111. Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-KR and 25GBASE-KR-S

111.1 Overview

This clause specifies the 25GBASE-KR PMD, the 25GBASE-KR-S PMD, and the baseband medium. The specifications are closely related to those of 100GBASE-KR4 (Clause 93) but with a single lane instead of four lanes. This clause also makes use of Annex 93A, Annex 93B, and Annex 93C.

When forming a complete Physical Layer, the PMD shall be connected as illustrated in Figure 111–1, to the appropriate PMA as shown in Table 111–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 111–1—Physical Layer clauses associated with the 25GBASE-KR and 25GBASE-KR-S PMDs

Associated clause	25GBASE-KR	25GBASE-KR-S
106—RS	Required	Required
106—25GMII[a]	Optional	Optional
107—PCS	Required	Required
74—BASE-R FEC[b]	Required	Required
108—RS-FEC[b]	Required	N/A
109—PMA	Required	Required
109A—25GAUI C2C	Optional	Optional
73—Auto-Negotiation	Required	Required
78—Energy Efficient Ethernet	Optional	Optional

[a]The 25GMII is an optional interface. However, if the 25GMII is not implemented, a conforming implementation behaves functionally as though the RS and 25GMII were present.
[b]FEC sublayers can be enabled or disabled according to the FEC mode (see 111.6).

A 25GBASE-KR PHY operates over a channel meeting the requirements of 111.9.1 or 111.9.2. A 25GBASE-KR-S PHY operates over a channel meeting the requirements of 111.9.2. A 25GBASE-KR PHY interoperates with a 25GBASE-KR-S PHY.

When forming a complete 25GBASE-KR or 25GBASE-KR-S Physical Layer, the link BER requirements depend on the FEC mode (see 111.6) according to the following guidelines.

a) If a PHY operates in the RS-FEC mode, and the RS-FEC decoder does not bypass error correction (see 108.5.3.2), the link is required to operate with a BER of 10^{-5} or better.
b) If a PHY operates in the BASE-R FEC mode, the link is required to operate with a BER of 10^{-8} or better.
c) If a PHY operates in the no-FEC mode, or in the RS-FEC mode with error correction bypassed, the link is required to operate with a BER of 10^{-12} or better.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In this context, a link consists of a compliant PMD transmitter, a compliant PMD receiver, and a channel meeting the requirements of 111.9.1 or 111.9.2.

For a complete Physical Layer, this specification is considered to be satisfied by a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

25GBASE-KR and 25GBASE-KR-S PHYs with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

Figure 111–1 shows the relationship of the PMD and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

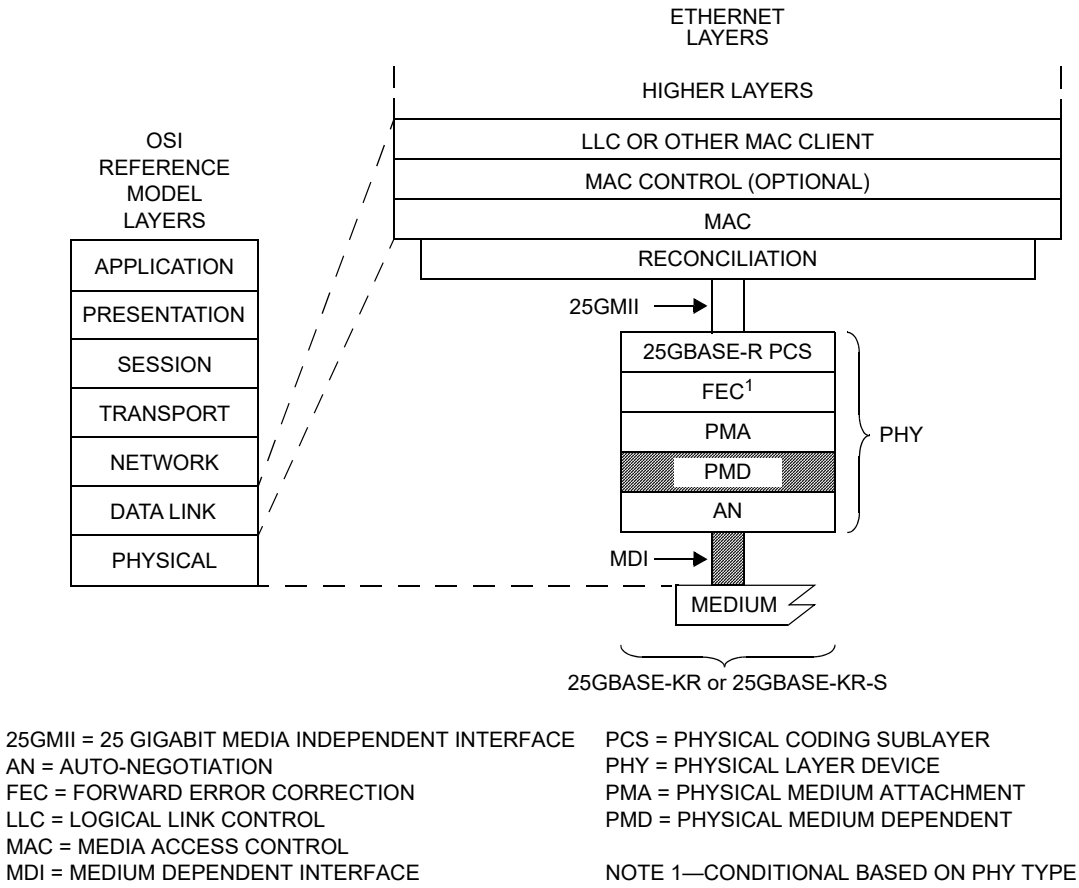

Figure 111–1—25GBASE-KR and 25GBASE-KR-S relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

111.2 PMD service interface

This subclause specifies the services provided by the 25GBASE-KR and 25GBASE-KR-S PMDs. The service interface for these PMDs is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data. The PMD translates the encoded data to and from signals suitable for the medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMD service interface is an instance of the inter-sublayer service interface defined in 105.4. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA.request
PMD:IS_UNITDATA.indication
PMD:IS_SIGNAL.indication

The PMA (or the PMD) continuously sends a bit stream to the PMD (or the PMA) at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable Global_PMD_signal_detect as defined in 111.7.4. When Global_PMD_signal_detect is one, SIGNAL_OK shall be assigned the value OK. When Global_PMD_signal_detect is zero, SIGNAL_OK shall be assigned the value FAIL. When SIGNAL_OK is FAIL, the PMD:IS_UNITDATA.indication parameter is undefined.

If the optional EEE deep sleep capability is supported, then the PMD service interface includes two additional primitives as follows:

PMD:IS_TX_MODE.request
PMD:IS_RX_MODE.request

111.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 107.5.)

25GBASE-KR and 25GBASE-KR-S PHYs may be extended using a 25GAUI chip-to-chip (C2C) as a physical instantiation of the inter-sublayer service interface between devices. If 25GAUI C2C is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

111.4 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the PMD, AN, and the medium in one direction shall be no more than 512 bit times (1 pause_quantum or 20.48 ns). It is assumed that the one way delay through the medium is no more than 200 bit times (8 ns).

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 105.5.

111.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control bits to PMD control variables as shown in Table 111–2, and MDIO status bits to PMD status variables as shown in Table 111–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 111–2—25GBASE-KR MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable	1.9.0	Global_PMD_transmit_disable
Restart training	BASE-R PMD control	1.150.0	mr_restart_training
Training enable	BASE-R PMD control	1.150.1	mr_training_enable
Polynomial identifier 0	PMD training pattern lane 0	1.1450.12:11	identifier_0
Seed 0	PMD training pattern lane 0	1.1450.10:0	seed_0

Table 111–3—25GBASE-KR MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/bit number	PMD status variable
Fault	PMA/PMD status 1	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect	1.10.0	Global_PMD_signal_detect
Receiver status 0	BASE-R PMD status	1.151.0	rx_trained
Frame lock 0	BASE-R PMD status	1.151.1	frame_lock
Startup protocol status 0	BASE-R PMD status	1.151.2	training
Training failure 0	BASE-R PMD status	1.151.3	training_failure

111.6 FEC modes

A 25GBASE-KR PHY implements the BASE-R FEC sublayer (Clause 74) and the 25GBASE-R RS-FEC sublayer (Clause 108). A 25GBASE-KR-S PHY implements the BASE-R FEC sublayer (Clause 74). Each FEC sublayer can be either enabled or disabled, according to AN resolution or management control.

Three FEC modes are supported:

a) When the 25GBASE-R RS-FEC sublayer is enabled, the PHY is defined to operate in the RS-FEC mode.
b) When the BASE-R FEC sublayer is enabled, the PHY is defined to operate in the BASE-R FEC mode.
c) When no FEC sublayer is enabled, the PHY is defined to operate in the no-FEC mode.

A 25GBASE-KR PHY can operate in RS-FEC, BASE-R FEC, or no-FEC mode. A 25GBASE-KR-S PHY can operate in either BASE-R FEC or no-FEC mode.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The channel specification (111.9) that the PHY supports and the required PMD receiver characteristics (111.8.3) depend on the FEC mode.

The FEC mode is determined using AN (Clause 73) and is used in both transmit direction and receive direction. It is recommended to configure the AN FEC advertisement such that only modes that are compatible with the specific channel are selected.

111.7 PMD functional specifications

111.7.1 Link block diagram

One direction of a 25GBASE-KR or 25GBASE-KR-S link is shown in Figure 111–2.

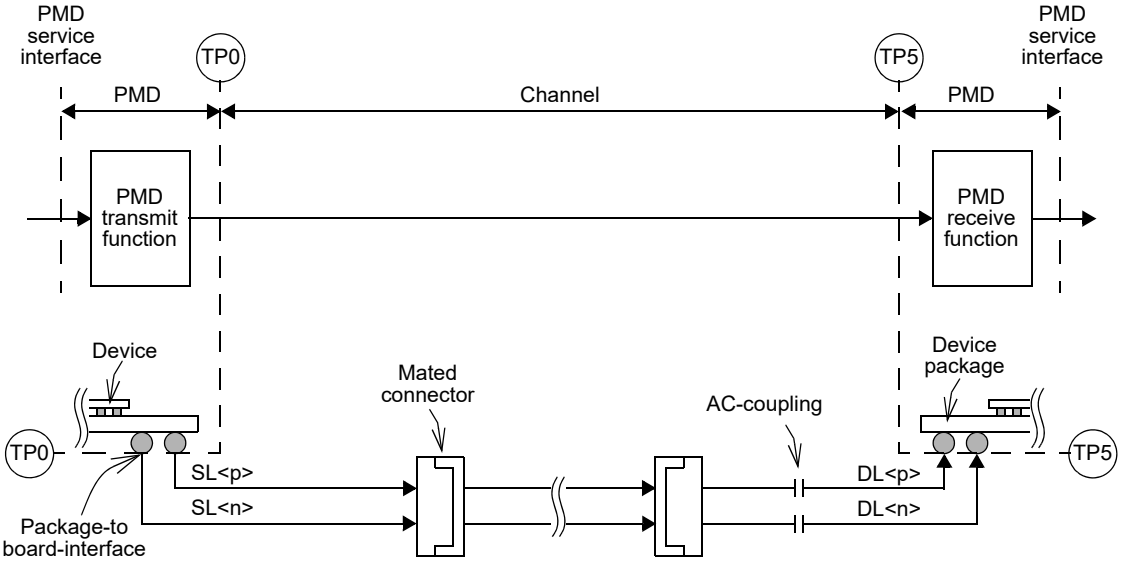

Figure 111–2—25GBASE-KR or 25GBASE-KR-S link (one direction is illustrated)

111.7.2 PMD transmit function

The PMD transmit function shall convert the bit stream requested by the PMD service interface message PMD:IS_UNITDATA.request(tx_bit) into an electrical signal. The electrical signal shall then be delivered to the MDI, according to the transmit electrical specifications in 111.8.2. A positive differential output voltage (SL<p> minus SL<n>) shall correspond to tx_bit = one.

If the optional EEE deep sleep capability is supported, the following requirements apply. When the PMD service interface message PMD:IS_TX_MODE.request(tx_mode) is received with tx_mode = ALERT, the PMD transmit function shall transmit a periodic sequence, where each period of the sequence consists of 8 ones followed by 8 zeros, with the transmit equalizer coefficients set to the preset values (see 72.6.10.2.3.1). This sequence is transmitted regardless of the value of tx_bit presented by the PMD:IS_UNITDATA.request primitive.When tx_mode is not set to ALERT, the transmit equalizer coefficients are set to the values determined via the startup protocol (see 111.7.10).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

111.7.3 PMD receive function

The PMD receive function shall convert the electrical signal from the MDI into a bit stream for delivery to the PMD service interface using the message PMD:IS_UNITDATA.indication(rx_bit). A positive differential input voltage (DL<p> minus DL<n>) shall correspond to rx_bit = one.

111.7.4 Global PMD signal detect function

The Global PMD signal detect function is used by the PMD to indicate the successful completion of the startup protocol by the PMD control function (see 111.7.10). Global_PMD_signal_detect is set to zero when the value of the variable signal_detect is set to false by the Training state diagram (see Figure 72–5). Global_PMD_signal_detect is set to one when the value of signal_detect is set to true.

If training is disabled by the management variable mr_training_enable (see 111.5), Global_PMD_signal_detect shall be set to one.

If the optional EEE deep sleep capability is supported, the following requirements apply. The value of Global_PMD_signal_detect is set to zero when the PMD service interface message PMD:IS_RX_MODE.request(rx_mode) is initially received with rx_mode = QUIET. While rx_mode is set to QUIET, Global_PMD_signal_detect shall be set to one within 500 ns of the application of the ALERT pattern defined in 111.7.2, with peak-to-peak differential voltage of 720 mV as measured at TP0a, to the differential pair at the input of the channel that connects the transmitter to the receiver. While rx_mode is set to QUIET, Global_PMD_signal_detect shall not be set to one when the voltage applied to the input of the differential pair of the channel that connects the transmitter to the receiver is less than or equal to 60 mV peak-to-peak differential.

When the MDIO is implemented, this function maps the variables to registers and bits as defined in 111.5.

111.7.5 Global PMD transmit disable function

The Global PMD transmit disable function is mandatory if the EEE deep sleep capability is supported and is otherwise optional. When this function is supported, it shall meet the following requirements:

a) When Global_PMD_transmit_disable variable is set to one, this function shall turn off the transmitter such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage in Table 93–4.
b) If a PMD fault (111.7.7) is detected, then the PMD may set Global_PMD_transmit_disable to one.
c) Loopback, as defined in 111.7.6, shall not be affected by Global_PMD_transmit_disable.
d) The following additional requirements apply when the optional EEE deep sleep capability is supported. The Global PMD transmit disable function shall turn off the transmitter as specified in 93.8.1.3 when tx_mode transitions to QUIET from any other value. The Global PMD transmit disable function shall turn on the transmitter as specified in 93.8.1.3 when tx_mode transitions from QUIET to any other value.

111.7.6 Loopback mode

Local loopback mode is provided by the adjacent PMA (see Clause 109) as a test function. When loopback mode is enabled, transmission requests passed to the transmitter are sent directly to the receiver, overriding any signal detected on its attached link. Note that loopback mode does not affect the state of the transmitter, which continues to send data (unless disabled).

Control of the loopback function is specified in 109.4.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

111.7.7 PMD fault function

PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault. If the MDIO is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

111.7.8 PMD transmit fault function

The PMD transmit fault function is optional. The faults detected by this function are implementation specific, but the assertion of Global_PMD_transmit_disable is not considered a transmit fault.

If PMD_transmit_fault is set to one, then Global_PMD_transmit_disable should also be set to one.

If the MDIO interface is implemented, then PMD_transmit_fault shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

111.7.9 PMD receive fault function

The PMD receive fault function is optional. The faults detected by this function are implementation specific. A fault is indicated by setting the variable PMD_receive_fault to one.

If the MDIO interface is implemented, then PMD_receive_fault shall be mapped to the Receive fault bit specified in 45.2.1.7.5.

111.7.10 PMD control function

25GBASE-KR and 25GBASE-KR-S PMDs shall use the same control function as lane 0 of 100GBASE-CR4, as defined in 92.7.12.

The variables seed_0 and polynomial_0 control the training pattern choice. It is recommended that implementations with multiple PMDs use distinct values of polynomial_0 for PMDs that are coupled by crosstalk.

111.8 Electrical characteristics

111.8.1 MDI

The MDI for 25GBASE-KR and 25GBASE-KR-S PHYs is an implementation-dependent direct electrical connection between the PMD and the medium. The MDI comprises two differential pairs, one for the transmit function and one for the receive function, marked by TP0 and TP5 in Figure 111–2.

Transmitter and receiver characteristics are defined at TP0a and TP5a, which are connected to the MDI through the test fixtures described in 93.8.1.1 and 93.8.2.1.

111.8.2 Transmitter characteristics

Transmitter electrical characteristics at TP0a for 25GBASE-KR and 25GBASE-KR-S shall be the same as those of a single lane of 100GBASE-KR4, as summarized in Table 93–4 and detailed in 93.8.1.1 through 93.8.1.7, with the exception that the value of linear fit pulse peak (min.) is $0.75 \times v_f$.

111.8.3 Receiver characteristics

Receiver electrical characteristics are specified at TP5a. The receiver shall meet the return loss specified in 93.8.2.2 using the text fixture specified in 93.8.2.1. In addition, the requirements in 111.8.3.1 and 111.8.3.2 apply.

111.8.3.1 Receiver interference tolerance

The receiver interference tolerance test setup and method are as specified in 93.8.2.3, for a single lane, with the following considerations:

a) The test requirements in this subclause replace the test requirements in Table 93–6. The test requirements for RS-FEC mode are provided in Table 111–4. The test requirements for BASE-R FEC mode are provided in Table 111–5. The test requirements for no-FEC mode are provided in Table 111–6.
b) COM is calculated using both Test 1 and Test 2 device package model transmission line lengths listed in Table 111–8 on the receiver side. The value of COM is taken as the lower of the two calculated values.
c) The transmitter device package model $S^{(tp)}$ is omitted from Equation (93A–3) in the calculation of COM. The filtered voltage transfer function $H^{(k)}(f)$ calculated in Equation (93A–19) uses the filter $H_t(f)$ defined by Equation (93A–46), where T_r is calculated as $T_r = 1.09 \times T_{rm} - 4.32$ ps and T_{rm} is the measured 20% to 80% transition time of the signal at TP0a. T_{rm} is measured using the method in 86A.5.3.3, with the exception that the observation filter bandwidth is 33 GHz instead of 12 GHz. T_{rm} is measured with the transmit equalizer turned off (i.e., coefficients set to the preset values, see 72.6.10.2.3.1).

It is recommended to adjust the test transmitter jitter such that the effective bounded uncorrelated jitter and the effective total uncorrelated jitter are as close as practical to their limits in Table 93–4.

A 25GBASE-KR PHY shall comply with the receiver interference tolerance test requirements for RS-FEC mode, BASE-R FEC mode and no-FEC mode. A 25GBASE-KR-S PHY shall comply with the receiver interference tolerance test requirements for BASE-R FEC mode and no-FEC mode.

Table 111–4—25GBASE-KR interference tolerance parameters, RS-FEC mode

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Insertion loss at 12.89 GHz[a]	30	30.5	35	35.5	dB
COM[b]	3		3		dB
Test pattern	Scrambled idle encoded by RS-FEC				
RSS_DFE4[c]	0.05	—	0.05	—	
RS-FEC symbol error ratio required[d]	$< 10^{-4}$				
b_{max} used in COM calculation	1				
DER_0 used in COM calculation	10^{-5}				

[a]Measured between TPt and TP5 (see Figure 93C–4).
[b]The COM value is the target for the receiver noise level calibration defined in 93C.2 step 7. The channel noise voltage applied in 93C.2 step 8 should be as close as practical to the value needed to produce the target COM. If higher channel noise voltage values are used, this would demonstrate margin to the specification but this is not required for compliance.
[c]The parameter RSS_DFE4 is a figure of merit for the test channel that is defined in 93A.2.
[d]The RS-FEC symbol error ratio is measured using the RS-FEC symbol error counter (see 108.6.9).

Table 111–5—25GBASE-KR and 25GBASE-KR-S interference tolerance parameters, BASE-R FEC mode

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Insertion loss at 12.89 GHz[a]	16	16.5	30	30.5	dB
COM[b]	3		3		dB
Test pattern	Scrambled idle encoded by BASE-R FEC				
RSS_DFE4[c]	0.05	—	0.05	—	
BASE-R FEC corrected block ratio required[d, e]	$< 2.1 \times 10^{-5}$				
b_{max} used in COM calculation	0.5				
DER_0 used in COM calculation	10^{-8}				

[a]Measured between TPt and TP5 (see Figure 93C–4).
[b]The COM value is the target for the receiver noise level calibration defined in 93C.2 step 7. The channel noise voltage applied in 93C.2 step 8 should be as close as practical to the value needed to produce the target COM. If higher channel noise voltage values are used, this would demonstrate margin to the specification but this is not required for compliance.
[c]The parameter RSS_DFE4 is a figure of merit for the test channel that is defined in 93A.2.
[d]The BASE-R FEC corrected block ratio is measured using the FEC corrected blocks counter (see 74.8.4.1).
[e]The FEC uncorrected blocks counter (see 74.8.4.2) is required to indicate zero errors during the test unless the test duration is such that the uncorrected block ratio can be verified to be less than 4.7×10^{-10}.

Table 111–6—25GBASE-KR and 25GBASE-KR-S interference tolerance parameters, no-FEC mode

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Insertion loss at 12.89 GHz[a]	16	16.5	30	30.5	dB
COM[b]	3		3		dB
Test pattern	Scrambled idle or PRBS31				
RSS_DFE4[c]	0.05	—	0.05	—	
Bit error ratio required[d]	$< 10^{-12}$				
b_{max} used in COM calculation	0.35				
DER_0 used in COM calculation	10^{-12}				

[a]Measured between TPt and TP5 (see Figure 93C–4).
[b]The COM value is the target for the receiver noise level calibration defined in 93C.2 step 7. The channel noise voltage applied in 93C.2 step 8 should be as close as practical to the value needed to produce the target COM. If higher channel noise voltage values are used, this would demonstrate margin to the specification but this is not required for compliance.
[c]The parameter RSS_DFE4 is a figure of merit for the test channel that is defined in 93A.2.
[d]The bit error ratio is measured using the PCS errored blocks counter (see 49.2.14.2) or the PMA PRBS31 error counter (see 109.4.4.4) as appropriate.

111.8.3.2 Receiver jitter tolerance

Jitter tolerance in the RS-FEC mode is measured with a channel meeting the insertion loss of Test 2 and the RS-FEC symbol error ratio requirement specified in Table 111–4. Jitter tolerance in the BASE-R FEC mode is measured with a channel meeting the insertion loss of Test 2 and the corrected block ratio requirement specified in Table 111–5. Jitter tolerance in the no-FEC mode is measured with a channel meeting the insertion loss of Test 2 and the bit error ratio requirement specified in Table 111–6.

Receiver jitter tolerance is verified for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 111–7. The test setup shown in Figure 93–12, or its equivalent, is used. The synthesizer frequency is set to the specified jitter frequency and the synthesizer output amplitude is adjusted until the specified peak-to-peak jitter amplitude for that frequency is measured at TP0a. The test procedure is the same as the one described in 111.8.3.1, with the exception that no broadband noise is added.

For 25GBASE-KR and 25GBASE-KR-S PHYs, the receiver under test shall meet the error requirement specified for the tests in Table 111–5 and Table 111–6, for each case listed in Table 111–7. For a 25GBASE-KR PHY, the receiver under test shall also meet the error requirement specified for the test in Table 111–4 for each case listed in Table 111–7.

Table 111–7—Receiver jitter tolerance parameters

Parameter	Case A values	Case B values	Units
Jitter frequency	190	940	kHz
Peak-to-peak jitter amplitude	5	1	UI

111.9 Channel characteristics

Channel characteristics are defined by Channel Operating Margin (COM), computed using the procedure in 93A.1, where T_r is 12 ps for $H_t(f)$ as used in Equation (93A–19). The parameters used for calculation of COM are different for channels used to connect two PHYs of type 25GBASE-KR and for channels used to connect two PHYs where one or both are of type 25GBASE-KR-S.

Channels used to connect PHYs that operate in the no-FEC mode of operation or in the RS-FEC mode with error correction bypassed shall meet the COM requirement with DER_0 set to 10^{-12} and b_{max} set to 0.35.

All channels shall have AC-coupling as specified in 93.9.4 and are recommended to meet the insertion loss limits in 93.9.2 and the return loss limits in 93.9.3.

111.9.1 25GBASE-KR channel

A 25GBASE-KR channel is used as a link connecting two 25GBASE-KR PHYs. COM parameter values for this channel are provided in Table 111–8.

COM is calculated for two test cases, Test 1 and Test 2, which differ in the value of the device package model transmission line length z_p. COM shall be greater than or equal to 3 dB for each test.

111.9.2 25GBASE-KR-S channel

A 25GBASE-KR-S channel is used as a link between a pair of 25GBASE-KR-S PHYs, between a pair of 25GBASE-KR PHYs, or between a 25GBASE-KR-S PHY and a 25GBASE-KR PHY. COM parameter values for this channel are provided in Table 111–8.

COM is calculated for two test cases, Test 1 and Test 2, which differ in the value of the device package model transmission line length z_p. COM shall be greater than or equal to 3 dB for each test.

Table 111–8—COM parameter values

Parameter	Symbol	25GBASE-KR[a]	25GBASE-KR-S	Units
Signaling rate	f_b	25.78125		GBd
Maximum start frequency	$f_{\min}$	0.05		GHz
Maximum frequency step	Δf	0.01		GHz
Device package model

111.11 Protocol implementation conformance statement (PICS) proforma for Clause 111, Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-KR and 25GBASE-KR-S[184]

111.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 111, Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-KR and 25GBASE-KR-S, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

111.11.2 Identification

111.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

111.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 111, Physical Medium Dependent (PMD) sublayer and baseband medium, type 25GBASE-KR and 25GBASE-KR-S
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[184] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

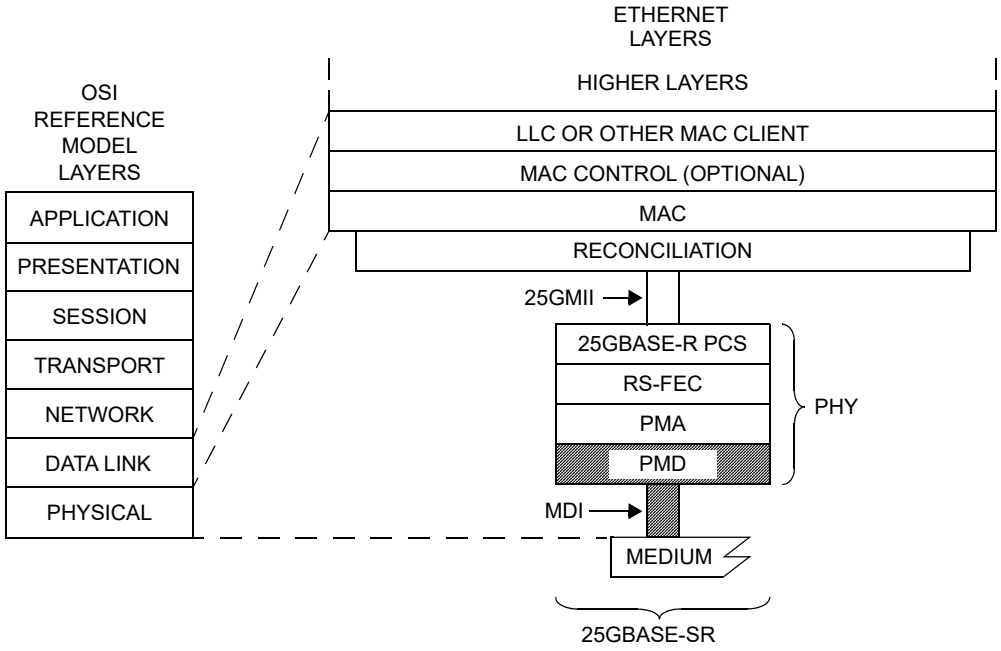
112. Physical Medium Dependent (PMD) sublayer and medium, type 25GBASE-SR

112.1 Overview

This clause specifies the 25GBASE-SR PMD together with the multimode fiber medium. The PMD sublayer provides a point-to-point 25 Gb/s Ethernet link over a pair of multimode fibers, up to at least 100 m. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 112–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 112–1—Physical Layer clauses associated with the 25GBASE-SR PMD

Associated clause	25GBASE-SR
106—RS	Required
106—25GMII[a]	Optional
107—PCS for 25GBASE-R	Required
108—RS-FEC[b]	Required
109—PMA for 25GBASE-R	Required
109A—25GAUI C2C	Optional
109B—25GAUI C2M	Optional
78—Energy Efficient Ethernet	Optional



[a]The 25GMII is an optional interface. However, if the 25GMII is not implemented, a conforming implementation behaves functionally as though the RS and 25GMII were present.
[b]The option to bypass the Clause 108 RS-FEC correction function is not supported.

Figure 112–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 25 Gigabit Ethernet is introduced in Clause 105 and the purpose of each PHY sublayer is summarized in 105.2.

25GBASE-SR PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions, and abbreviations) and Annex A (Bibliography, referenced as [B1], [B2], etc.).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION
SR = PMD FOR MULTIMODE FIBER

Figure 112–1—25GBASE-SR PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

112.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 5×10^{-5} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

112.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 25GBASE-SR PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMD service interface is an instance of the inter-sublayer service interface defined in 105.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA.request
PMD:IS_UNITDATA.indication
PMD:IS_SIGNAL.indication

In the transmit direction, the PMA continuously sends a bit stream to the PMD, at a nominal signaling rate of 25.78125 GBd. The PMD converts this stream of bits into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends a bit stream to the PMA corresponding to the signals received from the MDI, at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service primitive defined in 105.4.

The SIGNAL_DETECT parameter can take on one of the following two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_bit parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_bit parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 112.1.1.

112.3 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The sum of the transmit and receive delays at one end of the link contributed by the 25GBASE-SR PMD including 2 m of fiber in one direction shall be no more than 512 bit times (1 pause_quantum or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quantum can be found in 105.5 and its references.

112.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 112–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 112–3.

Table 112–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 112–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

112.5 PMD functional specifications

The 25GBASE-SR PMD performs the transmit and receive functions, which convey data between the PMD service interface and the MDI.

112.5.1 PMD block diagram

The PMD block diagram is shown in Figure 112–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a multimode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 112.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 112.10.3). Unless specified otherwise, all receiver measurements and tests defined in 112.7 are made at TP3.

TP1 and TP4 are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

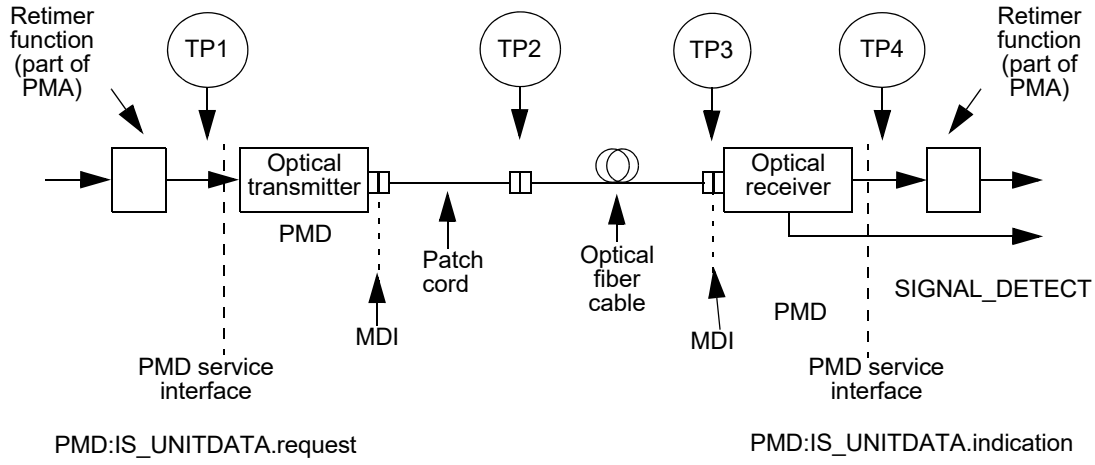

Figure 112–2—Block diagram for 25GBASE-SR transmit/receive paths

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

112.5.2 PMD transmit function

The PMD transmit function shall convert the bit stream requested by the PMD service interface messages PMD:IS_UNITDATA.request into an optical signal. The optical signal shall then be delivered to the MDI, according to the transmit optical specifications in this clause. The higher optical power level in each signal shall correspond to tx_bit = one.

112.5.3 PMD receive function

The PMD receive function shall convert the optical signal received from the MDI into a bit stream for delivery to the PMD service interface using the message PMD:IS_UNITDATA.indication, all according to the receive optical specifications in this clause. The higher optical power level in the signal shall correspond to rx_bit = one.

112.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 105.4.

SIGNAL_DETECT shall be an indicator of the presence of the optical signal. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 112–4. The PMD receiver is not required to verify whether a compliant 25GBASE-SR signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 112–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –30 dBm	FAIL
[(Optical power at TP3 ≥ average receive power (min) in Table 95–7) AND (compliant 25GBASE-SR signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the PMD global signal detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal. When the MDIO is implemented, the SIGNAL_DETECT value shall be continuously set in response to the magnitude of the optical signal, according to the requirements of Table 112–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

112.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

112.5.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows the optical transmitter to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of the OFF transmitter in Table 95–6.
b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

112.5.7 PMD fault function (optional)

If the PMD has detected a local fault on the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

112.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set PMD_transmit_fault to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

112.5.9 PMD receive fault function (optional)

If the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

112.6 PMD to MDI optical specifications for 25GBASE-SR

The operating range for the 25GBASE-SR PMD is defined in Table 112–5. A 25GBASE-SR compliant PMD operates on 50/125 μm multimode fibers, type A1a.2 (OM3) or type A1a.3 (OM4), according to the specifications defined in Table 112–7. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 25GBASE-SR PMD operating at 120 m meets the operating range requirement of 0.5 m to 100 m). The fiber type and operating range shown in Table 112–5 are the same as 100GBASE-SR4 (See Clause 95).

Table 112–5—25GBASE-SR operating range

PMD type	Required operating range[a]
25GBASE-SR	0.5 m to 70 m for OM3
	0.5 m to 100 m for OM4

[a]The RS-FEC correction function may not be bypassed for any operating distance.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

112.6.1 25GBASE-SR transmitter optical specifications

The optical characteristics of a 25GBASE-SR transmitter shall be the same as those of a single lane of 100GBASE-SR4, as specified in Table 95–6 and 95.7.1, with the exception that the test patterns are modified as stated in 112.7.1.

112.6.2 25GBASE-SR receive optical specifications

The optical characteristics of a 25GBASE-SR receiver shall be the same as those of a single lane of 100GBASE-SR4, as specified in Table 95–7 and 95.7.2, with the exceptions that there are no receiver aggressor lanes and the test patterns are modified as stated in 112.7.1.

112.6.3 25GBASE-SR illustrative link power budget

The illustrative power budget and penalties for 25GBASE-SR channels are the same as those of a single lane of 100GBASE-SR4, as specified in Table 95–8 and 95.7.3.

112.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified. Optical parameters and measurement methods for 25GBASE-SR are the same as for 100GBASE-SR4, with the exceptions that the multi-lane testing considerations described in 95.8.1.1 do not apply and the test patterns are modified as stated in 112.7.1.

112.7.1 Test patterns for optical parameters

The test patterns used in this clause shall be the same as those used for 100GBASE-SR4, as described in 95.8.1 and shown in Table 95–9, with the exception that pattern 5, the scrambled idle test pattern defined in 82.2.11, is encoded by Clause 108 RS-FEC for 25GBASE-SR. The multi-lane testing considerations described in 95.8.1.1 do not apply. Table 112–6 shows the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined.

Table 112–6—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength, spectral width	3, 5, or valid 25GBASE-SR signal	112.7.2
Average optical power	3, 5, or valid 25GBASE-SR signal	112.7.3
Optical modulation amplitude (OMA)	Square wave or 4	112.7.4
Transmitter and dispersion eye closure (TDEC)	3, 5, or valid 25GBASE-SR signal	112.7.5
Extinction ratio	3, 5, or valid 25GBASE-SR signal	112.7.6
Transmitter optical waveform	3, 5, or valid 25GBASE-SR signal	112.7.7
Stressed receiver sensitivity	3, 5, or valid 25GBASE-SR signal	112.7.8
Stressed eye closure (SEC), calibration	3, 5, or valid 25GBASE-SR signal	112.7.8

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

112.7.2 Center wavelength and spectral width

The center wavelength and RMS spectral width shall be within the range given in Table 95–6 if measured per IEC 61280-1-3. The transmitter is modulated using one of the test patterns specified in Table 112–6.

112.7.3 Average optical power

The average optical power shall be within the limits given in Table 95–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern defined in Table 112–6.

112.7.4 Optical Modulation Amplitude (OMA)

OMA shall be within the limits given in Table 95–6 if measured as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or as defined in 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern. See 112.7.1 for test-pattern information.

112.7.5 Transmitter and dispersion eye closure (TDEC)

TDEC is a measure of the optical transmitter's vertical eye closure, as described in 95.8.5. TDEC shall be within the limits given in Table 95–6 if measured using the methods specified in 95.8.5.1 and 95.8.5.2. Table 112–6 specifies the test patterns to be used for measurement of TDEC. Since 25GBASE-SR is a single lane in each direction, there are no transmitter aggressor lanes.

112.7.6 Extinction ratio

The extinction ratio shall be within the limits given in Table 95–6 if measured using the methods specified in IEC 61280-2-2. The extinction ratio is measured using one of the test patterns specified for extinction ratio in Table 112–6.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 112–6).

112.7.7 Transmitter optical waveform (transmit eye)

The transmitter optical waveform of a port transmitting the test pattern specified in Table 112–6 shall meet the transmitter eye mask coordinates and hit ratio specified in Table 95–6 if measured according to the methods specified in 95.8.7, with the exception that the test patterns are modified as stated in 112.7.1.

112.7.8 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 95–7 if measured using the methods defined in 95.8.8, with the exception that the test patterns are modified as stated in 112.7.1. Since 25GBASE-SR is a single lane in each direction, the conditions for receiver aggressor lanes in Table 95–7 do not apply.

112.8 Safety, installation, environment, and labeling

112.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

112.8.2 Laser safety

25GBASE-SR optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[185]

112.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

112.8.4 Environment

Normative specifications in this clause shall be met by a system integrating a 25GBASE-SR PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate, in the literature associated with the PHY, the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

112.8.5 Electromagnetic emission

A system integrating a 25GBASE-SR PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

112.8.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

112.8.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 25GBASE-SR).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 112.8.2.

[185]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

112.9 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 112–3. The fiber type and length are the same as 100GBASE-SR4 (See Clause 95).

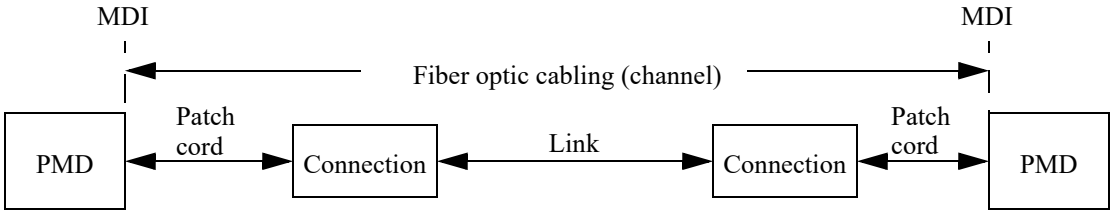

Figure 112–3—Fiber optic cabling model

The channel insertion loss is given in Table 112–7. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, modal dispersion, reflections and losses of all connectors and splices meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method. As OM4 optical fiber meets the requirements for OM3, a channel compliant to the "OM3" column may use OM4 optical fiber, or a combination of OM3 and OM4. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 112–7—Fiber optic cabling (channel) characteristics for 25GBASE-SR

Description	OM3	OM4	Unit
Operating distance (max)	70	100	m
Channel insertion loss[a] (max)	1.8	1.9	dB
Channel insertion loss (min)	0		dB

[a]These channel insertion loss values include cable loss plus 1.5 dB allocated for connection and splice loss, over the wavelength range 840 nm to 860 nm.

