unbalance to the effective system end-to-end resistance unbalance is determined by PD maximum (R_{PD_max}) and minimum (R_{PD_min}) common mode effective resistance in the powered pairs of same polarity. See Figure 145A–3. Effective resistances of R_{PD_min} and R_{PD_max} include the effects of PD pair to pair voltage difference and the PD PI resistive elements. See definition and measurements in Annex 145A.5.

R_{PD_max}, defined in Equation (145–26), for a given R_{PD_min}, is the highest supported common mode effective resistance in the powered pairs of the same polarity. PDs that meet Equation (145–26) intrinsically

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

meet unbalance requirements. Equation (145–26) is only applicable for R_{PD_min} up to a value of 1 Ω and power draw up to P_{Class_PD}.

$$0 < R_{PD_max} \leq \left\{ \begin{array}{ll} 2.182 \times R_{PD_min} + 0.125 & \text{for assigned Class 5} \\ 1.988 \times R_{PD_min} + 0.105 & \text{for assigned Class 6} \\ 1.784 \times R_{PD_min} + 0.08 & \text{for assigned Class 7} \\ 1.727 \times R_{PD_min} + 0.074 & \text{for assigned Class 8} \end{array} \right\}_{\Omega} \quad (145\text{–}26)$$

where

R_{PD_max} is, given R_{PD_min}, the highest supported common mode effective resistance in the powered pairs of the same polarity

R_{PD_min} is the lower PD common mode effective resistance in the powered pairs of the same polarity

Common mode effective resistance is the resistance of the two conductors (including their components on each conductor) in a powered pair of the same polarity connected in parallel.

Figure 145A–1 illustrates the relationship between R_{PD_max} and R_{PD_min} effective resistances at the PD PI as defined by Equation (145–26) and the rest of the end-to-end pair to pair effective resistance components.

Single-signature PDs shall not exceed $I_{Unbalance_PD\text{-}2P}$ for longer than T_{CUT} min and 5 % duty cycle, and shall not exceed $I_{Unbalance_peak\text{-}2P}$, as defined in Table 145–31 on any pair when the PD is connected per any valid 4-pair configuration, as defined in Table 145–20, to any voltage in the range of $V_{Port_PSE\text{-}2P}$ min + 0.31 V to $V_{Port_PSE\text{-}2P}$ max through two common mode resistances, R_{source_min} and R_{source_max}, as defined in Equation (145–27) and shown in Figure 145–32.

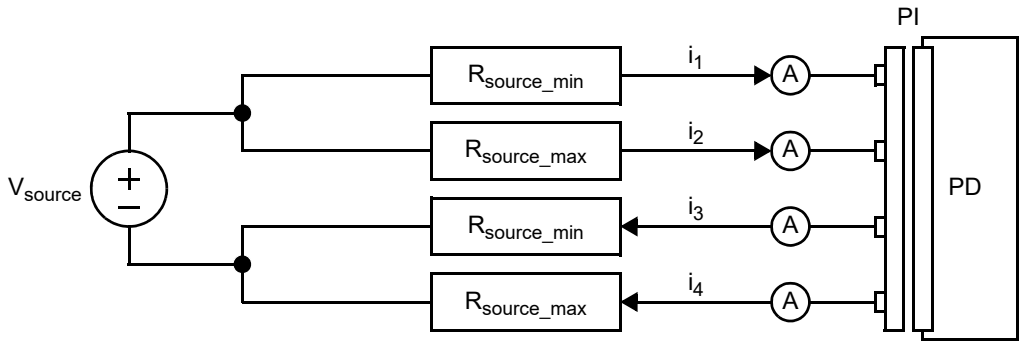

Figure 145–32—PD current unbalance verification circuit

Dual-signature PDs shall not exceed $I_{Con_PD\text{-}2P}$, as defined in Equation (145–28), for longer than T_{CUT} min and 5 % duty cycle, as defined in Table 145–16, and shall not exceed $I_{Peak_PD\text{-}2P}$, as defined in Equation (145–29), on any pair when the PD is connected per any valid 4-pair configuration, as defined in Table 145–20, to any voltage in the range of $V_{Port_PSE\text{-}2P}$ min + 0.31 V to $V_{Port_PSE\text{-}2P}$ max through two common mode resistances, R_{source_min} and R_{source_max}, as defined in Equation (145–27) and shown in Figure 145–32.

The unbalance current requirements for PDs apply at the PD PI connector (jack) when mated with a specified balanced cabling connector (plug).

NOTE 1—The duty cycle of the peak current is measured using a sliding window with a width of 1 second.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$R_{source_max} = \left\{ \begin{array}{l} (-0.03 \times R_{source_min} + 1.324) \times R_{source_min} \text{ for } (0.145\Omega \le R_{source_min} \le 5.47\Omega) \end{array} \right\}_{\Omega} \quad (145\text{–}27)$$

$$I_{Con_PD\text{-}2P} = \left\{ \frac{P_{Class_PD\text{-}2P}}{V_{PD}} \right\}_{A} \quad (145\text{–}28)$$

$$I_{Peak_PD\text{-}2P} = \left\{ \frac{P_{Peak_PD\text{-}2P}}{V_{PD}} \right\}_{A} \quad (145\text{–}29)$$

where

R_{source_min} is the lowest supported common mode effective source resistance in the powered pairs of the same polarity

$P_{Class_PD\text{-}2P}$ is the maximum power at the PD PI per the PDs assigned Class, as defined in Table 145–29

$P_{Peak_PD\text{-}2P}$ is the peak power a dual-signature PD may draw per its assigned Class on a pairset; see Table 145–29

V_{PD} is the voltage at the PD PI as defined in 145.1.3

R_{source_min} and R_{source_max} represent the V_{source} source common mode effective resistance that consists of the PSE PI components (R_{PSE_min} and R_{PSE_max} as defined in 145.2.10.6.1, $V_{Port_PSE_diff}$ as defined in Table 145–16, the link section resistance, and influence of R_{PD_min} and R_{PD_max} as function of system end-to-end unbalance). Common mode effective resistance is the resistance of two conductors of the same pair and their other components, which form R_{source}, connected in parallel including the effect of the system (PSE and PD) pair to pair voltage difference.

R_{PD_min}, R_{PD_max}, along with any other parts of the system, i.e., link section and the PSE, bounds the maximum current such that the maximum pair current including unbalance does not exceed $I_{Unbalance_PD\text{-}2P}$ as defined in Table 145–16 during normal operating conditions. See Annex 145A.

NOTE 2—The pairset current limit requirement also holds when R_{source_max} and R_{source_min} are exchanged.

145.3.9 PD Maintain Power Signature

A PD that requires power from the PI shall provide a valid Maintain Power Signature (MPS) at the PI. A PD that does not maintain the MPS components may have its power removed within the limits of T_{MPDO} as defined in Table 145–16. I_{Port_MPS}, $I_{Port_MPS\text{-}2P}$, T_{MPS_PD}, and T_{MPDO_PD}, are defined in Table 145–32. T_{LCE_PD} is defined in Table 145–25.

For single-signature PDs the MPS shall consist of current draw equal to or above I_{Port_MPS} for a minimum duration of T_{MPS_PD} followed by an optional MPS dropout for no longer than T_{MPDO_PD}. A single-signature PD shall use the I_{Port_MPS} value associated with assigned Class 1 to 4 when pse_assigned_class is 1, 2, 3, or 4, and MirroredPSEAllocatedPowerValue and PDRequestedPowerValue are less or equal to 255. A single-signature PD shall use the I_{Port_MPS} value associated with assigned Class 5 to 8 when pse_assigned_class is 5, 6, 7, or 8, or when PDRequestedPowerValue is in the range of 256 to 999. When PDRequestedPowerValue or PSEAllocatedPowerValue is equal to 0xACAC, the PD shall use the I_{Port_MPS} value associated with the assigned Class.

For dual-signature PDs the MPS shall consist of current draw equal to or above $I_{Port_MPS\text{-}2P}$ on each powered pairset independently for a minimum duration of T_{MPS_PD} followed by an optional MPS dropout for no longer than T_{MPDO_PD}.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 145–32—PD DC Maintain Power Signature

Item	Parameter	Symbol	Units	Min	Max	Conditions
1	Total input current per the assigned Class, for single-signature PDs					
	Class 1 to 4	I_{Port_MPS}	A	0.01	—	See 145.3.9
	Class 5 to 8			0.016		
2	Input current on each powered pairset for dual-signature PDs					
	Class 1 to 5	I_{Port_MPS-2P}	A	0.01	—	—
3	PD Maintain Power Signature Time	T_{MPS_PD}	ms	75	—	long_class_event = FALSE
				7	—	long_class_event = TRUE
4	PD Drop Out Period	T_{MPDO_PD}	ms	—	250	long_class_event = FALSE
				—	310	long_class_event = TRUE
NOTE—PDs may not be able to meet the I_{Port_MPS} or I_{Port_MPS-2P} specification in Table 145–32 during the maximum allowed port voltage droop (V_{Port_PSE-2P} max to V_{Port_PSE-2P} min with series resistance R_{Ch}). Such a PD should increase its I_{Port} or $I_{Port-2P}$ or make other such provisions to meet the Maintain Power Signature.						

A PD connected to a Type 1 or Type 2 PSE, shall also present input impedance with resistive and capacitive components defined in Table 145–33.

Table 145–33—PD Maintain Power Signature

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Input resistance	R_{pd_d}	kΩ	—	26.3	—
2	Input capacitance	C_{pd_d}	µF	0.05	—	—

PDs that detect a long first class event in the range of T_{LCE_PD} may use the shorter T_{MPS_PD} in order to draw a lower standby MPS power. In the absence of a long first class event, the minimum T_{MPS_PD} is higher and the standby MPS power is also higher.

A PD shall meet the T_{MPS_PD} and T_{MPDO_PD} requirements with any series resistance less than or equal to R_{Chan} max between the PD PI and the source.

Powered PDs that no longer require power, and identify the PSE as Type 1 or Type 2, shall remove both the current draw and impedance components of the MPS. To cause Type 1 and Type 2 PSE power removal, the impedance of the PI should rise above 1980 kΩ.

Powered PDs that no longer require power, and identify the PSE as Type 3 or Type 4, shall remove the current draw component and may remove the impedance components of the MPS. See 145.2.12, 145.2.10.4, and 145.3.8.8.

145.4 Additional electrical specifications

This clause defines additional electrical specifications for a fully connected PoE system (that is, PSE, cabling, PD, and related PHYs) and therefore to each element of such a system. The specifications apply for all PSE and PD operating conditions at the cabling side of the mated connection of the PI. The requirements apply during data transmission only when specified as an operating condition.

The requirements of 145.4 are consistent with the requirements of the 10BASE-T MAU and the 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, and 10GBASE-T PHYs.

145.4.1 Electrical isolation

PDs and PSEs shall provide isolation between all accessible external conductors, including frame ground (if any), and all MDI leads including those not used by the PD or PSE. Any equipment that can be connected to a PSE or PD through a non-MDI connector that is not isolated from the MDI leads needs to provide isolation between all accessible external conductors, including frame ground (if any), and the non-MDI connector. External accessibility to conductors is specified in Section 5.4.10.1 b) of IEC 62368-1:2018.

This electrical isolation shall meet the isolation requirements as specified in J.1 with electrical strength test c) details being replaced by: “An impulse test consisting of a 1500 V, 10/700 waveform, applied 10 times, with a 60 s interval between pulses. The shape of the impulses is 10/700 (10 μs virtual front time, 700 μs virtual time to half value), as defined in ITU-T Recommendation K.44.”

Conductive link segments that have differing isolation and grounding requirements shall have those requirements provided by the port-to-port isolation of network interface devices (NID).

In a multiport system, the implementer should maintain DC isolation through the termination circuitry to eliminate cross-port leakage currents. See 145.2.10.4.

Dual-signature PDs shall have less than or equal to 10 μA of current between any negative conductor of Mode A and any negative conductor of Mode B when V_{PD}, as defined in 145.1.3, is less than V_{Off_PD} min, as defined in Table 145–29, on either Mode. See Table 79–15.

145.4.1.1 Electrical isolation environments

There are two electrical power distribution environments to be considered that require different electrical isolation properties. They are as follows:

— **Environment A:** When a LAN or LAN segment, with all its associated interconnected equipment, is entirely contained within a single low-voltage power distribution system and within a single building.
— **Environment B:** When a LAN crosses the boundary between separate power distribution systems or the boundaries of a single building.

145.4.1.1.1 Environment A requirements

Attachment of network segments via NIDs that have multiple instances of a twisted-pair MDI requires electrical isolation between each segment and the protective ground of the NID.

For NIDs, the requirement for isolation is encompassed within the isolation requirements of the MAU or PHY (see 14.3.1.1, 25.4.6, and 40.6.1.1). Equipment with multiple instances of PSE, PD, or both shall meet or exceed the isolation requirement of the MAU/PHY with which they are associated.

An Environment A multiport NID does not require electrical power isolation between link segments.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

An Environment A PSE shall switch the more negative conductor. It is allowed to switch both conductors.

145.4.1.1.2 Environment B requirements

The attachment of network segments that cross Environment A boundaries requires electrical isolation between each segment and all other attached segments as well as to the protective ground of the NID.

For NIDs, the requirement for isolation is encompassed within the isolation requirements of the MAU or PHY (see 14.3.1.1, 25.4.6, and 40.6.1.1). Equipment with multiple instances of PSE, PD, or both shall meet or exceed the isolation requirement of the MAU/PHY with which each is associated.

An environment B PSE that supports 4-pair power shall switch the more negative conductor. It is allowed to switch both conductors.

The requirements for interconnected electrically conducting link segments that are partially or fully external to a single building environment may require additional protection against lightning strikes or other hazards. Protection requirements for such hazards are beyond the scope of this standard. Guidance on these requirements may be found in Section 6 of IEC 60950-1:2001 and throughout IEC 62368-1, as well as any local and national codes related to safety.

145.4.2 Fault tolerance

Each conductor pair of the PI, when it is also an MDI (e.g., an Endpoint PSE or PD), shall meet the fault tolerance requirements of the appropriate specifying clause. (See 14.3.1.2.7, 25.4, 40.8.3.4, 55.8.2.3, and 126.8.2.4.) When a PI is not an MDI (e.g., a Midspan PSE), the PSE PI shall meet the fault tolerance requirements of this subclause.

The PSE shall withstand without damage the application of short circuits of any conductors within the cable for an indefinite period of time. The magnitude of the current caused by a short circuit of any one conductor to another conductor in the cable

— Shall not exceed $I_{PSEUT\text{-}Type3\text{-}2P}$, as defined in Equation (145–17), for Type 3 PSEs.
— Shall not exceed $I_{PSEUT\text{-}Type4\text{-}2P}$, as defined in Equation (145–18), for Type 4 PSEs.

Each conductor pair shall withstand, without damage, a 1000 V common-mode impulse applied at E_{cm} of either polarity. The shape of the impulse shall be (0.3/50) μs (300 ns virtual front time, 50 μs virtual time of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

half value), as defined in IEC 60060, where E_{cm} is an externally applied AC voltage as shown in Figure 145–33.

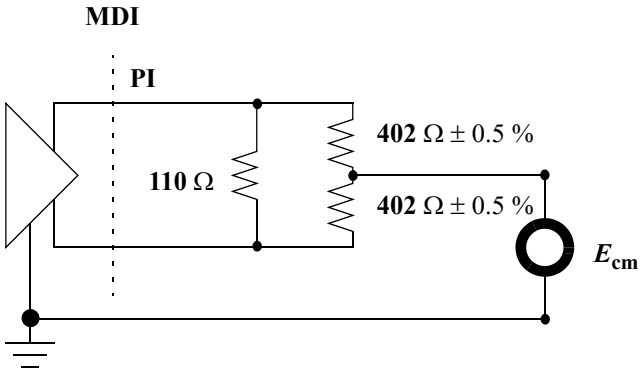

Figure 145–33—PI fault tolerance test circuit

NOTE—PDs may receive power from a PSE over fewer conductors than specified when a link section has a fault of one or more conductor open failures.

145.4.3 Impedance balance

Impedance balance is a measurement of the common-mode-to-differential-mode offset of the PI. The common-mode-to-differential-mode impedance balance for the transmit and receive pairs shall exceed the limits in Table 145–34 for all supported PHY speeds.

Table 145–34—Impedance balance limits for supported speeds

Supported speed	Impedance balance limit (dB)	Frequency range
10 Mb/s MAU	$29 - 17 \times \log_{10}(f/10)$	$1 \le f \le 20$ MHz
100 Mb/s or 1000 Mb/s PHY	$34 - 19.2 \times \log_{10}(f/50)$	$1 \le f \le 100$ MHz
2.5 Gb/s PHY	48	$1 \le f < 10$ MHz
	$48 - 20 \times \log_{10}(f/10)$	$10 \le f < 20$ MHz
	$42 - 15 \times \log_{10}(f/20)$	$20 \le f \le 125$ MHz
5 Gb/s PHY	48	$1 \le f < 30$ MHz
	$44 - 19.2 \times \log_{10}(f/50)$	$30 \le f \le 250$ MHz
10 Gb/s PHY	48	$1 \le f < 30$ MHz
	$44 - 19.2 \times \log_{10}(f/50)$	$30 \le f \le 500$ MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The impedance balance is defined as shown in Equation (145–30):

$$\left\{20 \times \log_{10}\left(\frac{E_{cm}}{E_{dif}}\right)\right\}_{dB} \quad (145–30)$$

where

E_{cm} is an externally applied sinusoidal voltage as shown in Figure 145–34
E_{dif} is the voltage of the resulting waveform due only to the applied sine wave measured as shown in Figure 145–34

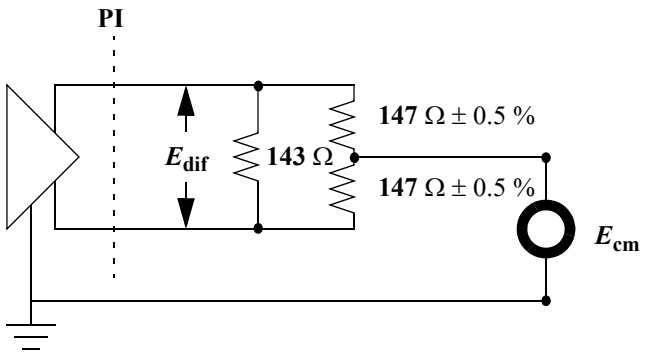

Figure 145–34—PI impedance balance test circuit

145.4.4 Common-mode output voltage

The magnitude of the common-mode AC output voltage measured according to Figure 145–35 and Figure 145–36 at the transmit PI while transmitting data and with power applied, E_{cm_out}, shall not exceed the values in Table 145–35 while operating at the specified speed, when measured over the specified bandwidth.

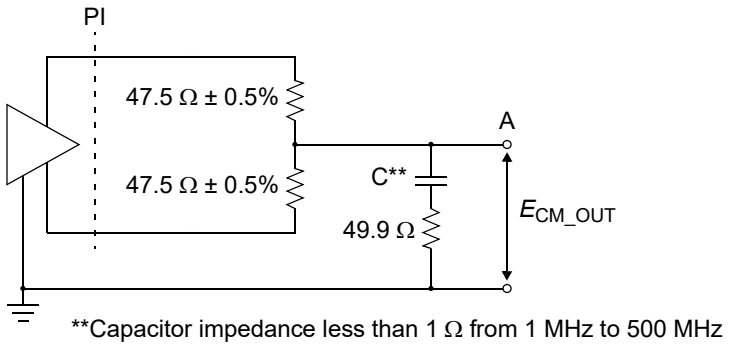

Figure 145–35—Common-mode output voltage test

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

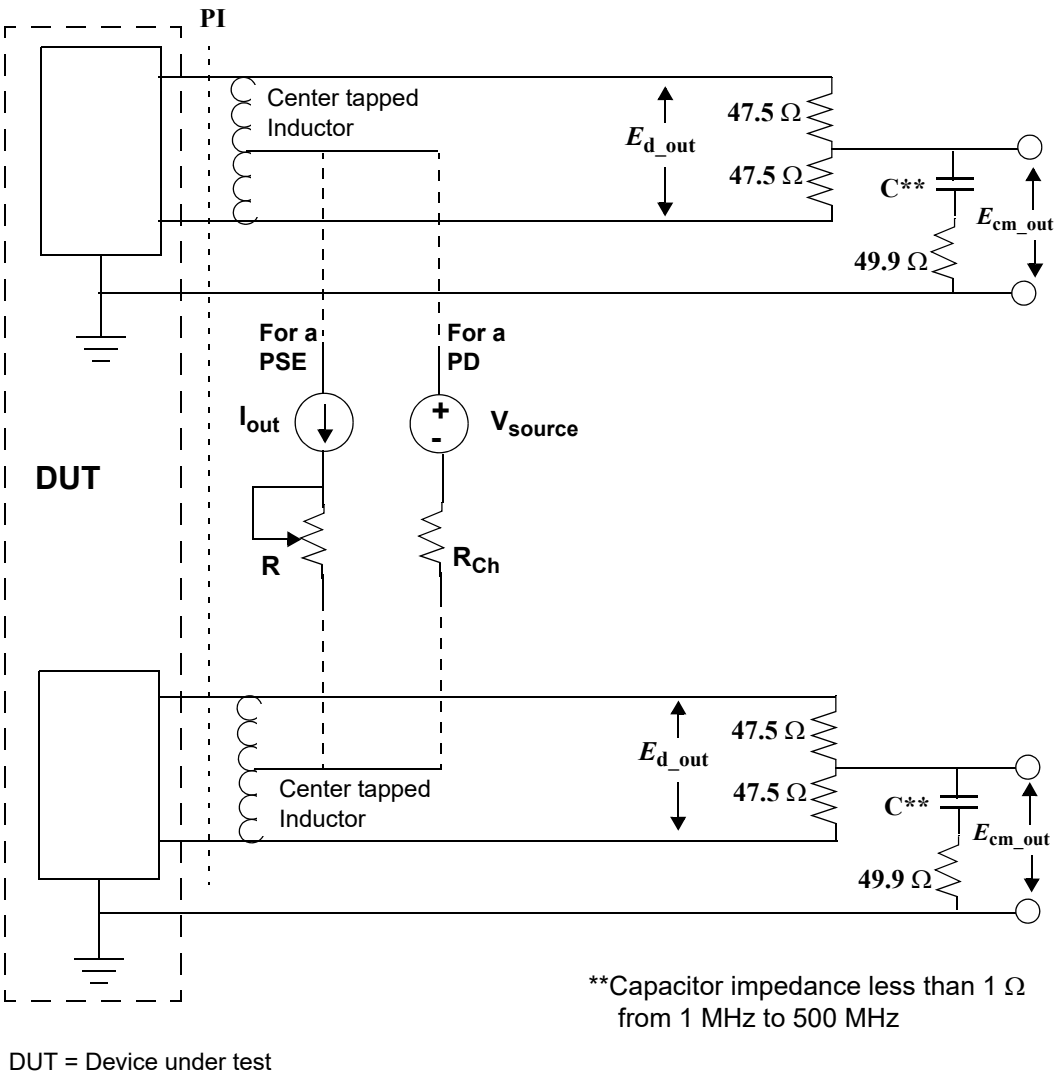

Figure 145–36—PSE and PD terminations for common-mode output voltage test

Table 145–35—Common-mode output voltage for given operating speed

Operating speed	Common-mode output voltage (E_{cm_out})	Measurement bandwidth
10 Mb/s MAU	50 mV peak	$1 \leq f \leq 100$ MHz
100 Mb/s or 1000 Mb/s PHY	50 mV_{pp}	$1 \leq f \leq 100$ MHz
2.5 Gb/s PHY	50 mV_{pp}	$1 \leq f \leq 100$ MHz
5 Gb/s PHY	50 mV_{pp}	$1 \leq f \leq 250$ MHz
10 Gb/s PHY	50 mV_{pp}	$1 \leq f \leq 500$ MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The common-mode AC output voltage shall be measured while the PHY is transmitting data, the PSE or PD is operating with the following PSE load or PD source:

1) For a PSE, the PI that supplies power is terminated as illustrated in Figure 145–36. The PSE load, R, in Figure 145–36 is adjusted so that the PSE output current, I_{out}, is 16 mA and then I_{Cable} for 2-pair operation or 2 × I_{Cable} for 4-pair operation, while measuring E_{cm_out} on the PI.
2) For a PD, the PI that requires power shall be terminated as illustrated in Figure 145–36. V_{source} in Figure 145–36 is adjusted to 36 Vdc and 57 Vdc, while measuring E_{cm_out} on the PI.

NOTE—The implementer should consider any applicable local, national, or international regulations that may require more stringent specifications. One such specification can be found in the European Standard EN 55022:1998.

145.4.5 Pair-to-pair output noise voltage

The pair-to-pair output noise voltage (see Figure 145–37) is limited by the resulting electromagnetic interference due to this AC voltage. This AC voltage can be ripple from the power supply, Table 145–16, 'power feeding ripple and noise', or from any other source. A system integrating a PSE shall comply with applicable local and national codes for the limitation of electromagnetic interference.

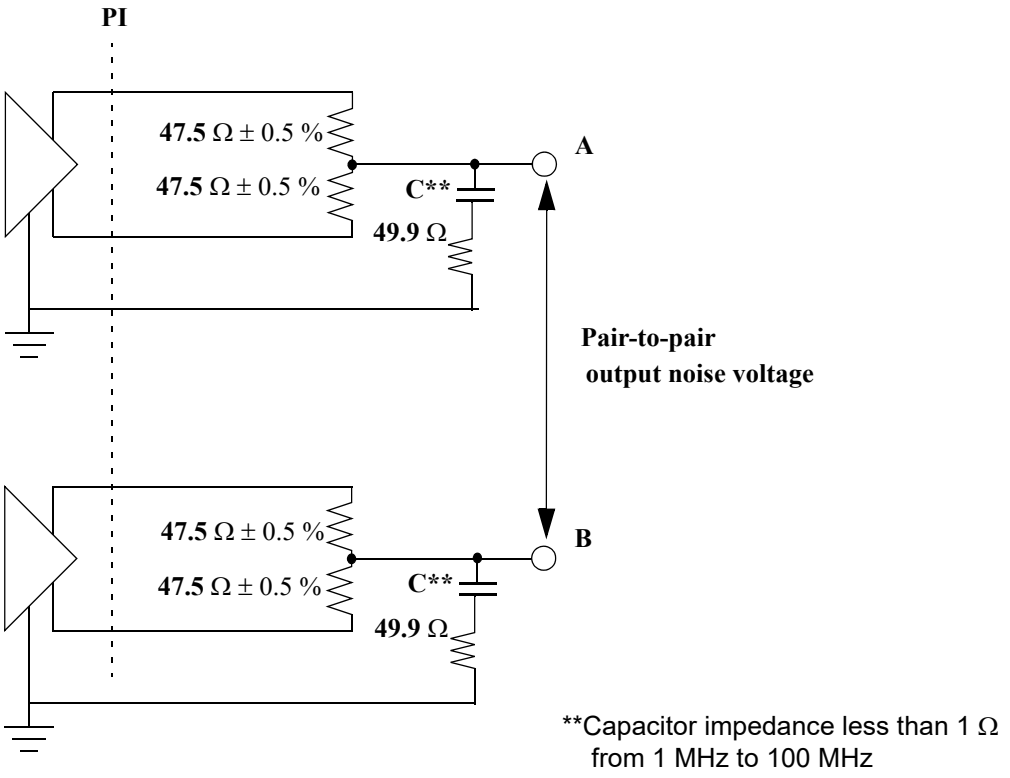

Figure 145–37—Pair-to-pair output noise voltage test

145.4.6 Differential noise voltage

For 10/100/1000 Mb/s, the coupled noise, E_{d_out} in Figure 145–36, from a PSE or PD to the differential transmit and receive pairs shall not exceed 10 mV peak-to-peak when measured from 1 MHz to 100 MHz under the conditions specified in 145.4.4, item 1) and item 2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For 2.5GBASE-T, 5GBASE-T, or 10GBASE-T, the coupled noise, E_{d_out} in Figure 145–36, from a PSE or PD to the differential transmit and receive pairs shall not exceed 10 mV peak-to-peak when measured in the band from 1 MHz to 10 MHz and shall not exceed 1 mV peak-to-peak when measured in the band from 10 MHz to 100 MHz for 2.5GBASE-T, 10 MHz to 250 MHz for 5GBASE-T, and 10 MHz to 500 MHz for 10GBASE-T under the conditions specified in 145.4.4, item 1) and item 2).

145.4.7 Return loss

The differential impedance of the transmit and receive pairs at the PHY's MDI shall be such that any reflection shall meet the return loss requirements as specified

— In 14.3.1.3.4 for a 10 Mb/s PHY.
— In ANSI INCITS 263-1995 for a 100 Mb/s PHY.
— In 40.8.3.1 for a 1000 Mb/s PHY.
— In 126.8.2.2 for a 2.5 Gb/s or 5 Gb/s PHY.
— In 55.8.2.1 for a 10 Gb/s PHY.

In addition, all pairs terminated at an MDI should maintain a nominal common-mode impedance of 75 Ω. The common-mode termination is affected by the presence of the power supply, and this should be considered to determine proper termination.

145.4.8 100BASE-TX transformer droop

100BASE-TX systems may contain a legacy PHY receiver that expects to be connected to a PHY transmitter with 350 μH open circuit inductance (OCL). Alternative A Midspan PSEs that support 100BASE-TX shall enforce intra-pair current unbalance (see 145A.1) less than or equal to I_{unb} (see 145.2.10.12) or meet 145.4.9.3.

100BASE-TX Endpoint PSEs and 100BASE-TX PDs shall meet the requirements of Clause 25 in the presence of (I_{unb}/2).

145.4.9 Midspan PSE device additional requirements

The cabling specifications for 100 Ω balanced cabling are described in ISO/IEC 11801:2002. Cable conforming to ANSI/TIA-568-C.2 also meets these requirements. Some cable category specifications that only appear in earlier editions are also supported. The terms "channel" and "permanent link" are defined in ISO/IEC 11801-1 subsection 5.3.5. Midspan PSE cabling system requirements are specified in 145.1.4.

ISO/IEC 11801-1 defines in 5.1 two types of Equipment interface to the cabling system: "Interconnect model" and the "cross-connect model." An equivalent "Interconnect model" and "cross-connect model" may be found in ANSI/TIA-568.0-D, 5.1. See Figure 145–38.

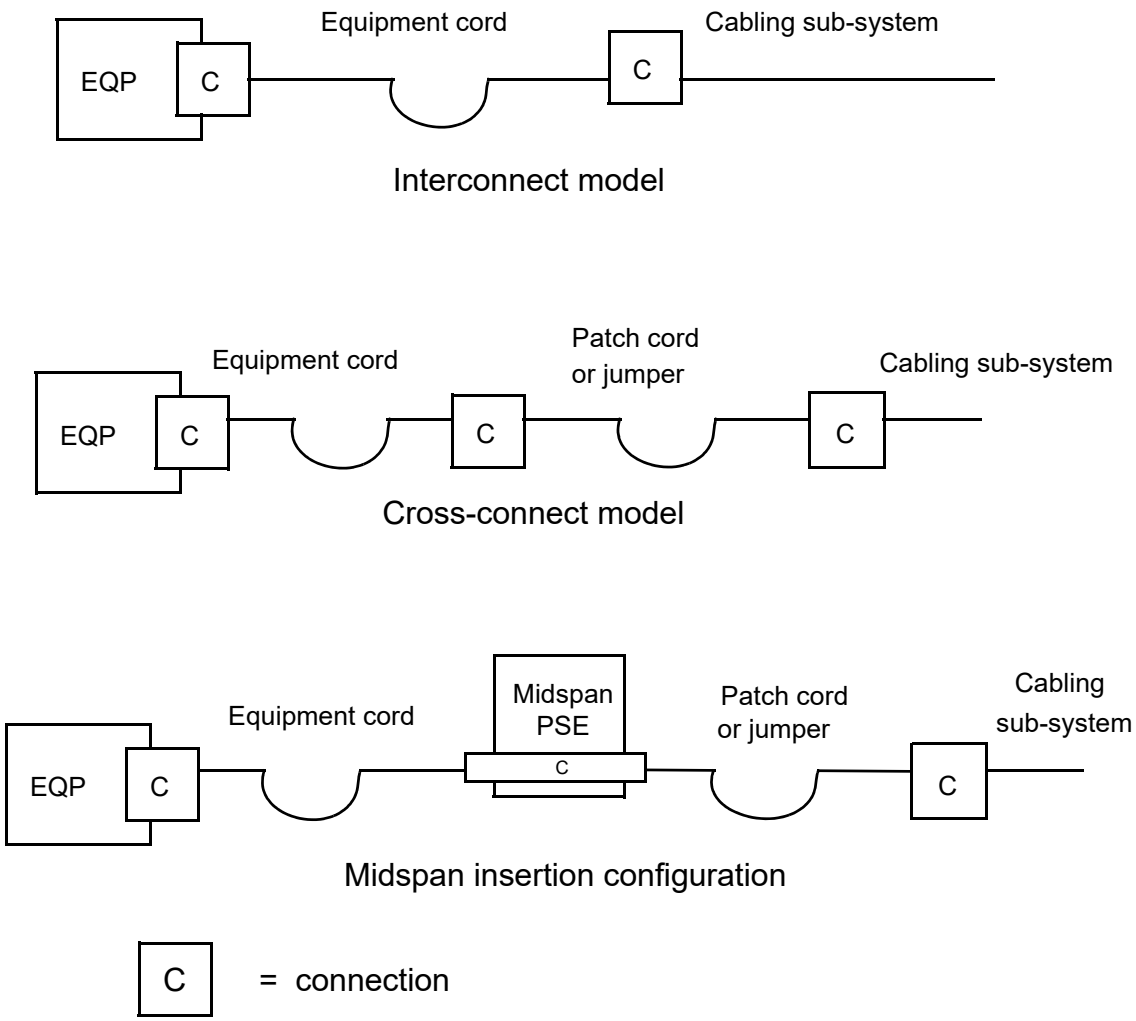

Figure 145–38—Interconnect model, cross-connect model, and midspan insertion configuration

The insertion of a Midspan PSE at the Floor Distributor (FD) shall comply with the following guidelines:

a) If the existing FD configuration is of the “Interconnect model” type, the Midspan PSE can be added, provided it does not increase the insertion loss of the resulting “channel” to more than specified for the same Class or category 100 m channel defined in ISO/IEC 11801-1 or ANSI/TIA-568.0-D.

b) If the existing FD configuration is of the “Cross-connect model” type, the Midspan PSE can be installed instead of one of the connection pairs in the FD. In addition, the installation of the Midspan PSE shall not increase the insertion loss of the resulting “channel” to more than specified for the same Class or category 100 m channel defined in ISO/IEC 11801-1 or ANSI/TIA-568.0-D.

c) For a 10GBASE-T midspan PSE, in meeting either of the above requirements, the Midspan PSE may be substituted for up to two connection pairs in the FD.

Configurations with the Midspan PSE in the cabling “channel” shall not alter the transmission requirements of the “permanent link.” A Midspan PSE shall not provide DC continuity between the two sides of the segment for the pairs that inject power.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The requirements for the two pair Category 5 link segment are found in 25.4.9. Specification of 4-pair cabling is beyond the scope of Clause 25.

NOTE—Appropriate terminations may be applied to the interrupted pairs on both sides of the Midspan device.

145.4.9.1 Connector Midspan PSE device transmission requirements

A connector Midspan PSE replaces one of the connectors in the link segment and shall meet the following transmission parameters. These parameters should be measured using the test procedures of ISO/IEC 11801-1 or ANSI/TIA-568-C.2 for connecting hardware.

There are five variants of Midspan PSEs defined with respect to transmission requirements:

1) 10BASE-T/100BASE-TX connector Midspan PSE
2) 1000BASE-T connector Midspan PSE
3) 2.5GBASE-T connector Midspan PSE
4) 5GBASE-T connector Midspan PSE
5) 10GBASE-T connector Midspan PSE

145.4.9.1.1 Near End Crosstalk (NEXT)

NEXT loss is a measure of the unwanted signal coupling from a transmitter at the near-end into neighboring pairs measured at the near-end. NEXT loss is expressed in dB relative to the received signal level. For operation with 2.5GBASE-T and lower rates, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–31) when measured for the transmit and receive pairs from 1 MHz to 100 MHz. For 5GBASE-T, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–31) when measured for the transmit and receive pairs from 1 MHz to 250 MHz. For operation with 5GBASE-T and lower rates, for frequencies that correspond to calculated values greater than 65 dB, the requirement reverts to the minimum requirement of 65 dB.

$$\{NEXTconn\}_{\text{dB}} \geq 43 - 20 \times \log_{10}\left(\frac{f}{100}\right) \tag{145–31}$$

where

NEXTconn is the Near End Crosstalk loss in dB
f is the frequency expressed in MHz

For 10GBASE-T operation, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–32) when measured for the transmit and receive pairs from 1 MHz to 500 MHz. However, for frequencies that correspond to calculated values greater than 75 dB, the requirement reverts to the minimum requirement of 75 dB.

$$\{NEXTconn\}_{\text{dB}} \leq \left\{ \begin{array}{ll} 54 - 20 \times \log_{10}\left(\frac{f}{100.}\right) & \text{for } (1 \leq f \leq 250) \\ 46.04 - 40 \times \log_{10}\left(\frac{f}{250}\right) & \text{for } (250 < f \leq 500) \end{array} \right\}_{\text{dB}} \tag{145–32}$$

where

NEXTconn is the Near End Crosstalk loss in dB
f is the frequency expressed in MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

145.4.9.1.2 Insertion loss

Insertion loss is a measure of the signal loss between the transmitter and receiver, expressed in dB relative to the received signal level. For other than 5GBASE-T or 10GBASE-T operation, insertion loss for Midspan PSE devices shall meet the values determined by Equation (145–33) when measured for the transmit and receive pairs from 1 MHz to 100 MHz. For 5GBASE-T capable midspans, insertion loss for Midspan PSE devices shall meet the values determined by Equation (145–33) when measured for the transmit and receive pairs from 1 MHz to 250 MHz. For 10GBASE-T operation, insertion loss for Midspan PSE devices shall meet the values determined by Equation (145–33) when measured from the transmit and receive pairs from 1 MHz to 500 MHz. For frequencies that correspond to calculated values less than 0.1 dB, the requirement reverts to the maximum requirement of 0.1 dB.

$$\{ILconn\}_{\text{dB}} \leq 0.04 \times \sqrt{f} \qquad (145–33)$$

where

ILconn is the insertion loss in dB
f is the frequency expressed in MHz

145.4.9.1.3 Return loss

Return loss is a measure of the reflected energy caused by impedance mismatches in the cabling system and is expressed in dB relative to the reflected signal level. Return loss for Midspan PSE devices shall meet or exceed the values specified in Table 145–36.

Table 145–36—Connector return loss

Midspan PSE Variant	Frequency	Return loss
10/100/1000BASE-T	1 MHz ≤ f < 20 MHz	23 dB
	20 MHz ≤ f ≤ 100 MHz	14 dB
2.5GBASE-T	1 MHz ≤ f < 31.5 MHz	30 dB
	31.5 MHz ≤ f < 100 MHz	20 – 20 $\log_{10}$(f/100)
5GBASE-T	1 MHz ≤ f < 31.5 MHz	30 dB
	31.5 MHz ≤ f < 250 MHz	20 – 20 $\log_{10}$(f/100)
10GBASE-T	1 MHz ≤ f < 79 MHz	30 dB
	79 MHz ≤ f ≤ 500 MHz	28 – 20 $\log_{10}$(f/100)

145.4.9.2 Cord Midspan PSE

A Midspan PSE replaces an element in a link segment and shall meet or exceed the insertion loss, NEXT, and return loss values specified Table 145–37 for all data transmitting pairs.

There are five variants of Midspan PSEs defined with respect to transmission requirements:

1) 10BASE-T/100BASE-TX cord Midspan PSE
2) 1000BASE-T cord Midspan PSE
3) 2.5GBASE-T cord Midspan PSE

Copyright © 2022 IEEE. All rights reserved.

4) 5GBASE-T cord Midspan PSE
5) 10GBASE-T cord Midspan PSE

Table 145–37—Cord specifications for use with Midspan PSEs

Highest PHY rate supported	Cord specification	Frequency range
Up to 1000BASE-T	Category 5 cord in ISO/IEC 11801:2002 or ANSI/TIA-568-A:1995	1 MHz ≤ f ≤ 100 MHz
Up to 2.5GBASE-T	Category 5e cord in ISO/IEC 11801:2002 or ANSI/TIA-568-C.2	1 MHz ≤ f ≤ 100 MHz
Up to 5GBASE-T	Category 6 cord in ISO/IEC 11801:2002 or ANSI/TIA-568-C.2	1 MHz ≤ f ≤ 250 MHz
Up to 10GBASE-T	Category 6A cord in ISO/IEC 11801-1 or ANSI/TIA-568-C.2	1 MHz ≤ f ≤ 500 MHz

145.4.9.2.1 Maximum link delay

The propagation delay contribution of the Midspan PSE device shall not exceed 2.5 ns from 1 MHz to the highest referenced frequency.

145.4.9.2.2 Maximum link delay skew

The propagation delay skew of the Midspan PSE device shall not exceed 1.25 ns from 1 MHz to the highest referenced frequency.

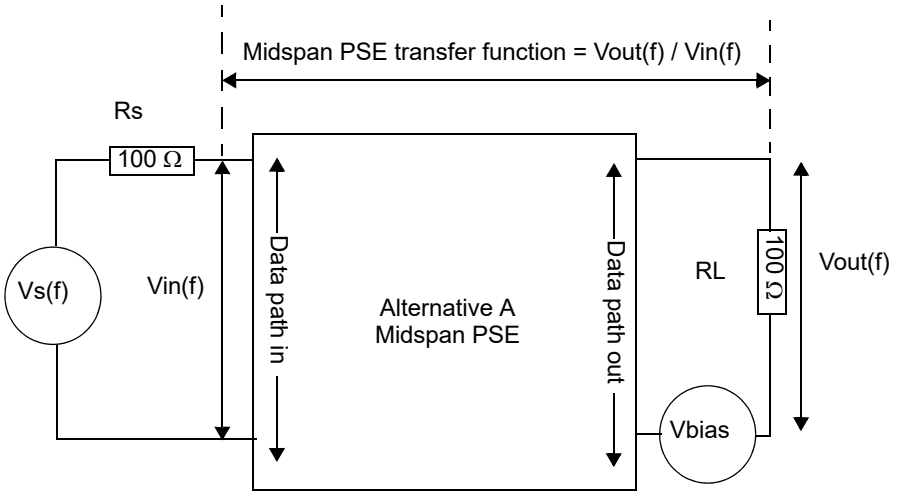
145.4.9.3 Midspan signal path requirements

An Alternative A Midspan PSE transfer function gain shall be greater than that expressed by Equation (145–34) for the frequency range from 0.1 MHz to 1 MHz, at the pins of the PI used as 100BASE-TX transmit pins.

$$\left\{ -0.1 + 37.5 \times \log_{10}\left(\frac{22.4 \times f}{\sqrt{1 + 521 \times f^2}} \right) \right\}_{\text{dB}} \quad (145\text{–}34)$$

where

f is the frequency expressed in MHz



The requirements shall be met with a DC bias current, I_{bias}, between 0 mA and (I_{unb}/2) mA (I_{unb} is defined in Table 145–16).

145.4.9.3.1 Alternative A Midspan PSE signal path transfer function

The transfer function is measured by applying a test signal to the Midspan PSE signal input through a source impedance of 100 Ω ± 1 %. The Midspan PSE signal input and output may be connected to a 0.5 m maximum length of cable, meeting the requirements of 25.4.9, terminated with 100 Ω ± 1 %.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The transfer function is defined from the output termination to the Midspan PSE input. See Figure 145–39.

Vin(f) is the sine wave signal to be used to measure the Midspan PSE transfer function.
Vbias is the DC offset voltage to be applied in series with RL in order to generate I_{bias}.
Vout(f) is the Midspan PSE response to Vin(f).
Some test equipment may require isolation between measurement ports.

Figure 145–39—Measurement setup for Alternative A Midspan PSE transfer function

145.4.9.4 Coupling parameters between link segments

Midspan PSEs intended for operation with 2.5G/5G/10GBASE-T (variants 3 through 5 in 145.4.9.1 and 145.4.9.2) are additionally required to meet the following specifications for PSANEXT and PSAFEXT for coupling signals between ports relating to different link segments. Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. To bound the total alien NEXT loss and alien FEXT loss coupled between link segments, multiple disturber alien near-end crosstalk (MDANEXT) loss and multiple disturber alien FEXT (MDAFEXT) loss is specified.

145.4.9.4.1 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

PSANEXT loss for 2.5G/5G/10GBASE-T capable Midspan PSE devices shall meet or exceed the values determined using Equation (145–35). For other than 5GBASE-T or 10GBASE-T operation, PSANEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–35) from 1 MHz to 100 MHz. For 5GBASE-T capable midspans, PSANEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–35) from 1 MHz to 250 MHz. For 10GBASE-T capable midspans, PSANEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–35) from 1 MHz to 500 MHz. When the computed PSANEXT value at a certain frequency exceeds 67 dB, the PSANEXT result at that frequency is for information only.

$$\text{PSANEXT loss} = 70.5 - 20 \times \log_{10}(f/100) \quad (145–35)$$

145.4.9.4.2 Multiple disturber power sum alien far-end crosstalk (PSAFEXT) loss

PSAFEXT loss for 2.5G/5G/10GBASE-T capable Midspan PSE devices shall meet or exceed the values determined in Equation (145–36). For other than 5GBASE-T or 10GBASE-T operation, PSAFEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–36) from 1 MHz to 100 MHz. For

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

5GBASE-T capable midspans, PSAFEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–36) from 1 MHz to 250 MHz. For 10GBASE-T capable midspans, PSAFEXT loss for Midspan PSE devices shall meet the values determined by Equation (145–36) from 1 MHz to 500 MHz. When the computed PSAFEXT value at a certain frequency exceeds 67 dB, the PSAFEXT result at that frequency is for information only.

$$\text{PSAFEXT loss} = 67 - 20 \times \log_{10}(f / 100) \quad (145\text{–}36)$$

145.5 Data Link Layer classification

Additional control and classification functions are supported using Data Link Layer classification using frames based on the IEEE 802.3 Organizationally Specific TLVs defined in Clause 79. Single-signature PDs that request Class 4 or higher and dual-signature PDs that request Class 4 or higher on either Mode support Data Link Layer classification (see 145.3.6). Data Link Layer classification is optional for all other devices.

145.5.1 TLV frame definition

Implementations that support Data Link Layer classification shall comply with all mandatory parts of IEEE Std 802.1AB-2016; shall support the Power via MDI Type, Length, Value (TLV) defined in 79.3.2 and may support the Power via MDI Measurements TLV defined in 79.3.8.

All reserved fields in transmitted Power via MDI TLVs shall contain zero, and all reserved fields in received Power via MDI TLVs shall be ignored.

145.5.2 Data Link Layer classification timing requirements

PSEs shall send an LLDPDU containing a Power via MDI TLV within 10 seconds of Data Link Layer classification being enabled in the PSE as indicated by the variable pse_dll_enable (145.2.5.4, 145.5.3.2.2).

PDs shall set the variable pd_dll_ready within 5 minutes of Data Link Layer classification being enabled in a PD as indicated by the variable pd_dll_enable (145.3.3.3.2, 145.3.3.4.2, and 145.5.3.3.1).

The PSE shall send an LLDPDU containing a Power via MDI TLV with an updated value for the ‘PSE allocated power value’ field, ‘PSE allocated power value Alternative A’ field, and ‘PSE allocated power value Alternative B’ field within 10 seconds of receiving an LLDPDU containing a Power via MDI TLV where the ‘PD requested power value’ field, ‘PD requested power value for Mode A’ field, or ‘PD requested power value for Mode B’ field is different from the previously communicated value.

The PD shall send an LLDPDU containing a Power via MDI TLV with an updated value for the ‘PD requested power value’ field, ‘PD requested power value for Mode A’ field, and ‘PD requested power value for Mode B’ field within 10 seconds of receiving an LLDPDU containing a Power via MDI TLV where the ‘PSE allocated power value’ field, ‘PSE allocated power value Alternative A’ field, or ‘PSE allocated power value Alternative B’ field is different from the previously communicated value.

145.5.3 Power control state diagrams

The power control state diagrams for PSEs and PDs specify the externally observable behavior of a PSE and PD Data Link Layer classification respectively.

Data Link Layer classification of PSEs shall provide the behavior in the state diagrams defined in Figure 145–40, Figure 145–41, Figure 145–42, and Figure 145–43.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Single-signature PD Data Link Layer classification shall provide the behavior of the state diagrams defined in Figure 145–44 and Figure 145–45. Dual-signature PD Data Link Layer classification shall provide the behavior of the state diagram defined in Figure 145–46 and Figure 145–47.

145.5.3.1 Conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of state diagrams as described in 145.2.5.2.

145.5.3.2 PSE power control state diagrams

145.5.3.2.1 Alternative designation

Dual-signature PSEs provide the behavior of the state diagram shown in Figure 145–46 over each pairset independently unless otherwise specified. All the parameters that apply to Alternative A and Alternative B are denoted with the suffix "_alt(X)" where "X" can be "A" or "B", or "_alt(P)" where "P" can be "A" or "B". A parameter that ends with the suffix "_alt(X)" may have different values for Alternative A and Alternative B.

PSEs providing power to a dual-signature PD operate over two semi-independent state diagrams, one for Alternative A, another for Alternative B. Alternative information is obtained by replacing the X in the desired variable or function with the letter of the Alternative of interest. Alternatives are referred to in general as follows:

X

Generic Alternative designator. When X is used in a state diagram, its value is local to that state diagram and not global to the set of state diagrams.
Values:
A: Alternative A
B: Alternative B

P

Powered Alternative designator. When P is used in a state diagram, its value is local to that state diagram and not global to the set of state diagrams. "P" refers to the Alternative that is currently powered. Its value is only defined when the PSE operates in 2-pair mode.
Values:
A: Alternative A
B: Alternative B

145.5.3.2.2 Variables

The PSE power control state diagrams in Figure 145–40, Figure 145–41, Figure 145–42, and Figure 145–43 use the following variables:

MirroredPDAutoclassRequest

The copy of the 'PD Autoclass request' field in the Power via MDI TLV that the PSE receives from the remote system. This variable is mapped from aLldpXdot3RemAutoclassRequest (30.12.3.1.35) and assigned through Table 145–38.
Values:
FALSE: The PD does not request an Autoclass measurement to be performed.
TRUE: The PD requests an Autoclass measurement to be performed.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

MirroredPDRequestedPowerValue

The copy of the ‘PD Requested Power Value’ field in the Power Via MDI TLV that the PSE receives from the remote system in units of 0.1 W. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValue attribute (30.12.3.1.17) and set through Table 145–38.

Values: 0 through 999, and 0xACAC

MirroredPDRequestedPowerValue_alt(X)

The copy of the ‘PD Requested Power Value’ field for Alternative(X) in the Power Via MDI TLV that the PSE receives from the remote system in units of 0.1 W. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValueA and aLldpXdot3RemPDRequestedPowerValueB attribute (30.12.3.1.18 and 30.12.3.1.19) and set through Table 145–38.

Values: 0 through 499

MirroredPSEAllocatedPowerValueEcho

The copy of the ‘PSE Allocated Power Value’ field in the Power Via MDI TLV that the PSE receives from the remote system. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValue attribute (30.12.3.1.20) and set through Table 145–38.

Values: 0 through 999, and 0xACAC

MirroredPSEAllocatedPowerValueEcho_alt(X)

The copy of the ‘PSE Allocated Power Value’ field for Alternative(X) in the Power Via MDI TLV that the PSE receives from the remote system. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValueA and aLldpXdot3RemPSEAllocatedPowerValueB attribute (30.12.3.1.21 and 30.12.3.1.22) and set through Table 145–38.

Values: 0 through 499

PDRequestedPowerValueEcho

This variable is updated by the PSE state diagram. This variable maps into the aLldpXdot3LocPDRequestedPowerValue attribute (30.12.2.1.17).

Values: 0 through 999, and 0xACAC

PDRequestedPowerValueEcho_alt(X)

This variable is updated by the PSE state diagram. This variable maps into the aLldpXdot3LocPDRequestedPowerValueA and aLldpXdot3LocPDRequestedPowerValueB attribute (30.12.2.1.18 and 30.12.2.1.19).

Values: 0 through 499

PSEAllocatedPowerValue

Integer that indicates the PSE allocated power value in the PSE in units of 0.1 W. The value is the maximum input average power (see 145.3.8.2) the PD ever draws. This variable maps to the aLldpXdot3LocPSEAllocatedPowerValue attribute (30.12.2.1.20). A value higher than 713 indicates that the PSE is capable of supporting a power level beyond P_{Class_PD} at the PD PI. This may require an output power level higher than P_{Type} min. See 145.2.8.

Values: 0 through 999, and 0xACAC

PSEAllocatedPowerValue_alt(X)

Integer that indicates the PSE allocated power value in the PSE in units of 0.1 W. The value is the maximum input average power (see 145.3.8.2) the PD ever draws. This variable maps to the aLldpXdot3LocPSEAllocatedPowerValueA and aLldpXdot3LocPSEAllocatedPowerValueB attribute (30.12.2.1.21 and 30.12.2.1.22). A value higher than 356 indicates that the PSE is capable of supporting a power level beyond P_{Class_PD} at the PD PI. This may require an output power level higher than P_{Type} min. See 145.2.8.

Values: 0 through 499

PSEAutoclassCompleted

A Boolean that indicates the PSE has completed the PD Autoclass request. This variable is mapped into the aLldpXdot3LocAutoclassCompleted (30.12.2.1.34) attribute.

Values:

FALSE: The PSE has not completed the Autoclass measurement, or it is not performing an Autoclass measurement.

TRUE: The PSE has completed the Autoclass measurement.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PSEAutoclassSupport

A Boolean variable that indicates if the PSE supports Autoclass in the PSE. This variable is mapped into the aLldpXdot3LocPSEAutoclassSupport (30.12.2.1.33) attribute.

Values:

FALSE: The PSE does not support Autoclass.

TRUE: The PSE supports Autoclass.

TempVar

A variable used to store Power Value in units of 0.1 W.

Values: 0 through 999, and 0xACAC

TempVar_alt(X)

A variable used to store a Power Value in units of 0.1 W.

Values: 0 through 499.

alt_pri

A variable used to select which Alternative assumes the role of Primary Alternative in the PSE state diagram in Figure 145–13.

Values:

a: Alternative A assumes the role of Primary Alternative. When operating over 4 pairs, Alternative B assumes the role of Secondary Alternative.

b: Alternative B assumes the role of Primary Alternative. When operating over 4 pairs, Alternative A assumes the role of Secondary Alternative.

fourpairmode

Alias for the following term: (alt_pwrd_pri * alt_pwrd_sec)

local_system_change

An implementation-specific variable that indicates that the local system wants to change the allocated power value. This indicates the PSE is going to change the power allocated to the PD. This variable may be set by the PSE at any time.

Values:

FALSE: The PSE does not want to change the power allocation.

TRUE: The PSE wants to change the power allocation.

local_system_change_alt(X)

An implementation-specific variable that indicates that the local system wants to change the allocated power value. This indicates the PSE is going to change the power allocated to the PD for Alternative(X). This variable may be set by the PSE at any time.

Values:

FALSE: The PSE does not wants to change the power allocation.

TRUE: The PSE wants to change the power allocation.

pse_alternative

This variable defined in 145.2.5.4 indicates which Pinout Alternative the PSE uses to apply power to the PI (see Table 145–3).

Values:

a: The PSE uses PSE pinout Alternative A.

b: The PSE uses PSE pinout Alternative B.

both: The PSE uses both Alternative A and Alternative B.

pse_dll_enable

A variable output by the PSE state diagram (Figure 145–13) to indicate if the PSE Data Link Layer classification mechanism is enabled.

Values:

FALSE: PSE Data Link Layer classification is not enabled.

TRUE: PSE Data Link Layer classification is enabled.

pse_dll_ready

See pse_dll_ready in 145.2.5.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pse_initial_value

The value of this variable is valid after classification and is derived from the pse_allocated_pwr, pd_autoclass, and pd_autoclass_cancelled variables (145.2.5.4), which are used in the PSE state diagrams in 145.2.5.7. The value is quantized to fit the available resolution. Additional information on power levels for Class 8 may be found in 145.3.8.2.1. This variable is set per this description.

Values:

pse_allocated_pwr	pse_initial_value
1	39
2	65
3	130
4	255
5	400
6	510
7	620
8	713
Autoclass	44 204

NOTE—If pd_autoclass is TRUE and pd_autoclass_cancelled is FALSE, then pse_initial_value is set to the value 0xACAC (decimal 44 204).

pse_initial_value_alt(X)

The value of this variable is valid after classification and is derived from pse_allocated_pwr_pri and pse_allocated_pwr_sec variables (145.2.5.6), which are used in the PSE state diagrams in 145.2.5.7. The value is quantized to fit the available resolution. Additional information on power levels for Class 5 may be found in 145.3.8.2.1. This variable is set per this description.

Values:

pse_allocated_pwr_pri/sec	pse_initial_value_alt(X)
1	39
2	65
3	130
4	255
5	356

pse_power_update

A variable that is set when the PSEAllocatedPowerValue in the DLL state diagram in Figure 145–40 has been updated.

Values:

FALSE: The value of PSEAllocatedPowerValue has not changed.
TRUE: The value of PSEAllocatedPowerValue has changed.

pse_power_update_pri

A variable that is set when the PSEAllocatedPowerValue_alt(X) in the DLL state diagram in Figure 145–42 or Figure 145–43 has been updated.

Values:

FALSE: The value of PSEAllocatedPowerValue_alt(X) has not changed.
TRUE: The value of PSEAllocatedPowerValue_alt(X) has changed.

pse_power_update_sec

A variable that is set when the PSEAllocatedPowerValue_alt(X) in the DLL state diagram in Figure 145–42 or Figure 145–43 has been updated.

Values:

FALSE: The value of PSEAllocatedPowerValue_alt(X) has not changed.
TRUE: The value of PSEAllocatedPowerValue_alt(X) has changed.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

sig_type

A variable generated from the do_cxn_chk function of the PSE state diagram in Figure 145–13, which indicates if the PSE is connected to a single-signature PD or a dual-signature PD.

Values:

- invalid: Neither a single-signature PD nor a dual-signature PD connection check signature has been found. This includes an open circuit condition.
- single: The PSE has determined there is a single-signature PD configuration connected to the PI.
- dual: The PSE has determined there is a dual-signature PD configuration connected to the PI.

twopairmode

Alias for the following term: (alt_pwrd_pri ^ alt_pwrd_sec)

A summary cross-references between the Power over Ethernet classification local and remote object class attributes and the PSE power control state diagrams, including the direction of the mapping, is provided in Table 145–38.

145.5.3.2.3 Functions

do_autoclass_measure

A function defined in the PSE state diagram, which measures $P_{Autoclass}$ as defined in 145.2.8.2.

do_pse_power_review

This function evaluates the power allocation or budget of the PSE based on local system changes or changes of the PD requested power value.

The function returns the following variable:

pse_new_value:

The new maximum power value that the PSE expects the PD to draw in units of 0.1 W.

Valid values: 1 through 999, and 0xACAC

do_pse_power_review_alt(X)

This function evaluates the power allocation or budget of the PSE based on local system changes.

The function returns the following variable:

pse_new_value_alt(X):

The new maximum power value that the PSE expects the PD to draw in units of 0.1 W.

145.5.3.3 Single-signature PD power control state diagrams

This state diagram controls the PDRequestedPowerValue variable, which is used to request power from a PSE, for single-signature PDs.

145.5.3.3.1 Variables

The PD power control state diagram (Figure 145–44 and Figure 145–45) uses the following variables:

MirroredPDRequestedPowerValueEcho
: The copy of the 'PD Requested Power Value' field in the Power Via MDI TLV that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValue attribute (30.12.3.1.17).
Values: 1 through 999, and 0xACAC

MirroredPSEAllocatedPowerValue
: The copy of the 'PSE Allocated Power Value' field in the Power Via MDI TLV that the PD receives from the remote system in units of 0.1 W. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValue attribute (30.12.3.1.20).
Values: 1 through 999, and 0xACAC

MirroredPSEAutoclassCompleted
: The copy of the 'PSE Autoclass completed' field in the Power via MDI TLV that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemAutoclassCompleted (30.12.3.1.34) attribute.
Values:
  FALSE: The PSE has not completed the Autoclass measurement, or it is not performing an Autoclass measurement.
  TRUE: The PSE has completed the Autoclass measurement.

MirroredPSEAutoclassSupport
: The copy of the 'PSE Autoclass support' field in the Power via MDI TLV that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemPSEAutoclassSupport (30.12.3.1.33) attribute.
Values:
  FALSE: The PSE does not support Autoclass
  TRUE: The PSE supports Autoclass

PDAutoclassRequest
: A Boolean that indicates if the PD requests Autoclass in the PD. This variable is mapped into aLldpXdot3LocAutoclassRequest (30.12.2.1.35).
Values:
  FALSE: The PD does not request an Autoclass measurement to be performed.
  TRUE: The PD requests an Autoclass measurement to be performed.

PDMaxPowerValue
: Integer that indicates the actual PD power value of the local system in units of 0.1 W. The actual PD power value for a PD is the maximum input average power (see 145.3.8.2) the PD ever draws under the current power allocation. See 145.3.8.2 for values higher than 713.
Values: 1 through 999, and 0xACAC

PDRequestedPowerValue
: Integer that indicates the PD requested power value in the PD in units of 0.1 W. The value is the maximum input average power (see 145.3.8.2) the PD requests. This variable is mapped into the aLldpXdot3LocPDRequestedPowerValue attribute (30.12.2.1.17). A value higher than 713 requires the PSE to support a power level higher than P_{Class_PD} at the PD PI.
Values: 1 through pd_dllmax_value, and 0xACAC

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PDRequestedPowerValue_mode(X)

Integer that indicates the PD requested power value in the PD in units of 0.1 W. This variable is set to 0 by the single-signature PD power control state diagram. This variable is mapped into the aLldpXdot3LocPDRequestedPowerValueA and aLldpXdot3LocPDRequestedPowerValueB attribute (30.12.2.1.18 and 30.12.2.1.19).

Values: 0

PSEAllocatedPowerValueEcho

This variable is updated by the PD state diagram. This variable maps into the aLldpXdot3LocPSEAllocatedPowerValue attribute (30.12.2.1.20).

Values: 1 through 999, and 0xACAC

PSEAllocatedPowerValueEcho_mode(X)

This variable is updated by the PD state diagram. This variable is set to 0 by the single-signature PD power control state diagram. This variable maps into the aLldpXdot3LocPSEAllocatedPowerValueA and aLldpXdot3LocPSEAllocatedPowerValueB attribute (30.12.2.1.21 and 30.12.2.1.22).

Values: 0

TempVar

A variable used to store Power Value in units of 0.1 W.

Values: 0 through 999, and 0xACAC

dll_4PID

A variable indicating the state of the PD 4PID bit in the ‘Power type/source/priority’ field, as defined in Table 79–7. This variable is assigned through Table 145–39.

Values:

FALSE: The PD does not support powering of both Modes simultaneously.
TRUE: The PD supports powering of both Modes simultaneously.

local_system_change

An implementation-specific variable that indicates that the local system wants to change the allocated power value. In a PD, this indicates it is going to request a new power allocation from the PSE. This value may be set by the PD at any time.

Values:

FALSE: The PD does not want to change the power allocation.
TRUE: The PD wants to change the power allocation.

pd_dllmax_value

This value is derived from pd_req_class (145.3.3.3.2). The value is quantized to fit the available resolution. Additional information on power levels for Class 8 may be found in 145.3.8.2.1. This variable is set per this description.

pd_req_class	pd_dllmax_value
1	39
2	65
3	130
4	255
5	400
6	510
7	620
8	999

pd_dll_enable

A variable output by the PD state diagram (Figure 145–25) to indicate if the PD Data Link Layer classification mechanism is enabled.

Values:

FALSE: PD Data Link Layer classification is not enabled.
TRUE: PD Data Link Layer classification is enabled.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_dll_ready

An implementation-specific variable that indicates that the PD has initialized Data Link Layer classification. This variable maps into the aLldpXdot3LocReady attribute (30.12.2.1.61).

Values:

FALSE: Data Link Layer classification has not completed initialization.
TRUE: Data Link Layer classification has completed initialization.

pd_initial_value

The value of this variable is valid after classification and is derived from the pd_max_power, pd_acs_cancel, and pd_autoclass_enable variables (145.3.3.3.2) used in the Single-signature PD state diagram (Figure 145–25). The value is quantized to fit the available resolution. Additional information on power levels for Class 8 may be found in 145.3.8.2.1. This variable is set per this description.

Values:

pd_max_power	pd_initial_value
1	≤ 39
2	≤ 65
3	≤ 130
4	≤ 255
5	≤ 400
6	≤ 510
7	≤ 620
8	≤ 713
Autoclass	44 204

NOTE—If pd_autoclass_enable is TRUE and pd_acs_cancel is FALSE, then pd_initial_value is set to the value 0xACAC (decimal 44 204).

pd_power_update

A variable that is set when the PDMaxPowerValue in the DLL state diagram in Figure 145–44 has been updated.

Values:

FALSE: The value of PDMaxPowerValue has not changed.
TRUE: The value of PDMaxPowerValue has changed.

trigger_autoclass

A variable used in the PD to trigger a new Autoclass measurement request to the PSE.

Values:

FALSE: The PD does not want to trigger a new Autoclass measurement.
TRUE: The PD wants to trigger a new Autoclass measurement.

A summary cross-references between the Power over Ethernet classification local and remote object class attributes and the PD power control state diagrams, including the direction of the mapping, is provided in Table 145–39.

145.5.3.3.2 Timers

tautoclass_timeout

A timer used to detect the timeout of a pending Autoclass request by the PD. The value of this timer may be set to any value greater than 30 seconds.

145.5.3.3.3 Functions

do_pd_power_review

This function evaluates the power requirements of the PD based on local system changes or changes in the PSE allocated power value. The function returns the following variable:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_new_value:
The new maximum power value that the PD wants to draw in units of 0.1 W.
Valid values: 1 through 999, and 0xACAC

145.5.3.3.4 Attribute to state diagram variable mapping

Table 145–39 shows the mapping between state diagram variables and Clause 30 attributes for single-signature PDs.

Table 145–39—Attribute to state diagram variable cross reference for single-signature PDs

Attribute	Mapping	State diagram variable
oLldpXdot3LocSystemsGroup Object Class		
aLldpXdot3LocPDRequestedPowerValue	⇐	PDRequestedPowerValue
aLldpXdot3LocPSEAllocatedPowerValue	⇐	PSEAllocatedPowerValueEcho

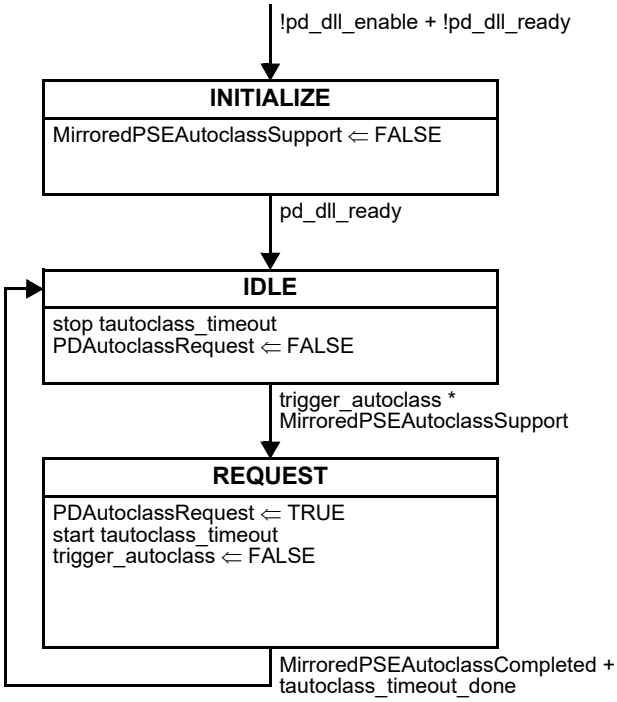

Figure 145–45—PD DLL Autoclass control state diagram

145.5.3.4 Dual-signature PD power control state diagrams

This state diagram controls the PDRequestedPowerValue_mode(X) variables, which are used to allocate power to the individual Modes of a dual-signature PD. It is applicable when the PD is a dual-signature PD that is supplied in 4-pair mode.

145.5.3.4.1 Mode designation

Dual-signature PDs provide the behavior of the state diagram shown in Figure 145–46 over each pairset independently unless otherwise specified. All the parameters that apply to Mode A and Mode B are denoted with the suffix "_mode(X)" where "X" can be "A" or "B", or "_mode(P)" where "P" can be "A" or "B". A parameter that ends with the suffix "_mode(X)" may have different values for Mode A and Mode B.

Dual-signature PDs are implemented on Mode A and Mode B as defined in 145.3.2. Mode information is obtained by replacing the X in the desired variable or function with the letter of the Mode of interest. Modes are referred to in general as follows:

X

Generic Mode designator. When X is used in a state diagram, its value is local to that state diagram and not global to the set of state diagrams.
Values:

A: Mode A
B: Mode B

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

P

Powered Mode designator. When P is used in a state diagram, its value is local to that state diagram and not global to the set of state diagrams. “P” refers to the Mode that is currently powered. Its value is only defined when the PD is powered over 2-pair.

Values:

A: Mode A

B: Mode B

145.5.3.4.2 Variables

The PD power control state diagram (Figure 145–46 and Figure 145–47) use the following variables:

MirroredPDRequestedPowerValueEcho

The copy of the ‘PD Requested Power Value’ field in the Power Via MDI TLV that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValue attribute (30.12.3.1.17).

Values: 0 through 999

MirroredPDRequestedPowerValueEcho_mode(X)

The copy of the ‘PD Requested Power Value’ field for Mode(X) in the Power Via MDI TLV that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValueA and aLldpXdot3RemPDRequestedPowerValueB attribute (30.12.3.1.18 and 30.12.3.1.19).

Values: 0 through 499

MirroredPSEAllocatedPowerValue

The copy of the ‘PSE Allocated Power Value’ field in the Power Via MDI TLV that the PD receives from the remote system in units of 0.1 W. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValue attribute (30.12.3.1.20).

Values: 0 through 999

MirroredPSEAllocatedPowerValue_mode(X)

The copy of the ‘PSE Allocated Power Value’ field for Mode(X) in the Power Via MDI TLV that the PD receives from the remote system in units of 0.1 W. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValueA and aLldpXdot3RemPSEAllocatedPowerValueB attribute (30.12.3.1.21 and 30.12.3.1.22).

Values: 0 through 499

PDMaxPowerValue_mode(X)

Integer that indicates the actual PD power value of the local system in units of 0.1 W. The actual PD power value for a PD is the maximum input average power (see 145.3.8.2) the PD ever draws under the current power allocation.

Values: 1 through 499

PDRequestedPowerValue

Integer that indicates the PD requested power value in the PD in units of 0.1 W. The value is the maximum input average power (see 145.3.8.2) the PD requests. This variable is mapped into the aLldpXdot3LocPDRequestedPowerValue attribute (30.12.2.1.17). A value higher than 713 requires the PSE to support a power level higher than P_{Class_PD} at the PD PI.

Values: 0 through pd_dllmax_value_mode(P)

PDRequestedPowerValue_mode(X)

Integer that indicates the PD requested power value in the PD in units of 0.1 W. The value is the maximum input average power (see 145.3.8.2) the PD requests. This variable is updated by the PD state diagram. This variable is mapped into the aLldpXdot3LocPDRequestedPowerValueA and aLldpXdot3LocPDRequestedPowerValueB attribute (30.12.2.1.18 and 30.12.2.1.19). A value higher than 356 requires the PSE to support a power level higher than P_{Class_PD} at the PD PI.

Values: 0 through pd_dllmax_value_mode(X)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PSEAllocatedPowerValueEcho

This variable is updated by the PD state diagram. This variable maps into the aLldpXdot3LocPSEAllocatedPowerValue attribute (30.12.2.1.20).

Values: 0 through 999

PSEAllocatedPowerValueEcho_mode(X)

This variable is updated by the PD state diagram. This variable maps into the aLldpXdot3LocPSEAllocatedPowerValueA and aLldpXdot3LocPSEAllocatedPowerValueB attribute (30.12.2.1.21 and 30.12.2.1.22).

Values: 0 through 499

TempVar

A variable used to store Power Value in units of 0.1 W.

Values: 0 through 999

TempVar_mode(X)

A variable used to store a Power Value in units of 0.1 W.

Values: 0 through 499.

dll_4PID

A variable indicating the state of the PD 4PID bit in the 'Power type/source/priority' field, as defined in Table 79–7. This variable is updated by the PD state diagram. This variable is mapped into the aLldpXdot3LocPD4PID attribute (30.12.2.1.31).

Values:

FALSE: The PD does not support powering of both Modes simultaneously.

TRUE: The PD supports powering of both Modes simultaneously.

fourpairmode

Alias for the following term: (present_mps_mode(A) * present_mps_mode(B))

local_system_change_mode(X)

An implementation-specific variable that indicates that the local system wants to change the allocated power value. This indicates the PD is going to request a new power allocation from the PSE over Mode(X).

Values:

FALSE: The local system does not wants to change the power allocation.

TRUE: The local system wants to change the power allocation.

pd_dllmax_value_mode(X)

This value is derived from pd_req_class_mode(X) (145.3.3.4.1). The value is quantized to fit the available resolution. Additional information on power levels for Class 5 may be found in 145.3.8.2.1. This variable is set per this description.

pd_req_class_mode(X)	pd_dllmax_value_mode(X)
1	39
2	65
3	130
4	255
5	356

pd_dll_enable

A variable output by the PD state diagram (Figure 145–25) to indicate if the PD Data Link Layer classification mechanism is enabled.

Values:

FALSE: PD Data Link Layer classification is not enabled.

TRUE: PD Data Link Layer classification is enabled.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_dll_ready

An implementation-specific variable that indicates that the PD has initialized Data Link Layer classification. This variable maps into the aLldpXdot3LocReadyattribute (30.12.2.1.61).

Values:

FALSE: Data Link Layer classification has not completed initialization.

TRUE: Data Link Layer classification has completed initialization.

pd_initial_value_mode(X)

The value of this variable is valid after classification and is derived from the pd_max_power_mode(X) (145.3.3.4.2) variable used in the PD state diagrams; defined in Figure 145–27. The value is quantized to fit the available resolution. Additional information on power levels for Class 5 may be found in 145.3.8.2.1.

Values:

pd_max_power_mode(X)	pd_initial_value_mode(X)
1	≤ 39
2	≤ 65
3	≤ 130
4	≤ 255
5	≤ 356

pd_power_update_mode(X)

A variable that is set when the PDMaxPowerValue_mode(X) has been updated.

Values:

FALSE: The value of PDMaxPowerValue_mode(X) has not changed.

TRUE: The value of PDMaxPowerValue_mode(X) has changed.

pd_requested_value_mode(X)

The value of this variable is used by the dual-signature PD to indicate the amount of power it requires on Mode A and Mode B, while it is being powered in 2-pair mode.

Values: 1 through 499

twopairmode

Alias for the following term: (present_mps_mode(A) ^ present_mps_mode(B))

145.5.3.4.3 Functions

do_pd_power_review_mode(X)

This function evaluates the power requirements of the PD based on local system changes or changes in the PSE allocated power value.

The function returns the following variable:

pd_new_value_mode(X):

The new maximum power value that the PD wants to draw in units of 0.1 W.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

145.5.3.4.4 Attribute to state diagram variable mapping

Table 145–40 shows the mapping between state diagram variables and Clause 30 attributes for dual-signature PDs.

Table 145–40—Attribute to state diagram variable cross reference for dual-signature PDs

Attribute	Mapping	State diagram variable

145.5.4 Power requests and allocations

The variables PDRequestedPowerValue and PDRequestedPowerValue_mode(X) allow a PD to request an amount of power from the PSE. The variables PSEAllocatedPowerValue and PSEAllocatedPowerValue_alt(X) allow the PSE to allocate an amount of power to the PD.

PSEs shall use values in the range defined in Table 145–41 for PSEAllocatedPowerValue and PSEAllocatedPowerValue_alt(X) where X can be A or B. PDs shall use the values in the range defined in Table 145–42 for PDRequestedPowerValue and PDRequestedPowerValue_mode(X) where X can be A or B.

Table 145–41—Permitted values for PSEAllocatedPowerValue and PSEAllocatedPowerValue_alt(X)

Powering mode	PD configuration	PSEAllocatedPowerValue	PSEAllocatedPowerValue_alt(X)
2-pair	—	1 to 255[a]	0
4-pair	single-signature	1 to 999	0
	dual-signature	0	1 to 499

[a] A PSE that has encountered a fault that requires to operate in 2-pair mode, may use values 1 to 499 for this variable.

Table 145–42—Permitted values for PDRequestedPowerValue and PDRequestedPowerValue_mode(X)

Powering mode	PD configuration	PDRequestedPowerValue	PDRequestedPowerValue_mode(X)
—	single-signature	1 to 999	0
2-pair	dual-signature	1 to 255[a]	1 to 499
4-pair		0	1 to 499

[a] A PD that has encountered a fault that requires to operate in 2-pair mode, may use values 1 to 499 for this variable.

Power requests and allocations greater than 713 (for single-signature PDs) or greater than 356 (for dual-signature PDs) are only used after the PSE and PD are in sync using the initial values that are assigned in INITIALIZE, as defined in Figure 145–40 through Figure 145–47.

145.5.5 State change procedure across a link (single-signature)

The PSE and PD utilize the LLDPDUs to advertise their various attributes to the other entity.

The PD may request a new power value through the aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17) attribute in the oLldpXdot3LocSystemsGroup object class. The request appears to the PSE as a change to the aLldpXdot3RemPDRequestedPowerValue (30.12.3.1.17) attribute in the oLldpXdot3RemSystemsGroup object class.

The PSE responds to the PD's request through the aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20) attribute in the oLldpXdot3LocSystemsGroup object class. The PSE also copies the value of the aLldpXdot3RemPDRequestedPowerValue (30.12.3.1.17) in the oLldpXdot3RemSystemsGroup object class to the aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17) in the oLldpXdot3LocSystemsGroup object

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

class. This appears to the PD as a change to the aLldpXdot3RemPSEAllocatedPowerValue (30.12.3.1.20) attribute in the oLldpXdot3RemSystemsGroup object class.

The PSE may allocate a new power value through the aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20) attribute in the oLldpXdot3LocSystemsGroup object class. The request appears to the PD as a change to the aLldpXdot3RemPSEAllocatedPowerValue (30.12.3.1.20) attribute in the oLldpXdot3RemSystemsGroup object class. The PD responds to a PSE's request through the aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17) attribute in the oLldpXdot3LocSystemsGroup object class. The PD also copies the value of the aLldpXdot3RemPSEAllocatedPowerValue (30.12.3.1.20) attribute in the oLldpXdot3RemSystemsGroup object class to the aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20) attribute in the oLldpXdot3LocSystemsGroup object class. This appears to the PSE as a change to the aLldpXdot3RemPDRequestedPowerValue (30.12.3.1.17) attribute in the oLldpXdot3RemSystemsGroup object class.

The state diagrams in Figure 145–40 and Figure 145–44 describe the behavior above.

145.5.5.1 PSE state change procedure across a link (single-signature)

A PSE is considered to be in sync with the PD when the value of PSEAllocatedPowerValue matches the value of MirroredPSEAllocatedPowerValueEcho.

During normal operation, the PSE is in RUNNING. If the PSE wants to initiate a change in the PD allocation, the local_system_change is asserted and the PSE enters PSE_POWER_REVIEW, where a new power allocation value, pse_new_value, is computed. If the PSE is in sync with the PD or if pse_new_value is smaller than PSEAllocatedPowerValue, it enters MIRROR_UPDATE where pse_new_value is assigned to PSEAllocatedPowerValue. It also updates PDRequestedPowerValueEcho and returns to RUNNING.

If the PSE's previously stored MirroredPDRequestedPowerValue changes, a request by the PD to change its power allocation is recognized. It entertains this request only when it is in sync with the PD. The PSE examines the request by entering PD_POWER_REQUEST. A new power allocation value, pse_new_value, is computed. It then enters MIRROR_UPDATE where pse_new_value is assigned to PSEAllocatedPowerValue. It also updates PDRequestedPowerValueEcho and returns to RUNNING.

145.5.5.2 PD state change procedure across a link (single-signature)

A PD is considered to be in sync with the PSE when the value of PDRequestedPowerValue matches the value of MirroredPDRequestedPowerValueEcho. The PD is not allowed to change its maximum power draw or the requested power value when it is not in sync with the PSE.

During normal operation, the PD is in RUNNING. If the PD's previously stored MirroredPSEAllocatedPowerValue is changed or local_system_change is asserted by the PD so as to change its power allocation, the PD enters PD_POWER_REVIEW. In this state, the PD evaluates the change and generates an updated power value called pd_new_value. If pd_new_value is less than PDMaxPowerValue, it updates PDMaxPowerValue in PD_POWER_REALLOCATION1. The PD then finally enters MIRROR_UPDATE where pd_new_value is assigned to PDRequestedPowerValue. It also updates PSEAllocatedPowerValueEcho and returns to RUNNING.

In the above flow, if pd_new_value is greater than PDMaxPowerValue, the PD waits until it is in sync with the PSE and the PSE grants the higher power value. When this condition arises, the PD enters PD_POWER_REALLOCATION2. In this state, the PD assigns PDMaxPowerValue to PDRequestedPowerValue and returns to RUNNING.

145.5.6 State change procedure across a link (dual-signature)

The PSE and PD use the LLDP protocol (see Clause 79) to advertise their various attributes to the other entity.

The PD may request a new power value through the aLldpXdot3LocPDRequestedPowerValueA and aLldpXdot3LocPDRequestedPowerValueB (30.12.2.1.18 and 30.12.2.1.19) attribute in the oLldpXdot3LocSystemsGroup object class. The request appears to the PSE as a change to the aLldpXdot3RemPDRequestedPowerValueA and aLldpXdot3RemPDRequestedPowerValueB (30.12.3.1.18 and 30.12.3.1.19) attribute in the oLldpXdot3RemSystemsGroup object class.

The PSE responds to the PD's request through the aLldpXdot3LocPSEAllocatedPowerValueA and aLldpXdot3LocPSEAllocatedPowerValueB (30.12.2.1.21 and 30.12.2.1.22) attribute in the oLldpXdot3LocSystemsGroup object class. The PSE also copies the value of the aLldpXdot3RemPDRequestedPowerValueA and aLldpXdot3RemPDRequestedPowerValueB (30.12.3.1.18 and 30.12.3.1.19) in the oLldpXdot3RemSystemsGroup object class to the aLldpXdot3LocPDRequestedPowerValueA and aLldpXdot3LocPDRequestedPowerValueB (30.12.2.1.18 and 30.12.2.1.19) in the oLldpXdot3LocSystemsGroup object class. This appears to the PD as a change to the aLldpXdot3RemPSEAllocatedPowerValueA and aLldpXdot3RemPSEAllocatedPowerValueB (30.12.3.1.21 and 30.12.3.1.22) attribute in the oLldpXdot3RemSystemsGroup object class.

The PSE may allocate a new power value through the aLldpXdot3LocPSEAllocatedPowerValueA and aLldpXdot3LocPSEAllocatedPowerValueB (30.12.2.1.18 and 30.12.2.1.19) attribute in the oLldpXdot3LocSystemsGroup object class. The request appears to the PD as a change to the aLldpXdot3RemPSEAllocatedPowerValueA and aLldpXdot3RemPSEAllocatedPowerValueB (30.12.3.1.21 and 30.12.3.1.22) attribute in the oLldpXdot3RemSystemsGroup object class. The PD responds to a PSE's request through the aLldpXdot3LocPDRequestedPowerValueA and aLldpXdot3LocPDRequestedPowerValueB (30.12.2.1.18 and 30.12.2.1.19) attribute in the oLldpXdot3LocSystemsGroup object class. The PD also copies the value of the aLldpXdot3RemPSEAllocatedPowerValueA and aLldpXdot3RemPSEAllocatedPowerValueB (30.12.3.1.21 and 30.12.3.1.22) attribute in the oLldpXdot3RemSystemsGroup object class to the aLldpXdot3LocPSEAllocatedPowerValueA and aLldpXdot3LocPSEAllocatedPowerValueB (30.12.2.1.18 and 30.12.2.1.19) attribute in the oLldpXdot3LocSystemsGroup object class. This appears to the PSE as a change to the aLldpXdot3RemPDRequestedPowerValueA and aLldpXdot3RemPDRequestedPowerValueB (30.12.3.1.18 and 30.12.3.1.19) attribute in the oLldpXdot3RemSystemsGroup object class.

The state diagrams in Figure 145–40, Figure 145–42, Figure 145–43, Figure 145–46, and Figure 145–47 describe the behavior above.

145.5.6.1 Transitions between 2-pair and 4-pair mode (dual-signature)

When a PSE, connected to a dual-signature PD, transitions from 4-pair to 2-pair operation, it shall assign the value of PSEAllocatedPowerValue_alt(X), where X is the powered Alternative, to PSEAllocatedPowerValue. The purpose of this is that the PD can continue operating over the remaining powered Mode.

When a PSE, connected to a dual-signature PD, transitions from 2-pair to 4-pair operation, it shall assign the value of PSEAllocatedPowerValue to PSEAllocatedPowerValue_alt(X), where X is the Alternative that was initially powered.

A dual-signature PD that is switched from 4-pair to 2-pair mode requests the amount of power it needs for 2-pair operation in the PDRequestedPowerValue variable. Per Table 145–42 this is the requested power for the powered Mode.

145.5.6.2 PSE state change procedure across a link (dual-signature)

A PSE is considered to be in sync with the PD when the value of PSEAllocatedPowerValue_alt(X) matches the value of MirroredPSEAllocatedPowerValueEcho_alt(X).

During normal operation, the PSE is in RUNNING. If the PSE wants to initiate a change in the PD allocation, the local_system_change_alt(X) is asserted and the PSE enters PSE_POWER_REVIEW, where a new power allocation value, pse_new_value_alt(X), is computed. If the PSE is in sync with the PD or if pse_new_value_alt(X) is smaller than PSEAllocatedPowerValue_alt(X), it enters MIRROR_UPDATE where pse_new_value_alt(X) is assigned to PSEAllocatedPowerValue_alt(X). It also updates PDRequestedPowerValueEcho_alt(X) and returns to RUNNING.

If the PSE's previously stored MirroredPDRequestedPowerValue_alt(X) changes, a request by the PD to change its power allocation is recognized. It entertains this request only when it is in sync with the PD. The PSE examines the request by entering PD_POWER_REQUEST. A new power allocation value, pse_new_value_alt(X), is computed. It then enters MIRROR_UPDATE where pse_new_value_alt(X) is assigned to PSEAllocatedPowerValue_alt(X). It also updates PDRequestedPowerValueEcho_alt(X) and returns to RUNNING.

145.5.6.3 PD state change procedure across a link (dual-signature)

A PD is considered to be in sync with the PSE when the value of PDRequestedPowerValue_mode(X) matches the value of MirroredPDRequestedPowerValueEcho_mode(X). The PD is not allowed to change its maximum power draw or the requested power value when it is not in sync with the PSE.

During normal operation, the PD is in RUNNING. If the PD's previously stored MirroredPSEAllocatedPowerValue_mode(X) is changed or local_system_change_mode(X) is asserted by the PD so as to change its power allocation, the PD enters PD_POWER_REVIEW. In this state, the PD evaluates the change and generates an updated power value called pd_new_value_mode(X). If pd_new_value_mode(X) is less than PDMaxPowerValue_mode(X), it updates PDMaxPowerValue_mode(X) in PD_POWER_REALLOCATION1. The PD finally enters MIRROR_UPDATE where pd_new_value_mode(X) is assigned to PDRequestedPower-Value_mode(X). It also updates PSEAllocatedPowerValueEcho_mode(X) and returns to RUNNING.

In the above flow, if pd_new_value_mode(X) is greater than PDMaxPowerValue_mode(X), the PD waits until it is in sync with the PSE and the PSE grants the higher power value. When this condition arises, the PD enters PD_POWER_REALLOCATION2. In this state, the PD assigns PDMaxPowerValue_mode(X) to PDRequestedPowerValue_mode(X) and returns to RUNNING.

145.5.7 Autoclass

A PSE can indicate it supports DLL Autoclass by means of the aLldpXdot3LocPSEAutoclassSupport (30.12.2.1.33) attribute in the oLldpXdot3LocSystemsGroup object class. This property appears to the PD as a change to aLldpXdot3RemPSEAutoclassSupport (30.12.3.1.33) attribute in the oLldpXdot3RemSystemsGroup object class.

A PD connected to a PSE that supports Autoclass can initiate an Autoclass request, to optimize the allocated power budget, through the aLldpXdot3LocAutoclassRequest (30.12.2.1.35) attribute in the oLldpXdot3LocSystemsGroup object class. This request will appear to the PSE as a change in the aLldpXdot3RemAutoclassRequest (30.12.3.1.35) attribute in the oLldpXdot3RemSystemsGroup object class. When the PD sends this request, it needs to be in a state where it consumes the amount of power that, from that moment onward, will be the maximum power drawn.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the PSE receives the request for Autoclass, and Autoclass is enabled, it shall measure the power consumption per the requirements in 145.2.8.2. After this measurement has been completed, the PSE may update the PSEAllocatedPowerValue and follow the procedure in 145.5.5.1. The PSE also communicates the completion of the Autoclass procedure by means of the aLldpXdot3LocAutoclassCompleted (30.12.2.1.34) attribute in the oLldpXdot3LocSystemsGroup object class. This will appear to the PD as a change in the aLldpXdot3RemAutoclassCompleted (30.12.3.1.34) attribute in the oLldpXdot3LocSystemsGroup object class.

A PD that receives the indication that Autoclass is completed through the MirroredPSEAutoclassCompleted then resets the PDAutoclassRequest variable, thereby completing the procedure.

145.6 Environmental

145.6.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2. In particular, the PSE shall be classified as a Limited Power Source in accordance with Annex Q of IEC 62368-1:2018, as applicable.

Equipment shall comply with all applicable local and national codes related to safety.

145.6.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns. The list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to verify compliance with the appropriate requirements. LAN cabling systems described in this clause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cabling and components.
c) High-energy transients coupled onto the LAN cabling system.
d) Voltage potential differences between safety grounds to which various LAN components are connected.

Such electrical safety hazards should be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures should be taken to verify that the intended safety features are not negated during installation of a new network or during modification of an existing network.

145.6.3 Installation and maintenance guidelines

It is a mandatory requirement that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable. In particular, users are cautioned to be aware of the ampacity of cabling, as installed, and local codes and regulations, e.g., the National Electrical Code® (NEC®) (NFPA 70®, 2017 Edition) [B56], relevant to the maximum class supported.

It is a mandatory requirement that, during installation of the cabling plant, care be taken to verify that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

145.6.4 Patch panel considerations

It is possible that the current carrying capability of a cabling cross-connect may be exceeded by a PSE. The designer should consult the manufacturers' specifications to verify compliance with the appropriate requirements.

145.6.5 Electromagnetic emissions

The PD and PSE powered cabling link shall comply with applicable local and national codes for the limitation of electromagnetic interference.

145.6.6 Temperature and humidity

The PD and PSE powered cabling link segment is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling. Specific requirements and values for these parameters are beyond the scope of this standard.

145.6.7 Labeling

It is recommended that the PSE or PD (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) Power classification and power level in terms of maximum current drain over the operating voltage range, 36 V to 57 V, applies for PD only
b) Port type (e.g., 100BASE-TX, TIA Category, or ISO Class)
c) Any applicable safety warnings
d) "PSE" or "PD" as appropriate
e) Indicate "single-signature PD" or "dual-signature PD" as appropriate.
f) Type (e.g., "Type 3" or "Type 4")

145.7 Protocol implementation conformance statement (PICS) proforma for Clause 145, Power over Ethernet[241]

145.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 145, Power over Ethernet, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

145.7.2 Identification

145.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

145.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 145, Power over Ethernet
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[241] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

PSE74	Upperbound template	145.2.10.9	Remove pairset power before the pairset current exceeds the upperbound template	M	Yes [ ]
PSE75	Turn off time	145.2.10.10	From $V_{Port_PSE\text{-}2P}$ min to V_{Off}	M	Yes [ ]
PSE76	PI voltage when idle	145.2.10.11	Equal to or less than V_{Off}, as defined in Table 145–16	M	Yes [ ]
PSE77	Pairset voltage when idle	145.2.10.11	Equal to or less than V_{Off}, as defined in Table 145–16	M	Yes [ ]
PSE78	Supported intra-pair current unbalance	145.2.10.12	I_{unb} in Equation (145–20)	M	Yes [ ]
PSE79	Endpoint PSEs transmitting 100BASE-TX in the presence of (I_{unb} / 2)	145.2.10.12	Meet the requirements of 25.4.5	M	Yes [ ]

145.7.3.2 Powered devices

Item	Feature	Subclause	Value/Comment	Status	Support
PD1	Accept power	145.3.2	Per any configuration defined in Table 145–20	M	Yes [ ]
PD2	Two positive pairs	145.3.2	Meet requirements of detection, signature configuration, and classification	M	Yes [ ]
PD3	Meet specification related to current (single-signature PD)	145.3.2	Total current	PDSS:M	Yes [ ] N/A [ ]
PD4	Meet specification related to current (dual-signature PD)	145.3.2	Current on the negative pair of the given Mode	PDDS:M	Yes [ ] N/A [ ]
PD5	Mode polarity	145.3.2	Insensitive to the polarity of the voltage	M	Yes [ ]
PD6	Operation of single-signature PDs that request Class 4 or less	145.3.2	Per any configuration defined in Table 145–20	PDSS:M	Yes [ ] N/A [ ]
PD7	Source power	145.3.2	Do not source power on the PI	M	Yes [ ]
PD8	Voltage tolerance	145.3.2	Withstand 0 V to 57 V at the PI indefinitely without permanent damage	M	Yes [ ]
PD9	Single-signature PD behavior	145.3.3.3	According to state diagram shown in Figure 145–25 and Figure 145–26	PDSS:M	Yes [ ] N/A [ ]
PD10	Dual-signature PD behavior	145.3.3.4	According to state diagram shown in Figure 145–27 over each pairset independently	PDDS:M	Yes [ ] N/A [ ]
PD11	Valid and non-valid detection signatures	145.3.4	Presented between positive V_{PD} and negative V_{PD} of PD Mode A and PD Mode B as defined in 145.3.2	M	Yes [ ]
PD12	Valid detection signature powering conditions	145.3.4	Per the list in 145.3.4	M	Yes [ ]
PD13	Single-signature PDs powered over only one pairset	145.3.4	Present a non-valid detection signature on the unpowered pairset	PDSS:M	Yes [ ] N/A [ ]
PD14	Dual signature PDs powered over only one pairset	145.3.4	Present a valid detection signature on the unpowered pairset	PDDS:M	Yes [ ] N/A [ ]
PD15	Valid detection signature	145.3.4	Characteristics defined in Table 145–21	M	Yes [ ]
PD16	Non-valid detection signature	145.3.4	Exhibit one or both of the characteristics described in Table 145–22	M	Yes [ ]
PD17	Single-signature PD configuration	145.3.5	Valid detection signature when no voltage/current applied across the other Mode	PDSS:M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD18	Single-signature PD configuration	145.3.5	Invalid detection signature when voltage/current applied across the other Mode	PDSS:M	Yes [ ] N/A [ ]
PD19	Dual-signature PD configuration	145.3.5	Valid detection signature regardless of voltage applied to the other Mode	PDDS:M	Yes [ ] N/A [ ]
PD20	Maximum power drawn	145.3.6	No more than defined for the requested Class in Table 145–26 and Table 145–27	M	Yes [ ]
PD21	Conform to the assigned Class	145.3.6	Regardless of requested Class	M	Yes [ ]
PD22	Multiple-Event classification	145.3.6	Supported by the PD	M	Yes [ ]
PD23	Data Link Layer classification	145.3.6	Supported by single-signature PDs that request Class 4 or higher, and dual-signature PDs that request Class 4 or higher on at least one of its Modes	M	Yes [ ]
PD24	PD classification behavior	145.3.6	Conforms to the state diagram in Figure 145–25, and Figure 145–27	M	Yes [ ]
PD25	PD classification electrical specifications	145.3.6	As defined in Table 145–24 and Table 145–25	M	Yes [ ]
PD26	Underpowered PDs	145.3.6	Provide user with active indication if underpowered	M	Yes [ ]
PD27	Class signature presented during classification events	145.3.6.1	Present class_sig_A during first and second event, class_sig_B during subsequent events	M	Yes [ ]
PD28	Class signature during Autoclass	145.3.6.1	Present class_sig_0	PDAC:M	Yes [ ] N/A [ ]
PD29	Class signature validity	145.3.6.1	Valid within T_{Class_PD} as defined in Table 145–29	M	Yes [ ]
PD30	Advertised class signatures for single-signature PDs	145.3.6.1	Per PD Type and requested Class, as defined in Table 145–26	PDSS:M	Yes [ ] N/A [ ]
PD31	Advertised class signature for dual-signature PDs	145.3.6.1	Per PD Type and requested Class, as defined in Table 145–27	PDDS:M	Yes [ ] N/A [ ]
PD32	Dual-signature PDs powered over only one pairset	145.3.6.1	Present a valid classification signature on the unpowered pairset	PDDS:M	Yes [ ] N/A [ ]
PD33	PD current draw when in a DO_MARK_EVENT state	145.3.6.1.1	Draw I_{Mark} and present a non-valid detection signature	M	Yes [ ]
PD34	Mark event current limits	145.3.6.1.1	Not exceed I_{Mark}	M	Yes [ ]
PD35	Autoclass class signature timing	145.3.6.2	Show class signature 0 between T_{ACS} min and T_{ACS} max	PDAC:M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD36	Autoclass power draw	145.3.6.2	Draw $P_{Autoclass_PD}$between T_{AUTO_PD1} and T_{AUTO_PD2}	PDAC:M	Yes [ ] N/A [ ]
PD37	PSE Type identification	145.3.7	Set long_class_event to TRUE if the first class event is longer than T_{LCE_PD} max	M	Yes [ ]
PD38	PD operation	145.3.8	Operate within the characteristics in Table 145–29	M	Yes [ ]
PD39	PD turn on voltage	145.3.8.1	At a voltage in the range of V_{On_PD}	M	Yes [ ]
PD40	PD stay on voltage	145.3.8.1	Over the entire V_{Port_PD-2P} range	M	Yes [ ]
PD41	PD turn off voltage	145.3.8.1	At a voltage in the range of V_{Off_PD}	M	Yes [ ]
PD42	Peak power draw or voltage transients present	145.3.8.1	PD not to turn off	M	Yes [ ]
PD43	Startup oscillations	145.3.8.1	Turn on or off without startup oscillations and within the first trial at any load value	M	Yes [ ]
PD44	P_{Port_PD} (single-signature PD)	145.3.8.2	Not to exceed P_{Class_PD} for the assigned class	PDSS:M	Yes [ ] N/A [ ]
PD45	P_{Port_PD-2P} (dual-signature PD)	145.3.8.2	Not to exceed P_{Class_PD-2P} for the assigned class	PDDS:M	Yes [ ] N/A [ ]
PD46	Power draw for Autoclass PDs	145.3.8.2	Not more than $P_{Autoclass_PD}$	PDAC:M	Yes [ ] N/A [ ]
PD47	Power consumption after DLL classification	145.3.8.2	PDMaxPowerValue as defined in 145.5.3.3.1	PDSS:M	Yes [ ] N/A [ ]
PD48	Power consumption after DLL classification	145.3.8.2	PDMaxPowerValue_mode(X) as defined in 145.5.3.4.2	PDDS:M	Yes [ ] N/A [ ]
PD49	Input average power exceptions for single-signature PDs	145.3.8.2.1	Limited to P_{Class} at the PSE PI and current draw of 2 x I_{Cable}	WEXP:M	Yes [ ] N/A [ ]
PD50	Input average power exceptions for dual-signature PDs	145.3.8.2.1	Limited to $P_{Class-2P}$ at the PSE PI and current draw of I_{Cable}	WEXP:M	Yes [ ] N/A [ ]
PD51	PD input inrush current	145.3.8.3	Draw less than I_{Inrush_PD} and I_{Inrush_PD-2P} from T_{Inrush_PD} max until T_{delay} min	M	Yes [ ]
PD52	P_{Class_PD} and P_{Peak_PD} for single-signature PDs assigned to Class 1, 2, or 3	145.3.8.3	Within T_{Inrush_PD} max as defined in Table 145–29	PDSS:M	Yes [ ] N/A [ ]
PD53	P_{Class_PD-2P} and P_{Peak_PD-2P} for dual-signature PDs assigned to Class 1, 2, or 3	145.3.8.3	Within T_{Inrush_PD} max as defined in Table 145–29 on that pairset	PDDS:M	Yes [ ] N/A [ ]
PD54	Peak power	145.3.8.4	Not to exceed P_{Class_PD} for more than T_{CUT} min and 5% duty cycle	!WEXP*PDSS:M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD55	Peak power	145.3.8.4	Not to exceed P_{Class_PD-2P} for more than T_{CUT} min and 5% duty cycle	!WEXP*PDDS: M	Yes [ ] N/A [ ]
PD56	Peak operating power exceptions	145.3.8.4.1	Not to exceed P_{Port_PD} max or P_{Port_PD-2P} max at the PSE PI for more than T_{CUT} min with 5% duty cycle	WEXP:M	Yes [ ] N/A [ ]
PD57	Peak operating power limit	145.3.8.4.1	Not to exceed $1.05 \times P_{Port_PD}$ max for single-signature PDs and $1.05 \times P_{Port_PD-2P}$ max for dual-signature PDs on each pairset	WEXP:M	Yes [ ] N/A [ ]
PD58	Peak transient current for single-signature PDs	145.3.8.5	Maximum $I_{Slewrate}$ as defined in Table 145–29	PDSS:M	Yes [ ] N/A [ ]
PD59	Peak transient current for dual-signature PDs	145.3.8.5	Maximum $I_{Slewrate}$ per pairset as defined in Table 145–29	PDDS:M	Yes [ ] N/A [ ]
PD60	Behavior during transients at the PSE PI	145.3.8.6	Continue to operate without interruption	M	Yes [ ]
PD61	Transient TR1 or TR2 applied (power limit)	145.3.8.6	Meet power limit within $T_{Transient}$	M	Yes [ ]
PD62	Transient TR1 or TR2 applied (source current limit)	145.3.8.6	Not cause source the limit current for longer than T_{LIM} min	M	Yes [ ]
PD63	Transient TR3 applied	145.3.8.6	PD meet operating power limits within 4 ms	M	Yes [ ]
PD64	Ripple and noise	145.3.8.7	As specified in Table 145–29 for the common-mode and/or differential pair-to-pair noise at the PD PI	M	Yes [ ]
PD65	Ripple and noise presence	145.3.8.7	Operate correctly in the presence of ripple and noise generated by the PSE that appears at the PD PI	M	Yes [ ]
PD66	Reflected voltage (single-signature PD)	145.3.8.8	Limited to V_{refl} with one positive pair connected	PDSS:M	Yes [ ]
PD67	Reflected voltage (dual-signature PD)	145.3.8.8	Limited to V_{refl} with one or two positive pairs connected	PDDS:M	Yes [ ]
PD68	Pair-to-pair current unbalance for single-signature PDs	145.3.8.9	Not to exceed $I_{Unbalance-2P}$ under conditions specified in 145.3.8.9	PDSS:M	Yes [ ] N/A [ ]
PD69	Pair-to-pair peak current unbalance for single-signature PDs	145.3.8.9	Not to exceed $I_{Unbalance_peak-2P}$ under conditions specified in 145.3.8.9	PDSS:M	Yes [ ] N/A [ ]
PD70	Pair-to-pair current unbalance for dual-signature PDs	145.3.8.9	Not to exceed I_{Con_PD-2P} under conditions specified in 145.3.8.9	PDDS:M	Yes [ ] N/A [ ]

145.7.3.3 Electrical specifications applicable to the PSE and PD

Item	Feature	Subclause	Value/Comment	Status	Support
EL1	Conductor isolation	145.4.1	Provided between accessible external conductors including frame ground and all MDI leads	M	Yes [ ]
EL2	Strength tests for electrical isolation	145.4.1	Conforms to J.1 with electrical strength test c) details as specified in 145.4.1	M	Yes [ ]
EL3	Isolation and grounding requirements	145.4.1	Conductive link segments that have different requirements have those requirements provided by the port-to-port isolation of the NID	M	Yes [ ]
EL4	Environment A requirements for multiple instances of PSE and/or PD	145.4.1.1.1	Meet or exceed the isolation requirement of the MAU/PHY with which they are associated	!MID:M	Yes [ ] N/A [ ]
EL5	Environment A requirement	145.4.1.1.1	Switch more negative conductor	M	Yes [ ]
EL6	Environment B requirements for multiple instances of PSE and/or PD	145.4.1.1.2	Meet or exceed the isolation requirement of the MAU/PHY with which they are associated	!MID:M	Yes [ ] N/A [ ]
EL7	Environment B requirements for PSE that supports 4-pair power	145.4.1.1.2	Switch more negative conductor	PS4P:M	Yes [ ] N/A [ ]
EL8	Fault tolerance for PIs encompassed within the MDI	145.4.2	Meet requirements of the appropriate specifying clause	!MID:M	Yes [ ] N/A [ ]
EL9	Fault tolerance for PSE PIs not encompassed within an MDI	145.4.2	Meet the requirements of 145.4.2	MID:M	Yes [ ] N/A [ ]
EL10	Common-mode fault tolerance	145.4.2	Each wire pair withstands without damage a 1000 V common-mode impulse applied at E_{cm} of either polarity	M	Yes [ ]
EL11	The shape of the impulse for item common-mode fault tolerance	145.4.2	0.3/50 μs (300 ns virtual front time, 50 μs virtual time of half value)	M	Yes [ ]
EL12	Common-mode to differential-mode impedance balance for transmit and receive pairs	145.4.3	Exceeds value in Table 145–34 for all supported PHY speeds	M	Yes [ ]
EL13	Common-mode AC output voltage	145.4.4	Magnitude while transmitting data and with power applied does not exceed the values in Table 145–35 while operating at the specified speed, when measured over the specified bandwidth	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
EL14	Common-mode AC output voltage measurement	145.4.4	While the PHY is transmitting data, the PSE or PD is operating, and with the enumerated PSE load or PD source	M	Yes [ ]
EL15	Noise from an operating 10/100/1000 Mb/s PSE or PD to the differential transmit and receive pairs	145.4.6	Per the limits in 145.4.6 under the conditions specified in 145.4.4	M	Yes [ ]
EL16	Noise from an operating 2.5GBASE-T, 5GBASE-T, or 10GBASE-T PSE or PD to the differential transmit and receive pairs	145.4.6	Per the limits in 145.4.6	M	Yes [ ]
EL17	Return loss requirements	145.4.7	Specified in 145.4.7 per PHY	M	Yes [ ]
EL18	100BASE-TX Endpoint PSE and 100BASE-TX PD unbalance	145.4.8	Meet requirements of Clause 25 in the presence of (I_{unb} / 2)	M	Yes [ ]

145.7.3.4 Electrical specifications applicable to the PSE

Item	Feature	Subclause	Value/Comment	Status	Support
PSEEL1	Withstand short circuits without damage	145.4.2	Of any conductors in the cable for an indefinite period of time	M	Yes [ ]
PSEEL2	Magnitude of short circuit current between any two conductors for Type 3 PSEs	145.4.2	Does not exceed $I_{PSEUT\text{-}Type3\text{-}2P}$, as defined in Equation (145–17)	PSET3:M	Yes [ ] N/A [ ]
PSEEL3	Magnitude of short circuit current between any two conductors for Type 4 PSEs	145.4.2	Does not exceed $I_{PSEUT\text{-}Type4\text{-}2P}$, as defined in Equation (145–18)	PSET4:M	Yes [ ] N/A [ ]
PSEEL4	Limitation of electromagnetic interference.	145.4.5	PSE complies with applicable local and national codes	M	Yes [ ]
PSEEL5	Alternative A Midspan PSEs that support 100BASE-TX	145.4.8	Enforce channel unbalance currents less than or equal to 10.5mA or meet 145.4.9.3.	MIDA:M	Yes [ ] N/A [ ]
PSEEL6	Insertion of Midspan at FD	145.4.9	Comply with the guidelines specified in 145.4.9 items a), b), and c)	MID:M	Yes [ ] N/A [ ]
PSEEL7	Resulting “channel”	145.4.9	Installation of a Midspan PSE does not increase the length to more than 100 m as defined in ISO/IEC 11801-1.	MID:M	Yes [ ] N/A [ ]
PSEEL8	Configurations with Midspan PSE	145.4.9	Not alter transmission requirements of the “permanent link”	MID:M	Yes [ ] N/A [ ]
PSEEL9	DC continuity in power injecting pairs	145.4.9	Does not provide DC continuity between the two sides of the segment for the pairs that inject power	MID:M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PSEEL10	Connector Midspan PSE device transmission requirements	145.4.9.1	Meet transmission parameters NEXT, insertion loss, and return loss	MID:M	Yes [ ] N/A [ ]
PSEEL11	Midspan PSE NEXT when operating with 10/100/1000 Mb/s or 2.5GBASE-T	145.4.9.1.1	Meet values determined by Equation (145–31) from 1 MHz to 100 MHz, but not greater than 65 dB	MID:M	Yes [ ] N/A [ ]
PSEEL12	Midspan PSE NEXT when operating with 5GBASE-T	145.4.9.1.1	Meet the values determined by Equation (145–31) from 1 MHz to 250 MHz, but not greater than 65 dB	MID:M	Yes [ ] N/A [ ]
PSEEL13	Midspan PSE NEXT when operating with 10GBASE-T	145.4.9.1.1	Meet the values determined by Equation (145–31)from 1 MHz to 500 MHz, but not greater than 75 dB	MID:M	Yes [ ] N/A [ ]
PSEEL14	Midspan PSE Insertion Loss when operating with 10/100/1000 Mb/s or 2.5GBASE-T	145.4.9.1.2	Meet values determined by Equation (145–33) from 1 MHz to 100 MHz, but not less than 0.1 dB	MID:M	Yes [ ] N/A [ ]
PSEEL15	Midspan PSE Insertion Loss when operating at 5GBASE-T	145.4.9.1.2	Meet values determined by Equation (145–33) from 1 MHz to 250 MHz, but not less than 0.1 dB	MID:M	Yes [ ] N/A [ ]
PSEEL16	Midspan PSE Insertion Loss when operating at 10GBASE-T	145.4.9.1.2	Meet values determined by Equation (145–33) from 1 MHz to 500 MHz, but not less than 0.1 dB	MID:M	Yes [ ] N/A [ ]
PSEEL17	Midspan PSE Return Loss	145.4.9.1.3	Meet or exceed values in Table 145–36	MID:M	Yes [ ] N/A [ ]
PSEEL18	Cord Midspan PSE	145.4.9.2	Meet the requirements of this clause and the specifications for a (jumper) cord for insertion loss, NEXT, and return loss for transmit and receive pairs, as defined in Table 145–37	MID:M	Yes [ ] N/A [ ]
PSEEL19	Midspan PSE maximum link delay	145.4.9.2.1	Not to exceed 2.5 ns from 1 MHz to the highest referenced frequency	MID:M	Yes [ ] N/A [ ]
PSEEL20	Midspan PSE maximum link delay skew	145.4.9.2.2	Not to exceed 1.25 ns from 1 MHz to the highest referenced frequency	MID:M	Yes [ ] N/A [ ]
PSEEL21	Alternative A Midspan PSE signal path requirements	145.4.9.3	Exceed transfer function gain expressed in Equation (145–34) from 0.1 MHz to 1 MHz at the pins of the PI used as 100BASE-TX transmit pins	MIDA:M	Yes [ ] N/A [ ]
PSEEL22	Alternative A Midspan PSE signal path requirements bias current	145.4.9.3	Met with DC bias current, I_{bias}, between 0 mA and (I_{unb}/2)	MIDA:M	Yes [ ] N/A [ ]

146. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1L

146.1 Overview

This clause defines the type 10BASE-T1L Physical Coding Sublayer (PCS) and type 10BASE-T1L Physical Medium Attachment (PMA) sublayer. Together, the PCS and PMA sublayers comprise a 10BASE-T1L Physical Layer device (PHY). Provided in this clause are functional and electrical specifications for the type 10BASE-T1L PCS, PMA, and MDI. 10BASE-T1L does not define an AUI.

The 10BASE-T1L PHY is a full-duplex PHY specification, capable of operating at 10 Mb/s. The 10BASE-T1L PHY is intended to be operated over a single balanced pair of conductors, defined in 146.7. The cabling supporting the operation of the 10BASE-T1L PHY is defined in terms of performance requirements between the DTE attachment points [Medium Dependent Interface (MDI)], allowing implementers to provide their own cabling to operate the 10BASE-T1L PHY as long as the normative requirements included in this clause are met.

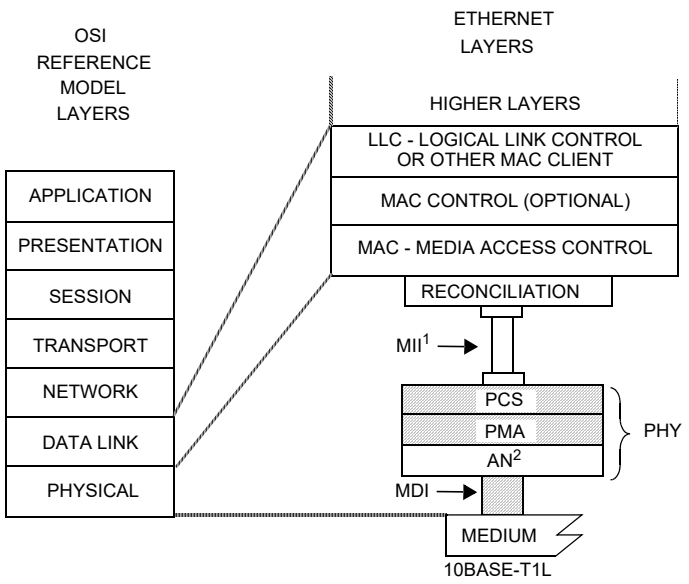
This clause also specifies an optional Energy-Efficient Ethernet (EEE) capability. A 10BASE-T1L PHY that supports this capability may enter a Low Power Idle (LPI) mode of operation during periods of low link utilization as described in Clause 78.

146.1.1 Relationship of 10BASE-T1L to other standards

The relationship between the 10BASE-T1L PHY, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 Ethernet model are shown in Figure 146–1. The PHY sublayers (shown shaded) in Figure 146–1 connect one Clause 4 Media Access Control (MAC) layer to the medium. Auto-Negotiation for 10BASE-T1L is defined in Clause 98. MII is defined in Clause 22.

146.1.2 Operation of 10BASE-T1L

The 10BASE-T1L PHY operates using full-duplex communications over a single balanced pair of conductors with an effective data rate of 10 Mb/s in each direction simultaneously. The PHY supports operation on a link segment supporting up to ten in-line connectors using a single balanced pair of conductors for up to at least 1000 meters.



The 10BASE-T1L PHY utilizes 3-level Pulse Amplitude Modulation (PAM3) transmitted at 7.5 MBd on the link segment. A 33-bit scrambler is used to improve the EMC performance. MII TXD<3:0>, TX_EN, and TX_ER are encoded together using 4B3T encoding, where 4B3T encoding is used to keep the running average (DC baseline) of the transmitted PAM3 symbols within bounds. The PAM3 mapping, scrambler, and 4B3T encoder/decoder are all contained in the PCS (see 146.3).

The 10BASE-T1L PHY may optionally support an increased transmit and receive capability, supporting 2.4 Vpp differential. See 146.5.4.1.

Auto-Negotiation may be used by 10BASE-T1L devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for normal operation. Auto-Negotiation is performed upon link startup through the use of half-duplex differential Manchester encoding. If Auto-Negotiation is implemented, it shall meet the requirements of Clause 98.

A 10BASE-T1L PHY optionally supports Energy-Efficient Ethernet (see Clause 78) and advertises the EEE capability during Auto-Negotiation as described in 98B.3. The EEE capability is a mechanism by which 10BASE-T1L PHYs are able to reduce power consumption during periods of low link utilization.

MDI = MEDIUM DEPENDENT INTERFACE
MII = MEDIA INDEPENDENT INTERFACE

NOTE 1—MII is optional
NOTE 2—Auto-Negotiation is optional

PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
AN = AUTO-NEGOTIATION

Figure 146–1—Relationship of 10BASE-T1L PHY to the ISO/IEC OSI reference model and the IEEE 802.3 Ethernet model

A 10BASE-T1L PHY is capable of operating both as MASTER or SLAVE, with one mode active as determined according to 146.6.2. A MASTER PHY uses a local clock to determine the timing of transmitter operations. A SLAVE PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations. When Auto-Negotiation is used, the MASTER-SLAVE relationship between two devices sharing a link segment is established during Auto-Negotiation (see Clause 98). If Auto-Negotiation is not used, a MASTER-SLAVE relationship shall be established by management or hardware configuration of the PHYs. The MASTER and SLAVE are synchronized by a PMA Clock Recovery function (see 146.4.6).

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

The 10BASE-T1L PMA couples messages from the PCS to the MDI and provides clock recovery, link management, and PHY Control functions. The PMA provides full duplex communications at 7.5 MBd over a single balanced pair of conductors. PMA functionality is described in 146.4. The MDI is specified in 146.8.

146.1.2.1 Physical Coding Sublayer (PCS)

The 10BASE-T1L PCS couples a Media Independent Interface (MII), as described in Clause 22, to the 10BASE-T1L Physical Medium Attachment (PMA) sublayer.

146.1.2.2 Physical Medium Attachment (PMA) sublayer

The 10BASE-T1L PMA couples messages from the PCS service interface onto a single balanced pair of conductors and supports the link management and the 10BASE-T1L PHY Control function. The PMA provides full duplex communications over a single balanced pair of conductors up to 1000 m in length.

146.1.2.3 EEE capability

A 10BASE-T1L PHY optionally supports the EEE capability, as described in 78.3. The EEE capability is a mechanism by which 10BASE-T1L PHYs are able to reduce power consumption during periods of low link utilization. PHYs can enter the LPI mode of operation after completing training. Each direction of the full duplex link is able to enter and exit the LPI mode independently, supporting symmetric and asymmetric LPI operation. This allows power savings when only one side of the full duplex link is in a period of low utilization. The transition to or from LPI mode does not cause any MAC frames to be lost or corrupted.

In the transmit direction, the transition to the LPI transmit mode begins when the PCS transmit function detects an "Assert Low Power Idle" condition on the MII. If this condition is detected, tx_lpi_active is set true and shortly after this the PHY asserts the loc_lpi signal, which is transmitted within the IDLE symbol stream to the remote PHY. This sleep signal indicates to the link partner that the transmit function of the PHY is entering the LPI transmit mode. After the transmission of the sleep indications, the transmit function of the local PHY enters the LPI transmit mode. While the transmit function is in the LPI mode, the PHY may cease transmission to save power and the link partner may disable receiver functions to save additional power. Periodically, the transmit function of the local PHY enters a refresh mode during which idle transmission resumes, and this may be used by the link partner to update adaptive filters and timing recovery circuits. Alternation between LPI quiet and refresh transmit modes proceeds according to a synchronized process between the PHYs, independent of data traffic patterns at the MII. The quiet-refresh cycling continues until the PCS function detects a condition that is not Assert Low Power Idle on the MII. This condition signals to the PHY that the LPI transmit mode should end. The PHY transmits an IDLE symbol stream with loc_lpi de-asserted, indicating to the remote PHY that the local PHY is back to normal transmit mode.

Support for EEE capability is advertised during Auto-Negotiation. See 98B.3 for details. Transitions to and from the LPI transmit mode are controlled via MII signaling. Transitions to and from the LPI receive mode are controlled by the link partner using sleep and wake signaling.

146.1.2.4 Signaling

10BASE-T1L signaling is performed by the PCS generating continuous code-group sequences that the PMA transmits over a single balanced pair of conductors. The signaling scheme achieves a number of objectives including the following:

a) Algorithm mapping and inverse mapping from nibble data to ternary symbols and back.
b) Uncorrelated symbols in the transmitted symbol stream.
c) No correlation between symbol streams traveling both directions.
d) Ability to rapidly or immediately determine if a symbol stream represents data or idle.
e) Robust delimiters for Start-of-Stream delimiter (SSD), End-of-Stream delimiter (ESD), and other control signals.
f) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining.
g) Optionally, ability to signal to the remote PHY that the transmitting PHY is entering the LPI mode or exiting the LPI mode and returning to normal power operation.

146.1.3 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.1.3.1 State diagram notation

The conventions of 21.5 are adopted with the extension that some states in the state diagrams use an IF-THEN-ELSE-END construct to condition which actions are taken within the state. If the logical expression associated with the IF evaluates TRUE, all the actions listed between THEN and ELSE will be executed. In the case where ELSE is omitted, the actions listed between THEN and END will be executed. If the logical expression associated with the IF evaluates FALSE, the actions listed between ELSE and END will be executed. After executing the actions listed between THEN and ELSE, between THEN and END, or between ELSE and END, the actions following the END, if any, will be executed.

146.1.3.2 State diagram timer specifications

All timers operate in the manner described in 40.4.5.2.

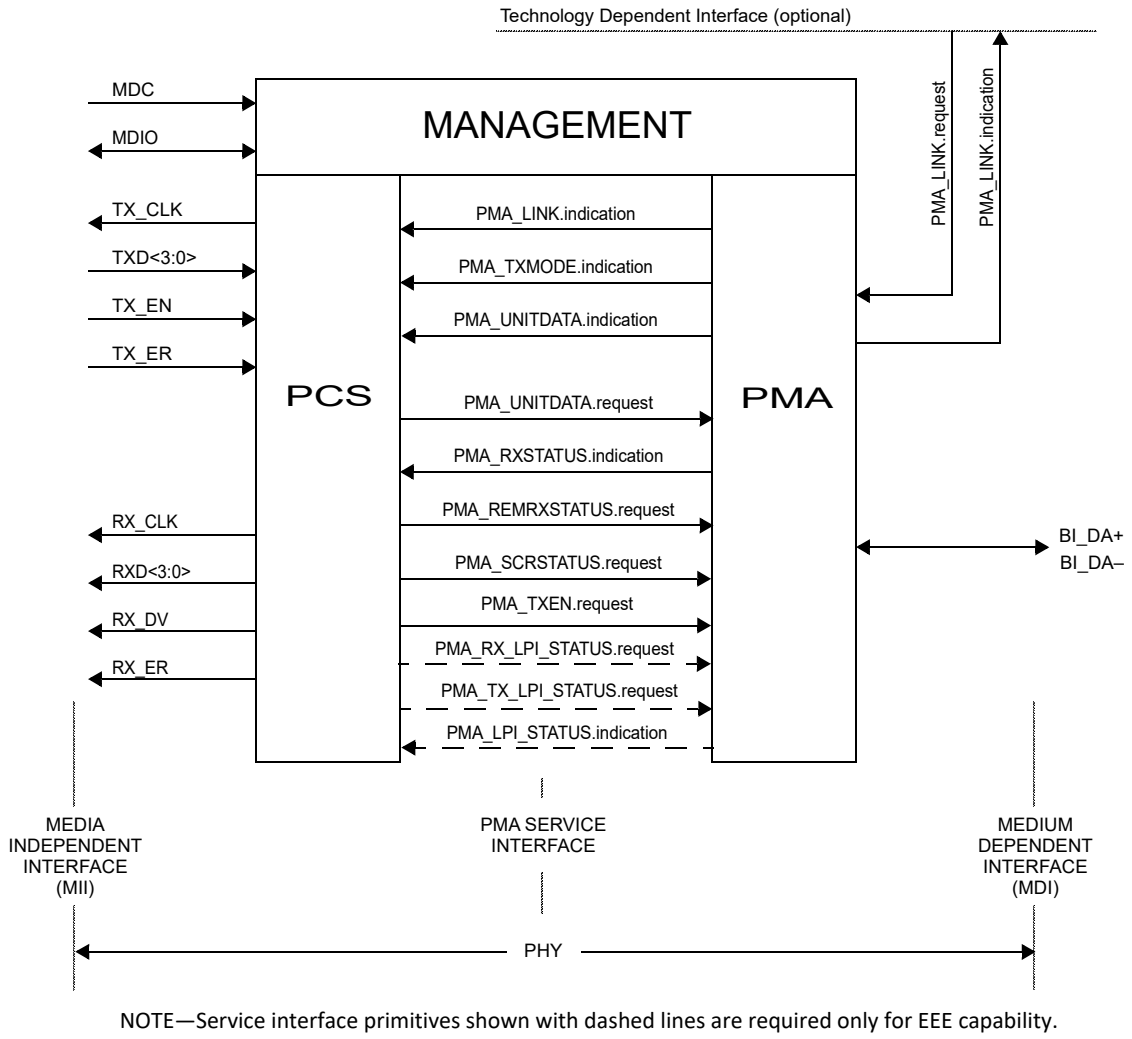
146.1.3.3 Service specifications

The method and notation used in the service specification follows the conventions of 1.2.2.

146.2 Service primitives and interfaces

The 10BASE-T1L PHY uses the service primitives and interfaces in 40.2, with exception of the following clarifications and differences noted in this subclause, in support of 10 Mb/s operations over a single balanced pair of conductors. Figure 146–2 shows the relationship of the service primitives and interfaces used by the 10BASE-T1L PHY.

The 10BASE-T1L PHY uses the Media Independent Interface (MII) as specified in Clause 22. The optional Technology Dependent Interface is used for Auto-Negotiation and is described in 98.4.



As shown in Figure 146–2, 10BASE-T1L uses the following service primitives to exchange symbol vectors, status indications, and control signals across the PMA service interface:

PMA_LINK.request (link_control)
PMA_LINK.indication (link_status)
PMA_TXMODE.indication (tx_mode)
PMA_UNITDATA.indication (rx_symb_vector)
PMA_UNITDATA.request (tx_symb_vector)
PMA_RXSTATUS.indication (loc_rcvr_status)
PMA_REMRXSTATUS.request (rem_rcvr_status)
PMA_SCRSTATUS.request (scr_status)
PMA_TXEN.request (tx_enable_mii)
PMA_RX_LPI_STATUS.request (rx_lpi_active)
PMA_TX_LPI_STATUS.request (tx_lpi_active)
PMA_LPI_STATUS.indication (loc_lpi)

146.2.1 PMA_LINK.request

This primitive allows the Auto-Negotiation or the PHY Link Synchronization algorithm to enable and disable operation of the PMA, as specified in 98.4.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Service interface primitives shown with dashed lines are required only for EEE capability.

Figure 146–2—10BASE-T1L PHY interfaces

146.2.1.1 Semantics of the primitive

PMA_LINK.request (link_control)

The link_control parameter can take on one of the following two values:

DISABLE:	Used by the Auto-Negotiation function to disable the PHY.
ENABLE:	Used by the Auto-Negotiation function to enable the PHY.

146.2.1.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in 98.4.

146.2.1.3 Effect of receipt

This primitive affects operation of the PMA Link Monitor function as described in 146.4.4 and the PMA Link Monitor function as described in 146.4.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.2.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 98.4.1. This primitive informs the Auto-Negotiation functions about the status of the underlying link.

146.2.2.1 Semantics of the primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on the following two values:

FAIL	No valid link established.
OK	The Link Monitor function indicates that a valid 10BASE-T1L link is established. Reliable reception of signals transmitted from the remote PHY is possible.

146.2.2.2 When generated

The PMA generates this primitive to indicate a change in link_status in compliance with the state diagram given in Figure 146–18.

146.2.2.3 Effect of receipt

The effect of receipt of this primitive is specified in 98.4.1.

146.2.3 PMA_TXMODE.indication

The transmitter in a 10BASE-T1L link normally sends symbols over the MDI that represent an MII data stream with framing, scrambling and encoding of data, control information, or idles.

146.2.3.1 Semantics of the primitive

PMA_TXMODE.indication (tx_mode)

The PMA_TXMODE.indication specifies to PCS Transmit, via the parameter tx_mode, what sequence of symbols the PCS should be transmitting. The parameter tx_mode can take on one of the following three values of the form:

SEND_N	This value is continuously asserted during transmission of sequences of symbols representing an MII data stream in the data mode.
SEND_I	This value is continuously asserted when transmission of sequences of idle symbols is to take place.
SEND_Z	This value is continuously asserted when transmission of sequences of zeros is required.

146.2.3.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages to indicate a change in tx_mode.

146.2.3.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 146.3.3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.2.4 PMA_UNITDATA.indication

This primitive defines the transfer of symbols in the form of the rx_symb_vector parameter from the PMA to the PCS.

146.2.4.1 Semantics of the primitive

PMA_UNITDATA.indication (rx_symb_vector)

During reception, the PMA_UNITDATA.indication conveys to the PCS, via the parameter rx_symb_vector, the value of symbols detected on the MDI during each cycle of the recovered clock.

146.2.4.2 When generated

The PMA generates PMA_UNITDATA.indication (rx_symb_vector) messages synchronously for every symbol received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is 7.5 MHz, as governed by the recovered clock.

146.2.4.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

146.2.5 PMA_UNITDATA.request

This primitive defines the transfer of symbols in the form of the tx_symb_vector parameter from the PCS to the PMA. The symbols are obtained in the PCS Transmit function using the encoding rules defined in 146.3.3 to represent MII data, idle data, or zero data.

146.2.5.1 Semantics of the primitive

PMA_UNITDATA.request (tx_symb_vector)

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA, via the parameter tx_symb_vector, the value of the symbols to be sent over the MDI. The tx_symb_vector may take on one of the values in the set {–1, 0, +1}.

146.2.5.2 When generated

The PCS generates PMA_UNITDATA.request (tx_symb_vector) synchronously with every transmit clock cycle.

146.2.5.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated symbols after processing with optional transmit filtering and other specified PMA Transmit processing.

146.2.6 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Receive and PMA PHY Control function the information on whether the status of the overall receive link is satisfactory or not. The criterion for setting the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting disparity errors during reception of the symbol stream.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.2.6.1 Semantics of the primitive

PMA_RXSTATUS.indication (loc_rcvr_status)

The loc_rcvr_status parameter can take on one of two values of the following form:

OK	This value is asserted and remains true during reliable operation of the receive link for the local PHY.
NOT_OK	This value is asserted whenever operation of the link for the local PHY is unreliable.

146.2.6.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages to indicate a change in loc_rcvr_status on the basis of signals received at the MDI.

146.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 146.3.3.4.3 and 146.3.4.

146.2.7 PMA_REMRXSTATUS.request

This primitive is generated by PMA Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The parameter rem_rcvr_status is set to the value received within the idle data stream of the remote PHY.

146.2.7.1 Semantics of the primitive

PMA_REMRXSTATUS.request (rem_rcvr_status)

The rem_rcvr_status parameter can take on one of two values of the following form:

OK	The receive link of the remote PHY is operating reliably.
NOT_OK	Reliable operation of the receive link for the remote PHY is not detected.

146.2.7.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages to indicate a change in rem_rcvr_status based on the PCS decoding the loc_rcvr_status bit in the idle data received from the remote PHY.

146.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in 146.4.4.

146.2.8 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the descrambler has achieved synchronization.

146.2.8.1 Semantics of the primitive

PMA_SCRSTATUS.request (scr_status)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The scr_status parameter can take on one of two values of the following form:

OK	The descrambler has achieved synchronization.
NOT_OK	The descrambler is not synchronized.

146.2.8.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages to indicate a change in scr_status.

146.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 146–15.

146.2.9 PMA_TXEN.request (tx_enable_mii)

This primitive is generated by PCS Data Transmission Enable function to communicate the status of the tx_enable_mii signal to the PMA. The parameter tx_enable_mii conveys to the PMA PHY Control function the information about the actual data transmission status.

146.2.9.1 Semantics of the primitive

PMA_TXEN.request (tx_enable_mii)

The tx_enable_mii parameter can take on one of two values of the following form:

TRUE	Transmission is enabled.
FALSE	Transmission is disabled.

146.2.9.2 When generated

PCS Data Transmission Enable function generates PMA_TXEN.request messages to indicate a change in tx_enable_mii variable.

146.2.9.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 146–15.

146.2.10 PMA_RX_LPI_STATUS.request (rx_lpi_active)

When the PHY supports the EEE capability, this primitive is generated by the PCS receive function to indicate the status of the receive link of the local PHY. The parameter PMA_RX_LPI_STATUS.request conveys to the PMA receive function and the PMA PHY control function information regarding whether the PCS receive function is in the LPI receive mode.

146.2.10.1 Semantics of the primitive

PMA_RX_LPI_STATUS.request (rx_lpi_active)

The rx_lpi_active parameter can take on one of two values of the following form:

TRUE	The PCS receive function is in the LPI receive mode.
FALSE	The PCS receive function is not in the LPI receive mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.2.10.2 When generated

The PCS generates PMA_RX_LPI_STATUS.request messages to indicate a change in the rx_lpi_active variable as described in Figure 146–9 and Figure 146–10.

146.2.10.3 Effect of receipt

The receiver may adjust the clock recovery while being in low power idle mode. Additionally, checking of the descrambler status in the PHY control state diagram is suppressed, as the receiver is disabled.

146.2.11 PMA_TX_LPI_STATUS.request (tx_lpi_active)

When the PHY supports the EEE capability, this primitive is generated by the PCS transmit function to indicate the status of "Assert Low Power Idle" on the MII. The parameter PMA_TX_LPI_STATUS.request conveys to the PMA control function information regarding whether the PCS transmit function is receiving "Assert Low Power Idle" on the MII.

146.2.11.1 Semantics of the primitive

PMA_TX_LPI_STATUS.request (tx_lpi_active)

The tx_lpi_active parameter can take on one of two values of the following form:

TRUE	The PCS transmit function is receiving "Assert Low Power Idle" on the MII.
FALSE	The PCS transmit function is not receiving "Assert Low Power Idle" on the MII.

146.2.11.2 When generated

The PCS generates PMA_TX_LPI_STATUS.request messages to indicate a change in the tx_lpi_active variable to the PMA PHY control function. Tx_lpi_active is set to true if "Assert Low Power Idle" is received from the MII; otherwise, it is set to false.

146.2.11.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 146–15 and Figure 146–17.

146.2.12 PMA_TX_LPI_STATUS.indication

When the PHY supports the EEE capability, this primitive is generated by the PMA PHY control function to indicate a sleep or wake event. The parameter PMA_TX_LPI_STATUS.indication conveys to the PCS transmit function information regarding whether the PHY should indicate a sleep or a wake event to the remote PHY.

146.2.12.1 Semantics of the primitive

PMA_TX_LPI_STATUS.indication (loc_lpi)

The loc_lpi parameter can take on one of two values of the following form:

TRUE	Communicate to the remote PHY that LPI mode will be entered by the local PHY.
FALSE	Communicate to the remote PHY that normal IDLE mode will be entered by the local PHY.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.2.12.2 When generated

The PMA generates PMA_TX_LPI_STATUS.indication messages to indicate a change in the loc_lpi variable.

146.2.12.3 Effect of receipt

The effect of receipt of this primitive is specified in 146.3.3.4.3.

146.3 Physical Coding Sublayer (PCS) functions

The Physical Coding Sublayer (PCS) consists of PCS Reset, the PCS Data Transmission Enable, PCS Transmit, and PCS Receive functions as shown in Figure 146–3. The PCS Reset function is explained in 146.3.1, the PCS Data Transmission Enable function is explained in 146.3.2, the PCS Transmit function is explained in 146.3.3, the PCS Receive function is explained in 146.3.4, and the PCS Loopback function is explained in 146.3.5.

146.3.1 PCS Reset function

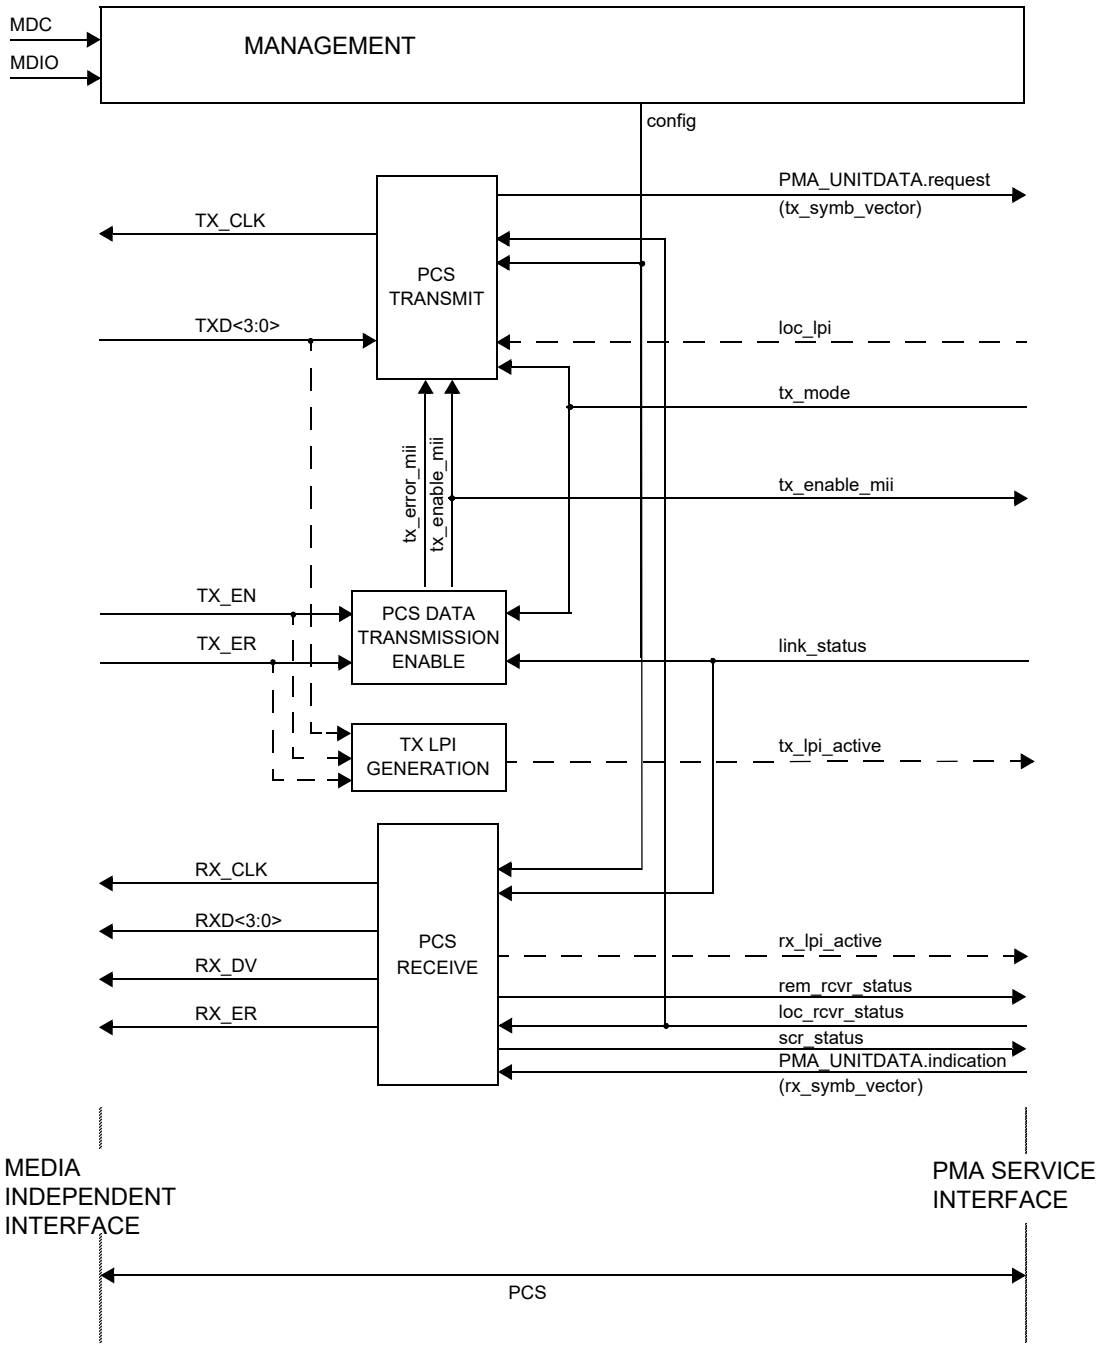
PCS reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

a) Power on (see 36.2.5.1.3).
b) The receipt of a request for reset from the management entity.

