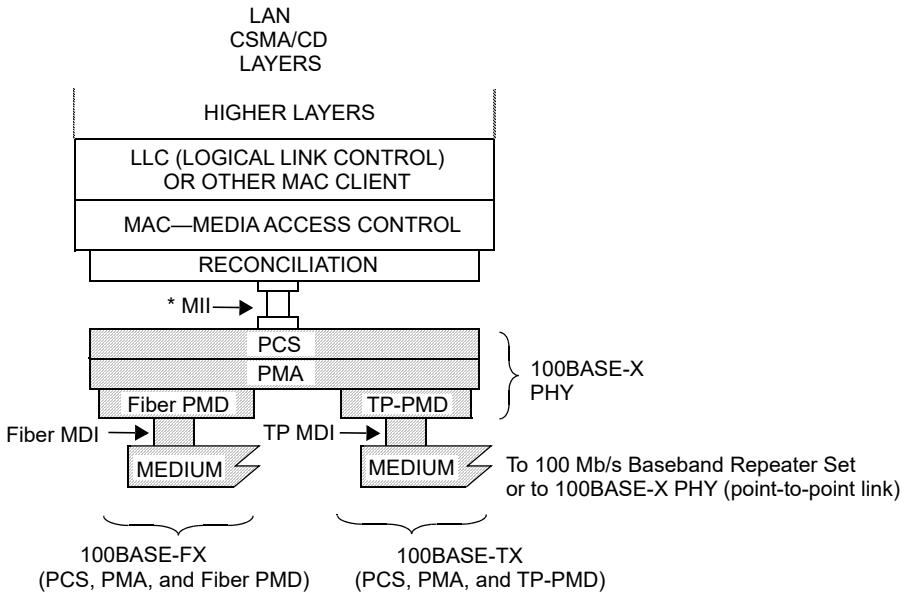
100BASE-X does not specify the PMD and MDI other than including the appropriate standard by reference along with the minor adaptations necessary for 100BASE-X. Figure 24–2 depicts the relationship between 100BASE-X and the PMDs of ISO/IEC 9314-3:1990 (for 100BASE-FX) and ANSI INCITS 263-1995 (for 100BASE-TX). The PMDs (and MDIs) for 100BASE-TX and 100BASE-FX are specified in subsequent clauses of this standard.

24.1.4.4 Auto-Negotiation



Auto-Negotiation shall be implemented for EEE capability. See Clause 28.

24.1.5 Inter-sublayer interfaces

There are a number of interfaces employed by 100BASE-X. Some (such as the PMA and PMD interfaces) use an abstract service model to define the operation of the interface. The PCS Interface is defined as a set of physical signals, in a medium-independent manner (MII). Figure 24–3 depicts the relationship and mapping of the services provided by all of the interfaces relevant to 100BASE-X.

It is important to note that, while this specification defines interfaces in terms of bits, nibbles, and code-groups, implementations may choose other data path widths for implementation convenience. The only exceptions are: a) the MII, which, when implemented, uses a nibble-wide data path as specified in Clause 22, and b) the MDI, which uses a serial, physical interface.

24.1.6 Functional block diagram

Figure 24–4 provides a functional block diagram of the 100BASE-X PHY. Signals or functions shown with dashed lines are optional.

24.1.7 State diagram conventions

The body of this standard is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5; state diagram timers follow the conventions of 14.2.3.2.

24.2 Physical Coding Sublayer (PCS)

24.2.1 Service Interface (MII)

The PCS Service Interface allows the 100BASE-X PCS to transfer information to and from the MAC (via the Reconciliation sublayer) or other PCS client, such as a repeater. The PCS Service Interface is precisely defined as the Media Independent Interface (MII) in Clause 22.

In this clause, the setting of MII variables to TRUE or FALSE is equivalent, respectively, to “asserting” or “deasserting” them as specified in Clause 22.

24.2.2 Functional requirements

The PCS comprises the Transmit, Receive, and Carrier Sense functions for 100BASE-T. In addition, the collisionDetect signal required by the MAC (COL on the MII) is derived from the PMA code-bit stream. The PCS shields the Reconciliation sublayer (and MAC) from the specific nature of the underlying channel. Specifically for receiving, the 100BASE-X PCS passes to the MII a sequence of data nibbles derived from incoming code-groups, each composed of five code-bits, received from the medium. Code-group alignment and MAC packet delimiting is performed by embedding special non-data code-groups. The MII uses a nibble-wide, synchronous data path, with packet delimiting being provided by separate TX_EN and RX_DV signals. The PCS provides the functions necessary to map these two views of the exchanged data. The process is reversed for transmit.

The following provides a detailed specification of the functions performed by the PCS, which comprise five parallel processes (Transmit, Transmit Bits, Receive, Receive Bits, and Carrier Sense). Figure 24–4 includes a functional block diagram of the PCS.

The Receive Bits process accepts continuous code-bits via the PMA_UNITDATA.indicate primitive. Receive monitors these bits and generates RXD<3:0>, RX_DV, and RX_ER on the MII, and the internal flag, receiving, used by the Carrier Sense and Transmit processes.

Upon receiving proper code-groups via rx_code_bits from the link partner as described in 24.2.2.1.6, the Receive process may support the LPI function by deactivating all or part of receive functional blocks of the PCS, PMA, and PMD to conserve energy during the low link utilization period, and generate commands through the MII as described in 22.2.2.8. By interacting with the Link Monitor of the PMA, a link failure detection mechanism is included to differentiate two conditions of link failure due to signal off: the loss of channel signal during the normal operation and the loss of refresh signal in the LPI mode.

The Transmit process generates continuous code-groups based upon the TXD<3:0>, TX_EN, and TX_ER signals on the MII. These code-groups are transmitted by Transmit Bits via the PMA_UNITDATA.request primitive. The Transmit process generates the MII signal COL based on whether a reception is occurring simultaneously with transmission. Additionally, it generates the internal flag, transmitting, for use by the Carrier Sense process.

The Transmit process may support the LPI function by deactivating all or part of the transmit functional blocks of the PCS, PMA, and PMD to conserve energy during the low link utilization period upon receiving the proper command from MII as described in 22.2.2.4. In this mode, the Transmit process is periodically activated to transmit refresh signal through tx_code_bits in order to allow the remote receiver to keep track of the long-term variation of channel characteristics and the clock drift between link partners.

The Carrier Sense process asserts the MII signal CRS when either transmitting or receiving is TRUE. Both the Transmit and Receive processes monitor link_status via the PMA_LINK.indicate primitive, to account for potential link failure conditions.

24.2.2.1 Code-groups

The PCS maps four-bit nibbles from the MII into five-bit code-groups, and vice versa, using a 4B/5B block coding scheme. A code-group is a consecutive sequence of five code-bits interpreted and mapped by the PCS. Implicit in the definition of a code-group is an establishment of code-group boundaries by an alignment function within the PCS Receive process. It is important to note that, with the sole exception of the SSD, which is used to achieve alignment, code-groups are undetectable and have no meaning outside the 100BASE-X physical protocol data unit, called a “stream.”

The coding method used, derived from ISO/IEC 9314-1, provides

a) Adequate codes (32) to provide for all Data code-groups (16) plus necessary control code-groups.
b) Appropriate coding efficiency (4 data bits per 5 code-bits; 80%) to effect a 100 Mb/s Physical Layer interface on a 125 Mb/s physical channel as provided by FDDI PMDs.
c) Sufficient transition density to facilitate clock recovery (when not scrambled).

Table 24–1 specifies the interpretation assigned to each five bit code-group, including the mapping to the nibble-wide (TXD or RXD) Data signals on the MII. The 32 code-groups are divided into four categories, as shown.

For clarity in the remainder of this clause, code-group names are shown between /slashes/. Code-group sequences are shown in succession, e.g., /1/2/....

The indicated code-group mapping is identical to ISO/IEC 9314-1:1989, with the following five exceptions:

a) The FDDI term *symbol* is avoided in order to prevent confusion with other 100BASE-T terminology. In general, the term *code-group* is used in its place.
b) The /S/ and /Q/ code-groups are not used by 100BASE-X and are interpreted as INVALID.
c) The /R/ code-group is used in 100BASE-X as the second code-group of the End-of-Stream delimiter rather than to indicate a Reset condition.
d) The /H/ code-group is used to propagate receive errors rather than to indicate the Halt Line State.
e) The /P/ code-group is used to indicate LPI.

24.2.2.1.1 Data code-groups

A Data code-group conveys one nibble of arbitrary data between the MII and the PCS. The sequence of Data code-groups is arbitrary, where any Data code-group can be followed by any other Data code-group. Data code-groups are coded and decoded but not interpreted by the PCS. Successful decoding of Data code-groups depends on proper receipt of the Start-of-Stream delimiter sequence, as defined in Table 24–1.

24.2.2.1.2 Idle code-groups

The Idle code-group (/I/) is transferred between streams. It provides a continuous fill pattern to establish and maintain clock synchronization. Idle code-groups are emitted from, and interpreted by, the PCS.

24.2.2.1.3 Control code-groups

The Control code-groups are used in pairs (/J/K/, /T/R/) to delimit MAC packets. Control code-groups are emitted from, and interpreted by, the PCS.

24.2.2.1.4 Start-of-Stream delimiter (/J/K/)

A Start-of-Stream delimiter (SSD) is used to delineate the boundary of a data transmission sequence and to authenticate carrier events. The SSD is unique in that it may be recognized independently of previously established code-group boundaries. The Receive function within the PCS uses the SSD to establish code-group boundaries. A SSD consists of the sequence /J/K/.

On transmission, the first 8 bits of the MAC preamble are replaced by the SSD, a replacement that is reversed on reception.

24.2.2.1.5 End-of-Stream delimiter (/T/R/)

An End-of-Stream delimiter (ESD) terminates all normal data transmissions. Unlike the SSD, an ESD cannot be recognized independent of previously established code-group boundaries. An ESD consists of the sequence /T/R/.

24.2.2.1.6 SLEEP code-groups (/P/)

The SLEEP code-group (/P/) is used to delineate the boundary of an LPI sequence and to deliver a refresh signal to maintain clock synchronization and verify the link status. The SLEEP code-groups are emitted from, and interpreted by, the PCS.

24.2.2.1.7 Invalid code-groups

The /H/ code-group indicates that the PCS's client wishes to indicate a Transmit Error to its peer entity. The normal use of this indicator is for repeaters to propagate received errors. Transmit Error code-groups are emitted from the PCS, at the request of the PCS's client through the use of the TX_ER signal, as described in 24.2.4.2.

The presence of any invalid code-group on the medium, including /H/, denotes a collision artifact or an error condition. Invalid code-groups are not intentionally transmitted onto the medium by DTE's. The PCS indicates the reception of an Invalid code-group on the MII through the use of the RX_ER signal, as described in 24.2.4.4.

24.2.2.2 Encapsulation

The 100BASE-X PCS accepts frames from the MAC through the Reconciliation sublayer and MII. Due to the continuously signaled nature of the underlying PMA, and the encoding performed by the PCS, the 100BASE-X PCS encapsulates the MAC frame (100BASE-X Service Data Unit, SDU) into a Physical Layer stream (100BASE-X Protocol Data Unit, PDU).

Except for the two code-group SSD, data nibbles within the SDU (including the non-SSD portions of the MAC preamble and SFD) are not interpreted by the 100BASE-X PHY. The conversion from a MAC frame to a Physical Layer stream and back to a MAC frame is transparent to the MAC.

Figure 24–5 depicts the mapping between MAC frames and Physical Layer streams.

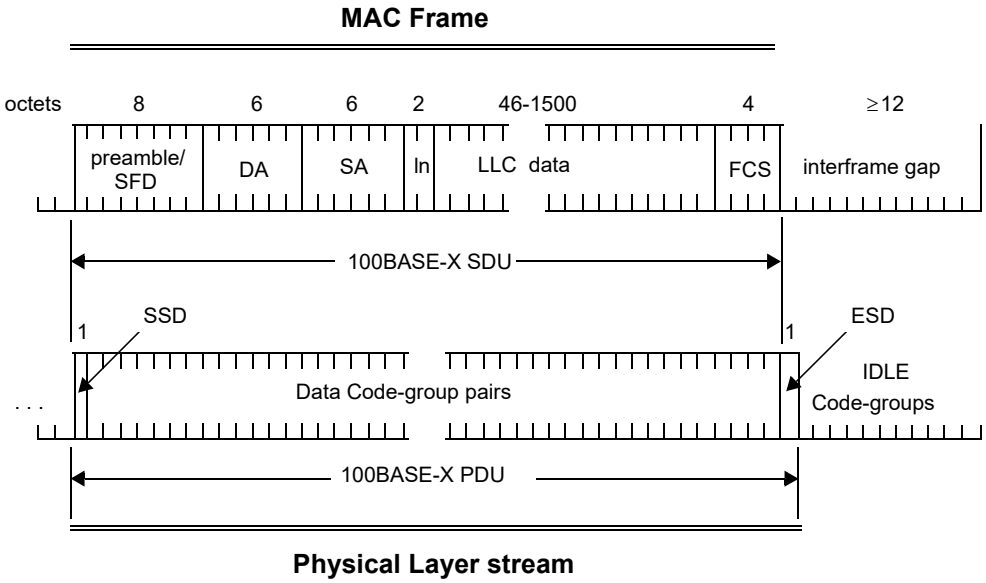

Figure 24–5—PCS encapsulation

A properly formed stream can be viewed as comprising the following three elements:

a) *Start-of-Stream Delimiter.* The start of a Physical Layer stream is indicated by a SSD, as defined in 24.2.2.1. The SSD replaces the first octet of the preamble from the MAC frame and vice versa.
b) *Data Code-groups.* Between delimiters (SSD and ESD), the PCS conveys Data code-groups corresponding to the data nibbles of the MII. These Data code-groups comprise the 100BASE-X Service Data Unit (SDU). Data nibbles within the SDU (including those corresponding to the MAC preamble and SFD) are not interpreted by the 100BASE-X PCS.
c) *End-of-Stream Delimiter.* The end of a properly formed stream is indicated by an ESD, as defined in 24.2.2.1. The ESD is transmitted by the PCS following the deassertion of TX_EN on the MII, which corresponds to the last data nibble composing the FCS from the MAC. It is transmitted during the period considered by the MAC to be the interframe gap (IFG). On reception, ESD is interpreted by the PCS as terminating the SDU.

Between streams, IDLE code-groups are conveyed between the PCS and PMA.

24.2.2.3 Data delay

The PCS maps a non-aligned code-bit data path from the PMA to an aligned, nibble-wide data path on the MII, both for Transmit and Receive. Logically, received bits have to be buffered to facilitate SSD detection and alignment, coding translation, and ESD detection. These functions necessitate an internal PCS delay of at least two code-groups. In practice, alignment may necessitate even longer delays of the incoming code-bit stream.

When the MII is present as an exposed interface, the MII signals TX_CLK and RX_CLK, not depicted in the following state diagrams, shall be generated by the PCS in accordance with Clause 22.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.2.2.4 Mapping between MII and PMA

Figure 24–6 depicts the mapping of the nibble-wide data path of the MII to the five-bit-wide code-groups (internal to the PCS) and the code-bit path of the PMA interface.

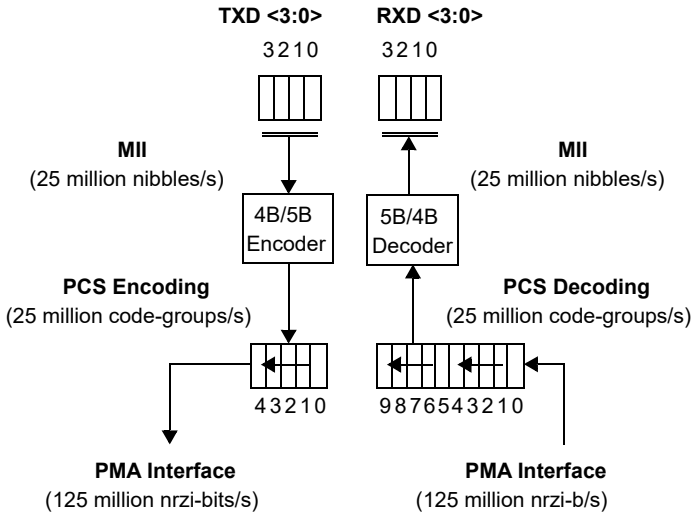

Figure 24–6—PCS reference diagram

Upon receipt of a nibble from the MII, the PCS encodes it into a five-bit code-group, according to 24.2.2.1. Code-groups are serialized into code-bits and passed to the PMA for transmission on the underlying medium, according to Figure 24–6. The first transmitted code-bit of a code-group is bit 4, and the last code-bit transmitted is bit 0. There is no numerical significance ascribed to the bits within a code-group; that is, the code-group is simply a five-bit pattern that has some predefined interpretation.

Similarly, the PCS deserializes code-bits received from the PMA, according to Figure 24–6. After alignment is achieved, based on SSD detection, the PCS converts code-groups into MII data nibbles, according to 24.2.2.1.

24.2.3 State variables

24.2.3.1 Constants

DATA

The set of 16 code-groups corresponding to valid DATA, as specified in 24.2.2.1. (In the Receive state diagram, the set operators $\in$ and $\notin$ are used to represent set membership and non-membership, respectively.)

ESD

The code-group pair corresponding to the End-of-Stream delimiter, as specified in 24.2.2.1.

ESD1

The code-group pair corresponding to the End-of-Stream delimiter, Part 1 (/T/), as specified in 24.2.2.1.

ESD2

The code-group pair corresponding to the End-of-Stream delimiter, Part 2 (/R/), as specified in

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.2.2.1.

HALT
: The Transmit Error code-group (/H/), as specified in 24.2.2.1.

IDLE
: The IDLE code-group, as specified in 24.2.2.1.

IDLES
: A code-group pair composed of /I/I/; /I/ as specified in 24.2.2.1.

SSD
: The code-group pair corresponding to the Start-of-Stream delimiter, as specified in 24.2.2.1.

SSD1
: The code-group corresponding to the Start-of-Stream delimiter, Part 1 (/J/), as specified in 24.2.2.1.

SSD2
: The code-group corresponding to the Start-of-Stream delimiter, Part 2 (/K/), as specified in 24.2.2.1.

The following constants are required only for the optional EEE capability:

SLEEP
: The SLEEP code-group (/P/) used by the LPI state delineator, as specified in 24.2.2.1.

TX_LP_IDLE
: A binary value 0001 of transmit nibble-wide Data signals (TXD), together with the deassertion of TX_EN and the assertion of TX_ER on the MII, used to indicate “Assert LPI”, as specified in 22.2.2.

RX_LP_IDLE
: A binary value 0001 of receive nibble-wide Data signals (RXD), together with the deassertion of RX_DV and the assertion of RX_ER on the MII, used to indicate “Assert LPI”, as specified in 22.2.2.

24.2.3.2 Variables

In the following, values for the MII parameters are definitively specified in Clause 22.

COL
: The COL signal of the MII as specified in Clause 22.

CRS
: The CRS signal of the MII as specified in Clause 22.

link_status
: The link_status parameter as communicated by the PMA_LINK.indicate primitive.

  Values: FAIL; the receive channel is not intact
  READY; the receive channel is intact and ready to be enabled by Auto-Negotiation
  OK; the receive channel is intact and enabled for reception

receiving
: A Boolean set by the Receive process to indicate non-IDLE activity (after squelch). Used by the Carrier Sense process, and also interpreted by the Transmit process for indicating a collision.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: TRUE; unsquelched carrier being received
FALSE; carrier not being received

rx_bits [9:0]

A vector of the 10 most recently received code-bits from the PMA as assembled by Receive Bits and processed by Receive. rx_bits [0] is the most recently received (newest) code-bit; rx_bits [9] is the least recently received code-bit (oldest). When alignment has been achieved, it contains the last two code-groups.

rx_code-bit

The rx_code-bit parameter as communicated by the most recent PMA_UNITDATA.indicate primitive (that is, the value of the most recently received code-bit from the PMA).

RX_DV

The RX_DV signal of the MII as specified in Clause 22. Set by the Receive process, RX_DV is also interpreted by the Receive Bits process as an indication that rx_bits is code-group aligned.

RX_ER

The RX_ER signal of the MII as specified in Clause 22.

RXD <3:0>

The RXD <3:0> signal of the MII as specified in Clause 22.

transmitting

A Boolean set by the Transmit Process to indicate a transmission in progress. Used by the Carrier Sense process.

Values: TRUE; the PCS's client is transmitting
FALSE; the PCS's client is not transmitting

tx_bits [4:0]

A vector of code-bits representing a code-group prepared for transmission by the Transmit Process and transmitted to the PMA by the Transmit Bits process.

TX_EN

The TX_EN signal of the MII as specified in Clause 22.

TX_ER

The TX_ER signal of the MII as specified in Clause 22.

TXD <3:0>

The TXD <3:0> signal of the MII as specified in Clause 22.

The following variables are required only for the optional EEE capability:

lpi_link_fail

A Boolean set by the Receive process to control the transition to a Link Down state when in the LPI mode. Used by the Link Monitor process of the PMA as communicated through the PMA_LPILINKFAIL.request primitive.

Values: TRUE; local receiver has detected a link failure status when in the LPI mode
FALSE; local receiver is functioning normally when in the LPI mode

rx_lpi

A Boolean set by the Receive process to indicate the LPI mode. Used by the Link Monitor process of the PMA as communicated through the PMA_RXLPI.request primitive. This parameter is used to alter the signal detection time as shown in Table 25–3. It can also be used to halt the clock RXC of MII as described in Clause 22.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: TRUE; local receiver is in the LPI mode
FALSE; local receiver is in the normal mode

rx_quiet

A Boolean set by the Receive process to indicate a Quiet state of the receiver in the LPI mode as communicated through the PMD_RXQUIET.request primitive. Also may be used to control the power-saving function of various receive blocks (PCS, PMA, and PMD).

Values: TRUE; the local receiver is in the Quiet state
FALSE; the local receiver is not in the Quiet state

tx_quiet

A Boolean set by the Transmit process to indicate a Quiet state of the transmitter in the LPI mode as communicated through the PMD_TXQUIET.request primitive. Also may be used to control the power-saving function of various transmit blocks (PCS, PMA, and PMD).

Values: TRUE; the local transmitter is in the Quiet state
FALSE; the local transmitter is not in the Quiet state

signal_status

The signal_status parameter as communicated by the PMD_SIGNAL.indicate primitive.

Values: ON; the quality and level of the received signal is satisfactory
OFF; the quality and level of the received signal is not satisfactory

24.2.3.3 Functions

nibble DECODE (code-group)

In Receive, this function takes as its argument a five-bit code-group and returns the corresponding MII RXD <3:0> nibble, per Table 24–1.

code-group ENCODE (nibble)

In the Transmit process, this function takes as its argument an MII TXD <3:0> nibble, and returns the corresponding five-bit code-group per Table 24–1.

SHIFTLEFT (rx_bits)

In Receive Bits, this function shifts rx_bits left one bit placing rx_bits [8] in rx_bits [9], rx_bits [7] in rx_bits [8] and so on until rx_bits [1] gets rx_bits [0].

24.2.3.4 Timers

code-bit_timer

In the Transmit Bits process, the timer governing the output of code-bits from the PCS to the PMA and thereby to the medium with a nominal 8 ns period. This timer shall be derived from a fixed frequency oscillator with a base frequency of 125 MHz ± 0.005% and phase jitter above 20 kHz less than ± 8°.

The following timers are required only for the optional EEE capability:

lpi_link_fail_timer

In the LPI mode, the receiver in Wake state is checking if valid symbols are properly received. This timer defines the maximum time allowed for the PHY between entry into the Wake state and subsequent entry into the Quiet, Sleep, or Idle states before assuming a link failure. The timer shall have a period between 90 μs and 110 μs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

lpi_rx_ti_timer

In the LPI mode, the receiver can move to the Idle state when it receives consecutive IDLE symbols. In order to distinguish the intended IDLE symbols sent by the link partner from ones falsely decoded during the transition from the Sleep state to the Quiet state before the signal status is deasserted, this receiver timer counts the minimum duration of received IDLE symbols. During this period of time, the receiver stays in an intermediate state. The timer shall have a period between 0.8 μs and 0.9 μs.

lpi_rx_tq_timer

In the LPI mode, this receiver timer counts the maximum duration the PHY stays in the Quiet state before it expects a Refresh signal. If the PHY fails to receive a valid Refresh signal or Wake signal before this timer expires, the receiver shall assume a link failure. The timer shall have a period between 24 ms and 26 ms.

lpi_rx_ts_timer

In the LPI mode, this receiver timer counts the maximum duration the PHY is allowed to stay in the Sleep state before assuming a link failure. The timer shall have a period between 240 μs and 260 μs.

lpi_rx_tw_timer

In the LPI mode, the receiver in the Quiet state is woken up by the receiving signal. This receiver timer counts the expected duration for the PHY to identify if valid SLEEP symbols for the Refresh state or valid IDLES for the Wake state have been properly received. If none of the SLEEP or IDLE symbols are received when the timer expires, the wake error counter as defined in MDIO manageable device (MMD) register 3.22 (see 45.2.3.12) shall be incremented. The timer shall have a period that does not exceed 20.5 μs.

lpi_tx_tq_timer

In the LPI mode, this transmitter timer counts the duration the PHY remains in the Quiet state before it has to wake to send a refresh signal. The timer shall have a period between 20 ms and 22 ms.

lpi_tx_ts_timer

In the LPI mode, this transmitter timer counts the duration the PHY is sending continuous SLEEP symbols in the Sleep state before going into the Quiet state. The timer shall have a period between 200 μs and 220 μs.

24.2.3.5 Messages

gotCodeGroup.indicate

A signal sent to the Receive process by the Receive Bits process after alignment has been achieved signifying completion of reception of the next code-group in rx_bits(4:0), with the preceding code-group moved to rx_bits [9:5]. rx_bits [9:5] may be considered as the “current” code-group.

PMA_UNITDATA.indicate (rx_code-bit)

A signal sent by the PMA signifying that the next code-bit from the medium is available in rx_code-bit.

sentCodeGroup.indicate

A signal sent to the Transmit process from the Transmit Bits process signifying the completion of transmission of the code-group in tx_bits [4:0].

24.2.4 State diagrams

24.2.4.1 Transmit Bits

Transmit Bits is responsible for taking code-groups prepared by the Transmit process and transmitting them to the PMA using PMA_UNITDATA.request, the frequency of which determines the transmit clock. Transmit deposits these code-groups in tx_bits with Transmit Bits signaling completion of a code-group transmission with sentCodeGroup.indicate.

The PCS shall implement the Transmit Bits process as depicted in Figure 24–7 including compliance with the associated state variables as specified in 24.2.3.

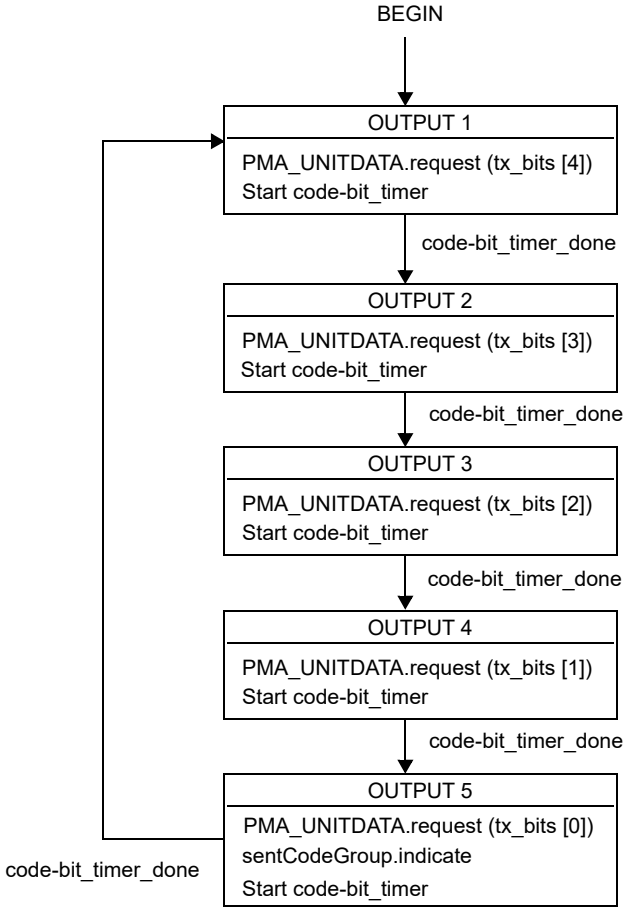

Figure 24–7—Transmit Bits state diagram

24.2.4.2 Transmit

The Transmit process sends code-groups to the PMA via tx_bits and the Transmit Bits process. When initially invoked, and between streams (delimited by TX_EN on the MII), except in the LPI mode for the optional EEE capability, the Transmit process sources continuous Idle code-groups (/I/) to the PMA. Upon the assertion of TX_EN by the MII, the Transmit process passes an SSD (/J/K/) to the PMA, ignoring the TXD<3:0> nibbles during these two code-group times. Following the SSD, each TXD<3:0> nibble is encoded into a five-bit code-group until TX_EN is deasserted. If, while TX_EN is asserted, the TX_ER signal is asserted, the Transmit process passes Transmit Error code-groups (/H/) to the PMA. Following the deassertion of TX_EN, an ESD (/T/R/) is generated, after which the transmission of Idle code-groups is resumed by the IDLE state.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If EEE Capability is supported, upon the assertion of LPI on the MII (a binary value 0001 of TXD, together with the deassertion of TX_EN and the assertion of TX_ER, see 22.2.2), the Transmit process enters the LPI mode and starts to source SLEEP (/P/) code-groups to the PMA. In the LPI mode, the Transmit process is controlled by timers to switch between the TX_SLEEP and TX_QUIET states. The Transmit process returns to the IDLE state whenever the MII deasserts LPI.

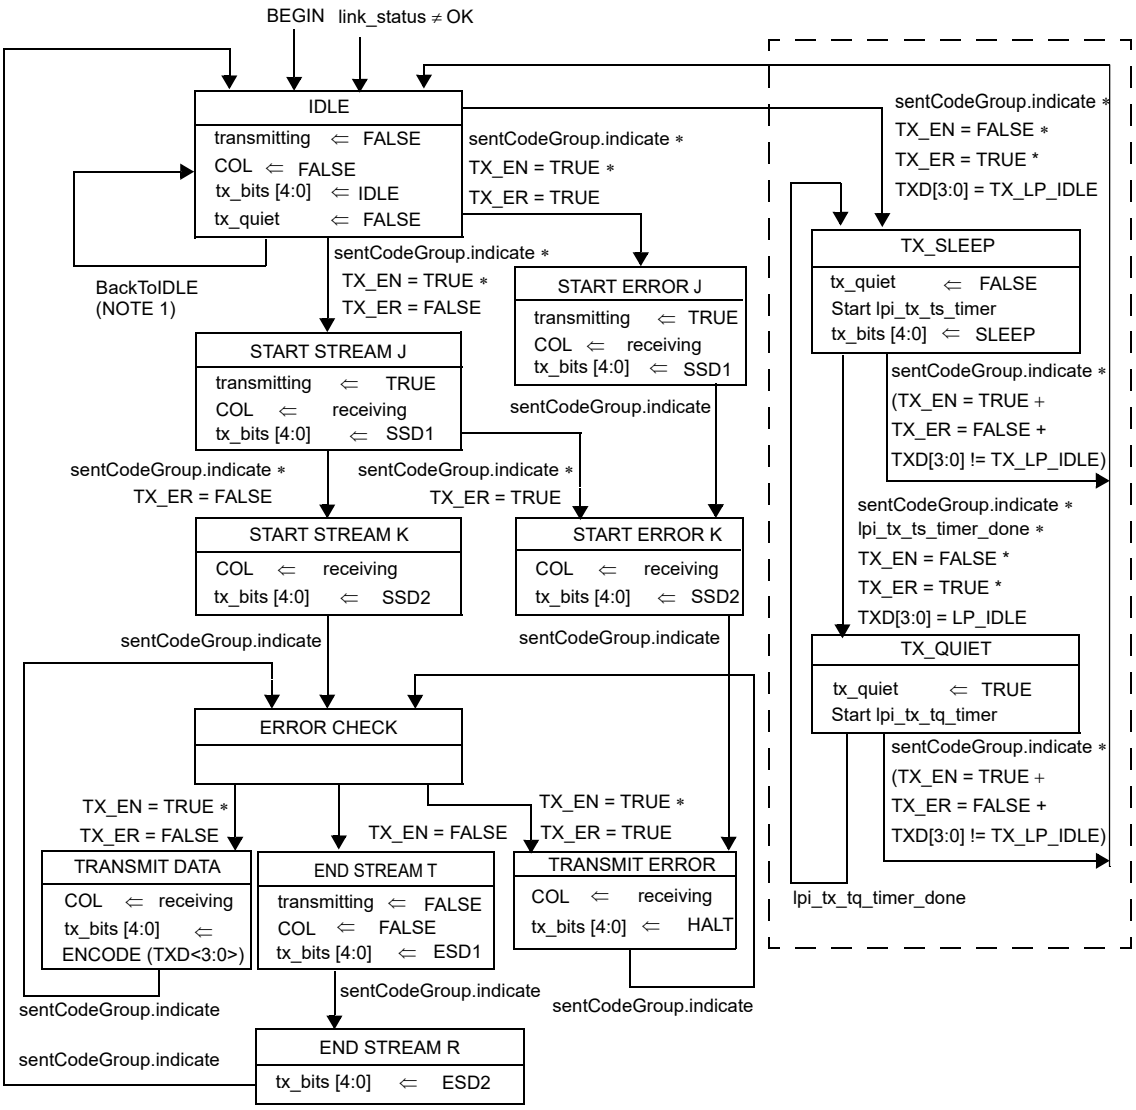
Collision detection is implemented by noting the occurrence of carrier receptions during transmissions, following the model of 10BASE-T.

The indication of link_status ≠ OK by the PMA at any time causes an immediate transition to the IDLE state and supersedes any other Transmit process operations.

The PCS shall implement the Transmit process as depicted in Figure 24–8 including compliance with the associated state variables as specified in 24.2.3.

24.2.4.3 Receive Bits

The Receive Bits process collects code-bits from the PMA interface passing them to the Receive process via rx_bits. rx_bits [9:0] represents a sliding, 10-bit window on the PMA code-bits, with newly received code-bits from the PMA (rx_code-bit) being shifted into rx_bits [0]. This is depicted in Figure 24–9. Bits are collected serially until Receive indicates alignment by asserting RX_DV, after which Receive Bits signals Receive for every five code-bits accumulated. Serial processing resumes with the deassertion of RX_DV.



The PCS shall implement the Receive Bits process as depicted in Figure 24–10 including compliance with the associated state variables as specified in 24.2.3.

24.2.4.4 Receive

The Receive process state diagram can be viewed as comprising two sections: prealigned and aligned. In the prealigned states, IDLE, CARRIER DETECT, and IDENTIFY JK, except for the detection of SLEEP code-groups when supporting the optional EEE capability, the Receive process is waiting for an indication of channel activity followed by an SSD. After successful alignment, the incoming code-groups are decoded while waiting for stream termination.

If EEE Capability is supported, when the Receive process successfully aligns and decodes two consecutive SLEEP (/P/) code-groups, it enters the LPI mode and stays in LPI states until either the IDLE code-groups are received, where it leads the Receive process to the IDLE state, or a link failure condition in the LPI mode occurs, where it causes the Receive process to enter the RX_LPI_LINK_FAIL state and eventually move to the IDLE state.

NOTE 1—BackToIDLE represents the following branch condition:

If the EEE capability is supported,
sentCodeGroup.indicate * TX_EN = FALSE * (TX_E R= FALSE + (TX_ER = TRUE * TXD[3:0] ≠ TX_LP_IDLE))
Otherwise,
sentCodeGroup.indicate * TX_EN = FALSE

NOTE 2—States and state transitions shown within the dashed box are only required for the EEE capability

Figure 24–8—Transmit state diagram

24.2.4.4.1 Detecting channel activity

In a DTE operating in half duplex mode, the detection of activity on the underlying channel is used both by the MAC (via the MII CRS signal and the Reconciliation sublayer) for deferral purposes, and by the Transmit process for collision detection. Activity, signaled by the assertion of receiving, is indicated by the receipt of two non-contiguous ZEROS within any 10 code-bits of the incoming code-bit stream.

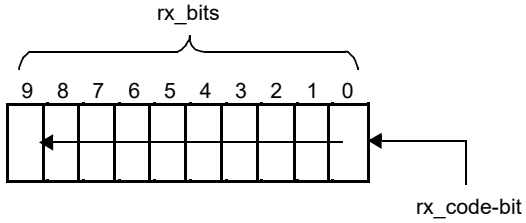

Figure 24–9—Receive Bits reference diagram

24.2.4.4.2 Code-group alignment

After channel activity is detected, the Receive process first aligns the incoming code-bits on code-group boundaries for subsequent data decoding. This is achieved by scanning the rx_bits vector for a SSD (/J/K/). The MII RX_DV signal remains deasserted during this time, which ensures that the Reconciliation sublayer will ignore any signals on RXD <3:0>. Detection of the SSD causes the Receive process to enter the START OF STREAM J state.

Well-formed streams contain SSD (/J/K/) in place of the first eight preamble bits. In the event that something else is sensed immediately following detection of carrier, a False Carrier Indication is signaled to the MII by asserting RX_ER and setting RXD to 1110 while RX_DV remains deasserted. The associated carrier event, as terminated by 10 ONEs, is otherwise ignored.

24.2.4.4.3 Stream decoding

The Receive process substitutes a sequence of alternating ONE and ZERO data-bits for the SSD, which is consistent with the preamble pattern expected by the MAC.

The Receive process then performs the DECODE function on the incoming code-groups, passing decoded data to the MII, including those corresponding to the remainder of the MAC preamble and SFD. The MII signal RX_ER is asserted upon decoding any code-group following the SSD that is neither a valid Data code-group nor a valid stream termination sequence.

24.2.4.4.4 Stream termination

There are two means of effecting stream termination in the Receive process (Figure 24–11 and Figure 24–12) .

NOTE—States and state transitions shown within the dashed box are only required for the EEE capability

Figure 24–11—Receive state diagram, part a

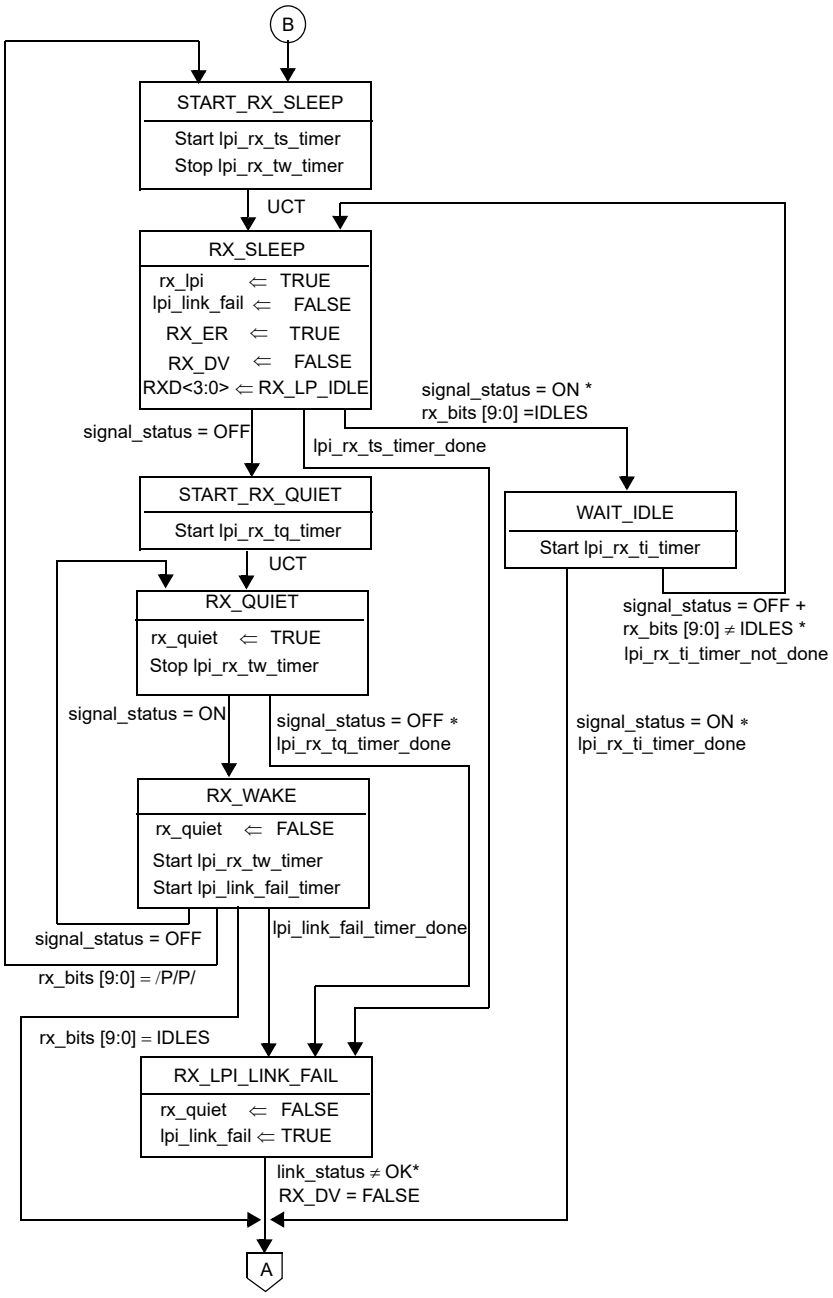

Figure 24–12—Receive state diagram, part b (only required for the EEE capability)

A normal stream termination is caused by detection of an ESD (/T/R/) in the rx_bits vector. In order to preserve the ability of the MAC to properly delimit the FCS at the end of the frame (that is, to avoid incorrect AlignmentErrors in the MAC) the internal signal receiving (and through it, the MII CRS signal, per Clause 22) is deasserted immediately following the last code-bit in the stream that maps to the FCS. Note that the condition link_status ≠ OK during stream reception (that is, when receiving = TRUE) causes an immediate transition to the LINK FAILED state and supersedes any other Receive process operations.

A premature stream termination is caused by the detection of two Idle code-groups (/I/I) in the rx_bits vector prior to an ESD. Note that RX_DV remains asserted during the nibble corresponding to the first five

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

contiguous ONEs while RX_ER is signaled on the MII. RX_ER is also asserted in the LINK FAILED state, which ensures that RX_ER remains asserted for sufficient time to be detected.

Stream termination causes a transition to the IDLE state.

The PCS shall implement the Receive process as depicted in Figure 24–11 and Figure 24–12 including compliance with the associated state variables as specified in 24.2.3.

24.2.4.5 Carrier Sense

The Carrier Sense process generates the signal CRS on the MII, which (via the Reconciliation sublayer) a MAC operating in half duplex mode uses for deferral. The process operates by performing a logical OR operation on the internal messages receiving and transmitting, generated by the Receive and Transmit processes, respectively.

The PCS shall implement the Carrier Sense process as depicted in Figure 24–13 including compliance with the associated state variables as specified in 24.2.3.

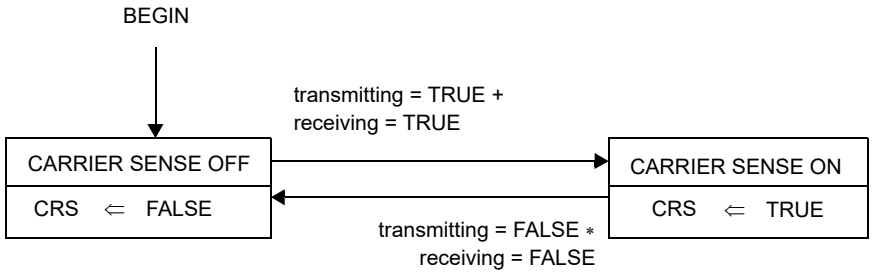

Figure 24–13—Carrier Sense state diagram

24.3 Physical Medium Attachment (PMA) sublayer

24.3.1 Service interface

The following specifies the service interface provided by the PMA to the PCS or another client, such as a repeater. These services are described in an abstract manner and do not imply any particular implementation.

The PMA Service Interface supports the exchange of code-bits between the PCS and/or Repeater entities. The PMA converts code-bits into NRZI format and passes these to the PMD, and vice versa. It also generates additional status indications for use by its client.

The following primitives are defined:

PMA_TYPE.indicate

PMA_UNITDATA.request

PMA_UNITDATA.indicate

PMA_CARRIER.indicate

PMA_LINK.indicate

PMA_LINK.request

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_RXERROR.indicate

PMA_LPILINKFAIL.request

PMA_RXLPI.request

24.3.1.1 PMA_TYPE.indicate

This primitive is generated by the PMA to indicate the nature of the PMA instantiation. The purpose of this primitive is to allow clients to support connections to the various types of 100BASE-T PMA entities in a generalized manner.

24.3.1.1.1 Semantics of the service primitive

PMA_TYPE.indicate (pma_type)

The pma_type parameter for use with a 100BASE-X PMA is “X”.

24.3.1.1.2 When generated

The PMA continuously generates this primitive to indicate the value of pma_type.

24.3.1.1.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

24.3.1.2 PMA_UNITDATA.request

This primitive defines the transfer of data (in the form of code-bits) from the PMA’s client to the PMA.

24.3.1.2.1 Semantics of the service primitive

PMA_UNITDATA.request (tx_code-bit)

This primitive defines the transfer of data (in the form of code-bits) from the PCS or other client to the PMA. The tx_code-bit parameter can take one of two values: ONE or ZERO.

24.3.1.2.2 When generated

The PCS or other client continuously sends, at a nominal 125 Mb/s rate, the appropriate code-bit for transmission on the medium.

24.3.1.2.3 Effect of receipt

Upon receipt of this primitive, the PMA generates a PMD_UNITDATA.request primitive, requesting transmission of the indicated code-bit, in NRZI format (tx_nrzi-bit), on the MDI.

24.3.1.3 PMA_UNITDATA.indicate

This primitive defines the transfer of data (in the form of code-bits) from the PMA to the PCS or other client.

24.3.1.3.1 Semantics of the service primitive

PMA_UNITDATA.indicate (rx_code-bit)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The data conveyed by PMA_UNITDATA.indicate is a continuous code-bit sequence at a nominal 125 Mb/s rate. The rx_code-bit parameter can take one of two values: ONE or ZERO.

24.3.1.3.2 When generated

The PMA continuously sends code-bits to the PCS or other client corresponding to the PMD_UNITDATA.indicate primitives received from the PMD.

24.3.1.3.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

24.3.1.4 PMA_CARRIER.indicate

This primitive is generated by the PMA to indicate that a non-squelched, non-IDLE code-bit sequence is being received from the PMD. The purpose of this primitive is to give clients the earliest reliable indication of activity on the underlying continuous-signaling channel.

24.3.1.4.1 Semantics of the service primitive

PMA_CARRIER.indicate (carrier_status)

The carrier_status parameter can take on one of two values, ON or OFF, indicating whether a non-squelched, non-IDLE code-bit sequence (that is, carrier) is being received (ON) or not (OFF).

24.3.1.4.2 When generated

The PMA generates this primitive to indicate a change in the value of carrier_status.

24.3.1.4.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

24.3.1.5 PMA_LINK.indicate

This primitive is generated by the PMA to indicate the status of the underlying PMD receive link.

24.3.1.5.1 Semantics of the service primitive

PMA_LINK.indicate (link_status)

The link_status parameter can take on one of three values: READY, OK, or FAIL, indicating whether the underlying receive channel is intact and ready to be enabled by Auto-Negotiation (READY), intact and enabled (OK), or not intact (FAIL). Link_status is set to FAIL when the PMD sets signal_status to OFF; when Auto-Negotiation (optional) sets link_control to DISABLE; or when Far-End Fault Detect (optional) sets faulting to TRUE. When link_status ≠ OK, then rx_code-bit and carrier_status are undefined.

24.3.1.5.2 When generated

The PMA generates this primitive to indicate a change in the value of link_status.

24.3.1.5.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.3.1.6 PMA_LINK.request

This primitive is generated by the Auto-Negotiation algorithm, when implemented, to allow it to enable and disable operation of the PMA. See Clause 28. When Auto-Negotiation is not implemented, the primitive is never invoked and the PMA behaves as if link_control = ENABLE.

24.3.1.6.1 Semantics of the service primitive

PMA_LINK.request (link_control)

The link_control parameter takes on one of three values: SCAN_FOR_CARRIER, DISABLE, or ENABLE. Auto-Negotiation sets link_control to SCAN_FOR_CARRIER prior to receiving any fast link pulses, permitting the PMA to sense a 100BASE-X signal. Auto-Negotiation sets link_control to DISABLE when it senses an Auto-Negotiation partner (fast link pulses) and has to temporarily disable the 100BASE-X PHY while negotiation ensues. Auto-Negotiation sets link_control to ENABLE when full control is passed to the 100BASE-X PHY.

24.3.1.6.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in Clause 28.

24.3.1.6.3 Effect of receipt

This primitive affects operation of the PMA Link Monitor function as described in 24.3.4.4.

24.3.1.7 PMA_RXERROR.indicate

This primitive is generated by the PMA to indicate that an error has been detected during a carrier event.

24.3.1.7.1 Semantics of the service primitive

PMA_RXERROR.indicate (rxerror_status)

The rxerror_status parameter can take on one of two values: ERROR or NO_ERROR, indicating whether the received carrier event contains a detectable error (ERROR) or not (NO_ERROR). A carrier event is considered to be in error when it is not started by a Start-of-Stream Delimiter.

24.3.1.7.2 When generated

The PMA generates this primitive whenever a new, non-squelched carrier event is not started by a Start-of-Stream Delimiter.

24.3.1.7.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

24.3.1.8 PMA_LPILINKFAIL.request

This primitive is generated by the Receive Process of the PCS only if EEE is supported to control one of the link failure conditions of the Link Monitor in the PMA (see 24.2.4.3 and Figure 24–12).

24.3.1.8.1 Semantics of the service primitive

PMA_LPILINKFAIL.request (lpi_link_fail)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The lpi_link_fail parameter takes on one of two values, TRUE or FALSE, indicating whether a link failure condition has been set (TRUE) or not (FALSE). The value of TRUE, when in the LPI mode, sets the link_status of the Link Monitor to FAIL (see 24.3.4.4 and Figure 24–15).

24.3.1.8.2 When generated

The PCS generates this primitive to indicate a link failure condition caused by the loss of Refresh signal when in the LPI mode.

24.3.1.8.3 Effect of receipt

This primitive affects operation of the PMA Link Monitor function as described in 24.3.4.4.

24.3.1.9 PMA_RXLPI.request

This primitive is generated by the Receive Process of the PCS only if EEE is supported to indicate that the receiver is in the LPI mode (see 24.2.4.3 and Figure 24–12).

24.3.1.9.1 Semantics of the service primitive

PMA_RXLPI.request (rx_lpi)

The rx_lpi parameter takes on one of two values, TRUE or FALSE, indicating whether the receiver is in the LPI mode (TRUE) or not (FALSE).

24.3.1.9.2 When generated

The PCS generates this primitive to indicate the LPI mode.

24.3.1.9.3 Effect of receipt

This primitive affects the operation of the PMA Link Monitor function as described in 24.3.4.4. Other use of receipt of this primitive by the client is unspecified by the PMA sublayer.

24.3.2 Functional requirements

The 100BASE-X PMA comprises the following functions:

a) Mapping of transmit and receive code-bits between the PMA Service Interface and the PMD Service Interface.
b) Link Monitor, which maps the PMD_SIGNAL.indicate primitive to the PMA_LINK.indicate primitive, indicating the availability of the underlying PMD.
c) Carrier Detection, which generates the PMA_CARRIER.indicate and PMA_RXERROR.indicate primitives from inspection of received PMD signals.
d) Far-End Fault (optional), composed of the Far-End Fault Generate and Far-End Fault Detect processes, which sense receive channel failures and send the Far-End Fault Indication, and sense the Far-End Fault Indication.
e) EEE capability, which disables the Far-End Fault function and modifies the link down condition with the PMA_RXLPI.request primitive.

Figure 24–4 includes a functional block diagram of the PMA.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.3.2.1 Far-End fault

Auto-Negotiation provides a Remote Fault capability useful for detection of asymmetric link failures; i.e., channel error conditions detected by the far-end station but not the near-end station. Since Auto-Negotiation is specified only for media supporting eight-pin modular connectors, such as used by 100BASE-TX over twisted pair, Auto-Negotiation's Remote Fault capability is unavailable to other media for which it may be functionally beneficial, such as 100BASE-TX over shielded twisted pair or 100BASE-FX. A remote fault capability for 100BASE-FX is particularly useful due to this medium's applicability over longer distances (making end-station checking inconvenient) and for backbones (in which detection of link failures can trigger redundant systems).

For these reasons, 100BASE-X provides an optional Far-End Fault facility when Auto-Negotiation cannot be used. Far-End Fault shall not be implemented for media capable of supporting Auto-Negotiation.

When no signal is being received, as indicated by the PMD's signal detect function, the Far-End Fault feature permits the station to transmit a special Far-End Fault Indication to its far-end peer. The Far-End Fault Indication is sent only when a physical error condition is sensed on the receive channel. In all other situations, including reception of the Far-End Fault Indication itself, the PMA passes through tx_code-bit. (Note that the Far-End Fault architecture is such that IDLEs are automatically transmitted when the Far-End Fault Indication is detected. This is necessary to re-establish communication when the link is repaired.)

The Far-End Fault Indication is composed of three or more repeating cycles, each of 84 ONEs followed by a single ZERO. This signal is sent in-band and is readily detectable but is constructed so as to not satisfy the 100BASE-X carrier sense criterion. It is therefore transparent to the PMA's client and to stations not implementing Far-End Fault.

As shown in Figure 24–4, Far-End Fault is implemented through the Far-End Fault Generate, Far-End Fault Detect, and the Link Monitor processes.

The Far-End Fault Generate process, which is interposed between the incoming tx_code-bit stream and the TX process, is responsible for sensing a receive channel failure (signal_status=OFF during the normal operation) and transmitting the Far-End Fault Indication in response. The transmission of the Far-End Fault Indication may start or stop at any time depending only on signal_status. The Far-End Fault shall not be generated when in the LPI mode.

The Far-End Fault Detect process continuously monitors rx_code-bits from the RX process for the Far-End Fault Indication. Detection of the Far-End Fault Indication disables the station by causing the Link Monitor process to deassert link_status, which in turn causes the station to source IDLEs. Far-End Fault detection can also be used by management functions not specified in this clause.

24.3.2.2 Comparison to previous IEEE 802.3 PMAs

Previous IEEE 802.3 PMAs perform the additional functions of SQE Test and Jabber. Neither of these functions is implemented in the 100BASE-X PMA.

SQE Test is provided in other Physical Layers to check the integrity of the Collision Detection mechanism independently of the Transmit and Receive capabilities of the Physical Layer. Since 100BASE-X effects collision detection by sensing receptions that occur during transmissions, collision detection is dependent on the health of the receive channel. By checking the ability to properly receive signals from the PMD, the Link Monitor function therefore functionally subsumes the functions previously implemented by SQE Test.

The Jabber function prevents a DTE from causing total network failure under certain classes of faults. When using mixing media (e.g., coaxial cables or passive optical star couplers), this function naturally has to be implemented in the DTE. 100BASE-X requires the use of an active repeater, with one DTE or repeater

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

attached to each port. As an implementation optimization, the Jabber function has therefore been moved to the repeater in 100BASE-X.

24.3.2.3 EEE capability

EEE capability, when communicated by the PMA_RXLPI.request primitive, affects the PMA in two ways. It disables the operation of the Far-End Fault processes to ignore the frequent on and off activity of signal_status. It receives link failure detection as communicated by the PMA_LPILINKFAIL.request primitive and changes the Link Monitor process to allow an exit from the LPI mode to a link down state. The EEE capability of the PMA is required only if the PCS supports EEE. If LPI is implemented, the operation of the PMA shall comply with the requirements in this subclause.

24.3.3 State variables

24.3.3.1 Constants

FEF_CYCLES

The number of consecutive cycles (of FEF_ONES ONEs and a single ZERO) necessary to indicate the Far-End Fault Indication. This value is 3.

FEF_ONES

The number of consecutive ONEs to be transmitted for each cycle of the Far-End Fault Indication. This value is 84.

24.3.3.2 Variables

carrier_status

The carrier_status parameter to be communicated by the Carrier Detect process through the PMA_CARRIER.indicate primitive. Carrier is defined as receipt of two noncontiguous ZEROs in 10 code-bits.

Values: ON; carrier is being received
OFF; carrier is not being received

faulting

The faulting variable set by the Far-End Fault Detect process, when implemented, indicating whether or not a Far-End Fault Indication is being sensed. This variable is used by the Link Monitor process to force link_status to FAIL.When Far-End Fault is not implemented, this variable is always FALSE.

Values: TRUE; Far-End Fault Indication is being sensed
FALSE; Far-End Fault Indication is not being sensed

link_control

The link_control parameter as communicated by the PMA_LINK.request primitive. When Auto-Negotiation is not implemented, the value of link_control is always ENABLE. See Clause 28 for a complete definition.

link_status

The link_status parameter as communicated by the Link Monitor process through the PMA_LINK.indicate primitive.

Values: FAIL; the receive channel is not intact

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

READY; the receive channel is intact and ready to be enabled by Auto-Negotiation
OK; the receive channel is intact and enabled for reception

r_bits [9:0]

In Carrier Detect, a vector of the 10 most recently received code-bits from the PMD RX process. r_bits [0] is the most recently received (newest) code-bit; r_bits [9] is the least recently received code-bit (oldest). r_bits is an internal variable used exclusively by the Carrier Detect process.

rx_code-bit

The rx_code-bit parameter as delivered by the RX process, which operates in synchronism with the PMD_UNITDATA.indicate primitive. rx_code-bit is the most recently received code-bit from the PMD after conversion from NRZI.

rxerror_status

The rxerror_status parameter to be communicated by the Carrier Detect process through the PMA_RXERROR.indicate primitive.

Values: NO_ERROR; no error detected in the carrier event being received
ERROR; the carrier event being received is in error

signal_status

The signal_status parameter as communicated by the PMD_SIGNAL.indicate primitive.

Values: ON; the quality and level of the received signal is satisfactory
OFF; the quality and level of the received signal is not satisfactory

tx_code-bit_in

In Link Fault Generate, the tx_code-bit parameter as conveyed to the PMA from the PMA client by the PMA_UNITDATA.request.

tx_code-bit_out

In Link Fault Generate, the tx_code-bit parameter to be passed to the TX process. Note that this is called tx_code-bit by the TX process.

The following variables are required only for the optional EEE capability:

lpi_link_fail

The lpi_link_fail parameter is communicated by the PMA_LPILINKFAIL.request primitive. In the LPI mode, this variable is generated by the Receive process of the PCS to control the transition to a Link Down state. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is FALSE.

Values: TRUE; local receiver has detected a link failure status when in an LPI state
FALSE; local receiver is functioning normally when in an LPI state

rx_lpi

The rx_lpi parameter is communicated by the PMA_RXLPI.request primitive. This variable is generated by the Receive process of the PCS to indicate the LPI mode. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is FALSE.

Values: TRUE; local receiver is in the LPI mode
FALSE; local receiver is in the normal operation mode

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.3.3.3 Functions

SHIFTLEFT (rx_bits)

In Carrier Detect, this function shifts rx_bits left one bit placing rx_bits [8] in rx_bits [9], rx_bits [7] in rx_bits [8] and so on until rx_bits [1] gets rx_bits [0].

24.3.3.4 Timers

stabilize_timer

An implementation-dependent delay timer between 330 µs and 1000 µs, inclusive, to ensure that the link is stable.

24.3.3.5 Counters

num_cycles

In Link Fault Detect, a counter containing the number of consecutive Far-End Fault cycles currently sensed. This counter gets reset on initialization or when the bit stream fails to qualify as a potential Far-End Fault Indication. It never exceeds FEF_CYCLES.

num_ones

This represents two separate and independent counters: In Link Fault Generate, a counter containing the number of consecutive ONEs already sent during this cycle of the Far-End Fault Indication. In Link Fault Detect, a counter containing the number of consecutive ONEs currently sensed; it gets reset whenever a ZERO is detected or when the bit stream fails to qualify as a potential Far-End Fault Indication. These counters never exceed FEF_ONES.

24.3.3.6 Messages

PMD_UNITDATA.indicate (rx_nrzi-bit)

A signal sent by the PMD signifying that the next nrzi-bit is available from the medium. nrzi-bit is converted (instantaneously) to code-bit by the RX process and used by the Carrier Detect process.

5xPMD_UNITDATA.indicates

In Carrier Detect, this shorthand notation represents repetition of the preceding state five times synchronized with five successive PMD_UNITDATA.indicates.

PMA_UNITDATA.request (tx_code-bit)

A signal sent by the PMA's client signifying that the next nrzi-bit is available for transmission. For this process, the tx_code-bit parameter is interpreted as tx_code-bit_in.

24.3.4 Process specifications and state diagrams

24.3.4.1 TX

The TX process passes data from the PMA's client directly to the PMD. The PMA shall implement the TX process as follows: Upon receipt of a PMA_UNITDATA.request (tx_code-bit), the PMA performs a conversion to NRZI format and generates a PMD_UNITDATA.request (tx_nrzi-bit) primitive with the same logical value for the tx_nrzi-bit parameter. Note that tx_code-bit is equivalent to tx_code-bit_out of the Link Fault Generate process when implemented.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.3.4.2 RX

The RX process passes data from the PMD directly to the PMA's client and to the Carrier Detect process. The PMA shall implement the RX process as follows: Upon receipt of a PMD_UNITDATA.indicate (rx_nrzi-bit), the PMA performs a conversion from NRZI format and generates a PMA_UNITDATA.indicate (rx_code-bit) primitive with the same logical value for the rx_code-bit parameter.

24.3.4.3 Carrier detect

The PMA Carrier Detect process provides repeater clients an indication that a carrier event has been sensed and an indication if it is deemed in error. A carrier event is defined as receipt of two non-contiguous ZEROS within any 10 rx_code-bits. A carrier event is in error if it does not start with an SSD. The Carrier Detect process performs this function by continuously monitoring the code-bits being delivered by the RX process, and checks for specific patterns that indicate non-IDLE activity and SSD bit patterns.

The Carrier Detect process collects code-bits from the PMD RX process. r_bits [9:0] represents a sliding, 10-bit window on the code-bit sequence, with newly received code-bits from the RX process being shifted into r_bits [0]. The process shifts the r_bits vector to the left, inserts the newly received code-bit into position 0, and waits for the next PMD.UNITDATA.indicate before repeating the operation. This is depicted in Figure 24–13. The Carrier Detect process monitors the r_bits vector until it detects two noncontiguous ZEROS in the incoming code-bit sequence. This signals a transition of carrier_status from OFF to ON. Each new carrier is further examined for a leading SSD (1100010001) with rxerror_status set to ERROR if it is not confirmed. A pattern of 10 contiguous ONEs in the stream indicates a return to carrier_status = OFF. Code-bit patterns of contiguous ONEs correspond to IDLE code-groups in the PCS, per the encoding specified in 24.2.2.1.

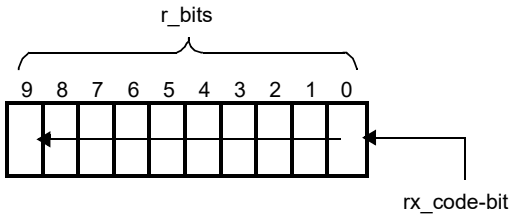

Figure 24–13—Carrier Detect reference diagram

The PMA shall, if it is supporting a repeater, implement the Carrier Detect process as depicted in Figure 24–14 including compliance with the associated state variables as specified in 24.3.3.

24.3.4.4 Link Monitor

The Link Monitor process is responsible for determining whether the underlying receive channel is providing reliable data. Failure of the underlying channel typically causes the PMA's client to suspend normal actions. The Link Monitor process takes advantage of the PMD sublayer's continuously signaled transmission scheme, which provides the PMA with a continuous indication of signal detection on the channel through signal_status as communicated by the PMD_SIGNAL.indicate primitive. It responds to control by Auto-Negotiation, when implemented, which is effected through the link_control parameter of PMA_SIGNAL.request.

The Link Monitor process monitors signal_status, setting link_status to FAIL whenever signal_status is OFF during the normal operation or when Auto-Negotiation sets link_control to DISABLE. If the EEE capability is supported, when the receiver is in the LPI mode, the assertion of lpi_link_fail shall set the link_status to FAIL and eventually brings the receiver out of the LPI mode. The link is deemed to be reliably operating

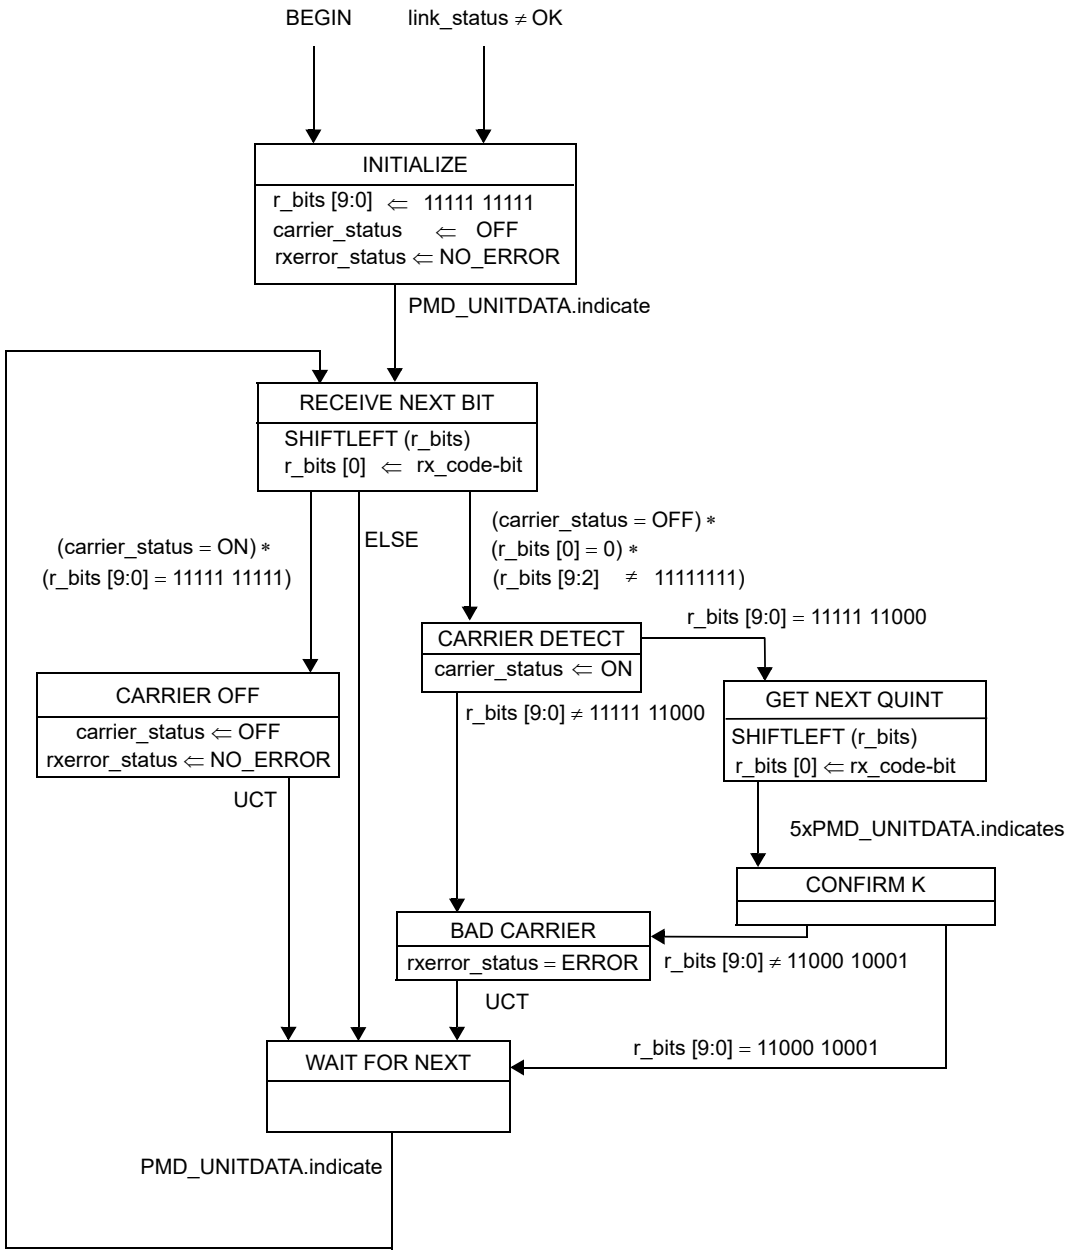
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



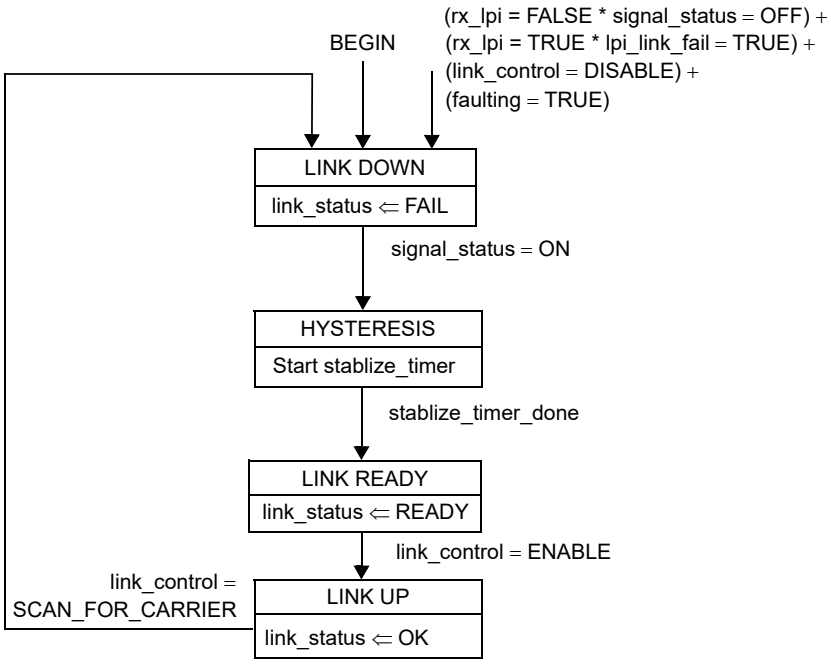


Figure 24–14—Carrier Detect state diagram

when signal_status has been continuously ON for a period of time. This period is implementation dependent but not less than 330 µs or greater than 1000 µs. If so qualified, Link Monitor sets link_status to READY in order to synchronize with Auto-Negotiation, when implemented. Auto-Negotiation permits full operation by setting link_control to ENABLE. When Auto-Negotiation is not implemented, Link Monitor operates with link_control always set to ENABLE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA shall implement the Link Monitor process as depicted in Figure 24–15 including compliance with the associated state variables as specified in 24.3.3.

NOTE 1—The variables link_control and link_status are designated as link_control_[TX] and link_status_[TX], respectively, by the Auto-Negotiation Arbitration state diagram (Figure 28–18).

NOTE 2—The variables rx_lpi and lpi_link_fail are only required for the EEE capability and should be treated as if the value of these two variables is FALSE otherwise.

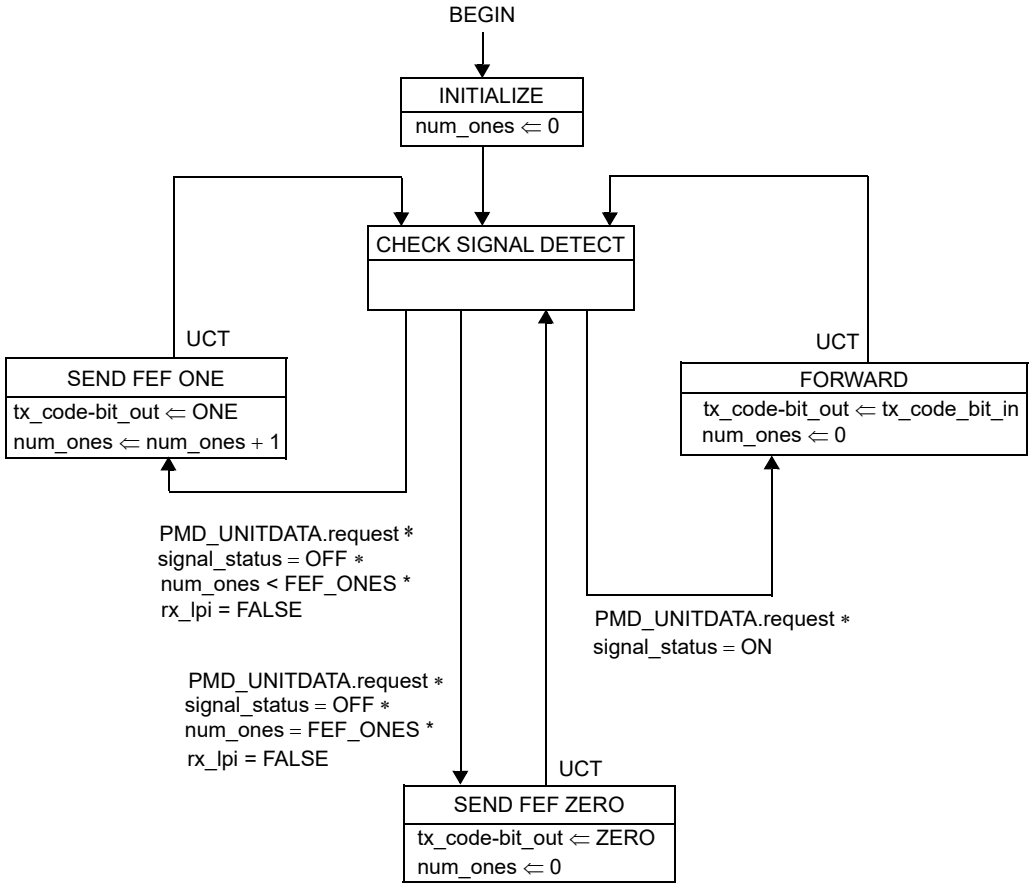

Figure 24–15—Link Monitor state diagram

24.3.4.5 Far-End Fault Generate

Far-End Fault Generate simply passes tx_code-bits to the TX process when signal_status=ON. When signal_status=OFF and not in the LPI mode, it repetitively generates each cycle of the Far-End Fault Indication until signal_status is reasserted.

If Far-End Fault is implemented, the PMA shall implement the Far-End Fault Generate process as depicted in Figure 24–16 including compliance with the associated state variables as specified in 24.3.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The variable rx_lpi is only required for the EEE capability and should be treated as if the value of this variable is FALSE otherwise.

Figure 24–16—Far-End Fault Generation state diagram

24.3.4.6 Far-End Fault Detect

Far-End Fault Detect passively monitors the rx_code-bit stream from the RX process for the Far-End Fault Indication. It does so by maintaining counters for the number of consecutive ONEs seen since the last ZERO (num_ones) and the number of cycles of 84 ONEs and a single ZERO (num_cycles). The Far-End Fault Indication is denoted by three or more cycles, each of 84 ONEs and a single ZERO. Note that the number of consecutive ONEs may exceed 84 on the first cycle.

If Far-End Fault is implemented, the PMA shall implement the Far-End Fault Detect process as depicted in Figure 24–17 including compliance with the associated state variables as specified in 24.3.3.

24.4 Physical Medium Dependent (PMD) sublayer service interface

24.4.1 PMD service interface

The following specifies the services provided by the PMD. The PMD is a sublayer within 100BASE-X and may not be present in other 100BASE-T PHY specifications. PMD services are described in an abstract manner and do not imply any particular implementation. It should be noted that these services are functionally identical to those defined in the FDDI standards, such as ISO/IEC 9314-3:1990 and ANSI INCITS 263-1995, with the following three exceptions:

a) 100BASE-X does not include a Station Management (SMT) function; therefore the PMD-to-SMT interface defined in ISO/IEC 9314-3:1990 and ANSI INCITS 263-1995.
b) 100BASE-X does not support multiple instances of a PMD in service to a single PMA; therefore, no qualifiers are needed to identify the unique PMD being referenced.
c) 100BASE-X may support LPI for the EEE capability.

There are also *editorial* differences between the interfaces specified here and in the referenced standards, as required by the context of 100BASE-X.

The PMD Service Interface supports the exchange of nrzi-bits between PMA entities. The PMD translates the nrzi-bits to and from signals suitable for the specified medium.

The following primitives are defined:

PMD_UNITDATA.request
PMD_UNITDATA.indicate
PMD_SIGNAL.indicate
PMD_RXQUIET.request
PMD_TXQUIET.request

24.4.1.1 PMD_UNITDATA.request

This primitive defines the transfer of data (in the form of nrzi-bits) from the PMA to the PMD.

24.4.1.1.1 Semantics of the service primitive

PMD_UNITDATA.request (tx_nrzi-bit)

The data conveyed by PMD_UNITDATA.request is a continuous sequence of nrzi-bits. The tx_nrzi-bit parameter can take one of two values: ONE or ZERO.

24.4.1.1.2 When generated

The PMA continuously sends, at a nominal 125 Mb/s rate, the PMD the appropriate nrzi-bits for transmission on the medium.

24.4.1.1.3 Effect of receipt

Upon receipt of this primitive, the PMD converts the specified nrzi-bit into the appropriate signals on the MDI.

24.4.1.2 PMD_UNITDATA.indicate

This primitive defines the transfer of data (in the form of nrzi-bits) from the PMD to the PMA.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.4.1.2.1 Semantics of the service primitive

PMD_UNITDATA.indicate (rx_nrzi-bit)

The data conveyed by PMD_UNITDATA.indicate is a continuous nrzi-bit sequence. The rx_nrzi-bit parameter can take one of two values: ONE or ZERO.

24.4.1.2.2 When generated

The PMD continuously sends nrzi-bits to the PMA corresponding to the signals received from the MDI.

24.4.1.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

24.4.1.3 PMD_SIGNAL.indicate

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

24.4.1.3.1 Semantics of the service primitive

PMD_SIGNAL.indicate (signal_status)

The signal_status parameter can take on one of two values: ON or OFF, indicating whether the quality and level of the received signal is satisfactory (ON) or unsatisfactory (OFF). When signal_status = OFF, then rx_nrzi-bit is undefined, but consequent actions based on PMD_SIGNAL.indicate, where necessary, interpret rx_nrzi-bit as logic ZERO.

24.4.1.3.2 When generated

The PMD generates this primitive to indicate a change in the value of signal_status.

24.4.1.3.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

24.4.1.4 PMD_RXQUIET.request

This primitive is generated by the Receive Process of the PCS only if EEE is supported to indicate that the receiver is in the LPI mode and the line is in the Quiet state (see 24.2.4.3 and Figure 24–12).

24.4.1.4.1 Semantics of the service primitive

PMD_RXQUIET.request(rx_quiet)

The rx_quiet parameter takes on one of two values, TRUE or FALSE, indicating whether the receiver is in the Quiet state (TRUE) or not (FALSE).

24.4.1.4.2 When generated

The PCS generates this primitive to indicate a Quiet state of the transmitter in the LPI mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.4.1.4.3 Effect of receipt

This primitive affects operation of the PMD function of type 100BASE-TX as described in 25.5.2. Other use of receipt of this primitive by the client is unspecified by the PMD sublayer.

24.4.1.5 PMD_TXQUIET.request

This primitive is generated by the Transmit Process of the PCS only if EEE is supported to indicate that the transmitter is in the LPI mode and the line is in the Quiet state (see 24.2.4.2 and Figure 24–8).

24.4.1.5.1 Semantics of the service primitive

PMD_TXQUIETrequest(tx_quiet)

The tx_quiet parameter takes on one of two values, TRUE or FALSE, indicating whether the transmitter is in the Quiet state (TRUE) or not (FALSE).

24.4.1.5.2 When generated

The PCS generates this primitive to indicate a Quiet state of the transmitter in the LPI mode.

24.4.1.5.3 Effect of receipt

This primitive affects operation of the PMD function of type 100BASE-TX as described in 25.5.1. Other use of receipt of this primitive by the client is unspecified by the PMD sublayer.

24.4.2 Medium Dependent Interface (MDI)

The MDI, a physical interface associated with a PMD, is composed of an electrical or optical medium connector. The 100BASE-X MDIs, defined in subsequent clauses, are specified by reference to the appropriate FDDI PMD, such as in ISO/IEC 9314-3:1990 and ANSI INCITS 263-1995, together with minor modifications (such as connectors and pin-outs) necessary for 100BASE-X.

24.5 Compatibility considerations

There is no requirement for a compliant device to implement or expose any of the interfaces specified for the PCS, PMA, or PMD. However, if an exposed interface is provided to the PCS, it shall comply with the requirements for the MII, as specified in Clause 22.

24.6 Delay constraints

In half duplex mode, proper operation of a CSMA/CD LAN demands that there be an upper bound on the propagation delays through the network. This implies that MAC, PHY, and repeater implementations conform to certain delay minima and maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

In full duplex mode, predictable operation of the (optional) MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

MAC constraints are contained in Clause 21. Topological constraints are contained in Clause 29. MAC Control sublayer constraints are contained in Clause 31.

The reference point for all MDI measurements is the 50% point of the mid-cell transition corresponding to the reference code-bit, as measured at the MDI. Although 100BASE-TX output is scrambled, it is assumed that these measurements are made via apparatuses that appropriately account for this.

24.6.1 PHY delay constraints (exposed MII)

Every 100BASE-X PHY with an exposed MII shall comply with the bit delay constraints specified in Table 24–2 and Table 24–3. These figures apply for all 100BASE-X PMDs.

Table 24–2—Bit delay constraints

a) MDI to MII delay constraints (exposed MII, half duplex mode)

Sublayer measurement points	Event	Min (bits)	Max (bits)	Input timing reference	Output timing reference
MII ⇔ MDI	TX_EN sampled to MDI output	6	14	TX_CLK rising	1st bit of /J/
	MDI input to CRS assert		20	1st bit of /J/	
	MDI input to CRS deassert (aligned)	13	24	1st bit of /T/	
	MDI input to CRS deassert (unaligned)	13	24	1st ONE	
	MDI input to COL assert		20	1st bit of /J/	
	MDI input to COL deassert (aligned)	13	24	1st bit of /T/	
	MDI input to COL deassert (unaligned)	13	24	1st ONE	
	TX_EN sampled to CRS assert	0	4	TX_CLK rising	
	TX_EN sampled to CRS deassert	0	16	TX_CLK rising	

Table 24–3—Bit delay constraints *(continued)*

b) PHY delay constraints (exposed MII, full duplex mode)

Sublayer measurement points	Event	Min (bits)	Max (bits)	Input timing reference	Output timing reference
MII ⇔ MDI	TX_EN sampled to MDI output		14	TX_CLK rising	1st bit of /J/
	MDI Input to RX_DV deassert		32	first bit of /T/	RX_CLK rising

24.6.2 DTE delay constraints (unexposed MII)

Every 100BASE-X DTE with no exposed MII shall comply with the bit delay constraints specified in Table 24–4. These figures apply for all 100BASE-X PMDs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 24–4—DTE delay constraints (unexposed MII, half duplex mode)

Sublayer measurement points	Event	Min (bits)	Max (bits)	Input timing reference	Output timing reference
MAC ⇔ MDI	MAC transmit start to MDI output		18		1st bit of /J/
	MDI input to MDI output (worst-case nondeferred transmit)		54	1st bit of /J/	1st bit of /J/
	MDI input to collision detect		28	1st bit of /J/	
	MDI input to MDI output = Jam (worst case collision response)		54	1st bit of /J/	1st bit of jam

24.6.3 Carrier deassertion/assertion constraint (half duplex mode only)

To ensure fair access to the network, each DTE shall, additionally, satisfy the following:

(MAX MDI to MAC Carrier Deassert Detect) – (MIN MDI to MAC Carrier Assert Detect) < 13

24.7 Environmental specifications

All equipment subject to this clause shall conform to the requirements of 14.7 and applicable sections of ISO/IEC 11801.

24.8 Protocol implementation conformance statement (PICS) proforma for Clause 24, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 100BASE-X[57]

24.8.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 24, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 100BASE-X, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

24.8.2 Identification

24.8.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

24.8.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 24, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 100BASE-X
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[57] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

24.8.2.3 Major capabilities/options

Item	Feature	Subclause	Status	Support	Value/Comment
*DTE	Supports DTE without MII	24.4	O/1		
*REP	Supports Repeater without MII	24.4	O/1		
*MII	Supports exposed MII interface	24.4	O/1		
*PCS	Implements PCS functions	24.2	REP: O DTE: M MII: M		
PMA	Implements PMA RX, TX and Link Monitor functions	24.3	M		
*LPC	PCS implementation of LPI	24.2	PCS:O		
*LPM	PMA implementation of LPI	24.3	LPC:M		
*NWC	Medium capable of supporting Auto-Negotiation		O		See Clause 28
*FEF	Implements Far-End Fault	24.3.2.1	NWC: X LPM:X		
NWY	Supports Auto-Negotiation (Clause 28)	24.1.4.4	NWC: O LPC:M		See Clause 28

24.8.3 PICS proforma tables for the Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 100BASE-X

24.8.3.1 General compatibility considerations

Item	Feature	Subclause	Status	Support	Value/Comment
GN1	Compliance with MII requirements	24.4	MII:M		See Clause 22
GN2	Environmental specifications	24.7	M

25. Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-TX

25.1 Overview

This clause specifies the 100BASE-X PMD (including MDI) and baseband medium for twisted-pair wiring, 100BASE-TX. In order to form a complete 100BASE-TX Physical Layer, the 100BASE-X PMD (including MDI) shall be integrated with the 100BASE-X PCS and PMA of Clause 24, which are assumed incorporated by reference. As such, the 100BASE-TX PMD shall comply with the PMD service interface specified in 24.4.1.

25.1.1 State diagram conventions

The body of this standard is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams follows the conventions of 21.5; state diagram timers follow the conventions of 14.2.3.2.

25.2 Functional specifications

The 100BASE-TX PMD (and MDI) is specified by incorporating the FDDI TP-PMD standard, ANSI INCITS 263-1995 (TP-PMD), by reference, with the modifications noted below. This standard provides support for Category 5 twisted pair cabling. For improved legibility in this clause, ANSI INCITS 263-1995 (TP-PMD), will henceforth be referred to as TP-PMD.

25.3 General exceptions

The 100BASE-TX PMD is precisely the PMD specified as TP-PMD, with the following general modifications:

a) The Scope and General description discussed in TP-PMD 1 and 5 relate to the use of those standards with an FDDI PHY, ISO/IEC 9314-1:1989, and MAC, ISO/IEC 9314-2:1989. These sections are not relevant to the use of the PMD with 100BASE-X.
b) The Normative references, Definitions and Conventions of TP-PMD 2, 3, and 4 are used only as necessary to interpret the applicable sections of TP-PMD referenced in this clause.
c) The PMD Service Specifications of TP-PMD 6 are replaced by those specified in 24.4.1. The 100BASE-TX PMD Service specification is a proper subset of the PMD Service Specification in TP-PMD.
d) The twisted-pair cabling specifications of TP-PMD 11.1 are replaced by those specified in 25.4.9.
e) 100BASE-TX optionally supports Energy-Efficient Ethernet (EEE), as described in Clause 78, with its Low Power Idle (LPI). Two new service primitives PMD_RXQUIET.request(rx_quiet) (see 24.4.1.4) and PMD_TXQUIET.request(tx_quiet) (see 24.4.1.5) are generated by the PCS to pass the energy saving requests.
f) There are minor terminology differences between this standard and TP-PMD that do not cause ambiguity. The terminology used in 100BASE-X was chosen to be consistent with other IEEE 802 standards, rather than with FDDI. Terminology is both defined and consistent within each standard. Special note should be made of the interpretations shown in Table 25–1.

Table 25–1—Interpretation of general FDDI terms and concepts

FDDI term or concept	Interpretation for 100BASE-TX
bypass	<unused>
Connection Management (CMT)	<no comparable entity>
frame	stream
Halt Line State (HLS)	<unused>
hybrid mode	<no comparable entity>
MAC (or MAC-2)	MAC
Master Line State (MLS)	<unused>
maximum frame size = 9000 symbols	maximum stream size = 4018 code-groups
PHY (or PHY-2)	PMA; i.e., PMD client
PHY Service Data Unit (SDU)	stream
PM_SIGNAL.indication (Signal_Detect)	PMD_SIGNAL.indication (signal_status)
PM_UNITDATA.indication (PM_Indication)	PMD_UNITDATA.indication (nrzi-bit)
PM_UNITDATA.request (PM_Request)	PMD_UNITDATA.request (nrzi-bit)
preamble	inter-packet IDLEs
Quiet Line State (QLS)	<unused>
SM_PM_BYPASS.request (Control_Action)	Assume: SM_PM_BYPASS.request(Control_Action = Insert)
SM_PM_CONTROL.request (Control_Action)	Assume: SM_PM_CONTROL.request (Control_Action = Transmit_Enable)
SM_PM_SIGNAL.indication (Signal_Detect)	<unused>
Station Management (SMT)	<no comparable entity>
symbol	code-group

25.4 Specific requirements and exceptions

The 100BASE-TX PMD (including MDI) shall comply to the requirements of TP-PMD, 7, 8, 9, 10, and 11, and normative Annex A with the exceptions listed below. In TP-PMD, informative annexes B, C, E, G, I, and J, with exceptions listed below, provide additional information useful to PMD sublayer implementers. Where there is conflict between specifications in TP-PMD and those in this standard, those of this standard shall prevail.

25.4.1 Change to 7.2.3.1.1, “Line state patterns”

Descrambler synchronization on the Quiet Line State (QLS), Halt Line State (HLS), and Master Line State (MLS) Line State Patterns cited in TP-PMD 7.2.3.1.1 is optional.

25.4.2 Change to 7.2.3.3, “Loss of synchronization”

The synchronization error triggered by PH_Invalid as defined in TP-PMD 7.2.3.3a is not applicable.

25.4.3 Change to Table 8-1, “Contact assignments for twisted pair”

100BASE-TX for twisted pair adopts the contact assignments of 10BASE-T. Therefore, the contact assignments shown in TP-PMD Table 8-1 shall instead be as depicted in Table 25–2.

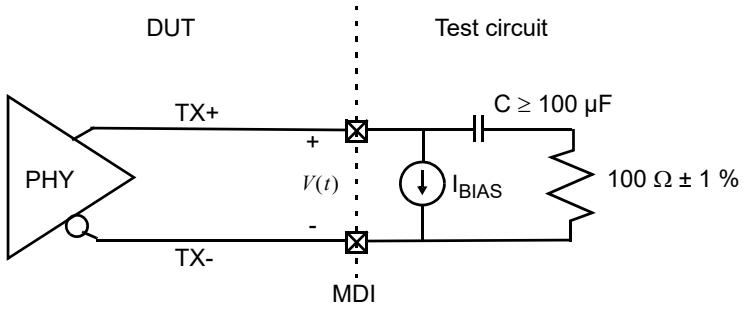
Table 25–2—Twisted-pair MDI contact assignments

Contact	PHY without internal crossover MDI SIGNAL	PHY with internal crossover MDI SIGNAL
1	Transmit +	Receive +
2	Transmit –	Receive –
3	Receive +	Transmit +
4		
5		
6	Receive –	Transmit –
7		
8		

25.4.4 Deletion of 8.3, “Station labelling”

Clause 8.3 of TP-PMD shall not be applied to 100BASE-TX.

25.4.5 Change to 9.1.7, “Worst case droop of transformer”



A 100BASE-TX receiver in a Type 2, Type 3, or Type 4 Endpoint PSE or Type 2, Type 3, or Type 4 PD (see Clause 33 and Clause 145) shall meet the requirements of 25.4.7. A 100BASE-TX transmitter in a Type 2 Endpoint PSE or Type 2 PD delivering or accepting more than 13.0 W average power shall meet either the Open Circuit Inductance (OCL) requirement in 9.1.7 of TP-PMD or meet the requirements of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25.4.5.1. A 100BASE-TX transmitter in a Type 3 or Type 4 Endpoint PSE or Type 3 or Type 4 PD shall meet either the Open Circuit Inductance (OCL) requirement in 9.1.7 of TP-PMD, or meet the requirements of 25.4.5.1.

25.4.5.1 Equivalent system time constant

While transmitting the Data Dependent Jitter (DDJ) packet of TP-PMD A.2, using the test circuit shown in Figure 25–1, the equivalent system time constant, τ, shall be greater than 2.4 µs when calculated using measurement points A and C as shown in Figure 25–2.

DUT = Device under test

NOTE— I_{BIAS} is the current I_{unb} / 2 defined in Clause 33.

Figure 25–1—Type 2 System time constant test circuit

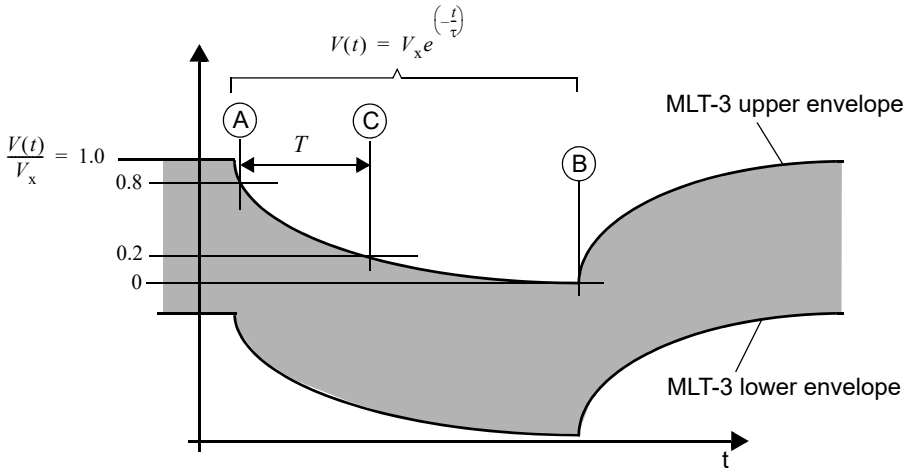


Figure 25–2—Type 2 System time constant measurement

Point B is the point of maximum baseline wander droop, and is the zero point for the vertical axis. Point A, with MDI voltage V_A, is earlier in time from B, with a magnitude that is 80 % of the MLT-3 upper envelope value. Point C, with MDI voltage V_C, is between A and B, with a magnitude that is 20 % of the MLT-3 upper envelope value. The time between A and C is *T*.

These measurements are to be made for the transmitter pair, observing the differential signal output at the MDI with intervening cable, meeting or exceeding the requirements of 25.4.7, less than 1 m long.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The time constant of the transmitter MDI connected to the test circuit of Figure 25–1 is given by Equation (25–1).

$$\left\{ \tau = \frac{T}{\ln\left(\frac{V_A}{V_C}\right)} = \frac{2L}{R} \right\}_s \tag{25–1}$$

where

τ	is the effective time constant of the transmitter
T	is the time in seconds from point A to point C as shown in Figure 25–2
V_A	is the MDI voltage at point A
V_C	is the MDI voltage at point C
L	is the open-circuit inductance of the Ethernet isolation transformer for all operating conditions
R	is the 100 Ω termination impedance

25.4.6 Replacement of 8.4.1, “UTP isolation requirements”

A PMD with a MDI that is a PI (see 33.1.3 and 145.1.3) shall meet the isolation requirements defined in 33.4.1 and 145.4.1.

A PMD with a MDI that is not a PI shall provide isolation between frame ground and all MDI leads including those not used by the 100BASE-TX PMD.

This electrical isolation shall meet the isolation requirements as specified in J.1.

NOTE—In the case of a PMD with a MDI that is not a PI, these requirements are equivalent to those found in TP-PMD.

25.4.7 Addition to 10.1, “Receiver”

Differential voltage signals generated by a remote transmitter that meets the specifications of Clause 25; passed through a link specified in 25.4.9; and received at the MDI of a 100BASE-TX PMD in a Type 2, Type 3, or Type 4 Endpoint PSE or a Type 2, Type 3, or Type 4 PD shall be translated into one of the PMD_UNITDATA.indicate messages with a bit error ratio less than 10^{-9} after link reset completion.

25.4.8 Change to 9.1.9, “Jitter”

The jitter measurement specified in 9.1.9 of TP-PMD may be performed using scrambled IDLEs.

In the LPI mode, jitter shall be measured using scrambled SLEEP code-groups transmitted during the TX_SLEEP state (see Figure 24–8). Total transmit jitter with respect to a continuous unjittered reference shall not exceed 1.4 ns peak-to-peak with the exception that the jitter contributions from the clock transitions occurring during the TX_QUIET state and the first 5 µs of the TX_SLEEP state or the first 5 µs of the IDLE state following a TX_QUIET state are ignored. The jitter measurement time period shall be not less than 100 ms and not greater than 1 s.

25.4.9 Cable plant

The twisted-pair cabling specification of TP-PMD 11.1 is replaced by that specified in this subclause. The term “link segment” used in this subclause refers to a duplex channel of two pairs. Specifications for a link

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

segment apply equally to each of the two pairs of a duplex channel. All implementations of the balanced cabling link shall be compatible at the MDI.

25.4.9.1 Cabling system characteristics

The cabling system used to support a 100BASE-TX duplex channel requires two pairs of Category 5 balanced cabling with a nominal impedance of 100 Ω. The cabling system components (cables, cords, and connectors) used to provide the link segment shall consist of Category 5 components as specified in ANSI/TIA/EIA-568-A:1995 and ISO/IEC 11801:1995 (Class D).

NOTE—ISO/IEC 11801:2002 provides a specification (Class D) for media that exceeds the minimum requirements of this standard.

25.4.9.2 Link transmission parameters

The transmission parameters contained in this subclause are specified to ensure that a Category 5 link segment of up to 100 m, will provide a reliable medium. The transmission parameters of the link segment include insertion loss, characteristics impedance, return loss, NEXT loss, and external coupled noise.

25.4.9.2.1 Insertion loss

The insertion loss of the link segment shall be less than,

$$\text{Insertion_Loss}(f) < 2.1f^{0.529} + 0.4/f \qquad \text{(dB)}$$

at all frequencies from 1 MHz to 100 MHz. This includes the attenuation of the balanced cabling pairs, including work area and equipment cables plus connector losses within the link segment.

The insertion loss specification shall be met when the link segment is terminated in 100 Ω.

NOTE—The above equation approximates the insertion loss specification at 20°C for discrete frequencies of Category 5 100-meter links specified in ANSI/TIA/EIA-568-A Annex E and in TIA/EIA TSB-67.

25.4.9.2.2 Differential characteristic impedance

The nominal differential characteristic impedance of each link segment, which includes cable cords and connecting hardware, is 100 Ω for all frequencies between 1 MHz and 100 MHz.

25.4.9.2.3 Return loss

Each link segment shall meet or exceed the return loss specified in the following equation at all frequencies from 1 MHz to 100 MHz.

$$\text{Return_Loss}(f) \begin{cases} 15 & (1 - 20\ \text{MHz}) \\ 15 - 10\log_{10}(f/20) & (20 - 100\ \text{MHz}) \end{cases} \text{(dB)}$$

where f is the frequency in MHz. The reference impedance shall be 100 Ω.

25.4.9.2.4 Differential near-end crosstalk (NEXT)

In order to limit the crosstalk at the near end of a duplex channel, the differential pair-to-pair near-end crosstalk (NEXT) loss between the two pairs of a duplex channel shall be at least,

$$27.1 - 16.8\log_{10}(f/100) \text{ (dB)}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where *f* is the frequency over the range of 1 MHz to 100 MHz.

NOTE—The above equation approximates the NEXT loss specification at discrete frequencies for Category 5 100-meter links specified in ANSI/TIA/EIA-568-A Annex E and in TIA/EIA TSB-67.

25.4.9.3 Noise environment

The 100BASE-TX noise environment consists of noise from external sources and could impact the objective BER. This noise may consist of sources outside the cabling that couple into the link segment via electric and magnetic fields. In addition noise from adjacent cables, referred to as alien crosstalk, may couple into the link segment. This alien crosstalk is generally present when cables are bound tightly together. To ensure robust operation a 100BASE-TX PHY should operate in the presence of an external noise as specified in 25.4.9.3.1.

25.4.9.3.1 External coupled noise

The differential noise coupled from external sources that is measured at the output of a filter connected to the output of the near end of a disturbed link segment should not exceed 40 mV peak-to-peak. The filter for this measurement is a fifth order Butterworth filter with a 3 dB cutoff at 100 MHz.

25.4.10 Replacement of 11.2, “Crossover function”

Subclause 11.2 of TP-PMD is replaced with the following:

A crossover function compliant with 14.5.2 shall be implemented except that a) the signal names are those used in TP-PMD, and b) the contact assignments for 150 Ω Type 1 STP are those shown in Table 8-2 of TP-PMD. Note that compliance with 14.5.2 implies a recommendation that crossover (for both balanced twisted-pair and 150 Ω Type 1 STP) be performed within repeater PHYs.

25.4.11 Change to A.2, “DDJ test pattern for baseline wander measurements”

The length of the test pattern specified in TP-PMD A.2 may be shortened to accommodate feasible 100BASE-X measurements, but shall not be shorter than 3000 code-groups.

NOTE—This pattern is to be applied to the MII. (When applied to the MAC, the nibbles within each byte are to be swapped, e.g., as delivered to the MAC, the test pattern would start, “60 C9 16 ...”.)

25.4.12 Change to Annex G, “Stream cipher scrambling function”

An example of a stream cipher scrambling implementation is shown in TP-PMD Annex G. This may be modified to allow synchronization solely on the IDLE sequences between packets.

25.4.13 Change to Annex I, “Common mode cable termination”

The contact assignments shown in TP-PMD Figures I-1 and I-2 shall instead comply with those specified in Table 25–2.

25.5 EEE capability

TP-PMD does not have an option to support EEE. In order to add this capability to existing TP-PMD specification, the TP-PMD 7.1.2, 7.2.2, 10.1.2, 10.1.3, and Table 4 are modified to incorporate the LPI function. This subclause only applies to the optional EEE capability. If LPI is implemented, the operation of the PMD shall comply with the requirements in this subclause.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25.5.1 Change to TP-PMD 7.1.2 “Encoder”

The Encoder receives the scrambled NRZ data stream from the scrambler (see TP-PMD 7.1.1) and encodes the stream into MLT3 code for presentation to the driver (see TP-PMD 7.1.3). MLT3 coding is similar to NRZI coding, but three instead of two levels are transmitted. The Encoder can be deactivated when in the LPI mode. The PMD Encoder function of the 100BASE-TX with EEE capability is identical to that of the TP-PMD except that the output of the Encoder is set to a value ZERO_VOLTAGE when the transmitter is in the Quiet state of the LPI mode (TX_QUIET, see Figure 24–8).

The PMD in the LPI mode shall implement the Encoder state diagram as depicted in Figure 25–3.

25.5.1.1 State variables

25.5.1.1.1 Variables

encoder_input
: Indicates the value of each scrambled NRZ bit to be encoded.

  Values: ZERO; the NRZ bit from the scrambler has a logical value 0
  ONE; the NRZ bit from the scrambler has a logical value 1

encoder_output
: Indicates the value from the encoder for each MLT-3 encoded bit.

  Values: POSITIVE_VOLTAGE; the output indicates a positive value of voltage to TP-PMD driver
  ZERO_VOLTAGE; the output indicates a zero value of voltage to TP-PMD driver
  NEGATIVE_VOLTAGE; the output indicates a negative value of voltage to TP-PMD driver

tx_quiet
: The tx_quiet parameter as communicated by the PMD_TXQUIET.request (tx_quiet) primitive. This variable is generated by the Transmit process of the PCS to control the power-saving function of the local transmitter. It sets the Encoder state diagram to an initial state of ZERO_V.

  Values: TRUE; the local transmitter is in the Quiet state
  FALSE; the local transmitter is not in the Quiet state

le_flag
: A Boolean set by the Encoder process to indicate whether the last non-zero value of encoder_output was POSITIVE_VOLTAGE. The flag le_flag is set upon entry to the PLUS_V state and is cleared upon entry to the MINUS_V state.

  Values: ONE; the encoder is in the PLUS_V state
  ZERO; the encoder is in the MINUS_V state

25.5.1.1.2 Messages

gotNRZbit.indicate
: A signal sent to the Encoder process by the scrambler after a scrambled NRZ text bit has been generated using recursive linear function by the scrambler from plaintext bit stream and is ready to transmit.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25.5.1.2 State diagram

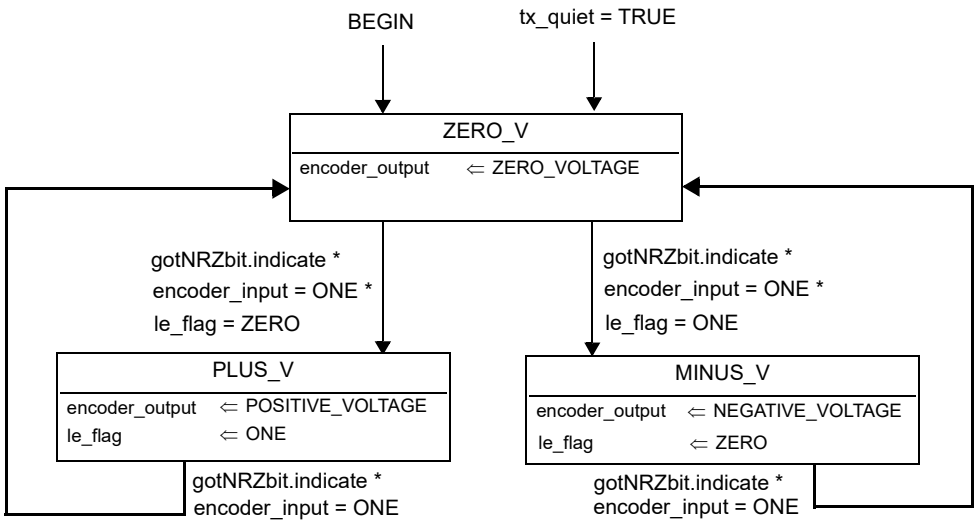

Figure 25–3—Encoder state diagram

25.5.2 Change to TP-PMD 7.2.2 “Decoder”

The Decoder receives the MLT3 encoded bit stream from the receiver (see TP-PMD 7.2.1), and decodes it into a NRZ encoded bit stream for presentation to the descrambler (see TP-PMD 7.2.3). The Decoder can be deactivated when in the LPI mode. The PMD Decoder function of the 100BASE-TX with EEE capability is identical to that of the TP-PMD except that the output of the Decoder is set to a value ZERO when the receiver is in the Quiet state of the LPI mode (RX_QUIET, Figure 24–12).

The PMD in the LPI mode shall implement the Decoder state diagram as depicted in Figure 25–4.

25.5.2.1 State variables

25.5.2.1.1 Variables

decoder_input
: Indicates the value of the MLT-3 encoded bit from the receiver.

  Values: ZERO; the MLT3 bit from the receiver has a logical value 0
  NONZERO; the MLT3 bit from the receiver has a non-zero logical value

decoder_output
: Indicates the value of the NRZ encoded bit.

  Values: ZERO; the output indicates a logical value of 0 to the descrambler
  ONE; the output indicates a logical value of 1 to the descrambler

rx_quiet
: The rx_quiet parameter as communicated by the PMD_RXQUIET.request (rx_quiet) primitive. This variable is generated by the Receive process of the PCS to control the power-saving function of local receiver. It sets the Decoder state diagram to an initial state of ZERO_VALUE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: TRUE; the local receiver is in the Quiet state
FALSE; the local receiver is not in the Quiet state

prev_data

Indicates whether the last value of decoder_input was ZERO or NONZERO.

Values: ZERO; the last value of MLT3 bit of decoder_input has a logical value 0
NONZERO; the last value of MLT3 bit of decoder_input has a non-zero logical value

25.5.2.1.2 Messages

sentNRZbit.indicate

A signal sent to the Decoder process by the descrambler after an NRZ bit from ciphertext bit stream has been processed using recursive linear function and is ready to process the next bit from Decoder.

25.5.2.2 State diagram

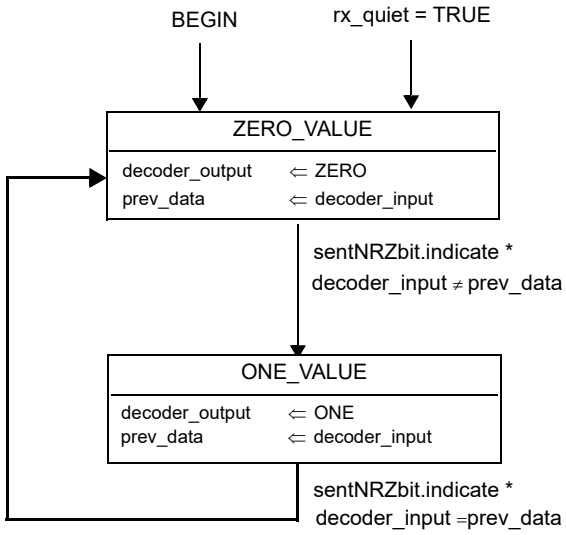

Figure 25–4—Decoder state diagram

25.5.3 Changes to 10.1.1.1 “Signal_Detect assertion threshold”

The TP-PMD 10.1.1.1 is applicable to the normal operation. In the LPI mode, when rx_lpi as communicated by the PMA_RXLPI.request primitive is asserted, Signal_Detect shall be asserted per 25.5.5 for any valid peak-to-peak signal, VSDA, of greater than 400 mV.

25.5.4 Changes to 10.1.1.2 “Signal_Detect deassertion threshold”

The TP-PMD 10.1.1.2 is applicable to the normal operation. In the LPI mode, when rx_lpi is deasserted, Signal_Detect shall be deasserted per 25.5.6 for any valid peak-to-peak signal, VSDD, of smaller than 200 mV.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25.5.5 Change to 10.1.2 “Signal_Detect timing requirements on assertion”

The TP-PMD 10.1.2 is applicable to the normal operation. In the LPI mode, when rx_lpi is asserted, Signal_Detect output shall be asserted within 5 µs under the same quality requirement of the received signal as in normal operation. The new definition of conditional parameter AS_Max is inserted in TP-PMD Table 4 as depicted in Table 25–3.

25.5.6 Change to 10.1.3 “Signal_Detect timing requirements on deassertion”

The TP-PMD 10.1.3 is applicable to the normal operation. In the LPI mode, when rx_lpi is asserted, Signal_Detect output shall be deasserted within 5 µs under the same quality requirement of the received signal as in normal operation. The new definition of conditional parameter ANS_Max is inserted in TP-PMD Table 4 as depicted in Table 25–3.

25.5.7 Changes to TP-PMD 10.2 “Transmitter”

For the optional EEE capability, when tx_quiet (as communicated by the PMD_TXQUIET.request primitive) is set to FALSE, the transmitter output shall deliver a signal that exceeds Signal_Detect assertion threshold within 2 µs. The scrambler shall continue to operate for the first 5 µs following tx_quiet = TRUE. Transmit functions may be deactivated after this period. The transmitter shall deliver a fully compliant signal when tx_quiet is set to FALSE less than 5 µs after being set to TRUE. If tx_quiet is set to FALSE more than 5 µs after being set to TRUE, then the transmitter shall deliver a fully compliant signal within 5 µs (see 25.4.8).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25.5.8 Replace TP-PMD Table 4 “Signal_Detect summary” with Table 25–3

The requirement of signal detection time and threshold are different between the normal operation mode and the LPI mode. In order to share one Signal_Detect, the timing and threshold characteristics may be qualified by LPI signal rx_lpi as communicated by the PMA_RXLPI.request primitive.

Table 25–3—Signal_Detect summary

Characteristic	Minimum	Maximum	Units
Assert time Normal operation mode		1000	µs
Deassert time Normal operation mode		350	µs
Assert time LPI mode		5	µs
Deassert time LPI mode		5	µs
Assert threshold VSDA 100 Ω balanced cable Normal operation mode		1000	mV peak to peak
Deassert threshold VSDD 100 Ω balanced cable Normal operation mode	200		mV peak to peak
Assert threshold VSDA 150 Ω balanced shielded cable Normal operation mode		1225	mV peak to peak
Deassert threshold VSDD 150 Ω balanced shielded cable Normal operation mode	245		mV peak to peak
Assert threshold VSDA LPI mode		400	mV peak to peak
Deassert threshold VSDD LPI mode	200		mV peak to peak

25.6 Protocol implementation conformance statement (PICS) proforma for Clause 25, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-TX[58]

25.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 25, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-TX, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

25.6.2 Identification

25.6.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

25.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 25, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-TX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[58] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

26. Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-FX

26.1 Overview

This clause specifies the 100BASE-X PMD (including MDI) and fiber optic medium for multimode fiber, 100BASE-FX. In order to form a complete 100BASE-FX Physical Layer it shall be integrated with the 100BASE-X PCS and PMA of Clause 24, which are assumed incorporated by reference. As such, the 100BASE-FX PMD shall comply with the PMD service interface specified in 24.4.1.

26.2 Functional specifications

The 100BASE-FX PMD (and MDI) is specified by incorporating the FDDI PMD standard, ISO/IEC 9314-3:1990, by reference, with the modifications noted below. This standard provides support for two optical fibers. For improved legibility in this clause, ISO/IEC 9314-3:1990 will henceforth be referred to as fiber-PMD.

26.3 General exceptions

The 100BASE-FX PMD is precisely the PMD specified as fiber-PMD, with the following general modifications:

a) The scope and general description discussed in fiber-PMD 1 and 5 relate to the use of those standards with an FDDI PHY, ISO/IEC 9314-1:1989, and MAC, ISO/IEC 9314-2:1989. These clauses are not relevant to the use of the PMD with 100BASE-X.
b) The normative references, definitions, and conventions of fiber-PMD 2, 3, and 4 are used only as necessary to interpret the applicable sections of fiber-PMD referenced in this clause.
c) The PMD Service Specifications of fiber-PMD 6 are replaced by those specified in 24.4.1. The 100BASE-FX PMD Service specification is a proper subset of the PMD service specification in fiber-PMD.
d) There are minor terminology differences between this standard and fiber-PMD that do not cause ambiguity. The terminology used in 100BASE-X was chosen to be consistent with other IEEE 802 standards, rather than with FDDI. Terminology is both defined and consistent within each standard. Special note should be made of the interpretations shown in Table 26–1.

Table 26–1—Interpretation of general FDDI terms and concepts

FDDI term or concept	Interpretation for 100BASE-X
bypass	<unused>
Connection Management (CMT)	<no comparable entity>
frame	stream
Halt Line State (HLS)	<unused>
hybrid mode	<no comparable entity>
MAC (or MAC-2)	MAC
Master Line State (MLS)	<unused>
maximum frame size = 9000 symbols	maximum stream size = 4018 code-groups

Table 26–1—Interpretation of general FDDI terms and concepts *(continued)*

FDDI term or concept	Interpretation for 100BASE-X
PHY (or PHY-2)	PMA; i.e., PMD client
PHY Service Data Unit (SDU)	stream
PM_SIGNAL.indication (Signal_Detect)	PMD_SIGNAL.indication (signal_status)
PM_UNITDATA.indication (PM_Indication)	PMD_UNITDATA.indication (nrzi-bit)
PM_UNITDATA.request (PM_Request)	PMD_UNITDATA.request (nrzi-bit)
preamble	inter-packet IDLEs
Quiet Line State (QLS)	<unused>
SM_PM_BYPASS.request (Control_Action)	Assume: SM_PM_BYPASS.request (Control_Action = Insert)
SM_PM_CONTROL.request (Control_Action)	Assume: SM_PM_CONTROL.request (Control_Action = Transmit_Enable)
SM_PM_SIGNAL.indication (Signal_Detect)	<unused>
Station Management (SMT)	<no comparable entity>
symbol	code-group

26.4 Specific requirements and exceptions

The 100BASE-FX PMD (including MDI) and baseband medium shall conform to the requirements of fiber-PMD Clauses 8, 9, and 10. In the referenced standard, fiber-PMD, informative Annex A through Annex G provide additional information useful to PMD sublayer implementers. Where there is conflict between specifications in fiber-PMD and those in this standard, those of this standard shall prevail.

26.4.1 Medium Dependent Interface (MDI)

The 100BASE-FX medium dependent interface (MDI) shall conform to one of the following connectors. The recommended alternative is the duplex SC connector.

a) The duplex SC connector as specified in IEC 61754-4 [B25][59] and IEC 61754-4, Interface 4-2. (See 38.11.3).
b) Media Interface Connector (MIC) as specified in fiber-PMD 7 and Annex F. When the MIC is used, the receptacle shall be keyed as “M”.
c) Optical Medium Connector Plug and Socket (commonly called ST[60] connector) as specified in 15.3.2.

26.4.2 Crossover function

A crossover function shall be implemented in every cable-pair link. The crossover function connects the transmitter of one PHY to the receiver of the PHY at the other end of the cable-pair link. For 100BASE-FX, the crossover function is realized in the cable plant.

[59]The numbers in brackets correspond to those of the bibliography in Annex A in Section One of this standard.

26.5 Protocol implementation conformance statement (PICS) proforma for Clause 26, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-FX[61]

26.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 26, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-FX, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

26.5.2 Identification

26.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

26.5.3 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 26, Physical Medium Dependent (PMD) sublayer and baseband medium, type 100BASE-FX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[61] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

27. Repeater for 100 Mb/s baseband networks

NOTE—This repeater is not recommended for new installations. Since September 2011, maintenance changes are no longer being considered for this clause.

27.1 Overview

27.1.1 Scope

Clause 27 defines the functional and electrical characteristics of a repeater for use with 100BASE-T 100 Mb/s baseband networks. A repeater for any other IEEE 802.3 network type is beyond the scope of this clause. The relationship of this standard to the OSI Reference Model is shown in Figure 27–1. The purpose of the repeater is to provide a simple, inexpensive, and flexible means of coupling two or more segments.

MDI = MEDIUM DEPENDENT INTERFACE
MII = MEDIA INDEPENDENT INTERFACE

PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
PMD = PHYSICAL MEDIUM DEPENDENT

* PMD is specified for 100BASE-TX and -FX only; 100BASE-T4 does not use this layer.
Use of MII between PCS and baseband repeater unit is optional.
** AUTONEG is optional.

Figure 27–1—100BASE-T repeater set relationship to the ISO/IEC OSI reference model

27.1.1.1 Repeater set

Repeater sets are an integral part of all 100 Mb/s baseband networks with more than two DTEs and are used to extend the physical system topology by providing a means of coupling two or more segments. Multiple repeater sets are permitted within a single collision domain to provide the maximum connection path length. Segments may be connected directly by a repeater or a pair of repeaters that are, in turn, connected by a inter-repeater link (IRL). Allowable topologies shall contain only one operative signal path between any two

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

points on the network. A repeater set is not a station and does not count toward the overall limit of 1024 stations on a network.

A repeater set can receive, and if necessary decode, data from any segment under worst-case noise, timing, and signal amplitude conditions. It retransmits the data to all other segments attached to it with timing, amplitude, and, if necessary, coding restored. The retransmission of data occurs simultaneously with reception. If a collision occurs, the repeater set propagates the collision event throughout the network by transmitting a Jam signal. A repeater set also provides a degree of protection to a network by isolating a faulty segment's carrier activity from propagating through the network.

27.1.1.2 Repeater unit

A repeater unit is a subset of a repeater set containing all the repeater-specific components and functions, exclusive of PHY components and functions. A repeater unit connects to the PMA and, if necessary, the PCS sublayers of its PHYs.

27.1.1.3 Repeater classes

Two classes of repeater sets are defined—Class I and Class II.

Class I:

A type of repeater set specified such that in a maximum length segment topology, only one such repeater set may exist between any two DTEs within a single collision domain.

Class II:

A type of repeater set specified such that in a maximum length segment topology, only two such repeater sets may exist between any two DTEs within a single collision domain.

More complex topologies are possible in systems that do not use worst-case cable. See Clause 29 for requirements.

27.1.2 Application perspective

This subclause states the broad objectives and assumptions underlying the specification defined through Clause 27.

27.1.2.1 Objectives

a) Provide physical means for coupling two or more LAN segments at the Physical Layer.
b) Support interoperability of independently developed physical, electrical, and optical interfaces.
c) Provide a communication channel with a mean bit error ratio, at the physical service interface equivalent to that for the attached PHY.
d) Provide for ease of installation and service.
e) Ensure that fairness of DTE access is not compromised.
f) Provide for low-cost networks, as related to both equipment and cabling.
g) Make use of building wiring appropriate for the supported PHYs and telephony wiring practices.

27.1.2.2 Compatibility considerations

All implementations of the repeater set shall be compatible at the MDI. The repeater set is defined to provide compatibility among devices designed by different manufacturers. Designers are free to implement circuitry within the repeater set in an application-dependent manner provided the appropriate PHY specifications are met.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

27.1.2.2.1 Internal segment compatibility

Implementations of the repeater set that contain a MAC layer for network management or other purposes, irrespective of whether they are connected through an exposed repeater port or are internally ported, shall conform to the requirements of Clause 30 on that port if repeater management is implemented.

27.1.3 Relationship to PHY

A close relationship exists between Clause 27 and the PHY clauses, Clause 23 for the 100BASE-T4 PHY and Clause 24 to Clause 26 for the 100BASE-X PHYs, and Clause 32 for the 100BASE-T2 PHY. The PHY's PMA, PCS, and MDI specifications provide the actual medium attachment, including drivers, receivers, and Medium Interface Connectors for the various supported media. The repeater clause does not define a new PHY; it utilizes the existing PHYs complete and without modification.

27.2 PMA interface messages

The messages between the repeater unit and the PMA in the PHY utilizes the PMA service interface defined in 23.3, 24.3, and 32.4.2. The PMA service interface primitives are summarized below:

PMA_TYPE.indication
PMA_UNITDATA.request
PMA_UNITDATA.indication
PMA_CARRIER.indication
PMA_LINK.indication
PMA_RXERROR.indication

27.3 Repeater functional specifications

A repeater set provides the means whereby data from any segment can be received under worst case noise, timing, and amplitude conditions and then retransmitted with timing and amplitude restored to all other attached segments. Retransmission of data occurs simultaneously with reception. If a collision occurs, the repeater set propagates the collision event throughout the network by transmitting a Jam signal. If an error is received by the repeater set, no attempt is made to correct it and it is propagated throughout the network by transmitting an invalid signal.

The repeater set provides the following functional capability to handle data flow between ports:

a) *Signal restoration.* Provides the ability to restore the timing and amplitude of the received signal prior to retransmission.
b) *Transmit function.* Provides the ability to output signals on the appropriate port and encoded appropriately for that port. Details of signal processing are described in the specifications for the PHYs.
c) *Receive function.* Provides the ability to receive input signals presented to the ports. Details of signal processing are described in the specifications for the PHYs.
d) *Data Handling function.* Provides the ability to transfer code-elements between ports in the absence of a collision.
e) *Received Event Handling requirement.* Provides the ability to derive a carrier signal from the input signals presented to the ports.
f) *Collision Handling function.* Provides the ability to detect the simultaneous reception of frames at two or more ports and then to propagate a Jam message to all connected ports.
g) *Error Handling function.* Provides the ability to prevent substandard links from generating streams of false carrier and interfering with other links.
h) *Partition function.* Provides the ability to prevent a malfunctioning port from generating an excessive number of consecutive collisions and indefinitely disrupting data transmission on the network.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

i) *Receive Jabber function.* Provides the ability to interrupt the reception of abnormally long streams of input data.

27.3.1 Repeater functions

The repeater set shall provide the Signal Restoration, Transmit, Receive, Data Handling, Received Event Handling, Collision Handling, Error Handling, Partition, and Receive Jabber functions. The repeater is transparent to all network acquisition activity and to all DTEs. The repeater will not alter the basic fairness criterion for all DTEs to access the network or weigh it toward any DTE or group of DTEs regardless of network location.

The Transmit and Receive functional requirements are specified by the PHY clauses, Clause 23 for 100BASE-T4, Clause 24 to Clause 26 for 100BASE-X, and Clause 32 for 100BASE-T2.

27.3.1.1 Signal restoration functional requirements

27.3.1.1.1 Signal amplification

The repeater set (including its integral PHYs) shall ensure that the amplitude characteristics of the signals at the MDI outputs of the repeater set are within the tolerances of the specification for the appropriate PHY type. Therefore, any loss of signal-to-noise ratio due to cable loss and noise pickup is regained at the output of the repeater set as long as the incoming data is within system specification.

27.3.1.1.2 Signal wave-shape restoration

The repeater set (including its integral PHYs) shall ensure that the wave-shape characteristics of the signals at the MDI outputs of a repeater set are within the specified tolerance for the appropriate PHY type. Therefore, any loss of wave-shape due to PHYs and media distortion is restored at the output of the repeater set.

27.3.1.1.3 Signal retiming

The repeater set (including its integral PHYs) shall ensure that the timing of the encoded data output at the MDI outputs of a repeater set are within the specified tolerance for the appropriate PHY type. Therefore, any receive jitter from the media is removed at the output of the repeater set.

27.3.1.2 Data handling functional requirements

27.3.1.2.1 Data frame forwarding

The repeater set shall ensure that the data frame received on a single input port is distributed to all other output ports in a manner appropriate for the PHY type of that port. The data frame is that portion of the packet after the SFD and before the end-of-frame delimiter. The only exceptions to this rule are when contention exists among any of the ports, when the receive port is partitioned as defined in 27.3.1.6, when the receive port is in the Jabber state as defined in 27.3.1.7, or when the receive port is in the Link Unstable state as defined in 27.3.1.5.1. Between unpartitioned ports, the rules for collision handling (see 27.3.1.4) take precedence.

27.3.1.2.2 Received code violations

The repeater set shall ensure that any code violations received while forwarding a packet are propagated to all outgoing segments. These code violations shall be forwarded as received or replaced by bad_code (see 23.2.1.2), /H/ (see 24.2.2.1), or (ESC/0, 0/ESC) (see Figure 32–9) code-groups, as appropriate for the outgoing PHY type. Once a received code violation has been replaced by the bad_code, /H/, or (ESC/0, 0/ESC) code-groups, this substitution shall continue for the remainder of the packet regardless of its content. The only exception to this rule is when contention exists among any of the ports, where the rules for collision handling (see 27.3.1.4) then take precedence.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

27.3.1.3 Received event handling functional requirements

27.3.1.3.1 Received event handling

For all its ports, the repeater set shall implement a function (scarrier_present) that represents a received event. Received events include both the Data Frame and any encapsulation of the Data Frame such as Preamble, SFD, and the code-groups /H/, /J/, /K/, bad_code, eop, /T/, /R/, SSD, ESD, etc. A received event is exclusive of the IDLE pattern. Upon detection of scarrier_present from one port, the repeater set repeats all received signals in the Data Frame from that port to the other port (or ports) as described in Figure 27–2.

27.3.1.3.2 Preamble regeneration

The repeater set shall output preamble as appropriate for the outgoing PHY type followed by the SFD.

27.3.1.3.3 Start-of-packet propagation delay

The start-of-packet propagation delay for a repeater set is the time delay between the start of the packet (see 24.6, 23.11.3, and 32.12.1) on its repeated-from (input) port to the start of the packet on its repeated-to (output) port (or ports). This parameter is referred to as the SOP delay. The maximum value of this delay is constrained by Table 27–2.

27.3.1.3.4 Start-of-packet variability

The start-of-packet variability for a repeater set is defined as the total worst-case difference between start-of-packet propagation delays for successive packets separated by 104 bit times (BT) or less at the same input port. The variability shall be less than or equal to those specified in Table 27–1.

Table 27–1—Start-of-packet variability

Input port type	Variability (BT)
100BASE-FX	7.0
100BASE-TX	7.0
100BASE-T4	8.0
100BASE-T2	8.0

27.3.1.4 Collision handling functional requirements

27.3.1.4.1 Collision detection

The repeater performs collision detection by monitoring all its enabled input ports for received events. When the repeater detects received events on more than one input port, it shall enter a collision state and transmit the Jam message to all of its output ports.

27.3.1.4.2 Jam generation

While a collision is occurring between any of its ports, the repeater unit shall transmit the Jam message to all of the PMAs to which it is connected. The Jam message shall be transmitted in accordance with the repeater state diagram in Figure 27–4 and Figure 27–5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

27.3.1.4.3 Collision-jam propagation delay

The start-of-collision Jam propagation delay for a repeater set is the time delay between the start of the second packet input signals to arrive at its port and the start of Jam (see 24.6, 23.11, and 32.12.1) out on all ports. This parameter is referred to as the SOJ delay. The delay shall be constrained by Table 27–2. Note that a device defined by two columns in Table 27–2 has to meet the performance requirements specified in both columns.

Table 27–2—Start-of-packet propagation and start-of-collision jam propagation delays

Class I repeater	Class II repeater with all ports TX/FX	Class II repeater with any port T4	Class II repeater with any port T2
SOP + SOJ ≤ 140 BT	SOP ≤ 46 BT, SOJ ≤ 46 BT	SOP+SOJ ≤ 67 BT	SOP+SOJ ≤ 90 BT

27.3.1.4.4 Cessation-of-collision Jam propagation delay

The cessation-of-collision Jam propagation delay for a repeater set is the time delay between the end of the packet (see 24.6 and 23.11.3) that creates a state such that Jam should end at a port and the end of Jam (see 24.6 and 23.11.3) at that port. The states of the input signals that should cause Jam to end are covered in detail in the repeater state diagrams. This parameter is referred to as the EOJ delay. The delay shall be constrained by Table 27–3.

Table 27–3—Cessation-of-collision Jam propagation delay

Class I repeater	Class II repeater
EOJ ≤ SOP	EOJ ≤ SOP

27.3.1.5 Error handling functional requirements

27.3.1.5.1 100BASE-X and 100BASE-T2 carrier integrity functional requirements

In 100BASE-TX, 100BASE-FX, and 100BASE-T2 systems, it is desirable that the repeater set protect the network from some transient fault conditions that would disrupt network communications. Potential likely causes of such conditions are DTE and repeater power-up and power-down transients, cabling disconnects, and faulty wiring.

Each 100BASE-TX, 100BASE-FX, and 100BASE-T2 repeater PMA interface shall contain a self-interrupt capability, as described in Figure 27–9, to prevent a segment's spurious carrier activity from reaching the repeater unit and hence propagating through the network.

The repeater PMA interface shall count consecutive false carrier events. A false carrier event is defined as a carrier event that does not begin with a valid start of stream delimiter (see 24.2.2.1.4 and 32.3.1.2.3). The count shall be incremented on each false carrier event and shall be reset on reception of a valid carrier event. In addition, each PMA interface shall contain a false carrier timer, which is enabled at the beginning of a false carrier event and reset at the conclusion of such an event. A repeater unit shall transmit the JAM message to all of the PMAs to which it is connected for the duration of the false carrier event or until the duration of the event exceeds the time specified by the false_carrier_timer (see 27.3.2.1.4), whichever is shorter. The JAM message shall be transmitted in accordance with the Repeater state diagram in Figure 27–4 and Figure 27–5. The LINK UNSTABLE condition shall be detected when the False Carrier Count exceeds

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the value FCCLimit (see 27.3.2.1.1) or the duration of a false carrier event exceeds the time specified by the false_carrier_timer. In addition, the LINK UNSTABLE condition shall be detected upon power-up reset.

Upon detection of LINK UNSTABLE, the port shall perform the following:

a) Inhibit sending further messages to the repeater unit.
b) Inhibit sending further output messages from the repeater unit.
c) Continue to monitor activity on that PMA interface.

The repeater shall exit the LINK UNSTABLE condition when one of the following is met:

a1) The repeater has detected no activity (Idle) for more than the time specified by ipg_timer plus idle_timer (see 27.3.2.1.4) on Port X.
b1) A valid carrier event with a duration greater than the time specified by valid_carrier_timer (see 27.3.2.1.4) has been received, preceded by no activity (Idle) for more than the time specified by ipg_timer (see 27.3.2.1.4) on Port X.

27.3.1.5.2 Speed handling

If the PHY has the capability of detecting speeds other than 100 Mb/s, then the repeater set shall have the capability of blocking the flow of non-100 Mb/s signals. The incorporation of 100 Mb/s and 10 Mb/s repeater functionality within a single repeater set is beyond the scope of this standard.

27.3.1.6 Partition functional requirements

In large multisegment networks it may be desirable that the repeater set protect the network from some fault conditions that would disrupt network communications. A potentially likely cause of this condition could be due to a cable fault.

Each repeater PMA interface shall contain a self-interrupt capability, as described in Figure 27–8, to prevent a faulty segment's carrier activity from reaching the repeater unit and hence propagating through the network. The repeater PMA interface shall count collisions. The count shall be incremented on each transmission that suffers a collision. The count shall be reset on a carrier event of duration in excess of no_collision_timer (see 27.3.2.1.4) without incurring a collision. If this count reaches the value CCLimit (see 27.3.2.1.1), the Partition condition shall be detected.

Upon detection of Partition, the port shall perform the following:

a) Inhibit sending further input messages to the repeater unit.
b) Continue to output messages from the repeater unit.
c) Continue to monitor activity on that PMA interface.

The repeater shall reset the Partition function when one of the following conditions is met:

a1) On power-up reset.
b1) The repeater has transmitted on the port for a duration in excess of no_collision_timer (see 27.3.2.1.4) without incurring a collision.

NOTE—It is possible that under some network conditions the partition state diagram will partition a port due to normal network collisions rather than a fault condition. It is also possible that some double fault conditions will remain undetected. To reduce the likelihood of these events occurring, the following optional measures, as described in Figure 27–8, are recommended:

a2) The collision count is additionally reset when the repeater has transmitted on the port for a duration in excess of no_collision_timer without detecting a collision.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b2) The Partition function is additionally reset when the repeater has received activity on the port for a duration in excess of no_collision_timer without detecting a collision.
c2) The Partition condition is additionally detected due to a carrier event of duration in excess of jabber_timer (see 27.3.1.7) in which a collision has occurred.

27.3.1.7 Receive jabber functional requirements

Each repeater PMA interface shall contain a self-interrupt capability, as described in Figure 27–7, to prevent an illegally long reception of data from reaching the repeater unit. The repeater PMA interface shall provide a window of duration jabber_timer bit times (see 27.3.2.1.4) during which the input messages may be passed on to other repeater unit functions. If a reception exceeds this duration, the jabber condition shall be detected.

Upon detection of jabber, the port shall perform the following:

a) Inhibit sending further input messages to the repeater unit.
b) Inhibit sending further output messages from the repeater unit.

The repeater PMA interface shall reset the Jabber function and re-enable data transmission and reception when either one of the following conditions is met:

a1) On power-up reset.
b1) When carrier is no longer detected.

27.3.2 Detailed repeater functions and state diagrams

A precise algorithmic definition is given in this subclause, providing a complete procedural model for the operation of a repeater, in the form of state diagrams. Note that whenever there is any apparent ambiguity concerning the definition of repeater operation, the state diagrams should be consulted for the definitive statement.

The model presented in this subclause is intended as a primary specification of the functions to be provided by any repeater unit. It is important to distinguish, however, between the model and a real implementation. The model is optimized for simplicity and clarity of presentation, while any realistic implementation should place heavier emphasis on such constraints as efficiency and suitability to a particular implementation technology.

It is the functional behavior of any repeater unit implementation that shall match the standard, not the internal structure. The internal details of the procedural model are useful only to the extent that they help specify the external behavior clearly and precisely. For example, the model uses a separate Receive Port Jabber state diagram for each port. However, in actual implementation, the hardware may be shared.

The notation used in the state diagram follows the conventions of 1.2.1. Note that transitions shown without source states are evaluated at the completion of every state and take precedence over other transition conditions.

27.3.2.1 State diagram variables

27.3.2.1.1 Constants

CCLimit

The number of consecutive collisions that have to occur before a segment is partitioned.

Values: Positive integer greater than 60.

FCCLimit

The number of consecutive False Carrier events that have to occur before a segment is isolated.

Value: 2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

27.3.2.1.2 Variables

activity(Port designation)

Indicates port activity status. The repeater core effects a summation of this variable received from all its attached ports and responds accordingly.

Values: 0; no frame or packet activity at any port.
1; exactly 1 port of the repeater set has frame or packet activity input.
>1; more than 1 port of the repeater set has frame or packet activity input. Alternately, one or more ports has detected a carrier that is not valid.

all_data_sent

Indicates if all received data frame bits or code-groups from the current frame have been sent. During or after collision the all_data_sent variable follows the inverse of the carrier of port N.

Values: true; all received data frame bits or code-groups have been sent.
false; all received data frame bits or code-groups have not been sent.

begin

The Interprocess flag controlling state diagram initialization values.

Values: true
false

carrier_status(X)

Signal received from PMA; indicates the status of sourced Carrier input at Port X.

Values: ON; the carrier_status parameter of the PMA_CARRIER.indication primitive for Port X is ON.
OFF; the carrier_status parameter of the PMA_CARRIER.indication primitive for Port X is OFF.

data_ready

Indicates if the repeater has detected and/or decoded the MAC SFD and is ready to send the received data.

Values: true; the MAC SFD has been detected and/or decoded.
false; the MAC SFD has not been detected nor decoded.

force_jam(X)

Flag from Carrier Integrity state diagram for Port X, which determines whether all ports should transmit Jam.

Values: true; the Carrier Integrity Monitor has determined that it requires all ports be forced to transmit Jam.
false; the Carrier Integrity Monitor has determined that it does not require all ports be forced to transmit Jam.

Default: for T4 ports: false

isolate(X)

Flag from Carrier Integrity state diagram for Port X, which determines whether a port should be enabled or disabled.

Values: true; the Carrier Integrity Monitor has determined the port should be disabled.
false; the Carrier Integrity Monitor has determined the port should be enabled.

jabber(X)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Flag from Receive Timer state diagram for Port X, which indicates that the port has received excessive length activity.

Values: true; port has exceeded the continuous activity limit.
false; port has not exceeded the continuous activity limit.

link_status(X)

Signal received from PMA; indicates link status for Port X (see 23.3.5, 24.3.1.5, and 32.4.1.3.1).

Values: OK; the link_status parameter of the PMA_LINK.indication primitive for Port X is OK.
READY; the link_status parameter of the PMA_LINK.indication primitive for Port X is READY (for 100BASE-TX and 100BASE-T4).
FAIL; the link_status parameter of the PMA_LINK.indication primitive for Port X is FAIL.

opt(X)

Implementation option. Either value may be chosen for repeater implementation.

Values: true; port will emit the JamT4 pattern in response to collision conditions.
false; port will append Jam pattern after preamble and SFD in response to collision conditions.

OUT(X)

Type of output repeater is sourcing at Port X.

Values: Idle; repeater is transmitting an IDLE pattern as described by 23.4.1.2, 24.2.2.1.2, or 32.3.1.2.3.
In(N); repeater is transmitting rx_code_bit(s) as received from Port (N) except /J/K/ (see 24.3.4.2), or recoded rx_symbol_vector as received from Port (N) except SSD (see 32.3.5.2).
Pream; repeater is sourcing preamble pattern as defined by the PMA or PCS of the port type (see 23.2.1.2, 24.2.2.2, 32.3.1.2, Figure 23–6 and Figure 24–9.)
Data; repeater is transmitting data frame on Port X. This data represents the original MAC source data field, properly encoded for the PHY type (see 23.2.1.2, 24.2.2.2, and 32.3.1.2.3).
Jam; repeater is sourcing well formed arbitrary data encodings, excluding SFD, to the port PMA.
JamX; repeater is sourcing a pattern representing 010101... repetitively on Port X.
JamT4; repeater is sourcing the pattern +-+-... repetitively on Port X.

JamT2; repeater is sending a pattern representing 010101... repetitively on Port X.
SFD; repeater is sourcing the Start Frame Delimiter on Port X encoded as defined by the appropriate PHY (see 23.2.3, Figure 24–9, and 32.3.1.2).
/J/K/; repeater is sourcing the code-groups /J/K/ as defined by the PMA on Port X (see 24.2.2.1.4).
/T/R/; repeater is sourcing the code-groups /T/R/ as defined by the PMA on Port X (see 24.2.2.1.5).

SSD; repeater is sourcing the code-groups SSD as defined by the PMA on Port X (see 32.4.2.5).

ESD; repeater is sourcing the code-groups ESD as defined by the PMA on Port X (see 32.3.1.2.3).
DF; repeater is sourcing the Data Frame of the packet on Port X. These are code elements originating on Port N exclusive of EOP1-5, SOSA and SOSB (see 23.2.3 and 23.2.4).
EOP; repeater is sourcing end of packet delimiter (EOP1-5) as defined by the appropriate PMA on Port X (see 23.2.1.2 and 23.2.4.1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bad_code; repeater is sourcing bad_code as defined by the PMA of the transmit port (see 23.2.4.1).
tx_err; repeater is sourcing a transmit error code element, either bad_code (see 23.2.4.1) or the code-group /H/ (see 24.2.2.1), or (ESC/0, 0/ESC) (see Figure 32–12) as appropriate to the outgoing PHY type.

partition(X)

Flag from Partition state diagram for Port X, which determines whether a port receive path should be enabled or disabled.

Values: true; port has exceeded the consecutive collision limit.
false; port has not exceeded the consecutive collision limit.

part_opt(X)

Implementation option. Either value may be chosen for repeater implementation (see 27.3.1.6).

Values: true; port supports the recommended optional measures in the partition state diagram.
false; port does not support the recommended optional measures in the partition state diagram.

rxerror_status(X)

Signal received from PMA; indicates if Port X has detected an error condition from the PMA (see 23.3.7.1, Figure 24–14, and Figure 32–14).The repeater need not propagate this error condition during collision events.

Values: ERROR; the rxerror_status parameter of the PMA_RXERROR.indication primitive for Port X is ERROR.
NO_ERROR; the rxerror_status parameter of the PMA_RXERROR.indication primitive for Port X is NO_ERROR.

RX_ER(X)

Signal received from PCS; indicates if Port X has detected an error condition from the PCS (see 23.2.1.4, 24.2.3.2, 32.3.4.1, Figure 23–10, Figure 24–15, and Figure 32–13). The repeater need not propagate this error condition during collision events.

Values: true; the PCS RX_ER signal for Port X is asserted.
false; the PCS RX_ER signal for Port X is negated.

scarrier_present(X)

Signal received from PMA; indicates the status of sourced Carrier input at Port X.

Values: true; the carrier_status parameter of the PMA_CARRIER.indication primitive for Port X is ON.
false; the carrier_status parameter of the PMA_CARRIER.indication primitive for Port X is OFF.

source_type(X)

Signal received from PMA; indicates PMA type for Port X. The first port to assert activity maintains the source type status for all transmitting port(s) until activity is deasserted. Repeaters may optionally force nonequality on comparisons using this variable. It has to then follow the behavior of the state diagrams accordingly and meet all the delay parameters as applicable for the real implemented port type(s).

Values: FXTX; the pma_type parameter of the PMA_TYPE.indication primitive for Port X is X.
T4; the pma_type parameter of the PMA_TYPE.indication primitive for Port X is T4.
T2; the pma_type parameter of the PMA_TYPE.indication primitive for Port X is T2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

27.3.2.1.3 Functions

command(X)

A function that passes an inter-process flag to all ports specified by X.

Values: copy; indicates that the repeater core has summed the activity levels of its active ports and is in the ACTIVE state.
collision; indicates that the repeater core has summed the activity levels of its active ports and is in the JAM state.
quiet; indicates that the repeater core has summed the activity levels of its active ports and is in the IDLE state.

port(Test)

A function that returns the designation of a port passing the test condition. For example, port(activity = scarrier_present) returns the designation: X for a port for which scarrier_present = true. If multiple ports meet the test condition, the Port function will be assigned one and only one of the acceptable values.

27.3.2.1.4 Timers

All timers operate in the same fashion. A timer is reset and starts timing upon entering a state where "start x_timer" is asserted. At time "x" after the timer has been started, "x_timer_done" is asserted and remains asserted until the timer is reset. At all other times, "x_timer_not_done" is asserted.

When entering a state where "start x_timer" is asserted, the timer is reset and restarted even if the entered state is the same as the exited state.

The timers used in the repeater state diagrams are defined as follows:

false_carrier_timer

Timer for length of false carrier (27.3.1.5.1) that has to be present before the ISOLATION state is entered. The timer is done when it reaches 450 – 500 BT.

idle_timer

Timer for length of time without carrier activity that has to be present before the ISOLATION state is exited (27.3.1.5.1). The timer is done when it reaches 33 000 BT ± 25% BT.

ipg_timer

Timer for length of time without carrier activity that has to be present before carrier integrity tests (27.3.1.5.1) are re-enabled. The timer is done when it reaches 64 – 86 BT.

jabber_timer

Timer for length of carrier that has to be present before the Jabber state (27.3.1.7), and optionally during a collision the Partition state (27.3.1.6), is entered. The timer is done when it reaches 40 000 – 75 000 BT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

no_collision_timer

Timer for length of packet without collision before the Partition state is exited (27.3.1.6). The timer is done when it reaches 450 – 560 BT.

valid_carrier_timer

Timer for length of valid carrier that has to be present before the Isolation state is exited (27.3.1.5.1). The timer is done when it reaches 450 – 500 BT.

27.3.2.1.5 Counters

CC(X)

Consecutive port collision count for Port X. Partitioning occurs on a terminal count of CCLimit being reached.

Values: Non-negative integers up to a terminal count of CCLimit.

FCC(X)

False Carrier Counter for Port X. Isolation occurs on a terminal count of FCCLimit being reached.

Values: Non-negative integers up to a terminal count of FCCLimit.

27.3.2.1.6 Port designation

Ports are referred to by number. Port information is obtained by replacing the X in the desired function with the number of the port of interest. Ports are referred to in general as follows:

X

Generic port designator. When X is used in a state diagram, its value is local to that diagram and not global to the set of state diagrams.

N

Is defined by the Port function on exiting the IDLE or JAM states of Figure 27–2. It indicates a port that caused the exit from these states.

ALL

Indicates all repeater ports are to be considered. All ports shall meet test conditions in order for the test to pass.

ALLXN

Indicates all ports except N should be considered. All ports considered shall meet the test conditions in order for the test to pass.

ANY

Indicates all ports are to be considered. One or more ports shall meet the test conditions in order for the test to pass.

ANYXN

Indicates any port other than N meeting the test conditions shall cause the test to pass.

27.4 Repeater electrical specifications

27.4.1 Electrical isolation

Network segments that have different isolation and grounding requirements shall have those requirements provided by the port-to-port isolation of the repeater set.

27.5 Environmental specifications

27.5.1 General safety

NOTE—Since September 2011, maintenance changes are no longer being considered for this clause. Since February 2021, safety information is in J.2.

All equipment meeting this standard shall conform to IEC 60950-1.

27.5.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns; the list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

LAN cable systems described in this subclause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cables and components.
c) High-energy transients coupled onto the LAN cable system.
d) Voltage potential differences between safety grounds to which the various LAN components are connected.

Such electrical safety hazards have to be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures have to be taken to ensure that the intended safety features are not negated during installation of a new network or during modification or maintenance of an existing network. Isolation requirements are defined in 27.5.3.

27.5.2.1 Installation

Sound installation practice, as defined by applicable local codes and regulations, shall be followed in every instance in which such practice is applicable.

27.5.2.2 Grounding

The safety ground, or chassis ground for the repeater set, shall be provided through the main ac power cord via the third wire ground as defined by applicable local codes and regulations. It is recommended that an external PHY to the repeater should also be mechanically grounded to the repeater unit through the power and ground signals in the MII connection and via the metal shell and shield of the MII connector if available.

If the MDI connector should provide a shield connection, the shield may be connected to the repeater safety ground. A network segment connected to the repeater set through the MDI may use a shield. If both ends of the network segment have a shielded MDI connector available, then the shield may be grounded at both ends according to local regulations and ISO/IEC 11801:1995, and as long as the ground potential difference

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

between both ends of the network segment is less than 1 V rms. The same rules apply towards an inter-repeater link between two repeaters. Multiple repeaters should reside on the same power main; if not, then it is highly recommended that the repeaters be connected via fiber.

WARNING

It is assumed that the equipment to which the repeater is attached is properly grounded and not left floating nor serviced by a "doubly insulated ac power distribution system." The use of floating or insulated equipment, and the consequent implications for safety, are beyond the scope of this standard.

27.5.2.3 Installation and maintenance guidelines

During installation and maintenance of the cable plant, care should be taken to ensure that uninsulated network cable connectors do not make electrical contact with unintended conductors or ground.

27.5.3 Electrical isolation

There are two electrical power distribution environments to be considered that require different electrical isolation properties:

a) *Environment A.* When a LAN or LAN segment, with all its associated interconnected equipment, is entirely contained within a single low-voltage power distribution system and within a single building.
b) *Environment B.* When a LAN crosses the boundary between separate power distribution systems or the boundary of a single building.

27.5.3.1 Environment A requirements

Attachment of network segments via repeater sets requires electrical isolation of 500 V rms, one-minute withstand, between the segment and the protective ground of the repeater unit.

27.5.3.2 Environment B requirements

The attachment of network segments that cross Environment B boundaries requires electrical isolation of 1500 V rms, one-minute withstand, between each segment and all other attached segments and also the protective ground of the repeater unit.

The requirements for interconnected electrically conducting LAN segments that are partially or fully external to a single building environment may require additional protection against lightning strike hazards. Such requirements are beyond the scope of this standard. It is recommended that the above situation be handled by the use of nonelectrically conducting segments (e.g., fiber optic).

It is assumed that any nonelectrically conducting segments will provide sufficient isolation within that media to satisfy the isolation requirements of Environment B.

27.5.4 Reliability

A two-port repeater set shall be designed to provide a mean time between failure (MTBF) of at least 50 000 hours of continuous operation without causing a communications failure among stations attached to the network medium. Repeater sets with more than two ports shall add no more than 3.46×10^{-6} failures per hour for each additional port.

The repeater set electronics should be designed to minimize the probability of component failures within the repeater electronics that prevent communications among other PHYs on the individual segments. Connec-

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tors and other passive components comprising the means of connecting the repeater to the cable should be designed to minimize the probability of total network failure.

27.5.5 Environment

27.5.5.1 Electromagnetic emission

The repeater shall comply with applicable local and national codes for the limitation of electromagnetic interference.

27.5.5.2 Temperature and humidity

The repeater is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

It is recommended that manufacturers indicate in the literature associated with the repeater the operating environmental conditions to facilitate selection, installation, and maintenance.

27.6 Repeater labeling

It is required that each repeater (and supporting documentation) shall be labeled in a manner visible to the user with these parameters:

a) Crossover ports appropriate to the respective PHY should be marked with an X.
b) The repeater set class type should be labeled in the following manner:
    1) Class I: a Roman numeral “I” centered within a circle.
    2) Class II: a Roman numeral “II” centered within a circle.

Additionally, it is recommended that each repeater (and supporting documentation) also be labeled in a manner visible to the user with at least these parameters:

c) Data rate capability in Mb/s
d) Any applicable safety warnings
e) Port type, i.e., 100BASE-TX, 100BASE-T4, or 100BASE-T2
f) Worst-case bit time delays between any two ports appropriate for
    1) Start-of-packet propagation delay
    2) Start-of-collision Jam propagation delay
    3) Cessation-of-collision Jam propagation delay

27.7 Protocol implementation conformance statement (PICS) proforma for Clause 27, Repeater for 100 Mb/s baseband networks[62]

27.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 27, Repeater for 100 Mb/s baseband networks, shall complete the following protocol implementation conformance statement (PICS) proforma.

27.7.2 Identification

27.7.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

27.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2018, Clause 27, Repeater for 100 Mb/s baseband networks
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2018.)	

Date of Statement	

[62] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

27.7.3 Major capabilities/options

Item	Feature	Subclause	Status	Support	Value/Comment
*FXP	Repeater supports 100BASE-FX connections	27.1.2.2	O		
*TXP	Repeater supports 100BASE-TX connections	27.1.2.2	O		
*T4P	Repeater supports 100BASE-T4 connections	27.1.2.2	O		
*T2P	Repeater supports 100BASE-T2 connections	27.1.2.2	O		
*CLI	Repeater meets Class I delays	27.1.1.3	O		
*CLII	Repeater meets Class II delays	27.1.1.3	O		
*PHYS	PHYs capable of detecting non 100BASE-T signals	27.3.1.5.2	O		
*OPF	Partition function supports the recommended optional measures as described	27.3.1.6	O		

In addition, the following predicate name is defined for use when different implementations from the set above have common parameters:

*XP:FXP or TXP

27.7.4 PICS proforma tables for the repeater for 100 Mb/s baseband networks

27.7.4.1 Compatibility considerations

Item	Feature	Subclause	Status	Support	Value/Comment
CC1	100BASE-FX port compatible at the MDI	27.1.2.2	FXP:M		
CC2	100BASE-TX port compatible at the MDI	27.1.2.2	TXP:M		
CC3	100BASE-T4 port compatible at the MDI	27.1.2.2	T4P:M		
CC4	Internal segment compatibility	27.1.2.2.1	M		Internal port meets Clause 30 when repeater management implemented
CC5	100BASE-T2 port compatible at the MDI	27.1.2.2	T2P:M

28. Physical Layer link signaling for Auto-Negotiation on twisted pair

28.1 Overview

28.1.1 Scope

Clause 28 describes the Auto-Negotiation function that allows a device to advertise enhanced modes of operation it possesses to a device at the remote end of a link segment and to detect corresponding enhanced operational modes that the other device may be advertising. The normative definitions for all extensions to Auto-Negotiation and all related register assignments for this standard are documented in Annex 28D.

The objective of the Auto-Negotiation function is to provide the means to exchange information between two devices that share a link segment and to automatically configure both devices to take maximum advantage of their abilities. Auto-Negotiation is performed using a modified 10BASE-T link integrity test pulse sequence, such that no packet or upper layer protocol overhead is added to the network devices (see Figure 28–1). Auto-Negotiation does not test the link segment characteristics (see 28.1.4).

The function allows the devices at both ends of a link segment to advertise abilities, acknowledge receipt and understanding of the common mode(s) of operation that both devices share, and to reject the use of operational modes that are not shared by both devices. Where more than one common mode exists between the two devices, a mechanism is provided to allow the devices to resolve to a single mode of operation using a predetermined priority resolution function. The Auto-Negotiation function allows the devices to switch between the various operational modes in an ordered fashion, permits management to disable or enable the Auto-Negotiation function, and allows management to select a specific operational mode. The Auto-Negotiation function also provides a Parallel Detection function to allow 10BASE-T, 100BASE-TX, and 100BASE-T4 compatible devices to be recognized, even though they may not provide Auto-Negotiation.

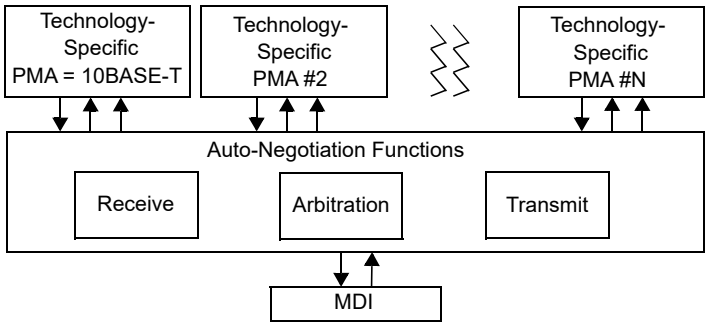

Figure 28–1—High-level model

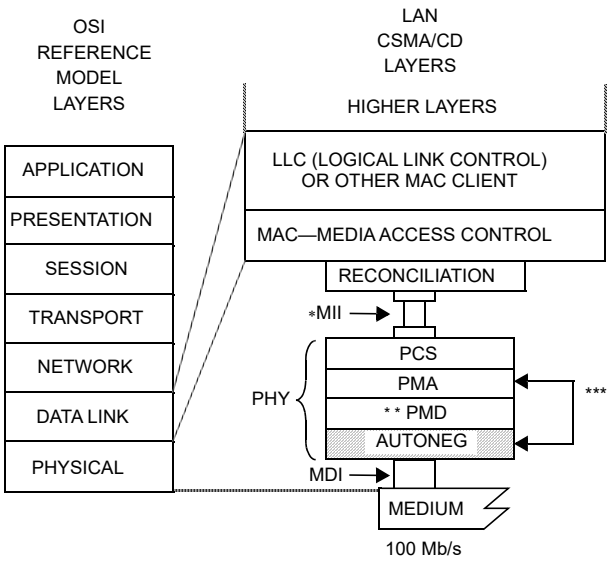
The basic mechanism to achieve Auto-Negotiation is to pass information encapsulated within a burst of closely spaced link integrity test pulses that individually meet the 10BASE-T Transmitter Waveform for Link Test Pulse (Figure 14–13). This burst of pulses is referred to as a Fast Link Pulse (FLP) Burst. Each device capable of Auto-Negotiation issues FLP Bursts at power up, on command from management, or due to user interaction. The FLP Burst consists of a series of link integrity test pulses that form an alternating clock/data sequence. Extraction of the data bits from the FLP Burst yields a link codeword that identifies the operational modes supported by the remote device, as well as some information used for the Auto-Negotiation function's handshake mechanism.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

To maintain interoperability with existing 10BASE-T devices, the function also supports the reception of 10BASE-T compliant link integrity test pulses. 10BASE-T link pulse activity is referred to as the Normal Link Pulse (NLP) sequence and is defined in 14.2.1.1. A device that fails to respond to the FLP Burst sequence by returning only the NLP sequence is treated as a 10BASE-T compatible device.

28.1.2 Application perspective/objectives

The Auto-Negotiation function is designed to be expandable and allow IEEE 802.3 compatible devices using an eight-pin modular connector to self-configure a jointly compatible operating mode. Implementation of the Auto-Negotiation function is optional. However, it is highly recommended that this method alone be utilized to perform the negotiation of the link operation.



The following are the objectives of Auto-Negotiation:

a) Interoperate with the IEEE 802.3 10BASE-T installed base.
b) Allow automatic upgrade from the 10BASE-T mode to the desired “High-Performance Mode.”
c) Requires that the 10BASE-T data service is the Lowest Common Denominator (LCD) that can be resolved. A 10BASE-T PMA is not required to be implemented, however. Only the NLP Receive Link Integrity Test function is required.
d) Reasonable and cost-effective to implement.
e) Provide a sufficiently extensible code space to
    1) Meet existing and future requirements.
    2) Allow simple extension without impacting the installed base.
    3) Accommodate remote fault signals.
    4) Accommodate Link Partner ability detection.
f) Allow manual or Network Management configuration to override the Auto-Negotiation.
g) Capable of operation in the absence of Network Management.
h) Does not preclude the ability to negotiate “back” to the 10BASE-T operational mode.
i) Operates when
    1) The link is initially electrically connected.
    2) A device at either end of the link is powered up, reset, or a renegotiation request is made.
j) The Auto-Negotiation function may be enabled by automatic, manual, or Network Management intervention.
k) Completes the Base Page Auto-Negotiation function in a bounded time period.
l) Will provide the basis for the link establishment process in future CSMA/CD compatible LAN standards that use an eight-pin modular connector.
m) Does not cause corruption of IEEE 802.3 Layer Management statistics.
n) Operates using a peer-to-peer exchange of information with no requirement for a master device (not master-slave).
o) To be robust in the UTP cable noise environment.
p) To not significantly impact EMI/RFI emissions.

28.1.3 Relationship to architectural layering

The Auto-Negotiation function is provided at the Physical Layer of the OSI reference model as shown in Figure 28–2. Devices that support multiple modes of operation may advertise this fact using this function. The actual transfer of information of ability is observable only at the MDI or on the medium. Auto-Negotiation signaling does not occur across either the AUI or MII. Control of the Auto-Negotiation function may be supported through the Management Interface of the MII or equivalent. If an explicit embodiment of the MII is supported, the control and status registers to support the Auto-Negotiation function shall be implemented in accordance with the definitions in Clause 22 and 28.2.4. If a physical embodiment of the MII management is not present, then it is strongly recommended that the implementation provide control and status mechanisms equivalent to those described in Clause 22 and 28.2.4 for manual and/or management interaction.

MDI = MEDIUM DEPENDENT INTERFACE
MII = MEDIA INDEPENDENT INTERFACE
AUTONEG = AUTO-NEGOTIATION
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
PMD = PHYSICAL MEDIUM DEPENDENT

* MII is optional for 10 Mb/s DTEs and for 100 Mb/s systems and is not specified for 1 Mb/s systems.
** PMD is specified for 100BASE-X only; 100BASE-T4 does not use this layer.
*** AUTONEG communicates with the PMA sublayer through the PMA service interface messages PMA_LINK.request and PMA_LINK.indication.

Figure 28–2—Location of Auto-Negotiation function within the ISO/IEC OSI reference model

28.1.4 Compatibility considerations

The Auto-Negotiation function is designed to be completely backwards compatible and interoperable with 10BASE-T compliant devices. In order to achieve this, a device supporting the Auto-Negotiation function has to provide the NLP Receive Link Integrity Test function as defined in Figure 28–19. The Auto-Negotiation function also supports connection to 100BASE-TX and 100BASE-T4 devices without Auto-Negotiation through the Parallel Detection function. Connection to technologies other than 10BASE-T, 100BASE-TX, or 100BASE-T4 that do not incorporate Auto-Negotiation is not supported.

Implementation of the Auto-Negotiation function is optional. For CSMA/CD compatible devices that use the eight-pin modular connector of IEC 60603-7 and that also encompass multiple operational modes, if a signaling method is used to automatically configure the preferred mode of operation, then the Auto-Negotiation function shall be used in compliance with Clause 28. If the device uses 10BASE-T compatible link signaling to advertise non-CSMA/CD abilities, the device shall implement the Auto-Negotiation function as administered by this specification. All future CSMA/CD implementations that use an eight-pin modular connector shall be interoperable with devices supporting Clause 28. If the implementer of a non-CSMA/CD eight-pin modular device wishes to assure that its operation does not conflict with CSMA/CD devices, then adherence to Clause 28 is recommended.

While this Auto-Negotiation function has to be implemented in CSMA/CD compatible devices that utilize the eight-pin modular connector, encompass multiple operational modes, and offer an Auto-Negotiation mechanism, the use of this function does not mandate that the 10BASE-T packet data communication service has to exist. A device that employs this function has to support the 10BASE-T Link Integrity Test

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

function through the NLP Receive Link Integrity Test state diagram. The device may also need to support other technology-dependent link test functions depending on the modes supported. Auto-Negotiation does not perform cable tests, such as detect number of conductor pairs (if more than two pairs are required) or cable performance measurements. Some PHYs that explicitly require use of high-performance cables, may require knowledge of the cable type, or additional robustness tests (such as monitoring CRC or framing errors) to determine if the link segment is adequate.

28.1.4.1 Interoperability with existing 10BASE-T devices

During Auto-Negotiation, FLP Bursts separated by 16 ms ± 8 ms are transmitted. The FLP Burst itself is a series of pulses separated by 62.5 μs ± 7 μs. The timing of FLP Bursts will cause a 10BASE-T device that is in the LINK TEST PASS state to remain in the LINK TEST PASS state while receiving FLP Bursts. An Auto-Negotiation able device has to recognize the NLP sequence from a 10BASE-T Link Partner, cease transmission of FLP Bursts, and enable the 10BASE-T PMA, if present. If the NLP sequence is detected and if the Auto-Negotiation able device does not have a 10BASE-T PMA, it will cease transmission of FLP Bursts, forcing the 10BASE-T Link Partner into the LINK TEST FAIL state(s) as indicated in Figure 14–6.

NOTE—Auto-Negotiation does not support the transmission of the NLP sequence. The 10BASE-T PMA provides this function if it is connected to the MDI. In the case where an Auto-Negotiation able device without a 10BASE-T PMA is connected to a 10BASE-T device without Auto-Negotiation, the NLP sequence is not transmitted because the Auto-Negotiation function has no 10BASE-T PMA to enable that can transmit the NLP sequence.

28.1.4.2 Interoperability with Auto-Negotiation compatible devices

An Auto-Negotiation compatible device decodes the base link codeword from the FLP Burst, and examines the contents for the highest common ability that both devices share. Both devices acknowledge correct receipt of each other's base link codewords by responding with FLP Bursts containing the Acknowledge Bit set. After both devices complete acknowledgment, and optionally, Next Page exchange, both devices enable the highest common mode negotiated. The highest common mode is resolved using the priority resolution hierarchy specified in Annex 28B. It may subsequently be the responsibility of a technology-dependent link integrity test function to verify operation of the link prior to enabling the data service.

28.1.4.3 Cabling compatibility with Auto-Negotiation

Provision has been made within Auto-Negotiation to limit the resulting link configuration in situations where the cabling may not support the highest common capability of the two end points. The system administrator/installer has to take the cabling capability into consideration when configuring a repeater port's advertised capability. That is, the advertised capability of a hub port should not result in an operational mode that is not compatible with the cabling.

28.2 Functional specifications

The Auto-Negotiation function provides a mechanism to control connection of a single MDI to a single PMA type, where more than one PMA type may exist. Management may provide additional control of Auto-Negotiation through the Management function, but the presence of a management agent is not required.

The Auto-Negotiation function shall provide the Auto-Negotiation Transmit, Receive, and Arbitration functions and comply with the state diagrams of Figure 28–16 to Figure 28–19. The Auto-Negotiation function shall provide the NLP Receive Link Integrity Test function and comply with the state diagram of Figure 28–19 if the PHY supports 10BASE-T operation.The Auto-Negotiation functions shall interact with the technology-dependent PMAs through the Technology-Dependent Interface. Technology-dependent PMAs include, but are not limited to, 100BASE-TX and 100BASE-T4. Technology-dependent link integrity test functions shall be implemented and interfaced to only if the device supports the given technology. For example, a 10BASE-T and 100BASE-TX Auto-Negotiation able device has to implement and interface to

the 100BASE-TX PMA/link integrity test function, but does not need to include the 100BASE-T4 PMA/ Link Integrity Test function. The Auto-Negotiation function may include a management function that provides a control and status mechanism.

28.2.1 Transmit function requirements

The Transmit function provides the ability to transmit FLP Bursts. The first FLP Bursts exchanged by the local device and its Link Partner after Power-On, link restart, or renegotiation contain the base link codeword defined in 28.2.1.2. The local device may modify the link codeword to disable an ability it possesses, but will not transmit an ability it does not possess. This makes possible the distinction between local abilities and advertised abilities so that multimode devices may Auto-Negotiate to a mode lower in priority than the highest common local ability.

28.2.1.1 Link pulse transmission

Auto-Negotiation's method of communication builds upon the link pulse mechanism employed by 10BASE-T MAUs to detect the status of the link. Compliant 10BASE-T MAUs transmit link integrity test pulses as a mechanism to determine if the link segment is operational in the absence of packet data. The 10BASE-T NLP sequence is a pulse (Figure 14–13) transmitted every 16 ms ± 8 ms while the data transmitter is idle.

Auto-Negotiation substitutes the FLP Burst in place of the single 10BASE-T link integrity test pulse within the NLP sequence (Figure 28–3). The FLP Burst encodes the data that is used to control the Auto-Negotiation function. FLP Bursts shall not be transmitted when Auto-Negotiation is complete and the highest common denominator PMA has been enabled.

FLP Bursts were designed to allow use beyond initial link Auto-Negotiation, such as for a link monitor type function. However, use of FLP Bursts beyond the current definition for link startup shall be prohibited. Definition of the use of FLP Bursts while in the FLP LINK GOOD state is reserved.

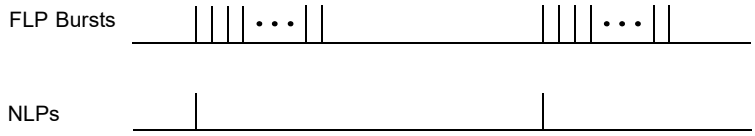

Figure 28–3—FLP Burst sequence to NLP sequence mapping

28.2.1.1.1 FLP burst encoding

All link test pulses in the FLP Burst sequence shall meet the template requirements of Figure 14–13 when measured across each of the test loads defined in Figure 14–12; both with the load connected directly to the TD circuit and with the load connected through all of the cable types and distances supported by the advertised capabilities. A Fast Link Pulse Burst consists of 33 pulse positions. The 17 odd-numbered pulse positions shall contain a link pulse and represent clock information. The 16 even-numbered pulse positions shall represent data information as follows: a link pulse present in an even-numbered pulse position represents a logic one, and a link pulse absent from an even-numbered pulse position represents a logic zero. Clock pulses are differentiated from data pulses by the spacing between pulses as shown in Figure 28–5 and

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

enumerated in Table 28–1. An extended FLP Burst contains 97 similarly defined pulse positions with 49 odd-numbered clock pulses and 48 even-numbered data pulses.

Table 28–1—FLP Burst timing summary

	Parameter	Min.	Typ.	Max.	Units
T1	Clock/Data Pulse Width (Figure 14–13)		100		ns
T2	Clock Pulse to Clock Pulse	111	125	139	μs
T3	Clock Pulse to Data Pulse (Data = 1)	55.5	62.5	69.5	μs
T4	Pulses in a Burst	17 for 16-bit 49 for 48-bit		33 for 16-bit 97 for 48-bit	—
T5	Burst Width		2 for 16-bit 6 for 48-bit		ms
T6	FLP Burst to FLP Burst	8	16	24	ms
T7	Optimized FLP Burst to FLP Burst	8		8.5	ms

The encoding of data using pulses in an FLP Burst is illustrated in Figure 28–4.

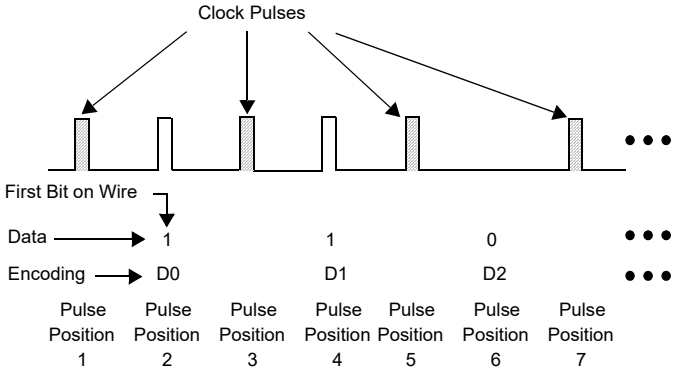

Figure 28–4—Data bit encoding within FLP Bursts

28.2.1.1.2 Transmit timing

The first pulse in an FLP Burst shall be defined as a clock pulse. Clock pulses within an FLP Burst shall be spaced at 125 μs ± 14 μs. If the data bit representation of logic one is to be transmitted, a pulse shall occur 62.5 μs ± 7 μs after the preceding clock pulse. If a data bit representing logic zero is to be transmitted, there shall be no link integrity test pulses within 111 μs of the preceding clock pulse.

The first link pulse in consecutive FLP Bursts shall occur at a 16 ms ± 8 ms interval when using non-optimized FLP Burst to FLP Burst timing, see parameter T6 (Figure 28–6). Devices supporting Extended Next Pages shall use optimized FLP Burst to FLP Burst timing. The first link pulse in consecutive FLP Bursts shall occur at a 8.25 ms ± 0.25 ms interval when using optimized FLP Burst to FLP Burst timing, see parameter T7 (Figure 28–6). Optimized FLP Burst to FLP Burst limits are intended to reduce negotiation time.

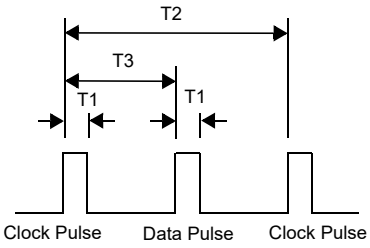

Figure 28–5—FLP Burst pulse-to-pulse timing

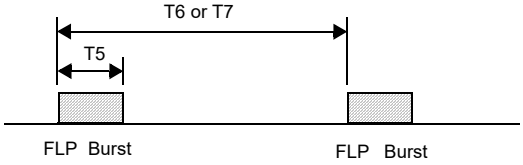

Figure 28–6—FLP Burst to FLP Burst timing

28.2.1.2 Link codeword encoding

The base link codeword (Base Page) transmitted within an FLP Burst shall convey the encoding shown in Figure 28–7. The Auto-Negotiation function may support additional pages using the Next Page function. Encodings for the link codeword(s) used in Next Page exchange are defined in 28.2.3.4. In an FLP Burst, D0 shall be the first bit transmitted.

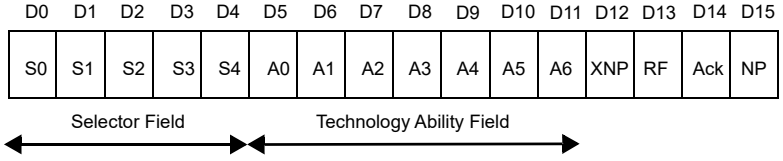

Figure 28–7—Base Page encoding

28.2.1.2.1 Selector Field

Selector Field (S[4:0]) is a five bit wide field, encoding 32 possible messages. Selector Field encoding definitions are shown in Annex 28A. Combinations not specified are reserved for future use. Reserved combinations of the Selector Field shall not be transmitted.

28.2.1.2.2 Technology Ability Field

Technology Ability Field (A[6:0]) is a seven-bit wide field containing information indicating supported technologies specific to the selector field value. These bits are mapped to individual technologies such that abilities are advertised in parallel for a single selector field value. The Technology Ability Field encoding for the IEEE 802.3 selector is described in Annex 28B.2 and in Annex 28D. Multiple technologies may be advertised in the link codeword. A device shall support the data service ability for a technology it advertises.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

It is the responsibility of the Arbitration function to determine the common mode of operation shared by a Link Partner and to resolve multiple common modes.

NOTE—While devices using a Selector Field value other than the IEEE 802.3 Selector Field value are free to define the Technology Ability Field bits, it is recommended that the 10BASE-T bit be encoded in the same bit position as in the IEEE 802.3 selector. A common bit position can be important if the technology using the other selector will ever coexist on a device that also offers a 10BASE-T mode.

28.2.1.2.3 Extended Next Page

Extended Next Page (XNP) is encoded in bit D12 of the base link codeword. The Extended Next Page bit indicates that the local device supports transmission of Extended Next Pages when set to a logic one, and indicates that the local device does not support Extended Next Pages when set to a logic zero. The use of Extended Next Page is orthogonal to the negotiated data rate, medium, or link technology. The Extended Next Page bit is used in accordance with the Extended Next Page function specifications in 28.2.3.4.

When the selector field value is the IEEE Std 802.5v-2001 (withdrawn) value or the IEEE Std 802.9a-1995 (withdrawn) value the Extended Next Page function is not supported and bit D12 is defined as being an additional Technology Ability Field bit A7, extending the Technology Ability Field to be an eight bit wide field (A[7:0]).

28.2.1.2.4 Remote Fault

Remote Fault (RF) is encoded in bit D13 of the base link codeword. The default value is logic zero. The Remote Fault bit provides a standard transport mechanism for the transmission of simple fault information. When the RF bit in the Auto-Negotiation advertisement register (register 4) is set to logic one, the RF bit in the transmitted base link codeword is set to logic one. When the RF bit in the received base link codeword is set to logic one, the Remote Fault bit in the MII status register (register 1) will be set to logic one, if the MII management function is present.

The Remote Fault bit shall be used in accordance with the Remote Fault function specifications (28.2.3.5).

28.2.1.2.5 Acknowledge

Acknowledge (Ack) is used by the Auto-Negotiation function to indicate that a device has successfully received its Link Partner’s link codeword. The Acknowledge Bit is encoded in bit D14 regardless of the value of the Selector Field or link codeword encoding. If no Next Page information is to be sent, this bit shall be set to logic one in the link codeword after the reception of at least three consecutive and consistent FLP Bursts (ignoring the Acknowledge bit value). If Next Page information is to be sent, this bit shall be set to logic one after the device has successfully received at least three consecutive and matching FLP Bursts (ignoring the Acknowledge bit value), and will remain set until the Next Page information has been loaded into the Auto-Negotiation Next Page transmit register (register 7). In order to save the current received link codeword, it has to be read from the Auto-Negotiation Link Partner ability register (register 6) before the Next Page of transmit information is loaded into the Auto-Negotiation Next Page transmit register. After the COMPLETE ACKNOWLEDGE state has been entered, the link codeword shall be transmitted six to eight (inclusive) times.

28.2.1.2.6 Next Page

Next Page (NP) is encoded in bit D15 regardless of the Selector Field value or link codeword encoding. Support for transmission and reception of additional link codeword encodings is optional. If Next Page ability is not supported, the NP bit shall always be set to logic zero. If a device implements Next Page ability and wishes to engage in Next Page exchange, it shall set the NP bit to logic one. A device may implement Next Page ability and choose not to engage in Next Page exchange by setting the NP bit to a logic zero. The Next Page function is defined in 28.2.3.4.

28.2.1.3 Transmit Switch function

The Transmit Switch function shall enable the transmit path from a single technology-dependent PMA to the MDI once a highest common denominator choice has been made and Auto-Negotiation has completed.

During Auto-Negotiation, the Transmit Switch function shall connect only the FLP Burst generator controlled by the Transmit State Diagram, Figure 28–16, to the MDI.

When a PMA is connected to the MDI through the Transmit Switch function, the signals at the MDI shall conform to all of the PHY's specifications.

28.2.2 Receive function requirements

The Receive function detects the NLP sequence using the NLP Receive Link Integrity Test function of Figure 28–19. The NLP Receive Link Integrity Test function will not detect link pass based on carrier sense.

The Receive function detects the FLP Burst sequence, decodes the information contained within, and stores the data in rx_link_code_word[16:1]. The Receive function incorporates a receive switch to control connection to the 100BASE-TX or 100BASE-T4 PMAs in addition to the NLP Receive Link Integrity Test function, excluding the 10BASE-T Link Integrity Test function present in a 10BASE-T PMA. If Auto-Negotiation detects link_status=READY from any of the technology-dependent PMAs prior to FLP Burst detection, the autoneg_wait_timer (28.3.2) is started. If any other technology-dependent PMA indicates link_status=READY when the autoneg_wait_timer expires, Auto-Negotiation will not allow any data service to be enabled and may signal this as a remote fault to the Link Partner using the Base Page and will flag this in the Local Device by setting the Parallel Detection Fault bit (6.4) in the Auto-Negotiation expansion register. If a 10BASE-T PMA exists above the Auto-Negotiation function, it is not permitted to receive MDI activity in parallel with the NLP Receive Link Integrity Test function or any other technology-dependent function.

28.2.2.1 FLP Burst ability detection and decoding

In Figure 28–8 to Figure 28–10, the symbol "t_0=0" indicates the event that caused the timers described to start, and all subsequent times given are referenced from that point. All timers referenced shall expire within the range specified in Table 28–9 in 28.3.2.

The Receive function shall identify the Link Partner as Auto-Negotiation able if it receives 6 to 17 (inclusive) consecutive link pulses that are separated by at least flp_test_min_timer time (5 µs to 25 µs) but less than flp_test_max_timer time (165 µs to 185 µs) as shown in Figure 28–8. The information contained in the FLP Burst that identifies the Link Partner as Auto-Negotiation able shall not be passed to the Arbitration function if the FLP Burst is not complete. The Receive function may use the FLP Burst that identifies the Link Partner as Auto-Negotiation able for ability matching if the FLP Burst is complete. However, it is not required to use this FLP Burst for any purpose other than identification of the Link Partner as Auto-Negotiation able. Implementations may ignore multiple FLP Bursts before identifying the Link Partner as Auto-Negotiation able to allow for potential receive equalization time.

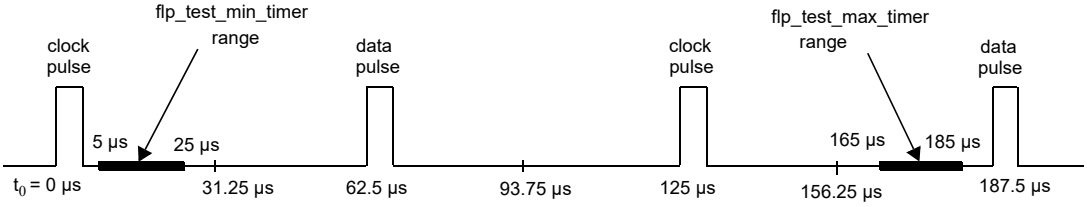

Figure 28–8—FLP detect timers (flp_test_min/max_timers)

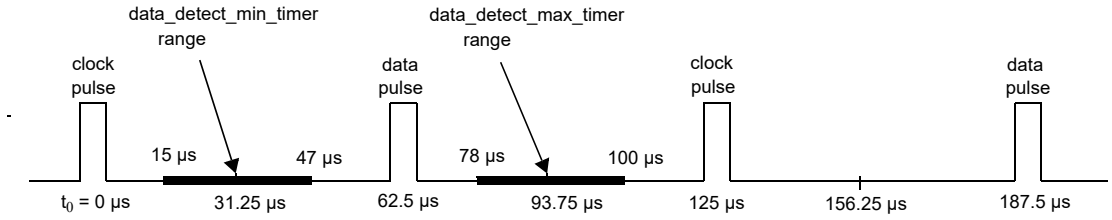
Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Receive function captures and decodes link pulses received in FLP Bursts. The first link pulse in an FLP Burst shall be interpreted as a clock link pulse. Detection of a clock link pulse shall restart the data_detect_min_timer and data_detect_max timer. The data_detect_min/max_timers enable the receiver to distinguish data pulses from clock pulses and logic one data from logic zero data, as follows:

a) If, during an FLP Burst, a link pulse is received when the data_detect_min_timer has expired while the data_detect_max_timer has not expired, the data bit shall be interpreted as a logic one (Figure 28–9).
b) If, during an FLP Burst, a link pulse is received after the data_detect_max_timer has expired, the data bit shall be interpreted as a logic zero (Figure 28–9) and that link pulse shall be interpreted as a clock link pulse.

As each data bit is identified it is stored in the appropriate rx_link_code_word[16:1] element.



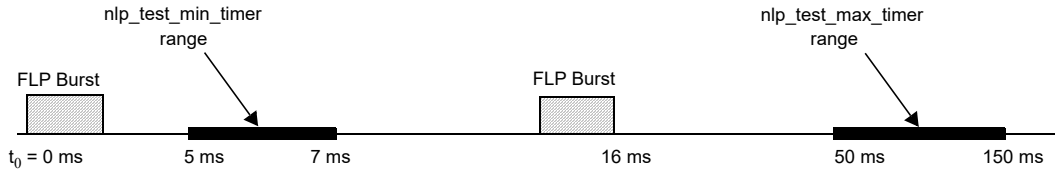


Figure 28–9—FLP data detect timers (data_detect_min/max_timers)

FLP Bursts conforming to the nlp_test_min_timer and nlp_test_max_timer timing as shown in Figure 28–10 shall be considered to have valid separation. The nlp_test_min_timer range for devices that do not support Extended Next Pages is shown in Figure 28–10. The range of nlp_test_min_timer for devices that support Extended Next Pages is specified in 28.3.2.

NOTE—The reference for the starting of the nlp_test_min_timer is from the beginning of the FLP Burst, as shown by t_0, while the reference for the starting of the nlp_test_max_timer is from the expiration of the nlp_test_min_timer.

Figure 28–10—FLP Burst timer (nlp_test_min/max_timers)

28.2.2.2 NLP detection

NLP detection is accomplished via the NLP Receive Link Integrity Test function in Figure 28–19. The NLP Receive Link Integrity Test function is a modification of the original 10BASE-T Link Integrity Test function (Figure 14–6), where the detection of receive activity will not cause a transition to the LINK TEST PASS state during Auto-Negotiation. The NLP Receive Link Integrity Test function also incorporates the Technology-Dependent Interface requirements.

28.2.2.3 Receive Switch function

The Receive Switch function shall enable the receive path from the MDI to a single technology-dependent PMA once a highest common denominator choice has been made and Auto-Negotiation has completed.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

During Auto-Negotiation, the Receive Switch function shall connect both the FLP Burst receiver controlled by the Receive state diagram, Figure 28–17, and the NLP Receive Link Integrity Test state diagram, Figure 28–19, to the MDI. During Auto-Negotiation, the Receive Switch function shall also connect the 100BASE-TX and 100BASE-T4 PMA receivers to the MDI if the 100BASE-TX and/or 100BASE-T4 PMAs are present.

When a PMA is connected to the MDI through the Receive Switch function, the signals at the PMA shall conform to all of the PHY's specifications.

28.2.2.4 Link codeword matching

The Receive function shall generate ability_match, acknowledge_match, and consistency_match variables as defined in 28.3.1.

28.2.3 Arbitration function requirements

The Arbitration function ensures proper sequencing of the Auto-Negotiation function using the Transmit function and Receive function. The Arbitration function enables the Transmit function to advertise and acknowledge abilities. Upon indication of acknowledgment, the Arbitration function determines the highest common denominator using the priority resolution function and enables the appropriate technology-dependent PMA via the Technology-Dependent Interface (28.2.6).

28.2.3.1 Parallel detection function

The Local Device detects a Link Partner that supports Auto-Negotiation by FLP Burst detection. The Parallel Detection function allows detection of Link Partners that support 100BASE-TX, 100BASE-T4, and/or 10BASE-T, but do not support Auto-Negotiation. Prior to detection of FLP Bursts, the Receive Switch shall direct MDI receive activity to the NLP Receive Link Integrity Test state diagram, 100BASE-TX and 100BASE-T4 PMAs, if present, but shall not direct MDI receive activity to the 10BASE-T or any other PMA. If at least one of the 100BASE-TX, 100BASE-T4, or NLP Receive Link Integrity Test functions establishes link_status=READY, the LINK STATUS CHECK state is entered and the autoneg_wait_timer is started. If exactly one link_status=READY indication is present when the autoneg_wait_timer expires, then Auto-Negotiation shall set link_control=ENABLE for the PMA indicating link_status=READY. If a PMA is enabled, the Arbitration function shall set link_control=DISABLE to all other PMAs and indicate that Auto-Negotiation has completed. On transition to the FLP LINK GOOD CHECK state from the LINK STATUS CHECK state the Parallel Detection function shall set the bit in the Link Partner ability register (register 5) corresponding to the technology detected by the Parallel Detection function.

NOTE 1—Native 10BASE-T devices will be detected by the NLP Receive Link Integrity Test function, an integrated part of the Auto-Negotiation function. Hence, Parallel Detection for the 10BASE-T PMA is not required or allowed.

NOTE 2—When selecting the highest common denominator through the Parallel Detection function, only the half-duplex mode corresponding to the selected PMA may automatically be detected.

28.2.3.2 Renegotiation function

A renegotiation request from any entity, such as a management agent, shall cause the Arbitration function to disable all technology-dependent PMAs and halt any transmit data and link pulse activity until the break_link_timer expires (28.3.2). Consequently, the Link Partner will go into link fail and normal Auto-Negotiation resumes. The Local Device shall resume Auto-Negotiation after the break_link_timer has expired by issuing FLP Bursts with the Base Page valid in tx_link_code_word[16:1].

Once Auto-Negotiation has completed, renegotiation will take place if the Highest Common Denominator technology that receives link_control=ENABLE returns link_status=FAIL. To allow the PMA an

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

opportunity to determine link integrity using its own link integrity test function, the link_fail_inhibit_timer qualifies the link_status=FAIL indication such that renegotiation takes place if the link_fail_inhibit_timer has expired and the PMA still indicates link_status=FAIL or link_status=READY.

28.2.3.3 Priority Resolution function

Since a Local Device and a Link Partner may have multiple common abilities, a mechanism to resolve which mode to configure is required. The mechanism used by Auto-Negotiation is a Priority Resolution function that predefines the hierarchy of supported technologies. The single PMA enabled to connect to the MDI by Auto-Negotiation shall be the technology corresponding to the bit in the Technology Ability Field common to the Local Device and Link Partner that has the highest priority as defined in Annex 28B. This technology is referred to as the Highest Common Denominator, or HCD, technology. If the Local Device receives a Technology Ability Field with a bit set that is reserved, the Local Device shall ignore that bit for priority resolution. Determination of the HCD technology occurs on entrance to the FLP LINK GOOD CHECK state. In the event that a technology is chosen through the Parallel Detection function, that technology shall be considered the highest common denominator (HCD) technology. In the event that there is no common technology, HCD shall have a value of "NULL," indicating that no PMA receives link_control=ENABLE, and link_status_[HCD]=FAIL.

28.2.3.4 Next Page function

The Next Page function uses the standard Auto-Negotiation arbitration mechanisms to allow exchange of arbitrary pieces of data. Data is carried by optional Next Pages of information, which follow the transmission and acknowledgment procedures used for the base link codeword. Four types of Next Page encodings are defined: Message Pages, Unformatted Pages, extended Message Pages, and extended Unformatted Pages.

A dual acknowledgment system is used. Acknowledge (Ack) is used to acknowledge receipt of the information; Acknowledge 2 (Ack2) is used to indicate that the receiver is able to act on the information (or perform the task) defined in the message.

Next Page operation is controlled by the same three mandatory control bits, Next Page, Extended Next Page, and Acknowledge, used in the base link codeword. Setting the NP bit in the base link codeword to logic one indicates that the device is Next Page able. Setting the Extended Next Page bit in the Base Page link codeword to logic one indicates that the device is Extended Next Page able. If both a device and its Link Partner are Next Page able, then Next Page exchange may occur. If both a device and its Link Partner are Extended Next Page able, then any Next Page exchange that occurs shall use the Extended Next Page encoding. If one or both devices are not Next Page able, then Next Page exchange will not occur and, after the base link codewords have been exchanged, the FLP LINK GOOD CHECK state will be entered. The Toggle bit is used to ensure proper synchronization between the Local Device and the Link Partner.

Next Page exchange occurs after the base link codewords have been exchanged. Next Page exchange consists of using the normal Auto-Negotiation arbitration process to send Next Page messages. Four message encodings are defined: Message Pages, Unformatted Pages, extended Message Pages, and extended Unformatted Pages. Unformatted Pages can be combined to send extended messages. If the Selector Field values do not match, then each series of Unformatted Pages shall be preceded by a Message Page containing a message code that defines how the following Unformatted Pages will be interpreted. If the Selector Field values match, then the convention governing the use of Message Pages shall be as defined by the Selector Field value definition. Any number of Next Pages may be sent in any order; however, it is recommended that the total number of Next Pages sent be kept small to minimize the link startup time.

Next Page transmission ends when both ends of a link segment set their Next Page bits to logic zero, indicating that neither has anything additional to transmit. It is possible for one device to have more pages to transmit than the other device. Once a device has completed transmission of its Next Page information, it

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

shall transmit Message Pages, or extended Message Pages, with Null message codes and the NP bit set to logic zero while its Link Partner continues to transmit valid Next Pages. An Auto-Negotiation able device shall recognize reception of Message Pages, or extended Message Pages, with Null message codes as the end of its Link Partner's Next Page information.

28.2.3.4.1 Next Page encodings

The Next Page shall use the encoding shown in Figure 28–11 and Figure 28–12 for the NP, Ack, MP, Ack2, and T bits. The 11-bit field D10–D0 shall be encoded as a Message Code Field if the MP bit is logic one and an Unformatted Code Field if MP is set to logic zero.

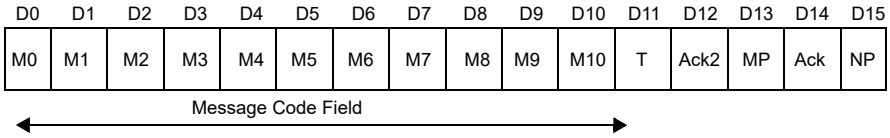

Figure 28–11—Message Page encoding

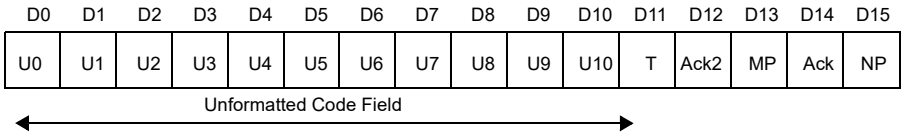

Figure 28–12—Unformatted Page encoding

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.2.3.4.2 Extended Next Page encodings

Extended Next Pages shall use the encoding shown in Figure 28–13 and Figure 28–14 for the NP, Ack, MP, Ack2, and T bits. The 11-bit field D10:D0 shall be encoded as a Message Code Field if the MP is a logic one and an Unformatted Code Field if the MP bit is set to logic zero.

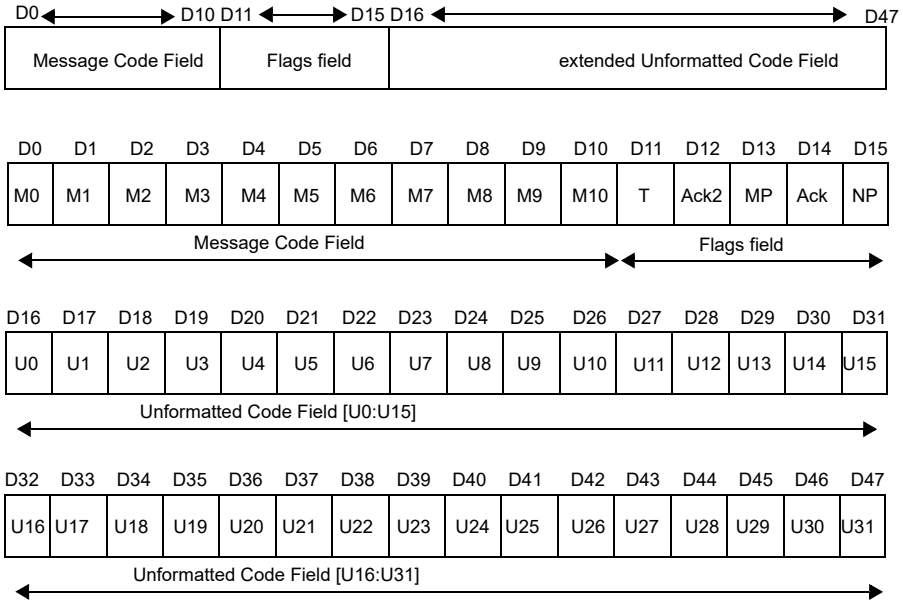

Figure 28–13—Extended Message Page encoding

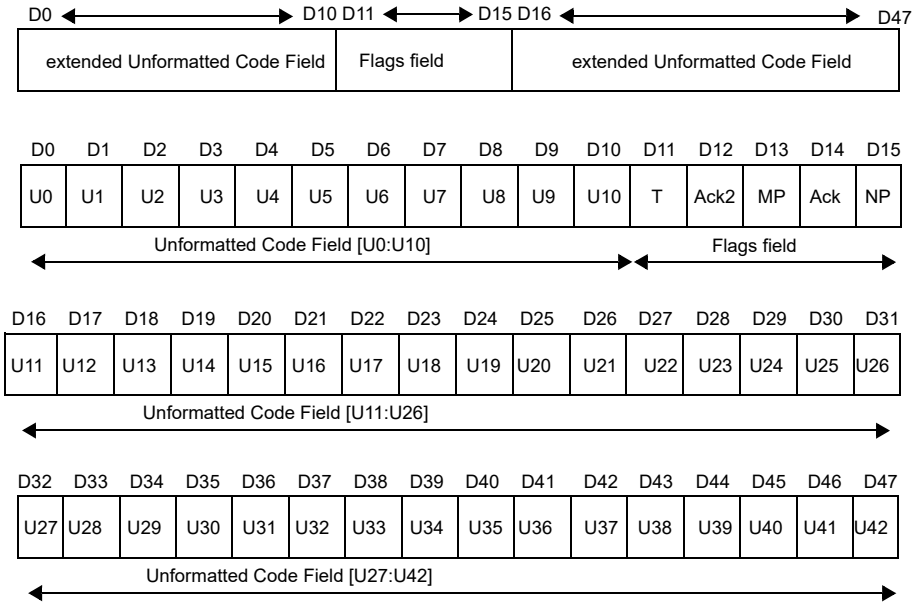

Figure 28–14—Extended Unformatted Page encoding

28.2.3.4.3 Next Page

Next Page (NP) is used by the Next Page function to indicate whether or not this is the last Next Page to be transmitted. NP shall be set as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

logic zero = last page.
logic one = additional Next Page(s) will follow.

28.2.3.4.4 Acknowledge

As defined in 28.2.1.2.5.

28.2.3.4.5 Message Page

Message Page (MP) is used by the Next Page function to differentiate a Message Page from an Unformatted Page. MP shall be set as follows:

logic zero = Unformatted Page.
logic one = Message Page.

28.2.3.4.6 Acknowledge 2

Acknowledge 2 (Ack2) is used by the Next Page function to indicate that a device has the ability to comply with the message. Ack2 shall be set as follows:

logic zero = cannot comply with message.
logic one = will comply with message.

28.2.3.4.7 Toggle

Toggle (T) is used by the Arbitration function to ensure synchronization with the Link Partner during Next Page exchange. This bit shall always take the opposite value of the Toggle bit in the previously exchanged link codeword. The initial value of the Toggle bit in the first Next Page transmitted is the inverse of bit D11 in the base link codeword and, therefore, may assume a value of logic one or zero. The Toggle bit shall be set as follows:

logic zero = previous value of the transmitted link codeword equaled logic one.
logic one = previous value of the transmitted link codeword equaled logic zero.

28.2.3.4.8 Message Page encoding

Message Pages are formatted pages that carry a single predefined message code, which is enumerated in Annex 28C. Two-thousand and forty-eight message codes are available. The allocation of these codes will be controlled by the contents of Annex 28C. If the Message Page bit is set to logic one, then the bit encoding of the link codeword shall be interpreted as a Message Page.

28.2.3.4.9 Message Code Field

Message Code Field (M[10:0]) is an eleven bit wide field, encoding 2048 possible messages. Message Code Field definitions are shown in Annex 28C. Combinations not specified are reserved for future use. Reserved combinations of the Message Code Field shall not be transmitted.

28.2.3.4.10 Unformatted Page encoding

Unformatted Pages carry the messages indicated by Message Pages. Five control bits are predefined, the remaining 11 bits may take on an arbitrary value. If the Message Page bit is set to logic zero, then the bit encoding of the link codeword shall be interpreted as an Unformatted Page.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.2.3.4.11 Unformatted Code Field

Unformatted Code Field (U[10:0]) is an eleven bit wide field, which may contain an arbitrary value.

28.2.3.4.12 Extended Unformatted Code Field

The extended Unformatted Code Field is a 32-bit or 43-bit wide field, which may contain an arbitrary value. The field is 32 bits wide in an extended Message Page and 43 bits wide in an extended Unformatted Page.

28.2.3.4.13 Use of Next Pages

a) Both devices have to indicate Next Page ability for either to commence exchange of Next Pages.
b) Both devices have to indicate Extended Next Page ability for either to commence exchange of Extended Next Pages.
c) If both devices are Next Page able, then both devices shall send at least one Next Page.
d) If both devices are Extended Next Page able, then both devices only transmit Extended Next Pages.
e) Next Page exchange shall continue until neither device on a link has more pages to transmit as indicated by the NP bit. A Message Page with a Null Message Code Field value shall be sent if the device has no other information to transmit.
f) A message code can carry either a specific message or information that defines how following Unformatted Page(s) should be interpreted.
g) If a message code references Unformatted Pages, the Unformatted Pages shall immediately follow the referencing message code in the order specified by the message code.
h) Unformatted Page users are responsible for controlling the format and sequencing for their Unformatted Pages.
i) An Extended Next Page provides a message code and extended Unformatted Code Field. The Message Code Field can carry either a specific message or information that defines how the following extended Unformatted Code Field should be interpreted.

28.2.3.4.14 MII register requirements

The Next Page Transmit register defined in 28.2.4.1.6 shall hold the Next Page to be sent by Auto-Negotiation. Received Next Pages may be stored in the Auto-Negotiation Link Partner ability register.

28.2.3.5 Remote fault sensing function

The Remote Fault function may indicate to the Link Partner that a fault condition has occurred using the Remote Fault bit and, optionally, the Next Page function.

Sensing of faults in a device as well as subsequent association of faults with the Remote Fault bit shall be optional. If the Local Device has no mechanism to detect a fault or associate a fault condition with the received Remote Fault bit indication, then it shall transmit the Remote Fault bit with the value contained in the Auto-Negotiation advertisement register bit (4.13).

A Local Device may indicate it has sensed a fault to its Link Partner by setting the Remote Fault bit in the Auto-Negotiation advertisement register and renegotiating.

If the Local Device sets the Remote Fault bit to logic one, it may also use the Next Page function to specify information about the fault that has occurred. Remote Fault Message Page Codes have been specified for this purpose.

The Remote Fault bit shall remain set until after successful negotiation with the base link codeword, at which time the Remote Fault bit shall be reset to a logic zero. On receipt of a base link codeword with the

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Remote Fault bit set to logic one, the device shall set the Remote Fault bit in the MII status register (1.4) to logic one if the MII management function is present.

28.2.4 Management function requirements

The management interface is used to communicate Auto-Negotiation information to the management entity. If an MII is physically implemented, then management access is via the MII Management interface. Where no physical embodiment of the MII exists, an equivalent to MII registers 0, 1, 4, 5, 6, and 7 (Clause 22) are recommended to be provided.

28.2.4.1 Media Independent Interface

The Auto-Negotiation function shall have five dedicated registers:

a) MII control register (register 0).
b) MII status register (register 1).
c) Auto-Negotiation advertisement register (register 4).
d) Auto-Negotiation Link Partner ability register (register 5).
e) Auto-Negotiation expansion register (register 6).

If the Next Page function is implemented, the Auto-Negotiation Next Page transmit register (register 7) shall be implemented.