112.10 Characteristics of the fiber optic cabling (channel)

The 25GBASE-SR fiber optic cabling shall meet the specifications defined in Table 112–7. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. The requirements for the optical fiber, connection insertion loss, and maximum discrete reflectance are the same as 100GBASE-SR4 (see Clause 95).

112.10.1 Optical fiber cable

The fiber contained within the 25GBASE-SR fiber optic cabling shall comply with the specifications and parameters of Table 112–8. A variety of multimode cable types may satisfy these requirements, provided the resulting channel also meets the specifications of Table 112–7.

112.10.2 Optical fiber connection

An optical fiber connection, as shown in Figure 112–3, consists of a mated pair of optical connectors.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 112–8—Optical fiber and cable characteristics

Description	OM3[a]	OM4[b]	Unit
Nominal core diameter	50		mm
Nominal fiber specification wavelength	850		nm
Effective modal bandwidth (min)[c]	2000	4700	MHz·km
Cabled optical fiber attenuation (max)	3.5		dB/km
Zero dispersion wavelength (λ_0)	$1295 \le \lambda_0 \le 1340$		nm
Chromatic dispersion slope (max) (S_0)	0.105 for $1295 \le \lambda_0 \le 1310$ and $0.000375 \times (1590 - l0)$ for $1310 \le \lambda_0 \le 1340$		ps/nm^2 km

[a]IEC 60793-2-10 type A1a.2
[b]IEC 60793-2-10 type A1a.3
[c]When measured with the launch conditions specified in Table 95–6

112.10.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 1.5 dB total connection and splice loss. For example, this allocation supports three connections with an average insertion loss per connection of 0.5 dB. Connections with lower loss characteristics may be used provided the requirements of Table 112–7 are met. However, the loss of a single connection shall not exceed 0.75 dB

112.10.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

112.10.3 Medium Dependent Interface (MDI)

The 25GBASE-SR PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 112–3). Examples of an MDI include the following:

a) Connectorized fiber pigtail.
b) PMD receptacle.

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 112.5.1, not at the MDI.

112.11 Protocol implementation conformance statement (PICS) proforma for Clause 112, Physical Medium Dependent (PMD) sublayer and medium, type 25GBASE-SR[186]

112.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 112, Physical Medium Dependent (PMD) sublayer and medium, type 25GBASE-SR, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

112.11.2 Identification

112.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

112.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 112, Physical Medium Dependent (PMD) sublayer and medium, type 25GBASE-SR
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

113. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 25GBASE-T and 40GBASE-T

113.1 Overview

The 25GBASE-T and 40GBASE-T PHYs are members of the 25 Gb/s and 40 Gb/s Ethernet family of high-speed network specifications. The 25GBASE-T PCS, PMA, and baseband medium specifications are intended for users who want 25 Gb/s performance over balanced twisted-pair structured cabling systems. The 40GBASE-T PCS, PMA, and baseband medium specifications are intended for users who want 40 Gb/s performance over balanced twisted-pair structured cabling systems. 25GBASE-T and 40GBASE-T signaling both require four pairs of balanced cabling as specified in ISO/IEC 11801-1:2016 and ANSI/TIA-568-C.2-1-2016.

This clause defines type 25GBASE-T and 40GBASE-T PCS, PMA sublayers, and Medium Dependent Interfaces (MDI). Together, the PCS and PMA sublayers define a Physical Layer device (PHY). Functional, electrical, and mechanical specifications for the type 25GBASE-T PMA, 40GBASE-T PMA, and MDI are provided in this clause. This clause also specifies the baseband medium used with 25GBASE-T and 40GBASE-T. Management functions are optionally accessible through the management interface defined in Clause 45, or equivalent. Please refer to Table 105–2 and Table 80–2 for associated sublayers and options for assembling a 25 Gb/s system with the 25GBASE-T PHY and a 40 Gb/s system with the 40GBASE-T PHY, respectively.

This clause also specifies 25GBASE-T and 40GBASE-T Low Power Idle (LPI) as part of Energy-Efficient Ethernet (EEE). This allows the PHY to enter a low power mode of operation during periods of low link utilization as described in Clause 78.

Both 25GBASE-T and 40GBASE-T PHYs may optionally support a fast retrain mechanism. Implementation of the fast retrain option is recommended. Configurations wishing to disable fast retrain on the link may do so by advertising lack of support during Auto-Negotiation, thus preventing the link partner from attempting fast retrain and potentially dropping the link, see 45.2.7.10.

113.1.1 Nomenclature

The 25GBASE-T and 40GBASE-T PHYs described in Clause 113 represent two distinct PHY types that share the same PCS, PMA, and MDI specifications subject to frequency scaling, and differences between the 25GMII and the XLGMII specifications. In order to efficiently describe the two PHYs, the nomenclature 25G/40GBASE-T is used to describe specifications that apply to both the 25GBASE-T and 40GBASE-T PHYs. Additionally, for parameters that scale with the PHYs data rate, the parameter *S* is used for scaling. For 25GBASE-T, $S = 0.625$ and for 40GBASE-T, $S = 1$.

Where a functionality or register refers to any member of the MultiGBASE-T set of PHYs, as defined in 1.4.406, that nomenclature is used.

Additionally, because the two PHYs specify different media independent interfaces, the nomenclature 25GMII/XLGMII is used as shorthand for referring to 25GMII for 25GBASE-T and XLGMII for 40GBASE-T. Note that 25GMII uses a 4-bit control word and a 32-bit data word, so that when a transfer of 64 bits (8 octets) is referred to on the media independent interface, this results in a reference like “two/one transfer(s) on the 25GMII/XLGMII.”

113.1.2 Relationship of 25GBASE-T and 40GBASE-T to other standards

Relations between the 25GBASE-T and 40GBASE-T PHYs, the ISO Open Systems Interconnection (OSI) reference model, and the IEEE 802.3 Ethernet model are shown in Figure 113–1. The PHY sublayers (shown shaded) in Figure 113–1 connect the IEEE 802.3 MAC to the medium.

The 25GBASE-T PHY service interface is the 25GMII, which is defined in Clause 106. The 40GBASE-T PHY service interface is the XLGMII, which is defined in Clause 81.

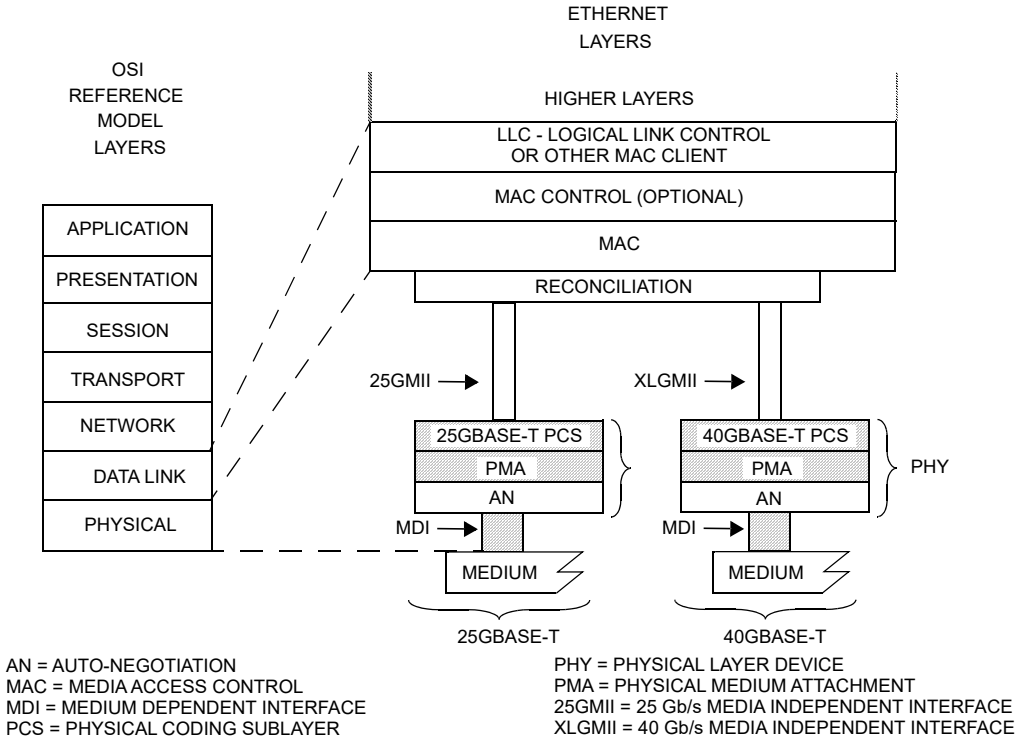

Figure 113–1—Types 25GBASE-T and 40GBASE-T PHY relationship to the ISO Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

113.1.3 Operation of 25GBASE-T and 40GBASE-T

The 25GBASE-T and 40GBASE-T PHY each employ full duplex baseband transmission over four pairs of balanced twisted-pair structured cabling. The aggregate data rates of 25 Gb/s or 40 Gb/s are achieved by transmitting one-quarter of the aggregate data rate in each direction simultaneously on each wire pair, as shown in Figure 113–2. Baseband 16-level PAM signaling with a modulation rate of 2000 MBd for 25GBASE-T and 3200 MBd for 40GBASE-T is used on each of the wire pairs. Ethernet data and control characters are encoded at a rate of 3.125 information bits per PAM16 symbol, along with auxiliary bits. Two consecutively transmitted PAM16 symbols are considered as one two-dimensional (2D) symbol. The 2D symbols are selected from a constrained constellation of 128 maximally spaced 2D symbols, called DSQ128 (double square 128).[187] After link startup, PHY frames consisting of 512 DSQ128 symbols are continuously transmitted. The DSQ128 symbols are determined by seven-bit labels, each comprising 3 RS-FEC (Reed-Solomon FEC) encoded bits and 4 LDPC-encoded bits. The 512 DSQ128 symbols of one PHY frame are

[187]The resulting checkerboard constellation is based on a lattice called RZ^2 in the literature (see Forney [B25]). DSQ constellations have previously been introduced under the name "AMPM" (see Gallagher [B26] for examples of 8 point and 32 point AMPM/DSQ constellations).

transmitted as 4 × 256 PAM16 symbols over the four wire pairs. Data and Control symbols are embedded in a framing scheme that runs continuously after startup of the link. For 25GBASE-T, the modulation symbol rate of 2000 MBd results in a symbol period of 500 ps. For 40GBASE-T, the modulation symbol rate of 3200 MBd results in a symbol period of 312.5 ps.

A 25GBASE-T or 40GBASE-T PHY can be configured either as a MASTER PHY or as a SLAVE PHY. The MASTER-SLAVE relationship between two stations sharing a link segment is established during Auto-Negotiation (see Clause 28, 113.6, Annex 28B, Annex 28C, and Annex 28D). The MASTER PHY uses a local clock to determine the timing of transmitter operations. The MASTER-SLAVE relationship includes loop timing. The SLAVE PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations, i.e., it performs loop timing, as illustrated in Figure 113–3.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

25GBASE-T and 40GBASE-T PHYs optionally provide support for LPI as part of EEE (see Clause 78). This extension allows PHYs to enter an LPI mode when either the local or link partner system requests low power operation. The transmit and receive functions may enter and leave the LPI mode independently so that both symmetric and asymmetric operation is supported. While the PHY is in the LPI mode, the PHY periodically transmits a refresh signal to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variation in the timing of the link or the underlying link segment characteristics. An easily detectable alert signal is transmitted to signal an end to the LPI mode. The alert signal is followed by a wake signal to enable a rapid transition back to the normal operational mode.

25GBASE-T and 40GBASE-T PHYs may optionally support a fast retrain mechanism. This function allows PHYs to quickly recover from link degradation without a normal two-second retrain.

The PCS and PMA subclauses of this document are summarized in 113.1.3.1 and 113.1.3.2. The EEE capability is summarized in 113.1.3.3. Figure 113–3 shows the functional block diagram.

NOTE 1—The recovered_clock arc is shown to indicate delivery of the received clock signal back to PMA TRANSMIT for loop timing.

NOTE 2—pcs_data_mode is required only for the EEE or fast retrain capabilities; alert_detect and rx_lpi_active are only required for the EEE capability; fr_active is only required for the fast retrain capability. Figures and capabilities only required for EEE are noted by dashed boxes.

NOTE 3— Word widths for only the 40 Gb/s Media Independent Interface (XLGMII) are shown for clarity. For the 25 Gb/s Media Independent Interface, a four-bit control word and 32-bit data word are used, i.e., RXC<3:0>, RXD<31:0>, TXC<3:0>, and TXD<31:0>.

113.1.3.1 Summary of Physical Coding Sublayer (PCS)

The 25GBASE-T PCS couples a 25 Gb/s Media Independent Interface (25GMII), as described in Clause 106, to the 25GBASE-T Physical Medium Attachment (PMA) sublayer.

The 40GBASE-T PCS couples a 40 Gb/s Media Independent Interface (XLGMII), as described in Clause 81, to the 40GBASE-T Physical Medium Attachment (PMA) sublayer.

In addition to the normal mode of operation, the PCS supports a training mode. Furthermore, the PCS contains a management interface.

In the transmit direction, in normal mode, the PCS receives eight 25GMII or XLGMII data octets provided by two transfers on the 25GMII service interface on TXD<31:0>, or one transfer on the XLGMII service interface of TXD<63:0>, and groups them into 64-bit blocks with the 64-bit block boundaries aligned with the boundary of the XLGMII transfer (or two 25GMII transfers). Each group of eight octets along with the data/control indications is transcoded into a 65-bit block. These 65-bit blocks are then aggregated into groups of 50 blocks. The first 48 65-bit blocks are transcoded into six 513-bit blocks, and the subsequent two 65-bit blocks are appended to complete a 50-group block. The resulting bits are then scrambled. This yields an Ethernet payload of $6 \times 513 + 2 \times 65 = 3208$ bits. An auxiliary bit is added after scrambling to obtain a block of 3209 bits.

The 3209 bits are divided into two groups, one of 1486 bits and the other of 1723 bits. To the 1486 bits, among them the auxiliary bit, 2 zero pad bits are added, and these are encoded into 192 eight-bit symbols of an RS-FEC(192, 186, 2^8), code. After substituting 2 random fill bits for the zero pad bits, a total of $1536 = 3 \times 512$ RS-FEC-coded bits are transmitted. The 1723 bits are encoded by a systematic LDPC(1723,2048) encoder, which adds 325 LDPC check bits to form an LDPC codeword of 2048 LDPC-coded bits. The 3×512 RS-FEC-coded bits and the $2048 = 4 \times 512$ LDPC-coded bits are arranged in a frame of 512 seven-bit labels. Each seven-bit label comprises 3 RS-FEC-coded bits and 4 LDPC-coded bits.

The 512 seven-bit labels are mapped into 512 2D modulation symbols selected from a DSQ128 constellation. The DSQ128 symbols are obtained by concatenating two time-adjacent 1D PAM16 symbols and retaining among the 256 possible Cartesian product combinations, 128 maximally spaced 2D symbols.[188]

The DSQ128 constellation is partitioned into eight subsets, each subset containing 16 maximally spaced 2D symbols. The three RS-FEC-coded bits of each seven-bit label select one DSQ128 subset, and the four LDPC-coded-bits of the label select one 2D symbol in this subset.

The obtained PHY frame of 512 DSQ128 symbols is passed on to the PMA as PMA_UNITDATA.request. The PMA transmits the DSQ128 symbols over the four wire pairs in the form of 256 constituent PAM16 symbols per pair.

In the receive direction, in normal mode, the PCS processes code-groups received from the remote PHY via the PMA in 256 4D symbol blocks and maps them to the 25GMII/XLGMII service interface in the receive path. In this receive processing scheme, symbol clock synchronization is done by the PMA Receive function.

For 25GBASE-T, the signals provided by the PCS at the 25GMII conform to the interface requirements of Clause 106. For 40GBASE-T, the signals provided by the PCS at the XLGMII conform to the interface requirements of Clause 81.

[188]The resulting checkerboard constellation is based on a lattice called RZ^2 in the literature (see Forney [B25]).

Details of the PCS functions and state diagrams are covered in 113.3. The interface to the PMA is an abstract message-passing interface specified in 113.2.

113.1.3.2 Summary of Physical Medium Attachment (PMA) sublayer

The PMA couples messages from the PCS service interface onto the balanced cabling physical medium via the Medium Dependent Interface (MDI) and provides the link management and PHY Control functions. The PMA provides full duplex communications at $3200 \times S$ MBd over four pairs of balanced cabling up to 30 m in length.

The PMA Transmit function comprises four transmitters to generate continuous time analog signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD, as described in 113.4.3.1. In normal mode, each four-dimensional (4D) symbol received from the PCS Transmit function undergoes multiple stages of processing. First the symbol goes through a Tomlinson-Harashima precoder (THP), which maps the PAM16 input (as described in 113.3.2.2.20) in each dimension of the four-dimensional symbol into a quasi-continuous discrete-time value in the range $-16 \le x < 16$. This THP-processed four-dimensional symbol stream may be further processed by a digital transmit filter and is then passed on to four digital to analog converters (DACs). The DAC outputs may be further processed with continuous time filters to roll off the high-frequency spectral response to limit high-frequency emissions and are then applied to each of the four balanced pairs via the MDI port.

The PMA Receive function comprises four independent receivers for pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD, as described in 113.4.3.2. The receivers are responsible for acquiring symbol timing and, when operating in normal mode, for canceling echo, near-end crosstalk, far-end crosstalk, and equalizing the signal. The 4D symbols are provided to the PCS Receive function via the PMA_UNITDATA.indication message. The PMA also contains functions for Link Monitor.

The PMA PHY Control function generates signals that control the PCS and PMA sublayer operations. PHY Control begins following the completion of Auto-Negotiation and provides the startup functions required for successful 25GBASE-T or 40GBASE-T operation. It determines whether the PHY operates in a normal mode, enabling data transmission over the link segment, or in training mode, in which it sends and receives special PAM2 code-groups and data transmission is disabled.

PMA functions and state diagrams are specified in 113.4. PMA electrical specifications are given in 113.5.

The PMA sublayer may also support a fast retrain function. The fast retrain function is specified in 113.4.2.5.16.

113.1.3.3 Summary of EEE capability

A 25GBASE-T or 40GBASE-T PHY may optionally support the EEE capability, as described in 78.1.4. The EEE capability is a mechanism by which 25GBASE-T and 40GBASE-T PHYs are able to reduce power consumption during periods of low link utilization. PHYs can enter this mode of operation after reaching PCS data mode. Each direction of the full duplex link is able to enter and exit the LPI mode independently, supporting symmetric and asymmetric LPI operation. This allows power savings when only one side of the full duplex link is in a period of low utilization. No data frames are lost or corrupted during the transition to or from the LPI mode.

In the transmit direction the transition to the LPI transmit mode begins when the PCS transmit function detects an LPI control character in all eight lanes of one transfer of TXD[63:0] that will be mapped into a single 64B/65B block, according to the position in the 25G/40GBASE-T LDPC frame. Following this event a sleep signal is transmitted by the PMA. The sleep signal is composed of LDPC frames that contain only LP_IDLE 512B/513B and 64B/65B blocks. The sleep signal indicates to the link partner that the transmit function of the PHY is entering the LPI transmit mode. Immediately after the transmission of the sleep

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

frames, the transmit function of the local PHY enters the LPI transmit mode. While the transmit function is in the LPI mode the PHY may disable data path and control logic to save additional power. Periodically the transmit function of the local PHY transmits refresh frames that are used by the link partner to update adaptive filters and timing circuits in order to maintain link integrity. The LPI mode begins with quiet signaling or with a full refresh period. Partial refreshes (defined as a refresh signal shorter than 6 LDPC frames) that immediately follow the transition to the LPI mode are replaced with quiet signaling. The quiet-refresh cycle continues until the PCS function detects IDLE characters on the 25GMII/XLGMII. These characters signal to the PHY that the LPI transmit mode should end. The PMA Transmit function in the PHY then sends an alert message to the link partner. The alert signal begins on a LDPC frame boundary, but has no fixed relationship to the quiet-refresh cycle. The alert signal wakes the link partner from sleep. The alert signal is followed by a wake signal, composed of LDPC frames containing only IDLE 512B/513B and 64B/65B blocks. After a short recovery time the normal operational mode is resumed.

In the receive direction the transition to the LPI mode is triggered when the PCS Receive function detects LPI control characters within received LDPC frames. This indicates that the link partner is about to enter the LPI transmit mode. Following these frames the link partner ceases transmission and begins quiet-refresh signaling. During the quiet time it is highly recommended that the local receiver power off circuits to reduce power consumption. Periodically the link partner transmits refresh frames that are used by the receiver to update adaptive coefficients and timing circuits. This quiet-refresh cycle continues until the link partner transmits the alert signal, initiating a transition back to the normal operational mode. The alert signal is detected in the PMA and signals that normal data frames will follow. The alert signal is followed by a wake signal that allows the local receiver time to prepare for the normal operational mode. The wake signal is composed of repeated IDLE 512B/513B and 64B/65B blocks. After a short recovery time the normal operational mode is resumed.

Support for the EEE capability is advertised in the Infofield (Octet 12 bit 7) during link startup. Transitions to and from the LPI transmit mode are controlled via 25GMII/XLGMII signaling. Transitions to and from the LPI receive mode are controlled by the link partner using sleep, alert, and wake signaling.

The PCS 64B/65B Transmit state diagram in Figure 113–18a and Figure 113–18b includes additional states for EEE. The PCS 64B/65B Receive state diagram in Figure 113–19a and Figure 113–19b includes additional states for EEE. The EEE Transmit state diagram is contained in the PCS Transmit function and is specified in Figure 113–20.

113.1.4 Signaling

25GBASE-T and 40GBASE-T signaling is performed by the PCS generating continuous code-group sequences that the PMA transmits over each wire pair. The signaling scheme achieves a number of objectives including:

a) Forward error correction (FEC) coded symbol mapping for data.
b) Algorithmic mapping from TXD<31:0> and TXC<3:0> for 25GBASE-T, or TXD<63:0> and TXC<7:0> for 40GBASE-T, to four-dimensional symbols in the transmit path.
c) Algorithmic mapping from the received four-dimensional signals on the MDI port to RXD<31:0> and RXC<3:0> for 25GBASE-T on the 25GMII interface, or RXD<63:0> and RXC<7:0> for 40GBASE-T on the XLGMII interface.
d) Uncorrelated symbols in the transmitted symbol stream.
e) No correlation between symbol streams traveling both directions on any pair combination.
f) No correlation between symbol streams on pairs BI_DA, BI_DB, BI_DC, and BI_DD.
g) Block framing and other control signals.
h) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining.
i) Ability to automatically detect and correct for pair swapping and crossover connections.
j) Ability to automatically detect and correct for incorrect polarity in the connections.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

k) Ability to automatically correct for differential delay variations across the wire pairs.
l) Ability to support refresh, quiet and alert signaling during LPI operation.

The PHY operates in two modes—normal mode or training mode. In normal mode, PCS generates a continuous stream of four-dimensional symbols that are transmitted via the PMA at one of eight power levels. In training mode, the PCS is directed to generate only PAM2 symbols for transmission by the PMA, which enable the receiver at the other end to train until it is ready to operate in normal mode. (See Figure 113–5.)

PHYs may also support the EEE capability as described in 113.1.3.3. Transitions to the LPI mode are supported after reaching normal mode.

113.1.5 Interfaces

All 25GBASE-T and 40GBASE-T PHY implementations are compatible at the MDI, and at the 25GMII/XLGMII, if implemented. Implementation of the 25GMII/XLGMII is optional. Designers are free to implement circuitry within the PCS and PMA in an application-dependent manner provided that the MDI and 25GMII/XLGMII (if the 25GMII/XLGMII is implemented) specifications are met. System operation from the perspective of signals at the MDI and management objects are identical whether the 25GMII/XLGMII is implemented or not.

113.1.6 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5.

Default initializations, unless specified, are left to the implementer.

113.2 25GBASE-T and 40GBASE-T service primitives and interfaces

25GBASE-T transfers data and control information across the following four service interfaces:

a) 25 Gb/s Media Independent Interface (25GMII)
b) Technology Dependent Interface
c) PMA service interface
d) Medium dependent interface (MDI)

The 25GMII is specified in Clause 106; the Technology Dependent Interface is specified in Clause 28. The PMA service interface is defined in 113.2.2 and the MDI is defined in 113.8.

40GBASE-T transfers data and control information across the following four service interfaces:

a1) 40 Gb/s Media Independent Interface (XLGMII)
b1) Technology Dependent Interface
c1) PMA service interface
d1) Medium dependent interface (MDI)

The XLGMII is specified in Clause 81; the Technology Dependent Interface is specified in Clause 28. The PMA service interface is defined in 113.2.2 and the MDI is defined in 113.8.

113.2.1 Technology Dependent Interface

25G/40GBASE-T use the following service primitives to exchange status indications and control signals across the Technology Dependent Interface as specified in Clause 28:

PMA_LINK.request (link_control)

PMA_LINK.indication (link_status)

113.2.1.1 PMA_LINK.request

This primitive allows the Auto-Negotiation algorithm to enable and disable operation of the PMA as specified in 28.2.6.2.

113.2.1.1.1 Semantics of the primitive

PMA_LINK.request (link_control)

The link_control parameter can take on one of three values: SCAN_FOR_CARRIER, DISABLE, or ENABLE.

SCAN_FOR_CARRIER	Used by the Auto-Negotiation algorithm prior to receiving any fast link pulses. During this mode the PMA reports link_status=FAIL. PHY processes are disabled.
DISABLE	Set by the Auto-Negotiation algorithm in the event fast link pulses are detected. PHY processes are disabled. This allows the Auto-Negotiation algorithm to determine how to configure the link.
ENABLE	Used by Auto-Negotiation to turn control over to the PHY for data processing functions.

113.2.1.1.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in Clause 28.

113.2.1.1.3 Effect of receipt

This primitive affects operation of the PMA Link Monitor function as defined in 113.4.2.6.

113.2.1.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 28.2.6.1. This primitive informs the Auto-Negotiation algorithm about the status of the underlying link.

113.2.1.2.1 Semantics of the primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on one of the following two values: FAIL or OK.

FAIL	No valid link established.
OK	The Link Monitor function indicates that a valid 25G/40GBASE-T link is established. Reliable reception of signals transmitted from the remote PHY is possible.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.2.1.2.2 When generated

The PMA generates this primitive to indicate a change in link_status in compliance with the state diagram given in Figure 113–31.

113.2.1.2.3 Effect of receipt

Auto-Negotiation uses this primitive to detect a change in link_status as described in Clause 28.

113.2.2 PMA service interface

25G/40GBASE-T use the following service primitives to exchange symbol vectors, status indications, and control signals across the service interfaces:

PMA_TXMODE.indication (tx_mode)

PMA_CONFIG.indication (config)

PMA_UNITDATA.request (tx_symb_vector)

PMA_UNITDATA.indication (rx_symb_vector)

PMA_SCRSTATUS.request (scr_status)

PMA_PCSSTATUS.request (pcs_status)

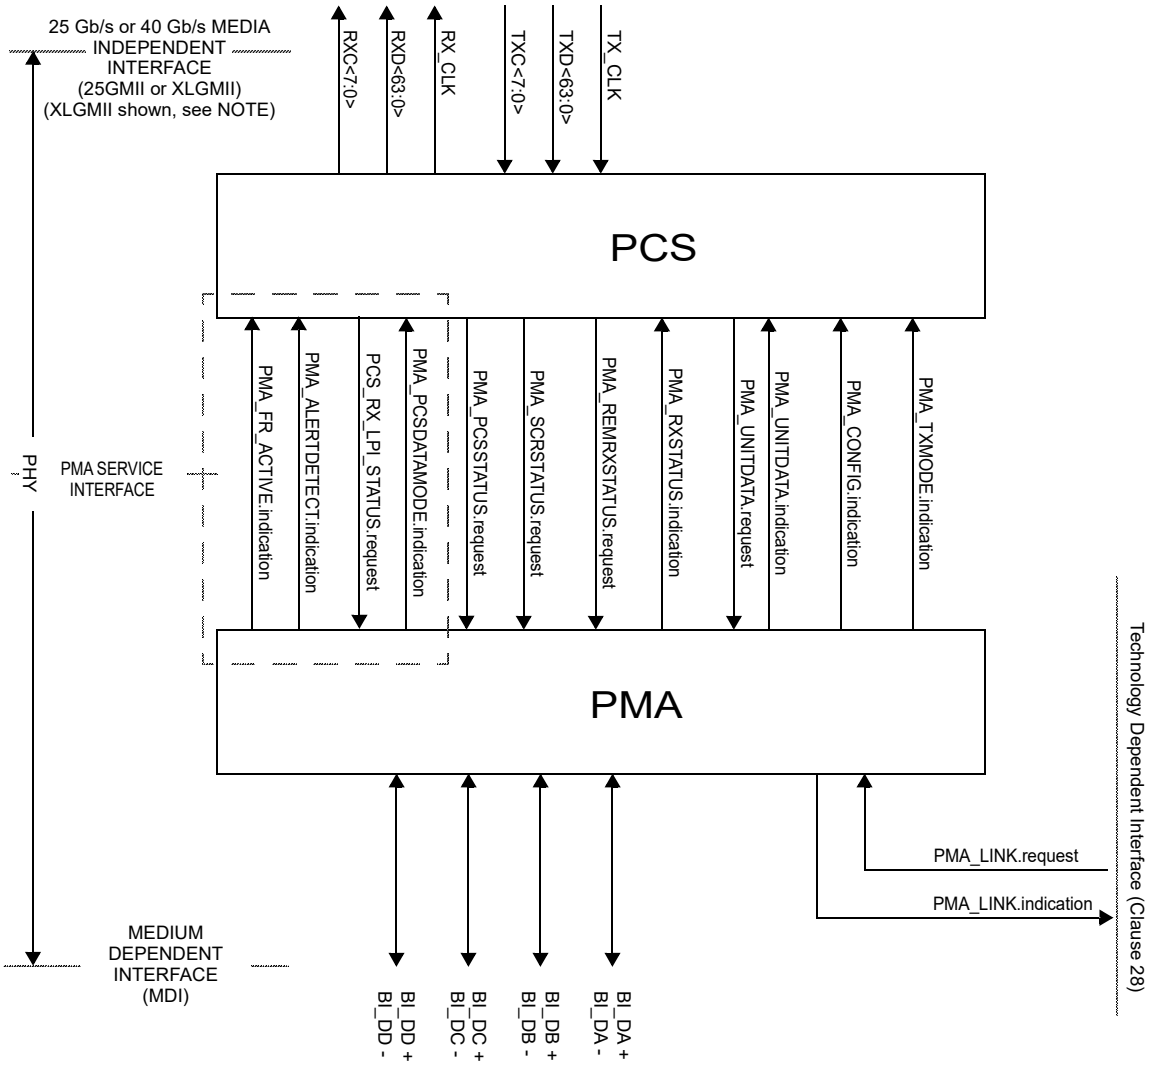
PMA_RXSTATUS.indication (loc_rcvr_status)

PMA_REMRXSTATUS.request (rem_rcvr_status)

EEE-capable PHYs additionally support the following service primitives:

PMA_ALERTDETECT.indication (alert_detect)

PCS_RX_LPI_STATUS.request (rx_lpi_active)



PMA_PCSDATAMODE.indication (PCS_data_mode)

Fast retrain capable PHYs additionally support the following service primitive:

PMA_FR_ACTIVE.indication (fr_active)

The use of these primitives is illustrated in Figure 113–4. Connections from the management interface (signals MDC and MDIO) to the sublayers are pervasive and are not shown in Figure 113–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—
PMA_PCSDATAMODE.indication is required only for the EEE or fast retrain capabilities.
PMA_ALERTDETECT.indication and PCS_RX_LPI_STATUS.request are only required for the EEE capability.
PMA_FR_ACTIVE.indication is only required for the fast retrain capability.
Word widths for only the 40 Gb/s Media Independent Interface (XLGMII) are shown for clarity. For the 25 Gb/s Media Independent Interface, a four-bit control word and 32-bit data word are used, i.e., RXC<3:0>, RXD<31:0>, TXC<3:0>, and TXD<31:0>.

Figure 113–4—25GBASE-T and 40GBASE-T service interfaces

113.2.2.1 PMA_TXMODE.indication

The transmitter in a 25G/40GBASE-T link normally sends over the four pairs, four-dimensional symbols that represent a 25GMII/XLGMII data stream with framing, scrambling and encoding of data, control information, or idles.

113.2.2.1.1 Semantics of the primitive

PMA_TXMODE.indication (tx_mode)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of code-groups the PCS should be transmitting. The parameter tx_mode can take on one of the following three values of the form:

SEND_N	This value is continuously asserted when transmission of sequences of four-dimensional symbols representing a 25GMII/XLGMII data stream in normal mode.
SEND_T	This value is continuously asserted in case transmission of sequences of code-groups representing the training mode is to take place.
SEND_Z	This value is continuously asserted in case transmission of zeros is required.

113.2.2.1.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages to indicate a change in tx_mode.

113.2.2.1.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 113.3.2.2.

113.2.2.2 PMA_CONFIG.indication

Each PHY in a 25G/40GBASE-T link is capable of operating as a MASTER PHY and as a SLAVE PHY. MASTER-SLAVE configuration is determined during Auto-Negotiation (113.6.1). The result of this negotiation is provided to the PMA.

113.2.2.2.1 Semantics of the primitive

PMA_CONFIG.indication (config)

PMA_CONFIG.indication specifies to PCS and PMA Transmit via the parameter config whether the PHY operates as a MASTER PHY or as a SLAVE PHY. The parameter config can take on one of the following two values of the form:

MASTER	This value is continuously asserted when the PHY operates as a MASTER PHY.
SLAVE	This value is continuously asserted when the PHY operates as a SLAVE PHY.

113.2.2.2.2 When generated

PMA generates PMA_CONFIG.indication messages to indicate a change in config.

113.2.2.2.3 Effect of receipt

PCS and PMA Clock Recovery perform their functions in MASTER or SLAVE configuration according to the value assumed by the parameter config.

113.2.2.3 PMA_UNITDATA.request

This primitive defines the transfer of code-groups in the form of the tx_symb_vector parameter from the PCS to the PMA. The code-groups are obtained in the PCS Transmit function using the encoding rules defined in 113.3.2.2 to represent 25GMII/XLGMII data and control streams or other sequences.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.2.2.3.1 Semantics of the primitive

PMA_UNITDATA.request (tx_symb_vector)

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb_vector the value of the symbols to be sent over each of the four transmit pairs BI_DA, BI_DB, BI_DC, and BI_DD. For EEE-capable PHYs, the vector also requests the PMA to send the ALERT signal during LPI. The tx_symb_vector parameter takes on the form:

SYMB_4D	A vector of four multi-level symbols, one for each of the four transmit pairs BI_DA, BI_DB, BI_DC, and BI_DD. In normal operation, each symbol takes on one of the values in the set {–15, –13, –11, –9, –7, –5, –3, –1, 1, 3, 5, 7, 9, 11, 13, 15}. The symbols additionally take the value 0 when zeros are to be transmitted in the following two cases: 1) when PMA_TXMODE.indication is SEND_Z during PMA training, and 2) after data mode is reached, the transmit function is in the LPI transmit mode and lpi_tx_mode is QUIET
ALERT	A vector used to indicate that the PMA should transmit the alert sequence. ALERT is asserted for a time equal to 4 LDPC frames.

The symbols that are elements of tx_symb_vector are called, according to the pair on which each is transmitted, tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD].

113.2.2.3.2 When generated

The PCS generates PMA_UNITDATA.request synchronously with every transmit clock cycle.

113.2.2.3.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated symbols after processing with the THP, the transmit filter and other specified PMA Transmit processing. The parameter tx_symb_vector is also used by the PMA Receive function to process the signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD for cancelling the echo and near-end crosstalk (NEXT).

113.2.2.4 PMA_UNITDATA.indication

This primitive defines the transfer of code-groups in the form of the rx_symb_vector parameter from the PMA to the PCS.

113.2.2.4.1 Semantics of the primitive

PMA_UNITDATA.indication (rx_symb_vector)

During reception the PMA_UNITDATA.indication simultaneously conveys to the PCS via the parameter rx_symb_vector the values of the symbols detected on each of the four receive pairs BI_DA, BI_DB, BI_DC, and BI_DD. The rx_symb_vector parameter takes on the form:

SYMB_4D	A vector of the four 1D symbols that is the receiver's best estimate of the symbols that were sent by the remote transmitter across the four pairs with reliability measures.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.2.2.4.2 When generated

The PMA generates PMA_UNITDATA.indication (SYMB_4D) messages synchronously every four symbols received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is $3200 \times S$ MHz, as governed by the recovered clock.

113.2.2.4.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

113.2.2.5 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the training mode descrambler has achieved synchronization.

113.2.2.5.1 Semantics of the primitive

PMA_SCRSTATUS.request (scr_status)

The scr_status parameter can take on one of the following two values of the form:

OK	The training mode descrambler has achieved synchronization.
NOT_OK	The training mode descrambler is not synchronized.

113.2.2.5.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages to indicate a change in scr_status.

113.2.2.5.3 Effect of receipt

The effect of receipt of this primitive is specified in 113.4.2.4, 113.4.2.5, and 113.4.6.1.

113.2.2.6 PMA_PCSSTATUS.request

This primitive is generated by PCS Receive to indicate the fully operational state of the PCS for the local PHY. The parameter pcs_status conveys to the PMA Receive function the information that the PCS is operating reliably in data mode.

113.2.2.6.1 Semantics of the primitive

PMA_PCSSTATUS.request (pcs_status)

The pcs_status parameter can take on one of the following two values of the form:

OK	The PCS is operating reliably in data mode.
NOT_OK	The PCS is not operating reliably in data mode.

113.2.2.6.2 When generated

PCS Receive generates PMA_PCSSTATUS.request messages to indicate a change in pcs_status.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.2.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 113.4.6.

113.2.2.7 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Transmit, PCS Receive, PMA PHY Control function, and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by the PCS Receive decoding functions. The criterion for setting the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting errors during reception of symbol streams.

113.2.2.7.1 Semantics of the primitive

PMA_RXSTATUS.indication (loc_rcvr_status)

The loc_rcvr_status parameter can take on one of the following two values of the form:

OK	This value is asserted and remains true during reliable operation of the receive link for the local PHY.
NOT_OK	This value is asserted whenever operation of the link for the local PHY is unreliable.

113.2.2.7.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages to indicate a change in loc_rcvr_status on the basis of signals received at the MDI.

113.2.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 113–28 and in 113.2 and 113.4.6.3.

113.2.2.8 PMA_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The criterion for setting the parameter rem_rcvr_status is left to the implementer. It can be based, for example, on asserting rem_rcvr_status is NOT_OK until loc_rcvr_status is OK and then asserting the detected value of rem_rcvr_status after proper PCS Receive decoding is achieved.

113.2.2.8.1 Semantics of the primitive

PMA_REMRXSTATUS.request (rem_rcvr_status)

The rem_rcvr_status parameter can take on one of the following two values of the form:

OK	The receive link for the remote PHY is operating reliably.
NOT_OK	Reliable operation of the receive link for the remote PHY is not detected.