PCS Reset shall set pcs_reset = TRUE while any of the above reset conditions holds true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

146.3.2 PCS Data Transmission Enable

The PCS Data Transmission Enable function shall conform to the PCS data transmission enabling state diagram in Figure 146–4. When tx_mode is equal to SEND_N, the signals tx_enable_mii and tx_error_mii are equal to the values of the MII signals TX_EN and TX_ER respectively; otherwise, tx_enable_mii and tx_error_mii are set to the value FALSE.



146.3.2.1 Variables

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: TRUE or FALSE

tx_enable_mii
: The tx_enable_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 146–4. When this variable is set to FALSE transmission is disabled, when set to TRUE transmission is enabled.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Signals shown with dashed lines are required only for EEE capability.

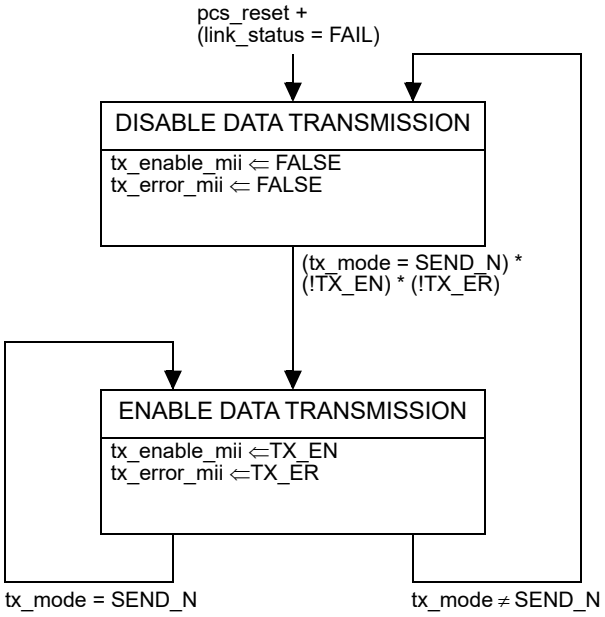

Figure 146–4—PCS data transmission enabling state diagram

tx_error_mii
: The tx_error_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 146–4.When this variable is set to FALSE it indicates a non-errored transmission, when set to TRUE it indicates an errored transmission.
Values: TRUE or FALSE

TX_EN
: The TX_EN signal of the MII as specified in 22.2.2.3.

TX_ER
: The TX_ER signal of the MII as specified in 22.2.2.5.

tx_mode
: The tx_mode parameter set by the PMA PHY Control function and passed to the PCS via the PMA_TXMODE.indication primitive.
Values: SEND_Z, SEND_N, or SEND_I

146.3.3 PCS Transmit

The PCS Transmit function shall conform to the PCS Transmit state diagram in Figure 146–5 (see 146.3.3.1.6) and the PCS Transmit multiplexer state diagram in Figure 146–6 (see 146.3.3.2.4) and to the associated state variables, functions, timers, and messages.

146.3.3.1 PCS Transmit state diagram

Upon the assertion of TX_EN, the PCS Transmit state diagram passes an SSD of 4 code-groups to the PMA, which replaces the first 2 bytes of the preamble. Following SSD, TXD[3:0] is encoded into ternary symbols using encoding rules, specified in 146.3.3.5.1, until TX_EN is de-asserted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Following the de-assertion of TX_EN, a special code ESD (or ERR_ESD when a transmit error is encountered, which means that TX_ER was high at any point during the transmission) of 4 code-groups is generated, after which the transmission of idle mode according to 146.3.3.5.1 is resumed.

10BASE-T1L has one special code-group {0, 0, 0} that is not used by Idle or Data symbols. This code-group is used for the COMMA symbols within the delimiters. See Figure 146–5 for more details.

The 10BASE-T1L PHY supports normal operation and link training operation. In training operation, the PCS ignores signals from the MII and sends only the idle signals to the PMA until the training process is complete.

If tx_mode has the value SEND_Z, PCS Transmit passes a vector of zeros at each symbol period to the PMA.

If tx_mode has the value SEND_I, PCS Transmit generates sequences of symbols according to the encoding rule in idle mode as described in 146.3.3.5.1.

If tx_mode has the value SEND_N, PCS Transmit generates symbols A_n at each symbol period representing data, special control symbols like SSD/ESD, or IDLE symbols as defined in 146.3.3.5.1. The transition from idle to data is signaled by an SSD and the end of transmission of data is signaled by an ESD.

During training operation (when tx_mode is SEND_I), knowledge of the transmitted symbols may be used at the receiver side to perform any signal conditioning necessary for meeting the required performance during normal operation. When the link is up, the PHY enters SEND_N mode and the transmitted PAM3 symbols are used at the receiver PHY for continued clock frequency/phase tracking.

146.3.3.1.1 Variables

error
: PCS local variable that records if an errored transmission has occured during data transmission.
Values: TRUE or FALSE

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: TRUE or FALSE

tx_enable_mii
: The tx_enable_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 146–4. When this variable is set to FALSE transmission is disabled, when set to TRUE transmission is enabled.
Values: TRUE or FALSE

tx_error_mii
: The tx_error_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 146–4.When this variable is set to FALSE it indicates a non-errored transmission, when set to TRUE it indicates an errored transmission.
Values: TRUE or FALSE

tx_mode
: The tx_mode parameter set by the PMA PHY Control function and passed to the PCS via the PMA_TXMODE.indication primitive.
Values: SEND_Z, SEND_N, or SEND_I

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

loc_rcvr_status

The loc_rcvr_status parameter set by the PMA Receive function and passed to the PCS via the PMA_RXSTATUS.indication primitive.
Values: OK or NOT_OK

loc_lpi

The variable loc_lpi is set by the PHY Control function in the PMA to indicate that it has entered low power idle mode.
Values: TRUE or FALSE

$Sy_n[4:0]$

The $Sy_n[4:0]$ bits from the scrambler as defined in 146.3.3.4.2.

$Sd_n[3:0]$

The $Sd_n[3:0]$ signal of the scrambler output as defined in 146.3.3.4.3.

Tx_n

Alias for tx_symb_vector at time n.

tx_code_group $\{TA_n, TB_n, TC_n\}$

A triplet of ternary symbols generated by the PCS Transmit state diagram. These include 4B3T encoded data and assigned values (see 146.3.3.5). The element TA_n is the first ternary symbol transmitted; TC_n is the last ternary symbol transmitted.
Value: A triplet of ternary transmit symbols. Each of the ternary symbols may take on one of the values {–1, 0, +1}.

tx_disparity

PCS local variable containing the running disparity. After PCS Reset, the initial value shall be set to 2.
Values: 1 to 4, depending on running disparity.

146.3.3.1.2 Functions

ENCODE

In the PCS Transmit process, this function takes as its arguments $Sd_n[3:0]$ and the tx_disparity and returns the corresponding tx_code_group as well as the updated tx_disparity. ENCODE follows the 4B3T rules defined in 146.3.3.5.1.

$$\{tx_code_group, tx_disparity\} = ENCODE(Sd_n[3:0], tx_disparity)$$

The tx_disparity can be between 1 and 4 and the respective tx_code_group is taken from the 4B3T encoding rules defined in Table 146–1 based on the $Sd_n[3:0]$ value and the tx_disparity:

$$tx_code_group = table_{4B3T}(Sd_n[3:0], tx_disparity)$$

The second output value of this function is an updated tx_disparity value, which is calculated in the following way:

$$tx_disparity = tx_disparity + disparity\ of\ currently\ encoded\ tx_code_group$$

DISPRES

The function DISPRES returns one of the eight possible DISPRESET3 values for tx_code_group (see Table 146–2), depending on the values of $Sy_n[4]$ and tx_disparity:

$$tx_code_group = table_{DISPRESET3}(Sy_n[4], tx_disparity)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RND_SSD4

The function RND_SSD4 takes $Sy_{n-1}[4]$ as its argument and returns the corresponding tx_code_group as well as the updated tx_disparity.

{tx_code_group, tx_disparity} = RND_SSD4($Sy_{n-1}[4]$)

The returned tx_code_group corresponds to one of the two possible SSD4 code-groups (see Table 146–3), depending on the value of $Sy_{n-1}[4]$:

tx_code_group = $table_{SSD4}(Sy_{n-1}[4])$

The returned tx_disparity also depends on the value of $Sy_{n-1}[4]$ as follows:

tx_disparity = *2, if $Sy_{n-1}[4] = 0$*
3, otherwise

RND_ESD4

The function RND_ESD4 takes $Sy_{n-1}[4]$ as its argument and returns the corresponding tx_code_group as well as the updated tx_disparity.

{tx_code_group, tx_disparity} = RND_ESD4($Sy_{n-1}[4]$)

The returned tx_code_group corresponds to one of the two possible ESD4 code-groups (see Table 146–3), depending on the value of $Sy_{n-1}[4]$:

tx_code_group = $table_{ESD4}(Sy_{n-1}[4])$

The returned tx_disparity also depends on the value of $Sy_{n-1}[4]$ as follows:

tx_disparity = *2, if $Sy_{n-1}[4] = 0$*
3, otherwise

RND_ESD_ERR4

The function RND_ESD_ERR4 takes $Sy_{n-1}[4]$ as its argument and returns the corresponding tx_code_group as well as the updated tx_disparity.

{tx_code_group, tx_disparity} = RND_ESD_ERR4($Sy_{n-1}[4]$)

The returned tx_code_group corresponds to one of the two possible ESD_ERR4 code-groups (see Table 146–3), depending on the value of $Sy_{n-1}[4]$:

tx_code_group = $table_{ESD_ERR4}(Sy_{n-1}[4])$

The returned tx_disparity also depends on the value of $Sy_{n-1}[4]$ as follows:

tx_disparity = *2, if $Sy_{n-1}[4] = 0$*
3, otherwise

146.3.3.1.3 Timers

symb_triplet_timer
: A continuous free-running timer that shall expire synchronously with every third expiration of symb_timer. TX_CLK (see 22.2.2.1) shall be generated from symb_triplet_timer with the rising edge of TX_CLK generated synchronously with symb_triplet_timer_done.
Restart time: Immediately after expiration; restarting the timer resets the condition symb_triplet_timer_done.
Duration: Three symbol times (see 146.5.4.5)

146.3.3.1.4 Abbreviations

STD
: Alias for symb_triplet_timer_done.

146.3.3.1.5 Constants

COMMA
: A vector of three ternary symbols in the first or second code-group of any delimiter as specified in 146.3.3.5.1.

ZERO
: A vector of three zero symbols sent when tx_mode = SEND_Z as specified in 146.3.3.5.2.

146.3.3.1.6 State diagram

146.3.3.2 PCS Transmit multiplexer state diagram

In each symbol period, the PCS Transmit multiplexer generates a ternary symbol that can take the values of {–1, 0, +1} and passes it to the PMA sublayer via the PMA_UNITDATA.request primitive. The nominal symbol clock frequency is specified in 146.5.4.5.

146.3.3.2.1 Variables

pcs_reset
: The pcs_reset parameter set by the PCS reset function.
Values: TRUE or FALSE

tx_symb_vector
: A ternary symbol generated through serialization of tx_code_group. This symbol is conveyed to the PMA as the parameter of a PMA_UNITDATA.request(tx_symb_vector) service primitive.
Values: A ternary transmit symbol. The ternary symbol may take on one of the values {–1, 0, +1}.

tx_code_group {TA_n, TB_n, TC_n}
: A triplet of ternary symbols generated by the PCS Transmit state diagram. The element TA_n is the first ternary symbol transmitted; TC_n is the last ternary symbol transmitted.
Value: A triplet of ternary transmit symbols. Each of the ternary symbols may take on one of the values {–1, 0, +1}.

146.3.3.2.2 Timers

symb_timer

A continuous free-running timer. The symb_timer expires when the PMA_UNITDATA.request is serviced, synchronously with TX_TCLK.
Continuous timer: The condition symb_timer_done becomes true upon timer expiration.
Restart time: Immediately after expiration; restarting the timer resets the condition symb_timer_done.
Duration: One symbol time (see 146.5.4.5)

146.3.3.2.3 Abbreviations

PUDR

Alias for PMA_UNITDATA.request(tx_symb_vector).

146.3.3.2.4 State diagram

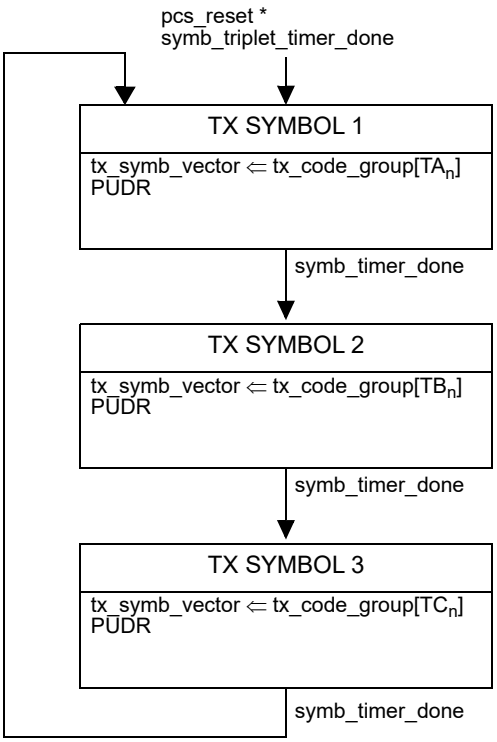

Figure 146–6—TX multiplexer state diagram

Copyright © 2022 IEEE. All rights reserved.

146.3.3.3 PCS Transmit symbol generation

The reference diagram of transmit symbol generation is indicated in Figure 146–7. The tx_code_group is the code-group $\{TA_n, TB_n, TC_n\}$.

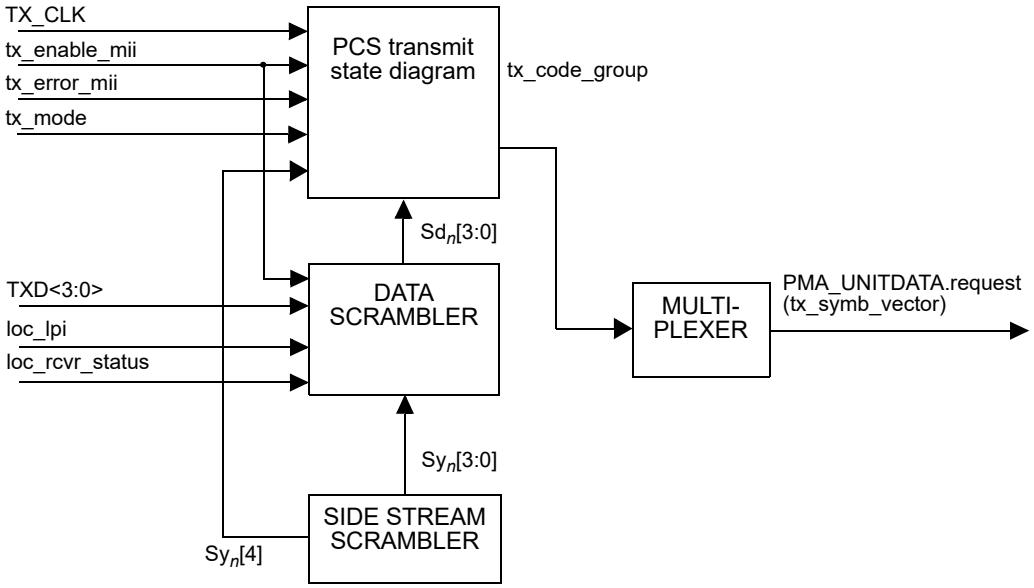

Figure 146–7—PCS transmit symbol generation

146.3.3.4 Data and idle stream scrambling

The scrambled bits $Sd_n[3:0]$ used by the ENCODE function defined in 146.3.3.1.2 are generated as follows.

146.3.3.4.1 Side-stream scrambler polynomial

The PCS Transmit function shall employ side-stream scrambling. For the master PHY, PCS Transmit shall employ

$$g_m(x) = 1 + x^{13} + x^{33} \tag{146–1}$$

as transmitter side-stream scrambler generator polynomial. For the slave PHY, PCS Transmit shall employ

$$g_s(x) = 1 + x^{20} + x^{33} \tag{146–2}$$

as transmitter side-stream scrambler generator polynomial. An implementation of master and slave PHY side-stream generator polynomials by linear-feedback shift registers is shown in Figure 146–8. The bits stored in the shift register delay line at time n are denoted by $Scr_n[32:0]$. At each tx_code_group period, the shift register is advanced by one bit, and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. The scrambler state shall not be initialized to all zeros.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

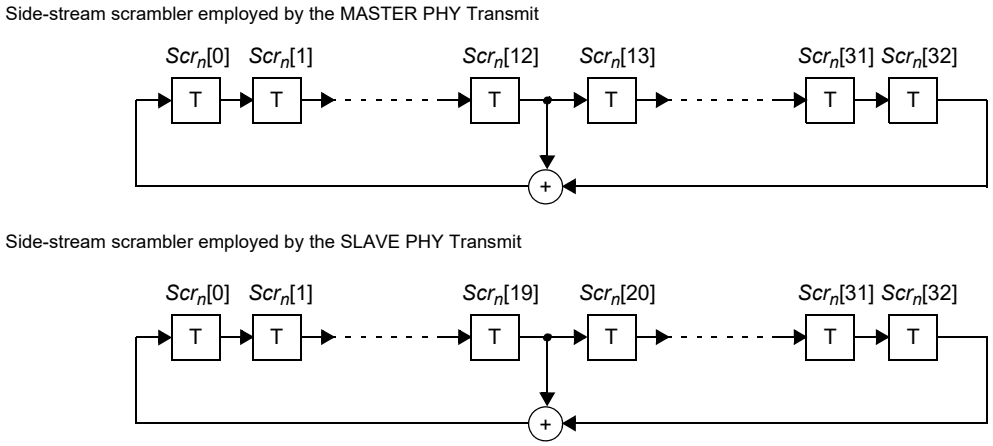

Figure 146–8—A realization of side-stream scramblers by linear feedback shift registers

146.3.3.4.2 Generation of $Sy_n[3:0]$

PCS Transmit encoding rules are based on the generation, at time n, of the five bits $Sy_n[4:0]$. The four bits $Sy_n[3:0]$ are used for de-correlating the MII data word TXD<3:0> during data transmission and for generating the idle symbols. The bit $Sy_n[4]$ is used to randomize the frame delimiters. These five bits are generated as described below, using the auxiliary generating polynomial, g(x) defined in Equation (146–3):

$$g(x) = x^3 \wedge x^8 \tag{146–3}$$

The five bits $Sy_n[4:0]$ shall be generated using the bit $Scr_n[0]$ and $g(x)$ as in the following equations:

$$Sy_n[0] = Scr_n[0]$$
$$Sy_n[1] = g(Scr_n[0]) = Scr_n[3] \wedge Scr_n[8]$$
$$Sy_n[2] = g^2(Scr_n[0]) = Scr_n[6] \wedge Scr_n[16]$$
$$Sy_n[3] = g^3(Scr_n[0]) = Scr_n[9] \wedge Scr_n[14] \wedge Scr_n[19] \wedge Scr_n[24].$$
$$Sy_n[4] = g^4(Scr_n[0]) = Scr_n[12] \wedge Scr_n[32]$$

By construction, the five bits $Sy_n[4:0]$ are derived from elements of the same maximum-length shift register sequence of length $2^{33}–1$ as $Scr_n[0]$, but shifted in time by varying delays. The associated delays are all large and different so that there is no apparent correlation among the bits.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.3.3.4.3 Generation of scrambled bits $Sd_n[3:0]$

From scrambler bits $Sy_n[3:0]$ and $TXD_n[3:0]$, bits $Sd_n[3:0]$ shall be generated as follows:

$$Sd_n[3] = \begin{cases} Sy_n[3] \wedge TXD_n[3] & \text{if (tx_enable_mii = TRUE)} \\ Sy_n[3] \wedge 1 & \text{else if (loc_rcvr_status = OK)} \\ Sy_n[3] & \text{else} \end{cases}$$

$$Sd_n[2] = \begin{cases} Sy_n[2] \wedge TXD_n[2] & \text{if (tx_enable_mii = TRUE)} \\ Sy_n[1] \wedge 1 & \text{else if (loc_lpi = TRUE)} \\ Sy_n[1] & \text{else} \end{cases}$$

$$Sd_n[1:0] = \begin{cases} Sy_n[1:0] \wedge TXD_n[1:0] & \text{if (tx_enable_mii = TRUE)} \\ (Sy_n[2], Sy_n[0]) & \text{else} \end{cases}$$

Note that during transmission of idles, bits $Sy_n[1]$ and $Sy_n[2]$ shall be swapped, compared to data transmission, to reliably distinguish idle data transmission from data transmission at the receiver side.

146.3.3.5 Generation of code-groups

The PCS transmit state diagram generates code-groups as follows. A code-group $\{TA_n, TB_n, TC_n\}$ is sent in the following order: TA_n, TB_n, TC_n, TA_{n+1}, TB_{n+1}, TC_{n+1}, ...

146.3.3.5.1 Generation of code-groups in mode SEND_N and SEND_I

Both SEND_I and SEND_N use the following ternary symbol encoding. The scrambled bits $Sd_n[3:0]$ are converted to a code-group $\{TA_n, TB_n, TC_n\}$ using the 4B3T algorithm in conjunction with a running disparity value, shown in Table 146–1. The 4B3T coding is DC-free. To achieve this, the difference between the number of transmitted “+1” and “–1” symbols is limited. The running disparity reflects this difference and is used to choose the coding of the next symbol.

The code-group {0, 0, 0} is used as the COMMA value and never occurs during normal 4B3T mapping. This can also be used to synchronize the receiver’s demultiplexer code-group boundary during training.

The DISPRESET3 code-group, together with the following fourth code-group, is used to bring back the running disparity to a defined value of either 2 or 3, depending on the value of bit $Sy_n[4]$ from the scrambler. The coding shown in Table 146–2 is used for the DISPRESET3 code-group.

The fourth code-group (SSD4/ESD4/ESD_ERR4) is encoded as shown in Table 146–3:

Table 146–3—Delimiters

	Delimiter	$\{TA_n, TB_n, TC_n\}$
$Sy_{n-1}[4] = 0$	SSD4	{+1, +1, –1}
	ESD4	{+1, –1, +1}
	ESD_ERR4	{–1, +1, +1}
$Sy_{n-1}[4] = 1$	SSD4	{–1, –1, +1}
	ESD4	{–1, +1, –1}
	ESD_ERR4	{+1, –1, –1}

146.3.3.5.2 Generation of code-groups in mode SEND_Z

The code-group $\{TA_n, TB_n, TC_n\}$ is a zero vector {0, 0, 0} when tx_mode = SEND_Z.

146.3.4 PCS Receive

146.3.4.1 PCS Receive overview

The PCS Receive function shall conform to the PCS Receive state diagram in Figure 146–9 and associated state variables.

The received code-group Rx_n, generated by PCS Receive at time n, is decoded using the inverse of the mapping shown in Table 146–1. The result of the decoding is $Sr_n[3:0]$.

The PCS Receive function shall conform to the Receive watchdog state diagram in Figure 146–11. This prevents the possible lock-up of the PCS Receive state diagram in the DATA state due to mis-detection of an ESD. The maximum dwelling time in DATA state shall be less than the period specified for rcv_max_timer. When rcv_max_timer expires, the PCS Receive state diagram is reset and transitions to IDLE.

In Figure 146–9, there are a total of five states after SSD4 detection before the DATA state; meanwhile, there are also five states before the IDLE state (including the DATA state) that perform data decoding. As a result, the depth of the data flush-in delay line is the same as the flush-out delay line ensuring correct packet reception at the MII. These delay lines are necessary to decode the stream delimiters prior to forwarding the received data to the MII interface.

The variables, functions, and timers used in Figure 146–9, Figure 146–10, and Figure 146–11 (in 146.3.4.1.5) are defined next. For the definition of IDLE, COMMA, DISPRESET3, SSD4, ESD4, and ESD_ERR4, see 146.3.3.5.1.

146.3.4.1.1 Variables

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: TRUE or FALSE

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

receiving
: Generated by the PCS Receive function; if set as TRUE, it indicates that the PCS is in Data mode.
Values: TRUE or FALSE

loc_rcvr_status
: The loc_rcvr_status parameter set by the PMA Receive function and passed to the PCS via the PMA_RXSTATUS.indication primitive.
Values: OK or NOT_OK

lpi_enabled
: This variable indicates whether Energy Efficient Ethernet is enabled for the PHY or not. If Auto-Negotiation is enabled, lpi_enabled reflects whether both PHYs have EEE capability advertised. If Auto-Negotiation is not enabled, and MDIO is implemented, lpi_enabled reflects bit 1.2294.10 as described in 45.2.1.231.5.
Values: TRUE or FALSE

RX_ER
: The RX_ER signal of the MII as specified in 22.2.2.10.

RX_DV
: The RX_DV signal of the MII as specified in 22.2.2.7.

RXD[3:0]
: The RXD signal of the MII as specified in 22.2.2.8.

Rx_n
: Received code-group generated by PCS Receive at time n.

rx_lpi_active
: This variable indicates to the PMA receive function if the receive state diagram is in low power idle state.
Values: TRUE or FALSE

rx_symb_vector
: A vector of ternary symbols received by the PMA and passed to the PCS via the PMA_UNITDATA.indication primitive.
Value: single ternary symbol

rx_disparity
: PCS local variable containing the calculated running disparity at the receiver side. After PCS Reset, the initial value shall be set to 2.
Values: 1 to 4, depending on running disparity.

scr_status
: The scr_status parameter as communicated by the PMA_SCRSTATUS.request primitive.
Values: OK: The descrambler has achieved synchronization.
NOT_OK: The descrambler is not synchronized.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

disparity_error

The disparity_error is set by the 4B3T decoder in the receiver, when a rx_code_group is received that is not allowed according to the running disparity calculated in the decoder.
Values: TRUE or FALSE

rcv_overrun_detected

Variable set as TRUE when in RECEIVE OVERRUN state as shown in Receive watchdog state diagram in Figure 146–11 and set FALSE otherwise.
Values: TRUE or FALSE

146.3.4.1.2 Functions

valid_idle

This function checks whether the decoded data bits $Sr_n[1:0]$ are equal to the expected $Sd_n[1:0]$ values from the local descrambler.
Values: TRUE or FALSE

check_idle

The check_idle function indicates a reliable detection of the idle data stream.
Values: TRUE or FALSE

rem_lpi

The rem_lpi function provides reliable detection of the received loc_lpi information from the remote PHY within the IDLE data stream.
Values: TRUE or FALSE

valid_dispreset

Determines if the received code-group is one of the DISPRESET3 code-groups as specified in 146.3.3.5.1. It returns a Boolean value indicating whether or not one of the eight possible DISPRESET3 code-groups has been received.
Values: TRUE or FALSE

valid_ssd4

Determines if the received code-group is one of the SSD4 code-groups as specified in 146.3.3.5.1. It returns a Boolean value indicating whether or not one of the two possible SSD4 code-groups has been received.
Values: TRUE or FALSE

valid_esd4

Determines if the received code-group is one of the ESD4 code-groups as specified in 146.3.3.5.1. It returns a Boolean value indicating whether or not one of the two possible ESD4 code-groups has been received.
Values: TRUE or FALSE

valid_esd_err4

Determines if the received code-group is one of the ESD_ERR4 code-groups as specified in 146.3.3.5.1. It returns a Boolean value indicating whether or not one of the two possible ESD_ERR4 code-groups has been received.
Values: TRUE or FALSE

DESCRAMBLE

This function takes as its arguments the value of Rx_n and returns the descrambler output according to 146.3.4.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

DECODE

In the PCS Receive process, this function takes as its arguments the value of the received code-group and rx_disparity and returns the corresponding RXD[3:0] as well as the updated rx_disparity. DECODE follows the rules outlined in 146.3.4.2 and the inverse encoding rules stated in Table 146–1.

$RXD[3:0] = DESCRAMBLE(inverse_table_{4B3T}(Rx_n))$

$rx_disparity = rx_disparity + disparity\ of\ currently\ received\ Rx_n$

CHECK_DISP

The CHECK_DISP function checks if the currently received code-group is allowed for the current rx_disparity, and returns TRUE or FALSE according to the relation:

$Rx_n \neq table_{4B3T}(inverse_table_{4B3T}(Rx_n), rx_disparity).$

The encoding rules for the 4B3T encoding are stated in Table 146–1.

RESET_DISP

This function takes as its argument the value of Rx_n, corresponding to a valid SSD4 code-group, and returns the updated rx_disparity as follows:

$$rx_disparity = \begin{cases} 2, & \text{if } Rx_n = \{+1, +1, -1\} \\ 3, & \text{otherwise} \end{cases}$$

146.3.4.1.3 Timers

RSTCD

Abbreviation for Receive Symbol Tripled Conversion Done, which is equivalent to the timer condition rcv_symb_triplet_timer_done.

rcv_max_timer

A timer used to determine the maximum amount of time the Receive watchdog state diagram stays in the RECEIVE state. The timer shall expire 4 ms ± 100 μs after being started. The condition rcv_max_timer_done becomes true upon timer expiration.

rcv_symb_triplet_timer

The rcv_symb_triplet_timer is a continuous free-running timer that shall expire with three times the period of the receive symbol clock synchronously to PMA_UNITDATA.indication. RX_CLK (see 22.2.2.2) shall be generated from rcv_symb_triplet_timer with the falling edge of RX_CLK generated synchronously with rcv_symb_triplet_timer_done. During initial link training, the phase of the rcv_symb_triplet_timer is aligned to the receive symbol clock as described in 146.3.4.2.

Continuous timer: The condition rcv_symb_triplet_timer_done becomes true upon timer expiration.

Restart time: Immediately after expiration.

Duration: Three symbol times (see 146.5.4.5)

146.3.4.1.4 Constants

COMMA

A vector of three ternary symbols in the first or second code-group of any delimiter as specified in 146.3.3.5.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.3.4.1.5 State diagrams

The PCS Receive state diagram is shown in Figure 146–9 and Figure 146–10 while the Receive watchdog state diagram is shown in Figure 146–11.

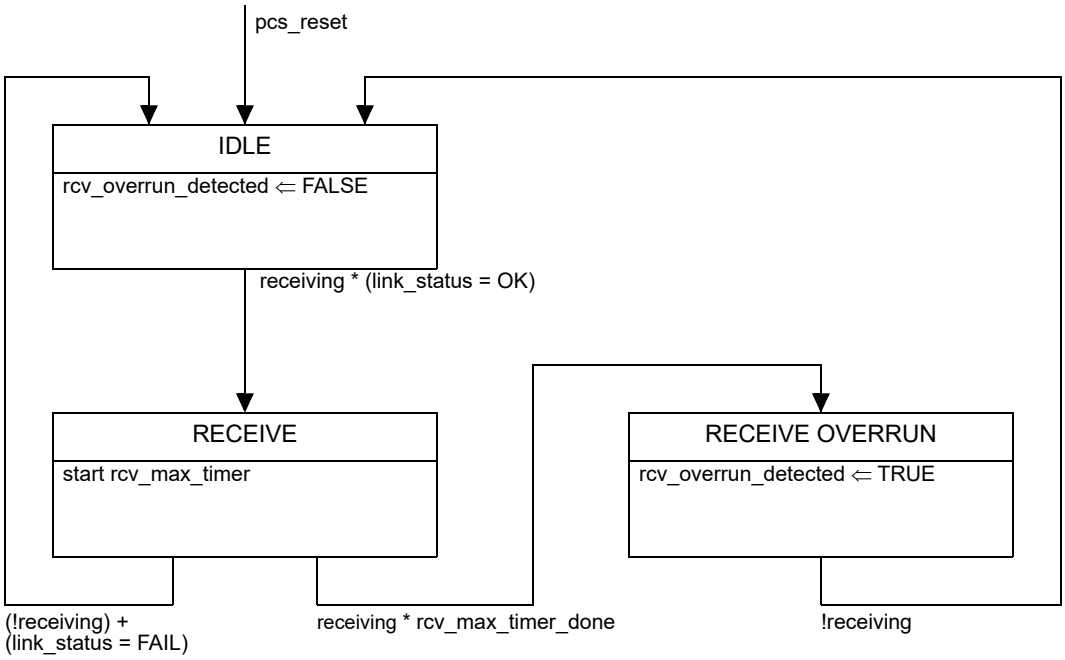

Figure 146–11—Receive watchdog state diagram

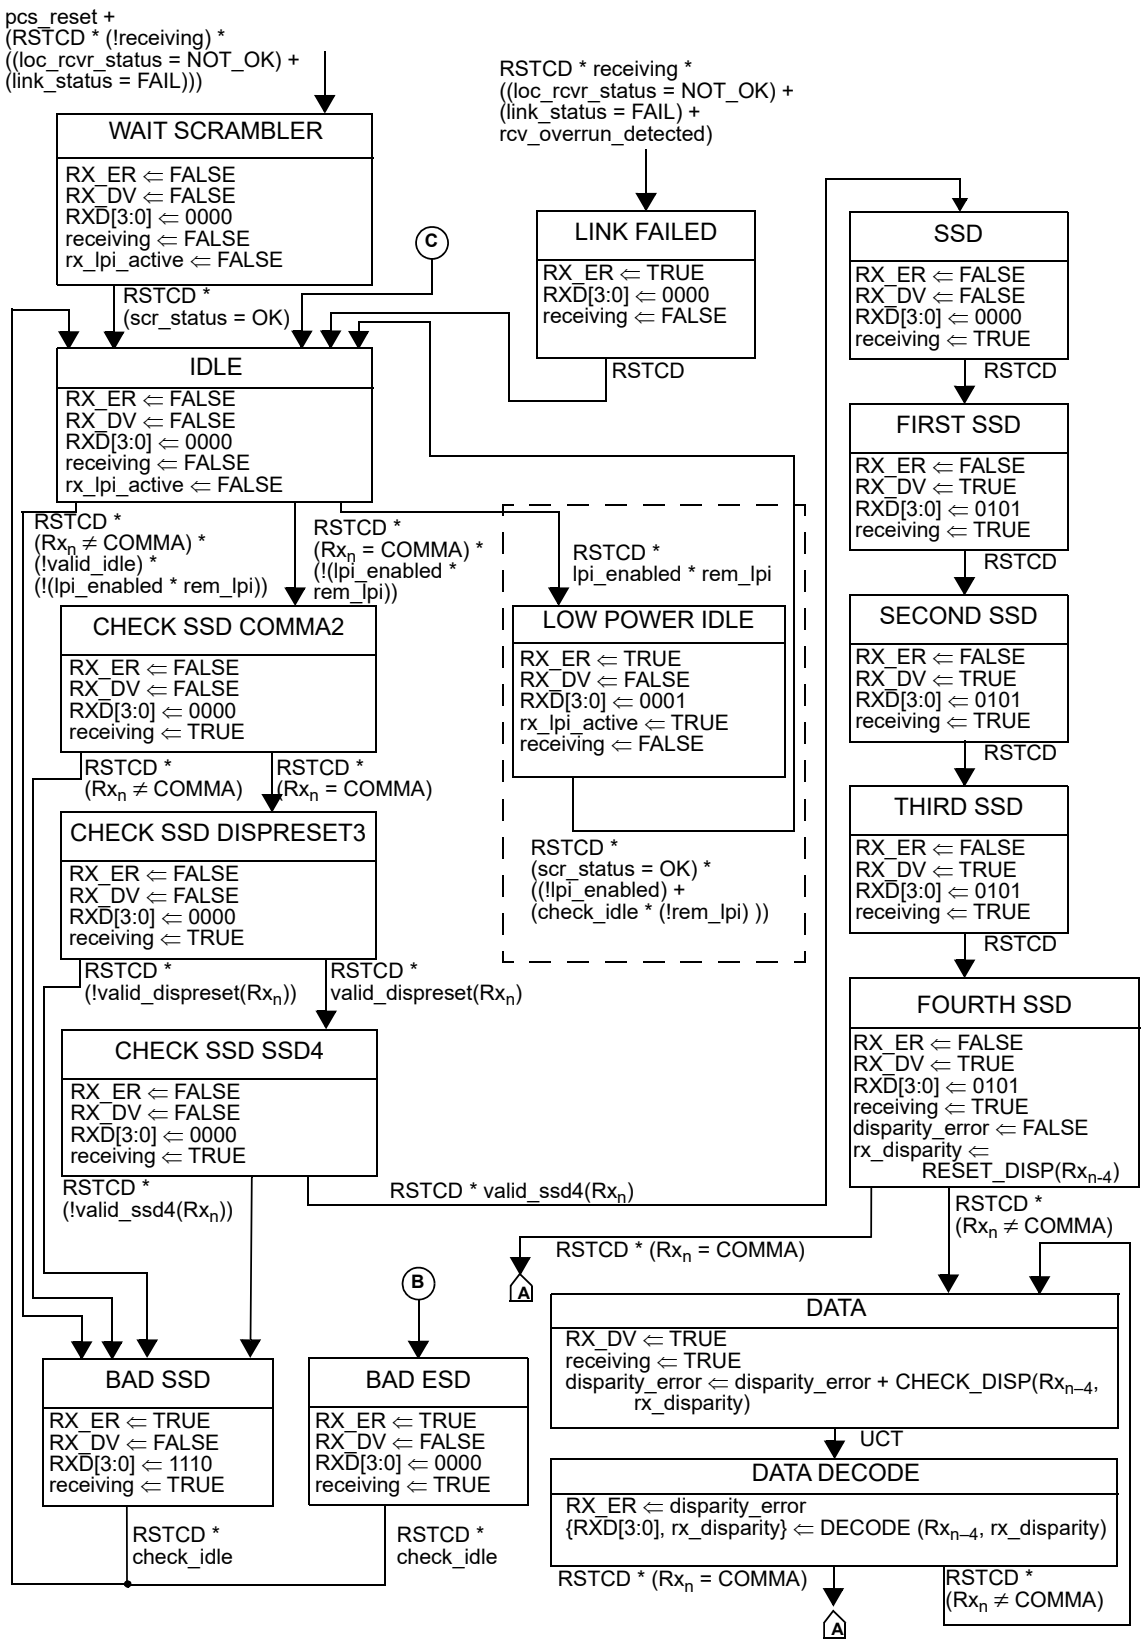
146.3.4.2 PCS Receive symbol decoding

When PMA Receive indicates normal operation and sets loc_rcvr_status = OK, the PCS Receive function checks the symbol sequences and searches for an SSD or a receive error indicator.



The received symbols, rx_symb_vector, are de-interleaved to generate received code-groups {RA_n, RB_n, RC_n}. To achieve correct operation, PCS Receive uses the knowledge of the encoding rules that are employed in the idle mode. The code-group {0, 0, 0} should never occur. The symbol synchronization in the de-interleaving block needs to be adjusted if the code-group {0, 0, 0} is being received. PCS Receive generates the sequence of symbols and indicates the reliable acquisition of the descrambler state by setting the parameter scr_status to OK. The descrambler can acquire synchronization during the PHY training.

The received code-groups {RA_n, RB_n, RC_n} are decoded to generate signals RXD[3:0], RX_DV, and RX_ER at the MII. The decoder shall also generate the disparity_error signal for the PCS Receive state diagram when a code-group is received that is not allowed according to the current running disparity value. Each time a code-group is received, the running disparity is updated. This is done using the current running disparity and adding the disparity change value as specified in Table 146–1 for the currently received code-group.

PCS Receive shall set RX_DV = TRUE when it receives an SSD, and shall set RX_DV = FALSE when it receives an ESD or ESD with error.

PCS Receive shall set RX_ER = TRUE when it receives bad ESDs, ERR_ESD, or bad SSDs. When the state diagram reaches the IDLE state, RX_ER shall be reset to FALSE.

146.3.4.3 PCS Receive descrambler polynomial

The PHY decodes the code-groups and returns the proper bit stream to the descrambling process for generation of RXD<3:0> to the MII. For side-stream descrambling, the MASTER PHY shall employ the following receiver descrambler generator polynomial:

$$g'_M(x) = 1 + x^{20} + x^{33} \quad (146–4)$$

and the SLAVE PHY shall employ the following receiver descrambler generator polynomial:

$$g'_S(x) = 1 + x^{13} + x^{33} \quad (146–5)$$

146.3.4.4 PCS Receive automatic polarity detection

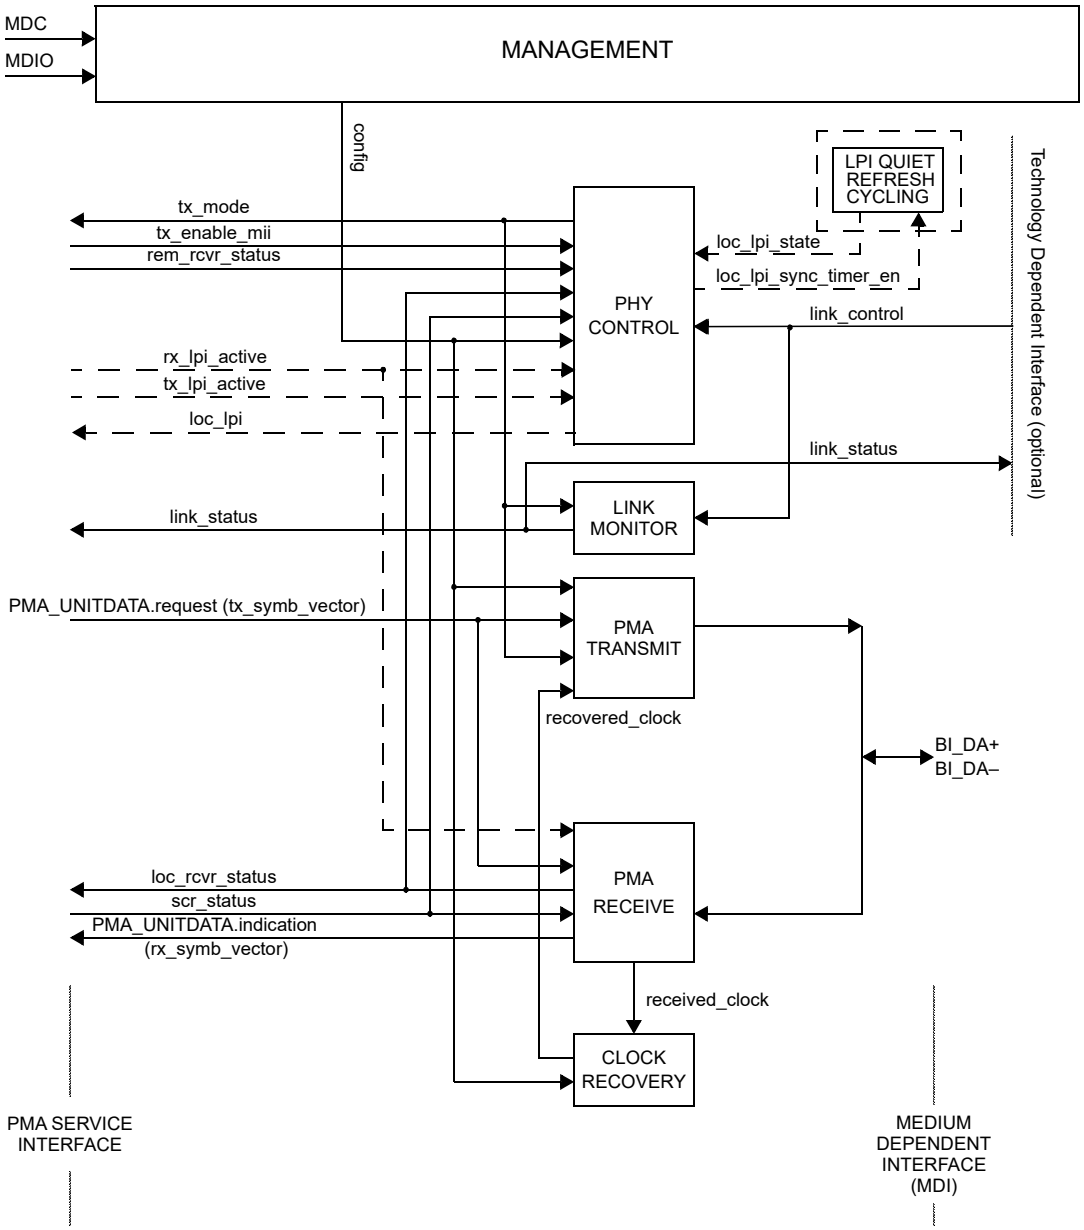
An automatic polarity detection and correction shall be implemented on the receive side of both master and slave PHY.

Polarity can be automatically detected in a recursive process: one assumption of polarity is made first and the descrambler synchronization is monitored within a certain period to determine whether such an assumption is correct; if not, the same procedure is repeated with a different polarity assumption and vice versa.

Receive polarity detection and correction can be done simultaneously at the earliest link up stages. Link up starts with the MASTER PHY sending symbols to the SLAVE PHY. If a polarity flip is detected, the SLAVE changes the sign of its received signals $\{RA_n, RB_n, RC_n\}$ to correct the polarity. There is no change in the polarity of the transmit signal. After the SLAVE PHY has started transmission, the MASTER PHY can use the same method for determining its receive polarity.

146.3.5 PCS loopback

The PCS shall be placed in loopback mode when the loopback bit in MDIO register 3.0.14, defined in 45.2.3.1.2, or the loopback bit in MDIO register 3.2278.14, defined in 45.2.3.70.2, is set to one (or by a similar functionality if MDIO is not implemented). In this mode, the PCS shall accept data on the transmit path from the MII and return it on the receive path to the MII. Additionally, the PHY receive circuitry shall be isolated from the network medium, and the assertion of TX_EN at the MII shall not result in the transmission of data on the network medium.



NOTE—The signal path through the PCS that is exercised in the loopback mode of operation is implementation specific, but it is recommended that the signal path encompasses as much of the PCS circuitry as is practical. The intention of providing this loopback mode of operation is to permit a diagnostic or self-test function testing the transmit and receive data paths.

146.4 Physical Medium Attachment (PMA) sublayer

The PMA couples messages from the PMA service interface specified in 146.3 onto the 10BASE-T1L physical medium, and provides the link management and PHY Control functions. The PMA provides full duplex communications to and from medium employing 3-level Pulse Amplitude Modulation (PAM3). The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 146.8.

PMA functions are illustrated in Figure 146–12.

NOTE 1—The “recovered_clock” shown indicates the delivery of the recovered clock back to PMA TRANSMIT in SLAVE mode for loop timing.

NOTE 2—Signals shown with dashed lines and blocks within dashed lines are required only for EEE functionality.

Figure 146–12—PMA functional block diagram

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.4.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

a) Power on (see 36.2.5.1.3).
b) The receipt of a request for reset from the management entity.

PMA Reset shall set pma_reset = TRUE while any of the above reset conditions hold true. All state diagrams take the open-ended pma_reset branch upon execution of PMA Reset. The reference diagrams do not explicitly show the PMA Reset function.

146.4.2 PMA Transmit function

Figure 146–13 illustrates the signal flow of the 10BASE-T1L PMA Transmit function. During transmission, PMA_UNITDATA.request conveys to the PMA via the parameter tx_symb_vector the value of the symbols to be sent over the single transmit pair.

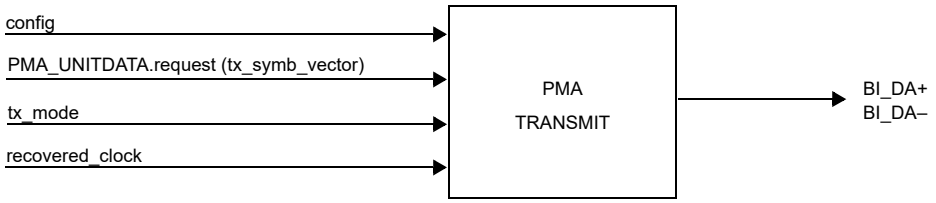

Figure 146–13—PMA Transmit

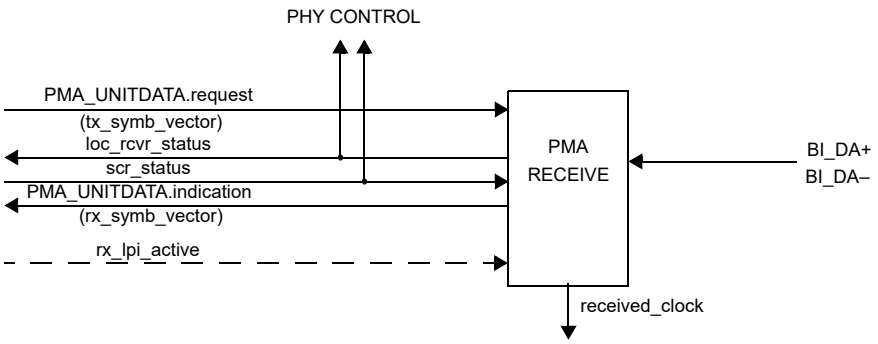
A single transmitter is used to generate the PAM3 signal BI_DA on the wire using the transmit clock, TX_TCLK (see 146.5.4.5). When the config parameter is set to MASTER, the PMA Transmit function derives the TX_TCLK from a local clock source. When the config parameter is set to SLAVE, the PMA Transmit function derives the TX_TCLK from the recovered clock.



The PMA Transmit fault function is optional. The faults detected by this function are implementation specific. If the MDIO interface is implemented, then this function shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

146.4.3 PMA Receive function

Figure 146–14 illustrates the signal flow of the 10BASE-T1L PMA Receive function. To achieve the indicated performance, it is highly recommended that PMA Receive includes the functions of signal equalization and echo cancellation. The sequence of symbols assigned to tx_symb_vector is needed to perform echo cancellation.

The 10BASE-T1L PMA Receive function comprises a single receiver (PMA Receive) for PAM3 modulated signals on a single balanced pair, BI_DA. PMA Receive has the ability to translate the received signals on the MDI into the PMA_UNITDATA.indication parameter rx_symb_vector. It detects ternary symbol sequences from the signals received at the MDI and presents these sequences to the PCS Receive function. The parameter loc_rcvr_status is generated by PMA Receive to indicate the status of the receive link at the local PHY. This variable indicates to the PCS Transmitter, PCS Receiver, and PMA PHY Control function whether the status of the overall received link is ok or not. Signal scr_status is generated by the PCS Receiver to indicate the status of the descrambler to the local PHY. It conveys the information on whether the scrambler has achieved synchronization or not to the PMA receive function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Signals shown with dashed lines are required only for EEE functionality.

Figure 146–14—PMA Receive

The PMA Receive fault function is optional. The PMA Receive fault function is the logical OR of the link_status = FAIL and any implementation specific fault. If the MDIO interface is implemented, this function shall contribute to the receive fault bit specified in 45.2.1.7.5 and 45.2.1.232.7.

146.4.4 PHY Control function

If the Auto-Negotiation process (Clause 98) is not implemented or not enabled, PMA_CONFIG MASTER-SLAVE configuration is predetermined to be MASTER or SLAVE via management control during initialization or via default hardware setup.

The PHY Control functions block governs the control actions needed to bring the PHY into the 10BASE-T1L mode of operation so that frames can be exchanged with the link partner. PMA PHY Control also generates the signals that control PCS and PMA sublayer operations. It determines whether the PHY operates in the normal mode, enabling data transmission over the link segment, or whether the PHY sends idle data. PHY Control sets tx_mode to SEND_N (transmission of normal MII Data Stream, Control Information, or Idle Data), SEND_I (transmission of Idle Data), or SEND_Z (transmission of zero symbol vectors).

If the time to reach link_status = OK exceeds the duration of the link_fail_inhibit timer used in the Auto-Negotiation Arbitration state diagram (see Figure 98–7), the training may be considered failed. Management reset of the PHY control state diagram when Auto-Negotiation is not enabled (or not present) is outside the scope of this standard.

To maximize power savings, maintain link integrity, and ensure interoperability, EEE-capable PHYs shall synchronize refresh intervals during the low power idle (LPI) mode.

LPI synchronization is established by the PHY Control function, towards the end of link startup, using a handshake scheme initiated by the MASTER. This scheme initiates LPI quiet-refresh cycling at the same time as a transition from TRUE to FALSE of the loc_lpi variable. As loc_lpi is conveyed to the link partner PHY, the time of the start of LPI quiet-refresh cycling is also conveyed. LPI quiet-refresh cycling is defined in 146.4.7.

Thereafter, the LPI quiet-refresh cycling runs freely, with a cycle of fixed period, and, because the SLAVE maintains timing lock with the MASTER, the timing relationship between the quiet-refresh cycling in both PHYs remains fixed.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PHY Control shall comply with the state diagram shown in Figure 146–15, Figure 146–16, and Figure 146–17. Figure 146–15 describes link startup sequencing. Figure 146–16 describes LPI synchronization sequencing (required only to support EEE capability). Figure 146–17 describes entry and exit to LPI mode (also required only to support EEE capability).

146.4.4.1 Variables

pma_reset
: Allows reset of all PMA functions.
Values: TRUE or FALSE
Set by: PMA Reset

link_control
: This variable is set by management control or via hardware.
Values: ENABLE or DISABLE

config
: The config parameter is set by management or set by auto-negotiation and passed to the PMA and PCS.
Values: MASTER or SLAVE

loc_lpi:
: The variable loc_lpi is set by the PHY Control function to indicate that it has entered low power idle mode.
Values: TRUE or FALSE

loc_lpi_timer_sync_en
: The variable loc_lpi_timer_sync_en is set by the PHY Control function to enable low power idle quiet-refresh cycling.
Values: TRUE: LPI quiet-refresh cycling is enabled.
FALSE: LPI quiet-refresh cycling is disabled.

loc_rcvr_status
: Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive function for the local PHY.
Values: OK: The receive function for the local PHY is operating reliably.
NOT_OK: Operation of the receive function for the local PHY is unreliable.

lpi_enabled
: This variable indicates whether Energy Efficient Ethernet is enabled for the PHY or not.
Values: TRUE: Energy Efficient Ethernet is enabled.
FALSE: Energy Efficient Ethernet is not enabled.

mr_autoneg_enable
: See 98.5.1.

rem_rcvr_status
: Variable set by the PCS Receive function to indicate whether correct operation of the receive function for the remote PHY is detected or not.
Values: OK: The receive function for the remote PHY is operating reliably.
NOT_OK: Reliable operation of the receive function for the remote PHY is not detected.

rx_lpi_active
: This variable indicates to the PMA receive function if the receive state diagram is in low power idle state.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

scr_status

The scr_status parameter as communicated by the PMA_SCRSTATUS.request primitive.
Values: OK: The descrambler has achieved synchronization.
NOT_OK: The descrambler is not synchronized.

slave_clock_locked

Variable indicates the status of the clock recovery on a slave PHY. Implementations may benefit from checking scr_status for determining whether the slave clock is locked to the master PHY.
Values: TRUE: The slave clock is stable and locked to the master PHY clock.
FALSE: The slave clock is not locked to the master PHY clock, or is otherwise unstable.

tx_enable_mii

The tx_enable_mii variable is generated in the PCS data transmission enabling state diagram as specified in Figure 146–4. When set to FALSE transmission is disabled; when set to TRUE transmission is enabled.
Values: TRUE or FALSE

tx_lpi_active

This variable indicates to the PMA PHY control function whether the “Assert Low Power Idle” condition on the MII is active.
Values: TRUE or FALSE

tx_mode

PCS Transmit sends code-groups according to the value of this variable.
Values: SEND_N: This value is continuously asserted when transmitting data, control information or idle during normal operation.
SEND_I: This value is continuously asserted when transmitting idle data during training.
SEND_Z: This value is asserted when transmitting zero code-groups.

146.4.4.2 Timers

maxtraining_timer

A timer used to limit the maximum allowed training time of the receiver. The timer shall expire 3000 ms ± 30 ms after being started.

mintraining_timer

A timer to define the minimum time a slave PHY stays in training mode before going to SILENT state when the slave loses clock lock. The slave clock may be unstable during this period. The timer shall expire 100 ms ± 1 ms after being started.

lpi_sleep_timer

A timer used to determine the duration of the SEND SLEEP state, where transmission comprises IDLE symbols with loc_lpi set. The timer shall expire 150 TX_TCLK periods (nominally 20 μs) after being started.

lpi_wake_timer

A timer used to determine how long the WAKE signal is being sent to the remote PHY. The timer shall expire 1875 TX_TCLK periods (nominally 250 μs) after being started.

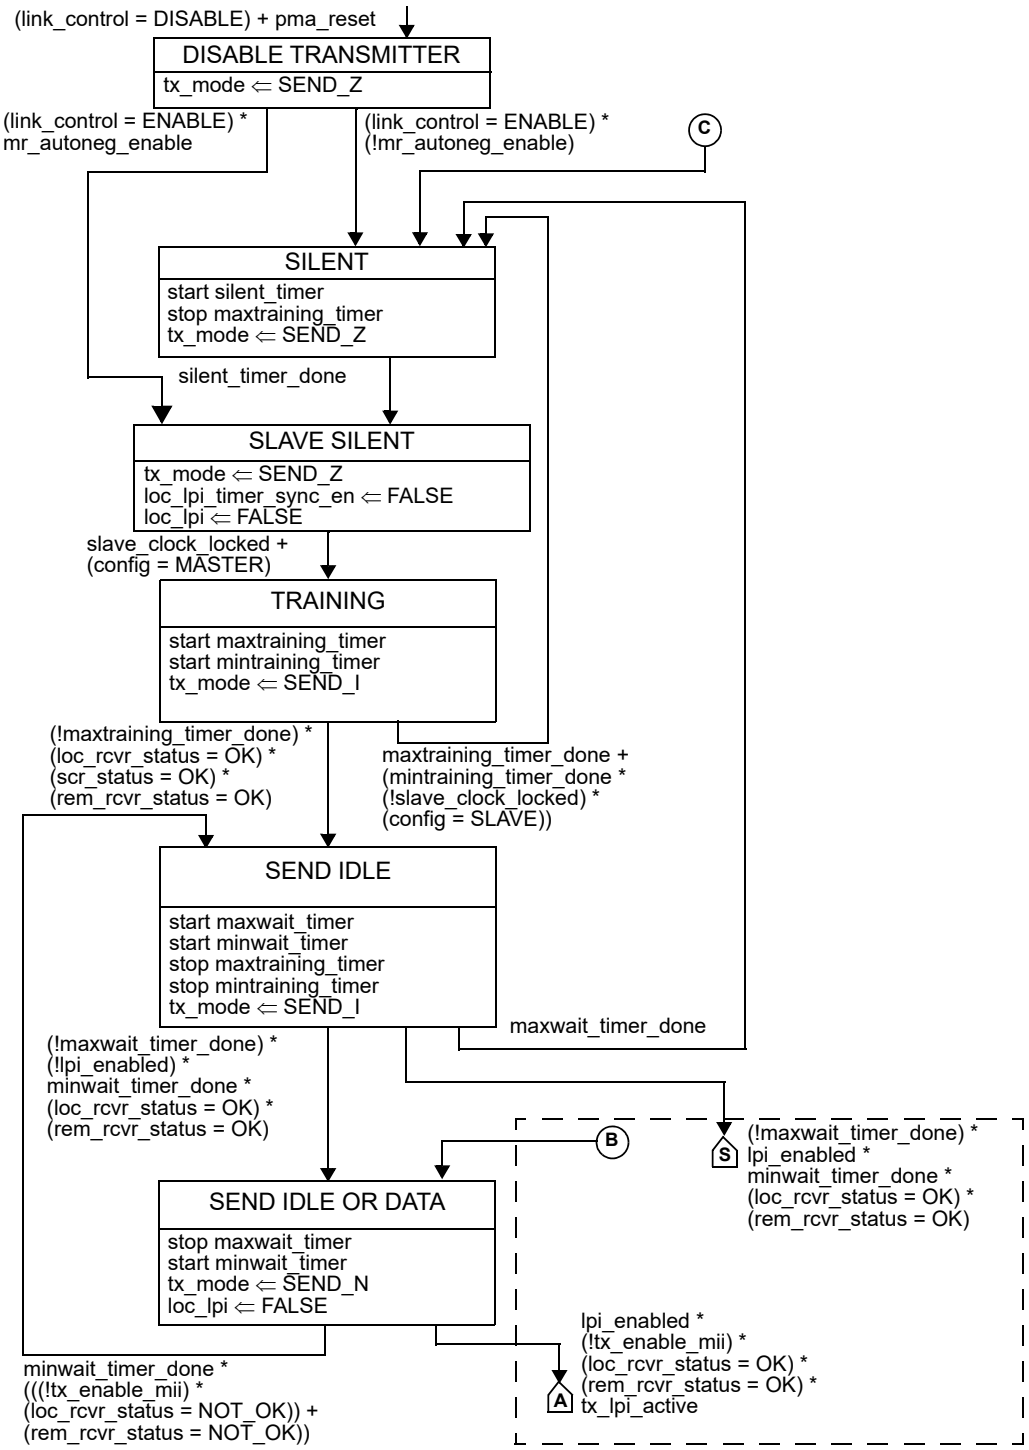
maxwait_timer

A timer used to limit the amount of time during which a receiver dwells in the SEND IDLE state. The timer shall expire 200 ms ± 2 ms after being started.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

minwait_timer

A timer used to determine the minimum amount of time the PHY Control stays in the SEND IDLE or DATA states. The timer shall expire 20 μs ± 1 μs after being started.



silent_timer

A timer used to set the time a PHY stays in the SILENT state. The timer shall expire 245 ms ± 5 ms after being started.

NOTE—After a disturbance on the link segment, e.g., when the current consumption on a powered link segment is quickly changed, the maxwait_timer allows the PHYs to stay in the SEND IDLE state before going to the SILENT state. This allows the PHYs to attempt to recover the link before a full retrain.

146.4.5 Link Monitor function

Link Monitor operation, as shown in state diagram of Figure 146–18, shall be provided to support PHY Control. Variable link_control is set to ENABLE through management control during the PHY initialization or via default hardware set-up.

146.4.5.1 Variables

tx_mode

The tx_mode parameter set by the PMA PHY Control function and passed to the PCS via the PMA_TXMODE.indication primitive.
Values: SEND_Z, SEND_N, or SEND_I

link_status

The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

146.4.5.2 State diagram

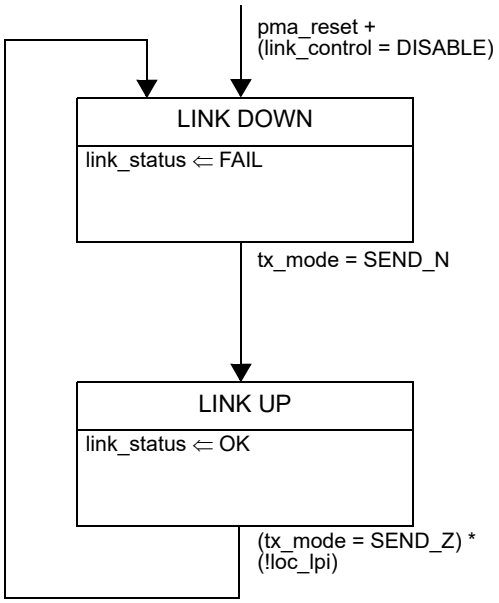

Figure 146–18—PHY Link Monitor state diagram

146.4.6 PMA clock recovery

The clock recovery provides a synchronous clock for sampling the signal on the pair. While it may not drive the MII directly, the Clock Recovery function is the underlying source of TX_CLK. This PMA function recovers the clock from the received stream. It is coupled to the receiver in order to provide for the SLAVE PHY a clock synchronous to the transmit clock of the MASTER PHY.

146.4.7 LPI quiet-refresh cycling

LPI quiet-refresh cycling is initiated on direction from the PHY Control function using the LPI synchronization mechanism.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Once initiated, LPI quiet-refresh cycling runs freely for the lifetime of the link.

The SLAVE PHY is required to implement an initial offset delay, to ensure that refresh intervals of MASTER and SLAVE are not coincident.

The quiet-refresh cycle timing is defined in terms of transmit symbol periods (TX_TCLK periods). As the SLAVE has to maintain timing lock with the MASTER, the timing relationship between the LPI quiet-refresh cycling of the two PHYs has to remain fixed for the lifetime of the link.

LPI quiet-refresh cycling shall comply with the state diagram of Figure 146–19.

146.4.7.1 Variables

loc_lpi_timer_sync_en

The variable loc_lpi_timer_sync_en is set by the PHY Control function to enable low power idle quiet-refresh cycling.

Values: TRUE: LPI quiet-refresh cycling is enabled.
FALSE: LPI quiet-refresh cycling is disabled.

loc_lpi_state

The variable loc_lpi_state sets the quiet-refresh state when the PHY is in low power idle mode.

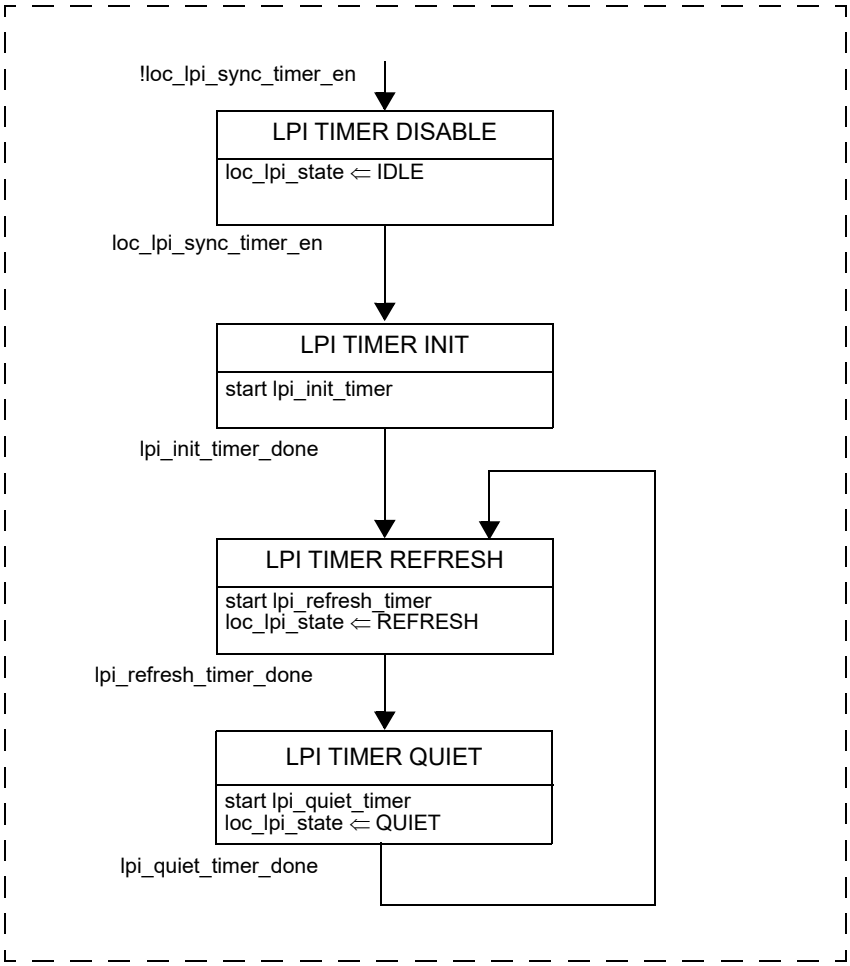
Values:
- IDLE: LPI quiet-refresh cycling is not enabled.
- REFRESH: The PHY is in the low power idle refresh phase.
- QUIET: The PHY is in the low power idle quiet phase.

146.4.7.2 Timers

lpi_init_timer

A timer used to set the duration of the LPI TIMER INIT state, which is intended to introduce a fixed offset between LPI refresh phases of the MASTER and SLAVE PHYs.
If config = MASTER, this timer shall expire after 0 TX_TCLK periods.
If config = SLAVE, this timer shall expire after 22500 TX_TCLK periods (nominally 3000 μs).

lpi_refresh_timer



A timer used to set the duration of the LPI refresh phase.
This timer shall expire after 1875 TX_TCLK periods (nominally 250 μs).

lpi_quiet_timer

A timer used to set the duration of the LPI quiet phase.
This timer shall expire after 45 000 TX_TCLK periods (nominally 6000 μs).

146.5 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA for a 10BASE-T1L Ethernet PHY.

146.5.1 EMC tests

Direct Power Injection (DPI) and 150 Ω emission tests for noise immunity and emission as per 146.5.1.1 and 146.5.1.2 can be used to establish a baseline for PHY EMC performance. These tests provide a high degree of repeatability and a good correlation to immunity and emission measurements.

146.5.1.1 Immunity—DPI test

In a real application, radio frequency (RF) common-mode (CM) noise at the PHY is the result of electromagnetic interference coupling to the cabling system. Additional differential-mode (DM) noise at the PHY is generated from the CM noise by mode conversion of all parts of the cabling system and the MDI. The sensitivity of the PMA's receiver to RF CM noise can be tested according to the DPI method of IEC 62132-4.

146.5.1.2 Emission—Conducted emission test

The emission of the PMA transmitter to its electrical environment can be tested according to the 150 Ω direct coupling method of IEC 61967-4.

146.5.2 Test modes

The test modes described in this subclause are provided to allow testing of the transmitter waveform, transmitter distortion, transmitter jitter, and transmitter droop. Test modes 1 through 3 shall be implemented as follows. The test modes can be enabled by setting bits 1.2296.15:13 (10BASE-T1L Test Mode Control Register) of the PHY Management register set as described in 45.2.1.233.1. If MDIO is not implemented, a similar functionality shall be provided by another interface. These test modes shall change only the data symbols provided to the transmitter circuitry and shall not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation.

a) Test mode 1—Transmitter output voltage and timing jitter test mode
b) Test mode 2—Transmitter output droop test mode
c) Test mode 3—Normal operation in Idle mode. This is for the PSD mask test.

When test mode 1 is enabled, the PHY shall repeatedly transmit the data symbol sequence (+1, –1). See 146.5.4.5 for transmit clock requirements.

When test mode 2 is enabled, the PHY shall transmit ten "+1" symbols followed by ten "–1" symbols. This sequence is repeated continually.

When test mode 3 is enabled, the 10BASE-T1L PHY shall transmit as in non-test operation and in the MASTER data mode with data set to normal Inter-Frame idle signals.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.5.3 Test fixture

The following fixtures (illustrated by Figure 146–20 and Figure 146–21), or their functional equivalents, can be used for measuring the transmitter specifications described in 146.5.4. All the transmitter tests are defined at the MDI.

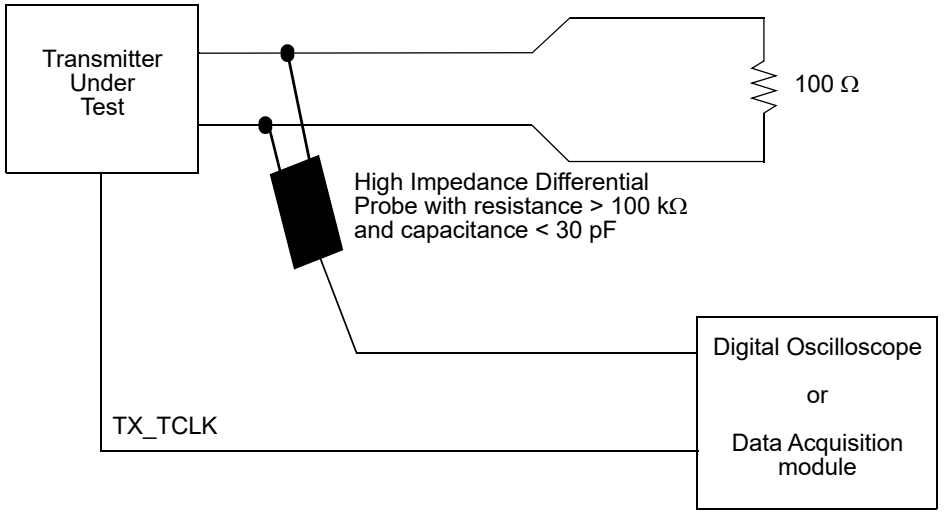

Figure 146–20—Transmitter test fixture 1 for transmitter voltage, transmitter droop, and transmitter timing jitter

To allow an easy synchronization of the measurement equipment, the PHY shall provide access to the symbol rate clock TX_TCLK, which times the transmitted symbols. For a MASTER PHY this is the output of the (divided) clock oscillator; for the SLAVE PHY this is the recovered clock.

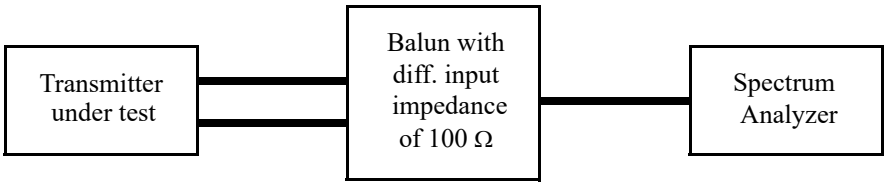

Figure 146–21—Transmitter test fixture 2 for power spectral density measurement and transmit power level measurement

146.5.4 Transmitter electrical specifications

The PMA shall operate with AC coupling to the MDI. Where a load is not specified, the transmitter shall meet the requirements of 146.5.4 with a 100 Ω ± 0.1% resistive differential load connected to the transmitter output.

146.5.4.1 Transmitter output voltage

When tested with the test fixture shown in Figure 146–20 with the transmitter in test mode 1, the transmitter output voltage shall be 2.4 V + 5%/– 15% peak-to-peak (for the 2.4 Vpp operating mode) and 1.0 V + 5%/– 15% peak-to-peak (for the 1.0 Vpp operating mode). Transmitter output voltage can be set using the management interface or by hardware default set-up.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—In all transmit modes, including SEND_I and SEND_N, when measured with a 100 Ω ± 0.1% termination, the transmit differential signal at the MDI is less than 2.64 Vpp for the 2.4 Vpp operating mode and 1.10 Vpp for the 1.0 Vpp operating mode including the signal droop.

146.5.4.2 Transmitter output droop

With the transmitter in test mode 2 and using the transmitter test fixture shown in Figure 146–20, the magnitude of both the positive and negative droop shall be less than 10% measured with respect to an initial value at 133.3 ns after the zero crossing and a final value at 800 ns after the zero crossing.

146.5.4.3 Transmitter timing jitter

When tested using the test fixture shown in Figure 146–20 with the transmitter in test mode 1, the maximum jitter at the transmitter side shall be less than 10 ns symbol-to-symbol jitter.

146.5.4.4 Transmitter Power Spectral Density (PSD) and power level

In test mode 3 (reflecting normal operation), the transmit power shall be 8.6 ± 1.2 dBm for the 2.4 Vpp operating mode and 1.0 ± 1.2 dBm for the 1.0 Vpp operating mode. The power spectral density of the transmitter, measured into a 100 Ω load using the test fixture shown in Figure 146–21, shall be between the upper and lower masks specified in Equation (146–6) and Equation (146–7) for the 2.4 Vpp transmit amplitude, and by Equation (146–8) and Equation (146–9) for the 1.0 Vpp transmit amplitude. The masks are shown in Figure 146–22 and Figure 146–23.

For the 2.4 Vpp transmit signal amplitude:

$$\text{Upper PSD Limit } (f) \geq \begin{cases} -54 \text{ dBm/Hz} & 0 \leq f \leq 2.5 \\ -54 - 1.6 \times (f - 2.5) \text{ dBm/Hz} & 2.5 < f < 12.5 \\ -70 \text{ dBm/Hz} & 12.5 \leq f \leq 20 \end{cases} \quad (146\text{–}6)$$

$$\text{Lower PSD Limit } (f) \geq \begin{cases} -60 \text{ dBm/Hz} & 0.625 \leq f \leq 2.5 \\ -60 - 4 \times (f - 2.5) \text{ dBm/Hz} & 2.5 < f \leq 5 \end{cases} \quad (146\text{–}7)$$

where f is the frequency in MHz, and for the 1.0 Vpp transmit signal amplitude:

$$\text{Upper PSD Limit } (f) \geq \begin{cases} -61.6 \text{ dBm/Hz} & 0 \leq f \leq 2.5 \\ -61.6 - 1.6 \times (f - 2.5) \text{ dBm/Hz} & 2.5 < f < 12.5 \\ -77.6 \text{ dBm/Hz} & 12.5 \leq f \leq 20 \end{cases} \quad (146\text{–}8)$$

$$\text{Lower PSD Limit } (f) \geq \begin{cases} -67.6 \text{ dBm/Hz} & 0.625 \leq f \leq 2.5 \\ -67.6 - 4 \times (f - 2.5) \text{ dBm/Hz} & 2.5 < f \leq 5 \end{cases} \quad (146\text{–}9)$$

where f is the frequency in MHz.

146.5.4.5 Transmit clock frequency

The symbol transmission rate of the MASTER PHY shall be within the range 7.5 MBd ± 50 ppm. For a MASTER PHY, when the transmitter is in the LPI transmit mode, the transmitter clock short-term rate of frequency variation shall be less than 0.1 ppm/second. The short-term frequency variation limit shall also apply when switching to and from the LPI mode.

146.5.5 Receiver electrical specifications

The PMA shall meet the requirements specified in PMA Receive function and the electrical specifications of this subclause. The link segment used in the test configurations shall be within the limits specified in 146.7.

146.5.5.1 Receiver differential input signals

Differential signals received at the MDI, that were transmitted from a remote transmitter within the specifications of 146.5.4, and have passed through a link segment specified in 146.7, shall be received with a bit error ratio less than 10^{-9} after PCS processing and sent to the MII after completion of link training. This specification can be verified by a frame error ratio less than 10^{-6} for 125 octet frames.

146.5.5.2 Receiver frequency tolerance

The receiver shall properly receive incoming data with a symbol rate within the range 7.5 MBd ± 50 ppm.

146.5.5.3 Alien crosstalk noise rejection

This specification is provided to verify the receiver's tolerance to alien crosstalk noise. The test is performed with a noise source such that noise with a Gaussian distribution, bandwidth of 10 MHz, and magnitude of –106 dBm/Hz is present at the MDI. The receive DUT is connected to these noise sources through a resistive network, as shown in Figure 146–24, with a link segment as defined in 146.7. The BER shall be less than 10^{-9}. This specification may be considered satisfied when the frame loss ratio is less than 10^{-6} for 125 octet packets measured at MAC/PLS service interface.

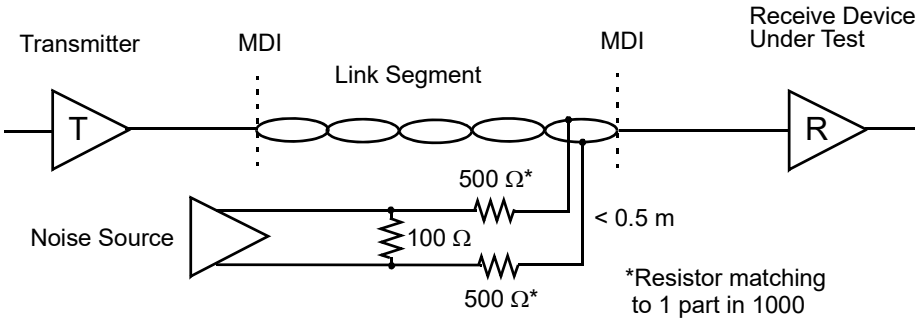

Figure 146–24—Alien crosstalk noise rejection test set-up

NOTE—If the output level is too high for the noise generator, the resistor divider network may be adapted to allow for a lower noise generator output level so that the noise signal fed into the receiver has a magnitude of –106 dBm/Hz with a bandwidth of 10 MHz, taking the 100 Ω termination within the PHY into account.

146.5.6 PMA local loopback

The PMA local loopback function is optional. If supported, the PMA shall be placed in local loopback mode when the PMA local loopback bit in MDIO register 1.0.0, defined in 45.2.1.1, or the PMA loopback bit in MDIO register 1.2294.0, defined in 45.2.1.231.6, is set to one (or PMA loopback mode is enabled by a similar functionality if MDIO is not implemented). When the PHY is in the PMA local loopback mode, the PMA Receive function utilizes the echo signals from the open MDI and decodes these signals to pass the data back to the MII Receive interface. The data flow of the external loopback is shown in Figure 146–25. When PMA loopback mode is present and enabled, the PCS transmit scrambler polynomial and the receiver descrambler polynomial should be matched, e.g., the MASTER scrambler polynomial and the SLAVE descrambler polynomial, in order for looped data to be properly descrambled at the MII.

A MAC client can compare the packets sent through the MII Transmit function to the packets received from the MII Receive function to validate the 10BASE-T1L PCS and PMA functions.

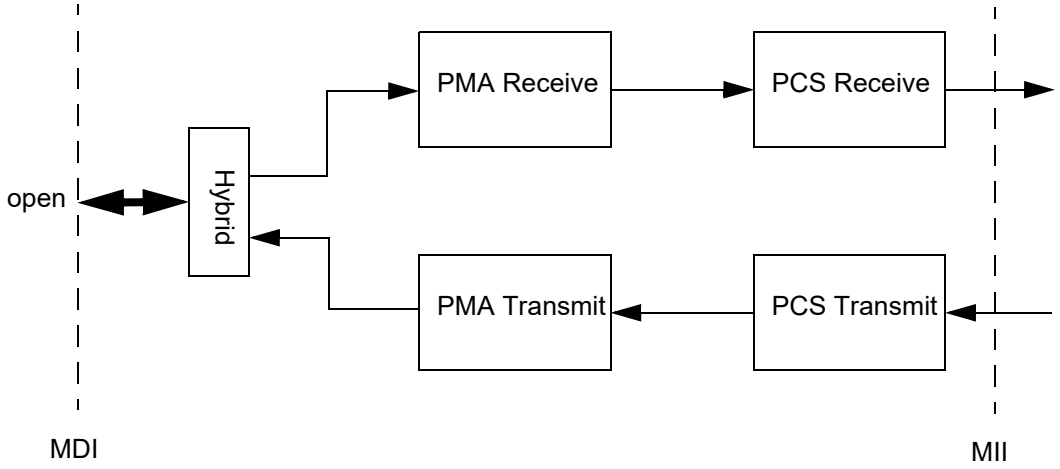

Figure 146–25—PMA loopback data flow

146.6 Management interface

10BASE-T1L uses the management interface as specified in Clause 45. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the registers is recommended.

146.6.1 Support for Auto-Negotiation

If Auto-Negotiation is supported and enabled, the mechanism described in Clause 98 shall be used. Auto-Negotiation may be performed as part of the initial set-up of the link and allows negotiation of MASTER/SLAVE for loop timing, increased transmit level, and EEE capabilities.

146.6.2 MASTER-SLAVE configuration

MASTER-SLAVE assignment for each link configuration is necessary for establishing the timing control of each PHY. In 10BASE-T1L, one PHY should be configured as MASTER and one PHY should be configured as SLAVE to operate. In the case where both PHYs are configured to be MASTER or both to be SLAVE, operation is undefined.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If Auto-Negotiation is available and enabled, the MASTER-SLAVE configuration between the PHYs is established using the method being described in 98.2.1.2.5 and Table 98–4. If there is no Auto-Negotiation functionality present or if Auto-Negotiation function has been disabled, the MASTER-SLAVE configuration is performed for each PHY using bit 1.2100.14 (BASE-T1 PMA/PMD control register) or equivalent functionality.

146.6.3 PHY initialization

Both PHYs sharing a link segment are capable of being MASTER or SLAVE. A forced assignment scheme or an Auto-Negotiation process is employed depending on the use case of the PHY. This process is conducted at the power-up or reset condition. The station management systems can manually configure the 10BASE-T1L PHY to be MASTER or to be SLAVE (before the link acquisition process starts) or a hardware set-up using bootstrap options can be implemented.

When MDIO is implemented, MASTER/SLAVE mode can be selected by setting bit 1.2100.14 (BASE-T1 PMA/PMD Control Register) of the PHY Management register set as described in 45.2.1.214. If MDIO is not implemented, a similar functionality shall be provided by another interface. The default setting is to use Auto-Negotiation, if available.

146.6.4 Increased transmit level configuration

The transmitter output voltage can be selected by setting bit 1.2294.12 (10BASE-T1L PMA control register) of the PHY Management register set as described in 45.2.1.231.3 if Auto-Negotiation is disabled or not present. If MDIO is not implemented, a similar functionality shall be provided by another interface.

When Auto-Negotiation is implemented and enabled, bit A23 shall contain a one if the PHY is requesting the increased transmit level from its link partner, and it shall contain a zero if the 2.4 Vpp operating mode is not requested from the link partner (see 146.5.4.1). Bit A24 shall contain a one if the PHY is supporting and advertising the 2.4 Vpp operating mode, and it shall contain a zero if the 2.4 Vpp operating mode is not supported or not advertised.

When Auto-Negotiation is present and enabled and both PHYs advertise an increased transmit/receive ability if at least one PHY requests the 10BASE-T1L increased transmit level, then both PHYs shall use the 2.4 Vpp operating mode, in all other cases both PHYs shall use the 1.0 Vpp operating mode.

146.6.5 EEE configuration

When Auto-Negotiation is implemented and enabled, bit A25 shall contain a one if the 10BASE-T1L PHY is supporting and advertising Energy Efficient Ethernet ability and it shall contain a zero if Energy Efficient Ethernet is not supported or not advertised.

146.6.6 PMA and PCS MDIO function mapping

The MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMA and PCS. When MDIO is implemented, mapping of MDIO register bits to PMA and PCS control/status variables is shown in Table 146–4. If no MDIO is implemented, a similar functionality shall be implemented to access the needed variables.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 146–4—MDIO register bit mapping

Register Name	Register/Bit Number	Control/Status variable
BASE-T1 PMA/PMD control register	1.2100.3:0	T1 PHY type selection
BASE-T1 PMA/PMD control register	1.2100.14	Master/Slave mode
PMA/PMD Control 1 register 10BASE-T1L PMA control register	1.0.15 1.2294.15	pma_reset
PMA/PMD Control 1 register 10BASE-T1L PMA control register	1.0.0 1.2294.0	PMA loopback
PMA/PMD Status 1 register 10BASE-T1L PMA status register	1.1.2 1.2295.0	link_status
10BASE-T1L PMA control register	1.2294.12	Transmit voltage amplitude control
PCS Control 1 register 10BASE-T1L PCA control register	3.0.15 3.2278.15	pcs_reset
PCS Control 1 register 10BASE-T1L PCA control register	3.0.14 3.2278.14	PCS loopback

146.7 Link segment characteristics

10BASE-T1L is designed to operate over a single balanced pair of conductors that meets the requirements specified in this subclause. The single balanced pair of conductors supports an effective data rate of 10 Mb/s in each direction simultaneously. The term “link segment” used in this clause refers to a single balanced pair of conductors operating in full duplex. Note that Annex 146B provides information on the optional powering topologies. The class power requirements are specified in Clause 104.

The link segment specified in this clause is based on process control application requirements and supports up to ten in-line connectors using a single balanced pair of conductors for up to at least 1000 m.

146.7.1 Link transmission parameters for 10BASE-T1L

The transmission characteristics for the 10BASE-T1L link segment are specified to support applications requiring long reach such as industrial and process control, for up to at least 1000 m. 10BASE-T1L link segments may be shielded or screened, consistent with the specification in 146.7.1.6 and 146.7.2 or unshielded consistent with the specifications in 146.7.1.6 and 146.7.1.4.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.7.1.1 Insertion loss

All 10BASE-T1L PHYs support the insertion loss specified in 146.7.1.1.2, but support of the insertion loss specified in 146.7.1.1.1 is required only when the 2.4 Vpp transmit/receive ability is operational.

146.7.1.1.1 Insertion loss for PHYs in the 2.4 Vpp operation mode

For PHYs in the 2.4 Vpp operation mode, the insertion loss of each 10BASE-T1L link segment shall meet the values determined using Equation (146–10).

$$\text{Insertion loss}(f) \le 10\left(1.23 \times \sqrt{f} + 0.01 \times f + \frac{0.2}{\sqrt{f}}\right) + 10 \times 0.02 \times \sqrt{f} \quad \text{(dB)} \tag{146–10}$$

where

f is the frequency in MHz; $0.1 \le f \le 20$

The insertion loss is illustrated in Figure 146–26.

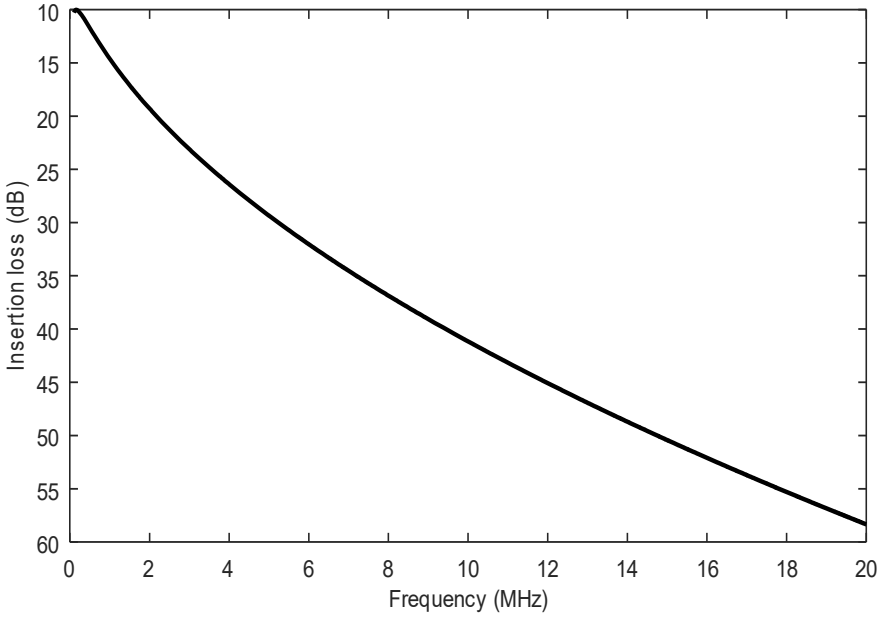

Figure 146–26—Insertion loss calculated using Equation (146–10)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

146.7.1.1.2 Insertion loss supported for PHYs in 1.0 Vpp operation mode

For PHYs in the 1.0 Vpp operation mode, the insertion loss of each 10BASE-T1L link segment shall meet the values determined using Equation (146–11).

$$\text{Insertion loss}(f) \le 5.9\left(1.23 \times \sqrt{f} + 0.01 \times f + \frac{0.2}{\sqrt{f}}\right) + 10 \times 0.02 \times \sqrt{f} \quad \text{(dB)} \tag{146–11}$$

where

f is the frequency in MHz; $0.1 \le f \le 20$

The insertion loss is illustrated in Figure 146–27.

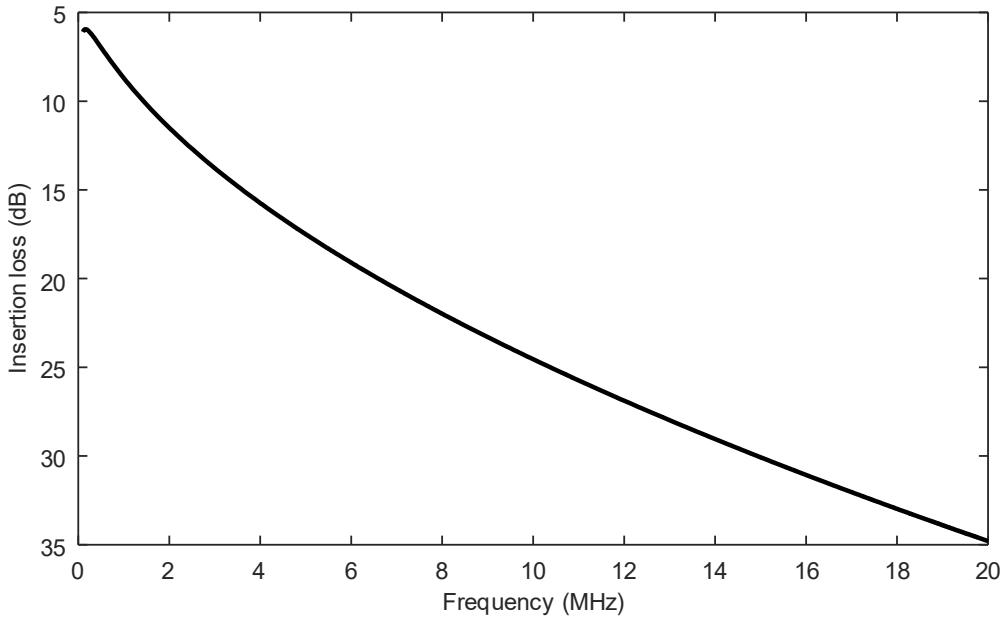

Figure 146–27—Insertion loss calculated using Equation (146–11)

146.7.1.2 Return loss

In order to limit the noise at the receiver due to impedance mismatches, each 10BASE-T1L link segment shall meet the values determined using Equation (146–12) at all frequencies from 0.1 MHz to 20 MHz. The reference impedance for the return loss specification is 100 Ω.

$$\text{Return loss} \ge \left\{ \begin{array}{rl} 9 + 8 \times f & 0.1 \le f < 0.5 \text{ MHz} \\ 13 & 0.5 \le f \le 20 \text{ MHz} \end{array} \right\} \text{dB} \tag{146–12}$$

where

f is the frequency in MHz; $0.1 \le f \le 20$

The return loss is illustrated in Figure 146–28.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

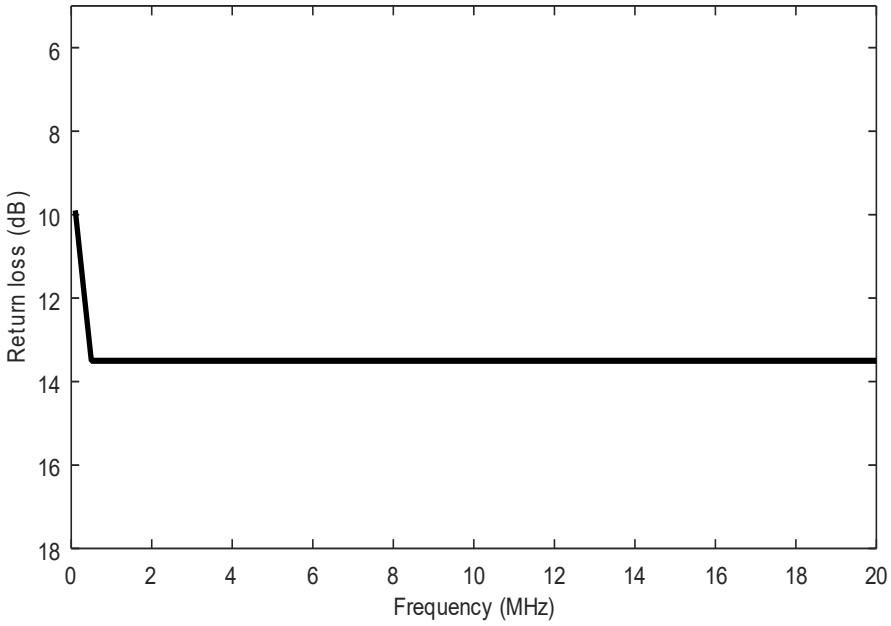

Figure 146–28—Return loss calculated using Equation (146–12)

146.7.1.3 Maximum link delay

The propagation delay of a 10BASE-T1L link segment shall not exceed 8834 ns at all frequencies between 0.1 MHz and 20 MHz. Note that the delay is derived from the point-to-point 1.63 mm (14 AWG) link segment length of 1589 m given in Table 146B–1 using Equation (80–1) with an 'n' of 0.6.

146.7.1.4 Differential-to-common-mode conversion

The differential-to-common-mode conversion requirement applies to unshielded link segments and depends on the electromagnetic noise environment. The requirements of Table 146–5 shall be met based on the local environment as described by the electromagnetic classifications given in Table 146–7, E_1 or E_2.

Table 146–5—Differential-to-common-mode conversion

	Frequency (MHz)	E_1	E_2
TCL	$0.1 \leq f \leq 10$	≥ 50 dB	≥ 50 dB
TCL	$10 < f \leq 20$	$\geq 50 - 20\log_{10}\left(\frac{f}{10}\right)$ dB	$\geq 50 - 20\log_{10}\left(\frac{f}{10}\right)$ dB

146.7.1.5 Coupling attenuation

The coupling attenuation requirement applies to shielded link segments and depends on the electromagnetic noise environment. The requirements in Table 146–6 shall be met based on the local environment as described by the electromagnetic classifications given in Table 146–7, E1, E2, or E3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 146–6—Coupling attenuation

Frequency (MHz)	(dB)		
	E_1	E_2	E_3
0.1 to 20	≥ 50	≥ 50	≥ 60

146.7.1.6 Electromagnetic classifications

Electromagnetic classifications for the link segment local environments are given in Table 146–7, for E_1, E_2, or E_3.

Table 146–7—Link segment electromagnetic classifications (ISO/IEC 11801-1)

Electromagnetic	E_1	E_2	E_3
Conducted RF	3 V at 150 kHz to 80 MHz	3 V at 150 kHz to 80 MHz	10 V at 150 kHz to 80 MHz

146.7.2 Coupling parameters between 10BASE-T1L link segments

Noise coupled between the disturbed 10BASE-T1L link segment and other disturbing 10BASE-T1L link segments is referred to as alien crosstalk noise. To ensure that the total alien NEXT loss and alien FEXT loss coupled between 10BASE-T1L link segments are limited, multiple disturber alien near-end crosstalk (MDANEXT) loss and multiple disturber alien far-end crosstalk (MDAFEXT) loss are specified.

146.7.2.1 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

In order to limit the alien crosstalk at the near end of a 10BASE-T1L link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between the disturbed 10BASE-T1L link segment and other disturbing 10BASE-T1L link segments is specified to meet the bit error ratio objective. To ensure that the total alien NEXT coupled into a 10BASE-T1L link segment is limited, multiple disturber alien NEXT loss is specified as the power sum of the individual alien NEXT disturbers.

PSANEXT loss is determined by summing the power of the individual pair-to-pair differential alien NEXT loss values over the frequency range 0.1 MHz to 20 MHz as follows in Equation (146–13).

$$\mathrm{PSANEXT}_N(f) = -10\log_{10}\sum_{j=1}^{m} 10^{\frac{-\mathrm{AN}(f)_{j,N}}{10}} \ \mathrm{dB} \qquad (146\text{–}13)$$

where the function $\mathrm{AN}(f)_{j,N}$ represents the magnitude (expressed in dB) of the alien NEXT loss at frequency f of the disturbing 10BASE-T1L link segment j (1 to m) for the disturbed 10BASE-T1L link segment N.

The power sum ANEXT loss between a disturbed 10BASE-T1L link segment and other disturbing 10BASE-T1L link segments shall meet the values determined using Equation (146–14) or 60 dB, whichever is less.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{PSANEXT}(f) \geq 37.5 - 17\log_{10}\left(\frac{f}{20}\right) \text{ dB} \quad (146\text{–}14)$$

where

f is the frequency in MHz; $0.1 \leq f \leq 20$

146.7.2.2 Multiple disturber power sum alien far-end crosstalk (PSAFEXT) loss

In order to limit the alien crosstalk at the far-end of a 10BASE-T1L link segment, the differential pair-to-pair alien far-end crosstalk (FEXT) loss between the disturbed 10BASE-T1L link segment and other disturbing 10BASE-T1L link segments is specified to meet the bit error ratio objective. To ensure that the total alien FEXT coupled into a 10BASE-T1L link segment is limited, multiple disturber AFEXT is specified as the power sum of the individual alien FEXT disturbers. Note that the MDAFEXT is specified as the power sum of the individual alien FEXT disturbers (PSAFEXT) and not individual alien ACRF disturbers (PSAACR-F).

PSAFEXT is determined by summing the power of the individual pair-to-pair differential alien FEXT values over the frequency range 0.1 MHz to 20 MHz as follows in Equation (146–15).

$$\text{PSAFEXT}_N(f) = -10\log_{10}\sum_{j=1}^{m} 10^{\frac{-\text{AF}(f)_{j,N}}{10}} \text{ dB} \quad (146\text{–}15)$$

where the function $\text{AF}(f)_{j,N}$ represents the magnitude (expressed in dB) of the alien FEXT of the disturbing 10BASE-T1L link segment j (1 to m) for disturbed 10BASE-T1L link segment N.

The power sum AFEXT between a disturbed 10BASE-T1L link segment and other disturbing 10BASE-T1L link segments shall meet the values determined using Equation (146–16) or 60 dB, whichever is less.

$$\text{PSAFEXT}(f) \geq 38 - 18\log_{10}\left(\frac{f}{20}\right) \text{ dB} \quad (146\text{–}16)$$

where

f is the frequency in MHz; $0.1 \leq f \leq 20$

146.8 MDI specification

This subclause describes connectors that may be used at the MDI. It also specifies electrical requirements, including fault tolerance, at the MDI.

146.8.1 MDI connectors

The mechanical interface to the balanced cabling is a 3-pin connector (BI_DA+, BI_DA–, and optional SHIELD) or alternatively a 2-pin connector with an optional additional mechanical shield connection that conforms to the link segment specification defined in 146.7.

Specific systems or applications can use connectors or terminals that support the link segment specification defined in 146.7.

Connectors meeting the mechanical requirements of IEC 63171-1 [B36] or IEC 63171-6:2020 [B37] may be used as the mechanical interface to the balanced cabling. The plug connector is used on the balanced cabling and the MDI jack connector on the PHY. The IEC 63171-1 plug and jack are depicted (for informational use only) in Figure 146–29 and Figure 146–30 respectively, and the mating interface is depicted in Figure 146–31. The IEC 63171-6 plug and jack are depicted (for informational use only) in Figure 146–32 and Figure 146–33 respectively, and the mating interface is depicted in Figure 146–34. These connectors should support link segment DCR characteristics for 1.02 mm (18 AWG) to 0.40 mm (26 AWG) in Table 146B–1.

146.8.2 MDI electrical specification

The electrical requirements specified in 146.5.4 and 146.5.5 shall be met when the PHY is connected to the MDI connector mated with the specified plug connector.

146.8.3 MDI return loss

The MDI return loss (RL) shall meet or exceed Equation (146–17) for all frequencies from 100 kHz to 20 MHz (with 100 Ω ± 0.1% reference impedance) at all times when the PHY is transmitting data or idle symbols.

$$\text{Return Loss } (f) \geq \begin{cases} 20 - 18 \times \log_{10}\left(\frac{0.2}{f}\right) \text{ dB} & 0.1 \leq f < 0.2 \text{ MHz} \\ 20 \text{ dB} & 0.2 \leq f \leq 1 \text{ MHz} \\ 20 - 16.7 \times \log_{10}(f) \text{ dB} & 1 < f \leq 10 \text{ MHz} \\ 3.3 - 7.6 \times \log_{10}\left(\frac{f}{10}\right) \text{ dB} & 10 < f \leq 20 \text{ MHz} \end{cases} \quad (146\text{–}17)$$

where f is the frequency in MHz.

146.8.4 MDI mode conversion loss

Mode conversion LCL (Sdc11) or TCL (Scd11) of the PHY measured at the MDI shall meet the values determined using Equation (146–18).

$$\text{Conversion Loss } (f) \geq \begin{bmatrix} 25 \text{ dB} & 0.1 \leq f \leq 10 \text{ MHz} \\ 25 - 20 \times \log_{10}\left(\frac{f}{10}\right) \text{ dB} & 10 < f \leq 20 \text{ MHz} \end{bmatrix} \quad (146\text{–}18)$$

where f is the frequency in MHz.

146.8.5 MDI DC power voltage tolerance

The DTE shall withstand without damage the application of any voltages between 0 V dc and 60 V dc with the source current limited to 2000 mA, applied across BI_DA+ and BI_DA–, in either polarity, under all operating conditions, for an indefinite period of time. This requirement ensures that all devices tolerate DC powering voltages, such as those in Clause 104, even if the device does not require power.

146.8.6 MDI fault tolerance

The wire pair of the MDI shall withstand without damage the application of short circuits of any wire to the other wire of the same pair or ground potential, as per Table 146–9, under all operating conditions, for an indefinite period of time with the source current limited to 2000 mA. Normal operation shall resume after the short circuit(s) is/are removed.

The wire pair of the MDI is expected to withstand, without damage, high-voltage transient noises and ESD per application requirements. Table 146–9 gives an overview about possible connection faults for the wire pair (BI_DA+ and BI_DA–).

Table 146–9—Fault conditions

BI_DA+	BI_DA–
BI_DA–	BI_DA+
Ground	No fault
No fault	Ground
Ground	Ground
+60 V dc	No fault
No fault	+60 V dc
+60 V dc	+60 V dc
Ground	+60 V dc
+60 V dc	Ground

146.9 Environmental specifications

146.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2 or IEC 61010-1, as appropriate. All equipment subject to this clause may be additionally required to conform to any applicable local, state, or national standards

146.9.2 Network safety

All cabling and equipment subject to this clause is expected to be mechanically and electrically secure in a professional manner. All 10BASE-T1L cabling is expected to be routed according to any applicable local, state, or national standards considering all relevant safety requirements.

146.9.2.1 Environmental safety

In industrial applications, all equipment subject to this clause is expected to conform to the potential environmental stresses with respect to their mounting location, as defined in the following specifications, where applicable:

— Environmental loads: IEC 60529 and ISO 4892
— Mechanical loads: IEC 60068-2-6 and IEC 60068-2-31
— Climatic loads: IEC 60068-2-1, IEC 60068-2-2, IEC 60068-2-14, IEC 60068-2-27, IEC 60068-2-30, IEC 60068-2-38, IEC 60068-2-52, and IEC 60068-2-78

146.9.2.2 Electromagnetic compatibility

A system integrating the 10BASE-T1L PHY is expected to comply with all applicable local and national codes for electromagnetic compatibility.

146.10 Delay constraints

Every 10BASE-T1L PHY associated with MII shall comply with the bit delay constraints for full duplex operation. The delay for the transmit path, from the MII input to the MDI, shall be less than

146.11 Protocol implementation conformance statement (PICS) proforma for Clause 146, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1L[242]

146.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 146, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1L, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

146.11.2 Identification

146.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

146.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 146, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1L
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[242] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

147. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1S

147.1 Overview

This clause defines the type 10BASE-T1S Physical Coding Sublayer (PCS) and type 10BASE-T1S Physical Medium Attachment (PMA) sublayer. Together, the PCS and PMA sublayers comprise a 10BASE-T1S Physical Layer device (PHY). Provided in this clause are full functional and electrical specifications for the type 10BASE-T1S PCS, PMA, and MDI.

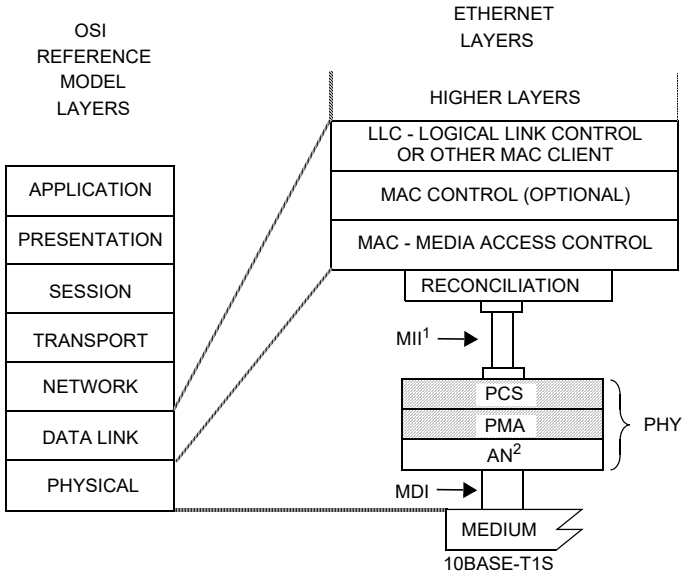
The 10BASE-T1S PHY is specified to be capable of operating at 10 Mb/s in several modes. All 10BASE-T1S PHYs can operate as a half-duplex PHY with a single link partner over a point-to-point link segment defined in 147.7, and, additionally, there are two mutually exclusive optional operating modes: a full-duplex point-to-point mode over the link segment, defined in 147.7, and a half-duplex shared-medium mode, referred to as multidrop mode, capable of operating with multiple stations connected to a mixing segment, defined in 147.8. The medium supporting the operation of the 10BASE-T1S PHY is defined in terms of performance requirements between the attachment points (Medium Dependent Interface (MDI)), allowing implementers to specify their own media to operate the 10BASE-T1S PHY as long as the normative requirements included in this clause are met.

10BASE-T1S PHYs optionally support PHY Level Collision Avoidance (PLCA), described in Clause 148.

10BASE-T1S follows an integrated PCS and PMA architecture and therefore does not support an AUI (see Figure 1–1).

147.1.1 Relationship of 10BASE-T1S to other standards

The relationship between the 10BASE-T1S, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 Ethernet model are shown in Figure 147–1. The PHY sublayers (shown shaded) in Figure 147–1 connect one Clause 4 Media Access Control (MAC) layer to the medium. Auto-Negotiation for 10BASE-T1S is defined in Clause 98 and is not available in multidrop mode. Selection between multidrop and point-to-point mode is made via the appropriate configuration bit. A Management Entity is required using MDIO or equivalent functionality. Optional MDIO is defined in Clause 45.



147.1.2 Operation of 10BASE-T1S

All 10BASE-T1S PHYs can operate using half-duplex point-to-point communications on a link segment using a single balanced pair of conductors, supporting up to four in-line connectors and up to at least 15 meters in reach, with an effective data rate of 10 Mb/s shared between the two directions of transmission. 10BASE-T1S PHYs supporting the option of full-duplex point-to-point operation may operate with an effective data rate of 10 Mb/s in each direction simultaneously, supporting up to four in-line connectors and up to at least 15 meters in reach.

Additionally, the 10BASE-T1S PHY may operate using half-duplex communications on a mixing segment using a single balanced pair of conductors, interconnecting up to at least 8 PHYs to a trunk up to at least 25 m. PHYs may be attached in-line with the trunk or at the end of stubs with a length of up to 10 cm. An overall effective data rate of 10 Mb/s is shared among the nodes. Larger PHY count and reach may be achieved provided the mixing segment specifications in 147.8 are met.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 10BASE-T1S PHY utilizes two level Differential Manchester Encoding (DME). A 17-bit self-synchronizing scrambler is used to improve the EMC performance. Following scrambling of the data, 4B/5B encoding is performed (see 147.3.2.4). DME is a self-clocked and intrinsically balanced line coding that guarantees very low DC baseline wander and allows for robust clock and data recovery in noisy environments. The 4B/5B mapping and the scrambler are contained within the PCS (see 147.3) while the DME encoder/decoder is contained in the PMA (see 147.4).

MDI = MEDIUM DEPENDENT INTERFACE
MII = MEDIA INDEPENDENT INTERFACE

NOTE 1—MII is optional
NOTE 2—Auto-Negotiation is optional

PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
AN = AUTO-NEGOTIATION

Figure 147–1—Relationship of 10BASE-T1S PHY to the ISO/IEC OSI reference model and the IEEE 802.3 Ethernet model

147.1.3 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

147.1.3.1 State diagram notation

The conventions of 21.5 are adopted with the extension that some states in the state diagrams use an IF-THEN-ELSE-END construct to condition which actions are taken within the state. If the logical expression associated with the IF evaluates TRUE, all the actions listed between THEN and ELSE will be executed. In the case where ELSE is omitted, the actions listed between THEN and END will be executed. If the logical expression associated with the IF evaluates FALSE, the actions listed between ELSE and END will be executed. After executing the actions listed between THEN and ELSE, between THEN and END, or between ELSE and END, the actions following the END, if any, will be executed.

147.1.3.2 State diagram timer specifications

All timers operate in the manner described in 40.4.5.2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.1.3.3 Service specifications

The method and notation used in the service specification follows the conventions of 1.2.2.

147.2 Service primitives and interfaces

The 10BASE-T1S PHY uses the service primitives and interfaces in 40.2, with exception of the following clarifications and differences noted in this subclause. Figure 147–2 shows the relationship of the service primitives and interfaces used by the 10BASE-T1S PHY.

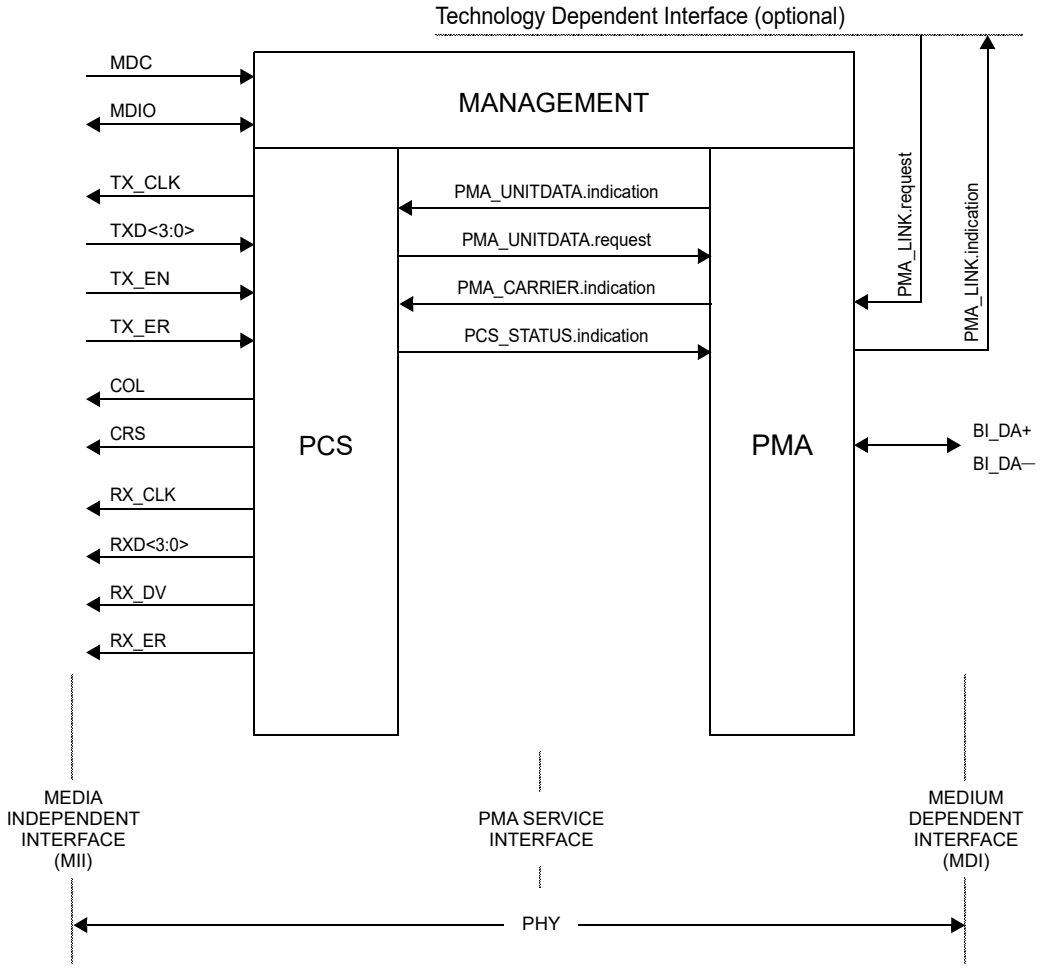

Figure 147–2—10BASE-T1S PHY interfaces

The 10BASE-T1S PHY uses the Media Independent Interface (MII) as specified in Clause 22.

As shown in Figure 147–2, 10BASE-T1S uses the following service primitives to exchange symbol vectors, status indications, and control signals across the PMA service interface:

PMA_UNITDATA.indication (rx_sym)
PMA_UNITDATA.request (tx_sym)
PMA_CARRIER.indication (pma_crs)
PMA_LINK.indication (link_status)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_LINK.request (link_control)

PCS_STATUS.indication (pcs_status)

147.2.1 PMA_UNITDATA.indication

This primitive defines the transfer of one 5B symbol in the form of the rx_sym parameter from the PMA to the PCS.

147.2.1.1 Semantics of the primitive

PMA_UNITDATA.indication (rx_sym)

During reception, the PMA_UNITDATA.indication conveys to the PCS, via the parameter rx_sym, the value of the 5B symbol detected on the MDI during each cycle of the recovered clock.

147.2.1.2 When generated

The PMA generates PMA_UNITDATA.indication (rx_sym) messages synchronously for every 5B symbol received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is 2.5 MHz, as governed by the recovered clock.

147.2.1.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

147.2.2 PMA_UNITDATA.request

This primitive defines the transfer of one symbol in the form of the tx_sym parameter from the PCS to the PMA.

The symbol is obtained in the PCS Transmit function using the encoding rules defined in 147.3.2 to represent 4B/5B encoded MII data or special out of band signaling.

147.2.2.1 Semantics of the primitive

PMA_UNITDATA.request (tx_sym)

During transmission, the PMA_UNITDATA.request conveys the value of the symbol to be sent over the MDI, via the parameter tx_sym.

The tx_sym parameter is one of the allowed 5B codes specified in Table 147–1.

147.2.2.2 When generated

The PCS generates PMA_UNITDATA.request (tx_sym) synchronously with every symb_timer expiration. The symb_timer is defined in 147.3.2.6.

147.2.2.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated 5B symbol after processing it with DME following the rules in 147.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.2.3 Mapping of PMA_CARRIER.indication

Reports whether a signal compatible with DME encoding rules specified in 147.4.2 is detected on the medium.

147.2.3.1 Function

Maps the primitive PMA_CARRIER.indication to the MII CRS signal.

147.2.3.2 Semantic of the service primitive

PMA_CARRIER.indication (pma_crs)

The pma_crs parameter can take one of two values: CARRIER_ON or CARRIER_OFF.

The pma_crs parameter is set to CARRIER_ON if a signal compatible with DME encoding rules specified in 147.4.2 is present on the medium. Otherwise, the pma_crs parameter is set to CARRIER_OFF.

147.2.3.3 When generated

The PMA_CARRIER.indication primitive is generated continuously by the PMA sublayer.

147.2.4 PMA_LINK.request

This primitive allows Auto-Negotiation to enable and disable operation of the PMA, as specified in 98.4.2.

147.2.4.1 Semantics of the primitive

PMA_LINK.request (link_control)

The link_control parameter can take on one of the following two values:

DISABLE	Used by Auto-Negotiation function to disable the PHY.
ENABLE	Used by Auto-Negotiation function to enable the PHY.

147.2.4.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in 98.4.

147.2.5 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 98.4.1. This primitive informs Auto-Negotiation functions about the status of the underlying link.

147.2.5.1 Semantics of the primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on the following two values:

FAIL	No valid link established.
OK	The Link Monitor function indicates that a valid 10BASE-T1S link is established. Reliable reception of signals transmitted from the remote PHY is possible.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.2.5.2 When generated

The PMA generates this primitive to indicate a change in link_status in compliance with the state diagram given in Figure 147–14.

147.2.5.3 Effect of receipt

The effect of receipt of this primitive is specified in 98.4.1.

147.2.6 PCS_STATUS.indication

This primitive is generated by the PCS to indicate PCS status to the PMA.

147.2.6.1 Semantics of the primitive

PCS_STATUS.indication (pcs_status)

The pcs_status parameter can take on the following two values:

NOT_OK	PCS is not receiving valid packets or heartbeat signals from the remote PHY.
OK	PCS is actively receiving valid packets and/or heartbeat signals from the remote PHY.

147.2.6.2 When generated

The PCS generates this primitive continuously. The pcs_status parameter is set according to the state diagram in Figure 147–11.

147.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 147.4.4.

147.3 Physical Coding Sublayer (PCS) functions

The Physical Coding Sublayer (PCS) consists of PCS Reset, PCS Transmit, and PCS Receive functions as shown in Figure 147–3. The PCS Reset function is explained in 147.3.1, the PCS Transmit function is explained in 147.3.2, the PCS Receive function is explained in 147.3.3, and the PCS Loopback function is explained in 147.3.4.

147.3.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever any of the following conditions occur:

a) Power on causes power_on = TRUE (see 36.2.5.1.3) while pcs_reset = FALSE.
b) The receipt of a request for reset from the management entity (bit 3.2291.15 defined in 45.2.3.72.1), independently from the current state of pcs_reset.

All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. PCS Reset shall keep pcs_reset = TRUE until the complete execution of the PCS Reset function, after which it is set to pcs_reset = FALSE. The reference diagrams do not explicitly show the PCS Reset function.

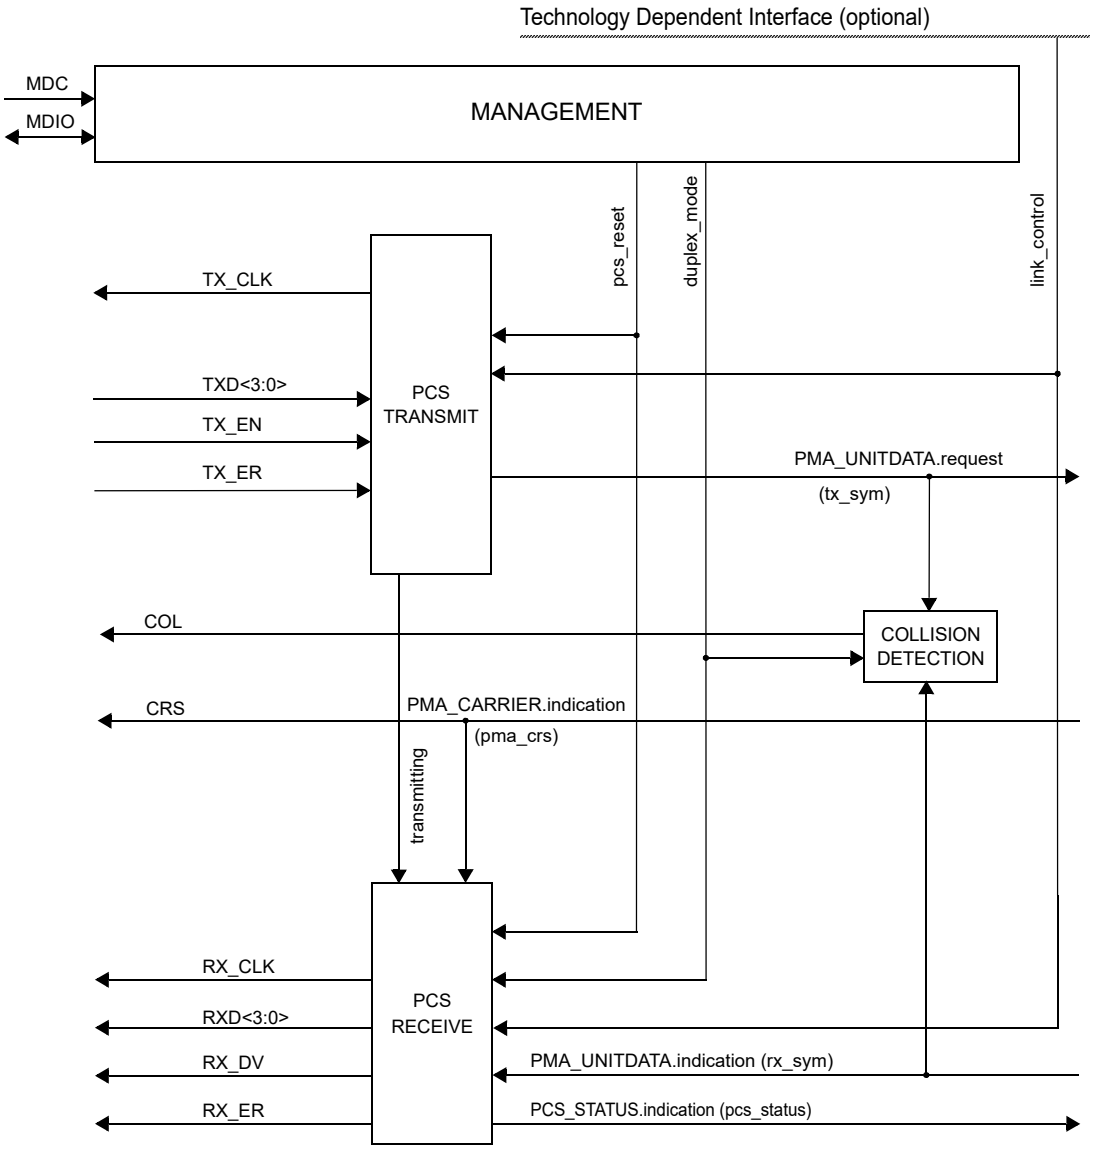

Figure 147–3—PCS reference diagram

147.3.2 PCS Transmit

147.3.2.1 PCS Transmit overview

The PCS Transmit function shall conform to the PCS Transmit state diagram in Figure 147–4 and Figure 147–5, and the associated state variables, functions, timers, and messages.

At each symbol period, PCS Transmit generates a symbol tx_sym conveyed to the PMA through the PMA_UNITDATA.request service primitive, where tx_sym is a 5B symbol. The PMA encodes tx_sym, LSB first, into a DME stream over the wire pair BI_DA as specified in Table 147–2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Upon assertion of TX_EN, the PCS Transmit function passes two SYNC symbols to the PMA, followed by two SSD symbols that replace the first 16 bits of the packet preamble. Following the second SSD, TXD<3:0> is encoded into 5B symbols using the encoding rules specified in Table 147–1, until TX_EN is deasserted.

Following the deassertion of TX_EN, the PCS Transmit generates a special code ESD. When there is no transmit error, ESD is followed by ESDOK. When there is a transmit error, ESD is followed by ESDERR. When a jabber condition is detected, ESD is followed by ESDJAB.

The 10BASE-T1S PHY has one special 5B symbol 'I' (see Table 147–1) which represents SILENCE. SILENCE represents an indication for the PMA to change the output according to 147.4.2.

147.3.2.2 Variables

err

This variable is set in the PCS Transmit state, as described in Figure 147–4 and Figure 147–5.
This variable is used to detect and latch a TX_ER = TRUE condition during data transmission; if such error is detected, an ESDERR symbol is sent at the end of transmission.
Values: TRUE or FALSE

hb_cmd

See 147.3.7.1.1.

link_control

This variable is generated by the Auto-Negotiation function. When Auto-Negotiation is not present or Auto-Negotiation is disabled, link_control has a default value of ENABLE, and may be provided by implementation-dependent functionality. When set to DISABLE, all PCS functions are switched off and no data can be sent or received.
Values: ENABLE or DISABLE

pcs_reset

The pcs_reset parameter set by the PCS Reset function.
Values: TRUE or FALSE

TX_EN

The TX_EN signal of the MII as specified in 22.2.2.3.
When set to FALSE transmission is disabled.
When set to TRUE transmission is enabled.
Values: TRUE or FALSE

TX_ER

The TX_ER signal of the MII as specified in 22.2.2.5.
When set to FALSE it indicates a non-errored transmission.
When set to TRUE it indicates an errored transmission.
Values: TRUE or FALSE

TXD

The TXD signal of the MII as specified in 22.2.2.4.
This signal represents a 4B data nibble to be transmitted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_cmd

Encoding present on TXD<3:0>, TX_ER, and TX_EN as defined in Table 22–1.
Values:
BEACON: PLCA BEACON indication encoding present on TXD<3:0>, TX_ER, and TX_EN.
COMMIT: PLCA COMMIT indication encoding present on TXD<3:0>, TX_ER, and TX_EN.
SILENCE: TXD<3:0> does not encode any of the above requests, or TX_ER = FALSE, or TX_EN = TRUE.

tx_sym

5B symbol to be conveyed to the PMA Transmit function by the means of the PMA_UNITDATA.request primitive specified in 147.2.2.

transmitting

This variable is set in the PCS Transmit state, as described in Figure 147–4.
When this variable is set to TRUE, it indicates a transmission is ongoing.
Values: TRUE or FALSE

147.3.2.3 Constants

SYNC / COMMIT

5B symbol defined as 'J' in 4B/5B encoding.

SSD

5B symbol defined as 'H' in 4B/5B encoding.

ESD

5B symbol defined as 'T' in 4B/5B encoding.

ESDERR

5B symbol defined as 'K' in 4B/5B encoding.

ESDOK / ESDBRS

5B symbol defined as 'R' in 4B/5B encoding.

SILENCE

5B symbol defined as 'I' in 4B/5B encoding.

ESDJAB

5B symbol defined as 'S' in 4B/5B encoding.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.3.2.4 Functions

ENCODE

This function takes a 4 bit input parameter Sc_n<3:0> and returns a 5B symbol according to the following procedure:

1. Convert Sc_n<3:0> into Sd_n<3:0> as specified in 147.3.2.8.
2. Convert Sd_n<3:0> (4B symbol) into the corresponding 5B symbol defined in Table 147–1.

Table 147–1—4B/5B Encoding

Name	4B	5B	Special function
0	0000	11110	—
1	0001	01001	—
2	0010	10100	—
3	0011	10101	—
4	0100	01010	—
5	0101	01011	—
6	0110	01110	—
7	0111	01111	—
8	1000	10010	—
9	1001	10011	—
A	1010	10110	—
B	1011	10111	—
C	1100	11010	—
D	1101	11011	—
E	1110	11100	—
F	1111	11101	—
I	N/A	11111	SILENCE
J	N/A	11000	SYNC / COMMIT
K	N/A	10001	ESDERR
T	N/A	01101	ESD / HB
R	N/A	00111	ESDOK / ESDBRS
H	N/A	00100	SSD
N	N/A	01000	BEACON
S	N/A	11001	ESDJAB

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TXCMD_ENCODE

In the PCS transmit process, this function takes as its arguments the values of tx_cmd and hb_cmd variables and returns a 5B symbol based on the following mapping:
'N' when the tx_cmd variable is set to BEACON,
'J' when the tx_cmd variable is set to COMMIT,
'T' when the hb_cmd variable is set to HEARTBEAT and the tx_cmd variable is not set to BEACON or COMMIT,
'I' otherwise.

147.3.2.5 Abbreviations

STD — Alias for symb_timer_done.

147.3.2.6 Timers

symb_timer

A continuous free-running timer. PMA_UNITDATA.request messages are issued by the PCS concurrently with symb_timer_done (see 147.2.2). TX_CLK (see 22.2.2.1) shall be generated from symb_timer with the rising edge of TX_CLK generated synchronously with symb_timer_done.
Continuous timer: The condition symb_timer_done becomes true upon timer expiration.
Restart time: Immediately after expiration.
Duration: 400 ns ± 100 ppm (see 22.2.2.1)

unjab_timer

Optionally times the minimum duration the PHY suppresses any transmission before reverting to normal operations.
Duration: 16 ms ± 100 μs

xmit_max_timer

Defines the maximum time the PCS Transmit state diagram can stay in DATA state.
The xmit_max_timer shall be implemented in such a way that, upon expiration, an even number of nibbles has been sent to prevent the MAC from counting false alignment errors.
Duration: 2 ms ± 100 μs
NOTE—This is approximately 25% greater than maxEnvelopeFrameSize specified in 4.2.7.1.

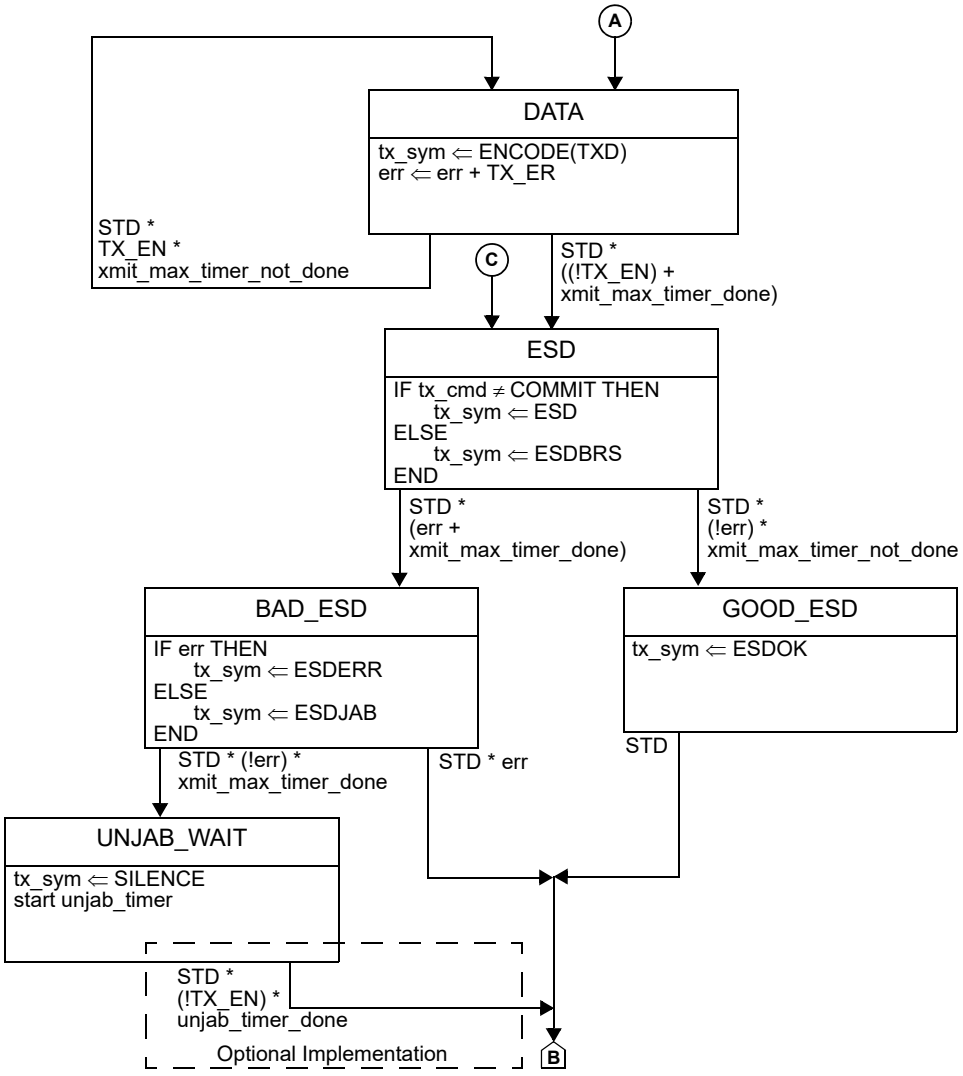

Figure 147–5—PCS Transmit state diagram, part b

147.3.2.8 Self-synchronizing scrambler

The PCS Transmit function shall implement multiplicative scrambling using the following generator polynomial $g(x) = x^{17} + x^{14} + 1$.

An implementation of a self-synchronizing scrambler by a linear-feedback shift register is shown in Figure 147–6. The bits stored in the shift register delay line at time n are denoted by Scr_n<16:0>. The '+' symbol denotes the exclusive-OR logical operation. When Sc_n<3:0> is presented at the input of the scrambler, Sd_n<3:0> is produced by shifting in each bit of Sc_n<3:0> as Sc_n<i>, with i ranging from 0 to 3 (i.e., LSB first). The scrambler is reset upon execution of the PCS Reset function. If the PCS Reset is executed, all bits of the 17-bit vector representing the self-synchronizing scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. In no case shall the scrambler state be initialized to all zeros. At every STD, if no data is presented at the scrambler input via Sc_n<3:0>, the scrambler may be fed with arbitrary inputs.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

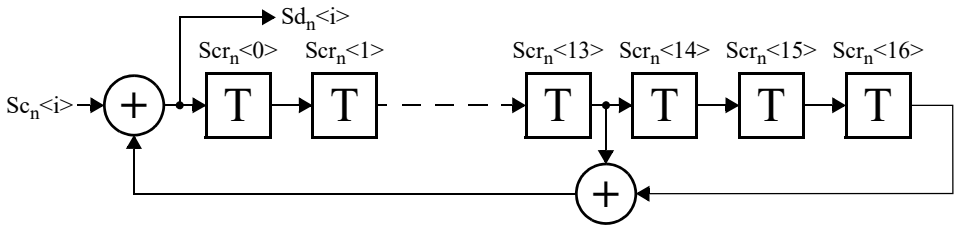

Figure 147–6—Self-synchronizing scrambler

147.3.2.9 Jabber functional requirements

The PCS Transmit function contains the capability to interrupt a transmission that exceeds a time duration determined by xmit_max_timer. If the packet being transmitted continues longer than the specified time duration, the PCS Transmit sends an ESD, ESDJAB symbol sequence to notify the receivers, then it inhibits further transmissions for at least the duration of unjab_timer. The PCS Transmit may return to normal operation automatically after unjab_timer elapsed and the error condition has been cleared, or it may keep silent until reset.

147.3.3 PCS Receive

147.3.3.1 PCS Receive overview

The PCS Receive function shall conform to the PCS Receive state diagram in Figure 147–7 and Figure 147–8, and associated state variables.

The state diagram defined in Figure 147–7 is triggered by the reception of a SYNC symbol from the PMA Receive function and waits for two SSD symbols to start regenerating the packet preamble whose start has been replaced with the SYNC, SYNC, SSD, SSD sequence by the PCS Transmit function as described in Figure 147–4. After the second SSD is received, the PCS Receive function discards the next nine symbols. These symbols can be used to achieve lock of the self-synchronizing descrambler.

During the descrambler locking time, the special value 5 is conveyed to the MII via the RXD variable in order to rebuild the original preamble transmitted by the MAC.

The DATA state, in which 5B symbols are decoded into MII data, is left when ESD or ESDBRS followed by either ESDOK, ESDERR, or ESDJAB symbol is encountered, or when the PMA detects SILENCE on the media (e.g., the transmitter prematurely stops data transmission).

During the WAIT_SYNC state, the PCS notifies the RS of a received BEACON indication by the means of the MII as specified in 22.2.2.8. When a sequence of at least two consecutive 'N' symbols is received, the MII signals RX_DV, RX_ER, and RXD<3:0> are set to the BEACON indication as shown in Table 22–2. Additionally, the PCS notifies the RS of a received COMMIT indication by the means of the MII as specified in 22.2.2.8. When a sequence of at least two consecutive SYNC is received, the MII signals RX_DV, RX_ER, and RXD<3:0> are set to the COMMIT indication as shown in Table 22–2.

147.3.3.2 Variables

duplex_mode

This variable indicates whether the PHY is configured for full-duplex operation (DUPLEX_FULL) or half-duplex operation (DUPLEX_HALF). If Multidrop mode MDIO register bit 1.2297.10 is set to one and multidrop mode is supported according to bit 1.2298.10 then duplex_mode is set to DUPLEX_HALF. Else, if Auto-Negotiation is enabled then duplex_mode is set by the priority resolution defined in 98B.4. Otherwise, this variable is set by MDIO register bit 3.2291.8. If MDIO is not implemented, duplex_mode is set by equivalent means.
Values: DUPLEX_FULL or DUPLEX_HALF

link_control

See 147.3.2.2.

multidrop

See 147.3.7.1.1.

precnt

Counter for preamble regeneration.

rx_cmd

See 147.3.7.1.1.