28.2.4.1.1 MII control register

MII control register (register 0) provides the mechanism to disable/enable and/or restart Auto-Negotiation. The definition for this register is provided in 22.2.4.1.

The Auto-Negotiation function shall be enabled by setting bit 0.12 to a logic one. If bit 0.12 is set to a logic one, then bits 0.13 and 0.8 shall have no effect on the link configuration, and the Auto-Negotiation process will determine the link configuration. If bit 0.12 is cleared to logic zero, then bits 0.13 and 0.8 will determine the link configuration regardless of the prior state of the link configuration and the Auto-Negotiation process.

A PHY shall return a value of one in bit 0.9 until the Auto-Negotiation process has been initiated. The Auto-Negotiation process shall be initiated by setting bit 0.9 to a logic one. If Auto-Negotiation was completed prior to this bit being set, the process shall be reinitiated. If a PHY reports via bit 1.3 that it lacks the ability to perform Auto-Negotiation, then this bit will have no meaning, and should be written as zero. This bit is self-clearing. The Auto-Negotiation process shall not be affected by clearing this bit to logic zero.

28.2.4.1.2 MII status register

The MII status register (register 1) includes information about all modes of operations supported by the Local Device's PHY, the status of Auto-Negotiation, and whether the Auto-Negotiation function is supported by the PHY or not. The definition for this register is provided in 22.2.4.2.

When read as a logic one, bit 1.5 indicates that the Auto-Negotiation process has been completed, and that the contents of registers 4, 5, and 6 are valid. When read as a logic zero, bit 1.5 indicates that the Auto-Negotiation process has not been completed, and that the contents of registers 4, 5, and 6 are meaningless. A PHY shall return a value of zero in bit 1.5 if Auto-Negotiation is disabled by clearing bit 0.12. A PHY shall also return a value of zero in bit 1.5 if it lacks the ability to perform Auto-Negotiation.

When read as logic one, bit 1.4 indicates that a remote fault condition has been detected. The type of fault as well as the criteria and method of fault detection is PHY specific. The Remote Fault bit shall be

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

implemented with a latching function, such that the occurrence of a remote fault will cause the Remote Fault bit to become set and remain set until it is cleared. The Remote Fault bit shall be cleared each time register 1 is read via the management interface, and shall also be cleared by a PHY reset.

When read as a one, bit 1.3 indicates that the PHY has the ability to perform Auto-Negotiation. When read as a logic zero, bit 1.3 indicates that the PHY lacks the ability to perform Auto-Negotiation.

28.2.4.1.3 Auto-Negotiation advertisement register (Register 4) (R/W)

This register contains the Advertised Ability of the PHY. (See Table 28–2). The bit definition for the Base Page is defined in 28.2.1.2. On power-up, before Auto-Negotiation starts, this register shall have the following configuration: The Selector Field (4.4:0) is set to an appropriate code as specified in Annex 28A. The Acknowledge bit (4.14) is set to logic zero. The Technology Ability Field (4.11:5) is set based on the values set in the MII status register (register 1) (1.15:11) or equivalent. See also 28.2.1.2.3 and Annex 28D.

Table 28–2—Advertisement register bit definitions

Bit(s)	Name	Description	R/W[a]
4.15	Next Page	See 28.2.1.2	R/W
4.14	Reserved	Write as zero, ignore on read	RO
4.13	Remote Fault	See 28.2.1.2	R/W
4.12	Extended Next Page	See 28.2.1.2	R/W
4.11:5	Technology Ability Field	See 28.2.1.2	R/W
4.4:0	Selector Field	See 28.2.1.2	R/W

[a]RO = Read only, R/W = Read/Write.

Only the bits in the Technology Ability Field that represent the technologies supported by the Local Device may be set. Any of the Technology Ability Field bits that may be set can also be cleared by management before a renegotiation. This can be used to enable management to Auto-Negotiate to an alternate common mode.

The management entity may initiate renegotiation with the Link Partner using alternate abilities by setting the Selector Field (4.4:0) and Technology Ability Field (4.11:5) to indicate the preferred mode of operation and setting the Restart Auto-Negotiation bit (0.9) in the control register (register 0) to logic one.

Any writes to this register prior to completion of Auto-Negotiation as indicated by bit 1.5 should be followed by a renegotiation for the new values to be properly used for Auto-Negotiation. Once Auto-Negotiation has completed, this register value may be examined by software to determine the highest common denominator technology.

28.2.4.1.4 Auto-Negotiation Link Partner ability register (Register 5) (RO)

All of the bits in the Auto-Negotiation Link Partner ability register are read only. A write to the Auto-Negotiation Link Partner ability register shall have no effect.

This register contains the Advertised Ability of the Link Partner's PHY. (See Tables 28–3 and 28–4.) The bit definitions shall be a direct representation of the received link codeword (Figure 28–7). Upon successful completion of Auto-Negotiation, status register (register 1) Auto-Negotiation Complete bit (1.5) shall be set

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to logic one. If the Next Page function is supported and bit (6.6) in the Auto-Negotiation expansion register (register 6) is set to logic zero, then the Auto-Negotiation Link Partner ability register may be used to store Link Partner Next Pages. If bit (6.6) in the Auto-Negotiation expansion register (register 6) is set to logic one, then bit (6.5) determines where the Link Partner Next Pages are stored.

Table 28–3—Link partner ability register bit definitions (Base Page)

Bit(s)	Name	Description	R/W[a]
5.15	Next Page	See 28.2.1.2	RO
5.14	Acknowledge	See 28.2.1.2	RO
5.13	Remote Fault	See 28.2.1.2	RO
5.12	Extended Next Page	See 28.2.1.2	RO
5.11:5	Technology Ability Field	See 28.2.1.2	RO
5.4:0	Selector Field	See 28.2.1.2	RO

[a]RO = Read only.

Table 28–4—Link partner ability register bit definitions (Next Page)

Bit(s)	Name	Description	R/W[a]
5.15	Next Page	See 28.2.3.4	RO
5.14	Acknowledge	See 28.2.3.4	RO
5.13	Message Page	See 28.2.3.4	RO
5.12	Acknowledge 2	See 28.2.3.4	RO
5.11	Toggle	See 28.2.3.4	RO
5.10:0	Message/Unformatted Code Field	See 28.2.3.4	RO

[a]RO = Read only.

The values contained in this register are only guaranteed to be valid once Auto-Negotiation has successfully completed, as indicated by bit 1.5 or, if used with Next Page exchange, after the Page Received bit (6.1) has been set to logic one.

NOTE—If this register is used to store Link Partner Next Pages, the previous value of this register is assumed to be stored by a management entity that needs the information overwritten by subsequent Link Partner Next Pages.

28.2.4.1.5 Auto-Negotiation expansion register (Register 6) (RO)

All of the bits in the Auto-Negotiation expansion register are read only; a write to the Auto-Negotiation expansion register shall have no effect. (See Table 28–5.)

Bits 6.15:7 are reserved for future Auto-Negotiation expansion.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 28–5—Expansion register bit definitions

Bit(s)	Name	Description	R/W[a]	Default
6.15:7	Reserved	Write as zero, ignore on read	RO	0
6.6	Receive Next Page Location Able	1 = Received Next Page storage location is specified by bit (6.5) 0 = Received Next Page storage location is not specified by bit (6.5)	RO	—
6.5	Received Next Page Storage Location	1 = Link Partner Next Pages are stored in register 8 0 = Link Partner Next Pages are stored in register 5	RO	—
6.4	Parallel Detection Fault	1 = A fault has been detected via the Parallel Detection function. 0 = A fault has not been detected via the Parallel Detection function.	RO/ LH	0
6.3	Link Partner Next Page Able	1 = Link Partner is Next Page able 0 = Link Partner is not Next Page able	RO	0
6.2	Next Page Able	1 = Local Device is Next Page able 0 = Local Device is not Next Page able	RO	0
6.1	Page Received	1 = A New Page has been received 0 = A New Page has not been received	RO/ LH	0
6.0	Link Partner Auto-Negotiation Able	1 = Link Partner is Auto-Negotiation able 0 = Link Partner is not Auto-Negotiation able	RO	0

[a]RO = Read only, LH = Latching high.

The Receive Next Page Location Able bit (6.6) shall be set to logic one to indicate that the Link Partner Next Page Storage Location bit (6.5) is supported.

The Receive Next Page Storage Location bit (6.5) shall be set to logic one to indicate that the Link Partner's Next Pages are stored in the Auto-Negotiation Link Partner Received Next Page register (register 8). This bit shall be set to logic zero to indicate that the Link Partner’s Next Pages are stored in the Auto-Negotiation Link Partner ability register (register 5). It is recommended that all new implementations store the Link Partner’s Next Pages in the Auto-Negotiation Link Partner Received Next Page ability register (register 8).

NOTE— It is highly recommended that the Link Partner Next Page Storage Location bit (6.5) is supported. If this bit is not supported there is no indication if the Link Partners Next Page is stored in register 5 or register 8.

The Parallel Detection Fault bit (6.4) shall be set to logic one to indicate that zero or more than one of the NLP Receive Link Integrity Test function, 100BASE-TX, or 100BASE-T4 PMAs have indicated link_status=READY when the autoneg_wait_timer expires. The Parallel Detection Fault bit shall be reset to logic zero on a read of the Auto-Negotiation expansion register (register 6).

The Link Partner Next Page Able bit (6.3) shall be set to logic one to indicate that the Link Partner supports the Next Page function. This bit shall be reset to logic zero to indicate that the Link Partner does not support the Next Page function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Next Page Able bit (6.2) shall be set to logic one to indicate that the Local Device supports the Next Page function. The Next Page Able bit (6.2) shall be set to logic zero if the Next Page function is not supported.

The Page Received bit (6.1) shall be set to logic one to indicate that a new link codeword has been received and stored in the Auto-Negotiation Link Partner ability register. The Page Received bit shall be reset to logic zero on a read of the Auto-Negotiation expansion register (register 6).

The Link Partner Auto-Negotiation Able bit (6.0) shall be set to logic one to indicate that the Link Partner is able to participate in the Auto-Negotiation function. This bit shall be reset to logic zero if the Link Partner is not Auto-Negotiation able.

28.2.4.1.6 Auto-Negotiation Next Page transmit register (Register 7) (R/W)

The Auto-Negotiation Next Page Transmit register contains the Next Page link codeword to be transmitted when Next Page ability is supported. (See Table 28–6.) The contents are defined in 28.2.3.4. On power-up, this register shall contain the default value of 2001H, which represents a Message Page with the message code set to Null Message. This value may be replaced by any valid Next Page message code that the device wishes to transmit. Writing to this register shall set mr_next_page_loaded to true.

Table 28–6—Next Page transmit register bit definitions

Bit(s)	Name	Description	R/W[a]
7.15	Next Page	See 28.2.3.4	R/W
7.14	Reserved	Write as 0, ignore on read	RO
7.13	Message Page	See 28.2.3.4	R/W
7.12	Acknowledge 2	See 28.2.3.4	R/W
7.11	Toggle	See 28.2.3.4	RO
7.10:0	Message/Unformatted Code field	See 28.2.3.4	R/W

[a]RO = Read only, R/W = Read/Write.

28.2.4.1.7 Auto-Negotiation Link Partner Received Next Page register (Register 8) (RO)

Support for 100BASE-T2 and 1000BASE-T requires support for Next Page and the provision of an Auto-Negotiation Link Partner Received Next Page register (register 8) to store Link Partner Next Pages as shown in Table 28–7. All of the bits in the Auto-Negotiation Link Partner Received Next Page register are read only. A write to the Auto-Negotiation Link Partner Received Next Page register shall have no effect.

The values contained in this register are only guaranteed to be valid after the Page Received bit (6.1) has been set to logical one or once Auto-Negotiation has successfully completed, as indicated by bit 1.5.

NOTE—If this register is used to store multiple Link Partner Next Pages, the previous value of this register is assumed to be stored by a management entity that needs the information overwritten by subsequent Link Partner Next Pages.

[a]RO = Read only.

28.2.4.1.8 State diagram variable to MII register mapping

The state diagrams of Figure 28–16 to Figure 28–19 generate and accept variables of the form "mr_x," where x is an individual signal name. These variables comprise a management interface that may be connected to the MII management function or other equivalent function. Table 28–8 describes how the MII registers map to the management function interface signals.

Table 28–8—State diagram variable to MII register mapping

State diagram variable	MII register	MDIO register
mr_adv_ability[16:1]	4.15:0 Auto-Negotiation advertisement register	7.16.15:0 AN advertisement register
mr_autoneg_complete	1.5 Auto-Negotiation Complete	7.1.5 Auto-Negotiation Complete
mr_autoneg_enable	0.12 Auto-Negotiation Enable	7.0.12 Auto-Negotiation Enable
mr_lp_adv_ability[16:1]	For Base Page: 5.15:0 Auto-Negotiation link partner ability register For Next Page(s): If 6.6=1 and 6.5=1 then 8.15:0 is Auto-Negotiation link partner Received Next Page register If 6.6=1 and 6.5= 0 then 5.15:0 is Auto-Negotiation link partner ability register If 6.6=0 then 8.15:0 or 5.15:0 is Auto-Negotiation link partner Next Page ability register	7.19.15:0 AN LP Base Page ability register

mr_page_rx	6.1 Page Received	7.1.6 Page Received
mr_parallel_detection_fault	6.4 Parallel Detection Fault	
mr_restart_negotiation	0.9 Auto-Negotiation Restart	7.0.9 Auto-Negotiation Restart
set if Auto-Negotiation is available	1.3 Auto-Negotiation Ability	7.1.3 Auto-Negotiation Ability

28.2.4.2 Auto-Negotiation managed object class

The Auto-Negotiation Managed Object Class is defined in Clause 30.

28.2.5 Absence of management function

In the absence of any management function, the advertised abilities shall be provided through a logical equivalent of mr_adv_ability[16:1]. A device shall comply with all Next Page function requirements, including the provision of the mr_np_able, mr_lp_np_able, and mr_next_page_loaded variables (or their logical equivalents), in order to permit the NP bit to be set to logic one in the transmitted link codeword.

NOTE—Storage of a valid base link codeword is required to prevent a deadlock situation where negotiation has to start again while Next Pages are being transmitted. If a shared transmit register were used, then renegotiation could not occur when Next Pages were being transmitted because the base link codeword would not be available. This requirement can be met using a number of different implementations, including use of temporary registers or register stacks.

28.2.6 Technology-Dependent Interface

The Technology-Dependent Interface is the communication mechanism between each technology's PMA and the Auto-Negotiation function. Auto-Negotiation can support multiple technologies, all of which need not be implemented in a given device. Each of these technologies may utilize its own technology-dependent link integrity test function.

28.2.6.1 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium. The purpose of this primitive is to give the PCS, repeater client, or Auto-Negotiation function a means of determining the validity of received code elements.

28.2.6.1.1 Semantics of the service primitive

PMA_LINK.indication(link_status)

The link_status parameter shall assume one of three values: READY, OK, or FAIL, indicating whether the underlying receive channel is intact and ready to be enabled (READY), intact and enabled (OK), or not

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

intact (FAIL). When link_status=FAIL or link_status=READY, the PMA_CARRIER.indication and PMA_UNITDATA.indication primitives are undefined.

28.2.6.1.2 When generated

A technology-dependent PMA and the NLP Receive Link Integrity Test state diagram (Figure 28–19) shall generate this primitive to indicate the value of link_status.

28.2.6.1.3 Effect of receipt

The effect of receipt of this primitive shall be governed by the state diagrams of Figure 28–18.

28.2.6.2 PMA_LINK.request

This primitive is generated by Auto-Negotiation to allow it to enable and disable operation of the PMA.

28.2.6.2.1 Semantics of the service primitive

PMA_LINK.request(link_control)

The link_control parameter shall assume one of three values: SCAN_FOR_CARRIER, DISABLE, or ENABLE.

The link_control=SCAN_FOR_CARRIER mode is used by the Auto-Negotiation function prior to receiving any FLP Bursts or link_status=READY indications. During this mode, the PMA shall search for carrier and report link_status=READY when carrier is received, but no other actions shall be enabled.

The link_control=DISABLE mode shall be used by the Auto-Negotiation function to disable PMA processing.

The link_control=ENABLE mode shall be used by Auto-Negotiation to turn control over to a single PMA for all normal processing functions.

28.2.6.2.2 When generated

The Auto-Negotiation function shall generate this primitive to indicate to the PHY how to respond, in accordance with the state diagrams of Figure 28–17 and Figure 28–18.

Upon power-on or reset, if the Auto-Negotiation function is enabled (mr_autoneg_enable=true) the PMA_LINK.request(DISABLE) message shall be issued to all technology-dependent PMAs. If Auto-Negotiation is disabled at any time including at power-on or reset, the state of PMA_LINK.request(link_control) is implementation dependent.

28.2.6.2.3 Effect of receipt

The effect of receipt of this primitive shall be governed by the NLP Receive Link Integrity Test state diagram (Figure 28–19) and the receiving technology-dependent link integrity test function, based on the intent specified in the primitive semantics.

28.2.6.3 PMA_LINKPULSE.request

This primitive is generated by Auto-Negotiation to indicate that a valid Link Pulse, as transmitted in compliance with Figure 14–13, has been received.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.2.6.3.1 Semantics of the service primitive

PMA_LINKPULSE.request (linkpulse)

The linkpulse parameter shall assume one of two values: TRUE or FALSE.

The linkpulse=FALSE mode shall be used by the Auto-Negotiation function to indicate that the Receive state diagram has performed a state transition.

The linkpulse=TRUE mode shall be used by the Auto-Negotiation function to indicate that a valid Link Pulse has been received.

28.2.6.3.2 When generated

The Auto-Negotiation function shall generate this primitive to indicate to the PHY how to respond, in accordance with the state diagram of Figure 28–17.

Upon power-on or reset, if the Auto-Negotiation function is enabled (mr_autoneg_enable=true) the PMA_LINKPULSE.request (FALSE) message shall be issued to all technology-dependent PMAs. If Auto-Negotiation is disabled at any time including at power-on or reset, the state of PMA_LINKPULSE.request (linkpulse) is implementation dependent.

28.2.6.3.3 Effect of receipt

The effect of receipt of this primitive shall be governed by the receiving technology-dependent PMA function, based on the intent specified in the primitive semantics.

28.3 State diagrams and variable definitions

The notation used in the state diagrams (Figure 28–16 to Figure 28–19) follows the conventions in 21.5. State diagram variables follow the conventions of 21.5.2 except when the variable has a default value. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set. Variables using the “mr_x” notation do not have state diagram defaults; however, their appropriate initialization conditions when mapped to the MII interface are covered in 28.2.4 and 22.2.4, and Clause 45 MDIO management interface. The variables, timers, and counters used in the state diagrams are defined in 28.3, 14.2.3, and 28.2.6.

Auto-Negotiation shall implement the Transmit state diagram, Receive state diagram, Arbitration state diagram, and NLP Receive Link Integrity Test state diagram as depicted in 28.3. Additional requirements to these state diagrams are made in the respective functional requirements sections. Options to these state diagrams clearly stated as such in the functional requirements sections or state diagrams shall be allowed. In the case of any ambiguity between stated requirements and the state diagrams, the state diagrams shall take precedence.

The functional reference diagram (Figure 28–15) provides a generic example, illustrated with initial PMA implementations and showing the mechanism for expansion. New PMAs are documented in Annex 28D.

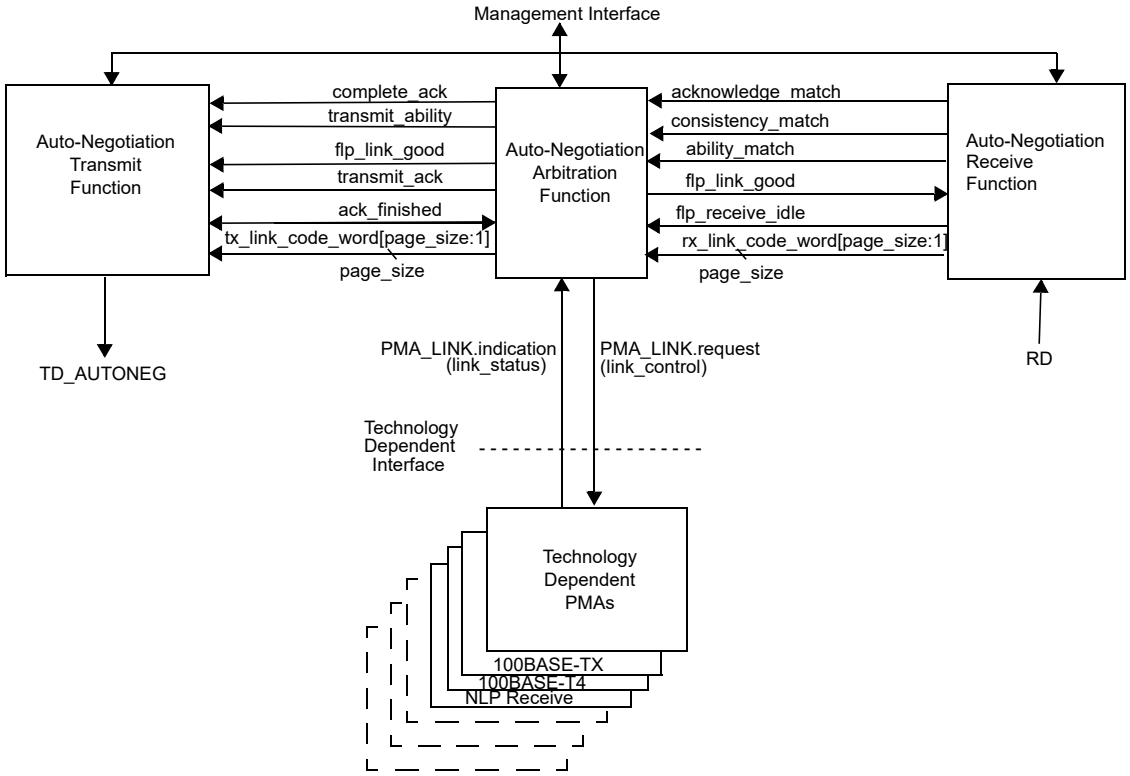

Figure 28–15—Functional reference diagram

28.3.1 State diagram variables

A variable with "_[x]" appended to the end of the variable name indicates a variable or set of variables as defined by "x". "x" may be as follows:

all;	represents all specific technology-dependent PMAs supported in the Local Device and the NLP Receive Link Integrity Test state diagram.
1GigT;	represents that the 1000BASE-T PMA is the signal source.
2p5GigT;	represents that the 2.5GBASE-T PMA is the signal source.
5GigT;	represents that the 5GBASE-T PMA is the signal source.
10GigT;	represents that the 10GBASE-T PMA is the signal source.
25GigT;	represents that the 25GBASE-T PMA is the signal source.
40GigT;	represents that the 40GBASE-T PMA is the signal source.
HCD;	represents the single technology-dependent PMA chosen by Auto-Negotiation as the highest common denominator technology through the Priority Resolution or Parallel Detection function. To select 10BASE-T, LIT is used instead of NLP to enable the full 10BASE-T Link Integrity Test function state diagram.
notHCD;	represents all technology-dependent PMAs not chosen by Auto-Negotiation as the highest common denominator technology through the Priority Resolution or Parallel Detection function.
TX;	represents that the 100BASE-TX PMA is the signal source.
T4;	represents that the 100BASE-T4 PMA is the signal source.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NLP; represents that the NLP Receive Link Integrity Test function is the signal source.

PD; represents all of the following that are present: 100BASE-TX PMA, 100BASE-T4 PMA, and the NLP Receive Link Integrity Test state diagram.

LIT; represents the 10BASE-T Link Integrity Test function state diagram is the signal source or destination.

Variables with [16:1] appended to the end of the variable name indicate arrays that can be directly mapped to 16-bit registers. For these variables, "[x]" indexes an element or set of elements in the array, where "[x]" may be as follows:

— Any integer.
— Any variable that takes on integer values.
— NP; represents the index of the Next Page bit.
— ACK; represents the index of the Acknowledge bit.
— RF; represents the index of the Remote Fault bit.

Variables of the form "mr_x", where x is a label, comprise a management interface that is intended to be connected to the MII Management function. However, an implementation-specific management interface may provide the control and status function of these bits.

ability_match

Indicates that three consecutive link codewords match, ignoring the Acknowledge bit. Three consecutive words are any three words received one after the other, regardless of whether the word has already been used in a word-match comparison or not.

Values: false; three matching consecutive link codewords have not been received, ignoring the Acknowledge bit (default).
true; three matching consecutive link codewords have been received, ignoring the Acknowledge bit.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

ability_match_word [16:1]

A 16-bit array that contains the last link codeword that caused ability_match = true. For each element in the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

ack_finished

Status indicating that the final remaining_ack_cnt link codewords with the Ack bit set have been transmitted.

Values: false; more link codewords with the Ack bit set to logic one have to be transmitted.
true; all remaining link codewords with the Ack bit set to logic one have been transmitted.

acknowledge_match

Indicates that three consecutive link codewords match and have the Acknowledge bit set. Three consecutive words are any three words received one after the other, regardless of whether the word has already been used in a word match comparison or not.

Values: false; three matching and consecutive link codewords have not been received with the Acknowledge bit set (default).
true; three matching and consecutive link codewords have been received with the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Acknowledge bit set.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

base_page

Status indicating that the page currently being transmitted by Auto-Negotiation is the initial link codeword encoding used to communicate the device's abilities.

Values: false; a page other than base link codeword is being transmitted.
true; the base link codeword is being transmitted.

complete_ack

Controls the counting of transmitted link codewords that have their Acknowledge bit set.

Values: false; transmitted link codewords with the Acknowledge bit set are not counted (default).
true; transmitted link codewords with the Acknowledge bit set are counted.

consistency_match

Indicates that the link codeword that caused ability_match to be set is the same as the link codeword that caused acknowledge_match to be set.

Values: false; the link codeword that caused ability_match to be set is not the same as the link codeword that caused acknowledge_match to be set, ignoring the Acknowledge bit value.
true; the link codeword that caused ability_match to be set is the same as the link codeword that caused acknowledge_match to be set, independent of the Acknowledge bit value.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

desire_np

Status indicating that the Local Device desires to engage in Next Page exchange. This information comes from the setting of the NP bit in the base link codeword stored in the Auto-Negotiation advertisement register (register 4).

Values: false; Next page exchange is not desired.
true; Next page exchange is desired.

flp_link_good

Indicates that Auto-Negotiation has completed.

Values: false; negotiation is in progress (default).
true; negotiation is complete, forcing the Transmit and Receive functions to IDLE.

flp_receive_idle

Indicates that the Receive state diagram is in the IDLE, LINK PULSE DETECT, or LINK PULSE COUNT state.

Values: false; the Receive state diagram is not in the IDLE, LINK PULSE DETECT, or LINK PULSE COUNT state (default).
true; the Receive state diagram is in the IDLE, LINK PULSE DETECT, or LINK PULSE COUNT state.

incompatible_link

Parameter used following Priority Resolution to indicate the resolved link is incompatible with the Local Device settings. A device's ability to set this variable to true is optional.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: false; A compatible link exists between the Local Device and Link Partner (default).
true; Optional indication that Priority Resolution has determined no highest common denominator exists following the most recent negotiation.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

link_control

This variable is defined in 28.2.6.2.1.

link_status

This variable is defined in 28.2.6.1.1.

linkpulse

This variable is defined in 28.2.6.3.1.

Values: false; linkpulse is set to false after any Receive State Diagram state transition (default).
true; linkpulse is set to true when a valid Link Pulse is received.

mr_autoneg_complete

Status indicating whether Auto-Negotiation has completed or not.

Values: false; Auto-Negotiation has not completed.
true; Auto-Negotiation has completed.

mr_autoneg_enable

Controls the enabling and disabling of the Auto-Negotiation function.

Values: false; Auto-Negotiation is disabled.
true; Auto-Negotiation is enabled.

mr_adv_ability[16:1]

A 16-bit array that contains the Advertised Abilities link codeword.
For each element within the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

mr_lp_adv_ability[16:1]

A 16-bit array that contains the Link Partner’s Advertised Abilities link codeword.
For each element within the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

mr_lp_np_able

Status indicating whether the Link Partner supports Next Page exchange.

Values: false; the Link Partner does not support Next Page exchange.
true; the Link Partner supports Next Page exchange.

mr_np_able

Status indicating whether the Local Device supports Next Page exchange.

Values: false; the Local Device does not support Next Page exchange.
true; the Local Device supports Next Page exchange.

mr_lp_autoneg_able

Status indicating whether the Link Partner supports Auto-Negotiation.

Values: false; the Link Partner does not support Auto-Negotiation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

true; the Link Partner supports Auto-Negotiation.

mr_main_reset

Controls the resetting of the Auto-Negotiation state diagrams.

Values: false; do not reset the Auto-Negotiation state diagrams.
true; reset the Auto-Negotiation state diagrams.

mr_next_page_loaded

Status indicating whether a new page has been loaded into the Auto-Negotiation Next Page Transmit register (register 7).

Values: false; a New Page has not been loaded.
true; a New Page has been loaded.

mr_np_tx[page_size:1]

A 16-bit or 48-bit array that contains the new Next Page to transmit.
For each element within the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

mr_page_rx

Status indicating whether a New Page has been received. A New Page has been successfully received when acknowledge_match=true and consistency_match=true and the link codeword has been written to mr_lp_adv_ability[16:1].

Values: false; a New Page has not been received.
true; a New Page has been received.

mr_parallel_detection_fault

Error condition indicating that while performing Parallel Detection, either flp_receive_idle = false, or zero or more than one of the following indications were present when the autoneg_wait_timer expired. This signal is cleared on read of the Auto-Negotiation expansion register.

1) link_status_ [NLP] = READY
2) link_status_[TX] = READY
3) link_status_[T4] = READY

Values: false; exactly one of the above three indications was true when the autoneg_wait_timer expired, and flp_receive_idle = true.
true; either zero or more than one of the above three indications was true when the autoneg_wait_timer expired, or flp_receive_idle = false.

mr_restart_negotiation

Controls the entrance to the TRANSMIT DISABLE state to break the link before Auto-Negotiation is allowed to renegotiate via management control.

Values: false; renegotiation is not taking place.
true; renegotiation is started.

np_rx

Flag to hold the value of rx_link_code_word[NP] upon entry to the COMPLETE ACKNOWLEDGE state. This value is associated with the value of rx_link_code_word[NP] when acknowledge_match was last set.

Values zero; local device np_rx bit equals a logical zero.
one; local device np_rx bit equals a logical one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

page_size

Status indicating the size of Next Page that the device is prepared to transmit and receive.

Values: 16; the device does not support Extended Next Pages or Extended Next Page ability has not been enabled.
48; Extended Next Page ability is supported and has been enabled.

NOTE— This variable is set by this variable definition; it is not set explicitly in the state diagrams. The variable takes on the value of 16 upon entry into the TRANSMIT DISABLE state and is updated upon entry into the NEXT PAGE WAIT state.

power_on

Condition that is true until such time as the power supply for the device that contains the Auto-Negotiation state diagrams has reached the operating region or the device has low power mode set via MII control register bit 0.11.

Values: false; the device is completely powered (default).
true; the device has not been completely powered.

rx_link_code_word[page_size:1]

A 16-bit or 48-bit array that contains the data bits to be received from an FLP Burst.
For each element within the array:

Values: zero; data bit is a logical zero.
one; data bit is a logical one.

single_link_ready

Status indicating that flp_receive_idle = true and only one the of the following indications is being received:

1) link_status_[NLP] = READY
2) link_status_[TX] = READY
3) link_status_[T4] = READY

Values: false; either zero or more than one of the above three indications are true or flp_receive_idle = false.
true; Exactly one of the above three indications is true and flp_receive_idle = true.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

TD_AUTONEG

Controls the signal sent by Auto-Negotiation on the TD_AUTONEG circuit.

Values: idle; Auto-Negotiation prevents transmission of all link pulses on the MDI.
link_test_pulse; Auto-Negotiation causes a single link pulse as defined by Figure 14–13 to be transmitted on the MDI.

toggle_rx

Flag to keep track of the state of the Link Partner’s Toggle bit.

Values: 0; Link Partner’s Toggle bit equals logic zero.
1; Link Partner’s Toggle bit equals logic one.

toggle_tx

Flag to keep track of the state of the Local Device’s Toggle bit.

Values: 0; Local Device’s Toggle bit equals logic zero.
1; Local Device’s Toggle bit equals logic one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transmit_ability
: Controls the transmission of the link codeword containing tx_link_code_word[page_size:1].

  Values: false; any transmission of tx_link_code_word[page_size:1] is halted (default).
  true; the transmit state diagram begins sending tx_link_code_word[page_size:1].

transmit_ack
: Controls the setting of the Acknowledge bit in the tx_link_code_word[page_size:1] to be transmitted.

  Values: false; sets the Acknowledge bit in the transmitted tx_link_code_word[page_size:1] to a logic zero (default).
  true; sets the Acknowledge bit in the transmitted tx_link_code_word[page_size:1] to a logic one.

transmit_disable
: Controls the transmission of tx_link_code_word[page_size:1].

  Values: false; tx_link_code_word[page_size:1] transmission is allowed (default).
  true; tx_link_code_word[page_size:1] transmission is halted.

tx_link_code_word[page_size:1]
: A 16-bit or 48-bit array that contains the data bits to be transmitted in an FLP Burst. This array may be loaded from mr_adv_ability or mr_np_tx.
  For each element within the array:

  Values: Zero; data bit is logical zero.
  One; data bit is logical one.

28.3.2 State diagram timers

All timers operate in the manner described in 14.2.3.2.

autoneg_wait_timer
: Timer for the amount of time to wait before evaluating the number of link integrity test functions with link_status=READY asserted. The autoneg_wait_timer shall expire 500 ms to 1000 ms from the assertion of link_status=READY from the 100BASE-TX PMA, 100BASE-T4 PMA, or the NLP Receive State diagram.

break_link_timer
: Timer for the amount of time to wait in order to assure that the Link Partner enters a Link Fail state. The timer shall expire 1200 ms to1500 ms after being started.

data_detect_max_timer
: Timer for the maximum time between a clock pulse and the next link pulse. This timer is used in conjunction with the data_detect_min_timer to detect whether the data bit between two clock pulses is a logic zero or a logic one. The data_detect_max_timer shall expire 78 µs to 100 µs from the last clock pulse.

data_detect_min_timer
: Timer for the minimum time between a clock pulse and the next link pulse. This timer is used in conjunction with the data_detect_max_timer to detect whether the data bit between two clock pulses is a logic zero or a logic one. The data_detect_min_timer shall expire 15 µs to 47 µs from the last clock pulse.

flp_test_max_timer
: Timer for the maximum time between two link pulses within an FLP Burst. This timer is used in conjunction with the flp_test_min_timer to detect whether the Link Partner is transmitting FLP

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Bursts. The flp_test_max_timer shall expire 165 µs to 185 µs from the last link pulse.

flp_test_min_timer
: Timer for the minimum time between two link pulses within an FLP Burst. This timer is used in conjunction with the flp_test_max_timer to detect whether the Link Partner is transmitting FLP Bursts. The flp_test_min_timer shall expire 5 µs to 25 µs from the last link pulse.

interval_timer
: Timer for the separation of a transmitted clock pulse from a data bit. The interval_timer shall expire 55.5 µs to 69.5 µs from each clock pulse and data bit.

link_fail_inhibit_timer
: Timer for qualifying a link_status=FAIL indication or a link_status=READY indication when a specific technology link is first being established. A link will only be considered "failed" if the link_fail_inhibit_timer has expired and the link has still not gone into the link_status=OK state. The link_fail_inhibit_timer shall expire 750 ms to 1000 ms after entering the FLP LINK GOOD CHECK state for devices operating at 10/100/1000 Mb/s. The link_fail_inhibit_timer shall expire 2000 ms to 2250 ms after entering the FLP LINK GOOD CHECK state for devices in the MultiGBASE-T PHY set.

  NOTE—The link_fail_inhibit_timer expiration value has to be greater than the time required for the Link Partner to complete Auto-Negotiation after the Local Device has completed Auto-Negotiation plus the time required for the specific technology to enter the link_status=OK state. The maximum time difference between a Local Device and its Link Partner completing Auto-Negotiation is

  (Maximum FLP Burst to FLP Burst separation) × (Maximum number of FLP Bursts needed to complete acknowledgment) = (24 ms) × (8 bursts) = 192 ms.

  For example, 100BASE-T4 requires approximately 460 ms to enter link_status=OK for a total minimum link_fail_inhibit_timer time of 652 ms. The lower bound for the link_fail_inhibit_timer was chosen to provide adequate margin for the current technologies and any future PMAs.

nlp_test_max_timer
: Timer for the maximum time that no FLP Burst may be seen before forcing the receive state diagram to the IDLE state. The nlp_test_max_timer shall expire 50 ms to 150 ms after being started or restarted.

nlp_test_min_timer
: Timer for the minimum time between two consecutive FLP Bursts. The nlp_test_min_timer shall expire 5 ms to 7 ms after being started or restarted for devices that do not support Extended Next Pages, and shall expire 6.75 ms to 7.25 ms after being started or restarted for devices that do support Extended Next Pages.

transmit_link_burst_timer
: Timer for the separation of a transmitted FLP Burst from the next FLP Burst. The transmit_link_burst_timer shall expire 5.7 ms to 22.3 ms after the last transmitted link pulse in an FLP Burst when Extended Next Pages are not supported. When Extended Next Pages are supported, the timer shall expire 5.7 ms to 6.8 ms after the last transmitted link pulse when transmitting 16-bit pages, and shall expire 1.3 ms to 3.1 ms after the last transmitted pulse when transmitting 48-bit pages.

Table 28–9—Timer min./max. value summary

Parameter	Min.	Typ.	Max.	Units
autoneg_wait_timer	500		1000	ms
break_link_timer	1200		1500	ms
data_detect_min_timer	15		47	µs
data_detect_max_timer	78		100	µs
flp_test_min_timer	5		25	µs
flp_test_max_timer	165		185	µs
interval_timer	55.5	62.5	69.5	µs
link_fail_inhibit_timer (10/100/1000 Mb/s devices)	750		1000	ms
link_fail_inhibit_timer (devices in the MultiGBASE-T set)	2000		2250	ms
nlp_test_max_timer	50		150	ms
nlp_test_min_timer (no support of Extended Next Pages)	5		7	ms
nlp_test_min_timer (support of Extended Next Pages)	6.75		7.25	ms
transmit_link_burst_timer (no support of Extended Next Pages)	5.7	14	22.3	ms
transmit_link_burst_timer (support of Extended Next Pages when page_size is 16)	5.7	6.25	6.8	ms
transmit_link_burst_timer (support of Extended Next Pages when page_size is 48)	1.3	2.25	3.2	ms

28.3.3 State diagram counters

flp_cnt

A counter that may take on integer values from 0 to 17. This counter is used to keep a count of the number of FLPs detected to enable the determination of whether the Link Partner supports Auto-Negotiation.

Values: not_done; 0 to 5 inclusive.
done; 6 to 17 inclusive.
init; counter is reset to zero.

remaining_ack_cnt

A counter that may take on integer values from 0 to 8. The number of additional link codewords with the Acknowledge Bit set to logic one to be sent to ensure that the Link Partner receives the acknowledgment.

Values: not_done; positive integers between 0 and 5 inclusive.
done; positive integers 6 to 8 inclusive (default).
init; counter is reset to zero.

rx_bit_cnt

A counter that may take on integer values from 0 to (page_size+1). This counter is used to keep a count of data bits received from an FLP Burst and to ensure that when erroneous extra pulses are received, the first page_size bits are kept while the rest are ignored. When this variable reaches page_size or (page_size+1), enough data bits have been received. This counter does not increment beyond (page_size+1) and does not return to 0 until it is reinitialized.

Values: not_done; 1 to (page_size–1) inclusive.
done; page_size or (page_size+1)
init; counter is reset to zero.
rx_bit_cnt_check; 10 to 17 inclusive.

tx_bit_cnt

A counter that may take on integer values from 1 to (page_size+1). This counter is used to keep a count of data bits sent within an FLP Burst. When this variable reaches (page_size+1), all data bits have been sent.

Values: not_done; 1 to page_size inclusive.
done; (page_size+1).
init; counter is initialized to 1.

NOTE—The variables link_control and link_status are viewed as dedicated signals by the NLP Receive Link integrity Test state diagram, but are viewed as link_control_[NLP] and link_status_[NLP] by the Auto-Negotiation Arbitration state diagram, Figure 28–18.

Figure 28–19—NLP Receive Link Integrity Test state diagram

28.4 Electrical specifications

The electrical characteristics of pulses within FLP Bursts shall be identical to the characteristics of NLPs and shall meet the requirements of Figure 14–13.

It is the responsibility of the technology-specific Transmit and Receive functions to interface to the MDI correctly.

NOTE—The requirements relative to the interface to the MDI are specified via the Transmit Switch and Receive Switch functions.

28.5 Protocol implementation conformance statement (PICS) proforma for Clause 28, Physical Layer link signaling for Auto-Negotiation on twisted pair[63]

28.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 28, Physical Layer link signaling for Auto-Negotiation on twisted pair, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

28.5.2 Identification

28.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

28.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 28, Physical Layer link signaling for 10 Mb/s, 100 Mb/s, and 1000 Mb/s Auto-Negotiation on twisted pair
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[63] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.3 Major capabilities/options

Item	Feature	Subclause	Status	Support	Value/Comment
10BT	Implementation supports a 10BASE-T data service	28.1.2	O		N/A
*NP	Implementation supports Next Page function	28.1.2	O		N/A
*MII	Implementation supports the MII Management Interface	28.1.2	O/1		N/A
MGMT	Implementation supports a non-MII Management Interface	28.1.2	O/1		N/A
*NOM	Implementation does not support management	28.1.2	O/1		N/A
*RF	Implementation supports Remote Fault Sensing	28.2.3.5	O		N/A
*NPSL	Link Partner Next Page Storage Location bit	28.2.4.1.5	O		N/A
*ENP	Implementation supports Extended Next Pages	28.2.3.4.2	O		N/A
*OPT	Implementation supports optimized FLP burst to FLP burst timing	28.2.1.1.2	ENP:M !ENP:O		N/A
*MG	Implementation supports a member of the MultiGBASE-T PHY set (see 1.4.406)	55, 113, and 126	O		N/A

28.5.4 PICS proforma tables for Physical Layer link signaling for Auto-Negotiation on twisted pair

28.5.4.1 Scope

Item	Feature	Subclause	Status	Support	Value/Comment
SC1	MII Management Interface control and status registers	28.1.3	MII:M		Implemented in accordance with the definitions in Clause 22 and 28.2.4
SC2	CSMA/CD compatible devices using an eight-pin modular connector and using a signaling method to automatically configure the preferred mode of operation	28.1.4	M		Auto-Negotiation function implemented in compliance with Clause 28
SC3	Device uses 10BASE-T compatible link signaling to advertise non-CSMA/CD abilities	28.1.4	M		Auto-Negotiation function implemented in compliance with Clause 28
SC4	Future CSMA/CD implementations that use an eight-pin modular connector	28.1.4	M		Interoperable with devices compliant with Clause 28

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.2 Auto-Negotiation functions

Item	Feature	Subclause	Status	Support	Value/Comment
AN1	Transmit	28.2	M		Complies with Figure 28–16
AN2	Receive	28.2	M		Complies with Figure 28–17
AN3	Arbitration	28.2	M		Complies with Figure 28–18
AN4	NLP Receive Link Integrity Test	28.2	10BT:M		Complies with Figure 28–19
AN5	Technology-Dependent Interface	28.2	M		Complies with 28.2.6
AN6	Technology-dependent link integrity test	28.2	M		Implemented and interfaced to for those technologies supported by device
AN7	Management function	28.2	O		

28.5.4.3 Transmit function requirements

Item	Feature	Subclause	Status	Support	Value/Comment
TF1	FLP Burst transmission	28.2.1.1	M		Not transmitted once Auto-Negotiation is complete and highest common denominator PMA has been enabled. Prohibited other than for link startup
TF2	FLP Burst composition	28.2.1.1.1	M		Pulses in FLP Bursts meet the requirements of Figure 14–13
TF3	FLP Burst pulse definition	28.2.1.1.1	M		Odd-numbered pulse positions represent clock information; even-numbered pulse positions represent data information
TF4	The first pulse in an FLP Burst	28.2.1.1.2	M		Defined as a clock pulse for timing purposes
TF5	FLP Burst clock pulse spacing	28.2.1.1.2	M		Within an FLP Burst, spacing is 125 μs ± 14 μs
TF6	Logic one data bit representation	28.2.1.1.2	M		Pulse transmitted 62.5 μs ± 7 μs after the preceding clock pulse
TF7	Logic zero data bit representation	28.2.1.1.2	M		No link integrity test pulses within 111 μs of the preceding clock pulse
TF8	Consecutive FLP Bursts	28.2.1.1.2	M		The first link pulse in each FLP Burst is separated by 16 ms ± 8 ms
TF9	Consecutive FLP Bursts	28.2.1.1.2	OPT:M		The first link pulse in each FLP Burst is separated by 8.25 ms ± 0.25 ms
TF10	FLP Burst Base Page	28.2.1.2	M		Conforms to Figure 28–7

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.3 Transmit function requirements *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
TF11	FLP Burst bit transmission order	28.2.1.2	M		Transmission is D0 first to D15 last
TF12	Selector Field values	28.2.1.2.1	M		Only defined values transmitted
TF13	Technology Ability Field values	28.2.1.2.2	M		Implementation supports a data service for each ability set in the Technology Ability Field
TF14	Remote Fault bit	28.2.1.2.4	M		Used in accordance with the Remote Fault function specifications
TF15	Acknowledge bit set, no Next Page to be sent	28.2.1.2.5	M		Set to logic one in the link codeword after the reception of at least three consecutive and consistent FLP Bursts
TF16	Acknowledge bit set, Next Page to be sent	28.2.1.2.5	NP:M		Set to logic one in the transmitted link codeword after the reception of at least three consecutive and consistent FLP Bursts and the current receive link codeword is saved
TF17	Number of link codewords sent with Acknowledge bit set	28.2.1.2.5	M		6 to 8 inclusive after COMPLETE ACKNOWLEDGE state entered
TF18	Device does not implement optional Next Page ability	28.2.1.2.6	M		NP=0 in base link codeword
TF19	Device implements optional Next Page ability and wishes to engage in Next Page exchange	28.2.1.2.6	NP:M		NP=1 in base link codeword
TF20	Transmit Switch function on completion of Auto-Negotiation	28.2.1.3	M		Enables the transmit path from a single technology-dependent PMA to the MDI once the highest common denominator has been selected
TF21	Transmit Switch function during Auto-Negotiation	28.2.1.3	M		Connects FLP Burst generator governed by Figure 28–16 to the MDI
TF22	Signals presented at MDI after connection through Transmit Switch from PMA	28.2.1.3	M		Conform to appropriate PHY specifications

28.5.4.4 Receive function requirements

Item	Feature	Subclause	Status	Support	Value/Comment
RF1	Timer expiration	28.2.2.1	M		Timer definition in 28.3.2, values shown in Table 28–9
RF2	Identification of Link Partner as Auto-Negotiation able	28.2.2.1	M		Reception of 6 to 17 (inclusive) consecutive link pulses separated by at least flp_test_min_timer time but less than flp_test_max_timer time
RF3	First FLP Burst identifying Link Partner as Auto-Negotiation able	28.2.2.1	M		Data recovered is discarded if FLP Burst is incomplete
RF4	First link pulse in an FLP Burst	28.2.2.1	M		Interpreted as a clock link pulse
RF5	Restart of the data_detect_min_timer and data_detect_max_timer	28.2.2.1	M		Detection of a clock link pulse (Figure 28–9)
RF6	Reception of logic one	28.2.2.1	M		Link pulse received between greater than data_detect_min_timer time and less than data_detect_max_timer time after a clock pulse (Figure 28–9)
RF7	Reception of logic zero	28.2.2.1	M		Link pulse received after greater than data_detect_max_timer time after clock pulse, is treated as clock pulse (Figure 28–9)
RF8	FLP Bursts separation	28.2.2.1	M		Conforms to the nlp_test_min_timer and nlp_test_max_timer timing (Figure 28–10)
RF9	Receive Switch function on completion of Auto-Negotiation	28.2.2.3	M		Enables the receive path from the MDI to a single technology-dependent PMA once the highest common denominator has been selected
RF10	Receive Switch function during Auto-Negotiation	28.2.2.3	M		Connects the MDI to the FLP and NLP receivers governed by Figure 28–17 and Figure 28–19, and to the 100BASE-TX and 100BASE-T4 receivers if present
RF11	Signals presented to PMA after connection through Receive Switch from MDI	28.2.2.3	M		Conform to appropriate PHY specifications
RF12	Generation of ability_match, acknowledge_match, and consistency_match	28.2.2.4	M		Responsibility of Receive function in accordance with 28.3.1

28.5.4.5 Arbitration functions

Item	Feature	Subclause	Status	Support	Value/Comment
AF1	MDI receive connection during Auto-Negotiation, prior to FLP detection	28.2.3.1	M		Connected to the NLP Receive Link Integrity Test state diagram, and the link integrity test functions of 100BASE-TX and/or 100BASE-T4. Not connected to the 10BASE-T or any other PMA
AF2	Parallel detection operational mode selection	28.2.3.1	M		Set link_control=ENABLE for the single PMA indicating link_status=READY when the autoneg_wait_timer expires
AF3	Parallel detection PMA control	28.2.3.1	M		Set link_control=DISABLE to all PMAs except the selected operational PMA and indicate Auto-Negotiation has completed
AF4	Parallel detection setting of Link Partner ability register	28.2.3.1	M		On transition to the FLP LINK GOOD CHECK state from the LINK STATUS CHECK state the Parallel Detection function shall set the bit in the Link Partner ability register (register 5) corresponding to the technology detected by the Parallel Detection function
AF5	Response to renegotiation request	28.2.3.2	M		Disable all technology-dependent link integrity test functions and halt transmit activity until break_link_timer expires
AF6	Auto-Negotiation resumption	28.2.3.2	M		Issue FLP Bursts with Base Page valid in tx_link_code_word[16:1] after break_link_timer expires
AF7	Priority resolution	28.2.3.3	M		Single PMA connected to MDI is enabled corresponding to Technology Ability Field bit common to both Local/Link Partner Device and that has highest priority as defined by Annex 28B
AF8	Effect of receipt of reserved Technology Ability Field bit on priority resolution	28.2.3.3	M		Local Device ignores during priority resolution
AF9	Effect of parallel detection on priority resolution	28.2.3.3	M		Local Device considers technology identified by parallel detection as HCD
AF10	Values for HCD and link_status_[HCD] in the event there is no common technology	28.2.3.3	M		HCD=NULL link_status_[HCD]=FAIL

Copyright © 2022 IEEE. All rights reserved.

28.5.4.5 Arbitration functions *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
AF11	Message Page to Unformatted Page relationship for non-matching Selector Fields	28.2.3.4	NP:M		Each series of Unformatted Pages is preceded by an Message Page containing a message code that defines how the following Unformatted Page(s) will be interpreted
AF12	Message Page to Unformatted Page relationship for matching Selector Fields	28.2.3.4	NP:M		Use of Message Pages is specified by the Selector Field value
AF13	Transmission of Null message codes	28.2.3.4	NP:M		Sent with NP=0 on completion of all Next Pages while Link Partner continues to transmit valid Next Page information
AF14	Reception of Null message codes	28.2.3.4	NP:M		Recognized as indicating end of Link Partner's Next Page information
AF15	Next Page encoding	28.2.3.4.1	NP:M		Comply with Figure 28–11 and Figure 28–12 for the NP, Ack, MP, Ack2, and T bits
AF16	Message/Unformatted Code Field	28.2.3.4.1	NP:M		D10-D0 encoded as Message Code Field if MP=1 or Unformatted Code Field if MP=0
AF17	NP bit encoding	28.2.3.4.3	NP:M		Logic 0=last page, logic 1=additional Next Page(s) follow
AF18	Message Page bit encoding	28.2.3.4.5	NP:M		Logic 0=Unformatted Page, logic 1=Message Page
AF19	Ack2 bit encoding	28.2.3.4.6	NP:M		Logic 0=cannot comply with message; logic 1= will comply with message
AF20	Toggle	28.2.3.4.7	NP:M		Takes the opposite value of the Toggle bit in the previously exchanged link codeword
AF21	Toggle encoding	28.2.3.4.7	NP:M		Logic zero = previous value of the transmitted link codeword equaled logic one Logic one = previous value of the transmitted link codeword equaled logic zero
AF22	Message Page encoding	28.2.3.4.8	NP:M		If MP=1, link codeword interpreted as Message Page
AF23	Message Code Field	28.2.3.4.9	NP:M		Combinations not shown in Annex 28C are reserved and may not be transmitted
AF24	Unformatted Page encoding	28.2.3.4.10	NP:M		If MP=0, link codeword interpreted as Unformatted Page

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.5 Arbitration functions *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
AF25	Minimum Next Page exchange	28.2.3.4.13	NP:M		If both devices indicate Next Page able, both send a minimum of one Next Page
AF26	Multiple Next Page exchange	28.2.3.4.13	NP:M		If both devices indicate Next Page able, exchange continues until neither Local/Remote Device has additional information; device sends Next Page with Null message code if it has no information to transmit
AF27	Unformatted Page ordering	28.2.3.4.13	NP:M		Unformatted Pages immediately follow the referencing message code in the order specified by the message code
AF28	Next Page Transmit register	28.2.3.4.14	NP:M		Defined in 28.2.4.1.6
AF29	Next Page receive data	28.2.3.4.14	NP:O		May be stored in Auto-Negotiation Link Partner ability register
AF30	Remote Fault sensing	28.2.3.5	RF:M		Optional
AF31	Transmission of RF bit by Local Device	28.2.3.5	M		If Local Device has no method to set RF bit, it transmits RF bit with value of RF bit in Auto-Negotiation advertisement register (4.13)
AF32	RF bit reset	28.2.3.5	M		Once set, the RF bit remains set until successful renegotiation with the base link codeword
AF33	Receipt of Remote Fault indication in base link codeword	28.2.3.5	MII:M		Device sets the Remote Fault bit in the MII status register (1.4) to logic one if MII is present
AF34	Extended Next Page exchange	28.2.3.4	ENP:M		If both device and link partner are ENP able, any NP exchange uses Extended Next Pages

28.5.4.6 Management function requirements

Item	Feature	Subclause	Status	Support	Value/Comment
MF1	Mandatory MII registers for Auto-Negotiation	28.2.4.1	MII:M		Registers 0, 1, 4, 5, 6
MF2	Optional MII register for Auto-Negotiation	28.2.4.1	MII* NP:M		Register 7
MF3	Auto-Negotiation enable	28.2.4.1.1	MII:M		Set control register Auto-Negotiation Enable bit (0.12)
MF4	Manual Speed/Duplex settings	28.2.4.1.1	MII:M		When bit 0.12 set, control register Speed Detection (0.13) and Duplex Mode (0.8) are ignored, and the Auto-Negotiation function determines link configuration
MF5	Control register (register 0) Restart Auto-Negotiation (0.9) default	28.2.4.1.1	MII:M		PHY returns value of one in 0.9 until Auto-Negotiation has been initiated
MF6	Control register (register 0) Restart Auto-Negotiation (0.9) set	28.2.4.1.1	MII:M		When 0.9 set, Auto-Negotiation will (re)initiate. On completion, 0.9 will be reset by the PHY device. Writing a zero to 0.9 at any time has no effect
MF7	Control register (register 0) Restart Auto-Negotiation (0.9) reset	28.2.4.1.1	MII:M		0.9 is self-clearing; writing a zero to 0.9 at any time has no effect
MF8	Status register (register 1) Auto-Negotiation Complete (1.5) reset	28.2.4.1.2	MII:M		If bit 0.12 reset, or a PHY lacks the ability to perform Auto-Negotiation, (1.5) is reset
MF9	Status register (register 1) Remote Fault (1.4)	28.2.4.1.2	MII:M		Set by the PHY and remains set until either the status register is read or the PHY is reset
MF10	Advertisement register power on default	28.2.4.1.3	MII:M		Selector field as defined in Annex 28A; Ack=0; Technology Ability Field based on MII status register (1.15:11) or logical equivalent
MF11	Link partner ability register read/write	28.2.4.1.4	MII:M		Read only; write has no effect
MF12	Link partner ability register bit definitions	28.2.4.1.4	MII:M		Direct representation of the received link codeword (Figure 28–7)
MF13	Status register (register 1) Auto-Negotiation Complete (1.5) set	28.2.4.1.4	MII:M		Set to logic one upon successful completion of Auto-Negotiation
MF14	Auto-Negotiation expansion register (register 6)	28.2.4.1.5	MII:M		Read only; write has no effect

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.6 Management function requirements *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
MF15	Link Partner Auto-Negotiation Able bit (6.0)	28.2.4.1.5	MII:M		Set to indicate that the Link Partner is able to participate in the Auto-Negotiation function
MF16	Page Received bit (6.1) set	28.2.4.1.5	MII:M		Set to indicate that a new link codeword has been received and stored in the Auto-Negotiation Link Partner ability register
MF17	Page Received bit (6.1) reset	28.2.4.1.5	MII:M		Reset on a read of the Auto-Negotiation expansion register (register 6)
MF18	The Next Page Able bit (6.2) set	28.2.4.1.5	NP* MII:M		Set to indicate that the Local Device supports the Next Page function
MF19	The Link Partner Next Page Able bit (6.3) set	28.2.4.1.5	MII:M		Set to indicate that the Link Partner supports the Next Page function
MF20	Parallel Detection Fault bit (6.4) set	28.2.4.1.5	MII:M		Set to indicate that zero or more than one of the NLP Receive Link Integrity Test function, 100BASE-TX, or 100BASE-T4 PMAs have indicated link_status=READY when the autoneg_wait_timer expires
MF21	Parallel Detection Fault bit (6.4) reset	28.2.4.1.5	MII:M		Reset on a read of the Auto-Negotiation expansion register (register 6)
MF22	Link Partner Next Page Storage Location bit	28.2.4.1.5	NPSL * MII:M		Indicates location of Link Partner Next Page
MF23	Receive Next Page Location Able bit	28.2.4.1.5	MII:M		Indicates if Link Partner Next Page Storage Location bit is supported.
MF24	Next Page Transmit register default	28.2.4.1.6	NP* MII:M		On power-up, contains value of 2001 H
MF25	Write to Next Page Transmit register	28.2.4.1.6	NP* MII:M		mr_next_page_loaded set to true
MF26	Absence of management function	28.2.5	NOM:M		Advertised abilities provided through a logical equivalent of mr_adv_ability[16:1]
MF27	Next Page support in absence of MII management	28.2.5	NOM:M		Device provides logical equivalent of mr_np_able, mr_lp_np_able, or mr_next_page_loaded variables in order to set NP bit in transmitted link codeword

28.5.4.7 Technology-dependent interface

Item	Feature	Subclause	Status	Support	Value/Comment
TD1	PMA_LINK.indication (link_status) values	28.2.6.1.1	M		link_status set to READY, OK or FAIL
TD2	PMA_LINK.indication (link_status) generation	28.2.6.1.2	M		Technology-dependent PMA and NLP Receive Link Integrity Test state diagram (Figure 28–19) responsibility
TD3	PMA_LINK.indication (link_status), effect of receipt	28.2.6.1.3	M		Governed by the state diagram of Figure 28–18
TD4	PMA_LINK.request (link_control) values	28.2.6.1.3	M		link_control set to SCAN_FOR_CARRIER, DISABLE, or ENABLE
TD5	Effect of link_control=SCAN_FOR_CARRIER	28.2.6.2.1	M		PMA to search for carrier and report link_status=READY when carrier is received, but no other actions are enabled
TD6	Effect of link_control=DISABLE	28.2.6.2.1	M		Disables PMA processing
TD7	Effect of link_control=ENABLE	28.2.6.2.1	M		Control passed to a single PMA for normal processing functions
TD8	PMA_LINK.request(link_control) generation	28.2.6.2.2	M		Auto-Negotiation function responsibility in accordance with Figure 28–17 and Figure 28–18
TD9	PMA_LINK.request(link_control) default upon power-on, reset, or release from power-down	28.2.6.2.2	M		link_control = DISABLE state to all technology-dependent PMAs
TD10	PMA_LINK.request(link_control) effect of receipt	28.2.6.2.3	M		Governed by Figure 28–19 and the receiving technology-dependent link integrity test function
TD11	The linkpulse parameter shall	28.2.6.3.1	M		TRUE or FALSE.
TD12	The linkpulse=FALSE shall be used	28.2.6.3.1	M		By the Auto-Negotiation function to indicate that the Receive State Diagram has performed a state transition
TD13	The linkpulse=TRUE shall be used	28.2.6.3.1	M		By the Auto-Negotiation function to indicate that a valid Link Pulse has been received

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.7 Technology-dependent interface *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
TD14	The Auto-Negotiation function shall generate linkpulse	28.2.6.3.2	M		To indicate to the PHY how to respond, in accordance with the state diagram of Figure 28–17
TD15	Upon power-on or reset, if Auto-Negotiation is enabled (mr_autoneg_enable=true) the PMA_LINKPULSE.request(FALSE) message shall be	28.2.6.3.2	M		Issued to all technology-dependent PMAs
TD16	The effect of the receipt of linkpulse shall be governed	28.2.6.3.3	M		By the receiving technology-dependent PMA function, based on the intent specified in the primitive semantics

28.5.4.8 State diagrams

Item	Feature	Subclause	Status	Support	Value/Comment
SD1	Adherence to state diagrams	28.3	M		Implement all features of Figure 28–16 to Figure 28–19. Identified options to Figure 28–16 to Figure 28–19 are permitted
SD2	Ambiguous requirements	28.3	M		State diagrams take precedence in defining functional operation
SD3	autoneg_wait_timer	28.3.2	M		Expires 500 ms to 1000 ms after being started
SD4	break_link_timer	28.3.2	M		Expires 1200 ms to 1500 ms after being started
SD5	data_detect_min_timer	28.3.2	M		Expires 15 μs to 47 μs from the last clock pulse
SD6	data_detect_max_timer	28.3.2	M		Expire 78 μs to 100 μs from the last clock pulse
SD7	flp_test_max_timer	28.3.2	M		Expires 165 μs to 185 μs from the last link pulse
SD8	flp_test_min_timer	28.3.2	M		Expires 5 μs to 25 μs from the last link pulse
SD9	interval_timer	28.3.2	M		Expires 55.5 μs to 69.5 μs from each clock pulse and data bit
SD10	link_fail_inhibit_timer (10/100/1000 Mb/s)	28.3.2	!MG:M		Expires 750 ms to 1000 ms after entering the FLP LINK GOOD CHECK state

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.8 State diagrams *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
SD11	link_fail_inhibit_timer (MultiGBASE-T devices)	28.3.2	MG:M		Expires 2000 ms to 2250 ms after entering the FLP LINK GOOD CHECK state upon successful master/slave resolution
SD12	nlp_test_max_timer	28.3.2	M		Expires 50 ms to 150 ms after being started if not restarted
SD13	nlp_test_min_timer	28.3.2	!ENP:M		Expires 5 ms to 7 ms after being started if not restarted
SD14	nlp_test_min_timer (with Extended Next Page)	28.3.2	ENP:M		Expires 6.75 ms to 7.25 ms after being started if not restarted
SD15	transmit_link_burst_timer (with no optimized timing)	28.3.1	!OPT:M		Expires 5.7 ms to 22.3 ms after the last transmitted link pulse in an FLP Burst
SD16	transmit_link_burst_timer (with optimized timing and 16-bit pages)	28.3.1	OPT:M		Expires 5.7 ms to 6.8 ms after the last transmitted link pulse in an FLP Burst
SD17	transmit_link_burst_timer (with optimized timing and 48-bit pages)	28.3.1	OPT:M		Expires 1.3 ms to 3.2 ms after the last transmitted link pulse in an FLP Burst containing Extended Next Pages

28.5.4.9 Electrical characteristics

Item	Feature	Subclause	Status	Support	Value/Comment
EC1	Pulses within FLP Bursts	28.4	M		Identical to the characteristics of NLPs and meet the requirements of Figure 14–13

28.5.4.10 Auto-Negotiation annexes

Item	Feature	Annex	Status	Support	Value/Comment
AA1	Selector field, S[4:0] values in the link codeword	Annex 28A	M		Identifies base message type as defined by Table 28A–1
AA2	Selector field reserved combinations	Annex 28A	M		Transmission not permitted
AA3	Relative priorities of the technologies supported by the IEEE 802.3 Selector Field value	28B.3	M		Defined in Annex 28B.3
AA4	Relative order of the technologies supported by IEEE 802.3 Selector Field	28B.3	M		Remain unchanged

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.5.4.10 Auto-Negotiation annexes *(continued)*

Item	Feature	Annex	Status	Support	Value/Comment
AA5	Addition of new technology	28B.3	M		Inserted into its appropriate place in the priority resolution hierarchy, shifting technologies of lesser priority lower in priority
AA6	Addition of vendor-specific technology	28B.3	M		Priority of IEEE 802.3 standard topologies maintained, vendor-specific technologies to be inserted into an appropriate location
AA7	Message Code Field	Annex 28C	NP:M		Defines how following Unformatted Pages (if applicable) are interpreted
AA8	Order of Unformatted Code Fields within extended Pages	Annex 28C	NP:M		Pages to be in order specified by message code
AA9	Message Code Field reserved combinations	Annex 28C	NP:M		Transmission not permitted
AA10	Auto-Negotiation reserved code 1	28C.1	NP:M		Transmission of M10 to M0 equals 0, not permitted
AA11	Null message code	28C.2	NP:M		Transmitted during Next Page exchange when the Local Device has no information to transmit and Link Partner has additional pages to transmit
AA12	Remote Fault Identifier message code	28C.5	NP:M		Followed by single Unformatted Page to identify fault type with types defined in 28C.5
AA13	Organizationally Unique Identifier message code	28C.6	NP:M		Followed by 4 Unformatted Pages. First Unformatted Page contains most significant 11 bits of OUI or CID (bits 23:13) with MSB in U10; Second Unformatted Page contains next most significant 11 bits of OUI or CID (bits 12:2), with MSB in U10; Third Unformatted Page contains the least significant 2 bits of OUI or CID (bits 1:0) with MSB in U10, bits U8:0 contains user-defined code specific to OUI or CID; Fourth Unformatted Page contains user-defined code specific to OUI or CID

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

28.6 Auto-Negotiation expansion

Auto-Negotiation is designed in a way that allows it to be easily expanded as new technologies are developed. When a new technology is developed, the following things have to be done to allow Auto-Negotiation to support it:

a) The appropriate Selector Field value to contain the new technology has to be selected and allocated.
b) A Technology bit has to be allocated for the new technology within the chosen Selector Field value.
c) The new technology's relative priority within the technologies supported within a Selector Field value has to be established.

Code space allocations are enumerated in Annex 28A, Annex 28B, and Annex 28C. Additions and insertions to the annexes are allowed. No changes to existing bits already defined are allowed.

29. System considerations for multisegment 100BASE-T networks

NOTE—This clause relates to clauses that are not recommended for new installations. This clause is not recommended for new installations. Since March 2012, maintenance changes are no longer being considered for this clause.

29.1 Overview

This clause provides information on building 100BASE-T networks. The 100BASE-T technology is designed to be deployed in both homogenous 100 Mb/s networks and heterogeneous 10/100 Mb/s mixed CSMA/CD networks. Network topologies can be developed within a single 100BASE-T collision domain, but maximum flexibility is achieved by designing multiple collision domain networks that are joined by bridges and/or routers configured to provide a range of service levels to DTEs. For example, a combined 100BASE-T/10BASE-T system built with repeaters and bridges can deliver dedicated 100 Mb/s, shared 100 Mb/s, dedicated 10 Mb/s, and shared 10 Mb/s service to DTEs. The effective bandwidth of shared services is controlled by the number of DTEs that share the service.

Linking multiple 100BASE-T collision domains with bridges maximizes flexibility. Bridged topology designs can provide single bandwidth (Figure 29–1) or multiple bandwidth (Figure 29–2) services.

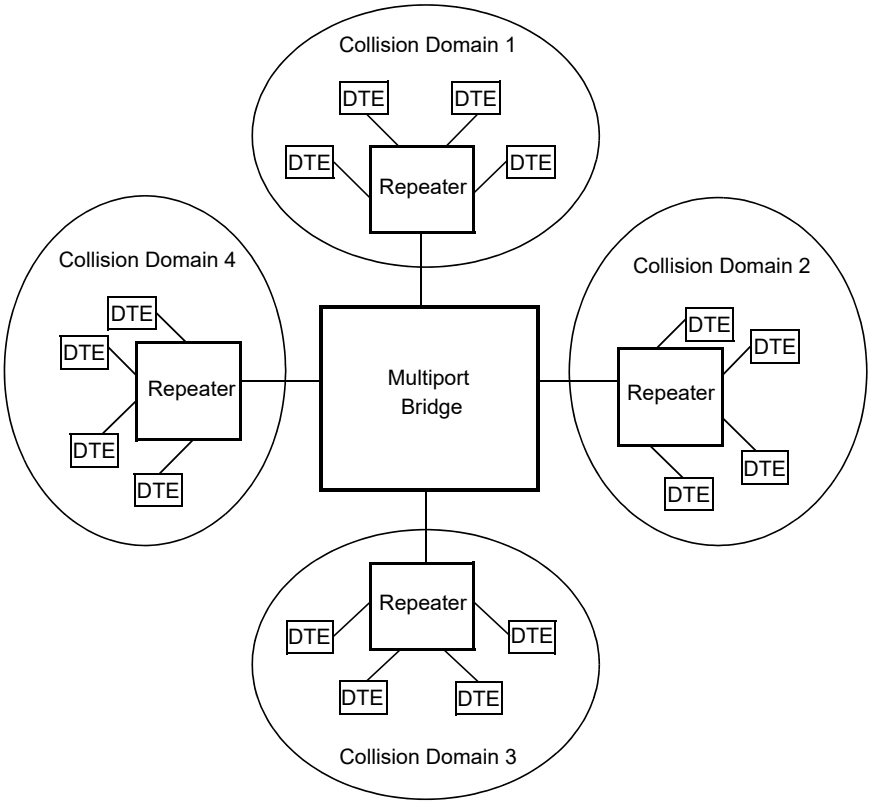

Figure 29–1—100 Mb/s multiple collision domain topology using multiport bridge

Individual collision domains can be linked by single devices (as shown in Figure 29–1 and Figure 29–2) or by multiple devices from any of several transmission systems. The design of multiple-collision-domain networks is governed by the rules defining each of the transmission systems incorporated into the design.

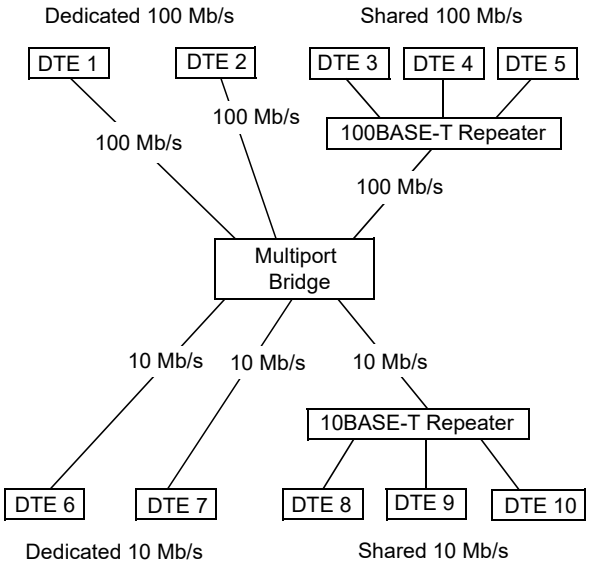

Figure 29–2—Multiple bandwidth, multiple collision domain topology using multiport bridge

The design of shared bandwidth 10 Mb/s collision domains is defined in 13.1 through 13.4; the design of shared bandwidth 100 Mb/s CSMA/CD collision domains is defined in 29.1.1 through 29.3.1.2. The design of 10BASE full duplex LANs is defined in 13.5; the design of full duplex 100BASE-X LANs is defined in 29.4.

29.1.1 Single collision domain multisegment networks

This clause provides information on building 100 Mb/s CSMA/CD multisegment networks within a single collision domain. The proper operation of a CSMA/CD network requires the physical size and number of repeaters to be limited in order to meet the round-trip propagation delay requirements of 4.2.3.2.3 and 4.4.2 and IPG requirements specified in 4.4.2.

This clause provides two network models. Transmission System Model 1 is a set of configurations that have been validated under conservative rules and have been qualified as meeting the requirements set forth above. Transmission System Model 2 is a set of calculation aids that allow those configuring a network to test a proposed configuration against a simple set of criteria that allows it to be qualified. Transmission System Model 2 validates an additional broad set of topologies that are fully functional and do not fit within the simpler, but more restrictive rules of Model 1.

The physical size of a CSMA/CD network is limited by the characteristics of individual network components. These characteristics include the following:

a) Media lengths and their associated propagation time delay
b) Delay of repeater units (startup, steady-state, and end of event)
c) Delay of MAUs and PHYs (startup, steady-state, and end of event)
d) Interpacket gap shrinkage due to repeater units
e) Delays within the DTE associated with the CSMA/CD access method
f) Collision detect and deassertion times associated with the MAUs and PHYs

Table 29–1 summarizes the delays for 100BASE-T media segments. For more detailed information on the delays associated with individual 100BASE-T components, see

MII: Annex 22A
100BASE-T2:32.12
100BASE-T4:23.11
100BASE-TX:24.6
100BASE-FX: ISO/IEC 9314-3:1990
Repeater:27.3

Table 29–1—Delays for network media segments Model 1

Media type	Maximum number of PHYs per segment	Maximum segment length (m)	Maximum medium round-trip delay per segment (BT)
Balanced cable link segment 100BASE-T	2	100	114
Fiber link segment	2	412	412

29.1.2 Repeater usage

Repeaters are the means used to connect segments of a network medium together into a single collision domain. Different signaling systems (i.e., 100BASE-T2, 100BASE-T4, 100BASE-TX, 100BASE-FX) can be joined into a common collision domain using repeaters. Bridges can also be used to connect different signaling systems; however, if a bridge is so used, each system connected to the bridge will be a separate collision domain.

Two types of repeaters are defined for 100BASE-T (see Clause 27). Class I repeaters are principally used to connect unlike physical signaling systems and have internal delays such that only one Class I repeater can reside within a single collision domain when maximum cable lengths are used (see Figure 29–4). Class II repeaters typically provide ports for only one physical signaling system type (e.g., 100BASE-TX but not 100BASE-T4) and have smaller internal delays so that two such repeaters may reside within a given collision domain when maximum cable lengths are used (see Figure 29–6). Cable length can be sacrificed to add additional repeaters in a collision domain (see 29.3).

29.2 Transmission System Model 1

The following network topology constraints apply to networks using Transmission System Model 1.

a) All balanced cable (copper) segments less than or equal to 100 m each.
b) Fiber segments less than or equal to 412 m each.
c) MII cables for 100BASE-T shall not exceed 0.5 m each. When evaluating system topology, MII cable delays need not be accounted for separately. Delays attributable to the MII are incorporated into DTE and repeater component delays.

29.3 Transmission System Model 2

The physical size and number of topological elements in a 100BASE-T network is limited primarily by round-trip collision delay. A network configuration has to be validated against collision delay using a net-

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

work model. Since there are a limited number of topology models for any 100BASE-T collision domain, the modeling process is quite straightforward and can easily be done either manually or with a spreadsheet.

The model proposed here is derived from the one presented in 13.4. Modifications have been made to accommodate adjustments for DTE, repeater, and cable speeds.

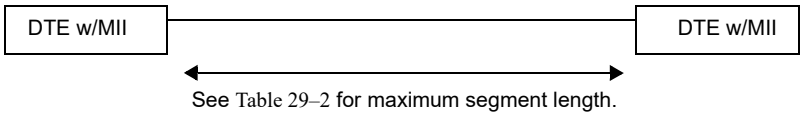

Figure 29–3—Model 1: Two DTEs, no repeater

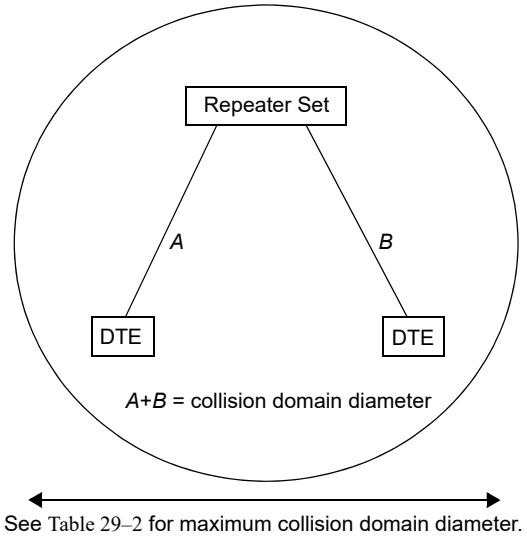

Figure 29–4—Model 1: Single repeater

Table 29–2—Maximum Model 1 collision domain diameter[a]

Model	Balanced cabling (copper)	Fiber	Balanced cabling & fiber (T2 or T4 and FX)	Balanced cabling & fiber (TX and FX)
DTE-DTE (see Figure 29–3)	100	412	NA	NA
One Class I repeater (see Figure 29–4)	200	272	231[a]	260.8[a]
One Class II repeater (see Figure 29–4)	200	320	304[b]	308.8[b]
Two Class II repeaters (see Figure 29–5)	205	228	236.3[c]	216.2[c]

[a]Assumes 100 m of balanced cabling and one fiber link.
[b]This entry included for completeness. It may be impractical to construct a T4 to FX class II repeater.
[c] Assumes 105 m of balanced cabling and one fiber link.

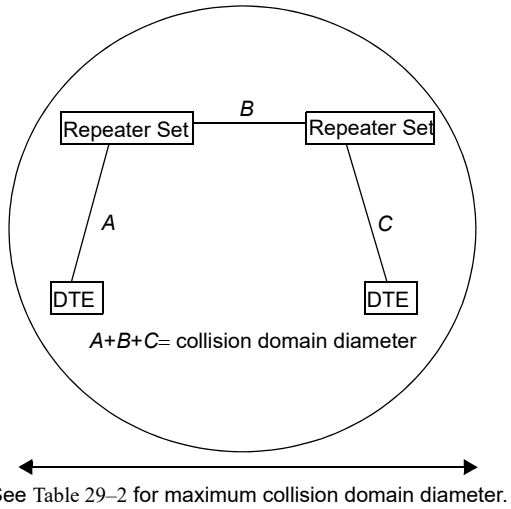

Figure 29–5—System Model 1: Two Class II repeaters

29.3.1 Round-trip collision delay

For a network to be valid, it has to be possible for any two DTEs on the network to contend for the network at the same time. Each station attempting to transmit has to be notified of the contention by the returned "collision" signal within the "collision window" (see 4.1.2.2 and 5.2.2.1.2). Additionally, the maximum length fragment created has to contain less than 512 bits after the start-of-frame delimiter (SFD). These requirements limit the physical diameter (maximum distance between DTEs) of a network. The maximum round-trip delay has to be qualified between all pairs of DTEs in the network. In practice this means that the qualification needs to be done between those that, by inspection of the topology, are candidates for the longest delay. The following network modeling methodology is provided to assist that calculation.

29.3.1.1 Worst-case path delay value (PDV) selection

The worst-case path through a network to be validated shall be identified by examination of aggregate DTE delays, cable delays, and repeater delays. The worst case consists of the path between the two DTEs at opposite ends of the network that have the longest round-trip time. Figure 29–6 and Figure 29–7 show schematic representations of one-repeater and two-repeater paths.

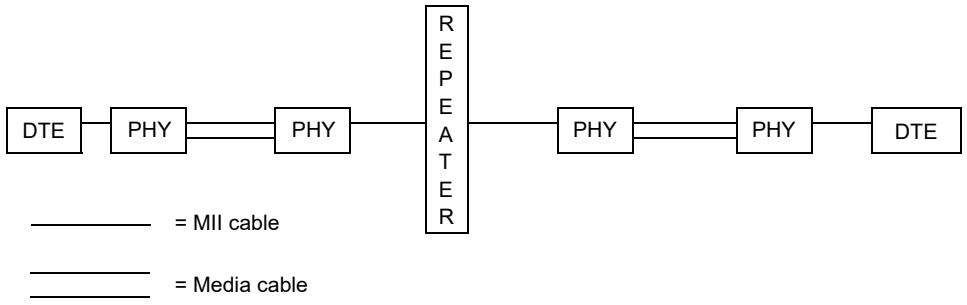

Figure 29–6—System Model 2: Single repeater

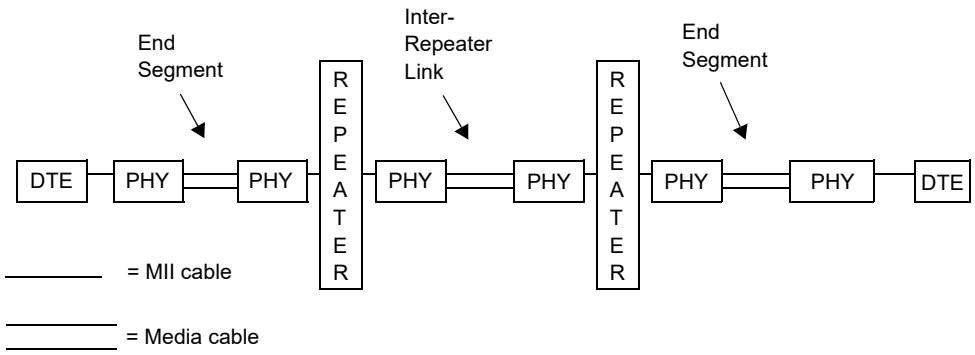

Figure 29–7—System Model 2-2: Two repeaters

29.3.1.2 Worst-case PDV calculation

Once a set of paths is chosen for calculation, each shall be checked for validity against the following formula:

$$PDV = \sum\text{link delays (LSDV)} + \sum\text{repeater delays} + \text{DTE delays} + \text{safety margin}$$

Values for the formula variables are determined by the following method:

a) Determine the delay for each link segment (Link Segment Delay Value, or LSDV), including inter-repeater links, using the formula

$$LSDV = 2 \text{ (for round-trip delay)} \times \text{segment length} \times \text{cable delay for this segment}$$

NOTE 1—Length is the sum of the cable lengths between the PHY interfaces at the repeater and the farthest DTE for End Segments plus the sum of the cable lengths between the repeater PHY interfaces for Inter-Repeater Links. All measurements are in meters.

NOTE 2—Cable delay is the delay specified by the manufacturer or the maximum value for the type of cable used as shown in Table 29–3. For this calculation, cable delay needs to be specified in bit times per meter (BT/m). Table 29–4 can be used to convert values specified relative to the speed of light (%c) or nanoseconds per meter (ns/m).

NOTE 3—When actual cable lengths or propagation delays are not known, use the Max delay in bit times as specified in Table 29–3 for copper cables. Delays for fiber should be calculated, as the value found in Table 29–3 will be too large for most applications.

b) Sum together the LSDVs for all segments in the path.

c) Determine the delay for each repeater in the path. If model-specific data are not available from the manufacturer, determine the class of each repeater (I or II) and enter the appropriate default value from Table 29–3.

d) MII cables for 100BASE-T shall not exceed 0.5 m each. When evaluating system topology, MII cable delays need not be accounted for separately. Delays attributable to the MII are incorporated into DTE and repeater component delays.

e) Use the DTE delay value shown in Table 29–3 unless your equipment manufacturer defines a different value.

f) Decide on appropriate safety margin—0 to 5 bit times—for the PDV calculation. Safety margin is used to provide additional margin to accommodate unanticipated delay elements, such as extra-long connecting cable runs between wall jacks and DTEs. (A safety margin of 4 BT is recommended.)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

g) Insert the values obtained through the calculations above into the following formula to calculate the PDV. (Some configurations may not use all the elements of the formula.)

PDV = ∑link delays (LSDV) + ∑repeater delays + DTE delay + safety margin

h) If the PDV is less than 512, the path is qualified in terms of worst-case delay.

i) Late collisions and/or CRC errors are indicators that path delays exceed 512 BT.

Table 29–3—Network component delays, Transmission System Model 2

Component	Round trip delay in bit times per meter	Maximum round trip delay in bit times
Two TX/FX DTEs		100
Two T4 DTEs		138
Two T2 DTEs		96
One T2 or T4 and one TX/FX DTE[a]		127
Cat 3 cabling segment	1.14	114 (100 m)
Cat 4 cabling segment	1.14	114 (100 m)
Cat 5 cabling segment	1.112	111.2 (100 m)
STP cabling segment	1.112	111.2 (100 m)
Fiber optic cabling segment	1.0	412 (412 m)
Class I repeater		140
Class II repeater with all ports TX/FX		92
Class II repeater with any port T4		67
Class II repeater with any port T2		90

[a] Worst-case values are used (TX/FX values for MAC transmit start and MDI input to collision detect; T4 value for MDI input to MDI output).

29.4 Full duplex 100 Mb/s topology limitations

Unlike half duplex CSMA/CD networks, the physical size of full duplex 100 Mb/s CSMA/CD networks is not limited by the round-trip collision propagation delay. Instead, the maximum link length between DTEs is limited only by the signal transmission characteristics of the specific cable, as specified in Table 29–5.

30. Management

30.1 Overview

This clause provides the Layer Management specification for DTEs, repeaters, MAUs, and Midspans based on the CSMA/CD access method. The clause is produced from the ISO framework additions to Clause 5, Layer Management; Clause 19, Repeater Management; and Clause 20, MAU Management. It incorporates additions to the objects, attributes, and behaviours to support 100 Mb/s, 1000 Mb/s and 10 Gb/s, full duplex operation, MAC Control, Link Aggregation, DTE Power via MDI, Power over Data Lines, subscriber access networks, and the Link Layer Discovery Protocol (LLDP) IEEE 802.3 Organizationally Specific TLVs. The objects, attributes, and behaviours to support Link Aggregation are deprecated by IEEE Std 802.1AX-2008.

The layout of this clause takes the same form as 5.1, 5.2, and Clause 19, and Clause 20, although with equivalent subclauses grouped together. It identifies a common management model and framework applicable to IEEE 802.3 managed elements, identifies those elements and defines their managed objects, attributes, and behaviours in a protocol-independent language.

This clause provides the Layer Management specification for DTEs, repeaters, and MAUs based on the CSMA/CD access method. It defines facilities composed of a set of statistics and actions needed to provide IEEE 802.3 Management services. The information in this clause should be used in conjunction with the Procedural Model defined in 4.2.7 through 4.2.10. The Procedural Model provides a formal description of the relationship between the CSMA/CD Layer Entities and the Layer Management facilities.

This management specification has been developed in accordance with the OSI management architecture as specified in the ISO Management Framework document, ISO/IEC 7498-4:1989. It is independent of any particular management application or management protocol.

The management facilities defined in this standard may be accessed both locally and remotely. Thus, the Layer Management specification provides facilities that can be accessed from within a station or can be accessed remotely by means of a peer-management protocol operating between application entities.

In CSMA/CD no peer management facilities are necessary for initiating or terminating normal protocol operations or for handling abnormal protocol conditions. Since these activities are subsumed by the normal operation of the protocol, they are not considered to be a function of Layer Management and are, therefore, not discussed in this clause.

Implementation of part or all of Layer Management is not a requirement for conformance to any other clause of this standard.

The intent of this standard is to furnish a management specification that can be used by the wide variety of different devices that may be attached to an Ethernet network. Thus, a comprehensive list of management facilities is provided.

The improper use of some of the facilities described in this clause may cause serious disruption of the network. In accordance with ISO management architecture, any necessary security provisions should be provided by the Agent in the Local System Environment. This can be in the form of specific security features or in the form of security features provided by the peer communication facilities.

The device that connects directly to the media is called MAU for 10 Mb/s operation and its equivalent is the combined PMA and PMD sublayers at higher operating speeds. Because this clause defines management for use at many speeds, it needs to be able to refer to MAUs and the PMA and PMD sublayer combination as a group. Therefore, in this clause, the term MAU will include PMA and PMD sublayers as well as MAUs, except in those instances where it is explicitly restricted to 10 Mb/s.

30.1.1 Scope

This clause includes selections from Clause 5, Clause 19, and Clause 20. It is intended to be an entirely equivalent specification for the management of 10 Mb/s DTEs, 10 Mb/s baseband repeater units, and 10 Mb/s integrated MAUs. It incorporates additions to the objects, attributes, and behaviours to support subsequent additions to this standard. Implementations of management for DTEs, repeater units, and embedded MAUs should follow the requirements of this clause (e.g., a 10 Mb/s implementation should incorporate the attributes to indicate that it is not capable of 100 Mb/s or 1000 Mb/s operation; half duplex DTE should incorporate the attributes to indicate that it is not capable of full duplex operation, etc.).

For 10 Mb/s ports without integral MAUs, attributes are provided for characteristics observable from the AUI of the connected DTE or repeater. Direct management of AUI MAUs that are external to their respective DTEs or repeaters is beyond the scope of this standard.

The managed objects within this standard are defined in terms of their behaviour, attributes, actions, notifications, and packages in accordance with IEEE 802.1 and ISO standards for network management. Managed objects are grouped into mandatory and optional packages.

This specification is defined to be independent of any particular management application or management protocol. The means by which the managed objects defined in this standard are accessed is beyond the scope of this standard.

30.1.2 Relationship to objects in IEEE 802.1F

The following managed object classes, if supported by an implementation, shall be as specified in IEEE Std 802.1F-1993 (withdrawn): ResourceTypeID, EWMAMetricMonitor.

oResourceTypeID

This object class is mandatory and shall be implemented as defined in IEEE 802.1F. This object is bound to oMAC-Entity, oRepeater, oMidSpan, and oMAU as defined by the NAMEBINDINGs. Note that the binding to oMAU is mandatory only when MII is present. The Entity Relationship Diagrams, Figure 30–3, Figure 30–4, and Figure 30–5 show these bindings pictorially.

oEWMAMetricMonitor

This object class is optional. When implemented, it shall be implemented as defined in IEEE 802.1F, subject to the specific requirements described below. This object is bound to system as defined by the NAMEBINDINGs.

Implementations of IEEE 802.3 Management that support the oEWMAMetricMonitor managed object class are required to support values of granularity period as small as one second. Implementations are required to support at least one sequence of low and high thresholds. The granularity period may be set to equal to the moving time period as a minimal conformant implementation.

30.1.3 Systems management overview

Within the ISO Open Systems Interconnection (OSI) architecture, the need to handle the special problems of initializing, terminating, and monitoring ongoing activities and assisting in their operations, as well as handling abnormal conditions, is recognized. These needs are collectively addressed by the systems management component of the OSI architecture.

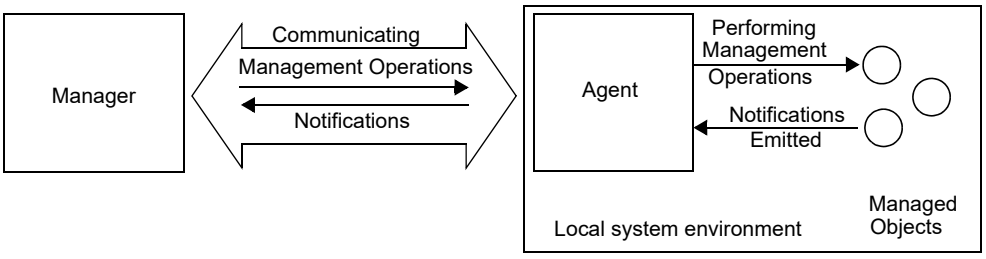
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A management protocol is required for the exchange of information between systems on a network. This management standard is independent of any particular management protocol.



This management standard, in conjunction with the management standards of other layers, provides the means to perform various management functions. IEEE 802.3 Management collects information needed from the MAC and Physical Layers and the devices defined in IEEE 802.3. It also provides a means to exercise control over those elements.

The relationship between the various management entities and the layer entities according to the ISO model is shown in Figure 30–1.

30.1.4 Management model

This standard describes management of DTEs, repeaters, and integrated MAUs in terms of a general model of management of resources within the open systems environment. The model, which is described in ISO/IEC 10040:1992, is briefly summarized here.

Management is viewed as a distributed application modeled as a set of interacting management processes. These processes are executed by systems within the open environment. A managing system executes a managing process that invokes management operations. A managed system executes a process that is receptive to these management operations and provides an interface to the resources to be managed. A managed object is the abstraction of a resource that represents its properties as seen by (and for the purpose of) management. Managed objects respond to a defined set of management operations. Managed objects are also capable of emitting a defined set of notifications. This interaction of processes is shown in Figure 30–1.

NOTE—This figure is drawn from Figure 1 of ISO/IEC 10040:1992, Information technology—Open Systems Interconnection—Systems management overview. In the event of any conflict, the depiction in ISO/IEC 10040:1992 takes precedence.

Figure 30–1—Interaction between manager, agent, and objects

A managed object is a management view of a resource. The resource may be a logical construct, function, physical device, or anything subject to management. Managed objects are defined in terms of four types of elements:

a) *Attributes.* Data-like properties (as seen by management) of a managed object.
b) *Actions.* Operations that a managing process may perform on an object or its attributes.
c) *Notifications.* Unsolicited reports of events that may be generated by an object.
d) *Behaviour.* The way in which managed objects, attributes, and actions interact with the actual resources they model and with each other.

The above items are defined in 30.3 through 30.16.1 of this clause in terms of the template requirements of ISO/IEC 10165-4:1991.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Some of the functions and resources within IEEE 802.3 devices are appropriate targets for management. They have been identified by specifying managed objects that provide a management view of the functions or resources. Within this general model, the IEEE 802.3 device is viewed as a managed device. It performs functions as defined by the applicable standard for such a device. Managed objects providing a view of those functions and resources appropriate to the management of the device are specified. The purpose of this standard is to define the object classes associated with the devices in terms of their attributes, operations, notifications, and behaviour.

30.2 Managed objects

30.2.1 Introduction

This clause identifies the Managed Object classes for IEEE 802.3 components within a managed system. It also identifies which managed objects and packages are applicable to which components.

All counters defined in this specification are assumed to be wrap-around counters. Wrap-around counters are those that automatically go from their maximum value (or final value) to zero and continue to operate. These unsigned counters do not provide for any explicit means to return them to their minimum (zero), i.e., reset. Because of their nature, wrap-around counters should be read frequently enough to avoid loss of information. When a counter has a maximum increment rate specified at one speed of operation, and that counter is appropriate to a higher speed of operation, then the maximum increment rate at that higher speed of operation is

$$\text{maximum increment rate specified} \times \left(\frac{\text{higher speed of operation in Mb/s}}{\text{specified speed of operation in Mb/s}} \right) \tag{30–1}$$

unless otherwise indicated.

30.2.2 Overview of managed objects

Managed objects provide a means to

— Identify a resource
— Control a resource
— Monitor a resource

30.2.2.1 Text description of managed objects

In case of conflict, the formal behaviour definitions in 30.3, 30.4, 30.5, 30.6, and 30.7 take precedence over the text descriptions in this subclause.

oAggPortDebugInformation

If oAggregator is implemented, a single instance of oAggPortDebugInformation may be contained within oAggregationPort. This managed object class provides optional additional information that can assist with debugging and fault finding in Systems that support Link Aggregation.

NOTE—This object is deprecated by IEEE Std 802.1AX-2008.

oAggPortStats

If oAggregator is implemented, a single instance of oAggPortStats may be contained within oAggregationPort. This managed object class

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

provides optional additional statistics related to LACP and Marker protocol activity on an instance of an Aggregation Port that is involved in Link Aggregation.

NOTE—This object is deprecated by IEEE Std 802.1AX-2008.

oAggregationPort If oAggregator is implemented, oAggregationPort is contained within oAggregator. An instance of this managed object class is present for each Aggregation Port that is part of the aggregation represented by the oAggregator instance. This managed object class provides the basic management controls necessary to allow an instance of an Aggregation Port to be managed, for the purposes of Link Aggregation.

NOTE—This object is deprecated by IEEE Std 802.1AX-2008.

oAggregator If implemented, oAggregator is the top-most managed object class of the DTE containment tree shown in Figure 30–4. Note that this managed object class may be contained within another superior managed object class. Such containment is expected, but is outside the scope of this International Standard. The oAggregator managed object class provides the management controls necessary to allow an instance of an Aggregator to be managed.

NOTE—This object is deprecated by IEEE Std 802.1AX-2008.

oAutoNegotiation The managed object of that portion of the containment trees shown in Figure 30–4 and Figure 30–5. The attributes, notifications, and actions defined in 30.6 are contained within the MAU managed object.

oGroup The group managed object class is a view of a collection of repeater ports.

oEXTENSION If implemented, oEXTENSION is contained within oMACControlEntity. The oEXTENSION managed object class provides the management controls necessary to allow an instance of the MAC Control EXTENSION function to be managed.

oLldpXdot3Config The top-most managed object class of the Link Layer Discovery Protocol (LLDP) containment tree shown in Figure 30–6. Note that this managed object class may be contained within another superior managed object class. Such containment is expected, but is outside the scope of this standard.

oLldpXdot3LocSystemsGroup
If oLldpXdot3Config is implemented, a single instance of oLldpXdot3LocSystemsGroup may be contained within oLldpXdot3Config. This managed object class provides the LLDP local system information.

oLldpXdot3RemSystemsGroup
If oLldpXdot3Config is implemented, a single instance of oLldpXdot3RemSystemsGroup may be contained within oLldpXdot3Config. This managed object class provides the LLDP remote system information.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

oMACControlEntity If implemented, and if oOAM is implemented, a single instance of oMACControlEntity is contained within oOAM. Otherwise, if implemented, and if oAggregator is implemented, oMACControlEntity is contained within oAggregator. Otherwise, if implemented, oMACControlEntity becomes the top-most managed object class of the DTE containment tree shown in Figure 30–4. Note that this managed object class may be contained within another superior managed object class. Such containment is expected, but is outside the scope of this International Standard.

oMACControlFunctionEntity
If implemented, oMACControlFunctionEntity is contained within oMACControlEntity. The oMACControlFunctionEntity managed object class provides the management controls necessary to allow an instance of the MAC Control PAUSE function to be managed.

oMACEntity If oMACControlEntity is implemented, oMACEntity is contained within oMACControlEntity. Otherwise, if oOAM is implemented, oMACEntity is contained within oOAM. Otherwise, if oAggregator is implemented, oMACEntity is contained within oAggregator. Otherwise, oMACEntity becomes the top-most managed object class of the DTE containment tree shown in Figure 30–3. Note that this managed object class may be contained within another superior managed object class. Such containment is expected, but is outside the scope of this International Standard. If oMACMergeEntity is implemented, the oMACEntity for the express MAC (eMAC) and the oMACEntity for the preemptable MAC (pMAC) are connected to an instance of oMACMergeEntity.

oMACMergeEntity If implemented, a single instance of oMACMergeEntity is contained within oMACEntity for an express MAC (eMAC) and oMACEntity for a preemptable MAC (pMAC) (see Clause 99). oMACMergeEntity managed object class provides the management controls necessary for the MAC Merge sublayer.

oMAU The managed object of that portion of the containment trees shown in Figure 30–3 and Figure 30–4. The attributes, notifications, and actions defined in 30.5 are contained within the MAU managed object. Neither counter values nor the value of MAUAdminState is required to be preserved across events involving the loss of power.

oMidSpan The top-most managed object class of the Midspan containment tree shown in Figure 30–5. Note that this managed object class may be contained within another superior managed object class. Such containment is expected, but is outside the scope of this standard.

oMPCP If implemented, oMPCP is contained within oMACControlEntity. The oMPCP managed object class provides the management controls necessary to allow an instance of the Multipoint MAC Control function to be managed.

oOAM If implemented, and if oAggregator is implemented, oOAM is contained within oAggregator. An instance of this managed object class is present for each Aggregation Port that is part of the aggregation represented by the oAggregator instance. Otherwise, if implemented, oOAM becomes the top-most managed object class of the DTE containment tree shown in Figure 30–3. Note that this managed object class may be contained

within another superior managed object class. Such containment is expected, but is outside the scope of this International Standard.

oOMPEmulation If implemented, oOMPEmulation is contained within oMACEntity. The oOMPEmulation managed object class provides the management controls necessary to allow an instance of an OMPEmulation sublayer to be managed.

oPHYEntity If oOMPEmulation is implemented, oPHYEntity is contained within oOMPEmulation. If oMACMergeEntity is implemented, oPHYEntity is contained within oMACMergeEntity. Otherwise oPHYEntity is contained within oMACEntity. Many instances of oPHYEntity may coexist within one instance of oMACEntity or oMACMergeEntity; however, only one PHY may be active for data transfer to and from the MAC at any one time. oPHYEntity is the managed object that contains the MAU, PAF, PLCA, PSE, and PoDLPSE managed objects in a DTE.

oPAF The oPAF managed object class provides the management controls necessary to allow an instance of a PME aggregation function (PAF) to be managed. The PAF managed object class also provides a view of a collection of PMEs.

oPLCA If implemented, oPLCA is contained within oPHYEntity. The oPLCA managed object class provides the management controls necessary to allow an instance of a PLCA RS to be managed.

oPME The oPME managed object class provides the management controls necessary to allow an instance of a PME to be managed. The oPAF managed object contains the PME managed object in a DTE.

oPoDLPSE The managed object of that portion of the containment trees shown in Figure 30–3. The attributes, notifications, and actions defined in 30.15 are contained within the PoDLPSE managed object.

oPSE The managed object of that portion of the containment trees shown in Figure 30–3, Figure 30–4, and Figure 30–5. This managed object class provides the attributes, actions, and notifications required for management of a PD system.

oPSEGroup The PSE Group managed object class is a view of a collection of PSEs.

oRepeater The top-most managed object class of the repeater containment tree shown in Figure 30–4. Note that this managed object class may be contained within another superior managed object class. Such containment is expected, but is outside the scope of this standard.

oRepeaterMonitor A managed object class called out by IEEE Std 802.1F-1993. See 30.1.2, oEWMAMetricMonitor.

oRepeaterPort The repeater port managed object class provides a view of the functional link between the data transfer service and a single PMA. The attributes associated with repeater port deal with the monitoring of traffic being handled by the repeater from the port and control of the operation of the port. The Port Enable/Disable function as reported by portAdminState is preserved across events involving loss of power. The oRepeaterPort managed object contains the MAU managed object in a repeater set.

NOTE—Attachment to nonstandard PMAs is outside the scope of this standard.

oResourceTypeID	A managed object class called out by IEEE Std 802.1F-1993. It is used within this clause to identify manufacturer, product, and revision of managed components that implement functions and interfaces defined within IEEE 802.3. The Clause 22 MII or Clause 35 GMII specifies two registers to carry PHY Identifier (22.2.4.3.1), which provides succinct information sufficient to support oResourceTypeID.
oTimeSync	If implemented, oTimeSync is contained within oPHYEntity. The oTimeSync managed object class provides the controls neccessary to manage the instance of the TimeSync function.
oWIS	The managed object of that portion of the containment tree shown in Figure 30–3. The attributes defined in 30.8 are contained within the oMAU managed object.

30.2.2.2 Functions to support management

Functions are defined in other clauses that facilitate managed operation. The functions in other clauses that facilitate managed operation are referenced from the text of this management clause.

30.2.2.2.1 DTE MAC sublayer functions

A hierarchical order has been established for DTE MAC reception-related error statistics such that, when multiple error statuses can be associated with one frame, only one status is returned to the upper client sublayer. This hierarchy in descending order is as follows:

— frameTooLong
— alignmentError
— frameCheckError
— lengthError

The counters are primarily incremented based on the status returned to the MAC client; therefore, the hierarchical order of the counters is determined by the order of the status. Frame fragments are not included in any of the statistics unless otherwise stated. In implementing any of the specified actions, receptions and transmissions that are in progress are completed before the action takes effect.

30.2.2.2.2 Repeater functions

The Repeater Port Object class contains seven functions which are defined in this clause and are used to collect statistics on the activity received by the port. The relationship of the functions to the repeater port and to the port attributes is shown in Figure 30–2.

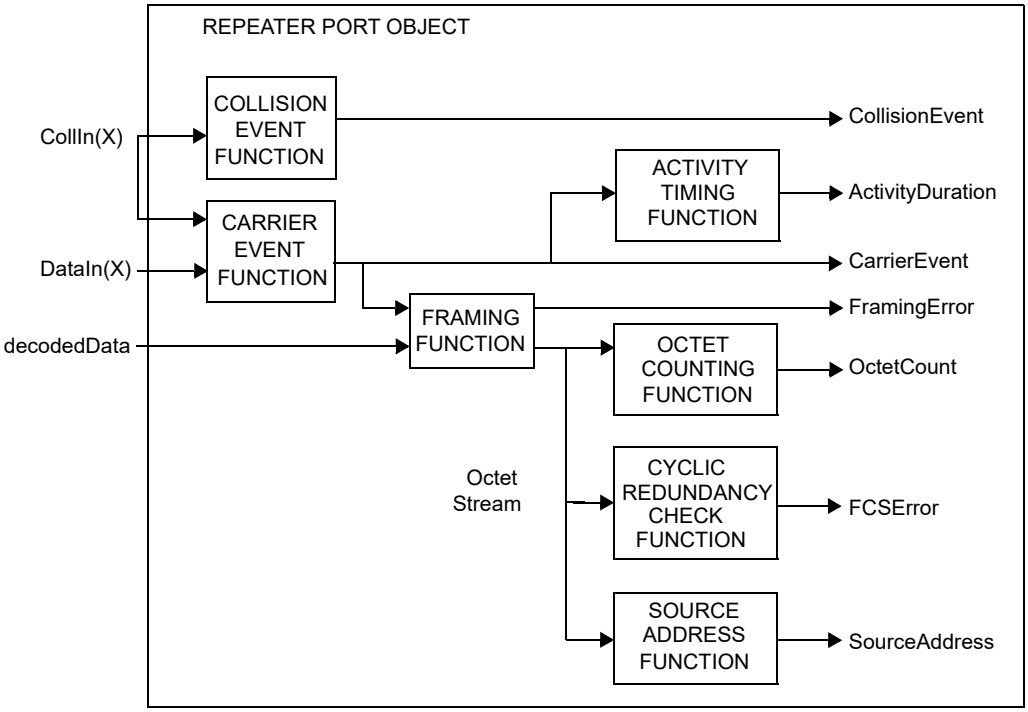

Figure 30–2—Functions relationship

Activity Timing function

The Activity Timing function measures the duration of the assertion of the CarrierEvent signal. For 10 Mb/s repeaters, this duration value has to be adjusted by removing the value of Carrier Recovery Time (see 9.5.6.5) to obtain the true duration of activity on the network. The output of the Activity Timing function is the ActivityDuration value, which represents the duration of the CarrierEvent signal as expressed in units of bit times.

Carrier Event function

For 10 Mb/s repeaters the Carrier Event function for port N asserts the CarrierEvent signal when the repeater exits the IDLE state (see Figure 9–2) and the port has been determined to be port N. It deasserts the CarrierEvent signal when, for a duration of at least Carrier Recovery Time (see 9.5.6.5), both the DataIn(N) variable has the value II and the CollIn(N) variable has the value –SQE. The value N is the port assigned at the time of transition from the IDLE state. For 100 and 1000 Mb/s repeaters the Carrier Event function for port N asserts the CarrierEvent signal when the repeater exits the IDLE state of the repeater state diagram (Figure 27–2 and Figure 41–2) and the port has been determined to be port N. The Carrier Event function for Port N deasserts the CarrierEvent signal when the repeater enters the IDLE state of the repeater state diagram (Figure 27–2 and Figure 41–2).

Collision Event function

The Collision Event function asserts the CollisionEvent signal when a

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

collision is detected at a repeater port. For a 10 Mb/s repeater port this is indicated by the CollIn(X) variable having the value SQE. For a 100 and 1000 Mb/s repeater port this is indicated by entering the COLLISION COUNT INCREMENT state of the partition state diagram (Figure 27–8 and Figure 41–4). The CollisionEvent signal remains asserted until the assertion of any CarrierEvent signal due to the reception of the following event.

Cyclic Redundancy Check function

The Cyclic Redundancy Check function verifies that the sequence of octets output by the Framing function contains a valid Frame Check Sequence Field. The Frame Check Sequence Field is the last four octets received from the output of the Framing function. The algorithm for generating an FCS from the octet stream is specified in 3.2.9. If the FCS generated according to this algorithm is not the same as the last four octets received from the Framing function, then the FCSError signal is asserted. The FCSError signal is cleared and the Cyclic Redundancy Check function is reinitialized upon the assertion of the CarrierEvent signal due to the reception of the following event and, additionally in the case of a frame burst on a 1000 Mb/s network, upon the recognition of a valid Start of Packet delimiter (see 35.2.3.6), once the duration of the CarrierEvent is greater than or equal to slotTime.

Framing function

The Framing function recognizes the boundaries of an incoming frame by monitoring the CarrierEvent signal and the decoded data stream. Data bits are accepted while the CarrierEvent signal is asserted. The framing function delineates frames by stripping the Start of Packet delimiter (see 35.2.3.6), preamble, Start of frame delimiter, End of Packet delimiter (see 35.2.3.6), and any Carrier Extend from the received data stream. The remaining bits of each frame are aligned along octet boundaries. If there is not an integral number of octets, then FramingError shall be asserted. The FramingError signal is cleared upon the assertion of the CarrierEvent signal due to the reception of the following event. For 1000 Mb/s repeaters, the data stream shall continue until the end of the CarrierEvent signal or upon the recognition of a valid Start of Packet delimiter once the duration of the CarrierEvent is greater than or equal to slotTime. Such a Start of Packet delimiter will begin a new data stream.

Octet Counting function

The Octet Counting function counts the number of complete octets received from the output of the framing function. The output of the octet counting function is the OctetCount value. The OctetCount value is reset to zero upon the assertion of the CarrierEvent signal due to the reception of the following event and, additionally in the case of a frame burst on a 1000 Mb/s network, upon the recognition of a valid Start of Packet delimiter (see 35.2.3.6), once the duration of the CarrierEvent is greater than or equal to slotTime.

Source Address function

The Source Address function extracts octets from the stream output by the framing function. The seventh through twelfth octets shall be extracted from the octet stream and output as the SourceAddress variable. The SourceAddress variable is set to an invalid state upon the

assertion of the CarrierEvent signal due to the reception of the following event and, additionally in the case of a frame burst on a 1000 Mb/s network, upon the recognition of a valid Start of Packet delimiter (see 35.2.3.6), once the duration of the CarrierEvent is greater than or equal to slotTime.

30.2.3 Containment

A containment relationship is a structuring relationship for managed objects in which the existence of a managed object is dependent on the existence of a containing managed object. The contained managed object is said to be the subordinate managed object, and the containing managed object the superior managed object. The containment relationship is used for naming managed objects. The local containment relationships among object classes are depicted in the entity relationship diagrams, Figure 30–3 through Figure 30–6. These figures show the names of the object classes and whether a particular containment relationship is one-to-one, one-to-many or many-to-one. For further requirements on this topic, see IEEE Std 802.1F-1993. PSE and PoDL PSE management are only valid in a system that provides management at the next higher containment level, that is, either a DTE, or in the case of PSE management only, a repeater or Midspan with management.

MAU management is only valid in a system that provides management at the next higher containment level, that is, either a DTE or repeater with management.

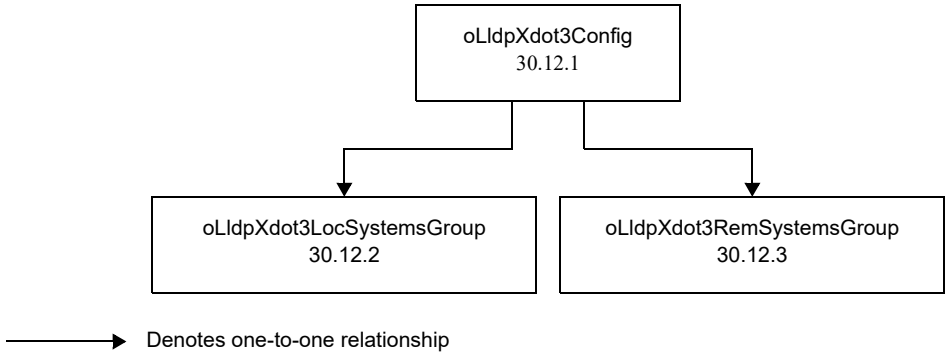

Figure 30–6—Link Layer Discovery Protocol entity relationship diagram

30.2.4 Naming

The name of an individual managed object is hierarchically defined within a managed system. For example, in the context of repeater management, a repeater port might be identified as "repeater 3, group 01, port 13," that is, port 13 of group 01 of a repeater with repeaterID 3 within the managed system.

In the case of MAU management, this will present itself in one of the two forms that are appropriate for a MAU's use, that is, as associated with a CSMA/CD interface of a DTE or with a particular port of a managed repeater. For example, a MAU could be identified as "repeater 3, group 01, port 13, MAU 1" or, that is, the MAU associated with port 13 of group 01 of a repeater with repeaterID 3 within the managed system. Examples of this are represented in the relationship of the naming attributes in the entity relationship diagram, Figure 30–3.

30.2.5 Capabilities

This standard makes use of the concept of *packages* as defined in ISO/IEC 10165-4:1992 as a means of grouping behaviour, attributes, actions, and notifications within a managed object class definition. Packages may either be mandatory, or be conditional, that is to say, present if a given condition is true. Within this standard *capabilities* are defined, each of which corresponds to a set of packages, which are components of a number of managed object class definitions and which share the same condition for presence. Implementation of the appropriate Basic and Mandatory packages is the minimum requirement for claiming conformance to IEEE 802.3 Management. Implementation of an entire optional capability is required in order to claim conformance to that capability. The capabilities and packages for IEEE 802.3 Management are specified in Table 30–1a through Table 30–11.

DTE Management has two packages that are required for management at the minimum conformance configuration—the Basic Package and the Mandatory Package. Systems that implement the optional MAC Control sublayer shall also implement the Basic and Mandatory Packages for the MAC Control Entity managed object class to claim DTE minimum conformance. For systems that include multiple PHY entities per MAC entity and implement the Multiple PHY Package to manage the selection of the active PHY, the optional Recommended Package shall be implemented. Systems that implement the optional Link Aggregation sublayer shall also implement the Basic and Mandatory Packages for the Aggregator and Aggregation Port managed object class to claim minimum DTE conformance.

For managed MAUs, the Basic Package is mandatory; all other packages are optional. For a managed MAU to be conformant to this standard, it shall fully implement the Basic Package. For a MAU to be conformant to an optional package it shall implement that entire package. While nonconformant (reference aMAUType

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

= “other”) MAUs may utilize some or all of this clause to specify their management, conformance to this clause requires both a conformant MAU and conformant management. MAU Management is optional with respect to all other CSMA/CD Management. If an MII is present then the conditional MII Capability has to be implemented. This provides the means to identify the vendor and type of the externally connected device.

There are two distinct aspects of Repeater Management.

The first aspect provides the means to monitor and control the functions of a repeater. These functions include, but are not limited to: identifying a repeater, testing and initializing a repeater, and enabling/disabling a port. This is encompassed by the mandatory Basic Control Capability.

The second aspect provides the means to monitor traffic from attached segments, and to measure traffic sourced by DTEs connected to these segments. This is done by gathering statistics on packets that enter a repeater and maintaining those statistics on a per port basis. This is encompassed by the optional Performance Monitor Capability. The optional Address Tracking Capability provides the means to identify existence and movement of attached DTEs by their MAC addresses. While nonconformant (reference aRepeaterType = “other”) repeaters may utilize some or all of this clause to specify their management, conformance to this clause requires both a conformant repeater and conformant management.

If link Auto-Negotiation is present and managed, the Auto-Negotiation managed object class shall be implemented in its entirety. All attributes and actions are mandatory.

The 1000 Mb/s Burst Monitor Capability provides additional attributes that relate only to 1000 Mb/s operation, while the 100 Mb/s Monitor Capability has attributes that apply to a mixed 100 and 1000 Mb/s operation. These attributes are provided to complement the counter attributes of the optional packages and capabilities that apply to 10 Mb/s and mixed 10, 100, and 1000 Mb/s implementations. It is recommended that when the 100/1000 Mb/s Monitor Capability or 1000 Mb/s Burst Monitor Capability is implemented, the appropriate complementary counter packages and capabilities are also implemented.

For managed PSEs, the PSE Basic Package is mandatory and the PSE Recommended Package is optional. For managed PoDL PSEs, the PoDLPSE Basic Package is mandatory and the PoDLPSE Recommended Package is optional. For managed PDs, the PD Basic Package is mandatory. For a managed PSE to be conformant to this standard, it shall fully implement the PSE Basic Package. For a managed PoDL PSE to be conformant to this standard, it shall fully implement the PoDLPSE Basic Package. For a managed PD to be conformant to this standard, it shall fully implement the PD Basic Package. For a managed PSE to be conformant to the optional Recommended Package it shall implement that entire package. For a managed PoDL PSE to be conformant to the optional PoDL PSE Recommended Package it shall implement that entire package. PSE, PD, PoDL PSE, and PoDL PD management is optional with respect to all other CSMA/CD management.

For managed Midspans, the Midspan managed object class shall be implemented in its entirety. All attributes and notifications are mandatory. Midspan management is optional with respect to all other CSMA/CD management.

For LLDP management, the LLDP Basic Package is mandatory. All other LLDP packages are conditional on the IEEE 802.3 Organizationally Specific TLVs supported and the LLDP operating mode (see IEEE Std 802.1AB, Clause 10).

LLDP MAC/PHY Configuration/Status Local Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “MAC/PHY Configuration/Status” and are either in LLDP transmit only mode or in LLDP transmit and receive mode. LLDP MAC/PHY Config/Status Remote Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “MAC/PHY Configuration/Status” and are either in LLDP receive only mode or in LLDP transmit and receive mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

LLDP Power via MDI Local Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “Power via MDI” and are either in LLDP transmit only mode or in LLDP transmit and receive mode. LLDP Power via MDI Remote Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “Power via MDI” and are either in LLDP receive only mode or in LLDP transmit and receive mode.

LLDP Link Aggregation Local Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “Link Aggregation” and are either in LLDP transmit only mode or in LLDP transmit and receive mode. LLDP Link Aggregation Remote Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “Link Aggregation” and are either in LLDP receive only mode or in LLDP transmit and receive mode.

LLDP Max Frame Size Local Package is mandatory for managed entities that support IEEE 802.3 Organizationally Specific TLV named “Max Frame Size” and are either in LLDP transmit only mode or in LLDP transmit and receive mode. LLDP Max Frame Size Remote Package is mandatory for managed entities that IEEE 802.3 Organizationally Specific TLV named “Max Frame Size” and are either in LLDP receive only mode or in LLDP transmit and receive mode. (See Table 30–7.)

30.3 Layer management for DTEs

30.3.1 MAC entity managed object class

This subclause formally defines the behaviours for the oMACEntity managed object class attributes, actions, and notifications.

30.3.1.1 MAC entity attributes

30.3.1.1.1 aMACID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aMACID is assigned so as to uniquely identify a MAC among the subordinate managed objects of the containing object.;

30.3.1.1.2 aFramesTransmittedOK

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
A count of frames that are successfully transmitted. This counter is incremented when the TransmitStatus is reported as transmitOK. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2).;

30.3.1.1.3 aSingleCollisionFrames

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 13 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
A count of frames that are involved in a single collision, and are subsequently transmitted successfully. This counter is incremented when the result of a transmission is reported as transmitOK and the attempt value is 2. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.4 aMultipleCollisionFrames

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 11 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
A count of frames that are involved in more than one collision and are subsequently transmitted

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

successfully. This counter is incremented when the TransmitStatus is reported as transmitOK and the value of the attempts variable is greater than 2 and less or equal to attemptLimit. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.5 aFramesReceivedOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames that are successfully received (receiveOK). This does not include frames received with frame-too-long, FCS, length or alignment errors, or frames lost due to internal MAC sublayer error. This counter is incremented when the ReceiveStatus is reported as receiveOK. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).;

30.3.1.1.6 aFrameCheckSequenceErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of receive frames that are an integral number of octets in length and do not pass the FCS check. This does not include frames received with frame-too-long, or frame-too-short (frame fragment) error. This counter is incremented when the ReceiveStatus is reported as frameCheckError. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).

NOTE—Coding errors detected by the Physical Layer for speeds above 10 Mb/s will cause the frame to fail the FCS check.;

30.3.1.1.7 aAlignmentErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames that are not an integral number of octets in length and do not pass the FCS check. This counter is incremented when the ReceiveStatus is reported as alignmentError. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3). This counter will not increment for group encoding schemes encoding greater than 4 bits per group.;

30.3.1.1.8 aOctetsTransmittedOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 230 000 counts per second at 10 Mb/s

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A count of data and padding octets of frames that are successfully transmitted. This counter is incremented when the TransmitStatus is reported as transmitOK. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2).;

30.3.1.1.9 aFramesWithDeferredXmissions

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 13 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames whose transmission was delayed on its first attempt because the medium was busy. This counter is incremented when the Boolean variable deferred has been asserted by the TransmitLinkMgmt function (4.2.8). Frames involved in any collisions are not counted. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.10 aLateCollisions

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of the times that a collision has been detected later than one slotTime from the start of the packet transmission. A late collision is counted twice, i.e., both as a collision and as a lateCollision. This counter is incremented when the lateCollisionCount variable is nonzero. The actual update is incremented in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.11 aFramesAbortedDueToXSColls

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 3255 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of the frames that, due to excessive collisions, are not transmitted successfully. This counter is incremented when the value of the attempts variable equals attemptLimit during a transmission. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.12 aFramesLostDueToIntMACXmitError

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 75 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A count of frames that would otherwise be transmitted by the station, but could not be sent due to an internal MAC sublayer transmit error. If this counter is incremented, then none of the other counters in this section are incremented. The exact meaning and mechanism for incrementing this counter is implementation dependent.;

30.3.1.1.13 aCarrierSenseErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of times that the carrierSense variable was not asserted or was deasserted during the transmission of a frame without collision. This counter is incremented when the carrierSenseFailure flag is true at the end of transmission. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.14 aOctetsReceivedOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 230 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of data and padding octets in frames that are successfully received. This does not include octets in frames received with frame-too-long, FCS, length or alignment errors, or frames lost due to internal MAC sublayer error. This counter is incremented when the result of a reception is reported as a receiveOK status. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).;

30.3.1.1.15 aFramesLostDueToIntMACRcvError

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames that would otherwise be received by the station, but could not be accepted due to an internal MAC sublayer receive error. If this counter is incremented, then none of the other counters in this section are incremented. The exact meaning and mechanism for incrementing this counter is implementation dependent.;

30.3.1.1.16 aPromiscuousStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A GET operation returns the value “true” for promiscuous mode enabled, and “false” otherwise.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Frames without errors received solely because this attribute has the value “true” are counted as frames received correctly; frames received in this mode that do contain errors update the appropriate error counters.

A SET operation to the value “true” provides a means to cause the LayerMgmtRecognizeAddress function to accept frames regardless of their destination address.

A SET operation to the value “false” causes the MAC sublayer to return to the normal operation of carrying out address recognition procedures for station, broadcast, and multicast group addresses (LayerMgmtRecognizeAddress function).;

30.3.1.1.17 aReadMulticastAddressList

ATTRIBUTE

APPROPRIATE SYNTAX:
SEQUENCE OF MAC addresses

BEHAVIOUR DEFINED AS:
The current multicast address list.;

30.3.1.1.18 aMulticastFramesXmittedOK

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
A count of frames that are successfully transmitted, as indicated by the status value transmitOK, to a group destination address other than broadcast. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2).;

30.3.1.1.19 aBroadcastFramesXmittedOK

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
A count of the frames that were successfully transmitted as indicated by the TransmitStatus transmitOK, to the broadcast address. Frames transmitted to multicast addresses are not broadcast frames and are excluded. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2).;

30.3.1.1.20 aFramesWithExcessiveDeferral

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 412 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A count of frames that deferred for an excessive period of time. This counter may only be incremented once per upper client sublayer transmission. This counter is incremented when the excessDefer flag is set. The actual update occurs in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode and also when connected to a PHY utilizing the MAC-PHY Rate Matching defined in 61.2.1.1.;

30.3.1.1.21 aMulticastFramesReceivedOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames that are successfully received and are directed to an active nonbroadcast group address. This does not include frames received with frame-too-long, FCS, length or alignment errors, or frames lost due to internal MAC sublayer error. This counter is incremented as indicated by the receiveOK status, and the value in the destinationField. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).;

30.3.1.1.22 aBroadcastFramesReceivedOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames that are successfully received and are directed to the broadcast group address. This does not include frames received with frame-too-long, FCS, length or alignment errors, or frames lost due to internal MAC sublayer error. This counter is incremented as indicated by the receiveOK status, and the value in the destinationField. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).;

30.3.1.1.23 aInRangeLengthErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC frames received with a Length/Type field (see 3.2.6) value between the minimum MAC client data size that does not require padding and maxBasicDataSize (see 4.2.7.1) inclusive, that does not match the number of data octets received. The counter also increments for frames whose Length/Type field value is less than the minimum allowed MAC client data size that does not require padding and the number of data octets received is greater than the minimum MAC client data size that does not require padding. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).;

30.3.1.1.24 aOutOfRangeLengthField

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC frames received with a Length/Type field value that is greater than maxBasicDataSize (see 4.2.7.1). The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).

NOTE—Before IEEE Std 802.3x-1997, this counter was incremented by frames containing “Type” fields. Due to the modification to legitimize “Type” fields, such frames will now increment aFramesReceivedOK and this counter may only increment with a Length/Type field value that is between maxBasicDataSize and minTypeValue, exclusive (see 4.2.7.1 and 4.2.9).;

30.3.1.1.25 aFrameTooLongErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 815 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC frames received that exceed maxFrameSizeLimit (see 4.2.7.1). This counter is incremented when the status of a frame reception is frameTooLong. The actual update occurs in the LayerMgmtReceiveCounters procedure (5.2.4.3).;

30.3.1.1.26 aMACEnableStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

True if MAC sublayer is enabled and false if disabled. This is accomplished by setting or checking the values of the receiveEnabled and transmitEnabled variables. Setting to true provides a means to cause the MAC sublayer to enter the normal operational state at idle. The PLS is reset by this operation (see 7.2.2.2.1). This is accomplished by setting receiveEnabled and transmitEnabled to true.

Setting to false causes the MAC sublayer to end all transmit and receive operations, leaving it in a disabled state. This is accomplished by setting receiveEnabled and transmitEnabled to false.;

30.3.1.1.27 aTransmitEnableStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

True if transmission is enabled and false otherwise. This is accomplished by setting or checking the value of the transmitEnabled variable.

Setting this to true provides a means to enable MAC sublayer frame transmission (TransmitFrame function). This is accomplished by setting transmitEnabled to true.

Setting this to false will inhibit the transmission of further frames by the MAC sublayer (TransmitFrame function). This is accomplished by setting transmitEnabled to false.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.3.1.1.28 aMulticastReceiveStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
True if multicast receive is enabled, and false otherwise. Setting this to true provides a means to cause the MAC sublayer to return to the normal operation of multicast frame reception. Setting this to false will inhibit the reception of further multicast frames by the MAC sublayer.;

30.3.1.1.29 aReadWriteMACAddress

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
Read the MAC station address or change the MAC station address to the one supplied (RecognizeAddress function). Note that the supplied station address shall not have the group bit set and shall not be the null address.;

30.3.1.1.30 aCollisionFrames

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE of 32 generalized nonresettable counters. Each counter has a maximum increment rate of 13 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
A histogram of collision activity. The indices of this array (1 to attemptLimit – 1) denote the number of collisions experienced in transmitting a frame. Each element of this array contains a counter that denotes the number of frames that have experienced a specific number of collisions. When the TransmitStatus is reported as transmitOK and the value of the attempts variable equals n, then collisionFrames[n–1] counter is incremented. The elements of this array are incremented in the LayerMgmtTransmitCounters procedure (5.2.4.2). The contents of this attribute are undefined for MAC entities operating in full duplex mode.;

30.3.1.1.31 aMACCapabilities

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE that meets the requirements of the description below:

half duplex	Capable of operating in half duplex mode
full duplex	Capable of operating in full duplex mode

BEHAVIOUR DEFINED AS:
This indicates the duplex capabilities of the MAC.;

30.3.1.1.32 aDuplexStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

An ENUMERATED VALUE that has one of the following entries:

half duplex	Half duplex mode
full duplex	Full duplex mode
unknown	Duplex status unknown

BEHAVIOUR DEFINED AS:

A GET operation returns the current mode of operation of the MAC entity, either half duplex, full duplex, or unknown. A SET operation changes the mode of operation of the MAC entity to the indicated value. A SET operation shall have no effect on a device whose mode cannot be changed through management or that can only operate in a single mode.;

30.3.1.1.33 aRateControlAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

"True" for operating speeds above 1000 Mb/s where Rate Control through lowering the average data rate of the MAC sublayer, with frame granularity, is supported (see 4.2.3.2.2), and "false" otherwise.;

30.3.1.1.34 aRateControlStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

rate control off	Rate control mode disabled
rate control on	Rate control mode enabled
unknown	Rate control mode unknown

BEHAVIOUR DEFINED AS:

A GET operation returns the current Rate Control mode of operation of the MAC sublayer.

A SET operation changes the mode of operation of the MAC sublayer to the indicated value. A SET operation shall have no effect on a device whose mode cannot be changed through management or that can only operate in a single mode.

This attribute maps to the variable ipgStretchMode (see 4.2.7.2).;

30.3.1.1.35 aDeferControlAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

The enumeration "true" is returned when the interframe spacing is accomplished within the MAC sublayer (see 4A.2.3.2.3), the enumeration "false" is returned otherwise.;

30.3.1.1.36 aDeferControlStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

An ENUMERATED VALUE that has one of the following entries:

unknown	defer control mode unknown
defer control off	defer control mode disabled
defer control on	defer control mode enabled

BEHAVIOUR DEFINED AS:

A GET operation returns the current Defer Control mode of operation of the MAC. A SET operation changes the mode of operation of the MAC sublayer to the indicated value. A SET operation shall have no effect on a device whose mode cannot be changed through management or that can only operate in a single mode.

This attribute maps to the variable deferenceMode (see 4A.2.7.2).;

30.3.1.1.37 aMaxFrameLength

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	Frame length capability unknown
basicFrame	Capable of supporting maxBasicFrameSize (1518 octet frames)
qTaggedFrame	Capable of supporting maxBasicFrameSize + qTagPrefixSize (1522 octet frames)
envelopeFrame	Capable of supporting maxEnvelopeFrameSize (2000 octet frames)

BEHAVIOUR DEFINED AS:

This indicates the MAC frame length at which the aFramesTooLong counter is incremented.

30.3.1.1.38 aSlowProtocolFrameLimit

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The maximum number of Slow Protocol frames of a given subtype that can be transmitted in a one-second period. The default value is 10.;

30.3.1.2 MAC entity actions

30.3.1.2.1 acInitializeMAC

ACTION

APPROPRIATE SYNTAX:

None required

BEHAVIOUR DEFINED AS:

This action provides a means to call the Initialize procedure (4.2.7.4). This action also results in the initialization of the PLS.;

30.3.1.2.2 acAddGroupAddress

ACTION

APPROPRIATE SYNTAX:

MACAddress

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

Add the supplied multicast group address to the address recognition filter (RecognizeAddress function).;

30.3.1.2.3 acDeleteGroupAddress

ACTION

APPROPRIATE SYNTAX:

MACAddress

BEHAVIOUR DEFINED AS:

Delete the supplied multicast group address from the address recognition filter (RecognizeAddress function).;

30.3.1.2.4 acExecuteSelfTest

ACTION

APPROPRIATE SYNTAX:

None required

BEHAVIOUR DEFINED AS:

Execute a self-test and report the results (success or failure). The actual mechanism employed to carry out the self-test is not defined in this standard. If PHY loopback is accessible through a Clause 22 MII, Clause 35 GMII, or Clause 45 MDIO interface, then this action shall also invoke a data integrity test using PHY loopback, returning to normal operation on completion of the test. In the case of a Clause 45 MDIO Interface where multiple loopbacks are available, the loopback in the MMD closest to the MDI should be used.;

30.3.2 PHY device managed object class

This subclause formally defines the behaviours for the oPHYEntity managed object class attributes, actions and notifications. Management of that portion of the physical sublayer whose physical containment within the DTE is optional is outside the scope of this clause.

30.3.2.1 PHY device attributes

30.3.2.1.1 aPHYID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of aPHYID is assigned so as to uniquely identify a PHY, i.e., Physical Layer among the subordinate managed objects of system (systemID and system are defined in ISO/IEC 10165-2:1992 [SMI], Definition of management information).;

30.3.2.1.2 aPhyType

ATTRIBUTE

APPROPRIATE SYNTAX:

other	Undefined
unknown	Initializing, true state or type not yet known
none	MII present and nothing connected

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

400GBASE-R	Clause 119 400 Gb/s multi-PCS lane 64B/66B

BEHAVIOUR DEFINED AS:

A read-only list of the possible types that the PHY could be, identifying the ability of the PHY. If Clause 28, Clause 37, or Clause 73 Auto-Negotiation is present, then this attribute will map to the local technology ability or advertised ability of the local device.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—At 10 Gb/s the ability of the PMD has to be taken into account when reporting the possible types that the PHY could be.;

30.3.2.1.4 aSQETestErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of times that the SQE_TEST_ERROR was received. The SQE_TEST_ERROR is set in accordance with the rules for verification of the SQE detection mechanism in the PLS Carrier Sense function (see 7.2.4.6). The SQE test function is not a part of 100 or 1000 Mb/s PHY operation, and so SQETestErrors will not occur in 100 or 1000 Mb/s PHYs. The contents of this attribute are undefined for full duplex operation.;

30.3.2.1.5 aSymbolErrorDuringCarrier

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 160 000 counts per second for 100 Mb/s implementations

BEHAVIOUR DEFINED AS:

For 100 Mb/s operation it is a count of the number of times when valid carrier was present and there was at least one occurrence of an invalid data symbol (see 23.2.1.4, 24.2.2.1.7, and 32.3.4.1).
For half duplex operation at 1000 Mb/s, it is a count of the number of times the receiving media is non-idle (a carrier event) for a period of time equal to or greater than slotTime (see 4.2.4), and during which there was at least one occurrence of an event that causes the PHY to indicate “Data reception error” or “Carrier Extend Error” on the GMII (see Table 35–2).
For full duplex operation at 1000 Mb/s, it is a count of the number of times the receiving media is non-idle (a carrier event) for a period of time equal to or greater than minFrameSize, and during which there was at least one occurrence of an event that causes the PHY to indicate “Data reception error” on the GMII (see Table 35–2).
For operation at 5 Gb/s, 10 Gb/s, 25 Gb/s, 40 Gb/s, 50 Gb/s, 100 Gb/s, 200 Gb/s, and 400 Gb/s, it is a count of the number of times the receiving media is non-idle (the time between the Start of Packet Delimiter and the End of Packet Delimiter as defined by 46.2.5 and 81.2.5) for a period of time equal to or greater than minFrameSize, and during which there was at least one occurrence of an event that causes the PHY to indicate “Receive Error” on the media independent interface (see Table 46–4 and Table 81–4).
At all speeds this counter shall be incremented only once per valid CarrierEvent and if a collision is present this counter shall not increment.;

30.3.2.1.6 aMIIDetect

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:
unknown
present, nothing connected
present, connected
absent

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

An attribute of the PhyEntity managed object class indicating whether an MII connector is physically present, and if so whether it is detectably connected as specified in 22.2.2.14.;

30.3.2.1.7 aPhyAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries:
disabled
enabled

BEHAVIOUR DEFINED AS:

A disabled PHY neither transmits nor receives. The PHY shall be explicitly enabled to restore operation. The acPhyAdminControl action provides this ability. The port enable/disable function as reported by this attribute is preserved across DTE reset including loss of power. Only one PHY per MAC can be enabled at any one time. Setting a PHY to the enabled state using the action acPhyAdminControl will result in all other instances of PHY (indicated by PhyID) instantiated within the same MAC to be disabled. If a Clause 22 MII or Clause 35 GMII is present then setting this attribute to “disabled” will result in electrical isolation as defined in 22.2.4.1.6, Isolate; and setting this attribute to “enabled” will result in normal operation as defined in 22.2.4.1.5, Power down; and 22.2.4.1.6, Isolate. For all MMDs that provide a Clause 45 MDIO Interface within the PHY, setting this attribute to “enabled” will result in the MMD Low-power bit being set for normal operation. MMDs that support Low Power are the PMA/PMD MMD (see 45.2.1.1.2 and 45.2.1.2.5), the WIS MMD (see 45.2.2.1.3 and 45.2.2.2.3), the PCS MMD (see 45.2.3.1.3 and 45.2.3.2.8), the PHY XS MMD (see 45.2.4.1.3 and 45.2.4.2.8) and the DTE XS MMD (see 45.2.5.1.3 and 45.2.5.2.8).;

30.3.2.1.8 aTransmitLPIMicroseconds

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 000 000 counts per second

BEHAVIOUR DEFINED AS:

A count reflecting the amount of time that the LPI_REQUEST parameter has the value ASSERT. The request is indicated to the PHY according to the requirements of the RS (see 22.7, 35.4, 46.4).;

30.3.2.1.9 aReceiveLPIMicroseconds

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 000 000 counts per second

BEHAVIOUR DEFINED AS:

A count reflecting the amount of time that the LPI_INDICATION parameter has the value ASSERT. The indication reflects the state of the PHY according to the requirements of the RS (see 22.7, 35.4, 46.4).;

30.3.2.1.10 aTransmitLPITransitions

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 50 000 counts per second at 100 Mb/s; 90 000 counts per second at 1000 Mb/s; and 230 000 counts per second at 10 Gb/s

BEHAVIOUR DEFINED AS:

A count of occurrences of the transition from state LPI_DEASSERTED to state LPI_ASSERTED of the LPI transmit state diagram is the RS. The state transition corresponds to the assertion of the LPI_REQUEST parameter. The request is indicated to the PHY according to the requirements of the RS (see 22.7, 35.4, 46.4).;

30.3.2.1.11 aReceiveLPITransitions

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 50 000 counts per second at 100 Mb/s; 90 000 counts per second at 1000 Mb/s; and 230 000 counts per second at 10 Gb/s

BEHAVIOUR DEFINED AS:

A count of occurrences of the transition from DEASSERT to ASSERT of the LPI_INDICATE parameter. The indication reflects the state of the PHY according to the requirements of the RS (see 22.7, 35.4, 46.4).;

30.3.2.2 PHY device actions

30.3.2.2.1 acPhyAdminControl

ACTION

APPROPRIATE SYNTAX:

Same as aPortAdminState

BEHAVIOUR DEFINED AS:

This action provides a means to alter aPhyAdminState. Setting a PHY to the enabled state will result in all other instances of PHY being disabled.;

30.3.3 MAC control entity object class

This subclause formally defines the behaviours for the oMACControlEntity managed object class attributes.

30.3.3.1 aMACControlID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of aMACControlID is assigned so as to uniquely identify a MAC Control entity among the subordinate managed objects of the containing object.;

30.3.3.2 aMACControlFunctionsSupported

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A SEQUENCE that meets the requirements of the description below:

PAUSE	PAUSE command implemented
MPCP	MPCP implemented
PFC	PFC implemented
EXTENSION	EXTENSION MAC Control frame supported

BEHAVIOUR DEFINED AS:

A read-write list of the possible MAC Control functions implemented within the device. Each function implemented will have an associated MAC Control Function Entity object class.;

30.3.3.3 aMACControlFramesTransmitted

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC Control frames passed to the MAC sublayer for transmission. This counter is incremented when a MA_CONTROL.request primitive is generated within the MAC Control sublayer.;

30.3.3.4 aMACControlFramesReceived

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC Control frames passed by the MAC sublayer to the MAC Control sublayer. This counter is incremented when a ReceiveFrame function call returns a valid frame with a lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3.;

30.3.3.5 aUnsupportedOpcodesReceived

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC Control frames received that contain an opcode from Table 31A–1 that is not supported by the device. This counter is incremented when a ReceiveFrame function call returns a valid frame with a lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3, and with an opcode for a function that is not supported by the device.;

30.3.3.6 aPFCEnableStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:
enabled

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

disabled

BEHAVIOUR DEFINED AS:

A read-only value that indicates whether PFC MAC Control operation is enabled. The value enabled indicates that operation of PFC MAC Control is enabled and operation of PAUSE MAC Control is disabled. The value disabled indicates that transmission and reception of PFC MAC Control is not enabled and PAUSE MAC Control may operate if it has been enabled through another mechanism.;

NOTE 1—aPFCEnableStatus is read-only to avoid the risk of it being set to a conflicting value with enablement of PFC in the MAC Control Client. It is intended that an implementation locally sets the value to enabled when the MAC Control Client has PFC enabled for any priority and to disabled when the MAC Control Client has PFC disabled for all priorities.

NOTE 2—There is no mechanism in this Clause to enable and disable PAUSE transmit and receive for PHYs without Auto-Negotiation. IEEE Std 802.3.1 provides dot3PauseAdminMode to enable and disable PAUSE in the absence of Auto-Negotiation.

30.3.4 PAUSE entity managed object class

This subclause formally defines the behaviours for the oMACControlFunctionEntity managed object class attributes.

30.3.4.1 aPAUSELinkDelayAllowance

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET operation returns the value, in bits, of the allowance made by the PAUSE MAC Control entity for round-trip propagation delay of the full duplex link. A SET operation changes the value of the allowance made by the PAUSE MAC Control entity for round-trip propagation delay of the full duplex link to the indicated value, in bits.;

30.3.4.2 aPAUSEMACCtrlFramesTransmitted

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of PAUSE frames passed to the MAC sublayer for transmission. This counter is incremented when a MA_CONTROL.request primitive is generated within the MAC Control sublayer with an opcode indicating the PAUSE operation.;

30.3.4.3 aPAUSEMACCtrlFramesReceived

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC Control frames passed by the MAC sublayer to the MAC Control sublayer. This

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

counter is incremented when a ReceiveFrame function call returns a valid frame with: (1) a lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3, and (2) an opcode indicating the PAUSE operation.;

30.3.5 MPCP managed object class

This subclause formally defines the behaviours for the oMPCP managed object class attributes and actions.

30.3.5.1 MPCP Attributes

30.3.5.1.1 aMPCPID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aMPCPID is assigned so as to uniquely identify an MPCP entity among the subordinate managed objects of the containing object.;

30.3.5.1.2 aMPCPAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:
A read-only value that identifies the operational state of the Multipoint MAC Control sublayer. An interface that can provide the Multipoint MAC Control sublayer functions specified in Clause 64, Clause 77, Clause 103, or Clause 144 is enabled to do so when this attribute has the enumeration "enabled". When this attribute has the enumeration "disabled", the interface acts as it would if it had no Multipoint MAC Control sublayer. The operational state of the Multipoint MAC Control sublayer can be changed using the acMPCPAdminControl action.;

30.3.5.1.3 aMPCPMode

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:
OLT
ONU
CLT
CNU

BEHAVIOUR DEFINED AS:
A read-only value that identifies the operational mode of the Multipoint MAC Control sublayer. An interface that can provide the Multipoint MAC Control sublayer functions specified in Clause 64, Clause 77, Clause 103, or Clause 144. When this attribute has the enumeration "OLT", the interface acts as an OLT. When this attribute has the enumeration "ONU", the interface acts as an ONU. When this attribute has the enumeration "CLT", the interface acts as a CLT. When this attribute has the enumeration "CNU", the interface acts as a CNU.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.3.5.1.4 aMPCPLinkID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A read-only value that identifies the Logical Link identity (LLID) associated with the MAC port as specified in 65.1.3.2.2, 76.2.6.1.3.2, or 144.3.4, as appropriate.;

30.3.5.1.5 aMPCPRemoteMACAddress

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A read-only value that identifies the source_address parameter of the last MPCPDU passed to MAC Control.

This value is updated on reception of a valid frame with (1) a destinationField equal to the assigned multicast address for MAC Control specified in 31A, (2) lengthOrType field value equal to the assigned Type for MAC Control as specified in 31A, (3) an opcode value assigned for one of MPCP messages, as specified in 31A.;

30.3.5.1.6 aMPCPRegistrationState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:

unregistered	unregistered
registering	registering with link-partner
registered	registered with a link-partner

BEHAVIOUR DEFINED AS:
A read-only value that identifies the operational state of an individual instance of Multipoint MAC Control. When this attribute has the enumeration “unregistered” the interface is ready for registering a link partner. When this attribute has the enumeration “registering” the interface is in the process of registering a link-partner. When this attribute has the enumeration “registered” the interface has an established and operational link-partner.

NOTE—This attribute may be used by layer management mechanisms or OAM client to obtain the status of logical links in P2MP networks. Specifically, in implementations where the OAM sublayer is interfaced with Multipoint MAC Control, theOAM_CTRL.request (local_link_status) primitive specified in 57.2.5.3 should be mapped to this attribute as follows:

When the value of this attribute changes from “registering” to “registered”, an OAM_CTRL.request primitive with parameter local_link_status = OK is generated.

When the value of this attribute changes from “registered” to “unregistered”, an OAM_CTRL.request primitive with parameter local_link_status = FAIL is generated.;

30.3.5.1.7 aMPCPMACCtrlFramesTransmitted

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of MPCP frames passed to the MAC sublayer for transmission.

Increment counter by one when a MA_CONTROL.request service primitive is generated within the MAC Control sublayer with an opcode indicating an MPCP frame.;

30.3.5.1.8 aMPCPMACCtrlFramesReceived

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of MPCP frames passed by the MAC sublayer to the MAC Control sublayer.

Increment counter by one when a ReceiveFrame function call returns a valid frame with: (1) a lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3, and (2) an opcode indicating an MPCP frame.;

30.3.5.1.9 aMPCPTxGate

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a GATE MPCP frames transmission occurs.

Increment the counter by one when a MA_CONTROL.request service primitive is generated within the MAC Control sublayer with an opcode indicating a GATE MPCPDU.;

30.3.5.1.10 aMPCPTxRegAck

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a REGISTER_ACK MPCP frames transmission occurs.

Increment the counter by one when a MA_CONTROL.request service primitive is generated within the MAC Control sublayer with an opcode indicating a REGISTER_ACK MPCPDU.;

30.3.5.1.11 aMPCPTxRegister

ATTRIBUTE

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a REGISTER MPCP frames transmission occurs.

Increment the counter by one when a MA_CONTROL.request service primitive is generated within the MAC Control sublayer with an opcode indicating a REGISTER MPCPDU.;

30.3.5.1.12 aMPCPTxRegRequest

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a REGISTER_REQ MPCP frames transmission occurs.

Increment the counter by one when a MA_CONTROL.request service primitive is generated within the MAC Control sublayer with an opcode indicating a REGISTER_REQ MPCPDU.;

30.3.5.1.13 aMPCPTxReport

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a REPORT MPCP frames transmission occurs.

Increment the counter by one when a MA_CONTROL.request service primitive is generated within the MAC Control sublayer with an opcode indicating a REPORT MPCPDU.;

30.3.5.1.14 aMPCPRxGate

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a GATE MPCP frames reception occurs.

Increment the counter by one when a ReceiveFrame function call returns a valid frame with: (1) a destinationField equal to the assigned multicast address for MAC Control specified in 31A, or unique physical address associated with this station, (2) a lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3, (3) an opcode indicating a GATE MPCPDU.;

lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3, (3) an opcode indicating a REPORT MPCPDU.;

30.3.5.1.19 aMPCPTransmitElapsed

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A read-only value that reports the interval from last MPCP frame transmission in increments of 16 ns. The value returned shall be (interval from last MPCP frame transmission in ns)/16, where this value exceeds (2^{32}–1) the value (2^{32}–1) shall be returned.;

30.3.5.1.20 aMPCPReceiveElapsed

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A read-only value that reports the interval from last MPCP frame reception in increments of 16 ns. The value returned shall be (interval from last MPCP frame reception in ns)/16, where this value exceeds (2^{32}–1) the value (2^{32}–1) shall be returned.;

30.3.5.1.21 aMPCPRoundTripTime

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A read-only value that reports the MPCP round trip time in increments of 16 ns. The value returned shall be (round trip time in ns)/16, where this value exceeds (2^{16}–1) the value (2^{16}–1) shall be returned. This value is only defined for an OLT. The contents of this attribute are undefined for an ONU.;

30.3.5.1.22 aMPCPDiscoveryWindowsSent

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 10 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:
A count of discovery windows generated. The counter is incremented by one for each generated discovery window.;

30.3.5.1.23 aMPCPDiscoveryTimeout

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 10 000 counts

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of times a discovery time-out occurs. The counter is incremented by one for each discovery processing state diagram reset resulting from time-out waiting for message arrival.;

30.3.5.1.24 aMPCPMaximumPendingGrants

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A read-only value that indicates the maximum number of grants an ONU can store. The maximum number of grants an ONU can store has a range of 0 to 255.;

30.3.5.1.25 aMPCPRecognizedMulticastIDs

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of INTEGERS

BEHAVIOUR DEFINED AS:

A An array of read-only values that identify the multicast Logical Link identities (LLID) associated with the MAC port as specified in 65.1.3.3.2 or 76.2.6.1.3.2, as appropriate.; These values are only defined for an ONU. The contents of this attribute are undefined for an OLT.;

30.3.5.2 MPCP Actions

30.3.5.2.1 acMPCPAdminControl

ACTION

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:

This action provides a means to alter aMPCPAdminState.;

30.3.6 OAM object class

This subclause formally defines the behaviours for the oOAM managed object class attributes.

30.3.6.1 OAM Attributes

30.3.6.1.1 aOAMID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of aOAMID is assigned so as to uniquely identify an OAM entity among the subordinate

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

managed objects of the containing object.;

30.3.6.1.2 aOAMAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:
A read-only value that identifies the operational state of the OAM sublayer.

An interface which can provide the OAM sublayer functions specified in Clause 57 will be enabled to do so when this attribute has the enumeration “enabled”. When this attribute has the enumeration “disabled” the interface will act as it would if it had no OAM sublayer. The operational state of the OAM sublayer can be changed using the acOAMAdminControl action.;

30.3.6.1.3 aOAMMode

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

passive	passive OAM mode
active	active OAM mode

BEHAVIOUR DEFINED AS:
A GET operation returns the current mode of the OAM sublayer entity (see 57.2.9), either “passive” or “active”. A SET operation changes the mode of operation of the OAM entity to the indicated value. A SET operation shall have no effect on a device whose mode cannot be changed through management or that can only operate in a single mode.;

30.3.6.1.4 aOAMDiscoveryState

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
link fault
active send local
passive wait
send local remote
send local remote ok
send any

BEHAVIOUR DEFINED AS:
A read-only value that identifies the current state of the OAM Discovery function. The enumerations match the states within the Discovery state diagram Figure 57–5.;

30.3.6.1.5 aOAMRemoteMACAddress

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The value of the source_address parameter of the last OAMPDU passed by the OAM subordinate sublayer to the OAM sublayer.

This value is updated on reception of a valid frame with (1) a destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3.;

30.3.6.1.6 aOAMLocalConfiguration

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (5)]

BEHAVIOUR DEFINED AS:
A string of five bits corresponding to the OAM Configuration field (see Table 57–8) in the most recently transmitted Information OAMPDU.;

The first bit corresponds to the OAM Mode bit in the OAM Configuration field. The second bit corresponds to the Unidirectional Support bit in the OAM Configuration field. The third bit corresponds to the Remote Loopback Support bit in the OAM Configuration field. The fourth bit corresponds to the Link Events bit in the OAM Configuration field. The fifth bit corresponds to the Variable Retrieval bit in the OAM Configuration field.;

30.3.6.1.7 aOAMRemoteConfiguration

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (5)]

BEHAVIOUR DEFINED AS:
A string of five bits corresponding to the OAM Configuration field (see Table 57–8) in the most recently received Information OAMPDU.

The first bit corresponds to the OAM Mode bit in the OAM Configuration field. The second bit corresponds to the Unidirectional Support bit in the OAM Configuration field. The third bit corresponds to the Remote Loopback Support bit in the OAM Configuration field.The fourth bit corresponds to the Link Events bit in the OAM Configuration field. The fifth bit corresponds to the Variable Retrieval bit in the OAM Configuration field.

This value is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAM code equals the OAM Information code as specified in Table 57–4, (5) the frame contains a Local Information TLV (see 57.5.2.1).;

30.3.6.1.8 aOAMLocalPDUConfiguration

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

An eleven bit value corresponding to the Maximum OAMPDU Size value within the OAMPDU Configuration field (see Table 57–9) in the most recently transmitted OAMPDU.;

30.3.6.1.9 aOAMRemotePDUConfiguration

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
An eleven bit value corresponding to the Maximum OAMPDU Size value within the OAMPDU Configuration field (see Table 57–9) in the most recently received Information OAMPDU.

This value is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAM code equals the OAM Information code as specified in Table 57–4, (5) the frame contains a Local Information TLV (see 57.5.2.1).;

30.3.6.1.10 aOAMLocalFlagsField

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (7)]

BEHAVIOUR DEFINED AS:
A string of seven bits corresponding to the Flags field (see Table 57–3) in the most recently transmitted OAMPDU.

The first bit corresponds to the Link Fault bit in the Flags field. The second bit corresponds to the Dying Gasp bit in the Flags field. The third bit corresponds to the Critical Event bit in the Flags field. The fourth bit corresponds to the Local Evaluating bit in the Flags field. The fifth bit corresponds to the Local Stable bit in the Flags field. The sixth bit corresponds to the Remote Evaluating bit in the Flags field. The seventh bit corresponds to the Remote Stable bit in the Flags field.;

30.3.6.1.11 aOAMRemoteFlagsField

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (7)]

BEHAVIOUR DEFINED AS:
A string of seven bits corresponding to the Flags field (see Table 57–3) in the most recently received OAMPDU.

The first bit corresponds to the Link Fault bit in the Flags field. The second bit corresponds to the Dying Gasp bit in the Flags field. The third bit corresponds to the Critical Event bit in the Flags field. The fourth bit corresponds to the Local Evaluating bit in the Flags field. The fifth bit corresponds to the Local Stable bit in the Flags field. The sixth bit corresponds to the Remote Evaluating bit in the Flags field. The seventh bit corresponds to the Remote Stable bit in the Flags field.

This value is updated on reception of a valid frame with (1) a destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAM code equals one of the codes as specified in Table 57–4.;

30.3.6.1.12 aOAMLocalRevision

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of the Revision field (see 57.5.2.1) in the Local Information TLV of the most recently transmitted Information OAMPDU.;

30.3.6.1.13 aOAMRemoteRevision

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of the Revision field (see 57.5.2.1) in the Local Information TLV of the most recently received Information OAMPDU.

This value is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equal to the Information code as specified in Table 57–4, (5) the frame contains a Local Information TLV (see 57.5.2.1).;

30.3.6.1.14 aOAMLocalState

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (3)]

BEHAVIOUR DEFINED AS:
A string of three bits corresponding to the State field (see Table 57–7) of the most recently transmitted Information OAMPDU. The first and second bits corresponds to the Parser Action bits in the State field. The third bit corresponds to the Multiplexer Action bit in the State field.;

30.3.6.1.15 aOAMRemoteState

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (3)]

BEHAVIOUR DEFINED AS:
A string of three bits corresponding to the State field (see Table 57–7) of the most recently received Information OAMPDU. The first and second bits corresponds to the Parser Action bits in the State field. The third bit corresponds to the Multiplexer Action bit in the State field.

This value is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equal to the Information code as specified in Table 57–4, (5) the frame contains a Local Information TLV (see 57.5.2.1).;

30.3.6.1.16 aOAMRemoteVendorOUI

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of the OUI/CID field (see Table 57–10) of the most recently received Information OAMPDU.

This value is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) a OAMPDU code equal to the Information code as specified in Table 57–4, (5) the frame contains a Local Information TLV (see 57.5.2.1).;

30.3.6.1.17 aOAMRemoteVendorSpecificInfo

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of the Vendor Specific Information field (see Table 57–11) of the most recently received Information OAMPDU.

This value is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equal to the Information code as specified in Table 57–4, (5) the frame contains a Local Information TLV (see 57.5.2.1).;

30.3.6.1.18 aOAMUnsupportedCodesTx

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of Slow_Protocol_Frames as defined in 57A.2.

BEHAVIOUR DEFINED AS:
A count of OAMPDUs passed to the OAM subordinate sublayer for transmission that are not supported by the device. This counter is incremented when a CTL:OAMI.request service primitive is generated within the OAM sublayer with an OAM code for a function that is not supported by the device.;

Event Notification code specified in Table 57–4. This counter is incremented when a CTL:OAMI.request service primitive is generated within the OAM sublayer, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equals the Event Notification code, (5) the Sequence Number field is not equal to the Sequence Number field of the last transmitted Event Notification OAMPDU.;

30.3.6.1.23 aOAMDuplicateEventNotificationTx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of Slow_Protocol_Frames as defined in 57A.2.

BEHAVIOUR DEFINED AS:

A count of OAMPDUs passed to the OAM subordinate sublayer for transmission that contain the Event Notification code specified in Table 57–4. This counter is incremented when a CTL:OAMI.request service primitive is generated within the OAM sublayer, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equals the Event Notification code, (5) the Sequence Number field is equal to the Sequence Number field of the last transmitted Event Notification OAMPDU.;

30.3.6.1.24 aOAMUniqueEventNotificationRx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of Slow_Protocol_Frames as defined in 57A.2.

BEHAVIOUR DEFINED AS:

A count of the OAMPDUs received that contain the Event Notification code specified in Table 57–4. This counter is incremented on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equals the Event Notification code, (5) the Sequence Number field is not equal to the Sequence Number field of the last received Event Notification OAMPDU and is supported by the device.;

30.3.6.1.25 aOAMDuplicateEventNotificationRx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of Slow_Protocol_Frames as defined in 57A.2.

BEHAVIOUR DEFINED AS:

A count of the OAMPDUs received that contain the Event Notification code specified in Table 57–4. This counter is incremented on reception of a valid frame, with (1) destinationField

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of Slow_Protocol_Frames as defined in 57A.2.

BEHAVIOUR DEFINED AS:

A count of OAMPDUs received that contain the Organization Specific code specified in Table 57–4. This counter is incremented on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) a Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) the OAMPDU code equals the Organization Specific code and is supported by the device.;

30.3.6.1.34 aOAMLocalErrSymPeriodConfig

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of two instances of the type INTEGER

BEHAVIOUR DEFINED AS:

The first integer is an eight-octet value indicating the duration of the Errored Symbol Period Event (see 57.5.3.1) window, in terms of symbols.
The second integer is an eight-octet value indicating the number of errored symbols in the period that has to be met or exceeded in order for the Errored Symbol Period Event to be generated.;

30.3.6.1.35 aOAMLocalErrSymPeriodEvent

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of six instances of the type INTEGER
The first INTEGER represents the Event Time Stamp field
The second INTEGER represents the Errored Symbol Window field
The third INTEGER represents the Errored Symbol Threshold field
The fourth INTEGER represents the Errored Symbols field
The fifth INTEGER represents the Error Running Total field
The sixth INTEGER represents the Event Running Total field

BEHAVIOUR DEFINED AS:

A sequence of six integers corresponding to the respective fields in the most recently transmitted Errored Symbol Period Event TLV in an Event Notification OAMPDU (see 57.4.3.2).

This sequence is updated when a CTL:OAMI.request service primitive is generated within the OAM sublayer with an OAMPDU Code field value equal to the Event Notification code as specified in Table 57–4 and Event TLV Type field equal to the Errored Symbol Period Event value as specified in Table 57–12.;

30.3.6.1.36 aOAMLocalErrFrameConfig

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of two instances of the type INTEGER

BEHAVIOUR DEFINED AS:

The first integer is a two-octet value indicating the duration of the Errored Frame Event (see 57.5.3.2) window, in terms of number of 100 ms intervals. The second integer is a four-octet value indicating the number of errored frames in the period that has to be met or exceeded in order for the Errored Frame Event to be generated.;

30.3.6.1.37 aOAMLocalErrFrameEvent

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of six instances of the type INTEGER
The first INTEGER represents the Event Time Stamp field
The second INTEGER represents the Errored Frame Window field
The third INTEGER represents the Errored Frame Threshold field
The fourth INTEGER represents the Errored Frames field
The fifth INTEGER represents the Error Running Total field
The sixth INTEGER represents the Event Running Total field

BEHAVIOUR DEFINED AS:

A sequence of six integers corresponding to the respective fields in the most recently transmitted Errored Frame Event TLV in an Event Notification OAMPDU (see 57.4.3.2).

This sequence is updated when a CTL:OAMI.request service primitive is generated within the OAM sublayer with an OAMPDU Code field value equal to the Event Notification code as specified in Table 57–4 and Event TLV Type field equal to the Errored Frame Event value as specified in Table 57–12.;

30.3.6.1.38 aOAMLocalErrFramePeriodConfig

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of two instances of the type INTEGER

BEHAVIOUR DEFINED AS:

The first integer is a four-octet value indicating the duration of the Errored Frame Period Event (see 57.5.3.3) window, in terms of the number of frames in the window.

The second integer is a four-octet value indicating the number of errored frames in the period that has to be met or exceeded in order for the Errored Frame Period Event to be generated.;

30.3.6.1.39 aOAMLocalErrFramePeriodEvent

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of six instances of the type INTEGER
The first INTEGER represents the Event Time Stamp field
The second INTEGER represents the Errored Frame Window field
The third INTEGER represents the Errored Frame Threshold field
The fourth INTEGER represents the Errored Frames field
The fifth INTEGER represents the Error Running Total field
The sixth INTEGER represents the Event Running Total field

Errored Frame Period Event TLV in an Event Notification OAMPDU (see 57.4.3.2).

This sequence is updated when a CTL:OAMI.request service primitive is generated within the OAM sublayer with an OAMPDU Code field value equal to the Event Notification code as specified in Table 57–4 and Event TLV Type field equal to the Errored Frame Period Event value as specified in Table 57–12.;

30.3.6.1.40 aOAMLocalErrFrameSecsSummaryConfig

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE of two instances of the type INTEGER

BEHAVIOUR DEFINED AS:
The first integer is a two-octet value indicating the duration of the Errored Frame Seconds Summary Event (see 57.5.3.4) window, in terms of number of 100 ms intervals. The second integer is a two-octet value indicating the number of errored frame seconds in the period that has to be met or exceeded in order for the Errored Frame Seconds Summary Event to be generated.;

30.3.6.1.41 aOAMLocalErrFrameSecsSummaryEvent

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE of six instances of the type INTEGER
The first INTEGER represents the Event Time Stamp field
The second INTEGER represents the Errored Frame Seconds Summary Window field
The third INTEGER represents the Errored Frame Seconds Summary Threshold field
The fourth INTEGER represents the Errored Frame Seconds Summary field
The fifth INTEGER represents the Error Running Total field
The sixth INTEGER represents the Event Running Total field

BEHAVIOUR DEFINED AS:
A sequence of six integers corresponding to the respective fields in the most recently transmitted Errored Frame Seconds Summary Event TLV in an Event Notification OAMPDU (see 57.4.3.2).

This sequence is updated when a CTL:OAMI.request service primitive is generated within the OAM sublayer with an OAMPDU Code field value equal to the Event Notification code as specified in Table 57–4 and Event TLV Type field equal to the Errored Frame Seconds Summary Event value as specified in Table 57–12.;

30.3.6.1.42 aOAMRemoteErrSymPeriodEvent

ATTRIBUTE

APPROPRIATE SYNTAX:

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Errored Frame Period Event TLV in an Event Notification OAMPDU (see 57.4.3.2).

This sequence is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) OAMPDU Code field value equal to the Event Notification code as specified in Table 57–4, (5) an Event TLV Type field equal to the Errored Frame Period Event value as specified in Table 57–12.

If more than one Event TLV of the same Event Type is present within an Event Notification OAMPDU, the Event with the most recent timestamp should be used.;

30.3.6.1.45 aOAMRemoteErrFrameSecsSummaryEvent

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of six instances of the type INTEGER
The first INTEGER represents the Event Time Stamp field
The second INTEGER represents the Errored Frame Seconds Summary Window field
The third INTEGER represents the Errored Frame Seconds Summary Threshold field
The fourth INTEGER represents the Errored Frame Seconds Summary field
The fifth INTEGER represents the Error Running Total field
The sixth INTEGER represents the Event Running Total field

BEHAVIOUR DEFINED AS:

A sequence of six integers corresponding to the respective fields in the most recently received Errored Frame Seconds Summary Event TLV in an Event Notification OAMPDU (see 57.4.3.2).

This sequence is updated on reception of a valid frame, with (1) destinationField equal to the assigned multicast address for Slow_Protocols specified in Table 57A–1, (2) lengthOrType field value equal to the assigned Type for Slow_Protocols as specified in Table 57A–2, (3) Slow_Protocols subtype value equal to the subtype assigned for OAM as specified in Table 57A–3, (4) OAMPDU Code field value equal to the Event Notification code as specified in Table 57–4, (5) an Event TLV Type field equal to the Errored Frame Seconds Summary Event value as specified in Table 57–12.

If more than one Event TLV of the same Event Type is present within an Event Notification OAMPDU, the Event with the most recent timestamp should be used.;

30.3.6.1.46 aFramesLostDueToOAMError

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames that would otherwise be transmitted by the OAM sublayer, but could not be due to an internal OAM sublayer transmit error. If this counter is incremented, then none of the other counters in this section are incremented. The exact meaning and mechanism for incrementing this counter is implementation dependent.;

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.3.6.2 OAM Actions

30.3.6.2.1 acOAMAdminControl

ACTION

APPROPRIATE SYNTAX:
Same as aPortAdminState

BEHAVIOUR DEFINED AS:
This action provides a means to alter aOAMAdminState.;

30.3.7 OMPEmulation managed object class

This subclause formally defines the behaviours for the oOMPEmulation managed object class attributes.

30.3.7.1 OMPEmulation Attributes

30.3.7.1.1aOMPEmulationID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aOAMID is assigned so as to uniquely identify an OMPEmulation entity among the subordinate managed objects of the containing object.;

30.3.7.1.2aOMPEmulationType

ATTRIBUTE

APPROPRIATE SYNTAX:
A ENUMERATION that meets the requirements of the description below:

unknown	initializing, true state or type not yet known
OLT	sublayer operating in OLT mode
ONU	sublayer operating in ONU mode

BEHAVIOUR DEFINED AS:
A read only value that indicates that mode of operation of the Reconciliation Sublayer for Point to Point Emulation (see 65.1.3.1 or 76.2.6.1.1, as appropriate).;

30.3.7.1.3aSLDErrors

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1 500 000 counts per second at 1000 Mb/s

BEHAVIOUR DEFINED AS:
A count of frames received that do not contain a valid SLD field as defined in 65.1.3.3.1or 76.2.6.1.3.1, as appropriate.;

30.3.7.1.4aCRC8Errors

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 500 000 counts per second at 1000 Mb/s

BEHAVIOUR DEFINED AS:

A count of frames received that contain a valid SLD field, as defined in 65.1.3.3.1or 76.2.6.1.3.1, as appropriate, but do not pass the CRC-8 check as defined in 65.1.3.3.3 or 76.2.6.1.3.3, as appropriate.;

30.3.7.1.5aGoodLLID

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 500 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of frames received that contain a valid SLD field in an OLT, as defined in 65.1.3.3.1 or 76.2.6.1.3.1, as appropriate, and pass the CRC-8 check, as defined in 65.1.3.3.3 or 76.2.6.1.3.3, as appropriate.;

30.3.7.1.6aONUPONcastLLID

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 500 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of frames received that: 1) contain a valid SLD field in an ONU, 2) meet the rules for frame acceptance, and 3) pass the CRC-8 check. The SLD is defined in 65.1.3.3.1 or 76.2.6.1.3.1, as appropriate. The rules for LLID acceptance are defined in 65.1.3.3.2 or 76.2.6.1.3.2, as appropriate. The CRC-8 check is defined in 65.1.3.3.3 or 76.2.6.1.3.3, as appropriate.;

30.3.7.1.7aOLTPONcastLLID

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 500 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

A count of frames received that contain a valid SLD field in an OLT, as defined in 65.1.3.3.1 or 76.2.6.1.3.1, as appropriate, passes the CRC-8 check, as defined in 65.1.3.3.3 or 76.2.6.1.3.3, as appropriate, and the frame meets the rule for acceptance defined in 65.1.3.3.2 or 76.2.6.1.3.2, as appropriate.;

30.3.7.1.8aBadLLID

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 500 000 counts per second at 1000 Mb/s.

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A count of frames received that contain a valid SLD field in an OLT, and pass the CRC-8 check, but are discarded due to the LLID check. The SLD is defined in 65.1.3.3.1 or 76.2.6.1.3.1, as appropriate. The CRC-8 check is defined in 65.1.3.3.3 or 76.2.6.1.3.3, as appropriate. The LLID check is defined in 65.1.3.3.2 or 76.2.6.1.3.2, as appropriate.;

30.3.8 EXTENSION entity managed object class

This subclause formally defines the behaviours for the oEXTENSION managed object class attributes.

30.3.8.1 aEXTENSIONMACCtrlFramesTransmitted

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s

BEHAVIOUR DEFINED AS:

A count of EXTENSION frames passed to the MAC sublayer for transmission. This counter is incremented when a MA_CONTROL.request primitive is generated within the MAC Control sublayer with an opcode indicating the EXTENSION operation.;

30.3.8.2 aEXTENSIONMACCtrlFramesReceived

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 600 000 counts per second at 1000 Mb/s

BEHAVIOUR DEFINED AS:

A count of MAC Control frames passed by the MAC sublayer to the MAC Control sublayer. This counter is incremented when a ReceiveFrame function call returns a valid frame with: (1) a lengthOrType field value equal to the assigned Type for 802.3_MAC_Control as specified in 31.4.1.3, and (2) an opcode indicating the EXTENSION operation.;

30.3.8.3 aEXTENSIONMACCtrlStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries: enabled disabled

BEHAVIOUR DEFINED AS:

A read-write value that identifies the current (when read) or target (when set) operational state of the EXTENSION MAC Control function (when read), as specified in Annex 31C.;

30.4 Layer management for 10, 100, and 1000 Mb/s baseband repeaters

30.4.1 Repeater managed object class

This subclause formally defines the behaviours for the oRepeater managed object class, attributes, actions, and notifications.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.4.1.1 Repeater attributes

30.4.1.1.1 aRepeaterID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aRepeaterID is assigned so as to uniquely identify a repeater among the subordinate managed objects of system (systemID and system are defined in ISO/IEC 10165-2:1992 [SMI], Definition of management information).;

30.4.1.1.2 aRepeaterType

ATTRIBUTE

APPROPRIATE SYNTAX:
An INTEGER that meets the requirements of the following description:

9	10 Mb/s Baseband
271	100 Mb/s Baseband, Class I
272	100 Mb/s Baseband, Class II
41	1000 Mb/s Baseband
other	See 30.2.5
unknown	Initializing, true state or type not yet known

BEHAVIOUR DEFINED AS:
Returns a value that identifies the CSMA/CD repeater type. The enumeration of the type is such that the value matches the clause number of the standard that specifies the particular repeater, with further numerical identification for the repeater classes within the same clause.;

30.4.1.1.3 aRepeaterGroupCapacity

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The aRepeaterGroupCapacity is the number of groups that can be contained within the repeater. Within each managed repeater, the groups are uniquely numbered in the range from 1 to aRepeaterGroupCapacity.

Some groups may not be present in a given repeater instance, in which case the actual number of groups present is less than aRepeaterGroupCapacity. The number of groups present is never greater than aRepeaterGroupCapacity.;

30.4.1.1.4 aGroupMap

ATTRIBUTE

APPROPRIATE SYNTAX:
BITSTRING

BEHAVIOUR DEFINED AS:
A string of bits which reflects the current configuration of units that are viewed by group managed objects. The length of the bitstring is “aRepeaterGroupCapacity” bits. The first bit relates to group

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1. A “1” in the bitstring indicates presence of the group, “0” represents absence of the group.;

30.4.1.1.5 aRepeaterHealthState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE LIST that has the following entries:

other	undefined or unknown
ok	no known failures
repeaterFailure	known to have a repeater related failure
groupFailure	known to have a group related failure
portFailure	known to have a port related failure
generalFailure	has a failure condition, unspecified type

BEHAVIOUR DEFINED AS:

The aRepeaterHealthState attribute indicates the operational state of the repeater. The aRepeaterHealthData and aRepeaterHealthText attributes may be consulted for more specific information about the state of the repeater’s health. In case of multiple kinds of failures (e.g., repeater failure and port failure), the value of this attribute shall reflect the highest priority in the following order:
repeater failure
group failure
port failure
general failure;

30.4.1.1.6 aRepeaterHealthText

ATTRIBUTE

APPROPRIATE SYNTAX:

A PrintableString, 255 characters max

BEHAVIOUR DEFINED AS:

The aRepeaterHealthText attribute is a text string that provides information relevant to the operational state of the repeater. Repeater vendors may use this mechanism to provide detailed failure information or instructions for problem resolution.

The contents are vendor specific.;

30.4.1.1.7 aRepeaterHealthData

ATTRIBUTE

APPROPRIATE SYNTAX:

OCTET STRING, 0–255

BEHAVIOUR DEFINED AS:

The aRepeaterHealthData attribute is a block of data octets that provides information relevant to the operational state of the repeater. The encoding of this data block is vendor dependent. Repeater vendors may use this mechanism to provide detailed failure information or instructions for problem resolution.;

30.4.1.1.8 aTransmitCollisions

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Generalized nonresettable counter. This counter has a maximum increment rate of 75 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

For a Clause 9 repeater, the counter increments every time the repeater state diagram enters the TRANSMIT COLLISION state from any state other than ONE PORT LEFT (Figure 9–2). For a Clause 27 repeater, the counter increments every time the Repeater Core state diagram enters the JAM state as a result of Activity(ALL) > 1 (Figure 27–2). For a Clause 41 repeater, the counter increments every time the Repeater Unit state diagram enters the JAM state (Figure 41–2).

NOTE—Some non-collision events such as false carriers will cause the repeater unit to enter the JAM state and increment this counter.;

30.4.1.2 Repeater actions

30.4.1.2.1 acResetRepeater

ACTION

APPROPRIATE SYNTAX:

None required

BEHAVIOUR DEFINED AS:

This causes a transition to the START state of Figure 9–2 for a Clause 9 repeater, to the START state of Figure 27–2 for a Clause 27 repeater, or to the START state of Figure 41–2 for a Clause 41 repeater. The repeater performs a disruptive self-test that has the following characteristics:

1. The components are not specified
2. The test resets the repeater but without affecting management information about the repeater
3. The test does not inject packets onto any segment
4. Packets received during the test may or may not be transferred
5. The test does not interfere with management functions

This causes a nRepeaterReset notification to be sent.;

30.4.1.2.2 acExecuteNonDisruptiveSelfTest

ACTION

APPROPRIATE SYNTAX:

None required

BEHAVIOUR DEFINED AS:

The repeater performs a vendor-specific, non-disruptive self-test that has the following characteristics:

1. The components are not specified
2. The test does not change the state of the repeater or management information about the repeater
3. The test does not inject packets onto any segment
4. The test does not prevent the transfer of any packets
5. Completion of the test causes a nRepeaterHealth to be sent.;

30.4.1.3 Repeater notifications

30.4.1.3.1 nRepeaterHealth

NOTIFICATION

APPROPRIATE SYNTAX:

A SEQUENCE of three data types. The first is mandatory, the following two are optional. The first

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

is the value of the attribute aRepeaterHealthState. The second is the value of the attribute aRepeaterHealthText. The third is the value of the attribute aRepeaterHealthData

BEHAVIOUR DEFINED AS:

This notification conveys information related to the operational state of the repeater. See the aRepeaterHealthState, aRepeaterHealthText, and aRepeaterHealthData attributes for descriptions of the information that is sent.

The nRepeaterHealth notification is sent only when the health state of the repeater changes. The nRepeaterHealth notification shall contain repeaterHealthState. repeaterHealthData and repeaterHealthText may or may not be included. The nRepeaterHealth notification is not sent as a result of powering up a repeater.;

30.4.1.3.2 nRepeaterReset

NOTIFICATION

APPROPRIATE SYNTAX:

A SEQUENCE of three data types. The first is mandatory, the following two are optional. The first is the value of the attribute aRepeaterHealthState. The second is the value of the attribute aRepeaterHealthText. The third is the value of the attribute aRepeaterHealthData

BEHAVIOUR DEFINED AS:

This notification conveys information related to the operational state of the repeater. The nRepeaterReset notification is sent when the repeater is reset as the result of a power-on condition or upon completion of the acResetRepeater action. The nRepeaterReset notification shall contain repeaterHealthState. repeaterHealthData and repeaterHealthText may or may not be included.;

30.4.1.3.3 nGroupMapChange

NOTIFICATION

APPROPRIATE SYNTAX:

BITSTRING

BEHAVIOUR DEFINED AS:

This notification is sent when a change occurs in the group structure of a repeater. This occurs only when a group is logically removed from or added to a repeater. The nGroupMapChange notification is not sent when powering up a repeater. The value of the notification is the updated value of the aGroupMap attribute.;

30.4.2 Group managed object class

This subclause formally defines the behaviours for the oGroup managed object class, attributes, actions, and notifications.

30.4.2.1 Group attributes

30.4.2.1.1 aGroupID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A value unique within the repeater. The value of aGroupID is assigned so as to uniquely identify

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a group among the subordinate managed objects of the containing object (oRepeater). This value is never greater than aRepeaterGroupCapacity.;

30.4.2.1.2 aGroupPortCapacity

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The aGroupPortCapacity is the number of ports contained within the group. Valid range is 1–1024. Within each group, the ports are uniquely numbered in the range from 1 to aGroupPortCapacity. Some ports may not be present in a given group instance, in which case the actual number of ports present is less than aGroupPortCapacity. The number of ports present is never greater than aGroupPortCapacity.;

30.4.2.1.3 aPortMap

ATTRIBUTE

APPROPRIATE SYNTAX:
BitString

BEHAVIOUR DEFINED AS:
A string of bits that reflects the current configuration of port managed objects within this group. The length of the bitstring is "aGroupPortCapacity" bits. The first bit relates to group 1. A "1" in the bitstring indicates presence of the port, "0" represents absence of the port.;

30.4.2.2 Group notifications

30.4.2.2.1 nPortMapChange

NOTIFICATION

APPROPRIATE SYNTAX:
BitString

BEHAVIOUR DEFINED AS:
This notification is sent when a change occurs in the port structure of a group. This occurs only when a port is logically removed from or added to a group. The nPortMapChange notification is not sent when powering up a repeater. The value of the notification is the updated value of the aPortMap attribute.;

30.4.3 Repeater port managed object class

This subclause formally defines the behaviours for the oRepeaterPort managed object class, attributes, actions, and notifications.

30.4.3.1 Port attributes

30.4.3.1.1 aPortID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A value unique in the group. It is assumed that ports are partitioned into groups that also have IDs. The value of aPortID is assigned so as to uniquely identify a repeater port among the subordinate managed objects of the containing object (oGroup). This value can never be greater than aGroupPortCapacity.;

30.4.3.1.2 aPortAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE LIST that has the following entries:
disabled
enabled

BEHAVIOUR DEFINED AS:

A disabled port neither transmits nor receives. The port shall be explicitly enabled to restore operation. The acPortAdminControl action provides this ability. The port enable/disable function as reported by this attribute is preserved across repeater reset including loss of power. aPortAdminState takes precedence over auto-partition and functionally operates between the auto-partition mechanism and the AUI/PMA, PCS/PMA, or GMII/PCS as applicable. For a Clause 9 and Clause 27 repeater, the port auto-partition is reinitialized upon acPortAdminControl taking the value “enabled”. For a Clause 41 repeater, the port auto-partition, receive jabber and carrier integrity functions are reinitialized upon acPortAdminControl taking the value “enabled”.;

30.4.3.1.3 aAutoPartitionState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE LIST that has the following entries:
autoPartitioned
notAutoPartitioned

BEHAVIOUR DEFINED AS:

The aAutoPartitionState flag indicates whether the port is currently partitioned by the repeater’s auto-partition protection. The conditions that cause port partitioning are specified in partition state diagram in Clause 9, Clause 27, and Clause 41. They are not differentiated here. A Clause 27 and Clause 41 repeater port partitions on entry to the PARTITION WAIT state of the partition state diagram (Figure 27–8 and Figure 41–4).;

30.4.3.1.4 aReadableFrames

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 15 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

A representation of the total frames of valid frame length. Increment counter by one for each frame whose OctetCount is greater than or equal to minFrameSize and for which the FCSError and CollisionEvent signals are not asserted, and for which the attribute aFramesTooLong has not been incremented. Additionally, for 1000 Mb/s repeaters, this count shall only be incremented for frames which are received within a CarrierEvent which has a ActivityDuration of greater than or equal to (slotTime + JamSize) BT (see 4.4.2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—This statistic provides one of the parameters necessary for obtaining the packet error ratio.;

30.4.3.1.5 aReadableOctets

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 240 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Increment counter by OctetCount for each frame which has been determined to be a readable frame.

NOTE—This statistic provides an indicator of the total data transferred.;

30.4.3.1.6 aFrameCheckSequenceErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 15 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Increment counter by one for each frame with the FCSError signal asserted and the FramingError and CollisionEvent signals deasserted and whose OctetCount is greater than or equal to minFrameSize and for which the attribute aFramesTooLong has not been incremented.;

30.4.3.1.7 aAlignmentErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 15 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Increment counter by one for each frame with the FCSError and FramingError signals asserted and CollisionEvent signal deasserted and whose OctetCount is greater than or equal to minFrameSize and for which the attribute aFramesTooLong has not been incremented. If aAlignmentErrors is incremented then the aFrameCheckSequenceErrors attribute shall not be incremented for the same frame. This counter will not increment for 8 bit wide group encoding schemes.;

30.4.3.1.8 aFramesTooLong

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 815 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Increment counter by one for each frame whose OctetCount is greater than maxFrameSizeLimit (see 4.2.7.1 and 4.4.2). If aFrameTooLong is counted then neither the aAlignmentErrors nor the aFrameCheckSequenceErrors attribute shall be incremented for the frame.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.4.3.1.9 aShortEvents

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 75 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Increment counter by one for each CarrierEvent with ActivityDuration less than ShortEventMaxTime. In the 10 Mb/s case ShortEventMaxTime is greater than 74 BT and less than 82 BT. ShortEventMaxTime has tolerances included to provide for circuit losses between a conformance test point at the AUI and the measurement point within the state diagram. In the 100 Mb/s case ShortEventMaxTime is 84 bits (21 nibbles), and for the 1000 Mb/s case ShortEventMaxTime is 72 bits (9 octets).

NOTE 1—shortEvents may indicate externally generated noise hits which will cause the repeater to transmit Runts to its other ports, or propagate a collision (which may be late) back to the transmitting DTE and damaged frames to the rest of the network.

NOTE 2—implementers may wish to consider selecting the ShortEventMaxTime towards the lower end of the allowed tolerance range to accommodate bit losses suffered through physical channel devices not budgeted for within this standard.

NOTE 3—Note also that the significance of this attribute is different in 10, 100, and 1000 Mb/s collision domains. Clause 9 repeaters perform fragment extension of short events which would be counted as runts on the interconnect ports of other repeaters. Clause 27 repeaters do not perform fragment extension. Clause 41 repeaters support one repeater per collision domain and do not perform fragment extension.;

30.4.3.1.10 aRunts

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 75 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

Increment counter by one for each CarrierEvent that meets one of the following two conditions. Only one test need be made. a) The ActivityDuration is greater than ShortEventMaxTime and less than ValidPacketMinTime and the CollisionEvent signal is deasserted. b) The OctetCount is less than 64, the ActivityDuration is greater than ShortEventMaxTime, and the CollisionEvent signal is deasserted. For 10 and 100 Mb/s repeaters, ValidPacketMinTime is greater than or equal to 552 BT and less than 565 BT. A CarrierEvent greater than or equal to 552 BT but less than 565 BT may or may not be counted as a runt. At 10 Mb/s an event whose length is greater than 74 BT but less than 82 BT shall increment either the aShortEvents attribute or the aRunts attribute, but not both. ValidPacketMinTime has tolerances included to provide for circuit losses between a conformance test point at the AUI and the measurement point within the state diagram.
For 1000 Mb/s repeaters, ValidPacketMinTime is 4136 BT.

NOTE—Runts usually indicate collision fragments, a normal network event. In certain situations associated with large diameter networks a percentage of runts may exceed ValidPacketMinTime.;

30.4.3.1.11 aCollisions

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Generalized nonresettable counter. This counter has a maximum increment rate of 75 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

This counter increments for any CarrierEvent signal on any port in which the CollisionEvent signal on this port is asserted.;

30.4.3.1.12 aLateEvents

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 75 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

For a Clause 9 repeater port this counter increments for each CarrierEvent in which the CollIn(X) variable transitions to the value SQE (see 9.6.6.2) while the ActivityDuration is greater than the LateEventThreshold. For a Clause 27 and Clause 41 repeater port this counter increments for each CarrierEvent in which the CollisionEvent signal assertion occurs while the ActivityDuration is greater than the LateEventThreshold. In both cases such a CarrierEvent is counted twice, as both an aCollision and as an aLateEvent.

For 10 and 100 Mb/s repeaters, the LateEventThreshold is greater than 480 BT and less than 565 BT. LateEventThreshold has tolerances included to permit an implementation to build a single threshold to serve as both the LateEventThreshold and ValidPacketMinTime threshold. For 1000 Mb/s repeaters, the LateEventThreshold is equal to ValidPacketMinTime.;

30.4.3.1.13 aVeryLongEvents

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 250 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:

For a Clause 9 repeater port this counter increments for each CarrierEvent whose ActivityDuration is greater than the MAU Jabber Lockup Protection timer TW3 (see 9.6.1, 9.6.5). For a Clause 27 and Clause 41 repeater port this counter increments on entry to the RX JABBER state of the receive timer state diagram (Figure 27–7 and Figure 41–3). Other counters may be incremented as appropriate.;

30.4.3.1.14 aDataRateMismatches

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter

BEHAVIOUR DEFINED AS:

Increment counter by one for each frame received by this port that meets all of the conditions required by only one of the following three measurement methods:

Measurement method A, which is valid for 10 and 100 Mb/s operation only: a) The CollisionEvent signal is not asserted. b) The ActivityDuration is greater than ValidPacketMinTime. c) The received frequency (data rate) is detectably mismatched from the local transmit frequency.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Measurement method B, which is valid for 10 and 100 Mb/s operation only: a) The CollisionEvent signal is not asserted. b) The OctetCount is greater than 63. c) The received frequency (data rate) is detectably mismatched from the local transmit frequency.

Measurement method C, which is valid for 1000 Mb/s operation only: The received frequency (data rate) is detectably mismatched from the local transmit frequency.

The exact degree of mismatch is vendor specific and is to be defined by the vendor for conformance testing. When this event occurs, other counters whose increment conditions were satisfied may or may not also be incremented, at the implementer's discretion.

NOTE—Whether or not the repeater was able to maintain data integrity is beyond the scope of this standard.;

30.4.3.1.15 aAutoPartitions

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter

BEHAVIOUR DEFINED AS:
Increment counter by one for each time that the repeater has automatically partitioned this port. The conditions that cause a Clause 9 repeater port to partition are specified in the partition state diagram in Clause 9. They are not differentiated here. A Clause 27 and Clause 41 repeater port partitions on entry to the PARTITION WAIT state of the partition state diagram (Figure 27–8 and Figure 41–4).;

30.4.3.1.16 aIsolates

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 400 counts per second at 100 Mb/s

BEHAVIOUR DEFINED AS:
Increment counter by one each time that the repeater port automatically isolates as a consequence of false carrier events. The conditions that cause a port to automatically isolate are as defined by the transition from the FALSE CARRIER state to the LINK UNSTABLE state of the carrier integrity state diagram (Figure 27–9 and Figure 41–5).

NOTE—Isolates do not affect the value of aPortAdminState.;

30.4.3.1.17 aSymbolErrorDuringPacket

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 160 000 counts per second for 100 Mb/s implementations

BEHAVIOUR DEFINED AS:
A count of the number of times when valid length packet was received at the port and there was at least one occurrence of an invalid data symbol. This can increment only once per valid CarrierEvent. A collision presence at any port of the repeater containing port N, will not cause this attribute to increment.;

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.4.3.1.18 aLastSourceAddress

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
The Source Address of the last readable Frame received by this port.;

30.4.3.1.19 aSourceAddressChanges

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 15 000 counts per second at 10 Mb/s

BEHAVIOUR DEFINED AS:
Increment counter by one each time that the aLastSourceAddress attribute has changed.

NOTE—This may indicate whether a link is connected to a single DTE or another multi-user segment.;

30.4.3.1.20 aBursts

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 235 000 counts per second at 1000 Mb/s

BEHAVIOUR DEFINED AS:
This counter is valid for 1000 Mb/s operation only. This counter increments by one for each CarrierEvent with ActivityDuration greater than or equal to slotTime during which the CollisionEvent signal has not been asserted. Note that this counter will not increment for a 10 or 100 Mb/s port as packet bursting is not supported at these speeds.;

30.4.3.2 Port actions

30.4.3.2.1 acPortAdminControl

ACTION

APPROPRIATE SYNTAX:
Same as aPortAdminState

BEHAVIOUR DEFINED AS:
This action provides a means to alter aPortAdminState. For a Clause 9 and Clause 27 repeater it should exert a BEGIN on the Partitioning state diagram (Figure 9–6 and Figure 27–8) upon taking the value “enabled”. For a Clause 41 repeater it shall exert a BEGIN on the receive timer, partition, and carrier integrity state diagrams (Figure 41–3, Figure 41–4, and Figure 41–5) upon taking the value “enabled”.;

30.5 Layer management for medium attachment units (MAUs)

30.5.1 MAU managed object class

This subclause formally defines the behaviours for the oMAU managed object class, attributes, actions, and notifications.

The sublayer that connects directly to the media is called MAU for 10 Mb/s operation and its equivalent is the combined PMA and PMD sublayers at higher operating speeds. Because this clause defines management for use at many speeds, it needs to be able to refer to MAUs and the PMA and PMD sublayers as a group. Therefore in this clause, the term MAU will include PMA and PMD sublayers, as well as MAUs, except in those instances where it is explicitly restricted to 10 Mb/s.