113.2.2.8.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages to indicate a change in rem_rcvr_status on the basis of signals received at the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.2.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 113–28.

113.2.2.9 PMA_ALERTDETECT.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY when rx_lpi_active is TRUE. The parameter alert_detect conveys to the PCS receive function information regarding the detection of the LPI alert signal by the PMA receive function. The criterion for setting the parameter alert_detect is left to the implementer.

113.2.2.9.1 Semantics of the primitive

PMA_ALERTDETECT.indication (alert_detect)

The alert_detect parameter can take on one of the following two values of the form:

TRUE	The alert signal has been reliably detected at the local receiver.
FALSE	The alert signal at the local receiver has not been detected.

113.2.2.9.2 When generated

The PMA generates PMA_ALERTDETECT.indication messages to indicate a change in the alert_detect status.

113.2.2.9.3 Effect of receipt

The effect of receipt of this primitive is specified in 113.3.2.3, Figure 113–19a, and Figure 113–19b.

113.2.2.10 PCS_RX_LPI_STATUS.request

When the PHY supports the EEE capability this primitive is generated by the PCS receive function to indicate the status of the receive link at the local PHY. The parameter PCS_RX_LPI_STATUS.request conveys to the PCS transmit and PMA receive functions information regarding whether the receive function is in the LPI receive mode. The parameter is generated by the Receive 64B/65B state diagram in Figure 113–19a.

113.2.2.10.1 Semantics of the primitive

PCS_RX_LPI_STATUS.request (rx_lpi_active)

The rx_lpi_active parameter can take on one of the following two values of the form:

TRUE	The receive function is in the LPI receive mode.
FALSE	The receive function is not in the LPI receive mode.

113.2.2.10.2 When generated

The PCS generates PCS_RX_LPI_STATUS.request messages to indicate a change in the rx_lpi_active variable as determined by the receive state diagram in Figure 113–19a.

113.2.2.10.3 Effect of receipt

The effect of receipt of this primitive is specified in 113.3.2.3 and Figure 113–32.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.2.2.11 PMA_PCSDATAMODE.indication

This primitive indicates whether or not the PCS state diagrams are able to transition from their initialization states. The pcs_data_mode variable is generated by the PMA PHY Control function. It is passed to the PCS Control function via the PMA_PCSDATAMODE.indication primitive.

113.2.2.11.1 Semantics of the primitive

PMA_PCSDATAMODE.indication (pcs_data_mode)

The pcs_data_mode parameter can take on one of the following two values of the form:

TRUE	PHY is in state PCS_Data (see Figure 113–28)
FALSE	PCS is not in state PCS_Data (see Figure 113–28)

113.2.2.11.2 When generated

The PMA PHY Control function generates PMA_PCSDATAMODE.indication messages continuously.

113.2.2.11.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 113.3.2.2.

113.2.2.12 PMA_FR_ACTIVE.indication

This primitive indicates whether or not the PMA is currently performing a fast retrain. The fr_active variable is generated by the PMA PHY Control function. It is passed to the PCS Receive Control function via the PMA_FR_ACTIVE.indication primitive. This primitive is only supported by PHYs with the fast retrain capability.

113.2.2.12.1 Semantics of the primitive

PMA_FR_ACTIVE.indication (fr_active)

The fr_active parameter can take on one of the following two values of the form:

TRUE	PHY is currently performing a fast retrain
FALSE	PCS is not currently performing a fast retrain

113.2.2.12.2 When generated

The PMA PHY Control function generates PMA_FR_ACTIVE.indication messages continuously.

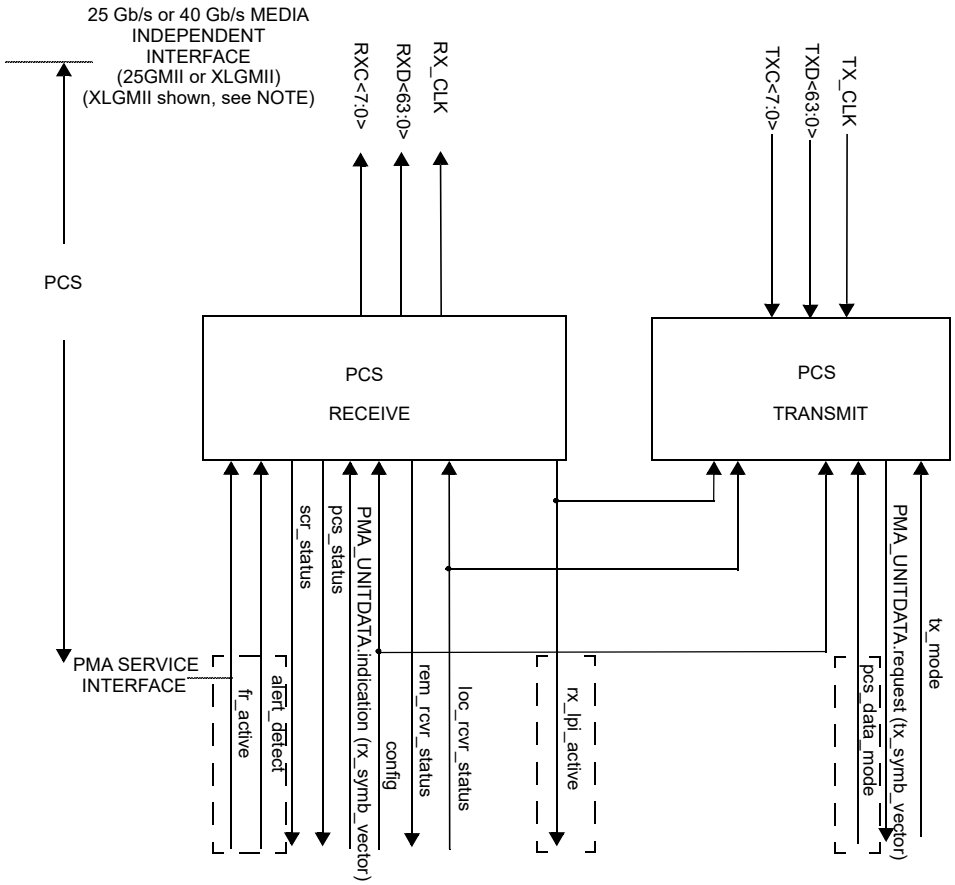
113.2.2.12.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 113–19a.

113.3 Physical Coding Sublayer (PCS)

113.3.1 PCS service interface (25GMII/XLGMII)

The PCS service interface allows the 25G/40GBASE-T PCS to transfer information to and from a PCS client. The PCS Interface is precisely defined for 25GBASE-T as the 25 Gb/s Media Independent Interface



Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

(25GMII) in Clause 106, and, for 40GBASE-T, the 40 Gb/s Media Independent Interface (XLGMII) in Clause 81.

113.3.2 PCS functions

The PCS comprises one PCS Reset function and two simultaneous and asynchronous operating functions. The PCS operating functions are: PCS Transmit and PCS Receive. All operating functions start immediately after the successful completion of the PCS Reset function.

The PCS reference diagram, Figure 113–5, shows how the two operating functions relate to the messages of the PCS-PMA interface. Connections from the management interface (signals MDC and MDIO) to other layers are pervasive and are not shown in Figure 113–5.

NOTE—
pcs_data_mode is required only for the EEE or fast retrain capabilities.
alert_detect and rx_lpi_active are only required for the EEE capability.
fr_active is only required for the fast retrain capability.
Word widths for only the 40 Gb/s Media Independent Interface (XLGMII) are shown for clarity. For the 25 Gb/s Media Independent Interface, a four-bit control word and 32-bit data word are used, i.e., RXC<3:0>, RXD<31:0>, TXC<3:0>, and TXD<31:0>.

Figure 113–5—PCS reference diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.3.2.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

a) Power on (see 113.3.6.2.2).
b) The receipt of a request for reset from the management entity.

PCS Reset sets pcs_reset = true while any of the above reset conditions hold true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

113.3.2.2 PCS Transmit function

The PCS Transmit function shall conform to the PCS 64B/65B Transmit state diagram in Figure 113–18a and Figure 113–18b, and to the PCS Transmit bit ordering in Figure 113–6 and Figure 113–8.

Dashed rectangles in Figure 113–18a and Figure 113–18b are used to indicate states and state transitions in the transmit process state diagram that shall be supported by PHYs with the EEE capability. PHYs without the EEE capability do not support these transitions.

When communicating with the 25GMII, the 25GBASE-T PCS uses a four octet-wide, synchronous data path, with packet delimiting being provided by transmit control signals and receive control signals. When communicating with the XLGMII, the 40GBASE-T PCS uses a eight octet-wide, synchronous data path, with packet delimiting being provided by transmit control signals and receive control signals. Alignment to 64B/65B is performed in the PCS. The PMA sublayer operates independently of block and packet boundaries. The PCS provides the functions necessary to map packets between the 25GMII/XLGMII format and the PMA service interface format.

When the transmitter is in normal mode, the PCS Transmit process continuously generates 65B blocks based upon the TXD <31:0> and TXC <3:0> signals on the 25GMII for 25GBASE-T, or the TXD <63:0> and TXC <7:0> signals on the XLGMII for 40GBASE-T. The subsequent functions of the PCS Transmit process then transcode the first 96 25GMII transfers for 25GBASE-T, or 48 XLGMII transfers for 40GBASE-T into 512B/513B blocks, append the subsequent four 25GMII transfers (25GBASE-T), or two XLGMII transfers (40GBASE-T) as (non-transcoded) 64B/65B blocks, scramble the bits, pack the resulting blocks, appending an unscrambled auxiliary bit, and split the bits into two sets. The first set is encoded by a Reed-Solomon encoder, and the second set is processed by a low density parity check (LDPC) encoder and then the two sets are joint mapped into a transmit LDPC frame of DSQ128 symbols. Transmit data-units are sent to the PMA service interface via the PMA_UNITDATA.request primitive.

In each symbol period, when communicating with the PMA, the PCS Transmit generates a code-group (A_n, B_n, C_n, D_n) that is transferred to the PMA via the PMA_UNITDATA.request primitive. The PMA transmits symbols A_n, B_n, C_n, D_n over wire pairs BI_DA, BI_DB, BI_DC, and BI_DD, respectively. The integer, n, is a time index that is introduced to establish a temporal relationship between different symbol periods. A symbol period, T, is 312.5/S ps.

If a PMA_TXMODE.indication message has the value SEND_Z, PCS Transmit shall pass a vector of zeros at each symbol period to the PMA via the PMA_UNITDATA.request primitive.

If a PMA_TXMODE.indication message has the value SEND_T, PCS Transmit shall generate sequences of code-groups (TA_n, TB_n, TC_n, TD_n) defined in 113.3.4.2 to the PMA via the PMA_UNITDATA.request primitive. These code-groups are used for training mode and only transmit the values {–9, 9} to keep the transmit power in the training mode the same as the transmit power in normal mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

During training mode an Infofield is transmitted at regular intervals containing messages for startup operation. By this mechanism, a PHY indicates the status of its own receiver to the link partner and makes requests for remote transmitter settings. (See 113.4.2.5.)

If a PMA_TXMODE.indication message has the value SEND_N, the PCS is in the normal mode of operation, and the PCS Transmit function shall use a 65B coding technique, transcoded to a mixed 513B-65B-RS-FEC-LDPC encoding to generate at each symbol period code-groups that represent data or control. During transmission, the six blocks of 513B transcoded bits and the two blocks of 65B encoded bits are scrambled by the PCS using a PCS scrambler and an auxiliary bit is added, then frames are encoded into a code-group of four-dimensional symbols and transferred to the PMA. During data encoding, PCS Transmit utilizes a Reed Solomon encoder to generate 3x512 bits and an LDPC frame encoder for the remaining 4x512 bits.

After reaching the normal mode of operation, EEE-capable PHYs may enter the LPI transmit mode under the control of the MAC via the 25GMII/XLGMII. The EEE Transmit state diagram is contained within the PCS Transmit function. The EEE capability is described in 113.3.2.2.23.

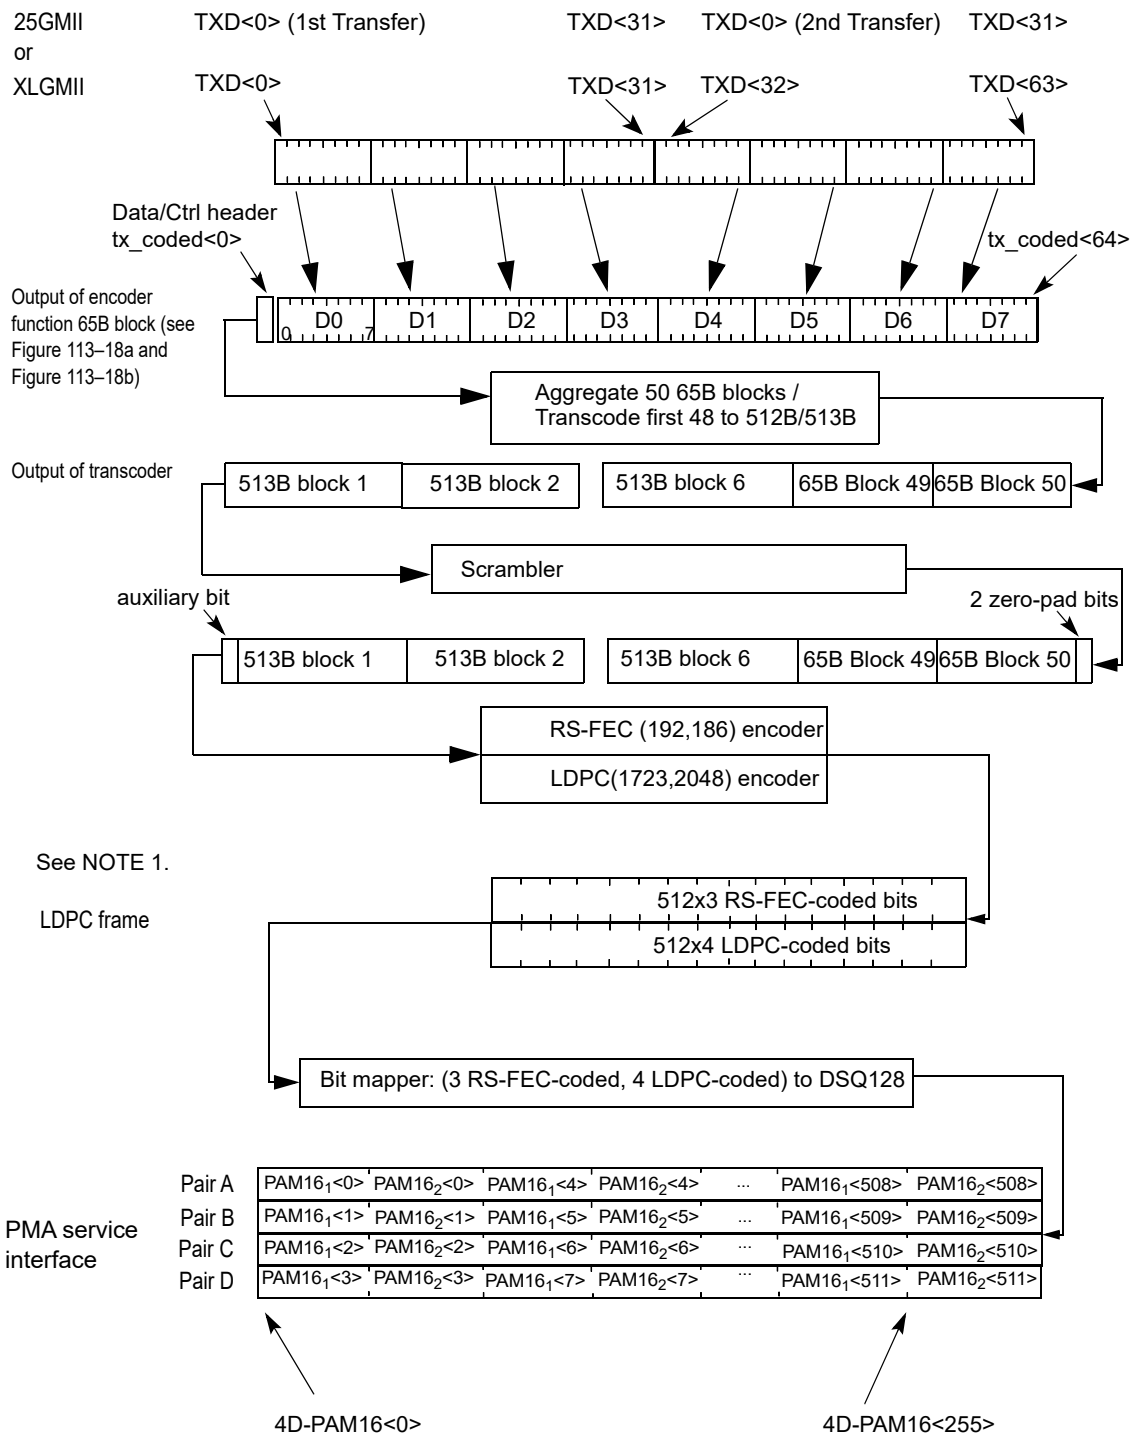
113.3.2.2.1 Use of blocks

The PCS maps 25GMII/XLGMII signals into 65-bit blocks inserted into an LDPC frame, and vice versa, using a 65B-LDPC coding scheme. The PAM2 PMA training frame synchronization allow establishment of LDPC frame and 65B boundaries by the PCS Synchronization process. Blocks and frames are unobservable and have no meaning outside the PCS. During the LPI mode, LDPC frame boundaries delimit sleep, wake, refresh, quiet, and alert cycles. The PCS functions ENCODE and DECODE generate, manipulate, and interpret blocks and frames as provided by the rules in 113.3.2.2.2.

113.3.2.2.2 65B-LDPC transmission code

The PCS uses a transmission code to improve the transmission characteristics of information to be transferred across the link and to support transmission of control and data characters. In addition, the code enables the receiver to achieve PCS synchronization alignment on the incoming PHY bit stream.

The relationship of block bit positions to 25GMII/XLGMII, PMA, and other PCS constructs is illustrated in Figure 113–6 for transmit and Figure 113–7 for receive. These figures illustrate the processing of a multiplicity of blocks containing 8 data octets. See 113.3.2.2.5 for information on how blocks containing control characters are mapped.



113.3.2.2.3 Notation conventions

For values shown as binary, the leftmost bit is the first transmitted bit.

64B/65B encodes 8 data octets or control characters into a block. Blocks containing control characters also contain a block type field. Data octets are labeled D0 to D7. Control characters other than /O/, /S/ and /T/ are labeled C0 to C7. The control character for ordered set is labeled as O0 or O4 since it is only valid on the first octet of the 25GMII/XLGMII. The control character for start is labeled as S0 or S4 for the same reason. The control character for terminate is labeled as T0 to T7.

For 25GBASE-T, two 25GMII transfers or, for 40GBASE-T, a single XLGMII transfer provide eight characters that are encoded into one 65-bit transmission block. The subscript in the above labels indicates the position of the character in the eight characters from the 25GMII/XLGMII transfer(s).

Contents of block type fields, data octets, and control characters are shown as hexadecimal values. The LSB of the hexadecimal value represents the first transmitted bit. For instance, the block type field 0x1E is sent from left to right as 01111000. The bits of a transmitted or received block are labeled TxB<31:0> and RxB<31:0> for 25GBASE-T, or TxB<64:0> and RxB<64:0> for 40GBASE-T, respectively where TxB<0> and RxB<0> represent the first transmitted bit. The value of the data/ctrl header is shown as a binary value. Binary values are shown with the first transmitted bit (the LSB) on the left.

113.3.2.2.4 Transmission order

The PCS Transmit bit ordering is shown in Figure 113–6 and Figure 113–8. Note that Figure 113–6 shows the mapping from the 25GMII/XLGMII to a 64B/65B block for a block containing eight data characters.

113.3.2.2.5 Block structure

Blocks consist of 65 bits. The first bit of a block is the data/ctrl header. Blocks are either data blocks or control blocks. The data/ctrl header is 0 for data blocks and 1 for control blocks. The remainder of the block contains the payload.

Data blocks contain eight data characters. Control blocks begin with an eight-bit block type field that indicates the format of the remainder of the block. For control blocks containing a Start or Terminate character, that character is implied by the block type field. Other control characters are encoded in a seven-bit control code or a four-bit O Code. Each control block contains eight characters.

The format of the blocks for 25GBASE-T is as shown in Figure 113–9. The format of the blocks for 40GBASE-T is as shown in Figure 113–10. In the figure, the column labeled Input Data shows, in abbreviated form, the eight characters used to create the 65-bit block. These characters are either data characters or control characters and, when transferred across the 25GMII/XLGMII interface, the corresponding TXC or RXC bit is set accordingly. Within the Input Data column, D_0 through D_7 are data octets and are transferred with the corresponding TXC or RXC bit set to zero. All other characters are control octets and are transferred with the corresponding TXC or RXC bit set to one. The single bit fields (thin rectangles with no label in the figure) are sent as zero and ignored upon receipt..

Bits and field positions are shown with the least significant bit on the left. Hexadecimal numbers are shown prepended with ‘0x’, and with the least significant digit on the right. For example the block type field 0x1E is sent as 01111000 representing bits 1 through 8 of the 65-bit block. The least significant bit for each field is placed in the lowest numbered position of the field.

All unused values of block type field are reserved.[189]

113.3.2.2.6 Control codes

The same set of control characters are supported by the 25GMII/XLGMII and the 25G/40GBASE-T PCS. The representations of the control characters are the control codes. The 25GMII/XLGMII encodes a control character into an octet (an eight-bit value). The 25G/40GBASE-T PCS encodes the start and terminate control characters implicitly by the block type field. The 25G/40GBASE-T PCS encodes the ordered set control codes using a combination of the block type field and a four-bit O code for each ordered set. The 25G/40GBASE-T PCS encodes each of the other control characters into a seven-bit C code.

[189]The block type field values have been chosen to have a four-bit Hamming distance between them. The only unused value that maintains the Hamming distance is 0x00.

Table 113–2—Control codes for 40GBASE-T *(continued)*

Control character	Notation	XLGMII control code	40GBASE-T control code	40GBASE-T O code
error	/E/	0xFE	0x1E	
Sequence ordered set	/Q/	0x9C	Encoded by block type field plus O code	0x0
Signal ordered set[b]	/Fsig/	0x5C	Encoded by block type field plus O code	0xF

[a]Use of idle and LPI ordered sets per 81.3.
[b]Used by INCITS T11 Fibre Channel.

113.3.2.2.7 Ordered sets

Ordered sets are used to extend the ability to send control and status information over the link such as remote fault and local fault status. Ordered sets consist of a control character followed by three data characters. Ordered sets always begin on the first octet of the 25GMII or XLGMII. 25 Gigabit and 40 Gigabit Ethernet use one kind of ordered set: the sequence ordered set (see 81.3.4). The sequence ordered set control character is denoted /Q/. An additional ordered set, the signal ordered set, is defined and it begins with another control code. The four-bit O field encodes the control code. See Table 113–1 for the mappings for 25GBASE-T, and Table 113–2 for the mappings for 40GBASE-T.

113.3.2.2.8 Idle (/I/)

Idle control characters (/I/) are transmitted when idle control characters are received from the 25GMII/XLGMII. Idle characters may be added or deleted by the PCS to adapt between clock rates. /I/ insertion and deletion shall occur in groups of 4. /I/s may be added following idle or ordered sets. They shall not be added while data is being received. When deleting /I/s, the first four characters after a /T/ shall not be deleted.

113.3.2.2.9 LPI (/LI/)

Low power idle (LPI) control characters (/LI/) on the 25GMII/XLGMII indicate that the LPI client is requesting operation in the LPI transmit mode. A continuous stream of LPI control characters (/LI/) is used to maintain a link in the LPI transmit mode. Idle control characters (/I/) are used to transition from the LPI transmit mode to the normal mode. PHYs that support EEE respond to the LPI 25GMII/XLGMII control characters using the procedure outlined in 113.1.3.3. LPI characters may be added or deleted by the PCS to adapt between clock rates. /LI/ insertion and deletion shall occur in groups of four. /LI/s may be added following low power idle characters. They shall not be added while data is being received.

If EEE is not supported, then /LI/ is not a valid control character.

113.3.2.2.10 Start (/S/)

The start control character (/S/) indicates the start of a packet. This delimiter is only valid on the first octet of the 25GMII (TXD<7:0> and RXD<7:0>), or XLGMII (TXD<7:0> and RXD<7:0>). Receipt of an /S/ on any other octet of TXD indicates an error. For 25 Gb/s and 40 Gb/s transmission, block type field values implicitly encode an /S/ as the first character of the block. These are the only characters of a block on which a start can occur.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.3.2.2.11 Terminate (/T/)

The terminate control character (/T/) indicates the end of a packet. Since packets may be any length, the /T/ can occur on any octet of the 25GMII/XLGMII interface and within any character of the block. The location of the /T/ in the block is implicitly encoded in the block type field. A valid end of packet occurs when a block containing a /T/ is followed by a control block that does not contain a /T/.

113.3.2.2.12 ordered set (/O/)

The ordered set control characters (/O/) indicate the start of an ordered set. There are two kinds of ordered sets: the sequence ordered set and the signal ordered set. When it is necessary to designate the control character for the sequence ordered set specifically, /Q/ is used. /O/ is only valid on the first octet of the 25GMII/XLGMII. Receipt of an /O/ on any other octet of TXD indicates an error. For 40 Gb/s transmission, block type field values implicitly encode an /O/ as the first character of the block. The four-bit O code encodes the specific /O/ character for the ordered set.

Sequence ordered sets may be deleted by the PCS to adapt between clock rates. Such deletion shall only occur when two consecutive sequence ordered sets have been received and shall delete only one of the two. Only Idles may be inserted for clock compensation. Signal ordered sets are not deleted for clock compensation.

113.3.2.2.13 Error (/E/)

The /E/ is sent whenever an /E/ is received. The /E/ allows physical sublayers such as the PCS to propagate received errors. See R_BLOCK_TYPE and T_BLOCK_TYPE function definitions in 113.3.6.2.4 for further information.

113.3.2.2.14 Transmit process

The transmit process generates blocks based upon the TXD and TXC signals received from the 25GMII/XLGMII. 100 25GMII or 50 XLGMII data transfers are encoded into an LDPC frame. It takes 256 PMA_UNITDATA transfers to send an LDPC frame of data. Therefore, for 25GBASE-T, if the PCS is connected to a 25GMII and PMA sublayer where the ratio of their transfer rates is exactly 25:64, or, for 40GBASE-T, an XLGMII and PMA sublayer where the ratio of their transfer rates is exactly 25:128, then the transmit process does not need to perform rate adaptation. Where the 25GMII or XLGMII and PMA sublayer data rates are not synchronized to that ratio, the transmit process needs to insert idles, delete idles, or delete sequence ordered sets to adapt between the rates.

The transmit process generates blocks as specified in the PCS 64B/65B Transmit state diagram (see Figure 113–18a and Figure 113–18b). The contents of each block are contained in a vector tx_coded<64:0>, which is passed to the transcoder/ scrambler. tx_coded<0> contains the data/ctrl header and the remainder of the bits contain the block payload.

113.3.2.2.15 64B/65B to 512B/513B Transcoder

The 513B transcoder constructs a 513-bit block tx_xcoded<512:0>, from a group of eight 65-bit blocks, tx_coded_*j*<64:0> where *j*=0 to 7. For each group of eight 65-bit blocks, *j*=7 corresponds to the most recently received block. Bit 0 in each 65-bit block is the first bit received and corresponds to the data control header.

If for all *j*=0 to 7, tx_coded_*j*<0> = 0, tx_xcoded<512:0> shall be constructed as follows:

a) tx_xcoded<0>=1

b) tx_xcoded<(64*j*+64):(64*j*+1)>=tx_coded_*j*<64:1> for *j*=0 to 7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If for any *j*=0 to 7, tx_coded_*j*<0>=1, tx_xcoded<512:0> shall be constructed as follows:

a1) tx_xcoded<0>=0

b1) Within the group of eight 65-bit blocks, let *C* be the set of *k* integers corresponding to the values of *j* that have tx_coded_*j*<0> = 1, and *U* be the set of 8–*k* integers corresponding to the values of *j* that have tx_coded_*j*<0> = 0, where the integers that comprise both *C* and *U* are arranged in ascending order. For instance, if tx_coded_1<0>=1 and tx_coded_4<0>=1, *C* = {1,4}, and *U* = {0,2,3,5,6,7}.

c1) For the allowed set of 25GBASE-T 64B/65B or 40GBASE-T 64B/65B control codes (see Figure 113–9 and Figure 113–10), let the four-bit code shown in the rightmost column of Table 113–4 represent the Block Type for transcoding purposes.

Given this, a 513-bit block can be constructed consisting of a leading 1, followed by all of the transcoded control blocks in *C*, followed by all of the data blocks in *U*.

Table 113–3 shows the transcoding scheme. The first column represents a 513B control byte that replaces the eight-bit block type found in the 64B/65B control code, and contains 3 fields:

a2) A continuation flag (FC) that if set to 1 indicates that another control block is to follow, and if set to 0 indicates that this is the last control block in the group of 8 transcoded 65B blocks, followed by

b2) Three position bits (Position) used to indicate which of the eight 65B blocks in the transcoding group the control block came from, followed by

c2) Four block-type bits (BlockType), which contain the transcoded block type, as shown in the right-most column of Table 113–4.

The resulting translation can be represented as the 513B control byte = {FC, Position<2:0>, BlockType<3:0>}.

Table 113–3—513B Transcoded Blocks including Control blocks (without leading 0)

513B control byte	64/65B block payload
513B Control Byte C_0 (1, Position<2:0>, Block Type<3:0>)	tx_coded_C_0<9:64>
513B Control Byte C_1 (1, Position<2:0>, Block Type<3:0>)	tx_coded_C_1<9:64>
:	:
513B Control Byte C_{k-1}(0, Position <2:0>, Block Type<3:0>)	tx_coded_C_{k-1}<9:64>
tx_coded_U_0<1:8>	tx_coded_U_0<9:64>
tx_coded_U_1<1:8>	tx_coded_U_1<9:64>
:	:
tx_coded_U_{7-k}<1:8>	tx_coded_U_{7-k}<9:64>

The following examples are provided for clarity, shown in Figure 113–11.

Example #1: *C* = {1,4}, and *U* = {0,2,3,5,6,7}, with the first control block being 0x1E, and the second being 0x78. Thus:

1.1) 65B control words are present, so the 513B control flag bit gets set to 0

0xCC	0011
0xD2	0110
0xE1	0000
0xFF	1111

1.2) The first control word is C_0 where Position = 0x1, and BlockType = 0x8. Since this is not the last control word the continuation flag FC = 1. Thus the 513B control word for this block is:
C_0 Control Word = {1,0x1, 0x8} = 1 100 0001 in bit order of transmission

1.3) The second control word is C_1 where Position = 0x4, and BlockType = 0x7. Since this is the last control word the continuation flag FC = 0. Thus the 513B control word for this block is:
C_4 Control Word = {0,0x4, 0x7} = 0 001 1110 in bit order of transmission

1.4) After this the payload of the remaining data blocks is placed

Example #2: C = {7}, and U = {0,1,2,3,4,5,6}, with the control block being 0xB4. Thus:

2.1) 65B control words are present, so the 513B control flag bit gets set to 0

2.2) The first and only control word is C_0 where Position = 0x7, and BlockType = 0x5. Since this is also the last control word the continuation flag FC = 0. Thus the 513B control word for this block is:
C_0 Control Word = {0,0x7, 0x5} = 0 111 1010 in bit order of transmission

2.3) After this the payload of the remaining data blocks is placed

Example #3: C = {}, and U = {0,1,2,3,4,5,6,7}. Thus:

3.1) No 65B control words are present, so the 513B control flag bit gets set to 1

3.2) After this the payload of all of the data blocks is placed

Example 3: All data blocks

Figure 113–11—Examples of the construction of tx_xcoded

113.3.2.2.16 Aggregation

The six 512B/513B transcoded blocks and two 64B/65B blocks are concatenated to form tx_aggregated<3207:0>. The tx_xcoded_*j*<512:0> is mapped into tx_aggregated<513*j*+512:513*j*> where j=0 to 5. tx_xcoded_0<512:0> is the first to be transmitted. The two 64B/65B blocks are mapped into tx_aggregated<3142:3078> and tx_aggregated<3207:3143>.

113.3.2.2.17 PCS Scrambler

The payload of the PCS PHY frame tx_aggregated<3207:0> is scrambled to tx_scrambled<3207:0> with a self-synchronizing scrambler. The scrambler for the MASTER shall produce the same result as the

Copyright © 2022 IEEE. All rights reserved.

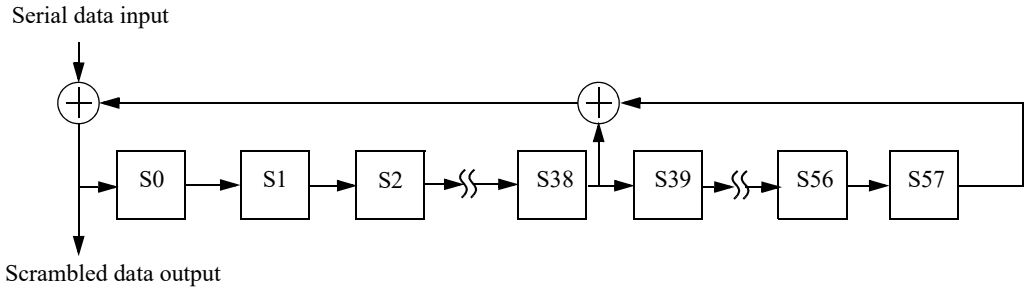
implementation shown in Figure 113–12. This implements the scrambler polynomial[190] as shown in Equation (113–1):



$$G(x) = 1 + x^{39} + x^{58} \quad (113–1)$$

The scrambler for the SLAVE shall produce the same result as the implementation shown in Figure 113–12. This implements the scrambler polynomial as shown in Equation (113–2):

$$G(x) = 1 + x^{19} + x^{58} \quad (113–2)$$

The initial seed values for the MASTER and SLAVE are left to the implementer. The scrambler is run continuously on all payload bits.

PCS scrambler employed by the MASTER

PCS scrambler employed by the SLAVE

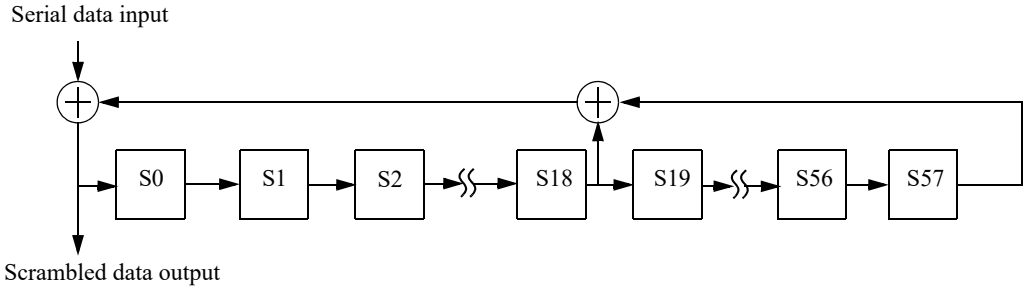


Figure 113–12—MASTER and SLAVE PCS scramblers

[190]The convention here, which considers the most recent bit into the scrambler to be the lowest order term, is consistent with most references and with other scramblers shown in this standard. Some references consider the most recent bit into the scrambler to be the highest order term and would therefore identify this as the inverse of the polynomial in Equation (113–1). In case of doubt, note that the conformance requirement is based on the representation of the scrambler in the figure rather than the polynomial equation.

113.3.2.2.18 LDPC framing and LDPC encoder

The resulting payload of scrambled six 513B transcoded blocks plus two 65B blocks, followed by two random fill bits, and six eight-bit Reed Solomon parity symbols and preceded by 1 auxiliary bit results in a total payload of 6 × 513 + 2 × 65 + 2+ 6× 8+ 1 = 3259 bits. The use of the auxiliary bit for vendor-specific communication is outside the scope of this document. It is highly recommended that the auxiliary bit be randomized. For the purposes of this standard it is ignored by the link partner, as are the random fill bits. From the total payload of 3259 bits, 1536 (3 bits for each of the 512 DSQ128 symbols) are RS-FEC-coded bits and the remaining 1723 shall be encoded by the LDPC(1723, 2048) generator matrix G. G is described in Annex 55A. See Figure 113–8 and 113.3.2.2.19 for details on PCS bit ordering and RS-FEC encoding.

The LPDC encoding takes the 1723-bit input code vector x = [x_0 x_1 x_2 ... x_{1722}], and shall generate the 2048-bit codeword c represented by the matrix multiplication c = x × G. For both x and c the encoder shall follow the notation described in 113.3.2.2.3 where the LSB (leftmost element of the vectors x and c) is the first bit into the LDPC encoder and the first transmitted bit.

113.3.2.2.19 Reed Solomon encoder

The group of 1536 bits are encoded using a Reed-Solomon encoder operating over the Galois Field GF(2^8) where the symbol size is 8 bits. The encoder processes k=186 eight-bit RS-FEC message symbols to generate 2t=6 eight-bit RS-FEC parity symbols, which are then appended to the message to produce a codeword of n=k+2t=192 eight-bit RS-FEC symbols. For the purposes of this clause, the Reed-Solomon code is denoted RS-FEC(n,k), and the particular Reed-Solomon code is RS-FEC(192,186).

The code is based on the generating polynomial given by Equation (113–3):

$$g(x) = \prod_{j=0}^{5} \left(x - \alpha^j\right) = g_6x^6 + g_5x^5 + g_4x^4 + g_3x^3 + g_2x^2 + g_1x + g_0 \quad (113–3)$$

In Equation (113–3), α , is a primitive element of the finite field defined by the primitive polynomial 0x11D = $x^8+x^4+x^3+x^2+1$.

Equation (113–4) defines the message polynomial m(x) whose coefficients are the message symbols m_{185} to m_0:

$$m(x) = m_{185}x^{191} + m_{184}x^{190} + \ldots + m_1x^7 + m_0x^6 \quad (113–4)$$

Each message symbol m_i is the bit vector ($m_{i,7}$, $m_{i,6}$, ... $m_{i,1}$,$m_{i,0}$) that is identified with the element of the finite field. The message symbols are composed of the bits in tx_RSmessage<1487:0> where

$m_{i,j}$=tx_RSmessage<(185-i)8 + j>, i=0 to 185, j=0 to 7.

tx_RSmessage<1487:0> is formed as follows:

tx_RSmessage<0> = Auxiliary bit
tx_RSmessage<2:1>=tx_scrambled<1:0>
tx_RSmessage<1292:3> = tx_RSmessage<3j+5:3j+3> = tx_scrambled<8+7j:6+7j> where j = 429 to 0
tx_RSmessage<1485:1293> = tx_scrambled<3207:3015>
tx_RSmessage<1487:1486> = 00 (It is highly recommended that two random fill bits be transmitted instead of zeros, and then this information is discarded upon receipt)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The first symbol input to the encoder is m_{185}.

tx_scrambled<3207:0> is defined in 113.3.2.2.17.

Equation (113–5) defines the parity polynomial *p(x)* whose coefficients are the parity symbols p_5 to p_0:

$$p(x) = p_5x^5 + p_4x^4 + p_3x^3 + p_2x^2 + p_1x + p_0 \quad (113–5)$$

The parity polynomial is the remainder from the division of m(x) by g(x). This may be computed using the shift register implementation illustrated in Figure 113–13. The outputs of the delay elements are initialized to zero prior to the computation of the parity for a given message. After the last message symbol, m_0, is processed by the encoder, the outputs of the delay elements are the parity symbols for that message.