RX_DV

The RX_DV signal of the MII as specified in 22.2.2.7.

RX_ER

The RX_ER signal of the MII as specified in 22.2.2.10.

RXD

PCS decoded data synchronous to RX_CLK as specified in 22.2.2.8.

pcs_reset

See 147.3.2.2.

RXn

The rx_sym parameter of the PMA_UNITADATA.indication primitive defined in 147.2.1.
The 'n' subscript denotes the rx_sym conveyed in the most recent recv_symb_conv_timer cycle.
The 'n-x' subscript indicates the rx_sym conveyed 'x' cycles before the most recent one.

transmitting

See 147.3.2.2.

147.3.3.3 Constants

fc_supported

Indicates whether the optional False Carrier detection is supported.
Values: TRUE or FALSE

BEACON

5B symbol defined as 'N' in 4B/5B encoding.

HB

5B symbol defined as 'T' in 4B/5B encoding.

See also 147.3.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.3.3.4 Functions

DECODE

This function takes a 5B symbol input parameter and returns a 4 bit value Dc_n<3:0> value according to the following procedure:
1. Convert the 5B input symbol into Dr_n<3:0> by performing a reverse lookup in Table 147–1. If no 4B value is associated to the given 5B symbol, the PCS Receive function shall assert RX_ER for at least one symbol period and Dr_n<3:0> may be set arbitrarily.
2. Convert Dr_n<3:0> to Dc_n<3:0> as specified in 147.3.3.8.

147.3.3.5 Abbreviations

RSCD Alias for recv_symb_conv_timer_done.

147.3.3.6 Timers

recv_symb_conv_timer

A continuous timer which expires when the PMA_UNITDATA.indication message is generated (see 147.2.1).
Continuous timer: The condition recv_symb_conv_timer_done becomes true upon timer expiration.
Restart time: Immediately after expiration.
Duration: timed by the PMA_UNITDATA.indication message generation.

147.3.3.8 Self-synchronizing descrambler

The PCS Receive function descrambles the 5B/4B decoded data stream and returns the value of RXD<3:0> to the MII. The descrambler shall employ the polynomial $g(x)$ defined in 147.3.2.8. The implementation of the self-synchronizing descrambler by linear-feedback shift register is shown in Figure 147–9. The bits stored in the shift register delay line at time n are denoted by Dcr_n<16:0>. The '+' symbol denotes the exclusive-OR logical operation.

When Dr_n<3:0> is presented at the input of the descrambler, Dc_n<3:0> is produced by shifting in each bit of Dr_n<3:0> as Dr_n<i>, with i ranging from 0 to 3 (i.e., LSB first). The descrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all the bits of the 17-bit vector representing the self-synchronizing descrambler state are arbitrarily set. The initialization of the descrambler state is left to the implementer. At every RSCD, if no data is presented at the descrambler input via Dr_n<3:0>, the descrambler may be fed with arbitrary inputs.

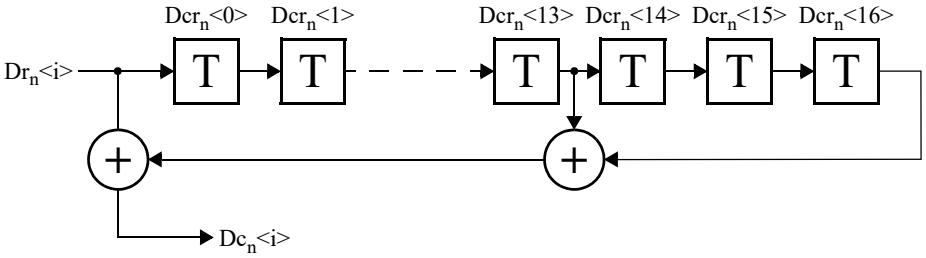

Figure 147–9—Self-synchronizing descrambler

147.3.3.9 Jabber diagnostics

The ESDJAB symbol informs the PCS Receiver that a frame was terminated by the jabber function. The number of received ESDJAB events can be reported to the management entity be the means of MDIO register 3.2293 or similar functionality if MDIO is not implemented.

147.3.4 PCS loopback

The PCS shall be placed in loopback mode when the loopback bit in MDIO register 3.0.14, defined in 45.2.3.1.2, is set to one (or PCS loopback mode is enabled by a similar functionality if MDIO is not implemented). In this mode, the PCS shall accept data on the transmit path from the MII and return it on the receive path to the MII. Additionally, the PHY receive circuitry shall be isolated from the network medium, and the assertion of TX_EN at the MII shall not result in the transmission of data on the network medium.

147.3.5 Collision detection

When operating in half-duplex mode, the 10BASE-T1S PHY shall detect when a transmission initiated locally results in a corrupted signal at the MDI as a collision. When collisions are detected, the PHY shall assert the signal COL on the MII for the duration of the collision or until TX_EN signal is FALSE.

The method for detecting a collision is implementation dependent but the following requirements have to be fulfilled:

a) The PHY shall assert COL when it is transmitting, and one or more other stations are also transmitting at the same time.
b) The PHY shall assert CRS in the presence of a signal resulting from a collision between two or more other stations.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.3.6 Carrier sense

When operating in half-duplex mode, the 10BASE-T1S PHY senses when the media is busy and conveys this information to the MAC by asserting the signal CRS on the MII as specified in 22.2.2.11.

CRS is generated by mapping the PMA_CARRIER.indication (pma_crs) primitive to the MII signal CRS:

a) CRS shall be asserted when the pma_crs parameter is CARRIER_ON.
b) CRS shall be deasserted when the pma_crs parameter is CARRIER_OFF.

147.3.7 Support for PCS status generation

If Clause 98 Auto-Negotiation functions are implemented and enabled, the PCS shall conform to the Heartbeat (HB) transmit and receive state diagrams in Figure 147–10, Figure 147–11, and the associated state variables, functions, timers, messages, and constants.

If Clause 98 Auto-Negotiation functions are not implemented or disabled, the PCS_STATUS.indication primitive conveys NOT_OK.

The pcs_status parameter of PCS_STATUS.indication primitive is set to OK after the reception of HB signals or valid data reception (RX_DV) according to the logic described in the HB receive state diagram.

The HB generation is disabled when the PHY is configured for operation over a mixing segment or a BEACON is detected.

147.3.7.1 Heartbeat transmit overview

HB signals are sent unsolicited by the PHY that negotiated the master role during auto-negotiation, while the slave PHY replies back to received HB signals.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

A heartbeat is sent only when the PHY is not in the multidrop mode and Auto-Negotiation has completed. The state diagram in Figure 147–10 is held in the INIT state when in the multidrop mode, Auto-Negotiation is not enabled, or Auto-Negotiation signals link_control = DISABLE.

When the PHY is not in multidrop mode and a BEACON request is received from the MII (see Table 22–2) or a BEACON signal is received from the line (see Table 147–1), the state diagram in Figure 147–10 enters the DISABLE_HB state. It remains in the DISABLE_HB state until at least one of the following occurs: PCS Reset is asserted, multidrop mode is enabled, the disable_hb_timer expires, Auto-Negotiation is disabled, or Auto-Negotiation stops reporting that it is complete.

NOTE—Any BEACON received either from the MII or the PMA restarts the disable_hb_timer.

147.3.7.1.1 Variables

pcs_reset
: See 147.3.2.2.

mr_autoneg_enable
: See 98.5.1.

link_control
: See 147.3.2.2.

multidrop

If MDIO is implemented, this variable is set according to bit 1.2297.10.
If MDIO is not implemented, multidrop should be set by equivalent means.
Values: TRUE or FALSE

master

Result of the role negotiated using method in 98.2.1.2.5 and Table 98–4.
Values: TRUE (negotiated role is master) or FALSE (negotiated role is slave)

hb_cmd

Enumerated variable that conveys the command to send an HB message to the PCS transmit function. This command is ignored or interrupted by the PCS transmit function when normal data is being sent or a higher priority request is in effect, as specified in 147.3.2.4.
Values: HEARTBEAT or NONE

rx_cmd

PLCA or HEARTBEAT signaling decoded by the PCS.

tx_cmd

See 147.3.2.2.

COL

The MII signal COL.
Values: TRUE or FALSE

CRS

The MII signal CRS.
Values: TRUE or FALSE

RX_DV

The MII signal RX_DV.
Values: TRUE or FALSE

147.3.7.1.2 Timers

disable_hb_timer

Time the heartbeat state diagram dwells in the DISABLE_HB state without receiving or transmitting a BEACON.
Duration: 1 s
Tolerance: ± 100 ms

hb_send_timer

Times the duration of the HB signal on the line.
Duration: 20 bit times
Tolerance: ± 0.5 bit times

hb_timer

Period between the transmission of two consecutive HB signals.
Duration: 50 ms
Tolerance: ± 100 μs

147.3.7.2 Heartbeat receive overview

The HB receive state diagram in Figure 147–11 generates the pcs_status parameter of the PCS_STATUS.indication primitive based on the reception of valid data packets and HB signals from the remote PHY.

The pcs_status is reported as OK when at least ACTIVE_CNT valid packets or HB messages, separated at max by link_hold_timer ms, are received.

The pcs_status is reported as NOT_OK when PCS is reset or when no valid packets nor HB messages are received within link_hold_timer for INACTIVE_CNT times in a row.

147.3.7.2.1 Variables

pcs_reset
: See 147.3.2.2.

pcs_status
: Parameter of the PCS_STATUS.indication primitive.
Values: OK or NOT_OK

mr_autoneg_enable
: See 98.5.1.

link_control
: See 147.3.2.2.

multidrop
: See 147.3.7.1.1.

rx_cmd
: See 147.3.7.1.1.

cnt_l
: Count of link_hold_timer expiration periods without HBs or receive packet when pcs_status is OK.
Values: integer number between 0 and INACTIVE_CNT

cnt_h
: Counter of HBs and receive packets when pcs_status is NOT_OK.
Values: integer number between 0 and ACTIVE_CNT

COL
: The MII signal COL.
Values: TRUE or FALSE

CRS
: The MII signal CRS.
Values: TRUE or FALSE

RX_DV
: The MII signal RX_DV.
Values: TRUE or FALSE

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.3.7.2.2 Constants

ACTIVE_CNT

Number of combined HBs and receive packets required to signal pcs_status = OK.
Value: integer number between 0 and 7
Default value: 2

INACTIVE_CNT

Number of link_hold_timer expirations without HBs or receive packets required to signal pcs_status = NOT_OK.
Value: integer number between 0 and 7
Default value: 5

147.3.7.2.3 Timers

link_hold_timer

Timer used to check inactivity.
Duration: 75 ms
Tolerance: ± 100 μs

147.4 Physical Medium Attachment (PMA) sublayer

PMA functions are illustrated in Figure 147–12.

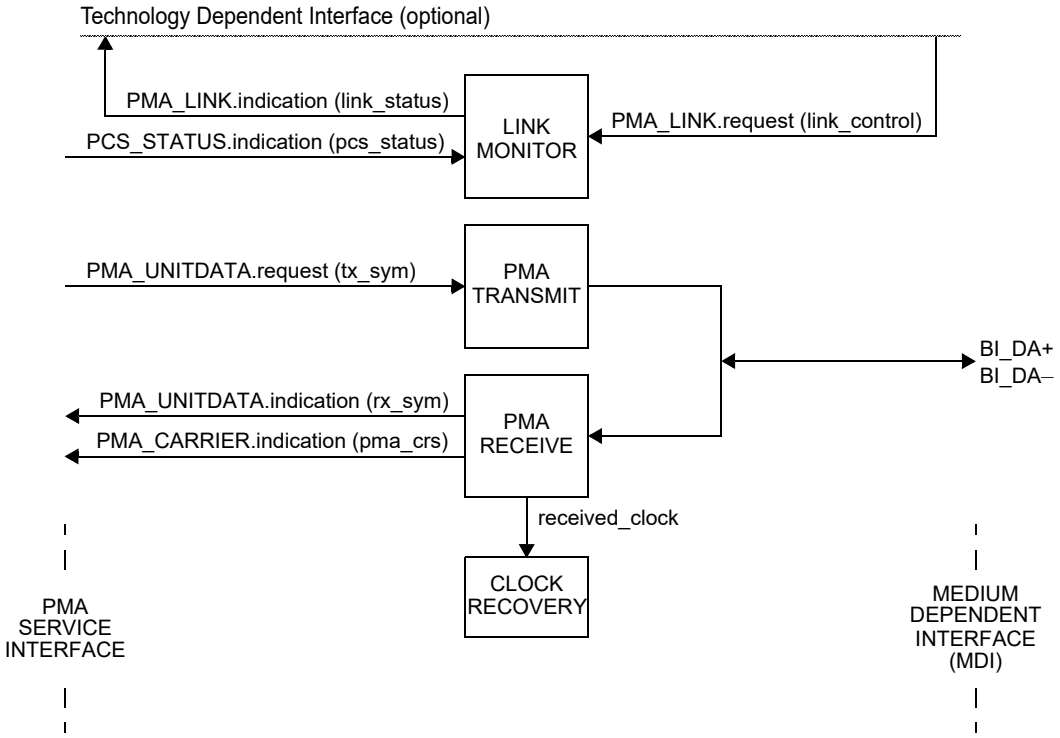

Figure 147–12—PMA functional block diagram

The reference diagrams do not explicitly show the PMA Reset function.

The PMA couples messages from the PMA service interface specified in 147.3.1 onto the 10BASE-T1S physical medium. The PMA provides half duplex communications to and from the medium. Optionally, the PMA may also provide full duplex communications to and from the medium. The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 147.9.

147.4.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

— Power on (see 36.2.5.1.3).
— The receipt of a request for reset from the management entity.

The PMA Reset function carries out the following tasks:

— PMA Transmit output is set to high-impedance state.
— PMA_UNITDATA.indication is cleared.

147.4.2 PMA Transmit function

During transmission, PMA_UNITDATA.request conveys the tx_sym variable to the PMA. The value of the tx_sym variable is sent over the single balanced pair of conductors, BI_DA.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The tx_sym variable is a 5B symbol, to be encoded LSB first, using DME rules defined below:

If the tx_sym parameter value is the special 5B symbol 'I', the PMA shall, in the following order:

a) Transmit an additional DME encoded 0 if the previous value of the tx_sym parameter was anything but the 5B symbol 'I'.
b) When operating in multidrop mode, present the minimum impedance described in 147.9.2 at the MDI. This shall happen within 40 ns after the additional DME encoded 0 has been transmitted.
c) When operating in point-to-point mode, drive BI_DA+ and BI_DA– to the same voltage with 100 Ω nominal impedance, so that their difference is 0 V.

If tx_sym value is anything other than 'I', the following rules apply:

— A “clock transition” shall always be generated at the start of each bit.
— A “data transition” in the middle of a nominal bit period shall be generated if the bit to be transmitted is a logical '1'. Otherwise, no transition shall be generated until the next bit.

See Figure 147–13 and Table 147–2.

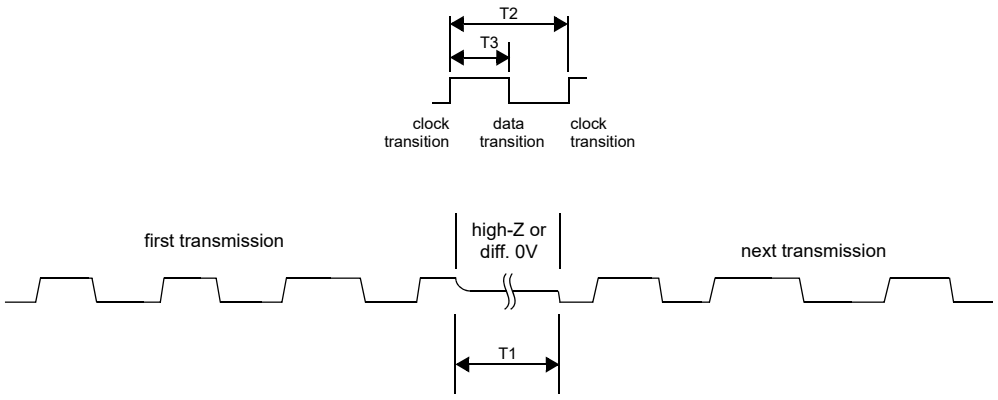

Figure 147–13—DME encoding scheme

Table 147–2—DME timings

Parameter name	Description	Minimum value	Nominal value	Maximum value	Unit of measure
T1	Delay between transmissions	480	—	—	ns
T2	Clock transition to clock transition	–100 ppm	80	+100 ppm	ns
T3	Clock transition to data transition (data = 1)	38	40	42	ns

147.4.3 PMA Receive function

The 10BASE-T1S PMA Receive function comprises a single receiver (PMA Receive) for DME modulated signals on a single balanced pair of conductors, BI_DA. PMA Receive has the ability to translate the received signals on the single balanced pair of conductors into the PMA_UNITDATA.indication parameter rx_sym. It detects 5B symbols from the signals received at the MDI and presents these sequences to the PCS Receive function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA Receive function recovers encoded clock and data information from the DME encoded stream received at the MDI. The clock recovery provides a synchronous clock for sampling the signal on the pair. While it may not drive the MII directly, the clock recovery function is the underlying source of RX_CLK. In order to meet the specifications of 147.5.5.1, the PMA Receive function has to achieve proper synchronization on both the DME stream and the 5B boundary within 800 ns.

The PMA Receive function interprets the signals at the MDI using the inverse mapping described in 147.4.2 for the PMA Transmit function and transfers the 5B code groups by the means of the PMA_UNITDATA.indication. When the PMA Receive function does not detect activity on the line, it shall convey the symbol 'I' (meaning SILENCE).

147.4.4 Link Monitor function

The PMA shall conform to the Link Monitor state diagram in Figure 147–14 and associated variables.

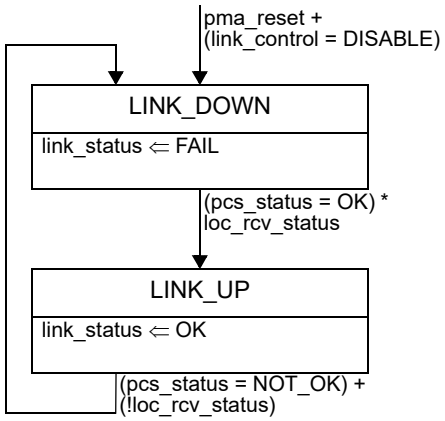

Figure 147–14—Link Monitor state diagram

147.4.4.1 Link Monitor overview

The link monitor function generates the link_status parameter of the PMA_LINK.indication primitive for the Clause 98 Auto-Negotiation function.

The link_status parameter is set after the result of the PCS_STATUS.indication primitive and the implementation defined variable loc_rcv_status.

147.4.4.2 Variables

pma_reset
: Allows reset of all PMA functions.
Values: TRUE or FALSE
Set by: PMA Reset function.

link_control
: See 147.3.2.2.

loc_rcv_status
: Implementation defined variable set to TRUE when the PMA is ready to decode valid data from the line, FALSE otherwise.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

link_status

The link_status parameter set by PMA Link Monitor and communicated to the Technology Dependent Interface through the PMA_LINK.indication primitive.
Values: OK or FAIL

pcs_status

See 147.3.7.2.1.

147.5 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA for a 10BASE-T1S PHY.

147.5.1 EMC tests

Direct Power Injection (DPI) and 150 Ω emission tests for noise immunity and emission as per 147.5.1.1 and 147.5.1.2 may be used to establish a baseline for PHY EMC performance. These tests provide a high degree of repeatability and a good correlation to immunity and emission measurements. Operational requirements of the transceiver during the test are determined by the manufacturer.

Applications for the specified device commonly have additional requirements that limit its conducted radio frequency emission and its susceptibility to electromagnetic interference. Such requirements are beyond the scope of this standard.

147.5.1.1 Immunity—DPI test

In a real application radio frequency (RF) common-mode (CM) noise at the PHY is the result of electromagnetic interference coupling to the cabling system. Additional differential-mode (DM) noise at the PHY is generated from the CM noise by mode conversion of all parts of the cabling system and the MDI. The sensitivity of the PMA's receiver to RF CM noise may be tested according to the DPI method of IEC 62132-4.

147.5.1.2 Emission—Conducted emission test

The emission of the PMA transmitter to its electrical environment may be tested according to the 150 Ω direct coupling method of IEC 61967-4, and may need to comply with more stringent requirements.

147.5.2 Test modes

The test modes described in this subclause shall be provided to allow testing of the transmitter. The test modes can be enabled by setting bits 1.2299.15:13 (10BASE-T1S test mode control register) of the PHY Management register set as described in 45.2.1.236.1. If MDIO is not implemented a similar functionality shall be provided by equivalent means. These test modes shall change only the data symbols provided to the transmitter circuitry and shall not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation.

a) Test mode 1—Transmitter output voltage, timing jitter
b) Test mode 2—Transmitter output droop test mode
c) Test mode 3—Transmitter PSD mask
d) Test mode 4—Transmitter high impedance mode

When test mode 1 is enabled, the PHY shall repeatedly transmit DME encoded ones.

When test mode 2 is enabled, the PHY shall transmit a positive differential voltage for 1.6 μs followed by a negative differential voltage level for 1.6 μs. This sequence is repeated continually.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When test mode 3 is enabled, the PHY shall transmit continually a pseudo-random sequence of positive and negative voltage levels, generated by the scrambler defined in 147.3.2.8 and encoded using DME as in 147.4.2.

PHYs supporting multidrop mode shall implement test mode 4. When test mode 4 is enabled and the PHY is configured for multidrop mode, the transmitter shall present a high impedance termination to the line as specified in 147.4.2 for the 'I' symbol when operating in multidrop mode.

PHYs not supporting multidrop mode are not required to implement test mode 4. When test mode 4 is enabled and the PHY is not configured for multidrop mode, the transmitter behavior is undefined and left up to the implementer.

147.5.3 Test fixtures

The following fixtures (illustrated by Figure 147–15 and Figure 147–16), or their functional equivalents, can be used for measuring the transmitter specifications described in 147.5.4.

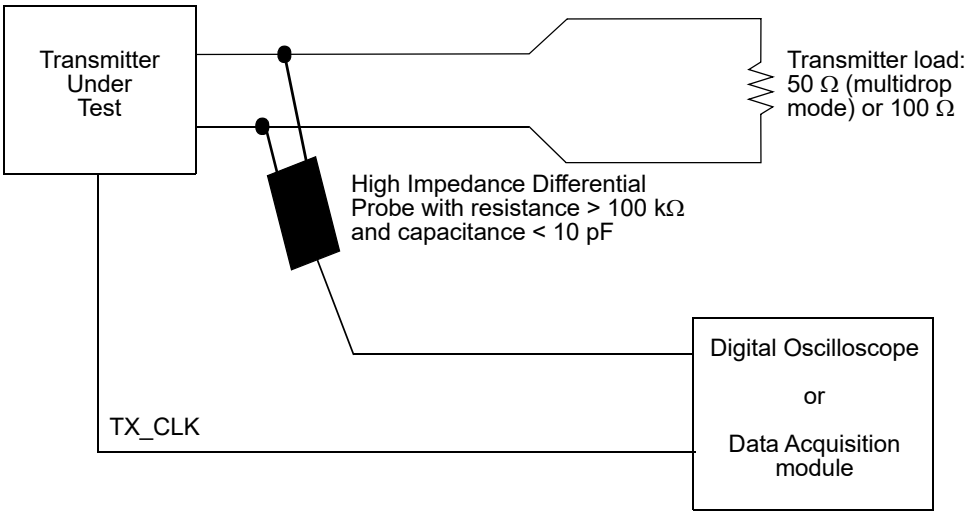

Figure 147–15—Transmitter test fixture 1 for transmitter voltage, transmitter droop, and transmitter timing jitter

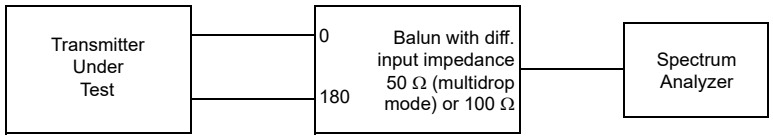

Figure 147–16—Transmitter test fixture 2 for power spectral density (PSD) measurement

To allow an easy synchronization of the measurement equipment, the PHY shall provide access to TX_CLK.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.5.4 Transmitter electrical specification

The PMA shall operate with AC coupling to the MDI.

Where a load is not specified and multidrop mode is supported and enabled, the transmitter shall meet the requirements of this subclause with a 50 Ω resistive differential load connected to the transmitter output. Otherwise, the transmitter shall meet the requirements of this subclause with a 100 Ω resistive differential load connected to the transmitter output. Transmitter electrical tests are specified with a load tolerance of ± 0.1%.

Unless otherwise specified, the specifications in 147.5.4.1 through 147.5.4.5 apply to transmitters in both point-to-point and multidrop mode, if supported.

147.5.4.1 Transmitter output voltage

When tested using the test fixture shown in Figure 147–15 with the transmitter in test mode 1, the transmitter output voltage shall be 1 V ± 20% peak-to-peak differential.

147.5.4.2 Transmitter output droop

When tested using the text fixture shown in Figure 147–15 with the transmitter in test mode 2, the magnitude of both the positive and negative droop measured with respect to the initial peak value after the zero crossing and the value 800 ns after the initial peak, depicted by Figure 147–17, shall be less than 30%.

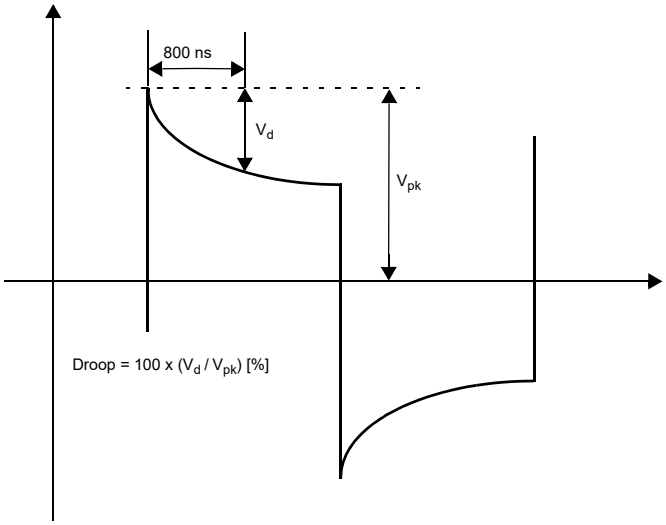

Figure 147–17—Transmitter output droop

147.5.4.3 Transmitter timing jitter

When measured using the test fixture shown in Figure 147–15 with the transmitter in test mode 1, the maximum jitter at the transmitter side shall be less than 5 ns symbol-to-symbol.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.5.4.4 Transmitter Power Spectral Density (PSD)

When measured using test mode 3 and the test fixture shown in Figure 147–16, or equivalent, the transmitter Power Spectral Density (PSD) shall be between the upper and lower masks specified in Equation (147–1) and Equation (147–2).

The upper and lower limits for multidrop mode are given in Equation (147–1) and Equation (147–2), and shown in Figure 147–18. In point-to-point mode both upper and lower limits are 3 dB lower than those for multidrop mode.

147.5.4.4.1 Upper PSD

$$\text{UpperPSD}(f) = \left\{ \begin{array}{ll} -61 & 0.3 \le f < 15 \\ -40 - 1.4f & 15 \le f < 25 \\ -75 & 25 \le f \le 40 \end{array} \right\} \text{ dBm/Hz} \quad (147\text{–}1)$$

where

f is the frequency in MHz; $0.3 \le f \le 40$

Lower PSD

$$\text{LowerPSD}(f) = \left\{ \begin{array}{ll} -87 + 2f & 5 \le f < 10 \\ -47 - 2f & 10 \le f \le 15 \end{array} \right\} \text{ dBm/Hz} \quad (147\text{–}2)$$

where

f is the frequency in MHz; $5 \le f \le 15$

147.5.4.4.2 PSD mask

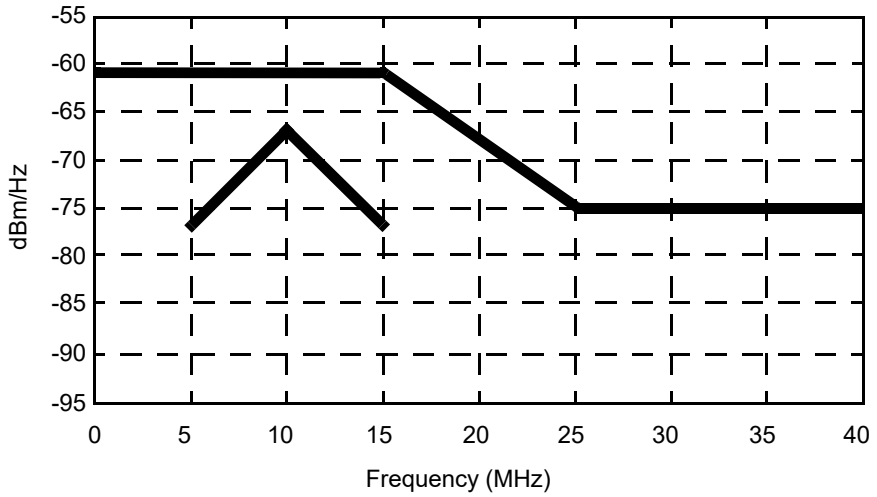

Figure 147–18—PSD upper and lower limits

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

147.5.4.5 Transmitter high impedance mode

In test mode 4, a transmitter with multidrop mode supported and enabled shall present the minimum parallel impedance across the MDI attachment points as specified in 147.9.2.

147.5.5 Receiver electrical specifications

147.5.5.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of 147.5.4 and have passed through a link segment specified in 147.7 or a mixing segment specified in 147.8 shall be received with a Bit Error Ratio (BER) of less than 10^{-10}, and sent to the MII during normal data transmission. This specification can be verified by a frame error ratio less than 10^{-7} for 125 octet frames.

147.5.5.2 Alien crosstalk noise rejection

The test is performed with a noise source such that noise with a Gaussian distribution, bandwidth of 40 MHz, and magnitude of –101 dBm/Hz is present at the MDI.

The receive DUT is connected to these noise sources through a resistive network, as shown in Figure 147–19, with link segments as defined in 147.7 and 147.8. The BER shall be less than 10^{-10}. This specification may be considered satisfied when the frame loss ratio is less than 10^{-7} for 125 octet frames measured at MAC/PLS service interface.

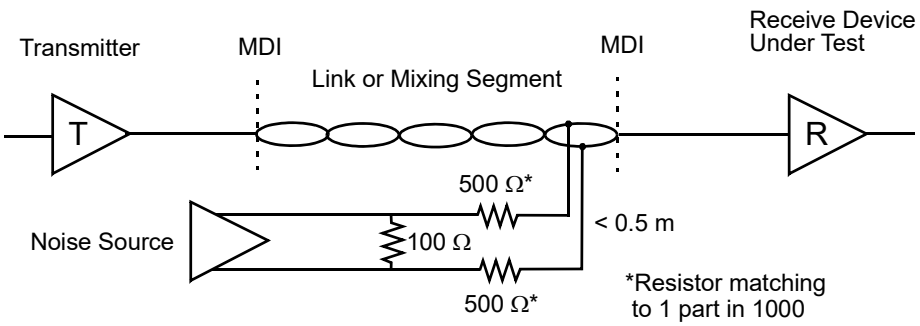

Figure 147–19—Alien crosstalk noise rejection test set-up

147.5.6 PMA local loopback

The PMA local loopback function is optional. If supported, the PMA shall be placed in local loopback mode when the PMA local loopback bit in MDIO register 1.0.0, defined in 45.2.1.1, or the PMA loopback bit in MDIO register 1.2297.13, defined in 45.2.1.234.5, is set to one (or PMA loopback mode is enabled by a similar functionality if MDIO is not implemented).

When the PHY is in the PMA local loopback mode, if the PHY supports full-duplex mode of operation, the PMA Receive function utilizes the echo signals from the open MDI and decodes these signals to pass the data back to the MII Receive interface.

If the PHY supports half-duplex mode of operation, the PMA and PCS Receive functions shall pass to the MII RX the data decoded from the signal which is normally received during a transmission for the purpose of detecting collisions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A MAC client can compare the packets sent through the MII Transmit function to the packets received from the MII Receive function to validate the 10BASE-T1S PCS and PMA functions.

147.6 Management interface

10BASE-T1S uses the management interface as specified in Clause 45. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the registers is recommended.

147.6.1 Support for Auto-Negotiation

Auto-Negotiation may be performed as part of the initial set-up of the link and allows negotiation of the duplex mode of operation. When Auto-Negotiation is used, Technology Ability Field bit A22 contains a one if the PHY is supporting and advertising 10BASE-T1S half duplex ability, and it contains a zero if 10BASE-T1S half duplex communication is not supported or not advertised. When Auto-Negotiation is used, Technology Ability Field bit A1 contains a one if the PHY is supporting and advertising 10BASE-T1S full duplex ability, and it contains a zero if 10BASE-T1S full duplex communication is not supported or not advertised. See 98B.4 for priority resolution.

147.7 Point-to-point link segment characteristics

The transmission characteristics for the 10BASE-T1S point-to-point link segment are specified to support applications requiring short physical reach, such as industrial, automotive, and building automation controls, for up to at least 15 m.

147.7.1 Insertion loss

The insertion loss of each 10BASE-T1S point-to-point link segment shall meet the values determined using Equation (147–3).

$$\text{Insertion loss}(f) < \left\{ \begin{array}{ll} 1.0 + \frac{1.6\,(f-1)}{9} & 0.3 \le f < 10 \\ 2.6 + \frac{2.3\,(f-10)}{23} & 10 \le f < 33 \\ 4.9 + \frac{2.3\,(f-33)}{33} & 33 \le f \le 40 \end{array} \right\} \text{ dB} \qquad (147\text{–}3)$$

where

f is the frequency in MHz; $0.3 \le f \le 40$

147.7.2 Return loss

In order to limit the noise at the receiver due to impedance mismatches, each 10BASE-T1S point-to-point link segment shall meet the values determined using Equation (147–4) at all frequencies from 0.3 MHz to 40 MHz. The reference impedance for the return loss specification is 100 Ω.

$$\text{Return loss}(f) > \left\{ \begin{array}{ll} 14 & 0.3 \le f < 10 \\ 14 - 10\log_{10}\left(\frac{f}{10}\right) & 10 \le f \le 40 \end{array} \right\} \text{ dB} \qquad (147\text{–}4)$$

where

f is the frequency in MHz; $0.3 \le f \le 40$

147.7.3 Mode conversion loss

The mode conversion loss of each 10BASE-T1S point-to-point link segment shall meet the values determined using Equation (147–5).

$$\text{Mode conversion loss}(f) > \left\{ \begin{array}{ll} 43 & 0.3 \le f < 20 \\ 43 - 20\log_{10}\left(\frac{f}{20}\right) & 20 \le f \le 200 \end{array} \right\} \text{ dB} \quad (147\text{–}5)$$

where

f is the frequency in MHz; $0.3 \le f \le 200$

147.7.4 Power sum alien near-end crosstalk (PSANEXT)

There is no FEXT or NEXT as 10BASE-T1S is a single pair solution. Noise coupled between the disturbed 10BASE-T1S link segment and other disturbing 10BASE-T1S link segments is referred to as alien crosstalk noise. Since the transmitted symbols from the alien noise source in one cable are not available to another cable, cancellation cannot be done. When there are multiple pairs of cables bundled together, where all pairs carry 10 Mb/s links, then each duplex link is disturbed by neighboring links, degrading the signal quality on the victim pair. In order to limit the near-end crosstalk noise for a 5-around-1 cable bundle (up to 15 m length and up to four in-line connectors, equally spaced), the power sum alien near-end crosstalk (PSANEXT) loss shall meet Equation (147–6).

$$\text{PSANEXT}(f) \ge 31.5 - 10\log_{10}\left(\frac{f}{100}\right) \text{ dB} \quad (147\text{–}6)$$

where

f is the frequency in MHz; $1 \le f \le 40$

147.7.5 Power sum alien attenuation to crosstalk ratio far-end (PSAACRF)

The power sum alien attenuation to crosstalk ratio far-end (PSAACRF) loss for a 5-around-1 cable bundle (up to 15 m length and up to four in-line connectors, equally spaced) shall meet Equation (147–7).

$$\text{PSAACRF}(f) \ge 16.5 - 20\log_{10}\left(\frac{f}{100}\right) \text{ dB} \quad (147\text{–}7)$$

where

f is the frequency in MHz; $1 \le f \le 40$

147.8 Mixing segment characteristics

10BASE-T1S PHYs supporting multidrop mode are designed to operate over media that meet the requirements specified in this subclause. The 10BASE-T1S mixing segment (1.4.403) is a single balanced pair of conductors that may have more than two MDIs attached.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A mixing segment is specified based on cabling that supports up to at least 8 nodes and 25 m in reach. Larger PHY count and/or reach may be achieved provided the mixing segment specifications in 147.8 are met. An example mixing segment and reference points are shown in Figure 147–20.

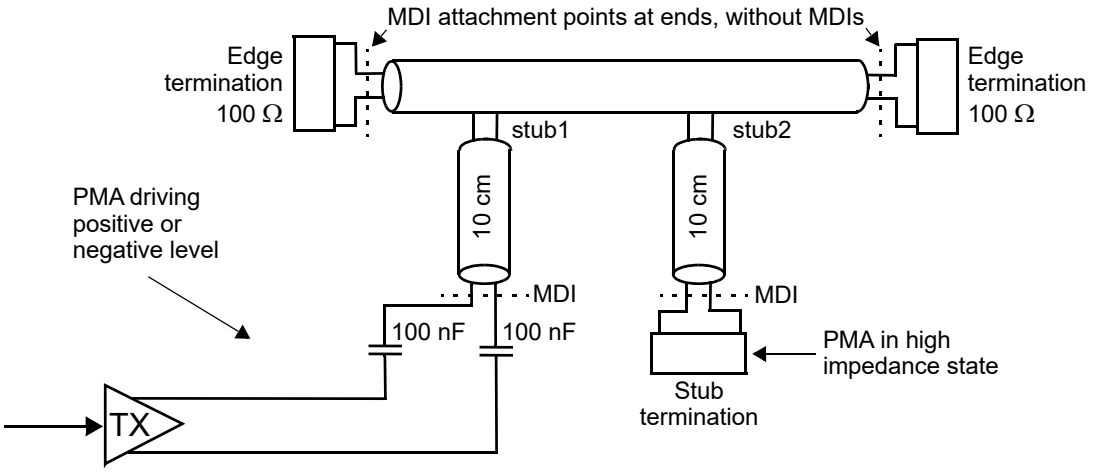

Figure 147–20—Multidrop line termination and PMA

147.8.1 Insertion loss

The mixing segment shall meet the insertion loss characteristics specified for link segments in 147.7.1 between any two MDI attachment points.

147.8.2 Return loss

The mixing segment shall meet the return loss characteristics specified for link segments in 147.7.2 at any MDI attachment point. The reference impedance for the return loss specification is 50 Ω.

147.8.3 Mode conversion loss

The mixing segment shall meet the mode conversion loss characteristics specified for link segments in 147.7.3 between any two MDI attachment points.

147.9 MDI specification

This subclause describes connectors which may be used at the MDI. It also specifies electrical requirements, including fault tolerance, at the MDI.

147.9.1 MDI connectors

In its minimum configuration, the mechanical interface to the balanced cabling is a 3-pin connector (BI_DA+, BI_DA–, and optional SHIELD) or alternatively a 2-pin connector with an optional additional mechanical shield connection which conforms to the link segment specification defined in 147.7 or to the mixing segment specification defined in 147.8.

Specific systems or applications can use connectors or terminals that support the link segment specification defined in 147.7 or the mixing segment specification defined in 147.8.

Connectors meeting the mechanical requirements of IEC 63171-1 [B36] or IEC 63171-6:2020 [B37] may be used as the mechanical interface to the balanced cabling. The plug connector is used on the balanced cabling and the MDI jack connector on the PHY. The IEC 63171-1 plug and jack are depicted (for informational use only) in Figure 147–21 and Figure 147–22 respectively, and the mating interface is depicted in Figure 147–23. The IEC 63171-6 plug and jack are depicted (for informational use only) in Figure 147–24 and Figure 147–25 respectively, and the mating interface is depicted in Figure 147–26. These connectors should support link segment DCR characteristics for 1.02 mm (18 AWG) to 0.40 mm (26 AWG) in Table 146B–1.

147.9.2 MDI electrical specification

When not in multidrop mode, the MDI shall meet the return loss limits as specified in Equation (96–12) in 96.8.2.1.

When in multidrop mode, the MDI shall present a minimum parallel impedance across the MDI attachment points per Equation (147–8) and the limits for R, L, C_{tot}, and C_{node} given in Table 147–4 over the stated frequency range. C_{tot} is the maximum total capacitance across all MDI attachment points, while R, L, and C_{node} are the resistance, inductance, and capacitance for each MDI attachment point.

Inductive elements are often used when power is applied across the data lines, and may be absent in non-powered implementations. Removing the parallel inductance is equivalent to setting L to infinity in Equation (147–8). The parasitic capacitance of inductive elements forms a portion of C_{node}.

$$|Z| = \frac{1}{\sqrt{\frac{1}{R^2} + \left(\frac{1}{2\pi \cdot f \cdot L} - 2\pi \cdot f \cdot C_{node}\right)^2}} \quad (147–8)$$

where

f is the frequency in MHz; $0.3 \leq f \leq 40$

Table 147–4—MDI impedance limit parameters

Parameter name	Unit of measure	Minimum value	Maximum value
R	kΩ	10	—
L	μH	80	—
C_{tot}	pF	—	180
C_{node}	pF	—	15

NOTE—The implementer is cautioned that loading the mixing segment with multiple nodes with worst case capacitance at the same location on the mixing segment may cause the mixing segment to exceed its return loss specification.

147.9.3 MDI line powering voltage tolerance

The DTE shall withstand without damage the application of any voltages between 0 V dc and 60 V dc with the source current limited to 2000 mA, applied across BI_DA+ and BI_DA–, in either polarity, under all operating conditions, for an indefinite period of time.

147.9.4 MDI fault tolerance

The wire pair of the MDI shall withstand without damage the application of short circuits of any wire to the other wire of the same pair or ground potential, as per Table 147–5, under all operating conditions indefinitely. Normal operation shall resume after all short circuits have been removed.

147.10 Environmental specifications

147.10.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2 or IEC 61010-1, as appropriate. All equipment subject to this clause is expected to conform to all applicable local, state, national, and application-specific standards.

147.10.2 Network safety

All cabling and equipment subject to this clause is expected to be mechanically and electrically secure in a professional manner. All 10BASE-T1S cabling is expected to be routed according to any applicable local, state, or national standards considering all relevant safety requirements. In automotive applications, all 10BASE-T1S cabling is expected to be routed to provide maximum protection by the motor vehicle sheet metal and structural components, following SAE J1292, ISO 14229, and ISO 15764. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

147.10.2.1 Environmental safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns; this list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

Systems described in this subclause are subject to various environmental hazards during their installation and use. In particular, equipment used in automotive and industrial environments can expect to meet the potential environmental stresses with respect to their mounting location defined for the application. Stresses expected in these environments may include but are not limited to those found in the listed specifications.

The following specifications describe potential environmental stresses in an automotive environment:

— General loads: ISO 16750-1
— Electrical loads: ISO 16750-2, ISO 7637-2, and ISO 8820-1
— Mechanical loads: ISO 16750-3, ASTM D4728, and ISO 12103-1

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Climatic loads: ISO 16750-4, and IEC 60068-2-1, IEC 60068-2-27, IEC 60068-2-30, IEC 60068-2-38, IEC 60068-2-52, IEC 60068-2-64, and IEC 60068-2-78
— Chemical loads: ISO 16750-5 and ISO 20653

The following specifications define potential environmental stresses in an industrial environment:

— Environmental loads: IEC 60529 and ISO 4892
— Mechanical loads: IEC 60068-2-6 and IEC 60068-2-31
— Climatic loads: IEC 60068-2-1, IEC 60068-2-2, IEC 60068-2-14, IEC 60068-2-27, IEC 60068-2-30, IEC 60068-2-38, IEC 60068-2-52, and IEC 60068-2-78

Additional environment(s) require careful analysis prior to implementation to determine appropriate environmental safety requirements.

147.10.2.2 Electromagnetic compatibility

A system integrating the 10BASE-T1S PHY is expected to comply with all applicable local and national codes for electromagnetic compatibility. In addition, the system may need to comply with more stringent requirements for the limitation of electromagnetic interference.

147.11 Delay constraints

The PHY shall comply with the timing requirements specified in Table 147–6.

Table 147–6—10BASE-T1S delay constraints

Event	Minimum value	Maximum value	Unit of measure	Input timing reference	Output timing reference
TX_EN/TX_ER sampled to MDI output	120	440	ns	Rising edge of MII TX_CLK	First DME clock transition at the MDI
MDI input to CRS asserted	400	1040	ns	First DME clock transition at the MDI	Rising edge of CRS
MDI input to CRS deasserted	640	1120	ns	Last DME encoded zero clock transition at the MDI	Falling edge of CRS
MDI input to COL asserted	0	5	µs	Start of corrupted transmitted signal at the MDI	Rising edge of COL
MDI input to COL deasserted	0	3.2	µs	End of transmission at the MDI	Falling edge of COL
MDI input to RX_DV asserted	2.4	4	µs	First DME clock transition at the MDI	Rising edge of RX_DV
MDI input to RX_ER asserted	1.6	4	µs	First DME clock transition at the MDI	Rising edge of RX_ER

147.12 Protocol implementation conformance statement (PICS) proforma for Clause 147, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1S[243]

147.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 147, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1S, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

147.12.2 Identification

147.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

147.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 147, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 10BASE-T1S
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[243] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

148. PLCA Reconciliation Sublayer (RS)

148.1 Introduction

This clause specifies a Reconciliation Sublayer to provide optional Physical Layer Collision Avoidance (PLCA) capabilities among participating stations. The PLCA RS is specified for operation with Clause 147 (10BASE-T1S) PHYs operating in half-duplex multidrop mode. PLCA can be dynamically enabled or disabled via management interface. When PLCA is disabled, the Reconciliation Sublayer mapping is identical to that specified in Clause 22.

When enabled, the PLCA RS aligns data from the MAC with transmission opportunities of the Physical Layer and maps the Physical Layer signals to PLS primitives towards the MAC. The use of PLCA-enabled Physical Layers in CSMA/CD half-duplex shared-medium networks can provide enhanced bandwidth and improved access latency under heavily loaded traffic conditions. PLCA-enabled nodes can coexist with nodes without PLCA enabled on the same mixing segment, all using IEEE 802.3 CSMA/CD.

148.1.1 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

148.1.1.1 State diagram notation

The conventions of 21.5 are adopted with the extension that some states in the state diagrams use an IF-THEN-ELSE-END construct to condition which actions are taken within the state. If the logical expression associated with the IF evaluates TRUE, all the actions listed between THEN and ELSE will be executed. In the case where ELSE is omitted, the actions listed between THEN and END will be executed. If the logical expression associated with the IF evaluates FALSE, the actions listed between ELSE and END will be executed. After executing the actions listed between THEN and ELSE, between THEN and END, or between ELSE and END, the actions following the END, if any, will be executed.

148.1.1.2 State diagram timer specifications

All timers operate in the manner described in 40.4.5.2.

148.1.1.3 Service specifications

The method and notation used in the service specification follows the conventions of 1.2.2.

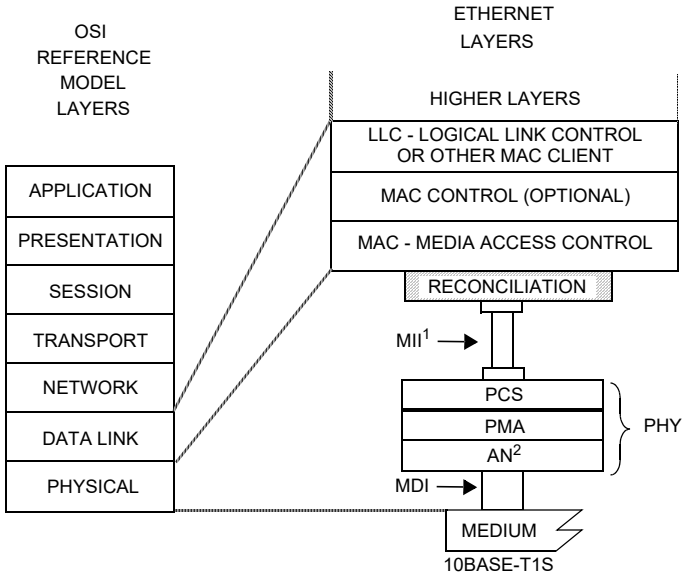
148.2 Overview

The working principle of PLCA is that transmit opportunities on a mixing segment are granted in sequence based on a node ID unique to the local collision domain (set by the management entity). The method of determination of the node ID and to_timer by the management entity is beyond the scope of this standard. Proper operation of the Clause 148 functionality assumes that the assigned node ID is unique in the local collision domain.

The node ID assignment value does not appear externally or in the payload packet format. The node ID assignment value is fully contained within the local collision domain.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Transmit opportunities are generated in a round-robin fashion. The node with ID = 0 signals a BEACON on the medium. Reception of a BEACON indicates the start of a new cycle of transmit opportunities. If the node with ID = 0 fails, the network is still operational with the same performance level of a CSMA/CD network without PLCA.



Each node is allowed to transmit a single packet during its own transmit opportunity. Individual nodes can be enabled to transmit a number of additional packets, up to the configured limit, within the same transmit opportunity.

PLCA relies on the PLS_SIGNAL.indication and PLS_CARRIER.indication primitives to have the MAC delay transmission until a transmit opportunity is available.

PLCA-enabled nodes may be used in the same CSMA/CD collision domain as non-PLCA enabled nodes. As the percentage of non-PLCA enabled nodes increases, performance advantages also decrease. If the node with ID = 0 fails, the network is still operational with the same performance level of a CSMA/CD network without PLCA.

148.3 Relationship with other IEEE standards

The relationship between the PLCA Reconciliation Sublayer, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 Ethernet model is shown in Figure 148–1. The Reconciliation Sublayer (shown shaded) in Figure 148–1 connects one Clause 4 Media Access Control (MAC) layer to the PHY. MII is defined in Clause 22.

MDI = MEDIUM DEPENDENT INTERFACE
MII = MEDIA INDEPENDENT INTERFACE

NOTE 1—MII is optional
NOTE 2—Auto-Negotiation is optional

PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
AN = AUTO-NEGOTIATION

148.4 PLCA Reconciliation Sublayer operation

148.4.1 General

This subclause specifies services provided by the PLCA RS as an extension to the RS specified in Clause 22. Figure 148–2 depicts the RS interlayer service interfaces. The PLCA RS contains the Control and Data state diagrams, the variable delay line, and command detect logic. When PLCA functions are not supported or are disabled by the management interface (plca_en = FALSE), RS operation shall conform to the RS definition in Clause 22.

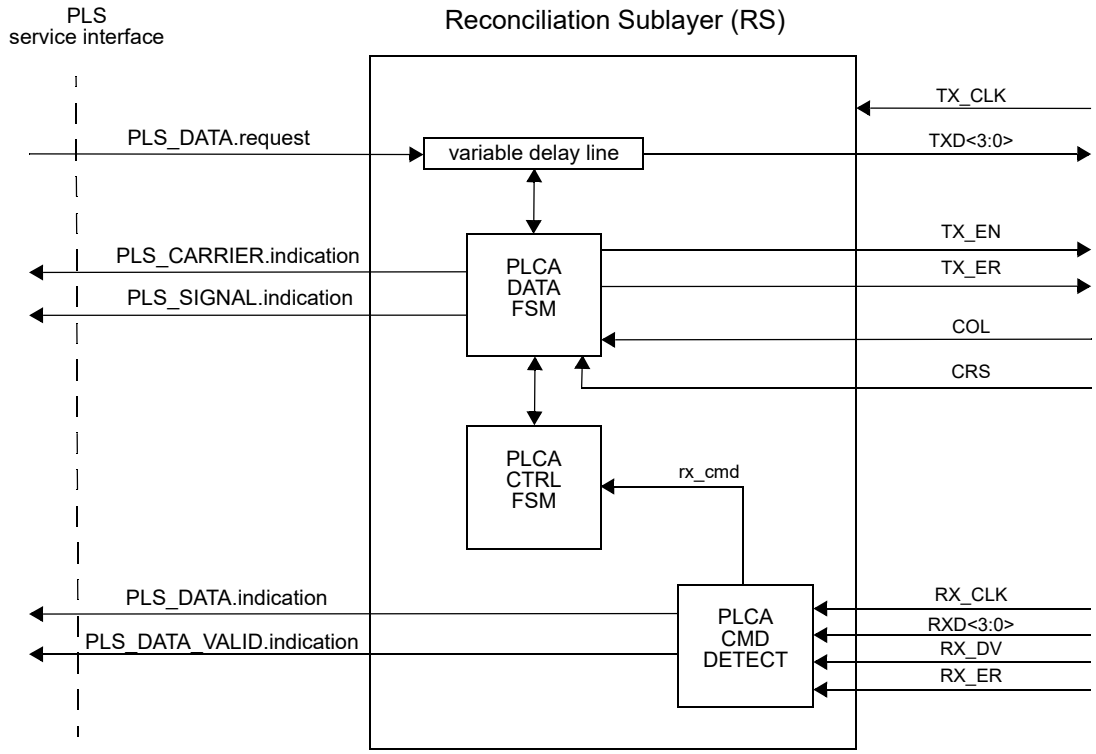

Figure 148–2—PLCA functions within the Reconciliation Sublayer (RS)

148.4.2 Mapping of MII signals to PLS service primitives and PLCA functions

The RS maps the signals provided at the MII to the PLS service primitives defined in Clause 6 via the PLCA state diagrams, variables, and functions (see 148.4.4 and 148.4.5). The PLS service primitives provided by the RS behave in exactly the same manner as defined in Clause 6.

148.4.2.1 Mapping of PLS_DATA.request

When PLCA is disabled (plca_en = FALSE), the mapping of the PLS_DATA.request primitive shall be the one specified in 22.2.1.1. Otherwise, the following applies.

148.4.2.1.1 Function

Maps the primitive PLS_DATA.request to PLCA variables which in turn generate the MII signals TXD<3:0> and TX_EN.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

148.4.2.1.2 Semantic of the service primitive

PLS_DATA.request (OUTPUT_UNIT)

The OUTPUT_UNIT parameter can take one of three values: ONE, ZERO, or DATA_COMPLETE. It represents a single data bit. The values ONE and ZERO are conveyed by the individual bits of the four-bit variable plca_txd<3:0>. Each bit of plca_txd<3:0> conveys one bit of data while plca_txen is set to TRUE. The value DATA_COMPLETE is conveyed by setting the variable plca_txen to FALSE. MII signals TXD<3:0> and TX_EN are generated by way of the PLCA Data state diagrams specified in 148.4.5. Synchronization between the RS and the PHY is achieved by way of the TX_CLK signal.

148.4.2.1.3 When generated

The plca_txd<3:0> and plca_txen variables are assigned after every group of four PLS_DATA.request transactions from the MAC sublayer to request the PLCA functions to transmit a nibble of data when the transmit opportunity is available, or to signal the end of the transmission. The TX_CLK signal is generated by the PHY. The TXD<3:0> and TX_EN signals are generated by the RS according to PLCA Data state diagrams (see 148.4.5).

148.4.2.2 Mapping of PLS_DATA.indication

Map of the primitive PLS_DATA.indication shall comply with 22.2.1.2.

148.4.2.3 Mapping of PLS_CARRIER.indication

When PLCA is disabled (plca_en = FALSE), the mapping of the PLS_CARRIER.indication primitive shall be the one specified in 22.2.1.3. Otherwise, the following applies

148.4.2.3.1 Function

Maps the primitive PLS_CARRIER.indication to the PLCA Data state diagram.

148.4.2.3.2 Semantic of the service primitive

PLS_CARRIER.indication (CARRIER_STATUS)

The CARRIER_STATUS parameter can take one of two values: CARRIER_ON or CARRIER_OFF.

148.4.2.3.3 When generated

The PLS_CARRIER.indication service primitive is generated by the RS according to the PLCA Data state diagram specified in 148.4.5.

148.4.2.4 Mapping of PLS_SIGNAL.indication

When PLCA is disabled (plca_en = FALSE) the mapping of the PLS_SIGNAL.indication primitive shall be the one specified in 22.2.1.4. Otherwise, the following applies.

148.4.2.4.1 Function

Map the primitive PLS_SIGNAL.indication to the PLCA Data state diagram.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

148.4.2.4.2 Semantic of the service primitive

PLS_SIGNAL.indication (SIGNAL_STATUS)

The SIGNAL_STATUS parameter can take one of two values: SIGNAL_ERROR or NO_SIGNAL_ERROR.

148.4.2.4.3 When generated

SIGNAL_STATUS is generated by the PLCA Data state diagram specified in 148.4.5.

148.4.2.5 Mapping of PLS_DATA_VALID.indication

Map of the primitive PLS_DATA_VALID.indication shall comply with 22.2.1.7.

148.4.2.6 Generation of TX_ER

Generation of TX_ER shall comply with the PLCA Data state diagram specified in 148.4.5.1.

148.4.2.7 Response to RX_ER indication

Response to RX_ER indication from the MII shall comply with 22.2.1.5.

148.4.3 Requirements for the PHY

In order to support PLCA, the RS has to be connected to a 10BASE-T1S PHY.

148.4.3.1 PHY response to PLCA commands and notifications

148.4.3.1.1 BEACON request

The BEACON function is specified in 148.4.4.1.

The RS conveys the BEACON request via MII interface.

Upon the reception of this request, the PHY encodes and transmits a signal communicating the BEACON to other PHYs on the segment so that they generate a BEACON indication.

Upon the reception of this request, the RX_DV signal is not asserted.

PHYs may map the BEACON request to any suitable line coding as long as the requirements defined in this subclause are met.

148.4.3.1.2 COMMIT request

The COMMIT function is specified in 148.4.4.1.

The PLCA Control state diagram generates a COMMIT request by way of the tx_cmd variable as specified in 148.4.4.2. The RS conveys such request via MII interface as defined in 22.2.2.4.

Upon the reception of this request, the RX_DV signal is not asserted.

PHYs may map the COMMIT request to any suitable line coding as long as the requirement defined in this subclause are met.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

148.4.3.2 Mapping of MII signals to PLCA variables

The PLCA RS is required to decode PLCA-specific signaling out of the MII.

148.4.3.2.1 BEACON indication

When the PHY receives a BEACON, it indicates this information to the RS by asserting MII signals.

The RS shall react to such indication by setting the PLCA variable rx_cmd to the value BEACON. The RS shall also reset the rx_cmd variable to NONE when the BEACON indication on the MII ceases, unless a COMMIT indication is signaled, in which case rx_cmd shall be set as specified in 148.4.3.2.2.

148.4.3.2.2 COMMIT indication

When the PHY receives a COMMIT from the line, it indicates this information to the RS by asserting MII signals. The PHY asserts CRS when a COMMIT indication is detected.

The RS shall react to such indication by setting the PLCA variable rx_cmd to the value COMMIT. The RS shall also reset the rx_cmd variable to NONE when the COMMIT indication on the MII ceases, unless a BEACON indication is signaled, in which case rx_cmd shall be set as specified in 148.4.3.2.1.

148.4.4 PLCA Control

148.4.4.1 PLCA Control state diagram

The PLCA Control function shall conform to the PLCA Control state diagram in Figure 148–3 and Figure 148–4 and associated state variables, functions, timers, and messages.

To achieve error free operation the PLCA node should be configured appropriately before transmit functions are enabled. Appropriate configuration includes the following:

a) Each local_nodeID is unique to the local collision domain.
b) There is one and only one node with local_nodeID = 0 on the local collision domain.
c) The transmit opportunity timer (to_timer) is set equal across all the nodes on the local collision domain.
d) plca_node_count is set on the node with local_nodeID = 0 to the maximum number of nodes supported on the local collision domain.

When PLCA functions are enabled and local_nodeID equals zero, PLCA switches to RECOVER state and waits one cycle of transmit opportunities. This prevents sending a BEACON at an inappropriate time (e.g., when the node with local_nodeID = 0 resets in the middle of a cycle of transmit opportunities and other nodes could still be sending valid data). A BEACON is then generated by such node by switching to SEND_BEACON state. On reception of a BEACON, all other nodes reset their own transmit opportunity counter and related timer.

When PLCA functions are enabled, nodes with nonzero local_nodeID wait in RESYNC state until a BEACON is received.

All nodes, including the one generating the BEACON, detect the end of the BEACON condition before proceeding to WAIT_TO state, in order to minimize latency differences across the network.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Entering WAIT_TO state, the node waits for one of these possible conditions:

1) CRS is asserted by the PHY through MII, indicating there is activity on the line.
2) curID becomes equal to local_nodeID while packetPending variable is TRUE, meaning that this node now owns a transmit opportunity and does have a packet to transmit.
3) curID becomes equal to local_nodeID while packetPending variable is FALSE, meaning that this node now owns a transmit opportunity but does not have a packet to transmit.
4) to_timer elapses, indicating the current transmit opportunity is yielded.

If condition (1) occurs, the node is about to receive either a valid packet, a COMMIT request, a BEACON request or it might be receiving a false carrier event.

In EARLY_RECEIVE state, the PLCA Control state diagram is waiting for the PHY to properly decode the incoming signal and to take the following actions:

— Switch to RECEIVE state if a COMMIT indication is reported or a valid packet is being decoded. The PLCA Control state diagram then remains in the RECEIVE state until the line is free (CRS deasserted).
— Switch to SYNCING state if a BEACON is received with local_nodeID ≠ 0, which starts a new cycle of transmit opportunities.
— Switch to RESYNC state if CRS is not followed by the reception of a packet and local_nodeID ≠ 0, meaning that a false carrier occurred and the curID variable might be out of synchronization. In this case, the node skips its transmit opportunity (TO) and waits for a new BEACON in order not to disrupt the current cycle of transmit opportunities.
— Switch to RECOVER state if local_nodeID is 0 and CRS is de-asserted but no packet is being received. In RECOVER state, since the curID variable might be out of synchronization, this node waits for the end of the current cycle of transmit opportunities before sending a new BEACON. This is required so as not to send a BEACON while other nodes might still be using their TO.

When condition (2) occurs, the node now gets a TO having at least one packet to be transmitted. COMMIT state is then entered to signal other nodes to stop their to_timer and wait for a packet by the means of a COMMIT request. COMMIT state is left once the data to be transmitted is available from the MAC or the PLCA delay line.

When condition (3) occurs, the node now gets a TO without being ready to send any packet. In this case, the YIELD state is entered to skip the TO, allowing other nodes a chance to transmit. In some rare cases (e.g., a non-PLCA enabled node is connected to the network) it is possible to receive data in YIELD state. If this unlikely event happens, PLCA switches to RECEIVE state to wait until the end of the transmission and increment curID properly.

When condition (4) is met, another node has yielded its transmit opportunity, causing the curID variable to be incremented and to_timer to be reset.

148.4.4.2 PLCA Control variables

plca_reset

The plca_reset signal is used to reset the optional PLCA function in the RS. This signal maps to TRUE when acPLCAReset is in reset and to FALSE when acPLCAReset is normal, but is further qualified.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

plca_en

The plca_en signal controls the optional PLCA function in the RS. This signal maps to TRUE when aPLCAAdminState is enabled and to FALSE when aPLCAAdminState is disabled.
Values: TRUE or FALSE

CRS

The MII signal CRS.
Values: TRUE or FALSE

RX_DV

The MII signal RX_DV.
Values: TRUE or FALSE

receiving

Defined as: (RX_DV = TRUE) + (rx_cmd = COMMIT).
Values: TRUE or FALSE

tx_cmd

Command for the PLCA Data state diagram to convey to the PHY via the MII.
Values: NONE, BEACON or COMMIT

rx_cmd

Encoding present on RXD<3:0>, RX_ER, and RX_DV as defined in Table 22–2.
Values:
BEACON: PLCA BEACON indication encoding present on RXD<3:0>, RX_ER, and RX_DV
COMMIT: PLCA COMMIT indication encoding present on RXD<3:0>, RX_ER, and RX_DV
NONE: PLCA BEACON or COMMIT indication encoding not present on RXD<3:0>, RX_ER, and RX_DV

TX_EN

The MII signal TX_EN.
Values: TRUE or FALSE

local_nodeID

ID representing the PLCA transmit opportunity number assigned to the node. This signal maps to aPLCALocalNodeID.
Values: integer value from 0 to 255

plca_node_count

Maximum number of PLCA nodes on the mixing segment receiving transmit opportunities before the node with local_nodeID = 0 generates a new BEACON, reflecting the value of aPLCANodeCount. This parameter is meaningful only for the node with local_nodeID = 0; otherwise, it is ignored.
Values: integer number from 0 to 255

committed

Internal variable used to synchronize PLCA Control and Data functions.
It is set by PLCA Control state diagram to signal that the current transmit opportunity has been committed and the PLCA Data state diagram is now allowed to convey MII data to the PHY.
Values: TRUE or FALSE

packetPending

Internal variable used to synchronize PLCA Control and Data functions.
The PLCA Data state diagram sets this variable when it detects the MAC is ready to send a packet and have PLCA Control state diagram actually commit for the next available transmit opportunity.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bc

Counts the number of additional packets currently sent in a burst after the first transmission.
Values: integer from 0 to 255

max_bc

Maximum number of additional packets the node is allowed to transmit in a single burst. This signal maps to aPLCAMaxBurstCount attribute.
Values: integer from 0 to 255

plca_active

Notifies the PLCA Status function whether the node is waiting for sending or receiving a BEACON or it already sent or received one.
Values: TRUE or FALSE

curID

Integer variable tracking the ID of the node that currently owns a transmit opportunity.
Values: integer from 0 to 255

PMCD

Prescient mii_clock_timer_done. This variable is set to FALSE on entry to the RESYNC state and becomes TRUE 1 ± ½ bit time prior to mii_clock_timer_done becoming TRUE.
Values: TRUE or FALSE

148.4.4.3 Functions

No functions are defined for the PLCA Control state diagram.

148.4.4.4 Timers

beacon_timer

Times the duration of the BEACON signal.
Duration: 20 bit times.
Tolerance: ± ½ bit time.

beacon_det_timer

Timer for detecting received BEACONs.
Duration: 22 bit times.
Tolerance: ± 1 bit time.

invalid_beacon_timer

Timer used for BEACON validation. This timer is stopped any time rx_cmd = BEACON.
Duration: 4000 ns.
Tolerance: ± 400 ns.

burst_timer

This timer determines how long to wait for the MAC to send a new packet before yielding the transmit opportunity. For PLCA burst mode to work properly this timer should be set greater than one IPG. Timer duration maps to aPLCABurstTimer attribute.
Duration: integer number between 0 and 255, expressed in bit times.
Tolerance: ± ½ bit time.
The default value is specified in 30.16.1.1.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to_timer

The transmit opportunity timer maps to aPLCATransmitOpportunityTimer. The timer value needs to meet Equation (148–1). The to_timer should be set equal across the mixing segment for PLCA to work properly.

$$\begin{aligned} to_timer > {} & 2 \times \max(t_{propdelay}) + \\ & \max(TX_EN\ sampled\ to\ MDI\ output) + \\ & \max(MDI\ input\ to\ CRS\ asserted) + \\ & \max(MDI\ input\ to\ CRS\ deasserted) - \\ & \min(MDI\ input\ to\ CRS\ deasserted) + \\ & \max(MII\ propagation\ delay) \end{aligned} \tag{148–1}$$

where $t_{propdelay}$ is the propagation delay between any two nodes on the mixing segment, and the delay specifications are the maxima and minima for the PHY type on the mixing segment (for 10BASE-T1S, see 147.11).

Duration: integer number between 1 and 255, expressed in bit times.
Tolerance: 100 ppm.
The default value is specified in 30.16.1.1.5.

148.4.5 PLCA Data

148.4.5.1 PLCA Data state diagram

The PLCA Data state diagram is responsible for detecting when the MAC is ready to send a packet and delaying the transmission until a transmit opportunity is detected.

The PLCA Data function shall conform to the PLCA Data state diagram in Figure 148–5 and Figure 148–6 and associated state variables, functions, timers, and messages.

When PLCA functions are enabled, the PLCA Data state diagram transitions to the IDLE state and waits for the MAC to start a transmission or the PHY to assert carrier sense. In the former case, the data conveyed by the MAC through the PLS_DATA.request primitive is delayed by switching to HOLD state. In the latter case, CARRIER_ON is signaled through the PLS_CARRIER.indication to have the MAC defer any new transmission, then the RECEIVE state is entered.

The MAC however, might have started a transmission right before a carrier is detected. In this case, the Data state diagram switches to the COLLIDE state asserting SIGNAL_STATUS = SIGNAL_ERROR via PLS_SIGNAL.indication primitive to have the MAC perform a backoff and send the packet again later, without actually forwarding any data for the PHY to transmit on the medium.

During the HOLD state, the PLCA Control state diagram is notified via the packetPending variable that data is available to be transmitted and the beginning of the transmission is held in the variable delay line. At the next transmit opportunity, the PLCA Control state diagram allows transmitting the delayed data by setting the committed variable to TRUE. In such a case, the PLCA Data state diagram switches to TRANSMIT state to actually deliver the data for the PHY to encode and transmit on the medium.

The variable delay line is a small buffer that aligns a transmission with the transmit opportunity.

If plca_txer is asserted during the HOLD state, the PLCA Data state diagram switches to ABORT state to assert packetPending = FALSE and to wait until the MAC stops sending data. The aborted packet will not be transmitted on the medium.

If another node starts a transmission during the HOLD state, the delayed data is dropped and a collision is triggered by switching to COLLIDE state.

During the COLLIDE state, packetPending = FALSE and CARRIER_STATUS = CARRIER_ON are asserted via the PLS_CARRIER.indication primitive. When the MAC has completed sending the jam bits as described in Clause 4, the PLCA Data state diagram waits for the next transmit opportunity by switching to DELAY_PENDING state. The PLCA Data state diagram transitions to the PENDING state after waiting for the pending_timer. The pending_timer is used to prevent committing to a transmit opportunity before transmit data is available. This prevents conveying unwanted long COMMIT requests to the PHY.

During the PENDING state, the PLCA Data state diagram asserts packetPending = TRUE and keeps CARRIER_STATUS = CARRIER_ON via the PLS_CARRIER.indication primitive to prevent the MAC from making new transmit attempts until the PLCA Control state diagram signals that a new transmit opportunity is available. At that point, CARRIER_STATUS is set to CARRIER_OFF to have the MAC resend data after waiting one IPG period as described in Clause 4.

148.4.5.2 Variables

a
: Current delay counter.

b
: Flush counter.

CARRIER_STATUS
: See 148.4.2.3.2.

COL
: The MII signal COL specified in 22.2.2.12.

committed
: See 148.4.4.2.

CRS
: The MII signal CRS (see 22.2.2.11).

packetPending
: See 148.4.4.2.

plca_en
: See 148.4.4.2.

plca_reset
: See 148.4.4.2.

plca_status
: See 148.4.6.2.

plca_txd<3:0>
: A four-bit data value conveying a nibble of data to transmit from four successive PLS_DATA.request(OUTPUT_UNIT) primitives where OUTPUT_UNIT has a value of ONE or ZERO. See 148.4.2.1.2. The addition of a subscript 'n-a', i.e., $plca_txd_{n-a}$ indicates the plca_txd conveyed ‘a’ mii_clock_timer expirations before the most recent one.

plca_txen
: See 148.4.2.1.2.

plca_txer
: The conditions for generating plca_txer are the same as defined in 22.2.1.6 and 22.2.2.5 for the TX_ER MII signal.
Values: TRUE or FALSE

receiving
: See 148.4.4.2.

rx_cmd
: See 148.4.4.2.

SIGNAL_STATUS
: See 148.4.2.4.2

tx_cmd
: See 148.4.4.2.

tx_cmd_sync
: The value of the tx_cmd variable sampled on the rising edge of the MII TX_CLK.
Values: see tx_cmd in 148.4.4.2

TXD
: The MII signals TXD<3:0> specified in 22.2.2.4.

TX_EN
: The MII signal TX_EN specified in 22.2.2.3.

TX_ER
: The MII signal TX_ER specified in 22.2.2.5.

148.4.5.3 Functions

ENCODE_TXER
: This function takes as its argument the tx_cmd_sync variable defined in 148.4.5.2.
It returns TRUE if tx_cmd_sync is BEACON or COMMIT. Otherwise, it returns the value of the plca_txer variable, defined in 148.4.5.2.

ENCODE_TXD
: This function takes as its argument the tx_cmd_sync variable defined in 148.4.5.2.
If tx_cmd_sync is BEACON, the return value is the TXD encoding defined in Table 22–1 for the BEACON request.
If tx_cmd_sync is COMMIT, the return value is the TXD encoding defined in Table 22–1 for the COMMIT request.
Otherwise, the return value is 0000.

148.4.5.4 Timers

commit_timer
: Defines the maximum time the PLCA Data state machine is allowed to stay in WAIT_MAC state.
Duration: 288 bit times.
Tolerance: ± ½ bit time.

mii_clock_timer
: A continuous free-running timer that shall expire synchronously with the rising edge of the MII TX_CLK.
Restart time: Immediately after expiration; restarting the timer resets the condition mii_clock_timer_done.
Duration: see 22.2.2.1.

pending_timer
: Defines the time the PLCA Data state diagram waits in the DELAY_PENDING state before switching to PENDING state.
Duration: 512 bit times.
Tolerance: ± ½ bit time.

148.4.5.5 Abbreviations

MCD Alias for mii_clock_timer_done

148.4.5.6 Constants

delay_line_length
: This constant is implementation dependent and specifies the maximum number of nibbles that the PLCA RS variable delay line can hold.
Value: up to 99

148.4.6 PLCA Status

148.4.6.1 PLCA Status state diagram

The PLCA Status state diagram is responsible for reporting whether nodes are actively sending/receiving the BEACON. The PLCA Status function shall conform to the PLCA Status state diagram in Figure 148–7 and associated state variables, functions, timers, and messages.

Upon reset or when PLCA is disabled, the PLCA Status function enters the INACTIVE state and reports plca_status as FAIL. As soon as the PLCA Control function enters the SYNCING state (i.e., receiving or transmitting the BEACON), the plca_active variable is set to TRUE and PLCA Status switches to the ACTIVE state, reporting plca_status as OK.

From the ACTIVE state, whenever plca_active is set to FALSE by the PLCA Control function, the PLCA Status function enters the HYSTERESIS state, still reporting plca_status as OK and arming plca_status_timer.

If plca_active is reset to TRUE, then PLCA Status reverts to the ACTIVE state, effectively filtering the momentarily inactive state. Instead, if plca_status_timer expires while plca_active is still FALSE, the PLCA Status function reverts to the INACTIVE state, reporting plca_status as FAIL.

148.4.6.2 PLCA Status variables

plca_status
: If plca_status is OK, BEACONs are being received or transmitted, and the PLCA Control state diagram is in normal operation. If plca_status is FAIL, the PLCA Control state diagram has been in the DISABLE, RESYNC, or RECOVER state for greater than the duration of the plca_status timer. This signal maps to aPLCAStatus attribute as specified in 30.16.1.1.2.
Values: OK or FAIL

plca_active
: See 148.4.4.2.

plca_en
: See 148.4.4.2.

plca_reset
: See 148.4.4.2.

148.4.6.3 Functions

No functions are defined for PLCA Status state diagram.

148.4.6.4 Timers

plca_status_timer
: Represents the time plca_status is maintained in OK state when plca_active is FALSE while in the HYSTERESIS state.
Duration: the duration of this timer is 130 090 bit times, which is 2 × (max to_timer × max plca_node_count + beacon_timer).
Tolerance: timer may expire up to 10 000 BT (nominally 1 ms at 10 Mb/s) greater than the specified duration

148.5 Protocol implementation conformance statement (PICS) proforma for Clause 148, PLCA Reconciliation Sublayer (RS)[244]

148.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 148, PLCA Reconciliation Sublayer (RS), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

148.5.2 Identification

148.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

148.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 148, PLCA Reconciliation Sublayer (RS)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[244]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

148.5.3 PICS proforma tables for PLCA Reconciliation Sublayer (RS)

149. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1

149.1 Overview

This clause defines the type 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 Physical Coding Sublayer (PCS) as well as the 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 Physical Medium Attachment (PMA) sublayers. Together, the corresponding PCS and PMA sublayers comprise a 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 Physical Layer device (PHY). Provided in this clause are functional and electrical specifications for the type 2.5GBASE-T1 PCS and PMA, 5GBASE-T1 PCS and PMA, and 10GBASE-T1 PCS and PMA.

The 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs are intended to be operated over a single balanced pair of conductors. The link segment specifications defined in 149.7 were derived from automotive requirements, but may also be used for non-automotive applications. The conductors supporting the operation of the 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs are defined in terms of performance requirements between the Medium Dependent Interfaces (MDIs) allowing implementers to provide their own conductors to operate the 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs as long as the normative requirements included in 149.7 are met.

This clause also specifies an optional Energy-Efficient Ethernet (EEE) capability. A 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHY that supports this capability may enter a Low Power Idle (LPI) mode of operation during periods of low link utilization as described in Clause 78.

149.1.1 Nomenclature

The 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs described in this clause represent three distinct PHY types that share the same PCS, PMA, and MDI specifications subject to frequency scaling. In order to efficiently describe the three PHYs, the nomenclature MultiGBASE-T1 is used to describe specifications that apply to the 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs. Additionally, for parameters that scale with the PHY's data rate, the parameter *S* is used for scaling, see Table 149–1.

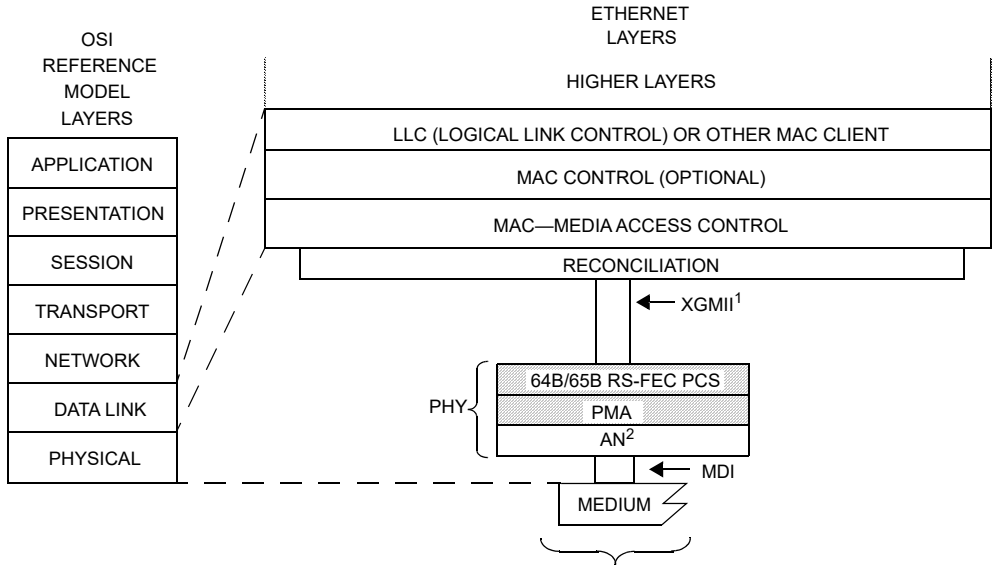

Table 149–1—Scaling parameter

PHY type	*S*
10GBASE-T1	1
5GBASE-T1	0.5
2.5GBASE-T1	0.25

149.1.2 Relationship of 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 to other standards

The relationship between the 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 Ethernet Model are shown in Figure 149–1. The PHY sublayers (shown shaded) in Figure 149–1 connect one Clause 4 Media Access Control (MAC) layer to the medium. Auto-Negotiation for 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs is defined in Clause 98. The XGMII is defined in Clause 46.

MDI = MEDIUM DEPENDENT INTERFACE
XGMII = 10 GIGABIT MEDIA INDEPENDENT INTERFACE

NOTE 1—XGMII is optional
NOTE 2—Auto-Negotiation is optional

PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
AN = AUTO-NEGOTIATION

Figure 149–1—Relationship of 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs to the ISO/IEC OSI reference model and the IEEE 802.3 Ethernet Model

149.1.3 Operation of 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1

The 2.5GBASE-T1 PHY, 5GBASE-T1 PHY, and 10GBASE-T1 PHY each operate using full-duplex communications over a single balanced pair of conductors with an effective rate of 2.5 Gb/s, 5 Gb/s, or 10 Gb/s in each direction simultaneously while meeting the requirements (EMC, temperature, etc.) of automotive environments. The PHY supports operation on an automotive link segment supporting up to four in-line connectors using a single balanced pair of conductors for up to at least 15 m. The 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs utilize 4-level pulse amplitude modulation (PAM4) transmitted at 1406.25 MBd, 2812.5 MBd, and 5625 MBd rates, respectively. A 33-bit scrambler is used to improve the EMC performance. XGMII TX_D, TX_EN, and TX_ER are encoded together using 64B/65B encoding. To maintain a bit error ratio (BER) of less than or equal to 10^{-12}, the 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs add 340 bits of Reed-Solomon forward error correction (RS-FEC) parity to each group of 50 64B/65B blocks. The PAM4 mapping, scrambler, RS-FEC, interleaver, and PAM4 encoder/decoder are all contained in the PCS (see 149.3).

Auto-Negotiation (Clause 98) may optionally be used by 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for normal operation. Auto-Negotiation is performed upon link startup through the use of half-duplex differential Manchester encoding. The implementation of the Auto-Negotiation function is optional. If Auto-Negotiation is implemented, it shall meet the requirements of Clause 98.

A 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHY shall be capable of operating as MASTER or SLAVE, per runtime configuration. A MASTER PHY uses a local clock to determine the timing of transmitter operations. A SLAVE PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations. When Auto-Negotiation is used, the MASTER-SLAVE relationship between two devices sharing a link segment is established during Auto-Negotiation (see Clause 98). If

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Auto-Negotiation is not used, a MASTER-SLAVE relationship shall be established by management or hardware configuration of the PHYs, and the MASTER and SLAVE are synchronized by the PHY Link Synchronization function in the PHY (see 149.4.2.6).

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

A 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHY may optionally support Energy-Efficient Ethernet (see Clause 78) and advertise the EEE capability as described in 149.4.2.4.5. The EEE capability is a mechanism by which 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHYs are able to reduce power consumption during periods of low link utilization.

The 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHY may optionally support the MultiGBASE-T1 PCS-based operations, administration, and maintenance (OAM). The MultiGBASE-T1 OAM is useful for monitoring link operation by exchanging PHY link health status and messages. The MultiGBASE-T1 OAM information is exchanged between two 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHYs out of band, that is, outside of the specified 2.5 Gb/s, 5 Gb/s, or 10 Gb/s Ethernet data stream. The MultiGBASE-T1 OAM is specified in 149.3.9, and the 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHY advertises its MultiGBASE-T1 OAM capability as described in 149.4.2.4.5.

The 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PMA couples messages from the PCS to the MDI and provides clock recovery, link management, and PHY Control functions. The PMA provides full duplex communications at 1406.25 MBd for 2.5GBASE-T1, 2812.5 MBd for 5GBASE-T1, and 5625 MBd for 10GBASE-T1 over the single balanced pair of conductors. PMA functionality is described in 149.4. The MDI is specified in 149.8. Figure 149–2 shows the functional block diagram.

149.1.3.1 Physical Coding Sublayer (PCS)

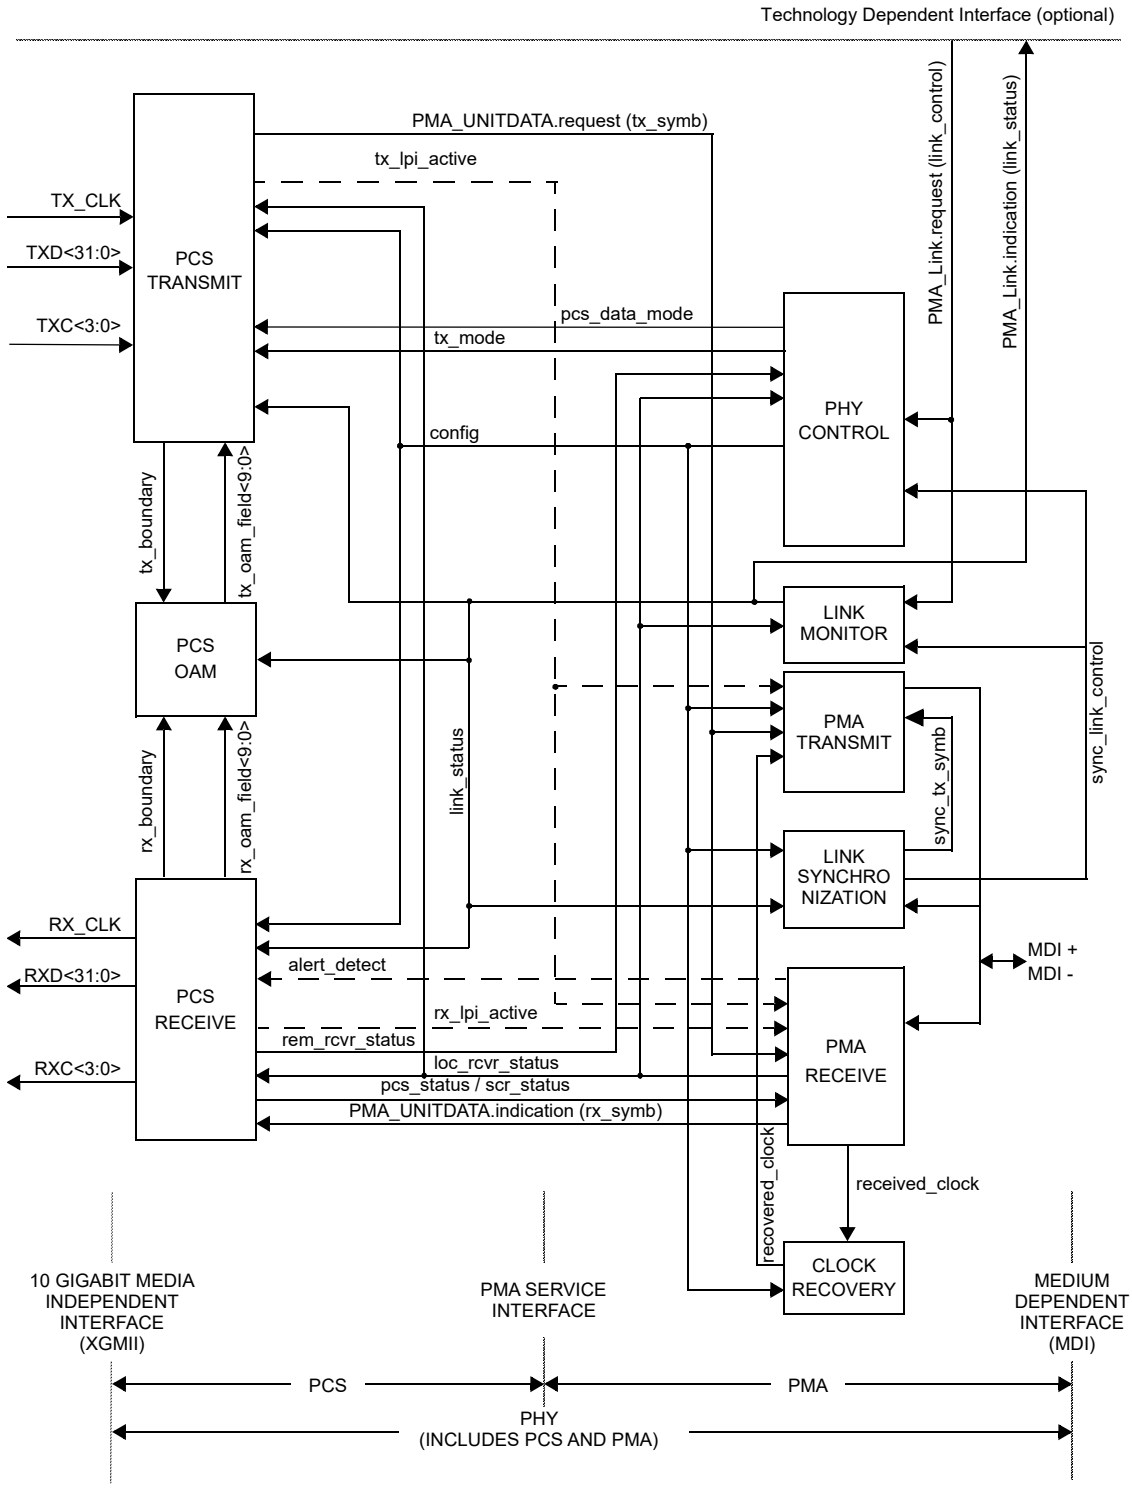
The MultiGBASE-T1 PCS couples a 10 Gigabit Media Independent Interface (XGMII), as described in Clause 46, to the 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 Physical Medium Attachment (PMA) sublayer.

In addition to the normal mode of operation, the PCS supports a training mode. Furthermore, the PCS contains a management interface.

In the transmit direction, in normal mode, the PCS receives eight XGMII data octets provided by two consecutive transfers on the XGMII service interface on TXD<31:0> and groups them into 64-bit blocks with the 64-bit block boundaries aligned with the boundary of the two XGMII transfers. Each group of eight octets along with the data/control indications is transcoded into a 65-bit block. These 65-bit blocks are then aggregated into groups of 50 blocks. The contents of each group are contained in a vector tx_group50x65B. Next, a 10-bit OAM field is appended to form a 3260-bit block. A number, L, of these 3260-bit blocks are formed into an RS-FEC input superframe, then encoded by the RS-FEC (360, 326, 2^{10}) and the round–robin interleaving as described in 149.3.2.2.16. The RS-FEC output superframe consists of L × 3600 bits. The duration of the superframe is L × 320 / *S* ns. Finally these bits are exclusive OR’d with a degree 33 scrambler to create the MultiGBASE-T1 payload. PCS transmit functions are described in 149.3.2.2.

tx_group50x65B<3249:0> is defined as:

$$\text{tx_group50x65B}\langle 65 \times i + j \rangle = \text{tx_coded}_i\langle j \rangle$$



where i = 0 to 49, j = 0 to 64, and tx_coded_i<64:0> is the i^{th} 64B/65B block where tx_coded_0<64:0> is the first block transmitted.

In the training mode (see 149.4.2.4), the PCS transmits and receives PAM2 training frames to synchronize to the PHY frame and exchanges EEE and MultiGBASE-T1 OAM capabilities.

149.1.3.2 Physical Medium Attachment (PMA) sublayer

The PMA couples messages from the PCS service interface onto the single balanced pair of conductors via the Medium Dependent Interface (MDI) and provides the link management and PHY Control functions. The PMA provides full duplex communications at 5625 × *S* MBd. See Table 149–1 for the definition of *S*.

The PMA PHY Control function generates signals that control the PCS and PMA sublayer operations. PHY Control is enabled following the completion of Auto-Negotiation or PHY Link Synchronization and provides the startup functions required for successful MultiGBASE-T1 operation. It determines whether the PHY operates in a disabled state, a training state, or a data state where MAC frames can be exchanged between the link partners.

The Link Monitor determines the status of the underlying link channel and communicates this status to other functional blocks. A failure of the receive channel causes the data mode operation to stop and Auto-Negotiation or Link Synchronization to restart.

PMA functions and state diagrams are specified in 149.4. The electrical parameters of the PMA, i.e., test modes and electrical specifications for the transmitter and receiver, are specified in 149.5.

149.1.3.3 EEE Capability

A MultiGBASE-T1 PHY may optionally support the EEE capability, as described in 78.3. The EEE capability is a mechanism by which MultiGBASE-T1 PHYs are able to reduce power consumption during periods of low link utilization. PHYs can enter the LPI mode of operation after completing training. Each direction of the full duplex link is able to enter and exit the LPI mode independently, supporting symmetric and asymmetric LPI operation. This allows power savings when only one side of the full duplex link is in a period of low utilization. The transition to or from LPI mode is not expected to cause any MAC frames to be lost or corrupted.

Support for the EEE capability is advertised in the Infofield (Octet 10 bit 6) during link startup. Transitions to and from the LPI transmit mode are controlled via XGMII signaling. Transitions to and from the LPI receive mode are controlled by the link partner using sleep and wake signaling.

When the PHY Health status received from the link partner indicates that LPI is insufficient to maintain PHY SNR, the PHY may temporarily exit LPI mode and send idles.

The PCS 64B/65B Transmit state diagram in Figure 149–16 and Figure 149–17 includes additional states for EEE. The PCS 64B/65B Receive state diagram in Figure 149–18 and Figure 149–19 includes additional states for EEE. The EEE transmit state diagram is contained in the PCS Transmit function and is specified in Figure 149–20.

149.1.3.4 Link Synchronization

The Link Synchronization function is used when Auto-Negotiation is disabled or not implemented to detect the presence of the link partner, time and control link failure, and act as the data source for the PHY control state diagram. Link Synchronization operates in a half-duplex fashion. Link Synchronization is defined in 149.4.2.6.

149.1.4 Signaling

MultiGBASE-T1 signaling is performed by the PCS generating continuous code-group sequences that the PMA transmits over the single balanced pair of conductors. The signaling scheme achieves a number of objectives including:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Forward error correction (FEC) coded symbol mapping for data.
b) Algorithmic mapping from TXD<31:0> and TXC<3:0> to PAM4 symbols in the transmit path.
c) Algorithmic mapping from the received signal on the MDI port to RXD<31:0> and RXC<3:0>.
d) Uncorrelated symbols in the transmitted symbol stream.
e) No correlation between symbol streams traveling both directions.
f) Block framing and other control signals.
g) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining.
h) Ability to automatically detect and correct for incorrect polarity in the connection.
i) Optionally, ability to support refresh, quiet, and alert signaling during LPI operation.

The PHY may operate in three basic modes: the normal data mode, the training mode, or an optional LPI mode.

In normal mode, the PCS generates a continuous stream of PAM4 symbols that are transmitted via the PMA at one of four voltage levels. In training mode, the PCS is directed to generate only PAM2 symbols for transmission by the PMA. (See Figure 149–32.)

PHYs may also support the EEE capability as described in 149.1.3.3. Transitions to the LPI mode are supported after reaching normal mode.

149.1.5 Interfaces

All 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHY implementations are compatible at the MDI and at the XGMII, if implemented. Implementation of the XGMII is optional. Designers are free to implement circuitry within the PCS and PMA in an application-dependent manner provided that the MDI and XGMII (if the XGMII is implemented) specifications are met. System operation from the perspective of signals at the MDI and management objects are identical whether the XGMII is implemented or not.

149.1.6 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of state diagrams as described in 21.5, along with the extensions described in 145.2.5.2. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

Default initializations, unless specified, are left to the implementer.

149.2 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 service primitives and interfaces

MultiGBASE-T1 transfers data and control information across the following four service interfaces:

a) 10 Gigabit Media Independent Interface (XGMII)
b) Technology Dependent Interface
c) PMA service interface
d) Medium Dependent Interface (MDI)

The XGMII is specified in Clause 46; the Technology Dependent Interface is specified in 98.4. The PMA service interface is defined in 149.2.2 and the MDI is defined in 149.8.

149.2.1 Technology Dependent Interface

MultiGBASE-T1 uses the following service primitives to exchange status indications and control signals across the Technology Dependent Interface, required in PHYs that implement Auto-Negotiation, as specified in 98.4:

PMA_LINK.request(link_control)
PMA_LINK.indication(link_status)

149.2.1.1 PMA_LINK.request

This primitive allows the Auto-Negotiation to enable and disable operation of the PMA, as specified in 98.4.2.

149.2.1.1.1 Semantics of the primitive

PMA_LINK.request(link_control)

The link_control parameter can take on one of two values: DISABLE, or ENABLE.

DISABLE Used by the Auto-Negotiation function to disable the PHY.

ENABLE Used by the Auto-Negotiation function to enable the PHY.

149.2.1.1.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in 98.4.

149.2.1.1.3 Effect of receipt

This primitive affects the operation of the PMA Link Monitor function as defined in 149.4.2.5, the PMA PHY Control function as defined in 149.4.2.4, and the PMA Receive function defined in 149.4.2.3.

149.2.1.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 98.4.1. This primitive informs the PCS, PMA PHY Control function, and the Auto-Negotiation functions about the status of the underlying link.

149.2.1.2.1 Semantics of the primitive

PMA_LINK.indication(link_status)

The link_status parameter can take on one of two values: FAIL or OK.

FAIL No valid link established.

OK The Link Monitor function indicates that a valid MultiGBASE-T1 link is established. Reliable reception of signals transmitted from the remote PHY is possible.

149.2.1.2.2 When generated

The PMA generates this primitive to indicate a change in link_status in compliance with the state diagram given in Figure 149–33.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.1.2.3 Effect of receipt

The effect of receipt of this primitive is specified in 98.4.1.

149.2.2 PMA service interface

MultiGBASE-T1 uses the following service primitives to exchange symbol vectors, status indications, and control signals across the service interfaces:

PMA_TXMODE.indication(tx_mode)
PMA_CONFIG.indication(config)
PMA_UNITDATA.request(tx_symb)
PMA_UNITDATA.indication(rx_symb)
PMA_SCRSTATUS.request(scr_status)
PMA_PCSSTATUS.request(pcs_status)
PMA_RXSTATUS.indication(loc_rcvr_status)
PMA_REMRXSTATUS.request(rem_rcvr_status)
PMA_PCSDATAMODE.indication (pcs_data_mode)

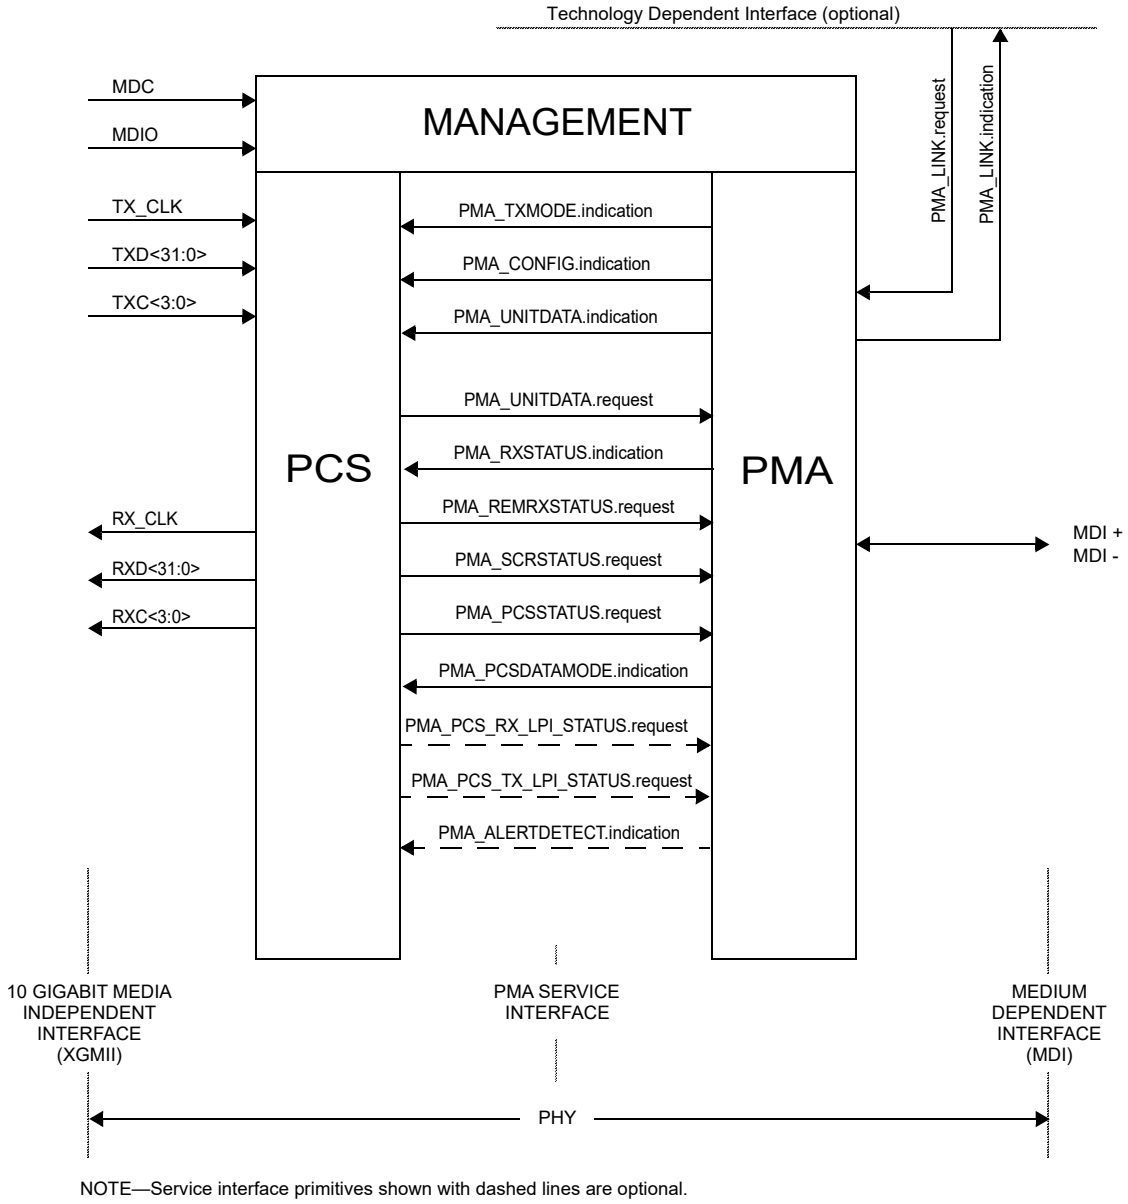
The use of these primitives is illustrated in Figure 149–3. Connections from the management interface (signals MDC and MDIO) to the sublayers are pervasive and are not shown in Figure 149–3.

EEE-capable PHYs additionally support the following service primitives:

PMA_PCS_RX_LPI_STATUS.request(rx_lpi_active)
PMA_PCS_TX_LPI_STATUS.request(tx_lpi_active)
PMA_ALERTDETECT.indication (alert_detect)

149.2.2.1 PMA_TXMODE.indication

The transmitter in a MultiGBASE-T1 link normally sends over the MDI symbols that represent an XGMII data stream with framing, scrambling and encoding of data, control information, or idles.



149.2.2.1.1 Semantics of the primitive

PMA_TXMODE.indication(tx_mode)

PMA_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of symbols the PCS should be transmitting. The parameter tx_mode can take on one of the following values of the form:

SEND_N	This value is continuously asserted during transmission of sequences of symbols representing an XGMII data stream in the data mode.
SEND_T	This value is continuously asserted in case transmission of sequences of symbols representing the training mode is to take place.
SEND_Z	This value is continuously asserted in case transmission of zeros is required.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Service interface primitives shown with dashed lines are optional.

Figure 149–3—2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 service interfaces

149.2.2.1.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages to indicate a change in tx_mode.

149.2.2.1.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 149.3.2.2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.2.2 PMA_CONFIG.indication

Each PHY in a MultiGBASE-T1 link is capable of operating as a MASTER PHY and as a SLAVE PHY. If the Auto-Negotiation process is enabled, PMA_CONFIG MASTER-SLAVE configuration is determined during Auto-Negotiation (see Clause 98) and the result is provided to the PMA. If the Auto-Negotiation process is not implemented or not enabled, PMA_CONFIG MASTER-SLAVE configuration is predetermined to be MASTER or SLAVE via management control during initialization or via default hardware setup.

149.2.2.2.1 Semantics of the primitive

PMA_CONFIG.indication(config)

PMA_CONFIG.indication specifies to the PCS and PMA Transmit via the parameter config whether the PHY operates as a MASTER PHY or as a SLAVE PHY. The parameter config can take on one of the following two values of the form:

MASTER	This value is continuously asserted when the PHY operates as a MASTER PHY.
SLAVE	This value is continuously asserted when the PHY operates as a SLAVE PHY.

149.2.2.2.2 When generated

PMA generates PMA_CONFIG.indication messages to indicate a change in configuration.

149.2.2.2.3 Effect of receipt

PCS and PMA Clock Recovery perform their functions in MASTER or SLAVE configuration according to the value assumed by the parameter config.

149.2.2.3 PMA_UNITDATA.request

This primitive defines the transfer of symbols in the form of the tx_symb parameter from the PCS to the PMA. The symbols are obtained in the PCS Transmit function using the encoding rules defined in 149.3.2.2 to represent XGMII data and control streams or other sequences.

149.2.2.3.1 Semantics of the primitive

PMA_UNITDATA.request(tx_symb)

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb the value of the symbols to be sent over the MDI. The tx_symb may take on one of the following values:

{–1, –1/3, +1/3, +1}	in normal operation.
0	when zeros are to be transmitted in the following two cases: 1) when PMA_TXMODE.indication is SEND_Z during PMA training, and 2) after data mode is reached, the transmit function is in the LPI transmit mode, and lpi_tx_mode is QUIET.

149.2.2.3.2 When generated

The PCS generates PMA_UNITDATA.request(tx_symb) synchronously with every transmit clock cycle.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.2.3.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated symbols processed to conform to 149.5.2.

149.2.2.4 PMA_UNITDATA.indication

This primitive defines the transfer of symbols in the form of the rx_symb parameter from the PMA to the PCS.

149.2.2.4.1 Semantics of the primitive

PMA_UNITDATA.indication(rx_symb)

During reception the PMA_UNITDATA.indication conveys to the PCS via the parameter rx_symb the value of symbols detected on the MDI during each cycle of the recovered clock.

149.2.2.4.2 When generated

The PMA generates PMA_UNITDATA.indication(rx_symb) messages synchronously for every symbol received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is 1406.25 MHz for 2.5GBASE-T1, 2812.5 MHz for 5GBASE-T1, and 5625 MHz for 10GBASE-T1; as governed by the recovered clock.

149.2.2.4.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

149.2.2.5 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the training mode descrambler has achieved synchronization.

149.2.2.5.1 Semantics of the primitive

PMA_SCRSTATUS.request(scr_status)

The scr_status parameter can take on one of two values of the form:

OK	The training mode descrambler has achieved synchronization.
NOT_OK	The training mode descrambler is not synchronized.

149.2.2.5.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages to indicate a change in scr_status.

149.2.2.5.3 Effect of receipt

The effect of receipt of this primitive is specified in 149.4.2.3 and 149.4.2.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.2.6 PMA_PCSSTATUS.request

This primitive is generated by PCS Receive to indicate the fully operational state of the PCS for the local PHY. The parameter pcs_status conveys to the PMA Receive function the information that the PCS is operating reliably in the data mode.

149.2.2.6.1 Semantics of the primitive

PMA_PCSSTATUS.request(pcs_status)

The pcs_status parameter can take on one of two values of the form:

OK	The PCS is operating reliably in the data mode.
NOT_OK	The PCS is not operating reliably in the data mode.

149.2.2.6.2 When generated

PCS Receive generates PMA_PCSSTATUS.request messages to indicate a change in pcs_status.

149.2.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 149.4.4.1.

149.2.2.7 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Transmit, PCS Receive, PMA PHY Control function, and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by the PCS Receive decoding functions. The criterion for setting the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting errors during reception of symbol stream.

149.2.2.7.1 Semantics of the primitive

PMA_RXSTATUS.indication(loc_rcvr_status)

The loc_rcvr_status parameter can take on one of two values of the form:

OK	This value is asserted and remains true during reliable operation of the receive link for the local PHY.
NOT_OK	This value is asserted whenever operation of the link for the local PHY is unreliable.

149.2.2.7.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages to indicate a change in loc_rcvr_status on the basis of signals received at the MDI.

149.2.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 149–33, 149.3.2.3, 149.4.2.4, and 149.4.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.2.8 PMA_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The parameter rem_rcvr_status is set to the value received in the loc_rcvr_status bit in the Infofield from the remote PHY. The rem_rcvr_status is set to NOT_OK if the PCS has not decoded a valid Infofield from the remote PHY.

149.2.2.8.1 Semantics of the primitive

PMA_REMRXSTATUS.request(rem_rcvr_status)

The rem_rcvr_status parameter can take on one of two values of the form:

OK	The receive link for the remote PHY is operating reliably.
NOT_OK	Reliable operation of the receive link for the remote PHY is not detected.

149.2.2.8.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages to indicate a change in rem_rcvr_status based on the PCS decoding the loc_rcvr_status bit in Infofield messages received from the remote PHY during training.

149.2.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 149–32.

149.2.2.9 PMA_PCSDATAMODE.indication

This primitive indicates whether or not the PCS state diagrams are able to transition from their initialization states. The pcs_data_mode variable is generated by the PMA PHY Control function. It is passed to the PCS Control function via the PMA_PCSDATAMODE.indication primitive.

149.2.2.9.1 Semantics of the primitive

PMA_PCSDATAMODE.indication(pcs_data_mode)

149.2.2.9.2 When generated

The PMA PHY Control function generates PMA_PCSDATAMODE.indication messages continuously.

149.2.2.9.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 149.3.2.2.

149.2.2.10 PMA_PCS_RX_LPI_STATUS.request

When the PHY supports the EEE capability this primitive is generated by the PCS Receive function to indicate the status of the receive link at the local PHY. The parameter PMA_PCS_RX_LPI_STATUS.request conveys to the PCS Transmit and PMA Receive functions information regarding whether the receive function is in the LPI receive mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.2.10.1 Semantics of the primitive

PMA_PCS_RX_LPI_STATUS.request(rx_lpi_active)

The rx_lpi_active parameter can take on one of two values of the form:

TRUE	The receive function is in the LPI receive mode.
FALSE	The receive function is not in the LPI receive mode.

149.2.2.10.2 When generated

The PCS generates PMA_PCS_RX_LPI_STATUS.request messages to indicate a change in the rx_lpi_active variable as described in 149.3.2.3 and 149.3.7.2.2.

149.2.2.10.3 Effect of receipt

The effect of receipt of this primitive is specified in 149.3.7.3.

149.2.2.11 PMA_PCS_TX_LPI_STATUS.request

When the PHY supports the EEE capability this primitive is generated by the PCS Transmit function to indicate the status of the transmit link at the local PHY. The parameter PMA_PCS_TX_LPI_STATUS.request conveys to the PCS Transmit and PMA Receive functions information regarding whether the transmit function is in the LPI transmit mode.

149.2.2.11.1 Semantics of the primitive

PMA_PCS_TX_LPI_STATUS.request(tx_lpi_active)

The tx_lpi_active parameter can take on one of two values of the form:

TRUE	The transmit function is in the LPI transmit mode.
FALSE	The transmit function is not in the LPI transmit mode.

149.2.2.11.2 When generated

The PCS generates PMA_PCS_TX_LPI_STATUS.request messages to indicate a change in the tx_lpi_active variable as described in 149.3.6 and 149.3.7.2.2.

149.2.2.11.3 Effect of receipt

The effect of receipt of this primitive is specified in 149.3.7.3.

149.2.2.12 PMA_ALERTDETECT.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY when rx_lpi_active is TRUE. The parameter alert_detect conveys to the PCS Receive function information regarding the detection of the LPI alert signal by the PMA Receive function. The criterion for setting the parameter alert_detect is left to the implementer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.2.2.12.1 Semantics of the primitive

PMA_ALERTDETECT.indication (alert_detect)

The alert_detect parameter can take on one of two values of the form:

TRUE	The alert signal has been reliably detected at the local receiver.
FALSE	The alert signal at the local receiver has not been detected.

149.2.2.12.2 When generated

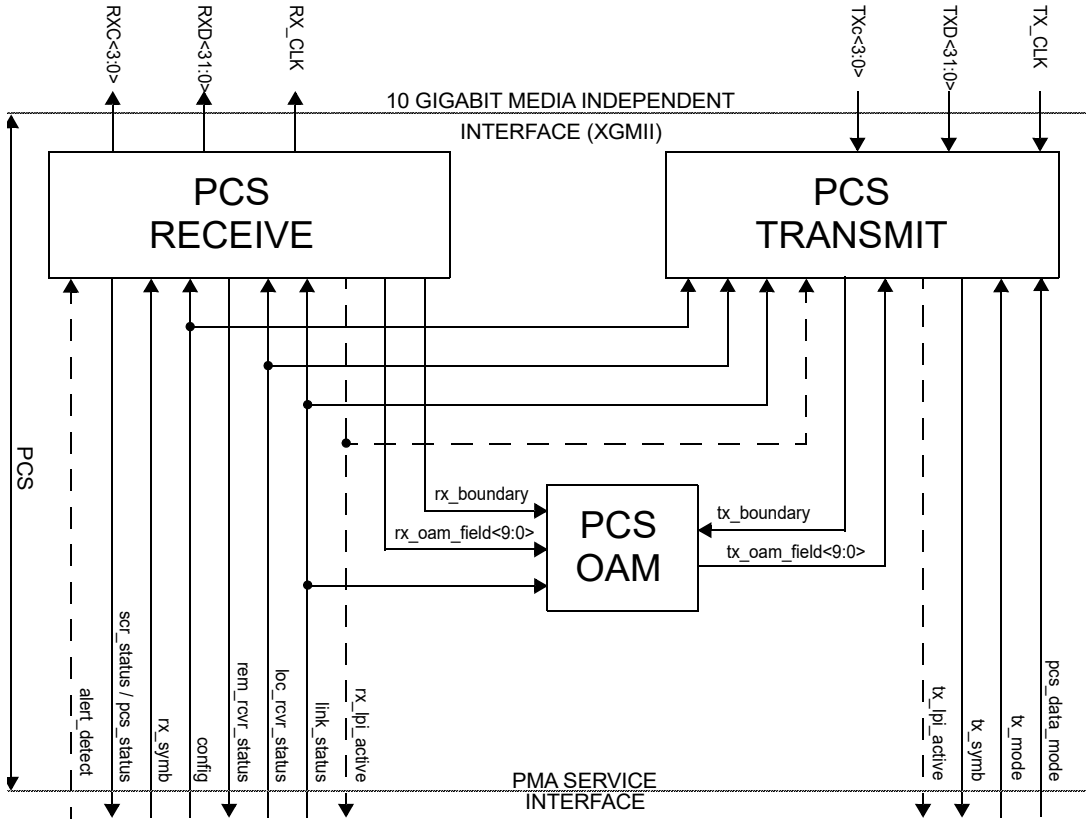
The PMA generates PMA_ALERTDETECT.indication messages to indicate a change in the alert_detect status.

149.2.2.12.3 Effect of receipt

The effect of receipt of this primitive is specified in 149.3.2.3, Figure 149–17.

149.3 Physical Coding Sublayer (PCS) functions

149.3.1 PCS service interface (XGMII)



The PCS service interface allows the MultiGBASE-T1 PCS to transfer information to and from a PCS client. The PCS service interface is precisely defined as the 10 Gigabit Media Independent Interface (XGMII) in Clause 46.

149.3.2 PCS functions

The PCS comprises one PCS Reset function and two simultaneous and asynchronous operating functions. The PCS operating functions are: PCS Transmit and PCS Receive. All operating functions start immediately after the successful completion of the PCS Reset function.

The PCS reference diagram, Figure 149–4, shows how the two operating functions relate to the messages of the PCS-PMA interface. Connections from the management interface (signals MDC and MDIO) to other layers are pervasive and are not shown in Figure 149–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—rx_lpi_active and tx_lpi_active are only required for the EEE capability.

Figure 149–4—PCS reference diagram

149.3.2.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

a) Power on (see 149.3.7.2.2).
b) The receipt of a request for reset from the management entity.

PCS Reset sets pcs_reset = TRUE while any of the above reset conditions hold true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

The control and management interface shall be restored to operation within 10 ms from the setting of bit 3.2322.15.

149.3.2.2 PCS Transmit function

The PCS Transmit function shall conform to the PCS 64B/65B Transmit state diagram in Figure 149–16 and Figure 149–17, and to the PCS Transmit bit ordering in Figure 149–6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Dashed rectangles in Figure 149–16 and Figure 149–17 are used to indicate states and state transitions in the transmit process state diagram that shall be supported by PHYs with the EEE capability. PHYs without the EEE capability do not support these states or transitions.

When communicating with the XGMII, the MultiGBASE-T1 PCS uses a four octet-wide, synchronous data path, with packet delimiting being provided by transmit control signals and receive control signals. Alignment of pairs of XGMII transfers to 64B/65B blocks is performed in the PCS. The PMA sublayer operates independently of PCS block, RS-FEC frames, and higher-layer packet boundaries. The PCS provides the functions necessary to map packets between the XGMII format and the PMA service interface format.

After mapping the XGMII transfers to 64B/65B blocks, the subsequent functions of the PCS Transmit process take L groups of 50 65B blocks and append a 10-bit OAM field to each group. This forms the input to an L-interleaved RS-FEC which adds L × 340 parity bits. The resulting L × 3600 bits are then scrambled. These bits are then mapped, two at a time, into a PAM4 symbol. Transmit data-units are sent to the PMA service interface via the PMA_UNITDATA.request primitive.

In each symbol period, when communicating with the PMA, the PCS Transmit generates a PAM4 symbol that is transferred to the PMA via the PMA_UNITDATA.request primitive. The symbol period, *T*, is 1000 / (5.625 × *S)* ps. See Table 149–1 for the definition of *S*.

The operation of the PCS Transmit function is controlled by the PMA_TXMODE.indication message received from the PMA PHY Control function.

If a PMA_TXMODE.indication message has the value SEND_Z, PCS Transmit shall pass a vector of zeros at each symbol period to the PMA via the PMA_UNITDATA.request primitive.

If a PMA_TXMODE.indication message has the value SEND_T, PCS Transmit shall generate a sequence (T_n) defined in 149.3.5.1 to the PMA via the PMA_UNITDATA.request primitive. These code-groups are used for training mode and only transmit the values {–1, +1}.

During training mode an Infofield is transmitted at regular intervals containing messages for startup operation. By this mechanism, a PHY indicates the status of its own receiver to the link partner and makes requests for remote transmitter settings. (See 149.4.2.4.)

If a PMA_TXMODE.indication message has the value SEND_N, the PCS is in the normal mode of operation and the PCS Transmit function shall use a 65B coding technique to generate, at each symbol period, code-groups that represent data or control. During transmission, the 50 blocks of 65B encoded bits are appended with a 10-bit OAM field to form the RS-FEC input frame. During data encoding, PCS Transmit utilizes L-interleaved (L = 1, 2, or 4) Reed-Solomon encoders to generate and append 340 parity check bits to form 3600-bit (360,326) RS-FEC frames that are interleaved into an L-interleaved RS-FEC superframe.

Each RS-FEC input superframe consists of 3260 × L bits, or 326 × L Reed-Solomon message symbols. The interleaving function is integrated with the RS-FEC encoding, applying a round-robin interleaving scheme and distributing the 10-bit Reed-Solomon message symbols into L RS-FEC encoders. After encoding, the RS-FEC frames from each encoder are recombined into one single interleaved RS-FEC superframe, which consists of 360 × L symbols, or 3600 × L bits. The bits of the RS-FEC superframe are then scrambled by the PCS using an additive scrambler, encoded in PAM4 symbols, and transferred to the PMA.

L is called the interleaving depth, and the possible choices of L are 1, 2, and 4. The interleaver settings requested in each direction of transmission may be different, and the value of L used by the transmitter is determined by the link partner and signaled during the PAM2 training mode Infofield exchange.

After reaching the normal mode of operation, EEE-capable PHYs may enter the LPI transmit mode under the control of the RS via the XGMII. The EEE Transmit state diagram is contained within the PCS Transmit function. The EEE capability is described in 149.3.2.2.22.

A block diagram of the PCS Transmit functions is shown in Figure 149–5.

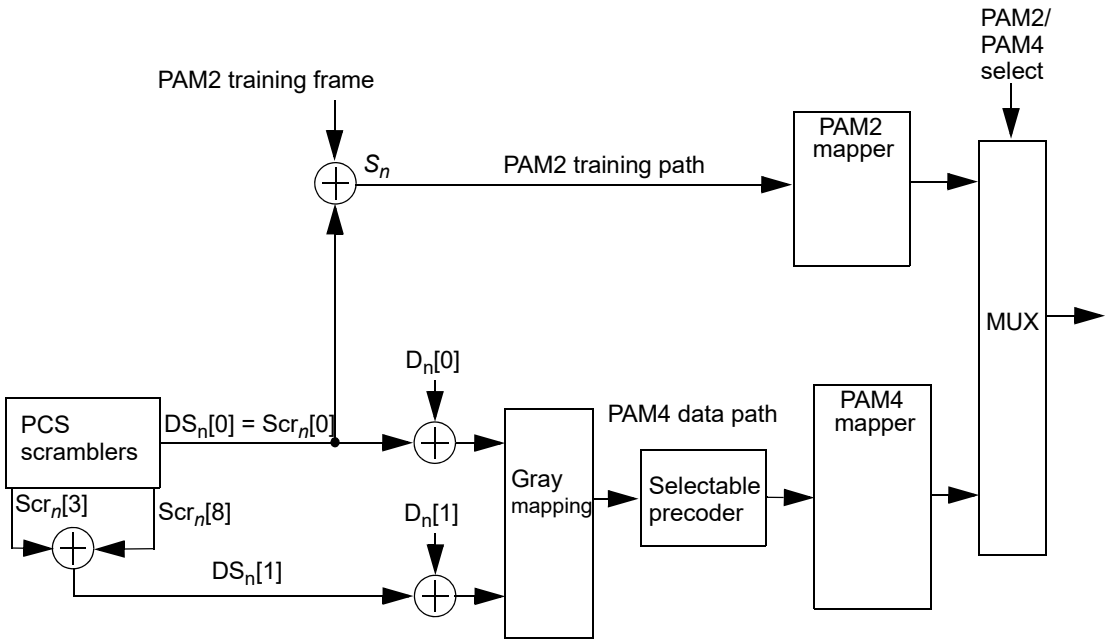

Figure 149–5—PCS Transmit function block diagram

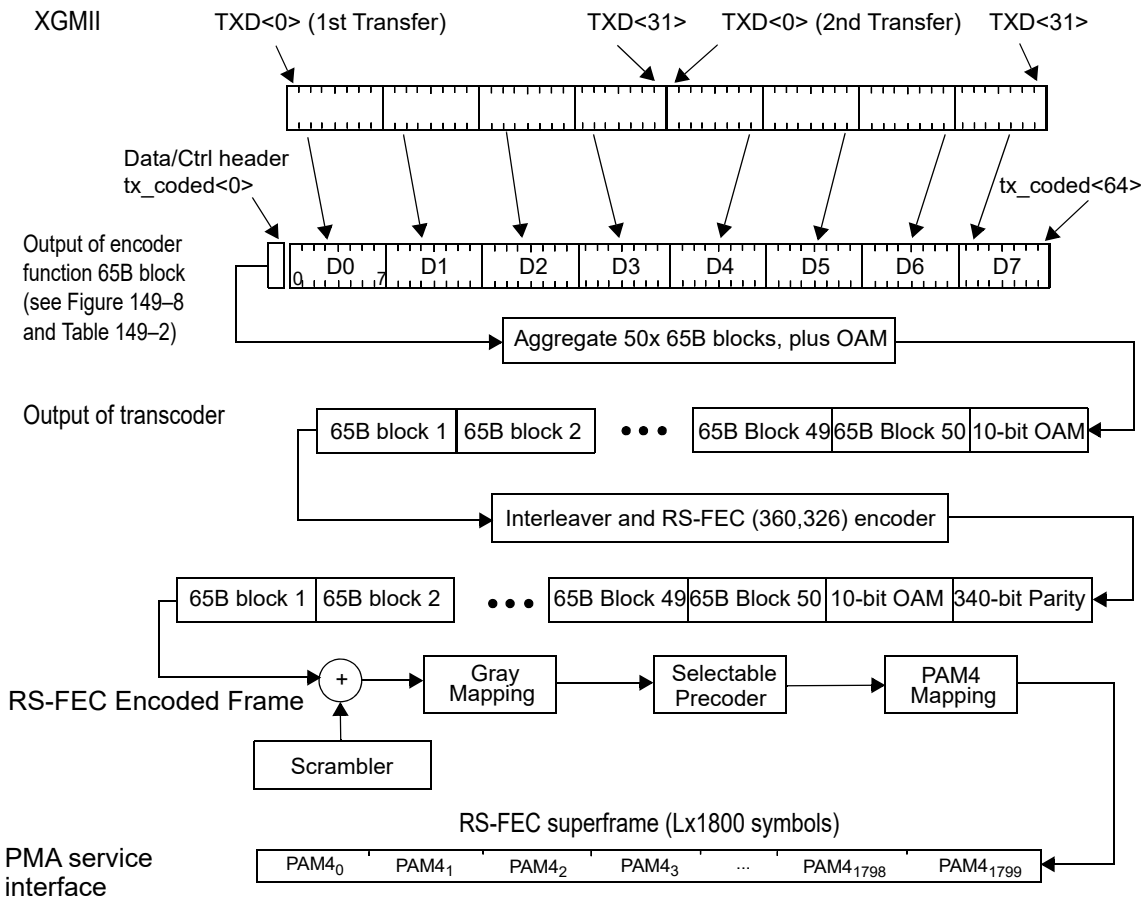
149.3.2.2.1 Use of blocks



The PCS maps XGMII signals into 65-bit blocks inserted into an RS-FEC frame, and vice versa, using a 65B RS-FEC coding scheme. The PAM2 PMA training frame synchronization allows establishment of RS-FEC frame and 65B boundaries by the PCS Synchronization process. Blocks and frames are unobservable and have no meaning outside the PCS. During the LPI mode, RS-FEC frame boundaries delimit sleep, wake, refresh, quiet, and alert cycles. The PCS functions ENCODE and DECODE generate, manipulate, and interpret blocks and frames as provided by the rules in 149.3.2.2.2.

149.3.2.2.2 65B RS-FEC transmission code

The PCS uses a transmission code to improve the transmission characteristics of information to be transferred across the link and to support transmission of control and data characters.

The relationship of block bit positions to XGMII, PMA, and other PCS constructs is illustrated in Figure 149–6 for transmit and Figure 149–7 for receive. These figures illustrate the processing of a multiplicity of blocks containing 8 data octets. See 149.3.2.2.4 for information on how blocks containing control characters are mapped.

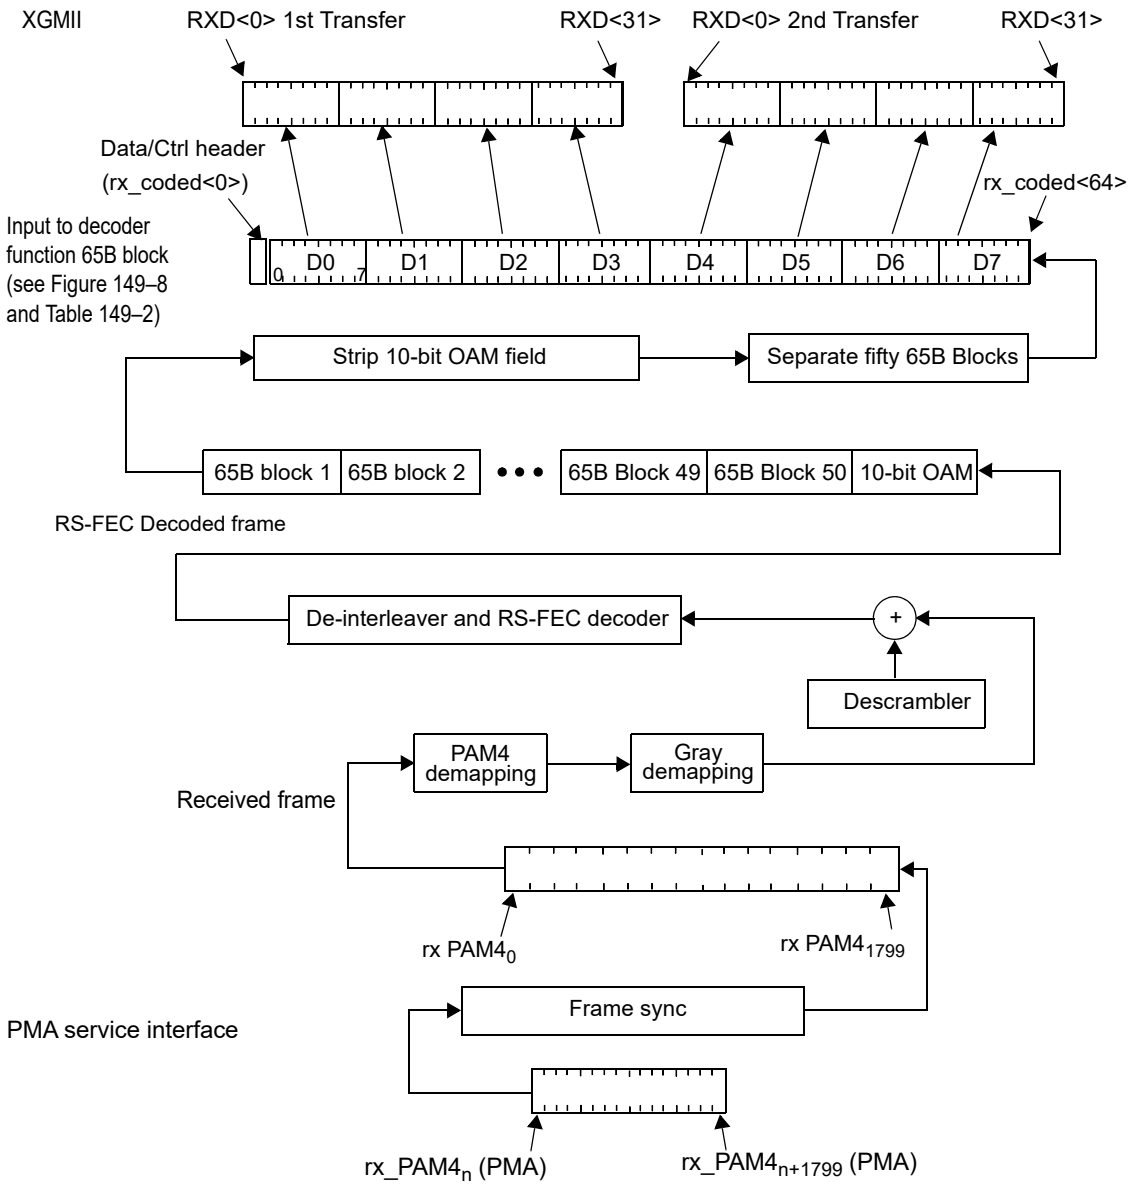
NOTE 1—This figure shows the mapping from the XGMII to a 64B/65B block for a block containing eight data characters.

NOTE 2—Figure shown for L = 1.

Figure 149–6—PCS Transmit bit ordering



149.3.2.2.3 Notation conventions

For values shown as binary, the leftmost bit is the first transmitted bit.

64B/65B encodes 8 data octets or control characters into a block. Blocks containing control characters also contain a block type field. Data octets are labeled D_0 to D_7. Control characters other than /O/, /S/, and /T/ are labeled C_0 to C_7. The control character for ordered set is labeled as O_0 or O_4 since it is only valid on the first octet of the XGMII. The control character for start is labeled as S_0 or S_4 for the same reason. The control character for terminate is labeled as T_0 to T_7.

For MultiGBASE-T1, two XGMII transfers provide eight characters that are encoded into one 65-bit transmission block. The subscript in the above labels indicates the position of the character in the eight characters from the XGMII transfer(s).

NOTE 1—This figure shows the mapping from a 64B/65B block a block containing eight data characters to the XGMII.

NOTE 2—Figure shown for L = 1.

Figure 149–7—PCS Receive bit ordering

Contents of block type fields, data octets, and control characters are shown as hexadecimal values. The LSB of the hexadecimal value represents the first transmitted bit. For instance, the block type field 0x1E is sent from left to right as 01111000. The bits of a transmitted or received block are labeled tx_coded<31:0> and rx_coded<31:0> where tx_coded<0> and rx_coded<0> represent the first transmitted bit. The value of the data/ctrl header is shown as a binary value. Binary values are shown with the first transmitted bit (the LSB) on the left.

149.3.2.2.4 Block structure

Blocks consist of 65 bits. The first bit of a block is the data/ctrl header. Blocks are either data blocks or control blocks. The data/ctrl header is 0 for data blocks and 1 for control blocks. The remainder of the block contains the payload.

Data blocks contain eight data characters. Control blocks begin with an eight-bit block type field that indicates the format of the remainder of the block. For control blocks containing a Start or Terminate character, that character is implied by the block type field. Other control characters are encoded in a seven-bit control code or a four-bit O Code. Each control block contains eight characters.

The format of the blocks for MultiGBASE-T1 is as shown in Figure 149–8. In the figure, the column labeled Input Data shows, in abbreviated form, the eight characters used to create the 65-bit block. These characters are either data characters or control characters and, when transferred across the XGMII interface, the corresponding TXC or RXC bit is set accordingly. Within the Input Data column, D_0 through D_7 are data octets and are transferred with the corresponding TXC or RXC bit set to zero. All other characters are control octets and are transferred with the corresponding TXC or RXC bit set to one. The single bit fields (thin rectangles with no label in the figure) are sent as zero and ignored upon receipt.

Input Data	data ctrl header	**Block Payload**							
Bit Position: / **Data Block Format:**	0	1							64

Figure 149–8—64B/65B block formats for MultiGBASE-T1

Bits and field positions are shown with the least significant bit on the left. Hexadecimal numbers are shown prepended with ‘0x’, and with the least significant digit on the right. For example the block type field 0x1E

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

is sent as 01111000 representing bits 1 through 8 of the 65-bit block. The least significant bit for each field is placed in the lowest numbered position of the field.

All unused values of block type field[245] are reserved.

149.3.2.2.5 Control codes

The same set of control characters are supported by the XGMII and the 2.5G/5G/10GBASE-T1 PCS. The representations of the control characters are the control codes. The XGMII encodes a control character into an octet (an eight-bit value). The 2.5G/5G/10GBASE-T1 PCS encodes the start and terminate control characters implicitly by the block type field. The 2.5G/5G/10GBASE-T1 PCS encodes the ordered set control codes using a combination of the block type field and a four-bit O code for each ordered set. The 2.5G/5G/10GBASE-T1 PCS encodes each of the other control characters into a seven-bit C code.

The control characters and their mappings to 2.5G/5G/10GBASE-T1 control codes and XGMII control codes are specified in Table 149–2. All XGMII control code values that do not appear in the table shall not be transmitted and shall be treated as an error if received.

149.3.2.2.6 Ordered sets

Ordered sets are used to extend the ability to send control and status information over the link such as remote fault and local fault status. Ordered sets consist of a control character followed by three data characters. Ordered sets always begin on the first octet of the XGMII. 2.5, 5, and 10 Gigabit Ethernet use one kind of ordered set: the sequence ordered set (see 46.3.4). The sequence ordered set control character is denoted /Q/. An additional ordered set, the signal ordered set, has been reserved and it begins with another control code. The four-bit O field encodes the control code. See Table 149–2 for the mappings.

149.3.2.2.7 Idle (/I/)

Idle control characters (/I/) are transmitted when idle control characters are received from the XGMII. Idle characters may be added or deleted by the PCS to adapt between clock rates. /I/ insertion and deletion shall occur in groups of 4. /I/s may be added following idle or ordered sets. They shall not be added while data is being received. When deleting /I/s, the first four characters after a /T/ shall not be deleted.

149.3.2.2.8 LPI (/LI/)

Low Power Idle (LPI) control characters (/LI/) on the XGMII indicate that the LPI client is requesting operation in the LPI transmit mode. A continuous stream of LPI control characters (/LI/) is used to maintain a link in the LPI transmit mode. Idle control characters (/I/) are used to transition from the LPI transmit mode to the normal mode. PHYs that support EEE respond to the LPI XGMII control characters using the procedure outlined in 149.1.3.3. LPI characters may be added or deleted by the PCS to adapt between clock rates. /LI/ insertion and deletion shall occur in groups of four. /LI/s may be added following Low Power Idle characters. They shall not be added while data is being received.

If EEE is not supported, then /LI/ is not a valid control character.

149.3.2.2.9 Start (/S/)

The start control character (/S/) indicates the start of a packet. This delimiter is only valid on the first octet of the XGMII (TXD<7:0> and RXD<7:0>). Receipt of an /S/ on any other octet of TXD indicates an error.

[245]The block type field values have been chosen to have a four-bit Hamming distance between them. The only unused value that maintains this Hamming distance is 0x00.

Table 149–2—Control codes for MultiGBASE-T1

Control character	Notation	XGMII control code	2.5G/5G/10G BASE-T1 control code	2.5G/5G/10G BASE-T1 O code
idle	/I/	0x07	0x00	
LPI	/LI/	0x06	0x06	
start	/S/	0xFB	Encoded by block type field	
terminate	/T/	0xFD	Encoded by block type field	
error	/E/	0xFE	0x1E	
Sequence ordered set	/Q/	0x9C	Encoded by block type field plus O code	0x0
reserved0		0x1C	0x2D	reserved0
reserved1		0x3C	0x33	reserved1
reserved2		0x7C	0x4B	reserved2
reserved3		0xBC	0x55	reserved3
reserved4		0xDC	0x66	reserved4
reserved5		0xF7	0x78	reserved5
Signal ordered set[1]	/Fsig/	0x5C	Encoded by block type field plus O code	0xF

[1]Reserved for INCITS T11 Fibre Channel use.

Block type field values implicitly encode an /S/ as the fifth or first character of the block. These are the only characters of a block on which a start can occur.

149.3.2.2.10 Terminate (/T/)

The terminate control character (/T/) indicates the end of a packet. Since packets may be any length, the /T/ can occur on any octet of the XGMII interface and within any character of the block. The location of the /T/ in the block is implicitly encoded in the block type field. A valid end of packet occurs when a block containing a /T/ is followed by a control block that does not contain a /T/.

149.3.2.2.11 Ordered set (/O/)

The ordered set control characters (/O/) indicate the start of an ordered set. There are two kinds of ordered sets: the sequence ordered set and the signal ordered set, which is reserved. When it is necessary to designate the control character for the sequence ordered set specifically, /Q/ is used. /O/ is only valid on the first octet of the XGMII. Receipt of an /O/ on any other octet of TXD indicates an error. Block type field values implicitly encode an /O/ as the first or fifth character of the block. The 4-bit O code encodes the specific /O/ character for the ordered set.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Sequence ordered sets may be deleted by the PCS to adapt between clock rates. Such deletion shall only occur when two consecutive sequence ordered sets have been received and shall delete only one of the two. Only Idles may be inserted for clock compensation. Signal ordered sets are not deleted for clock compensation.

149.3.2.2.12 Error (/E/)

The /E/ is sent whenever an /E/ is received. The /E/ allows physical sublayers such as the PCS to propagate received errors. See R_BLOCK_TYPE and T_BLOCK_TYPE function definitions in 149.3.7.2.4 for further information.

149.3.2.2.13 Transmit process

The transmit process generates blocks based upon the TXD and TXC signals received from the XGMII. 100 XGMII data transfers are encoded into an RS-FEC frame. It takes 1800 PMA_UNITDATA transfers to send an RS-FEC frame of data. Therefore, for MultiGBASE-T1, if the PCS is connected to an XGMII and PMA sublayer where the ratio of their transfer rates is exactly 1:18, then the transmit process does not need to perform rate adaptation. Where the XGMII and PMA sublayer data rates are not synchronized to that ratio, the transmit process needs to insert idles, delete idles, or delete sequence ordered sets to adapt between the rates.