30.5.1.1 MAU attributes

30.5.1.1.1 aMAUID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aMAUID is assigned so as to uniquely identify a MAU among the subordinate managed objects of the containing object.;

30.5.1.1.2 aMAUType

ATTRIBUTE

APPROPRIATE SYNTAX:
A GET-SET ENUMERATION that meets the requirements of the following description:

global	undefined
other	See 30.2.5
unknown	Initializing, true state or type not yet known
AUI	no internal MAU, view from AUI
2BASE-TL	Voice grade twisted-pair cabling PHY as specified in Clause 61 and 63
10BASE2	Thin coax MAU as specified in Clause 10
10BASE5	Thick coax MAU as specified in Clause 8
10BASE-FB	Synchronous fiber MAU as specified in Clause 17
10BASE-FL	Asynchronous fiber MAU as specified in Clause 18, duplex mode unknown
10BASE-FLFD	Asynchronous fiber MAU as specified in Clause 18, full duplex mode
10BASE-FLHD	Asynchronous fiber MAU as specified in Clause 18, half duplex mode
10BASE-FP	Passive fiber MAU as specified in Clause 16
10BASE-T	Twisted-pair cabling MAU as specified in Clause 14, duplex mode unknown
10BASE-T1L	Single balanced pair PHY as specified in Clause 146
10BASE-T1SFD	Single balanced pair PHY as specified in Clause 147, full duplex mode
10BASE-T1SHD	Single balanced pair PHY as specified in Clause 147, half duplex mode
10BASE-T1SMD	Single balanced pair PHY as specified in Clause 147, multidrop mode
10BASE-TFD	Twisted-pair cabling MAU as specified in Clause 14, full duplex mode
10BASE-THD	Twisted-pair cabling MAU as specified in Clause 14, half duplex mode
10BROAD36	Broadband DTE MAU as specified in Clause 11
10PASS-TS	Voice grade twisted-pair cabling PHY as specified in Clause 61 and 62

FOIRL	FOIRL MAU as specified in 9.9
100BASE-BX10D	One single-mode fiber OLT PHY as specified in Clause 58
100BASE-BX10U	One single-mode fiber ONU PHY as specified in Clause 58
100BASE-FX	X fiber over PMD as specified in Clause 26, duplex mode unknown
100BASE-FXFD	X fiber over PMD as specified in Clause 26, full duplex mode
100BASE-FXHD	X fiber over PMD as specified in Clause 26, half duplex mode
100BASE-LX10	Two fiber PHY as specified in Clause 58
100BASE-T1	Single balanced twisted-pair copper cabling PHY as specified in Clause 96
100BASE-T2	Two-pair Category 3 twisted-pair cabling as specified in Clause 32, duplex mode unknown
100BASE-T2FD	Two-pair Category 3 twisted-pair cabling as specified in Clause 32, full duplex mode
100BASE-T2HD	Two-pair Category 3 twisted-pair cabling as specified in Clause 32, half duplex mode
100BASE-T4	Four-pair Category 3 twisted-pair cabling as specified in Clause 23
100BASE-TX	Two-pair Category 5 twisted-pair cabling as specified in Clause 25, duplex mode unknown
100BASE-TXFD	Two-pair Category 5 twisted-pair cabling as specified in Clause 25, full duplex mode
100BASE-TXHD	Two-pair Category 5 twisted-pair cabling as specified in Clause 25, half duplex mode
1000BASE-BX10D	One single-mode fiber OLT PHY as specified in Clause 59
1000BASE-BX10U	One single-mode fiber ONU PHY as specified in Clause 59
1000BASE-CX	X copper over 150-Ohm balanced cable PMD as specified in Clause 39, duplex mode unknown
1000BASE-CXFD	X copper over 150-Ohm balanced cable PMD as specified in Clause 39, full duplex mode
1000BASE-CXHD	X copper over 150-Ohm balanced cable PMD as specified in Clause 39, half duplex mode
1000BASE-KX	X PCS/PMA over an electrical backplane PMD as specified in Clause 70
1000BASE-LX	X fiber over long-wavelength laser PMD as specified in Clause 38, duplex mode unknown
1000BASE-LX10	Two fiber 10 km PHY as specified in Clause 59
1000BASE-LXFD	X fiber over long-wavelength laser PMD as specified in Clause 38, full duplex mode
1000BASE-LXHD	X fiber over long-wavelength laser PMD as specified in Clause 38, half duplex mode
1000BASE-PX10-D	One single-mode fiber OMP OLT PHY, as specified in Clause 60, supporting a distance of at least 10 km, and a split of at least 1:16
1000BASE-PX10-U	One single-mode fiber OMP ONU PHY, as specified in Clause 60, supporting a distance of at least 10 km, and a split of at least 1:16
1000BASE-PX20-D	One single-mode fiber OMP OLT PHY, as specified in Clause 60, supporting a distance of at least 20 km, and a split of at least 1:16
1000BASE-PX20-U	One single-mode fiber OMP ONU PHY, as specified in Clause 60, supporting a distance of at least 20 km, and a split of at least 1:16
1000BASE-PX30-D	One single-mode fiber OMP OLT PHY, as specified in Clause 60, supporting a distance of at least 20 km, and a split of at least 1:32
1000BASE-PX30-U	One single-mode fiber OMP ONU PHY, as specified in Clause 60, supporting a distance of at least 20 km, and a split of at least 1:32
1000BASE-PX40-D	One single-mode fiber OMP OLT PHY as specified in Clause 60, supporting a distance of at least 20 km, and a split of at least 1:64
1000BASE-PX40-U	One single-mode fiber OMP ONU PHY as specified in Clause 60, supporting a distance of at least 20 km, and a split of at least 1:64

1000BASE-RHA	Plastic optical fiber PHY as specified in Clause 115.
1000BASE-RHB	Plastic optical fiber PHY as specified in Clause 115.
1000BASE-RHC	Plastic optical fiber PHY as specified in Clause 115.
1000BASE-SX	X fiber over short-wavelength laser PMD as specified in Clause 38, duplex mode unknown
1000BASE-SXFD	X fiber over short-wavelength laser PMD as specified in Clause 38, full duplex mode
1000BASE-SXHD	X fiber over short-wavelength laser PMD as specified in Clause 38, half duplex mode
1000BASE-T	Four-pair Category 5 twisted-pair cabling PHY as specified in Clause 40, duplex mode unknown
1000BASE-T1	Single twisted-pair copper cable PHY as specified in Clause 97
1000BASE-TFD	Four-pair Category 5 twisted-pair cabling PHY as specified in Clause 40, full duplex mode
1000BASE-THD	Four-pair Category 5 twisted-pair cabling PHY as specified in Clause 40, half duplex mode
1000BASE-X	X PCS/PMA as specified in Clause 36 over undefined PMD, duplex mode unknown
1000BASE-XFD	X PCS/PMA as specified in Clause 36 over undefined PMD, full duplex mode
1000BASE-XHD	X PCS/PMA as specified in Clause 36 over undefined PMD, half duplex mode
2.5GBASE-KX	2.5GBASE-X PMD as specified in Clause 128 over an electrical backplane as specified in Clause 128
2.5GBASE-T	Four-pair twisted-pair balanced copper cabling PHY as specified in Clause 126
2.5GBASE-T1	Single balanced pair of conductors PHY as specified in Clause 149
2.5GBASE-X	2.5GBASE-X PCS/PMA as specified in Clause 127 over undefined PMD
5GBASE-KR	5GBASE-KR PMD as specified in Clause 130 over an electrical backplane as specified in Clause 130
5GBASE-R	5GBASE-R PCS/PMA as specified in Clause 129 over undefined PMD
5GBASE-T	Four-pair twisted-pair balanced copper cabling PHY as specified in Clause 126
5GBASE-T1	Single balanced pair of conductors PHY as specified in Clause 149
10/1GBASE-PRX-D1	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream OLT PHY as specified in Clause 75
10/1GBASE-PRX-D2	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream OLT PHY as specified in Clause 75
10/1GBASE-PRX-D3	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream OLT PHY as specified in Clause 75
10/1GBASE-PRX-D4	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream OLT PHY as specified in Clause 75
10/1GBASE-PRX-U1	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream ONU PHY as specified in Clause 75
10/1GBASE-PRX-U2	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream ONU PHY as specified in Clause 75
10/1GBASE-PRX-U3	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream ONU PHY as specified in Clause 75
10/1GBASE-PRX-U4	One single-mode fiber 10.3125 GBd continuous downstream / 1.25 GBd burst mode upstream ONU PHY as specified in Clause 75
10GBASE-BR10-D	One single-mode fiber OLT PHY supporting a distance of at least 10 km as specified in Clause 158
10GBASE-BR10-U	One single-mode fiber ONU PHY supporting a distance of at least

	10 km as specified in Clause 158
10GBASE-BR20-D	One single-mode fiber OLT PHY supporting a distance of at least 20 km as specified in Clause 158
10GBASE-BR20-U	One single-mode fiber ONU PHY supporting a distance of at least 20 km as specified in Clause 158
10GBASE-BR40-D	One single-mode fiber OLT PHY upporting a distance of at least 40 km as specified in Clause 158
10GBASE-BR40-U	One single-mode fiber ONU PHY supporting a distance of at least 40 km as specified in Clause 158
10GBASE-CX4	X copper over 8 pair 100-Ohm balanced cable as specified in Clause 54
10GBASE-ER	R fiber over 1550nm optics as specified in Clause 52
10GBASE-EW	W fiber over 1550nm optics as specified in Clause 52
10GBASE-KR	R PCS/PMA over an electrical backplane PMD as specified in Clause 72
10GBASE-KX4	X PCS/PMA over an electrical backplane PMD as specified in Clause 71
10GBASE-LR	R fiber over 1310nm optics as specified in Clause 52
10GBASE-LRM	R fiber over 1310 nm optics as specified in Clause 68
10GBASE-LW	W fiber over 1310nm optics as specified in Clause 52
10GBASE-LX4	X fiber over 4 lane 1310nm optics as specified in Clause 53
10GBASE-PR-D1	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream OLT PHY as specified in Clause 75
10GBASE-PR-D2	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream OLT PHY as specified in Clause 75
10GBASE-PR-D3	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream OLT PHY as specified in Clause 75
10GBASE-PR-D4	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream OLT PHY as specified in Clause 75
10GBASE-PR-U1	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream ONU PHY as specified in Clause 75
10GBASE-PR-U3	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream ONU PHY as specified in Clause 75
10GBASE–PR–U4	One single-mode fiber 10.3125 GBd continuous downstream / burst mode upstream ONU PHY as specified in Clause 75
10GBASE-R	R PCS/PMA as specified in Clause 49 over undefined PMD
10GBASE-SR	R fiber over 850nm optics as specified in Clause 52
10GBASE-SW	W fiber over 850nm optics as specified in Clause 52
10GBASE-T	Four-pair twisted-pair balanced copper cabling PHY as specified in Clause 55
10GBASE-T1	Single balanced pair of conductors PHY as specified in Clause 149
10GBASE-W	W PCS/PMA as specified in Clause 49 and 50 over undefined PMD
10GBASE-X	X PCS/PMA as specified in Clause 48 over undefined PMD
10GPASS-XR	Coax cable distribution network PHY continuous downstream/burst mode upstream PHY as specified in Clause 100 and Clause 101
25/10GBASE-PQG-D2	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, medium power class, as specified in Clause 141
25/10GBASE-PQG-D3	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, high power class, as specified in Clause 141
25/10GBASE-PQG-U2	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, medium power class, as specified in Clause 141
25/10GBASE-PQG-U3	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, high power class, as specified in Clause 141

25/10GBASE-PQX-D2	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, medium power class, as specified in Clause 141
25/10GBASE-PQX-D3	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, high power class, as specified in Clause 141
25/10GBASE-PQX-U2	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, medium power class, as specified in Clause 141
25/10GBASE-PQX-U3	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, high power class, as specified in Clause 141
25GBASE-BR10-D	One single-mode fiber OLT PHY supporting a distance of at least 10 km as specified in Clause 159
25GBASE-BR10-U	One single-mode fiber ONU PHY supporting a distance of at least 10 km as specified in Clause 159
25GBASE-BR20-D	One single-mode fiber OLT PHY supporting a distance of at least 20 km as specified in Clause 159
25GBASE-BR20-U	One single-mode fiber ONU PHY supporting a distance of at least 20 km as specified in Clause 159
25GBASE-BR40-D	One single-mode fiber OLT PHY supporting a distance of at least 40 km as specified in Clause 159
25GBASE-BR40-U	One single-mode fiber ONU PHY supporting a distance of at least 40 km as specified in Clause 159
25GBASE-CR	25GBASE-R PCS/PMA over shielded balanced copper cable PMD as specified in Clause 110
25GBASE-CR-S	25GBASE-R PCS/PMA over shielded balanced copper cable PMD as specified in Clause 110 without support for RS-FEC
25GBASE-ER	25GBASE-R PCS/PMA over single-mode fiber PMD, with extended reach, as specified in Clause 114
25GBASE-KR	25GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 111
25GBASE-KR-S	25GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 111 without support for RS-FEC
25GBASE-LR	25GBASE-R PCS/PMA over single-mode fiber PMD, with long reach, as specified in Clause 114
25GBASE-PQG-D2	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, medium power class, as specified in Clause 141
25GBASE-PQG-D3	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, high power class, as specified in Clause 141
25GBASE-PQG-U2	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, medium power class, as specified in Clause 141
25GBASE-PQG-U3	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, high power class, as specified in Clause 141
25GBASE-PQX-D2	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, medium power class, as specified in Clause 141
25GBASE-PQX-D3	One single mode fiber, 1 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, high power class, as specified in Clause 141

25GBASE-PQX-U2	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, medium power class, as specified in Clause 141
25GBASE-PQX-U3	One single mode fiber, 1 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, high power class, as specified in Clause 141
25GBASE-R	PCS as specified in Clause 107 with PMA as specified in Clause 109 over undefined PMD
25GBASE-SR	25GBASE-R PCS/PMA over multimode fiber PMD as specified in Clause 112
25GBASE-T	Four-pair twisted-pair balanced copper cabling PHY as specified in Clause 113
40GBASE-CR4	40GBASE-R PCS/PMA over 4 lane shielded copper balanced cable PMD as specified in Clause 85
40GBASE-ER4	40GBASE-R PCS/PMA over 4 WDM lane single mode fiber PMD, with extended reach, as specified in Clause 87
40GBASE-FR	40GBASE-R PCS/PMA over single mode fiber PMD as specified in Clause 89
40GBASE-KR4	40GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 84
40GBASE-LR4	40GBASE-R PCS/PMA over 4 WDM lane single mode fiber PMD, with long reach, as specified in Clause 87
40GBASE-R	Multi-lane PCS as specified in Clause 82 over undefined PMA/PMD
40GBASE-SR4	40GBASE-R PCS/PMA over 4 lane multimode fiber PMD as specified in Clause 86
40GBASE-T	Four-pair twisted-pair balanced copper cabling PHY as specified in Clause 113
50/10GBASE-PQG-D2	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, medium power class, as specified in Clause 141
50/10GBASE-PQG-D3	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, high power class, as specified in Clause 141
50/10GBASE-PQG-U2	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, medium power class, as specified in Clause 141
50/10GBASE-PQG-U3	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, high power class, as specified in Clause 141
50/10GBASE-PQX-D2	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, medium power class, as specified in Clause 141
50/10GBASE-PQX-D3	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 10.3125 GBd burst mode reception, high power class, as specified in Clause 141
50/10GBASE-PQX-U2	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, medium power class, as specified in Clause 141
50/10GBASE-PQX-U3	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 10.3125 GBd burst mode transmission, high power class, as specified in Clause 141
50/25GBASE-PQG-D2	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, medium power class, as specified in Clause 141

50/25GBASE-PQG-D3	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, high power class, as specified in Clause 141
50/25GBASE-PQG-U2	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, medium power class, as specified in Clause 141
50/25GBASE-PQG-U3	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, high power class, as specified in Clause 141
50/25GBASE-PQX-D2	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, medium power class, as specified in Clause 141
50/25GBASE-PQX-D3	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 1 × 25.78125 GBd burst mode reception, high power class, as specified in Clause 141
50/25GBASE-PQX-U2	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, medium power class, as specified in Clause 141
50/25GBASE-PQX-U3	One single mode fiber, 2 × 25.78125 GBd continuous reception / 1 × 25.78125 GBd burst mode transmission, high power class, as specified in Clause 141
50GBASE-BR10-D	One single-mode fiber OLT PHY supporting a distance of at least 10 km as specified in Clause 160
50GBASE-BR10-U	One single-mode fiber ONU PHY supporting a distance of at least 10 km as specified in Clause 160
50GBASE-BR20-D	One single-mode fiber OLT PHY supporting a distance of at least 20 km as specified in Clause 160
50GBASE-BR20-U	One single-mode fiber ONU PHY supporting a distance of at least 20 km as specified in Clause 160
50GBASE-BR40-D	One single-mode fiber OLT PHY supporting a distance of at least 40 km as specified in Clause 160
50GBASE-BR40-U	One single-mode fiber ONU PHY supporting a distance of at least 40 km as specified in Clause 160
50GBASE-CR	50GBASE-R PCS/PMA over shielded copper balanced cable PMD as specified in Clause 136
50GBASE-ER	50GBASE-R PCS/PMA over single-mode fiber PMD with reach up to at least 40 km as specified in Clause 139
50GBASE-FR	50GBASE-R PCS/PMA over single mode fiber PMD as specified in Clause 139
50GBASE-KR	50GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 137
50GBASE-LR	50GBASE-R PCS/PMA over single mode fiber PMD as specified in Clause 139
50GBASE-PQG-D2	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 2 × 25.78125 GBd burst mode reception, medium power class, as specified in Clause 141
50GBASE-PQG-D3	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 2 × 25.78125 GBd burst mode reception, high power class, as specified in Clause 141
50GBASE-PQG-U2	One single mode fiber, 2 × 25.78125 GBd continuous reception / 2 × 25.78125 GBd burst mode transmission, medium power class, as specified in Clause 141
50GBASE-PQG-U3	One single mode fiber, 2 × 25.78125 GBd continuous reception /

	2 × 25.78125 GBd burst mode transmission, high power class, as specified in Clause 141
50GBASE-PQX-D2	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 2 × 25.78125 GBd burst mode reception, medium power class, as specified in Clause 141
50GBASE-PQX-D3	One single mode fiber, 2 × 25.78125 GBd continuous transmission / 2 × 25.78125 GBd burst mode reception, high power class, as specified in Clause 141
50GBASE-PQX-U2	One single mode fiber, 2 × 25.78125 GBd continuous reception / 2 × 25.78125 GBd burst mode transmission, medium power class, as specified in Clause 141
50GBASE-PQX-U3	One single mode fiber, 2 × 25.78125 GBd continuous reception / 2 × 25.78125 GBd burst mode transmission, high power class, as specified in Clause 141
50GBASE-R	Multi-lane PCS as specified in Clause 133 with PMA as specified in Clause 135 over undefined PMD
50GBASE-SR	50GBASE-R PCS/PMA over multimode fiber PMD as specified in Clause 138
100GBASE-CR2	100GBASE-R PCS/PMA over 2 lane shielded copper balanced cable PMD as specified in Clause 136
100GBASE-CR4	100GBASE-R PCS/PMA over 4 lane shielded copper balanced cable PMD as specified in Clause 92
100GBASE-CR10	100GBASE-R PCS/PMA over 10 lane shielded copper balanced cable PMD as specified in Clause 85
100GBASE-DR	100GBASE-R PCS/PMA over single mode fiber PMD as specified in Clause 140
100GBASE-ER4	100GBASE-R PCS/PMA over 4 WDM lane single mode fiber PMD, with extended reach, as specified in Clause 88
100GBASE-FR1	100GBASE-R PCS/PMA over single-mode fiber PMD with reach up to at least 2 km as specified in Clause 140
100GBASE-KP4	100GBASE-P PCS/PMA over an electrical backplane PMD as specified in Clause 94
100GBASE-KR2	100GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 137
100GBASE-KR4	100GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 93
100GBASE-LR1	100GBASE-R PCS/PMA over single-mode fiber PMD with reach up to at least 10 km as specified in Clause 140
100GBASE-LR4	100GBASE-R PCS/PMA over 4 WDM lane single mode fiber PMD, with long reach, as specified in Clause 88
100GBASE-R	Multi-lane PCS as specified in Clause 82 over undefined 100GBASE-R or 100GBASE-P PMA/PMD
100GBASE-SR2	100GBASE-R PCS/PMA over 2 lane multimode fiber PMD as specified in Clause 138
100GBASE-SR4	100GBASE-R PCS/PMA over 4 lane multimode fiber PMD as specified in Clause 95
100GBASE-SR10	100GBASE-R PCS/PMA over 10 lane multimode fiber PMD as specified in Clause 86
100GBASE-ZR	100GBASE-R PCS/100GBASE-ZR PMA over a PMD with reach up to at least 80 km as specified in Clause 154
200GBASE-CR4	200GBASE-R PCS/PMA over 4 lane shielded copper balanced cable PMD as specified in Clause 136
200GBASE-DR4	200GBASE-R PCS/PMA over 4-lane single-mode fiber PMD as specified in Clause 121

200GBASE-ER4	200GBASE-R PCS/PMA over 4 WDM lane single-mode fiber PMD with reach up to at least 40 km as specified in Clause 122
200GBASE-FR4	200GBASE-R PCS/PMA over 4 WDM lane single-mode fiber PMD with reach up to at least 2 km as specified in Clause 122
200GBASE-KR4	200GBASE-R PCS/PMA over an electrical backplane PMD as specified in Clause 137
200GBASE-LR4	200GBASE-R PCS/PMA over 4 WDM lane single-mode fiber PMD with reach up to at least 10 km as specified in Clause 122
200GBASE-R	Multi-lane PCS as specified in Clause 119 over undefined PMA/PMD
200GBASE-SR4	200GBASE-R PCS/PMA over 4 lane multimode fiber PMD as specified in Clause 138
400GBASE-DR4	400GBASE-R PCS/PMA over 4-lane single-mode fiber PMD as specified in Clause 124
400GBASE-ER8	400GBASE-R PCS/PMA over 8 WDM lane single-mode fiber PMD with reach up to at least 40 km as specified in Clause 122
400GBASE-FR4	400GBASE-R PCS/PMA over 4 WDM lane single-mode fiber PMD with reach up to at least 2 km as specified in Clause 151
400GBASE-FR8	400GBASE-R PCS/PMA over 8 WDM lane single-mode fiber PMD with reach up to at least 2 km as specified in Clause 122
400GBASE-LR4-6	400GBASE-R PCS/PMA over 4 WDM lane single-mode fiber PMD with reach up to at least 6 km as specified in Clause 151
400GBASE-LR8	400GBASE-R PCS/PMA over 8 WDM lane single-mode fiber PMD with reach up to at least 10 km as specified in Clause 122
400GBASE-R	Multi-lane PCS as specified in Clause 119 over undefined PMA/PMD
400GBASE-SR4.2	400GBASE-R PCS/PMA over 8-lane multimode fiber PMD as specified in Clause 150
400GBASE-SR8	400GBASE-R PCS/PMA over 8-lane multimode fiber PMD as specified in Clause 138
400GBASE-SR16	400GBASE-R PCS/PMA over 16-lane multimode fiber PMD as specified in Clause 123
802.9a	Integrated services MAU as specified in IEEE Std 802.9a-1995 (withdrawn)

BEHAVIOUR DEFINED AS:

Returns a value that identifies the internal MAU type. If an AUI is to be identified to access an external MAU, the type “AUI” is returned. A SET operation to one of the possible enumerations indicated by aMAUTypeList will force the MAU into the new operating mode. If a Clause 22 MII or Clause 35 GMII is present, then this will map to the mode force bits specified in 22.2.4.1. If a Clause 45 MDIO Interface is present, then this will map to the PCS type selection bit(s) in the 10G WIS Control 2 register specified in 45.2.2.6.6, the PCS Control 2 register specified in 45.2.3.6.1, the PMA/PMD type selection bits in the PMA/PMD Control 2 register specified in 45.2.1.6, the PMA/PMD control 1 register specified in 45.2.1.1, the RS-FEC Enable bit in the RS-FEC control register specified in 45.2.1.116.3, and the PCS control 1 register 45.2.3.1. If Clause 28, Clause 37, or Clause 73 Auto-Negotiation is operational, then this will change the advertised ability to the single enumeration specified in the SET operation, and cause an immediate link renegotiation. A change in the MAU type will also be reflected in aPHYType.

The enumerations 1000BASE-X, 1000BASE-XHD, 1000BASE-XFD, 2.5GBASE-X, 5GBASE-R, 10GBASE-X, 10GBASE-R, 10GBASE-W, 25GBASE-R, 40GBASE-R, 50GBASE-R, 100GBASE-R, 200GBASE-R, and 400GBASE-R shall only be returned if the underlying PMD type is unknown.;

30.5.1.1.3 aMAUTypeList

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of ENUMERATIONS that match the syntax of aMAUType

BEHAVIOUR DEFINED AS:

A GET attribute that returns the possible types that the MAU could be, identifying the ability of the MAU. This attribute maps to aPHYTypeList.;

30.5.1.1.4 aMediaAvailable

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

other	undefined
unknown	initializing, true state not yet known
available	link or light normal, loopback normal
available reduced	link normal, reduced bandwidth, applies only to 2BASE-TL and 10PASS-TS
not available	link loss or low light, no loopback
remote fault	remote fault with no detail
invalid signal	invalid signal, applies only to 10BASE-FB
remote jabber	remote fault, reason known to be jabber
remote link loss	remote fault, reason known to be far-end link loss
remote test	remote fault, reason known to be test
ready	at least one PME available, applies only to 2BASE-TL and 10PASS-TS
offline	offline, applies only to Clause 37 Auto-Negotiation
auto neg error	Auto-Negotiation Error, applies only to Clause 37 Auto-Negotiation
PMD link fault	PMD/PMA receive link fault
WIS frame loss	WIS loss of frame, applies only to 10GBASE-W
WIS signal loss	WIS loss of signal, applies only to 10GBASE-W
PCS link fault	PCS receive link fault
excessive BER	PCS Bit Error Ratio monitor reporting excessive error ratio
DXS link fault	DTE XGXS receive link fault, applies only to XAUI
PXS link fault	PHY XGXS transmit link fault, applies only to XAUI

BEHAVIOUR DEFINED AS:

If the MAU is a 10 Mb/s link or fiber type (FOIRL, 10BASE-T, 10BASE-F), then this is equivalent to the link test fail state/low light function. For an AUI, 10BASE2, 10BASE5, or 10BROAD36 MAU, this indicates whether or not loopback is detected on the DI circuit. The value of this attribute persists between packets for MAU types AUI, 10BASE5, 10BASE2, 10BROAD36, and 10BASE-FP.

At power-up or following a reset, the value of this attribute will be “unknown” for AUI, 10BASE5, 10BASE2, 10BROAD36, and 10BASE-FP MAUs. For these MAUs loopback will be tested on each transmission during which no collision is detected. If DI is receiving *input* when DO returns to IDL after a transmission and there has been no collision during the transmission, then loopback will be detected. The value of this attribute will only change during noncollided transmissions for AUI, 10BASE2, 10BASE5, 10BROAD36, and 10BASE-FP MAUs.

For 100BASE-T2 and 100BASE-T4 PHYs the enumerations match the states within the respective link integrity state diagrams, Figure 32-16 and Figure 23–12. For 100BASE-TX, 100BASE-FX, 100BASE-LX10 and 100BASE-BX10 PHYs the enumerations match the states within the link integrity state diagram Figure 24–15. For 1000BASE-RHx, a link_status (see 115.3.5.4 and 45.2.3.54) of OK maps to the enumeration “available” and a link_status of FAIL maps to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

enumeration “not available”. For 10BASE-T1L and 100BASE-T1, a link_status of OK maps to the enumeration “available”. All other states of link_status map to the enumeration “not available”. For 1000BASE-T1, a link_status of OK maps to the enumeration “available”. All other states of link_status map to the enumeration “not available”. Any MAU that implements management of Clause 28, Clause 73, or Clause 98 Auto-Negotiation will map remote fault indication to MediaAvailable “remote fault”. Any MAU that implements management of Clause 37 Auto-Negotiation will map the received RF1 and RF2 bits as specified in Table 37–3, as follows. Offline maps to the enumeration “offline”, Link_Failure maps to the enumeration “remote fault” and Auto-Negotiation Error maps to the enumeration “auto neg error”.

The enumeration “remote fault” applies to 10BASE-FB remote fault indication, the 100BASE-X far-end fault indication and nonspecified remote faults from a system running Clause 28 Auto-Negotiation. The enumerations “remote jabber”, “remote link loss”, or “remote test” should be used instead of “remote fault” where the reason for remote fault is identified in the remote signaling protocol.

Where a Clause 22 MII or Clause 35 GMII is present, a one in the remote fault bit (22.2.4.2.11) maps to the enumeration “remote fault”, a zero in the link status bit (22.2.4.2.13) maps to the enumeration “not available”. The enumeration “not available” takes precedence over “remote fault”.

For 40 Gb/s, 50 Gb/s, 100 Gb/s, 200 Gb/s, and 400 Gb/s, the enumerations map to value of the link_fault variable (see 81.3.4.1) within the Link Fault Signaling state diagram (see Figure 81–11) as follows: the values OK and Link Interruption map to the enumeration “available”, the value Local Fault maps to the enumeration “not available” and the value Remote Fault maps to the enumeration “remote fault”.

For 2BASE-TL and 10PASS-TS PHYs, the enumeration “unknown” maps to the condition where the PHY is initializing, the enumeration “ready” maps to the condition where at least one PME is available and is ready for handshake, the enumeration “available” maps to the condition where, at the PCS, at least one PME is operationally linked, the enumeration “not available” maps to the condition where the PCS is not operationally linked, the enumeration “available reduced” maps to the condition where a link fault is detected at the receive direction by one or more PMEs in the aggregation group and the enumeration “PMD link fault” maps to the condition where a link fault is detected at the receive direction by all of the PMA/PMDs in the aggregation group.

For 2.5 Gb/s, 5 Gb/s, 10 Gb/s, and 25 Gb/s the enumerations map to value of the link_fault variable within the Link Fault Signaling state diagram (Figure 46–11) as follows: the values OK and Link Interruption map to the enumeration “available”, the value Local Fault maps to the enumeration “not available” and the value Remote Fault maps to the enumeration “remote fault”. The enumeration “PMD link fault”, “WIS frame loss”, “WIS signal loss”, “PCS link fault”, “excessive BER” or “DXS link fault” should be used instead of the enumeration “not available” where the reason for the Local Fault state can be identified through the use of the Clause 45 MDIO Interface. Where multiple reasons for the Local Fault state can be identified only the highest precedence error should be reported. This precedence in descending order is as follows: “PXS link fault”, “PMD link fault”, “WIS frame loss”, “WIS signal loss”, “PCS link fault”, “excessive BER”, “DXS link fault”. Where a Clause 45 MDIO interface is present a zero in the PMA/PMD Receive link status bit (45.2.1.2.4) maps to the enumeration “PMD link fault”, a one in the LOF status bit (45.2.2.10.4) maps to the enumeration “WIS frame loss”, a one in the LOS status bit (45.2.2.10.5) maps to the enumeration “WIS signal loss”, a zero in the PCS Receive link status bit (45.2.3.2.7 or 45.2.3.87.1) maps to the enumeration “PCS link fault”, a one in the 10/40/100GBASE-R PCS Latched high BER status bit (45.2.3.16.2) or a one in the MultiGBASE-T1 PCS status 2 Latched high BER status bit (45.2.3.87.4) maps to the enumeration “excessive BER”, a zero in the DTE XS receive link status bit (45.2.5.2.7) maps to the enumeration “DXS link fault” and a zero in the PHY XS transmit link status bit (45.2.4.2.7) maps to the enumeration “PXS link fault”.;

30.5.1.1.5 aLoseMediaCounter

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 10 counts per second

BEHAVIOUR DEFINED AS:

Counts the number of times that the MediaAvailable attribute changes from the enumeration "available" to any other enumeration. Mandatory for MAU type "AUI", optional for all others.;

30.5.1.1.6 aJabber

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of two indications. The first, JabberFlag, consists of an ENUMERATED value list that has the following entries:

other	undefined
unknown	initializing, true state not yet known
normal	state is true or normal
fault	state is false, fault, or abnormal

The second, jabberCounter, is a generalized nonresettable counter. This counter has a maximum increment rate of 40 counts per second

BEHAVIOUR DEFINED AS:

If the MAU is in the JABBER state, the jabberFlag portion of the attribute is set to the "fault" value. The jabberCounter portion of the attribute is incremented each time the flag is set to the "fault" value. This attribute returns the value "other" for type AUI. Note that this counter will increment for a 10 Mb/s baseband and broadband MAUs only.;

30.5.1.1.7 aMAUAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

other	undefined
unknown	initializing, true state not yet known
operational	powered and connected
standby	inactive but on
shutdown	similar to power down

BEHAVIOUR DEFINED AS:

A MAU in management state "standby" forces DI and CI to idle and the media transmitter to idle or fault, if supported. The management state "standby" only applies to link type MAUs. The state of MediaAvailable is unaffected. A MAU or AUI in the management state "shutdown" assumes the same condition on DI, CI and the media transmitter as if it were powered down or not connected. For an AUI, this management state will remove power from the AUI. The MAU may return the value "undefined" for Jabber and MediaAvailable attributes when it is in this management state. A MAU in the management state "operational" is fully functional, and operates and passes signals to its attached DTE or repeater port in accordance with its specification.;

30.5.1.1.8 aBbMAUXmitRcvSplitType

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

other	undefined

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

single	single-cable system
dual	dual-cable system, offset normally zero

BEHAVIOUR DEFINED AS:

Returns a value that indicates the type of frequency multiplexing/cabling system used to separate the transmit and receive paths for the 10BROAD36 MAU. All other types return “undefined”.;

30.5.1.1.9 aBroadbandFrequencies

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of two instances of the type INTEGER.

The first INTEGER represents the Transmitter Carrier Frequency. The value of its INTEGER represents the frequency of the carrier divided by 250 kHz.

The second INTEGER represents the Translation Offset Frequency. The value of its INTEGER represents the frequency of the offset divided by 250 kHz

BEHAVIOUR DEFINED AS:

Returns a value that indicates the transmit carrier frequency and translation offset frequency in MHz/4 for the 10BROAD36 MAU. This allows the frequencies to be defined to a resolution of 250 kHz.;

30.5.1.1.10 aFalseCarriers

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 160 000 counts per second under maximum network load, and 10 counts per second under zero network load, for 100 Mb/s implementations. This counter has a maximum increment rate of 1 600 000 counts per second under maximum network load, and 100 000 counts per second under zero network load, for 1000 Mb/s implementations

BEHAVIOUR DEFINED AS:

A count of the number of false carrier events during IDLE in 100BASE-X and 1000BASE-X links. This counter does not increment at the symbol rate. For 100BASE-X, it can increment after a valid carrier completion at a maximum rate of once per 100 ms until the nextCarrierEvent. For 1000BASE-X, it can increment after a valid carrier completion at a maximum rate of once per 10 μs until the next CarrierEvent.

NOTE—The increased increment rate for this attribute at 1000 Mb/s relative to its increment rate at 100 Mb/s has been provided to improve its use as an indication of line quality.;

30.5.1.1.11 aBIPErrorCount

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of generalized nonresettable counters. Each counter has a maximum increment rate of 10 000 counts per second for 40 Gb/s and 50 Gb/s implementations and 5 000 counts per second for 100 Gb/s implementations.

BEHAVIOUR DEFINED AS:

For 40/50/100GBASE-R PHYs and 100GBASE-P PHYS, an array of BIP error counters. The counters do not increment for other PHY types. The indices of this array (0 to n – 1) denote the PCS lane number where n is the number of PCS lanes in use. Each element of this array contains

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a count of BIP errors for that PCS lane. Increment the counter by one for each BIP error detected during alignment marker removal in the PCS for the corresponding lane.
If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the BIP error counters (see 45.2.3.47 and 45.2.3.48).;

30.5.1.1.12 aLaneMapping

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE of INTEGERs.

BEHAVIOUR DEFINED AS:
For 40/50/100/200/400GBASE-R PHYs and 100GBASE-P PHYs, an array of PCS lane identifiers. The indices of this array (0 to n – 1) denote the service interface lane number where n is the number of PCS lanes in use. Each element of this array contains the PCS lane number for the PCS lane that has been detected in the corresponding service interface lane.
If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the Lane mapping registers (see 45.2.3.49 and 45.2.3.50).;

30.5.1.1.13 aIdleErrorCount

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
This attribute takes the eight-bit value from the 100BASE-T2 Status register (MII management register 10) bits 7:0 “Idle Error Count” as described in 100BASE-T2, 32.5.3.2.6 and 40.5.;

30.5.1.1.14 aPCSCodingViolation

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 25 000 000 counts per second for 100 Mb/s implementations and 125 000 000 counts per second for 1000 Mb/s implementations.

BEHAVIOUR DEFINED AS:
For 100 Mb/s operation it is a count of the number of events that cause the PHY to indicate “Data reception with errors” on the MII (see Table 22–2). For 1000 Mb/s operation it is a count of the number of events that cause the PHY to indicate “Data reception error” or “Carrier Extend Error” on the GMII (see Table 35–1). The contents of this attribute is undefined when FEC is operating.;

30.5.1.1.15 aFECAbility

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that meets the requirement of the description below

unknown	initializing, true state not yet known
supported	FEC supported
not supported	FEC not supported

BEHAVIOUR DEFINED AS:
A read-only value that indicates if the PHY supports an optional FEC sublayer for forward error

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

correction across the MDI (see 65.2, Clause 74, Clause 91, and Clause 108).

If a Clause 45 MDIO Interface is present, then this attribute maps to the FEC capability register (see 45.2.10.2 or 45.2.1.107).;

30.5.1.1.16 aFECmode

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that meets the requirement of the description below

unknown	initializing, true state not yet known
disabled	FEC disabled
BASE-R enabled	BASE-R FEC enabled
RS-FEC enabled	RS-FEC enabled
enabled	FEC enabled

BEHAVIOUR DEFINED AS:

A read-write value for a PHY that supports an optional FEC sublayer that indicates the mode of operation of the FEC sublayer for forward error correction across the MDI (see 65.2, Clause 74, Clause 91, and Clause 108).

A GET operation returns the current mode of operation of the PHY. A SET operation changes the mode of operation of the PHY to the indicated value. The enumerations “BASE-R enabled” and “RS-FEC enabled” are only used for 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, and 25GBASE-KR-S PHYs where operation in the no-FEC mode maps to the enumeration “disabled”, operation in the BASE-R FEC mode maps to the enumeration “BASE-R enabled”, and operation in the RS-FEC mode maps to the enumeration “RS-FEC enabled” (see 110.6 and 111.6).

When Clause 73 Auto-Negotiation is enabled for a 25GBASE-R PHY, a SET operation is not allowed and a GET operation maps to the variables FEC_enable in Clause 74 and FEC_enable in Clause 108. When Clause 73 Auto-Negotiation is enabled for a non-25GBASE-R PHY supporting Clause 74 FEC a SET operation is not allowed and a GET operation maps to the variable FEC_enable in Clause 74.

If a Clause 45 MDIO Interface is present, then this attribute maps to the FEC enable bit or to the RS-FEC enable bit in the appropriate FEC control register based upon the PHY type and the FEC operating mode (see 45.2.10.3, 45.2.1.108, and 45.2.1.116).;

30.5.1.1.17 aFECCorrectedBlocks

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of generalized nonresettable counters. Each counter has a maximum increment rate of 1 200 000 counts per second for 1000 Mb/s implementations, 5 000 000 counts per second for 10 Gb/s, 25 Gb/s, and 40 Gb/s implementations, 10 000 000 counts per second for 50 Gb/s implementations, 2 500 000 counts per second for 100 Gb/s implementations, 40 000 000 counts per second for 200 Gb/s implementations, and 80 000 000 counts per second for 400 Gb/s implementations.

BEHAVIOUR DEFINED AS:

For 1000BASE-PX, 10/25/40/50/100/200/400GBASE-R, 100GBASE-P, 10GBASE-PR, or 10/1GBASE-PRX PHYs that support FEC across the MDI, an array of corrected FEC block counters. The counters do not increment for other PHY types. The indices of this array (0 to N – 1)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

denote the FEC sublayer instance number where N is the number of FEC sublayer instances in use. The number of FEC sublayer instances in use is set to one for PHYs that do not use PCS lanes or use a single FEC instance for all lanes. Each element of this array contains a count of corrected FEC blocks for that FEC sublayer instance.

Increment the counter by one for each FEC block received across the MDI that is corrected by the FEC function in the PHY for the corresponding lane or FEC sublayer instance.

If a Clause 45 MDIO Interface is present, then this attribute maps to the FEC corrected blocks counter(s) (see 45.2.10.5 and 45.2.1.109 for 10GBASE-R, 45.2.3.41 for 10GBASE-PR and 10/1GBASE-PRX, 45.2.1.131 for BASE-R, 45.2.1.118 for RS-FEC, 45.2.3.62 for PCS FEC, and 45.2.1.227 for SC-FEC).;

30.5.1.1.18 aFECUncorrectableBlocks

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of generalized nonresettable counters. Each counter has a maximum increment rate of 1 200 000 counts per second for 1000 Mb/s implementations, and 5 000 000 counts per second for 10 Gb/s, 25 Gb/s, and 40 Gb/s implementations, 10 000 000 counts per second for 50 Gb/s implementations, 2 500 000 counts per second for 100 Gb/s implementations, 40 000 000 counts per second for 200 Gb/s implementations, and 80 000 000 counts per second for 400 Gb/s implementations.

BEHAVIOUR DEFINED AS:

For 1000BASE-PX, 10/25/40/50/100/200/400GBASE-R, 100GBASE-P, 10GBASE-PR, or 10/1GBASE-PRX PHYs that support FEC across the MDI, an array of uncorrectable FEC block counters. The counters do not increment for other PHY types. The indices of this array (0 to N – 1) denote the FEC sublayer instance number where N is the number of FEC sublayer instances in use. The number of FEC sublayer instances in use is set to one for PHYs that do not use PCS lanes or use a single FEC instance for all lanes. Each element of this array contains a count of uncorrectable FEC blocks for that FEC sublayer instance.

Increment the counter by one for each FEC block received across the MDI that is determined to be uncorrectable by the FEC function in the PHY for the corresponding lane or FEC sublayer instance.

If a Clause 45 MDIO Interface is present, then this attribute maps to the FEC uncorrectable blocks counter(s) (see 45.2.10.6 and 45.2.1.110 for 10GBASE-R, 45.2.3.42 for 10GBASE-PR and 10/1GBASE-PRX, 45.2.1.149 for BASE-R, 45.2.1.119 for RS-FEC, 45.2.3.63 for PCS FEC, and 45.2.1.228 for SC-FEC).;

30.5.1.1.19 aSNROpMarginChnlA

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The current SNR operating margin measured at the slicer input for channel A for the MultiGBASE-T PMA. It is reported in units of 0.1 dB to an accuracy of 0.5 dB within the range of –12.7 dB to 12.7 dB. If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute maps to the SNR operating margin channel A register (see 45.2.1.81).;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.5.1.1.20 aSNROpMarginChnlB

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current SNR operating margin measured at the slicer input for channel B for the MultiGBASE-T PMA. It is reported in units of 0.1 dB to an accuracy of 0.5 dB within the range of –12.7 dB to 12.7 dB. If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute maps to the SNR operating margin channel B register (see 45.2.1.82).;

30.5.1.1.21 aSNROpMarginChnlC

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current SNR operating margin measured at the slicer input for channel C for the MultiGBASE-T PMA. It is reported in units of 0.1 dB to an accuracy of 0.5 dB within the range of –12.7 dB to 12.7 dB. If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute maps to the SNR operating margin channel C register (see 45.2.1.83).;

30.5.1.1.22 aSNROpMarginChnlD

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current SNR operating margin measured at the slicer input for channel D for the MultiGBASE-T PMA. It is reported in units of 0.1 dB to an accuracy of 0.5 dB within the range of –12.7 dB to 12.7 dB. If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute maps to the SNR operating margin channel D register (see 45.2.1.84).;

30.5.1.1.23 aEEESupportList

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE of ENUMERATIONS that match the syntax of aMAUType

BEHAVIOUR DEFINED AS:
A read-only list of the possible PHY types for which the underlying system supports Energy-Efficient Ethernet (EEE) as defined in Clause 78. If Clause 28 or Clause 73 Auto-Negotiation is present, then this attribute will map to the local technology ability or advertised ability of the local device;

30.5.1.1.24 aLDFastRetrainCount

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1000 counts per

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

second

BEHAVIOUR DEFINED AS:

A count of the number of fast retrains initiated by the local device. This counter can be derived from fr_tx_counter (see 55.4.5.4, 113.4.5.4, and 126.4.5.4). If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute can be derived from the LD fast retrain count register (see 45.2.1.94.2).;

30.5.1.1.25 aLPFastRetrainCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1000 counts per second

BEHAVIOUR DEFINED AS:

A count of the number of fast retrains initiated by the link partner. This counter can be derived from fr_rx_counter (see 55.4.5.4, 113.4.5.4, and 126.4.5.4). If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute can be derived from the LP fast retrain count register (see 45.2.1.94.1).

30.5.1.1.26 aRSFECBIPErrorCount

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of generalized nonresetable counters. Each counter has a maximum increment rate of 5 000 counts per second for 50 Gb/s and 100 Gb/s implementations.

BEHAVIOUR DEFINED AS:

For 50GBASE-R, 100GBASE-R, and 100GBASE-P PHYs that support RS-FEC across the MDI, an array of BIP error counters. The counters do not increment for other PHY types. The indices of this array (0 to N – 1) denote the PCS lane number where N is the number of PCS lanes in use. Each element of this array contains a count of BIP errors for that PCS lane.
Increment the counter by one for each BIP error across the MDI detected during alignment marker removal in the PCS for the corresponding lane.
If a Clause 45 MDIO Interface is present, then this attribute maps to the BIP error counters (see 45.2.1.123 and 45.2.1.124).;

30.5.1.1.27 aRSFECLaneMapping

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of INTEGERs.

BEHAVIOUR DEFINED AS:

For 50GBASE-R, 100GBASE-R, and 100GBASE-P PHYs that support RS-FEC across the MDI, an array of PCS lane identifiers. The indices of this array (0 to N – 1) denote the service interface lane number where N is the number of PCS lanes in use. Each element of this array contains the PCS lane number for the PCS lane across the MDI that has been detected in the corresponding service interface lane.
If a Clause 45 MDIO Interface is present, then this attribute maps to the Lane mapping registers (see 45.2.1.125 and 45.2.1.126).;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.5.1.1.28 aSCFECLaneMapping

ATTRIBUTE

APPROPRIATE SYNTAX:
A SEQUENCE of INTEGERs.

BEHAVIOUR DEFINED AS:
For a 100GBASE-R PHY that supports SC-FEC (see Clause 153) across the MDI, an array of PCS lane identifiers. The indices of this array (0 to N – 1) denote the service interface lane number where N is the number of PCS lanes in use. Each element of this array contains the PCS lane number for the PCS lane across the MDI that has been detected in the corresponding service interface lane.
If a Clause 45 MDIO Interface is present, then this attribute maps to the Lane mapping registers (see 45.2.1.225 and 45.2.1.226).;

30.5.1.1.29 aRSFECBypassAbility

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that meets the requirement of the following description:

unknown	initializing, true state not yet known
supported	FEC bypass ability supported
not supported	FEC bypass ability not supported

BEHAVIOUR DEFINED AS:
A read-only value that indicates if a PHY that supports RS-FEC across the MDI supports the optional RS-FEC bypass ability (see 91.5.3.3).
For a PHY that does not support RS-FEC across the MDI, this attribute is not applicable.
If a Clause 45 MDIO Interface is present, then this attribute maps to the RS-FEC status register (see 45.2.1.117).;

30.5.1.1.30 aRSFECBypassIndicationAbility

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that meets the requirement of the following description:

unknown	initializing, true state not yet known
supported	FEC error indication bypass ability supported
not supported	FEC error indication bypass ability not supported

BEHAVIOUR DEFINED AS:
A read-only value that indicates if a PHY that supports RS-FEC across the MDI supports the optional RS-FEC error indication bypass ability.
For a PHY that does not support RS-FEC across the MDI, this attribute is not applicable.
If a Clause 45 MDIO Interface is present, then this attribute maps to the RS-FEC status register (see 45.2.1.117).;

30.5.1.1.31 aRSFECBypassEnable

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that meets the requirement of the following description:

unknown	initializing, true state not yet known

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

disabled	FEC bypass disabled
enabled	FEC bypass enabled

BEHAVIOUR DEFINED AS:

A read-write value that indicates the mode of operation of the RS-FEC bypass function (see 91.5.3.3).

A GET operation returns the current mode of operation of the RS-FEC. A SET operation changes the mode of operation of the RS-FEC to the indicated value.

If a Clause 45 MDIO Interface is present, then this attribute maps to the RS-FEC control register (see 45.2.1.116).;

30.5.1.1.32 aRSFECBypassIndicationEnable

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that meets the requirement of the following description:

unknown	initializing, true state not yet known
disabled	FEC error indication bypass disabled
enabled	FEC error indication bypass enabled

BEHAVIOUR DEFINED AS:

A read-write value that indicates the mode of operation of the RS-FEC error indication bypass function.

A GET operation returns the current mode of operation of the RS-FEC. A SET operation changes the mode of operation of the RS-FEC to the indicated value.

If a Clause 45 MDIO Interface is present, then this attribute maps to the RS-FEC control register (see 45.2.1.116).;

30.5.1.1.33 aPCSFECBypassIndicationAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that meets the requirement of the following description:

unknown	initializing, true state not yet known
supported	PCS FEC error indication bypass ability supported
not supported	PCS FEC error indication bypass ability not supported

BEHAVIOUR DEFINED AS:

For 200/400GBASE-R, a read-only value that indicates if a PHY that supports PCS-FEC across the MDI supports the optional PCS FEC error indication bypass ability (see 119.2.5.3).

For a PHY that does not support PCS-FEC across the MDI, this attribute is not applicable.

If a Clause 45 MDIO Interface is present, then this attribute maps to the PCS FEC status register (see 45.2.3.61).;

30.5.1.1.34 aPCSFECBypassIndicationEnable

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that meets the requirement of the following description:

unknown	initializing, true state not yet known
disabled	PCS FEC error indication bypass disabled
enabled	PCS FEC error indication bypass enabled

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A read-write value that indicates the mode of operation of the PCS FEC error indication bypass function (see 119.2.5.3).
A GET operation returns the current mode of operation of the PCS FEC. A SET operation changes the mode of operation of the PCS FEC to the indicated value.
If a Clause 45 MDIO Interface is present, then this attribute maps to the PCS FEC control register (see 45.2.3.60).;

30.5.1.2 MAU actions

30.5.1.2.1 acResetMAU

ACTION

APPROPRIATE SYNTAX:
None required

BEHAVIOUR DEFINED AS:
Resets the MAU in the same manner as would a power-off, power-on cycle of at least 0.5 s duration. During the 0.5 s DO, DI, and CI should be idle.;

30.5.1.2.2 acMAUAdminControl

ACTION

APPROPRIATE SYNTAX:
The same as used for aMAUAdminState

BEHAVIOUR DEFINED AS:
Executing an acMAUAdminControl action causes the MAU to assume the aMAUAdminState attribute value of one of the defined valid management states for control input. The valid inputs are “standby”, “operational”, and “shutdown” state (see the behaviour definition bMAUAdminState for the description of each of these states) except that a “standby” action to a mixing type MAU or an AUI will cause the MAU to enter the “shutdown” management state.;

30.5.1.3 MAU notifications

30.5.1.3.1 nJabber

NOTIFICATION

APPROPRIATE SYNTAX:
The same as used for aJabber

BEHAVIOUR DEFINED AS:
The notification is sent whenever a managed 10 Mb/s baseband or broadband MAU enters the JABBER state.;

30.6 Management for link Auto-Negotiation

30.6.1 Auto-Negotiation managed object class

This subclause formally defines the behaviours for the oAuto-Negotiation managed object class, attributes, actions, and notifications.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.6.1.1 Auto-Negotiation attributes

30.6.1.1.1 aAutoNegID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aAutoNegID is assigned so as to uniquely identify an Auto-Negotiation managed object among the subordinate managed objects of the containing object.;

30.6.1.1.2 aAutoNegAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:
An interface which has Auto-Negotiation signaling ability will be enabled to do so when this attribute is in the enabled state. If disabled then the interface will act as it would if it had no Auto-Negotiation signaling.;

30.6.1.1.3 aAutoNegRemoteSignaling

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
detected
notdetected

BEHAVIOUR DEFINED AS:
The value indicates whether the remote end of the link is operating Auto-Negotiation signaling or not. It shall take the value detected if, during the previous link negotiation, FLP Bursts, /C/ ordered sets (see 36.2.4.10) or DME signals (see 73.5 and 98.2.1.1) were received from the remote end.;

30.6.1.1.4 aAutoNegAutoConfig

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
other
configuring
complete
disabled
parallel detect fail

BEHAVIOUR DEFINED AS:
Indicates whether Auto-Negotiation signaling is in progress or has completed. The enumeration “parallel detect fail” maps to a failure in parallel detection as defined in 28.2.3.1 or 73.7.4.1.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.6.1.1.5 aAutoNegLocalTechnologyAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE that meets the requirements of the description below:

global	Reserved for future use
other	See 30.2.5
unknown	Initializing, true state or type not yet known
10BASE-T	10BASE-T half duplex as defined in Clause 14
10BASE-T1L	10BASE-T1L as specified in Clause 146
10BASE-T1S	10BASE-T1S as specified in Clause 147
10BASE-TFD	Full duplex 10BASE-T as defined in Clause 14 and Clause 31
100BASE-T4	100BASE-T4 half duplex as defined in Clause 23
100BASE-TX	100BASE-TX half duplex as defined in Clause 25
100BASE-TXFD	Full duplex 100BASE-TX as defined in Clause 25 and Clause 31
FDX PAUSE	PAUSE operation for full duplex links as defined in Annex 31B
FDX APAUSE	Asymmetric PAUSE operation for full duplex links as defined in Clause 37, Annex 28B, and Annex 31B
FDX SPAUSE	Symmetric PAUSE operation for full duplex links as defined in Clause 37, Annex 28B, and Annex 31B
FDX BPAUSE	Asymmetric and Symmetric PAUSE operation for full duplex links as defined in Clause 37, Annex 28B, and Annex 31B
100BASE-T2	100BASE-T2 half duplex as defined in Clause 32
100BASE-T2FD	Full duplex 100BASE-T2 as defined in Clause 31 and Clause 32
1000BASE-X	1000BASE-X half duplex as specified in Clause 36
1000BASE-XFD	Full duplex 1000BASE-X as specified in Clause 31 and Clause 36
1000BASE-T	1000BASE-T half duplex PHY as specified in Clause 40
1000BASE-TFD	Full duplex 1000BASE-T PHY as specified in Clause 31 and as specified in Clause 40
1000BASE-T1	1000BASE-T1 as specified in Clause 97
2.5GBASE-T	2.5GBASE-T PHY as specified in Clause 126
2.5GBASE-T1	2.5GBASE-T1 as specified in Clause 149
2.5GKX	2.5GBASE-KX as specified in Clause 128
5GBASE-T	5GBASE-T PHY as specified in Clause 126
5GBASE-T1	5GBASE-T1 as specified in Clause 149
5GKR	5GBASE-KR as specified in Clause 130
Rem Fault1	Remote fault bit 1 (RF1) as specified in Clause 37
Rem Fault2	Remote fault bit 2 (RF2) as specified in Clause 37
10GBASE-T	10GBASE-T PHY as specified in Clause 55
10GBASE-T1	10GBASE-T1 as specified in Clause 149
1000BASE-KXFD	Full duplex 1000BASE-KX as specified in Clause 70
10GBASE-KX4FD	Full duplex 10GBASE-KX4 as specified in Clause 71
10GBASE-KRFD	Full duplex 10GBASE-KR as specified in Clause 72
25GBASE-T	25GBASE-T as specified in Clause 113
25GR-S	25GBASE-CR-S as specified in Clause 110 or 25GBASE-KR-S as specified in Clause 111
25GR	25GBASE-CR as specified in Clause 110 or 25GBASE-KR as specified in Clause 111
40GBASE-KR4	40GBASE-KR4 as specified in Clause 84
40GBASE-CR4	40GBASE-CR4 as specified in Clause 85
40GBASE-T	40GBASE-T as specified in Clause 113
50GR	50GBASE-CR as specified in Clause 136 or 50GBASE-KR as specified in Clause 137

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

100GBASE-CR10	100GBASE-CR10 as specified in Clause 85
100GBASE-CR4	100GBASE-CR4 as specified in Clause 92
100GBASE-KR4	100GBASE-KR4 as specified in Clause 93
100GBASE-KP4	100GBASE-KP4 as specified in Clause 94
100GR2	100GBASE-CR2 as specified in Clause 136 or 100GBASE-KR2 as specified in Clause 137
200GR4	200GBASE-CR4 as specified in Clause 136 or 200GBASE-KR4 as specified in Clause 137
Rem Fault	Remote fault bit (RF) as specified in Clause 73 and Clause 98
FEC Capable	FEC ability as specified in Clause 73 (see 73.6.5) and Clause 74
FEC Requested	FEC requested as specified in Clause 73 (see 73.6.5) and Clause 74
RS-FEC25G Req	25G RS-FEC requested as specified in Clause 73 (see 73.6.5) and Clause 108
BASE-RFEC25G Req	25G BASE-R FEC requested as specified in Clause 73 (see 73.6.5) and Clause 74
Force MS	Force MASTER-SLAVE as specified in Clause 98 (see 98.2.1.2.5)
isoethernet	IEEE Std 802.9 ISLAN-16T

BEHAVIOUR DEFINED AS:

This indicates the technology ability of the local device, as defined in Clause 28, Clause 37, Clause 73, and Clause 98.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.;

30.6.1.1.6 aAutoNegAdvertisedTechnologyAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

Same as aAutoNegLocalTechnologyAbility

BEHAVIOUR DEFINED AS:

This GET-SET attribute maps to the technology ability of the local device, as defined in Clause 28, Clause 37, and Clause 98.

NOTE—This will in every case cause temporary link loss during link renegotiation. If set to a value incompatible with aAutoNegReceivedTechnologyAbility, link negotiation will not be successful and will cause permanent link loss.;

30.6.1.1.7 aAutoNegReceivedTechnologyAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

Same as aAutoNegLocalTechnologyAbility

BEHAVIOUR DEFINED AS:

Indicates the advertised technology ability of the remote hardware. For Clause 28 Auto-Negotiation, this attribute maps to the Technology Ability Field of the last received Auto-Negotiation link codeword(s). For Clause 37 Auto-Negotiation, this attribute maps to bits D0-D13 of the received Config_Reg Base Page (see 37.2.1). For Clause 73 Auto-Negotiation, this attribute maps to bits D10-D13 and D21-D47 of the last received link codeword Base Page (see 73.6). For Clause 98 Auto-Negotiation, this attribute maps to bits D10-D13 and D21-D47 of the last received link codeword Base Page (see 98.2.1.2).;

30.6.1.1.8 aAutoNegLocalSelectorAbility

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

A SEQUENCE that meets the requirements of the selector field definitions in Annex 28A.

BEHAVIOUR DEFINED AS:

This indicates the value of the selector field of the local hardware. The Selector Field is defined in 28.2.1.2.1 for Clause 28 Auto-Negotiation, in 73.6.1 for Clause 73 Auto- Negotiation, and in 98.2.1.2.1 for Clause 98 Auto-Negotiation. The enumeration of the Selector Field indicates the standard that defines the remaining encodings for Auto-Negotiation using that value of enumeration. For Clause 37 Auto-Negotiation devices, a SET of this attribute will have no effect, and a GET will return the enumeration “ethernet”.;

30.6.1.1.9 aAutoNegAdvertisedSelectorAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

Same as aAutoNegLocalSelectorAbility

BEHAVIOUR DEFINED AS:

In the case of Clause 28 Auto-Negotiation, this GET-SET attribute maps to the Message Selector Field of the Auto-Negotiation link codeword. For Clause 73 Auto-Negotiation, this attribute maps to the Selector Field of the Clause 73 Auto-Negotiation link codeword (see 73.6.1). For Clause 98 Auto-Negotiation, this attribute maps to the Selector Field of the Clause 98 Auto-Negotiation link codeword (see 98.2.1.2.1). A SET operation to a value not available in aAutoNegLocalSelectorAbility will be rejected. A successful SET operation will result in immediate link renegotiation if aAutoNegAdminState is enabled. For Clause 37 Auto-Negotiation devices, a SET of this attribute will have no effect, and a GET will return the enumeration “ethernet”.

NOTE—This will in every case cause temporary link loss during link renegotiation. If set to a value incompatible with aAutoNegReceivedSelectorAbility, link negotiation will not be successful and will cause permanent link loss.;

30.6.1.1.10 aAutoNegReceivedSelectorAbility

ATTRIBUTE

APPROPRIATE SYNTAX:

Same as aAutoNegLocalSelectorAbility

BEHAVIOUR DEFINED AS:

In the case of Clause 28 Auto-Negotiation, this attribute indicates the advertised message transmission ability of the remote hardware. It maps to the Message Selector Field of the last received Auto-Negotiation link codeword. For Clause 73 Auto-Negotiation, this attribute indicates the advertised message transmission ability of the remote hardware and maps to the Selector Field of the last received Clause 73 Auto-Negotiation link codeword (see 73.6.1). For Clause 98 Auto-Negotiation, this attribute indicates the advertised message transmission ability of the remote hardware and maps to the Selector Field of the last received Clause 98 Auto-Negotiation link codeword (see 98.2.1.2.1). For Clause 37 Auto-Negotiation devices, a SET of this attribute will have no effect, and a GET will return the enumeration “ethernet”.;

30.6.1.2 Auto-Negotiation actions

30.6.1.2.1 acAutoNegRestartAutoConfig

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

None required

BEHAVIOUR DEFINED AS:

Forces Auto-Negotiation to begin link renegotiation. Has no effect if Auto-Negotiation signaling is disabled.;

30.6.1.2.2 acAutoNegAdminControl

ATTRIBUTE

APPROPRIATE SYNTAX:

Same as aAutoNegAdminState

BEHAVIOUR DEFINED AS:

This action provides a means to turn Auto-Negotiation signaling on or off.;

30.7 Management for Link Aggregation

Subclause 30.7 is deprecated by IEEE Std 802.1AX-2008.

30.7.1 Aggregator managed object class

This subclause formally defines the behaviours for the oAggregator managed object class, attributes, and notifications.

Some of the attributes that are part of the definition of the oAggregator managed object class are derived by summing counter values from attributes of other objects; e.g., to generate a count of received frames for the Aggregator, the individual value for each Aggregation Port contributes to the sum. Where calculations of this form are used, the values that contribute to the Aggregator's attributes are *increments* in the values of the component attributes, not their absolute values. As any individual Aggregation Port is potentially only temporarily attached to its current Aggregator, the count values it contributes to the Aggregator's counters are the increments in its values that it has experienced during the period of time that it has been attached to that Aggregator.

The counter values defined for the Aggregator have been formulated as far as possible to make the Aggregator behave like an individual IEEE 802.3 MAC. The counts of frames received and transmitted are formulated to reflect the counts that would be expected by the MAC Client; they do not include frames transmitted and received as part of the operation of LACP or the Marker protocol, only frames that pass through the interface between the MAC Client and the Aggregator. However, as LACP and the Marker protocol are, as far as the individual MACs are concerned, part of their MAC Client, the RX/TX counters for the individual MACs will reflect both control and data traffic. As counts of errors at the port level cannot always be cleanly delineated between those that occurred as a result of aggregation activity and those that did not, no attempt has been made to separate these aspects of the port error counts. Therefore, there is not necessarily a direct correspondence between the individual MAC counters and the corresponding derived counters at the Aggregator level.

It should also be noted that the counters defined for the Aggregator include values that can only apply to half duplex links. This is consistent with the approach taken in Link Aggregation that a link that can only operate as an individual link is nonetheless considered as being attached to an Aggregator. This simplifies the modelling of managed objects for links that can operate in either half or full duplex, and ensures a consistent presentation of the attributes regardless of the type of links attached to the Aggregator.

NOTE—The operation of Auto-Negotiation may mean that a given link can operate in full duplex or half duplex, depending upon the capabilities of the device(s) connected to it. Keeping the management view the same regardless of a link's current mode of operation allows a consistent management approach to be taken across all types of links.

30.7.1.1 Aggregator attributes

30.7.1.1.1 aAggID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The unique identifier allocated to this Aggregator by the local System. This attribute identifies an Aggregator instance among the subordinate managed objects of the containing object. This value is read-only.

30.7.1.1.2 aAggDescription

ATTRIBUTE

APPROPRIATE SYNTAX:
A PrintableString, 255 characters max.

BEHAVIOUR DEFINED AS:
A human-readable text string containing information about the Aggregator. This string could include information about the distribution algorithm in use on this Aggregator; for example, “Aggregator 1, Dist Alg=Dest MAC address”. This string is read-only. The contents are vendor specific.;

30.7.1.1.3 aAggName

ATTRIBUTE

APPROPRIATE SYNTAX:
A PrintableString, 255 characters max.

BEHAVIOUR DEFINED AS:
A human-readable text string containing a locally significant name for the Aggregator. This string is read-write.;

30.7.1.1.4 aAggActorSystemID

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A 6-octet read-write MAC address value used as a unique identifier for the System that contains this Aggregator.

NOTE—From the perspective of the Link Aggregation mechanisms described in Clause 43, only a single combination of Actor’s System ID and System Priority are considered, and no distinction is made between the values of these parameters for an Aggregator and the port(s) that are associated with it (i.e., the protocol is described in terms of the operation of aggregation within a single System). However, the managed objects provided for the Aggregator and the port both allow management of these parameters. The result of this is to permit a single piece of equipment to be configured by management to contain more than one System from the point of view of the operation of Link Aggregation. This may be of particular use in the configuration of equipment that has limited aggregation capability (see 43.6).;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.1.1.5 aAggActorSystemPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A 2-octet read-write value indicating the priority value associated with the Actor's System ID.;

30.7.1.1.6 aAggAggregateOrIndividual

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value indicating whether the Aggregator represents an Aggregate ("TRUE") or an Individual link ("FALSE").;

30.7.1.1.7 aAggActorAdminKey

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current administrative value of the Key for the Aggregator. The administrative Key value may differ from the operational Key value for the reasons discussed in 43.6.2. This is a 16-bit read-write value. The meaning of particular Key values is of local significance.;

30.7.1.1.8 aAggActorOperKey

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current operational value of the Key for the Aggregator. The administrative Key value may differ from the operational Key value for the reasons discussed in 43.6.2. This is a 16-bit read-only value. The meaning of particular Key values is of local significance.;

30.7.1.1.9 aAggMACAddress

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A 6-octet read-only value carrying the individual MAC address assigned to the Aggregator.;

30.7.1.1.10 aAggPartnerSystemID

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A 6-octet read-only MAC address value consisting of the unique identifier for the current protocol Partner of this Aggregator. A value of zero indicates that there is no known Partner. If the aggregation is manually configured, this System ID value will be a value assigned by the local System.;

30.7.1.1.11 aAggPartnerSystemPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A 2-octet read-only value that indicates the priority value associated with the Partner's System ID. If the aggregation is manually configured, this System Priority value will be a value assigned by the local System.;

30.7.1.1.12 aAggPartnerOperKey

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current operational value of the Key for the Aggregator's current protocol Partner. This is a 16-bit read-only value. If the aggregation is manually configured, this Key value will be a value assigned by the local System.;

30.7.1.1.13 aAggAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
up
down

BEHAVIOUR DEFINED AS:
This read-write value defines the administrative state of the Aggregator. A value of "up" indicates that the operational state of the Aggregator (aAggOperState) is permitted to be either up or down. A value of "down" forces the operational state of the Aggregator to be down. Changes to the administrative state affect the operational state of the Aggregator only, not the operational state of the Aggregation Ports that are attached to the Aggregator. A GET operation returns the current administrative state. A SET operation changes the administrative state to a new value.;

30.7.1.1.14 aAggOperState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
up
down

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

This read-only value defines the operational state of the Aggregator. The operational state is “up” if one or more of the Aggregation Ports that are attached to the Aggregator are collecting, or both collecting and distributing, and if the value of aAggAdminState for the Aggregator is also “up”. If none of the Aggregation Ports that are attached to the Aggregator are collecting and/or distributing, or if there are no Aggregation Ports attached to this Aggregator, then the operational state is “down”. An operational state of “up” indicates that the Aggregator is available for use by the MAC Client; a value of “down” indicates that the Aggregator is not available for use by the MAC Client.;

30.7.1.1.15 aAggTimeOfLastOperChange

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of aTimeSinceSystemReset (Annex F.2.1) at the time the interface entered its current operational state. If the current state was entered prior to the last re-initialization of the local network management subsystem, then this object contains a value of zero. This value is read-only.;

30.7.1.1.16 aAggDataRate

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The current data rate, in bits per second, of the aggregate link. The value is calculated as N times the data rate of a single link in the aggregation, where N is the number of active links. This attribute is read-only.;

30.7.1.1.17 aAggOctetsTxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 230 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the data and padding octets transmitted by this Aggregator on all Aggregation Ports that are (or have been) members of the aggregation. The count does not include octets transmitted by the Aggregator in frames that carry LACPDUs or Marker PDUs (30.7.3.1.7, 30.7.3.1.8, 30.7.3.1.9). However, it includes frames discarded by the Distribution function of the Aggregator (30.7.1.1.25). This value is read-only.;

30.7.1.1.18 aAggOctetsRxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 230 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the data and padding octets received by this Aggregator, from the Aggregation Ports

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

that are (or have been) members of the aggregation. The count does not include octets received in frames that carry LACP or Marker PDUs (30.7.3.1.2, 30.7.3.1.3, 30.7.3.1.4), or frames discarded by the Collection function of the Aggregator (30.7.1.1.26). This value is read-only.;

30.7.1.1.19 aAggFramesTxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the data frames transmitted by this Aggregator on all Aggregation Ports that are (or have been) members of the aggregation. The count does not include frames transmitted by the Aggregator that carry LACP or Marker PDUs (30.7.3.1.7, 30.7.3.1.8, 30.7.3.1.9). However, it includes frames discarded by the Distribution function of the Aggregator (30.7.1.1.25). This value is read-only.;

30.7.1.1.20 aAggFramesRxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the data frames received by this Aggregator, from the Aggregation Ports that are (or have been) members of the aggregation. The count does not include frames that carry LACP or Marker PDUs (30.7.3.1.2, 30.7.3.1.3, 30.7.3.1.4), or frames discarded by the Collection function of the Aggregator (30.7.1.1.26). This value is read-only.;

30.7.1.1.21 aAggMulticastFramesTxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the data frames transmitted by this Aggregator on all Aggregation Ports that are (or have been) members of the aggregation, to a group destination address other than the broadcast address. The count does not include frames transmitted by the Aggregator that carry LACP or Marker PDUs (30.7.3.1.7, 30.7.3.1.8, 30.7.3.1.9). However, it includes frames discarded by the Distribution function of the Aggregator (30.7.1.1.25). This value is read-only.;

30.7.1.1.22 aAggMulticastFramesRxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the data frames received by this Aggregator, from the Aggregation Ports that are (or

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

have been) members of the aggregation, that were addressed to an active group address other than the broadcast address. The count does not include frames that carry LACP or Marker PDUs (30.7.3.1.2, 30.7.3.1.3, 30.7.3.1.4), or frames discarded by the Collection function of the Aggregator (30.7.1.1.26). This value is read-only.;

30.7.1.1.23 aAggBroadcastFramesTxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the broadcast data frames transmitted by this Aggregator on all Aggregation Ports that are (or have been) members of the aggregation. The count does not include frames transmitted by the Aggregator that carry LACP or Marker PDUs (30.7.3.1.7, 30.7.3.1.8, 30.7.3.1.9). However, it includes frames discarded by the Distribution function of the Aggregator (30.7.1.1.25). This value is read-only.;

30.7.1.1.24 aAggBroadcastFramesRxOK

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of the broadcast data frames received by this Aggregator, from the Aggregation Ports that are (or have been) members of the aggregation. The count does not include frames that carry LACP or Marker PDUs (30.7.3.1.2, 30.7.3.1.3, 30.7.3.1.4), illegal or unknown protocol frames (30.7.3.1.5, 30.7.3.1.6), or frames discarded by the Collection function of the Aggregator (30.7.1.1.26). This value is read-only.;

30.7.1.1.25 aAggFramesDiscardedOnTx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of data frames requested to be transmitted by this Aggregator that were discarded by the Distribution function of the Aggregator when conversations are re-allocated to different ports, due to the requirement to ensure that the conversations are flushed on the old ports in order to maintain proper frame ordering (43A.3), or discarded as a result of excessive collisions by ports that are (or have been) members of the aggregation. This value is read-only.;

30.7.1.1.26 aAggFramesDiscardedOnRx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A count of data frames, received on all ports that are (or have been) members of the aggregation, that were discarded by the Collection function of the Aggregator as they were received on ports whose Collection function was disabled. This value is read-only.;

30.7.1.1.27 aAggFramesWithTxErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of data frames requested to be transmitted by this Aggregator that experienced transmission errors on ports that are (or have been) members of the aggregation. This count does not include frames discarded due to excess collisions. This value is read-only.;

30.7.1.1.28 aAggFramesWithRxErrors

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of data frames discarded on reception by all ports that are (or have been) members of the aggregation, or that were discarded by the Collection function of the Aggregator, or that were discarded by the Aggregator due to the detection of an illegal Slow Protocols PDU (30.7.3.1.6). This value is read-only.;

30.7.1.1.29 aAggUnknownProtocolFrames

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 16 000 counts per second for a single 10 Mb/s aggregation.

BEHAVIOUR DEFINED AS:

A count of data frames discarded on reception by all ports that are (or have been) members of the aggregation, due to the detection of an unknown Slow Protocols PDU (30.7.3.1.5). This value is read-only.;

30.7.1.1.30 aAggPortList

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE OF INTEGERs that match the syntax of aAggPortID.

BEHAVIOUR DEFINED AS:

The value of this read-only attribute contains the list of Aggregation Ports that are currently attached to the Aggregator. An empty list indicates that there are no Aggregation Ports attached. Each integer value in the list carries an aAggPortID attribute value (30.7.2.1.1).;

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.1.1.31 aAggLinkUpDownNotificationEnable

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:
When set to “enabled”, Link Up and Link Down notifications are enabled for this Aggregator. When set to “disabled”, Link Up and Link Down notifications are disabled for this Aggregator. This value is read-write.;

30.7.1.1.32 aAggCollectorMaxDelay

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of this 16-bit read-write attribute defines the maximum delay, in tens of microseconds, that may be imposed by the Frame Collector between receiving a frame from an Aggregator Parser, and either delivering the frame to its MAC Client or discarding the frame (see 43.2.3.1.1).;

30.7.1.2 Aggregator Notifications

30.7.1.2.1 nAggLinkUpNotification

NOTIFICATION

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
When aAggLinkUpDownNotificationEnable is set to “enabled”, a Link Up notification is generated when the Operational State of the aggregator changes from “down” to “up”. When aAggLinkUpDownNotificationEnable is set to “disabled”, no Link Up notifications are generated. The notification carries the identifier of the Aggregator whose state has changed.;

30.7.1.2.2 nAggLinkDownNotification

NOTIFICATION

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
When aAggLinkUpDownNotificationEnable is set to “enabled”, a Link Down notification is generated when the Operational State of the aggregator changes from “up” to “down”. When aAggLinkUpDownNotificationEnable is set to “disabled”, no Link Down notifications are generated. The notification carries the identifier of the Aggregator whose state has changed.;

30.7.2 Aggregation Port managed object class

This subclause formally defines the behaviours for the oAggregationPort managed object class attributes.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.2.1 Aggregation Port Attributes

30.7.2.1.1 aAggPortID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The unique identifier allocated to this Aggregation Port by the local System. This attribute identifies an Aggregation Port instance among the subordinate managed objects of the containing object. This value is read-only.

30.7.2.1.2 aAggPortActorSystemPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A 2-octet read-write value used to define the priority value associated with the Actor's System ID.;

30.7.2.1.3 aAggPortActorSystemID

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A 6-octet read-only MAC address value that defines the value of the System ID for the System that contains this Aggregation Port.;

30.7.2.1.4 aAggPortActorAdminKey

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current administrative value of the Key for the Aggregation Port. This is a 16-bit read-write value. The meaning of particular Key values is of local significance.;

30.7.2.1.5 aAggPortActorOperKey

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current operational value of the Key for the Aggregation Port. This is a 16-bit read-only value. The meaning of particular Key values is of local significance.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.2.1.6 aAggPortPartnerAdminSystemPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A 2-octet read-write value used to define the administrative value of priority associated with the Partner's System ID. The assigned value is used, along with the value of aAggPortPartnerAdminSystemID, aAggPortPartnerAdminKey, aAggPortPartnerAdminPort, and aAggPortPartnerAdminPortPriority, in order to achieve manually configured aggregation.;

30.7.2.1.7 aAggPortPartnerOperSystemPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A 2-octet read-only value indicating the operational value of priority associated with the Partner's System ID. The value of this attribute may contain the manually configured value carried in aAggPortPartnerAdminSystemPriority if there is no protocol Partner.;

30.7.2.1.8 aAggPortPartnerAdminSystemID

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A 6-octet read-write MACAddress value representing the administrative value of the Aggregation Port's protocol Partner's System ID. The assigned value is used, along with the value of aAggPortPartnerAdminSystemPriority, aAggPortPartnerAdminKey, aAggPortPartnerAdminPort, and aAggPortPartnerAdminPortPriority, in order to achieve manually configured aggregation.;

30.7.2.1.9 aAggPortPartnerOperSystemID

ATTRIBUTE

APPROPRIATE SYNTAX:
MACAddress

BEHAVIOUR DEFINED AS:
A 6-octet read-only MACAddress value representing the current value of the Aggregation Port's protocol Partner's System ID. A value of zero indicates that there is no known protocol Partner. The value of this attribute may contain the manually configured value carried in aAggPortPartnerAdminSystemID if there is no protocol Partner.;

30.7.2.1.10 aAggPortPartnerAdminKey

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

The current administrative value of the Key for the protocol Partner. This is a 16-bit read-write value. The assigned value is used, along with the value of aAggPortPartnerAdminSystemPriority, aAggPortPartnerAdminSystemID, aAggPortPartnerAdminPort, and aAggPortPartnerAdminPortPriority, in order to achieve manually configured aggregation.;

30.7.2.1.11 aAggPortPartnerOperKey

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The current operational value of the Key for the protocol Partner. The value of this attribute may contain the manually configured value carried in aAggPortPartnerAdminKey if there is no protocol Partner. This is a 16-bit read-only value.;

30.7.2.1.12 aAggPortSelectedAggID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The identifier value of the Aggregator that this Aggregation Port has currently selected. Zero indicates that the Aggregation Port has not selected an Aggregator, either because it is in the process of detaching from an Aggregator or because there is no suitable Aggregator available for it to select. This value is read-only.;

30.7.2.1.13 aAggPortAttachedAggID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The identifier value of the Aggregator that this Aggregation Port is currently attached to. Zero indicates that the Aggregation Port is not currently attached to an Aggregator. This value is read-only.;

30.7.2.1.14 aAggPortActorPort

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The port number locally assigned to the Aggregation Port. The port number is communicated in LACPDUs as the Actor_Port. This value is read-only.;

30.7.2.1.15 aAggPortActorPortPriority

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The priority value assigned to this Aggregation Port. This 16-bit value is read-write.;

30.7.2.1.16 aAggPortPartnerAdminPort

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current administrative value of the port number for the protocol Partner. This is a 16-bit read-write value. The assigned value is used, along with the value of aAggPortPartnerAdminSystemPriority, aAggPortPartnerAdminSystemID, aAggPortPartnerAdminKey, and aAggPortPartnerAdminPortPriority, in order to achieve manually configured aggregation.;

30.7.2.1.17 aAggPortPartnerOperPort

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The operational port number assigned to this Aggregation Port by the Aggregation Port's protocol Partner. The value of this attribute may contain the manually configured value carried in aAggPortPartnerAdminPort if there is no protocol Partner. This 16-bit value is read-only.;

30.7.2.1.18 aAggPortPartnerAdminPortPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The current administrative value of the port priority for the protocol Partner. This is a 16-bit read-write value. The assigned value is used, along with the value of aAggPortPartnerAdminSystemPriority, aAggPortPartnerAdminSystemID, aAggPortPartnerAdminKey, and aAggPortPartnerAdminPort, in order to achieve manually configured aggregation.;

30.7.2.1.19 aAggPortPartnerOperPortPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The priority value assigned to this Aggregation Port by the Partner. The value of this attribute may contain the manually configured value carried in aAggPortPartnerAdminPortPriority if there is no protocol Partner. This 16-bit value is read-only.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.2.1.20 aAggPortActorAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1..8)]

BEHAVIOUR DEFINED AS:
A string of 8 bits, corresponding to the administrative values of Actor_State (43.4.2) as transmitted by the Actor in LACPDUs. The first bit corresponds to bit 0 of Actor_State (LACP_Activity), the second bit corresponds to bit 1 (LACP_Timeout), the third bit corresponds to bit 2 (Aggregation), the fourth bit corresponds to bit 3 (Synchronization), the fifth bit corresponds to bit 4 (Collecting), the sixth bit corresponds to bit 5 (Distributing), the seventh bit corresponds to bit 6 (Defaulted), and the eighth bit corresponds to bit 7 (Expired). These values allow administrative control over the values of LACP_Activity, LACP_Timeout, and Aggregation. This attribute value is read-write.;

30.7.2.1.21 aAggPortActorOperState

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1..8)]

BEHAVIOUR DEFINED AS:
A string of 8 bits, corresponding to the current operational values of Actor_State (43.4.2) as transmitted by the Actor in LACPDUs. The bit allocations are as defined in 30.7.2.1.20. This attribute value is read-only.;

30.7.2.1.22 aAggPortPartnerAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1..8)]

BEHAVIOUR DEFINED AS:
A string of 8 bits, corresponding to the current administrative value of Actor_State for the protocol Partner. The bit allocations are as defined in 30.7.2.1.20. This attribute value is read-write. The assigned value is used in order to achieve manually configured aggregation.;

30.7.2.1.23 aAggPortPartnerOperState

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1..8)]

BEHAVIOUR DEFINED AS:
A string of 8 bits, corresponding to the current values of Actor_State in the most recently received LACPDU transmitted by the protocol Partner. The bit allocations are as defined in 30.7.2.1.20. In the absence of an active protocol Partner, this value may reflect the manually configured value aAggPortPartnerAdminState. This attribute value is read-only.;

30.7.2.1.24 aAggPortAggregateOrIndividual

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value indicating whether the Aggregation Port is able to Aggregate ("TRUE") or is only able to operate as an Individual link ("FALSE").;

30.7.3 Aggregation Port Statistics managed object class

This subclause formally defines the behaviours for the oAggPortStats managed object class attributes.

30.7.3.1 Aggregation Port Statistics attributes

30.7.3.1.1 aAggPortStatsID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
This read-only attribute identifies an Aggregation Port Statistics object instance among the subordinate managed objects of the containing object. The value allocated to this attribute shall be the same as the containing oAggregationPort managed object.;

30.7.3.1.2 aAggPortStatsLACPDUsRx

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:
The number of valid LACPDUs received on this Aggregation Port. This value is read-only.;

30.7.3.1.3 aAggPortStatsMarkerPDUsRx

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:
The number of valid Marker PDUs received on this Aggregation Port. This value is read-only.;

30.7.3.1.4 aAggPortStatsMarkerResponsePDUsRx

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:
The number of valid Marker Response PDUs received on this Aggregation Port. This value is read-only.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.3.1.5 aAggPortStatsUnknownRx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 50 counts per second.

BEHAVIOUR DEFINED AS:

The number of frames received that either

— Carry the Slow Protocols Ethernet Type value (43B.4), but contain an unknown PDU, or

— Are addressed to the Slow Protocols group MAC Address (43B.3), but do not carry the Slow Protocols Ethernet Type. This value is read-only.;

30.7.3.1.6 aAggPortStatsIllegalRx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 50 counts per second.

BEHAVIOUR DEFINED AS:

The number of frames received that carry the Slow Protocols Ethernet Type value (43B.4), but contain a badly formed PDU or an illegal value of Protocol Subtype (43B.3). This value is read-only.;

30.7.3.1.7 aAggPortStatsLACPDUsTx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

The number of LACPDUs transmitted on this Aggregation Port. This value is read-only.;

30.7.3.1.8 aAggPortStatsMarkerPDUsTx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

The number of Marker PDUs transmitted on this Aggregation Port. This value is read-only.;

30.7.3.1.9 aAggPortStatsMarkerResponsePDUsTx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

The number of Marker Response PDUs transmitted on this Aggregation Port. This value is read-only.;

30.7.4 Aggregation Port Debug Information managed object class

This subclause formally defines the behaviours for the oAggPortDebugInformation managed object class attributes.

30.7.4.1 Aggregation Port Debug Information attributes

30.7.4.1.1 aAggPortDebugInformationID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

This read-only attribute identifies an LACP Debug Information object instance among the subordinate managed objects of the containing object. The value allocated to this attribute shall be the same as the containing oAggregationPort managed object.;

30.7.4.1.2 aAggPortDebugRxState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:
current
expired
defaulted
initialize
lacpDisabled
portDisabled

BEHAVIOUR DEFINED AS:

This attribute holds the value “current” if the Receive state machine for the Aggregation Port is in the CURRENT state, “expired” if the Receive state machine is in the EXPIRED state, “defaulted” if the Receive state machine is in the DEFAULTED state, “initialize” if the Receive state machine is in the INITIALIZE state, “lacpDisabled” if the Receive state machine is in the LACP_DISABLED state, or “portDisabled” if the Receive state machine is in the PORT_DISABLED state. This value is read-only.;

30.7.4.1.3 aAggPortDebugLastRxTime

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of aTimeSinceSystemReset (F.2.1) when the last LACPDU was received by this Aggregation Port. This value is read-only.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.7.4.1.4 aAggPortDebugMuxState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:
detached
waiting
attached
collecting
distributing
collecting_distributing

BEHAVIOUR DEFINED AS:

This attribute holds the value “detached” if the Mux state machine (43.4.15) for the Aggregation Port is in the DETACHED state, “waiting” if the Mux state machine for the Aggregation Port is in the WAITING state, “attached” if the Mux state machine for the Aggregation Port is in the ATTACHED state, “collecting” if the Mux state machine for the Aggregation Port is in the COLLECTING state, “distributing” if the Mux state machine for the Aggregation Port is in the DISTRIBUTING state, and “collecting_distributing” if the Mux state machine for the Aggregation Port is in the COLLECTING_DISTRIBUTING state. This value is read-only.;

30.7.4.1.5 aAggPortDebugMuxReason

ATTRIBUTE

APPROPRIATE SYNTAX:

A PrintableString, 255 characters max.

BEHAVIOUR DEFINED AS:

A human-readable text string indicating the reason for the most recent change of Mux machine state. This value is read-only.;

30.7.4.1.6 aAggPortDebugActorChurnState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:
noChurn
churn

BEHAVIOUR DEFINED AS:

The state of the Actor Churn Detection machine (43.4.17) for the Aggregation Port. A value of “noChurn” indicates that the state machine is in either the NO_ACTOR_CHURN or the ACTOR_CHURN_MONITOR state, and “churn” indicates that the state machine is in the ACTOR_CHURN state. This value is read-only.;

30.7.4.1.7 aAggPortDebugPartnerChurnState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:
noChurn
churn

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The state of the Partner Churn Detection machine (43.4.17) for the Aggregation Port. A value of "noChurn" indicates that the state machine is in either the NO_PARTNER_CHURN or the PARTNER_CHURN_MONITOR state, and "churn" indicates that the state machine is in the PARTNER_CHURN state. This value is read-only.;

30.7.4.1.8 aAggPortDebugActorChurnCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

Count of the number of times the Actor Churn state machine has entered the ACTOR_CHURN state. This value is read-only.;

30.7.4.1.9 aAggPortDebugPartnerChurnCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

Count of the number of times the Partner Churn state machine has entered the PARTNER_CHURN state. This value is read-only.;

30.7.4.1.10 aAggPortDebugActorSyncTransitionCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

Count of the number of times the Actor's Mux state machine (43.4.15) has entered the IN_SYNC state. This value is read-only.;

30.7.4.1.11 aAggPortDebugPartnerSyncTransitionCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

Count of the number of times the Partner's Mux state machine (43.4.15) has entered the IN_SYNC state. This value is read-only.;

30.7.4.1.12 aAggPortDebugActorChangeCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

Count of the number of times the Actor's perception of the LAG ID for this Aggregation Port has changed. This value is read-only.;

30.7.4.1.13 aAggPortDebugPartnerChangeCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 5 counts per second.

BEHAVIOUR DEFINED AS:

Count of the number of times the Partner's perception of the LAG ID (43.3.6.1) for this Aggregation Port has changed. This value is read-only.;

30.8 Management for WAN Interface Sublayer (WIS)

30.8.1 WIS managed object class

This subclause formally defines the behaviours for the oWIS managed object class and attributes.

30.8.1.1 WIS attributes

The attributes in 30.8.1.1.1 through 30.8.1.1.28 may be used, possibly in conjunction with other attributes, to derive various system performance monitoring parameters and information.

30.8.1.1.1 aWISID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of aWISID is assigned so as to uniquely identify a WIS among the subordinate managed objects of the containing object.;

30.8.1.1.2 aSectionStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:

A string of 2 bits corresponding to the Section Status (50.3.2.5). The first bit corresponds to the Loss of Signal flag and maps to the LOS bit in the WIS Status 3 register. The second bit corresponds to the Loss of Frame flag and maps to the LOF bit in the WIS Status 3 register. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS Status 3 register specified in 45.2.2.10.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.8.1.1.3 aSectionSESThreshold

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET operation returns the value for *x* for Section SES definition (30.8.1.1.4). A SET operation changes the value for *x* for Section SES definition. After reset (or power-off, power-on cycle), *x* for Section SES returns to the default value 8554.

NOTE—8554 is selected to reflect the number of Section BIP-8 Errors that would occur with a random bit error ratio of 1×10^{-6} (see Annex 50A).;

30.8.1.1.4 aSectionSESs

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:
Increment counter by one in a "Severely Errored Second" (SES), i.e., a second that had *x* or more Section BIP-8 Errors (50.3.2.5) or one or more Section Defects, i.e., the LOS flag (50.3.2.5) was equal to 1 or the LOF flag (50.3.2.5) was equal to 1, where *x* is the Section SES threshold defined by aSectionSESThreshold (30.8.1.1.3).;

30.8.1.1.5 aSectionESs

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:
Increment counter by one in an "Errored Second" (ES), i.e., a second that had one or more Section BIP-8 Errors (50.3.2.5) or one or more Section Defects, i.e., the LOS flag (50.3.2.5) was equal to 1 or the LOF flag (50.3.2.5) was equal to 1.;

30.8.1.1.6 aSectionSEFSs

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:
Increment counter by one in a "Severely Errored Framing Second" (SEFS), i.e., a second containing one or more SEF events (50.3.2.5).;

30.8.1.1.7 aSectionCVs

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Generalized nonresettable counter. This counter has a maximum increment rate of 64 000 counts per second.

BEHAVIOUR DEFINED AS:

For every received B1 octet, increment counter by the number of detected Section BIP-8 Errors (50.3.2.5).;

30.8.1.1.8 aJ0ValueTX

ATTRIBUTE

APPROPRIATE SYNTAX:

OCTET STRING, 15

BEHAVIOUR DEFINED AS:

An 16 octet value defining the transmitter's Section Trace message as defined in 50.3.2.3. The first octet of the string is transmitted first, and the last octet is transmitted last. A SET operation changes the Section Trace message value. A GET operation returns the current Section Trace message value. The default transmitter's Section Trace message is the hexadecimal value 89, followed by 15 NULL characters, the hexadecimal value 00. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS J0 transmit registers specified in 45.2.2.18.;

30.8.1.1.9 aJ0ValueRX

ATTRIBUTE

APPROPRIATE SYNTAX:

OCTET STRING, 15

BEHAVIOUR DEFINED AS:

An 16 octet value indicating the received Section Trace message as defined in 50.3.2.4. The first octet in this string was received first, and the last octet received last. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS J0 receive registers specified in 45.2.2.19.;

30.8.1.1.10 aLineStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:

A string of 2 bits reflecting the Line status (50.3.2.5). The first bit corresponds to the Line Alarm Indication Signal flag and maps to the AIS-L bit. The second bit corresponds to the Line Remote Defect Indication flag and maps to the RDI-L bit. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS Status 3 register specified in 45.2.2.10;

30.8.1.1.11 aLineSESThreshold

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET operation returns the value for *x* for Line SES definition (30.8.1.1.12). A SET operation changes the value for x for Line SES definition. After WIS reset (or power-off, power-on cycle),

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

x for Line SES returns to the default value 9835.;

NOTE—9835 is selected to reflect the number of Line BIP Errors that would occur with a random bit error ratio of 1×10^{-6} (see Annex 50A).;

30.8.1.1.12 aLineSESs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:

Increment counter by one in a "Severely Errored Second" (SES), i.e., a second that had *x* or more Line BIP Errors (50.3.2.5) or an AIS-L defect was present, i.e., the AIS-L flag (50.3.2.5) was equal to 1, where *x* is the Line SES threshold defined by aLineSESThreshold (30.8.1.1.11).;

30.8.1.1.13 aLineESs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:

Increment counter by one in an "Errored Second" (ES), i.e., a second that had one or more Line BIP Errors (50.3.2.5) or an AIS-L defect was present, i.e., the AIS-L flag (50.3.2.5) was equal to 1.;

30.8.1.1.14 aLineCVs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 12 288 000 counts per second at 10 Gb/s.

BEHAVIOUR DEFINED AS:

For every received WIS frame (50.3.2), increment counter by the number of detected Line BIP Errors (50.3.2.5).;

30.8.1.1.15 aFarEndLineSESs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 count second independent of speed of operation.

BEHAVIOUR DEFINED AS:

Increment counter by one in a "Severely Errored Second" (SES), i.e., a second that had *x* or more Far End Line BIP Errors (50.3.2.5) or an RDI-L defect was present, i.e., the RDI-L flag (50.3.2.5) was equal to 1, where *x* is the Line SES threshold defined by aLineSESThreshold (30.8.1.1.11).;

30.8.1.1.16 aFarEndLineESs

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:

Increment counter by one in an “Errored Second” (ES), i.e., a second that had one or more Far End Line BIP Errors (50.3.2.5) or an RDI-L defect was present, i.e., the RDI-L flag (50.3.2.5) was equal to 1.;

30.8.1.1.17 aFarEndLineCVs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 040 000 counts per second at 10 Gb/s.

BEHAVIOUR DEFINED AS:

For every received WIS frame (50.3.2), increment counter by the number of reported Far End Line BIP Errors (50.3.2.5).;

30.8.1.1.18 aPathStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BIT STRING [SIZE (4)]

BEHAVIOUR DEFINED AS:

A string of 4 bits corresponding to the Path Status (50.3.2.5). The first bit corresponds to the Loss of Pointer flag and maps to the LOP-P bit, the second bit corresponds to the Alarm Indication Signal and maps to the AIS-P bit, the third bit corresponds to the Path Label Mismatch flag and maps to the PLM-P bit and the fourth bit corresponds to the Path Loss of Cell Delineation flag and maps to the LCD-P bit. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS Status 3 register specified in 45.2.2.10;

30.8.1.1.19 aPathSESThreshold

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET operation returns the value for *x* for Path SES definition (30.8.1.1.20). A SET operation changes the value for *x* for Path SES definition. After reset (or power-off, power-on cycle), *x* for Path SES is set to the default value 2400.

NOTE—2400 is selected to reflect the point where 30% of all SPEs have a Path Block Error (see Annex 50A).;

30.8.1.1.20 aPathSESs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

Increment counter by one in a “Severely Errored Second” (SES), i.e., a second that had *x* or more Path Block Errors (Annex 50A) or one or more Path Defects, i.e., the LOP-P flag (50.3.2.5) was equal to 1, the AIS-P flag (50.3.2.5) was equal to 1, the PLM-P flag (50.3.2.5) was equal to 1, or the LCD-P flag (50.3.2.5) was equal to 1, where *x* is the Path SES threshold defined by aPathSESThreshold (30.8.1.1.19).;

30.8.1.1.21 aPathESs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:

Increment counter by one in an Errored Second (ES), i.e., a second that had one or more Path Block Errors (Annex 50A) or one or more Path Defects, i.e., the LOP-P flag (50.3.2.5) was equal to 1, the AIS-P flag (50.3.2.5) was equal to 1, the PLM-P flag (50.3.2.5) was equal to 1, or the LCD-P flag (50.3.2.5) was equal to 1.;

30.8.1.1.22 aPathCVs

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 8000 counts per second.

BEHAVIOUR DEFINED AS:

Increment counter by one for every received B3 indicating a Path Block Error (Annex 50A).;

30.8.1.1.23 aJ1ValueTX

ATTRIBUTE

APPROPRIATE SYNTAX:

OCTET STRING, 15

BEHAVIOUR DEFINED AS:

An 16 octet value defining the transmitter’s Path Trace message as defined in 50.3.2.1. The first octet of the string is transmitted first, and the last octet is transmitted last. A SET operation changes the Path Trace message value. A GET operation returns the current Path Trace message value. The default transmitter’s Path Trace message is the hexadecimal value 89, followed by 15 NULL characters, the hexadecimal value 00. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS J1 transmit registers specified in 45.2.2.12.;

30.8.1.1.24 aJ1ValueRX

ATTRIBUTE

APPROPRIATE SYNTAX:

OCTET STRING, 15

BEHAVIOUR DEFINED AS:

An 16 octet value indicating the received Path Trace message as defined in 50.3.2.4. The first octet in this string was received first, and the last octet received last. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS J1 receive registers specified in

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

45.2.2.13.;

30.8.1.1.25 aFarEndPathStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A string of 2 bits corresponding to the Far End Path Status (50.3.2.5). The first bit corresponds to the Far End Path Label Mismatch/Path Loss of Cell Delineation flag and maps to the Far End PLM-P/LCD-P bit, and the second bit corresponds to the Far End Path Alarm Indication Signal/Path Loss of Pointer flag and maps to the Far End AIS-P/LOP-P bit. If a Clause 45 MDIO Interface to the WIS is present, then this attribute will map to the WIS Status 3 register specified in 45.2.2.10;

30.8.1.1.26 aFarEndPathSESs

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:
Increment counter by one in a “Severely Errored Second” (SES), i.e., a second that had *x* or more Far End Path Block Errors or one or more Far End Path Defects reported in the Far End PLM-P/LCD-P, AIS-P, and LOP-P bits (50.3.2.5), where *x* is the Path SES threshold defined by aPathSESThreshold (30.8.1.1.19).;

30.8.1.1.27 aFarEndPathESs

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 1 count per second independent of speed of operation.

BEHAVIOUR DEFINED AS:
Increment counter by one in an “Errored Second” (ES), i.e., a second that had one or more Far End Path Block Errors or one or more Far End Path Defects reported in the Far End PLM-P/LCD-P, AIS-P, and LOP-P bits (50.3.2.5).;

30.8.1.1.28 aFarEndPathCVs

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 8000 counts per second.

BEHAVIOUR DEFINED AS:
Increment counter by one for each received G1 octet indicating a Far End Path Block Error reported in REI-P (50.3.2.5).;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.9 Management for Power over Ethernet

30.9.1 PSE managed object class

This subclause formally defines the behaviours for the oPSE managed object class attributes and actions.

30.9.1.1 PSE attributes

30.9.1.1.1 aPSEID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aPSEID is assigned so as to uniquely identify a PSE among the subordinate managed objects of the containing object.;

30.9.1.1.2 aPSEAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

enabled	PSE functions enabled
disabled	PSE functions disabled

BEHAVIOUR DEFINED AS:
A read-only value that identifies the operational state of the PSE functions. An interface which can provide the PSE functions specified in Clause 33 will be enabled to do so when this attribute has the enumeration “enabled”. When this attribute has the enumeration “disabled” the interface will act as it would if it had no PSE function. The operational state of the PSE function can be changed using the acPSEAdminControl action. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the PSE Enable bit specified in 33.5.1.1.5.;

30.9.1.1.3 aPSEPowerPairsControlAbility

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
Indicates the ability to control which PSE Pinout Alternative (see 33.2.3 and 145.2.4) is used for PD detection and power. When “true” the PSE Pinout Alternative used can be controlled through the aPSEPowerPairs attribute. When “false”, the PSE Pinout Alternative used cannot be controlled through the aPSEPowerPairs attribute. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the Pair Control Ability bit specified in 33.5.1.2.12.;

30.9.1.1.4 aPSEPowerPairs

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

signal	PSE Pinout Alternative A

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

spare	PSE Pinout Alternative B
both	PSE Pinout Alternative A and Alternative B

BEHAVIOUR DEFINED AS:

A read-write value that identifies the supported PSE Pinout Alternative specified in 33.2.3 and 145.2.4. A GET operation returns the PSE Pinout Alternative in use. If the attribute aPSEPowerPairsControlAbility is “true”, a SET operation will cause the PSE functions to be disabled, the PSE Pinout Alternative used to be changed to the value indicated if supported, and then the PSE functions to be enabled. If the attribute aPSEPowerPairsControlAbility is “false”, a SET operation has no effect.

The enumeration “signal” indicates that PSE Pinout Alternative A is used for PD detection and power. The enumeration “spare” indicates that PSE Pinout Alternative B is used for PD detection and power. The enumeration “both” indicates that the PSE Pinout uses both Alternative A and Alternative B for detection and power. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the Pair Control bits specified in 33.5.1.1.4.;

30.9.1.1.5 aPSEPowerDetectionStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

disabled	PSE disabled
searching	PSE searching
deliveringPower	PSE delivering power
test	PSE test mode
fault	PSE fault detected
otherFault	PSE implementation specific fault detected

BEHAVIOUR DEFINED AS:

A read-only value that indicates the current status of the PD Detection function specified in 33.2.5 and 145.2.6.

The enumeration “disabled” indicates that the PSE State diagram (Figure 33–9) is in the state DISABLED. The enumeration “deliveringPower” indicates that the PSE State diagram is in the state POWER_ON. The enumeration “test” indicates that the PSE State diagram is in the state TEST_MODE. The enumeration “fault” indicates that the PSE State diagram is in the state TEST_ERROR. The enumeration “otherFault” indicates that the PSE State diagram is in the state IDLE due to the variable error_condition = TRUE. The enumeration “searching” indicates the PSE State diagram is in a state other than those listed above. Type 3 and Type 4 PSEs do not use the values “test” or “fault”. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the PSE Status bits specified in 33.5.1.2.11.

NOTE—A derivative attribute may wish to apply a delay to the use of the “deliveringPower” enumeration as the PSE state diagram will enter and then quickly exit the POWER_ON state if a short-circuit or overcurrent condition is present when power is first applied.;

30.9.1.1.6 aPSEPowerDetectionStatusA

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

searchingAltA	PSE searching

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

deliveringPowerAltA	PSE delivering power
faultAltA	PSE fault detected

BEHAVIOUR DEFINED AS:

A read-only value that indicates the current status of the PD Detection function specified in 145.2.6.

The enumeration “deliveringPowerAltA” indicates that the PSE State diagram is in the state POWER_ON_PRI if alt_pri=‘a’ or the state POWER_ON_SEC if alt_pri=‘b’. The enumeration “faultAltA” indicates that the PSE State diagram is in the state IDLE_PRI if alt_pri=‘a’ or the state IDLE_SEC if alt_pri=‘b’ due to the variable error_condition_pri = TRUE (if alt_pri=‘a’) or error_condition_sec = TRUE (if alt_pri=‘b’). The enumeration “searchingAltA” indicates the PSE State diagram is in a state other than those listed above.

NOTE—A derivative attribute may wish to apply a delay to the use of the “deliveringPowerAltA” enumeration as the PSE state diagram will enter and then quickly exit the POWER_ON_PRI (if alt_pri=‘a’) state or the POWER_ON_SEC (if alt_pri=‘b’) state if a short-circuit or overcurrent condition is present when power is first applied.;

30.9.1.1.7 aPSEPowerDetectionStatusB

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

searchingAltB	PSE searching
deliveringPowerAltB	PSE delivering power
faultAltB	PSE fault detected

BEHAVIOUR DEFINED AS:

A read-only value that indicates the current status of the PD Detection function specified in 145.2.6.

The enumeration “deliveringPowerAltB” indicates that the PSE State diagram is in the state POWER_ON_SEC if alt_pri=‘a’ or the state POWER_ON_PRI if alt_pri=‘b’. The enumeration “faultAltB” indicates that the PSE State diagram is in the state IDLE_SEC if alt_pri=‘a’ or the state IDLE_PRI if alt_pri=‘b’ due to the variable error_condition_sec = TRUE (if alt_pri=‘a’) or error_condition_pri = TRUE (if alt_pri=‘b’). The enumeration “searchingAltB” indicates the PSE State diagram is in a state other than those listed above.

NOTE—A derivative attribute may wish to apply a delay to the use of the “deliveringPowerAltB” enumeration as the PSE state diagram will enter and then quickly exit the POWER_ON_SEC (if alt_pri=‘a’) state or the POWER_ON_PRI (if alt_pri=‘b’) state if a short-circuit or overcurrent condition is present when power is first applied.;

30.9.1.1.8 aPSEPowerClassification

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

class0	Class 0 PD
class1	Class 1 PD
class2	Class 2 PD
class3	Class 3 PD
class4	Class 4 PD
class5	Class 5 PD

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

class6	Class 6 PD
class7	Class 7 PD
class8	Class 8 PD

BEHAVIOUR DEFINED AS:

A read-only value that indicates the PD Class of a detected PD as specified in 33.2.6.1 and 145.2.8.1.

This value is only valid while a PD is being powered, that is the attribute aPSEPowerDetectionStatus reporting the enumeration “deliveringPower”. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the PD Class bits specified in 33.5.1.2.10.;

30.9.1.1.9 aPSEPowerClassificationA

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

class1	Class 1 PD
class2	Class 2 PD
class3	Class 3 PD
class4	Class 4 PD
class5	Class 5 PD

BEHAVIOUR DEFINED AS:

A read-only value that indicates the PD Class of a detected dual-signature PD as specified in 145.2.8.1.

This value is only valid while a PD is being powered, that is the attribute aPSEPowerDetectionStatusA reporting the enumeration “deliveringPowerAltA”.;

30.9.1.1.10 aPSEPowerClassificationB

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

class1	Class 1 PD
class2	Class 2 PD
class3	Class 3 PD
class4	Class 4 PD
class5	Class 5 PD

BEHAVIOUR DEFINED AS:

A read-only value that indicates the PD Class of a detected dual-signature PD as specified in 145.2.8.1.

This value is only valid while a PD is being powered, that is the attribute aPSEPowerDetectionStatusB reporting the enumeration “deliveringPowerAltB”.;

30.9.1.1.11 aPSEInvalidSignatureCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the Type 1 and Type 2 PSE state diagram (Figure 33–9) enters the state SIGNATURE_INVALID. This counter is not defined for Type 3 and Type 4 PSEs. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the Invalid Signature bit specified in 33.5.1.2.6.;

30.9.1.1.12 aPSEInvalidSignatureCounterA

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the do_detect_pri or do_detect_sec function in Figure 145–13, Figure 145–15, and Figure 145–16, whichever corresponds to Alternative A depending on the value of alt_pri, returns ‘invalid’.;

30.9.1.1.13 aPSEInvalidSignatureCounterB

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the do_detect_pri or do_detect_sec function in Figure 145–13, Figure 145–15, and Figure 145–16, whichever corresponds to Alternative B depending on the value of alt_pri, returns ‘invalid’.;

30.9.1.1.14 aPSEPowerDeniedCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 33–9 and Figure 145–13) enters the state POWER_DENIED. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the Power Denied bit specified in 33.5.1.2.4.;

30.9.1.1.15 aPSEPowerDeniedCounterA

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 145–15 or Figure 145–16) enters

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the state POWER_DENIED_PRI if alt_pri='a' or enters the state POWER_DENIED_SEC if alt_pri='b'.;

30.9.1.1.16 aPSEPowerDeniedCounterB

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 145–15 or Figure 145–16) enters the state POWER_DENIED_SEC if alt_pri='a' or enters the state POWER_DENIED_PRI if alt_pri='b'.;

30.9.1.1.17 aPSEOverLoadCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 33–9 and Figure 145–13) enters the state ERROR_DELAY due to the ovld_detected variable being TRUE. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the Overload bit specified in 33.5.1.2.8.;

30.9.1.1.18 aPSEOverLoadCounterA

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 145–15 or Figure 145–16) enters the state ERROR_DELAY_PRI if alt_pri='a' or enters the state ERROR_DELAY_SEC if alt_pri='b'.;

30.9.1.1.19 aPSEOverLoadCounterB

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 145–15 or Figure 145–16) enters the state ERROR_DELAY_SEC if alt_pri='a' or enters the state ERROR_DELAY_PRI if alt_pri='b'.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.9.1.1.20 aPSEMPSAbsentCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 33–9 and Figure 145–13) transitions directly from the state POWER_ON to the state IDLE due to tmpdo_timer_done being asserted. For Type 1 or Type 2 PSEs, if a Clause 22 MII or Clause 35 GMII is present, then this will map to the MPS Absent bit specified in 33.5.1.2.9.;

30.9.1.1.21 aPSEMPSAbsentCounterA

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 145–15 or Figure 145–16) transitions directly from the state POWER_ON_PRI to the state IDLE_PRI due to mpdo_timer_pri_done being asserted if alt_pri='a' or transitions directly from the state POWER_ON_SEC to the state IDLE_SEC due to mpdo_timer_sec_done being asserted if alt_pri='b'.;

30.9.1.1.22 aPSEMPSAbsentCounterB

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram (Figure 145–15 or Figure 145–16) transitions directly from the state POWER_ON_SEC to the state IDLE_SEC due to mpdo_timer_sec_done being asserted if alt_pri='a' or transitions directly from the state POWER_ON_PRI to the state IDLE_PRI due to mpdo_timer_pri_done being asserted if alt_pri='b'.;

30.9.1.1.23 aPSEActualPower

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

An integer value indicating present (actual) power being supplied by the PSE as measured at the MDI in milliwatts. The behaviour is undefined if the state of aPSEPowerDetectionStatus is anything other than deliveringPower. The sampling frequency and averaging is vendor-defined.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.9.1.1.24 aPSEPowerAccuracy

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
An integer value indicating the accuracy associated with aPSEActualPower in +/- milliwatts.;

30.9.1.1.25 aPSECumulativeEnergy

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. The counter has a maximum increment rate of 100 000 per second.

BEHAVIOUR DEFINED AS:
A count of the cumulative energy supplied by the PSE as measured at the MDI in millijoules.;

30.9.1.2 PSE actions

30.9.1.2.1 acPSEAdminControl

ACTION

APPROPRIATE SYNTAX:
Same as aPSEAdminState

BEHAVIOUR DEFINED AS:
This action provides a means to alter aPSEAdminState.;

30.10 Layer management for Midspan

30.10.1 Midspan managed object class

This subclause formally defines the behaviours for the oMidSpan managed object class, attributes, and notifications.

30.10.1.1 Midspan attributes

30.10.1.1.1 aMidSpanID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aMidSpanID is assigned so as to uniquely identify a Midspan device among the subordinate managed objects of system (systemID and system are defined in ISO/IEC 10165-2:1992 [SMI]).;

30.10.1.1.2 aMidSpanPSEGroupCapacity

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The aMidSpanPSEGroupCapacity is the number of PSE groups that can be contained within the Midspan device. Within each managed Midspan device, the PSE groups are uniquely numbered in the range from 1 to aMidSpanPSEGroupCapacity.

Some PSE groups may not be present in a given Midspan instance, in which case the actual number of PSE groups present is less than aMidSpanPSEGroupCapacity. The number of PSE groups present is never greater than aMidSpanPSEGroupCapacity.;

30.10.1.1.3 aMidSpanPSEGroupMap

ATTRIBUTE

APPROPRIATE SYNTAX:
BITSTRING

BEHAVIOUR DEFINED AS:
A string of bits which reflects the current configuration of PSE groups that are viewed by PSE group managed objects. The length of the bitstring is “aMidSpanPSEGroupCapacity” bits. The first bit relates to PSE group 1. A “1” in the bitstring indicates presence of the PSE group, “0” represents absence of the PSE group.;

30.10.1.2 Midspan notifications

30.10.1.2.1 nMidSpanPSEGroupMapChange

NOTIFICATION

APPROPRIATE SYNTAX:
BITSTRING

BEHAVIOUR DEFINED AS:
This notification is sent when a change occurs in the PSE group structure of a Midspan device. This occurs only when a PSE group is logically removed from or added to a Midspan device. The nMidSpanPSEGroupMapChange notification is not sent when powering up a Midspan device. The value of the notification is the updated value of the aMidSpanPSEGroupMap attribute.;

30.10.2 PSE Group managed object class

This subclause formally defines the behaviours for the oPSEGroup managed object class, attributes, actions, and notifications.

30.10.2.1 PSE Group attributes

30.10.2.1.1 aPSEGroupID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A value unique within the Midspan device. The value of aPSEGroupID is assigned so as to uniquely identify a PSE group among the subordinate managed objects of the containing object (oMidSpan). This value is never greater than aMidSpanPSEGroupCapacity.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.10.2.1.2 aPSECapacity

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The aPSECapacity is the number of PSEs contained within the PSE group. Valid range is 1–1024. Within each PSE group, the PSEs are uniquely numbered in the range from 1 to aPSECapacity. Some PSEs may not be present in a given PSE group instance, in which case the actual number of PSEs present is less than aPSECapacity. The number of PSEs present is never greater than aPSECapacity.;

30.10.2.1.3 aPSEMap

ATTRIBUTE

APPROPRIATE SYNTAX:
BitString

BEHAVIOUR DEFINED AS:
A string of bits that reflects the current configuration of PSE managed objects within this PSE group. The length of the bitstring is “aPSECapacity” bits. The first bit relates to PSE 1. A “1” in the bitstring indicates presence of the PSE, “0” represents absence of the PSE.;

30.10.2.2 PSE Group notifications

30.10.2.2.1 nPSEMapChange

NOTIFICATION

APPROPRIATE SYNTAX:
BitString

BEHAVIOUR DEFINED AS:
This notification is sent when a change occurs in the PSE structure of a PSE group. This occurs only when a PSE is logically removed from or added to a PSE group. The nPSEMapChange notification is not sent when powering up a Midspan device. The value of the notification is the updated value of the aPSEMap attribute.;

30.11 Layer Management for Physical Medium Entity (PME)

30.11.1 PAF managed object class

This subclause formally defines the behaviours for the oPAF managed object class attributes.

30.11.1.1 PAFAttributes

30.11.1.1.1 aPAFID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aTCID is assigned so as to uniquely identify a PAF among the subordinate managed

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

objects of the containing object.

30.11.1.1.2 aPhyEnd

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value that has one of the following entries:

subscriber	subscriber mode of operation
office	office mode of operation

BEHAVIOUR DEFINED AS:

A read-only value that indicates the subtype of the PHY (see 61.1). The enumeration “subscriber” indicates the PHY is operating as a -R subtype, the enumeration “office” indicates the PHY is operating as a -O subtype.;

30.11.1.1.3 aPHYCurrentStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries:

noPMEAssigned	no PME assigned in case of PME aggregation
lossOfFraming	one or more PME in aggregation indicates Loss of Framing
lossOfSignal	one or more PME in aggregation indicates Loss of Signal
lossOfPower	one or more PME in aggregation indicates Loss of Power
configInitFailure	configuration initialization failure
noPeerPMEPresent	one or more PME in aggregation indicates no peer PME present
snrMarginViolation	one or more PME in aggregation indicates SNR Margin Violation
lineAttenViolation	one or more PME in aggregation indicates Loop Attenuation Violation

BEHAVIOUR DEFINED AS:

This read-only value indicates the current operational state of the PHY (see 62.3.4.8 and 63.2.2.3).

The enumeration “noPMEAssigned” indicates that the PAF is enabled but that there are no PMEs available for aggregation (no modems assigned), the enumeration “lossOfFraming” indicates one or more PMEs in the aggregation are reporting loss of framing, the enumeration “lossOfSignal” indicates one or more PMEs in the aggregation are reporting loss of signal, the enumeration “lossOfPower” indicates one or more PMEs in the aggregation are reporting loss of power, the enumeration “configInitFailure” indicates configuration initialization failure, the enumeration “noPeerPMEPresent” indicates one or more PMEs in the aggregation are reporting that there was no handshake message/tones send by the remote end during initialization, the enumeration “snrMarginViolation” indicates one or more PMEs in the aggregation are reporting a SNR margin violation and the enumeration “lineAttenViolation” indicates one or more PMEs in the aggregation are reporting a loop attenuation violation.;

30.11.1.1.4 aPAFSupported

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A read-only value that indicates if the TPS-TC supports the PME aggregation function (see 61.2.2). A TPS-TC that can perform PME aggregation on the available PMEs shall return the enumeration “true”. A TPS-TC that is incapable of PME aggregation shall return the enumeration

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

"false".

If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the PAF available bit in the 10P/2B capability register (see 45.2.3.27.1).;

30.11.1.1.5 aPAFAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:
A read-write value that indicates the state of the PME aggregation function (see 61.2.2). When "disabled", PME aggregation will not be performed, when "enabled", PME aggregation will be performed when the link is Up, even on a single PME. As changing the state of the PME aggregation function is a traffic disruptive operation this can only occur when the link is down.

A GET operation returns the current state of the PME aggregation function. A SET operation changes the state of the PME aggregation function to the indicated value only if the attribute aPAFSupported is "true" and the link is down. If the attribute aPAFSupported is "false", or the link is not down, a SET operation has no effect.

If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the PAF enable bit in the 10P/2B capability register (see 45.2.3.28.3).;

30.11.1.1.6 aLocalPAFCapacity

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The aLocalPAFCapacity is the number of PMEs that can be aggregated by the PME aggregation function (PAF) of the PHY. Valid range is 1–32. Within each PHY, the PMEs are uniquely numbered in the range from 1 to aLocalPAFCapacity. Some PMEs may not be present in a given PHY instance, in which case the actual number of PMEs present is less than aLocalPAFCapacity. The number of PMEs present is never greater than aLocalPAFCapacity.;

30.11.1.1.7 aLocalPMEAvailable

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (32)]

BEHAVIOUR DEFINED AS:
A string of bits that indicates which PMEs are currently available for aggregation by the PME aggregation function (PAF) of the PHY (see 61.1.5.3) and therefore reflects the current configuration of PME managed objects within this PAF. The length of the bitstring is "aLocalPAFCapacity" bits. The first bit relates to PME[0]. A "1" in the bitstring indicates the PME is present and is available to the PAF for aggregation. A "0" in the bitstring indicates the PME is absent and not available to the PAF for aggregation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the 10P/2B PME available register (see 45.2.3.29).;

30.11.1.1.8 aLocalPMEAggregate

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (32)]

BEHAVIOUR DEFINED AS:
A string of bits that indicates which PMEs are in an active aggregation in the PHY. The length of the bitstring is "aLocalPAFCapacity" bits. The first bit relates to PME[0]. A "1" in the bitstring indicates the PME is in an active aggregation. A "0" in the bitstring indicates the PME is not in an active aggregation.

If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the 10P/2B PME available registers (see 45.2.3.30).;

30.11.1.1.9 aRemotePAFSupported

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:

unknown	initializing, true state not yet know
supported	PAF supported
not supported	PAF not supported

BEHAVIOUR DEFINED AS:
A read-only value that indicates if the link-partner PHY supports the PME aggregation function (see 61.2.2). When the link-partner PHY can perform PME aggregation on its available PMEs the enumeration "supported" shall be returned. When the link-partner PHY is incapable of PME aggregation the enumeration "not supported" shall be returned.

If a Clause 45 MDIO Interface to the local PCS is present, then this attribute will map to the Remote PAF supported bit in the 10P/2B capability register (see 45.2.3.27.2).;

30.11.1.1.10 aRemotePAFCapacity

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The aRemotePAFCapacity indicates the number of PME that can be aggregated by the PME aggregation function (PAF) of the link-partner PHY. Valid range is 1–32. Within the link-partner PHY, the PMEs are uniquely numbered in the range from 1 to aRemotePAFCapacity. Some PMEs may not be present in a given PHY instance, in which case the actual number of PMEs present is less than aRemotePAFCapacity. The number of PMEs present is never greater than aRemotePAFCapacity.;

30.11.1.1.11 aRemotePMEAggregate

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BIT STRING [SIZE (32)]

BEHAVIOUR DEFINED AS:

A string of bits that indicates which PMEs are in an active aggregation in the link-partner PHY. The length of the bitstring is “aRemotePAFCapacity” bits. The first bit relates to PME[0]. A “1” in the bitstring indicates the PME is in an active aggregation. A “0” in the bitstring indicates the PME is not in an active aggregation.

If a Clause 45 MDIO Interface to the local PCS is present, then this attribute will map to the 10P/2B PME available registers (see 45.2.6.10).;

30.11.2 PME managed object class

This subclause formally defines the behaviours for the oPME managed object class attributes.

30.11.2.1 PME Attributes

30.11.2.1.1 aPMEID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A value unique within the PAF. The value of aPMEID is assigned so as to uniquely identify a PME among the subordinate managed objects of the containing object (oPAF). This value is never greater than aLocalPAFCapacity.;

30.11.2.1.2 aPMEAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries:
enabled
disabled

BEHAVIOUR DEFINED AS:

A read-write value that indicates the state of the PME. The enumeration “disabled” indicates that the PME is disabled, the enumeration “enabled” indicates that the PME is enabled.
A GET operation returns the current state of the PME. A SET operation changes the state of the PME to the indicated value. The PME is enabled and link initialization initiated when the a SET operation is performed with the value “enabled” when the current value is “disabled”. A SET operation performed with the value “enabled” when the current value is already “enabled” will have shall have no effect.

If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute will map to the PMA/PMD link control register (see 45.2.1.11).;

30.11.2.1.3 aPMEStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

A ENUMERATED VALUE that has the following entries:
down not ready link is down, not ready

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

down ready	link is down, ready
initializing	link is initializing
10PASS-TS	link is up as 10PASS-TS
2BASE-TL	link is up as 2BASE-TL

BEHAVIOUR DEFINED AS:

A read-only value that indicates the PME status. The enumeration “not ready” indicates that the link is down and handshake tones are not being received from a link partner, the enumeration “ready” indicates that the link is down and that handshake tones are being received from a link partner, the enumeration “initializing” indicates that the link is initializing, the enumeration “10PASS-TS” indicates that the link is up and the remote PHY is a 10PASS-TS PHY and the enumeration “2BASE-TL” indicates that the link is up and the remote PHY is a 2BASE-TL PHY.

If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute will map to the PMA/PMD link status register (see 45.2.1.29.4).;

30.11.2.1.4 aPMESNRMgn

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A read-only value that indicates the PME current signal-to-noise ratio (SNR) Margin (see 62.3.4.7 and 63.2.2.3) with respect to the received signal in increments of dB rounded down to the nearest dB.

If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute will map to the 10P/2B RX SNR margin register (see 45.2.1.35).;

30.11.2.1.5 aTCCodingViolations

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 19 230 counts per second for 10 Mb/s implementations.

BEHAVIOUR DEFINED AS:

A count of 64/65-octet encapsulation error. Increment the counter by one for each 64/65-octet encapsulation error detected by the 64/65-octet receive function (see Figure 61–19).;

If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the TC coding violations register (see 45.2.6.12).;

30.11.2.1.6 aProfileSelect

ATTRIBUTE

APPROPRIATE SYNTAX:

SEQUENCE of the type INTEGER

BEHAVIOUR DEFINED AS:

A SEQUENCE of read-write values that indicates the operating profile numbers (see 62A.3.7 and 63A.4) of the PME. A 2BASE-TL PME supports a maximum of six values, 10PASS-TS PME can only support one. The operating profile can only be changed in a PME that is operating within a -O PHY subtype (see 61.1). As changing the operating profile is a traffic disruptive operation

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

this can only occur when the link is down.

A GET operation returns the current operating profile number(s). A SET operation changes the operating profile to the indicated profile number only if the attribute aPHYEnd is “office” and the link is down. If the attribute aPHYEnd is “subscriber”, or the link is not down, a SET operation has no effect. If all values are zero, the PME operation is defined via the Clause 45 register settings (Table 45–57 and Table 45–58) rather than a specific profile.

NOTE 1—The profile selected by a particular value is different for 10PASS-TS and 2BASE-TL PHY types.

NOTE 2—For a 2BASE-TL PHY six profiles per region can be chosen for handshake (see 61.4) and the one with the highest data rate will be used.;

30.11.2.1.7 aOperatingProfile

ATTRIBUTE

APPROPRIATE SYNTAX:

A SEQUENCE of two instances, the first instances PMEProfileState is an ENUMERATED VALUE that has the following entries:

no link	link is down
match	link up using a profile
no match	link up not using a profile
activate failure	link activate failure

The second instances is an INTEGER

BEHAVIOUR DEFINED AS:

The ProfileState portion of the attribute is a read-only value that indicates the state of the operating profile. The enumeration “no link” indicates that the link is down, the enumeration “match” indicates that the link is up and achieved operating parameters match a defined complete profile (63A.3 and Table 63A–1), the enumeration “no match” indicates that the link is up but the achieved operating parameters do not match a defined complete profile and the enumeration “activate failure” indicates that the link failed to come up in any of the selected profiles.

The integer portion of the attribute is a read-only value that indicates the operating profile number. This value is only valid when the ProfileState portion of the attribute is “match”;

30.11.2.1.8 aPMEFECCorrectedBlocks

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 10 000 counts per second for 10 Mb/s implementations.

BEHAVIOUR DEFINED AS:

For a 10PASS-TS PME, a count of corrected FEC blocks. This counter will not increment for other PHY types.

Increment the counter by one for each received block that is corrected by the FEC function in the PME.

If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute will map to the 10P FEC correctable errors (see 45.2.1.41).;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.11.2.1.9 aPMEFECUncorrectableBlocks

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 10 000 counts per second for 10 Mb/s implementations.

BEHAVIOUR DEFINED AS:
For a 10PASS-TS PME, a count of uncorrectable FEC blocks. This counter will not increment for other PME types.

Increment the counter by one for each FEC block that is determined to be uncorrectable by the FEC function in the PME.

If a Clause 45 MDIO Interface to the PMA/PMD is present, then this attribute will map to the 10P FEC uncorrectable errors counter (see 45.2.1.42).;

30.11.2.1.10 aTCCRCErrors

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter. This counter has a maximum increment rate of 19 230 counts per second for 10 Mb/s implementations.

BEHAVIOUR DEFINED AS:
A count of TC-CRC errors.

Increment the counter by one for each TC-CRC error detected by the 64/65-octet receive function (see 61.3.3 and Figure 61–19).;

If a Clause 45 MDIO Interface to the PCS is present, then this attribute will map to the TC CRC error register (see 45.2.6.11).;

30.12 Layer Management for Link Layer Discovery Protocol (LLDP)

30.12.1 LLDP Configuration managed object class

This subclause formally defines the behaviours for the oLldpXdot3Config managed object class attributes.

30.12.1.1 LLDP Configuration attributes

30.12.1.1.1 aLldpXdot3PortConfigTLVsTxEnable

ATTRIBUTE

APPROPRIATE SYNTAX:
BITSTRING

BEHAVIOUR DEFINED AS:
A read-write string of 7 bits indicating, for each of the IEEE 802.3 optional LLDP TLVs, if transmit is enabled on the local LLDP agent by the network management. A “1” in the bitstring indicates transmit of the TLV is enabled, “0” indicates transmit of the TLV is disabled. The value of this attribute is preserved across reset including loss of power.

Each bit of the bit string indicates whether transmit is enabled for the TLV corresponding to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bit. The mapping of bits to TLVs is:

first	MAC/PHY configuration/status TLV
second	Power via MDI TLV
third	Link Aggregation TLV (deprecated)
fourth	Maximum Frame Size TLV
fifth	EEE TLV
sixth	EEE Fast Wake TLV
seventh	Additional Ethernet Capabilities TLV.;

30.12.2 LLDP Local System Group managed object class

This subclause formally defines the behaviours for the oLldpXdot3LocSystemsGroup managed object class attributes.

30.12.2.1 LLDP Local System Group attributes

30.12.2.1.1 aLldpXdot3LocPortAutoNegSupported

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the given port (associated with the local system) supports Auto-negotiation.;

30.12.2.1.2 aLldpXdot3LocPortAutoNegEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether port Auto-negotiation is enabled on the given port associated with the local system.;

30.12.2.1.3 aLldpXdot3LocPortAutoNegAdvertisedCap

ATTRIBUTE

APPROPRIATE SYNTAX:
OCTET STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A read-only 2-octet value that contains the value (bitmap) of the ifMauAutoNegCapAdvertisedBits object (defined in IETF RFC 4836) which is associated with the given port on the local system.;

30.12.2.1.4 aLldpXdot3LocPortOperMauType

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A read-only 32-bit integer value that indicates the operational MAU type of the given port on the local system.

This object contains an integer value derived from the list position of the corresponding dot3MauType as listed in IETF RFC 4836 (or subsequent revisions) and is equal to the last number in the respective dot3MauType Object Identifier (OID).

For example, if the ifMauType object is dot3MauType1000BaseTHD which corresponds to {dot3MauType 29}, the numerical value of this field is 29. For MAU types not listed in IETF RFC 4836 (or subsequent revisions), the value of this field shall be set to zero.;

30.12.2.1.5 aLldpXdot3LocPowerPortClass

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

pClassPSE	PSE
pClassPD	PD

BEHAVIOUR DEFINED AS:

A read-only value that identifies the port Class of the given port associated with the local system.;

30.12.2.1.6 aLldpXdot3LocPowerMDISupported

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

For a PSE, this attribute contains a read-only Boolean value used to indicate whether the MDI power is supported on the given port associated with the local system. For a PD, the value of this attribute is undefined.;

30.12.2.1.7 aLldpXdot3LocPowerMDIEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

For a PSE, this attribute contains a read-only Boolean value used to identify whether MDI power is enabled on the given port associated with the local system. For a PD, the value of this attribute is undefined.;

30.12.2.1.8 aLldpXdot3LocPowerPairControllable

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A read-only Boolean value used to indicate the ability to control which PSE Pinout Alternative (see 33.2.3 and 145.2.4) is used for PD detection and power. For a PSE, this attribute contains the value of the aPSEPowerPairsControlAbility attribute (see 30.9.1.1.3). For a PD, the contents of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

this attribute are undefined.;

30.12.2.1.9 aLldpXdot3LocPowerPairs

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

signal	PSE Pinout Alternative A
spare	PSE Pinout Alternative B

BEHAVIOUR DEFINED AS:

A read-only value that identifies the PSE Pinout Alternative (see 33.2.3 and 145.2.4) in use for detecting and supplying power to the PD. For a PSE, this attribute contains a value derived from the aPSEPowerPairs attribute (see 30.9.1.1.4). For a PD, the contents of this attribute are undefined. A Type 3 or Type 4 PSE detecting or supplying power on both PSE Pinout Alternatives may return either PSE Pinout Alternative as this configuration is communicated through the aLldpXdot3LocPowerPairsExt attribute. A Type 3 or Type 4 PSE supplying power on only one PSE Pinout Alternative returns that PSE Pinout Alternative. For a PD, the contents of this attribute are undefined.;

30.12.2.1.10 aLldpXdot3LocPowerClass

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

class0	Class 0 PD
class1	Class 1 PD
class2	Class 2 PD
class3	Class 3 PD
class4	Class 4 PD

BEHAVIOUR DEFINED AS:

A read-only value that indicates the requested Class of the PD as specified in 33.2.6 and 145.2.8. This attribute returns an enumeration of “class4” for a PD of Class 4 or higher as such PD Classes are identified through the aLldpXdot3LocPowerClassExt attribute.;

30.12.2.1.11 aLldpXdot3LocLinkAggStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BITSTRING

BEHAVIOUR DEFINED AS:

The bitmap value which contains the link aggregation capabilities and the current aggregation status of the link (see 79.3.3.1).;

30.12.2.1.12 aLldpXdot3LocLinkAggPortId

ATTRIBUTE

APPROPRIATE SYNTAX:

The same as used for aAggPortID

BEHAVIOUR DEFINED AS:

This object contains the IEEE 802.3 aggregated port identifier, aAggPortID (see 30.7.2.1.1),

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

derived from the ifNumber of the ifIndex for the port component in link aggregation.

If the port is not in link aggregation state and/or it does not support link aggregation, this value should be set to zero.;

30.12.2.1.13 aLldpXdot3LocMaxFrameSize

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
An integer value indicating the maximum supported frame size in octets on the given port of the local system.;

30.12.2.1.14 aLldpXdot3LocPowerType

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A GET attribute that returns a bit string indicating whether the local system is a PSE or a PD and whether it is Type 1 or greater than Type 1. The first bit indicates Type 1 or greater than Type 1. The second bit indicates PSE or PD. A PSE sets this bit to indicate a PSE. A PD sets this bit to indicate a PD. See also aLldpXdot3LocPowerTypeExt.;

30.12.2.1.15 aLldpXdot3LocPowerSource

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A GET attribute that returns a bit string indicating the power sources of the local system. A PSE indicates whether it is being powered by a primary power source; a backup power source; or unknown. A PD indicates whether it is being powered by a PSE and locally; by a PSE only; or unknown.;

30.12.2.1.16 aLldpXdot3LocPowerPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED value list that has the following entries:

low	low priority PD
high	high priority PD
critical	critical priority PD
unknown	priority unknown

BEHAVIOUR DEFINED AS:
A GET attribute that returns the priority of a PD system. For a PSE, this is the priority that the PSE assigns to the PD. For a PD, this is the priority that the PD requests from the PSE.
A SET operation changes the priority of the PD system to the indicated value.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.2.1.17 aLldpXdot3LocPDRequestedPowerValue

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PD requested power value in units of 0.1 W. For a PD, it is the power value that the PD has currently requested from the remote system. The PD requested power value is the maximum input average power the PD ever draws under this power allocation if accepted. For a PSE, it is the power value that the PSE echoes back to the remote system. This is the PD requested power value that was used by the PSE to compute the power it has currently allocated to the remote system.;

30.12.2.1.18 aLldpXdot3LocPDRequestedPowerValueA

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PD requested power value for the Mode A pairset in units of 0.1 W. For a PD, it is the power value that the PD has currently requested from the remote system for the Mode A pairset. For a PSE, it is the power value for the Alternative A pairset that the PSE echoes back to the remote system.;

30.12.2.1.19 aLldpXdot3LocPDRequestedPowerValueB

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PD requested power value for the Mode B pairset in units of 0.1 W. For a PD, it is the power value that the PD has currently requested from the remote system for the Mode B pairset. For a PSE, it is the power value for the Alternative B pairset that the PSE echoes back to the remote system.;

30.12.2.1.20 aLldpXdot3LocPSEAllocatedPowerValue

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PSE allocated power value in units of 0.1 W. For a PSE, it is the power value that the PSE has currently allocated to the remote system. The PSE allocated power value is the maximum input average power that the PSE wants the PD to ever draw under this allocation if it is accepted. For a PD, it is the power value that the PD echoed back to the remote system.;

30.12.2.1.21 aLldpXdot3LocPSEAllocatedPowerValueA

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PSE allocated power value for the Alternative A pairset in units of 0.1 W. For a PSE, it is the power value for the Alternative A pairset that the PSE has currently allocated to the remote system. For a PD, it is the power value for the Mode A pairset that the PD echoes back to the remote system.;

30.12.2.1.22 aLldpXdot3LocPSEAllocatedPowerValueB

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PSE allocated power value for the Alternative B pairset in units of 0.1 W. For a PSE, it is the power value for the Alternative B pairset that the PSE has currently allocated to the remote system. For a PD, it is the power value for the Mode B pairset that the PD echoes back to the remote system.;

30.12.2.1.23 aLldpXdot3LocPSEPoweringStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

4PdualsigPD	4-pair powering a dual-signature PD
4PsinglesigPD	4-pair powering a single-signature PD
2P	2-pair powering

BEHAVIOUR DEFINED AS:
A read only value that indicates the powering status of the PSE. For a PD, the contents of this attribute are undefined.;

30.12.2.1.24 aLldpXdot3LocPDPoweredStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

4PdualsigPD	4-pair powered dual-signature PD
2PdualsigPD	2-pair powered dual-signature PD
singlesigPD	powered single-signature PD

BEHAVIOUR DEFINED AS:
A read only value that indicates the powering status of the PD. For a PSE, the contents of this attribute are undefined.;

30.12.2.1.25 aLldpXdot3LocPowerPairsExt

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

altA	Alternative A

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

altB	Alternative B
both	Both Alternatives

BEHAVIOUR DEFINED AS:

A read-only value that identifies the supported PSE Pinout Alternative specified in 145.2.4. For a PSE, this attribute contains the value of the aPSEPowerPairs attribute (see 30.9.1.1.4). For a PD, the contents of this attribute are undefined.;

30.12.2.1.26 aLldpXdot3LocPowerClassExtA

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

singlesig	Single-signature PD or 2-pair only PSE
class1	Class 1
class2	Class 2
class3	Class 3
class4	Class 4
class5	Class 5

BEHAVIOUR DEFINED AS:

For a dual-signature PD, a read-only value that indicates the requested Class for Mode A during Physical Layer Classification (see 145.3.6). For a single-signature PD, a read-only value set to ‘singlesig’.

For a PSE connected to a dual-signature PD, a read-only value that indicates the currently assigned Class for Mode A (see 145.2.8). For a PSE connected to a single-signature PD or a PSE that operates only in 2-pair mode, a read-only value set to ‘singlesig’.;

30.12.2.1.27 aLldpXdot3LocPowerClassExtB

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

singlesig	Single-signature PD or 2-pair only PSE
class1	Class 1
class2	Class 2
class3	Class 3
class4	Class 4
class5	Class 5

BEHAVIOUR DEFINED AS:

For a dual-signature PD, a read-only value that indicates the requested Class for Mode B during Physical Layer Classification (see 145.3.6). For a single-signature PD, a read-only value set to ‘singlesig’.

For a PSE connected to a dual-signature PD, a read-only value that indicates the currently assigned Class for Mode B (see 145.2.8). For a PSE connected to a single-signature PD or a PSE that operates only in 2-pair mode, a read-only value set to ‘singlesig’.;

30.12.2.1.28 aLldpXdot3LocPowerClassExt

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

dualsig	Dual-signature PD

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

class1	Class 1
class2	Class 2
class3	Class 3
class4	Class 4
class5	Class 5
class6	Class 6
class7	Class 7
class8	Class 8

BEHAVIOUR DEFINED AS:

For a single-signature PD, a read-only value that indicates the requested Class during Physical Layer Classification (see 145.3.6). For a dual-signature PD, a read-only value set to ‘dualsig’. For a PSE connected to a single-signature PD or a PSE that operates only in 2-pair mode, a read-only value that indicates the currently assigned Class (see 145.2.8). For a PSE connected to a dual-signature PD, a read-only value set to ‘dualsig’.;

30.12.2.1.29 aLldpXdot3LocPowerTypeExt

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

type4dualsigPD	Type 4 dual-signature PD
type4singlesigPD	Type 4 single-signature PD
type3dualsigPD	Type 3 dual-signature PD
type3singlesigPD	Type 3 single-signature PD
type4PSE	Type 4 PSE
type3PSE	Type 3 PSE

BEHAVIOUR DEFINED AS:

A read-only attribute that returns a value to indicate if the local system is a Type 3 or Type 4 PSE or PD and, in the case of a Type 3 or Type 4 PD, if it is a single-signature PD or a dual-signature PD.;

30.12.2.1.30 aLldpXdot3LocPDLoad

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

For a dual-signature PD, a GET attribute that returns whether the load of a dual-signature PD is electrically isolated, as defined in 79.3.2.10.2. For a single-signature PD or a PSE, the value of this attribute is FALSE.;

30.12.2.1.31 aLldpXdot3LocPD4PID

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A read-only Boolean attribute indicating whether the local PD system supports powering of both PD Modes.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.2.1.32 aLldpXdot3LocPSEMaxAvailPower

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the local PSE maximum available power value in units of 0.1 W.;

30.12.2.1.33 aLldpXdot3LocPSEAutoclassSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A read-only attribute that returns a bit string indicating whether the local PSE system supports Autoclass.;

30.12.2.1.34 aLldpXdot3LocAutoclassCompleted

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A read-only attribute that returns a bit string indicating whether the local PSE system has completed the Autoclass measurement.;

30.12.2.1.35 aLldpXdot3LocAutoclassRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A read-only attribute that returns a bit string indicating whether the local PD system is requesting an Autoclass measurement and power budget adjustment.;

30.12.2.1.36 aLldpXdot3LocPowerDownRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A SET attribute that indicates the local PD system is requesting a power down when the value is 0x1D.;

30.12.2.1.37 aLldpXdot3LocPowerDownTime

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A SET attribute that indicates the number of seconds the PD requests to stay powered off. A value of zero indicates an indefinite amount of time.;

30.12.2.1.38 aLldpXdot3LocMeasVoltageSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is capable of providing a voltage measurement.;

30.12.2.1.39 aLldpXdot3LocMeasCurrentSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is capable of providing a current measurement.;

30.12.2.1.40 aLldpXdot3LocMeasPowerSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is capable of providing a power measurement.;

30.12.2.1.41 aLldpXdot3LocMeasEnergySupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is capable of providing an energy measurement.;

30.12.2.1.42 aLldpXdot3LocMeasurementSource

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A SET attribute value that indicates to local device on which Alternative or Mode the measurement is to be taken.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.2.1.43 aLldpXdot3LocMeasVoltageRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is requesting a voltage measurement from the remote device.;

30.12.2.1.44 aLldpXdot3LocMeasCurrentRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is requesting a current measurement from the remote device.;

30.12.2.1.45 aLldpXdot3LocMeasPowerRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is requesting a power measurement from the remote device.;

30.12.2.1.46 aLldpXdot3LocMeasEnergyRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device is requesting an energy measurement from the remote device.;

30.12.2.1.47 aLldpXdot3LocMeasVoltageValid

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device’s voltage measurement is valid.;

30.12.2.1.48 aLldpXdot3LocMeasCurrentValid

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device's current measurement is valid.;

30.12.2.1.49 aLldpXdot3LocMeasPowerValid

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device's power measurement is valid.;

30.12.2.1.50 aLldpXdot3LocMeasEnergyValid

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (1)]

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the local device's energy measurement is valid.;

30.12.2.1.51 aLldpXdot3LocMeasVoltageUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the device's voltage measurement. See Table 79–21.;

30.12.2.1.52 aLldpXdot3LocMeasCurrentUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the device's current measurement. See Table 79–21.;

30.12.2.1.53 aLldpXdot3LocMeasPowerUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the device's power measurement. See Table 79–21.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.2.1.54 aLldpXdot3LocMeasEnergyUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the device's energy measurement. See Table 79–21.;

30.12.2.1.55 aLldpXdot3LocVoltageMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the measured device voltage. See Table 79–21.;

30.12.2.1.56 aLldpXdot3LocCurrentMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the measured device current. See Table 79–21.;

30.12.2.1.57 aLldpXdot3LocPowerMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the measured device power. See Table 79–21.;

30.12.2.1.58 aLldpXdot3LocEnergyMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the measured device energy. See Table 79–21.;

30.12.2.1.59 aLldpXdot3LocPSEPowerPriceIndex

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A GET attribute that returns an index of the price of power being sourced by the PSE. For a PD, this value is undefined.;

30.12.2.1.60 aLldpXdot3LocResponseTime

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the response time in seconds of the local system. For a PD, it is the maximum time required to update the value of attribute aLldpXdot3LocPDRequestedPowerValue when the remote system requests the PD to change its max power draw. For a PSE, it is the maximum time required to update the value of attribute aLldpXdot3LocPDRequestedPowerValue when the remote system requests of the PSE a new power value.;

30.12.2.1.61 aLldpXdot3LocReady

ATTRIBUTE

APPROPRIATE SYNTAX:

A BOOLEAN value:

FALSE:	Local system has not completed initialization of the Data Link Layer classification engine and is not ready to receive/transmit an LLDPDU containing a Power via MDI TLV.
TRUE:	Local system has initialized the Data Link Layer classification engine and is ready to receive/transmit an LLDPDU containing a Power via MDI TLV.

BEHAVIOUR DEFINED AS:

A GET operation returns the initialization status of the Data Link Layer classification engine on the local system.;

30.12.2.1.62 aLldpXdot3LocTxTwSys

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the value of $T_{w_sys_tx}$ that the local system can support in the transmit direction. This attribute maps to the variable LocTxSystemValue as defined in 78.4.2.3;

30.12.2.1.63 aLldpXdot3LocTxTwSysEcho

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the value of $T_{w_sys_tx}$ that the remote system is advertising that it can support in the transmit direction and is echoed by the local system under the control of the EEE DLL receiver state diagram. This attribute maps to the variable LocTxSystemValueEcho as

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

defined in 78.4.2.3;

30.12.2.1.64 aLldpXdot3LocRxTwSys

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of $T_{w_sys_tx}$ that the local system is requesting in the receive direction. This attribute maps to the variable LocRxSystemValue as defined in 78.4.2.3;

30.12.2.1.65 aLldpXdot3LocRxTwSysEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of $T_{w_sys_tx}$ that the remote system is advertising that it is requesting in the receive direction and is echoed by the local system under the control of the EEE DLL transmitter state diagram. This attribute maps to the variable LocRxSystemValueEcho as defined in 78.4.2.3;

30.12.2.1.66 aLldpXdot3LocFbTwSys

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of the fallback $T_{w_sys_tx}$ that the local system is advertising to the remote system. This attribute maps to the variable LocFbSystemValue as defined in 78.4.2.3;

30.12.2.1.67 aLldpXdot3TxDllReady

ATTRIBUTE

APPROPRIATE SYNTAX:
A BOOLEAN value:

FALSE:	Local system has not completed initialization of the EEE transmit Data Link Layer management function and is not ready to receive/transmit an LLDPDU containing a EEE TLV.
TRUE:	Local system has initialized the EEE transmit Data Link Layer management function and is ready to receive/transmit an LLDPDU containing a EEE TLV.

BEHAVIOUR DEFINED AS:
A GET operation returns the initialization status of the EEE transmit Data Link Layer management function on the local system.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.2.1.68 aLldpXdot3RxDllReady

ATTRIBUTE

APPROPRIATE SYNTAX:
A BOOLEAN value:

FALSE:	Local system has not completed initialization of the EEE receive Data Link Layer management function and is not ready to receive/transmit an LLDPDU containing a EEE TLV.
TRUE:	Local system has initialized the EEE receive Data Link Layer management function and is ready to receive/transmit an LLDPDU containing a EEE TLV.

BEHAVIOUR DEFINED AS:
A GET operation returns the initialization status of the EEE receive Data Link Layer management function on the local system.;

30.12.2.1.69 aLldpXdot3LocDllEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:
A BOOLEAN value:

FALSE:	Local system has not completed auto-negotiation with a link partner that has indicated at least one EEE capability.
TRUE:	Local system has completed auto-negotiation with a link partner that has indicated at least one EEE capability.

BEHAVIOUR DEFINED AS:
A GET operation returns the status of the EEE capability negotiation on the local system.;

30.12.2.1.70 aLldpXdot3LocTxFw

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the local system can support in the transmit direction. This attribute maps to the variable LocTxSystemFW as defined in 78.4.2.3;

30.12.2.1.71 aLldpXdot3LocTxFwEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the remote system is advertising that it can support in the transmit direction and is echoed by the local system under the control of the EEE DLL receiver state diagram. This attribute maps to the variable LocTxSystemFWEcho as defined in 78.4.2.3;

30.12.2.1.72 aLldpXdot3LocRxFw

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the local system is requesting in the receive direction. This attribute maps to the variable LocRxSystemFW as defined in 78.4.2.3;

30.12.2.1.73 aLldpXdot3LocRxFwEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the remote system is advertising that it is requesting in the receive direction and is echoed by the local system under the control of the EEE DLL transmitter state diagram. This attribute maps to the variable LocRxSystemFWEcho as defined in 78.4.2.3;

30.12.2.1.74 aLldpXdot3LocPreemptSupported

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the given port (associated with the local System) supports the preemption capability.;

30.12.2.1.75 aLldpXdot3LocPreemptEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the preemption capability is enabled on the given port associated with the local System.;

30.12.2.1.76 aLldpXdot3LocPreemptActive

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the preemption capability is active on the given port associated with the local System.;

30.12.2.1.77 aLldpXdot3LocAddFragSize

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A 2-bit integer value used to indicate the minimum size of non-final fragments supported by the receiver on the given port associated with the local System. This value is expressed in units of 64 octets of additional fragment length. The minimum non-final fragment size is (aLldpXdot3LocAddFragSize + 1) × 64 octets.;

30.12.3 LLDP Remote System Group managed object class

This subclause formally defines the behaviours for the oLldpXdot3RemSystemsGroup managed object class attributes.

30.12.3.1 LLDP Remote System Group attributes

30.12.3.1.1 aLldpXdot3RemPortAutoNegSupported

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A read-only Boolean value used to indicate whether the given port (associated with the remote system) supports Auto-negotiation.;

30.12.3.1.2 aLldpXdot3RemPortAutoNegEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A read-only Boolean value used to indicate whether port Auto-negotiation is enabled on the given port associated with the remote system.;

30.12.3.1.3 aLldpXdot3RemPortAutoNegAdvertisedCap

ATTRIBUTE

APPROPRIATE SYNTAX:

OCTET STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:

A read-only 2-octet value that contains the value (bitmap) of the ifMauAutoNegCapAdvertisedBits object (defined in IETF RFC 4836) which is associated with the given port on the remote system.;

30.12.3.1.4 aLldpXdot3RemPortOperMauType

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A read-only 32-bit integer value that indicates the operational MAU type of the given port on the remote system.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This object contains an integer value derived from the list position of the corresponding dot3MauType as listed in IETF RFC 4836 (or subsequent revisions) and is equal to the last number in the respective dot3MauType OID.

For example, if the ifMauType object is dot3MauType1000BaseTHD which corresponds to {dot3MauType 29}, the numerical value of this field is 29. For MAU types not listed in IETF RFC 4836 (or subsequent revisions), the value of this field shall be set to zero.;

30.12.3.1.5 aLldpXdot3RemPowerPortClass

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

pClassPSE	PSE
pClassPD	PD

BEHAVIOUR DEFINED AS:

A read-only value that identifies the port Class of the given port associated with the remote system.;

30.12.3.1.6 aLldpXdot3RemPowerMDISupported

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

This attribute contains a read-only Boolean value used to indicate whether the MDI power is supported on the given port associated with the remote PSE system. When the remote system is a PD, the value of this attribute is undefined.;

30.12.3.1.7 aLldpXdot3RemPowerMDIEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

This attribute contains a read-only Boolean value used to identify whether MDI power is enabled on the given port associated with the remote PSE system. When the remote system is a PD, the value of this attribute is undefined.;

30.12.3.1.8 aLldpXdot3RemPowerPairControllable

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A read-only Boolean value used to indicate the ability to control which PSE Pinout Alternative (see 33.2.3 and 145.2.4) is used for PD detection and power on the given port on the remote system. For a PD, this attribute contains the value of the aPSEPowerPairsControlAbility attribute (see 30.9.1.1.3) on the given port on the remote system. For a PSE, the contents of this attribute are undefined.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.3.1.9 aLldpXdot3RemPowerPairs

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

signal	PSE Pinout Alternative A
spare	PSE Pinout Alternative B

BEHAVIOUR DEFINED AS:

A read-only value that identifies the supported PSE Pinout Alternative (see 33.2.3 and 145.2.4) in use for supplying power to the PD on the given port on the remote system. For a PD, this attribute contains a value derived from the aPSEPowerPairs attribute (see 30.9.1.1.4) on the given port on the remote system. For a PSE, the contents of this attribute are undefined. When the remote system is a Type 3 or Type 4 PSE supplying power on both PSE Pinout Alternatives, the value of this attribute can indicate either pinout. If the aLldpXdot3RemPowerPairsExt attribute is available, it will report this configuration.;

30.12.3.1.10 aLldpXdot3RemPowerClass

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED value list that has the following entries:

class0	Class 0 PD
class1	Class 1 PD
class2	Class 2 PD
class3	Class 3 PD
class4	Class 4 PD

BEHAVIOUR DEFINED AS:

A read-only value that identifies the requested Class of the PD as specified in 33.2.6 and 145.2.8 on the given port on the remote system. This attribute will return an enumeration of “class4” for a PD of Class 4 or higher as such PD Classes are identified through the aLldpXdot3RemPowerClassExt attribute.;

30.12.3.1.11 aLldpXdot3RemLinkAggStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

BITSTRING

BEHAVIOUR DEFINED AS:

The bitmap value which contains the link aggregation capabilities and the current aggregation status of the link (see 79.3.3.1).;

30.12.3.1.12 aLldpXdot3RemLinkAggPortId

ATTRIBUTE

APPROPRIATE SYNTAX:

The same as used for aAggPortID

BEHAVIOUR DEFINED AS:

This object contains the IEEE 802.3 aggregated port identifier, aAggPortID (see 30.7.2.1.1), derived from the ifNumber of the ifIndex for the port component in link aggregation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the port is not in link aggregation state and/or it does not support link aggregation, this value should be set to zero.;

30.12.3.1.13 aLldpXdot3RemMaxFrameSize

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
An integer value indicating the maximum supported frame size in octets on the given port of the remote system.;

30.12.3.1.14 aLldpXdot3RemPowerType

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A GET attribute that returns a bit string indicating whether the remote system is a PSE or a PD and whether it is Type 1 or greater than Type 1. The first bit indicates Type 1 or greater than Type 1. The second bit indicates PSE or PD. See also aLldpXdot3RemPowerTypeExt.;

30.12.3.1.15 aLldpXdot3RemPowerSource

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

BEHAVIOUR DEFINED AS:
A GET attribute that returns a bit string indicating the power sources of the remote system. When the remote system is a PSE, it indicates whether it is being powered by a primary power source; a backup power source; or unknown. When the remote system is a PD, it indicates whether it is being powered by a PSE and locally; locally only; by a PSE only; or unknown.;

30.12.3.1.16 aLldpXdot3RemPowerPriority

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED value list that has the following entries:

low	low priority PD
high	high priority PD
critical	critical priority PD
unknown	priority unknown

BEHAVIOUR DEFINED AS:
A GET operation returns the priority of the PD system received from the remote system. For a PSE, this is the priority that the remote system requests from the PSE. For a PD, this is the priority that the remote system has assigned to the PD.;

30.12.3.1.17 aLldpXdot3RemPDRequestedPowerValue

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PD requested power value that was used by the remote system to compute the power value that it has currently allocated to the PD. For a PSE, it is the PD requested power value received from the remote system. The definition and encoding of PD requested power value is the same as described in aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17). For a PD, it is the mirrored copy of the requested power field echoed back by the remote PSE.;

30.12.3.1.18 aLldpXdot3RemPDRequestedPowerValueA

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PD requested power value for the Mode A pairset that was used by the remote system to compute the power value that it has currently allocated to the PD. For a PSE, it is the PD requested power value for the Alternative A pairset received from the remote system. For a PD, it is the PD requested power value for the Alternative A pairset that the PSE echoes back to the remote system. The definition and encoding of PD requested power value for the Mode A pairset is the same as described in aLldpXdot3LocPDRequestedPowerValueA (30.12.2.1.18).;

30.12.3.1.19 aLldpXdot3RemPDRequestedPowerValueB

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PD requested power value for the Mode B pairset that was used by the remote system to compute the power value that it has currently allocated to the PD. For a PSE, it is the PD requested power value for the Alternative B pairset received from the remote system. For a PD, it is the PD requested power value for the Alternative B pairset that the PSE echoes back to the remote system. The definition and encoding of PD requested power value for the Mode B pairset is the same as described in aLldpXdot3LocPDRequestedPowerValueB (30.12.2.1.19).;

30.12.3.1.20 aLldpXdot3RemPSEAllocatedPowerValue

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PSE allocated power value received from the remote system. For a PSE, it is the PSE allocated power value that was echoed back by the remote PD. For a PD, it is the PSE allocated power value received from the remote system. The definition and encoding of PSE allocated power value is the same as described in aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20).;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.3.1.21 aLldpXdot3RemPSEAllocatedPowerValueA

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PSE allocated power value for the Alternative A pairset received from the remote system. For a PSE, it is the PSE allocated power value for the Alternative A pairset that was echoed back by the remote PD. For a PD, it is the PSE allocated power value for the Mode A pairset received from the remote system. The definition and encoding of PSE allocated power value for the Alternative A pairset is the same as described in aLldpXdot3LocPSEAllocatedPowerValueA (30.12.2.1.21).;

30.12.3.1.22 aLldpXdot3RemPSEAllocatedPowerValueB

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the PSE allocated power value for the Alternative B pairset received from the remote system. For a PSE, it is the PSE allocated power value for the Alternative B pairset that was echoed back by the remote PD. For a PD, it is the PSE allocated power value for the Mode B pairset received from the remote system. The definition and encoding of PSE allocated power value for the Alternative B pairset is the same as described in aLldpXdot3LocPSEAllocatedPowerValueB (30.12.2.1.22).;

30.12.3.1.23 aLldpXdot3RemPSEPoweringStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

4PdualsigPD	4-pair powering a dual-signature PD
4PsinglesigPD	4-pair powering a single-signature PD
2P	2-pair powering

BEHAVIOUR DEFINED AS:
A read only value that indicates the powering status of the remote PSE. For a PSE, the contents of this attribute are undefined.;

30.12.3.1.24 aLldpXdot3RemPDPoweredStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

4PdualsigPD	4-pair powered dual-signature PD
2PdualsigPD	2-pair powered dual-signature PD
singlesigPD	powered single-signature PD

BEHAVIOUR DEFINED AS:
A read only value that indicates the powering status of the remote PD. For a PD, the contents of this attribute are undefined.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.3.1.25 aLldpXdot3RemPowerPairsExt

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

altA	Alternative A
altB	Alternative B
both	Both Alternatives

BEHAVIOUR DEFINED AS:

A read-only value that identifies the supported PSE Pinout Alternative specified in 145.2.4. For a PD, this attribute contains the value of the aPSEPowerPairs attribute (see 30.9.1.1.4) as sent by the remote PSE. For a PSE, the contents of this attribute are undefined.;

30.12.3.1.26 aLldpXdot3RemPowerClassExtA

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

singlesig	Single-signature PD or 2-pair only PSE
class1	Class 1
class2	Class 2
class3	Class 3
class4	Class 4
class5	Class 5

BEHAVIOUR DEFINED AS:

For a dual-signature PD, a read-only value that indicates the currently assigned Class for Mode A by the remote 4-pair PSE. For a single-signature PD or a dual-signature PD connected to a 2-pair only PSE, a read-only value set to ‘singlesig’ by the remote PSE. For a PSE connected to a dual-signature PD, a read-only value that indicates the requested Class for Mode A during Physical Layer classification (see 145.2.8) by the remote PD. For a PSE connected to a single-signature PD, a read-only value set to ‘singlesig’ by the remote PD.;

30.12.3.1.27 aLldpXdot3RemPowerClassExtB

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

singlesig	Single-signature PD or 2-pair only PSE
class1	Class 1
class2	Class 2
class3	Class 3
class4	Class 4
class5	Class 5

BEHAVIOUR DEFINED AS:

For a dual-signature PD, a read-only value that indicates the currently assigned Class for Mode B by the remote 4-pair PSE. For a single-signature PD or a dual-signature PD connected to a 2-pair only PSE, a read-only value set to ‘singlesig’ by the remote PSE. For a PSE connected to a dual-signature PD, a read-only value that indicates the requested Class for Mode B during Physical Layer classification (see 145.2.8) by the remote PD. For a PSE connected to a single-signature PD, a read-only value set to ‘singlesig’ by the remote PD.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.3.1.28 aLldpXdot3RemPowerClassExt

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

dualsig	Dual-signature PD
class1	Class 1
class2	Class 2
class3	Class 3
class4	Class 4
class5	Class 5
class6	Class 6
class7	Class 7
class8	Class 8

BEHAVIOUR DEFINED AS:

For a single-signature PD or a dual-signature PD connected to a 2-pair only PSE, a read-only value that indicates the currently assigned Class by the remote PSE. For a dual-signature PD connected to a 4-pair capable PSE, a read-only value set to ‘dualsig’ by the remote PSE. For a PSE connected to a single-signature PD, a read-only value that indicates the requested Class during Physical Layer classification (see 145.2.8) by the remote PD. For a PSE connected to a dual-signature PD, a read-only value set to ‘dualsig’ by the remote PD.;

30.12.3.1.29 aLldpXdot3RemPowerTypeExt

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

type4dualsigPD	Type 4 dual-signature PD
type4singlesigPD	Type 4 single-signature PD
type3dualsigPD	Type 3 dual-signature PD
type3singlesigPD	Type 3 single-signature PD
type4PSE	Type 4 PSE
type3PSE	Type 3 PSE

BEHAVIOUR DEFINED AS:

A read-only attribute that returns a value to indicate if the remote system is a Type 3 or Type 4 PSE or PD and, in the case of a Type 3 or Type 4 PD, if it is a single-signature PD or dual-signature PD.;

30.12.3.1.30 aLldpXdot3RemPDLoad

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

For a PSE, a GET attribute that returns whether the load of the remote dual-signature PD is electrically isolated, as defined in 79.3.2.10.2. For a PD, this attribute is set to FALSE.;

30.12.3.1.31 aLldpXdot3RemPD4PID

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean attribute indicating whether the remote PD system supports powering of both PD Modes.;

30.12.3.1.32 aLldpXdot3RemPSEMaxAvailPower

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the remote PSE maximum available power value in units of 0.1 W.;

30.12.3.1.33 aLldpXdot3RemPSEAutoclassSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean attribute indicating whether the remote PSE system supports Autoclass.;

30.12.3.1.34 aLldpXdot3RemAutoclassCompleted

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean attribute indicating whether the remote PSE system has completed the Autoclass measurement.;

30.12.3.1.35 aLldpXdot3RemAutoclassRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean attribute indicating whether the remote PD system is requesting an Autoclass measurement.;

30.12.3.1.36 aLldpXdot3RemPowerDownRequest

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A read-only attribute that indicates the remote PD system is requesting a power down when the value is 0x1D.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.3.1.37 aLldpXdot3RemPowerDownTime

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the number of seconds the remote PD requests to stay powered off. A value of zero indicates an indefinite amount of time.;

30.12.3.1.38 aLldpXdot3RemMeasVoltageSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates if the remote device is capable of providing a voltage measurement.;

30.12.3.1.39 aLldpXdot3RemMeasCurrentSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates if the remote device is capable of providing a current measurement.;

30.12.3.1.40 aLldpXdot3RemMeasPowerSupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates if the remote device is capable of providing a power measurement.;

30.12.3.1.41 aLldpXdot3RemMeasEnergySupport

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates if the remote device is capable of providing an energy measurement.;

30.12.3.1.42 aLldpXdot3RemMeasurementSource

ATTRIBUTE

APPROPRIATE SYNTAX:
BIT STRING [SIZE (2)]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A SET attribute value that indicates on which Alternative or Mode the measurement was taken by the remote device.;

30.12.3.1.43 aLldpXdot3RemMeasVoltageRequest

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the remote device is requesting a voltage measurement from the local device.;

30.12.3.1.44 aLldpXdot3RemMeasCurrentRequest

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the remote device is requesting a current measurement from the local device.;

30.12.3.1.45 aLldpXdot3RemMeasPowerRequest

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the remote device is requesting a power measurement from the local device.;

30.12.3.1.46 aLldpXdot3RemMeasEnergyRequest

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the remote device is requesting an energy measurement from the local device.;

30.12.3.1.47 aLldpXdot3RemMeasVoltageValid

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the remote device’s voltage measurement is valid.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.12.3.1.48 aLldpXdot3RemMeasCurrentValid

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the remote device's current measurement is valid.;

30.12.3.1.49 aLldpXdot3RemMeasPowerValid

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the remote device's power measurement is valid.;

30.12.3.1.50 aLldpXdot3RemMeasEnergyValid

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the remote device's energy measurement is valid.;

30.12.3.1.51 aLldpXdot3RemMeasVoltageUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the remote device's voltage measurement. See Table 79–21.;

30.12.3.1.52 aLldpXdot3RemMeasCurrentUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the remote device's current measurement. See Table 79–21.;

30.12.3.1.53 aLldpXdot3RemMeasPowerUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the remote device's power measurement. See Table 79–21.;

30.12.3.1.54 aLldpXdot3RemMeasEnergyUncertainty

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that indicates the expanded uncertainty (coverage factor k = 2) for the remote device's energy measurement. See Table 79–21.;

30.12.3.1.55 aLldpXdot3RemVoltageMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the measured remote device voltage. See Table 79–21.;

30.12.3.1.56 aLldpXdot3RemCurrentMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the measured remote device current. See Table 79–21.;

30.12.3.1.57 aLldpXdot3RemPowerMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the measured remote device power. See Table 79–21.;

30.12.3.1.58 aLldpXdot3RemEnergyMeasurement

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A GET attribute that returns the measured remote device energy. See Table 79–21.;

30.12.3.1.59 aLldpXdot3RemPSEPowerPriceIndex

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns an index of the price of power being sourced by the remote PSE. For a PSE, this value is undefined.;

30.12.3.1.60 aLldpXdot3RemTxTwSys

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of $T_{w_sys_tx}$ that the remote system can support in the transmit direction. This attribute maps to the variable RemTxSystemValue as defined in 78.4.2.3;

30.12.3.1.61 aLldpXdot3RemTxTwSysEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of $T_{w_sys_tx}$ that the local system is advertising that it can support in the transmit direction as echoed by the remote system under the control of the EEE DLL receiver state diagram. This attribute maps to the variable RemTxSystemValueEcho as defined in 78.4.2.3;

30.12.3.1.62 aLldpXdot3RemRxTwSys

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of $T_{w_sys_tx}$ that the remote system is requesting in the receive direction. This attribute maps to the variable RemRxSystemValue as defined in 78.4.2.3;

30.12.3.1.63 aLldpXdot3RemRxTwSysEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of $T_{w_sys_tx}$ that the local system is advertising that it is requesting in the receive direction as echoed by the remote system under the control of the EEE DLL transmitter state diagram. This attribute maps to the variable RemRxSystemValueEcho as defined in 78.4.2.3;

30.12.3.1.64 aLldpXdot3RemFbTwSys

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of fallback $T_{w_sys_tx}$ that the remote system is advertising. This attribute maps to the variable RemFbSystemValue as defined in 78.4.2.3;

30.12.3.1.24 aLldpXdot3RemTxFw

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the remote system can support in the transmit direction. This attribute maps to the variable RemTxSystemFW as defined in 78.4.2.3;

30.12.3.1.25 aLldpXdot3RemTxFwEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the local system is advertising that it can support in the transmit direction as echoed by the remote system under the control of the EEE DLL receiver state diagram. This attribute maps to the variable RemTxSystemFWEcho as defined in 78.4.2.3;

30.12.3.1.26 aLldpXdot3RemRxFw

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the remote system is requesting in the receive direction. This attribute maps to the variable RemRxSystemFW as defined in 78.4.2.3;

30.12.3.1.27 aLldpXdot3RemRxFwEcho

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A GET attribute that returns the value of LPI_FW that the local system is advertising that it is requesting in the receive direction as echoed by the remote system under the control of the EEE DLL transmitter state diagram. This attribute maps to the variable RemRxSystemFWEcho as defined in 78.4.2.3;

30.12.3.1.28 aLldpXdot3RemPreemptSupported

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the given port (associated with the remote system) supports the preemption capability.;

30.12.3.1.29 aLldpXdot3RemPreemptEnabled

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the preemption capability is enabled on the given port associated with the remote system.;

30.12.3.1.30 aLldpXdot3RemPreemptActive

ATTRIBUTE

APPROPRIATE SYNTAX:
BOOLEAN

BEHAVIOUR DEFINED AS:
A read-only Boolean value used to indicate whether the preemption capability is active on the given port associated with the remote system.;

30.12.3.1.31 aLldpXdot3RemAddFragSize

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
A 2-bit integer value used to indicate, in units of 64 octets, the minimum number of octets over 64 octets required in non-final fragments by the receiver on the given port associated with the remote system. The minimum non-final fragment size is (aLldpXdot3LocAddFragSize + 1) × 64 octets.;

30.13 Management for oTimeSync entity

If the optional TimeSync function is implemented, then the oTimeSync managed object class shall be implemented in its entirety. All attributes of this managed object class are mandatory. TimeSync management is optional with respect to all other CSMA/CD management.

30.13.1 TimeSync entity managed object class

This subclause formally defines the behaviours for the oTimeSync managed object class attributes.

30.13.1.1 aTimeSyncCapabilityTX

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BOOLEAN

BEHAVIOUR DEFINED AS:

True if the TimeSync capability is supported in the transmit path and false otherwise.
If a Clause 45 MDIO Interface to PMA/PMD, WIS, PCS, PHY XS, DTE XS and/or TC is present, then the value stored in this attribute is equal to the logical OR operation over the values stored in the following instantiated MDIO registers (for each MMD, in case of multiple instances) 1.1800.1, 2.1800.1, 3.1800.1, 4.1800.1, 5.1800.1, and 6.1800.1 (see 45.2.1.175, 45.2.2.20, 45.2.3.67, 45.2.4.28, 45.2.5.28, 45.2.6.14, respectively).

30.13.1.2 aTimeSyncCapabilityRX

ATTRIBUTE

APPROPRIATE SYNTAX:

BOOLEAN

BEHAVIOUR DEFINED AS:

True if the TimeSync capability is supported in the receive path and false otherwise.
If a Clause 45 MDIO Interface to PMA/PMD, WIS, PCS, PHY XS, DTE XS and/or TC is present, then the value stored in this attribute is equal to the logical OR operation over the values stored in the following instantiated MDIO registers (for each MMD, in case of multiple instances) 1.1800.0, 2.1800.0, 3.1800.0, 4.1800.0, 5.1800.0, and 6.1800.0 (see 45.2.1.175, 45.2.2.20, 45.2.3.67, 45.2.4.28, 45.2.5.28, 45.2.6.14, respectively).

30.13.1.3 aTimeSyncDelayTXmax

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The maximum data delay as specified in 90.7, expressed in units of ns.
If a Clause 45 MDIO Interface to PMA/PMD, WIS, PCS, PHY XS, DTE XS and/or TC is present, then the value stored in this attribute represents the maximum transmit path data delay values, consisting of the sum of the values of the registers in the instantiated sublayers (for each MMD, in case of multiple instances):

— for PMA/PMD: 1.1801 and 1.1802, see 45.2.1.176
— for WIS: 2.1801 and 2.1802, see 45.2.2.21
— for PCS: 3.1801 and 3.1802, see 45.2.3.68
— for PHY XS: 4.1801 and 4.1802, see 45.2.4.29
— for DTE XS: 5.1801 and 5.1802, see 45.2.5.29
— for TC: 6.1801 and 6.1802, see 45.2.6.15

30.13.1.4 aTimeSyncDelayTXmin

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The minimum data delay as specified in 90.7, expressed in units of ns.
If a Clause 45 MDIO Interface to PMA/PMD, WIS, PCS, PHY XS, DTE XS and/or TC is present,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

then the value stored in this attribute represents the minimum transmit path data delay values, consisting of the sum of the values of the registers in the instantiated sublayers (for each MMD, in case of multiple instances):

— for PMA/PMD: 1.1803 and 1.1804, see 45.2.1.176
— for WIS: 2.1803 and 2.1804, see 45.2.2.21
— for PCS: 3.1803 and 3.1804, see 45.2.3.68
— for PHY XS: 4.1803 and 4.1804, see 45.2.4.29
— for DTE XS: 5.1803 and 5.1804, see 45.2.5.29
— for TC: 6.1803 and 6.1804, see 45.2.6.15

30.13.1.5 aTimeSyncDelayRXmax

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The maximum data delay as specified in 90.7, expressed in units of ns.
If a Clause 45 MDIO Interface to PMA/PMD, WIS, PCS, PHY XS, DTE XS and/or TC is present, then the value stored in this attribute represents the maximum receive path data delay values, consisting of the sum of the values of the registers in the instantiated sublayers (for each MMD, in case of multiple instances):

— for PMA/PMD: 1.1805 and 1.1806, see 45.2.1.177
— for WIS: 2.1805 and 2.1806, see 45.2.2.22
— for PCS: 3.1805 and 3.1806, see 45.2.3.69
— for PHY XS: 4.1805 and 4.1806, see 45.2.4.30
— for DTE XS: 5.1805 and 5.1806, see 45.2.5.30
— for TC: 6.1805 and 6.1806, see 45.2.6.16

30.13.1.6 aTimeSyncDelayRXmin

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The minimum data delay as specified in 90.7, expressed in units of ns.
If a Clause 45 MDIO Interface to to PMA/PMD, WIS, PCS, PHY XS, DTE XS and/or TC is present, then the value stored in this attribute represents the minimum receive path data delay values, consisting of the sum of the values of the registers in the instantiated sublayers (for each MMD, in case of multiple instances):

— for PMA/PMD: 1.1807 and 1.1808, see 45.2.1.177
— for WIS: 2.1807 and 2.1808, see 45.2.2.22
— for PCS: 3.1807 and 3.1808, see 45.2.3.69
— for PHY XS: 4.1807 and 4.1808, see 45.2.4.30
— for DTE XS: 5.1807 and 5.1808, see 45.2.5.30
— for TC: 6.1807 and 6.1808, see 45.2.6.16

30.14 Management for MAC Merge Sublayer

30.14.1 oMACMergeEntity managed object class

This subclause formally defines the behaviours for the oMACMergeEntity managed object class attributes.

30.14.1.1 aMACMergeSupport

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

supported	MAC Merge sublayer is supported on the device
not supported	MAC Merge sublayer is not supported on the device

BEHAVIOUR DEFINED AS:

This attribute indicates (when accessed via a GET operation) whether the given device supports a MAC Merge sublayer. The SET operation shall have no effect on a device.;

30.14.1.2 aMACMergeStatusVerify

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	verification status is unknown
initial	the Verify State diagram (Figure 99–8) is in the state INIT_VERIFICATION
verifying	the Verify State diagram is in the state VERIFICATION_IDLE, SEND_VERIFY or WAIT_FOR_RESPONSE
succeeded	indicates that the Verify State diagram is in the state VERIFIED
failed	the Verify State diagram is in the state VERIFY_FAIL
disabled	verification of preemption operation is disabled

BEHAVIOUR DEFINED AS:

This attribute indicates (when accessed via a GET operation) the status of the MAC Merge sublayer verification on the given device. The SET operation shall have no effect on a device.;

30.14.1.3 aMACMergeEnableTx

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

disabled	transmit preemption is disabled
enabled	transmit preemption is enabled

BEHAVIOUR DEFINED AS:

This attribute indicates (when accessed via a GET operation) the status of the MAC Merge sublayer on the given device in the transmit direction. The status of the MAC Merge sublayer may be modified to the indicated value via a SET operation. This attribute maps to the variable pEnable (see 99.4.7.3).;

30.14.1.4 aMACMergeVerifyDisableTx

ATTRIBUTE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

disabled	verify is disabled
enabled	verify is enabled

BEHAVIOUR DEFINED AS:

This attribute indicates (when accessed via a GET operation) the status of the Verify function of MAC Merge sublayer on the given device in the transmit direction. The status of the Verify function may be modified to the indicated value via a SET operation. This attribute maps to the variable disableVerify (see 99.4.7.3).;

30.14.1.5 aMACMergeStatusTx

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	transmit preemption status is unknown
inactive	transmit preemption is inactive
active	transmit preemption is active

BEHAVIOUR DEFINED AS:

This attribute indicates (when accessed via a GET operation) the status of the MAC Merge sublayer on the given device in the transmit direction. The SET operation shall have no effect on a device. This attribute maps to the variable preempt (see 99.4.7.3).;

30.14.1.6 aMACMergeVerifyTime

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

The value of this attribute defines the nominal wait time between verification attempts in milliseconds. Valid range is 1 to 128 inclusive. The default value is 10. This attribute maps to the variable verifyTime (see 99.4.7.3).;

30.14.1.7 aMACMergeAddFragSize

ATTRIBUTE

APPROPRIATE SYNTAX

INTEGER

BEHAVIOUR DEFINED AS:

A 2-bit integer value used to indicate the value of addFragSize variable used by the Transmit Processing State Diagram (see Figure 99–5).;

30.14.1.8 aMACMergeFrameAssErrorCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter.
This counter has a maximum increment rate of 160 000 counts per second at 100 Mb/s.

BEHAVIOUR DEFINED AS:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A count of MAC frames with reassembly errors. The counter is incremented by one every time the ASSEMBLY_ERROR state in the Receive Processing State Diagram is entered (see Figure 99–6).;

30.14.1.9 aMACMergeFrameSmdErrorCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter.
This counter has a maximum increment rate of 160 000 counts per second at 100 Mb/s.

BEHAVIOUR DEFINED AS:

A count of received MAC frames / MAC frame fragments rejected due to unknown SMD value or arriving with an SMD-C when no frame is in progress. The counter is incremented by one every time the BAD_FRAG state in the Receive Processing State Diagram is entered and every time the WAIT_FOR_DV_FALSE state is entered due to the invocation of the SMD_DECODE function returning the value “ERR” (see Figure 99–6).;

30.14.1.10 aMACMergeFrameAssOkCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter.
This counter has a maximum increment rate of 160 000 counts per second at 100 Mb/s.

BEHAVIOUR DEFINED AS:

A count of MAC frames that were successfully reassembled and delivered to MAC. The counter is incremented by one every time the FRAME_COMPLETE state in the Receive Processing state diagram (see Figure 99–6) is entered if the state CHECK_FOR_RESUME was previously entered while processing the packet.;

30.14.1.11 aMACMergeFragCountRx

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter.
This counter has a maximum increment rate of 160 000 counts per second at 100 Mb/s.

BEHAVIOUR DEFINED AS:

A count of the number of additional mPackets received due to preemption. The counter is incremented by one every time the state CHECK_FRAG_CNT in the Receive Processing State Diagram (see Figure 99–6) is entered.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.14.1.12 aMACMergeFragCountTx

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter.
This counter has a maximum increment rate of 160 000 counts per second at 100 Mb/s

BEHAVIOUR DEFINED AS:
A count of the number of additional mPackets transmitted due to preemption. This counter is incremented by one every time the SEND_SMD_C state in the Transmit Processing State Diagram (see Figure 99–5) is entered.;

30.14.1.13 aMACMergeHoldCount

ATTRIBUTE

APPROPRIATE SYNTAX:
Generalized nonresettable counter.
This counter has a maximum increment rate of 160 000 counts per second at 100 Mb/s.

BEHAVIOUR DEFINED AS:
A count of the number of times the variable hold (see 99.4.7.3) transitions from FALSE to TRUE.;

30.15 Layer management for Power over Data Lines (PoDL) of Single Pair Ethernet

30.15.1 PoDL PSE managed object class

This subclause formally defines the behaviours for the oPoDLPSE managed object class attributes and actions.

30.15.1.1 PoDL PSE attributes

30.15.1.1.1 aPoDLPSEID

ATTRIBUTE

APPROPRIATE SYNTAX:
INTEGER

BEHAVIOUR DEFINED AS:
The value of aPoDLPSEID is assigned so as to uniquely identify a PoDL PSE among the subordinate managed objects of the containing object.;

30.15.1.1.2 aPoDLPSEAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

enabled	PoDL PSE functions enabled
disabled	PoDL PSE functions disabled

BEHAVIOUR DEFINED AS:
A read-only value that identifies the operational state of the PoDL PSE functions. An interface that can provide the PoDL PSE functions specified in Clause 104 is enabled to do so when this attribute has the enumeration “enabled”. When this attribute has the enumeration “disabled” the interface

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

acts as if it had no PoDL PSE function. The operational state of the PSE function can be changed using the acPoDLPSEAdminControl action.

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the PSE Enable bit specified in 45.2.9.1.2.;

30.15.1.1.3 aPoDLPSEPowerDetectionStatus

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	true state unknown
disabled	PoDL PSE disabled
searching	PoDL PSE searching
deliveringPower	PoDL PSE delivering power
sleep	PoDL PSE sleep
idle	PoDL PSE idle
error	PoDL PSE error

BEHAVIOUR DEFINED AS:

A read-only value that indicates the current status of the PoDL PSE.

The enumeration “disabled” is asserted true when the PoDL PSE state diagram variable mr_pse_enable is false (see 104.4.4.3). The enumeration “deliveringPower” is asserted true when the PoDL PSE state diagram variable pi_powered is true. The enumeration “sleep” is asserted true when the PoDL PSE state diagram variable pi_sleeping is true. The enumeration “searching” is asserted true when either of the PSE state diagram variables pi_detecting or pi_classifying is true. The enumeration “idle” is asserted true when the logical combination of the PoDL PSE state diagram variables pi_prebiased*!pi_sleeping is true. The enumeration “error” is asserted true when the PoDL PSE state diagram variable overload_held is true.

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the PSE Status bits specified in 45.2.9.2.9.;

30.15.1.1.4 aPoDLPSEType

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	initializing, true state not yet known
typeA	Type A PoDL PSE
typeB	Type B PoDL PSE
typeC	Type C PoDL PSE
typeD	Type D PoDL PSE
typeE	Type E PoDL PSE
typeF	Type F PoDL PSE

BEHAVIOUR DEFINED AS:

A read-only value that identifies the PoDL PSE Type specified in 104.4.1.

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the PSE Type bits specified in 45.2.9.2.7.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.15.1.1.5 aPoDLPSEDetectedPDType

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	initializing, true state not yet known
typeA	Type A PoDL PD
typeB	Type B PoDL PD
typeC	Type C PoDL PD
typeD	Type D PoDL PD
typeE	Type E PoDL PD
typeF	Type F PoDL PD

BEHAVIOUR DEFINED AS:

A read-only value that indicates the Type of the detected PoDL PD as specified in 104.5.1. This value is only valid while a PD is being powered, that is the attribute aPoDLPSEPowerDetectionStatus is reporting the enumeration “deliveringPower”.

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the PD Type bits specified in 45.2.9.3.3.;

30.15.1.1.6 aPoDLPSEDetectedPDPowerClass

ATTRIBUTE

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has one of the following entries:

unknown	initializing, true state not yet known
class0	Class 0 PoDL PD
class1	Class 1 PoDL PD
class2	Class 2 PoDL PD
class3	Class 3 PoDL PD
class4	Class 4 PoDL PD
class5	Class 5 PoDL PD
class6	Class 6 PoDL PD
class7	Class 7 PoDL PD
class8	Class 8 PoDL PD
class9	Class 9 PoDL PD
class10	Class 10 PoDL PD
class11	Class 11 PoDL PD
class12	Class 12 PoDL PD
class13	Class 13 PoDL PD
class14	Class 14 PoDL PD
class15	Class 15 PoDL PD

BEHAVIOUR DEFINED AS:

A read-only value that indicates the class of the detected PoDL PD as specified in Table 104–1 and Table 104–2. This value is only valid while a PD is being powered, that is the attribute aPoDLPSEPowerDetectionStatus is reporting the enumeration “deliveringPower”.

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the PD Class and PD Extended Class bits specified in 45.2.9.2.8 and 45.2.9.3.2.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.15.1.1.7 aPoDLPSEInvalidSignatureCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PoDL PSE state diagram variable mr_invalid_signature transitions from false to true (see 104.4.4.3).

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the invalid signature bit specified in 45.2.9.2.3.;

30.15.1.1.8 aPoDLPSEInvalidClassCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PoDL PSE state diagram variable tclass_timer_done transitions from false to true or when the valid_class variable transitions from true to false (see 104.4.4.3).

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the class timeout bit specified in 45.2.9.2.4.;

30.15.1.1.9 aPoDLPSEPowerDeniedCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 2 counts per second.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PoDL PSE state diagram variable power_available transitions from true to false (see 104.4.4.3).

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the power denied bit specified in 45.2.9.2.1.;

30.15.1.1.10 aPoDLPSEOverLoadCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 13 counts per 10 seconds.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PSE state diagram variable overload_held transitions from false to true (see 104.4.4.3).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the overload bit specified in 45.2.9.2.5.;

30.15.1.1.11 aPoDLPSEMaintainFullVoltageSignatureAbsentCounter

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. This counter has a maximum increment rate of 33 counts per 10 seconds.

BEHAVIOUR DEFINED AS:

This counter is incremented when the PoDL PSE state diagram variable mfvs_timeout transitions from false to true (see 104.4.4.3).

If a Clause 45 MDIO Interface to the PoDL PSE function is present, then this attribute may be derived from the Maintain Full Voltage Signature Absent bit specified in 45.2.9.2.6.;

30.15.1.1.12 aPoDLPSEActualPower

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

An integer value indicating present (actual) power being supplied by the PoDL PSE as measured at the MDI in milliwatts. The behaviour is undefined if the state of aPoDLPSEPowerDetectionStatus is anything other than “deliveringPower”. The sampling frequency and averaging are vendor-defined.;

30.15.1.1.13 aPoDLPSEPowerAccuracy

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

A signed integer value indicating the accuracy associated with aPoDLPSEActualPower in milliwatts.;

30.15.1.1.14 aPoDLPSECumulativeEnergy

ATTRIBUTE

APPROPRIATE SYNTAX:

Generalized nonresettable counter. The counter has a maximum increment rate of 100 000 per second.

BEHAVIOUR DEFINED AS:

A count of the cumulative energy supplied by the PoDL PSE, measured at the MDI, and expressed in units of millijoules.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

30.15.1.2 PoDL PSE actions

30.15.1.2.1 acPoDLPSEAdminControl

ACTION

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has one of the following entries:

enabled	PoDL PSE functions enabled
disabled	PoDL PSE functions disabled

BEHAVIOUR DEFINED AS:
This action provides a means to alter aPoDLPSEAdminState.;

30.16 Management for PLCA Reconciliation Sublayer

30.16.1 PLCA managed object class

This subclause formally defines the behaviours for the oPLCA managed object class attributes and actions.

30.16.1.1 PLCA attributes

30.16.1.1.1 aPLCAAdminState

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:
disabled
enabled

BEHAVIOUR DEFINED AS:
A read-only value that indicates the mode of operation of the Reconciliation Sublayer for PLCA operation. When PLCA is enabled, the Reconciliation Sublayer functions in PLCA mode, whose operation is defined by Clause 148. When PLCA functions are not supported or are disabled by the management interface (plca_en = FALSE), RS operation shall conform to the RS definition in Clause 22. By default, PLCA is disabled.;

30.16.1.1.2 aPLCAStatus

ATTRIBUTE

APPROPRIATE SYNTAX:
An ENUMERATED VALUE that has the following entries:
TRUE
FALSE

BEHAVIOUR DEFINED AS:
A read-only value that indicates whether PLCA Control state diagram is receiving BEACON indication or transmitting BEACON request. This parameter maps to the plca_status variable in 148.4.6.2.;

30.16.1.1.3 aPLCANodeCount

ATTRIBUTE

APPROPRIATE SYNTAX:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

INTEGER

BEHAVIOUR DEFINED AS:

This value is assigned to define the number of nodes getting a transmit opportunity before a new BEACON is generated. Valid range is 0 to 255, inclusive. The default value is 8.;

30.16.1.1.4 aPLCALocalNodeID

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

This value is assigned to define the ID of the local node on the PLCA network. The default value is 255. Value range is 0 to 255, inclusive.;

30.16.1.1.5 aPLCATransmitOpportunityTimer

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

This value is assigned to define the time between PLCA transmit opportunities for the node. aPLCATransmitOpportunityTimer maps to the duration of the timer to_timer. The value of aPLCATransmitOpportunityTimer represents the duration of to_timer in bit times. Valid range is 1 to 255, inclusive. The default value is 32. See 148.4.4.4.;

30.16.1.1.6 aPLCAMaxBurstCount

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

Maximum number of additional packets the node is allowed to transmit in a single transmit opportunity as specified in 148.4.4.2. Valid range is 0 to 255, inclusive. The default value is 0.;

30.16.1.1.7 aPLCABurstTimer

ATTRIBUTE

APPROPRIATE SYNTAX:

INTEGER

BEHAVIOUR DEFINED AS:

This value sets the maximum number of bit-times PLCA waits for the MAC to send a new packet before yielding the transmit opportunity. See definition in 148.4.4.4. Valid range is 0 to 255, inclusive. The default value is 128.;

30.16.1.2 PLCA device actions

30.16.1.2.1 acPLCAAdminControl

ACTION

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries:
disabled
enabled

BEHAVIOUR DEFINED AS:

This action provides a means to alter aPLCAAdminState. Setting acPLCAAdminControl to the disabled state sets the variable plca_en to FALSE and disables the PLCA functionality specified in Clause 148. Setting acPLCAAdminControl to the enabled state sets the variable plca_en to TRUE in Figure 148–3, Figure 148–4, Figure 148–5, Figure 148–6, and Figure 148–7.;

30.16.1.2.2 acPLCAReset

ACTION

APPROPRIATE SYNTAX:

An ENUMERATED VALUE that has the following entries:
reset
normal

BEHAVIOUR DEFINED AS:

This action provides a means to reset the PLCA Reconciliation Sublayer functions. See 148.4.4.2.;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31. MAC Control

31.1 Overview

This clause specifies an optional MAC Control sublayer (MAC Control) for use with the CSMA/CD MAC. MAC Control provides for real-time control and manipulation of MAC sublayer operation. This clause specifies a generalized architecture and protocol for MAC Control. Specific implementations of control functions using this protocol are specified in the normative annexes to this clause. The MAC Control protocol is specified such that it can support new functions to be implemented and added to this standard in the future.

Non-realtime, or quasistatic control (e.g., configuration of MAC operational parameters) is provided by Layer Management.

Operation of the MAC Control sublayer is transparent to the CSMA/CD MAC.

The body of this clause and its associated annexes contain state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram shall prevail. The notation used in the state diagrams follows the conventions of 21.5.

31.2 Layer architecture

The MAC Control sublayer is a client of the CSMA/CD MAC. Figure 31–1 depicts the architectural positioning of the MAC Control sublayer with respect to the CSMA/CD MAC and the MAC Control client. MAC Control clients may include the Bridge Relay Entity, LLC, or other applications.

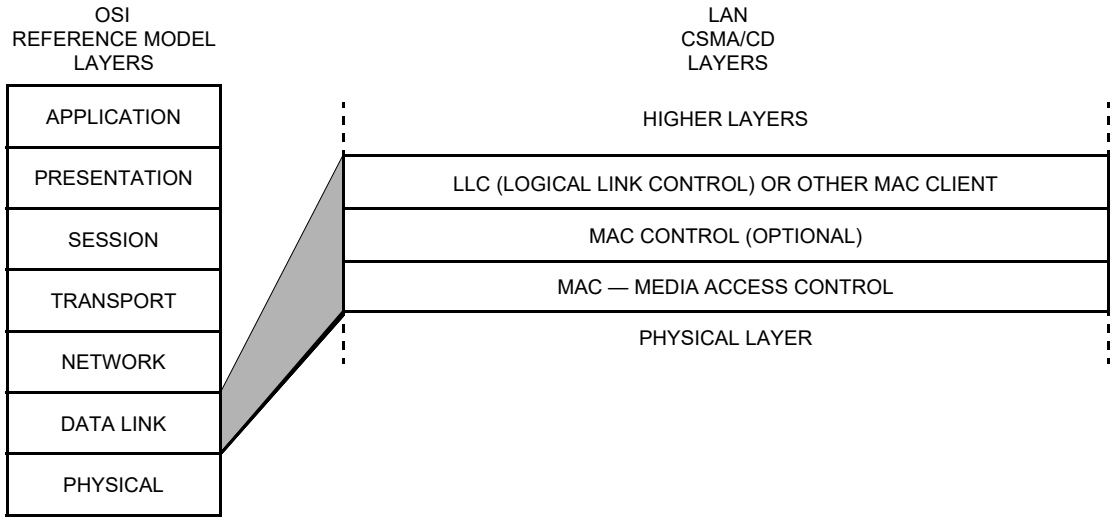

Figure 31–1—Architectural positioning of MAC Control sublayer

31.3 Support by interlayer interfaces

This subclause describes how the MAC Control sublayer uses the MAC service interface specified in Clause 2. The optional MAC Control sublayer is inserted between the MAC sublayer and its MAC client. The MAC Control sublayer uses the MAC service interface to interface to the MAC client and to the MAC.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Figure 31–2 depicts the usage of interlayer interfaces by the MAC Control sublayer. Devices that implement the MAC Control sublayer shall support the MAC service primitives, MA_CONTROL.request and MA_-CONTROL.indication, as specified in this clause.

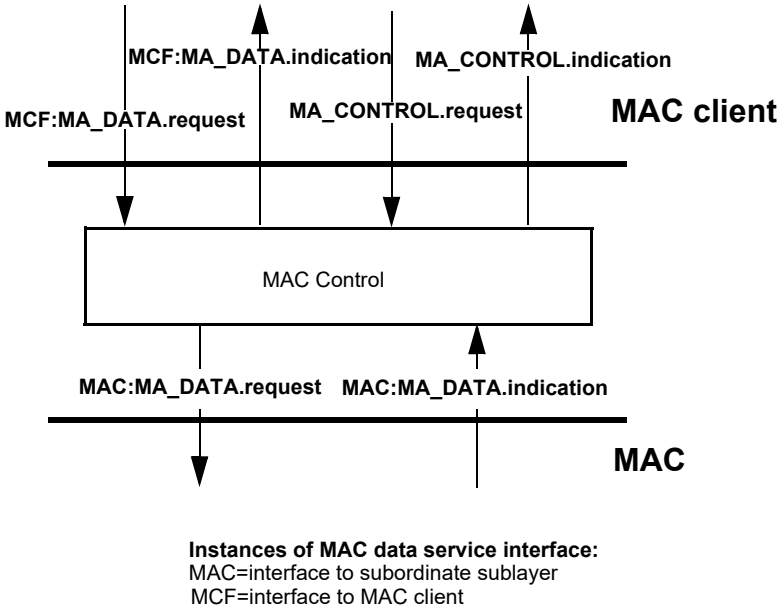

Figure 31–2—MAC Control sublayer support of interlayer service interfaces

Clients of the MAC Control sublayer may generate either MCF:MA_CONTROL.request or MCF:MA_-DATA.request primitives. MA_CONTROL.request primitives generated by MAC clients are interpreted by the MAC Control sublayer, and may result in the generation of MAC:MA_DATA.request calls to the MAC sublayer, or other actions as necessary to support the requested MAC Control sublayer function. Based upon the state of the MAC Control sublayer, MCF:MA_DATA.request primitives may cause the immediate generation of a MAC:MA_DATA.request call to the MAC sublayer, or be delayed, discarded, or modified in order to perform the requested MAC Control function.

All MAC frames validly received by the CSMA/CD MAC are passed to the MAC Control sublayer for interpretation. If the MAC frame is destined for the MAC client, the MAC Control sublayer generates an MCF:MA_DATA.indication primitive, providing complete transparency for normal data exchange between MAC clients. If the MAC frame is destined for the MAC Control sublayer entity, it is interpreted and acted on internal to the MAC Control sublayer. This may result in state changes within the MAC Control sublayer, the generation of MA_CONTROL.indication primitives, or other actions as necessary to support the MAC Control sublayer function. MAC Control sublayer functions shall always sink MAC Control frames.

In the MAC:MA_DATA.indication primitive, MAC frames destined for the MAC Control sublayer (MAC Control frames) are distinguished from MAC frames destined for MAC clients by a unique Length/Type field identifier.

The MAC Control sublayer generates MA_CONTROL.indication primitives to its client, signaling the current value of internal state variables. Each MAC Control function implemented may have its own function-specific state indications.

31.3.1 MA_CONTROL.request

Implementation of the MA_CONTROL.request primitive is mandatory.

31.3.1.1 Function

This primitive defines the transfer of control commands from a MAC client entity to the local MAC Control sublayer entity.

31.3.1.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
MA_CONTROL.request      (
                        destination_address,
                        opcode,
                        request_operand_list
                        )
```

The destination_address parameter may specify either an individual or a group MAC entity address. It has to contain sufficient information to create the DA field that is prepended to the MAC frame by the local MAC sublayer entity. The opcode specifies the control operation requested by the MAC client entity. The request_operand_list is an opcode-specific set of parameters.

The valid opcodes and their respective meanings are defined in Annex 31A.

31.3.1.3 When generated

This primitive is generated by a MAC client whenever it wishes to use the services of the optional MAC Control sublayer entity.

31.3.1.4 Effect of receipt

The effect of receipt of this primitive by the MAC Control sublayer is opcode-specific. (See Annex 31A.)

31.3.2 MA_CONTROL.indication

Implementation of the MA_CONTROL.indication primitive is mandatory.

31.3.2.1 Function

This primitive defines the transfer of control status indications from the MAC Control sublayer entity to the MAC client entity.

31.3.2.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
MA_CONTROL.indication       (
                            opcode,
                            indication_operand_list
                            )
```

The elements of the indication_operand_list are opcode-specific, and specified in Annex 31A.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31.3.2.3 When generated

The MA_CONTROL.indication is generated by the MAC Control sublayer under conditions specific to each MAC Control operation.

31.3.2.4 Effect of receipt

The effect of receipt of this primitive by the MAC client is not specified in this clause. See the list of MAC control functions in Annex 31A.

31.4 MAC Control frames

MAC Control frames comprise MAC client data for the CSMA/CD MAC, as specified in Clause 3. They are encapsulated by the CSMA/CD MAC; that is, they are prepended by a Preamble and Start-of-Frame delimiter and appended by an FCS.

MAC Control frames are distinguished from other MAC frames only by their Length/Type field identifier.

31.4.1 MAC Control frame format

For any particular implementation of this standard, MAC Control frames are fixed length, containing minFrameSize–32 bits. The underlying MAC prepends the Preamble and Start-of-Frame delimiter fields, and appends the FCS. Figure 31–3 depicts the MAC Control frame format.

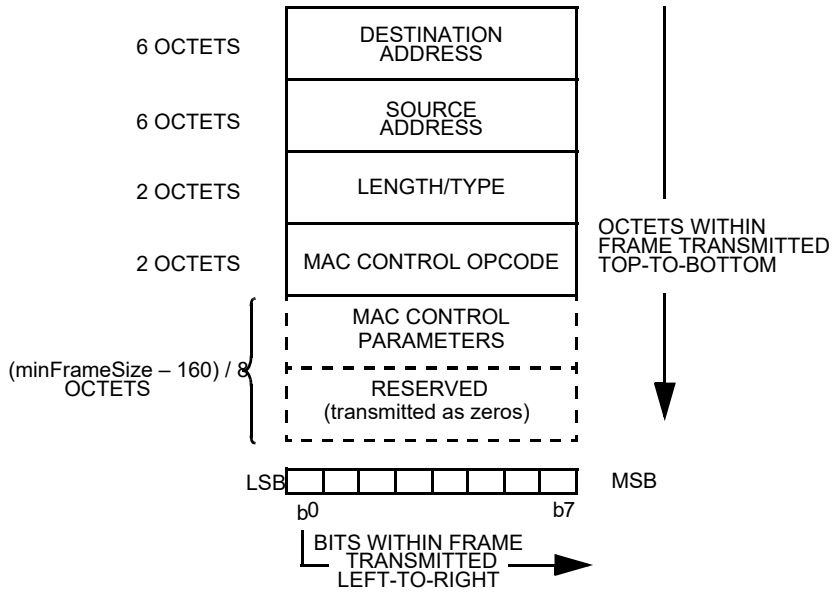

Figure 31–3—MAC Control frame format

31.4.1.1 Destination Address field

The Destination Address field of a MAC Control frame contains the 48-bit address of the station(s) for which the frame is intended. It may be an individual or multicast (including broadcast) address. Permitted values for the Destination Address field may be specified separately for each MAC Control opcode in the annexes to Clause 31.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31.4.1.2 Source Address field

The Source Address field of a MAC Control frame contains the 48-bit individual address of the station sending the frame.

31.4.1.3 Length/Type field

The Length/Type field of a MAC Control frame is a 2-octet field that shall contain the hexadecimal value: 88-08. This value carries the EtherType interpretation (see 3.2.6), and has been universally assigned for MAC Control of CSMA/CD LANs.

31.4.1.4 MAC Control Opcode field

The MAC Control Opcode field shall contain a 2-octet operation code indicating the MAC Control function. It defines the semantics of the MAC Control Parameters field specified in 31.4.1.5. Annex 31A contains the list of defined MAC Control opcodes and interpretations.

A MAC Control frame shall contain exactly one MAC Control opcode.

31.4.1.5 MAC Control Parameters field

The MAC Control Parameters field shall contain MAC Control opcode-specific parameters. This field may contain none, one, or more parameters as defined by the MAC Control Opcode. The opcode-specific semantics of the MAC Control Parameters field are defined in the normative annex specifying each MAC Control function.

The MAC Control Parameters field shall contain an integral number of octets. The length of the MAC Control Parameters field varies from a minimum of zero, to a maximum of minFrameSize –160 bits. See 4.2.3.3 for a discussion of minFrameSize.

31.4.1.6 Reserved field

The Reserved field is used when the MAC Control parameters do not fill the fixed length MAC Control frame. The size of the Reserved field, if any, is determined by the size of the MAC Control Parameters field supplied by MAC Control and the minimum frame size parameter of the particular implementation.

The length of Reserved field required for a MAC Control Parameters field that is n octets long is [minFrameSize – $(8 \times n + 160)$] bits. See 4.2.3.3 for a discussion of minFrameSize. The Reserved field is transmitted as all zeros.

31.5 Opcode-independent MAC Control sublayer operation

The MAC passes to the MAC Control sublayer all valid MAC frames via the MA_DATA.indication primitive. Invalid MAC frames are not passed to the MAC Control sublayer (see 3.4).

31.5.1 Frame parsing and data frame reception

Upon receipt, the MAC Control sublayer parses the incoming MAC frame to determine whether it is destined for the MAC client (data frame) or for a specific function within the MAC Control sublayer entity itself (MAC Control frame). MAC Control frames with a length of minFrameSize and a supported opcode field are interpreted and acted upon by the MAC Control sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A MAC frame that does not contain the unique Length/Type field specified in 31.4.1.3 is a data frame. The receipt of a data frame results in the generation of a MCF:MA_DATA.indication primitive by the MAC Control sublayer, with its parameters identical to the MAC:MA_DATA.indication primitive.

NOTE—For Length/Type field values in the range between maxBasicDataSize and minTypeValue, the behavior of the RemovePad function in the underlying MAC sublayer is unspecified. Frames with Length/Type field values in this range may or may not be passed up by the MAC sublayer.

MAC Control frames with a length greater than minFrameSize and a supported opcode field may be either discarded, or truncated to minFrameSize, interpreted, and acted upon. Unsupported MAC Control frames are discarded. Discarded frames are neither interpreted nor acted upon by the MAC Control sublayer.

31.5.2 Control frame reception

Validly received MAC Control frames are further parsed to determine the opcode. The location of the opcode within a valid MAC Control frame and its format are specified in 31.4.1.4 and Figure 31–3. If the MAC Control sublayer entity supports the function requested by the specified opcode, it interprets and acts upon the MAC Control frame in an opcode- and request_operand-specific manner. (See Annex 31A.) This action may change the state of the MAC Control sublayer, affecting its behavior with respect to data transmission requests by the MAC client, future control frame receptions, or control indications to the MAC client.

If the MAC Control sublayer entity does not support the function requested by the specified opcode, it discards the MAC Control frame. The discard of a frame in this manner may be reported to network management.

31.5.3 Opcode-independent MAC Control receive state diagram

The MAC Control sublayer shall implement the Receive state diagram specified in this subclause.

31.5.3.1 Constants

802.3_MAC_Control
: The 16-bit Length/Type field value used for CSMA/CD MAC Control, specified in 31.4.1.3.

31.5.3.2 Variables

receiveEnabled
: A Boolean set by Network Management to indicate that the station is permitted to receive from the network.

  Values: true; Receiver is enabled by management
  false; Receiver is disabled by management

DA
: The destination address field parsed from the received frame.

SA
: The source address field parsed from the received frame.

lengthOrType
: The lengthOrType field parsed from the received frame.

data
: The data payload field parsed from the received frame.

fcs
: The fcs field parsed from the received frame.

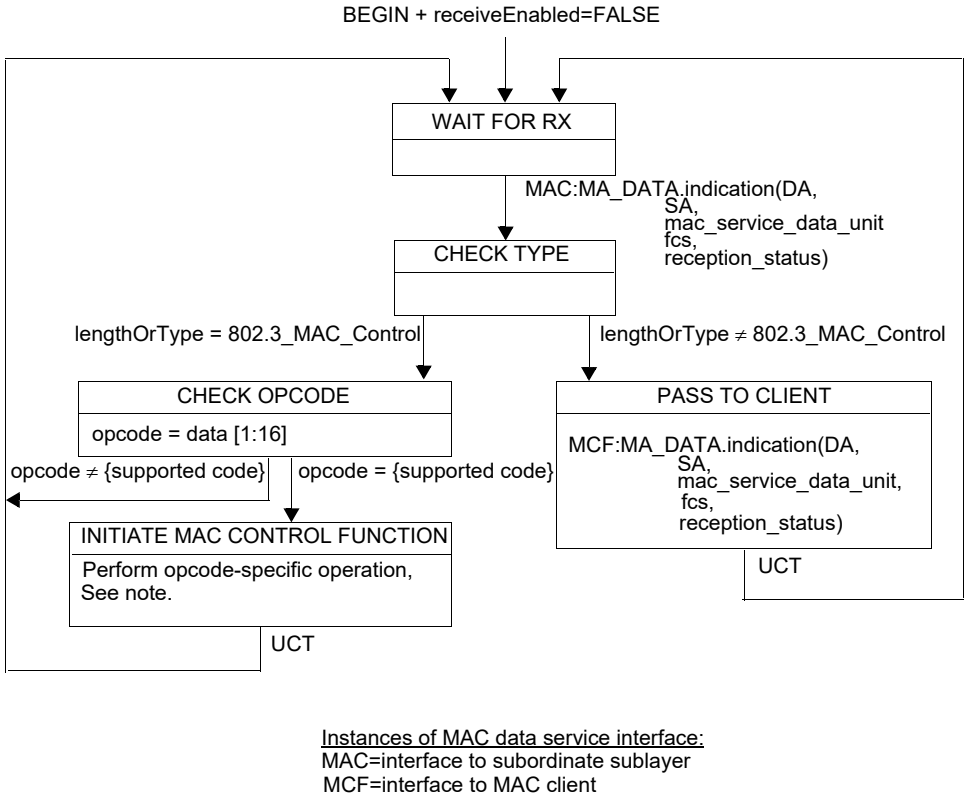
Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

fcsPresent
: A Boolean set by the MAC sublayer. See 4.3.2.

mac_service_data_unit
: The concatenation of lengthOrType, data.

ReceiveStatus
: Indicates the status of the received frame. See 4.3.2.

opcode
: The MAC Control opcode field parsed from the received frame.



31.5.3.3 Messages

MA_DATA.indication

The service primitive used to pass a validly received MAC frame between the MAC and the MAC Control sublayers, or between the MAC Control sublayer and the MAC client. When generated by the MAC sublayer, this message is used by the MAC Control Receive state diagram as the condition for transition between WAIT FOR RX and CHECK TYPE states. While in the PASS TO CLIENT state, the MAC Control Receive state diagram generates this message to the MAC client.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31.5.3.4 Opcode-independent MAC Control Receive state diagram

NOTE—The opcode-specific operation (see Annex 31A) is launched as a parallel process by the MAC Control sublayer, and not as a synchronous function. Progress of the generic MAC Control Receive state diagram (as shown in this figure) is not implicitly impeded by the launching of the opcode-specific function.

Figure 31–4—Generic MAC Control Receive state diagram

The functions performed in the INITIATE MAC CONTROL FUNCTION state are opcode-specific (see Annex 31A).

31.6 Compatibility requirements

An instantiation of the MAC Control sublayer is not required to implement all valid control functions specified in Annex 31A.

31.7 MAC Control client behavior

The MAC Control sublayer uses the services of the underlying connectionless-mode MAC sublayer to exchange both Data and Control frames. The MAC Control sublayer does not provide any mechanism for recovery from lost, discarded, damaged, or delayed frames. It is the responsibility of the MAC Control client to implement mechanisms for dealing with lost, discarded, damaged, and delayed frames, if necessary.

Since implementation of the MAC Control sublayer is optional, a MAC Control client cannot assume the existence of a MAC Control sublayer entity in a peer DTE.

31.8 Protocol implementation conformance statement (PICS) proforma for Clause 31, MAC Control[64]

31.8.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 31, the optional MAC Control sublayer, shall complete the following PICS proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

31.8.2 Identification

31.8.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations, other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

31.8.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 31, MAC Control
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; The answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[64] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

32. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T2

NOTE—This PHY is not recommended for new installations. Since September 2003, maintenance changes are no longer being considered for this clause.

32.1 Overview

The 100BASE-T2 PHY is one of the 100BASE-T family of high-speed CSMA/CD network specifications. The 100BASE-T2 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA), and baseband medium specifications are aimed at users who want 100 Mb/s performance over basic data grade Category 3 twisted-pair cabling systems. 100BASE-T2 signaling requires two pairs of Category 3 cabling, or cabling with better transfer characteristics than Category 3, installed according to ISO/IEC 11801, as specified in 32.7. This type of cabling, and the connectors used with it, are simple to install and reconfigure.

This clause defines the type 100BASE-T2 PCS, type 100BASE-T2 PMA sublayer, and type 100BASE-T2 Medium Dependent Interface (MDI). Together, the PCS and the PMA sublayer comprise a 100BASE-T2 Physical Layer device (PHY). Control actions needed for correct PHY operations are specified by the 100BASE-T2 PHY Control function. Provided in this document are full functional, electrical, and mechanical specifications for the type 100BASE-T2 PHY Control function, PCS, PMA, and MDI. This clause also specifies the baseband medium used with 100BASE-T2.

The objectives of 100BASE-T2 are as follows:

a) To support the CSMA/CD MAC;

b) To support the 100BASE-T Media Independent Interface (MII), repeater, and Auto-Negotiation;

c) To support full duplex operations (Clause 31);

d) To provide 100 Mb/s data rate at the MII;

e) To provide for operating over two pairs of Category 3, 4, or 5 balanced twisted-pair cabling systems installed in accordance with ISO/IEC 11801, as specified in 32.7, at distances up to 100 m;

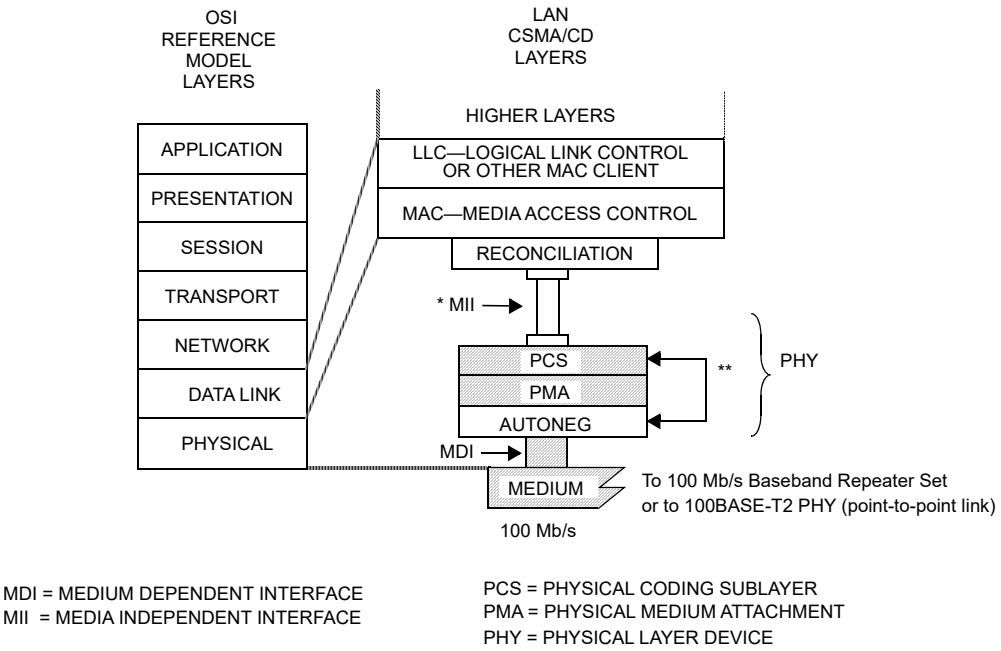
f) To support operation of other applications on adjacent pairs;

g) To allow for a nominal network extent of 200 m including

   1) Balanced cabling links of 100 m to support both half duplex and full duplex operation and

   2) Two-repeater networks of approximately 200 m span;

h) To provide a communication channel with a symbol error ratio of less than one part in 10^{10} at the PMA service interface.