The codeword polynomial c(x) is then the sum of m(x) and p(x) where the coefficient of the highest power of x, $c_{191} = m_{185}$ is transmitted first and the coefficient of the lowest power of *x*, $c_0 = p_0$ is transmitted last. The first bit transmitted from each symbol is bit 0.

The coefficients of the generator polynomial for the code are presented in Table 113–5.

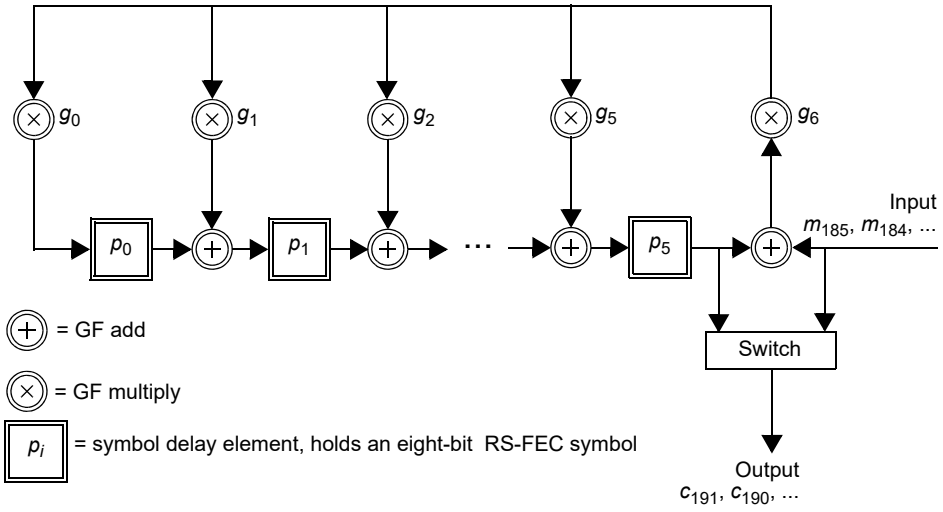

Figure 113–13—Reed-Solomon encoder functional model

113.3.2.2.20 DSQ128 bit mapping

DSQ128 refers to a two-dimensional constellation with 128 possible 2D values, such that the combined 2D symbol carries $\log_2(128)$ or 7 bits. The PHY frame of 1536 RS-FEC-coded bits and 2048 (LDPC output) LDPC-coded bits described in Figure 113–6 shall be partitioned into seven-bit groups of (3 RS-FEC-coded, 4 LDPC-coded) as described in Figure 113–8. The bit partition is as follows, the first 1290 (3 × 430) RS-FEC-coded bits are paired with the first 1720 (4 × 430) LDPC input bits. The following 3 RS-FEC-coded bits are paired with the last 3 LDPC input bits and the first LDPC parity bit. Finally the remaining 243 (3 × 81) RS-FEC-coded bits are paired with the remaining 324 (4 × 81) LDPC parity bits.

0	38
1	227
2	32
3	218
4	1
5	63
6	1

Each 2D-DSQ128 value has two PAM16 components denoted $PAM16_1$ and $PAM16_2$ respectively. The DSQ128 can be constructed by pruning the 256 values of a 2D-PAM16 where every other point in 2D is discarded (like the black or white squares in a checkerboard). The PAM16 components $PAM16_1$ and $PAM16_2$ can each take any of the values from the set {–15, –13, –11, –9, –7, –5, –3, –1, 1, 3, 5, 7, 9, 11, 13, 15}. The mapping from 7 bits where u_0 u_1 u_2 denote the 3 RS-FEC-coded bits and c_0 c_1 c_2 c_3 denote the 4 LDPC-coded bits to the DSQ128 is described by the following four steps (the bits from the scrambler output shall be read LSB first):

Step 1:

$x_{13} = (!u_0)\ \&\ u_2$

$x_{12} = u_0\ \text{XOR}\ u_2$

$x_{11} = c_0$

$x_{10} = c_0\ \text{XOR}\ c_1$

$x_{23} = (u_1\ \&\ u_2)\ \text{OR}\ (u_0\ \&\ !u_1)$

$x_{22} = u_1\ \text{XOR}\ u_2$

$x_{21} = c_2$

$x_{20} = c_2\ \text{XOR}\ c_3$

Step 2:

$x_1 = 8x_{13} + 4x_{12} + 2x_{11} + x_{10}$

$x_2 = 8x_{23} + 4x_{22} + 2x_{21} + x_{20}$

Step 3:

$y_1 = (x_1 + x_2)\ \text{mod}16$

$y_2 = (–x_1 + x_2)\ \text{mod}16$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Step 4:

$$PAM16_1 = 2y_1 - 15$$

$$PAM16_2 = 2y_2 - 15$$

where '*n* mod16' for an integer *n*, is defined as the integer value *p* in the range 0 to 15 (both inclusive) such that '$p = n + 16m$', for some integer *m*.

113.3.2.2.21 DSQ128 to 4D-PAM16

The DSQ mapper generates 512 2D-DSQ128 symbols per LDPC frame that are mapped onto 256 4D-PAM16 symbols prior to sending to the PMA via PMA_UNITDATA.request. The mapping of DSQ128 to 4D-PAM16 is illustrated in Figure 113–6. As shown in Figure 113–6, the two PAM16 components of each DSQ128 symbol are mapped onto two consecutive time periods on the same wire pair.

113.3.2.2.22 Block-LDPC framer

The Block-LDPC framer adapts between the mixed 513B and 65B blocks and the 4D-PAM16 width of the PMA. When the transmitter is operating in normal mode, the 65B-LDPC sends four PAM16 of transmit data at a time via PMA_UNITDATA.request primitives. The PMA_UNITDATA.request primitives are fully packed with bits.

113.3.2.2.23 EEE capability

The optional 25G/40GBASE-T EEE capability allows compliant PHYs to transition to an LPI mode of operation when link utilization is low.

PHYs that support EEE shall implement the EEE transmit state diagram, shown in Figure 113–20, within the PCS.

When PCS_Reset is asserted or pcs_data_mode is not asserted, the state diagram enters the TX_NORMAL state.

When a complete 64B/65B block of LPI characters is generated by the PCS transmit function, the PHY transmits the sleep signal to indicate to the link partner that it is transitioning to the LPI transmit mode. If the sleep signal begins on an LDPC frame boundary, then it contains 6 full LDPC frames each composed entirely of RS-FEC and LDPC encoded LP_IDLE blocks. If the sleep signal does not begin on an LDPC frame boundary, then it contains one LDPC frame partially composed of LP_IDLE blocks followed by 6 LDPC frames fully composed of LP_IDLE blocks.

Following the transmission of the sleep signal, quiet-refresh signaling begins, as described in 113.3.5.

After the sleep signal is transmitted LPI control characters shall be input to the PCS scrambler continuously until the PCS Transmit Function exits the LPI transmit mode.

While the PMA asserts SEND_N, the lpi_tx_mode variable shall control the transmit signal through the PMA_UNITDATA.request primitive described as follows:

When the PHY is not in the PCS_Data state, the lpi_tx_mode variable is ignored.

When the lpi_tx_mode variable takes the value NORMAL and the PMA asserts SEND_N, the PCS passes coded data to the PMA via the PMA_UNITDATA.request primitive as described in 113.3.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the lpi_tx_mode variable takes the value QUIET and the PMA asserts SEND_N, the PCS passes zeros to the PMA through the PMA_UNITDATA.request primitive.

When the lpi_tx_mode variable takes the value REFRESH_A and the PMA asserts SEND_N, the PCS passes the PMA training signal to the PMA on pair A, to allow both the local and remote PHY to refresh adaptive filters and timing loops. The PCS passes zeros to all other pairs in this condition. REFRESH_B, REFRESH_C and REFRESH_D operate in an analogous manner for the other pairs.

When the lpi_tx_mode variable takes the value ALERT and the PMA asserts SEND_N, the PCS passes the ALERT vector to the PMA.

The quiet-refresh cycle is repeated until codewords other than LP_IDLE are detected at the 25GMII/XLGMII. These codewords indicate that the local system is requesting a transition back to the normal operational mode. Following this event, the PMA_UNITDATA.request parameter tx_symb_vector is set to the value ALERT. The alert signal is not synchronized with respect to the quiet-refresh cycle but shall be synchronized so that the alert signal from the PMA begins on a LDPC frame boundary.

The PHY will also transition back to the normal operation mode if an error condition occurs. This error condition is defined as the detection of any characters other than LPI or IDLE at the 25GMII/XLGMII.

After the alert signal the PCS completes the transition from LPI mode to normal mode by sending a wake signal containing lpi_wake_time LDPC frames composed of IDLE 64B/65B blocks.

lpi_wake_time is a fixed parameter that is defined as 9 LDPC frames as shown in Table 113–6. The maximum PHY wake time when wake is requested before sleep has been completely transmitted is 1.6 μs (lpi_wake_timer=T_{w_phy} as defined by Clause 78). The maximum PHY wake time when wake is requested after sleep has been completely transmitted is 1.12 μs.

Table 113–6—LPI wake time

lpi_wake_time	lpi_wake_timer when wake starts before sleep signal is complete		lpi_wake_timer when wake starts after sleep signal is complete	
(frames)	(frames)	(μs)	(frames)	(μs)
9	20	1.6	14	1.12

113.3.2.3 PCS Receive function

The PCS Receive function shall conform to the PCS 64B/65B receive state diagram in Figure 113–19a and Figure 113–19b and the PCS Receive bit ordering in Figure 113–7 including compliance with the associated state variables as specified in 113.3.6.

The PCS Receive function accepts received code-groups provided by the PMA Receive function via the parameter rx_symb_vector. The PCS receiver uses knowledge of the encoding rules to correctly align the 65B-LDPC frames. The received 65B-LDPC frames are decoded with error correction on both the RS-FEC and LDPC codes, and framing is checked; the six 512B/513B blocks are transcoded to 64B/65B. This process generates the 64B/65B block vector rx_coded<64:0> that is then decoded to form the 25GMII signals RXD<31:0> and RXC<3:0> for 25GBASE-T or the XLGMII signals RXD<63:0> and RXC<7:0> for 40GBASE-T, as specified in the PCS 64B/65B Receive state diagram (see Figure 113–19a and Figure 113–19b). 100 25GMII or 50 XLGMII data transfers are decoded from one LDPC frame. Where the 25GMII or XLGMII and PMA sublayer data rates are not synchronized in a 25:64 ratio or 25:128 ratio,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

respectively, the receive process inserts idles, deletes idles, or deletes sequence ordered sets to adapt between rates.

During PMA training mode, PCS Receive checks the received PAM2 framing and signals the reliable acquisition of the descrambler state by setting the scr_status parameter of the PMA_SCRSTATUS.request primitive to OK.

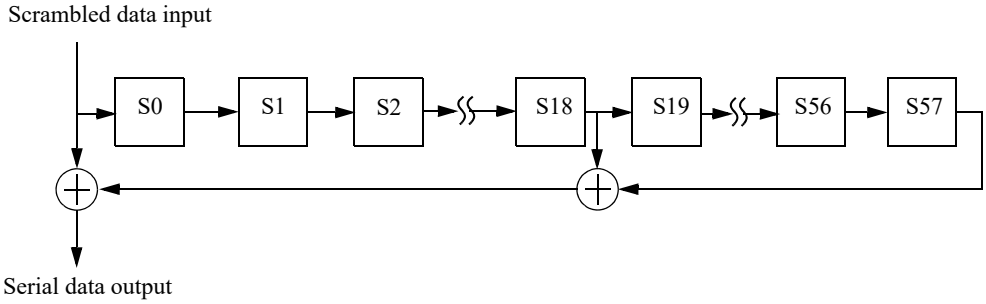
When the PCS Synchronization process has obtained synchronization, the LDPC frame error ratio (LFER) monitor process monitors the signal quality asserting hi_lfer if excessive LDPC frame errors are detected (LDPC parity error or uncorrectable RS-FEC error). If 40 consecutive LDPC frame errors are detected, the block_lock flag is de-asserted. When block_lock is asserted and hi_lfer is de-asserted, the pcs_status parameter of the PMA_PCSSTATUS.request primitive is set to OK, and the PCS Receive process continuously accepts blocks. The PCS Receive process monitors these blocks and generates RXD and RXC on the 25GMII/XLGMII.

When the receiver is in training mode, the PCS Synchronization process continuously monitors PMA_RXSTATUS.indication (loc_rcvr_status). When loc_rcvr_status indicates OK, then the PCS Synchronization process accepts data-units via the PMA_UNITDATA.request primitive. It attains frame and block synchronization based on the PMA training frames and conveys received blocks to the PCS Receive process. The PCS Synchronization process sets the block_lock flag to indicate whether the PCS has obtained synchronization. The PMA training sequence includes one-bit pattern on pair A every 256 PAM2 symbols, which is aligned with the PCS PHY frame boundary. When the PCS Synchronization process is synchronized to this pattern, block_lock is asserted.

PHYs with the EEE capability support transition to the LPI mode when the PHY has successfully completed training and pcs_data_mode is TRUE. Transitions to and from the LPI mode are allowed to occur independently in the transmit and receive functions. The PCS receive function is responsible for detecting transitions to and from the LPI receive mode and indicating these transitions using signals defined in 113.2.2.

The link partner signals a transition to the LPI mode of operation by transmitting 6 LDPC frames composed entirely of 64B/65B blocks of /LI/. When blocks of /LI/ are detected at the output of the 64B/65B decoder, rx_lpi_active is asserted by the PCS receive function and the /LI/ character is continuously asserted at the receive 25GMII/XLGMII. These frames may be preceded by a frame composed partially of /LI/ characters. After these frames the link partner begins transmitting zeros, and it is recommended that the receiver power down receive circuits to reduce power consumption. The receive function uses LDPC frame counters to maintain synchronization with the remote PHY and receives periodic refresh signals that are used to update coefficients, so that the integrity of adaptive filters and timing loops in the PMA is maintained. LPI signaling is defined in 113.3.5. The quiet-refresh cycle continues until the PMA asserts alert_detect to indicate that the alert signal has been reliably detected. After the alert signal the link partner transmits repeated /I/ characters, representing a wake signal. The PHY receive function sends /I/ to the 25GMII/XLGMII for 9 LDPC frame periods and then resumes normal operation.

113.3.2.3.1 Frame and block synchronization



When the receiver is operating in normal mode, the frame and block synchronization function receives data via 4D-PAM16 PMA_UNITDATA.request primitives. It shall form a 4D-PAM16 stream from the primitives by concatenating requests with the PAM16s of each primitive in order from rx_data-group<0> to rx_data-group<255> (see Figure 113–7). It obtains block_lock to the LDPC frames during the PAM2 training pattern using synchronization bits provided on pair A. The 65-bit blocks are extracted based on their location in the LDPC frame.

113.3.2.3.2 PCS descrambler

The descrambler processes the payload to reverse the effect of the scrambler using the same polynomial. It shall produce the same result as the implementations shown in Figure 113–14 for the MASTER and the SLAVE.

PCS descrambler employed by the MASTER

PCS descrambler employed by the SLAVE

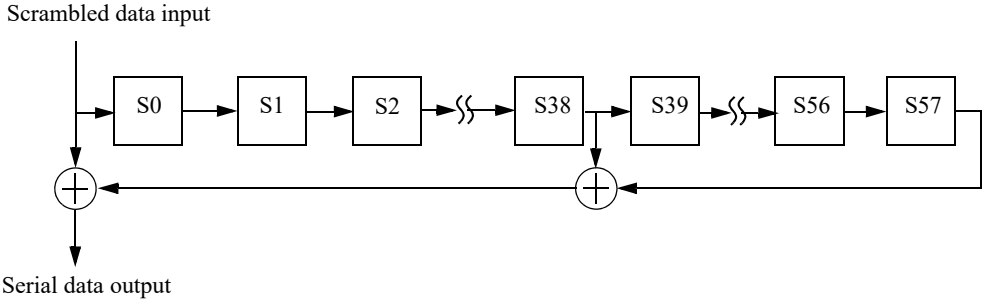

Figure 113–14—MASTER and SLAVE PCS descramblers

113.3.2.3.3 Invalid blocks

A block is invalid if any of the following conditions exists:

a) The block type field contains a reserved value.
b) For 25GBASE-T, any control character contains a value not in Table 113–1, or Table 113–2 for 40GBASE-T.
c) For 25GBASE-T, any O code contains a value not in Table 113–1, or Table 113–2 for 40GBASE-T.
d) The block contains information from the payload of an invalid received PHY frame or the first 64B/65B block following an invalid received PHY frame.

The PCS Receive function shall check the integrity of the LDPC and RS-FEC parity bits defined in 113.3.2.2.18 and 113.3.2.2.19, respectively. If either check fails the PHY frame is invalid.

R_BLOCK_TYPE of an invalid block is set to E.

113.3.3 Test-pattern generators

The test-pattern generator mode is provided for enabling joint testing of the local transmitter, link segment, and remote receiver. When the transmit PCS is operating in test-pattern mode it shall transmit continuously

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

as illustrated in Figure 113–6, with the input to the scrambler set to zero and the initial condition of the scrambler set to any non-zero value. When the receiver PCS is operating in test-pattern mode it shall receive continuously as illustrated in Figure 113–7. After acquiring the self-synchronizing scrambler state, the output of the received scrambled values should ideally be zero. Any nonzero values correspond to receiver bit errors. This mode is further described as test mode 7 in 113.5.2.

113.3.4 PMA training side-stream scrambler polynomials

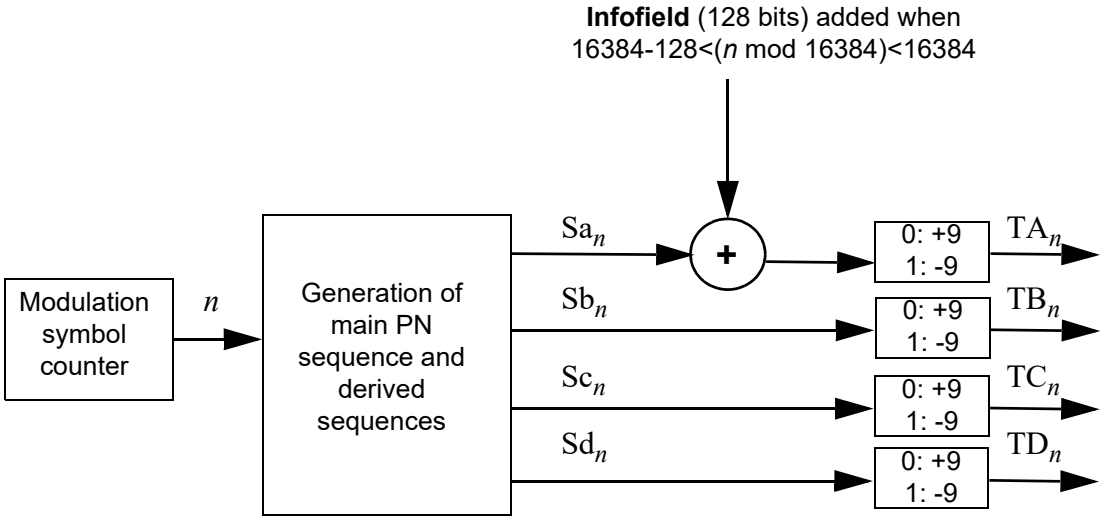
The PCS Transmit function employs side-stream scrambling for generating 2-level PAM PMA training sequences as shown in Figure 113–15. An implementation of MASTER and SLAVE PHY side-stream scramblers is shown in the "Main PN sequence" box. The bits stored in the shift register delay line at time n are denoted by $Scr_n[32:0]$. At each symbol period, the shift register is advanced by one bit, and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. In no case shall the scrambler state be initialized to all zeros.

113.3.4.1 Generation of bits Sa_n, Sb_n, Sc_n, Sd_n

PMA training signal encoding rules are based on the generation, at time n, of the four bits Sa_n, Sb_n, Sc_n, Sd_n. These four bits are generated in a systematic fashion using the bits in $Scr_n[32:0]$, and an auxiliary generating polynomial. For both MASTER and SLAVE PHYs, they are obtained by the same linear combinations of bits stored in the transmit scrambler shift register delay line. These four bits are derived from elements of the same maximum-length shift register sequence of length $2^{33}–1$ as $Scr_n[0]$, but shifted in time. The associated delays are all large and different so that there is no short-term correlation among the bits Sa_n, Sb_n, Sc_n, Sd_n. The four bits are generated using the bit $Scr_n[0]$ and the equations in Figure 113–15 in the "Derived sequences" box.

113.3.4.2 Generation of 4D symbols TA_n, TB_n, TC_n, TD_n

The four bits Sa_n, Sb_n, Sc_n, Sd_n are mapped to a 4D symbol (TA_n, TB_n, TC_n, TD_n) as shown in Figure 113–15.



The inversion on pair A at 256 intervals ($n = k \times 256$, $k = 0, 1, 2, \ldots$) defines the LDPC boundary during data mode.

Notice that over the repeating time intervals of 16384 and of length 128, $m \times 16384 – 128 \le n < m \times 16384$, $m = 1, 2, 3, \ldots$, the PMA training pattern in pair A is XOR'ed with the Infofield. Thus, pair A transmits the Infofield, which communicates to the remote transceiver settings of THP and power backoff and other control information.

113.3.4.3 PMA training mode descrambler polynomials

The PHY shall acquire descrambler state synchronization to the PAM2 training sequence and report success through scr_status. For side-stream descrambling, the MASTER PHY shall employ the receiver descrambler generator polynomial $g'_M(x) = 1 + x^{20} + x^{33}$ and the SLAVE PHY shall employ the receiver descrambler generator polynomial $g'_S(x) = 1 + x^{13} + x^{33}$.

Main PN sequence:

$$Scr_n[32:1] = Scr_{n-1}[31:0]$$

$$Scr_n[0] = \begin{cases} Scr_{n-1}[12]+Scr_{n-1}[32] \text{ if PMA_CONFIG=MASTER} \\ Scr_{n-1}[19]+Scr_{n-1}[32] \text{ if PMA_CONFIG = SLAVE} \end{cases}$$

Derived sequences:

$$Sa_n = \begin{cases} Scr_n[0] \oplus 1 & \text{if } n \bmod 256 = 0 \\ Scr_n[0] & \text{otherwise} \end{cases}$$

$$Sb_n = Scr_n[3] \oplus Scr_n[8]$$

$$Sc_n = Scr_n[6] \oplus Scr_n[16]$$

$$Sd_n = Scr_n[9] \oplus Scr_n([14] \oplus Scr_n([19] \oplus Scr_n[24]))$$

Figure 113–15—A realization of PMA training PAM2 sequences

113.3.5 LPI signaling

PHYs with EEE capability have transmit and receive functions that can enter and leave the LPI mode independently. The PHY can transition to the LPI mode when the PHY has successfully completed training and pcs_data_mode is TRUE. The transmit function of the PHY initiates a transition to the LPI transmit mode when it generates 64B/65B blocks composed entirely of LPI control characters, as described in 113.3.2.2.23. The transmit function of the link partner signals the transition using the sleep signal. When the transmitter begins to send the sleep signal, it asserts tx_lpi_active and the transmit function enters the LPI transmit mode.

Within the LPI mode PHYs use a repeating quiet-refresh cycle (see Figure 113–16). The first part of this cycle is known as the quiet period and lasts for a time lpi_quiet_time equal to 122 LDPC frame periods. The quiet period is defined in 113.3.5.2. The second part of this cycle is known as the refresh period and lasts for a time lpi_refresh_time equal to 6 LDPC frame periods. The refresh period is defined in 113.3.5.3. A cycle composed of one quiet period and one refresh period is known as a *single pair LPI cycle* and lasts for a time lpi_qr_time equal to 128 LDPC frame periods. The time taken to complete a quiet-refresh cycle for all four pairs is known as a *complete LPI cycle*.

lpi_offset, lpi_quiet_time, lpi_refresh_time, lpi_qr_time, and lpi_allpairs_qr_time are timing parameters that are integer multiples of the LDPC frame period. lpi_offset is a fixed value equal to lpi_qr_time/2 that is used to ensure refresh signals are appropriately offset by the link partners.

PHYs begin the transition from the LPI receive mode when the alert signal is detected by the PMA as defined in 113.4.2.4.

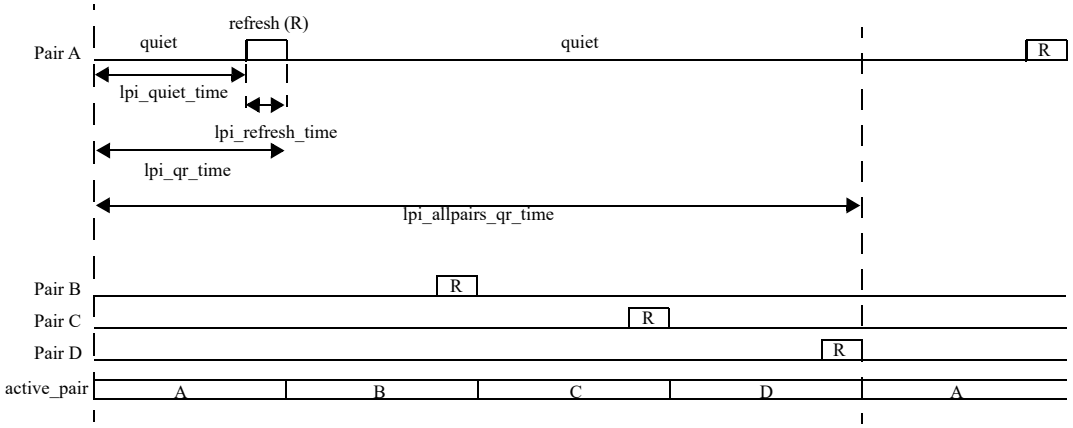

Figure 113–16—Timing periods for LPI signals

113.3.5.1 LPI Synchronization

To maximize power savings, maintain link integrity, and ensure interoperability, EEE-capable PHYs synchronize refresh intervals during the LPI mode. The transition to PCS_Test is used as a fixed timing reference for the link partners. Refresh signaling is derived by counting LDPC frames from the transition to PCS_Test.

In initial training, normal retraining, and fast retraining, with or without the EEE capability being supported, the master and slave signal when they will transition to PCS_Test using the transition counter following the procedure described in 113.4.2.5.15.

An EEE-capable PHY in slave mode is responsible for synchronizing its PMA training frame to the master's PMA training frame during the transition to PMA_Training_Init_S. The slave shall ensure that its PMA training frames are synchronized to the master's PMA training frames within 1 LDPC frame, measured at the slave MDI on pair A. In addition, the slave shall initialize its transition counter so that it transitions to PCS_Test within 1 LDPC frame of the master PHY's transition to PCS_Test, measured at the slave PHY's MDI on pair A. This mechanism ensures that the refresh offset is bounded to a small value at both MDI interfaces, thus ensuring there is no overlap of master and slave signals when both transmit and receive are in the LPI mode.

Following the transition to PCS_Test, the PCS counts transmitted and received LDPC frames, and uses these counters to generate refresh and pair control signals for the transmit and receive functions. The transmitted LDPC frame count is named tx_ldpc_frame_cnt. The received LDPC frame count is named rx_ldpc_frame_cnt.

The master and slave shall derive the active pair and refresh_active signals from the LDPC frame counters as shown in Table 113–7 and Table 113–8.

Table 113–7—Synchronization logic derived from slave signal LDPC frame count

Slave-side variable	Master-side variable	for master u=rx_ldpc_frame_cnt for slave u=tx_ldpc_frame_cnt
tx_refresh_active=true	rx_refresh_active=true	lpi_offset – lpi_refresh_time ≤ mod(u,lpi_qr_time) < lpi_offset
tx_lpi_full_refresh=true	N/A	lpi_offset – lpi_refresh_time = mod(u,lpi_qr_time)
tx_active_pair=PAIR_A	rx_active_pair=PAIR_A	lpi_offset + lpi_qr_time £ u < lpi_offset + 2 × lpi_qr_time
tx_active_pair=PAIR_B	rx_active_pair=PAIR_B	lpi_offset + 2 × lpi_qr_time ≤ u < lpi_offset + 3 × lpi_qr_time
tx_active_pair=PAIR_C	rx_active_pair=PAIR_C	lpi_offset + 3 × lpi_qr_time ≤ u < 4 × lpi_qr_time OR 0 ≤ u < lpi_offset
tx_active_pair=PAIR_D	rx_active_pair=PAIR_D	lpi_offset ≤ u < lpi_offset + lpi_qr_time

Table 113–8—Synchronization logic derived from master signal LDPC frame count

Slave-side variable	Master-side variable	for master v=tx_ldpc_frame_cnt for slave v=rx_ldpc_frame_cnt
rx_refresh_active=true	tx_refresh_active=true	lpi_quiet_time ≤ mod(v,lpi_qr_time)
N/A	tx_lpi_full_refresh=true	lpi_quiet_time = mod(v,lpi_qr_time)
rx_active_pair=PAIR_A	tx_active_pair=PAIR_A	0 ≤ v < lpi_qr_time
rx_active_pair=PAIR_B	tx_active_pair=PAIR_B	lpi_qr_time ≤ v < 2 × lpi_qr_time
rx_active_pair=PAIR_C	tx_active_pair=PAIR_C	2 × lpi_qr_time ≤ v < 3 × lpi_qr_time
rx_active_pair=PAIR_D	tx_active_pair=PAIR_D	3 × lpi_qr_time ≤ v < 4 × lpi_qr_time

113.3.5.2 Quiet period signaling

During the quiet period the transmitters on all four pairs should be turned off. Average launch power (as measured from 28 LDPC frames after a refresh period to 28 LDPC frames before the next refresh period on the same lane) for each Transmitter shall be less than –41 dBm. This requirement does not apply to the periods when the alert signal is transmitted as defined in 113.4.2.2.1.

113.3.5.3 Refresh period signaling

During the LPI mode 25G/40GBASE-T PHYs use staggered, out-of-phase refresh signaling to maximize power savings. Two-level PAM refresh symbols are generated using the PMA side-stream scrambler polynomials described in 113.3.4 and exactly as is shown in Figure 113–15 with the exception that the Infofield consists of a sequence of 128 zeros. The training sequence shall be used during the LPI mode.

Refresh signals shall be sent using the THP filter as described in 113.4.3.1. At the start of each refresh signal the THP feedback delay line shall be initialized with zeros.

While a transmit function is in the LPI transmit mode only one of the transmit pairs is active during a refresh period. tx_symb_vector for all transmit pairs that are not active shall be set to zero.

When tx_symb_vector has the value ALERT and the PHY is master, the transmitter on pair A shall be active and all other pairs shall be quiet. When tx_symb_vector has the value ALERT and the PHY is slave, the transmitter on pair C shall be active and all other pairs shall be quiet. If lpi_tx_mode=REFRESH_A on a MASTER PHY or lpi_tx_mode=REFRESH_C on a SLAVE PHY, and tx_symb_vector has the value ALERT, then the alert signalling shall be transmitted in place of the refresh signalling where the signals overlap.

113.3.6 Detailed functions and state diagrams

113.3.6.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

113.3.6.2 State diagram parameters

113.3.6.2.1 Constants

EBLOCK_R<71:0>
: 72-bit vector to be sent to the 25GMII/XLGMII interface containing /E/ in all the eight character locations.

EBLOCK_T<64:0>
: 65-bit vector to be sent to the 512B/513B transcoder and block-LDPC framer containing /E/ in all the eight character locations.

LBLOCK_R<71:0>
: 72-bit vector to be sent to the 25GMII/XLGMII interface containing a Local Fault ordered set. The Local Fault ordered set is defined in 81.3.4.

LBLOCK_T<64:0>
: 65-bit vector to be sent to the 512B/513B transcoder and block-LDPC framer containing a Local Fault ordered set.

LPBLOCK_R<71:0>
: 72-bit vector to be sent to the 25GMII/XLGMII containing /LI/ in all the eight character locations.

LPBLOCK_T<64:0>
: 65-bit vector to be sent to the 512B/513B transcoder and block-LDPC framer containing /LI/ in all the eight character locations.

IBLOCK_R<71:0>
: 72-bit vector to be sent to the 25GMII/XLGMII containing /I/ in all the eight character locations.

IBLOCK_T<64:0>
: 65-bit vector to be sent to the 512B/513B transcoder and block-LDPC framer containing /I/ in all the eight character locations.

UBLOCK_R<71:0>

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72-bit vector to be sent to the 25GMII/XLGMII containing a Link Interruption ordered set. The Link Interruption ordered set is defined in 81.3.4.

113.3.6.2.2 Variables

lfer_test_lf
: Boolean variable that is set true when a new LDPC frame is available for testing and false when LFER_TEST_LF state is entered. A new LDPC frame is available for testing when the Block Sync process has accumulated enough symbols from the PMA to evaluate the next LDPC frame.

block_lock
: Boolean variable that is set true when receiver acquires block delineation.

hi_lfer
: Boolean variable that is asserted true when the lfer_cnt reaches 16 errors in one lfer_timer interval.

pcs_reset
: Boolean variable that controls the resetting of the PCS. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS into low-power mode.

rx_coded<64:0>
: Vector containing the input to the 64B/65B decoder. The format for this vector is shown in Figure 113–10. The leftmost bit in the figure is rx_coded<0> and the rightmost bit is rx_coded<64>.

rx_raw<71:0>
: Vector containing two successive 25GMII transfers or a single XLGMII output transfer. For 25GBASE-T, RXC<0> through RXC<3> for the first transfer are taken from rx_raw<0> through rx_raw<3>, respectively. RXC<0> through RXC<3> for the second transfer are taken from rx_raw<4> through rx_raw<7>, respectively. RXD<0> through RXD<31> for the first transfer are taken from rx_raw<8> through rx_raw<39>, respectively. RXD<0> through RXD<31> for the second transfer are taken from rx_raw<40> through rx_raw<71>, respectively. For 40GBASE-T, RXC<0> through RXC<7> for the transfer are taken from rx_raw<0> through rx_raw<7>, respectively. RXD<0> through RXD<63> for the transfer are taken from rx_raw<8> through rx_raw<71>, respectively.

lf_valid
: Boolean indication that is set true if received LDPC frame is valid. LDPC frame is valid if both:
  a. All parity checks of the LDPC-coded bits are satisfied
  b. The RS-FEC-coded bits, after decoding, form a valid RS-FEC codeword.

tx_coded<64:0>
: Vector containing the output from the 64B/65B encoder. The format for this vector is shown in Figure 113–10. The leftmost bit in the figure is tx_coded<0> and the rightmost bit is tx_coded<64>.

tx_raw<71:0>
: Vector containing two successive 25GMII transfers or a single XLGMII transfer. For 25GBASE-T, TXC<0> through TXC<3> for the first transfer are placed in tx_raw<0> through tx_raw<3>, respectively. TXC<0> through TXC<3> for the second transfer are placed in tx_raw<4> through tx_raw<7>, respectively. TXD<0> through TXD<31> for the first transfer are placed in tx_raw<8> through tx_raw<39>, respectively. TXD<0> through TXD<31> for the second transfer are placed in tx_raw<40> through tx_raw<71>, respectively. For 40GBASE-T, TXC<0> through TXC<7> for the transfer are placed in tx_raw<0> through tx_raw<7>, respectively. TXD<0> through TXD<63> for the transfer are placed in tx_raw<8> through tx_raw<71>, respectively.

The following variables are required for PHYs that support the EEE capability:

tx_lpi_active
: A Boolean variable that is set true when the PHY transmit function is operating in the LPI transmit

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mode and during transitions to and from the LPI transmit mode (i.e., at any time when the PHY is transmitting sleep, alert, wake, or quiet-refresh signaling). It is set false otherwise.

tx_lpi_qr_active
: A Boolean variable that is set true during the LPI transmit mode, when the PHY is transmitting quiet-refresh signaling. Set false otherwise.

rx_lpi_active
: A Boolean variable that is set true when the PHY receive function is operating in the LPI receive mode and set false otherwise. The LPI receive mode begins when the sleep signal is detected and lasts until the alert signal is detected. When the EEE capability is not supported, rx_lpi_active is set false.

tx_lpi_req
: A Boolean variable that is set true when the LPI client indicates that it is requesting operation in the LPI transmit mode via the 25GMII/XLGMII and set false otherwise.

alert_detect
: Indicates that an alert signal from the link partner has been received at the MDI as indicated by PMA_ALERTDETECT.indication(alert_detect).

tx_lpi_alert_active
: A Boolean variable that is set true when the PHY is transmitting ALERT signaling. Set false otherwise.

rx_lpi_wake
: A Boolean variable that is set true when the PHY receiver is in the WAKE state and sending IDLE to the 25GMII/XLGMII. Set false otherwise. When the EEE capability is not supported, rx_lpi_wake is set false.

tx_active_pair
: A variable indicating the transmit active pair during the LPI transmit mode. The variable may take the values PAIR_A, PAIR_B, PAIR_C, PAIR_D. This variable is defined in 113.3.5.1.

lpi_tx_mode
: A variable indicating the signaling to be used from the PCS to the PMA across the PMA_UNITDATA.request (tx_symb_vector) interface.
: lpi_tx_mode controls tx_symb_vector only when tx_mode is set to SEND_N.
: The variable is set to NORMAL when (!tx_lpi_qr_active * !tx_lpi_alert_active), indicating that the PCS is in the normal mode of operation and will encode code-groups as described in Figure 113–18a and Figure 113–18b.
: The variable is set to REFRESH_A when (tx_lpi_qr_active * (tx_active_pair=PAIR_A) * tx_refresh active).
: The variable is set to REFRESH_B when (tx_lpi_qr_active * (tx_active_pair=PAIR_B) * tx_refresh active).
: The variable is set to REFRESH_C when (tx_lpi_qr_active * (tx_active_pair=PAIR_C) * tx_refresh active).
: The variable is set to REFRESH_D when (tx_lpi_qr_active * (tx_active_pair=PAIR_D) * tx_refresh active).
: The variable is set to QUIET when (tx_lpi_qr_active * (!tx_refresh_active + tx_lpi_initial_quiet))
: The variable is set to ALERT when (tx_lpi_alert_active)

tx_refresh_active
: A Boolean value. This variable is set true following the logic described in 113.3.5.1.

tx_lpi_full_refresh
: A Boolean value. This variable is set true following the logic described in 113.3.5.1.

tx_lpi_initial_quiet
: A Boolean value. This variable is set true when the transmit function enters the LPI transmit mode and a partial refresh will be replaced by quiet signaling.

ldpc_frame_done
: A Boolean value. This variable is set true when the final symbol of each LDPC frame is transmitted and is set false otherwise.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following variable is only required for PHYs that support the fast retrain capability:

fr_sigtype

If fast retrain is supported, this variable controls the block type the PMA sends on the receive path during fast retrain. If MDIO is supported, this variable is set based on the value in 1.147.2:1 as follows:

00 IBLOCK_R
01 LBLOCK_R
10 UBLOCK_R
11 Reserved.

If MDIO is not supported, an equivalent method of controlling fast retrain functionality should be provided.

113.3.6.2.3 Timers

State diagram timers follow the conventions described in 14.2.3.2.

lfer_timer
: Timer that is triggered every $125/(4 \times S)$ μs +1%, –25%. When the timer reaches its terminal count, lfer_timer_done = TRUE

The following timers are required for PHYs that support the EEE capability:

lpi_tx_sleep_timer
: This timer defines the time the local transmitter sends the sleep signal to the link partner.
Values: The condition lpi_tx_sleep_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 6 LDPC frame periods.

lpi_tx_alert_timer
: This timer defines the time the local transmitter transmits the alert signal.
Values: The condition lpi_tx_alert_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 4 LDPC frame periods.

lpi_tx_wake_timer
: This timer defines the time the local transmitter transmits the wake signal.
Values: The condition lpi_tx_wake_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to lpi_wake_time LDPC frame periods.

lpi_rx_wake_timer
: This timer defines the time the receiver sends IDLE blocks to the 25GMII/XLGMII after the alert signal is detected.
Values: The condition lpi_rx_wake_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to lpi_wake_time LDPC frame periods.