The transmit process generates blocks as specified in the PCS 64B/65B Transmit state diagram (see Figure 149–16 and Figure 149–17). The contents of each block are contained in a vector tx_coded<64:0>, which is passed to the transcoder and scrambler. tx_coded<0> contains the data/ctrl header and the remainder of the bits contain the block payload.

149.3.2.2.14 RS-FEC framing and RS-FEC encoder

The resulting RS-FEC frame of 50 65B blocks, followed by the 10-bit OAM field and 340 parity bits is 3600 bits. See Figure 149–6 and 149.3.2.2.17 for details on PCS bit ordering and RS-FEC encoding.

The RS-FEC encoding takes the 3260-bit vector, consisting of tx_group50x65B, and the 10-bit OAM_field, and shall generate the 34 10-bit parity symbols (340 bits total).

149.3.2.2.15 RS-FEC superframe and round-robin interleaving

The interleaver depth L of the transmitter shall be set to the InterleaverDepth requested by the link partner during Infofield exchange, as specified in 149.4.2.4.5.

When the selected interleaving depth L = 1, there is no interleaving, and the RS-FEC superframe is the same as the RS-FEC frame.

When the selected interleaving depth L > 1, the round-robin interleaving scheme as shown in Figure 149–9 shall be applied.

2.5GBASE-T1 only supports L = 1.

5GBASE-T1 supports L = 1 and L = 2.

10GBASE-T1 supports L = 1, L = 2, and L = 4.

The PCS Transmit shall aggregate L RS-FEC input frames into an interleaved RS-FEC input superframe. There are 3260 × L bits, or 326 × L Reed-Solomon message symbols in total in the input superframe. The corresponding message symbols are $m_{326 \times L-1}$, $m_{326 \times L-2}$,…,m_1, m_0. These message symbols are

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

distributed to L RS-FEC encoders. When L > 1, each RS-FEC encoder receives one out of every L message symbols from the superframe; otherwise, the RS-FEC encoder operates exactly the same as specified in 149.3.2.2.17.

149.3.2.2.16 RS-FEC recombine

The L encoded RS-FEC frames are recombined into an interleaved RS-FEC superframe. The output symbols are as follows:

$m_{326 \times L-1}, m_{326 \times L-2}, \ldots, m_1, m_0, p_{1,33}, \ldots, p_{L,33}, \ldots, p_{1,0}, \ldots, p_{L,0}$, where $p_{i,r}$ is the r^{th} parity symbol of the i^{th} encoder.

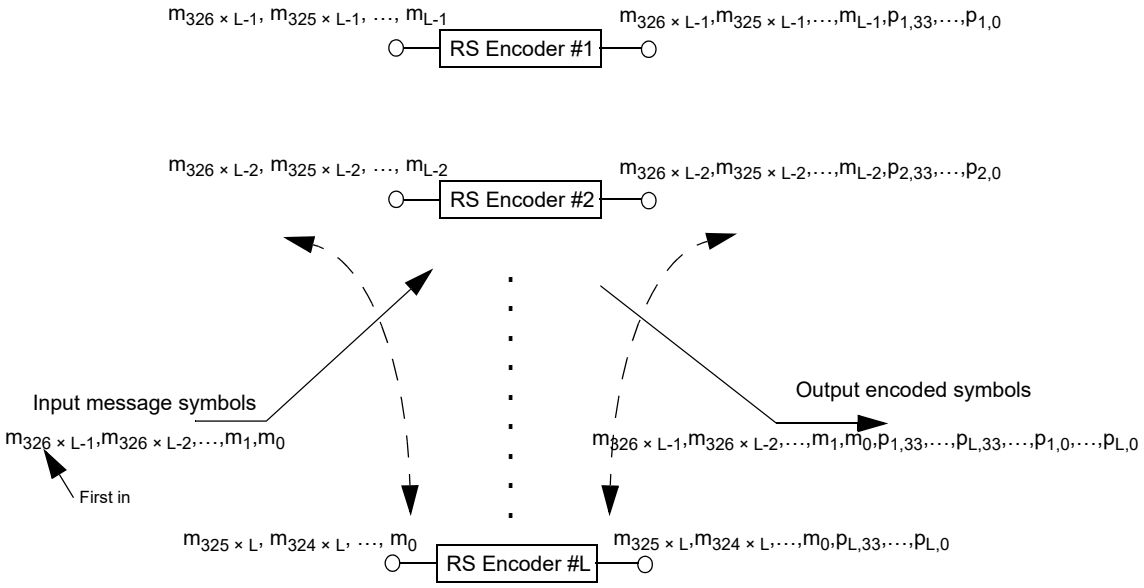

Figure 149–9—Interleaving block diagram with interleaving depth L

149.3.2.2.17 Reed-Solomon encoder

The group of 3260 bits are encoded using a Reed-Solomon encoder operating over the Galois Field GF(2^{10}) where the symbol size is 10 bits. The encoder processes 326 ten-bit RS-FEC message symbols to generate 34 ten-bit RS-FEC parity symbols, which are then appended to the message to produce a codeword of 360 ten-bit RS-FEC symbols. For the purposes of this clause, the particular Reed-Solomon code is denoted as RS-FEC(360,326).

The code is based on the generating polynomial given by Equation (149–1).

$$g(x) = \prod_{j=0}^{33}(x - \alpha^j) = g_{34}x^{34} + g_{33}x^{33} + \ldots + g_4x^4 + g_3x^3 + g_2x^2 + g_1x + g_0 \quad (149\text{–}1)$$

In Equation (149–1), α, is a primitive element of the finite field defined by the primitive polynomial $0x409 = x^{10} + x^3 + 1$.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Equation (149–2) defines the message polynomial $m(x)$ whose coefficients are the message symbols m_{325} to $m_{0.}$

$$m(x) = m_{325}x^{359} + m_{324}x^{358} + \ldots + m_1x^{35} + m_0x^{34} \quad (149–2)$$

Each message symbol m_i is the bit vector ($m_{i,9}$, $m_{i,8}$, ... $m_{i,1}$,$m_{i,0}$), which is identified with the element of the finite field. $m_{i,0}$ is the first bit transmitted. The message symbols are composed of the bits in tx_RSmessage<3259:0> where
$m_{i,j}$ = tx_RSmessage <(325 – i) × 10 + j>, for i = 0 to 325, and j = 0 to 9.

tx_RSmessage<3259:0> prior to RS-FEC (360,326) encoder is formed as follows:

tx_RSmessage<3249:0> = tx_group50x65B<3249:0>.
tx_RSmessage<3259:3250> = OAM_field<9:0>.

The first symbol input to the encoder is m_{325}.

Equation (149–3) defines the parity polynomial $p(x)$ whose coefficients are the parity symbols p_{33} to $p_{0.}$

$$p(x) = p_{33}x^{33} + p_{32}x^{32} + \ldots + p_2x^2 + p_1x + p_0 \quad (149–3)$$

Each parity symbol p_i is the bit vector ($p_{i,9}$, $p_{i,8}$, ... $p_{i,1}$,$p_{i,0}$), which is identified with the element of the finite field. $p_{i,0}$ is the first bit transmitted.

The parity polynomial is the remainder from the division of $m(x)$ by $g(x)$. This can be computed using the shift register implementation illustrated in Figure 149–10. The outputs of the delay elements are initialized to zero prior to the computation of the parity for a given message. After the last message symbol, m_0, is processed by the encoder, the outputs of the delay elements are the parity symbols for that message.

The codeword polynomial $c(x)$ is then the sum of $m(x)$ and $p(x)$ where the coefficient of the highest power of x, $c_{359} = m_{325}$ is transmitted first and the coefficient of the lowest power of x, $c_0 = p_0$ is transmitted last. The first bit transmitted from each symbol is bit 0.

17	878	—	—

149.3.2.2.18 PCS scrambler

The bits of the interleaved RS-FEC superframe are grouped into pairs, and each pair of bits, $D_n[0]$ and $D_n[1]$, where n is an index indicating the symbol number, is scrambled using an additive scrambler. For each pair of interleaved bits, two scrambler bits are generated from the side-stream scrambler. The first (LSB) bit is $DS_n[0]$ equal to $Scr_n[0]$ defined in 149.3.4. The second (MSB) bit is $DS_n[1]$ equal to $Scr_n[3] \oplus Scr_n[8]$.

$DS_n[0]$ and $DS_n[1]$ are applied as additive scrambler sequences to incoming data bits $D_n[0]$ (LSB) and $D_n[1]$ (MSB) to generate two scrambled data bits $\{A_n, B_n\}$ as shown in Equation (149–4).

$$A_n = DS_n[0] \oplus D_n[0]$$
$$B_n = DS_n[1] \oplus D_n[1] \quad (149–4)$$

149.3.2.2.19 Gray mapping for PAM4 encoding

For output symbols, the PCS transmit process shall map consecutive pairs of bits, $\{A_n, B_n\}$, where A_n is the bit arriving first, and n is an index indicating the symbol number, to Gray-coded symbols $G(n)$ with one of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

four levels as follows:

{0, 0} maps to 0,
{0, 1} maps to 1,
{1, 1} maps to 2, and
{1, 0} maps to 3.

For input symbols, the PCS receive process shall map Gray-coded PAM4 symbols G(n), with one of four levels, to pairs of bits, {A_n, B_n}, where A_n is considered to be the first bit as follows:

0 maps to {0, 0},
1 maps to {0, 1},
2 maps to {1, 1}, and
3 maps to {1, 0}.

149.3.2.2.20 Selectable precoder

The PCS transmit process shall precode the Gray-coded symbols as specified in this subclause.

In normal operation the value of precoder_type (see 45.2.1.246.3) shall be set to the value of PrecodeSel received from the link partner in the Infofield messages (see 149.4.2.4.5):

0 0: No precoder,
0 1: Precoder for 1 – D channel,
1 0: Precoder for 1 + D channel, and
1 1: Precoder for 1 – D^2 channel.

For each Gray-coded symbol G(n), a precoded symbol P(n) shall be determined by the following algorithm, where n is an index indicating the symbol number:

P(n) = G(n), when precoder_type = No precoder,
P(n) = (G(n) + P(n–1)) mod 4, when precoder_type = Precoder for 1 – D channel,
P(n) = (G(n) – P(n–1)) mod 4, when precoder_type = Precoder for 1 + D channel, and
P(n) = (G(n) + P(n–2)) mod 4, when precoder_type = Precoder for 1 – D^2 channel.

In normal data mode, the precoder should be initialized to the zero state when entering TX_SWITCH state of the startup sequence. In EEE mode, the precoder should be initialized to the zero state when transitioning to PAM4 encoding. When the precoder is not initialized to the zero state as described, there may be a short period of errors when entering the associated state.

149.3.2.2.21 PAM4 encoding

The PCS transmit process shall encode each precoder output symbol to one of four PAM4 levels as specified in this subclause.

The PAM4 encoded symbols are denoted M(n), where:

n is an index indicating the symbol number.

Each consecutive precoder output symbol, P(n), is mapped to one of four PAM4 levels and assigned to the PAM4 encoder output M(n).

Mapping from the precoder output symbol P(n) to a PAM4 encoded symbol M(n) is as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

0 maps to –1,
1 maps to –1/3,
2 maps to +1/3, and
3 maps to +1.

149.3.2.2.22 EEE capability

The optional 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 EEE capability allows compliant PHYs to transition to an LPI mode of operation when link utilization is low in either direction of transmission.

PHYs that support EEE shall conform to the EEE transmit state diagram, shown in Figure 149–20, within the PCS.

In the transmit direction, the transition to the LPI transmit mode begins when the PCS Transmit function detects an LPI control character in the last 64B/65B block of a Reed-Solomon frame. Following this event, the PMA transmits the sleep signal to indicate to the link partner that it is transitioning to the LPI transmit mode. The sleep signal is composed of eight Reed-Solomon frames that contain only LP_IDLE 64B/65B blocks. Once initiated, the complete sleep signal consisting of eight RS-FEC frames of LP_IDLE shall be transmitted.

Following the transmission of the sleep signal, quiet-refresh signaling begins, as described in 149.3.6.

After the sleep signal is transmitted, LPI control characters shall be input to the PCS scrambler continuously until the PCS Transmit function exits the LPI transmit mode.

While the PMA asserts SEND_N, the lpi_tx_mode variable shall control the transmit signal through the PMA_UNITDATA.request primitive described as follows:

> When the PHY is not in the PCS_DATA state, the lpi_tx_mode variable is ignored.
>
> When the lpi_tx_mode variable takes the value NORMAL and the PMA asserts SEND_N, the PCS passes coded data to the PMA via the PMA_UNITDATA.request primitive as described in 149.3.2.2.
>
> When the lpi_tx_mode variable takes the value QUIET and the PMA asserts SEND_N, the PCS passes zeros to the PMA through the PMA_UNITDATA.request primitive.
>
> When the lpi_tx_mode variable takes the value REFRESH and the PMA asserts SEND_N, the PCS passes the PMA training signal to the PMA, to allow both the local and remote PHY to refresh adaptive filters and timing loops.
>
> When the lpi_tx_mode variable takes the value ALERT, the PMA transmits the link synchronization sequence onto the MDI as provided by the link synchronization block via sync_tx_symb.

The quiet-refresh cycle is repeated until codewords other than LP_IDLE are detected at the XGMII. These codewords indicate that the local system is requesting a transition back to the normal operational mode. Following this event, the PMA_UNITDATA.request parameter tx_symb_vector is set to the value ALERT.

After transmitting the alert signal, the PCS completes the transition from LPI mode to normal mode by sending a wake signal containing lpi_wake_time RS-FEC frames composed of IDLE 64B/65B blocks.

lpi_wake_time is a fixed parameter that is defined in Table 149–4. See Table 149–1 for the definition of *S*.

8	28	8.96/*S*	20	6.4/*S*

149.3.2.3 PCS Receive function

The PCS Receive function shall conform to the PCS 64B/65B Receive state diagram in Figure 149–18 and Figure 149–19, and the PCS Receive bit ordering in Figure 149–7 including compliance with the associated state variables as specified in 149.3.7.2.2.

The PCS Receive function accepts received code-groups provided by the PMA Receive function via the parameter rx_symb. The PCS receiver uses knowledge of the encoding rules and PMA training alignment to correctly align the 65B RS-FEC frames. The received PAM4 symbols are demapped and descrambling is performed.

Following descrambling, the L-interleaved RS-FEC superframe is de-interleaved and the Reed-Solomon frames are decoded with Reed-Solomon error correction. Frames that cannot be corrected are marked with error symbols by the decoder. The RS-FEC decoded frame is then separated into a 10-bit OAM field and 50 64B/65B blocks. This process generates the 64B/65B block vector rx_coded<64:0>, which is then decoded to form the XGMII signals RXD<31:0> and RXC<3:0> as specified in the PCS 64B/65B Receive state diagram (see Figure 149–18 and Figure 149–19). Two XGMII data transfers are decoded from each block. Where the XGMII and PMA sublayer data rates are not synchronized, the receive process inserts idles, deletes idles, or deletes sequence ordered sets to adapt between rates.

During PMA training mode, PCS Receive checks the received PAM2 framing and signals the reliable acquisition of the descrambler state by setting the scr_status parameter of the PMA_SCRSTATUS.request primitive to OK.

When the PCS Synchronization process has obtained synchronization, the RS-FEC frame error ratio (RFER) monitor process monitors the signal quality and asserts hi_rfer to indicate excessive RS-FEC frame errors. If 40 consecutive RS-FEC frame errors are detected, the block_lock flag is de-asserted. The block_lock flag is re-asserted upon detection of a valid RS-FEC frame. When block_lock is asserted and hi_rfer is de-asserted, the PCS Receive process continuously accepts blocks. The PCS Receive process monitors these blocks and generates RXD <31:0> and RXC <3:0> on the XGMII.

When the receive channel is in training mode, the PCS Synchronization process continuously monitors PMA_RXSTATUS.indication(loc_rcvr_status). When loc_rcvr_status indicates OK, then the PCS Synchronization process accepts data-units via the PMA_UNITDATA.indication primitive. It attains frame and block synchronization based on the PMA training frames and conveys received blocks to the PCS Receive process. The PCS Synchronization process sets the block_lock flag to indicate whether the PCS has obtained synchronization. The PMA training frame includes an alignment bit every 450 PAM2 symbols, which is aligned with the PCS partial PHY frame boundary, as well as an Infofield, which is inserted in the 16th PCS partial PHY frame. When the PCS Synchronization process is synchronized to this pattern, block_lock is asserted.

PHYs with the EEE capability support transition to the LPI mode when the PHY has successfully completed training and pcs_data_mode is TRUE and subject to the timing requirements of 46.1.7. Transitions to and

from the LPI mode are allowed to occur independently in the transmit and receive functions. The PCS Receive function is responsible for detecting transitions to and from the LPI receive mode and indicating these transitions using signals defined in 149.2.2.

The link partner signals a transition to the LPI mode of operation by transmitting eight RS-FEC frames composed entirely of 64B/65B blocks of /LI/. When blocks of /LI/ are detected at the output of the 64B/65B decoder, rx_lpi_active is asserted by the PCS Receive function and the /LI/ character is continuously asserted at the receive XGMII. These frames may be preceded by a frame composed partially of /LI/ characters. After these frames, the link partner begins transmitting zeros, and it is recommended that the receiver power down receive circuits to reduce power consumption. The receive function uses RS-FEC frame counters to maintain synchronization with the remote PHY and receives periodic refresh signals that are used to update coefficients, so that the integrity of adaptive filters and timing loops in the PMA is maintained. LPI signaling is defined in 149.3.6. The quiet-refresh cycle continues until the PMA Receive function asserts alert_detect to indicate that the alert (link synchronization) sequence has been reliably detected. After the alert sequence, the link partner transmits repeated /I/ characters, representing a wake signal. The PHY receive function sends /I/ to the XGMII for eight RS-Frame periods (wake duration) and then resumes normal operation.

149.3.2.3.1 Frame and block synchronization

When operating in the data mode, the receiving PCS shall form a PAM4 stream from the PMA_UNITDATA.indication primitive by concatenating requests in order from rx_PAM4_0 to rx_PAM4_1799 (see Figure 149–7). It obtains block lock to the PHY frames during PAM2 training using synchronization bits provided in the training frames.

149.3.2.3.2 PCS descrambler

The descrambler processes the payload to reverse the effect of the scrambler using the same polynomial. The PCS descrambles the data stream and returns the proper sequence of symbols to the decoding process for generation of RXD<31:0> to the XGMII. For side-stream descrambling, the MASTER PHY shall employ the receiver descrambler generator polynomial per Equation (149–6) and the SLAVE PHY shall employ the receiver descrambler generator polynomial per Equation (149–5).

149.3.2.3.3 Invalid blocks

A block is invalid if any of the following conditions exist:

a) The block type field contains a reserved value.
b) Any control character contains a value not in Table 149–2.
c) Any O code contains a value not in Table 149–2.
d) The block contains information from the payload of an invalid RS-FEC frame.

The PCS Receive function shall check the integrity of the RS-FEC parity bits defined in 149.3.2.2.14. If the check fails the RS-FEC frame is invalid.

The R_BLOCK_TYPE of an invalid block is set to E.

149.3.3 Test-pattern generators

The test-pattern generator mode is provided for enabling joint testing of the local transmitter, the channel, and remote receiver. When the transmit PCS is operating in test-pattern mode it shall transmit continuously as illustrated in Figure 149–6, with the input to the RS-FEC encoder set to zero and the initial condition of the scrambler set to any non-zero value. This has the same effect as setting the input to the scrambler to zero.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the receiver PCS is operating in test-pattern mode it shall receive continuously as illustrated in Figure 149–7. The output of the received descrambled values should be zero. Any nonzero values correspond to receiver bit errors. The output of the RS-FEC decoder should also be zero; however, there is the possibility that the RS-FEC decoder corrected some errors. This mode is further described as test mode 7 in 149.5.1.

149.3.4 Side-stream scrambler polynomials

The PCS Transmit function employs side-stream scrambling. If the parameter config provided to the PCS by the PMA PHY Control function via the PMA_CONFIG.indication message assumes the value MASTER, PCS Transmit shall employ Equation (149–5) as transmitter side-stream scrambler generator polynomial.

$$g_M(x) = 1 + x^{13} + x^{33} \tag{149–5}$$

If the PMA_CONFIG.indication message assumes the value of SLAVE, PCS Transmit shall employ Equation (149–6) as transmitter side-stream scrambler generator polynomial.

$$g_S(x) = 1 + x^{20} + x^{33} \tag{149–6}$$

An implementation of MASTER and SLAVE PHY side-stream scramblers by linear-feedback shift registers is shown in Figure 149–11. The bits stored in the shift register delay line at time *n* are denoted by $Scr_n[32:0]$. At each symbol period, the shift register is advanced by one bit, and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. In no case shall the scrambler state be initialized to all zeros.

This scrambler, once started during PMA training, shall continue to run uninterrupted during the transition from PAM2 to PAM4.

149.3.5 PMA training frame

During PMA training, the training frames are embedded with indicators to establish alignment to the RS-FEC superframe composed of 16 partial PHY frames that comprise the block. The last partial PHY frame is embedded with an information field used to exchange messages between link partners. The timing relationship among training frame, partial frame, RS-FEC frame, superframe, and partial PHY frame count (PFC24) are shown in Figure 149–12.

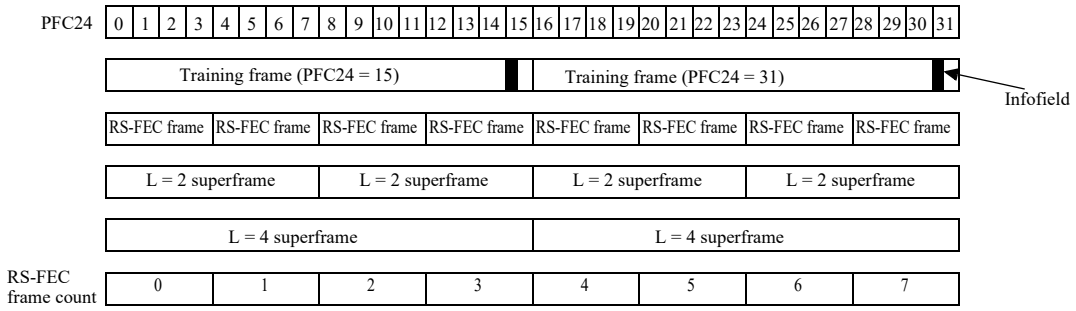

Figure 149–12—Timing relationship to PFC24

PMA training frame encoding is based on the generation, at time n, of the bit S_n. The first bit is inverted in the first 15 partial PHY frames of each RS-FEC block. The first 96 bits of the 16th partial PHY frame are XORed with the contents of the Infofield. Each partial PHY frame is 450 bits long, beginning at S_n where (n mod 450) = 0. See Equation (149–7).

$$S_n = \begin{cases} Scr_n[0] \oplus InfoField_{(n \bmod 450)} & 6750 \le (n \bmod 7200) \le 6845 \\ Scr_n[0] \oplus 1 & \text{else if } (n \bmod 450) = 0 \\ Scr_n[0] & \text{otherwise} \end{cases} \quad (149\text{–}7)$$

149.3.5.1 Generation of symbol T_n

The bit S_n is mapped to the transmit symbol T_n as follows: if $S_n = 0$ then $T_n = +1$, if $S_n = 1$ then $T_n = -1$.

149.3.5.2 PMA training mode descrambler polynomials

The PHY shall acquire descrambler state synchronization to the PAM2 training sequence and report success through scr_status. For side-stream descrambling, the MASTER PHY employs the receiver descrambler generator polynomial per Equation (149–6) and the SLAVE PHY employs the receiver descrambler generator polynomial per Equation (149–5).

149.3.6 LPI signaling

PHYs with EEE capability have transmit and receive functions that can enter and leave the LPI mode independently. The PHY can transition to the LPI mode when the PHY has successfully completed training and pcs_data_mode is TRUE. The transmit function of the PHY initiates a transition to the LPI transmit mode by generating the sleep signal composed of eight RS-FEC frames composed entirely of LPI control characters, as described in 149.3.2.2.22. When the transmitter begins to send the sleep signal, it asserts tx_lpi_active and the transmit function enters the LPI transmit mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Within the LPI mode, PHYs use a repeating quiet-refresh cycle (see Figure 149–13 and Figure 149–14). The LPI timing parameters are shown in Table 149–5. The first part of this cycle is known as the quiet period and lasts for a time lpi_quiet_time. The quiet period is defined in 149.3.6.2. The second part of this cycle is known as the refresh period and lasts for a time lpi_refresh_time. The refresh period is defined in 149.3.6.3. A cycle composed of one quiet period and one refresh period is known as an LPI cycle and lasts for a time lpi_qr_time.

The parameters lpi_offset, lpi_quiet_time, lpi_refresh_time, and lpi_qr_time are timing parameters that are integer multiples of the RS-FEC frame period. lpi_offset is a fixed value equal to lpi_qr_time / 2 + 4 (52 RS-FEC frame periods).

The end of LPI mode occurs at the transmission of the alert signal indicating the end of quiet-refresh cycle.

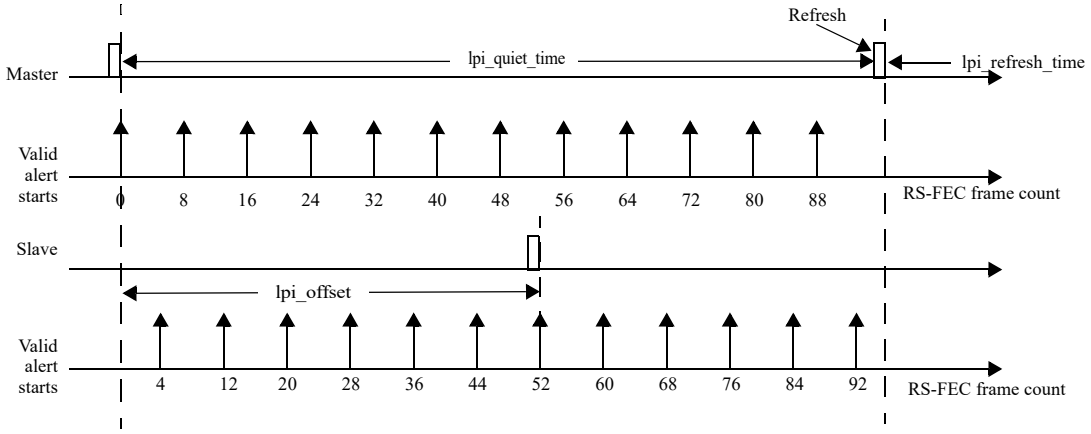

Figure 149–13—Timing periods for LPI signals when Slow Wake not active

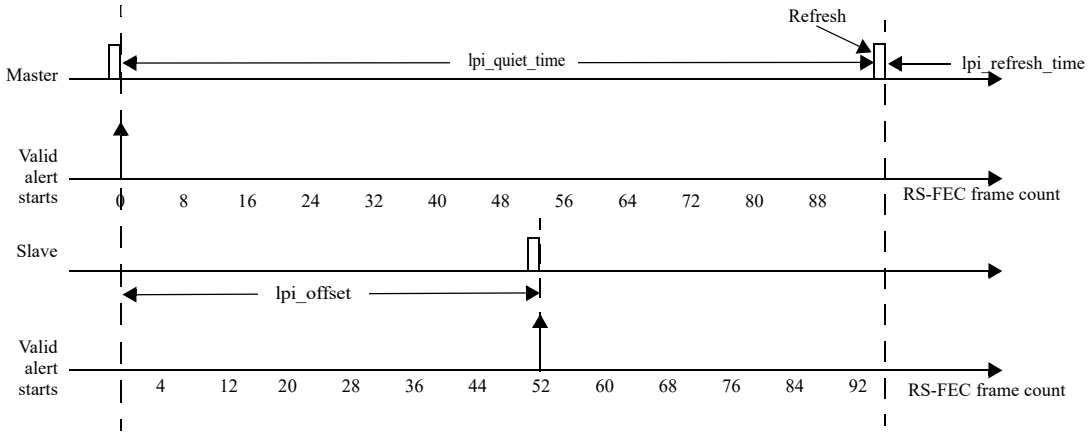

Figure 149–14—Timing periods for LPI signals when Slow Wake is active

149.3.6.1 LPI synchronization

EEE-capable PHYs shall synchronize refresh intervals during the LPI mode. A PHY in SLAVE mode is responsible for synchronizing its partial PHY frame count (PFC24) to the MASTER's PFC24 during PAM2 training. For the requirements on the SLAVE and the MASTER frame alignment, see 149.4.2.4.10.

Table 149–5—LPI timing parameters

Parameter	Number of RS-FEC frame periods
alert_length	4
alert_period	8
lpi_offset	52
lpi_qr_time	96
lpi_quiet_time	95
lpi_refresh_time	1

Refresh signaling is derived by tracking the RS-FEC frame count as shown in Figure 149–13, where:

RS-FEC frame count = floor (PFC24 / 4) mod 96.

The start of the SLAVE quiet-refresh cycle is delayed from the MASTER by lpi_offset. The MASTER and SLAVE alert windows are offset from each other and the refresh periods are close to half a cycle offset.

Following the transition to PAM4, the PCS continues with the RS-FEC frame count and uses the count to generate refresh, alert, and wake control signals for the transmit functions.

Alert, a four RS-FEC frame long sequence (alert_length), shall start at the beginning of any eighth PHY frame boundary starting at the beginning of the frame following a refresh PHY frame. This offsets the MASTER and SLAVE alert start times by alert_period/2 and provides two benefits. The first benefit is that alert transmissions do not overlap with the device's own refresh. The second benefit is that the MASTER and SLAVE alert transmissions generally do not overlap, and only overlap at the limits of tolerances. The MASTER and SLAVE shall derive the tx_refresh_active and tx_alert_start_next signals from the transmitted PHY frames as shown in Table 149–6 and Table 149–7. When Slow Wake is active, alert can be transmitted in only a single QR cycle location.

Table 149–6—Synchronization logic derived from slave signal RS-FEC frame count

Slave-side variable	Condition (where u = RS-FEC frame count)	Slow Wake
tx_refresh_active = TRUE	lpi_offset – lpi_refresh_time ≤mod(u, lpi_qr_time) < lpi_offset	0 or 1
tx_alert_start_next = TRUE	mod(u, alert_period) = alert_period/2 –1	0
tx_alert_start_next = TRUE	mod(u, lpi_qr_time) = lpi_qr_time/2 + alert_period/2 –1	1

149.3.6.2 Quiet period signaling

During the quiet period the PCS transmitter shall pass zeros to the PMA via the PMA_UNITDATA.request primitive.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 149–7—Synchronization logic derived from master signal RS-FEC frame count

Master-side variable	Condition (where v = RS-FEC frame count)	Slow Wake
tx_refresh_active = TRUE	mod(v, lpi_qr_time) ≥ lpi_quiet_time	0 or 1
tx_alert_start_next = TRUE	mod(v, alert_period) = alert_period –1	0
tx_alert_start_next = TRUE	mod(v, lpi_qr_time) = lpi_qr_time –1	1

149.3.6.3 Refresh period signaling

During the LPI mode the MultiGBASE-T1 PHY uses staggered, out-of-phase refresh signaling. Two-level PAM refresh symbols are generated from the T_n mapping defined in 149.3.5.1 of S_n defined in 149.3.5, with the exception that the Infofield consists of zeros. The 10-bit OAM symbol to be transmitted is XORed with the last 10 bits of the PAM2 refresh transmission.

149.3.7 Detailed functions and state diagrams

149.3.7.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

149.3.7.2 State diagram parameters

149.3.7.2.1 Constants

EBLOCK_R<71:0>
: 72-bit vector to be sent to the XGMII interface containing /E/ in all the eight character locations.

EBLOCK_T<64:0>
: 65-bit vector to be sent to the RS-FEC encoder containing /E/ in all the eight character locations.

LBLOCK_R<71:0>
: 72-bit vector to be sent to the XGMII interface containing two Local Fault ordered sets. The Local Fault ordered set is defined in 46.3.4.

LBLOCK_T<64:0>
: 65-bit vector to be sent to the RS-FEC encoder containing two Local Fault ordered sets.

LPBLOCK_R<71:0>
: 72-bit vector to be sent to the XGMII containing /LI/ in all the eight character locations.

LPBLOCK_T<64:0>
: 65-bit vector to be sent to the RS-FEC encoder containing /LI/ in all the eight character locations.

IBLOCK_R<71:0>
: 72-bit vector to be sent to the XGMII containing /I/ in all the eight character locations.

IBLOCK_T<64:0>
: 65-bit vector to be sent to the RS-FEC encoder containing /I/ in all the eight character locations.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RFER_CNT_LIMIT
TYPE: Integer
VALUE: 16
Number of Reed-Solomon frames with uncorrectable errors.

RFRX_CNT_LIMIT
TYPE: Integer
VALUE: 88
Number of Reed-Solomon frames received over bit error ratio interval.

UBLOCK_R<71:0>
72-bit vector to be sent to the XGMII containing two Link Interruption ordered sets.
The Link Interruption ordered set is defined in 46.3.4.

149.3.7.2.2 Variables

block_lock
Boolean variable that is set TRUE when receiver acquires block delineation.

hi_rfer
Boolean variable that is asserted TRUE when the rfer_cnt reaches 16 errors in one rfer_timer interval.

lp_low_snr
Boolean variable that is set TRUE when the link partner indicates LPI refresh is insufficient to maintain PHY SNR. It is set FALSE otherwise.

pcs_data_mode
Variable set by the PMA PHY Control function. See 149.4.4.1.

pcs_reset
Boolean variable that controls the resetting of the PCS. It is TRUE whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS into low-power mode.

rx_coded<64:0>
Vector containing the input to the 64B/65B decoder. The format for this vector is shown in Figure 149–8. The leftmost bit in the figure is rx_coded<0> and the rightmost bit is rx_coded<64>.

rx_raw<71:0>
Vector containing two successive XGMII output transfers. RXC<3:0> for the first transfer are taken from rx_raw<3:0>. RXC<3:0> for the second transfer are taken from rx_raw<7:4>. RXD<31:0> for the first transfer are taken from rx_raw<39:8>. RXD<31:0> for the second transfer are taken from rx_raw<71:40>.

rf_valid
Boolean indication that is set TRUE if received Reed-Solomon frame is valid. Reed-Solomon frame is valid if and only if all parity checks of the Reed-Solomon code are satisfied.

tx_coded<64:0>
Vector containing the output from the 64B/65B encoder. The format for this vector is shown in Figure 149–8. The leftmost bit in the figure is tx_coded<0> and the rightmost bit is tx_coded<64>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_raw<71:0>
: Vector containing two successive XGMII transfers. TXC<3:0> for the first transfer are placed in tx_raw<3:0>. TXC<3:0> for the second transfer are placed in tx_raw<7:4>. TXD<31:0> for the first transfer are placed in tx_raw<39:8>. TXD<31:0> for the second transfer are placed in tx_raw<71:40>.

The following variables are required for PHYs that support the EEE capability:

alert_detect
: Indicates that an alert signal from the link partner has been received at the MDI as indicated by PMA_ALERTDETECT.indication(alert_detect).

lpi_refresh_detect
: Set TRUE when the receiver has reliably detected refresh signaling. It is set FALSE otherwise.

lpi_tx_mode
: A variable indicating the signaling to be used from the PCS to the PMA across the PMA_UNITDATA.request (tx_symb) interface.
lpi_tx_mode controls tx_symb only when tx_mode is set to SEND_N.
The variable is set to NORMAL when (!tx_lpi_qr_active * !tx_lpi_alert_active), indicating that the PCS is in the normal mode of operation and will encode code-groups as described in Figure 149–16 and Figure 149–17.
The variable is set to REFRESH when (tx_lpi_qr_active * tx_refresh active).
The variable is set to QUIET when (tx_lpi_qr_active * !tx_refresh_active).
The variable is set to ALERT when (tx_lpi_alert_active).

rs_fec_frame_done
: A Boolean value. This variable is set TRUE when the final symbol of each RS-FEC frame is transmitted. It is set FALSE otherwise.

rx_lpi_active
: A Boolean variable that is set TRUE when the PHY receive function is operating in the LPI receive mode and set FALSE otherwise. The LPI receive mode begins when the sleep signal is detected and lasts until the alert signal is detected. When the EEE capability is not supported, rx_lpi_active is set FALSE.

rx_lpi_wake
: A Boolean variable that is set TRUE when the PHY receiver is in the WAKE state and sending IDLE to the XGMII. Set FALSE otherwise. When the EEE capability is not supported, rx_lpi_wake is set FALSE.

tx_alert_start_next
: A Boolean variable that is set TRUE on the frame prior to the one on which the alert transmission can start. It is set FALSE otherwise.

tx_lpi_active
: A Boolean variable that is set TRUE when the PHY transmit function is operating in the LPI transmit mode and during transitions to and from the LPI transmit mode (i.e., at any time when the PHY is transmitting sleep, alert, wake, or quiet-refresh signaling). It is set FALSE otherwise.

tx_lpi_qr_active
: A Boolean variable that is set TRUE during the LPI transmit mode, when the PHY is transmitting quiet-refresh signaling. It is set FALSE otherwise.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_refresh_active
: A Boolean value. This variable is set TRUE following the logic described in 149.3.6.1.

tx_sleep_start_next
: A Boolean value. This variable is set TRUE during the seventh RS-FEC frame in every group of eight RS-FEC frames, where the group of eight RS-FEC frames start with the RS-FEC frame after refresh.

tx_lpi_req
: A Boolean variable that is set TRUE when the LPI client indicates that it is requesting operation in the LPI transmit mode via the XGMII. It is set FALSE otherwise.

149.3.7.2.3 Timers

rfer_timer
: Timer that is triggered every $125/(4 \times S)$ μs +1%, –25%. When the timer reaches its terminal count, rfer_timer_done = TRUE. See Table 149–1 for the definition of *S*.

The following timers are required for PHYs that support the EEE capability:

lpi_tx_sleep_timer
: This timer defines the time the local transmitter sends the sleep signal to the link partner.
Values: The condition lpi_tx_sleep_timer_done becomes TRUE upon timer expiration.
Duration: This timer shall have a period equal to eight RS-FEC frame periods.

lpi_tx_alert_timer
: This timer defines the time the local transmitter transmits the alert signal.
Values: The condition lpi_tx_alert_timer_done becomes TRUE upon timer expiration.
Duration: This timer shall have a period equal to four RS-FEC frame periods.

lpi_tx_wake_timer
: This timer defines the time the local transmitter transmits the wake signal.
Values: The condition lpi_tx_wake_timer_done becomes TRUE upon timer expiration.
Duration: This timer shall have a period equal to lpi_wake_time RS-FEC frame periods.

lpi_rx_wake_timer
: This timer defines the time the receiver sends IDLE blocks to the XGMII after the alert signal is detected.
Values: The condition lpi_rx_wake_timer_done becomes TRUE upon timer expiration.
Duration: This timer shall have a period equal to lpi_wake_time RS-FEC frame periods.

149.3.7.2.4 Functions

DECODE(rx_coded<64:0>)
: In the PCS Receive process, this function takes as its argument 65-bit rx_coded<64:0> from the RS-FEC decoder and decodes the 65B RS-FEC bit vector returning a vector rx_raw<71:0>, which is sent to the XGMII. The DECODE function shall decode the block based on code specified in 149.3.2.2.2.

ENCODE(tx_raw<71:0>)
: Encodes the 72-bit vector received from the XGMII, returning 65-bit vector tx_coded. The ENCODE function shall encode the block as specified in 149.3.2.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

R_BLOCK_TYPE = {C, S, T, D, E, I, LI, LII}

When the EEE capability is not supported, this function classifies each 65-bit rx_coded vector as belonging to one of the five types {C, S, T, D, E} depending on its contents.

When the EEE capability is supported, this function classifies each 65-bit rx_coded vector as belonging to one or more of the eight types depending on its contents. A vector may simultaneously belong to the C and I types when it contains eight valid control characters that are all /I/, but in every other case the vector belongs to only one type.

Values: C; The vector contains a data/ctrl header of 1 and one of the following:

a) A block type field of 0x1E and eight valid control characters other than /E/ and /LI/;
b) A block type field 0x2D or 0x4B, a valid O code, and four valid control characters;
c) A block type field of 0x55 and two valid O codes.

S; The vector contains a data/ctrl header of 1 and one of the following:

a) A block type field of 0x33 and four valid control characters;
b) A block type field of 0x66 and a valid O code;
c) A block type field of 0x78.

T; The vector contains a data/ctrl header of 1, a block type field of 0x87, 0x99, 0xAA, 0xB4, 0xCC, 0xD2, 0xE1 or 0xFF and all control characters are valid.

D; The vector contains a data/ctrl header of 0.

I; If the optional EEE capability is supported, then the I type is a special case of the C type where the vector contains a data/ctrl header of 1, a block type field of 0x1E, and eight control characters of /I/.

LI: If the optional EEE capability is supported, then the LI type occurs when the vector contains a data/ctrl header of 1, a block type field of 0x1E, and eight control characters of /LI/.

LII: If the optional EEE capability is supported, then the LII type occurs when the vector contains a data/ctrl header of 1, a block type field of 0x1E, and one of the following:

a) Four control characters of /LI/ followed by four control characters of /I/;
b) Four control characters of /I/ followed by four control characters of /LI/

E; The vector does not meet the criteria for any other value.

A valid control character is one containing a MultiGBASE-T1 control code specified in Table 149–2. A valid O code is one containing an O code specified in Table 149–2.

R_TYPE(rx_coded<64:0>)

Returns the R_BLOCK_TYPE of the rx_coded<64:0> bit vector.

R_TYPE_NEXT

Prescient end of packet check function. It returns the R_BLOCK_TYPE of the rx_coded vector immediately following the current rx_coded vector.

T_BLOCK_TYPE = {C, S, T, D, E, I, LI, LII}

When the EEE capability is not supported, this function classifies each 72-bit tx_raw vector as belonging to one of the five types {C, S, T, D, E} depending on its contents.

When the EEE capability is supported, this function classifies each 72-bit tx_raw vector as belonging to one or more of the eight types depending on its contents. A vector may simultaneously belong to the C and I types when it contains eight valid control characters that are all /I/, but in every other case the vector belongs to only one type.

Values: C; The vector contains one of the following:

a) Eight valid control characters other than /O/, /S/, /T/, /E/, and /LI/;
b) One valid ordered set and four valid control characters other than /O/, /S/, and /T/;
c) Two valid ordered sets.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

S; The vector contains an /S/ in its first or fifth character. Any characters before the S character are valid control characters other than /O/, /S/ and /T/ or form a valid ordered set, and all characters following the /S/ are data characters.

T; The vector contains a /T/ in one of its characters, all characters before the /T/ are data characters, and all characters following the /T/ are valid control characters other than /O/, /S/ and /T/.

D; The vector contains eight data characters.

I; If the optional EEE capability is supported, then the I type is a special case of the C type where the vector contains eight control characters of /I/.

LI; If the optional EEE capability is supported, then the LI type occurs when the vector contains eight control characters of /LI/.

LII; If the optional EEE capability is supported, then the LII type occurs when the vector contains one of the following:

a) Four control characters of /LI/ followed by four control characters of /I/;

b) Four control characters of /I/ followed by four control characters of /LI/.

E; The vector does not meet the criteria for any other value.

A tx_raw character is a control character if its associated TXC bit is asserted. A valid control character is one containing an XGMII control code specified in Table 149–2. A valid ordered set consists of a valid /O/ character in the first or fifth characters and data characters in the three characters following the /O/. A valid /O/ is any character with a value for O code in Table 149–2.

T_TYPE(tx_raw<71:0>)

Returns the T_BLOCK_TYPE of the tx_raw<71:0> bit vector.

T_TYPE_NEXT

Prescient end of packet check function. It returns the FRAME_TYPE of the tx_raw vector immediately following the current tx_raw vector.

149.3.7.2.5 Counters

lpi_rxw_err_cnt

An integer value that counts the number of receive wake time faults. lpi_rxw_err_cnt is reset to zero during PCS_TEST. The counter is reflected in register 3.22 (see 45.2.3.12).

rfer_cnt

Count up to a maximum of RFER_CNT_LIMIT of the number of invalid Reed-Solomon frames within the current RFRX_CNT_LIMIT Reed-Solomon frame period.

rfrx_cnt

Count number Reed-Solomon frames received during current period.

149.3.7.2.6 Messages

RX_FRAME

A signal sent to PCS Receive indicating that a full Reed-Solomon frame has been decoded and the variable rf_valid is updated.

149.3.7.3 State diagrams

The RFER monitor state diagram shown in Figure 149–15 monitors the received signal for high RS-FEC frame error ratio.

The PCS 64B/65B Transmit state diagram shown in Figure 149–16 and Figure 149–17 controls the encoding of 65B transmitted blocks. It makes exactly one transition for each 65B transmit block processed. Though

the state diagram sends Local Fault ordered sets when reset is asserted, the scrambler and 65B RS-FEC are not guaranteed to be operational during reset. Thus, the Local Fault ordered sets are not guaranteed to appear on the PMA service interface.

NOTE—This figure is mandatory for PHYs with the EEE capability.

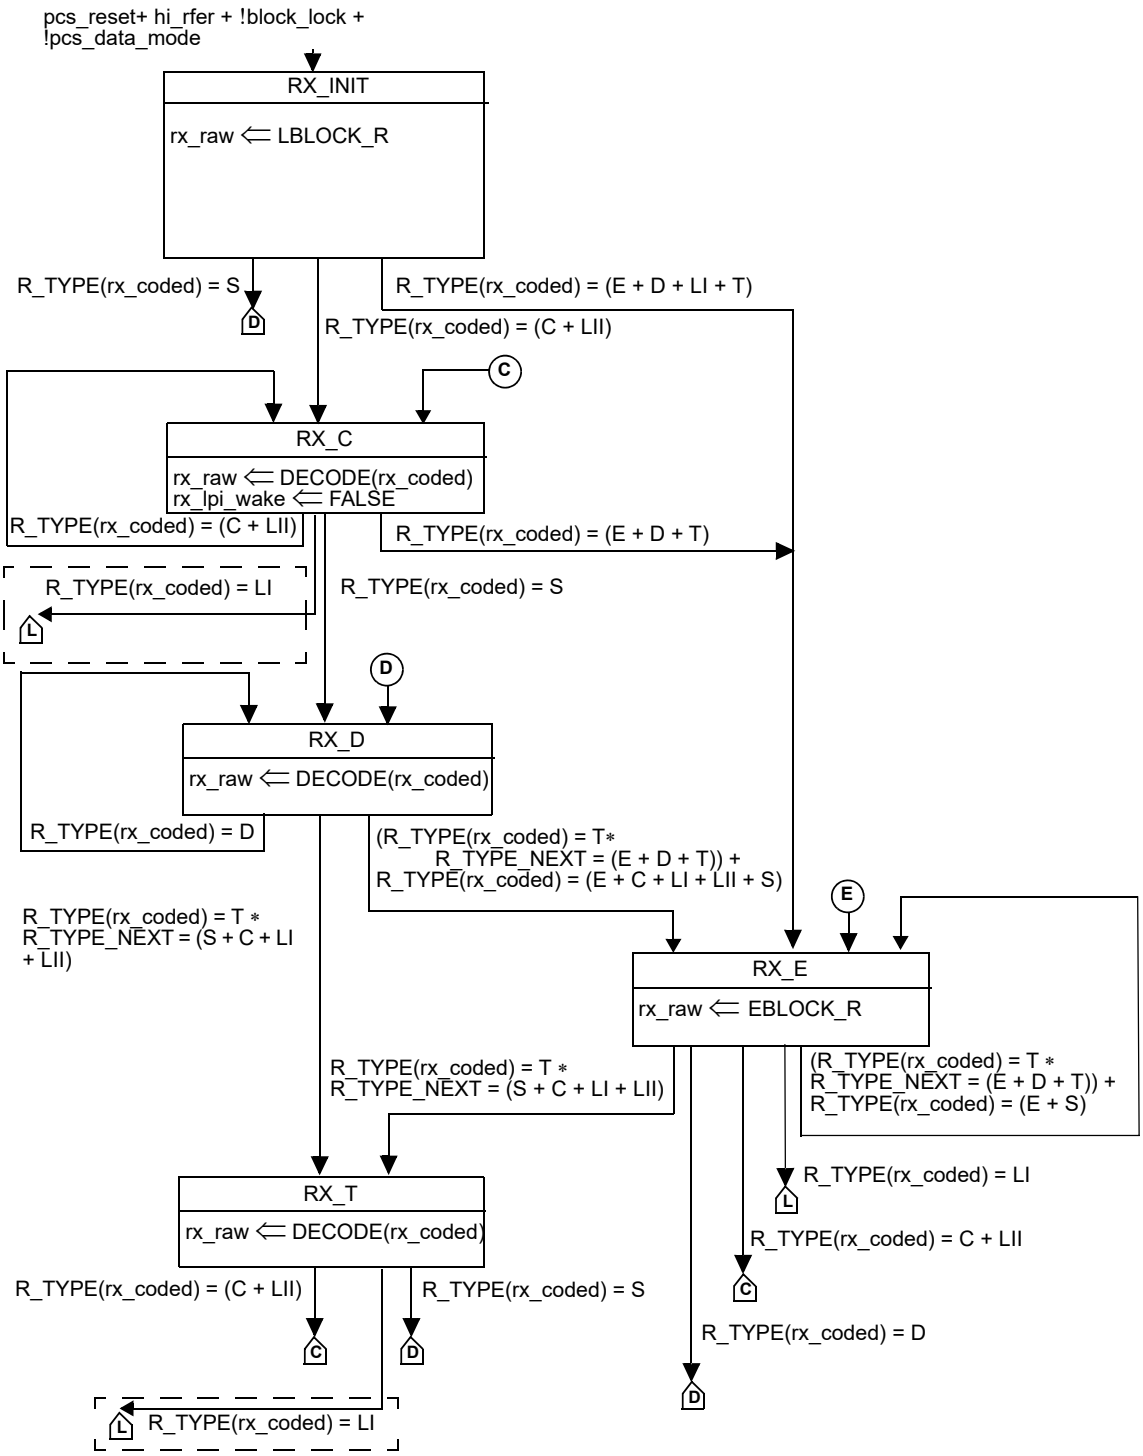

Figure 149–17—PCS 64B/65B Transmit state diagram, part b

The PCS 64B/65B Receive state diagram is shown in Figure 149–18 and Figure 149–19 and controls the decoding of 65B received blocks. It makes exactly one transition for each receive block processed except for the transition from RX_WE to RX_E, which occurs immediately after the RX_WE processes are complete.

The PCS shall perform the functions of RFER monitor, Transmit, and Receive as specified in these state diagrams. The PCS shall not perform the RFER monitor function during LPI receive operation from the time that the PCS 64B/65B Receiver enters the state RX_L, until the state RX_W is exited.

Transitions surrounded by dashed rectangles indicate requirements for MultiGBASE-T1 EEE-capable implementations.

149.3.8 PCS management

The following objects apply to PCS management. If an MDIO Interface is provided (see Clause 45), they are accessed via that interface. If not, it is recommended that an equivalent access be provided.

149.3.8.1 Status

pcs_status:
: Indicates whether the PCS is in a fully operational state. It is only TRUE if pcs_data_mode is TRUE, block_lock is TRUE, and hi_rfer is FALSE. This status is reflected in MDIO bit 3.2324.10. A latch low view of this status is reflected in MDIO bit 3.2323.2 and the inverse of this status is reflected in MDIO bit 3.2323.7.

block_lock:
: Indicates the state of the block_lock variable. This status is reflected in MDIO bit 3.2324.8. A latching low version of this status is reflected in MDIO bit 3.2324.6.

hi_rfer:
: Indicates the state of the hi_rfer variable. This status is reflected in MDIO bit 3.2324.9. A latching high version of this status is reflected in MDIO bit 3.2324.7.

Rx LPI indication:
: For EEE capability, this variable indicates the current state of the receive LPI function. This flag is set to TRUE (register bit set to one) when the PCS Receive state diagram (Figure 149–19) is in the RX_L or RX_W states. This status is reflected in MDIO bit 3.2323.8. A latching high version of this status is reflected in MDIO bit 3.2323.10 (Rx LPI received).

Tx LPI indication:
: For EEE capability, this variable indicates the current state of the transmit LPI function. This flag is set to TRUE (register bit set to one) when the PCS Transmit state diagram (Figure 149–17) is in the TX_L or TX_WN states. This status is reflected in MDIO bit 3.2323.9. A latching high version of this status is reflected in MDIO bit 3.2323.11 (Tx LPI received).

149.3.8.2 Counter

The following counter is reset to zero upon read and upon reset of the PCS. When it reaches all ones, it stops counting. Its purpose is to help monitor the quality of the link.

RFER_count:
: 6-bit counter that counts each time the RFER_BAD_RF of the RFER monitor state diagram (see Figure 149–15) is entered. This counter is reflected in MDIO register bits 3.2324.5:0. The counter is reset when register 3.2324 is read by management. Note that this counter counts a maximum of RFER_CNT_LIMIT counts per RFRX_CNT_LIMIT period since the RFER_BAD_RF state can be entered a maximum of RFER_CNT_LIMIT times per RFRX_CNT_LIMIT window.

149.3.8.3 Loopback

The PCS shall be placed in loopback mode when the loopback bit (MDIO bit 3.2322.14) is set to a one. In this mode, the PCS shall accept data on the transmit path from the XGMII and return it on the receive path to the XGMII. In addition, the PCS shall transmit a continuous stream of 65B RS-FEC encoded PAM4 symbols to the PMA sublayer, and shall ignore all data presented to it by the PMA sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.3.9 MultiGBASE-T1 operations, administration, and maintenance (OAM)

The MultiGBASE-T1 PCS level operations, administration, and maintenance (OAM) provides an optional mechanism useful for monitoring link operation such as exchanging PHY link health status and message exchange. When OAM is implemented, behavior shall conform to the state diagrams in Figure 149–24 and Figure 149–25. OAM information is exchanged out of band between two PHYs using excess bandwidth available on the link. The OAM is strictly between two PHYs on the Physical Layer and their associated management entities if present. Passing OAM information to other layers is outside the scope of this standard.

OAM is operational as long as both PHYs implement this mechanism and the link is up. It continues to be operational during Low Power Idle, albeit the information is transferred at a slower rate during the refresh cycle.

The OAM frame data is carried in the OAM 10-bit field described in 149.3.2.2.14 for the normal power data mode and 149.3.6.3 for low power mode. This 10-bit field is used to exchange OAM frames. The implementation of the OAM frame exchange function is optional. However, if EEE is implemented, then the OAM frame exchange function is implemented to exchange, at a minimum, the link partner OAM status.

For the remainder of this subclause, the term OAM is specific to the MultiGBASE-T1 PCS level OAM.

149.3.9.1 Definitions

OAM frame: A frame consisting of 14 octets of data, 14 framing bits, 14 reserved bits and two 10-bit Reed-Solomon parity symbols.

OAM symbol: A 10-bit symbol consisting of either one data octet plus a framing bit and a reserved bit, or a 10-bit Reed-Solomon parity symbol. Sixteen OAM symbols make up an OAM frame.

OAM field: A 10-bit field in each PHY frame reserved for the OAM symbol as described in 149.3.2.2.14 or in each refresh cycle as described in 149.3.6.3.

OAM message: A message contains a 4-bit message number plus 8 octets of message data (Message<7:0><7:0>) embedded in an OAM frame. The same OAM message can be repeated on multiple OAM frames.

OAM status: The 4 octets of status data (Message<11:8><7:0>) that is embedded in each OAM frame.

149.3.9.2 Functional specifications

149.3.9.2.1 MultiGBASE-T1 OAM frame structure

Each OAM frame is made up of 16 OAM symbols. Each of the first 14 symbols is made up of one octet of data, one framing bit, and one reserved bit. The last 2 symbols are the Reed-Solomon (16,14) parity symbols.

One OAM symbol is placed in the 10-bit OAM field in each PHY frame during normal power operation in the data mode. One OAM symbol is placed in the 10-bit OAM field in each refresh cycle during Low Power Idle. The sixteen OAM symbols are consecutively inserted into sixteen consecutive PHY frames and/or refresh cycles. Once the sixteen symbols of the current OAM frame are inserted, the sixteen symbols of the next OAM frame are inserted. This process is continuous without any break in the insertion of OAM symbols with the exception noted below.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the PCS frame is operating in interleaved mode of 2x or 4x, the first symbol (OAM<0>) shall be inserted in the first RS frame in the superframe so that the full OAM frame can be packed into eight superframes in the 2x interleaved mode, and into four superframes in the 4x interleaved mode.

When transitioning from normal operation to Low Power Idle, it is possible that part of the OAM frame is packed in RS frames and the remainder of the OAM frame is sent over the LPI refreshes.

When transitioning from Low Power Idle to normal operation, it is possible that part of the OAM frame is sent over the LPI refreshes and the remainder of the OAM frame is packed in RS frames. In some instances, it is possible that the remainder of the OAM frame cannot be aligned where the next OAM frame will have its first symbol (OAM<0>) inserted in the first RS frame of the superframe. In such cases, the partially transmitted OAM frame shall be interrupted according to the following rules:

1x interleaving — no interruption is required.

2x interleaving — insert 0 or 1 dummy OAM symbol into the superframe for alignment before continuing.

4x interleaving — insert 0 to 3 dummy OAM symbols into the superframe for alignment before continuing.

The receiver can anticipate when the dummy OAM symbols will be inserted based on the sequence of refresh and wake events.

The dummy OAM symbol is all 0’s and its value is ignored at the receiver.

An example in Figure 149–21 shows two dummy OAM symbols inserted to realign OAM<0> to the 4x interleaved superframe boundary.

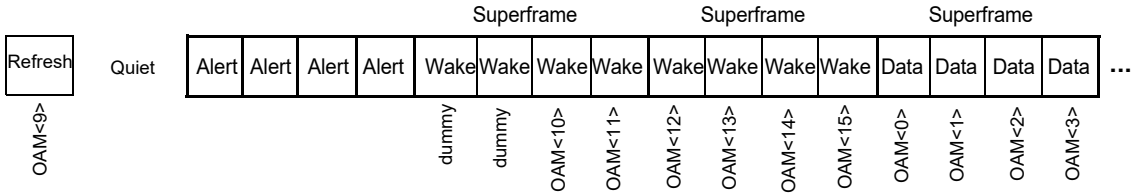

Figure 149–21—Example of 4x interleave dummy data insertion

Bit 0 of each OAM symbol is the first bit transmitted in the 10-bit OAM field. Symbol 0 is the first symbol transmitted in each OAM frame.

The OAM frame boundary can be found at the receiver by looking at bit D8. The boundary is a 0 followed by thirteen 1’s followed by two don’t care.

If OAM is not implemented then the 10-bit OAM field shall be set to all 0’s. If the link partner does not implement OAM, the 10-bit OAM field will remain static.

149.3.9.2.2 OAM frame data

The OAM frame data is shown in Figure 149–22. OAM<*x*><*y*> refers to symbol *x*, bit *y* of the OAM frame. Reserved fields shall be set to 0.

Figure 149–22—OAM frame

149.3.9.2.3 Ping RX

The Ping RX is indicated in OAM<0><3>.

This bit is set by the PHY to the same value as the Ping TX bit received from the link partner.

149.3.9.2.4 Ping TX

The Ping TX is indicated in OAM<0><2>.

This bit is set by the PHY for the link partner to echo on Ping RX.

149.3.9.2.5 PHY health

The PHY Health (SNR<1:0>) is indicated in OAM<0><1:0>.

This status is set by the PHY to indicate the status of the receiver. The definitions of good, marginal, when to request idles, and when to request retrain are implementation dependent.

— 00: PHY link is failing and will drop link and relink within 2 ms to 4 ms after the end of the current OAM frame

— 01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled)

— 10: PHY SNR is marginal

— 11: PHY SNR is good

149.3.9.2.6 OAM message valid

The OAM message valid (Valid) is indicated in OAM<1><7>.

- 0: Current OAM frame does not contain a valid OAM message
- 1: Current OAM frame contains a valid OAM message

149.3.9.2.7 OAM message toggle

The OAM message toggle (Toggle) is indicated in OAM<1><6>.

The toggle bit lets the management entity determine which OAM message is being referenced. The toggle bit in the current OAM message is set to the opposite value of the toggle bit in the previous OAM message only if link partner acknowledges the OAM message is received. This allows one OAM message to be delineated from a second OAM message since the same OAM message may be repeated over multiple OAM frames. This bit is valid only if Valid is set to 1.

149.3.9.2.8 OAM message acknowledge

The OAM message acknowledge (Ack) is indicated in OAM<1><5>.

Ack is set by the PHY to let the link partner know that the OAM message sent by the link partner was successfully received as defined in 149.3.9.2.14 and the PHY is ready to accept a new OAM message. An OAM message is defined to be Message_Number<3:0> and Message<7:0><7:0>.

- 0: No acknowledge
- 1: Acknowledge

149.3.9.2.9 OAM message toggle acknowledge

The OAM message toggle acknowledge (TogAck) is indicated in OAM<1><4>.

TogAck is set by the PHY to let the link partner know that the OAM message is being acknowledged. TogAck takes the value of Toggle bit of the OAM message being acknowledged. This bit is valid only if Ack is set to 1.

149.3.9.2.10 OAM message number

The OAM message number is indicated in OAM<1><3:0>.

This field is user-defined but it is recommended that it be used to indicate the meaning of the 8-octet message that follows. If used this way, up to 16 different 8-octet messages can be exchanged.

The message number is user-defined and its definition is outside the scope of this standard.

149.3.9.2.11 OAM message data

The OAM message data is indicated in OAM<9:2><7:0>.

The 8-octet message data is user-defined and its definition is outside the scope of this standard.

Ack is set by the PHY to let the link partner know that the OAM frame sent by the link partner is successfully received as defined. The OAM frame octet is the lower 8 bits of the 10-bit OAM symbol.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.3.9.2.12 OAM status

The OAM status data is indicated in OAM<13:10><7:0>.

These 32 bits are set by the PHY to convey its status in the mr_tx_message[95:64] to the link partner.

For additional information on the usage of these bits see Annex 149B.

149.3.9.2.13 OAM Reed-Solomon

The RS(16, 14) parity symbols are indicated in OAM<15:14><9:0>.

The OAM frame shall encode the 14 data symbols using Reed-Solomon code (16,14). The FEC code used is a shortened Reed-Solomon (16,14) code over the Galois Field of GF(2^{10}) — a code operating on 10-bit symbols. The code encodes 14 information symbols and adds 2 parity symbols, enabling correction of up to 1 symbol error. The code is systematic, meaning that the information symbols are not disturbed in any way in the encoder and the parity symbols are added separately to each block, and is based on the generating polynomial shown in Equation (149–8).

$$G(Z) = (Z - \alpha)(Z - 1) = A_2Z^2 + A_1Z^1 + A_0Z^0 \quad (149–8)$$

where

α is a root of the binary primitive polynomial $x^{10} + x^3 + 1$ and is represented as 0x002.
A is a series representing the resulting polynomial coefficients of $G(Z)$, (A_2 is equal to 0x001).
Z corresponds to a 10-bit GF(2^{10}) symbol.

The parity calculation shall produce the same result as the shift register implementation shown in Figure 149–23. Before calculation begins, the shift register shall be initialized to zero. The contents of the shift register are transmitted without inversion.

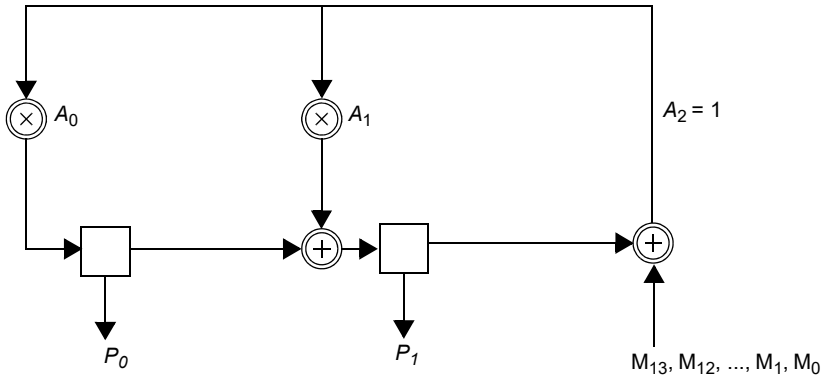

Figure 149–23—OAM FEC parity vector model

An FEC parity vector is represented by Equation (149–9).

$$P(Z) = M(Z) \bmod G(Z) \quad (149–9)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where

M(Z)	is the data vector $M(Z) = M_{13}Z^{15} + M_{12}Z^{14} + \ldots + M_0Z^2$. M_{13} is the first 10-bit data symbol and M_0 is the last. (M_{13} corresponds to OAM<0><9:0>, M_{12} corresponds to OAM<1><9:0>, etc.)
P(Z)	is the parity vector $P(Z) = P_1Z^1 + P_0Z^0$. P_1 (OAM<14><9:0>) is the first 10-bit parity symbol and P_0 (OAM<15><9:0>) is the last.
A data/parity symbol	(d_9, d_8, …, d_0) is identified with the element: $d_9\alpha^9 + d_8\alpha^8 + \ldots + d_0\alpha^0$ in GF(2^{10}), the finite field with 2^{10} elements.
d_0	is identified as the LSB (OAM<*><0>).
d_9	is identified as the MSB (OAM<*><9>) for all symbols.

The OAM Reed-Solomon parity symbol generation/correction is required only when EEE is implemented. When all 16 symbols of the OAM are embedded in tx_RSmessage<9:0> as described in 149.3.2.2.17 then OAM<15:14><9:0> are dummy symbols and are ignored at the receiver.

149.3.9.2.14 MultiGBASE-T1 OAM frame acceptance criteria

All fields of the OAM frame shall be accepted and updated, unless any of the following occurs:

a) RS(16, 14) contains an uncorrectable error, or

b) there is an uncorrectable PHY frame on any of the 16 symbols.

149.3.9.2.15 PHY health indicator

The PHY current health is sent to the link partner on a per OAM frame basis using the SNR<1:0> bits as described in 149.3.9.2.5. It lets the link partner have an early indication of potential problems that can cause the PHY to drop link or have high error rates.

If EEE is implemented, there can be a case where a PHY's receiver can no longer maintain good SNR based on quiet/refresh cycles. Instead of dropping the link, the PHY can attempt to recover the link by forcing the link partner to exit LPI in its egress direction so that the PHY can use normal power mode to recover. This is done by transmitting SNR<1:0> with a value of 01.

If a PHY receives SNR<1:0> set to 01 by its link partner, then it cannot enter into LPI in the egress direction. If the PHY is already in LPI then the PHY shall immediately exit LPI.

149.3.9.2.16 Ping

The PingTx bit is set based on the value in mr_tx_ping. The PingRx bit is set based on the latest PingTx received from the link partner. The value in mr_rx_ping is set based on the received PingRx from the link partner. The user can determine that the link partner OAM is operating properly by toggling mr_tx_ping and observing mr_rx_ping matches after a short delay.

The Ping bits are updated on a per OAM frame basis.

149.3.9.2.17 OAM message exchange

Unlike the PHY health indicator, the ping function, and the OAM status that operate on a per OAM frame basis, the OAM message exchange operates on a per OAM message basis that may occur over many OAM frames. The OAM message exchange mechanism allows a management entity attached to a PHY and its peer attached to the link partner to asynchronously pass OAM messages and verify their delivery.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The OAM message is first written into the OAM transmit registers in the PHY. The OAM message is then read out of the OAM transmit registers and transmitted to the link partner. After the link partner receives the OAM message, it transfers it into the link partner's OAM receive registers and also sends an acknowledge back to the PHY indicating that the next OAM message can be transmitted. One OAM message can be loaded into the OAM transmit registers while another OAM message is being transmitted by the PHY to the link partner, while yet another OAM message is being read out at the link partner's OAM receive registers. The exchange of OAM messages is occurring concurrently and bi-directionally. The transfers between the management entities can be done asynchronously. On the transmit side, mr_tx_valid = 0 indicates that the next OAM message can be written into the OAM transmit registers. Once the registers are written, the management entity sets mr_tx_valid to 1 to indicate that the OAM transmit registers contain a valid OAM message. Once the message is read out atomically, the state diagram clears the mr_tx_valid to 0 to indicate that the registers are ready to accept the next OAM message.

On the receive side, mr_rx_lp_valid indicates that valid OAM message can be read from the OAM receive registers. Once these registers are read, the mr_rx_lp_valid should be cleared to 0 to indicate that the registers are ready to receive the next OAM message. If mr_rx_lp_valid is not cleared, then the OAM message transfer will eventually stall since the sender cannot send new OAM messages if the receiver does not acknowledge that an OAM message has been transferred into the OAM receive registers.

The management entities can asynchronously read mr_tx_valid and mr_rx_lp_valid to know when OAM messages can be transferred in and out of the OAM registers.

The toggle bit alternates between 0 and 1, which lets the management entity determine which OAM message is being referred to. The toggle bit transitioning rules between one OAM frame and the next OAM frame are shown in Table 149–8.

Table 149–8—Toggle bit transition rules

Previous Valid	Previous Toggle	Current Valid	Current Toggle	Description
0	0	0	0	No valid OAM message
0	0	0	1	Illegal transition (Error)
0	0	1	0	New OAM message starting
0	0	1	1	Illegal transition (Error)
0	1	0	0	Illegal transition (Error)
0	1	0	1	No valid OAM message
0	1	1	0	Illegal transition (Error)

149.3.9.3 State diagram variable to OAM register mapping

The state diagrams of Figure 149–24 and Figure 149–25 generate and accept variables of the form "mr_x," where x is an individual signal name. These variables comprise a management interface to communicate the OAM information to and from the management entity. Clause 45 MDIO registers are defined in MMD3 to support the OAM. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the information is recommended. Table 97–6 and Table 149–9 describe the MDIO register to the state diagrams variable mapping.

Table 149–9—State variables to OAM register mapping

MDIO control/status variable	PCS register name	Register/bit number	PCS control/status variable
MultiGBASE-T1 OAM status Message 8	MultiGBASE-T1 OAM status message register	3.2318.7:0	mr_tx_message[71:64]
MultiGBASE-T1 OAM status Message 9	MultiGBASE-T1 OAM status message register	3.2318.15:8	mr_tx_message[79:72]

149.3.9.4 Detailed functions and state diagrams

149.3.9.4.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, counters, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.3.9.4.2 State diagram parameters

149.3.9.4.3 Variables

frame_boundary

Frame boundary detection based on the latest 16 rx_oam_field<8> received. The leftmost bit is the earliest received bit.

Values:

TRUE: latest 16 rx_oam_field<8> = 01111111111111xx

FALSE: latest 16 rx_oam_field<8> ≠ 01111111111111xx

link_status

The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive. This variable takes the values of OK or FAIL.

mr_rx_lp_message[95:0]

Twelve octet OAM message from the link partner. mr_rx_lp_message[63:0] in this variable is valid only when mr_rx_lp_valid is 1. mr_rx_lp_message[95:64] is always valid and continuously updated.

mr_rx_lp_message_num[3:0]

Four bit message number from the link partner. The value in this variable is valid only when mr_rx_lp_valid is 1.

mr_rx_lp_SNR[1:0]

Link partner health status.

Values:

00: PHY link is failing and will drop link and relink within 2 ms to 4 ms after the end of the current OAM frame.

01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled).

10: PHY SNR is marginal.

11: PHY SNR is good.

The threshold for the status is implementation dependent.

mr_rx_lp_toggle

The toggle bit value associated with the eight octet BASE-T1 OAM message from the link partner.

Values:

The toggle bit alternates between 0 and 1.

mr_rx_lp_valid

Indicates whether the OAM message in mr_rx_lp_message[63:0], mr_rx_lp_message_num[3:0] and the toggle bit in mr_rx_lp_toggle is valid or not. This variable should be cleared when mr_rx_lp_message[63:48] is read and is not explicitly shown in the state diagram. The clearing of this variable indicates to the state diagram that the BASE-T1 OAM message is read by the user and the state diagram can proceed to load in the next BASE-T1 OAM message.

Values:

0: invalid

1: valid

mr_rx_ping

Echoed ping value from the link partner.

Values:

The value can be 0 or 1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mr_tx_message[95:0]

Eight-octet BASE-T1 OAM message and four-octet MultiGBASE-T1 status transmitted by the local PHY. mr_tx_message[63:0] in this variable is valid only when mr_tx_valid is 1. mr_tx_message[95:64] in this variable is always valid.

mr_tx_message_num[3:0]

Four-bit message number transmitted by the local PHY. The value in this variable is valid only when mr_tx_valid is 1.

mr_tx_ping

Ping value transmitted by the local PHY.

Values:

The value can be 0 or 1.

mr_tx_received

Indicates whether the most recently transmitted BASE-T1 OAM message with a toggle bit value of mr_tx_received_toggle was received, read, and acknowledged by the link partner. This variable shall clear on read.

Values:

0: BASE-T1 OAM message was not received and read by the link partner.

1: BASE-T1 OAM message was received by the link partner.

mr_tx_received_toggle

Toggle bit value of the BASE-T1 OAM message that was received, read, and most recently acknowledged by the link partner. This bit is valid only if mr_tx_received is 1.

Values:

The value can be 0 or 1.

mr_tx_SNR[1:0]

Status register indicating PHY health status.

Values:

00: PHY link is failing and will drop link and relink within 2 to 4 ms after the end of the current OAM frame.

01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled).

10: PHY SNR is marginal.

11: PHY SNR is good.

The threshold for the status is implementation dependent.

mr_tx_toggle

The toggle bit value associated with the eight-octet BASE-T1 OAM message transmitted by the PHY. The value is automatically set by the state diagram and cannot be set by the user. This bit should be read and recorded prior to setting mr_tx_valid to 1.

Values:

The toggle bit alternates between 0 and 1.

mr_tx_valid

Indicates whether BASE-T1 OAM message in mr_tx_message[63:0] and mr_rx_lp_message_num[3:0] is valid or not. This register will be cleared by the state diagram to indicate whether the next BASE-T1 OAM message can be written into the registers.

Values:

0: invalid

1: valid

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

reset

Reset

Values:

FALSE: OAM circuit is not in reset.

TRUE: OAM circuit is in reset.

rs_check

Status of the latest rs_correct() operation

Values:

GOOD: no errors or correctable error

BAD: uncorrectable error

rx_ack

Acknowledge from link partner in response to PHY's BASE-T1 OAM message.

Values:

0: no acknowledge

1: acknowledge

rx_ack_toggle

The toggle value corresponding to the PHY's BASE-T1 OAM message that the link partner is acknowledging. This value is valid only if the rx_ack is set to 1.

Values:

The toggle bit can take on values of 0 or 1.

rx_boundary

This variable is set to TRUE whenever the receive data stream reaches the end of a Reed-Solomon frame and a dummy OAM symbol is not expected per 149.3.9.2.1 during normal power operation in the data mode, or at the end of a received refresh cycle during Low Power Idle operation. This variable is set to FALSE at other times.

Values:

FALSE: Receive stream is not at a boundary end.

TRUE: Receive stream is at a boundary end.

rx_exp_toggle

This variable holds the expected toggle value of the next BASE-T1 OAM message. This is normally the opposite value of the current toggle value, but shall reset on error conditions where two back-to-back BASE-T1 OAM messages separated by BASE-T1 OAM frames without a valid message have the same toggle value.

Values:

The toggle bit can take on values of 0 or 1.

rx_lp_ack

Acknowledge from PHY in response to link partner's BASE-T1 OAM message. Indicates whether valid BASE-T1 OAM message from the link partner has been sampled into the PHY's registers.

Values:

0: no acknowledge / not sampled

1: acknowledge / sampled

rx_lp_ping

Ping value received from the link partner that is looped back.

Values:

The value can be 0 or 1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_lp_toggle

The toggle bit value in the previous BASE-T1 OAM frame received from the link partner.

Values:

The toggle bit alternates between 0 and 1.

rx_lp_valid

Indicates whether BASE-T1 OAM message in previous BASE-T1 OAM frame received from the link partner is valid or not.

Values:

0: invalid
1: valid

rx_oam_field<9:0>

Ten-bit BASE-T1 OAM symbol extracted from a received Reed-Solomon frame during normal power operation in the data mode, or from a received refresh cycle during Low Power Idle operation.

rx_oam<15 to 0><9:0>

Raw 16-symbol OAM frame received from the link partner.

SNR[1:0]

PHY health status.

Values:

00: PHY link is failing and will drop link and relink within 2 ms to 4 ms after the end of the current OAM frame.
01: LPI refresh is insufficient to maintain PHY SNR. Request link partner to exit LPI and send idles (used only when EEE is enabled).
10: PHY SNR is marginal.
11: PHY SNR is good.

Both the status threshold and condition for generating this status are implementation dependent.

tx_boundary

This variable is set to TRUE whenever the transmit data stream reaches the start of a PHY frame and a dummy OAM symbol is not transmitted per 149.3.9.2.1 during normal power operation in the data mode, or at the start of a transmit refresh cycle during Low Power Idle operation. This variable is set to FALSE at other times.

Values:

FALSE: Transmit stream is not at a boundary end.
TRUE: Transmit stream is at a boundary end.

tx_oam_field<9:0>

Ten-bit BASE-T1 OAM symbol inserted into a transmitted Reed-Solomon frame during normal power operation in the data mode, or into a transmitted refresh cycle during Low Power Idle operation.

tx_oam<15 to 0><9:0>

Raw 16-symbol OAM frame transmitted from the PHY.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_lp_ready

Indicates whether the link partner is ready to receive the next BASE-T1 OAM message from the PHY. If ready, then the PHY will load the next BASE-T1 OAM message from the registers and begin transmitting them.

Values:

0: not ready
1: ready

tx_toggle

The toggle bit value being sent in the current BASE-T1 OAM frame transmitted by the PHY.

Values:

The value can be 0 or 1.

149.3.9.4.4 Counters

rx_cnt

A count of received OAM frame symbols.

Values:

The value can be any integer from 0 to 16, inclusive.

tx_cnt

OAM frame transmit symbol count.

Values:

The value can be any integer from 0 to 16, inclusive.

tx_rec

A count of received RS-FEC block errors, both correctable and uncorrectable.

Values:

The value can be any integer from 0 to 65 535, inclusive.

149.3.9.4.5 Functions

rs (14 OAM symbols)

This function outputs the 2 parity symbols as defined in 149.3.9.2.13.

If all 16 symbols of the OAM frame are embedded in tx_RSmessage<9:0> as described in 149.3.2.2.15 then this function can return any arbitrary value.

rs_correct (16 OAM symbols)

This function outputs the 14 corrected data symbols as defined in 149.3.9.2.13 and sets/clears the rs_check variable when at least one of the 16 symbols of the OAM frame is embedded in a LPI refresh.

Otherwise, this function returns the 14 data symbols unmodified and sets rs_check to GOOD if none of the 16 RS(360, 326) frames are uncorrectable.

149.4 Physical Medium Attachment (PMA) sublayer

149.4.1 PMA functional specifications

The PMA couples messages from the PMA service interface specified in 149.2.2 to the MultiGBASE-T1 baseband medium, specified in 149.7.

The interface between the PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 149.8.

NOTE—The recovered_clock arc is shown to indicate delivery of the recovered clock signal back to PMA TRANSMIT for loop timing.

Figure 149–26—PMA reference diagram

149.4.2 PMA functions

The PMA sublayer comprises one PMA Reset function and five simultaneous and asynchronous operating functions. The PMA operating functions are PHY Control, PMA Transmit, PMA Receive, Link Monitor, and Clock Recovery. All operating functions are started immediately after the successful completion of the PMA Reset function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA reference diagram, Figure 149–26, shows how the operating functions relate to the messages of the PMA service interface and the signals of the MDI. Connections from the management interface, comprising the signals MDC and MDIO, to other layers are pervasive and are not shown in Figure 149–26.

149.4.2.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

a) Power for the device containing the PMA has not reached the operating state.
b) The receipt of a request for reset from the management entity.

PMA Reset sets pma_reset = ON while any of the above reset conditions hold TRUE. All state diagrams take the open-ended pma_reset branch upon execution of PMA Reset. The reference diagrams do not explicitly show the PMA Reset function.

The MultiGBASE-T1 PMA takes no longer than 100 ms to enter the PCS_DATA state after exiting from reset or low power mode (see Figure 149–32).

149.4.2.2 PMA Transmit function

The PMA Transmit function comprises a transmitter to generate a four-level modulated signal on the single balanced pair of conductors. When the PHY Control state diagram (Figure 149–32) is not in the DISABLE_TRANSMITTER state, PMA Transmit shall continuously transmit pulses modulated by the symbols given by tx_symb onto the MDI. During Link Synchronization, when sync_link_control = DISABLE and Auto-Negotiation is either not enabled or is not implemented, the sync_tx_symb output by the PHY Link Synchronization function shall be used in place of tx_symb as the data source for PMA Transmit. When lpi_tx_mode = ALERT, the PN sequence defined in 149.4.2.6 shall be used in place of tx_symb as the data source for PMA Transmit. The signals generated by PMA Transmit shall comply with the electrical specifications given in 149.5.2.

When the PMA_CONFIG.indication parameter config is MASTER, the PMA Transmit function shall source TX_TCLK from a local clock source while meeting the transmit jitter requirements of 149.5.2.3. The MASTER-SLAVE relationship shall include loop timing. If the PMA_CONFIG.indication parameter config is SLAVE, the PMA Transmit function shall source TX_TCLK from the recovered clock of 149.4.2.8 while meeting the jitter requirements of 149.5.2.3.

The PMA Transmit fault function is optional. The faults detected by this function are implementation specific. If the MDIO interface is implemented, then this function shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

149.4.2.2.1 Global PMA transmit disable

When the PMA_transmit_disable variable is set to TRUE, this function shall turn off the transmitter so that the average launch power of the transmitter is less than –53 dBm.

149.4.2.3 PMA Receive function

The PMA Receive function comprises a receiver for PAM4 signals on the balanced pair. PMA Receive contains the circuits necessary to both detect symbol sequences from the signals received at the MDI over the receive pair and to present these sequences to the PCS Receive function. The PMA translates the signals received on the pair into the PMA_UNITDATA.indication parameter rx_symb. The quality of these symbols shall allow RFER of less than 2×10^{-10} after RS-FEC decoding, over a channel meeting the requirements of 149.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

To achieve the indicated performance, it is highly recommended that PMA Receive include the functions of signal equalization and echo cancellation. The sequence of symbols assigned to tx_symb is needed to perform echo cancellation.

The PMA Receive function uses the parameters pcs_status and scr_status, and the state of the equalization, cancellation, and estimation functions to determine the quality of the receiver performance, and generates the loc_rcvr_status variable accordingly. The loc_rcvr_status variable is expected to become NOT_OK when the link partner's tx_mode changes to SEND_Z from any other value (see the PHY Control state diagram in Figure 149–32). The precise algorithm for generation of loc_rcvr_status is implementation dependent.

The receiver uses the sequence of symbols during the training sequence to detect and correct for pair polarity swaps.

The PMA Receive fault function is optional. The PMA Receive fault function is the logical OR of the link_status = FAIL and any implementation specific fault. If the MDIO interface is implemented, then this function shall contribute to the receive fault bit specified in 45.2.1.7.5 and 45.2.1.243.7.

149.4.2.4 PHY Control function

PHY Control generates the control actions that are needed to bring the PHY into a mode of operation during which frames can be exchanged with the link partner. PHY Control shall comply with the state diagram in Figure 149–32.

During PMA training (TRAINING and COUNTDOWN states in Figure 149–32), PHY Control information is exchanged between link partners with a 12-octet Infofield, which is XORed with the first 96 bits of the 16th partial PHY frame (bits 6750 to 6845). The Infofield is also denoted IF. The link partner is not required to decode every IF transmitted but is required to decode IFs at a rate that enables the correct actions prior to the PAM2 to PAM4 transition.

The 12-octet Infofield shall include the fields in 149.4.2.4.2 through 149.4.2.4.8, also shown in Figure 149–27 and Figure 149–28. Infofield shall be transmitted at least 256 times with each change to octets 7 to 10.

PMA_state = 00

octet 1	octet 2	octet 3	octets 4/5/6	octet 7	octets 8/9/10	octets 11/12
0xBB	0xA7	0x00	PFC24	Message	PHY Capability Bits	CRC16

Figure 149–27—Infofield TRAINING format

PMA_state = 01

octet 1	octet 2	octet 3	octets 4/5/6	octet 7	octets 8/9/10	octets 11/12
0xBB	0xA7	0x00	PFC24	Message	DataSwPFC24	CRC16

Figure 149–28—Infofield COUNTDOWN format

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.4.2.4.1 Infofield notation

For all the Infofield notations in the following subclauses, Reserved<bit location> represents any unused values and shall be set to zero on transmit and ignored when received by the link partner. The Infofield is transmitted following the notation where the LSB of each octet is sent first and the octets are sent in increasing number order (that is, the LSB of Oct1 is sent first).

149.4.2.4.2 Start of Frame Delimiter

The start of Frame Delimiter consists of three octets [Octet 1<7:0>, Octet 2<7:0>, Octet 3<7:0>] and shall use the hexadecimal value 0xBBA700. 0xBB corresponds to Octet 1<7:0> and so forth.

149.4.2.4.3 Partial PHY frame count (PFC24)

The partial PHY frame count consists of 3 octets [Oct4<7:0>, Oct5<7:0>, Oct6<7:0>] and indicates the running count of partial PHY frames sent LSB first. There are 16 partial PHY frames per PHY frame and the Infofield is embedded within the 16th partial PHY frame. The first partial PHY frame is zero, thus the first partial PHY frame count field after a reset is 15.

PFC24 continues to run uninterrupted for the duration of the link. The resolution of PFC24 is large enough that it does not rollover during the allotted training time. However, it will rollover if allowed to run indefinitely. PFC24 is defined to rollover to 0 after it reaches 16 776 959 to align with the EEE QR cycle.

149.4.2.4.4 Message Field

The Message Field is one octet. For the MASTER, this field is represented by Oct7{PMA_state<7:6>, loc_rcvr_status<5>, en_slave_tx<4>, reserved<3:0>}. For the SLAVE, this field is represented by Oct7{PMA_state<7:6>, loc_rcvr_status<5>, timing_lock_OK<4>, reserved<3:0>}.

The two state-indicator bits PMA_state<7:6> shall communicate the state of the transmitting transceiver to the link partner. PMA_state<7:6> = 00 indicates TRAINING, and PMA_state<7:6> = 01 indicates COUNTDOWN.

All possible Message Field settings are listed in Table 149–10 for the MASTER and Table 149–11 for the SLAVE. Any other value shall not be transmitted and shall be ignored at the receiver. The Message Field setting for the first transmitted PMA frame shall be the first row of Table 149–10 for the MASTER and the first or second row of Table 149–11 for the SLAVE. Moreover, for a given Message Field setting, the next Message Field setting shall be the same Message Field setting or the Message Field setting corresponding to a row below the current setting. When loc_rcvr_status = OK the Infofield variable is set to loc_rcvr_status<5> = 1 and set to 0 otherwise.

Table 149–10—Infofield message field valid MASTER settings

PMA_state<7:6>	loc_rcvr_status	en_slave_tx	reserved	reserved	reserved	reserved
00	0	0	0	0	0	0
00	0	1	0	0	0	0
00	1	1	0	0	0	0
01	1	1	0	0	0	0

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 149–11—Infofield message field valid SLAVE settings

PMA_state<7:6>	loc_rcvr_status	timing_lock_OK	reserved	reserved	reserved	reserved
00	0	0	0	0	0	0
00	0	1	0	0	0	0
00	1	1	0	0	0	0
01	1	1	0	0	0	0

149.4.2.4.5 PHY capability bits

When PMA_state<7:6> = 00, then [Oct8<7:0>, Oct9<7:0>, Oct10<7:0>] contains the PHY capability bits. Each octet is sent LSB first. See Table 149–12 for the details.

Table 149–12—PHY capability bits

octet 8								octet 9								octet 10							
0	1	2	3	4	5	6	7	0	1	2	3	4	5	6	7	0	1	2	3	4	5	6	7
VendorSpecificData																Reserved	InterleaverDepth		PrecodeSel		SlowWakeRequest	EEEen	OAMen

The format of PHY capability bits is Oct10<2:1> = InterleaverDepth[1:0], Oct10<4:3> = PrecodeSel[1:0], Oct10<5> = SlowWakeRequest, Oct10<6> = EEEen, Oct10<7> = OAMen, Oct8<7:0> = VendorSpecificData[7:0], and Oct9<7:0> = VendorSpecificData[15:8].

EEEen and OAMen indicate EEE and MultiGBASE-T1 OAM capability enable, respectively. The PHY shall indicate the support of these two optional capabilities by setting the corresponding capability bits.

The optional EEE capability shall be enabled only if both PHYs set the capability bit EEEen = 1. The optional BASE-T1 OAM capability shall be enabled only if both PHYs set the capability bit OAMen = 1. InterleaverDepth indicates the requested data mode interleaving depth. PrecodeSel indicates the requested precoder. SlowWakeRequest is set to indicate to the link partner that the PHY will transmit alert only immediately following a refresh.

The capability bit values shall be considered as valid only when the loc_rcvr_status bit is 1.

The remaining bits shall be reserved and set to 0.

149.4.2.4.6 Data switch partial PHY frame count

When PMA_state<7:6> = 01, then [Oct8<7:0>, Oct9<7:0>, Oct10<7:0>] contains the data switch partial PHY frame count (DataSwPFC24) sent LSB first. DataSwPFC24 indicates the partial PHY frame count

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

when the transmitter switches from PAM2 to PAM4, which occurs at the start of an RS-FEC superframe. The last value of PFC24 prior to the transition is DataSwPFC24 – 1. DataSwPFC24 shall be set to an integer multiple of 16. When the value of DataSwPFC24 is a multiple of 16 the switch from PAM2 to PAM4 occurs on a PHY frame boundary. DataSwPFC24 shall be a minimum of 4081 and a maximum of 4785 from the current PFC24 value.

149.4.2.4.7 Reserved fields

When PMA_state<7:6> is greater than 01, then [Oct8<7:0>, Oct9<7:0>, Oct10<7:0>] contains a reserved field. All Infofield fields denoted reserved are reserved for future use.

149.4.2.4.8 CRC16

CRC16 (2 octets) shall implement the CRC16 polynomial $(x + 1)(x^{15} + x + 1)$ of the previous 7 octets, Oct4<7:0>, Oct5<7:0>, Oct6<7:0>, Oct7<7:0>, Oct8<7:0>, Oct9<7:0>, and Oct10<7:0>. The CRC16 shall produce the same result as the implementation shown in Figure 149–29. In Figure 149–29 the 16 delay elements S0,..., S15, shall be initialized to zero. After initialization, the switch is set to CRCgen, as shown in Figure 149–29, and Oct4 through Oct10 are used to compute the CRC16 output. After all 7 octets have been processed, the switch is disconnected (setting CRCout) and the 16 values stored in the delay elements are transmitted in the order illustrated, first S15, followed by S14, and so on, until the final value S0.

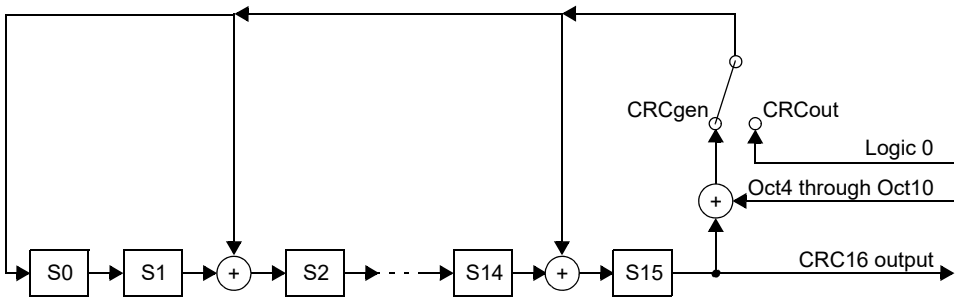

Figure 149–29—CRC16

149.4.2.4.9 PMA MDIO function mapping

The MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMA. Mapping of MDIO control variables to PMA control variables is shown in Table 149–13. Mapping of MDIO status variables to PMA status variables is shown in Table 149–14.

Table 149–13—MDIO/PMA control variable mapping

MDIO control variable	PMA register name	Register/bit number	PMA control variable
Reset	PMA/PMD control 1 register/ MultiGBASE-T1 PMA control register	1.0.15 / 1.2309.15	pma_reset
Transmit disable	MultiGBASE-T1 PMA control register	1.2309.14	PMA_transmit_disable

Table 149–14—MDIO/PMA status variable mapping

MDIO status variable	PMA register name	Register/bit number	PMA status variable
Receive fault	MultiGBASE-T1 PMA status register	1.2310.1	PMA_receive_fault

149.4.2.4.10 Startup sequence

The startup sequence shall comply with the state diagram description given in Figure 149–32. If the Auto-Negotiation function is not implemented, or disabled (mr_autoneg_en = FALSE), PMA_CONFIG is predetermined to be MASTER or SLAVE via management control during initialization or via default hardware setup. The Auto-Negotiation function is optional for 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs. If the Auto-Negotiation function is implemented and enabled, Auto-Negotiation is the source of control (via link_control) and MASTER/SLAVE configuration; however, if Auto-Negotiation is either not enabled or is not implemented, the Link Synchronization function is the source of control (via sync_link_control) and MASTER/SLAVE configuration.

During startup, prior to entering the TRAINING state, the SLAVE shall align its transmit 65B RS-FEC frame to within +0/–4 × *S* (See Table 149–1 for the definition of *S*.) partial PHY frames of the MASTER as seen at the SLAVE MDI. The SLAVE Infofield partial PHY frame count shall match the MASTER Infofield partial PHY frame count for the aligned frame.

In the TRAINING state, PAM 2 transmission is used and PHY capabilities are exchanged with Infofields as specified in 149.4.2.4.5.

At any time following the TRAINING state, if the local receiver status (indicated by loc_rcvr_status) transitions to NOT_OK, PHY Control returns to the SILENT state and attempts a retrain.

The startup timing shall comply with Table 149–15 for MASTER and Table 149–16 for SLAVE.

NOTE—See Table 149–1 for the definition of S.

Table 149–15—Startup timing maximums for MASTER

Timing interval	Maximum time (ms)
From entry to SILENT state until en_slave_tx = 1 is transmitted	40 – 0.384 / *S*
From entry of SILENT state until entry to COUNTDOWN state	95.975 – 0.384 / *S*
Entry to COUNTDOWN until entry of TX_SWITCH	0.384 / *S*
Entry to exit of PCS TEST	1.025
Total (Entry to SILENT to exit of PCS TEST)	97

149.4.2.5 Link Monitor function

Link Monitor determines the status of the underlying receive channel and communicates it via the variable link_status. Failure of the underlying receive channel causes the PMA to set link_status to FAIL, which in turn causes the PMA's clients to stop exchanging frames and restart the Auto-Negotiation (if enabled) or Link Synchronization (if Auto-Negotiation is not enabled) process.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 149–16—Startup timing maximums for SLAVE

Timing interval	Maximum time (ms)
Entry to exit of SILENT state	40
Entry of SILENT state to exit of TRAINING state	95.975 – 0.384 / *S*
Entry to COUNTDOWN until entry of TX_SWITCH	0.384 / *S*
Entry to exit of PCS TEST	1.025
Total (Entry to SILENT to exit of PCS TEST)	97

The Link Monitor function shall comply with the state diagram of Figure 149–33.

Upon power on, reset, or release from power down, the Auto-Negotiation function sets link_control = DISABLE, or PHY Link Synchronization algorithms set sync_link_control = DISABLE. During this period, link_status = FAIL is asserted. When the Auto-Negotiation function establishes the presence of a remote MultiGBASE-T1 PHY, link_control is set to ENABLE, or when the PHY Link Synchronization finishes the synchronization function, sync_link_control is set to ENABLE, and the Link Monitor state diagram begins monitoring the PCS and receiver lock status. As soon as reliable transmission is achieved, the variable link_status = OK is asserted, upon which further PHY operations can take place.

149.4.2.6 PHY Link Synchronization

If the optional Clause 98 Auto-Negotiation function is disabled or not implemented, then the Link Synchronization function shall establish the start of PHY PMA training as defined in 149.4.2.4.

When operating, the Link Synchronization function is the data source for the PMA Transmit function (see 149.4.2.2), and uses a signal, SEND_S. This signal is used by the MASTER and SLAVE to discover the link partner and synchronize the start of PMA training.

The frequency of the SEND_S signal shall be 703.125 MHz.

Link Synchronization employs the SEND_S signal to achieve synchronization prior to link training. If the PHY is configured as MASTER, Link Synchronization shall employ Equation (149–10) as the PN sequence generator.

$$p_M(x) = x^8 + x^4 + x^3 + x^2 + 1 \quad (149–10)$$

If the PHY is configured as SLAVE, Link Synchronization shall employ Equation (149–11) as PN sequence generator.

$$p_{MS}(x) = x^8 + x^6 + x^5 + x^4 + 1 \quad (149–11)$$

The period of both PN sequences is 255.

An implementation of MASTER and SLAVE PHY SEND_S PN sequence generators by linear-feedback shift registers is shown in Figure 149–30. The bits stored in the shift register delay line at time *n* are denoted by $S_n[7:0]$. At each symbol period, the shift register is advanced by one bit, and one new bit represented by $S_n[0]$ is generated. The PN sequence generator shift registers shall be reset to a value of $S_n[7:0]$ = 0000 0001 upon entering into the TRANSMIT_DISABLE state (see Figure 149–30) or on the transmission of the first

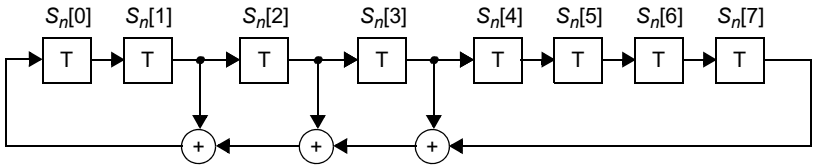
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



symbol of the alert sequence. The receiver may not necessarily receive a continuous PN sequence between separate periods of the SEND_S signal.

For 10GBASE-T1, the bit $S_n[0]$ shall be mapped to the transmit symbol T_n as follows: if $S_n[0] = 0$ then $T_n = +1\ +1\ +1\ +1\ +1\ +1\ +1\ +1$, if $S_n[0] = 1$ then $T_n = -1\ -1\ -1\ -1\ -1\ -1\ -1\ -1$.

For 5GBASE-T1, the bit $S_n[0]$ shall be mapped to the transmit symbol T_n as follows: if $S_n[0] = 0$ then $T_n = +1\ +1\ +1\ +1$, if $S_n[0] = 1$ then $T_n = -1\ -1\ -1\ -1$.

For 2.5GBASE-T1, the bit $S_n[0]$ shall be mapped to the transmit symbol T_n as follows: if $S_n[0] = 0$ then $T_n = +1\ +1$, if $S_n[0] = 1$ then $T_n = -1\ -1$.

MASTER PHY SEND_S PN sequence generator

SLAVE PHY SEND_S PN sequence generator

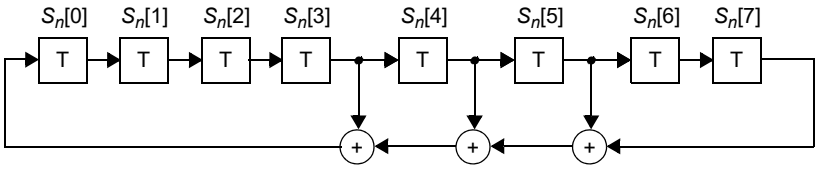


Figure 149–30—SEND_S PN sequence generator by linear feedback shift registers S_n

The PHY Link Synchronization state diagram in Figure 149–31 shall be used to synchronize 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 PHYs prior to the MultiGBASE-T1 link training. If the Clause 98 Auto-Negotiation function is enabled, then the Auto-Negotiation function shall be used as the mechanism for PHY synchronization and the PHY Link Synchronization state diagram in Figure 149–31 remains in the SYNC_DISABLE state.

149.4.2.6.1 State diagram variables

force_config

This variable indicates whether the PHY operates as a MASTER or as a SLAVE. The variable takes on one of the following values:

MASTER: This value is continuously asserted when the PHY operates as a MASTER.
SLAVE: This value is continuously asserted when the PHY operates as a SLAVE.

force_phy_type

This variable indicates what speed the PHY is to operate when Auto-Negotiation is disabled or not implemented. The variable takes on one of the following values:

10G-T1: If Auto-Negotiation is disabled or not implemented and 10GBASE-T1 is selected.
5G-T1: If Auto-Negotiation is disabled or not implemented and 5GBASE-T1 is selected.
2.5G-T1: If Auto-Negotiation is disabled or not implemented and 2.5GBASE-T1 is selected.

Other values are implementation-dependent and beyond the scope of this clause.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

link_status
: The link_status parameter is set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive. This variable takes the values of OK or FAIL.

mr_autoneg_enable:
: see 98.5.1.

mr_main_reset
: see 98.5.1.

power_on
: see 98.5.1.

send_s_sigdet
: This variable indicates whether the SEND_S signal was detected. This variable shall be set FALSE no later than 1 μs after the signal goes quiet on the MDI.
Values:
TRUE: SEND_S signal detected.
FALSE: SEND_S signal not detected.

sync_link_control
: This variable indicates the data source for the PMA Transmit function.
Values:
DISABLE: The data source is the PHY Link Synchronization function (sync_tx_symb).
ENABLE: The data source is PMA_UNITDATA.request (tx_symb).

149.4.2.6.2 State diagram timers

break_link_timer
: see 98.5.2.

link_fail_inhibit_timer
: see 98.5.2.

send_s_timer
: This timer is used to control the duration SEND_S is transmitted. The timer shall expire 1.25 μs ± 0.05 μs after being started.

sigdet_wait_timer
: This timer is used to control the wait time after transmitting or detecting the end of SEND_S. The timer shall expire 5 μs ± 0.15 μs after being started.

149.4.2.6.3 Messages

sync_tx_symb
: The value of sync_tx_symb is set by the Link Synchronization state diagram and indicates the symbols sent from the PHY Link Synchronization block to PMA Transmit. The Link Synchronization block generates sync_tx_symb synchronously with every transmit clock cycle.
Values:
SEND_S: Transmit the SEND_S signal defined in 149.4.2.6.
SEND_Z: Transmit a zero value.

149.4.2.7 Refresh monitor function

The Refresh monitor is required for PHYs that support the EEE capability. The Refresh monitor operates when the PHY is in the LPI receive mode. The Refresh monitor shall comply with the state diagram of Figure 149–34. The Refresh monitor sets the PMA_refresh_status variable, which forces a link retrain if a refresh signal is not reliably detected within a moving time window equivalent to 50 complete quiet-refresh cycles (nominally equal to 1.536/*S* ms), when the PHY is in the lower power receive mode. See Table 149–1 for the definition of *S*.

149.4.2.8 Clock Recovery function

The Clock Recovery function shall provide a clock suitable for signal sampling so that the RFER indicated in 149.4.2.3 is achieved. The received clock signal is expected to be stable and ready for use when training has been completed. The received clock signal is supplied to the PMA Transmit function by received_clock.

149.4.3 MDI

Communication through the MDI is summarized in 149.4.3.1 and 149.4.3.2.

149.4.3.1 MDI signals transmitted by the PHY

The symbols to be transmitted by the PMA are denoted by tx_symb. PMA Transmit generates a pulse-amplitude modulated signal on each pair in the following form:

$$s(t) = \sum_{n=0}^{\infty} a_n h_T(t - nT) \quad (149–12)$$

In Equation (149–12), a_n is the PAM4 modulation symbol from the set {–1, –1/3, +1/3, +1} to be transmitted at time nT, and $h_T(t)$ denotes the system symbol response at the MDI. This symbol response shall comply with the electrical specifications given in 149.5.2.

149.4.3.2 Signals received at the MDI

Signals received at the MDI can be expressed as pulse-amplitude modulated signals that are corrupted by noise as follows:

$$r(t) = \sum_{n=0}^{\infty} a_n h_R(t - nT) + w(t) \quad (149–13)$$

In Equation (149–13) $h_R(t)$ denotes the symbol response of the overall channel impulse response between the transmit symbol source and the receive MDI and $w(t)$ represents the contribution of various noise sources including uncancelled echo. The receive signal is processed within the PMA Receive function to yield the received symbols rx_symb.

149.4.4 State variables

149.4.4.1 State diagram variables

auto_neg_imp
: This variable indicates if an optional Auto-Negotiation sublayer is associated with the PMA.
Values:
TRUE: An optional Auto-Negotiation sublayer is associated with the PMA.
FALSE: An optional Auto-Negotiation sublayer is not associated with the PMA.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

config

The PMA generates this variable continuously and passes it to the PCS via the PMA_CONFIG.indication primitive.
Values: MASTER or SLAVE.

en_slave_tx

The en_slave_tx variable in the Infofield received by the SLAVE.
Values:

0: MASTER is not ready for the SLAVE to transmit.
1: MASTER is ready for the SLAVE to transmit.

infofield_complete

This variable indicates that a complete set of Infofield messages has been sent (see 149.4.2.4).
Values:

FALSE: A complete set of Infofield messages has not been sent.
TRUE: A complete set of Infofield messages has been sent.

link_control

This variable is defined in 149.2.1.1.1.

link_status

The link_status parameter set by PMA Link Monitor state diagram and communicated through the PMA_LINK.indication primitive.
Values: OK or FAIL.

loc_countdown_done

This variable is set to FALSE when the PHY Control state diagram is in the DISABLE_TRANSMITTER state and is set to TRUE immediately after transmitting the last bit of the DataSwPFC24–1 partial PHY frame.

loc_rcvr_status

Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive link for the local PHY.
Values:

OK: The receive link for the local PHY is operating reliably.
NOT_OK: Operation of the receive link for the local PHY is unreliable.

loc_SNR_margin

This variable reports whether the local device has sufficient SNR margin to continue to the next state. The criterion for setting the parameter loc_SNR_margin is left to the implementer.
Values:

OK: The local device has sufficient SNR margin.
NOT_OK: The local device does not have sufficient SNR margin.

pcs_data_mode

Generated by the PMA PHY Control function and indicates whether or not the local PHY may transition its PCS state diagrams out of their initialization states. The current value of the pcs_data_mode is passed to the PCS via the PMA_PCSDATAMODE.indication primitive.

PMA_refresh_status

This variable indicates the status of the Refresh monitor as described in 149.4.2.7.
Values: OK or FAIL.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pma_reset
: Allows reset of the PHY Control and Link Monitor state diagrams.
Values: ON or OFF.

PMA_state
: Variable for the value transmitted in the PMA_state<7:6> of the Infofield by the local PHY.
Values:
00: TRAINING state
01: COUNTDOWN state

rem_countdown_done
: This variable is set to FALSE when the PHY Control state diagram is in the DISABLE_TRANSMITTER state or SILENT state and is set to TRUE once the receiver has transitioned from PAM2 to PAM4.

rem_rcvr_status
: Variable set by the PCS Receive function to indicate whether correct operation of the receive link for the remote PHY is detected or not.
Values:
OK: The receive link for the remote PHY is operating reliably.
NOT_OK: Reliable operation of the receive link for the remote PHY is not detected.

sync_link_control
: This variable is defined in 149.4.2.6.1.

tx_mode
: The PMA generates this variable continuously and passes it to the PCS via the PMA_TXMODE.indication primitive.
Values:
SEND_N: This value is continuously asserted when transmission of sequences of symbols representing a XGMII data stream take place.
SEND_T: This value is continuously asserted when transmission of sequences of symbols representing the training sequences of symbols is to take place.
SEND_Z: This value is asserted when transmission of zero symbols is to take place.

149.4.4.2 Timers

All timers operate in the manner described in 14.2.3.2.

minwait_timer
: A timer used to determine the minimum amount of time the PHY Control stays in the SILENT, TRAINING, PCS_TEST, and PCS_DATA states. The timer shall expire 975 μs ± 50 μs after being started.

The following timer is required only for PHYs that support the EEE capability:

lpi_refresh_rx_timer
: This timer is used to monitor link quality during the LPI receive mode. If the PHY does not detect reliable refresh signaling before this timer expires then a full retrain is performed.
Values: The condition lpi_refresh_rx_timer_done becomes TRUE upon timer expiration.
Duration: This timer shall have a period equal to 50 complete quiet-refresh signal periods, equivalent to 1.536/*S* ms. See Table 149–1 for the definition of *S*.

149.5 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA and specifies PMA-to-MDI interface tests.

149.5.1 Test modes

The test modes described as follows shall be provided to allow for testing of the transmitter jitter, transmitter distortion, transmitter PSD, transmitter droop, and BER.

If MDIO is implemented, these test modes shall be enabled by setting a control register, 1.2313.15:13, as shown in Table 149–17. If MDIO is not implemented then equivalent functionality shall be provided. The test modes shall only change the data symbols provided to the transmitter circuitry and do not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation.

Table 149–17—MDIO management registers settings for test modes

Register value	Register description
000	Normal (non-test mode) operation.
001	Test mode 1—Setting MASTER and SLAVE PHYs for transmit clock jitter test in linked mode.
010	Test mode 2—Transmit MDI jitter test in MASTER mode.
011	Test mode 3—Precoder test mode.
100	Test mode 4—Transmitter linearity test.
101	Test mode 5—Normal operation in Idle mode. This is for the PSD Mask test.
110	Test mode 6—Transmitter droop test mode.
111	Test mode 7—Normal operation with zero data pattern. This is for BER monitoring.

Test mode 1 enables testing of timing jitter on MASTER and SLAVE transmitters. MASTER and SLAVE PHYs are connected over a link segment defined in 149.7. When in this mode, the PHY shall provide access to a frequency reduced version of the transmit symbol clock or TX_TCLK_175. TX_TCLK_175 is equal to 175.78125 MHz.

Test mode 2 is for transmitter jitter testing on the MDI when the transmitter is in MASTER timing mode. When test mode 2 is enabled, the PHY shall transmit a continuous pattern of JP03A (as specified in 94.2.9.1) or JP03B (as specified in 94.2.9.2) with the transmitted symbols timed from its local clock source.

Test mode 3 is for testing the precoder operation. When test mode 3 is enabled, the PCS shall generate a continuous pattern of {0, 3} symbols to be input to the transmit precoder specified in 149.3.2.2.20, to be precoded according to the transmit precoder settings as determined by the value set in register 1.2313:10:9, or equivalent functionality if MDIO is not implemented, and transmitted by the PMA timed from its local clock source.

Test mode 4 is for transmitter linearity testing. When test mode 4 is enabled, the PHY shall transmit a continuous pattern of PRBS13Q (as specified in 120.5.11.2.1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Test mode 5 is for checking whether the transmitter is compliant with the transmit PSD mask and the transmit power level. When test mode 5 is enabled, the PHY shall transmit as in non-test operation and in the MASTER data mode with data set to normal interframe idle signals.

When test mode 6 is enabled, the PHY shall transmit a continuous pattern of 128 × *S* {+1} symbols followed by 128 × *S* {–1} symbols with the transmitted symbols timed from its local clock source. See Table 149–1 for the definition of *S*.

Test mode 7 is for enabling measurement of the bit error ratio of the link including the RS-FEC encoder/decoder, transmit and receive analog front ends of the PHY, and a cable connecting two PHYs. This mode reuses the 2.5GBASE-T1, 5GBASE-T1, or 10GBASE-T1 normal (non-test) mode with zero data pattern. Instead of encoding data received from the MAC, continuous zero data pattern is encoded. On the receive side, after PCS FEC decoding processing, a zero data sequence is expected with no errors. Any block received with non-zero data bits is counted as an error and calculated in the RS-FEC block error ratio.

149.5.1.1 Test fixtures

The following fixtures, or their equivalents, as shown in Figure 149–35, Figure 149–36, Figure 149–37, and Figure 149–38, in stated respective tests, are defined for measuring the transmitter specifications for data communication only.

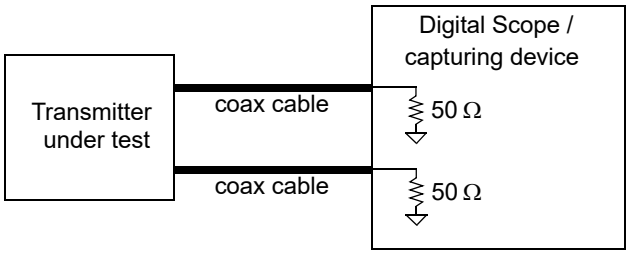

Figure 149–35—Transmitter test fixture 1 for transmitter droop measurement and transmitter linearity measurement

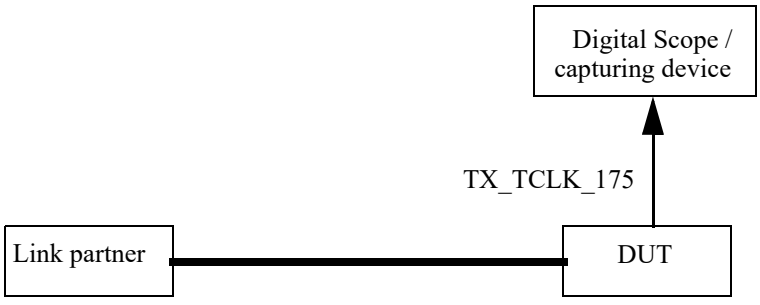

Figure 149–36—Transmitter test fixture 2 for MASTER and SLAVE clock jitter measurement

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

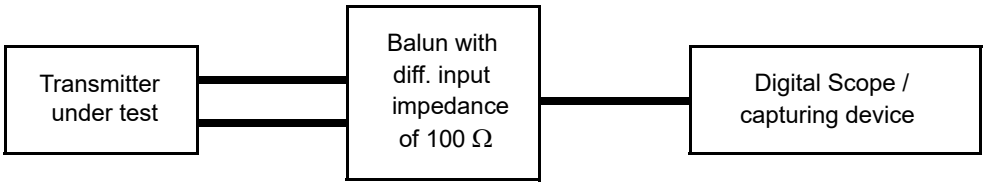

Figure 149–37—Transmitter test fixture 3 for MDI jitter measurement

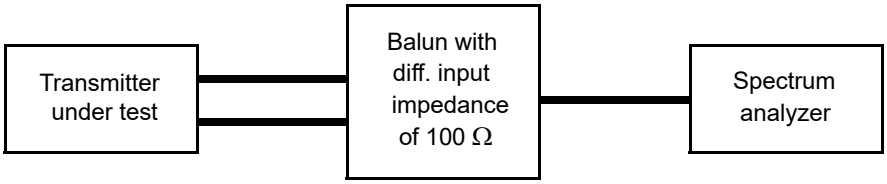

Figure 149–38—Transmitter test fixture 4 for power spectral density measurement and transmit power level measurement

149.5.2 Transmitter electrical specifications

The PMA provides the Transmit function specified in 149.4.2.2 in accordance with the electrical specifications of this clause. The electrical input shall be AC-coupled, i.e., it shall present a high DC common-mode impedance at the MDI. There may be various methods for AC-coupling in actual implementations.

Where a load is not specified, the transmitter shall meet the requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output. Transmitter electrical tests are specified with a load tolerance of ± 0.1%.

149.5.2.1 Maximum output droop

With the transmitter in test mode 6 and using the transmitter test fixture 1 shown in Figure 149–35, the magnitude of both the positive and negative droop shall be less than 15%, measured with respect to an initial value at 4 ns after the zero crossing and a final value at 16 ns after the zero crossing (12 ns period).

149.5.2.2 Transmitter linearity

With the transmitter in test mode 4 and using the transmitter test fixture 1 shown in Figure 149–35, the test defined in 120D.3.1.2 shall be performed. The ideal PAM4 level of 1/3 should be used for effective symbol levels of ES1 and ES2. The transmitter SNDR distortion, as specified in 120D.3.1.6, shall exceed 38 dB in 10GBASE-T1, 36 dB in 5GBASE-T1, and 35 dB in 2.5G modes.

149.5.2.3 Transmitter timing jitter

The transmitter timing jitter is measured by capturing the TX_TCLK_175 waveform in both MASTER and SLAVE configurations while in test mode 1 using the transmitter test fixture 2 shown in Figure 149–36.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When in test mode 1 and the link is up and the two PHYs have established link (link_status is set to OK), the RMS value of the MASTER TX_TCLK_175 jitter relative to an unjittered reference shall be less than 1/*S* ps. The peak-to-peak value of the MASTER TX_TCLK_175 jitter relative to an unjittered reference shall be less than 10/*S* ps. See Table 149–1 for the definition of *S*.

When in test mode 1 and the link is up and the two PHYs have established link (link_status is set to OK), the RMS value of the SLAVE TX_TCLK_175 jitter relative to an unjittered reference shall be less than 2/*S* ps. The peak-to-peak value of the SLAVE TX_TCLK_175 jitter relative to an unjittered reference shall be less than 20/*S* ps.

TX_TCLK_175 jitter shall be measured over an interval of 1 ms ± 10%. The band-pass bandwidth of the capturing device shall be at least 200 MHz (this is equivalent to phase noise integration of the clock over a bandwidth of at least 100 MHz from the carrier frequency). The unjittered reference is a constant clock frequency extracted from each record of captured TX_TCLK_175. The unjittered reference is based on linear regression of frequency and phase that produces minimum Time Interval Error.

149.5.2.3.1 Transmit MDI random jitter in MASTER mode

In addition to jitter measurement for transmit clock, MDI jitter is measured when in test mode 2 with the square wave pattern (see Table 149–18) and using test fixture 3 as shown in Figure 149–37. The RMS value of the MDI output jitter relative to an unjittered reference shall be less than 1/*S* ps. The peak-to-peak value of the MDI output jitter relative to an unjittered reference shall be less than 10/*S* ps. Jitter shall be measured over an interval of 1 ms ± 10%. The band-pass bandwidth of the measurement device shall be larger than 200 MHz. The unjittered reference is a constant clock frequency extracted from each record of captured differential output on MDI. The unjittered reference is based on linear regression of frequency and phase that produces minimum Time Interval Error.

Table 149–18—Jitter test modes

Bit 1.2313.1	Bit 1.2313.0	Test pattern
0	0	Square wave: TX_TCLK_175
0	1	JP03A (as specified in 94.2.9.1)
1	0	JP03B (as specified in 94.2.9.2)
1	1	Reserved

149.5.2.3.2 Transmit MDI deterministic jitter in MASTER mode

Jitter measurements in this subclause are performed with the transmitter enabled in MASTER timing mode in test mode 2, with the patterns as defined by Table 149–18, and timed with a local clock.

To measure the peak-to-peak deterministic jitter ($DJ_{pk\text{-}pk}$) follow the steps as specified in 94.3.12.6.1, with the following modifications to step 5:

$f_n = 1 \times S$ MHz, $T = 68 / S$ ns.

Using this method, $DJ_{pk\text{-}pk}$ shall be less than 9 / *S* ps.

To measure peak-to-peak even-odd jitter ($EOJ_{pk\text{-}pk}$) follow the steps as specified in 94.3.12.6.2.

Using this method, $EOJ_{pk\text{-}pk}$ shall be less than 4 / *S* ps. See Table 149–1 for the definition of *S*.

149.5.2.4 Transmitter power spectral density (PSD) and power level

In test mode 5 (normal operation), the transmit power shall be in the range of –1 dBm to 2 dBm and the power spectral density of the transmitter, measured into a 100 Ω load using test fixture 4 shown in Figure 149–38 shall be between the upper and lower masks specified in Equation (149–14) and Equation (149–15). The upper and lower masks for each data rate, 2.5 Gb/s, 5 Gb/s, and 10 Gb/s, are shown in Figure 149–39. See Table 149–1 for the definition of *S*.

$$UPSD(f) = \begin{cases} -90 - K & \text{dBm/Hz} \quad 0 < f \le 600 \times S \\ -89 - K - \dfrac{f}{600 \times S} & \text{dBm/Hz} \quad 600 \times S < f \le 3000 \times S \\ -82 - K - \dfrac{f}{250 \times S} & \text{dBm/Hz} \quad 3000 \times S < f \le 5500 \times S \end{cases} \tag{149–14}$$

$$LPSD(f) = \begin{cases} -96 - K & \text{dBm/Hz} \quad 5 < f \le 400 \times S \\ -95 - K - \dfrac{f}{400 \times S} & \text{dBm/Hz} \quad 400 \times S < f \le 2000 \times S \\ -90 - K - \dfrac{f}{200 \times S} & \text{dBm/Hz} \quad 2000 \times S < f \le 3000 \times S \end{cases} \tag{149–15}$$

where

f is the frequency in MHz

$$K = 10\log_{10}(S) \tag{149–16}$$

149.5.2.5 Transmitter peak differential output

When measured with 100 Ω termination, the transmit differential signal at the MDI shall be less than 1.3 V peak-to-peak. This limit applies to all transmitted symbol sequences, including SEND_S, SEND_T, and SEND_N.

149.5.2.6 Transmitter clock frequency

The symbol transmission rate of the MASTER PHY shall be within the range $5625 \times S$ MHz ± 50 ppm. See Table 149–1 for the definition of *S*.

For a MASTER PHY, when the transmitter is in the LPI transmit mode, the transmitter clock short-term rate of frequency variation shall be less than 0.1 ppm/second. The short-term frequency variation limit shall also apply when switching to and from the LPI mode.

149.5.3 Receiver electrical specifications

The PMA provides the Receive function specified in 149.4.2.3 in accordance with the electrical specifications of this clause using cabling that is within the limits specified in 149.7.

149.5.3.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of 149.5.2 and have passed through a link specified in 149.7 shall be received with a BER less than 10^{-12} after RS-FEC decoding, and sent to the XGMII after link reset completion. This specification can be verified by a frame error ratio less than 7.8×10^{-9} for 800 octet frames with minimum IPG or greater than 220-octet IPG.

149.5.3.2 Alien crosstalk noise rejection

This specification is provided to verify the receiver's tolerance to alien crosstalk noise. The test is performed with a noise source consisting of a signal generator with Gaussian distribution, bandwidths, and magnitudes shown in Table 149–19. The receive DUT is connected to the noise source through a directional coupler, as shown in Figure 149–40, with a link segment as defined in 149.7. The BER is expected to be less than 10^{-12}, and to satisfy this specification the frame loss ratio is less than 10^{-9} for 125-octet packets measured at the MAC/PLS service interface.

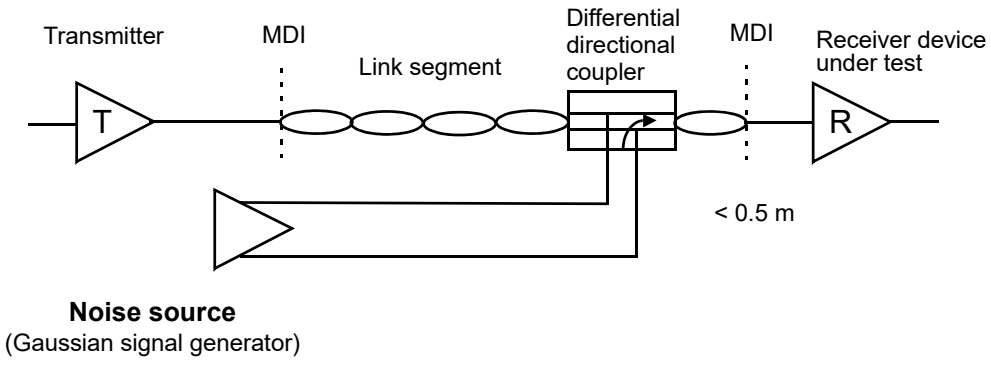

Figure 149–40—Alien crosstalk noise rejection test setup

Table 149–19—Alien crosstalk noise source

PHY type	Noise bandwidth (MHz)	Added noise at MDI (dBm/Hz)
10GBASE-T1	3500	–152
5GBASE-T1	1750	–149
2.5GBASE-T1	875	–146

149.6 Management interface

2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 make extensive use of the management functions that may be provided by the optional MDIO (Clause 45), and the communication and self-configuration functions provided by the optional Auto-Negotiation (Clause 98).

149.6.1 Optional Support for Auto-Negotiation

If Auto-Negotiation is supported and enabled the mechanism described in Clause 98 shall be used.

Auto-Negotiation is performed as part of the initial setup of the link, and allows the PHYs at each end to advertise their capabilities and to automatically select the operating mode for communication on the link. Auto-Negotiation signaling is used for the following primary purposes for 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1:

a) To negotiate that the PHY is capable of supporting 2.5GBASE-T1 transmission.
b) To negotiate that the PHY is capable of supporting 5GBASE-T1 transmission.
c) To negotiate that the PHY is capable of supporting 10GBASE-T1 transmission.
d) To determine the MASTER-SLAVE relationship between the PHYs at each end of the link.

149.7 Link segment characteristics

2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 are designed to operate over a single shielded balanced pair of conductors that meet the requirements specified in this subclause. The single shielded balanced pair of conductors supports an effective data rate of 2.5 Gb/s, 5 Gb/s, and 10 Gb/s in each direction simultaneously. The term *link segment* used in this clause refers to a single balanced pair of conductors (cable or backplane) operating in full duplex.

For the three different PHY types, link segment parameters are specified to different upper frequencies, given by the parameter F_{max} shown in Equation (149–17).

$$F_{max} = 4000 \times S \quad (149–17)$$

See Table 149–1 for the definition of *S*.

149.7.1 Link transmission parameters

The transmission characteristics for the MultiGBASE-T1 link segment are specified to support operation over automotive temperature and electromagnetic conditions.

149.7.1.1 Insertion loss

The insertion loss of each MultiGBASE-T1 link segment shall meet the values determined using Equation (149–18).

$$Insertion\ loss(f) \le 0.002\,f + 0.68 f^{0.45} \quad \text{(dB)} \tag{149–18}$$

where

f is the frequency in MHz; $1 \le f \le F_{max}$

The insertion loss is illustrated in Figure 149–41.

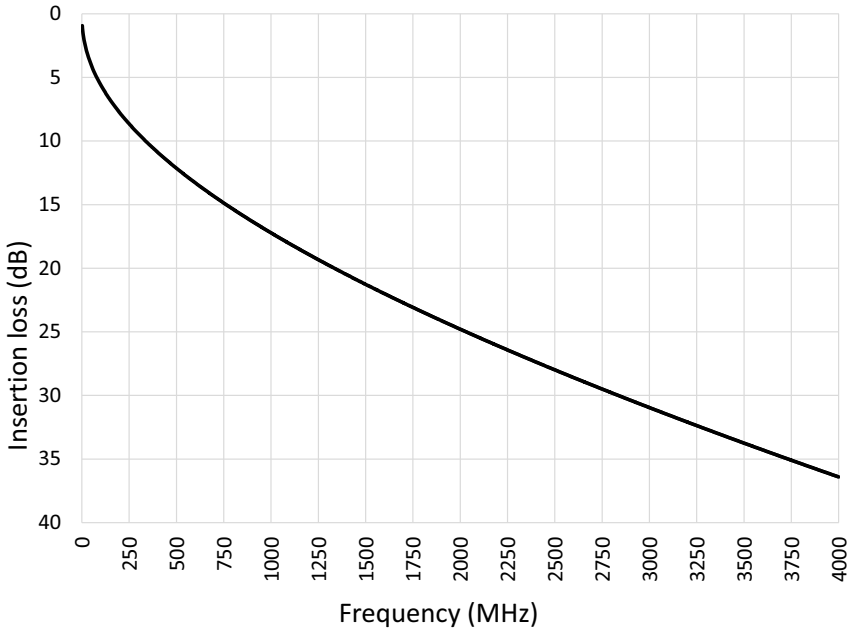

Figure 149–41—Insertion loss calculated using Equation (149–18)

149.7.1.2 Differential characteristic impedance

The nominal differential characteristic impedance of the link segment is 100 Ω.

149.7.1.3 Return loss

149.7.1.3.1 2.5GBASE-T1 link segment return loss

In order to limit the noise at the receiver due to impedance mismatches each 2.5GBASE-T1 link segment shall meet the values determined by using Equation (149–19) at all frequencies from 1 MHz to 1000 MHz. The reference impedance for the return loss specification is 100 Ω.

$$2.5G_Return_Loss \ge \left\{ \begin{array}{ll} 20 & 1 \le f < 240 \\ 20 - 10\log_{10}(f/240) & 240 \le f \le 1000 \end{array} \right\} \text{(dB)} \tag{149–19}$$

where

f is the frequency in MHz; $1 \le f \le 1000$

The 2.5GBASE-T1 return loss is illustrated in Figure 149–42.

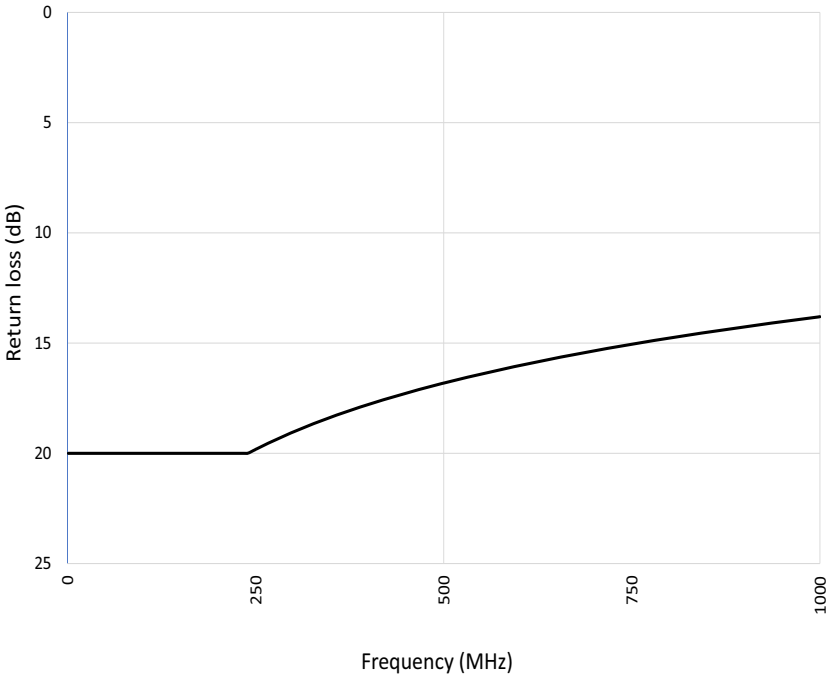

Figure 149–42—Return loss calculated using Equation (149–19)

149.7.1.3.2 5GBASE-T1 link segment return loss

In order to limit the noise at the receiver due to impedance mismatches each 5GBASE-T1 link segment shall meet the values determined by using Equation (149–20) at all frequencies from 1 MHz to 2000 MHz. The reference impedance for the return loss specification is 100 Ω. The return loss is dependent on the insertion loss at 1.5 GHz as determined by using Equation (149–21) to calculate *N*.

$$5G_Return_Loss \ge \left\{ \begin{array}{ll} 20 & 1 \le f < 480/2^N \\ 20 - 10\log_{10}((2^N \times f)/480) & 480/2^N \le f \le 2000 \end{array} \right\} \text{(dB)} \qquad (149\text{–}20)$$

where

f is the frequency in MHz; $1 \le f \le 2000$

$$N = \left\{ \begin{array}{ll} 0 & 15 \text{ dB} < IL\ (1.5\ GHz) \\ 1 & IL\ (1.5\ GHz) \le 15 \text{ dB} \end{array} \right. \qquad (149\text{–}21)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 5GBASE-T1 return loss is illustrated in Figure 149–43.

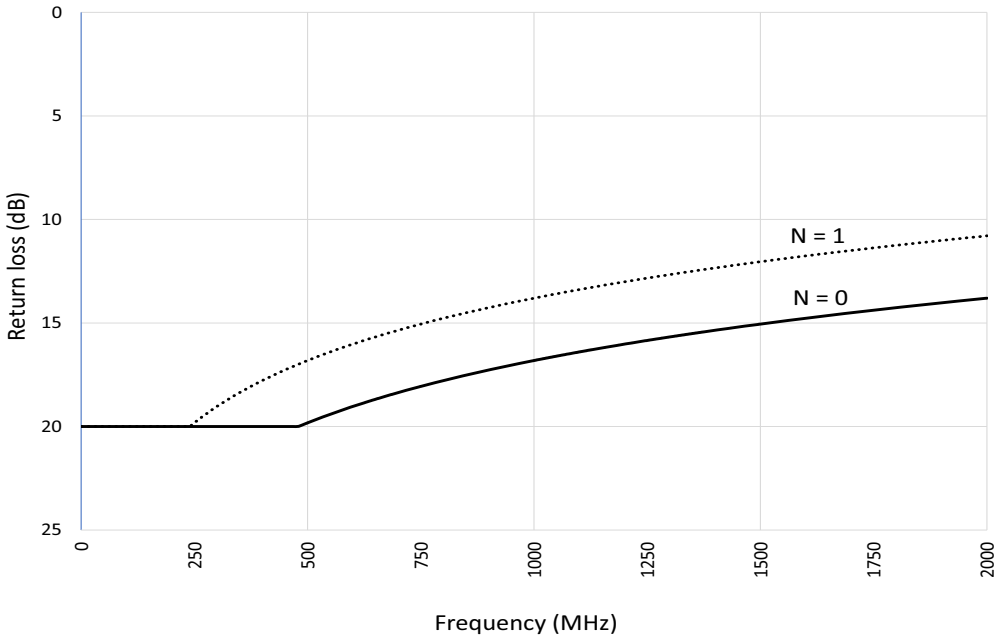

Figure 149–43—Return loss calculated using Equation (149–20) and Equation (149–21)

149.7.1.3.3 10GBASE-T1 link segment return loss

In order to limit the noise at the receiver due to impedance mismatches each 10GBASE-T1 link segment shall meet the values determined by using Equation (149–22) at all frequencies from 1 MHz to 4 GHz. The reference impedance for the return loss specification is 100 Ω. The return loss is dependent on the insertion loss at 3 GHz as determined by using Equation (149–23) to calculate *N*.

$$10G_Return_Loss \geq \left\{ \begin{array}{rl} 20 & 1 \leq f < 480/2^N \\ 20 - 10\log_{10}((2^N \times f)/480) & 480/2^N \leq f < 3000 \\ 12 - 3N & 3000 \leq f \leq 4000 \end{array} \right\} \text{(dB)} \qquad (149\text{–}22)$$

where

f is the frequency in MHz; $1 \leq f \leq 4000$

$$N = \left\{ \begin{array}{ll} 0 & 15 \text{ dB} < IL\ (3\ GHz) \\ 1 & IL\ (3\ GHz) \leq 15 \text{ dB} \end{array} \right. \qquad (149\text{–}23)$$

The 10GBASE-T1 return loss is illustrated in Figure 149–44.

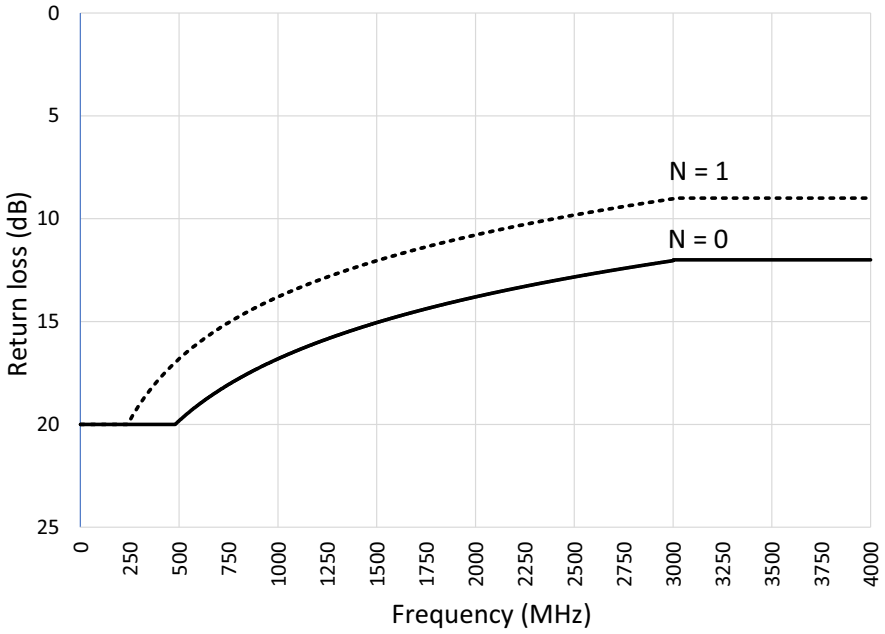

Figure 149–44—Return loss calculated using Equation (149–22) and Equation (149–23)

149.7.1.4 Coupling attenuation

In order to limit the noise at the receiver as well as emissions, when tested using the IEC 62153-4-7 triaxial tube in tube method as specified in Annex 149A, where shielded balanced pair cabling is used, the MultiGBASE-T1 link segment shall meet the coupling attenuation values determined by using Equation (149–24).

$$Coupling\ Attenuation(f) \geq \left\{ \begin{array}{ll} 70 & 30 \leq f < 750\ \text{MHz} \\ 50 - 20\log_{10}\left(\frac{f}{7500}\right) & 750 \leq f \leq 4000\ \text{MHz} \end{array} \right\} \text{(dB)} \qquad (149–24)$$

where

f is the frequency in MHz; $30 \leq f \leq 4000$

The coupling attenuation is illustrated in Figure 149–45.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

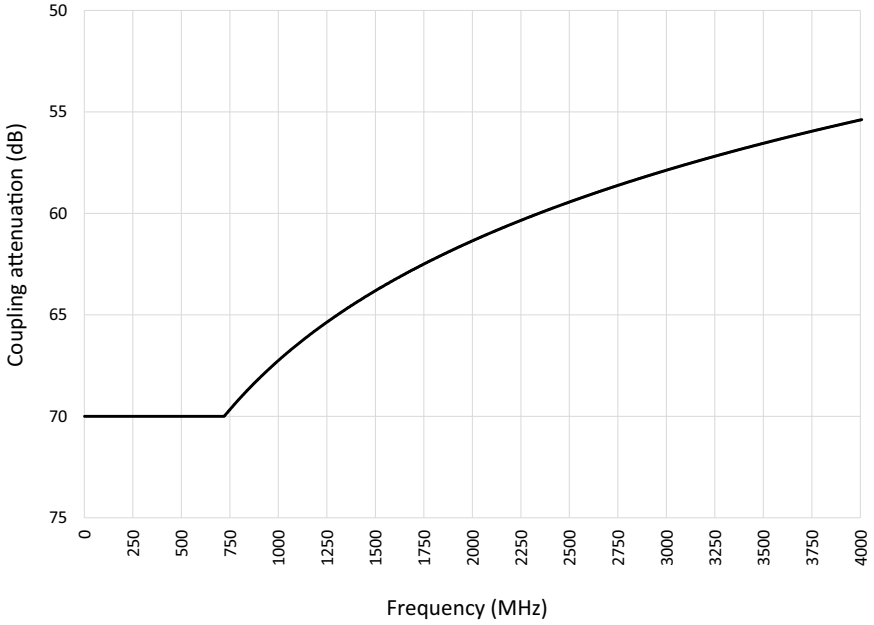

Figure 149–45—Coupling attenuation calculated using Equation (149–24)

149.7.1.5 Screening attenuation

Where shielded balanced pair cabling is used, the minimum screening attenuation for a link segment is 45 dB for all frequencies between 30 MHz and F_{max} MHz. Screening attenuation is tested as specified in IEC 62153-4-7 using triaxial tube-in-tube method. Additional screening attenuation test methodologies are defined in Annex 149A.

149.7.1.6 Maximum link delay

The propagation delay of a link segment shall not exceed 94 ns at all frequencies between 2 MHz and F_{max} MHz.