32.1.1 Relation of 100BASE-T2 to other standards

Relations between the 100BASE-T2 PHY and the ISO/IEC Open Systems Interconnection (OSI) Reference Model and the IEEE 802.3 CSMA/CD LAN Model are shown in Figure 32–1. The PHY layers shown in Figure 32–1 connect one Clause 4 Media Access Control (MAC) layer to a Clause 27 repeater. This clause also discusses other variations of the basic configuration shown in Figure 32–1. This whole clause builds on Clauses 1, 2, 3, 4, 21, 22, 27, 28, 29, and 30 of this standard.

32.1.2 Operation of 100BASE-T2

The 100BASE-T2 PHY employs dual-duplex baseband transmission over two wire pairs BI_DA and BI_DB, whereby the aggregate data rate of 100 Mb/s is achieved by transmission at a modulation rate of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—* MII is optional.

NOTE 2—** AUTONEG communicates with the PMA sublayer through the PMA service interface messages PMA_LINK.request and PMA_LINK.indication.

Figure 32–1—Type 100BASE-T2 PHY relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 CSMA/CD LAN model

25 MBd over each wire pair in each direction simultaneously (full duplex transmission), as shown in Figure 32–2. Transmitted symbols are selected from the two-dimensional 5 × 5 symbol constellation illustrated in Figure 32–3. Redundancy in the 5 × 5 constellation allows specific encoding rules to be employed to represent MII data streams, an idle mode or control signals as sequences of two-dimensional symbols. Each two-dimensional symbol can be viewed as a pair (A_n, B_n) of one-dimensional quinary symbols taken from the set {–2, –1, 0, +1, +2}. Five-level Pulse Amplitude Modulation is employed for transmission over each wire pair (PAM 5 × 5). The modulation rate of 25 MBd matches the MII clock rate of 25 MHz. The corresponding symbol period is 40 ns. This specification permits the use of Category 3, 4, or 5 balanced cabling, installed according to ISO/IEC 11801, as defined in 32.7.

A 100BASE-T2 PHY can be configured either as a *master* PHY or as a *slave* PHY. The master-slave relationship between two stations sharing a link segment is established during Auto-Negotiation (see Clause 28, 32.5, Annex 28C, and 32.5.2). The master PHY uses an external clock to determine the timing of transmitter and receiver operations. The slave PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations, i.e., it performs loop timing, as illustrated in Figure 32–2. In a DTE to repeater connection, the repeater is typically set to be master and the DTE is typically set to be slave.

The following subclauses summarize the PCS, PMA, and PHY Control sections of this document. Figure 32–4 shows the division of responsibilities between the PCS, the PMA sublayer, and the PHY Control function.

32.1.2.1 Physical coding sublayer (PCS)

The 100BASE-T2 PCS couples an MII, as described in Clause 22, to a PMA sublayer.

The functions performed by the PCS comprise the generation of continuous quinary symbol sequences to be transmitted over each wire pair. During *data mode*, i.e., when a data stream from the MII is transmitted, the four bits representing the TXD<3:0> data nibble are scrambled by a side-stream scrambler and encoded into a pair of quinary symbols. During *idle mode*, i.e., between transmission of consecutive data streams, the sequences of quinary symbols are generated with an encoding rule that differs from the encoding rule used in data mode. Through this technique, sequences of arbitrary quinary symbols that represent data can easily be distinguished from sequences that represent the idle mode. Furthermore, idle mode encoding takes into account the information of whether the local PHY is operating reliably or not and allows conveying this information to the remote station. A transition from the idle to the data mode is signaled by inserting a Start-of-Stream delimiter that consists of a pattern of two consecutive pairs of quinary symbols. Similarly, the end of a data stream transmission is signaled by inserting an End-of-Stream delimiter that also consists of a pattern of two consecutive pairs of quinary symbols. Further patterns are used for signaling a transmit error during transmission of a data stream.

PCS Receive processes pairs of quinary symbols provided by the PMA. It detects the beginning and the end of streams of data and, during the reception of a data stream, descrambles and decodes the received quinary symbol pairs into nibbles RXD<3:0> that are passed to the MII. PCS Receive also detects errors in the received sequences and signals them to the MII. Furthermore, the PCS contains a PCS Carrier Sense function, a PCS Collision Presence function, and a management interface.

The PCS functions and state diagrams are specified in 32.3. The signals provided by the PCS at the MII conform to the interface requirements of Clause 22. The PCS interfaces to PHY Control and to the PMA are abstract message-passing interfaces specified in 32.2 and 32.4, respectively.

32.1.2.2 PMA sublayer

The PMA couples messages from the PMA service interface onto the balanced cabling physical medium. The PMA provides dual-duplex communications at 25 MBd over two pairs of balanced cabling up to 100 m in length.

The PMA Transmit function comprises two independent transmitters to generate five-level pulse-amplitude modulated signals on each of the two pairs BI_DA and BI_DB, as described in 32.4.1.1.2.

The PMA Receive function comprises two independent receivers for five-level pulse-amplitude modulated signals on each of the two pairs BI_DA and BI_DB, as described in 32.4.1.1.3. The receivers are responsible for acquiring clock, and providing quinary symbol pairs to the PCS as defined by the PMA_UNITDATA.indication message. The PMA also contains functions for Link Monitor.

PMA functions and state diagrams are specified in 32.4. PMA electrical specifications are given in 32.6.

32.1.2.3 PHY Control function

PCS and PMA sublayer operations are controlled via signals generated by the PHY Control function. PHY Control does not itself represent a sublayer but rather a logical grouping of the control functions necessary for proper operations of a 100BASE-T2 transceiver.

PHY Control determines whether the PHY should operate in a normal state, where packets can be exchanged over the link segment, or whether the PHY should be forced to send quinary symbol sequences that represent the idle mode. The latter occurs when either one of the PHYs, or both PHYs, that share a link segment are not operating reliably.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PHY Control function and state diagram are specified in 32.2, prior to introducing the PCS and PMA functional specifications. The PHY Control interface to the PCS and PMA sublayer is an abstract message-passing interface also specified in 32.2.

32.1.3 Application of 100BASE-T2

32.1.3.1 Compatibility considerations

All implementations of the balanced cabling link shall be compatible at the MDI. The PCS, PMA, and the medium are defined to provide compatibility among devices designed by different manufacturers. Designers are free to implement circuitry within the PCS and PMA in an application-dependent manner provided the MDI and MII specifications are met.

32.1.3.2 Incorporating the 100BASE-T2 PHY into a DTE

When the PHY is incorporated within the physical bounds of a DTE, conformance to the MII is optional, provided that the observable behavior of the resulting system is identical to that of a system with a full MII implementation. For example, an integrated PHY may incorporate an interface between PCS and MAC that is logically equivalent to the MII, but does not have the full output current drive capability called for in the MII specification.

32.1.3.3 Use of 100BASE-T2 PHY for point-to-point communication

The 100BASE-T2 PHY, in conjunction with the MAC specified in Clause 1 through Clause 4 (including parameterized values in 4.4.2 to support 100 Mb/s operation) may be used at both ends of a link for point-to-point applications between two DTEs. Such a configuration does not require a repeater. In this case each PHY may connect through an MII to its respective DTE. Optionally, either PHY (or both PHYs) may be incorporated into the DTEs without an exposed MII.

32.1.3.4 Auto-Negotiation requirement

Full Auto-Negotiation, as specified in Clause 28, shall be included in all compliant implementations.

32.1.4 State diagram conventions

The body of this clause and its associated annexes contain state diagrams, including definitions of variables, constants and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram shall prevail. The notation used in the state diagrams follows the conventions of 21.5.

32.2 PHY Control functional specifications and service interface

32.2.1 PHY Control function

PHY Control generates the control actions that are needed to bring the PHY in a mode of operation during which packets can be exchanged with the link partner. PHY Control shall comply with the state diagram description given in Figure 32–5.

During Auto-Negotiation, PHY Control ensures that the transmitter is disabled. When the Auto-Negotiation process asserts link_control=ENABLE, PHY Control enters the TRAINING state. During training, PHY Control enforces transmission in the idle mode by setting tx_mode=SEND_I and the PHY transmits sequences of quinary symbols encoded with the parameter loc_rcvr_status=NOT_OK. When the PHY achieves successful training and establishes proper receiver operations, PCS Receive asserts the parameter loc_rcvr_status=OK, and PCS Transmit conveys this information to the link partner via idle transmission.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The criterion for assertion of the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver or detecting errors during reception of symbol streams that represent the idle mode. Upon observation that the remote PHY also operates reliably (rem_rcvr_status=OK), the normal mode of operation is entered where transmission of packets over the link segment can take place.

The normal mode of operation corresponds to the SEND IDLE OR DATA state, where PHY Control asserts tx_mode=SEND_N. In this state, when no packets have to be sent, idle mode transmission takes place. Encoding of quinary symbols is realized with the parameter loc_rcvr_status = OK.

If during the normal mode of operation unsatisfactory receiver operations is detected (loc_rcvr_status=NOT_OK), transmission of the current packet, if any, is completed and PHY Control enters the TRAINING state.

Whenever a PHY that operates reliably detects unsatisfactory operation of the remote PHY (rem_rcvr_status=NOT_OK), it enters the SEND IDLE state where tx_mode=SEND_I is asserted and idle transmission takes place. In this state, encoding is performed with the parameter loc_rcvr_status=OK. As soon as the remote PHY signals satisfactory receiver operation (rem_rcvr_status=OK), the SEND IDLE OR DATA state is entered. Note that if in the SEND IDLE state loc_rcvr_status takes the value NOT_OK transition to the TRAINING state occurs.

PHY Control may force the transmit scrambler state to be initialized to a random value by requesting the execution of the PCS Reset function defined in 32.3.1.1.

32.2.2 PHY Control Service interface

The following specifies the services provided by PHY Control. These services are described in an abstract manner and do not imply any particular implementation.

The following primitives are defined:

PHYC_CONFIG.indication
PHYC_TXMODE.indication
PHYC_RXSTATUS.request
PHYC_REMRXSTATUS.request

The parameter link_control is identical to the link_control parameter defined for the PMA Service interface in 32.4.2.4.

32.2.2.1 PHYC_CONFIG.indication

Each PHY in a 100BASE-T2 link is configured as a master PHY or as a slave PHY. Master/slave configuration is determined during Auto-Negotiation (see 32.5). The result of this negotiation is provided to PHY Control.

32.2.2.1.1 Semantics of the primitive

PHYC_CONFIG.indication (config)

PHYC_CONFIG.indication specifies to PCS and PMA Clock Recovery via the parameter config whether the PHY operates as a master PHY or as a slave PHY. The parameter config can take on one of two values of the form:

MASTER This value is continuously asserted when the PHY operates as a master PHY.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SLAVE This value is continuously asserted when the PHY operates as a slave PHY.

32.2.2.1.2 When generated

PHY Control shall generate PHYC_CONFIG.indication messages synchronously with every MII TX_CLK cycle.

32.2.2.1.3 Effect of receipt

Upon reception of this primitive, PCS and PMA Clock Recovery shall perform their functions in master or slave configuration according to the value assumed by the parameter config.

32.2.2.2 PHYC_TXMODE.indication

The transmitter in a 100BASE-T2 link normally sends over the two pairs quinary symbols that can represent an MII data stream or the idle mode.

32.2.2.2.1 Semantics of the primitive

PHYC_TXMODE.indication (tx_mode)

PHYC_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of quinary symbols the PCS should be transmitting. The parameter tx_mode can take on one of two values of the form:

SEND_N This value is continuously asserted when transmission of sequences of quinary symbols representing an MII data stream or the idle mode is to take place.

SEND_I This value is continuously asserted in case transmission of sequences of quinary symbols representing the idle mode is to take place.

32.2.2.2.2 When generated

PHY Control shall generate PHYC_TXMODE.indication messages synchronously with every MII TX_CLK cycle.

32.2.2.2.3 Effect of receipt

Upon receipt of this primitive, the PCS shall perform its Transmit function as described in 32.3.1.2.

32.2.2.3 PHYC_RXSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the receive link for the local PHY. The parameter loc_rcvr_status conveys to PHY Control and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by PCS Transmit encoding functions.

32.2.2.3.1 Semantics of the primitive

PHYC_RXSTATUS.request (loc_rcvr_status)

The loc_rcvr_status parameter can take on one of two values of the form:

OK This value is asserted and remains true during reliable operation of the receive link for

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the local PHY.

NOT_OK This value is asserted whenever operation of the receive link for the local PHY is unreliable.

32.2.2.3.2 When generated

PCS Receive shall generate PHYC_RXSTATUS.request messages synchronously with signals received at the MDI. It shall prevent that the value of the parameter loc_rcvr_status is modified while TX_EN=1 in order to avoid that a transition from data to idle mode or from idle to data mode occurs while a packet is being presented to the PCS at the MII.

32.2.2.3.3 Effect of receipt

The effect of receipt of this primitive is specified in 32.2.5 and 32.4.1.3.3.

32.2.2.4 PHYC_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link as communicated by the remote PHY. The parameter rem_rcvr_status conveys to PHY Control the information on whether reliable operation of the remote PHY is detected or not.

32.2.2.4.1 Semantics of the primitive

PHYC_REMRXSTATUS.request (rem_rcvr_status)

The rem_rcvr_status parameter can take on one of two values of the form:

OK The receive link for the remote PHY is operating reliably.

NOT_OK Reliable operation of the receive link for the remote PHY is not detected.

32.2.2.4.2 When generated

The PCS shall generate PHYC_REMRXSTATUS.request messages synchronously with signals received at the MDI.

32.2.2.4.3 Effect of receipt

The effect of receipt of this primitive is specified in 32.2.5.

32.2.3 State diagram variables

link_control
: See 32.4.1.3.1.

link_status
: See 32.4.1.3.1.

loc_rcvr_status
: Variable set by the PCS Receive function to indicate correct or incorrect operation of the receive link for the local PHY.

  Values: OK: the receive link for the local PHY is operating reliably,
  NOT_OK: operation of the receive link for the local PHY is not reliable.

pma_reset
: Allows reset of all PMA functions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: ON and OFF

Set by: PMA Reset

rem_rcvr_status

Variable set by the PCS Receive function to indicate whether correct operation of the receive link for the remote PHY is detected or not.

Values: OK: the receive link for the remote PHY is operating reliably,
NOT_OK: reliable operation of the receive link for the remote PHY is not detected.

tx_mode

PCS Transmit shall send quinary symbols according to the value assumed by this variable.

Values: SEND_N: transmission of sequences of quinary symbols representing an MII data stream, the idle mode, or control signals shall take place,
SEND_I: transmission of sequences of quinary symbols representing the idle mode shall take place.

32.2.4 State diagram timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where “stop x_timer” is asserted.

maxwait_timer

A timer used to measure the amount of time during which a receiver dwells in the TRAINING state. The timer shall expire 2500 ms to 3000 ms after entering the TRAINING state.

minwait_timer

A timer used to measure the amount of time during which a receiver waits in the SEND IDLE OR DATA, the TRAINING, or the SEND IDLE state before being allowed to leave the current state. The timer shall expire 128T = 5.12 μs after being started.

32.2.5 PHY Control state diagram

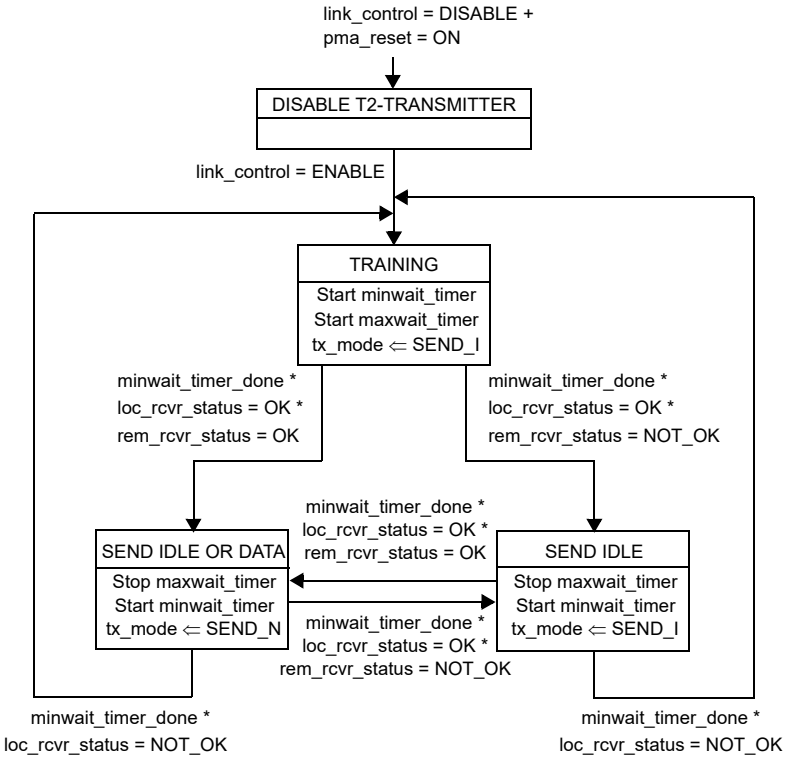

Figure 32–5—PHY Control state diagram

32.3 PCS functional specifications

The PCS comprises one PCS Reset function and four simultaneous and asynchronous operating functions. The PCS operating functions are: PCS Transmit, PCS Receive, PCS Carrier Sense, and PCS Collision Presence. All operating functions start immediately after the successful completion of the PCS Reset function.

The PCS reference diagram, Figure 32–5, shows how the four operating functions relate to the messages of the PCS-PMA and the PCS-PHY Control interfaces. Connections from the management interface (signals MDC and MDIO) to other layers are pervasive, and are not shown in Figure 32–5. The management functions are specified in Clause 30. See also Figure 32–7, which presents a block diagram helpful for understanding the definitions of PCS Transmit function variables, and Figure 32–11, which defines the structure of frames passed from PCS to PMA.

32.3.1 PCS functions

32.3.1.1 PCS Reset function

The PCS Reset function shall be executed any time one of three conditions occurs. These three conditions are “power on,” the receipt of a request for reset from the management entity, and the receipt of a request for reset from PHY Control. PCS Reset initializes all PCS functions. PCS Reset sets pcs_reset = ON for the duration of its Reset function. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

32.3.1.2 PCS Transmit function

The PCS Transmit function shall conform to the PCS Transmit state diagram in Figure 32–12.

In normal mode of operation, the tx_mode parameter, which is transferred from PHY Control to the PCS via the PHYC_TXMODE.indication message, assumes the value tx_mode=SEND_N, and the PCS Transmit function generates at each symbol period pairs of quinary symbols that represent data or the idle mode. A symbol period T is equal to 40 ns. A time index n, where n is an integer, is introduced to establish a temporal relationship between different symbol periods. The tx_symb_vector parameter at time n is a two-element vector of quinary symbols (A_n, B_n) that is transferred to the PMA via PMA_UNITDATA.request. The PMA shall transmit symbols A_n and B_n over wire pairs BI_DA and BI_DB, respectively. During transmission of data, the four bits representing the TXD<3:0> data nibble are scrambled by the OCS using a side-stream scrambler then encoded into a pair of quinary symbols and transferred to the PMA. The idle mode is signaled by a sequence of pairs of quinary symbols that are also generated using the side-stream transmit scrambler. However, the encoding rules by which the quinary symbols are obtained are different for the data and the idle modes. This allows, at the receiver, sequences of quinary symbol pairs that represent data to be distinguished from sequences of quinary symbol pairs that represent the idle mode. A transition from the idle mode to the data mode is signalled by inserting a Start-of-Stream delimiter that consists of a pattern of two consecutive pairs of quinary symbols. Similarly, the end of transmission of data is signalled by an End-of-Stream delimiter that also consists of a pattern of two consecutive pairs of quinary symbols. Further patterns are used for signaling the assertion of TX_ER within a stream of data.

If tx_mode = SEND_I is asserted, PCS Transmit generates sequences of symbol pairs (A_n, B_n) according to the encoding rule in idle mode. Idle mode encoding takes into account the value of the parameter loc_rcvr_status. By this mechanism, a PHY indicates during idle transmission the status of its own receiver to the link partner.

The PCS Transmit reference diagram is shown in Figure 32–7. PCS encoding involves the generation of the three-bit words Sa_n[2:0], Sb_n[2:0], Ta_n[2:0], and Tb_n[2:0], from which the pairs of quinary symbols (A_n, B_n) are obtained. The three-bit words Sa_n[2:0] and Sb_n[2:0] are determined first, as explained in 32.3.1.2.2, from sequences of random binary symbols derived from the transmit side-stream scrambler. The generation of Ta_n[2:0] and Tb_n[2:0] and the quinary symbols A_n and B_n is given in 32.3.1.2.3. The physical structure represented in Figure 32–7 is not required. Implementers are free to construct any logical devices having functionality identical to that described by the following specifications and the PCS Transmit state diagram.

32.3.1.2.1 Side-stream scrambler polynomials

The PCS Transmit function employs side-stream scrambling. If the parameter config provided to the PCS by the PHY Control function via the PHYC_CONFIG.indication message assumes the value MASTER, PCS Transmit shall employ

$$g_M(x) = 1 + x^{13} + x^{33}$$

as transmitter side-stream scrambler generator polynomial. If config = SLAVE, PCS Transmit shall employ

$$g_S(x) = 1 + x^{20} + x^{33}$$

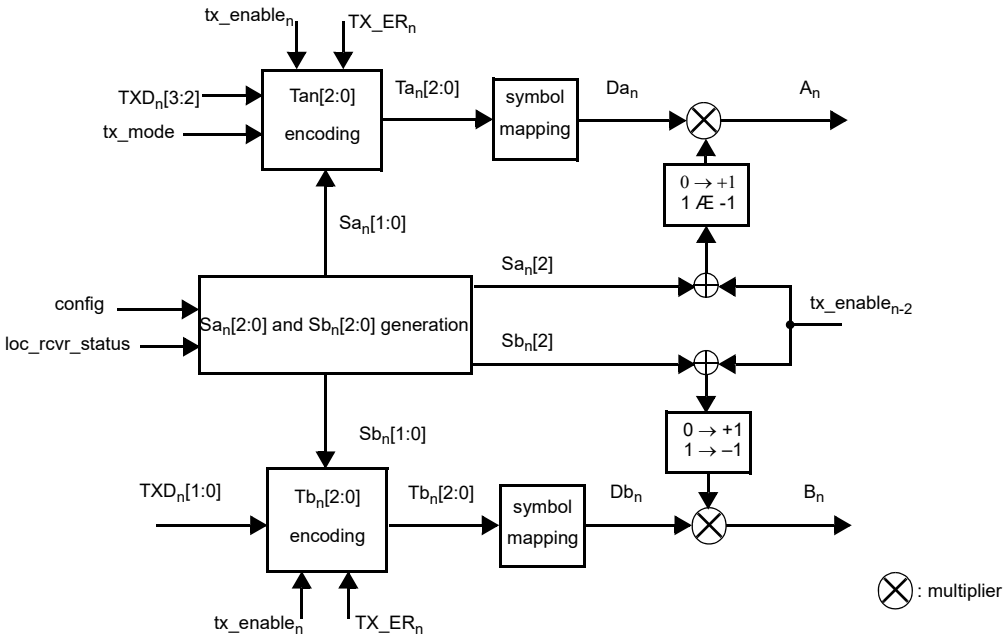

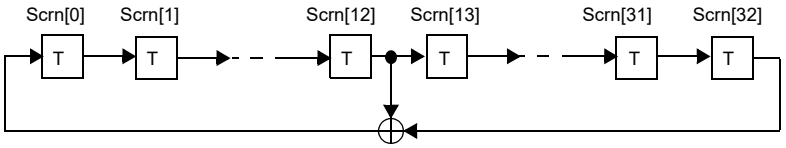

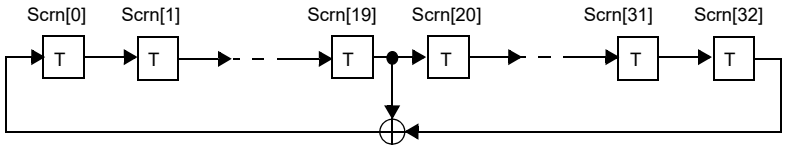

Figure 32–7—PCS Transmit reference diagram

as transmitter side-stream scrambler generator polynomial. The implementation of master and slave PHY side-stream scramblers by linear-feedback shift registers is shown in Figure 32–8. The bits stored in the shift register delay line at time n are denoted by $Scr_n[32:0]$. At each symbol period, the shift register is advanced by one bit and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are randomly set. The generation of the random bits is left to the implementer.

a) Side-stream scrambler employed by the master PHY

b) Side-stream scrambler employed by the slave PHY

Figure 32–8—Realization of side-stream scramblers by linear feedback shift registers

32.3.1.2.2 Generation of bits $Sa_n[2:0]$ and $Sb_n[2:0]$

PCS Transmit encoding rules are based on the generation, at time n, of the four bits Sx_n, Sy_n, $Sa_n[2]$, and $Sb_n[2]$. These four bits are mutually uncorrelated and also uncorrelated with the bit $Scr_n[0]$ in data and idle

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

modes. For both master and slave PHYs, they are obtained by the same linear combinations of bits stored in the transmit scrambler shift register delay line. The four bits are elements of the same maximum-length shift register sequence of length $2^{33} - 1$ as $Scr_n[0]$, but shifted in time. The associated delays are all large and different, such that there is no apparent correlation among the five bits $Scr_n[0]$, Sx_n, Sy_n, $Sa_n[2]$, and $Sb_n[2]$. The bits Sx_n and Sy_n are given by

$$Sx_n = Scr_n[3] \oplus Scr_n[8]$$

$$Sy_n = Scr_n[4] \oplus Scr_n[6]$$

where $\oplus$ denotes the XOR logic operator. Four bits $X_n[1:0]$ and $Y_n[1:0]$ are obtained by

$$X_n[0] = \begin{cases} Sx_n & \text{if } \{n - n_0 = 0 \text{ (mod 2) or loc_rcvr_status = OK }\} \\ Sx_n \oplus 1 & \text{else} \end{cases}$$

$$X_n[1] = X_n[0] \oplus 1$$

$$Y_n[0] = \begin{cases} Sy_n & \text{if } n - n_0 = 0 \text{ (mod 2)} \\ Sy_{n-1} \oplus 1 & \text{else} \end{cases}$$

$$Y_n[1] = Y_n[0]$$

where n_0 denotes the time index of the last transmitter side-stream scrambler reset.

The bits San[2:0] and Sbn[2:0] are given by

$$Sa_n[2] = Scr_n[1] \oplus Scr_n[5]$$

$$Sa_n[1:0] = \begin{cases} X_n[1:0] & \text{if } Scr_n[0] = 1 \\ Y_n[1:0] & \text{else} \end{cases}$$

$$Sb_n[2] = Scr_n[2] \oplus Scr_n[12]$$

$$Sb_n[1:0] = \begin{cases} Y_n[1:0] & \text{if } Scr_n[0] = 1 \\ X_n[1:0] & \text{else} \end{cases}$$

32.3.1.2.3 Generation of sequences A_n and B_n

If tx_mode = SEND_N, the PCS Transmit function generates sequences A_n and B_n that represent either a stream of data or an idle mode. If tx_mode = SEND_I, idle transmission is enforced. The encoding rule is determined by the value of the signal tx_enable_n, given by

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{tx_enable}_n = \begin{cases} TX_EN_n & \text{if tx_mode = SEND_N} \\ 0 & \text{else} \end{cases}$$

where TX_EN_n represents the MII signal TX_EN at time n. If $tx_enable_n = 1$, transmission of a stream of data takes place. As illustrated in Figure 32–11, the definition of a Start-of-Stream Delimiter ("SSD") is related to the condition $SSD_n = (tx_enable_n) * (! tx_enable_{n-2}) = 1$, where "*" and "!" denote the logic AND and NOT operators, respectively. For the generation of "SSD", PCS Transmit replaces the first two nibbles of the preamble in a data stream with the symbols defined below. Similarly, the definition of an End-of-Stream Delimiter (ESD) is related to the condition $ESD_n = (! tx_enable) * (tx_enable_{n-2}) = 1$. This occurs during the first two symbol periods after transmission of the last nibble of a data stream.

The symbols A_n and B_n are obtained from the three-bit words $Ta_n[2:0]$ and $Tb_n[2:0]$ whose definitions in the data and the idle modes are given below.

Data mode (tx_enable_n=1):

Definition of "SSD":

$Ta_n[2:0] = [1, 0, 0]$

$Tb_n[2:0] = [!tx_enable_{n-1}, tx_enable_{n-2}, tx_enable_{n-2}]$

A most significant bit $Ta_n[2]=1$ or $Tb_n[2]=1$ results in the transmission of a symbol that can be interpreted as an ESC symbol.

Encoding of data nibbles:

$$Ta_n[2:0] = [0,(Sa_n[1] \oplus TXD_n[3]),(Sa_n[0] \oplus TXD_n[2] \oplus 1)]$$

$$Tb_n[2:0] = [0, (Sb_n[1] \oplus TXD_n[1]),(Sb_n[0] \oplus TXD_n[0] \oplus 1)]$$

where $TXD_n[3:0]$ denotes the data nibble TXD[3:0] at time n.

Encoding of error indication:

If $TX_ER_n=1$ is asserted, where TX_ER_n denotes the value of the signal TX_ER at time n, error indication is signaled by means of the ESC and 0 symbols. The encoding rule is given by

$$Ta_n[2:0] = [(Sa_n[1] \oplus Sa_n[0]),0,0]$$

$$Tb_n[2:0] = [(Sb_n[1] \oplus Sb_n[0]),0,0]$$

Idle mode (tx_enable_n=0):

Definition of "ESD":

$Ta_n[2:0] = [1, 0, 0]$

$Tb_n[2:0] = [tx_enable_{n-1}, !tx_enable_{n-2}, !tx_enable_{n-2}]$

Encoding in the idle mode:

$$Ta_n[2:0] = [0,Sa_n[1],Sa_n[0]]$$

$$Tb_n[2:0] = [0,Sb_n[1],Sb_n[0]]$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The mapping of $Ta_n[2:0]$ and $Tb_n[2:0]$ into quinary symbols Da_n and Db_n is given in Figure 32–9. This mapping ensures that the symbols representing data are Gray coded. The quinary symbols A_n and B_n are obtained from Da_n and Db_n by

Symbol mapping	
Ta/Tb	Da/Db
000	0
001	+1
010	-1
011	-2
100 (ESC)	+2

Idle or data	
Da_n:	0, +1, -1, or -2
Db_n:	0, +1, -1, or -2

Data stream delimiters	
Da_n: ESC	Dan+1: ESC
Db_n: ESC	Dbn+1: 0

Error indication	
Da_n: ESC	Da_n: 0
or	
Db_n: 0	Db_n: ESC

Figure 32–9—Symbol mapping and encoding rule summary

$$A_n = \begin{cases} Da_n & \text{if } \text{Sa}_n[2] \oplus \text{tx_enable}_{n-2} = 0 \\ -Da_n & \text{else} \end{cases}$$

$$B_n = \begin{cases} Db_n & \text{if } \text{Sb}_n[2] \oplus \text{tx_enable}_{n-2} = 0 \\ -Db_n & \text{else} \end{cases}$$

With the rules defined in this subclause, if in idle mode a transmitted symbol on one wire pair belongs to the set {–2,0,+2}, the symbol on the other wire pair belongs to the set {–1,+1}. Moreover, one of the quinary symbols that are transmitted at time $2(n–n_0)$ and $2(n–n_0)+1$ is guaranteed to be either +2 or –2. Both in data and idle modes, the symbol sequences on each wire pair can be modeled as sequences of independent and identically distributed quinary symbols. The symbol constellations and symbol probabilities for these two modes are shown in Figure 32–10. The average symbol energy is the same in data and idle modes.

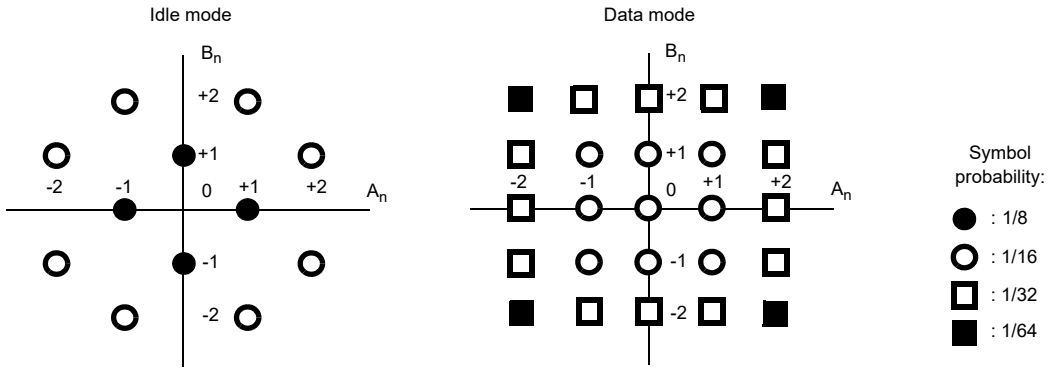

Figure 32–10—Symbol constellations in idle and data modes

32.3.1.3 PCS Receive function

The PCS Receive function shall conform to the PCS Receive state diagram in Figure 32–13.

The PCS Receive function accepts pairs of detected quinary symbols provided by the PMA Receive function via the parameter rx_symb_vector. To achieve correct operation, PCS Receive uses the knowledge of the encoding rules that are employed in the idle mode. For example, the property that in the idle mode if A_n belongs to the set {–2,0,+2} then B_n belongs to the set {–1,+1}, and vice versa, can be used to acquire the correct state for the receiver side-stream descrambler, and to determine which detected quinary symbol was transmitted on wire pair BI_DA and which on wire pair BI_DB. Also, correct polarity of the detected quinary symbols can reliably be obtained by ensuring in the idle mode that the encoding rule holds whenever a –2 symbol is received. PCS Receive generates the sequence of vectors of two quinary symbols (RA_n, RB_n) and indicates the reliability of receiver operations by setting the parameter loc_rcvr_status to OK (logic high) or NOT_OK (logic low). The sequence (RA_n, RB_n) is processed to generate the signals RXD<3:0>, RX_DV, and RX_ER, which are presented to the MII. PCS Receive detects the transmission of a stream of data from the remote station and conveys this information to the PCS Carrier Sense and PCS Collision Presence functions via the parameter receiving.

32.3.1.3.1 Receiver descrambler polynomials

For side-stream descrambling, the master PHY shall employ the receiver descrambler generator polynomial $g'_M(x) = 1 + x^{20} + x^{33}$, and the slave PHY shall employ the receiver descrambler generator polynomial $g'_S(x) = 1 + x^{13} + x^{33}$.

32.3.1.3.2 Decoding of quinary symbols

At the beginning of a stream of data, PCS Receive detects “SSD” and asserts the signal RX_DV. Detection of “SSD” is achieved by processing two consecutive vectors ($RA_{n–1}$, $RB_{n–1}$) and (RA_n, RB_n) at each time n. Upon detection of “SSD,” PCS Receive also assigns the value TRUE to the parameter receiving that is provided to the PCS Carrier Sense and Collision Presence functions.

Table 32–1 shows the mapping of symbols RA_n and RB_n into two-bit words Qa_n[1:0] and Qb_n[1:0] that are descrambled and decoded to generate nibbles of data RXD[3:0].

Table 32–1—Inverse quinary symbol mapping

RA_n/RB_n	$Qa_n[1:0]/Qb_n[1:0]$
0	00
+1	01 or 10
–1	01 or 10
± 2	11

The mapping shown in Table 32–1 corresponds to the inverse of the encoding function employed by PCS Transmit. For example, a symbol $A_n = +1$ is generated by Ta_n[1:0] being equal to “01” or “10.” Hence, in the above table the value of Qa_n[1:0] for $RA_n = +1$ is specified as being equal to “01 or 10.” Similarly for other entries in the table.

During reception of a stream of data, PCS Receive checks that the symbols RA_n and RB_n follow the encoding rule defined in 32.3.1.2 whenever they assume values ± 2. PCS Receive processes two consecutive vectors at each time n to detect “ESD.” Upon detection of “ESD,” PCS Receive deasserts the signal RX_DV, and assigns the value FALSE to the parameter receiving. If a violation of the encoding rules is detected, PCS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Receive asserts the signal RX_ER for at least one symbol period. During reception of an idle sequence, PCS Receive checks that the symbols RA_n and RB_n follow the encoding rule defined in 32.3.1.2.

32.3.1.4 PCS Carrier Sense function

The PCS Carrier Sense function shall conform to the PCS Carrier Sense state diagram in Figure 32–14.

The PCS Carrier Sense function controls the MII signal CRS according to the rules presented in this clause. While link_status = OK, CRS is asserted whenever receiving=TRUE or TX_EN=1.

32.3.1.5 PCS Collision Presence function

A PCS collision is defined as the simultaneous occurrence of TX_EN=1 and the assertion of the parameter receiving=TRUE while link_status=OK. While a PCS collision is detected, the MII signal COL shall be asserted. At other times COL shall remain deasserted.

32.3.2 PCS interfaces

32.3.2.1 PCS–MII interface signals

The signals in Table 32–2 are formally defined in 22.2.2. Jabber detection as specified in 22.2.4.2.12 is not required by this standard.

Table 32–2—MII interface signals

Signal name	Meaning	Subclause
TX_CLK	Transmit clock	22.2.2.1
RX_CLK	Receive clock	22.2.2.2
TX_EN	Frames transmit data	22.2.2.3
TXD<3:0>	Transmit data	22.2.2.4
TX_ER	Forces transmission of illegal code	22.2.2.5
RX_DV	Frames receive SFD and DATA	22.2.2.7
RXD<3:0>	Receive data	22.2.2.8
RX_ER	Receive error indication	22.2.2.10
CRS	Non-idle medium indication	22.2.2.11
COL	Collision indication	22.2.2.12
MDC	Management data clock	22.2.2.13
MDIO	Management data	22.2.2.14

32.3.2.2 PCS–management entity signals

The management interface has pervasive connections to all functions. Operation of the management control lines MDC and MDIO, and requirements for managed objects inside the PCS and PMA, are specified in Clause 22 and Clause 30, respectively.

No spurious signals shall be emitted onto the MDI when the PHY is held in power down mode as defined in 22.2.4.1.5, independently of the value of TX_EN, or when released from power down mode, or when external power is first applied to the PHY.

32.3.3 Frame structure

Frames passed from the PCS to the PMA sublayer shall have the structure shown in Figure 32–11. This figure shows the temporal relationship between the signals tx_enable_n, and TXD[3:0] and the sequences of quinary symbol pairs (A_n, B_n) in correspondence of transitions from the idle mode to transmission of data and vice versa. Time proceeds from left to right in the figure.

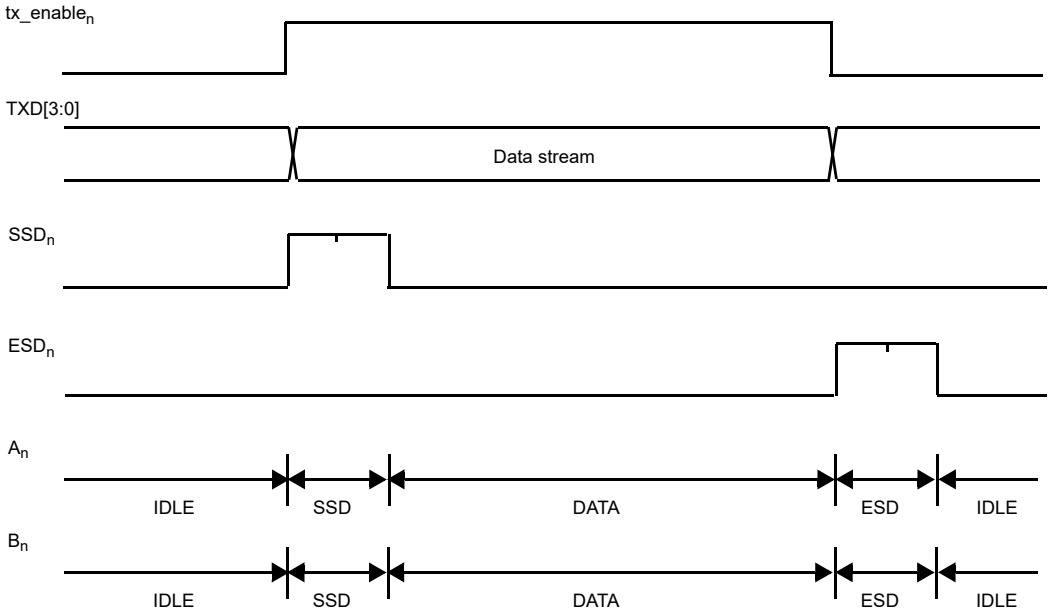

Figure 32–11—PCS sublayer to PMA sublayer frame structure

32.3.4 State variables

32.3.4.1 Variables

COL

The COL signal of the MII as specified in Clause 22.

config

The config parameter set by PHY Control and passed to the PCS via the PHYC_CONFIG.indication primitive.
Values: MASTER and SLAVE.

CRS

The CRS signal of the MII as specified in Clause 22.

DATA

A sequence of vectors of two quinary symbols corresponding to valid data, as specified in 32.3.1.2.

ESD

Two consecutive vectors of two quinary symbols corresponding to the End-of-Stream delimiter, as specified in 32.3.1.2.

IDLE

A sequence of vectors of two quinary symbols generated in idle mode, as specified in 32.3.1.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

link_status

The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK, READY, and FAIL

loc_rcvr_status

The loc_rcvr_status parameter generated by PCS Receive.
Values: OK and NOT_OK

pcs_reset

The pcs_reset parameter set by the PCS Reset function.
Values: ON and OFF

(RA_n, RB_n)

The vector of the two correctly aligned most recently received quinary symbols generated by PCS Receive.

receiving

The receiving parameter generated by the PCS Receive function.
Values: TRUE and FALSE

rxerror_status

The rxerror_status parameter set by the PCS Receive function. Although this variable is set by PCS Receive, it achieves the same function as the variable rxerror_status of Clause 24 that is set by PMA and communicated through the PMA_RXERROR.indication primitive.
Values: ERROR and NO_ERROR

RX_DV

The RX_DV signal of the MII as specified in Clause 22.

RX_ER

The RX_ER signal of the MII as specified in Clause 22.

rx_symb_vector

A vector of two quinary symbols received by the PMA and passed to the PCS via the PMA_UNITDATA.indication primitive.
Value: SYMB_PAIR

RXD[3:0]

The RXD<3:0> signal of the MII as specified in Clause 22.

SSD

Two consecutive vectors of two quinary symbols corresponding to the Start-of-Stream delimiter, as specified in 32.3.1.2.

tx_enable

The tx_enable parameter generated by PCS Transmit as specified in 32.3.1.2.3.

TX_ER

The TX_ER signal of the MII as specified in Clause 22.

tx_mode

The tx_mode parameter set by PHY Control and passed to the PCS via the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PHYC_TXMODE.indication primitive.
Values: SEND_N and SEND_I

tx_symb_vector

A vector of two quinary symbols generated by the PCS Transmit function and passed to the PMA via the PMA_UNITDATA.request primitive.
Value: SYMB_PAIR

32.3.4.2 Timer

symb_timer

A continuous free-running timer. The condition symb_timer_done becomes true upon timer expiration.

Restart time: Immediately after expiration; timer restart resets the condition symb_timer_done.

Duration: 40 ns nominal.

TX_CLK shall be generated synchronously with symb_timer (see tolerance required for TX_CLK in 32.6.1.2.6). In the PCS Transmit state diagram, the message PMA_UNITDATA.request is issued concurrently with symb_timer_done.

32.3.4.3 Messages

PMA_UNITDATA.indication (rx_symb_vector)
A signal sent by PMA Receive indicating that a vector of two quinary symbols is available in rx_symb_vector.

PMA_UNITDATA.request (tx_symb_vector)
A signal sent to PMA Transmit indicating that a vector of two quinary symbols is available in tx_symb_vector.

32.3.5 State diagrams

32.3.5.1 PCS Transmit

PCS Transmit sends vectors of two quinary symbols to the PMA via the tx_symb_vector parameter. In normal mode of operation, between streams indicated by the parameter tx_enable, PCS Transmit generates sequences of vectors using the encoding rules defined for the idle mode. Upon assertion of tx_enable, PCS Transmit passes an “SSD” of two consecutive vectors of two quinary symbols to the PMA replacing the preamble bits of a stream of data during these two symbol periods. Following the “SSD,” each TXD<3:0> nibble is encoded into a vector of two quinary symbols until tx_enable is deasserted. If, while tx_enable is asserted, the TX_ER signal is also asserted, PCS Transmit passes to the PMA vectors indicating a transmit error. Note that if the signal TX_ER is asserted while “SSD” is being sent, the transmission of the error condition is delayed until transmission of “SSD” has been completed. Following the deassertion of tx_enable, an “ESD” of two consecutive vectors of two quinary symbols is generated, after which the transmission of a sequence indicating the idle mode is resumed.

Collision detection is implemented by noting the occurrence of carrier receptions during transmissions, following the model of 10BASE-T. The PCS shall implement the Transmit process as depicted in Figure 32–12 including compliance with the associated state variables as specified in 32.3.4.

32.3.5.2 PCS Receive

PCS Receive accepts vectors of two quinary symbols from the PMA via the rx_symb_vector parameter. After correct receiver operation has been achieved, the loc_rcvr_status parameter assumes the value OK, and PCS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

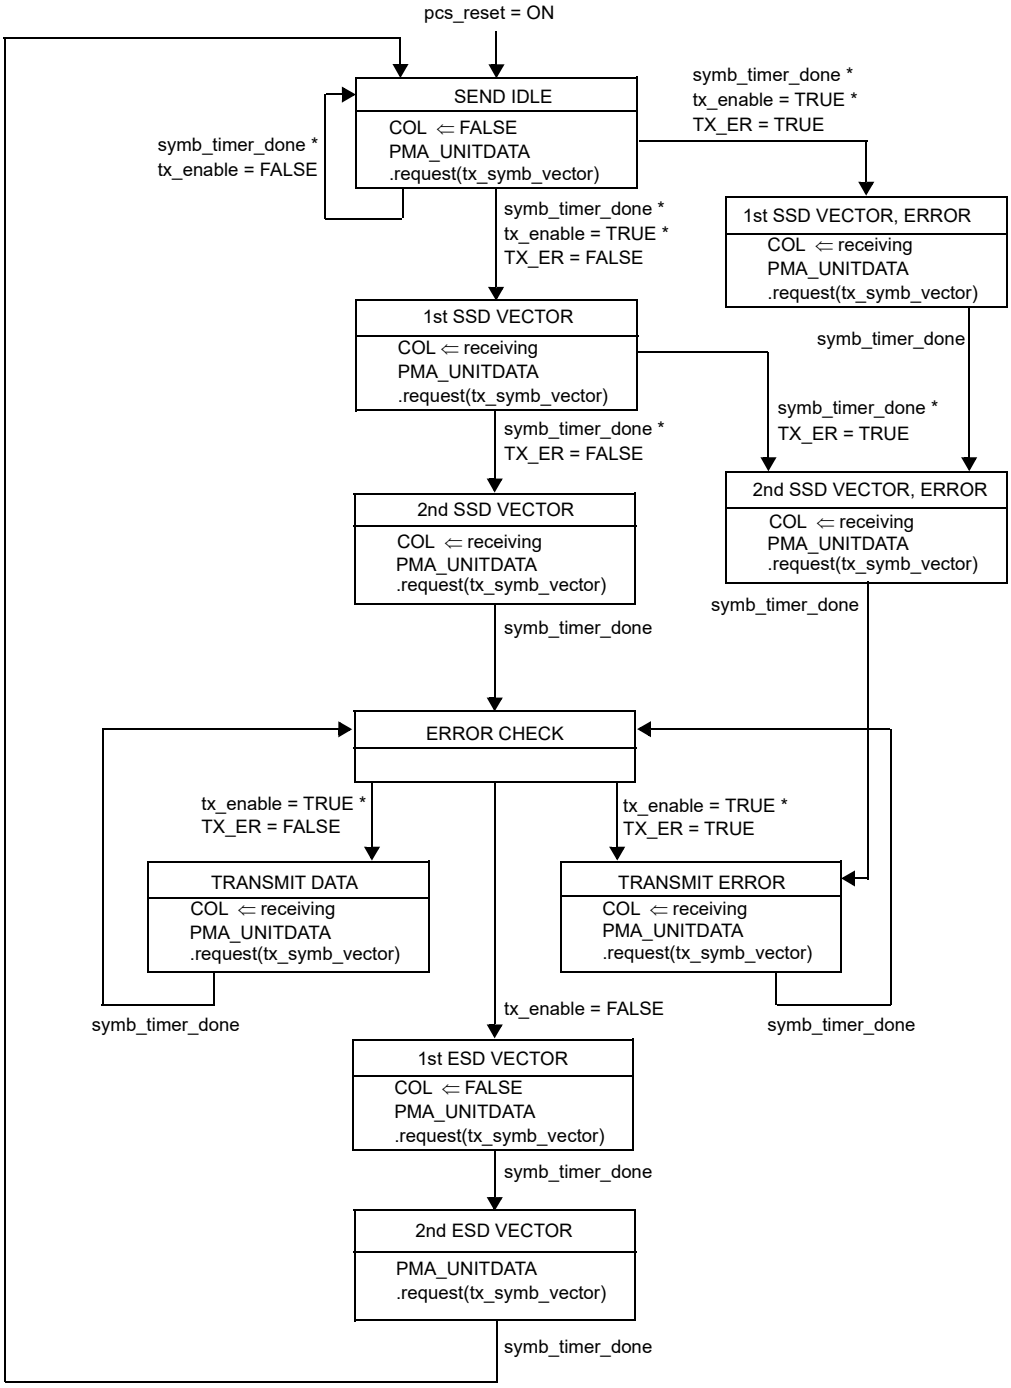
Receive continuously checks that the received sequence satisfies the encoding rule used in idle mode. As soon as a violation is detected, PCS Receive asserts the parameter receiving and determines whether the violation is due to reception of "SSD" or to a receiver error by examining the last two received vectors (RA_{n-1}, RB_{n-1}) and (RA_n, RB_n). In the first case, during the two symbol periods corresponding to "SSD," PCS Receive replaces "SSD" by preamble bits. Following "SSD," the signal RX_DV is asserted and each received vector is decoded into a data nibble RXD<3:0> until "ESD" is detected. Deassertion of RX_DV and transition to the IDLE state take place upon detection of "ESD". The signal RX_ER is asserted if a receiver error occurs before proper stream termination. In the second case, the signal RX_ER is asserted and the parameter rxerror_status assumes the value ERROR. Deassertion of RX_DV and transition to the IDLE state (rxerror_status=NO_ERROR) takes place upon detection of a sequence generated in idle mode.

A premature stream termination is caused by the detection of four consecutive vectors satisfying the encoding rule used in idle mode prior to the detection of "ESD", provided that the first vector is not a valid data vector. Note that RX_DV remains asserted during the symbol periods corresponding to the first three idle vectors, while RX_ER=TRUE is signaled on the MII. The signal RX_ER is also asserted in the LINK FAILED state, which ensures that RX_ER remains asserted for at least one symbol period. The PCS shall implement the Receive process as depicted in Figure 32–13 including compliance with the associated state variables as specified in 32.3.4.

The parameters receiving and rxerror_status are communicated to the PCS's clients by the following primitives:

PCS_CARRIER.indication (carrier_status)
: A signal generated by PCS Receive to indicate reception of non-idle quinary symbols. The purpose of this primitive is to give clients indication of activity on the underlying continuous-signaling channel.

PCS_RXERROR.indication (rxerror_status)
: A signal generated by PCS Receive to indicate a reception of non-idle symbols that does not start with "SSD."



32.3.5.3 PCS Carrier Sense

The PCS Carrier Sense process generates the signal CRS on the MII, which the MAC uses via the Reconciliation sublayer for frame receptions and for deferral. The process operates by performing logical operations on TX_EN and receiving. The PCS shall implement the Carrier Sense process as depicted in Figure 32–14 including compliance with the associated state variables as specified in 32.3.4.

32.3.6 PCS electrical specifications

The interface between PCS, PMA and PHY Control is an abstract message-passing interface, having no specified electrical properties. Electrical characteristics of the signals passing between the PCS and MII may be found in Clause 22.

32.4 PMA functional specifications and service interface

32.4.1 PMA functional specifications

The PMA couples messages from a PMA service interface specified in 32.4.2 to the 100BASE-T2 baseband medium, specified in 32.7. The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), specified in 32.8.

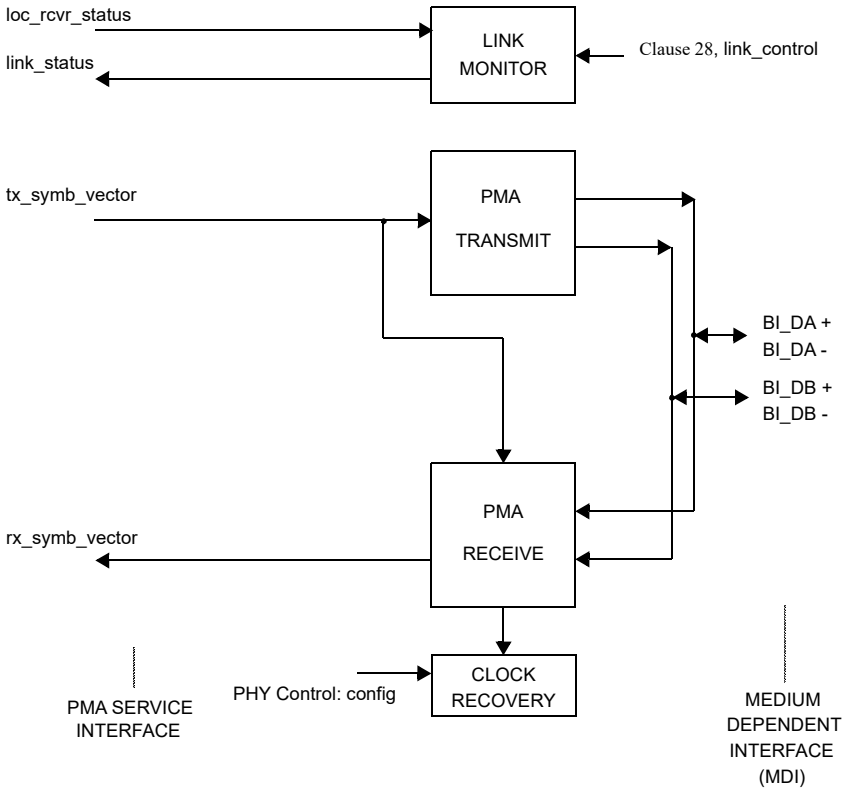

Figure 32–15—PMA reference diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.4.1.1 PMA functions

The PMA sublayer comprises one PMA Reset function and four simultaneous and asynchronous operating functions. The PMA operating functions are PMA Transmit, PMA Receive, Link Monitor, and Clock Recovery. All operating functions are started immediately after the successful completion of the PMA Reset function. The Reset function may be shared between PMA and PCS sublayers.

The PMA reference diagram, Figure 32–15, shows how the operating functions relate to the messages of the PMA Service interface, PHY Control Service interface, and the signals of the MDI. Connections from the management interface, comprising the signals MDC and MDIO, to other layers are pervasive, and are not shown in Figure 32–15. The management interface and its functions are specified in Clause 22.

32.4.1.1.1 PMA Reset function

The PMA Reset function shall be executed any time either of two conditions occurs. These two conditions are "power on" and the receipt of a reset request from the management entity. The PMA Reset function initializes all PMA functions and forces Auto-Negotiation to be executed. The PMA Reset function sets pma_reset = ON for the duration of its reset function. All state diagrams take the open ended pma_reset branch upon execution of the PMA Reset function. The reference diagrams do not explicitly show the PMA Reset function.

32.4.1.1.2 PMA Transmit function

The PMA Transmit function comprises two independent transmitters to generate five-level pulse-amplitude modulated signals on each of the two pairs BI_DA and BI_DB. PMA Transmit shall continuously transmit onto the MDI pulses modulated by the quinary symbols given by tx_symb_vector[BI_DA] and tx_symb_vector[BI_DB], respectively. The two transmitters shall be driven by the same transmit clock. The signals generated by PMA Transmit will follow the mathematical description given in 32.4.1.2.1, and shall comply with the electrical specifications given in 32.6.

32.4.1.1.3 PMA Receive function

The PMA Receive function comprises two independent receivers for quinary pulse-amplitude modulated signals on each of the two pairs BI_DA and BI_DB. PMA Receive contains the circuits necessary to detect quinary symbol sequences from the signals received at the MDI over receive pairs BI_DA and BI_DB and present these sequences to the PCS Receive function. The signals received at the MDI are described mathematically in 32.4.1.2.2. The PHY shall translate the signals received on pairs BI_DA and BI_DB into the PMA_UNITDATA.indication parameter rx_symb_vector with a symbol error ratio of less than one part in 10^{10}.

To achieve the indicated performance, it is highly recommended that PMA Receive include the functions of signal equalization, suppression of cyclo-stationary interference signals created by alien near-end crosstalk sources, and echo and self near-end crosstalk cancellation. The sequence of quinary transmitted symbols tx_symb_vector is needed to perform echo and self near-end crosstalk cancellation.

32.4.1.1.4 Link Monitor function

Link Monitor determines the status of the underlying receive channel. Failure of the underlying receive channel typically causes the PMA's clients to suspend normal operation.

The Auto-Negotiation process notifies Link Monitor whether the device connected to the far end is of type 100BASE-T2. Based on this and other information, Link Monitor sets two important internal variables:

a) The pma_type variable that indicates whether the remote station is of type 100BASE-T2 or not,
b) The link_status variable that is sent across the PMA Service interface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Link Monitor function shall comply with the state diagram of Figure 32-16.

Upon power-on, reset, or release from power-down, the Auto-Negotiation algorithm sets link_control=SCAN_FOR_CARRIER and sends during this period fast link pulses to signal its presence to a remote station. If the presence of a remote station is sensed through reception of fast link pulses, the Auto-Negotiation algorithm sets link_control=DISABLE and exchanges Auto-Negotiation information with the remote station. During this period, link_status=FAIL is asserted. If the presence of a remote 100BASE-T2 station is established, the Auto-Negotiation algorithm permits full operation by setting link_control=ENABLE. As soon as reliable transmission is achieved, the variable link_status=OK is asserted, upon which further PHY operations can take place.

32.4.1.1.5 Clock Recovery function

The Clock Recovery function couples to both receive pairs. It provides a synchronous clock for sampling the signals on the two pairs.

The Clock Recovery function shall provide a clock suitable for synchronous signal sampling on each line so that the symbol error ratio indicated in 32.4.1.1.3 is achieved. The received clock signal has to be stable and ready for use when training has been completed (loc_rcvr_status=OK).

32.4.1.2 PMA interface messages

The messages between the PMA, PCS, and PHY Control are defined in 32.4.2, PMA Service Interface. Communication through the MDI is summarized below.

32.4.1.2.1 MDI signals transmitted by the PHY

The quinary symbols to be transmitted by the PMA on the two pairs BI_DA and BI_DB are denoted by tx_symb_vector[BI_DA] and tx_symb_vector[BI_DB], respectively. Five-level Pulse Amplitude Modulation over each pair (PAM5×5) is the modulation scheme employed in 100BASE-T2. It is the function of PMA Transmit to generate on each pair a pulse-amplitude modulated signal of the form

$$s(t) = \sum_k a_k h_1(t - kT)$$

where a_k represents the quinary symbol from the set {–2, –1, 0, +1, +2} to be transmitted at time kT, and $h_1(t)$ denotes the system symbol response at the MDI. This symbol response shall comply with the electrical specifications given in 32.6.

32.4.1.2.2 Signals received at the MDI

Signals received at the MDI can be expressed for each pair as pulse-amplitude modulated signals that are corrupted by noise:

$$r(t) = \sum_k a_k h_2(t - kT) + w(t)$$

In this equation, $h_2(t)$ denotes the impulse response of the overall channel from the transmit side up to the MDI at the receive side, and $w(t)$ is a term that includes the contribution of various noise sources. The two signals received on pair BI_DA and BI_DB shall be processed within the PMA Receive function to yield the quinary received symbols rx_symb_vector[BI_DA] and rx_symb_vector[BI_DB].

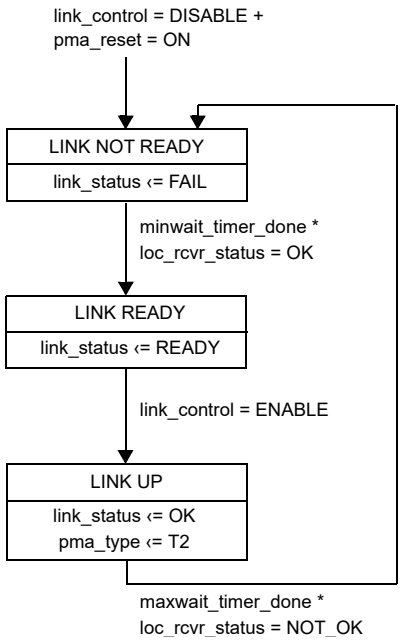
32.4.1.3 PMA state diagram

32.4.1.3.1 State diagram variables

link_control
: The link_control parameter as communicated by the PMA_LINK.request primitive.
Values: See 32.4.2.4.

link_status
: The link_status parameter as communicated by the Link Monitor function through the PMA_LINK.indication primitive.
Values: See 32.4.2.5.

loc_rcvr_status
: The loc_rcvr_status parameter as communicated by the PMA_RXSTATUS.request primitive.
Values: See 32.2.2.3.1.



pma_reset
: Allows reset of all PMA functions.
Values: ON and OFF
Set by: PMA Reset

32.4.1.3.2 Timers

maxwait_timer
: Values: See 32.2.4.

minwait_timer
: Values: See 32.2.4.

32.4.1.3.3 Link Monitor state diagram

NOTE—The variables link_control and link_status are designated as link_control_[T2] and link_status_[T2], respectively, by the Auto-Negotiation Arbitration state diagram (Figure 28–18).

32.4.2 PMA service interface

This subclause specifies the services provided by the PMA. These services are described in an abstract manner and do not imply any particular implementation. The PMA Service Interface supports the exchange of symbol vectors, status indications, and control signals between the PMA, the PCS, and PHY Control. The following primitives are defined:

PMA_TYPE.indication
PMA_UNITDATA.request
PMA_UNITDATA.indication
PMA_LINK.request
PMA_LINK.indication
PMA_CARRIER.indication
PMA_RXERROR.indication

The parameter config is passed from PHY Control to the PMA via the primitive PHYC_CONFIG.indication. The definition of this parameter is given for the PHY Control Service interface in 32.2.2.1 and is not repeated here for the PMA Service interface.

32.4.2.1 PMA_TYPE.indication

This primitive is generated by the PMA to indicate the nature of the PMA instantiation. Its purpose is to allow clients to support connections to the various types of 100BASE-T PMA entities in a generalized manner.

32.4.2.1.1 Semantics of the service primitive

PMA_TYPE.indication (pma_type)

The pma_type parameter for use with the 100BASE-T2 PMA is T2.

32.4.2.1.2 When generated

The PMA shall continuously generate this primitive to indicate the value of pma_type.

32.4.2.1.3 Effect of receipt

The client uses the value of pma_type to define the semantics of the primitives defined at the PMA service interface.

32.4.2.2 PMA_UNITDATA.request

This primitive defines the transfer of pairs of quinary symbols in the form of the tx_symb_vector parameter from the PCS to the PMA. The quinary symbols are obtained in the PCS Transmit function using the encoding rules defined in 32.3.1.2 to represent MII data streams, an idle mode, or other sequences.

32.4.2.2.1 Semantics of the service primitive

PMA_UNITDATA.request (tx_symb_vector)

During transmission using 100BASE-T2 signaling, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb_vector the value of the symbols to be sent over each of the two transmit pairs BI_DA and BI_DB. The tx_symb_vector parameter takes on the form:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SYMB_PAIR A vector of two quinary symbols, one for each of the two transmit pairs BI_DA and BI_DB. Each quinary symbol may take on one of the values –2, –1, 0, +1 or +2.

The quinary symbols that are elements of tx_symb_vector are called, according to the pair on which each will be transmitted, tx_symb_vector[BI_DA] and tx_symb_vector[BI_DB].

32.4.2.2.2 When generated

The PCS generates PMA_UNITDATA.request (SYMB_PAIR) synchronously with every MII TX_CLK cycle.

32.4.2.2.3 Effect of receipt

Upon receipt of this primitive, the PMA transmits on the MDI the signals corresponding to the indicated quinary symbols. The parameter tx_symb_vector is also used by the PMA Receive function to process the signals received on pairs BI_DA and BI_DB.

32.4.2.3 PMA_UNITDATA.indication

This primitive defines the transfer of pairs of quinary symbols in the form of the rx_symb_vector parameter from the PMA to the PCS.

32.4.2.3.1 Semantics of the service primitive

PMA_UNITDATA.indication (rx_symb_vector)

During reception of PAM5×5 signals using 100BASE-T2 signaling, the PMA_UNITDATA.indication simultaneously conveys to the PCS via the parameter rx_symb_vector the values of the symbols detected on each of the two receive pairs BI_DA and BI_DB. The rx_symbol_vector parameter takes on the form:

SYMB_PAIR A vector of two quinary symbols, one for each of the two receive pairs BI_DA and BI_DB. Each quinary symbol may take on one of the values –2, –1, 0, +1 or +2.

The quinary symbols that are elements of rx_symb_vector are called, according to the pair upon which each symbol was received, rx_symbol_vector[BI_DA] and rx_symb_vector[BI_DB].

32.4.2.3.2 When generated

The PMA shall generate PMA_UNITDATA.indication (SYMB_PAIR) messages synchronously with signals received at the MDI.

32.4.2.3.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

32.4.2.4 PMA_LINK.request

This primitive allows the Auto-Negotiation algorithm to enable and disable operation of the PMA.

32.4.2.4.1 Semantics of the service primitive

PMA_LINK.request (link_control)

The link_control parameter can take on one of three values: SCAN_FOR_CARRIER, DISABLE, or ENABLE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SCAN_FOR_CARRIER	Used by the Auto-Negotiation algorithm prior to receiving any fast link pulses. During this mode the PMA reports link_status=FAIL. PHY processes are disabled.
DISABLE	Set by the Auto-Negotiation algorithm in the event fast link pulses are detected. *PHY processes are disabled.* This allows the Auto-Negotiation algorithm to determine how to configure the link.
ENABLE	Used by Auto-Negotiation to turn control over to the PHY for data processing functions.

32.4.2.4.2 When generated

Upon power on, reset, or release from power down, the Auto-Negotiation algorithm issues the message PMA_LINK.request (SCAN_FOR_CARRIER).

32.4.2.4.3 Effect of receipt

While link_control=SCAN_FOR_CARRIER or link_control=DISABLE, the PMA shall report link_status=FAIL. While link_control=ENABLE, PHY Control determines the operations to be performed by the PHY.

32.4.2.5 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium. This primitive informs the PCS, PHY Control and the Auto-Negotiation algorithm about the status of the underlying link.

32.4.2.5.1 Semantics of the service primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on one of three values: FAIL, READY, or OK.

FAIL	No valid link established.
READY	Training completed after Auto-Negotiation.
OK	The Link Monitor function indicates that a valid 100BASE-T2 link is established. Reliable reception of signals transmitted from the remote PHY is possible.

32.4.2.5.2 When generated

The PMA shall generate this primitive to indicate the value of link_status in compliance with the state diagrams given in Figure 32-16.

32.4.2.5.3 Effect of receipt

The effect of receipt of this primitive is specified in 32.2 and 32.3.

32.4.2.6 PMA_CARRIER.indication

This primitive is identical to PCS_CARRIER.indication defined in 32.3.5.2. It is not explicitly shown in the PMA reference diagram.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.4.2.7 PMA_RXERROR.indication

This primitive is identical to PCS_RXERROR.indication defined in 32.3.5.2. It is not explicitly shown in the PMA reference diagram.

32.4.2.8 PMA_RXSTATUS.request

This primitive allows the Link Monitor to determine via the parameter loc_rcvr_status generated by the PCS Receive function whether reliable receiver operations are established. The parameter loc_rcvr_status is also passed from the PCS Receive function to the PHY Control Service interface via the primitive PHYC_RXSTATUS.request. The definition of this parameter is given for the PHY Control Service interface in 32.2.2.3 and is not repeated here for the PMA Service interface.

32.5 Management functions

100BASE-T2 makes extensive use of the management functions provided by the Media Independent Interface (Clause 22) and the communication and self-configuration functions provided by Auto-Negotiation (Clause 28.)

In addition to the provision of MII registers 0, 1, 4, 5, 6, and 7, it is required that implementations that support 100BASE-T2 also provide equivalents to MII registers 8, 9, and 10 (Clause 22). Register 8 is used to provide the Auto-Negotiation Link Partner NEXT Page Register, register 9 is used to provide the MASTER-SLAVE Control Register, and register 10 is used to provide the MASTER-SLAVE Status Register. These registers are used to configure PHYs for testing, to manually configure PHYs for MASTER-SLAVE negotiation, to store the contents of Next Pages during the Auto-Negotiation process, and to store information reporting the results of the master/slave configuration process as described in the next subclause.

32.5.1 100BASE-T2 Use of Auto-Negotiation and MII Registers 8, 9, and 10

On power-up, before Auto-Negotiation starts, the Auto-Negotiation Advertisement register shall have the following configuration: The Selector Field (4.4:0) is set to an appropriate code as specified in Annex 28A. The Acknowledge bit (4.14) is set to logic zero. The Technology Ability Field (4:9:5) is set based on the values set in the MII Status Register (register 1) (1.15:11) or equivalent and (4.11:10) is set based on the values set in the MII Status Register (register 1) (1.10:9) or equivalent.

When Auto-Negotiation begins, 100BASE-T2 implementations send an Auto-Negotiation Base Page with bit D15 set to logical one to indicate that a Next Page follows (see 28.2.1.2.)

The Base Page is followed by a formatted Next Page containing the 100BASE-T2 Technology Ability Message Code (7), which indicates that two Unformatted Next Pages containing the 100BASE-T2 Technology Ability fields follow (see Table 28C–1.)

Two Unformatted Next Pages are sent using the 100BASE-T2 Technology Ability fields shown in Table 32–6 Register 8 will be used to store the transmitted information while it is being processed as described below.

Bit U0 of page 1 shall be copied from MII register 4.10 to indicate 100BASE-T2FD advertised ability.

Bit U1 of page 1 shall be copied from MII register 4.11 to indicate 100BASE-T2HD advertised ability.

Bit U2 of page 1 shall be copied from MASTER-SLAVE control register 9.10 to indicate that the PHY device is a repeater port or DTE for 100BASE-T2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Bits U3 and U4 shall be copied from MASTER-SLAVE control register (bits 9.12 and 9.11) for use by the MASTER-SLAVE negotiation process as described below.

Bits U5-U10 of page 1 and U0-U9 of page 2 shall be used to define the seed used for the MASTER-SLAVE negotiation process described as follows.

Using the information described above, the PHY performs a MASTER-SLAVE configuration process as defined in 32.5.4.3. This process is conducted at the entrance to the FLP LINK GOOD CHECK state shown Auto-Negotiation Arbitration State Diagram (Figure 28–18.)

If the local device detects that both the local device and the remote device are of the same type (either repeater or DTE) and that both have generated the same random seed, it sets the Ack2 bit of register 8 to logical zero and generates and transmits a new random seed for MASTER-SLAVE negotiation.

The MASTER-SLAVE configuration process returns one of the three following outcomes.

Successful: Bit 10:15 of the MASTER-SLAVE Status Register is set to logical zero and bit 10.14 is set to logical one. 100BASE-T2 returns control to Auto-Negotiation (at the entrance to the FLP LINK GOOD CHECK state in Figure 28–18) and passes the value of MASTER or SLAVE to PHYC_CONFIG.indication (see 32.2.2.)

Unsuccessful: link_status_T2 is set to FAIL and Auto-Negotiation restarts (see Figure 28–18.)

Fault detected: (This happens when both end stations are set for manual configuration and both are set to MASTER or both are set to SLAVE.) Bit 10.15 of the MASTER-SLAVE Status Register is set to logical one to indicate that a manual configuration fault has been detected and bit 10.14 is set to logical one to indicate that MASTER-SLAVE resolution completed with a fault. Because the MASTER-SLAVE relationship was not established, link_status_T2 is set to FAIL, causing Auto-Negotiation to restart.

32.5.2 Management functions

The management interface specified in Clause 22 provides a simple, two-wire, serial interface to connect a management entity and a managed PHY for the purposes of controlling the PHY and gathering status from the PHY. This interface is referred to as the MII Management Interface. The register definition specifies a basic register set with an extension mechanism.

100BASE-T2 requires the basic register set that consists of two registers referred to as the Control Register (register 0) and the Status Register (register 1) and of some PHY-specific registers. The detailed definitions of these registers are given in 22.2.4.

The full set of management registers is listed in Table 22–6 and 100BASE-T2 PHY specific registers are given in Table 32–3.

Table 32–3—100BASE-T2 Control and Status registers

Register address	Register name	Basic/Extended
9	MASTER-SLAVE Control register	E
10	MASTER-SLAVE Status register	E

32.5.3 PHY specific registers for 100BASE-T2

Some of the extended registers (registers with addresses 2 to 15) are used as PHY specific registers as described in 22.2.4.3. A 100BASE-T2 PHY shall use register addresses 9 and 10 for its control and status functions. The bits in the 100BASE-T2 Control register are used to place the PHY into several possible test modes and to determine the MASTER-SLAVE relationship during Auto-Negotiation. The bits in the 100BASE-T2 Status register are used to report the MASTER-SLAVE relationship determined during Auto-Negotiation, the local and remote receiver status, and provide an idle error counter.

32.5.3.1 100BASE-T2 Control register (Register 9)

Register 9 shall provide the following values for 100BASE-T2. The assignment of bits in the register is shown in Table 32–4. The default value for each bit of the register should be chosen so that the initial state of the PHY upon power up or reset is a normal operational state without management intervention.

Table 32–4—100BASE-T2 Control register (MII management Register 9) bit definition

Bit(s)	Name	Description	R/W
9.15:14	Transmitter test mode	Default bit values are “00”	R/W
9.13	Receiver test mode	Default bit value is “0”	R/W
9.12	MASTER-SLAVE Manual Configuration Enable	1 = Enable MASTER-SLAVE Manual Configuration value 0 = Disable MASTER-SLAVE Manual Configuration value (default)	R/W
9.11	MASTER-SLAVE Manual Configuration Value	1 = Configure PHY as MASTER during MASTER-SLAVE negotiation, only when 9.12 is set to logical one. 0 = Configure PHY as SLAVE during MASTER-SLAVE negotiation, only when 9.12 is set to logical one.	R/W
9.10	T2_Repeater/DTE bit	1 = Repeater device port 0 = DTE device	R/W
9.9:0	Reserved		

32.5.3.1.1 Transmitter test mode

For a PHY with 100BASE-T2 capability, the PHY shall be placed in transmitter test mode 1 operation (described in 32.6.1.2.1) when bit 9.15 is set to logical zero and bit 9.14 is set to logical one. When bit 9.15 is set to logical one and bit 9.14 is set to logical zero, the PHY shall be placed in transmitter test mode 2 operation as described in 32.6.1.2.1. When bit 9.15 is set to logical one and bit 9.14 is set to logical one, the PHY shall be placed in the transmitter test mode 3 operation as described in 32.6.1.2.1.

The default value for bits 9.15:14 are all zero.

32.5.3.1.2 Receive test mode

The PHY shall be placed in the receiver test mode as described in 32.6.1.3.2 when the bit 9.13 is set to logical one.

The default value for bit 9.13 is zero.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.5.3.1.3 MASTER-SLAVE Manual Configuration Enable

The MASTER-SLAVE relationship is established during Auto-Negotiation via either automatic MASTER-SLAVE configuration or manual configuration. If bit 9.12 is set to logical zero, then the MASTER-SLAVE configuration negotiation function will determine the PHY configuration. If bit 9.12 is set to logical one, then manual MASTER-SLAVE configuration is enabled, using 9.11 to specify the value. (Usage of this bit is further described in 32.5.3.1.)

The default value of bit 9.12 is zero.

32.5.3.1.4 MASTER-SLAVE Manual Configuration Value

MASTER-SLAVE Manual configuration is enabled by setting bit 9.12 to logical one. When manual configuration mode is enabled, setting bit 9.11 to logical one configures the PHY as MASTER, and setting bit 9.11 to logic zero configures the PHY as SLAVE during MASTER-SLAVE negotiation process and shall be used to report the result of the MASTER-SLAVE configuration resolution for that PHY. Detailed description of the use of this bit in MASTER-SLAVE configuration resolution is provided in 32.5.3.1.

The default value of bit 9.11 is zero.

32.5.3.1.5 T2_Repeater/DTE Bit

Bit 9.10 shall be set to logical zero if the PHY is a DTE device and shall be set to a logical one if the PHY is a repeater device port (usage of this bit is described in 32.5.2.)

32.5.3.1.6 Reserved bits

Bits 9.9:0 are reserved for future standardization. They shall be written as zero and shall be ignored when read; however, a PHY shall return the value zero in these bits.

32.5.3.2 100BASE-T2 Status register (Register 10)

Register 10 shall provide the following values for 100BASE-T2. The assignment of bits in the register is shown in Table 32–5. The default value for each bit of the register should be chosen so that the initial state of the PHY upon power up or reset is a normal operational state without management intervention.

Table 32–5—100BASE-T2 Status register (MII management Register 10) bit definition

Bit(s)	Name	Description	R/W[a]
10.15	MASTER-SLAVE manual configuration fault	1 = MASTER-SLAVE manual configuration fault detected 0 = No MASTER-SLAVE manual configuration fault detected	RO/SC
10.14	MASTER-SLAVE configuration resolution complete	1 = MASTER-SLAVE configuration resolution has completed 0 = MASTER-SLAVE configuration resolution has not completed	RO
10.13	Local Receiver Status	1 = Local Receiver OK 0 = Local Receiver not OK	RO
10.12	Remote Receiver Status	1 = Remote Receiver OK 0 = Remote Receiver not OK	RO
10.11:8	Reserved		
10.7:0	Idle Error Count	Idle Error count	RO/SC

[a]R/W = Read/Write, SC = Self Clearing, RO = Read Only

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.5.3.2.1 MASTER-SLAVE Manual Configuration Fault

When read as a logical one, bit 10.15 indicates that a MASTER-SLAVE Manual Configuration Fault condition has been detected. The type of fault as well as the criteria and method of fault detection is PHY specific. The MASTER-SLAVE Manual Configuration Fault bit shall be implemented with a latching function, such that the occurrence of a MASTER-SLAVE Manual Configuration Fault will cause the MASTER-SLAVE Manual Configuration Fault bit to be set and remain set until it is cleared. The MASTER-SLAVE Manual Configuration Fault bit shall be cleared each time register 10 is read via the management interface and shall also be cleared by a 100BASE-T2 PMA reset.

For 100BASE-T2, this fault condition will occur when both PHYs are forced to be MASTER or SLAVE at the same time using bits 9.12 and 9.11. Bit 10.15 should be set via the MASTER-SLAVE Configuration Resolution function described in 32.5.4.

32.5.3.2.2 MASTER-SLAVE Configuration Resolution Complete

When read as a logical one, bit 10.14 indicates that the MASTER-SLAVE Resolution process has been completed and that the contents of registers 9 and 10 related to MASTER-SLAVE are valid. When read as a logic zero, bit 10.14 indicates that the MASTER-SLAVE Configuration Resolution process has not been completed and that the contents of registers 9 and 10 which are related to MASTER-SLAVE resolution are invalid. Bit 10.14 should be set via the MASTER-SLAVE Configuration Resolution function described in 32.5.4.

32.5.3.2.3 Local Receiver Status

Bit 10.13 indicates the status of the local receiver. Local receiver status is defined by the value of the loc_rcvr_status variable described in 32.2.3.

32.5.3.2.4 Remote Receiver Status

Bit 10.12 indicates the status of the remote receiver. Remote receiver status is defined by the value of the rem_rcvr_status variable described in 32.2.3.

32.5.3.2.5 Reserved bits

Bit 10.11:8 are reserved for future standardization. They shall be written as zero and shall be ignored when read; however, a PHY shall return the value zero in these bits.

32.5.3.2.6 Idle Error count

Bits 10.7:0 indicate the Idle Error count, where 10.7 is the most significant bit. During normal operation these bits contain a cumulative count of the errors detected when the receiver is receiving idles and the PHY Control parameter tx_mode is equal to SEND_N (indicating that both local and remote receiver status have been detected to be OK). When the PHY has receiver test mode (bit 9.13) enabled, these bits contain a cumulative count of the errors detected at all times when the local receiver status is OK. These bits are reset to all zeros when the error count is read by the management function or upon execution of the PCS Reset function and they are held at all ones in case of overflow (see 30.5.1.1.13).

32.5.4 Changes and additions to Auto-Negotiation (Clause 28)

32.5.4.1 Change to 28.2.4.1.3 (Auto-Negotiation Advertisement register)

For implementations which support 100BASE-T2, the Technology Ability Field (4:9:5) is set based on the values set in the MII Status Register (register 1) (1.15:11) or equivalent and (4.11:10) is set based on the values set in the MII Status Register (register 1) (1.10:9) or equivalent. Use of register 4 is defined in 28.2.4.1.3.

32.5.4.2 Use of Auto-Negotiation Next Page codes for 100BASE-T2 PHYs

For a PHY capable of 100BASE-T2 transmission, during Auto-Negotiation the Base Page will be followed by a Next Page with a message code containing the 100BASE-T2 Technology Ability Message Code (7) as shown in Table 28C–1. This Message Next Page indicates that two Unformatted Message Next Pages will follow which contain the 100BASE-T2 Technology Ability Fields as described in Table 32–6.

Table 32–6—Bit assignments for Unformatted Next Pages containing 100BASE-T2 Technology Ability Field

Bit	Technology	MII register bit/source
PAGE 1		
U0	100BASE-T2 Half Duplex (1 = Half Duplex and 0 = no Half Duplex)	MII register 4.10
U1	100BASE-T2 Full Duplex (1=Full Duplex and 0 = no Full Duplex)	MII register 4.11
U2	100BASE-T2 Repeater/DTE bit (1 = Repeater and 0 = DTE)	MII register 9.10 (MASTER-SLAVE Control register)
U3	100BASE-T2 MASTER-SLAVE Manual Configuration Enable (1 = Manual Configuration Enable); intended to be used for manual selection in a particular MASTER-SLAVE mode. To be used in conjunction with bit U4	MII register 9.12 (MASTER-SLAVE Control register)
U4	100BASE-T2 MASTER-SLAVE Manual Configuration value 1 = MASTER and 0 = SLAVE. This bit is ignored if U3 = 0.	MII register 9.11 (MASTER-SLAVE Control register)
U5	100BASE-T2 MASTER-SLAVE Seed Bit 0 (SB0) (LSB)	MASTER-SLAVE seed value (15.0)
U6	100BASE-T2 MASTER-SLAVE Seed Bit 1 (SB1)	
U7	100BASE-T2 MASTER-SLAVE Seed Bit 2 (SB2)	
U8	100BASE-T2 MASTER-SLAVE Seed Bit 3 (SB3)	
U9	100BASE-T2 MASTER-SLAVE Seed Bit 4 (SB4)	
U10	100BASE-T2 MASTER-SLAVE Seed Bit 5 (SB5)	
PAGE 2		
U0	100BASE-T2 MASTER-SLAVE Seed Bit 6 (SB6)	
U1	100BASE-T2 MASTER-SLAVE Seed Bit 7 (SB7)	
U2	100BASE-T2 MASTER-SLAVE Seed Bit 8 (SB8)	
U3	100BASE-T2 MASTER-SLAVE Seed Bit 9 (SB9)	
U4	100BASE-T2 MASTER-SLAVE Seed Bit 10 (SB10)	
U5	100BASE-T2 MASTER-SLAVE Seed Bit 11 (SB11)	
U6	100BASE-T2 MASTER-SLAVE Seed Bit 12 (SB12)	
U7	100BASE-T2 MASTER-SLAVE Seed Bit 13 (SB13)	
U8	100BASE-T2 MASTER-SLAVE Seed Bit 14 (SB14)	
U9	100BASE-T2 MASTER-SLAVE Seed Bit 15 (SB15)	
U10	unused

32.5.4.3 MASTER-SLAVE Configuration Resolution

Since both PHYs that share a link segment are capable of being MASTER or SLAVE, a prioritization scheme exists to ensure that the correct mode is chosen. The MASTER-SLAVE relationship shall be determined during Auto-Negotiation using Table 32–7 with the 100BASE-T2 Technology Ability Next Page bit values specified in Table 32–7 and information received from the link partner.

Table 32–7—100BASE-T2 MASTER-SLAVE Configuration Resolution table

Local Device Type	Remote Link Partner Type	Resolution Function result	
		Local Device	Remote Link Partner
DTE (U2=0 & U3=0) or Manual SLAVE (U3=1 & U4=0)	Repeater (U2=1 & U3=0) or Manual MASTER (U3=1 & U4=1)	SLAVE	MASTER
Repeater (U2=1 & U3=0)	Manual MASTER (U3=1 & U4=1)		
Manual SLAVE (U3=1 & U4=0)	DTE (U2=0 & U3=0)		
Repeater (U2=1 & U3=0) or Manual MASTER (U3=1 & U4=1)	DTE (U2=0 & U3=0) or Manual SLAVE (U3=1 & U4=0)	MASTER	SLAVE
DTE (U2=0 & U3=0)	Manual Slave (U3=1 & U4=0)		
Manual Master (U3=1 & U4=1)	Repeater (U2=1 & U3=0)		
Repeater (U2=1 & U3=0)	Repeater (U2=1 & U3=0)	PHY with higher seed value is the MASTER. If the seeds are equal, the MASTER-SLAVE resolution is unsuccessful, set link_status_T2=FAIL, causing Auto-Negotiation to restart.	
DTE (U2=0 & U3=0)	DTE (U2=0 & U3=0)		
Manual SLAVE (U3=1 & U4=0)	Manual SLAVE (U3=1 & U4=0)	Fault detected Set link_status_T2=FAIL, forcing Auto-Negotiation to restart.	
Manual MASTER (U3=1 & U4=1)	Manual MASTER (U3=1 & U4=1)		

The rationale for this hierarchy is straightforward. A 100BASE-T2 repeater has higher priority than a DTE to become the MASTER. In the case where both devices are of the same type, e.g., both devices are Repeaters, the device with the higher MASTER-SLAVE seed bits (SB0..SB15), where SB15 is the MSB, becomes the MASTER and the device with the lower seed value becomes the SLAVE. In case both devices have the same seed value, both should assert link_status_T2=FAIL (as defined in 28.3.1) and restart Auto-Negotiation. Successful completion of the MASTER-SLAVE resolution shall be treated as MASTER-SLAVE configuration resolution complete and the 100BASE-T2 Status Register bit 10.14 shall be set to logical one.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The method of generating a random seed is left to the implementer. The generated random seeds should belong to a sequence of independent, identically distributed integer numbers with a uniform distribution in the range of 0 to 65535. The algorithm used to generate the integer should be designed to minimize the correlation between the number generated by any two devices at any given time. A seed counter shall be provided to track the number of seed attempts. The seed counter shall be set to zero at startup and shall be incremented each time a seed is generated. A MASTER-SLAVE resolution fault shall be declared if resolution is not reached after the generation of seven seeds.

The MASTER-SLAVE Manual Configuration Enable bit (control register bit 9.12) is used to manually set a device to become the MASTER or the SLAVE. In case both devices are manually set to become the MASTER or the SLAVE, this condition shall be flagged as a MASTER-SLAVE Manual Configuration fault condition, thus the MASTER-SLAVE Manual Configuration fault bit (status register bit 10.15) shall be set to logical one. The MASTER-SLAVE Manual Configuration fault condition shall be treated as MASTER-SLAVE configuration resolution complete and status register bit 10.14 shall be set to logical one. In this case, link_status_T2 will be set to FAIL, because the MASTER-SLAVE relationship was not resolved. This will force Auto-Negotiation to restart after the link_fail_inhibit_timer has expired. Determination of MASTER-SLAVE values occur on the entrance to the FLP LINK GOOD CHECK state (Figure 28–18) when the highest common denominator (HCD) technology is 100BASE-T2. The resulting MASTER-SLAVE value is used by the 100BASE-T2 PHY control (32.2.2.1).

32.6 PMA electrical specifications

This clause defines the electrical characteristics of the PHY at the MDI.

The ground reference point for all common-mode tests is the MII ground circuit. Implementations without an MII use the chassis ground. The values of all components in test circuits shall be accurate to within ±1% unless otherwise stated.

32.6.1 PMA-to-MDI interface characteristics

32.6.1.1 Isolation requirement

NOTE—Since September 2003, maintenance changes are no longer being considered for this clause. Since February 2021, electrical isolation requirements are in J.1.

The PHY shall provide electrical isolation between the DTE or repeater circuits, including frame ground and all MDI leads. This electrical separation shall withstand at least one of the following electrical strength tests:

a) 1500 V rms at 50–60 Hz for 60 s, applied as specified in Section 5.3.2 of IEC 60950
b) 2250 Vdc for 60 s, applied as specified in Section 5.3.2 of IEC 60950
c) A sequence of ten 2400 V impulses of alternating polarity, applied at intervals of not less than 1 s. The shape of the impulses shall be 1.2/50 μs (1.2 μs virtual front time, 50 μs virtual time or half value), as defined in IEC 60060.

There shall be no insulation breakdown, as defined in Section 5.3.2 of IEC 60950, during the test. The resistance after the test shall be at least 2 MΩ, measured at 500 Vdc.

32.6.1.2 Transmitter electrical specifications

The PMA shall provide the Transmit function specified in 32.4.1.1.2 in accordance with the electrical specifications of this clause.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Where a load is not specified, the transmitter shall meet requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output.

The tolerance on the poles of the test filters used in this clause shall be ±1%.

32.6.1.2.1 Transmitter test modes

Since the 100BASE-T2 PCS employs scrambling, synchronization of data at the MII to the scrambled state is virtually impossible. Therefore a special transmit test mode shall be required to allow for testing of the transmitter waveform. Additionally, a test mode for measuring transmitter output jitter is also required.

For a PHY with a MII interface, these modes shall be enabled by setting bits 9.14 and 9.15 (MASTER-SLAVE Control Register) of the MII Management register set as shown in Table 32–8. These test modes shall only change the data symbols provided to the transmitter circuitry and may not alter the electrical characteristics of the transmitter. A PHY without an MII shall provide a means to provide these functions. The vendor shall provide a means to enable these modes for conformance testing.

Table 32–8—MII management register set

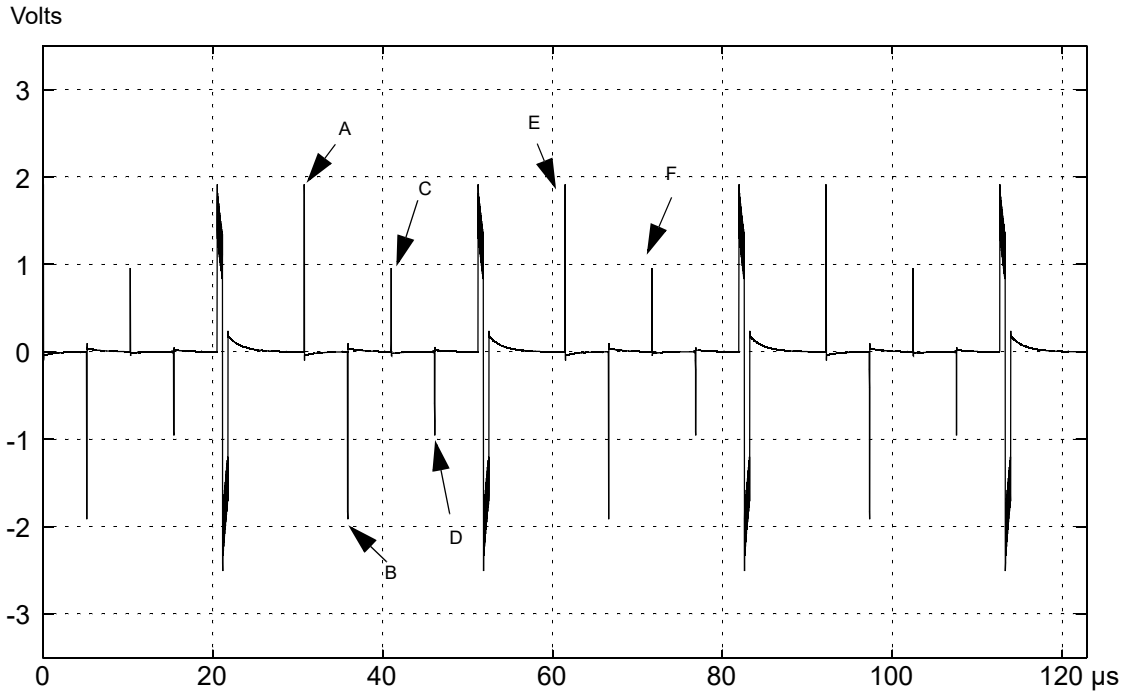
Bit 9.15	Bit 9.14	Mode
0	0	Normal operation
0	1	TX Test mode 1—waveform test
1	0	TX Test mode 2—jitter test
1	1	TX Test mode 3—idle

When transmit test mode 1 is enabled, the PHY shall transmit the following sequence of data symbols (A_n and B_n of 32.3.1.2.3) continually from both transmitters:

{{+2 followed by 127 0 symbols}, {-2 followed by 127 0 symbols},{+1 followed by 127 0 symbols}, {–1 followed by 127 0 symbols}, {16 +2 symbols, 16 –2 symbols followed by 224 0 symbols}}

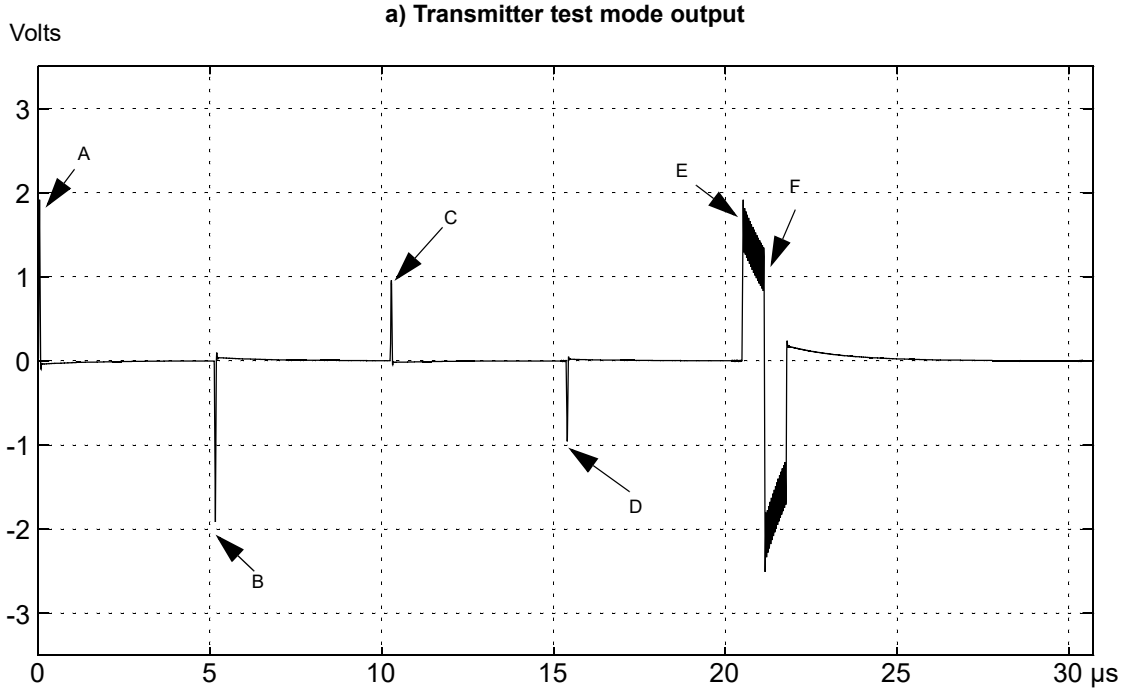
This sequence is repeated continually without breaks between the repetitions when the transmit test mode is enabled. A typical transmitter output is shown below in Figure 32–17. The transmitter shall time the transmitted symbols from a 25.000 MHz ± 0.01% clock.

When transmit test mode 2 is enabled, the PHY shall transmit the data symbol sequence {+2,–2} repeatedly on both channels. The transmitter shall time the transmitted symbols from a 25.000 MHz ± 0.01% clock.



When transmit test mode 3 is enabled, the PHY shall transmit idle data compliant with the idle signaling specified in 32.3 with loc_rcvr_status=OK.

32.6.1.2.2 Peak differential output voltage and level distortion



When in transmit test mode 1 and observing the differential signal output at the MDI terminated in 100 Ω, preprocessed by the high pass filter defined below, for each pair, with no intervening cable, the absolute value of the peak of the waveform at points A and B as defined in Figure 32–17 shall fall within 1.71 V to 1.91 V (1.81 V ± 0.5 dB).

The absolute value of the peak of the waveforms at points A and B shall differ by less than 1%.

The absolute value of the peak of the waveform at points C and D as defined in Figure 32–17 shall differ from 0.5 times the average of the absolute values of the peaks of the waveform at points A and B by less than 2%.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

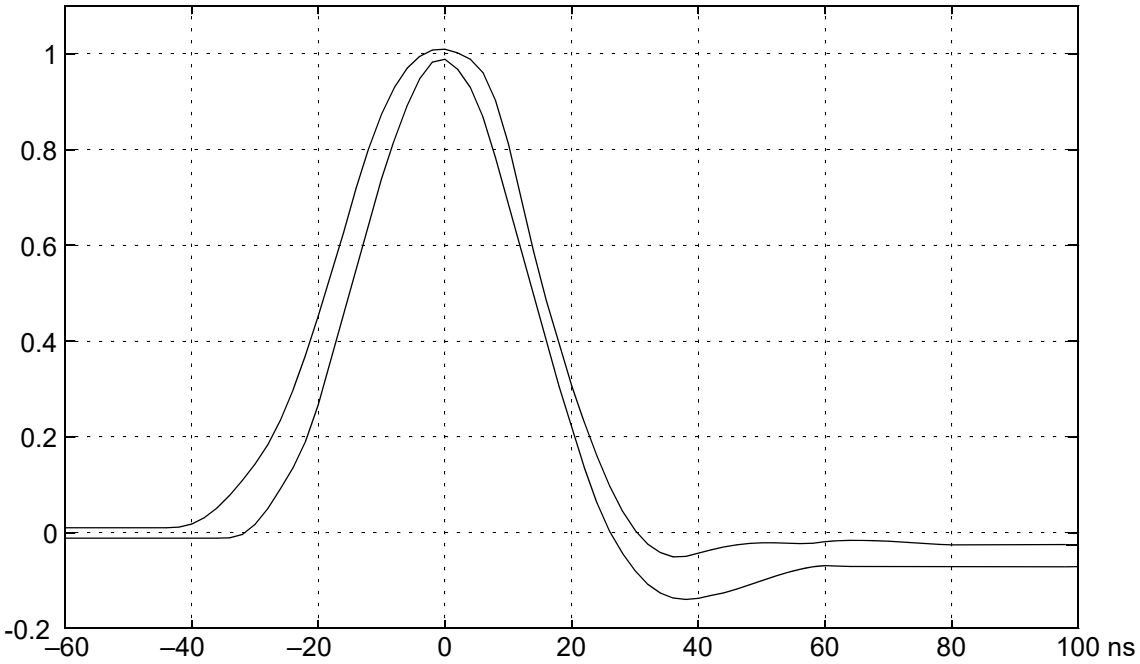
The preprocessing filter shall have the following transfer function:[65]

$$H_{\text{preprocess}}(f) = \frac{\mathrm{j}f}{\mathrm{j}f + 200 \times 10^3} \quad f \text{ in Hz}$$

32.6.1.2.3 Maximum output droop

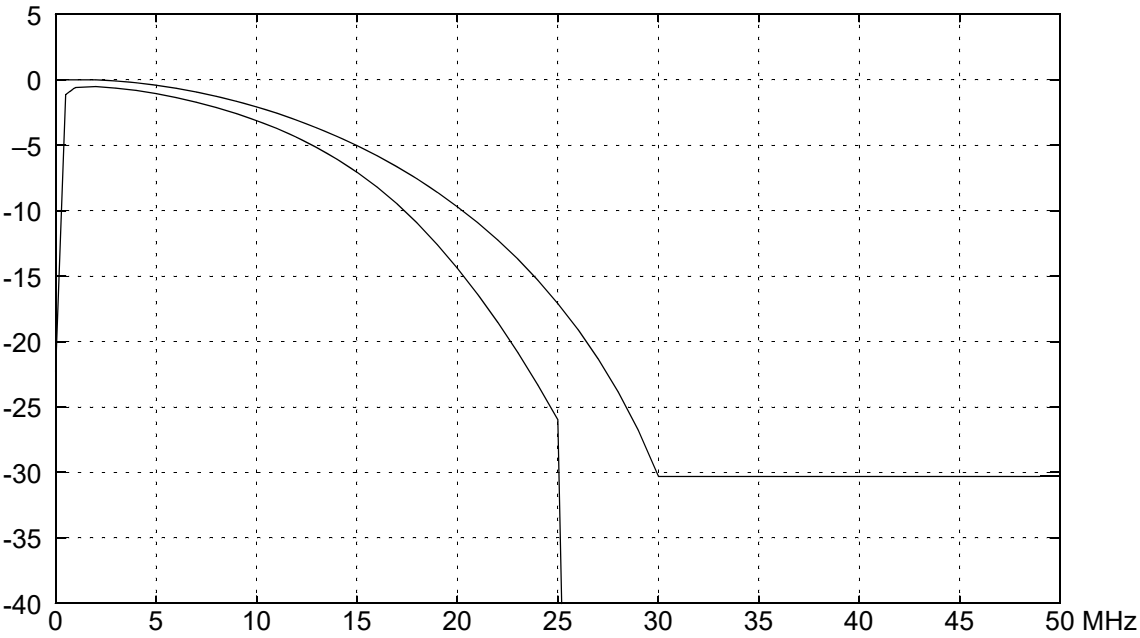
When in transmit test mode 1 and observing the differential signal output at the MDI, for either pair, with no intervening cable, the peak value of the waveform at point F as defined in Figure 32–17 shall be greater than 70.5% of the peak value of the waveform at point E. A preprocessing filter is not used for this measurement.

32.6.1.2.4 Differential output templates



The transmitter differential output voltage shall be measured at the output of the high pass preprocessing filter defined in 32.6.1.2.2, with no intervening cables. The voltage waveforms A, B, C and D defined in Figure 32–17, after normalization by their respective peak values, shall lie within the time domain template defined in Figure 32–18 and the piecewise linear interpolation between the points in Table 32–9. The waveforms may be shifted in time as appropriate to fit within the template.

Additionally, the magnitude in dB of the Fourier transform of the preprocessed waveforms A, B, C and D shall lie within the frequency domain template defined in Figure 32–18 and the piecewise linear interpolation between the points in Table 32–9. The time span of the waveforms so processed shall be –80 ns to +2000 ns with the 0 ns point of the waveform aligned as for the time domain mask shown in Figure 32–18 and the magnitude of the Fourier transform should be normalized so that the maximum value is at 0 dB.[66]



[65]"j" denotes the positive square root of –1.

[66]A sampling rate of 100 MHz is adequate to generate the frequency domain mask.

32.6.1.2.5 Transmitter timing jitter

When in transmit test mode 2, the peak-to-peak jitter of the zero crossings of the differential signal output at the MDI shall be less than 0.5 ns.

32.6.1.2.6 Transmit clock frequency

The quinary symbol transmission rate on each pair shall be 25.000 MHz ± 0.01%.

32.6.1.3 Receiver electrical specifications

The PMA shall provide the Receive function specified in 32.4.1.1.3 in accordance with the electrical specifications of this clause. The patch cabling and interconnecting hardware used in test configurations shall meet or exceed ISO/IEC 11801, Category 3 specifications.

32.6.1.3.1 Test channel

To perform the Receiver Alien NEXT Tolerance test and Receiver timing jitter test described in this clause, a test channel including transmitter, cabling and NEXT models is required. This test channel is shown conceptually in Figure 32–19.

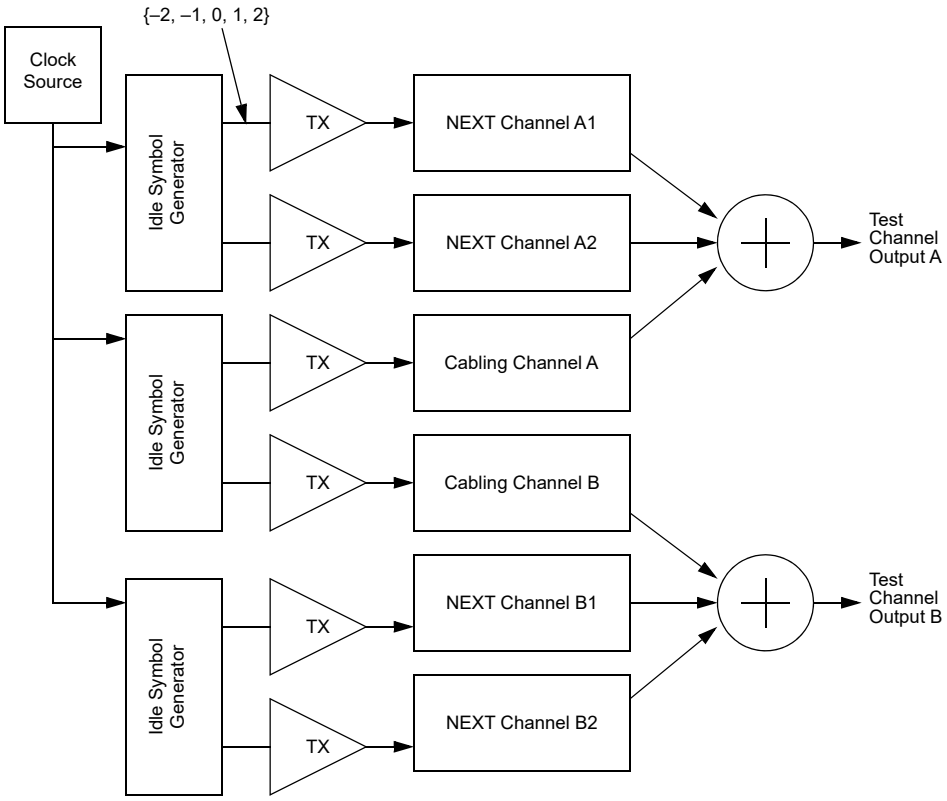

Figure 32–19—Conceptual diagram of test channel

The combined responses of the TX block and NEXT or cabling channel blocks shall be those defined in Table 32–8. The responses of Table 32–10 are shown in Figure 32–20. The responses represent the response of the test channel to isolated "1" symbols in a stream of "0" symbols at the input to the transmitter blocks. The test channel may also include a first order high pass filter with 3 dB cutoff frequency of less than 100 kHz in addition to the tabulated responses. The output impedance of the test channel shall be consistent with 32.6.1.4.1. The idle symbol generator outputs shall be conformant with the idle signaling specified in 32.3 with loc_rcvr_status=OK. The clock source shall result in a quinary symbol transmission rate conformant with 32.6.1.2.6. The peak-to-peak jitter on the clock source shall be less than 0.2 ns.

The test channel may be implemented in any fashion consistent with the above specifications and with the further constraint that the ratio of the squared error between the implemented NEXT channel symbol responses and the specified NEXT channel symbol responses to the energy in the specified NEXT channel symbol responses shall be less than 5% and the energy of the implemented NEXT channel symbol responses and the energy of the specified NEXT channel symbol responses shall differ by less than ± 0.25 dB. If digital filters are used to generate the channel characteristics, care has to be taken to ensure that the signal to quantization noise at the channel output is greater than 35 dB.

The NEXT channel impulse responses defined in Table 32–11 have been developed to simulate the attenuation and phase characteristics of worst case 100BASE-T2 alien NEXT.

The cabling attenuation and group delay characteristics used to derive the cable symbol responses specified in Table 32–8 at 0 m and 100 m are obtained from the following worst-case model of the cabling attenuation. The model includes 1.2 dB of flat loss simulating three worst-case Category 3 connectors. The group delay of the model is relative and does not include the fixed delay associated with 100 m of Category 3 cabling. An additional 570 ns of fixed delay should be added in order to obtain the absolute group delay; however, it is not necessary to add this fixed delay to the test channel.

$$\gamma(f) = -\left(1.537\times10^{-6}\sqrt{\pi f} + j1.537\times10^{-6}\sqrt{\pi f} + 44.5\times10^{-12}2\pi f\right)$$

$$H(f, l) = e^{\gamma(f)l}10^{-1.2/20}$$

f in Hz

32.6.1.3.2 Receiver test mode

To facilitate the testing of the receiver in the presence of synchronous 100BASE-T2 alien NEXT, a special receiver test mode shall be required to allow for receiver alien NEXT tolerance and jitter testing. For a PHY with an MII, this mode shall be enabled by setting bit 9.13 (MASTER-SLAVE Control register) of the MII management register set to a 1. A PHY without an MII shall provide a means to enable this test mode. This mode shall not be overridden except by clearing bit 9.13 or resetting the PHY.

When the receive test mode is enabled, the receiver shall configure itself in SLAVE mode, continually attempt to bring its receiver up until successful receiver operation is achieved and transmit symbols in idle mode. For a PHY with an MII, when the receiver is properly detecting the received data (loc_rcvr_status=OK), it shall set bit 10.13 of the MII management register to 1 and reset the error count in bits 10.0 through 10.7 (MSB) to zero. The error count shall be incremented for every symbol error detected in the received idle sequence (where rem_rcvr_status is assumed to be OK). Upon loss of proper data reception, the receiver shall clear bit 10.13. A PHY without an MII shall provide a means to realize this function. The vendor shall provide a means to enable this mode for conformance testing.

32.6.1.3.3 Receiver differential input signals

Differential signals received on the receive inputs that were transmitted within the specifications given in 32.6.1.2, and have then passed through a link as defined in 32.7, shall be translated into one of the PMA_UNITDATA.indication messages with an symbol error ratio less than 10^{-10} and sent to the PCS after link bring-up.

Performance shall be tested in at least two configurations: using a 100 m link segment conformant to 32.7 and with a link segment less than 1 m in length between transmitter and receiver.

32.6.1.3.4 Receiver Alien NEXT tolerance

Differential signals received from the test channel defined in 32.6.1.3.1 shall be detected with a symbol error ratio less than 10^{-8} when the PHY is in receiver test mode for the following combinations of channel and worst-case alien NEXT responses, as shown in Table 32-13.

Table 32-13—Receiver Alien NEXT test cases

Case	Cable channels	NEXT Channels			
		A1	A2	B1	B2
1	0 m	Alien NEXT 1	Alien NEXT 3	Alien NEXT 4	Alien NEXT 2
2	0 m	Alien NEXT 1	Alien NEXT 4	Alien NEXT 3	Alien NEXT 2
3	100 m	Alien NEXT 1	Alien NEXT 3	Alien NEXT 4	Alien NEXT 2
4	100 m	Alien NEXT 1	Alien NEXT 4	Alien NEXT 3	Alien NEXT 2

NOTE—Implementers will find it practically impossible to meet the requirements of this subclause without using some form of adaptive equalization and cyclostationary interference suppression.

32.6.1.3.5 Receiver timing jitter

For the test channels described below, the peak-to-peak value of RX_CLK zero-crossing jitter shall be less than 1.3 ns after the receiver is properly receiving the data and has set bit 9.13 of the MII management register set to 1. When the jitter waveform on RX_CLK is filtered by a high pass filter having the transfer function below,[67] the peak-to-peak value of the resulting filtered timing jitter shall be less than 0.8 ns.

Test channels:

Channels 1–4 are the test channels described in 32.6.1.3.1 with the four combinations of worst-case channel and alien NEXT responses tabulated in 32.6.1.3.4.

Channels 5–6 are the test channels described in 32.6.1.3.1 with the combinations of worst-case channel and alien NEXT responses tabulated in cases 1 and 2 of 32.6.1.3.4 plus the addition of 100 m of Category 3 compliant cable between the test channel fixture and the PHY under test.

$$H_{\text{jitterfilter}}(f) = \frac{jf}{jf + 1000} \qquad f \text{ in Hz}$$

The RX_CLK of the MII shall be made available for this test. A PHY without an MII shall provide an equivalent clock.

[67] "j" denotes the positive square root of –1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.6.1.3.6 Common-mode noise rejection

While receiving packets from a compliant 100BASE-T2 transmitter, connected to all MDI pins, a receiver shall send the proper PMA_UNITDATA.indication messages to the PCS for any differential input signal E_s that results in a signal E_{dif} that meets 32.6.1.3.3 even in the presence of common-mode voltages E_{cm} (applied as shown in Figure 32–21). E_{cm} shall be a 25 V peak-to-peak square wave, 500 kHz or lower in frequency, with edges no slower than 4 ns (20%-80%), connected to each of the pairs (BI_DA+, BI_DA-) and (BI_DB+, BI_DB-).

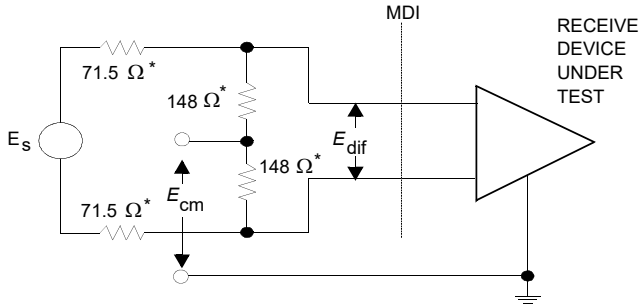

Figure 32–21—Receiver common-mode noise rejection test circuit

32.6.1.3.7 Receiver frequency tolerance

The receive feature shall properly receive incoming data with a 5-level symbol rate within the range 25.000 MHz ± 0.01%.

32.6.1.4 MDI Specifications

32.6.1.4.1 MDI differential impedance

The differential impedance as measured at the MDI for each transmit/receive channel shall be such that any reflection due to differential signals incident upon the MDI from a balanced cabling having an impedance of 100 Ω is at least 17 dB below the incident signal over the frequency range 2.0 MHz to 6.5 MHz and at least 12.9–20 $\log_{10}(f/10)$ dB over the frequency range 6.5 MHz to 25 MHz (f in MHz). This return loss shall be maintained at all times when the PHY is transmitting data.

32.6.1.4.2 MDI impedance balance

Over the frequency range 2.0 MHz to 25.0 MHz, the common-mode to differential-mode impedance balance of each channel of the MDI shall exceed

$$29 - 17\log\left(\frac{f}{10}\right) \text{ dB}$$

where f is the frequency in MHz when the transmitter is transmitting idle mode data (transmit test mode 3).

The balance is defined as

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$20\log\left(\frac{E_{cm}}{E_{dif}}\right)$$

where E_{cm} is an externally applied sine wave voltage as shown in Figure 32–22 and E_{dif} is the resulting waveform due only to the applied sine wave and not the transmitted data.[68]

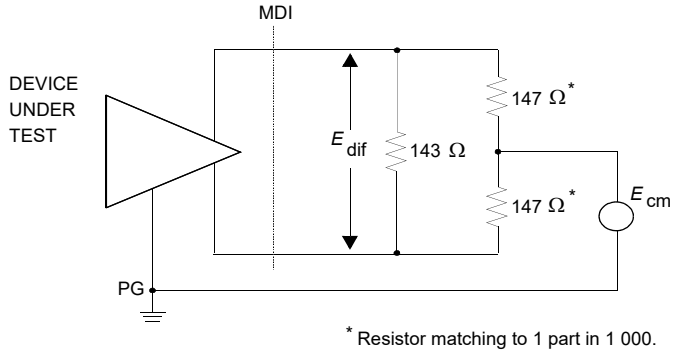

Figure 32–22—MDI impedance balance test circuit

NOTE—The balance of the test equipment (such as the matching of the test resistors) has to be insignificant relative to the balance requirements.

32.6.1.4.3 MDI common-mode output voltage

The implementer should consider any applicable local, national, or international regulations. Driving balanced cable pairs with high-frequency common-mode voltages may cause radiated emissions that may result in interference to other equipment. FCC conducted and radiated emissions tests may require that the magnitude of the total common-mode output voltage, E_{cm_out}, on any transmit circuit, when measured as shown in Figure 32–23, be less than a few millivolts when transmitting data.

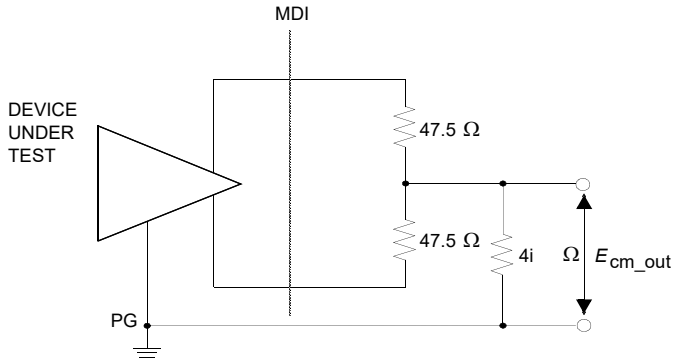

Figure 32–23—Common-mode output voltage test circuit

NOTE—The balance of the test equipment (such as the matching of the test resistors) has to be insignificant relative to the balance requirements.

[68]Triggered averaging can be used to separate the component due to the applied common-mode sine wave from the transmitted data component.

32.6.1.4.4 MDI fault tolerance

Transmitters and receivers shall withstand without damage the application of short circuits across any MDI port for an indefinite period of time and shall resume normal operation after such faults are removed. The magnitude of the current through such a short circuit shall not exceed 300 mA.

Transmitters shall withstand without damage a 1000 V common-mode impulse applied at E_{cm} of either polarity (as indicated in Figure 32–24). The shape of the impulse shall be 0.3/50 μs (300 ns virtual front time, 50 μs virtual time of half value), as defined in IEC 60060.

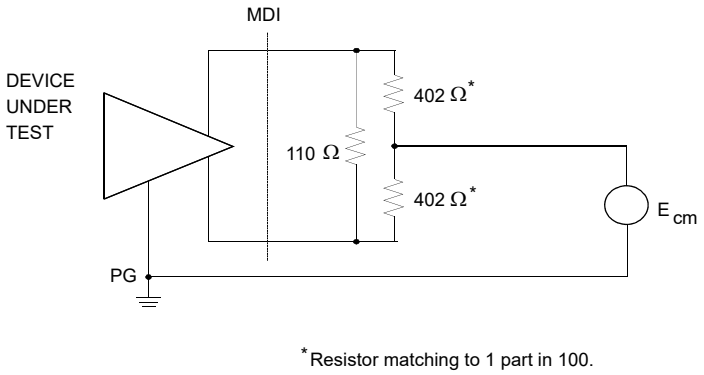

Figure 32–24—MDI fault tolerance test circuit

32.6.2 Power consumption

After 100 ms following PowerOn, the current drawn by the PHY shall not exceed 1.0 A when powered through the MII.

The PHY shall be capable of operating from all voltage sources allowed by Clause 22, including those current limited to 1.0 A, as supplied by the DTE or repeater through the resistance of all permissible MII cabling.

The PHY shall not introduce extraneous signals on the MII control circuits during normal power-up and power-down.

While in power-down mode, the PHY is not required to meet any of the 100BASE-T2 performance requirements.

32.7 Link segment characteristics

100BASE-T2 employs a dual duplex transmission system, i.e., two full duplex channels are used simultaneously to transmit data. The use of the term *link segment* in this clause refers to two duplex channels and the specifications for a link segment apply individually to each of the two duplex channels. Furthermore, the term duplex channel will be used to refer a single channel of the dual duplex link segment.

100BASE-T2 is designed to allow use of the pairs of the cabling other than the two used for the full duplex channels of the 100BASE-T2 service. Services supported for use in the other pairs are as follows:

a) 100BASE-T2
b) 10BASE-T
c) Digital phone services compliant with the ITU-T Recommendation I.430 and ATIS-0600605 and ATIS-0600601

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.7.1 Cabling

Cabling and installation practices generally suitable for use with this standard appear in ISO/IEC 11801. Exceptions, notes, and additional requirements are as listed below.

a) 100BASE-T2 uses a star topology. Balanced cabling is used to connect PHY entities.
b) 100BASE-T2 is an ISO 11801 class C application, with additional installation requirements and transmission parameters specified in 32.7.2–32.7.4. The width of the PAM5 × 5 transmit spectrum is approximately 25 MHz (as shown in Figure 32–19). The aggregate data rate for two pairs using PAM5 × 5 coding is 100 Mb/s.
c) 100BASE-T2 shall use 2 pairs of balanced cabling, Category 3 or better, with a nominal characteristic impedance of 100 Ω.
d) When using Category 3 cabling for the link segment, Clause 32 recommends, but does not require, the use of Category 4 or better connecting hardware, patch cords and jumpers. The use of Category 4 or better connecting hardware increases the link segment composite NEXT loss, composite ELFEXT loss and reduces the link segment insertion loss. This lowers the link segment crosstalk noise which in turn decreases the probability of errors.
e) The use of shielding is outside the scope of this standard.
f) The use of other cabling systems is discussed in Annex 32A.

32.7.2 Link transmission parameters

Unless otherwise specified, link segment testing shall be conducted using source and load impedances of 100 Ω.

The tolerance on the poles of the test filter used in this clause shall be ± 1%.

32.7.2.1 Insertion loss

The insertion loss of a link segment shall be no more than 14.6 dB at all frequencies between 2 and 16 MHz. This consists of the attenuation of the balanced cabling pairs, connector losses, and reflection losses due to impedance mismatches between the various components of the link segment. The insertion loss specification shall be met when the link segment is terminated in source and load impedances that satisfy 32.6.1.4.1.

NOTE—The loss of PVC-insulated cabling exhibits significant temperature dependence. At temperatures greater than 40 ^{o}C, it may be necessary to use a less temperature-dependent cabling, such as many Fluorinated Ethylene Propylene (FEP), Polytetrafluoroethylene (PTFE), or Perfluoroalkoxy (PFA) plenum-rated cabling.

32.7.2.2 Differential characteristic impedance

The cable used in the links shall meet the requirements for characteristic impedance specified in ISO/IEC 11801. Connecting hardware shall meet the return loss requirements for connecting hardware specified in ISO/IEC 11801.

32.7.2.3 Coupling parameters

In order to limit the noise coupled into a duplex channel from an adjacent duplex channel, Near-End Crosstalk (NEXT) loss and Equal Level Far-End Crosstalk (ELFEXT) loss are specified for each link segment. In addition, since two dual-duplex connections may co-exist in a 4-pair cabling and a receiver on a duplex channel will be disturbed by crosstalk from one to three other duplex (or simplex) channels, Multiple-Disturber NEXT loss and Multiple-Disturber ELFEXT loss are also specified. When a 10BASE-T service is used within the same cabling, a restriction on the allowable NEXT loss to Insertion Loss (NIR) of the cabling is required and is specified in 32.7.2.3.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.7.2.3.1 Differential near-end crosstalk (NEXT) loss

The differential Near-End Crosstalk (NEXT) loss between the two duplex channels of a link segment is specified in order to limit the crosstalk noise at the near end of a link segment to meet the symbol error ratio objective specified in 32.1 and the noise specifications of 32.7.3. The NEXT loss between the two duplex channels of a link segment shall be at least $19.3 - 16.6\log_{10}(f/16)$ (where f is the frequency in MHz) over the frequency range 2 MHz to 16 MHz.

32.7.2.3.2 Multiple-disturber NEXT (MDNEXT) loss

Since two dual duplex applications (connections) may exist in a 4-pair cabling system, a received signal may be disturbed by multiple alien NEXT signals. The MDNEXT loss between each link segment duplex channel and the two alien data carrying duplex channels shall be at least $19.0 - 16.6\log_{10}(f/16)$ dB (where f is the frequency in MHz) over the frequency range 2.0 MHz to 16 MHz. MDNEXT is computed as the power sum of the individual NEXT losses. This specification is consistent with two disturbers, each with a NEXT loss of at least $22.0 - 16.6\log_{10}(f/16)$.

NOTE—Since the self NEXT noise from the other duplex channel of a connection can be cancelled using digital signal processing techniques whereas the alien NEXT noise from an alien connection can not be cancelled in the same fashion, the self NEXT noise is treated differently than the alien NEXT noise and is not included in the MDNEXT calculation.

32.7.2.3.3 Equal level far-end crosstalk loss (ELFEXT)

Equal Level Far-End Crosstalk (ELFEXT) loss is specified in order to limit the crosstalk noise at the far end of a link segment to meet the symbol error ratio objective specified in 32.1 and the noise specifications of 32.7.3. Far-End Crosstalk (FEXT) noise is the crosstalk noise that appears at the far end of one of the duplex channels which is coupled from one of the duplex channels with the noise source (transmitters) at the near end. ELFEXT loss is the ratio of the data signal to FEXT noise at the far end output of a duplex channel. To limit the FEXT noise from an adjacent duplex channel, the ELFEXT loss between each duplex channel shall be greater than $20.9 - 20\log_{10}(f/16)$ dB (where f is the frequency in MHz) over the frequency range 2 MHz to16 MHz. ELFEXT loss at frequency f and distance l is defined as

$$ELFEXT_Loss(f,l) = 20\log_{10}(V\text{pds}/V\text{pcn}) - SLS_Loss(\text{dB})$$

where Vpds = peak voltage of disturbing signal (near-end transmitter), Vpcn = peak crosstalk noise at far-end of disturbed channel, and SLS_Loss = insertion loss of the disturbing channel.

32.7.2.3.4 Multiple-disturber ELFEXT (MDELFEXT) loss

Since two duplex channels are used to transfer data between PHYs and two connections can exist in a 4-pair cabling, the FEXT noise that is coupled into a data carrying duplex channel is from one to three disturbers. The MDELFEXT loss between a duplex channel and the other data carrying duplex channels shall be greater than $19.9 - 20\log_{10}(f/16)$ (where f is the frequency in MHz) over the frequency range 2 MHz to 16 MHz.This specification is consistent with three disturbers, one with a FEXT loss of at least $20.9 - 20\log_{10}(f/16)$ and two with a FEXT loss of at least $27.0 - 20\log_{10}(f/16)$.

MDELNEXT is computed as the power sum of the individual FEXT losses.

32.7.2.3.5 10BASE-T NEXT loss to insertion loss ratio requirement

The objective of this specification is to support the coexistence of a 100BASE-T2 link segment and a 10BASE-T link segment in a 4-pair cable. When a 100BASE-T2 link segment operates in the same 4-pair cable with a 10BASE-T link segment, each 100BASE-T2 duplex channel will receive alien NEXT noise signals from the 10BASE-T link segment. To ensure reliable operation, a minimum signal-to-noise ratio has to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

be maintained. This minimum signal-to-noise ratio is assured by meeting the following NEXT loss to insertion loss ratio (NIR).

NIR is defined by the following equation:

$$NIR\ (\text{dB}) = (AdjustedNEXTLoss - InsertionLoss_{6\ \text{MHz}})$$

where $InsertionLoss_{6\ \text{MHz}}$ is the maximum of the insertion loss at 6 MHz of the two duplex channels of the 100BASE-T2 link segment and *AdjustedNEXTLoss* is determined by the following algorithm:

AdjustedNEXTLoss Algorithm

Step 1. Measure the NEXT loss as a function of frequency over the range 1 MHz to 16 MHz for each of the six pair combinations between the four pairs of the cabling. The maximum spacing in frequency of the samples shall be 250 kHz.

Step 2. Add $16.6\log_{10}(f/16)$ to the NEXT loss measurements (where f is frequency in MHz) to normalize the NEXT loss as a function of frequency.

Step 3. Determine the minimum value of the normalized NEXT loss across the frequency range over all pair combinations. The minimum value is the AdjustedNEXTLoss.

The NIR shall be greater than 19.4 dB.

32.7.2.4 Delay

Since 100BASE-T2 sends information over two duplex channels in parallel, the propagation delay of each channel and the difference in delay are specified to comply with network round-trip delay of the two channels and ensure proper decoding by receivers, respectively.

32.7.2.4.1 Maximum link delay

The propagation delay of a link segment shall not exceed 5.7 ns/m at all frequencies between 2 MHz and 25 MHz.

32.7.2.4.2 Difference in link delays

The difference in propagation delay, or skew, under all conditions, between the two duplex channels of a link segment shall not exceed 90 ns at all frequencies between 2 MHz and 25 MHz. It is a further functional requirement that, once installed, the skew between the duplex links due to environmental conditions shall not vary more than ± 20 ns, within the above requirement.

32.7.3 Noise

The noise level on the link segments shall be such that the cabling noise requirements which follow are met. The noise environment consists generally of a main contributor, self-induced and alien near-end crosstalk noise, and a lessor contributor, far-end crosstalk noise.

The noise environment for 100BASE-T2 can consist of the following elements:

a) Echo from the local transmitter on the same pair (duplex channel). Echo is caused by the hybrid used to achieve simultaneous bidirectional transmission of data in the T2 system and by impedance mismatches in the link segment. It is practically impossible to achieve robust performance without using echo cancellation to reduce this noise to a small residual. Echo cancellation is possible since the symbols transmitted from the disturbing local transmitter are available to the cancellation processor.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Near-end crosstalk (NEXT) noise from the local transmitter on the other pair (duplex channel) of the link segment. This is often referred to as self NEXT noise since the source is from the same link segment. NEXT noise cancellation is typically used to reduce this noise to a small residual. NEXT noise cancellation is possible since the symbols transmitted from the disturbing local transmitter are available to the cancellation processor.

c) Far-end crosstalk (FEXT) noise from the remote transmitters on the other pair (duplex channel) of the link segment. This is often referred to as self FEXT noise since the source is from the same link segment. Self FEXT noise can not be cancelled in the same way as echo and self NEXT noise since the symbols from the remote transmitter are not immediately available; however, in the link configurations used for 100BASE-T2, self FEXT noise is much smaller than self NEXT noise and can generally be neglected.[69]

d) Noise from non-idealities in the duplex channels, transmitters and receivers; for example, DAC/ADC non-linearity, electrical noise (shot and thermal) and non-linear channel characteristics.

e) Noise from sources outside the cabling which couple into the link segment via electric and magnetic fields.

f) Noise from services in adjacent wire pairs in the same cable sheath. These services generate near- and far-end crosstalk and are often referred to as alien NEXT noise and alien FEXT noise since the sources are not from the link segment of the disturbed duplex channel. Since the transmitted symbols from an alien NEXT noise source are not available to the PHY of the disturbed duplex channel, it is not possible to cancel the alien NEXT noise as can be done for self NEXT noise. If the alien NEXT noise is from a 100BASE-T2 transceiver, a technique termed cyclostationary interference suppression can be used to suppress the alien NEXT noise. It will be practically impossible achieve reliable operation in the presence of alien NEXT noise meeting the limits of the specifications in subclause 32.6 without using some form of cyclostationary interference suppression. 10BASE-T can not be suppressed and therefore an additional constraint has been placed on the link (see subclause 32.7.2.3.5) to ensure adequate signal to noise levels for reliable performance. Digital phone services compliant with the ITU-T Recommendation I.430 and ATIS-0600605 and ATIS-0600601 also can not be suppressed but produce substantially smaller crosstalk than 10BASE-T and thus do not require any additional constraints on the link.

100BASE-T2 supports three types of service in adjacent pairs of the same cable: 100BASE-T2, 10BASE-T, and digital phone service compliant with the ISDN-BR U and S/T interfaces. Analog phone service is not supported since the noise generated during off-hook transitions and ringing source from older PBX equipment can cause bit errors to occur.

NOTE—Due to the use of noise cancellation, cyclostationary interference suppression and the use of adaptive equalization, there is no meaningful way to add up the noises at the input to the receiver into an overall noise level and simulation of a design is required to determine the contribution of each source to the final error at the symbol decision point.

32.7.3.1 Near-end crosstalk noise

The MDNEXT (Multiple-Disturber Near-End Crosstalk) noise on a duplex channel from an alien connection depends on the signal spectrum on the alien channels and the crosstalk between the alien channels and the disturbed channel.

The MDNEXT noise on each duplex link of a link segment shall not exceed 182 mVp.

This specification is compatible with the following assumptions:

[69]Additionally, FEXT noise may be suppressed to some degree via cyclostationary interference suppression; however, in the presence of alien NEXT noise, the equalizer will be primarily suppressing the alien NEXT noise.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Two disturbing alien pairs with a NEXT loss greater than 22.0 dB at 16 MHz
b) All disturbers combined on a power sum basis

The MDNEXT noise is the noise measured at the output of a filter connected to the output of the near end of a disturbed link segment using maximum level 100BASE-T2 transmitters attached to the near end of an alien disturbing link segment. Each continuous transmit signal is generated by a transceiver in idle mode meeting the data scrambling and encoding rules in 32.3, e.g., a transmitter in transmit test mode 3.

32.7.3.2 Far-end crosstalk noise

The MDFEXT (Multiple-Disturber Far-End Crosstalk) noise on a duplex channel depends on the signal spectrum on the disturbing channels and the various crosstalk losses between those channels and the disturbed channel.

The MDFEXT noise on a link segment shall not exceed 54.4 mVp.

This specification is compatible with the following assumptions:

a) One disturbing pair with ELFEXT (Equal Level Far-End Crosstalk) loss greater than 20.9 dB at 16 MHz
b) Two additional disturbers with ELFEXT (Equal Level Far-End Crosstalk) loss greater than 27.0 dB at 16 MHz
c) All disturbers combined on a power sum basis

The MDFEXT noise is the noise measured at the output of a filter connected to the output of the far end of a disturbed link segment using maximum level 100BASE-T2 transmitters attached to the near end of the other duplex channel of the link segment and both duplex channels of an alien disturbing link segment. Each continuous transmit signal is generated by a transceiver in idle mode meeting the data scrambling and encoding rules in 32.3, e.g., a transmitter in transmit test mode 3.

The filter is a 5th order Butterworth filter with a 3 dB cutoff at 23 MHz.

32.7.3.3 External coupled noise

Noise coupled from external sources, measured at the output of a filter connected to the output of the near end of a disturbed link segment shall not exceed 25 mV peak.[70]

The filter is a 5th order Butterworth filter with a 3 dB cutoff at 23 MHz.

32.7.4 Installation practice

32.7.4.1 Connector installation practices

The amount of untwisting in a pair as a result of termination to connecting hardware should be no greater than 25 mm (1.0 in.) for Category 3 cabling. This is the same value recommended in ISO/IEC 11801 for Category 4 connectors.

32.7.4.2 Restrictions on use of Category 3 cabling with more than four pairs

Jumper cabling, or horizontal runs, made from more than four pairs of Category 3 cabling shall not be used.

[70]This assumes the link has worst-case attenuation and alien NEXT and that the noise has the worst possible properties. In the absence of alien NEXT the tolerance to external noise sources is substantially increased. Tolerance to stationary noise such as continuous wave interference from AM radio can be substantially higher since the equalizer can notch out frequencies with poor signal-to-noise ratios. Tolerance to isolated impulse noise events is also typically much higher and dependent on the shape of the impulse.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.7.4.3 Restrictions on use of Category 5 cabling with up to 25 pairs

Cables made from up to 25 pairs of Category 5 cable are allowed. Such cables, if used, shall be limited in length to no more than 90 m total. The services in the cable shall be limited to any combination 100BASE-T2, 10BASE-T and digital phone services compliant with the ITU-T Recommendation I.430 and ATIS-0600605 and ATIS-0600601 interfaces up to a total of 12 services in the cable.

32.8 MDI specification

This subclause defines the MDI. The link topology requires a crossover function between PMAs. Implementation and location of this crossover are also defined in this subclause.

32.8.1 MDI connectors

Eight-pin connectors meeting the requirements of section 3 and Figures 1–4 of IEC 60603-7, Detail Specification for Connectors, 8-Way shall be used as the mechanical interface to the balanced cabling. The plug connector shall be used on the balanced cabling and the jack on the PHY. These connectors are depicted (for informational use only) in Figures 32–25 and 32–26. Table 32–14 shows the assignment of PMA signals to connector contacts for PHYs.

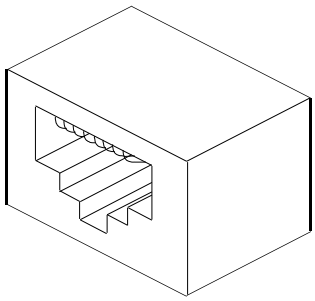

Figure 32–25—MDI connector

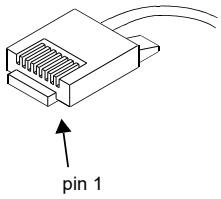

Figure 32–26—Balanced cabling connector

32.8.2 Crossover function

Although the crossover function is not required for successful operation of 100BASE-T2, it is a functional requirement that a crossover function be implemented in every link segment to support the operation of Auto-Negotiation. The crossover function connects the transmitters of one PHY to the receivers of the PHY at the other end of the link segment. Crossover functions may be implemented internally to a PHY or elsewhere in the link segment. For a PHY that does not implement the crossover function, the MDI labels in the last column of Table 32–14 refer to its own internal circuits (second column). For PHYs that do implement the internal crossover, the MDI labels in the last column of Table 32–14 refer to the internal circuits of the remote PHY of the link segment. Additionally, the MDI connector for a PHY that implements the crossover function shall be marked with the graphical symbol X. The crossover function specified here is compatible with the crossover function specified in 14.5.2 for pairs TD and RD.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 32–14—Assignment of PMA signals to MDI pin-outs

Contact	PHY without internal crossover (100BASE-T2 operation)	PHY with internal crossover (Auto-Negotiation operation)	MDI labeling requirement
1	BI_DA+	BI_DB+	BI_DA+
2	BI_DA-	BI_DB-	BI_DA-
3	BI_DB+	BI_DA+	BI_DB+
4	Not used	Not used	
5	Not used	Not used	
6	BI_DB-	BI_DA-	BI_DB-
7	Not used	Not used	
8	Not used	Not used	

When a link segment connects a DTE to a repeater, it is recommended the crossover be implemented in the PHY local to the repeater. If both PHYs of a link segment contain internal crossover functions, an additional external crossover is necessary. It is recommended that the crossover be visible to an installer from one of the PHYs. When both PHYs contain internal crossovers, it is further recommended in networks in which the topology identifies either a central backbone segment or a central repeater that the PHY furthest from the central element be assigned the external crossover to maintain consistency.

Implicit implementation of the crossover function within a twisted-pair cable, or at a wiring panel, while not expressly forbidden, is beyond the scope of this standard.

32.9 System considerations

The repeater unit specified in Clause 27 forms the central unit for interconnecting 100BASE-T2 twisted-pair links in networks of more than two nodes. It also provides the means for connecting 100BASE-T2 balanced cabling links to other 100 Mb/s baseband segments. The proper operation of a CSMA/CD network requires that network size be limited to control round-trip propagation delay as specified in Clause 29.

When operated in Full Duplex mode where CSMA/CD requirements do not apply, 100BASE-T2 balanced cabling links are limited to 100 m as per ISO/IEC 11801.

32.10 Environmental specifications

32.10.1 General safety

NOTE—Since September 2003, maintenance changes are no longer being considered for this clause. Since February 2021, safety information is in J.2.

All equipment meeting this standard shall conform to IEC 60950.

32.10.2 Network safety

This clause sets forth a number of recommendations and guidelines related to safety concerns; the list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

LAN cabling systems described in this clause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Direct contact between LAN components and power, lighting, or communications circuits
b) Static charge buildup on LAN cabling and components
c) High-energy transients coupled onto the LAN cabling system
d) Voltage potential differences between safety grounds to which various LAN components are connected

Such electrical safety hazards have to be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures have to be taken to ensure that the intended safety features are not negated during installation of a new network or during modification or maintenance of an existing network.

32.10.2.1 Installation

It is a mandatory functional requirement that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

32.10.2.2 Grounding

Any safety grounding path for an externally connected PHY shall be provided through the circuit ground of the MII connection.

WARNING

It is assumed that the equipment to which the PHY is attached is properly grounded, and not left floating nor serviced by a "doubly insulated, ac power distribution system." The use of floating or insulated equipment, and the consequent implications for safety, are beyond the scope of this standard.

32.10.2.3 Installation and maintenance guidelines

It is a mandatory functional requirement that, during installation and maintenance of the cabling plant, care be taken to ensure that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

32.10.2.4 Telephony voltages

The use of building wiring brings with it the possibility of wiring errors that may connect telephony voltages to 100BASE-T2 equipment. Other than voice signals (which are low voltage), the primary voltages that may be encountered are the "battery" and ringing voltages. Although there is no universal standard, the following maximums generally apply.

Battery voltage to a telephone line is generally 56 Vdc applied to the line through a balanced 400 Ω source impedance.

Ringing voltage is a composite signal consisting of an AC component and a DC component. The ac component is up to 175 V peak at 20 Hz to 60 Hz with a 100 Ω source resistance. The DC component is 56 Vdc with 300 Ω to 600 Ω source resistance. Large reactive transients can occur at the start and end of each ring interval.

Although 100BASE-T2 equipment is not required to survive such wiring hazards without damage, application of any of the above voltages shall not result in any safety hazard.

NOTE—Wiring errors may impose telephony voltages differentially across 100BASE-T2 transmitters or receivers. Because the termination resistance likely to be present across a receiver's input is of substantially lower impedance than an off-hook telephone instrument, receivers will generally appear to the telephone system as off-hook telephones. There-

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

fore, full-ring voltages will be applied for only short periods. Transmitters that are coupled using transformers will similarly appear like off-hook telephones (though perhaps a bit more slowly) due to the low resistance of the transformer coil.

32.10.3 Environment

32.10.3.1 Electromagnetic emission

The twisted-pair link shall comply with applicable local and national codes for the limitation of electromagnetic interference.

32.10.3.2 Temperature and humidity

The twisted-pair link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

32.10.4 Cabling specifications

All equipment subject to this clause shall conform to the requirements of 14.7 and applicable sections of ISO/IEC 11801.

32.11 PHY labeling

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) Data rate capability in Mb/s
b) Power level in terms of maximum current drain (for external PHYs)
c) Port type (i.e., 100BASE-T2)
d) Any applicable safety warnings

See also 32.8.2.

32.12 Delay constraints

Proper operation of a CSMA/CD LAN, operating in half duplex mode, demands that there be an upper bound on the propagation delays through the network. This implies that MAC, PHY and repeater implementations conform to certain delay minima and maxima, and that network planners and administrators conform to constraints regarding the cabling topology and concatenation of devices. MAC constraints are contained in Clause 21. Topological constraints are contained in Clause 29. In the full duplex mode of operation, DTEs are not required to conform to the constraints specified in this clause.

The reference point for all MDI measurements is the peak point of the mid-cell transition corresponding to the reference code-bit, as measured at the MDI. Although 100BASE-T2 output is scrambled, it is assumed that these measurements are made via apparatuses that appropriately account for this.

32.12.1 PHY delay constraints (exposed MII)

Every 100BASE-T2 PHY with an exposed MII shall comply with the bit delay constraints specified in Table 32–15. These figures apply for all 100BASE-T2 PMDs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 32–15—MDI to MII delay constraints (exposed MII)

Sublayer Measurement Points	Event	Min (bits)	Max (bits)	Input Timing Reference	Output Timing Reference
MII ⇔ MDI	TX_EN Sampled to MDI Output	7	9	TX_CLK rising	1st symbol of SSD
	MDI input to CRS assert		25	1st symbol of SSD	
	MDI input to CRS deassert		29	1st ONE	
	MDI input to COL assert		25	1st symbol of SSD	
	MDI input to COL deassert		29	1st symbol of SSD	
	TX_EN sampled to CRS assert	0	4	TX_CLK rising	
	TX_EN sampled to CRS deassert	0	16	TX_CLK rising	

32.12.2 DTE delay constraints (unexposed MII)

Every 100BASE-T2 DTE with no exposed MII shall comply with the bit delay constraints specified in Table 32–16. These figures apply for all 100BASE-T2 PMDs.

Table 32–16—DTE delay constraints (unexposed MII)

Sublayer Measurement Points	Event	Min (bits)	Max (bits)	Input Timing Reference	Output Timing Reference
MAC ⇔ MDI	MAC transmit start to MDI output		13		1st symbol of SSD
	MDI input to MDI output (worst-case non-deferred transmit)		50	1st symbol of SSD	1st symbol of SSD
	MDI input to collision detect		33	1st symbol of SSD	
	MDI input to MDI output = Jam (worst-case collision response)		50	1st symbol of SSD	1st symbol of SSD

32.13 Protocol implementation conformance statement (PICS) proforma for Clause 32, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T2[71]

The supplier of a protocol implementation that is claimed to conform to Clause 32, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T2, shall complete the following protocol implementation conformance statement (PICS) proforma.

Instructions for interpreting and filling out the PICS proforma may be found in Clause 21.

32.13.1 Identification

32.13.1.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1— Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

32.13.1.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2018, Clause 32, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 100BASE-T2
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exceptions items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2018.)	

Date of Statement	

[71] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

32.13.2 Major capabilities/options

Item	Feature	Subclause	Status	Support	Value/Comment
*MII	Exposed MII interface	32.1.3.2	O	Yes [ ] No [ ]	Devices supporting this option also have to support the PCS option.
PC	PHY Control functions	32.2	M	Yes [ ]	Required for proper operation of the PHY.
*PCS	PCS functions	32.3	O	Yes [ ] No [ ]	Required for integration with DTE or MII.
*PMA	Exposed PMA service interface	32.4.2	O	Yes [ ] No [ ]	Required for integration into symbol level repeater core.
NWY	Support for Auto-Negotiation (Clause 28)	32.1.3.4	M	Yes [ ]	Required
*INS	Installation/cabling	32.7.4	O	Yes [ ] No [ ]	Items marked with INS include installation practices and cabling specifications not applicable to a PHY manufacturer.

32.13.3 Compatibility considerations

Item	Feature	Subclause	Status	Support	Value/Comment
CCO1	Compatibility at the MDI	32.1.3.1	M	Yes [ ]	
CCO2	Auto-Negotiation required	32.1.3.4	M	Yes [ ]	
CCO3	State diagrams prevail	32.1.4	M	Yes [ ]	In discrepancy between text and state diagram.

32.13.4 PHY control function

Item	Feature	Subclause	Status	Support	Value/Comment
PC01	PHY Control shall	32.2.1	M	Yes [ ]	Comply with the state diagram descriptions given in Figure 32–5.
PC02	PHY Control shall	32.2.2.1.2	M	Yes [ ]	Generate PHYC_CONFIG.indication messages synchronously with every MII TX_CLK cycle.
PC03	Upon receipt of the PHYC_CONFIG primitive, PCS Transmit and PMA Clock Recovery shall	32.2.2.1.3	M	Yes [ ]	Perform their functions in master or slave configuration according to the value of the parameter config.
PC04	PHY Control shall	32.2.2.2.2	M	Yes [ ]	Generate PHYC_LOCRXSTATUS.indication messages synchronously with every MII TX_CLK cycle.
PC05	Upon reception of the PHYC_LOCRXSTATUS.indication primitive, PCS Transmit shall	32.2.2.2.3	M	Yes [ ]	Perform its function according to the value assumed by the parameter loc_cvr_status.
PC06	PHY Control shall	32.2.2.3.2	M	Yes [ ]	Generate PHYC_TXMODE.indication messages synchronously with every MII TX_CLK cycle.
PC07	Upon receipt of the PHYC_TXMODE.indication primitive, the PCS shall	32.2.2.3.3	M	Yes [ ]	Perform its Transmit function as described in 32.3.1.2.
PC8	The PCS shall	32.2.2.3.2	M	Yes [ ]	Generate PHYC_RXSTATUS.request messages synchronously with signals received at the MDI.
PC9	The PCS shall	32.2.2.4.2	M	Yes [ ]	Generate PHYC_REMRXSTATUS.request messages synchronously with signals received at the MDI.
PC10	PCS Transmit shall	32.2.3	M	Yes [ ]	Send quinary symbols according to the value assumed by tx_mode.
PC11	When tx_mode assumes the value of SEND_N	32.2.3	M	Yes [ ]	Transmission of sequences of quinary symbols representing an MII data stream, the idle mode, or control sequences shall take place.
PC12	When tx_mode assumes the value of SEND_I	32.2.3	M	Yes [ ]	Transmission of sequences of quinary symbols representing the idle mode shall take place.

32.13.5 Physical Coding Sublayer (PCS) or Physical Medium Attachment (PMA) sublayer

32.13.5.1 PCS transmit functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCT01	The PCS shall	32.3.5.1	M	Yes [ ]	Implement the Transmit process as depicted in Figure 32–12 including compliance with the associated state variables specified in 32.3.4.
PCT02	PCS Transmit function shall	32.3.1.2	M	Yes [ ]	Conform to the PCS Transmit state diagram in Figure 32–12.
PCT03	If the parameter config provided to the PCS by the PHY Control function via the PHY-C_CONFIG.indication message assumes the value MASTER, PCS Transmit shall	32.3.1.2.1	M	Yes [ ]	Employ the transmitter side-stream scrambler generator polynomial specified for use with MASTER in 32.3.1.2.1.
PCT04	If the parameter config provided to the PCS by the PHY Control function via the PHY-C_CONFIG.indication message assumes the value SLAVE, PCS Transmit shall	32.3.1.2.1	M	Yes [ ]	Employ the transmitter side-stream scrambler generator polynomial specified for use with SLAVE in 32.3.1.2.1.
PCT05	Transmission of quinary symbol pairs over wire pairs	32.3.1.2	M	Yes [ ]	Symbols A_n and B_n are transmitted over BI_DA and BI_DB respectively.

32.13.5.2 PCS receive functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCR01	The PCS shall	32.3.5.2	M	Yes [ ]	Implement the Receive process as depicted in Figure 32–13 including compliance with the associated state variables as specified in 32.3.4.
PCR02	PCS Receive function shall	32.3.1.3	M	Yes [ ]	Conform to the PCS Receive state diagram shown in Figure 32–13.
PCR03	For side-stream descrambling, the MASTER PHY shall employ	32.3.1.3.1	M	Yes [ ]	The receiver scrambler generator polynomial specified for MASTER operation in 32.3.1.3.1.
PCR04	For side-stream descrambling, the SLAVE PHY shall employ	32.3.1.3.1	M	Yes [ ]	The receiver scrambler generator polynomial specified for SLAVE operation in 32.3.1.3.1.

32.13.5.3 Other PCS functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCO1	The PCS Reset function shall	32.3.1.1	M	Yes [ ]	Be executed any time “power on,” receipt of a request for reset from the management entity, or receipt of a request for reset from the PHY Control occur.
PCO2	THE PCS shall	32.3.1.4	M	Yes [ ]	Implement the PCS Carrier Sense function shown in Figure 32–14.
PCO3	PCS Carrier Sense function shall	32.3.5.3	M	Yes [ ]	Comply with the PCS Carrier Sense state diagram shown in Figure 32–14 including compliance with the associated state variables specified in 32.3.4.
PCO4	MII COL signal shall be asserted while	32.3.1.5	M	Yes [ ]	A PCS collision is being detected.
PCO5	The MII signal COL shall remain deasserted.	32.3.1.5	M	Yes [ ]	A PCS collision is not being detected.
PCO6	No spurious PCS management entity signals shall be emitted onto the MDI while the PHY is held in power down mode as defined in 22.2.4.1.5, independently of the value of TX_EN, or when released from power down mode, or when power is first applied to the PHY.	32.3.2.2	M	Yes [ ]	
PCO7	Frames passed from the PCS to the PMA sublayer shall	32.3.3	M	Yes [ ]	Have the structure shown in Figure 32–11.
PCO8	TX_CLK shall be generated	32.3.4.2	M	Yes [ ]	Synchronously with symb_-timer with tolerance as specified in 32.6.1.2.6.

32.13.5.4 PMA functions

Item	Feature	Subclause	Status	Support	Value/Comment
PMF1	PMA Reset function shall be executed	32.4.1.1.1	M	Yes [ ]	At power on and upon receipt of a reset request from the management entity.
PMF2	PMA transmit shall continuously transmit	32.3.1.2	M	Yes [ ]	Onto the MDI pulses modulated by the quinary symbols given by tx_symb_vector[BI_DA] and tx_symb_vector[BI_DB] respectively.
PMF3	The two transmitters shall be driven by the same transmit clock.	32.4.1.1.2	M	Yes [ ]	
PMF4	PMA Transmit function will follow	32.4.1.1.2	M	Yes [ ]	The mathematical description given in 32.4.1.2.1.
PMF5	PMA Transmit shall comply with	32.4.1.1.2	M	Yes [ ]	The electrical specifications given in 32.6.
PMF6	PMA Receive function shall translate	32.4.1.1.3	M	Yes [ ]	The signals received on pairs BI_DA and BI_DB into the PMA_UNITDATA.indication parameter rx_symb_vector with a symbol error ratio of less than one part in 10^{10}.
PMF7	The Link Monitor function shall	32.4.1.1.4	M	Yes [ ]	Comply with the state diagram shown in Figure 32–17.
PMF8	Clock Recovery function shall provide	32.4.1.1.5	M	Yes [ ]	A clock suitable for synchronous signal sampling on each line so that the symbol error ratio indicated in 32.4.1.1.3 is achieved.
PMF9	The waveform obtained at the MDI shall comply with	32.4.1.2.1	M	Yes [ ]	The electrical specifications given in 32.6.
PMF10	The two signals received on pair BI_DA and BI_DB shall be processed within the PMA Receive function to yield	32.4.1.2.2	M	Yes [ ]	The quinary received symbols rx_symb_vector[BI_DA] and rx_symb_vector[BI_DB].

32.13.5.5 PMA service interface

Item	Feature	Subclause	Status	Support	Value/Comment
PMS1	Continuous generation of PMA_TYPE	32.4.1.2.2	M	Yes [ ]	
PMS2	Generation of PMA_UNIT-DATA.indication (SYM-B_PAIR) messages	32.4.2.3.2	M	Yes [ ]	Synchronous with data received at the MDI.
PMS3	The PMA shall generate	32.4.2.5.2	M	Yes [ ]	PMA_LINK.indication to indicate the value of link_status.
PMS4	Effect of receipt of PMA_LINK.request messages	32.4.2.4.3	M	Yes [ ]	While link_control=SCAN_-FOR_CARRIER or link_control=DISABLE, the PMA shall report link_status=fail; while link_control=ENABLE, PHY determines operations to be performed by the PHY.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

32.13.5.6 Management functions

Item	Feature	Subclause	Status	Support	Value/Comment
MF1	A 100BASE-T2 PHY shall	32.5	M	Yes [ ]	Use register addresses 9 and 10 for its control and status functions.
MF2	Register 9 shall	32.5.3.1	M	Yes [ ]	Provide values as specified in Table 32–4.
MF3	A PHY with 100BASE-T2 capability shall	32.5.3.1.1	M	Yes [ ]	Be placed in transmitter test mode 1 when bit 9.15 is set to logic zero and bit 9.14 is set to logic one.
MF4	A PHY with 100BASE-T2 capability shall	32.5.3.1.1	M	Yes [ ]	Be placed in transmitter test mode 2 when bit 9.15 is set to logic one and bit 9.14 is set to logic zero.
MF5	A PHY with 100BASE-T2 capability shall	32.5.3.1.1	M	Yes [ ]	Be placed in transmitter test mode 3 when bit 9.15 is set to logic one and bit 9.14 is set to logic one.
MF6	A PHY with 100BASE-T2 capability shall	32.5.3.1.2	M	Yes [ ]	Be placed in receiver test mode when bit 9.13 is set to logic one.
MF7	MASTER-SLAVE configuration negotiation will determine PHY configuration if	32.5.3.1.3	M	Yes [ ]	Bit 9.12 is set to logic zero.
MF8	Manual MASTER-SLAVE configuration will be set manually using bit 9.11 to set the value if	32.5.3.1.3	M	Yes [ ]	Bit 9.12 is set to logic one.
MF9	Bit 9.11 shall be used to report the results of manual MASTER-SLAVE configuration.	32.5.3.1.4	M	Yes [ ]	
MF10	Bit 9.10 shall	32.5.3.1.5	M	Yes [ ]	Be set to logic zero if the PHY is a DTE device and be set to logic one if the PHY is a repeater device port.
MF11	Bits 9.9:0 shall	32.5.3.1.6	M	Yes [ ]	Be set to logic zero.
MF12	Bits 9.9:0 shall be ignored when read	32.5.3.1.6	M	Yes [ ]	
MF13	A PHY shall return a value of zero for bits 9.9:0.	32.5.3.1.6	M	Yes [ ]	
MF14	Register 10 shall	32.5.3.1.2	M	Yes [ ]	Be used as shown in Table 32–5.
MF15	Bits 10.11:8 shall	32.5.3.2.5	M	Yes [ ]	Be set to logic zeros by default.
MF16	The MASTER-SLAVE Manual Configuration Fault bit shall be implemented	32.5.3.2.1	M	Yes [ ]	With a latching function, such that the occurrence of a MASTER-SLAVE Manual Configuration Fault will cause the MASTER-SLAVE Manual Configuration Fault bit to be set and remain set until cleared.

32.13.5.6 Management functions *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
MF17	The MASTER-SLAVE Manual Configuration Fault bit shall be cleared	32.5.3.2.1	M	Yes [ ]	Each time register 10 is read by the management interface.
MF18	The MASTER-SLAVE Management Configuration Fault bit shall also be cleared by	32.5.3.2.1	M	Yes [ ]	A 100BASE-T2 PMA reset.
MF19	Bits 10:11:8 shall	32.5.3.2.5	M	Yes [ ]	Be ignored when read.
MF20	A PHY shall return a value of zero for bits10.11:8.	32.5.3.2.5	M	Yes [ ]	

32.13.5.7 100BASE-T2 specific Auto-Negotiation requirements

Item	Feature	Subclause	Status	Support	Value/Comment
AN1	Base Page will be followed with	32.5.4.2	M	Yes [ ]	A Next Page with a message code containing the 100BASE-T2 Technology Ability Message Code (7).
AN2	Message Next Page shall be followed with	32.5.4.2	M	Yes [ ]	Unformatted Message Next Page containing the 100BASE-T2 Technology Ability Fields as described in Table 32–6.
AN3	MASTER-SLAVE relationship shall be determined by	32.5.4.3	M	Yes [ ]	Using Table 32–7with the 100BASE-T2 Technology Ability Next Page bit values specified in Table 32–6.
AN4	A seed counter shall be provided to	32.5.4.3	M	Yes [ ]	Track the generation of seeds.
AN5	At startup, the seed counter shall be set to	32.5.4.3	M	Yes [ ]	Zero.
AN6	The seed counter shall be incremented	32.5.4.3	M	Yes [ ]	Every time a new random seed is sent.
AN7	Maximum seed attempts before declaring a MASTER_SLAVE configuration Resolution Fault	32.5.4.3	M	Yes [ ]	Seven.
AN8	During MASTER_SLAVE configuration, the device with the lower seed value shall	32.5.4.3	M	Yes [ ]	Become the SLAVE.

32.13.5.7 100BASE-T2 specific Auto-Negotiation requirements *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
AN9	Both PHYs set in manual mode to be either MASTER or SLAVE shall be treated as	32.5.4.3	M	Yes [ ]	MASTER-SLAVE resolution fault (Failure) condition
AN10	MASTER-SLAVE resolution fault (failure) condition shall result in	32.5.4.3	M	Yes [ ]	MASTER-SLAVE Configuration Resolution Fault bit (10.15) to be set
AN11	MASTER-SLAVE Configuration resolution fault condition shall be treated as	32.5.4.3	M	Yes [ ]	MASTER-SLAVE Configuration Resolution complete

32.13.5.8 PMA electrical specifications

Item	Feature	Subclause	Status	Support	Value/Comment
PME1	The value of all components in test circuits shall be accurate to within	32.6	M	Yes [ ]	±1%.
PME2	The PHY shall provide electrical isolation between	32.6.1.1	M	Yes [ ]	The DTE or repeater circuits including frame ground, and all MDI leads.
PME3	PHY-provided electrical separation shall withstand at least one of three electrical strength tests	32.6.1.1	M	Yes [ ]	a) 1500 V rms at 50–60Hz for 60 s, applied as specified in section 5.3.2 of IEC 60950. b) 2250 Vdc for 60 s, applied as specified in Section 5.3.2 of IEC 60950. c) a sequence of ten 2400 V impulses of alternating polarity, applied at intervals of not less than 1 s. The shape of the impulses shall be 1.2/50 μs. (1.2 μs virtual front time, 50 μs virtual time or half value), as defined in IEC 60950.
PME4	There shall be no insulation breakdown as defined in Section 5.3.2 of IEC 60950, during the test.	32.6.1.1	M	Yes [ ]	
PME5	The resistance after the test shall be at least	32.6.1.1	M	Yes [ ]	2 MΩ, measured at 500 Vdc.
PME6	The PMA shall provide the Transmit function specified in 32.4.1.1.2 in accordance with the electrical specifications of this clause.	32.6.1.2	M	Yes [ ]

32.13.5.8 PMA electrical specifications *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
PME7	Where a load is not specified, the transmitter shall meet all the requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output.	32.6.1.2	M	Yes [ ]	
PME8	The tolerance on the poles of the test filters used in 32.6 shall be	32.6.1.2	M	Yes [ ]	±1%
PME9	A special transmit test mode shall be required to allow for testing of the transmitter waveform	32.6.1.2.1	M	Yes [ ]	
PME10	A test mode for measuring transmitter output jitter is required.	32.6.1.2.1	M	Yes [ ]	
PME11	For a PHY with a MII interface, the transmit test mode shall be enabled by	32.6.1.2.1	M	Yes [ ]	Setting bit 9.15 and 9.14 (MASTER-SLAVE Control register) of the MII management register set as shown in Table 32–6.
PME12	These test modes shall only change the data symbols provided to the transmitter circuitry and may not alter the electrical characteristics of the transmitter	32.6.1.2.1	M	Yes [ ]	
PME13	When transmit test mode 1 is enabled, the PHY shall transmit	32.6.1.2.1	M	Yes [ ]	The sequence of data symbols specified in 32.6.1.2.1 continuously from both transmitters.
PME14	When in test mode 1, the transmitter shall time the transmitted symbols	32.6.1.2.1	M	Yes [ ]	From a 25.000 MHz ± 0.01% clock.
PME15	When test mode 2 is enabled, the PHY shall transmit	32.6.1.2.1	M	Yes [ ]	The data symbol sequence {+2,–2} repeatedly on both channels.
PME16	When in test mode 2, the transmitter shall time the transmitted symbols	32.6.1.2.1	M	Yes [ ]	From a 25.000 MHz ± 0.01% clock.
PME17	A PHY without a MII shall provide a means to enter this test mode.	32.6.1.2.1	M	Yes [ ]	
PME18	The vendor shall	32.6.1.2.1	M	Yes [ ]	Provide a means to enable these modes for testing.

32.13.5.8 PMA electrical specifications *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
PME19	When in transmit test mode 1 and observing the differential signal output at the MDI, terminated in 100 Ω, preprocessed by the high pass filter defined below, for either pair, with no intervening cable, the absolute value of the peak of the waveform at points A and B as defined in Figure 32–18 shall fall within	32.6.1.2.2	M	Yes [ ]	The range of 1.71V to 1.91 V (1.81 V ± 0.5 dB).
PME20	The absolute value of the peak of the waveforms at points A and B shall	32.6.1.2.2	M	Yes [ ]	Differ by less than 2%.
PME21	The absolute value of the peak of the waveform at points C and D as defined in Figure 32–18 shall differ	32.6.1.2.2	M	Yes [ ]	From 0.5 times the average of the absolute values of the peaks of the waveform at points A and B by less than 2%.
PME22	The preprocessing filter shall have	32.6.1.2.2	M	Yes [ ]	The transfer function specified in 32.6.1.2.2.
PME23	When in transmit test mode 1 and observing the differential transmitted output at the MDI, for either pair, with no intervening cabling, the peak value of the waveform at point F as defined in Figure 32–17 shall be	32.6.1.2.3	M	Yes [ ]	Greater than 70.5% of the peak value of the waveform at point E. A preprocessing filter is not used for this measurement.
PME24	The transmitter differential output voltage shall be measured at the output of the high pass filter defined in 32.6.1.2.2 with no intervening cables.	32.6.1.2.4	M	Yes [ ]	
PME25	The voltage waveforms at points A, B, C and D as defined in Figure 32–17,when normalized by their respective peak values, shall	32.6.1.2.4	M	Yes [ ]	Lie within the time domain template defined in Figure 32–18 and the piecewise linear interpolation between the points in Table 32–6
PME26	The magnitude in dB of the Fourier transform of the waveforms at points A, B, C and D shall	32.6.1.2.4	M	Yes [ ]	Lie within the transmit frequency domain template defined in Figure 32–18 and the piecewise linear interpolation between the points in Table 32–7.
PME27	The time span of the waveforms so processed shall be	32.6.1.2.4	M	Yes [ ]	–80 ns to +2000 ns with the 0 ns point of the waveform aligned as for the time domain mask shown in Figure 32–18 and the magnitude of the Fourier transform should be normalized so that the maximum value is at 0 dB.

32.13.5.8 PMA electrical specifications *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
PME28	When in transmit mode 2, the peak-to-peak jitter of the zero crossings of the differential signal output at the MDI shall	32.6.1.2.5	M	Yes [ ]	Be less than 0.5 ns.
PME29	The quinary symbol transmission rate on each pair shall be	32.6.1.2.6	M	Yes [ ]	25.000 MHz ± 0.01%.
PME30	The PMA shall provide	32.6.1.3	M	Yes [ ]	The Receive function specified in 32.4.1.3 in accordance with the electrical specifications of this clause.
PME31	The patch cabling and interconnecting hardware used in test configurations shall	32.6.1.3	M	Yes [ ]	Meet or exceed ISO/IEC 11801 Category 3 specifications.
PME32	The combined responses of the test fixture TX block and NEXT or cabling channel blocks shall be	32.6.1.3.1	M	Yes [ ]	Those defined in Table 32–8.
PME33	The output impedance of the test channel shall be	32.6.1.3	M	Yes [ ]	Consistent with 32.6.1.4.1.
PME34	The idle symbol generator outputs shall be	32.6.1.3	M	Yes [ ]	Conformant with the idle signaling specified in 32.3 with loc_rcvr_status=OK.
PME35	The clock source shall	32.6.1.3	M	Yes [ ]	Result in a quinary symbol transmission rate conformant with 32.6.1.2.6.
PME36	The jitter on the clock source shall be	32.6.1.3	M	Yes [ ]	Less than 0.2 ns.
PME37	The test channel implementation shall ensure that the ratio of the squared error between the implemented NEXT channel symbol responses and the specified NEXT channel symbol responses to the energy in the specified NEXT channel symbol responses shall be	32.6.1.3	M	Yes [ ]	Less than 5%.
PME38	The test channel implementation shall ensure that the energy of the implemented NEXT channel impulse responses and the energy of the specified NEXT channel impulse responses shall	32.6.1.3	M	Yes [ ]	Differ by less than ±0.25 dB.
PME39	A special receiver test mode shall be required to allow for receiver alien NEXT tolerance and jitter testing.	32.6.1.3.2	M	Yes [ ]	
PME40	For a PHY with a MII interface, this mode shall be enabled by	32.6.1.3.2	M	Yes [ ]	Setting bit 9.13 (MASTER-SLAVE Control Register) of the MII management register set to a 1.

32.13.5.8 PMA electrical specifications *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
PME41	A PHY without an MII shall provide	32.6.1.3.2	M	Yes [ ]	A means to enable this test mode.
PME42	This mode shall not be overridden except by	32.6.1.3.2	M	Yes [ ]	Clearing bit 9.13 or resetting the PHY.
PME43	When the receive test mode is enabled, the receiver shall	32.6.1.3.2	M	Yes [ ]	Configure itself in SLAVE mode, continually attempt to bring its receiver up until successful receiver operation is achieved and transmit symbols in idle mode.
PME44	For a PHY with a MII interface, when the receiver is properly detecting the received data, it shall set	32.6.1.3.2	M	Yes [ ]	Bit 10.13 of the MII management register set to 1 and reset the error count in bit 10.0–10.7 (MSB) to zero.
PME45	The error count shall be incremented	32.6.1.3.2	M	Yes [ ]	For every symbol error detected in the received idle sequence.
PME46	Upon loss of proper data reception, the receiver shall	32.6.1.3.2	M	Yes [ ]	Clear bit 10.13.
PME47	A PHY without an MII shall provide	32.6.1.3.2	M	Yes [ ]	A means to provide the functions defined in PME43 through PME46.
PME48	The vendor shall provide a means to enable this mode for conformance testing.	32.6.1.3.2	M	Yes [ ]	
PME49	Differential signals received on the receive inputs that were transmitted within the constraints of 32.6.1.2, and have then passed through a link as defined in 32.7, shall be translated into	32.6.1.3.3	M	Yes [ ]	One of the PMA_UNITDATA.indication messages with an bit error ratio less than 10^{-10} and sent to the PCS after link bring-up.
PME50	Performance shall be tested	32.6.1.3.3	M	Yes [ ]	In at least two configurations: using a 100 m link segment conformant to 32.7 and with a link segment less than one meter in length between transmitter and receiver.
PME51	Differential signals received from the test channel defined in 32.6.1.3.1 shall be detected	32.6.1.3.4	M	Yes [ ]	With a symbol error ratio less than 10^{-10} when the PHY is in receiver test mode for the combinations of channel and worst-case alien NEXT responses specified in 32.6.1.2.
PME52	In the test configuration described in 32.6.1.3.1 and for all combinations of worst-case channel and alien NEXT coefficients tabulated in 32.6.1.3.4, the peak-to-peak value of the RX_CLK zero-crossing jitter shall be less than	32.6.1.3.5	M	Yes [ ]	1.3 ns after the receiver is properly receiving the data and has set bit 9.13 of the MII management register set to 1.

32.13.5.8 PMA electrical specifications *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
PME53	When the jitter waveform is filtered by a high pass filter having the transfer function specified in 32.6.1.3.4, the peak-to-peak value of the jitter waveform shall be less than	32.6.1.3.5	M	Yes [ ]	0.8 ns.
PME54	The RX_CLK of the MII shall be made available for the receiver jitter test specified in 32.6.1.3.5.	32.6.1.3.5	M	Yes [ ]	
PME55	A PHY without an MII shall provide an equivalent to the MII RX-CLK clock for the receiver jitter test specified in 32.6.1.3.5.	32.6.1.3.5	M	Yes [ ]	
PME56	While receiving packets from a compliant 100BASE-T2 transmitter connected to all MDI pins, a receiver shall send the	32.6.1.3.6	M	Yes [ ]	Proper PMA_UNITDATA.indication messages to the PCS for any differential input signal E_s that results in a signal E_{dif} that meets 32.6.1.3.3 even in the presence of common-mode voltages E_{cm} (applied as shown in Figure 32–21).
PME57	E_{cm} shall be	32.6.1.3.6	M	Yes [ ]	A 25 V peak-to-peak square wave, 500 kHz or lower in frequency, with edges no slower than 4 ns (20%–80%), connected to each of the pairs BI_DA+, BI_DA-, BI_DB+ and BI_DB-.
PME58	The receive feature shall properly receive	32.6.1.3.7	M	Yes [ ]	Incoming data with a 5-level symbol rate within the range 25.000 MHz ± 0.01%.
PME59	The differential impedance as measured at the MDI for each transmit/receive channel shall be such that	32.6.1.4.1	M	Yes [ ]	Any reflection due to differential signals incident upon the MDI from a balanced cabling having an impedance of 100 Ω is at least 17 dB below the incident signal, over the frequency range of 2.0 MHz to 25.0 MHz and at least $12.9–20\log_{10}(f/10)$ dB over the frequency range 6.5 MHz to 25 MHz (f in MHz).
PME60	This return loss shall be maintained	32.6.1.4.1	M	Yes [ ]	At all times when the PHY is transmitting data.
PME61	The common-mode to differential-mode impedance balance of each transmit output shall exceed	32.6.1.4.2	M	Yes [ ]	The value specified by the equations specified in 32.6.1.2.6 over the range 2.0–25.0 MHz.

32.13.5.8 PMA electrical specifications *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
PME62	Transmitters and receivers shall tolerate	32.6.1.4.4	M	Yes [ ]	The application of short circuits between the leads of any receive input for an indefinite period of time without damage.
PME63	Transmitters and receivers shall resume	32.6.1.4.4	M	Yes [ ]	Normal operation after such faults are removed.
PME64	The magnitude of the current through the short circuit specified in PME62 shall not exceed	32.6.1.4.4	M	Yes [ ]	300 mA.
PME65	Transmitters shall withstand without damage	32.6.1.4.4	M	Yes [ ]	A 1000 V common-mode impulse of either polarity (E_{cm} as indicated in Figure 32–24).
PME66	The shape of the impulse shall be	32.6.1.4.4	M	Yes [ ]	0.3/50 μs (300 ns virtual front time, 50 μs virtual time of half value), as defined in IEC 60060.
PME67	After 100 ms following PowerOn, the current drawn by the PHY shall not exceed	32.6.2	M	Yes [ ]	1.0 A when powered through the MII.
PME68	The PHY shall	32.6.2	M	Yes [ ]	Be capable of operating from all voltage sources allowed by Clause 22, including those current limited to1.0 A, as supplied by the DTE or repeater through the resistance of all permissible MII cabling.
PME69	The PHY shall not introduce	32.6.2	M	Yes [ ]	Extraneous signals on the MII control circuits during normal power-up and power-down.

32.13.5.9 Characteristics of the link segment

Item	Feature	Subclause	Status	Support	Value/Comment
LKS1	100BASE-T2 links shall use	32.7.1	M	Yes [ ]	2 pair of balanced cabling, CAT 3 or better, with a nominal impedance of 100 Ω.
LKS2	Unless otherwise specified, link segment testing shall be conducted using	32.7.2	M	Yes [ ]	Source and load impedances of 100 Ω.
LKS3	The tolerance on the poles of the test filter used in this section shall be	32.7.2	M	Yes [ ]	± 1%.
LKS4	The insertion loss of a link segment shall be no more than	32.7.2.1	M	Yes [ ]	14.6 dB at all frequencies between 2 and 16 MHz.
LKS5	The insertion loss specification shall be met when	32.7.2.1	M	Yes [ ]	The link segment is terminated in source and load impedances that satisfy 32.6.1.4.1.
LKS6	The magnitude of the differential characteristic impedance of a 3 m segment of balanced cabling pair used in a link shall be	32.7.2.2	M	Yes [ ]	Between 85 and 115 Ω for all frequencies between 2 and 16 MHz.
LKS7	The NEXT loss between each of the two duplex channels of a link segment shall be	32.7.2.3.1	M	Yes [ ]	At least $19.3–16.6\log_{10}(f/16)$ (where f is the frequency in MHz) over the frequency range 2.0 to 16 MHz.
LKS8	The NEXT loss between link segments of two different connections shall be	32.7.2.3.1	M	Yes [ ]	At least $22.0 –16.6\log_{10}(f/16)$ (where f is the frequency in MHz) over the frequency range 2.0 to 16 MHz.
LKS9	The MDNEXT loss between a link segment and the two alien data carrying channels shall be	32.7.2.3.2	M	Yes [ ]	At least $19.0–16.6\log_{10}(f/16)$ dB (where f is the frequency in MHz) over the frequency range 2.0 to 16 MHz.
LKS10	To limit the FEXT noise from an adjacent channel, the ELFEXT loss between channels shall be	32.7.2.3.3	M	Yes [ ]	Greater than $20.9–20\log_{10}(f/16)$ dB as defined in 32.7.2.3.3
LKS11	The MDELFEXT loss between a duplex channel and the other data carrying duplex channels shall be	32.7.2.3.4	M	Yes [ ]	Greater than $19.9–20\log10(f/16)$ (where f is the frequency in MHz) over the frequency range 2.0 to 16 MHz.
LKS12	The maximum spacing of the frequency in the sample shall be	32.7.2.3.5	M	Yes [ ]	250 kHz.

32.13.5.9 Characteristics of the link segment *(continued)*

Item	Feature	Subclause	Status	Support	Value/Comment
LKS13	When 10BASE-T service is used in adjacent pairs, the channel shall provide	32.7.2.3.5	M	Yes [ ]	A NEXT loss to Insertion loss Ratio (NIR) greater than 19.4 dB.
LKS14	The propagation delay of a link segment shall not exceed	32.7.2.4.1	M	Yes [ ]	5.7 ns/meter at all frequencies between 2.0–25.0 MHz.
LKS15	The difference in propagation delay, or skew, under all conditions, between the fastest and the slowest channel in a link segment shall not exceed	32.7.2.4.2	M	Yes [ ]	50 ns at all frequencies between 2.0–25.0 MHz.
LKS16	Once installed, the skew between pairs due to environmental conditions shall not vary	32.7.2.4.2	M	Yes [ ]	More than ± 10 ns.
LKS17	The noise level on the link segments shall be such that	32.7.3	M	Yes [ ]	The objective error ratio is met.
LKS18	The MDNEXT noise on a link segment shall not exceed	32.7.3.1	M	Yes [ ]	182 mVp.
LKS19	The MDFEXT noise on a link segment shall not exceed	32.7.3.2	M	Yes [ ]	54.4 mVp.
LKS20	Cables made from up to 25 pairs of Category 5 cabling, if used, shall be limited in length to no more than	32.7.4.3	O	Yes [ ]	90 m total.
LKS21	The services in 25 pair Category 5 cabling shall be limited to any combination of 100BASE-T2, 10BASE-T and digital phone service compliant with the ISDN-BR U and S/T interfaces up to a total of 12 services in the cable.	32.7.4.3	M	Yes [ ]	
LKS22	Jumper cabling, or horizontal runs, made from more than 4 pairs of Category 3 cabling shall not be used	32.7.4.3	M	Yes [ ]

32.13.5.10 MDI requirements

Item	Feature	Subclause	Status	Support	Value/Comment
MDI1	MDI connector	32.8.1	M	Yes [ ]	8-Way connector as per IEC 60603-7.
MDI2	Connector used on cabling	32.8.1	M	Yes [ ]	Plug.
MDI3	Connector used on PHY	32.8.1	M	Yes [ ]	Jack (as opposed to plug).
MDI4	AN MDI connector for the PHY that implements the crossover function shall be marked	32.8.2	M	Yes [ ]	With the graphical symbol “X”.

32.13.5.11 General safety and environmental requirements

Item	Feature	Subclause	Status	Support	Value/Comment
ENV1	Conformance to safety specifications	32.10.1	M	Yes [ ]	IEC 60950.
ENV2	Installation practice	32.10.2.1	M	Yes [ ]	Sound practice, as defined by applicable local codes.
ENV3	Any safety grounding path for an externally connected PHY shall be provided through the circuit ground of the MII connection.	32.10.2.2	M	Yes [ ]	
ENV4	Care taken during installation to ensure that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.	32.10.2.3	M	Yes [ ]	
ENV5	Application of voltages specified in 32.10.2.4 does not result in any safety hazard.	32.10.2.4	M	Yes [ ]	
ENV6	Conformance with local and national codes for the limitation of electromagnetic interference.	32.10.3.1	M	Yes [ ]	
ENV7	All equipment subject to this clause shall conform to	32.10.4	M	Yes [ ]	The requirements of 14.7 and the applicable sections of ISO/IEC 11801.

32.13.5.12 Timing requirements exposed MII

Item	Feature	Subclause	Status	Support	Value/Comment
TME1	TX-EN (sampled to MDI output)	32.12.1	M	Yes [ ]	7–9 bit times
TME2	MDI input to CRS assert	32.12.1	M	Yes [ ]	25 bit times
TME3	MDI input to CRS deassert	32.12.1	M	Yes [ ]	29 bit times
TME4	MDI input to COL assert	32.12.1	M	Yes [ ]	25 bit times
TME5	MDI input to COL deassert	32.12.1	M	Yes [ ]	29 bit times
TME6	TX_EN sampled to CRS assert	32.12.1	M	Yes [ ]	0–4 bit times
TME7	TX_EN sampled to CRS deassert	32.12.1	M	Yes [ ]	0–16 bit times

32.13.5.13 Timing requirements unexposed MII

Item	Feature	Subclause	Status	Support	Value/Comment
TMU1	MAC transmit start to MDI output	32.12.2	M	Yes [ ]	13 bit times
TMU2	MDI input to MDI output (worst-case non-deferred transmit)	32.12.2	M	Yes [ ]	50 bit times
TMU3	MDI input to collision detect	32.12.2	M	Yes [ ]	33 bit times
TMU4	MDI input to MDI output = Jam (worst-case collision response)	32.12.2	M	Yes [ ]	50 bit times

32.13.5.14 Timing requirements: carrier assertion/deassertion constraint

Item	Feature	Subclause	Status	Support	Value/Comment
TMC1	Each DTE shall satisfy the relationship	36.5.3	M	Yes [ ]	(MAX MDI to MAC Carrier Deassert Detect)–(MIN MDI to MAC Carrier Assert Detect).

33. Power over Ethernet over 2 Pairs

33.1 Overview

This clause defines the functional and electrical characteristics for providing a Power over Ethernet (PoE) system. The system consists of two optional power (non-data) entities, a Powered Device (PD) and Power Sourcing Equipment (PSE), for use with the MAU defined in Clause 14 and the PHYs defined in Clause 25, Clause 40, Clause 55, and Clause 126. These entities allow devices to draw/supply power using the same generic cabling as is used for data transmission.

This clause specifies Type 1 and Type 2 devices. References to PSEs and PDs without a Type qualifier refer to Type 1 and Type 2 devices. See Clause 145 for the specification of Type 3 and Type 4 devices.

Power over Ethernet is intended to provide a 10BASE-T, 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, or 10GBASE-T device with a single interface to both the data it requires and the power to process this data. This clause specifies the following:

a) A power source to add power to the 100 Ω balanced cabling system
b) The characteristics of a powered device's load on the power source and the structured cabling
c) A protocol allowing the detection of a device that requests power from a PSE
d) Methods to classify devices based on their power needs
e) A method for powered devices and power sourcing equipment to dynamically negotiate and allocate power
f) A method for scaling supplied power back to the detect level when power is no longer requested or required

The importance of item c) above should not be overlooked. Given the large number of legacy devices (both IEEE 802.3 and other types of devices) that could be connected to a 100 Ω balanced cabling system, and the possible consequences of applying power to such devices, the protocol to distinguish compatible devices and non-compatible devices is important to prevent damage to non-compatible devices.

The detection and powering algorithms are likely to be compromised by cabling that is not point-to-point, resulting in unpredictable performance and possibly damaged equipment.

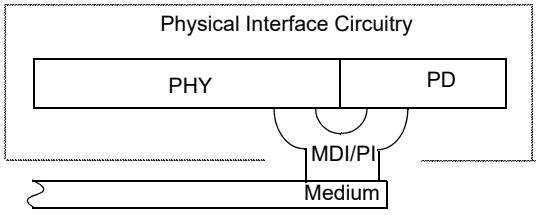
This clause differentiates between the two ends of the powered portion of the link, defining the PSE and the PD as separate but related devices.

33.1.1 Objectives

The following are objectives of Power via MDI:

a) *Power*—A PD designed to the standard, and within its range of available power, can obtain both power and data for operation through the MDI and therefore needs no additional connections.
b) *Safety*—A PSE designed to the standard does not introduce non-SELV (Safety Extra Low Voltage) power, as defined by IEC 60950-1, into the wiring plant.
c) *Compatibility*—Clause 33 utilizes the MDIs of 10BASE-T, 100BASE-TX, and 1000BASE-T without modification. Type 1 operation adds no significant requirements to the cabling. Type 2 operation requires ISO/IEC 11801:1995 Class D or better cabling and a derating of the cabling maximum ambient operating temperature.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

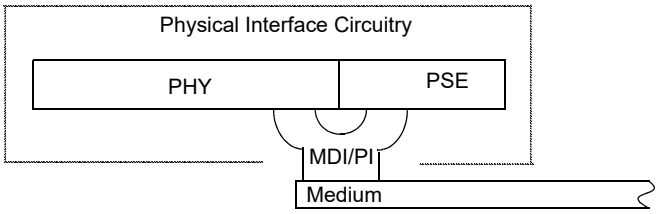


d) *Simplicity*—The powering system described here is no more burdensome on the end users than the requirements of 10BASE-T, 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, or 10GBASE-T.

33.1.2 Compatibility considerations

All implementations of PD and PSE systems shall be compatible at their respective Power Interfaces (PIs) when used in accordance with the restrictions of Clause 33 where appropriate. Designers are free to implement circuitry within the PD and PSE in an application-dependent manner provided that the respective PI specifications are satisfied.

33.1.3 Relationship of Power over Ethernet to the IEEE 802.3 Architecture



Power over Ethernet comprises an optional non-data entity. As a non-data entity, it does not appear in a depiction of the OSI Reference Model. Figure 33–1 depicts the positioning of Power over Ethernet (PoE) in the case of the PD.

MDI = Medium Dependent Interface
PD = Powered Device
PHY = Physical Layer Device
PI = Power Interface

Figure 33–1—PoE powered device relationship to the physical interface circuitry and the IEEE 802.3 CSMA/CD LAN model

Figure 33–2 and Figure 33–3 depict the positioning of Power over Ethernet in the cases of the Endpoint PSE and the Midspan PSE, respectively.

MDI = Medium Dependent Interface
PHY = Physical Layer Device
PI = Power Interface
PSE = Power Sourcing Equipment

Figure 33–2—PoE Endpoint power sourcing equipment relationship to the physical interface circuitry and the IEEE 802.3 CSMA/CD LAN model

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

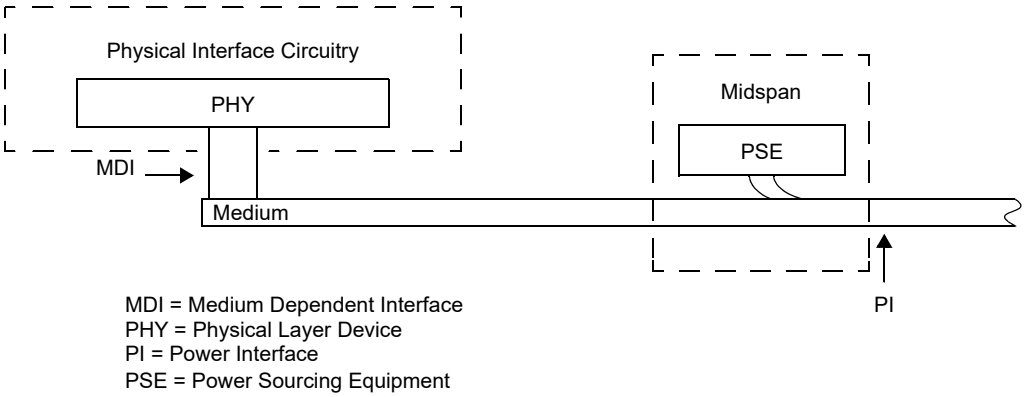

Figure 33–3—PoE Midspan power sourcing equipment relationship to the physical interface circuitry and the IEEE 802.3 CSMA/CD LAN model

The Power Interface (PI), as defined in 1.4.484, is the mechanical and electrical interface between the Power Sourcing Equipment (PSE) or Powered Device (PD) and the transmission medium.

The PI in both an Endpoint PSE and in a PD is the MDI as defined in 1.4.395.

PSE power interface specifications that are defined at the MDI apply to an Endpoint PSE. They may or may not apply to a Midspan PSE PI.

33.1.4 Type 1 and Type 2 system parameters

A power system, consisting of a single PSE, link section, and a single PD, defined as either Type 1 or Type 2, has certain basic parameters defined according to Table 33–1. These parameters define not only certain performance characteristics of the system, but are also used in calculating the various electrical characteristics of PSEs and PDs as described in 33.2 and 33.3.

Table 33–1—Type 1 and Type 2 system parameters

Parameter	Symbol	Units	Type 1 value	Type 2 value	Additional information
Nominal highest DC current per pair	I_{Cable}	A	0.350	0.600	
Channel maximum DC pair loop resistance	R_{Ch}	Ω	20.0	12.5	
Minimum cable type			twisted-pair cabling per 14.4 and 14.5[a]	Class D	See 33.1.4.1, 33.1.4.2

[a]Class D recommended.

I_{Cable} is the current on one twisted pair in the multi-twisted pair cable. Two twisted pairs are required to source I_{Cable}—one carrying (+ I_{Cable}) and one carrying (– I_{Cable}), from the perspective of the PI.

It should be noted that the cable references use “DC loop resistance,” which refers to a single conductor. This clause uses “DC pair loop resistance,” which refers to a pair of conductors in parallel. Therefore, R_{Ch} is related to, but not equivalent to, the “DC loop resistance” called out in the cable references.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

I_{Port} is the current on either powered pair.

V_{PD} is the voltage at the PD PI, measured between any positive conductor and any negative conductor of the powered pairs.

V_{PSE} is the voltage at the PSE PI, measured between any positive conductor and any negative conductor of the powered pairs.

33.1.4.1 Type 2 cabling requirement

Type 2 operation requires Class D, or better, cabling as specified in ISO/IEC 11801:1995 with the additional requirement that channel DC loop resistance shall be 25 Ω or less. These requirements are also met by Category 5e or better cable and components as specified in ANSI/TIA-568-C.2; or Category 5 cable and components as specified in ANSI/TIA/EIA-568-A.

Under worst-case conditions, Type 2 operation requires a 10 °C reduction in the maximum ambient operating temperature of the cable when all cable pairs are energized at I_{Cable} (see Table 33–1), or a 5 °C reduction in the maximum ambient operating temperature of the cable when half of the cable pairs are energized at I_{Cable}. Additional cable ambient operating temperature guidelines for Type 2 operation are provided in ISO/IEC TR 29125 [B44][72] and TIA TSB-184 [B65].

33.1.4.2 Type 1 and Type 2 channel requirement

Type 1 and Type 2 operation requires that the resistance unbalance shall be 3% or less. Resistance unbalance is a measure of the difference between the two conductors of a twisted pair in the 100 Ω balanced cabling system. Resistance unbalance is defined as in Equation (33–1):

$$\left.\frac{(R_{max} - R_{min})}{(R_{max} + R_{min})} \times 100 \right\}_{\%} \tag{33–1}$$

where

R_{max} is the resistance of the channel conductor with the highest resistance
R_{min} is the resistance of the channel conductor with the lowest resistance

33.2 Power sourcing equipment (PSE)

The PSE is the portion of the end station or midspan equipment that provides the power to a single PD. The PSE's main functions are as follows:

— To search the link section for a PD
— To supply power to the detected PD through the link section
— To monitor the power on the link section
— To remove power when no longer requested or required, returning to the searching state

An unplugged link section is one instance when power is no longer required. In addition, power classification mechanisms exist to provide the PSE with detailed information regarding the power needs of the PD.

A PSE is electrically specified at the point of the physical connection to the cabling.

[72]The numbers in brackets correspond to those of the bibliography in Annex A.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.2.1 PSE location

PSEs may be placed in two locations with respect to the link segment, either coincident with the DTE/Repeater or midspan. A PSE that is coincident with the DTE/Repeater is an “Endpoint PSE.” A PSE that is located within a link segment that is distinctly separate from and between the MDIs is a “Midspan PSE.” The requirements of this document shall apply equally to Endpoint and Midspan PSEs unless the requirement contains an explicit statement that it applies to only one implementation. The location of Alternative A and Alternative B Endpoint PSEs and Midspan PSEs are illustrated in Figure 33–4, Figure 33–5, Figure 33–6, and Figure 33–7.

The PSE specification is designed to be compatible with any of the following: 10BASE-T, 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, 10GBASE-T. PSEs may support either Alternative A, Alternative B, or both.

33.2.2 Midspan PSE types

There are several variants of Midspan PSEs defined:

10BASE-T/100BASE-TX Midspan PSE:
: A Midspan PSE that results in a link that can support only 10BASE-T and 100BASE-TX operation (see Figure 33–6). Note that this limitation is due to the presence of the Midspan PSE whether it is supplying power or not.

1000BASE-T Midspan PSE:
: A Midspan PSE that results in a link that can support 10BASE-T, 100BASE-TX, and 1000BASE-T operation (see Figure 33–7).

2.5GBASE-T Midspan PSE:
: A Midspan PSE that results in a link that can support 1000BASE-T and 2.5GBASE-T operation and optionally support 10BASE-T and 100BASE-TX operation (see Figure 33–7).

5GBASE-T Midspan PSE:
: A Midspan PSE that results in a link that can support 1000BASE-T, 2.5GBASE-T, and 5GBASE-T operation and optionally support 10BASE-T and 100BASE-TX operation (see Figure 33–7).

10GBASE-T Midspan PSE:
: A Midspan PSE that results in a link that can support 1000BASE-T, 2.5GBASE-T, 5GBASE-T, and 10GBASE-T operation and optionally support 10BASE-T and 100BASE-TX operation (see Figure 33–7).

NOTE—See 33.4.9.4 for Alternative A Midspan PSEs.

33.2.3 PI pin assignments

A PSE device may provide power via one of two valid four-wire connections. In each four-wire connection, the two conductors associated with a pair each carry the same nominal current in both magnitude and polarity. Figure 33–8, in conjunction with Table 33–2, illustrates the valid alternatives.

Table 33–2—PSE Pinout alternatives

Conductor	Alternative A (MDI-X)	Alternative A (MDI)	Alternative B (All)
1	Negative V_{PSE}	Positive V_{PSE}	
2	Negative V_{PSE}	Positive V_{PSE}	
3	Positive V_{PSE}	Negative V_{PSE}	
4			Positive V_{PSE}
5			Positive V_{PSE}
6	Positive V_{PSE}	Negative V_{PSE}	
7			Negative V_{PSE}
8			Negative V_{PSE}

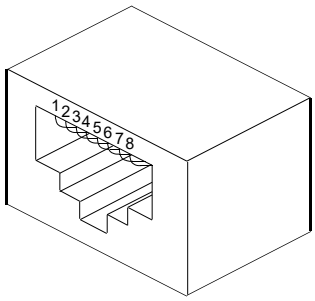

Figure 33–8—PD and PSE eight-pin modular jack

For the purposes of data transfer, the type of PSE data port is relevant to the far-end PD, and in some cases, to the cabling system between them. Therefore, Alternative A matches the positive voltage to the transmit pair of the PSE. PSEs that use automatically-configuring MDI/MDI-X ("Auto MDI-X") ports may choose either polarity choice associated with Alternative A configurations. For further information on the placement of MDI vs. MDI-X, see 14.5.2.

A PSE shall implement Alternative A, Alternative B, or both. While a PSE may be capable of both Alternative A and Alternative B, PSEs shall not operate both Alternative A and Alternative B on the same link section simultaneously.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.2.4 PSE state diagrams

The PSE shall provide the behavior of the state diagrams shown in Figure 33–9, Figure 33–9 continued, and Figure 33–10.

33.2.4.1 Overview

Detection, classification, and power turn-on timing shall meet the specifications in Table 33–4, Table 33–10, and Table 33–11.

If power is to be applied, the PSE turns on power after a valid detection in less than T_{pon} as specified in Table 33–11. If the PSE cannot supply power within T_{pon}, it initiates and successfully completes a new detection cycle before applying power.

It is possible that two separate PSEs, one that implements Alternative A and one that implements Alternative B (see 33.2.1), may be attached to the same link segment. In such a configuration, and without the required backoff algorithm, the PSEs could prevent each other from ever detecting a PD by interfering with the detection process of the other.

A PSE performing detection using Alternative B may fail to detect a valid PD detection signature. When this occurs, the PSE backs off for at least T_{dbo} as specified in Table 33–11 before attempting another detection. During this backoff, the PSE shall not apply a voltage greater than V_{Off} to the PI.

If a PSE performing detection using Alternative B detects an open circuit (see 33.2.5.5) on the link section, then that PSE may optionally omit the detection backoff.

If a PSE performing detection using Alternative A detects an invalid signature, it should complete a second detection in less than T_{dbo} min after the beginning of the first detection attempt. This allows an Alternative A PSE to complete a successful detection cycle prior to an Alternative B PSE present on the same link section that may have caused the invalid signature.

NOTE—A Type 1 PSE performing detection using Alternative A may need to have its DTE powering ability disabled when it is attached to the same link segment as a Type 2 Midspan PSE performing detection using Alternative B. This allows the Midspan PSE to successfully complete a detection cycle.

33.2.4.2 Conventions

The notation used in the state diagrams follows the conventions of state diagrams as described in 21.5.

33.2.4.3 Constants

The PSE state diagrams use the following constants:

PSE_TYPE
: A constant indicating the type of the PSE
Values: 1: Type 1 PSE
2: Type 2 PSE

33.2.4.4 Variables

The PSE state diagrams use the following variables:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

class_num_events

A variable indicating the number of classification events performed by the PSE. A variable that is set in an implementation-dependent manner.

Values:0: PSE does not perform Physical Layer classification.
1: PSE performs 1-Event Physical Layer classification.
2: PSE performs 2-Event Physical Layer classification.

error_condition

A variable indicating the status of implementation-specific fault conditions or optionally other system faults that prevent the PSE from meeting the specifications in Table 33–11 and that require the PSE not to source power. These error conditions are different from those monitored by the state diagrams in Figure 33–10.

Values:FALSE:No fault indication.
TRUE:A fault indication exists.

I_{Inrush}

Output current during POWER_UP (see Table 33–11 and Figure 33–13).

I_{Port}

Output current (see 33.2.7.6).

legacy_powerup

This variable is provided for PSEs that monitor the PI voltage output and use that information to indicate the completion of PD inrush current during POWER_UP operation. Using only the PI voltage information may be insufficient to determine the true end of PD inrush current; use of a fixed T_{Inrush} period is recommended. A variable that is set in an implementation-dependent manner.

Values:TRUE:The PSE supports legacy power up; this value is not recommended.
FALSE:The PSE does not support legacy power up. It is highly recommended that new equipment use this value.

mr_mps_valid

The PSE monitors either the DC or AC Maintain Power Signature (MPS, see 33.2.9.1). This variable indicates the presence or absence of a valid MPS.

Values:FALSE:If monitoring both components of the MPS, the DC component of MPS is absent or the AC component of MPS is absent. If monitoring only one component of MPS, that component of MPS is absent.
TRUE: If monitoring both components of the MPS, the DC component of MPS and the AC component of MPS are both present. If monitoring only one component of MPS, that component of MPS is present.

mr_pse_alternative

This variable indicates which Pinout Alternative the PSE uses to apply power to the link (see Table 33–2). This variable is provided by a management interface that may be mapped to the PSE Control register Pair Control bits (11.3:2) or other equivalent function.

Values:A: The PSE uses PSE pinout Alternative A.
B: The PSE uses PSE pinout Alternative B.

mr_pse_enable

A control variable that selects PSE operation and test functions. This variables is provided by a management interface that may be mapped to the PSE Control register PSE Enable bits (11.1:0), as described below, or other equivalent functions.

Values:disable: All PSE functions disabled (behavior is as if there was no PSE functionality). This value corresponds to MDIO register bits 11.1:0 = '00'.
enable: Normal PSE operation. This value corresponds to MDIO register bits 11.1:0 = '01'.
force_power: Test mode selected that causes the PSE to apply power to the PI when there are no detected error conditions. This value corresponds to MDIO register bits 11.1:0 = '10'.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

option_detect_ted

This variable indicates if detection can be performed by the PSE during the ted_timer interval.

Values:FALSE:Do not perform detection during ted_timer interval.

TRUE:Perform detection during ted_timer interval.

option_vport_lim

This optional variable indicates if V_{PSE} is out of the operating range during normal operating state.

Values:FALSE:V_{PSE} is within the V_{Port_PSE} operating range as defined in Table 33–11.

TRUE:V_{PSE} is outside of the V_{Port_PSE} operating range as defined in Table 33–11.

ovld_detected

A variable indicating if the PSE output current has been in an overload condition (see 33.2.7.6) for at least T_{CUT} of a one second sliding time.

Values:FALSE:The PSE has not detected an overload condition.

TRUE:The PSE has detected an overload condition.

pd_dll_power_type

A control variable initially output by the PSE power control state diagram (Figure 33–27), which can be updated by LLDP (see Table 33–26), that indicates the type of PD as advertised through Data Link Layer classification.

Values:1: PD is a Type 1 PD (default)

2: PD is a Type 2 PD

pi_powered

A variable that controls the circuitry that the PSE uses to power the PD.