113.3.6.2.4 Functions

DECODE(rx_symb_vector<64:0>)
: In the PCS Receive process, this function takes as its argument 65-bit rx_coded<64:0> from the LDPC decoder and decodes the 65B-LDPC bit vector returning a vector rx_raw<71:0>, which is sent to the 25GMII/XLGMII. The DECODE function shall decode the block based on code specified in 113.3.2.2.2.

ENCODE(tx_raw<71:0>)
: Encodes the 72-bit vector received from the 25GMII/XLGMII, returning 65-bit vector tx_coded. The ENCODE function shall encode the block as specified in 113.3.2.2.2.

Copyright © 2022 IEEE. All rights reserved.

R_BLOCK_TYPE = {C, S, T, D, E, I, LI, LII}

When the EEE capability is not supported, this function classifies each 65-bit rx_coded vector as belonging to one of the five types {C, S, T, D, E} depending on its contents.

When the EEE capability is supported, this function classifies each 65-bit rx_coded vector as belonging to the eight types depending on its contents. A vector may simultaneously belong to the C and I types when it contains eight valid control characters that are all /I/, but in every other case the vector belongs to only one type.

Values: C; The vector contains a data/ctrl header of 1 and one of the following:

a) A block type field of 0x1E and eight valid control characters other than /E/ and /LI/;
b) a block type field 0x4B, a valid O code, and zeros;
c) for 25GBASE-T only, a block type field 0x2D, a valid O code, and four valid control characters;
d) for 25GBASE-T only, a blcok type field of 0x55 and two valid O codes.

S; The vector contains a data/ctrl header of 1 and one of the following:

a) A block type field of 0x78;
b) for 25GBASE-T only, a block type field of 0x66 and a valid O code;
c) for 25GBASE-T only, a block type field of 0x33 and four valid control characters.

T; The vector contains a data/ctrl header of 1, a block type field of 0x87, 0x99, 0xAA, 0xB4, 0xCC, 0xD2, 0xE1, or 0xFF and all control characters are valid.

D; The vector contains a data/ctrl header of 0.

I; If the optional EEE capability is supported, then the I type is a special case of the C type where the vector contains a data/ctrl header of 1, a block type field of 0x1E, and eight control characters of /I/.

LI: If the optional EEE capability is supported, then the LI type occurs when the vector contains a data/ctrl header of 1, a block type field of 0x1E, and eight control characters of /LI/.

LII: If the optional EEE capability is supported, then the LII type occurs when the vector contains a data/ctrl header of 1, a block type field of 0x1E, and one of the following:

a) four control characters of /LI/ followed by four control characters of /I/;
b) four control characters of /I/ followed by four control characters of /LI/

E; The vector does not meet the criteria for any other value.

For 25GBASE-T, a valid control character is one containing a 25GBASE-T control code specified in Table 113–1. A valid O code is one containing an O code specified in Table 113–1,

For 40GBASE-T, a valid control character is one containing a 40GBASE-T control code specified in Table 113–2. A valid O code is one containing an O code specified in Table 113–2.

R_TYPE(rx_coded<64:0>)

Returns the R_BLOCK_TYPE of the rx_coded<64:0> bit vector.

R_TYPE_NEXT

Prescient end of packet check function. It returns the R_BLOCK_TYPE of the rx_coded vector immediately following the current rx_coded vector.

T_BLOCK_TYPE = {C, S, T, D, E, I, LI, LII}

When the EEE capability is not supported, this function classifies each 72-bit tx_raw vector as belonging to one of the five types {C, S, T, D, E} depending on its contents.

When the EEE capability is supported, this function classifies each 72-bit tx_raw vector as belonging to the eight types depending on its contents. A vector may simultaneously belong to the C and I types when it contains eight valid control characters that are all /I/, but in every other case the vector belongs to only one type.

Values: C; The vector contains one of the following:

a) eight valid control characters other than /O/, /S/, /T/, /E/, and /LI/;
b) one valid ordered set followed by four data bytes and zeros for block code 0x4B;
c) for 25GBASE-T only, one valid ordered set followed by four valid control characters other than /O/, /S/ and /T/;

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) for 25GBASE-T only, two valid ordered sets.

S; The vector contains an /S/ in its first character, or, for 25GBASE-T, its first or fifth character. Any characters before the S character are valid control characters other than /O/, /S/ and /T/ or form a valid ordered set, and all characters following the /S/ are data characters.

T; The vector contains a /T/ in one of its characters, all characters before the /T/ are data characters, and all characters following the /T/ are valid control characters other than /O/, /S/ and /T/.

D; The vector contains eight data characters.

I; If the optional EEE capability is supported, then the I type is a special case of the C type where the vector contains eight control characters of /I/.

LI: If the optional EEE capability is supported, then the LI type occurs when the vector contains eight control characters of /LI/.

LII: If the optional EEE capability is supported, then the LII type occurs when the vector contains one of the following:

a) four control characters of /LI/ followed by four control characters of /I/;

b) four control characters of /I/ followed by four control characters of /LI/.

E; The vector does not meet the criteria for any other value.

A tx_raw character is a control character if its associated TXC bit is asserted. For 25GBASE-T, a valid control character is one containing a 25GMII control code specified in Table 113–1. A valid ordered set consists of a valid /O/ character in the first or fifth characters and data characters in the three characters following the /O/. A valid /O/ is any character with a value for O code in Table 113–1. For 40GBASE-T, a valid control character is one containing an XLGMII control code specified in Table 113–2. A valid ordered set consists of a valid /O/ character in the first character and data characters in the three characters following the /O/. A valid /O/ is any character with a value for O code in Table 113–2.

T_TYPE(tx_raw<71:0>)
: Returns the T_BLOCK_TYPE of the tx_raw<71:0> bit vector.

T_TYPE_NEXT
: Prescient end of packet check function. It returns the FRAME_TYPE of the tx_raw vector immediately following the current tx_raw vector.

113.3.6.2.5 Counters

lfer_cnt
: Count up to a maximum of 16 of the number of invalid LDPC frames within the current lfer_timer period.

The following counters are required for PHYs that support the EEE capability:

tx_ldpc_frame_cnt
: An integer value that counts transmit LDPC frame periods. The counter is reset when the first symbol of the first LDPC frame crosses the MDI on pair A in the transmit direction after normal training or fast retraining. It is incremented after the last symbol of each transmitted LDPC frame. tx_ldpc_frame_cnt is reset to 0 when tx_ldpc_frame_cnt = lpi_qr_time × 4.

rx_ldpc_frame_cnt
: An integer value that counts receive LDPC frame periods. The counter is reset when the first symbol of the first LDPC frame crosses the MDI on pair A in the receive direction after normal training or fast retraining. It is incremented after the last symbol of each received LDPC frame. rx_ldpc_frame_cnt is reset to 0 when rx_ldpc_frame_cnt = lpi_qr_time × 4.

lpi_rxw_err_cnt
: An integer value that counts the number of receive wake on error conditions. lpi_rxw_err_cnt is reset to zero during PCS_Test. The counter is reflected in register 3.22 (see 45.2.3.12).

113.3.6.3 State diagrams

The LFER Monitor state diagram shown in Figure 113–17 monitors the received signal for high LDPC frame error ratio.

The 64B/65B Transmit state diagram shown in Figure 113–18a controls the encoding of 65B transmitted blocks. It makes exactly one transition for each 65B transmit block processed. Though the Transmit state diagram sends Local Fault ordered sets when reset is asserted, the scrambler and 65B-LDPC are not guaranteed to be operational during reset. Thus, the Local Fault ordered sets are not guaranteed to appear on the PMA service interface.

The 64B/65B Receive state diagram shown in Figure 113–19a controls the decoding of 65B received blocks. It makes exactly one transition for each receive block processed except for the transition from RX_WE to RX_E, which occurs immediately after the RX_WE processes are complete.

The PCS shall perform the functions of LFER Monitor, Transmit, and Receive as specified in these state diagrams. The PCS shall not perform the LFER Monitor function during LPI receive operation from the time that the PCS 64B/65B Receiver enters the state RX_L, until the state RX_W is exited.

Transitions surrounded by dashed rectangles indicate requirements for 25G/40GBASE-T EEE-capable implementations.

113.3.7 PCS management

The following objects apply to PCS management. If an MDIO Interface is provided (see Clause 45), they are accessed via that interface. If not, it is recommended that an equivalent access be provided.

113.3.7.1 Status

pcs_status
: Indicates whether the PCS is in a fully operational state. It is only true if block_lock is true and hi_lfer is false. This status is reflected in MDIO register 3.32.12. A latch low view of this status is reflected in MDIO register 3.1.2 and a latch high of the inverse of this status, Receive fault, is reflected in MDIO register 3.8.10.

block_lock
: Indicates the state of the block_lock variable. This status is reflected in MDIO register 3.32.0. A latch low view of this status is reflected in MDIO register 3.33.15.

hi_lfer
: Indicates the state of the hi_lfer variable. This status is reflected in MDIO register 3.32.1. A latch high view of this status is reflected in MDIO register 3.33.14.

Rx LPI indication
: For EEE capability, this variable indicates the current state of the receive LPI function. This flag is set to TRUE (register bit set to one) when the PCS 64B/65B Receive state diagram (Figure 113–19b) is in the RX_L or RX_W states. This status is reflected in MDIO register 3.1.8. A latch high view of this status is reflected in MDIO register 3.1.10 (Rx LPI received).

Tx LPI indication
: For EEE capability, this variable indicates the current state of the transmit LPI function. This flag is set to TRUE (register bit set to one) when the PCS 64B/65B Transmit state diagram (Figure 113–18b) is in the TX_L or TX_W states. This status is reflected in MDIO register 3.1.9. A latch high view of this status is reflected in MDIO register 3.1.11 (Tx LPI received).

113.3.7.2 Counters

The following counters are reset to zero upon read and upon reset of the PCS. When they reach all ones, they stop counting. Their purpose is to help monitor the quality of the link.

lfer_count
: Six-bit counter that counts each time LFER_BAD_LF state is entered. This counter is reflected in MDIO register bits 3.33.13:8. The counter is reset when register 3.33 is read by management. Note that this counter counts a maximum of 16 counts per lfer_timer period since the LFER_BAD_LF can be entered a maximum of 16 times per lfer_timer window.

errored_block_count
: Eight-bit counter. When the receiver is in normal mode, errored_block_count counts once for each time RX_E state is entered. This counter is reflected in MDIO register bits 3.33.7:0

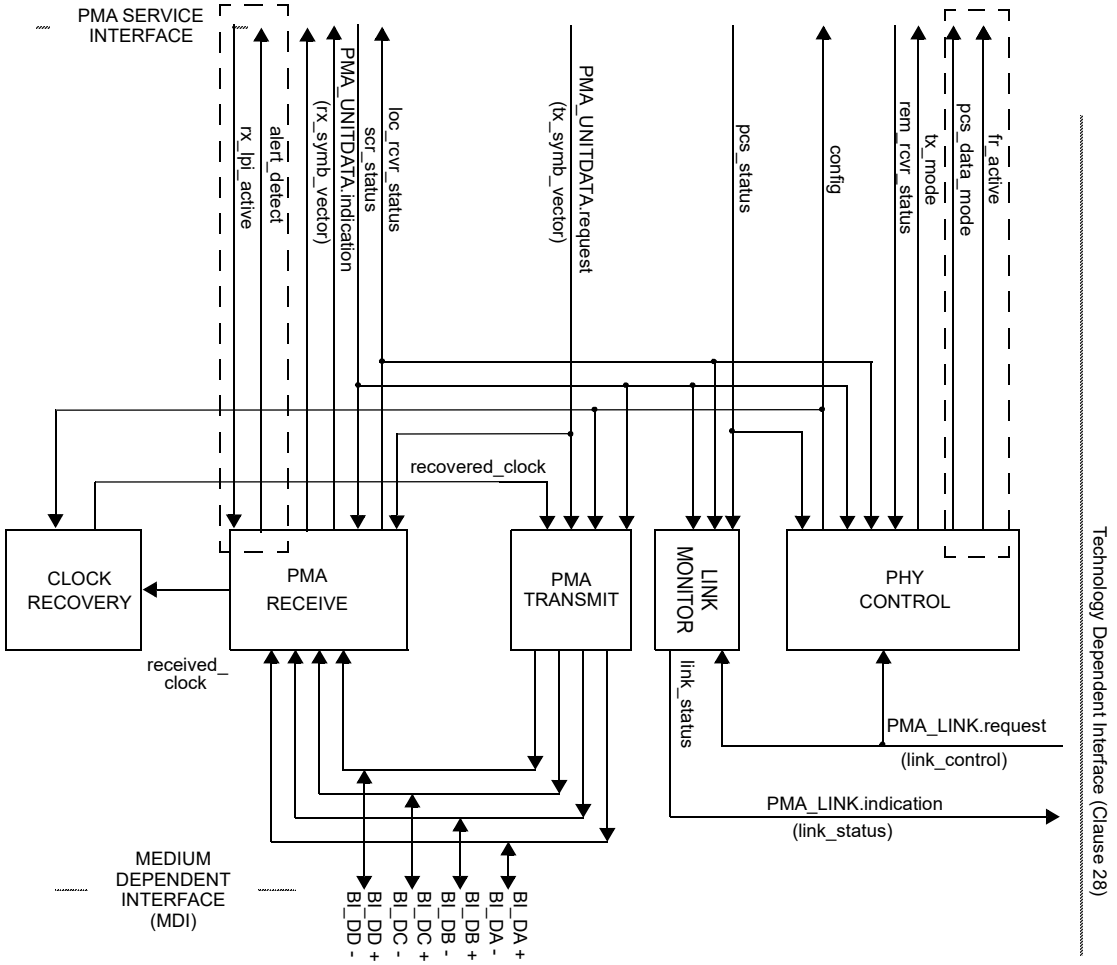
113.3.7.3 Loopback



The PCS shall be placed in loopback mode when the loopback bit in MDIO register 3.0.14 is set to a one. In this mode, the PCS shall accept data on the transmit path from the 25GMII/XLGMII and return it on the receive path to the 25GMII/XLGMII. In addition, the PCS shall transmit a continuous stream of 65B-LDPC encoded 4D-PAM16 symbols to the PMA sublayer, and shall ignore all data presented to it by the PMA sublayer.

113.4 Physical Medium Attachment (PMA) sublayer

113.4.1 PMA functional specifications

The PMA couples messages from a PMA service interface specified in 113.2.2 to the 25G/40GBASE-T baseband medium, specified in 113.7.

The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 113.8.

NOTE 1—The recovered_clock arc is shown to indicate delivery of the recovered clock signal back to PMA TRANSMIT for loop timing.

NOTE 2—pcs_data_mode is required only for the EEE or fast retrain capabilities alert_detect and rx_lpi_active are only required for the EEE capability fr_active is only required for the fast retrain capability.

113.4.2 PMA functions

The PMA sublayer comprises one PMA Reset function and five simultaneous and asynchronous operating functions. The PMA operating functions are PHY Control, PMA Transmit, PMA Receive, Link Monitor, and Clock Recovery. All operating functions are started immediately after the successful completion of the PMA Reset function.

The PMA reference diagram, Figure 113–21, shows how the operating functions relate to the messages of the PMA Service interface and the signals of the MDI. Connections from the management interface, comprising the signals MDC and MDIO, to other layers are pervasive and are not shown in Figure 113–21.

113.4.2.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

a) Power on (see 113.3.6.2.2)
b) The receipt of a request for reset from the management entity

All state diagrams take the open-ended pma_reset branch upon execution of PMA Reset. The reference diagrams do not explicitly show the PMA Reset function.

113.4.2.2 PMA Transmit function

The PMA Transmit function comprises four synchronous transmitters to generate four pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD. While send_fail is FALSE and ALERT is not indicated by tx_symb_vector, PMA Transmit shall continuously transmit onto the MDI pulses modulated by the symbols given by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD], respectively, after processing with the THP, optional transmit filtering, digital to analog conversion (DAC), and subsequent analog filtering. When ALERT is indicated by tx_symb_vector, the alert signal is transmitted as specified in 113.4.2.2.1. When send_fail is TRUE, the link failure signal is transmitted as specified in 113.4.2.2.2. The four transmitters shall be driven by the same transmit clock, TX_TCLK. The signals generated by PMA Transmit shall follow the mathematical description given in 113.4.3.1 and shall comply with the electrical specifications given in 113.5.

When the PMA_CONFIG.indication parameter config is MASTER, for both normal and LPI operation, the PMA Transmit function shall source TX_TCLK from a local clock source while meeting the transmit jitter requirements of 113.5.3.3. The MASTER/SLAVE relationship includes loop timing. If the PMA_CONFIG.indication parameter config is SLAVE, the PMA Transmit function shall source TX_TCLK from the recovered clock of 113.4.2.8 while meeting the jitter requirements of 113.5.3.3.

The PMA Transmit fault function is optional. The faults detected by this function are implementation specific. If the MDIO interface is implemented, then this function shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

EEE-capable PHYs shall implement a PMA Transmit function that generates the alert signal as defined in 113.4.2.2.1. PHYs that support the fast retrain capability shall implement a PMA Transmit function that generates the link failure signal as defined in 113.4.2.2.2. If ALERT is indicated by tx_symb_vector at the same time as send_fail is TRUE, then link failure signaling is transmitted.

113.4.2.2.1 Alert signal

PHYs that support the optional EEE capability transmit the following PAM2 sequence when the PMA_UNITDATA.request parameter is set to ALERT. The alert signal is sent for a total of 4 LDPC frame

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

periods and begins on a LDPC frame boundary. The alert signal is transmitted without THP filtering. The alert signal is transmitted on pair A when the PHY operates as a MASTER. The alert signal is transmitted on pair C when the PHY operates as a SLAVE. All other pairs transmit quiet as described in 113.3.5.

When the PMA_CONFIG.indication(config) is MASTER, the alert signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xpr_master =

9 9 –9 –9 –9 –9 –9 –9 9 9 –9 –9 9 9 9 9

9 9 9 9 –9 –9 9 9 9 9 –9 –9 9 9 –9 –9

–9 –9 –9 –9 –9 –9 9 9 –9 –9 –9 –9 –9 –9 9 9

–9 –9 –9 –9 –9 –9 –9 –9 9 9 –9 –9 9 9 –9 –9

–9 –9 9 9 9 9 9 9 9 9 9 9 –9 –9 –9 –9

9 9 –9 –9 –9 –9 9 9 9 9 –9 –9 9 9 –9 –9

–9 –9 –9 –9 –9 –9 –9 –9 9 9 9 9 –9 –9 9 9

9 9 –9 –9 9 9 –9 –9 9 9 9 9 –9 –9 –9 –9

When the PMA_CONFIG.indication(config) is SLAVE, the alert signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols:

xpr_slave =

–9 –9 –9 –9 9 9 9 9 –9 –9 9 9 –9 –9 9 9

9 9 –9 –9 9 9 9 9 –9 –9 –9 –9 –9 –9 –9 –9

–9 –9 9 9 –9 –9 9 9 9 9 –9 –9 –9 –9 9 9

–9 –9 –9 –9 9 9 9 9 9 9 9 9 9 9 –9 –9

–9 –9 9 9 –9 –9 9 9 –9 –9 –9 –9 –9 –9 –9 –9

9 9 –9 –9 –9 –9 –9 –9 9 9 –9 –9 –9 –9 –9 –9

–9 –9 9 9 –9 –9 9 9 9 9 –9 –9 9 9 9 9

9 9 9 9 –9 –9 9 9 –9 –9 –9 –9 –9 –9 9 9

The alert signal is followed by a wake signal composed of repeated IDLE characters encoded using the mixed 512B/513B 64B/65B RS-FEC and LDPC encoding used in normal data mode. At the start of the wake signal all THP feedback delay lines are initialized with zeros.

113.4.2.2.2 Link failure signal

PHYs that support the fast retrain capability transmit the link failure signal under the control of the Fast Retrain state diagram. The link failure signal indicates to the link partner that a link failure has been detected and that the link partners should begin the fast retrain procedure.

The link failure signal is sent for 4 LDPC frames and begins on a LDPC frame boundary. The link failure signal is transmitted without THP filtering. The link failure signal is transmitted on pair A when the PHY operates as a MASTER. The link failure signal is transmitted on pair C when the PHY operates as a SLAVE. All other pairs transmit quiet as described in 113.3.5.

When the PMA_CONFIG.indication(config) is MASTER, the link failure signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xfr_master = xpr_master × (–1)

When the PMA_CONFIG.indication(config) is SLAVE, the link failure signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xfr_slave = xpr_slave × (–1)

113.4.2.3 PMA transmit disable function

113.4.2.3.1 Global PMA transmit disable function

The Global_PMA_transmit_disable function allows all of the transmitters to be disabled, when either:

a) When a Global_PMA_transmit_disable variable is set to TRUE, this function shall turn off all of the transmitters so that the each transmitter Average Launch Power of the OFF Transmitter is less than –53 dBm.
b) If a PMA_transmit_fault is detected, then the PMA may set the Global_PMA_transmit_disable to TRUE, turning off the transmitter on each pair.

113.4.2.3.2 PMA pair by pair transmit disable function

The PMA_transmit_disable function allows the transmitters on each pair to be selectively disabled.

When a PMA_transmit_disable_N variable is set to TRUE, this function shall turn off the transmitter associated with that variable so that the transmitter Average Launch Power of the OFF Transmitter is less than –53 dBm.

113.4.2.3.3 PMA MDIO function mapping

The MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMA. Mapping of MDIO control variables to PMA control variables is shown in Table 113–9. Mapping of MDIO status variables to PMA status variables is shown in Table 113–10.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 113–9—MDIO/PMA control variable mapping

MDIO control variable	PMA register name	Register/bit number	PMA control variable
Reset	Control register 1	1.0.15	PMA_reset
Global PMD transmit disable	Transmit disable register	1.9.0	Global_PMA_transmit_disable
Transmit disable pair D	Transmit disable register	1.9.4	PMA_transmit_disable_D
Transmit disable pair C	Transmit disable register	1.9.3	PMA_transmit_disable_C
Transmit disable pair B	Transmit disable register	1.9.2	PMA_transmit_disable_B
Transmit disable pair A	Transmit disable register	1.9.1	PMA_transmit_disable_A

Table 113–10—MDIO/PMA status variable mapping

MDIO status variable	PMA register name	Register/bit number	PMA status variable
Fault	Status register 1	1.1.7	PMA_fault
Transmit fault	Status register 2	1.8.11	PMA_transmit_fault
Receive fault	Status register 2	1.8.10	PMA_receive_fault

113.4.2.4 PMA Receive function

The PMA Receive function comprises four independent receivers for pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD. The PMA Receive function contains the circuits necessary to both detect symbol sequences from the signals received at the MDI over receive pairs BI_DA, BI_DB, BI_DC, and BI_DD and to present these sequences to the PCS Receive function. The signals received at the MDI are described mathematically in 113.4.3.2. The PMA translates the signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD into the PMA_UNITDATA.indication parameter rx_symb_vector. The quality of these symbols shall allow an LFER of less than 3.2×10^{-9} after RS-FEC and LDPC decoding, over a link segment meeting the requirements of 113.7. The receiver shall correct for differential delay variations of up to 17 ns across the wire pairs. The delay skew is removed by computing the relative received delay of the four known transmit patterns described in 113.3.4.

To achieve the indicated performance, it is highly recommended that PMA Receive include the functions of signal equalization, echo, and crosstalk cancellation. The sequence of code-groups assigned to tx_symb_vector is needed to perform echo and self near-end crosstalk cancellation.

The PMA Receive function uses the scr_status parameter and the state of the equalization, cancellation, estimation, and LPI functions to determine the quality of the receiver performance, and generates the loc_rcvr_status variable accordingly. The precise algorithm for generation of loc_rcvr_status is implementation dependent.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The receiver uses the sequence of symbols during the training sequence to detect and correct for pair swaps and crossovers. The receiver pairs BI_DA, BI_DB, BI_DC, and BI_DD may be connected in any manner described in 113.4.4 to the corresponding transmit pairs. The receiver also detects and corrects for polarity mismatches on any pairs and corrects for differential delay variations across the wire pairs.

The PMA Receive fault function is optional. The PMA Receive fault function is the logical OR of the link_status = FAIL and any implementation specific fault. If the MDIO interface is implemented, then this function shall contribute to the receive fault bit specified in 45.2.1.7.5.

PMA receive functions that support the optional EEE capability shall generate alert_detect when the alert signal is detected at the receiver. The PMA receive function asserts alert_detect after the entire alert signal (3.5 LDPC frame periods of the xpr_master or xpr_slave sequence and 0.5 frames of silence) has been detected. The alert signal is specified in 113.4.2.2.1. The criterion used to generate alert_detect is left to the implementer.

PHYs that support the fast retrain capability shall set link_fail_detect to TRUE when the link failure signal is reliably detected at the receiver. The PMA receive function asserts link_fail_detect after the entire link failure signal (3.5 LDPC frame periods of the xfr_master or xfr_slave sequence and 0.5 frames of silence) has been detected. The link failure signal is specified in 113.4.2.2.2. The criterion used to generate link_fail_detect is left to the implementer. It is highly recommended that the generation of link_fail_detect is qualified with repeated errored frames at the LDPC decoder output.

113.4.2.5 PHY Control function

PHY Control generates the control actions that are needed to bring the PHY into a mode of operation during which frames can be exchanged with the link partner. PHY Control shall comply with the state diagram description given in Figure 113–28.

During PMA training (includes PMA_Training_Init_M, PMA_Training_Init_S, PMA_PBO_Exch, PMA_Coeff_Exch, and PMA_Fine_Adjust states in Figure 113–28), PHY Control information is exchanged between link partners with a 16 octet Infofield, which is XOR'ed with the last 128 bits of the PMA 16384 PAM2 frame on pair A (see Figure 113–15). The link partner is not required to decode every Infofield transmitted but is required to decode Infofields at a rate that enables the correct actions to timer expiration times, transition counter values, etc. described in Figure 113–28, Figure 113–29, and Figure 113–30.

The 16-octet Infofield shall include the fields in 113.4.2.5.2 through 113.4.2.5.14, also shown in the overview Figure 113–22, and the more detailed Figure 113–23, Figure 113–24, and Figure 113–25.

113.4.2.5.1 Infofield notation

For all the Infofield notation in the following subclauses, Reserved<bit location> represents any unused values and shall be set to zero and ignored by the link partner. For all PBO Infofield values in the following subclauses, the PBO<6:4> are unsigned three-bit values 000, 001, 010, 011, 100, 101, 110, and 111 shall indicate power backoffs of 0 dB, 2 dB, 4 dB, 6 dB, 8 dB, 10 dB, 12 dB, and 14 dB, respectively. The Infofield is transmitted following the notation described in 113.3.2.2.3 where the LSB of each octet is sent first and the octets are sent in increasing number order (that is, the LSB of Octet 1 is sent first).

113.4.2.5.2 Start of Frame Delimiter

The start of Frame Delimiter consist of 4 octets [Octet 1<7:0>, Octet 2<7:0>, Octet 3<7:0>, Octet 4<7:0>] and shall use the hexadecimal value 0xBBA70000. 0xBB corresponds to Octet 1<7:0> and so forth.

113.4.2.5.3 Current transmitter settings

Current transmitter setting (1 octet). Represented by Octet 5{Valid<7>, PBO<6:4>, Reserved<3:0>} and shown in Figure 113–26. Used to announce the current fixed PBO setting during PMA_Training_Init_M, PMA_Training_Init_S, and PMA_PBO_Exch, and the current programmable PBO setting during PMA_Coeff_Exch. For every other state this octet is set to zero and ignored by the link partner. The bit Valid

shall be set to one if the corresponding octet information is valid and shall be set to zero if it the octet information is not valid. If Valid is set to zero, the octet is ignored by the link partner.

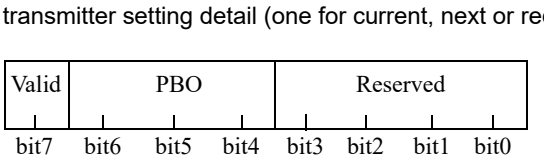

Figure 113–26—Infofield transmitter setting format

113.4.2.5.4 Next transmitter settings

Next transmitter setting (1 octet). Represented by Octet 6{Valid<7>, PBO<6:4>, Reserved<3:0>} and shown in Figure 113–26. Used to announce the next programmable PBO setting during PMA_PBO_Exch that takes effect upon entering PMA_Coeff_Exch state. For every other state, this octet is set to zero and ignored by the link partner. The bit Valid shall be set to one if the corresponding octet information is valid and shall be set to zero if it the octet information is not valid. If Valid is set to zero, the octet is ignored by the link partner.

113.4.2.5.5 Requested transmitter settings

Requested remote transmitter setting (1 octet). Represented by Octet 7{Valid<7>, PBO<6:4>, Reserved<3:0>} and shown in Figure 113–26. Used to request the remote transmitter programmable PBO setting during PMA_PBO_Exch that takes effect upon entering PMA_Coeff_Exch state. For every other state, this octet is set to zero and ignored by the link partner. The bit Valid shall be set to one if the corresponding octet information is valid and shall be set to zero if it the octet information is not valid. If Valid is set to zero, the octet is ignored by the link partner.

113.4.2.5.6 Message Field

Message Field (1 octet). For the MASTER, this field is represented by Octet 8{PMA_state<7:6>, loc_rcvr_status<5>, en_slave_tx<4>, trans_to_Coeff_Exch<3>, Coeff_exchange<2>, trans_to_Fine_Adjust<1>, trans_to_PCS_Test<0>}. For the SLAVE, this field is represented by Octet 8{PMA_state<7:6>, loc_rcvr_status<5>, timing_lock_OK<4>, trans_to_Coeff_Exch<3>, Coeff_exchange<2>, trans_to_Fine_Adjust <1>, trans_to_PCS_Test<0>}.

The two state-indicator bits PMA_state<7:6> shall communicate the state of the transmitting transceiver to the link partner. PMA_state<7:6>=00 indicates PMA_Training_Init_M or PMA_Training_Init_S, PMA_state<7:6>=01 indicates PMA_PBO_Exch, PMA_state<7:6>=10 indicates PMA_Coeff_Exch, and PMA_state<7:6>=11 indicates PMA_Fine_Adjust.

All possible Message Field settings are listed in Table 113–11 for the MASTER and Table 113–12 for the SLAVE. No other value shall be transmitted, and all other values shall be ignored at the receiver. The Message Field setting for the first transmitted PMA frame shall be the first row of Table 113–11 for the MASTER and the first row of Table 113–12 for the SLAVE. Moreover, for a given Message Field setting, the following Message Field setting shall be the same Message Field setting or the Message Field setting corresponding to a row below the current setting. When loc_rcvr_status=OK the Infofield variable is set to loc_rcvr_status<5>=1 and set to 0 otherwise.

113.4.2.5.7 SNR_margin

SNR_margin (4 bits). Represented by Octet 9<7:4>, which reports received decision point SNR margin in 1/2 dB steps. SNR_margin is relative to the SNR required for reception of LDPC-coded DSQ128 at an LDPC frame error ratio of less than 3.2×10^{-9}. The SNR_margin<7:4> four-bit values, 0010, 0011, 0100, 0101, 0110, 0111, 1000, 1001, 1010, 1011, 1100, 1101, 1110 shall indicate the decision point SNR margin

values of –1.5, –1, –0.5, 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5 dB, respectively. The value 0001 shall indicate a margin of –2 dB or less, and the value 1111 shall indicate 5 dB or more. Finally the value 0000 shall indicate that the SNR margin value is unknown.

113.4.2.5.8 Transition counter

Transition counter (10 bits). Represented by the 1.25 octets [Octet 9<1:0>, Octet 10<7:0>]. When configured as Transition counter (Coeff_exchange<2>=0 and a transition is announced to PMA_Coeff_Exch, PMA_Fine_Adjust or PCS_Test), this field is used as a 10-bit counter that counts the number of remaining frames until the next transition (PMA_Coeff_Exch, PMA_Fine_Adjust, PCS_Test).

113.4.2.5.9 Coefficient exchange handshake

Coefficient exchange handshake (12 bits). Represented by the 1.5 octets [Octet 9<3:0>, Octet 10<7:0>]. If Coeff_exchange<2>=1, this field is configured as a Coefficient exchange handshake and is used as a handshake control channel during programmable THP coefficient exchange. The details of the coefficient exchange are described in 113.4.2.5.15.

113.4.2.5.10 Ability Fields

Ability field (1 octet). Represented by Octet 12{EEE Ability<7>, THP Bypass Request<6>, Fast Retrain<5>, Reserved<4:0>}. Used to advertise the abilities of the PHY during the PMA_PBO_Exch state when Message<7:6> = 01.

For every other state, this octet is set to zero and ignored by the link partner. The Ability bits are defined as follows:

Octet 12<4:0> = Reserved

Octet 12<5> = Fast Retrain

0 = Fast Retrain not supported

1 = Fast Retrain supported

Octet 12<6> = THP Bypass Request in PMA_Coeff_Exchstate

0 = Local device requests link partner not to bypass THP during fast retrain

1 = Local device requests link partner to bypass THP during fast retrain

Octet 12<7> = EEE Ability

0 = EEE not supported

1 = EEE supported.

113.4.2.5.11 Reserved fields

All Infofield fields denoted Reserved in Figure 113–23, Figure 113–24, and Figure 113–25 are reserved for future use. This includes Octet 11 and Octet 12 when Coeff_exchange<2>=0 and Message<7:6>!=01, Octet 9<3:2> when transition counter is announced and [Octet 9<3:0>, Octet 10<7:0>] when no transition is announced and no coefficients are exchanged.

113.4.2.5.12 Vendor-specific field

If Coeff_exchange<2>=0 Octet 13 and Octet 14 are vendor-specific fields. If during Auto-Negotiation both transceivers agree on the use of the two vendor-specific octets, they may be used as a PHY communication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

channel; otherwise they are set to zero and ignored by the link partner. Represented by Octet 13<7:0> and Octet 14<7:0>.

113.4.2.5.13 Coefficient Field

Coefficient Field (4 octets). Represented by Octet 11<7:0>, Octet 12<7:0>, Octet 13<7:0>, and Octet 14<7:0>. When Coeff_exchange<2>=1, this field is used to exchange programmable THP coefficients. It transmits four 8-bit THP coefficients out of the total of 64 (16 coefficients over each of the 4 pairs). The order is pair A, coefficients 0:3, followed by coefficients 4:7, followed by 8:11 and 12:15. For all cases the first coefficient (indices 0, 4, 8 and 12) is mapped to Octet 11, the second coefficient (indices 1, 5, 9, 13) is mapped to Octet 12 and so on. The same coefficient order is followed to transmit the coefficients for pair B, followed by pair C, and finally pair D. The details of the coefficient exchange are described in 113.4.2.5.15.

113.4.2.5.14 CRC16

CRC16 (2 octets). Shall implement the CRC16 polynomial $(x+1)(x^{15}+x+1)$ of the previous 10 octets, Octet 5<7:0>, Octet 6<7:0>, Octet 7<7:0>, Octet 8<7:0>, Octet 9<7:0>, Octet 10<7:0>, Octet 11<7:0>, Octet 12<7:0>, Octet 13<7:0>, and Octet 14<7:0>. The CRC16 shall produce the same result as the implementation shown in Figure 113–27. In Figure 113–27 the 16 delay elements S0,..., S15, shall be initialized to zero. Afterwards Octet 5 through Octet 14 are used to compute the CRC16 with the switch connected, which is setting CRCgen in Figure 113–27. After all the 10 octets have been processed, the switch is disconnected (setting CRCout) and the 16 values stored in the delay elements are transmitted in the order illustrated, first S15, followed by S14, and so on, until the final value S0.

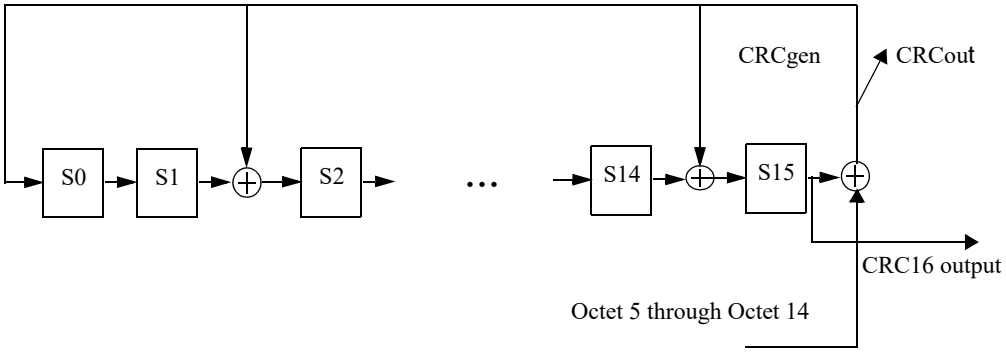

Figure 113–27—CRC16

113.4.2.5.15 Startup sequence

The startup sequence shall comply with the state diagram description given in Figure 113–28 and the transition counter state diagrams Figure 113–29 and Figure 113–30.

During Auto-Negotiation, PHY Control is in the DISABLE_25G/40GBASE-T_TRANSMITTER state and the transmitters are disabled. During normal training, prior to enabling the transmitter, the THP coefficients are set to zero.

When the Auto-Negotiation process asserts link_control=ENABLE, PHY Control enters the INIT_MAXWAIT_TIMER state. Upon entering this state, the maxwait_timer is started and PHY Control enters the SILENT state, which starts the minwait_timer and forces transmission of zeros by setting tx_mode=SEND_Z.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In MASTER mode, after expiration of the minwait_timer, PHY Control transitions to the PMA_Training_Init_M state.

Upon entering the PMA_Training_Init_M and PMA_Training_Init_S states, the PHY Control forces transmission into the training mode by asserting tx_mode=SEND_T, which includes the transmission of Infofields.

Upon entering state PMA_Training_Init_M, the MASTER starts transmission with a fixed transmit power level, PBO=4 (corresponding to a power backoff of 8 dB). The PBO variable is communicated to the link partner via the current transmitter octet of the Infofield.

Initially the MASTER is not ready for the SLAVE to respond and sets en_slave_tx=0, which is communicated to the link partner via the Infofield. After the MASTER has sufficiently converged the necessary circuitry, the MASTER sets en_slave_tx=1 to allow the SLAVE to transition to PMA_Training_Init_S.

In SLAVE mode, PHY Control transitions to the PMA_Training_Init_S state only after the SLAVE PHY acquires timing, converges its equalizers, acquires its descrambler state, and sets loc_SNR_margin=OK. The SLAVE shall respond using the fixed PBO transmit power level, PBO=4 (corresponding to a power backoff of 8 dB). For PHYs with the EEE capability, further requirements for this transition are described in 113.3.5.1.

While in states PMA_Training_Init_S, PMA_PBO_Exch, or PMA_Coeff_Exch, whenever a SLAVE operating in loop timing mode loses the MASTER timing reference (for example, after transmit power level transitions) it sets timing_lock_OK=0, which is communicated to the link partner via the Infofield. Otherwise, timing_lock_OK is set to one.

In MASTER mode, PHY Control enters the PMA_PBO_Exch state after loc_SNR_margin=OK and in SLAVE mode PHY Control enters the PMA_PBO_Exch state after the loc_SNR_margin=OK and minwait_timer expires. In the PMA_PBO_Exch state while Infofield Message<7:6> = 01, the PHY advertises EEE and Fast Retrain capability in octet 12 of the Infofield. When both the local device and remote device advertise EEE capability then EEE is supported. When both the local device and remote device advertise Fast Retrain capability then Fast Retrain is supported. In the PMA_PBO_Exch state, after the MASTER has computed the final desired programmable PBO level, it shall request a PBO change using the requested transmitter setting in the Infofield (octet 7). In SLAVE mode, after the MASTER has requested the desired PBO level, the SLAVE shall request a desired PBO level that is within two levels (within 4 dB) of the requested MASTER PBO level. Both MASTER and SLAVE shall use the lower of the two PBO levels (i.e., that providing the larger transmit power).