149.7.2 Coupling parameters between link segments

Noise coupled between the disturbed link segment and the disturbing link segment is referred to as *alien crosstalk noise*. Power sum alien near-end crosstalk (PSANEXT) loss and power sum alien attenuation to crosstalk ratio far-end (PSAACRF) are specified to limit the total alien NEXT and alien FEXT coupled between link segments. The test methodologies are specified in Annex 97B.

For implementations with multiple MultiGBASE-T1 ports on the same MDI connector assembly, coupling between ports on the MDI connector is not considered to be part of the alien crosstalk specifications. For further information, see 149C.5.

149.7.2.1 Power sum alien near-end crosstalk (PSANEXT)

The differential pair-to-pair near-end crosstalk (NEXT) loss between the disturbed link segment and the disturbing link segment is specified to meet the bit error ratio objective by limiting the alien crosstalk at the near end of a link segment. Multiple disturber alien NEXT loss is specified as the power sum of the individual alien NEXT disturbers. The power ANEXT loss is derived using Equation (97–25).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The power sum ANEXT loss between a disturbed link segment and the disturbing link segment shall meet the values determined using Equation (149–25).

$$\text{PSANEXTloss}(f) \geq \min\left(75,\ 80 - 15\log_{10}\frac{f}{100}\right)\ \text{dB} \qquad (149\text{–}25)$$

where

f is the frequency in MHz; $1 \leq f \leq 4000$

PSANEXT is illustrated in Figure 149–46.

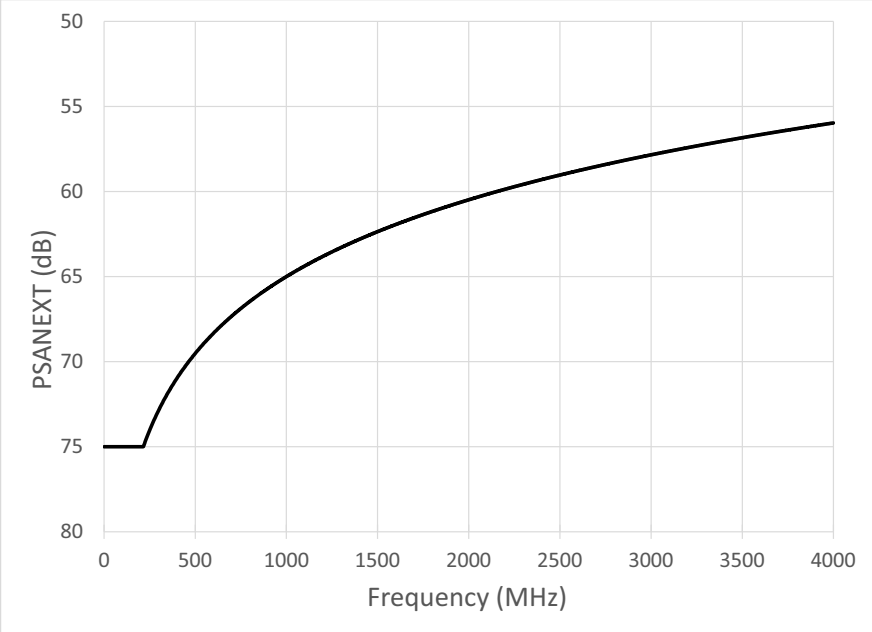

Figure 149–46—PSANEXT calculated using Equation (149–25)

149.7.2.2 Power sum alien attenuation to crosstalk ratio far-end (PSAACRF)

In order to limit the alien crosstalk at the far-end of a link segment, the differential pair-to-pair alien far-end crosstalk (FEXT) loss between the disturbed link segment and the disturbing link segment is specified to meet the bit error ratio objective. Multiple disturber attenuation to crosstalk ratio far-end ACRF is specified as the power sum of the individual alien ACRF disturbers to limit the total alien FEXT coupled into a link segment. The power AACRF is derived using Equation (97–27).

The power sum AACRF between a disturbed link segment and the disturbing link segment shall meet the values determined using Equation (149–26).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{PSAACRF}(f) \geq \min\left(75,\ 86 - 20\log_{10}\frac{f}{100}\right)\ \text{dB} \qquad (149\text{–}26)$$

where

f is the frequency in MHz; $1 \leq f \leq 4000$

PSAACRF is illustrated in Figure 149–47.

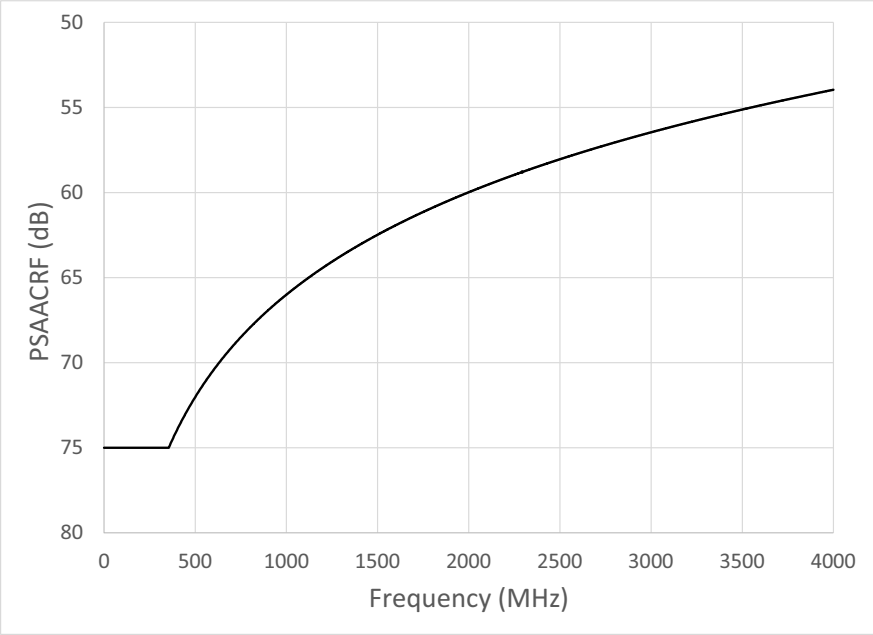

Figure 149–47—PSAACRF calculated using Equation (149–26)

149.8 MDI specification

149.8.1 MDI connectors

Where shielded balanced pair cabling is used, the mechanical interface to the shielded balanced cabling is a 2-pin connector with a shield. Further specification of the mechanical interface is beyond the scope of this standard.

149.8.2 MDI electrical specification

The electrical requirements specified in 149.5.2 and 149.5.3 shall be met when the PHY is connected to the MDI connector mated with a specified connector to a shielded balanced pair of conductors.

149.8.2.1 MDI return loss

The differential impedance at the MDI (see Figure 149–48) for each transmit/receive channel shall be such that any reflection (due to differential signals incident upon the MDI with a test port having a differential impedance of 100 Ω) is attenuated relative to the incident signal per Equation (149–27).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$MDI_Return_Loss(f) \leq \begin{cases} 20 - 20\left(\log_{10}\frac{10}{f}\right) & 1 \leq f < 10 \\ 20 & 10 \leq f < 280S \\ 20 - 10\log_{10}(f/(280S)) & 280S \leq f < 2800S \\ 10 - 16\log_{10}(f/(2800S)) & 2800S \leq f \leq F_{\max} \end{cases} \text{ (dB)} \quad (149\text{–}27)$$

where

f is the frequency in MHz.

For 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1, the maximum applicable frequency for the MDI return loss is 4000 × S MHz. See Table 149–1 for the definition of S.

The MDI return loss is illustrated in Figure 149–48.

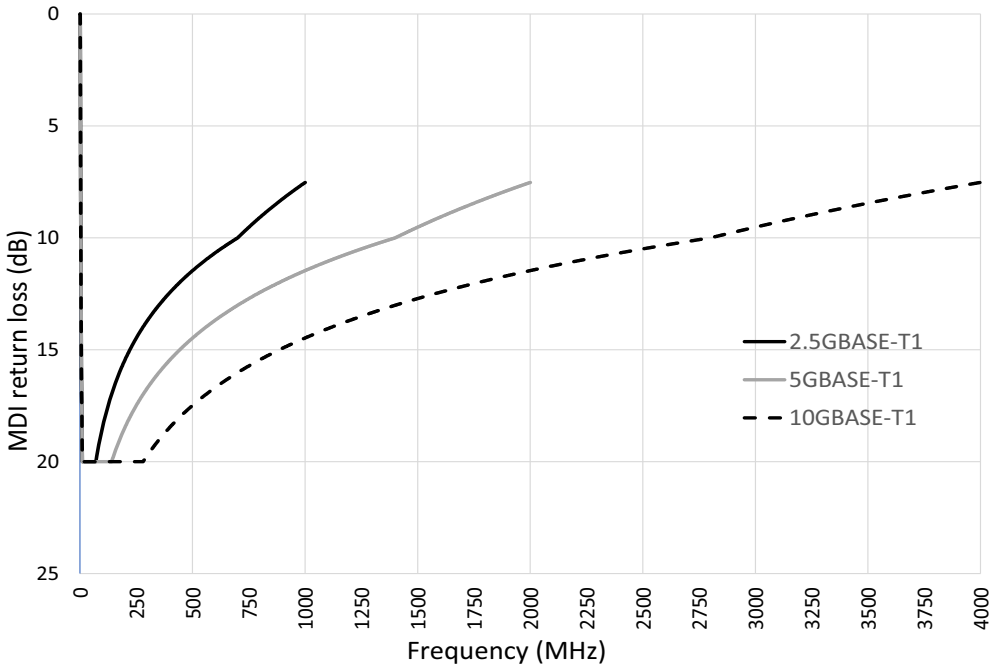

Figure 149–48—MDI return loss calculated using Equation (149–27)

149.8.3 MDI fault tolerance

See 96.8.3.

149.9 Environmental specifications

149.9.1 General safety

All equipment subject to this clause is expected to conform to all applicable local, state, national, and application-specific standards.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.9.2 Network safety

All cabling and equipment subject to this clause is expected to be mechanically and electrically secure in a professional manner.

149.9.2.1 Environmental safety

All equipment subject to this clause, when used in the automotive environment, is expected to conform to the potential environmental stresses with respect to their mounting location, as defined in the following specifications:

a) General loads: ISO 16750–1
b) Electrical loads: ISO 16750–2, ISO 7637–2:2008, and ISO 8820–1
c) Mechanical loads: ISO 16750–3, ASTM D4728, and ISO 12103–1
d) Climatic loads: ISO 16750–4, IEC 60068–2–1, IEC 60068–2–27, IEC 60068–2–30, IEC 60068–2–38, IEC 60068–2–52, IEC 60068–2–64, and IEC 60068–2–78
e) Chemical loads: ISO 16750–5 and ISO 20653

Automotive environmental conditions are generally more severe than those found in many commercial and industrial environments. The target automotive, industrial, or commercial environment(s) require careful analysis prior to implementation.

149.9.2.2 Electromagnetic compatibility

A system integrating a PHY intended for automotive applications is expected to comply with all applicable local and national codes. In addition, the system may need to comply with more stringent requirements for the limitation of electromagnetic interference. When used in an automotive environment, the PHY is expected to meet the following motor vehicle EMC requirements:

a) Radiated/conducted emissions: CISPR 25, IEC 61967–1, IEC 61967–4, and IEC 61000–4–21
b) Radiated/conducted immunity: ISO 11452, IEC 62132–1, IEC 62132–4, and IEC 61000–4–21
c) Electrostatic discharge: ISO 10605, IEC 61000–4–2, and IEC 61000–4–3
d) Electrical disturbances: IEC 62215–3, ISO 7637–2, and ISO 7637–3

Exact test setup and test limit values may be adapted to each specific application.

149.10 Delay constraints

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementers conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The sum of the transmit and receive data delays for an implementation of the PHY shall not exceed the limits shown in Table 149–20. Transmit data delay is measured from the input of a given unit of data at the XGMII to the presentation of the same unit of data by the PHY to the MDI. Receive data delay is measured from the input of a given unit of data at the MDI to the presentation of the same unit of data by the PHY to the XGMII.

NOTE—The physical medium interconnecting two PHYs introduces additional delay in a link.

149.11 Protocol implementation conformance statement (PICS) proforma for Clause 149, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1[246]

149.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 149, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

149.11.2 Identification

149.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

149.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 149, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[246]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

PCT3	PCS 64B/65B Transmit state diagram	149.3.2.2	Figure 149–16 and Figure 149–17.	M	Yes [ ]
PCT4	PCS Transmit bit ordering	149.3.2.2	Figure 149–6.	M	Yes [ ]
PCT5	If a PMA_TXMODE.indication message has the value SEND_Z, PCS Transmit shall pass a vector of zeros at each symbol period to the PMA via the PMA_UNITDATA.request primitive.	149.3.2.2		M	Yes [ ]
PCT6	If a PMA_TXMODE.indication message has the value SEND_T, PCS Transmit shall generate a sequence (T_n) defined in 149.3.5.1 to the PMA via the PMA_UNITDATA.request primitive.	149.3.2.2		M	Yes [ ]
PCT7	If a PMA_TXMODE.indication message has the value SEND_N, the PCS is in the normal mode of operation and the PCS Transmit function shall use a 65B coding technique to generate, at each symbol period, code-groups that represent data or control.	149.3.2.2		M	Yes [ ]
PCT8	All XGMII control code values that do not appear in the Table 149–2 shall not be transmitted and shall be treated as an error if received.	149.3.2.2.5		M	Yes [ ]
PCT9	Idle control characters	149.3.2.2.7	/I/ insertion and deletion shall occur in groups of 4.	M	Yes [ ]
PCT10	Adding Idle control characters	149.3.2.2.7	/I/s shall not be added while data is being received.	M	Yes [ ]
PCT11	Deleting Idle control characters	149.3.2.2.7	When deleting /I/s, the first four characters after a /T/ shall not be deleted.	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PCT12	LPI control characters	149.3.2.2.8	/LI/ insertion and deletion shall occur in groups of four.	M	Yes [ ]
PCT13	Adding LPI control characters	149.3.2.2.8	/LI/s shall not be added while data is being received.	M	Yes [ ]
PCT14	Ordered set	149.3.2.2.11	Sequence ordered set deletion shall only occur when two consecutive sequence ordered sets have been received and shall delete only one of the two.	M	Yes [ ]
PCT15	RS-FEC encoding	149.3.2.2.14	The RS-FEC encoding takes the 3260-bit vector tx_group50x65B, and shall generate the 34 10-bit parity symbols (340 bits total).	M	Yes [ ]
PCT16	Interleave set to depth setting	149.3.2.2.15	Interleaver depth set to value requested by link partner during Infofield exchange.	M	Yes [ ]
PCT17	Round-robin interleaving scheme	149.3.2.2.15	Figure 149–9.	M	Yes [ ]
PCT18	The PCS Transmit shall aggregate L RS-FEC input frames into an interleaved RS-FEC input superframe.	149.3.2.2.15		M	Yes [ ]
PCT19	Gray mapping for PAM4 encoding	149.3.2.2.19	Described in 149.3.2.2.19.	M	Yes [ ]
PCT20	Selectable precoder	149.3.2.2.20	Described in 149.3.2.2.20.	M	Yes [ ]
PCT21	PAM4 encoding	149.3.2.2.21	Described in 149.3.2.2.21.	M	Yes [ ]
PCT22	EEE transmit state diagram	149.3.2.2.22	Figure 149–20.	EEE:M	Yes [ ] N/A [ ]
PCT23	Sleep signal	149.3.2.2.22	Shall be transmitted when an LPI control character in the last 64B/65B block of a Reed-Solomon frame is detected by the PCS Transmit function.	EEE:M	Yes [ ] N/A [ ]
PCT24	After the sleep signal is transmitted, LPI control characters shall be input to the PCS scrambler continuously until the PCS Transmit function exits the LPI transmit mode.	149.3.2.2.22		EEE:M	Yes [ ] N/A [ ]
PCT25	While the PMA asserts SEND_N, the lpi_tx_mode variable shall control the transmit signal through the PMA_UNITDATA.request primitive.	149.3.2.2.22	Described in 149.3.2.2.22.	M	Yes [ ]

149.11.4.2.2 PCS Receive

Item	Feature	Subclause	Value/Comment	Status	Support
PCR1	PCS 64B/65B Receive state diagram	149.3.2.3	Figure 149–18 and Figure 149–19	M	Yes [ ]
PCR2	PCS receive bit ordering	149.3.2.3	Figure 149–7	M	Yes [ ]
PCR3	Frame and block synchronization	149.3.2.3.1	Described in 149.3.2.3.1	M	Yes [ ]
PCR4	MASTER PHY receiver descrambler generator polynomial	149.3.2.3.2	Equation (149–6)	M	Yes [ ]
PCR5	SLAVE PHY receiver descrambler generator polynomial	149.3.2.3.2	Equation (149–5)	M	Yes [ ]
PCR6	RS-FEC parity bits	149.3.2.3.3	Defined in 149.3.2.2.14	M	Yes [ ]

149.11.4.2.3 Test-pattern generators

Item	Feature	Subclause	Value/Comment	Status	Support
TPG1	Transmit PCS operating in test-pattern mode.	149.3.3	Transmit continuously as illustrated in Figure 149–6, with the input to the RS-FEC encoder set to zero and the initial condition of the scrambler set to any non-zero value.	M	Yes [ ]
TPG2	Receive PCS operating in test-pattern mode.	149.3.3	Receive continuously as illustrated in Figure 149–7.	M	Yes [ ]

149.11.4.2.4 Side-stream scrambler

Item	Feature	Subclause	Value/Comment	Status	Support
SSS1	MASTER PCS transmit side-stream scrambler	149.3.4	Equation (149–5).	M	Yes [ ]
SSS2	SLAVE PCS transmit side-stream scrambler	149.3.4	Equation (149–6).	M	Yes [ ]
SSS3	Initialized scrambler state	149.3.4	Never all zeros.	M	Yes [ ]
SSS4	Scrambler starting during PMA training	149.3.4	Continue to run uninterrupted during the transition from PAM2 to PAM4.	M	Yes [ ]
SSS5	Descrambler state synchronization	149.3.5.2	The PHY shall acquire descrambler state synchronization to the PAM2 training sequence and report success through scr_status.	M	Yes [ ]

149.11.4.2.5 LPI signaling

Item	Feature	Subclause	Value/Comment	Status	Support
LPI1	EEE-capable PHYs shall synchronize refresh intervals during LPI mode	149.3.6.1		EEE:M	Yes [ ] N/A [ ]
LPI2	Alert	149.3.6.1	Start at the beginning of any eighth PHY frame boundary starting at the beginning of the frame following a refresh PHY frame.	EEE:M	Yes [ ] N/A [ ]
LPI3	tx_refresh_active	149.3.6.1	Derived from the transmitted PHY frames as shown in Table 149–6.	EEE:M	Yes [ ] N/A [ ]
LPI4	tx_alert_start_next	149.3.6.1	Derived from the transmitted PHY frames as shown in Table 149–7.	EEE:M	Yes [ ] N/A [ ]
LPI5	During the quiet period	149.3.6.2	PHY stops transmitting.	EEE:M	Yes [ ] N/A [ ]

149.11.4.2.6 Functions and state diagrams

Item	Feature	Subclause	Value/Comment	Status	Support
FSD1	lpi_tx_sleep_timer	149.3.7.2.3	Period equal to eight RS-FEC frame periods.	EEE:M	Yes [ ] N/A [ ]
FSD2	lpi_tx_alert_timer	149.3.7.2.3	Period equal to four RS-FEC frame periods.	EEE:M	Yes [ ] N/A [ ]
FSD3	lpi_tx_wake_timer	149.3.7.2.3	Period equal to lpi_wake_time RS-FEC frame periods.	EEE:M	Yes [ ] N/A [ ]
FSD4	lpi_rx_wake_timer	149.3.7.2.3	Period equal to lpi_wake_time RS-FEC frame periods.	EEE:M	Yes [ ] N/A [ ]
FSD5	DECODE function	149.3.7.2.4	Decode the block based on code specified in 149.3.2.2.2.	M	Yes [ ]
FSD6	ENCODE function	149.3.7.2.4	Encode the block as specified in 149.3.2.2.2.	M	Yes [ ]
FSD7	RFER monitor state diagram functions	149.3.7.3	Implemented.	M	Yes [ ]
FSD8	PCS Transmit state diagram functions	149.3.7.3	Implemented.	M	Yes [ ]
FSD9	PCS Receive state diagram functions	149.3.7.3	Implemented.	M	Yes [ ]
FSD10	RFER function during LPI receive operation	149.3.7.3	Not performed from the time that the PCS 64B/65B Receiver enters the state RX_L, until the state RX_W is exited.	EEE:M	Yes [ ] N/A [ ]

149.11.4.2.7 PCS loopback

Item	Feature	Subclause	Value/Comment	Status	Support
PCSL1	Placed in loopback mode	149.3.8.3	When MDIO register 3.0.14 is set to a one.	MDIO:M	Yes [ ] N/A [ ]
PCSL2	When in PCS loopback mode	149.3.8.3	Accept data on the transmit path from the XGMII and return it on the receive path to the XGMII.	M	Yes [ ]
PCSL3	When in PCS loopback mode	149.3.8.3	Transmit a continuous stream of 65B RS-FEC encoded PAM4 symbols to the PMA sublayer.	M	Yes [ ]
PCSL4	When in PCS loopback mode	149.3.8.3	Ignore all data presented to it by the PMA sublayer.	M	Yes [ ]

149.11.4.2.8 OAM

Item	Feature	Subclause	Value/Comment	Status	Support
OAM1	State diagram behavior	149.3.9.4	Conforms to Figure 149–24 and Figure 149–25	OAM:M	Yes [ ] N/A [ ]
OAM2	When the PCS frame is operating in interleaved mode of 2x or 4x, the first symbol (OAM<0>) shall be inserted in the first RS frame in the superframe so that the full OAM frame can packed into 8 superframes in the 2x interleaved mode, and into 4 superframes in the 4x interleaved mode.	149.3.9.2.1		OAM:M	Yes [ ] N/A [ ]
OAM3	Partially transmitted OAM frame	149.3.9.2.1	Described in 149.3.9.2.1	OAM:M	Yes [ ] N/A [ ]
OAM4	When OAM is not implemented	149.3.9.2.1	10-bit OAM field shall be set to all 0's	OAM:M	Yes [ ] N/A [ ]
OAM5	OAM frame data	149.3.9.2.2	Reserved fields shall be set to 0	OAM:M	Yes [ ] N/A [ ]
OAM6	OAM frame data symbol encoding	149.3.9.2.13	Using Reed-Solomon code (16,14)	OAM:M	Yes [ ] N/A [ ]
OAM7	Parity calculation	149.3.9.2.13	Same result as the shift register implementation shown in Figure 149–23	OAM:M	Yes [ ] N/A [ ]
OAM8	OAM Reed-Solomon shift register	149.3.9.2.13	Initialized to zero	OAM:M	Yes [ ] N/A [ ]
OAM9	BASE-T1 OAM Frame acceptance criteria	149.3.9.2.14	Described in 149.3.9.2.14	OAM:M	Yes [ ] N/A [ ]
OAMl0	If a PHY is already in LPI mode and receives SNR<1:0> set to 01 by its link partner.	149.3.9.2.15	Immediately exit LPI	EEE*O AM:M	Yes [ ] N/A [ ]
OAMl1	mr_tx_received	149.3.9.4.3	Clear on read	OAM:M	Yes [ ] N/A [ ]

149.11.4.3 Physical Medium Attachment (PMA)

149.11.4.3.1 PMA Reset function

Item	Feature	Subclause	Value/Comment	Status	Support
PR1	PMA Reset	149.4.2.1	Described in 149.4.2.1	M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.11.4.3.2 PMA Transmit function

Item	Feature	Subclause	Value/Comment	Status	Support
PMAT1	When the PHY Control state diagram is not in the DISABLE_TRANSMITTER state, PMA Transmit.	149.4.2.2	Continuously transmit pulses modulated by the symbols given by tx_symb onto the MDI.	M	Yes [ ]
PMAT2	During Link Synchronization, when sync_link_control = DISABLE and Auto-Negotiation is either not enabled or is not implemented, the sync_tx_symb output by the PHY Link Synchronization function shall be used in place of tx_symb as the data source for PMA Transmit.	149.4.2.2		AN:M	Yes [ ] N/A [ ]
PMAT3	When lpi_tx_mode = ALERT, the PN sequence defined in 149.4.2.6 shall be used in place of tx_symb as the data source for PMA Transmit.	149.4.2.2		EEE:M	Yes [ ] N/A [ ]
PMAT4	Signals generated by PMA Transmit.	149.4.2.2	Comply with 149.1.3.	M	Yes [ ]
PMAT5	TX_TCLK when MASTER	149.4.2.2	Sourced from a local clock source while meeting the transmit jitter requirements of 149.5.2.3.	M	Yes [ ]
PMAT6	MASTER-SLAVE relationship	149.4.2.2	Include loop timing.	M	Yes [ ]
PMAT7	TX_TCLK when SLAVE	149.4.2.2	Sourced from the recovered clock of 149.4.2.8 while meeting the transmit jitter requirements of 149.5.2.3.	M	Yes [ ]
PMAT8	PMA transmit fault function	149.4.2.2	Mapped to the transmit fault bit as specified in 45.2.1.7.4.	MDIO:M	Yes [ ] N/A [ ]
PMAT9	Average launch power of the transmitter when the PMA_transmit_disable variable is set to TRUE.	149.4.2.2.1	Less than –53 dBm.	M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.11.4.3.3 PMA Receive function

Item	Feature	Subclause	Value/Comment	Status	Support
PMAR1	Quality of received symbols	149.4.2.3	RFER of less than 2×10^{-10} after RS-FEC decoding, over a channel meeting the requirements of 149.7.	M	Yes [ ]
PMAR2	If the MDIO interface is implemented, then this function shall contribute to the receive fault bit specified in 45.2.1.243.7.	149.4.2.3		MDIO:M	Yes [ ] N/A [ ]

149.11.4.3.4 PHY Control function

Item	Feature	Subclause	Value/Comment	Status	Support
PCF1	PHY Control state diagram	149.4.2.4	Figure 149–32	M	Yes [ ]
PCF2	12-octet Infofield	149.4.2.4	Include the fields in 149.4.2.4.2 through 149.4.2.4.8	M	Yes [ ]
PCF3	Infofield shall be transmitted at least 256 times with each change to octets 7 to 10.	149.4.2.4		M	Yes [ ]
PCF4	Infofield reserved bits	149.4.2.4.1	Set to zero on transmit and ignored when received by the link partner	M	Yes [ ]
PCF5	Start of Frame Delimiter hexadecimal value	149.4.2.4.2	0xBBA700	M	Yes [ ]
PCF6	PMA_state<7:6>	149.4.2.4.4	Communicate the state of the transmitting transceiver to the link partner	M	Yes [ ]
PCF7	Any Message Field value not listed in Table 149–10 or Table 149–11 shall not be transmitted and shall be ignored at the receiver.	149.4.2.4.4		M	Yes [ ]
PCF8	Any Message Field value not listed in Table 149–10 or Table 149–11 shall be ignored at the receiver.	149.4.2.4.4		M	Yes [ ]
PCF9	The Message Field setting for the first transmitted PMA frame shall be the first row of Table 149–10 for the MASTER and the first or second row of Table 149–11 for the SLAVE.	149.4.2.4.4		M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
PCF10	For a given Message Field setting, the next Message Field setting shall be the same Message Field setting or the Message Field setting corresponding to a row below the current setting.	149.4.2.4.4		M	Yes [ ]
PCF11	The optional EEE capability shall be enabled only if both PHYs set the capability bit EEEen = 1.	149.4.2.4.5		EEE:M	Yes [ ] N/A [ ]
PCF12	The optional BASE-T1 OAM capability shall be enabled only if both PHYs set the capability bit OAMen = 1.	149.4.2.4.5		OAM:M	Yes [ ] N/A [ ]
PCF13	The capability bit values shall be considered as valid only when the loc_rcvr_status bit is 1.	149.4.2.4.5		M	Yes [ ]
PCF14	Remaining PHY capability bits shall be reserved and set to 0.	149.4.2.4.5		M	Yes [ ]
PCF15	DataSwPFC24	149.4.2.4.6	Set to an integer multiple of 16	M	Yes [ ]
PCF16	DataSwPFC24 on switch from PAM2 to PAM4		Minimum of 4081 and maximum of 4785	M	Yes [ ]
PCF17	CRC16 polynomial	149.4.2.4.8	$(x + 1)(x^{15} + x + 1)$ of the previous 7 octets	M	Yes [ ]
PCF18	CRC16	149.4.2.4.8	Figure 149–29	M	Yes [ ]
PCF19	CRC16 delay elements	149.4.2.4.8	All initialized to zero	M	Yes [ ]
PCF20	Startup sequence	149.4.2.4.10	Comply with Figure 149–32	M	Yes [ ]
PCF21	During startup, prior to entering the COUNTDOWN state, the SLAVE shall align its transmit 65B RS-FEC frame to within +0/–4 × *S* partial PHY frames of the MASTER as seen at the SLAVE MDI.	149.4.2.4.10		M	Yes [ ]
PCF22	SLAVE Infofield partial PHY frame count	149.4.2.4.10	Match the MASTER Infofield partial PHY frame count for the aligned frame	M	Yes [ ]
PCF23	MASTER startup timing	149.4.2.4.10	Comply with values in Table 149–15	M	Yes [ ]
PCF24	SLAVE startup timing	149.4.2.4.10	Comply with values in Table 149–16	M	Yes [ ]

149.11.4.3.5 Link Monitor function

Item	Feature	Subclause	Value/Comment	Status	Support
LMK1	Link Monitor function	149.4.2.5	Comply with Figure 149–33	M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149.11.4.3.6 PHY Link Synchronization

Item	Feature	Subclause	Value/Comment	Status	Support
PLS1	Link Synchronization PHY PMA training when Auto-Negotiation is disabled or not implemented.	149.4.2.6	Described in 149.4.2.4.	M	Yes [ ]
PLS2	SEND_S signal frequency	149.4.2.6	703.125 MHz.	M	Yes [ ]
PLS3	MASTER PN sequence generator	149.4.2.6	Equation (149–10).	M	Yes [ ]
PLS4	SLAVE PN sequence generator	149.4.2.6	Equation (149–11).	M	Yes [ ]
PLS5	PN sequence generator shift registers when entering TRANSMIT_DISABLE state.	149.4.2.6	reset to S[7:0] = 0000 0001.	M	Yes [ ]
PLS6	10GBASE-T1 mapping of $S_n[0]$ to T_n	149.4.2.6	If $Sn[0] = 0$ then $T_n = +1\ +1\ +1\ +1\ +1\ +1\ +1\ +1$. If $Sn[0] = 1$ then $T_n = -1\ -1\ -1\ -1\ -1\ -1\ -1\ -1$.	M	Yes [ ]
PLS7	5GBASE-T1 mapping of $S_n[0]$ to T_n	149.4.2.6	If $Sn[0] = 0$ then $T_n = +1\ +1\ +1\ +1$. If $Sn[0] = 1$ then $T_n = -1\ -1\ -1\ -1$.	M	Yes [ ]
PLS8	2.5GBASE-T1 mapping of $S_n[0]$ to T_n	149.4.2.6	If $Sn[0] = 0$ then $T_n = +1\ +1$. If $Sn[0] = 1$ then $T_n = -1\ -1$.	M	Yes [ ]
PLS9	The synchronization state diagram shall be used to synchronize 2.5GBASE-T1, 5GBASET1, or 10GBASE-T1 PHYs prior to the MultiGBASE-T1 link training.	149.4.2.6		M	Yes [ ]
PLS10	If Clause 98 Auto-Negotiation function is enabled, then the Auto-Negotiation function shall be used as the mechanism for PHY synchronization and the synchronization state diagram in Figure 149–31 remains in the SYNC_DISABLE state.	149.4.2.6		AN:M	Yes [ ] N/A [ ]
PLS11	send_s_sigdet	149.4.2.6.1	This variable shall be set FALSE no later than 1 µs after the signal goes quiet on the MDI.	M	Yes [ ]
PLS12	send_s_timer	149.4.2.6.2	Expires 1.25 µs ± 0.05 µs after being started.	M	Yes [ ]
PLS13	sigdet_wait_timer	149.4.2.6.2	Expires 5 µs ± 0.15 µs after being started.	M	Yes [ ]

149.11.4.3.7 Refresh monitor function

Item	Feature	Subclause	Value/Comment	Status	Support
RMF1	Refresh monitor function	149.4.2.7	Comply with Figure 149–34	EEE:M	Yes [ ] N/A [ ]

149.11.4.3.8 Clock Recovery function

Item	Feature	Subclause	Value/Comment	Status	Support
CRF1	Clock Recovery function	149.4.2.8	Provide a clock suitable for signal sampling so that the RS FER indicated in 149.4.2.3 is achieved	M	Yes [ ]

149.11.4.3.9 MDI

Item	Feature	Subclause	Value/Comment	Status	Support
MDIS1	Symbol response $s(t)$	149.4.3.1	Comply with the electrical specifications given in 149.5.2	M	Yes [ ]

149.11.4.3.10 PMA State variables

Item	Feature	Subclause	Value/Comment	Status	Support
PMAS1	minwait_timer	149.4.4.2	Expires 975 μs ± 50 μs after being started	M	Yes [ ]
PMAS2	lpi_refresh_rx_timer	149.4.4.2	Period equal to 50 complete quiet-refresh signal periods, equivalent to 1.536/S ms	EEE:M	Yes [ ] N/A [ ]

Copyright © 2022 IEEE. All rights reserved.

149.11.4.4 PMA electrical specifications

149.11.4.4.1 Test modes

Item	Feature	Subclause	Value/Comment	Status	Support
TM1	Test modes	149.5.1	Provided to allow for testing of the transmitter jitter, transmitter distortion, transmitter PSD, transmitter droop, and BER testing	M	Yes [ ]
TM2	Test mode enabling	149.5.1	Enabled by setting a control register, 1.2313.15:13, or equivalent functionality	MDIO:M	Yes [ ] N/A [ ]
TM3	The test modes shall only change the data symbols provided to the transmitter circuitry and do not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal operation.	149.5.1		M	Yes [ ]
TM4	Test Mode 1	149.5.1	Described in 149.5.1	M	Yes [ ]
TM5	Test Mode 2	149.5.1	Described in 149.5.1	M	Yes [ ]
TM6	Test Mode 3	149.5.1	Described in 149.5.1	M	Yes [ ]
TM7	Test Mode 4	149.5.1	Described in 149.5.1	M	Yes [ ]
TM8	Test Mode 5	149.5.1	Described in 149.5.1	M	Yes [ ]
TM9	Test Mode 6	149.5.1	Described in 149.5.1	M	Yes [ ]

149.11.4.4.2 Transmitter electrical specifications

Item	Feature	Subclause	Value/Comment	Status	Support
TES1	Coupling	149.5.2	Operate with AC coupling to the MDI	M	Yes [ ]
TES2	Resistive differential load	149.5.2	Meet electrical requirements of this clause with a 100 Ω resistive differential load connected to transmitter output if load is not specified	M	Yes [ ]
TES3	Maximum output droop	149.5.2.1	Positive and negative droop shall be less than 15%	M	Yes [ ]
TES4	Transmitter linearity	149.5.2.2	Defined in 120D.3.1.2	M	Yes [ ]

150. Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR4.2

150.1 Overview

This clause specifies the 400GBASE-SR4.2 PMD together with the multimode fiber medium. 400GBASE-SR4.2 uses the same media as 200GBASE-SR4. The 4.2 nomenclature is used to indicate that transmission is over four fiber pairs (eight individual fibers) with the use of two wavelengths. For 400GBASE-SR4.2 these wavelengths propagate in opposite directions on each individual fiber. The optical signal generated by this PMD type is modulated using a 4-level pulse amplitude modulation (PAM4) format. The PMD sublayer provides point-to-point 400 Gigabit Ethernet links over four pairs of multimode fiber, with a reach of up to at least 70 m on OM3, 100 m on OM4, and 150 m on OM5. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA, as shown in Table 150–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 150–1—Physical Layer clauses associated with the 400GBASE-SR4.2 PMD

Associated clause	400GBASE-SR4.2
117—RS	Required
117—400GMII[a]	Optional
118—400GMII Extender	Optional
119—PCS for 400GBASE-R	Required
120—PMA for 400GBASE-R	Required
120B—400GAUI-16 C2C	Optional
120C—400GAUI-16 C2M	Optional
120D—400GAUI-8 C2C	Optional
120E—400GAUI-8 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a]The 400GMII is an optional interface. However, if the 400GMII is not implemented, a conforming implementation is required to behave functionally as though the RS and 400GMII were present.

Figure 150–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 400 Gigabit Ethernet is introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

400GBASE-SR4.2 PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions and abbreviations) and Annex A (bibliography, referenced as [B1], [B2], etc.).

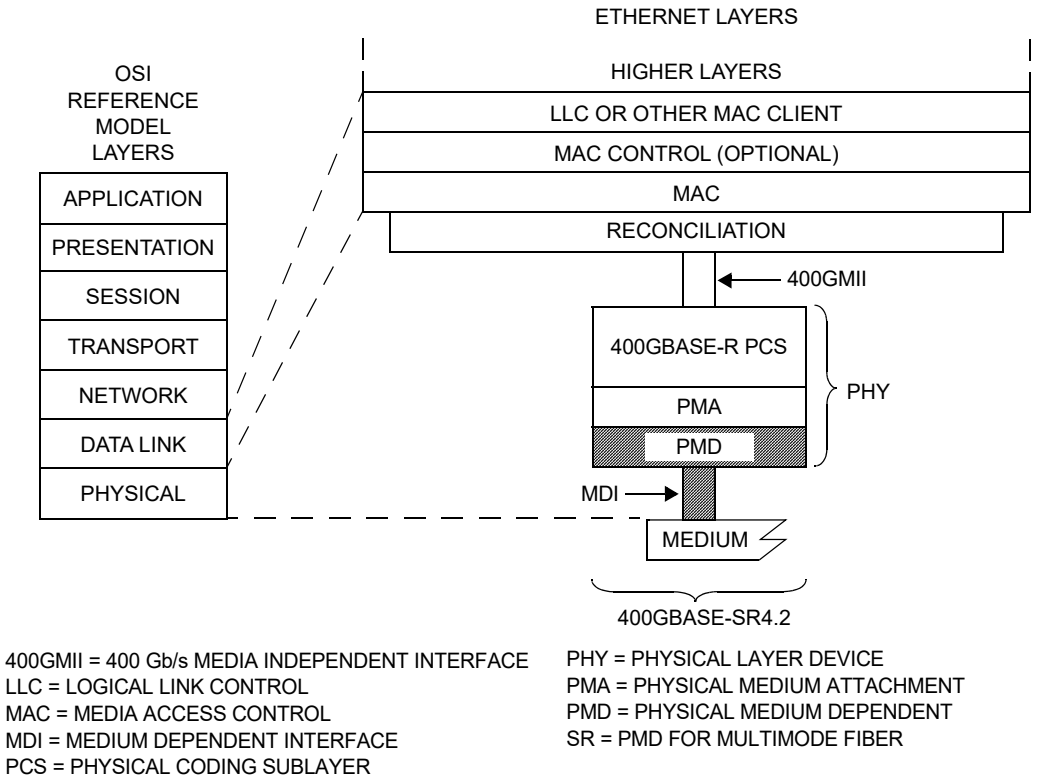

Figure 150–1—400GBASE-SR4.2 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

150.1.1 Bit error ratio

The bit error ratio (BER) when processed by the PMA (Clause 120) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when additionally processed by the PCS (Clause 119). For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces. If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

150.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 400GBASE-SR4.2 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 400GBASE-SR4.2 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with eight parallel symbol streams (n = 8).

The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 400GBASE-SR4.2 PMD has eight parallel symbol streams, hence i = 0 to 7.

In the transmit direction, the PMA continuously sends n streams of PAM4 symbols to the PMD, one per lane, using the PMD:IS_UNITDATA_*i*.request primitive, at a nominal signaling rate of 26.5625 GBd. The PMD converts these streams of symbols into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends n streams of PAM4 symbols to the PMA, corresponding to the signals received from the MDI, one per lane, using the PMD:IS_UNITDATA_*i*.indication primitive, at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable SIGNAL_DETECT parameter as defined in 150.5.4. The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 150.1.1.

150.3 Delay and Skew

150.3.1 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation.

The sum of the transmit and receive delays at one end of the link contributed by the 400GBASE-SR4.2 PMD including 2 m of fiber in one direction shall be no more than 8192 bit times (16 pause_quanta or 20.48 ns).

Descriptions of overall system delay constraints and the definitions for bit times and pause_quanta, can be found in 116.4 and its references.

150.3.2 Skew constraints

The Skew (relative delay) between the PCS lanes is kept within limits so that the information on the PCS lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane.

Skew and Skew Variation are defined in 116.5 and specified at the points SP1 to SP6 shown in Figure 116–4 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 116.5.

150.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 150–2, and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 150–3.

Table 150–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 7 to PMD transmit disable 0	PMD transmit disable register	1.9.8 to 1.9.1	PMD_transmit_disable_7 to PMD_transmit_disable_0

Table 150–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 7 to PMD receive signal detect 0	PMD receive signal detect register	1.10.8 to 1.10.1	PMD_signal_detect_7 to PMD_signal_detect_0

150.5 PMD functional specifications

The 400GBASE-SR4.2 PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

150.5.1 PMD block diagram

The PMD block diagram is shown in Figure 150–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a multimode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 150.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 150.10.3). Unless specified otherwise, all receiver measurements and tests defined in 150.8 are made at TP3.

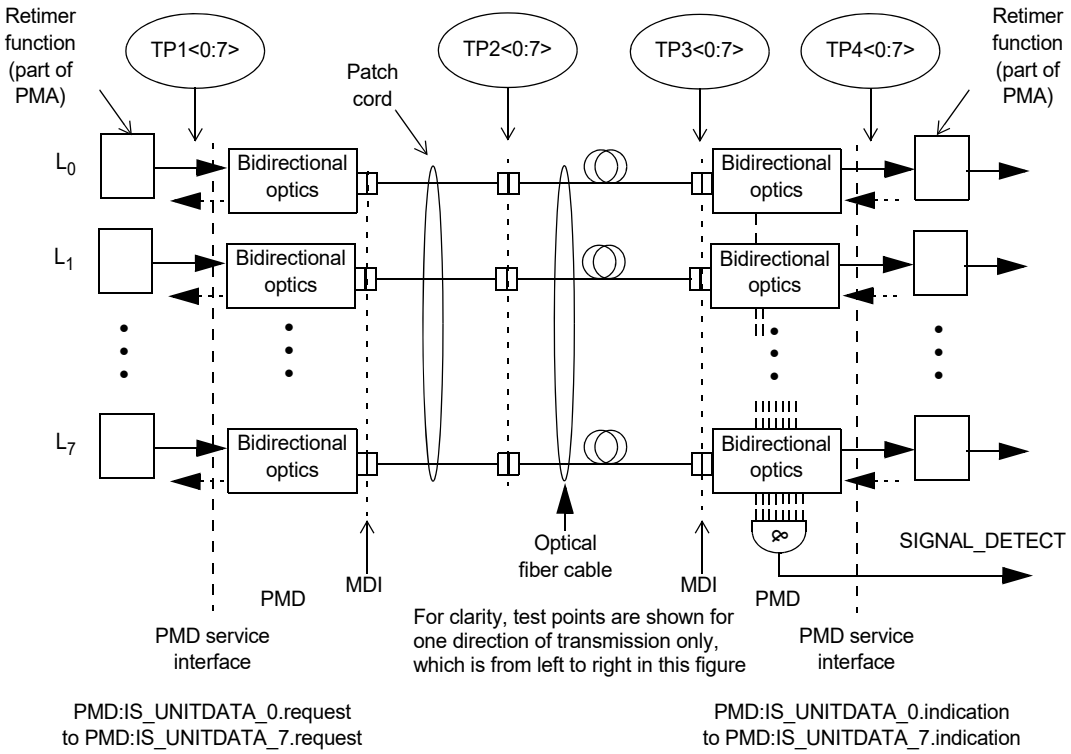

Figure 150–2—Block diagram for 400GBASE-SR4.2 transmit/receive paths

TP1<0:7> and TP4<0:7> are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

150.5.2 PMD transmit function

The PMD Transmit function shall convert the eight signals requested by the PMD service interface messages PMD:IS_UNITDATA_*i*.request into eight separate optical signals. The 400GBASE-SR4.2 PMD has eight parallel symbol streams, hence $i = 0$ to 7. Each optical signal shall then be delivered to the MDI, which contains eight parallel light paths for transmit, according to the transmit optical specifications in this clause. The four optical power levels in the signal in order from lowest to highest shall correspond to tx_symbol values zero, one, two, and three, respectively.

150.5.3 PMD receive function

The PMD Receive function shall convert the eight parallel optical signals received from the MDI into separate symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_7.indication, all according to the receive

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

optical specifications in this clause. The four optical power levels in each signal in order from lowest to highest shall correspond to rx_symbol values zero, one, two, and three, respectively.

150.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 116.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 150–4. The PMD receiver is not required to verify whether a compliant 400GBASE-SR4.2 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 150–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For TxRx pair type TR[a]; Average optical power at TP3 ≤ –30 dBm for wavelength range 900 nm to 918 nm	FAIL
For TxRx pair type RT[a]; Average optical power at TP3 ≤ –30 dBm for wavelength range 844 nm to 863 nm	FAIL
For TxRx pair type TR[a]; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 150–7 for wavelength range 900 nm to 918 nm) AND (compliant 400GBASE-SR4.2 signal input)]	OK
For TxRx pair type RT[a]; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 150–7 for wavelength range 844 nm to 863 nm) AND (compliant 400GBASE-SR4.2 signal input)]	OK
All other conditions	Unspecified

[a]TxRx pair types are defined in 150.6.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

150.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:7, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 150–4.

150.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

150.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 150–7.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

150.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitter in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:7) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 150–7.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane.

150.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

150.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set PMD_transmit_fault to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

150.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

150.6 Wavelength ranges

The transmit and receive wavelength ranges for the 400GBASE-SR4.2 PMD are defined in Table 150–5. Two TxRx pair types (combinations of Tx and Rx types that connect to a single fiber) are defined:

— TxRx pair type TR comprises a transmitter that uses the wavelength range 844 nm to 863 nm and a receiver that uses the wavelength range 900 nm to 918 nm.

— TxRx pair type RT comprises a transmitter that uses the wavelength range 900 nm to 918 nm and a receiver that uses the wavelength range 844 nm to 863 nm.

When connecting a 400GBASE-SR4.2 PMD to another 400GBASE-SR4.2 PMD, it is a requirement that every TxRx pair type RT at each end of the link be connected to a TxRx pair type TR at the other end of the link. The positioning of transmit and receive lanes at the MDI is specified in 150.10.3.1.

NOTE—There is no requirement to associate a particular electrical lane with a particular optical lane, as the PCS is capable of receiving lanes in any arrangement.

Table 150–5—Wavelength ranges

TxRx pair type	Transmit wavelength range	Receive wavelength range
TR	844 nm to 863 nm	900 nm to 918 nm
RT	900 nm to 918 nm	844 nm to 863 nm

150.7 PMD to MDI optical specifications for 400GBASE-SR4.2

The operating range for the 400GBASE-SR4.2 PMD is defined in Table 150–6. A compliant PMD operates on 50/125 μm multimode fibers, type A1a.2 (OM3), type A1a.3 (OM4), or type A1a.4 (OM5), according to the specifications defined in Table 150–13. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 400GBASE-SR4.2 PMD operating at 120 m on OM4 meets the operating range requirement of 0.5 m to 100 m on OM4).

Table 150–6—Operating range

PMD type	Required operating range[a]
400GBASE-SR4.2	0.5 m to 70 m for OM3
	0.5 m to 100 m for OM4
	0.5 m to 150 m for OM5

[a]The PCS FEC correction function may not be bypassed for any operating distance.

150.7.1 Transmitter optical specifications

Each lane of a 400GBASE-SR4.2 transmitter shall meet the specifications in Table 150–7 per the definitions in 150.8.

Table 150–7—Transmit characteristics

Description	Value	Unit
Signaling rate, each lane (range)	26.5625 ± 100 ppm	GBd
Modulation format	PAM4	—
Center wavelength (range), λ_1 for TxRx pair type TR Center wavelength (range), λ_2 for TxRx pair type RT	844 to 863 900 to 918	nm nm
RMS spectral width[a] (max) for TxRx pair type TR RMS spectral width[a] (max) for TxRx pair type RT	0.6 0.65	nm nm
Average launch power, each lane (max)	4	dBm
Average launch power, each lane (min)	–6.2	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	3	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min)[b]	–4.2	dBm
Launch power in OMA_{outer} minus TDECQ (min)	–5.6	dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	4.5	dB
TDECQ – $10\log_{10}(C_{eq})$[c], each lane (max)	4.5	dB
Average launch power of OFF transmitter, each lane (max)	–30	dBm
Extinction ratio, each lane (min)	3	dB
Transmitter transition time, each lane (max)	31	ps
$RIN_{12}OMA$ (max)	–128	dB/Hz
Optical return loss tolerance (max)	12	dB
Encircled flux[d]	≥ 86% at 19 μm ≤ 30% at 4.5 μm	—

[a]RMS spectral width is the standard deviation of the spectrum.
[b]Even if the TDECQ < 1.4 dB, the OMA (min) has to exceed this value.
[c]C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d]If measured into type A1a.2, type A1a.3, or type A1a.4, 50 μm fiber, in accordance with IEC 61280-1-4:2009.

150.7.2 Receiver optical specifications

Each lane of a 400GBASE-SR4.2 receiver shall meet the specifications in Table 150–8 per the definitions in 150.8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 150–8—Receive characteristics

Description	Value	Unit

Center wavelength (range), λ_1 for TxRx pair type RT Center wavelength (range), λ_2 for TxRx pair type TR	844 to 863 900 to 918	nm nm
Damage threshold[a] (min)	5	dBm
Average receive power, each lane (max)	4	dBm
Average receive power, each lane[b] (min)	–8.2	dBm
Receive power, each lane (OMA_{outer}) (max)	3	dBm
Receiver reflectance (max)	–12	dB
Stressed receiver sensitivity (OMA_{outer}), each lane[c] (max)	–3.5	dBm
Receiver sensitivity (OMA_{outer}), each lane[d] (max)	Equation (150–1)	dBm
Conditions of stressed receiver sensitivity test:[e]		
Stressed eye closure for PAM4 (SECQ), lane under test	4.5	dB
SECQ – $10\log_{10}(C_{eq})$[f] (max), lane under test	4.5	dB
OMA_{outer} of each aggressor lane	3	dBm

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level on one lane. The receiver does not have to operate correctly at this input power.
[b]Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c]Measured with conformance test signal at TP3 (see 150.8.10) for the BER specified in 150.1.1.
[d]Receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 4.5 dB.
[e]These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.
[f]C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.

150.7.3 Illustrative link power budget

An illustrative power budget and penalties for 400GBASE-SR4.2 channels, which apply to both wavelength ranges, are shown in Table 150–9.

Table 150–9—Illustrative link power budget

Parameter	OM3	OM4	OM5	Unit
Effective modal bandwidth at 850 nm (min)[a]	2000	4700		MHz·km
Effective modal bandwidth at 910 nm (min)[a]	1260	1980	3100	MHz·km
Power budget (for max TDECQ)	6.9			dB
Operating distance	0.5 to 70	0.5 to 100	0.5 to 150	m
Channel insertion loss[b]	1.7	1.8	2	dB
Allocation for penalties[c] (for max TDECQ)	4.9			dB
Additional insertion loss allowed	0.3	0.2	0	dB

[a]Per IEC 60793-2-10.
[b]The channel insertion loss is calculated using the maximum distance specified in Table 150–6 and cabled optical fiber attenuation of 3 dB/km at 850 nm plus an allocation for connection and splice loss given in 150.10.2.2.1.
[c]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

150.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

150.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 150–11 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 150–11 may be used to perform that test. The test patterns used in this clause are shown in Table 150–10.

Table 150–10—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle	119.2.4.9
6	SSPRQ	120.5.11.2.3

Table 150–11—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength, spectral width	3, 4, 5, 6, or valid 400GBASE-SR4.2 signal	150.8.2
Average optical power	3, 4, 5, 6, or valid 400GBASE-SR4.2 signal	150.8.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	150.8.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	150.8.5
Extinction ratio	4 or 6	150.8.6
Transmitter transition time	Square wave or 6	150.8.7
$RIN_{12}OMA$	Square wave	150.8.8
Stressed receiver sensitivity	3, 5, or valid 400GBASE-SR4.2 signal	150.8.10
Stressed eye closure for PAM4 (SECQ), calibration	6	150.8.10

150.8.1.1 Multi-lane testing considerations

Stressed receiver sensitivity is defined for each lane at the BER specified in 150.1.1. Measurements with Pattern 3 (PRBS31Q) allow lane-by-lane BER measurements. In stressed receiver sensitivity measurements, unstressed lanes may be created by setting the power at the receiver under test well above its sensitivity and/or not stressing those lanes with ISI and jitter, or by other means. Each receive lane is stressed in turn while all are operated. All aggressor lanes are operated as specified. Where relevant, parameters are defined with all co-propagating and counter-propagating lanes operational so that crosstalk effects are included. Where not otherwise specified, the maximum amplitude (OMA_{outer}) for a particular situation is used. Alternative test methods that generate equivalent results may be used. While the lanes in a particular direction may share a common clock, the Tx and Rx directions are not synchronous to each other. If Pattern 3 is used for the lanes not under test using a common clock, there is at least 31 UI delay between the PRBS31Q patterns on one lane and any other lane so that the symbols on each lane are not correlated within the PMD.

150.8.2 Center wavelength and spectral width

The center wavelength and RMS spectral width of each optical lane shall be within the range given in Table 150–7 if measured per IEC 61280-1-3. The lane under test is modulated using one of the test patterns specified in Table 150–11.

150.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 150–7 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using one of the test patterns defined in Table 150–11.

150.8.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} of each lane shall be within the limits given in Table 150–7 if measured as defined in 121.8.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

150.8.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

TDECQ is a measure of each optical transmitter's vertical eye closure as measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a combined reference receiver and worst case optical channel, and equalized with the reference equalizer specified in 150.8.5.1. Table 150–11 specifies the test pattern to be used for measurement of TDECQ.

The TDECQ and TDECQ – $10\log_{10}(C_{eq})$ of each lane shall be within the limits given in Table 150–7 if measured using the methods specified in 121.8.5, with the following exceptions:

— The polarization rotator and test fiber shown in Figure 121–4 are not used.

— The optical channel requirements in 121.8.5.2 do not apply. Instead, the optical splitter and variable reflector are adjusted so that each transmitter is tested with an optical return loss equal to the "Optical return loss tolerance (max)" given in Table 150–7.

— The combination of the O/E converter and the oscilloscope used to measure the optical waveform has a 3 dB bandwidth of 8.96 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 17.92 GHz. At frequencies above 1.5 × 17.92 GHz the response should not exceed −24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

— The reference equalizer to be used for TDECQ is specified in 150.8.5.1.

150.8.5.1 TDECQ reference equalizer

The reference equalizer for 400GBASE-SR4.2 is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 150–3. The sum of the equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3, has the largest magnitude tap coefficient, which is constrained to be at least 0.85.

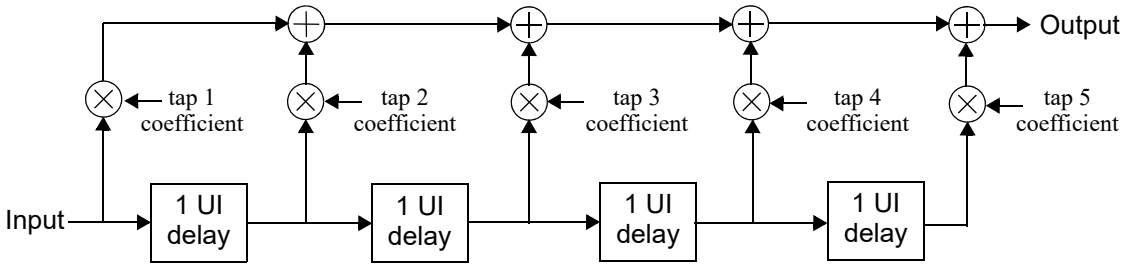

Figure 150–3—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver implementation.

150.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 150–7 if measured using the methods specified in 121.8.6.

150.8.7 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 150–7 if measured using a test pattern specified for transmitter transition time in Table 150–11.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

edges respectively, as measured through an O/E converter and oscilloscope with response defined as follows. The combined response of the O/E converter and oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz. At frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 150.8.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence and the falling edge is that within the 33333000000 symbol sequence

150.8.8 Relative intensity noise ($RIN_{12}OMA$)

$RIN_{12}OMA$ shall be as defined by the measurement methodology of 52.9.6 using an optical return loss of 12 dB and with the following exceptions:

a) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 26.6 GHz).

b) The test pattern is according to Table 150–11.

150.8.9 Receiver sensitivity

Receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 4.5 dB. Receiver sensitivity should meet Equation (150–1), which is illustrated in Figure 150–4.

$$RS = \max(-6.6, SECQ - 8) \quad \text{(dBm)} \tag{150–1}$$

where

RS	is the receiver sensitivity
SECQ	is the SECQ of the transmitter used to measure the receiver sensitivity

The normative requirement for receivers is stressed receiver sensitivity.

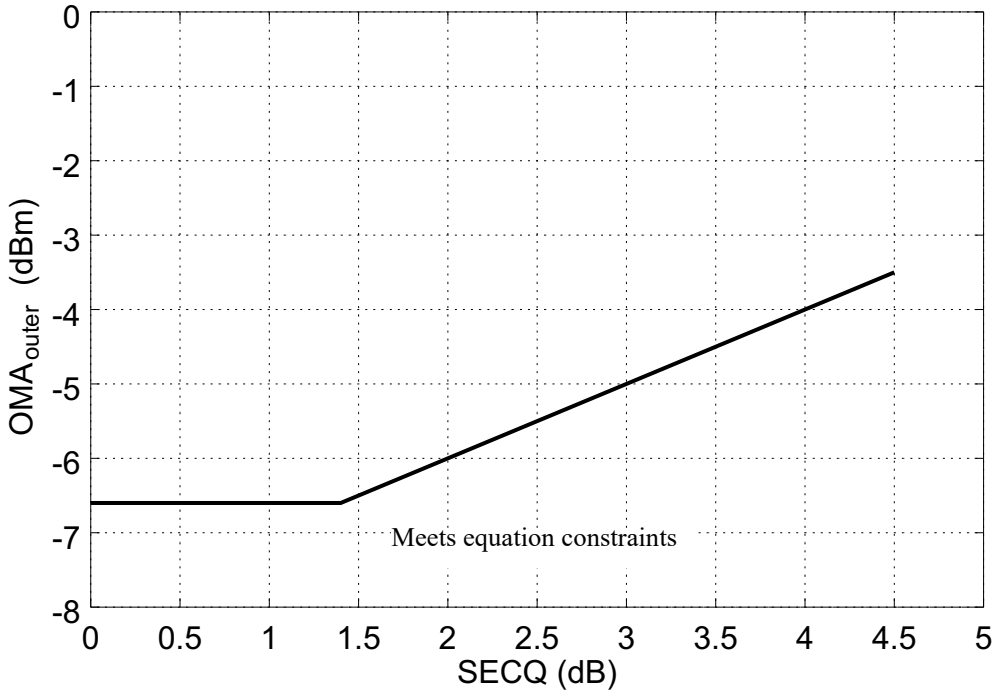

Figure 150–4—Illustration of receiver sensitivity

150.8.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 150–8 if measured using the methodology defined in 121.8.10.1 and 121.8.10.3, with the conformance test signal at TP3 as described in 121.8.10.2, with the following exceptions:

- The SECQ of the stressed receiver conformance test signal is measured according to 150.8.5, except that the combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz. At frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response. The optical splitter and variable reflector shown in Figure 121–4 are not used, and the transition time is no greater than the value specified in Table 150–7.
- With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_{12}OMA$ of the SRS test source should be no greater than the $RIN_{12}OMA$ (max) specified for the transmit characteristics in Table 150–7.
- The test patterns used for stressed receiver sensitivity are specified in Table 150–11.
- The signaling rate, the required stressed eye closure (SECQ), and the maximum $SECQ - 10\log_{10}(C_{eq})$ of the stressed receiver conformance test signal are as specified in Table 150–8.
- The applied sinusoidal jitter is specified in 150.8.10.1.
- The OMA_{outer} of the aggressor lanes is specified in Table 150–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The BER is required to be met for each lane under test on its own. Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Any of the patterns specified for stressed receiver sensitivity in Table 150–11 is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.

150.8.10.1 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. The amplitude of the applied sinusoidal jitter is dependent on frequency as specified in Table 150–12.

Table 150–12—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter peak-to-peak (UI)
$f < 40$ kHz	Not specified
40 kHz $< f \leq 4$ MHz	2×10^5 Hz/f
4 MHz $< f \leq 10\ LB$[a]	0.05

[a]LB = loop bandwidth; upper frequency bound for added sinusoidal jitter should be at least 10 times the loop bandwidth of the receiver being tested.

150.9 Safety, installation, environment, and labeling

150.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

150.9.2 Laser safety

400GBASE-SR4.2 optical transceivers shall conform to Hazard Level 1M laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[247]

150.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

[247]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

150.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 400GBASE-SR4.2 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate, in the literature associated with the PHY, the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

150.9.5 Electromagnetic emission

A system integrating a 400GBASE-SR4.2 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

150.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

150.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (i.e., 400GBASE-SR4.2).

Labeling requirements for Hazard Level 1M lasers are given in the laser safety standards referenced in 150.9.2.

150.10 Fiber optic cabling model

The fiber optic cabling (channel) contains eight optical fibers, each of which carries bidirectional traffic, to support 400GBASE-SR4.2. The fiber optic cabling interconnects the TxRx pairs (see 150.6) at the MDI on one end of the channel to the TxRx pairs at the MDI on the other end of the channel. As defined in 150.10.3, the optical lanes appear in defined locations at the MDI but the locations are not assigned specific lane numbers within this standard because any TxRx pair at the MDI on one end of the channel may be connected to any TxRx pair of the opposite type on the other end of the channel.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

150.10.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 150–5.

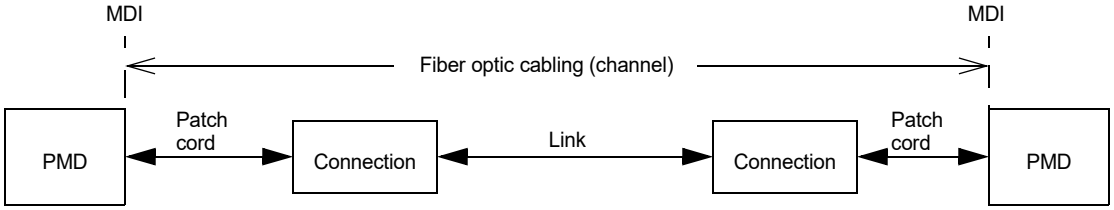

Figure 150–5—Fiber optic cabling model

The channel insertion loss is given in Table 150–13. A channel may contain additional connectors as long as the optical characteristics of the channel (such as attenuation, modal dispersion, reflections and losses of all connectors and splices) meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method. As OM4 and OM5 optical fiber meet the requirements for OM3, a channel compliant to the "OM3" column may use OM4 or OM5 optical fiber, or a combination of OM3, OM4, and OM5. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 150–13—Fiber optic cabling (channel) characteristics

Description	OM3	OM4	OM5	Unit
Operating distance (max)	70	100	150	m
Cabling Skew (max)	79			ns
Cabling Skew Variation[a] (max)	2.4			ns
Channel insertion loss[b] (max)	1.7	1.8	2	dB
Channel insertion loss (min)	0			dB

[a]An additional 400 ps of Skew Variation could be caused by wavelength changes, which are attributable to the transmitter not the channel.

[b]These channel insertion loss values include cable loss plus 1.5 dB allocated for connection and splice loss, over the wavelength ranges 844 nm to 863 nm and 900 nm to 918 nm. Compliant channel insertion loss at 850 nm also demonstrates compliance at 910 nm.

150.10.2 Characteristics of the fiber optic cabling (channel)

The fiber optic cabling shall meet the specifications defined in Table 150–13. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

150.10.2.1 Optical fiber cable

The fiber contained within the fiber optic cabling shall comply with the specifications and parameters of Table 150–14. A variety of multimode cable types may satisfy these requirements, provided the resulting channel also meets the specifications of Table 150–13.

Table 150–14—Optical fiber and cable characteristics

Description	OM3[a]	OM4[b]	OM5[c]	Unit
Nominal core diameter	50			μm
Nominal fiber specification wavelength	850		850 and 953	nm
Effective modal bandwidth at 850 nm (min)[d]	2000	4700		MHz·km
Effective modal bandwidth at 910 nm (min)[d]	Not specified[e]			MHz·km
Effective modal bandwidth at 953 nm (min)[d]	Not specified[e]		2470	MHz·km
Cabled optical fiber attenuation (max)	3			dB/km
Zero dispersion wavelength (λ_0)	$1295 \le \lambda_0 \le 1340$		$1297 \le \lambda_0 \le 1328$	nm
Chromatic dispersion slope (max) (S_0)	0.105 for $1295 \le \lambda_0 \le 1310$ and $0.000375 \times (1590 - \lambda_0)$ for $1310 \le \lambda_0 \le 1340$		$-412/(840(1-(\lambda_0/840)^4))$	ps/(nm^2·km)

[a]IEC 60793-2-10 type A1a.2.
[b]IEC 60793-2-10 type A1a.3.
[c]IEC 60793-2-10 type A1a.4.
[d]When measured with the launch conditions specified in Table 150–7.
[e]Effective modal bandwidth guidance is provided at all wavelengths in the 840 nm to 953 nm range in IEC 60793-2-10. For OM3, the guidance is 1260 MHz·km at 910 nm and 1033 MHz·km at 953 nm. For OM4, the guidance is 1980 MHz·km at 910 nm and 1459 MHz·km at 953 nm. For OM5, the guidance is 3100 MHz·km at 910 nm.

150.10.2.2 Optical fiber connection

An optical fiber connection, as shown in Figure 150–5, consists of a mated pair of optical connectors.

150.10.2.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 1.5 dB total connection and splice loss. For example, this allocation supports three connections with an average insertion loss per connection of 0.5 dB. Connections with lower loss characteristics may be used provided the requirements of Table 150–13 are met. However, the loss of a single connection shall not exceed 0.75 dB.

150.10.2.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

150.10.3 Medium Dependent Interface (MDI)

The 400GBASE-SR4.2 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 150–5). The 400GBASE-SR4.2 PMD is coupled to the fiber optic cabling through one connector plug into the MDI optical receptacle as shown in Figure 150–7. Example constructions of the MDI include the following:

a) PMD with a connectorized fiber pigtail plugged into an adapter;
b) PMD receptacle.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 150.5.1, not at the MDI.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

150.10.3.1 Optical lane assignments

The four type TR and four type RT TxRx pairs of 400GBASE-SR4.2 shall occupy the positions depicted in Figure 150–6 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains 8 active positions within 12 total positions. The four center positions are unused. The TR TxRx pair types occupy the leftmost four positions. The RT TxRx pair types occupy the rightmost four positions. Transmit wavelengths in the range defined for λ_1 in Table 150–7 and receive wavelengths in the range defined for λ_2 in Table 150–7 shall use TR positions. Receive wavelengths in the range defined for λ_1 and transmit wavelengths in the range defined for λ_2 shall use RT positions.

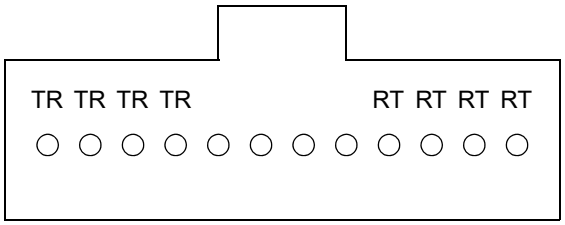

Figure 150–6—Optical lane assignments

150.10.3.2 MDI requirements

The MDI shall optically mate with the compatible plug on the optical fiber cabling. The MDI adapter or receptacle shall meet the dimensional specifications for interface 7-1-3: *MPO adapter interface - opposed keyway configuration*, or interface 7-1-10: *MPO active device receptacle, flat interface*, as defined in IEC 61754-7-1. The plug terminating the optical fiber cabling shall meet the dimensional specifications of interface 7-1-4: *MPO female plug connector, flat interface for 2 to 12 fibers*, as defined in IEC 61754-7-1. Figure 150–7 shows an MPO female plug connector with flat interface, and an MDI. The MDI connection shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2 for performance grade Bm/2m.

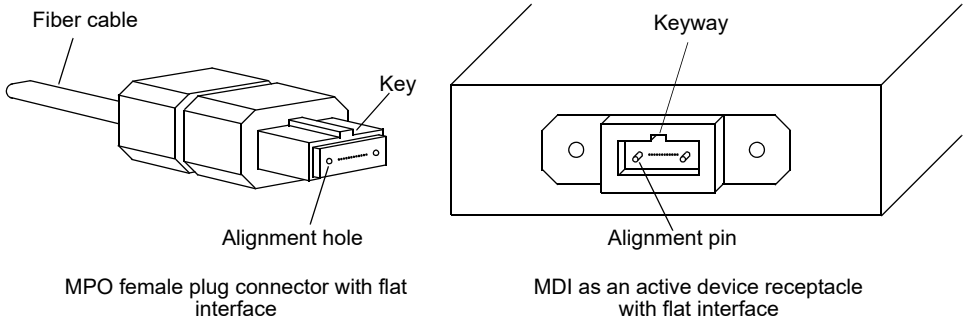

Figure 150–7—MPO female plug with flat interface and MDI active device receptacle with flat interface

150.11 Protocol implementation conformance statement (PICS) proforma for Clause 150, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR4.2[248]

150.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 150, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR4.2, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

150.11.2 Identification

150.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

150.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 150, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR4.2
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[248]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

150.11.4.3 PMD to MDI optical specifications

Item	Feature	Subclause	Value/Comment	Status	Support
S1	Transmitter meets specifications in Table 150–7	150.7.1	Per definitions in 150.8	M	Yes [ ]
S2	Receiver meets specifications in Table 150–8	150.7.2	Per definitions in 150.8	M	Yes [ ]

150.11.4.4 Optical measurement methods

Item	Feature	Subclause	Value/Comment	Status	Support
OM1	Measurement cable	150.8	2 m to 5 m in length	M	Yes [ ]
OM2	Center wavelength and spectral width	150.8.2	Per IEC 61280-1-3 under modulated conditions	M	Yes [ ]
OM3	Average optical power	150.8.3	Per IEC 61280-1-1	M	Yes [ ]
OM4	OMA_{outer} measurements	150.8.4	Each lane	M	Yes [ ]
OM5	Transmitter and dispersion eye closure for PAM4 (TDECQ)	150.8.5	Each lane	M	Yes [ ]
OM6	Extinction ratio	150.8.6	Per IEC 61280-2-2	M	Yes [ ]
OM7	Transmitter transition time	150.8.7	Each lane	M	Yes [ ]
OM8	$RIN_{12}OMA$ measurement procedure	150.8.8	Each lane	M	Yes [ ]
OM9	Stressed receiver sensitivity	150.8.10	See 150.8.10	M	Yes [ ]

150.11.4.5 Environmental specifications

Item	Feature	Subclause	Value/Comment	Status	Support
ES1	General safety	150.9.1	Conforms to the general safety requirements in J.2	M	Yes [ ]
ES2	Laser safety—IEC Hazard Level 1M	150.9.2	Conforms to Hazard Level 1M laser requirements defined in IEC 60825-1 and IEC 60825-2	M	Yes [ ]
ES3	Electromagnetic interference	150.9.5	Complies with applicable local and national codes for the limitation of electromagnetic interference	M	Yes [ ]

151. Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-FR4 and 400GBASE-LR4-6

151.1 Overview

This clause specifies the 400GBASE-FR4 and the 400GBASE-LR4-6 PMDs together with the single-mode fiber medium. The optical signals generated by these two PMD types are modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 151–1 to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 151–1—Physical Layer clauses associated with the 400GBASE-FR4 and 400GBASE-LR4-6 PMDs

Associated clause	400GBASE-FR4, 400GBASE-LR4-6
117—RS	Required
117—400GMII[a]	Optional
118—400GMII Extender	Optional
119—PCS for 400GBASE-R	Required
120—PMA for 400GBASE-R	Required
120B—400GAUI-16 C2C	Optional
120C—400GAUI-16 C2M	Optional
120D—400GAUI-8 C2C	Optional
120E—400GAUI-8 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a]The 400GMII is an optional interface. However, if the 400GMII is not implemented, a conforming implementation behaves functionally as though the RS and 400GMII were present.

Figure 151–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 400 Gb/s Ethernet is introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

400GBASE-FR4 and 400GBASE-LR4-6 PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

151.1.1 Bit error ratio

The bit error ratio (BER) when processed according to Clause 120 shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when processed according to Clause 120 and

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

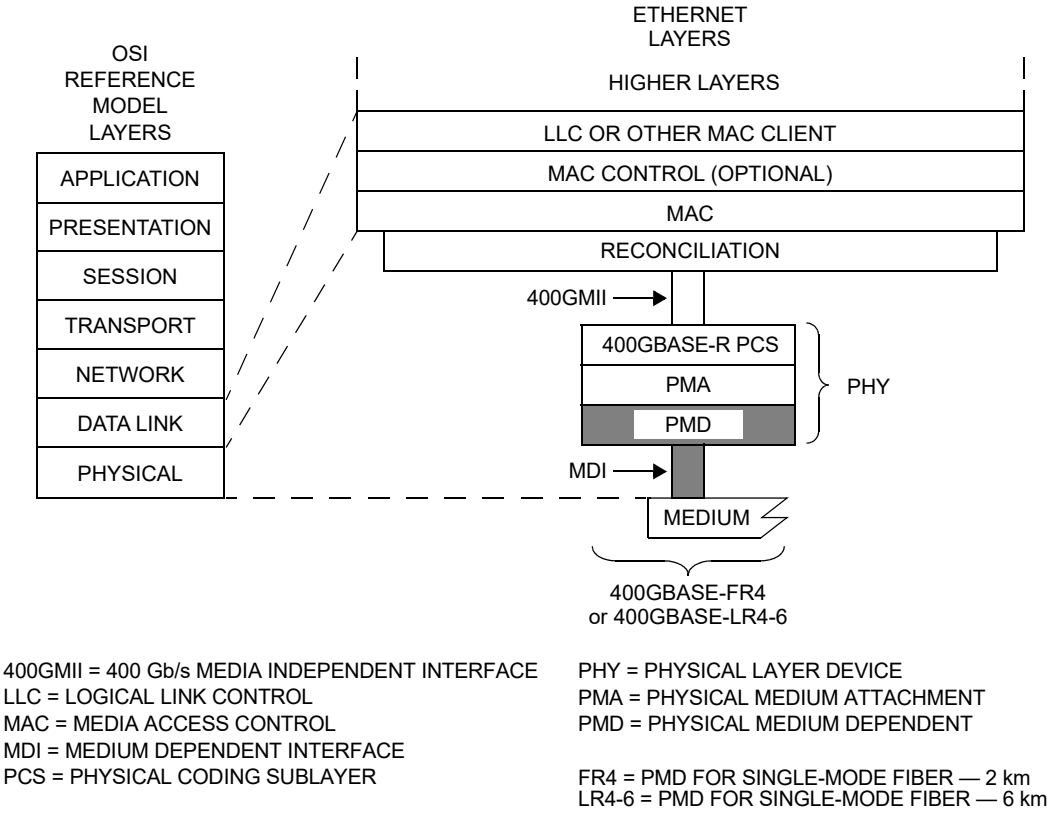

Figure 151–1—400GBASE-FR4 and 400GBASE-LR4-6 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

then Clause 119. For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

151.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 400GBASE-FR4 and 400GBASE-LR4-6 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 116.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the transmit direction, the PMA continuously sends four parallel symbol streams to the PMD, one per lane, each at a nominal signaling rate of 53.125 GBd. The PMD then converts these streams of data units into the appropriate signals on the MDI.

In the receive direction, the PMD continuously sends four parallel symbol streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 53.125 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service interface primitive defined in 116.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 151.1.1.

151.3 Delay and Skew

151.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 400GBASE-FR4 or 400GBASE-LR4-6 PMD including 2 m of fiber in one direction shall be no more than 8192 bit times (16 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

151.3.2 Skew constraints

The Skew (relative delay between the lanes) and Skew Variation are kept within limits so that the information on the lanes can be reassembled by the PCS. Skew and Skew Variation are defined in 116.5 and specified at the points SP1 to SP6 shown in Figure 116–4 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 116.5. The measurements of Skew and Skew Variation are defined in 87.8.2.

151.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

control variables to PMD control variables shall be as shown in Table 151–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 151–3.

Table 151–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 3 to PMD transmit disable 0	PMD transmit disable register	1.9.4 to 1.9.1	PMD_transmit_disable_3 to PMD_transmit_disable_0

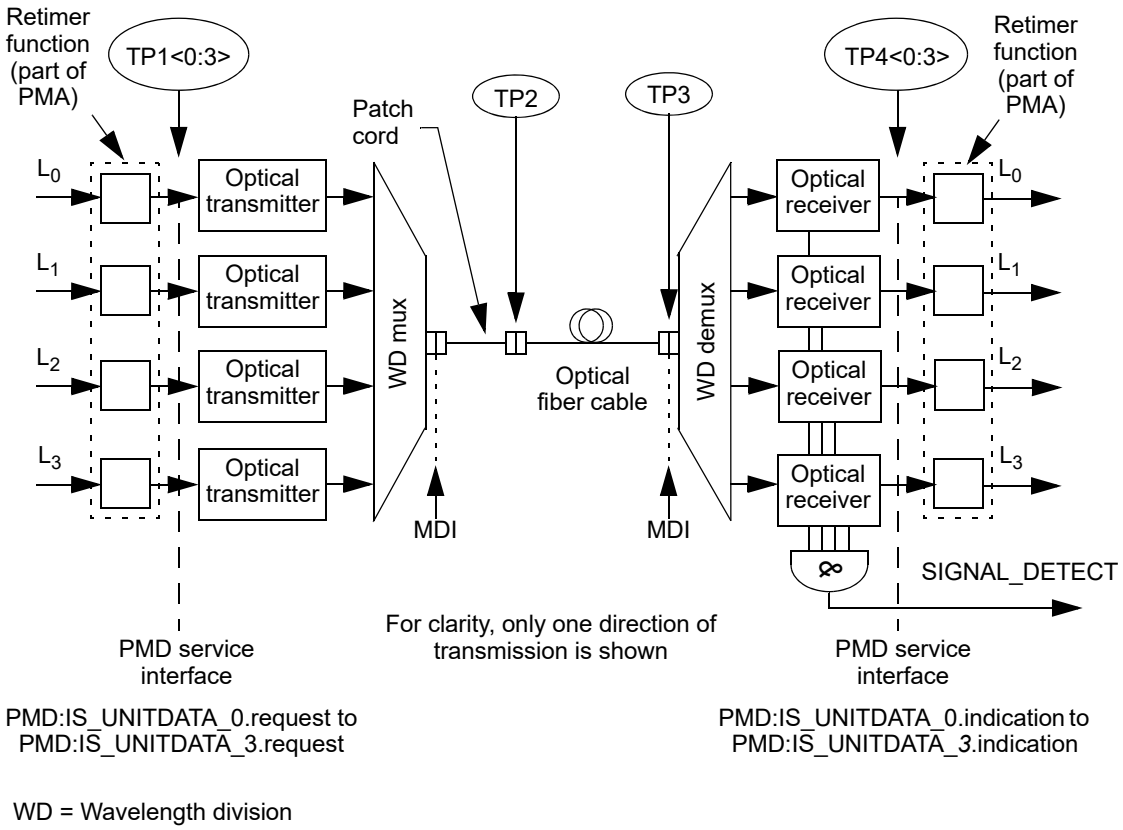
Table 151–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 3 to PMD receive signal detect 0	PMD receive signal detect register	1.10.4 to 1.10.1	PMD_signal_detect_3 to PMD_signal_detect_0

151.5 PMD functional specifications

The 400GBASE-FR4 and 400GBASE-LR4-6 PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

151.5.1 PMD block diagram



The PMD block diagram is shown in Figure 151–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 151.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 151.11.3). Unless specified otherwise, all receiver measurements and tests defined in 151.8 are made at TP3.

TP1<0:3> and TP4<0:3> are optional reference points that may be useful to implementers for testing components (these test points are not typically accessible in an implemented system).

151.5.2 PMD transmit function

The PMD Transmit function shall convert the four symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate optical signals. The four optical signals shall then be wavelength division multiplexed and delivered to the MDI, all

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Specification of the retimer function and the electrical implementation of the PMD service interface is beyond the scope of this standard.

Figure 151–2—Block diagram for 400GBASE-FR4 and 400GBASE-LR4-6 transmit/receive paths

according to the transmit optical specifications in this clause. The four optical power levels in the signal in order from lowest to highest shall correspond to tx_symbol values zero, one, two, and three, respectively.

151.5.3 PMD receive function

The PMD Receive function shall demultiplex the composite optical signal received from the MDI into four separate optical signals. The four optical signals shall then be converted into four symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication, all according to the receive optical specifications in this clause. The four optical power levels in each signal in order from lowest to highest shall correspond to rx_symbol values zero, one, two, and three, respectively.

151.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 151.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all four lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 151–4. The PMD receiver is not required to verify whether a compliant 400GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 151–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –16 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 151–8) AND (compliant 400GBASE-R signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

151.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:3, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 151–4.

151.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

151.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 151–7.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

151.5.8 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function allows the optical transmitters in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3 for 400GBASE-FR4 and 400GBASE-LR4-6) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 151–7.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method shall be provided to independently disable each transmit lane for testing purposes.

151.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

151.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

151.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

151.6 Wavelength-division-multiplexed lane assignments

The wavelength range for each lane of the 400GBASE-FR4 and 400GBASE-LR4-6 PMDs is defined in Table 151–5. The 400GBASE-FR4 and 400GBASE-LR4-6 center wavelengths are members of the CWDM wavelength grid defined in ITU-T G.694.2 and are spaced at 20 nm.

Table 151–5—400GBASE-FR4 and 400GBASE-LR4-6 wavelength-division-multiplexed lane assignments

Lane	Center wavelength	Wavelength range
L_0	1271 nm	1264.5 to 1277.5 nm
L_1	1291 nm	1284.5 to 1297.5 nm
L_2	1311 nm	1304.5 to 1317.5 nm
L_3	1331 nm	1324.5 to 1337.5 nm

NOTE—There is no requirement to associate a particular electrical lane with a particular optical lane, as the PCS is capable of receiving lanes in any arrangement.

151.7 PMD to MDI optical specifications for 400GBASE-FR4 and 400GBASE-LR4-6

The operating ranges for the 400GBASE-FR4 and 400GBASE-LR4-6 PMDs are defined in Table 151–6. A 400GBASE-FR4 or 400GBASE-LR4-6 compliant PMD operates on type G.652.B, G.652.D, G.657.A1, or G.657.A2 single-mode fibers according to the specifications defined in Table 151–14. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 400GBASE-FR4 PMD operating at 2.5 km meets the operating range requirement of 2 m to 2 km).

The 400GBASE-LR4-6 PMD interoperates with the 400GBASE-FR4 PMD provided that the channel guidelines defined in 151.12 are met.

Table 151–6—400GBASE-FR4 and 400GBASE-LR4-6 operating ranges

PMD type	Required operating range
400GBASE-FR4	2 m to 2 km
400GBASE-LR4-6	2 m to 6 km

151.7.1 400GBASE-FR4 and 400GBASE-LR4-6 transmitter optical specifications

The 400GBASE-FR4 transmitter shall meet the specifications defined in Table 151–7 per the definitions in 151.8. The 400GBASE-LR4-6 transmitter shall meet the specifications defined in Table 151–7 per the definitions in 151.8.

Table 151–7—400GBASE-FR4 and 400GBASE-LR4-6 transmit characteristics

Description	400GBASE-FR4	400GBASE-LR4-6	Unit
Signaling rate, each lane (range)	53.125 ± 100 ppm		GBd
Modulation format	PAM4		—
Lane wavelengths (range)	1264.5 to 1277.5 1284.5 to 1297.5 1304.5 to 1317.5 1324.5 to 1337.5		nm
Side-mode suppression ratio (SMSR), (min)	30		dB
Total average launch power (max)	10.4	11.1	dBm
Average launch power, each lane (max)	4.4	5.1	dBm
Average launch power, each lane[a] (min)	–3.2	–2.7	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	3.7	4.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min) for TDECQ <1.4 dB for 1.4 dB ≤ TDECQ ≤ 3.4 dB	 –0.2 –1.6 + TDECQ	 0.3 –1.1 + TDECQ	 dBm dBm
Difference in launch power between any two lanes (OMA_{outer}) (max)	3.9	4	dB
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	3.4	3.4	dB
Transmitter eye closure for PAM4 (TECQ), each lane (max)	3.4	3.4	dB
| TDECQ – TECQ | (max)	2.5	2.5	dB
Over/under-shoot (max)	22	22	%
Transmitter power excursion (max)	1.8	2.5	dBm
Extinction ratio, each lane (min)	3.5	3.5	dB
Transmitter transition time (max)	17		ps
Average launch power of OFF transmitter, each lane (max)	–16	–16	dBm
$RIN_{17.1}OMA$ (max)	–136	—	dB/Hz
$RIN_{15.6}OMA$ (max)	—	–136	dB/Hz
Optical return loss tolerance (max)	17.1	15.6	dB
Transmitter reflectance[b] (max)	–26		dB

[a] Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] Transmitter reflectance is defined looking into the transmitter.

The values for OMA_{outer} each lane (min) in Table 151–7 vary with TDECQ. The relationships are illustrated in Figure 151–3 along with the values for OMA_{outer} each lane (max).

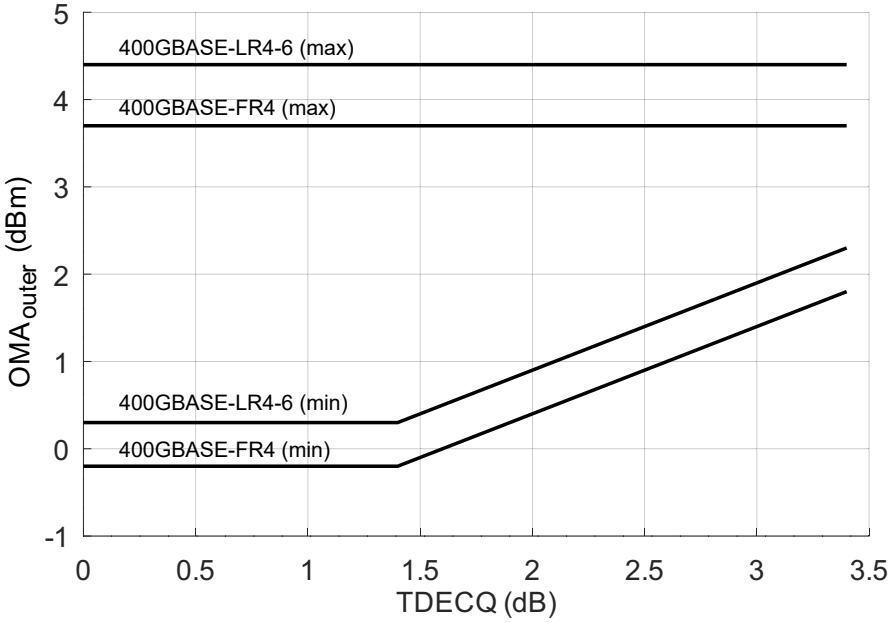

Figure 151–3—OMA_{outer} each lane (max) and OMA_{outer} each lane (min) versus TDECQ for 400GBASE-FR4 and 400GBASE-LR4-6

151.7.2 400GBASE-FR4 and 400GBASE-LR4-6 receive optical specifications

The 400GBASE-FR4 receiver shall meet the specifications in Table 151–8 per the definitions in 151.8. The 400GBASE-LR4-6 receiver shall meet the specifications in Table 151–8 per the definitions in 151.8.

Table 151–8—400GBASE-FR4 and 400GBASE-LR4-6 receive characteristics

Description	400GBASE-FR4	400GBASE-LR4-6	Unit
Signaling rate, each lane (range)	53.125 ± 100 ppm		GBd
Modulation format	PAM4		—
Lane wavelengths (range)	1264.5 to 1277.5 1284.5 to 1297.5 1304.5 to 1317.5 1324.5 to 1337.5		nm
Damage threshold[a], each lane	5.4	6.1	dBm
Average receive power, each lane (max)	4.4	5.1	dBm
Average receive power, each lane[b] (min)	–7.2	–9	dBm
Receive power (OMA_{outer}), each lane (max)	3.7	4.4	dBm
Difference in receive power between any two lanes (OMA_{outer}) (max)	4.1	4.3	dB
Receiver reflectance (max)	–26		dB
Receiver sensitivity (OMA_{outer}), each lane (max) for TECQ < 1.4 dB for 1.4 dB ≤ TECQ ≤ 3.4 dB	 –4.6 –6 + TECQ	 –6.8 –8.2 + TECQ	 dBm dBm
Stressed receiver sensitivity (OMA_{outer}), each lane[c] (max)	–2.6	–4.8	dBm
Conditions of stressed receiver sensitivity test:[d]			
Stressed eye closure for PAM4 (SECQ), lane under test	3.4	3.4	dB
OMA_{outer} of each aggressor lane	1.4	–0.4	dBm

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b] Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Measured with conformance test signal at TP3 (see 151.8.13) for the BER specified in 151.1.1.
[d] These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

The values for receiver sensitivity (OMA_{outer}), each lane (max) in Table 151–8 vary depending on the value of TECQ for the test source used for measurement. Figure 151–4 illustrates this.

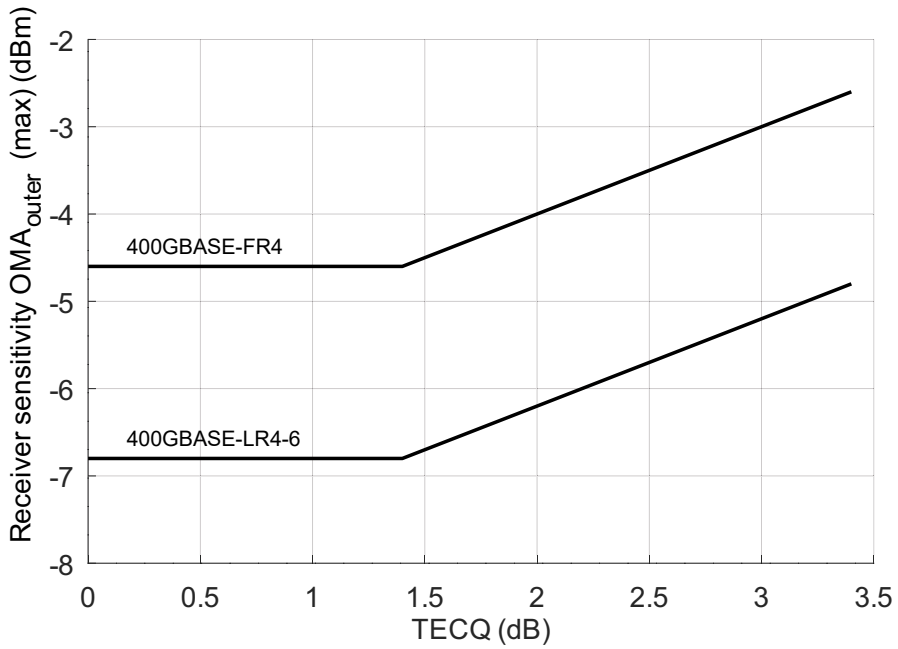

Figure 151–4—Receiver sensitivity (OMA_{outer}), each lane (max) for 400GBASE-FR4 and 400GBASE-LR4-6

151.7.3 400GBASE-FR4 and 400GBASE-LR4-6 illustrative link power budgets

Illustrative power budgets and penalties for 400GBASE-FR4 and 400GBASE-LR4-6 channels are shown in Table 151–9.

Table 151–9—400GBASE-FR4 and 400GBASE-LR4-6 illustrative link power budgets

Parameter	400GBASE-FR4	400GBASE-LR4-6	Unit
Power budget (for maximum TDECQ)	7.8	10.5	dB
Operating distance	2	6	km
Channel insertion loss[a]	4	5	dB
Maximum discrete reflectance[b]	–35[c]	–35[d]	dB
Allocation for penalties[e] (for maximum TDECQ)	3.8	4.2	dB
Additional insertion loss allowed[f]	0	1.3	dB

[a] The channel insertion loss is calculated using the maximum distance specified in Table 151–6 and fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 151.11.2.1.
[b] See 151.11.2.2 for details and specifications as a function of the number of discrete reflectances within the channel.
[c] Maximum value for each discrete reflectance with 4 discrete reflectances above –55 dB within the channel.
[d] Maximum value for each discrete reflectance with 6 discrete reflectances above –55 dB within the channel.
[e] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.
[f] The additional insertion loss may be allocated for cable, connectors or splices, provided the fiber optic cabling (channel) characteristics in 151.11 are met.

151.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

151.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 151–11 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 151–11 may be used to perform that test. The test patterns used in this clause are shown in Table 151–10.

Table 151–10—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle	119.2.4.9
6	SSPRQ	120.5.11.2.3

Table 151–11—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 400GBASE-R signal	151.8.2
Side mode suppression ratio	3, 5, 6 or valid 400GBASE-R signal	151.8.2
Average optical power	3, 5, 6 or valid 400GBASE-R signal	151.8.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	151.8.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	151.8.5
Transmitter eye closure for PAM4 (TECQ)	6	151.8.6
Over/under-shoot	6	151.8.7
Transmitter power excursion	6	151.8.8
Extinction ratio	4 or 6	151.8.9
Transmitter transition time	Square wave or 6	151.8.10
$RIN_{17.1}OMA$ and $RIN_{15.6}OMA$	Square wave	151.8.11
Receiver sensitivity	3 or 5	151.8.12
Stressed receiver conformance test signal calibration	6	151.8.13
Stressed receiver sensitivity	3 or 5	151.8.13

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

151.8.2 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR of each optical lane shall be within the ranges given in Table 151–7 if measured per IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 151–11.

151.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 151–7 if measured using the methods given in IEC 61280-1-1, with the sum of the optical power from all of the lanes not under test below –30 dBm, per the test setup in Figure 53–6.

151.8.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} of each lane shall be within the limits given in Table 151–7. OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 151–11, using the measurement method in 122.8.4.

151.8.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

The TDECQ of each lane shall be within the limits given in Table 151–7 if measured using the test setup specified in 122.8.5.1, with the optical channel specified in 151.8.5.1, the measurement method in 121.8.5.3, and the reference equalizer in 122.8.5.4, with the following exceptions:

— The signaling rate of the test pattern generator is as given in Table 151–7 and uses a test pattern specified for TDECQ in Table 151–11.

— The combination of O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 26.5625 GHz with a fourth-order Bessel-Thomson response to at least 1.3 × 53.125 GHz and at frequencies above 1.3 × 53.125 GHz the response should not exceed –20 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

— The normalized noise power density spectrum, $N(f)$ in Equation (121–9), is equivalent to white noise filtered by a fourth-order Bessel-Thomson response filter with a 3 dB bandwidth of 26.5625 GHz.

151.8.5.1 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 151–12.

Table 151–12—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
400GBASE-FR4	$0.046\times\lambda\times[1-(1324/\lambda)^4]$	$0.046\times\lambda\times[1-(1300/\lambda)^4]$	Minimum	17.1 dB	0.8 ps
400GBASE-LR4-6	$0.138\times\lambda\times[1-(1324/\lambda)^4]$	$0.138\times\lambda\times[1-(1300/\lambda)^4]$	Minimum	15.6 dB	0.8 ps

[a] The dispersion is measured for the wavelength of the transmitter lane under test (λ in nm). The coefficient assumes 2 km for 400GBASE-FR4 and 6 km for 400GBASE-LR4-6.
[b] There is no intent to stress the sensitivity of the O/E converter associated with the oscilloscope.
[c] The optical return loss is applied at TP2.

A 400GBASE-FR4 or 400GBASE-LR4-6 transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 151–12 for the wavelength of the transmitter lane under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 151–12. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 151–12.

151.8.6 Transmitter eye closure for PAM4 (TECQ)

The transmitter eye closure for PAM4 (TECQ) is a measure of the optical transmitter's eye closure at TP2. The TECQ of each lane shall be within the limits given in Table 151–7 if measured using a test pattern specified for TECQ in Table 151–11. The TECQ of each lane is measured using the methods specified for TDECQ in 151.8.5, except that the test fiber is not used.

151.8.7 Over/under-shoot

The over/under-shoot of each lane shall be within the limits given in Table 151–7 if measured using a test pattern specified for over/under-shoot in Table 151–11.

Overshoot and undershoot are measured using the waveform captured for the TDECQ test (see 151.8.5) and the waveform captured for the TECQ test (see 151.8.6), but without the reference equalizer being applied in each case.

Overshoot and undershoot are calculated using the methods in 140.7.7.

151.8.8 Transmitter power excursion

The transmitter power excursion of each lane shall be within the limits given in Table 151–7 if measured using a test pattern specified for transmitter power excursion in Table 151–11.

Transmitter power excursion is measured using the waveforms captured for the TECQ test (see 151.8.6), but without the reference equalizer being applied. Transmitter power excursion is defined as:

$$\text{Transmitter power excursion} = \max\left(P_{max} - P_{average}, P_{average} - P_{min}\right)$$

where

P_{max} and P_{min}	are defined in 140.7.7
$P_{average}$	is the average optical power of each lane defined in 151.8.3

151.8.9 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 151–7 if measured using a test pattern specified for extinction ratio in Table 151–11 with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test. The extinction ratio of a PAM4 optical signal is defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 122–3.

151.8.10 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 151–7 if measured using a test pattern specified for transmitter transition time in Table 151–11.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer} or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with response defined as follows. The combined response of the O/E converter and oscilloscope has a 3 dB bandwidth of approximately 26.5625 GHz with a fourth-order Bessel-Thomson response to at least 1.3 × 53.125 GHz. At frequencies above 1.3 × 53.125 GHz the response should not exceed –20 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 151.8.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence and the falling edge is that within the 33333000000 symbol sequence.

151.8.11 Relative intensity noise ($RIN_{17.1}OMA$ and $RIN_{15.6}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 17.1 dB for 400GBASE-FR4 and 15.6 dB for 400GBASE-LR4-6.

b) Each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.

c) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 53.125 GHz).

d) The test pattern is according to Table 151–11.

151.8.12 Receiver sensitivity

The receiver sensitivity (OMA_{outer}) of each lane shall be within the limits given in Table 151–8 if measured using a test pattern specified for receiver sensitivity in Table 151–11.

The conformance test signal applied at TP3 meets the requirements for a 400GBASE-FR4 or 400GBASE-LR4-6 transmitter followed by an attenuator. An optical demultiplexer may be used to separate the lane having the wavelength for the lane under test as specified in Table 151–8 for calibrating the TECQ.

The TECQ of the conformance test signal is measured according to 151.8.5, except that the test fiber is not used. The measured value of TECQ is then used to calculate the limit for receiver sensitivity (OMA_{outer}) as specified in Table 151–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

151.8.13 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 151–8 if measured using the method defined in 122.8.10, with the following exceptions:

- The SECQ of the stressed receiver conformance test signal is measured according to 151.8.5, except that the test fiber is not used. The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 151–7.
- With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_x OMA$ of the SRS test source (where x is the value for optical return loss tolerance from Table 151–7) shall be no greater than the value specified in Table 151–7.
- An example stressed receiver conformance test setup is shown in Figure 122–8; however, alternative test setups that generate equivalent stress conditions may be used.
- The signaling rate of the test pattern generator and the extinction ratio of the E/O converter are as given in Table 151–7.
- The values of over/under-shoot and transmitter power excursion of the stressed receiver conformance test signal are within the limits specified in Table 151–7.
- The required values of the "Stressed receiver sensitivity (OMA_{outer}), each lane (max)", "Stressed eye closure for PAM4 (SECQ), lane under test" and "OMA_{outer} of each aggressor lane" are as given in Table 151–8.

151.9 Safety, installation, environment, and labeling

151.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

151.9.2 Laser safety

400GBASE-FR4 and 400GBASE-LR4-6 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[249]

151.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

[249]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

151.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 400GBASE-FR4 or 400GBASE-LR4-6 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause are met.

151.9.5 Electromagnetic emission

A system integrating a 400GBASE-FR4 or 400GBASE-LR4-6 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

151.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

151.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 400GBASE-FR4).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 151.9.2.

151.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 151–7.

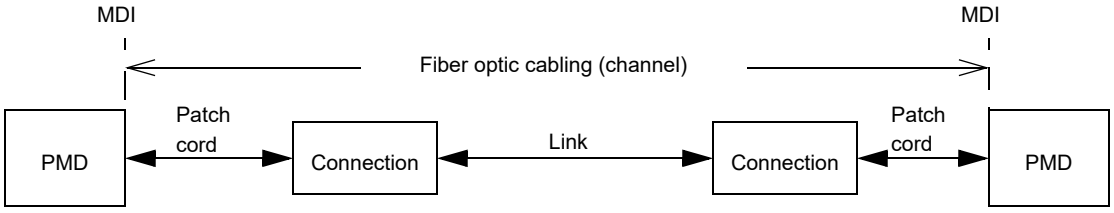

Figure 151–7—Fiber optic cabling model

The channel insertion loss is given in Table 151–13. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards..

Table 151–13—Fiber optic cabling (channel) characteristics

Description	400GBASE-FR4	400GBASE-LR4-6	Unit
Operating distance (max)	2	6	km
Channel insertion loss[a, b](max)	4	6.3	dB
Channel insertion loss (min)	0	0	dB
Positive dispersion[b] (max)	6.6	19.9	ps/nm
Negative dispersion[b] (min)	–11.7	–35.2	ps/nm
DGD_max[c]	2.3	4	ps
Optical return loss (min)	25	22	dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1264.5 nm to 1337.5 nm for 400GBASE-FR4 and 400GBASE-LR4-6.
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

151.11 Characteristics of the fiber optic cabling (channel)

The 400GBASE-FR4 and 400GBASE-LR4-6 fiber optic cabling shall meet the specifications defined in Table 151–13. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

151.11.1 Optical fiber cable

The optical fiber cable requirements are satisfied by cables containing ITU-T G.652.B (dispersion unshifted), type G.652.D (low water peak, dispersion unshifted), or type G.657.A1, or type G.657.A2 (bend insensitive) fibers, or the requirements in Table 151–14 where they differ.

Table 151–14—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.47[a] or 0.5[b]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.092	ps/nm^2 km

[a] The 0.47 dB/km at 1264.5 nm attenuation for optical fiber cables is derived from Appendix I of ITU-T G.695.
[b] The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3.

151.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 151–7, consists of a mated pair of optical connectors.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

151.11.2.1 Connection insertion loss

The maximum link distance for 400GBASE-LR4-6 is based on an allocation of 2 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. The maximum link distance for 400GBASE-FR4 is based on an allocation of 3 dB total connection and splice loss. Connections with different loss characteristics may be used provided the requirements of Table 151–13 are met.

151.11.2.2 Maximum discrete reflectance

The maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 151–15 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

Table 151–15—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance		Unit
	400GBASE-FR4	400GBASE-LR4-6	
1	–25	–22	dB
2	–31	–29	dB
4	–35	–33	dB
6	–38	–35	dB
8	–40	–37	dB
10	–41	–39	dB

151.11.3 Medium Dependent Interface (MDI) requirements

The 400GBASE-FR4 or 400GBASE-LR4-6 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 151–7). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 151.5.1, not at the MDI.

151.12 Interoperation between 400GBASE-LR4-6 and 400GBASE-FR4

The 400GBASE-LR4-6 and 400GBASE-FR4 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 400GBASE-FR4 are met, with the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

exception of the maximum and minimum channel insertion loss values, which are given in Table 151–16 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 151–16—Channel insertion loss for interoperation between 400GBASE-LR4-6 and 400GBASE-FR4

Direction	Min loss	Max loss	Unit
400GBASE-LR4-6 transmitter to 400GBASE-FR4 receiver	0.7	4.5	dB

151.13 Protocol implementation conformance statement (PICS) proforma for Clause 151, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-FR4 and 400GBASE-LR4-6[250]

151.13.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 151, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-FR4 and 400GBASE-LR4-6, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

151.13.2 Identification

151.13.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

151.13.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 151, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-FR4 and 400GBASE-LR4-6
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[250]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

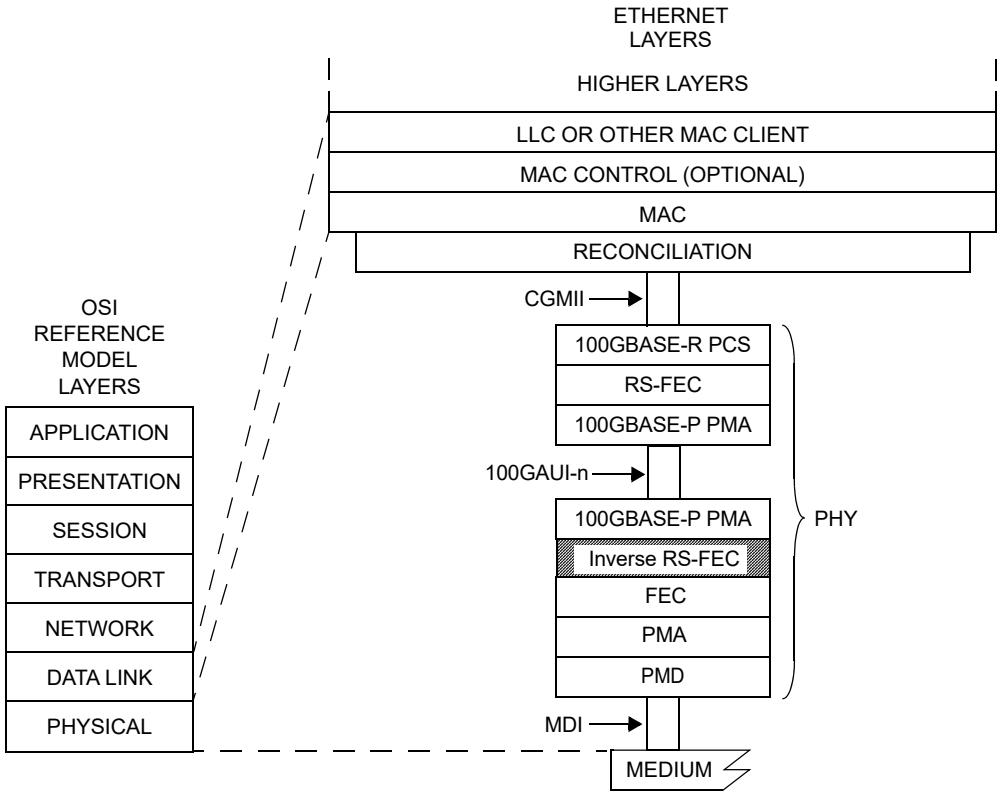
152. Inverse RS-FEC sublayer



152.1 Overview

152.1.1 Scope

The Inverse RS-FEC sublayer specifies a Reed-Solomon forward error correction (RS-FEC) sublayer for 100GBASE-R, 100GBASE-P, and 100GBASE-Z PHYs. This sublayer is used in cases where the RS-FEC specified in Clause 91 is used across a physically instantiated 100GAUI-n and a different FEC is used for the PMD.

152.1.2 Position of Inverse RS-FEC in the 100GBASE-R sublayers

Figure 152–1 shows the relationship of the Inverse RS-FEC sublayer to the ISO/IEC Open System Interconnection (OSI) reference model.

100GAUI-n = 100 Gb/s n-LANE ATTACHMENT UNIT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
Inverse RS-FEC = Inverse REED-SOLOMON FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 152–1—Inverse RS-FEC relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

152.2 Inverse RS-FEC service interface

This subclause specifies the services provided by the Inverse RS-FEC sublayer. The service interface is described in an abstract manner and does not imply any particular implementation. The Inverse RS-FEC service interface is an instance of the inter-sublayer service interface defined in 80.3. The service interface primitives are summarized as follows:

IFEC:IS_UNITDATA_*i*.request
IFEC:IS_UNITDATA_*i*.indication
IFEC:IS_SIGNAL.indication

The primitives are defined for $i = 0$ to 3. The PMA continuously sends 4 parallel bit streams to the Inverse RS-FEC sublayer, each at a nominal signaling rate of 26.5625 GBd. The Inverse RS-FEC sublayer continuously sends 4 parallel bit streams to the PMA, each at a nominal signaling rate of 26.5625 GBd.

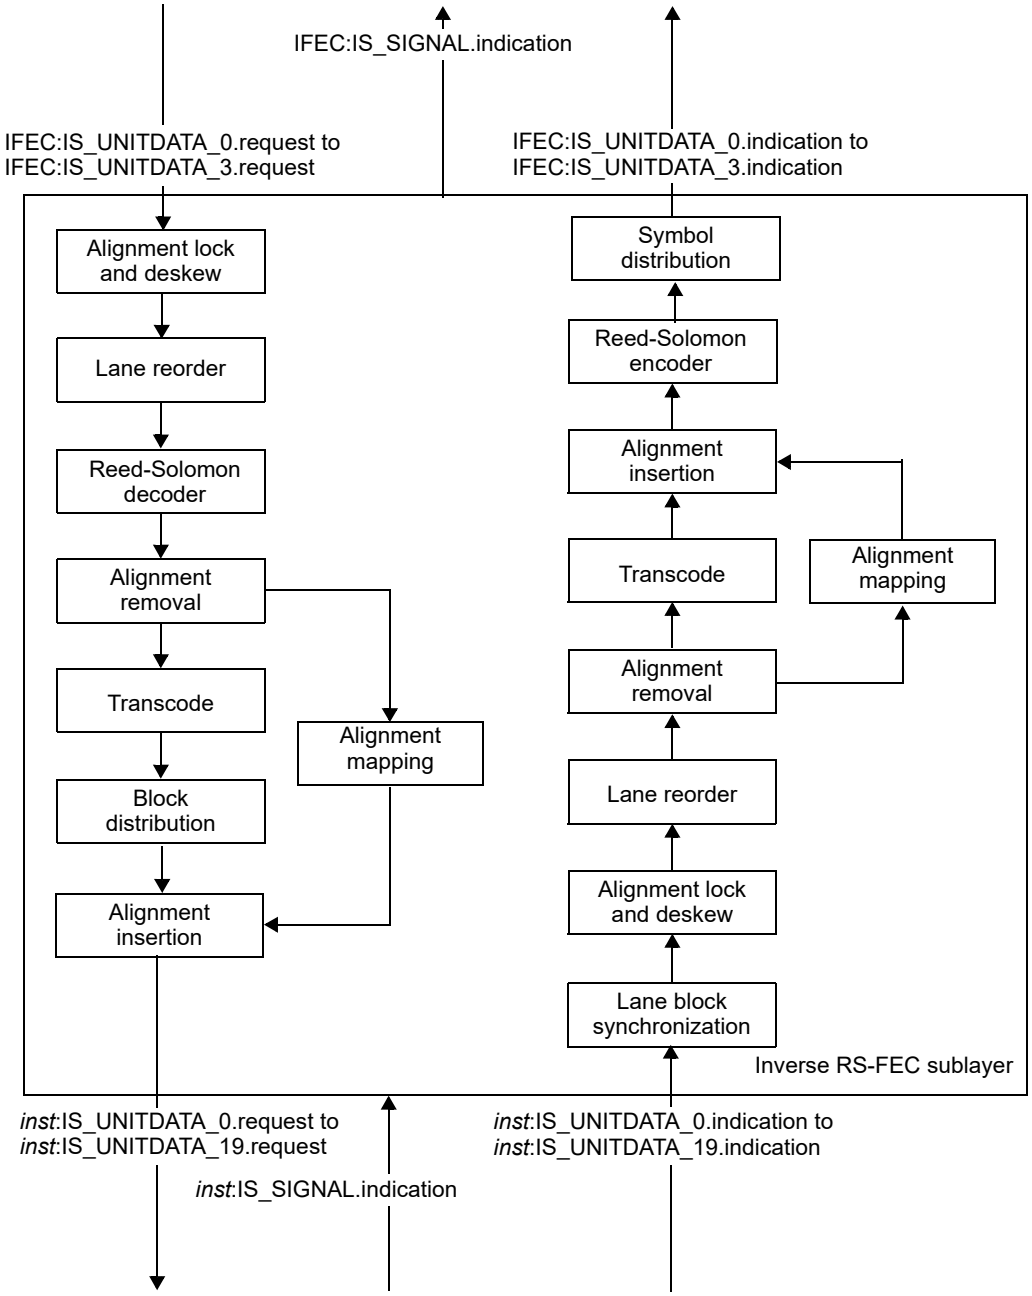
The SIGNAL_OK parameter of the IFEC:IS_SIGNAL.indication primitive can take one of two values: OK or FAIL. The value is set to OK when align_status (see 152.6.12) is true. The value is set to FAIL when align_status is false.

152.3 PMA or FEC sublayer compatibility

The Inverse RS-FEC sublayer requires that the PMA or FEC service interface below the Inverse RS-FEC sublayer consists of twenty upstream lanes and twenty downstream lanes. The restriction that all PMA service interfaces between the RS-FEC sublayer and the PMD sublayer consist of four or fewer lanes (see 91.3) is removed below the Inverse RS-FEC sublayer.

152.4 Delay constraints

The maximum delay contributed by the Inverse RS-FEC sublayer (sum of transmit and receive delays at one end of the link) shall be no more than 40 960 bit times (80 pause_quanta or 409.6 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.



152.5 Functions within the Inverse RS-FEC sublayer

The Inverse RS-FEC sublayer performs a subset of the functions defined for the RS-FEC sublayer described in Clause 91 with the Tx and Rx directions reversed. Specific limitations as compared to Clause 91 are that only RS(544,514) FEC is supported and EEE deep sleep mode is not supported. The FEC optional states in Clause 91 are mandatory for the Inverse RS-FEC sublayer.

152.5.1 Functional block diagram

A functional block diagram of the Inverse RS-FEC sublayer is shown in Figure 152–2.

inst PMA or FEC, depending on which sublayer is below the Inverse RS-FEC sublayer

Figure 152–2—Inverse RS-FEC sublayer functional block diagram

152.5.2 Transmit function

152.5.2.1 Alignment lock and deskew

The Inverse RS-FEC transmit function forms 4 bit streams by concatenating the bits received from each of the 4 IFEC:IS_UNITDATA_*i*.request primitives in the order they are received. It obtains lock to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

alignment markers as specified by the FEC synchronization state diagram shown in Figure 91–8. The FEC optional states and transition A in Figure 91–8 are mandatory for the Inverse RS-FEC sublayer.

After alignment marker lock is achieved on all 4 lanes, all inter-lane Skew is removed as specified by the FEC alignment state diagram shown in Figure 91–9. The Inverse RS-FEC transmit function shall support a maximum Skew of 49 ns between FEC lanes and a maximum Skew Variation of 400 ps.

152.5.2.2 Lane reorder

A particular FEC lane can be received on any of the lanes of the Inverse FEC service interface. The Inverse RS-FEC transmit function shall order the FEC lanes according to the FEC lane number (see 91.5.2.6). The FEC lane number is defined by the sequence of alignment markers that are mapped to each FEC lane.

After all FEC lanes are aligned, deskewed, and reordered, the FEC lanes are multiplexed together in the proper order to reconstruct the original stream of FEC codewords.

152.5.2.3 Reed-Solomon decoder

The Reed-Solomon decoder implements the RS(544,514) FEC decoder described in 91.5.3.3 with the exception that message symbols come from tx_scrambled rather than rx_scrambled. The optional subclause 91.5.3.3.1 is not supported for the Inverse RS-FEC sublayer.

152.5.2.4 Alignment marker removal

The first 1285 message bits in every 4096th codeword is the vector am_txmapped<1284:0> where bit 0 is the first bit received. The specific codewords that include this vector are indicated by the alignment lock and deskew function (refer to 152.5.2.1).

The vector am_txmapped shall be removed prior to transcoding.

152.5.2.5 256B/257B to 64B/66B transcoder

The transcoder extracts a group of four 66-bit blocks, tx_coded_j<65:0> where j = 0 to 3, from each 257-bit block tx_scrambled<256:0>. Bit 0 of the 257-bit block is the first bit received.

First, descramble the first 5 bits, based on reception order, of tx_scrambled<256:0> to yield tx_xcoded<256:0> as follows:

a) Set tx_xcoded<4:0> to the result of the bit-wise exclusive-OR of tx_scrambled<4:0> and tx_scrambled<12:8>.
b) Set tx_xcoded<256:5> to tx_scrambled<256:5>.

If tx_xcoded<0> is 1, tx_coded_j<65:0> for j = 0 to 3 shall be derived as follows:

a1) tx_coded_j<65:2> = tx_xcoded<(64j + 64):(64j + 1)> for j = 0 to 3.
b1) tx_coded_j<0> = 0 and tx_coded_j<1> = 1 for all j = 0 to 3.

If tx_xcoded<0> is 0 and any tx_xcoded<j + 1> = 0 for j = 0 to 3, tx_coded_j<65:0> for j = 0 to 3 shall be derived as follows:

a2) Let c be the smallest value of j such that tx_xcoded<j + 1> = 0. In other words, tx_coded_c is the first 66-bit control block in the resulting group of four blocks.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b2) Let tx_payloads be a vector representing the payloads of the four 66-bit blocks. It is derived using the following expressions:
tx_payloads<(64*c* + 3):0> = tx_xcoded<(64*c* + 8):5>
tx_payloads<(64*c* + 7):(64*c* + 4)> = 0000 (an arbitrary value that is later replaced by s_*c*)
tx_payloads<255:(64*c* + 8)> = tx_xcoded<256:(64*c* + 9)>

c2) tx_coded_*j*<65:2> = tx_payloads<(64*j* + 63):64*j*> for *j* = 0 to 3.

d2) Let f_*c*<3:0> = tx_coded_*c*<5:2> be the scrambled first nibble (based on transmission order) of the block type field for tx_coded_*c*.

e2) Descramble f_*c*<3:0> to yield g<3:0> per the following expression where "^" denotes the exclusive-OR operation. When *c* = 0, tx_coded_(*c* – 1) corresponds to tx_coded_3 from the previous 257-bit block.
g<*i*> = f_*c*<*i*> ^ tx_coded_(*c* – 1)<*i* + 8> ^ tx_coded_(*c* – 1)<*i* + 27> for *i* = 0 to 3.

f2) The block type field may be uniquely identified by either its most or least significant nibble. Since g<3:0> is the least significant nibble of the block type field (per the transmission order), derive h<3:0> by cross-referencing to g<3:0> using Figure 82–5. For example, if g<3:0> is 0xE then h<3:0> is 0x1. If no match to g<3:0> is found, h<3:0> is set to 0000.

g2) If tx_xcoded<*j* + 1> = 0, tx_coded_*j*<0> = 1 and tx_coded_*j*<1> = 0 for *j* = 0 to 3.

h2) If tx_xcoded<*j*+1> = 1, tx_coded_*j*<0> = 0 and tx_coded_*j*<1> = 1 for *j* = 0 to 3.

i2) If h<3:0> = 0000, tx_coded_*c*<1> = 1 (invalidate synchronization header).

If tx_xcoded<0> is 0 and all tx_xcoded<*j* + 1> = 1 for *j* = 0 to 3, tx_coded_*j*<65:0> for *j* = 0 to 3 shall be derived as follows:

a3) Set *c* = 0 and h<3:0> = 0000.

b3) Let tx_payloads be a vector representing the payloads of the four 66-bit blocks. It is derived using the following expressions.
tx_payloads<(64*c* + 3):0> = tx_xcoded<(64*c* + 8):5>
tx_payloads<(64*c* + 7):(64*c* + 4)> = 0000 (an arbitrary value that is later replaced by s_*c*)
tx_payloads<255:(64*c* + 8)> = tx_xcoded<256:(64*c* + 9)>

c3) tx_coded_*j*<65:2> = tx_payloads<(64*j* + 63):(64*j*)> for *j* = 0 to 3.

d3) tx_coded_*j*<0> = 0 and tx_coded_*j*<1> = 0 for *j* = 0 and 2.

e3) tx_coded_*j*<0> = 1 and tx_coded_*j*<1> = 1 for *j* = 1 and 3.

If tx_xcoded<0> is 0, scramble h<3:0> to yield s_*c*<3:0> and assign it to tx_coded_*c* per the following expressions.

a4) s_*c*<*i*> = h<*i*> ^ tx_coded_(*c* – 1)<*i* + 12> ^ tx_coded_(*c* – 1)<*i* + 31> for *i* = 0 to 3.

b4) tx_coded_*c*<9:6> = s_*c*<3:0>.

The 66-bit blocks are transmitted in order from *j* = 0 to 3. Bit 0 of each block is the first bit transmitted.

152.5.2.6 Block distribution

After the data has been transcoded, it shall be distributed to 20 PCS lanes, one 66-bit block at a time in a round-robin distribution from the lowest to the highest numbered PCS lanes. The distribution process is shown in Figure 82–6.

152.5.2.7 Alignment marker mapping and insertion

The alignment marker mapping function compensates for the operation of the lane reorder function (refer to 152.5.2.2) to derive the PCS lane alignment markers, am_tx_*x*<65:0> for *x* = 0 to 19, from am_txmapped<1284:0> (refer to 152.5.2.4).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The alignment markers shall be derived from am_txmapped<1284:0> in a manner that yields the same result as the following process.

Given $i = 0$ to 3, $k = 0$ to 31, and $y = i + 4k$, am_txpayloads may be derived from am_txmapped per the following expression:

am_txpayloads<i, ($10k$ + 9):$10k$> = am_txmapped<($10y$ + 9):$10y$>

The 5-bit pad am_txmapped<1284:1280> is ignored. Given $i = 0$ to 3, $j = 0$ to 4, and $x = i + 4j$, amp_tx_x may be derived from am_txpayloads by the following expression:

amp_tx_x<63:0> = am_txpayloads<i, (64j + 63):64j>

For $x = 0$ to 19, am_tx_x<65:0> is constructed as follows:

a) am_tx_x<0> = 1 and am_tx_x<1> = 0.
b) am_tx_x<25:2> is set to M_0, M_1, and M_2 as shown in Figure 82–9 using the values in Table 82–2 for PCS lane number x.
c) am_tx_x<33:26> = amp_tx_x<31:24>.
d) am_tx_x<57:34> is set to M_4, M_5, and M_6 as shown in Figure 82–9 using the values in Table 82–2 for PCS lane number x.
e) am_tx_x<65:58> = amp_tx_x<63:56>.

One vector is mapped to 20 alignment markers every 4096 Reed-Solomon codewords (see 152.5.2.4). The alignment markers are simultaneously transmitted on the 20 PCS lanes after every 16 383rd column of 20 66-bit blocks.

The alignment markers am_tx_0 to am_tx_3 shall be inserted so that they are immediately followed by tx_coded_0 to tx_coded_3, respectively, as derived from the first 257-bit block following am_txmapped. Similarly am_tx_4 to am_tx_7 are followed by the 66-bit blocks corresponding to the second 257-bit block following am_txmapped, and so on.

152.5.2.8 Transmit bit ordering

The transmit bit ordering is illustrated in Figure 152–3. This illustration shows the case where the FEC lanes appear across the IFEC:IS_UNITDATA_i.request primitives in the correct order.

152.5.3 Receive function

152.5.3.1 Lane block synchronization

The Inverse RS-FEC receive function forms 20 bit streams by concatenating the bits from each of the 20 FEC:IS_UNITDATA_*i*.indication primitives from the sublayer below in the order they are received. It obtains lock to the 66-bit blocks in each bit stream using the sync headers and outputs 66-bit blocks. Block lock is obtained as specified in the block lock state diagram shown in Figure 82–12.

152.5.3.2 Alignment lock and deskew

Once the Inverse RS-FEC receive function achieves block lock on a PCS lane, it then begins obtaining alignment marker lock as specified in the alignment marker lock state diagram shown in Figure 82–13. This process identifies the PCS lane number received on a particular lane of the service interface of the sublayer below. After alignment marker lock is achieved on all 20 lanes, all inter-lane Skew is removed as specified by the PCS deskew state diagram shown in Figure 82–14. The Inverse RS-FEC receive function shall support a maximum Skew of 49 ns between PCS lanes and a maximum Skew Variation of 400 ps. Skew and Skew Variation are defined in 80.5.

152.5.3.3 Lane reorder

Any PCS lane may be received on any lane of the service interface. The Inverse RS-FEC receive function shall order the PCS lanes according to the PCS lane number.

152.5.3.4 Alignment marker removal

After all PCS lanes are aligned and deskewed, the PCS lanes are multiplexed together in the proper order to reconstruct the original stream of blocks and the alignment markers are removed from the data stream. Note that an alignment marker is always removed when am_lock is true for a given PCS lane even if it does not match the expected alignment marker value (due to a bit error, for example). Repeated alignment marker errors result in am_lock being set to false for a given PCS lane, but until that happens, it is sufficient to remove the block in the alignment marker position.

As part of the alignment marker removal process, the BIP_3 field is compared to the calculated Bit Interleaved Parity (BIP) value (see 82.2.8) for each PCS lane. If a Clause 45 MDIO is implemented, then the appropriate BIP error counter register (registers 1.230 to 1.249) is incremented by one each time the calculated BIP value does not equal the value received in the BIP_3 field. The bit error ratio in the data received from the far-end PCS can be estimated by dividing the BIP block error ratio by a factor of 1 081 344.

152.5.3.5 64B/66B to 256B/257B transcoder

The transcoder constructs a 257-bit block, rx_scrambled<256:0>, from a group of four 66-bit blocks, rx_coded_*j*<65:0> where *j* = 0 to 3. For each group of four 66-bit blocks, *j* = 3 corresponds to the most recently received block. Bit 0 in each 66-bit block is the first bit received and corresponds to the first bit of the synchronization header.

If for all *j* = 0 to 3, rx_coded_*j*<0> = 0 and rx_coded_*j*<1> = 1, rx_xcoded<256:0> shall be constructed as follows:

a) rx_xcoded<0> = 1.
b) rx_xcoded<(64*j* + 64):(64*j* + 1)> = rx_coded_*j*<65:2> for *j* = 0 to 3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If for all j = 0 to 3, rx_coded_j<0> ≠ rx_coded_j<1> (valid synchronization header) and for any j = 0 to 3, rx_coded_j<0> = 1 and rx_coded_j<1> = 0, rx_xcoded<256:0> shall be constructed as follows:

a1) rx_xcoded<0> = 0.
b1) rx_xcoded<j + 1> = rx_coded_j<1> for j = 0 to 3.
c1) Let c be the smallest value of j such that rx_coded_c<0> = 1. In other words, rx_coded_c is the first 66-bit control block that was received in the current group of four blocks.
d1) Let rx_payloads<(64j + 63):64j> = rx_coded_j<65:2> for j = 0 to 3.
e1) Omit rx_coded_c<9:6>, which is the second nibble (based on transmission order) of the block type field for rx_coded_c, from rx_xcoded per the following expressions:
rx_xcoded<(64c + 8):5> = rx_payloads<(64c + 3):0>
rx_xcoded<256:(64c + 9)> = rx_payloads<255:(64c + 8)>

If for any j = 0 to 3, rx_coded_j<0> = rx_coded_j<1> (invalid synchronization header), rx_xcoded<256:0> shall be constructed as follows:

a2) rx_xcoded<0> = 0.
b2) rx_xcoded<j + 1> = 1 for j = 0 to 3.
c2) Let rx_payloads<(64j + 63):64j> = rx_coded_j<65:2> for j = 0 to 3.
d2) Omit the second nibble (based on transmission order) of rx_coded_0 per the following expressions.
rx_xcoded<8:5> = rx_payloads<3:0>
rx_xcoded<256:9> = rx_payloads<255:8>

Finally, scramble the first 5 bits, based on transmission order, of rx_xcoded<256:0> to yield rx_scrambled<256:0> as follows:

a3) Set rx_scrambled<4:0> to the result of the bit-wise exclusive-OR of rx_xcoded<4:0> and rx_xcoded<12:8>.
b3) Set rx_scrambled<256:5> to rx_xcoded<256:5>.

For each 257-bit block, bit 0 shall be the first bit transmitted.

152.5.3.6 Alignment marker mapping and insertion

The alignment markers that were removed per 152.5.3.4 are re-inserted after being processed by the alignment marker mapping function. The alignment marker mapping function compensates for the operation of the symbol distribution function defined in 152.5.3.8 and rearranges the alignment marker bits so that they appear on the FEC lanes intact and in the desired sequence. This preserves the properties of the alignment markers (e.g., DC balance, transition density) and provides a deterministic pattern for the purpose of synchronization. The receive function in the RS-FEC sublayer above uses knowledge of this mapping to determine the FEC lane that is received on a given lane of the PMA service interface below the RS-FEC sublayer, to compensate for skew between FEC lanes, and to identify RS-FEC codeword boundaries.

The alignment marker mapping function operates on a group of 20 aligned and reordered alignment markers. Let am_rx_x<65:0> be the alignment marker for PCS lane x, x = 0 to 19, where bit 0 is the first bit transmitted. The alignment markers shall be mapped to am_rxmapped<1284:0> in a manner that yields the same result as the following process.

For x = 0 to 19, amp_rx_x<63:0> is constructed as follows:

a) Set y = 0 when $x \leq 3$, set y = 16 when $x \geq 16$, otherwise set $y = x$.
b) amp_rx_x<23:0> is set to M_0, M_1, and M_2 as shown in Figure 82–9 (bits 25 to 2) using the values in Table 82–2 for PCS lane number y.
c) amp_rx_x<31:24> = am_rx_x<33:26>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) amp_rx_*x*<55:32> is set to M_4, M_5, and M_6 as shown in Figure 82–9 (bits 57 to 34) using the values in Table 82–2 for PCS lane number *y*.
e) amp_rx_*x*<63:56> = am_rx_*x*<65:58>.

This process replaces the fixed bytes of the alignment markers received, possibly with errors, with the values from Table 82–2. In addition it substitutes the fixed bytes of the alignment markers corresponding to PCS lanes 1, 2, and 3 with the fixed bytes for the alignment marker corresponding to PCS lane 0. Similarly, it substitutes the fixed bytes of the alignment markers corresponding to PCS lanes 17, 18, and 19 with the fixed bytes for the alignment marker corresponding to PCS lane 16. The variable bytes BIP or CD are unchanged. This process simplifies receiver synchronization since the receiver only needs to search for the fixed bytes corresponding to PCS lane 0 on each FEC lane.

Construct a matrix of 4 rows and 320 columns, am_rxpayloads, as shown in Figure 152–4. Given $i = 0$ to 3, $j = 0$ to 4, and $x = i + 4j$, the matrix is derived per the following expression:

am_rxpayloads<*i*, (64*j* + 63):64*j*> = amp_rx_*x*<63:0>

Given $i = 0$ to 3, $k = 0$ to 31, and $y = i + 4k$, am_rxmapped may then be derived from am_rxpayloads per the following expression:

am_rxmapped<(10*y* + 9):10*y*> = am_rxpayloads<*i*, (10*k* + 9):10*k*>

A 5-bit pad is appended to the mapped alignment markers to yield the equivalent of five 257-bit blocks. The pad bits, am_rxmapped<1284:1280>, shall be set to the binary values 00101 and 11010 (the leftmost bit is assigned to the highest bit index) in an alternating pattern. In other words, if a pad value of 00101 is used for the current iteration of the mapping function, a value of 11010 is used in the next iteration and vice versa.

The result of the alignment marker mapping function is a deterministic mapping between alignment marker payloads and FEC lanes. The alignment marker payloads corresponding to PCS lanes 0, 4, 8, 12, and 16 are transmitted on FEC lane 0, the alignment marker payloads corresponding to PCS lanes 0, 5, 9, 13, and 16 are transmitted on FEC lane 1, and so on (see Figure 152–4).

As a result of this process, the BIP_3 and BIP_7 fields from normal alignment markers are carried across the link protected by FEC. These fields cannot be used to monitor errors on the link protected by FEC as 64B/66B to 256B/257B transcoding and Reed-Solomon encoding alters the bit sequence. However, these fields may again be used to monitor errors after the original bit sequence is restored, that is following Reed-Solomon decoding and 256B/257B to 64B/66B transcoding.

One group of aligned and reordered alignment markers are mapped every 20 × 16 384 66-bit blocks. This corresponds to 4096 Reed-Solomon codewords (refer to 152.5.3.7). The mapped alignment markers, am_txmapped<1284:0> shall be inserted as the first 1285 message bits to be transmitted from every 4096th codeword.

The first 257-bit block inserted after am_rxmapped shall correspond to the four 66-bit blocks received on PCS lanes 0, 1, 2, and 3 that immediately followed the alignment marker on each respective lane.

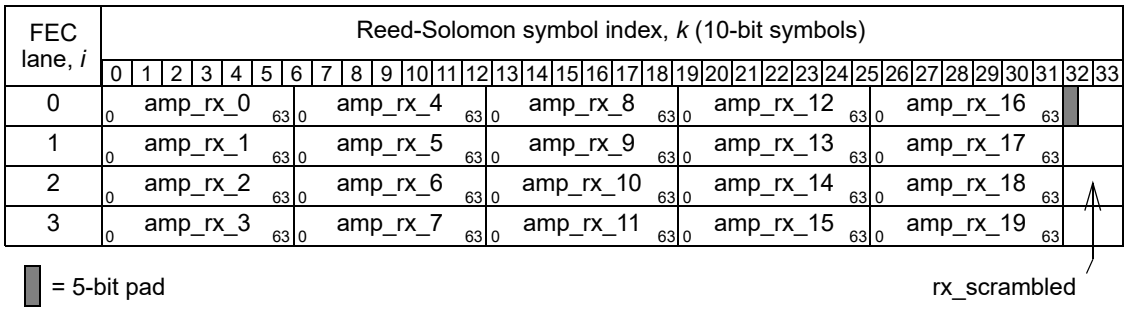

Figure 152–4—Alignment marker mapping to FEC lanes

152.5.3.7 Reed-Solomon encoder

The Reed-Solomon encoder implements the RS(544,514) FEC encoder described in 91.5.2.7. Since the encoder is used in the receive direction of transmission, the message symbols come from rs_scrambled and rx_ammapped rather than tx_scrambled and tx_ammapped.

152.5.3.8 Symbol distribution

Once the data has been Reed-Solomon encoded, it shall be distributed to 4 FEC lanes, one 10-bit symbol at a time in a round-robin distribution from the lowest to the highest numbered FEC lane. The distribution process is shown in Figure 152–5.

152.5.3.9 Receive bit ordering

The receive bit ordering is illustrated in Figure 152–5.

152.5.4 Detailed functions and state diagrams

Most functions and state diagrams are identical to those described in 91.5.4, with only the modifications to variable naming that arise from reversing the Tx and Rx directions, and omission of EEE deep sleep capability due to the fact that this sublayer only supports optical PHY types.

152.5.4.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, functions, and counters. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

152.5.4.2 State variables

152.5.4.2.1 Variables

all_locked
: A Boolean variable that is set to true when amps_lock<*x*> is true for all *x* and is set to false when amps_lock<*x*> is false for any *x*.

amp_counter_done
: Boolean variable that indicates that amp_counter has reached its terminal count.

amp_match
: Boolean variable that holds the output of the function AMP_COMPARE.

amp_valid
: Boolean variable that is set to true if the received 64-bit block is a valid alignment marker payload. The alignment marker payload, mapped to an FEC lane according to the process described in 152.5.3.6, consists of 48 known bits and 16 variable bits (the BIP_3 or CD_3 field and its complement BIP_7 or CD_7, see 82.2.7). The bits of the candidate block that are in the positions of the known bits in the alignment marker payload are compared on a nibble-wise basis (12 comparisons). If no more than 3 nibbles in the candidate block fail to match the corresponding known nibbles in the alignment marker payload, the candidate block is considered a valid alignment marker payload. Each FEC lane compares the candidate block to the alignment marker payload for PCS lane 0.

amps_lock<*x*>
: Boolean variable that is set to true when the receiver has detected the location of the alignment marker payload sequence for a given lane on the IFEC service interface, where *x* = 0:3.

current_pcsl
: A variable that holds the PCS lane number corresponding to the current alignment marker payload that is recognized on a given lane of the FEC service interface. It is compared to the variable first_pcsl to confirm that the location of the alignment marker payload sequence has been detected.

cw_bad
: A Boolean variable that is set to true if the Reed-Solomon decoder (see 152.5.2.3) fails to correct the current FEC codeword and is set to false otherwise.

deskew_done
: A Boolean variable that is set to true when fec_enable_deskew is set to true and the deskew process is completed. Otherwise, this variable is set to false.

fec_align_status
: A Boolean variable set by the FEC alignment process to reflect the status of FEC lane-to-lane alignment. Set to true when all lanes are synchronized and aligned and set to false when the deskew process is not complete.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

fec_alignment_valid
: Boolean variable that is set to true if all FEC lanes are aligned. FEC lanes are considered to be aligned when amps_lock<*x*> is true for all *x*, each FEC lane is locked to a unique alignment marker payload sequence (see 152.5.3.6), and the FEC lanes are deskewed. Otherwise, this variable is set to false.

fec_enable_deskew
: A Boolean variable that enables and disables the deskew process. Received bits may be discarded whenever deskew is enabled. It is set to true when deskew is enabled and set to false when deskew is disabled.

fec_lane
: A variable that holds the FEC lane number (0 to 3) received on lane *x* of the IFEC service interface when amps_lock<*x*> = true. The FEC lane number is determined by the alignment marker payloads in the 2nd, 3rd, or 4th positions of the sequence based on the mapping defined in 152.5.3.6. The 48 bits that are in the positions of the known bits in the received alignment marker payload are compared to the expected values for a given payload position and FEC lane on a nibble-wise basis (12 comparisons). If no more than 3 nibbles in the candidate block fail to match the corresponding known nibbles for any payload position on a given FEC lane, then the FEC lane number is assigned accordingly.

fec_optional_states
: Boolean variable that is always set to true to indicate that the optional states in the FEC synchronization state diagram in Figure 91–8 are implemented.

first_pcsl
: A variable that holds the PCS lane number that corresponds to the first alignment marker payload that is recognized on a given lane of the FEC service interface. It is compared to the PCS lane number corresponding to the second alignment marker payload that is tested.

reset
: Boolean variable that controls the resetting of the Inverse RS-FEC sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on.

restart_lock
: Boolean variable that is set by the FEC alignment process to reset the synchronization process on all FEC lanes. It is set to true after 3 consecutive uncorrected codewords are received (3_BAD state) and set to false upon entry into the LOSS_OF_ALIGNMENT state. It is also set to true when 5 Alignment Markers in a row fail to match (5_BAD state).

rx_align_status
: Boolean variable that is set by the alignment lock and deskew function (see 152.5.3.2).

signal_ok
: Boolean variable that is set based on the most recently received value of FEC:IS_SIGNAL.indication(SIGNAL_OK). It is true if the value was OK and false if the value was FAIL.

slip_done
: Boolean variable that is set to true when the SLIP requested by the synchronization state diagram has been completed indicating that the next candidate 64-bit block position can be tested.

test_amp
: Boolean variable that is set to true when a candidate block position is available for testing and false when the FIND_1ST state is entered.

test_cw
: Boolean variable that is set to true when a new FEC codeword is available for decoding and is set to false when the TEST_CW state is entered.