Values:FALSE:The PSE is not to apply power to the link (default).

TRUE:The PSE has detected a PD, classified it if applicable, and determined the PD is to be powered; or power is being forced on in TEST_MODE.

power_applied

A variable indicating that the PSE has begun steady state operation by having asserted pi_powered, completed the ramp of voltage, is not in a current limiting mode, and is operating beyond the POWER_UP requirements of 33.2.7.5.

Values:FALSE:The PSE is either not applying power or has begun applying power but is still in POWER_UP.

TRUE:The PSE has begun steady state operation.

power_not_available

Variable that is asserted in an implementation-dependent manner when the PSE is no longer capable of sourcing sufficient power to support the attached PD. Sufficient power is defined by classification; see 33.2.6.

Values:FALSE:PSE is capable to continue to source power to a PD.

TRUE:PSE is no longer capable of sourcing power to a PD.

pse_available_power

This variable indicates the highest power PD Class that could be supported. The value is determined in an implementation-specific manner.

Values:0: Class 1

1: Class 2

2: Class 0 and Class 3

3: Class 4

pse_dll_capable

This variable indicates whether the PSE is capable of performing optional Data Link Layer classification. See 33.6. This variable is provided by a management interface that may be mapped to the PSE Control register Data Link Layer Classification Capability bit (11.5), as described below, or other equivalent functions. A variable that is set in an implementation-dependent manner.

Values:FALSE:The PSE’s Data Link Layer classification capability is not enabled.

TRUE:The PSE’s Data Link Layer classification capability is enabled.

pse_dll_enabled

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A variable indicating whether the Data Link Layer classification mechanism is enabled. See 33.6.
Values:FALSE:Data Link Layer classification is not enabled.
TRUE:Data Link Layer classification is enabled.

pse_ready
Variable that is asserted in an implementation-dependent manner to probe the link segment.
Values:FALSE:PSE is not ready to probe the link segment.
TRUE:PSE is ready to probe the link segment.

NOTE—Care should be taken when negating this variable in a PSE performing detection using Alternative A after an invalid signature is detected due to the delay it introduces between detection attempts (see 33.2.4.1).

pse_reset
Controls the resetting of the PSE state diagram. Condition that is TRUE until such time as the power supply for the device that contains the PSE overall state diagrams has reached the operating region. It is also TRUE when implementation-specific reasons require reset of PSE functionality.
Values:FALSE:Do not reset the PSE state diagram.
TRUE:Reset the PSE state diagram.

pse_skips_event2
The PSE can choose to bypass a portion of the classification state flow. A variable that is set in an implementation-dependent manner.
Values:FALSE:The PSE does not bypass MARK_EV1.
TRUE:The PSE does bypass MARK_EV1.

short_detected
A variable indicating if the PSE output current has been in a short circuit condition for T_{LIM} within a sliding window (see 33.2.7.7).
Values:FALSE:The PSE has not detected a short circuit condition.
TRUE:The PSE has detected qualified short circuit condition.

temp_var
A temporary variable used to store the value of the state variable mr_pd_class_detected.

PSEs shall meet at least one of the allowable variable definition permutations described in Table 33–3.

Table 33–3—Allowed PSE variable definition permutations

PSE Type	Variables	
	class_num_events	**pse_dll_capable**
Type 2	2	FALSE
		TRUE
	1	TRUE
Type 1	1	FALSE
		TRUE
	0	FALSE
		TRUE

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.2.4.5 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition: a timer is reset and stops counting upon entering a state where “stop x_timer” is asserted.

tcle1_timer
: A timer used to limit the first classification event time in 2-Event classification; see T_{CLE1} in Table 33–10.

tcle2_timer
: A timer used to limit the second classification event time in 2-Event classification; see T_{CLE2} in Table 33–10.

tdbo_timer
: A timer used to regulate backoff upon detection of an invalid signature; see T_{dbo} in Table 33–11.

tdet_timer
: A timer used to limit an attempt to detect a PD; see T_{det} in Table 33–11.

ted_timer
: A timer used to regulate a subsequent attempt to power a PD after an error condition causes power removal; see T_{ed} in Table 33–11. The default state of this timer is ted_timer_done.

tinrush_timer
: A timer used to monitor the duration of the inrush event; see T_{Inrush} in Table 33–11.

tme1_timer
: A timer used to limit the first mark event time in 2-Event classification; see T_{ME1} in Table 33–10.

tme2_timer
: A timer used to limit the second mark event time in 2-Event classification; see T_{ME2} in Table 33–10.

tmpdo_timer
: A timer used to monitor the dropout of the MPS; see T_{MPDO} in Table 33–11.

tpdc_timer
: A timer used to limit the classification time; see T_{pdc} in Table 33–10.

tpon_timer
: A timer used to limit the time for power turn-on; see T_{pon} in Table 33–11.

33.2.4.6 Functions

do_classification
: This function returns the following variables:

  pd_requested_power: This variable indicates the power class requested by the PD. A Type 1 PSE that measures a Class 4 signature assigns that PD to Class 0. See 33.2.6.

  Values:
  - 0: Class 1
  - 1: Class 2
  - 2: Class 0 or Class 3
  - 3: Class 4

  mr_pd_class_detected: The class of the PD associated with the PD classification signature; see Table 33–7 and 33.2.6.

  Values:
  - 0: Class 0
  - 1: Class 1
  - 2: Class 2
  - 3: Class 3
  - 4: Class 4

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

do_detection

This function returns the following variables:

signature:

This variable indicates the presence or absence of a PD.

Values: open_circuit: The PSE has detected an open circuit. This value is optionally returned by a PSE performing detection using Alternative B.
valid: The PSE has detected a PD requesting power.
invalid: Neither open_circuit, nor valid PD detection signature has been found.

mr_valid_signature:

This variable indicates that the PSE has detected a valid signature.

Values: FALSE: No valid signature detected.
TRUE: Valid signature detected.

do_mark

This function produces the classification mark event voltage. This function does not return any variables.

set_parameter_type

This function is used by a Type 2 PSE to evaluate the type of PD connected to the link based on Physical Layer classification or Data Link Layer classification results. The PSE's PI electrical requirements defined in Table 33–11 are set to values corresponding to either a Type 1 or Type 2 PSE. This function returns the following variable:

parameter_type: A variable used by a Type 2 PSE to pick between Type 1 and Type 2 PI electrical requirement parameter values defined in Table 33–11.

Values: 1: Type 1 PSE parameter values (default)
2: Type 2 PSE parameter values

When a Type 2 PSE powers a Type 2 PD, the PSE may choose to assign a value of '1' to parameter_type if mutual identification is not complete (see 33.2.6) and shall assign a value of '2' to parameter_type if mutual identification is complete.

When a Type 2 PSE powers a Type 1 PD, the PSE shall meet the PI electrical requirements of a Type 1 PSE, but may choose to meet the electrical requirements of a Type 2 PSE for I_{Con}, I_{LIM}, T_{LIM}, and P_{Type} (see Table 33–11).

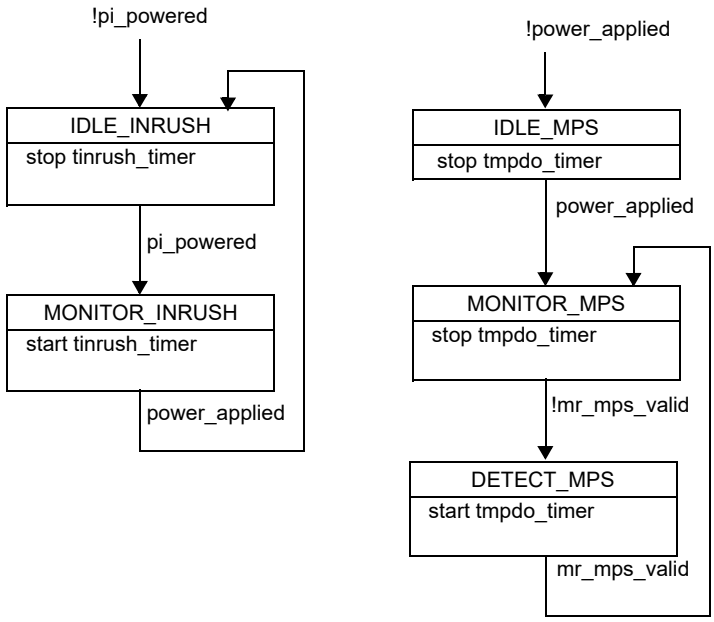

Figure 33–10—PSE monitor inrush and monitor MPS state diagrams

33.2.5 PSE detection of PDs

In any operational state, the PSE shall not apply operating power to the PI until the PSE has successfully detected a PD requesting power.

The PSE probes the link section in order to detect a valid PD detection signature. The PSE PI is connected to a PD through a link section. In the following subclauses, the link is not called out to preserve clarity.

The PSE is not required to continuously probe to detect a PD signature. The period of time when a PSE is not attempting to detect a PD signature is implementation dependent. Also, a PSE may successfully detect a PD but then opt not to power the detected PD.

The PSE shall turn on power only on the same pairs as those used for detection.

33.2.5.1 PSE detection validation circuit

The PSE shall detect the PD by probing via the PSE PI. The PSE shall present a non-valid PD detection signature as defined in Table 33–15 when probed in either polarity by another PSE. An illustrative embodiment of a detection circuit is shown in Figure 33–11.

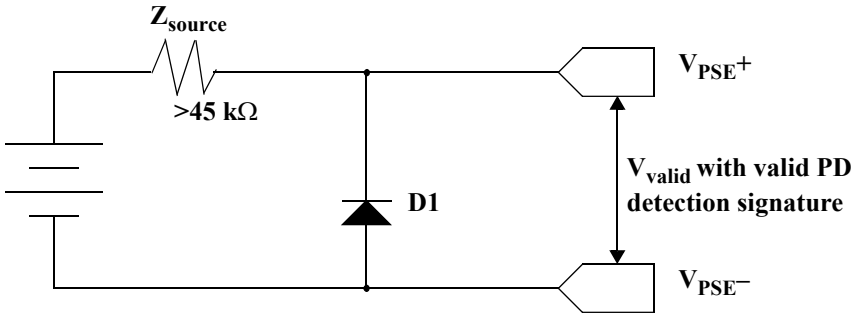

Figure 33–11—PSE detection source

A functional equivalent of the detection circuit that has no source impedance limitation but restricts the PSE detection circuit to the first quadrant is shown in Figure 33–12.

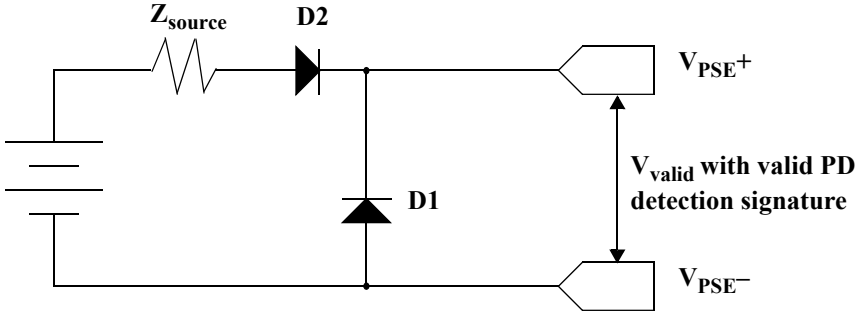

Figure 33–12—Alternative PSE detection source

In Figure 33–11 and Figure 33–12, the diode D1 presents a non-valid PD detection signature for a reversed voltage PSE to PSE connection.

The open circuit voltage and short circuit current shall meet the specifications in Table 33–4. The PSE shall not be damaged by up to 5 mA backdriven current over the range of V_{oc} as specified in Table 33–4. Output capacitance shall be as specified in Table 33–11.

Table 33–4—PSE PI detection state electrical requirements

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Open circuit voltage	V_{oc}	V		30.0	In detection state only
2	Short circuit current	I_{sc}	A		0.005	In detection state only
3	Valid test voltage	V_{valid}	V	2.80	10.0	—
4	Voltage difference between test points	ΔV_{test}	V	1.00		—
5	Slew rate	V_{slew}	V/μs		0.100	—

33.2.5.2 Detection probe requirements

The detection voltage at the PSE PI shall be within the V_{valid} voltage range (as specified in Table 33–4) with a valid PD detection signature connected (as specified in Table 33–14).

In evaluating the presence of a valid PD, the PSE shall make at least two measurements with V_{PSE} values that create at least a ΔV_{test} difference as specified in Table 33–4. An effective resistance is calculated from two voltage/current measurements made during the detection process.

The resistance is calculated with Equation (33–2):

$$R = \left\{ \frac{(V_2 - V_1)}{(I_2 - I_1)} \right\}_{\Omega} \tag{33–2}$$

where

V_1 and V_2	are the first and second voltage measurements made at the PSE PI, respectively
I_1 and I_2	are the first and second current measurements made at the PSE PI, respectively
R	is the effective resistance

Attached PI capacitance may be determined using these measurements and the port RC time-constant charging characteristics.

NOTE—Settling time before voltage or current measurement: the voltage or current measurement should be taken after V_{PSE} has settled to within 1% of its steady state condition with a valid PD detection signature connected (as specified in Table 33–14).

The PSE shall control the slew rate of the probing detection voltage when switching between detection voltages to be less than V_{slew} as specified in Table 33–4.

33.2.5.3 Detection criteria

A PSE shall accept as a valid signature a link section with both of the following characteristics between the powering pairs with an offset voltage up to V_{os} max and an offset current up to I_{os} max, as specified in Table 33–5:

a) Signature resistance R_{good}, and
b) Parallel signature capacitance C_{good}.

Table 33–5—Valid PD detection signature electrical characteristics

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Accept signature resistance	R_{good}	kΩ	19.0	26.5	—
2	Accept signature capacitance	C_{good}	µF		0.150	—
3	Signature offset voltage tolerance	V_{os}	V	0	2.00	—
4	Signature offset current tolerance	I_{os}	µA	0	12.0	—

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

CAUTION

In a multiport system, the implementer should maintain DC isolation through the termination circuitry to eliminate cross-port leakage currents.

33.2.5.4 Rejection criteria

The PSE shall reject link sections as having an invalid signature, when those link sections exhibit any of the following characteristics between the powering pairs, as specified in Table 33–6:

a) Resistance less than or equal to R_{bad} min, or
b) Resistance greater than or equal to R_{bad} max, or
c) Capacitance greater than or equal to C_{bad} min.

A PSE may accept or reject a signature resistance in the band between R_{good} min and R_{bad} min, and in the band between R_{good} max and R_{bad} max. A PSE may accept or reject a parallel signature capacitance in the band between C_{good} max and C_{bad} min.

In instances where the resistance and capacitance meet the detection criteria, but one or both of the offset tolerances are exceeded, the detection behavior of the PSE is undefined.

Table 33–6—Invalid PD detection signature electrical characteristics

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Reject signature resistance	R_{bad}	kΩ	15.0	33.0	—
2	Reject signature capacitance	C_{bad}	μF	10.0		—
3	Open circuit resistance	R_{open}	MΩ	0.500		—

33.2.5.5 Open circuit criteria

If a PSE that is performing detection using Alternative B (see 33.2.3) determines that the impedance at the PI is greater than R_{open} as defined in Table 33–4, it may optionally consider the link to be open circuit and omit the tdbo_timer interval.

33.2.6 PSE classification of PDs and mutual identification

The ability for the PSE to query the PD in order to determine the power requirements of that PD is called classification. The interrogation and power classification function is intended to establish mutual identification and is intended for use with advanced features such as power management.

Mutual identification is the mechanism that allows a Type 2 PD to differentiate Type 1 PSEs from Type 2 PSEs. Additionally, mutual identification allows Type 2 PSEs to differentiate between Type 1 and Type 2 PDs. PDs or PSEs that do not implement classification will not be able to complete mutual identification and can only perform as Type 1 devices.

There are two forms of classification: Physical Layer classification and Data Link Layer classification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Physical Layer classification occurs before a PSE supplies power to a PD when the PSE asserts a voltage onto the PI and the PD responds with a current representing a limited number of power classifications. Based on the response of the PD, the minimum power level at the output of the PSE is P_{Class} as shown in Equation (33–3). Physical Layer classification encompasses two methods, known as 1-Event Physical Layer classification (see 33.2.6.1) and 2-Event Physical Layer classification (see 33.2.6.2).

The minimum power output by the PSE for a particular PD class is defined by Equation (33–3). Alternatively, PSE implementations may use $V_{PSE} = V_{Port_PSE}$ min and $R_{Chan} = R_{Ch}$ max to arrive at over-margined values as shown in Table 33–7.

$$P_{Class} = \left\{ V_{PSE} \times \left(\frac{V_{PSE} - \sqrt{V_{PSE}^2 - 4 \times R_{Chan} \times P_{Class_PD}}}{2 \times R_{Chan}} \right) \right\}_W \quad (33–3)$$

where

V_{PSE} is the voltage at the PSE PI as defined in 33.1.4
R_{Chan} is the channel DC pair loop resistance
P_{Class_PD} is the PD's power classification (see Table 33–18)

Table 33–7—Physical Layer power classifications (P_{Class})

Class	Minimum power levels at output of PSE (P_{Class})
0	15.4 Watts
1	4.00 Watts
2	7.00 Watts
3	15.4 Watts
4	P_{Type} as defined in Table 33–11
NOTE 1—This is the minimum power at the PSE PI. For maximum power available to PDs, see Table 33–18. NOTE 2—Data Link Layer classification takes precedence over Physical Layer classification.	

With Data Link Layer classification, the PSE and PD communicate using the Data Link Layer Protocol (see 33.6) after the data link is established. The Data Link Layer classification has finer power resolution and the ability for the PSE and PD to participate in dynamic power allocation wherein allocated power to the PD may change one or more times during PD operation.

A PSE shall meet one of the allowable classification permutations listed in Table 33–8.

Subsequent to successful detection, a Type 1 PSE may optionally classify a PD using 1-Event Physical Layer classification. Valid classification results are Classes 0, 1, 2, 3, and 4, as listed in Table 33–7. If a Type 1 PSE does not implement classification, then the Type 1 PSE shall assign all PDs to Class 0. A Type 1 PSE may optionally implement Data Link Layer classification.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 33–8—PSE and PD classification permutations

Permutations			PSE allowed?	PD allowed?
PSE/PD Type	Physical Layer classification	Data Link Layer classification		
Type 2	2-Event	No	Yes	No
		Yes	Yes	Yes
	1-Event	No	No	No
		Yes	Yes	No
	None	No	No	No
		Yes	No	No
Type 1	2-Event	No	No	Yes
		Yes	No	Yes
	1-Event	No	Yes	Yes
		Yes	Yes	Yes
	None	No	Yes	No
		Yes	Yes	No

Subsequent to successful detection, all Type 2 PSEs perform classification using at least one of the following: 2-Event Physical Layer classification; 2-Event Physical Layer classification and Data Link Layer classification; or 1-Event Physical Layer classification and Data Link Layer classification.

If a PSE successfully completes detection of a PD, but the PSE fails to complete classification of a PD, then a Type 1 PSE shall either return to the IDLE state or assign the PD to Class 0; a Type 2 PSE shall return to the IDLE state.

33.2.6.1 PSE 1-Event Physical Layer classification

When 1-Event Physical Layer classification is implemented, classification consists of the application of V_{Class} and the measurement of I_{Class} in a single classification event—1-EVENT_CLASS—as defined in the state diagram in Figure 33–9.

The PSE shall provide to the PI V_{Class} with a current limitation of I_{Class_LIM}, as defined in Table 33–10. Polarity shall be the same as defined for V_{Port_PSE} in 33.2.3 and timing specifications shall be as defined by T_{pdc} in Table 33–10.

The PSE shall measure the resultant I_{Class} and classify the PD based on the observed current according to Table 33–9. All measurements of I_{Class} shall be taken after the minimum relevant class event timing in Table 33–10. This measurement is referenced from the application of V_{Class} min to ignore initial transients.

If the result of the class event is Class 4, a Type 1 PSE shall assign the PD to Class 0; a Type 2 PSE treats the PD as a Type 2 PD but may provide Class 0 power until mutual identification is complete.

If the measured I_{Class} is within the range of I_{Class_LIM}, a Type 1 PSE shall either return to the IDLE state or classify the PD as Class 0; a Type 2 PSE shall return to the IDLE state.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.2.6.2 PSE 2-Event Physical Layer classification

When 2-Event Physical Layer classification is implemented, classification consists of the application of V_{Class} and the measurement of I_{Class} in a series of classification and mark events—CLASS_EV1, MARK_EV1, CLASS_EV2, and MARK_EV2—as defined in the state diagram in Figure 33–9.

The PSE in the state CLASS_EV1 shall provide to the PI V_{Class} as defined in Table 33–10. The timing specification shall be as defined by T_{CLE1} in Table 33–10. The PSE shall measure I_{Class} and classify the PD based on the observed current according to Table 33–9.

When the PSE is in the state MARK_EV1, the PSE shall provide to the PI V_{Mark} as defined in Table 33–10. The timing specification shall be as defined by T_{ME1} in Table 33–10.

When the PSE is in the state CLASS_EV2, the PSE shall provide to the PI V_{Class}, subject to the T_{CLE2} timing specification, as defined in Table 33–10. The PSE shall measure I_{Class} and classify the PD based on the observed current according to Table 33–9.

When the PSE is in the state MARK_EV2, the PSE shall provide to the PI V_{Mark} as defined in Table 33–10. The timing specification shall be as defined by T_{ME2} in Table 33–10.

The mark event states, MARK_EV1 and MARK_EV2, commence when the PI voltage falls below V_{Class} min and end when the PI voltage exceeds V_{Class} min. The V_{Mark} requirement is to be met with load currents in the range of I_{Mark} as defined in Table 33–17.

NOTE—In a properly operating system, the port may or may not discharge to the V_{Mark} range due to the combination of channel and PD capacitance and PD current loading. This is normal and acceptable system operation. For compliance testing, it is necessary to discharge the port in order to observe the V_{Mark} voltage. Discharge can be accomplished with a 2 mA load for 3 ms, after which V_{Mark} can be observed with minimum and maximum load current.

If any measured I_{Class} is equal to or greater than I_{Class_LIM} min as defined in Table 33–10, a Type 2 PSE shall return to the IDLE state. The class events shall meet the I_{Class_LIM} current limitation. The mark events shall meet the I_{Mark_LIM} current limitation. All measurements of I_{Class} shall be taken after the minimum relevant class event timing of Table 33–10. This measurement is referenced from the application of V_{Class} min to ignore initial transients.

All class event voltages and mark event voltages shall have the same polarity as defined for V_{Port_PSE} in 33.2.3. The PSE shall complete 2-Event Physical Layer classification and transition to the POWER_ON state without allowing the voltage at the PI to go below V_{Mark} min. If the PSE returns to the IDLE state, it shall maintain the PI voltage at V_{Reset} for a period of at least T_{Reset} min before starting a new detection cycle.

If the result of the first class event is Class 4, the PSE may omit the subsequent mark and class events only if the PSE implements Data Link Layer classification. In this case, a Type 2 PSE treats the PD as a Type 2 PD but may provide Class 0 power until mutual identification is complete.

If the result of the first class event is any of Classes 0, 1, 2, or 3, the PSE treats the PD as a Type 1 PD and may omit the subsequent mark and class events and classify the PD according to the result of the first class event.

Table 33–9—PD classification

Measured I_{Class}	Classification
0 mA to 5.00 mA	Class 0
> 5.00 mA and < 8.00 mA	May be Class 0 or 1
8.00 mA to 13.0 mA	Class 1
> 13.0 mA and < 16.0 mA	Either Class 1 or 2
16.0 mA to 21.0 mA	Class 2
> 21.0 mA and < 25.0 mA	Either Class 2 or 3
25.0 mA to 31.0 mA	Class 3
> 31.0 mA and < 35.0 mA	Either Class 3 or 4
35.0 mA to 45.0 mA	Class 4
> 45.0 mA and < 51.0 mA	Either Class 4 or invalid class

NOTE—A Type 1 PSE may ignore I_{Class} and report Class 0.

Table 33–10—PSE Physical Layer classification electrical requirements

Item	Parameter	Symbol	Units	Min	Max	1- or 2-Event	Additional information
1	Class event voltage	V_{Class}	V	15.5	20.5	1, 2	
2	Class event current limitation	I_{Class_LIM}	A	0.051	0.100	1, 2	
3	Mark event voltage	V_{Mark}	V	7.00	10.0	2	
4	Mark event current limitation	I_{Mark_LIM}	A	0.005	0.100	2	
5	1st class event timing	T_{CLE1}	ms	6.00	30.0	2	
6	1st mark event timing	T_{ME1}	ms	6.00	12.0	2	
7	2nd class event timing	T_{CLE2}	ms	6.00	30.0	2	
8	2nd mark event timing	T_{ME2}	ms	6.00		2	Time from end of detection until power-on is limited by 33.2.7.12.
9	Classification reset voltage	V_{Reset}	V	0	2.80	2	
10	Classification reset timing	T_{Reset}	ms	15.0		2

33.2.7 Power supply output

PSE behavior conforms to the state diagrams in Figure 33–9, Figure 33–9 continued, and Figure 33–10. When the PSE provides power to the PI, it shall conform with Table 33–11.

Table 33–11 limits show values that support worst-case operating limits. These ranges may be narrowed when additional information is known and applied in accordance with this specification.

Table 33–11—PSE output PI electrical requirements for all PD classes, unless otherwise specified

Item	Parameter	Symbol	Unit	Min	Max	PSE Type	Additional information
1	Output voltage in the POWER_ON state	V_{Port_PSE}	V	44.0	57.0	1	See 33.2.7.1.
				50.0	57.0	2	
2	Voltage transient below V_{Port_PSE} min	K_{Tran_lo}	%		7.6	2	See 33.2.7.2.
3	Power feeding ripple and noise:						
	f < 500 Hz		V_{pp}		0.500	1, 2	See 33.2.7.3.
	500 Hz to 150 kHz				0.200		
	150 kHz to 500 kHz				0.150		
	500 kHz to 1 MHz				0.100		
4	Continuous output current capability in POWER_ON state	I_{Con}	A	P_{Class} / V_{Port_PSE}		1, 2	See 33.2.7.4.
5	Output current in POWER_UP state	I_{Inrush}	A	0.400	See info	1, 2	See 33.2.7.5. Max value defined by Figure 33–13.
6	Inrush time	T_{Inrush}	s	0.050	0.075	1, 2	See 33.2.7.5
7	Overload current detection range	I_{CUT}	A	P_{Class} / V_{Port_PSE}	I_{LIM}	1,2	Optional limit; see 33.2.7.6, Table 33–7.
8	Overload time limit	T_{CUT}	s	0.050	0.075	1, 2	See 33.2.7.7.
9	Output current – at short circuit condition	I_{LIM}	A	0.400	See info	1	See 33.2.7.7. Max value defined by Figure 33–14.
				1.14 × I_{Cable}		2

Table 33–11—PSE output PI electrical requirements for all PD classes, unless otherwise specified *(continued)*

Item	Parameter	Symbol	Unit	Min	Max	PSE Type	Additional information
14	Turn on rise time	T_{Rise}	µs	15.0		1, 2	From 10 % to 90 % of the voltage difference at the PI in POWER_ON state from the beginning of POWER_UP.
15	Turn off time	T_{Off}	s		0.500	1, 2	See 33.2.7.8.
16	Turn off voltage	V_{Off}	V		2.80	1, 2	See 33.2.7.9.
17	DC MPS current	I_{Hold}	A	0.005	0.010	1, 2	See 33.2.9.1.2.
18	PD Maintain Power Signature dropout time limit	T_{MPDO}	s	0.300	0.400	1, 2	See 33.2.9.
19	PD Maintain Power Signature time for validity	T_{MPS}	s	0.060		1, 2	See 33.2.9.
20	Current unbalance	I_{unb}	A		3 % × I_{Cable}	1	See 33.2.7.11, 33.4.8. NOTE—For practical implementations, it is recommended that Type 1 PSEs support Type 2 I_{unb} requirements.
					3 % × I_{Peak}	2	
21	Alternative B detection backoff time	T_{dbo}	s	2.00		1, 2	
22	Output capacitance during detection state	C_{out}	µF		0.520	1, 2	
23	Detection timing	T_{det}	s		0.500	1, 2	Time to complete detection of a PD.
24	Error delay timing	T_{ed}	s	0.750		1, 2	Delay before PSE may attempt subsequent powering after power removal because of error condition.

33.2.7.1 Output voltage in the POWER_ON state

The specification for V_{Port_PSE} in Table 33–11 shall be met with a (I_{Hold} max × V_{Port_PSE} min) to P_{Type} min load step at a rate of change of up to 15 mA/µs. The voltage transients as a result of load changes up to 35 mA/µs shall be limited to 3.5 V/µs max.

A PSE in the POWER_ON state may remove power from the PI when the PI voltage no longer meets the V_{Port_PSE} specification.

33.2.7.2 Voltage transients

A Type 2 PSE shall maintain an output voltage no less than K_{Tran_lo} below V_{Port_PSE} min for transient conditions lasting more than 30 µs and less than 250 µs, and meet the requirements of 33.2.7.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Transients less than 30 µs in duration may cause the voltage at the PI to fall more than K_{Tran_lo}. The minimum PD input capacitance allows the PD to operate for any input voltage transient lasting less than 30 µs. Transients lasting more than 250 µs shall meet the V_{Port_PSE} specification.

33.2.7.3 Power feeding ripple and noise

The specification for power feeding ripple and noise in Table 33–11 shall be met for common-mode and/or pair-to-pair noise values for power outputs from (I_{Hold} max × V_{Port_PSE} min) to P_{Type} min for PSEs at static operating $V_{Port_PSE.}$ The limits are meant to preserve data integrity. To meet EMI standards, lower values may be needed. For higher frequencies, see 33.4.4 and 33.4.5.

33.2.7.4 Continuous output current capability in the POWER_ON state

In addition to I_{Con} as specified in Table 33–11, the PSE shall support the following AC current waveform parameters, while within the operating voltage range of V_{Port_PSE}:

I_{Peak} minimum for T_{CUT} minimum and 5 % duty cycle minimum, where

$$I_{\text{Peak}} = \left\{ \frac{V_{\text{PSE}} - \sqrt{V_{\text{PSE}}^2 - 4(R_{\text{Chan}})(P_{\text{Peak_PD}})}}{2(R_{\text{Chan}})} \right\}_{\text{A}} \tag{33–4}$$

where

V_{PSE} is the voltage at the PSE PI as defined in 33.1.4

R_{Chan} is the channel loop resistance as defined in 33.1.4; this parameter has a worst-case value of R_{Ch}, defined in Table 33–1

$P_{\text{Peak_PD}}$ is the peak power a PD may draw for its class; see Table 33–18

33.2.7.5 Output current in POWER_UP mode

POWER_UP mode occurs between the PSE's transition to the POWER_UP state and either the expiration of T_{Inrush} or the conclusion of PD inrush currents (see 33.3.7.3). However, for practical implementations, it is recommended that the POWER_UP mode persist for the complete duration of T_{Inrush}, as the PSE may not be able to correctly ascertain the conclusion of a PD's inrush behavior.

The PSE shall limit the maximum current sourced at the PI during POWER_UP. The maximum inrush current sourced by the PSE shall not exceed the PSE inrush template in Figure 33–13.

a) During POWER_UP, for PI voltages between 0 V and 10 V, the minimum I_{Inrush} requirement is 5 mA.
b) During POWER_UP, for PI voltages between 10 V and 30 V, the minimum I_{Inrush} requirement is 60 mA.
c) During POWER_UP, for PI voltages above 30 V, the minimum I_{Inrush} requirement is as specified in Table 33–11.
d) For Type 1 PSE, measurement of minimum I_{Inrush} requirement to be taken after 1 ms to allow startup transients. A Type 2 PSE that uses 1-Event physical layer classification, and requires the 1 ms settling time, shall power up a class 4 PD as if it used 2-Event physical layer classification.

The PSE inrush template, I_{PSEIT}, is defined by the following segments:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

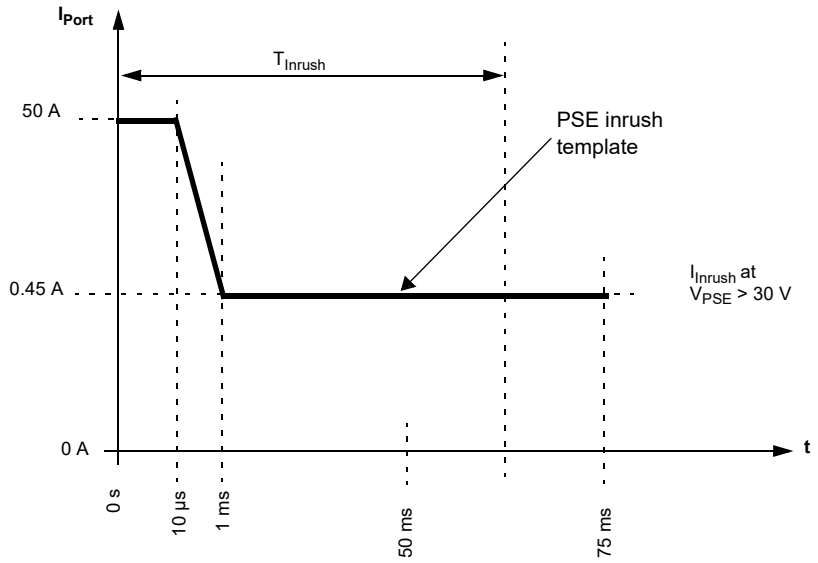

Figure 33–13—I_{Inrush} current and timing limits in POWER_UP state

$$I_{\mathrm{PSEIT}}(t) = \begin{cases} 50.0 & \text{for } 0 < t < 10.0\times10^{-6} \\ 50.0 - \dfrac{\left(t - 10.0\times10^{-6}\right) \times 49.6}{0.990\times10^{-6}} & \text{for } 10.0\times10^{-6} \le t < 0.001 \\ 0.450 & 0.001 \le t < 0.075 \end{cases} \quad (33\text{–}5)$$

where

t is the time in seconds

33.2.7.6 Overload current

If I_{Port}, the current supplied by the PSE to the PI, exceeds I_{CUT} for longer than T_{CUT}, the PSE may remove power from the PI. The cumulative duration of T_{CUT} is measured with a sliding window of at least 1 second width.

The I_{CUT} threshold may equal the I_{Peak} value determined by Equation (33–4).

33.2.7.7 Output current—at short circuit condition

A PSE may remove power from the PI if the PI current meets or exceeds the “PSE lowerbound template” in Figure 33–14. Power shall be removed from the PI of a PSE before the PI current exceeds the “PSE upperbound template” in Figure 33–14.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

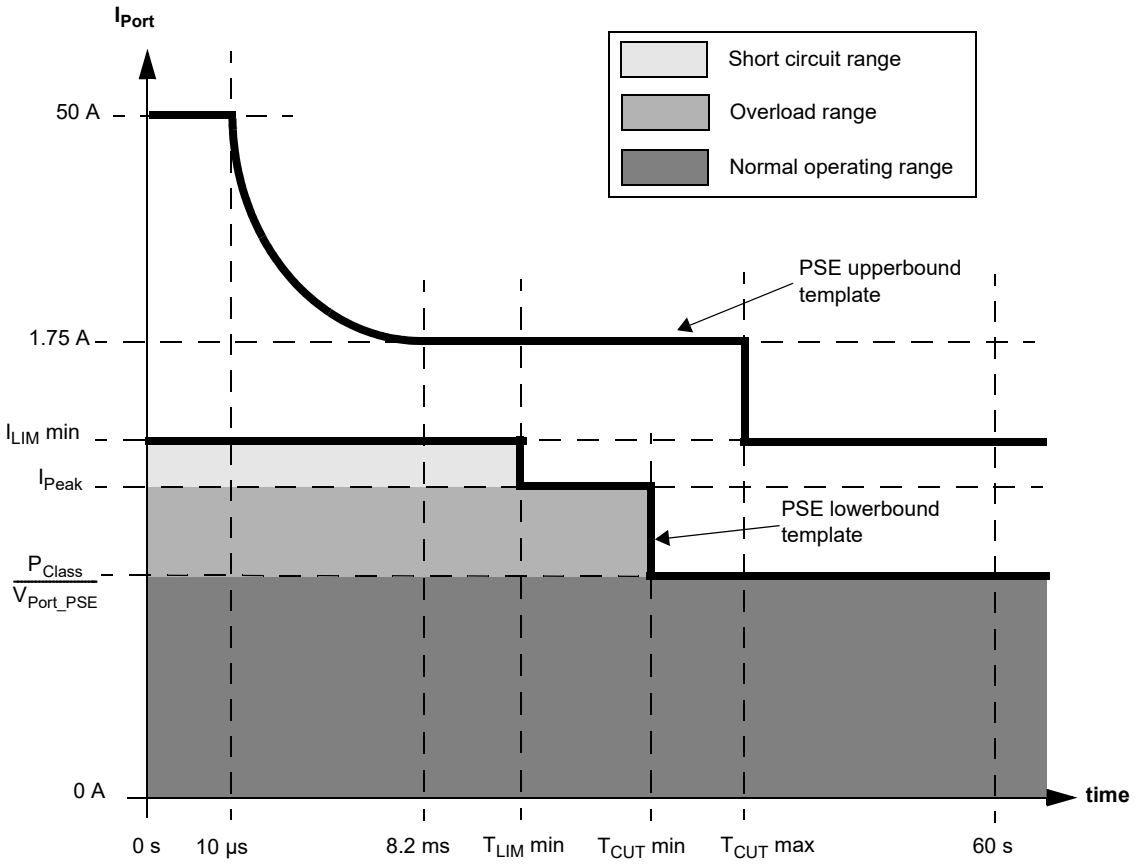

Figure 33–14—POWER_ON state PI operating current templates

The maximum value of I_{LIM} is the PSE upperbound template described by Equation (33–6) and Figure 33–14.

The PSE upperbound template, I_{PSEUT}, is defined by the following segments:

$$I_{\mathrm{PSEUT}}(t) = \left\{ \begin{array}{ll} 50.0 & \text{for } \left(0 \le t < 10.0\times10^{-6}\right) \\ \sqrt{\frac{K}{t}} & \text{for } \left(10.0\times10^{-6} \le t < 8.20\times10^{-3}\right) \\ 1.75 & \text{for } \left(8.20\times10^{-3} \le t < T_{\mathrm{cutmax}}\right) \\ I_{\mathrm{limmin}} & \text{for } \left(T_{\mathrm{cutmax}} \le t\right) \end{array} \right\} \quad (33\text{–}6)$$

where

t	is the duration in seconds that the PSE sources I_{Port}
K	is 0.025 A^2s, an energy limitation constant for the port current when it is not in steady state normal operation
T_{cutmax}	is T_{CUT} max, as defined in Table 33–11
I_{limmin}	is I_{LIM} min, as defined in Table 33–11

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PSE shall limit the current to I_{LIM} for a duration of up to T_{LIM} in order to account for PSE dV/dt transients at the PI. The cumulative duration of T_{LIM} may be measured with a sliding window.

The PSE lowerbound template, I_{PSELT}, is defined by the following segments:

$$I_{PSELT}(t) = \left\{ \begin{array}{ll} I_{LIMmin} & \text{for } (0 \le t < T_{limmin}) \\ I_{Peak} & \text{for } (T_{limmin} \le t < T_{cutmin}) \\ \dfrac{P_{Class}}{V_{PSE}} & \text{for } (T_{cutmin} \le t) \end{array} \right\}_{A} \quad (33\text{–}7)$$

where

I_{LIMmin} is the I_{LIM} min value for the PSE (see Table 33–11)
t is the duration that the PI sources I_{Port}
T_{limmin} is T_{LIM} min as defined in Table 33–11
T_{cutmin} is T_{CUT} min, as defined in Table 33–11
I_{Peak} is I_{Peak}, as defined in Equation (33–4)
P_{Class} is P_{Class}, as defined in Table 33–7
V_{PSE} is the voltage at the PSE PI

If a short circuit condition is detected, power removal from the PI shall begin within T_{LIM} as specified in Table 33–11. If I_{Port} exceeds the PSE lowerbound template, the PSE output voltage may drop below V_{Port_PSE} min.

33.2.7.8 Turn off time

The specification for T_{Off} in Table 33–11 shall apply to the discharge time from V_{Port_PSE} to V_{Off} with a test resistor of 320 kΩ attached to the PI. In addition, it is recommended that the PI be discharged when turned off. T_{Off} starts when V_{PSE} drops 1 V below the steady-state value after the pi_powered variable is cleared (see Figure 33–9). T_{Off} ends when $V_{PSE} \le V_{Off}$ max. The IDLE state is the state when the PSE is not in detection, classification, or normal powering states.

33.2.7.9 Turn off voltage

The specification for V_{Off} in Table 33–11 shall apply to the PI voltage in the IDLE State.

33.2.7.10 Continuous output power capability in POWER_ON state

P_{Class} is the class power defined in 33.2.6 and Equation (33–3), or PSE allocated power (as defined in 79.3.2.6) added to the channel power loss.

P_{Con} is valid over the range of V_{Port_PSE} defined in Table 33–11. Measurement of P_{Con} should be averaged using any sliding window with a width of 1 s.

A PSE may remove power from a PD that causes the PSE to source more than P_{Class}.

33.2.7.11 Current unbalance

The specification for I_{unb} in Table 33–11 shall apply to the current unbalance between the two conductors of a power pair over the current load range.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Type 2 Endpoint PSEs shall meet the requirements of 25.4.5 in the presence of (I_{unb} / 2).

33.2.7.12 Power turn on time

The specification for T_{pon} in Table 33–11 applies to the PSE power up time for a PD after completion of detection. If power is not applied as specified, a new detection cycle is initiated (see 33.2.4.1).

33.2.7.13 PSE stability

When connected together as a system, the PSE and PD might exhibit instability at the PSE side or the PD side or both due to the presence of negative impedance at the PD input. See Annex 33A for PSE design guidelines for stable operation.

33.2.8 Power supply allocation

A PSE does not initiate power provision to a link if the PSE has less than Class 3 power available and the connected PD requests more than the available power.

The PSE may manage the allocation of power based on additional information beyond the classification of the attached PD. Allocating power based on additional information about the attached PD, and the mechanism for obtaining that additional information, is beyond the scope of this standard with the exception that the allocation of power shall not be based solely on the historical data of the power consumption of the attached PD.

See 33.6 for a description of Data Link Layer classification.

If the system implements a power allocation algorithm, no additional behavioral requirement is placed on the system as it approaches or reaches its maximum power subscription. Specifically, the interaction between one PSE PI and another PSE PI in the same system is beyond the scope of this standard.

33.2.9 PSE power removal

Figure 33–10 shows the PSE monitor state diagrams. These state diagrams monitor for inrush current and the absence of the Maintain Power Signature (MPS).

If any of these conditions exist for longer than its related time limit, the power is removed from the PI.

33.2.9.1 PSE Maintain Power Signature (MPS) requirements

The MPS consists of two components, an AC MPS component and a DC MPS component.

The PSE shall monitor either the DC MPS component, the AC MPS component, or both.

33.2.9.1.1 PSE AC MPS component requirements

A PSE that monitors the AC MPS component shall meet the “AC Signal parameters” and “PSE PI voltage during AC disconnect detection” parameters in Table 33–12.

A PSE shall consider the AC MPS component to be present when it detects an AC impedance at the PI equal to or lower than $|Z_{ac1}|$ as defined in Table 33–12.

A PSE shall consider the AC MPS component to be absent when it detects an AC impedance at the PI equal to or greater than $|Z_{ac2}|$ as defined in Table 33–12. Power shall be removed from the PI when AC MPS has been absent for a time duration greater than T_{MPDO}.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A PSE may consider the AC MPS component to be either present or absent when it detects a AC impedance between the values $|Z_{ac1}|$ max and $|Z_{ac2}|$ min.

33.2.9.1.2 PSE DC MPS component requirements

A PSE shall consider the DC MPS component to be present if I_{Port} is greater than or equal to I_{Hold} max for a minimum of T_{MPS}. A PSE shall consider the DC MPS component to be absent if I_{Port} is less than or equal to I_{Hold} min. A PSE may consider the DC MPS component to be either present or absent if I_{Port} is in the range of I_{Hold}.

Power shall be removed from the PI when DC MPS has been absent for a duration greater than T_{MPDO}.

The specification for T_{MPS} in Table 33–11 applies only to the DC MPS component. In addition to the requirements on T_{MPS} and T_{MPDO} in Table 33–11, the PSE shall use values for T_{MPS} and T_{MPDO} that meet Equation (33–8).

$$T_{MPDO} - T_{MPS} \geq 250 \text{ ms} \tag{33–8}$$

The PSE shall not remove power from the port when less than T_{MPDO} has passed since MPS was last present. This allows a PD to minimize its power consumption.

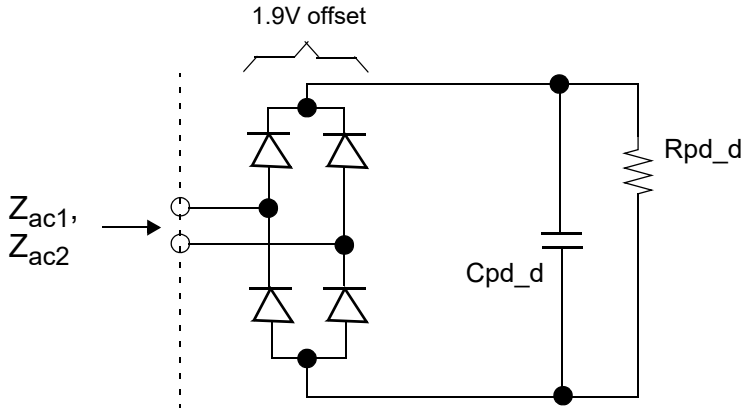

Table 33–12—PSE PI parameters for AC disconnect-detection function

Item	Parameter	Symbol	Unit	Min	Max	Additional information
	AC signal parameters					
1a	PI probing AC voltage	V_open	V_{pp}	1.90	10% of the average value of V_{Port_PSE} within the limits of Table 33–11	Includes noise, ripple, etc. V_open is the AC voltage across the PI when the PD is not connected to the PI and before the detection of this condition by the PSE.
		V_open1	V_p		30.0 V, $V_{PSE} \leq$ 44.0 V	V_open1 is the AC voltage across the PI when the PD is not connected to the PI and after the detection of this condition by the PSE and the removal of power from the PI.
1b	AC probing signal frequency	F_p	kHz		0.500	
1c	AC probing signal slew rate	SR	V/µs		0.100	Positive or negative.
	AC source output impedance					
2a	Source output current during the operation of the AC disconnect detection function	I_sac	mA		5.00	During operation of the AC disconnect detection function.

Table 33–12—PSE PI parameters for AC disconnect-detection function *(continued)*

Item	Parameter	Symbol	Unit	Min	Max	Additional information
2b	PSE PI impedance during PD detection when measured at the PSE PI	R_rev	kΩ	45.0		Specified in 33.2.5.1 and Figure 33–11. Shown here to clarify the difference in PI impedance during the signature detection function.
	PSE PI voltage during AC disconnect detection					
3a	PI AC voltage when PD is connected	V_{CLOSE}	V_{pp}			See Table 33–11, item 3.
3b	PI voltage when PD is disconnected	V_{PSE}	V_p		60.0	
	AC Maintain Power Signature					
4a	Valid impedance	$\lvert Z_{ac1} \rvert$	kΩ		27.0	F_p = 5 Hz, Testing voltage >2.5 V. See Figure 33–15.
4b	Invalid impedance	$\lvert Z_{ac2} \rvert$	kΩ	1980		See Figure 33–15.

NOTE—Rpd_d and Cpd_d are specified in Table 33–19. Cpd_d may be located either in parallel with Z_{ac1} or as shown above.

Figure 33–15—Z_{ac1} and Z_{ac2} definition as indicated in Table 33–12

33.3 Powered devices (PDs)

A PD is the portion of a device that is either drawing power or requesting power by participating in the PD detection algorithm. A device that is capable of becoming a powered device may or may not have the ability to draw power from an alternate power source and, if doing so, may or may not require power from the PI. PD capable devices that are neither drawing nor requesting power are also covered in this subclause.

A PD is specified at the point of the physical connection to the cabling. Characteristics such as the losses due to voltage correction circuits, power supply inefficiencies, separation of internal circuits from external

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ground or other characteristics induced by circuits after the PI connector are not specified. Limits defined for the PD are specified at the PI, not at any point internal to the PD, unless specifically stated.

33.3.1 PD PI

The PD shall be capable of accepting power on either of two sets of PI conductors. The two conductor sets are named Mode A and Mode B. In each four-wire connection, the two wires associated with a pair are at the same nominal average voltage. Figure 33–8 in conjunction with Table 33–13 illustrates the two power modes.

Table 33–13—PD pinout

Conductor	Mode A	Mode B
1	Positive V_{PD}, Negative V_{PD}	
2	Positive V_P, Negative V_{PD}	
3	Negative V_{PD}, Positive V_{PD}	
4		Positive V_{PD}, Negative V_{PD}
5		Positive V_{PD}, Negative V_{PD}
6	Negative V_{PD}, Positive V_{PD}	
7		Negative V_{PD}, Positive V_{PD}
8		Negative V_{PD}, Positive V_{PD}

The PD shall be implemented to be insensitive to the polarity of the power supply and shall be able to operate per the PD Mode A column and the PD Mode B column in Table 33–13.

NOTE—PDs that implement only Mode A or Mode B are specifically not allowed by this standard. PDs that simultaneously require power from both Mode A and Mode B are specifically not allowed by this clause. A PD may indicate the ability to accept power on both pairsets from a Clause 145 PSE using TLV variable PD 4PID; see 79.3.2.4.3.

The PD shall not source power on its PI.

The PD shall withstand any voltage from 0 V to 57 V at the PI indefinitely without permanent damage.

33.3.2 PD type descriptions

PDs can be categorized as either Type 1 or Type 2.

Type 1 PDs implement a minimum of 1-Event Physical Layer classification and advertise a 1-Event class signature of 0, 1, 2, or 3.

Type 2 PDs implement both 2-Event Physical Layer classification (see 33.3.5.2) and Data Link Layer classification (see 33.6) and advertise a 2-Event class signature of 4.

The maximum power a PD expects to draw from a PSE is P_{Class_PD} max as defined in Table 33–18.

A Type 2 PD that does not successfully observe a 2-Event Physical Layer classification or Data Link Layer classification shall conform to Type 1 PD power restrictions and shall provide the user with an active indication if underpowered. The method of active indication is left to the implementer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Type 2 PDs shall meet the requirements of 25.4.5 in the presence of (I_{unb} / 2).

33.3.3 PD state diagram

The PD state diagram specifies the externally observable behavior of a PD. The PD shall provide the behavior of the state diagram shown in Figure 33–16.

33.3.3.1 Conventions

The notation used in the state diagram follows the conventions of state diagrams as described in 21.5.

33.3.3.2 Constants

The PD state diagram uses the following constants:

V_{Reset_th}
: Reset voltage threshold (see Table 33–17)

V_{Mark_th}
: Mark event voltage threshold (see Table 33–17)

class_sig
: PD classification, one of either 0, 1, 2, 3, or 4 (see Table 33–16)

33.3.3.3 Variables

The PD state diagram uses the following variables:

mdi_power_required
: A control variable indicating the PD is enabled and should request power from the PSE by applying a PD detection signature to the link, and when the PSE sources power to apply the MPS to keep the PSE sourcing power. A variable that is set in an implementation-dependent manner.
Values:FALSE:PD functionality is disabled.
TRUE:PD functionality is enabled.

pd_2-event
: A control variable indicating whether the PD presents a 2-Event class signature.
Values:FALSE:PD does not present a 2-Event class signature.
TRUE:PD does present a 2-Event class signature.

pd_dll_capable
: This variable indicates whether the PD implements Data Link Layer classification.
Values:FALSE:The PD does not implement Data Link Layer classification.
TRUE:The PD does implement Data Link Layer classification.

pd_dll_enabled
: A variable indicating whether the Data Link Layer classification mechanism is enabled.
Values:FALSE:Data Link Layer classification is not enabled.
TRUE:Data Link Layer classification is enabled.

pd_max_power
: A control variable indicating the max power that the PD may draw from the PSE. See power classifications in Table 33–18.
Values:0: PD may draw Class 0 power
1: PD may draw Class 1 power
2: PD may draw Class 2 power
3: PD may draw Class 3 power
4: PD may draw Class 4 power

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pd_reset
: An implementation-specific control variable that unconditionally resets the PD state diagram to the OFFLINE state.
Values:FALSE:The device has not been reset (default).
TRUE:The device has been reset.

power_received
: An indication from the circuitry that power is present on the PD's PI.
Values:FALSE:The input voltage does not meet the requirements of V_{Port_PD} in Table 33–18.
TRUE:The input voltage meets the requirements of V_{Port_PD}.

present_class_sig
: Controls presenting the classification signature (see 33.3.5) by the PD.
Values:FALSE:The PD classification signature is not to be applied to the link.
TRUE:The PD classification signature is to be applied to the link.

present_det_sig
: Controls presenting the detection signature (see 33.3.4) by the PD.
Values:FALSE:A non-valid PD detection signature is to be applied to the link.
TRUE:A valid PD detection signature is to be applied to the link.

present_mark_sig
: Controls presenting the mark event current and impedance (see 33.3.5.2.1) by the PD.
Values:FALSE:The PD does not present mark event behavior.
TRUE:The PD does present mark event behavior.

present_mps
: Controls applying MPS (see 33.3.8) to the PD's PI.
Values:FALSE:The Maintain Power Signature (MPS) is not to be applied to the PD's PI.
TRUE:The MPS is to be applied to the PD's PI.

pse_dll_power_type
: A control variable initially output by the PD power control state diagram (Figure 33–28), which can be updated by LLDP (see Table 33–26), that indicates the type of PSE by which the PD is being powered.
Values:1: The PSE is a Type 1 PSE (default).
2: The PSE is a Type 2 PSE.

pse_power_type
: A control variable that indicates to the PD the type of PSE by which it is being powered.
Values:1: The PSE is a Type 1 PSE.
2: The PSE is a Type 2 PSE.

V_{PD}
: Voltage at the PD PI as defined in 33.1.4.

33.3.3.4 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where "stop x_timer" is asserted.

tpowerdly_timer
: A timer used to prevent the Type 2 PD from drawing more than inrush current during the PSE's inrush period; see T_{delay} in Table 33–18.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—DO_CLASS_EVENT3 creates a defined behavior for a Type 2 PD that is brought into the classification range repeatedly.

NOTE 2—In general, there is no requirement for a PD to respond with a valid classification signature for any DO_CLASS_EVENT duration less than T_{class}.

33.3.4 PD valid and non-valid detection signatures

A PD presents a valid detection signature while it is in a state where it accepts power via the PI, but is not powered via the PI per Figure 33–16.

A PD presents a non-valid detection signature at the PI while it is in a state where it does not accept power via the PI per Figure 33–16.

A Type 2 PD presents a non-valid detection signature when in a mark event state per Figure 33–16.

When a PD presents a valid or non-valid detection signature, it shall present the detection signature at the PI between Positive V_{PD} and Negative V_{PD} of PD Mode A and PD Mode B as defined in 33.3.1. When a PD becomes powered via the PI, it shall present a non-valid detection signature on the set of pairs from which it is not drawing power.

A PD may or may not present a valid detection signature when in the IDLE state.

The detection signature is a resistance calculated from two voltage/current measurements made during the detection process.

$$R_{\text{detect}} = \left\{ \frac{(V_2 - V_1)}{(I_2 - I_1)} \right\}_{\Omega} \tag{33–9}$$

where

V_1 and V_2	are the first and second voltage measurements made at the PD PI, respectively
I_1 and I_2	are the first and second current measurements made at the PD PI, respectively
R_{detect}	is the effective resistance

A valid PD detection signature shall have the characteristics of Table 33–14.

A non-valid detection signature shall have one or both of the characteristics in Table 33–15.

A PD that presents a signature outside of Table 33–14 is non-compliant, while a PD that present the signature of Table 33–15 is assured to fail detection.

Table 33–14—Valid PD detection signature characteristics, measured at PD input connector

Parameter	Conditions	Minimum	Maximum	Unit
R_{detect} (at any 1 V or greater chord within the voltage range conditions)	2.70 V to 10.1 V	23.7	26.3	kΩ
V offset	See Figure 33–17	0	1.90	V
Voltage at the PI	I_{Port} = 124 μA	2.70		V
Input capacitance	2.70 V to 10.1 V	0.050	0.120	μF
Series input inductance	2.70 V to 10.1 V		0.100	mH

Table 33–15—Non-valid PD detection signature characteristics, measured at PD input connector

Parameter	Conditions	Range of values	Unit
R_{detect}	V < 10.1 V	Either greater than 45.0 or less than 12.0	kΩ
Input capacitance	V < 10.1 V	Greater than 10.0	μF

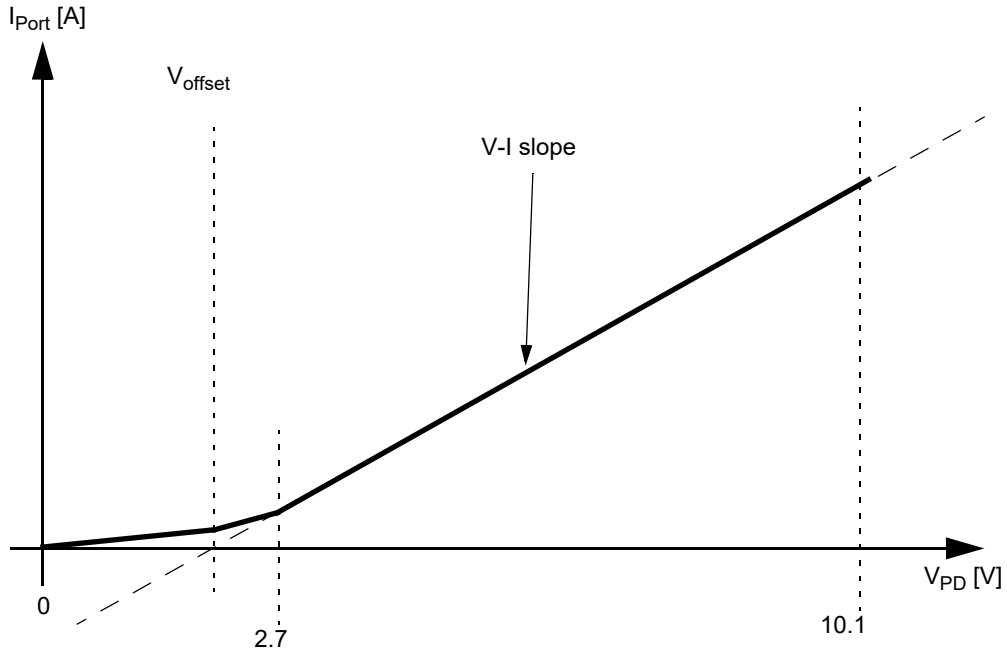

Figure 33–17—Valid PD detection signature offset

33.3.5 PD classifications

See 33.2.6 for a general description of classification mechanisms.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A PD may be classified by the PSE based on the Physical Layer classification information, Data Link Layer classification, or a combination of both provided by the PD. The intent of PD classification is to provide information about the maximum power required by the PD during operation. Additionally, classification is used to establish mutual identification between Type 2 PSEs and Type 2 PDs.

The method of classification depends on the type of the PD and the type of the attached PSE.

A PD shall meet at least one of the allowable classification permutations listed in Table 33–8.

A Type 1 PD may implement any of the class signatures in 33.3.5 and 33.6.

Type 2 PDs implement both 2-Event class signature (see 33.3.5.2) and Data Link Layer classification (see 33.6).

PD classification behavior conforms to the state diagram in Figure 33–16.

33.3.5.1 PD 1-Event class signature

Class 0 is the default for PDs. However, to improve power management at the PSE, a Type 1 PD may opt to provide a signature for Class 1 to 3.

The PD is classified based on power. The Physical Layer classification of the PD is the maximum power that the PD draws across all input voltages and operational modes.

PDs implementing a 2-Event class signature shall return Class 4 in accordance with the maximum power draw, P_{Class_PD}, as specified in Table 33–18. Since 1-Event classification is a subset of 2-Event classification, Type 2 PDs respond to 1-Event classification with a Class 4 signature. Type 1 PDs may choose to implement a 2-Event class signature and return Class 0, 1, 2, or 3 in accordance with the maximum power draw, P_{Class_PD}. The Type 2 PD's classification behavior shall conform to the electrical specifications defined by Table 33–17.

In addition to a valid detection signature, PDs shall provide the characteristics of a classification signature as specified in Table 33–16. A PD shall present one, and only one, classification signature during classification.

Table 33–16—Classification signature, measured at PD input connector

Parameter	Conditions	Minimum	Maximum	Unit
Current for Class 0	14.5 V to 20.5 V	0	4.00	mA
Current for Class 1	14.5 V to 20.5 V	9.00	12.0	mA
Current for Class 2	14.5 V to 20.5 V	17.0	20.0	mA
Current for Class 3	14.5 V to 20.5 V	26.0	30.0	mA
Current for Class 4	14.5 V to 20.5 V	36.0	44.0	mA

33.3.5.2 PD 2-Event class signature

PDs implementing a 2-Event class signature shall return a Class 4 classification signature in accordance with the maximum power draw, P_{Class_PD}, as specified by Table 33–18. The PD's classification behavior shall conform to the electrical specifications defined by Table 33–17.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Until successful 2-Event Physical Layer classification or Data Link Layer classification has completed, a Type 2 PD's pse_power_type state variable is set to '1.' A Type 2 PD shall conform to the electrical requirements as defined by Table 33–18 for the type defined in its pse_power_type state variable.

Table 33–17—2-Event Physical Layer classification electrical requirements

Item	Parameter	Symbol	Units	Min	Max	Additional information
1	Class event voltage	V_{Class}	V	14.5	20.5	
2	Mark event voltage	V_{Mark}	V	6.90	10.1	
3	Mark event current	I_{Mark}	mA	0.250	4.00	See 33.3.5.2.1
4	Mark event threshold	V_{Mark_th}	V	10.1	14.5	See 33.3.5.2.1
5	Classification reset threshold	V_{Reset_th}	V	2.81	6.90	See 33.3.5.2.1
6	Classification reset voltage	V_{Reset}	V	0	2.81	See 33.3.5.2.1

33.3.5.2.1 Mark Event behavior

When the PD is presenting a mark event signature as shown in the state diagram of Figure 33–16, the PD shall draw I_{Mark} as defined in Table 33–17 and present a non-valid detection signature as defined in Table 33–15.

The PD shall not exceed the I_{Mark} current limits when voltage at the PI enters the V_{Mark} specification as defined in Table 33–17.

V_{Mark_th} is the PI voltage threshold at which the PD implementing 2-Event class signature transitions into and out of the DO_CLASS_EVENT1 or DO_CLASS_EVENT2 states as shown in Figure 33–16.

The PD shall draw I_{Mark} until the PD transitions from a DO_MARK_EVENT state to the IDLE state.

V_{Reset_th} is the PI voltage threshold at which the PD implementing 2-Event class signature transitions from a DO_MARK_EVENT state to the IDLE state as shown in Figure 33–16.

33.3.6 PSE Type identification

A Type 2 PD shall identify the PSE Type as either Type 1 or Type 2 (see Figure 33–16).

The default value of pse_power_type is 1. After a successful 2-Event Physical Layer classification or Data Link Layer classification has completed, the pse_power_type is set to 2.

The PD resets the pse_power_type to '1' when the PD enters the DO_DETECTION state.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.3.7 PD power

The power supply of the PD shall operate within the characteristics in Table 33–18.

The PD may be capable of drawing power from a local power source. When a local power source is provided, the PD may draw some, none, or all of its power from the PI.

Table 33–18—PD power supply limits

Item	Parameter	Symbol	Unit	Min	Max	PD Type	Additional information
1	Input voltage	V_{Port_PD}	V	37.0	57.0	1	See 33.3.7.1, Table 33–1
				42.5	57.0	2	
2	Transient operating input voltage	V_{Tran_lo}	V	36.0		2	For time duration defined in 33.2.7.2
3	Input voltage range during overload	$V_{Overload}$	V	36.0	57.0	1	See 33.3.7.4, Table 33–1
				41.4	57.0	2

12	PD classification stability time	T_{class}	s		0.005		See 33.3.7.8
13	Backfeed voltage	V_{bfd}	V		2.80		See 33.3.7.9

33.3.7.1 Input voltage

The specification for V_{Port_PD} in Table 33–18 is for the input voltage range after startup (see 33.3.7.3), and accounts for loss in the cabling plant. Note, $V_{PD} = V_{PSE} - (R_{Chan} \times I_{Port})$.

The PD shall turn on at a voltage less than or equal to V_{On}. After the PD turns on, the PD shall stay on over the entire V_{Port_PD} range. The PD shall turn off at a voltage less than V_{Port_PD} minimum and greater than or equal to V_{Off}.

The PD shall turn on or off without startup oscillation and within the first trial at any load value when fed by V_{Port_PSE} min to V_{Port_PSE} max (as defined in Table 33–11) with a series resistance within the range of valid Channel Resistance.

33.3.7.2 Input average power

The maximum average power, P_{Class_PD} in Table 33–18 or PDMaxPowerValue in 33.6.3.3, is calculated over a 1 second interval. PDs may dynamically adjust their maximum required operating power below P_{Class_PD} as described in 33.6.

NOTE—Average power is calculated using any sliding window with a width of 1 s.

33.3.7.2.1 System stability test conditions during startup and steady state operation

When the PD is fed by V_{Port_PSE} min to V_{Port_PSE} max with R_{Ch} (as defined in Table 33–1) in series, P_{Port_PD} shall be defined as shown in Equation (33–10):

$$P_{Port_PD} = \{V_{Port_PD} \times I_{Port}\}_W \quad (33–10)$$

where

P_{Port_PD} is the average input power at the PD PI

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

V_{Port_PD} is the static input voltage at the PD PI
I_{Port} is the input current, either DC or RMS

NOTE—When connected together as a system, the PSE and PD might exhibit instability at the PSE side, the PD side, or both due to the presence of negative impedance at the PD input. See Annex 33A for PD design guidelines for stable operation.

33.3.7.3 Input inrush current

The PD inrush time duration is defined as beginning with the application of input voltage at the PI when V_{PD} crosses the PD power supply turn on voltage, V_{On} as defined in Table 33–18, and ends after T_{delay}.

The inrush current is the initial current drawn by the PD, which is used to charge C_{Port}. A PD may limit the inrush current below I_{Inrush_PD} to allow for large values of C_{Port}.

The PSE either uses the legacy power up method, whereby it limits the inrush current to I_{Inrush} until the PD input voltage reaches 99% of steady state, or it limits the inrush current for a fixed amount of time, T_{Inrush}, as defined in Table 33–11. See legacy_powerup in 33.2.4.4.

PDs shall draw less than I_{Inrush_PD} from T_{Inrush} min until T_{delay}, when connected to a source that meets the requirements of 33.2.7.5. This delay is required so that the PD does not enter a high power state before the PSE has had time to change the available current from the POWER_UP to the POWER_ON limits. A PD can meet this requirement by either having C_{Port} charged within T_{Inrush} min or by limiting the input inrush current.

PDs with pse_power_type set to 1 shall conform to P_{Class_PD} and P_{Peak_PD} requirements within T_{Inrush} min as defined in Table 33–11. PDs with pse_power_type set to 2 shall not exceed Class 3 P_{Peak_PD}, as defined in Table 33–18, from T_{Inrush} min until T_{delay}.

33.3.7.4 Peak operating power

$V_{Overload}$ is the PD PI voltage when the PD is drawing the permissible P_{Peak_PD}.

At any static voltage at the PI, and any PD operating condition, the peak power shall not exceed P_{Class_PD} max for more than T_{CUT} min, as defined in Table 33–11 and 5% duty cycle. Peak operating power shall not exceed P_{Peak_PD} max.

Ripple current content (I_{Port_ac}) superimposed on the DC current level (I_{Port_dc}) is allowed if the total input power is less than or equal to P_{Class_PD} max.

The RMS, DC and ripple current shall be bounded by Equation (33–11):

$$I_{Port} = \left\{ \sqrt{(I_{Port_dc})^2 + (I_{Port_ac})^2} \right\}_A \quad (33–11)$$

where
I_{Port} is the RMS input current
I_{Port_dc} is the DC component of the input current
I_{Port_ac} is the RMS value of the AC component of the input current

The maximum I_{Port} value for all operating V_{Port_PD} range shall be defined by the following equation:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$I_{\text{portmax}} = \left\{ \frac{P_{\text{Class_PD}}}{V_{\text{Port_PD}}} \right\}_{\text{A}} \quad (33\text{–}12)$$

where

I_{portmax}	is the maximum DC and RMS input current
$V_{\text{Port_PD}}$	is the static input voltage at the PD PI
$P_{\text{Class_PD}}$	is the maximum power, $P_{\text{Class_PD}}$ max, as defined in Table 33–18

Peak power, $P_{\text{Peak_PD}}$, for Class 4 is based on Equation (33–13), which approximates the ratiometric peak powers of Class 0 through Class 3. This equation may be used to calculate peak operating power for $P_{\text{Peak_PD}}$ values obtained via Data Link Layer classification.

$$P_{\text{Peak_PD}} = \{1.11 \times P_{\text{Class_PD}}\}_{\text{W}} \quad (33\text{–}13)$$

where

$P_{\text{Peak_PD}}$	is the peak operating power
$P_{\text{Class_PD}}$	is the input average power

NOTE—The duty cycle of the peak current is calculated using any sliding window with a width of 1 s.

33.3.7.5 Peak transient current

When the input voltage at the PI is static and in the range of $V_{\text{Port_PD}}$ defined by Table 33–18, the transient current drawn by the PD shall not exceed 4.70 mA/µs in either polarity. This limitation applies after inrush has completed (33.3.7.3) and before the PD has disconnected.

Under normal operating conditions when there are no transients applied at the PD PI, the PD shall operate below the PD upperbound template defined in Figure 33–18.

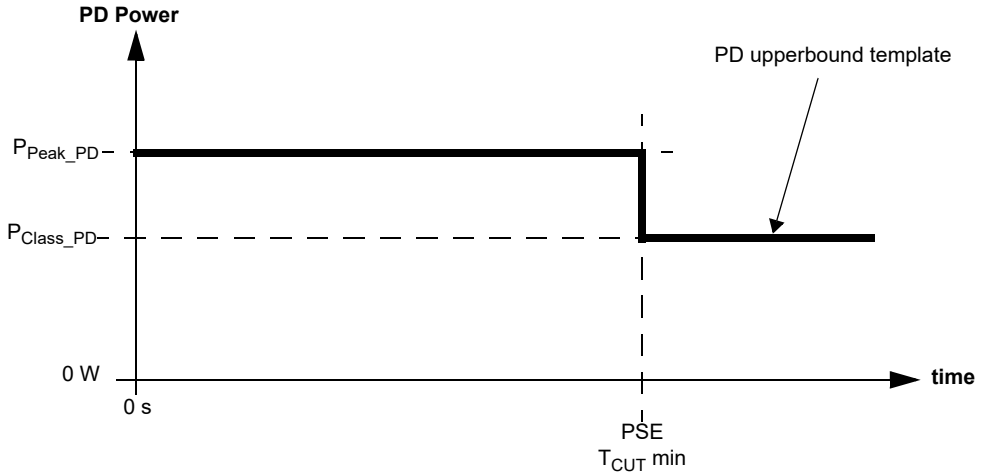

Figure 33–18—PD static operating mask

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PD upperbound template in Figure 33–18, P_{PDUT}, is described by Equation (33–14):

$$P_{PDUT}(t) = \left\{ \begin{array}{ll} P_{Peak_PD} & \text{for } (0 \le t < T_{cutmin}) \\ P_{Class_PD} & \text{for } (T_{cutmin} \le t) \end{array} \right\}_{W} \quad (33–14)$$

where

t	is the duration in seconds that the PD sinks I_{Port}
P_{Peak_PD}	is the peak operating power, P_{Peak_PD} max, as defined in Table 33–18
P_{Class_PD}	is the maximum power, P_{Class_PD} max, as defined in Table 33–18
T_{cutmin}	is T_{CUT} min, as defined in Table 33–11

During PSE transient conditions in which the voltage at the PI is undergoing dynamic change, the PSE is responsible for limiting the transient current drawn by the PD for at least T_{LIM} min as defined in Table 33–11.

33.3.7.6 PD behavior during transients at the PSE PI

A Type 1 PD with input capacitance of 180 µF or less requires no special considerations with regard to transients at the PD PI. A Type 2 PD with peak power draw that does not exceed P_{Class_PD} max and has an input capacitance of 180 µF or less requires no special considerations with regard to transients at the PD PI. PDs that do not meet these requirements shall comply with the following:

— A Type 1 PD input current shall not exceed the PD upperbound template (see Figure 33–18) after T_{LIM} min (see Table 33–11 for a Type 1 PSE) when the following input voltage is applied. A current limited voltage source is applied to the PI through a R_{Ch} resistance (see Table 33–1). The current limit meets Equation (33–15) and the voltage ramps from V_{Port_PSE} min to V_{Port_PSE} max at 2250 V/s.

A Type 2 PD shall meet both of the following:

a) The PD input current spike shall not exceed 2.5 A and shall settle below the PD upperbound template (see Figure 33–18) within 4 ms. During this test, the PD PI voltage is driven from 50 V to 52.5 V at greater than 3.5 V/µs, a source impedance of 1.5 Ω, and a source that supports a current greater than 2.5 A.
b) The PD shall not exceed the PD upperbound template beyond T_{LIM} min under worst-case current draw under the following conditions. The input voltage source drives V_{PD} from V_{Port_PSE} min to 56 V at 2250 V/s, the source impedance is R_{Ch} (see Table 33–1), and the voltage source limits the current to MDI I_{LIM} per Equation (33–15).

The current limit at the MDI (MDI I_{LIM}) is defined by Equation (33–15):

$$\{pse_{ILIMmin}\}_{mA} < \{mdi_{ILIM}\}_{mA} \le \{pse_{ILIMmin}\}_{mA} + 5.00 \quad (33–15)$$

where

$pse_{ILIMmin}$	is the PSE I_{LIM} min as defined in Table 33–11
mdi_{ILIM}	is the current limit at the MDI (MDI I_{LIM})

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.3.7.7 Ripple and noise

The specification for ripple and noise in Table 33–18 shall be for the common-mode and/or differential pair-to-pair noise at the PD PI generated by the PD circuitry. The ripple and noise specification shall be for all operating voltages in the range of V_{Port_PD}, and over the range of input power of the device.

The PD shall operate correctly in the presence of ripple and noise generated by the PSE that appears at the PD PI. These levels are specified in Table 33–11, item 3.

Limits are provided to preserve data integrity. To meet EMI standards, lower values may be needed.

The system designer is advised to assume the worst-case condition in which both PSE and PD generate the maximum noise allowed by Table 33–11 and Table 33–18, which may cause a higher noise level to appear at the PI than the standalone case as specified by this clause.

33.3.7.8 PD classification stability time

Following a valid detection and a rising voltage transition from V_{valid} to V_{Class}, the PD Physical Layer classification signature shall be valid within T_{class} as specified in Table 33–18 and remain valid for the duration of the classification period.

33.3.7.9 Backfeed voltage

When any voltage in the range of 0 V to V_{Port_PD} max is applied across the PI at either polarity specified on the conductors for Mode A according to Table 33–13, the voltage measured across the PI for Mode B with a 100 kΩ load resistor connected across Mode B shall not exceed V_{bfd} max as specified in Table 33–18.

When any voltage in the range of 0 V to V_{Port_PD} max is applied across the PI at either polarity specified on the conductors for Mode B according to Table 33–13, the voltage measured across the PI for Mode A with a 100 kΩ load resistor connected across Mode A shall not exceed V_{bfd} max as specified in Table 33–18.

33.3.8 PD Maintain Power Signature

In order to maintain power, the PD shall provide a valid Maintain Power Signature (MPS) at the PI. The MPS shall be both:

a) Current draw equal to or above the minimum input current (I_{Port_MPS} min) as specified in Table 33–19 for a minimum duration of 75 ms followed by an optional MPS dropout for no longer than 250 ms, and
b) Input impedance with resistive and capacitive components as defined in Table 33–19.

A PD that does not maintain the MPS components in a) and b) above may have its power removed within the limits of T_{MPDO} as specified in Table 33–11.

Powered PDs that no longer require power shall remove both components a) and b) of the MPS. To cause PSE power removal, the impedance of the PI should rise above Z_{ac2} as specified in Table 33–12.

NOTE—A PD with $C_{port} > 180$ µF may not be able to meet the I_{Port_MPS} specification in Table 33–19 during the maximum allowed port voltage droop (V_{Port_PSE} max to V_{Port_PSE} min with series resistance R_{Ch}). Such a PD should increase its I_{Port} min or make other such provisions to meet the Maintain Power Signature.

Table 33–19—PD Maintain Power Signature

Item	Parameter	Symbol	Unit	Min	Max	Additional information
1	Input current	I_{Port_MPS}	A	0.010		See 33.3.8
2	Input resistance	R_{pd_d}	kΩ		26.3	
3	Input capacitance	C_{pd_d}	μF	0.050		See Table 33–12

33.4 Additional electrical specifications

This clause defines additional electrical specifications for both the PSE and PD. The specifications apply for all PSE and PD operating conditions at the cabling side of the mated connection of the PI. The requirements apply during data transmission only when specified as an operating condition.

The requirements of 33.4 are consistent with the requirements of the 10BASE-T MAU and the 100BASE-TX, 1000BASE-T, 2.5GBASE-T, 5GBASE-T, and 10GBASE-T PHYs.

33.4.1 Electrical isolation

PDs and PSEs shall provide isolation between all accessible external conductors, including frame ground (if any), and all MDI leads including those not used by the PD or PSE. Any equipment that can be connected to a PSE or PD through a non-MDI connector that is not isolated from the MDI leads needs to provide isolation between all accessible external conductors, including frame ground (if any), and the non-MDI connector.

This electrical isolation shall meet the isolation requirements as specified in J.1 with electrical strength test c) details being replaced by: “An impulse test consisting of a 1500 V, 10/700 waveform, applied 10 times, with a 60 s interval between pulses. The shape of the impulses is 10/700 (10 μs virtual front time, 700 μs virtual time to half value), as defined in ITU-T Recommendation K.44.”

Conductive link segments that have differing isolation and grounding requirements shall have those requirements provided by the port-to-port isolation of network interface devices (NID).

33.4.1.1 Electrical isolation environments

There are two electrical power distribution environments to be considered that require different electrical isolation properties. They are as follows:

— **Environment A:** When a LAN or LAN segment, with all its associated interconnected equipment, is entirely contained within a single low-voltage power distribution system and within a single building.
— **Environment B:** When a LAN crosses the boundary between separate power distribution systems or the boundaries of a single building.

33.4.1.1.1 Environment A requirements

Attachment of network segments via NIDs that have multiple instances of a twisted pair MDI requires electrical isolation between each segment and the protective ground of the NID.

For NIDs, the requirement for isolation is encompassed within the isolation requirements of the MAU or PHY (see 14.3.1.1, 25.4.6, and 40.6.1.1.). Equipment with multiple instances of PSE, PD, or both shall meet or exceed the isolation requirement of the MAU/PHY with which they are associated.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A multiport NID complying with Environment A requirements does not require electrical power isolation between link segments.

An Environment A PSE shall switch the more negative conductor. It is allowable to switch both conductors.

33.4.1.1.2 Environment B requirements

The attachment of network segments that cross Environment A boundaries requires electrical isolation between each segment and all other attached segments as well as to the protective ground of the NID.

For NIDs, the requirement for isolation is encompassed within the isolation requirements of the MAU or PHY (see 14.3.1.1, 25.4.6, and 40.6.1.1.). Equipment with multiple instances of PSE, PD, or both shall meet or exceed the isolation requirement of the MAU/PHY with which each is associated.

The requirements for interconnected electrically conducting link segments that are partially or fully external to a single building environment may require additional protection against lightning strikes or other hazards. Protection requirements for such hazards are beyond the scope of this standard. Guidance on these requirements may be found in Section 6 of IEC 60950-1:2001, as well as any local and national codes related to safety.

33.4.2 Fault tolerance

Each wire pair of the PI, when it is also an MDI (e.g., an Endpoint PSE or PD), shall meet the fault tolerance requirements of the appropriate specifying clause. (See 14.3.1.2.7, 25.4, 40.8.3.4, 55.8.2.3, and 126.8.2.4.) When a PI is not an MDI (e.g., a Midspan PSE), the PSE PI shall meet the fault tolerance requirements of this subclause.

The PSE PI shall withstand without damage the application of short circuits of any wire to any other wire within the cable for an indefinite period of time. The magnitude of the current through such a short circuit shall not exceed I_{LIM} max as defined in Table 33–11.

Each wire pair shall withstand, without damage, a 1000 V common-mode impulse applied at E_{cm} of either polarity. The shape of the impulse shall be (0.3/50) μs (300 ns virtual front time, 50 μs virtual time of half value), as defined in IEC 60060, where E_{cm} is an externally applied AC voltage as shown in Figure 33–19.

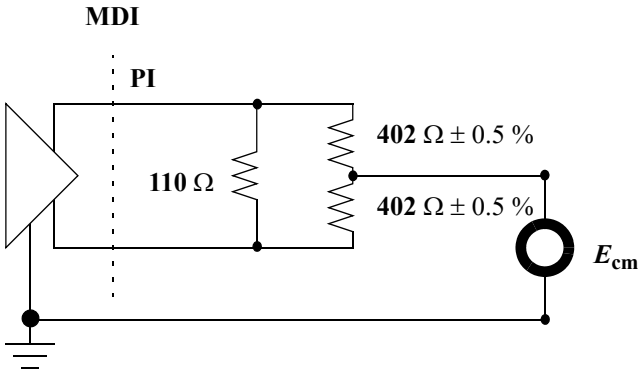

Figure 33–19—PI fault tolerance test circuit

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.4.3 Impedance balance

Impedance balance is a measurement of the common-mode-to-differential-mode offset of the PI. The common-mode-to-differential-mode impedance balance for the transmit and receive pairs shall exceed the limits in Table 33–20 for all supported PHY speeds.

Table 33–20—Impedance balance limits for supported speeds

Supported speed	Impedance balance limit (dB)	Frequency range
10 Mb/s MAU	$29 - 17 \times \log_{10}(f/10)$	$1 \le f \le 20$ MHz
100 Mb/s or 1000 Mb/s PHY	$34 - 19.2 \times \log_{10}(f/50)$	$1 \le f \le 100$ MHz
2.5 Gb/s PHY	48	$1 \le f < 10$ MHz
	$48 - 20 \times \log_{10}(f/10)$	$10 \le f < 20$ MHz
	$42 - 15 \times \log_{10}(f/20)$	$20 \le f \le 125$ MHz
5 Gb/s PHY	48	$1 \le f < 30$ MHz
	$44 - 19.2 \times \log_{10}(f/50)$	$30 \le f \le 250$ MHz
10 Gb/s PHY	48	$1 \le f < 30$ MHz
	$44 - 19.2 \times \log_{10}(f/50)$	$30 \le f \le 500$ MHz

The impedance balance is defined as shown in Equation (33–16):

$$\left\{20.0 \times \log_{10}\left(\frac{E_{\text{cm}}}{E_{\text{dif}}}\right)\right\}_{\text{dB}} \tag{33–16}$$

where

E_{cm} is an externally applied sinusoidal voltage as shown in Figure 33–20

E_{dif} is the voltage of the resulting waveform due only to the applied sine wave measured as shown in Figure 33–20

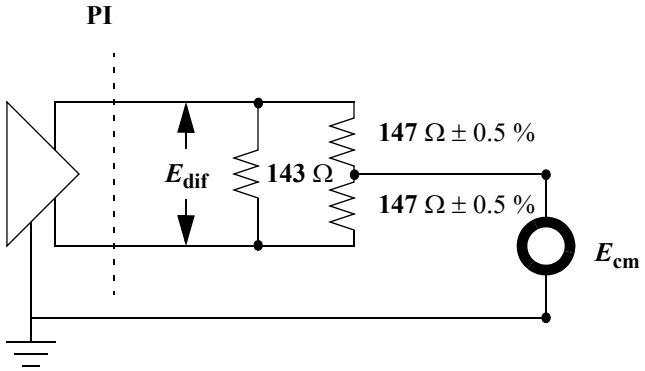

Figure 33–20—PI impedance balance test circuit

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.4.4 Common-mode output voltage

The magnitude of the common-mode AC output voltage measured according to Figure 33–21 and Figure 33–22 at the transmit PI while transmitting data and with power applied, E_{cm_out}, shall not exceed the values in Table 33–21 while operating at the specified speed, when measured over the specified bandwidth.

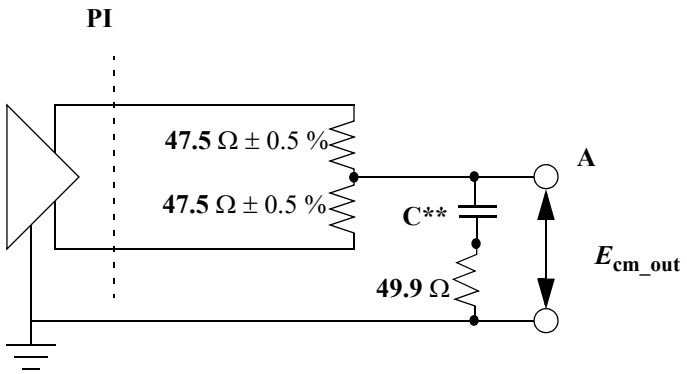

Figure 33–21—Common-mode output voltage test

The common-mode AC output voltage shall be measured while the PHY is transmitting data, the PSE or PD is operating with the following PSE load or PD source:

1) For a PSE, the PI that supplies power is terminated as illustrated in Figure 33–22. The PSE load, R, in Figure 33–22 is adjusted so that the PSE output current, I_{out}, is 10 mA and then 350 mA, while measuring E_{cm_out} on the PI.
2) For a PD, the PI that requires power shall be terminated as illustrated in Figure 33–22. V_{source} in Figure 33–22 is adjusted to 36 Vdc and 57 Vdc, while measuring E_{cm_out} on the PI.

Table 33–21—Common-mode output voltage for given operating speed

Operating speed	Common-mode output voltage (E_{cm_out})	Measurement bandwidth
10 Mb/s MAU	50 mV peak	$1 \leq f \leq 100$ MHz
100 Mb/s or 1000 Mb/s PHY	50 mV_{pp}	$1 \leq f \leq 100$ MHz
2.5 Gb/s PHY	50 mV_{pp}	$1 \leq f \leq 100$ MHz
5 Gb/s PHY	50 mV_{pp}	$1 \leq f \leq 250$ MHz
10 Gb/s PHY	50 mV_{pp}	$1 \leq f \leq 500$ MHz

NOTE—The implementer should consider any applicable local, national, or international regulations that may require more stringent specifications. One such specification can be found in the European Standard EN 55022:1998.

33.4.5 Pair-to-pair output noise voltage

The pair-to-pair output noise voltage (see Figure 33–23) is limited by the resulting electromagnetic interference due to this AC voltage. This AC voltage can be ripple from the power supply (Table 33–11, item 3) or from any other source. A system integrating a PSE shall comply with applicable local and national codes for the limitation of electromagnetic interference.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

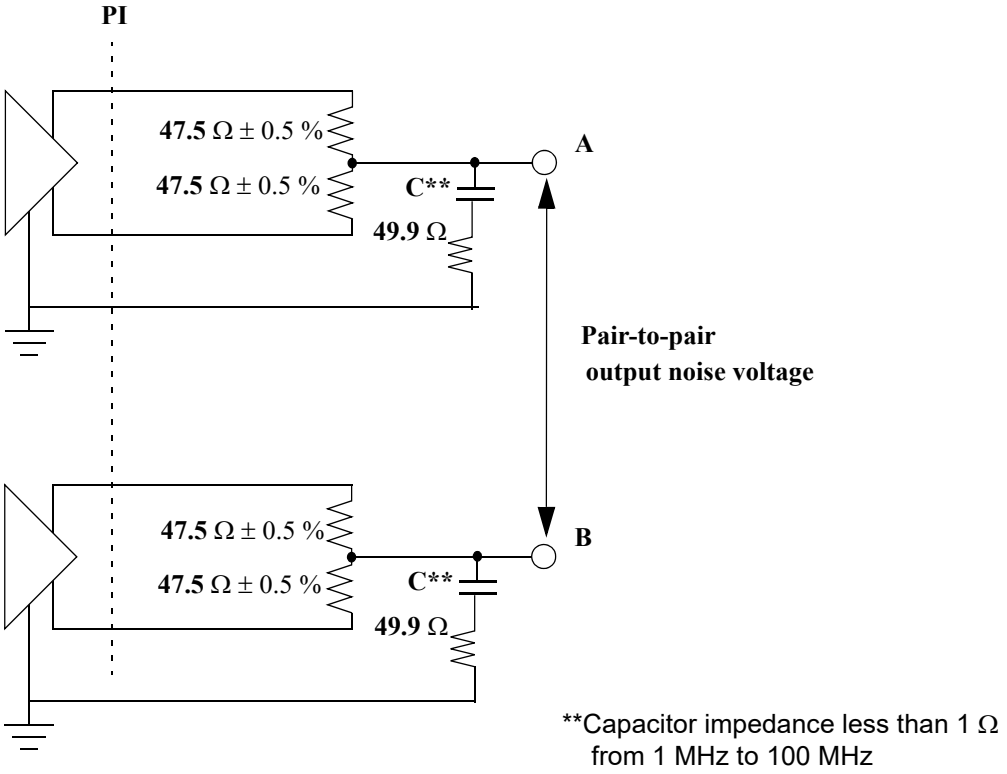

Figure 33–23—Pair-to-pair output noise voltage test

33.4.6 Differential noise voltage

For 10/100/1000 Mb/s, the coupled noise, E_{d_out} in Figure 33–22, from a PSE or PD to the differential transmit and receive pairs shall not exceed 10 mV peak-to-peak when measured from 1 MHz to 100 MHz under the conditions specified in 33.4.4, item 1) and item 2).

For 2.5GBASE-T, 5GBASE-T, or 10GBASE-T, the coupled noise, E_{d_out} in Figure 33–22, from a PSE or PD to the differential transmit and receive pairs shall not exceed 10 mV peak-to-peak when measured in the band from 1 MHz to 10 MHz and shall not exceed 1 mV peak-to-peak when measured in the band from 10 MHz to 100 MHz for 2.5GBASE-T, 10 MHz to 250 MHz for 5GBASE-T, and 10 MHz to 500 MHz for 10GBASE-T under the conditions specified in 33.4.4, item 1) and item 2).

33.4.7 Return loss

The differential impedance of the transmit and receive pairs at the PHY's MDI shall be such that any reflection shall meet the return loss requirements as specified in 14.3.1.3.4 for a 10 Mb/s PHY, in ANSI INCITS 263-1995 for a 100 Mb/s PHY, in 40.8.3.1 for a 1000 Mb/s PHY, in 126.8.2.2 for a 2.5 Gb/s or 5 Gb/s PHY, and in 55.8.2.1 for a 10 Gb/s PHY. In addition, all pairs terminated at an MDI should maintain a nominal common-mode impedance of 75 Ω. The common-mode termination is affected by the presence of the power supply, and this should be considered to determine proper termination.

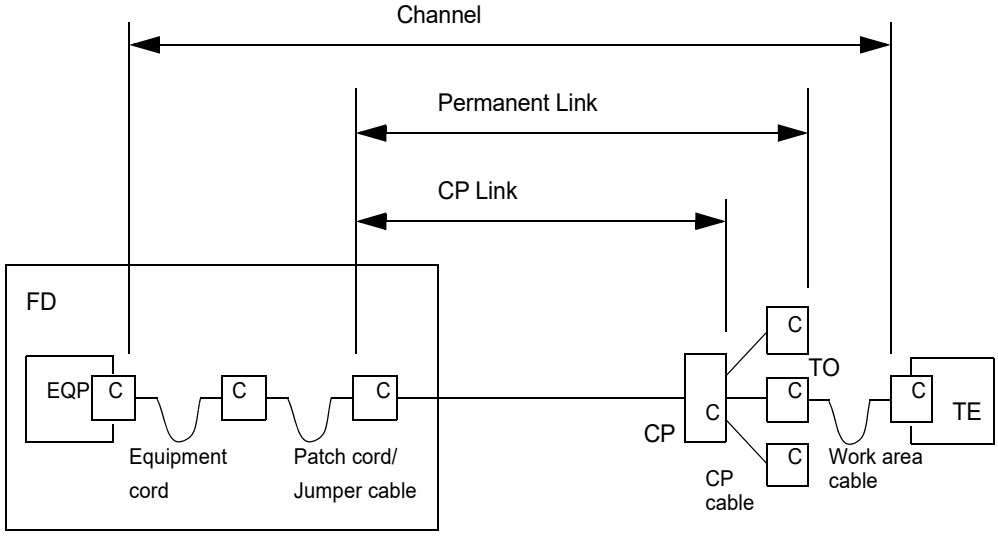
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



33.4.8 100BASE-TX transformer droop

100BASE-TX systems may contain a legacy PHY receiver that expects to be connected to a PHY transmitter with 350 μH open circuit inductance (OCL). Alternative A Type 2 Midspan PSEs that support 100BASE-TX shall enforce channel unbalance currents less than or equal to Type 1 I_{unb} (see Table 33–11) or meet 33.4.9.4.

100BASE-TX Type 2 Endpoint PSEs and 100BASE-TX Type 2 PDs shall meet the requirements of Clause 25 in the presence of (I_{unb}/2).

33.4.9 Midspan PSE device additional requirements

The cabling specifications for 100 Ω balanced cabling are described in ISO/IEC 11801-2002. Cable conforming to ANSI/TIA-568-C.2 also meets these requirements. Some cable category specifications that only appear in earlier editions are also supported. The configuration of "channel" and "permanent link" is defined in Figure 33–24. Type 2 Midspan PSE cabling system requirements are specified in 33.1.4.1.

FD = floor distributor; EQP = equipment; C = connection (mated pair);
CP = consolidation point; TO = telecommunications outlet;
TE = terminal equipment

Figure 33–24—Floor distributor channel configuration

ISO/IEC 11801 defines in 5.6.1 two types of Equipment interface to the cabling system: "Interconnect model" and the "cross-connect model." An equivalent "Interconnect model" and "cross-connect model" can be found in ANSI/TIA-568-C.0, 4.2. See Figure 33–25.

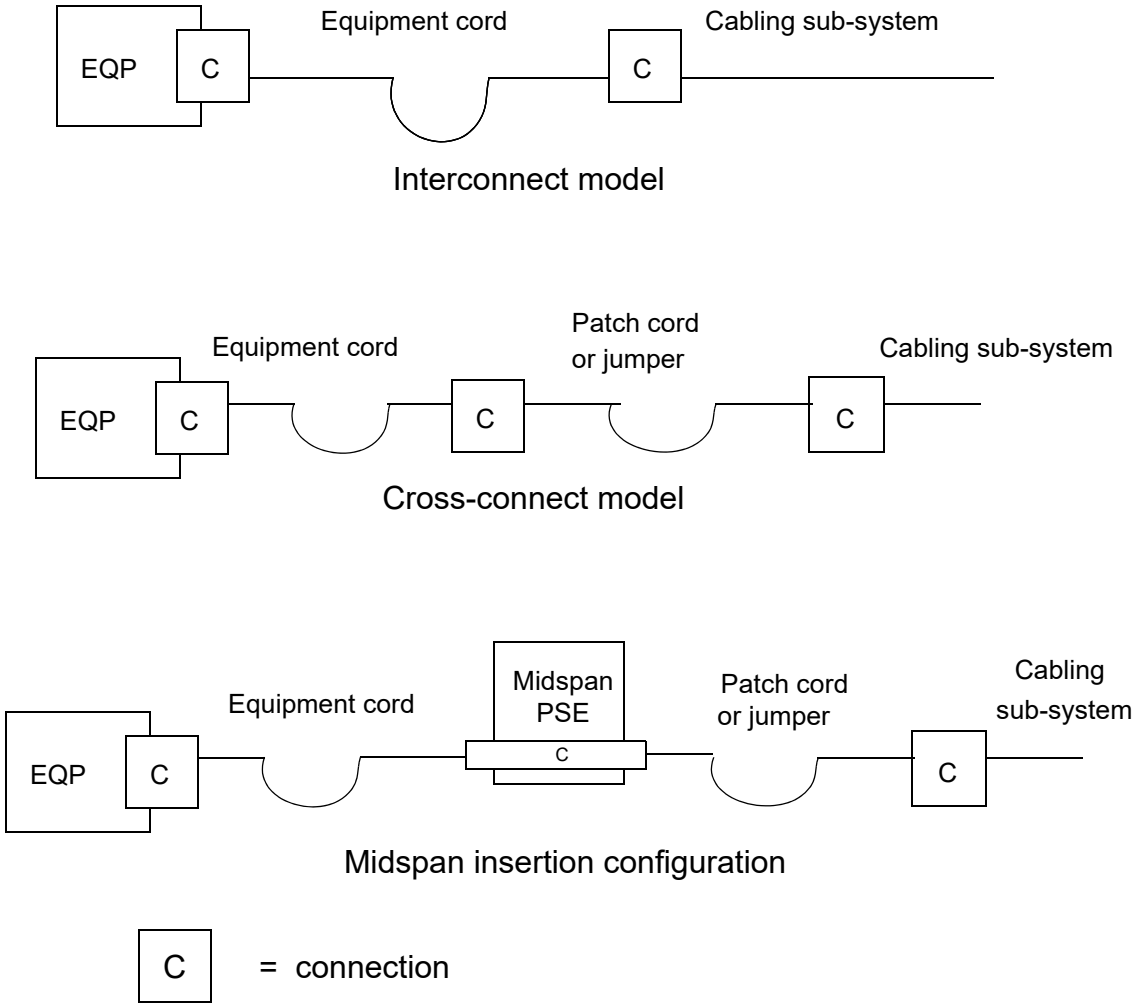

Figure 33–25—Interconnect model, cross-connect model, and midspan insertion configuration

The insertion of a Midspan PSE at the Floor Distributor (FD) shall comply with the following guidelines:

a) If the existing FD configuration is of the “Interconnect model” type, the Midspan PSE can be added, provided it does not increase the insertion loss of the resulting “channel” to more than that specified for the same Class or category 100 m channel defined in ISO/IEC 11801 or ANSI/TIA-568-C.0.

b) If the existing FD configuration is of the “Cross-connect model” type, the Midspan PSE can be installed instead of one of the connection pairs in the FD. In addition, the installation of the Midspan PSE shall not increase the insertion loss of the resulting “channel” to more than that specified for the same Class or category 100 m channel defined in ISO/IEC 11801 or ANSI/TIA-568-C.0.

c) For a 10GBASE-T midspan PSE, in meeting either of the above requirements, the Midspan PSE may be substituted for up to two connection pairs in the FD.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Configurations with the Midspan PSE in the cabling channel shall not alter the transmission requirements of the "permanent link." A Midspan PSE shall not provide DC continuity between the two sides of the segment for the pairs that inject power.

The requirements for the two pair Category 5 channel are found in 25.4.9. The specification of Midspan PSE operation on a two pair cable is beyond the scope of this document.

NOTE—Appropriate terminations may be applied to the interrupted pairs on both sides of the Midspan device.

33.4.9.1 Connector Midspan PSE device transmission requirements

The Midspan PSE to be inserted as a connection or telecommunications outlet shall meet the following transmission parameters. These parameters should be measured using the test procedures of ISO 11801:2002 or ANSI/TIA-568-C.2 for connecting hardware.

There are five variants of Midspan PSEs defined with respect to transmission requirements:

1) 10BASE-T/100BASE-TX connector Midspan PSE
2) 1000BASE-T connector Midspan PSE
3) 2.5GBASE-T connector Midspan PSE
4) 5GBASE-T connector Midspan PSE
5) 10GBASE-T connector Midspan PSE

33.4.9.1.1 Near End Crosstalk (NEXT)

NEXT loss is a measure of the unwanted signal coupling from a transmitter at the near-end into neighboring pairs measured at the near-end. NEXT loss is expressed in dB relative to the received signal level. For operation with 1000BASE-T and lower rates, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–17) when measured for the transmit and receive pairs from 1 MHz to 100 MHz. For operation with 5GBASE-T and lower rates, for frequencies that correspond to calculated values greater than 65 dB, the requirement reverts to the minimum requirement of 65 dB.

$$\{NEXTconn\}_{\mathrm{dB}} \geq 40.0 - 20.0 \times \log_{10}\left(\frac{f}{100}\right) \tag{33–17}$$

where

NEXTconn is the Near End Crosstalk loss
f is the frequency expressed in MHz

For 2.5GBASE-T, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–18) when measured for the transmit and receive pairs from 1 MHz to 100 MHz. For 5GBASE-T, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–18) when measured for the transmit and receive pairs from 1 MHz to 250 MHz. For operation with 2.5GBASE-T and 5GBASE-T, for frequencies that correspond to calculated values greater than 65 dB, the requirement reverts to the minimum requirement of 65 dB.

$$\{NEXTconn\}_{\mathrm{dB}} \geq 43 - 20 \times \log_{10}\left(\frac{f}{100}\right) \tag{33–18}$$

where

NEXTconn is the Near End Crosstalk loss
f is the frequency expressed in MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For 10GBASE-T operation, NEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–19) when measured for the transmit and receive pairs from 1 MHz to 500 MHz. However, for frequencies that correspond to calculated values greater than 75 dB, the requirement reverts to the minimum requirement of 75 dB.

$$\{NEXTconn\}_{\text{dB}} \leq \left\{ \begin{array}{ll} 54 - 20 \times \log_{10}\left(\frac{f}{100}\right) & \text{for } (1 \leq f \leq 250) \\ 46.04 - 40 \times \log_{10}\left(\frac{f}{250}\right) & \text{for } (250 < f \leq 500) \end{array} \right\}_{dB} \quad (33\text{–}19)$$

where

NEXTconn is the Near End Crosstalk loss in dB
f is the frequency expressed in MHz

33.4.9.1.2 Insertion loss

Insertion loss is a measure of the signal loss between the transmitter and receiver, expressed in dB relative to the received signal level. For other than 5GBASE-T or 10GBASE-T operation, insertion loss for Midspan PSE devices shall meet the values determined by Equation (33–20) when measured for the transmit and receive pairs from 1 MHz to 100 MHz. For 5GBASE-T capable midspans, insertion loss for Midspan PSE devices shall meet the values determined by Equation (33–20) when measured for the transmit and receive pairs from 1 MHz to 250 MHz. For frequencies that correspond to calculated values less than 0.1 dB, the requirement reverts to the maximum requirement of 0.1 dB. For 10GBASE-T operation, insertion loss for Midspan PSE devices shall meet the values determined by Equation (33–20) when measured from the transmit and receive pairs from 1 MHz to 500 MHz.

$$\{ILconn\}_{\text{dB}} \leq 0.040 \times \sqrt{f} \quad (33\text{–}20)$$

where

ILconn is the insertion loss
f is the frequency expressed in MHz

33.4.9.1.3 Return loss

Return loss is a measure of the reflected energy caused by impedance mismatches in the cabling system and is expressed in dB relative to the reflected signal level. Return loss for Midspan PSE devices shall meet or exceed the values specified in Table 33–22.

Table 33–22—Connector return loss

Midspan PSE variant	Frequency	Return loss
10/100/1000BASE-T	1 MHz ≤ *f* < 20 MHz	23 dB
	20 MHz ≤ *f* ≤ 100 MHz	14 dB
2.5GBASE-T	1 MHz ≤ *f* < 31.5 MHz	30 dB
	31.5 MHz ≤ *f* < 100 MHz	20 – 20 $\log_{10}$(f / 100)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 33–22—Connector return loss *(continued)*

Midspan PSE variant	Frequency	Return loss
5GBASE-T	1 MHz ≤ f < 31.5 MHz	30 dB
	31.5 MHz ≤ f ≤ 250 MHz	20 – 20 $\log_{10}$(f / 100)
10GBASE-T	1 MHz ≤ f < 79 MHz	30 dB
	79 MHz ≤ f ≤ 500 MHz	28 – 20 $\log_{10}$(f / 100)

33.4.9.2 Cord Midspan PSE

Replacing the work area or equipment cable with a cable that includes a Midspan PSE should not alter the requirements of the cable. This cable shall meet the requirements of this clause and the specifications for a (jumper) cord for insertion loss, NEXT, and return loss for the transmit and receive pairs, as shown in Table 33–23.

There are five variants of Midspan PSEs defined with respect to transmission requirements:

1) 10BASE-T/100BASE-TX cord Midspan PSE
2) 1000BASE-T cord Midspan PSE
3) 2.5GBASE-T cord Midspan PSE
4) 5GBASE-T cord Midspan PSE
5) 10GBASE-T cord Midspan PSE

Table 33–23—Cord specifications for use with Midspan PSEs

Highest PHY rate supported	Cord specification	Frequency range
Up to 1000BASE-T	Category 5 cord in ISO/IEC 11801:2002 or ANSI/TIA-568-A:1995	1 MHz ≤ f ≤ 100 MHz
Up to 2.5GBASE-T	Category 5e cord in ISO/IEC 11801:2002 or ANSI/TIA-568-C.2	1 MHz ≤ f ≤ 100 MHz
Up to 5GBASE-T	Category 6 cord in ISO/IEC 11801:2002 or ANSI/TIA-568-C.2	1 MHz ≤ f ≤ 250 MHz
Up to 10GBASE-T	Category 6A cord in ISO/IEC 11801-1 or ANSI/TIA-568-C.2	1 MHz ≤ f ≤ 500 MHz

33.4.9.2.1 Maximum link delay

The propagation delay contribution of the Midspan PSE device shall not exceed 2.5 ns from 1 MHz to the highest referenced frequency.

33.4.9.2.2 Maximum link delay skew

The propagation delay skew of the Midspan PSE device shall not exceed 1.25 ns from 1 MHz to the highest referenced frequency.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.4.9.3 Coupling parameters between link segments

Midspan PSEs intended for operation with 2.5G/5G/10GBASE-T (variants 3 through 5 in 33.4.9.1 and 33.4.9.2) are additionally required to meet the following parameters for coupling signals between ports relating to different link segments. Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. To bound the total alien NEXT loss and alien FEXT loss coupled between link segments, multiple disturber alien near-end crosstalk (MDANEXT) loss and multiple disturber alien FEXT (MDAFEXT) loss are specified.

33.4.9.3.1 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

PSANEXT loss for 2.5G/5G/10GBASE-T capable Midspan PSE devices shall meet or exceed the values determined using Equation (33–21). For other than 5GBASE-T or 10GBASE-T operation, PSANEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–21) from 1 MHz to 100 MHz. For 5GBASE-T capable midspans, PSANEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–21) from 1 MHz to 250 MHz. For 10GBASE-T capable midspans, PSANEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–21) from 1 MHz to 500 MHz. When the computed PSANEXT value at a certain frequency exceeds 67 dB, the PSANEXT result at that frequency is for information only.

$$\text{PSANEXT Loss} = 70.5 - 20\log_{10}(f/100) \tag{33–21}$$

33.4.9.3.2 Multiple disturber power sum alien far-end crosstalk (PSAFEXT) loss

PSAFEXT loss for 2.5G/5G/10GBASE-T capable Midspan PSE devices shall meet or exceed the values determined using Equation (33–22). For other than 5GBASE-T or 10GBASE-T operation, PSAFEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–22) from 1 MHz to 100 MHz. For 5GBASE-T capable midspans, PSAFEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–22) from 1 MHz to 250 MHz. For 10GBASE-T capable midspans, PSAFEXT loss for Midspan PSE devices shall meet the values determined by Equation (33–22) from 1 MHz to 500 MHz. When the computed PSAFEXT value at a certain frequency exceeds 67 dB, the PSANEXT result at that frequency is for information only.

$$\text{PSAFEXT Loss} = 67 - 20\log_{10}(f/100) \tag{33–22}$$

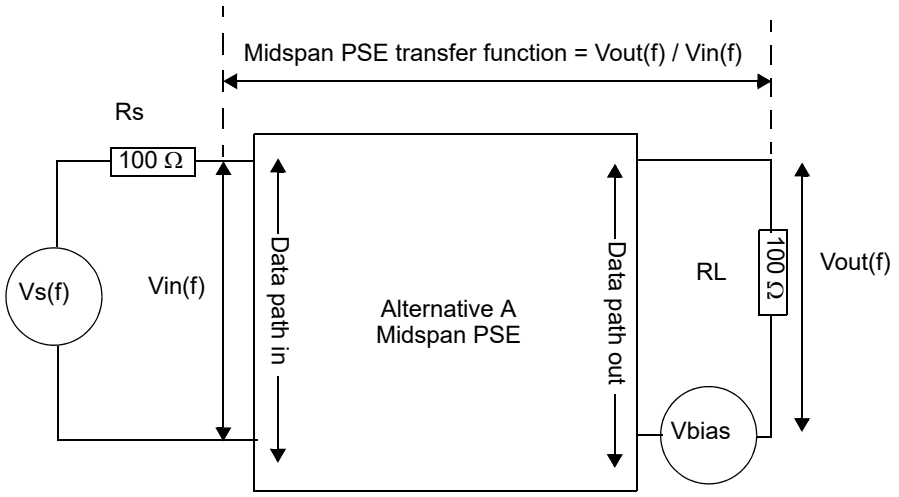
33.4.9.4 Midspan signal path requirements

An Alternative A Midspan PSE transfer function gain shall be greater than that expressed by Equation (33–23) for the frequency range from 0.1 MHz to 1 MHz, at the pins of the PI used as 100BASE-TX transmit pins.

$$\left\{ -0.100 + 37.5 \times \log_{10}\left(\frac{22.4 \times f}{\sqrt{1.00 + 521 \times f^2}} \right) \right\} \text{dB} \tag{33–23}$$

where

f is the frequency expressed in MHz.



The requirements shall be met with a DC bias current, I_{bias}, between 0 mA and (I_{unb}/2) mA (I_{unb} is defined in Table 33–11).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.4.9.4.1 Alternative A Midspan PSE signal path transfer function

The transfer function is measured by applying a test signal to the Midspan PSE signal input through a source impedance of 100 Ω ± 1 %. The Midspan PSE signal input and output may be connected to a 0.5 m maximum length of cable, meeting the requirements of 25.4.9, terminated with 100 Ω ± 1 %.

The transfer function is defined from the output termination to the Midspan PSE input. See Figure 33–26.

Vin(f) is the sine wave signal to be used to measure the Midspan PSE transfer function.
Vbias is the DC offset voltage to be applied in series with RL in order to generate I_{bias}.
Vout(f) is the Midspan PSE response to Vin(f).
Some test equipment may require isolation between measurement ports.

Figure 33–26—Measurement setup for Alternative A Midspan PSE transfer function

33.5 Management function requirements

NOTE—33.5 has been deprecated. Since May 2019, maintenance changes are no longer being considered for this subclause.

If the PSE is implemented with a management interface described in 22.2.4 or 45.2 (MDIO), then the management access shall use the PSE register definitions shown in 33.5.1. Where no physical embodiment of the Clause 22 or Clause 45 management is supported, equivalent management capability shall be provided. Managed objects corresponding to PSE and PD control parameters and states are described in Clause 30.

33.5.1 PSE registers

A PSE implementing either Clause 22 or Clause 45 management interface shall use register address 11 for its control and register address 12 for its status functions. The full set of management registers is listed in Table 22–6.

Some of the bits within registers are defined as latching high (LH). When a bit is defined as latching high and the condition for the bit to be high has occurred, the bit shall remain high until after it has been read via the management interface. Once such a read has occurred, the bit shall assume a value based on the current state of the condition it monitors.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.5.1.1 PSE Control register (Register 11) (R/W)

The assignment of bits in the PSE Control register is shown in Table 33–24. The default value for each bit of the PSE Control register should be chosen so that the initial state of the PSE upon power up or reset is a normal operational state without management intervention.

Table 33–24—PSE Control register bit definitions

Bit(s)	Name	Description	R/W[a]
11.15:6	Reserved	Ignore when read	RO
11.5	Data Link Layer Classification Capability	1 = Data Link Layer classification capability enabled 0 = Data Link Layer classification capability disabled	R/W
11.4	Enable Physical Layer Classification	1 = Physical Layer classification enabled 0 = Physical Layer classification disabled	R/W
11.3:2	Pair Control	(11.3) (11.2) 1 1 = Reserved 1 0 = PSE pinout Alternative B 0 1 = PSE pinout Alternative A 0 0 = Reserved	R/W
11.1:0	PSE Enable	(11.1) (11.0) 1 1 = Reserved 1 0 = Force Power Test Mode 0 1 = PSE Enabled 0 0 = PSE Disabled	R/W

[a]R/W = Read/Write, RO = Read Only

33.5.1.1.1 Reserved bits (11.15:6)

Bits 11.15:6 are reserved for future standardization. They shall not be affected by writes and shall return a value of zero when read. For compatibility with future use of reserved bits and registers, if the management entity writes to a reserved bit, it should use a value of zero. If it reads a reserved bit, it should ignore the results.

33.5.1.1.2 Data Link Layer Classification capability (11.5)

Bit 11.5 controls a PSEs capability of performing Data Link Layer classification as specified in 33.6.

A PSE that does not support Data Link Layer classification shall ignore writes to bit 11.5 and shall return a value of zero when read. A PSE that supports Data Link Layer classification, but does not allow the capability to be disabled, shall ignore writes to bit 11.5 and shall return a value of one when read.

A PSE that supports Data Link Layer classification and supports the ability to enable and disable it shall enable Data Link Layer classification by setting bit 11.5 to one and disable it by setting bit 11.5 to zero.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.5.1.1.3 Enable Physical Layer classification (11.4)

Bit 11.4 controls Physical Layer classification as specified in 33.2.6. A PSE that indicates support for Physical Layer classification in register 12.13 may also provide the option of disabling Physical Layer classification through bit 11.4.

A PSE that does not support Physical Layer classification shall ignore writes to bit 11.4 and shall return a value of zero when read. A PSE that supports Physical Layer classification, but does not allow the function to be disabled, shall ignore writes to bit 11.4 and shall return a value of one when read.

The Physical Layer classification function shall be enabled by setting bit 11.4 to one and disabled by setting bit 11.4 to zero.

33.5.1.1.4 Pair Control (11.3:2)

Bits 11.3:2 report the supported PSE Pinout Alternative specified in 33.2.1. A PSE may also provide the option of controlling the PSE Pinout Alternative through these bits. Provision of this option is indicated through the Pair Control Ability (12.0) bit. A PSE that does not support this option shall ignore writes to these bits and shall return the value that reports the supported PSE Pinout Alternative.

When read as ‘01’, bits 11.3:2 indicate that only PSE Pinout Alternative A is supported by the PSE. When read as ‘10’, bits 11.3:2 indicate that only PSE Pinout Alternative B is supported by the PSE.

Where the option of controlling the PSE Pinout Alternative through these bits is provided, setting bits 11.3:2 to ‘01’ shall force the PSE to use only PSE Pinout Alternative A and setting bits 11.3:2 to ‘10’ shall force the PSE to use only PSE Pinout Alternative B.

If bit 12.0 is one, writing to these register bits shall set mr_pse_alternative to the corresponding value: ‘01’ = A and ‘10’ = B. The combinations ‘00’ and ‘11’ for bits 11.3:2 are reserved and will never be assigned. Reading bits 11.3:2 returns an unambiguous result of ‘01’ or ‘10’ that may be used to determine the presence of the PSE Control register.

33.5.1.1.5 PSE enable (11.1:0)

The PSE function shall be disabled by setting bit 11.1 to zero and bit 11.0 to zero. When the PSE function is disabled, the MDI shall function as it would if it had no PSE function. The PSE function shall be enabled by setting bits 11.1 to a zero and 11.0 to a one. When bit 11.1 is a one, and bit 11.0 is a zero, a test mode is enabled. This test mode supplies power without regard to PD detection.

Writing to these register bits shall set mr_pse_enable to the corresponding value: ‘00’ = disable, ‘01’ = enable and ‘10’ = force power. The combination ‘11’ for bits 11.1:0 has been reserved for future use.

CAUTION

Test mode may damage connected non-PD, legacy, twisted pair Ethernet devices, or other non-Ethernet devices, especially in split application wiring schemes.

33.5.1.2 PSE Status register (Register 12) (R/W)

The assignment of bits in the PSE Status register is shown in Table 33–25.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 33–25—PSE Status register bit definitions

Bit(s)	Name	Description	R/W[a]
12.15	PSE Type Electrical Parameters	1 = PSE is using Type 2 PSE electrical parameters 0 = PSE is using Type 1 PSE electrical parameters	RO
12.14	Data Link Layer Classification Enabled	1 = Data Link Layer classification is enabled 0 = Data Link Layer classification is not supported or is not enabled	RO
12.13	Physical Layer Classification Supported	1 = PSE supports Physical Layer classification 0 = PSE does not support Physical Layer classification	RO
12.12	Power Denied or Removed	1 = Power has been denied or removed due to fault 0 = Power has not been denied or removed	RO/ LH
12.11	Valid Signature	1 = Valid PD signature detected 0 = No valid PD signature detected	RO/ LH
12.10	Invalid Signature	1 = Invalid PD signature detected 0 = No invalid PD signature detected	RO/ LH
12.9	Short Circuit	1 = Short circuit condition detected 0 = No short circuit condition detected	RO/ LH
12.8	Overload	1 = Overload condition detected 0 = No overload condition detected	RO/ LH
12.7	MPS Absent	1 = MPS absent condition detected 0 = No MPS absent condition detected	RO/ LH
12.6:4	PD Class	(12.6) (12.5) (12.4) 1 1 1 = Reserved 1 1 0 = Reserved 1 0 1 = Invalid Class 1 0 0 = Class 4 0 1 1 = Class 3 0 1 0 = Class 2 0 0 1 = Class 1 0 0 0 = Class 0	RO
12.3:1	PSE Status	(12.3) (12.2) (12.1) 1 1 1 = Reserved 1 1 0 = Reserved 1 0 1 = implementation-specific fault 1 0 0 = Test error 0 1 1 = Test mode 0 1 0 = Delivering power 0 0 1 = Searching 0 0 0 = Disabled	RO
12.0	Pair Control Ability	1 = PSE pinout controllable by Pair Control bits 0 = PSE Pinout Alternative fixed	RO

[a]RO = Read Only, LH = Latched High

33.5.1.2.1 PSE Type electrical parameters (12.15)

When read as a zero, bit 12.15 indicates that the PSE is operating with Type 1 PSE electrical parameters. When read as a one, bit 12.15 indicates that the PSE is operating with Type 2 PSE electrical parameters. This

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bit shall be set to zero when the PSE state diagram sets the state variable set_parameter_type to 1. This bit shall be set to one when the PSE state diagram sets set_parameter_type to 2.

33.5.1.2.2 Data Link Layer Classification Enabled (12.14)

When read as a one, bit 12.14 indicates the PSE supports Data Link Layer classification as defined in 33.2.6 and that it is enabled. When read as a zero, bit 12.14 indicates that the PSE lacks support for Data Link Layer classification or that Data Link Layer classification is not enabled. If supported, the Data Link Layer classification may be enabled or disabled through the state diagram variable pse_dll_enabled (see 33.2.4.4).

This bit shall be set to one when the PSE state diagram (Figure 33–9) sets true the state variable pse_dll_enabled. This bit shall be set to zero when the PSE state diagram sets false the state variable pss_dll_enabled.

33.5.1.2.3 Physical Layer Classification Supported (12.13)

When read as a one, bit 12.13 indicates that the PSE supports Physical Layer classification as defined in 33.2.6. When read as a zero, bit 12.13 indicates that the PSE lacks support for Physical Layer classification. If supported, the function may be enabled or disabled through the Enable Physical Layer Classification bit (11.4).

33.5.1.2.4 Power Denied or Removed (12.12)

When read as a one, bit 12.12 indicates that power has been denied or has been removed due to a fault condition. This bit shall be set to one when the PSE state diagram (Figure 33–9) enters the states ‘POWER_DENIED’ or ‘ERROR_DELAY.’ The Power Denied bit shall be implemented with latching high behavior as defined in 33.5.1.

33.5.1.2.5 Valid Signature (12.11)

When read as a one, bit 12.11 indicates that a valid signature has been detected. This bit shall be set to one when mr_valid_signature transitions from FALSE to TRUE. The Valid Signature bit shall be implemented with latching high behavior as defined in 33.5.1.

33.5.1.2.6 Invalid Signature (12.10)

When read as a one, bit 12.10 indicates that an invalid signature has been detected. This bit shall be set to one when the PSE state diagram (Figure 33–9) enters the state ‘SIGNATURE_INVALID’. The Invalid Signature bit shall be implemented with latching high behavior as defined in 33.5.1.

33.5.1.2.7 Short Circuit (12.9)

When read as a one, bit 12.9 indicates that a short circuit condition has been detected. This bit shall be set to one when the PSE state diagram (Figure 33–9) enters the state ‘ERROR_DELAY’ due to the short_detected variable being TRUE. The Short Circuit bit shall be implemented with latching high behavior as defined in 33.5.1.

33.5.1.2.8 Overload (12.8)

When read as a one, bit 12.8 indicates that an overload condition has been detected. This bit shall be set to one when the PSE state diagram (Figure 33–9) enters the state ‘ERROR_DELAY’ due to the ovld_detected variable being TRUE. The Overload bit shall be implemented with latching high behavior as defined in 33.5.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

33.5.1.2.9 MPS Absent (12.7)

When read as a one, bit 12.7 indicates that an MPS Absent condition has been detected. The MPS Absent bit shall be set to one when the PSE state diagram (Figure 33–9) transitions directly from the state POWER_ON to IDLE due to tmpdo_timer_done being asserted. The MPS Absent bit shall be implemented with latching high behavior as defined in 33.5.1.

33.5.1.2.10 PD Class (12.6:4)

Bits 12.6:4 report the PD Class of a detected PD as specified in 33.2.5 and 33.2.6. The value in this register is valid while a PD is connected, i.e., while the PSE Status (12.3:1) bits are reporting "delivering power." The combinations '110' and '111' for bits 12.6:4 have been reserved for future use.

33.5.1.2.11 PSE Status (12.3:1)

Bits 12.3:1 report the current status of the PSE. When read as '000', bits 12.3:1 indicate that the PSE state diagram (Figure 33–9) is in the state DISABLED. When read as '010', bits 12.3:1 indicate that the PSE state diagram is in the state POWER_ON. When read as '011', bits 12.3:1 indicate that the PSE state diagram is in the state TEST_MODE. When read as '100', bits 12.3:1 indicate that the PSE state diagram is in the state TEST_ERROR. When read as '101', bits 12.3:1 indicate that the PSE state diagram is in the state IDLE due to the variable error_condition = true. When read as '001', bits 12.3:1 indicate that the PSE state diagram is in a state other than those listed above.

The combinations '111' and '110' for bits 12.3:1 have been reserved for future use.

33.5.1.2.12 Pair Control Ability (12.0)

When read as a one, bit 12.0 indicates that the PSE supports the option to control which PSE Pinout Alternative (see 33.2.1) is used for PD detection and power through the Pair Control (11.3:2) bits. When read as a zero, bit 12.0 indicates that the PSE lacks support of the option to control which PSE Pinout Alternative is used for PD detection and power through the Pair Control (11.3:2) bits.

33.6 Data Link Layer classification

Additional control and classification functions are supported using Data Link Layer classification using frames based on the IEEE 802.3 Organizationally Specific TLVs defined in Clause 79. Type 2 PDs that require more than 13.0 W support Data Link Layer classification (see 33.3.5). Data Link Layer classification is optional for all other devices.

All reserved fields in transmitted Power via MDI TLVs shall contain zero, and all reserved fields in received Power via MDI TLVs shall be ignored.

33.6.1 TLV frame definition

Implementations that support Data Link Layer classification shall comply with all mandatory parts of IEEE Std 802.1AB-2009; shall support the Power via MDI Type, Length, Value (TLV) defined in 79.3.2; and shall support the control state diagrams defined in 33.6.3.

33.6.2 Data Link Layer classification timing requirements

A Type 2 PSE shall send an LLDPDU containing a Power via MDI TLV within 10 seconds of Data Link Layer classification being enabled in the PSE as indicated by the variable pse_dll_enabled (33.2.4.4, 33.6.3.3).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A Type 1 PSE that implements Data Link Layer classification shall send an LLDPDU containing a Power via MDI TLV when the PSE Data Link Layer classification engine is ready as indicated by the variable pse_dll_ready (33.6.3.3).

All Type 1 PDs that implement Data Link Layer classification and Type 2 PDs shall set the state variable pd_dll_ready within 5 minutes of Data Link Layer classification being enabled in a PD as indicated by the variable pd_dll_enabled (33.3.3.3, 33.6.3.3).

Under normal operation, an LLDPDU containing a Power via MDI TLV with an updated value for the “PSE allocated power value” field shall be sent within 10 seconds of receipt of an LLDPDU containing a Power via MDI TLV where the “PD requested power value” field is different from the previously communicated value.

Under normal operation, an LLDPDU containing a Power via MDI TLV with an updated value for the “PD requested power value” field shall be sent within 10 seconds of receipt of an LLDPDU containing a Power via MDI TLV where the “PSE allocated power value” field is different from the previously communicated value.

33.6.3 Power control state diagrams

The power control state diagrams for PSEs and PDs specify the externally observable behavior of a PSE and PD Data Link Layer classification respectively. PSE Data Link Layer classification shall provide the behavior of the state diagram as shown in Figure 33–27. PD Data Link Layer classification shall provide the behavior of the state diagram as shown in Figure 33–28.

33.6.3.1 Conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of state diagrams as described in 21.5.

33.6.3.2 Constants

PD_DLLMAX_VALUE

This value is derived from pd_max_power variable (33.3.3.3) described as follows:

pd_max_power	PD_DLLMAX_VALUE
0	130
1	39
2	65
3	130
4	255

PD_INITIAL_VALUE

This value is derived as follows from the pd_max_power (33.3.3.3) variable used in the PD state diagram (Figure 33–16):

pd_max_power	PD_INITIAL_VALUE
0	≤ 130
1	≤ 39
2	≤ 65
3	≤ 130
4	≤ 255

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PSE_INITIAL_VALUE

This value is derived as follows from parameter_type and the mr_pd_class_detected (33.2.4.6) variable used in the PSE state diagram (Figure 33–9):

parameter_type	mr_pd_class_detected	PSE_INITIAL_VALUE
1	0	130
1	1	39
1	2	65
1	3	130
1	4	130
2	4	255

33.6.3.3 Variables

The PSE power control state diagram (Figure 33–27) and PD power control state diagram (Figure 33–28) use the following variables:

MirroredPDRequestedPowerValue

The copy of PDRequestedPowerValue that the PSE receives from the remote system. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValue attribute (30.12.3.1.17). Power numbers are represented using an integer value in units of 0.1 W.

Values: 1 through 255

MirroredPDRequestedPowerValueEcho

The copy of PDRequestedPowerValueEcho that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemPDRequestedPowerValue attribute (30.12.3.1.17).

MirroredPSEAllocatedPowerValue

The copy of PSEAllocatedPowerValue that the PD receives from the remote system. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValue attribute (30.12.3.1.20). Power numbers are represented using an integer value in units of 0.1 W.

Values: 1 through 255

MirroredPSEAllocatedPowerValueEcho

The copy of PSEAllocatedPowerValue that the PSE receives from the remote system. This variable is mapped from the aLldpXdot3RemPSEAllocatedPowerValue attribute (30.12.3.1.20).

PDRequestedPowerValueEcho

This variable is updated by the PSE state diagram. This variable maps into the aLldpXdot3LocPDRequestedPowerValue attribute (30.12.2.1.17).

Values: 1 through 255

PDMaxPowerValue

Integer that indicates the actual PD power value of the local system. The actual PD power value for a PD is the maximum input average power (see 33.3.7.2) the PD ever draws under the current power allocation. Power numbers are represented using an integer value in units of 0.1 W.

PDRequestedPowerValue

Integer that indicates the PD requested power value in the PD. The value is the maximum input average power (see 33.3.7.2) the PD requests. Power numbers are represented using an integer value in units of 0.1 W. This variable is mapped from the aLldpXdot3LocPDRequestedPowerValue attribute (30.12.2.1.17).

Values: 1 through PD_DLLMAX_VALUE

PSEAllocatedPowerValue

Integer that indicates the PSE allocated power value in the PSE. Power numbers are represented using an integer value in units of 0.1 W. This variable is mapped from the aLldpXdot3LocPSEAllocatedPowerValue attribute (30.12.2.1.20).

Values: 1 through 255

PSEAllocatedPowerValueEcho

This variable is updated by the PD state diagram. This variable maps into the aLldpXdot3LocPSEAllocatedPowerValue attribute (30.12.2.1.20).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: 1 through 255

TempVar

A temporary variable used to store Power Value, represented by an integer value in units of 0.1 W.

local_system_change

An implementation-specific control variable that indicates that the local system wants to change the allocated power value. In a PSE, this indicates it is going to change the power allocated to the PD. In a PD, this indicates it is going to request a new power allocation from the PSE.

Values:FALSE:The local system does not wants to change the power allocation.
TRUE:The local system wants to change the power allocation.

parameter_type

A control variable output by the PSE state diagram (Figure 33–9) used by a Type 2 PSE to choose operation with Type 1 or Type 2 PSE output PI electrical requirement parameter values defined in Table 33–11.

Values: 1: Type 1 PSE parameter values (default).
2: Type 2 PSE parameter values.

pd_dll_enabled

A variable output by the PD state diagram (Figure 33–16) to indicate if the PD Data Link Layer classification mechanism is enabled.

Values: FALSE:PD Data Link Layer classification is not enabled.
TRUE:PD Data Link Layer classification is enabled.

pd_dll_power_type

A control variable that indicates the type of PD that is connected to the PSE as advertised through Data Link Layer classification.

Values: 1: PD is a Type 1 PD (default).
2: PD is a Type 2 PD.

pd_dll_ready

An implementation-specific control variable that indicates that the PD has initialized Data Link Layer classification. This variable maps into the aLldpXdot3LocReady attribute (30.12.2.1.61).

Values:FALSE:Data Link Layer classification has not completed initialization.
TRUE:Data Link Layer classification has completed initialization.

pse_dll_enabled

A variable output by the PSE state diagram (Figure 33–9) to indicate if the PSE Data Link Layer classification mechanism is enabled.

Values: FALSE:PSE Data Link Layer classification is not enabled.
TRUE:PSE Data Link Layer classification is enabled.

pse_dll_power_type

A control variable that indicates the type of the PSE by which the PD is being powered.

Values: 1: PSE is a Type 1 PSE (default).
2: PSE is a Type 2 PSE.

pse_dll_ready

An implementation-specific control variable that indicates that the PSE has initialized Data Link Layer classification. This variable maps into the aLldpXdot3LocReady attribute (30.12.2.1.61).

Values:FALSE:Data Link Layer classification has not completed initialization.
TRUE:Data Link Layer classification has completed initialization.

pse_power_type

A control variable output by the PD state diagram (Figure 33–16) to indicate the type of PSE by which it is being powered.

A summary cross-references between the Power over Ethernet classification local and remote object class attributes and the PSE and PD power control state diagrams, including the direction of the mapping, is provided in Table 33–26.

Table 33–26—Attribute to state diagram variable cross-reference

Entity	Attribute	Mapping	State diagram variable
oLldpXdot3LocSystemsGroup Object Class			
PSE	aLldpXdot3LocPDRequestedPowerValue	⇐	PDRequestedPowerValueEcho
	aLldpXdot3LocPSEAllocatedPowerValue	⇐	PSEAllocatedPowerValue
	aLldpXdot3LocReady	⇐	pse_dll_ready
PD	aLldpXdot3LocPDRequestedPowerValue	⇐	PDRequestedPowerValue
	aLldpXdot3LocPSEAllocatedPowerValue	⇐	PSEAllocatedPowerValueEcho
	aLldpXdot3LocReady	⇐	pd_dll_ready
oLldpXdot3RemSystemsGroup Object Class			
PSE	aLldpXdot3RemPDRequestedPowerValue	⇒	MirroredPDRequestedPowerValue
	aLldpXdot3RemPSEAllocatedPowerValue	⇒	MirroredPSEAllocatedPowerValueEcho
	aLldpXdot3RemPowerType Value[a] 11 01	 ⇒ ⇒	pd_dll_power_type Value[a] 01 10
PD	aLldpXdot3RemPSEAllocatedPowerValue	⇒	MirroredPSEAllocatedPowerValue
	aLldpXdot3RemPDRequestedPowerValue	⇒	MirroredPDRequestedPowerValueEcho
	aLldpXdot3RemPowerType Value[a] 10 00	 ⇒ ⇒	pse_dll_power_type Value[a] 01 10

[a]Other value combinations mapping from aLldpXdot3RemPowerType to pd_dll_power_type or pse_dll_power_type are not possible.

33.6.3.4 Functions

pse_power_review

This function evaluates the power allocation or budget of the PSE based on local system changes. The function returns the following variables:

PSE_NEW_VALUE:

The new maximum power value that the PSE expects the PD to draw. Power numbers are represented using an integer value in units of 0.1 W.

pd_power_review

This function evaluates the power requirements of the PD based on local system changes and/or changes in the PSE allocated power value. The function returns the following variables:

PD_NEW_VALUE:

The new maximum power value that the PD wants to draw. Power numbers are represented using an integer value in units of 0.1 W.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The general state change procedure for PDs is shown in Figure 33–28.

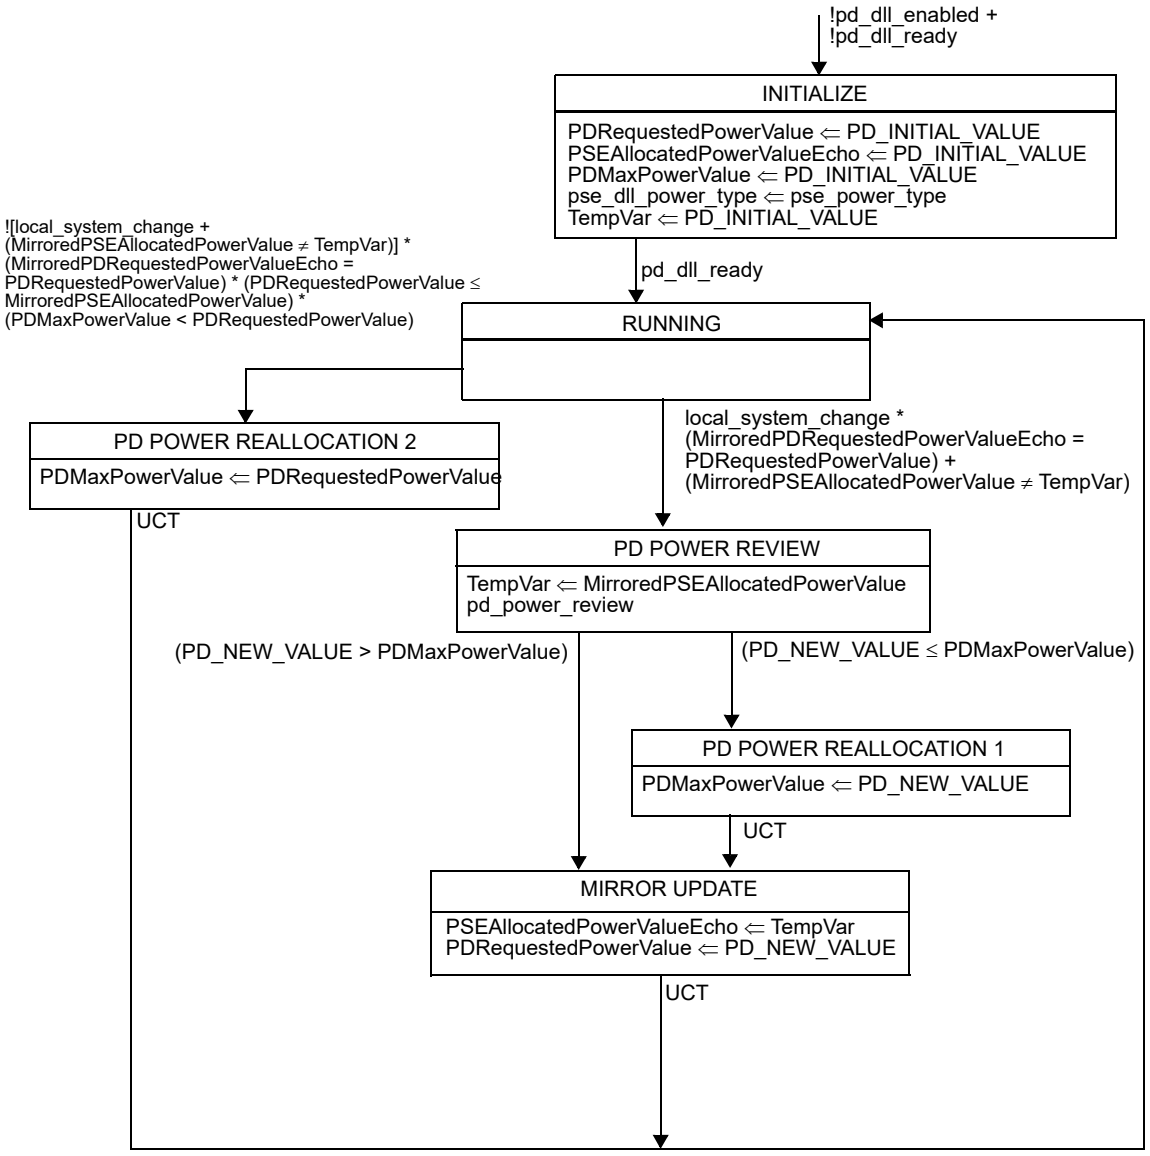

Figure 33–28—PD power control state diagram

33.6.4 State change procedure across a link

The PSE and PD utilize the LLDPDUs to advertise their various attributes to the other entity.

The PD may request a new power value through the aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17) attribute in the oLldpXdot3LocSystemsGroup object class. The request appears to the PSE as a change to the aLldpXdot3RemPDRequestedPowerValue (30.12.3.1.17) attribute in the oLldpXdot3RemSystemsGroup object class.

The PSE responds to the PD's request through the aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20) attribute in the oLldpXdot3LocSystemsGroup object class. The PSE also copies the value of the aLldpXdot3RemPDRequestedPowerValue (30.12.3.1.17) in the oLldpXdot3RemSystemsGroup object class

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to the aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17) in the oLldpXdot3LocSystemsGroup object class. This appears to the PD as a change to the aLldpXdot3RemPSEAllocatedPowerValue (30.12.3.1.20) attribute in the oLldpXdot3RemSystemsGroup object class.

The PSE may allocate a new power value through the aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20) attribute in the oLldpXdot3LocSystemsGroup object class. The request appears to the PD as a change to the aLldpXdot3RemPSEAllocatedPowerValue (30.12.3.1.20) attribute in the oLldpXdot3RemSystemsGroup object class. The PD responds to a PSE's request through the aLldpXdot3LocPDRequestedPowerValue (30.12.2.1.17) attribute in the oLldpXdot3LocSystemsGroup object class. The PD also copies the value of the aLldpXdot3RemPSEAllocatedPowerValue (30.12.3.1.20) attribute in the oLldpXdot3RemSystemsGroup object class to the aLldpXdot3LocPSEAllocatedPowerValue (30.12.2.1.20) attribute in the oLldpXdot3LocSystemsGroup object class. This appears to the PSE as a change to the aLldpXdot3RemPDRequestedPowerValue (30.12.3.1.17) attribute in the oLldpXdot3RemSystemsGroup object class.

The state diagrams describe the behavior above.

33.6.4.1 PSE state change procedure across a link

A PSE is considered to be in sync with the PD when the value of PSEAllocatedPowerValue matches the value of MirroredPSEAllocatedPowerValueEcho. When the PSE is not in sync with the PD, the PSE is only allowed to decrease its power allocation.

During normal operation, the PSE is in the RUNNING state. If the PSE wants to initiate a change in the PD allocation, the local_system_change is asserted and the PSE enters the PSE POWER REVIEW state, where a new power allocation value, PSE_NEW_VALUE, is computed. If the PSE is in sync with the PD or if PSE_NEW_VALUE is smaller than PSEAllocatedPowerValue, it enters the MIRROR UPDATE state where PSE_NEW_VALUE is assigned to PSEAllocatedPowerValue. It also updates PDRequestedPowerValueEcho and returns to the RUNNING state.

If the PSE sees a change to the previously stored MirroredPDRequestedPowerValue, it recognizes a request by the PD to change its power allocation. It entertains this request only when it is in sync with the PD. The PSE examines the request by entering the PD POWER REQUEST state. A new power allocation value, PSE_NEW_VALUE, is computed. It then enters the MIRROR UPDATE state where PSE_NEW_VALUE is assigned to PSEAllocatedPowerValue. It also updates PDRequestedPowerValueEcho and returns to the RUNNING state.

33.6.4.2 PD state change procedure across a link

A PD is considered to be in sync with the PSE when the value of PDRequestedPowerValue matches the value of MirroredPDRequestedPowerValueEcho. The PD is not allowed to change its maximum power draw or the requested power value when it is not in sync with the PSE.

During normal operation, the PD is in the RUNNING state. If the PD sees a change to the previously stored MirroredPSEAllocatedPowerValue or local_system_change is asserted by the PD so as to change its power allocation, it enters the PD POWER REVIEW state. In this state, the PD evaluates the change and generates an updated power value called PD_NEW_VALUE. If PD_NEW_VALUE is less than PDMaxPowerValue, it updates PDMaxPowerValue in the PD POWER REALLOCATION 1 state. The PD finally enters the MIRROR UPDATE state where PD_NEW_VALUE is assigned to PDRequestedPowerValue. It also updates PSEAllocatedPowerValueEcho and returns to the RUNNING state.

In the above flow, if PD_NEW_VALUE is greater than PDMaxPowerValue, the PD waits until it is in sync with the PSE and the PSE grants the higher power value. When this condition arises, the PD enters the PD

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

POWER REALLOCATION 2 state. In this state, the PD assigns PDMaxPowerValue to PDRequestedPowerValue and returns to the RUNNING state.

33.7 Environmental

33.7.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2. The PSE shall be classified as a Limited Power Source in accordance with Annex Q of IEC 62368-1:2018, as applicable.

Equipment shall comply with all applicable local and national codes related to safety.

33.7.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns. The list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to verify compliance with the appropriate requirements. LAN cabling systems described in this clause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cabling and components.
c) High-energy transients coupled onto the LAN cabling system.
d) Voltage potential differences between safety grounds to which various LAN components are connected.

Such electrical safety hazards should be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures should be taken to verify that the intended safety features are not negated during installation of a new network or during modification of an existing network.

33.7.3 Installation and maintenance guidelines

It is a mandatory requirement that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

It is a mandatory requirement that, during installation of the cabling plant, care be taken to verify that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

33.7.4 Patch panel considerations

It is possible that the current carrying capability of a cabling cross-connect may be exceeded by a PSE. The designer should consult the manufacturers' specifications to verify compliance with the appropriate requirements.

33.7.5 Telephony voltages

The use of building wiring brings with it the possibility of wiring errors that may connect telephony voltages to a PSE or PD. Other than voice signals, the primary voltages that may be encountered are the "battery" and ringing voltages. Although there is no universal standard, the following maximums generally apply:

Battery voltage to a telephone line is generally 56 Vdc, applied to the line through a balanced 400 Ω source impedance. Ringing voltage is a composite signal consisting of an AC component and a DC component. The

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

AC component is up to 175 Vp at 20 Hz to 60 Hz with a 100 Ω source resistance. The DC component is 56 Vdc with 300 Ω to 600 Ω source resistance. Large reactive transients can occur at the start and end of each ring interval.

Application of any of the above voltages to the PI of a PSE or a PD shall not result in any safety hazard.

33.7.6 Electromagnetic emissions

The PD and PSE powered cabling link shall comply with applicable local and national codes for the limitation of electromagnetic interference.

33.7.7 Temperature and humidity

The PD and PSE powered cabling link segment is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling. Specific requirements and values for these parameters are beyond the scope of this standard.

33.7.8 Labeling

It is recommended that the PSE or PD (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) Power classification and power level in terms of maximum current drain over the operating voltage range, 36 V to 57 V, applies for PD only
b) Port type (e.g., 100BASE-TX, TIA Category, or ISO Class)
c) Any applicable safety warnings
d) “PSE” or “PD” as appropriate
e) Type (e.g., “Type 1” or “Type 2”)

33.8 Protocol implementation conformance statement (PICS) proforma for Clause 33, Power over Ethernet over 2 Pairs[73]

33.8.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 33, Power over Ethernet over 2 Pairs, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

33.8.2 Identification

33.8.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

33.8.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 33, Power over Ethernet over 2 Pairs
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[73] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Item	Feature	Subclause	Value/Comment	Status	Support
PSE8	Type 2 PSE powering a Type 1 PD	33.2.4.6	Meets the PI electrical requirements of a Type 1 PSE, but may choose to meet the electrical requirements of a Type 2 PSE for I_{Con}, I_{LIM}, T_{LIM}, and P_{Type}	PSET2: M	Yes [ ] N/A [ ]
PSE9	Applying power	33.2.5	Not until a PD requesting power has been successfully detected	M	Yes [ ]
PSE10	Power pairs	33.2.5	Power supplied on the same pairs as those used for detection	M	Yes [ ]
PSE11	Detecting PDs	33.2.5.1	Performed via the PSE PI	M	Yes [ ]
PSE12	PSE presents non-valid signature	33.2.5.1	As defined in Table 33–15	M	Yes [ ]
PSE13	Open circuit voltage and short circuit current	33.2.5.1	Meet specifications for V_{oc} and I_{sc} in Table 33–4	M	Yes [ ]
PSE14	Backdriven current	33.2.5.1	Not be damaged by up to 5 mA over the range of V_{Port_PSE}	M	Yes [ ]
PSE15	Output capacitance	33.2.5.1	C_{out} in Table 33–11	M	Yes [ ]
PSE16	Detection voltage with a valid PD signature connected	33.2.5.2	Meets V_{valid} in Table 33–4	M	Yes [ ]
PSE17	Detection voltage measurements	33.2.5.2	At least two that create at least ΔV_{test} difference	M	Yes [ ]
PSE18	Control slew rate when switching detection voltages	33.2.5.2	Less than V_{slew} in Table 33–4	M	Yes [ ]
PSE19	Accept as a valid signature	33.2.5.3	R_{good} and C_{good}, with up to V_{os} max and I_{os} max as defined in Table 33–5	M	Yes [ ]
PSE20	Reject as an invalid signature	33.2.5.4	Resistance less than R_{bad} min, resistance greater than R_{bad} max, or capacitance greater than C_{bad} min	M	Yes [ ]
PSE21	Classification permutations	33.2.6	Meet one allowable permutation in Table 33–8	M	Yes [ ]
PSE22	Type 1 PSE does not implement Physical Layer classification	33.2.6	Assign all PDs to Class 0	PSET1: M	Yes [ ] N/A [ ]
PSE23	Type 1 PSE failure to complete classification	33.2.6	Return to IDLE state or assign PD to Class 0	PSET1: M	Yes [ ] N/A [ ]
PSE24	Type 2 PSE failure to complete classification	33.2.6	Return to IDLE state	PSET2: M	Yes [ ] N/A [ ]
PSE25	Provide V_{Class} for 1-Event Physical Layer classification	33.2.6.1	Limited to I_{Class_LIM} as defined by Table 33–10	1EPLC: M	Yes [ ] N/A [ ]
PSE26	Classification polarity for 1-Event Physical Layer classification	33.2.6.1	Same as V_{Port_PSE}	1EPLC: M	Yes [ ] N/A [ ]
PSE27	Classification timing for 1-Event Physical Layer classification	33.2.6.1	In accordance with T_{pdc} in Table 33–10	1EPLC: M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PSE28	Measurement result of 1-Event Physical Layer classification I_{Class}	33.2.6.1	Classify PD according to observed current based on Table 33–9	1EPLC: M	Yes [ ] N/A [ ]
PSE29	Measurement timing of 1-Event Physical Layer classification I_{Class}	33.2.6.1	Measurement taken after the minimum relevant class event timing in Table 33–10	1EPLC: M	Yes [ ] N/A [ ]
PSE30	Class 4 result for 1-Event Physical Layer classification with a Type 1 PSE	33.2.6.1	Assign the PD to Class 0	PSET1: M	Yes [ ] N/A [ ]
PSE31	Type 1 PSE 1-Event Physical Layer classification if I_{Class} is in the range of I_{Class_LIM}	33.2.6.1	Return to IDLE state or assign PD to Class 0	PSET1: M	Yes [ ] N/A [ ]
PSE32	Type 2 PSE 1-Event Physical Layer classification if I_{Class} is in the range of I_{Class_LIM}	33.2.6.1	Return to IDLE state	PSET2: M	Yes [ ] N/A [ ]
PSE33	In the CLASS_EV1 and CLASS_EV2 states, provide V_{Class}	33.2.6.2	As defined in Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE34	Classification timing in CLASS_EV1 state	33.2.6.2	In accordance with T_{CLE1} in Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE35	In the CLASS_EV1 and CLASS_EV2 states, measurement result I_{Class}	33.2.6.2	Classify PD according to Table 33–9	2EPLC: M	Yes [ ] N/A [ ]
PSE36	In the MARK_EV1 and MARK_EV2 states, provide V_{Mark}	33.2.6.2	In accordance with Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE37	Classification timing in MARK_EV1	33.2.6.2	In accordance with T_{ME1} in Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE38	Classification timing in CLASS_EV2 state	33.2.6.2	In accordance with T_{CLE2} in Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE39	Classification timing in MARK_EV2 state	33.2.6.2	In accordance with T_{ME2} in Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE40	Type 2 PSE 2-Event Physical Layer classification if I_{Class} is greater than or equal to I_{Class_LIM} min	33.2.6.2	Returns to IDLE state	2EPLC: M	Yes [ ] N/A [ ]
PSE41	Current limitation during class events	33.2.6.2	Meet I_{Class_LIM}	2EPLC: M	Yes [ ] N/A [ ]
PSE42	Current limitation during mark events	33.2.6.2	Meet I_{Mark_LIM}	2EPLC: M	Yes [ ] N/A [ ]
PSE43	Measurement timing of 2-Event Physical Layer classification I_{Class}	33.2.6.2	Taken after the minimum relevant class event timing in Table 33–10	2EPLC: M	Yes [ ] N/A [ ]
PSE44	Class event and mark event voltages polarity	33.2.6.2	Same as V_{Port_PSE}	2EPLC: M	Yes [ ] N/A [ ]
PSE45	Voltage level at PI when transition to POWER_ON state	33.2.6.2	Completes 2-Event classification and transitions to POWER_ON with PI voltage greater than or equal to V_{Mark} min	2EPLC: M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PSE46	Return to IDLE state	33.2.6.2	Maintains PI voltage at V_{Reset} for at least T_{Reset} min before starting new detection cycle	2EPLC: M	Yes [ ] N/A [ ]
PSE47	Power supply output	33.2.7	When the PSE provides power to the PI, conforms with Table 33–11	M	Yes [ ]
PSE48	Load regulation	33.2.7.1	Met with (I_{Hold} max × V_{Port_PSE} min) to P_{Type} min load step at a rate of change of up to 15 mA/µs max	M	Yes [ ]
PSE49	Voltage transients	33.2.7.1	Limited to 3.5 V/µs max for load changes up to 35 mA/µs	M	Yes [ ]
PSE50	Voltage transients (30 µs to 250 µs)	33.2.7.2	No less than K_{Tran_lo} below V_{Port_PSE} min and meet requirements of 33.2.7.7.	PSET2: M	Yes [ ]
PSE51	Voltage transients (greater than 250 µs)	33.2.7.2	Meet V_{Port_PSE} specification	M	Yes [ ]
PSE52	Power feeding ripple and noise	33.2.7.3	Met for common-mode and/or pair-to-pair noise values for power outputs from (I_{Hold} max × V_{Port_PSE} min) to P_{Type} min at static operating V_{Port_PSE}	M	Yes [ ]
PSE53	AC current waveform parameters	33.2.7.4	I_{Peak} minimum equals Equation (33–4) for T_{CUT} minimum and 5% duty cycle minimum.	M	Yes [ ]
PSE54	Inrush current limit	33.2.7.5	PSE limits the maximum current sourced at the PI	M	Yes [ ]
PSE55	Inrush current template	33.2.7.5	Current sourced does not exceed the PSE inrush template in Figure 33–13	M	Yes [ ]
PSE56	Short circuit condition	33.2.7.7	Remove power from PI before I_{PSEUT} is exceeded. Equation (33–6) and Figure 33–14.	M	Yes [ ]
PSE57	Short circuit current and time	33.2.7.7	In accordance with I_{LIM} and T_{LIM} in Table 33–11	M	Yes [ ]
PSE58	Short circuit power removal	33.2.7.7	Begins within T_{LIM} in Table 33–11	M	Yes [ ]
PSE59	Turn off time	33.2.7.8	Applies to the discharge time from V_{Port_PSE} to V_{Off} with a test resistor of 320 kΩ attached to the PI.	M	Yes [ ]
PSE60	Turn off voltage	33.2.7.9	Applies to the PI voltage in the IDLE state	M	Yes [ ]
PSE61	Current unbalance	33.2.7.11	Applies to the two conductors of a power pair over the current load range in accordance with I_{unb} in Table 33–11.	M	Yes [ ]
PSE62	Type 2 PSEs in the presence of (I_{unb} / 2)	33.2.7.11	Meet the requirements of 25.4.5	PSET2: M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PSE63	Power allocation	33.2.8	Not be based solely on historical data of power consumption of the attached PD	PA:M	Yes [ ] N/A [ ]
PSE64	PSE monitoring AC MPS component	33.2.9.1.1	Meets “AC Signal parameters” and “PSE PI voltage during AC disconnect detection” parameters in Table 33–12	AC:M	Yes [ ] N/A [ ]
PSE65	PSE AC MPS component present	33.2.9.1.1	When AC impedance at the PI is equal to or lower than $\|Z_{ac1}\|$ in Table 33–12	AC:M	Yes [ ] N/A [ ]
PSE66	PSE AC MPS component absent	33.2.9.1.1	When AC impedance at the PI equal to or greater than $\|Z_{ac2}\|$ in Table 33–12	AC:M	Yes [ ] N/A [ ]
PSE67	Power removal	33.2.9.1.1	When AC MPS has been absent for a time duration greater than T_{MPDO}	AC:M	Yes [ ] N/A [ ]
PSE68	PSE DC MPS component present	33.2.9.1.2	I_{Port} is greater than or equal to I_{Hold} max for at least T_{MPS} min as specified in Table 33–11	DC:M	Yes [ ] N/A [ ]
PSE69	PSE DC MPS component absent	33.2.9.1.2	I_{Port} is less than or equal to I_{Hold} min as specified in Table 33–11	DC:M	Yes [ ] N/A [ ]
PSE70	Power removal	33.2.9.1.2	When DC MPS has been absent for a time duration greater than T_{MPDO}	DC:M	Yes [ ] N/A [ ]
PSE71	T_{MPS} and T_{MPDO} values	33.2.9.1.2	Meet Equation (33–8)	DC:M	Yes [ ] N/A [ ]
PSE72	Not remove power	33.2.9.1.2	When less than T_{MPDO} has passed since MPS was last present	DC:M	Yes [ ] N/A [ ]

33.8.3.3 Powered devices

Item	Feature	Subclause	Value/Comment	Status	Support
PD1	Accept power	33.3.1	On either set of PI conductors	M	Yes [ ]
PD2	Polarity insensitive	33.3.1	Both Mode A and Mode B per Table 33–13	M	Yes [ ]
PD3	Source power	33.3.1	The PD does not source power on its PI	M	Yes [ ]
PD4	Voltage tolerance	33.3.1	Withstand 0 V to 57 V at the PI indefinitely without permanent damage	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD5	Underpowered Type 2 PD	33.3.2	If PD does not successfully observe 2-Event Physical Layer classification or Data Link Layer classification, conforms to Type 1 PD power restrictions and provides the user with an active indication if underpowered	PDT2:M	Yes [ ] N/A [ ]
PD6	Current unbalance	33.3.2	Type 2 PDs meet the requirements of 25.4.5 in presence of (I_{unb}/2)	PDT2:M	Yes [ ] N/A [ ]
PD7	PD behavior	33.3.3	According to state diagram shown in Figure 33–16	M	Yes [ ]
PD8	Valid and non-valid detection signatures	33.3.4	Presented between positive V_{PD} and negative V_{PD} on each set of pairs defined in 33.3.1	M	Yes [ ]
PD9	Non-valid detection signature	33.3.4	When powered, present an invalid signature on the set of pairs not drawing power	M	Yes [ ]
PD10	Valid detection signature	33.3.4	Characteristics defined in Table 33–14	M	Yes [ ]
PD11	Non-valid detection signature	33.3.4	Exhibit one or both of the characteristics described in Table 33–15	M	Yes [ ]
PD12	PD classifications	33.3.5	Meets at least one permutation listed in Table 33–8	PDCL:M	Yes [ ]
PD13	PD implementing 2-Event class signature	33.3.5.1	Returns Class 4	PDCL2:M	Yes [ ] N/A [ ]
PD14	Type 2 PD classification behavior	33.3.5.1	Conforms to electrical specifications in Table 33–17	PDT2:M	Yes [ ] N/A [ ]
PD15	Classification signature	33.3.5.1	As defined in Table 33–16	PDCL:M	Yes [ ] N/A [ ]
PD16	Classification signature	33.3.5.1	One classification signature during classification	PDCL:M	Yes [ ] N/A [ ]
PD17	2-Event class signature	33.3.5.2	Class 4 in accordance with the maximum power draw as specified in Table 33–18	PDCL2:M	Yes [ ] N/A [ ]
PD18	2-Event class signature behavior	33.3.5.2	As defined in Table 33–17	PDCL2:M	Yes [ ] N/A [ ]
PD19	Type 2 PD electrical requirements	33.3.5.2	As defined by Table 33–18 of the Type defined in its pse_power_type state variable	PDT2:M	Yes [ ] N/A [ ]
PD20	Mark event current and 2-Event class signature	33.3.5.2.1	Draw I_{Mark} and present a non-valid detection signature as defined in Table 33–15	PDCL2:M	Yes [ ] N/A [ ]
PD21	Mark event current limits	33.3.5.2.1	Not exceed I_{Mark} when voltage at the PI enters V_{Mark} as defined in Table 33–17	PDCL2:M	Yes [ ] N/A [ ]
PD22	PD current draw	33.3.5.2.1	I_{Mark} until the PD transitions from DO_MARK_EVENT state to the IDLE state	PDCL2:M	Yes [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD23	PSE identification	33.3.6	Identify as Type 1 or Type 2 (see Figure 33–16)	PDT2:M	Yes [ ]
PD24	PD power supply	33.3.7	Operate within the characteristics in Table 33–18	M	Yes [ ]
PD25	PD turn on voltage	33.3.7.1	PD turns on at a voltage less than or equal to V_{On}	M	Yes [ ]
PD26	PD stay on voltage	33.3.7.1	Stay on for all voltages in the range of V_{Port_PD}	M	Yes [ ]
PD27	PD turn off voltage	33.3.7.1	Turn off at a voltage less than V_{Port_PD} min and greater than V_{Off}	M	Yes [ ]
PD28	Startup oscillations	33.3.7.1	Shall turn on or off without startup oscillations and within the first trial at any load value	M	Yes [ ]
PD29	P_{Port_PD} definition	33.3.7.2.1	When PD is fed by V_{Port_PD} min to V_{Port_PD} max with R_{Ch} (as defined in Table 33–1) in series	M	Yes [ ]
PD30	PD input inrush current	33.3.7.3	Draw less than I_{Inrush_PD} from T_{Inrush} min until T_{delay}	M	Yes [ ]
PD31	Power limits when pse_power_type = 1	33.3.7.3	Conform to P_{Class_PD} and P_{Peak_PD} within T_{Inrush} min	M	Yes [ ]
PD32	Power limits when pse_power_type = 2	33.3.7.3	Conform to Class 3 P_{Peak_PD} from T_{Inrush} min until T_{delay}	PDT2:M	Yes [ ] N/A [ ]
PD33	Peak power	33.3.7.4	Not to exceed P_{Class_PD} max for more than T_{CUT} min and 5% duty cycle	M	Yes [ ]
PD34	Peak operating power	33.3.7.4	Not to exceed P_{Peak_PD} max	M	Yes [ ]
PD35	RMS, DC, and ripple current	33.3.7.4	Bounded by Equation (33–11)	M	Yes [ ]
PD36	Maximum I_{Port} for all operating V_{Port_PD}	33.3.7.4	Defined by Equation (33–12)	M	Yes [ ]
PD37	Peak transient current	33.3.7.5	Not to exceed 4.70 mA/µs in either polarity	M	Yes [ ]
PD38	Specifications for I_{PDUT}	33.3.7.5	Operate below upperbound template defined in Figure 33–18	M	Yes [ ]
PD39	Behavior during transients at the PSE PI	33.3.7.6	As specified in 33.3.7.6	M	Yes [ ]
PD40	Ripple and noise	33.3.7.7	As specified in Table 33–18 for the common-mode and/or differential pair-to-pair noise at the PD PI	M	Yes [ ]
PD41	Ripple and noise specification	33.3.7.7	For all operating voltages in the range defined by V_{Port_PD} in Table 33–18	M	Yes [ ]
PD42	Ripple and noise presence	33.3.7.7	Operates in the presence of ripple and noise generated by the PSE that appears at the PD PI	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PD43	Classification stability	33.3.7.8	Class signature valid within T_{class} and remains valid for the duration of the classification period	M	Yes [ ]
PD44	Backfeed voltage for Mode A	33.3.7.9	As specified in 33.3.7.9	M	Yes [ ]
PD45	Backfeed voltage for Mode B	33.3.7.9	As specified in 33.3.7.9	M	Yes [ ]
PD46	Maintain power signature	33.3.8	PD provides a valid MPS at the PI as defined in 33.3.8	M	Yes [ ]
PD47	No longer require power	33.3.8	Remove both components of the Maintain Power Signature	M	Yes [ ]

33.8.3.4 Electrical specifications applicable to the PSE and PD

Item	Feature	Subclause	Value/Comment	Status	Support
EL1	Conductor isolation	33.4.1	Conforms to J.1 with electrical strength test c) details as specified in 33.4.1	M	Yes [ ]
EL2	Isolation and grounding requirements	33.4.1	Conductive link segments that have different requirements have those requirements provided by the port-to-port isolation of the NID	M	Yes [ ]
EL3	Environment A requirements for multiple instances of PSE and/or PD	33.4.1.1.1	Meet or exceed the isolation requirement of the MAU/PHY with which they are associated	!MID:M	Yes [ ] N/A [ ]
EL4	Environment A requirement	33.4.1.1.1	Switch more negative conductor	M	Yes [ ] N/A [ ]
EL5	Environment B requirements for multiple instances of PSE and/or PD	33.4.1.1.2	Meet or exceed the isolation requirement of the MAU/PHY with which they are associated	!MID:M	Yes [ ] N/A [ ]
EL6	Fault tolerance for PIs encompassed within the MDI	33.4.2	Meet requirements of the appropriate specifying clause	!MID:M	Yes [ ] N/A [ ]
EL7	Fault tolerance for PSE PIs not encompassed within an MDI	33.4.2	Meet the requirements of 33.4.2	M	Yes [ ] N/A [ ]
EL8	Common-mode fault tolerance	33.4.2	Each wire pair withstands without damage a 1000 V common-mode impulse applied at E_{cm} of either polarity	M	Yes [ ]
EL9	The shape of the impulse for item common-mode fault tolerance	33.4.2	0.3/50 µs (300 ns virtual front time, 50 µs virtual time of half value)	M	Yes [ ]
EL10	Common-mode to differential-mode impedance balance for transmit and receive pairs	33.4.3	Exceeds value in Table 33–20 for all supported PHY speeds	M	Yes [ ]
EL11	Common-mode AC output voltage	33.4.4	Not to exceed the values in Table 33–21	M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
EL12	Common-mode AC output voltage measurement	33.4.4	While the PHY is transmitting data, the PSE or PD is operating, and with the enumerated PSE load or PD source	M	Yes [ ]
EL13	Noise from an operating PSE or PD to the differential transmit and receive pairs	33.4.6	Does not exceed 10 mV peak-to-peak measured from 1 MHz to 100 MHz under the conditions specified in 33.4.4	M	Yes [ ]
EL14	Coupled noise E_{d_out}	33.4.6	Not to exceed 10 mV peak-to-peak in the band from 1 MHz to 10 MHz	M	Yes [ ]
EL15	Coupled noise E_{d_out}	33.4.6	Not to exceed 10 mV peak-to-peak in the band from 10 MHz to 100 MHz (for 2.5GBASE-T), 10 MHz to 250 MHz (for 5GBASE-T), and 10 MHz to 500 MHz (for 10GBASE-T) under the conditions specified in 33.4.4.	M	Yes [ ]
EL16	Return loss requirements	33.4.7	Specified in 14.3.1.3.4 for a 10 Mb/s PHY, in ANSI INCITS 263-1995 for a 100 Mb/s PHY, and 40.8.3.1 for a 1000 Mb/s PHY	M	Yes [ ]
EL17	100BASE-TX Type 2 Endpoint PSE and PD channel unbalance	33.4.8	Meet requirements of Clause 25 in the presence of (I_{unb}/2)	M	Yes [ ] N/A [ ]

33.8.3.5 Electrical specifications applicable to the PSE

Item	Feature	Subclause	Value/Comment	Status	Support
PSEEL1	Short circuit fault tolerance	33.4.2	Any wire pair withstands any short circuit to any other pair for an indefinite amount of time	M	Yes [ ]
PSEEL2	Magnitude of short circuit current	33.4.2	Does not exceed I_{LIM} max	M	Yes [ ]
PSEEL3	Limitation of electromagnetic interference.	33.4.5	PSE complies with applicable local and national codes	M	Yes [ ]
PSEEL4	Alternative A Type 2 Midspan PSEs that support 100BASE-TX	33.4.8	Enforce channel unbalance currents less than or equal to Type 1 Iunb (see Table 33–11) or meet 33.4.9.4.	MIDA: M	Yes [ ] N/A [ ]
PSEEL5	Insertion of Midspan at FD	33.4.9	Comply with the guidelines specified in 33.4.9 items a) and b)	MID:M	Yes [ ] N/A [ ]
PSEEL6	Resulting “channel”	33.4.9	Installation of a Midspan PSE does not increase the length to more than 100 m as defined in ISO/IEC 11801.	MID:M	Yes [ ] N/A [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
PSEEL7	Configurations with Midspan PSE	33.4.9	Not alter transmission requirements of the "permanent link"	MID:M	Yes [ ] N/A [ ]
PSEEL8	DC continuity in power injecting pairs	33.4.9	Does not provide DC continuity between the two sides of the segment for the pairs that inject power	MID:M	Yes [ ] N/A [ ]
PSEEL9	Midspan PSE inserted as a connection or telecommunications outlet	33.4.9.1	Meet transmission parameters NEXT, insertion loss, and return loss	MID:M	Yes [ ] N/A [ ]
PSEEL10	Midspan PSE NEXT	33.4.9.1.1	Meet values detemined by Equation (33–17) from 1 MHz to 100 MHz, but not greater than 65 dB	MID:M	Yes [ ] N/A [ ]
PSEEL11	Midspan PSE Insertion Loss	33.4.9.1.2	Meet values determined by Equation (33–20) from 1 MHz to 100 MHz, but not less than 0.1 dB	MID:M	Yes [ ] N/A [ ]
PSEEL12	Midspan PSE Return Loss	33.4.9.1.3	Meet or exceed values in Table 33–22 for transmit and receive pairs from 1 MHz to 100 MHz	MID:M	Yes [ ] N/A [ ]
PSEEL13	Work area or equipment cable Midspan PSE	33.4.9.2	Meet the requirements of this clause and the specifications for a Category 5 (jumper) cord as specified in ISO/IEC 11801-2002 or ANSI/TIA-568-C.2 for insertion loss, NEXT, and return loss for transmit and receive pairs	MID:M	Yes [ ] N/A [ ]
PSEEL14	Alternative A Midspan PSE signal path requirements	33.4.9.4	Exceed transfer function gain expressed in Equation (33–23) from 0.10 MHz to 1 MHz at the pins of the PI used as 100BASE-TX transmit pins	MIDA: M	Yes [ ] N/A [ ]
PSEEL15	Alternative A Midspan PSE signal path requirements bias current	33.4.9.4	Met with DC bias current between 0 mA and (I_{unb}/2)	MIDA: M	Yes [ ] N/A [ ]

33.8.3.6 Electrical specifications applicable to the PD

Item	Feature	Subclause	Value/Comment	Status	Support
PDEL1	PD common-mode test requirement	33.4.4	The PIs that require power terminated as illustrated in Figure 33–22	M	Yes [ ]

33.8.3.7 Management function requirements

Item	Feature	Subclause	Value/Comment	Status	Support
MF1	Management capability	33.5	Access to register definitions defined in 33.5.1 via interface described in 22.2.4 or 45.2 or equivalent.	MAN:M	Yes [ ] N/A [ ]
MF2	PSE registers	33.5.1	Register address 11 for control functions and register address 12 for status functions.	MAN:M	Yes [ ] N/A [ ]
MF3	Register bits latching high (LH)	33.5.1	Remain high until read via the management interface.	MAN:M	Yes [ ] N/A [ ]
MF4	Latching register bit after read	33.5.1	Assumes a value based on the current state of the condition it monitors.	MAN:M	Yes [ ] N/A [ ]
MF5	PSE Control register reserved bits (11.15:6)	33.5.1.1.1	Not affected by writes and return a value of zero when read.	MAN:M	Yes [ ] N/A [ ]
MF6	Data Link Layer classification not supported	33.5.1.1.2	Ignore writes to bit 11.5 and return a value of zero when read.	MAN* !DLLC: M	Yes [ ] N/A [ ]
MF7	Data Link Layer classification supported	33.5.1.1.2	Ignore writes to bit 11.5 and return a value of one when function cannot be disabled.	MAN* DLLC: M	Yes [ ] N/A [ ]
MF8	Enable/disable Data Link Layer classification capability	33.5.1.1.2	Capability enabled by setting bit 11.5 to one and disabled by setting bit 11.5 to zero.	MAN* DLLC: M	Yes [ ] N/A [ ]
MF9	Physical Layer classification not supported	33.5.1.1.3	Ignore writes to bit 11.4 and return a value of zero when read.	MAN* !CL:M	Yes [ ] N/A [ ]
MF10	Physical Layer classification supported	33.5.1.1.3	Ignore writes to bit 11.4 and return a value of one when function cannot be disabled.	MAN* CL:M	Yes [ ] N/A [ ]
MF11	Enable/disable Physical Layer classification	33.5.1.1.3	Function enabled by setting bit 11.4 to one and disabled by setting bit 11.5 to zero.	MAN* CL:M	Yes [ ] N/A [ ]
MF12	Pair Control Ability not supported	33.5.1.1.4	Ignore writes to bits 11.3:2.	MAN* !PCA:M	Yes [ ] N/A [ ]
MF13	Writes to 11.3:2 when Pair Control Ability not supported	33.5.1.1.4	Return the value that reports the supported PSE Pinout Alternative.	MAN* !PCA:M	Yes [ ] N/A [ ]
MF14	Bits 11.3:2 set to '01'	33.5.1.1.4	Forces the PSE to use Alternative A.	MAN* PCA:M	Yes [ ] N/A [ ]
MF15	Bits 11.3:2 set to '10'	33.5.1.1.4	Forces the PSE to use Alternative B.	MAN* PCA:M	Yes [ ] N/A [ ]
MF16	Pair control ability bit (12.0)	33.5.1.1.4	A value of one sets the mr_pse_alternative variable.	MAN* PCA:M	Yes [ ] N/A [ ]
MF17	PSE function disabled	33.5.1.1.5	Setting PSE Enable bits 11.1:0 to a ‘00’, also the MDI shall function as it would if it had no PSE function.	MAN:M	Yes [ ] N/A [ ]

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
MF18	PSE function enabled	33.5.1.1.5	Setting PSE Enable bits 11.1:0 to a '01'.	MAN:M	Yes [ ] N/A [ ]
MF19	PSE enable bits (11.1:0)	33.5.1.1.5	Writing to these register bits shall set mr_pse_enable to the corresponding value: '00' = disable, '01' = enable and '10' = force power.	MAN:M	Yes [ ] N/A [ ]
MF20	PSE Type electrical parameters bit (12.15)	33.5.1.2.1	Set to zero when the PSE state diagram sets the state variable set_parameter_type to 1. Set to one when set_parameter_type is set to 2.	MAN:M	Yes [ ] N/A [ ]
MF21	Data Link Layer classification enabled bit (12.14)	33.5.1.2.2	Set to one when the PSE state diagram sets true pse_dll_enabled. Set to zero when the PSE state diagram sets false pss_dll_enabled.	MAN:M	Yes [ ] N/A [ ]
MF22	Power denied bit (12.12)	33.5.1.2.4	A value of one indicates power has been denied or removed due to an error condition.	MAN:M	Yes [ ] N/A [ ]
MF23	Power denied bit implementation	33.5.1.2.4	Implemented with a latching high behavior as defined in 33.5.1.	MAN:M	Yes [ ] N/A [ ]
MF24	Valid signature bit (12.11)	33.5.1.2.5	One indicates a valid signature has been detected. Set to one when mr_valid_signature transitions from FALSE to TRUE.	MAN:M	Yes [ ] N/A [ ]
MF25	Valid signature bit implementation	33.5.1.2.5	Implemented with a latching high behavior as defined in 33.5.1.	MAN:M	Yes [ ] N/A [ ]
MF26	Invalid signature bit (12.10)	33.5.1.2.6	One indicates an invalid signature has been detected. Set to one entering SIGNATURE_INVALID state.	MAN:M	Yes [ ] N/A [ ]
MF27	Invalid signature bit implementation	33.5.1.2.6	Implemented with a latching high behavior as defined in 33.5.1.	MAN:M	Yes [ ] N/A [ ]
MF28	Short circuit bit (12.9)	33.5.1.2.7	Bit indicates a short circuit condition has been detected. Set to one entering ERROR_DELAY state due to the short_detected variable being TRUE.	MAN:M	Yes [ ] N/A [ ]
MF29	Short circuit bit implementation	33.5.1.2.7	Implemented with a latching high behavior as defined in 33.5.1.	MAN:M	Yes [ ] N/A [ ]
MF30	Overload bit (12.8)	33.5.1.2.8	Bit indicates an overload condition has been detected. Set to one when entering the ERROR_DELAY state due to the ovld_detected variable being TRUE.	MAN:M	Yes [ ] N/A [ ]

34. Introduction to 1000 Mb/s baseband networks

34.1 Overview

Gigabit Ethernet couples an extended version of Ethernet to a family of 1000 Mb/s Physical Layers. The relationships among Gigabit Ethernet, the extended Ethernet, and the ISO/IEC Open System Interconnection (OSI) reference model are shown in Figure 34–1.

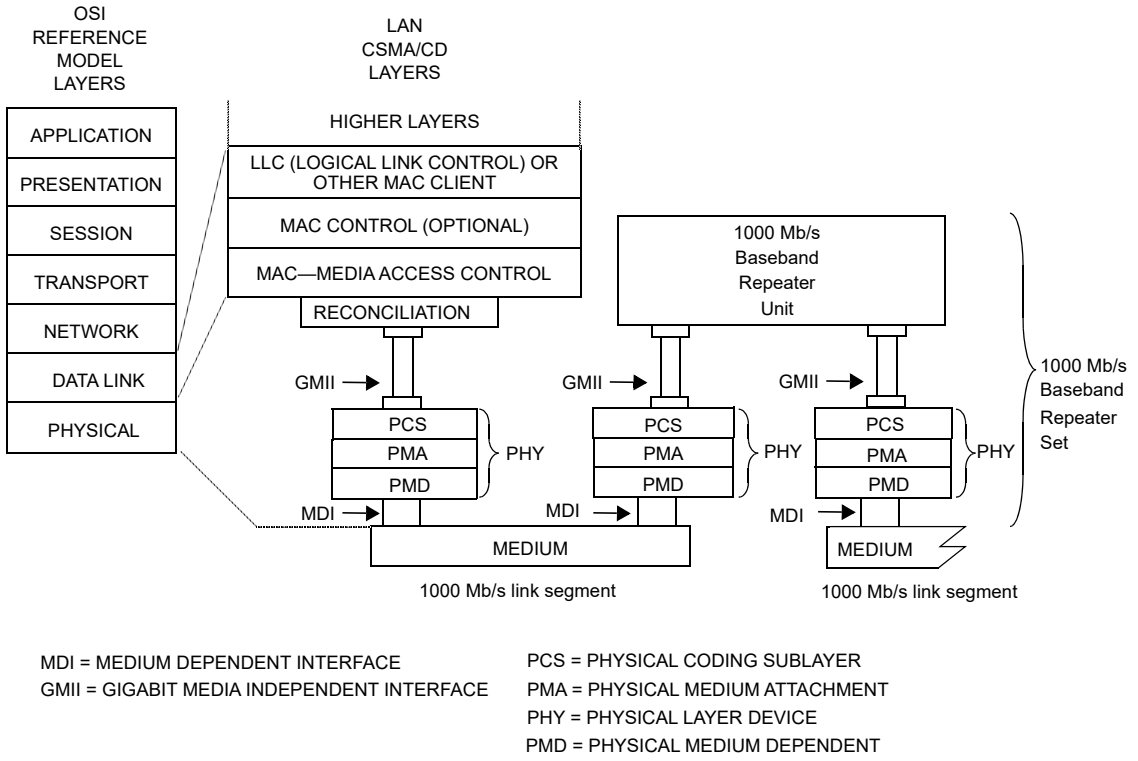

Figure 34–1—Architectural positioning of Gigabit Ethernet (1000 Mb/s operation)

The Gigabit Ethernet MAC layer interface connects through a Gigabit Media Independent Interface layer to Physical Layer entities (PHY sublayers). The set of PHY sublayer specifications include operation over multiple media (e.g., copper cables, fiber optic cables and backplanes).

Gigabit Ethernet extends the Ethernet MAC beyond 100 Mb/s to 1000 Mb/s. The bit rate is faster, and the bit times are shorter—both in proportion to the change in bandwidth. In full duplex mode, the minimum packet transmission time has been reduced by a factor of ten. Achievable topologies for 1000 Mb/s full duplex operation are comparable to those found in 100BASE-T full duplex mode. In half duplex mode, the minimum packet transmission time has been reduced, but not by a factor of ten. Cable delay budgets are similar to those in 100BASE-T. The resulting achievable topologies for the half duplex 1000 Mb/s CSMA/CD MAC are similar to those found in half duplex 100BASE-T.

34.1.1 Reconciliation Sublayer (RS) and Gigabit Media Independent Interface (GMII)

The Gigabit Media Independent Interface (Clause 35) provides an interconnection between the Media Access Control (MAC) sublayer and Physical Layer device (PHY) and between PHY Layer and Station

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Management (STA) entities. This GMII supports 1000 Mb/s operation through its eight bit wide (octet wide) transmit and receive paths. The Reconciliation sublayer provides a mapping between the signals provided at the GMII and the MAC/PLS service definition.

34.1.2 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. The generic term 1000 Mb/s MAC refers to any use of the 1000 Mb/s IEEE 802.3 MAC (the Gigabit Ethernet MAC) coupled with any Physical Layer implementation.

Various clauses of this standard comprise a family of Physical Layer implementations for operation at 1000 Mb/s. Each PHY type includes specifications for encoding and decoding of information, and how those encoded data are transmitted on the supported transmission medium or media. These PHY types may share some PHY sublayer components and signaling methods, or may use signaling methods specific to the supported media and applications.

34.1.3 Repeater

A repeater set (Clause 41) is an integral part of any half duplex Gigabit Ethernet network with more than two DTEs in a collision domain. A repeater set extends the physical system topology by coupling two or more segments. Only one repeater is permitted within a single collision domain. Some Gigabit Ethernet PHY types only support full duplex operation. Topologies composed of full duplex only devices do not allow repeaters.

34.1.4 Auto-Negotiation, type 1000BASE-X

Auto-Negotiation (Clause 37) provides a 1000BASE-X device with the capability to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for joint operation. Auto-Negotiation is performed upon link startup through the use of a special sequence of link codewords. Clause 37 adopts the basic architecture and algorithms from Clause 28, but not the use of fast link pulses. Auto-Negotiation for 1000BASE-KX is defined in Clause 73.

34.1.5 Auto-Negotiation, type 1000BASE-T

Auto-Negotiation (Clause 28) is used by 1000BASE-T devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for joint operation. Auto-Negotiation is performed upon link startup through the use of a special sequence of fast link pulses.

34.1.6 Auto-Negotiation, type 1000BASE-T1

Auto-Negotiation (Clause 98) may be used by 1000BASE-T1 devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for joint operation. Auto-Negotiation is performed upon link startup through the use of half-duplex differential Manchester encoding.

The use of Clause 98 Auto-Negotiation is optional for a 1000BASE-T1 PHY.

34.1.7 Management

Managed objects, attributes, and actions are defined for all Gigabit Ethernet components (Clause 30).

34.2 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

34.3 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE 802.3, Clause 35 through Clause 41, shall complete a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the Gigabit Ethernet PICS conforms to the same notation and conventions used in 100BASE-T (see 21.6).

35. Reconciliation Sublayer (RS) and Gigabit Media Independent Interface (GMII)

35.1 Overview

This clause defines the logical and electrical characteristics for the Reconciliation Sublayer (RS) and Gigabit Media Independent Interface (GMII) between CSMA/CD media access controllers and various PHYs. Figure 35–1 shows the relationship of the Reconciliation sublayer and GMII to the ISO/IEC OSI reference model.

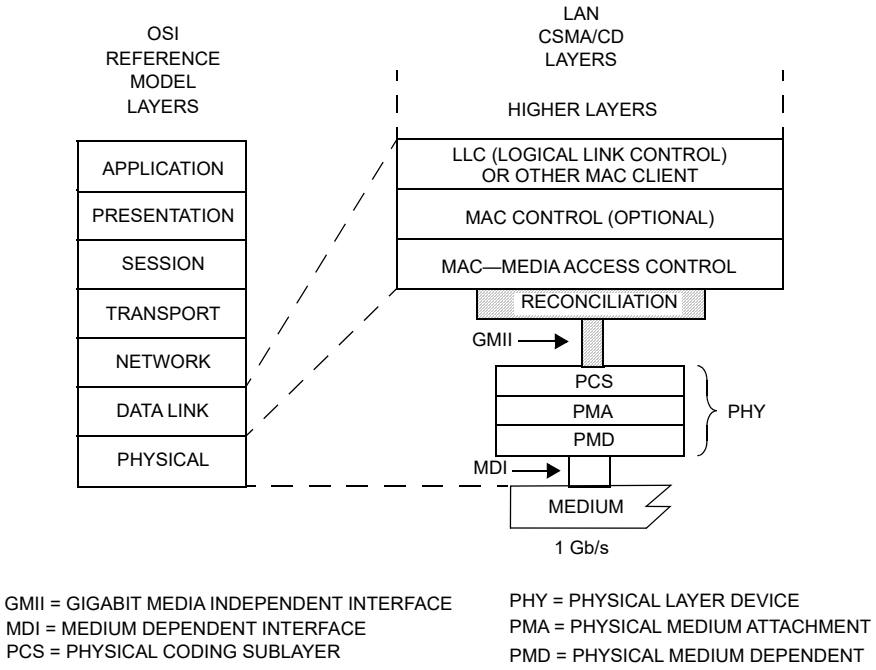

Figure 35–1—GMII relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 CSMA/CD LAN model

The purpose of this interface is to provide a simple, inexpensive, and easy-to-implement interconnection between Media Access Control (MAC) sublayer and PHYs, and between PHYs and Station Management (STA) entities.

This interface has the following characteristics:

a) It is capable of supporting 1000 Mb/s operation.
b) Data and delimiters are synchronous to clock references.
c) It provides independent eight-bit-wide transmit and receive data paths.
d) It provides a simple management interface.
e) It uses signal levels, compatible with common CMOS digital ASIC processes and some bipolar processes.
f) It provides for full duplex operation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

35.1.1 Summary of major concepts

a) The GMII is based on the MII defined in Clause 22.
b) Each direction of data transfer is serviced by Data (an eight-bit bundle), Delimiter, Error, and Clock signals.
c) Two media status signals are provided. One indicates the presence of carrier, and the other indicates the occurrence of a collision.
d) The GMII uses the MII management interface composed of two signals that provide access to management parameters and services as specified in Clause 22.
e) MII signal names have been retained and the functions of most signals are the same, but additional valid combinations of signals have been defined for 1000 Mb/s operation.
f) The Reconciliation sublayer maps the signal set provided at the GMII to the PLS service primitives provided to the MAC.
g) GMII signals are defined such that an implementation may multiplex most GMII signals with the similar PMA service interface defined in Clause 36 and Clause 97.
h) The GMII may also support Low Power Idle (LPI) signaling as defined for Energy-Efficient Ethernet in Clause 78 for certain PHY types.

35.1.2 Application

This clause applies to the interface between the MAC and PHYs, and between PHYs and Station Management entities. The implementation of the interface is primarily intended as a chip-to-chip (integrated circuit to integrated circuit) interface implemented with traces on a printed circuit board. A motherboard-to-daughterboard interface between two or more printed circuit boards is not precluded. The use of parts of the GMII (e.g., data paths, but not the Clause 22 management interface or associated management registers), and the use of the GMII as an interface between logic modules on the same chip is not precluded.

This interface is used to provide media independence so that an identical media access controller may be used with any of the copper and optical PHY types.

35.1.3 Rate of operation

The GMII supports only 1000 Mb/s operation and is defined within this clause. Operation at 10 Mb/s and 100 Mb/s is supported by the MII defined in Clause 22.

PHYs that provide a GMII shall support 1000 Mb/s operation, and may support additional rates using other interfaces (e.g., MII). PHYs have to report the rates at which they are capable of operating via the management interface. Reconciliation sublayers that provide a GMII shall support 1000 Mb/s and may support additional rates using other interfaces.

35.1.4 Allocation of functions

The allocation of functions at the GMII balances the need for media independence with the need for a simple and cost-effective interface.

While the Attachment Unit Interface (AUI) was defined to exist between the Physical Signaling (PLS) and Physical Medium Attachment (PMA) sublayers for 10 Mb/s DTEs, the GMII (like the Clause 22 MII) maximizes media independence by cleanly separating the Data Link and Physical Layers of the ISO/IEC seven-layer reference model. This allocation also recognizes that implementations can benefit from a close coupling between the PLS or PCS sublayer and the PMA sublayer.

35.2 Functional specifications

The GMII is designed to make the differences among the various media transparent to the MAC sublayer. The selection of logical control signals and the functional procedures are all designed to this end.

35.2.1 Mapping of GMII signals to PLS service primitives and Station Management

The Reconciliation sublayer maps the signals provided at the GMII to the PLS service primitives defined in Clause 6. The PLS service primitives provided by the Reconciliation sublayer, and described here, behave in exactly the same manner as defined in Clause 6. The mapping is changed for EEE capability (see 78.3), as described in 35.4.

An LPI_IDLE.request primitive with value ASSERT shall not be generated unless the attached link is operational (i.e., link_status = OK, according to the underlying PCS/PMA). The PHY shall not cause an LP_IDLE.request primitive with value ASSERT to be generated for at least one second following a link_status change to OK (see 78.1.2.1.2).

EEE capability requires the use of the MAC defined in Annex 4A for simplified full duplex operation (with carrier sense deferral). This provides full duplex operation but uses the carrier sense signal to defer transmission when the PHY is in its low power state.

Figure 35–2 depicts a schematic view of the Reconciliation sublayer inputs and outputs, and demonstrates that the GMII management interface is controlled by the Station Management entity (STA).

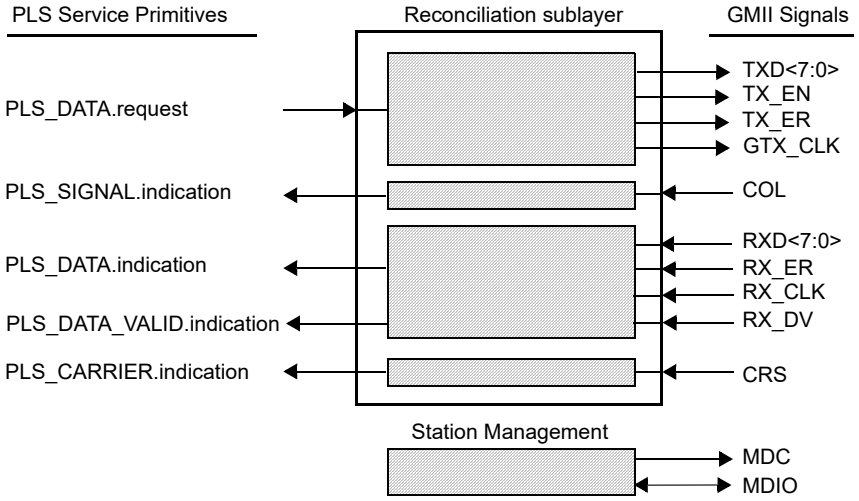

Figure 35–2—Reconciliation Sublayer (RS) inputs and outputs and STA connections to GMII

35.2.1.1 Mapping of PLS_DATA.request

35.2.1.1.1 Function

Map the primitive PLS_DATA.request to the GMII signals TXD<7:0>, TX_EN, TX_ER, and GTX_CLK.

35.2.1.1.2 Semantics of the service primitive

PLS_DATA.request (OUTPUT_UNIT)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The OUTPUT_UNIT parameter can take one of five values: ONE, ZERO, DATA_COMPLETE, EXTEND, or EXTEND_ERROR. It represents or is equivalent to a single data bit. These values are conveyed by the signals TX_EN, TX_ER, TXD<7>, TXD<6>, TXD<5>, TXD<4>, TXD<3>, TXD<2>, TXD<1>, and TXD<0>.

Each of the eight TXD signals conveys either a ONE or ZERO of data while TX_EN is asserted. Eight data bit equivalents of EXTEND or EXTEND_ERROR are conveyed by a specific encoding of the TXD<7:0> signals when TX_EN is not asserted, and TX_ER is asserted, see Table 35–1. Synchronization between the Reconciliation sublayer and the PHY is achieved by way of the GTX_CLK signal. The value DATA_COMPLETE is conveyed by the deassertion of either TX_EN or TX_ER at the end of a MAC's transmission.

35.2.1.1.3 When generated

The GTX_CLK signal is generated by the Reconciliation sublayer. The TXD<7:0>, TX_EN and TX_ER signals are generated by the Reconciliation sublayer after every group of eight PLS_DATA.request transactions from the MAC sublayer to request the transmission of eight data bits on the physical medium, to extend the carrier event the equivalent of eight bits, or to stop transmission.

35.2.1.2 Mapping of PLS_DATA.indication

35.2.1.2.1 Function

Map the primitive PLS_DATA.indication to the GMII signals RXD<7:0>, RX_DV, RX_ER, and RX_CLK.

35.2.1.2.2 Semantics of the service primitive

PLS_DATA.indication (INPUT_UNIT)

The INPUT_UNIT parameter can take one of three values: ONE, ZERO or EXTEND. It represents or is equivalent to a single data bit. These values are derived from the signals RX_DV, RX_ER, RXD<7>, RXD<6>, RXD<5>, RXD<4>, RXD<3>, RXD<2>, RXD<1>, and RXD<0>. The value of the data transferred to the MAC is controlled by GMII error indications, see 35.2.1.5.

Each of the eight RXD signals conveys either a ONE or ZERO of data while RX_DV is asserted. Eight data bit equivalents of EXTEND are conveyed by a specific encoding of the RXD<7:0> signals when RX_DV is not asserted, and RX_ER is asserted; see Table 35–2. Synchronization between the Reconciliation sublayer and the PHY is achieved by way of the RX_CLK signal.

35.2.1.2.3 When generated

This primitive is generated to all MAC sublayer entities in the network after a PLS_DATA.request is issued. Each octet transferred on RXD<7:0> will result in the generation of eight PLS_DATA.indication transactions.

35.2.1.3 Mapping of PLS_CARRIER.indication

35.2.1.3.1 Function

Map the primitive PLS_CARRIER.indication to the GMII signal CRS.

35.2.1.3.2 Semantics of the service primitive

PLS_CARRIER.indication (CARRIER_STATUS)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The CARRIER_STATUS parameter can take one of two values: CARRIER_ON or CARRIER_OFF. CARRIER_STATUS assumes the value CARRIER_ON when the GMII signal CRS is asserted and assumes the value CARRIER_OFF when CRS is deasserted.

35.2.1.3.3 When generated

The PLS_CARRIER.indication service primitive is generated by the Reconciliation sublayer whenever the CARRIER_STATUS parameter changes from CARRIER_ON to CARRIER_OFF or vice versa.

35.2.1.4 Mapping of PLS_SIGNAL.indication

35.2.1.4.1 Function

Map the primitive PLS_SIGNAL.indication to the GMII signal COL.

35.2.1.4.2 Semantics of the service primitive

PLS_SIGNAL.indication (SIGNAL_STATUS)

The SIGNAL_STATUS parameter can take one of two values: SIGNAL_ERROR or NO_SIGNAL_ERROR. SIGNAL_STATUS assumes the value SIGNAL_ERROR when the GMII signal COL is asserted, and assumes the value NO_SIGNAL_ERROR when COL is deasserted.

35.2.1.4.3 When generated

The PLS_SIGNAL.indication service primitive is generated whenever SIGNAL_STATUS makes a transition from SIGNAL_ERROR to NO_SIGNAL_ERROR or vice versa.

35.2.1.5 Response to error indications from GMII

If, during frame reception, both RX_DV and RX_ER are asserted, the Reconciliation sublayer shall ensure that the MAC will detect a FrameCheckError in that frame.

Carrier is extended when RX_DV is not asserted and RX_ER is asserted with a proper encoding of RXD<7:0>. When a Carrier Extend Error is received during the extension, the Reconciliation sublayer shall send PLS_DATA.indication values of ONE or ZERO and ensure that the MAC will detect a FrameCheckError in the sequence.

These requirements may be met by incorporating a function in the Reconciliation sublayer that produces a received frame data sequence delivered to the MAC sublayer that is guaranteed to not yield a valid CRC result, as specified by the algorithm in 3.2.9. This data sequence may be produced by substituting data delivered to the MAC.

Other techniques may be employed to respond to Data Reception Error or Carrier Extend Error provided that the result is that the MAC sublayer behaves as though a FrameCheckError occurred in the received frame.

35.2.1.6 Conditions for generation of TX_ER

If, during the process of transmitting a frame, it is necessary to request that the PHY deliberately corrupt the contents of the frame in such a manner that a receiver will detect the corruption with the highest degree of probability, then Transmit Error Propagation shall be asserted by the appropriate encoding of TX_ER, and TX_EN. Similarly, if during the process of transmitting carrier extension to a frame, it is necessary to request that the PHY deliberately corrupt the contents of the carrier extension in such a manner that a receiver will detect

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the corruption with the highest degree of probability, then Carrier Extend Error shall be signaled by the appropriate encoding of TXD<7:0>.

This capability has additional use within a repeater. For example, a repeater that detects an RX_ER during frame reception on an input port may propagate that error indication to its output ports by asserting TX_ER during the process of transmitting that frame.

35.2.1.7 Mapping of PLS_DATA_VALID.indication

35.2.1.7.1 Function

Map the primitive PLS_DATA_VALID.indication to the GMII signals RX_DV, RX_ER, and RXD<7:0>.

35.2.1.7.2 Semantics of the service primitive

PLS_DATA_VALID.indication (DATA_VALID_STATUS)

The DATA_VALID_STATUS parameter can take one of two values: DATA_VALID or DATA_NOT_VALID. DATA_VALID_STATUS assumes the value DATA_VALID when the GMII signal RX_DV is asserted, or when RX_DV is not asserted, RX_ER is asserted and the values of RXD<7:0> indicate Carrier Extend or Carrier Extend Error. DATA_VALID_STATUS assumes the value DATA_NOT_VALID at all other times.

35.2.1.7.3 When generated

The PLS_DATA_VALID.indication service primitive is generated by the Reconciliation sublayer whenever DATA_VALID_STATUS parameter changes from DATA_VALID to DATA_NOT_VALID or vice versa.

35.2.2 GMII signal functional specifications

35.2.2.1 GTX_CLK (1000 Mb/s transmit clock)

GTX_CLK is a continuous clock used for operation at 1000 Mb/s. GTX_CLK provides the timing reference for the transfer of the TX_EN, TX_ER, and TXD signals from the Reconciliation sublayer to the PHY. The values of TX_EN, TX_ER, and TXD are sampled by the PHY on the rising edge of GTX_CLK. GTX_CLK is sourced by the Reconciliation sublayer.

The GTX_CLK frequency is nominally 125 MHz, one-eighth of the transmit data rate.

NOTE—For EEE capability, GTX_CLK may be halted according to 35.2.2.6.

35.2.2.2 RX_CLK (receive clock)

RX_CLK is a continuous clock that provides the timing reference for the transfer of the RX_DV, RX_ER and RXD signals from the PHY to the Reconciliation sublayer. RX_DV, RX_ER and RXD are sampled by the Reconciliation sublayer on the rising edge of RX_CLK. RX_CLK is sourced by the PHY.

The frequency of RX_CLK may be derived from the received data or it may be that of a nominal clock (e.g., GTX_CLK). When the received data rate at the PHY is within tolerance, the RX_CLK frequency shall be 125MHz ±0.01%, one-eighth of the MAC receive data rate.

There is no need to transition between the recovered clock reference and a nominal clock reference on a frame-by-frame basis. If loss of received signal from the medium causes a PHY to lose the recovered RX_CLK reference, the PHY shall source the RX_CLK from a nominal clock reference. Transitions from nominal clock to recovered clock or from recovered clock to nominal clock shall not decrease the period, or time between

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

adjacent edges, of RX_CLK below the limits specified in Table 35–8, and shall not increase the time between adjacent edges of RX_CLK more than twice the nominal clock period.

Transitions from local clock to recovered clock or from recovered clock to local clock shall be made only while RX_DV and RX_ER are deasserted. During the interval between the assertion of CRS and the assertion of RX_DV at the beginning of a frame, the PHY may extend a cycle of RX_CLK by holding it in either the high or low condition until the PHY has successfully locked onto the recovered clock. Following the deassertion of RX_DV at the end of a frame, or the deassertion of RX_ER at the end of carrier extension, the PHY may extend a cycle of RX_CLK by holding it in either the high or low condition for an interval that shall not exceed twice the nominal clock period.

NOTE 1—This standard neither requires nor assumes a guaranteed phase relationship between the RX_CLK and GTX_CLK signals. See additional information in 35.5.

NOTE 2—For EEE capability, RX_CLK may be halted during periods of low utilization according to 35.2.2.10.

35.2.2.3 TX_EN (transmit enable)

TX_EN in combination with TX_ER indicates the Reconciliation sublayer is presenting data on the GMII for transmission. It shall be asserted by the Reconciliation sublayer synchronously with the first octet of the preamble and shall remain asserted while all octets to be transmitted are presented to the GMII. TX_EN shall be negated prior to the first rising edge of GTX_CLK following the final data octet of a frame. TX_EN is driven by the Reconciliation sublayer and shall transition synchronously with respect to the GTX_CLK.

Figure 35–3 depicts TX_EN behavior during a frame transmission with no collisions and without carrier extension or errors.

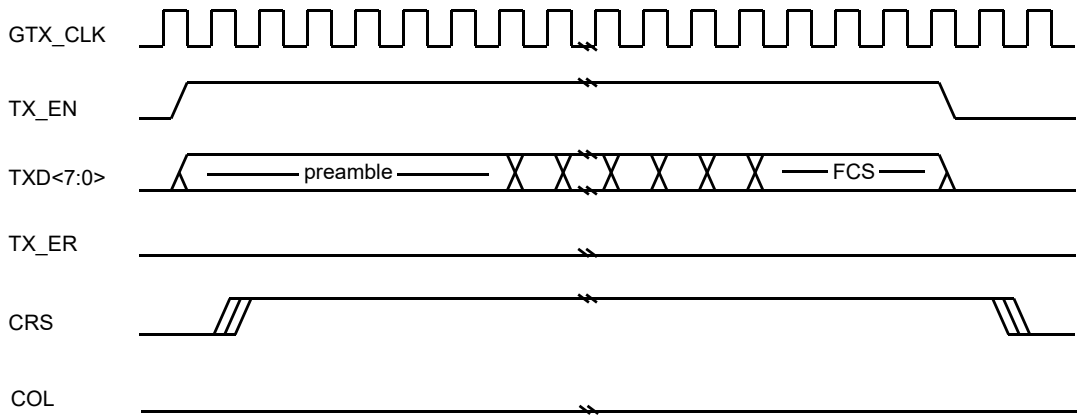

Figure 35–3—Basic frame transmission

35.2.2.4 TXD (transmit data)

TXD is a bundle of eight data signals (TXD<7:0>) that are driven by the Reconciliation sublayer. TXD<7:0> shall transition synchronously with respect to the GTX_CLK. For each GTX_CLK period in which TX_EN is asserted and TX_ER is deasserted, data are presented on TXD<7:0> to the PHY for transmission. TXD<0> is the least significant bit. While TX_EN and TX_ER are both deasserted, TXD<7:0> shall have no effect upon the PHY.