Following PBO exchange for both transceivers, each PHY shall announce the next PBO setting using the next transmitter setting (octet 6). Afterwards, each PHY announces a transition to the PMA_Coeff_Exch state using the trans_to_Coeff_Exch=1 and transition_count as described in 113.4.5.1. MASTER initiates the transition to PMA_Coeff_Exch count with the trans_to_Coeff_Exch=1 flag and a transition counter value of 2^9. The SLAVE responds prior to the MASTER transition counter reaching 2^6 by setting trans_to_Coeff_Exch=1 flag and a transition counter value matching the MASTER. The PMA frame after each transceiver transition_count reaches zero, the PHYs shall enter the PMA_Coeff_Exch state and enable the requested PBO. Therefore, both PHYs will enter the PMA_Coeff_Exch state within one PMA frame.

While both MASTER and SLAVE are in state PMA_Coeff_Exch, when either end has computed the programmable THP settings, the programmable THP coefficient exchange process can begin, using the 1.5 octet Coefficient exchange handshake and the 4 octet Coefficient Field as follows:

a) During PMA_Coeff_Exch each PHY begins a coefficient exchange by setting the Coeff_Exchange flag to 1 in the Message Field.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) During coefficient exchange, the transition counter bits are used as the Coefficient Exchange Handshake
   1) Octet 9{Reserved<3:0>}: unused
   2) Coefficient Pair Received, Octet 10<7:6>: 01 for local transmitter pair A, 10 for B, 11 for C, and 00 for D (default). This is the handshake to tell the remote unit the last coefficients received.
   3) Coefficient Group Received, Octet 10<5:4>: 01 for coefficients 0:3, 10 for 4:7, 11 for 8:11, and 00 for 12:15 (default). This is the handshake to tell the remote unit the last coefficients received.
   4) Coefficient Pair Sent, Octet 10<3:2>: 01 for remote transmitter pair A, 10 for B, 11 for C, and 00 for D (default). This is the handshake to tell the remote unit the current coefficients being sent.
   5) Coefficient Group Sent, Octet 10<1:0>: 01 for 0:3, 10 for 4:7, 11 for 8:11, and 00 for 12:15 (default). This is the handshake to tell the remote unit the current coefficients being sent.
c) The Coefficient Field is used to send four 8-bit coefficients in each frame designated by the Coefficient Pair Sent and Coefficient Group Sent bits. The coefficient format is:
   1) 8 bits per coefficient. Use one octet per coefficient in twos complement notation
   2) Coefficient range is –2.0 to 1.984375 in steps of 0.015625
   3) The sign of the coefficients shall be consistent with Equation (113–6)
d) Each PHY begins the exchange by sending pair A coefficients 0:3 with Coefficient Pair Sent=01 and Coefficient Group Sent=01.
e) The remote unit acknowledges by setting Coefficient Pair Received=01 and Coefficient Group Received=01.
f) Following each acknowledgement, the PHY increments through the Coefficient Group and then Coefficient Pair settings until Coefficient Pair Sent=00 and Coefficient Group Sent=00 and Coefficient Pair Received=00 and Coefficient Group Received=00. At this time, coefficient exchange is done and both PHYs set Coeff_Exchange=0.

Following coefficient exchange for both transceivers, each PHY announces a transition to the PMA_Fine_Adjust state (trans_to_Fine_Adjust=1) and starts the transition_count as described in 113.4.5.1. During the first PMA frame after the transition_count reaches zero, the PHYs enter the PMA_Fine_Adjust state and enable the THP precoders with the requested coefficients. At the closure of the THP feedback loop, the initial state of the THP feedback filters shall be the last 16 symbols from the state PMA_Coeff_Exch.

The THP coefficients and PBO setting are not changed during PMA_Fine_Adjust. The final convergence of the adaptive filter parameters is completed in the PMA_Fine_Adjust state.

After the PHY completes successful training and establishes proper receiver operations, PCS Transmit conveys this information to the link partner via transmission of the parameter Infofield value loc_rcvr_status. The link partner's value for loc_rcvr_status is stored in the local device parameter rem_rcvr_status. When the condition loc_rcvr_status=OK and rem_rcvr_status=OK is satisfied, each PHY announces a transition to the PCS_Test state (trans_to_PCS_Test=1) and start the transition counter as described in 113.4.5.1. For PHYs with the EEE capability, further requirements for this transition are described in 113.3.5.1.

The normal mode of operation corresponds to the PCS_Data state, where PHY Control asserts tx_mode=SEND_N and transmission of data over the link can take place.

PHY Control may force the transmit scrambler state to be initialized to an arbitrary value by requesting the execution of the PCS Reset function defined in 113.3.2.1.

The operation of the maxwait_timer requires that the PHY complete the startup sequence from state SILENT to PMA_Fine_Adjust in the PHY Control state diagram (Figure 113–28) in less than 2000 ms to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

avoid link_status being changed to FAIL by the Link Monitor state diagram (Figure 113–31). To ensure interoperability the timing in Table 113–13 should be observed.

After reaching the PCS_Data state PHYs with the EEE capability can transition to the LPI receive mode under the control of the link partner and to the LPI transmit mode under control of the local LPI client.

Table 113–13—Recommended startup sequence timing

Master	Recommended maximum time (ms)	Recommended average time (ms)	Slave
SILENT plus (PMA_Training_Init_M state AND en_slave_tx = 0)	350	315	SILENT
(PMA_Training_Init_M state AND en_slave_tx = 1) plus PMA_PBO_Exch state	480	432	PMA_Training_Init_S state plus PMA_PBO_Exch state
PMA_Coeff_Exch state	100	90	PMA_Coeff_Exch state with timing_lock_OK=0
	520	468	Total for PMA Coeff Exch state
PMA_Fine_Adjust state	650	585	PMA_Fine_Adjust state
Total	2000	1800	

113.4.2.5.16 Fast retrain function

PHYs that support the fast retrain capability shall implement the fast retrain state diagram shown in Figure 113–33. PHYs may request a fast retrain by setting the variable loc_fr_req to TRUE. This causes the transmission of an easily detected link failure signal specified in 113.4.2.2.2. After completing the link failure signal the PHY shall transition to the PMA_INIT_FR state followed immediately by the PMA_Coeff_Exch state. If the link partner requested THP bypass for fast retrain the PHY shall bypass the THP (or set THP coefficients to zero). Otherwise the PHY shall keep its THP turned on with its previously exchanged coefficients, and send PAM2 signaling within a time period equivalent to 9 LDPC frame periods.

After the detection of the link failure signal, a PHY shall transition to the PMA_Coeff_Exch state and respond with PAM2 signaling within a time period equivalent to 9 LDPC frame periods after receiving the link failure signal.

The PAM2 symbols are generated using the PMA sidestream scrambler polynomials shown in Figure 113–15. The training sequence in 113.3.4 shall be used during fast retraining.

Note that reliable traffic on the transmitter may be interrupted when the local receiver requests a fast retrain.

Following the link failure signal, the two link partners transition back to the PMA_Coeff_Exch state and follow the training procedure described in 113.4.2.5.15, with the exception that the initial infofield countdown values are reduced as indicated in Figure 113–29 and Figure 113–30.

To ensure interoperability the training times in Table 113–14 should be observed during the fast retrain.

Table 113–14—Recommended fast retrain sequence timing

State	Recommended maximum time (ms)
PMA_Coeff_Exch state	20
PMA_Fine_Adjust state	10

113.4.2.6 Link Monitor function

Link Monitor determines the status of the receiver and communicates it via the variable link_status. Failure of the receiver typically causes the PMA's clients to suspend normal operation.

The Link Monitor function shall comply with the state diagram of Figure 113–31.

Upon power on, reset, or release from power down, the Auto-Negotiation algorithm sets link_control=SCAN_FOR_CARRIER and, during this period, sends fast link pulses to signal its presence to a remote station. If the presence of a remote station is sensed through reception of fast link pulses, the Auto-Negotiation algorithm sets link_control=DISABLE and exchanges Auto-Negotiation information with the remote station. During this period, link_status=FAIL is asserted. If the presence of a remote 25G/40GBASE-T station is established, the Auto-Negotiation algorithm permits full operation by setting link_control=ENABLE. As soon as reliable transmission is achieved, the variable link_status=OK is asserted, upon which further PHY operations can take place.

113.4.2.7 Refresh Monitor function

The Refresh Monitor is required for PHYs that support the EEE capability. The Refresh Monitor operates when the PHY is in the LPI receive mode. The Refresh Monitor shall comply with the state diagram of Figure 113–19b. The function forces a link retrain if a refresh signal is not reliably detected within a moving time window equivalent to 50 complete quiet-refresh cycles (nominally equal to 2.048 ms), when the PHY is in the lower power receive mode.

113.4.2.8 Clock Recovery function

The Clock Recovery function couples to all four receive pairs. It may provide independent clock phases for sampling the signals on each of the four pairs.

The Clock Recovery function shall provide clocks suitable for signal sampling on each line so that the LDPC FER indicated in 113.4.2.4 is achieved. The received clock signal should be stable and ready for use when training has been completed (loc_rcvr_status=OK). The received clock signal is supplied to the PMA Transmit function by received_clock.

113.4.3 MDI

Communication through the MDI is summarized in 113.4.3.1 and 113.4.3.2.

113.4.3.1 MDI signals transmitted by the PHY

The symbols to be transmitted by the PMA on the four pairs BI_DA, BI_DB, BI_DC, and BI_DD are denoted by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD], respectively. The modulation scheme used over each pair is PAM16. PMA Transmit generates a pulse-amplitude modulated signal on each pair in the following form:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$x_n = M\left(a_n - \sum_{k=1}^{16} x_{n-k}c_k\right) = a_n + 32m_n - \sum_{k=1}^{16} x_{n-k}c_k \quad (113\text{–}6)$$

$$s(t) = \sum_{n=0}^{\infty} x_n h_T(t - nT) \quad (113\text{–}7)$$

In Equation (113–6), a_n is the PAM16 modulation symbol from the set {–15, –13, –11, –9, –7, –5, –3, –1, 1, 3, 5, 7, 9, 11, 13, 15} to be transmitted at time nT. Each of the 16 THP coefficients c_1, c_2,..., c_{16} per wire pair is represented in two's complement form by 8 bits described in 113.4.2.5. The nonlinear THP operation given by $M(\alpha) = (\alpha + 16) mod 32 - 16$ corresponds to changing the modulation symbol a_n to an augmented modulation symbol $\tilde{a}_n = a_n + 32m_n$ with the integer m_n chosen such that the THP output lies in the interval $-16 \le x_n < 16$. Equation (113–7) describes the convolution of the THP output signals with the transmitter symbol response $h_T(t)$ to obtain the transmit signal $s(t)$ at the MDI. The values of the programmable THP coefficients are exchanged in the Infofield during PMA_Coeff_Exch. The THP filter coefficients shall be fixed after startup.

The nominal power (denoted Ptx) and the symbol response of the PMA transmitted signal $s(t)$ shall comply with the electrical specifications given in 113.5. When the link segment does not experience the maximum insertion loss (IL), each transceiver indicates to the link partner that the link partner PMA Transmit signal shall be reduced in increments of 2 dB. The minimum power backoff level requested shall comply with the power backoff schedule in Table 113–15. If a given receiver has sufficient decision point SNR margin, it may choose to request from the link partner larger power backoff (up to 14 dB) than shown in Table 113–15. Additionally, the Slave shall select a PBO level as described in the PMA_PBO_Exch state of 113.4.2.5.15. The PMA Transmit shall be capable of eight power backoff settings in approximately 2 dB steps. The difference between each consecutive power setting shall be 2 ± 0.25 dB, and each step shall be centered at $2 \times n$ dB (n = 0 to 7) reduction from nominal, with a maximum error of ± 1 dB.

The received signal power at the MDI, P (dBm), in Table 113–15, should be the estimate of the average received power across all four pairs from the remote transmitter when the link partner PMA Transmit is at nominal power (after accounting for local transmitter power). If the remote transmitter is not at nominal power during the measurement, the estimate of the received power should be incremented by the amount of power backoff of the link partner transmitter during the measurement. Nominal power refers to the transmit power without any power backoff and is specified in 113.5.3.4. The estimate of the received signal power is stored in registers 1.141 to 1.144 as described in 45.2.1. The values in the length, L (m), column in Table 113–15 are for reference only (not required for power backoff evaluation).

Table 113–15—Power backoff schedule

Received signal power at MDI, P (dBm)	Length L(m) (reference)	Minimum power backoff (dB)
$-7.2 < P$	$0 \le L < 13$	6
$-9.4 < P \le 7.2$	$13 \le L < 19$	4
$-11.4 < P \le -9.4$	$19 \le L < 25$	2
$P \le -11.4$	$25 \le L$	0

113.4.3.2 Signals received at the MDI

Signals received at the MDI can be expressed for each pair as pulse-amplitude modulated signals that are corrupted by noise as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$r(t) = \sum_{n=0}^{\infty} \tilde{a}_n h_R(t - nT) + w(t) \quad (113–8)$$

In Equation (113–8), $\tilde{a}_n$ are the augmented PAM16 modulation symbols described in 113.4.3.1, $h_R(t)$ denotes the symbol response of the overall signal path from the THP precoder to the MDI at the receiver, and $w(t)$ represents the contribution of various noise sources including uncancelled crosstalk. The four signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD are processed within the PMA Receive function to yield the received symbols rx_symb_vector.

113.4.4 Automatic MDI/MDI-X configuration

Automatic MDI/MDI-X configuration is intended to eliminate the need for crossover cables between similar devices. Automatic MDI/MDI-X configuration is required for 25G/40GBASE-T devices and shall comply with 40.4.4.1 and 40.4.4.2.

Having established MDI/MDI-X configuration, the receiver shall detect and correct for several configurations of pair swaps and crossovers and arbitrary polarity swaps. The receiver pairs BI_DA, BI_DB, BI_DC, and BI_DD might be connected to the corresponding transmit pairs in any of the following ways with arbitrary polarity:

a) No crossover
b) A/B crossover only
c) C/D crossover only
d) A/B crossover and C/D crossover

For EEE-capable PHYs, the MDI/MDIX function configuration shall apply to refresh and alert signaling. For PHYs with the fast retrain capability, the MDI/MDIX function configuration shall apply to link failure signaling.

113.4.5 State variables

113.4.5.1 State diagram variables

coeff_exchange_done
: This variable reports that both transceivers have received the corresponding coefficients from the link partner.
Values: TRUE: The coefficient exchange has completed.
FALSE: The coefficient exchange has not completed.

config
: The PMA shall generate this variable continuously and pass it to the PCS via the PMA_CONFIG.indication primitive.
Values: MASTER or SLAVE

link_control
: The link_control parameter generated by Auto-Negotiation and passed to the PMA via the PMA_LINK.request primitive (see 113.2.1.1)

link_status
: The link_status parameter set by PMA Link Monitor state diagram and communicated through the PMA_LINK.indication primitive.
Values: OK or FAIL

loc_rcvr_status
: Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive link for the local PHY.
Values: OK: The receive link for the local PHY is operating reliably.
NOT_OK: Operation of the receive link for the local PHY is unreliable.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

loc_SNR_margin

This variable reports whether the local device has sufficient SNR margin to continue to the next state. The criterion for setting the parameter loc_SNR_margin is left to the implementer.

Values: OK: The local device has sufficient SNR margin.
NOT_OK: The local device does not have sufficient SNR margin.

master_transition_counter

This variable reports the current value of the MASTER's transition counter reported in the Infofield defined in 113.4.2.5.

Values: 0 to 2^9

MessageField_IF

This variable reports that a receiver has successfully received and decoded the Infofield from the remote device. This variable takes on the value contained in the Message Field. If the Message Field cannot be decoded or no explicit action is outstanding the value Null is returned.

Values: trans_to_Coeff_Exch, trans_to_Fine_Adjust, trans_to_PCS_Test or Null

PBO

PBO is a variable that can take any integer value from 0 to 7 and indicates the power backoff level. Denoting Ptx as the maximum nominal power, the PBO values are:

Values: 0, 1, 2, 3, 4, 5, 6, 7, which correspond to transmit power levels of
Ptx, *Ptx*–2 dB, *Ptx*–4 dB, *Ptx*–6 dB, *Ptx*–8 dB, *Ptx*–10 dB, *Ptx*–12 dB, *Ptx*–14 dB, respectively

PBO_next

PBO_next is a variable that can take any integer value from 0 to 7 and indicates the next power backoff level to be used at the local transmitter. The value is taken from the fixed set of values during PMA_Training_Init_M and PMA_Training_Init_S as described in 113.4.2.5. The value is taken from the decoded value of the link partner Infofield during PMA_PBO_Exch

Values: 0, 1, 2, 3, 4, 5, 6, 7, which correspond to transmit power levels of
Ptx, *Ptx*–2 dB, *Ptx*–4 dB, *Ptx*–6 dB, *Ptx*–8 dB, *Ptx*–10 dB, *Ptx*–12 dB, *Ptx*–14 dB, respectively

PBO_tx

PBO_tx is a variable that can take any integer value from 0 to 7 and indicates the power backoff level currently used at the local transmitter.

Values: 0, 1, 2, 3, 4, 5, 6, 7, which correspond to transmit power levels of
Ptx, *Ptx*–2 dB, *Ptx*–4 dB, *Ptx*–6 dB, *Ptx*–8 dB, *Ptx*–10 dB, *Ptx*–12 dB, *Ptx*–14 dB, respectively

PBO_exchange_done

This variable reports that both transceivers have received the corresponding PBO levels from the link partner.

Values: TRUE: The PBO exchange has completed.
FALSE: The PBO exchange has not completed.

pcs_status

The pcs_status parameter generated by the PCS and passed to the PMA via the PMA_PCSTATUS.request primitive (see 113.2.2.6).

pma_reset

Allows reset of the PHY Control and Link Monitor state diagrams.

Values: ON or OFF

rem_rcvr_status

Variable set by the PCS Receive function to indicate whether correct operation of the receive link for the remote PHY is detected or not.

Values: OK: The receive link for the remote PHY is operating reliably.
NOT_OK: Reliable operation of the receive link for the remote PHY is not detected.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

THP_next

THP_next is a variable that contains sixteen eight-bit values and describes the next transmitter setting of the THP coefficients. It refers to the programmable THP coefficients selected during coefficient exchange described in 113.4.2.5.

Values: 16 coefficients of 8-bit values each. Range is –2.0 to 1.984375 in steps of 0.015625

THP_tx

THP_tx is a variable that contains sixteen 8-bit values and describes the current transmitter setting of the THP coefficients. It refers to the programmable THP coefficients selected during coefficient exchange described in 113.4.2.5.

Values: 16 coefficients of eight-bit values each. Range is –2.0 to 1.984375 in steps of 0.015625

trans_to_Coeff_Exch

Message field variable defined in 113.4.2.5 that flags a transition by the local device to the PMA_Coeff_Exch state.

Values: 1: The local device transitions to the PMA_Coeff_Exch state on expiration of the transition counter.

0: The local device does not transition to the PMA_Coeff_Exch state.

trans_to_Fine_Adjust

Message field variable defined in 113.4.2.5 that flags a transition by the local device to the PMA_Fine_Adjust state.

Values: 1: The local device transitions to the PMA_Fine_Adjust state on expiration of the transition counter.

0: The local device does not transition to the PMA_Fine_Adjust state.

trans_to_PCS_Test

Message field variable defined in 113.4.2.5 that flags a transition by the local device to the PCS_Test state.

Values: 1: The local device transitions to the PCS_Test state on expiration of the transition counter.

0: The local device does not transition to the PCS_Test state.

transition_count

This variable reports the value of the transition counter contained in the Infofield sent to the remote device. Transition_count has to comply with the state diagram description given in 113.4.6.2. When the message field contains a flag for a state transition, the transition counter denotes the remaining number of Infofield until the next state transition. MASTER initiates the transition to PMA_Coeff_Exch count with the trans_to_Coeff_Exch=1 flag and a counter value of 2^9. The SLAVE responds prior to the counter reaching 2^6 with the same flag and a count value matching the MASTER. Then both PHYs transition to PMA_Coeff_Exch within one PMA frame. The same sequence is performed in the transition to PMA_Fine_Adjust state and PCS_Test state using the trans_to_Fine_Adjust=1 and trans_to_PCS_Test=1 flags, respectively. In EEE-capable PHYs, synchronization of the PMA frames is tightly controlled as described in 113.3.5.1. When the message field does not contain a flag for a state transition, the transition counter is set to zero and ignored by the receiver.

Values: 0 to 2^9

tx_mode

PCS Transmit sends code-groups according to the value assumed by this variable.

Values: SEND_N: This value is continuously asserted when transmission of sequences of code-groups representing a 25GMII/XLGMII data stream take place.

SEND_T: This value is continuously asserted when transmission of sequences of code-groups representing the sequences of code-groups (TA_n, TB_n, TC_n, TD_n) defined in 113.3.4.2 is to take place.

SEND_Z: This value is asserted when transmission of zero code-groups is to take place.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following variables are required only for PHYs that support the EEE capability:

lpi_refresh_detect
: Set TRUE when the receiver has reliably detected refresh signaling and FALSE otherwise. The exact criteria left to the implementer.

pcs_data_mode
: Generated by the PMA PHY Control function and indicates whether or not the local PHY may transition its PCS state diagrams out of their initialization states. The current value of the pcs_data_mode is passed to the PCS via the PMA_PCSDATAMODE.indicate primitive. In the absence of the optional EEE and fast retrain capabilities, the PHY operates as if the value of this variable is TRUE.

mtc
: mtc is the transition count for a MASTER PHY during normal training and fast retraining. mtc shall be equal to 2^9 for normal training and 2^5 for fast retrain.

stc
: stc is the transition count for a SLAVE PHY during normal training and fast retraining. stc shall be equal to 2^6 for normal training and 2^4 for fast retrain.

The following six variables are required only for PHYs that support the fast retrain capability:

fr_enable
: This variable is set to TRUE if fast retrain is supported. The variable is set to FALSE otherwise. If MDIO is supported, this variable is based on the value of 1.147.0 with the value of TRUE corresponding to 1.147.0 set to 1. If MDIO is not supported, an equivalent method of controlling fast retrain functionality should be provided.

loc_fr_req
: Set TRUE when the receiver has detected a link failure condition and is requesting a fast retrain; set FALSE otherwise.

loc_fr_detect
: Set TRUE when the receiver has reliably detected the link failure signal. It is highly recommended that loc_fr_detect is qualified with the reception of errored blocks at the LDPC decoder output. Set FALSE when the link failure signal is not detected.

send_link_fail
: When TRUE indicates that the PMA should send the link failure signal. When FALSE the variable has no effect.

fr_active
: Set TRUE when the PHY is performing a fast retrain and set FALSE otherwise.

fast_retrain_flag
: Set TRUE after the PHY generates or detects a link failure signal and set FALSE otherwise.

113.4.5.2 Timers

All timers operate in the manner described in 14.2.3.2.

maxwait_timer
: A timer used to limit the amount of time during which a receiver dwells in the SILENT and TRAINING states. The timer shall expire 2000 ms ± 10 ms after being started. This timer is used jointly in the PHY Control and Link Monitor state diagrams. The maxwait_timer is tested by the Link Monitor to force link_status to be set to FAIL if the timer expires and loc_rcvr_status is NOT_OK. See Figure 113–28 and Figure 113–31.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

minwait_timer
: A timer used to determine the minimum amount of time the PHY Control stays in the SILENT, PMA_Training_Init_S, PCS_Test and PCS_Data states. The timer shall expire 1 ms ± 0.1 ms after being started.

The following timer is required only for PHYs that support the EEE capability:

lpi_refresh_rx_timer
: This timer is used to monitor link quality during the LPI receive mode. If the PHY does not reliably detect reliable refresh signaling before this timer expires then a full retrain is performed.
Values: The condition lpi_refresh_rx_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 50 complete quiet-refresh signal periods, equivalent to 2.048× *S* ms.

The following two timers are required only for PHYs that support the fast retrain capability:

link_fail_sig_timer
: Determines the period of time the PHY sends the link failure signal.
Values: The condition link_fail_sig_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 4 LDPC frame periods.

fr_maxwait_timer
: Determines the period of time the PHY has to transition its PCS Control State to PCS_Test following a fast retrain before the fast retrain is aborted and a full retrain performed.
Values: The condition fr_maxwait_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 30 ms.

113.4.5.3 Functions

Exchange_Final_PBO
: This function transmits and receives the final PBO settings using the Infofield as described in 113.4.2.5.

Exchange_THP_Coefficients
: This function compiles and sends to the link partner and receives from the link partner the desired programmable THP coefficients using the Infofield as described in 113.4.2.5.

113.4.5.4 Counters

The following two counters are required only for PHYs that support the fast retrain capability:

fr_tx_counter
: Counts the number of times the PHY initiates a fast link retrain by transmitting the link failure signal. This counter is reflected in MDIO register 1.147.10:6 specified in 45.2.1.94.2.

fr_rx_counter
: Counts the number of times the PHY begins a fast link retrain in response to the detection of link failure signalling from the link partner. This counter is reflected in MDIO register 1.147.15:11 specified in 45.2.1.94.1.

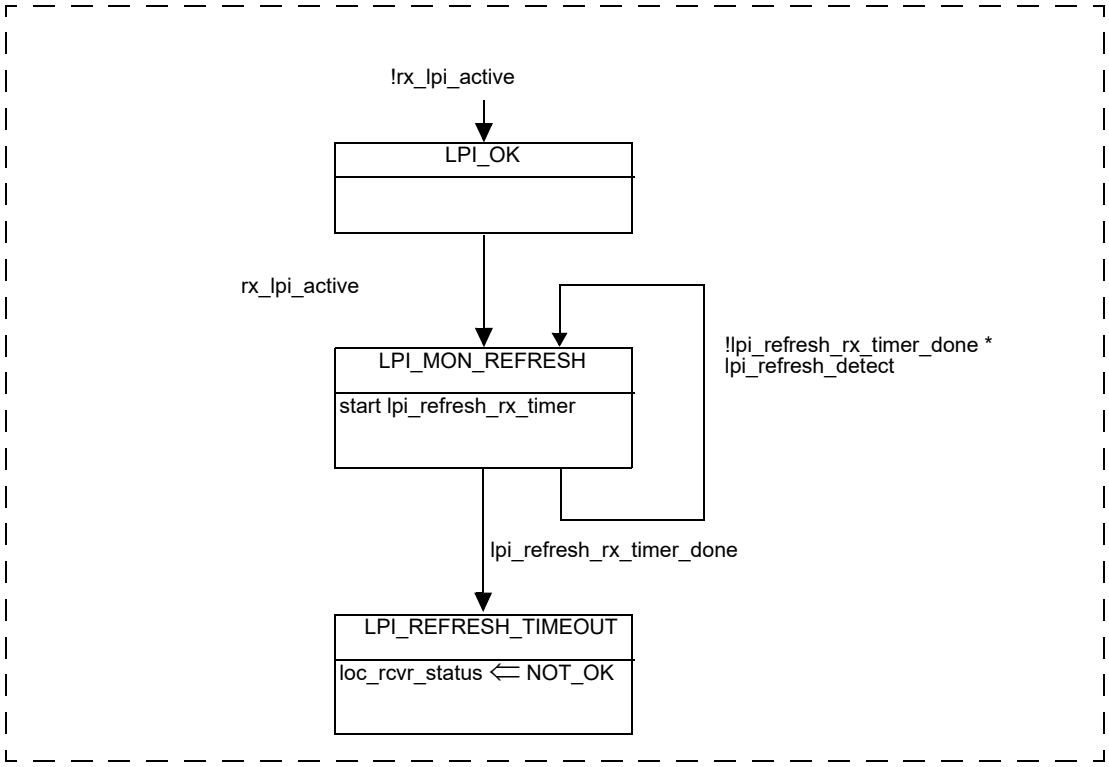
113.4.6.5 Fast retrain state diagram

113.5 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA and specifies PMA-to-MDI interface tests.

113.5.1 Electrical isolation



The PHY shall provide electrical isolation between the port device circuits, including frame ground (if any) and all MDI leads. This electrical isolation shall meet the isolation requirements as specified in J.1.

113.5.2 Test modes

The test modes described below shall be provided to allow for testing of the transmitter waveform, transmitter distortion, transmitted jitter, transmitter droop, and BER testing.

For a PHY with an MDIO management interface, these modes shall be enabled by setting bits 1.132.15:13 (MultiGBASE-T test mode register) of the MDIO Management register set as shown in Table 113–16. These test modes shall only change the data symbols provided to the transmitter circuitry and shall not alter the

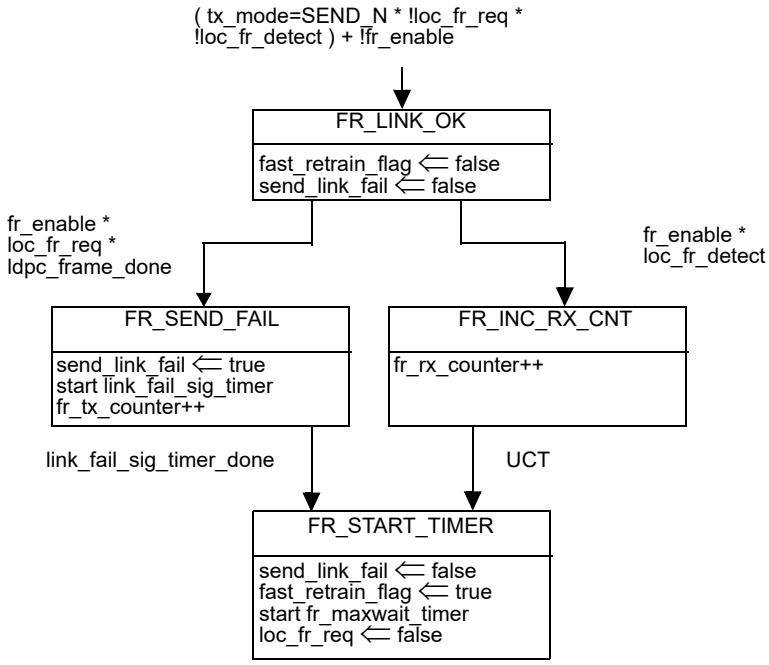
NOTE—This state diagram is only required when the PHY supports the EEE capability.

Figure 113–32—EEE Refresh monitor state diagram



electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation. PHYs without a MDIO shall provide a means to enable these modes for conformance testing.

Table 113–16—MDIO management register settings for test modes

1.132.15	1.132.14	1.132.13	Mode
0	0	0	Normal operation.
0	0	1	Test mode 1—Setting of MASTER transmitter required by SLAVE for transmit jitter test in SLAVE mode.
0	1	0	Test mode 2—Transmit jitter test in MASTER mode.
0	1	1	Test mode 3—Transmit jitter test in SLAVE mode.
1	0	0	Test mode 4—Transmit distortion test.
1	0	1	Test mode 5—Normal operation with no power backoff. This is for the PSD mask and power level test.
1	1	0	Test mode 6—Transmitter droop test mode.
1	1	1	Test mode 7—Pseudo random test mode for BER Monitor.

Test mode 1 is a mode provided for enabling testing of timing jitter on a SLAVE transmitter. When test mode 1 is enabled, the PHY shall transmit the PMA training pattern (PRBS 33) continually from all four

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—This state diagram is only required when the PHY supports the fast retrain capability.

Figure 113–33—Fast retrain control state diagram

transmitters with the THP turned off, with no power backoff and with the transmitted symbols timed from its local clock source.

Test mode 2 is for transmitter jitter testing when transmitter is in MASTER timing mode. When test mode 2 is enabled, the PHY shall transmit {two +16 symbols followed by two –16 symbols} continually from all four transmitters with the THP turned off, with no power backoff and with the transmitted symbols timed from its local clock source. The transmitter output is a $800 \times S$ MHz signal.

When test mode 3 is enabled on a PHY, the PHY shall transmit, with THP turned off, the data symbol sequence {two +16 symbols followed by two –16 symbols} repeatedly on pair D with the symbols timed from its recovered receive data clock in SLAVE timing mode. A PHY operates in test mode 3 when there is no input signal on pair D. The transmitter output is a $800 \times S$ MHz signal on pair D and shall be silence on pairs A, B, and C.

Test mode 4 is for transmitter nonlinear distortion testing. When test mode 4 is enabled, the PHY shall transmit, with the THP turned off, transmitted symbols, timed from a transmit clock (as specified in 113.5.3.5) in the MASTER timing mode, defined by the bits1.132.12:10 and Table 113–17.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 113–17—MDIO management register settings for transmit frequencies in test mode 4

1.132.12	1.132.11	1.132.10	Output waveform frequencies in MHz
			Two tone frequency pairs
0	0	0	Reserved
0	1	1	Reserved
1	1	1	Reserved
0	0	1	(3200 × *S*/1024) × 47, (3200 × *S*/1024) × 53
0	1	0	(3200 × *S*/1024) × 101, (3200 × *S*/1024) × 103
1	0	0	(3200 × *S*/1024) × 179, (3200 × *S*/1024) × 181
1	0	1	(3200 × *S*/1024) × 277, (3200 × *S*/1024) × 281
1	1	0	(3200 × *S*/1024) × 397, (3200 × *S*/1024) × 401

The peak-to-peak levels used in this test shall correspond to the ± 16 symbol levels and the relative amplitudes of the tones in a two-tone pair shall be within 0.5 dB of each other.

Test mode 5 is for checking whether the transmitter is compliant with the transmit PSD mask and the transmit power level. When test mode 5 is enabled, the PHY shall transmit as in normal operation but with the power backoff disabled.

Test mode 6 is for testing transmitter droop. When test mode 6 is enabled, the PHY shall transmit the following sequence of data symbols A_n, B_n, C_n, D_n, of 113.4.3.1 continually from all four transmitters, with the THP turned off:

{One hundred twenty eight +16 followed by one hundred twenty eight –16 symbols}.

Test mode 7 is for enabling measurement of the bit error ratio of the link including the LDPC encoder/decoder, the transmit and receive analog front ends of the PHY and a cable connecting two PHYs. This mode shall reuse the 25G/40GBASE-T scrambler and is defined in detail in 113.3.3.

113.5.2.1 Test fixtures

The following fixtures (illustrated by Figure 113–34, Figure 113–35, and Figure 113–36), or their functional equivalents, can be used for measuring the transmitter specifications described in 113.5.3.

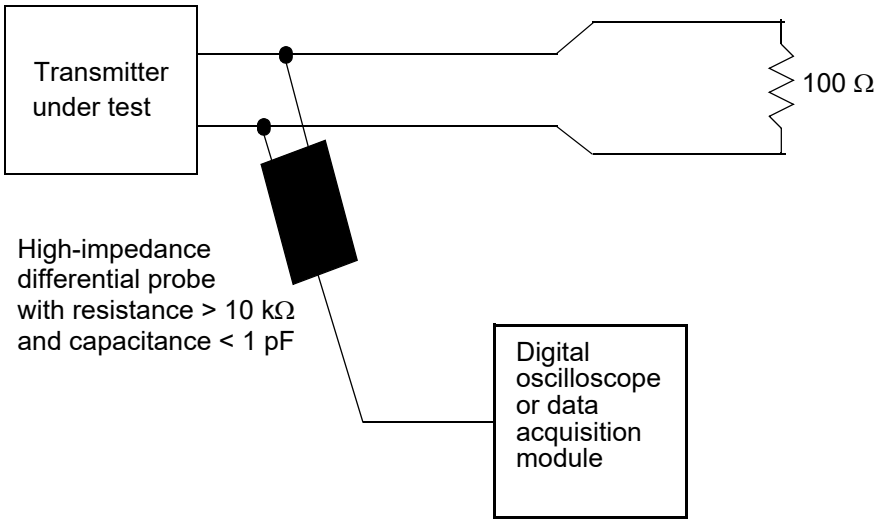

Figure 113–34—Transmitter test fixture 1 for transmitter droop measurement

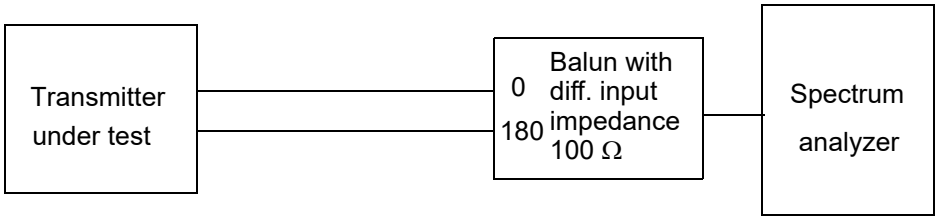

Figure 113–35—Transmitter test fixture 2 for linearity measurement, power spectral density measurement, and transmit power level measurement

The high-impedance probe shown in Figure 113–34 in transmitter test fixture 1 has resistance > 10 KΩ and capacitance < 1 pF over the frequency range of 1 MHz to 1600 MHz. Figure 113–35 includes a power summer or balun device to couple the 100 Ω differential output of the transmitter to the 50 Ω single-ended input typically found in a spectrum analyzer input. The center frequency (F_c) of the band pass filter show in Figure 113–36 is $800 \times S$ MHz ± 200 kHz and the band pass filter noise bandwidth (B_n) is 2 MHz ± 200 kHz.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

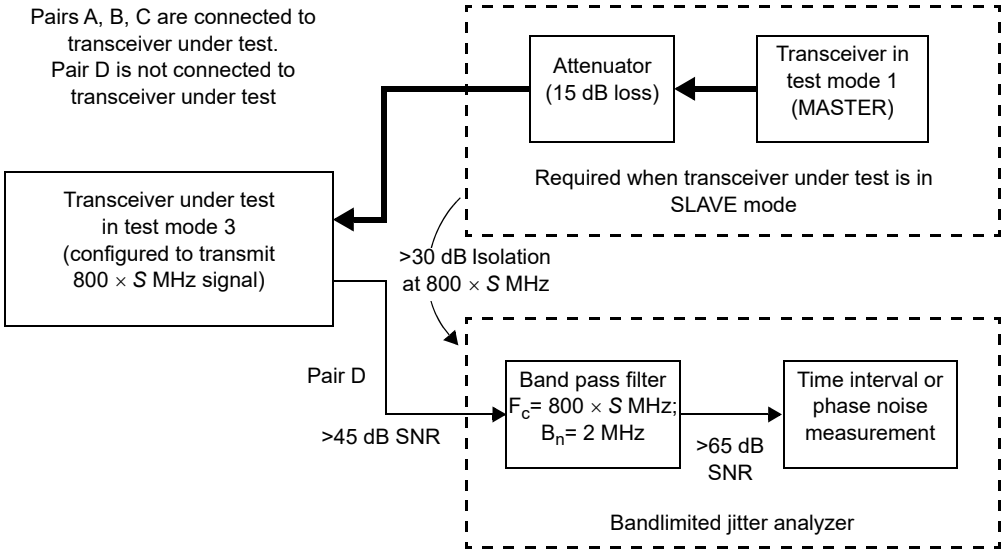

Figure 113–36—Transmitter test fixture 3 for transmitter jitter measurement

113.5.3 Transmitter electrical specifications

The PMA provides the Transmit function specified in 113.4.2.2 in accordance with the electrical specifications of this clause. The PMA shall operate with AC-coupling to the MDI.

Where a load is not specified, the transmitter shall meet the requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output.

113.5.3.1 Maximum output droop

With the transmitter in test mode 6 and using the transmitter test fixture 1, the magnitude of both the positive and negative droop shall be less than 10%, measured with respect to an initial value at 2.5/*S* ns after the zero crossing and a final value at 22.5/*S* ns after the zero crossing.