152.5.4.2.2 Functions

The AMP_COMPARE and SLIP functions as defined in 91.5.4.2.2 are used by the Inverse RS-FEC sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

152.5.4.2.3 Counters

amp_bad_count
: Counts the number of consecutive alignment markers that don't match the expected values for a given FEC lane.

amp_counter
: This counter counts the 4096 FEC codewords that separate the ends of two consecutive normal alignment marker payload sequences. An FEC codeword is 1360 bits per FEC lane.

cw_bad_count
: Counts the number of consecutive uncorrected FEC codewords. This counter is set to zero when an FEC codeword is received and cw_bad is false for that codeword.

152.5.4.3 State diagrams

The FEC shall implement four synchronization processes as shown in Figure 91–8. The synchronization process operates independently on each lane. The synchronization state diagram determines when the FEC has detected the location of the alignment marker payload sequence in the received bit stream for a given lane of the service interface.

The FEC shall implement the alignment process as shown in Figure 91–9.

152.6 Inverse RS-FEC MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the Inverse RS-FEC. If MDIO is implemented, it shall map MDIO control bits to Inverse RS-FEC control variables as shown in Table 152–1, and MDIO status bits to Inverse RS-FEC status variables as shown in Table 152–2, and if a separated PMA (see 45.2.1) is connected to the FEC service interface it shall map additional MDIO status bits to additional RS-FEC status variables as shown in Table 152–3.

Table 152–1—MDIO/Inverse RS-FEC control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	IFEC variable
IFEC bypass correction enable	IFEC control	1.2200.0	IFEC_bypass_correction_enable
IFEC bypass indication enable	IFEC control	1.2200.1	IFEC_bypass_indication_enable

The following subclauses define variables that are not otherwise defined, for example for use by state diagrams.

152.6.1 IFEC_bypass_correction_enable

When this variable is set to one, the Reed-Solomon decoder performs error detection without error correction (see 152.5.2.3). When this variable is set to zero, the decoder also performs error correction. The default value of the variable is zero. This variable is mapped to the bit defined in 45.2.1.216.2 (1.2200.0).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 152–2—MDIO/Inverse RS-FEC status variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
IFEC bypass correction ability	IFEC status	1.2201.0	IFEC_bypass_correction_ability
IFEC bypass indication ability	IFEC status	1.2201.1	IFEC_bypass_indication_ability
IFEC high SER	IFEC status	1.2201.2	hi_ser
IFEC AM lock *x*, *x* = 0 to 3	IFEC status	1.2201.8:11	amps_lock<*x*>
IFEC align status	IFEC status	1.2201.14	IFEC_align_status
IFEC corrected codewords	IFEC corrected codewords counter	1.2202, 1.2203	IFEC_corrected_cw_counter
IFEC uncorrected codewords	IFEC uncorrected codewords counter	1.2204, 1.2205	IFEC_uncorrected_cw_counter
RS-FEC lane *x* mapping	IFEC lane mapping	1.2206	IFEC_lane_mapping<*x*>
IFEC symbol errors, lane 0 to 3	IFEC symbol error counter, lane 0 to 3	1.2210 to 1.2217	IFEC_symbol_error_counter_*i*

Table 152–3—MDIO/Inverse RS-FEC status variable mapping for separated PMA

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
PCS align status	RS-FEC status	1.201.15	align_status
BIP error counter, lane 0 to 19	RS-FEC BIP error counter, lane 0 to 19	1.230 to 1.249	BIP_error_counter_*i*
Lane *x* mapping	RS-FEC PCS lane *x* mapping	1.250 to 1.269	lane_mapping<*x*>
Block lock *x*	RS-FEC PCS alignment status 1 and 2	1.280, 1.281	block_lock<*x*>
Lane *x* aligned	RS-FEC PCS alignment status 3 and 4	1.282, 1.283	am_lock<*x*>

152.6.2 IFEC_bypass_indication_enable

This variable is set to one to bypass the error indication function (see 152.5.2.3) when this ability is supported. When this variable is set to zero, the decoder indicates errors to the PCS sublayer. This variable has no effect (the decoder does not bypass error indication) if IFEC_bypass_correction_enable (1.2200.0) is set to one. The default value of this variable is zero. This variable is mapped to the bit defined in 45.2.1.216.1 (1.2200.1).

152.6.3 IFEC_bypass_correction_ability

The Reed-Solomon decoder may have the option to perform error detection without error correction (see 152.5.2.3) to reduce the delay contributed by the Inverse RS-FEC sublayer. This variable is set to one to indicate that the decoder has the ability to bypass error correction. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.217.9 (1.2201.0).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

152.6.4 IFEC_bypass_indication_ability

The Reed-Solomon decoder may have the option to bypass the error indication function (see 152.5.2.3) to reduce the delay contributed by the Inverse RS-FEC sublayer. This variable is set to one to indicate that the decoder has the ability to bypass the error indication function. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.217.8 (1.2201.1).

152.6.5 hi_ser

This variable is defined when the FEC_bypass_indication_ability variable is set to one. When FEC_bypass_indication_enable is set to one, this bit is set to one if the number of RS-FEC symbol errors in a window of 8192 codewords exceeds the threshold (see 152.5.2.3) and is set to zero otherwise. This variable is mapped to the bit defined in 45.2.1.217.7 (1.2201.2).

152.6.6 amps_lock<*x*>

These variables are assigned by the FEC synchronization state diagram shown in Figure 91–8 (see 152.5.4.3). They are mapped to the bits defined in 45.2.1.217 (1.2201.8 to 1.2201.11 for FEC lanes 0 to 3, respectively).

152.6.7 IFEC_align_status

This variable is assigned by the FEC alignment state diagram shown in Figure 91–9 (see 152.5.4.3). It is mapped to the bit defined in 45.2.1.217.2 (1.2201.14).

152.6.8 IFEC_corrected_cw_counter

A corrected FEC codeword is a codeword that contained errors and was corrected.

The IFEC_corrected_cw_counter is a 32-bit counter that counts once for each corrected FEC codeword processed when IFEC_align_status is true. This variable is mapped to the registers defined in 45.2.1.218 (1.2202, 1.2203).

152.6.9 IFEC_uncorrected_cw_counter

An uncorrected FEC codeword is a codeword that contains errors (when the bypass correction feature is supported and enabled) or contains errors that were not corrected (when the bypass correction feature is not supported or not enabled).

The IFEC_uncorrected_cw_counter is a 32-bit counter that counts once for each uncorrected FEC codeword processed when IFEC_align_status is true. This variable is mapped to the registers defined in 45.2.1.219 (1.2204, 1.2205).

152.6.10 IFEC_lane_mapping<*x*>

When the Inverse RS-FEC transmit function detects and locks to an alignment marker payload on the service interface lane *x*, the FEC lane number corresponding to the detected alignment marker payload is assigned to the variable IFEC_lane_mapping<*x*>. These variables are mapped to the register defined in 45.2.1.220 (1.2206).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

152.6.11 IFEC_symbol_error_counter_*i*

IFEC_symbol_error_counter_*i*, where *i* = 0 to 3, is a 32-bit counter that counts once for each 10-bit symbol corrected on FEC lane *i* when IFEC_align_status is true. These variables are mapped to the registers defined in 45.2.1.221 and 45.2.1.222 (1.2210 to 1.2217).

152.6.12 align_status

This variable is assigned the value of rx_align_status as defined by the PCS deskew state diagram shown in Figure 82–14 (see 152.5.3.2). It is mapped to the bit defined in 45.2.1.117 (1.201.15).

152.6.13 BIP_error_counter_*i*

BIP_error_counter_*i*, where *i* = 0 to 19, is a 16-bit counter that holds the BIP error count for PCS lane *i* as calculated by the RS-FEC receive function (see 152.5.3.4). These variables are mapped to the registers defined in 45.2.1.123 and 45.2.1.124 (1.230 to 1.249).

152.6.14 lane_mapping<*x*>

When the RS-FEC transmit function detects and locks to an alignment marker on FEC service interface lane *x*, the PCS lane number corresponding to the detected alignment marker is assigned to the variable lane_mapping<*x*>. These variables are mapped to the registers defined in 45.2.1.125 and 45.2.1.126 (1.250 to 1.269).

152.6.15 block_lock<*x*>

These variables are assigned by the block lock state diagram shown in Figure 82–12 (see 152.5.3.1). They are mapped to the registers defined in 45.2.1.127 and 45.2.1.128 (1.280 and 1.281).

152.6.16 am_lock<*x*>

These variables are assigned by the alignment marker lock state diagram shown in Figure 82–13 (see 152.5.3.2). They are mapped to the registers defined in 45.2.1.129 and 45.2.1.130 (1.282 and 1.283).

152.7 Protocol implementation conformance statement (PICS) proforma for Clause 152, Inverse RS-FEC sublayer[251]

152.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 152, Inverse RS-FEC sublayer, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

152.7.2 Identification

152.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

152.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 152, Inverse RS-FEC sublayer
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[251] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

153. SC-FEC and 100GBASE-ZR Physical Medium Attachment (PMA) sublayer for 100GBASE-ZR PHYs

153.1 Overview

153.1.1 Scope

This clause specifies a staircase FEC (SC-FEC) and PMA sublayer for 100GBASE-ZR PHYs.

153.1.2 Position of SC-FEC and 100GBASE-ZR PMA in the 100GBASE-R sublayers

Figure 153–1 shows the relationship of the SC-FEC and 100GBASE-ZR PMA to the ISO/IEC Open System Interconnection (OSI) reference model.

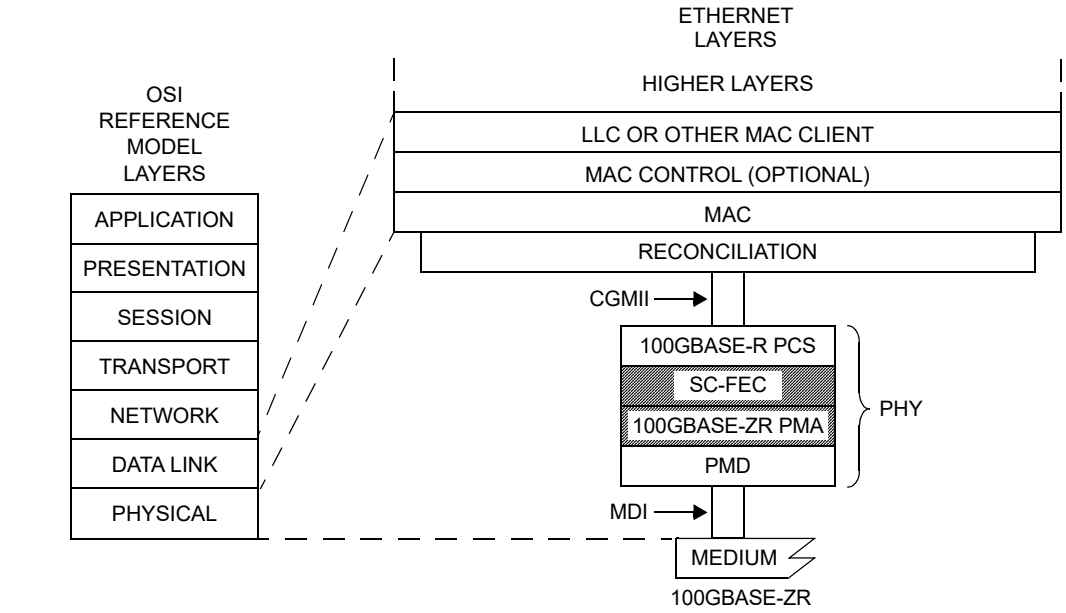

Figure 153–1—SC-FEC and 100GBASE-ZR PMA relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

153.2 SC-FEC sublayer

153.2.1 FEC service interface

This subclause specifies the services provided by the SC-FEC sublayer.

The FEC service interface is provided to allow the PCS, Inverse RS-FEC, or PMA to transfer information to and from the SC-FEC. The service interface is described in an abstract manner and does not imply any particular implementation. The FEC service interface is an instance of the inter-sublayer service interface defined in 80.3. The service interface primitives are summarized as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FEC:IS_UNITDATA_*i*.request
FEC:IS_UNITDATA_*i*.indication
FEC:IS_SIGNAL.indication

The FEC:IS_UNITDATA_*i* primitives are defined for $i = 0$ to 19. The PCS, Inverse RS-FEC, or PMA continuously sends 20 parallel bit streams to the SC-FEC sublayer, each at a nominal signaling rate of 5.15625 GBd. The SC-FEC sublayer continuously sends 20 parallel bit streams to the PCS, Inverse RS-FEC, or PMA, one per lane, each at a nominal signaling rate of 5.15625 GBd.

The SIGNAL_OK parameter of the FEC:IS_SIGNAL.indication primitive can take one of two values: OK or FAIL. The value is set to OK when the FEC receive function has identified codeword boundaries as indicated by fec_align_status equal to TRUE. The value is set to FAIL when the FEC receive function is unable to reliably establish codeword boundaries as indicated by fec_align_status equal to FALSE. When SIGNAL_OK is FAIL, the rx_bit parameters of the FEC:IS_UNITDATA_*i*.indication primitives are undefined.

The PCS or Inverse RS-FEC may be connected to the SC-FEC using an optional instantiation of the PMA service interface (see Annex 83A, Annex 83B, Annex 83D, and Annex 83E) in which case a PMA (see Clause 83) or Inverse FEC (see Clause 152) is a client of the FEC service interface.

153.2.2 Delay constraints

The maximum delay contributed by the SC-FEC sublayer (sum of transmit and receive delays at one end of the link) shall be no more than 1 827 840 bit times (3570 pause_quanta or 18 278.4 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

153.2.3 Functions within the SC-FEC sublayer

153.2.3.1 Functional block diagram

A functional block diagram of the SC-FEC sublayer is shown in Figure 153–2.

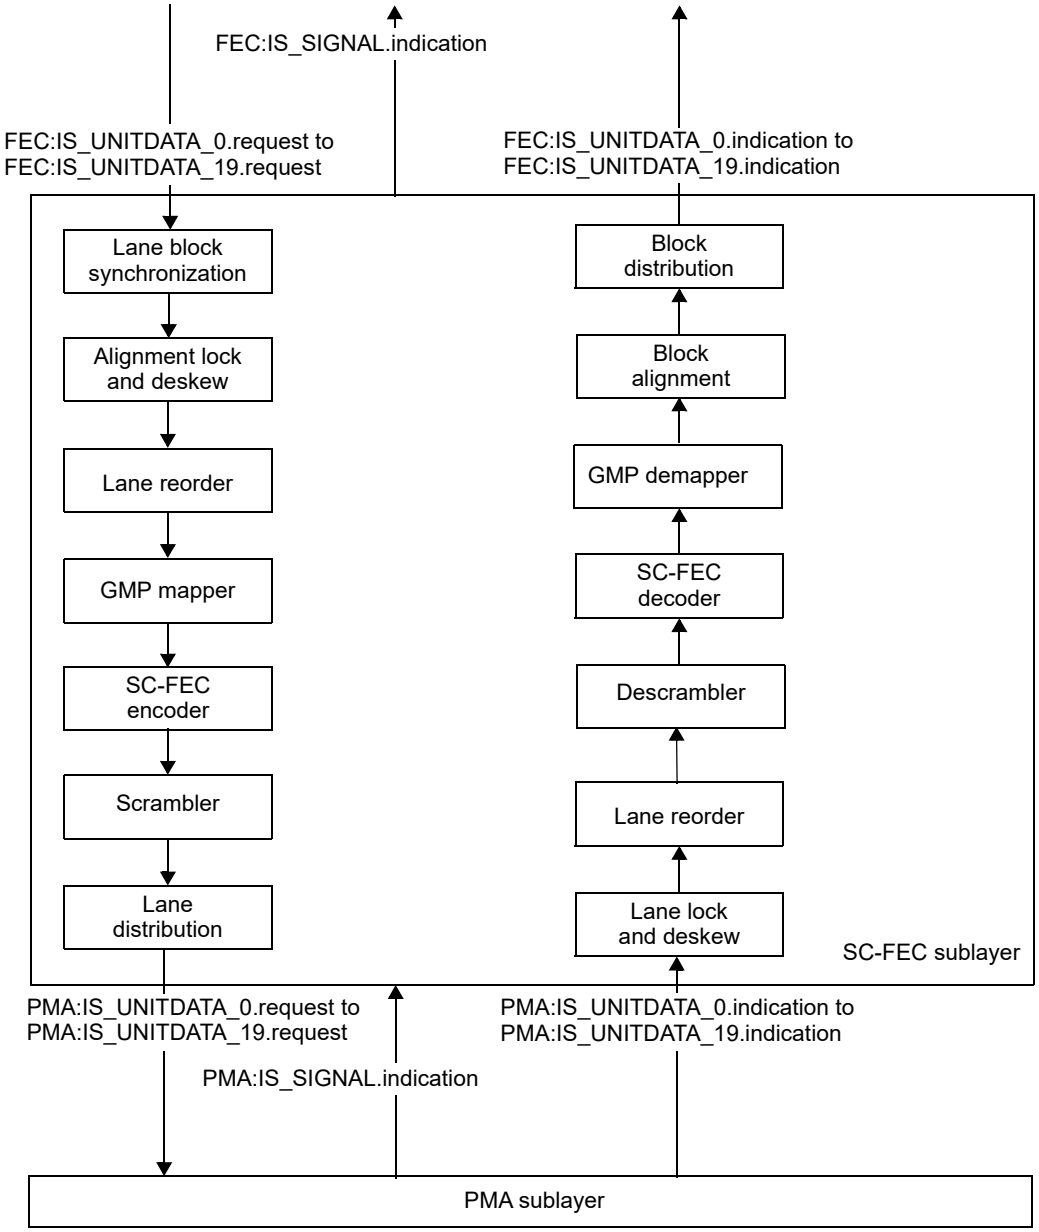

Figure 153–2—SC-FEC functional block diagram

153.2.3.2 Transmit function

153.2.3.2.1 Lane block synchronization

The SC-FEC transmit function forms 20 bit streams by concatenating the bits from each of the 20 FEC:IS_UNITDATA_*i*.request primitives in the order they are received. It obtains lock to the 66-bit blocks

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

in each bit stream using the sync headers and outputs 66-bit blocks. Block lock is obtained as specified in the block lock state diagram shown in Figure 82–12.

153.2.3.2.2 Alignment lock and deskew

Once the SC-FEC transmit function achieves block lock on a PCS lane, it then begins obtaining alignment marker lock as specified by the alignment marker lock state diagram shown in Figure 82–13. This process identifies the PCS lane number received on a particular lane of the service interface. After alignment marker lock is achieved on all 20 lanes, all inter-lane Skew is removed as specified by the PCS deskew state diagram shown in Figure 82–14. The SC-FEC transmit function shall support a maximum Skew of 49 ns between PCS lanes and a maximum Skew Variation of 400 ps. Skew and Skew Variation are defined in 80.5.

153.2.3.2.3 Lane reorder

PCS lanes can be received on different lanes of the service interface from which they were originally transmitted due to Skew between lanes and multiplexing by the PMA. The SC-FEC transmit function shall order the PCS lanes according to the PCS lane number. The result of this process is a logically serial stream of 66B block encoded information, including alignment markers, at a nominal signaling rate of 103.125 Gb/s.

153.2.3.2.4 GMP mapper

The generic mapping procedure (GMP) mapper inserts the serialized and deskewed stream of 66B blocks into an SC-FEC frame. The frame is similar to the OTU4 frame specified in ITU-T G.709 with the insertion of an SC-FEC parity specified in ITU-T G.709.2 Annex A. The frame consists of 16 320 octets, which for the purpose of description are illustrated as a four row, 4080 column structure with a logical transmission order left to right, top to bottom. This frame is illustrated in Figure 153–3.

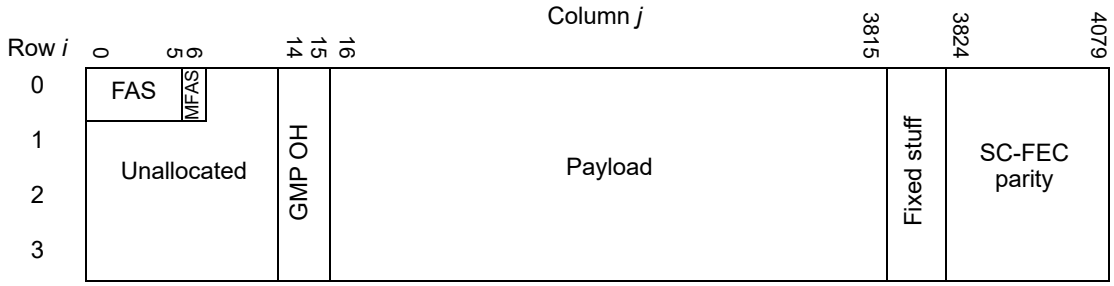

Figure 153–3—SC-FEC frame

The majority of the frame is scrambled prior to transmission (see 153.2.3.2.6). The information in the SC-FEC frame includes the following, described before scrambling:

1) The frame alignment signal (FAS) is similar in concept to the codeword marker described in Clause 108, being a fixed bit pattern occurring in the data stream at regular intervals allowing the receiver to locate and distinguish various elements in the transmitted data stream such as the payload and the FEC parity. The FAS is the following fixed bit pattern, transmitted left to right:
   1111 0110 1111 0110 1111 0110 0010 1000 0010 1000 0010 1000
2) The multi-frame alignment signal (MFAS) is a field that counts from 0 to 255, encoded with the most significant bit transmitted first. This is used for aligning SC-FEC base blocks with the SC-FEC frame and synchronizing the SC-FEC error decorrelator.
3) The unallocated portion of the frame corresponds to octet positions that are used for OTN path and section overhead in ITU-T G.709.2. These byte positions are not used for 100GBASE-ZR. They are transmitted with the value zero and are ignored on receipt.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

4) The GMP mapping overhead (GMP OH) is encoded in the eight octets from columns 14 and 15 of each of the four rows of the SC-FEC frame.
5) The 100GBASE-R PCS payload is GMP mapped in the area of the SC-FEC frame in the octets in columns 16 through 3815 in each of the four rows as shown in Figure 153–3.
6) The octets in the fixed stuff area of the frame are transmitted with the value zero and are ignored on receipt.
7) The SC-FEC parity area of the frame is allocated for FEC parity to be inserted as described in 153.2.3.2.5.

GMP is a generic mechanism that uses a sigma/delta distribution algorithm to accommodate an arbitrary signaling rate difference between a payload and the space in which it is carried. The principles of the GMP mapper are described in ITU-T G.709 (06/2020) Annex D, with details of the encoding of the GMP overhead in ITU-T G.709 Clause 19.4.3.2.

The payload area of the SC-FEC frame is divided into 190 GMP words of 80 octets each. Each 80-octet GMP word is either filled with data (the logically serialized 66B encoded stream produced according to 153.2.3.2.3) or stuff, which is transmitted as zero prior to scrambling and ignored on receipt.

The 66B encoded data is a logically serial stream at a rate of 103.125 Gb/s ± 100 ppm. The payload area of the SC-FEC frame has a capacity of (255/227) × (3800/4080) × 99.5328 Gb/s ± 20 ppm (~104.1367 Gb/s). The clocks for the PCS and the SC-FEC frame are independent. This results in an average number of 80-octet GMP words filled per SC-FEC frame between ~188.1315 and ~188.1766. Since the number of GMP words filled in a frame is always an integer, a given SC-FEC frame will have either 188 or 189 filled GMP words. While the GMP mechanism is generic, the particular clock rates and tolerances for this application result in a small number of cases, allowing the positions of data and stuff to be pre-computed. For either 188 or 189 GMP words filled in the SC-FEC frame, the GMP word consisting of the octets from column 16 to column 95 of row 0 will always be stuff (filled with zero rather than 66B encoded data prior to scrambling). In the case of 188 GMP words filled in the SC-FEC frame, the GMP word consisting of the octets from column 16 to column 95 of row 2 will also be stuff. Given the range of clock rate differences that may exist between the 66B encoded data and the SC-FEC frame payload capacity, there will tend to be between 4 and 7 frames with 188 filled GMP words between every frame with 189 filled GMP words. There is not a circumstance where there would be two consecutive frames containing 189 filled GMP words.

The GMP overhead is illustrated in Figure 153–4.

	Column															
	14								15							
Row	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
0	0	0	0	D9	D8	D7	D6	D5	C13	C12	C11	C10	C9	C8	C7	C6
1	0	0	0	D4	D3	D2	D1	D0	C5	C4	C3	C2	C1	C0	II	DI
2	0	0	0	CRC-5					CRC-8							
3	0x00								0x00							

Figure 153–4—GMP overhead encoding

The information in rows 0 and 1 of column 15 indicates how many (188 or 189) GMP words are filled in the next SC-FEC frame. While GMP is a generic mechanism, the particular use on this interface leaves only a small number of ways to fill in this information. Since the number of GMP words to be filled in a frame is normally expected to vary within a small range, special coding is used to indicate when the number of filled GMP words is the same, one greater, or one fewer than in the previous frame. The following cases exist for this interface:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— The number of GMP words to be filled in the next SC-FEC frame is the same as the number of GMP words filled in this frame. This can only occur in the case of 188 filled GMP words, as the ratio of the two clock rates does not provide a case where two consecutive frames will contain 189 filled GMP words. The number 188 is encoded in bits C0 through C13, with C0 being the least significant bit and C13 being the most significant bit. The increment indicator (II bit) and decrement indicator (DI bit) are set to zero.

— The number of GMP words to be filled in the next SC-FEC frame is one greater than the number of GMP words filled in this SC-FEC frame. This will only occur in the case where the number of GMP words filled in this SC-FEC frame is 188 and the number of GMP words to be filled in the next SC-FEC frame is 189. This is signaled by inverting all of the odd-numbered C bits (C13, C11, C9, C7, C5, C3, and C1) from the value in the previous frame, setting the increment indicator (II bit) to one, and setting the decrement indicator (DI bit) to zero.

— The number of GMP words to be filled in the next SC-FEC frame is one fewer than the number of GMP words filled in this SC-FEC frame. This will only occur in the case where the number of GMP words filled in this SC-FEC frame is 189 and the number of GMP words to be filled in the next SC-FEC frame is 188. This is signaled by inverting all of the even-numbered C bits (C12, C10, C8, C6, C4, C2, C0) from the numeric value of GMP words filled in the previous frame (189), setting the decrement indicator (DI bit) to one, and setting the increment indicator (II bit) to zero.

The bit values for these three cases are shown in Table 153–1.

Table 153–1—Encoding of GMP words in next SC-FEC frame

This frame	Next frame	C13	C12	C11	C10	C9	C8	C7	C6	C5	C4	C3	C2	C1	C0	II	DI
188	188	0	0	0	0	0	0	1	0	1	1	1	1	0	0	0	0
	189	1	0	1	0	1	0	0	0	0	1	0	1	1	0	1	0
189	188	0	1	0	1	0	1	1	1	1	0	1	0	0	0	0	1

While there is an 8-bit Hamming distance between valid values that can go in rows 0 and 1 of column 15, this information is also protected by a CRC-8 inserted into row 2 of column 15. The generator polynomial for this CRC-8 is $x^8 + x^3 + x^2 + 1$, and is calculated as follows:

— The octets from rows 0 and 1 of column 15 are taken in network octet order, most significant/first transmitted bit first, to form a 16-bit pattern representing the coefficients of a polynomial $M(x)$ of degree 15.

— $M(x)$ is multiplied by x^8 and divided (modulo 2) by the generating polynomial, producing a remainder $R(x)$ of degree 7 or less.

— The coefficients of $R(x)$ are considered to be an 8-bit sequence, where x^7 is the most significant bit.

— This 8-bit sequence is the CRC-8 where the first bit of the CRC-8 to be transmitted is the coefficient of x^7 and the last bit transmitted is the coefficient of x^0.

To reduce the mapping jitter, extra timing information is provided to allow the Tx to inform the Rx how many octets of 66B encoded PCS data are received in each SC-FEC frame period. This can be understood as the number of extra octets (or portions of octets) that are held in the Tx buffer, whose fill level varies with the clock offset of the incoming 66B blocks and depending on whether 188 or 189 GMP words are filled in a given SC-FEC frame. As an example, consider a case where both the PCS and SC-FEC clocks are running at approximately nominal rate, and an average of 15 052 octets of 66B encoded PCS data are to be transmitted in each SC-FEC frame period. This is 12 octets more than 188 filled GMP words of 80 octets.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Assume in the first frame period, where 188 GMP words are filled, that there are 15 excess octets in the Tx buffer, fewer than required to fill 189 GMP words. 188 × 80 octets of 66B encoded data are transmitted, and in the next SC-FEC frame period the Tx buffer fill has grown to 27 excess octets. The Tx buffer fill grows by 12 octets each frame period when 188 GMP words are filled, so grows from 39 to 51 to 63 to 75 octets. Then, in the seventh SC-FEC frame, there are sufficient extra octets in the Tx buffer to fill 189 × 80 octets in the SC-FEC frame, so 189 × 80 octets are transmitted, and the buffer fill level drops to 75 + 12 – 80 = 7 octets.

This extra timing information, essentially the number of excess octets in the Tx buffer, is signaled from the Tx to the Rx in rows 0 and 1 of column 14 of the SC-FEC frame. This is signaled as a 10-bit value in bits D0 through D9, with D0 being the least significant bit. This field may take values from 0 to 80 to reflect the number of excess full or partial octets in the Tx buffer. This information allows the Rx to know how many octets to distribute from its buffer in each SC-FEC frame period, and hence allows maintaining one-octet timing granularity even though the mapping granularity into the SC-FEC frame is 80 octet groups.

The bits D0 through D9 are protected by a CRC-5, which is calculated using a generator polynomial of $x^5 + x + 1$. This is calculated by the following steps:

— The bits D9 through D0 are taken in transmission order, most significant bit first, to form a 10-bit pattern representing the coefficients of a polynomial $M(x)$ of degree 9.
— $M(x)$ is multiplied by x^5 and divided (modulo 2) by the generator polynomial, producing a remainder $R(x)$ of degree 4 or less.
— The coefficients of $R(x)$ are considered to be a 5-bit sequence, where x^4 is the most significant bit.
— This 5-bit sequence is the CRC-5 where the first bit of the CRC-5 to be transmitted is the coefficient of x^4 and the last bit transmitted is the coefficient of x^0.

The third row of the GMP overhead is transmitted as zero and ignored on receipt.

153.2.3.2.5 SC-FEC encoder

The SC-FEC parity is calculated and inserted into the octets in columns 3824 through 4079 of each row of the FEC frame shown in Figure 153–3. The SC-FEC code is a blockwise recursively encoded 512 × 510 staircase code, sandwiched between a 30 592 + 2048 bit-wide optimized error decorrelator interleaver and error correlator de-interleaver. Computation of the FEC parity is described in ITU-T G.709.2 Annex A. The 512 × 510 code block distributes over two of the FEC frames shown in Figure 153–3.

153.2.3.2.6 Scrambler

The operation of the scrambler shall be functionally identical to a frame synchronous scrambler of length 65 535 operating at the bit-rate of the SC-FEC frame. The generating polynomial shall be $1 + x + x^3 + x^{12} + x^{16}$. The scrambler shall be reset to 0xFFFF at the first transmitted bit of the MFAS octet. The FAS octets are not scrambled. Figure 153–5 provides a functional block diagram of the frame synchronous scrambler.

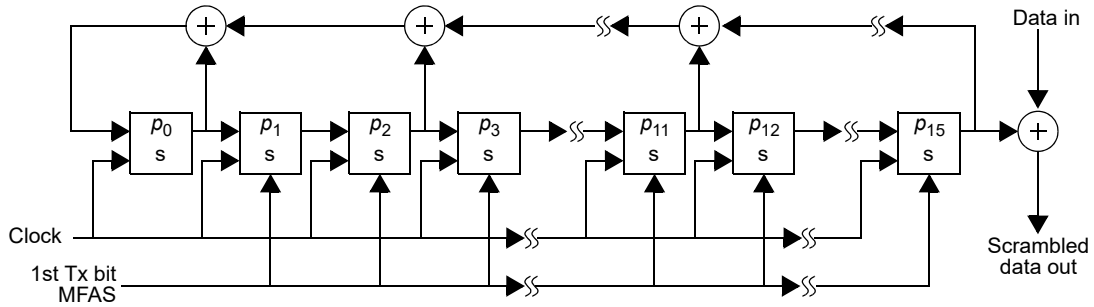

Figure 153–5—Frame synchronous scrambler

153.2.3.2.7 Lane distribution

The octets of the FEC frame are distributed to 20 FEC lanes as follows: The 6th octet of the FAS is replaced by a lane counter that increments from 0 to 239 on successive frames, with the most significant bit of the counter transmitted first. The lane counter 0 position shall be aligned with MFAS = 0 position every 3840 (the least common multiple of 240 and 256) frame periods. The counter resets to 0 on the first frame following the frame where the counter reaches the value 239.

Starting from the beginning of an FEC frame where the lane counter modulo 20 equals zero, the FEC frame is distributed to 20 FEC lanes 16 octets at a time in a round-robin manner as illustrated in Figure 153–6.

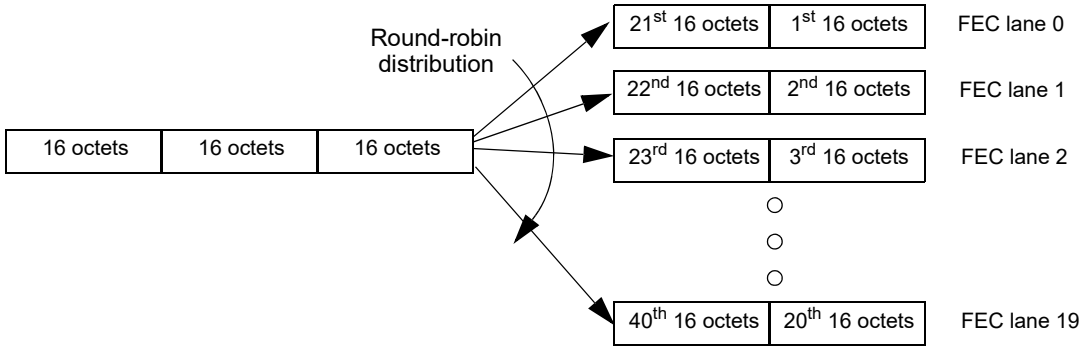

Figure 153–6—Lane distribution

51 groups of 16 octets are distributed from the FEC frame (consisting of 4080 × 4 octets) to each of the 20 FEC lanes.

At each FEC frame boundary, the assignment of 16-octet groups to FEC lanes is rotated, such that for each FEC frame where the lane counter modulo 20 equals 1, the first 16 octets of the FEC frame is distributed to FEC lane 1, the second 16 octets of the FEC frame is distributed to FEC lane 2, and so forth, with the 20th 16 octets of the FEC frame distributed to FEC lane 0. This pattern continues, with the final rotation occurring where the lane counter modulo 20 equals 19, where the first 16 octets of the FEC frame is distributed to FEC lane 19.

NOTE—This distribution to FEC lanes follows the distribution method of OTU4 to parallel lanes described in ITU-T G.709 Annex C.

153.2.3.3 Receive function

153.2.3.3.1 Lane lock and deskew

The SC-FEC receive function forms 20 bit streams by concatenating the bits from each of the 20 PMA:IS_UNITDATA_*i*.indication primitives in the order they are received. It obtains lock to the FAS as specified by the SC-FEC synchronization state diagram shown in Figure 153–7. After frame alignment lock is achieved on all 20 lanes, all inter-lane Skew is removed as specified by the SC-FEC deskew state diagram shown in Figure 153–8. The FEC receive function shall support a maximum Skew of 180 ns between FEC lanes and a maximum Skew Variation of 4 ns.

NOTE—An alternative method for frame alignment of OTU4 distributed to parallel lanes described in ITU-T G.709 Annex C is described in ITU-T G.798 [B46]. Equipment using this alternative method of frame alignment can interconnect with equipment implementing the SC-FEC synchronization state diagram shown in Figure 153–7, with each end of the link identifying and deskewing lanes according to its own method. The methods should not be combined at the same end of the link: in particular, if the ITU-T G.798 [B46] process is used, SIGNAL_OK=FALSE should not be indicated when in the out-of-frame (OOF) or out-of-recovery (OOR) states.

153.2.3.3.2 Lane reorder

Transmit FEC lanes can be received on different lanes of the service interface from which they were originally transmitted due to Skew between lanes and multiplexing by the PMA. The receive SC-FEC shall order the received FEC lanes according to the FEC lane number, which is the 6th octet of the FAS (inserted as per 153.2.3.2.7) modulo 20. As the reordered lanes are interleaved in the original order, the FEC lane number is replaced by the original final octet of the FAS, which has a value of 0010 1000.

153.2.3.3.3 De-scrambler

The de-scrambler reverses the effects of the scrambler described in 153.2.3.2.6. Since the scrambler is frame synchronous, this is accomplished by XORing each bit after the FAS, which is not scrambled, with the same sequence resulting from the generating polynomial used by the scrambler.

153.2.3.3.4 SC-FEC decoder

Errors are corrected by applying the process described in ITU-T G.709.2 Annex A. This operates by passing the received information and parity bits through an error decorrelator interleaver process, a parity compute, compare, and error correction process, and an error decorrelator deinterleaver process. The FEC parity is removed from the frame shown in Figure 153–3 after error correction.

The SC-FEC decoder indicates errors to the PCS sublayer by replacing all 66-bit blocks (extracted from the SC-FEC frame using the process described in 153.2.3.3.5) that are fully or partially contained within an uncorrected codeword (including uncorrectable codewords, or potentially mis-corrected or not fully corrected codewords) with error control blocks. An error control block has control block type 0x1E and carries eight /E/ control characters. The marking includes a 66-bit block that begins in the SC-FEC codeword preceding the uncorrected SC-FEC codeword and ending in the uncorrected codeword, and a 66-bit block that begins in the uncorrected codeword and ends in the next codeword. The probability that the SC-FEC decoder fails to replace 66-bit blocks in an uncorrectable codeword is expected to be less than 10^{-6}.

153.2.3.3.5 GMP demapper

The GMP demapper extracts the deskewed and serialized stream of 66B blocks that was inserted according to the process described in 153.2.3.2.4 from the SC-FEC frame.

The principles of the GMP demapper are described in ITU-T G.709 Annex D, with details of the encoding of the GMP overhead in ITU-T G.709 Clause 19.4.3.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The GMP demapper extracts 188 or 189 groups of 80 octets of 66B encoded data from each SC-FEC frame (frame *n*), controlled by the GMP overhead (see Table 153–1) in the previous SC-FEC frame (frame *n* – 1). If a C13:C0 value other than 188 or 189, or DI=1 and II=1 is received, the GMP demapper behavior is undefined. The number of 80-octet groups demapped from SC-FEC frame *n*, together with the change in value of the extra timing information (see 153.2.3.2.4) in between SC-FEC frames *n* – 1 and *n* – 2 are used to calculate how many octets of 66B encoded data are sent towards the FEC service interface in each SC-FEC frame period.

153.2.3.3.6 Block alignment

Block lock is obtained on the bit sequence extracted by the GMP demapper using the block lock state diagram shown in Figure 82–12.

153.2.3.3.7 Block distribution

Once block alignment has been achieved per 153.2.3.3.6, 66B blocks are distributed round robin to the lanes of the service interface as described in 82.2.6.

153.2.4 Detailed functions and state diagrams

The body of this subclause includes state diagrams, including the associated definitions of variables, functions, and counters. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

153.2.4.1 State variables

153.2.4.1.1 Variables

all_locked
: A Boolean variable that is set to TRUE when fas_lock<*x*> is TRUE for all *x* and is set to FALSE when fas_lock<*x*> is FALSE for any *x*.

current_fecl
: A variable that holds the FEC lane identification octet corresponding to the current FAS that is recognized on a given lane of the PMA service interface. The value of this variable modulo 20 represents the FEC lane number. It is compared to the expected value based on the variable prev_fecl to confirm that the location of the FAS has been detected. This value is interpreted with the most significant bit transmitted first.

fas_counter_done
: Boolean variable that indicates that fas_counter has reached its terminal count.

fas_match
: Boolean variable that holds the output of the function FAS_COMPARE.

fas_valid
: Boolean variable that is set to TRUE if the received 6-octet sequence is a valid FAS. The FAS consists of five known octets and one variable octet. The sequence is considered to be valid if at least four of the first five octets match the known bits of the pattern described in 153.2.3.2.4, and the 6th octet represents a numerical value in the range 0 to 239 with the most-significant bit transmitted first.

fas_lock<*x*>
: Boolean variable that is set to TRUE when the receiver has detected the location of the FAS for a given lane on the PMA service interface, where *x* = 0:19.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

fec_align_status
: A Boolean variable set by the FEC alignment process to reflect the status of FEC lane-to-lane alignment. Set to TRUE when all lanes are synchronized and aligned and set to FALSE when the deskew process is not complete.

fec_alignment_valid
: Boolean variable that is set to TRUE if all FEC lanes are aligned. FEC lanes are considered to be aligned when fas_lock<*x*> is TRUE for all *x*, each FEC lane has a unique lane number, and the FEC lanes are deskewed. Otherwise, this variable is set to FALSE.

fec_enable_deskew
: A Boolean variable that indicates the enabling and disabling of the deskew process. Data may be discarded whenever deskew is enabled. TRUE when deskew is enabled. FALSE when deskew is disabled.

fec_lane
: A variable that holds the FEC lane number (0 to 19) received on lane *x* of the PMA service interface when fas_lock<*x*> = TRUE. The FEC lane number is determined by the 6th octet of the FAS, interpreted with the most significant bit transmitted first, modulo 20. It is set to current_fecl modulo 20 when the expected FAS is found in the expected location in a second consecutive SC-FEC frame.

FEC_lane_mapping<*x*>
: This variable indicates which FEC lane is received on lane *x* of the PMA service interface when fas_lock<*x*> = TRUE, where *x* = 0:19.

prev_fecl
: A variable that holds the value of the lane identification octet (or the expected value of the lane identification octet) from the previous SC_FEC frame. The value is interpreted with the most significant bit transmitted first. The lane represented is this value modulo 20. It is used to calculate the expected value of the lane identification octet in the next SC-FEC frame period that is tested.

reset
: Boolean variable that controls the resetting of the SC-FEC sublayer. It is TRUE whenever a reset is necessary including when reset is initiated from the MDIO and during power on.

restart_lock
: Boolean variable that is set by the FEC alignment process to reset the synchronization process on all FEC lanes. It is set to TRUE when 15 FASs in a row fail to match (15_BAD state).

rx_align_status
: Boolean variable that is set by the lane lock and deskew function (see 153.2.3.3.1).

signal_ok
: Boolean variable that is set based on the most recently received value of PMA:IS_SIGNAL.indication (SIGNAL_OK). It is TRUE if the value was OK and FALSE if the value was FAIL.

slip_done
: Boolean variable that is set to TRUE when the SLIP requested by the synchronization state diagram has been completed indicating that the next candidate FAS position can be tested.

test_fas
: Boolean variable that is set to TRUE when a candidate FAS position is available for testing and FALSE when the FIND_1ST state is entered.

153.2.4.2 Functions

FAS_COMPARE
: This function compares the FAS with its expected value to determine if a valid frame alignment sequence has been detected and returns the result of the comparison using the variable fas_match. FAS_COMPARE is TRUE if fas_valid is TRUE, and current_fecl (interpreted with the most significant bit transmitted first) is equal to the prev_fecl plus 20 modulo 240. Otherwise, fas_match is FALSE.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SLIP

Causes the next candidate FAS position to be tested. The precise method for determining the next candidate FAS position is not specified and is implementation dependent. An implementation shall ensure that the FAS pattern can be detected in any possible position.

153.2.4.3 Counters

fas_bad_count

Counts the number of consecutive FASs that don't match the expected value for a given FEC lane.

fas_counter

Counts the 16 320 octets between the starting position of one FAS and the expected starting position of the next FAS on an FEC lane. This counter starts with a value of zero when start fas_counter is asserted (at the position of the first octet of a matched FAS pattern on an FEC lane), is incremented for each octet on that FEC lane, and reaches a terminal value of 16 320 at the expected position of the next FAS pattern on that FEC lane.

153.2.4.4 State diagrams

The SC-FEC shall implement 20 synchronization processes as shown in Figure 153–7. The synchronization process operates independently on each lane. The SC-FEC sublayer uses this process to detect the location of the frame alignment sequence in the received bit stream on each lane of the PMA service interface.

The SC-FEC shall implement the deskew process as shown in Figure 153–8.

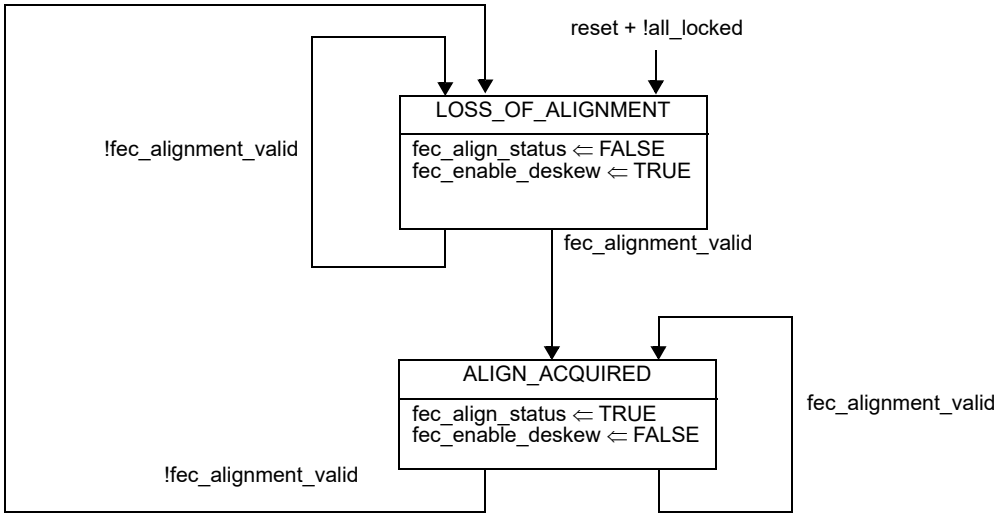

Figure 153–8—SC-FEC deskew state diagram

153.2.5 SC-FEC MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the SC-FEC. If MDIO is implemented, it shall map MDIO status bits to SC-FEC status variables as shown in Table 153–2.

153.2.5.1 FEC_corrected_cw_counter

A corrected FEC codeword is a codeword that contained errors and was corrected.

The FEC_corrected_cw_counter is a 32-bit counter that counts once for each corrected FEC codeword processed when fec_align_status is TRUE. This variable is mapped to the registers defined in 45.2.1.227 (1.2276, 1.2277).

153.2.5.2 FEC_uncorrected_cw_counter

An uncorrected FEC codeword is a codeword that contains errors that were not corrected, including FEC codewords that may have been mis-corrected or not completely corrected.

The FEC_uncorrected_cw_counter is a 32-bit counter that counts once for each uncorrected FEC codeword processed when fec_align_status is TRUE. This variable is mapped to the registers defined in 45.2.1.228 (1.2278, 1.2279).

153.2.5.3 FEC_total_bits_counter

The FEC_total_bits_counter is a 64-bit counter that counts once for each bit processed by the SC-FEC decoder. This variable is mapped to the registers defined in 45.2.1.229 (1.2280, 1.2281, 1.2282, 1.2283). This may used together with the FEC_corrected_bits_counter (see 153.2.5.4) as a measure of pre-FEC BER.

Table 153–2—MDIO/SC-FEC Status variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
SC-FEC FAS lock *x*, *x* = 0 to 19	SC-FEC alignment status 1 and 2 registers	1.2246.7:0 1.2247.11:0	fas_lock<*x*>
SC-FEC align status	SC-FEC alignment status 1 register	1.2246.12	fec_align_status
Lane *x* mapping, *x* = 0 to 19	SC-FEC lane mapping, lane *x* register	1.2250 through 1.2269	FEC_lane_mapping<*x*>
FEC corrected codewords	SC-FEC corrected codewords counter register	1.2276, 1.2277	FEC_corrected_cw_counter
FEC uncorrected codewords	SC-FEC uncorrected codewords counter register	1.2278, 1.2279	FEC_uncorrected_cw_counter
FEC total bits	SC-FEC total bits register	1.2280, 1.2281, 1.2282, 1.2283	FEC_total_bits_counter
FEC corrected bits	SC-FEC corrected bits register	1.2284, 1.2285, 1.2286, 1.2287	FEC_corrected_bits_counter

153.2.5.4 FEC_corrected_bits_counter

The FEC_corrected_bits_counter is a 64-bit counter that counts once for each bit corrected by the SC-FEC decoder. This variable is mapped to the registers defined in 45.2.1.230 (1.2284, 1.2285, 1.2286, 1.2287). This may be used together with the FEC_total_bits_counter (see 153.2.5.3) to calculate pre-FEC BER.

153.3 100GBASE-ZR PMA sublayer

153.3.1 100GBASE-ZR PMA service interface

This subclause specifies the services provided by the 100GBASE-ZR PMA sublayer. The 100GBASE-ZR PMA service interface is provided to allow the SC-FEC to transfer information to and from the 100GBASE-ZR PMD. The service interface is specified in an abstract manner and does not imply any particular implementation. The service interface primitives are summarized as follows:

PMA:IS_UNITDATA_*i*.request
PMA:IS_UNITDATA_*i*.indication
PMA:IS_SIGNAL.indication

The primitives are defined for i = 0 to 19. The SC-FEC continuously sends 20 parallel bit streams to the 100GBASE-ZR PMA sublayer, each at a nominal signaling rate of (255/227) × 4.97664 Gb/s ± 20 ppm (~5.59049868 Gb/s). Likewise the 100GBASE-ZR PMA sublayer continuously sends 20 parallel bit streams to the SC-FEC sublayer, each at a nominal signaling rate of (255/227) × 4.97664 Gb/s ± 20 ppm (~5.59049868 Gb/s).

Copyright © 2022 IEEE. All rights reserved.

153.3.2 Functions within the 100GBASE-ZR PMA sublayer

153.3.2.1 Functional block diagram

A functional diagram of the 100GBASE-ZR PMA sublayer is shown in Figure 153–9.

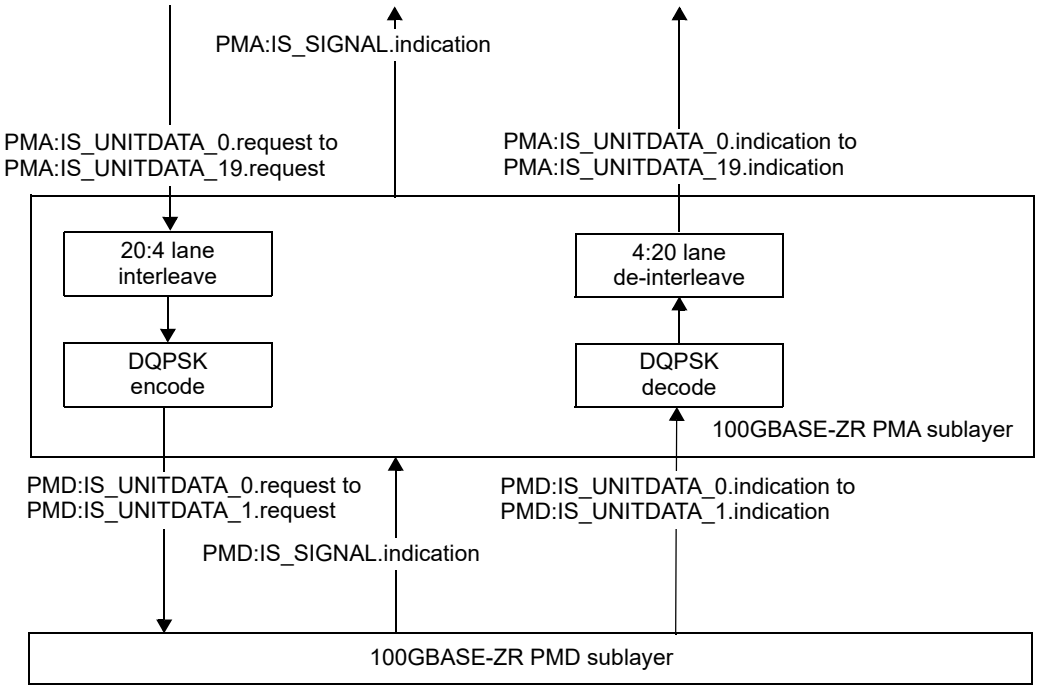

Figure 153–9—100GBASE-ZR PMA functional block diagram

153.3.2.2 Transmit function

153.3.2.2.1 Lane interleave

The lane interleave function bit-multiplexes groups of five lanes of the PMA service interface to form four logical bit streams operating at five times the service interface signaling rate. Each of the four bit streams constructed in this manner operates at a signaling rate of (255/227) × 24.8832 Gb/s ± 20 ppm (~27.9525 Gb/s). The selection of which five lanes of the service interface is used to form each lane of the four-lane interface is arbitrary, but the combination of service interface lanes used to form each of the four lanes, and the order in which the bits are multiplexed from each of the input lanes, does not change while the link is in service. Each service interface lane is bit-multiplexed into exactly one lane of the four-lane interface.

NOTE—This four-lane interface format is referred to in ITU-T G.709 and ITU-T G.709.2 as OTL4.4.

153.3.2.2.2 DQPSK encode

The differential quadrature phase shift keying (DQPSK) encode function takes information from pairs of lanes (A, B) of the four-lane interface produced by the lane interleave function described in 153.3.2.2.1 and encodes them as a two streams of DQPSK symbols, one stream formed from each lane pair. The selection of the two lanes of the four-lane interface used to form each stream of DQPSK symbols is arbitrary, but does not change while the link is in service. The signaling rate of each stream of DQPSK symbols is (255/227) × 24.8832 GBd ± 20 ppm (~27.9525 GBd).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

With differential encoding, each DQPSK symbol can take one of four values 0 to 3. These four values are associated with the values of the pair of bits from the two lanes of the four-lane interface used to form each DQPSK symbol stream. The mapping of pairs of bits to DQPSK symbol values is given in Table 153–3.

Table 153–3—Bit mapping to DQPSK symbol values

Lane bit values A, B	DQPSK symbol value
00	0
10	1
11	2
01	3

153.3.2.3 Receive function

153.3.2.3.1 DQPSK decode

The 100GBASE-ZR PMA receives from the 100GBASE-ZR PMD two streams of DQPSK symbols at a signaling rate of (255/227) × 24.8832 GBd ± 20 ppm (~27.9525 Gbd). The two streams of DQPSK symbols are converted to a four-lane digital interface as follows:

1) Each received DQPSK symbol is converted to a pair of bits as shown in Table 153–3.
2) One bit of each DQPSK symbol (A, B) is sent on a different lane of the four-lane digital interface. The assignment of each bit-position from the DQPSK symbols on the two DQPSK symbol streams to lanes of the four-lane digital interface is arbitrary, but does not change while the link is in service.

NOTE—This four-lane interface format is referred to in ITU-T G.709 and ITU-T G.709.2 as OTL4.4.

153.3.2.3.2 Lane de-interleave

Each lane of the four-lane digital signal produced by decoding of DQPSK symbols described in 153.3.2.3.1 is de-interleaved to five lanes of the 100GBASE-ZR PMA service interface by distributing successive bits round robin to each of the 100GBASE-ZR PMA service interface lanes. The assignment of bit positions on each of the lanes of the four-lane interface to the service interface lanes is arbitrary, but does not change while the link is in service.

153.4 Protocol implementation conformance statement (PICS) proforma for Clause 153, SC-FEC and 100GBASE-ZR Physical Medium Attachment (PMA) sublayer for 100GBASE-ZR PHYs[252]

153.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 153, SC-FEC and 100GBASE-ZR Physical Medium Attachment (PMA) sublayer for 100GBASE-ZR PHYs, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

153.4.2 Identification

153.4.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

153.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 153, SC-FEC and 100GBASE-ZR Physical Medium Attachment (PMA) sublayer for 100GBASE-ZR PHYs
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[252]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

154. Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-ZR

154.1 Overview

This clause specifies the 100GBASE-ZR PMD together with the associated single-mode fiber-based dense wavelength division multiplexing (DWDM) channel that may contain one or more optical amplifiers and is specified using a black link approach (see 154.6). The optical signal generated by this PMD type is modulated using a dual polarization differential quadrature phase shift keying (DP-DQPSK) format suitable for reception by a coherent optical receiver. When forming a complete Physical Layer, a PMD shall be connected to the 100GBASE-ZR PMA as shown in Table 154–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 154–1—Physical Layer clauses associated with the 100GBASE-ZR PMD

Associated clause	100GBASE-ZR
81—RS	Required
81—CGMII[a]	Optional
82—PCS	Required
83—100GBASE-R PMA	Optional
91—RS-FEC	Optional
83A—CAUI-10 C2C	Optional
83B—CAUI-10 C2M	Optional
83D—CAUI-4 C2C	Optional
83E—CAUI-4 C2M	Optional
152—Inverse RS-FEC	Conditional[b]
153—SC-FEC	Required
153—100GBASE-ZR PMA	Required
135—100GBASE-P PMA	Optional
135D—100GAUI-4 C2C	Optional
135E—100GAUI-4 C2M	Optional
135F—100GAUI-2 C2C	Optional
135G—100GAUI-2 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]Clause 152 inverse RS-FEC mandatory when Clause 91 RS-FEC is present.

Figure 154–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 100 Gigabit Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2.

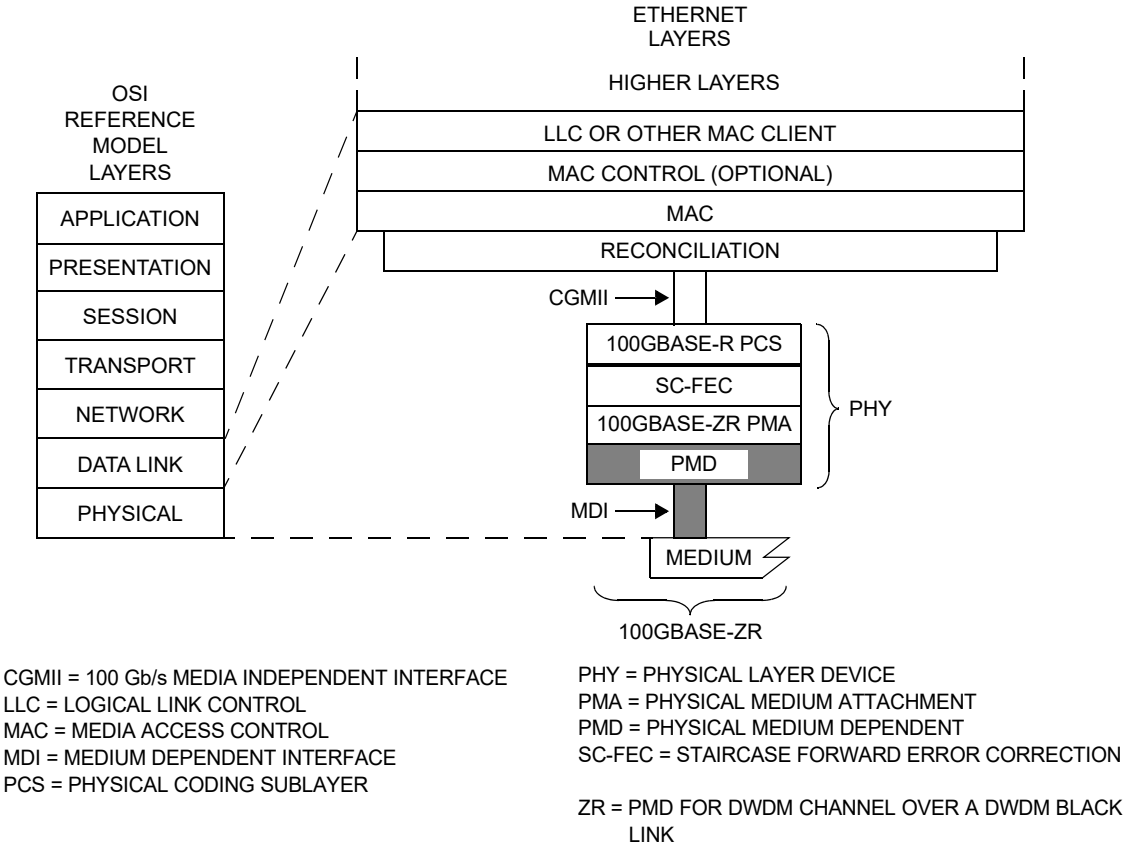

Figure 154–1—100GBASE-ZR PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

100GBASE-ZR PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

154.1.1 Bit error ratio

The bit error ratio (BER) when processed by the PMA (Clause 153) shall be less than 4.62×10^{-3} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when additionally processed by the FEC (Clause 153) and PCS (Clause 82).

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

154.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 100GBASE-ZR PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The 100GBASE-ZR PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with two symbol streams, one for each polarization. The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 100GBASE-ZR PMD has two parallel symbol streams, in which case $i = 0$ to 1.

In the transmit direction, the PMA continuously sends two parallel DQPSK symbol streams to the PMD, one stream per polarization, each with symbol values 0 to 3 and at a nominal signaling rate of (255/227) × 24.8832 GBd (~27.9525 GBd), using the PMD:IS_UNITDATA_*i*.request primitive. The PMD then converts these streams of symbols into the appropriate signals on the MDI.

In the receive direction, the PMD continuously sends two parallel DQPSK symbol streams to the PMA, corresponding to the signals received from the MDI, each with symbol values 0 to 3, using the PMD:IS_UNITDATA_*i*.indication primitive, at a nominal signaling rate of (255/227) × 24.8832 GBd (~27.9525 GBd).

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable SIGNAL_DETECT parameter as defined in 154.5.4. The SIGNAL_DETECT parameter takes a fixed value of OK.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 154.1.1.

154.3 Delay and Skew

154.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 100GBASE-ZR PMD including 2 m of fiber in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

154.3.2 Skew constraints

The Skew (relative delay) between the FEC lanes is kept within limits so that the information on the FEC lanes can be reassembled by the FEC. The Skew Variation is also limited to ensure that a given FEC lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP0 to SP7 shown in Figure 80–9.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation, see 80.5.

154.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 154–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 154–3.

Table 154–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
Tx optical channel index	Tx optical channel control register	1.800.5:0	Tx_optical_channel_index
Rx optical channel index	Rx optical channel control register	1.820.5:0	Rx_optical_channel_index

Table 154–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
Tx index ability 0 to Tx index ability 47	Tx optical channel ability 1 register to Tx optical channel ability 3 register	1.801 to 1.803	Tx_index_ability_0 to Tx_index_ability_47
Tx Rx different optical channel ability	Rx optical channel control register	1.820.15	Tx_Rx_diff_opt_chan_ability
Rx index ability 0 to Rx index ability 47	Rx optical channel ability 1 register to Rx optical channel ability 3 register	1.821 to 1.823	Rx_index_ability_0 to Rx_index_ability_47

154.5 PMD functional specifications

The 100GBASE-ZR PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

154.5.1 PMD block diagram

The PMD block diagram is shown in Figure 154–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 154.9 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 154.11). Unless specified otherwise, all receiver measurements and tests defined in 154.9 are made at TP3.

TP1 and TP4 are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

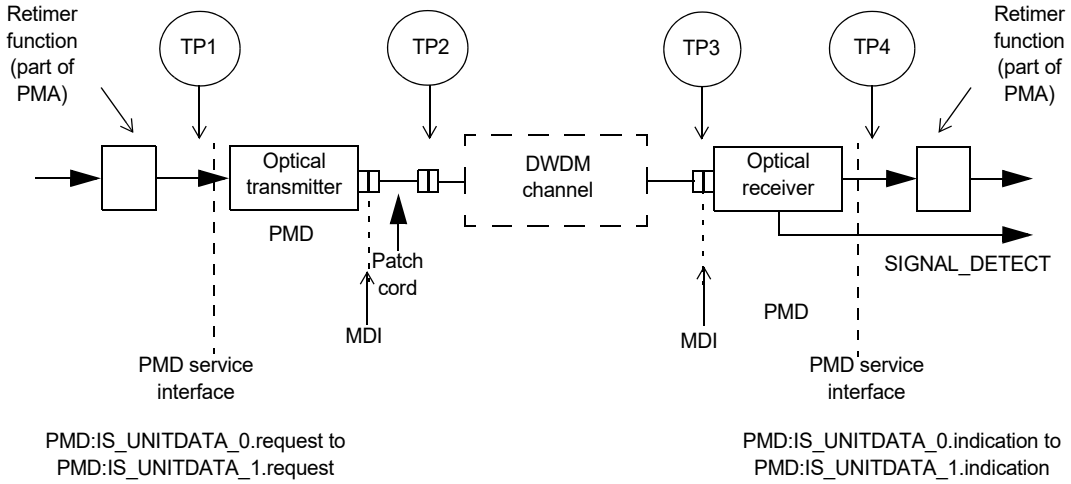

Figure 154–2—Block diagram for 100GBASE-ZR transmit/receive paths

154.5.2 PMD transmit function

The PMD Transmit function shall convert the two DQPSK symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request(tx_symbol) and PMD:IS_UNITDATA_1.request(tx_symbol) into two DQPSK optical signals on orthogonal polarizations and delivered to the MDI, all according to the transmit optical specifications in this clause.

The PMD maps symbols from each tx_symbol parameter to phase changes of each of the DQPSK optical signals as specified in Table 154–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 154–4—Symbol mapping for the phase change of one polarization of the DP-DQPSK 100 Gb/s optical signal

DQPSK symbol value	Phase change between successive symbols (radians)
0	0
1	$\pi/2$, $-3\pi/2$
2	π, $-\pi$
3	$3\pi/2$, $-\pi/2$

154.5.3 PMD receive function

The PMD Receive function shall convert the composite optical signal received from the MDI into two DQPSK symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication(rx_symbol) and PMD:IS_UNITDATA_1.indication(rx_symbol), all according to the receive optical specifications in this clause. The PMD maps the phase changes of each of the retrieved DQPSK signals to the DQPSK rx_symbol streams for delivery to the PMD service interface, as specified in Table 154–4.

NOTE—After transmission through the DWDM black link the direct correlation between symbol stream and polarization has been lost due to non-negligible polarization rotation and signal mixing. It is therefore the task of the receiver to retrieve the original symbol streams transmitted from the composite optical signal at TP3.

154.5.4 PMD global signal detect function

The PMD global signal detect function shall set the state of the SIGNAL_DETECT parameter to a fixed OK value. The presence of a valid signal is determined only by the SC-FEC sublayer (see 153.2.1).

NOTE—Average input power is not a reliable indication of signal failure in an optically amplified system.

154.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

154.5.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows the optical transmitter to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of the OFF transmitter in Table 154–7.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

154.5.7 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

154.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

154.5.9 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

154.6 DWDM channel over a DWDM black link

This subclause provides details of the medium associated with the 100GBASE-ZR PMD, over which the PHY operates at a single optical frequency (often also referred to by its associated wavelength) on a defined frequency grid. The medium associated with the 100GBASE-ZR PMD (excluding the patch cord between the MDI and TP2, if present) is also referred to as a DWDM channel.

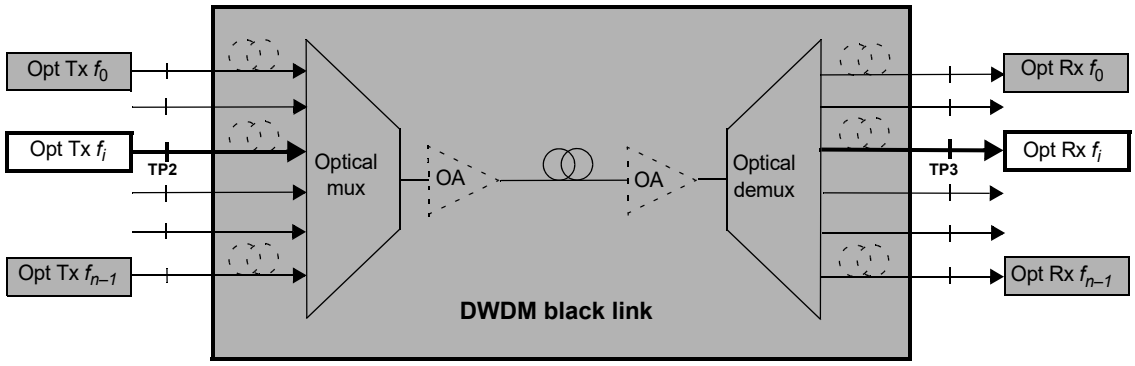
In this application, DWDM technology is used to enable the transport of multiple DWDM channels over a single fiber. A black link approach is used to allow specification of the (single) DWDM channel in a way that takes into account the effects of other DWDM channels that may be simultaneously present on the multi-channel part of the link. By using this methodology this PMD type can support a wide range of applications, as long as the link requirements specified in 154.8 are met.

Figure 154–3 shows a generic example of a DWDM black link. Functions carried out by the DWDM black link may include:

— Optical wavelength division multiplexing and demultiplexing.
— Simultaneous transport of a number of DWDM channels on a single fiber, where the channels supporting the full duplex links may be implemented on one fiber per direction, as illustrated in Figure 154A–1, or implemented on one fiber for both directions, as illustrated in Figure 154A–2.
— Optical amplification.

The arrangement of (DWDM) elements within the DWDM black link example shown in Figure 154–3 is not intended to place constraints on the construction of the DWDM black link, but simply to define the location of the single channel interfaces at TP2 and TP3. The DWDM black link in Figure 154–3 is an example of a DWDM black link, where a grey shaded box is used to illustrate that the details of the DWDM black link are not specified.

The black link approach implies that no details are provided on how the DWDM black link is constructed, configured or operated so that the end-to-end parameter requirements are met. This approach enables interoperability at the single-channel points (TP2 and TP3). However, it does not enable interoperability at multichannel points between TP2 and TP3 inside the DWDM black link.



NOTE 1—The presence of one or more optical add-drop multiplexers (OADMs) is not directly assumed but also not specifically excluded as long at the end-to-end link requirements are met.

Optical interface parameters are specified only at the single-channel points at the input (TP2 in Figure 154–2) and output (TP3 in Figure 154–2) of the DWDM black link, which are applicable for all

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

channel frequencies f_i. Additional specifications are provided for the transfer parameters from TP2 to TP3, such as chromatic dispersion, ripple, polarization mode dispersion, etc. In this way the (single channel) DWDM channel is completely specified.

NOTE 2—Coexistence of DWDM optical signals with characteristics other than the 100GBASE-ZR PMD over the same DWDM black link is not covered by this standard.

For clarity, only one direction of transmission is shown

Figure 154–3—DWDM black link example configuration for specifying *n* DWDM channels

The 100GBASE-ZR PMD is specified on the basis that it can be connected to a DWDM black link that contains a portion where multiple DWDM optical channels are present, each connected to a separate 100GBASE-ZR transmitter. These multiple DWDM channels have optical channel center frequencies that are part of a DWDM frequency grid defined in ITU-T G.694.1. Table 154–5 shows the mapping of the 100GBASE-ZR channel index numbers to the optical channel center frequencies. The 100GBASE-ZR PMD specification covers a maximum of 48 channels over a DWDM black link that supports between 1 and 48 channels with center frequencies defined in Table 154–5. In a working 100GBASE-ZR link the PMD operates on one of 48 frequencies in each direction of transmission over a pair of DWDM channels. The 100GBASE-ZR Tx, the associated DWDM channel, and the 100GBASE-ZR Rx connected to the output of the DWDM black link, are all selected to have the same channel center frequency.

Table 154–5—Mapping of the 100GBASE-ZR channel index numbers to optical channel center frequencies

Channel index number	Channel center frequency [THz]	Approximate channel center wavelength [nm]	Channel index number	Channel center frequency [THz]	Approximate channel center wavelength [nm]
0	191.4	1566.31	24	193.8	1546.92
1	191.5	1565.50	25	193.9	1546.12
2	191.6	1564.68	26	194	1545.32
3	191.7	1563.86	27	194.1	1544.53
4	191.8	1563.05	28	194.2	1543.73
5	191.9	1562.23	29	194.3	1542.94

Table 154–5—Mapping of the 100GBASE-ZR channel index numbers to optical channel center frequencies *(continued)*

Channel index number	Channel center frequency [THz]	Approximate channel center wavelength [nm]	Channel index number	Channel center frequency [THz]	Approximate channel center wavelength [nm]
7	192.1	1560.61	31	194.5	1541.35
8	192.2	1559.79	32	194.6	1540.56
9	192.3	1558.98	33	194.7	1539.77
10	192.4	1558.17	34	194.8	1538.98
11	192.5	1557.36	35	194.9	1538.19
12	192.6	1556.55	36	195	1537.40
13	192.7	1555.75	37	195.1	1536.61
14	192.8	1554.94	38	195.2	1535.82
15	192.9	1554.13	39	195.3	1535.04
16	193	1553.33	40	195.4	1534.25
17	193.1	1552.52	41	195.5	1533.47
18	193.2	1551.72	42	195.6	1532.68
19	193.3	1550.92	43	195.7	1531.90
20	193.4	1550.12	44	195.8	1531.12
21	193.5	1549.32	45	195.9	1530.33
22	193.6	1548.51	46	196	1529.55
23	193.7	1547.72	47	196.1	1528.77

The transmitter nominal center frequency is the optical frequency in Table 154–5 corresponding to the variable Tx_optical_channel_index. If the PMD is able to operate with an Rx_optical_channel_index that is different from the Tx_optical_channel_index (Tx_Rx_diff_opt_chan_ability is one), the receiver nominal center frequency is the optical frequency in Table 154–5 corresponding to the variable Rx_optical_channel_index, otherwise it is the same as the transmitter nominal center frequency. The mapping of the Tx_optical_channel_index, the Rx_optical_channel_index, and the Tx_Rx_diff_opt_chan_ability variables to the relevant optional MDIO variables and PMA/PMD register names is shown in 154.4.

154.7 PMD to MDI optical specifications for 100GBASE-ZR

The operating range for the 100GBASE-ZR PMD is defined in Table 154–6. A 100GBASE-ZR compliant PMD operates over a DWDM black link meeting the specifications in Table 154–9. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

(e.g., a 100GBASE-ZR PMD that could operate over 90 km would meet the operating range requirement of 2 m to 80 km).

Table 154–6—100GBASE-ZR operating range

PMD type	Required operating range
100GBASE-ZR	2 m to 80 km

154.7.1 100GBASE-ZR transmitter optical specifications

The 100GBASE-ZR transmitter shall meet the specifications defined in Table 154–7 per the definitions in 154.9.

Table 154–7—100GBASE-ZR transmit characteristics

Description	Value	Unit
Signaling rate (range)	27.9525 ± 20 ppm	GBd
Modulation format	DP-DQPSK	—
Minimum channel spacing	100	GHz
Average channel output power (max)	0	dBm
Average channel output power (min)	–8	dBm
Nominal center frequency	The frequency in Table 154–5 where the channel index number equals the variable Tx_optical_channel_index	THz
Spectral excursion (max)	±15	GHz
Side-mode suppression ratio (SMSR) (min)	30	dB
Laser linewidth (max)	1000	kHz
Offset between the carrier and the nominal center frequency (max)	1.8	GHz
Power difference between X and Y polarizations (max)	1.5	dB
Skew between X and Y polarizations (max)	10	ps
Error vector magnitude (max)	23	%
I-Q offset (max)	–25	dB
Transmitter in-band OSNR (min)	35	dB (12.5 GHz)
Average launch power of OFF transmitter (max)	–35	dBm
Transmitter reflectance[a] (max)	–20	dB

[a] Transmitter reflectance is defined looking into the transmitter.

154.7.2 100GBASE-ZR receive optical specifications

The 100GBASE-ZR receiver shall meet the specifications defined in Table 154–8 per the definitions in 154.9.

Table 154–8—100GBASE-ZR receive characteristics

Description	Value	Unit
Signaling rate (range)	27.9525 ± 20 ppm	GBd
Modulation format	DP-DQPSK	—
Nominal center frequency	The frequency in Table 154–5 where the channel index number equals the variable Rx_optical_channel_index	THz
Damage threshold[a]	3	dBm
Average receive power (max)	0	dBm
Average receive power (min)	–27	dBm
Receiver sensitivity[b] (max)	–30	dBm
Receiver OSNR (min): for average receive power < –16 dBm for average receive power ≥ –16 dBm	 35 19.5	 dB (12.5 GHz) dB (12.5 GHz)
Receiver OSNR tolerance[b] for average receive power ≥ –16 dBm	16.5	dB (12.5 GHz)
Receiver reflectance (max)	–20	dB

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level. The receiver does not have to operate correctly at this input power.
[b] Receiver sensitivity (max), for OSNR ≥ 35 dB (12.5 GHz), and Receiver OSNR tolerance are optional.

154.8 100GBASE-ZR DWDM black link transfer characteristics

The 100GBASE-ZR DWDM black link characteristics shall meet the specifications defined in Table 154–9 per the definitions in 154.9. Some clarification of the requirements in Table 154–9 is provided in informative Annex 154A, as well as examples of compliant DWDM black links.

154.9 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

154.9.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 154–11 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 154–11 may be used to perform that test. The test pattern used in this clause is shown in Table 154–10.

Table 154–9—100GBASE-ZR DWDM black link characteristics

Description	Value	Unit
Channel spacing (min)	100	GHz
Ripple (max)	2.5	dB
Average output power at TP3 (max)	0	dBm
Average output power at TP3 (min): for OSNR at TP3 < 35 dB (12.5 GHz) for OSNR at TP3 ≥ 35 dB (12.5 GHz)	 –16 –27	 dBm dBm
OSNR at TP3 (min)	19.5	dB (12.5 GHz)
Optical path OSNR penalty (max), for OSNR at TP3 < 35 dB (12.5 GHz)	3	dB
Optical path power penalty (max), for OSNR at TP3 ≥ 35 dB (12.5 GHz)	3	dB
Chromatic dispersion (max)	2000	ps/nm
Chromatic dispersion (min)	0	ps/nm
Fiber chromatic dispersion slope at channel center frequencies[a] (min)	0.05	ps/nm^2 km
Optical return loss at TP2 (min)	25	dB
Maximum differential group delay, DGD_max[b]	20	ps
Polarization dependent loss (max)	1.5	dB
Polarization rotation speed (max)	50	krad/s
Inter-channel crosstalk at TP3 (max)	–16	dB
Interferometric crosstalk at TP3 (max)	–25	dB

[a] The applicable channel center frequencies are specified in Table 154–5.
[b] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

Table 154–10—Test pattern

Pattern	Pattern description	Defined in
5	Scrambled idle encoded by SC-FEC	82.2.11, Clause 153

Table 154–11—Test-pattern definitions and related subclauses *(continued)*

Parameter	Pattern	Related subclause
Offset between the carrier and the nominal center frequency	5	154.9.6
Power difference between X and Y polarizations	5	154.9.7
Skew between X and Y polarizations	5	154.9.8
Error vector magnitude	5	154.9.9
I-Q offset	5	154.9.10
Optical signal-to-noise ratio (OSNR)	5	154.9.11
Transmitter in-band OSNR	5	154.9.12
Average receive power	5	154.9.13
Receiver sensitivity	5	154.9.14
Receiver OSNR	5	154.9.15
Receiver OSNR tolerance	5	154.9.16
Ripple	5	154.9.17
Optical path OSNR penalty	5	154.9.18
Optical path power penalty	5	154.9.19
Polarization dependent loss	5	154.9.20
Polarization rotation speed	5	154.9.21
Inter-channel crosstalk at TP3	5	154.9.22
Interferometric crosstalk at TP3	5	154.9.23

154.9.2 Optical center frequency (wavelength) and side-mode suppression ratio (SMSR)

The optical frequency (wavelength) and SMSR shall be within the range given in Table 154–7 if measured per IEC 61280-1-3. The transmitter is modulated using the test pattern defined in Table 154–11.

154.9.3 Average channel output power

The average channel output power shall be within the limits given in Table 154–7 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern defined in Table 154–11, per the test setup in Figure 53–6.

154.9.4 Spectral excursion

The maximum spectral excursion, as defined in ITU-T G.698.2 for DP-DQPSK signals, shall be within the limits given in Table 154–7.

154.9.5 Laser linewidth

The laser linewidth, as defined in ITU-T G.698.2, shall be within the limits given in Table 154–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

154.9.6 Offset between the carrier and the nominal center frequency

The offset between the carrier and the nominal center frequency, as defined in ITU-T G.698.2, shall be within the limits given in Table 154–7.

154.9.7 Power difference between X and Y polarizations

The power difference between X and Y polarizations, as defined in ITU-T G.698.2, shall be within the limits given in Table 154–7.

154.9.8 Skew between X and Y polarizations

The skew between X and Y polarizations, as defined in ITU-T G.698.2, shall be within the limits given in Table 154–7.

154.9.9 Error vector magnitude

The error vector magnitude shall be within the limits given in Table 154–7 and is as defined in ITU-T G.698.2, with the exception that the samples are acquired with the effect of a clock recovery unit (CRU) with a corner frequency of 1.5 MHz and a slope of 20 dB/decade.

NOTE—This definition in ITU-T G.698.2 includes the definition of a reference equalizer.

154.9.10 I-Q offset

The I-Q offset, as defined in ITU-T G.698.2 for DP-DQPSK signals, shall be within the limits given in Table 154–7.

154.9.11 Optical signal-to-noise ratio (OSNR)

The optical signal-to-noise ratio (OSNR) at TP3 shall be within the limits given in Table 154–9. The OSNR is defined as the ratio of the average signal power in the wanted channel to the highest noise power density (referred to 12.5 GHz) in the range of the central frequency plus and minus the maximum spectral excursion. For the purposes of this definition, the noise is defined to be that which would be present if the signal in the wanted channel were removed from the DWDM black link while keeping all other DWDM black link conditions the same (e.g., the gain and noise figure of all amplifiers).

NOTE—This definition of OSNR is consistent with the definition of OSNR in ITU-T G.698.2, except that in this clause the noise power density is referred to 12.5 GHz, instead of 0.1 nm in G.698.2. At a frequency of 193.6 GHz a measurement bandwidth of 0.1 nm is identical to 12.5 GHz.

154.9.12 Transmitter in-band OSNR

The transmitter in-band OSNR shall be within the limits given in Table 154–7. OSNR is defined in 154.9.11.

154.9.13 Average receive power

The average receive power shall be within the limits given in Table 154–8. These limits define the range of average receiver input power over which the BER requirement in 154.1.1 has to be met at the values of minimum OSNR defined in Table 154–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

154.9.14 Receiver sensitivity

Receiver sensitivity is defined as the minimum value of average receive power at TP3 to achieve the specified maximum BER in 154.1.1. This is to be met with a transmitter with worst-case values of error vector magnitude, optical return loss at TP2, connector degradations, and OSNR. This does not have to be met in the presence of impairments caused by the DWDM black link, such as dispersion or reflections from the optical path. These effects are specified separately in the allocation of maximum optical path power penalty.

Receiver sensitivity is optional and compliance is not required.

154.9.15 Receiver OSNR

The Receiver shall be able to tolerate an OSNR specified in Table 154–8 while achieving the specified maximum BER in 154.1.1 over the average receive power range specified in Table 154–8. This parameter is defined at TP3, which is after the DWDM black link and at the input to the receiver, and therefore includes effects associated with impairments of the transmitter and inside the DWDM black link.

OSNR is defined in 154.9.11.

154.9.16 Receiver OSNR tolerance

Receiver OSNR tolerance is as defined in ITU-T G.698.2 for “100 Gbit/s applications”, with the exception that it is valid for all frequencies, due to the definition of a measurement bandwidth of 12.5 GHz instead of 0.1 nm in ITU-T G.698.2.

OSNR tolerance is optional and compliance is not required.

154.9.17 Ripple

The ripple, as defined in ITU-T G.698.2, shall be within the limit given in Table 154–9.

154.9.18 Optical path OSNR penalty

The optical path OSNR penalty, as defined in ITU-T G.698.2, shall be within the limit given in Table 154–9.

154.9.19 Optical path power penalty

The optical path power penalty shall be within the limit given in Table 154–9 and is defined as the apparent reduction of receiver sensitivity due to distortion of the signal during its transmission over the DWDM black link, using the reference receiver as defined in Annex A of ITU-T G.698.2. It is manifested as a shift of the system's BER curves towards higher receiver input power levels. This corresponds to a positive path penalty. Negative path penalties may exist under some circumstances, but should be small. A negative path penalty indicates that a less than perfect transmitter signal has been partially improved by the path-dependent distortions. Since the path penalty is a change in the receiver's sensitivity, it is measured at the BER defined in 154.1.1.

154.9.20 Polarization dependent loss

The polarization dependent loss, as defined in ITU-T G.698.2, shall be within the limit given in Table 154–9.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

154.9.21 Polarization rotation speed

The polarization rotation speed, as defined in ITU-T G.698.2, shall be within the limit given in Table 154–9.

154.9.22 Inter-channel crosstalk at TP3

The inter-channel crosstalk at TP3, as defined in ITU-T G.698.2, shall be within the limit given in Table 154–9.

154.9.23 Interferometric crosstalk at TP3

The interferometric crosstalk at TP3, as defined in ITU-T G.698.2, shall be within the limit given in Table 154–9.

154.10 Safety, installation, environment, and labeling

154.10.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

154.10.2 Laser safety

100GBASE-ZR optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

NOTE—The laser safety requirements apply only to the single channel points at TP2 and TP3, as shown in Figure 154–3, and not to any (multi-channel) point inside the DWDM black link, which is outside the scope of this clause.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[253]

154.10.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

154.10.4 Environment

Normative specifications in this clause shall be met by a system integrating a 100GBASE-ZR PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

[253]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

154.10.5 Electromagnetic emission

A system integrating a 100GBASE-ZR PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

154.10.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

154.10.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 100GBASE-ZR).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 154.10.2.

154.11 Medium Dependent Interface (MDI)

The 100GBASE-ZR PMD is coupled to the DWDM black link medium at the MDI, being the interface between the PMD and the medium. Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 154.5.1, not at the MDI.

154.12 Protocol implementation conformance statement (PICS) proforma for Clause 154, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-ZR[254]

154.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 154, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-ZR, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

154.12.2 Identification

154.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

154.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 154, Physical Medium Dependent (PMD) sublayer and medium, type 100GBASE-ZR
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[254]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

157. Introduction to 10 Gb/s, 25 Gb/s, and 50 Gb/s BiDi PHYs

157.1 Overview

157.1.1 Scope

This clause describes the general requirements for 10 Gb/s, 25 Gb/s, and 50 Gb/s Ethernet bidirectional Physical Layer devices (PHYs). Within this clause this family of PHYs is collectively referred to as Multi-Gigabit Ethernet BiDi PHYs. These PHYs are divided into two variants based on the direction of transmission; optical line terminal (OLT) PHYs transmit in the downstream direction and optical network unit (ONU) PHYs transmit in the upstream direction.

All Multi-Gigabit Ethernet BiDi PHYs specified herein use the IEEE 802.3 MAC sublayer operating at a data rate of 10 Gb/s, 25 Gb/s, or 50 Gb/s as appropriate and are defined for full duplex operation only.

The Multi-Gigabit Ethernet BiDi PHYs provide a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

157.1.2 Relationship of Multi-Gigabit Ethernet BiDi PHYs to the ISO OSI reference model

The Multi-Gigabit Ethernet BiDi PHYs couple to the IEEE 802.3 MAC. The relationships among the IEEE 802.3 Multi-Gigabit Ethernet BiDi Physical Coding Sublayer (PCS), forward error correction (FEC), physical medium attachment (PMA), and physical medium dependent (PMD) sublayers and the IEEE 802.3 MAC, with respect to the ISO Open System Interconnection (OSI) reference model are shown in Figure 157–1. While this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data path widths for implementation convenience. Exceptions to this are specified in 44.1.3 (for 10 Gb/s), 105.1.2 (for 25 Gb/s), and 131.1.2 (for 50 Gb/s). In addition to these exceptions the MDI specifications for Multi-Gigabit Ethernet BiDi PHYs are as follows:

— For 10 Gb/s PHYs, see Clause 158
— For 25 Gb/s PHYs, see Clause 159
— For 50 Gb/s PHYs, see Clause 160

157.1.3 Nomenclature

For Multi-Gigabit Ethernet BiDi PHYs, the following nomenclature is used, with individual elements shown in Table 157–1:

rGBASE-BRx-d

Table 157–1—PMD parameter elements

Parameter	Description	Allowed values
r	PMD rate	10, 25, 50
x	PMD reach in km	10, 20, 40
d	PMD transmit direction	D = OLT PMDs, U = ONU PMDs

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

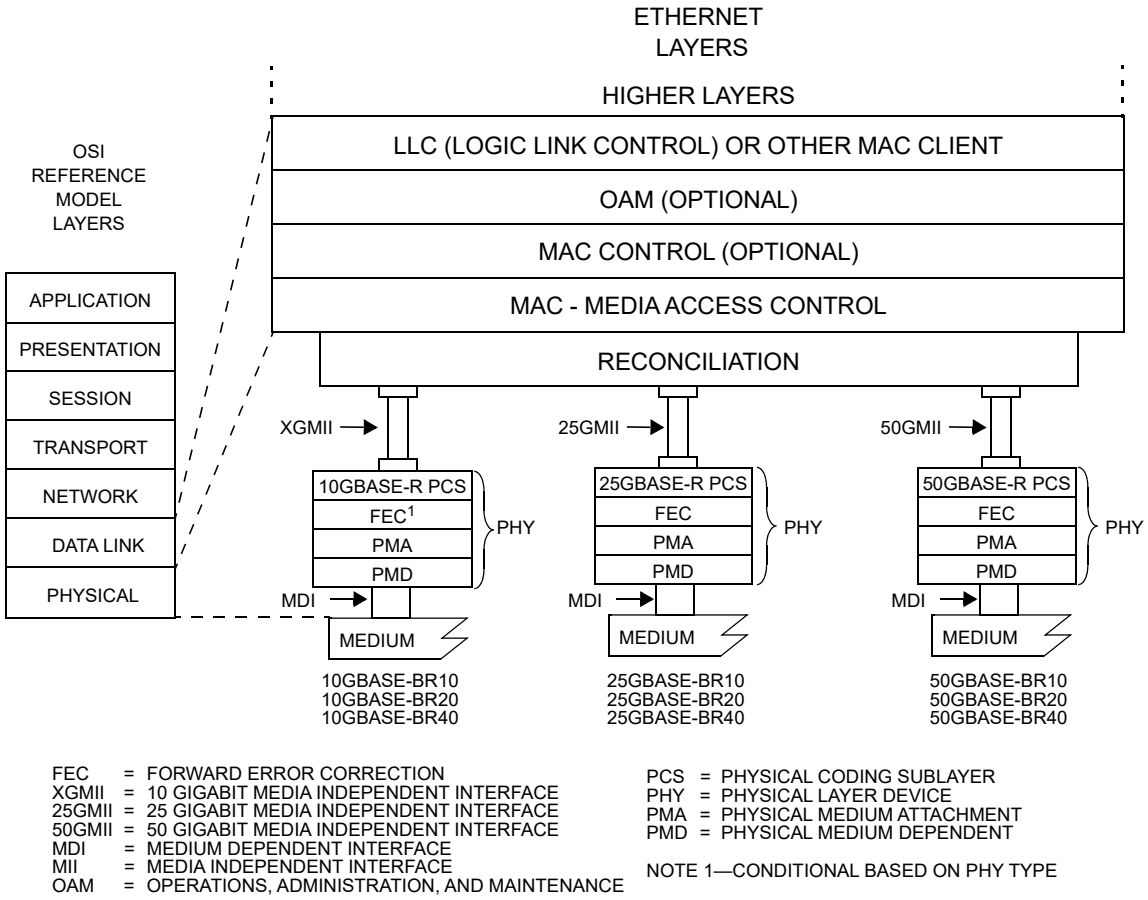

Figure 157–1—Architectural positioning of Multi-Gigabit Ethernet BiDi PHYs

B refers to bidirectional, and R refers to the 64B/66B encoding. The term xMII is used to generically refer to the family of Media Independent Interfaces (MII) including the XGMII, 25GMII, or 50GMII. All Multi-Gigabit Ethernet BiDi PHYs are listed in Table 157–2.

Table 157–2—Multi-Gigabit Ethernet BiDi PHYs

Name	Description
10GBASE-BR10-D	10 Gb/s OLT PHY using 10GBASE-R encoding over one single-mode fiber, with reach up to at least 10 km (see Clause 158).
10GBASE-BR20-D	10 Gb/s OLT PHY using 10GBASE-R encoding over one single-mode fiber, with reach up to at least 20 km (see Clause 158).
10GBASE-BR40-D	10 Gb/s OLT PHY using 10GBASE-R encoding over one single-mode fiber, with reach up to at least 40 km (see Clause 158).
10GBASE-BR10-U	10 Gb/s ONU PHY using 10GBASE-R encoding over one single-mode fiber, with reach up to at least 10 km (see Clause 158).

Table 157–2—Multi-Gigabit Ethernet BiDi PHYs *(continued)*

Name	Description
10GBASE-BR20-U	10 Gb/s ONU PHY using 10GBASE-R encoding over one single-mode fiber, with reach up to at least 20 km (see Clause 158).
10GBASE-BR40-U	10 Gb/s ONU PHY using 10GBASE-R encoding over one single-mode fiber, with reach up to at least 40 km (see Clause 158).
25GBASE-BR10-D	25 Gb/s OLT PHY using 25GBASE-R encoding over one single-mode fiber, with reach up to at least 10 km (see Clause 159).
25GBASE-BR20-D	25 Gb/s OLT PHY using 25GBASE-R encoding over one single-mode fiber, with reach up to at least 20 km (see Clause 159).
25GBASE-BR40-D	25 Gb/s OLT PHY using 25GBASE-R encoding over one single-mode fiber, with reach up to at least 40 km (see Clause 159).
25GBASE-BR10-U	25 Gb/s ONU PHY using 25GBASE-R encoding over one single-mode fiber, with reach up to at least 10 km (see Clause 159).
25GBASE-BR20-U	25 Gb/s ONU PHY using 25GBASE-R encoding over one single-mode fiber, with reach up to at least 20 km (see Clause 159).
25GBASE-BR40-U	25 Gb/s ONU PHY using 25GBASE-R encoding over one single-mode fiber, with reach up to at least 40 km (see Clause 159).
50GBASE-BR10-D	50 Gb/s OLT PHY using 50GBASE-R encoding over one single-mode fiber, with reach up to at least 10 km (see Clause 160).
50GBASE-BR20-D	50 Gb/s OLT PHY using 50GBASE-R encoding over one single-mode fiber, with reach up to at least 20 km (see Clause 160).
50GBASE-BR40-D	50 Gb/s OLT PHY using 50GBASE-R encoding over one single-mode fiber, with reach up to at least 40 km (see Clause 160).
50GBASE-BR10-U	50 Gb/s ONU PHY using 50GBASE-R encoding over one single-mode fiber, with reach up to at least 10 km (see Clause 160).
50GBASE-BR20-U	50 Gb/s ONU PHY using 50GBASE-R encoding over one single-mode fiber, with reach up to at least 20 km (see Clause 160).
50GBASE-BR40-U	50 Gb/s ONU PHY using 50GBASE-R encoding over one single-mode fiber, with reach up to at least 40 km (see Clause 160).

157.1.4 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. Table 157–3, Table 157–4, and Table 157–5 specify the correlation between PHY types and specific clauses for the PCS, FEC, PMA and PMD. Implementations conforming to one or more PHY types meet the requirements of the corresponding clauses.

157.2 Summary of Multi-Gigabit Ethernet BiDi sublayers

157.2.1 Reconciliation Sublayer (RS) and Media Independent Interface (XGMII, 25GMII, and 50GMII)

The RS provides a mapping between the signals provided at the xMII and the MAC/PLS service definition. The xMII provides a logical interconnection between the MAC sublayer and Physical Layer devices (PHYs). The xMII may be physically instantiated or can logically connect layers within a device. While the xMII is an optional interface, it is used extensively in this standard as a basis for functional specification and provides a common service interface for the Physical Coding Sublayer (PCS). The specific RS and xMII for each Multi-Gigabit Ethernet BiDi PHY are given in Table 157–3, Table 157–4, and Table 157–5.

157.2.2 Physical Coding Sublayer (PCS)

The PCS performs encoding of data from the xMII to 64B/66B code blocks and transfers the encoded data to the PMA or FEC sublayer and performs decoding of 64B/66B blocks from the PMA or FEC sublayer and transfers the decoded data to the xMII. The specific PCS for each Multi-Gigabit Ethernet BiDi PHY is given in Table 157–3, Table 157–4, and Table 157–5.

157.2.3 Forward error correction (FEC) sublayer

An FEC sublayer is required for all Multi-Gigabit BiDi PHYs except 10GBASE-BR10 and 10GBASE-BR40, where the FEC sublayer is not applicable. The FEC sublayer can be placed in between the PCS and PMA sublayers or between two PMA sublayers. The specific FEC for each Multi-Gigabit Ethernet BiDi PHY is given in Table 157–3, Table 157–4, and Table 157–5.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

157.2.4 Physical Medium Attachment (PMA) sublayer

The PMA sublayer provides a medium independent means for the PCS or FEC sublayers to support the use of a range of physical media. The PMA performs the mapping of transmit and receive data streams between the PCS or FEC and PMA via the PMA service interface and mapping of transmit and receive data streams between the PMA and PMD via the PMD service interface.

The PMA performs retiming of the received data stream when appropriate, optionally provides data loopback at the PMA or PMD service interface, and optionally provides test pattern generation and checking. The PMA also may provide an observable electrical interface for the 25GAUI or 50GAUI chip-to-chip (C2C) or chip-to-module (C2M).

The specific PMA for each Multi-Gigabit Ethernet BiDi PHY is given in Table 157–3, Table 157–4, and Table 157–5.

157.2.5 Physical Medium Dependent (PMD) sublayer

The PMD sublayer is responsible for interfacing to the transmission medium. The MDI connects the PMD to the medium and is defined in the associated PMD clause. The specific PMD for each Multi-Gigabit Ethernet BiDi PHY is given in Table 157–3, Table 157–4, and Table 157–5.

157.2.6 Management interface (MDIO/MDC)

The optional MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMDs) and Station Management (STA) entities.

157.2.7 Management

Managed objects, attributes, and actions are defined for all Multi-Gigabit Ethernet BiDi PHY components. These items are defined in Clause 30.

157.3 Service interface specification method and notation

The service interface specification for Multi-Gigabit Ethernet BiDi Physical Layers is as per the definition in 1.2.2.

The 10GBASE-BRx PHYs use the inter-sublayer service interfaces specified in 49.2.2.

The 25GBASE-BRx PHYs use the inter-sublayer service interfaces specified in 105.4.

The 50GBASE-BRx PHYs use the inter-sublayer service interfaces specified in 131.3.

157.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The maximum delay constraints for 10GBASE-BRx PHY sublayers are specified in 44.3.

The maximum delay constraints for 25GBASE-BRx PHY sublayers are specified in 105.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The maximum delay constraints for 50GBASE-BRx PHY sublayers are specified in 131.4.

157.5 ONU silent start

Silent start is provided by Multi-Gigabit Ethernet BiDi ONU PHYs to reduce the likelihood of disruption to established services if a Multi-Gigabit Ethernet BiDi ONU PHY is inadvertently attached to a point-to-multipoint network.

All members of the Multi-Gigabit Ethernet BiDi PHY family include PCS registers or variable equivalents that:

a) Indicate the receive status of the PCS (see 49.2.14.1 and 45.2.3.15.1).
b) Disable the PHYs transmitter (see 45.2.1.8).

By monitoring the PCS receive status indicator and appropriately setting the PHY transmitter control, upper layer management can prevent transmission by a Multi-Gigabit Ethernet BiDi ONU PHY when connected to an incompatible network (e.g., an EPON).

Transmission by a Multi-Gigabit Ethernet BiDi ONU PHY is disallowed whenever a receive fault is declared by the status indicator; once the status indicator declares the PCS is receiving a proper Multi-Gigabit Ethernet BiDi PHY signal for a pre-determined time period (e.g., 1 second) transmission may be enabled. Note that silent start does not apply to the OLT PHY types.

157.6 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 45, Clause 49, Clause 73, Clause 74, Clause 106 through Clause 112, Clause 114, Clause 158 through Clause 160, and related annexes demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the Multi-Gigabit Ethernet BiDi PICS conforms to the same notation and conventions used in 21.6.

158. Physical Medium Dependent (PMD) sublayer and medium, types 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40

158.1 Overview

This clause specifies the 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40 PMDs together with the single-mode fiber medium, shown in Table 158–1. Within this clause these PMDs are jointly referred to by the term 10GBASE-BRx. The 10GBASE-BRx PHYs are divided into two variants based on the direction of transmission. Optical line terminal (OLT) PMDs transmit in the downstream direction and receive in the upstream direction. Optical network unit (ONU) PMDs transmit in the upstream direction and receive in the downstream direction. The PMD variant is indicated with a suffix of D for OLT PMDs and U for ONU PMDs.

In order to form a complete Physical Layer, each PMD is combined with the appropriate physical sublayers indicated in Table 158–1 and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 158–1—PMD type and associated clauses

Associated clause	10GBASE-BR10 10GBASE-BR40	10GBASE-BR20
46—RS	Required	Required
46—XGMII	Optional	Optional
47—XGXS and XAUI	Optional	Optional
49—Type R PCS	Required	Required
108—RS-FEC	Not applicable	Required[a]
51—Serial PMA	Required	Required

[a] The option to bypass the Clause 108 RS-FEC correction function is not supported (see 108.6.3).

Figure 158–1 depicts the relationships of the serial PMD (shown shaded) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

158.1.1 Bit error ratio

For the 10GBASE-BR10 and 10GBASE-BR40 PMDs, the bit error ratio (BER) shall be less than 10^{-12}.

For the 10GBASE-BR20 PMD, the BER shall be less than 5×10^{-5} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108. If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

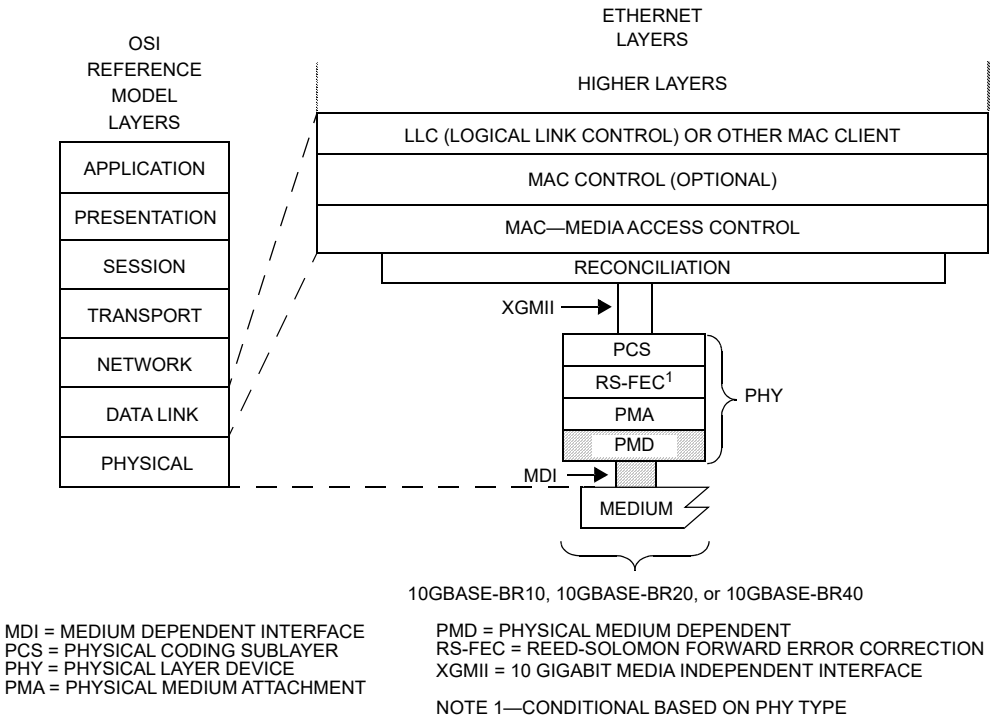

Figure 158–1—10GBASE-BRx PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

158.2 PMD sublayer service interface

The PMD service interfaces for 10GBASE-BRx are the same as PMD service interface for 10GBASE-R as described in 49.2 with the BER as specified in 158.1.1.

158.3 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The PMA and PMD shall incur a round-trip delay (transmit and receive) of not more than 512 bit times, or 1 pause_quantum, including 2 m of fiber. A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 44.3.

158.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 158–2, and MDIO status variables to PMD status variables as shown in Table 158–3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 158–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	Control register 1	1.0.15	PMD_reset
Global Transmit Disable	Transmit disable register	1.9.0	PMD_global_transmit_disable

Table 158–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	Status register 1	1.1.7	PMD_fault
Transmit fault	Status register 2	1.8.11	PMD_transmit_fault
Receive fault	Status register 2	1.8.10	PMD_receive_fault
Global PMD Receive signal detect	Receive signal detect register	1.10.0	PMD_global_signal_detect

158.5 PMD functional specifications

The 10GBASE-BRx PMDs perform the Transmit and Receive functions that convey data between the PMD service interface and the MDI.

158.5.1 PMD block diagram

For purposes of system conformance, the PMD sublayer is standardized at test points TP2 and TP3 as shown in Figure 158–2. The optical transmit signal is defined at the output end of a patch cord (TP2), between 2 m and 5 m in length, of a type consistent with the link type connected to the transmitter. Unless specified otherwise, all transmitter measurements and tests defined in 158.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) connected to the receiver. Unless specified otherwise, all receiver measurements and tests defined in 158.8 are made at TP3. TP1 and TP4 are optional reference points that may be useful to implementers for testing components (these test points are not typically accessible in an implemented system).

158.5.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) defined in 52.1.1.1 to the MDI according to the optical specifications in this clause. The higher optical power level shall correspond to tx_bit = ONE.

158.5.3 PMD receive function

The PMD Receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit) defined in 52.1.1.2. The higher optical power level shall correspond to rx_bit = ONE.

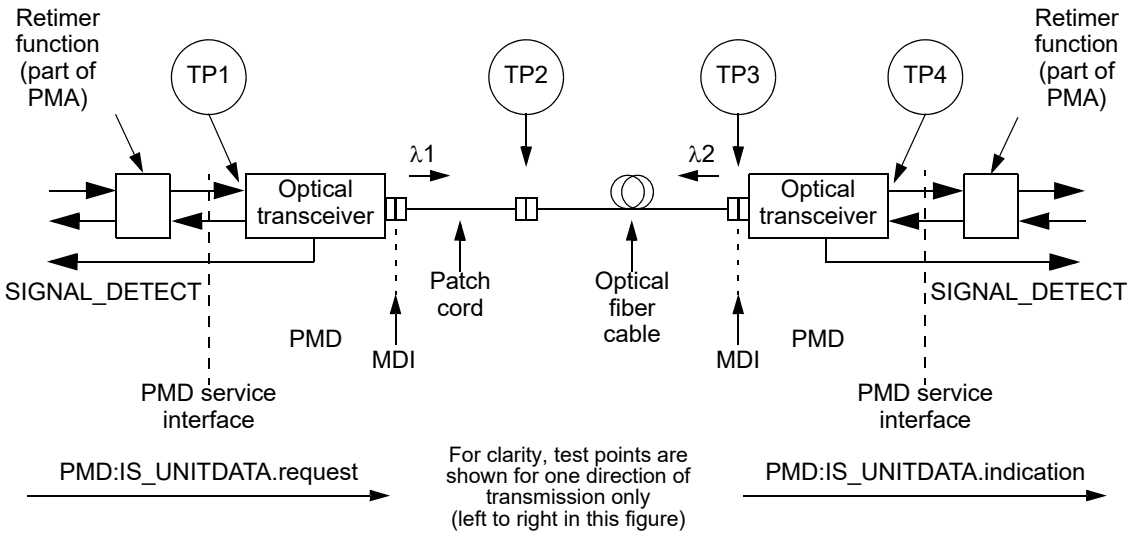

Figure 158–2—Block diagram for 10GBASE-BRx transmit/receive paths

158.5.4 PMD signal detect function

The PMD Signal Detect function shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT) which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence. If the MDIO interface is implemented, then PMD_global_signal_detect (MDIO register bit 1.10.0) shall be continuously set to the value of SIGNAL_DETECT as described in 45.2.1.9.7.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 158–4. The PMD receiver is not required to verify whether a compliant 10GBASE-BRx signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Implementations should provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Table 158–4—SIGNAL_DETECT value definition

Receive conditions	Signal Detect value
Input optical power ≤ –30 dBm average power for 10GBASE-BR10 and 10GBASE-BR40, input optical power ≤ –33 dBm average power for 10GBASE-BR20	FAIL
Input optical power ≥ Receiver sensitivity (max) in OMA in Table 158–7 AND compliant 10GBASE-BRx signal input	OK
All other conditions	Unspecified

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

158.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

158.5.6 PMD global transmit disable function

PMDs compliant with this clause shall include the PMD_global_transmit_disable function that allows the optical transmitter to be disabled.

When asserted, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of OFF transmitter in Table 158–6.

If a PMD_transmit_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

158.5.7 PMD fault function

If the MDIO is implemented, PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault and any other implementation specific fault.

158.5.8 PMD transmit fault function

The PMD_transmit_fault function is optional. The faults detected by this function are implementation specific, but should not include the assertion of the PMD_global_transmit_disable function.

If a PMD_transmit_fault (optional) is detected, then the PMD_global_transmit_disable function should also be asserted.

158.5.9 PMD receive fault function

The 10GBASE-BRx-U PMD shall include the PMD_receive_fault function, in the 10GBASE-BRx-D PMD this function is optional. PMD_receive_fault is the logical OR of NOT SIGNAL_DETECT and any implementation specific fault.

158.5.10 ONU silent start

Silent start shall be provided by 10GBASE-BR10-U, 10GBASE-BR20-U, and 10GBASE-BR40-U PHYs. See 157.5.

158.6 PMD to MDI optical specifications for 10GBASE-BRx

The operating range for 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40 PMDs is defined in Table 158–5. A 10GBASE-BRx compliant PMD supports Types B1.1 and B1.3 single-mode fibers according to the specifications defined in 158.11. A PMD that exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., operating at 12.5 km meets the minimum range requirement of 2 m to 10 km).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 158–5—10GBASE-BRx operating ranges

PMD Type	Required operating range
10GBASE-BR10	2 m to 10 km
10GBASE-BR20[a]	2 m to 20 km
10GBASE-BR40	2 m to 40 km

[a] The RS-FEC correction function may not be bypassed for any operating distance.

158.6.1 10GBASE-BRx transmitter optical specifications

The 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40 transmitters shall meet the specifications defined in Table 158–6 per the measurement techniques defined in 158.8.

Table 158–6—10GBASE-BRx transmit characteristics

Description	10GBASE-BR10	10GBASE-BR20	10GBASE-BR40	Unit
Signaling speed (nominal)	10.3125			GBd
Signaling speed variation from nominal (max)	±100			ppm
10GBASE-BRx-D center wavelength (range)	1320 to 1340			nm
10GBASE-BRx-U center wavelength (range)	1260 to 1280			nm
Side-mode suppression ratio (min)	30			dB
Average launch power (max)	0.5	–5.6	3	dBm
Average launch power[a] (min)	–8.2	–12	–3	dBm
Optical Modulation Amplitude[b] (OMA) (min)	–5.2	–9	0	dBm
Transmitter and dispersion penalty (TDP) (max)	3.2	2	2.6	dB
Launch power (min) in OMA minus TDP	–6.2	–10	–1	dBm
Average launch power of OFF transmitter[c] (max)	–30			dBm
Extinction ratio (min)	3.5	5	5.5	dB
RIN_xOMA (max)[d]	–128			dB/Hz
Optical return loss tolerance (max)	12	21		dB
Transmitter reflectance[e] (max)	–12			dB
Transmitter eye mask definition B {X1, X2, X3, Y1, Y2, Y3}, hit ratio 5×10^{-5} per sample	{0.235, 0.395, 0.45, 0.235, 0.265, 0.4}			—

[a] Average launch power (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] The OMA (min) requirement holds even if the TDP < 1 dB.
[c] Examples of an OFF transmitter are: no power supplied to the PMD, laser shutdown for safety conditions, activation of a PMD_global_transmit_disable, or other optional transmitter shutdown conditions.
[d] In RIN_xOMA, "*x*" is the optical return loss tolerance (max) for the PHY under test.
[e] Transmitter reflectance is defined looking into the transmitter.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

158.6.2 10GBASE-BRx receive optical specifications

The 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40 receivers shall meet the specifications defined in Table 158–7 per the measurement techniques defined in 158.8.

Table 158–7—10GBASE-BRx receive characteristics

Description	10GBASE-BR10	10GBASE-BR20	10GBASE-BR40	Unit
Signaling speed (nominal)	10.3125			GBd
Signaling speed variation from nominal (max)	±100			ppm
10GBASE-BRx-D center wavelength (range)	1260 to 1280			nm
10GBASE-BRx-U center wavelength (range)	1320 to 1340			nm
Damage threshold[a] (min)	4	–4.6	4	dBm
Average receive power (max)	0.5	–5.6	–7	dBm
Average receive power[b] (min)	–14.4	–27.2	–21.2	dBm
Receiver sensitivity (max) in OMA[c]	–12.6	–25	–19	dBm
Receiver reflectance (max)	–12	–26		dB
Stressed receiver sensitivity (max) in OMA[d, e]	–10.3	–22.7	–16.8	dBm
Conditions of stressed receiver sensitivity test:				
Vertical eye closure penalty[f] (min)	2.2	—	2.7	dB
Stressed eye jitter[g] (min)	0.3	—	0.3	UI pk-pk
Stressed eye closure[h]	—	2.5	—	dB
Stressed eye J2 Jitter[h]	—	0.27	—	UI
Stressed eye J4 Jitter[h]	—	0.39	—	UI
SRS eye mask definition {X1, X2, X3, Y1, Y2, Y3}, hit ratio 5×10^{-5} hits per sample	—	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}	—	—

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level. The receiver does not have to operate correctly at this input power.
[b] Average receive power (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity is optional.
[d] Measured with conformance test signal at TP3 (see 158.8.9.1.3) for BER = 10^{-12} for BR10 and BR40, and for BER = 5×10^{-5} for BR20.
[e] The stressed sensitivity values in the table are for system level BER measurements, which include the effects of CDR circuits. It is recommended that at least 0.4 dB additional margin be allocated if component level measurements are made without the effect of CDR circuits.
[f] Vertical eye closure penalty is a test condition for measuring stressed receiver sensitivity. It is not a required characteristic of the receiver.
[g] Stressed eye jitter is a test condition for measuring stressed receiver sensitivity. It is not a required characteristic of the receiver.
[h] Stressed eye closure, stressed eye J2 Jitter, and stressed eye J4 Jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

158.6.3 10GBASE-BRx illustrative link power budgets

Illustrative power budgets and penalties for a 10GBASE-BRx channel are shown in Table 158–8.

Table 158–8—10GBASE-BRx illustrative link power budget[a, b]

Parameter	10GBASE-BR10	10GBASE-BR20	10GBASE-BR40	Unit
Power budget	9.4	18	21	dB
Operating distance	10	20	40[c]	km
Channel insertion loss	6.2[d]	15[e]	18[e]	dB
Maximum discrete reflectance (max)	–26			dB
Allocation for penalties	3.2	3		dB

[a] Budget numbers are rounded to nearest 0.1 dB.
[b] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.
[c] Links longer than 30 km are considered engineered links.
[d] The channel insertion loss is calculated using the maximum distance specified in Table 158–5 and cabled optical fiber attenuation of 0.4 dB/km plus an allocation for connection and splice loss given in 158.11.2.1.
[e] The channel insertion loss is calculated using the maximum distance specified in Table 158–5 and cabled optical fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 158.11.2.1.

158.7 Jitter specifications for 10GBASE-BRx

The jitter specifications for 10GBASE-BRx are defined by the transmitter eye mask requirements in Table 158–7, using the definitions in 158.8.7 and the reference receiver defined in 158.8.10.3.

158.8 Definition of optical parameters and measurement methods

All optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

158.8.1 Test patterns

Compliance is to be achieved in normal operation. Two types of test pattern are used, square wave (158.8.1.2) and others (158.8.1.1). Table 158–11 shows the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined.

Test pattern generation and checking functions, such as the ones defined in 49.2.8 and in 49.2.12, are required for testing a PMD. Tests may utilize test pattern generators and checkers in other sublayers (e.g., the PCS of Clause 49) or in the test equipment, as appropriate.

NOTE—Test patterns for specific optical tests are designed to emulate system operation, which would entail passing valid 10GBASE-BRx data.

158.8.1.1 Test pattern definition

Patterns 1, 2, and 3 are defined in Table 158–10.

For 10GBASE-BRx, two test pattern segments are specified, in two variants, “normal” (n) and “inverted” (i). Both are 8448 bits long. They may be generated dynamically by the 58-bit scrambler and

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

"control block" sync header generation defined in 49.2.6, and using the scrambler starting seeds specified in Table 158–9 and the method of generation in 49.2.8. The segments are assembled into patterns, each containing four segments, as described in Table 158–10. Each may be held as a static pattern in test equipment, or generated or detected dynamically using the methods of 49.2.8 and 49.2.12 respectively, or otherwise.

Each segment contains a sync header transition every 66 bits.

Table 158–9—Pattern segments

Segments	Seed[57:0][a]
A_n	0x3C8B44DCAB6804F
B_n	0x34906BB85A38884

[a] The "invert" segments A_i and B_i are generated using the inverted seeds for A_n and B_n, respectively.

Table 158–10—Test patterns

Pattern	Pattern for 10GBASE-R
1	$B_n\, B_i\, B_n\, B_i$
2	$A_n\, A_i\, A_n\, A_i$
3	PRBS31[a]

[a] The PRBS31 test pattern is identical to the one defined in 49.2.8.

Test pattern 1 is generated with the data input mode programmed to select LF data input. Test pattern 2 is generated with the data input mode programmed to select all zero data input.

Pattern 1 represents typical scrambled data while pattern 2 represents a less typical pattern that could happen by chance and is thought to be more demanding of the transmission process including the clock recovery subsystem. Both patterns are balanced over their length of 33 792 bits.

NOTE—While other test methods and patterns could be used, it is the implementer's responsibility to ensure that measurements carried out with the specified patterns achieve the requirements specified.

158.8.1.2 Square wave pattern definition

A pattern consisting of four to eleven consecutive ones followed by an equal run of zeros may be used as a square wave. These patterns have fundamental frequencies between approximately 469 MHz and 1289 MHz.

158.8.2 Wavelength and side-mode suppression ratio (SMSR)

The wavelength and SMSR shall be within the range given in Table 158–6 if measured per IEC 61280-1-3. The transmitter is modulated using the test pattern defined in Table 158–11.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 158–11—Test pattern definitions and related subclauses

Test	Pattern	Related subclause
Average optical power	1, 3, or valid 10GBASE-R signal	158.8.3
OMA (modulated optical power)	Square	158.8.5
Extinction ratio	1 or 3	158.8.4
Transmit eye	1 or 3	158.8.7
RIN_xOMA	Square	158.8.6
Wavelength	1, 3, or valid 10GBASE-R signal	158.8.2
Side-mode suppression ratio	1, 3, or valid 10GBASE-R signal	158.8.2
Vertical eye closure penalty calibration	2 or 3	158.8.9
Receiver sensitivity	1 or 3	158.8.9
Receiver overload	1 or 3	—
Stressed receive conformance	2 or 3	158.8.9
Transmitter and dispersion penalty	2 or 3	158.8.10

158.8.3 Average optical power

The average optical power shall be within the limits given in Table 158–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern specified in Table 158–11.

158.8.4 Extinction ratio

The extinction ratio shall be within the limits given in Table 158–6 if measured using the methods specified in IEC 61280-2-2. The extinction ratio is measured using the test pattern defined in Table 158–11.

158.8.5 Optical Modulation Amplitude (OMA)

OMA shall meet the requirements in Table 158–7 when measured using the method defined in 52.9.5. See 158.8.1 for test pattern information.

158.8.6 Relative Intensity Noise (RIN_xOMA)

RIN_xOMA shall meet the requirement in Table 158–7 when measured using the method of 52.9.6, with x being the “Optical return loss tolerance (max)” specified in Table 158–7 for the PMD under test.

158.8.7 Transmitter optical waveform (transmitter eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4. The transmitter optical waveform of a port transmitting

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the test pattern specified in Table 158–11 shall meet specifications according to the methods specified in 86.8.4.6.1 with the filter nominal reference frequency f_r of 7.5 GHz and the filter tolerances as specified for STM-64 in ITU-T G.691. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response.

158.8.8 Receiver sensitivity

Receiver sensitivity, which is defined for an ideal input signal, is optional and testing is not required. If measured, the test signal should have negligible impairments such as intersymbol interference (ISI), rise/fall times, jitter and RIN. Instead, the normative requirement for receivers is stressed receiver sensitivity.

158.8.9 Stressed receiver sensitivity

158.8.9.1 Stressed receiver sensitivity for 10GBASE-BR10 and 10GBASE-BR40

Stressed receiver sensitivity shall be within the limits given in Table 158–7 if measured using the method defined in 158.8.9.1.1, 158.8.9.1.2, and 158.8.9.1.4, with the conformance test signal at TP3 as described in 158.8.9.1.3 and 158.8.9.1.5, using the test pattern specified for SRS in Table 158–11.

Receivers shall operate with BER less than 10^{-12} when tested with a conditioned input signal that combines vertical eye closure and jitter according to this clause.

The measurements in this subclause are performed with asynchronous data flowing out of the optical transmitter of the system under test. The output data pattern from the transmitter of the system under test is to be the same pattern defined for this measurement in 158.8.1. The reflectance of the optical link should be at its maximum level.

158.8.9.1.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 158–3. A suitable pattern generator is used to continuously generate a signal or test pattern according to 158.8.1. The optical test signal is conditioned (stressed) using the methodology as defined in 158.8.9.1.3, while applying sinusoidal jitter as defined in 158.8.9.1.5. The receiver of the system under test is tested for conformance by enabling the error counter on the receiving side. The optical power penalty for the stressed eye is intended to be similar to its vertical eye closure penalty. This is not necessarily the same as the highest TDP anticipated in service, but represents a standardized test condition for the receiver.

A suitable test set is needed to characterize and verify that the signal used to test the receiver has the appropriate characteristics. The test fiber called out for 10GBASE-BRx is not needed to characterize the receiver input signal; nor is it used during testing.

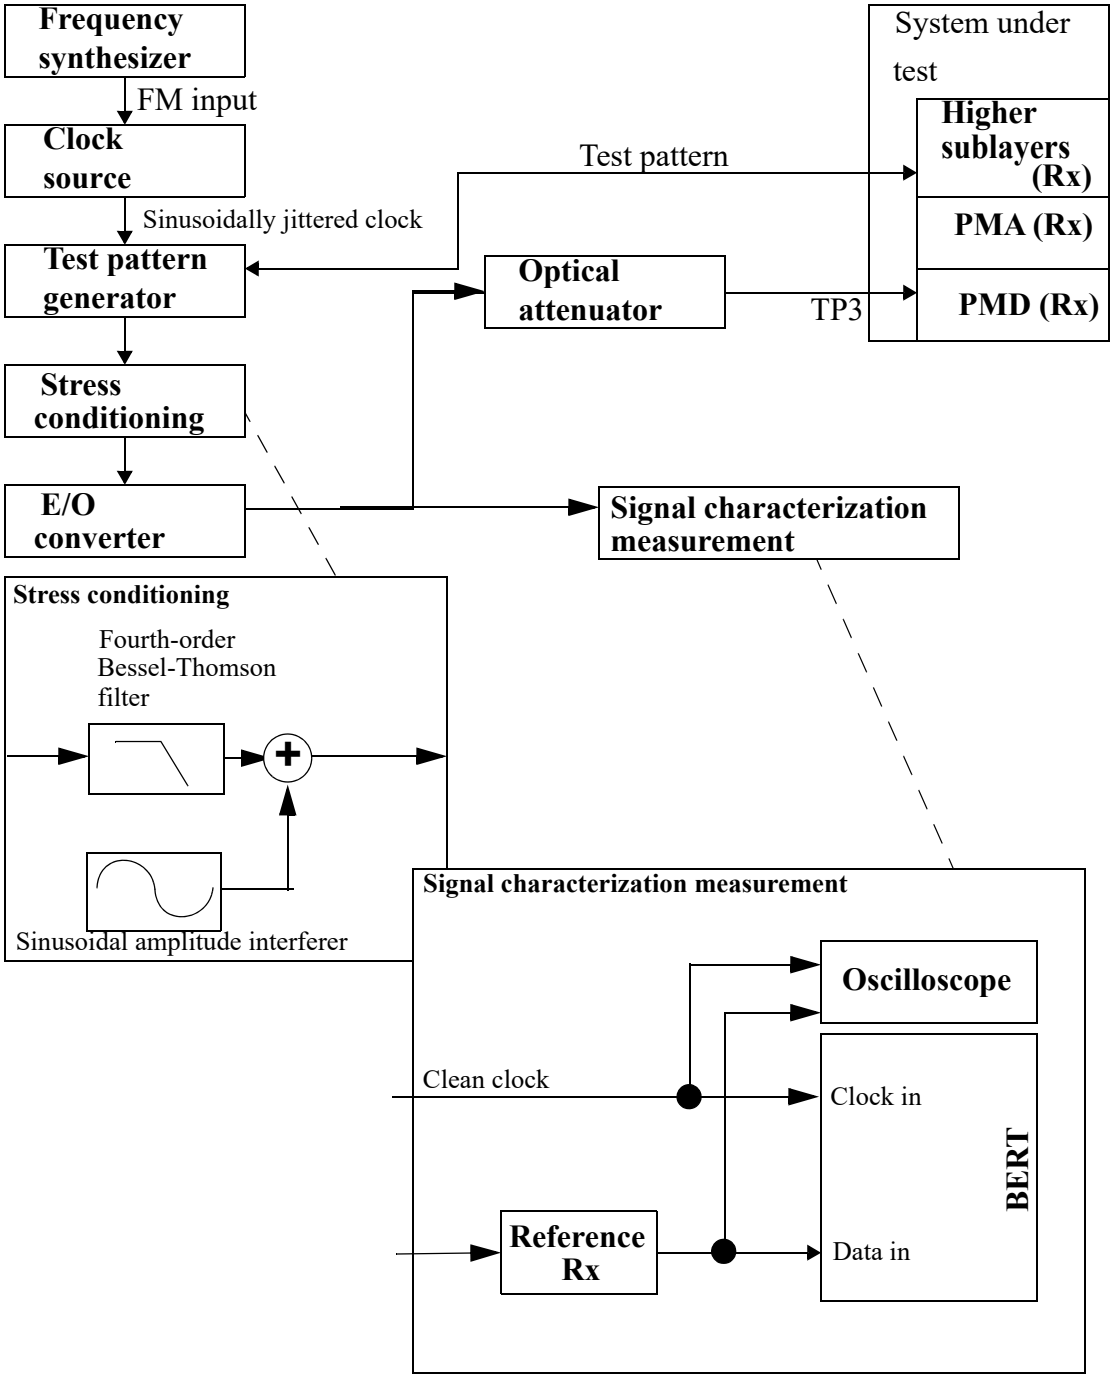

Figure 158–3—Stressed receiver conformance test block diagram

The fourth-order Bessel-Thomson filter is used to create ISI-induced vertical eye closure penalty (VECP). The sinusoidal amplitude interferer causes additional eye closure, but in conjunction with the slowed edge rates from the filter, also causes jitter. The nature of the jitter is intended to emulate instantaneous bit shrinkage that can occur with DDJ. This type of jitter cannot be created by simple phase modulation. The sinusoidal phase modulation represents other forms of jitter and also verifies that the receiver under test can

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

track low-frequency jitter. The frequency of the sinusoidal interference may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid a harmonic relationship between the sinusoidal interference, the sinusoidal jitter, the data rate, and the pattern repetition rate.

For improved visibility for calibration, it is imperative that the Bessel-Thomson filter and all other elements in the signal path (cables, DC blocks, E/O converter, etc.) have wide and smooth frequency response and linear phase response throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be minimized. If this is achieved, then data dependent effects should be minimal, and short data patterns can be used for calibration with the benefit of providing much improved trace visibility on sampling oscilloscopes. Actual patterns for testing the receiver shall be as specified in Table 158–11.

To further improve visibility for calibration, random noise effects, such as RIN and random clock jitter, should also be minimized. A small amount of residual noise and jitter from all sources is unavoidable, but should be less than 0.25 UI peak-peak of jitter at the 10^{-12} points.

The Bessel-Thomson filter and the E/O converter should have the appropriate frequency response to result in the appropriate level of initial ISI eye closure before the sinusoidal terms are added. The E/O converter should be fast and linear such that the waveshape and edge rates are predominantly controlled or limited by the electrical circuitry. Electrical summing requires high linearity of all elements including the E/O converter. Summing with an optical coupler after the E/O converter is an option that eases linearity requirements, but requires a second source for the interfering signal, complicates settings of extinction ratio, and adds more RIN.

The vertical and horizontal eye closures to be used for receiver conformance testing are verified using an optical reference receiver with a 7.5 GHz fourth-order ideal Bessel-Thomson response. Use of ITU-T G.691 tolerance filters may significantly degrade this calibration. Care should be taken to ensure that all the light from the fiber is collected by the fast photodetector and that there is negligible mode selective loss, especially in the optical attenuator and the optical coupler, if used.

The clock output from the clock source in Figure 158–3 is modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye jitter that includes the sinusoidal jitter component, a separate clock source (clean clock of Figure 158–3) is required that is synchronized to the source clock, but not modulated with the jitter source.

158.8.9.1.2 Parameter definitions

The primary parameters of the conformance test signal are vertical eye closure penalty (VECP) and stressed eye jitter, J. Vertical eye closure penalty is measured at the time center of the eye (halfway between 0 and 1 on the unit interval scale as defined in 158.8.7) and is calculated relative to the measured OMA value. J is defined from the 0.5th to the 99.5th percentile of the jitter histogram. J is measured at the average optical power, which can be obtained with AC-coupling. The values of these components are defined by their histogram results.

The vertical eye closure penalty is given by Equation (158–1).

$$\text{Vertical eye closure penalty [dB, optical]} = 10 \times \log\frac{OMA}{A_O} \tag{158–1}$$

where

A_O is the amplitude of the eye opening from the 99.95th percentile of the lower histogram to the 0.05th percentile of the upper histogram.

OMA is the normal amplitude without ISI, as shown in Figure 158–4.

158.8.9.1.3 Stressed receiver conformance test signal characteristics and calibration

The conformance test signal is used to validate that the PMD receiver meets BER requirements with near worst case waveforms including pulse width shrinkage, power, simulated channel penalties, and a swept frequency sinusoidal jitter contribution applied at TP3.

Signal characteristics are described below along with a suggested approach for calibration.

The test signal includes vertical eye closure and high-probability jitter components. For this test, these two components are defined by peak values that include all but 0.1% for VECP and all but 1% for jitter of their histograms. Histograms should include at least 10 000 hits, and should be about 1% width in the direction not being measured. Residual low-probability noise and jitter should be minimized—that is, the outer slopes of the final histograms should be as steep as possible down to very low probabilities.

The following steps describe a suggested method for calibrating a stressed eye generator:

1) Set the signaling speed of the test pattern generator to satisfy the requirements of 158.6.2.
2) Turn on the calibration pattern. A short pattern may be used for calibration if the conditions described in 158.8.9.1.1 are met, but this increases the risk that the longer test pattern used during testing over-stresses the device under test. In any case, a pattern shorter than PRBS10 is not recommended.
3) Set the extinction ratio to approximately the “Extinction ratio (min)” value given in 158.6.1. Sinusoidal interference and jitter signals should be turned off at this point. If optical summing is used, the extinction ratio may need to be adjusted after the sinusoidal interference signal is added below.
4) Measure the OMA of the test signal (without attenuation). OMA is measured per the method in 158.8.5 using the square wave pattern.
5) The requirements for vertical eye closure and jitter of the stressed eye test signal are given by the Vertical eye closure penalty (VECP) and Stressed eye jitter (J) values given in Table 158–7.

   There are three components involved in calibration for vertical eye closure and J. These are a linear phase filter, sinusoidal interference, and sinusoidal jitter.

   Without sinusoidal jitter or sinusoidal interference, greater than two thirds of the vertical eye closure penalty value should be created by use of a linear phase, low jitter filter (such as Bessel-Thomson). The filter should be tested with the prescribed test patterns to verify that residual jitter and baseline wander are small, not to exceed 0.25 UI peak-peak. If not, the stress may be more than desired, leading to conservative results. However, compensation is not allowed. Once done, revert to the calibration pattern, if different than the final test pattern specified in Table 158–11.

   Any remaining vertical eye closure required should be created with sinusoidal interference or sinusoidal jitter.

   Sinusoidal jitter (phase modulation) should be added per the template of Table 158–12. For calibration purposes, sinusoidal jitter frequencies should be well within the flat portion of the template greater than 4 MHz.

   Iterate the settings for sinusoidal interference and/or jitter until all constraints are met, including jitter (J), vertical eye closure (VECP), and that sinusoidal jitter above 4 MHz is as specified in Table 158–12.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Verify that the optical power penalty for the stressed eye (relative to the reference transmitter per 158.8.10) is greater than or equal to VECP.

To emulate the effects of DCD or data-dependent jitter, at least 5 ps peak-to-peak of pulse shrinkage jitter should have been achieved.

6) Decrease the amplitude with the optical attenuator until the OMA complies with the OMA values given in Table 158–7 for 10GBASE-BRx. If high linearity exists, then the sinusoidal interference should not change the OMA value. OMA can be approximated with histograms as suggested in Figure 158–4. However, the normative definition for OMA is as given in 158.8.5.

7) For testing, turn on the actual required test pattern(s) per 158.8.1.

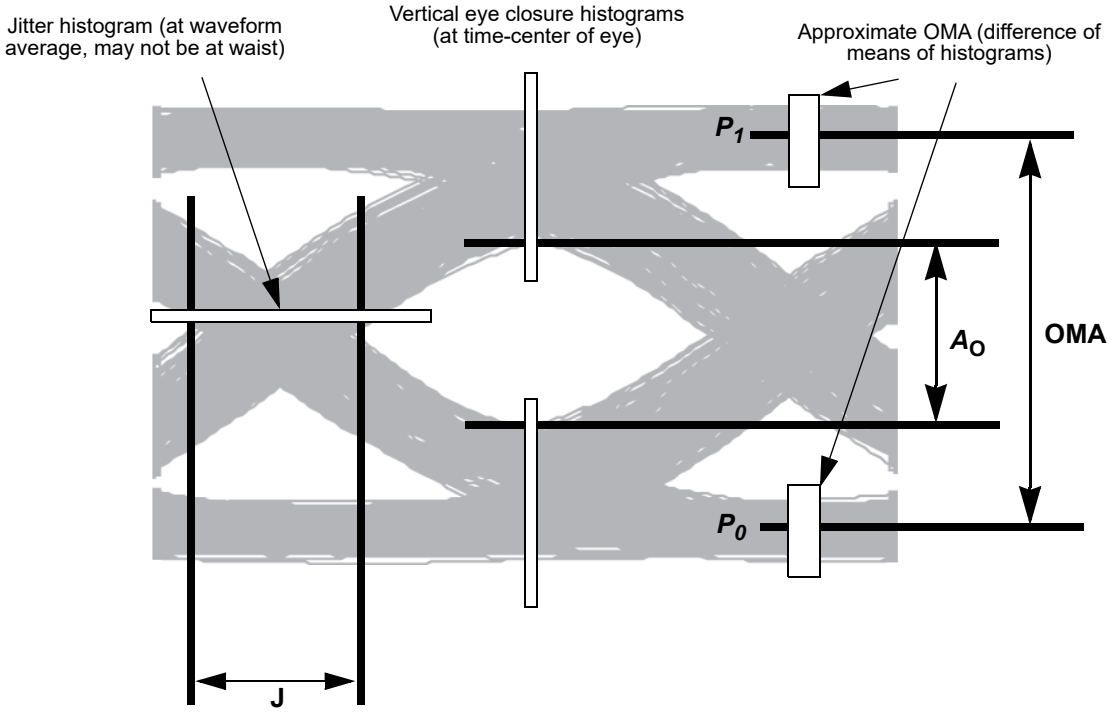

Figure 158–4—Required characteristics of the conformance test signal at TP3

Care should be taken when characterizing the signal used to make receiver tolerance measurements. In the case of a transmit jitter measurement, excessive and/or uncalibrated noise/jitter in the test system makes it more difficult to meet the specification and may have a negative impact on yield but does not effect interoperability. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. Care should be taken to minimize and/or correct for the noise/jitter introduced by the reference receiver, filters, oscilloscope, and BERT. While the details of measurement and test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands to ensure that the receive input signal meets the specified requirements.

158.8.9.1.4 Stressed receiver conformance test procedure

The test apparatus is set up as described in 158.8.9.1.1, 158.8.9.1.2 and 158.8.9.1.3. The sinusoidal jitter is then stepped across the frequency and amplitude range specified in 158.8.9.1.5 while monitoring BER at the receiver. The BER is to be compliant for all jitter frequencies. This method does not result in values for jitter contributed by the receiver. A receiver meeting the requirements of this test is expected to operate with the worst-case optical input.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

158.8.9.1.5 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. The amplitude of the applied sinusoidal jitter is dependent on frequency as specified in Table 158–12.

Table 158–12—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 40$ kHz	Not specified
40 kHz $< f \leq 4$ MHz	2×10^5 Hz/ f
4 MHz $< f <$ 10 LB[a]	0.05

[a] LB = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

158.8.9.2 Stressed receiver sensitivity for 10GBASE-BR20

Stressed receiver sensitivity shall be within the limits given in Table 158–7 if measured using the method defined in 95.8.8 with the following exceptions:

a) The centers of the vertical histograms through the eye diagram are 0.45 UI and 0.55 UI, and the width of each histogram is 0.02 UI (see Figure 95–4).
b) Added sinusoidal jitter is as specified in Table 158–12.
c) The stressed eye J2 Jitter, stressed eye J4 Jitter, stressed eye closure, and SRS eye mask are as given in Table 158–7.
d) The test pattern is as given in Table 158–11.
e) The reference receiver used to verify the conformance test signal is required to have the bandwidth given in 158.8.7.
f) The SEC created by the selection of the appropriate bandwidth for the combination of the low-pass filter and the E/O converter with the sinusoidal jitter, sinusoidal interferer 1, sinusoidal interferer 2, and the Gaussian noise generator turned off is at least 1.5 dB.
g) The conditions for receiver aggressor lanes do not apply.
h) The reflectance of the optical link should be at its maximum level.

158.8.10 Transmitter and dispersion penalty (TDP)

Transmitter and dispersion penalty (TDP) shall be as defined in 52.9.10 with the BER as specified in 158.1.1. The measurement procedure for 10GBASE-BRx is detailed in 158.8.10.1 to 158.8.10.4.

158.8.10.1 Reference transmitter requirements

The reference transmitter is a high-quality instrument-grade device, which can be implemented by a CW laser modulated by a high-performance modulator. The basic requirements are as follows:

a) The rise/fall times are less than 30 ps at 20% to 80%.
b) The output optical eye is symmetric and passes the eye mask test of 158.8.7.
c) In the center 20% region of the eye, the worst case vertical eye closure penalty as defined in 87.8.11.2 is less than 0.5 dB.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) Jitter less than 0.2 UI peak-peak.

e) RIN is minimized to less than –136 dB/Hz.