While TX_EN is deasserted and TX_ER is asserted, TXD<7:0> are used to request the PHY to generate LPI, Carrier Extend, or Carrier Extend Error code-groups. The use of TXD<7:0> during the transmission of a frame

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

with carrier extension is described in 35.2.2.5. Carrier extension shall only be signaled immediately following the data portion of a frame. The use of TXD<7:0> to signal LPI transitions is described in 35.2.2.6.

For EEE capability, the RS shall use the combination of TX_EN deasserted, TX_ER asserted, and TXD<7:0> equal to 0x01 as shown in Table 35–1 as a request to enter, or remain in the LPI state. Transition into and out of the LPI state is shown in Figure 35–8.

Table 35–1 specifies the permissible encodings of TXD<7:0>, TX_EN, and TX_ER.

Table 35–1—Permissible encodings of TXD<7:0>, TX_EN, and TX_ER

TX_EN	TX_ER	TXD<7:0>	Description	PLS_DATA.request parameter
0	0	00 through FF	Normal inter-frame	DATA_COMPLETE
0	1	00	Reserved	—
0	1	01	Assert LPI	—
0	1	02 through 0E	Reserved	—
0	1	0F	Carrier Extend	EXTEND (eight bits)
0	1	10 through 1E	Reserved	—
0	1	1F	Carrier Extend Error	EXTEND_ERROR (eight bits)
0	1	20 through FF	Reserved	—
1	0	00 through FF	Normal data transmission	ZERO, ONE (eight bits)
1	1	00 through FF	Transmit error propagation	No applicable parameter
NOTE—Values in TXD<7:0> column are in hexadecimal.				

35.2.2.5 TX_ER (transmit coding error)

TX_ER is driven by the Reconciliation Sublayer and shall transition synchronously with respect to the GTX_CLK. When TX_ER is asserted for one or more TX_CLK periods while TX_EN is also asserted, the PHY shall emit one or more code-groups that are not part of the valid data or delimiter set somewhere in the frame being transmitted. The relative position of the error within the frame need not be preserved. Figure 35–4 shows the behavior of TX_ER during the transmission of a frame propagating an error.

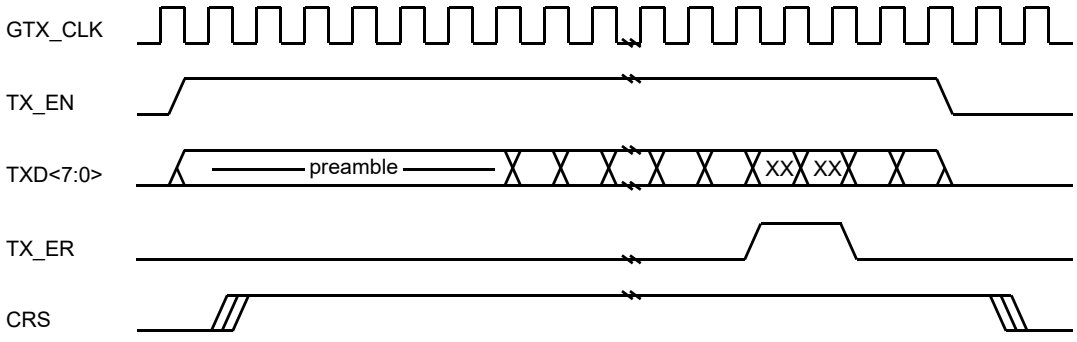

Figure 35–4—Propagating an error within a frame

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Assertion of appropriate TXD values when TX_EN is deasserted and TX_ER is asserted will cause the PHY to generate either Carrier Extend or Carrier Extend Error code-groups. The transition from TX_EN asserted and TX_ER deasserted to TX_EN deasserted and TX_ER asserted with TXD specifying Carrier Extend shall result in the PHY transmitting an end-of-packet delimiter as the initial code-groups of the carrier extension. Figure 35–5 and Figure 35–6 show the behavior of TX_ER during the transmission of carrier extension. The propagation of an error in carrier extension is requested by holding TX_EN deasserted and TX_ER asserted along with the appropriate value of TXD<7:0>.

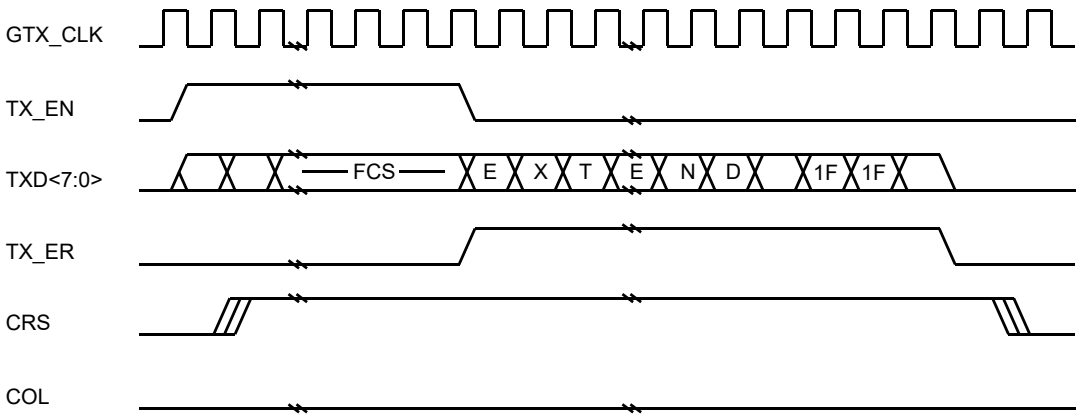

Figure 35–5—Propagating an error within carrier extension

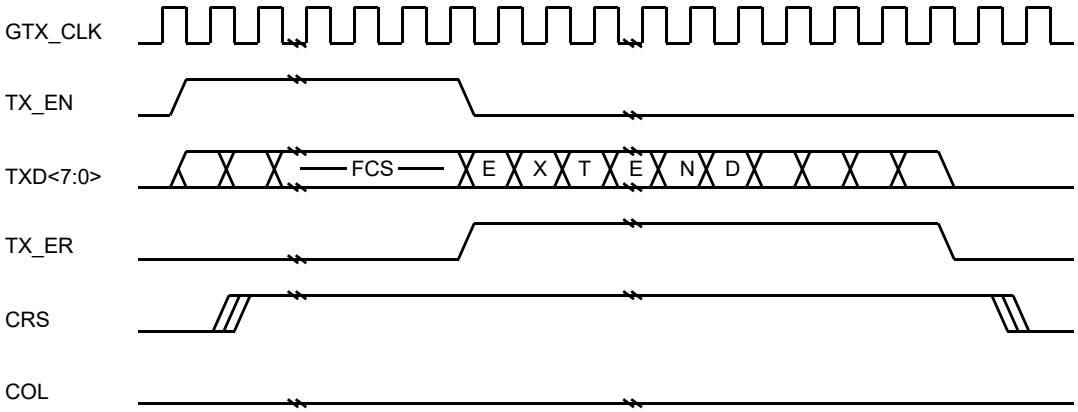

Figure 35–6—Transmission with carrier extension

Burst transmission of frames also uses carrier extension between frames of the burst. Figure 35–7 shows the behavior of TX_ER and TX_EN during burst transmission.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

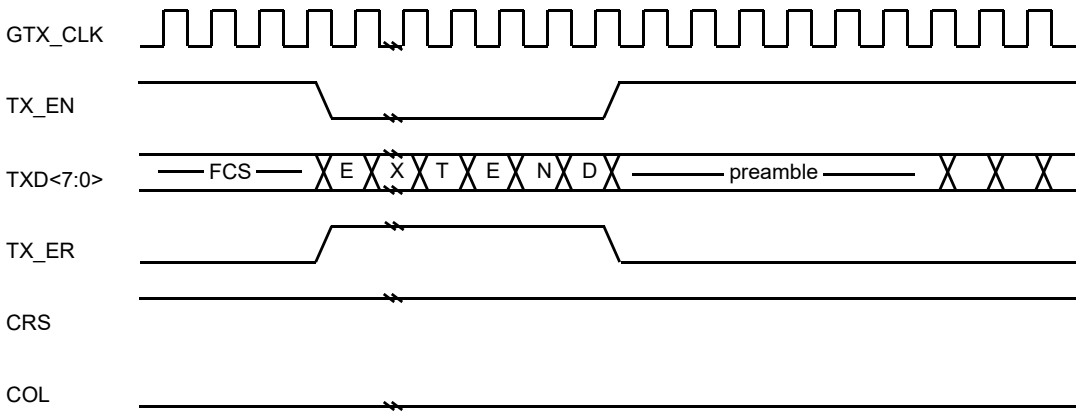

Figure 35–7—Burst transmission

35.2.2.6 Transmit direction LPI transition

EEE capability and the LPI client are described in 78.1. The LPI client requests the PHY to transition to its low power state by asserting TX_ER and setting TXD<7:0> to 0x01. The LPI client maintains the same state for these signals for the entire time that the PHY is to remain in the low power state.

The LPI client may halt GTX_CLK at any time more than 9 clock cycles after the start of the LPI state as shown in Figure 35–8 if and only if the Clock stop capable bit is asserted (45.2.3.1.4).

The LPI client requests the PHY to transition out of its low power state by deasserting TX_ER and TXD. The LPI client should not assert TX_EN for valid transmit data until after the wake-up time specified for the PHY.

Figure 35–8 shows the behavior of TX_EN, TX_ER and TXD<7:0> during the transition into and out of the LPI state.

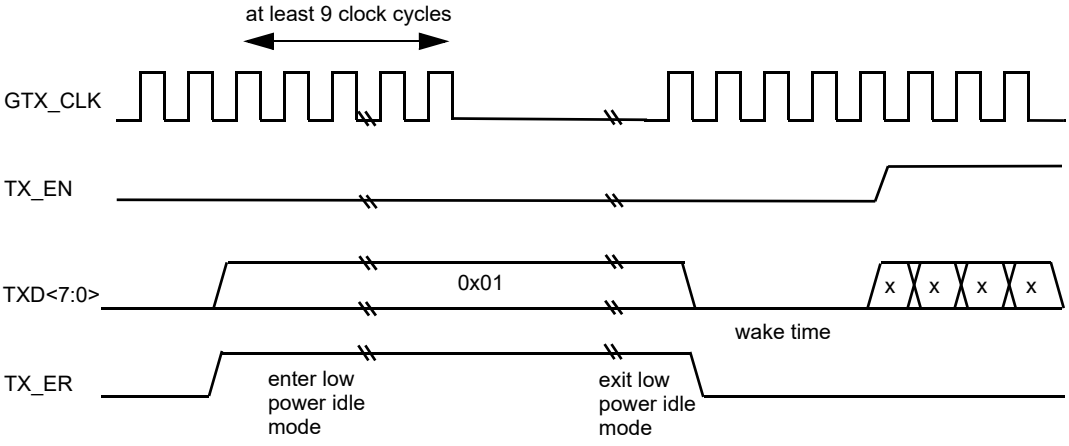

Figure 35–8—LPI transition

Table 35–1 summarizes the permissible encodings of TXD<7:0>, TX_EN, and TX_ER.

35.2.2.7 RX_DV (receive data valid)

RX_DV is driven by the PHY to indicate that the PHY is presenting recovered and decoded data on the RXD<7:0> bundle. RX_DV shall transition synchronously with respect to the RX_CLK. RX_DV shall be asserted continuously from the first recovered octet of the frame through the final recovered octet and shall be negated prior to the first rising edge of RX_CLK that follows the final octet. In order for a received frame to be correctly interpreted by the Reconciliation sublayer and the MAC sublayer, RX_DV has to encompass the frame, starting no later than the Start Frame Delimiter (SFD) and excluding any End-of-Frame delimiter.

Figure 35–9 shows the behavior of RX_DV during frame reception with no errors or carrier extension.

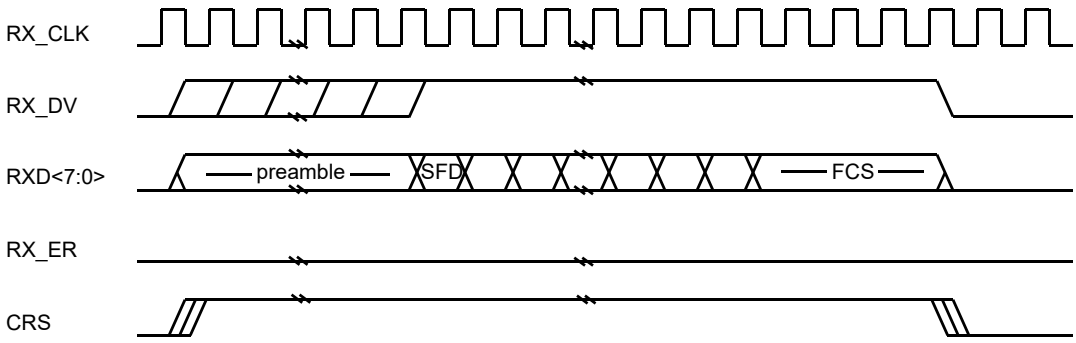

Figure 35–9—Basic frame reception

35.2.2.8 RXD (receive data)

RXD is a bundle of eight data signals (RXD<7:0>) that are driven by the PHY. RXD<7:0> shall transition synchronously with respect to RX_CLK. For each RX_CLK period in which RX_DV is asserted, RXD<7:0> transfer eight bits of recovered data from the PHY to the Reconciliation sublayer. RXD<0> is the least significant bit. Figure 35–9 shows the behavior of RXD<7:0> during frame reception.

While RX_DV is deasserted, the PHY may provide a False Carrier indication by asserting the RX_ER signal while driving the specific value listed in Table 35–2 onto RXD<7:0>. See 36.2.5.2.3 for a description of the conditions under which a PHY will provide a False Carrier indication. LPI transitions are described in 35.2.2.10.

While RX_DV is deasserted, the PHY may indicate that it is receiving LPI by asserting the RX_ER signal while driving the value 0x01 onto RXD<7:0>.

In order for a frame to be correctly interpreted by the MAC sublayer, a completely formed SFD has to be passed across the GMII.

In a DTE operating in half duplex mode, a PHY is not required to loop data transmitted on TXD<7:0> back to RXD<7:0> unless the loopback mode of operation is selected as defined in 22.2.4.1.2. In a DTE operating in full duplex mode, data transmitted on TXD <7:0> shall not be looped back to RXD <7:0> unless the loopback mode of operation is selected.

While RX_DV is deasserted and RX_ER is asserted, a specific RXD<7:0> value is used to transfer recovered Carrier Extend from the PHY to the Reconciliation sublayer. A Carrier Extend Error is indicated by another specific value of RXD<7:0>. Figure 35–10 shows the behavior of RX_DV during frame reception with carrier extension. Carrier extension shall only be signaled immediately following frame reception.

Burst transmission of frames also uses carrier extension between frames of the burst. Figure 35–11 shows the behavior of RX_ER and RX_DV during burst reception.

Table 35–2—Permissible encoding of RXD<7:0>, RX_ER, and RX_DV *(continued)*

RX_DV	RX_ER	RXD<7:0>	Description	PLS_DATA.indication parameter
0	1	01	Assert LPI	No applicable parameter
0	1	02 through 0D	Reserved	—
0	1	0E	False Carrier indication	No applicable parameter
0	1	0F	Carrier Extend	EXTEND (eight bits)
0	1	10 through 1E	Reserved	—
0	1	1F	Carrier Extend Error	ZERO, ONE (eight bits)
0	1	20 through FF	Reserved	—
1	0	00 through FF	Normal data reception	ZERO, ONE (eight bits)
1	1	00 through FF	Data reception error	ZERO, ONE (eight bits)
NOTE—Values in RXD<7:0> column are in hexadecimal.				

35.2.2.9 RX_ER (receive error)

RX_ER is driven by the PHY and shall transition synchronously with respect to RX_CLK. When RX_DV is asserted, RX_ER shall be asserted for one or more RX_CLK periods to indicate to the Reconciliation sublayer that an error (e.g., a coding error, or another error that the PHY is capable of detecting that may otherwise be undetectable at the MAC sublayer) was detected somewhere in the frame presently being transferred from the PHY to the Reconciliation sublayer.

The effect of RX_ER on the Reconciliation sublayer is defined in 35.2.1.5. Figure 35–12 shows the behavior of RX_ER during the reception of a frame with errors. Two independent error cases are illustrated. When RX_DV is asserted, assertion of RX_ER indicates an error within the data octets of a frame. An error within carrier extension is indicated by driving the appropriate value on RXD<7:0> while keeping RX_ER asserted.

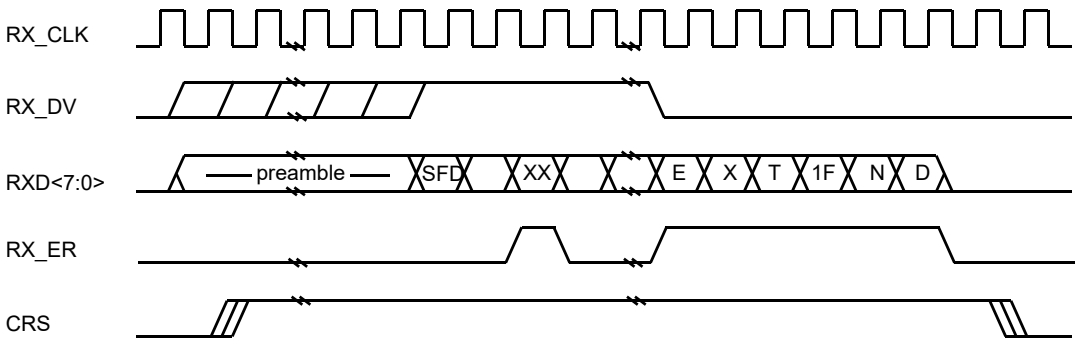

Figure 35–12—Two examples of reception with error

Assertion of RX_ER when RX_DV is deasserted with specific RXD values indicates the decode of carrier extension by the PHY. The transition from RX_DV asserted and RX_ER deasserted to RX_DV deasserted and RX_ER asserted with RXD specifying Carrier Extend shall result in the Reconciliation sublayer indicating EXTEND INPUT_UNITs to the MAC. Figure 35–10 shows the behavior of RX_DV and RX_ER during frame reception with carrier extension.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

While RX_DV is deasserted, the PHY may provide a False Carrier indication by asserting the RX_ER signal for at least one cycle of the RX_CLK while driving the appropriate value onto RXD<7:0>, as defined in Table 35–2. See 36.2.5.2.3 for a description of the conditions under which a PHY will provide a False Carrier indication. Figure 35–13 shows the behavior of RX_ER, RX_DV and RXD<7:0> during a False Carrier indication.

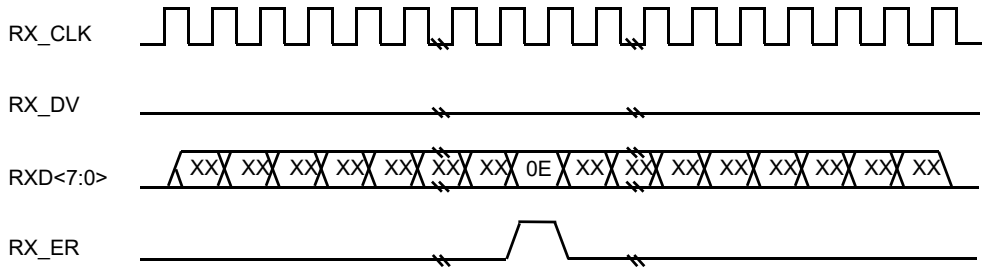

Figure 35–13—False Carrier indication

35.2.2.10 Receive direction LPI transition

EEE capability and the LPI client are described in 78.1. When the PHY receives signals from the link partner indicating LPI, it signals this to the LPI client by asserting RX_ER and setting RXD<7:0> to 0x01 while keeping RX_DV deasserted. The PHY maintains these signals in this state while it remains in the low power state. When the PHY receives signals from the link partner indicating its transition out of the low power state, it signals this to the LPI client by deasserting RX_ER and returning to normal interframe encoding.

While the PHY device is indicating LPI, the PHY device may halt the RX_CLK as shown in Figure 35–14 if and only if the Clock stop enable bit is asserted (see 45.2.3.1.4). The PHY may restart RX_CLK at any time while it is asserting LPI, but shall restart RX_CLK so that at least one positive transition occurs before it deasserts LPI.

Figure 35–14 shows the behavior of RX_ER, RX_DV, and RXD<7:0> during LPI transitions.

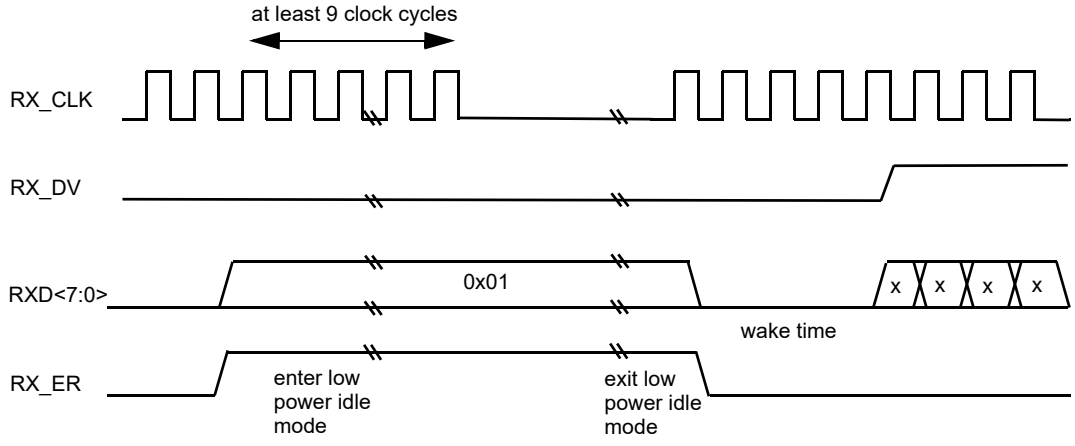

Figure 35–14—LPI transitions (receive)

35.2.2.11 CRS (carrier sense)

CRS is driven by the PHY. Except when used in a repeater, a PHY in half duplex mode shall assert CRS when either the transmit or receive medium is non-idle and shall deassert CRS when both the transmit and receive media are idle. The PHY shall ensure that CRS remains asserted throughout the duration of a collision condition.

When used in a repeater, a PHY shall assert CRS when the receive medium is non-idle and shall deassert CRS when the receive medium is idle.

CRS is not required to transition synchronously with respect to either the GTX_CLK or the RX_CLK.

The behavior of CRS is unspecified when the PHY is in full duplex mode.

Figure 35–3 and Figure 35–5 show the behavior of CRS during a frame transmission without a collision, while Figure 35–15 and Figure 35–16 show the behavior of CRS during a frame transmission with a collision.

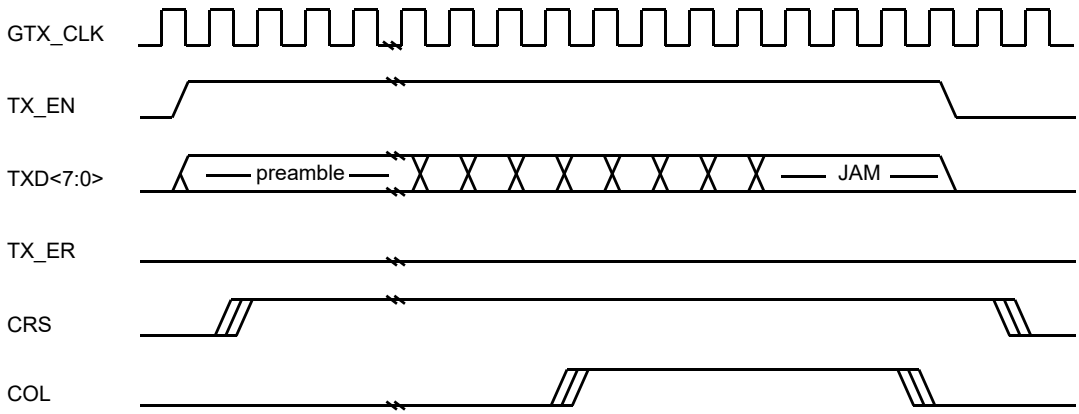

Figure 35–15—Transmission with collision

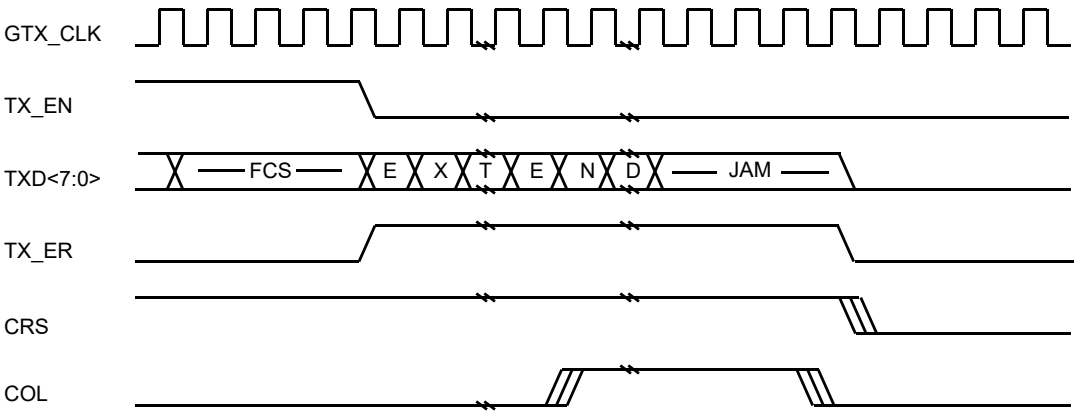

Figure 35–16—Transmission with collision in carrier extension

35.2.2.12 COL (collision detected)

COL is driven by the PHY and shall be asserted upon detection of a collision on the medium, and shall remain asserted while the collision condition persists.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

COL is not required to transition synchronously with respect to either the GTX_CLK or the RX_CLK.

The behavior of the COL signal is unspecified when the PHY is in full duplex mode.

Figure 35–15 and Figure 35–16 show the behavior of COL during a frame transmission with a collision.

35.2.2.13 MDC (management data clock)

MDC is specified in 22.2.2.13.

35.2.2.14 MDIO (management data input/output)

MDIO is specified in 22.2.2.14.

35.2.3 GMII data stream

Packets transmitted through the GMII shall be transferred within the data stream shown in Figure 35–17.

<inter-frame><preamble><sfd><data><efd><extend>

Figure 35–17—GMII data stream

For the GMII, transmission and reception of each octet of data shall be as shown in Figure 35–18.

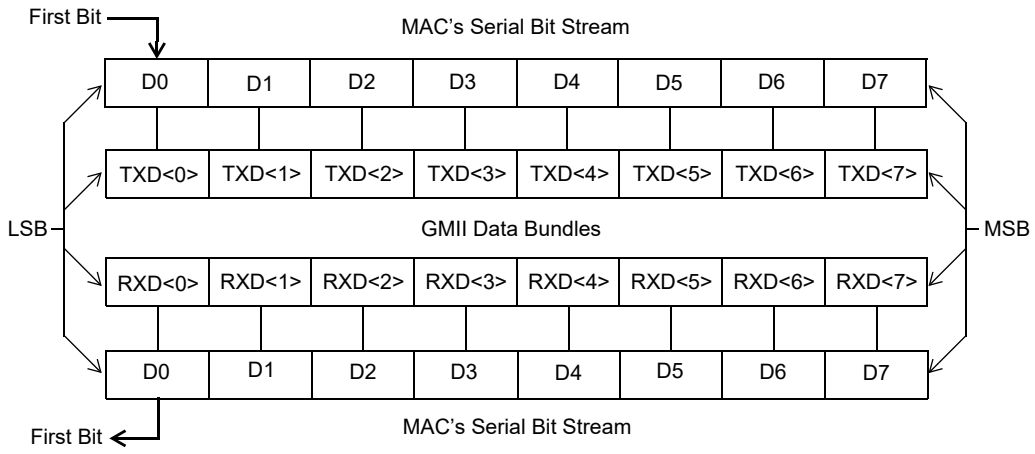

Figure 35–18—Relationship of data bundles to MAC serial bit stream

35.2.3.1 Inter-frame <inter-frame>

The inter-frame <inter-frame> period on a GMII transmit or receive path is an interval during which no data activity occurs on the path. Between bursts or single frame transmissions, the absence of data activity on the receive path is indicated by the deassertion of both RX_DV and RX_ER or the deassertion of the RX_DV signal with an RXD<7:0> value of 00 hexadecimal. On the transmit path the absence of data activity is indicated by the deassertion of both TX_EN and TX_ER.

Between frames within a burst, the inter-frame period is signaled as Carrier Extend on the GMII. As shown in Figure 35–7, this is done by asserting TX_ER with the appropriate encoding of TXD<7:0> simultaneous with

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the deassertion of TX_EN on the transmit path; and, as shown in Figure 35–11, by asserting RX_ER with the appropriate encoding of RXD<7:0> simultaneous with the deassertion of RX_DV on the receive path.

Within a burst, the MAC interFrameSpacing parameter defined in Clause 4, is measured from the deassertion of the TX_EN signal to the assertion of the TX_EN signal, and between bursts measured from the deassertion of the CRS signal to the assertion of the CRS signal.

35.2.3.2 Preamble <preamble> and start of frame delimiter <sfd>

35.2.3.2.1 Transmit case

The preamble <preamble> begins a frame transmission. The bit value of the preamble field at the GMII is unchanged from that specified in 4.2.5 and when generated by a MAC shall consist of 7 octets with the following bit values:

10101010 10101010 10101010 10101010 10101010 10101010 10101010

The SFD (Start Frame Delimiter) <sfd> indicates the start of a frame and immediately follows the preamble. The bit value of the SFD at the GMII is unchanged from that specified in 4.2.6, and is the following bit sequence:

10101011

The preamble and SFD are shown above with their bits ordered for serial transmission from left to right. As shown, the leftmost bit of each octet is the LSB of the octet and the rightmost bit of each octet is the MSB of the octet.

The preamble and SFD shall be transmitted through the GMII as octets starting from the assertion of TX_EN.

35.2.3.2.2 Receive case

The conditions for assertion of RX_DV are defined in 35.2.2.7. The operation of 1000 Mb/s PHYs can result in shrinkage of the preamble between transmission at the source GMII and reception at the destination GMII. Table 35–3 depicts the case where no preamble bytes are conveyed across the GMII. This case may not be possible with a specific PHY, but illustrates the minimum preamble with which MAC shall be able to operate. Table 35–4 depicts the case where the entire preamble is conveyed across the GMII.

Table 35–3—Start of receive with no preamble preceding SFD

Signal	Bit values of octets received through GMII[a]			
RXD0	X	X	1[b]	D0[c]
RXD1	X	X	0	D1
RXD2	X	X	1	D2
RXD3	X	X	0	D3
RXD4	X	X	1	D4
RXD5	X	X	0	D5
RXD6	X	X	1	D6
RXD7	X	X	1	D7
RX_DV	0	0	1	1

[a]Leftmost octet is the first received.
[b]Start Frame Delimiter octet.
[c]D0 through D7 is the first octet of the PDU (first octet of the Destination Address).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 35–4—Start of receive with entire preamble preceding SFD

Signal	Bit values of octets received through GMII[a]									
RXD0	X	1	1	1	1	1	1	1	1[b]	D0[c]
RXD1	X	0	0	0	0	0	0	0	0	D1
RXD2	X	1	1	1	1	1	1	1	1	D2
RXD3	X	0	0	0	0	0	0	0	0	D3
RXD4	X	1	1	1	1	1	1	1	1	D4
RXD5	X	0	0	0	0	0	0	0	0	D5
RXD6	X	1	1	1	1	1	1	1	1	D6
RXD7	X	0	0	0	0	0	0	0	1	D7
RX_DV	0	1	1	1	1	1	1	1	1	1

[a]Leftmost octet is the first received.
[b]Start Frame Delimiter octet.
[c]D0 through D7 is the first octet of the PDU (first octet of the Destination Address).

35.2.3.3 Data <data>

The data <data> in a well-formed frame shall consist of a set of data octets.

35.2.3.4 End-of-Frame delimiter <efd>

Deassertion of the TX_EN signal constitutes an End-of-Frame delimiter <efd> for data conveyed on TXD<7:0>, and deassertion of RX_DV constitutes an End-of-Frame delimiter for data conveyed on RXD<7:0>.

35.2.3.5 Carrier extension <extend>

The Reconciliation sublayer signals carrier extension <extend> on the transmit path by the assertion of the TX_ER signal with the appropriate value of TXD<7:0> simultaneous with the deassertion of the TX_EN signal. Carrier extension is signaled on the receive path by the assertion of the RX_ER signal with the appropriate encoding on RXD<7:0> simultaneous with the deassertion of RX_DV. Carrier extension may not be present on all frames.

35.2.3.6 Definition of Start of Packet and End of Packet Delimiters

For the purposes of Clause 30 layer management, the Start of Packet delimiter is defined as the rising edge of RX_DV; and the End of Packet delimiter is defined as the falling edge of RX_DV. (See 30.2.2.2.2.)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

35.2.4 MAC delay constraints (with GMII)

A Gigabit Ethernet MAC with a GMII shall comply with the delay constraints in Table 35–5.

Table 35–5—MAC delay constraints (with GMII)

Sublayer measurement points	Event	Min (bits)	Max (bits)	Input timing reference	Output timing reference
MAC ⇔ GMII	MAC transmit start to TX_EN = 1 sampled		48		GTX_CLK rising
	CRS assert to MAC detect[a]	0	48		
	CRS deassert to MAC detect[a]	0	48		
	CRS assert to TX_EN = 1 sampled (worst-case nondeferred transmit)		112		GTX_CLK rising
	COL assert to MAC detect	0	48		
	COL deassert to MAC detect	0	48		
	COL assert to TXD = Jam sampled (worst-case collision response)		112		GTX_CLK rising; first octet of Jam

[a]For any given implementation: Max deassert – Min. assert ≤ 16 bits.

35.2.5 Management functions

The GMII shall use the MII management register set specified in 22.2.4. The detailed description of some management registers is dependent on the PHY type and is specified in either 22.2.4 or 37.2.5.

35.3 Signal mapping

The GMII is specified such that implementers may share pins for implementation of the GMII, the MII specified in Clause 22 and the TBI specified in Clause 36. A recommended mapping of the signals for the GMII, MII, and TBI is shown in Table 35–6. Implementers using this recommended mapping are to comply with the GMII electrical characteristics in 35.5, MII electrical characteristics in 22.3, and the TBI electrical characteristics in 36.3 as appropriate for the implemented interfaces.

In an implementation supporting the MII and GMII, some signal pins are not used in both interfaces. For example, the TXD and RXD data bundles are four bits wide for the MII and eight bits wide for the GMII. Also, the GTX_CLK is only used when operating as a GMII while TX_CLK is used when operating as an MII.

Similarly, an implementation supporting both the GMII and TBI interfaces will map TBI signals onto the GMII control signal pins of TX_ER, TX_EN, RX_ER, and RX_DV. The COL and CRS signals of the GMII have no corollary in the TBI.

It is recommended that unused signal pins be driven to a valid logic state.

35.4 LPI Assertion and Detection

Certain PHYs support Energy-Efficient Ethernet (see Clause 78). PHYs with EEE capability support LPI assertion and detection. LPI operation and the LPI client are described in 78.1. LPI signaling allows the LPI client to signal to the PHY and to the link partner that a break in the data stream is expected and components may use this information to enter power-saving modes that require additional time to resume normal operation. Similarly, it allows the LPI client to understand that the link partner has sent such an indication.

The LPI assertion and detection mechanism fits conceptually between the PLS Service Primitives and the GMII signals as shown in Figure 35–19.

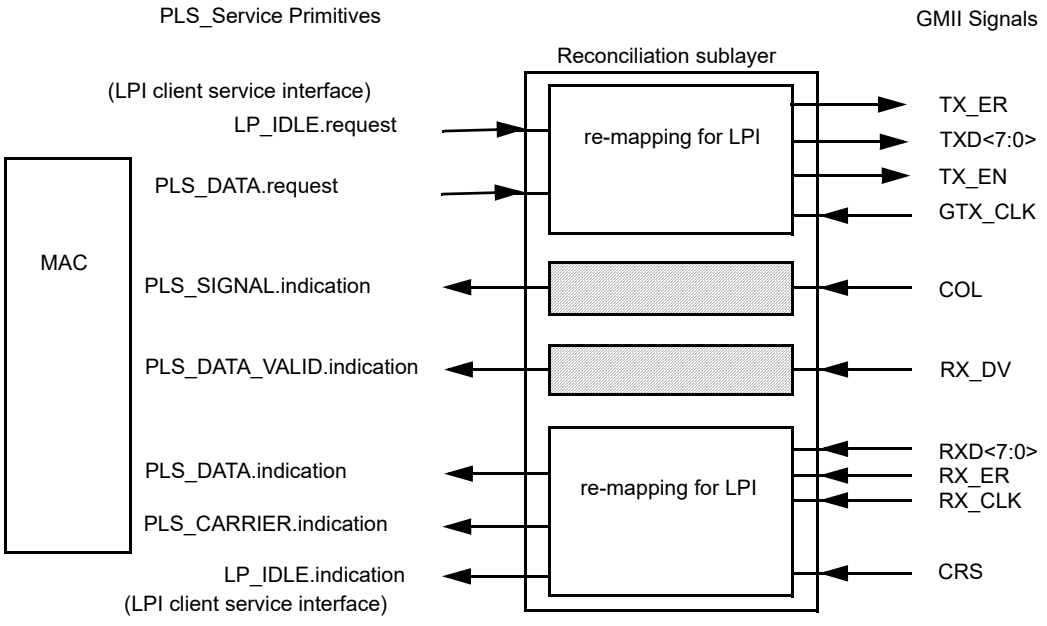

Figure 35–19—LPI assertion and detection mechanism

The definition of TX_EN, TX_ER and TXD<7:0> is derived from the state of PLS_DATA.request (35.2.1.1), except when it is overridden by an assertion of LP_IDLE.request.

Similarly, RX_ER and RXD<7:0> are mapped to PLS_DATA.indication except when LP_IDLE is detected

CRS is mapped to PLS_CARRIER.indication except when LP_IDLE.request is asserted or the wake timer has yet to expire.

The timing of PLS_CARRIER.indication when used for the LPI function is controlled by the LPI transmit state diagram.

35.4.1 LPI messages

LP_IDLE.indication(LPI_INDICATION)

A primitive that indicates to the LPI client that the PHY has detected the assertion or deassertion of LPI from the link partner.

Values:DEASSERT: The link partner is operating with normal interframe behavior (default).
ASSERT: The link partner has asserted LPI.

LP_IDLE.request(LPI_REQUEST)

The LPI_REQUEST parameter can take one of two values: ASSERT or DEASSERT. ASSERT initiates the signaling of LPI to the link partner. DEASSERT stops the signaling of LPI to the link partner. The effect of receipt of this primitive is undefined if link_status is not OK (see 28.2.6.1.1) or if LPI_REQUEST=ASSERT within 1 s of the change of link_status to OK.

35.4.2 Transmit LPI state diagram

The operation of LPI in the PHY requires that the MAC does not send valid data for a time after LPI has been deasserted as governed by resolved Transmit T_{w_sys} defined in 78.4.2.3.

This wake-up time is enforced by the transmit LPI state diagram and the rules mapping CARRIER_SENSE.indication defined in 35.2.1. The implementation shall conform to the behavior described by the transmit LPI state diagram shown in Figure 35–20.

35.4.2.1 Conventions

The notation used in the state diagram follows the conventions of 34.2.

35.4.2.2 Variables and counters

The transmit LPI state diagram uses the following variables and counters:

power_on

Condition that is true until such time as the power supply for the device that contains the RS has reached the operating region.

Values:FALSE: The device is completely powered (default).
TRUE: The device has not been completely powered.

rs_reset

Used by management to control the resetting of the RS.

Values:FALSE: Do not reset the RS (default).
TRUE: Reset the RS.

tw_timer

A timer that counts the time since the deassertion of LPI. The terminal count of the timer is the value of the resolved $T_{w_sys_tx}$ as defined in 78.2 and 78.4. The minimum value of $T_{w_sys_tx}$ shall be 16.5 μs for 1000BASE-T and 13.26 μs for 1000BASE-KX. Signal tw_timer_done is asserted on reaching its terminal count.

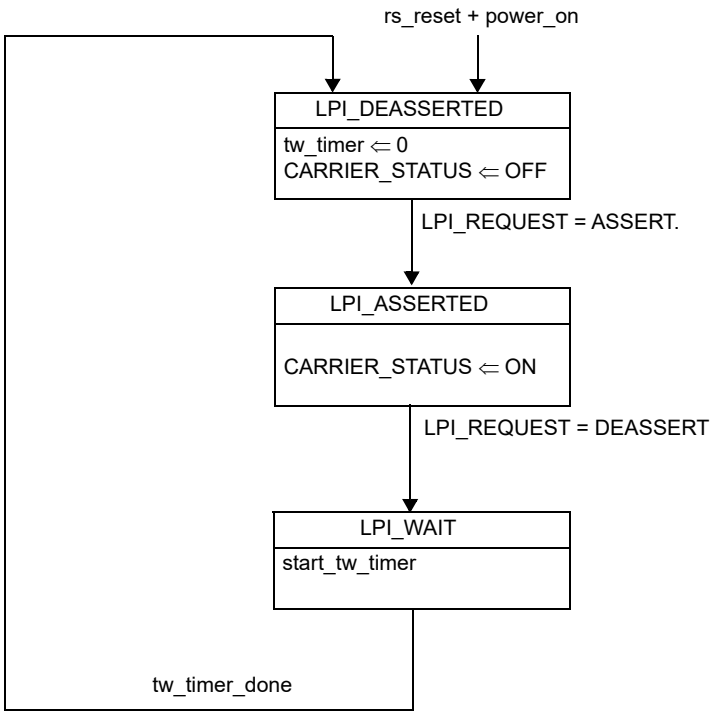

Figure 35–20—Transmit LPI state diagram

35.4.2.3 State diagram

35.4.3 Considerations for transmit system behavior

The transmit system should expect that egress data flow will be halted for at least resolved $T_{w_sys_tx}$ (see 78.2) time, in microseconds, after it requests the deassertion of LPI. Buffering and queue management should be designed to accommodate this.

35.4.3.1 Considerations for receive system behavior

The mapping function of the Reconciliation Sublayer shall continue to signal IDLE on PLS_DATA.indicate while it is detecting LP_IDLE on the GMII. The receive system should be aware that data frames may arrive at the GMII following the deassertion of LPI_INDICATION with a delay corresponding to the link partner's resolved $T_{w_sys_rx}$ (as specified in 78.5) time, in microseconds.

35.5 Electrical characteristics

The electrical characteristics of the GMII are specified such that the GMII can be applied within a variety of 1000 Mb/s equipment types. The electrical specifications are optimized for an integrated circuit to integrated circuit application environment. This includes applications where a number of PHY integrated circuits may be connected to a single integrated circuit as may be found in a repeater. Though specified for use on a single circuit board, applications to a motherboard-to-daughterboard interconnection are not precluded.

The electrical characteristics specified in this clause apply to all GMII signals except MDIO and MDC. The electrical characteristics for MDIO and MDC are specified in 22.3.4.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

35.5.1 DC characteristics

All GMII drivers and receivers shall comply with the dc parametric attributes specified in Table 35–7.

The potential applied to the input of a GMII receiver may exceed the potential of the receiver's power supply (i.e., a GMII driver powered from a 3.6 V supply driving V_{OH} into a GMII receiver powered from a 2.5 V supply). Tolerance for dissimilar GMII driver and receiver supply potentials is implicit in these specifications.

Table 35–7—DC specifications

Symbol	Parameter	Conditions		Min	Max	Units
V_{OH}	Output High Voltage	I_{OH} = -1.0 mA	V_{CC} = Min	2.10	3.60	V
V_{OL}	Output Low Voltage	I_{OL} = 1.0 mA	V_{CC} = Min	GND	0.50	V
V_{IH}	Input High Voltage			1.70	—	V
V_{IL}	Input Low Voltage			—	0.90	V
I_{IH}	Input High Current	V_{CC} = Max	V_{IN} = 2.1 V	—	40	µA
I_{IL}	Input Low Current	V_{CC} = Max	V_{IN} = 0.5 V	–600	—	µA

35.5.2 AC characteristics

The GMII ac electrical characteristics are specified in a manner that allows the implementer flexibility in selecting the GMII topologies its devices support and the techniques used to achieve the specified characteristics.

All GMII devices are required to support point-to-point links. The electrical length of the circuit board traces used to implement these links can be long enough to exhibit transmission line effects and require some form of termination. The implementer is allowed the flexibility to select the driver output characteristics and the termination technique and components to be used with its drivers for point-to-point links.

Implementers may elect to support other GMII topologies in addition to the point-to-point topology and may specify different termination techniques and components for each supported topology.

Since the output characteristics and output voltage waveforms of GMII drivers depend on the termination technique and the location of the termination components, the ac output characteristics of GMII drivers are not explicitly specified. Rather, the ac characteristics of the signal delivered to a GMII receiver are specified. These characteristics are independent of the topology and termination technique and apply uniformly to all GMII applications.

35.5.2.1 Signal Timing measurements

All GMII ac timing measurements are made at the GMII receiver input and are specified relative to the $V_{IL_AC(\max)}$ and $V_{IH_AC(\min)}$ thresholds.

The GTX_CLK and RX_CLK parameters t_{PERIOD}, t_{HIGH}, and t_{LOW} are defined in Figure 35–21. The GTX_CLK and RX_CLK parameters t_R and t_F and other transient performance specifications are defined in Figure 35–22. These parameters and the GTX_CLK and RX_CLK rising and falling slew rates are measured using the GMII point-to-point test circuit shown in Figure 35–24.

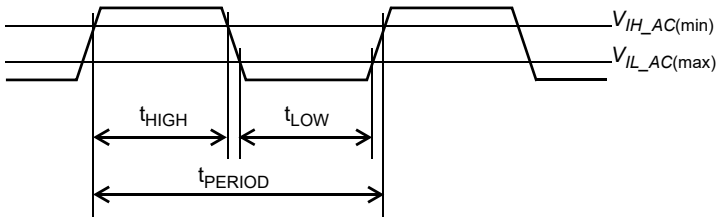

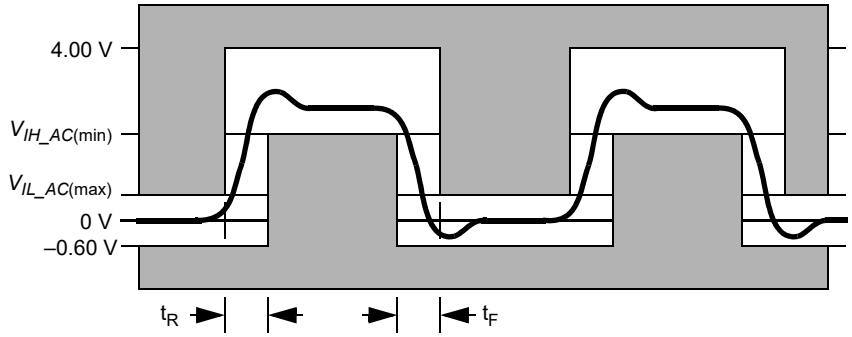

Figure 35–21—GTX_CLK and RX_CLK timing parameters at receiver input

NOTE—As measured at input measurement point

Figure 35–22—GMII receiver input potential template

The t_{SETUP} and t_{HOLD} parameters are defined in Figure 35–23. These parameters are measured using the GMII setup and hold time test circuit shown in Figure 35–25.

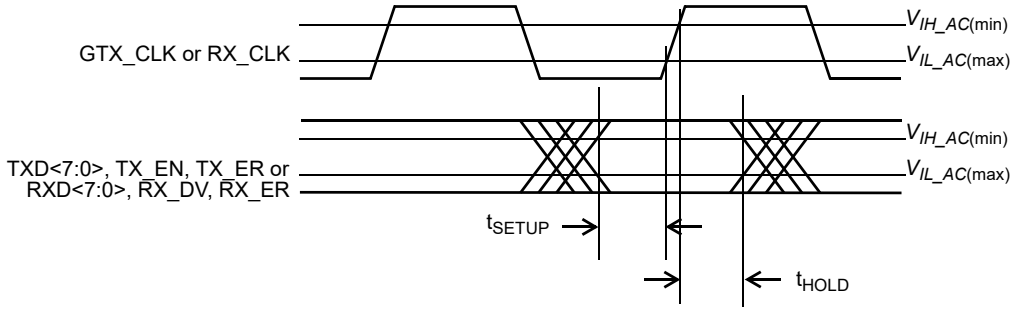

Figure 35–23—GMII signal timing at receiver input

35.5.2.2 GMII test circuit topology

The GMII point-to-point test circuit is defined in Figure 35–24. All parameter measurements made with this circuit are made at the Input Measurement Point defined in Figure 35–24. The 5 pF capacitor is included to approximate the input load of a GMII receiver. The termination networks used to implement the GMII point-to-point test circuit shall be those specified by the implementer of the GMII driver for 50 Ω ± 15% impedance transmission line point-to-point links. One or both of the termination networks specified by the implementer of the GMII driver may be straight-through connections if the networks are not needed to comply with the GMII ac and transient performance specifications.

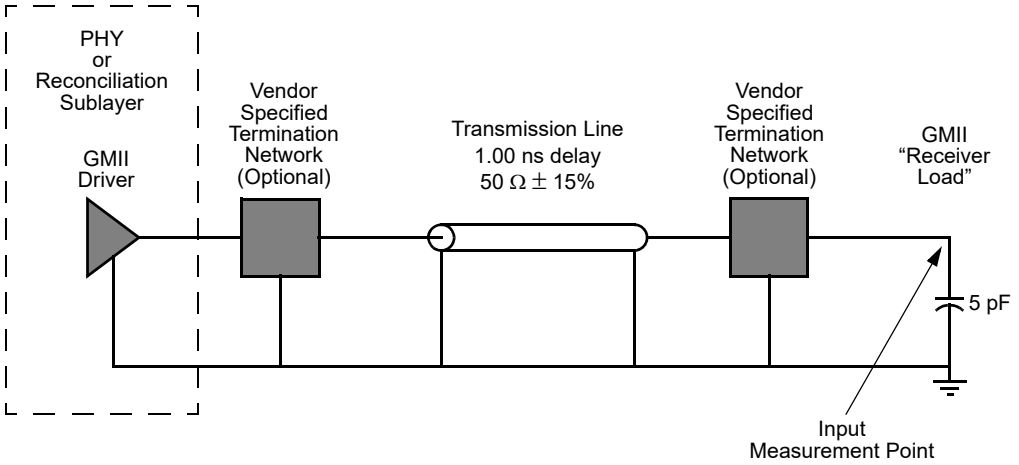

Figure 35–24—GMII point-to-point test circuit

The GMII point-to-point test circuit specifies a 1 ns transmission line. In a GMII implementation, the circuit board traces between the PHY and Reconciliation sublayer are not restricted to a delay of 1 ns.

The GMII setup and hold time test circuit is defined in Figure 35–25. The circuit is composed of the source of the synchronous GMII signal under test and its clock (the Reconciliation Layer or the PHY) and two GMII point-to-point test circuits. One of the test circuits includes the GMII driver for the signal under test, the other test circuit includes the GMII driver for the clock that provides timing for the signal under test. The signal under test is measured at the "Signal Measurement Point" relative to its clock, which is measured at the Clock Measurement Point as defined in Figure 35–25.

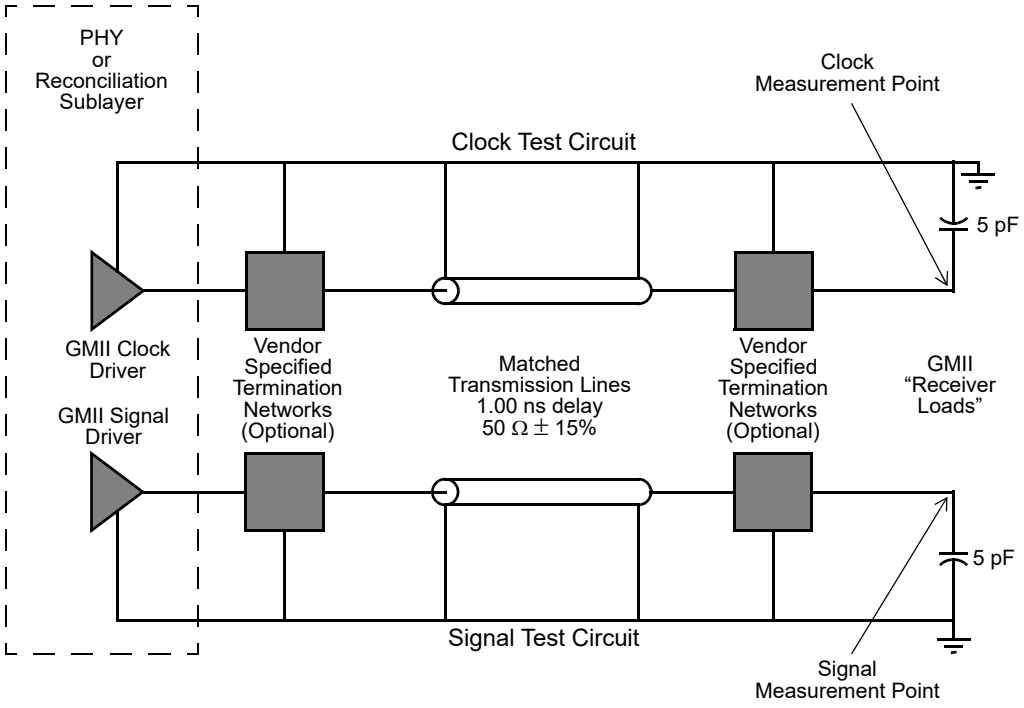

Figure 35–25—GMII setup and hold time test circuit

35.5.2.3 GMII ac specifications

A GMII driver, when used in combination with the termination networks specified by the implementer of the driver for a specific GMII topology, shall produce a potential at the input pin of any GMII receiver in that topology that complies with the input potential template shown in Figure 35–22. This requirement applies for all GMII signals and any GMII topology.

To ensure that all GMII devices support point-to-point links, a GMII driver, when driving the GMII point-to-point test circuit shown in Figure 35–24, shall produce a potential at the Input Measurement Point of the GMII point-to-point test circuit that complies with the input potential template shown in Figure 35–22.

All GMII signal sources, including the GMII drivers, GMII receivers and GMII signals shall comply with the ac specifications in Table 35–8.

Table 35–8—AC specifications

Symbol	Parameter	Conditions	Min	Max	Units
V_{IL_AC}	Input Low Voltage ac	—	—	0.70	V
V_{IH_AC}	Input High Voltage ac	—	1.90	—	V
f_{FREQ}	GTX_CLK Frequency	—	125 – 100 ppm	125 + 100 ppm	MHz
t_{PERIOD}	GTX_CLK Period	—	7.50	8.50	ns
t_{PERIOD}	RX_CLK Period	—	7.50	—	ns
t_{HIGH}	GTX_CLK, RX_CLK Time High	—	2.50	—	ns
t_{LOW}	GTX_CLK, RX_CLK Time Low	—	2.50	—	ns
t_R	GTX_CLK, RX_CLK Rise Time	V_{IL_AC}(max) to V_{IH_AC}(min)	—	1.00	ns
t_F	GTX_CLK, RX_CLK Fall Time	V_{IH_AC}(min) to V_{IL_AC}(max)	—	1.00	ns
—	Magnitude of GTX_CLK, RX_CLK Slew Rate (rising)[a]	V_{IL_AC}(max) to V_{IH_AC}(min)	0.6	—	V/ns
—	Magnitude of GTX_CLK, RX_CLK Slew Rate (falling)[a]	V_{IH_AC}(min) to V_{IL_AC}(max)	0.6	—	V/ns
t_{SETUP}	TXD, TX_EN, TX_ER Setup to ↑ GTX_CLK and RXD, RX_DV, RX_ER Setup to ↑ RX_CLK	—	2.50	—	ns
t_{HOLD}	TXD, TX_EN, TX_ER Hold from ↑ GTX_CLK and RXD, RX_DV, RX_ER Hold from ↑ RX_CLK	—	0.50	—	ns
t_{SETUP} (RCVR)	TXD, TX_EN, TX_ER Setup to ↑ GTX_CLK and RXD, RX_DV, RX_ER Setup to ↑ RX_CLK	—	2.00	—	ns
t_{HOLD} (RCVR)	TXD, TX_EN, TX_ER Hold from ↑ GTX_CLK and RXD, RX_DV, RX_ER Hold from ↑ RX_CLK	—	0.00	—	ns

[a]Clock Skew rate is the instantaneous rate of change of the clock potential with respect to time (dV/dt), not an average value over the entire rise or fall time interval. Conformance with this specification guarantees that the clock signals will rise and fall monotonically through the switching region.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Two sets of setup and hold time parameters are specified in Table 35–8. The first set, t_{SETUP} and t_{HOLD}, applies to the source of a synchronous GMII signal and its clock and is measured using the "GMII Setup and Hold Time Test Circuit," which has transmission lines with matched propagation delays in the "clock" and "signal" paths. The second set, $t_{SETUP(RCVR)}$ and $t_{HOLD(RCVR)}$, applies to the GMII receiver and specifies the minimum setup and hold times available to the GMII receiver at its input pins. The difference between the two sets of setup and hold time parameters provides margin for a small amount of mismatch in the propagation delays of the "clock" path and the "signal" paths in GMII applications.

The GMII ac specifications in Table 35–8 and the transient performance specifications in Figure 35–22 shall be met under all combination of worst-case GMII driver process and supply potential variation, ambient temperature, transmission line impedance variation, and termination network component impedance variation.

Designers of components containing GMII receivers should note that there is no upper bound specified on the magnitude of the slew rate of signals that may be applied to the input of a GMII receiver. The high-frequency energy in a high slew rate (short rise time) signal can excite the parasitic reactances of the receiver package and input pad to such a degree that the signal at the receiver input pin and the signal at the input pad differ significantly. This is particularly true for GTX_CLK and RX_CLK, which transition at twice the rate of other signals in the interface.

35.6 Protocol implementation conformance statement (PICS) proforma for Clause 35, Reconciliation Sublayer (RS) and Gigabit Media Independent Interface (GMII)[74]

35.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 35, Reconciliation Sublayer (RS) and Gigabit Media Independent Interface (GMII), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

35.6.2 Identification

35.6.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

35.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 35, Reconciliation Sublayer (RS) and Gigabit Media Independent Interface (GMII)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[74] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

36. Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 1000BASE-X

36.1 Overview

36.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) and the Physical Medium Attachment (PMA) sublayer that are common to a family of 1000 Mb/s Physical Layer implementations, collectively known as 1000BASE-X.

1000BASE-X is based on the Physical Layer standards developed by ANSI INCITS 230-1994 (Fibre Channel Physical and Signaling Interface). In particular, this standard uses the same 8B/10B coding as Fibre Channel, a PMA sublayer compatible with speed-enhanced versions of the ANSI 10-bit serializer chip, and similar optical and electrical specifications.

1000BASE-X PCS and PMA sublayers map the interface characteristics of the PMD sublayer (including MDI) to the services expected by the Reconciliation sublayer. 1000BASE-X can be extended to support any other full duplex medium requiring only that the medium be compliant at the PMD level.

36.1.2 Objectives

The following are the objectives of 1000BASE-X:

a) To support the CSMA/CD MAC
b) To support the 1000 Mb/s repeater
c) To provide for Auto-Negotiation among like 1000 Mb/s PMDs
d) To provide 1000 Mb/s data rate at the GMII
e) To support cable plants using 150 Ω balanced copper cabling, or cabled optical fiber compliant with ISO/IEC 11801:1995
f) To allow for a nominal network extent of up to 5 km, including
    1) 150 Ω balanced links of 25 m span
    2) one-repeater networks of 50 m span (using all 150 Ω balanced copper cabling)
    3) one-repeater networks of 200 m span (using fiber)
    4) DTE/DTE links of 5000 m (using fiber)
g) To preserve full duplex behavior of underlying PMD channels
h) To support a BER objective of 10^{-12}

NOTE—The 1000BASE-X PCS and PMA do not constrain the extent of a full duplex network. PMDs in Clause 59 and Clause 60 have ranges beyond 5 km.

36.1.3 Relationship of 1000BASE-X to other standards

Figure 36–1 depicts the relationships among the 1000BASE-X sublayers (shown shaded), the CSMA/CD MAC and reconciliation layers, and upper layer clients such as the ISO/IEC 8802-2 LLC.

36.1.4 Summary of 1000BASE-X sublayers

The following provides an overview of the 1000BASE-X sublayers.[75]

36.1.4.1 Physical Coding Sublayer (PCS)

The PCS interface is the Gigabit Media Independent Interface (GMII) that provides a uniform interface to the Reconciliation sublayer for all 1000 Mb/s PHY implementations (e.g., not only 1000BASE-X but also other possible types of gigabit PHY entities). 1000BASE-X provides services to the GMII in a manner analogous to how 100BASE-X provides services to the 100 Mb/s MII.

The 1000BASE-X PCS provides all services required by the GMII, including

a) Encoding (decoding) of GMII data octets to (from) ten-bit code-groups (8B/10B) for communication with the underlying PMA
b) Generating Carrier Sense and Collision Detect indications for use by PHY's half duplex clients
c) Managing the Auto-Negotiation process, and informing the management entity via the GMII when the PHY is ready for use

36.1.4.2 Physical Medium Attachment (PMA) sublayer

The PMA provides a medium-independent means for the PCS to support the use of a range of serial-bit-oriented physical media. The 1000BASE-X PMA performs the following functions:

a) Mapping of transmit and receive code-groups between the PCS and PMA via the PMA Service Interface
b) Serialization (deserialization) of code-groups for transmission (reception) on the underlying serial PMD
c) Recovery of clock from the 8B/10B-coded data supplied by the PMD
d) Mapping of transmit and receive bits between the PMA and PMD via the PMD Service Interface
e) Data loopback at the PMD Service Interface

36.1.4.3 Physical Medium Dependent (PMD) sublayer

1000BASE-X Physical Layer signaling for fiber and copper media is adapted from ANSI INCITS 230-1994 (FC-PH), Clauses 6 and 7 respectively. These clauses define 1062.5 Mb/s, full duplex signaling systems that accommodate single-mode optical fiber, multimode optical fiber, and 150 Ω balanced copper cabling. 1000BASE-X adapts these basic Physical Layer specifications for use with the PMD sublayer and media specified in Clause 38 and Clause 39.

The MDI, logically subsumed within each PMD subclause, is the actual medium attachment, including connectors, for the various supported media.

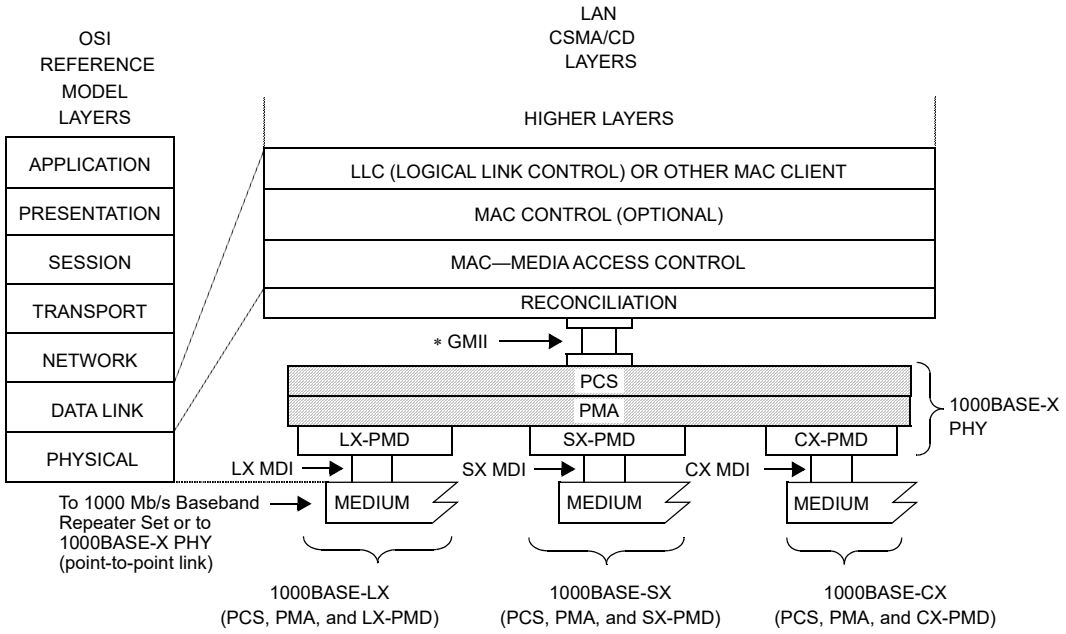

Figure 36–1 depicts the relationship between 1000BASE-X and its associated PMD sublayers.

36.1.5 Inter-sublayer interfaces

There are a number of interfaces employed by 1000BASE-X. Some (such as the PMA Service Interface) use an abstract service model to define the operation of the interface. An optional physical instantiation of the PCS Interface has been defined. It is called the GMII (Gigabit Media Independent Interface). An optional

[75]The 1000BASE-X PHY consists of that portion of the Physical Layer between the MDI and GMII consisting of the PCS, PMA, and PMD sublayers. The 1000BASE-X PHY is roughly analogous to the 100BASE-X PHY.

SX-PMD=PMD FOR FIBER—SHORT WAVELENGTH, Clause 38
CX-PMD=PMD FOR 150 Ω BALANCED COPPER CABLING, Clause 39

NOTE—The PMD sublayers are mutually independent.

* GMII is optional.

Figure 36–1—Relationship of 1000BASE-X and the PMDs

physical instantiation of the PMA Service Interface has also been defined (see 36.3.3). It is adapted from ANSI Technical Report TR/X3.18-1997 (Fibre Channel—10-bit Interface). Figure 36–2 depicts the relationship and mapping of the services provided by all of the interfaces relevant to 1000BASE-X.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and code-groups, implementers may choose other data path widths for implementation convenience. The only exceptions are a) the GMII, which, when implemented at an observable interconnection port, uses an octet-wide data path as specified in Clause 35, b) the PMA Service Interface, which, when physically implemented as the TBI (Ten-Bit Interface) at an observable interconnection port, uses a 10-bit wide data path as specified in 36.3.3, and c) the MDI, which uses a serial, physical interface.

36.1.6 Functional block diagram

Figure 36–2 provides a functional block diagram of the 1000BASE-X PHY.

36.1.7 State diagram conventions

The body of this standard is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

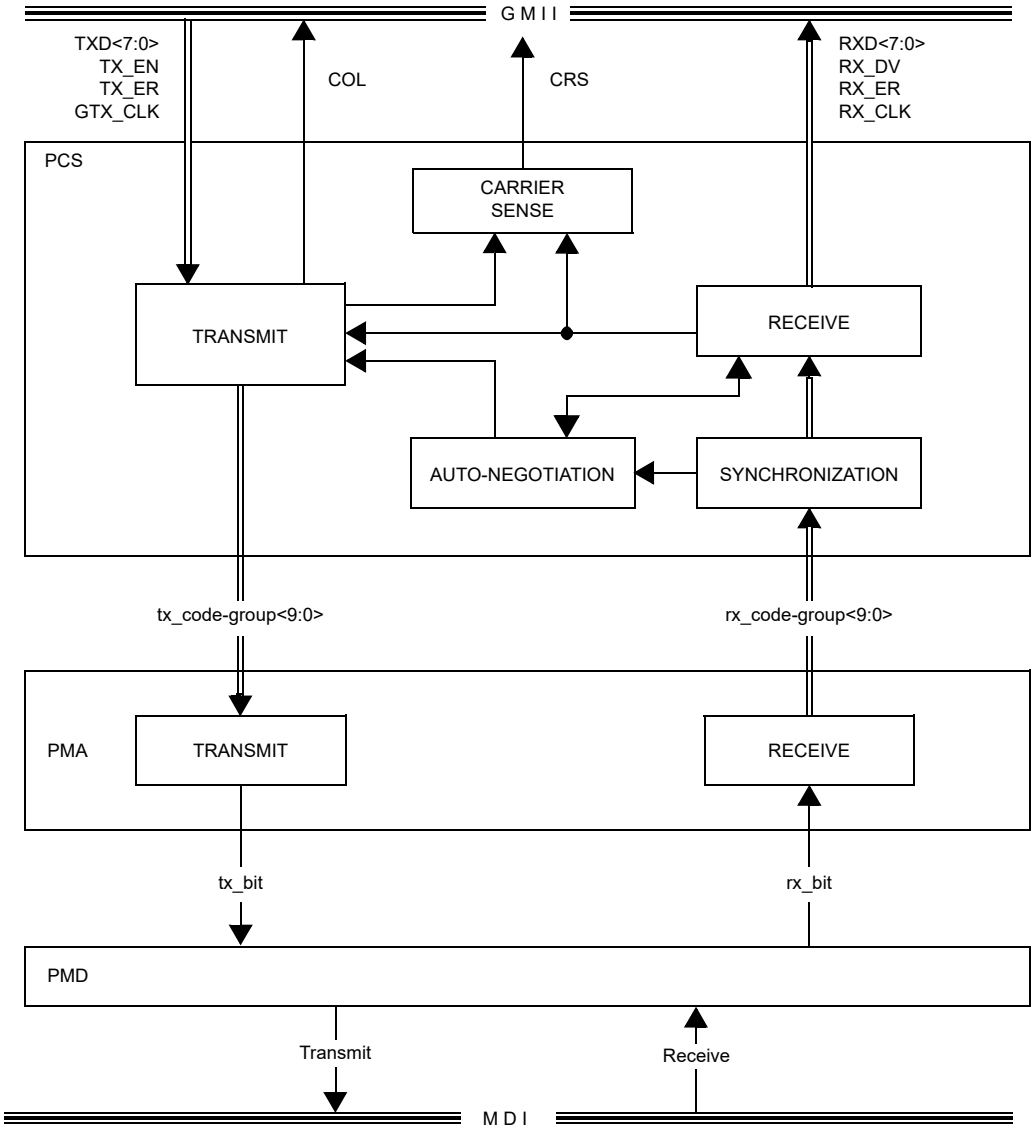

Figure 36–2—Functional block diagram

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2.

36.2 Physical Coding Sublayer (PCS)

36.2.1 PCS Interface (GMII)

The PCS Service Interface allows the 1000BASE-X PCS to transfer information to and from a PCS client. PCS clients include the MAC (via the Reconciliation sublayer) and repeater. The PCS Interface is precisely defined as the Gigabit Media Independent Interface (GMII) in Clause 35.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In this clause, the setting of GMII variables to TRUE or FALSE is equivalent, respectively, to “asserting” or “deasserting” them as specified in Clause 35.

36.2.2 Functions within the PCS

The PCS comprises the PCS Transmit, Carrier Sense, Synchronization, PCS Receive, and Auto-Negotiation processes for 1000BASE-X. The PCS shields the Reconciliation sublayer (and MAC) from the specific nature of the underlying channel. When communicating with the GMII, the PCS uses an octet-wide, synchronous data path, with packet delimiting being provided by separate transmit control signals (TX_EN and TX_ER) and receive control signals (RX_DV and RX_ER). When communicating with the PMA, the PCS uses a ten-bit wide, synchronous data path, which conveys ten-bit code-groups. At the PMA Service Interface, code-group alignment and MAC packet delimiting are made possible by embedding special non-data code-groups in the transmitted code-group stream. The PCS provides the functions necessary to map packets between the GMII format and the PMA Service Interface format.

The PCS Transmit process continuously generates code-groups based upon the TXD <7:0>, TX_EN, and TX_ER signals on the GMII, sending them immediately to the PMA Service Interface via the PMA_UNITDATA.request primitive. The PCS Transmit process generates the GMII signal COL based on whether a reception is occurring simultaneously with transmission. Additionally, it generates the internal flag, transmitting, for use by the Carrier Sense process. The PCS Transmit process monitors the Auto-Negotiation process xmit flag to determine whether to transmit data or reconfigure the link.

The Carrier Sense process controls the GMII signal CRS (see Figure 36–8).

The PCS Synchronization process continuously accepts code-groups via the PMA_UNITDATA.indication primitive and conveys received code-groups to the PCS Receive process via the SYNC_UNITDATA.indicate primitive. The PCS Synchronization process sets the sync_status flag to indicate whether the PMA is functioning dependably (as well as can be determined without exhaustive error-ratio analysis).

The PCS Receive process continuously accepts code-groups via the SYNC_UNITDATA.indicate primitive. The PCS Receive process monitors these code-groups and generates RXD <7:0>, RX_DV, and RX_ER on the GMII, and the internal flag, receiving, used by the Carrier Sense and Transmit processes.

The PCS Auto-Negotiation process sets the xmit flag to inform the PCS Transmit process to either transmit normal idles interspersed with packets as requested by the GMII or to reconfigure the link. The PCS Auto-Negotiation process is specified in Clause 37.

36.2.3 Use of code-groups

The PCS maps GMII signals into ten-bit code groups, and vice versa, using an 8B/10B block coding scheme. Implicit in the definition of a code-group is an establishment of code-group boundaries by a PMA code-group alignment function as specified in 36.3.2.4. Code-groups are unobservable and have no meaning outside the PCS. The PCS functions ENCODE and DECODE generate, manipulate, and interpret code-groups as provided by the rules in 36.2.4.

36.2.4 8B/10B transmission code

The PCS uses a transmission code to improve the transmission characteristics of information to be transferred across the link. The encodings defined by the transmission code ensure that sufficient transitions are present in the PHY bit stream to make clock recovery possible at the receiver. Such encoding also greatly increases the likelihood of detecting any single or multiple bit errors that may occur during transmission and reception of information. In addition, some of the special code-groups of the transmission code contain a distinct and easily recognizable bit pattern that assists a receiver in achieving code-group alignment on the

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

incoming PHY bit stream. The 8B/10B transmission code specified for use in this standard has a high transition density, is a run-length-limited code, and is DC-balanced. The transition density of the 8B/10B symbols ranges from 3 to 8 transitions per symbol.

The definition of the 8B/10B transmission code in this standard is identical to that specified in ANSI INCITS 230-1994 (FC-PH), Clause 11. The relationship of code-group bit positions to PMA and other PCS constructs is illustrated in Figure 36–3.

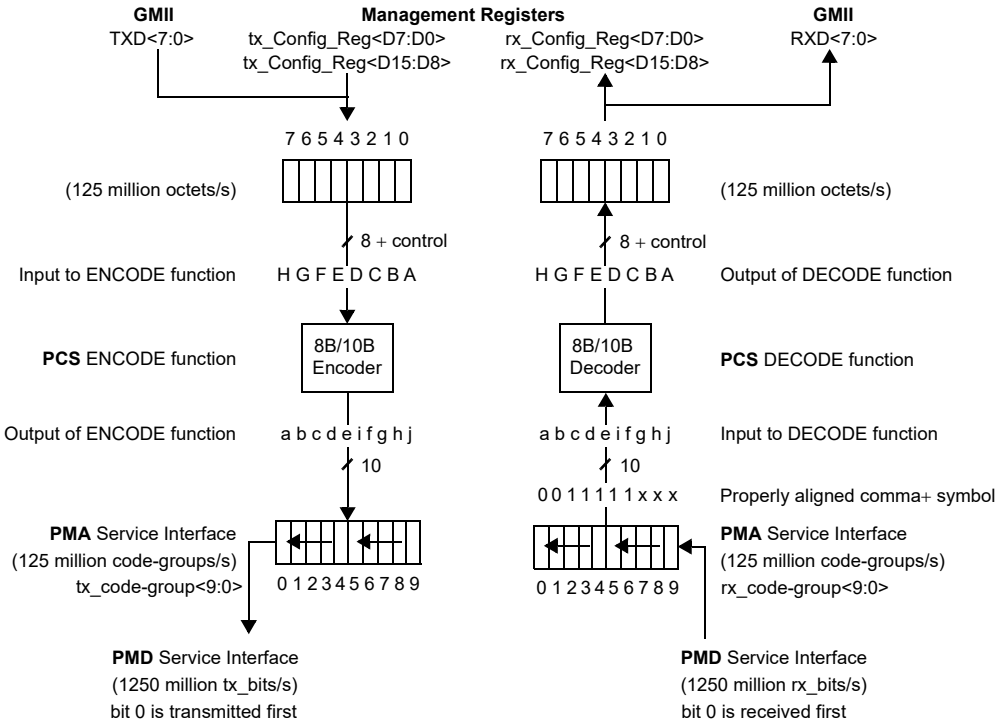

Figure 36–3—PCS reference diagram

36.2.4.1 Notation conventions

8B/10B transmission code uses letter notation for describing the bits of an unencoded information octet and a single control variable. Each bit of the unencoded information octet contains either a binary zero or a binary one. A control variable, Z, has either the value D or the value K. When the control variable associated with an unencoded information octet contains the value D, the associated encoded code-group is referred to as a data code-group. When the control variable associated with an unencoded information octet contains the value K, the associated encoded code-group is referred to as a special code-group.

The bit notation of A,B,C,D,E,F,G,H for an unencoded information octet is used in the description of the 8B/10B transmission code. The bits A,B,C,D,E,F,G,H are translated to bits a,b,c,d,e,i,f,g,h,j of 10-bit transmission code-groups. 8B/10B code-group bit assignments are illustrated in Figure 36–3. Each valid code-group has been given a name using the following convention: /Dx.y/ for the 256 valid data code-groups, and /Kx.y/ for special control code-groups, where x is the decimal value of bits EDCBA, and y is the decimal value of bits HGF.

36.2.4.2 Transmission order

Code-group bit transmission order is illustrated in Figure 36–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Code-groups within multi-code-group ordered sets (as specified in Table 36–3) are transmitted sequentially beginning with the special code-group used to distinguish the ordered set (e.g., /K28.5/) and proceeding code-group by code-group from left to right within the definition of the ordered set until all code-groups of the ordered set are transmitted.

The first code-group of every multi-code-group ordered set is transmitted in an even-numbered code-group position counting from the first code-group after a reset or power-on. Subsequent code-groups continuously alternate as odd and even-numbered code-groups.

The contents of a packet are transmitted sequentially beginning with the ordered set used to denote the Start_of_Packet (the SPD delimiter) and proceeding code-group by code-group from left to right within the definition of the packet until the ordered set used to denote the End_of_Packet (the EPD delimiter) is transmitted.

36.2.4.3 Valid and invalid code-groups

Table 36–1a–e defines the valid data code-groups (D code-groups) of the 8B/10B transmission code. Table 36–2 defines the valid special code-groups (K code-groups) of the code. The tables are used for both generating valid code-groups (encoding) and checking the validity of received code-groups (decoding). In the tables, each octet entry has two columns that represent two (not necessarily different) code-groups. The two columns correspond to the valid code-group based on the current value of the running disparity (Current RD – or Current RD +). Running disparity is a binary parameter with either the value negative (–) or the value positive (+). Annex 36B provides several 8B/10B transmission code running disparity calculation examples.

36.2.4.4 Running disparity rules

After powering on or exiting a test mode, the transmitter shall assume the negative value for its initial running disparity. Upon transmission of any code-group, the transmitter shall calculate a new value for its running disparity based on the contents of the transmitted code-group.

After powering on or exiting a test mode, the receiver should assume either the positive or negative value for its initial running disparity. Upon the reception of any code-group, the receiver determines whether the code-group is valid or invalid and calculates a new value for its running disparity based on the contents of the received code-group.

The following rules for running disparity shall be used to calculate the new running disparity value for code-groups that have been transmitted (transmitter's running disparity) and that have been received (receiver’s running disparity).

Running disparity for a code-group is calculated on the basis of sub-blocks, where the first six bits (abcdei) form one sub-block (six-bit sub-block) and the second four bits (fghj) form the other sub-block (four-bit sub-block). Running disparity at the beginning of the six-bit sub-block is the running disparity at the end of the last code-group. Running disparity at the beginning of the four-bit sub-block is the running disparity at the end of the six-bit sub-block. Running disparity at the end of the code-group is the running disparity at the end of the four-bit sub-block.

Running disparity for the sub-blocks is calculated as follows:

a) Running disparity at the end of any sub-block is positive if the sub-block contains more ones than zeros. It is also positive at the end of the six-bit sub-block if the six-bit sub-block is 000111, and it is positive at the end of the four-bit sub-block if the four-bit sub-block is 0011.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Running disparity at the end of any sub-block is negative if the sub-block contains more zeros than ones. It is also negative at the end of the six-bit sub-block if the six-bit sub-block is 111000, and it is negative at the end of the four-bit sub-block if the four-bit sub-block is 1100.

c) Otherwise, running disparity at the end of the sub-block is the same as at the beginning of the sub-block.

NOTE—All sub-blocks with equal numbers of zeros and ones are disparity neutral. In order to limit the run length of 0's or 1's between sub-blocks, the 8B/10B transmission code rules specify that sub-blocks encoded as 000111 or 0011 are generated only when the running disparity at the beginning of the sub-block is positive; thus, running disparity at the end of these sub-blocks is also positive. Likewise, sub-blocks containing 111000 or 1100 are generated only when the running disparity at the beginning of the sub-block is negative; thus, running disparity at the end of these sub-blocks is also negative.

36.2.4.5 Generating code-groups

The appropriate entry in either Table 36–1a–e or Table 36–2 is found for each octet for which a code-group is to be generated (encoded). The current value of the transmitter's running disparity shall be used to select the code-group from its corresponding column. For each code-group transmitted, a new value of the running disparity is calculated. This new value is used as the transmitter's current running disparity for the next octet to be encoded and transmitted.

36.2.4.6 Checking the validity of received code-groups

The following rules shall be used to determine the validity of received code groups:

a) The column in Table 36–1a–e and Table 36–2 corresponding to the current value of the receiver's running disparity is searched for the received code-group.

b) If the received code-group is found in the proper column, according to the current running disparity, then the code-group is considered valid and, for data code-groups, the associated data octet determined (decoded).

c) If the received code-group is not found in that column, then the code-group is considered invalid.

d) Independent of the code-group's validity, the received code-group is used to calculate a new value of running disparity. The new value is used as the receiver's current running disparity for the next received code-group.

Detection of an invalid code-group does not necessarily indicate that the code-group in which the invalid code-group was detected is in error. Invalid code-groups may result from a prior error which altered the running disparity of the PHY bit stream but which did not result in a detectable error at the code-group in which the error occurred.

The number of invalid code-groups detected is proportional to the bit error ratio (BER) of the link. Link error monitoring may be performed by counting invalid code-groups.

36.2.4.7 Ordered sets

Eight ordered sets, consisting of a single special code-group or combinations of special and data code-groups are specifically defined. Ordered sets which include /K28.5/ provide the ability to obtain bit and code-group synchronization and establish ordered set alignment (see 36.2.4.9 and 36.3.2.4). Ordered sets provide for the delineation of a packet and synchronization between the transmitter and receiver circuits at opposite ends of a link. Table 36–3 lists the defined ordered sets. Certain PHYs include an option (see 78.3) to transmit or receive /LI/, /LI1/ and /LI2/ to support Energy-Efficient Ethernet (see Clause 78).

NOTE 1—Reserved.

NOTE 2—Contains a comma.

36.2.4.7.1 Ordered set rules

Ordered sets are specified according to the following rules:

a) Ordered sets consist of either one, two, or four code-groups.
b) The first code-group of all ordered sets is always a special code-group.
c) The second code-group of all multi-code-group ordered sets is always a data code-group. The second code-group is used to distinguish the ordered set from all other ordered sets. The second code-group provides a high bit transition density.

Table 36–3 lists the defined ordered sets.

Table 36–3—Defined ordered sets

Code	Ordered Set	Number of Code-Groups	Encoding
/C/	**Configuration**		Alternating /C1/ and /C2/
/C1/	Configuration 1	4	/K28.5/D21.5/Config_Reg[a]
/C2/	Configuration 2	4	/K28.5/D2.2/Config_Reg[a]
/I/	**IDLE**		Correcting /I1/, Preserving /I2/
/I1/	IDLE 1	2	/K28.5/D5.6/
/I2/	IDLE 2	2	/K28.5/D16.2/
	Encapsulation		
/R/	Carrier_Extend	1	/K23.7/
/S/	Start_of_Packet	1	/K27.7/
/T/	End_of_Packet	1	/K29.7/
/V/	Error_Propagation	1	/K30.7/
/LI/	**LPI**		Correcting /LI1/, Preserving /LI2/
/LI1/	LPI 1	2	/K28.5/D6.5/
/LI2/	LPI 2	2	/K28.5/D26.4/

[a]Two data code-groups representing the Config_Reg value.

36.2.4.8 /K28.5/ code-group considerations

The /K28.5/ special code-group is chosen as the first code-group of all ordered sets that are signaled repeatedly and for the purpose of allowing a receiver to synchronize to the incoming bit stream (i.e., /C/ and /I/), for the following reasons:

a) Bits abcdeif make up a comma. The comma can be used to easily find and verify code-group and ordered set boundaries of the rx_bit stream.
b) Bits ghj of the encoded code-group present the maximum number of transitions, simplifying receiver acquisition of bit synchronization.

36.2.4.9 Comma considerations

The seven bit comma string is defined as either b'0011111' (comma+) or b'1100000' (comma-). The /I/ and /C/ ordered sets and their associated protocols are specified to ensure that comma+ is transmitted with either equivalent or greater frequency than comma- for the duration of their transmission. This is done to ensure compatibility with common components.

The comma contained within the /K28.1/, /K28.5/, and /K28.7/ special code-groups is a singular bit pattern, which, in the absence of transmission errors, cannot appear in any other location of a code-group and cannot be generated across the boundaries of any two adjacent code-groups with the following exception:

The /K28.7/ special code-group is used by 1000BASE-X for diagnostic purposes only (see Annex 36A). This code-group, if followed by any of the following special or data code-groups: /K28.x/, /D3.x/, /D11.x/, /D12.x/, /D19.x/, /D20.x/, or /D28.x/, where x is a value in the range 0 to 7, inclusive, causes a comma to be

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

generated across the boundaries of the two adjacent code-groups. A comma across the boundaries of any two adjacent code-groups may cause code-group realignment (see 36.3.2.4).

36.2.4.10 Configuration (/C/)

Configuration, defined as the continuous repetition of the ordered sets /C1/ and /C2/, is used to convey the 16-bit Configuration Register (Config_Reg) to the link partner. See Clause 37 for a description of the Config_Reg contents.

The ordered sets, /C1/ and /C2/, are defined in Table 36–3. The /C1/ ordered set is defined such that the running disparity at the end of the first two code-groups is opposite that of the beginning running disparity. The /C2/ ordered set is defined such that the running disparity at the end of the first two code-groups is the same as the beginning running disparity. For a constant Config_Reg value, the running disparity after transmitting the sequence /C1/C2/ will be the opposite of what it was at the start of the sequence. This ensures that K28.5s containing comma+ will be sent during configuration.

36.2.4.11 Data (/D/)

A data code-group, when not used to distinguish or convey information for a defined ordered set, conveys one octet of arbitrary data between the GMII and the PCS. The sequence of data code-groups is arbitrary, where any data code-group can be followed by any other data code-group. Data code-groups are coded and decoded but not interpreted by the PCS. Successful decoding of the data code-groups depends on proper receipt of the Start_of_Packet delimiter, as defined in 36.2.4.14 and the checking of validity, as defined in 36.2.4.6.

36.2.4.12 IDLE (/I/)

IDLE ordered sets (/I/) are transmitted continuously and repetitively whenever the GMII is idle (TX_EN and TX_ER are both inactive). /I/ provides a continuous fill pattern to establish and maintain clock synchronization. /I/ is emitted from, and interpreted by, the PCS. /I/ consists of one or more consecutively transmitted /I1/ or /I2/ ordered sets, as defined in Table 36–3.

The /I1/ ordered set is defined such that the running disparity at the end of the transmitted /I1/ is opposite that of the beginning running disparity. The /I2/ ordered set is defined such that the running disparity at the end of the transmitted /I2/ is the same as the beginning running disparity. The first /I/ following a packet or Configuration ordered set restores the current positive or negative running disparity to a negative value. All subsequent /I/s are /I2/ to ensure negative ending running disparity.

Distinct carrier events are separated by /I/s.

Implementations of this standard may benefit from the ability to add or remove /I2/ from the code-group stream one /I2/ at a time without altering the beginning running disparity associated with the code-group subsequent to the removed /I2/.

A received ordered set that consists of two code-groups, the first of which is /K28.5/ and the second of which is a data code-group other than /D21.5/ or /D2.2/ (or /D6.5/ or /D26.4/ to support EEE capability), is treated as an /I/ ordered set.

36.2.4.13 Low Power Idle (LPI)

LPI is transmitted in the same manner as IDLE. LPI ordered sets (/LI/) are transmitted continuously and repetitively whenever the GMII is indicating “Assert LPI”. See 35.2.2.6 and 35.2.2.10 for corresponding GMII definitions.

36.2.4.14 Start_of_Packet (SPD) delimiter

A Start_of_Packet delimiter (SPD) is used to delineate the starting boundary of a data transmission sequence and to authenticate carrier events. Upon each fresh assertion of TX_EN by the GMII, and subsequent to the completion of PCS transmission of the current ordered set, the PCS replaces the current octet of the MAC preamble with SPD. Upon initiation of packet reception, the PCS replaces the received SPD delimiter with the data octet value associated with the first preamble octet. A SPD delimiter consists of the code-group /S/, as defined in Table 36–3.

SPD follows /I/ for a single packet or the first packet in a burst.

SPD follows /R/ for the second and subsequent packets of a burst.

36.2.4.15 End_of_Packet delimiter (EPD)

An End_of_Packet delimiter (EPD) is used to delineate the ending boundary of a packet. The EPD is transmitted by the PCS following each deassertion of TX_EN on the GMII, which follows the last data octet comprising the FCS of the MAC packet. On reception, EPD is interpreted by the PCS as terminating a packet. A EPD delimiter consists of the code-groups /T/R/R/ or /T/R/K28.5/. The code-group /T/ is defined in Table 36–3. See 36.2.4.16 for the definition of code-groups used for /R/. /K28.5/ normally occurs as the first code-group of the /I/ ordered set. See 36.2.4.12 for the definition of code-groups used for /I/.

The receiver considers the MAC interpacket gap (IPG) to have begun two octets prior to the transmission of /I/. For example, when a packet is terminated by EPD, the /T/R/ portion of the EPD occupies part of the region considered by the MAC to be the IPG.

36.2.4.15.1 EPD rules

a) The PCS transmits a /T/R/ following the last data octet from the MAC;
b) If the MAC indicates carrier extension to the PCS, Carrier_Extend rules are in effect. See 36.2.4.16.1;
c) If the MAC does not indicate carrier extension to the PCS, perform the following:
    1) If /R/ is transmitted in an even-numbered code-group position, the PCS appends a single additional /R/ to the code-group stream to ensure that the subsequent /I/ is aligned on an even-numbered code-group boundary and EPD transmission is complete;
    2) The PCS transmits /I/.

36.2.4.16 Carrier_Extend (/R/)

Carrier_Extend (/R/) is used for the following purposes:

a) Carrier extension: Used by the MAC to extend the duration of the carrier event. When used for this purpose, carrier extension is emitted from and interpreted by the MAC and coded to and decoded from the corresponding code-group by the PCS. In order to extend carrier, the GMII has to deassert TX_EN. The deassertion of TX_EN and simultaneous assertion of TX_ER causes the PCS to emit an /R/ with a two-octet delay, which gives the PCS time to complete its EPD before commencing transmissions. The number of /R/ code-groups emitted from the PCS equals the number of GMII GTX_CLK periods during which it extends carrier;
b) Packet separation: Carrier extension is used by the MAC to separate packets within a burst of packets. When used for this purpose, carrier extension is emitted from and interpreted by the MAC and coded to and decoded from the corresponding code-group by the PCS;
c) EPD2: The first /R/ following the /T/ in the End_of_Packet delimiters /T/R/I/ or /T/R/R/I/;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) EPD3: The second /R/ following the /T/ in the End_of_Packet delimiter /T/R/R/I/. This /R/ is used, if necessary, to pad the only or last packet of a burst of packets so that the subsequent /I/ is aligned on an even-numbered code-group boundary. When used for this purpose, Carrier_Extend is emitted from, and interpreted by, the PCS. An EPD of /T/R/R/ results in one /R/ being delivered to the PCS client (see 36.2.4.15.1).

Carrier_Extend consists of one or more consecutively transmitted /R/ ordered sets, as defined in Table 36–3.

36.2.4.16.1 Carrier_Extend rules

a) If the MAC indicates carrier extension to the PCS, the initial /T/R/ is followed by one /R/ for each octet of carrier extension received from the MAC;
b) If the last /R/ is transmitted in an even-numbered code-group position, the PCS appends a single additional /R/ to the code-group stream to ensure that the subsequent /I/ is aligned on an even-numbered code-group boundary.

36.2.4.17 Error_Propagation (/V/)

Error_Propagation (/V/) indicates that the PCS client wishes to indicate a transmission error to its peer entity. The normal use of Error_Propagation is for repeaters to propagate received errors. /V/ is emitted from the PCS, at the request of the PCS client through the use of the TX_ER signal, as described in Clause 35. Error_Propagation is emitted from, and interpreted by, the PCS. Error_Propagation consists of the ordered set /V/, as defined in Table 36–3.

The presence of Error_Propagation or any invalid code-group on the medium denotes a collision artifact or an error condition. Invalid code-groups are not intentionally transmitted onto the medium by DTEs. The PCS processes and conditionally indicates the reception of /V/ or an invalid code-group on the GMII as false carrier, data errors, or carrier extend errors, depending on its current context.

36.2.4.18 Encapsulation

The 1000BASE-X PCS accepts packets from the MAC through the Reconciliation sublayer and GMII. Due to the continuously signaled nature of the underlying PMA, and the encoding performed by the PCS, the 1000BASE-X PCS encapsulates MAC frames into a code-group stream. The PCS decodes the code-group stream received from the PMA, extracts packets from it, and passes the packets to the MAC via the Reconciliation sublayer and GMII.

Figure 36–4 depicts the PCS encapsulation of a MAC packet based on GMII signals.

36.2.4.19 Mapping between GMII, PCS and PMA

Figure 36–3 depicts the mapping of the octet-wide data path of the GMII to the ten-bit-wide code-groups of the PCS, and the one-bit paths of the PMA/PMD interface.

The PCS encodes an octet received from the GMII into a ten-bit code-group, according to Figure 36–3. Code-groups are serialized into a tx_bit stream by the PMA and passed to the PMD for transmission on the underlying medium, according to Figure 36–3. The first transmitted tx_bit is tx_code-group<0>, and the last tx_bit transmitted is tx_code-group<9>. There is no numerical significance ascribed to the bits within a code-group; that is, the code-group is simply a ten-bit pattern that has some predefined interpretation.

Similarly, the PMA deserializes rx_bits received from the PMD, according to Figure 36–3. The PCS Receive process converts rx_code-group<9:0>'s into GMII data octets, according to 36.2.5.2.2.

36.2.5 Detailed functions and state diagrams

The notation used in the state diagrams in this clause follow the conventions in 21.5. State diagram variables follow the conventions of 21.5.2 except when the variable has a default value. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set.

Timeless states are employed as an editorial convenience to facilitate the distribution of transition conditions from prior states. No actions are taken within these states. Exit conditions are evaluated for timeless states. Timeless states are as follows:

a) PCS transmit ordered set state TX_PACKET;
b) PCS transmit code-group state GENERATE_CODE_GROUPS;
c) PCS transmit code-group state IDLE_DISPARITY_TEST;
d) PCS receive state RECEIVE;
e) PCS receive state EPD2_CHECK_END.

36.2.5.1 State variables

36.2.5.1.1 Notation conventions

/x/

Denotes the constant code-group specified in 36.2.5.1.2 (valid code-groups have to follow the rules of running disparity as per 36.2.4.5 and 36.2.4.6).

[/x/]

Denotes the latched received value of the constant code-group (/x/) specified in 36.2.5.1.2 and conveyed by the SYNC_UNITDATA.indicate message described in 36.2.5.1.6.

Copyright © 2022 IEEE. All rights reserved.

36.2.5.1.2 Constants

/C/
: The Configuration ordered set group, comprising either the /C1/ or /C2/ ordered set, as specified in 36.2.4.10. Conveys the Config_Reg value as tx_Config_Reg<D15:D0> for the PCS Transmit process and rx_Config_Reg<D15:D0> for the PCS Receive process.

/COMMA/
: The set of special code-groups which include a comma as specified in 36.2.4.9 and listed in Table 36–2.

/D/
: The set of 256 code-groups corresponding to valid data, as specified in 36.2.4.11.

/Dx.y/
: One of the set of 256 code-groups corresponding to valid data, as specified in 36.2.4.11.

/I/
: The IDLE ordered set group, comprising either the /I1/ or /I2/ ordered sets, as specified in 36.2.4.12.

/INVALID/
: The set of invalid data or special code-groups, as specified in 36.2.4.6.

/Kx.y/
: One of the set of 12 code-groups corresponding to valid special code-groups, as specified in Table 36–2.

/R/
: The code-group used as either: End_of_Packet delimiter part 2; End_of_Packet delimiter part 3; Carrier_Extend; and /I/ alignment.

/S/
: The code-group corresponding to the Start_of_Packet delimiter (SPD) as specified in 36.2.4.14.

/T/
: The code-group used for the End_of_Packet delimiter part 1.

/V/
: The Error_Propagation code-group, as specified in 36.2.4.17.

The following constant is used only for the EEE capability:

/LI/
: The LP_IDLE ordered set group, comprising either the /LI1/ or /LI2/ ordered sets, as specified in 36.2.4.13.

36.2.5.1.3 Variables

cgbad
: Alias for the following terms: ((rx_code-group∈/INVALID/) + (rx_code-group=/COMMA/ *rx_even=TRUE)) * PMA_UNITDATA.indication

cggood
: Alias for the following terms: !((rx_code-group∈/INVALID/) + (rx_code-group=/COMMA/ *rx_even=TRUE)) * PMA_UNITDATA.indication

COL

The COL signal of the GMII as specified in Clause 35.

CRS

The CRS signal of the GMII as specified in Clause 35.

EVEN

The latched state of the rx_even variable, when rx_even=TRUE, as conveyed by the SYNC_UNITDATA.indicate message described in 36.2.5.1.6.

mr_loopback

A Boolean that indicates the enabling and disabling of data being looped back through the PHY. Loopback of data through the PHY is enabled when Control register bit 0.14 is set to one.

Values: FALSE; Loopback through the PHY is disabled.
TRUE; Loopback through the PHY is enabled.

mr_main_reset

Controls the resetting of the PCS via Control Register bit 0.15.

Values: FALSE; Do not reset the PCS.
TRUE; Reset the PCS.

ODD

The latched state of the rx_even variable, when rx_even=FALSE, as conveyed by the SYNC_UNITDATA.indicate message described in 36.2.5.1.6.

power_on

Condition that is true until such time as the power supply for the device that contains the PCS has reached the operating region. The condition is also true when the device has low power mode set via Control register bit 0.11.

Values: FALSE; The device is completely powered (default).
TRUE; The device has not been completely powered.

NOTE—Power_on evaluates to its default value in each state where it is not explicitly set.

receiving

A Boolean set by the PCS Receive process to indicate carrier activity. Used by the Carrier Sense process, and also interpreted by the PCS Transmit process for indicating a collision. (See also 36.2.5.1.4, carrier_detect(x).)

Values: TRUE; Carrier being received.
FALSE; Carrier not being received.

repeater_mode

A Boolean used to make the assertion of Carrier Sense occur only in response to receive activity when the PCS is used in a CSMA/CD repeater. This variable is set to TRUE in a repeater application, and set to FALSE in all other applications.

Values: TRUE; Allows the assertion of CRS in response to receive activity only.
FALSE; Allows the assertion of CRS in response to either transmit or receive activity.

rx_bit

A binary parameter conveyed by the PMD_UNITDATA.indication service primitive, as specified in 38.1.1.2, to the PMA.

Values: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_code-group<9:0>

A 10-bit vector represented by the most recently received code-group from the PMA. The element rx_code-group<0> is the least recently received (oldest) rx_bit; rx_code-group<9> is the most recently received rx_bit (newest). When code-group alignment has been achieved, this vector contains precisely one code-group.

rx_Config_Reg<D15:D0>

A 16-bit array that contains the data bits received from a /C/ ordered set as defined in 36.2.4.10. Conveyed by the PCS Receive process to the PCS Auto-Negotiation process. The format of the data bits is context dependent, relative to the state of the Auto-Negotiation function, and is presented in 37.2.1.1 and 37.2.4.3.1. For each element within the array:

Values: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

RX_DV

The RX_DV signal of the GMII as specified in Clause 35. Set by the PCS Receive process.

RX_ER

The RX_ER signal of the GMII as specified in Clause 35. Set by the PCS Receive process.

rx_even

A Boolean set by the PCS Synchronization process to designate received code-groups as either even- or odd-numbered code-groups as specified in 36.2.4.2.

Values: TRUE; Even-numbered code-group being received.
FALSE; Odd-numbered code-group being received.

RXD<7:0>

The RXD<7:0> signal of the GMII as specified in Clause 35. Set by the PCS Receive process.

signal_detect

A Boolean set by the PMD continuously via the PMD_SIGNAL.indication(signal_detect) message to indicate the status of the incoming link signal.

Values: FAIL; A signal is not present on the link.
OK; A signal is present on the link.

sync_status

A parameter set by the PCS Synchronization process to reflect the status of the link as viewed by the receiver. The values of the parameter are defined for code_sync_status. The equation for this parameter is

sync_status = code_sync_status + rx_lpi_active

NOTE—If EEE is not supported, the variable rx_lpi_active is always false, and this variable is identical to code_sync_status controlled by the synchronization state diagram.

transmitting

A Boolean set by the PCS Transmit process to indicate that packet transmission is in progress. Used by the Carrier Sense process and internally by the PCS Transmit process for indicating a collision.

Values: TRUE; The PCS is transmitting a packet.
FALSE; The PCS is not transmitting a packet.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_bit

A binary parameter used to convey data from the PMA to the PMD via the PMD_UNITDATA.request service primitive as specified in 38.1.1.1.

Values: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

tx_code-group<9:0>

A vector of bits representing one code-group, as specified in Tables 36–1a–e or 36–2, which has been prepared for transmission by the PCS Transmit process. This vector is conveyed to the PMA as the parameter of a PMD_UNITDATA.request(tx_bit) service primitive. The element tx_code-group<0> is the first tx_bit transmitted; tx_code-group<9> is the last tx_bit transmitted.

tx_Config_Reg<D15:D0>

A 16-bit array that contains the data bits to be transmitted in a /C/ ordered set as defined in 36.2.4.10. Conveyed by the PCS Auto-Negotiation process to the PCS Transmit process. The format of the data bits is context dependent, relative to the state of the Auto-Negotiation function, and is presented in 37.2.1.1 and 37.2.4.3.1. For each element within the array:

Values: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

tx_disparity

A Boolean set by the PCS Transmit process to indicate the running disparity at the end of code-group transmission as a binary value. Running disparity is described in 36.2.4.3.

Values: POSITIVE
NEGATIVE

TX_EN

The TX_EN signal of the GMII as specified in Clause 35.

TX_ER

The TX_ER signal of the GMII as specified in Clause 35.

tx_even

A Boolean set by the PCS Transmit process to designate transmitted code-groups as either even- or odd-numbered code-groups as specified in 36.2.4.2.

Values: TRUE; Even-numbered code-group being transmitted.
FALSE; Odd-numbered code-group being transmitted.

tx_o_set

One of the following defined ordered sets: /C/, /T/, /R/, /I/, /LI/, /S/, /V/, or the code-group /D/.

TXD<7:0>

The TXD<7:0> signal of the GMII as specified in Clause 35.

xmit

Defined in 37.3.1.1.

The following variables are used only for the EEE capability:

assert_lpidle

Alias used for the optional LPI function, consisting of the following terms:

(TX_EN=FALSE * TX_ER=TRUE * (TXD<7:0>=0x01))

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

code_sync_status

A parameter set by the PCS Synchronization process to reflect the status of the link as viewed by the receiver.

Values: FAIL; The receiver is not synchronized to code-group boundaries.
OK; The receiver is synchronized to code-group boundaries.

idle_d

Alias for the following terms:

SUDI(![/D21.5/] * ![/D2.2/])
that uses an alternate form to support the EEE capability:
SUDI(![/D21.5/] * ![/D2.2/] * ![/D6.5/] * ![/D26.4/])

rx_lpi_active

A Boolean variable that is set to TRUE when the receiver is in a low power state and set to FALSE when it is in an active state and capable of receiving data.

rx_quiet

A Boolean variable set to TRUE while in the RX_QUIET state and set to FALSE otherwise.

tx_quiet

A Boolean variable set to TRUE when the transmitter is in the TX_QUIET state and set to FALSE otherwise. When set to TRUE, the PMD will disable the transmitter as described in 70.6.5.

36.2.5.1.4 Functions

carrier_detect

In the PCS Receive process, this function uses for input the latched code-group ([/x/]) and latched rx_even (EVEN/ODD) parameters of the SYNC_UNITDATA.indicate message from the PCS Synchronization process. When SYNC_UNITDATA.indicate message indicates EVEN, the carrier_detect function detects carrier when either:

a) A two or more bit difference between [/x/] and both /K28.5/ encodings exists (see Table 36–2); or

b) A two to nine bit difference between [/x/] and the expected /K28.5/ (based on current running disparity) exists.

Values: TRUE; Carrier is detected.
FALSE; Carrier is not detected.

check_end

Prescient End_of_Packet and Carrier_Extend function used by the PCS Receive process to set RX_ER and RXD<7:0> signals. The check_end function returns the current and next two code-groups in rx_code-group<9:0>.

DECODE ([/x]/)

In the PCS Receive process, this function takes as its argument the latched value of rx_code-group<9:0> ([/x/]) and the current running disparity, and returns the corresponding GMII RXD<7:0>, rx_Config_Reg<D7:D0>, or rx_Config_Reg<D15:D8> octet, per Table 36–1a–e. DECODE also updates the current running disparity per the running disparity rules outlined in 36.2.4.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ENCODE(x)

In the PCS Transmit process, this function takes as its argument (x), where x is a GMII TXD<7:0>, tx_Config_Reg<D7:D0>, or tx_Config_Reg<D15:D8> octet, and the current running disparity, and returns the corresponding ten-bit code-group per Table 36–1a–e. ENCODE also updates the current running disparity per Table 36–1a–e.

signal_detectCHANGE

In the PCS Synchronization process, this function monitors the signal_detect variable for a state change. The function is set upon state change detection.

Values: TRUE; A signal_detect variable state change has been detected.
FALSE; A signal_detect variable state change has not been detected (default).

NOTE—Signal_detectCHANGE is set by this function definition; it is not set explicitly in the state diagrams. Signal_detectCHANGE evaluates to its default value upon state entry.

VOID(x)

x ∈ /D/, /T/, /R/, /K28.5/. Substitutes /V/ on a per code-group basis as requested by the GMII.

If [TX_EN=FALSE * TX_ER=TRUE * TXD≠(0000 1111)],

then return /V/;

Else if [TX_EN=TRUE * TX_ER=TRUE],

then return /V/;

Else return x.

xmitCHANGE

In the PCS Transmit process, this function monitors the xmit variable for a state change. The function is set upon state change detection.

Values: TRUE; An xmit variable state change has been detected.
FALSE; An xmit variable state change has not been detected (default).

NOTE—XmitCHANGE is set by this function definition; it is not set explicitly in the state diagrams. XmitCHANGE evaluates to its default value upon entry to state TX_TEST_XMIT.

36.2.5.1.5 Counters

good_cgs

Count of consecutive valid code-groups received.

The following counter is used only for the EEE capability:

wake_error_counter

A counter that is incremented each time that the LPI receive state diagram enters the RX_WTF state indicating that a wake time fault has been detected. The counter is reflected in register 3.22 (see 45.2.3.12).

36.2.5.1.6 Messages

PMA_UNITDATA.indication(rx_code-group<9:0>)

A signal sent by the PMA Receive process conveying the next code-group received over the medium (see 36.3.1.2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_UNITDATA.request(tx_code-group<9:0>)
A signal sent to the PMA Transmit process conveying the next code-group ready for transmission over the medium (see 36.3.1.1).

PMD_SIGNAL.indication(signal_detect)
A signal sent by the PMD to indicate the status of the signal being received on the MDI.

PUDI
Alias for PMA_UNITDATA.indication(rx_code-group<9:0>).

PUDR
Alias for PMA_UNITDATA.request(tx_code-group<9:0>).

RUDI
Alias for RX_UNITDATA.indicate(parameter).

RX_UNITDATA.indicate(parameter)
A signal sent by the PCS Receive process to the PCS Auto_Negotiation process conveying the following parameters:

Parameters: INVALID; indicates that an error condition has been detected while receiving /C/ or /I/ ordered sets;
/C/; the /C/ ordered set has been received;
/I/; the /I/ ordered set has been received.

SUDI
Alias for SYNC_UNITDATA.indicate(parameters).

SYNC_UNITDATA.indicate(parameters)
A signal sent by the PCS Synchronization process to the PCS Receive process conveying the following parameters:

Parameters: [/x/]; the latched value of the indicated code-group (/x/);
EVEN/ODD; The latched state of the rx_even variable;

Value: EVEN; Passed when the latched state of rx_even=TRUE.
ODD; Passed when the latched state of rx_even=FALSE.

TX_OSET.indicate
A signal sent to the PCS Transmit ordered set process from the PCS Transmit code-group process signifying the completion of transmission of one ordered set.

The following messages are used only for the EEE capability:

PMD_RXQUIET.request(rx_quiet)
A signal sent by the PCS/PMA LPI receive state diagram to the PMD. Note that this message is ignored by devices that do not support EEE capability.

Values: TRUE: The receiver is in a quiet state and is not expecting incoming data.
FALSE: The receiver is ready to receive data.

PMD_TXQUIET.request(tx_quiet)
A signal sent by the PCS/PMA LPI transmit state diagram to the PMD. Note that this message is ignored by devices that do not support the optional LPI mechanism.

Values: TRUE: The transmitter is in a quiet state and may cease to transmit a signal on the medium.
FALSE: The transmitter is ready to transmit data.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

36.2.5.1.7 Timers

cg_timer
: A continuous free-running timer.

  Values: The condition cg_timer_done becomes true upon timer expiration.

  Restart when: immediately after expiration; restarting the timer resets the condition cg_timer_done.

  Duration: 8 ns nominal.

  If the GMII is implemented, cg_timer shall expire synchronously with the rising edge of GTX_CLK (see tolerance required for GTX_CLK in 35.5.2.3). In the absence of a GMII, cg_timer shall expire every 8 ns ± 0.01%. In the PCS transmit code-group state diagram, the message PMA_UNITDATA.request is issued concurrently with cg_timer_done.

The following timers are used only for the EEE capability:

rx_tq_timer
: This timer is started when the PCS receiver enters the START_TQ_TIMER state. The timer terminal count is set to T_{QR}. When the timer reaches terminal count, it will set the rx_tq_timer_done = TRUE.

rx_tw_timer
: This timer is started when the PCS receiver enters the RX_WAKE state. The timer terminal count shall not exceed the maximum value of T_{WR} in Table 36–9. When the timer reaches terminal count, it will set the rx_tw_timer_done = TRUE.

rx_wf_timer
: This timer is started when the PCS receiver enters the RX_WTF state, indicating that the receiver has encountered a wake time fault. The rx_wf_timer allows the receiver an additional period in which to synchronize or return to the quiescent state before a link failure is indicated. The timer terminal count is set to T_{WTF}. When the timer reaches terminal count, it will set the rx_wf_timer_done = TRUE.

tx_ts_timer
: This timer is started when the PCS transmitter enters the TX_SLEEP state. The timer terminal count is set to T_{SL}. When the timer reaches terminal count, it will set the tx_ts_timer_done = TRUE.

tx_tq_timer
: This timer is started when the PCS transmitter enters the TX_QUIET state. The timer terminal count is set to T_{QL}. When the timer reaches terminal count, it will set the tx_tq_timer_done = TRUE.

tx_tr_timer
: This timer is started when the PCS transmitter enters the TX_REFRESH state. The timer terminal count is set to T_{UL}. When the timer reaches terminal count, it will set the tx_tr_timer_done = TRUE.

36.2.5.2 State diagrams

36.2.5.2.1 Transmit

The PCS Transmit process is depicted in two state diagrams: PCS Transmit ordered set and PCS Transmit code-group. The PCS shall implement its Transmit process as depicted in Figure 36–5 and Figure 36–6, including compliance with the associated state variables as specified in 36.2.5.1.

The Transmit ordered set process continuously sources ordered sets to the Transmit code-group process. When initially invoked, and when the Auto-Negotiation process xmit flag indicates CONFIGURATION, the Auto-Negotiation process is invoked. When the Auto-Negotiation process xmit flag indicates IDLE, and between packets (as delimited by the GMII), /I/ is sourced. Upon the assertion of TX_EN by the GMII when the Auto-Negotiation process xmit flag indicates DATA, the SPD ordered set is sourced. Following the SPD, /D/ code-groups are sourced until TX_EN is deasserted. Following the deassertion of TX_EN, EPD ordered sets are sourced. If TX_ER is asserted when TX_EN is deasserted and carrier extend error is not indicated by TXD, /R/ ordered sets are sourced for as many GTX_CLK periods as TX_ER is asserted with a delay of two GTX_CLK periods to first source the /T/ and /R/ ordered sets. If carrier extend error is indicated by TXD during carrier extend, /V/ ordered sets are sourced. If TX_EN and TX_ER are both deasserted, the /R/ ordered set may be sourced, after which the sourcing of /I/ is resumed. If, while TX_EN is asserted, the TX_ER signal is asserted, the /V/ ordered set is sourced except when the SPD ordered set is selected for sourcing.

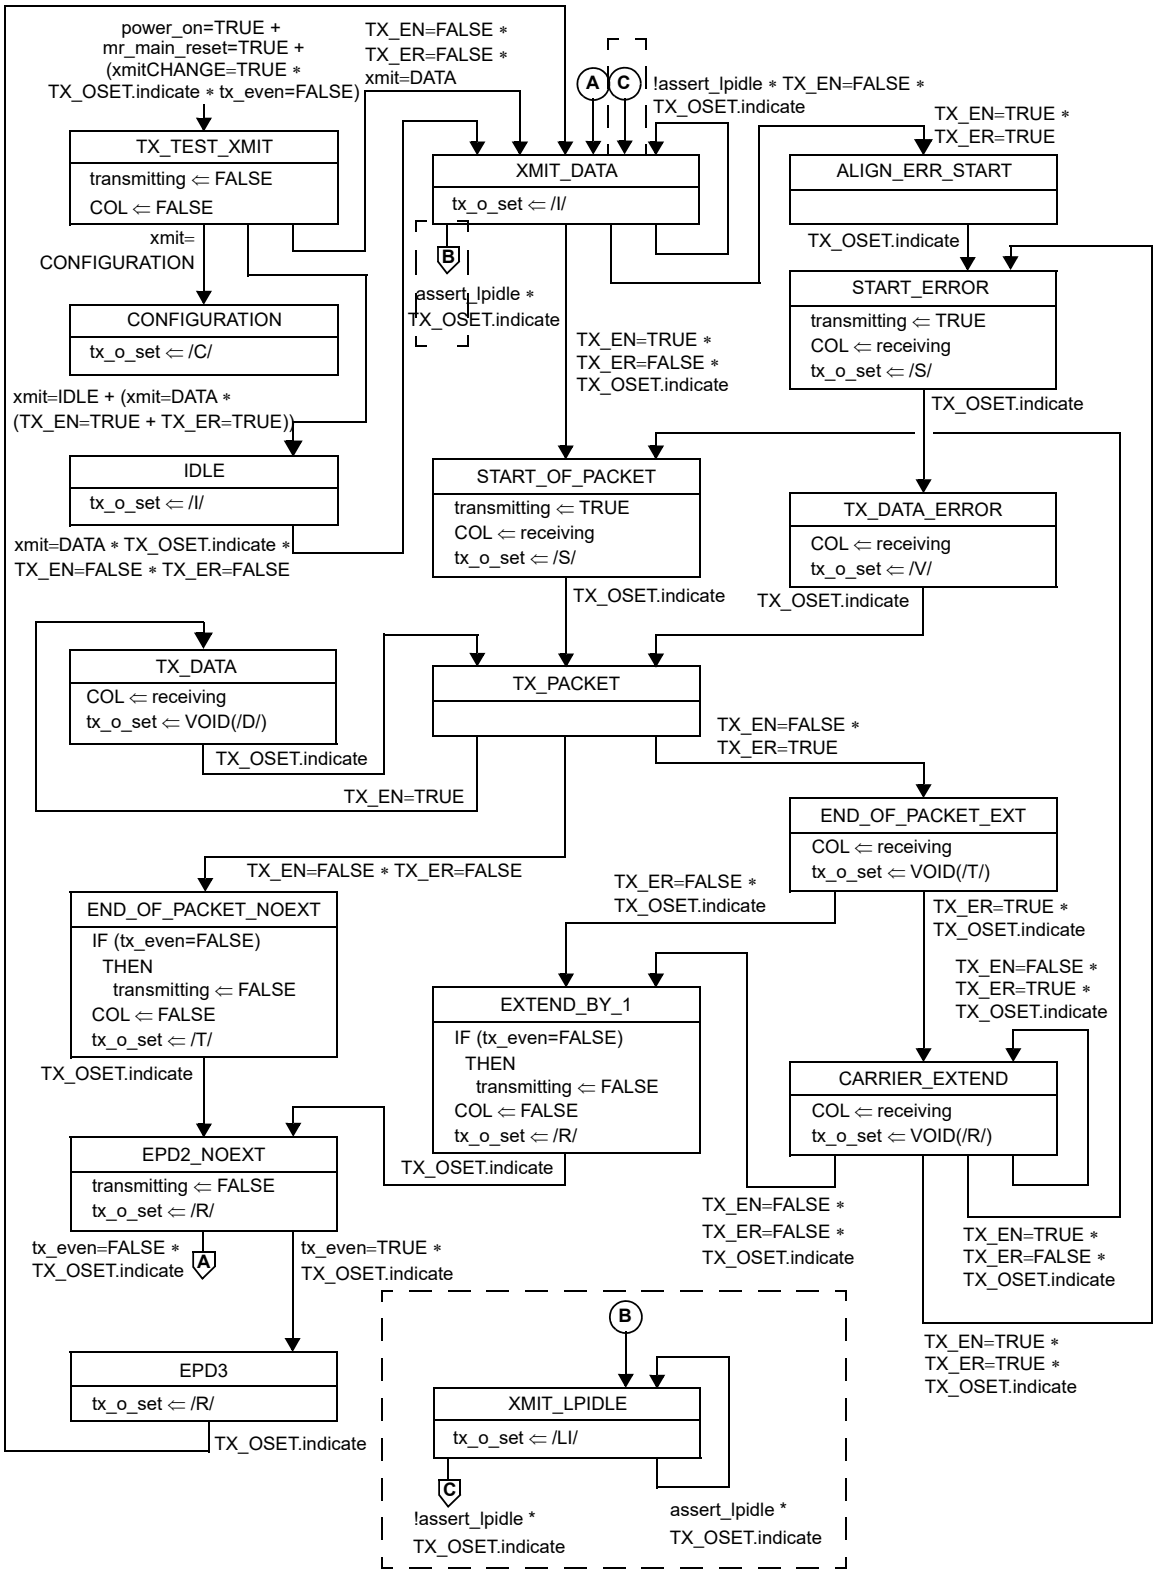
Collision detection is implemented by noting the occurrence of carrier receptions during transmissions, following the models of 10BASE-T and 100BASE-X.

The Transmit code-group process continuously sources tx_code-group<9:0> to the PMA based on the ordered sets sourced to it by the Transmit ordered set process. The Transmit code-group process determines the proper code-group to source based on even/odd-numbered code-group alignment, running disparity requirements, and ordered set format.

36.2.5.2.2 Receive

The PCS shall implement its Receive process as depicted in Figure 36–7a and Figure 36–7b, including compliance with the associated state variables as specified in 36.2.5.1.

The PCS Receive process continuously passes RXD<7:0> and sets the RX_DV and RX_ER signals to the GMII based on the received code-group from the PMA.



When the Auto-Negotiation process xmit flag indicates CONFIGURATION or IDLE, the PCS Receive process continuously passes /C/ and /I/ ordered sets and rx_Config_Reg<D15:D0> to the Auto-Negotiation process.

36.2.5.2.3 State variable function carrier_detect(x)

The detection of carrier on the underlying channel is used both by the MAC (via the GMII CRS signal and the Reconciliation sublayer) for deferral purposes, and by the PCS Transmit process for collision detection. A carrier event, signaled by the assertion of receiving, is indicated by the detection of a difference between the received code-group and /K28.5/ as specified in 36.2.5.1.4.

A carrier event is in error if it does not start with an SPD. The PCS Receive process performs this function by continuously monitoring incoming code-groups for specific patterns that indicate non-/I/ activity such as SPD. The detection of an SPD carrier event causes the PCS to substitute the value (01010101) for the SPD, set RXD<7:0> to this value, and assert RX_DV. The pattern substituted for the SPD is consistent with the preamble pattern expected by the MAC. The detection of a non-SPD carrier event (false carrier) causes the PCS to substitute the value (00001110) for the code-group received, set RXD<7:0> to this value, and assert RX_ER.

36.2.5.2.4 Code-group stream decoding

Subsequent to the detection of an SPD carrier event, the PCS Receive process performs the DECODE function on the incoming code-groups, passing decoded data to the GMII, including those corresponding to the remainder of the MAC preamble and SFD. The GMII signal RX_ER is asserted upon decoding any code-group following the SPD that neither is a valid /D/ code-group nor follows the EPD rules in 36.2.4.15.1.

Packets are terminated with an EPD as specified in 36.2.4.15. The PCS Receive process performs the check_end function to preserve the ability of the MAC to properly delimit the FCS at the end of a packet.

Detection of /T/R/R/ or /T/R/K28.5/ by the check_end function denotes normal (i.e., non-error) packet termination. Detection of /R/R/R/ by the check_end function denotes packet termination with error and Carrier_Extend processing. Detection of /K28.5/D/K28.5/ by the check_end function denotes packet termination with error. Detection of /K28.5/(D21.5 or D2.2)/D0.0 by the check_end function denotes packet termination with error.

36.2.5.2.5 Carrier sense

The Carrier Sense process generates the signal CRS on the GMII, which (via the Reconciliation sublayer) the MAC uses for deferral.

The PCS shall implement the Carrier Sense process as depicted in Figure 36–8 including compliance with the associated state variables as specified in 36.2.5.1.

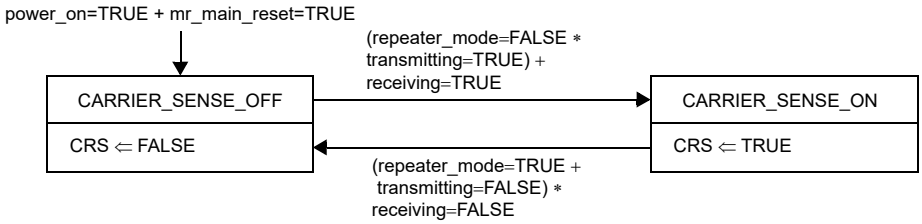

Figure 36–8—Carrier sense state diagram

36.2.5.2.6 Synchronization

The PCS shall implement the Synchronization process as depicted in Figure 36–9 including compliance with the associated state variables as specified in 36.2.5.1. The Synchronization process is responsible for determining whether the underlying receive channel is ready for operation. Failure of the underlying channel typically causes the PMA client to suspend normal actions.

A receiver that is in the LOSS_OF_SYNC state and that has acquired bit synchronization attempts to acquire code-group synchronization via the Synchronization process. Code-group synchronization is acquired by the detection of three ordered sets containing commas in their leftmost bit positions without intervening invalid code-group errors. Upon acquisition of code-group synchronization, the receiver enters the SYNC_ACQUIRED_1 state. Acquisition of synchronization ensures the alignment of multi-code-group ordered sets to even-numbered code-group boundaries.

Once synchronization is acquired, the Synchronization process tests received code-groups in sets of four code-groups and employs multiple sub-states, effecting hysteresis, to move between the SYNC_ACQUIRED_1 and LOSS_OF_SYNC states.

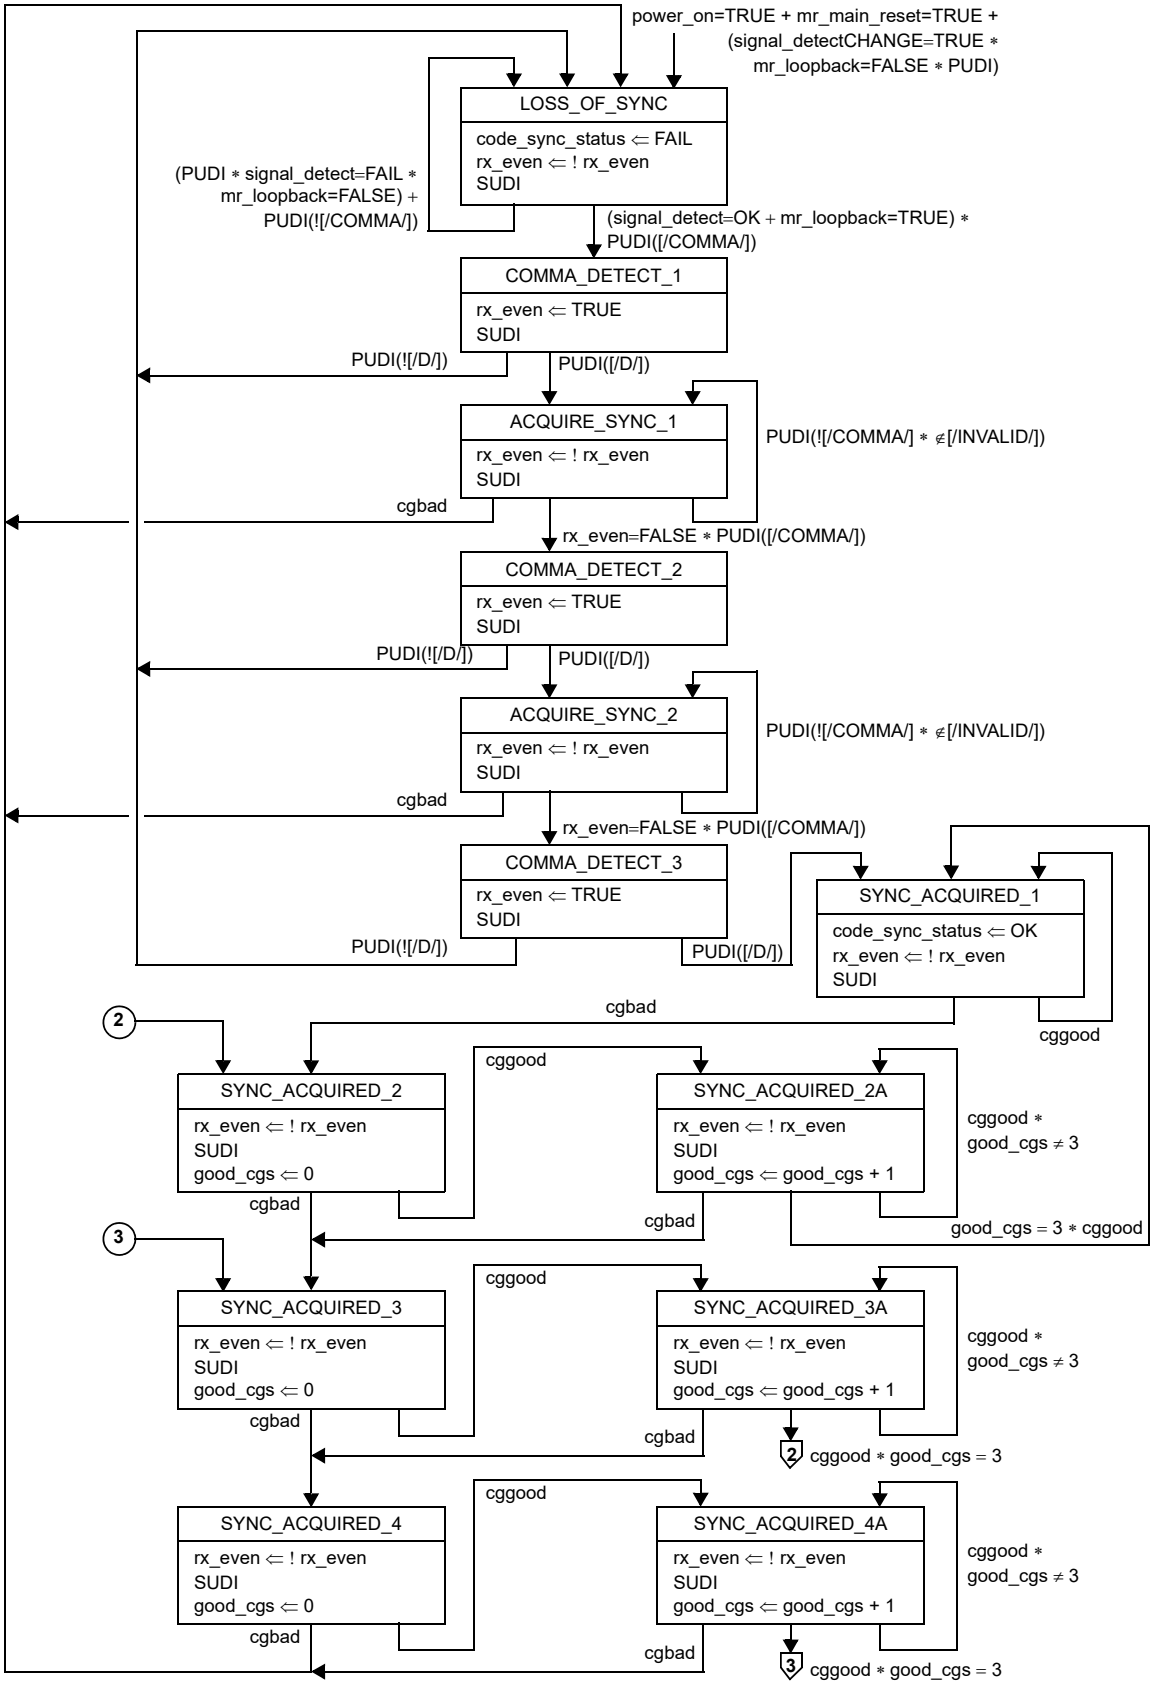

Figure 36–9—Synchronization state diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For EEE capability the relationship between sync_status and code_sync_status is given by Figure 36–7c; otherwise sync_status is identical to code_sync_status.

The condition sync_status=FAIL existing for ten ms or more causes the PCS Auto-Negotiation process to begin and the PCS Transmit process to begin transmission of /C/. Upon reception of three matching /C/s from the link partner, the PCS Auto-Negotiation process begins. The internal signal receiving is deasserted in the PCS Receive process LINK_FAILED state when sync_status=FAIL and a code-group is received.

36.2.5.2.7 Auto-Negotiation process

The Auto-Negotiation process shall provide the means to exchange configuration information between two devices that share a link segment and to automatically configure both devices to take maximum advantage of their abilities. When the PCS is used with a PMD other than 1000BASE-KX, see Clause 37 for a description of the Auto-Negotiation process and Config_Reg contents.

Upon successful completion of the Clause 37 Auto-Negotiation process, the xmit flag is set to DATA and normal link operation is enabled. The Clause 37 Auto-Negotiation process utilizes the PCS Transmit and Receive processes to convey Config_Reg contents.

When the PCS is used with a 1000BASE-KX PMD, see Clause 73 for a description of the Auto-Negotiation process. The following requirements apply to a PCS used with a 1000BASE-KX PMD. The PCS shall support the primitive AN_LINK.indication(link_status) (see 73.9). The parameter link_status shall take the value FAIL when sync_status=FAIL and the value OK when sync_status=OK. The primitive shall be generated when the value of link_status changes. If Clause 37 Auto-Negotiation is not present, xmit shall be DATA. If Clause 37 Auto-Negotiation is present the variable mr_an_enable should be false when 1000BASE-KX operation is negotiated through Clause 73 Auto-Negotiation.

36.2.5.2.8 LPI state diagram

A PCS that supports the EEE capability shall implement the LPI transmit process as shown in Figure 36–10. The transmit LPI state diagram controls tx_quiet, which disables the transmitter when true.

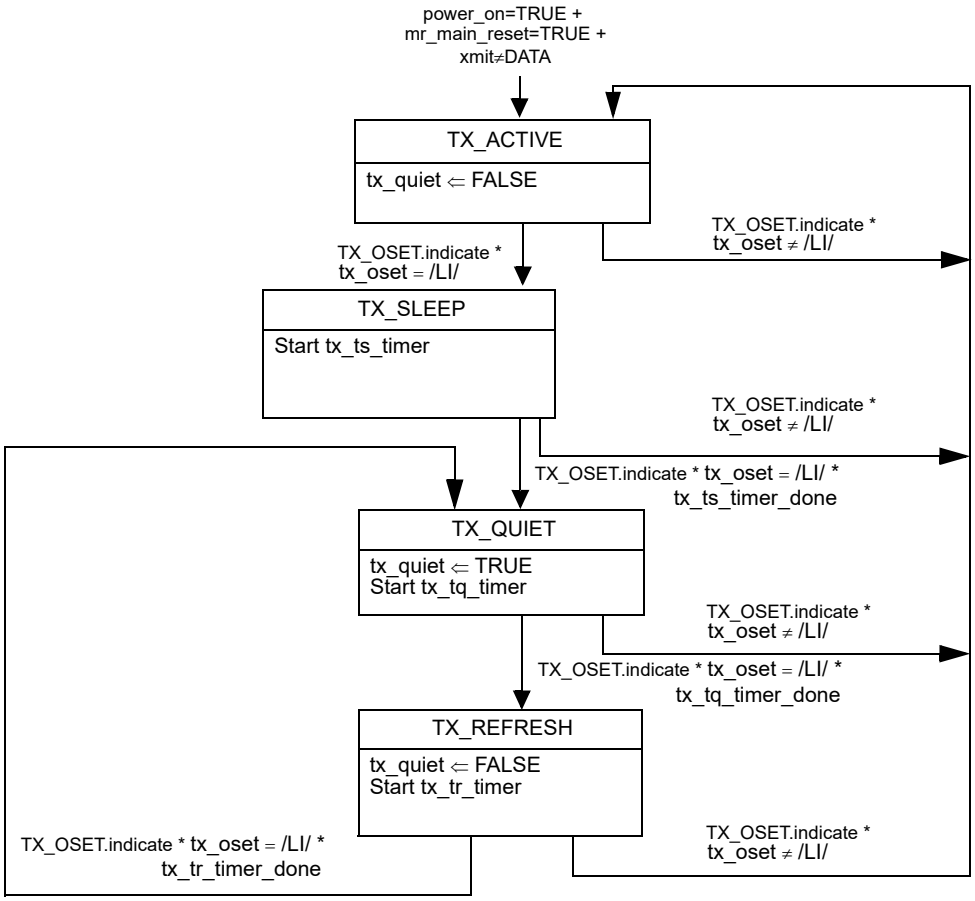

Figure 36–10—LPI Transmit state diagram

The timer values for these state diagrams are shown in Table 36–8 for transmit and Table 36–9 for receive.

Table 36–8—Transmitter LPI timing parameters

Parameter	Description	Min	Max	Units
T_{SL}	Local Sleep Time from entering the TX_SLEEP state to when tx_quiet is set to TRUE	19.9	20.1	µs
T_{QL}	Local Quiet Time from when tx_quiet is set to TRUE to entry into the TX_REFRESH state	2.5	2.6	ms
T_{UL}	Local Refresh Time from entry into the TX_REFRESH state to entry into the TX_QUIET state	19.9	20.1	µs

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 36–9—Receiver LPI timing parameters

Parameter	Description	Min	Max	Units
T_{QR}	The time the receiver waits for signal detect to be set to OK while in the LP_IDLE_D, LPI_K and RX_QUIET states before asserting a rx_fault	3	4	ms
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault (WTF)		11	µs
T_{WTF}	Wake time fault recovery time		1	ms

36.2.5.2.9 LPI status and management

For EEE capability, the PCS indicates to the management system that LPI is currently active in the receive and transmit directions using the status variables shown in Table 36–10.

Table 36–10—MDIO status indications

MDIO status variable	Register name	Register address	Note
Tx LPI received	PCS status register 1	3.1.11	Latched version of 3.1.9
Rx LPI received	PCS status register 1	3.1.10	Latched version of 3.1.8
Tx LPI indication	PCS status register 1	3.1.9	TRUE when not in state TX_ACTIVE
Rx LPI indication	PCS status register 1	3.1.8	TRUE when not in state RX_ACTIVE

36.3 Physical Medium Attachment (PMA) sublayer

36.3.1 Service Interface

The PMA provides a Service Interface to the PCS. These services are described in an abstract manner and do not imply any particular implementation. The PMA Service Interface supports the exchange of code-groups between PCS entities. The PMA converts code-groups into bits and passes these to the PMD, and vice versa. It also generates an additional status indication for use by its client.

The following primitives are defined:

PMA_UNITDATA.request(tx_code-group<9:0>)
PMA_UNITDATA.indication(rx_code-group<9:0>)

36.3.1.1 PMA_UNITDATA.request

This primitive defines the transfer of data (in the form of code-groups) from the PCS to the PMA. PMA_UNITDATA.request is generated by the PCS Transmit process.

36.3.1.1.1 Semantics of the service primitive

PMA_UNITDATA.request(tx_code-group<9:0>)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The data conveyed by PMA_UNITDATA.request is the tx_code-group<9:0> parameter defined in 36.2.5.1.3.

36.3.1.1.2 When generated

The PCS continuously sends, at a nominal rate of 125 MHz, as governed by GTX_CLK, tx_code-group<9:0> to the PMA.

36.3.1.1.3 Effect of receipt

Upon receipt of this primitive, the PMA generates a series of ten PMD_UNITDATA.request primitives, requesting transmission of the indicated tx_bit to the PMD.

36.3.1.2 PMA_UNITDATA.indication

This primitive defines the transfer of data (in the form of code-groups) from the PMA to the PCS. PMA_UNITDATA.indication is used by the PCS Synchronization process.

36.3.1.2.1 Semantics of the service primitive

PMA_UNITDATA.indication(rx_code-group<9:0>)

The data conveyed by PMA_UNITDATA.indication is the rx_code-group<9:0> parameter defined in 36.2.5.1.3.

36.3.1.2.2 When generated

The PMA continuously sends one rx_code-group<9:0> to the PCS corresponding to the receipt of each code-group aligned set of ten PMD_UNITDATA.indication primitives received from the PMD. The nominal rate of the PMA_UNITDATA.indication primitive is 125 MHz, as governed by the recovered bit clock.

36.3.1.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

36.3.2 Functions within the PMA

Figure 36–3 depicts the mapping of the octet-wide data path of the GMII to the ten-bit-wide code-groups of the PMA Service Interface, and on to the serial PMD Service Interface. The PMA comprises the PMA Transmit and PMA Receive processes for 1000BASE-X.

The PMA Transmit process serializes tx_code-groups into tx_bits and passes them to the PMD for transmission on the underlying medium, according to Figure 36–3. Similarly, the PMA Receive process deserializes rx_bits received from the PMD according to Figure 36–3. The PMA continuously conveys ten-bit code-groups to the PCS, independent of code-group alignment. After code-group alignment is achieved, based on comma detection, the PCS converts code-groups into GMII data octets, according to 36.2.5.2.2.

The proper alignment of a comma used for code-group synchronization is depicted in Figure 36–3.

NOTE—Strict adherence to manufacturer-supplied guidelines for the operation and use of PMA serializer components is required to meet the jitter specifications of Clause 38 and Clause 39. The supplied guidelines should address the quality of power supply filtering associated with the transmit clock generator, and also the purity of the reference clock fed to the transmit clock generator.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

36.3.2.1 Data delay

The PMA maps a nonaligned one-bit data path from the PMD to an aligned, ten-bit-wide data path to the PCS, on the receive side. Logically, received bits have to be buffered to facilitate proper code-group alignment. These functions necessitate an internal PMA delay of at least ten bit times. In practice, code-group alignment may necessitate even longer delays of the incoming rx_bit stream.

36.3.2.2 PMA transmit function

The PMA Transmit function passes data unaltered (except for serializing) from the PCS directly to the PMD. Upon receipt of a PMA_UNITDATA.request primitive, the PMA Transmit function shall serialize the ten bits of the tx_code-group<9:0> parameter and transmit them to the PMD in the form of ten successive PMD_UNITDATA.request primitives, with tx_code-group<0> transmitted first, and tx_code-group<9> transmitted last.

36.3.2.3 PMA receive function

The PMA Receive function passes data unaltered (except for deserializing and possible code-group slipping upon code-group alignment) from the PMD directly to the PCS. Upon receipt of ten successive PMD_UNITDATA.indication primitives, the PMA shall assemble the ten received rx_bits into a single ten-bit value and pass that value to the PCS as the rx_code-group<9:0> parameter of the primitive PMA_UNITDATA.indication, with the first received bit installed in rx_code-group<0> and the last received bit installed in rx_code-group<9>. An exception to this operation is specified in 36.3.2.4.

36.3.2.4 Code-group alignment

In the event the PMA sublayer detects a comma+ within the incoming rx_bit stream, it may realign its current code-group boundary, if necessary, to that of the received comma+ as shown in Figure 36–3. This process is referred to in this document as code-group alignment. The code-group alignment function shall be operational when the EN_CDET signal is active (see 36.3.3.1). During the code-group alignment process, the PMA sublayer may delete or modify up to four, but shall delete or modify no more than four, ten-bit code-groups in order to align the correct receive clock and code-group containing the comma+. This process is referred to as code-group slipping.

In addition, the PMA sublayer is permitted to realign the current code-group boundary upon receipt of a comma-pattern.

36.3.3 A physical instantiation of the PMA Service Interface

The ten-bit interface (TBI) is defined to provide compatibility among devices designed by different manufacturers. There is no requirement for a compliant device to implement or expose the TBI. A TBI implementation shall behave as described in 36.3.3 through 36.3.6.

Figure 36–11 illustrates the TBI functions and interfaces.

As depicted in Figure 36–11, the TBI connects the PCS and PMD sublayers. It is equipped for full duplex transmission of code-groups at 125 MHz. The PCS provides code-groups on tx_code-group<9:0> to the PMA transmit function, which latches the data on the rising edge of the 125 MHz PMA_TX_CLK. An internal Clock Multiplier Unit uses PMA_TX_CLK to generate the internal 1250 MHz bit clock that is used to serialize the latched data out of the PMA outputs, if EWRAP is Low, or internally loop it back to the Receive function input, if EWRAP is High.

The PMA Receive function accepts 1250 Mb/s serial data from either the PMD, if EWRAP is Low, or the PMA transmit function, if EWRAP is High, and extracts a bit clock and recovered data from the serial inputs

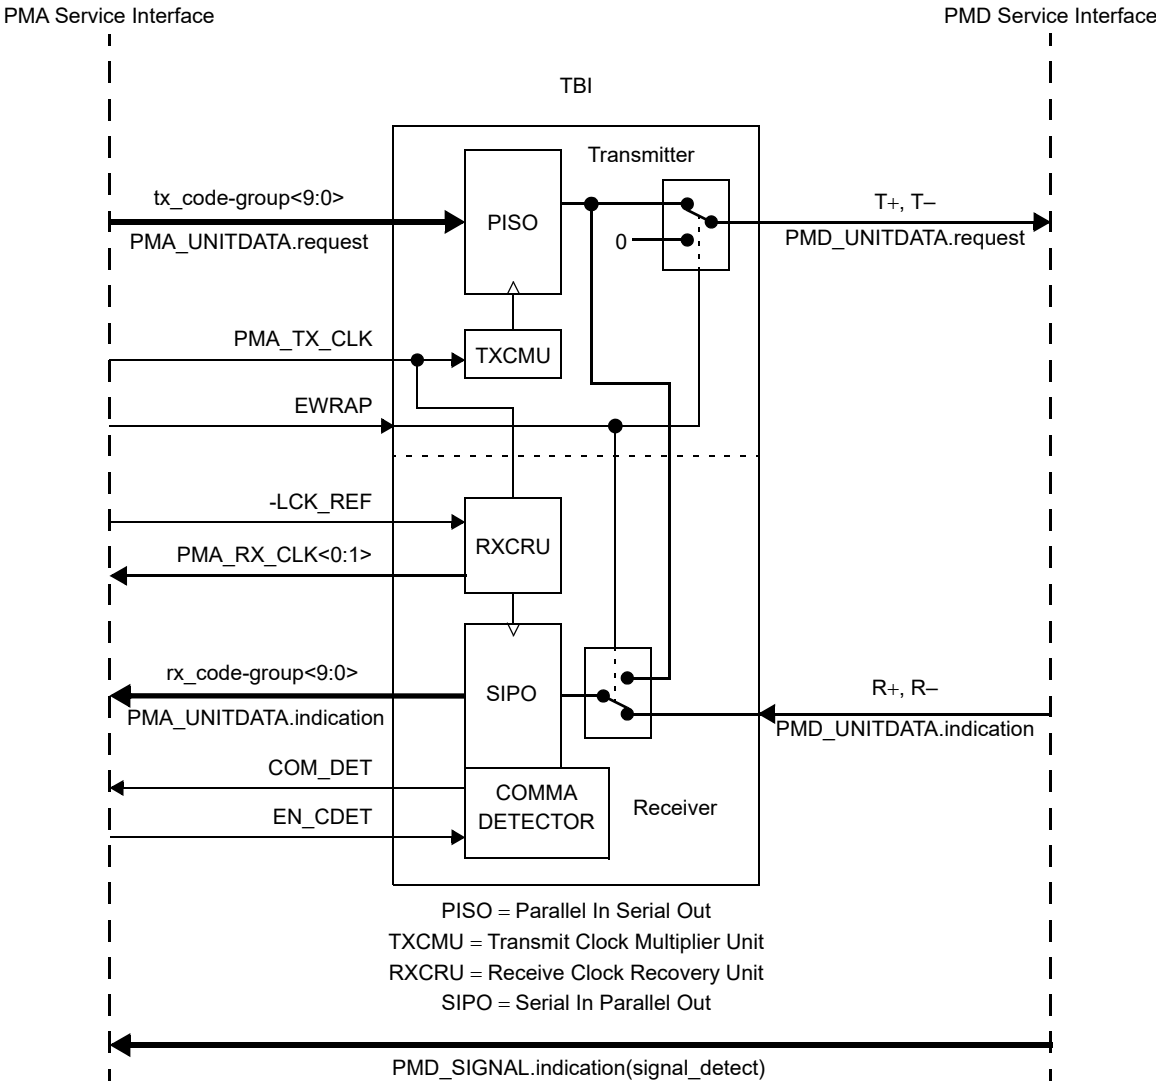

Figure 36–11—TBI reference diagram

in a clock recovery unit. The recovered data is deserialized and conveyed to the PCS on rx_code-group<9:0>. Two recovered clocks, PMA_RX_CLK<0> and PMA_RX_CLK<1>, which are at 1/20th the baud (62.5 MHz), and 180° out-of-phase with one another, are used by the PMA to latch the received 10-bit code-groups. Even and odd-numbered code-groups are latched on successive rising edges of PMA_RX_CLK<1> and PMA_RX_CLK<0>, respectively.

Code-group alignment occurs in the PMA Receive function, if enabled by EN_CDET, when a comma pattern occurs in the PHY bit stream. Upon recognition of the comma pattern, the PMA Receive function outputs the ten-bit code-group containing the comma on rx_code-group<9:0> with the alignment specified in Figure 36–3, and clocked on the rising edge of PMA_RX_CLK<1>.

This TBI provides a Lock_to_Reference_Clock (LCK_REF) input, which may be used to lock the clock recovery unit to PMA_TX_CLK rather than incoming serial data. In the absence of serial data or invalid serial data, the PMA Receive function passes many 8B/10B invalid code-groups across to the PCS. A circuit may be constructed to detect those errors and, using LCK_REF, re-center the receiver clock recovery unit to PMA_TX_CLK in preparation for reacquiring lock on the incoming PHY bit stream.

36.3.3.1 Required signals

In the event this TBI is made accessible, the signals listed in Table 36–11 are provided, with the meanings described elsewhere in this section. Note that not all of these signals are used by the PCS.

Table 36–11—TBI required signals

Symbol	Signal Name	Signal Type	Active Level
tx_code-group<9:0>	Transmit Data	Input	H
PMA_TX_CLK	Transmit Clock	Input	↑
EWRAP	Enable Wrap	Input	H
rx_code-group<9:0>	Receive Data	Output	H
PMA_RX_CLK<0>	Receive Clock 0	Output	↑
PMA_RX_CLK<1>	Receive Clock 1	Output	↑
COM_DET	Comma Detect	Output	H
-LCK_REF	Lock to Reference	Input	L
EN_CDET	Enable Comma Detect	Input	H

tx_code-group<9:0>
: The 10-bit parallel transmit data presented to the PMA for serialization and transmission onto the media. The order of transmission is tx_bit<0> first, followed by tx_bit<1> through tx_bit<9>.

PMA_TX_CLK
: The 125 MHz transmit code-group clock. This code-group clock is used to latch data into the PMA for transmission. PMA_TX_CLK is also used by the transmitter clock multiplier unit to generate the 1250 MHz bit rate clock. PMA_TX_CLK is also used by the receiver when -LCK_REF is active. PMA_TX_CLK has a ±100 ppm tolerance. PMA_TX_CLK is derived from GMII GTX_CLK.

EWRAP
: EWRAP enables the TBI to electrically loop transmit data to the receiver. The serial outputs on the transmitter are held in a static state during EWRAP operation. EWRAP may optionally be tied low (function disabled).

rx_code-group<9:0>
: Presents the 10-bit parallel receive code-group data to the PCS for further processing. When code-groups are properly aligned, any received code-group containing a comma is clocked by PMA_RX_CLK<1>.

PMA_RX_CLK<0>
: The 62.5 MHz receive clock that the protocol device uses to latch odd-numbered code-groups in the received PHY bit stream. This clock may be stretched during code-group alignment, and is not shortened.

PMA_RX_CLK<1>
: The 62.5 MHz receive clock that the protocol device uses to latch even-numbered code-groups in the received PHY bit stream. PMA_RX_CLK<1> is 180° out-of-phase with PMA_RX_CLK<0>. This clock may be stretched during code-group alignment, and is not shortened.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

COM_DET

An indication that the code-group associated with the current PMA_RX_CLK<1> contains a valid comma. When EN_CDET is asserted, the TBI is required to detect and code-group-align to the comma+ bit sequence. Optionally, the TBI may also detect and code-group-align to the comma- bit sequence. The TBI provides this signal as an output, but it may not be used by the PCS.

-LCK_REF

Causes the TBI clock recovery unit to lock to PMA_TX_CLK. The TBI attains frequency lock within 500 ms. This function is not used by the PCS.

NOTE—Implementers may find it necessary to use this signal in order to meet the clock recovery requirements of the PMA sublayer.

EN_CDET

Enables the TBI to perform the code-group alignment function on a comma (see 36.2.4.9, 36.3.2.4). When EN_CDET is asserted the code-group alignment function is operational. This signal is optionally generated by the PMA client. The PMA sublayer may leave this function always enabled.

36.3.3.2 Summary of control signal usage

Table 36–12 lists all possible combinations of control signals on this TBI, including the valid combinations as well as the undefined combinations.

Table 36–12—TBI combinations of control signals

EWRAP	-LCK_REF	EN_CDET	Interpretation
L	L	L	Undefined
L	L	H	Lock receiver clock recovery unit to PMA_TX_CLK
L	H	L	Normal operation; COM_DET disabled
L	H	H	Normal operation; COM_DET enabled
H	L	L	Undefined
H	L	H	Undefined
H	H	L	Loop transmit data to receiver; COM_DET disabled
H	H	H	Loop transmit data to receiver; COM_DET enabled

36.3.4 General electrical characteristics of the TBI

In the event this TBI is made accessible, the following subclauses specify the general electrical characteristics of the TBI.

36.3.4.1 DC characteristics

Table 36–13 documents the required dc parametric attributes required of all inputs to the TBI and the dc parametric attributes associated with the outputs of the TBI. The inputs levels to the TBI may be greater than the power supply level (i.e., 5 V output driving V_{OH} into a 3.3 V input), tolerance to mismatched input levels is optional. TBI devices not tolerant of mismatched inputs levels that meet Table 36–13 requirements are still regarded as compliant.

Table 36–13—DC specifications

Symbol	Parameter	Conditions		Min	Typ	Max	Units
V_{OH}	Output High Voltage	I_{OH} = –400 µA	V_{CC} = Min	2.2	3.0	V_{CC}	V
V_{OL}	Output Low Voltage	I_{OL} = 1 mA	V_{CC} = Min	GND	0.25	0.6	V
V_{IH}	Input High Voltage			2.0	—	V_{CC}[a] + 10%	V
V_{IL}	Input Low Voltage			GND	—	0.8	V
I_{IH}	Input High Current	V_{CC} = Max	V_{IN} = 2.4 V	—	—	40	µA
I_{IL}	Input Low Current	V_{CC} = Max	V_{IN} = 0.4 V	—	—	600	µA
C_{IN}	Input Capacitance			—	—	4.0	pf
t_R	Clock Rise Time	0.8 V to 2.0 V		0.7	—	2.4	ns
t_F	Clock Fall Time	2.0 V to 0.8 V		0.7	—	2.4	ns
t_R	Data Rise Time	0.8 V to 2.0 V		0.7	—	—	ns
t_F	Data Fall Time	2.0 V to 0.8 V		0.7	—	—	ns

[a]Refers to the driving device power supply.

36.3.4.2 Valid signal levels

All ac measurements are made from the 1.4 V level of the clock to the valid input or output data levels as shown in Figure 36–12.

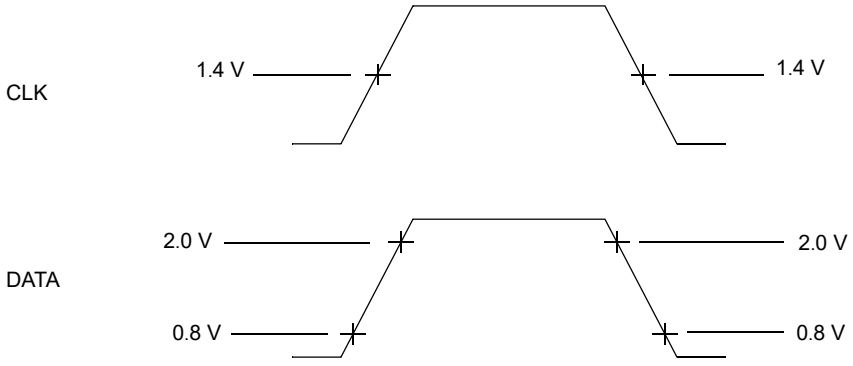

Figure 36–12—Input/output valid level for ac measurements

36.3.4.3 Rise and fall time definition

The rise and fall time definition for PMA_TX-CLK, PMA_RX_CLK<0>, PMA_RX_CLK<1>, and DATA is shown in Figure 36–13.

36.3.4.4 Output load

All ac measurements are assumed to have the output load of 10 pF.

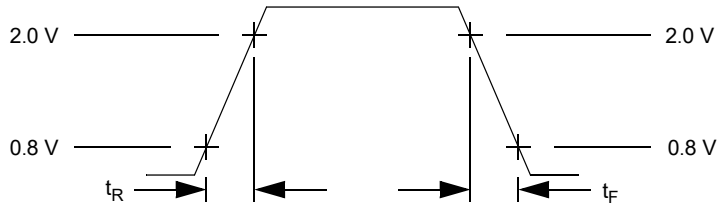

Figure 36–13—Rise and fall time definition

36.3.5 TBI transmit interface electrical characteristics

In the event this TBI is made accessible, the electrical characteristics of the TBI transmit interface are specified in the following subclauses.

36.3.5.1 Transmit data (tx_code-group<9:0>)

The tx_code-group<9:0> signals carry data from the PCS to PMA to be serialized to the PMD in accordance with the transmission order shown in Figure 36–3. All tx_code-group<9:0> data conforms to valid code-groups.

36.3.5.2 TBI transmit interface timing

The TBI transmit interface timings in Table 36–14 defines the TBI input. All transitions in Figure 36–14 are specified from the PMA_TX_CLK reference level (1.4 V), to valid input signal levels.

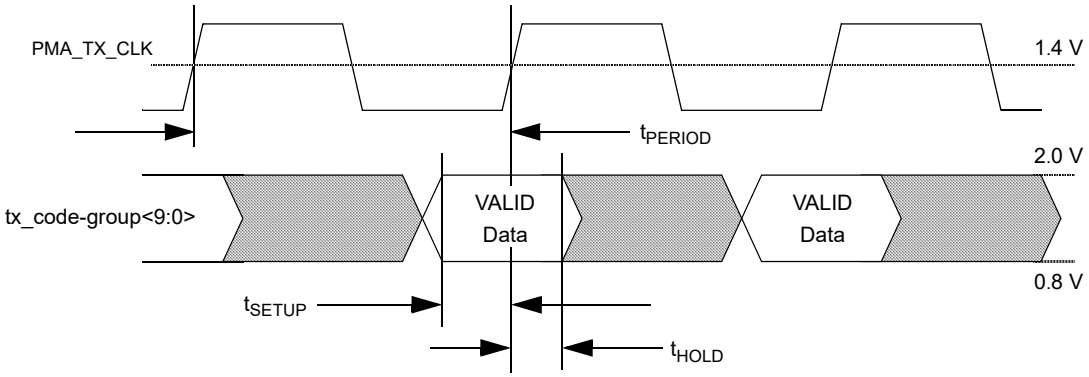

Figure 36–14—TBI transmit interface timing diagram

Table 36–14—Transmit AC specification

Parameter	Description	Min	Typ	Max	Units
t_{PERIOD}	PMA_TX_CLK Period[a]	—	8	—	ns
t_{SETUP}	Data Setup to ↑ PMA_TX_CLK	2.0	—	—	ns
t_{HOLD}	Data Hold from ↑ PMA_TX_CLK	1.0	—	—	ns
t_{DUTY}	PMA_TX_CLK Duty Cycle	40		60	%

[a] ±100 ppm tolerance on PMA_TX_CLK frequency.

36.3.6 TBI receive interface electrical characteristics

In the event this TBI is made accessible, the electrical characteristics of the TBI receive interface are specified in the following subclauses.

The TBI receive interface timings in Table 36–15 define the TBI output. All transitions in Figure 36–15 are specified from the Receive Clock reference level (1.4 V) to valid output signal levels.

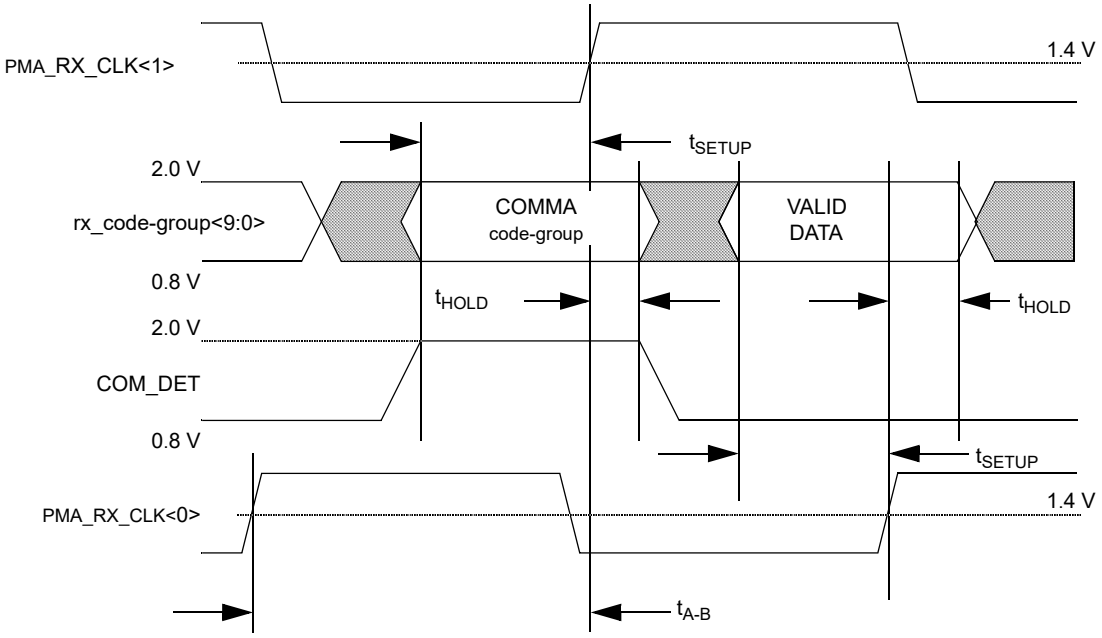

Figure 36–15—TBI receive interface timing diagram

36.3.6.1 Receive data (rx_code-group<9:0>)

The 10 receive data signals rx_code-group<9:0> carry parallel data from the PMA sublayer to the PCS sublayer during the rising edge of the receive clock (i.e., PMA_RX_CLK<1> transitions from Low to High). When properly locked and aligned, data transferred across this interface conforms to valid code-groups.

36.3.6.2 Receive clock (PMA_RX_CLK<0>, PMA_RX_CLK<1>)

The receive clocks supplied to the PCS and GMII are derived from the recovered bit clock. PMA_RX_CLK<0> is 180° out-of-phase with PMA_RX_CLK<1>.

Table 36–15 specifies a receive clock drift (t_{DRIFT}), which is applicable under all input conditions to the receiver (including invalid or absent input signals). However, the restriction does not apply when the receiver is realigning to a new code-group boundary and the receive clocks are being stretched to a new code-group boundary to avoid short pulses. During the code-group alignment process the receive clocks may slow a fixed amount, depending on the bit offset of the new comma and then return to the nominal frequency.

36.3.7 Loopback mode

Loopback mode shall be provided, as specified in this subclause, by the transmitter and receiver of a device as a test function to the device. When Loopback mode is selected, transmission requests passed to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 36–15—Receive bus AC specification

Parameter	Description	Min	Typ	Max	Units
t_{FREQ}	PMA_RX_CLK Frequency	—	62.5	—	MHz
t_{DRIFT}	PMA_RX_CLK Drift Rate[a]	0.2	—	—	µs/MHz
t_{SETUP}	Data Setup Before ↑PMA_RX_CLK	2.5	—	—	ns
t_{HOLD}	Data Hold After ↑PMA_RX_CLK	1.5	—	—	ns
t_{DUTY}	PMA_RX_CLK Duty Cycle	40	—	60	%
t_{A-B}	PMA_RX_CLK Skew	7.5	—	8.5	ns

[a]t_{DRIFT} is the (minimum) time for PMA_RX_CLK to drift from 63.5 MHz to 64.5 MHz or 60 MHz to 59 MHz from the PMA_RX_CLK lock value. It is applicable under all input signal conditions (except where noted in 36.3.2.4), including invalid or absent input signals, provided that the receiver clock recovery unit was previously locked to PMA_TX_CLK or to a valid input signal.

transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. A device is explicitly placed in Loopback mode (i.e., Loopback mode is not the normal mode of operation of a device). The method of implementing Loopback mode is not defined by this standard.

NOTE—Loopback mode may be implemented either in the parallel or the serial circuitry of a device.

36.3.7.1 Receiver considerations

A receiver may be placed in Loopback mode. Entry into or exit from Loopback mode may result in a temporary loss of synchronization.

36.3.7.2 Transmitter considerations

A transmitter may be placed in Loopback mode. The external behavior of a transmitter (i.e., the activity of a transmitter with respect to its attached link) in Loopback mode is specified in 22.2.4.1.2.

36.3.8 Test functions

A limited set of test functions may be provided as an implementation option for testing of the transmitter function.

Some test functions that are not defined by this standard may be provided by certain implementations. Compliance with the standard is not affected by the provision or exclusion of such functions by an implementation. Random jitter test patterns for 1000BASE-X are specified in Annex 36A.

A typical test function is the ability to transmit invalid code-groups within an otherwise valid PHY bit stream. Certain invalid PHY bit streams may cause a receiver to lose word and/or bit synchronization. See ANSI INCITS 230-1994 (FC-PH), subclause 5.4, for a more detailed discussion of receiver and transmitter behavior under various test conditions.

36.4 Compatibility considerations

There is no requirement for a compliant device to implement or expose any of the interfaces specified for the PCS or PMA. Implementations of a GMII shall comply with the requirements as specified in Clause 35. Implementations of a TBI shall comply with the requirements as specified in 36.3.3.

36.5 Delay constraints

In half duplex mode, proper operation of a CSMA/CD LAN demands that there be an upper bound on the propagation delays through the network. This implies that MAC, PHY, and repeater implementations conform to certain delay minima and maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices. MAC constraints are contained in 35.2.4 and Table 35–5. Topological constraints are contained in Clause 42.

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The reference point for all MDI measurements is the 50% point of the mid-cell transition corresponding to the reference bit, as measured at the MDI.

36.5.1 MDI to GMII delay constraints

Every 1000BASE-X PHY associated with a GMII shall comply with the bit time delay constraints specified in Table 36–16 for half duplex operation and Table 36–17 for full duplex operation. These figures apply for all 1000BASE-X PMDs. For any given implementation, the assertion and deassertion delays on CRS shall be equal.

Table 36–16—MDI to GMII delay constraints (half duplex mode)

Sublayer measurement points	Event	Min (bit time)	Max (bit time)	Input timing reference	Output timing reference
GMII ⇔ MDI	TX_EN=1 sampled to MDI output	—	136	PMA_TX_CLK rising	1st bit of /S/
	MDI input to CRS assert	—	192	1st bit of /S/	
	MDI input to CRS deassert	—	192	1st bit of /K28.5/	
	MDI input to COL assert	—	192	1st bit of /S/	
	MDI input to COL deassert	—	192	1st bit of /K28.5/	
	TX_EN=1 sampled to CRS assert	—	16	PMA_TX_CLK rising	
	TX_EN=0 sampled to CRS deassert	—	16	PMA_TX_CLK rising	

Table 36–17—MDI to GMII delay constraints (full duplex mode)

Sublayer measurement points	Event	Min (bit time)	Max (bit time)	Input timing reference	Output timing reference
GMII ⇔ MDI	TX_EN=1 sampled to MDI output	—	136	PMA_TX_CLK rising	1st bit of /S/
	MDI input to RX_DV deassert	—	192	1st bit of /T/	RX_CLK rising

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

36.5.2 DTE delay constraints (half duplex mode)

Every DTE with a 1000BASE-X PHY shall comply with the bit time delay constraints specified in Table 36–18 for half duplex operation. These figures apply for all 1000BASE-X PMDs.

Table 36–18—DTE delay constraints (half duplex mode)

Sublayer measurement points	Event	Min (bit time)	Max (bit time)	Input timing reference	Output timing reference
MAC ⇔ MDI	MAC transmit start to MDI output	—	184		1st bit of /S/
	MDI input to MDI output (worst-case nondeferred transmit)	—	440	1st bit of /S/	1st bit of /S/
	MDI input to collision detect	—	240	1st bit of /S/	
	MDI input to MDI output = Jam (worst-case collision response)	—	440	1st bit of /S/	1st bit of jam

36.5.3 Carrier deassertion/assertion constraint (half duplex mode)

To ensure fair access to the network, each DTE operating in half duplex mode shall, additionally, satisfy the following:

(MAX MDI to MAC Carrier Deassert Detect) – (MIN MDI to MAC Carrier Assert Detect) < 16 bits

36.6 Environmental specifications

All equipment subject to this clause shall conform to the requirements of 14.7 and applicable sections of ISO/IEC 11801:1995.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

36.7 Protocol implementation conformance statement (PICS) proforma for Clause 36, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 1000BASE-X[76]

36.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 36, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 1000BASE-X, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

36.7.2 Identification

36.7.2.1 Implementation identification

Supplier (Note 1)	
Contact point for inquiries about the PICS (Note 1)	
Implementation Name(s) and Version(s) (Notes 1 and 3)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s) (Note 2)	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

36.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 36, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer, type 1000BASE-X
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[76] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

37. Auto-Negotiation function, type 1000BASE-X

37.1 Overview

37.1.1 Scope

Clause 37 describes the 1000BASE-X Auto-Negotiation (AN) function that allows a device (local device) to advertise modes of operation it possesses to a device at the remote end of a link segment (link partner) and to detect corresponding operational modes that the link partner may be advertising. Backplane Auto-Negotiation defined in Clause 73 applies to 1000BASE-KX.

The Auto-Negotiation function exchanges information between two devices that share a link segment and automatically configures both devices to take maximum advantage of their abilities. Auto-Negotiation is performed with /C/ and /I/ ordered sets defined in Clause 36, such that no packet or upper layer protocol overhead is added to the network devices. Auto-Negotiation does not test the link segment characteristics (see 37.1.4).

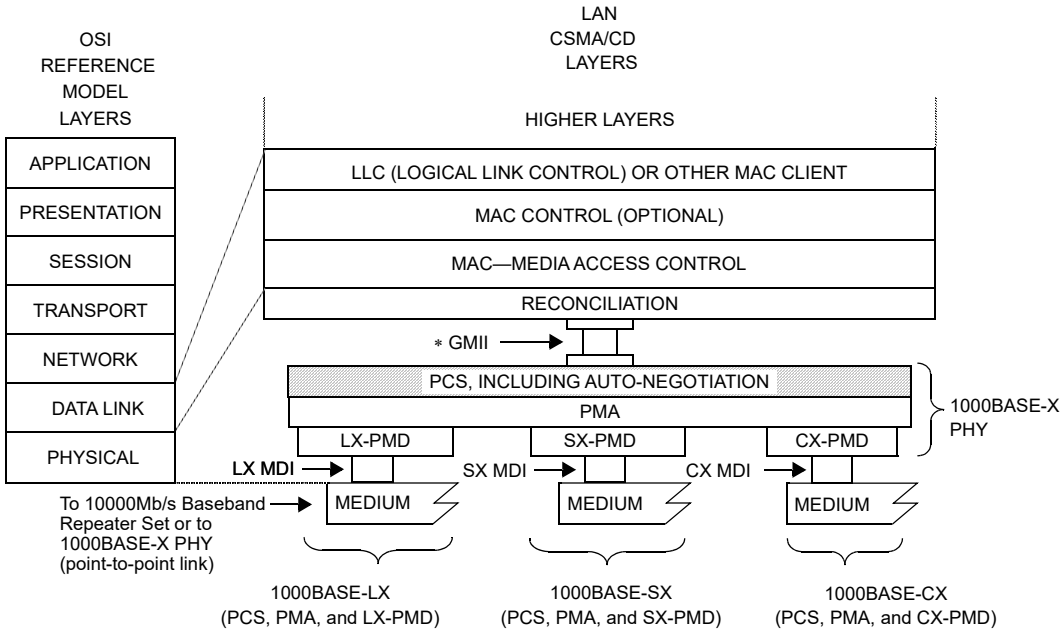
The function allows the devices at both ends of a link segment to advertise abilities, acknowledge receipt and understanding of the common mode(s) of operation that both devices share, and to reject the use of operational modes that are not shared by both devices. Where more than one common mode exists between the two devices, a mechanism is provided to allow the devices to resolve to a single mode of operation using a predetermined priority resolution function (see 37.2.4.2). The Auto-Negotiation function allows the devices to switch between the various operational modes in an ordered fashion, permits management to disable or enable the Auto-Negotiation function, and allows management to select a specific operational mode.

The basic mechanism to achieve Auto-Negotiation is to pass information encapsulated within /C/ ordered sets. /C/ ordered sets are directly analogous to FLP Bursts as defined in Clause 28 that accomplish the same function. Each device issues /C/ ordered sets at power up, on command from management, upon detection of a PHY error, or due to user interaction.

37.1.2 Application perspective/objectives

This Auto-Negotiation function is designed to be expandable and allows 1000BASE-X devices to self-configure a jointly compatible operating mode.

The following are the objectives of Auto-Negotiation:



a) To be reasonable and cost-effective to implement;
b) Provide a sufficiently extensible code space to
    1) Meet existing and future requirements;
    2) Allow simple extension without impacting the installed base;
    3) Accommodate remote fault signals; and
    4) Accommodate link partner ability detection.
c) Allow manual or Network Management configuration to override the Auto-Negotiation;
d) Capable of operation in the absence of Network Management;
e) Allow the ability to renegotiate;
f) Operate when
    1) The link is initially connected;
    2) A device at either end of the link is powered up, reset, or a renegotiation request is made.
g) May be enabled by automatic, manual, or Network Management intervention;
h) To complete the base page Auto-Negotiation function in a bounded time period;

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

i) To operate using a peer-to-peer exchange of information with no requirement for a master device (not master-slave);
j) To be robust in the 1000BASE-X MDI cable noise environment;
k) To not significantly impact EMI/RFI emissions.

37.1.3 Relationship to architectural layering

The Auto-Negotiation function is provided at the PCS sublayer of the Physical Layer of the OSI reference model as shown in Figure 36–1. Devices that support multiple modes of operation may advertise this fact using this function. The transfer of information is observable only at the MDI or on the medium.

MDI=MEDIUM DEPENDENT INTERFACE
GMII=GIGABIT MEDIA INDEPENDENT INTERFACE
PCS=PHYSICAL CODING SUBLAYER
PMA=PHYSICAL MEDIUM ATTACHMENT
PHY=PHYSICAL LAYER DEVICE
PMD=PHYSICAL MEDIUM DEPENDENT
LX-PMD=PMD FOR FIBER—LONG WAVELENGTH, Clause 38
SX-PMD=PMD FOR FIBER—SHORT WAVELENGTH, Clause 38
CX-PMD=PMD FOR 150 Ω BALANCED COPPER CABLING, Clause 39

NOTE—The PMD sublayers are mutually independent.
∗ GMII is optional.

Figure 37–1—Location of the Auto-Negotiation function

37.1.4 Compatibility considerations

37.1.4.1 Auto-Negotiation

1000BASE-X devices provide the Auto-Negotiation function. Auto-Negotiation does not perform cable tests, such as cable performance measurements. Some PHYs that explicitly require use of high-performance cables, may require knowledge of the cable type, or additional robustness tests (such as monitoring invalid code-groups, CRC, or framing errors) to determine if the link segment is adequate.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

37.1.4.2 Management interface

Manual or automatic invocation of Auto-Negotiation may result in frame loss. Exit from Auto-Negotiation to normal MAC frame processing may also result in frame loss as one link end may resume normal MAC frame processing ahead of its link partner.

37.1.4.2.1 GMII management interface

Auto-Negotiation signaling does not occur across the GMII. Control of the Auto-Negotiation function may be supported through the Management Interface of the GMII or equivalent. If an explicit embodiment of the GMII is supported, the Control and Status registers to support the Auto-Negotiation function shall be implemented in accordance with the definitions in Clause 22 and 37.2.5.

37.1.4.3 Interoperability between Auto-Negotiation compatible devices

An Auto-Negotiation compatible device decodes the Base Page from the received /C/ ordered sets and examines the contents for the highest common ability that both devices share. Both devices acknowledge correct receipt of each other's Base Page by responding with Base Pages containing the Acknowledge Bit set. After both devices complete acknowledgment, and any desired Next Page exchange, both devices enable the highest common mode negotiated. The highest common mode is resolved using the priority resolution hierarchy specified in 37.2.4.2.

37.1.4.4 User Configuration with Auto-Negotiation

Rather than disabling Auto-Negotiation, the following behavior is suggested in order to improve interoperability with other Auto-Negotiation devices. When a device is configured for one specific mode of operation (e.g. 1000BASE-X Full Duplex), it is recommended to continue using Auto-Negotiation but only advertise the specifically selected ability or abilities. This can be done by the Management agent only setting the bits in the advertisement registers that correspond to the selected abilities.

37.2 Functional specifications

The Auto-Negotiation function includes the Auto-Negotiation Transmit, Receive, and Arbitration functions specified in the state diagram of Figure 37–6 and utilizes the PCS Transmit and Receive state diagrams of Clause 36.

The Auto-Negotiation function provides an optional Management function that provides a control and status mechanism. Management may provide additional control of Auto-Negotiation through the Management function, but the presence of a management agent is not required.

37.2.1 Config_Reg encoding

The Config_Reg Base Page, transmitted by a local device or received from a link partner, is encapsulated within a /C/ ordered set and shall convey the encoding shown in Figure 37–2. Auto-Negotiation supports additional pages using the Next Page function. Encodings for the Config_Reg(s) used in Next Page exchange are defined in 37.2.4.3.1. Config_Reg bits labeled as "rsvd" are reserved and shall be set to a logic zero.

37.2.1.1 Base Page to management register mapping

Several Base Page bits shown in Figure 37–2 indicate capabilities that are sourced from management registers. Table 37–1 describes how the management registers map to the management function interface signals. The bit format of the rx_Config_Reg<D15:D0> and tx_Config_Reg<D15:D0> variables is context dependent, relative to the state of the Auto-Negotiation function, and is presented here and in 37.2.4.3.1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

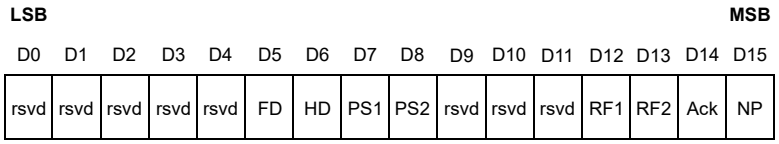

Figure 37–2—Config_Reg Base Page encoding

Table 37–1—Config_Reg Base Page to management register mapping

Config_Reg Base Page bits	Management register bit
Full Duplex (FD)	4.5 Full Duplex
Half Duplex (HD)	4.6 Half Duplex
PAUSE (PS1)	4.7 PAUSE
ASM_DIR (PS2)	4.8 ASM_DIR
Remote Fault (RF2, RF1)	4.13:12 Remote Fault

37.2.1.2 Full duplex

Full Duplex (FD) is encoded in bit D5 of the base Config_Reg.

37.2.1.3 Half duplex

Half Duplex (HD) is encoded in bit D6 of the base Config_Reg.

37.2.1.4 Pause

Pause (PS1, PS2) is encoded in bits D7 and D8 of the base Config_Reg. Pause provides a pause capability exchange mechanism. Pause encoding is specified in Table 37–2.

Table 37–2—Pause encoding

PAUSE (D7)	ASM_DIR(D8)	Capability
0	0	No PAUSE
0	1	Asymmetric PAUSE toward link partner
1	0	Symmetric PAUSE
1	1	Both Symmetric PAUSE and Asymmetric PAUSE toward local device

The PAUSE bit indicates that the device is capable of providing the symmetric PAUSE functions as defined in Annex 31B. The ASM_DIR bit indicates that asymmetric PAUSE operation is supported. The value of the PAUSE bit when the ASM_DIR bit is set indicates the direction PAUSE frames are supported for flow

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

across the link. Asymmetric PAUSE configuration results in independent enabling of the PAUSE receive and PAUSE transmit functions as defined by Annex 31B. See 37.2.4.2 for PAUSE configuration resolution.

37.2.1.5 Remote fault

Sensing of faults in a device as well as subsequent association of faults with the Remote Fault function encodings is optional. Remote Fault (RF) is encoded in bits D12 and D13 of the Base Page. The default value is 0b00. Remote Fault provides a standard transport mechanism for the transmission of simple fault and error information. The Remote Fault function may indicate to the link partner that a fault or error condition has occurred. The two Remote Fault bits, RF1 and RF2, shall be encoded as specified in Table 37–3.

Table 37–3—Remote Fault encoding

RF1	RF2	Description
0	0	No error, link OK (default)
0	1	Offline
1	0	Link_Failure
1	1	Auto-Negotiation_Error

If the local device has no mechanism to detect a fault or associate a fault condition with the received Remote Fault function encodings, then it shall transmit the default Remote Fault encoding of 0b00.

A local device may indicate it has sensed a fault to its link partner by setting a nonzero Remote Fault encoding in its Base Page and renegotiating.

If the local device sets the Remote Fault encoding to a nonzero value, it may also use the Next Page function to specify information about the fault that has occurred. Remote Fault Message Page Codes may be specified for this purpose (see Annex 28C).

The Remote Fault encoding shall remain set until after the Auto-Negotiation process transitions into IDLE_DETECT state with the Base Page, at which time the Remote Fault encoding is reset to 0b00. On receipt of a Base Page with a nonzero Remote Fault encoding, the device shall set the Remote Fault bit in the Status register (1.4) to logic one if the GMII management function is present.

37.2.1.5.1 No error, link OK

A Remote Fault encoding of 0b00 indicates that no remote fault or error condition has been detected by the local device.

37.2.1.5.2 Offline

A Remote Fault encoding of 0b01 indicates that the local device is going Offline. A local device may indicate Offline prior to powering off, running transmitter tests, or removing the local device from the active configuration. A local device need not successfully complete the Auto-Negotiation function from the receive perspective after completing the Auto-Negotiation function indicating Offline from its transmit perspective before further action is taken (e.g., powering off, running transmitter tests, removing the local device from the active configuration, etc.).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

37.2.1.5.3 Link_Failure

A Remote Fault encoding of 0b10 indicates that the local device has detected a Link_Failure condition indicated by loss of synchronization. While sync_status = FAIL, remote fault information is not signaled. When sync_status becomes OK, stored remote fault information is signaled (see 36.2.5.1.3 and 36.2.5.2.6). Another indication of a link failure condition is provided by the reception of /C/ ordered sets having rx_Config_Reg<D15:D0> = 0 for a duration exceeding link_timer.

37.2.1.5.4 Auto-Negotiation_Error

A Remote Fault encoding of 0b11 indicates that the local device has detected a Auto-Negotiation_Error. Resolution which precludes operation between a local device and link partner shall be reflected to the link partner by the local device by indicating a Remote Fault code of Auto-Negotiation_Error.

37.2.1.6 Acknowledge

Acknowledge (Ack) is encoded in bit D14 of the base and Next Pages (see Figures 37–2, 37–3, and 37–4). The Ack bit is used by the Auto-Negotiation function to indicate that a device has successfully received its link partner's base or Next Page.

This bit is set to logic one after the device has successfully received at least three consecutive and matching rx_Config_Reg<D15:D0> values (ignoring the Acknowledge bit value), and, for Next Page exchanges, remains set until the Next Page information has been loaded into the AN Next Page transmit register (register 7). After the Auto-Negotiation process COMPLETE_ACKNOWLEDGE state has been entered, the tx_Config_Reg<D15:D0> value is transmitted for the link_timer duration.

37.2.1.7 Next Page

The Base Page and subsequent Next Pages may set the NP bit to a logic one to request Next Page transmission. Subsequent Next Pages may set the NP bit to a logic zero in order to communicate that there is no more Next Page information to be sent (see 37.2.4.3). A device may implement Next Page ability and choose not to engage in a Next Page exchange by setting the NP bit to a logic zero.

37.2.2 Transmit function requirements

The Transmit function provides the ability to transmit /C/ ordered sets. After Power-On, link restart, or renegotiation, the Transmit function transmits /C/ ordered sets containing zeros indicating the restart condition. After sending sufficient zeros, the /C/ ordered sets contain the Config_Reg Base Page value defined in 37.2.1. The local device may modify the Config_Reg value to disable an ability it possesses, but shall not transmit an ability it does not possess. This makes possible the distinction between local abilities and advertised abilities so that devices capable of multiple modes may negotiate to a mode lower in priority than the highest common local ability.

The Transmit function shall utilize the PCS Transmit process specified in 36.2.5.2.1.

37.2.2.1 Transmit function to Auto-Negotiation process interface requirements

The variable tx_Config_Reg<D15:D0> is derived from mr_adv_abilities<16:1> or mr_np_tx<16:1>. This variable is the management representation of the AN advertisement register during Base Page exchange and the AN Next Page transmit register during Next Page exchange.

When the xmit variable is set to CONFIGURATION by the Auto-Negotiation process, the PCS Transmit function encodes the contents of the tx_Config_Reg<D15:D0> into the appropriate /C/ ordered set for transmission onto the MDI. When the xmit variable is set to IDLE by the Auto-Negotiation process, the PCS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Transmit function transmits /I/ ordered sets onto the MDI. When the xmit variable is set to DATA by the Auto-Negotiation process, the PCS Transmit function transmits /I/ ordered sets interspersed with packets onto the MDI.

37.2.3 Receive function requirements

The PCS Receive function detects /C/ and /I/ ordered sets. For received /C/, the PCS Receive function decodes the information contained within, and stores the data in rx_Config_Reg<D15:D0>.

The Receive function shall utilize the PCS Receive process specified in 36.2.5.2.2.

37.2.3.1 Receive function to Auto-Negotiation process interface requirements

The PCS Receive function provides the Auto-Negotiation process and management function with the results of rx_Config_Reg<D15:D0>. The PCS Auto-Negotiation function generates the ability_match, acknowledge_match, consistency_match, and idle_match signals.

The PCS Receive process sets the RX_UNITDATA.indicate(/C/) message when a /C/ ordered set is received.

The PCS Receive process sets the RX_UNITDATA.indicate(/I/) message when a /I/ ordered set is received.

The PCS Receive process sets the RX_UNITDATA.indicate(INVALID) message when an error condition is detected while not in normal receive processing (when the xmit variable is set to CONFIGURATION). The error conditions are specified in the PCS Receive state diagram of Figure 36–7a.

37.2.4 Arbitration process requirements

The Arbitration process ensures proper sequencing of the Auto-Negotiation function using the Transmit function and Receive function. The Arbitration process enables the Transmit function to advertise and acknowledge abilities. Upon completion of Auto-Negotiation information exchange, the Arbitration process determines the highest common mode using the priority resolution function and enables the appropriate functions.

37.2.4.1 Renegotiation function

A renegotiation request from any entity, such as a management agent, causes the Auto-Negotiation function to be restarted from Auto-Negotiation process state AN_ENABLE.

37.2.4.2 Priority resolution function

Since a local device and a link partner may have multiple common abilities, a mechanism to resolve which mode to configure is necessary. Auto-Negotiation shall provide the Priority Resolution function that defines the hierarchy of supported technologies.

Priority resolution is supported for pause and half/full duplex modes of operation. Full duplex shall have priority over half duplex mode. Priority resolution for pause capability shall be resolved as specified by Table 37–4. Resolution that precludes operation between a local device and link partner is reflected to the link partner by the local device by indicating a Remote Fault code of Auto-Negotiation_Error, if the remote fault function is supported (see 37.2.1.5).

1	1	1	—	Enable PAUSE Transmit and Receive	Enable PAUSE Transmit and Receive

37.2.4.3 Next Page function

Support for transmission and reception of additional page encodings beyond the Base Page (Next Pages) is optional. The Next Page function enables the exchange of user or application specific data. Data is carried by Next Pages of information, which follow the transmission and acknowledgment procedures used for the Base Pages. Two types of Next Page encodings are defined:

a) Message Pages (contain an eleven-bit formatted Message Code Field);
b) Unformatted Pages (contain an eleven-bit Unformatted Code Field).

A dual acknowledgment system is used. Acknowledge (Ack) is used to acknowledge receipt of the information (see 37.2.1.6). Acknowledge 2 (Ack2) is used to indicate that the receiver is able to act on the information (or perform the task) defined in the message (see 37.2.4.3.5).

Next Page operation is controlled by the same two mandatory control bits, NP and Ack, used in the Base Page. The Toggle bit is used to ensure proper synchronization between the local device and the link partner.

Next Page exchange occurs after the Base Page exchange has been completed. Next Page exchange consists of using the Auto-Negotiation arbitration process to send Message or Unformatted Next Pages. Unformatted Pages can be combined to send extended messages. Any number of Next Pages may be sent in any order.

Subsequent to Base Page exchange, a Next Page exchange is invoked only if both the local device and its link partner have advertised Next Page ability during the Base Page exchange.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the Next Page function is supported by both link ends and a Next Page exchange has been invoked by both link ends, the Next Page exchange ends when both ends of a link segment set their NP bits to logic zero, indicating that neither link end has further pages to transmit. It is possible for the link partner to have more Next Pages to transmit than the local device. Once a local device has completed transmission of its Next Page information, if any, it shall transmit Message Pages with a Null message code (see Annex 28C) and the NP bit set to logic zero while its link partner continues to transmit valid Next Pages. A device shall recognize reception of Message Pages with a Null message code and the NP bit set to logic zero as the end of its link partner's Next Page information. If both the local device and its link partner advertise Next Page ability in their Base Pages, then both devices shall send at least one Next Page. If a device advertises Next Page ability and has no Next Page information to send but is willing to receive Next Pages, and its link partner also advertises Next Page ability, it shall send a Message Page with a Null message code. The variable mr_np_loaded is set to TRUE to indicate that the local device has loaded its Auto-Negotiation Next Page transmit register with Next Page information for transmission.

A local device that requires or expects an Ack2 response from its link partner (to indicate a Next Page transaction has been received and can be acted upon), has to terminate the Next Page sequence with a Null message code, in order to allow the link partner to transport the final Ack2 status.

37.2.4.3.1 Next Page encodings

The Next Page shall use the encoding shown in Figure 37–3 and Figure 37–4 for the NP, Ack, MP, Ack2, and T bits. The eleven-bit field <D10:D0> is encoded as a Message Code Field if the MP bit is logic one and an Unformatted Code Field if MP is set to logic zero. The bit format of the rx_Config_Reg<D15:D0> and tx_Config_Reg<D15:D0> variables is context dependent, relative to the state of the Auto-Negotiation function, and is presented here and in 37.2.1.1.

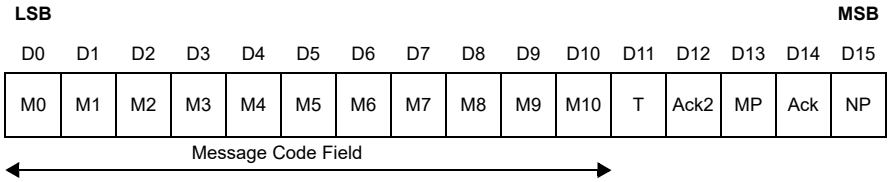

Figure 37–3—Message page encoding

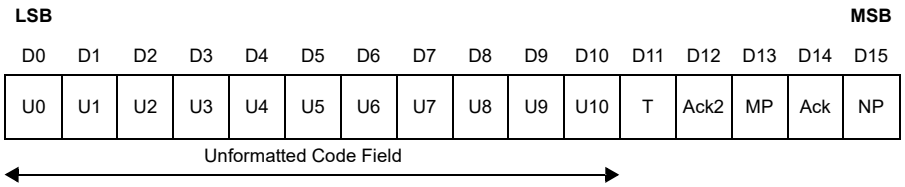

Figure 37–4—Unformatted page encoding

37.2.4.3.2 Next Page

The Next Page (NP) bit is used by the Next Page function to indicate whether or not this is the last Next Page to be transmitted. NP shall be set as follows:

logic zero = Last page.
logic one = Additional Next Page(s) to follow.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

37.2.4.3.3 Acknowledge

As defined in 37.2.1.6.

37.2.4.3.4 Message page

The Message Page (MP) bit is used by the Next Page function to differentiate a Message Page from an Unformatted Page. MP shall be set as follows:

logic zero = Unformatted Page.
logic one = Message Page.

37.2.4.3.5 Acknowledge 2

The Acknowledge 2 (Ack2) bit is used by the Next Page function to indicate that a device has the ability to comply with the message. Ack2 shall be set as follows:

logic zero = Cannot comply with message.
logic one = Can comply with message.

37.2.4.3.6 Toggle

The Toggle (T) bit is used by the Arbitration function to ensure synchronization with the link partner during Next Page exchange. This bit takes the opposite value of the Toggle bit in the previously exchanged page. The initial value of the Toggle bit in the first Next Page transmitted is the inverse of tx_Config_Reg<D11> in the Base Page that preceded the Next Page exchange and, therefore, may assume a value of logic one or zero. The Toggle bit is set as follows:

logic zero = Previous value of tx_Config_Reg<D11> equalled logic one.
logic one = Previous value of tx_Config_Reg<D11> equalled logic zero.

37.2.4.3.7 Message page encoding

Message Pages are formatted pages that carry a single predefined message code, which is enumerated in Annex 28C. There are 2048 message codes available. The allocation of these codes is specified in Annex 28C. If the Message Page bit is set to logic one, the bit encoding of the Config_Reg value is interpreted as a Message Page.

37.2.4.3.8 Message Code Field

Message Code Field (M<10:0>) is an eleven-bit wide field, encoding 2048 possible messages. Message Code Field definitions are shown in Annex 28C. Combinations not specified are reserved for future use. Reserved combinations of the Message Code Field shall not be transmitted.

37.2.4.3.9 Unformatted page encoding

Unformatted Pages carry the messages indicated by Message Pages. Five control bits are predefined, the remaining eleven bits are interpreted based on the preceding message page. If the Message Page bit is set to logic zero, then the bit encoding of the Config_Reg value is interpreted as an Unformatted Page.

37.2.4.3.10 Unformatted Code Field

Unformatted Code Field (U<10:0>) is an eleven-bit wide field, which may contain an arbitrary value.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

37.2.4.3.11 Use of Next Pages

The following rules for Next Page usage shall be observed:

a) A Next Page exchange is invoked when the local device and the link partner advertise (in their Base Pages) that they have Next Page information to transmit;
b) Next Page exchange continues until neither device on a link has more pages to transmit as indicated by the NP bit. A Message Page with a Null Message Code Field value is sent if the device has no other information to transmit;
c) A message code can carry either a specific message or information that defines how following Unformatted Page(s) should be interpreted;
d) If a message code references Unformatted Pages, the Unformatted Pages immediately follow the referencing message code in the order specified by the message code;
e) Unformatted Page users are responsible for controlling the format and sequencing for their Unformatted Pages.

37.2.4.3.12 Management register requirements

The AN Next Page transmit register defined in 37.2.5.1.6 holds the Next Page to be sent by Auto-Negotiation. Received Next Pages are stored in the AN link partner ability Next Page register defined in 37.2.5.1.7.

37.2.5 Management function requirements

The management interface is used to communicate Auto-Negotiation information to the management entity. Mandatory functions specified here reference bits in GMII registers 0, 1, 4, 5, 6, 7, 8, 15. Where an implementation does not use a GMII, equivalent functions to these bits have to be included.

37.2.5.1 Management registers

The Auto-Negotiation function shall utilize six dedicated management registers:

a) Control register (Register 0);
b) Status register (Register 1);
c) AN advertisement register (Register 4);
d) AN link partner ability Base Page register (Register 5);
e) AN expansion register (Register 6);
f) Extended Status register (Register 15).

If Next Page is supported, the Auto-Negotiation function shall utilize an additional two management registers:

g) AN Next Page transmit register (Register 7);
h) AN link partner ability Next Page register (Register 8).

37.2.5.1.1 Control register (Register 0)

This register provides the mechanism to enable or disable Auto-Negotiation, restart Auto-Negotiation, and allow for manual configuration when Auto-Negotiation is not enabled. The definition for this register is provided in Clause 22.

When manual configuration is in effect at a local device, manual configuration should also be effected for the link partner to ensure predictable configuration. When manual configuration is in effect, values for the PAUSE bits (PS1, PS2) should result in a valid operational mode between the local device and the link partner.

37.2.5.1.2 Status register (Register 1)

This register includes information about all modes of operations supported by the local device and the status of Auto-Negotiation. The definition for this register is provided in Clause 22.

37.2.5.1.3 AN advertisement register (Register 4) (R/W)

This register contains the advertised ability of the local device (see Table 37–5). Before Auto-Negotiation starts, this register is configured to advertise the abilities of the local device.

Table 37–5—AN advertisement register bit definitions

Bit(s)	Name	Description	R/W
4.15	Next Page	See 37.2.1.7	R/W
4.14	Reserved	Write as zero, ignore on read	RO
4.13:12	Remote Fault	See 37.2.1.5	R/W
4.11:9	Reserved	Write as zero, ignore on read	RO
4.8:7	Pause	See 37.2.1.4	R/W
4.6	Half Duplex	See 37.2.1.3	R/W
4.5	Full Duplex	See 37.2.1.2	R/W
4.4:0	Reserved	Write as zero, ignore on read	RO

37.2.5.1.4 AN link partner ability Base Page register (Register 5) (RO)

All of the bits in the AN link partner ability Base Page register are read only. A write to the AN link partner ability Base Page register has no effect.

This register contains the advertised ability of the link partner (see Table 37–6). The bit definitions are a direct representation of the link partner's Base Page. Upon successful completion of Auto-Negotiation, the Status register Auto-Negotiation Complete bit (1.5) is set to logic one.

The values contained in this register are guaranteed to be valid either once Auto-Negotiation has successfully completed, as indicated by bit 1.5 or when the Page Received bit (6.1) is set to logic one to indicate that a new Base Page has been received and stored in the Auto-Negotiation link partner ability base register.

37.2.5.1.5 AN expansion register (Register 6) (RO)

All of the bits in the Auto-Negotiation expansion register are read only; a write to the Auto-Negotiation expansion register has no effect.

Bits 6.15:3 and 6.0 are reserved for future Auto-Negotiation expansion.

The Next Page Able bit (6.2) is set to logic one to indicate that the local device supports the Next Page function. The Next Page Able bit is set to logic zero if the Next Page function is not supported by the local device.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 37–6—AN link partner ability Base Page register bit definitions

Bit(s)	Name	Description	R/W
5.15	Next Page	See 37.2.1.7	RO
5.14	Acknowledge	See 37.2.1.6	RO
5.13:12	Remote Fault	See 37.2.1.5	RO
5.11:9	Reserved	Ignore on read	RO
5.8:7	Pause	See 37.2.1.4	RO
5.6	Half Duplex	See 37.2.1.3	RO
5.5	Full Duplex	See 37.2.1.2	RO
5.4:0	Reserved	Ignore on read	RO

Table 37–7—AN expansion register bit definitions

Bit(s)	Name	Description	R/W	Default
6.15:3	Reserved	Ignore on read	RO	0
6.2	Next Page Able	1 = Local device is Next Page able 0 = Local device is not Next Page able	RO	0
6.1	Page Received	1 = A new page has been received 0 = A new page has not been received	RO/ LH	0
6.0	Reserved	Ignore on read	RO	0

The Page Received bit (6.1) is set to logic one to indicate that a new page has been received and stored in the applicable AN link partner ability base or Next Page register.

The Page Received bit shall be reset to logic zero on a read of the AN expansion register (Register 6). Subsequent to the setting of the Page Received bit, and in order to prevent overlay of the AN link partner ability Next Page register, the AN link partner ability Next Page register should be read before the AN Next Page transmit register is written.

37.2.5.1.6 AN Next Page transmit register (Register 7)

This register contains the Next Page value to be transmitted, if required. The definition for this register is provided in 22.2.4.1.6.

37.2.5.1.7 AN link partner ability Next Page register (Register 8)

This register contains the advertised ability of the link partner's Next Page. The definition for this register is provided in 32.5.4.2 for changes to 28.2.4.1.4.

37.2.5.1.8 Extended status register (Register 15)

This register includes additional information about all modes of operations supported by the local device. The definition for this register is provided in Clause 22.

37.2.5.1.9 State diagram variable to management register mapping

The state diagram of Figure 37–6 generates and accepts variables of the form "mr_x," where x is an individual signal name. These variables comprise a management interface that may be connected to the GMII management function or other equivalent function. Table 37–8 describes how PCS state diagram variables in both Clauses 36 and 37 map to management register bits.

Table 37–8—PCS state diagram variable to management register mapping

State diagram variable	Management register bit
mr_adv_ability<16:1>	4.15:0 Auto-Negotiation advertisement register
mr_an_complete	1.5 Auto-Negotiation complete
mr_an_enable	0.12 Auto-Negotiation enable
mr_loopback	0.14 Loopback (see 36.2.5.1.3)
mr_lp_adv_ability<16:1>	5.15:0 AN link partner ability register
mr_lp_np_rx<16:1>	8.15:0 AN link partner Next Page ability register
mr_main_reset	0.15 Reset
mr_np_able	6.2 Next Page Able
mr_np_loaded	Set on write to the AN Next Page transmit register; cleared by Auto-Negotiation state diagram
mr_np_tx<16:1>	7.15:0 AN Next Page transmit register
mr_page_rx	6.1 Page received
mr_restart_an	0.9 Auto-Negotiation restart
xmit=DATA	1.2 Link status

37.2.5.2 Auto-Negotiation managed object class

The Auto-Negotiation Managed Object Class is defined in Clause 30.

37.2.6 Absence of management function

In the absence of any management function, the advertised abilities shall be provided through a logical equivalent of mr_adv_ability<16:1>.

37.3 Detailed functions and state diagrams

The notation used in the state diagram in Figure 37–6 follows the conventions in 21.5. State diagram variables follow the conventions of 21.5.2 except when the variable has a default value. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set. Variables using the "mr_x" notation do not have state diagram defaults; however, their appropriate initialization conditions when mapped to the management interface are covered in 22.2.4. The variables, timers, and counters used in the state diagrams are defined in 37.3.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Auto-Negotiation shall implement the Auto-Negotiation state diagram and meet the Auto-Negotiation state diagram interface requirements of the Receive and Transmit functions. Additional requirements to these state diagrams are made in the respective functional requirements sections. In the case of any ambiguity between stated requirements and the state diagrams, the state diagrams take precedence. A functional reference diagram of Auto-Negotiation is shown in Figure 37–5.