113.5.3.2 Transmitter nonlinear distortion

When in test mode 4 and observing the spectrum of the differential signal output at the MDI using transmitter test fixture 2, for each pair, with no intervening cable, the transmitter nonlinear distortion mask is defined as follows:

The SFDR of the transmitter, with dual tone inputs as specified in test mode 4, shall meet the requirement shown in Equation (113–9) that:

$$\text{SFDR} \geq \quad 2.5 + \ \min\{52,\ 58 - 20 \times \log_{10}(f/(100 \times S))\} \tag{113–9}$$

where f is the maximum frequency of the two test tones in MHz, and SFDR is the ratio in dB of the minimum RMS value of either input tone to the RMS value of the worst intermodulation product in the frequency range of 1 MHz to 1600 × S MHz.

This specification on transmit linearity is derived from the requirement for interoperability with the far-end device.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.5.3.3 Transmitter timing jitter

When in test mode 2, the PHY transmits {two +16 symbols followed by two –16 symbols} continually with the THP turned off and with no power backoff. In this mode, the transmitter output should be a $800 \times S$ MHz signal and the RMS period jitter measured at the PHY MDI output shall be less than $1.3/S$ ps. The RMS period jitter is measured as per the test configuration shown in Figure 113–36 over an integration time interval of 1 ms ± 10%.

The SLAVE mode RMS period jitter test is measured using the test configuration shown in Figure 113–36. For this test, the MASTER PHY is in test mode 1 and the SLAVE PHY is in test mode 3. The MASTER is transmitting the PMA training pattern (PRBS 33) to the SLAVE PHY on pairs A, B, and C. The SLAVE PHY is in loop timing mode, synchronizing its transmit clock to the signals received from the MASTER PHY on pairs A, B, and C. In this configuration, the transmitter output on pair D should be a $800 \times S$ MHz signal and the RMS period jitter measured at the SLAVE PHY MDI output shall be less than $1.3/S$ ps. The RMS period jitter is measured over an integration time interval of 1 ms ± 10%.

RMS period jitter over an integration time interval of 1 ms ± 10% is defined as the root mean square period difference from the average period ($T - T_{avg}$), accumulated over a sample size of 200 000 ± 20 000, as shown in Equation (113–10):

$$\text{RMS period jitter} = \sqrt{\frac{\sum[(T - T_{avg})^2]}{\text{Sample size}}} \tag{113–10}$$

113.5.3.4 Transmitter power spectral density (PSD) and power level

In test mode 5 (normal operation with no power backoff), the transmit power shall be in the range –1.0 dBm to 1.0 dBm and the power spectral density of the transmitter, measured into a 100 Ω, load using the test fixture shown in Figure 113–35 shall be between the upper and lower masks specified in Equation (113–11) and Equation (113–12). The masks are shown graphically in Figure 113–37.

$$\text{Upper PSD}(f) \leq \begin{cases} -88.5 - 10\log_{10} S \text{ dBm/Hz} & 0 < \frac{f}{S} \leq 280 \\ -88.5 - 10\log_{10} S - \left(\frac{\frac{f}{S} - 280}{320}\right) \text{dBm/Hz} & 280 < \frac{f}{S} \leq 600 \\ -89.5 - 10\log_{10} S - \left(\frac{\frac{f}{S} - 600}{232}\right) \text{dBm/Hz} & 600 < \frac{f}{S} \leq 2920 \\ -89.5 - 10\log_{10} S - \left(\frac{\frac{f}{S} - 1320}{160}\right) \text{dBm/Hz} & 2920 < \frac{f}{S} \leq 7160 \\ -126 \text{ dBm/Hz} & 7160 < \frac{f}{S} \leq \frac{12000}{S} \end{cases} \tag{113–11}$$

$$\text{Lower PSD}\ (f) \geq \begin{cases} -93\ \text{dBm/Hz} & 20 \leq f \leq 200 \\ -93 - \left(\dfrac{\dfrac{f}{S} - 200}{200}\right)\text{dBm/Hz} & 200 < \dfrac{f}{S} \leq 800 \\ -96 - \left(\dfrac{\dfrac{f}{S} - 800}{100}\right)\text{dBm/Hz} & 800 < \dfrac{f}{S} \leq \dfrac{1600}{S} \end{cases} \quad (113\text{–}12)$$

where f is in MHz.

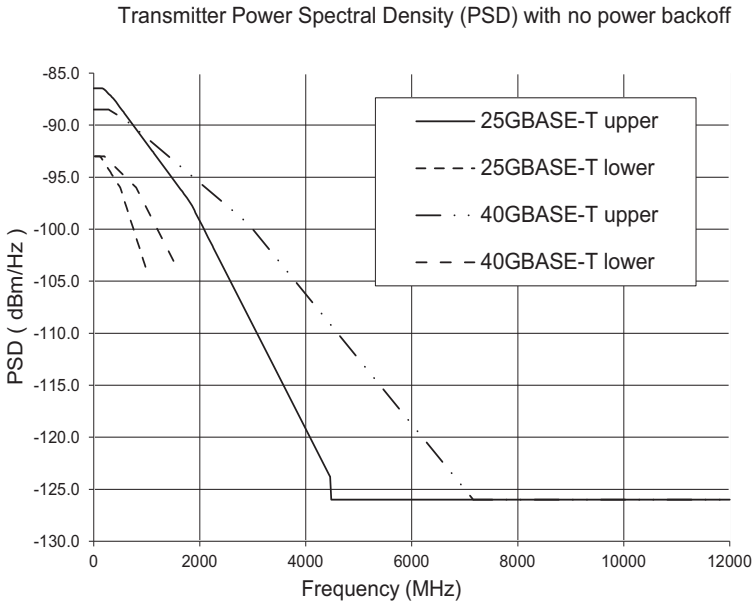

Figure 113–37—Transmitter power spectral density masks

113.5.3.5 Transmit clock frequency

The symbol transmission rate on each pair of the MASTER PHY shall be within the range 3 200× S MBd ± 50 ppm.

For a MASTER PHY, when the transmitter is in the LPI transmit mode or when the receiver is in the LPI receive mode the transmitter clock short-term rate of frequency variation shall be less than 0.1 ppm/second. The short-term frequency variation limit shall also apply when switching to and from the LPI mode.

113.5.4 Receiver electrical specifications

The PMA provides the Receive function specified in 113.4.2.4 in accordance with the electrical specifications of this clause using cabling that is within the limits specified in 113.7.

113.5.4.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of 113.5.3 and have passed through a link specified in 113.7 shall be received with a BER less

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

than 10^{-12} after LDPC and RS-FEC decoding, and sent to the 25GMII/XLGMII after link reset completion. This specification can be verified by a frame error ratio less than 9.6×10^{-9} for 800 octet frames with minimum IPG or greater than 799 octet IPG.

113.5.4.2 Receiver frequency tolerance

The receive feature shall properly receive incoming data, per the requirements of 113.5.4.1, with a symbol rate within the range 3200× *S* MBd ± 50 ppm.

113.5.4.3 Rejection of External EM Fields

When the cabling system is subjected to electromagnetic fields, currents are generated in the shield that can be converted to interference. This specification is provided to limit the sensitivity of the PMA receiver to external EM fields picked up by the cabling and interconnect system. It provides an assessment method of the electromagnetic performance of the link segment and the PHY, including the MDI.

An 80 MHz to 2000 MHz test can be made based on the cable clamp test described in Annex 113A, a 30 m plug-terminated cabling span that meets the requirements of 113.7, and suitable broadband ferrites. All components that are exposed to the induced fields should remain over the ground reference plane. A sine wave with the amplitude held constant over the whole frequency range from 80 MHz to 2000 MHz, with the amplitude calibrated so that the signal power measured at the output of the clamp does not exceed 6 dBm, is used to generate the external electromagnetic field and corresponding shield current.

A system integrating a 25G/40GBASE-T PHY may perform this test to evaluate anticipated performance in regulatory test environments. Operational requirements of the transceiver during the test are determined by the manufacturer.

NOTE—The 6 dBm limit includes the 10% frequency-dependent variation mentioned in Annex 113A.3.

113.5.4.4 Alien crosstalk noise rejection

While receiving data from a transmitter compliant with specifications in 113.5.3, through a 30 m link segment compliant with the specifications in 113.7, a receiver shall operate with an Ethernet frame error ratio less than 9.6×10^{-9} for 800 octet frames with either a minimum IPG or greater than 799 octet IPG with four noise sources at the specified levels representing alien crosstalk, one connected to each of the four pairs. Independent noise sources should be injected into each MDI input using couplers that do not significantly alter the link segment characteristics. Each noise source shall have a flat noise spectrum, with 3 dB bandwidth at least 10 MHz to 2000 MHz and a power spectral density such that at the MDI port of the device under test the power spectral density of the injected noise is –154 dBm/Hz. A flat noise source is chosen to model the sum of all alien noise sources. See Figure 113–38.

The structure shown for injecting the noise in Figure 113–38 is illustrative and alternative approaches are possible. The loss of the coupling structure shown in Figure 113–38, which consists of two baluns and a coupler, is approximately 2.5 dB. The overall insertion loss of the link segment together with the insertion loss of the coupling structure should be adjusted to match the insertion loss specified in 113.7.2.1 to within ± 0.5 dB. The balun-coupler-balun structure shown in Figure 113–38 can be replaced by resistively coupling a balanced noise source to the twisted-pair using 500 Ω resistors. In either case, calibration of the test setup is required to confirm the overall insertion loss and the injected noise power at the MDI of the receiver under test.

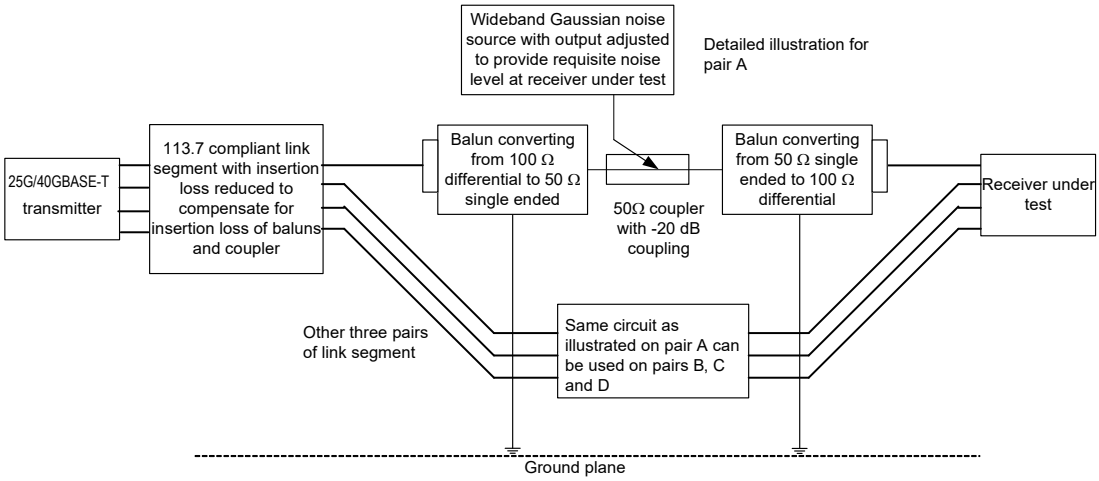

Figure 113–38—Alien crosstalk noise rejection test

113.5.4.5 Short reach mode

The PHY short reach register setting 1.131.0 indicates whether the PHY is operating in the short reach mode.

In short reach mode (indicating operation over a short reach link segment) while receiving data from a transmitter compliant with specifications in 113.5.3 (whether or not in short reach mode), through a short reach link segment meeting the requirements of 113.7.4, a receiver shall operate with a frame error ratio less than 9.6×10^{-9} for 800 octet frames with minimum IPG or greater than 799 octet IPG (e.g., operate with a BER less than 10^{-12}). When operating in short reach mode, only operation over the direct attach link segment specified in 113.7.4 is required.

113.6 Management interfaces

25G/40GBASE-T makes extensive use of the management functions that may be provided by the MDIO (Clause 45), and the communication and self-configuration functions provided by Auto-Negotiation (Clause 28). Additional Auto-Negotiation requirements are set forth within this subclause.

113.6.1 Support for Auto-Negotiation

All 25GBASE-T and 40GBASE-T PHYs shall provide support for Auto-Negotiation (Clause 28) and shall be capable of operating as MASTER or SLAVE. All 25GBASE-T and 40GBASE-T PHYs shall provide support for Extended Next Pages as defined in 28.2.3.4.2 and shall support and use optimized FLP Burst to FLP burst timing as defined in 28.2.1.1.1, and nlp_link_test_min_timer and link_fail_inhibit_timer as defined in 28.3.2.

Auto-Negotiation is performed as part of the initial setup of the link and allows the PHYs at each end to advertise their capabilities (speed, PHY type, half or full duplex) and to automatically select the operating mode for communication on the link. Auto-Negotiation signaling is used for the following primary purposes for 25G/40GBASE-T:

a) To negotiate that the PHY is capable of supporting 25GBASE-T or 40GBASE-T transmission.
b) To determine the MASTER-SLAVE relationship between the PHYs at each end of the link.

113.6.1.1 25G/40GBASE-T use of registers during Auto-Negotiation

When Clause 45 registers are implemented, a 25G/40GBASE-T PHY shall use the management register definitions and values specified in Table 113–18.

Table 113–18—25G/40GBASE-T registers

Register	Bit	Name	Description	Type[a]
7.0	7.0.15:0	AN control register	Defined in 45.2.7.1	R/W

[a]R/W = Read/Write, RO = Read only

113.6.1.2 25G/40GBASE-T Auto-Negotiation page use

25G/40GBASE-T PHYs shall exchange a MultiGBASE-T and 1000BASE-T formatted Extended Next Page, as specified in Table 113–19, immediately following the exchange of the Base Page.

Note that the Acknowledge 2 bit is not utilized and has no meaning when used for the 25G/40GBASE-T message page exchange.

113.6.1.3 Sending Next Pages

Implementers who do not wish to send additional Extended Next Pages (i.e., Extended Next Pages in addition to those required to perform PHY configuration as defined in this clause) can use Auto-Negotiation as defined in Clause 28. Implementers who wish to send additional Extended Next Pages may do so using the AN XNP transmit registers. See 45.2.7.8.

U4	MASTER-SLAVE seed Bit 4 (SB4)	
U3	MASTER-SLAVE seed Bit 3 (SB3)	
U2	MASTER-SLAVE seed Bit 2 (SB2)	
U1	MASTER-SLAVE seed Bit 1 (SB1)	
U0	MASTER-SLAVE seed Bit 0 (SB0)	

113.6.2 MASTER-SLAVE configuration resolution

Since both PHYs that share a link segment are capable of being MASTER or SLAVE, a prioritization scheme exists to ensure that the correct mode is chosen. The MASTER-SLAVE relationship shall be determined during Auto-Negotiation using Table 113–20 with the 25G/40GBASE-T Technology Ability Next Page bit values specified in Table 113–19 and information received from the link partner. This process is conducted at the entrance to the FLP LINK GOOD CHECK state shown in the Arbitration state diagram (Figure 28–18.)

The following four equations are used to determine these relationships:

manual_MASTER = U11 * U12

manual_SLAVE = U11 * !U12

single-port device = !U11 * !U13

multiport device = !U11 * U13

where

U11 is bit 11 of MultiGBASE-T and 1000BASE-T Technology message code,

U12 is bit 12 of MultiGBASE-T 1000BASE-T Technology message code,

U13 is bit 13 of MultiGBASE-T and 1000BASE-T Technology message code (see Table 113–19).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

25GBASE-T and 40GBASE-T PHYs are capable of operating either as the MASTER or SLAVE. In the scenario of a link between a single-port device and a multiport device, the preferred relationship is for the multiport device to be the MASTER PHY and the single-port device to be the SLAVE. However, other topologies can result in contention. The resolution function of Table 113–20 is defined to handle any relationship conflicts.

The resolution shown in Table 113–20 shall be used.

Table 113–20—25G/40GBASE-T MASTER-SLAVE configuration resolution table

Local device type	Remote device type	Local device resolution	Remote device resolution
single-port device	multiport device	SLAVE	MASTER
single-port device	manual_MASTER	SLAVE	MASTER
manual_SLAVE	manual_MASTER	SLAVE	MASTER
manual_SLAVE	multiport device	SLAVE	MASTER
multiport device	manual_MASTER	SLAVE	MASTER
manual_SLAVE	single-port device	SLAVE	MASTER
multiport device	single-port device	MASTER	SLAVE
multiport device	manual_SLAVE	MASTER	SLAVE
manual_MASTER	manual_SLAVE	MASTER	SLAVE
manual_MASTER	single-port device	MASTER	SLAVE
single-port device	manual_SLAVE	MASTER	SLAVE
manual_MASTER	multiport device	MASTER	SLAVE
multiport device	multiport device	The device with the higher seed value is configured as MASTER, otherwise SLAVE.	The device with the higher seed value is configured as MASTER, otherwise SLAVE.
single-port device	single-port device	The device with the higher seed value is configured as MASTER, otherwise SLAVE	The device with the higher seed value is configured as MASTER, otherwise SLAVE.
manual_SLAVE	manual_SLAVE	MASTER-SLAVE configuration fault	MASTER-SLAVE configuration fault
manual_MASTER	manual_MASTER	MASTER-SLAVE configuration fault	MASTER-SLAVE configuration fault

A 25G/40GBASE-T multiport device has higher priority than a single-port device to become the MASTER. In the case where both devices are of the same type, e.g., both devices are multiport devices, the device with the higher MASTER-SLAVE seed bits (SB0...SB10), where SB10 is the MSB, shall become the MASTER and the device with the lower seed value shall become the SLAVE. In case both devices have the same seed value, both should assert either link_status_25GigT=FAIL (for 25GBASE-T) or link_status_40GigT=FAIL (for 40GBASE-T) (as defined in 28.3.1) to force a new cycle through Auto-Negotiation. Successful completion of the MASTER-SLAVE resolution shall be treated as MASTER-SLAVE configuration resolution complete.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The method of generating a random or pseudorandom seed is left to the implementer. The generated random seeds should belong to a sequence of independent, identically distributed integer numbers with a uniform distribution in the range of 0 to 2^{11}– 2. The algorithm used to generate the integer should be designed to minimize the correlation between the number generated by any two devices at any given time. A seed counter shall be provided to track the number of seed attempts. The seed counter shall be set to zero at startup and shall be incremented each time a seed is generated. When MASTER-SLAVE resolution is complete, the seed counter shall be reset to 0 and bit 7.33.15 shall be set to zero. A MASTER-SLAVE resolution fault shall be declared if resolution is not reached after the generation of seven seeds.

The MASTER-SLAVE manual configuration enable bit (control register bit 7.32.15) and the MASTER-SLAVE config value bit (control register bit 7.32.14) are used to manually set a device to become the MASTER or the SLAVE. In case both devices are manually set to become the MASTER or the SLAVE, this condition shall be flagged as a MASTER-SLAVE configuration fault condition; thus the MASTER-SLAVE configuration fault bit (status register bit 7.33.15) shall be set to logical one. The MASTER-SLAVE configuration fault condition shall be treated as MASTER-SLAVE configuration resolution complete and link_status_25GigT or link_status_40GigT shall be set to FAIL, for 25GBASE-T or 40GBASE-T, respectively, because the MASTER-SLAVE relationship was not resolved. This forces a new cycle through Auto-Negotiation after the link_fail_inhibit_timer has expired. Determination of MASTER-SLAVE values occur on the entrance to the FLP LINK GOOD CHECK state (Figure 28–18) when the highest common denominator (HCD) technology is 25GBASE-T or 40GBASE-T. The resulting MASTER-SLAVE value is used by the 25G/40GBASE-T PHY Control (113.4.2.5).

If MASTER-SLAVE manual configuration is disabled (bit 7.32.15 is set to 0) and the local device detects that both the local device and the remote device are of the same type (either multiport device or single-port device) and that both have generated the same random seed, it generates and transmits a new random seed for MASTER-SLAVE negotiation by setting link_status to FAIL and cycling through the Auto-Negotiation process again.

The MASTER-SLAVE configuration process returns one of the three following outcomes:

a) *Successful:* Bit 7.33.15 of the 25G/40GBASE-T status register is set to logical zero and bit 7.33.14 is set to logical one for MASTER resolution or for logical zero for SLAVE resolution. 25G/40GBASE-T returns control to Auto-Negotiation (at the entrance to the FLP LINK GOOD CHECK state in Figure 28–18) and passes the value MASTER or SLAVE to PMA_CONFIG.indication (see 113.2.2.2).
b) *Unsuccessful:* link_status_25GigT or link_status_40GigT is set to FAIL and Auto-Negotiation restarts (see Figure 28–18).
c) *Fault detected:* Bit 7.33.15 of the 25G/40GBASE-T status register is set to logical one to indicate that a configuration fault has been detected. This bit also is set when seven attempts to configure the MASTER-SLAVE relationship via the seed method have failed. When a fault is detected, link_status_25GigT or link_status_40GigT is set to FAIL, causing Auto-Negotiation to cycle through again.

NOTE—MASTER-SLAVE arbitration only occurs if 40GBASE-T, 25GBASE-T, 10GBASE-T, or 1000BASE-T is selected as the highest common denominator.

113.7 Link segment characteristics

25G/40GBASE-T is designed to operate over 4-pair balanced cabling listed in Table 113–21 that meets the additional requirements specified in this subclause. Each of the four pairs supports an effective data rate of 10 Gb/s for 40GBASE-T and 6.25 Gb/s for 25GBASE-T in each direction simultaneously. The term *duplex channel* used in this clause refers to a single cable pair with full duplex capability. The term *link segment* used in this clause refers to four duplex channels. All implementations of the balanced cabling link segment

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

specification shall be compatible at the MDI. It is recommended that the guidelines in ISO/IEC 11801-1:2016 and ANSI/TIA-568-C.2-1 Category 8 Cabling be considered before the installation of 25G/40GBASE-T equipment for any cabling system.

The short reach link segment meeting the transmission requirements in 113.7.4 are specified to support up to 5 m.

113.7.1 Cabling system characteristics

The cabling system used to support 25G/40GBASE-T requires 4-pair balanced cabling with a nominal impedance of 100 Ω listed in Table 113–21. Operation on other classes of cabling may be supported if the link segment meets the requirements of 113.7.

Additionally:

a) 25G/40GBASE-T uses balanced cabling listed in Table 113–21 to connect PHY entities.
b) 25G/40GBASE-T is an application of the balanced cabling listed in Table 113–21 with the additional transmission requirements specified in this subclause.

NOTE—ISO/IEC TR 11801-9905 [B43] provides guidance on the use of channels constructed from components of other categories with this standard at the 25 Gb/s rate. It provides specifications for cabling, certification, and mitigation procedures suitable for use with this standard.

113.7.2 Link segment transmission parameters

A link segment consisting of up to 30 m of cabling that meets the transmission parameters of this subclause provides a reliable medium. The transmission parameters of the link segment include insertion loss, delay parameters, nominal impedance, NEXT loss, ACRF, and return loss. In addition, the requirements for the alien crosstalk coupled "between" link segments is specified. The parameter S is used in 113.7.2 to scale the data rate for each PHY. For 25GBASE-T, $S = 0.625$ and for 40GBASE-T, $S = 1$.

Table 113–21 lists the supported cabling types and distances.

Table 113–21—Cabling types and distances

Cabling	Supported link segment distances	Cabling references
ISO/IEC Class I / Class II	30 m	ISO/IEC DIS 11801-1:2016
Category 8	30 m	ANSI/TIA-568-C.2-1-2016

113.7.2.1 Insertion loss

The insertion loss of each duplex channel shall meet the values determined using Equation (113–13).

$$\text{Insertion loss}(f) \le \frac{0.0856}{\sqrt{f}} + 0.6371 \times \sqrt{f} + 0.0023 \times f + 1.0285 \times 10^{-7} \times f^2 (\text{dB}) \quad (113\text{–}13)$$

where

f is the frequency in MHz; $1 \le f \le 2000 \times S$

Calculations that result in insertion loss values less than 2 dB revert to a requirement of 2 dB.

This includes the insertion loss of the balanced cabling pairs, including work area and equipment cables plus connector losses within each duplex channel. Note that Equation (113–13) is an approximation of the ISO/IEC Class I channel insertion loss.

113.7.2.2 Differential characteristic impedance

The nominal differential characteristic impedance of each link segment duplex channel, which includes cable cords and connecting hardware, is 100 Ω for all frequencies between 1 MHz and 2000 × *S* MHz.

113.7.2.3 Return loss

In order to limit the noise at the receiver due to impedance mismatches in the cabling system, each link segment duplex channel shall meet the values determined using Equation (113–14) at all frequencies from 1 MHz to 2000 × *S* MHz. The reference impedance for the return loss specification is 100 Ω.

$$\text{Return Loss} \geq \begin{cases} 19 & 1 \leq f < 10 \\ 24 - 5\log_{10} f & 10 \leq f < 40 \\ 16 & 40 \leq f < 130 \\ 35 - 9\log_{10} f & 130 \leq f < 1000 \\ 8 & 1000 \leq f < 1250 \\ 8 & 1250 \leq f < 1600 \text{ (for 40GBASE-T)} \\ 8 - 19\log_{10}\left(\frac{f}{1600}\right) & 1600 \leq f < 2000 \text{ (for 40GBASE-T)} \end{cases} \text{ dB} \qquad (113\text{–}14)$$

where

f is the frequency in MHz.

113.7.2.4 Coupling parameters between duplex channels comprising one link segment

In order to limit the noise coupled into a duplex channel from adjacent duplex channels, near-end crosstalk (NEXT) loss and attenuation to crosstalk ratio, far-end (ACRF) are specified for each link segment. In addition, each duplex channel can be disturbed by more than one duplex channel. To ensure the total NEXT loss and FEXT loss coupled into a duplex channel is limited, multiple disturber near-end crosstalk (MDNEXT) and multiple disturber ACRF (MDACRF) is specified.

113.7.2.4.1 Differential near-end crosstalk

In order to limit the crosstalk at the near end of a link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between a duplex channel and the other three duplex channels is specified to meet the bit error ratio objective specified in 113.1.2. The NEXT loss between any two duplex channels of a link segment shall meet the values determined using Equation (113–15) to Equation (113–17).

$$\text{NEXT loss}(f) \geq -20\log_{10}\left[10^{\frac{45.3 - 15\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{54 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right] \text{ (dB)} \qquad (113\text{–}15)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where

f is the frequency in MHz $1 \le f \le 440$.

$$\text{NEXT loss}(f) \ge -20\log_{10}\left[10^{\frac{45.3 - 15\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{39.12 - 36.14\log_{10}\left(\frac{f}{500}\right)}{-20}}\right] \text{(dB)} \quad (113\text{–}16)$$

where

f is the frequency in MHz $440 < f \le 1486$.

$$\text{NEXT loss}(f) \ge -20\log_{10}\left[10^{\frac{45.3 - 15\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{40 - 38\log_{10}\left(\frac{f}{500}\right)}{-20}}\right] \text{(dB)} \quad (113\text{–}17)$$

where

f is the frequency in MHz $1486 < f \le 2000 \times S$.

Calculations that result in NEXT loss values greater than 65 dB revert to a requirement of 65 dB minimum.

113.7.2.4.2 Multiple disturber near-end crosstalk (MDNEXT) loss

Since four duplex channels are used to transfer data between PMAs, the NEXT that is coupled into a data carrying duplex channel is from the three adjacent disturbing duplex channels.

To ensure the total NEXT coupled into a duplex channel is limited, multiple disturber NEXT loss is specified as the power sum of the individual NEXT losses. The power sum loss between a duplex channel and the three adjacent disturbers shall meet the values determined using Equation (113–18) to Equation (113–20).

$$\text{MDNEXT loss}(f) \ge -20\log_{10}\left[10^{\frac{42.3 - 15\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{50 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right] \text{(dB)} \quad (113\text{–}18)$$

where

f is the frequency in MHz $1 \le f \le 500$.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{MDNEXT loss}(f) \geq -20\log_{10}\left[10^{\frac{42.3 - 15\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2\times 10^{\frac{35.95 - 34.85\log_{10}\left(\frac{f}{500}\right)}{-20}}\right] \text{ (dB)} \quad (113\text{–}19)$$

where

f is the frequency in MHz $500 < f \leq 1100$.

$$\text{MDNEXT loss}(f) \geq -20\log_{10}\left[10^{\frac{42.3 - 15\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{37 - 38\log_{10}\left(\frac{f}{500}\right)}{-20}}\right] \text{ (dB)} \quad (113\text{–}20)$$

where

f is the frequency in MHz $1100 < f \leq 2000 \times S$.

Calculations that result in MDNEXT loss values greater than 62 dB revert to a requirement of 62 dB minimum.

113.7.2.4.3 Multiple disturber power sum near-end crosstalk (PSNEXT) loss

PSNEXT loss is determined by summing the power of the three individual pair-to-pair differential NEXT loss values over the frequency range 1 MHz to $2000 \times S$ MHz as follows in Equation (113–21).

$$\text{PSNEXT loss}(f) = \left(-10\log_{10}\sum_{i=1}^{n} 10^{\frac{-NL(f)i}{10}}\right) \text{ (dB)} \quad (113\text{–}21)$$

Copyright © 2022 IEEE. All rights reserved.

where

NL(f)i is the magnitude in dB of NEXT loss at frequency *f* (in MHz) of pair combination *i*
i is the pair-to-pair combination (1 to *n*)
n is the number of pair-to-pair combinations (*n*=3)

113.7.2.4.4 Attenuation to crosstalk ratio, far end (ACRF)

Attenuation to crosstalk ratio, far-end (ACRF) is specified in order to limit the crosstalk at the far end of each link segment duplex channel and meet the bit error ratio objective specified in 113.1.2. Far-end crosstalk (FEXT) is crosstalk that appears at the far end of a duplex channel (disturbed channel), which is coupled from another duplex channel (disturbing channel) with the noise source (transmitters) at the near end.

FEXT loss is defined in Equation (113–22) as

$$\text{FEXT loss}(f) = 20\log_{10}\left(\frac{V_{pds}(f)}{V_{pcn}(f)}\right) \quad \text{(dB)} \tag{113–22}$$

and ACRF is defined in Equation (113–23) as

$$\text{ACRF}(f) = 20\log_{10}\left(\frac{V_{pds}(f)}{V_{pcn}(f)}\right) - \text{SLS_Loss(f)} \text{ (dB)} \tag{113–23}$$

where

Vpds is the peak voltage of disturbing signal (near-end transmitter)
Vpcn is the peak crosstalk noise at far end of disturbed channel
SLS_Loss is the insertion loss of disturbed channel in dB

The worst pair ACRF between any two duplex channels shall meet the values determined using Equation (113–24).

$$\text{ACRF loss}(f) \geq -20\log_{10}\left[10^{\frac{39.0 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{43.1 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right] \text{(dB)} \tag{113–24}$$

where

f is the frequency in MHz $1 \leq f \leq 2000 \times S$.

Calculations that result in ACRF loss values greater than 65 dB revert to a requirement of 65 dB minimum.

113.7.2.4.5 Multiple disturber attenuation to crosstalk ratio, far-end (MDACRF)

Since four duplex channels are used to transfer data between PMAs, the FEXT that is coupled into a data carrying duplex channel is from the three adjacent disturbing duplex channels. To ensure the total FEXT coupled into a duplex channel is limited, multiple disturber ACRF is specified as the power sum of the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

individual ACRF disturbers. The power sum loss between a duplex channel and the three adjacent disturbers shall meet the values determined using Equation (113–25).

$$\mathrm{MDACRF}(f) \geq -20\log_{10}\left[10^{\frac{36-20\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2\times 10^{\frac{40.1-20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right] \quad \text{(dB)} \qquad (113\text{–}25)$$

where

f is the frequency $1 \leq f \leq 2000 \times S$.

Calculations that result in MDACRF loss values greater than 62 dB revert to a requirement of 62 dB minimum.

113.7.2.4.6 Multiple disturber power sum attenuation to crosstalk ratio, far-end (PS-ACRF)

PS-ACRF is determined by summing the power of the three individual pair-to-pair differential ACRF values over the frequency range 1 MHz to 2000 × *S* MHz as follows in Equation (113–26):

$$\mathrm{PSACRF}\ (f) = -10\log_{10}\sum_{i=1}^{i=n} 10^{\frac{-ACRF(f)i}{10}} \quad \text{(dB)} \qquad (113\text{–}26)$$

where

ACRF(f)i is the magnitude of ACRF at frequency *f* of pair combination *i*
i is the pair-to-pair combination (1 to *n*)
f is the frequency in MHz
n is the number of pair-to-pair combinations (*n*=3)

113.7.2.5 Maximum link delay

The propagation delay of a link segment shall not exceed 185 ns at all frequencies between 2 MHz and 2000 × *S* MHz.

113.7.2.6 Link delay skew

The difference in propagation delay, or skew, between all duplex channel pair combinations of a link segment, under all conditions, shall not exceed 17 ns at all frequencies from 2 MHz to 2000 × *S* MHz. It is a further functional requirement that, once installed, the skew between any two of the four duplex channels due to environmental conditions shall not vary more than 3 ns within the above requirement.

113.7.3 Coupling parameters between link segments

Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. To ensure the total alien NEXT loss and alien FEXT loss coupled between link segments is limited, multiple disturber alien near-end crosstalk (MD ANEXT) loss and multiple disturber alien FEXT (MDAFEXT) loss is specified. In addition, to ensure the reliable operation of the link segment, a minimum alien crosstalk to insertion loss ratio are specified.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

113.7.3.1 Multiple disturber alien near-end crosstalk (MDANEXT) loss

In order to limit the alien crosstalk at the near end of a link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is specified to meet the bit error ratio objective specified in 113.1.2. To ensure the total alien NEXT coupled into a duplex channel is limited, multiple disturber alien NEXT loss is specified as the power sum of the individual alien NEXT disturbers.

113.7.3.1.1 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

PSANEXT loss is determined by summing the power of the individual pair-to-pair differential alien NEXT loss values over the frequency range 1 MHz to 2000 × *S* MHz as follows in Equation (113–27):

$$\mathrm{PSANEXT}_N(f) = -10\log_{10}\sum_{j=1}^{m}\sum_{i=1}^{4} 10^{\frac{-AN(f)_{i,j,N}}{10}} \quad (\mathrm{dB}) \qquad (113\text{–}27)$$

where

$AN(f)_{i,j,N}$ is the magnitude in dB of the alien NEXT loss at frequency f of the individual pair combination i (1 to 4) of the disturbing link j (1 to m) for each disturbed pair N

Annex 55B provides additional information on identifying the number of adjacent link segments to consider in the PSANEXT calculation.

The power sum ANEXT loss between a disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments shall meet the values determined using Equation (113–28) independent of length.

$$\mathrm{PSANEXT}(f) \geq 85 - 15\log_{10}\left(\frac{f}{100}\right) \quad (\mathrm{dB}) \qquad 1 \leq f \leq 2000 \times S \qquad (113\text{–}28)$$

where

f is the frequency in MHz

When Equation (113–28) values are greater than 75 dB, they revert to 75 dB.

113.7.3.2 Multiple disturber alien far-end crosstalk (MDAFEXT) loss

In order to limit the alien crosstalk at the far-end of a link segment, the differential pair-to-pair alien far-end crosstalk loss between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is specified to meet the bit error ratio objective specified in 113.1.2. To ensure the total alien FEXT coupled into a duplex channel is limited, multiple disturber ACRF is specified as the power sum of the individual alien ACRF disturbers.

113.7.3.2.1 Multiple disturber power sum alien attenuation to crosstalk, far end crosstalk (PSAACRF)

Power sum alien ACRF is determined by summing the power of the individual pair-to-pair differential alien ACRF values over the frequency range 1 MHz to 2000 × *S* MHz as follows in Equation (113–29):

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{PSAACRF}_N(f) = -10\log_{10}\sum_{j=1}^{m}\sum_{i=1}^{4} 10^{\frac{-AACRF(f)_{i,j,N}}{10}} \quad \text{(dB)} \qquad (113\text{–}29)$$

where

$AACRF(f)_{i,j,N}$ is the magnitude in dB of the alien ACRF at frequency f of the individual pair combination i (1 to 4) of the disturbing link j (1 to m) for each disturbed pair N

NOTE—ELFEXT used in 55.7 is changed to ACRF in Clause 113 to align with TIA and ISO/IEC cabling standards definitions.

The PSAACRF between a disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments shall meet the values determined using Equation (113–30).

$$\text{PSAACRF}(f) \geq 61 - 20\log_{10}\left(\frac{f}{100}\right) \quad \text{(dB)} \qquad 1 \leq f \leq 2000 \times S \qquad (113\text{–}30)$$

where

f is the frequency in MHz,

When Equation (113–30) values are greater than 75 dB, they revert to 75 dB.

113.7.4 Direct attach cable assembly—Short Reach Mode

The direct attach cable assembly is a 4-pair balanced twisted-pair link segment terminated in a connector at each end for use as a short reach link segment between MDIs. The direct attach cable assembly comprises a short reach link segment meeting the transmission requirements in 113.7.4 are specified to support up to 5 m. The transmission parameters of the short reach link segment include insertion loss, delay parameters, nominal impedance, NEXT loss, ACRF, and return loss. In addition, the requirements for the alien crosstalk coupled “between” link segments is specified

113.7.4.1 Insertion loss

The insertion loss of each direct attach cable assembly duplex channel shall meet the values determined using Equation (113–31):

$$\text{Insertion loss}(f) \leq 0.05 \times 1.5\left(1.8 \times \sqrt{f} + 0.005 \times f + \frac{0.25}{\sqrt{f}}\right) + 2 \times B + 0.0324 \times \sqrt{f} \quad \text{(dB)} \qquad (113\text{–}31)$$

where

f is the frequency in MHz; $1 \leq f \leq 2000 \times S$

$$B = \begin{bmatrix} 0.02 \times \sqrt{f} & 1 \leq f \leq 500 \\ 0.00649 \times \sqrt{f} + 0.000605 \times f & 500 < f \leq 2000 \times S \end{bmatrix} \quad \text{(dB)}$$

Calculations that result in insertion loss values less than 3 dB revert to a requirement of 3 dB.

113.7.4.2 Return loss

In order to limit the noise at the receiver due to impedance mismatches in the cabling system, each direct attach cable assembly link segment duplex channel shall meet the values determined using Equation (113–32)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

at all frequencies from 1 MHz to 2000 × *S* MHz. The reference impedance for the return loss specification is 100 Ω.

$$\text{Return Loss} \geq \begin{cases} 24 + 3\log_{10}\left(\frac{f}{25}\right) & 1 \leq f \leq 25 \\ 8 - 10\log_{10}\left(\frac{f}{1000}\right) & 25 < f \leq 1000 \\ 8 & 1000 \leq f < 1250 \\ 8 & 1250 \leq f < 1600 \text{ (for 40GBASE-T)} \\ 8 - 19\log_{10}\left(\frac{f}{1600}\right) & 1600 \leq f < 2000 \text{ (for 40GBASE-T)} \end{cases} \quad \text{(dB)} \qquad (113\text{–}32)$$

where

f is the frequency in MHz.

113.7.4.3 Coupling parameters between direct attach cable assembly duplex channels comprising one link segment

In order to limit the noise coupled into a direct attach cable assembly duplex channel from adjacent duplex channels, near-end crosstalk (NEXT) loss and attenuation to crosstalk ratio, far-end (ACRF) are specified for each direct attach cable assembly link segment. In addition, each duplex channel can be disturbed by more than one duplex channel. To ensure the total NEXT loss and FEXT loss coupled into a duplex channel is limited, multiple disturber near-end crosstalk (MDNEXT) and multiple disturber ACRF (MDACRF) is specified.

113.7.4.3.1 Differential near-end crosstalk

In order to limit the crosstalk at the near end of a direct attach cable assembly link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between a duplex channel and the other three duplex channels is specified to meet the bit error ratio objective specified in 113.1.2. The NEXT loss between any two duplex channels of a direct attach cable assembly link segment shall meet the values determined using Table 113–22.