158.8.10.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 158–13.

Table 158–13—Transmitter compliance channel specifications

PMD Type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c] (max)
	Minimum	Maximum		
10GBASE-BR10	$0.23 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.23 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	12 dB
10GBASE-BR20	$0.46 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.46 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	21 dB
10GBASE-BR40	$0.92 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.92 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	21 dB

[a] The dispersion is measured for the wavelength of the device under test. The coefficient assumes 10 km for 10GBASE-BR10, 20 km for 10GBASE-BR20, and 40 km for 10GBASE-BR40. The link may be as short as 2 m, and the minimum or maximum dispersion may be 0.
[b] There is no intent to stress the sensitivity of the BERT's optical receiver.
[c] The optical return loss is applied at TP2.

A 10GBASE-BRx transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 158–13 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides a maximum optical return loss specified in Table 158–13. The state of polarization of the back reflection is adjusted to create the greatest RIN. The method of 158.8.6 may be used.

158.8.10.3 Reference receiver requirements

The reference receiver is required to have the bandwidth given in 158.8.7. The sensitivity of the reference receiver is limited by Gaussian noise. The receiver has minimal threshold offset, deadband, hysteresis, baseline wander, deterministic jitter, or other distortions. Decision sampling is instantaneous with minimal uncertainty and setup/hold properties.

The nominal sensitivity of the reference receiver, S, is measured in OMA using the set up of Figure 52–12 without the test fiber and with the transversal filter removed. The sensitivity S has to be corrected for any significant reference transmitter impairments including any vertical eye closure. It is measured while sampling at the eye center or corrected for off-center sampling. It is calibrated at the wavelength of the transmitter under test.

For all transmitter and dispersion penalty measurements, determination of the center of the eye is required. Center of the eye is defined as the time halfway between the left and right sampling points within the eye where the measured BER is greater than or equal to 10^{-3}.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The clock recovery unit (CRU) used in the TDP measurement has a corner frequency of 4 MHz and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the data to the clock removes this low-frequency jitter from the measurement.

158.8.10.4 Test procedure

The test procedure is as defined in 52.9.10.4 with the BER as specified in 158.1.1.

158.9 Safety, installation, environment, and labeling

158.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

158.9.2 Laser safety

10GBASE-BRx optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[255]

158.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

158.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 10GBASE-BRx PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause are met.

158.9.5 Electromagnetic emission

A system integrating a 10GBASE-BRx PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

[255] A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

158.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

158.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 10GBASE-BR10-D). Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 158.9.2.

158.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 158–5.

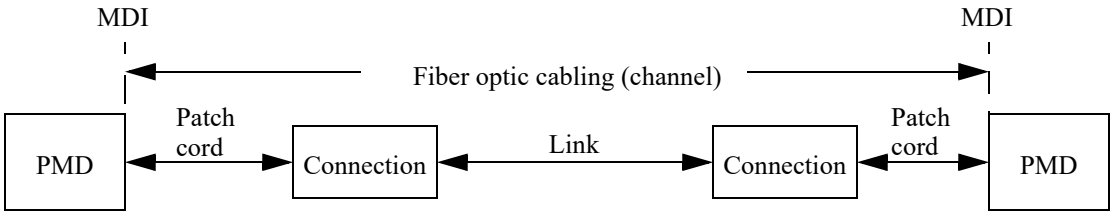

Figure 158–5—Fiber optic cabling model

The channel insertion loss is given in Table 158–8. A channel may contain additional connectors or other optical elements as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Channel insertion loss[a, b] (max)	6.2	15	18	dB
Channel insertion loss (min)	0	0	10	dB
Positive dispersion[b] (max)	35	70	141	ps/nm
Negative dispersion[b] (min)	–64	–127	–254	ps/nm
DGD_max[c]	10	10	10	ps
Optical return loss (min)	21	21	21	dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1260 nm to 1340 nm.
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

158.11 Characteristics of the fiber optic cabling (channel)

The 10GBASE-BRx fiber optic cabling shall meet the specifications defined in Table 158–14. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

158.11.1 Optical fiber and cable

The optical fiber cable requirements are satisfied by cables containing ITU-T G.652.B (dispersion unshifted), type G.652.D (low water peak, dispersion unshifted), or type G.657.A1 or type G.657.A2 (bend insensitive) fibers or the requirements in Table 158–14 where they differ.

158.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 158–5, consists of a mated pair of optical connectors.

158.11.2.1 Connection insertion loss

The maximum link distances for single-mode fiber are calculated based on an allocation of 2 dB total connection and splice loss for 10GBASE-BR10 and 10GBASE-BR40. The maximum link distances for single-mode fiber are calculated based on an allocation of 5 dB total connection and splice loss for 10GBASE-BR20.

158.11.2.2 Maximum discrete reflectance

The maximum discrete reflectance for 10GBASE-BR10 shall be less than –20 dB.

The maximum discrete reflectance for 10GBASE-BR20 and 10GBASE-BR40 shall be less than –26 dB.

158.11.3 Medium Dependent Interface (MDI) requirements

The 10GBASE-BRx PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 158–5). Examples of an MDI include the following:

a) Connectorized fiber pigtail.

b) PMD receptacle.

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1, IEC 61753-021-2, and IEC 61753-022-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 158.5.1, not at the MDI.

158.12 Requirements for interoperation between 10GBASE-BRx PMDs

The 10GBASE-BR10 and 10GBASE-BR40 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 158–15 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 158–15—Channel insertion loss requirements for interoperation between 10GBASE-BR10 and 10GBASE-BR40

Direction	Min loss	Max loss	Unit
10GBASE-BR10 transmitter to 10GBASE-BR40 receiver	7.5	12.8	dB
10GBASE-BR40 transmitter to10GBASE-BR10 receiver	2.5	11.6	dB

158.13 Protocol implementation conformance statement (PICS) proforma for Clause 158, Physical Medium Dependent (PMD) sublayer and medium, types 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40[256]

158.13.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 158, Physical Medium Dependent (PMD) sublayer and medium, types 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

158.13.2 Identification

158.13.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

158.13.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 158, Physical Medium Dependent (PMD) sublayer and medium, types 10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[256]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

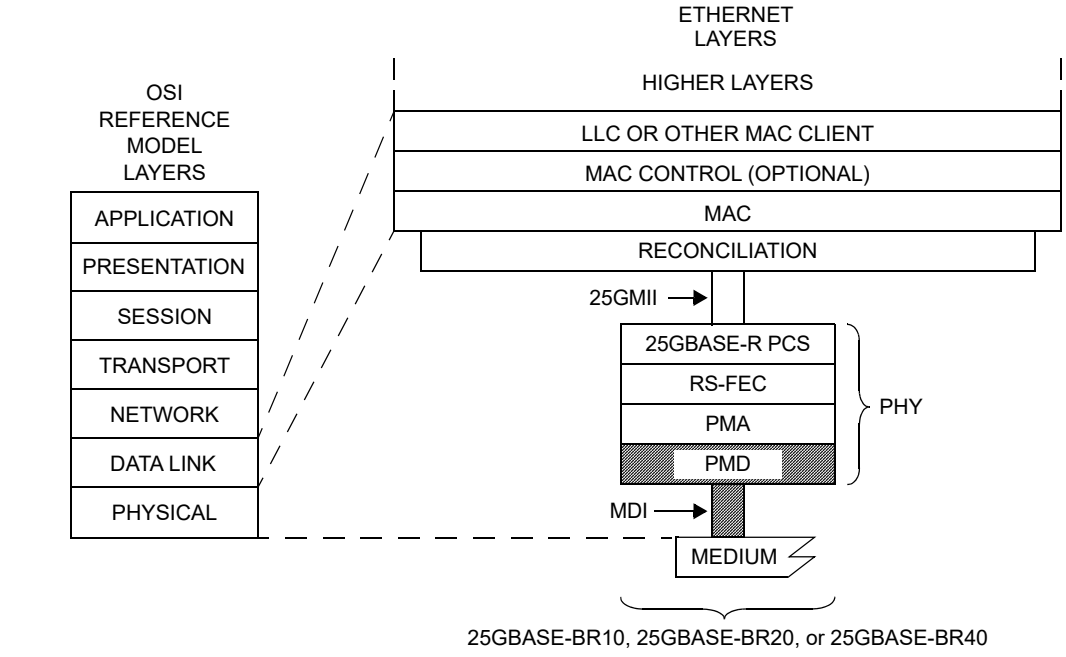
159. Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-BR10, 25GBASE-BR20, and 25GBASE-BR40

159.1 Overview

This clause specifies the 25GBASE-BR10, 25GBASE-BR20, and 25GBASE-BR40 PMDs together with the single-mode fiber medium. Within this clause these PMDs are jointly referred to by the term 25GBASE-BRx. The 25GBASE-BRx PHYs are divided into two variants based on the direction of transmission. Optical line terminal (OLT) PMDs transmit in the downstream direction and receive in the upstream direction. Optical network unit (ONU) PHYs transmit in the upstream direction and receive in the downstream direction. The PMD variant is indicated with a suffix of D for OLT PMDs and U for ONU PMDs. The PMD sublayer provides a point-to-point 25 Gb/s Ethernet link over one single-mode fiber. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 159–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 159–1—Physical Layer clauses associated with the 25GBASE-BRx PMDs

Associated clause	25GBASE-BR10, 25GBASE-BR20, 25GBASE-BR40
106—RS	Required
106—25GMII[a]	Optional
107—PCS for 25GBASE-R	Required
108—RS-FEC[b]	Required
109—PMA for 25GBASE-R	Required
109A—25GAUI C2C	Optional
109B—25GAUI C2M	Optional
78—Energy-Efficient Ethernet	Optional



[a] The 25GMII is an optional interface. However, if the 25GMII is not implemented, a conforming implementation behaves functionally as though the RS and 25GMII were present.
[b] The option to bypass the Clause 108 RS-FEC correction function is not supported.

Figure 159–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 25 Gigabit Ethernet is introduced in Clause 105 and the purpose of each PHY sublayer is summarized in 105.3.

The 25GBASE-BRx PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions, and abbreviations) and Annex A (Bibliography, referenced as [B1], [B2], etc.).

25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 159–1—25GBASE-BRx PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

159.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 5×10^{-5} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

159.2 Physical Medium Dependent (PMD) service interface

The PMD service interfaces for 25GBASE-BRx are the same as PMD service interface for 25GBASE-SR as described in 112.2 with the BER as specified in 159.1.1.

159.3 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The sum of the transmit and receive delays at one end of the link contributed by

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a 25GBASE-BRx PMD including 2 m of fiber in one direction shall be no more than 512 bit times (1 pause_quantum or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quantum can be found in 105.5 and its references.

159.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 159–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 159–3.

Table 159–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable

Table 159–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

159.5 PMD functional specifications

The 25GBASE-BRx PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

159.5.1 PMD block diagram

The PMD block diagram is shown in Figure 159–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 159.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 88.11.3). Unless specified otherwise, all receiver measurements and tests defined in 159.7 are made at TP3. TP1 and TP4 are optional reference points that may be useful to implementers for testing components (these test points are not typically accessible in an implemented system).

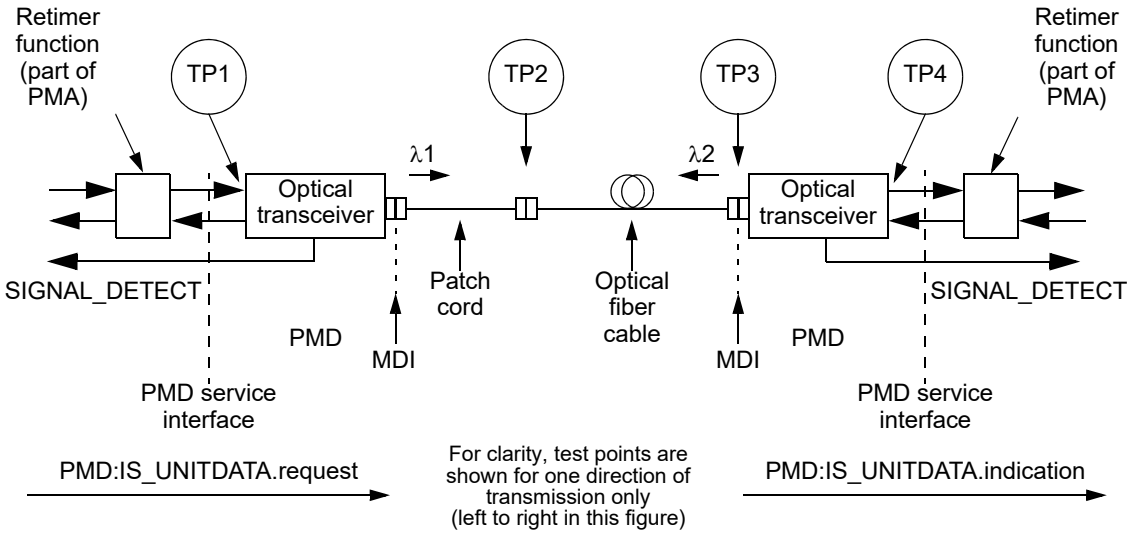

Figure 159–2—Block diagram for 25GBASE-BRx transmit/receive paths

159.5.2 PMD transmit function

The PMD Transmit function shall convert the bit stream requested by the PMD service interface messages PMD:IS_UNITDATA.request into an optical signal. The optical signal shall then be delivered to the MDI, all according to the transmit optical specifications in this clause. The higher optical power level in the signal shall correspond to tx_bit = one.

159.5.3 PMD receive function

The PMD Receive function shall convert the optical signal received from the MDI into a bit stream for delivery to the PMD service interface using the messages PMD:IS_UNITDATA.indication, all according to the receive optical specifications in this clause. The higher optical power level in the signal shall correspond to rx_bit = one.

159.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 105.4.

SIGNAL_DETECT shall be the indicator of the presence of the optical signal. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 159–4. The PMD receiver is not required to verify whether a compliant 25GBASE-BRx signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 159–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –20 dBm for 25GBASE-BR10 and ≤ –26 dBm for 25GBASE-BR20 and 25GBASE-BR40	FAIL
[(Optical power at TP3 ≥ receiver sensitivity (max) in OMA in Table 159–7) AND (compliant 25GBASE–BRx signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the PMD global signal detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal. When the MDIO is implemented, the SIGNAL_DETECT value shall be continuously set in response to the magnitude of the optical signal, according to the requirements of Table 159–4.

159.5.5 PMD reset function

If PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

159.5.6 PMD global transmit disable function

PMDs compliant with this clause shall include the PMD global transmit disable function that allows the optical transmitter to be disabled.

When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirement of the average launch power of the OFF transmitter in Table 159–6.

If PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

159.5.7 PMD fault function (optional)

If the PMD has detected a local fault on the transmit or receive paths, the PMD shall set PMD_fault to one.

159.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set PMD_transmit_fault to one.

PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

159.5.9 PMD receive fault function

The 25GBASE-BRx-U PMD shall include the PMD_receive_fault function, in the 25GBASE-BRx-D PMD this function is optional. If the PMD has detected a local fault on the receiver, the PMD shall set PMD_receive_fault to one.

PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

159.5.10 ONU silent start

Silent start shall be provided by 25GBASE-BR10-U, 25GBASE-BR20-U, and 25GBASE-BR40-U PHYs. See 157.5.

159.6 PMD to MDI optical specifications for 25GBASE-BRx

The operating ranges for the 25GBASE-BRx PMDs are defined in Table 159–5. 25GBASE-BRx compliant PMDs operate on ITU-T G.652.B (dispersion unshifted), type G.652.D (low water peak, dispersion unshifted), or type G.657.A1 or type G.657.A2 (bend insensitive) single-mode fibers according to the specifications defined in 159.7. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 25GBASE-BR10 PMD operating at 12.5 km meets the operating range requirement of 2 m to 10 km).

Table 159–5—25GBASE-BRx operating ranges

PMD type	Required operating range[a]
25GBASE-BR10	2 m to 10 km
25GBASE-BR20	2 m to 20 km
25GBASE-BR40	2 m to 40 km

[a] The RS-FEC correction function may not be bypassed for any operating distance.

159.6.1 25GBASE-BRx transmitter optical specifications

The 25GBASE-BRx transmitters shall meet the specifications in Table 159–6 per the definitions in 159.7.

Table 159–6—25GBASE-BRx transmit characteristics

Description	25GBASE-BR10	25GBASE-BR20	25GBASE-BR40	Unit
Signaling rate (range)	25.78125 ± 100 ppm			GBd
25GBASE-BRx-D center wavelength (range)	1320 to 1340	1306 to 1322		nm
25GBASE-BRx-U center wavelength (range)	1260 to 1280	1281 to 1297		nm
Side-mode suppression ratio (SMSR), (min)	30			dB
Average launch power (max)	2	0	6	dBm
Average launch power[a] (min)	–7	–7.5	–3	dBm
Optical Modulation Amplitude (OMA), (max)	2.2	3	6	dBm
Optical Modulation Amplitude (OMA)[b], (min)	–4	–4.5	0	dBm
Launch power in OMA minus TDP (min)	–5	–5.5	–1	dBm
Transmitter and dispersion penalty (TDP), (max)	2.7			dB
Average launch power of OFF transmitter (max)	–20			dBm
Extinction ratio (min)	3	4		dB
$RIN_{20}OMA$ (max)	–130			dB/Hz
Optical return loss tolerance (max)	20			dB
Transmitter reflectance[c] (max)	–26			dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}, hit ratio 5×10^{-5} hits per sample.	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}			—

[a] Average launch power (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] The OMA (min) requirement holds even if the TDP < 1 dB.
[c] Transmitter reflectance is defined looking into the transmitter.

159.6.2 25GBASE-BRx receiver optical specifications

The 25GBASE-BRx receivers shall meet the specifications in Table 159–7 per the definitions in 159.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 159–7—25GBASE-BRx receive characteristics

Description	25GBASE-BR10	25GBASE-BR20	25GBASE-BR40	Unit
Signaling rate (range)	25.78125 ± 100 ppm			GBd
25GBASE-BRx-D center wavelength (range)	1260 to 1280	1281 to 1297		nm
25GBASE-BRx-U center wavelength (range)	1320 to 1340	1306 to 1322		nm
Damage threshold[a] (min)	3	1	–3	dBm
Average receive power (max)	2	0	–4	dBm
Average receive power[b] (min)	–13.3	–22.5	–21	dBm
Receive power (OMA), (max)	2.2	–4		dBm
Receiver reflectance (max)	–26			dB
Receiver sensitivity (OMA)[c], (max)	–12	–20.5	–19	dBm
Stressed receiver sensitivity (OMA)[d], (max)	–9.5	–16.5		dBm
Conditions of stressed receiver sensitivity test				
Stressed eye closure[e]	2.5			dB
Stressed eye J2 Jitter[e]	0.27			UI
Stressed eye J4 Jitter[e]	0.39			UI
SRS eye mask definition {X1, X2, X3, Y1, Y2, Y3}, hit ratio 5×10^{-5} hits per sample.	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}			—

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b] Average receive power (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity (OMA), (max) is optional.
[d] Measured with conformance test signal at TP3 (see 159.7) for the BER specified in 159.1.1.
[e] Stressed eye closure, stressed eye J2 Jitter, and stressed eye J4 Jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

159.6.3 25GBASE-BRx illustrative link power budgets

Illustrative power budgets and penalties for 25GBASE-BRx channels are shown in Table 159–8.

Table 159–8—25GBASE-BRx illustrative link power budgets

Parameter	25GBASE-BR10	25GBASE-BR20	25GBASE-BR40	Unit
Power budget (for maximum TDP)	9	17.7	20.7	dB
Operating distance	10	20	40	km
Channel insertion loss	6.3[a]	15[b]	18[a]	dB
Maximum discrete reflectance	See 159.10	–26		dB
Allocation for penalties[c] (for maximum TDP)	2.7			dB

[a] The channel insertion loss is calculated using the maximum distance specified in Table 159–5 and fiber attenuation of 0.4 dB/km plus an allocation for connection and splice loss given in 159.10.2.1.
[b] The channel insertion loss is calculated using the maximum distance specified in Table 159–5 and fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 159.10.2.1.
[c] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

159.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

159.7.1 Test patterns for optical parameters

The test patterns used in this clause shall be the same as those used for 100GBASE-SR4, as described in 95.8.1 and shown in Table 159–9, with the exception that pattern 5, the scrambled idle test pattern defined in 82.2.11, is encoded by Clause 108 RS-FEC for 25GBASE-BRx. The multi-lane testing considerations described in 95.8.1.1 do not apply. Table 159–9 shows the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined.

159.7.2 Wavelength and side-mode suppression ratio (SMSR)

The wavelength and SMSR shall be within the ranges given in Table 159–6 if measured per IEC 61280-1-3. The signal is modulated using the test pattern specified in Table 159–9.

159.7.3 Average optical power

The average optical power shall be within the limits given in Table 159–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern specified in Table 159–9.

Table 159–9—Test pattern definitions and related subclauses

Test	Pattern	Related subclause
Wavelength	3, 5 or valid 25GBASE-R signal	159.7.2
Side--mode suppression ratio	3, 5 or valid 25GBASE-R signal	159.7.2
Average optical power	3, 5 or valid 25GBASE-R signal	159.7.3
Optical modulation amplitude (OMA)	Square wave or 4	159.7.4
Transmitter and dispersion penalty (TDP)	3, 5 or valid 25GBASE-R signal	159.7.5
Extinction ratio	3, 5 or valid 25GBASE-R signal	159.7.6
$RIN_{20}OMA$	Square wave or 4	159.7.7
Transmitter optical waveform	3, 5 or valid 25GBASE-R signal	159.7.8
Stressed receiver sensitivity	3, 5 or valid 25GBASE-R signal	159.7.10
Calibration of OMA for receiver tests	Square wave or 4	87.8.11
Vertical eye closure penalty calibration	3, 5 or valid 25GBASE-R signal	87.8.11

159.7.4 Optical Modulation Amplitude (OMA)

OMA shall meet the requirements in Table 159–6 when measured using the method defined in 52.9.5 with a square wave (8 ones, 8 zeros) test pattern, or in 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) with a PRBS9 test pattern. See 159.7.1 for test pattern information.

159.7.5 Transmitter and dispersion penalty (TDP)

Transmitter and dispersion penalty (TDP) shall be as defined in 52.9.10 with the BER as specified in 159.1.1. The measurement procedure for 25GBASE-BRx is detailed in 159.7.5.1 to 159.7.5.4.

159.7.5.1 Reference transmitter requirements

The reference transmitter is a high-quality instrument-grade device, which can be implemented by a CW laser modulated by a high-performance modulator. The basic requirements are as follows:

a) Rise/fall times of less than 12 ps at 20% to 80%.
b) The output optical eye is symmetric and passes the transmitter optical waveform test of 159.7.8.
c) In the center 20% region of the eye, the worst-case vertical eye closure penalty as defined in 87.8.11.2 is less than 0.5 dB.
d) Total Jitter less than 0.2 UI peak-to-peak.
e) RIN of less than –138 dB/Hz.

159.7.5.2 Channel requirements

The channel requirements for testing the transmitter are described in 88.8.5.2, where the requirements for 100GBASE-LR4 apply to 25GBASE-BR10 and the requirements for 100GBASE-ER4 apply to 25GBASE-BR20 and 25GBASE-BR40.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

159.7.5.3 Reference receiver requirements

The reference receiver is required to have the bandwidth given in 159.7.8. The sensitivity of the reference receiver is limited by Gaussian noise. The receiver has minimal threshold offset, deadband, hysteresis, baseline wander, deterministic jitter, or other distortions. Decision sampling has minimal uncertainty and setup/hold times.

The nominal sensitivity of the reference receiver, S, is measured in OMA using the setup of Figure 52–12 without the test fiber and with the transversal filter removed. The sensitivity S has to be corrected for any significant reference transmitter impairments including any vertical eye closure. It is measured while sampling at the eye center or corrected for off-center sampling. It is calibrated at the wavelength of the transmitter under test.

For all transmitter and dispersion penalty measurements, determination of the center of the eye is required. Center of the eye is defined as the time halfway between the left and right sampling points within the eye where the measured BER is greater than or equal to 10^{-3}.

The clock recovery unit (CRU) used in the TDP measurement has a corner frequency of 10 MHz and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the data to the clock removes this low-frequency jitter from the measurement.

159.7.5.4 Test procedure

The test procedure is as defined in 52.9.10.4 with the BER as specified in 159.1.1.

159.7.6 Extinction ratio

The extinction ratio shall be within the limits given in Table 159–6 if measured using the methods specified in IEC 61280-2-2. The extinction ratio is measured using the test pattern defined in Table 159–9.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 159–9).

159.7.7 Relative Intensity Noise ($RIN_{20}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 20 dB.

b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 25.8 GHz).

159.7.8 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4. The transmitter optical waveform of a port transmitting the test pattern specified in Table 159–9 shall meet specifications according to the methods specified in 86.8.4.6.1 with the exception that the clock recovery unit's high-frequency corner bandwidth is 10 MHz. The filter nominal reference frequency f_r is 19.34 GHz and the filter tolerances are as specified for STM-64 in ITU-T G.691. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response and for any excess reference receiver noise.

159.7.9 Receiver sensitivity

Receiver sensitivity, which is defined for an ideal input signal, is optional and compliance is not required. If measured, the test signal should have negligible impairments such as intersymbol interference (ISI), rise/fall times, jitter and RIN. Instead, the normative requirement for receivers is stressed receiver sensitivity.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

159.7.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 159–7 if measured using the method defined in 95.8.8 with the following exceptions:

a) The centers of the vertical histograms through the eye diagram are 0.45 UI and 0.55 UI, and the width of each histogram is 0.02 UI (see Figure 95–4).
b) Added sinusoidal jitter is as specified in Table 159–10.
c) The stressed eye J2 Jitter, stressed eye J4 Jitter, stressed eye closure, and SRS eye mask are as given in Table 159–7.
d) The test pattern is as given in Table 159–9.
e) The reference receiver used to verify the conformance test signal is required to have the bandwidth given in 159.7.8.
f) The SEC created by the selection of the appropriate bandwidth for the combination of the low-pass filter and the E/O converter with the sinusoidal jitter, sinusoidal interferer 1, sinusoidal interferer 2, and the Gaussian noise generator turned off is at least 1.5 dB.
g) The conditions for receiver aggressor lanes do not apply.
h) The reflectance of the optical link should be at its maximum level.

Table 159–10—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 100$ kHz	Not specified
100 kHz $< f \leq 10$ MHz	5×10^5 Hz/f
10 MHz $< f <$ 10 LB[a]	0.05

[a] LB = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

159.8 Safety, installation, environment, and labeling

159.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

159.8.2 Laser safety

25GBASE-BRx optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[257]

[257] A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

159.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

159.8.4 Environment

Normative specifications in this clause shall be met by a system integrating a 25GBASE-BRx PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause are met.

159.8.5 Electromagnetic emission

A system integrating a 25GBASE-BRx PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

159.8.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

159.8.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 25GBASE-BR10-D). Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 159.8.2.

159.9 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 159–3.

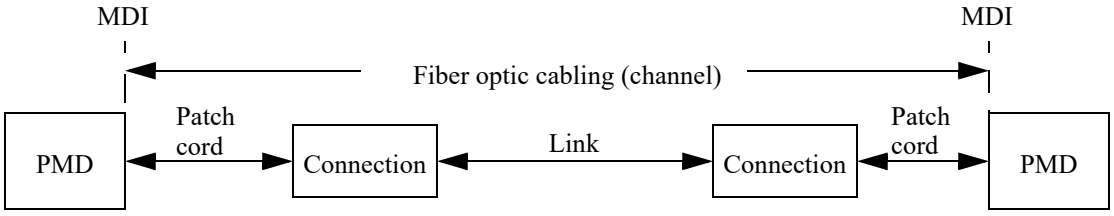

Figure 159–3—Fiber optic cabling model

The channel insertion loss is given in Table 159–8. A channel may contain additional connectors or other optical elements as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of

installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards. The maximum channel insertion loss for 25GBASE-BR40 is specified by Table 159–11.

Table 159–11—Maximum channel insertion loss versus number of discrete reflectances for 25GBASE-BR40

Maximum channel insertion loss (dB)		Number of discrete reflectances > –55 dB and ≤ –35 dB										
		0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
Number of discrete reflectances > –35 dB and ≤ –26 dB	**0**	18	18	18	17.9	17.9	17.9	17.8	17.8	17.8	17.7	17.7
	1	17.9	17.9	17.9	17.8	17.8	17.7	17.7	17.6	17.6	17.5	—[a]
	2	17.8	17.8	17.7	17.7	17.6	17.6	17.5	17.4	17.4	—[a]	—[a]
	3	17.7	17.6	17.6	17.4	17.4	17.3	—[a]	—[a]	—[a]	—[a]	—[a]
	4	17.5	17.4	17.3	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]
	> 4	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]

[a]The indicated combination of reflectances is not supported.

159.10 Characteristics of the fiber optic cabling (channel)

The 25GBASE-BRx fiber optic cabling shall meet the specifications defined in Table 159–12. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

Table 159–12—Fiber optic cabling (channel) characteristics

Description	25GBASE-BR10	25GBASE-BR20	25GBASE-BR40	Unit
Operating distance (max)	10	20	40	km
Channel insertion loss[a, b](max)	6.2	15	18	dB
Channel insertion loss (min)	0	0	10	dB
Positive dispersion[b] (max)	35	38.5	79	ps/nm
Negative dispersion[b] (min)	–64	–83	–166	ps/nm
DGD_max[c]	8	10.3	10.3	ps
Optical return loss (min)	21	21	21	dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1260 nm to 1340 nm for 25GBASE-BR10 and 1281 nm to 1322 nm for 25GBASE-BR20 and 25GBASE-BR40.
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

159.10.1 Optical fiber cable

The optical fiber cable requirements are satisfied by cables containing ITU-T G.652.B (dispersion unshifted), type G.652.D (low water peak, dispersion unshifted), or type G.657.A1 or type G.657.A2 (bend insensitive) fibers or the requirements in Table 159–12 where they differ.

159.10.2 Optical fiber connection

An optical fiber connection, as shown in Figure 159–3, consists of a mated pair of optical connectors.

159.10.2.1 Connection insertion loss

Connections with different loss characteristics may be used provided the requirements of Table 159–12 are met. The maximum link distance for 25GBASE-BR10 and 25GBASE-BR40 is based on an allocation of 2 dB total connection and splice loss. The maximum link distance for 25GBASE-BR20 is based on an allocation of 5 dB total connection and splice loss.

159.10.2.2 Maximum discrete reflectance

For 25GBASE-BR10, the maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 159–13 corresponding to the number of discrete reflectances above –55 dB within the channel.

For 25GBASE-BR40, the maximum value of channel insertion loss is dependent on the number and maximum value of the discrete reflectances within the channel as given in Table 159–11. Discrete reflectances below –55 dB may be ignored when determining the supported channel insertion loss.

Table 159–13—Maximum value of each discrete reflectance for 25GBASE-BR10

Number of discrete reflectances above –55 dB[a]	Maximum value for each discrete reflectance for 25GBASE-BR10
1 to 4	–26 dB
6	–30 dB
8	–32 dB
10	–34 dB

[a] For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

159.10.3 Medium Dependent Interface (MDI) requirements

The 25GBASE-BRx PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” (as shown in Figure 159–3). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 159.5.1, not at the MDI.

159.11 Requirements for interoperation between 25GBASE-BRx PMDs

The 25GBASE-BR20 and 25GBASE-BR40 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 159–14 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 159–14—Channel insertion loss requirements for interoperation between 25GBASE-BR20 and 25GBASE-BR40

Direction	Min loss	Max loss	Unit
25GBASE-BR20 transmitter to 25GBASE-BR40 receiver	4	15	dB
25GBASE-BR40 transmitter to 25GBASE-BR20 receiver	6	18	dB

159.12 Protocol implementation conformance statement (PICS) proforma for Clause 159, Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-BR10, 25GBASE-BR20, and 25GBASE-BR40[258]

159.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 159, Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-BR10, 25GBASE-BR20, and 25GBASE-BR40, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

159.12.2 Identification

159.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

159.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 159, Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-BR10, 25GBASE-BR20, and 25GBASE-BR40
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

160. Physical Medium Dependent (PMD) sublayer and medium, types 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40

160.1 Overview

This clause specifies the 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40 PMDs together with one single-mode fiber medium. Within this clause these PMDs are jointly referred to by the term 50GBASE-BRx. The 50GBASE-BRx PHYs are divided into two variants based on the direction of transmission. Optical line terminal (OLT) PMDs transmit in the downstream direction and receive in the upstream direction. Optical network unit (ONU) PMDs transmit in the upstream direction and receive in the downstream direction. The PMD variant is indicated with a suffix of D for OLT PMDs and U for ONU PMDs. The optical signals generated by these three PMD types are modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 160–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 160–1—Physical Layer clauses associated with the 50GBASE-BRx PMDs

Associated clause	50GBASE-BR10, 50GBASE-BR20, 50GBASE-BR40
132—RS	Required
132—50GMII[a]	Optional
133—PCS for 50GBASE-R	Required
134—RS-FEC for 50GBASE-R	Required
135—PMA for 50GBASE-R	Required
135B—LAUI-2 C2C	Optional
135C—LAUI-2 C2M	Optional
135D—50GAUI-2 C2C	Optional
135E—50GAUI-2 C2M	Optional
135F—50GAUI-1 C2C	Optional
135G—50GAUI-1 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a] 50GMII is an optional interface. However, if the appropriate interface is not implemented, a conforming implementation behaves functionally as though the RS and 50GMII were present.

Figure 160–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 50 Gigabit Ethernet is introduced in Clause 131 and the purpose of each PHY sublayer is summarized in 131.2.

50GBASE-BRx PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

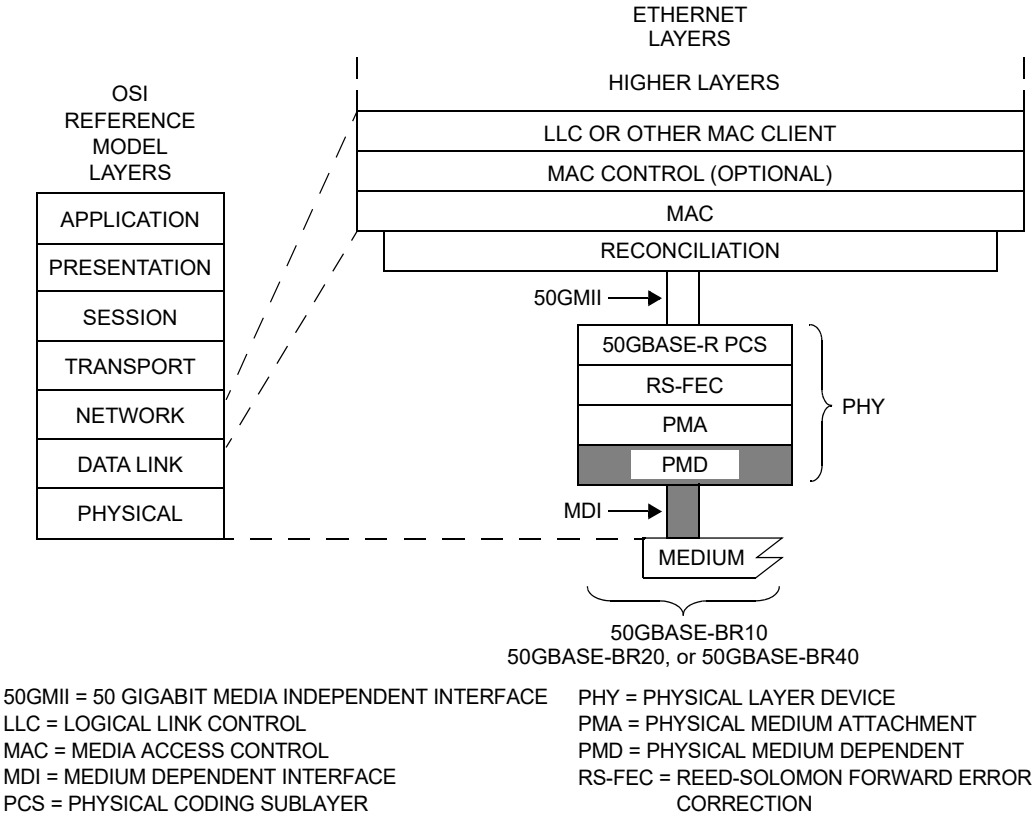

Figure 160–1—50GBASE-BRx PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

160.1.1 Bit error ratio

The bit error ratio (BER) when processed by the PMA (Clause 135) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap when additionally processed by the FEC (Clause 134) and PCS (Clause 133). For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-10} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap.

160.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 50GBASE-BRx PMDs. The service interface for these PMDs is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 50GBASE-BRx PMD service interface is an instance of the inter-sublayer service interface defined in 131.3, with a single symbol stream (n = 1).

The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_0.request
PMD:IS_UNITDATA_0.indication
PMD:IS_SIGNAL.indication

In the transmit direction, the PMA continuously sends one stream of PAM4 symbols to the PMD using the PMD:IS_UNITDATA_0.request primitive, at a nominal signaling rate of 26.5625 GBd. The PMD converts these streams of symbols into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends one stream of PAM4 symbols to the PMA, corresponding to the signals received from the MDI, using the PMD:IS_UNITDATA_0.indication primitive, at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable SIGNAL_DETECT parameter as defined in 160.5.4. The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 160.1.1.

160.3 Delay and Skew

160.3.1 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The sum of the transmit and receive delays at one end of the link contributed by the 50GBASE-BRx PMDs including 2 m of fiber in one direction shall be no more than 1024 bit times (2 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quantum can be found in 131.4 and its references.

160.3.2 Skew constraints

The Skew (relative delay) between the FEC lanes is kept within limits so that the information on the lanes can be reassembled by the FEC. The Skew Variation is also limited to ensure that a given FEC lane always traverses the same physical lane. Skew and Skew Variation are defined in 131.5 and specified at the points SP0 to SP7 shown in Figure 131–3.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 135.5.3.5. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

For more information on Skew and Skew Variation, see 131.5. The measurements of Skew and Skew Variation are defined in 89.7.2 with the exception that the measurement clock and data recovery unit high-frequency corner bandwidth is 4 MHz.

160.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 160–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 160–3.

Table 160–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable

Table 160–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

160.5 PMD functional specifications

The 50GBASE-BRx PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

160.5.1 PMD block diagram

The PMD block diagram is shown in Figure 160–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 160.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 160.10.3). Unless specified otherwise, all receiver measurements and tests defined in 160.7 are made at TP3. TP1 and TP4 are optional reference points that

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

may be useful to implementers for testing components (these test points are not typically be accessible in an implemented system).

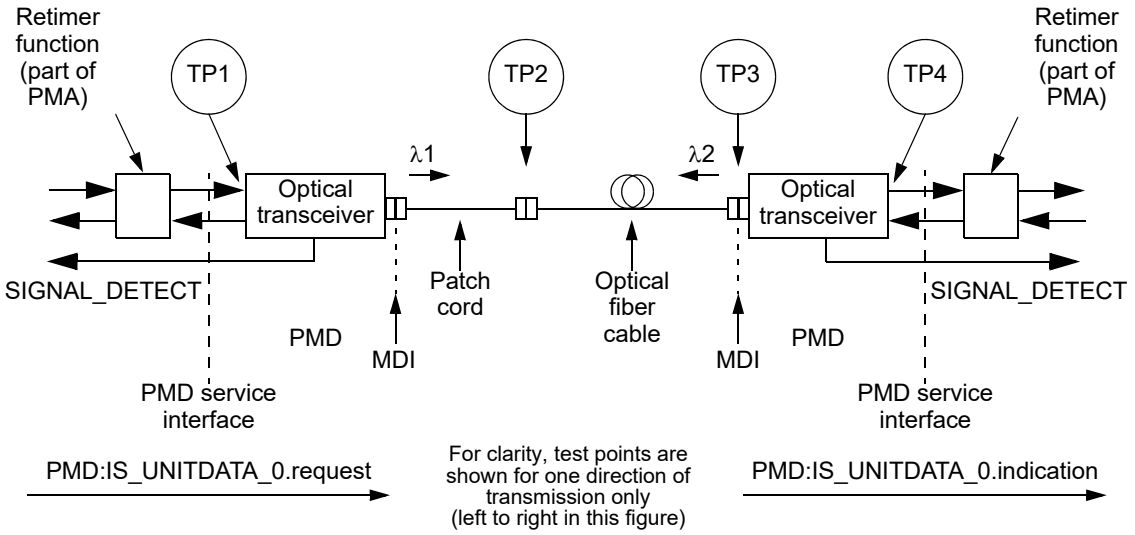

Figure 160–2—Block diagram for 50GBASE-BRx transmit/receive paths

160.5.2 PMD transmit function

The PMD Transmit function shall convert the symbol stream requested by the PMD service interface messages PMD:IS_UNITDATA_0.request into an optical signal. The optical signal shall then be delivered to the MDI, according to the transmit optical specifications in this clause. The four optical power levels in the signal in order from lowest to highest shall correspond to tx_symbol values zero, one, two, and three, respectively.

160.5.3 PMD receive function

The PMD receive function shall convert the optical signal received from the MDI into a symbol stream for delivery to the PMD service interface using the message PMD:IS_UNITDATA_0.indication, all according to the receive optical specifications in this clause. The four optical power levels in each signal in order from lowest to highest shall correspond to rx_symbol values zero, one, two, and three, respectively.

160.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 131.3.

SIGNAL_DETECT shall be a global indicator of the presence of the optical signal. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 160–4. The PMD receiver is not required to verify whether a compliant 50GBASE-BRx signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 160–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –20 dBm	FAIL
[(Optical power at TP3 ≥ average receive power in Table 160–7) AND (compliant 50GBASE-BRx signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

160.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

160.5.6 PMD global transmit disable function

PMDs compliant with this clause shall include the PMD global transmit disable function that allows the optical transmitter to be disabled.

When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of the OFF transmitter in Table 160–6.

If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

160.5.7 PMD fault function (optional)

If the PMD has detected a local fault on the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

160.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

160.5.9 PMD receive fault function

The 50GBASE-BRx-U PMD shall include the PMD_receive_fault function, in the 50GBASE-BRx-D PMD this function is optional. If the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

160.5.10 ONU silent start

Silent start shall be provided by 50GBASE-BR10-U, 50GBASE-BR20-U, and 50GBASE-BR40-U PHYs. See 157.5.

160.6 PMD to MDI optical specifications for 50GBASE-BRx

The operating ranges for the 50GBASE-BRx PMDs are defined in Table 160–5. A 50GBASE-BRx compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 160–12. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 50GBASE-BR10 PMD operating at 12.5 km meets the operating range requirement of 2 m to 10 km). The 50GBASE-BR40 PMD interoperates with the 50GBASE-BR10 or 50GBASE-BR20 PMD provided that the channel requirements for the 50GBASE-BR10 or 50GBASE-BR20 PMD are met.

Table 160–5—50GBASE-BRx operating ranges

PMD type	Required operating range[a]
50GBASE-BR10	2 m to 10 km
50GBASE-BR20	2 m to 20 km
50GBASE-BR40	2 m to 40 km

[a] The RS-FEC correction function may not be bypassed for any operating distance.

160.6.1 50GBASE-BRx transmitter optical specifications

The 50GBASE-BRx transmitters shall meet the specifications defined in Table 160–6 per the definitions in 160.7.

Table 160–6—50GBASE-BRx transmit characteristics

Description	50GBASE-BR10	50GBASE-BR20	50GBASE-BR40	Unit
Signaling rate (range)	26.5625 ± 100 ppm			GBd
Modulation format	PAM4			—
50GBASE-BRx-D center wavelengths (range)	1320 to 1340	1306 to 1322		nm
50GBASE-BRx-U center wavelengths (range)	1260 to 1280	1281 to 1297		nm

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 160–6—50GBASE-BRx transmit characteristics *(continued)*

Description	50GBASE-BR10	50GBASE-BR20	50GBASE-BR40	Unit
Side-mode suppression ratio (SMSR), (min)	30			dB
Average launch power (max)	4.2	3.6	6.6	dBm
Average launch power[a] (min)	–4.5	–2.6	0.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}) (max)	4	4.4	7.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}) (min)[b]: for TDECQ < 1.4 dB for 1.4 dB ≤ TDECQ ≤ 3.2 dB	 –1.5 –2.9 + TDECQ	 0.4 –1 + TDECQ	 3.4 2 + TDECQ	 dBm dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ) (max)	3.2			dB
TDECQ – $10\log_{10}(C_{eq})$[c] (max)	3.2			dB
TECQ (max)	3.2			dB
| TDECQ – TECQ | (max)	2.5			dB
Average launch power of OFF transmitter (max)	–16	–20	–15	dBm
Extinction ratio (min)	3.5	6		dB
Transmitter transition time (max)	34			ps
RIN_xOMA (max)[d]	–132			dB/Hz
Optical return loss tolerance (max)	15.6	15		dB
Transmitter reflectance[e] (max)	–26			dB

[a] Average launch power (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] The OMA_{outer} (min) requirement holds even if the TDECQ < 1.4 dB. Even though the representation of the OMA_{outer} requirement is different from that in Clause 139, they are consistent.
[c] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d] In RIN_xOMA, "x" is the optical return loss tolerance (max) for the PHY under test.
[e] Transmitter reflectance is defined looking into the transmitter.

160.6.2 50GBASE-BRx receive optical specifications

The 50GBASE-BRx receiver shall meet the specifications defined in Table 160–7 per the definitions in 160.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 160–7—50GBASE-BRx receive characteristics

Description	50GBASE-BR10	50GBASE-BR20	50GBASE-BR40	Unit
Signaling rate (range)	26.5625 ± 100 ppm			GBd
Modulation format	PAM4			—
50GBASE-BRx-D center wavelengths (range)	1260 to 1280	1281 to 1297		nm
50GBASE-BRx-U center wavelengths (range)	1320 to 1340	1306 to 1322		nm
Damage threshold[a]	5.2	4.6	–2.4	dBm
Average receive power (max)	4.2	3.6	–3.4	dBm
Average receive power[b] (min)	–10.8	–17.6		dBm
Receive power (OMA_{outer}) (max)	4	4.4	–2.6	dBm
Receiver reflectance (max)	–26			dB
Receiver sensitivity (OMA_{outer})[c] (max) for TECQ < 1.4 dB for 1.4 dB ≤ TECQ ≤ 3.2 dB	 –8.4 –9.8 + TECQ	 –15.1 –16.5 + TECQ		 dBm dBm
Stressed receiver sensitivity (OMA_{outer})[d] (max)	–6.6	–13.3		dBm
Conditions of stressed receiver sensitivity test:[e]				
Stressed eye closure for PAM4 (SECQ)	3.2			dB

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b] Average receive power (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity (OMA_{outer}) (max) is optional and is defined for a transmitter with a value of SECQ up to 3 dB for 50GBASE-BR10 and 3.2 dB for 50GBASE-BR20, and 50GBASE-BR40.
[d] Measured with conformance test signal at TP3 (see 160.7) for the BER specified in 160.1.1.
[e] These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

160.6.3 50GBASE-BRx illustrative link power budgets

Illustrative power budgets and penalties for 50GBASE-BRx channels are shown in Table 160–8.

Table 160–8—50GBASE-BRx illustrative link power budgets

Parameter	50GBASE-BR10	50GBASE-BR20	50GBASE-BR40	Unit
Power budget (for maximum TDECQ)	10.1	18.7	21.7	dB
Operating distance	10	20	40	km
Channel insertion loss	6.3[a]	15[b]	18[a]	dB
Maximum discrete reflectance	–26	–26	–26	dB
Allocation for penalties[c] (for maximum TDECQ)	3.8	3.7	3.7	dB

[a] The channel insertion loss is calculated using the maximum distance specified in Table 160–5 for 50GBASE-BR10 and 50GBASE-BR40 and fiber attenuation of 0.4 dB/km plus an allocation for connection and splice loss given in 160.10.2.1.
[b] The channel insertion loss is calculated using the maximum distance specified in Table 160–5 for 50GBASE-BR20 and fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 160.10.2.1.
[c] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

160.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

160.7.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 160–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 160–10 may be used to perform that test. The test patterns used in this clause are shown in Table 160–9.

Table 160–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle encoded by RS-FEC	82.2.11[a], 134
6	SSPRQ	120.5.11.2.3

[a]As modified by Clause 133.

Table 160–10—Test pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 50GBASE-R signal	160.7.2
Side-mode suppression ratio	3, 5, 6 or valid 50GBASE-R signal	160.7.2
Average optical power	3, 5, 6 or valid 50GBASE-R signal	160.7.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	160.7.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	160.7.5
Transmitter eye closure for PAM4 (TECQ)	6	160.7.6
Extinction ratio	4 or 6	160.7.7
Transmitter transition time	Square wave or 6	160.7.8
$RIN_x OMA$	Square wave	160.7.9
Receiver sensitivity	3 or 5	160.7.10
Stressed receiver conformance test signal calibration	6	160.7.11.2
Stressed receiver sensitivity	3 or 5	160.7.11

160.7.2 Wavelength and side-mode suppression ratio (SMSR)

The wavelength and SMSR shall be within the ranges given in Table 160–6 for 50GBASE-BRx, if measured per IEC 61280-1-3. The transmitter is modulated using the test pattern defined in Table 160–10.

160.7.3 Average optical power

The average optical power shall be within the limits given in Table 160–6 for 50GBASE-BRx if measured using the methods given in IEC 61280-1-1.

160.7.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} shall be within the limits given in Table 160–6 for 50GBASE-BRx. The OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 160–10 as the difference between the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 160–3.

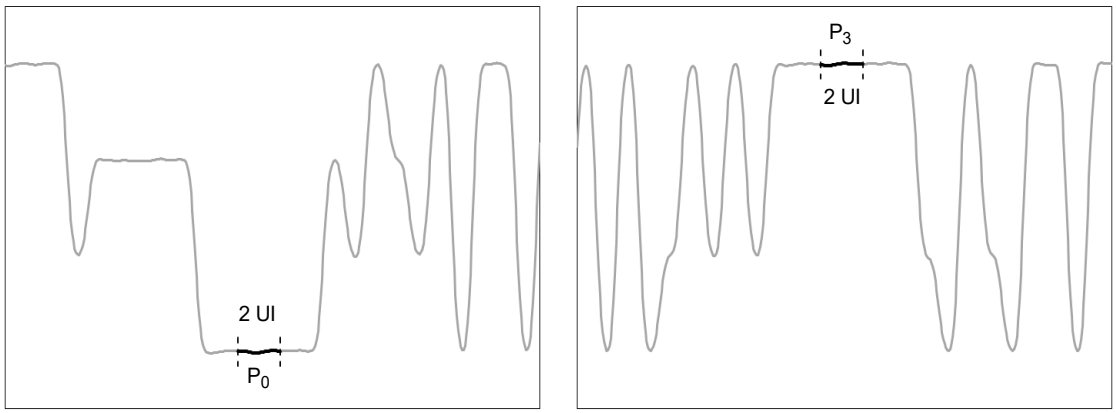

Figure 160–3—Example power levels P_0 and P_3 from PRBS13Q test pattern

160.7.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

The TDECQ shall be within the limits given in Table 160–6 for 50GBASE-BRx if measured using the methods specified in 160.7.5.1, 160.7.5.2, and 160.7.5.3.

TDECQ is a measure of each optical transmitter's vertical eye closure when transmitted through a worst case optical channel (specified in 160.7.5.2), as measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a reference receiver, and equalized with the reference equalizer (as described in 160.7.5.4). The reference receiver and equalizer may be implemented in software or may be part of the oscilloscope.

Table 160–10 specifies the test patterns to be used for measurement of TDECQ.

160.7.5.1 TDECQ conformance test setup

A block diagram for the TDECQ conformance test is shown in Figure 160–4. Other equivalent measurement implementations may be used with suitable calibration.

The optical splitter and variable reflector are adjusted so that each transmitter is tested with the optical return loss specified in Table 160–11. The state of polarization of the back reflection is adjusted to create the greatest RIN. The signal is tested with the optical channel described in 160.7.5.2. The combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5×26.5625 GHz and at frequencies above 1.5×26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The test pattern (specified in Table 160–10) is transmitted repetitively and the oscilloscope is set up to capture the complete pattern for TDECQ analysis as described in 160.7.5.3. The clock recovery unit (CRU) has a corner frequency of 4 MHz and a slope of 20 dB/decade. The CRU can be implemented in hardware or software depending on oscilloscope technology.

160.7.5.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 160–11.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

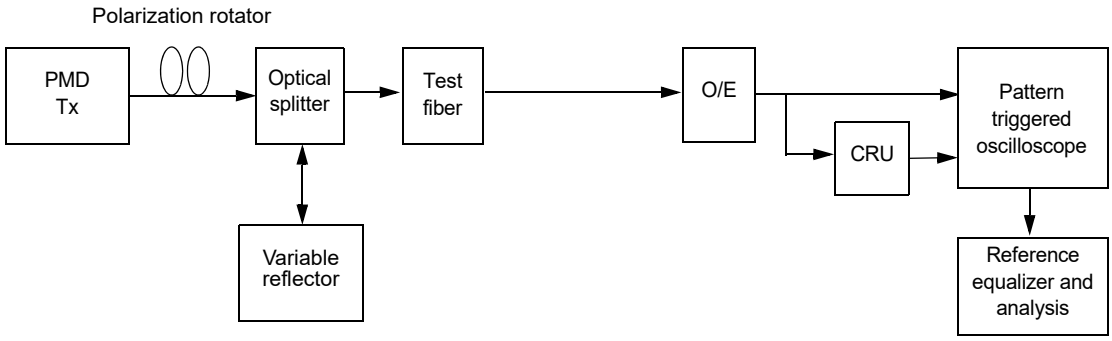

Figure 160–4—TDECQ conformance test block diagram

Table 160–11—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
50GBASE-BR10	$0.23 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.23 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	15.6 dB	0.8 ps
50GBASE-BR20	$0.46 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.46 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	15 dB	0.8 ps
50GBASE-BR40	$0.92 \times \lambda \times [1 - (1324 / \lambda)^4]$	$0.92 \times \lambda \times [1 - (1300 / \lambda)^4]$	Minimum	15 dB	0.8 ps

[a] The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes 10 km for 50GBASE-BR10, 20 km for 50GBASE-BR20, and 40 km for 50GBASE-BR40. The link may be as short as 2 m, and the minimum or maximum dispersion may be 0.
[b] There is no intent to stress the sensitivity of the O/E converter associated with the oscilloscope.
[c] The optical return loss is applied at TP2.

A 50GBASE-BRx transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 160–11 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 160–11. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 160–11.

160.7.5.3 TDECQ measurement method

TDECQ for 50GBASE-BRx is measured as described in 121.8.5.3 with the following exception:

— The reference equalizer is as specified in 160.7.5.4.

160.7.5.4 TDECQ reference equalizer

The reference equalizer for 50GBASE-BRx is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 160–5. The sum of the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3, has the largest magnitude tap coefficient, which is constrained to be at least 0.8.

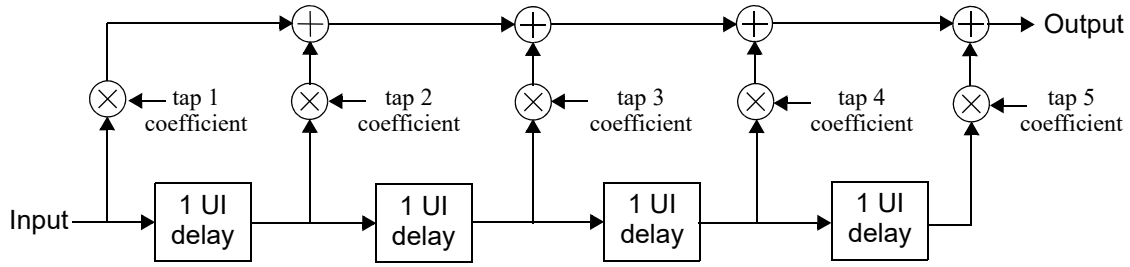

Figure 160–5—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver equalizer implementation.

160.7.6 Transmitter eye closure for PAM4 (TECQ)

The transmitter eye closure for PAM4 (TECQ) is a measure of the optical transmitter's eye closure at TP2. The TECQ of each lane shall be within the limits given in Table 160–6 for 50GBASE-BRx if measured using a test pattern specified for TECQ in Table 160–10. The TECQ of each lane is measured using the methods specified for TDECQ in 160.7.5, except that the test fiber is not used.

160.7.7 Extinction ratio

The extinction ratio shall be within the limits given in Table 160–6 for 50GBASE-BRx if measured using a test pattern specified for extinction ratio in Table 160–10. The extinction ratio of a PAM4 optical signal is defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 160–3.

160.7.8 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 160–6 if measured using a test pattern specified for transmitter transition time in Table 160–10.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with a combined 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz and at frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 160.7.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence and the falling edge is that within the 33333000000 symbol sequence.

160.7.9 Relative intensity noise (RIN_xOMA)

RIN_xOMA shall meet the requirements in Table 160–7 when measured using the method defined in 52.9.6

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

with the following exceptions:

a) The optical return loss *x* is 15.6 dB for 50GBASE-BR10, 15 dB for 50GBASE-BR20, and 15 dB for 50GBASE-BR40.
b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 26.6 GHz).
c) The test pattern is according to Table 160–10.

160.7.10 Receiver sensitivity

For 50GBASE-BR10, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (160–1), which is illustrated in Figure 160–6.

For 50GBASE-BR20 and 50GBASE-BR40, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (160–2), which is illustrated in Figure 160–6.

$$RS = \max(-8.4, SECQ - 9.8) \quad \text{(dBm)} \tag{160–1}$$

$$RS = \max(-15.1, SECQ - 16.5) \quad \text{(dBm)} \tag{160–2}$$

where

RS is the receiver sensitivity
SECQ is the SECQ of the transmitter used to measure the receiver sensitivity

The normative requirement for receivers is stressed receiver sensitivity.

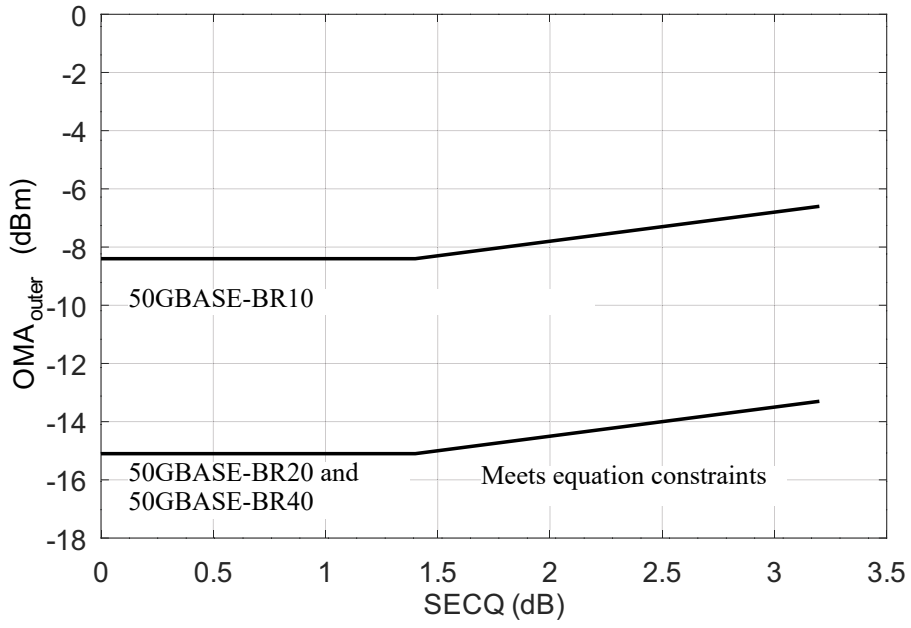

Figure 160–6—Illustration of receiver sensitivity

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

160.7.11 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 160–7 for 50GBASE-BRx if measured using the method defined in 160.7.11.1 and 160.7.11.3, with the conformance test signal at TP3 as described in 160.7.11.2, using the test pattern specified for SRS in Table 160–10.

Any of the patterns specified for SRS in Table 160–10 is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal. The reflectance of the optical link should be at its maximum level.

160.7.11.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 160–7. The patterns used for the received conformance signal are specified in Table 160–10. The optical test signal is conditioned (stressed) using the stressed receiver methodology defined in 160.7.11.2 and has sinusoidal jitter applied as specified in 121.8.10.4. A suitable test set is needed to characterize the signal used to test the receiver. Stressed receiver conformance test signal verification is described in 160.7.11.3.

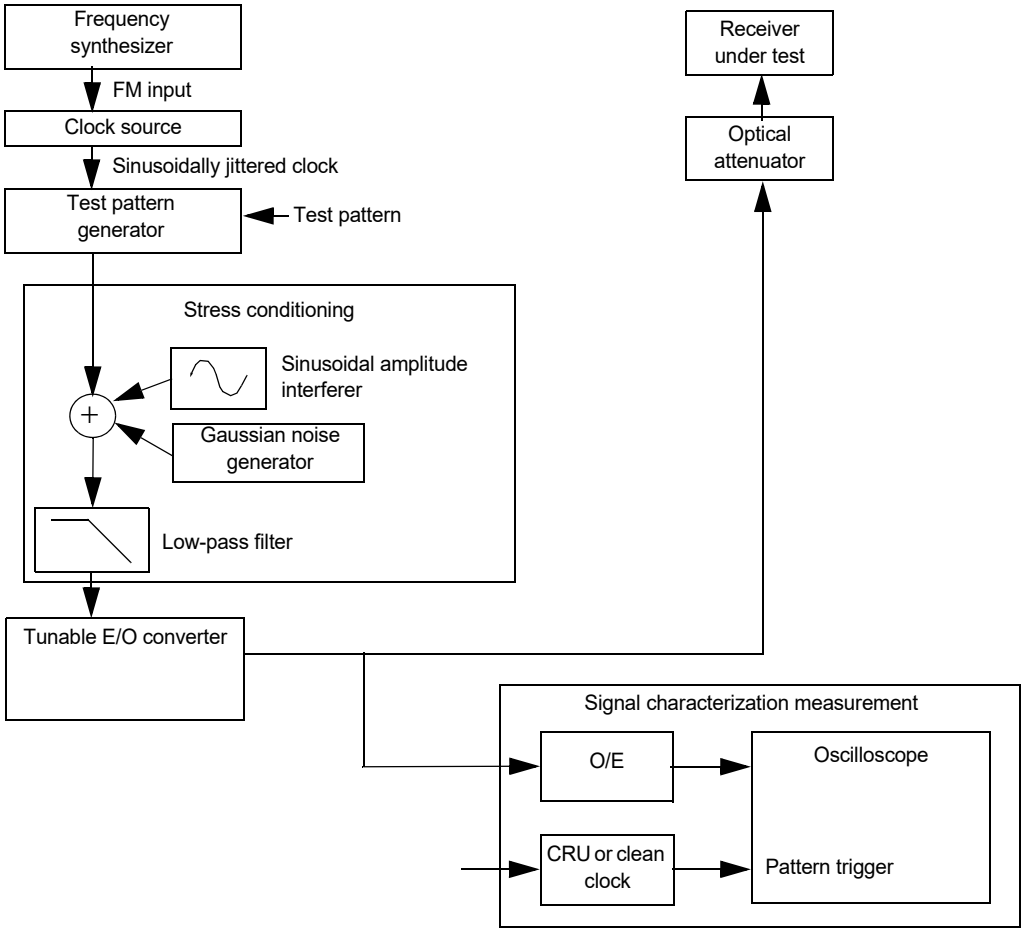

Figure 160–7—Stressed receiver conformance test block diagram

The low-pass filter is used to create ISI. The sinusoidal amplitude interferer causes additional eye closure, but in conjunction with the finite edge rates, also causes some jitter.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The sinusoidally jittered clock represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter. The sinusoidal amplitude interferer may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid harmonic relationships between the sinusoidal interferer, the sinusoidal jitter, the signaling rate, and the pattern repetition rate. The Gaussian noise generator, the amplitude of the sinusoidal interferer, and the low-pass filter are adjusted so that the SECQ specified in Table 160–7 is met, according to the methods specified in 160.7.11.2.

For improved visibility for calibration, all elements in the signal path (cables, DC blocks, E/O converter, etc.) should have wide and smooth frequency response, and linear phase response, throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be negligible.

160.7.11.2 Stressed receiver conformance test signal characteristics and calibration

The stressed receiver conformance test signal characteristics and calibration methods are as described in 121.8.10.2 with the following exceptions:

- The SECQ of the stressed receiver conformance test signal is measured according to 160.7.5, except that the test fiber is not used. The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 160–6.
- With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, $RIN_{15.6}OMA$, $RIN_{15}OMA$, and $RIN_{15}OMA$ of the SRS test source for 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40, respectively, should be no greater than the values specified in Table 160–6.
- An example stressed receiver conformance test setup is shown in Figure 160–7; however, alternative test setups that generate equivalent stress conditions may be used.
- The signaling rate of the test pattern generator and the extinction ratio of the E/O converter are as given in Table 160–6 for 50GBASE-BRx.
- The required values of the “Stressed receiver sensitivity (OMA_{outer}) (max)” and “Stressed eye closure for PAM4 (SECQ)” are as given in Table 160–7 for 50GBASE-BRx.

160.7.11.3 Stressed receiver conformance test signal verification

The SECQ of the stressed receiver conformance test signal is measured according to 160.7.5, except that the test fiber is not used. The clock output from the clock source in Figure 160–7 is modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye jitter that includes the sinusoidal jitter component, a separate clock source (clean clock of Figure 160–7) is required that is synchronized to the source clock, but not modulated with the jitter source.

Care should be taken when characterizing the test signal because excessive noise/jitter in the measurement system would result in an input signal that does not fully stress the receiver under test. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. The noise/jitter introduced by the O/E, filters, and oscilloscope should be negligible or the results should be corrected for its effects. While the details of test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands to ensure that the stressed receiver conformance input signal meets the stress and sinusoidal jitter specified in 160.7.11.2 and 121.8.10.4.

160.8 Safety, installation, environment, and labeling

160.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

160.8.2 Laser safety

50GBASE-BRx optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[259]

160.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

160.8.4 Environment

Normative specifications in this clause shall be met by a system integrating a 50GBASE-BRx PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause are met.

160.8.5 Electromagnetic emission

A system integrating a 50GBASE-BRx PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

160.8.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

160.8.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 50GBASE-BR10-D). Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 160.8.2.

[259] A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

160.9 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 160–8.

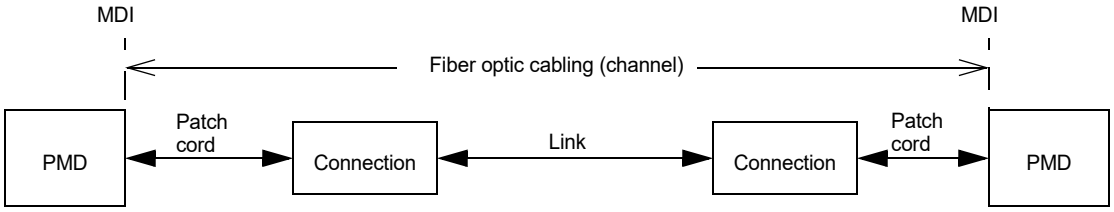

Figure 160–8—Fiber optic cabling model

The channel insertion loss is given in Table 160–12. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 160–12—Fiber optic cabling (channel) characteristics

Description	50GBASE-BR10	50GBASE-BR20	50GBASE-BR40	Unit
Operating distance (max)	10	20	40	km
Channel insertion loss[a, b] (max)	6.2	15	18	dB
Channel insertion loss (min)	0	0	10	dB
Positive dispersion[b] (max)	35	38.5	79	ps/nm
Negative dispersion[b] (min)	–64	–83	–166	ps/nm
DGD_max[c]	8	10.3	10.3	ps
Optical return loss (min)	21	21	21	dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1260 nm to 1340 nm for 50GBASE-BR10 and 1281 nm to 1322 nm for 50GBASE-BR20 and 50GBASE-BR40.
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

160.10 Characteristics of the fiber optic cabling (channel)

The 50GBASE-BRx fiber optic cabling shall meet the specifications defined in Table 160–12. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

160.10.1 Optical fiber cable

The optical fiber cable requirements are satisfied by cables containing ITU-T G.652.B (dispersion unshifted), type G.652.D (low water peak, dispersion unshifted), or type G.657.A1 or type G.657.A2 (bend insensitive) fibers or the requirements in Table 160–12 where they differ.

160.10.2 Optical fiber connection

An optical fiber connection, as shown in Figure 160–8, consists of a mated pair of optical connectors.

160.10.2.1 Connection insertion loss

Connections with different loss characteristics may be used provided the requirements of Table 160–12 are met. The maximum link distance for 50GBASE-BR10 and 50GBASE-BR40 is based on an allocation of 2 dB total connection and splice loss. The maximum link distance for 50GBASE-BR20 is based on an allocation of 5 dB total connection and splice loss.

160.10.2.2 Maximum discrete reflectance

The maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 160–13 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

Table 160–13—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance		
	50GBASE-BR10	50GBASE-BR20	50GBASE-BR40
1	–25 dB	–22 dB	–19 dB
2	–31 dB	–29 dB	–27 dB
4	–35 dB	–34 dB	–32 dB
6	–38 dB	–37 dB	–35 dB
8	–40 dB	–39 dB	–37 dB
10	–41 dB	–40 dB	–39 dB

160.10.3 Medium Dependent Interface (MDI) requirements

The 50GBASE-BRx PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” (as shown in Figure 160–8). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 160.5.1, not at the MDI.

160.11 Requirements for interoperation between 50GBASE-BRx PMDs

The 50GBASE-BR20 and 50GBASE-BR40 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 160–14 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 160–14—Channel insertion loss requirements for interoperation between 50GBASE-BR20 and 50GBASE-BR40

Direction	Min loss	Max loss	Unit
50GBASE-BR20 transmitter to 50GBASE-BR40 receiver	7	15	dB
50GBASE-BR40 transmitter to 50GBASE-BR20 receiver	3	18	dB

160.12 Protocol implementation conformance statement (PICS) proforma for Clause 160, Physical Medium Dependent (PMD) sublayer and medium, types 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40[260]

160.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 160, Physical Medium Dependent (PMD) sublayer and medium, types 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

160.12.2 Identification

160.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

160.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 160, Physical Medium Dependent (PMD) sublayer and medium, types 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40,
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

160.12.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
*BR10	50GBASE-BR10 PMD	160.6	Device supports requirements for 50GBASE-BR10 PHY	O.1	Yes [ ] No [ ]
*BR20	50GBASE-BR20 PMD	160.6	Device supports requirements for 50GBASE-BR20 PHY	O.1	Yes [ ] No [ ]
*BR40	50GBASE-BR40 PMD	160.6	Device supports requirements for 50GBASE-BR40 PHY	O.1	Yes [ ] No [ ]
*INS	Installation / cable	160.10	Items marked with INS include installation practices and cable specifications not applicable to a PHY manufacturer	O	Yes [ ] No [ ]
TP1	Reference point TP1 exposed and available for testing	160.5.1	This point may be made available for use by implementers to certify component conformance	O	Yes [ ] No [ ]
TP4	Reference point TP4 exposed and available for testing	160.5.1	This point may be made available for use by implementers to certify component conformance	O	Yes [ ] No [ ]
DC	Delay constraints	160.3	Device conforms to delay constraints	M	Yes [ ]
*MD	MDIO capability	160.4	Registers and interface supported	O	Yes [ ] No [ ]

160.12.4 PICS proforma tables for PMD sublayer and medium, types 50GBASE-BR10, 50GBASE-BR20, and 50GBASE-BR40

160.12.4.1 PMD functional specifications

Item	Feature	Subclause	Value/Comment	Status	Support
F1	Compatible with 50GBASE-R PCS, RS-FEC, and PMA	160.1		M	Yes [ ]
F2	Integration with management functions	160.1		O	Yes [ ] No [ ]
F3	Bit error ratio	160.1.1	Meets the BER specified in 160.1.1	M	Yes [ ]
F4	Transmit function	160.5.2	Conveys symbols from PMD service interface to MDI	M	Yes [ ]

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
F5	Mapping between optical signal and logical signal for transmitter	160.5.2	Optical power levels from lowest to highest correspond to tx_symbol values zero, one, two, and three, respectively	M	Yes [ ]
F6	Receive function	160.5.3	Conveys symbols from MDI to PMD service interface	M	Yes [ ]
F7	Conversion of optical signal to electrical signal	160.5.3	For delivery to the PMD service interface	M	Yes [ ]
F8	Mapping between optical signal and logical signal for receiver	160.5.3	Optical power levels from lowest to highest correspond to rx_symbol values zero, one, two, and three, respectively	M	Yes [ ]
F9	Global Signal Detect function	160.5.4	Report to the PMD service interface the message PMD:IS_SIGNAL.indication (SIGNAL_DETECT)	M	Yes [ ]
F10	Global Signal Detect behavior	160.5.4	SIGNAL_DETECT is a global indicator of the presence of an optical signal	M	Yes [ ]
F11	PMD reset function	160.5.5	Resets the PMD sublayer	MD:O	Yes [ ] No [ ] N/A [ ]
F12	ONU silent start	160.5.10	Meets the specifications defined in 160.5.10	M	Yes [ ]

160.12.4.2 Management functions

Item	Feature	Subclause	Value/Comment	Status	Support
M1	Management register set	160.4		MD:M	Yes [ ] N/A [ ]
M2	Global transmit disable function	160.5.6	Disables the optical transmitter with the PMD_global_transmit_disable variable	M	Yes [ ]
M3	PMD_fault function	160.5.7	Sets PMD_fault to one if a local fault is detected	MD:O	Yes [ ] No [ ] N/A [ ]
M4	PMD_transmit_fault function	160.5.8	Sets PMD_transmit_fault to one if a local fault is detected	MD:O	Yes [ ] No [ ] N/A [ ]
M5	PMD_receive_fault function	160.5.9	Sets PMD_receive_fault to one if a local fault is detected	MD:O	Yes [ ] No [ ] N/A [ ]

160.12.4.3 PMD to MDI optical specifications for 50GBASE-BR10

Item	Feature	Subclause	Value/Comment	Status	Support
BR101	Transmitter meets specifications in Table 160–6	160.6.1	Per the definitions in 160.7	BR10:M	Yes [ ] N/A [ ]
BR102	Receiver meets specifications in Table 160–7	160.6.2	Per the definitions in 160.7	BR10:M	Yes [ ] N/A [ ]

160.12.4.4 PMD to MDI optical specifications for 50GBASE-BR20

Item	Feature	Subclause	Value/Comment	Status	Support
BR201	Transmitter meets specifications in Table 160–6	160.6.1	Per the definitions in 160.7	BR20:M	Yes [ ] N/A [ ]
BR202	Receiver meets specifications in Table 160–7	160.6.2	Per the definitions in 160.7	BR20:M	Yes [ ] N/A [ ]

160.12.4.5 PMD to MDI optical specifications for 50GBASE-BR40

Item	Feature	Subclause	Value/Comment	Status	Support
BR401	Transmitter meets specifications in Table 160–6	160.6.1	Per the definitions in 160.7	BR40:M	Yes [ ] N/A [ ]
BR402	Receiver meets specifications in Table 160–7	160.6.2	Per the definitions in 160.7	BR40:M	Yes [ ] N/A [ ]

160.12.4.6 Optical measurement methods

Item	Feature	Subclause	Value/Comment	Status	Support
M1	General measurement	160.7	Meets the specifications defined in 160.7	M	Yes [ ]

160.12.4.7 Environmental specifications

Item	Feature	Subclause	Value/Comment	Status	Support
ES1	General safety	160.8.1	Conforms to the general safety requirements in J.2	M	Yes [ ]
ES2	Laser safety —IEC Hazard Level 1	160.8.2	Conforms to Hazard Level 1 laser requirements defined in IEC 60825-1 and IEC 60825-2	M	Yes [ ]
ES3	Electromagnetic interference	160.8.5	Complies with applicable local and national codes for the limitation of electromagnetic interference	M	Yes [ ]

160.12.4.8 Characteristics of the fiber optic cabling and MDI

Item	Feature	Subclause	Value/Comment	Status	Support
OC1	Fiber optic cabling	160.10	Meets the specifications defined in Table 160–12	INS: M	Yes [ ] N/A [ ]
OC2	Maximum discrete reflectance	160.12.2.2	Less than or equal to the value shown in Table 160–13	INS: M	Yes [ ] N/A [ ]
OC3	MDI requirements	160.6.3	Meets IEC 61753-1-1 and IEC 61753-021-2	INS: M	Yes [ ] N/A [ ]

Annex B

(informative)

System guidelines

B.1 Baseband system guidelines and concepts, 10 Mb/s

B.1.1 Overall system objectives

The CSMA/CD Access Method, supported by baseband technology, depends on a variety of analog system components at and below the physical level of the OSI Reference Model. These components provide basic interconnection facilities for the CSMA/CD access mechanism itself and are defined throughout Clause 6, Clause 7, and Clause 8.

Overall performance of the analog baseband medium and related Physical Layer capabilities depends on an optimal and known set of analog capabilities within each of these critical system elements: the coaxial trunk cable, MAUs, branch cables, DTEs, and repeater units. These system elements affect the integrity with which the serial data bit stream analog signals are carried between open systems. There are at least three critical parameters of interest: bits lost in the transmission system, signal delays, and phase jitter. It is important that these be apportioned properly among the affected system elements.

The successful interconnection of multivendor system components mandates that the values for bits lost, signal delays, and phase jitter be allocated fairly and realistically among the various system elements. The balance of Annex B identifies the upper limits of values to be placed on the subject parameters. These values are based on the maximal system configuration (for example, four repeater units, 2.5 km trunk coaxial cable medium).

B.1.2 Analog system components and parameter values

The values given in the following table are in terms of bits and are stated as maximum values except for values given within ranges.

The initial mnemonic under each component entry refers to the system component as identified in Figure B–1. System parameters are stated in terms of the intralayer or interlayer messages sent within a station. Specific delays are called out as = delay.

The repeater concepts described throughout this annex are considered to be an acceptable set of specifications for a multirepeatered system. It is noted that the exact parametric values specified for the repeater environment are subject to minor refinement.

B.1.3 Minimum frame length determination

The following table indicates the system elements that make up the minimum frame length calculation based on the worst-case numbers as outlined in the bit budget of B.1.2. The compilation in the following table is based on the following scenario:

a) DTE 1 transmits to an adjacent DTE 2 on coaxial segment 1.
b) DTE 3 transmission collides with DTE 1 transmission.
c) DTE 3 is assumed to be the worst-case distance from DTE 1 and its transmission just misses deferring to the DTE 1 message.
d) The collision fragment travels back down the network to inform DTE 1 that a collision has occurred on its message.

Component and function	Direction	Table entry	Delay	Total delay
DTE 1 STARTS TO PUT OUT FIRST BIT				0.0
DTE 1	FWD	D2	3.0	3.0

The frame length is constrained by two parameters:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— The message from DTE 1 shall be long enough so that it is still sending when the collision is detected.
— The message from DTE 1 shall be short enough such that DTE 2 can throw out the message on the basis of being too short.

The above table provides the scenario that enables DTE 1 to determine a collision is taking place. DTE 1 shall transmit for at least 499 bit times. To determine how much longer DTE 2 will continue to receive bits, assume that DTE 1 is the last transmitter to provide bits to the DTE 2 MAU. DTE 2 then sees the following:

Component and function	Direction	Table entry	Delay	Total delay
DTE 1	FWD	D11	16.0	514.9
DTE 1	FWD	D12	32.0	547.9
AUI M1	FWD	A1	2.57	549.4

If Repeater Set 1 is the last system component to provide bits to DTE 2, then DTE 2 will see the following:

Component and function	Direction	Table entry	Delay	Total delay
REPEATER SET 1 (1st JAM BIT)				454.6
REP 1	REV	R5	96.0	550.6
COAX 1	REV	C1	21.65	572.3

The Repeater Set is the last transmitter to provide a bit to DTE 2. The DTE 2 MAU starts seeing bits at time 8.6, which means that DTE 2 sees 563.7 bits (572.3 – 8.6). DTE 2 sees a minimum of 61 preamble bits and 8 SFD bits. The preamble and SFD bits can be deleted from the 563.7 total because they are not counted in minimum frame length.

The minimum frame length determination from the above scenario is then 564.7 – 69.0 = 494.7 bits. The 10 Mb/s system value for minimum frame length has been set at 512 bits.

B.1.4 System jitter budgets

The typical jitter budget expected for the baseband system is apportioned in the following manner:

Encoder	0.5 ns
AUI Cable	1.0 ns (transmit end)
MAU Transmit	2.0 ns
Trunk Coax	7.0 ns
MAU Receive	–1.0 ns (with compensation)
AUI Cable	1.0 ns (receive end)
SNR on COAX	5.0 ns (SNR = 5:1)
SNR on AUI	0.5 ns (SNR = 5:1, transmit end)
SNR on AUI	0.5 ns (SNR = 5:1, receive end)
	16.5 ns

The 18 ns jitter budget leaves adequate design margin for implementation-dependent considerations.

B.1.4.1 Nominal jitter values

The jitter budget values given above are not expected to accommodate all step changes in phase jitter due to system parameter variations within one or a few bit times.

B.1.4.2 Decoder evaluation

The phase decoder in the PLS sublayer should correctly decode a Manchester-encoded signal whose data transition point (center of a bit cell) has a peak-to-peak jitter of no more than 36 ns (± 18 ns deviation from the bit cell center). Figure B–2 and Figure B–3 show the test method.

Evaluation of decoder performance may be simulated and tested by application of three distinct waveforms representing worst-case and normal conditions. The waveforms contain Manchester-encoded bits whose center transitions represent the extremes of maximum skew. A 5 MHz (repetition rate) pulse train whose pulse width is either 64 ns or 136 ns simulates the two worst-case jitter conditions. The data output from the decoder should remain stable for each of the three test patterns and shifts between these extremes where there is a low rate of change in center transition skew. Note that the actual transmission system is not expected to permit sudden drastic changes in the steady-state edge deviation during the reception of any given frame. The above evaluation process is not intended to guarantee proper decoder performance under all operating conditions.

B.1.5 Systems consideration calculations

B.1.5.1 Overview

Subclause B.1.3 contains a calculation of maximum fragment size for a network of 10BASE5 and IRL segments. That calculation was based on the maximum delay for a transmission to reach the far end of the network and for a collision to propagate back. Since that calculation was written, many new media and MAU types have been added to this standard. Also, the calculation of B.1.3 did not address the interpacket gap shrinkage, which can limit the network size. It is not practical to perform a separate calculation for each possible combination of segment types.

Some new segment types also support much longer media (up to 2 km). Introduction of longer media also required a more flexible calculation method that allowed trading segment length for repeaters. The method in this section was developed to meet these needs.

Actual numbers used to calculate delay and variability are tabulated (Table B–1) at the end of this subclause.

B.1.5.2 Maximum collision fragment size

The round-trip delay has to be calculated to determine that collision will be received within the collision window of transmitting DTEs and that collision fragments will be less than the minimum frame size. The following scenario is used for the calculations (see Figure B–4):

a) DTE1 transmits.
b) DTE1's transmission propagates to DTE2.
c) DTE2 begins transmitting at the last possible time, colliding and transmitting 96 bits.
d) DTE2's transmission propagates to DTE1.
e) DTE1 detects collision, jams, and stops transmitting.

The following conditions have to be met for proper network operation:

— DTE1 has to detect collision before having transmitted the 512th bit (including preamble and SFD bits).
— DTE1 has to stop transmitting before having transmitted a minimum length frame, 576 bits (512 bits after SFD).
— The overlap between DTE1's transmission and DTE2's transmission has to be less than 575 bits (511 bits after the SFD transmitted by DTE1).

For all existing segment types, the last condition is the limiting factor; if it is met then the other two conditions are also met.

The maximum time between the first bit and the last bit of the overlapping transmissions of the two DTEs colliding across a path will be called the Path Delay Value (PDV). Many factors contribute to this delay. Simplification of the delay calculation, as compared to the method used in B.1.3, can be achieved by using a set of base numbers, Segment Delay Values (SDV), for each segment type that combines the factors that contribute to the round-trip delay associated with that segment. The PDV is the sum of SDVs of the segments that comprise the path.

For each segment type, one of three base SDVs is used depending on the position of the segment: left-end, mid-, or right-end. The left-end segment is connected to the DTE that transmits first (DTE1). The right-end segment is connected to the colliding DTE (DTE2). All segments between these are mid-segments.

For this calculation, the left-end base SDV contains all delays from DTE1 through the MAU and its AUI connected to the repeater unit. Each mid-base SDV includes the delays from the repeater unit on the left

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

through the MAU and its AUI connected to the right repeater unit. The right-end base SDV includes the delays from the repeater unit immediately to its left through DTE2. (See Figure B–4.)

Only the bit loss of DTE1's MAU on the left-end segment contributes to fragment size. The steady-state delay of that MAU and the AUI cable delay do not contribute. For the remainder of the network, startup delay (the sum of steady-state delay and bit loss) contribute. Therefore, the left-end base SDV uses MAU transmit bit loss and 1 AUI delay. In all other cases, startup delay and 2 AUI delays are used.

Propagation delays for media are not included in the base SDVs. These are added in separately to allow for various segment lengths (see 13.4.1). The base SDVs for the mid- and right-end segments (except 10BASE-FB) include two 2 m AUI cables and the delay of each one is experienced twice, once in the forward path and once in the reverse path. Therefore, a delay of 0.5 BT per segment is added and corresponds to the round-trip delay through two 2 m AUI cables. The base numbers for the left segment include one 2 m AUI cable, 0.25 BT.

For each segment type, both the delay to transmission of the 96th bit after collision rise and delay to transmission of the last bit due to collision fall are calculated. The base SDV is the larger of these two.

The maximum allowed sum of SDVs plus media propagation delays is 575 BT.

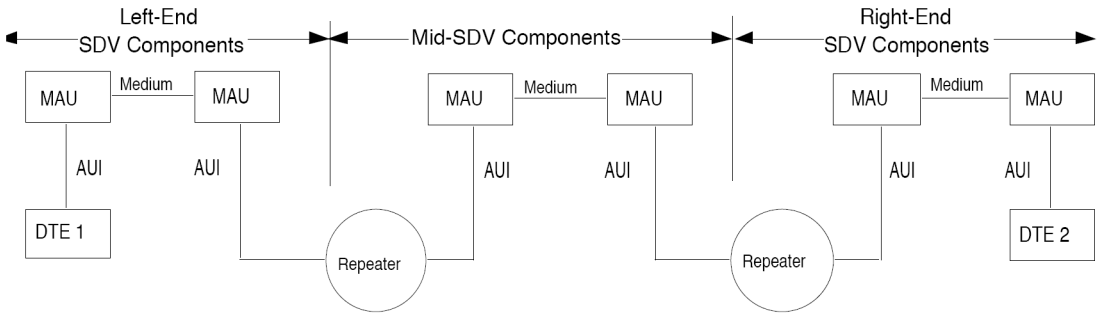

Figure B–4—Round-trip delay calculation model

B.1.5.2.1 Left-end base SDV

The Left-End Segment collision delay is the sum of the following:

Forward delay:
- AUI
- MAU transmit bit-loss delay
- Media rise time
- MAU receive startup delay

Reverse delay:
- MAU transmit fall delay after collision
- MAU receive fall delay after collision

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

B.1.5.2.2 Mid-base SDV

The Mid-Segment collision rise delay is the sum of the following:

Forward delay:
- AUI × 2
- Repeater start-of-packet propagation delay
- MAU transmit startup delay
- Media rise time
- MAU receive startup delay

Reverse delay:
- MAU transmit startup delay
- MAU collision detect delay
- Repeater start-of-collision propagation delay

The Mid-Segment collision fall delay is the sum of the following:

Forward delay:
- AUI × 2
- Repeater start-of-packet propagation delay
- MAU transmit startup delay
- Media rise time
- MAU receive startup delay

Reverse delay:
- MAU transmit fall delay
- MAU collision fall delay
- Repeater cessation-of-jam propagation delay

B.1.5.2.3 Right-end base SDV

The Right-End Segment collision rise delay is the sum of the following:

Forward delay:
- AUI × 2
- Repeater start-of-packet propagation delay
- MAU transmit startup delay
- Media rise time
- MAU receive startup delay
- DTE receive-to-transmit-not-deferred delay

Reverse delay:
- MAU transmit startup delay
- MAU collision detect delay
- Repeater start-of-collision propagation delay
- Repeater minimum transmit length

The Right-End Segment collision fall delay is the sum of the following:

Forward delay:
- AUI × 2
- Repeater start-of-packet propagation delay
- MAU transmit startup delay

Copyright © 2022 IEEE. All rights reserved.

Media rise time
MAU receive startup delay
DTE receive-to-transmit-not-deferred delay
DTE minimum transmit length

Reverse delay:
MAU transmit fall delay
MAU collision fall delay
Repeater cessation-of-jam propagation delay

B.1.5.3 Interpacket Gap (IPG) shrinkage

IPG shrinkage occurs because two successive packets may experience differing bit loss on the same path. When the packet passes through a repeater, the lost preamble bits are regenerated. If the first packet experiences greater bit loss than the second, the IPG between them will shrink.

IPG shrinkage is also calculated using a lumped number for each segment, the Segment Variability Value (SVV). For each segment type, one of two SVVs is used depending on the position of the segment: transmitting end or mid. The transmitting end segment is connected to the transmitting DTE or DTEs. The mid-segments are all the remaining segments except the one connected to the receiving DTE.

The transmitting end segment and the mid-segment SVVs each include the variability from the transmitting MAU through the repeater unit. Since, IPG shrinkage only occurs when a repeater restores the lost bits, the final segment does not contribute any variability (see Figure B–5).

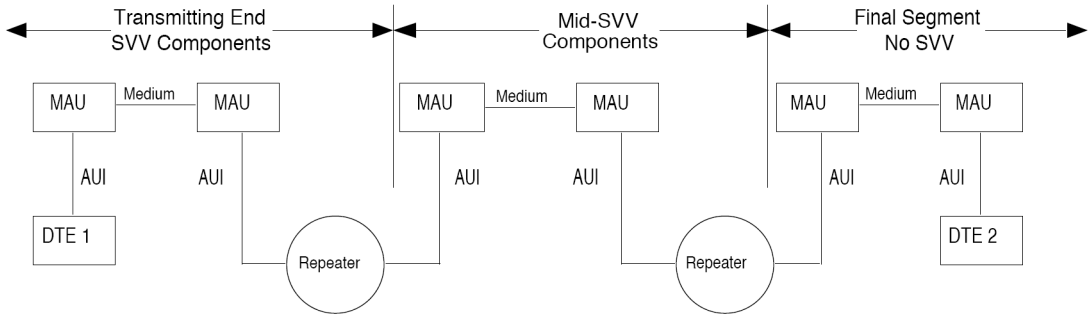

Figure B–5—Variability calculation model

B.1.5.3.1 Transmitting end segment variability value

The transmitting end segment variability value is the sum of the following:
MAU transmit startup-delay variability
MAU transmit startup-delay variability correction
MAU receive startup-delay variability
MAU receive startup-delay variability correction
Repeater start-of-packet propagation delay variability
Clock skew (2.5 BT)

NOTE—The variability correction values account for the possibility that on mixing segments the two successive packets can be originated by two different MAUs.

B.1.5.3.2 Mid-segment variability value

The mid-segment variability value is the sum of the following:

MAU transmit startup-delay variability
MAU receive startup-delay variability
Repeater start-of-packet propagation delay variability

B.1.5.4 Timing parameters for round-trip delay and variability calculations

Table B–1 contains the timing parameters used in the calculation of SDVs and SVVs. The values in the table for MAU Collision Rise and MAU Collision Fall are those specific to the worst-case scenario. The parameters are defined in the following subclauses.

B.1.5.4.1 MAU parameters

Transmit Bit Loss: Number of bits received on the DO circuit and not transmitted to the MDI.

Transmit Startup Delay: Delay from the first bit received on the DO circuit to the first bit transmitted to the MDI. This is the sum of transmit bit loss and steady-state delay.

Receive Startup Delay: Delay from the first bit received on the MDI to the first bit transmitted to the DI circuit. This is the sum of receive bit loss and steady-state delay.

Collision Detect Delay: Delay from the arrival of collision at the MDI to transmission of signal_quality_error to the CI circuit. For 10BASE2 and 10BASE5, this includes the DC rise time on the media, given that the MAU has been transmitting for at least 20 BT when the collision arrives. For 10BASE-FP, this includes the delay until the second CRV occurs on the media (16.3.4.3).

Transmit Fall Delay: Delay from the last bit received on the DO circuit to the last bit transmitted to the MDI. This is the same as the steady-state delay.

Collision Fall Delay: Delay from arrival of end of collision at the MDI to end of transmission of signal_quality_error to the CI circuit. For 10BASE2 and 10BASE5, it includes the DC fall time of the media. For 10BASE-FP it includes the delay of 33 BT to pass with no more than one ORD_crv.

Transmit Startup Delay Variability: Packet-to-packet variations in transmit startup delay.

Transmit Startup Delay Variability Correction: Additional variability, when the transmitting end segment is a mixing segment, due to two MAUs transmitting with different startup delays. For 10BASE5 and 10BASE2, startup delay variability plus transmit startup delay variability correction equal transmit startup delay since these MAUs may transmit with as little as 0 BT delay. For 10BASE-FP MAUs, implementation considerations imposed by the requirements of 16.3.1.1 require the MAU to have at least 2 BT startup delay. Therefore, the transmit startup delay variability correction equals the transmit startup delay minus 2 BT.

Receive Startup Delay Variability: Packet-to-packet variability in receive startup delay.

Transmit Fall Delay After Collision: Delay from the last bit received on the DO circuit to the last bit transmitted to the MDI after the MAU has detected a collision. For all MAUs except 10BASE-FB, this is the same as transmit fall delay.

Receive Fall Delay After Collision: Delay from the last bit received on the MDI to the last bit transmitted to DI. For all MAUs except 10BASE-FB and 10BASE-FP, this is the same as receive steady-state delay.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

B.1.5.4.2 Repeater parameters

Start-of-Packet Propagation Delay: Delay from first bit received on DI to first bit transmitted on DO.

Start-of-Collision Propagation Delay: Delay from start of signal_quality_error on CI to first bit transmitted on DO.

Cessation-of-Jam Propagation Delay: Delay from end of signal_quality_error on CI to last bit transmitted on DO.

Minimum Transmit Length: Minimum delay from first bit transmitted on DO to last bit transmitted on DO.

Start-of-Packet Propagation Delay Variability: Packet-to-packet variation in start-of-packet propagation delay.

B.1.5.4.3 Media parameters

Media Rise Time: Start-of-packet DC rise time on 10BASE2 and 10BASE5 segments.

B.1.5.4.4 DTE parameters

Receive-to-Transmit-Not-Deferred Delay: Delay from first bit on DI to first bit on DO when the DTE does not detect carrier in time to defer.

Minimum Transmit Length: Minimum delay from first bit transmitted on DO to last bit transmitted on DO.

B.2 System parameters and budgets for 1BASE5

B.2.1 Delay budget

The successful interconnection of multivendor system components mandates that the values for bits lost and signal delays be allocated fairly and realistically among the various system elements. The following table summarizes and indicates the derivation of some of the delays specified in 12.9. The breakdowns shown for the parameters are illustrative only; implementers are free to make other allocations of delay *within* a device so long as the specifications of 12.9 are not violated.

Component	Delay (BT)
DTE Initial Transmit Delay (see 12.9.2)	**3**
DTE Deference Delay (see 12.9.2)	**21**
unsquelch	3
Carrier detect	5
MAC detects carrier and defers	10
DTE Initial Transmit Delay	3
DTE Collision Shutdown Delay (see 12.9.2)	**58**
detect CP and report SIGNAL_ERROR	10
detect SIGNAL_ERROR and start jamming	16
jamSize	32
Medium Transit Delay (see 12.9.3)	**4**
Special Link Transit Delay (see 12.9.4)	**15**
Hub Startup Delay (see 12.9.5)	**12**
unsquelch	4
half fill FIFO	6
analogue of DTE Initial Transmit Delay	3
Hub Idle Collision Startup Delay (see 12.9.5) (same as Hub Startup Delay)	**12**
Hub Transit Delay (see 12.9.5)	**9**
half fill FIFO	6
analogue of DTE Initial Transmit Delay	3
Hub Delay Stretch/Shrink (see 12.9.5) ((preamble + <sfd> + maxFrameSize) · 0.01% · 2)	**3**
Hub Collision Detect Delay (see 12.9.5)	**21**
unsquelch	3
detect collision	6
Hub Transit Delay	9
First CVL or CVH may be preceded by CD0s and CD1s	3
Hub Active Collision Startup Delay (see 12.9.5)	**12**
Hub Transit Delay	9
First CVL or CVH may be preceded by CD0s and CD1s	3
Hub Collision Shutdown Delay (downward) (see 12.9.5) (same as Hub Transit Delay)	**9**
Hub Collision Shutdown Delay (upward) (see 12.9.5)	**25**
detect loss of carrier	20
clear FIFO, if necessary	2
analogue of DTE Initial Transmit Delay	3

B.2.2 Minimum frame length determination

The minimum frame length for 1BASE5 is determined using the values specified in 4.4.2 and 12.9, applied to the following (worst) case:

a) DTE 1, connected to Hub 1 at a network extremity, transmits a message upward toward Hub 5.
b) There is a special link in the path between Hub 1 and Hub 5.
c) DTE 2, also connected to Hub 1, transmits, just missing deferring to the downward signal from DTE 1 that was wrapped around at Hub 5.
d) DTE 3, also connected to Hub 1, receives the transmission from DTE 1.
e) Hub 1 generates CP, which travels up and then back down the network to inform DTE 1 and DTE 2 that a collision has occurred on their messages.
f) DTE 1 and DTE 2 continue to transmit until they have received CP, reacted to it, and completed their jams.
g) DTE 3 continues to receive until the end of CP.

The minimum frame length has to allow both of the following conditions to be met:

— DTE 1 is still sending when CP is received and recognized.
— DTE 3 can discard the message fragment it receives because it is too short.

Event	Bits	Total
DTE 1 → DTE 2		
DTE Initial Transmit Delay	3	3
8 · Medium Transit Delay	32	35
2 · Special Link Transit Delay	30	65
10 · Hub Startup Delay	120	185
DTE Deference Delay	21	206
DTE 2 → HUB 1 CP		
Medium Transit Delay	4	210
Hub Collision Detect Delay	21	231
HUB 1 CP → HUB 5 CP		
3 · Medium Transit Delay	12	243
Special Link Transit Delay	15	358
4 · max(Hub Startup Delay, Hub Active Collision Startup Delay, Hub Idle Collision Startup Delay)	48	306
HUB 5 CP → DTE 1 receives CP		
5 · Hub Active Collision Startup Delay	60	366
4 · Medium Transit Delay	16	382
Special Link Transit Delay	15	397
DTE 1 receives CP → DTE 1 stops transmitting DTE Collision Shutdown Delay	58	455
COMPUTATION OF MINIMUM FRAME SIZE	–64	391 = data bits transmitted
original preamble + <sfd>		
5 · (Hub Collision Shutdown Delay (upward) – Hub Transit Delay)	80	471
5 · (Hub Collision Shutdown Delay (downward) – Hub Transit Delay)	0	471
Tiny fraction of Hub Delay Stretch/Shrink	0	471 = data bits received

The minimum frame length has to exceed both the maximum number of bits sent before recognizing CP (391 – jamsize = 359) and the maximum collision fragment size (471), as computed above. The 1BASE5

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

system value for minimum frame length has been set at 512 bits, which exceeds both of these values with a margin for error.

B.2.3 Jitter budget

The total edge jitter of the signals on each link has to be limited to allow proper decoding at the receiver. The following budget has been used to allocate jitter to the indicated components that contribute to the total jitter on each link:

Component	Jitter (ns)
Transmitter skew	±10
Cable intersymbol interference	9
Cable reflections	8
Reflections due to receiver termination mismatch	5
Total	±32

The cable intersymbol interference and reflection allowances form the basis for the limit specified in 12.7.2.3; the reflection component is sufficient to allow a single 20 Ω impedance mismatch anywhere along a cable segment. The receiver-mismatch allowance is derived from the reflection attenuation specified in 12.5.3.2.4. The total forms the basis for the specification in 12.5.3.2.2.

The remainder of the jitter that can be tolerated by the Manchester decoder in a receiver is allocated to allow for distortion of the signal due to noise, receiver threshold offset, receiver skew, and receiver sampling timing error.

A simple clocked receiver/decoder with an 8 MHz sampling rate (the worst case allowed for in the design of this standard), can achieve proper decoding with up to ± 125 ns of jitter between two edges, which is equivalent to ±62.5 ns on each edge. Other receiver designs may tolerate more edge jitter. For example, a 6 MHz sampling rate would allow up to ±83.33 ns of jitter on each edge and a 16 MHz sampling rate allows up to ±93.75 ns of jitter.

It may be necessary to use a low-pass filter as part of the receiver to reduce the noise level seen by that receiver (see 12.7.4 for a description of the noise environment). A filter that reduces the noise may also have an effect on the amplitude and edge rate of the received signal. The filtered signal's edge rate near the zero-crossing is used in the critical translation from mV of noise and receiver offset into ns of jitter.

An example receiver design using an 8 MHz sampling rate and a 2 MHz Butterworth input filter might be based on the following jitter budget:

Component	Jitter (ns)
Input jitter (from above)	±32
Noise and receiver threshold offset	19.5
Receiver skew (analog)	4
Receiver skew (digital)	7
Total	±62.5

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The two primary contributors to noise in a 1BASE5 cable are self-crosstalk and impulse noise (see 12.7.4). Because it is unlikely that both will be present at their 1% worst-case levels on any particular cable, the required bit error ratio attributable to each source can be set at half of the one in 10^8 error ratio required by 12.5.3.2.6.

Crosstalk noise is specified to be no more than 105 mV (peak) through a 2 MHz filter (see 12.7.4.2). Because crosstalk is present for the entire transmission of a packet, some crosstalk will coincide with the most sensitive part of the received signal. Therefore, the receiver has to operate without error in the presence of this 105 mV of noise.

Impulse noise has a peak amplitude of 170 mV for ≤ 0.005 counts/s through the 2 MHz filter (see 12.7.4.1). This threshold does not directly correlate to jitter, however, because the derivation of the 62.5 ns jitter tolerance for an 8 MHz clock assumed worst-case sampling error. Assuming a random phasing of the sampling clock to the received signals, it can be shown that the 170 mV of noise is equivalent to a level of 85 mV with a worst-phase clock.

Jitter due to noise should be computed using the larger of the above two levels. The 105 mV for crosstalk noise, therefore, should be added to 50 mV for receiver threshold offset and the result should be divided by the edge rate of the filtered signal near the zero-crossing (7.9 mV/ns for the 2 MHz filter), yielding the 19.5 ns indicated above.

B.3 Example crosstalk computation for multiple disturbers, balanced-pair cable

A method for computing multiple-disturber, near end, crosstalk attenuation (MDNEXT) into each 1BASE5 pair is specified in 12.7.3.2. This annex provides example computations of MDNEXT using that method when only the distribution of X_{ij} is known.

The single-disturber probability distribution curve (labelled “1”) shown in Figure B–6 is based on actual measurement of 25-pair, 24-gauge, unshielded, twisted pair cable. The remaining probability distribution curves (labeled with the number of disturbing pairs) were computed using Monte Carlo simulation. To compute each sample $MDNEXT_j$ for N disturbers, N values of crosstalk attenuation (X_i) were chosen from the single-disturber distribution and N values of crosstalk phase (θ_i) were chosen from a uniform distribution between 0 and 2π rad. These values were then used with the following equations to compute $MDNEXT_j$:

$$H_j = \sum_{1 \le i \le N} 10^{(-X_i/20)} \cos\theta_i$$

$$V_j = \sum_{1 \le i \le N} 10^{(-X_i/20)} \sin\theta_i$$

$$MDNEXT_j = 10\log_{10}(H_j^2 + V_j^2)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Iterating this process several hundred times, each time producing a single $MDNEXT_j$ sample, resulted in distributions for MDNEXT that are summarized in the following table and Figure B–6:

Disturbers	Iterations	MDNEXT: Mean (dB)	Std. Dev. (dB)	99% (dB)
1		61.2	7.0	48.6
2	500	57.2	6.2	46.4
3	500	55.1	5.8	45.2
6	500	52.0	5.7	42.5
13	1000	48.5	5.4	39.1
18	500	47.1	5.3	37.8
24	500	45.9	5.9	36.2

Because two pairs are used for each 1BASE5 connection, the entries in this table for 18 and 24 disturbers are not applicable for normal installation of 25-pair cables. Furthermore, telephone cables with larger numbers of pairs are often constructed using sub-bundles of 25 pairs each and so might yield similar results (for example, the curves for 13 or fewer disturbers would be the most applicable ones).

The calculation method of this annex, though not the numeric values, applies to 10BASE-T.

B.4 10BASE-T guidelines

B.4.1 System jitter budget

The jitter budget for 10BASE-T is apportioned as follows:

Jitter budget	Maximum-length twisted-pair link	Short-length twisted-pair link
	(jitter expressed in ±ns)	
Encoder	0.5	0.5
AUI cable including SNR (DO pair)	1.5	1.5
MAU transmitter	2.0	2.0
Twisted-pair medium with equalization	1.5	6.0
Noise jitter on twisted-pair medium	8.0	2.5
MAU receiver	1.5	1.5
AUI cable including SNR (DI pair)	1.5	1.5
Total	16.5	15.5

NOTE—Total transmit jitter for the combination of the MAU transmitter and link segment (14.3.1.2.3) is ±3.5 ns and ±8.0 ns for maximum- and short-length twisted-pair link segments, respectively. It is the sum of the entries for MAU transmitter and twisted-pair medium with equalization. The individual components cannot be easily observed on MAUs. Short-length segment is defined as a short, non-zero-length twisted-pair link. A short- rather than a zero-length segment is used in the calculation since a zero-length segment will have no significant noise and is a less severe case.

B.4.2 Filter characteristics

The implementation of the 3-pole, low-pass Butterworth filter should have the following characteristics:

3 dB cutoff frequency	15 MHz
Insertion loss (5 MHz to 10 MHz)	≤ 1.0 dB
30 MHz attenuation	≥17.5 dB
Input impedance (5 MHz to 10 MHz)	100 Ω
Return loss with 100 Ω load (5 MHz to 10 MHz)	≥20 dB

This filter is only used for the tests described in 14.3.1.3.2, 14.4.4.1, and 14.4.4.2. A buffer may be needed to achieve the above return loss when using an LC implementation of this filter.

B.4.3 Notes for conformance testing

The following notes are provided to assist in developing the conformance test.

B.4.3.1 Notes for 14.3.1.2.1 on differential output voltage

For testing harmonics measured on the TD circuit when the DO circuit is driven by an all-ones Manchester-encoded signal, it is acceptable to use a pattern of maximum length packets whose data field is all ones.

For testing of the maximum and minimum output signal to the template in Figure 14–10, the recommended measurement procedure is described as follows. An oscilloscope set for a zero voltage trigger with a positive slope is allowed to accumulate an eye pattern that has to be within the template. Acquisition has to be long

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

enough to ensure that all data variations have been observed. When using packetized data, the TP_IDL and the first transmitted bit should be excluded from this measurement. Also, the interpacket interval may be adjusted so that transition-to-idle transient effects are excluded. When testing with the inverted template, the slope of the scope trigger should be negative.

B.4.3.2 Note for 14.3.1.2.2 on transmitter differential output impedance

The return loss (*RL*) is defined as follows:

$$RL = 20\log_{10}\frac{|Z_{\text{transmitter}} + Z_{\text{cable}}|}{|Z_{\text{transmitter}} - Z_{\text{cable}}|}$$

and also

$$RL = 20\log_{10}\frac{|V_{\text{i}}|}{|V_{\text{r}}|}$$

where

$Z_{\text{transmitter}}$ is the impedance of the transmitter
Z_{cable} is the impedance of the cable
V_{i} is the differential voltage incident upon the transmitter
V_{r} is the differential voltage reflected from the transmitter

a) A transmitter with a purely resistive source impedance of 96 Ω ± 20% will satisfy this requirement.
b) The requirement of 14.3.1.2.2 is equivalent to the following two constraints:
    1) The return loss when measured with an 85 Ω resistive source is at least 15 dB in the frequency range of 5 MHz to 10 MHz.
    2) The return loss when measured with a 111 Ω resistive source is at least 15 dB in the frequency range of 5 MHz to 10 MHz.

B.4.3.3 Note for 14.3.1.2.3 on output timing jitter

Adherence to the template of 14.3.1.2.1 with a jitterless source driving DO and the zero crossings constrained to 46.5 ns to 53.5 ns and 96.5 ns to 103.5 ns is sufficient to demonstrate compliance with the 3.5 ns jitter requirement. When measuring an integrated MAU, the zero crossing time interval should be constrained to 44.5 ns to 55.5 ns and 94.5 ns to 105.5 ns due to the additional allocation for encoder and AUI jitter. This test is simpler to perform than the test which follows, but failure of this test does not demonstrate noncompliance.

When triggering on one edge of the transmitted signal and observing another edge, the observed jitter measures the difference between the jitter of the triggering edge and the observed edge. When the two edges are separated such that the jitter of the edges is independent and clock drift is insignificant, the observed jitter is twice that of a single edge.

Therefore, a test that demonstrates compliance or noncompliance is as follows: Observe the zero crossings 8 BT and 8.5 BT from the triggering zero crossing while transmitting a pseudo-random data sequence of at least 511 bits. An external MAU with a jitterless source driving DO is compliant when all zero crossings fall within the time intervals 8.0 BT ± 7 ns and 8.5 BT ± 7 ns. An integrated MAU is compliant when all zero crossings fall within the time intervals 8.0 BT ± 11 ns and 8.5 BT ± 11 ns.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When using packetized data, the TP_IDL and the first transmitted bit should be excluded from these measurements.

B.4.3.4 General note on common-mode tests

When performing tests specified as balanced or common-mode, the balance of the test equipment (such as matching resistors) has to exceed that required by the test.

B.4.3.5 Note for 14.3.1.3.4 on receiver differential input impedance

The return loss (*RL*) is defined as follows:

$$RL = 20\log_{10}\frac{\left|Z_{\text{receiver}} + Z_{\text{cable}}\right|}{\left|Z_{\text{receiver}} - Z_{\text{cable}}\right|}$$

and also

$$RL = 20\log_{10}\frac{\left|V_{\text{i}}\right|}{\left|V_{\text{r}}\right|}$$

where

Z_{receiver} is the impedance of the receiver
Z_{cable} is the impedance of the cable
V_{i} is the differential voltage incident upon the receiver
V_{r} is the differential voltage reflected from the receiver

a) A receiver with a resistive input impedance of 96 Ω ± 20% will satisfy this requirement.
b) The requirement of 14.3.1.3.4 is equivalent to the following two constraints:
    1) The return loss when measured with an 85 Ω resistive source is at least 15 dB in the frequency range of 5 MHz to 10 MHz.
    2) The return loss when measured with a 111 Ω resistive source is at least 15 dB in the frequency range of 5 MHz to 10 MHz.

B.4.3.6 Note for 14.3.1.3.3 on receiver idle input behavior

For conformance testing of receivers, the start of idle shall conform to the template shown in Figure 14–11. Additionally, the magnitude of the voltage-time integral of the undershoot (measured from the negative zero crossing that ends the positive idle pulse to the time when the differential signal settles to 0.0 mV ± 50 mV) shall be no greater than 1.2 times the voltage-time integral of the positive idle pulse (measured from the last positive zero crossing to the negative zero crossing).

B.4.3.7 Note for 14.3.1.3.5 on receiver common-mode rejection

For a stand-alone MAU, the receiver common-mode test may be performed with a jitterless E_s, so that the DI circuit should have no more than 4.0 ns of edge jitter.

For an integrated MAU, the common-mode test is performed with an E_s that has zero crossing jitter up to 11 ns from the ideal.

B.5 10BASE-F

B.5.1 System jitter budget

The jitter budgets for 10BASE-FP, 10BASE-FB, and 10BASE-FL are apportioned as shown in Table B–2.

Table B–2—System jitter budgets

Encoder	10BASE-FP	10BASE-FB	10BASE-FL
Encoder	0.5	0.5	0.5
AUI Cable including SNR (DO Pair)	1.5	N/A	1.5
MAU DO Receiver (10BASE-FP only)	2.0	N/A	N/A
10BASE-FP total at retiming	4.0	N/A	N/A
Subtotal (10BASE-FP Retimes)	0.0	0.5	2.0
Transmitter*	2.0	4.0	4.5
Subtotal (at the MDI)	2.0	4.5	6.5
Fiber optic medium	0.0	0.0	0.0
10BASE-FP Passive Star	0.0	N/A	N/A
Fiber optic medium (10BASE-FP return)	0.0	N/A	N/A
Receiver**	1.0	2.0	8.5
10BASE-FP total at retiming	3.0	N/A	N/A
Subtotal (10BASE-FP Retimes)	0.0	6.5	15.0
Unallocated	8.5	10.0	0.0
MAU DI Transmitter (10BASE-FP only)	6.5	N/A	N/A
AUI cable incl-SNR (DI Pair)	1.5	N/A	1.5
Total	16.5 ns	16.5 ns	16.5 ns
*Includes jitter plus duty cycle distortion.			
** 10BASE-FL figure includes MAU DI Transmitter jitter allocation.			

B.5.2 10BASE-FP fiber optic segment loss budget

The 10BASE-FP MDI optical parameters specified in 15.2.1 and 15.2.2 have been selected to guarantee operation using a properly specified system of up to 500 m radius segment. This annex illustrates how the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

loss budget may be allocated to star, optical fiber, and patch panel connectors, including examples at 100 m and 500 m radius.

The allowed system attenuation values are determined by the average transmit and receive power ranges specified in Table 15–1. The average optical power launched into a 62.5 μm fiber has to be greater than –15 dBm and less than –11 dBm. (This includes any launch power variation and source degradation.) Receiver operation is specified for average received power greater than –41 dBm and less than –27 dBm. Thus the maximum attenuation allowed for optical plant, including star, is 26 dB, and the minimum allowed attenuation is 16 dB.

This attenuation can be allocated between the star, cabled optical fiber, and patch panel connectors in any manner as long as the maximum and minimum losses are within the limits stated in Table B–3. Note that the 10BASE-FP Star insertion loss includes the loss of one optical connector pair as specified in 16.5.2.1.

Table B–3—10BASE-FP fiber optic segment loss budget

Item	Min (dB)	Max (dB)
Star	16	20
Cabled optical fiber and connectors	0	6
Totals	16	26

Example 1: For a 500 m radius segment (1 km MDI to MDI) of 3.75 dB/km (measured at 850 nm) cabled optical fiber and a connector system with a maximum loss of 2 dB, the worst-case optical fiber and connector loss would be 5.75 dB. This would fall within the 6 dB limit, and result in a worst-case margin of 0.25 dB

Example 2: A horizontal structured building wiring system (e.g., as detailed in ANSI/TIA-568-C.0) of 100 m from the wiring closet to the desk top (100 m radius segment, 200 m MDI to MDI) of 3.75 dB/km optical fiber would have a loss of 0.75 dB. With four connector pairs in the path from MDI to MDI (wall plate, patch panel, patch panel, wall plate [see Figure 15–2]) and one connector pair at the 10BASE-FP Star (the other star connector pair is already included in the star loss [see 16.5.2.1)], and using a worst-case loss of 1 dB for each connector pair, the worst-case optical fiber and connector loss would be 5.75 dB. This would fall within the 6 dB limit, and would result in a worst-case margin of 0.25 dB.

In addition to these loss budgets, the overall system return loss has to be greater than 27 dB. The return loss is the ratio of the desired signal to all undesired, multiple reflected signals, observed at a 10BASE-FP MAU MDI. Use of connectors with less return loss than specified in 15.3.2.2 as well as use of more than two patch panels on each side of the star is permitted, as long as the overall system return loss requirement is met.

The 8.0 dB differential flux budget (16.3.4.2) can be allocated as shown in Table B–4.

Table B–4—Eight decibel differential flux budget

Contribution	(dB)
Variation at Star Input due to combined effects	4.8
1/2 star connector	0.5
Star including 1/2 connector	2.5
Wavelength in ORD leg	0.2
Total	8.0

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each of these contributions to the differential budget is a measurable quantity. For example, the variation in the optical power at the star input due to combined effects of launch power, LED lifetime degradation, connectors, distance from 10BASE-FP MAU to Star, and wavelength of transmitter can be measured at the star input port. Also, star differential loss measurement is described in 16.5.2.2.

Annex D

(informative)

Application context, selected medium specifications

D.1 Introduction

This annex provides general guidance, to both the design engineer and the eventual user of specific product implementations, on the particular clauses of this standard considered useful for different 10 Mb/s application environments. It is to be emphasized that the material in this annex is very general, as the standard specifications are intended to be relatively application-independent. Nevertheless, certain specifications may apply more to one application environment than another. What follows are brief descriptions of application environments and lists of those generic parameters of the Physical Layer specifications thought to be useful in relating a general set of user requirements to a specific standard specification and its related medium. *Once a basic relationship is identified, the reader is directed to a specific clause of the standard for detailed design specifications.*

D.2 Type 10BASE5 applications

One of the major arenas for local area networks is the interconnection of work stations throughout a large department or single building. The ability to handle all kinds of message traffic at relatively high data rates among a large set of work stations are typical characteristics of these environments. Usually the basic interconnection trunk cable is installed and left in place permanently or for extended periods while work station placement may shift from time to time. The Type 10BASE5 specification provides the primary baseband backbone for intraplant CSMA/CD interconnections. Clause 7 and Clause 8 of the standard provide detailed specifications for the Physical Layers associated with Type 10BASE5 environments. The generic Physical Layer parameters are as follows:

Maximum unrepeatered cable segment500 m
Maximum number of MAUs per segment100
Connector typeType N or coaxial “tap”
Breakdown voltage, MAU function250 V ac rms
MTBF1 million hours
Total Segment Resistance5 Ω
MAU separation2.5 m
Connection shunt capacitance4 pF
AUI functionalityDO, DI, CI, (CO optional)

D.3 Type 10BASE2 applications

Another major arena for local area networks is the interconnection of work stations throughout a small department or work area. The ability to handle all kinds of message traffic at relatively high data rates among a selected set of locally clustered work stations are the typical characteristics of these environments. In addition, the basic interconnection trunk cable is likely to be moved frequently by the local users of the equipment to suit evolving needs. The Type 10BASE2 specification provides an interconnection schema that complements the Type 10BASE5 backbone in a hierarchical manner for intradepartment or work area CSMA/CD interconnections. Clause 7 and Clause 10 of the standard provide detailed specifications for the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Physical Layers associated with Type 10BASE2 environments. The generic Physical Layer parameters are as follows:

Maximum unrepeatered cable segment185 m
Maximum number of MAUs per segment30
Connector typeType BNC “T”
Breakdown voltage, MAU function500 V ac rms
MTBF100 000 hours
Total Segment Resistance10 Ω
MAU separation0.5 m
Connection shunt capacitance8 pF
AUI functionalityDO, DI, CI

D.4 Type FOIRL and 10BASE-F applications; alternative fiber optic medium applications

D.4.1 Alternative fiber types

Table D–1 provides a listing of other fiber types that may be used in an FOIRL or a 10BASE-F Cable Link Segment. These fiber types have not been studied, and details for their use are not provided for in the main body of the standard. Therefore, using these fiber types may reduce the maximum achievable distance.

Table D–1—Alternative fiber types

Nominal Core diameter (µm) IEC 60793-2:1992	Nominal cladding diameter (µm) IEC 60793-2:1992	Nominal Numerical aperture IEC 60793-2:1992
50	125	0.2
50	125	0.21
50	125	0.22
85	125	0.26
100	140	0.29

D.4.1.1 Theoretical coupling losses

The body of the standard references a single fiber type to facilitate interoperability and conformance testing; however, other fiber types may also be used. The use of an alternative fiber type with a particular implementation may have the following consequences. At the transmit MDI, more or less light may be launched into the fiber, depending on whether the optics are optimized for a core size and a numerical aperture (NA) that are smaller or larger than that of the alternative fiber size. At the receive MDI, the sensitivity may be increased or decreased depending on the optimization of the collecting optics. Table D–2 summarizes the potential effects of the use of alternative fiber sizes and provides the loss budget remaining for cable plant attenuation. All adjustments are relative to an implementation using the minimum diameter and NA 62.5 µm core fiber as specified in IEC 60793-2:1992, Type A1b, Category ≤ 3.5 dB/km. This cable plant has a loss budget of 9 dB for FOIRL segments and 12.5 dB for 10BASE-FL and 10BASE-FB link segments.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The worst-case loss budget in Table D–2 is calculated on the assumption that the transmitter and receiver core diameter and NA are 62.5 µm and 0.275, respectively. Launching into a smaller core diameter or NA will incur a loss. Launching into a larger core diameter or NA will not result in a gain.

Similarly, receiving from a larger core diameter or NA incurs a loss, but receiving from smaller core diameter or NA provides no gain.

The values for transmit powers assume a worst-case condition that no additional power is launched into an increased core diameter and NA link fiber when referred to the 62.5 µm core fiber. This assumption is valid for underfilled launch conditions such as may occur from a MAU containing a pigtailed or laser emitter.

Table D–2—Worst-case loss budget

Fiber type	Transmit loss (dB)	Receive loss (dB)	Loss budget remaining (dB)	
			FOIRL	10BASE-FB/L
50 µm/NA=0.20	5.7	0	3.3	6.8
50 µm/NA=0.21	5.2	0	3.8	7.3
50 µm/NA=0.22	4.8	0	4.2	7.7
85 µm/NA=0.26	1.6	2.6	4.8	8.3
100 µm/NA=0.29	0.5	4.5	4.0	7.5

D.4.1.2 Maximum launch power

When large core diameter and NA launch conditions are used in conjunction with a launch fiber of larger core diameter and NA than the 62.5 µm reference, significantly greater launch power can occur. For example, this is typically the case with wide area surface emitter LED devices that are directly aligned with a fiber in a device mount header.

Table D–3 summarizes the maximum launch power into fibers with larger core diameters than 62.5 µm and the corresponding excess power that can result with a receiver utilizing all the optical power from the fiber.

Table D–3—Worst-case launch power

Fiber type	Maximum transmit power (dBm)	Maximum excess power (dBm)
85 µm/NA=0.26	–6.1	2.9
100 µm/NA=0.29	–3.8	5.2

In this case, sufficient attenuation should be installed in the link segment to ensure that for FOIRL segments the peak received optical power does not exceed –9 dBm, and for 10BASE-F segments the average received optical power does not exceed the appropriate optical Receive Average Power (Max) in Table 15–1.

D.4.2 Type 10BASE-FP applications using 50/125 μm fiber

It is recognized that, in some cases, designers are constrained to use fiber sizes other than 62.5/125 μm in LAN designs. Such LAN designs are beyond the scope of this standard but can operate properly if optical power and loss budgets are adjusted to compensate for the different fiber characteristics. The following guidance is provided for system implementers who are constrained to design LANs with the 50/125 μm fiber described in D.4.1.

WARNING

Interoperability of nonconforming implementations cannot be ensured. It is the responsibility of the designer(s) of nonconforming implementation(s) to assure LAN operation. The following is only advisory information for implementations outside the scope of this standard.

D.4.2.1 Coupled transmit power

As shown in D.4.1, reduction of coupled power introduces the greatest difference between LANs using 62.5/125 μm and those using 50/125 μm fiber. Typically, for an emitter technology that produces a uniform, overfilled launch condition, this difference will be 3.5 dB. Implementers of 50/125 μm systems may choose to deal with this by trying one of the following alternatives:

a) Selecting an emitter technology with coupled power that is less susceptible to variation with fiber size, or
b) Increasing receiver sensitivity and dynamic range, or
c) Reducing the star coupler loss to compensate for the reduction in coupled transmit power. This may be accomplished by reducing the number of ports on the star coupler, or
d) Reducing the connector losses in the system, either by reducing the number of in-line connectors or reducing the loss per connector.

D.4.2.2 Star coupler loss

Also in accordance with D.4.1, the transmission loss of 50/125 μm star couplers may be as much as 1 dB greater than their 62.5/125 μm counterparts. Implementers of 50/125 μm systems may choose to deal with this by trying one of the following alternatives:

a) Procurement—specification of coupler loss characteristics to be the same as those shown for 62.5/125 μm star couplers, per 16.5, or
b) Compensation—all items shown in D.4.2.1 a) to d) may be used to compensate for an increase in coupler loss.

For example, a passive-star coupler (with connectors) with 33 ports typically has the following losses:

Contributor	Loss (dB)
Splitting	–15
Connector (1)	–1
Excess	0 to –4
Total	–16 to –20

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If, in a LAN that used 50/125 μm fiber, the maximum allowable number of ports per passive-star coupler was reduced to 17, the appropriate losses would be as follows:

Contributor	Loss (dB)
Splitting:	–12
Connector (1):	–1
Excess:	0 to –3
Total:	–13 to –16

The 3.5 dB lost to the MDI OTD would then be recovered allowing this "reduced nodes" LAN to still operate at the proposed maximum of 500 m MAU to the star.

It should be noted that the MAU parameters remain unchanged.

D.4.2.3 Collision detection

Reliable collision detection requires that designers of systems using nonconforming fiber optic cable ensure that the optical power levels of all possible colliding signals on the LAN differ at the mixing element (passive-star coupler) by no more than that specified in 16.3.4.2. This requires that
$10 \times \text{abs}\,(\log((P_{Ti} - L_{Ti} - U_{Ti})/(P_{Tj} - L_{Tj} - U_{Tj}))) \leq$ that specified in 16.3.4.2.

for all *i* not equal *j*, and

where

P_{Tn} is coupled optical transmit power, MAU *n*
L_{Tn} is optical cable and connector and transmit fiber loss, from MAU n to star input port *m*
U_{Tm} is input port uniformity, port *m*

D.5 10BASE-T use of cabling systems with a nominal differential characteristic impedance of 120 Ω

Clause 14 specifies the use of 100 Ω link segments. This subclause specifies the conditions for the use of cabling with a nominal characteristic impedance of 120 Ω by 10BASE-T conformant stations.

The use of cables with a characteristic impedance outside the range specified in 14.4.2.2 will generally increase the mismatching effects in the link components, inducing additional jitter in the received signal.

In particular, the use of a homogeneous link segment having a characteristic impedance of 120 Ω ± 15 Ω over the frequency band 1 to 16 MHz may add from 0.15 ns (maximum-length segment) up to 0.63 ns (short-length segment) of additional jitter to the signal at the input of the receiver.

Consequently, in order to keep the overall jitter budget at the same value as for a 100 Ω link segment when using a 120 Ω link segment, the following modifications to the specifications of 14.4 apply:

a) The maximum medium timing jitter specified in 14.4.2.3 for a simplex link segment is increased from 5 ns to 5.5 ns.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) The NEXT loss values specified in 14.4.3 are increased by 3 dB, i.e., the applicable formulas are replaced by the following:
   1) in 14.4.3.1.1 for 25-pair cables/binder groups: $33–15 \log_{10}(f/10)$ dB.
   2) in 14.4.3.1.2 for 4-pair cables: $29–15 \log_{10}(f/10)$ dB.
   3) in 14.4.3.2 for MDNEXT: $26–15 \log_{10}(f/10)$ dB.

NOTE—In addition to the case of 120 Ω homogeneous link segments, the above figures encompass the case where 100 Ω terminal cords are used in conjunction with 120 Ω premises cabling. This configuration results in adding up to 0.5 ns of jitter for a maximum-length segment (instead of 0.15 ns) and up to 1.3 ns for a short-length segment (instead of 0.63 ns).

The use of 100 Ω cords at any intermediate cross-connects on 120 Ω links as well as the use of cords with a characteristic impedance of 120 Ω ± 15 Ω in conjunction with 100 Ω ±15 Ω premises cabling is not allowed since it would result in worst-case jitter greater than that allowed in the standard.

D.6 10BASE-T use of cabling systems with a nominal differential characteristic impedance of 150 Ω

This subclause outlines the philosophy and methodology for allowing 10BASE-T stations to support transmission on 150 Ω balanced STP cabling, as specified by ISO/IEC 11801:1995, Clause 8, with the use of impedance matching transformers.

The 10BASE-T specification was designed to support Manchester signaling over a link segment consisting of 100 Ω cabling system. The MAU link interface specifications were designed to ensure that jitter due to impedance discontinuities were minimized as specified in 14.4.2.3. In theory and in practice, a 150 Ω cabling system may be used to provide the link segment function provided the proper impedance match (100 Ω) with the MAU over the frequency range of interest as specified in 14.4, and the resultant transmission characteristics of the cabling system used to provide the link segment function meet or exceed those specified in 14.4. Therefore, to ensure the jitter specification of 14.4.2.3 and the jitter budget of B.4.1 are met, the following approach is recommended when using 150 Ω balanced STP cabling (as specified in ISO/IEC 11801:1995):

a) The 150 Ω section included in the link segment shown in Figure D–1 meets the specifications of ISO/IEC 11801:1995, 7.2.

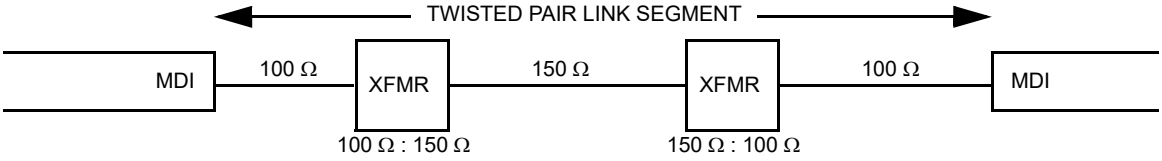

Figure D–1—Link segment incorporating 150 Ω cable section

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) The link segment, including impedance matching transformers as shown in Figure D–2, meets all applicable specifications of 14.4.

c) A link test point is shown in Figure D–2. The transformers shown are the same as the ones shown in Figure D–1. The attaching cables between the MAU and the link test point should be the minimum required to attach the components. As tested in this configuration, the MAU transmitter requirements meet all applicable requirements for the MAU as specified in Clause 14, except for signal levels which may be up to 1.0 dB lower than that specified there.

NOTE—This 1.0 dB (0.5 dB per transformer) effectively requires the attenuation of the 150 Ω cable section of the twisted-pair link segment (see Figure D–1) to be less than or equal to 10.5 dB in order to meet the requirements of 14.4.2.

Annex E

(informative)

Receiver wavelength design considerations (FOIRL)

NOTE—This annex relates to a clause that is not recommended for new installations. This annex is not recommended for new installations. Since March 2012, maintenance changes are no longer being considered for this annex.

The center wavelength of the optical source emission is specified in 9.9.4.1.1 to be between 790 nm and 860 nm. Although these limits are acceptable, it is currently recognized, through the examination of manufacturers' current data, that greater choices of emitters can be obtained by extending the allowable wavelength to 910 nm.

An upper limit of 910 nm allows the selection of devices nominally centered at a lower wavelength, for example, 880 nm. This allows a tolerance for manufacturing variations, for example, ±20 nm, and a tolerance for an operating temperature range (typically, 0.3 nm/°C).

It is anticipated that future fiber optic applications including Local Area Networks will use the 910 nm upper limit for first window systems. It is therefore recommended that implementers specify receiver sensitivity over a center wavelength range from 790 nm to 910 nm.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Annex F

(normative)

Additional attributes required for systems

F.1 Introduction

During the development of Repeater Management, some attributes and operations were identified as items that were necessary to fill out the management of a complete intermediate system such as a repeater. These items are generic in the sense that they are required for managed systems in general. They are not normally specified as attributes of the lower layers. In repeater management, the entire system is at the lowest layers so there is no other group to turn to for systems management. The following items are defined to aid in the completeness of this standard, although it is recognized that they are outside the bounds of the definition area for a layer1/2 device.

F.1.1 Scope

This annex defines additional managed objects and attributes that have been identified by the IEEE 802.3 Repeater Management Task Force as being necessary to the management of an IEEE 802.3 repeater. These objects and attributes, while necessary to the management of an IEEE 802.3 repeater, are not specifically related to the CSMA/CD access method or to Clause 9 repeaters; rather, they are objects and attributes that are appropriate for any managed system.

This annex does not necessarily define the complete set of generic objects and attributes required to support a managed system. It contains only those objects and attributes that were identified in the process of developing the repeater management standard and were identified as not being uniquely appropriate to a CSMA/CD layer management standard.

When a generic systems management standard is available that is appropriate for managed systems of the complexity of a repeater, it is expected that this portion of the standard will no longer be appropriate and will be deprecated.

F.2 Objects/Attributes/Actions/Notifications

F.2.1 TimeSinceSystemReset attribute

aTimeSinceSystemReset **ATTRIBUTE**
DERIVED FROM AttributeModule.ResettableCounter32;
BEHAVIOUR bTimeSinceSystemReset;
REGISTERED AS {iso(1) member-body(2) us(840) 802dot3(10006) repeaterMgt(19) attribute(7) sysResetTime(47)};

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bTimeSinceSystemReset **BEHAVIOUR**
DEFINED AS The time in tens of milliseconds since the last time that the system including network management was reset. This may have been caused by ResetSystemAction or other means. This counter has a value of 0 when initialized.

Though the count is reported in tens of milliseconds, the required resolution is to the nearest 100 ms. The clocking source for the counter shall be accurate to within 1% throughout the full counting range.;

NOTE—The approximate minimum time for counter rollover is 497 days.

F.2.2 RepeaterResetTimeStamp attribute

aRepeaterResetTimeStamp **ATTRIBUTE**
WITH ATTRIBUTE SYNTAX AttributeModule.Integer32;
BEHAVIOUR bRepeaterResetTimeStamp;
REGISTERED AS {iso(1) member-body(2) us(840) 802dot3(10006) repeaterMgt(19) attribute(7) repeaterResetTimeStamp(48)};

bRepeaterResetTimeStamp **BEHAVIOUR**
DEFINED AS Not a counter, this attribute provides the value of aTimeSinceSystemReset when the repeater was last reset. This value is recorded whenever the repeater enters the START state of Figure 9–2 in the 802.3 repeater standard. This value may never be greater than aTimeSinceSystemReset.;

F.2.3 ResetSystemAction action

acResetSystemAction **ACTION**
BEHAVIOUR acResetSystem;
MODE CONFIRMED;
REGISTERED AS {iso(1) member-body(2) us(840) 802dot3(10006) repeaterMgt(19) action(9) resetSystem(49)};

acResetSystem **BEHAVIOUR**
DEFINED AS This action initializes the resettable management counters of the system and also of all contained objects. The value of non-resettable counters may change as a result of this action.;

NOTE—This action may result in the loss of packets.

Annex G

(normative)

Additional material required for conformance testing

NOTE—This annex relates to a clause that has been deprecated. Since March 2012, maintenance changes are no longer being considered for this annex.

G.1 Introduction

This material was generated during the development of Clause 19. It was felt that it was required to support the development of conformance test material that was not included in the charter of the development of the original repeater management standard.

G.1.1 Material in support of the aDataRateMismatches attribute

A vendor submitting equipment for conformance testing under Clause 19 shall provide minimum frequency difference data (two values) such that a test can be done for exertion and another test can be done for non-exertion of the aDataRateMismatch attribute (see 19.2.6.2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Annex H

(normative)

GDMO specifications for CSMA/CD managed objects

NOTE—GDMO specifications were moved to Annex B of IEEE Std 802.3.1-2011 and removed from this annex in IEEE Std 802.3-2012.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Annex J

(normative)

Electrical isolation and general safety

The requirements specified in this annex are to be used in conjunction with the requirements in the clause that specifies the interface(s) under consideration.

J.1 Electrical isolation

Electrical isolation shall withstand at least one of the following electrical strength tests:

a) 1500 V rms at 50 Hz to 60 Hz. This test voltage amplitude is raised from zero to the prescribed voltage and held at that value for 60 s.

b) 2250 V dc. This test voltage is raised from zero to the prescribed voltage and held at that value for 60 s.

c) A sequence of ten 2400 V impulses of alternating polarity, applied at intervals of not less than 1 s. The shape of the impulses is 1.2/50 (1.2 μs virtual front time, 50 μs virtual time to half value), such as one produced by a 1.2/50-8/20 combination wave generator, as defined in ITU-T Recommendation K.44.

NOTE 1—If the MDI is also a Clause 33 or Clause 145 PI then see 33.4.1 or 145.4.1 for specific requirements associated with option c).

There shall be no insulation breakdown during the test. Insulation breakdown is considered to have occurred when the current that flows as a result of the application of the test voltage rapidly increases in an uncontrolled manner; that is, the insulation does not restrict the flow of the current. Corona discharge is not regarded as insulation breakdown. The resistance after the test shall be at least 2 MΩ, measured at 500 V dc.

NOTE 2—IEEE Std 802.3-2018 and previous revisions provided references to various editions of the IEC 60950-1 standard for guidance in performing the isolation test for options a) and b). IEC 60950-1 has been withdrawn. References to IEC standards are not essential to performing the isolation test specified in J.1. No technical change is implied by the removal of these references.

NOTE 3—Implementers should consider the effect of whether other ports are terminated or unterminated when testing the insulation of multi-port devices.

J.2 General safety

Equipment shall comply with all applicable local, state, national and application-specific standards, such as the applicable sections of IEC 62368-1:2018.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

J.3 Protocol implementation conformance statement (PICS) proforma for Annex J, Electrical isolation and general safety[270]

J.3.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex J, Electrical isolation and general safety, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

J.3.2 Identification

J.3.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

J.3.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex J, Electrical isolation and general safety
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

Annex K

(informative)

Optional alternative terminology for “master” and “slave”

The IEEE 802.3 Ethernet standard uses the terms “master” and “slave” to assign roles, for example to define timing roles for certain PHYs. These terms, even while used strictly in a technical context, still have widely held negative social connotations. Because of this, some organizations with an interest in IEEE 802.3 Ethernet have policies, or are considering policies, to discontinue the use of the master-slave terminology and replace it with other terms that have less negative social connotations.

If alternative terms for “master” and “slave” are used in implementations, then the following substitutions are recommended:

In place of “master”, the term “leader” should be used. In place of the term “slave”, the term “follower” should be used. For example, “MASTER PHY” would be replaced with “LEADER PHY”. This includes the use of “master” or “slave” as part of a compound term. For example, “slave_transition_counter” would be replaced with “follower_transition_counter”.

When translating into languages other than English, synonyms may be selected for “leader” and “follower” to avoid widely held negative social connotations.

NOTE—This annex is numbered in correspondence to its associated clause; i.e., Annex 4A corresponds to Clause 4.

Annex 4A

(normative)

Simplified full duplex media access control

This annex is based on the Clause 4 MAC, with simplifications for use in networks that do not require the half duplex operational mode. Additional functionality is included for managing Physical Layer congestion and for support of interframe spacing outside this sublayer. This annex stands alone and does not rely on information within Clause 4 to be implemented.

4A.1 Functional model of the MAC method

4A.1.1 Overview

The architectural model described in Clause 1 is used in this clause to provide a functional description of the LAN full duplex MAC sublayer.

The MAC sublayer defines a medium-independent facility, built on the medium-dependent physical facility provided by the Physical Layer, and under the access-layer-independent LAN LLC sublayer (or other MAC client). It is applicable to a general class of media suitable for use with the full duplex media access discipline.