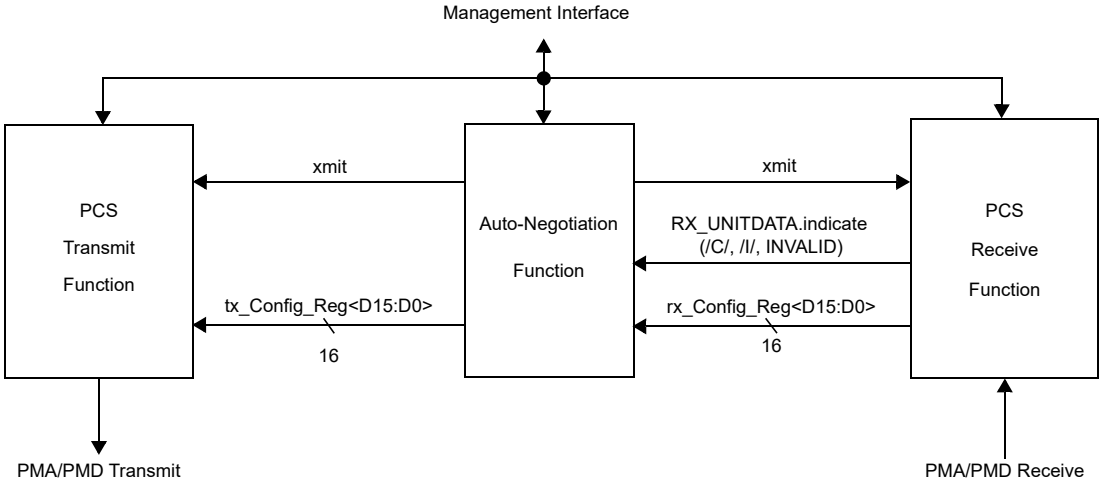

Figure 37–5—Functional reference diagram

37.3.1 State diagram variables

Variables with <16:1> or <D15:D0> appended to the end of the variable name indicate arrays that can be mapped to 16-bit management registers. For these variables, "<x>" indexes an element or set of elements in the array, where "x" may be as follows:

— Any integer or set of integers.
— Any variable that takes on integer values.
— NP; represents the index of the Next Page bit.
— ACK; represents the index of the Acknowledge bit.
— RF; represents the index of the Remote Fault bits.

Variables of the form "mr_x," where x is a label, comprise a management interface that is intended to be connected to the GMII Management function. However, an implementation-specific management interface may provide the control and status function of these bits.

37.3.1.1 Variables

an_sync_status

Qualified version of sync_status for use by Auto-Negotiation to detect a sync_status timeout condition.

Values: OK; The variable sync_status defined in 36.2.5.1.3 is OK.
FAIL; The variable sync_status defined in 36.2.5.1.3 is FAIL for a duration greater than or equal to the link timer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mr_adv_ability<16:1>

A 16-bit array that contains the advertised ability Base Page of the local device to be conveyed to tx_Config_Reg<D15:D0> for transmission to the link partner. For each element within the array:

Values: ZERO; Data bit is logical zero.
ONE; Data bit is logical one.

mr_an_complete

Status indicating whether Auto-Negotiation has completed or not.

Values: FALSE; Auto-Negotiation has not completed.
TRUE; Auto-Negotiation has completed.

mr_an_enable

Controls the enabling and disabling of the Auto-Negotiation function for 1000BASE-X. Auto-Negotiation function for 1000BASE-X is enabled when Control register bit 0.12 is set to one.

Values: FALSE; Auto-Negotiation is disabled.
TRUE; Auto-Negotiation is enabled.

mr_lp_adv_ability<16:1>

A 16-bit array that contains the advertised ability Base Page of the link partner conveyed from rx_Config_Reg<D15:D0>. For each element within the array:

Values: ZERO; Data bit is logical zero.
ONE; Data bit is logical one.

mr_lp_np_rx<16:1>

A 16-bit array that contains the advertised ability of the link partner's Next Page conveyed from rx_Config_Reg<D15:D0>. For each element within the array:

Values: ZERO; Data bit is logical zero.
ONE; Data bit is logical one.

mr_main_reset

Controls the resetting of the Auto-Negotiation function.

Values: FALSE; Do not reset the Auto-Negotiation function.
TRUE; Reset the Auto-Negotiation function.

mr_np_able

Status indicating whether the local device supports Next Page exchange.

Values: FALSE; The local device does not support Next Page exchange.
TRUE; The local device supports Next Page exchange.

mr_np_loaded

Status indicating whether a new page has been loaded into the AN Next Page transmit register (register 7).

Values: FALSE; A new page has not been loaded.
TRUE; A new page has been loaded.

mr_np_tx<16:1>

A 16-bit array that contains the new Next Page to transmit. If a Next Page exchange is invoked, this array is conveyed to tx_Config_Reg<D15:D0> for transmission to the link partner. For each element within the array:

Values: ZERO; Data bit is logical zero.
ONE; Data bit is logical one.

mr_page_rx

Status indicating whether a new page has been received. A new page has been successfully received when acknowledge_match=TRUE and consistency_match=TRUE and the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_Config_Reg<D15:D0> value has been written to mr_lp_adv_ability<16:1> or mr_lp_np_rx<16:1>, depending on whether the page received was a base or Next Page, respectively.

Values: FALSE; A new page has not been received.
TRUE; A new page has been received.

NOTE—For the first setting of mr_page_rx, mr_lp_adv_ability is valid but need not be read as it is preserved through a Next Page operation. On subsequent settings of mr_page_rx, mr_lp_np_rx should be read prior to loading mr_np_tx register in order to avoid the overlay of Next Page information.

mr_restart_an

Controls renegotiation via management control.

Values: FALSE; Do not restart Auto-Negotiation.
TRUE; Restart Auto-Negotiation.

np_rx

Flag to hold value of rx_Config_Reg<NP> upon entry to state COMPLETE ACKNOWLEDGE. This value is associated with the value of rx_Config_Reg<NP> when acknowledge_match was last set.

Values: ZERO; The local device np_rx bit equals logic zero.
ONE; The local device np_rx bit equals logic one.

power_on

Condition that is true until such time as the power supply for the device that contains the Auto-Negotiation function has reached the operating region. The condition is also true when the device has low power mode set via Control register bit 0.11.

Values: FALSE; The device is completely powered (default).
TRUE; The device has not been completely powered.

NOTE—Power_on evaluates to its default value in each state where it is not explicitly set.

resolve_priority

Controls the invocation of the priority resolution function specified in Table 37–4.

Values: OFF; The priority resolution function is not invoked (default).
ON; The priority resolution function is invoked.

NOTE—Resolve_priority evaluates to its default value in each state where it is not explicitly set.

rx_Config_Reg<D15:D0>

Defined in 36.2.5.1.3.

sync_status

Defined in 36.2.5.1.3.

toggle_rx

Flag to keep track of the state of the link partner Toggle bit.

Values: ZERO; The link partner Toggle bit equals logic zero.
ONE; The link partner Toggle bit equals logic one.

toggle_tx

Flag to keep track of the state of the local device Toggle bit.

Values: ZERO; The local device Toggle bit equals logic zero.
ONE; The local device Toggle bit equals logic one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_Config_Reg<D15:D0>

Defined in 36.2.5.1.3. This array may be loaded from mr_adv_ability or mr_np_tx.

xmit

A parameter set by the PCS Auto-Negotiation process to reflect the source of information to the PCS Transmit process.

Values: CONFIGURATION: Tx_Config_Reg<D15:D0> information is being sourced from the PCS Auto-Negotiation process.
DATA: /I/, sourced from the PCS, is interspersed with packets sourced from the MAC.
IDLE: /I/ is being sourced from the PCS Auto-Negotiation process.

37.3.1.2 Functions

ability_match

For a stream of /C/ and /I/ ordered sets, this function continuously indicates whether the last three consecutive rx_Config_Reg<D15,D13:D0> values match. Three consecutive rx_Config_Reg<D15,D13:D0> values are any three rx_Config_Reg<D15,D13:D0> values received one after the other, regardless of whether the rx_Config_Reg<D15,D13:D0> value has already been used in a rx_Config_Reg<D15,D13:D0> match comparison or not. The match count is reset upon receipt of /I/. The match count is reset upon receipt of a second or third consecutive rx_Config_Reg<D15,D13:D0> value which does not match the rx_Config_Reg<D15,D13:D0> values for which the match count was set to one.

Values: FALSE; Three matching consecutive rx_Config_Reg<D15,D13:D0> values have not been received (default).
TRUE; Three matching consecutive rx_Config_Reg<D15,D13:D0> values have been received.

NOTE—Ability_match is set by this function definition; it is not set explicitly in the state diagrams. Ability_match evaluates to its default value upon state entry.

acknowledge_match

For a stream of /C/ and /I/ ordered sets, this function continuously indicates whether the last three consecutive rx_Config_Reg<D15:D0> values match and have the Acknowledge bit set. Three consecutive rx_Config_Reg<D15:D0> values are any three rx_Config_Reg<D15:D0> values contained within three /C/ ordered sets received one after the other, regardless of whether the rx_Config_Reg<D15:D0> value has already been used in a rx_Config_Reg<D15:D0> match comparison or not. The match count is reset upon receipt of /I/. The match count is reset upon receipt of a second or third consecutive rx_Config_Reg<D15:D0> value which does not match the rx_Config_Reg<D15:D0> values for which the match count was set to one.

Values: FALSE; Three matching and consecutive rx_Config_Reg<D15:D0> values have not been received with the Acknowledge bit set (default).
TRUE; Three matching and consecutive rx_Config_Reg<D15:D0> values have been received with the Acknowledge bit set.

NOTE—Acknowledge_match is set by this function definition; it is not set explicitly in the state diagrams. Acknowledge_match evaluates to its default value upon state entry.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

an_enableCHANGE

This function monitors the mr_an_enable variable for a state change. The function is set to TRUE on state change detection.

Values: TRUE; A mr_an_enable variable state change has been detected.
FALSE; A mr_an_enable variable state change has not been detected (default).

NOTE—An_enableCHANGE is set by this function definition; it is not set explicitly in the state diagrams. An_enableCHANGE evaluates to its default value upon state entry.

consistency_match

Indicates that the rx_Config_Reg<D15,D13:D0> value that caused ability_match to be set, for the transition from states ABILITY_DETECT or NEXT_PAGE_WAIT to state ACKNOWLEDGE_DETECT, is the same as the rx_Config_Reg<D15,D13:D0> value that caused acknowledge_match to be set.

Values: FALSE; The rx_Config_Reg<D15,D13:D0> value that caused ability_match to be set is not the same as the rx_Config_Reg<D15,D13:D0> value that caused acknowledge_match to be set, ignoring the Acknowledge bit value.
TRUE; The rx_Config_Reg<D15,D13:D0> value that caused ability_match to be set is the same as the rx_Config_Reg<D15,D13:D0> value that caused acknowledge_match to be set, independent of the Acknowledge bit value.

NOTE—Consistency_match is set by this function definition; it is not set explicitly in the state diagrams.

idle_match

For a stream of /C/ and /I/ ordered sets, this function continuously indicates whether three consecutive /I/ ordered sets have been received. The match count is reset upon receipt of /C/.

Values: FALSE; Three consecutive /I/ ordered sets have not been received (default).
TRUE; Three consecutive /I/ ordered sets have been received.

NOTE—Idle_match is set by this function definition; it is not set explicitly in the state diagrams. Idle_match evaluates to its default value upon state entry.

37.3.1.3 Messages

RUDI

Alias for RX_UNITDATA.indicate(parameter). Defined in 36.2.5.1.6.

RX_UNITDATA.indicate

Defined in 36.2.5.1.6.

37.3.1.4 Timers

All timers operate in the manner described in 14.2.3.2.

link_timer

Timer used to ensure Auto-Negotiation protocol stability and register read/write by the management interface.

Duration: 10 ms, tolerance +10 ms, –0 s.

37.3.1.5 State diagrams

The Auto-Negotiation state diagram is specified in Figure 37–6.

37.5 Protocol implementation conformance statement (PICS) proforma for Clause 37, Auto-Negotiation function, type 1000BASE-X[77]

37.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 37, Auto-Negotiation function, type 1000BASE-X, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

37.5.2 Identification

37.5.2.1 Implementation identification

Supplier (Note 1)	
Contact point for inquiries about the PICS (Note 1)	
Implementation Name(s) and Version(s) (Notes 1 and 3)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s) (Note 2)	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

37.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 37, Auto-Negotiation function, type 1000BASE-X
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[77] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

38. Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-LX (long wavelength laser) and 1000BASE-SX (short wavelength laser)

38.1 Overview

This clause specifies the 1000BASE-SX PMD and the 1000BASE-LX PMD (including MDI) and baseband medium for multimode and single-mode fiber. In order to form a complete Physical Layer, it shall be integrated with the 1000BASE-X PCS and PMA of Clause 36, and integrated with the management functions which are accessible through the Management Interface defined in Clause 35, which are hereby incorporated by reference.

38.1.1 Physical Medium Dependent (PMD) sublayer service interface

The following specifies the services provided by the 1000BASE-SX and 1000BASE-LX PMD. These PMD sublayers are described in an abstract manner and do not imply any particular implementation. It should be noted that these services are based on similar interfaces defined in ANSI INCITS 230-1994 (FC-PH).

The PMD Service Interface supports the exchange of encoded 8B/10B characters between PMA entities. The PMD translates the encoded 8B/10B characters to and from signals suitable for the specified medium.

The following primitives are defined:

PMD_UNITDATA.request
PMD_UNITDATA.indication
PMD_SIGNAL.indication

NOTE—Delay requirements from the MDI to GMII that include the PMD layer are specified in Clause 36. Of this budget, 4 ns is allocated for each of the transmit and receive functions of the PMD.

38.1.1.1 PMD_UNITDATA.request

This primitive defines the transfer of data (in the form of encoded 8B/10B characters) from the PMA to the PMD.

38.1.1.1.1 Semantics of the service primitive

PMD_UNITDATA.request (tx_bit)

The data conveyed by PMD_UNITDATA.request is a continuous sequence of encoded 8B/10B characters. The tx_bit parameter can take one of two values: ONE or ZERO.

38.1.1.1.2 When generated

The PMA continuously sends the appropriate encoded 8B/10B characters to the PMD for transmission on the medium, at a nominal 1.25 GBd signaling speed.

38.1.1.1.3 Effect of receipt

Upon receipt of this primitive, the PMD converts the specified encoded 8B/10B characters into the appropriate signals on the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.1.1.2 PMD_UNITDATA.indication

This primitive defines the transfer of data (in the form of encoded 8B/10B characters) from the PMD to the PMA.

38.1.1.2.1 Semantics of the service primitive

PMD_UNITDATA.indication (rx_bit)

The data conveyed by PMD_UNITDATA.indication is a continuous sequence of encoded 8B/10B characters. The rx_bit parameter can take one of two values: ONE or ZERO.

38.1.1.2.2 When generated

The PMD continuously sends encoded 8B/10B characters to the PMA corresponding to the signals received from the MDI.

38.1.1.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

38.1.1.3 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

38.1.1.3.1 Semantics of the service primitive

PMD_SIGNAL.indication(SIGNAL_DETECT)

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting light at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, then rx_bit is undefined, but consequent actions based on PMD_UNITDATA.indication, where necessary, interpret rx_bit as a logic ZERO.

NOTE—SIGNAL_DETECT = OK does not guarantee that rx_bit is known good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the 10^{-12} BER objective.

38.1.1.3.2 When generated

The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT.

38.1.1.3.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

38.1.2 Medium Dependent Interface (MDI)

The MDI, a physical interface associated with a PMD, is composed of an electrical or optical medium connection.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.2 PMD functional specifications

The 1000BASE-X PMDs perform the Transmit and Receive functions that convey data between the PMD service interface and the MDI.

38.2.1 PMD block diagram

For purposes of system conformance, the PMD sublayer is standardized at the following points. The optical transmit signal is defined at the output end of a patch cord (TP2), between 2 and 5 m in length, of a type consistent with the link type connected to the transmitter receptacle defined in 38.11.2. If a single-mode fiber offset-launch mode-conditioning patch cord is used, the optical transmit signal is defined at the end of this single-mode fiber offset-launch mode-conditioning patch cord at TP2. Unless specified otherwise, all transmitter measurements and tests defined in 38.6 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) connected to the receiver receptacle defined in 38.11.2. Unless specified otherwise, all receiver measurements and tests defined in 38.6 are made at TP3.

TP1 and TP4 are standardized reference points for use by implementers to certify component conformance. The electrical specifications of the PMD service interface (TP1 and TP4) are not system compliance points (these are not readily testable in a system implementation). It is expected that in many implementations, TP1 and TP4 will be common between 1000BASE-SX, 1000BASE-LX, and 1000BASE-CX (Clause 39).

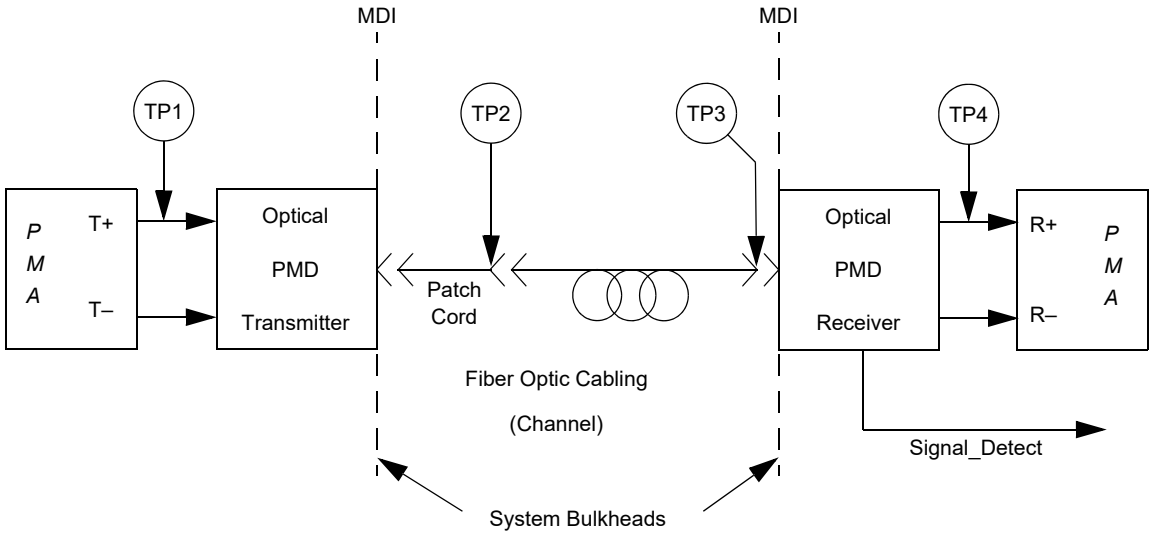

Figure 38–1—1000BASE-X block diagram

38.2.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the optical specifications in this clause. The higher optical power level shall correspond to tx_bit = ONE.

38.2.3 PMD receive function

The PMD Receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher optical power level shall correspond to rx_bit = ONE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.2.4 PMD signal detect function

The PMD Signal Detect function shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 38–1. The PMD receiver is not required to verify whether a compliant 1000BASE-X signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 38–1—SIGNAL_DETECT value definition

Receive conditions	Signal detect value
Input_optical_power ≤ –30 dBm	FAIL
Input_optical_power ≥ Receive sensitivity AND compliant 1000BASE-X signal input	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD due to cross talk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations which generate the SIGNAL_DETECT parameter values in response to the amplitude of the 8B/10B modulation of the optical signal and implementations that respond to the average optical power of the 8B/10B-modulated optical signal.

38.3 PMD to MDI optical specifications for 1000BASE-SX

The operating range for 1000BASE-SX is defined in Table 38–2. A 1000BASE-SX compliant transceiver supports both multimode fiber media types listed in Table 38–2 (i.e., both 50 μm and 62.5 μm multimode fiber) according to the specifications defined in 38.11. A transceiver that exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., a 50 μm solution operating at 600 m meets the minimum range requirement of 2 to 550 m).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 38–2—Operating range for 1000BASE-SX over each optical fiber type

Fiber type	Modal bandwidth @ 850 nm (min. overfilled launch) (MHz · km)	Minimum range (m)
62.5 μm MMF	160	2 to 220
62.5 μm MMF	200	2 to 275
50 μm MMF	400	2 to 500
50 μm MMF	500	2 to 550
SMF	N/A	Not supported

38.3.1 Transmitter optical specifications

The 1000BASE-SX transmitter shall meet the specifications defined in Table 38–3 per measurement techniques defined in 38.6. It shall also meet a transmit mask of the eye measurement as defined in 38.6.5.

Table 38–3—1000BASE-SX transmit characteristics

Description	62.5 μm MMF	50 μm MMF	Unit
Transmitter type	Shortwave Laser		
Signaling speed (range)	1.25 ± 100 ppm		GBd
Wavelength (λ, range)	770 to 860		nm
T_{rise}/T_{fall} (max; 20%-80%; λ > 830 nm)	0.26		ns
T_{rise}/T_{fall} (max; 20%-80%; λ ≤ 830 nm)	0.21		ns
RMS spectral width (max)	0.85		nm
Average launch power (max)	See footnote [a]		dBm
Average launch power (min)	–9.5		dBm
Average launch power of OFF transmitter (max)[b]	–30		dBm
Extinction ratio (min)	9		dB
RIN (max)	–117		dB/Hz
Coupled Power Ratio (CPR) (min)[c]	9 < CPR		dB

[a]The 1000BASE-SX launch power shall be the lesser of the Hazard Level 1 safety limit as defined by 38.7.2 or the average receive power (max) defined by Table 38–4.
[b]Examples of an OFF transmitter are: no power supplied to the PMD, laser shutdown for safety conditions, activation of a "transmit disable" or other optional module laser shut down conditions. During all conditions when the PMA is powered, the ac signal (data) into the transmit port will be valid encoded 8B/10B patterns (this is a requirement of the PCS layers) except for short durations during system power-on-reset or diagnostics when the PMA is placed in a loopback mode.
[c]Radial overfilled launches as described in 38A.2, while they may meet CPR ranges, should be avoided.

The CPR specification provides sufficient mode volume so that individual multimode fiber (MMF) modes do not dominate fiber performance. This reduces the effect of peak-to-peak differential mode delay (DMD) between the launched mode groups and diminishes the resulting pulse-splitting-induced nulls in the frequency response.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.3.2 Receive optical specifications

The 1000BASE-SX receiver shall meet the specifications defined in Table 38–4 per measurement techniques defined in 38.6. The sampling instant is defined to occur at the eye center. The receive sensitivity includes the extinction ratio penalty.

Table 38–4—1000BASE-SX receive characteristics

Description	62.5 μm MMF	50 μm MMF	Unit
Signaling Speed (range)	1.25 ± 100 ppm		GBd
Wavelength (range)	770 to 860		nm
Average receive power (max)	0		dBm
Receive sensitivity	–17		dBm
Return loss (min)	12		dB
Stressed receive sensitivity[a, b]	–12.5	–13.5	dBm
Vertical eye-closure penalty[c]	2.60	2.20	dB
Receive electrical 3 dB upper cutoff frequency (max)	1500		MHz

[a]Measured with conformance test signal at TP3 (see 38.6.11) for BER = 10^{-12} at the eye center.
[b]Measured with a transmit signal having a 9 dB extinction ratio. If another extinction ratio is used, the stressed receive sensitivity should be corrected for the extinction ratio penalty.
[c]Vertical eye-closure penalty is a test condition for measuring stressed receive sensitivity. It is not a required characteristic of the receiver.

38.3.3 Illustrative 1000BASE-SX link power budget and penalties

The worst-case power budget and link penalties for a 1000BASE-SX channel are shown in Table 38–5.

Table 38–5—Worst-case 1000BASE-SX link power budget and penalties[a]

Parameter	62.5 μm MMF		50 μm MMF		Unit
Modal bandwidth as measured at 850 nm (minimum, overfilled launch)	160	200	400	500	MHz · km
Link power budget	7.5	7.5	7.5	7.5	dB
Operating distance	220	275	500	550	m
Channel insertion loss[b, c]	2.38	2.60	3.37	3.56	dB
Link power penalties[c]	4.27	4.29	4.07	3.57	dB
Unallocated margin in link power budget[c]	0.84	0.60	0.05	0.37	dB

[a]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.
[b]Operating distances used to calculate the channel insertion loss (see 1.4) are the maximum values specified in Table 38–2.
[c]A wavelength of 830 nm is used to calculate channel insertion loss, link power penalties, and unallocated margin.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.4 PMD to MDI optical specifications for 1000BASE-LX

The operating range for 1000BASE-LX is defined in Table 38–6. A 1000BASE-LX compliant transceiver supports all media types listed in Table 38–6 (i.e., 50 μm and 62.5 μm multimode fiber, and single-mode fiber) according to the specifications defined in 38.11. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., a single-mode solution operating at 5500 m meets the minimum range requirement of 2 to 5000 m).

Table 38–6—Operating range for 1000BASE-LX over each optical fiber type

Fiber type	Modal bandwidth @ 1300 nm (min. overfilled launch) (MHz · km)	Minimum range (m)
62.5 μm MMF	500	2 to 550
50 μm MMF	400	2 to 550
50 μm MMF	500	2 to 550
SMF	N/A	2 to 5000

38.4.1 Transmitter optical specifications

The 1000BASE-LX transmitter shall meet the specifications defined in Table 38–7 per measurement techniques defined in 38.6. It shall also meet a transmit mask of the eye measurement as defined in 38.6.5. To ensure that the specifications of Table 38–7 are met with MMF links, the 1000BASE-LX transmitter output shall be coupled through a single-mode fiber offset-launch mode-conditioning patch cord, as defined in 38.11.4.

Table 38–7—1000BASE-LX transmit characteristics

Description	62.5 μm MMF	50 μm MMF	SMF	Unit
Transmitter type	Longwave Laser			
Signaling speed (range)	1.25 ± 100 ppm			GBd
Wavelength (range)	1270 to 1355			nm
T_{rise}/T_{fall} (max, 20-80% response time)	0.26			ns
RMS spectral width (max)	4			nm
Average launch power (max)	–3			dBm
Average launch power (min)	–11.5	–11.5	–11.0	dBm
Average launch power of OFF transmitter (max)	–30			dBm
Extinction ratio (min)	9			dB
RIN (max)	–120			dB/Hz
Coupled Power Ratio (CPR)[a]	28 < CPR< 40	12 < CPR < 20	N/A	dB

[a]Due to the dual media (single-mode and multimode) support of the LX transmitter, fulfillment of this specification requires a single-mode fiber offset-launch mode-conditioning patch cord described in 38.11.4 for MMF operation. This patch cord is not used for single-mode operation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Conditioned launch (CL) produces sufficient mode volume so that individual multimode fiber (MMF) modes do not dominate fiber performance. This reduces the effect of peak-to-peak differential mode delay (DMD) between the launched mode groups and diminishes the resulting pulse-splitting-induced nulls in the frequency response.

A CL is produced by using a single-mode fiber offset-launch mode-conditioning patch cord, inserted at both ends of a full duplex link, between the optical PMD MDI and the remainder of the link segment. The single-mode fiber offset-launch mode-conditioning patch cord contains a fiber of the same type as the cable (i.e., 62.5 μm or 50 μm fiber) connected to the optical PMD receiver input MDI and a specialized fiber/connector assembly connected to the optical PMD transmitter output.

38.4.2 Receive optical specifications

The 1000BASE-LX receiver shall meet the specifications defined in Table 38–8 per measurement techniques defined in 38.6. The sampling instant is defined to occur at the eye center. The receive sensitivity includes the extinction ratio penalty.

Table 38–8—1000BASE-LX receive characteristics

Description	Value	Unit
Signaling speed (range)	1.25 ± 100 ppm	GBd
Wavelength (range)	1270 to 1355	nm
Average receive power (max)	–3	dBm
Receive sensitivity	–19	dBm
Return loss (min)	12	dB
Stressed receive sensitivity[a, b]	–14.4	dBm
Vertical eye-closure penalty[c]	2.60	dB
Receive electrical 3 dB upper cutoff frequency (max)	1500	MHz

[a]Measured with conformance test signal at TP3 (see 38.6.11) for BER = 10^{-12} at the eye center.
[b]Measured with a transmit signal having a 9 dB extinction ratio. If another extinction ratio is used, the stressed receive sensitivity should be corrected for the extinction ratio penalty.
[c]Vertical eye-closure penalty is a test condition for measuring stressed receive sensitivity. It is not a required characteristic of the receiver.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.4.3 Illustrative 1000BASE-LX link power budget and penalties

The worst-case power budget and link penalties for a 1000BASE-LX channel are shown in Table 38–9.

Table 38–9—Worst-case 1000BASE-LX link power budget and penalties[a]

Parameter	62.5 μm MMF	50 μm MMF		SMF	Unit
Modal bandwidth as measured at 1300 nm (minimum, overfilled launch)	500	400	500	N/A	MHz · km
Link power budget	7.5	7.5	7.5	8.0	dB
Operating distance	550	550	550	5000	m
Channel insertion loss[b, c]	2.35	2.35	2.35	4.57	dB
Link power penalties[c]	3.48	5.08	3.96	3.27	dB
Unallocated margin in link power budget[c]	1.67	0.07	1.19	0.16	dB

[a]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.
[b]Operating distances used to calculate the channel insertion loss (see 1.4) are the maximum values specified in Table 38–6.
[c]A wavelength of 1270 nm is used to calculate channel insertion loss, link power penalties, and unallocated margin.

38.5 Jitter specifications for 1000BASE-SX and 1000BASE-LX

Numbers in the Table 38–10 represent high-frequency jitter (above 637 kHz) and do not include low-frequency jitter or wander. Implementations shall conform to the normative values highlighted **in bold** in Table 38–10 (see measurement procedure in 38.6.8). All other values are optional.

Table 38–10—1000BASE-SX and 1000BASE-LX jitter budget

Compliance point	Total jitter[a]		Deterministic jitter	
	UI	ps	UI	ps
TP1	**0.240**	**192**	0.100	80
TP1 to TP2	0.284	227	0.100	80
TP2	**0.431**	**345**	0.200	160
TP2 to TP3	0.170	136	0.050	40
TP3	**0.510**	**408**	0.250	200
TP3 to TP4	0.332	266	0.212	170
TP4[b]	**0.749**	**599**	0.462	370

[a] Total jitter is composed of both deterministic and random components. The allowed random jitter equals the allowed total jitter minus the actual deterministic jitter at that point.
[b]Measured with a conformance test signal at TP3 (see 38.6.11) set to an average optical power 0.5 dB greater than the stressed receive sensitivity from Table 38–4 for 1000BASE-SX and Table 38–8 for 1000BASE-LX.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.6 Optical measurement requirements

All optical measurements shall be made through a short patch cable, between 2 and 5 m in length. If a single-mode fiber offset-launch mode-conditioning patch cord is used, the optical transmit signal is defined at the output end (TP2) of the single-mode fiber offset-launch mode-conditioning patch cord.

38.6.1 Center wavelength and spectral width measurements

The center wavelength and spectral width (RMS) shall be measured using an optical spectrum analyzer per the centroidal wavelength and RMS spectral width definitions in IEC 61280-1-3. Center wavelength and spectral width shall be measured under modulated conditions using a valid 1000BASE-X signal.

38.6.2 Optical power measurements

Optical power shall be measured using the methods specified in ANSI/TIA/EIA-455-95. This measurement may be made with the node transmitting any valid encoded 8B/10B data stream.

38.6.3 Extinction ratio measurements

Extinction ratio shall be measured using the methods specified in IEC 61280-2-2. This measurement may be made with the node transmitting a data pattern defined in 36A.2. This is a repeating K28.7 data pattern. The extinction ratio is measured under fully modulated conditions with worst-case reflections.

NOTE—A repeating K28.7 data pattern generates a 125 MHz square wave.

38.6.4 Relative Intensity Noise (RIN)

This procedure describes a component test which may not be appropriate for a system level test depending on the implementation. RIN shall be measured according to 58.7.7 with the following exceptions:

1) the low pass filter bandwidth is 937.5 MHz
2) step d) of the test procedure is replaced by measuring the value of the photocurrent of the optical to electrical converter I_{oe}
3) step e) of the test procedure is replaced by using the following equation to evaluate RIN:

$$\mathrm{RIN} = 10\log_{10}\frac{P_N}{BW \times I_{oe}^2 \times R} - G \ \text{(dB/Hz)}$$

where:

RIN	is the relative intensity noise,
P_N	is the electrical noise power in Watts with modulation off,
BW	is the low-pass bandwidth of apparatus – high-pass bandwidth of apparatus due to DC-blocking capacitor,
I_{oe}	is the photocurrent of the optical to electrical converter,
R	is the effective load impedance of the optical to electrical converter (for example, a 50 Ω detector load in parallel with a 50 Ω power meter would give R equal to 25),
G	is the Gain in dB of any amplifier in the noise measurement path.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.6.5 Transmitter optical waveform (transmit eye)

The required transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 38–2. The transmit mask is not used for response time and jitter specification.

Normalized amplitudes of 0.0 and 1.0 represent the amplitudes of logic ZERO and ONE, respectively.

The eye shall be measured with respect to the mask of the eye using a fourth-order Bessel-Thomson filter having a transfer function given by

$$H(p) = \frac{105}{105 + 105y + 45y^2 + 10y^3 + y^4}$$

where

$$y = 2.114p\ ; \quad p = \frac{j\omega}{\omega_r}\ ; \quad \omega_r = 2\pi f_r\ ; \quad f_r = 0.9375\text{GHz}$$

and where the filter response vs. frequency range for this fourth order Bessel-Thomson filter is defined in ITU-T G.957, along with the allowed tolerances (STM-16 values) for its physical implementation.

NOTE 1—This Bessel-Thomson filter is not intended to represent the noise filter used within an optical receiver, but is intended to provide uniform measurement conditions at the transmitter.

NOTE 2—The fourth-order Bessel-Thomson filter is reactive. In order to suppress reflections, a 6 dB attenuator may be required at the filter input and/or output.

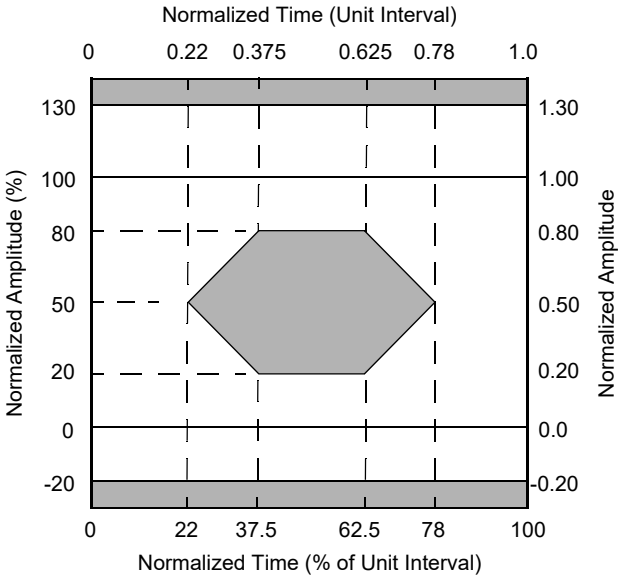

Figure 38–2—Transmitter eye mask definition

38.6.6 Transmit rise/fall characteristics

Optical response time specifications are based on unfiltered waveforms. Some lasers have overshoot and ringing on the optical waveforms which, if unfiltered, reduce the accuracy of the measured 20–80%

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

response times. For the purpose of standardizing the measurement method, measured waveforms shall conform to the mask defined in Figure 38–2. If a filter is needed to conform to the mask, the filter response should be removed using the equation:

$$T_{\text{rise,fall}} = \sqrt{(T_{\text{rise,fall_measured}})^2 - (T_{\text{rise,fall_filter}})^2}$$

where the filter may be different for rise and fall. Any filter should have an impulse response equivalent to a fourth order Bessel-Thomson filter. The fourth-order Bessel-Thomson filter defined in 38.6.5 may be a convenient filter for this measurement; however, its low bandwidth adversely impacts the accuracy of the $T_{\text{rise,fall}}$ measurements.

38.6.7 Receive sensitivity measurements

The receive sensitivity shall be measured using a worst-case extinction ratio penalty while sampling at the eye center.

The stressed receive sensitivity shall be measured using the conformance test signal at TP3, as specified in 38.6.11. After correcting for the extinction ratio of the source, the stressed receive sensitivity shall meet the conditions specified in Table 38–4 for 1000BASE-SX and in Table 38–8 for 1000BASE-LX.

38.6.8 Total jitter measurements

All total jitter measurements shall be made according to the method in ANSI INCITS 230-1994 (FC-PH), Annex A, A.4.2, *Active output interface eye opening measurement*. Total jitter at TP2 shall be measured utilizing a BERT (Bit Error Ratio Test) test set. References to use of the Bessel-Thomson filter shall substitute use of the Bessel-Thomson filter defined in this clause (see 38.6.5). The test shall utilize the mixed frequency test pattern specified in 36A.3.

Total jitter at TP4 shall be measured using the conformance test signal at TP3, as specified in 38.6.11. The optical power shall be 0.5 dB greater than (to account for eye opening penalty) the stressed receive sensitivity level in Table 38–4 for 1000BASE-SX and in Table 38–8 for 1000BASE-LX. This power level shall be corrected if the extinction ratio differs from the specified extinction ratio (min) of 9 dB. Measurements shall be taken directly at TP4 without additional Bessel-Thomson filters.

Jitter measurement may use a clock recovery unit (commonly referred to in the industry as a “golden PLL”) to remove low-frequency jitter from the measurement as shown in Figure 38–3. The clock recovery unit has a low-pass filter with 20 dB/decade rolloff with –3 dB point of 637 kHz. For this measurement, the recovered clock will run at the signaling speed. The golden PLL is used to approximate the PLL in the deserializer function of the PMA. The PMA deserializer is able to track a large amount of low-frequency jitter (such as drift or wander) below its bandwidth. This low-frequency jitter would create a large measurement penalty, but does not affect operation of the link.

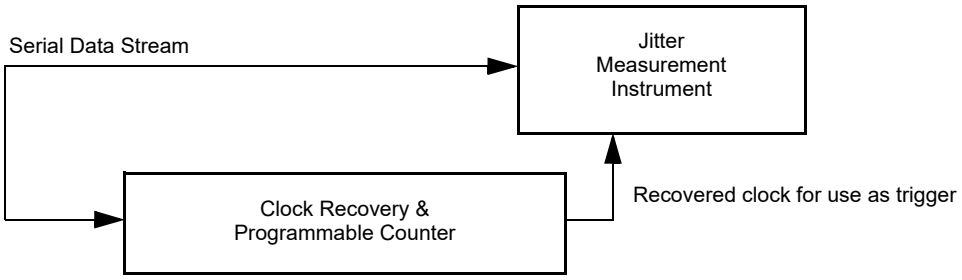

Figure 38–3—Utilization of clock recovery unit during measurement

38.6.9 Deterministic jitter measurement (optional)

Deterministic jitter should be measured according to ANSI INCITS 230-1994 (FC-PH), Annex A, A.4.3, *DJ Measurement.* The test utilizes the mixed frequency test pattern specified in 36A.3. This method utilizes a digital sampling scope to measure actual vs. predicted arrival of bit transitions of the 36A.3 data pattern (alternating K28.5 code-groups).

It is convenient to use the clock recovery unit described in 38.6.8 for purposes of generating a trigger for the test equipment. This recovered clock should have a frequency equivalent to 1/20th of the signaling speed.

38.6.10 Coupled Power Ratio (CPR) measurements

Coupled Power Ratio (CPR) is measured in accordance with ANSI/EIA/TIA-526-14A [B12]. Measured CPR values are time averaged to eliminate variation from speckle fluctuations. The coupled power ratio shall be measured for compliance with Table 38–3 and Table 38–7.

38.6.11 Conformance test signal at TP3 for receiver testing

Receivers being tested for conformance to the stressed receive sensitivity requirements of 38.6.7 and the total jitter requirements of 38.6.8 shall be tested using a conformance test signal at TP3 conforming to the requirements described in Figure 38–4. The conformance test signal shall be generated using the short continuous random test pattern defined in 36A.5. The conformance test signal is conditioned by applying deterministic jitter (DJ) and intersymbol interference (ISI). The conditioned conformance test signal is shown schematically in Figure 38–4. The horizontal eye closure (reduction of pulse width) caused by the duty cycle distortion (DCD) component of DJ shall be no less than 65 ps. The vertical eye-closure penalty shall be greater than or equal to the value specified in Table 38–4 for 1000BASE-SX and Table 38–8 for 1000BASE-LX. The DJ cannot be added with a simple phase modulation, which does not account for the DCD component of DJ.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

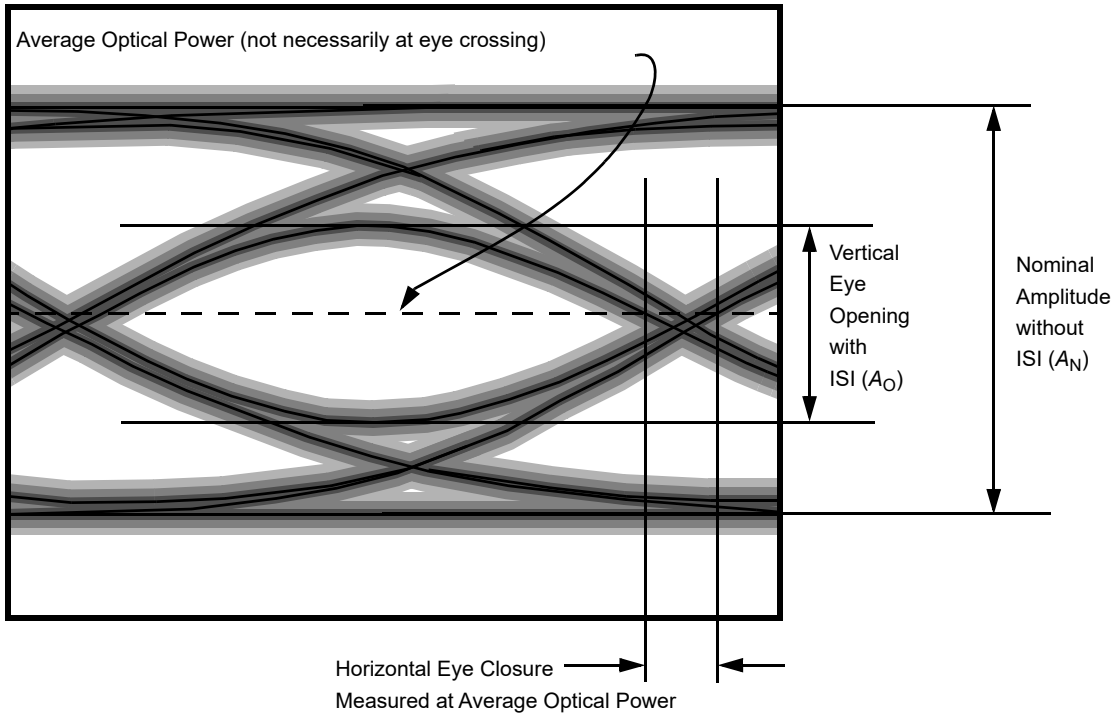

Figure 38–4—Required characteristics of the conformance test signal at TP3

The vertical eye-closure penalty is given by

$$\text{Vertical eye-closure penalty [dB]} = 10\log\frac{A_N}{A_O}$$

where A_O is the amplitude of the eye opening, and A_N is the normal amplitude without ISI, as measured in Figure 38–4.

Figure 38–5 shows the recommended test set up for producing the conformance test signal at TP3. The coaxial cable is adjusted in length to produce the correct DCD component of DJ. Since the coaxial cable can produce the incorrect ISI, a limiting amplifier is used to restore fast rise and fall times. A Bessel-Thomson filter is selected to produce the minimum ISI induced eye closure as specified per Table 38–4 for 1000BASE-SX and Table 38–8 for 1000BASE-LX. This conditioned signal is used to drive a high bandwidth linearly modulated laser source.

The vertical and horizontal eye closures to be used for receiver conformance testing are verified using a fast photodetector and amplifier. The bandwidth of the photodetector shall be at least 2.5 GHz and be coupled through a 1.875 GHz fourth-order Bessel-Thomson filter to the oscilloscope input. Special care should be taken to ensure that all the light from the fiber is collected by the fast photodetector and that there is negligible mode selective loss, especially in the optical attenuator.

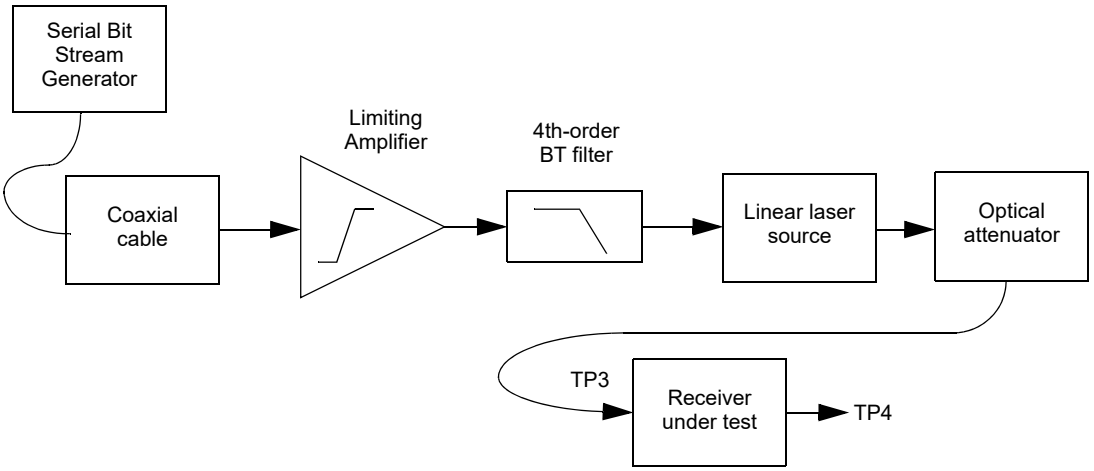

Figure 38–5—Apparatus for generating receiver conformance test signal at TP3

38.6.12 Measurement of the receiver 3 dB electrical upper cutoff frequency

The receiver 3 dB electrical upper cutoff frequency shall be measured as described below. The test setup is shown in Figure 38–6. The test is performed with a laser that is suitable for analog signal transmission. The laser is modulated by a digital data signal. In addition to the digital modulation, the laser is modulated with an analog signal. The analog and digital signals should be asynchronous. The data pattern to be used for this test is the short continuous random test pattern defined in 36A.5. The frequency response of the laser needs to be sufficient to allow it to respond to both the digital modulation and the analog modulation. The laser should be biased so that it remains linear when driven by the combined signals.

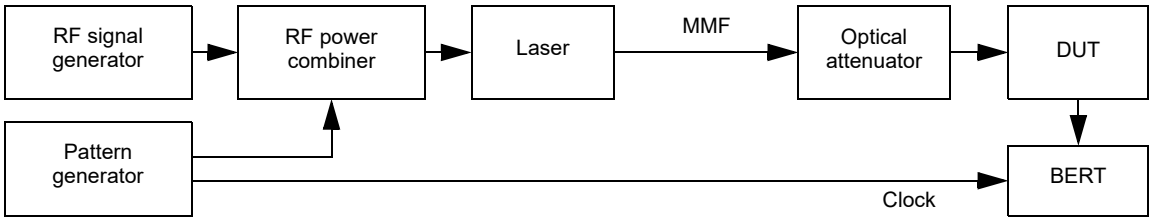

Figure 38–6—Test setup for receiver bandwidth measurement

The 3 dB upper cutoff frequency is measured using the following steps a) through e):

a) Calibrate the frequency response characteristics of the test equipment including the analog radio frequency (RF) signal generator, RF power combiner, and laser source. Measure the laser's extinction ratio according to 38.6.3. With the exception of extinction ratio, the optical source shall meet the requirements of Clause 38.
b) Configure the test equipment as shown in Figure 38–6. Take care to minimize changes to the signal path that could affect the system frequency response after the calibration in step a. Connect the laser output with no RF modulation applied to the receiver under test through an optical attenuator and taking into account the extinction ratio of the source, set the optical power to a level that approximates the stressed receive sensitivity level in Table 38–4 for 1000BASE-SX and in Table 38–8 for 1000BASE-LX.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) Locate the center of the eye with the BERT. Turn on the RF modulation while maintaining the same average optical power established in step b.
d) Measure the necessary RF modulation amplitude (in dBm) required to achieve a constant BER (e.g., 10^{-8}) for a number of frequencies.
e) The receiver 3 dB electrical upper cutoff frequency is that frequency where the corrected RF modulation amplitude (the measured amplitude in "d" corrected with the calibration data in "a") increases by 3 dB (electrical). If necessary, interpolate between the measured response values.

38.7 Environmental specifications

38.7.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

38.7.2 Laser safety

1000BASE-X optical transceivers shall be Hazard Level 1 laser certified under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore. Transceivers shall be certified to be in conformance with IEC 60825-1 and IEC 60825-2.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance and service. This documentation shall explicitly define requirements and usage restrictions on the host system necessary to meet these safety certifications.[78]

38.7.3 Installation

Sound installation practice, as defined by applicable local codes and regulations, shall be followed in every instance in which such practice is applicable.

38.8 Environment

Normative specifications in this clause shall be met by a system integrating a 1000BASE-X PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

38.8.1 Electromagnetic emission

A system integrating a 1000BASE-X PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

[78]A host system that fails to meet the manufacturers requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

38.8.2 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

38.9 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters, according to the PMD-MDI type.

PMD MDI type 1000BASE-SX:

a) 1000BASE-SX
b) Applicable safety warnings

PMD MDI type 1000BASE-LX:

c) 1000BASE-LX
d) Applicable safety warnings

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 38.7.2.

38.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 38–7.

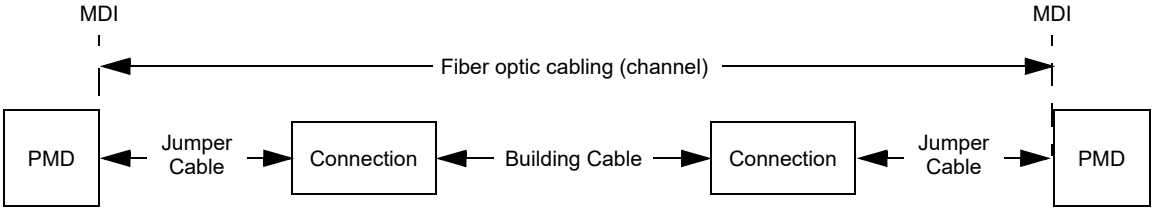

Figure 38–7—Fiber optic cabling model

The channel insertion loss is given in Table 38–11. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method for multimode cabling and IEC 61280-4-2 one-cord reference method for single-mode cabling. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

38.11 Characteristics of the fiber optic cabling

The 1000BASE-SX and 1000BASE-LX fiber optic cabling shall meet the specifications defined in Table 38–12. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. It also includes a connector plug at each end to connect to the MDI. The fiber optic cabling spans from one MDI to another MDI, as shown in Figure 38–7.

Table 38–11—Channel insertion loss

Description	62.5 μm MMF			50 μm MMF			SMF	Unit
Wavelength	850	850	1300	850	850	1300	1310	nm
Modal bandwidth (min; overfilled launch)	160	200	500	400	500	400 or 500	N/A	MHz · km
Operating distance	220	275	550	500	550	550	5000	m
Channel insertion loss[a] [b]	2.33	2.53	2.32	3.25	3.43	2.32	4.5	dB

[a]These channel insertion loss numbers are based on the nominal operating wavelength.
[b]Operating distances used to calculate channel insertion loss are those listed in this table.

38.11.1 Optical fiber and cable

The fiber optic cable requirements are satisfied by the fibers specified in IEC 60793-2:1992. Types A1a (50/125 μm multimode), A1b (62.5/125 μm multimode), and B1 (single-mode) with the exceptions noted in Table 38–12.

Table 38–12—Optical fiber and cable characteristics

Description	62.5 μm MMF		50 μm MMF		SMF	Unit
Nominal fiber specification wavelength	**850**	**1300**	**850**	**1300**	**1310**	**nm**
Fiber cable attenuation (max)	3.75[a]	1.5	3.5	1.5	0.5	dB/km
Modal Bandwidth (min; overfilled launch)	160	500	400	400	N/A	MHz · km
	200	500	500	500	N/A	MHz · km
Zero dispersion wavelength (λ_0)	$1320 \le \lambda_0 \le 1365$		$1295 \le \lambda_0 \le 1320$		$1300 \le \lambda_0 \le 1324$	nm
Dispersion slope (max) (S_0)	0.11 for $1320 \le \lambda_0 \le 1348$ and $0.001(1458 - \lambda_0)$ for $1348 \le \lambda_0 \le 1365$		0.11 for $1300 \le \lambda_0 \le 1320$ and $0.001(\lambda_0 - 1190)$ for $1295 \le \lambda_0 \le 1300$		0.093	ps / nm^2 · km

[a]This value of attenuation is a relaxation of the standard (IEC 60793-2, type A1b, category less than or equal to 3.5 dB/km).

38.11.2 Optical fiber connection

An optical fiber connection as shown in Figure 38–7 consists of a mated pair of optical connectors. The 1000BASE-SX or 1000BASE-LX PMD is coupled to the fiber optic cabling through a connector plug into the MDI optical receptacle, as shown in 38.11.3.

38.11.2.1 Connection insertion loss

The insertion loss is specified for a connection, which consists of a mated pair of optical connectors.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

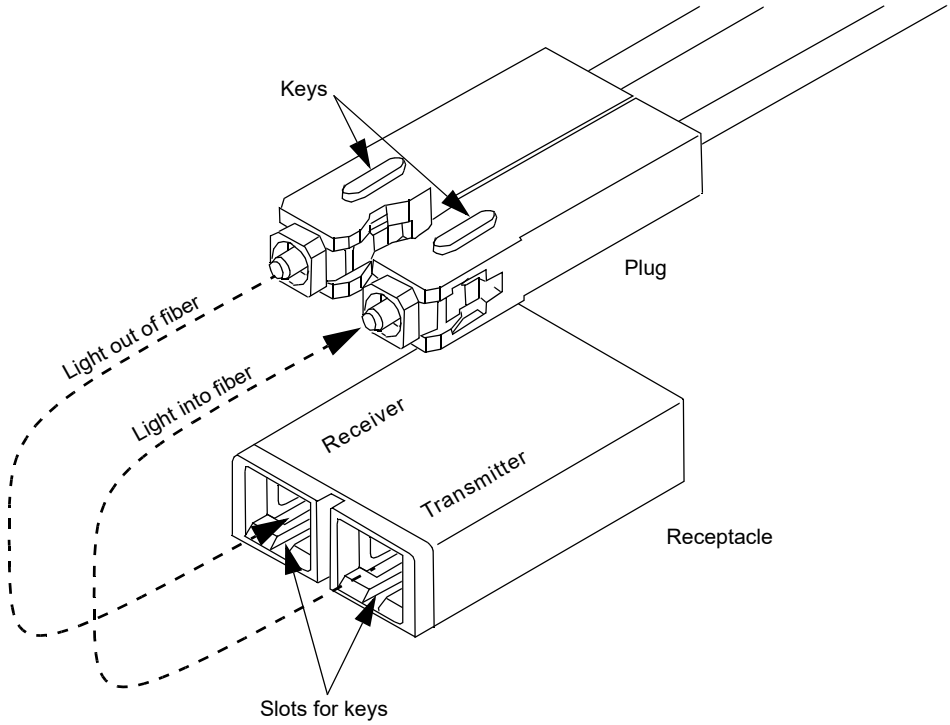
The maximum link distances for multimode fiber are calculated based on an allocation of 1.5 dB total connection and splice loss. For example, this allocation supports three connections with an average insertion loss equal to 0.5 dB (or less) per connection, or two connections (as shown in Figure 38–7) with a maximum insertion loss of 0.75 dB. Connections with different loss characteristics may be used provided the requirements of Table 38–11 and Table 38–12 are met.

The maximum link distances for single-mode fiber are calculated based on an allocation of 2.0 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 38–11 and Table 38–12 are met.

38.11.2.2 Connection return loss

The return loss for multimode connections shall be greater than 20 dB.

The return loss for single-mode connections shall be greater than 26 dB.



38.11.3 Medium Dependent Interface (MDI)

The 1000BASE-SX and 1000BASE-LX PMD is coupled to the fiber optic cabling through a connector plug into the MDI optical receptacle. The 1000BASE-SX and 1000BASE-LX MDI optical receptacles shall be the duplex SC, meeting the following requirements:

a) Meet the dimension and interface specifications of IEC 61754-4 [B33] and IEC 61754-4, Interface 4-2.
b) Meet the performance specifications as specified in ISO/IEC 11801.
c) Ensure that polarity is maintained.
d) The receive side of the receptacle is located on the left when viewed looking into the transceiver optical ports with the keys on the bottom surface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A sample drawing of a duplex SC connector and receptacle is provided in Figure 38–8.

NOTE—Connector keys are used for transmit/receive polarity only. The connector keys do not differentiate between single-mode and multimode connectors.

Figure 38–8—Duplex SC connector and receptacle (example)

38.11.4 Single-mode fiber offset-launch mode-conditioning patch cord for MMF operation of 1000BASE-LX

This subclause specifies an example embodiment of a mode conditioner for 1000BASE-LX operation with MMF cabling. The MMF cabling should meet all of the specifications of 38.10. For 1000BASE-LX the mode conditioner consists of a single-mode fiber permanently coupled off-center to a graded index fiber. This example embodiment of a patch cord is not intended to exclude other physical implementations of offset-launch mode conditioners. However, any implementation of an offset-launch mode conditioner used for 1000BASE-LX shall meet the specifications of Table 38–13. The offset launch has to be contained within the patch cord assembly and is not adjustable by the user.

Table 38–13—Single-mode fiber offset-launch mode conditioner specifications

Description	62.5 μm MMF	50 μm MMF	Unit
Maximum insertion loss	0.5	0.5	dB
Coupled Power Ratio (CPR)	28 < CPR < 40	12 < CPR < 20	dB
Optical center offset between SMF and MMF	17 < Offset < 23	10 < Offset < 16	μm
Maximum angular offset	1	1	degree

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

All patch cord connecting ferrules containing the single-mode-to-multimode offset launch shall have single-mode tolerances (IEC 61754-4 [B33] grade 1 ferrule).

The single-mode fiber used in the construction of the single-mode fiber offset-launch mode conditioner shall meet the requirements of 38.11.1. The multimode fiber used in the construction of the single-mode fiber offset-launch mode conditioner shall be of the same type as the cabling over which the 1000BASE-LX link is to be operated. If the cabling is 62.5 μm MMF then the MMF used in the construction of the mode conditioner should be of type 62.5 μm MMF. If the cabling is 50 μm MMF, then the MMF used in the construction of the mode conditioner should be of type 50 μm MMF.

Figure 38–9 shows the preferred embodiment of the single-mode fiber offset-launch mode-conditioning patch cord. This patch cord consists of duplex fibers including a single-mode-to-multimode offset launch fiber connected to the transmitter MDI and a second conventional graded index MMF connected to the receiver MDI. The preferred configuration is a plug-to-plug patch cord since it maximizes the power budget margin of the 1000BASE-LX link. The single-mode end of the patch cord shall be labeled “To Equipment”. The multimode end of the patch cord shall be labeled “To Cable”. The color identifier of the single-mode fiber connector shall be blue. The color identifier of all multimode fiber connector plugs shall be beige. The patch cord assembly is labeled “Offset-launch mode-conditioning patch cord assembly”. Labelling identifies which size multimode fiber is used in the construction of the patch cord. The keying of the SC duplex optical plug ensures that the single-mode fiber end is automatically aligned to the transmitter MDI.

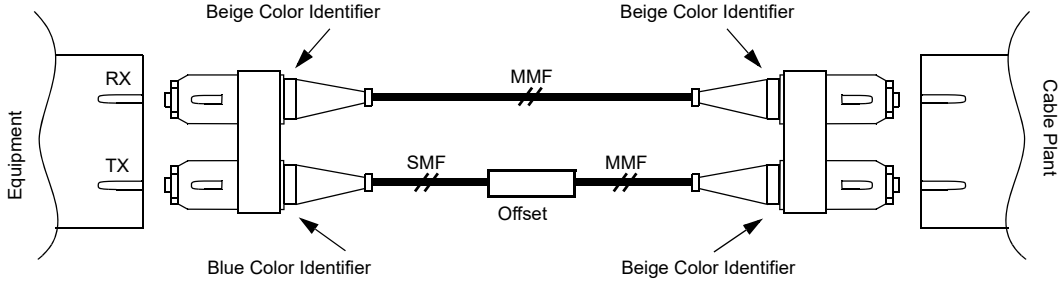


Figure 38–9—1000BASE-LX single-mode fiber offset-launch mode-conditioning patch cord assembly

38.12 Protocol implementation conformance statement (PICS) proforma for Clause 38, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-LX (Long Wavelength Laser) and 1000BASE-SX (Short Wavelength Laser)[79]

38.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 38, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-LX (Long Wavelength Laser) and 1000BASE-SX (Short Wavelength Laser), shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

38.12.2 Identification

38.12.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

38.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 38, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-LX (Long Wavelength Laser) and 1000BASE-SX (Short Wavelength Laser)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[79] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

39. Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-CX (short-haul copper)

39.1 Overview

This clause specifies the 1000BASE-CX PMD (including MDI) and baseband medium for short-haul copper. In order to form a complete 1000BASE-CX Physical Layer it shall be integrated with the 1000BASE-X PCS of Clause 36 and the PMD of Clause 38, which are hereby incorporated by reference. As such, the 1000BASE-CX PMD shall comply with the PMD service interface specified in 38.1.1.

1000BASE-CX has a minimum operating range of 0.1 to 25 m. Jumper cables, described in 39.4, are used to interconnect 1000BASE-CX PMDs. These cables shall not be concatenated to achieve longer distances. A 1000BASE-CX jumper cable assembly consists of a continuous shielded balanced cable terminated at each end with a polarized shielded plug described in 39.5.1. The jumper cable assembly provides an output signal on contacts R+/R– meeting the requirements shown in Figure 39–5 when a transmit signal compliant with Figures 39–3 and 39–4 is connected to the T+/T– contacts at the near-end MDI connector.

The links described in this clause are applied only to homogenous ground applications such as between devices within a cabinet or rack, or between cabinets interconnected by a common ground return or ground plane. This restriction minimizes safety and interference concerns caused by any voltage differences that could otherwise exist between equipment grounds.

39.2 Functional specifications

The 1000BASE-CX PMD performs three functions, Transmit, Receive, and Signal Status according to the service interface definition in 38.1.

39.2.1 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according electrical specifications in 39.3.1. The higher output voltage of T+ minus T– (differential voltage) shall correspond to tx_bit = ONE.

39.2.2 PMD receive function

The PMD Receive function shall convey the bits received at the MDI in accordance with the electrical specifications of 39.3.2 to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher output voltage of R+ minus R– (differential voltage) shall correspond to rx_bit = ONE.

39.2.3 PMD signal detect function

The PMD Signal Detect function shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of electrical signal presence.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 39–1. The PMD receiver is not required to verify whether a compliant 1000BASE-X signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 39–1—SIGNAL_DETECT value definition

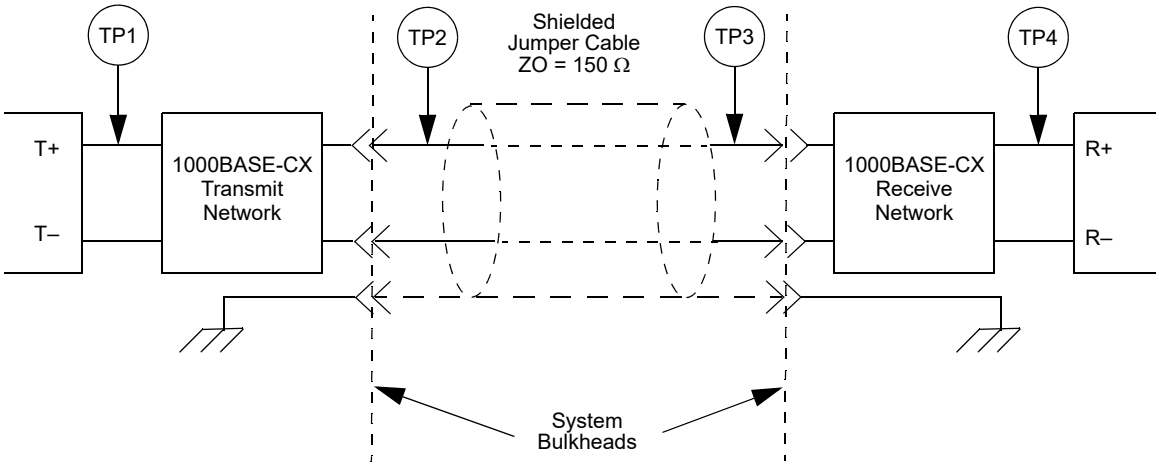
Receive Conditions	Signal Detect Value
V_{input}, Receiver < (receiver sensitivity + worst-case local system noise)[a]	FAIL
Minimum differential sensitivity ≤ $V_{input,}$ Receiver ≤ Maximum differential input AND compliant 1000BASE-X signal input	OK
All other conditions	Unspecified

[a]Worst-case local system noise includes all receiver coupled noise sources (NEXT, power supply noise, and any reflected signals). Receive sensitivity is the actual sensitivity of the specific port (as opposed to the minimum differential sensitivity).

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input signal level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD due to cross talk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations which generate the SIGNAL_DETECT parameter values in response to the amplitude of the 8B/10B modulation of the electrical signal

39.3 PMD to MDI electrical specifications



All interface specifications are valid only at the point of entry and exit from the equipment. These points are identified as points TP2 and TP3 as shown in Figure 39–1. The specifications assume that all measurements are made after a mated connector pair, relative to the source or destination.

TP1 and TP4 are standardized reference points for use by implementers to certify component conformance. The electrical specifications of the PMD service interface (TP1 and TP4) are not system compliance points (these are not readily testable in a system implementation). It is expected that in many implementations TP1 and TP4 will be common between 1000BASE-SX (Clause 38), 1000BASE-LX (Clause 38), and 1000BASE-CX.

PMD specifications shall be measured using the measurement techniques defined in 39.6.

The reference points for all connections are those points TP2 and TP3 where the cabinet Faraday shield transitions between the cabinet and the jumper cable shield. If sections of transmission line exist within the Faraday shield, they are considered to be part of the associated transmit or receive network, and not part of the jumper cable assembly.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Jumper cable assembly shielding is attached to the system chassis via the connector shroud.

Figure 39–1—1000BASE-CX link (half link is shown)

Schematics in the diagrams in this clause are for illustration only and do not represent the only feasible implementation.

39.3.1 Transmitter electrical specifications

The output driver is assumed to have output levels approximating those of Emitter Coupled Logic (ECL), as measured at TP1. The transmitter shall meet the specifications in Table 39–2.

Table 39–2—Transmitter characteristics at TP2

Description	Value	Unit
Type	(P)ECL	
Data rate	1000	Mb/s
Clock tolerance	±100	ppm
Nominal signaling speed	1250	MBd
Differential amplitude (p-p)		
Max (worst case p-p)	2000	mV
Min (opening)	1100	mV
Max (OFF)[a]	170	mV
Rise/Fall time (20-80%)		
maximum	327	ps
minimum	85	ps
Differential skew (max)	25	ps

[a]Examples of an OFF transmitter are no power supplied to the PMD and PMA transmit output being driven to a static state during loopback.

For all links, the output driver shall be AC-coupled to the jumper cable assembly through a transmission network, and have output levels, measured at the input to the jumper cable assembly (TP2), meeting the eye diagram requirements of Figure 39–3 and Figure 39–4, when terminated as shown in Figure 39–2. The symbols X1 and X2 in Figure 39–3 and Figure 39–4 are defined in Table 39–3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

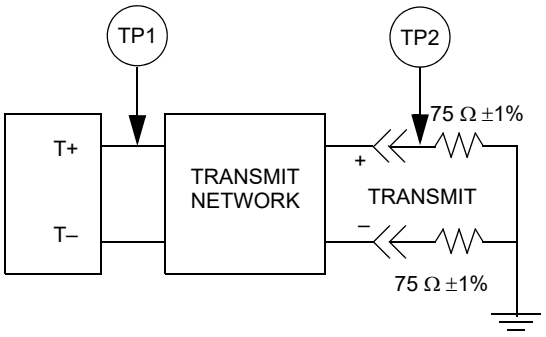

Figure 39–2—Balanced transmitter test load

The normalized amplitude limits in Figure 39–3 are set to allow signal overshoot of 10% and undershoot of 20%, relative to the amplitudes determined to be a logic 1 and 0. The absolute transmitter output timing and amplitude requirements are specified in Table 39–2, Table 39–3, and Figure 39–4. The normalized transmitter output timing and amplitude requirements are specified in Table 39–2, Table 39–3, and Figure 39–3. The transmit masks of Figure 39–3 and Figure 39–4 are not used for response time and jitter specifications.

NOTE 1—The relationship between Figure 39–3 and Figure 39–4 can best be explained by a counter example. If a transmitter outputs a nominal 600 mV-ppd logic one level with overshoot to 900 mV-ppd, it will pass the absolute mask of Figure 39–4 but will not pass the normalized mask of Figure 39–3. Normalized, this signal would have 50% overshoot. This exceeds the 10% overshoot limit defined by the normalized eye mask.

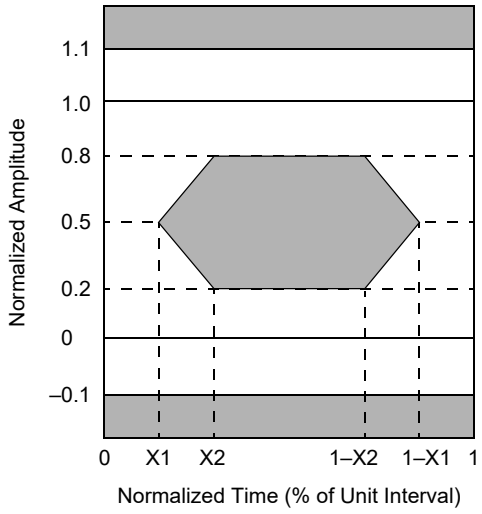

Figure 39–3—Normalized eye diagram mask at TP2

Table 39–3—Normalized time intervals for TP2

Symbol	Value	Units
X1	0.14	Unit Intervals (UI)
X2	0.34	Unit Intervals (UI)

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

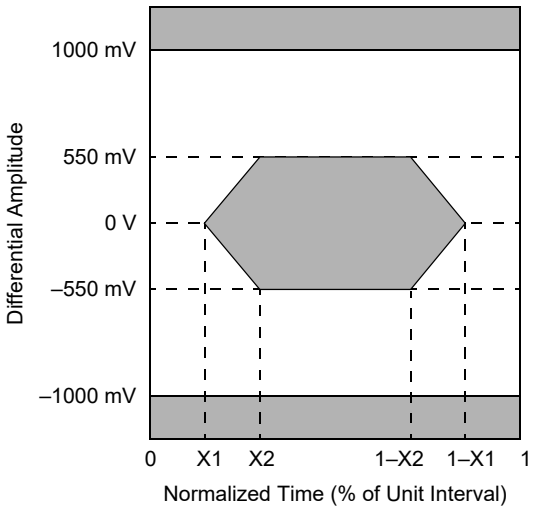

Figure 39–4—Absolute eye diagram mask at TP2

The recommended interface to electrical transmission media is via transformer or capacitive coupling.

NOTE 2—All specifications, unless specifically listed otherwise, are based on differential measurements.

NOTE 3—All times indicated for TDR measurements are recorded times. Recorded times are twice the transit time of the TDR signal.

NOTE 4—The transmit differential skew is the maximum allowed time difference (on both low-to-high and high-to low transitions) as measured at TP2, between the true and complement signals. This time difference is measured at the midway point on the signal swing of the true and complement signals. These are single-ended measurements.

NOTE 5—The transmitter amplitude maximum specification identifies the maximum p-p signal that can be delivered into a resistive load matching that shown in Figure 39–2.

NOTE 6—The transmitter amplitude minimum specification identifies the minimum allowed p-p eye amplitude opening that can be delivered into a resistive load matching that shown in Figure 39–2.

NOTE 7—The normalized 1 is that amplitude determined to be the average amplitude when driving a logic 1. The normalized 0 is that amplitude determined to be the average amplitude when driving a logic 0.

NOTE 8—Eye diagram assumes the presence of only high-frequency jitter components that are not tracked by the clock recovery circuit. For this standard the lower cutoff frequency for jitter is 637 kHz.

39.3.2 Receiver electrical specifications

The receiver shall be AC-coupled to the media through a receive network located between TP3 and TP4 as shown in Figure 39–1. The receiver shall meet the signal requirements listed in Table 39–4.

The minimum input amplitude to the receiver listed in Table 39–4 and Figure 39–5 is a worst case specification across all environmental conditions. Restricted environments may allow operation at lower minimum differential voltages, allowing significantly longer operating distances.

NOTE 1—All specifications, unless specifically listed otherwise, are based on differential measurements.

NOTE 2—The receiver minimum differential sensitivity identifies the minimum p-p eye amplitude at TP3 to meet the BER objective.

NOTE 3—Eye diagrams assume the presence of only high-frequency jitter components that are not tracked by the clock recovery circuit. For this standard the lower cutoff frequency for jitter is 637 kHz.

NOTE 4—All times indicated for TDR measurements are recorded times. Recorded times are twice the transit time of the TDR signal.

NOTE 5—Through_Connection impedance describes the impedance tolerance through a mated connector. This tolerance is greater than the termination or cable impedance due to limits in the technology of the connectors.

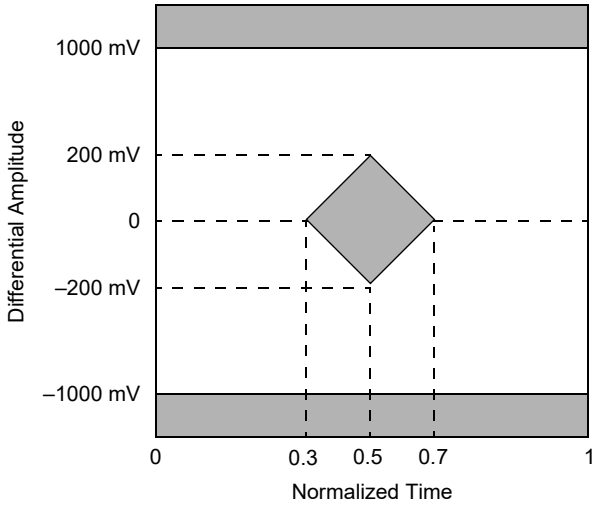

Figure 39–5—Eye diagram mask at point-TP3

Table 39–4—Receiver characteristics (TP3)

Description	Value	Units
Data rate	1000	Mb/s
Nominal signaling speed	1250	MBd
Tolerance	±100	ppm
Minimum differential sensitivity (peak-peak)	400	mV
Maximum differential input (peak-peak)	2000	mV
Input Impedance @ TP3		
TDR Rise Time	85	ps
Exception_window[a]	700	ps
Through_connection	150 ± 30	Ω
At Termination[b]	150 ± 10	Ω
Differential Skew	175	ps

[a]Within the Exception_window no single impedance excursion shall exceed the Through_Connection-impedance tolerance for a period of twice the TDR rise time specification.

[b]The input impedance at TP3, for the termination, shall be recorded 4.0 ns following the reference location determined by an open connector between TP3 and TP4.

39.3.3 Jitter specifications for 1000BASE-CX

The 1000BASE-CX PMD shall meet the total jitter specifications defined in Table 38–10. Normative values are highlighted **in bold.** All other values are optional. Compliance points are defined in 39.3.

Jitter shall be measured as defined in 38.6.8 with the exception that no measurement will require the use of an optical to electrical converter (O/E).

Deterministic jitter budgetary specifications are included here to assist implementers in specifying components. Measurements for DJ are described in 38.6.9 with the exception that no measurement will require the use of an O/E.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 39–5—1000BASE-CX jitter budget

Compliance point	Total jitter[a]		Deterministic jitter	
	UI	ps	UI	ps
TP1	**0.240**	**192**	0.120	96
TP1 to TP2	0.090	72	0.020	16
TP2	**0.279**	**223**	0.140	112
TP2 to TP3	0.480	384	0.260	208
TP3	**0.660**	**528**	0.400	320
TP3 to TP4	0.050	40	0.050	40
TP4	**0.710**	**568**	0.450	360

[a]Total jitter is composed of both deterministic and random components. The allowed random jitter equals the allowed total jitter minus the actual deterministic jitter at that point.

39.4 Jumper cable assembly characteristics

A 1000BASE-CX compliant jumper cable assembly shall consist of a continuous shielded balanced cable terminated at each end with a polarized shielded plug as described in 39.5.1. The jumper cable assembly shall provide an output signal on contacts R+/R– meeting the requirements shown in Figure 39–5 when a transmit signal compliant with Figures 39–3 and 39–4 is connected to the T+/T– contacts at the near-end MDI connector. This jumper cable assembly shall have electrical and performance characteristics as described in Table 39–6. Jumper cable assembly specifications shall be measured using the measurement techniques defined in 39.6. The jumper cable assembly may have integrated compensation networks.

NOTE 1—Jumper cable assemblies that meet the requirements for ANSI INCITS 230-1994 (FC-PH) may not meet the requirements of this clause.

NOTE 2—Through_Connection impedance describes the impedance tolerance through a mated connector. This tolerance is greater than the termination or cable impedance due to limits in the technology of the connectors.

To produce jumper cable assemblies capable of delivering signals compliant with the requirements of 39.4, the assemblies should generally have characteristics equal to or better than those in Table 39–7.

39.4.1 Compensation networks

A jumper cable assembly may include an equalizer network to meet the specifications and signal quality requirements (e.g., receiver eye mask at TP3) of this clause. The equalizer shall need no adjustment. All jumper cable assemblies containing such circuits shall be marked with information identifying the specific designed operational characteristics of the jumper cable assembly.

39.4.2 Shielding

The jumper cable assembly shall provide class 2 or better shielding in accordance with IEC 61196-1.

39.5 MDI specification

This clause defines the Media Dependent Interface (MDI). The 1000BASE-CX PMD of 39.3 is coupled to the jumper cable assembly by the media dependent interface (MDI).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 39–6—Jumper cable assembly characteristics (normative)

Description	Value	Unit
Differential skew (max)	150	ps
Link Impedance @ TP2/TP3[a] Through_connection Cable	 150 ± 30 150 ± 10	 W W
TDR rise time Exception_window[b]	85 700	ps ps
Round-trip delay (max)[c]	253 253	bit times ns

[a]The link impedance measurement identifies the impedance mismatches present in the jumper cable assembly when terminated in its characteristic impedance. This measurement includes mated connectors at both ends of the Jumper cable assembly (points TP2 and TP3). The link impedance for the jumper cable assembly, shall be recorded 4.0 ns following the reference location determined by an open connector at TP2 and TP3.

[b]Within the Exception_window no single impedance excursion shall exceed the Through_Connection-impedance tolerance for a period of twice the TDR rise time specification. The Exception_window (used with specific impedance measurements) identifies the maximum time period during which the measured impedance is allowed to exceed the listed impedance tolerance. The maximum excursion within the Exception_window at TP3 shall not exceed ±33% of the nominal cable impedance.

[c]Used in Clause 42. This delay is a budgetary requirement of the upper layers. It is easily met by the jumper cable delay characteristics in this clause.

Table 39–7—Jumper cable assembly characteristics (recommended)

Description	Value	Unit
Attenuation (max.) at 625 MHz	8.8	dB
Minimum NEXT loss @ 85 ps Tr (max)	6 24.5	% dB

39.5.1 MDI connectors

Connectors meeting the requirements of 39.5.1.1 (Style-1) and 39.5.1.2 (Style-2) shall be used as the mechanical interface between the PMD of 39.3 and the jumper cable assembly of 39.4. The plug connector shall be used on the jumper cable assembly and the receptacle on the PHY. Style-1 or style-2 connectors may be used as the MDI interface. To limit possible cross-plugging with non-1000BASE-CX interfaces that make use of the Style-1 connector, it is recommended that the Style-2 connector be used as the MDI connector.

39.5.1.1 Style-1 connector specification

The style-1 balanced connector for balanced jumper cable assemblies shall be the 9-pin shielded D-subminiature connector, with the mechanical mating interface defined by IEC 60807-3, having pinouts matching those in Figure 39–6, and the signal quality and electrical requirements of this clause. The style-1 connector pin assignments are shown in Figure 39–6 and Table 39–8.

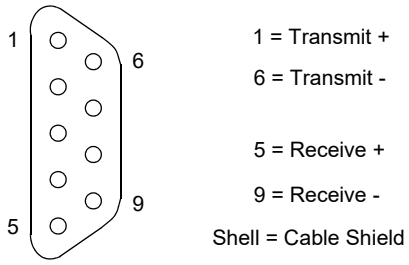

Figure 39–6—Style-1 balanced connector receptacle pin assignments

39.5.1.2 Style-2 connector specification

The style-2 balanced cable connector is the 8-pin shielded ANSI Fibre Channel style-2 connector with the mechanical mating interface defined by IEC 61076-3-103, having pinouts matching those shown in Figure 39–7, and conforming to the signal quality and electrical requirements of this clause.

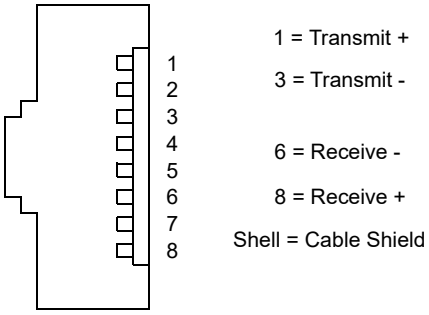

Figure 39–7—Style-2 balanced connector receptacle pin assignments

The style-1 or style-2 connector may be populated with optional contacts to support additional functions. The presence of such contacts in the connector assemblies does not imply support for these additional functions.

NOTE 1—Style-1 pins 2 and 8 (Style-2 pins 7 and 2) are reserved for applications that assign these pins to power and ground.

NOTE 2—Style-1 pin 3 (Style-2 pin 4) is reserved for applications that assign this pin to a Fault Detect function.

NOTE 3—Style-1 pin 7 (Style-2 pin 5) is reserved for applications that assign this pin to an Output Disable function.

5	8	Receive +
6	3	Transmit –
7	5	Reserved
8	2	Reserved
9	6	Receive –

39.5.1.3 Style-2 connector example drawing

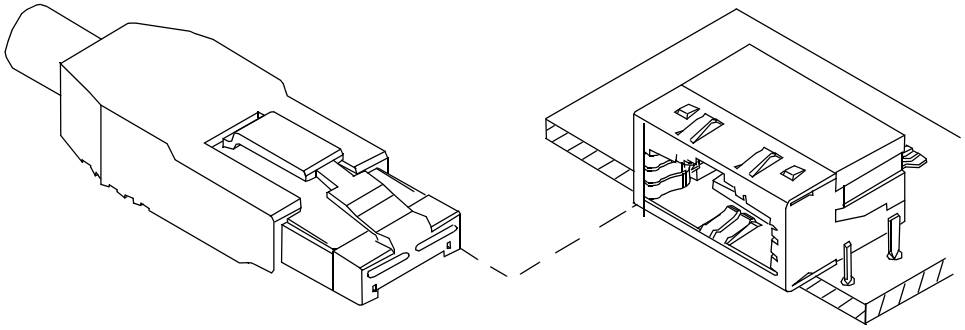

Figure 39–8—Style-2 connector, example drawing

39.5.2 Crossover function

The default jumper cable assembly shall be wired in a crossover fashion as shown in Figure 39–9, with each pair being attached to the transmitter contacts at one end and the receiver contacts at the other end.

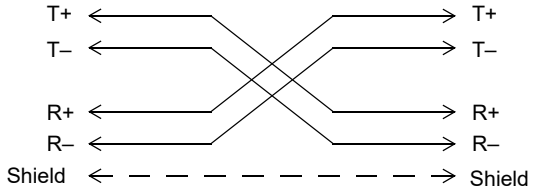

Figure 39–9—Balanced cable wiring

39.6 Electrical measurement requirements

Electrical measurements shall be performed as described in this subclause.

39.6.1 Transmit rise/fall time

Rise time is a differential measurement across the T+ and T– outputs with a load present (including test equipment) equivalent to that shown in Figure 39–2. Both rising and falling edges are measured. The 100% and 0% levels are the normalized 1 and 0 levels present when sending an alternating K28.5 character stream.

Once the normalized amplitude is determined, the data pattern is changed to a continuous D21.5 character stream. The rise time specification is the time interval between the normalized 20% and 80% amplitude levels.

39.6.2 Transmit skew measurement

The transmitter skew is the time difference between the T+ and T– outputs measured at the normalized 50% crossover point with a load present (including test equipment) equivalent to that shown in Figure 39–2. This measurement is taken using two single ended probes. Skew in the test set-up has to be calibrated out.

Normalized amplitudes can be determined using the method described in 39.6.1.

A continuous D21.5 or K28.7 data pattern is transmitted by the device under test. The data is averaged using an averaging scope. An easy method to view and measure the skew between these signals is to invert one.

39.6.3 Transmit eye (normalized and absolute)

This test is made as a differential measurement at the bulkhead connector. The scope trigger has to either be a recovered clock as defined in 38.6.8 or a character clock internal to the equipment. The data pattern for this is the alternating K28.5.

If a character trigger is used, the overshoot/undershoot percentages have to be measured at all ten bit positions. The load for this test is that shown in Figure 39–2.

39.6.4 Through_connection impedance

This is a differential TDR or equivalent measurement that has to be made through a mated connector pair or pairs. Any lead-in trace or cable to the connector that is part of the test fixture should provide a reasonable impedance match so as to not effect the actual measurement. All TDR measurements have to be filtered to the TDR rise time specification. Any test fixture used with these TDR tests has to be calibrated to remove the effects of the test fixture, and verified to produce accurate results.

The impedance Through_connection interval starts at the first point where the measured impedance exceeds the limits for the termination and ends at the point that the impedance returns to within the termination impedance limits and remains there.

Within this Through_connection interval, an Exception_window exists where the impedance is allowed to exceed the Through_connection impedance limits up to a maximum deviation of ±33% of the nominal link impedance. The Exception_window begins at the point where the measured impedance first exceeds the impedance tolerance limits for Through_connection.

39.6.5 Jumper cable intra-pair differential skew

The jumper cable intra-pair differential skew measurement is conducted to determine the skew, or difference in velocity, of each wire in a cable pair when driven with a differential source. This measurement requires two

mated connectors, one at the signal source and one at the opposite end of the cable. A pair of matched, complimentary signals (S+, S–) are driven into the T+ and T– contacts of the connector. These signals are time conditioned to start at the same point. This test shall be performed at both ends of the jumper cable assembly.

The jumper cable intra-pair skew is the time difference between the R+ and R– outputs of the excited pair within the jumper cable assembly measured at the normalized 50% crossover point with a load present (including test equipment) equivalent to that shown in Figure 39–2. This measurement is taken using two single ended probes. Skew in the test set-up has to be calibrated out.

Normalized amplitudes can be determined using the method described in 39.6.1.

A continuous square wave is used for S+, S–. The data is averaged using an averaging scope. An easy method to view and measure the skew between these signals is to invert one. A differential TDR can provide a convenient method to time condition the input signals.

39.6.6 Receiver link signal

This differential measurement is made at the end of the jumper cable assembly, through mated connectors with a load present (including test equipment) equivalent to that shown in Figure 39–2. The signal is measured with an alternating K28.5 character stream and is tested to the mask requirements of Figure 39–5.

39.6.7 Near-End Cross Talk (NEXT)

NEXT Loss tests are conducted using a differential TDR (or equivalent) filtered to the rise time limit (near-end cross talk at a maximum T_r of 85 ps) in Table 39–6. The T+ and T– inputs of the jumper cable connector are excited to create a disturber pair while the R+ and R– contacts of the disturbed pair are measured within the same connector. The far-end R+/R– outputs of the disturber pair are terminated per Figure 39–2. The R+ and R– signals of the disturbed pair are terminated with a load (including test equipment) equivalent to that shown in Figure 39–2. The T+ and T– inputs of disturbed pair shall be terminated per Figure 39–2. This test shall be performed at both ends of the jumper cable assembly.

39.6.8 Differential time-domain reflectometry (TDR) measurement procedure

The differential TDR test setup measures the reflected waveform returned from a load when driven with a step input. It is obtained by driving the load under test with a step waveform using a driver with a specified source impedance and rise time. The reflected waveform is the difference between (a) the observed waveform at the device under test when driven with the specified test signal, and (b) the waveform that results when driving a standard test load with the same specified test signal. From this measured result we can infer the impedance of the device under test. The derivative of a time-domain reflectometry measurement is the time-domain equivalent of S_{11} parameter testing used in carrier-based systems.

For the measurement of 1000BASE-CX jumper cables, the following test conditions apply:

a) The driving waveform is sourced from a balanced, differential 150 Ω source with an 85 ps rise time (see 39.6.8.1).
b) The test setup is calibrated (see 39.6.8.2).

39.6.8.1 Driving waveform

If the natural differential output impedance of the driving waveform is not 75 Ω, it may be adjusted to within 75 Ω ± 5 Ω by an attenuating resistive pad. When the driving point resistance is 100 Ω (as would be the case with a differential signal source having two independent, antipodal, 50 Ω sources), a good pad design is shown in Figure 39–10, where R1 = 173.2 Ω and R2 = 43.3 Ω. All resistors are surface-mount packages

soldered directly to the test fixture with no intervening leads or traces, and the whole structure is mounted on a solid ground plane (used in three places).

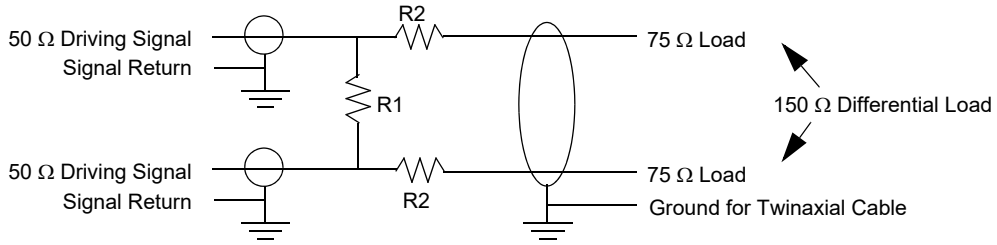

Figure 39–10—Differential TDR pad adapter

If the natural rise time of the driver is less than 85 ps, the resulting measured time-waveforms have to be filtered to reduce the apparent rise time to 85 ps ± 10 ps.

39.6.8.2 Calibration of the test setup

Three measurements are made, with a short, and open, and a known test load. The value of the test resistance should be constant to within 1% over the frequency range dc to 6 GHz, and of known value. The value of the test resistance should be within the range 75 Ω ± 5 Ω.

The differential voltages measured across the device-under-test terminals in these three cases are called V_{short}, V_{open}, and V_{test}, respectively. From these three measurements we will compute three intermediate quantities:

$$A = (V_{open} - V_{short}) /2$$

$$B = (V_{open} + V_{short}) /2$$

$$Z_0 = Z_{test} \times (V_{open} - V_{test})/(V_{test} - V_{short})$$

The value of Z_0 is the actual driving point impedance of the tester. It has to be within 75 Ω ± 5 Ω.

For any device under test, the conversion from measured voltage $V_{measured}$ to impedance is as follows:

Measured impedance = $Z_0 \times (1 + V')/(1 - V')$

where $V' = (V_{measured} - B)/A$.

39.7 Environmental specifications

All equipment subject to this clause shall conform to the requirements of 14.7 and applicable sections of ISO/IEC 11801:1995. References to the MAU or AUI should be replaced with PHY or DTE and AUI to jumper cable assembly, as appropriate. Subclause 14.7.2.4, *Telephony voltage*, should be ignored. Should a case occur where, through a cabling error, two transmitters or receivers are directly connected, no damage shall occur to any transmitter, receiver, or other link component in the system. The link shall be able to withstand such an invalid connection without component failure or degradation for an indefinite period of time.

Systems connected with 1000BASE-CX links shall meet the bonding requirements (common ground connection) of ISO/IEC 11801:1995, subclause 9.2, for shielded cable assemblies. Cable shield(s) shall be

earthed (chassis ground) through the bulkhead connector shell(s) on both ends of the jumper cable assembly as shown in Figure 39–1.

39.8 Protocol implementation conformance statement (PICS) proforma for Clause 39, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-CX[80]

39.8.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 39, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-CX, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

39.8.2 Identification

39.8.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

39.8.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 39, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-CX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[80] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

40. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer and baseband medium, type 1000BASE-T

40.1 Overview

The 1000BASE-T PHY is one of the Gigabit Ethernet family of high-speed CSMA/CD network specifications. The 1000BASE-T Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) and baseband medium specifications are intended for users who want 1000 Mb/s performance over Category 5 balanced twisted-pair cabling systems. 1000BASE-T signaling requires four pairs of balanced cabling, as specified in ISO/IEC 11801:1995 (Class D) and ANSI/EIA/TIA-568-A-1995 (Category 5), and tested for the additional performance parameters specified in ANSI/EIA/TIA-568-B1 Annex D.

NOTE—ISO/IEC 11801:2002 provides a specification (Class D) for media that exceeds the minimum requirements of this standard.

This clause defines the type 1000BASE-T PCS, type 1000BASE-T PMA sublayer, and type 1000BASE-T Medium Dependent Interface (MDI). Together, the PCS and the PMA sublayer comprise a 1000BASE-T Physical Layer device (PHY). Provided in this document are fully functional, electrical, and mechanical specifications for the type 1000BASE-T PCS, PMA, and MDI. This clause also specifies the baseband medium used with 1000BASE-T.

40.1.1 Objectives

The following are the objectives of 1000BASE-T:

a) Support the CSMA/CD MAC
b) Comply with the specifications for the GMII (Clause 35)
c) Support the 1000 Mb/s repeater (Clause 41)
d) Provide line transmission that supports full and half duplex operation
e) Meet or exceed FCC Class A/CISPR or better operation
f) Support operation over 100 meters of copper balanced cabling as defined in 40.7
g) Bit Error Ratio of less than or equal to 10^{-10}
h) Support Auto-Negotiation (Clause 28)

40.1.2 Relationship of 1000BASE-T to other standards

Relations between the 1000BASE-T PHY, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 CSMA/CD LAN Model are shown in Figure 40–1. The PHY sublayers (shown shaded) in Figure 40–1 connect one Clause 4 Media Access Control (MAC) layer to the medium.

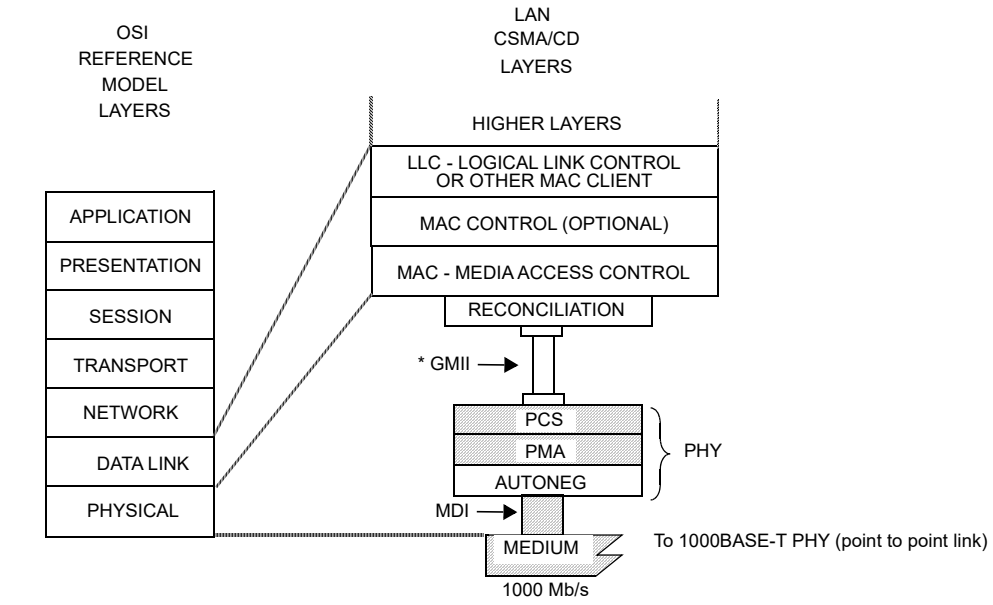

Figure 40–1—Type 1000BASE-T PHY relationship to the ISO Open Systems Interconnection (OSI) Reference Model and the IEEE 802.3 CSMA/CD LAN Model

40.1.3 Operation of 1000BASE-T

The 1000BASE-T PHY employs full duplex baseband transmission over four pairs of Category 5 balanced cabling. The aggregate data rate of 1000 Mb/s is achieved by transmission at a data rate of 250 Mb/s over each wire pair, as shown in Figure 40–2. The use of hybrids and cancellers enables full duplex transmission by allowing symbols to be transmitted and received on the same wire pairs at the same time. Baseband signaling with a modulation rate of 125 MBd is used on each of the wire pairs. The transmitted symbols are selected from a four-dimensional 5-level symbol constellation. Each four-dimensional symbol can be viewed as a 4-tuple (A_n, B_n, C_n, D_n) of one-dimensional quinary symbols taken from the set {2, 1, 0, –1, –2}. 1000BASE-T uses a continuous signaling system; in the absence of data, Idle symbols are transmitted. Idle mode is a subset of code-groups in that each symbol is restricted to the set {2, 0, –2}to improve synchronization. Five-level Pulse Amplitude Modulation (PAM5) is employed for transmission over each wire pair. The modulation rate of 125 MBd matches the GMII clock rate of 125 MHz and results in a symbol period of 8 ns.

A 1000BASE-T PHY can be configured either as a MASTER PHY or as a SLAVE PHY. The MASTER-SLAVE relationship between two stations sharing a link segment is established during Auto-Negotiation (see Clause 28, 40.5, and Annex 28C). The MASTER PHY uses a local clock to determine the timing of transmitter operations. The SLAVE PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations, i.e., it performs loop timing, as illustrated in Figure 40–3. In

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a multiport to single-port connection, the multiport device is typically set to be MASTER and the single-port device is set to be SLAVE.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

The PCS and PMA subclauses of this document are summarized in 40.1.3.1 and 40.1.3.2. Figure 40–3 shows the functional block diagram.

A 1000BASE-T PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization. The “Assert LPI” request at the GMII is encoded in the transmitted symbols. Detection of LPI signaling in the received symbols is indicated as “Assert LPI” at the GMII. When LPI signaling is simultaneously transmitted and received, an energy-efficient 1000BASE-T PHY ceases transmission and deactivates transmit and receive functions to conserve energy. The PHY periodically transmits during this quiet period to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variation in the timing of the link or the underlying channel characteristics. If, during the quiet or refresh periods, normal interframe is asserted at the GMII, the PHY reactivates transmit and receive functions and initiates transmission. This transmission will be detected by the remote PHY, causing it to also exit the LPI mode.

The conditions for supporting the optional EEE capability are defined in 78.3.

40.1.3.1 Physical Coding Sublayer (PCS)

The 1000BASE-T PCS couples a Gigabit Media Independent Interface (GMII), as described in Clause 35, to a Physical Medium Attachment (PMA) sublayer.

The functions performed by the PCS comprise the generation of continuous code-groups to be transmitted over four channels and the processing of code-groups received from the remote PHY. The process of converting data bits to code-groups is called 4D-PAM5, which refers to the four-dimensional 5-level Pulse Amplitude Modulation coding technique used. Through this coding scheme, eight bits are converted to one transmission of four quinary symbols.

During the beginning of a frame's transmission, when TX_EN is asserted from the GMII, two code-groups representing the Start-of-Stream delimiter are transmitted followed by code-groups representing the octets coming from the GMII. Immediately following the data octets, the GMII sets TX_EN=FALSE, upon which the end of a frame is transmitted. The end of a frame consists of two convolutional state reset symbol periods and two End-of-Stream delimiter symbol periods. This is followed by an optional series of carrier extend symbol periods and, possibly, the start of a new frame during frame bursting. Otherwise, the end of a frame is followed by a series of symbols encoded in the idle mode. The nature of the encoding that follows the end of a frame is determined by the GMII signals TX_ER and TXD<7:0> as specified in Clause 35.

Between frames, a special subset of code-groups using only the symbols {2, 0, –2} is transmitted. This is called idle mode. Idle mode encoding takes into account the information of whether the local PHY is operating reliably or not (see 40.4.2.4) and allows this information to be conveyed to the remote station. During normal operation, idle mode is followed by a data mode that begins with a Start-of-Stream delimiter.

When the PHY supports the optional EEE capability, Idle mode encoding also conveys to the remote PHY information of whether the local PHY is requesting entry into the LPI mode or not. Such requests are a direct translation of "Assert LPI" at the GMII. In addition, Idle mode encoding conveys to the remote PHY whether the local PHY has completed the update of its receiver state or not, as indicated by the PMA PHY Control function.

Further patterns are used for signaling a transmit error and other control functions during transmission of a data stream.

The PCS Receive processes code-groups provided by the PMA. The PCS Receive detects the beginning and the end of frames of data and, during the reception of data, descrambles and decodes the received code-groups into octets RXD<7:0> that are passed to the GMII. The conversion of code-groups to octets uses an 8B1Q4 data decoding technique. PCS Receive also detects errors in the received sequences and signals them to the GMII. Furthermore, the PCS contains a PCS Carrier Sense function, a PCS Collision Presence function, and a management interface.

The PCS functions and state diagrams are specified in 40.3. The signals provided by the PCS at the GMII conform to the interface requirements of Clause 35. The PCS Service Interfaces to the GMII and the PMA are abstract message-passing interfaces specified in 40.2.

40.1.3.2 Physical Medium Attachment (PMA) sublayer

The PMA couples messages from the PMA service interface onto the balanced cabling physical medium and provides the link management and PHY Control functions. The PMA provides full duplex communications at 125 MBd over four pairs of balanced cabling up to 100 m in length.

The PMA Transmit function comprises four independent transmitters to generate five-level, pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD, as described in 40.4.3.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA Receive function comprises four independent receivers for five-level pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD, as described in 40.4.3.2. This signal encoding technique is referred to as 4D-PAM5. The receivers are responsible for acquiring clock and providing code-groups to the PCS as defined by the PMA_UNITDATA.indication message. The PMA also contains functions for Link Monitor.

The PMA PHY Control function generates signals that control the PCS and PMA sublayer operations. PHY Control begins following the completion of Auto-Negotiation and provides the startup functions required for successful 1000BASE-T operation. It determines whether the PHY operates in a normal state, enabling data transmission over the link segment, or whether the PHY sends special code-groups that represent the idle mode. The latter occurs when either one or both of the PHYs that share a link segment are not operating reliably.

When the PHY supports the optional EEE capability, the PMA PHY Control function also coordinates transitions between the LPI mode and the normal operating mode.

PMA functions and state diagrams are specified in 40.4. PMA electrical specifications are given in 40.6.

40.1.4 Signaling

1000BASE-T signaling is performed by the PCS generating continuous code-group sequences that the PMA transmits over each wire pair. The signaling scheme achieves a number of objectives including

a) Forward error correction (FEC) coded symbol mapping for data.
b) Algorithmic mapping and inverse mapping from octet data to a quartet of quinary symbols and back.
c) Uncorrelated symbols in the transmitted symbol stream.
d) No correlation between symbol streams traveling both directions on any pair combination.
e) No correlation between symbol streams on pairs BI_DA, BI_DB, BI_DC, and BI_DD.
f) Idle mode uses a subset of code-groups in that each symbol is restricted to the set {2, 0, –2}to ease synchronization, startup, and retraining.
g) Ability to rapidly or immediately determine if a symbol stream represents data or idle or carrier extension.
h) Robust delimiters for Start-of-Stream delimiter (SSD), End-of-Stream delimiter (ESD), and other control signals.
i) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining.
j) Optionally, ability to signal to the remote PHY a request to enter the LPI mode and to exit the LPI mode and return to normal operation.
k) Optionally, ability to signal to the remote PHY that the update of the local receiver state (e.g., timing recovery, adaptive filter coefficients) has completed.
l) Ability to automatically detect and correct for pair swapping and unexpected crossover connections.
m) Ability to automatically detect and correct for incorrect polarity in the connections.
n) Ability to automatically correct for differential delay variations across the wire-pairs.

The PHY may operate in three basic modes, normal mode, training mode, or an optional LPI mode. In normal mode, PCS generates code-groups that represent data, control, or idles for transmission by the PMA. In training mode, the PCS is directed to generate only idle code-groups for transmission by the PMA, which enable the receiver at the other end to train until it is ready to operate in normal mode. In LPI mode, the PCS is directed to generate only idle code-groups encoded with LPI request and update status indications, or zeros as dictated by the PMA PHY Control function. (See the PCS reference diagram in 40.2.)

40.1.5 Inter-sublayer interfaces

All implementations of the balanced cabling link are compatible at the MDI. Designers are free to implement circuitry within the PCS and PMA in an application-dependent manner provided that the MDI and GMII (if the GMII is implemented) specifications are met. When the PHY is incorporated within the physical bounds of a single-port device or a multiport device, implementation of the GMII is optional. System operation from the perspective of signals at the MDI and management objects are identical whether the GMII is implemented or not.

40.1.6 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5.

The values of all components in test circuits shall be accurate to within ±1% unless otherwise stated.

Default initializations, unless specifically specified, are left to the implementer.

40.2 1000BASE-T Service Primitives and Interfaces

1000BASE-T transfers data and control information across the following four service interfaces:

a) Gigabit Media Independent Interface (GMII)
b) PMA Service Interface
c) Medium Dependent Interface (MDI)
d) Technology-Dependent Interface

The GMII is specified in Clause 35; the Technology-Dependent Interface is specified in Clause 28. The PMA Service Interface is defined in 40.2.2 and the MDI is defined in 40.8.

40.2.1 Technology-Dependent Interface

1000BASE-T uses the following service primitives to exchange status indications and control signals across the Technology-Dependent Interface as specified in Clause 28:

PMA_LINK.request (link_control)

PMA_LINK.indication (link_status)

40.2.1.1 PMA_LINK.request

This primitive allows the Auto-Negotiation algorithm to enable and disable operation of the PMA as specified in 28.2.6.2.

40.2.1.1.1 Semantics of the primitive

PMA_LINK.request (link_control)

The link_control parameter can take on one of three values: SCAN_FOR_CARRIER, DISABLE, or ENABLE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SCAN_FOR_CARRIER	Used by the Auto-Negotiation algorithm prior to receiving any fast link pulses. During this mode the PMA reports link_status=FAIL.PHY processes are disabled.
DISABLE	Set by the Auto-Negotiation algorithm in the event fast link pulses are detected. PHY processes are disabled. This allows the Auto-Negotiation algorithm to determine how to configure the link.
ENABLE	Used by Auto-Negotiation to turn control over to the PHY for data processing functions.

40.2.1.1.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in Clause 28.

40.2.1.1.3 Effect of receipt

This primitive affects operation of the PMA Link Monitor function as defined in 40.4.2.5.

40.2.1.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 28.2.6.1. This primitive informs the PCS, PMA PHY Control function, and the Auto-Negotiation algorithm about the status of the underlying link.

40.2.1.2.1 Semantics of the primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on one of three values: FAIL, READY, or OK.

FAIL	No valid link established.
READY	The Link Monitor function indicates that a 1000BASE-T link is intact and ready to be established.
OK	The Link Monitor function indicates that a valid 1000BASE-T link is established. Reliable reception of signals transmitted from the remote PHY is possible.

40.2.1.2.2 When generated

The PMA generates this primitive continuously to indicate the value of link_status in compliance with the state diagram given in Figure 40–17.

40.2.1.2.3 Effect of receipt

The effect of receipt of this primitive is specified in 40.3.3.1.

40.2.2 PMA Service Interface

1000BASE-T uses the following service primitives to exchange symbol vectors, status indications, and control signals across the service interfaces:

PMA_TXMODE.indication (tx_mode)

PMA_CONFIG.indication (config)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_UNITDATA.request (tx_symb_vector)

PMA_UNITDATA.indication (rx_symb_vector)

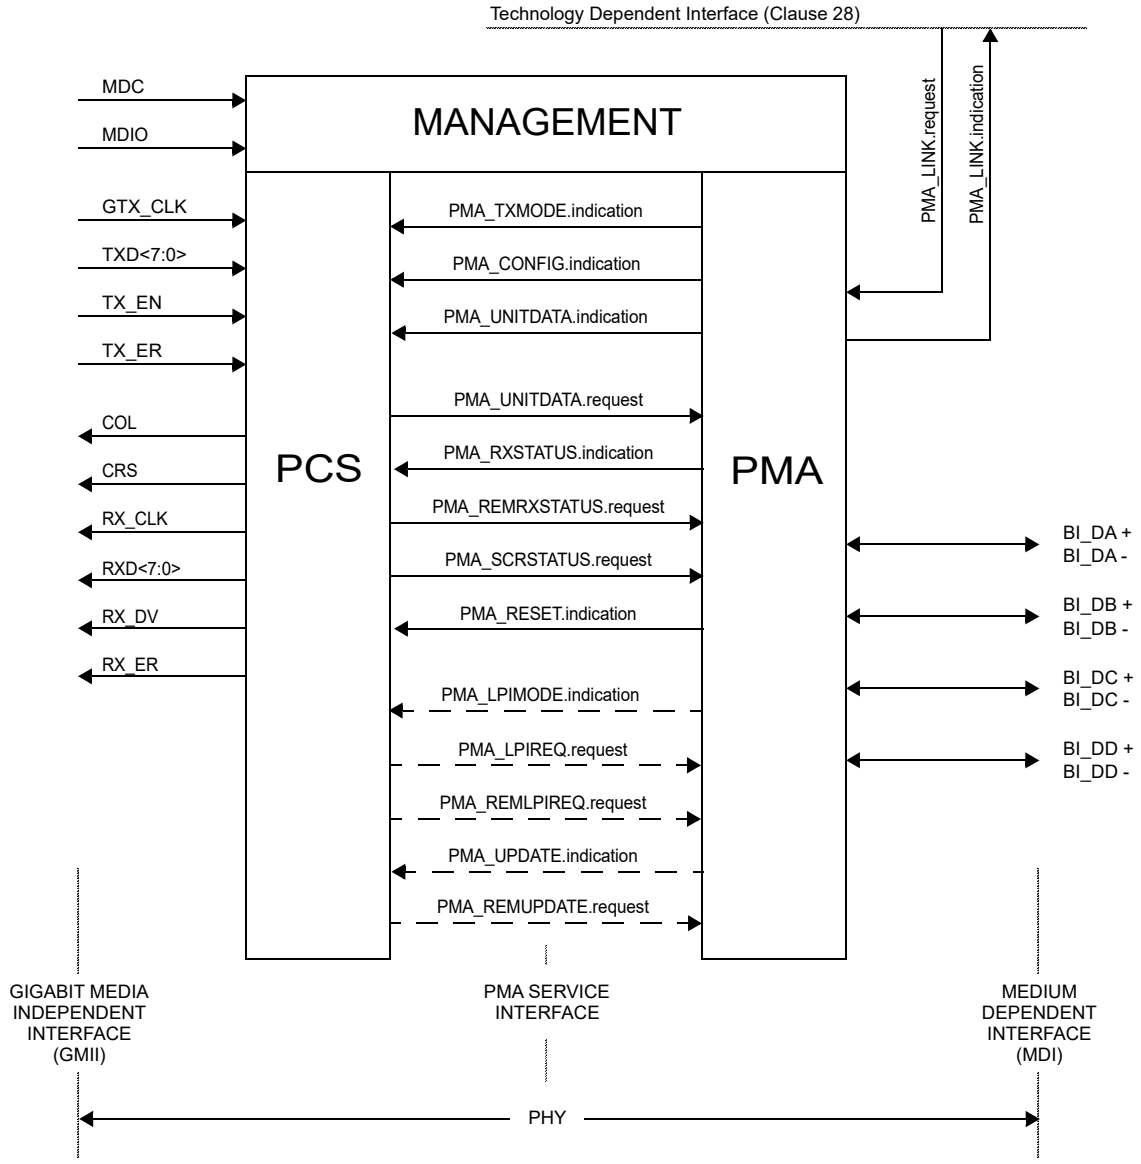
PMA_SCRSTATUS.request (scr_status)

PMA_RXSTATUS.indication (loc_rcvr_status)

PMA_REMRXSTATUS.request (rem_rcvr_status)

PMA_LPIMODE.indication(lpi_mode)

PMA_LPIREQ.request(loc_lpi_req)



PMA_REMLPIREQ.request(rem_lpi_req)

PMA_UPDATE.indication(loc_update_done)

PMA_REMUPDATE.request(rem_update_done)

The use of these primitives is illustrated in Figure 40–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—Service interface primitives shown with dashed lines are only required for the EEE capability.

Figure 40–4—1000BASE-T service interfaces

40.2.3 PMA_TXMODE.indication

The transmitter in a 1000BASE-T link normally sends over the four pairs, code-groups that can represent a GMII data stream, control information, or idles.

40.2.3.1 Semantics of the primitive

PMA_TXMODE.indication (tx_mode)

PMA_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of code-groups the PCS should be transmitting. The parameter tx_mode can take on one of the following three values of the form:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SEND_N This value is continuously asserted when transmission of sequences of code-groups representing a GMII data stream (data mode), control mode or idle mode is to take place.

SEND_I This value is continuously asserted in case transmission of sequences of code-groups representing the idle mode is to take place.

SEND_Z This value is continuously asserted in case transmission of zeros is required.

40.2.3.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages continuously.

40.2.3.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its Transmit function as described in 40.3.1.3.

40.2.4 PMA_CONFIG.indication

Each PHY in a 1000BASE-T link is capable of operating as a MASTER PHY and as a SLAVE PHY. MASTER-SLAVE configuration is determined during Auto-Negotiation (40.5). The result of this negotiation is provided to the PMA.

40.2.4.1 Semantics of the primitive

PMA_CONFIG.indication (config)

PMA_CONFIG.indication specifies to PCS and PMA Transmit via the parameter config whether the PHY operates as a MASTER PHY or as a SLAVE PHY. The parameter config can take on one of the following two values of the form:

MASTER This value is continuously asserted when the PHY operates as a MASTER PHY.

SLAVE This value is continuously asserted when the PHY operates as a SLAVE PHY.

40.2.4.2 When generated

PMA generates PMA_CONFIG.indication messages continuously.

40.2.4.3 Effect of receipt

PCS and PMA Clock Recovery perform their functions in MASTER or SLAVE configuration according to the value assumed by the parameter config.

40.2.5 PMA_UNITDATA.request

This primitive defines the transfer of code-groups in the form of the tx_symb_vector parameter from the PCS to the PMA. The code-groups are obtained in the PCS Transmit function using the encoding rules defined in 40.3.1.3 to represent GMII data streams, an idle mode, or other sequences.

40.2.5.1 Semantics of the primitive

PMA_UNITDATA.request (tx_symb_vector)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb_vector the value of the symbols to be sent over each of the four transmit pairs BI_DA, BI_DB, BI_DC, and BI_DD. The tx_symb_vector parameter takes on the form:

SYMB_4D A vector of four quinary symbols, one for each of the four transmit pairs
BI_DA, BI_DB, BI_DC, and BI_DD. Each quinary symbol may take on
one of the values –2, –1, 0, +1, or +2.

The quinary symbols that are elements of tx_symb_vector are called, according to the pair on which each will be transmitted, tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD].

40.2.5.2 When generated

The PCS generates PMA_UNITDATA.request (SYMB_4D) synchronously with every transmit clock cycle.

40.2.5.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated quinary symbols. The parameter tx_symb_vector is also used by the PMA Receive function to process the signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD.

40.2.6 PMA_UNITDATA.indication

This primitive defines the transfer of code-groups in the form of the rx_symb_vector parameter from the PMA to the PCS.

40.2.6.1 Semantics of the primitive

PMA_UNITDATA.indication (rx_symb_vector)

During reception the PMA_UNITDATA.indication simultaneously conveys to the PCS via the parameter rx_symb_vector the values of the symbols detected on each of the four receive pairs BI_DA, BI_DB, BI_DC, and BI_DD. The rx_symbol_vector parameter takes on the form:

SYMB_4DA vector of four quinary symbols, one for each of the four receive pairs
BI_DA, BI_DB, BI_DC, and BI_DD. Each quinary symbol may take on
one of the values –2, –1, 0, +1, or +2.

The quinary symbols that are elements of rx_symb_vector are called, according to the pair upon which each symbol was received, rx_symbol_vector[BI_DA], rx_symbol_vector[BI_DB], rx_symbol_vector[BI_DC], and rx_symb_vector[BI_DD].

40.2.6.2 When generated

The PMA generates PMA_UNITDATA.indication (SYMB_4D) messages synchronously with signals received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is 125 MHz, as governed by the recovered clock.

40.2.6.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.2.7 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the descrambler has achieved synchronization.

40.2.7.1 Semantics of the primitive

PMA_SCRSTATUS.request (scr_status)

The scr_status parameter can take on one of two values of the form:

OK The descrambler has achieved synchronization.
NOT_OK The descrambler is not synchronized.

40.2.7.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages continuously.

40.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in 40.4.2.3, 40.4.2.4, and 40.4.6.1.

40.2.8 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Transmit, PCS Receive, PMA PHY Control function, and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by the PCS Receive decoding functions. The criterion for setting the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting errors during reception of symbol streams that represent the idle mode.

40.2.8.1 Semantics of the primitive

PMA_RXSTATUS.indication (loc_rcvr_status)

The loc_rcvr_status parameter can take on one of two values of the form:

OK This value is asserted and remains true during reliable operation of the receive link for the local PHY.
NOT_OKThis value is asserted whenever operation of the link for the local PHY is unreliable.

40.2.8.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages continuously on the basis of signals received at the MDI.

40.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 40–16a and in subclauses 40.2 and 40.4.6.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.2.9 PMA_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The criterion for setting the parameter rem_rcvr_status is left to the implementer. It can be based, for example, on asserting rem_rcvr_status is NOT_OK until loc_rcvr_status is OK and then asserting the detected value of rem_rcvr_status after proper PCS receive decoding is achieved.

40.2.9.1 Semantics of the primitive

PMA_REMRXSTATUS.request (rem_rcvr_status)

The rem_rcvr_status parameter can take on one of two values of the form:

OK The receive link for the remote PHY is operating reliably.
NOT_OKReliable operation of the receive link for the remote PHY is not detected.

40.2.9.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages continuously on the basis on signals received at the MDI.

40.2.9.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 40–16a.

40.2.10 PMA_RESET.indication

This primitive is used to pass the PMA Reset function to the PCS (pcs_reset=ON) when reset is enabled.

The PMA_RESET.indication primitive can take on one of two values:

TRUE Reset is enabled.
FALSE Reset is not enabled.

40.2.10.1 When generated

The PMA Reset function is executed as described in 40.4.2.1.

40.2.10.2 Effect of receipt

The effect of receipt of this primitive is specified in 40.4.2.1.

40.2.11 PMA_LPIMODE.indication

This primitive is generated by the PMA to indicate that the PHY has entered the LPI mode of operation.

40.2.11.1 Semantics of the primitive

PMA_LPIMODE.indication(lpi_mode)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_LPIMODE.indication specifies to the PCS Receive function, via the parameter lpi_mode, whether or not the PHY has entered LPI mode. The parameter lpi_mode can take on one of the following values of the form:

ON	This value is asserted with the PHY is operating in LPI mode.
OFF	This value is asserted during normal operation.

40.2.11.2 When generated

The PMA PHY Control function generates PMA_LPIMODE.indication messages continuously.

40.2.11.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its Receive function as described in 40.3.1.4.

40.2.12 PMA_LPIREQ.request

This primitive is generated by the PCS to indicate a request to enter the LPI mode.

40.2.12.1 Semantics of the primitive

PMA_LPIREQ.request (loc_lpi_req)

PMA_LPIREQ.request specifies to the PMA PHY Control, via the parameter loc_lpi_req, whether or not the PHY is requested to enter the LPI mode. The parameter loc_lpi_req can take on one of the following values of the form:

TRUE	This value is continuously asserted when “Assert LPI” is present on the GMII. Note that “Assert LPI” at the GMII implies that no frame transmission is in progress hence 1000BTtransmit (see 40.3.3.1) will be set to FALSE by the PCS Transmit state diagram.
FALSE	This value is continuously asserted when “Assert LPI” is not present at the GMII.

40.2.12.2 When generated

The PCS Local LPI Request function generates PMA_LPIREQ.request messages continuously.

40.2.12.3 Effect of receipt

Upon receipt of this primitive, the PMA performs its PHY Control function as described in 40.4.2.4.

40.2.13 PMA_REMLPIREQ.request

This primitive is generated by the PCS to indicate a request to enter LPI mode as communicated by the remote PHY via its encoding of its loc_lpi_req parameter.

40.2.13.1 Semantics of the primitive

PMA_REMLPIREQ.request (rem_lpi_req)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_REMLPIREQ.request specifies to the PMA PHY Control, via the parameter rem_lpi_req, whether or not the remote PHY is requesting entry into the LPI mode. The parameter rem_lpi_req can take on one of the following values of the form:

TRUE	This value is continuously asserted when LPI is encoded in the received symbols.
FALSE	This value is continuously asserted when LPI is not encoded in the received symbols.

40.2.13.2 When generated

The PCS Receive function generates PMA_REMLPIREQ.request messages continuously on the basis of the signals received at the MDI.

40.2.13.3 Effect of receipt

Upon receipt of this primitive, the PMA performs its PHY Control function as described in 40.4.2.4.

40.2.14 PMA_UPDATE.indication

This primitive is generated by the PMA to indicate that the PHY has completed the update of its receiver state (e.g., timing recovery, adaptive filter coefficients).

40.2.14.1 Semantics of the primitive

PMA_UPDATE.indication(loc_update_done)

PMA_UPDATE.indication specifies to the PCS Transmit functions, via the parameter loc_update_done, whether or not the PHY has completed the update of its receiver state. The parameter loc_update_done can take on one of the following values of the form:

TRUE	This value is asserted when the PHY has completed the current update.
FALSE	This value is asserted when the PHY is ready for the next update or when the current update is still in progress.

40.2.14.2 When generated

The PMA PHY Control function generates PMA_UPDATE.indication messages continuously.

40.2.14.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its Transmit function as described in 40.3.1.3 and 40.3.1.4.

40.2.15 PMA_REMUPDATE.request

This primitive is generated by the PCS to indicate that the remote PHY has completed the update of its receiver state (e.g., timing recovery, adaptive filter coefficients).

40.2.15.1 Semantics of the primitive

PMA_REMUPDATE.request(rem_update_done)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

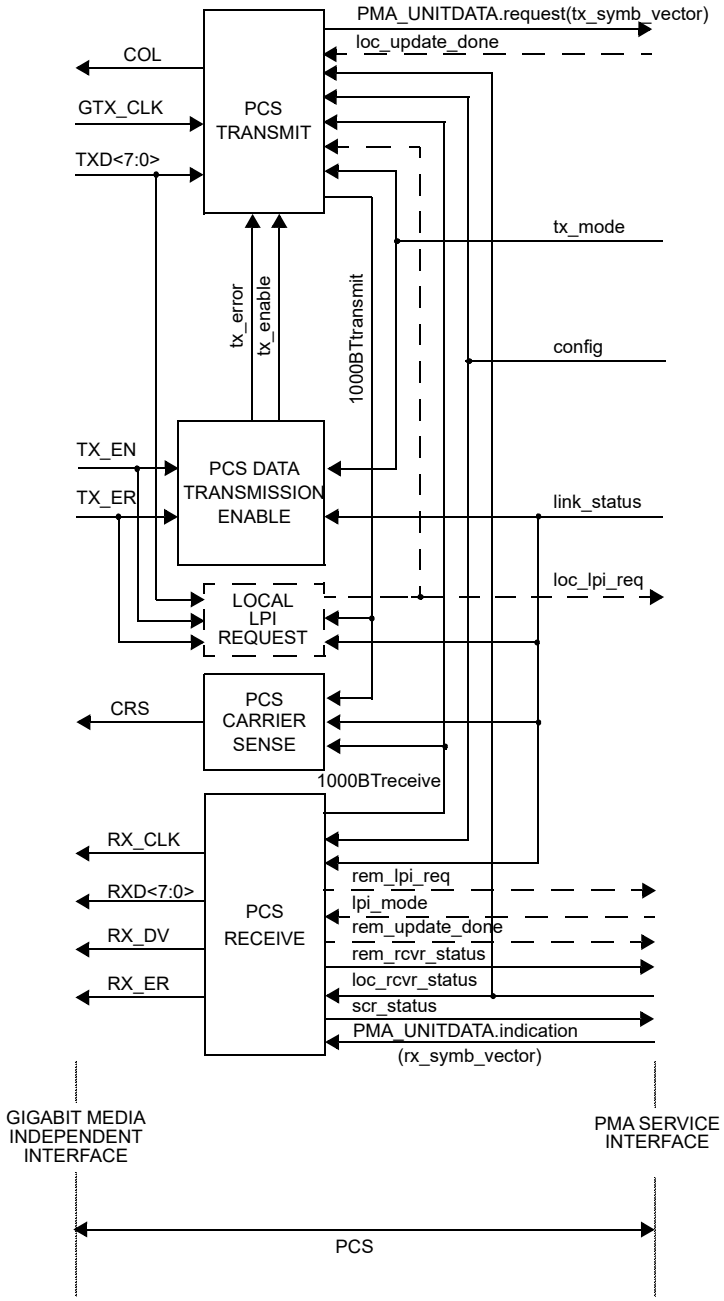
PMA_REMUPDATE.indication specifies to the PMA PHY Control function, via the parameter rem_update_done, whether or not the remote PHY has completed the update of its receiver state. The parameter rem_update_done can take on one of the following values of the form:

TRUE	This value is asserted when the remote PHY has completed the current update.
FALSE	This value is asserted to when the remote PHY is ready for the next update or when the current update is still in progress.

40.2.15.2 When generated

The PCS Receive function generates PMA_REMUDPATE.request messages continuously.

40.2.15.3 Effect of receipt



Upon receipt of this primitive, the PMA performs its PHY Control function as described in 40.4.2.4.

40.3 Physical Coding Sublayer (PCS)

The PCS comprises one PCS Reset function and four simultaneous and asynchronous operating functions. The PCS operating functions are: PCS Transmit Enable, PCS Transmit, PCS Receive, and PCS Carrier Sense. All operating functions start immediately after the successful completion of the PCS Reset function.

The PCS reference diagram, Figure 40–5, shows how the four operating functions relate to the messages of the PCS-PMA interface. Connections from the management interface (signals MDC and MDIO) to other layers are pervasive, and are not shown in Figure 40–5. Management is specified in Clause 30. See also Figure 40–7, which defines the structure of frames passed from PCS to PMA.

NOTE—Signals and functions shown with dashed lines are only required for the EEE capability.

Figure 40–5—PCS reference diagram

40.3.1 PCS functions

40.3.1.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Power on (see 36.2.5.1.3).
b) The receipt of a request for reset from the management entity.

PCS Reset sets pcs_reset=ON while any of the above reset conditions hold true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

40.3.1.2 PCS Data Transmission Enable

The PCS Data Transmission Enabling process generates the signals tx_enable and tx_error, which PCS Transmit uses for data and carrier extension encoding. The process uses logical operations on tx_mode, TX_ER, TX_EN, and TXD<7:0>. The PCS shall implement the Data Transmission Enabling process as depicted in Figure 40–8 including compliance with the associated state variables as specified in 40.3.3.

40.3.1.3 PCS Transmit function

The PCS Transmit function shall conform to the PCS Transmit state diagram in Figure 40–10.

The PCS Transmit function generates the GMII signal COL based on whether a reception is occurring simultaneously with transmission. The PCS Transmit function is not required to generate the GMII signal COL in a 1000BASE-T PHY that does not support half duplex operation.

In each symbol period, PCS Transmit generates a code-group (A_n, B_n, C_n, D_n) that is transferred to the PMA via the PMA_UNITDATA.request primitive. The PMA transmits symbols A_n, B_n, C_n, D_n over wire-pairs BI_DA, BI_DB, BI_DC, and BI_DD respectively. The integer, n, is a time index that is introduced to establish a temporal relationship between different symbol periods. A symbol period, T, is nominally equal to 8 ns. In normal mode of operation, between streams of data indicated by the parameter tx_enable, PCS Transmit generates sequences of vectors using the encoding rules defined for the idle mode. Upon assertion of tx_enable, PCS Transmit passes a SSD of two consecutive vectors of four quinary symbols to the PMA, replacing the first two preamble octets. Following the SSD, each TXD<7:0> octet is encoded using an 4D-PAM5 technique into a vector of four quinary symbols until tx_enable is de-asserted. If TX_ER is asserted while tx_enable is also asserted, then PCS Transmit passes to the PMA vectors indicating a transmit error. Note that if the signal TX_ER is asserted while SSD is being sent, the transmission of the error condition is delayed until transmission of SSD has been completed. Following the de-assertion of tx_enable, a Convolutional State Reset (CSReset) of two consecutive code-groups, followed by an ESD of two consecutive code-groups, is generated, after which the transmission of idle or control mode is resumed.

If a PMA_TXMODE.indication message has the value SEND_Z, PCS Transmit passes a vector of zeros at each symbol period to the PMA via the PMA_UNITDATA.request primitive.

If a PMA_TXMODE.indication message has the value SEND_I, PCS Transmit generates sequences of code-groups according to the encoding rule in training mode. Special code-groups that use only the values {+2, 0, –2} are transmitted in this case. Training mode encoding also takes into account the value of the parameter loc_rcvr_status. By this mechanism, a PHY indicates the status of its own receiver to the link partner during idle transmission.

When the PHY supports the optional EEE capability, the LPI mode encoding also takes into account the value of the parameter loc_lpi_req. By this mechanism, the PHY indicates whether it requests to operate in LPI mode or return to the normal mode of operation. In addition, LPI mode encoding takes into account the value of loc_update_done. By this mechanism, the PHY indicates whether it has completed the update of its receiver state (e.g., timing recovery, adaptive filter coefficients) or not, as indicated by the PMA PHY Control function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the normal mode of operation, the PMA_TXMODE.indication message has the value SEND_N, and the PCS Transmit function uses an 8B1Q4 coding technique to generate at each symbol period code-groups that represent data, control or idle based on the code-groups defined in Table 40–1 and Table 40–2. During transmission of data, the TXD<7:0> bits are scrambled by the PCS using a side-stream scrambler, then encoded into a code-group of quinary symbols and transferred to the PMA. During data encoding, PCS Transmit utilizes a three-state convolutional encoder.

The transition from idle or carrier extension to data is signaled by inserting a SSD, and the end of transmission of data is signaled by an ESD. Further code-groups are used for signaling the assertion of TX_ER within a stream of data, carrier extension, CSReset, and other control functions. During idle and carrier extension encoding, special code-groups with symbol values restricted to the set {2, 0, –2} are used. These code-groups are also generated using the transmit side-stream scrambler. However, the encoding rules for the idle, SSD, and carrier extend code-groups are different from the encoding rules for data, CSReset, CSExtend, and ESD code-groups. During idle, SSD, and carrier extension, the PCS Transmit function reverses the sign of the transmitted symbols. This allows, at the receiver, sequences of code-groups that represent data, CSReset, CSExtend, and ESD to be easily distinguished from sequences of code-groups that represent SSD, carrier extension, and idle.

PCS encoding involves the generation of the four-bit words $Sx_n[3:0]$, $Sy_n[3:0]$, and $Sg_n[3:0]$ from which the quinary symbols (A_n, B_n, C_n, D_n) are obtained. The four-bit words $Sx_n[3:0]$, $Sy_n[3:0]$, and $Sg_n[3:0]$ are determined (as explained in 40.3.1.3.2) from sequences of pseudorandom binary symbols derived from the transmit side-stream scrambler.

40.3.1.3.1 Side-stream scrambler polynomials

The PCS Transmit function employs side-stream scrambling. If the parameter config provided to the PCS by the PMA PHY Control function via the PMA_CONFIG.indication message assumes the value MASTER, PCS Transmit shall employ

$$g_M(x) = 1 + x^{13} + x^{33}$$

as transmitter side-stream scrambler generator polynomial. If the PMA_CONFIG.indication message assumes the value of SLAVE, PCS Transmit shall employ

$$g_S(x) = 1 + x^{20} + x^{33}$$

as transmitter side-stream scrambler generator polynomial. An implementation of master and slave PHY side-stream scramblers by linear-feedback shift registers is shown in Figure 40–6. The bits stored in the shift register delay line at time n are denoted by $Scr_n[32:0]$. At each symbol period, the shift register is advanced by one bit, and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. In no case shall the scrambler state be initialized to all zeros.

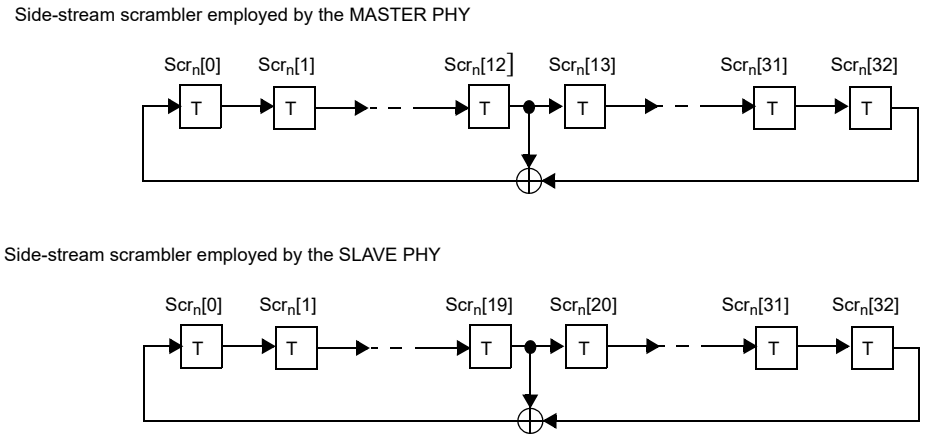

Figure 40–6—A realization of side-stream scramblers by linear feedback shift registers

40.3.1.3.2 Generation of bits $Sx_n[3:0]$, $Sy_n[3:0]$, and $Sg_n[3:0]$

PCS Transmit encoding rules are based on the generation, at time n, of the twelve bits $Sx_n[3:0]$, $Sy_n[3:0]$, and $Sg_n[3:0]$. The eight bits, $Sx_n[3:0]$ and $Sy_n[3:0]$, are used to generate the scrambler octet $Sc_n[7:0]$ for decorrelating the GMII data word TXD<7:0> during data transmission and for generating the idle and training symbols. The four bits, $Sg_n[3:0]$, are used to randomize the signs of the quinary symbols (A_n, B_n, C_n, D_n) so that each symbol stream has no dc bias. These twelve bits are generated in a systematic fashion using three bits, X_n, Y_n, and $Scr_n[0]$, and an auxiliary generating polynomial, g(x). The two bits, X_n and Y_n, are mutually uncorrelated and also uncorrelated with the bit $Scr_n[0]$. For both master and slave PHYs, they are obtained by the same linear combinations of bits stored in the transmit scrambler shift register delay line. These two bits are derived from elements of the same maximum-length shift register sequence of length $2^{33} - 1$ as $Scr_n[0]$, but shifted in time. The associated delays are all large and different so that there is no short-term correlation among the bits $Scr_n[0]$, X_n, and Y_n. The bits X_n and Y_n are generated as follows:

$$X_n = Scr_n[4] \wedge Scr_n[6]$$

$$Y_n = Scr_n[1] \wedge Scr_n[5]$$

where ^ denotes the XOR logic operator. From the three bits X_n, Y_n, and $Scr_n[0]$, further mutually uncorrelated bit streams are obtained systematically using the generating polynomial

$$g(x) = x^3 \wedge x^8$$

The four bits $Sy_n[3:0]$ are generated using the bit $Scr_n[0]$ and g(x) as in the following equations:

$$Sy_n[0] = Scr_n[0]$$

$$Sy_n[1] = g(Scr_n[0]) = Scr_n[3] \wedge Scr_n[8]$$

$$Sy_n[2] = g^2(Scr_n[0]) = Scr_n[6] \wedge Scr_n[16]$$

$$Sy_n[3] = g^3(Scr_n[0]) = Scr_n[9] \wedge Scr_n[14] \wedge Scr_n[19] \wedge Scr_n[24]$$

The four bits $Sx_n[3:0]$ are generated using the bit X_n and g(x) as in the following equations:

Copyright © 2022 IEEE. All rights reserved.

$Sx_n[0] = X_n = Scr_n[4] \wedge Scr_n[6]$

$Sx_n[1] = g(X_n) = Scr_n[7] \wedge Scr_n[9] \wedge Scr_n[12] \wedge Scr_n[14]$

$Sx_n[2] = g^2(X_n) = Scr_n[10] \wedge Scr_n[12] \wedge Scr_n[20] \wedge Scr_n[22]$

$Sx_n[3] = g^3(X_n) = Scr_n[13] \wedge Scr_n[15] \wedge Scr_n[18] \wedge Scr_n[20] \wedge Scr_n[23] \wedge Scr_n[25] \wedge Scr_n[28] \wedge Scr_n[30]$

The four bits $Sg_n[3:0]$ are generated using the bit Y_n and g(x) as in the following equations:

$Sg_n[0] = Y_n = Scr_n[1] \wedge Scr_n[5]$

$Sg_n[1] = g(Y_n) = Scr_n[4] \wedge Scr_n[8] \wedge Scr_n[9] \wedge Scr_n[13]$

$Sg_n[2] = g^2(Y_n) = Scr_n[7] \wedge Scr_n[11] \wedge Scr_n[17] \wedge Scr_n[21]$

$Sg_n[3] = g^3(Y_n) = Scr_n[10] \wedge Scr_n[14] \wedge Scr_n[15] \wedge Scr_n[19] \wedge Scr_n[20] \wedge Scr_n[24] \wedge Scr_n[25] \wedge Scr_n[29]$

By construction, the twelve bits $Sx_n[3:0]$, $Sy_n[3:0]$, and $Sg_n[3:0]$ are derived from elements of the same maximum-length shift register sequence of length $2^{33}-1$ as $Scr_n[0]$, but shifted in time by varying delays. The associated delays are all large and different so that there is no apparent correlation among the bits.

40.3.1.3.3 Generation of bits $Sc_n[7:0]$

The bits $Sc_n[7:0]$ are used to scramble the GMII data octet TXD[7:0] and for control, idle, and training mode quartet generation. The definition of these bits is dependent upon the bits $Sx_n[3:0]$ and $Sy_n[3:0]$ that are specified in 40.3.1.3.2, the variable tx_mode that is obtained through the PMA Service Interface, the variable tx_enable_n that is defined in Figure 40–8, and the time index n.

The four bits $Sc_n[7:4]$ are defined as

$$Sc_n[7:4] = \begin{cases} Sx_n[3:0] & \text{if } (tx_enable_{n-2} = 1) \\ [0\ 0\ 0\ 0] & \text{else} \end{cases}$$

The bits $Sc_n[3:1]$ are defined as

$$Sc_n[3:1] = \begin{cases} [0\ 0\ 0] & \text{if } (tx_mode = SEND_Z) \\ Sy_n[3:1] & \text{else if } (n\text{-}n_0) = 0 \pmod 2 \\ (Sy_{n-1}[3:1] \wedge [1\ 1\ 1]) & \text{else} \end{cases}$$

where n_0 denotes the time index of the last transmitter side-stream scrambler reset.

The bit $Sc_n[0]$ is defined as

$$Sc_n[0] = \begin{cases} 0 & \text{if } (tx_mode = SEND_Z) \\ Sy_n[0] & \text{else} \end{cases}$$

40.3.1.3.4 Generation of bits $Sd_n[8:0]$

The PCS Transmit function generates a nine-bit word $Sd_n[8:0]$ from Sc_n that represents either a convolutionally encoded stream of data, control, or idle mode code-groups. The convolutional encoder uses a three-bit word $cs_n[2:0]$, which is defined as

$$cs_n[1] = \begin{cases} Sd_n[6] \wedge cs_{n-1}[0] & \text{if } (tx_enable_{n-2} = 1) \\ 0 & \text{else} \end{cases}$$

$$cs_n[2] = \begin{cases} Sd_n[7] \wedge cs_{n-1}[1] & \text{if } (tx_enable_{n-2} = 1) \\ 0 & \text{else} \end{cases}$$

$$cs_n[0] = cs_{n-1}[2]$$

from which $Sd_n[8]$ is obtained as

$$Sd_n[8] = cs_n[0]$$

The convolutional encoder bits are non-zero only during the transmission of data. Upon the completion of a frame, the convolutional encoder bits are reset using the bit $csreset_n$. The bit $csreset_n$ is defined as

$$csreset_n = (tx_enable_{n-2}) \text{ and } (\text{not } tx_enable_n)$$

The bits $Sd_n[7:6]$ are derived from the bits $Sc_n[7:6]$, the GMII data bits $TXD_n[7:6]$, and from the convolutional encoder bits as

$$Sd_n[7] = \begin{cases} Sc_n[7] \wedge TXD_n[7] & \text{if } (csreset_n = 0 \text{ and } tx_enable_{n-2} = 1) \\ cs_{n-1}[1] & \text{else if } (csreset_n = 1) \\ Sc_n[7] & \text{else} \end{cases}$$

$$Sd_n[6] = \begin{cases} Sc_n[6] \wedge TXD_n[6] & \text{if } (csreset_n = 0 \text{ and } tx_enable_{n-2} = 1) \\ cs_{n-1}[0] & \text{else if } (csreset_n = 1) \\ Sc_n[6] & \text{else} \end{cases}$$

The bits $Sd_n[5:4]$ are derived from the bits $Sc_n[5:4]$ and the GMII data bits $TXD_n[5:4]$ as

$$Sd_n[5:4] = \begin{cases} Sc_n[5:4] \wedge TXD_n[5:4] & \text{if } (tx_enable_{n-2} = 1) \\ Sc_n[5:4] & \text{else} \end{cases}$$

The bit $Sd_n[3]$ is used to scramble the GMII data bit $TXD_n[3]$ during data mode and to encode loc_lpi_req otherwise. It is defined as

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$Sd_n[3] = \begin{cases} Sc_n[3] \wedge TXD_n[3] & \text{if } (tx_enable_{n-2} = 1) \\ Sc_n[3] \wedge 1 & \text{else if } ((loc_lpi_req = \text{TRUE}) \text{ and } (tx_mode \neq \text{SEND_Z})) \\ Sc_n[3] & \text{else} \end{cases}$$

The bit $Sd_n[2]$ is used to scramble the GMII data bit $TXD_n[2]$ during data mode and to encode loc_rcvr_status otherwise. It is defined as

$$Sd_n[2] = \begin{cases} Sc_n[2] \wedge TXD_n[2] & \text{if } (tx_enable_{n-2} = 1) \\ Sc_n[2] \wedge 1 & \text{else if } ((loc_rcvr_status = \text{OK}) \text{ and } (tx_mode \neq \text{SEND_Z})) \\ Sc_n[2] & \text{else} \end{cases}$$

The bits $Sd_n[1:0]$ are used to transmit carrier extension information during tx_mode=SEND_N and are thus dependent upon the bits $cext_n$ and $cext_err_n$. In addition, bit $Sd_n[1]$ is used to encode loc_update_done. These bits are dependent on the variable tx_error_n, which is defined in Figure 40–8. These bits are defined as

$$cext_n = \begin{cases} tx_error_n & \text{if } ((tx_enable_n = 0) \text{ and } (TXD_n[7:0] = 0\text{x}0\text{F})) \\ 0 & \text{else} \end{cases}$$

$$cext_err_n = \begin{cases} tx_error_n & \text{if } ((tx_enable_n = 0) \text{ and } (TXD_n[7:0] \neq 0\text{x}0\text{F}) \text{ and } (loc_lpi_req = FALSE)) \\ 0 & \text{else} \end{cases}$$

$$Sd_n[1] = \begin{cases} Sc_n[1] \wedge TXD_n[1] & \text{if } (tx_enable_{n-2} = 1) \\ Sc_n[1] \wedge 1 & \text{else if } ((loc_update_done = \text{TRUE}) \text{ and } (tx_mode \neq \text{SEND_Z})) \\ Sc_n[1] \wedge cext_err_n & \text{else} \end{cases}$$

$$Sd_n[0] = \begin{cases} Sc_n[0] \wedge TXD_n[0] & \text{if } (tx_enable_{n-2} = 1) \\ Sc_n[0] \wedge cext_n & \text{else} \end{cases}$$

40.3.1.3.5 Generation of quinary symbols TA_n, TB_n, TC_n, TD_n

The nine-bit word $Sd_n[8:0]$ is mapped to a quartet of quinary symbols (TA_n, TB_n, TC_n, TD_n) according to Table 40–1 and Table 40–2 shown as $Sd_n[6:8] + Sd_n[5:0]$.

Encoding of error indication:

If tx_error_n=1 when (tx_enable_n * tx_enable_{n-2}) = 1, error indication is signaled by means of symbol substitution. In this condition, the values of $Sd_n[5:0]$ are ignored during mapping and the symbols corresponding to the row denoted as “xmt_err” in Table 40–1 and Table 40–2 shall be used.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Encoding of Convolutional Encoder Reset:

If tx_error_n=0 when the variable $csreset_n$ = 1, the convolutional encoder reset condition is normal. This condition is indicated by means of symbol substitution, where the values of $Sd_n[5:0]$ are ignored during mapping and the symbols corresponding to the row denoted as "CSReset" in Table 40–1 and Table 40–2 shall be used.

Encoding of Carrier Extension during Convolutional Encoder Reset:

If tx_error_n=1 when the variable $csreset_n$ = 1, the convolutional encoder reset condition indicates carrier extension. In this condition, the values of $Sd_n[5:0]$ are ignored during mapping and the symbols corresponding to the row denoted as "CSExtend" in Table 40–1 and Table 40–2 shall be used when TXD_n = 0x0F, and the row denoted as "CSExtend_Err" in Table 40–1 and Table 40–2 shall be used when $TXD_n \neq$ 0x0F. The latter condition denotes carrier extension with error. In case carrier extension with error is indicated during the first octet of CSReset, the error condition shall be encoded during the second octet of CSReset, and during the subsequent two octets of the End-of-Stream delimiter as well. Thus, the error condition is assumed to persist during the symbol substitutions at the End-of-Stream.

Encoding of Start-of-Stream delimiter:

The Start-of-Stream delimiter (SSD) is related to the condition SSD_n, which is defined as $(tx_enable_n) * (!tx_enable_{n-2}) = 1$, where "*" and "!" denote the logic AND and NOT operators, respectively. For the generation of SSD, the first two octets of the preamble in a data stream are mapped to the symbols corresponding to the rows denoted as SSD1 and SSD2 respectively in Table 40–1. The symbols corresponding to the SSD1 row shall be used when $(tx_enable_n) * (!tx_enable_{n-1}) = 1$. The symbols corresponding to the SSD2 row shall be used when $(tx_enable_{n-1}) * (!tx_enable_{n-2}) = 1$.

Encoding of End-of-Stream delimiter:

The definition of an End-of-Stream delimiter (ESD) is related to the condition ESD_n, which is defined as $(!tx_enable_{n-2}) * (tx_enable_{n-4}) = 1$. This occurs during the third and fourth symbol periods after transmission of the last octet of a data stream.

If carrier extend error is indicated during ESD, the symbols corresponding to the ESD_Ext_Err row shall be used. The two conditions upon which this may occur are

$(tx_error_n) * (tx_error_{n-1}) * (tx_error_{n-2}) * (TXD_n \neq 0x0F) = 1$, and
$(tx_error_n) * (tx_error_{n-1}) * (tx_error_{n-2}) * (tx_error_{n-3}) * (TXD_n \neq 0x0F) = 1$.

The symbols corresponding to the ESD1 row in Table 40–1 shall be used when $(!tx_enable_{n-2}) * (tx_enable_{n-3}) = 1$, in the absence of carrier extend error indication at time n.

The symbols corresponding to the ESD2_Ext_0 row in Table 40–1 shall be used when $(!tx_enable_{n-3}) * (tx_enable_{n-4}) * (!tx_error_n) * (!tx_error_{n-1}) = 1$.

The symbols corresponding to the ESD2_Ext_1 row in Table 40–1 shall be used when $(!tx_enable_{n-3}) * (tx_enable_{n-4}) * (!tx_error_n) * (tx_error_{n-1}) * (tx_error_{n-2}) * (tx_error_{n-3}) = 1$.

The symbols corresponding to the ESD2_Ext_2 row in Table 40–1 shall be used when $(!tx_enable_{n-3}) * (tx_enable_{n-4}) * (tx_error_n) * (tx_error_{n-1}) * (tx_error_{n-2}) * (tx_error_{n-3}) * (TXD_n = 0x0F) = 1$, in the absence of carrier extend error indication.

NOTE—The ASCII for Table 40–1 and Table 40–2 is available at https://standards.ieee.org/downloads/802.3/.[81]

40.3.1.3.6 Generation of A_n, B_n, C_n, D_n

The four bits $Sg_n[3:0]$ are used to randomize the signs of the quinary symbols (A_n, B_n, C_n, D_n) so that each symbol stream has no dc bias. The bits are used to generate binary symbols (SnA_n, SnB_n, SnC_n, SnD_n) that, when multiplied by the quinary symbols (TA_n, TB_n, TC_n, TD_n), result in (A_n, B_n, C_n, D_n).

PCS Transmit ensures a distinction between code-groups transmitted during idle mode plus SSD and those transmitted during other symbol periods. This distinction is accomplished by reversing the mapping of the sign bits when (tx_enable_{n-2} + tx_enable_{n-4}) = 1. This sign reversal is controlled by the variable $Srev_n$ defined as

$$Srev_n = tx_enable_{n-2} + tx_enable_{n-4}$$

The binary symbols SnA_n, SnB_n, SnC_n, and SnD_n are defined using $Sg_n[3:0]$ as

$$SnA_n = \begin{cases} +1 \text{ if } [(Sg_n[0] \wedge Srev_n) = 0] \\ -1 \text{ else} \end{cases}$$

$$SnB_n = \begin{cases} +1 \text{ if } [(Sg_n[1] \wedge Srev_n) = 0] \\ -1 \text{ else} \end{cases}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$SnC_n = \begin{cases} +1 \text{ if } [(Sg_n[2] \wedge Srev_n) = 0] \\ -1 \text{ else} \end{cases}$$

$$SnD_n = \begin{cases} +1 \text{ if } [(Sg_n[3] \wedge Srev_n) = 0] \\ -1 \text{ else} \end{cases}$$

The quinary symbols (A_n, B_n, C_n, D_n) are generated as the product of (SnA_n, SnB_n, SnC_n, SnD_n) and (TA_n, TB_n, TC_n, TD_n) respectively.

$$A_n = TA_n \times SnA_n$$

$$B_n = TB_n \times SnB_n$$

$$C_n = TC_n \times SnC_n$$

$$D_n = TD_n \times SnD_n$$

40.3.1.4 PCS Receive function

The PCS Receive function shall conform to the PCS Receive state diagram in Figure 40–11a including compliance with the associated state variables as specified in 40.3.3.

The PCS Receive function accepts received code-groups provided by the PMA Receive function via the parameter rx_symb_vector. To achieve correct operation, PCS Receive uses the knowledge of the encoding rules that are employed in the idle mode. PCS Receive generates the sequence of vectors of four quinary symbols (RA_n, RB_n, RC_n, RD_n) and indicates the reliable acquisition of the descrambler state by setting the parameter scr_status to OK. The sequence (RA_n, RB_n, RC_n, RD_n) is processed to generate the signals RXD<7:0>, RX_DV, and RX_ER, which are presented to the GMII. PCS Receive detects the transmission of a stream of data from the remote station and conveys this information to the PCS Carrier Sense and PCS Transmit functions via the parameter 1000BTreceive.

When the PHY supports the optional EEE capability, the PCS Receive uses the knowledge of the encoding rules that are employed in the idle mode to derive the values of the variables rem_lpi_req and rem_update_done.

40.3.1.4.1 Decoding of code-groups

When the PMA indicates that correct receiver operation has been achieved by setting the loc_rcvr_status parameter to the value OK, the PCS Receive continuously checks that the received sequence satisfies the encoding rule used in idle mode. When a violation is detected, PCS Receive assigns the value TRUE to the parameter 1000BTreceive and, by examining the last two received vectors (RA_{n-1}, RB_{n-1}, RC_{n-1}, RD_{n-1}) and (RA_n, RB_n, RC_n, RD_n), determines whether the violation is due to reception of SSD or to a receiver error.

Upon detection of SSD, PCS Receive also assigns the value TRUE to the parameter 1000BTreceive that is provided to the PCS Carrier Sense and Collision Presence functions. During the two symbol periods corresponding to SSD, PCS Receive replaces SSD by preamble bits. Upon the detection of SSD, the signal RX_DV is asserted and each received vector is decoded into a data octet RXD<7:0> until ESD is detected.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Upon detection of a receiver error, the signal RX_ER is asserted and the parameter rxerror_status assumes the value ERROR. De-assertion of RX_ER and transition to the IDLE state (rxerror_status=NO_ERROR) takes place upon detection of four consecutive vectors satisfying the encoding rule used in idle mode.

During reception of a stream of data, PCS Receive checks that the symbols RA_n, RB_n, RC_n, RD_n follow the encoding rule defined in 40.3.1.3.5 for ESD whenever they assume values ± 2. PCS Receive processes two consecutive vectors at each time n to detect ESD. Upon detection of ESD, PCS Receive de-asserts the signal RX_DV on the GMII. If the last symbol period of ESD indicates that a carrier extension is present, PCS Receive will assert the RX_ER signal on the GMII. If no extension is indicated in the ESD2 quartet, PCS Receive assigns the value FALSE to the parameter receiving. If an extension is present, the transition to the IDLE state occurs after detection of a valid idle symbol period and the parameter receiving remains TRUE until check_idle is TRUE. If a violation of the encoding rules is detected, PCS Receive asserts the signal RX_ER for at least one symbol period.

A premature stream termination is caused by the detection of invalid symbols during the reception of a data stream. Then, PCS Receive waits for the reception of four consecutive vectors satisfying the encoding rule used in idle mode prior to de-asserting the error indication. Note that RX_DV remains asserted during the symbol periods corresponding to the first three idle vectors, while RX_ER=TRUE is signaled on the GMII. The signal RX_ER is also asserted in the LINK FAILED state, which ensures that RX_ER remains asserted for at least one symbol period.

40.3.1.4.2 Receiver descrambler polynomials

The PHY shall descramble the data stream and return the proper sequence of code-groups to the decoding process for generation of RXD<7:0> to the GMII. For side-stream descrambling, the MASTER PHY shall employ the receiver descrambler generator polynomial $g'_M(x) = 1 + x^{20} + x^{33}$ and the SLAVE PHY shall employ the receiver descrambler generator polynomial $g'_S(x) = 1 + x^{13} + x^{33}$.

40.3.1.5 PCS Carrier Sense function

The PCS Carrier Sense function generates the GMII signal CRS, which the MAC uses for deferral in half duplex mode. The PCS shall conform to the Carrier Sense state diagram as depicted in Figure 40–12 including compliance with the associated state variables as specified in 40.3.3. The PCS Carrier Sense function is not required in a 1000BASE-T PHY that does not support half duplex operation.

40.3.1.6 PCS Local LPI Request function

The PCS Local LPI Request function generates the signal loc_lpi_req, which indicates to the PMA PHY Control function whether or not the local PHY is requested to enter the LPI mode. When the PHY supports the optional EEE capability, the PCS shall conform to the Local LPI Request state diagram as depicted in Figure 40–9 including compliance with the associated state variables as specified in 40.3.3.

40.3.2 Stream structure

The tx_symb_vector and rx-symb_vector structure is shown in Figure 40–7.

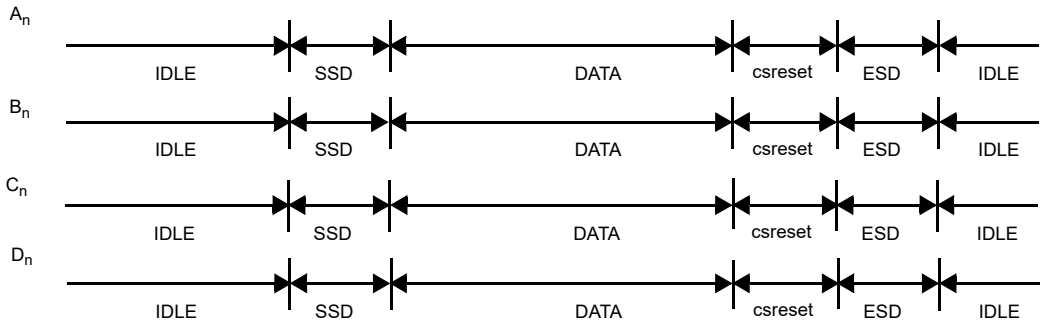

Figure 40–7—The tx_symb_vector and rx-symb_vector structure

40.3.3 State variables

40.3.3.1 Variables

CEXT
: A sequence of vectors of four quinary symbols corresponding to the code-group generated in idle mode to denote carrier extension, as specified in 40.3.1.3.

CEXT_Err
: A sequence of vectors of four quinary symbols corresponding to the code-group generated in idle mode to denote carrier extension with error indication, as specified in 40.3.1.3.

COL
: The COL signal of the GMII as specified in 35.2.2.12.

config
: The config parameter set by PMA and passed to the PCS via the PMA_CONFIG.indication primitive.
Values: MASTER, SLAVE.

CRS
: The CRS signal of the GMII as specified in 35.2.2.11.

CSExtend
: A vector of four quinary symbols corresponding to the code-group indicating convolutional encoder reset condition during carrier extension, as specified in 40.3.1.3.

CSExtend_Err
: A vector of four quinary symbols corresponding to the code-group indicating convolutional encoder reset condition during carrier extension with error indication, as specified in 40.3.1.3.

CSReset
: A vector of four quinary symbols corresponding to the code-group indicating convolutional encoder reset condition in the absence of carrier extension, as specified in 40.3.1.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

DATA
: A vector of four quinary symbols corresponding to the code-group indicating valid data, as specified in 40.3.1.3.

ESD1
: A vector of four quinary symbols corresponding to the first code-group of End-of-Stream delimiter, as specified in 40.3.1.3.

ESD2_Ext_0
: A vector of four quinary symbols corresponding to the second code-group of End-of-Stream delimiter in the absence of carrier extension over the two ESD symbol periods, as specified in 40.3.1.3.

ESD2_Ext_1
: A vector of four quinary symbols corresponding to the second code-group of End-of-Stream delimiter when carrier extension is indicated during the first symbol period of the End-of-Stream delimiter, but not during the second symbol period, as specified in 40.3.1.3.

ESD2_Ext_2
: A vector of four quinary symbols corresponding to the second code-group of End-of-Stream delimiter when carrier extension is indicated during the two symbol periods of the End-of-Stream delimiter, as specified in 40.3.1.3.

ESD_Ext_Err
: A vector of four quinary symbols corresponding to either the first or second code-group of End-of-Stream delimiter when carrier extension with error is indicated during the End-of-Stream delimiter, as specified in 40.3.1.3.

IDLE
: A sequence of vectors of four quinary symbols representing the special code-group generated in idle mode in the absence of carrier extension or carrier extension with error indication, as specified in 40.3.1.3.

link_status
: The link_status parameter set by PMA Link Monitor and passed to the PCS via the PMA_LINK.indication primitive.
Values: OK or FAIL

loc_rcvr_status
: The loc_rcvr_status parameter set by the PMA Receive function and passed to the PCS via the PMA_RXSTATUS.indication primitive.
Values: OK or NOT_OK

pcs_reset
: The pcs_reset parameter set by the PCS Reset function.
Values: ON or OFF

(RA_n, RB_n, RC_n, RD_n)
: The vector of the four correctly aligned most recently received quinary symbols generated by PCS Receive at time n.

1000BTreceive
: The receiving parameter generated by the PCS Receive function.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rem_rcvr_status
: The rem_rcvr_status parameter generated by PCS Receive.
Values: OK or NOT_OK

repeater_mode
: See 36.2.5.1.3

Rx_n
: Alias for rx_symb_vector (a vector RA_n, RB_n, RC_n, RD_n) at time n.

rxerror_status
: The rxerror_status parameter set by the PCS Receive function.
Values: ERROR or NO_ERROR

RX_DV
: The RX_DV signal of the GMII as specified in 35.2.2.7.

RX_ER
: The RX_ER signal of the GMII as specified in 35.2.2.9.

rx_symb_vector
: A vector of four quinary symbols received by the PMA and passed to the PCS via the PMA_UNITDATA.indication primitive.
Value: SYMB_4D

RXD[7:0]
: The RXD<7:0> signal of the GMII as specified in 35.2.2.8.

SSD1
: A vector of four quinary symbols corresponding to the first code-group of the Start-of-Stream delimiter, as specified in 40.3.1.3.5.

SSD2
: A vector of four quinary symbols corresponding to the second code-group of the Start-of-Stream delimiter, as specified in 40.3.1.3.5.

1000BTtransmit
: A Boolean used by the PCS Transmit Process to indicate whether a frame transmission is in progress. Also used by the Carrier Sense and Local LPI Request processes.
Values: TRUE: The PCS is transmitting a stream
FALSE: The PCS is not transmitting a stream

TXD[7:0]
: The TXD<7:0> signal of the GMII as specified in 35.2.2.4.

tx_enable
: The tx_enable parameter generated by PCS Transmit as specified in Figure 40–8.
Values: TRUE or FALSE

tx_error
: The tx_error parameter generated by PCS Transmit as specified in Figure 40–8.
Values: TRUE or FALSE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TX_EN
: The TX_EN signal of the GMII as specified in 35.2.2.3.

TX_ER
: The TX_ER signal of the GMII as specified in 35.2.2.5.

tx_mode
: The tx_mode parameter set by the PMA PHY Control function and passed to the PCS via the PMA_TXMODE.indication primitive.
Values: SEND_Z, SEND_N, or SEND_I

Tx_n
: Alias for tx_symb_vector at time n.

tx_symb_vector
: A vector of four quinary symbols generated by the PCS Transmit function and passed to the PMA via the PMA_UNITDATA.request primitive.
Value: SYMB_4D

xmt_err
: A vector of four quinary symbols corresponding to a transmit error indication during normal data transmission or reception, as specified in 40.3.1.3.

The following state variables are only required for the optional EEE capability:

loc_lpi_req
: The loc_lpi_req variable is set by the PCS Local LPI Request function and indicates whether or not the local PHY is requested to enter the LPI mode. It is passed to the PMA PHY Control function via the PMA_LPIREQ.request primitive. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is FALSE.
Values: TRUE or FALSE

lpi_mode
: The lpi_mode variable is generated by the PMA PHY Control function and indicates whether or not the local PHY has entered LPI mode. It is passed to the PCS Receive function via the PMA_LPIMODE.indication primitive. In the absence of the optional EEE capability, the PHY operates as if the value of this variable is OFF.
Values: ON or OFF

rem_lpi_req
: The rem_lpi_req variable is generated by the PCS Receive function and indicates whether or not the remote PHY is requesting entry into LPI mode. It is passed to the PMA PHY Control function via the PMA_REMLPIREQ.request primitive. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is FALSE.
Values: TRUE or FALSE

40.3.3.2 Functions

check_end
: A function used by the PCS Receive process to detect the reception of valid ESD symbols. The check_end function operates on the next two rx_symb_vectors, (Rx_{n+1}) and (Rx_{n+2}), available via PMA_UNITDATA.indication, and returns a Boolean value indicating whether these two consecutive vecctors contain symbols corresponding to a legal ESD encoding or not, as specified in 40.3.1.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

check_idle
: A function used by the PCS Receive process to detect the reception of valid idle code-groups after an error condition during the process. The check_idle function operates on the current rx_symb_vector and the next three rx_symb_vectors available via PMA_UNITDATA.indication and returns a Boolean value indicating whether the four consecutive vectors contain symbols corresponding to the idle mode encoding or not, as specified in 40.3.1.3.

DECODE
: In the PCS Receive process, this function takes as its argument the value of rx_symb_vector and returns the corresponding GMII RXD<7:0> octet. DECODE follows the rules outlined in 40.2.6.1.

ENCODE
: In the PCS Transmit process, this function takes as its argument GMII TXD <7:0> and returns the corresponding tx_symb_vector. ENCODE follows the rules outlined in 40.2.5.1.

40.3.3.3 Timer

symb_timer
: Continuous timer: The condition symb_timer_done becomes true upon timer expiration.

  Restart time: Immediately after expiration; timer restart resets the condition symb_timer_done.

  Duration: 8 ns nominal. (See clock tolerance in 40.6.1.2.6.)

  Symb-timer shall be generated synchronously with TX_TCLK. In the PCS Transmit state diagram, the message PMA_UNITDATA.request is issued concurrently with symb_timer_done.

40.3.3.4 Messages

PMA_UNITDATA.indication (rx_symb_vector)
: A signal sent by PMA Receive indicating that a vector of four quinary symbols is available in rx_symb_vector. (See 40.2.6.)

PMA_UNITDATA.request (tx_symb_vector)
: A signal sent to PMA Transmit indicating that a vector of four quinary symbols is available in tx_symb_vector. (See 40.2.5.)

PUDI
: Alias for PMA_UNITDATA.indication (rx_symb_vector).

PUDR
: Alias for PMA_UNITDATA.request (tx_symb_vector).

STD
: Alias for symb_timer_done.

40.4 Physical Medium Attachment (PMA) sublayer

40.4.1 PMA functional specifications

The PMA couples messages from a PMA service interface specified in 40.2.2 to the 1000BASE-T baseband medium, specified in 40.7.

The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 40.8.

NOTE 1—The recovered_clock arc is shown to indicate delivery of the received clock signal back the PMA TRANSMIT for loop timing.

NOTE 2—Signals and functions shown with dashed lines are only required for the EEE capability.

Figure 40–14—PMA reference diagram

40.4.2 PMA functions

The PMA sublayer comprises one PMA Reset function and five simultaneous and asynchronous operating functions. The PMA operating functions are PHY Control, PMA Transmit, PMA Receive, Link Monitor, and Clock Recovery. All operating functions are started immediately after the successful completion of the PMA Reset function.

The PMA reference diagram, Figure 40–14, shows how the operating functions relate to the messages of the PMA Service interface and the signals of the MDI. Connections from the management interface, comprising the signals MDC and MDIO, to other layers are pervasive and are not shown in Figure 40–14. The management interface and its functions are specified in Clause 22.

40.4.2.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

a) Power on (see 36.2.5.1.3)
b) The receipt of a request for reset from the management entity

PMA Reset sets pcs_reset=ON while any of the above reset conditions hold true. All state diagrams take the open-ended pma_reset branch upon execution of PMA Reset. The reference diagrams do not explicitly show the PMA Reset function.

40.4.2.2 PMA Transmit function

The PMA Transmit function comprises four synchronous transmitters to generate four 5-level pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD. PMA Transmit shall continuously transmit onto the MDI pulses modulated by the quinary symbols given by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC] and tx_symb_vector[BI_DD], respectively. The four transmitters shall be driven by the same transmit clock, TX_TCLK. The signals generated by PMA Transmit shall follow the mathematical description given in 40.4.3.1, and shall comply with the electrical specifications given in 40.6.

When the PMA_CONFIG.indication parameter config is MASTER, the PMA Transmit function shall source TX_TCLK from a local clock source while meeting the transmit jitter requirements of 40.6.1.2.5. When the PMA_CONFIG.indication parameter config is SLAVE, the PMA Transmit function shall source TX_TCLK from the recovered clock of 40.4.2.6 while meeting the jitter requirements of 40.6.1.2.5.

40.4.2.3 PMA Receive function

The PMA Receive function comprises four independent receivers for quinary pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD. PMA Receive contains the circuits necessary to both detect quinary symbol sequences from the signals received at the MDI over receive pairs BI_DA, BI_DB, BI_DC, and BI_DD and to present these sequences to the PCS Receive function. The signals received at the MDI are described mathematically in 40.4.3.2. The PMA shall translate the signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DB into the PMA_UNITDATA.indication parameter rx_symb_vector with a symbol error ratio of less than 10^{-10} over a channel meeting the requirements of 40.7.

To achieve the indicated performance, it is highly recommended that PMA Receive include the functions of signal equalization, echo and crosstalk cancellation, and sequence estimation. The sequence of code-groups assigned to tx_symb_vector is needed to perform echo and self near-end crosstalk cancellation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA Receive function uses the scr_status parameter and the state of the equalization, cancellation, and estimation functions to determine the quality of the receiver performance, and generates the loc_rcvr_status variable accordingly. The precise algorithm for generation of loc_rcvr_status is implementation dependent.

40.4.2.4 PHY Control function

PHY Control generates the control actions that are needed to bring the PHY into a mode of operation during which frames can be exchanged with the link partner. PHY Control shall comply with the state diagram description given in Figure 40–16a and Figure 40–16b.

During Auto-Negotiation PHY Control is in the DISABLE 1000BASE-T TRANSMITTER state and the transmitters are disabled. When the Auto-Negotiation process asserts link_control=ENABLE, PHY Control enters the SLAVE SILENT state. Upon entering this state, the maxwait timer is started and PHY Control forces transmission of zeros by setting tx_mode=SEND_Z. The transition out of the SLAVE SILENT state depends on whether the PHY is operating in MASTER or SLAVE mode. In MASTER mode, PHY Control transitions immediately to the TRAINING state. In SLAVE mode, PHY Control transitions to the TRAINING state only after the SLAVE PHY converges its decision feedback equalizer (DFE), acquires timing, and acquires its descrambler state, and sets scr_status=OK**.**

For the SLAVE PHY, the final convergence of the adaptive filter parameters is completed in the TRAINING state. The MASTER PHY performs all its receiver convergence functions in the TRAINING state. Upon entering the TRAINING state, the minwait_timer is started and PHY Control forces transmission into the idle mode by asserting tx_mode=SEND_I. After the PHY completes successful training and establishes proper receiver operations, PCS Transmit conveys this information to the link partner via transmission of the parameter loc_rcvr_status. (See Sd_n[2] in 40.3.1.3.4.) The link partner's value for loc_rcvr_status is stored in the local device parameter rem_rcvr status. When the minwait_timer expires and the condition loc_rcvr_status=OK is satisfied, PHY Control transitions into either the SEND IDLE OR DATA state if rem_rcvr_status=OK or the SEND IDLE state if rem_rcvr_status=NOT_OK. On entry into either the SEND IDLE or SEND IDLE OR DATA states, the maxwait_timer is stopped and the minwait_timer is started.

The normal mode of operation corresponds to the SEND IDLE OR DATA state, where PHY Control asserts tx_mode=SEND_N and transmission of data over the link can take place. In this state, when no frames have to be sent, idle transmission takes place.

If unsatisfactory receiver operation is detected in the SEND IDLE OR DATA or SEND IDLE states (loc_rcvr_status=NOT_OK) and the minwait_timer has expired, transmission of the current frame is completed and PHY Control enters the SLAVE SILENT state. In the SEND IDLE OR DATA state, whenever a PHY that operates reliably detects unsatisfactory operation of the remote PHY (rem_rcvr_status=NOT_OK) and the minwait_timer has expired, it enters the SEND IDLE state where tx_mode=SEND_I is asserted and idle transmission takes place. In this state, encoding is performed with the parameter loc_rcvr_status=OK. As soon as the remote PHY signals satisfactory receiver operation (rem_rcvr_status=OK) and the minwait_timer has expired, the SEND IDLE OR DATA state is entered.

When the PHY supports the optional EEE capability, PHY Control will transition to the LPI mode in response to concurrent requests for LPI mode from the local PHY (loc_lpi_req = TRUE) and remote PHY (rem_lpi_req = TRUE).

Upon activation of the LPI mode, the PHY Control asserts tx_mode = SEND_I for a period of time defined by lpi_update_timer, which allows the remote PHY to prepare for cessation of transmission. When lpi_update_timer expires, PHY Control transitions to the POST_UPDATE state, signals to the remote PHY that is has completed the update by setting loc_update_done = TRUE, and starts the lpi_postupdate_timer. When lpi_postupdate_timer expires, PHY Control transitions to the WAIT_QUIET state. If there is a request to wake (loc_lpi_req = FALSE or rem_lpi_req = FALSE) while in the POST_UPDATE state, PHY Control

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

will wait for confirmation that the remote PHY has completed the update (rem_update_done = TRUE) and is prepared for cessation of transmission before proceeding to the WAIT_QUIET state.

Upon entry into the WAIT_QUIET state, PHY Control asserts tx_mode = SEND_Z and transmission ceases. During the WAIT_QUIET and QUIET states, the PHY may deactivate transmit and receive functions in order to conserve energy. However, in the WAIT_QUIET state, the PHY shall be capable of correctly decoding rem_lpi_req. The PHY will remain in the QUIET state no longer than the time implied by lpi_quiet_timer.

When lpi_quiet_timer expires, the PHY initiates a wake sequence. The wake sequence begins with a transition to the WAKE state where the PHY will transmit (tx_mode = SEND_I) for the period lpi_waketx_timer and simultaneously start a parallel timer, lpi_wakemz_timer. Since it is likely that transmit circuits were deactivated while in the QUIET state, this transmission is not expected to be compliant 1000BASE-T signaling, but rather of sufficient quality and duration to be detected by the remote PHY receiver and initiate the wake sequence in the remote PHY.

Upon expiration of lpi_waketx_timer, the PHY will enter the WAKE_SILENT state and cease transmission (tx_mode = SEND_Z). The PHY will remain in the WAKE_SILENT state until lpi_wakemz_timer has expired, at which point it is assumed that the transmitter circuits have stabilized and compliant 1000BASE-T signaling can be transmitted. At this point the MASTER transitions to the WAKE_TRAINING state and transmits to the SLAVE PHY.

The remaining wake sequence is essentially an accelerated training mode sequence leading to entry into the UPDATE state.

Once scrambler synchronization is achieved, the incoming value of rem_lpi_req can be determined. If the LPI mode is no longer requested by either the local or remote PHY, then both PHYs return to the SEND IDLE OR DATA state and the normal mode of operation (tx_mode = SEND_N). If both PHYs continue to request the LPI mode, then both PHYs remain in the UPDATE state and continue to transmit for a time defined by lpi_update_timer. This time is intended to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variation in the timing of the link or the underlying channel characteristics. If lpi_update_timer expires and both PHYs continue to request the LPI mode, then the PHY transitions to the POST_UPDATE state.

PHY Control may force the transmit scrambler state to be initialized to an arbitrary value by requesting the execution of the PCS Reset function defined in 40.3.1.1.

40.4.2.5 Link Monitor function

Link Monitor determines the status of the underlying receive channel and communicates it via the variable link_status. Failure of the underlying receive channel typically causes the PMA’s clients to suspend normal operation.

The Link Monitor function shall comply with the state diagram of Figure 40–17.

Upon power on, reset, or release from power down, the Auto-Negotiation algorithm sets link_control=SCAN_FOR_CARRIER and, during this period, sends fast link pulses to signal its presence to a remote station. If the presence of a remote station is sensed through reception of fast link pulses, the Auto-Negotiation algorithm sets link_control=DISABLE and exchanges Auto-Negotiation information with the remote station. During this period, link_status=FAIL is asserted. If the presence of a remote 1000BASE-T station is established, the Auto-Negotiation algorithm permits full operation by setting link_control=ENABLE. As soon as reliable transmission is achieved, the variable link_status=OK is asserted, upon which further PHY operations can take place.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.4.2.6 Clock Recovery function

The Clock Recovery function couples to all four receive pairs. It may provide independent clock phases for sampling the signals on each of the four pairs.

The Clock Recovery function shall provide clocks suitable for signal sampling on each line so that the symbol error ratio indicated in 40.4.2.3 is achieved. The received clock signal has to be stable and ready for use when training has been completed (loc_rcvr_status=OK). The received clock signal is supplied to the PMA Transmit function by received_clock.

40.4.3 MDI

Communication through the MDI is summarized in 40.4.3.1 and 40.4.3.2.

40.4.3.1 MDI signals transmitted by the PHY

The quinary symbols to be transmitted by the PMA on the four pairs BI_DA, BI_DB, BI_DC, and BI_DD are denoted by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD], respectively. The modulation scheme used over each pair is 5-level Pulse Amplitude Modulation. PMA Transmit generates a pulse-amplitude modulated signal on each pair in the following form:

$$s(t) = \sum_k a_k h_1(t - kT)$$

In the above equation, a_k represents the quinary symbol from the set {2, 1, 0, –1, –2} to be transmitted at time kT, and $h_1(t)$ denotes the system symbol response at the MDI. This symbol response shall comply with the electrical specifications given in 40.6.

40.4.3.2 Signals received at the MDI

Signals received at the MDI can be expressed for each pair as pulse-amplitude modulated signals that are corrupted by noise as follows:

$$r(t) = \sum_k a_k h_2(t - kT) + w(t)$$

In this equation, $h_2(t)$ denotes the impulse response of the overall channel between the transmit symbol source and the receive MDI and $w(t)$ is a term that represents the contribution of various noise sources. The four signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD shall be processed within the PMA Receive function to yield the quinary received symbols rx_symb_vector[BI_DA], rx_symb_vector[BI_DB], rx_symb_vector[BI_DC], and rx_symb_vector[BI_DD].

40.4.4 Automatic MDI/MDI-X Configuration

Automatic MDI/MDI-X Configuration is intended to eliminate the need for crossover cables between similar devices. Implementation of an automatic MDI/MDI-X configuration is optional for 1000BASE-T devices. If an automatic configuration method is used, it shall comply with the following specifications. The assignment of pin-outs for a 1000BASE-T crossover function cable is shown in Table 40–12 in 40.8.

40.4.4.1 Description of Automatic MDI/MDI-X state diagram

The Automatic MDI/MDI-X state diagram facilitates switching the BI_DA(C)+ and BI_DA(C)– with the BI_DB(D)+ and BI_DB(D)– signals respectively prior to the auto-negotiation mode of operation so that FLPs can be transmitted and received in compliance with Clause 28 Auto-Negotiation specifications. The

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

correct polarization of the crossover circuit is determined by an algorithm that controls the switching function. This algorithm uses an 11-bit linear feedback shift register (LFSR) to create a pseudo-random sequence that each end of the link uses to determine its proposed configuration. Upon making the selection to either MDI or MDI-X, the node waits for a specified amount of time while evaluating its receive channel to determine whether the other end of the link is sending link pulses or PHY-dependent data. If link pulses or PHY-dependent data are detected, it remains in that configuration. If link pulses or PHY-dependent data are not detected, it increments its LFSR and makes a decision to switch based on the value of the next bit. The state diagram does not move from one state to another while link pulses are being transmitted.

40.4.4.2 Pseudo-random sequence generator

One possible implementation of the pseudo-random sequence generator using a linear-feedback shift register is shown in Figure 40–15. The bits stored in the shift register delay line at time n are denoted by S[10:0]. At each sample period, the shift register is advanced by one bit and one new bit represented by S[0] is generated. Switch control is determined by S[10].

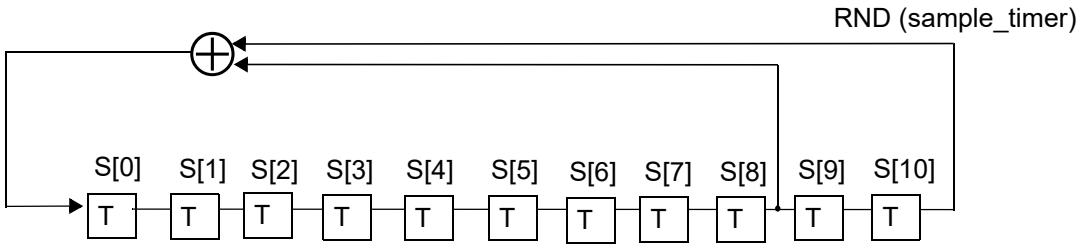

Figure 40–15—Automatic MDI/MDI-X linear-feedback shift register

40.4.5 State variables

40.4.5.1 State diagram variables

config
: The PMA shall generate this variable continuously and pass it to the PCS via the PMA_CONFIG.indication primitive.

  Values: MASTER or SLAVE

link_control
: This variable is defined in 28.2.6.2.

Link_Det
: This variable indicates linkpulse = true or link_status = READY or OK has occurred at the receiver since the last time sample_timer has been started.

  Values: TRUE: linkpulse = true or link_status = READY or OK has occurred since the last time sample_timer has been started.

  FALSE: otherwise

linkpulse
: This variable is defined in 28.2.6.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

link_status
: This variable is defined in 28.2.6.1.

loc_rcvr_status
: Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive link for the local PHY.

Values: OK: The receive link for the local PHY is operating reliably.
NOT_OK: Operation of the receive link for the local PHY is unreliable.

MDI_Status
: This variable defines the condition of the Automatic MDI/MDI-X physical connection.

Values: MDI: The BI_DA, BI_DB, BI_DC, and BI_DD pairs follow the connections as described in the MDI column of Table 40–12.

MDI-X: The BI_DA, BI_DB, BI_DC, and BI_DD pairs follow the connections as described in the MDI-X column of Table 40–12.

pma_reset
: Allows reset of all PMA functions.

Values: ON or OFF

Set by: PMA Reset

rem_rcvr_status
: Variable set by the PCS Receive function to indicate whether correct operation of the receive link for the remote PHY is detected or not.

Values: OK: The receive link for the remote PHY is operating reliably.

NOT_OK: Reliable operation of the receive link for the remote PHY is not detected.

RND (sample_timer)
: This variable is defined as bit S[10] of the LSFR described in 40.4.4.2

scr_status
: The scr_status parameter as communicated by the PMA_SCRSTATUS.request primitive.

Values: OK: The descrambler has achieved synchronization.

NOT_OK: The descrambler is not synchronized. Note that when the PHY supports the optional EEE capability and signal_detect is FALSE, scr_status is set to NOT_OK.

T_Pulse
: This variable indicates that a linkpulse is being transmitted to the MDI.

Values: TRUE: Pulse being transmitted to the MDI

FALSE: Otherwise

tx_enable
: The tx_enable parameter generated by PCS Transmit as specified in Figure 40–8.

Values: TRUE or FALSE as per 40.3.3.1.

tx_mode
: PCS Transmit sends code-groups according to the value assumed by this variable.

Values: SEND_N: This value is continuously asserted when transmission of sequences of code-groups representing a GMII data stream, control information, or idle mode is to take place.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SEND_I: This value is continuously asserted when transmission of sequences of code-groups representing the idle mode is to take place.

SEND_Z: This value is asserted when transmission of zero code-groups is to take place.

The following state variables are only required for the optional EEE capability:

loc_lpi_req

The loc_lpi_req variable is set by the PCS Local LPI Request function and indicates whether or not the local PHY is requested to enter the LPI mode. It is passed to the PMA PHY Control function via the PMA_LPIREQ.request primitive. In the absence of the optional EEE capability, the PHY operates as if the value of this variable is FALSE.

Values: TRUE: "Assert LPI" is present at the GMII.
FALSE: "Assert LPI" is not present at the GMII.

loc_udpate_done

The loc_update_done variable is generated by the PMA PHY Control function and indicates whether or not the local PHY has completed the update of its receiver state. It is passed to the PCS Transmit function via the PMA_UPDATE.indication primitive. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is FALSE.

Values: TRUE: The PHY has completed the current update.
FALSE: The PHY is ready for the next update or the current update is still in progress.

lpi_mode

The lpi_mode variable is generated by the PMA PHY Control function and indicates whether or not the local PHY has entered the LPI mode. It is passed to the PCS Receive function via the PMA_LPIMODE.indication primitive. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is OFF.

Values: ON: The PHY is operating in LPI mode.
OFF: The PHY is in normal operation.

rem_lpi_req

The rem_lpi_req variable is generated by the PCS Receive function and indicates whether or not the remote PHY is requesting entry into LPI mode. It is passed to the PMA PHY Control function via the PMA_REMLPIREQ.request primitive. In the absence of the optional EEE capability, the PHY operates as if the value of this variable is FALSE.

Values: TRUE: LPI is encoded in the received symbols.
FALSE: LPI is not encoded in the received symbols.

rem_update_done

The rem_update_done variable is generated by the PCS Receive function and indicates whether or not the remote PHY has completed the update of its receiver state. It is passed to the PMA PHY Control function via the PMA_REMUPDATE.request primitive. In the absence of the optional EEE capability, the PHY shall operate as if the value of this variable is FALSE.

Values: TRUE: The remote PHY has completed the current update.
FALSE: The remote PHY is ready for the next update or the current update is still in progress.

signal_detect

The signal_detect variable is set by the PMA Receive function and indicates the presence of a signal at the MDI, as defined in 40.6.1.3.5.

Values: TRUE: There is a signal present at the MDI.
FALSE: There is no signal present at the MDI.

40.4.5.2 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where “stop timer” is asserted.

A_timer

An asynchronous (to the Auto-Crossover state diagram) free-running timer that provides for a relatively arbitrary reset of the state diagram to its initial state. This timer is used to reduce the probability of a lock-up condition where both nodes have the same identical seed initialization at the same point in time.

Values: The condition A_timer_done becomes true upon timer expiration.

Duration: This timer shall have a period of 1.3 s ± 25%.

Initialization of A_timer is implementation specific.

maxwait_timer

A timer used to limit the amount of time during which a receiver dwells in the SLAVE SILENT and TRAINING states. The timer shall expire 750 ms ± 10 ms if config = MASTER or 350 ms ± 5 ms if config = SLAVE. This timer is used jointly in the PHY Control and Link Monitor state diagrams. The maxwait_timer is tested by the Link Monitor to force link_status to be set to FAIL if the timer expires and loc_rcvr_status is NOT_OK. See Figure 40–16a.

minwait_timer

A timer used to determine the minimum amount of time the PHY Control stays in the TRAINING, SEND IDLE, or DATA states. The timer shall expire 1 μs ± 0.1μs after being started.

sample_timer

This timer provides a long enough sampling window to ensure detection of Link Pulses or link_status, if they exist at the receiver.

Values: The condition sample_timer_done becomes true upon timer expiration.

Duration: This timer shall have a period of 62 ms ± 2 ms.

stabilize_timer

A timer used to control the minimum time that loc_rcvr_status has to be OK before a transition to Link Up can occur. The timer shall expire 1 μs ± 0.1 μs after being started.

The following timers are only required for the optional EEE capability:

lpi_link_fail_timer

This timer defines the maximum time the PHY allows between entry into the WAKE state and subsequent entry into the UPDATE or SEND IDLE OR DATA states before forcing the link to restart.

Values: The condition lpi_link_fail_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period between 90 μs and 110 μs.

lpi_postupdate_timer

This timer defines the maximum time the PHY dwells in the POST_UPDATE state before proceeding to the WAIT_QUIET state.

Values: The condition lpi_postupdate_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period between 2.0 μs and 3.2 μs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

lpi_quiet_timer

This timer defines the maximum time the PHY remains quiet before initiating transmission to refresh the remote PHY.

Values: The condition lpi_quiet_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period between 20 ms and 24 ms.

lpi_waitwq_timer

This timer defines the maximum time the PHY dwells in the WAIT_QUIET state before forcing the link to restart.

Values: The condition lpi_waitwq_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period between 10 µs and 12 µs.

lpi_wake_timer

This timer defines the expected time for the PHY to transition from the LPI mode to normal operation.

Values: The condition lpi_wake_timer_done becomes true upon timer expiration. For each transition of lpi_wake_timer_done from false to true, the wake error counter (see 40.5.1.1) shall be incremented.
Duration: This timer shall have a period that does not exceed 16.5 µs.

lpi_waketx_timer

This timer defines the time the PHY transmits to ensure detection by the remote PHY receiver and trigger an exit from the low power state.

Values: The condition lpi_waketx_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period between 1.2 µs and 1.4 µs.

lpi_wakemz_timer

This timer defines the time allowed for the PHY transmitter to achieve compliant operation following activation.

Values: The condition lpi_wakemz_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period between 4.25 µs and 5.00 µs.

lpi_update_timer

This timer defines the time the PHY transmits to facilitate a refresh of the remote PHY receiver.

Values: The condition lpi_update_timer_done becomes true upon timer expiration.
Duration: For a PHY configured as the MASTER, this timer shall have a period between 0.23 ms and 0.25 ms. For a PHY configured as the SLAVE, this timer shall have a period between 0.18 ms and 0.20 ms.

40.4.6.2.1 Auto Crossover state diagram

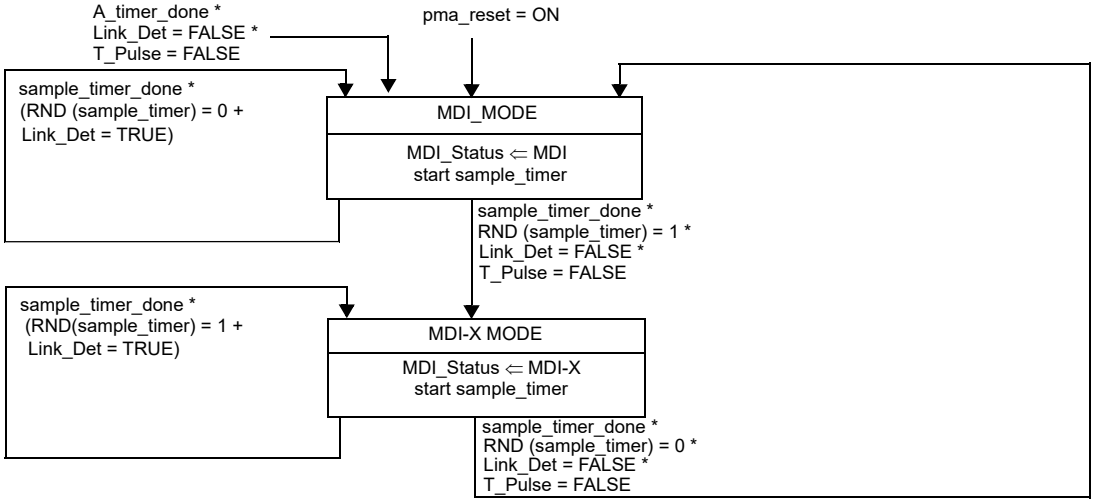

Figure 40–18—Auto Crossover state diagram

40.5 Management interface

1000BASE-T makes extensive use of the management functions provided by the MII Management Interface (see 22.2.4), and the communication and self-configuration functions provided by Auto-Negotiation (Clause 28).

40.5.1 Support for Auto-Negotiation

All 1000BASE-T PHYs shall provide support for Auto-Negotiation (Clause 28) and shall be capable of operating as MASTER or SLAVE.

Auto-Negotiation is performed as part of the initial set-up of the link, and allows the PHYs at each end to advertise their capabilities (speed, PHY type, half or full duplex) and to automatically select the operating mode for communication on the link. Auto-negotiation signaling is used for the following two primary purposes for 1000BASE-T:

a) To negotiate that the PHY is capable of supporting 1000BASE-T half duplex or full duplex transmission.
b) To determine the MASTER-SLAVE relationship between the PHYs at each end of the link.
c) To negotiate EEE capabilities as specified in 28C.12.

This relationship is necessary for establishing the timing control of each PHY. The 1000BASE-T MASTER PHY is clocked from a local source. The SLAVE PHY uses loop timing where the clock is recovered from the received data stream.

40.5.1.1 1000BASE-T use of registers during Auto-Negotiation

A 1000BASE-T PHY shall use the management register definitions and values specified in Table 40–3.

Table 40–3—1000BASE-T Registers

Register	Bit	Name	Description	Type [a]
0	0.15:0	MII control register	Defined in 28.2.4.1.1	RO
1	1.15:0	MII status register	Defined in 28.2.4.1.2	RO
4	4.15:0	Auto-Negotiation advertisement register	The Selector Field (4.4:0) is set to the appropriate code as specified in Annex 28A. The Technology Ability Field bits 4.12:5 are set to the appropriate code as specified in Annexes 28B and 28D. Bit 4.15 is set to logical one to indicate the desired exchange of Next Pages describing the gigabit extended capabilities.	R/W
5	5.15:0	Auto-Negotiation link partner ability register	Defined in 28.2.4.1.4. 1000BASE-T implementations do not use this register to store Auto-Negotiation Link Partner Next Page data.	RO
6	6.15:0	Auto-Negotiation expansion register	Defined in 28.2.4.1.5	RO
7	7.15:0	Auto-Negotiation Next Page transmit register	Defined in 28.2.4.1.6	R/W
8	8.15:0	Auto-Negotiation link partner Next Page register	Defined in 28.2.4.1.8	RO
9	9.15:13	Test mode bits	Transmitter test mode operations are defined by bits 9.15:13 as described in 40.6.1.1.2 and Table 40–7. The default values for bits 9.15:13 are all zero.	R/W
9	9.12	MASTER-SLAVE Manual Config Enable	1=Enable MASTER-SLAVE Manual configuration value 0=Disable MASTER-SLAVE Manual configuration value Default bit value is 0.	R/W
9	9.11	MASTER-SLAVE Config Value	1=Configure PHY as MASTER during MASTER-SLAVE negotiation, only when 9.12 is set to logical one. 0=Configure PHY as SLAVE during MASTER-SLAVE negotiation, only when 9.12 is set to logical one. Default bit value is 0.	R/W
9	9.10	Port type	Bit 9.10 is to be used to indicate the preference to operate as MASTER (multiport device) or as SLAVE (single-port device) if the MASTER-SLAVE Manual Configuration Enable bit, 9.12, is not set. Usage of this bit is described in 40.5.2. 1=Multiport device 0=single-port device	R/W
9	9.9	1000BASE-T Full Duplex	1 = Advertise PHY is 1000BASE-T full duplex capable. 0 = Advertise PHY is not 1000BASE-T full duplex capable.	R/W
9	9.8	1000BASE-T Half Duplex	1 = Advertise PHY is 1000BASE-T half duplex capable. 0 = Advertise PHY is not 1000BASE-T half duplex capable.	R/W
9	9.7:0	Reserved	Write as 0, ignore on read.	R/W

Table 40–3—1000BASE-T Registers *(continued)*

Register	Bit	Name	Description	Type [a]
10	10.15	MASTER-SLAVE configuration fault	Configuration fault, as well as the criteria and method of fault detection, is PHY specific. The MASTER-SLAVE Configuration Fault bit will be cleared each time register 10 is read via the management interface and will be cleared by a 1000BASE-T PMA reset. This bit will self clear on Auto-Negotiation enable or Auto-Negotiation complete.This bit will be set if the number of failed MASTER-SLAVE resolutions reaches 7. For l000BASE-T, the fault condition will occur when both PHYs are forced to be MASTERs or SLAVEs at the same time using bits 9.12 and 9.11. Bit 10.15 should be set via the MASTER-SLAVE Configuration Resolution function described in 40.5.2. 1 = MASTER-SLAVE configuration fault detected 0 = No MASTER-SLAVE configuration fault detected	RO/LH/SC
10	10.14	MASTER-SLAVE configuration resolution	1 = Local PHY configuration resolved to MASTER 0 = Local PHY configuration resolved to SLAVE	RO
10	10.13	Local Receiver Status	1 = Local Receiver OK (loc_rcvr_status=OK) 0 = Local Receiver not OK (loc_rcvr_status=NOT_OK) Defined by the value of loc_rcvr_status as per 40.4.5.1.	RO
10	10.12	Remote Receiver Status	1 = Remote Receiver OK (rem_rcvr_status=OK) 0 = Remote Receiver not OK (rem_rcvr_status=NOT_OK) Defined by the value of rem_rcvr_status as per 40.4.5.1.	RO
10	10.11	LP 1000T FD	1 = Link Partner is capable of 1000BASE-T full duplex 0 = Link Partner is not capable of 1000BASE-T full duplex This bit is guaranteed to be valid only when the Page received bit (6.1) has been set to 1.	RO
10	10.10	LP 1000T HD	1 = Link Partner is capable of 1000BASE-T half duplex 0 = Link Partner is not capable of 1000BASE-T half duplex This bit is guaranteed to be valid only when the Page received bit (6.1) has been set to 1.	RO
10	10.9:8	Reserved	Reserved	RO
10	10.7:0	Idle Error Count	Bits 10.7:0 indicate the Idle Error count, where 10.7 is the most significant bit. These bits contain a cumulative count of the errors detected when the receiver is receiving idles and PMA_TXMODE.indication is equal to SEND_N (indicating that both local and remote receiver status have been detected to be OK). The counter is incremented every symbol period that rxerror_status is equal to ERROR. These bits are reset to all zeros when the error count is read by the management function or upon execution of the PCS Reset function and are to be held at all ones in case of overflow (see 30.5.1.1.13).	RO/SC
15	15.15:12	Extended status register	See 22.2.4.4	RO

Table 40–3—1000BASE-T Registers *(continued)*

Register	Bit	Name	Description	Type [a]
3.0[b]	3.0.10	Clock stop enable	Defined in 45.2.3.1.4. When the PHY supports the optional EEE capability, it may stop the derived GMII receive clock while it is signaling LPI in the receive direction. If this bit is set to 1, then the PHY may stop the receive GMII clock while it is signaling LPI; otherwise it keeps the clock active.	R/W
3.1	3.1.11	Transmit LPI received	Defined in 45.2.3.2.1.	RO/LH
3.1	3.1.10	Receive LPI received	Defined in 45.2.3.2.2.	RO/LH
3.1	3.1.9	Transmit LPI indication	Defined in 45.2.3.2.3.	RO
3.1	3.1.8	Receive LPI indication	Defined in 45.2.3.2.4.	RO
3.1	3.1.6	Clock stop capable	Defined in 45.2.3.2.6. When the PHY supports the optional EEE capability, this bit may be set to 1 to allow the MAC to stop the GMII clock while it is signaling LPI in the transmit direction. If this bit is 0, then the MAC keeps the clock active.	RO
3.20	3.20.2	1000BASE-T EEE supported	If the local device supports the optional EEE capability for 1000BASE-T, this bit is set to 1.	RO
3.22	3.22.15:0	EEE wake error counter	This counter is incremented for each transition of lpi_wake_timer_done from FALSE to TRUE (see 40.4.5.2).	RO, NR
7.60	7.60.2	1000BASE-T EEE advertisement	If the local device supports the optional EEE capability for 1000BASE-T and EEE is desired, this bit is set to 1.	R/W
7.61	7.61.2	LP 1000BASE-T EEE advertisement	If the link partner supports the optional EEE capability for 1000BASE-T and EEE is desired, this bit is set to 1.	RO

[a] R/W = Read/Write, RO = Read only, SC = Self-clearing, LH = Latching high.
[b] This register resides in the Clause 45 management space and is designated by the format M.R.B where M is the MDIO manageable device address (MMD), R is the register address, and B is the bit.

40.5.1.2 1000BASE-T Auto-Negotiation page use

1000BASE-T PHYs shall exchange one Auto-Negotiation Base Page, a 1000BASE-T formatted Next Page, and two 1000BASE-T Unformatted Next Pages in sequence, without interruption, as specified in Table 40–4. Additional Next Pages can be exchanged as described in Annex 40C.

Note that the Acknowledge 2 bit is not utilized and has no meaning when used for the 1000BASE-T message page exchange.

When the PHY supports the optional EEE capability, a 1000BASE-T PHY shall exchange an additional formatted Next Page and Unformatted Next Page in sequence, without interruption, as specified in Table 40–4.

40.5.1.3 Sending Next Pages

Implementers who do not wish to send additional Next Pages (i.e., Next Pages in addition to those required to perform PHY configuration as defined in this clause) can use Auto-Negotiation as defined in Clause 28 and the Next Pages defined in 40.5.1.2. Implementers who wish to send additional Next Pages are advised to consult Annex 40C.

40.5.2 MASTER-SLAVE configuration resolution

Since both PHYs that share a link segment are capable of being MASTER or SLAVE, a prioritization scheme exists to ensure that the correct mode is chosen. The MASTER-SLAVE relationship shall be determined during Auto-Negotiation using Table 40–5 with the 1000BASE-T Technology Ability Next Page bit values specified in Table 40–4 and information received from the link partner. This process is conducted at the entrance to the FLP LINK GOOD CHECK state shown in the Arbitration state diagram (Figure 28–15.)

The following four equations are used to determine these relationships:

manual_MASTER = U0 * U1
manual_SLAVE = U0 * !U1
single-port device = !U0 * !U2,
multiport device = !U0 * U2

where

U0 is bit 0 of unformatted page 1,
U1 is bit 1 of unformatted page 1, and
U2 is bit 2 of unformatted page 1 (see Table 40–4).

A 1000BASE-T PHY is capable of operating either as the MASTER or SLAVE. In the scenario of a link between a single-port device and a multiport device, the preferred relationship is for the multiport device to be the MASTER PHY and the single-port device to be the SLAVE. However, other topologies may result in contention. The resolution function of Table 40–5 is defined to handle any relationship conflicts.

Table 40–5—1000BASE-T MASTER-SLAVE configuration resolution table

Local device type	Remote device type	Local device resolution	Remote device resolution
single-port device	multiport device	SLAVE	MASTER
single-port device	manual_MASTER	SLAVE	MASTER
manual_SLAVE	manual_MASTER	SLAVE	MASTER
manual_SLAVE	multiport device	SLAVE	MASTER
multiport device	manual_MASTER	SLAVE	MASTER
manual_SLAVE	single-port device	SLAVE	MASTER
multiport device	single-port device	MASTER	SLAVE
multiport device	manual_SLAVE	MASTER	SLAVE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 40–5—1000BASE-T MASTER-SLAVE configuration resolution table *(continued)*

Local device type	Remote device type	Local device resolution	Remote device resolution
manual_MASTER	manual_SLAVE	MASTER	SLAVE
manual_MASTER	single-port device	MASTER	SLAVE
single-port device	manual_SLAVE	MASTER	SLAVE
manual_MASTER	multiport device	MASTER	SLAVE
multiport device	multiport device	The device with the higher SEED value is configured as MASTER, otherwise SLAVE.	The device with the higher SEED value is configured as MASTER, otherwise SLAVE.
single-port device	single-port device	The device with the higher SEED value is configured as MASTER, otherwise SLAVE	The device with the higher SEED value is configured as MASTER, otherwise SLAVE.
manual_SLAVE	manual_SLAVE	MASTER-SLAVE configuration fault	MASTER-SLAVE configuration fault
manual_MASTER	manual_MASTER	MASTER-SLAVE configuration fault	MASTER-SLAVE configuration fault

The rationale for the hierarchy illustrated in Table 40–5 is straightforward. A 1000BASE-T multiport device has higher priority than a single-port device to become the MASTER. In the case where both devices are of the same type, e.g., both devices are multiport devices, the device with the higher MASTER-SLAVE seed bits (SB0...SB10), where SB10 is the MSB, shall become the MASTER and the device with the lower seed value shall become the SLAVE. In case both devices have the same seed value, both should assert link_status_1GigT=FAIL (as defined in 28.3.1) to force a new cycle through Auto-Negotiation. Successful completion of the MASTER-SLAVE resolution shall be treated as MASTER-SLAVE configuration resolution complete.

The method of generating a random or pseudorandom seed is left to the implementer. The generated random seeds should belong to a sequence of independent, identically distributed integer numbers with a uniform distribution in the range of 0 to 2^{11}– 2. The algorithm used to generate the integer should be designed to minimize the correlation between the number generated by any two devices at any given time. A seed counter shall be provided to track the number of seed attempts. The seed counter shall be set to zero at startup and shall be incremented each time a seed is generated. When MASTER-SLAVE resolution is complete, the seed counter shall be reset to 0 and bit 10.15 shall be set to logical zero. A MASTER-SLAVE resolution fault shall be declared if resolution is not reached after the generation of seven seeds.

The MASTER-SLAVE Manual Configuration Enable bit (control register bit 9.12) and the MASTER-SLAVE Config Value bit (control register bit 9.11) are used to manually set a device to become the MASTER or the SLAVE. In case both devices are manually set to become the MASTER or the SLAVE, this condition shall be flagged as a MASTER-SLAVE Configuration fault condition, thus the MASTER-SLAVE Configuration fault bit (status register bit 10.15) shall be set to logical one. The MASTER-SLAVE Configuration fault condition shall be treated as MASTER-SLAVE configuration resolution complete and link_status_1GigT shall be set to FAIL, because the MASTER-SLAVE relationship was not resolved. This will force a new cycle through Auto-Negotiation after the link_fail_inhibit_timer has expired. Determination of MASTER-SLAVE values occur on the entrance to the FLP LINK GOOD CHECK state (Figure 28–18) when the highest common denominator (HCD) technology is 1000BASE-T. The resulting MASTER-SLAVE value is used by the 1000BASE-T PHY control (40.4.2.4).

If MASTER-SLAVE Manual Configuration is disabled (bit 9.12 is set to 0) and the local device detects that both the local device and the remote device are of the same type (either multiport device or single-port device) and that both have generated the same random seed, it generates and transmits a new random seed for MASTER-SLAVE negotiation by setting link_status to FAIL and cycling through the Auto-Negotiation process again.

The MASTER-SLAVE configuration process returns one of the three following outcomes:

a) *Successful:* Bit 10.15 of the 1000BASE-T Status Register is set to logical zero and bit 10.14 is set to logical one for MASTER resolution or for logical zero for SLAVE resolution. 1000BASE-T returns control to Auto_Negotiation (at the entrance to the FLP LINK GOOD CHECK state in Figure 28–18) and passes the value MASTER or SLAVE to PMA_CONFIG.indication (see 40.2.4.)
b) *Unsuccessful:* link_status_1GigT is set to FAIL and Auto-Negotiation restarts (see Figure 28–18.)
c) *Fault detected:* (This happens when both end stations are set for manual configuration and both are set to MASTER or both are set to SLAVE.) Bit 10.15 of the 1000BASE-T Status Register is set to logical one to indicate that a configuration fault has been detected. This bit also is set when seven attempts to configure the MASTER SLAVE relationship via the seed method have failed. When a fault is detected, link_status_1GigT is set to FAIL, causing Auto-Negotiation to cycle through again.

NOTE—MASTER-SLAVE arbitration only occurs if 1000BASE-T is selected as the highest common denominator; otherwise, it is assumed to have passed this condition.

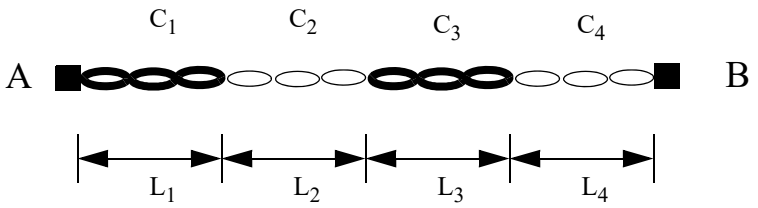
40.6 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA.

Common-mode tests use the common-mode return point as a reference.

40.6.1 PMA-to-MDI interface tests

40.6.1.1 Electrical isolation



A PHY with a MDI that is a PI (see 33.1.3) shall meet the isolation requirements defined in 33.4.1 or 145.4.1.

A PHY with a MDI that is not a PI shall provide electrical isolation between the port device circuits, including frame ground (if any) and all MDI leads. This electrical isolation shall meet the isolation requirements as specified in J.1.

40.6.1.1.1 Test channel

To perform the transmitter MASTER-SLAVE timing jitter tests described in this clause, a test channel is required to ensure that jitter is measured under conditions of poor signal to echo ratio. This test channel shall be constructed by combining 100 and 120 Ω cable segments that both meet or exceed ISO/IEC 11801 Category 5 specifications for each pair, as shown in Figure 40–19, with the lengths and additional restrictions on parameters described in Table 40–6. The ends of the test channel shall be terminated with connectors meeting or exceeding ISO/IEC 11801:1995 Category 5 specifications. The return loss of the resulting test channel shall meet the return loss requirements of 40.7.2.3 and the crosstalk requirements of 40.7.3.

Identical for each of the four pairs.

Figure 40–19—Test channel topology for each cable pair

Table 40–6—Test channel cable segment specifications

Cable segment	Length (meters)	Characteristic impedance (at frequencies > 1 MHz)	Attenuation (per 100 meters at 31.25 MHz)
1	L_1=1.20	120 Ω ± 5 Ω	7.8 to 8.8 dB
2	L_2=x	100 Ω ± 5 Ω	10.8 to 11.8 dB
3	L_3=1.48	120 Ω ± 5 Ω	7.8 to 8.8 dB
4	L_4=y	100 Ω ± 5 Ω	10.8 to 11.8 dB

NOTE—x is chosen so that the total delay of segments C1, C2, and C3, averaged across all pairs, is equal to 570 ns at 31.25 MHz; however, if this would cause the total attenuation of segments C1, C2, and C3, averaged across all pairs, to exceed the worst case insertion loss specified in 40.7.2.1 then x is chosen so that the total attenuation of segments C1, C2, and C3, averaged across all pairs, does not violate 40.7.2.1 at any frequencies. The value of y is chosen so that the total attenuation of segments C1, C2, C3, and C4, averaged across all pairs, does not violate 40.7.2.1 at any frequency (y may be 0).

40.6.1.1.2 Test modes

The test modes described below shall be provided to allow for testing of the transmitter waveform, transmitter distortion, and transmitted jitter.

For a PHY with a GMII interface, these modes shall be enabled by setting bits 9.13:15 (1000BASE-T Control Register) of the GMII Management register set as shown in Table 40–7. These test modes shall only change the data symbols provided to the transmitter circuitry and shall not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation. PHYs without a GMII shall provide a means to enable these modes for conformance testing.

Table 40–7—GMII management register settings for test modes

Bit 1 (9.15)	Bit 2 (9.14)	Bit 3 (9.13)	Mode
0	0	0	Normal operation
0	0	1	Test mode 1—Transmit waveform test
0	1	0	Test mode 2—Transmit jitter test in MASTER mode
0	1	1	Test mode 3—Transmit jitter test in SLAVE mode
1	0	0	Test mode 4—Transmitter distortion test
1	0	1	Reserved, operations not identified.
1	1	0	Reserved, operations not identified.
1	1	1	Reserved, operations not identified.

When test mode 1 is enabled, the PHY shall transmit the following sequence of data symbols A_n, B_n, C_n, D_n, of 40.3.1.3.6 continually from all four transmitters:

{{+2 followed by 127 0 symbols}, {–2 followed by 127 0 symbols},{+1 followed by 127 0 symbols}, {–1 followed by 127 0 symbols}, {128 +2 symbols, 128 –2 symbols, 128 +2 symbols, 128 –2 symbols}, {1024 0 symbols}}

This sequence is repeated continually without breaks between the repetitions when the test mode is enabled. A typical transmitter output is shown in Figure 40–20. The transmitter shall time the transmitted symbols from a 125.00 MHz ± 0.01% clock in the MASTER timing mode.

When test mode 2 is enabled, the PHY shall transmit the data symbol sequence {+2, –2} repeatedly on all channels. The transmitter shall time the transmitted symbols from a 125.00 MHz ± 0.01% clock in the MASTER timing mode.

When test mode 3 is enabled, the PHY shall transmit the data symbol sequence {+2, –2} repeatedly on all channels. The transmitter shall time the transmitted symbols from a 125.00 MHz ± 0.01% clock in the SLAVE timing mode. A typical transmitter output for transmitter test modes 2 and 3 is shown in Figure 40–21.

When test mode 4 is enabled, the PHY shall transmit the sequence of symbols generated by the following scrambler generator polynomial, bit generation, and level mappings:

$$g_{s1} = 1 + x^9 + x^{11}$$

The maximum-length shift register used to generate the sequences defined by this polynomial shall be updated once per symbol interval (8 ns). The bits stored in the shift register delay line at a particular time n are denoted by $Scr_n[10:0]$. At each symbol period the shift register is advanced by one bit and one new bit represented by $Scr_n[0]$ is generated. Bits $Scr_n[8]$ and $Scr_n[10]$ are exclusive OR'd together to generate the next $Scr_n[0]$ bit. The bit sequences, $x0_n$, $x1_n$, and $x2_n$, generated from combinations of the scrambler bits as shown in the following equations, shall be used to generate the quinary symbols, s_n, as shown in Table 40–8. The quinary symbol sequence shall be presented simultaneously to all transmitters. The transmitter shall time the transmitted symbols from a 125.00 MHz ± 0.01% clock in the MASTER timing mode. A typical transmitter output for transmitter test mode 4 is shown in Figure 40–22.

40.6.1.1.3 Test Fixtures

The following fixtures (illustrated by Figure 40–23, Figure 40–24, Figure 40–25, and Figure 40–26), or their functional equivalents, shall be used for measuring the transmitter specifications described in 40.6.1.2.

The test filter, $H_{tf}(f)$, used in transmitter test fixtures 1 and 3 may be located between the points A and B as long as the test filter does not significantly alter the impedance seen by the transmitter. The test filter may instead be implemented as a digital filter in the post processing block. The test filter shall have the following continuous time transfer function or its discrete time equivalent:

$$H_{tf}(f) = \frac{jf}{jf + 2\times10^{6}} \qquad f \text{ in Hz}$$

NOTE—j denotes the square root of –1.

The disturbing signal, V_d, shall have the characteristics listed in Table 40–9.

Table 40–9—V_d Characteristics

Characteristic	Transmit test fixture 1	Transmit test fixture 2	Transmit test fixture 3
Waveform	Sine wave		
Amplitude	2.8 volts peak-to-peak	2.8 volts peak-to-peak	5.4 volts peak-to-peak
Frequency	31.25 MHz	31.25 MHz	20.833 MHz (125/6 MHz)
Purity	All harmonics >40 dB below fundamental		

The post-processing block has two roles. The first is to remove the disturbing signal from the measurement. A method of removing the disturbing signal is to take a single shot acquisition of the transmitted signal plus test pattern, then remove the best fit of a sine wave at the fundamental frequency of the disturbing signal from the measurement. It will be necessary to allow the fitting algorithm to adjust the frequency, phase, and amplitude parameters of the sine wave to achieve the best fit.

The second role of the post-processing block is to compare the measured data with the templates, droop specification, or distortion specification.

Trigger averaging of the transmitter output to remove measurement noise and increase measurement resolution is acceptable provided it is done in a manner that does not average out possible distortions caused by the interaction of the transmitter and the disturbing voltage. For transmitter template and droop measurements, averaging can be done by ensuring the disturbing signal is exactly synchronous to the test pattern so that the phase of the disturbing signal at any particular point in the test pattern remains constant. Trigger averaging also requires a triggering event that is synchronous to the test pattern. A trigger pulse generated by the PHY would be ideal for this purpose; however, in practice, triggering off the waveform generated by one of the other transmitter outputs that does not have the disturbing signal present may be possible.

NOTE—The disturbing signal may be made synchronous to the test pattern by creating the disturbing signal using a source of the transmit clock for the PHY under test, dividing it down to the proper frequency for the disturbing signal, passing the result through a high Q bandpass filter to eliminate harmonics and then amplifying the result to the proper amplitude.

The generator of the disturbing signal should have sufficient linearity and range that it does not introduce any appreciable distortion when connected to the transmitter output (see Table 40–9). This may be verified by replacing the transmitter under test with another identical disturbing signal generator having a different frequency output and verifying that the resulting waveform's spectrum does not show significant distortion products.

Additionally, to allow for measurement of transmitted jitter in master and slave modes, the PHY shall provide access to the 125 MHz symbol clock, TX_TCLK, that times the transmitted symbols (see 40.4.2.2). The PHY shall provide a means to enable this clock output if it is not normally enabled.

40.6.1.2 Transmitter electrical specifications

The PMA shall provide the Transmit function specified in 40.4.2.2 in accordance with the electrical specifications of this clause.

Where a load is not specified, the transmitter shall meet the requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output.

The tolerance on the poles of the test filters used in this subclause shall be ±1%.

Practical considerations prevent measurement of the local transmitter performance in the presence of the remotely driven signal in this standard; however, the design of the transmitter to tolerate the presence of the remotely driven signal with acceptable distortion or other changes in performance is a critical issue and needs to be addressed by the implementer. To this end, a disturbing sine wave is used to simulate the presence of a remote transmitter for a number of the transmitter tests described in the following subordinate subclauses.

40.6.1.2.1 Peak differential output voltage and level accuracy

The absolute value of the peak of the waveform at points A and B, as defined in Figure 40–20, shall fall within the range of 0.67 V to 0.82 V (0.75 V ± 0.83 dB). These measurements are to be made for each pair while operating in test mode 1 and observing the differential signal output at the MDI using transmitter test fixture 1 with no intervening cable.

The absolute value of the peak of the waveforms at points A and B shall differ by less than 1% from the average of the absolute values of the peaks of the waveform at points A and B.

The absolute value of the peak of the waveform at points C and D as defined in Figure 40–20 shall differ by less than 2% from 0.5 times the average of the absolute values of the peaks of the waveform at points A and B.

40.6.1.2.2 Maximum output droop

The magnitude of the negative peak value of the waveform at point G, as defined in Figure 40–20, shall be greater than 73.1% of the magnitude of the negative peak value of the waveform at point F. These measurements are to be made for each pair while in test mode 1 and observing the differential signal output at the MDI using transmit test fixture 2 with no intervening cable. Point G is defined as the point exactly 500 ns after point F. Point F is defined as the point where the waveform reaches its minimum value at the location indicated in Figure 40–20. Additionally, the magnitude of the peak value of the waveform at point J as defined in Figure 40–20 shall be greater than 73.1% of the magnitude of the peak value of the waveform at point H. Point J is defined as the point exactly 500 ns after point H. Point H is defined as the point where the waveform reaches its maximum value at the location indicated in Figure 40–20.

40.6.1.2.3 Differential output templates

The voltage waveforms around points A, B, C, D defined in Figure 40–20, after the normalization described herein, shall lie within the time domain template 1 defined in Figure 40–27 and the piecewise linear interpolation between the points in Table 40–10. These measurements are to be made for each pair while in test mode 1 and while observing the differential signal output at the MDI using transmitter test fixture 1 with no intervening cable. The waveforms may be shifted in time as appropriate to fit within the template.

The waveform around point A is normalized by dividing by the peak value of the waveform at A.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The waveform around point B is normalized by dividing by the negative of the peak value of the waveform at A.

The waveform around point C is normalized by dividing by 1/2 the peak value of the waveform at A.

The waveform around point D is normalized by dividing by the negative of 1/2 the peak value of the waveform at A.

The voltage waveforms around points F and H defined in Figure 40–20, after the normalization described herein, shall lie within the time domain template 2 defined in Figure 40–27 and the piecewise linear interpolation between the points in Table 40–11. These measurements are to be made for each pair while in test mode 1 and while observing the differential signal output at the MDI using transmitter test fixture 1 with no intervening cable. The waveforms may be shifted in time as appropriate to fit within the template.

The waveform around point F is normalized by dividing by the peak value of the waveform at F.

The waveform around point H is normalized by dividing by the peak value of the waveform at H.

NOTE 1—The templates were created with the following assumptions about the elements in the transmit path:

1) Digital Filter: $0.75 + 0.25\ z^{-1}$
2) Ideal DAC
3) Single pole continuous time low-pass filter with pole varying from 70.8 MHz to 117 MHz or linear rise/fall time of 5 ns.
4) Single pole continuous time high-pass filter (transformer high pass) with pole varying from 1 Hz to 100 kHz.
5) Single pole continuous time high-pass filter (test filter) with pole varying from 1.8 MHz to 2.2 MHz.
6) Additionally, +0.025 was added to the upper template and –0.025 was added to the lower template to allow for noise and measurement error.

NOTE 2—The transmit templates are not intended to address electromagnetic radiation limits.

40.6.1.2.4 Transmitter distortion

When in test mode 4 and observing the differential signal output at the MDI using transmitter test fixture 3, for each pair, with no intervening cable, the peak distortion as defined below shall be less than 10 mV.

The peak distortion is determined by sampling the differential signal output with the symbol rate TX_TCLK at an arbitrary phase and processing a block of any 2047 consecutive samples with the code listed below.[83] Note that this code assumes that the differential signal has already been filtered by the test filter. A PHY is considered to pass this test if the peak distortion is below 10 mV for at least 60% of the UI within the eye opening.

NOTE—The ASCII for the following code is available at https://standards.ieee.org/downloads/802.3/.[84]

Code for Distortion Post Processing is as follows:

```
%
% Distortion Specification Post Processing
%

% Initialize Variables
clear
symbolRate=125e6;                                % symbol rate
dataFile=input('Data file name: ','s')

% Generate test pattern symbol sequence

scramblerSequence=ones(1,2047);
for i=12:2047
  scramblerSequence(i)=mod(scramblerSequence(i-11) + scramblerSequence(i-9),2);
end

for i=1:2047
  temp=scramblerSequence(mod(i-1,2047)+1) + ...
      2*mod(scramblerSequence(mod(i-2,2047)+1) + scramblerSequence(mod(i-
5,2047)+1),2) + ...
      4*mod(scramblerSequence(mod(i-3,2047)+1) + scramblerSequence(mod(i-
5,2047)+1),2);
  switch temp
    case 0,
      testPattern(i)=0;
    case 1,
      testPattern(i)=1;

```

40.6.1.2.5 Transmitter timing jitter

When in test mode 2 or test mode 3, the peak-to-peak jitter J_{txout} of the zero crossings of the differential signal output at the MDI relative to the corresponding edge of TX_TCLK is measured. The corresponding edge of TX_TCLK is the edge of the transmit test clock, in polarity and time, that generates the zero-crossing transition being measured.

When in the normal mode of operation as the MASTER, the peak-to-peak value of the MASTER TX_TCLK jitter relative to an unjittered reference shall be less than 1.4 ns. When the jitter waveform on TX_TCLK is filtered by a high-pass filter, $H_{jf1}(f)$, having the transfer function below, the peak-to-peak value of the resulting filtered timing jitter plus J_{txout} shall be less than 0.3 ns.

$$H_{jf1}(f) = \frac{jf}{jf + 5000} \qquad f \text{ in Hz}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When in the normal mode of operation as the SLAVE, receiving valid signals from a compliant PHY operating as the MASTER using the test channel defined in 40.6.1.1.1, with test channel port A connected to the SLAVE, the peak-to-peak value of the SLAVE TX_TCLK jitter relative to the MASTER TX_TCLK shall be less than 1.4 ns after the receiver is properly receiving the data and has set bit 10.13 of the GMII management register set to 1. When the jitter waveform on TX_TCLK is filtered by a high-pass filter, $H_{jf2}(f)$, having the transfer function below, the peak-to-peak value of the resulting filtered timing jitter plus J_{txout} shall be no more than 0.4 ns greater than the simultaneously measured peak-to-peak value of the MASTER jitter filtered by $H_{jf1}(f)$.

$$H_{jf2}(f) = \frac{jf}{jf + 32000} \qquad f \text{ in Hz}$$

NOTE—j denotes the square root of –1.

For all high-pass filtered jitter measurements, the peak-to-peak value shall be measured over an unbiased sample of at least 10^5 clock edges. For all unfiltered jitter measurements, the peak-to-peak value shall be measured over an interval of not less than 100 ms and not more than 1 second.

When the PHY supports the optional EEE capability, the unfiltered jitter requirements shall also be satisfied during the LPI mode, with the exception that clock edges corresponding to the WAIT_QUIET, QUIET, WAKE, and WAKE_SILENT states are not considered in the measurement. The PHY may turn off TX_TCLK during these states. For a MASTER PHY operating in the LPI mode, the unjittered reference shall be continuous.

40.6.1.2.6 Transmit clock frequency

The quinary symbol transmission rate on each pair of the master PHY shall be 125.00 MHz ± 0.01%.

40.6.1.2.7 Transmitter operation following a transition from the QUIET to the WAKE state

When the PHY supports the optional EEE capability, it transmits Idle symbols while in the WAKE state (see Figure 40–16b). This signal may be transmitted during reactivation of the PHY analog front-end and is not guaranteed or intended to be compliant.

The transmit levels of the Idle symbols transmitted during the WAKE state shall exceed 65% of the transmit levels of compliant Idle symbols for a period of at least 500 ns.

The PHY shall achieve compliant operation upon entry to the WAKE_TRAINING state (see Figure 40–16b).

40.6.1.3 Receiver electrical specifications

The PMA shall provide the Receive function specified in 40.4.2.3 in accordance with the electrical specifications of this clause. The patch cabling and interconnecting hardware used in test configurations shall be within the limits specified in 40.7.

40.6.1.3.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of 40.6.1.2 and have passed through a link specified in 40.7 are translated into one of the PMA_UNITDATA.indication messages with a bit error ratio less than 10^{-10} and sent to the PCS after link reset completion. Since the 4-D symbols are not accessible, this specification shall be satisfied by a frame error ratio less than 10^{-7} for 125 octet frames.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.6.1.3.2 Receiver frequency tolerance

The receive feature shall properly receive incoming data with a 5-level symbol rate within the range 125.00 MHz ± 0.01%.

40.6.1.3.3 Common-mode noise rejection

This specification is provided to limit the sensitivity of the PMA receiver to common-mode noise from the cabling system. Common-mode noise generally results when the cabling system is subjected to electromagnetic fields. Figure 40–28 shows the test configuration, which uses a capacitive cable clamp, that injects common-mode signals into a cabling system.

A 100-meter, 4-pair Category 5 cable that meets the specification of 40.7 is connected between two 1000BASE-T PHYs and inserted into the cable clamp. The cable should be terminated on each end with an MDI connector plug specified in 40.8.1. The clamp should be located a distance of ~20 cm from the receiver. It is recommended that the cable between the transmitter and the cable clamp be installed either in a linear run or wrapped randomly on a cable rack. The cable rack should be at least 3 m from the cable clamp. In addition, the cable clamp and 1000BASE-T receiver should be placed on a common copper ground plane and the ground of the receiver should be in contact with the ground plane. The chassis grounds of all test equipment used should be connected to the copper ground plane. No connection is required between the copper ground plane and an external reference. A description of the cable clamp, as well as the validation procedure, can be found in Annex 40B.

A signal generator with a 50 Ω impedance is connected to one end of the clamp and an oscilloscope with a 50 Ω input is connected to the other end of the clamp. The signal generator shall be capable of providing a sine wave signal of 1 MHz to 250 MHz. The output of the signal generator is adjusted for a voltage of 1.0 Vrms (1.414 Vpeak) on the oscilloscope.

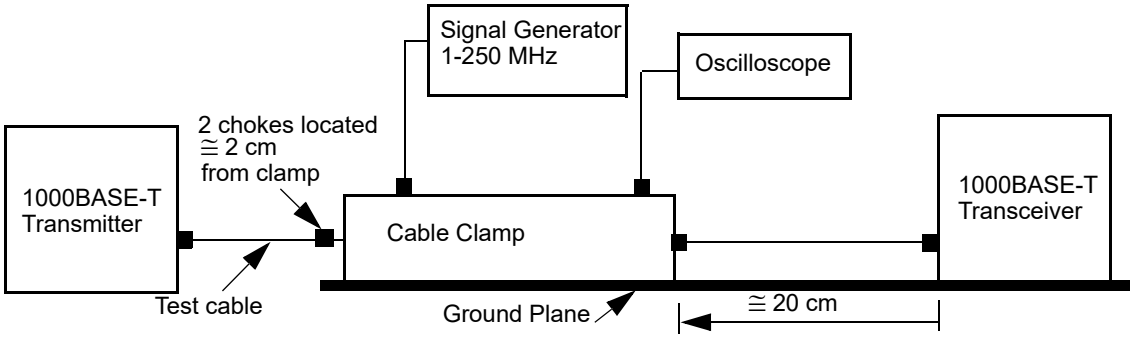

Figure 40–28—Receiver common-mode noise rejection test

While sending data from the transmitter, the receiver shall send the proper PMA_UNITDATA.indication messages to the PCS as the signal generator frequency is varied from 1 MHz to 250 MHz.

NOTE—Although the signal specification is constrained within the 1–100 MHz band, this test is performed up to 250 MHz to ensure the receiver under test can tolerate out-of-band (100–250 MHz) noise.

40.6.1.3.4 Alien Crosstalk noise rejection

While receiving data from a transmitter specified in 40.6.1.2 through a link segment specified in 40.7 connected to all MDI duplex channels, a receiver shall send the proper PMA_UNITDATA.indication message to the PCS when any one of the four pairs is connected to a noise source as described in Figure 40–29. Because symbol encoding is employed, this specification shall be satisfied by a frame error ratio of less than 10^{-7} for 125 octet frames. The level of the noise signal at the MDI is nominally 25 mV

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

peak-to-peak. (Measurements are to be made on each of the four pairs.) The noise source shall be connected to one of the MDI inputs using Category 5 balanced cable of a maximum length of 0.5 m.

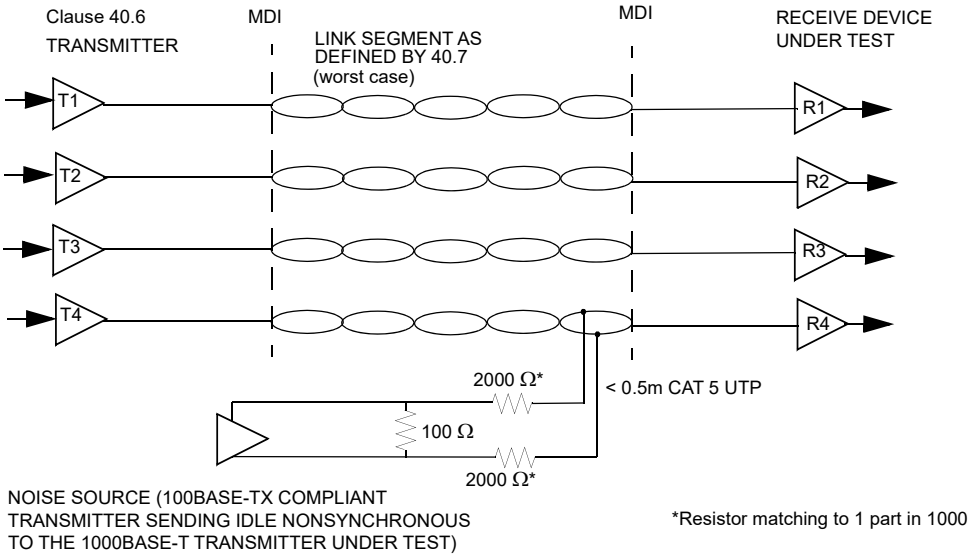

Figure 40–29—Differential mode noise rejection test

40.6.1.3.5 Signal_detect

When the PHY supports the optional EEE capability, the PMA Receive function shall convey an indicator of signal presence, referred to as signal_detect, to the PMA PHY Control function. The value of signal_detect shall be set to TRUE within 0.5 µs of the receipt of a wake signal meeting the requirements of 40.6.1.2.7. The value of signal_detect shall be set to FALSE within 0.5 µs of the receipt of a continuous sequence of zeros.

40.7 Link segment characteristics

1000BASE-T is designed to operate over a 4-pair Category 5/Class D balanced cabling system. Each of the four pairs supports an effective data rate of 250 Mb/s in each direction simultaneously. The term “link segment” used in this clause refers to four duplex channels. The term “duplex channel” will be used to refer to a single channel with full duplex capability. Specifications for a link segment apply equally to each of the four duplex channels. All implementations of the balanced cabling link shall be compatible at the MDI.

40.7.1 Cabling system characteristics

1000BASE-T requires 4-pair Class D cabling with a nominal impedance of 100 Ω, as specified in ISO/IEC 11801:1995. The cabling system components (cables, cords, and connectors) used to provide the link segment shall consist of Category 5 components as specified in ANSI/TIA/EIA-568-A:1995 and ISO/IEC 11801:1995. Additionally:

a) 1000BASE-T is an ISO/IEC 11801 Class D application, with additional installation requirements and transmission parameters specified in Annex 40A.
b) The width of the PMD transmit signal spectrum is approximately 80 MHz.
c) The use of shielding is outside the scope of this standard.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.7.2 Link transmission parameters

The transmission parameters contained in this subclause are specified to ensure that a Class D link segment of up to at least 100 m will provide a reliable medium. The transmission parameters of the link segment include insertion loss, delay parameters, characteristic impedance, NEXT loss, ELFEXT loss, and return loss.

Link segment testing shall be conducted using source and load impedances of 100 Ω. The tolerance on the poles of the test filter used in this subclause shall be no worse than 1%.

40.7.2.1 Insertion loss

The insertion loss of each duplex channel shall be less than

$$Insertion_Loss(f) < 2.1\,f^{0.529} + 0.4/f \quad \text{(dB)}$$

at all frequencies from 1 MHz to 100 MHz. This includes the attenuation of the balanced cabling pairs, including work area and equipment cables plus connector losses within each duplex channel. The insertion loss specification shall be met when the duplex channel is terminated in 100 Ω.

NOTE—The above equation approximates the insertion loss specification at discrete frequencies for Class D 100 m channels specified by ISO/IEC 11801:1995.

40.7.2.2 Differential characteristic impedance

The nominal differential characteristic impedance of each link segment duplex channel, which includes cable cords and connecting hardware, is 100 Ω for all frequencies between 1 MHz and 100 MHz.

40.7.2.3 Return loss

Each link segment duplex channel shall meet or exceed the return loss specified in the following equation at all frequencies from 1 MHz to 100 MHz.

$$Return_Loss(f) \begin{cases} 15 & (1 - 20\ \text{MHz}) \\ 15 - 10\log_{10}(f/20) & (20 - 100\ \text{MHz}) \end{cases} \text{(dB)}$$

where f is the frequency in MHz. The reference impedance shall be 100 Ω.

40.7.3 Coupling parameters

In order to limit the noise coupled into a duplex channel from adjacent duplex channels, Near-End Crosstalk (NEXT) loss and Equal Level Far-End Crosstalk (ELFEXT) loss are specified for each link segment. Each duplex channel can be disturbed by more than one duplex channel. Requirements for Multiple Disturber Near-End Crosstalk (MDNEXT) are satisfied even when worst case conditions of differential pair-to-pair NEXT as specified under 40.7.3.1.1 occur. Therefore, there are no separate requirements for MDNEXT. Requirements for Multiple Disturber Equal-Level Far-End Crosstalk (MDELFEXT) loss are specified in 40.7.3.2.2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.7.3.1 Near-End Crosstalk (NEXT)

40.7.3.1.1 Differential Near-End Crosstalk

In order to limit the crosstalk at the near end of a link segment, the differential pair-to-pair Near-End Crosstalk (NEXT) loss between a duplex channel and the other three duplex channels is specified to meet the symbol error ratio objective specified in 40.1. The NEXT loss between any two duplex channels of a link segment shall be at least

$$27.1 - 16.8\log_{10}(f/100)$$

where f is the frequency over the range of 1 MHz to 100 MHz.

NOTE—The previous equation approximates the NEXT loss specification at discrete frequencies for Class D 100 m channels specified by ISO/IEC 11801:1995.

40.7.3.2 Far-End Crosstalk (FEXT)

40.7.3.2.1 Equal Level Far-End Crosstalk (ELFEXT) loss

Equal Level Far-End Crosstalk (ELFEXT) loss is specified in order to limit the crosstalk at the far end of each link segment duplex channel and meet the BER objective specified in 40.6.1.3.1. Far-End Crosstalk (FEXT) is crosstalk that appears at the far end of a duplex channel (disturbed channel), which is coupled from another duplex channel (disturbing channel) with the noise source (transmitters) at the near end. FEXT loss is defined as

$$FEXT_Loss(f) = 20\log_{10}[V\text{pds}(f)/V\text{pcn}(f)]$$

and ELFEXT_Loss is defined as

$$ELFEXT_Loss(f) = 20\log_{10}[V\text{pds}(f)/V\text{pcn}(f)] - SLS_Loss(f)$$

where

Vpds	is the peak voltage of disturbing signal (near-end transmitter)
Vpcn	is the peak crosstalk noise at far end of disturbed channel
SLS_Loss	is the insertion loss of disturbed channel in dB

The worst pair ELFEXT loss between any two duplex channels shall be greater than $17 - 20\log_{10}(f/100)$ dB where f is the frequency over the range of 1 MHz to 100 MHz.

40.7.3.2.2 Multiple Disturber Equal Level Far-End Crosstalk (MDELFEXT) loss

Since four duplex channels are used to transfer data between PMDs, the FEXT that is coupled into a data carrying channel will be from the three adjacent disturbing duplex channels. This specification is consistent with three channel-to-channel disturbers—one with a ELFEXT loss of at least $17 - 20\log_{10}(f/100)$ dB, one with a ELFEXT loss of at least $19.5 - 20\log_{10}(f/100)$ dB, and one with a ELFEXT loss of at least $23 - 20\log_{10}(f/100)$ dB. To ensure the total FEXT coupled into a duplex channel is limited, multiple disturber ELFEXT loss is specified as the power sum of the individual ELFEXT losses.

The Power Sum loss between a duplex channel and the three adjacent disturbers shall be

$$PSELFEXT\ loss > 14.4 - 20\log_{10}(f/100)\ \text{dB}$$

where f is the frequency over the range of 1 MHz to 100 MHz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.7.3.2.3 Multiple-Disturber Power Sum Equal Level Far-End Crosstalk (PSELFEXT) loss

PSELFEXT loss is determined by summing the magnitude of the three individual pair-to-pair differential ELFEXT loss values over the frequency range 1 to 100 MHz as follows:

$$\text{PSELFEXT_Loss(f)} = -10\log_{10}\sum_{i=1}^{i=3} 10^{-(NL(f)i)/10}$$

where

NL(*f*)i is the magnitude of ELFEXT loss at frequency *f* of pair combination *i*
i is the 1, 2, or 3 (pair-to-pair combination)

40.7.4 Delay

In order to simultaneously send data over four duplex channels in parallel, the propagation delay of each duplex channel as well as the difference in delay between any two of the four channels are specified. This ensures the 1000 Mb/s data that is divided across four channels can be properly reassembled at the far-end receiver. This also ensures the round-trip delay requirement for effective collision detection is met.

40.7.4.1 Maximum link delay

The propagation delay of a link segment shall not exceed 570 ns at all frequencies between 2 MHz and 100 MHz.

40.7.4.2 Link delay skew

The difference in propagation delay, or skew, between all duplex channel pair combinations of a link segment, under all conditions, shall not exceed 50 ns at all frequencies from 2 MHz to 100 MHz. It is a further functional requirement that, once installed, the skew between any two of the four duplex channels due to environmental conditions shall not vary more than 10 ns within the above requirement.

40.7.5 Noise environment

The 1000BASE-T noise environment consists of noise from many sources. The primary noise sources that impact the objective BER are NEXT and echo interference, which are reduced to a small residual noise using cancelers. The remaining noise sources, which are secondary sources, are discussed in the following list.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 1000BASE-T noise environment consists of the following:

a) Echo from the local transmitter on the same duplex channel (cable pair). Echo is caused by the hybrid function used to achieve simultaneous bidirectional transmission of data and by impedance discontinuities in the link segment. It is impractical to achieve the objective BER without using echo cancellation. Since the symbols transmitted by the local disturbing transmitter are available to the cancellation processor, echo interference can be reduced to a small residual noise using echo cancellation methods.

b) Near-End Crosstalk (NEXT) interference from the local transmitters on the duplex channels (cable pairs) of the link segment. Each receiver will experience NEXT interference from three adjacent transmitters. NEXT cancelers are used to reduce the interference from each of the three disturbing transmitters to a small residual noise. NEXT cancellation is possible since the symbols transmitted by the three disturbing local transmitters are available to the cancellation processor. NEXT cancelers can reduce NEXT interference by at least 20 dB.

c) Far-End Crosstalk (FEXT) noise at a receiver is from three disturbing transmitters at the far end of the duplex channel (cable pairs) of the link segment. FEXT noise can be cancelled in the same way as echo and NEXT interference although the symbols from the remote transmitters are not immediately available. However, FEXT noise is much smaller than NEXT interference and can generally be tolerated.

d) Intersymbol interference (ISI). ISI is the extraneous energy from one signaling symbol that interferes with the reception of another symbol on the same channel.

e) Noise from non-idealities in the duplex channel, transmitters, and receivers; for example, DAC/ADC non-linearity, electrical noise (shot and thermal), and non-linear channel characteristics.

f) Noise from sources outside the cabling that couple into the link segment via electric and magnetic fields.

g) Noise from signals in adjacent cables. This noise is referred to as alien NEXT noise and is generally present when cables are bound tightly together. Since the transmitted symbols from the alien NEXT noise source are not available to the cancellation processor (they are in another cable), it is not possible to cancel the alien NEXT noise. To ensure robust operation the alien NEXT noise has to meet the specification of 40.7.6.

40.7.6 External coupled noise

The noise coupled from external sources that is measured at the output of a filter connected to the output of the near end of a disturbed duplex channel should not exceed 40 mV peak-to-peak. The filter for this measurement is a fifth order Butterworth filter with a 3 dB cutoff at 100MHz.

40.8 MDI specification

This subclause defines the MDI. The link topology requires a crossover function in a DTE-to-DTE connection. See 40.4.4 for a description of the automatic MDI/MDI-X configuration.

40.8.1 MDI connectors

Eight-pin connectors meeting the requirements of subclause 3 and Figures 1 through 4 of IEC 60603-7:1990 shall be used as the mechanical interface to the balanced cabling. The plug connector shall be used on the balanced cabling and the jack on the PHY. These connectors are depicted (for informational use only) in Figure 40–30 and Figure 40–31. The assignment of PMA signals to connector contacts for PHYs is shown in Table 40–12.

2	BI_DA–	BI_DB–
3	BI_DB+	BI_DA+
4	BI_DC+	BI_DD+
5	BI_DC–	BI_DD–
6	BI_DB–	BI_DA–
7	BI_DD+	BI_DC+
8	BI_DD–	BI_DC–

40.8.2 Crossover function

Although the automatic MDI/MDI-X configuration (see 40.4.4) is not required for successful operation of 1000BASE-T, a crossover function has to be implemented for every link segment to support the operation of Auto-Negotiation. The crossover function connects the transmitters of one PHY to the receivers of the PHY at the other end of the link segment. Crossover functions may be implemented internally to a PHY or elsewhere in the link segment. For a PHY that does not implement the crossover function, the MDI labels in the middle column of Table 40–12 refer to its own internal circuits. For PHYs that do implement the internal crossover, the MDI labels in the last column of Table 40–12 refer to the internal circuits of the remote PHY of the link segment. Additionally, the MDI connector for a PHY that implements the crossover function shall be marked with the graphical symbol X. The crossover function specified here is not compatible with the crossover function specified in 14.5.2 for pairs TD and RD.

When a link segment connects a single-port device to a multiport device, it is recommended that the crossover be implemented in the PHY local to the multiport device. If neither or both PHYs of a link segment contain internal crossover functions, an additional external crossover is necessary. It is recommended that the crossover be visible to an installer from one of the PHYs. When both PHYs contain

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

internal crossovers, it is further recommended that, in networks in which the topology identifies either a central backbone segment or a central device, the PHY furthest from the central element be assigned the external crossover to maintain consistency.

Implicit implementation of the crossover function within a twisted-pair cable or at a wiring panel, while not expressly forbidden, is beyond the scope of this standard.

40.8.3 MDI electrical specifications

The MDI connector (jack) when mated with a specified balanced cabling connector (plug) shall meet the electrical requirements for Category 5 connecting hardware for use with 100-ohm Category 5 cable as specified in ISO/IEC 11801:1995.

The mated MDI/balanced cabling connector pair shall have a FEXT loss not less than $40 - 20\log_{10}(f/100)$ (where f is the frequency over the range 1 MHz to 100 MHz) between all contact pair combinations shown in Table 40–12.

No spurious signals shall be emitted onto the MDI when the PHY is held in power-down mode (as defined in 22.2.4.1.5) independent of the value of TX_EN, when released from power-down mode, or when external power is first applied to the PHY.

40.8.3.1 MDI return loss

The differential impedance at the MDI for each transmit/receive channel shall be such that any reflection due to differential signals incident upon the MDI from a balanced cabling having an impedance of 100 Ω ± 15% is attenuated, relative to the incident signal, at least 16 dB over the frequency range of 1.0 MHz to 40 MHz and at least $10 - 20\log_{10}(f/80)$ dB over the frequency range 40 MHz to 100 MHz (f in MHz). This return loss shall be maintained at all times when the PHY is transmitting data or control symbols.

40.8.3.2 MDI impedance balance

Impedance balance is a measurement of the impedance-to-ground difference between the two MDI contacts used by a duplex link channel and is referred to as common-mode-to-differential-mode impedance balance. Over the frequency range 1.0 MHz to 100.0 MHz, the common-mode-to-differential-mode impedance balance of each channel of the MDI shall exceed

$$34 - 19.2\log_{10}\left(\frac{f}{50}\right) \quad \text{dB}$$

where f is the frequency in MHz when the transmitter is transmitting random or pseudo random data. Test-mode 4 may be used to generate an appropriate transmitter output.

The balance is defined as

$$20\log_{10}\left(\frac{E_{cm}}{E_{dif}}\right)$$

where E_{cm} is an externally applied sine wave voltage as shown in Figure 40–32 and E_{dif} is the resulting waveform due only to the applied sine wave and not the transmitted data.

NOTE 1—Triggered averaging can be used to separate the component due to the applied common-mode sine wave from the transmitted data component.

NOTE 2—The imbalance of the test equipment (such as the matching of the test resistors) has to be insignificant relative to the balance requirements.

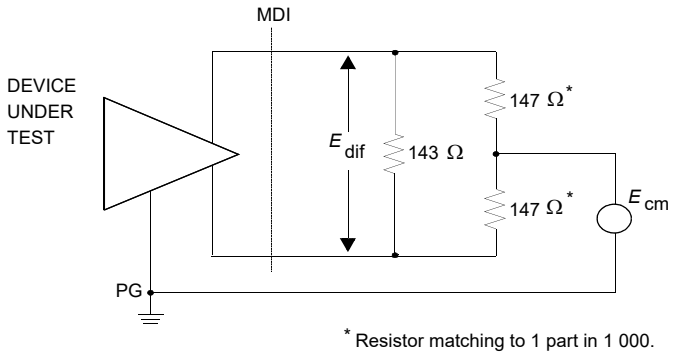

Figure 40–32—MDI impedance balance test circuit

40.8.3.3 MDI common-mode output voltage

The magnitude of the total common-mode output voltage, E_{cm_out}, on any transmit circuit, when measured as shown in Figure 40–33, shall be less than 50 mV peak-to-peak when transmitting data at frequencies above 1 MHz.

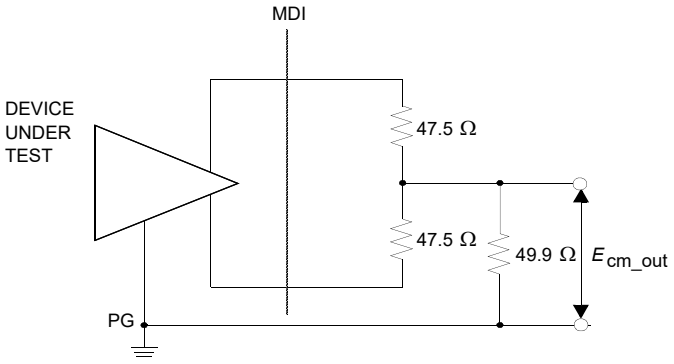

Figure 40–33—Common-mode output voltage test circuit

NOTE—The imbalance of the test equipment (such as the matching of the test resistors) should be insignificant relative to the balance requirements.

40.8.3.4 MDI fault tolerance

Each wire pair of the MDI shall, under all operating conditions, withstand without damage the application of short circuits of any wire to any other wire within the 4-pair cable for an indefinite period of time and shall resume normal operation after the short circuit(s) are removed. The magnitude of the current through such a short circuit shall not exceed 300 mA.

Each wire pair shall withstand without damage a 1000 V common-mode impulse applied at E_{cm} of either polarity (as indicated in Figure 40–34). The shape of the impulse shall be 0.3/50 μs (300 ns virtual front time, 50 μs virtual time of half value), as defined in IEC 60060.

40.9 Environmental specifications

40.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

40.9.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns; the list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

LAN cabling systems described in this subclause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cabling and components.
c) High-energy transients coupled onto the LAN cabling system.
d) Voltage potential differences between safety grounds to which various LAN components are connected.

Such electrical safety hazards have to be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures have to be taken to ensure that the intended safety features are not negated during installation of a new network or during modification or maintenance of an existing network.

40.9.2.1 Installation

It is a mandatory requirement that sound installation practice, as defined by applicable local codes and regulations, is followed in every instance in which such practice is applicable.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.9.2.2 Installation and maintenance guidelines

It is a mandatory requirement that, during installation and maintenance of the cabling plant, care is taken to ensure that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

40.9.2.3 Telephony voltages

The use of building wiring brings with it the possibility of wiring errors that may connect telephony voltages to 1000BASE-T equipment. Other than voice signals (which are low voltage), the primary voltages that may be encountered are the “battery” and ringing voltages. Although there is no universal standard, the following maximums generally apply:

Battery voltage to a telephone line is generally 56 Vdc applied to the line through a balanced 400 Ω source impedance.

Ringing voltage is a composite signal consisting of an ac component and a dc component. The ac component is up to 175 V peak at 20 Hz to 60 Hz with a 100 Ω source resistance. The dc component is 56 Vdc with a 300 Ω to 600 Ω source resistance. Large reactive transients can occur at the start and end of each ring interval.

Although 1000BASE-T equipment is not required to survive such wiring hazards without damage, application of any of the above voltages shall not result in any safety hazard.

NOTE—Wiring errors may impose telephony voltages differentially across 1000BASE-T transmitters or receivers. Because the termination resistance likely to be present across a receiver’s input is of substantially lower impedance than an off-hook telephone instrument, receivers will generally appear to the telephone system as off-hook telephones. Therefore, full-ring voltages will be applied for only short periods. Transmitters that are coupled using transformers will similarly appear like off-hook telephones (though perhaps a bit more slowly) due to the low resistance of the transformer coil.

40.9.3 Environment

40.9.3.1 Electromagnetic emission

A system integrating the 1000BASE-T PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

40.9.3.2 Temperature and humidity

A system integrating the 1000BASE-T PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

40.10 PHY labeling

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) Data rate capability in Mb/s
b) Power level in terms of maximum current drain (for external PHYs)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) Port type (i.e., 1000BASE-T)

d) Any applicable safety warnings

40.11 Delay constraints

In half duplex mode, proper operation of a CSMA/CD LAN demands that there be an upper bound on the propagation delays through the network. This implies that MAC, PHY, and repeater implementations conform to certain delay minima and maxima, and that network planners and administrators conform to constraints regarding the cabling topology and concatenation of devices. MAC constraints are specified in 35.2.4. Topological constraints are contained in Clause 42.

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The reference point for all MDI measurements is the peak point of the mid-cell transition corresponding to the reference code-bit, as measured at the MDI.

40.11.1 MDI to GMII delay constraints

Every 1000BASE-T PHY associated with a GMII shall comply with the bit delay constraints specified in Table 40–13 for half duplex operation and Table 40–14 for full duplex operation. These constraints apply for all 1000BASE-T PHYs. For any given implementation, the assertion and de-assertion delays on CRS shall be equal.

Table 40–13—MDI to GMII delay constraints (half duplex mode)

Sublayer measurement points	Event	Min (bit times)	Max (bit times)	Input timing reference	Output timing reference
GMII ⇔ MDI	TX_EN Sampled to MDI Output	—	84	GTX_CLK rising	1st symbol of SSD/CSReset/ CSExtend/ CSExtend_Err
	MDI input to CRS assert	—	244	1st symbol of SSD/CSReset	—
	MDI input to CRS de-assert	—	244	1st symbol of SSD/CSReset	—
	MDI input to COL assert	—	244	1st symbol of SSD/CSReset	—
	MDI input to COL de-assert	—	244	1st symbol of SSD/CSReset	—
	TX_EN sampled to CRS assert	—	16	GTX_CLK rising	—
	TX_EN sampled to CRS de-assert	—	16	GTX_CLK rising	—

Table 40–14—MDI to GMII delay constraints (full duplex mode)

Sublayer measurement points	Event	Min (bit times)	Max (bit times)	Input timing reference	Output timing reference
GMII ⇔ MDI	TX_EN Sampled to MDI Output	—	84	GTX_CLK rising	1st symbol of SSD/CSReset/ CSExtend/ CSExtend_Err
	MDI input to RX_DV de-assert	—	244	1st symbol of CSReset	—

40.11.2 DTE delay constraints (half duplex only)

Every DTE with a 1000BASE-T PHY shall comply with the bit delay constraints specified in Table 40–15 for half duplex operation.

Table 40–15— DTE delay constraints (half duplex mode)

Sublayer measurement points	Event	Min (bit times)	Max (bit times)	Input timing reference	Output timing reference
MAC ⇔ MDI	MAC transmit start to MDI output	—	132	—	1st symbol of SSD
	MDI input to collision detect	—	292	1st symbol of SSD	—
	MDI input to MDI output (nondeferred or Jam)	—	440	1st symbol of SSD	1st symbol of SSD
	MDI Input to MDI output (worst-case non-deferred transmit)	—	440	1st symbol of SSD	1st symbol of SSD

40.11.3 Carrier de-assertion/assertion constraint (half duplex mode)

To ensure fair access to the network, each DTE operating in half duplex mode shall, additionally, satisfy the following: (MAX MDI to MAC Carrier De-assert Detect) – (MIN MDI to MAC Carrier Assert Detect) < 16 Bit Times.

40.12 Protocol implementation conformance statement (PICS) proforma for Clause 40—Physical coding sublayer (PCS), physical medium attachment (PMA) sublayer and baseband medium, type 1000BASE-T[85]

The supplier of a protocol implementation that is claimed to conform to this clause shall complete the protocol implementation conformance statement (PICS) proforma listed in the following subclauses.

Instructions for interpreting and filling out the PICS proforma may be found in Clause 21.

40.12.1 Identification

40.12.1.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

40.12.1.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 40, Physical coding sublayer (PCS), physical medium attachment (PMA) sublayer, and baseband medium, type 1000BASE-T
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exceptions items been required? No [ ] Yes [ ] (See Clause 21—The answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

40.12.2 Major capabilities/options

Item	Feature	Subclause	Status	Support	Value/Comment
*GMII	PHY associated with GMII	40.1	O	Yes [ ] No [ ]	
*DTE	DTE with PHY not associated with GMII	40.1	O	Yes [ ] No [ ]	
*EEE	EEE	40.1.3	O	Yes [ ] No [ ]	
AN	Support for Auto-Negotiation (Clause 28)	40.5.1	M	Yes [ ]	Required

Item	Feature	Subclause	Status	Support	Value/Comment
PCT5	If the parameter config provided to the PCS by the PHY Control function via the PMA_CONFIG.indication message assumes the value SLAVE, PCS Transmit shall	40.3.1.3.1	M	Yes [ ]	Employ the transmitter side-stream scrambler generator polynomial specified for use with SLAVE in 40.3.1.3.1.
PCT6	In no case shall	40.3.1.3.1	M	Yes [ ]	The scrambler state be initialized to all zeros.
PCT7	If tx_error_n=1 when (tx_enable_n * tx_enable_{n-2}) = 1, error indication is signaled by means of symbol substitution, wherein the values of Sd_n[5:0] are ignored during mapping and the symbols corresponding to the row denoted as “xmt_err” in Table 40–1 and Table 40–2 shall be used.	40.3.1.3.5	M	Yes [ ]	
PCT8	If tx_error_n=0 when the variable $csreset_n$ = 1, the convolutional encoder reset condition is normal. This condition is indicated by means of symbol substitution, where the values of Sd_n[5:0] are ignored during mapping and the symbols corresponding to the row denoted as “CSReset” in Table 40–1 and Table 40–2 shall be used.	40.3.1.3.5	M	Yes [ ]	
PCT9	If tx_error_n=1 is asserted when the variable $csreset_n$ = 1, the convolutional encoder reset indicates carrier extension. In this condition, the values of Sd_n[5:0] are ignored during mapping and the symbols corresponding to the row denoted as “CSExtend” in Table 40–1 and Table 40–2 shall be used when TXD_n = 0x0F, and the row denoted as “CSExtend_Err” in Table 40–1 and Table 40–2 shall be used when $TXD_n \neq$ 0x0F.	40.3.1.3.5	M	Yes [ ]	
PCT10	In case carrier extension with error is indicated during the first octet of CSReset, the error condition shall be encoded during the second octet of CSReset, and during the subsequent two octets of the End-of-Stream delimiter.	40.3.1.3.5	M	Yes [ ]

40.12.4.1 PCS receive functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCR1	PCS Receive function shall	40.3.1.4	M	Yes [ ]	Conform to the PCS Receive state diagram shown in Figure 40–11a including compliance with the associated state variables as specified in 40.3.3.
PCR2	The PHY shall	40.3.1.4.2	M	Yes [ ]	Descramble the data stream and return the proper sequence of data bits RXD<7:0> to the GMII.
PCR3	For side-stream descrambling, the MASTER PHY shall employ	40.3.1.4.2	M	Yes [ ]	The receiver scrambler generator polynomial specified for MASTER operation in 40.3.1.4.2.
PCR4	For side-stream descrambling, the SLAVE PHY shall employ	40.3.1.4.2	M	Yes [ ]	The receiver scrambler generator polynomial specified for SLAVE operation in 40.3.1.4.2.
PCR5	In the absence of the optional EEE capability, the PHY shall	40.3.3.1	!EEE:M	Yes [ ]	Operate as if the value of rem_lpi_req is FALSE.

40.12.4.2 Other PCS functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCO1	The PCS Reset function shall	40.3.1.1	M	Yes [ ]	Be executed any time “power on” or receipt of a request for reset from the management entity occurs, including compliance with the associated state variables as specified in 40.3.3.
PCO2	The PCS shall	40.3.1.5	M	Yes [ ]	Implement the Carrier Sense process as depicted in Figure 40–12, including compliance with the associated state variables as specified in 40.3.3.
PCO3	Symb-timer shall be generated	40.3.3.3	M	Yes [ ]	Synchronously with TX_TCLK.

40.12.5 Physical Medium Attachment (PMA)

Item	Feature	Subclause	Status	Support	Value/Comment
PMF1	PMA Reset function shall be executed	40.4.2.1	M	Yes [ ]	At power on and upon receipt of a reset request from the management entity or from PHY Control.
PMF2	PMA Transmit shall	40.4.2.2	M	Yes [ ]	Continuously transmit onto the MDI pulses modulated by the quinary symbols given by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD], respectively.
PMF3	The four transmitters shall be driven by the same transmit clock, TX_TCLK	40.4.2.2	M	Yes [ ]	
PMF4	PMA Transmit shall	40.4.2.2	M	Yes [ ]	Follow the mathematical description given in 40.4.3.1.
PMF5	PMA Transmit shall comply with	40.4.2.2	M	Yes [ ]	The electrical specifications given in 40.6.
PMF6	When the PMA_CONFIG.indication parameter config is MASTER, the PMA Transmit function shall	40.4.2.2	M	Yes [ ]	Source the transmit clock TX_TCLK from a local clock source while meeting the transmit jitter requirements of 40.6.1.2.5.
PMF7	When the PMA_CONFIG.indication parameter config is SLAVE, the PMA Transmit function shall	40.4.2.2	M	Yes [ ]	Source the transmit clock TX_TCLK from the recovered clock of 40.4.2.5 while meeting the jitter requirements of 40.6.1.2.5.
PMF8	PMA Receive function shall translate	40.4.2.3	M	Yes [ ]	The signals received on pairs BI_DA BI_DB, BI_DC and BI_DD into the PMA_UNITDATA.indication parameter rx_symb_vector with a symbol error ratio of less than one part in 10^{10}.
PMF9	PHY Control function shall	40.4.2.4	M	Yes [ ]	Comply with the state diagram descriptions given in Figure 40–16a.
PMF10	The Link Monitor function shall	40.4.2.5	M	Yes [ ]	Comply with the state diagram shown in Figure 40–17.
PMF11	Clock Recovery function shall provide	40.4.2.6	M	Yes [ ]	Clocks suitable for signal sampling on each line so that the symbol error ratio indicated in 40.4.2.3 is achieved.
PMF12	The symbol response shall comply with	40.4.3.1	M	Yes [ ]	The electrical specifications given in 40.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
PMF13	The four signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD shall be processed within the PMA Receive function to yield	40.4.3.2	M	Yes [ ]	The quinary received symbols rx_symb_vector[BI_DA], rx_symb_vector[BI_DB], rx_symb_vector[BI_DC], and rx_symb_vector[BI_DD].
PMF14	If an automatic configuration method is used, it shall	40.4.4	M	Yes [ ]	Comply with the specifications of 40.4.4.
PMF15	The PMA shall	40.4.5.1	M	Yes [ ]	Generate the config variable continuously and pass it to the PCS via the PMA_CONFIG.indication primitive.
PMF16	The variable link_det shall take the value	40.4.5.1	AXO:M	N/A [ ] Yes [ ]	TRUE or FALSE as per 40.4.4.1.
PMF17	The variable MDI_status shall take the value	40.4.5.1	AXO:M	N/A [ ] Yes [ ]	MDI or MDI-X as per Table 40–12.
PMF18	PCS Transmit shall	40.4.5.1	M	Yes [ ]	Send code-groups according to the value assumed by tx_mode.
PMF19	The A_timer shall have a period of	40.4.5.2	AXO:M	N/A [ ] Yes [ ]	1.3s ± 25%.
PMF20	The maxwait_timer timer shall expire	40.4.5.2	M	Yes [ ]	750 ms ± 10 ms if config = MASTER or 350 ms ± 5ms if config = SLAVE
PMF21	The minwait_timer timer shall expire	40.4.5.2	M	Yes [ ]	1 µs ±0.1µs after being started.
PMF22	The sample_timer shall have a period of	40.4.5.2	AXO:M	N/A [ ] Yes [ ]	62 ms ± 2ms.
PMF23	The stabilize_timer shall expire	40.4.5.2	M	Yes [ ]	1 µs ± 0.1 µs after being started.
PMF24	PHY Control shall	40.4.2.4	EEE:M	Yes [ ]	Comply with the state diagram description given in Figure 40–16a and Figure 40–16b.
PMF25	In the WAIT_QUIET state, the PHY shall	40.4.2.4	EEE:M	Yes [ ]	Be capable of correctly decoding rem_lpi_req.
PMF26	In the absence of the optional EEE capability, the PHY shall	40.4.5.1	EEE:M	Yes [ ]	Operate as if the value of loc_update_done is FALSE.
PMF27	In the absence of the optional EEE capability, the PHY shall	40.4.5.1	EEE:M	Yes [ ]	Operate as if the value of lpi_mode is OFF.
PMF28	In the absence of the optional EEE capability, the PHY shall	40.4.5.1	EEE:M	Yes [ ]	Operate as if the value of rem_lpi_req is FALSE.
PMF29	lpi_link_fail_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 90 µs and 110 µs.
PMF30	lpi_postupdate_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 2.0 µs and 3.2 µs.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
PMF31	lpi_quiet_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 20 ms and 24 ms.
PMF32	lpi_waitwq_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 10 µs and 12 µs.
PMF33	For each transition of lpi_wake_timer_done from false to true, the wake error counter shall	40.4.5.2	EEE:M	Yes [ ]	Be incremented.
PMF34	lpi_wake_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period that does not exceed 16.5 µs.
PMF35	lpi_waketx_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 1.2_µs and 1.4 µs.
PMF36	lpi_wakemz_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 4.25 µs and 5.00 µs.
PMF37	lpi_update_timer shall	40.4.5.2	EEE:M	Yes [ ]	Have a period between 0.23 ms and 0.25 ms for a PHY configured as the MASTER and a period between 0.18 ms and 0.20 ms for a PHY configured as the SLAVE.

40.12.6 Management interface

Item	Feature	Subclause	Status	Support	Value/Comment
MF1	All 1000BASE-T PHYs shall provide support for Auto-Negotiation (Clause 28) and shall be capable of operating as MASTER or SLAVE.	40.5.1	M	Yes [ ]	
MF2	A 100BASE-T PHY shall	40.5.1.1	M	Yes [ ]	Use the management register definitions and values specified in Table 40–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

40.12.6.1 1000BASE-T Specific Auto-Negotiation Requirements

Item	Feature	Subclause	Status	Support	Value/Comment
AN1	1000BASE-T PHYs shall	40.5.1.2	M	Yes [ ]	Exchange one Auto-Negotiation Base Page, a 1000BASE-T formatted Next Page, and two 1000BASE-T Unformatted Next Pages in sequence, without interruption, as specified in Table 40–4.
AN2	The MASTER-SLAVE relationship shall be determined during Auto-Negotiation	40.5.2	M	Yes [ ]	Using Table 40–5 with the 1000BASE-T Technology Ability Next Page bit values specified in Table 40–4 and information received from the link partner.
AN3	Successful completion of the MASTER-SLAVE resolution shall	40.5.2	M	Yes [ ]	Be treated as MASTER-SLAVE configuration resolution complete.
AN4	A seed counter shall be provided to	40.5.2	M	Yes [ ]	Track the number of seed attempts.
AN5	At startup, the seed counter shall be set to	40.5.2	M	Yes [ ]	Zero.
AN6	The seed counter shall be incremented	40.5.2	M	Yes [ ]	Every time a new random seed is sent.
AN7	When MASTER-SLAVE resolution is complete, the seed counter shall be reset to 0 and bit 10.15 shall be set to logical zero.	40.5.2	M	Yes [ ]	
AN8	Maximum seed attempts before declaring a MASTER_SLAVE configuration Resolution Fault	40.5.2	M	Yes [ ]	Seven.
AN9	During MASTER_SLAVE configuration, the device with the higher seed value shall	40.5.2	M	Yes [ ]	Become the MASTER.
AN10	During MASTER_SLAVE configuration, the device with the lower seed value shall	40.5.2	M	Yes [ ]	Become the SLAVE.
AN11	Both PHYs set in manual mode to be either MASTER or SLAVE shall be treated as	40.5.2	M	Yes [ ]	MASTER-SLAVE resolution fault (failure) condition.
AN12	MASTER-SLAVE resolution fault (failure) condition shall result in	40.5.2	M	Yes [ ]	MASTER-SLAVE Configuration Resolution Fault bit (10.15) to be set to logical one.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
AN13	MASTER-SLAVE Configuration resolution fault condition shall be treated as	40.5.2	M	Yes [ ]	MASTER-SLAVE Configuration Resolution complete.
AN14	MASTER-SLAVE Configuration resolution fault condition shall	40.5.2	M	Yes [ ]	Cause link_status_1000BASE-T to be set to FAIL.
AN15	When EEE is supported, a 1000BASE-T PHY shall	40.5.1.2	EEE:M	Yes [ ]	Exchange an additional formatted Next Page and Unformatted Next Page in sequence, without interruption, as specified in Table 40–4.

40.12.7 PMA Electrical Specifications

Item	Feature	Subclause	Status	Support	Value/Comment
PME1	Electrical isolation	40.6.1.1	!PD:M	Yes [ ] N/A [ ]	Conforms to J.1.
PME2	The PHY shall provide electrical isolation between	40.6.1.1	PD:M	Yes [ ] N/A [ ]	All external conductors, including frame ground, and all MDI leads.
PME3	The transmitter MASTER-SLAVE timing jitter test channel shall	40.6.1.1.1	M	Yes [ ]	Be constructed by combining 100 Ω and 120 Ω cable segments that meet or exceed ISO/IEC 11801 Category 5 specifications for each pair as shown in Figure 40–19 with the lengths and additional restrictions on parameters described in Table 40–6.
PME4	The ends of the MASTER-SLAVE timing jitter test channel shall	40.6.1.1.1	M	Yes [ ]	Be connectorized with connectors meeting or exceeding ISO/IEC 11801:1995 Category 5 specifications.
PME5	The return loss of the MASTER-SLAVE timing jitter test channel shall	40.6.1.1.1	M	Yes [ ]	Meet the return loss requirements of 40.7.2.3.
PME6	The return loss of the MASTER-SLAVE timing jitter test channel shall	40.6.1.1.1	M	Yes [ ]	Meet the crosstalk requirements of 40.7.3 on each pair.
PME7	The test modes described in 40.6.1.1.2 shall be provided for testing of the transmitted waveform, transmitter distortion and transmitted jitter.	40.6.1.1.2	M	Yes [ ]	
PME8	For a PHY with a GMII interface the test modes shall be enabled by	40.6.1.1.2	M	Yes [ ]	Setting bits 9:13-15 (1000BASE-T Control Register) of the GMII Management register set as shown in Table 40–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
PME9	The test modes shall only change the data symbols provided to the transmitter circuitry and shall not alter the electrical and jitter characteristics of the transmitter and receiver from those of normal operation.	40.6.1.1.2	M	Yes [ ]	
PME10	A PHY without a GMII shall provide a means to enable the test modes for conformance testing.	40.6.1.1.2	M	Yes [ ]	
PME11	When transmit test mode 1 is enabled, the PHY shall transmit	40.6.1.1.2	M	Yes [ ]	The sequence of data symbols specified in 40.6.1.1.2 continuously from all four transmitters.
PME12	When in test mode 1, the transmitter shall time the transmitted symbols	40.6.1.1.2	M	Yes [ ]	From a 125.00 MHz ± 0.01% clock in the MASTER timing mode.
PME13	When test mode 2 is enabled, the PHY shall transmit	40.6.1.1.2	M	Yes [ ]	The data symbol sequence {+2,–2} repeatedly on all four channels.
PME14	When in test mode 2, the transmitter shall time the transmitted symbols	40.6.1.1.2	M	Yes [ ]	From a 125.00 MHz ± 0.01% clock in the MASTER timing mode.
PME15	When transmit test mode 3 is enabled, the PHY shall transmit	40.6.1.1.2	M	Yes [ ]	The data symbol sequence {+2,–2} repeatedly on all four channels.
PME16	When in test mode 3, the transmitter shall time the transmitted symbols	40.6.1.1.2	M	Yes [ ]	From a 125 MHz ± 1% clock in the SLAVE timing mode.
PME17	When test mode 4 is enabled, the PHY shall transmit	40.6.1.1.2	M	Yes [ ]	The data symbols generated by the scrambler polynomial specified in 40.6.1.1.2.
PME18	When test mode 4 is enabled, the PHY shall	40.6.1.1.2	M	Yes [ ]	Use the bit sequences generated by the scrambler bits shown in 40.6.1.1.2 to generate the quinary symbols, s_n, as shown in Table 40–8.
PME19	When test mode 4 is enabled, the maximum-length shift register used to generate the sequences defined by this polynomial shall be	40.6.1.1.2	M	Yes [ ]	Updated once per symbol interval (8 ns).
PME20	When test mode 4 is enabled, the bit sequences, $x0_n$, $x1_n$, and $x2_n$, generated from combinations of the scrambler bits shown in 40.6.1.1.2 shall be	40.6.1.1.2	M	Yes [ ]	Used to generate the quinary symbols, s_n, as shown in Table 40–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
PME21	When test mode 4 is enabled, the quinary symbol sequence shall be	40.6.1.1.2	M	Yes [ ]	Presented simultaneously to all transmitters.
PME22	When in test mode 4, the transmitter shall time the transmitted symbols	40.6.1.1.2	M	Yes [ ]	From a 125.00 MHz ± 0.01% clock in the MASTER timing mode.
PME23	The test fixtures defined in Figure 40–23, Figure 40–24, Figure 40–25, and Figure 40–26 or their functional equivalents shall be used for measuring transmitter specifications.	40.6.1.1.3	M	Yes [ ]	
PME24	The test filter used in transmitter test fixtures 1 and 3 shall	40.6.1.1.3	M	Yes [ ]	Have the continuous time transfer function specified in 40.6.1.1.3 or its discrete time equivalent.
PME25	The disturbing signal V_d shall	40.6.1.1.3	M	Yes [ ]	Have the characteristics listed in Table 40–9.
PME26	To allow for measurement of transmitted jitter in MASTER and SLAVE modes the PHY shall provide access to the 125 MHz symbol clock, TX_TCLK that times the transmitted symbols.	40.6.1.1.3	M	Yes [ ]	
PME27	To allow for measurement of transmitted jitter in MASTER and SLAVE modes the PHY shall provide a means to enable the TX_TCLK output if it is not normally enabled.	40.6.1.1.3	M	Yes [ ]	
PME28	The PMA shall	40.6.1.2	M	Yes [ ]	Provide the Transmit function specified in 40.4.2.2 in accordance with the electrical specifications of this clause.
PME29	Where a load is not specified, the transmitter shall	40.6.1.2	M	Yes [ ]	Meet the requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output.
PME30	The tolerance on the poles of the test filters used in 40.6 shall be ± 1%.	40.6.1.2	M	Yes [ ]	
PME31	When in transmit test mode 1 and observing the differential signal output at the MDI using test fixture 1, for each pair, with no intervening cable, the absolute value of the peak of the waveform at points A and B as defined in Figure 40–20 shall fall within	40.6.1.2.1	M	Yes [ ]	The range of 0.67 V to 0.82 V (0.75 V ± 0.83 dB).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
PME32	The absolute value of the peak of the waveforms at points A and B shall	40.6.1.2.1	M	Yes [ ]	Differ by less than 1%.
PME33	The absolute value of the peak of the waveform at points C and D as defined in Figure 40–20 shall differ	40.6.1.2.1	M	Yes [ ]	From 0.5 times the average of the absolute values of the peaks of the waveform at points A and B by less than 2%.
PME34	When in transmit test mode 1 and observing the differential transmitted output at the MDI, for either pair, with no intervening cabling, the peak value of the waveform at point F as defined in Figure 40–20 shall be	40.6.1.2.2	M	Yes [ ]	Greater than 73.1% of the magnitude of the negative peak value of the waveform at point F. Point G is defined as the point exactly 500 ns after point F. Point F is defined as the point where the waveform reaches its minimum value at the location indicated in Figure 40–20.
PME35	When in transmit test mode 1 and observing the differential transmitted output at the MDI, for either pair, with no intervening cabling, the peak value of the waveform at point J as defined in Figure 40–20 shall be	40.6.1.2.2	M	Yes [ ]	Greater than 73.1% of the magnitude of the peak value of the waveform at point H. Point J is defined as the point exactly 500 ns after point H. Point H is defined as the point where the waveform reaches its maximum value at the location indicated in Figure 40–20.
PME36	When in test mode 1 and observing the differential signal output at the MDI using transmitter test fixture 1, for each pair, with no intervening cable, the voltage waveforms at points A, B, C, D defined in Figure 40–20, after the normalization described within the referenced subclause, shall	40.6.1.2.3	M	Yes [ ]	Lie within the time domain template 1 defined in Figure 40–27 and the piecewise linear interpolation between the points in Table 40–10. The waveforms may be shifted in time as appropriate to fit within the template.
PME37	When in test mode 1 and observing the differential signal output at the MDI using transmitter test fixture 1, for each pair, with no intervening cable, the voltage waveforms at points F and H defined in Figure 40–20, after the normalization described within the referenced subclause, shall	40.6.1.2.3	M	Yes [ ]	Lie within the time domain template 2 defined in Figure 40–27 and the piecewise linear interpolation between the points in Table 40–11. The waveforms may be shifted in time as appropriate to fit within the template.
PME38	When in test mode 4 and observing the differential signal output at the MDI using transmitter test fixture 3, for each pair, with no intervening cable, the peak distortion as defined below shall be	40.6.1.2.4	M	Yes [ ]	Less than 10 mV.

Item	Feature	Subclause	Status	Support	Value/Comment
PME39	When in the normal mode of operation as the MASTER, the peak-to-peak value of the MASTER TX_TCLK jitter relative to an unjittered reference shall be	40.6.1.2.5	M	Yes [ ]	Less than 1.4 ns.
PME40	When the jitter waveform on TX_TCLK is filtered by a high-pass filter, $H_{jf1}(f)$ having the transfer function specified in 40.6.1.2.5, the peak-to-peak value of the resulting filtered timing jitter plus J_{txout}, shall be	40.6.1.2.5	M	Yes [ ]	Less than 0.3 ns.
PME41	When in the normal mode of operation as the SLAVE, receiving valid signals from a compliant PHY operating as the MASTER using the test channel defined in 40.6.1.1.1, with test channel port A connected to the SLAVE, the peak-to-peak value of the SLAVE TX_TCLK jitter relative to the MASTER TX_TCLK shall be	40.6.1.2.5	M	Yes [ ]	Less than 1.4 ns after the receiver is properly receiving the data and has set bit 10.13 of the GMII management register set to 1.
PME42	When the jitter waveform on TX_TCLK is filtered by a high-pass filter, $H_{jf2}(f)$, having the transfer function specified in 40.6.1.2.5, the peak-to-peak value of the resulting filtered timing jitter plus J_{txout} shall be	40.6.1.2.5	M	Yes [ ]	No more than 0.4 ns greater than the simultaneously measured peak-to-peak value of the MASTER jitter filtered by $H_{jf1}(f)$
PME43	For all jitter measurements the peak-to-peak value shall be	40.6.1.2.5	M	Yes [ ]	Measured over an unbiased sample of at least 10^5 clock edges.
PME44	For all unfiltered jitter measurements the peak-to-peak value shall be	40.6.1.2.5	M	Yes [ ]	Measured over an interval of not less than 100 ms and not more than 1 second.
PME45	The quinary symbol transmission rate on each pair of the MASTER PHY shall be	40.6.1.2.6	M	Yes [ ]	125.00 MHz ± 0.01%
PME46	The PMA shall provide the Receive function specified in 40.3.1.4 in accordance with the electrical specifications of this clause.	40.6.1.3	M	Yes [ ]	
PME47	The patch cabling and interconnecting hardware used in test configurations shall be	40.6.1.3	M	Yes [ ]	Within the limits specified in 40.7.

Item	Feature	Subclause	Status	Support	Value/Comment
PME48	Differential signals received on the receive inputs that were transmitted within the specifications given in 40.6.1.2 and have then passed through a link compatible with 40.7, shall be translated into	40.6.1.3.1	M	Yes [ ]	One of the PMA_UNITDATA.indication messages with a 4-D symbol rate error less than 10^{-10} and sent to the PCS after link bring-up. Since the 4-D symbols are not accessible, this specification shall be satisfied by a frame error ratio less than 10^{-7} for 125 octet frames.
PME49	The receive feature shall	40.6.1.3.2	M	Yes [ ]	Properly receive incoming data with a 5-level symbol rate within the range 125.00 MHz ± 0.01%.
PME50	The signal generator for the common-mode test shall be	40.6.1.3.3	M	Yes [ ]	Capable of providing a sine wave signal of 1 MHz to 250 MHz.
PME51	While sending data from the transmitter the receiver shall	40.6.1.3.3	M	Yes [ ]	Send the proper PMA_UNITDATA.indication messages to the PCS as the signal generator frequency is varied from 1 MHz to 250 MHz.
PME52	While receiving data from a transmitter specified in 40.6.1.2 through a link segment specified in 40.7 connected to all MDI duplex channels, a receiver shall	40.6.1.3.4	M	Yes [ ]	Send the proper PMA_UNITDATA.indication message to the PCS when any one of the four pairs is connected to a noise source as described in Figure 40–29.
PME53	The alien crosstalk test specified in 40.6.1.3.4 shall be satisfied by	40.6.1.3.4	M	Yes [ ]	A frame error ratio of less than 10^{-7} for 125 octet frames
PME54	The noise source shall be	40.6.1.3.4	M	Yes [ ]	Connected to one of the MDI inputs using Category 5 balanced cable of a maximum length of 0.5 m.
PME55	The unfiltered jitter requirements shall	40.6	EEE:M	Yes [ ]	Be satisfied during the LPI mode, with the exception that clock edges corresponding to the WAIT_QUIET, QUIET, WAKE, and WAKE_SILENT states are not considered in the measurement.
PME56	For a MASTER PHY operating in the LPI mode, the unjittered reference shall	40.6	EEE:M	Yes [ ]	Be continuous.
PME57	The transmit levels of the Idle symbols transmitted during the WAKE state shall	40.6.1.2.7	EEE:M	Yes [ ]	Exceed 65% of the transmit levels of compliant Idle symbols for a period of at least 500 ns.

Item	Feature	Subclause	Status	Support	Value/Comment
PME58	The PHY shall	40.6.1.2.7	EEE:M	Yes [ ]	Achieve compliant operation upon entry to the WAKE_TRAINING state (see Figure 40–16b).
PME59	PMA Receive function shall	40.6.1.3.5	EEE:M	Yes [ ]	Convey an indicator of signal presence, referred to as signal_detect, to the PMA PHY Control function.
PME60	The value of signal_detect shall	40.6.1.3.5	EEE:M	Yes [ ]	Be set to TRUE within 0.5 µs of the receipt of a wake signal meeting the requirements of 40.6.1.2.7.
PME61	The value of signal_detect shall	40.6.1.3.5	EEE:M	Yes [ ]	Be set to FALSE within 0.5 µs of the receipt of a continuous sequence of zeros.

40.12.8 Characteristics of the link segment

Item	Feature	Subclause	Status	Support	Value/Comment
LKS1	All implementations of the balanced cabling link shall	40.7.1	INS:M	N/A [ ] Yes [ ]	Be compatible at the MDI.
LKS2	1000BASE-T links shall be compliant	40.7.1	INS:M	N/A [ ] Yes [ ]	With Class D performance requirements, as specified by ISO/IEC 11801:1995.
LKS3	Link segment testing shall be conducted using	40.7.2	INS:M	N/A [ ] Yes [ ]	Source and load impedances of 100 Ω.
LKS4	The tolerance on the poles of the test filter used in this section shall be	40.7.2	INS:M	N/A [ ] Yes [ ]	± 1%.
LKS5	The insertion loss of each duplex channel shall be	40.7.2.1	INS:M	N/A [ ] Yes [ ]	Less than $2.1 f^{0.529} + 0.4/f$ (dB) at all frequencies from 1 MHz to 100 MHz. This includes the attenuation of the balanced cabling pairs, connector losses, and patch cord losses of the duplex channel.
LKS6	The insertion loss specification shall be met when	40.7.2.1	INS:M	N/A [ ] Yes [ ]	The duplex channel is terminated in 100 Ω.
LKS7	The return loss of each duplex channel shall be	40.7.2.3	INS:M	N/A [ ] Yes [ ]	As specified in 40.7.2.3 at all frequencies from 1 MHz to 100 MHz.
LKS8	The reference impedance for return loss measurement shall be	40.7.2.3	INS:M	N/A [ ] Yes [ ]	100 Ω.

Item	Feature	Subclause	Status	Support	Value/Comment
LKS9	The NEXT loss between duplex channel pairs of a link segment shall be	40.7.3.1.1	INS:M	N/A [ ] Yes [ ]	At least $27.1 - 16.8\log_{10}(f/100)$ (where f is the frequency in MHz over the frequency range 1 MHz to 100 MHz.)
LKS10	The worst case ELFEXT loss between duplex channel pairs of a link segment shall be	40.7.3.2	INS:M	N/A [ ] Yes [ ]	Greater than $17 - 20\log_{10}(f/100)$ dB (where f is the frequency in MHz) over the frequency range 1 MHz to 100 MHz.
LKS11	The Power Sum loss between a duplex channel and the three adjacent disturbers shall be	40.7.3.2.2	INS:M	N/A [ ] Yes [ ]	Greater than $14.4 - 20\log_{10}(f/100)$ dB where f is the frequency in MHz over the frequency range of 1 MHz to 100 MHz.
LKS12	The propagation delay of a link segment shall	40.7.4.1	INS:M	N/A [ ] Yes [ ]	Not exceed 570 ns at all frequencies from 2 MHz to 100 MHz.
LKS13	The difference in propagation delay, or skew, between all duplex channel pair combinations of a link segment under all conditions shall not exceed	40.7.4.2	INS:M	N/A [ ] Yes [ ]	50 ns at all frequencies between 2 MHz and 100 MHz.
LKS14	Once installed, the skew between pairs due to environmental conditions shall not vary	40.7.4.2	INS:M	N/A [ ] Yes [ ]	More than ± 10 ns.

40.12.9 MDI requirements

Item	Feature	Subclause	Status	Support	Value/Comment
MDI1	MDI connector	40.8.1	M	Yes [ ]	8-Way connector as per IEC 60603-7:1990.
MDI2	Connector used on cabling	40.8.1	INS:M	N/A [ ] Yes [ ]	Plug.
MDI3	Connector used on PHY	40.8.1	M	Yes [ ]	Jack (as opposed to plug).
MDI4	MDI connector	40.8.2	M	Yes [ ]	A PHY that implements the crossover function shall be marked with the graphical symbol X.
MDI5	The MDI connector (jack) when mated with a balanced cabling connector (plug) shall meet	40.8.3	INS:M	N/A [ ] Yes [ ]	The electrical requirements for Category 5 connecting hardware for use with 100 Ω Category 5 cable as specified in ISO/IEC 11801:1995.

Item	Feature	Subclause	Status	Support	Value/Comment
MDI6	The mated MDI connector and balanced cabling connector shall	40.8.3	INS:M	N/A [ ] Yes [ ]	Not have a FEXT loss greater than $40 - 20\log_{10}(f/100)$ over the frequency range 1 MHz to 100 MHz between all contact pair combinations shown in Table 40–12.
MDI7	No spurious signals shall be emitted onto the MDI when the PHY is held in power down mode as defined in 22.2.4.1.5, independent of the value of TX_EN, when released from power down mode, or when external power is first applied to the PHY.	40.8.3	M	Yes [ ]	
MDI8	The differential impedance as measured at the MDI for each transmit/receive channel shall be such that	40.8.3.1	M	Yes [ ]	Any reflection due to differential signals incident upon the MDI from a balanced cabling having an impedance of 100 Ω ± 15% is at least 16 dB over the frequency range of 2.0 MHz to 40 MHz and at least $10 - 20\log_{10}(f/80)$ dB over the frequency range 40 MHz to 100 MHz (f in MHz).
MDI9	This return loss shall be maintained	40.8.3.1	M	Yes [ ]	At all times when the PHY is transmitting data or control symbols.
MDI10	The common-mode to differential-mode impedance balance of each transmit output shall exceed	40.8.3.2	M	Yes [ ]	The value specified by the equations specified in 40.8.3.2. Test mode 4 may be used to generate an appropriate transmitter output.
MDI11	The magnitude of the total common-mode output voltage, E_{cm_out}, on any transmit circuit, when measured as shown in Figure 40–33, shall be	40.8.3.3	M	Yes [ ]	Less than 50 mv peak-to-peak when transmitting data.
MDI12	Each wire pair of the MDI shall	40.8.3.4	M	Yes [ ]	Withstand without damage the application of short circuits across the MDI port for an indefinite period of time without damage.
MDI13	Each wire pair of the MDI shall resume	40.8.3.4	M	Yes [ ]	Normal operation after such faults are removed.

41. Repeater for 1000 Mb/s baseband networks

NOTE—This repeater is not recommended for new installations. Since September 2011, maintenance changes are no longer being considered for this clause.

41.1 Overview

41.1.1 Scope

Clause 41 defines the functional and electrical characteristics of a repeater for use with Ethernet 1000 Mb/s baseband networks. A repeater for any other Ethernet network type is beyond the scope of this clause. The relationship of this standard to the OSI Reference Model is shown in Figure 41–1. The purpose of the repeater is to provide a simple, inexpensive, and flexible means of coupling two or more segments.

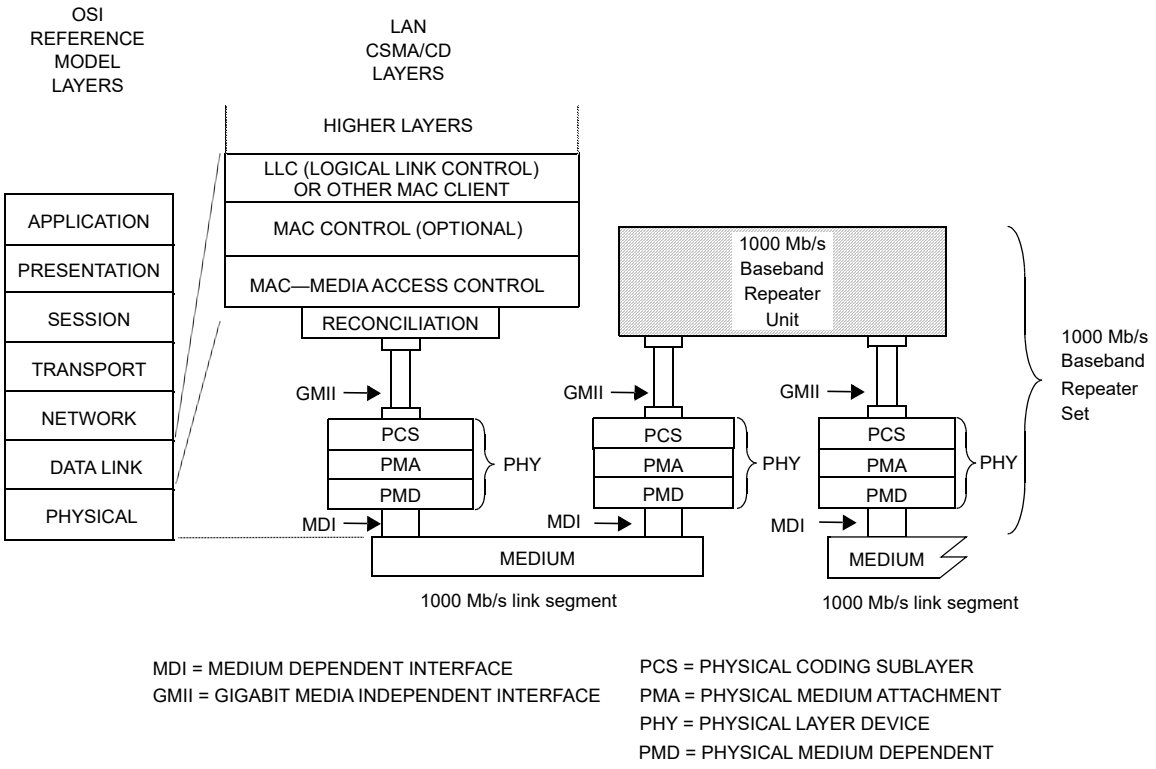

Figure 41–1—1000 Mb/s repeater set relationship to the ISO/IEC OSI reference model

41.1.1.1 Repeater set

Repeater sets are an integral part of all 1000 Mb/s baseband networks with more than two DTEs and are used to extend the physical system topology by providing a means of coupling two or more segments. A single repeater set is permitted within a single collision domain to provide the maximum connection path length. Allowable topologies contain only one operative signal path between any two points on the network. A repeater set is not a station and does not count toward the overall limit of 1024 stations on a network.

A repeater set can receive and decode data from any segment under worst-case noise, timing, and signal amplitude conditions. It retransmits the data to all other segments attached to it with timing, amplitude, and coding restored. The retransmission of data occurs simultaneously with reception. If a collision occurs, the repeater set propagates the collision event throughout the network by transmitting a Jam signal. A repeater

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

set also provides a degree of protection to a network by isolating a faulty segment's carrier activity from propagating through the network.

41.1.1.2 Repeater unit

A repeater unit is a subset of a repeater set containing all the repeater-specific components and functions, exclusive of PHY components and functions. A repeater unit connects to the PHYs using the Gigabit Media Independent Interface (GMII) defined in Clause 35.

41.1.2 Application perspective

This subclause states the broad objectives and assumptions underlying the specification defined through Clause 41.

41.1.2.1 Objectives

a) Provide physical means for coupling two or more LAN segments at the Physical Layer.
b) Support interoperability of independently developed physical, electrical, and optical interfaces.
c) Provide a communication channel with a mean bit error ratio, at the physical service interface equivalent to that for the attached PHY.
d) Provide for ease of installation and service.
e) Ensure that fairness of DTE access is not compromised.
f) Provide for low-cost networks, as related to both equipment and cabling.

41.1.2.2 Compatibility considerations

All implementations of the repeater set shall be compatible at the MDI. The repeater set is defined to provide compatibility among devices designed by different manufacturers. Designers are free to implement circuitry within the repeater set in an application-dependent manner provided the appropriate PHY specifications are met.

41.1.2.2.1 Internal segment compatibility

Implementations of the repeater set that contain a MAC layer for network management or other purposes, irrespective of whether they are connected through an exposed repeater port or are internally ported, shall conform to the requirements of Clause 30 on that port if repeater management is implemented.

41.1.3 Relationship to PHY

A close relationship exists between Clause 41 and the GMII clause (Clause 35) and the PHY clauses (Clauses 36–39 for 1000BASE-X PHYs and Clause 40 for 1000BASE-T PHYs). The PHY's PMA, PCS, and MDI specification provide the actual medium attachment, including drivers, receivers, and Medium Interface Connectors for the various supported media. The repeater clause does not define a new PHY; it utilizes the existing PHYs complete and without modification. The repeater_mode variable in each PHY is set, so that the CRS signal of the GMII is asserted only in response to receive activity (see 36.2.5.1.3).

41.2 Repeater functional specifications

A repeater set provides the means whereby data from any segment can be received under worst-case noise, timing, and amplitude conditions and then retransmitted with timing and amplitude restored to all other attached segments. Retransmission of data occurs simultaneously with reception. If a collision occurs, the repeater set propagates the collision event throughout the network by transmitting a Jam signal. If an error is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

received by the repeater set, no attempt is made to correct it and it is propagated throughout the network by transmitting an explicit error code.

The repeater set provides the following functional capability to handle data flow between ports:

a) *Signal restoration.* Provides the ability to restore the timing and amplitude of the received signal prior to retransmission.
b) *Transmit function.* Provides the ability to output signals on the appropriate port and encoded appropriately for that port. Details of signal processing are described in the specifications for the PHYs.
c) *Receive function.* Provides the ability to receive input signals presented to the ports. Details of signal processing are described in the specifications for the PHYs.
d) *Data-Handling function.* Provides the ability to transfer code-elements between ports in the absence of a collision.
e) *Received Event-Handling requirement.* Provides the ability to derive a carrier signal from the input signals presented to the ports.
f) *Collision-Handling function.* Provides the ability to detect the simultaneous reception of frames at two or more ports and then to propagate a Jam message to all connected ports.
g) *Error-Handling function.* Provides the ability to prevent substandard links from generating streams of false carrier and interfering with other links.
h) *Partition function.* Provides the ability to prevent a malfunctioning port from generating an excessive number of consecutive collisions and indefinitely disrupting data transmission on the network.
i) *Receive Jabber function.* Provides the ability to interrupt the reception of abnormally long streams of input data.

41.2.1 Repeater functions

The repeater set shall provide the Signal Restoration, Transmit, Receive, Data Handling, Received Event Handling, Collision Handling, Error Handling, Partition, and Receive Jabber functions. The repeater is transparent to all network acquisition activity and to all DTEs. The repeater will not alter the basic fairness criterion for all DTEs to access the network or weigh it toward any DTE or group of DTEs regardless of network location.

The Transmit and Receive functional requirements are specified by the PHY clauses, Clause 40 for 1000BASE-T and Clauses 36 to 39 for 1000BASE-X.

41.2.1.1 Signal restoration functional requirements

41.2.1.1.1 Signal amplification

The repeater set (including its integral PHYs) shall ensure that the amplitude characteristics of the signals at the MDI outputs of the repeater set are within the tolerances of the specification for the appropriate PHY type. Therefore, any loss of signal-to-noise ratio due to cable loss and noise pickup is regained at the output of the repeater set as long as the incoming data is within system specification.

41.2.1.1.2 Signal wave-shape restoration

The repeater set (including its integral PHYs) shall ensure that the wave-shape characteristics of the signals at the MDI outputs of a repeater set are within the specified tolerance for the appropriate PHY type. Therefore, any loss of wave-shape due to PHYs and media distortion is restored at the output of the repeater set.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

41.2.1.1.3 Signal retiming

The repeater set (including its integral PHYs) shall ensure that the timing of the encoded data output at the MDI outputs of a repeater set are within the specified tolerance for the appropriate PHY type. Therefore, any receive jitter from the media is removed at the output of the repeater set.

41.2.1.2 Data-handling functional requirements

41.2.1.2.1 Data frame forwarding

The repeater set shall ensure that the data frame received on a single input port is distributed to all other output ports in a manner appropriate for the PHY type of that port. The data frame is that portion of the packet after the SFD and before the end-of-frame delimiter. The only exceptions to this rule are when contention exists among any of the ports, when the receive port is partitioned as defined in 41.2.1.6, when the receive port is in the Jabber state as defined in 41.2.1.7, or when the receive port is in the Link Unstable state as defined in 41.2.1.5.1. Between unpartitioned ports, the rules for collision handling (see 41.2.1.4) take precedence.

41.2.1.2.2 Received code violations

The repeater set shall ensure that any code violations received while forwarding a packet are propagated to all outgoing segments. These code violations shall be replaced by a code-group that provide an explicit indication that an error was received, as appropriate for the outgoing PHY type. Once a received code violation has been replaced by a code-group indicating a receive error, this substitution shall continue for the remainder of the received event regardless of its content. The only exception to this rule is when contention exists among any of the ports, where the rules for collision handling (see 41.2.1.4) then take precedence.

41.2.1.3 Received event-handling functional requirements

41.2.1.3.1 Received event handling

For all its ports, the repeater set shall detect received events by monitoring the port for any assertion of the GMII CRS signal that is the result of receive activity. The repeater_mode variable in the PHY shall be set to ensure that the CRS signal is not asserted in response to transmit activity. Received events include both the data frame and any encapsulation of the data frame such as Preamble, SFD, start and end of packet delimiters, carrier extension symbols, and error propagation symbols. A received event is exclusive of the IDLE pattern. Upon detection of a received event from one port, the repeater set shall repeat all received signals in the data frame from that port to the other ports as described in Figure 41–2.

41.2.1.3.2 Preamble regeneration

The repeater set shall output preamble as appropriate for the outgoing PHY type followed by the SFD. The duration of the output preamble shall not vary more than 8 bit times from the duration of the received preamble.

41.2.1.3.3 Start-of-packet propagation delay

The start-of-packet propagation delay for a repeater set is the time delay between the start of a received event on a repeated-from (input) port to the start of transmit on the repeated-to (output) port (or ports). This parameter is referred to as the SOP delay, and is measured at the MDI of the repeater ports. The maximum value of this delay is constrained such that the sum of the SOP delay and SOJ delay shall not exceed the value specified in 41.2.1.4.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

41.2.1.3.4 Start-of-packet variability

The start-of-packet variability for a repeater set is defined as the total worst-case difference between start-of-packet propagation delays for successive received events separated by 112 bit times or less at the same input port. The variability shall be less than or equal to 16 bit times.

41.2.1.4 Collision-handling functional requirements

41.2.1.4.1 Collision detection

The repeater performs collision detection by monitoring all its enabled input ports for received events. When the repeater detects received events on more than one input port, it shall enter a collision state and transmit the Jam message to all of its output ports.

41.2.1.4.2 Jam generation

While a collision is occurring between any of its ports, the repeater unit shall transmit the Jam message to all of the ports. The Jam message shall be transmitted in accordance with the repeater state diagram in Figure 41–2. The Jam message is signaled across the GMII using the Transmit Error Propagation encoding if the collision is detected during Normal Data Transmission, or using the Carrier Extend Error encoding if the collision is detected during Carrier Extension.

41.2.1.4.3 Start-of-collision-jam propagation delay

The start-of-collision Jam propagation delay for a repeater set is the time delay between the start of the second received event (that results in a collision) to arrive at its port and the start of Jam out on all ports. This parameter is referred to as the SOJ delay, and is measured at the MDI of the repeater ports. The sum of the SOP delay and SOJ delay shall not exceed 976 bit times (BT).

41.2.1.4.4 Cessation-of-collision Jam propagation delay

The cessation-of-collision Jam propagation delay for a repeater set is the time delay between the end of the received event that creates a state such that Jam should end at a port and the end of Jam at that port. The states of the input signals that should cause Jam to end are covered in detail in the repeater state diagram in Figure 41–2. This parameter is referred to as the EOJ delay. This delay shall not exceed the SOP delay.

41.2.1.5 Error-handling functional requirements

41.2.1.5.1 Carrier integrity functional requirements

It is desirable that the repeater set protect the network from some transient fault conditions that would disrupt network communications. Potential likely causes of such conditions are DTE and repeater power-up and power-down transients, cable disconnects, and faulty wiring.

The repeater unit shall provide a self-interrupt capability at each port, as described in Figure 41–5, to prevent a segment's spurious carrier activity from propagating through the network.

At each port the repeater shall count consecutive false carrier events signaled across the GMII. The count shall be incremented on each false carrier event and shall be reset on reception of a valid carrier event. In addition, each port shall have a false carrier timer, which is enabled at the beginning of a false carrier event and reset at the conclusion of such an event. A repeater unit shall transmit the Jam signals to all ports for the duration of the false carrier event or until the duration of the event exceeds the time specified by the false_carrier_timer (see 41.2.2.1.4), whichever is shorter. The Jam message shall be transmitted in accordance with the repeater state diagram in Figure 41–2. The LINK UNSTABLE condition shall be

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

detected when the False Carrier Event Count equals the value FCELimit (see 41.2.2.1.1) or the duration of a false carrier event exceeds the time specified by the false_carrier_timer. In addition, the LINK UNSTABLE condition shall be detected upon power-up reset.

Upon detection of LINK UNSTABLE at a port, the repeater unit shall perform the following:

a) Inhibit sending further messages from that port to the repeater unit.
b) Inhibit sending further output messages to that port from the repeater unit.
c) Continue to monitor activity on that port.

The repeater unit shall exit the LINK UNSTABLE condition at the port when one of the following is met:

a) The repeater has detected no activity (Idle) for more than the time specified by ipg_timer plus idle_timer (see 41.2.2.1.4) on port X.
b) A valid carrier event with a duration greater than the time specified by valid_carrier_timer (see 41.2.2.1.4) has been received, preceded by no activity (Idle) for more than the time specified by ipg_timer (see 41.2.2.1.4) on port X.

The false_carrier_timer duration is longer than the maximum round-trip latency from a repeater to a DTE, but less than a slot time. This allows a properly functioning DTE to respond to the Jam message by detecting collision and terminating the transmission prior to the expiration of the timer. The upper limit on the false_carrier_timer prevents the Jam message from exceeding the maximum fragment size.

The combination of the ipg_timer, idle_timer, and valid_carrier_timer filter transient activity that can occur on a link during power cycles or mechanical connection. The duration of the ipg_timer is greater than two-thirds of the minimum IPG, and less than the minimum IPG less some shrinkage. The idle_timer is specified as approximately 320 μs based upon empirical data on such transients. The valid_carrier_timer duration is less than the duration of a minimum valid carrier event, but long enough to filter most spurious carrier events (note that there can be no valid collision fragments on an isolated link in a single repeater topology). The range of the valid_carrier_timer is specified to be the same as the false_carrier_timer range for the convenience of implementations.

41.2.1.5.2 Speed handling

If the PHY has the capability of detecting speeds other than 1000 Mb/s, then the repeater set shall have the capability of blocking the flow of non-1000 Mb/s signals. The incorporation of 1000 Mb/s and 100 Mb/s or 10 Mb/s repeater functionality within a single repeater set is beyond the scope of this standard.

41.2.1.6 Partition functional requirements

It is desirable that the repeater set protect the network from some fault conditions that would disrupt network communications. A potentially likely cause of this condition could be due to a cable fault.

The repeater unit shall provide a self-interrupt capability at each port, as described in Figure 41–4, to prevent a faulty segment's carrier activity from propagating through the network. The repeater unit shall count consecutive collision events at each port. The count shall be incremented on each transmission that suffers a collision and shall be reset on a successful transmission or reception. If this count equals or exceeds the value CELimit (see 41.2.2.1.1), the Partition condition shall be detected. In addition, the partition condition shall be detected due to a carrier event of duration in excess of jabber_timer in which a collision has occurred.

Upon detection of Partition at a port, the repeater unit shall perform the following:

a) Inhibit sending further input messages from that port to the repeater unit.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Continue to output messages to that port from the repeater unit.
c) Continue to monitor activity on that port.

The repeater unit shall reset the Partition function at the port when one of the following conditions is met:

— On power-up reset.
— The repeater has detected activity on the port for more than the number of bits specified for no_collision_timer (see 41.2.2.1.4) without incurring a collision.
— The repeater has transmitted on the port for more than the number of bits specified for no_collision_timer (see 41.2.2.1.4) without incurring a collision.

The no_collision_timer duration is longer than the maximum round-trip latency from a repeater to a DTE (maximum time required for a repeater to detect a collision), and less than the minimum valid carrier event duration (slot time plus header_size minus preamble shrinkage).

41.2.1.7 Receive jabber functional requirements

The repeater unit shall provide a self-interrupt capability at each port, as described in Figure 41–3, to prevent an illegally long reception of data from propagating through the network. The repeater unit shall provide a window of duration jabber_timer bit times (see 41.2.2.1.4) during which the input messages from a port may be passed on to other repeater unit functions. If a reception exceeds this duration, the jabber condition shall be detected.

Upon detection of the jabber condition at a port, the repeater unit shall perform the following:

a) Inhibit sending further input messages from that port to the repeater unit.
b) Inhibit sending further output messages to that port from the repeater unit.

The repeater shall reset the Jabber function at the port, and re-enable data transmission and reception, when either one of the following conditions is met:

— On power-up reset.
— When carrier is no longer detected at that port.

The lower bound of the jabber_timer is longer than the carrier event of a maximum length burst. The upper bound is large enough to permit a wide variety of implementations.

41.2.2 Detailed repeater functions and state diagrams

A precise algorithmic definition is given in this subclause, providing a complete procedural model for the operation of a repeater, in the form of state diagrams. Note that whenever there is any apparent ambiguity concerning the definition of repeater operation, the state diagrams should be consulted for the definitive statement.

The model presented in this subclause is intended as a primary specification of the functions to be provided by any repeater unit. It is important to distinguish, however, between the model and a real implementation. The model is optimized for simplicity and clarity of presentation, while any realistic implementation should place heavier emphasis on such constraints as efficiency and suitability to a particular implementation technology.

It is the functional behavior of any repeater set implementation that is expected to match the standard, not the internal structure. The internal details of the procedural model are useful only to the extent that they help specify the external behavior clearly and precisely. For example, the model uses a separate Receive Port Jabber state diagram for each port. However, in actual implementation, the hardware may be shared.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The notation used in the state diagram follows the conventions of 1.2.1. Note that transitions shown without source states are evaluated at the completion of every state and take precedence over other transition conditions.

41.2.2.1 State diagram variables

41.2.2.1.1 Constants

CELimit

The number of consecutive Collision Events that have to occur before a segment is partitioned.

Values: Positive integer greater than 60.

FCELimit

The number of consecutive False Carrier Events that have to occur before a segment is isolated.

Value: 2.

41.2.2.1.2 Variables

begin

The Interprocess flag controlling state diagram initialization values.

Values: true
false

CRS(X), RXD(X), RX_DV(X), RX_ER(X), TXD(X), TX_EN(X), TX_ER(X)

GMII signals received from or sent to the PHY at port X (see Clause 35). The repeater_mode variable in the PHY is set to ensure that the CRS(X) signal is asserted in response to receive activity only.

RXERROR(X)

A combination of the GMII signal encodings indicating that the PHY has detected a Data Error, Carrier Extend Error, or False Carrier Error.

Value: RXERROR(X) ⇐ ((RX_ER(X) = true) *
((RX_DV(X) = true) + (RXD(X) = FalseCarrier) + (RXD(X) = CarrierExtendError)))

TX(X)

A combination of the GMII signal encodings indicating that port X is transmitting a frame.

Value: TX(X) ⇐ ((TX_EN(X) = true) + (TX_ER(X) = true))

isolate(X)

Flag from Carrier Integrity state diagram for port X, which determines whether a port should be enabled or disabled.

Values: true; the Carrier Integrity Monitor has determined the port should be disabled.
false; the Carrier Integrity Monitor has determined the port should be enabled.

force_jam(X)

Flag from Carrier Integrity state diagram for port X, which causes the Repeater Unit to enter the Jam state.

Values: true; the port is in the False Carrier state.
false; the port is not in the False Carrier state.

jabber(X)

Flag from Receive Timer state diagram for port X which indicates that the port has received

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

excessive length activity.

Values: true; port has exceeded the continuous activity limit.
false; port has not exceeded the continuous activity limit.

link_status(X)

Indication from the Auto-Negotiation process (Clauses 28 and 37) that Auto-Negotiation has completed and the priority resolution function has determined that the link will be operated in half duplex mode.

Values: OK; the link is operational in half duplex mode.
FAIL; the link is not operational in half duplex mode.

partition(X)

Flag from Partition state diagram for port X, which determines whether a port receive path should be enabled or disabled.

Values: true; port has exceeded the consecutive collision limit.
false; port has not exceeded the consecutive collision limit.

41.2.2.1.3 Functions

port(Test)

A function that returns the designation of a port passing the test condition. For example, port(CRS = true) returns the designation: X for a port for which CRS is asserted. If multiple ports meet the test condition, the Port function will be assigned one and only one of the acceptable values.

41.2.2.1.4 Timers

All timers operate in the same fashion. A timer is reset and starts timing upon entering a state where “start x_timer” is asserted. At time “x” after the timer has been started, “x_timer_done” is asserted and remains asserted until the timer is reset. At all other times, “x_timer_not_done” is asserted.

When entering a state where “start x_timer” is asserted, the timer is reset and restarted even if the entered state is the same as the exited state.

The timers used in the repeater state diagrams are defined as follows:

false_carrier_timer

Timer for length of false carrier (41.2.1.5.1) that has to be present to set isolate(X) to true. The timer is done when it reaches 3600–4000 BT.

idle_timer

Timer for length of time without carrier activity that has to be present to set isolate(X) to false. The timer is done when it reaches 240 000–400 000 BT.

ipg_timer

Timer for length of time without carrier activity that has to be present before carrier integrity tests (41.2.1.5.1) are re-enabled. The timer is done when it reaches 64–86 BT.

jabber_timer

Timer for length of carrier which has to be present before the Jabber state is entered (41.2.1.7). The timer is done when it reaches 80 000–150 000 BT.

no_collision_timer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Timer for length of packet without collision before partition(X) is set to false (41.2.1.6). The timer is done when it reaches 3600–4144 BT.

valid_carrier_timer

Timer for length of valid carrier that has to be present to cause isolate(X) to be set to false at the end of the carrier event. The timer is done when it reaches 3600–4000 BT.

41.2.2.1.5 Counters

CE(X)

Consecutive port Collision Event count for port X. Partitioning occurs on a terminal count of CELimit being reached.

Values: Non-negative integers up to a terminal count of CELimit.

FCE(X)

False Carrier Event count for port X. Isolation occurs on a terminal count of FCELimit being reached.

Values: Non-negative integers up to a terminal count of FCELimit.

41.2.2.1.6 Port designation

Ports are referred to by number. Port information is obtained by replacing the X in the desired function with the number of the port of interest. Ports are referred to in general as follows:

X

Generic port designator. When X is used in a state diagram, its value is local to that diagram and not global to the set of state diagrams.

N

Identifies the port that caused the exit from the IDLE or JAM states of Figure 41–2. The value is assigned in the term assignment statement on the transition out of these states (see 1.2.1 for State Diagram Conventions).

ALL

Indicates all repeater ports are to be considered. The test passes when all ports meet the test conditions.

ALLXJIPN

The test passes when all ports, excluding those indicated by J, I, P, or N, meet the test conditions. One or more of the J, I, P, or N indications are used to exclude from the test ports with Jabber = true, Isolate = true, Partition = true, or port N, respectively.

ANY

Indicates all ports are to be considered. The test passes when one or more ports meet the test conditions.

ANYXJIPN

The test passes when one or more ports, excluding those indicated by J, I, P, or N, meet the test conditions. One or more of the J, I, P, or N indications are used to exclude from the test ports with Jabber = true, Isolate = true, Partition = true, or port N, respectively.

ONLY1

Indicates all ports except those with Jabber = true, Isolate = true, or Partition = true are to be considered. The test passes when one and only one port meet the test conditions.

41.3 Repeater electrical specifications

41.3.1 Electrical isolation

Network segments that have different isolation and grounding requirements shall have those requirements provided by the port-to-port isolation of the repeater set.

41.4 Environmental specifications

41.4.1 General safety

NOTE—Since September 2011, maintenance changes are no longer being considered for this clause. Since February 2021, safety information is in J.2.

All equipment meeting this standard shall conform to IEC 60950: 1991.

41.4.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns; the list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

LAN cable systems described in this subclause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cables and components.
c) High-energy transients coupled onto the LAN cable system.
d) Voltage potential differences between safety grounds to which the various LAN components are connected.

Such electrical safety hazards have to be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures have to be taken to ensure that the intended safety features are not negated during installation of a new network or during modification or maintenance of an existing network. Isolation requirements are defined in 41.4.3.

41.4.2.1 Installation

Sound installation practice, as defined by applicable local codes and regulations, shall be followed in every instance in which such practice is applicable.

41.4.2.2 Grounding

The safety ground, or chassis ground for the repeater set, shall be provided through the main ac power cord via the third wire ground as defined by applicable local codes and regulations.

If the MDI connector should provide a shield connection, the shield may be connected to the repeater safety ground. A network segment connected to the repeater set through the MDI may use a shield. If both ends of the network segment have a shielded MDI connector available, then the shield may be grounded at both ends according to local regulations and ISO/IEC 11801: 1995, and as long as the ground potential difference between both ends of the network segment is less than 1 V rms.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

WARNING

It is assumed that the equipment to which the repeater is attached is properly grounded and not left floating nor serviced by a "doubly insulated ac power distribution system." The use of floating or insulated equipment, and the consequent implications for safety, are beyond the scope of this standard.

41.4.2.3 Installation and maintenance guidelines

During installation and maintenance of the cable plant, care should be taken to ensure that uninsulated network cable connectors do not make electrical contact with unintended conductors or ground.

41.4.3 Electrical isolation

There are two electrical power distribution environments to be considered that require different electrical isolation properties:

a) *Environment A.* When a LAN or LAN segment, with all its associated interconnected equipment, is entirely contained within a single low-voltage power distribution system and within a single building.
b) *Environment B.* When a LAN crosses the boundary between separate power distribution systems or the boundary of a single building.

41.4.3.1 Environment A requirements

Attachment of network segments via repeater sets requires electrical isolation of 500 V rms, one-minute withstand, between the segment and the protective ground of the repeater unit.

41.4.3.2 Environment B requirements

The attachment of network segments that cross environment B boundaries requires electrical isolation of 1500 Vrms, one-minute withstand, between each segment and all other attached segments and also the protective ground of the repeater unit.

The requirements for interconnected electrically conducting LAN segments that are partially or fully external to a single building environment may require additional protection against lightning strike hazards. Such requirements are beyond the scope of this standard. It is recommended that the above situation be handled by the use of nonelectrically conducting segments (e.g., fiber optic).

It is assumed that any nonelectrically conducting segments will provide sufficient isolation within that media to satisfy the isolation requirements of environment B.

41.4.4 Reliability

A two-port repeater set shall be designed to provide a mean time between failure (MTBF) of at least 50 000 hours of continuous operation without causing a communications failure among stations attached to the network medium. Repeater sets with more than two ports shall add no more than 3.46×10^{-6} failures per hour for each additional port.

The repeater set electronics should be designed to minimize the probability of component failures within the repeater electronics that prevent communications among other PHYs on the individual segments. Connectors and other passive components comprising the means of connecting the repeater to the cable should be designed to minimize the probability of total network failure.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

41.4.5 Environment

41.4.5.1 Electromagnetic emission

The repeater shall comply with applicable local and national codes for the limitation of electromagnetic interference.

41.4.5.2 Temperature and humidity

The repeater is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

It is recommended that manufacturers indicate in the literature associated with the repeater the operating environmental conditions to facilitate selection, installation, and maintenance.

41.5 Repeater labeling

It is required that each repeater (and supporting documentation) shall be labeled in a manner visible to the user with these parameters:

a) Crossover ports appropriate to the respective PHY shall be marked with an X.

Additionally it is recommended that each repeater (and supporting documentation) also be labeled in a manner visible to the user with at least these parameters:

b) Data rate capability in Mb/s
c) Any applicable safety warnings
d) Port type, i.e., 1000BASE-CX, 1000BASE-SX, 1000BASE-LX, and 1000BASE-T
e) Worst-case bit time delays between any two ports appropriate for
    1) Start-of-packet propagation delay
    2) Start-of-collision Jam propagation delay
    3) Cessation-of-collision Jam propagation delay

41.6 Protocol implementation conformance statement (PICS) proforma for Clause 41, Repeater for 1000 Mb/s baseband networks[86]

41.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 41, Repeater for 1000 Mb/s baseband networks, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

[86] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

41.6.2 Identification

41.6.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

41.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2018, Clause 41, Repeater for 1000 Mb/s baseband networks
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2018.)	

Date of Statement	

41.6.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
*SXP	Repeater supports 1000BASE-SX connections	41.1.2.2		O	Yes [ ] No [ ]

42. System considerations for multisegment 1000 Mb/s networks

42.1 Overview

This clause provides information on building 1000 Mb/s networks. The 1000 Mb/s technology is designed to be deployed in both homogenous 1000 Mb/s networks and 10/100/1000 Mb/s mixed networks using bridges and/or routers. Network topologies can be developed within a single 1000 Mb/s collision domain, but maximum flexibility is achieved by designing multiple collision domain networks that are joined by bridges and/or routers configured to provide a range of service levels to DTEs. For example, a combined 1000BASE-T/100BASE-T/10BASE-T system built with repeaters and bridges can deliver dedicated or shared service to DTEs at 1000 Mb/s, 100 Mb/s, or 10 Mb/s.

Linking multiple collision domains with bridges maximizes flexibility. Bridged topology designs can provide single data rate (Figure 42–1) or multiple data rate (Figure 42–2) services.

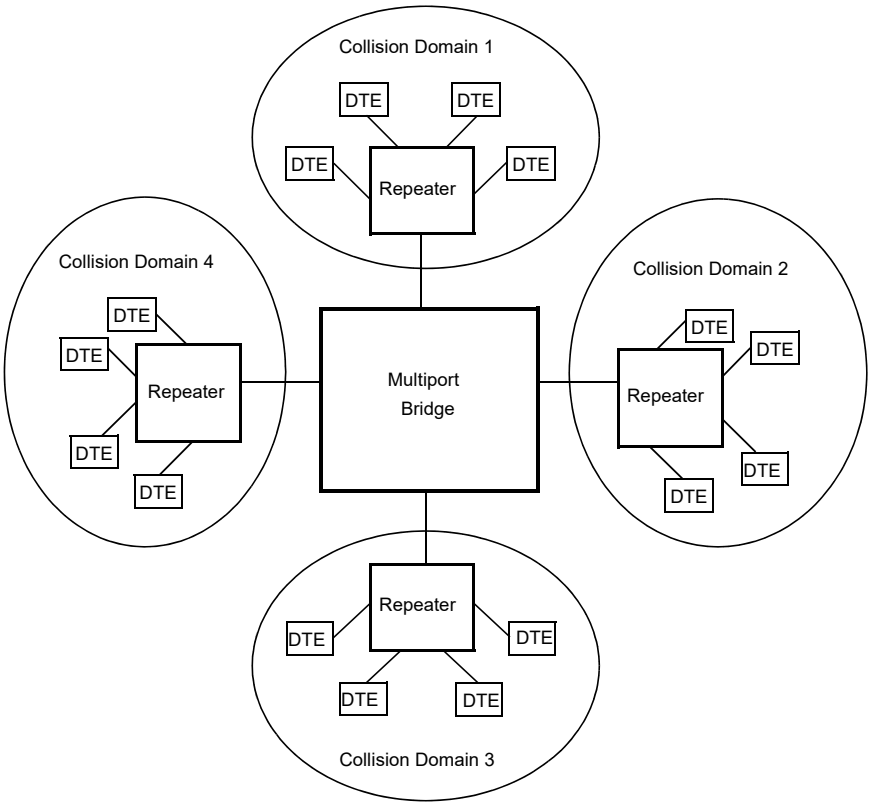

Figure 42–1—1000 Mb/s multiple collision domain topology using multiport bridge

Individual collision domains can be linked by single devices (as shown in Figure 42–1 and Figure 42–2) or by multiple devices from any of several transmission systems. The design of multiple-collision-domain networks is governed by the rules defining each of the transmission systems incorporated into the design.

The design of shared bandwidth 10 Mb/s collision domains is defined in Clause 13; the design of shared bandwidth 100 Mb/s CSMA/CD collision domains is defined in Clause 29; the design of shared bandwidth 1000 Mb/s CSMA/CD collision domains is defined in the following subclauses.

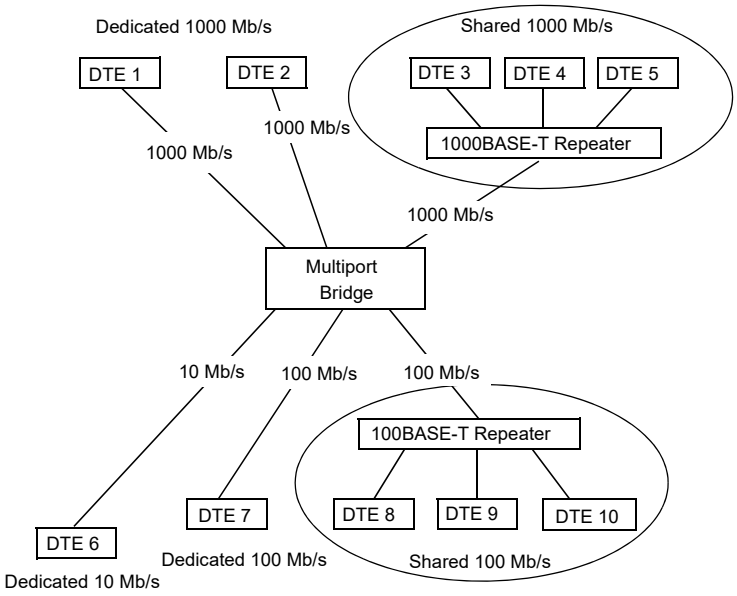

Figure 42–2—Multiple data rate, multiple collision domain topology using multiport bridge

42.1.1 Single collision domain multisegment networks

This clause provides information on building 1000 Mb/s CSMA/CD multisegment networks within a single collision domain. The proper operation of a CSMA/CD network requires the physical size of the collision domain to be limited in order to meet the round-trip propagation delay requirements of 4.2.3.2.3 and 4.4.2, and requires the number of repeaters to be limited to one so as not to exceed the InterFrameGap shrinkage noted in 4.4.2.

This clause provides two network models. Transmission System Model 1 is a set of configurations that have been validated under conservative rules and have been qualified as meeting the requirements set forth above. Transmission System Model 2 is a set of calculation aids that allow those configuring a network to test a proposed configuration against a simple set of criteria that allows it to be qualified. Transmission System Model 2 validates an additional broad set of topologies that are fully functional and do not fit within the simpler, but more restrictive rules of Model 1.

The physical size of a CSMA/CD network is limited by the characteristics of individual network components. These characteristics include the following:

a) Media lengths and their associated propagation time delay.
b) Delay of repeater units (startup, steady-state, and end of event).
c) Delay of MAUs and PHYs (startup, steady-state, and end of event).
d) Interpacket gap shrinkage due to repeater units.
e) Delays within the DTE associated with the CSMA/CD access method.
f) Collision detect and deassertion times associated with the MAUs and PHYs.

Table 42–1 summarizes the delays, measured in Bit Times (BTs), for 1000 Mb/s media segments.

Table 42–1—Delays for network media segments Model 1

Media type	Maximum number of PHYs per segment	Maximum segment length (m)	Maximum medium round-trip delay per segment (BT)
Category 5 Link Segment (1000BASE-T)	2	100	1112
Shielded Jumper Cable Link Segment (1000BASE-CX)	2	25	253
Optical Fiber Link Segment (1000BASE-SX, 1000BASE-LX)	2	316[a]	3192

[a]May be limited by the maximum transmission distance of the link.

42.1.2 Repeater usage

Repeaters are the means used to connect segments of a network medium together into a single collision domain. Different physical signaling systems (e.g., 1000BASE-CX, 1000BASE-SX, 1000BASE-LX, 1000BASE-T) can be joined into a common collision domain using a repeater. Bridges can also be used to connect different signaling systems; however, if a bridge is so used, each LAN connected to the bridge will comprise a separate collision domain.

42.2 Transmission System Model 1

The following network topology constraints apply to networks using Transmission System Model 1.

a) Single repeater topology maximum.
b) Link distances not to exceed the lesser of 316 m or the segment lengths as shown in Table 42–1.

42.3 Transmission System Model 2

Transmission System Model 2 is a single repeater topology with the physical size limited primarily by round-trip collision delay. A network configuration has to be validated against collision delay using a network model for a 1000 Mb/s collision domain. The modeling process is quite straightforward and can easily be done either manually or with a spreadsheet.

The model proposed here is derived from the one presented in 13.4. Modifications have been made to accommodate adjustments for DTE, repeater, and cable speeds.

For a network consisting of two 1000BASE-T DTEs as shown in Figure 42–3, a crossover connection may be required if the auto-crossover function is not implemented. See 40.4 and 40.8.

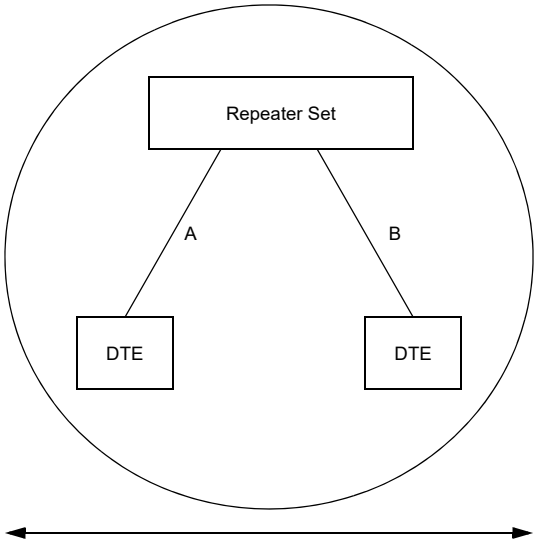

Figure 42–4—Model 1: Single repeater

Table 42–2—Maximum Model 1 collision domain diameter[a]

Configuration	Category 5 Twisted-Pair (T)	Shielded Jumper Cable (CX)	Optical Fiber (SX/LX)	Mixed Category 5 and Fiber (T and SX/LX)	Mixed Shielded Jumper and Fiber (CX and SX/LX)
DTE-DTE (see Figure 42–3)	100	25	316[b]	NA	NA
One repeater (see Figure 42–4)	200	50	220	210[c]	220[d]

[a]In meters.
[b]May be limited by the maximum transmission distance of the link.
[c]Assumes 100 m of Category 5 twisted-pair and one Optical Fiber link of 110 m.
[d]Assumes 25 m of Shielded Jumper Cable and one Optical Fiber link of 195 m.

42.3.1 Round-trip collision delay

For a network configuration to be valid, it has to be possible for any two DTEs on the network to properly arbitrate for the network. When two or more stations attempt to transmit within a slot time interval, each station has to be notified of the contention by the returned “collision” signal within the “collision window” (see 4.1.2.2). Additionally, the maximum length fragment created on a 1000 Mb/s network has to contain less than 512 bytes after the Start Frame Delimiter (SFD). These requirements limit the physical diameter (maximum distance between DTEs) of a network. The maximum round-trip delay has to be qualified between all pairs of DTEs in the network. In practice this means that the qualification has to be done between those that, by inspection of the topology, are candidates for the longest delay. The following network modeling methodology is provided to assist that calculation.

42.3.1.1 Worst-case path delay value (PDV) selection

The worst-case path through a network to be validated is identified by examination of aggregate DTE delays, cable delays, and repeater delay. The worst case consists of the path between the two DTEs at opposite ends of the network that have the longest round-trip time. Figure 42–5 shows a schematic representation of a one-repeater path.

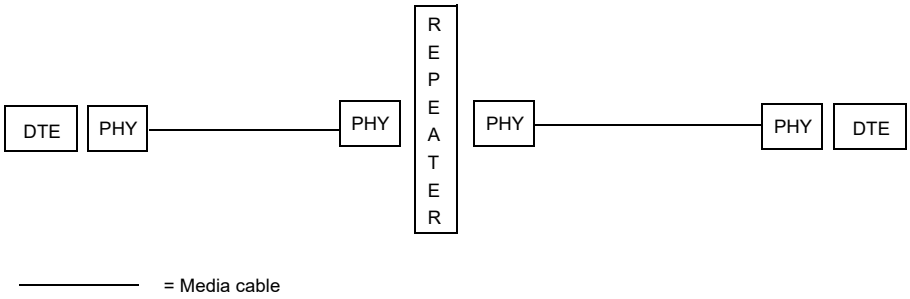

Figure 42–5—System Model 2: Single repeater

42.3.1.2 Worst-case PDV calculation

Once a set of paths is chosen for calculation, each is checked for validity against the following formula:

PDV = ∑link delays (LSDV) + repeater delay + DTE delays + safety margin

Values for the formula variables are determined by the following method:

a) Determine the delay for each link segment (Link Segment Delay Value, or LSDV), using the formula

LSDV=2 (for round-trip delay) × segment length × cable delay for this segment

NOTE 1—Length is the sum of the cable lengths between the PHY interfaces at the repeater and PHY interfaces at the farthest DTE. All measurements are in meters.

NOTE 2—Cable delay is the delay specified by the manufacturer or the maximum value for the type of cable used as shown in Table 42–3. For this calculation, cable delay needs to be specified in bit times per meter (BT/m). Table 42–4 can be used to convert values specified relative to the speed of light (%c) or nanoseconds per meter (ns/m).

NOTE 3—When actual cable lengths or propagation delays are not known, use the Max delay in bit times as specified in Table 42–3 for copper cables. Delays for fiber should be calculated, as the value found in Table 42–3 will be too large for most applications.

NOTE 4—The value found in Table 42–3 for Shielded Jumper Cable is the maximum delay for cable with solid dielectric. Cables with foam dielectric may have a significantly smaller delay.

b) Sum together the LSDVs for all segments in the path.
c) Determine the delay for the repeater. If model-specific data is not available from the manufacturer, enter the appropriate default value from Table 42–3.
d) Use the DTE delay value shown in Table 42–3 unless your equipment manufacturer defines a different value. If the manufacturer's supplied values are used, the DTE delays of both ends of the worst- case path should be summed together.
e) Decide on appropriate safety margin—0 to 40 bit times—for the PDV calculation. Safety margin is used to provide additional margin to accommodate unanticipated delay elements, such as extra-long connecting cable runs between wall jacks and DTEs. (A safety margin of 32 BT is recommended.)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

f) Insert the values obtained through the calculations above into the following formula to calculate the PDV. (Some configurations may not use all the elements of the formula.)

$$PDV = \sum \text{link delays (LSDV)} + \text{repeater delay} + \text{DTE delay} + \text{safety margin}$$

g) If the PDV is less than 4096, the path is qualified in terms of worst-case delay.
h) Late collisions and/or CRC errors may be indications that path delays exceed 4096 BT.

Table 42–3—Network component delays, Transmission System Model 2

Component	Round-trip delay in bit times per meter (BT/m)	Maximum round-trip delay in bit times (BT)
Two DTEs		864
Category 5 Cable segment	11.12	1112 (100 m)
Shielded Jumper Cable segment	10.10	253 (25 m)
Optical Fiber Cable segment	10.10	1111 (110 m)
Repeater		976

Table 42–4—Conversion table for cable delays

0.9	3.71	3.71

42.4 Full duplex 1000 Mb/s topology limitations

Unlike half duplex CSMA/CD networks, the physical size of full duplex 1000 Mb/s networks is not limited by the round-trip collision propagation delay. Instead, the maximum link length between DTEs is limited only by the signal transmission characteristics of the specific link.

44. Introduction to 10 Gb/s baseband networks

44.1 Overview

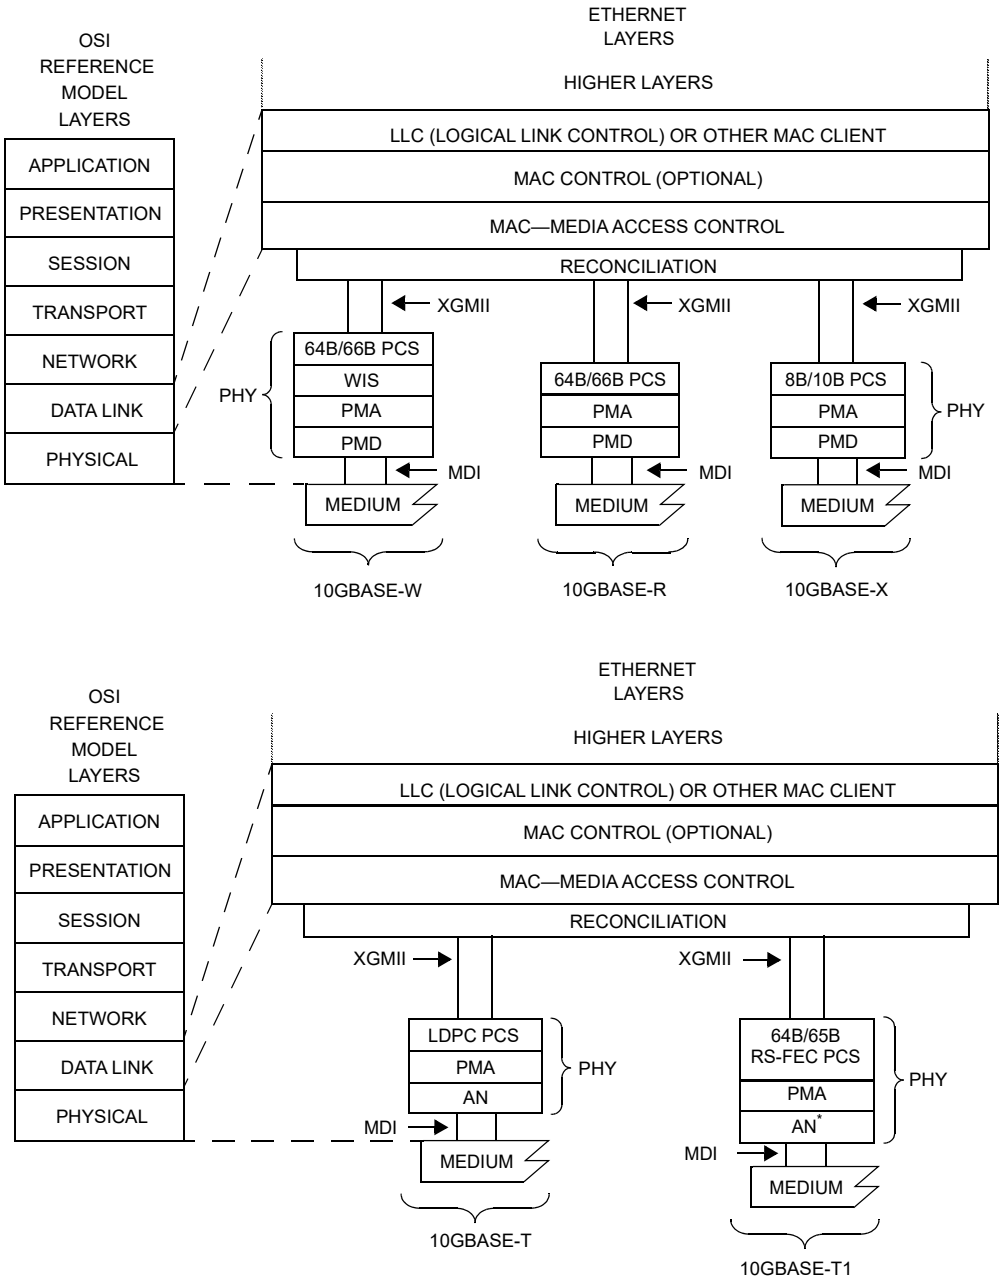
44.1.1 Scope

10 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer, connected through a 10 Gigabit Media Independent Interface (XGMII) to Physical Layer devices (PHYs) such as 10GBASE-SR, 10GBASE-LX4, 10GBASE-CX4, 10GBASE-LRM, 10GBASE-LR, 10GBASE-ER, 10GBASE-SW, 10GBASE-LW, 10GBASE-EW, 10GBASE-T, and 10GBASE-T1.

10 Gigabit Ethernet extends the IEEE 802.3 MAC beyond 1000 Mb/s to 10 Gb/s. The bit rate is faster and the bit times are shorter—both in proportion to the change in bandwidth. The minimum packet transmission time has been reduced by a factor of ten. A rate control mode (see 4.2.3.2.2) is added to the MAC to adapt the average MAC data rate to the SONET/SDH data rate for WAN-compatible applications of this standard. Achievable topologies for 10 Gb/s operation are comparable to those found in 1000BASE-X full duplex mode and equivalent to those found in WAN applications.

10 Gigabit Ethernet is defined for full duplex mode of operation only.

44.1.2 Objectives



The following are the objectives of 10 Gigabit Ethernet:

a) Support the full duplex Ethernet MAC.
b) Provide 10 Gb/s data rate at the XGMII.
c) Support LAN PMDs operating at 10 Gb/s, and WAN PMDs operating at SONET STS-192c/SDH VC-4-64c rate.
d) Support cable plants using cabled optical fiber compliant with ISO/IEC 11801:1995.
e) Allow for a nominal network extent of up to 40 km.
f) Support operation over a twinaxial cable assembly for wiring closet and data center applications.
g) Support operation over selected copper media from ISO/IEC 11801:2002.
h) Support operation over a single balanced pair of conductors.
i) Support a BER objective of 10^{-12}.

44.1.3 Relationship of 10 Gigabit Ethernet to the ISO OSI reference model

10 Gigabit Ethernet couples the IEEE 802.3 MAC to a family of 10 Gb/s Physical Layers. The relationships among 10 Gigabit Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 44–1.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience. The only exceptions are as follows:

a) The XGMII, which, when implemented at an observable interconnection port, uses a four octet-wide data path as specified in Clause 46.
b) The management interface, which, when physically implemented as the MDIO/MDC (Management Data Input/Output and Management Data Clock) at an observable interconnection port, uses a bit-wide data path as specified in Clause 45.
c) The PMA Service Interface, which, when physically implemented as the XSBI (10 Gigabit Sixteen Bit Interface) at an observable interconnection port, uses a 16-bit-wide data path as specified in Clause 51.
d) The MDI as specified in Clause 53 for 10GBASE-LX4, in Clause 54 for 10GBASE-CX4, in Clause 55 for 10GBASE-T, in Clause 68 for 10GBASE-LRM, in Clause 149 for 10GBASE-T1, and in Clause 52 for other PMD types.

44.1.4 Summary of 10 Gigabit Ethernet sublayers

44.1.4.1 Reconciliation Sublayer (RS) and 10 Gigabit Media Independent Interface (XGMII)

The 10 Gigabit Media Independent Interface (Clause 46) provides an interconnection between the Media Access Control (MAC) sublayer and Physical Layer devices (PHYs). This XGMII supports 10 Gb/s operation through its 32-bit-wide transmit and receive data paths. The Reconciliation Sublayer provides a mapping between the signals provided at the XGMII and the MAC/PLS service definition.

While the XGMII is an optional interface, it is used extensively in this standard as a basis for functional specification and provides a common service interface for Clause 47, Clause 48, Clause 49, Clause 55, and Clause 149.

44.1.4.2 XGMII Extender Sublayer (XGXS) and 10 Gigabit Attachment Unit Interface (XAUI)

The 10 Gigabit Attachment Unit Interface (Clause 47) provides an interconnection between two XGMII Extender sublayers to increase the reach of the XGMII. This XAUI supports 10 Gb/s operation through its four-lane, differential-pair transmit and receive paths. The XGXS provides a mapping between the signals provided at the XGMII and the XAUI.

44.1.4.3 Management interface (MDIO/MDC)

The MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMD) and Station Management (STA) entities.

44.1.4.4 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. The generic term 10 Gigabit Ethernet refers to any use of the 10 Gb/s IEEE 802.3 MAC (the 10 Gigabit Ethernet MAC) coupled with any IEEE 802.3 10GBASE Physical Layer implementation. Table 44–1 specifies the correlation between nomenclature and clauses. Implementations conforming to one or more nomenclatures shall meet the requirements of the corresponding clauses.

10GBASE-LW		M	M	M		M						
10GBASE-ER		M		M			M					
10GBASE-EW		M	M	M			M					

[a] M = Mandatory

The term 10GBASE-X, specified in Clause 48, Clause 53, and Clause 54, refers to a specific family of Physical Layer implementations based upon 8B/10B data coding method. The 10GBASE-X family of Physical Layer implementations is composed of 10GBASE-LX4 and 10GBASE-CX4.

The term 10GBASE-R refers to a specific family of Physical Layer implementations. The 10GBASE-R family of Physical Layer implementations based upon 64B/66B data coding method is composed of 10GBASE-SR, 10GBASE-LR, 10GBASE-ER, and 10GBASE-LRM.

The term 10GBASE-W, specified in Clause 49 through Clause 52, refers to a specific family of Physical Layer implementations based upon STS-192c/SDH VC-4-64c encapsulation of 64B/66B encoded data. The 10GBASE-W family of Physical Layer standards has been adapted from the ATIS-0600416.1999(R2010) (SONET STS-192c/SDH VC-4-64c) Physical Layer specifications. The 10GBASE-W family of Physical Layer implementations is composed of 10GBASE-SW, 10GBASE-LW, and 10GBASE-EW.

All 10GBASE-R and 10GBASE-W PHY devices share a common PCS specification (see Clause 49). The 10GBASE-W PHY devices also require the use of the WAN Interface Sublayer, (WIS) (Clause 50).

The term 10GBASE-T, specified in Clause 55, refers to a specific Physical Layer implementation based upon 64B/65B data coding placed in a low density parity check (LDPC) frame that is mapped to a 128 double-square (DSQ128) constellation for transmission on 4-pair, twisted-pair copper cabling.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The term 10GBASE-T1, specified in Clause 149, refers to a specific Physical Layer implementation based upon 64B/65B data coding method placed in an RS-FEC frame that is Gray-code mapped to PAM4 for transmission over a single balanced pair of conductors.

Physical Layer device specifications are contained in Clause 52, Clause 53, Clause 54, Clause 55, Clause 68, and Clause 149.

Annex 44A contains diagrams of the data flow between the MAC and the MDI, as well as information on the relation between data valid signals and loopback.

44.1.4.5 WAN Interface Sublayer (WIS), type 10GBASE-W

The WIS provides a 10GBASE-W device with the capability to transmit and receive IEEE 802.3 MAC frames within the payload envelope of a SONET STS-192c/SDH VC-4-64c frame.

44.1.5 Management

Managed objects, attributes, and actions are defined for all 10 Gigabit Ethernet components. These items are defined in Clause 30.

44.2 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

44.3 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices. Table 44–2 contains the values of maximum sublayer round-trip (sum of transmit and receive) delay in bit time as specified in 1.4 and pause_quanta as specified in 31B.2.

Equation (44–1) specifies the calculation of bit time per meter of fiber or electrical cable based upon the parameter *n*, which represents the ratio of the speed of electromagnetic propagation in the fiber or electrical cable to the speed of light in a vacuum. The value of *n* should be available from the fiber or electrical cable manufacturer, but if no value is known then a conservative delay estimate can be calculated using a default value of $n = 0.66$. The speed of light in a vacuum is $c = 3 \times 10^8$ m/s. Table 44–3 can be used to convert fiber or electrical cable delay values specified relative to the speed of light or in nanoseconds per meter.

$$\text{cable delay} = \frac{10^{10}}{nc} \text{ BT/m} \tag{44–1}$$

44.4 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 45 through Clause 55, Clause 68, and Clause 149, demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the 10 Gigabit Ethernet PICS conforms to the same notation and conventions used in 100BASE-T (see 21.6).

45. Management Data Input/Output (MDIO) Interface

45.1 Overview

This clause defines the logical and electrical characteristics of an extension to the two signal Management Data Input/Output (MDIO) Interface specified in Clause 22.

The purpose of this extension is to provide the ability to access more device registers while still retaining logical compatibility with the MDIO interface defined in Clause 22. Clause 22 specifies the MDIO frame format and uses an ST code of 01 to access registers. In this clause, additional registers are added to the address space by defining MDIO frames that use an ST code of 00.

This extension to the MDIO interface is applicable to the following:

— Implementations that operate at speeds of 2.5 Gb/s and above.
— Implementations of 10PASS-TS and 2BASE-TL subscriber network Physical Layer devices.
— Implementations of 10, 100, or 1000 Mb/s with additional management functions beyond those defined in Clause 22.

The MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the registers is recommended.

Throughout this clause, an “a.b.c” format is used to identify register bits, where “a” is the device address, “b” is the register address, and “c” is the bit number within the register.

45.1.1 Summary of major concepts

The following are major concepts of the MDIO Interface:

a) Preserve the management frame structure defined in 22.2.4.5.
b) Define a mechanism to address more registers than specified in 22.2.4.5.
c) Define ST and OP codes to identify and control the extended access functions.
d) Provide an electrical interface specification that is compatible with common digital CMOS ASIC processes.

45.1.2 Application

This clause defines a management interface between Station Management (STA) and the sublayers that form a Physical Layer device (PHY) entity. Where a sublayer, or grouping of sublayers, is an individually manageable entity, it is known as an MDIO Manageable Device (MMD). This clause allows a single STA, through a single MDIO interface, to access up to 32 PHYs (defined as PRTAD in the frame format defined in 45.3) consisting of up to 32 MMDs as shown in Figure 45–1. The MDIO interface can support up to a maximum of 65 536 registers in each MMD.

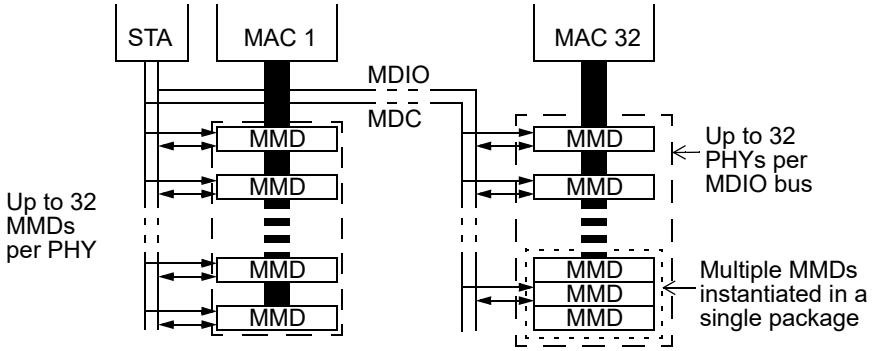

Figure 45–1—DTE and MMD devices

45.2 MDIO Interface registers

The management interface specified in Clause 22 provides a simple, two signal, serial interface to connect a Station Management entity and a managed PHY for providing access to management parameters and services. The interface is referred to as the MII management interface.

The MDIO interface is based on the MII management interface, but differs from it in several ways. The MDIO interface uses indirect addressing to create an extended address space allowing a much larger number of registers to be accessed within each MMD. The MDIO address space is orthogonal to the MII management interface address space. The mechanism for the addressing is defined in 45.3. The MDIO electrical interface operates at lower voltages than those specified for the MII management interface. The electrical interface is specified in 45.4. For cases where a single entity combines Clause 45 MMDs with Clause 22 registers, then the Clause 22 registers may be accessed using the Clause 45 electrical interface and the Clause 22 management frame structure. The list of possible MMDs is shown in Table 45–1. The PHY XS and DTE XS devices are the two partner devices used to extend the interface that sits immediately below the Reconciliation Sublayer. For 10 Gigabit Ethernet, the interface extenders are defined as the XGXS devices. For 10PASS-TS and 2BASE-TL, control and monitoring of the TC sublayer is defined in the TC MMD. For 10, 100 and 1000 Mb/s PHYs, further management capability is defined in the Clause 22 extension MMD.

30	Vendor specific 1
31	Vendor specific 2

10PASS-TS and 2BASE-TL each have two port subtypes, 10PASS-TS-O, 10PASS-TS-R, 2BASE-TL-O and 2BASE-TL-R. Hereafter, referred to generically as -O and -R. The -O subtype corresponds to the port located at the service provider end of a subscriber link (the central office end). The -R subtype corresponds to the port located at the subscriber end of a subscriber link (the remote end). See 61.1 for more information.

Some register behavior may differ based on the port subtype. In the case where a register's behavior or definition differs between port subtypes, it is noted in the register description and in the bit definition tables (denoted by "O:" and "R:" in the R/W column).

The Clause 22 extension MMD allows new features to be added to 10, 100, and 1000 Mb/s PHYs beyond those already defined in Clause 22.

If a device supports the MDIO interface it shall respond to all possible register addresses for the device and return a value of zero for undefined and unsupported registers. Writes to undefined registers and read-only registers shall have no effect. The operation of an MMD shall not be affected by writes to reserved and unsupported register bits, and such register bits shall return a value of zero when read.

In the case of two registers that together form a 32-bit counter, whenever the most significant 16-bit register of the counter is read, the 32-bit counter value is latched into the register pair, the value being latched before the contents of the most significant 16 bits are driven on the MDIO interface and the contents of both registers are cleared to all zeros. A subsequent read from the least significant 16-bit register will return the least significant 16 bits of the latched value, but will not change the contents of the register pair. Writing to these registers has no effect. Counters that adhere to this behavior are marked in their bit definition tables with the tag "MW = Multi-word".

To ensure compatibility with future use of reserved bits and registers, the Management Entity should write to reserved bits with a value of zero and ignore reserved bits on read.

Some of the bits within MMD registers are defined as latching low (LL) or latching high (LH). When a bit is defined as latching low and the condition for the bit to be low has occurred, the bit shall remain low until after it has been read via the management interface. Once such a read has occurred, the bit shall assume a value based on the current state of the condition it monitors. When a bit is defined as latching high and the condition for the bit to be high has occurred, the bit shall remain high until after it has been read via the management interface. Once such a read has occurred, the bit shall assume a value based on the current state of the condition it monitors.

For multi-bit fields, the lowest numbered bit of the field in the register corresponds to the least significant bit of the field.

Figure 45–2 describes the signal terminology used for the MMDs.

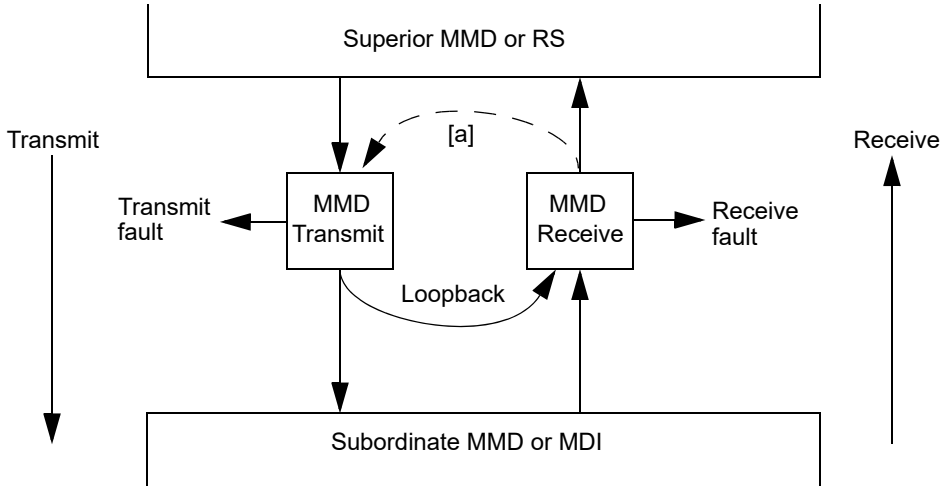

Figure 45–2—MMD signal terminology

[a] Direction of the optional PHY XS loopback

Each MMD contains registers 5 and 6, as defined in Table 45–2. Bits read as a one in this register indicate which MMDs are instantiated within the same package as the MMD being accessed. Bit 5.0 is used to indicate that Clause 22 functionality has been implemented within a Clause 45 electrical interface device. Bit 6.13 indicates that Clause 22 functionality is extended using the Clause 45 electrical interface through MMD 29. The definition of the term package is vendor specific and could be a chip, module, or other similar entity.

Table 45–2—Devices in package registers bit definitions

Bit(s)[a]	Name	Description	R/W[b]

[a]m = address of MMD accessed (see Table 45–1)
[b]RO = Read only
[c]Separated PMAs are defined in 45.2.1

45.2.1 PMA/PMD registers

For devices operating at 25 Gb/s or higher speeds, the PMA may be instantiated as multiple sublayers (see 83.1.4, 109.1.4, and 120.1.4 for how MMD addresses are allocated to multiple PMA sublayers for the respective speeds). A PMA sublayer that is packaged with the PMD is addressed as MMD 1. More addressable instances of PMA sublayers, each one separated from lower addressable instances, may be implemented and addressed as MMD 8, 9, 10, and 11 where MMD 8 is the closest to the PMD and MMD 11 is the furthest from the PMD. The addresses and functions of all registers in MMD 8, 9, 10, and 11 are defined identically to MMD 1, except registers m.5 and m.6 as defined in Table 45–2.

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.98	2B link partner unavailable seconds[a]	45.2.1.72
1.99	2B state defects	45.2.1.73
1.100	2B link partner state defects[a]	45.2.1.74
1.101	2B negotiated constellation	45.2.1.75
1.102 through 1.109	2B extended PMD parameters	45.2.1.76
1.110 through 1.128	Reserved	
1.129	MultiGBASE-T status	45.2.1.77
1.130	MultiGBASE-T pair swap and polarity	45.2.1.78
1.131	MultiGBASE-T TX power backoff and PHY short reach setting	45.2.1.79
1.132	MultiGBASE-T test mode	45.2.1.80
1.133	SNR operating margin channel A	45.2.1.81
1.134	SNR operating margin channel B	45.2.1.82
1.135	SNR operating margin channel C	45.2.1.83
1.136	SNR operating margin channel D	45.2.1.84
1.137	Minimum margin channel A	45.2.1.85
1.138	Minimum margin channel B	45.2.1.86
1.139	Minimum margin channel C	45.2.1.87
1.140	Minimum margin channel D	45.2.1.88
1.141	RX signal power channel A	45.2.1.89
1.142	RX signal power channel B	45.2.1.90
1.143	RX signal power channel C	45.2.1.91
1.144	RX signal power channel D	45.2.1.92
1.145 through 1.146	MultiGBASE-T skew delay	45.2.1.93
1.147	MultiGBASE-T fast retrain status and control	45.2.1.94
1.148 through 1.149	Reserved	
1.150	BASE-R PMD control	45.2.1.95
1.151	BASE-R PMD status	45.2.1.96
1.152	BASE-R LP coefficient update, lane 0	45.2.1.97
1.153	BASE-R LP status report, lane 0	45.2.1.98
1.154	BASE-R LD coefficient update, lane 0	45.2.1.99
1.155	BASE-R LD status report, lane 0	45.2.1.100
1.156	BASE-R PMD status 2	45.2.1.101
1.157	BASE-R PMD status 3	45.2.1.102
1.158 through 1.159	Reserved	
1.160	1000BASE-KX/2.5GBASE-KX control	45.2.1.103
1.161	1000BASE-KX/2.5GBASE-KX status	45.2.1.104
1.162 through 1.164	PMA overhead control 1, 2, and 3	45.2.1.105

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.165, 1.166	PMA overhead status 1 and 2	45.2.1.106
1.167 through 1.169	Reserved	
1.170	BASE-R FEC ability	45.2.1.107
1.171	BASE-R FEC control	45.2.1.108
1.172 through 1.173	Single-lane PHY BASE-R FEC corrected blocks counter	45.2.1.109
1.174 through 1.175	Single-lane PHY BASE-R FEC uncorrected blocks counter	45.2.1.110
1.176 through 1.178	Reserved	
1.179	CAUI-4 C2M and 25GAUI C2M recommended CTLE	45.2.1.111
1.180	25GAUI C2C and lane 0 CAUI-4 C2C transmitter equalization, receive direction	45.2.1.112
1.181 through 1.183	CAUI-4 chip-to-chip transmitter equalization, receive direction, lane 1 through lane 3	45.2.1.113
1.184	25GAUI C2C and lane 0 CAUI-4 C2C transmitter equalization, transmit direction	45.2.1.114
1.185 through 1.187	CAUI-4 chip-to-chip transmitter equalization, transmit direction, lane 1 through lane 3	45.2.1.115
1.188 through 1.199	Reserved	
1.200	RS-FEC control	45.2.1.116
1.201	RS-FEC status	45.2.1.117
1.202, 1.203	RS-FEC corrected codewords counter	45.2.1.118
1.204, 1.205	RS-FEC uncorrected codewords counter	45.2.1.119
1.206	RS-FEC lane mapping	45.2.1.120
1.207 through 1.209	Reserved	
1.210 through 1.217	RS-FEC symbol error counter, lane 0 to 3	45.2.1.121, 45.2.1.122
1.218 through 1.229	Reserved	
1.230 through 1.249	RS-FEC BIP error counter, lane 0 to 19	45.2.1.123, 45.2.1.124
1.250 through 1.269	RS-FEC PCS lane mapping, lane 0 to 19	45.2.1.125, 45.2.1.126
1.270 through 1.279	Reserved	
1.280 through 1.283	RS-FEC PCS alignment status 1 through 4	45.2.1.127 to 45.2.1.130
1.284 through 1.299	Reserved	
1.300 through 1.339	BASE-R FEC corrected blocks counter, lanes 0 through 19	45.2.1.131
1.340 through 1.399	Reserved	
1.400 through 1.407	200GAUI-8 and 400GAUI-16 chip-to-module recommended CTLE, lane 0 through lane 7	45.2.1.132, 45.2.1.133
1.408 through 1.415	400GAUI-16 chip-to-module recommended CTLE, lane 8 through lane 15	45.2.1.134
1.416 through 1.499	Reserved

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.500 through 1.515	50GAUI-n, 100GAUI-2, 200GAUI-n, and 400GAUI-n chip-to-chip transmitter equalization, receive direction, lane 0 through lane 15	45.2.1.135, 45.2.1.136
1.516 through 1.531	50GAUI-n, 100GAUI-2, 200GAUI-n, and 400GAUI-n chip-to-chip transmitter equalization, transmit direction, lane 0 through lane 15	45.2.1.137, 45.2.1.138
1.532 through 1.599	Reserved	
1.600	PMA precoder control Tx output	45.2.1.139
1.601	PMA precoder control Rx input	45.2.1.140
1.602	PMA precoder control Rx output	45.2.1.141
1.603	PMA precoder control Tx input	45.2.1.142
1.604	PMA precoder request flag	45.2.1.143
1.605	PMA precoder request Rx input status	45.2.1.144
1.606	PMA precoder request Tx input status	45.2.1.145
1.607 through 1.649	Reserved	
1.650, 1.651	RS-FEC degraded SER activate threshold	45.2.1.146
1.652, 1.653	RS-FEC degraded SER deactivate threshold	45.2.1.147
1.654, 1.655	RS-FEC degraded SER interval	45.2.1.148
1.656 through 1.699	Reserved	
1.700 through 1.739	BASE-R FEC uncorrected blocks counter, lanes 0 through 19	45.2.1.149
1.740 through 1.799	Reserved	
1.800	Tx optical channel control	45.2.1.150
1.801	Tx optical channel ability 1	45.2.1.151
1.802	Tx optical channel ability 2	45.2.1.152
1.803	Tx optical channel ability 3	45.2.1.153
1.804 through 1.819	Reserved	
1.820	Rx optical channel control	45.2.1.154
1.821	Rx optical channel ability 1	45.2.1.155
1.822	Rx optical channel ability 2	45.2.1.156
1.823	Rx optical channel ability 3	45.2.1.157
1.824 through 1.899	Reserved	
1.900	BASE-H PMA/PMD control	45.2.1.158
1.901 through 1.999	Reserved	
1.1000 through 1.1002	Nx25G-EPON PMA/PMD extended ability	45.2.1.159
1.1003 through 1.1099	Reserved	
1.1100	BASE-R LP coefficient update, lane 0 (copy)	45.2.1.97
1.1101 through 1.1109	BASE-R LP coefficient update, lanes 1 through 9	45.2.1.160
1.1110 through 1.1119	Reserved	
1.1120 through 1.1123	BASE-R PAM4 PMD training LP control, lane 0 through lane 3	45.2.1.161
1.1124 through 1.1199	Reserved

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.1200	BASE-R LP status report, lane 0 (copy)	45.2.1.98
1.1201 through 1.1209	BASE-R LP status report, lanes 1 through 9	45.2.1.162
1.1210 through 1.1219	Reserved	
1.1220 through 1.1223	BASE-R PAM4 PMD training LP status, lane 0 through lane 3	45.2.1.163
1.1224 through 1.1299	Reserved	
1.1300	BASE-R LD coefficient update, lane 0 (copy)	45.2.1.99
1.1301 through 1.1309	BASE-R LD coefficient update, lanes 1 through 9	45.2.1.164
1.1310 through 1.1319	Reserved	
1.1320 through 1.1323	BASE-R PAM4 PMD training LD control, lane 0 through lane 3	45.2.1.165
1.1324 through 1.1399	Reserved	
1.1400	BASE-R LD status report, lane 0 (copy)	45.2.1.100
1.1401 through 1.1409	BASE-R LD status report, lanes 1 through 9	45.2.1.166
1.1410 through 1.1419	Reserved	
1.1420 through 1.1423	BASE-R PAM4 PMD training LD status, lane 0 through lane 3	45.2.1.167
1.1424 through 1.1449	Reserved	
1.1450 through 1.1453	PMD training pattern, lanes 0 to 3	45.2.1.168
1.1454 through 1.1499	Reserved	
1.1500	Test-pattern ability	45.2.1.169
1.1501	PRBS pattern testing control	45.2.1.170
1.1502 through 1.1509	Reserved	
1.1510	Square wave testing control	45.2.1.171
1.1511	Reserved	
1.1512	PRBS13Q testing control	45.2.1.172
1.1513 through 1.1599	Reserved	
1.1600 through 1.1615	PRBS Tx error counters, lane 0 through lane 15	45.2.1.173
1.1616 through 1.1699	Reserved	
1.1700 through 1.1715	PRBS Rx error counters, lane 0 through lane 15	45.2.1.174
1.1716 through 1.1799	Reserved	
1.1800	TimeSync PMA/PMD capability	45.2.1.175
1.1801 through 1.1804	TimeSync PMA/PMD transmit path data delay	45.2.1.176
1.1805 through 1.1808	TimeSync PMA/PMD receive path data delay	45.2.1.177
1.1809 through 1.1899	Reserved	
1.1900	10GPASS-XR control and status	45.2.1.178
1.1901	DS OFDM control	45.2.1.179
1.1902 through 1.1906	DS OFDM channel frequency control	45.2.1.180
1.1907	US OFDM control	45.2.1.181
1.1908	US OFDM channel frequency control	45.2.1.182

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.1909	US OFDMA pilot pattern	45.2.1.183
1.1910	Profile control	45.2.1.184
1.1911	DS PHY Link control	45.2.1.185
1.1912	US PHY Link control	45.2.1.186
1.1913 and 1.1914	PHY Discovery control	45.2.1.187
1.1915	New CNU control	45.2.1.188
1.1916 through 1.1920	New CNU info	45.2.1.189
1.1921	DS PHY Link frame counter	45.2.1.190
1.1922 and 1.1923	PMA/PMD timing offset	45.2.1.191
1.1924	PMA/PMD power offset	45.2.1.192
1.1925 and 1.1926	PMA/PMD ranging offset	45.2.1.193
1.1927 through 1.1929	DS PMA/PMD data rate	45.2.1.194
1.1930 through 1.1932	US PMA/PMD data rate	45.2.1.195
1.1933 and 1.1934	10GPASS-XR FEC codeword counter	45.2.1.196
1.1935 and 1.1936	10GPASS-XR FEC codeword success counter	45.2.1.197
1.1937 and 1.1938	10GPASS-XR FEC codeword fail counter	45.2.1.198
1.1939	PHY Link EPFH counter	45.2.1.199
1.1940	PHY Link EPFH error counter	45.2.1.200
1.1941	PHY Link EPCH counter	45.2.1.201
1.1942	PHY Link EPCH error counter	45.2.1.202
1.1943	PHY Link EMB counter	45.2.1.203
1.1944	PHY Link EMB error counter	45.2.1.204
1.1945	PHY Link FPMB counter	45.2.1.205
1.1946	PHY Link FPMB error counter	45.2.1.206
1.1947	US PHY Link response time	45.2.1.207
1.1948	10GPASS-XR modulation ability	45.2.1.208
1.1949	PHY Discovery Response power control	45.2.1.209
1.1950	US target receive power	45.2.1.210
1.1951 through 1.1955	DS transmit power	45.2.1.211
1.1956 and 1.1957	US receive power measurement	45.2.1.212
1.1958	Reported power	45.2.1.213
1.1959 through 1.2099	Reserved	
1.2100	BASE-T1 PMA/PMD control	45.2.1.214
1.2101	Reserved	
1.2102	100BASE-T1 PMA/PMD test control	45.2.1.215
1.2103 through 1.2199	Reserved	
1.2200	IFEC control	45.2.1.216

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.2201	IFEC status	45.2.1.217
1.2202, 1.2203	IFEC corrected codewords counter	45.2.1.218
1.2204, 1.2205	IFEC uncorrected codewords counter	45.2.1.219
1.2206	IFEC lane mapping	45.2.1.220
1.2207 through 1.2209	Reserved	
1.2210 through 1.2217	IFEC symbol error counter, lane 0 to 3	45.2.1.221, 45.2.1.222
1.2218 through 1.2245	Reserved	
1.2246	SC-FEC alignment status 1	45.2.1.223
1.2247	SC-FEC alignment status 2	45.2.1.224
1.2248, 1.2249	Reserved	
1.2250 through 1.2269	SC-FEC lane mapping, lane 0 through 19	45.2.1.225, 45.2.1.226
1.2270 through 1.2275	Reserved	
1.2276, 12277	SC-FEC corrected codewords counter	45.2.1.227
1.2278, 1.2279	SC-FEC uncorrected codewords counter	45.2.1.228
1.2280 through 1.2283	SC-FEC total bits	45.2.1.229
1.2284 through 1.2287	SC-FEC corrected bits	45.2.1.230
1.2288 through 1.2293	Reserved	
1.2294	10BASE-T1L PMA control	45.2.1.231
1.2295	10BASE-T1L PMA status	45.2.1.232
1.2296	10BASE-T1L test mode control	45.2.1.233
1.2297	10BASE-T1S PMA control	45.2.1.234
1.2298	10BASE-T1S PMA status	45.2.1.235
1.2299	10BASE-T1S test mode control	45.2.1.236
1.2300 through 1.2303	Reserved	
1.2304	1000BASE-T1 PMA control	45.2.1.237
1.2305	1000BASE-T1 PMA status	45.2.1.238
1.2306	1000BASE-T1 training	45.2.1.239
1.2307	1000BASE-T1 link partner training	45.2.1.240
1.2308	1000BASE-T1 test mode control	45.2.1.241
1.2309	MultiGBASE-T1 PMA control	45.2.1.242
1.2310	MultiGBASE-T1 PMA status	45.2.1.243
1.2311	MultiGBASE-T1 training	45.2.1.244
1.2312	MultiGBASE-T1 link partner training	45.2.1.245
1.2313	MultiGBASE-T1 test mode control	45.2.1.246
1.2314	MultiGBASE-T1 SNR operating margin	45.2.1.247
1.2315	MultiGBASE-T1 minimum SNR margin	45.2.1.248

Table 45–3—PMA/PMD registers *(continued)*

Register address	Register name	Subclause
1.2316	MultiGBASE-T1 user defined data	45.2.1.249
1.2317	MultiGBASE-T1 link partner user defined data	45.2.1.250
1.2318 through 1.32767	Reserved	
1.32 768 through 1.65 535	Vendor specific	

[a]Register is defined only for -O port types and is reserved for -R ports.

45.2.1.1 PMA/PMD control 1 register (Register 1.0)

The assignment of bits in the PMA/PMD control 1 register is shown in Table 45–4. The default value for each bit of the PMA/PMD control 1 register has been chosen so that the initial state of the device upon power up or completion of reset is a normal operational state without management intervention.

Table 45–4—PMA/PMD control 1 register bit definitions

Bit(s)	Name	Description	R/W[a]
1.0.15	Reset	1 = PMA/PMD reset 0 = Normal operation	R/W SC
1.0.14	Reserved	Value always 0	RO
1.0.13	Speed selection (LSB)	1.0.6 1.0.13 1 1 = bits 5:2 select speed 1 0 = 1000 Mb/s 0 1 = 100 Mb/s 0 0 = 10 Mb/s	R/W
1.0.12	Reserved	Value always 0	RO
1.0.11	Low power	1 = Low-power mode 0 = Normal operation	R/W
1.0.10:7	Reserved	Value always 0	RO
1.0.6	Speed selection (MSB)	1.0.6 1.0.13 1 1 = bits 5:2 select speed 1 0 = 1000 Mb/s 0 1 = 100 Mb/s 0 0 = 10 Mb/s	R/W

Table 45–4—PMA/PMD control 1 register bit definitions *(continued)*

Bit(s)	Name	Description	R/W[a]
1.0.5:2	Speed selection	5 4 3 2 1 1 x x = Reserved 1 0 1 x = Reserved 1 0 0 1 = 400 Gb/s 1 0 0 0 = 200 Gb/s 0 1 1 1 = 5 Gb/s 0 1 1 0 = 2.5 Gb/s 0 1 0 1 = 50 Gb/s 0 1 0 0 = 25 Gb/s 0 0 1 1 = 100 Gb/s 0 0 1 0 = 40 Gb/s 0 0 0 1 = 10PASS-TS/2BASE-TL 0 0 0 0 = 10 Gb/s	R/W
1.0.1	PMA remote loopback	1 = Enable PMA remote loopback mode 0 = Disable PMA remote loopback mode	R/W
1.0.0	PMA local loopback	1 = Enable PMA local loopback mode 0 = Disable PMA local loopback mode	R/W

[a]R/W = Read/Write, SC = Self-clearing, RO = Read only

45.2.1.1.1 Reset (1.0.15)

Resetting a PMA/PMD is accomplished by setting bit 1.0.15 to a one. This action shall set all PMA/PMD registers to their default states. As a consequence, this action may change the internal state of the PMA/PMD and the state of the physical link. This action may also initiate a reset in any other MMDs that are instantiated in the same package. This bit is self-clearing, and a PMA/PMD shall return a value of one in bit 1.0.15 when a reset is in progress; otherwise, it shall return a value of zero. A PMA/PMD is not required to accept a write transaction to any of its registers until the reset process is completed. The control and management interface shall be restored to operation within 0.5 s from the setting of bit 1.0.15. During a reset, a PMD/PMA shall respond to reads from register bits 1.0.15 and 1.8.15:14. All other register bits should be ignored.

NOTE—This operation may interrupt data communication. The data path of a PMD, depending on type and temperature, may take many seconds to run at optimum error ratio after exiting from reset or low-power mode.

45.2.1.1.2 Low power (1.0.11)

A PMA/PMD may be placed into a low-power mode by setting bit 1.0.11 to a one. This action may also initiate a low-power mode in any other MMDs that are instantiated in the same package. The low-power mode is exited by resetting the PMA/PMD. The behavior of the PMA/PMD in transition to and from the low-power mode is implementation specific and any interface signals should not be relied upon. While in the low-power mode, the device shall, as a minimum, respond to management transactions necessary to exit the low-power mode. The default value of bit 1.0.11 is zero.

NOTE—This operation will interrupt data communication. The data path of a PMD, depending on type and temperature, may take many seconds to run at optimum error ratio after exiting from reset or low-power mode.

45.2.1.1.3 Speed selection (1.0.13, 1.0.6, 1.0.5:2)

For devices operating at 10 Mb/s, 100 Mb/s, or 1000 Mb/s the speed of the PMA/PMD may be selected using bits 13 and 6. The speed abilities of the PMA/PMD are advertised in the PMA/PMD speed ability register. These two bits use the same definition as the speed selection bits defined in Clause 22.

For devices not operating at 10 Mb/s, 100 Mb/s, or 1000 Mb/s, the speed of the PMA/PMD may be selected using bits 5 through 2. When bits 5 through 2 are set to 0000 the use of a 10G PMA/PMD is selected. More specific selection is performed using the PMA/PMD control 2 register (register 1.7) (see 45.2.1.6). The speed abilities of the PMA/PMD are advertised in the PMA/PMD speed ability register. A PMA/PMD may ignore writes to the PMA/PMD speed selection bits that select speeds it has not advertised in the PMA/PMD speed ability register. It is the responsibility of the STA entity to ensure that mutually acceptable speeds are applied consistently across all the MMDs on a particular PHY.

The PMA/PMD speed selection defaults to a supported ability.

When set to 0001, bits 5:2 select the use of the 10PASS-TS or 2BASE-TL PMA/PMD. More specific mode selection is performed using the 10P/2B PMA control register (45.2.1.28).

When bits 5 through 2 are set to 0010 the use of a 40G PMA/PMD is selected; when set to 0011 the use of a 100G PMA/PMD is selected; when set to 0100 the use of a 25G PMA/PMD is selected; when set to 0101 the use of a 50G PMA/PMD is selected; when set to 0110 the use of a 2.5G PMA/PMD is selected; when set to 0111 the use of a 5G PMA/PMD is selected; when set to 1000 the use of a 200G PMA/PMD is selected; when set to 1001 the use of a 400G PMA/PMD is selected. More specific selection is performed using the PMA/PMD control 2 register (register 1.7) (see 45.2.1.6.3).

45.2.1.1.4 PMA remote loopback (1.0.1)

The PMA shall be placed in a remote loopback mode of operation when bit 1.0.1 is set to a one. When bit 1.0.1 is set to a one, the PMA shall accept data on the receive path and return it on the transmit path.

The remote loopback function is optional for all port types, except 2BASE-TL and 10PASS-TS, which do not support loopback. A device's ability to perform the remote loopback function is advertised in the remote loopback ability bit of the related speed-dependent status register. A PMA that is unable to perform the remote loopback function shall ignore writes to this bit and shall return a value of zero when read. For 25/40/100 Gb/s operation, the remote loopback ability bit is specified in register 1.13. For 200 Gb/s and 400 Gb/s operation, the remote loopback ability bit is specified in registers 1.23 and 1.24, respectively.

The default value of bit 1.0.1 is zero.

45.2.1.1.5 PMA local loopback (1.0.0)

The PMA shall be placed in a local loopback mode of operation when bit 1.0.0 is set to a one. When bit 1.0.0 is set to a one, the PMA shall accept data on the transmit path and return it on the receive path.

The local loopback function is mandatory for the 1000BASE-KX, 2.5GBASE-X, 5GBASE-R, 10GBASE-KR, 10GBASE-X, 40GBASE-KR4, 40GBASE-CR4, and 100GBASE-CR10 port type and optional for all other port types, except 2BASE-TL, 10PASS-TS, and 10/1GBASE-PRX, which do not support loopback. A PMA that is unable to perform the local loopback function shall ignore writes to this bit and shall return a value of zero when read. The local loopback functionality is detailed in the relevant PMA clause. For 10/25/40/100/200/400 Gb/s operation, the local loopback ability bit is specified in the PMA/PMD status 2 register.

The default value of bit 1.0.0 is zero.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The signal path through the PMA that is exercised in the loopback mode of operation is implementation specific, but it is recommended that the signal path encompass as much of the PMA circuitry as is practical. The intention of providing this loopback mode of operation is to permit a diagnostic or self-test function to perform the transmission and reception of a PDU, thus testing the transmit and receive data paths. Other loopback signal paths may be enabled using loopback controls within other MMDs.

45.2.1.2 PMA/PMD status 1 register (Register 1.1)

The assignment of bits in the PMA/PMD status 1 register is shown in Table 45–5. All the bits in the PMA/PMD status 1 register are read only; therefore, a write to the PMA/PMD status 1 register shall have no effect.

Table 45–5—PMA/PMD status 1 register bit definitions

Bit(s)	Name	Description	R/W[a]
1.1.15:10	Reserved	Value always 0	RO
1.1.9	PIASA	PMA ingress AUI stop ability	RO
1.1.8	PEASA	PMA egress AUI stop ability	RO
1.1.7	Fault	1 = Fault condition detected 0 = Fault condition not detected	RO
1.1.6:3	Reserved	Value always 0	RO
1.1.2	Receive link status	1 = PMA/PMD receive link up 0 = PMA/PMD receive link down	RO/LL
1.1.1	Low-power ability	1 = PMA/PMD supports low-power mode 0 = PMA/PMD does not support low-power mode	RO
1.1.0	Reserved	Value always 0	RO

[a]RO = Read only, LL = Latching low

45.2.1.2.1 PMA ingress AUI stop ability (1.1.9)

If bit 1.1.9 is set to one, then the PMA is indicating that the PMA sublayer attached by the ingress AUI is permitted to stop signaling during LPI. If the bit is set to zero, then the PMA is indicating that the PMA sublayer attached by the ingress AUI is not permitted to stop signaling during LPI. If the PMA sublayer attached by the ingress AUI does not support EEE capability or is not capable to stop signaling, then this bit has no effect.

45.2.1.2.2 PMA egress AUI stop ability (1.1.8)

If bit 1.1.8 is set to one, then the PMA is indicating that the PMA sublayer attached by the egress AUI is permitted to stop signaling during LPI. If the bit is set to zero, then the PMA is indicating that the PMA sublayer attached by the egress AUI is not permitted to stop signaling during LPI. If the PMA sublayer attached by the egress AUI does not support EEE capability or is not capable to stop signaling, then this bit has no effect.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

45.2.1.2.3 Fault (1.1.7)

Fault is a global PMA/PMD variable. When read as a one, bit 1.1.7 indicates that either (or both) the PMA or the PMD has detected a fault condition on either the transmit or receive paths. When read as a zero, bit 1.1.7 indicates that neither the PMA nor the PMD has detected a fault condition. For 10/25/40/50/100/200/400 Gb/s operation, bit 1.1.7 is set to a one when either of the fault bits (1.8.11, 1.8.10) located in register 1.8 are set to a one. For 10PASS-TS or 2BASE-TL operations, when read as a one, a fault has been detected and more detailed information is conveyed in 45.2.1.34, 45.2.1.57, 45.2.1.58, and 45.2.1.73.

45.2.1.2.4 Receive link status (1.1.2)

When read as a one, bit 1.1.2 indicates that the PMA/PMD receive link is up. When read as a zero, bit 1.1.2 indicates that the PMA/PMD receive link is down. The receive link status bit shall be implemented with latching low behavior.

While a 10PASS-TS or 2BASE-TL PMA/PMD is initializing, this bit shall indicate receive link down (see 45.2.1.29).

45.2.1.2.5 Low-power ability (1.1.1)

When read as a one, bit 1.1.1 indicates that the PMA/PMD supports the low-power feature. When read as a zero, bit 1.1.1 indicates that the PMA/PMD does not support the low-power feature. If a PMA/PMD supports the low-power feature, then it is controlled using the low-power bit 1.0.11.

45.2.1.3 PMA/PMD device identifier (Registers 1.2 and 1.3)

Registers 1.2 and 1.3 provide a 32-bit value, which may constitute a unique identifier for a particular type of PMA/PMD. The identifier shall be composed of the 3rd through 24th bits of the Organizationally Unique Identifier (OUI) assigned to the device manufacturer by the IEEE, plus a six-bit model number, plus a four-bit revision number.

A PMA/PMD may return a value of zero in each of the 32 bits of the PMA/PMD device identifier to indicate that a unique identifier as described above is not provided.

The format of the PMA/PMD device identifier is specified in 22.2.4.3.1.

NOTE—The use of only 22 bits of the OUI as described here has been deprecated by the IEEE Registration Authority. In this case, Company ID (CID) is not an acceptable alternative to OUI due to the possibility that a CID and OUI could be identical in the 22-bit subset. The definition of vendor-specific device identifiers for other applications is expected to use the full 24 bits to accommodate the use of either an OUI or CID.

45.2.1.4 PMA/PMD speed ability (Register 1.4)

The assignment of bits in the PMA/PMD speed ability register is shown in Table 45–6.

45.2.1.4.1 400G capable (1.4.15)

When read as a one, bit 1.4.15 indicates that the PMA/PMD is able to operate at a data rate of 400 Gb/s. When read as a zero, bit 1.4.15 indicates that the PMA/PMD is not able to operate at a data rate of 400 Gb/s.

Table 45–6—PMA/PMD speed ability register bit definitions

Bit(s)	Name	Description	R/W[a]
1.4.15	400G capable	1 = PMA/PMD is capable of operating at 400 Gb/s 0 = PMA/PMD is not capable of operating at 400 Gb/s	RO
1.4.14	5G capable	1 = PMA/PMD is capable of operating at 5 Gb/s 0 = PMA/PMD is not capable of operating as 5 Gb/s	RO
1.4.13	2.5G capable	1 = PMA/PMD is capable of operating at 2.5 Gb/s 0 = PMA/PMD is not capable of operating as 2.5 Gb/s	RO
1.4.12	200G capable	1 = PMA/PMD is capable of operating at 200 Gb/s 0 = PMA/PMD is not capable of operating at 200 Gb/s	RO
1.4.11	25G capable	1 = PMA/PMD is capable of operating at 25 Gb/s 0 = PMA/PMD is not capable of operating at 25 Gb/s	RO
1.4.10	10GPASS-XR capable	1 = PMA/PMD is capable of operating as 10GPASS-XR 0 = PMA/PMD is not capable of operating as 10GPASS-XR	RO
1.4.9	100G capable	1 = PMA/PMD is capable of operating at 100 Gb/s 0 = PMA/PMD is not capable of operating as 100 Gb/s	RO
1.4.8	40G capable	1 = PMA/PMD is capable of operating at 40 Gb/s 0 = PMA/PMD is not capable of operating as 40 Gb/s	RO
1.4.7	10/1G capable	1 = PMA/PMD is capable of operating at 10 Gb/s downstream and 1 Gb/s upstream 0 = PMA/PMD is not capable of operating at 10 Gb/s downstream and 1 Gb/s upstream.	RO
1.4.6	10M capable	1 = PMA/PMD is capable of operating at 10 Mb/s 0 = PMA/PMD is not capable of operating as 10 Mb/s	RO
1.4.5	100M capable	1 = PMA/PMD is capable of operating at 100 Mb/s 0 = PMA/PMD is not capable of operating at 100 Mb/s	RO
1.4.4	1000M capable	1 = PMA/PMD is capable of operating at 1000 Mb/s 0 = PMA/PMD is not capable of operating at 1000 Mb/s	RO
1.4.3	50G capable	1 = PMA/PMD is capable of operating at 50 Gb/s 0 = PMA/PMD is not capable of operating at 50 Gb/s	RO
1.4.2	10PASS-TS capable	1 = PMA/PMD is capable of operating as 10PASS-TS 0 = PMA/PMD is not capable of operating as 10PASS-TS	RO
1.4.1	2BASE-TL capable	1 = PMA/PMD is capable of operating as 2BASE-TL 0 = PMA/PMD is not capable of operating as 2BASE-TL	RO
1.4.0	10G capable	1 = PMA/PMD is capable of operating at 10 Gb/s 0 = PMA/PMD is not capable of operating at 10 Gb/s	RO

[a]RO = Read only

45.2.1.4.2 5G capable (1.4.14)

When read as a one, bit 1.4.14 indicates that the PMA/PMD is able to operate at a data rate of 5 Gb/s. When read as a zero, bit 1.4.14 indicates that the PMA/PMD is not able to operate at a data rate of 5 Gb/s.

45.2.1.4.3 2.5G capable (1.4.13)

When read as a one, bit 1.4.13 indicates that the PMA/PMD is able to operate at a data rate of 2.5 Gb/s. When read as a zero, bit 1.4.13 indicates that the PMA/PMD is not able to operate at a data rate of 2.5 Gb/s.

45.2.1.4.4 200G capable (1.4.12)

When read as a one, bit 1.4.12 indicates that the PMA/PMD is able to operate at a data rate of 200 Gb/s. When read as a zero, bit 1.4.12 indicates that the PMA/PMD is not able to operate at a data rate of 200 Gb/s.

45.2.1.4.5 25G capable (1.4.11)

When read as a one, bit 1.4.11 indicates that the PMA/PMD is able to operate at a data rate of 25 Gb/s. When read as a zero, bit 1.4.11 indicates that the PMA/PMD is not able to operate at a data rate of 25 Gb/s.

45.2.1.4.6 10GPASS-XR capable (1.4.10)

When read as one, bit 1.4.10 indicates that the PMA/PMD is able to operate as 10GPASS-XR. When read as zero, bit 1.4.10 indicates that the PMA/PMD is not able to operate as 10GPASS-XR.

45.2.1.4.7 100G capable (1.4.9)

When read as a one, bit 1.4.9 indicates that the PMA/PMD is able to operate at a data rate of 100 Gb/s. When read as a zero, bit 1.4.9 indicates that the PMA/PMD is not able to operate at a data rate of 100 Gb/s.

45.2.1.4.8 40G capable (1.4.8)

When read as a one, bit 1.4.8 indicates that the PMA/PMD is able to operate at a data rate of 40 Gb/s. When read as a zero, bit 1.4.8 indicates that the PMA/PMD is not able to operate at a data rate of 40 Gb/s.

45.2.1.4.9 10/1G capable (1.4.7)

When read as a one, bit 1.4.7 indicates that the PMA/PMD is able to operate at a data rate of 10 Gb/s in the downstream direction and 1 Gb/s in the upstream direction. When read as a zero, bit 1.4.7 indicates that the PMA/PMD is not able to operate at a data rate of 10 Gb/s in the downstream direction and 1 Gb/s in the upstream direction.

45.2.1.4.10 10M capable (1.4.6)

When read as a one, bit 1.4.6 indicates that the PMA/PMD is able to operate at a data rate of 10 Mb/s. When read as a zero, bit 1.4.6 indicates that the PMA/PMD is not able to operate at a data rate of 10 Mb/s.

45.2.1.4.11 100M capable (1.4.5)

When read as a one, bit 1.4.5 indicates that the PMA/PMD is able to operate at a data rate of 100 Mb/s. When read as a zero, bit 1.4.5 indicates that the PMA/PMD is not able to operate at a data rate of 100 Mb/s.

45.2.1.4.12 1000M capable (1.4.4)

When read as a one, bit 1.4.4 indicates that the PMA/PMD is able to operate at a data rate of 1000 Mb/s. When read as a zero, bit 1.4.4 indicates that the PMA/PMD is not able to operate at a data rate of 1000 Mb/s.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

45.2.1.4.13 50G capable (1.4.3)

When read as a one, bit 1.4.3 indicates that the PMA/PMD is able to operate at a data rate of 50 Gb/s. When read as a zero, bit 1.4.3 indicates that the PMA/PMD is not able to operate at a data rate of 50 Gb/s.

45.2.1.4.14 10PASS-TS capable (1.4.2)

When read as a one, bit 1.4.2 indicates that the PMA/PMD is able to operate as 10PASS-TS. When read as a zero, bit 1.4.2 indicates that the PMA/PMD is not able to operate as 10PASS-TS.

45.2.1.4.15 2BASE-TL capable (1.4.1)

When read as a one, bit 1.4.1 indicates that the PMA/PMD is able to operate as 2BASE-TL. When read as a zero, bit 1.4.1 indicates that the PMA/PMD is not able to operate as 2BASE-TL.

45.2.1.4.16 10G capable (1.4.0)

When read as a one, bit 1.4.0 indicates that the PMA/PMD is able to operate at a data rate of 10 Gb/s. When read as a zero, bit 1.4.0 indicates that the PMA/PMD is not able to operate at a data rate of 10 Gb/s.

45.2.1.5 PMA/PMD devices in package (Registers 1.5 and 1.6)

The PMA/PMD devices in package registers are defined in Table 45–2.

45.2.1.6 PMA/PMD control 2 register (Register 1.7)

The assignment of bits in the PMA/PMD control 2 register is shown in Table 45–7.

45.2.1.6.1 PMA ingress AUI stop enable (1.7.9)

If bit 1.7.9 is set to one then the PMA may stop the ingress direction AUI signaling during LPI otherwise it shall keep active signaling on that AUI. If the PMA does not support EEE capability or is not able to stop the ingress direction AUI signaling (see 45.2.1.2.1) then this bit has no effect.

45.2.1.6.2 PMA egress AUI stop enable (1.7.8)

If bit 1.7.8 is set to one then the PMA may stop the egress direction AUI signaling during LPI otherwise it shall keep active signaling on that AUI. If the PMA does not support EEE capability or is not able to stop the egress direction AUI signaling (see 45.2.1.2.2) then this bit has no effect.

45.2.1.6.3 PMA/PMD type selection (1.7.6:0)

The PMA/PMD type of the PMA/PMD shall be selected using bits 6 to 0. The PMA/PMD type abilities of the PMA/PMD are advertised in bits 9 and 7 through 0 of the PMA/PMD status 2 register; the PMA/PMD extended ability register; the 40G/100G PMA/PMD extended ability register; the 50G PMA/PMD extended ability register; the 200G PMA/PMD extended ability register; and the 400G PMA/PMD extended ability register. A PMA/PMD shall ignore writes to the PMA/PMD type selection bits that select PMA/PMD types it has not advertised. It is the responsibility of the STA entity to ensure that mutually acceptable MMD types are applied consistently across all the MMDs on a particular PHY.

The PMA/PMD type selection defaults to a supported ability.

Table 45–7—PMA/PMD control 2 register bit definitions *(continued)*

Bit(s)	Name	Description	R/W[a]
1.7.6:0 (*continued*)	PMA/PMD type selection (*continued*)	0 0 0 1 0 1 1 = 10GBASE-KR PMA/PMD 0 0 0 1 0 1 0 = 10GBASE-KX4 PMA/PMD 0 0 0 1 0 0 1 = 10GBASE-T PMA 0 0 0 1 0 0 0 = 10GBASE-LRM PMA/PMD 0 0 0 0 1 1 1 = 10GBASE-SR PMA/PMD 0 0 0 0 1 1 0 = 10GBASE-LR PMA/PMD 0 0 0 0 1 0 1 = 10GBASE-ER PMA/PMD 0 0 0 0 1 0 0 = 10GBASE-LX4 PMA/PMD 0 0 0 0 0 1 1 = 10GBASE-SW PMA/PMD 0 0 0 0 0 1 0 = 10GBASE-LW PMA/PMD 0 0 0 0 0 0 1 = 10GBASE-EW PMA/PMD 0 0 0 0 0 0 0 = 10GBASE-CX4 PMA/PMD	

[a]R/W = Read/Write, RO = Read only
[b]If BASE-T1 is selected, bits 1.2100.3:0 are used to differentiate which BASE-T1 PMA/PMD is selected.
[c]If BASE-H PMA/PMD is selected, register 1.900 is used to differentiate which BASE-H PMA/PMD is selected.

45.2.1.7 PMA/PMD status 2 register (Register 1.8)

The assignment of bits in the PMA/PMD status 2 register is shown in Table 45–8. All the bits in the PMA/PMD status 2 register are read only; a write to the PMA/PMD status 2 register shall have no effect.

Table 45–8—PMA/PMD status 2 register bit definitions

Bit(s)	Name	Description	R/W[a]
1.8.15:14	Device present	15 14 1 0 = Device responding at this address 1 1 = No device responding at this address 0 1 = No device responding at this address 0 0 = No device responding at this address	RO
1.8.13	Transmit fault ability	1 = PMA/PMD has the ability to detect a fault condition on the transmit path 0 = PMA/PMD does not have the ability to detect a fault condition on the transmit path	RO
1.8.12	Receive fault ability	1 = PMA/PMD has the ability to detect a fault condition on the receive path 0 = PMA/PMD does not have the ability to detect a fault condition on the receive path	RO
1.8.11	Transmit fault	1 = Fault condition on transmit path 0 = No fault condition on transmit path	RO/LH
1.8.10	Receive fault	1 = Fault condition on receive path 0 = No fault condition on receive path	RO/LH
1.8.9	Extended abilities	1 = PMA/PMD has extended abilities listed in register 1.11 0 = PMA/PMD does not have extended abilities	RO
1.8.8	PMD transmit disable ability	1 = PMD has the ability to disable the transmit path 0 = PMD does not have the ability to disable the transmit path	RO
1.8.7	10GBASE-SR ability	1 = PMA/PMD is able to perform 10GBASE-SR 0 = PMA/PMD is not able to perform 10GBASE-SR	RO

Table 45–8—PMA/PMD status 2 register bit definitions *(continued)*

Bit(s)	Name	Description	R/W[a]
1.8.6	10GBASE-LR ability	1 = PMA/PMD is able to perform 10GBASE-LR 0 = PMA/PMD is not able to perform 10GBASE-LR	RO
1.8.5	10GBASE-ER ability	1 = PMA/PMD is able to perform 10GBASE-ER 0 = PMA/PMD is not able to perform 10GBASE-ER	RO
1.8.4	10GBASE-LX4 ability	1 = PMA/PMD is able to perform 10GBASE-LX4 0 = PMA/PMD is not able to perform 10GBASE-LX4	RO
1.8.3	10GBASE-SW ability	1 = PMA/PMD is able to perform 10GBASE-SW 0 = PMA/PMD is not able to perform 10GBASE-SW	RO
1.8.2	10GBASE-LW ability	1 = PMA/PMD is able to perform 10GBASE-LW 0 = PMA/PMD is not able to perform 10GBASE-LW	RO
1.8.1	10GBASE-EW ability	1 = PMA/PMD is able to perform 10GBASE-EW 0 = PMA/PMD is not able to perform 10GBASE-EW	RO
1.8.0	PMA local loopback ability	1 = PMA has the ability to perform a local loopback function 0 = PMA does not have the ability to perform a local loopback function	RO

[a]RO = Read only, LH = Latching high

45.2.1.7.1 Device present (1.8.15:14)

When read as <10>, bits 1.8.15:14 indicate that a device is present and responding at this register address. When read as anything other than <10>, bits 1.8.15:14 indicate that no device is present at this register address or that the device is not functioning properly.

45.2.1.7.2 Transmit fault ability (1.8.13)

When read as a one, bit 1.8.13 indicates that the PMA/PMD has the ability to detect a fault condition on the transmit path. When read as a zero, bit 1.8.13 indicates that the PMA/PMD does not have the ability to detect a fault condition on the transmit path.

45.2.1.7.3 Receive fault ability (1.8.12)

When read as a one, bit 1.8.12 indicates that the PMA/PMD has the ability to detect a fault condition on the receive path. When read as a zero, bit 1.8.12 indicates that the PMA/PMD does not have the ability to detect a fault condition on the receive path.

45.2.1.7.4 Transmit fault (1.8.11)

When read as a one, bit 1.8.11 indicates that the PMA/PMD has detected a fault condition on the transmit path. When read as a zero, bit 1.8.11 indicates that the PMA/PMD has not detected a fault condition on the transmit path. Detection of a fault condition on the transmit path is optional and the ability to detect such a condition is advertised by bit 1.8.13. A PMA/PMD that is unable to detect a fault condition on the transmit path shall return a value of zero for this bit. The description of the transmit fault function for the various PMA/PMDs is given in Table 45–9.

The transmit fault bit shall be implemented with latching high behavior.

The default value of bit 1.8.11 is zero.

45.2.1.7.5 Receive fault (1.8.10)

When read as a one, bit 1.8.10 indicates that the PMA/PMD has detected a fault condition on the receive path. When read as a zero, bit 1.8.10 indicates that the PMA/PMD has not detected a fault condition on the receive path. Detection of a fault condition on the receive path is optional and the ability to detect such a condition is advertised by bit 1.8.12. A PMA/PMD that is unable to detect a fault condition on the receive path shall return a value of zero for this bit. The description of the receive fault function for the various PMA/PMDs is given in Table 45–10.

The receive fault bit shall be implemented with latching high behavior.

45.2.1.7.6 PMA/PMD extended abilities (1.8.9)

When read as a one, bit 1.8.9 indicates that the PMA/PMD has extended abilities listed in register 1.11. When read as a zero, bit 1.8.9 indicates that the PMA/PMD does not have extended abilities.

45.2.1.7.7 PMD transmit disable ability (1.8.8)

When read as a one, bit 1.8.8 indicates that the PMD is able to perform the transmit disable function. When read as a zero, bit 1.8.8 indicates that the PMD is not able to perform the transmit disable function. If a PMD is able to perform the transmit disable function, then it is controlled using the PMD transmit disable register.

45.2.1.7.8 10GBASE-SR ability (1.8.7)

When read as a one, bit 1.8.7 indicates that the PMA/PMD is able to support a 10GBASE-SR PMA/PMD type. When read as a zero, bit 1.8.7 indicates that the PMA/PMD is not able to support a 10GBASE-SR PMA/PMD type.

45.2.1.7.9 10GBASE-LR ability (1.8.6)

When read as a one, bit 1.8.6 indicates that the PMA/PMD is able to support a 10GBASE-LR PMA/PMD type. When read as a zero, bit 1.8.6 indicates that the PMA/PMD is not able to support a 10GBASE-LR PMA/PMD type.

45.2.1.7.10 10GBASE-ER ability (1.8.5)

When read as a one, bit 1.8.5 indicates that the PMA/PMD is able to support a 10GBASE-ER PMA/PMD type. When read as a zero, bit 1.8.5 indicates that the PMA/PMD is not able to support a 10GBASE-ER PMA/PMD type.

45.2.1.7.11 10GBASE-LX4 ability (1.8.4)

When read as a one, bit 1.8.4 indicates that the PMA/PMD is able to support a 10GBASE-LX4 PMA/PMD type. When read as a zero, bit 1.8.4 indicates that the PMA/PMD is not able to support a 10GBASE-LX4 PMA/PMD type.

45.2.1.7.12 10GBASE-SW ability (1.8.3)

When read as a one, bit 1.8.3 indicates that the PMA/PMD is able to support a 10GBASE-SW PMA/PMD type. When read as a zero, bit 1.8.3 indicates that the PMA/PMD is not able to support a 10GBASE-SW PMA/PMD type.

45.2.1.7.13 10GBASE-LW ability (1.8.2)

When read as a one, bit 1.8.2 indicates that the PMA/PMD is able to support a 10GBASE-LW PMA/PMD type. When read as a zero, bit 1.8.2 indicates that the PMA/PMD is not able to support a 10GBASE-LW PMA/PMD type.

45.2.1.7.14 10GBASE-EW ability (1.8.1)

When read as a one, bit 1.8.1 indicates that the PMA/PMD is able to support a 10GBASE-EW PMA/PMD type. When read as a zero, bit 1.8.1 indicates that the PMA/PMD is not able to support a 10GBASE-EW PMA/PMD type.

45.2.1.7.15 PMA local loopback ability (1.8.0)

When read as a one, bit 1.8.0 indicates that the PMA is able to perform the local loopback function. When read as a zero, bit 1.8.0 indicates that the PMA is not able to perform the local loopback function. If a PMA is able to perform the local loopback function, then it is controlled using the PMA local loopback bit 1.0.0.

45.2.1.8 PMD transmit disable register (Register 1.9)

The assignment of bits in the PMD transmit disable register is shown in Table 45–11. The transmit disable functionality is optional and a PMD's ability to perform the transmit disable functionality is advertised in the PMD transmit disable ability bit 1.8.8. A PMD that does not implement the transmit disable functionality shall ignore writes to the PMD transmit disable register and may return a value of zero for all bits. A PMD device that operates using a single lane and has implemented the transmit disable function shall use bit 1.9.0 to control the function. Such devices shall ignore writes to bits 1.9.15:1 and return a value of zero for those bits when they are read. The description of the transmit disable function for the various PMA/PMDs is given in Table 45–12.

NOTE 1—This register is extended by the PMD transmit disable extension register (see 45.2.1.25).

NOTE 2—Disabling the transmitter on one or more lanes stops the entire link from carrying data.

Table 45–11—PMD transmit disable register bit definitions

Bit(s)	Name	Description	R/W[a]
1.9.15	PMD transmit disable 14	1 = Disable output on transmit lane 14 0 = Enable output on transmit lane 14	R/W
1.9.14	PMD transmit disable 13	1 = Disable output on transmit lane 13 0 = Enable output on transmit lane 13	R/W
1.9.13	PMD transmit disable 12	1 = Disable output on transmit lane 12 0 = Enable output on transmit lane 12	R/W
1.9.12	PMD transmit disable 11	1 = Disable output on transmit lane 11 0 = Enable output on transmit lane 11	R/W
1.9.11	PMD transmit disable 10	1 = Disable output on transmit lane 10 0 = Enable output on transmit lane 10	R/W
1.9.10	PMD transmit disable 9	1 = Disable output on transmit lane 9 0 = Enable output on transmit lane 9	R/W
1.9.9	PMD transmit disable 8	1 = Disable output on transmit lane 8 0 = Enable output on transmit lane 8	R/W
1.9.8	PMD transmit disable 7	1 = Disable output on transmit lane 7 0 = Enable output on transmit lane 7	R/W
1.9.7	PMD transmit disable 6	1 = Disable output on transmit lane 6 0 = Enable output on transmit lane 6	R/W
1.9.6	PMD transmit disable 5	1 = Disable output on transmit lane 5 0 = Enable output on transmit lane 5	R/W
1.9.5	PMD transmit disable 4	1 = Disable output on transmit lane 4 0 = Enable output on transmit lane 4	R/W
1.9.4	PMD transmit disable 3	1 = Disable output on transmit lane 3 0 = Enable output on transmit lane 3	R/W

Table 45–11—PMD transmit disable register bit definitions *(continued)*

Bit(s)	Name	Description	R/W[a]
1.9.3	PMD transmit disable 2	1 = Disable output on transmit lane 2 0 = Enable output on transmit lane 2	R/W
1.9.2	PMD transmit disable 1	1 = Disable output on transmit lane 1 0 = Enable output on transmit lane 1	R/W
1.9.1	PMD transmit disable 0	1 = Disable output on transmit lane 0 0 = Enable output on transmit lane 0	R/W
1.9.0	Global PMD transmit disable	1 = Disable transmitter output 0 = Enable transmitter output	R/W

[a]R/W = Read/Write

45.2.1.8.1 PMD transmit disable 14 (1.9.15)

When bit 1.9.15 is set to a one, the PMD shall disable output on lane 14 of the transmit path. When bit 1.9.15 is set to zero, the PMD shall enable output on lane 14 of the transmit path.

The default value for bit 1.9.15 is zero.

NOTE—Transmission will not be enabled when this bit is set to zero unless the global PMD transmit disable bit is also zero.

Table 45–12—Transmit disable description location

PMA/PMD	Description location
2.5GBASE-KX	128.6.5
2.5GBASE-T and 5GBASE-T	126.4.2.3
5GBASE-KR	130.6.5
10GBASE-BR10, 10GBASE-BR20, and 10GBASE-BR40	158.5.6
10GBASE-KR	72.6.5
10GBASE-LRM	68.4.7
Other 10GBASE-R	52.4.7
10GBASE-LX4	53.4.7
10GBASE-CX4	54.5.6
10GBASE-T	55.4.2.3
10GBASE-KX4	71.6.6
25GBASE-KR and 25GBASE-KR-S	111.7.5
25GBASE-CR and 25GBASE-CR-S	110.7.5
25GBASE-SR	112.5.6
25GBASE-LR and 25GBASE-ER	114.5.6