The LLC sublayer and the MAC sublayer together are intended to have the same function as that described in the OSI model for the Data Link Layer alone. The partitioning of functions presented in this standard requires two main functions generally associated with a data link control procedure to be performed in the MAC sublayer. They are as follows:

a) Data encapsulation (transmit and receive)
    1) Framing (frame boundary delimitation, frame synchronization)
    2) Addressing (handling of source and destination addresses)
    3) Error detection (detection of physical medium transmission errors)
b) Media access management (Physical Layer congestion)

This MAC does not support the *half duplex* mode of operation so there is no need for collision detection or handling. However, this MAC does have the ability to avoid congestion within the Physical Layer. Therefore, Media Access Management comprises the transmission of bits to the Physical Layer and optionally delaying any transmission for an interframe gap or for a longer period of time based on congestion within the Physical Layer.

An optional MAC control sublayer, architecturally positioned between LLC (or other MAC client) and the MAC, is specified in Clause 31 and Clause 64. This MAC Control sublayer is transparent to both the underlying MAC and its client (typically LLC). The MAC sublayer operates independently of its client; i.e., it is unaware whether the client is LLC or the MAC Control sublayer. This allows the MAC to be specified and implemented in one manner, whether or not the MAC Control sublayer is implemented. References to LLC as the MAC client in text and figures apply equally to the MAC Control sublayer, if implemented.

The remainder of this clause provides a functional model of this MAC method.

4A.1.2 Full duplex operation

This subclause provides an overview of frame transmission and reception in terms of the functional model of the architecture. This overview is descriptive, rather than definitional; the formal specifications of the operations described here are given in 4A.2 and 4A.3. Specific implementations for full duplex mechanisms that meet this standard are given in 4A.4. Figure 1–1 provides the architectural model described functionally in the subclauses that follow.

The Physical Layer Signaling (PLS) component of the Physical Layer provides an interface to the MAC sublayer for the serial transmission of bits onto the physical media. For completeness, in the operational description that follows some of these functions are included as descriptive material. The concise specification of these functions is given in 4A.2 for the MAC functions and in Clause 7 for PLS.

Transmit frame operations are independent from receive frame operations and respond to different signals from the Physical Layer. The carrierSense signal indicates that the transmit function has to defer because of congestion at the Physical Layer (see 4A.2.3.2.1). The receiveDataValid signal indicates the presence of incoming data to the receive function (see 4A.2.4.2).

4A.1.2.1 Transmission

When a MAC client requests the transmission of a frame, the Transmit Data Encapsulation component of the full duplex MAC sublayer constructs the frame from the client-supplied data. It prepends a preamble and a Start Frame Delimiter to the beginning of the frame. Using information provided by the client, the MAC sublayer also appends a Pad at the end of the MAC information field of sufficient length to ensure that the transmitted frame length satisfies a minimum frame-size requirement (see 4A.2.3.2.4). It also prepends destination and source addresses, the length/type field, and appends a frame check sequence to provide for error detection. If the MAC supports the use of client-supplied frame check sequence values, then it shall use the client-supplied value, when present. If the use of client-supplied frame check sequence values is not supported, or if the client-supplied frame check sequence value is not present, then the MAC shall compute this value. Frame transmission may be initiated once the carrierSense signal has been removed and after the interframe delay, regardless of the presence of receive activity.

The Physical Layer performs the task of generating the signals on the medium that represent the bits of the frame. Once the Physical Layer has indicated its readiness to transmit another frame by removing the carrierSense signal, it shall accept a complete frame from the MAC layer. A functional description of the Physical Layer is given in Clause 7 and beyond.

When transmission has completed, the MAC sublayer so informs the MAC client and awaits the next request for frame transmission.

4A.1.2.2 Reception

At each receiving station, the arrival of a frame is first detected by the Physical Layer, which responds by synchronizing with the incoming preamble, and by turning on the receiveDataValid signal. As the encoded bits arrive from the medium, they are decoded and translated back into binary data. The Physical Layer passes subsequent bits up to the MAC sublayer, where the leading bits are discarded, up to and including the end of the preamble and Start Frame Delimiter.

Meanwhile, the Receive Media Access Management component of the MAC sublayer, having observed receiveDataValid, has been waiting for the incoming bits to be delivered. Receive Media Access Management collects bits from the Physical Layer entity as long as the receiveDataValid signal remains on. When the receiveDataValid signal is removed, the frame is truncated to an octet boundary, if necessary, and passed to Receive Data Decapsulation for processing.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Receive Data Decapsulation checks the frame's Destination Address field to decide whether the frame should be received by this station. If so, it passes the Destination Address (DA), the Source Address (SA), the Length/Type, the Data, and (optionally) the Frame Check Sequence (FCS) fields to the MAC client, along with an appropriate status code, as defined in 4A.3.2. It also checks for invalid MAC frames by inspecting the FCS to detect any damage to the frame enroute, and by checking for proper octet-boundary alignment of the end of the frame. Frames with a valid FCS may also be checked for proper octet-boundary alignment.

4A.1.3 Relationships to the MAC client and Physical Layers

The MAC sublayer provides services to the MAC client required for the transmission and reception of frames. Access to these services is specified in 4A.3. The MAC sublayer makes a best effort to transfer a serial stream of bits to the Physical Layer. Although certain errors are reported to the client, error recovery is not provided by MAC. Error recovery may be provided by the MAC client or higher (sub)layers.

4A.2 Media access control (MAC) method: precise specification

4A.2.1 Introduction

A precise algorithmic definition is given in this subclause, providing a procedural model for the MAC process with a program in the computer language Pascal. See references [B9] and [B17] for resource material. Note whenever there is any apparent ambiguity concerning the definition of some aspect of the MAC method, it is the Pascal procedural specification in 4A.2.7 through 4A.2.10 that should be consulted for the definitive statement. Subclauses 4A.2.2 through 4A.2.6 provide, in prose, a description of the access mechanism with the formal terminology to be used in the remaining subclauses.

4A.2.2 Overview of the procedural model

The functions of the MAC method are presented below, modeled as a program written in the computer language Pascal. This procedural model is intended as the primary specification of the functions to be provided in any MAC sublayer implementation. It is important to distinguish, however, between the model and a real implementation. The model is optimized for simplicity and clarity of presentation, while any realistic implementation shall place heavier emphasis on such constraints as efficiency and suitability to a particular implementation technology or computer architecture. In this context, several important properties of the procedural model shall be considered.

4A.2.2.1 Ground rules for the procedural model

a) First, it shall be emphasized that *the description of the MAC sublayer in a computer language is in no way intended to imply that procedures shall be implemented as a program executed by a computer.* The implementation may consist of any appropriate technology including hardware, firmware, software, or any combination.
b) Similarly, it shall be emphasized that it is the behavior of any MAC sublayer implementations that shall match the standard, not their internal structure. The internal details of the procedural model are useful only to the extent that they help specify that behavior clearly and precisely.
c) The handling of incoming and outgoing frames is rather stylized in the procedural model, in the sense that frames are handled as single entities by most of the MAC sublayer and are only serialized for presentation to the Physical Layer. In reality, many implementations will instead handle frames serially on a bit, octet or word basis. This approach has not been reflected in the procedural model, since this only complicates the description of the functions without changing them in any way.
d) The model consists of algorithms designed to be executed by a number of concurrent processes; these algorithms collectively implement the MAC procedure. The timing dependencies introduced by the need for concurrent activity are resolved in two ways:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1) *Processes Versus External Events.* It is assumed that the algorithms are executed "very fast" relative to external events, in the sense that a process never falls behind in its work and fails to respond to an external event in a timely manner. For example, when a frame is to be received, it is assumed that the Media Access procedure ReceiveFrame is always called well before the frame in question has started to arrive.
2) *Processes Versus Processes.* Among processes, no assumptions are made about relative speeds of execution. This means that each interaction between two processes shall be structured to work correctly independent of their respective speeds. Note, however, that the timing of interactions among processes is often, in part, an indirect reflection of the timing of external events, in which case appropriate timing assumptions may still be made.

It is intended that the concurrency in the model reflect the parallelism intrinsic to the task of implementing the MAC client and MAC procedures, although the actual parallel structure of the implementations is likely to vary.

4A.2.2.2 Use of Pascal in the procedural model

Several observations need to be made regarding the method with which Pascal is used for the model. Some of these observations are as follows:

a) The following limitations of the language have been circumvented to simplify the specification:
   1) The elements of the program (variables and procedures, for example) are presented in logical groupings, in top-down order. Certain Pascal ordering restrictions have thus been circumvented to improve readability.
   2) The *process* and *cycle* constructs of Concurrent Pascal, a Pascal derivative, have been introduced to indicate the sites of autonomous concurrent activity. As used here, a process is simply a parameterless procedure that begins execution at "the beginning of time" rather than being invoked by a procedure call. A cycle statement represents the main body of a process and is executed repeatedly forever.
   3) The lack of variable array bounds in the language has been circumvented by treating frames as if they are always of a single fixed size (which is never actually specified). The size of a frame depends on the size of its data field, hence the value of the "pseudo-constant" frameSize should be thought of as varying in the long term, even though it is fixed for any given frame.
   4) The use of a variant record to represent a frame (as fields and as bits) follows the spirit but not the letter of the Pascal Report, since it allows the underlying representation to be viewed as two different data types.
b) The model makes no use of any explicit interprocess synchronization primitives. Instead, all interprocess interaction is done by way of carefully stylized manipulation of shared variables. For example, some variables are set by only one process and inspected by another process in such a manner that the net result is independent of their execution speeds. While such techniques are not generally suitable for the construction of large concurrent programs, they simplify the model and more nearly resemble the methods appropriate to the most likely implementation technologies (microcode, hardware state machines, etc.)

4A.2.2.3 Organization of the procedural model

The procedural model used here is based on five cooperating concurrent processes. The Frame Transmitter process and the Frame Receiver process are provided by the clients of the MAC sublayer (which may include the LLC sublayer) and make use of the interface operations provided by the MAC sublayer. The other three processes are defined to reside in the MAC sublayer. The five processes are as follows:

a) Frame Transmitter process
b) Frame Receiver process
c) Bit Transmitter process
d) Bit Receiver process
e) Deference process

This organization of the model is illustrated in Figure 4A–1 and reflects the fact that the communication of entire frames is initiated by the client of the MAC sublayer, while the timing of individual bit transfers is based on interactions between the MAC sublayer and the Physical-Layer-dependent bit time.

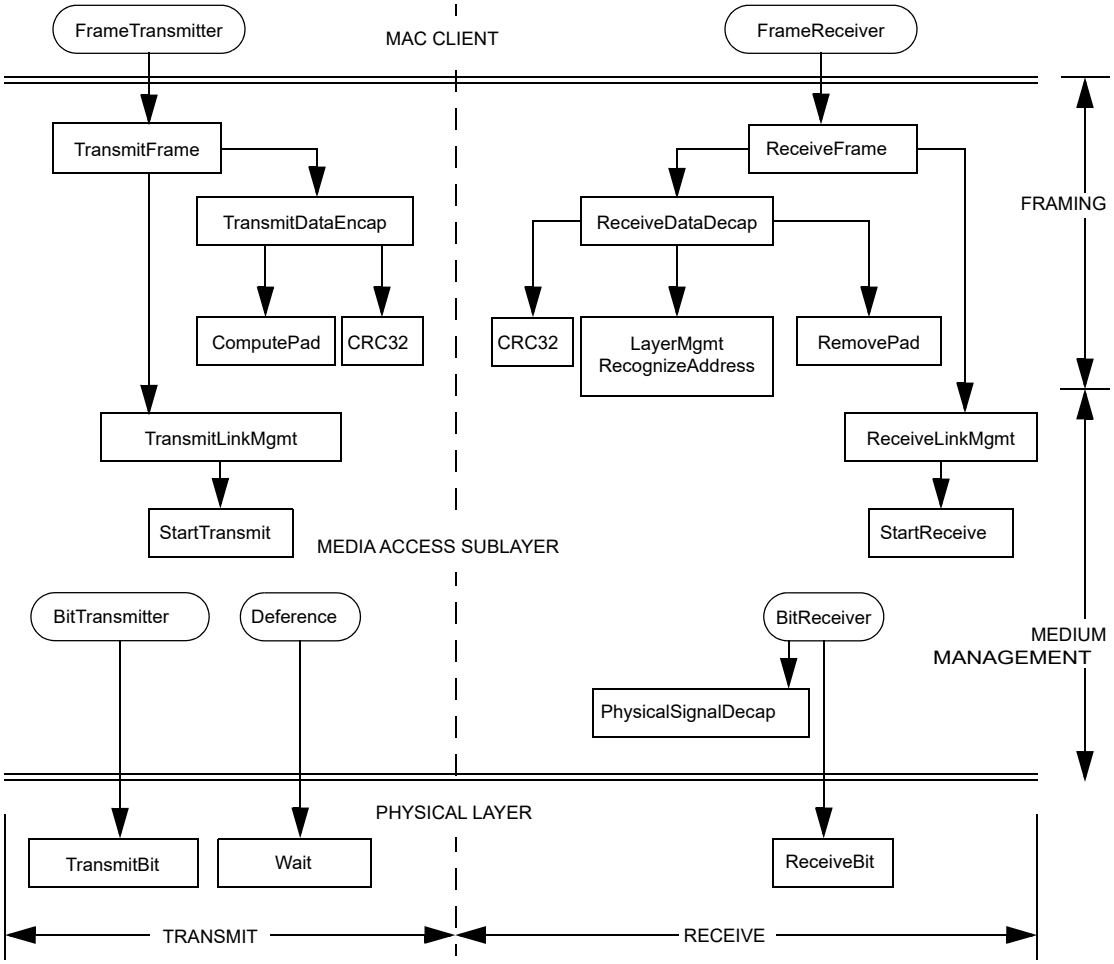

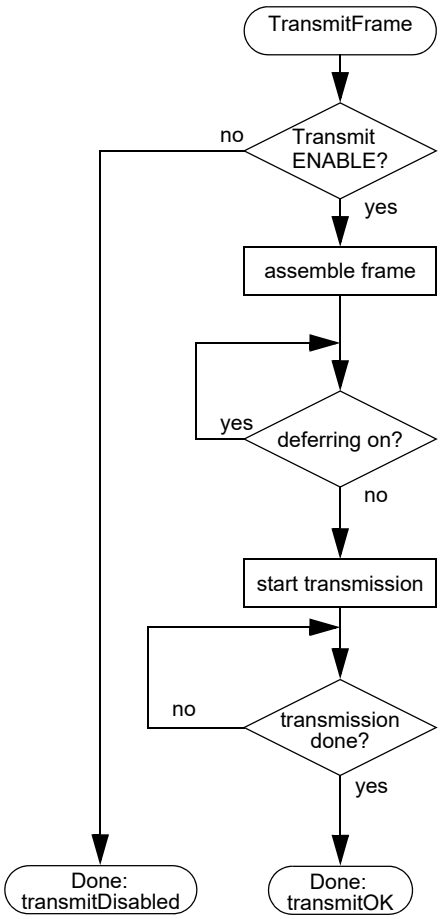

Figure 4A–1—Relationship among MAC procedures

Figure 4A–1 depicts the static structure of the procedural model, showing how the various processes and procedures interact by invoking each other. Figure 4A–2a, Figure 4A–2b, and Figure 4A–2c summarize the dynamic behavior of the model during transmission and reception, focusing on the steps that shall be performed, rather than the procedural structure that performs them. The usage of the shared state variables is not depicted in the figures, but is described in the comments and prose in the following subclauses.

4A.2.2.4 Layer management extensions to procedural model

In order to incorporate network management functions, this Procedural Model has been expanded. Network management functions have been incorporated in two ways. First, 4A.2.7–4A.2.10, 4A.3.2, Figure 4A–2a, and Figure 4A–2b have been modified and expanded to provide management services. Second, Layer Management procedures have been added as 5.2.4. The Pascal variables are shared between Annex 4A and Clause 5.

The Pascal procedural specification shall be consulted for the definitive statement when there is any apparent ambiguity concerning the definition of some aspect of the MAC access method.

The Layer Management facilities provided by the MAC and Physical Layer management definitions provide the ability to manipulate management counters and initiate actions within the layers. The managed objects within this standard are defined as sets of attributes, actions, notifications, and behaviours in accordance with IEEE Std 802.1F-1993, and ISO/IEC International Standards for network management.

4A.2.3 Packet transmission model

Packet transmission includes data encapsulation and Media Access management aspects:

a) Transmit Data Encapsulation includes the assembly of the outgoing packet (from the values provided by the MAC client) and frame check sequence generation.
b) Transmit Media Access Management includes carrier deference, interpacket gap and bit transmission.

4A.2.3.1 Transmit data encapsulation

The fields of the MAC frame are set to the values provided by the MAC client as arguments to the TransmitFrame operation (see 4A.3) with the following possible exceptions: the padding field and the frame check sequence. The padding field is necessary to enforce the minimum frame size. The frame check sequence field may be (optionally) provided as an argument to the MAC sublayer. It is optional for a MAC to support the provision of the frame check sequence in such an argument. If this field is provided by the MAC client, the padding field shall also be provided by the MAC client, if necessary. If this field is not provided by the MAC client, or if the MAC does not support the provision of the frame check sequence as an external argument, it is set to the CRC value as generated by the MAC sublayer, after appending the padding field, if necessary.

4A.2.3.2 Transmit media access management

4A.2.3.2.1 Deference

When a packet is submitted by the MAC client for transmission, the transmission is initiated as soon as possible, but in conformance with the following rules. The variable carrierSense is ignored in process Deference when the variable carrierSenseMode is FALSE.

The MAC sublayer monitors the transmitting variable, which indicates the MAC is transmitting data to the Physical Layer, as well as the carrierSense signal provided by the PLS, which indicates the Physical Layer is not ready for the next frame. When either transmitting or carrierSense is true, the MAC delays any pending transmission. When both are false, the MAC continues to defer for a proper interPacketGap (see 4A.2.3.2.2).

If, at the end of the interPacketGap, a packet is waiting to be transmitted, transmission is initiated. When transmission has completed (or immediately, if there was nothing to transmit) the MAC sublayer resumes its original monitoring of transmitting and carrierSense.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

4A.2.3.2.2 Interpacket gap

As defined in 4A.2.3.2.1, the rules for deferring ensure a minimum interpacket spacing of interPacketGap bit times. This is intended to provide interframe recovery time to aid in packet delineation on the physical medium.

Note that interPacketGap is the minimum value of the interpacket gap. If necessary for implementation reasons, a transmitting sublayer may use a larger value with a resulting decrease in its throughput. The larger value is determined by the parameters of the implementation, see 4A.4.

4A.2.3.2.3 Transmission

Transmissions may be initiated whenever the station has a frame queued, subject only to the Physical Layer congestion and interframe spacing required to allow recovery for the physical medium. In certain implementations, interframe spacing is accomplished outside this layer. These implementations are allowed to ignore the deference process and always initiate transmissions immediately, subject only to conditions enforced outside this sublayer.

4A.2.3.2.4 Minimum frame size

The MAC requires that a minimum frame length of minFrameSize bits be transmitted. If frameSize is less than minFrameSize, then the MAC sublayer shall append extra bits in units of octets (pad), after the end of the MAC client data field but prior to calculating, and appending, the FCS (if not provided by the MAC client). The number of extra bits shall be sufficient to ensure that the frame, from the DA field through the FCS field inclusive, is at least minFrameSize bits. If the FCS is (optionally) provided by the MAC client, the pad shall also be provided by the MAC client. The content of the pad is unspecified.

4A.2.4 Frame reception model

The MAC sublayer frame reception includes both data decapsulation and Media Access management aspects:

a) Receive data decapsulation comprises address recognition, frame check sequence validation, and frame disassembly to pass the fields of the received frame to the MAC client.

b) Receive media access management comprises recognition of collision fragments from incoming frames and truncation of frames to octet boundaries.

4A.2.4.1 Receive data decapsulation

4A.2.4.1.1 Address recognition

The MAC sublayer is capable of recognizing individual and group addresses.

a) *Individual Addresses.* The MAC sublayer recognizes and accepts any frame whose DA field contains the individual address of the station.

b) *Group Addresses.* The MAC sublayer recognizes and accepts any frame whose DA field contains the Broadcast address.

The MAC sublayer is capable of activating some number of group addresses as specified by higher layers. The MAC sublayer recognizes and accepts any frame whose Destination Address field contains an active group address. An active group address may be deactivated.

The MAC sublayer may also provide the capability of operating in the promiscuous receive mode. In this mode of operation, the MAC sublayer recognizes and accepts all valid frames, regardless of their Destination Address field values.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

4A.2.4.1.2 Frame check sequence validation

FCS validation is essentially identical to FCS generation. If the bits of the incoming frame (exclusive of the FCS field itself) do not generate a CRC value identical to the one received, an error has occurred and the frame is identified as invalid.

4A.2.4.1.3 Frame disassembly

Upon recognition of the Start Frame Delimiter at the end of the preamble sequence, the MAC sublayer accepts the frame. If there are no errors, the frame is disassembled and the fields are passed to the MAC client by way of the output parameters of the ReceiveFrame operation.

4A.2.4.2 Receive media access management

The MAC sublayer recognizes the boundaries of an incoming MAC frame by monitoring the receiveDataValid signal provided by the Physical Layer. Two possible length errors can occur that indicate ill-framed data: the MAC frame may be too long, or its length may not be an integer number of octets.

a) *Maximum Frame Size.* The receiving MAC sublayer is not required to enforce the MAC frame size limit, but it is allowed to truncate MAC frames longer than maxFrameSizeLimit octets (see 4.2.7.1). If optional layer management is implemented, such frames may be counted whether or not they are truncated. They may also be reported as an implementation-dependent error.

CAUTION

It is recommended that any implementation that truncates MAC frames should invalidate those frames as they may have severely weakened error protection and may cause serious problems if forwarded to the MAC client.

b) *Integer Number of Octets in Frame.* Since the format of a valid MAC frame specifies an integer number of octets, only a collision or an error can produce a MAC frame with a length that is not an integer multiple of 8 bits. Complete MAC frames (that is, not rejected for being too small) that do not contain an integer number of octets are truncated to the nearest octet boundary. If frame check sequence validation detects an error in such a MAC frame, the status code alignmentError is reported

4A.2.5 Preamble generation

In a LAN implementation, most of the Physical Layer components are allowed to provide valid output some number of bit times after being presented valid input signals. Thus it is necessary for a preamble to be sent before the start of data, to allow the PLS circuitry to reach its steady state. Upon request by TransmitLinkMgmt to transmit the first bit of a new frame, BitTransmitter shall first transmit the preamble, a bit sequence used for physical medium stabilization and synchronization, followed by the Start Frame Delimiter. The preamble pattern is:

10101010 10101010 10101010 10101010 10101010 10101010 10101010

The bits are transmitted in order, from left to right. The nature of the pattern is such that, for Manchester encoding, it appears as a periodic waveform on the medium that enables bit synchronization. It should be noted that the preamble ends with a 0.

4A.2.6 Start frame sequence

The receiveDataValid signal is the indication to the MAC that the frame reception process should begin. Upon reception of the sequence 10101011 following the assertion of receiveDataValid, PhysicalSignalDecap shall begin passing successive bits to ReceiveLinkMgmt for passing to the MAC client.

4A.2.7 Global declarations

This subclause provides detailed formal specifications for the MAC sublayer. It is a specification of generic features and parameters to be used in systems implementing this media access method. 4A.4 provides values for these sets of parameters for recommended implementations of this media access mechanism.

4A.2.7.1 Common constants, types, and variables

The following declarations of constants, types and variables are used by the MAC frame transmission and reception sections of each MAC sublayer:

```
const
    addressSize = 48; {In bits, in compliance with 3.2.3}
    lengthOrTypeSize = 16; {In bits}
    clientDataSize = ...; {In bits, size of MAC Client Data; see 4A.2.2.2, a) 3)}
    padSize = ...; {In bits, = max (0, minFrameSize ─ (2 × addressSize + lengthOrTypeSize +
                                                        clientDataSize + crcSize))}
    dataSize = ...; {In bits, = clientDataSize + padSize}
    crcSize = 32; {In bits, 32-bit CRC}
    frameSize = ...; {In bits, = 2 × addressSize + lengthOrTypeSize + dataSize + crcSize; see 4A.2.2.2, a)}
    minFrameSize = ...; {In bits, see 4A.4}
    maxBasicFrameSize = 1518; {In octets, see 3.2.7, 4A.4}
    maxEnvelopeFrameSize = 2000; {In octets, see 3.2.7, 4A.4}
    qTagPrefixSize = 4; {In octets, length of Q-tag Prefix, see 3.2.7, 4A.4}
    maxFrameSizeLimit = maxBasicFrameSize or (maxBasicFrameSize + qTagPrefixSize) or
                        maxEnvelopeFrameSize ; {in octets}
    minTypeValue = 1536; {Minimum value of the Length/Type field for Type interpretation}
    maxBasicDataSize = 1500;
                        {In octets, the maximum length of the MAC Client Data field of the basic frame.}
    preambleSize = 56; {In bits, see 4A.2.5}
    sfdSize = 8; {In bits, Start Frame Delimiter}
    headerSize = 64; {In bits, sum of preambleSize and sfdSize}
type
    Bit = (0, 1);
    AddressValue = array [1..addressSize] of Bit;
    LengthOrTypeValue = array [1..lengthOrTypeSize] of Bit;
    DataValue = array [1..dataSize] of Bit; {Contains the portion of the MAC frame that starts with the first
                                             bit following the Length/Type field and ends with the last bit
                                             prior to the FCS field.
    CRCValue = array [1..crcSize] of Bit;
    PreambleValue = array [1..preambleSize] of Bit;
    SfdValue = array [1..sfdSize] of Bit;
    ViewPoint = (fields, bits); {Two ways to view the contents of a MAC frame}
    HeaderViewPoint = (headerFields, headerBits);
    Frame = record {Format of MAC frame}
        case view: ViewPoint of
            fields: (
                destinationField: AddressValue;
                sourceField: AddressValue;
                lengthOrTypeField: LengthOrTypeValue;
                dataField: DataValue;
                fcsField: CRCValue);
            bits: (contents: array [1..frameSize] of Bit)
        end; {MAC frame}
    Header = record {Format of Preamble and Start Frame Delimiter}
        case headerView: HeaderViewPoint of
```

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
        headerFields: (
          preamble: PreambleValue;
          sfd: SfdValue);
        headerBits: (headerContents: array [1..headerSize] of Bit)
    end; {Defines header for MAC frame}
  TransmitStatus = (transmitDisabled, transmitOK, excessiveCollisionError, lateCollisionErrorStatus);
  ReceiveStatus = (receiveDisabled, receiveOK, frameTooLong, frameCheckError, lengthError,
                   alignmentError);
```

4A.2.7.2 Transmit state variables

The following items are specific to packet transmission. (See also 4A.4.)

```
const
  interPacketGap = ...; {In bit times, minimum gap between packets,
                         see 4A.4}
var
  outgoingFrame: Frame; {The frame to be transmitted}
  outgoingHeader: Header;
  currentTransmitBit, lastTransmitBit: 1..frameSize; {Positions of current and last outgoing bits in
                                                      outgoingFrame}
  lastHeaderBit: 1..headerSize;
  deferring: Boolean; {Implies any pending transmission has to wait for the Physical Layer to be ready for
                       the next packet and for the interpacket gap}
  deferenceMode: Boolean; {Indicates the desired mode of operation, and enables waiting for
                           interpacket gap during the deference process}
  carrierSenseMode: Boolean; {Indicates the desired mode of operation, and enables using carrierSense
                              to extend deference due to congestion in the PHY}
```

4A.2.7.3 Receive state variables

The following items are specific to frame reception. (See also 4A.4.)

```
var
  incomingFrame: Frame; {The frame being received}
  receiving: Boolean; {Indicates that a frame reception is in progress}
  excessBits: 0..7; {Count of excess trailing bits beyond octet boundary}
  receiveSucceeding: Boolean; {Running indicator of whether reception is succeeding}
  validLength: Boolean; {Indicator of whether received frame has a length error}
  exceedsMaxLength: Boolean; {Indicator of whether received frame has a length longer than the
                              maximum permitted length}
  passReceiveFCSMode: Boolean; {Indicates the desired mode of operation, and enables passing of
                                the frame check sequence field of all received frames from the
                                MAC sublayer to the MAC client. passReceiveFCSMode is a
                                static variable}
```

4A.2.7.4 State variable initialization

The procedure Initialize has to be run when the MAC sublayer begins operation, before any of the processes begin execution. Initialize sets certain crucial shared state variables to their initial values. (All other global variables are appropriately reinitialized before each use.) Initialize then waits for the medium to be idle, and starts operation of the various processes.

NOTE—Care should be taken to ensure that the time from the completion of the Initialize process to when the first packet transmission begins is at least an interFrameGap.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If Layer Management is implemented, the Initialize procedure shall only be called as the result of the initializeMAC action (30.3.1.2.1).

```
procedure Initialize;
begin
    deferring := false;
    transmitting := false; {An interface to Physical Layer; see below}
    receiving := false;
    passReceiveFCSMode := ...; {True when enabling the passing of the frame check sequence of all
                                received frames from the MAC sublayer to the MAC client is desired and
                                supported, false otherwise}
    deferenceMode := ...; {False for implementations that cannot rely on deference within the MAC to
                           provide an interframe gap, true otherwise}
    carrierSenseMode := ...; {True for implementations that use carrierSense to indicate congestion in the
                           PHY, false otherwise.}
    while ((carrierSenseMode and carrierSense) or receiveDataValid) do nothing
    {Start execution of all processes}
end; {Initialize}
```

4A.2.8 Frame transmission

The algorithms in this subclause define MAC sublayer frame transmission. The function TransmitFrame implements the frame transmission operation provided to the MAC client.

The TransmitFrame operation is synchronous. Its duration is the entire attempt to transmit the frame; when the operation completes, transmission has either succeeded or failed, as indicated by the TransmitStatus status code.

The transmitDisabled status code indicates that the transmitter is not enabled. Successful transmission is indicated by the status code transmitOK. The codes excessiveCollisionError and lateCollisionErrorStatus are artifacts of the CSMA/CD MAC and maintained here for historical purposes. These codes are never generated by this full duplex MAC. TransmitStatus is not used by the service interface defined in 2.3.1. TransmitStatus may be used in an implementation dependent manner.

```
function TransmitFrame (
    destinationParam: AddressValue;
    sourceParam: AddressValue;
    lengthOrTypeParam: LengthOrTypeValue;
    dataParam: DataValue;
    fcsParamValue: CRCValue;
    fcsParamPresent: Bit): TransmitStatus;
procedure TransmitDataEncap; {Nested procedure; see body below}
begin
    if transmitEnabled then
        begin
            TransmitDataEncap;
            TransmitFrame := TransmitLinkMgmt
        end
    else TransmitFrame := transmitDisabled
end; {TransmitFrame}
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If transmission is enabled, TransmitFrame calls the internal procedure TransmitDataEncap to construct the frame. Next, TransmitLinkMgmt is called to perform the actual transmission. The TransmitStatus returned indicates the success or failure of the transmission attempt.

TransmitDataEncap builds the frame and places the 32-bit CRC in the frame check sequence field:

```
procedure TransmitDataEncap;
begin
   with outgoingFrame do
      begin {Assemble frame}
         view := fields;
         destinationField := destinationParam;
         sourceField := sourceParam;
         lengthOrTypeField := lengthOrTypeParam;
         if fcsParamPresent then
            begin
               dataField := dataParam; {No need to generate pad if the FCS is passed from MAC client}
               fcsField := fcsParamValue {Use the FCS passed from MAC client}
            end
         else
            begin
               dataField := ComputePad(dataParam);
               fcsField := CRC32(outgoingFrame)
            end;
         view := bits
      end {Assemble frame}
   with outgoingHeader do
      begin
         headerView := headerFields;
         preamble := ...; {* '1010...10,' LSB to MSB*}
         sfd := ...; {* '10101011,' LSB to MSB*}
         headerView := headerBits
      end
end; {TransmitDataEncap}
```

If the MAC client chooses to generate the frame check sequence field for the frame, it passes this field to the MAC sublayer via the fcsParamValue parameter. If the fcsParamPresent parameter is true, TransmitDataEncap uses the fcsParamValue parameter as the frame check sequence field for the frame. Such a frame shall not require any padding, since it is the responsibility of the MAC client to ensure that the frame meets the minFrameSize constraint. If the fcsParamPresent parameter is false, the fcsParamValue parameter is unspecified. TransmitDataEncap first calls the ComputePad function, followed by a call to the CRC32 function to generate the padding (if necessary) and the frame check sequence field for the frame internally to the MAC sublayer.

ComputePad appends an array of arbitrary bits to the MAC client data to pad the frame to the minimum frame size:

```
function ComputePad(var dataParam: DataValue): DataValue;
begin
   ComputePad := {Append an array of size padSize of arbitrary bits to the MAC client dataField}
end; {ComputePad}
```

TransmitLinkMgmt attempts to transmit the frame. When deferenceMode is true, it first defers to the Physical Layer if it is not ready for the next packet and to ensure proper interframe spacing. When deferenceMode is false, it begins transmitting immediately:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
function TransmitLinkMgmt: TransmitStatus;
begin
   while deferring do nothing {Defer to Physical Layer congestion and IFS}
   StartTransmit;
   while transmitting do nothing
   LayerMgmtTransmitCounters; {Update transmit and transmit error counters in 5.2.4.2}
   TransmitLinkMgmt := transmitOK
end; {TransmitLinkMgmt}
```

Each time a frame transmission attempt is initiated, StartTransmit is called to alert the BitTransmitter process that bit transmission should begin:

```
procedure StartTransmit;
begin
   currentTransmitBit := 1;
   lastTransmitBit := frameSize;
   lastHeaderBit:= headerSize;
   transmitting := true
end; {StartTransmit}
```

The Deference process runs asynchronously to continuously compute the proper value for the variable deferring:

```
process Deference;
begin
   cycle {Main loop}
      while (not transmitting and not (carrierSenseMode and carrierSense)) do nothing; {Wait for the start
                                                                                          of transmission or congestion}
      deferring := true; {Inhibit future transmissions}
      while (transmitting or (carrierSenseMode and carrierSense)) do nothing; {Wait for the end of
                                                                                transmission and congestion}
      if deferenceMode then Wait(interPacketGap);
            {Time out entire interpacket gap if enabled}
      deferring := false {Don't inhibit transmission}
   end {Main loop}
end; {Deference}
```

The BitTransmitter process runs asynchronously, transmitting bits at a rate determined by the Physical Layer's TransmitBit operation:

```
process BitTransmitter;
begin
   cycle {Outer loop}
      if transmitting then
         begin {Inner loop}
            while (currentTransmitBit ≤ lastHeaderBit) do
               begin
                  TransmitBit(outgoingHeader[currentTransmitBit]);
                  currentTransmitBit := currentTransmitBit + 1
               end;
            currentTransmitBit := 1;
            while transmitting do
               begin
                  TransmitBit(outgoingFrame[currentTransmitBit]);
                  currentTransmitBit := currentTransmitBit + 1;
                  transmitting := (currentTransmitBit ≤ lastTransmitBit)
               end
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
            end {Inner loop}
        end {Outer loop}
    end; {BitTransmitter}
```

4A.2.9 Frame reception

The algorithms in this subclause define the MAC sublayer frame reception.

The function ReceiveFrame implements the frame reception operation provided to the MAC client.

The ReceiveFrame operation is synchronous. The operation does not complete until a frame has been received. The fields of the frame are delivered via the output parameters with the ReceiveStatus status code.

The receiveDisabled status indicates that the receiver is not enabled. Successful reception is indicated by the status code receiveOK. The frameTooLong error indicates that the last frame received had a frameSize beyond the maximum allowable frame size. The code frameCheckError indicates that the frame received was damaged by a transmission error. The lengthError indicates that the lengthOrTypeParam value was both consistent with a length interpretation of this field (i.e., its value was less than or equal to maxValidFrame), and inconsistent with the frameSize of the received frame. The code alignmentError indicates that the frame received was damaged, and that in addition, its length was not an integer number of octets. ReceiveStatus is not mapped to any MAC client parameter by the service interface defined in 2.3.2. ReceiveStatus may be used in an implementation dependent manner.

```
    function ReceiveFrame (
        var destinationParam: AddressValue;
        var sourceParam: AddressValue;
        var lengthOrTypeParam: LengthOrTypeValue;
        var dataParam: DataValue;
        var fcsParamValue: CRCValue;
        var fcsParamPresent: Bit): ReceiveStatus;

    function ReceiveDataDecap: ReceiveStatus; {Nested function; see body below}
    begin
        if receiveEnabled then
            repeat
                ReceiveLinkMgmt;
                ReceiveFrame := ReceiveDataDecap;
            until receiveSucceeding
        else ReceiveFrame := receiveDisabled
    end; {ReceiveFrame}
```

If enabled, ReceiveFrame calls ReceiveLinkMgmt to receive the next valid frame, and then calls the internal function ReceiveDataDecap to return the frame's fields to the MAC client if the frame's address indicates that it should do so. The returned ReceiveStatus indicates the presence or absence of detected transmission errors in the frame.

```
    function ReceiveDataDecap: ReceiveStatus;
        var status: ReceiveStatus; {Holds receive status information}
    begin
        with incomingFrame do
            begin
                view := fields;
                receiveSucceeding := LayerMgmtRecognizeAddress(destinationField);
                if receiveSucceeding then
```

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
            begin {Disassemble MAC frame}
               destinationParam := destinationField;
               sourceParam := sourceField;
               lengthOrTypeParam := lengthOrTypeField;
               dataParam := RemovePad(lengthOrTypeField, dataField);
               fcsParamValue := fcsField;
               fcsParamPresent := passReceiveFCSMode;
               exceedsMaxLength := ...; {Check to determine if received MAC frame size exceeds
                                         maxFrameSizeLimit.
                                         MAC implementations use maxFrameSizeLimit to
                                         determine if management counts the frame as too long.
                                         It is recommended that new implementations support
                                         maxFrameSizeLimit = maxEnvelopeFrameSize )
               if exceedsMaxLength then status := frameTooLong
               else if fcsField = CRC32(incomingFrame) then
                     if validLength then status := receiveOK else status := lengthError
               else if excessBits = 0 then status := frameCheckError
               else status := alignmentError;
               LayerMgmtReceiveCounters(status); {Update receive counters in 5.2.4.3}
               view := bits
            end {Disassemble MAC frame}
         end; {With incomingFrame}
      ReceiveDataDecap := status
   end; {ReceiveDataDecap}

   function LayerMgmtRecognizeAddress(address: AddressValue): Boolean;
   begin
      if {promiscuous receive enabled} then LayerMgmtRecognizeAddress := true;
      else if address = ... {MAC station address} then LayerMgmtRecognizeAddress := true;
      else if address = ... {Broadcast address} then LayerMgmtRecognizeAddress := true;
      else if address = ... {One of the addresses on the multicast list and multicast reception is enabled} then
                                                                  LayerMgmtRecognizeAddress := true;
      else LayerMgmtRecognizeAddress := false
   end; {LayerMgmtRecognizeAddress}
```

The function RemovePad strips any padding that was generated to meet the minFrameSize constraint, if possible. When the MAC sublayer operates in the mode that enables passing of the frame check sequence field of all received MAC frames to the MAC client (passReceiveFCSMode variable is true), it shall not strip the padding and it shall leave the data field of the MAC frame intact. Length checking is provided for Length interpretations of the Length/Type field. For Length/Type field values in the range between maxBasicDataSize and minTypeValue the behavior of the RemovePad function is unspecified:

```
   function RemovePad(var lengthOrTypeParam: LengthOrTypeValue; dataParam: DataValue): DataValue;
   begin
      if lengthOrTypeParam ≥ minTypeValue then
         begin
            validLength := true; {Don't perform length checking for Type interpretation}
            RemovePad := dataParam
         end
      else if lengthOrTypeParam ≤ maxBasicDataSize then
         begin
            validLength := {For length interpretations of the Length/Type field, check to determine if value
                              represented by Length/Type field matches the received clientDataSize};
            if validLength and not passReceiveFCSMode then
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
            RemovePad := {Truncate the dataParam (when present) to the value represented by the
                          lengthOrTypeParam (in octets) and return the result}
        else RemovePad := dataParam
      end
end; {RemovePad}
```

ReceiveLinkMgmt attempts repeatedly to receive the bits of a frame, discarding any fragments smaller than the minimum valid frame size:

```
procedure ReceiveLinkMgmt;
begin
  repeat
    StartReceive;
    while receiving do nothing; {Wait for frame to finish arriving}
    excessBits := frameSize mod 8;
    frameSize := frameSize – excessBits; {Truncate to octet boundary}
    receiveSucceeding := (frameSize ≥ minFrameSize) {Reject frames too small}
  until receiveSucceeding
end; {ReceiveLinkMgmt}

procedure StartReceive;
begin
  receiving := true
end; {StartReceive}
```

The BitReceiver process runs asynchronously, receiving bits from the medium at the rate determined by the Physical Layer's ReceiveBit operation, partitioning them into frames, and optionally receiving them:

```
process BitReceiver;
  var   b: Bit;
        currentReceiveBit: 1..frameSize; {Position of current bit in incomingFrame}
begin
  cycle {Outer loop}
    if receiveEnabled then
      begin {Receive next frame from Physical Layer}
        currentReceiveBit := 1;
        PhysicalSignalDecap; {Skip idle, strip off preamble and sfd}
        while receiveDataValid do
          begin {Inner loop to receive the rest of an incoming frame}
            b := ReceiveBit; {Next bit from physical medium}
            if receiving then {Append to frame}
            begin
              incomingFrame[currentReceiveBit] := b;
              currentReceiveBit := currentReceiveBit + 1
            end; {append bit to frame}
            receiving := receiveDataValid
          end; {Inner loop}
        frameSize := currentReceiveBit – 1
      end {Enabled}
  end {Outer loop}
end; {BitReceiver}

procedure PhysicalSignalDecap;
begin
  {Receive one bit at a time from physical medium until a valid sfd is detected, discard bits and return}
end; {PhysicalSignalDecap}
```

4A.2.10 Common procedures

The function CRC32 is used by both the transmit and receive algorithms to generate a 32-bit CRC value:

```
function CRC32(f: Frame): CRCValue;
begin
    CRC32 := {The 32-bit CRC for the entire frame as defined in 3.2.9, excluding the FCS field (if
             present)}
end; {CRC32}
```

Purely to enhance readability, the following procedure is also defined:

procedure nothing; *begin end*;

The idle state of a process (that is, while waiting for some event) is cast as repeated calls on this procedure.

4A.3 Interfaces to/from adjacent layers

4A.3.1 Overview

The purpose of this clause is to provide precise definitions of the interfaces between the architectural layers defined in Clause 1 in compliance with the Media Access Service Specification given in Clause 2. In addition, the services required from the physical medium are defined.

The notation used here is the Pascal language, in keeping with the procedural nature of the precise MAC sublayer specification (see 4A.2). Each interface is described as a set of procedures or shared variables, or both, that collectively provide the only valid interactions between layers. The accompanying text describes the meaning of each procedure or variable and points out any implicit interactions among them.

The description of the interfaces in Pascal is a notational technique, and in no way implies that they can or should be implemented in software. This point is discussed more fully in 4A.2, that provides complete Pascal declarations for the data types used in the remainder of this clause. The synchronous (one frame at a time) nature of the frame transmission and reception operations is a property of the architectural interface between the MAC client and MAC sublayers, and need not be reflected in the implementation interface between a station and its sublayer.

4A.3.2 MAC service

The services provided to the MAC client by the MAC sublayer are transmission and reception of MAC frames using service primitives MA_DATA.request and MA_DATA.indication, as defined in Clause 2. For historical reasons the MAC sublayer definitions use two functions, TransmitFrame and ReceiveFrame, defined in 4A.2.8 and 4A.2.9. The relationship between these two functions and the service primitives is defined by the MAC client state diagrams in 4A.3.2.1 and 4A.3.2.2.

The state machines in 4A.3.2 follow the conventions in 21.5.

4A.3.2.1 MAC client transmit interface state diagram

4A.3.2.1.1 Variables

data
: The value of mac_service_data_unit excluding the first two octets (Length/Type field).

destination_address
: The Destination Address field parsed from the client request.

fcsPresent
: Indicates whether the MA_DATA.request service primitive contained the frame_check_sequence field.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

frame_check_sequence
: The fcs field parsed from the client request.

lengthOrType
: The value of the first two octets at the start of the mac_service_data_unit.

mac_service_data_unit
: The concatenation of the lengthOrType field and the data field parsed from the client request.

source_address
: The Source Address field parsed from the client request

TransmitStatus
: Indicates the status of the transmitted MAC frame. See 4.2.8.

4A.3.2.1.2 Functions

TransmitFrame
: The MAC sublayer function invoked to transmit a MAC frame with the specified parameters. See 4A.2.8.

4A.3.2.1.3 Messages

MA_DATA.request
: The service primitive used to convey a MAC frame to be transmitted from the MAC client. See 2.3.1. The action invoked is not considered to end until the transmission of the frame by the MAC has concluded.

4A.3.2.1.4 MAC client transmit interface state diagram

4A.3.2.2 MAC client receive interface state diagram

4A.3.2.2.1 Variables

destination_address
: The Destination Address field parsed from the received MAC frame.

source_address
: The Source Address field parsed from the received MAC frame.

lengthOrType
: The lengthOrType field parsed from the received MAC frame.

data
: The data payload field parsed from the received MAC frame.

fcsPresent
: A Boolean set by the MAC sublayer.

ReceiveStatus
: Indicates the status of the received MAC frame.

mac_service_data_unit
: The concatenation of the lengthOrType field and the data field parsed from the received MAC frame.

frame_check_sequence
: The fcs field parsed from the received MAC frame.

4A.3.2.2.2 Functions

ReceiveFrame
: The MAC sublayer function invoked to accept an incoming MAC frame with the specified parameters. See 4A.2.9.

4A.3.2.2.3 Messages

MA_DATA.indication
: The service primitive used to transfer an incoming MAC frame to the MAC client with the specified parameters. See 2.3.2.

4A.3.2.2.4 MAC client receive interface state diagram

Figure 4A–4 specifies the behavior of the receive interface to the MAC client.

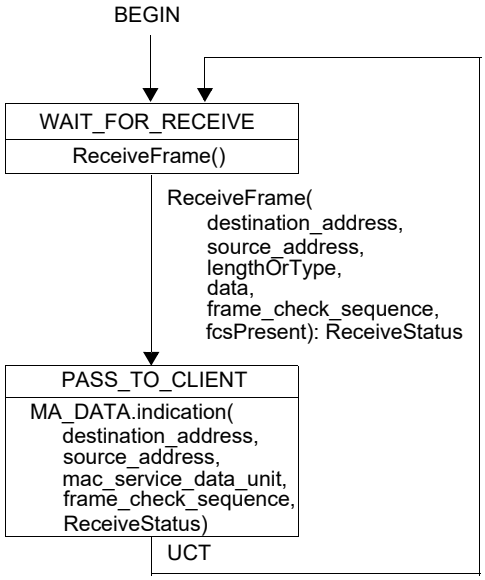

Figure 4A–4—MAC client receive interface state diagram

4A.3.3 Services required from the Physical Layer

The interface through which the MAC sublayer uses the facilities of the Physical Layer consists of a function, a pair of procedures and four Boolean variables as described in Table 4A–1.

Table 4A–1—Full duplex MAC functions, procedures and variables

Function	Procedures	Variables
ReceiveBit	**TransmitBit**	**collisionDetect**
	Wait	**carrierSense**
		receiveDataValid
		transmitting

During transmission, the contents of an outgoing frame are passed from the MAC sublayer to the Physical Layer by way of repeated use of the TransmitBit operation:

procedure TransmitBit (bitParam: Bit);

Each invocation of TransmitBit passes one new bit of the outgoing frame to the Physical Layer. The TransmitBit operation is synchronous. The duration of the operation is the entire transmission of the bit. The operation completes when the Physical Layer is ready to accept the next bit and it transfers control to the MAC sublayer.

The overall event of data being transmitted is signaled to the Physical Layer by way of the variable transmitting:

var transmitting: Boolean*;*

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Before sending the first bit of a frame, the MAC sublayer sets transmitting to true, to inform the Physical Layer that a stream of bits will be presented via the TransmitBit operation. After the last bit of the frame has been presented, the MAC sublayer sets transmitting to false to indicate the end of the frame.

The collisionDetect variable is not used by this full duplex MAC but maintained as an artifact of the CSMA/CD MAC's interface to the Physical Layer.

var collisionDetect: Boolean*;*

During reception, the contents of an incoming frame are retrieved from the Physical Layer by the MAC sublayer via repeated use of the ReceiveBit operation:

function ReceiveBit: Bit;

Each invocation of ReceiveBit retrieves one new bit of the incoming frame from the Physical Layer. The ReceiveBit operation is synchronous. Its duration is the entire reception of a single bit. Upon receiving a bit, the MAC sublayer shall immediately request the next bit until all bits of the frame have been received (see 4A.2 for details).

The overall event of data being received is signaled to the MAC sublayer by the variable receiveDataValid:

var receiveDataValid: Boolean*;*

When the Physical Layer sets receiveDataValid to true, the MAC sublayer shall immediately begin retrieving the incoming bits by the ReceiveBit operation. When receiveDataValid subsequently becomes false, the MAC sublayer can begin processing the received bits as a completed frame. If an invocation of ReceiveBit is pending when receiveDataValid becomes false, ReceiveBit returns an undefined value, which should be discarded by the MAC sublayer (see 4A.2 for details).

The overall event of congestion at the Physical Layer, indicating that the Physical Layer is not ready to accept the next packet, is signaled to the MAC sublayer by the variable carrierSense:

var carrierSense: Boolean*;*

When the value of variable carrierSenseMode is set to TRUE, the MAC sublayer shall monitor the value of carrierSense to defer its own transmissions when the Physical Layer is busy. The Physical Layer sets carrierSense to true immediately upon congestion within the Physical Layer. After the congestion ceases, carrierSense is set to false. When the value of variable carrierSenseMode is set to FALSE, the carrierSense variable is ignored by the MAC.

While the label carrierSense does not accurately describe the condition presented by this variable, the name is maintained as an artifact of the CSMA/CD MAC interface to the Physical Layer.

The Physical Layer also provides the procedure Wait:

procedure Wait (bitTimes: integer)*;*

This procedure waits for the specified number of bit times. This allows the MAC sublayer to measure time intervals in units of the (physical-medium-dependent) bit time.

4A.4 Specific implementations

4A.4.1 Compatibility overview

To provide total compatibility at all levels of the standard, it is required that each network component implementing the MAC sublayer procedure adheres rigidly to these specifications. The information provided in 4A.4.2 provides design parameters for specific implementations of this access method. Variations from these values result in a system implementation that violates the standard. See the warning in 4A.4.2.

4A.4.2 MAC parameters

The parameter values shown in Table 4A–2 shall be used.

Table 4A–2—Full duplex MAC parameter values

Parameters	Values
interPacketGap	96 bits
maxBasicFrameSize	1518 octets
maxEnvelopeFrameSize	2000 octets
minFrameSize	512 bits (64 octets)

The minimum interPacketGap shall be enforced in this sublayer, when the deferenceMode variable is set to TRUE, or outside this sublayer, when the deferenceMode variable is set to FALSE.

NOTE 1—For 10 Mb/s operation, the spacing between two successive non-colliding packets, from start of idle at the end of the first packet to start of Preamble of the subsequent packet, can have a minimum value of 47 BT (bit times), at the AUI receive line of the DTE. This interpacket gap shrinkage is caused by variable network delays, added preamble bits, and clock skew.

NOTE 2—For 1 Gb/s operation, the spacing between two non-colliding packets, from the last bit of the FCS field of the first packet to the first bit of the Preamble of the second packet, can have a minimum value of 64 BT (bit times), as measured at the GMII receive signals at the DTE. This interpacket gap shrinkage may be caused by variable network delays, added preamble bits, and clock tolerances.

NOTE 3—For 10 Gb/s and 25 Gb/s operation, the spacing between two packets, from the last bit of the FCS field of the first packet to the first bit of the Preamble of the second packet, can have a minimum value of 40 BT (bit times), as measured at the XGMII or 25GMII receive signals at the DTE. This interpacket gap shrinkage may be caused by variable network delays and clock tolerances.

NOTE 4—For 40 Gb/s, 50 Gb/s, 100 Gb/s, 200 Gb/s, and 400 Gb/s operation, the received interpacket gap (the spacing between two packets, from the last bit of the FCS field of the first packet to the first bit of the Preamble of the second packet) can have a minimum value of 8 BT (bit times), as measured at the XLGMII, 50GMII, CGMII, 200GMII, or 400GMII receive signals at the DTE due to clock tolerance and lane alignment requirements.

WARNING

Any deviation from the above specified values may affect proper operation of the network.

NOTE—The remaining annexes in the standard are numbered in correspondence to their associated clauses; e.g., Annexes 22A, 22B, 22C, and 22D correspond to Clause 22.

Annex 22A

(informative)

MII output delay, setup, and hold time budget

22A.1 System model

The discussion of signal timing characteristics that follows will refer to the system model depicted in Figure 22A–1, Figure 22A–2, and Figure 22A–3. This system model can be applied to each of the three application environments defined in 22.2.1.

Figure 22A–1 depicts a simple system model in which the MII is used to interconnect two integrated circuits on the same circuit assembly. In this model the Reconciliation sublayer comprises one integrated circuit, and the PHY comprises the other. A Reconciliation sublayer or a PHY may actually be composed of several separate integrated circuits. The system model in Figure 22A–1 includes two unidirectional signal transmission paths, one from the Reconciliation sublayer to the PHY and one from the PHY to the Reconciliation sublayer. The path from the Reconciliation sublayer to the PHY is separated into two sections, labeled A1 and B1. The path from the PHY to the Reconciliation sublayer is separated into two sections, labeled C1 and D1.

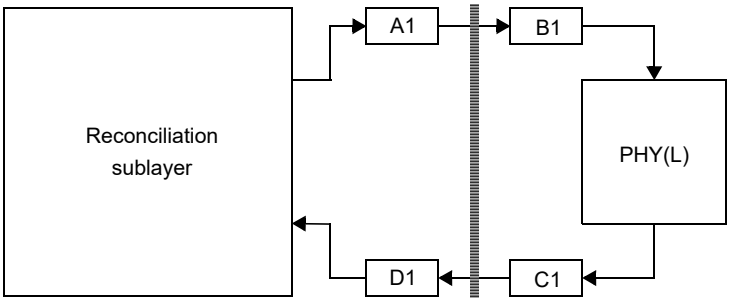

Figure 22A–1—Model for integrated circuit to integrated circuit connection

Figure 22A–2 depicts a system model for the case where the MII is used to interconnect two circuit assemblies. The circuit assemblies may be physically connected in a motherboard/daughterboard arrangement, or they may be physically connected with the cable defined in 22.4.5 and the line interface connector defined in 22.6. The system model in Figure 22A–2 includes two unidirectional signal transmission paths, one from the Reconciliation sublayer to the PHY and one from the PHY to the Reconciliation sublayer. The path from the Reconciliation sublayer to the PHY is separated into two sections, labeled A2 and B2. The path from the PHY to the Reconciliation sublayer is separated into two sections, labeled C2 and D2.

Figure 22A–3 depicts a system model in which the MII is used to interconnect both integrated circuits and circuit assemblies. This system model allows for separate signal transmission paths to exist between the Reconciliation sublayer and a local PHY(L), and between the Reconciliation sublayer and a remote PHY(R). The unidirectional paths between the Reconciliation sublayer and the PHY(L) are composed of sections A1,

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

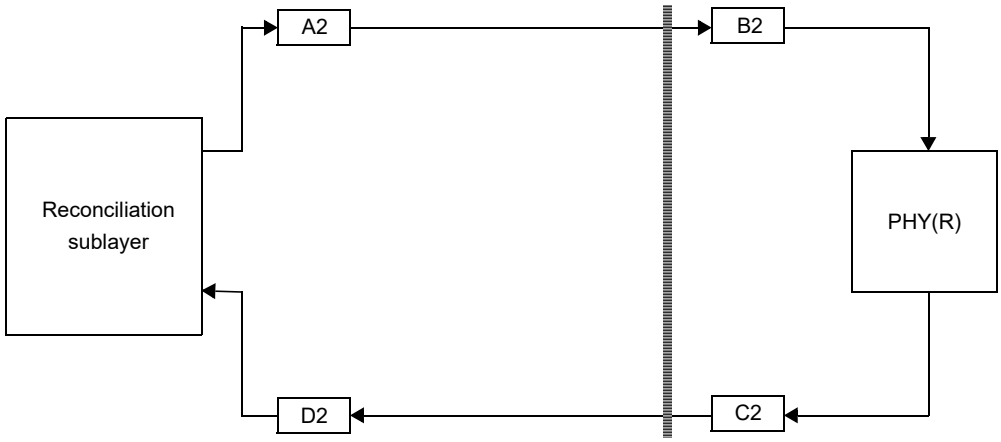

Figure 22A–2—Model for circuit assembly to circuit assembly connection

B1, C1, and D1. The unidirectional paths between the Reconciliation sublayer and the remote PHY(R) are composed of sections A2, B2, C2, and D2.

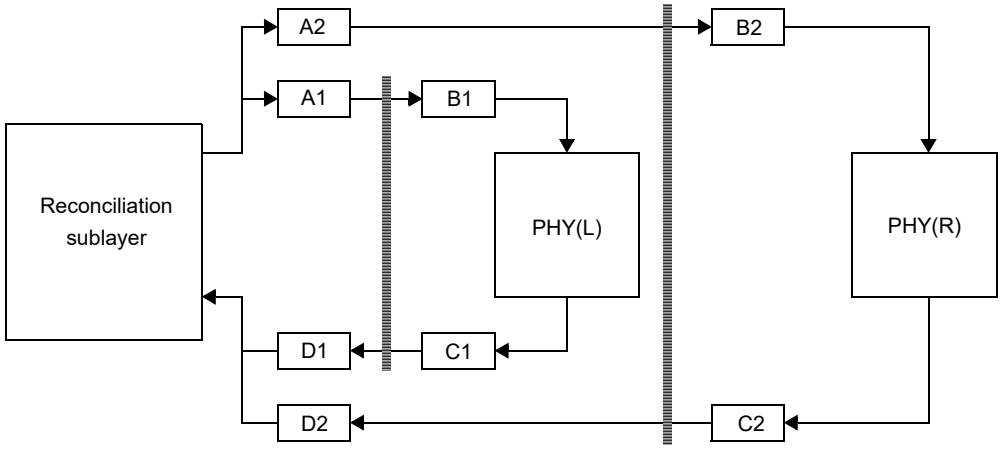

Figure 22A–3—Combined model

Each of these system models assumes a set of common timing and electrical characteristics that shall be met at the input and output ports of the Reconciliation sublayer and PHY devices. The characteristics of the signal transmission paths are identified for each of the sections A1, B1, C1, D1, A2, B2, C2, and D2.

22A.2 Signal transmission path characteristics

The signal transmission path characteristics are specified for each of the path sections defined in 22A.1. The characteristics for these sections are specified so as to allow sections A1, B1, C1, and D1 to be implemented in the form of printed circuit board traces, while sections A2, B2, C2, and D2 may be implemented with a combination of printed circuit board traces and wire conductors in a cable assembly.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The signal transmission path characteristics are stated in terms of their maximum delay and their characteristic impedance. These values are summarized in Table 22A–1.

Table 22A–1—Signal transmission path characteristics

Section	Maximum delay (ns)	Impedance (Ω)
A1, D1	5	68 ± 15%
B1, C1	2.5	68 ± 15%
A2, D2	5	68 ± 10%
B2, C2	2.5	68 ± 10%

The driver characteristics specified in 22.4.3, the receiver characteristics specified in 22.4.4, and the signal transmission path characteristics specified in Table 22A–1 can be applied to the system models shown in Figure 22A–1 or Figure 22A–2. The combination of loads presented in Figure 22A–3 cannot be adequately driven by an output buffer that meets the driver characteristics specified in 22.4.3 while being sampled by an input buffer that meets the receiver characteristics specified in 22.4.4.

To address the system model depicted in Figure 22A–3, it is permissible to incorporate an additional stage of buffering into path sections A1, A2, D1, and D2, provided that the resulting maximum delay characteristic for those path sections does not exceed the value stated in Table 22A–1. The delay characteristic for transmission path sections A2 and D2 includes an allowance for the delay that results from the presence of a lumped capacitive load at the end of the path. For a transmission path section with a characteristic impedance Z_o, with a lumped capacitive load C_L, this delay is nominally Z_oC_L. In the case of a maximum transmission path section impedance of 78 Ω with a lumped load of 8 pF, the nominal delay is 0.6 ns. Thus the allowable delay for a buffer inserted into transmission path section A2 or D2 is 4.4 ns.

22A.3 Budget calculation

A recommended timing budget is shown in Table 22A–2. This budget assumes that the combined system model shown in Figure 22A–3 represents a worst case.

Table 22A–2—Round-trip delay budget

Description	Incremental delay (ns)	Cumulative delay (ns)
TX_CLK output at PHY(R)	0.0	0.0
Transmission path section C2	2.5	2.5
Transmission path section D2	5.0	7.5
Clock to output in Reconciliation sublayer	15.0	22.5

Annex 22B

(informative)

MII driver ac characteristics

22B.1 Implications of CMOS ASIC processes

For MII drivers that drive rail to rail, such as those commonly used in CMOS ASICs (complimentary metal oxide semiconductor application-specific integrated circuits), the ac characteristic performance requirements of 22.4.3.2 can be met if the V_{oh} vs. I_{oh} and V_{ol} vs. I_{ol} dc characteristics of the driver stay within the unshaded areas of Figure 22B–1.

The variation in output resistance of a field effect transistor (FET) due to variations in supply voltage, temperature, and process may require that a resistance be placed in series with the output of the FETs to meet this specification. The series resistance can be part of the driver circuit, or external to the driver. If the series resistance is not part of the driver circuit, the driver vendor shall specify the value of series resistance required to meet the specification. A series resistor used to meet this specification is conceptually part of the driver regardless of whether it is physically internal or external to the driver.

The propagation delay of the path between the driver and an external series resistor used to meet the specification shall not exceed 10% of the 10–90% rise/fall time of the driver.

22B.2 $R_{o(min)}$ and V, I values for operation from 5 V ± 10% supply

Referring to Figure 22B–1, $R_{oh(min)}$ and $R_{ol(min)}$ both equal 40 Ω, and the values for the V-I points on the curve are given in Table 22B–1 for MII drivers that drive rail to rail from a +5 V ± 10% power supply.

Table 22B–1—Values for driver output V-I curve (5 V supply)

V–I point	I (mA)	V (V)
I_1, V_1	–20	1.10
I_2, V_2	–4	2.4
I_3, V_3	4	0.40
I_4, V_4	43	3.05

22B.3 $R_{o(min)}$ and V, I values for operation from 3.3 V ± 0.3 V supply

Referring to Figure 22B–1, $R_{oh(min)}$ and $R_{ol(min)}$ both equal 33 Ω, and the values for the V–I points on the curve are given in Table 22B–2 for MII drivers that drive rail to rail from a +3.3 V ± 0.3 V power supply.

Table 22B–2—Values for driver output V-I curve (3.3 V supply)

V-I point	I (mA)	V (V)
I_1,V_1	–20	1.10
I_2,V_2	–4	2.4
I_3,V_3	4	0.40
I_4,V_4	26	2.10

Annex 22C

(informative)

Measurement techniques for MII signal timing characteristics

22C.1 Measuring timing characteristics of source terminated signals

The measurement of timing relationships between MII signals at the MII connector is complicated by the use of driver output impedance to control transmission line reflections on point-to-point transmission paths passing through the connector. The voltage waveforms on point-to-point transmission paths can be different at the MII connector and at the end of the paths. A clean transition (or step) from one logic state to the other at the end of a point to point path can appear as two half-steps at the MII connector.

To eliminate ambiguity as to where on a two half-step state transition to measure timing, all timing measurements on point-to-point transmission paths will be at the end of the path. In some cases, an end of path has to be artificially created.

22C.2 Measuring timing characteristics of transmit signals at the MII

The timing of TX_EN, TX_ER, and TXD<3:0> relative to TX_CLK at the MII connector is measured as follows.

Use the time base for TX_CLK as a timing reference. Break the TX_CLK path at the MII connector, forcing the TX_CLK point-to-point transmission path to end at the connector. Measure when the rising edge of TX_CLK passes through $V_{ih(min)}$ at the MII connector. Call this time T_{clk}. Reconnect the TX_CLK path at the MII connector and break the paths of TX_EN, TX_ER, and TXD<3:0> at the MII connector, forcing the paths to end at the connector. Measure when TX_EN, TX_ER, and TXD<3:0> exit the switching region at the MII connector. Call these times T_{en}, T_{er}, and $T_{<3:0>}$, respectively.

The timing relationships at the MII connector for TX_EN, TX_ER, and TXD<3:0> relative to TX_CLK are met if ($T_{en} - T_{clk}$), ($T_{er} - T_{clk}$), ($T_3 - T_{clk}$), ($T_2 - T_{clk}$), ($T_1 - T_{clk}$), and ($T_0 - T_{clk}$), respectively, meet the timing relationships specified in 22.3.1.

22C.3 Measuring timing characteristics of receive signals at the MII

The timing of RX_DV, RX_ER, and RXD<3:0> relative to RX_CLK at the MII connector is measured as follows.

Break the paths of RX_CLK, RX_DV, RX_ER, and RXD<3:0> at the MII connector, forcing the paths to end at the connector. Measure when RX_DV, RX_ER, and RXD<3:0> exit the switching region at the MII connector relative to when the rising edge of RX_CLK passes through $V_{il(max)}$). Also measure when RX_DV, RX_ER, and RXD<3:0> reenter the switching region relative to when the rising edge of RX_CLK passes through $V_{ih(min)}$.

The timing relationships at the MII connector for RX_DV, RX_ER, and RXD<3:0> relative to RX_CLK are met if the times measured in the previous step meet the timing relationships specified in 22.3.2.

22C.4 Measuring timing characteristics of MDIO

The MDIO and MDC signal timing characteristics cannot be measured using the techniques defined for the transmit and receive signals since MDIO and MDC may connect a single station management entity to multiple PHY devices. The MDIO and MDC timing characteristics are measured with a PHY connected to the MII connector. The signal timing characteristics for MDC and MDIO have to be met over the range of conditions which occur when from one to 32 PHYs are connected to an STA. When 32 PHYs are connected to an STA, the total capacitance can be as large as 390 pF on MDC, and as large as 470 pF on MDIO.

Annex 22D

(informative)

Clause 22 access to Clause 45 MMD registers

Clause 22 provides access to registers in a Clause 45 MMD using registers 13 and 14. This informative annex provides users with some insight how these registers can be utilized to access Clause 45 MMD registers. Accesses to registers 13 and 14, for the purpose of accessing registers in a Clause 45 MMD, should be performed atomically to avoid the chance of another process changing the Function, DEVAD or address fields within the MMD. This is the same requirement of Clause 45 accesses.

22D.1 Write operation

To write a Clause 45 register using the Clause 22 access mechanism, perform the following accesses using the appropriate PHY address for the PHY of interest:

a) To register 13, write the Function field to 00 (address) and DEVAD field to the device address value for the desired MMD;
b) To register 14, write the desired address value to the MMD's address register;
c) To register 13, write the Function field to 01 (Data, no post increment) and DEVAD field to the same device address value for the desired MMD;
d) To register 14, write the content of the MMD's selected register.

Step a) and Step b) can be skipped if the MMD's address register was previously configured.

22D.2 Read operation

To read a Clause 45 register using the Clause 22 access mechanism, perform the following accesses using the appropriate PHY address for the PHY of interest:

a) To register 13, write the Function field to 00 (address) and DEVAD field to the device address value for the desired MMD;
b) To register 14, write the desired address value to the MMD's address register;
c) To register 13, write the Function field to 01 (Data, no post increment) and DEVAD field to the same device address value for the desired MMD;
d) From register 14, read the content of the MMD's selected register.

Step a) and Step b) can be skipped if the MMD's address register was previously configured.

22D.3 MMD address operations

22D.3.1 Address

While the Function field contains the value 00 (address):

a) subsequent writes to register 14 continue to rewrite MMD DEVAD's address register;
b) subsequent reads from register 14 continue to reread MMD DEVAD's address register.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

22D.3.2 Data, no post increment

While the Function field contains the value 01 (Data, no post increment):

a) subsequent writes to register 14 continue to rewrite the data register selected by the value in MMD DEVAD's address register;
b) subsequent reads from register 14 continue to reread the data register selected by the value in MMD DEVAD's address register.

22D.3.3 Data, post increment on reads and writes

While the Function field contains the value 10 (Data, post increment on reads and writes):

a) subsequent writes to register 14 write the next higher addressed data register selected by the value in MMD DEVAD's address register, i.e. MMD DEVAD's address register is incremented after each access;
b) subsequent reads from register 14 read the next higher addressed data register selected by the value in MMD DEVAD's address register, i.e. MMD DEVAD's address register is incremented after each access.

22D.3.4 Data, post increment on writes only

While the Function field contains the value 11 (Data, post increment on writes only):

a) subsequent writes to register 14 write the next higher addressed data register selected by the value in MMD DEVAD's address register, i.e. MMD DEVAD's address register is incremented after each access;
b) subsequent reads from register 14 continue to reread the data register selected by the value in MMD DEVAD's address register.

This Function enables a read-modify-write capability for successively addressed registers within a MMD.

22D.4 PHY Coexistence and bus conflict avoidance

There are multiple levels of coexistence on the MDIO bus:

a) PHYs accessible via the Clause 22 access mechanism can coexist on the same bus using different PHY address values;
b) Ports accessible via the Clause 45 access mechanism can coexist on the same bus using different port address values;
c) PHYs accessible via the Clause 22 access mechanism can coexist on the same bus with ports accessible via the Clause 45 access mechanism, even with identical PHY/port address values due to the different ST (start of frame) encodings of the frame structures (see 45A.3 and 45A.4, which discuss the need for protocol aware voltage translators for this type of coexistence);
d) MMDs accessible via the Clause 45 access mechanism with the same port address can coexist on the same bus using different device address values.

Annex 23C

(informative)

Use of cabling systems with a nominal differential characteristic impedance of 120 Ω

The 100BASE-T4 standard specifies only the use of 100 Ω link segments for conformance. Since ISO/IEC 11801: 1995 also recognizes 120 Ω cabling, this informative annex specifies the conditions for using cabling systems with a nominal characteristic impedance of 120 Ω by 100BASE-T4 conformant stations.

The use of cables with a characteristic impedance outside the range specified in 23.6 will generally increase the mismatching effects in the link components, inducing additional noise in the received signals.

In particular, the use of a homogeneous link segment having a characteristic impedance of 120 Ω ±15 Ω over the frequency band 1 to 16 MHz may add up to 1.4% of additional noise to the signals at the input of the receivers (worst-case short-length link segment).

Therefore, in order to keep the overall noise (MDFEXT + reflections) at the same value as for a 100 Ω link segment when using a 120 Ω link segment, the minimum ELFEXT loss requirement for the cable has to be increased by 2 dB (i.e., from 23 dB to 25 dB at 12.5 MHz, see 23.6.3.2). Accordingly, the MDFEXT noise requirement shall be decreased from 87 mV peak to 69 mV peak. In practice, this means that cables rated category 4 or higher, as specified in ISO/IEC 11801: 1995, are required when 120 Ω cables are used with 100BASE-T4 compliant PMDs.

NOTE 1—The use of 100 Ω cords at end points in conjunction with 120 Ω premises cabling may be tolerated provided that all the components of the link are of Category 5, as defined in ISO/IEC 11801: 1995.

NOTE 2—The use of 100 Ω cords at any intermediate cross-connect points on 120 Ω links as well as the use of 120 Ω cords in conjunction with 100 Ω premises cabling is not allowed since it would result in worst-case jitter greater than that allowed in this standard.

CAUTION

Users of this annex are further advised to check with the manufacturer of the particular 100BASE-T4 couplers they intend to use with a 120 Ω link to see whether those couplers can operate correctly on cables with Z_c as high as 120 Ω ± 15 Ω.

Annex 27A

(normative)

Repeater delay consistency requirements

Proper operation of the network requires that repeaters do not cause the interpacket gap (IPG) to disappear by propagating the end of any carrier event to different output ports with greatly different delay times. Maximum port-to-port delays have been assigned as absolute delays to meet requirements for detection of collision within a slot time and limiting the length of collision fragments to less than minimum frame size. To avoid specification of minimum input-to-output propagation time as absolute values that reduce implementation flexibility, these delays are instead implied by imposing a triangular delay inequality relationship.

Consider three ports {A, B, C}. Using the notation SOP(xy) to mean the start-of-packet delay for an input at port x to resulting output on port y, repeaters shall achieve this relationship for all groups of three ports within a repeater set:

SOP(AC) < SOP(AB) + SOP(BC)

Following a frame transmitted by node A that propagates to nodes B and C, this constraint ensures that node B cannot complete an IPG timer and initiate a transmission that arrives at node C before node C has also advanced its own IPG timer sufficiently that a pending frame can contend for access to the network.

There is a second delay consistency requirement, one that relates to jam propagation by repeaters. Using a notation similar to that above, SOJ(xy) stands for the start-of-jam propagation delay from port x to port y and EOJ(xy) for the end-of-jam delay between same two ports.

To ensure proper detection of collisions and avoid generation of fragments that exceed minimum frame size, maximum values have been imposed on SOJ and EOJ delays through repeaters. No specific minima have been specified as all delays less than the maxima meet the collision detection and fragment length criteria. To prevent the jam pattern from shrinking excessively as it propagates through repeaters, repeaters shall meet this relationship between all pairs of ports:

EOJ(AB) >= SOJ(AB) – 4 bit times

Annex 28A

(normative)

Selector Field definitions

The Selector Field, S[4:0] in the link codeword, shall be used to identify the type of message being sent by Auto-Negotiation. The following table identifies the types of messages that may be sent. As new messages are developed, this table will be updated accordingly.

The Selector Field uses a 5-bit binary encoding, which allows 32 messages to be defined. All unspecified combinations are reserved. Reserved combinations shall not be transmitted.

Table 28A–1—Selector Field value mappings

S4	S3	S2	S1	S0	Selector description
0	0	0	0	0	Reserved for future Auto-Negotiation development
0	0	0	0	1	IEEE Std 802.3

Annex 28B

(normative)

IEEE 802.3 Selector Base Page definition

This annex provides the Technology Ability Field bit assignments, Priority Resolution table, and Message Page transmission conventions relative to the IEEE 802.3 Selector Field value within the Base Page encoding for devices using Clause 28 Auto-Negotiation.

As new IEEE 802.3 LAN technologies are developed, a reserved bit in the Technology Ability field may be assigned to each technology by the standards body.

The new technology will then be inserted into the Priority Resolution hierarchy and made a part of the Auto-Negotiation standard. The relative hierarchy of the existing technologies will not change, thus providing backward compatibility with existing Auto-Negotiation implementations.

It is important to note that the reserved bits are required to be transmitted as logic zeros. This guarantees that devices implemented using the current priority table will be forward compatible with future devices using an updated priority table.

28B.1 Selector field value

The value of the IEEE 802.3 Selector Field is S[4:0] = 00001.

28B.2 Technology Ability Field bit assignments

The Technology bit field consists of bits D5 through D11 (A0–A6, respectively) in the IEEE 802.3 Selector Base Page. Table 28B–1 summarizes the bit assignments.

Note that the order of the bits within the Technology Ability Field has no relationship to the relative priority of the technologies.

Setting Bit A5 or Bit A6 indicates that the DTE has implemented both the optional MAC control sublayer and the PAUSE function as specified in Clause 31 and Annex 31B. This capability is significant only when the link is configured for full duplex operation, regardless of data rate and medium. The encoding of Bits A5 and A6 is specified in Table 28B–2.

Table 28B–1—Technology Ability Field bit assignments

Bit	Technology	Minimum cabling requirement
A0	10BASE-T	Two-pair Category 3
A1	10BASE-T full duplex	Two-pair Category 3
A2	100BASE-TX	Two-pair Category 5
A3	100BASE-TX full duplex	Two-pair Category 5

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 28B–1—Technology Ability Field bit assignments

Bit	Technology	Minimum cabling requirement
A4	100BASE-T4	Four-pair Category 3
A5	PAUSE operation for full duplex links	Not applicable
A6	Asymmetric PAUSE operation for full duplex Links	Not applicable

Table 28B–2—Pause encoding

PAUSE (A5)	ASM_DIR (A6)	Capability
0	0	No PAUSE
0	1	Asymmetric PAUSE toward link partner
1	0	Symmetric PAUSE
1	1	Both Symmetric PAUSE and Asymmetric PAUSE toward local device

The PAUSE bit indicates that the device is capable of providing the symmetric PAUSE functions as defined in Annex 31B. The ASM_DIR bit indicates that asymmetric PAUSE is supported. The value of the PAUSE bit when the ASM_DIR bit is set indicates the direction the PAUSE frames are supported for flow across the link. Asymmetric PAUSE configuration results in independent enabling of the PAUSE receive and PAUSE transmit functions as defined by Annex 31B. See 28B.3 regarding PAUSE configuration resolution.

28B.3 Priority resolution

Since two devices may have multiple abilities in common, a prioritization scheme exists to ensure that the highest common denominator ability is chosen. The following list shall represent the relative priorities of the technologies supported by the IEEE 802.3 Selector Field value, where priorities are listed from highest to lowest.

a) 40GBASE-T full duplex
b) 25GBASE-T full duplex
c) 10GBASE-T full duplex
d) 5GBASE-T full duplex
e) 2.5GBASE-T full duplex
f) 1000BASE-T full duplex
g) 1000BASE-T
h) 100BASE-T2 full duplex
i) 100BASE-TX full duplex
j) 100BASE-T2
k) 100BASE-T4
l) 100BASE-TX
m) 10BASE-T full duplex
n) 10BASE-T

The rationale for this hierarchy is straightforward. First, higher rates are always higher in priority than lower rates. Second, full duplex solutions are always higher in priority than their half duplex counterparts. Third, higher priority is given to PHY types that run on broader spectrum of copper cabling. 100BASE-T2 is ahead of 100BASE-TX and 100BASE-T4 because 100BASE-T2 runs across a broader spectrum of copper cabling and can support a wider base of configurations. 100BASE-T4 is ahead of 100BASE-TX because 100BASE-

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

T4 runs across a broader spectrum of copper cabling. The relative order of the technologies specified herein shall not be changed. As each new technology is added, it shall be inserted into its appropriate place in the list, shifting technologies of lesser priority lower in priority. If a vendor-specific technology is implemented, the priority of all IEEE 802.3 standard technologies shall be maintained, with the vendor specific technology inserted at any appropriate priority location.

NOTE—Refer to 28.2.1.2.3 for resolution of Extended Next Pages.

The use of the PAUSE operation for full duplex links (as indicated by bits A5 and A6) is orthogonal to the negotiated data rate, medium, or link technology. The setting of these bits indicates the availability of additional DTE capability when full duplex operation is in use. The PAUSE function shall be enabled according to Table 28B–3 only if the highest common denominator is a full duplex technology. There is no priority resolution associated with the PAUSE operation.

Table 28B–3—Pause resolution

Local device		Link partner		Local device resolution	Link partner resolution
PAUSE	**ASM_DIR**	**PAUSE**	**ASM_DIR**		
0	0	Don’t care	Don’t care	Disable PAUSE Transmit and Receive	Disable PAUSE Transmit and Receive
0	1	0	Don’t care	Disable PAUSE Transmit and Receive	Disable PAUSE Transmit and Receive
0	1	1	0	Disable PAUSE Transmit and Receive	Disable PAUSE Transmit and Receive
0	1	1	1	Enable PAUSE transmit Disable PAUSE receive	Enable PAUSE receive Disable PAUSE transmit
1	0	0	Don’t care	Disable PAUSE Transmit and Receive	Disable PAUSE Transmit and Receive
1	Don’t care	1	Don’t care	Enable PAUSE Transmit and Receive	Enable PAUSE Transmit and Receive
1	1	0	0	Disable PAUSE Transmit and Receive	Disable PAUSE Transmit and Receive
1	1	0	1	Enable PAUSE receive Disable PAUSE transmit	Enable PAUSE transmit Disable PAUSE receive

28B.4 Message Page transmission convention

Each series of Unformatted Pages shall be preceded by a Message Page containing a message code that defines how the following Unformatted Pages will be used.

Next Page message codes should be allocated globally across Selector Field values so that meaningful communication is possible between technologies using different Selector Field values.

Annex 28C

(normative)

Next Page Message Code field definitions

This Annex defines the Next Page message code fields for devices using Clause 28 Auto-Negotiation. The Message Code Field of a message page used in Next Page exchange shall be used to identify the meaning of a message. The following table identifies the types of messages that may be sent. As new messages are developed, this table will be updated accordingly.

The Message Code Field uses an 11-bit binary encoding that allows 2048 messages to be defined. All message codes not specified shall be reserved for IEEE use or allocation. Devices that have negotiated Extended Next Page support transmit Extended Next Pages but not other Next Pages.

Extended Next Pages are used to transmit Extended Next Page message codes and the subsequent Extended Next Pages and extended Unformatted Pages. In addition, Extended Next Pages may be used to transmit multiple Message Pages and Unformatted Pages in the following manner. The Message Code Field is mapped to bits M0:10 of the extended Message Page, and the first two Unformatted Code Fields associated with the Message Code Field value are mapped to bits U0:U10 and U16:U26, respectively, of the extended Message Page. Additional Unformatted Code Fields would be mapped to bits U0:U42 of subsequent extended Unformatted Pages. Any unused bits in the Extended Next Pages are transmitted as zero and ignored by the receiver.

If more than two Unformatted Code fields are required by a message code, then additional Unformatted Code Fields are transmitted in the extended Unformatted Pages immediately following the extended Message Page. Up to three Unformatted Code Fields can be transmitted in each extended Unformatted Page, the first in bits U0:10, the second in bits U11:21, and the third in bits U27:37.

When a message code requires the transmission of one or more extended Unformatted Pages, due to the number of Unformatted Code Fields it defines, the Unformatted Code Fields in the extended Message and extended Unformatted Pages shall be in the order specified by the message code.

Table 28C–1—Message code field values

Message code	M 10	M 9	M 8	M 7	M 6	M 5	M 4	M 3	M 2	M 1	M 0	Message code description
0	0	0	0	0	0	0	0	0	0	0	0	Reserved for future Auto-Negotiation use
1	0	0	0	0	0	0	0	0	0	0	1	Null Message
2	0	0	0	0	0	0	0	0	0	1	0	One UP with Technology Ability Field follows
3	0	0	0	0	0	0	0	0	0	1	1	Two UPs with Technology Ability Field follow
4	0	0	0	0	0	0	0	0	1	0	0	One UP with Binary coded Remote fault follows
5	0	0	0	0	0	0	0	0	1	0	1	Organizationally Unique Identifier Tagged Message

Table 28C–1—Message code field values *(continued)*

Message code	M 10	M 9	M 8	M 7	M 6	M 5	M 4	M 3	M 2	M 1	M 0	Message code description
6	0	0	0	0	0	0	0	0	1	1	0	PHY Identifier Tag Code
7	0	0	0	0	0	0	0	0	1	1	1	100BASE-T2 Technology message code. 100BASE-T2 Ability Page to follow using Unformatted Next Page
8	0	0	0	0	0	0	0	1	0	0	0	1000BASE-T Technology message code. Two 1000BASE-T Ability Pages to follow using Unformatted Next Pages.
9	0	0	0	0	0	0	0	1	0	0	1	MultiGBASE-T and 1000BASE-T Technology message code (Extended Next Page)
10	0	0	0	0	0	0	0	1	0	1	0	EEE Technology Message Code. EEE capability to follow using Unformatted Next Page.
11	0	0	0	0	0	0	0	1	0	1	1	Organizationally Unique Identifier Tagged Message (Extended Next Page)
12.....	0	0	0	0	0	0	0	1	1	0	0	Reserved for future Auto-Negotiation use
.....2047	1	1	1	1	1	1	1	1	1	1	1	Reserved for future Auto-Negotiation use

28C.1 Message code 0—Auto-Negotiation reserved code 1

This code is reserved for future Auto-Negotiation function enhancements. Devices shall not transmit this code.

28C.2 Message code 1—Null Message code

The Null Message code shall be transmitted during Next Page exchange when the Local Device has no further messages to transmit and the Link Partner is still transmitting valid Next Pages. See 28.2.3.4 for more details.

28C.3 Message code 2—Technology Ability extension code 1

This message code is reserved for future expansion of the Technology Ability Field and indicates that a defined user code with a specific Technology Ability Field encoding follows.

28C.4 Message code 3—Technology Ability extension code 2

This message code is reserved for future expansion of the Technology Ability Field and indicates that two defined user codes with specific Technology Ability Field encodings follow.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28C.5 Message code 4—Remote fault number code

This message code shall be followed by a single user code whose encoding specifies the type of fault that has occurred. The following user codes are defined:

0: RF Test
This code can be used to test Remote Fault operation.
1: Link Loss
2: Jabber
3: Parallel Detection Fault
This code may be sent to identify when bit 6.4 is set.

28C.6 Message code 5—Organizationally Unique Identifier (OUI) tag code

The OUI Tagged Message shall consist of a single message code of 0000 0000 0101 followed by four user codes defined as follows. The first user code shall contain the most significant 11 bits of the OUI or CID (bits 23:13) with the most significant bit in bit 10 of the user code. The second user code shall contain the next most significant 11 bits of the OUI or CID (bits 12:2) with the most significant bit in bit 10 of the user code. The third user code shall contain the remaining least significant 2 bits of the OUI or CID (bits 1:0) with the most significant bit in bit 10 of the user code. Bits 8:0 of the third user code contain a user-defined user code value that is specific to the OUI or CID transmitted. The fourth and final user code shall contain a user-defined user code value that is specific to the OUI or CID transmitted.

For example, assume that a manufacturer's IEEE-assigned OUI/CID value is AC-DE-48 and the manufacturer-selected user-defined user code associated with the OUI or CID is 0xCE1FC (binary 1100 1110 0001 1111 1100). The message code values generated from these two numbers is encoded into four message codes, as specified in Figure 28C–1. For clarity, the position of the M bit[271] is illustrated.

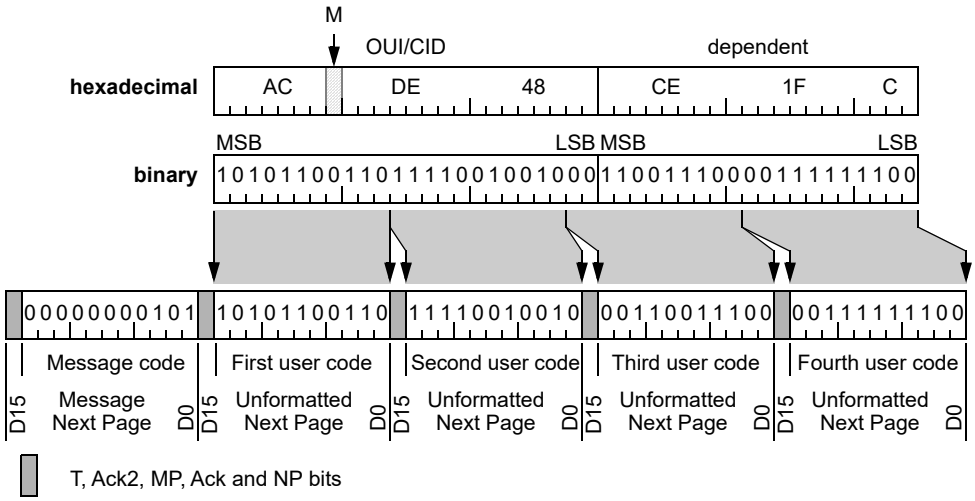

Figure 28C–1—Message code 5 sequence

NOTE—Figure 28C–1 shows the order Next Pages are transmitted, with the first transmitted Next Page shown in the leftmost position. While Figure 28–11 and Figure 28–12 use the convention that the most significant bit (i.e., the last bit to be transmitted) is the rightmost bit, Figure 28C–1 uses the opposite convention, i.e., the most significant bit of each

[271] See IEEE Std 802, subclause 9.3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

page is shown in the leftmost position. This is a pictorial difference only; there is no difference in the actual order of bits transmitted.

Devices that negotiate the use of Extended Next Page messages may use this message encapsulated within the Extended Next Page message as described in Annex 28C, however it is recommended that devices use message code 11 for Extended Next Page OUI tagged messages.

28C.7 Message code 6—PHY identifier tag code

The PHY ID tag code message shall consist of a single message code of 0000 0000 0110 followed by four user codes defined as follows. The first user code shall contain the most significant 11 bits of the PHY ID (2.15:5) with the most significant bit in bit 10 of the user code. The second user code shall contain bits 2.4:0 to 3.15:10 of the PHY ID with the most significant bit in bit 10 of the user code. The third user code shall contain bits 3.9:0 of the PHY ID with the most significant bit in bit 10 of the user code. Bit 0 in the third user code shall contain a user-defined user code value that is specific to the PHY ID transmitted. The fourth and final user code shall contain a user-defined user code value that is specific to the PHY ID transmitted.

28C.8 Message code 2047—Auto-Negotiation reserved code 2

This code is reserved for future Auto-Negotiation function enhancements. Devices shall not transmit this code.

28C.9 Message code 7—100BASE-T2 technology message code

Clause 32 (100BASE-T2) uses Next Page message code 7 to indicate that T2 implementations will follow the transmission of this page [the initial, Message (formatted) Next Page] with two Unformatted Next Pages which contain information defined in 32.5.4.2.

28C.10 Message code 8—1000BASE-T technology message code

Clause 40 (1000BASE-T) uses Next Page message code 8 to indicate that 1000BASE-T implementations will follow the transmission of this page [the initial, Message (formatted) Next Page] with two Unformatted Next Pages that contain information defined in 40.5.1.2.

28C.11 Message code 9—MultiGBASE-T and 1000BASE-T technology message code

Clause 55 (10GBASE-T), Clause 126 (2.5G/5GBASE-T), and Clause 113 (25GBASE-T and 40GBASE-T) use Extended Next Page message code 9 to indicate that 40GBASE-T, 25GBASE-T, 2.5G/5GBASE-T, 10GBASE-T, and 1000BASE-T abilities are contained within this Extended Next Page. The Next Page that contains this information is defined in 55.6.1, 113.6.1, and 126.6.1. This page shall not be sent if Extended Next Page mode is disabled.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28C.12 Message code 10—EEE technology message code

Multiple clauses use Next Page message code 10 to indicate that EEE technology messages will follow the transmission of this page [the initial, Message (formatted) Next Page] with one Unformatted Next Page. The contents of the unformatted code field bits (U10:U0) shall be as defined in 45.2.7.14.

EEE capability negotiation is defined in 78.3.

28C.13 Message code 11—Organizationally Unique Identifier Tagged Message (Extended Next Page)

Devices that negotiate the use of Extended Next Page messages may use the Extended Next Page OUI Tagged Message. This shall consist of a single message code of 000 0000 1011 and bits U23-U0 of the unformatted code field shall contain the OUI or CID (with most significant bit of the OUI or CID in U23, the second most significant bit in U22, etc.). Bits U31-U24 contain user-defined data. If the Next Page flag is set, the message page shall be followed by an unformatted Extended Next Page containing user-defined data.

Annex 28D

(normative)

Description of extensions to Clause 28 and associated annexes

28D.1 Introduction

This annex is to be used to document extensions and modifications to Clause 28 required by IEEE 802.3 clauses and other standards that use Auto-Negotiation and that were approved after July 1995. It provides a single location to define such extensions and modifications without changing the basic contents of Clause 28.

Subclause 28D.2 lists those clauses and standards that require extensions to Clause 28 and provides pointers to the subclauses where those extensions are listed.

28D.2 Extensions to Clause 28

28D.2.1 Extensions required for Clause 31 (full duplex)

Clause 31 (full duplex) requires the use of Auto-Negotiation. Extensions to Clause 28 and associated annexes required for the correct operation of full duplex are shown in 28D.3.

28D.2.2 Extensions required for Clause 32 (100BASE-T2)

Clause 32 (100BASE-T2) requires the use of Auto-Negotiation. Extensions to Clause 28 required for correct operation of 100BASE-T2 are shown in 28D.4.

28D.3 Extensions for Clause 31

Full duplex requires the use of bit A5 in the Technology Ability Field of the IEEE 802.3 Selector Base Page. (This bit is also defined as MII bit 4.10.) This bit was previously defined as “reserved for future technology.”

Bit	Technology	Minimum cabling requirement
A5	PAUSE operation for full duplex links	Not applicable

Bit A5 (PAUSE operation for full duplex links) signifies that the DTE has implemented both the optional MAC Control sublayer and the PAUSE function as specified in Clause 31 and Annex 31B. This capability is significant only when the link is configured for full duplex operation, regardless of data rate and medium.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28D.4 Extensions for Clause 32 (100BASE-T2)

Clause 32 (100BASE-T2) makes special use of Auto-Negotiation and requires additional MII registers. This use is summarized below. Details are provided in 32.5.

Auto-Negotiation is mandatory for 100BASE-T2 (32.1.3.4).

100BASE-T2 introduces the concept of MASTER and SLAVE to define DTEs and to facilitate the timing of transmit and receive operations. Auto-Negotiation is used to provide information used to configure MASTER/SLAVE status (32.5.4.3).

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

100BASE-T2 uses unique Next Page transmit and receive registers (MII registers 8, 9, and 10) in conjunctions with Auto-Negotiation. These registers are in addition to registers 0–7 as defined in 28.2.4 (32.5.2).

100BASE-T2 use of Auto-Negotiation generates information which is stored in configuration and status bits defined for the MASTER-SLAVE Control register (MII register 9) and the MASTER-SLAVE Status register (MII register 10).

100BASE-T2 requires an ordered exchange of Next Page messages (32.5.1).

100BASE-T2 parameters are configured based on information provided by the ordered exchange of Next Page messages.

100BASE-T2 adds new message codes to be transmitted during Auto-Negotiation (32.5.4.2).

100BASE-T2 adds 100BASE-T2 full duplex and half duplex capabilities to the priority resolution table (28B.3) and MII Status Register (22.2.4.2).

T2 is defined as a valid value for “x” in 28.3.1 (e.g., link_status_T2). T2 represents that the 100BASE-T2 PMA is the signal source.

28D.5 Extensions required for Clause 40 (1000BASE-T)

Clause 40 (1000BASE-T) makes special use of Auto-Negotiation and requires additional MII registers. This use is summarized below. Details are provided in 40.5.

a) Auto-Negotiation is mandatory for 1000BASE-T (see 40.5.1).
b) 1000BASE-T requires an ordered exchange of Next Page messages (see 40.5.1.2), or optionally an exchange of an Extended Next Page message
c) 1000BASE-T parameters are configured based on information provided by the exchange of Next Page messages.
d) 1000BASE-T uses MASTER and SLAVE to define PHY operations and to facilitate the timing of transmit and receive operations. Auto-Negotiation is used to provide information used to configure MASTER-SLAVE status (see 40.5.2).
e) 1000BASE-T transmits and receives Next Pages for exchange of information related to MASTER-SLAVE operation. The information is specified in MII registers 9 and 10 (see 32.5.2 and 40.5.1.1), which are required in addition to registers 0-8 as defined in 28.2.4.
f) 1000BASE-T adds new message codes to be transmitted during Auto-Negotiation (see 40.5.1.3).
g) 1000BASE-T adds 1000BASE-T full duplex and half duplex capabilities to the priority resolution table (see 28B.3) and MII Extended Status Register (see 22.2.2.4).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

h) 1000BASE-T is defined as a valid value for "x" in 28.3.1 (e.g., link_status_1GigT.) 1GigT represents that the 1000BASE-T PMA is the signal source.
i) 1000BASE-T supports Asymmetric Pause as defined in Annex 28B.

28D.6 Extensions required for Clause 55 (10GBASE-T)

Clause 55 (10GBASE-T) makes special use of Auto-Negotiation and requires additional MDIO registers. This use is summarized below. Details are provided in 55.6.

a) Auto-Negotiation is mandatory for 10GBASE-T.
b) Extended Next Page support is mandatory for 10GBASE-T.
c) 10GBASE-T requires an exchange of an Extended Next Page message.
d) 10GBASE-T parameters are configured based on information provided by the exchange of an Extended Next Page message.
e) 10GBASE-T uses MASTER and SLAVE to define PHY operations and to facilitate the timing of transmit and receive operations. Auto-Negotiation is used to provide information used to configure MASTER-SLAVE status.
f) 10GBASE-T transmits and receives an Extended Next Page for exchange of information related to MASTER-SLAVE operation. The information is specified in 45.2.7.
g) 10GBASE-T adds new message codes to be transmitted during Auto-Negotiation.
h) 10GBASE-T adds 10GBASE-T full duplex capabilities to the priority resolution table (see 28B.3).
i) 10GBASE-T is defined as a valid value for "x" in 28.3.1 (e.g., link_status_10GigT.) 10GigT represents that the 10GBASE-T PMA is the signal source.
j) 10GBASE-T supports Asymmetric Pause as defined in Annex 28B.

28D.7 Extensions required for Energy-Efficient Ethernet (Clause 78)

Energy-Efficient Ethernet (Clause 78) makes use of Auto-Negotiation and requires additional MDIO registers. Auto-negotiation is mandatory for all EEE PHYs that support LPI. Details are provided in 78.3.

28D.8 Extensions required for Clause 113 (25GBASE-T and 40GBASE-T)

Clause 113 (25GBASE-T and 40GBASE-T) makes special use of Auto-Negotiation and defines additional MDIO registers for use when Clause 45 is implemented. This use is summarized below. Details are provided in 113.6.

a) Auto-Negotiation is mandatory for 25GBASE-T and 40GBASE-T.
b) Extended Next Page support is mandatory for 25GBASE-T and 40GBASE-T.
c) 25GBASE-T and 40GBASE-T require an exchange of an Extended Next Page message.
d) 25GBASE-T and 40GBASE-T parameters are configured based on information provided by the exchange of an Extended Next Page message.
e) 25GBASE-T and 40GBASE-T use MASTER and SLAVE to define PHY operations and to facilitate the timing of transmit and receive operations. Auto-Negotiation is used to provide information used to configure MASTER-SLAVE status.
f) 25GBASE-T and 40GBASE-T transmit and receive an Extended Next Page for exchange of information related to MASTER-SLAVE operation. The information is specified in 45.2.7.
g) 25GBASE-T and 40GBASE-T add 25GBASE-T and 40GBASE-T full duplex capabilities to the priority resolution table (see 28B.3).
h) 25GBASE-T and 40GBASE-T are defined as a valid value for "x" in 28.3.1 (e.g., link_status_25GigT and link_status_40GigT). 25GigT represents that the 25GBASE-T PMA is the signal source, and 40GigT represents that the 40GBASE-T PMA is the signal source.
i) 25GBASE-T and 40GBASE-T support Asymmetric Pause as defined in Annex 28B.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28D.9 Extensions required for Clause 126 (2.5G/5GBASE-T)

Clause 126 (2.5G/5GBASE-T) makes special use of Auto-Negotiation and defines additional MDIO registers for use when Clause 45 is implemented. This use is summarized in the following list. Details are provided in 126.6.

a) Auto-Negotiation is mandatory for 2.5BASE-T and 5GBASE-T.
b) Extended Next Page support is mandatory for 2.5BASE-T and 5GBASE-T.
c) 2.5GBASE-T and 5GBASE-T require an exchange of an Extended Next Page message.
d) 2.5GBASE-T and 5GBASE-T parameters are configured based on information provided by the exchange of an Extended Next Page message and information provided by the exchange of Infofields during link training.
e) 2.5GBASE-T and 5GBASE-T use MASTER and SLAVE to define PHY operations and to facilitate the timing of transmit and receive operations. Auto-Negotiation is used to provide information used to configure MASTER-SLAVE status.
f) 2.5GBASE-T and 5GBASE-T transmit and receive an Extended Next Page for exchange of information related to MASTER-SLAVE operation. The information is specified in 45.2.7.
g) 2.5GBASE-T and 5GBASE-T add 2.5GBASE-T and 5GBASE-T full duplex capabilities to the priority resolution table (see 28B.3).
h) 2.5GBASE-T and 5GBASE-T are defined as valid values for “x” in 28.3.1 (e.g., link_status_2p5GigT or link_status_5GigT.) 2p5GigT represents that the 2.5GBASE-T PMA is the signal source, and 5GigT represents that the 5GBASE-T PMA is the signal source.
i) 2.5GBASE-T and 5GBASE-T support Asymmetric Pause as defined in Annex 28B.

Annex 29A

(informative)

DTE and repeater delay components

29A.1 DTE delay

Round-trip DTE delay = MAC transmit start to MDI output
+ MDI input to MDI output (worst case, nondeferred)
+ MDI input to collision detect

NOTE 1—Refer to Clause 23, Clause 24, Clause 25, and Clause 26.

NOTE 2—Worst-case values are used for the one T4 and one TX/FX value shown in Table 29–3. (TX/FX values for MAC transmit start and MDI input to collision detect; T4 value for MDI input to MDI output.)

29A.2 Repeater delay

Repeater delay= SOP (start-of-packet propagation delay)
+ SOJ (start-of-jam propagation delay)

NOTE—Refer to Clause 27.

Annex 29B

(informative)

Recommended topology documentation

It is strongly recommended that detailed records documenting the topology components of 100BASE-T networks be prepared and maintained to facilitate subsequent modification. Proper 100BASE-T topology design requires an accurate knowledge of link segment and hub parameters to ensure proper operation of single and multisegment, single collision domain networks. Link segment documentation is site-specific and requires careful documentation. It is recommended that the information shown in Table 29B–1 be collected for each link segment and archived for future reference. Hub performance parameters may be obtained from manufacturer documentation.

MAC Control opcode assignments

Table 31A–1 shows the currently defined opcode values and interpretations:

Table 31A–1—MAC Control opcodes

Opcode (Hexadecimal)	MAC Control function	Specified in	Value/Comment	Timestamp[a]
00-00	Reserved			
00-01	PAUSE	Annex 31B	Requests that the recipient stops transmitting non-control frames for a period of time indicated by the parameters of this function.	No
00-02	GATE	Clause 64, Clause 77, Clause 103	Request that the recipient allows transmission of frames at a time, and for a period of time indicated by the parameters of this function.	Yes
00-03	REPORT	Clause 64, Clause 77, Clause 103	Notify the recipient of pending transmission requests as indicated by the parameters of this function.	Yes
00-04	REGISTER_REQ	Clause 64, Clause 77, Clause 103	Request that the station be recognized by the protocol as participating in a gated transmission procedure as indicated by the parameters of this function.	Yes
00-05	REGISTER	Clause 64, Clause 77, Clause 103	Notify the recipient that the station is recognized by the protocol as participating in a gated transmission procedure as indicated by the parameters of this function.	Yes
00-06	REGISTER_ACK	Clause 64, Clause 77, Clause 103	Notify the recipient that the station acknowledges participation in a gated transmission procedure.	Yes
00-07 through 00-11	Reserved			
00-12	GATE	144.3.6.1	Request that the recipient allows transmission of frames at a time, and for a period of time indicated by the parameters of this function.	Yes
00-13	REPORT	144.3.6.2	Notify the recipient of pending transmission requests as indicated by the parameters of this function.	Yes
00-14	REGISTER_REQ	144.3.6.3	Request that the station be recognized by the protocol as participating in a gated transmission procedure as indicated by the parameters of this function.	Yes

Table 31A–1—MAC Control opcodes *(continued)*

Opcode (Hexadecimal)	MAC Control function	Specified in	Value/Comment	Timestamp[a]
00-15	REGISTER	144.3.6.4	Notify the recipient that the station is recognized by the protocol as participating in a gated transmission procedure as indicated by the parameters of this function.	Yes
00-16	REGISTER_ACK	144.3.6.5	Notify the recipient that the station acknowledges participation in a gated transmission procedure.	Yes
00-17	DISCOVERY	144.3.6.6	Request that recipients attempt registration during the discovery window.	Yes
00-18	SYNC_PATTERN	144.3.6.7	Announces burst synchronization patterns to all unregistered ONUs, multiple/all registered ONUs, or individual registered ONUs.	Yes
00-19 through 00-1F	Reserved			
00-20	CC_REQUEST	144.4.3.1	Query or change the state of ONU channel(s).	No
00-21	CC_RESPONSE	144.4.3.2	Report current channel(s) state and action result code.	No
00-22 through 01-00	Reserved			
01-01	PFC	Annex 31D and IEEE Std 802.1Q	Requests that the recipient stops transmissions in the priorities indicated in the parameters of the function for a period of time also indicated in the parameters.	No
01-02 through FF-FD	Reserved			
FF–FE	EXTENSION	Annex 31C	This frame is used for Organization–Specific Extension. Upon reception of this message, the MAC Control generates MA_CONTROL.Indication informing the MAC Control Client to perform the relevant action.	No
FF-FF	Reserved			

[a]The value of the Timestamp field is generated by MAC Control and is not exposed through the client interface.

Opcodes are transmitted high-order octet first. Within each octet, bits are transmitted least-significant bit first. Reserved opcodes shall not be used by MAC Control sublayer entities.

Table 31A–2 through Table 31A–9 show the elements and semantics of the indication_operand_list for MA_CONTROL.indication primitives for each currently defined opcode value in Table 31A–1:

Table 31A–2—PAUSE MAC Control indications

PAUSE (opcode 0x0001)		
indication_operand_list element	**Value**	**Interpretation**
pause_status	paused	Indicates that the PAUSE function is inhibiting transmission of data frames by the MAC client.
	not_paused	Indicates that the PAUSE function is not inhibiting transmission of data frames by the MAC client.

Table 31A–3—GATE MAC Control indications

GATE (opcode 0x0002)		
indication_operand_list element	**Value**	**Interpretation**
start	32 bit	Time when transmission should be initiated.
length	16 bit	Interval of time during which transmission is allowed.
status	arrive	Indicates that a grant has been received for future activation.
	active	Indicates that the GATE function is allowing transmission of frames.
	deactive	Indicates that the GATE function is inhibiting transmission of frames.
force_report	true	The OLT expects the ONU to transmit a REPORT message during the transmission opportunity identified by start and length fields.
	false	The OLT does not request the ONU to transmit a REPORT message during the transmission opportunity identified by start and length fields.
discovery	true	This grant is reserved for use during discovery.
	false	This grant is not reserved for use by the discovery process, and is available for use by all traffic.
discoveryInformation[a]	16 bits	See Table 77–3 for the internal structure of the discoveryInformation field.

Table 31A–4—REPORT MAC Control indications

REPORT (opcode 0x0003)		
indication_operand_list element	**Value**	**Interpretation**
RTT	32 bit	Indicates the calculated round trip time for the station, as calculated following the REPORT message reception.
n	Integer	Indicates the number of queue status reports present
report_list	valid[8]	Indicates whether the corresponding status element is present when set to true.
	status[8]	Indicates amount of data waiting in the corresponding queue including the associated transmission overhead.

Table 31A–5—REGISTER_REQ MAC Control indications

REGISTER_REQ (opcode 0x0004)		
indication_operand_list element	**Value**	**Interpretation**
status	incoming	Indicates that a station is requesting recognition.
	retry	Indicates that the station should reattempt registration.
flags	register	Indicates that the station is requesting to register.
	deregister	Indicates that the station is requesting to deregister.
pending_grants	Integer	Indicates the maximum number of future GATES that can be stored by the GATE function.
RTT	32 bit	Indicates the calculated round trip time for the station, as calculated following the REGISTER_REQ message reception.
laserOnTime[a]	8 bits	Indicates the Laser On Time characteristic for the given ONU transmitter, expressed in the units of time_quanta.
laserOffTime[a]	8 bits	Indicates the Laser Off Time characteristic for the given ONU transmitter, expressed in the units of time_quanta.
discoveryInformation[a]	16 bits	See Table 77–7 for the internal structure of the discoveryInformation field.

[a]Only present in 10G–EPON REGISTER_REQ MAC Control indication (Clause 77).

Table 31A–6—REGISTER MAC Control indications

REGISTER (opcode 0x0005)		
indication_operand_list element	**Value**	**Interpretation**
SA	48 bit	MAC address of OLT to which registration is being performed.
ID	16 bit	LLID assigned by the OLT for use by the ONU.

Table 31A–6—REGISTER MAC Control indications *(continued)*

REGISTER (opcode 0x0005)		
indication_operand_list element	**Value**	**Interpretation**
status	accepted	Indicates that the requested registration is successful.
	denied	Indicates that the requested registration attempt is denied by the higher-layer-entity.
	deregistered	Indicates that the ONU has been deregistered, i.e., the associated LLID has been deallocated.
	reregistered	Indicates that the ONU is explicitly asked to re-register.
laserOnTime[a]	8 bits	Indicates the Laser On Time characteristic for the given ONU transmitter, expressed in the units of time_quanta.
laserOffTime[a]	8 bits	Indicates the Laser Off Time characteristic for the given ONU transmitter, expressed in the units of time_quanta.

[a]Only present in 10G–EPON REGISTER MAC Control indication (Clause 77).

Table 31A–7—REGISTER_ACK MAC Control indications

REGISTER_ACK (opcode 0x0006)		
indication_operand_list element	**Value**	**Interpretation**
SA	48 bit	MAC address of ONU to which registration is being performed.
ID	16 bit	Indicates the LLID allocated to the ONU.
status	accepted	Indicates the station has been recognized as participating in gated transmission.
	denied	Indicates the station has been excluded from participating in gated transmission.
	reset	Indicates the station has been requested to resubmit a registration request.
	deregistered	Indicates that the station will no longer be participating in gated transmission.
RTT	32 bit	Indicates the calculated round trip time for the station, as calculated following the REGISTER_ACK message reception.

Table 31A–8—EXTENSION MAC Control indications

EXTENSION (opcode 0xFFFE)		
indication_operand_list element	**Value**	**Interpretation**
OUI	24 bits	Organizationally-Unique Identifier (OUI) or Company ID (CID) that determines the format and semantics of the Value field and its subfields, if any are defined.
Value	Variable	Organization-specific value, distinguished by the OUI or CID.

Table 31A–9—PFC MAC Control indications

PFC (opcode 0x0101)		
indication_operand_list element	**Value**	**Interpretation**
priority_enable_vector	2 octets	The most significant octet is reserved (i.e., set to zero on transmission and ignored on receipt). Each bit of the least significant octet indicates if the corresponding field in the time_vector parameter is valid. The bits of the least significant octet are named e[0] (the least significant bit) to e[7] (the most significant bit). Bit e[n] refers to Priority n. For each e[n] bit set to one, the corresponding time[n] value is valid. For each e[n] bit set to zero, the corresponding time[n] value is invalid.
time_vector	a list of eight 2-octet unsigned integers	A list of eight 2-octet fields named time[0] to time[7]. The eight time[n] values are always present regardless of the value of the corresponding e[n] bit. Each time[n] field is a 2-octet, unsigned integer containing the length of time for which the receiving station is requested to inhibit transmission of data frames associated with Priority n. The field is transmitted most significant octet first, and least significant octet second. The time[n] fields are transmitted sequentially, with time[0] transmitted first and time[7] transmitted last. Each time[n] value is measured in units of pause_quanta, equal to the time required to transmit 512 bits of a frame at the data rate of the MAC. Each time[n] field can assume a value in the range of 0 to 65 535 pause_quanta.

Annex 31B

(normative)

MAC Control PAUSE operation

31B.1 PAUSE description

The PAUSE operation is used to inhibit transmission of data frames for a specified period of time. A MAC Control client wishing to inhibit transmission of data frames from another station on the network generates a MA_CONTROL.request primitive specifying the following:

a) The globally assigned 48-bit multicast address 01-80-C2-00-00-01
b) The PAUSE opcode
c) A request_operand indicating the length of time for which it wishes to inhibit data frame transmission (see 31B.2)

The PAUSE operation cannot be used to inhibit transmission of MAC Control frames.

PAUSE frames shall only be sent by DTEs configured to the full duplex mode of operation.

The globally assigned 48-bit multicast address 01-80-C2-00-00-01 has been reserved for use in MAC Control PAUSE frames for inhibiting transmission of data frames from a DTE in a full duplex mode IEEE 802.3 LAN. IEEE 802.1Q-conformant bridges will not forward frames sent to this multicast destination address, regardless of the state of the bridge's ports, or whether or not the bridge implements the MAC Control sublayer. To allow generic full duplex flow control, stations implementing the PAUSE operation shall instruct the MAC (e.g., through layer management) to enable reception of frames with destination address equal to this multicast address.

NOTE—By definition, an IEEE 802.3 LAN operating in full duplex mode comprises exactly two stations, thus there is no ambiguity regarding the destination DTE's identity. The use of a well-known multicast address relieves the MAC Control sublayer and its client from having to know, and maintain knowledge of, the individual 48-bit address of the other DTE in a full duplex environment.

When MAC Control PFC operation (see Annex 31D and IEEE Std 802.1Q) has been enabled, MAC Control PAUSE operation shall be disabled.

31B.2 Parameter semantics

The PAUSE opcode takes the following request_operand:

pause_time
: A 2-octet, unsigned integer containing the length of time for which the receiving station is requested to inhibit data frame transmission. The field is transmitted most-significant octet first, and least-significant octet second. The pause_time is measured in units of pause_quanta, equal to 512 bit times of the particular implementation (see 4.4). The range of possible pause_time is 0 to 65535 pause_quanta.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31B.3 Detailed specification of PAUSE operation

The state machines in 31B.3 follow the conventions in 21.5. (See 25.1.1 for an example statement. That also covers the timer conventions from 14 which apply here.)

31B.3.1 Transmit operation

Upon receipt of a MA_CONTROL.request primitive containing the PAUSE opcode from a MAC client, the MAC Control sublayer calls the MAC sublayer MAC:MA_DATA.request service primitive with the following parameters:

a) The destination_address is set equal to the destination_address parameter of the MA_CONTROL.request primitive. This parameter is currently restricted to the value specified in 31B.1.
b) The source_address is set equal to the 48-bit individual address of the station.
c) The length/type field (i.e., the first two octets) within the mac_service_data_unit parameter is set to the IEEE 802.3 MAC Control EtherType value assigned in 31.4.1.3.
d) The remainder of the mac_service_data_unit is set equal to the concatenation of the PAUSE opcode encoding (see Annex 31A), the pause_time request_operand specified in the MA_CONTROL.request primitive, and a field containing zeros of the length specified in 31.4.1.6.
e) The frame_check_sequence is omitted.

Upon receipt of a data transmission request from the MAC client through the MCF:MA_DATA.request primitive, if the transmission of data frames has not been inhibited due to reception of a valid MAC Control frame specifying the PAUSE operation and a non-zero pause_time, the MAC Control sublayer calls the MAC sublayer MAC:MA_DATA.request service primitive with its parameters identical to the MCF:MA_DATA.indication primitive.

31B.3.2 Transmit state diagram for PAUSE operation

It is not required that an implementation be able to transmit PAUSE frames. MAC Control sublayer entities that transmit PAUSE frames shall implement the Transmit state diagram specified in this subclause.

31B.3.2.1 Constants

pause_command
: The 2-octet encoding of the PAUSE command, as specified in Annex 31A.

reserved_multicast_address
: The 48-bit address specified in 31B.1 item a).

802.3_MAC_Control
: The 16 bit EtherType field assignment for IEEE 802.3 MAC Control specified in 31.4.1.3.

phys_Address
: A 48-bit value, equal to the unicast address of the station implementing the MAC Control sublayer.

31B.3.2.2 Variables

transmitEnabled
: A Boolean set by network management to indicate that the station is permitted to transmit on the network.
: Values: true; Transmitter is enabled by management
false; Transmitter is disabled by management

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transmission_in_progress
: A Boolean used to indicate to the Receive state diagram that a MAC:MA_DATA.request service primitive call is pending.

  Values: true; transmission is in progress
  false; transmission is not in progress

n_quanta_tx
: An integer indicating the number of pause_quanta that the transmitter of a PAUSE frame is requesting that the receiver pause.

pause_timer_Done
: A Boolean set by the MAC Control PAUSE Operation Receive state diagram to indicate the expiration of a pause_timer initiated by reception of a MAC Control frame with a PAUSE opcode.

  Values: true; The pause_timer has expired.
  false; The pause_timer has not expired.

pause_mac_service_data_unit
: The concatenation of IEEE 802.3_MAC_Control, pause_command, n_quanta_tx, zeros.

31B.3.2.3 Functions

None

31B.3.2.4 Timers

pause_timer
: The timer governing the inhibition of transmission of data frames (see 31.5.1) from a MAC Client by the PAUSE function.

31B.3.2.5 Messages

MA_CONTROL.request
: The service primitive used by a client to request a MAC Control sublayer function with the specified request_operands.

MCF:MA_DATA.request
: The service primitive used by a client to request MAC data transmission with the specified parameters.

MAC:MA_DATA.request
: The service primitive issued by the MAC Control sublayer to transmit a MAC frame with the specified parameters. The action invoked is not considered to end until the transmission of the frame by the MAC has concluded and the ability of the MAC control layer to determine this is implementation dependent.

31B.3.2.6 Transmit state diagram for PAUSE operation

Figure 31B–1 depicts the Transmit state diagram for a MAC Control sublayer entity implementing the PAUSE operation.

31B.3.3 Receive operation

The opcode-independent MAC Control sublayer Receive state diagram accepts and parses valid frames received from the MAC sublayer. MAC Control sublayer entities that implement the PAUSE operation shall implement the Receive state diagram specified in this subclause. The functions specified in this subclause are performed upon receipt of a valid Control frame containing the PAUSE opcode, and define the function called by the INITIATE MAC CONTROL FUNCTION state of Figure 31–4. (See 31.5.3.)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

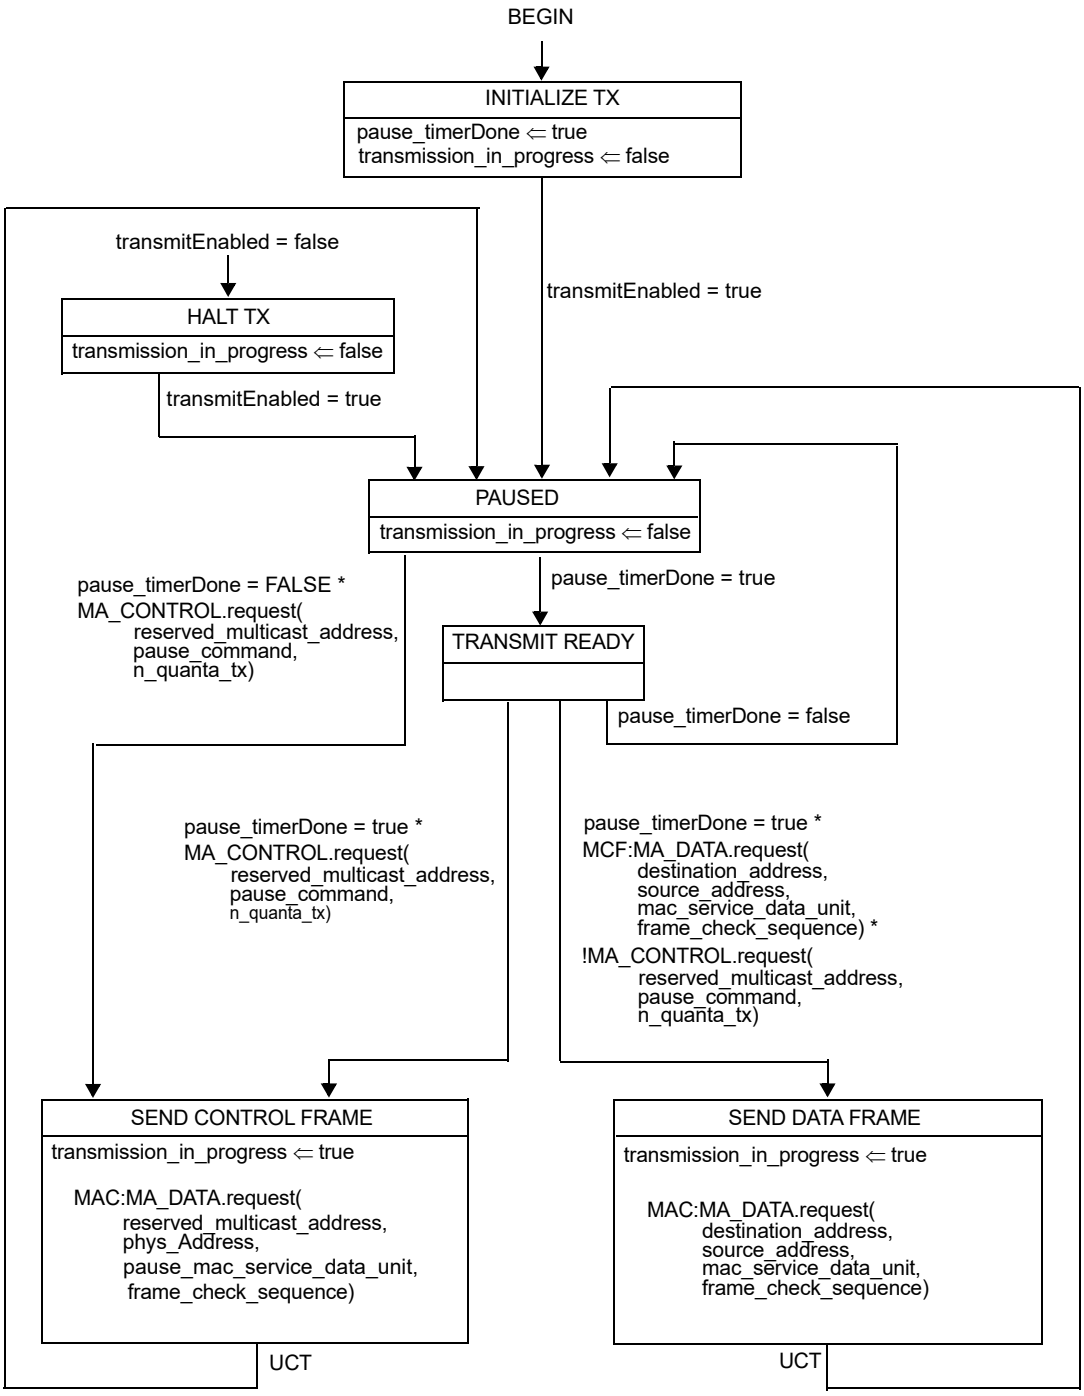

Figure 31B–1—PAUSE Operation Transmit state diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Upon receipt of a valid MAC Control frame with the opcode indicating PAUSE and the destination address indicating either: (1) the globally assigned multicast address specified in 31B.1, or (2) the unique physical address associated with this station, the MAC Control sublayer starts a timer for the length of time specified by the pause_time request_operand in the Control frame (see 31B.2). The value of the variable pause_timer_Done is set to false upon the setting of the pause_timer to a non-zero value by the MAC Control PAUSE Operation Receive state diagram. The value of the variable pause_timer_Done is set to true when the timer value reaches zero (i.e., the timer expires). If the received PAUSE operation indicates a pause_timer value of zero, the value of pause_timer_Done is set to true immediately.

The receipt of a valid MAC Control frame with the opcode indicating PAUSE and the destination address indicating the globally assigned multicast address specified in 31B.1 or the unique physical address associated with this station will cause the pause_timer to be set according to the pause_time request_operand in the newly received frame, regardless of the current setting of the pause_timer, i.e., new PAUSE operations override earlier PAUSE operations.

31B.3.4 Receive state diagram for PAUSE operation

31B.3.4.1 Constants

pause_quantum
: The unit of measurement for pause time specified in 31B.2

pause_command
: The 2-octet encoding of the PAUSE command, as specified in Annex 31A.

reserved_multicast_address
: The 48-bit address specified in 31B.1 item a).

phys_Address
: A 48-bit value, equal to the unicast address of the station implementing the MAC Control sublayer.

31B.3.4.2 Variables

n_quanta_rx
: An integer used to extract the number of pause_quanta to set the pause_timer from the dataParam of the received MAC frame.

opcode
: The opcode parsed from the received MAC frame.

DA
: The destination address from the MAC:MA_DATA.indication service primitive.

data
: The data payload parsed from the received MAC frame.

transmission_in_progress
: A Boolean used by the Transmit state diagram to indicate that a MAC:MA_DATA.request service primitive call is pending.

  Values: true; transmission is in progress
  false; transmission is not in progress

31B.3.4.3 Timers

pause_timer
: The timer governing the inhibition of transmission of data frames.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31B.3.4.4 Receive state diagram (INITIATE MAC CONTROL FUNCTION) for PAUSE operation

Figure 31B–2 depicts the INITIATE MAC CONTROL FUNCTION for the PAUSE operation. (See 31.5.3.)

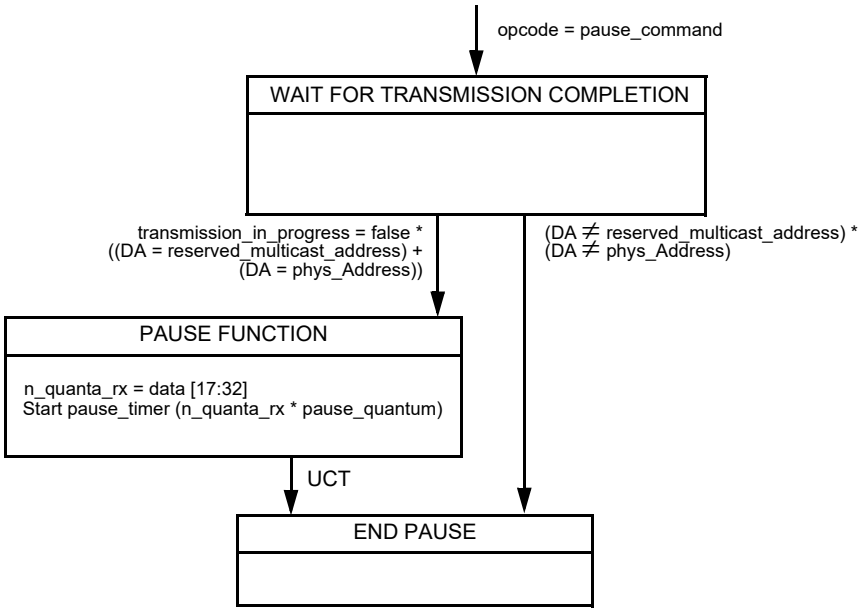

Figure 31B–2—PAUSE Operation Receive state diagram

31B.3.5 Status indication operation

MAC Control sublayer entities that implement the PAUSE operation shall implement the Indication state diagram specified in this subclause.

The PAUSE function sets the pause_status variable to one of two values: paused or not_paused, and indicates this to its client through the MA_CONTROL.indication primitive.

31B.3.6 Indication state diagram for pause operation

31B.3.6.1 Constants

pause_command
: The 2-octet encoding of the PAUSE command, as specified in Annex 31A.

31B.3.6.2 Variables

pause_status
: Used to indicate the state of the MAC Control sublayer for the PAUSE operation. It takes one of two values: paused or not_paused.

pause_timer_Done
: A Boolean set by the MAC Control PAUSE Operation Receive state diagram to indicate the expiration of a pause_timer initiated by reception of a MAC Control frame with a PAUSE opcode.

Values: true; The pause_timer has expired.
false; The pause_timer has not expired.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31B.3.6.3 Messages

MA_CONTROL.indication

The service primitive used to indicate the state of the MAC Control sublayer to its client.

31B.3.6.4 Indication state diagram for PAUSE operation

Figure 31B–3 depicts the Indication State Diagram for a MAC Control sublayer implementing the PAUSE operation.

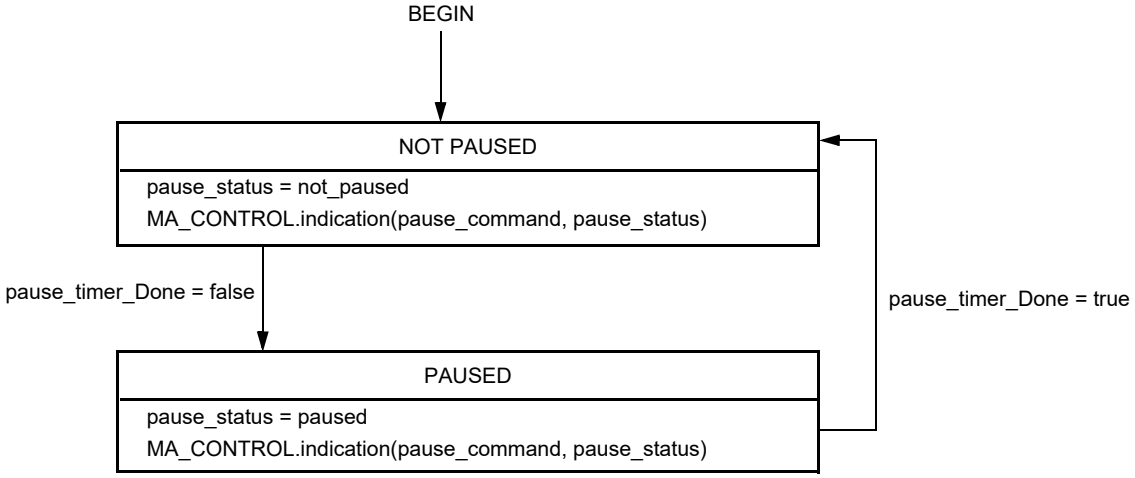

Figure 31B–3—PAUSE Operation Indication state diagram

31B.3.7 Timing considerations for PAUSE operation

In a full duplex mode DTE, it is possible to receive PAUSE frames asynchronously with respect to the transmission of MAC frames. For effective flow control, it is necessary to place an upper bound on the length of time that a DTE can transmit data frames after receiving a valid PAUSE frame with a non-zero pause_time request_operand.

Reception of a PAUSE frame shall not affect the transmission of a MAC frame that has been submitted by the MAC Control sublayer to the underlying MAC (i.e., the MAC:MA_DATA.request service primitive is synchronous, and is never interrupted).

At operating speeds of 100 Mb/s or less, a station that implements an exposed MII, shall not begin to transmit a (new) frame (assertion of TX_EN at the MII, see 22.2.2.3) more than one pause_quantum after the reception of a valid PAUSE frame (deassertion of RX_DV at the MII, see 22.2.2.7) that contains a nonzero value of pause_time. Stations that do not implement an exposed MII, shall measure this time at the MDI, with the timing specification increased to one pause_quantum + 64 BT.

At an operating speed of 1000 Mb/s, a station shall not begin to transmit a (new) frame more than two pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 2.5 Gb/s, a station with a 2.5GBASE-T PHY shall not begin to transmit a (new) frame more than 34 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI. A station using any other 2.5 Gb/s PHY shall not begin to transmit a (new) frame more than 6 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 5 Gb/s, a station with a 5GBASE-T PHY shall not begin to transmit a (new) frame more than 42 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI. A station using any other 5 Gb/s PHY shall not begin to transmit a (new) frame more than 12 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 10 Gb/s, a station with a 10GBASE-T PHY shall not begin to transmit a (new) frame more than 74 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI. A station using any other 10 Gb/s PHY shall not begin to transmit a (new) frame more than 60 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 25 Gb/s, a station shall not begin to transmit a (new) frame more than 80 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 40 Gb/s, a station shall not begin to transmit a (new) frame more than 118 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 50 Gb/s, a station shall not begin to transmit a (new) frame more than 117 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 100 Gb/s, a station shall not begin to transmit a (new) frame more than 394 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 200 Gb/s, a station shall not begin to transmit a (new) frame more than 453 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

At operating speeds of 400 Gb/s, a station shall not begin to transmit a (new) frame more than 905 pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

In addition to DTE and MAC Control delays, system designers should take into account the delay of the link segment when designing devices that implement the PAUSE operation.

The PAUSE response time may be verified by demonstrating that no more than max_overrun bytes of frame data are sent by the station after reception of a valid PAUSE frame that contains a non-zero value of pause_time. The value of max_overun is defined for the following operating speeds, where frame_length is the maximum frame length transmitted by the station during the test:

2.5 Gb/s (using 2.5GBASE-T) – max_overrun = 2176 + frame_length.

2.5 Gb/s (not using 2.5GBASE-T) – max_overrun = 384 + frame_length

5 Gb/s (using 5GBASE-T) – max_overrun = 2624 + frame_length.

5 Gb/s (not using 5GBASE-T) – max_overrun = 768 + frame_length

10 Gb/s (using 10GBASE-T) – max_overrun = 4736 + frame_length.

10 Gb/s (not using 10GBASE-T) – max_overrun = 3840 + frame_length.

25 Gb/s – max_overrun = 5120 + frame_length.

40 Gb/s – max_overrun = 7552 + frame_length.

50 Gb/s – max_overrun = 7488 + frame_length.

100 Gb/s – max_overrun = 25216 + frame_length.

200 Gb/s – max_overrun = 28992 + frame_length.

400 Gb/s – max_overrun = 57920 + frame_length.

31B.4 Protocol implementation conformance statement (PICS) proforma for MAC Control PAUSE operation[272]

31B.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 31B, MAC Control PAUSE operation, shall complete the following PICS proforma in addition to the PICS of Clause 31.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

31B.4.2 Identification

31B.4.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations, other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

31B.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 31B, MAC Control PAUSE operation
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; The answer Yes means that the implementation does not conform to IEEE Std 802.3-2022)	

Date of Statement	

[272]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

31B.4.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
*PST	Support for transmit of PAUSE frames	31B.3.2	N/A	O	Yes [ ] No [ ]
*MIIa	At operating speeds of 100 Mb/s or less, MII connection exists and is accessible for test.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIb	At operating speeds of 100 Mb/s or less, MII connection does not exist or is not accessible for test.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIc	At operating speeds of 1000 Mb/s	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIId	At operating speeds of 2.5 Gb/s with PHY types other than 2.5GBASE-T.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIe	At operating speeds of 2.5 Gb/s with PHY types of 2.5GBASE-T.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIf	At operating speeds of 5 Gb/s with PHY types other than 5GBASE-T.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIg	At operating speeds of 5 Gb/s with PHY types of 5GBASE-T.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIh	At operating speeds of 10 Gb/s with PHY types other than 10GBASE-T.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIi	At operating speeds of 10 Gb/s with PHY types of 10GBASE-T.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIj	At operating speeds of 25 Gb/s.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIk	At operating speeds of 40 Gb/s.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIl	At operating speeds of 50 Gb/s.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIm	At operating speeds of 100 Gb/s.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIn	At operating speeds of 200 Gb/s.	31B.3.7	N/A	O	Yes [ ] No [ ]
*MIIo	At operating speeds of 400 Gb/s.	31B.3.7	N/A	O	Yes [ ] No [ ]

31B.4.4 PAUSE command requirements

Item	Feature	Subclause	Value/Comment	Status	Support
PCR1	Duplex mode of DTE	31B.1	Full duplex	M	Yes [ ]
PCR2	Reception of frames with destination address equal to the multicast address 01-80-C2-00-00-01	31B.1	Enabled	M	Yes [ ]
PCR3	PAUSE operation on PFC enable	31B.1	Disabled	PFC: M	Yes [ ]

31B.4.5 PAUSE command state diagram requirements

Item	Feature	Subclause	Value/Comment	Status	Support
PSD1	Transmit state diagram for PAUSE operation	31B.3.2	Meets requirements of Figure 31B–1	PST: M	N/A [ ] M:Yes [ ]
PSD2	Receive state diagram for PAUSE operation	31B.3.4	Meets requirements of Figure 31B–2	M	Yes [ ]
PSD3	Indication state diagram for PAUSE operation	31B.3.6	Meets requirements of Figure 31B–3	M	Yes [ ]

31B.4.6 PAUSE command MAC timing considerations

Item	Feature	Subclause	Value/Comment	Status	Support
TIM1	Effect of PAUSE frame on a frame already submitted to underlying MAC	31B.3.7	Has no effect	M	Yes [ ]
TIM2	Measurement point for station with MII	31B.3.7	Delay at MII ≤ one pause_quantum[a]	MIIa:M	Yes [ ] N/A [ ]
TIM3	Measurement point for station without MII at 100 Mb/s or less	31B.3.7	Delay at MDI ≤ one pause_quantum + 64 BT[a]	MIIb:M	Yes [ ] N/A [ ]
TIM4	Measurement point for station at 1000 Mb/s	31B.3.7	Delay at MDI ≤ two pause_quanta[a]	MIIc:M	Yes [ ] N/A [ ]
TIM5	Measurement point for station at 2.5 Gb/s with PHY type other than 2.5GBASE-T	31B.3.7	Delay at MDI ≤ 6 pause_quanta[a]	MIId:M	Yes [ ] N/A [ ]
TIM6	Measurement point for station at 2.5 Gb/s with PHY type of 2.5GBASE-T	31B.3.7	Delay at MDI ≤ 34 pause_quanta[a]	MIIe:M	Yes [ ] N/A [ ]
TIM7	Measurement point for station at 5 Gb/s with PHY type other than 5GBASE-T	31B.3.7	Delay at MDI ≤ 12 pause_quanta[a]	MIIf:M	Yes [ ] N/A [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
TIM8	Measurement point for station at 5 Gb/s with PHY type of 5GBASE-T	31B.3.7	Delay at MDI ≤ 42 pause_quanta[a]	MIIg:M	Yes [ ] N/A [ ]
TIM9	Measurement point for station at 10 Gb/s with PHY types other than 10GBASE-T	31B.3.7	Delay at MDI ≤ 60 pause_quanta[a]	MIIh:M	Yes [ ] N/A [ ]
TIM10	Measurement point for station at 10Gb/s with PHY type of 10GBASE-T	31B.3.7	Delay at MDI ≤ 74 pause_quanta[a]	MIIi:M	Yes [ ] N/A [ ]
TIM11	Measurement point for station at 25 Gb/s	31B.3.7	Delay at MDI ≤ 60 pause_quanta[a]	MIIj:M	Yes [ ] N/A [ ]
TIM12	Measurement point for station at 40 Gb/s	31B.3.7	Delay at MDI ≤ 118 pause_quanta[a]	MIIk:M	Yes [ ] N/A [ ]
TIM13	Measurement point for station at 50 Gb/s	31B.3.7	Delay at MDI ≤ 118 pause_quanta[a]	MIIl:M	Yes [ ] N/A [ ]
TIM14	Measurement point for station at 100 Gb/s	31B.3.7	Delay at MDI ≤ 117 pause_quanta[a]	MIIm:M	Yes [ ] N/A [ ]
TIM15	Measurement point for station at 200 Gb/s	31B.3.7	Delay at MDI ≤ 453 pause_quanta[a]	MIIn: M	Yes [ ] N/A [ ]
TIM16	Measurement point for station at 400 Gb/s	31B.3.7	Delay at MDI ≤ 905 pause_quanta[a]	MIIo: M	Yes [ ] N/A [ ]

[a]Delay from receiving valid PAUSE command, with nonzero value for pause_time, to cessation of transmission.

Annex 31C

(normative)

MAC Control organization specific extension operation

31C.1 Organization specific extension description

The extension operation is used to provide a standardized means for other organizations, to define their own MAC Control protocols outside the scope of this standard. The requirements defined in Clause 31 apply to these protocols.

31C.2 Transmission of Extension MAC Control frame

Upon receipt of a MA_CONTROL.request primitive containing the EXTENSION opcode from a MAC client, the MAC control sublayer calls the MAC sublayer MAC:MA_DATA.request service primitive with the following parameters:

a) The destination_address is set equal to the destination_address parameter of the MA_CONTROL.request primitive. This parameter is currently restricted to either the value 01–80–C2–00–00–01 or to the 48 bit individual address of the destination station.
b) The source_address is set equal to the 48 bit individual address of the station.