Table 113–22—Direct Attach NEXT Loss

Frequency (MHz)	NEXT Loss (dB)
$1 \leq f < 250$	$82.9 - 18.5\log_{10}(f)$
$250 \leq f < 383$	$93 - 22.72\log_{10}(f)$
$383 \leq f < 500$	$109 - 28.92\log_{10}(f)$
$500 \leq f \leq 2000 \times S$	$133.5 - 38\log_{10}(f)$
Calculations that result in values greater than 65dB revert to 65dB.	

113.7.4.3.2 Multiple disturber near-end crosstalk (MDNEXT) loss

Since four direct attach cable assembly duplex channels are used to transfer data between PMAs, the NEXT that is coupled into a data carrying duplex channel is from the three adjacent disturbing duplex channels.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

To ensure the total NEXT coupled into a duplex channel is limited, multiple disturber NEXT loss is specified as the power sum of the individual NEXT losses. The power sum loss between a duplex channel and the three adjacent disturbers shall meet the values determined Table 113–23.

Table 113–23—Direct Attach MDNEXT Loss

Frequency (MHz)	MDNEXT Loss (dB)
$1 \le f < 250$	$79.4 - 18.5\log_{10}(f)$
$250 \le f < 331$	$90.65 - 23.2\log_{10}(f)$
$331 \le f < 500$	$105.26 - 29\log_{10}(f)$
$500 \le f \le 2000 \times S$	$129.5 - 38\log_{10}(f)$
Calculations that result in values greater than 62dB revert to 62dB.	

113.7.4.3.3 Multiple disturber power sum near-end crosstalk (PSNEXT) loss

PSNEXT loss is determined by summing the power of the three individual pair-to-pair differential NEXT loss values over the frequency range 1 MHz to $2000 \times S$ MHz in Equation (113–21).

113.7.4.3.4 Attenuation to crosstalk ratio, far end (ACRF)

Attenuation to crosstalk ratio, far-end (ACRF) is specified in order to limit the crosstalk at the far end of each direct attach cable assembly link segment duplex channel and meet the bit error ratio objective specified in 113.1.2. Far-end crosstalk (FEXT) is crosstalk that appears at the far end of a duplex channel (disturbed channel), which is coupled from another duplex channel (disturbing channel) with the noise source (transmitters) at the near end. FEXT loss is defined in Equation (113–22). ACRF is defined in Equation (113–23).

The worst pair ACRF between any two direct attach cable assembly duplex channels shall meet the values determined using Equation (113–33).

$$\mathrm{ACRF}(f) \ge -20\log_{10}\left[10^{\frac{10\log_{10}\left(\frac{24}{5}\right) + 40 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{48.1 - 20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right] \text{ (dB)}$$

where (113–33)

f is the frequency in MHz $1 \le f \le 2000 \times S$.

When Equation (113–33) values are greater than 65 dB, they revert to 65 dB.

113.7.4.3.5 Multiple disturber attenuation to crosstalk ratio, far-end (MDACRF)

Since four direct attach cable assembly duplex channels are used to transfer data between PMAs, the FEXT that is coupled into a data carrying duplex channel is from the three adjacent disturbing duplex channels. To ensure the total FEXT coupled into a duplex channel is limited, multiple disturber ACRF is specified as the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

power sum of the individual ACRF disturbers. PS ACRF is determined by summing the power of the three individual pair-to-pair differential ACRF values over the frequency range 1 MHz to $2000 \times S$ MHz in Equation (113–26).

The power sum loss between a duplex channel and the three adjacent disturbers shall meet the values determined using Equation (113–34).

$$\mathrm{MDACRF}(f) \geq -20\log_{10}\left[10^{\frac{10\log_{10}\left(\frac{24}{5}\right)+37-20\log_{10}\left(\frac{f}{100}\right)}{-20}} + 2 \times 10^{\frac{45.1-20\log_{10}\left(\frac{f}{100}\right)}{-20}}\right] \text{(dB)} \quad (113\text{–}34)$$

where

f is the frequency $1 \leq f \leq 2000 \times S$.

When Equation (113–34) values are greater than 62 dB, they revert to 62 dB.

113.7.4.3.6 Maximum link delay

The propagation delay of a link segment shall not exceed 32 ns at all frequencies between 2 MHz and $2000 \times S$ MHz.

113.7.4.3.7 Link delay skew

The difference in propagation delay, or skew, between all duplex channel pair combinations of a link segment, under all conditions, shall not exceed 4.8 ns at all frequencies from 2 MHz to $2000 \times S$ MHz. It is a further functional requirement that, once installed, the skew between any two of the four duplex channels due to environmental conditions shall not vary more than 0.5 ns within the above requirement.

113.7.4.3.8 Multiple disturber alien near-end crosstalk (MDANEXT) loss

Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as *alien crosstalk noise*. In order to limit the alien crosstalk at the near end of a link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is specified to meet the bit error ratio objective specified in 113.1.2. To ensure the total alien NEXT coupled into a duplex channel is limited, multiple disturber alien NEXT loss is specified as the power sum of the individual alien NEXT disturbers.

113.7.4.3.9 Multiple disturber power sum alien near-end crosstalk (PSANEXT) loss

PSANEXT loss is determined by summing the power of the individual pair-to-pair differential alien NEXT loss values over the frequency range 1 MHz to $2000 \times S$ MHz in Equation (113–27).

The power sum ANEXT loss between a disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments shall meet the values determined using Equation (113–35) independent of length.

$$\mathrm{PSANEXT}(f) = 85 - 15\log_{10}\left(\frac{f}{100}\right) \text{ (dB)} \qquad 1 \leq f \leq 2000 \times S \qquad (113\text{–}35)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where

f is the frequency in MHz

When Equation (113–35) values are greater than 75 dB, they revert to 75 dB.

113.7.4.3.10 Multiple disturber power sum alien attenuation to crosstalk, far end crosstalk (PSAACRF)

Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. In order to limit the alien crosstalk at the far-end of a link segment, the differential pair-to-pair alien far-end crosstalk loss between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is specified to meet the bit error ratio objective specified in 113.1.2. To ensure the total alien FEXT coupled into a duplex channel is limited, multiple disturber ACRF is specified as the power sum of the individual alien ACRF disturbers.

Power sum alien ACRF is determined by summing the power of the individual pair-to-pair differential alien ACRF values over the frequency range 1 MHz to 2000 × S MHz as follows in Equation (113–36):

$$\mathrm{PSAACRF}_N(f) = -10\log_{10}\sum_{j=1}^{m}\sum_{i=1}^{4} 10^{\frac{-AL(f)_{i,j,N}}{10}} \quad (\mathrm{dB}) \qquad (113\text{–}36)$$

where

$AL(f)_{i,j,N}$ is the magnitude in dB of the alien ACRF at frequency f of the individual pair combination i (1 to 4) of the disturbing link j (1 to m) for each disturbed pair N.

NOTE—ELFEXT used in 55.7 is changed to ACRF in Clause 113 to align with TIA and ISO/IEC cabling standards definitions.

The PSAACRF between a disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments shall meet the values determined using Equation (113–37).

$$\mathrm{PSAACRF}(f) \geq 61 - 20\log_{10}\left(\frac{f}{100}\right) \quad (dB) \qquad 1 \leq f \leq 2000 \times S \qquad (113\text{–}37)$$

where

f is the frequency in MHz,

When Equation (113–37) values are greater than 75 dB, they revert to 75 dB.

113.7.5 Noise environment

The 25G/40GBASE-T noise environment consists of the following:

a) Echo from the local transmitter on the same duplex channel (cable pair). Echo is caused by the hybrid function used to achieve simultaneous bi-directional transmission of data and by impedance mismatches in the link segment. It is impractical to achieve the objective BER without using echo cancellation. Since the symbols transmitted by the local disturbing transmitter are available to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

cancellation processor, echo interference can be reduced to a small residual noise using echo cancellation methods.

b) Near-end crosstalk (NEXT) interference from the local transmitters on the duplex channels (cable pairs) of the link segment. Each receiver experiences NEXT interference from three adjacent transmitters. NEXT cancellers are used to reduce the interference from each of the three disturbing transmitters to a small residual noise. NEXT cancellation is possible since the symbols transmitted by the three disturbing local transmitters are available to the cancellation processor.

c) Far-end crosstalk (FEXT) noise at a receiver is from three disturbing transmitters at the far end of the duplex channel (cable pairs) of the link segment. FEXT noise can be reduced through cross coupled equalizers although the symbols from the remote transmitters are not immediately available.

d) Intersymbol interference (ISI). ISI is the extraneous energy from one signaling symbol that interferes with the reception of another symbol on the same balanced twisted pair. 25G/40GBASE-T supports the use of Tomlinson-Harashima Precoding as a mechanism to reduce the effects of ISI.

e) Noise from non-idealities in the duplex channel, transmitters, and receivers; for example, DAC/ADC non-linearity, electrical noise (shot and thermal), and nonlinear duplex channel characteristics. 25G/40GBASE-T limits the effects of some of these non-idealities by a variety of PMA electrical specifications.

f) Noise coupled between link segments. Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. Since the transmitted symbols from the alien crosstalk noise sources are not available to the cancellation processor (they are in another cable), it is very difficult to cancel the alien crosstalk noise. To ensure robust operation the alien crosstalk is specified in 113.7.3.

g) The background noise for 25G/40GBASE-T is expected not to exceed –150 dBm/Hz. A background noise limit of –150 dBm/Hz was assumed for determining the minimum signal-to-noise ratio.

113.8 MDI specification

This subclause defines the MDI. The link topology requires a crossover function in a DTE-to-DTE connection. See 113.4.4 for a description of the automatic MDI/MDI-X configuration.

113.8.1 MDI connectors

Eight-pin connectors meeting the requirements of IEC 60603-7-51 with the improved characteristics and frequency extensions specified in IEC 60603-7-81 shall be used as the mechanical interface to the balanced cabling. The plug connector shall be used on the balanced cabling and the jack on the PHY. These connectors are depicted (for informational use only) in Figure 113–39 and Figure 113–40. The assignment of PMA signals to connector contacts for PHYs is shown in Table 113–24.

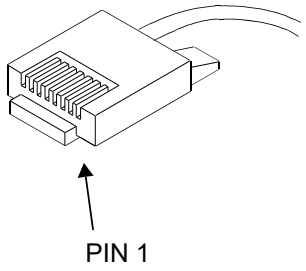

Figure 113–40—Balanced cabling connector

Table 113–24—Assignment of PMA signal to MDI and MDI-X pin-outs

Contact	MDI	MDI-X
1	BI_DA+	BI_DB+
2	BI_DA–	BI_DB–
3	BI_DB+	BI_DA+
4	BI_DC+	BI_DD+
5	BI_DC–	BI_DD–
6	BI_DB–	BI_DA–
7	BI_DD+	BI_DC+
8	BI_DD–	BI_DC–

113.8.2 MDI electrical specifications

The MDI connector (jack) when mated with a specified balanced cabling connector (plug) shall meet the FEXT requirements as specified in Equation (113–38):

$$\text{FEXT loss} \geq 43.1 - 20\log_{10}(f/100) \quad \text{(dB)} \tag{113–38}$$

where f is the frequency over the range 1 MHz to $2000 \times S$ MHz between all contact pair combinations shown in Table 113–24.

No spurious signals shall be emitted onto the MDI when the PHY is held in power-down mode (as defined in 22.2.4.1.5), when released from power-down mode, or when external power is first applied to the PHY.

113.8.2.1 MDI return loss

The differential impedance at the MDI for each duplex channel shall be such that any reflection due to differential signals incident upon the MDI from a balanced cabling having a nominal differential characteristic impedance of 100 Ω is attenuated, relative to the incident signal as per the relationship shown in Equation (113–39):

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{Return loss} \geq \begin{cases} 16 & 1 \leq f \leq 40 \quad \text{(dB)} \\ 16 - 10\log_{10}(f/40) & 40 < f \leq 400 \quad \text{(dB)} \\ 6 & 400 < f \leq 2000 \times S \quad \text{(dB)} \end{cases} \tag{113–39}$$

where f is in MHz.

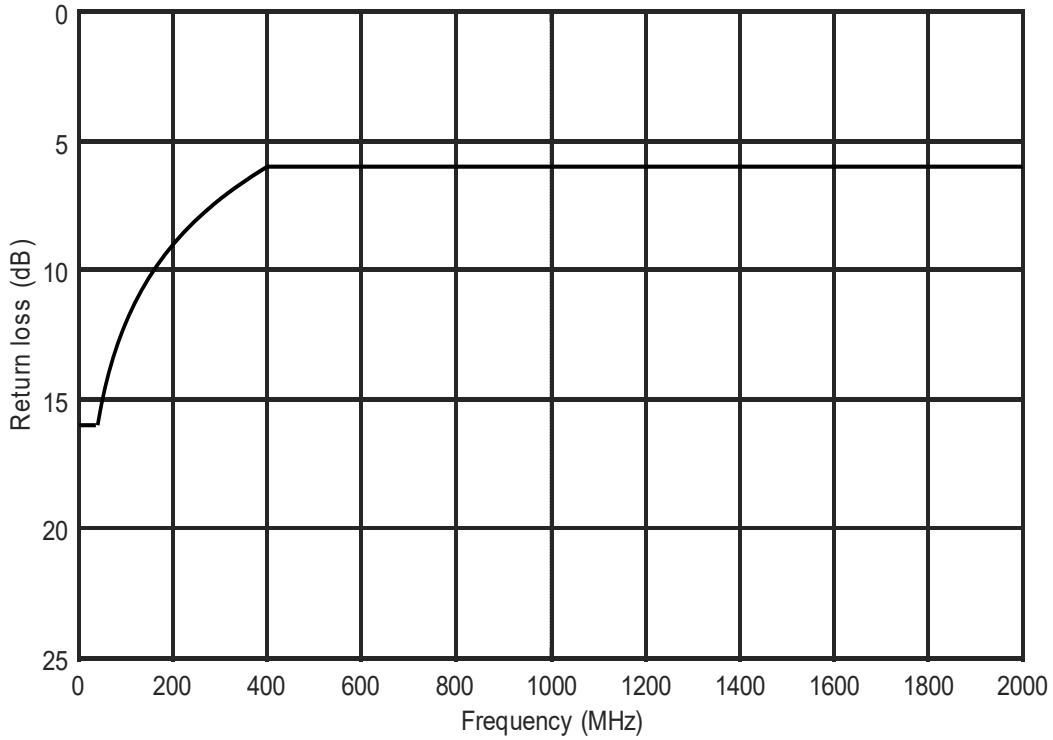

Figure 113–41—MDI return loss

113.8.2.2 MDI impedance balance

Impedance balance is a measure of the impedance-to-ground difference between the two MDI contacts used by a duplex channel and is referred to as *common-mode-to-differential-mode impedance balance*. When the transmitter is transmitting random or pseudo random data, the common-mode-to-differential-mode impedance balance, *Bal*(*f*), of each duplex channel of the MDI shall meet the relationship shown in Equation (113–40):

$$Bal(f) \geq \begin{cases} 48 & 1 \leq f \leq 40 \quad \text{(dB)} \\ 44 - 19.2\log_{10}(f/40) & 40 < f \leq 2000 \times S \quad \text{(dB)} \end{cases} \tag{113–40}$$

where f is the frequency in MHz. Test mode 5 may be used to generate an appropriate transmitter output.

The impedance balance is defined as the S parameter measurement of Sdc11 in dB at the MDI.

The impedance balance may be measured with a mixed mode four port network analyzer capable of measuring the common-mode voltage and differential mode voltage of a balanced port. Impedance balance is the S parameter measurement of Sdc11 in dB at the MDI where two ports of the four port network analyzer are connected between two MDI contacts used by a duplex channel and these two ports are configured as a single balanced port. For this test the PHY ground is connected to the network analyzer

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ground. The other two ports of the network analyzer are unconnected. The network analyzer should be capable of measuring Sdc11 to at least –60 dB and should use a differential input impedance of 100 Ω and a common-mode impedance of 75 Ω.

During the test the PHY is connected to the MDI as in normal operation.

113.8.2.3 MDI fault tolerance

Each wire pair of the MDI shall, under all operating conditions, withstand without damage the application of short circuits of any wire to any other wire within the 4-pair cable for an indefinite period of time and shall resume normal operation after the short circuit(s) are removed. The magnitude of the current through such a short circuit shall not exceed 300 mA.

A 25G/40GBASE-T PHY shall be able to sustain, without damage, connection to a PSE and shall not cause damage to the PSE as defined in 33.2.

Each wire pair shall withstand without damage a 1000 V common-mode impulse of either polarity. The shape of the impulse is 0.3/50 μs (300 ns virtual front time, 50 μs virtual time of half value), as defined in IEC 60060. See Figure 40–34 in 40.8.3.4.

113.9 Environmental specifications

113.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

113.9.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns; the list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

LAN cabling systems described in this subclause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cabling and components.
c) High-energy transients coupled onto the LAN cabling system.
d) Voltage potential differences between safety grounds to which various LAN components are connected.

Such electrical safety hazards should be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures should be taken to ensure that the intended safety features are not negated during installation of a new network or during modification or maintenance of an existing network.

113.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, including screen management, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable. Installation practices for screened cabling are found in ISO/IEC 14763-2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

It is a mandatory requirement that, during installation of the cabling plant, care be taken to ensure that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

113.9.4 Telephone voltages

The use of building wiring brings with it the possibility of wiring errors that connect telephony voltages to 25G/40GBASE-T. Other than voice signals (which are low voltage), the primary voltages that can be encountered are the "battery" and ringing voltages. Although there is no universal standard, the following maximums generally apply.

a) Battery voltage to a telephone line is generally 56 V dc applied to the line through a balanced 400 Ω source impedance.
b) Ringing voltage is a composite signal consisting of an ac component and a dc component. The ac component is up to 175 V peak at 20 Hz to 60 Hz with a 100 Ω source resistance. The dc component is 56 V dc with a 300 Ω to 600 Ω source resistance. Large reactive transients can occur at the start and end of each ring interval.

Although 25G/40GBASE-T equipment is not required to survive such wiring hazards without damage, application of any of the preceding voltages shall not result in any safety hazard.

113.9.5 Electromagnetic compatibility

A system integrating the 25G/40GBASE-T shall comply with applicable local and national codes for the limitation of electromagnetic interference.

113.9.6 Temperature and humidity

A system integrating the 25G/40GBASE-T is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

113.10 PHY labeling

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) Data rate capability and units thereof
b) Power level in terms of maximum current drain (for external PHYs)
c) Port type (i.e., 25GBASE-T or 40GBASE-T)
d) Any applicable safety warnings
e) EEE support
f) Fast retrain support

113.11 Delay constraints

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The sum of the transmit and receive data delays for an implementation of a 25GBASE-T or 40GBASE-T PHY shall not exceed 25 600 BT. Transmit data delay is measured from the input of a given unit of data at the 25GMII or XLGMII to the presentation of the same unit of data by the PHY to the MDI. Receive data

delay is measured from the input of a given unit of data at the MDI to the presentation of the same unit of data by the PHY to the 25GMII or XLGMII.

NOTE—The physical medium interconnecting two PHYs introduces additional delay in a link. Equation (105–1) specifies the calculation of bit time per meter of electrical cable for 25GBASE-T. Equation (80–1) specifies the delay per meter of electrical cable in nanoseconds and may be used for 40GBASE-T, given the bit time for 40 Gb/s Ethernet of 25 ps (see notes to Table 80–7).

113.12 Protocol implementation conformance statement (PICS) proforma for Clause 113, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 25GBASE-T and 40GBASE-T[191]

The supplier of a protocol implementation that is claimed to conform to Clause 113, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 25GBASE-T and 40GBASE-T, shall complete the protocol implementation conformance statement (PICS) proforma listed in the following subclauses.

Instructions for interpreting and filling out the PICS proforma are found in Clause 21.

113.12.1 Identification

113.12.1.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

113.12.1.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 113, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 25GBASE-T and 40GBASE-T
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exceptions items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[191] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so it can be used for its intended purpose and may further publish the completed PICS.

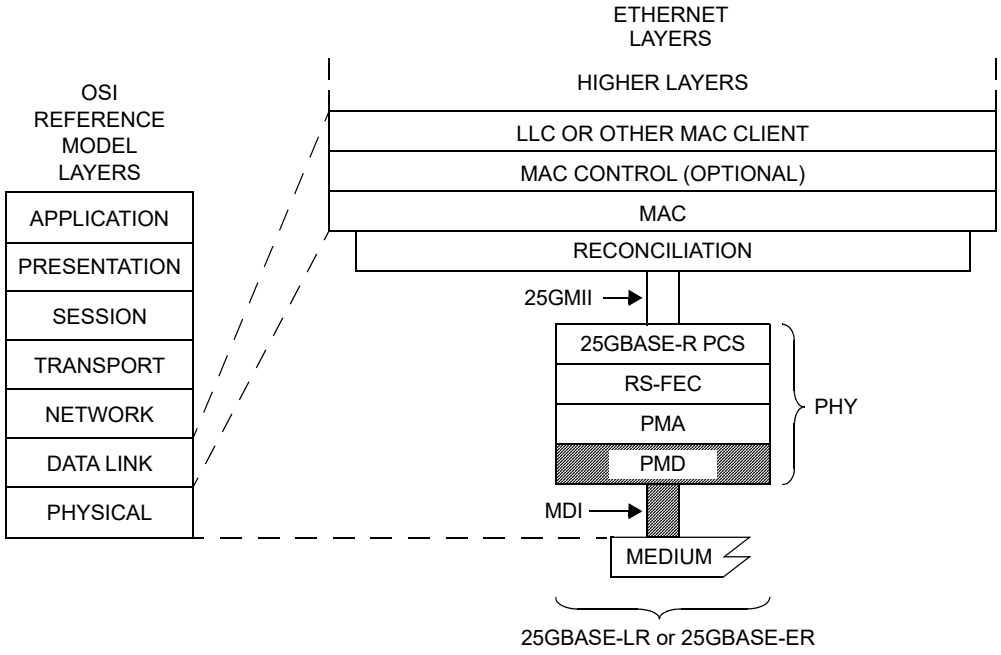
114. Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-LR and 25GBASE-ER

114.1 Overview

This clause specifies the 25GBASE-LR PMD and 25GBASE-ER PMD together with the single-mode fiber medium. The PMD sublayer provides a point-to-point 25 Gb/s Ethernet link over a pair of single-mode fibers. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 114–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 114–1—Physical Layer clauses associated with the 25GBASE-LR and 25GBASE-ER PMDs

Associated clause	25GBASE-LR	25GBASE-ER
106—RS	Required	Required
106—25GMII[a]	Optional	Optional
107—PCS for 25GBASE-R	Required	Required
108—RS-FEC[b]	Required	Required
109—PMA for 25GBASE-R	Required	Required
109A—25GAUI C2C	Optional	Optional
109B—25GAUI C2M	Optional	Optional
78—Energy Efficient Ethernet	Optional	Optional



[a]The 25GMII is an optional interface. However, if the 25GMII is not implemented, a conforming implementation behaves functionally as though the RS and 25GMII were present.
[b]The option to bypass the Clause 108 RS-FEC correction function is not supported.

Figure 114–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 25 Gigabit Ethernet is introduced in Clause 105 and the purpose of each PHY sublayer is summarized in 105.3.

25GBASE-LR and 25GBASE-ER PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions, and abbreviations) and Annex A (Bibliography, referenced as [B1], [B2], etc.).

25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION
LR = PMD FOR SINGLE-MODE FIBER - 10 km
ER = PMD FOR SINGLE-MODE FIBER - 40 km

Figure 114–1—25GBASE-LR and 25GBASE-ER PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

114.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 5×10^{-5} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

114.2 Physical Medium Dependent (PMD) service interface

The PMD service interfaces for 25GBASE-LR and 25GBASE-ER are the same as PMD service interface for 25GBASE-SR as described in 112.2 with the BER as specified in 114.1.1.

114.3 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The sum of the transmit and receive delays at one end of the link contributed by

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the 25GBASE-LR or 25GBASE-ER PMD including 2 m of fiber in one direction shall be no more than 512 bit times (1 pause_quantum or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quantum can be found in 105.5 and its references.

114.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 114–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 114–3.

Table 114–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable

Table 114–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

114.5 PMD functional specifications

The 25GBASE-LR and 25GBASE-ER PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

114.5.1 PMD block diagram

The PMD block diagram is shown in Figure 114–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 114.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 88.11.3). Unless specified otherwise, all receiver measurements and tests defined in 114.7 are made at TP3.

TP1 and TP4 are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

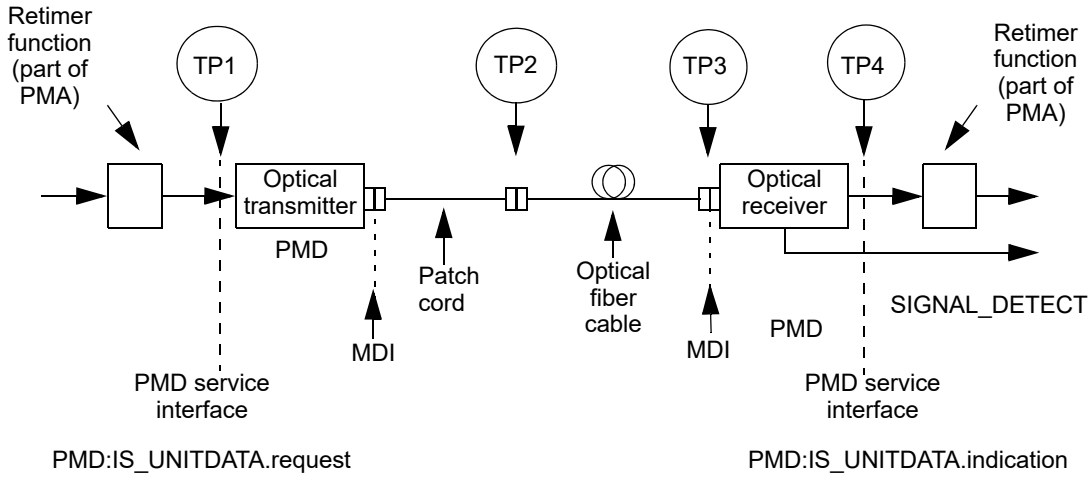

Figure 114–2—Block diagram for 25GBASE-LR and 25GBASE-ER transmit/receive paths

114.5.2 PMD transmit function

The PMD Transmit function shall convert the bit stream requested by the PMD service interface messages PMD:IS_UNITDATA.request into an optical signal. The optical signal shall then be delivered to the MDI, all according to the transmit optical specifications in this clause. The higher optical power level in the signal shall correspond to tx_bit = one.

114.5.3 PMD receive function

The PMD Receive function shall convert the optical signal received from the MDI into a bit stream for delivery to the PMD service interface using the messages PMD:IS_UNITDATA.indication, all according to the receive optical specifications in this clause. The higher optical power level in the signal shall correspond to rx_bit = one.

114.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 105.4.

SIGNAL_DETECT shall be the indicator of the presence of the optical signal. The value of the SIGNAL_-DETECT parameter shall be generated according to the conditions defined in Table 114–4. The PMD receiver is not required to verify whether a compliant 25GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT

Table 114–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –20 dBm for 25GBASE-LR and ≤ –26 dBm for 25GBASE-ER	FAIL
[(Optical power at TP3 ≥ receiver sensitivity (max) in OMA in Table 114–7) AND (compliant 25GBASE–R signal input)]	OK
All other conditions	Unspecified

parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the PMD global signal detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal. When the MDIO is implemented, the SIGNAL_DETECT value shall be continuously set in response to the magnitude of the optical signal, according to the requirements of Table 114–4.

114.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

114.5.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows the optical transmitter to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirement of the average launch power of the OFF transmitter in Table 114–6.
b) If PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

114.5.7 PMD fault function (optional)

If the PMD has detected a local fault on the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

114.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set PMD_transmit_fault to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

114.5.9 PMD receive fault function (optional)

If the PMD has detected a local fault on the receiver, the PMD shall set PMD_receive_fault to one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

114.6 PMD to MDI optical specifications for 25GBASE-LR and 25GBASE-ER

The operating ranges for the 25GBASE-LR and 25GBASE-ER PMDs are defined in Table 114–5. A 25GBASE-LR or 25GBASE-ER compliant PMD operates on IEC 60793-2-50 type B1.1 (dispersion unshifted), type B1.3 (low water peak), or type B6_a (bend insensitive) single-mode fibers according to the specifications defined in Table 114–11. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 25GBASE-LR PMD operating at 12.5 km meets the operating range requirement of 2 m to 10 km). The 25GBASE-ER PMD interoperates with the 25GBASE-LR PMD provided that the channel requirements defined in 114.11 are met.

Table 114–5—25GBASE-LR and 25GBASE-ER operating ranges

PMD type	Required operating range[a]
25GBASE-LR	2 m to 10 km
25GBASE-ER	2 m to 30 km
	2 m to 40 km[b]

[a]The RS-FEC correction function may not be bypassed for any operating distance.
[b]Links longer than 30 km for the same link power budget are considered engineered links. Attenuation for such links needs to be less than the worst case specified for IEC 60793-2-50 type B1.1, type B1.3, or type B6_a single-mode fiber.

114.6.1 25GBASE-LR and 25GBASE-ER transmitter optical specifications

The 25GBASE-LR and 25GBASE-ER transmitters shall meet the specifications in Table 114–6 per the definitions in 114.7.

Table 114–6—25GBASE-LR and 25GBASE-ER transmit characteristics

Description	25GBASE-LR	25GBASE-ER	Unit
Signaling rate (range)	25.78125 ± 100 ppm		GBd
Center wavelength (range)	1295 to 1325	1295 to 1310	nm
Side-mode suppression ratio (SMSR), (min)	30		dB
Average launch power (max)	2	6	dBm
Average launch power[a] (min)	–7	–3	dBm
Optical Modulation Amplitude (OMA), (max)	2.2	6	dBm
Optical Modulation Amplitude (OMA)[b], (min)	–4	0	dBm
Launch power in OMA minus TDP (min)	–5	–1	dBm
Transmitter and dispersion penalty (TDP), (max)	2.7	2.7	dB
Average launch power of OFF transmitter (max)	–20		dBm
Extinction ratio (min)	3	4	dB
$RIN_{20}OMA$ (max)	–130		dB/Hz
Optical return loss tolerance (max)	20		dB
Transmitter reflectance[c] (max)	–26		dB
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3} Hit ratio 5×10^{-5} hits per sample.	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}		

[a]Average launch power (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b]Even if the TDP < 1 dB, the OMA (min) has to exceed this value.
[c]Transmitter reflectance is defined looking into the transmitter.

114.6.2 25GBASE-LR and 25GBASE-ER receive optical specifications

The 25GBASE-LR and 25GBASE-ER receivers shall meet the specifications in Table 114–7 per the definitions in 114.7.

Table 114–7—25GBASE-LR and 25GBASE-ER receive characteristics

Description	25GBASE-LR	25GBASE-ER	Unit
Signaling rate (range)	25.78125 ± 100 ppm		GBd
Center wavelength (range)	1295 to 1325		nm
Damage threshold[a] (min)	3	–3	dBm
Average receive power (max)	2	–4	dBm
Average receive power[b] (min)	–13.3	–21	dBm
Receive power (OMA), (max)	2.2	–4	dBm
Receiver reflectance (max)	–26		dB
Receiver sensitivity (OMA)[c], (max)	–12	–19	dBm
Stressed receiver sensitivity (OMA)[d], (max)	–9.5	–16.5	dBm
Conditions of stressed receiver sensitivity test			
Stressed eye closure[e]	2.5	2.5	dB
Stressed eye J2 Jitter[e]	0.27	0.27	UI
Stressed eye J4 Jitter[e]	0.39	0.39	UI
SRS eye mask definition {X1, X2, X3, Y1, Y2, Y3} Hit ratio 5×10^{-5} hits per sample.	{0.31, 0.4, 0.45, 0.34, 0.38, 0.4}		

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b]Average receive power (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c]Receiver sensitivity (OMA), (max) is optional.
[d]Measured with conformance test signal at TP3 (see 114.7.10) for the BER specified in 114.1.1.
[e]Stressed eye closure, stressed eye J2 Jitter, and stressed eye J4 Jitter are test conditions for measuring stressed receiver sensitivity. They are not characteristics of the receiver.

114.6.3 25GBASE-LR and 25GBASE-ER illustrative link power budgets

Illustrative power budgets and penalties for 25GBASE-LR and 25GBASE-ER channels are shown in Table 114–8.

Table 114–8—25GBASE-LR and 25GBASE-ER illustrative link power budgets

Parameter	25GBASE-LR	25GBASE-ER		Unit
Power budget (for maximum TDP)	9.7	20.7		dB
Operating distance	10	30	40[a]	km
Channel insertion loss	6.3[b]	15[b]	See 114.9[a]	dB
Maximum discrete reflectance	See 114.10	See 114.10		dB
Allocation for penalties[c] (for maximum TDP)	3.4	20.7 minus maximum channel insertion loss per Table 114–12		dB
Additional insertion loss allowed	0	Maximum channel insertion loss per Table 114–12 minus 15	0	dB

[a]Links longer than 30 km are considered engineered links. Attenuation for such links needs to be less than the worst case for cables containing IEC 60793-2-50 type B1.1, type B1.3, or type B6_a single-mode cabled optical fiber.
[b]The channel insertion loss is calculated using the maximum distance specified in Table 114–5 and fiber attenuation of 0.43 dB/km at 1295 nm plus an allocation for connection and splice loss given in 88.11.2.1.
[c]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

114.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

114.7.1 Test patterns for optical parameters

The test patterns used in this clause shall be the same as those used for 100GBASE-SR4, as described in 95.8.1 and shown in Table 95–9, with the exception that pattern 5, the scrambled idle test pattern defined in 82.2.11, is encoded by Clause 108 RS-FEC for 25GBASE-LR and 25GBASE-ER. The multi-lane testing considerations described in 95.8.1.1 do not apply. Table 114–9 shows the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined.

114.7.2 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR shall be within the ranges given in Table 114–6 if measured per IEC 61280-1-3. The signal is modulated using the test pattern specified in Table 114–9.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 114–9—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	3, 5 or valid 25GBASE-R signal	114.7.2
Side mode suppression ratio	3, 5 or valid 25GBASE-R signal	—
Average optical power	3, 5 or valid 25GBASE-R signal	114.7.3
Optical modulation amplitude (OMA)	Square wave or 4	114.7.4
Transmitter and dispersion penalty (TDP)	3, 5 or valid 25GBASE-R signal	114.7.5
Extinction ratio	3, 5 or valid 25GBASE-R signal	114.7.6
$RIN_{20}OMA$	Square wave or 4	114.7.7
Transmitter optical waveform	3, 5 or valid 25GBASE-R signal	114.7.8
Stressed receiver sensitivity	3, 5 or valid 25GBASE-R signal	114.7.10
Calibration of OMA for receiver tests	Square wave or 4	87.8.11
Vertical eye closure penalty calibration	3, 5 or valid 25GBASE-R signal	87.8.11

114.7.3 Average optical power

The average optical power shall be within the limits given in Table 114–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern specified in Table 114–9.

114.7.4 Optical Modulation Amplitude (OMA)

OMA shall be as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern. See 114.7.1 for test pattern information.

114.7.5 Transmitter and dispersion penalty (TDP)

Transmitter and dispersion penalty (TDP) shall be as defined in 52.9.10 with the BER as specified in 114.1.1. The measurement procedure for 25GBASE-LR and 25GBASE-ER is detailed in 114.7.5.1 to 114.7.5.4.

114.7.5.1 Reference transmitter requirements

The reference transmitter is a high-quality instrument-grade device, which can be implemented by a CW laser modulated by a high-performance modulator. The basic requirements are as follows:

a) Rise/fall times of less than 12 ps at 20% to 80%.
b) The output optical eye is symmetric and passes the transmitter optical waveform test of 114.7.8.
c) In the center 20% region of the eye, the worst-case vertical eye closure penalty as defined in 87.8.11.2 is less than 0.5 dB.
d) Total Jitter less than 0.2 UI peak-to-peak.
e) RIN of less than –138 dB/Hz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

114.7.5.2 Channel requirements

The channel requirements for testing the transmitter are described in 88.8.5.2, where the requirements for 100GBASE-LR4 apply to 25GBASE-LR and the requirements for 100GBASE-ER4 apply to 25GBASE-ER.

114.7.5.3 Reference receiver requirements

The reference receiver is required to have the bandwidth given in 114.7.8. The sensitivity of the reference receiver is limited by Gaussian noise. The receiver has minimal threshold offset, deadband, hysteresis, baseline wander, deterministic jitter, or other distortions. Decision sampling has minimal uncertainty and setup/hold times.

The nominal sensitivity of the reference receiver, S, is measured in OMA using the setup of Figure 52–12 without the test fiber and with the transversal filter removed. The sensitivity S has to be corrected for any significant reference transmitter impairments including any vertical eye closure. It is measured while sampling at the eye center or corrected for off-center sampling. It is calibrated at the wavelength of the transmitter under test.

For all transmitter and dispersion penalty measurements, determination of the center of the eye is required. Center of the eye is defined as the time halfway between the left and right sampling points within the eye where the measured BER is greater than or equal to 1×10^{-3}.

The clock recovery unit (CRU) used in the TDP measurement has a corner frequency of 10 MHz and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the data to the clock removes this low-frequency jitter from the measurement.

114.7.5.4 Test procedure

The test procedure is as defined in 52.9.10.4 with the BER as specified in 114.1.1.

114.7.6 Extinction ratio

The extinction ratio shall be within the limits given in Table 114–6 if measured using the methods specified in IEC 61280-2-2. The extinction ratio is measured using the test pattern defined in Table 114–9.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 114–9).

114.7.7 Relative Intensity Noise ($RIN_{20}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 20 dB.
b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 25.8 GHz).

114.7.8 Transmitter optical waveform (transmit eye)

The required optical transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 86–4. The transmitter optical waveform of a port transmitting the test pattern specified in Table 114–9 shall meet specifications according to the methods specified in 86.8.4.6.1 with the exception that the clock recovery unit's high-frequency corner bandwidth is 10 MHz. The filter nominal reference frequency f_r is 19.34 GHz and the filter tolerances are as specified for STM-64 in ITU-T G.691. Compensation may be made for variation of the reference receiver filter response from an ideal fourth-order Bessel-Thomson response and for any excess reference receiver noise.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

114.7.9 Receiver sensitivity

Receiver sensitivity, which is defined for an ideal input signal, is optional and compliance is not required. If measured, the test signal should have negligible impairments such as intersymbol interference (ISI), rise/fall times, jitter and RIN. Instead, the normative requirement for receivers is stressed receiver sensitivity.

114.7.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 114–7 if measured using the method defined in 95.8.8 with the following exceptions:

a) The centers of the vertical histograms through the eye diagram are 0.45 UI and 0.55 UI, and the width of each histogram is 0.02 UI (see Figure 95–4).

b) Added sinusoidal jitter is as specified in Table 114–10.

c) The stressed eye J2 Jitter, stressed eye J4 Jitter, stressed eye closure, and SRS eye mask are as given in Table 114–7.

d) The test pattern is as given in Table 114–9.

e) The reference receiver used to verify the conformance test signal is required to have the bandwidth given in 114.7.8.

f) The SEC created by the selection of the appropriate bandwidth for the combination of the low-pass filter and the E/O converter with the sinusoidal jitter, sinusoidal interferer 1, sinusoidal interferer 2, and the Gaussian noise generator turned off is at least 1.5 dB.

Table 114–10—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 100$ kHz	Not specified
100 kHz $< f \leq$ 10 MHz	5×10^5 Hz / f
10 MHz $< f <$ 10 LB[a]	0.05

[a]LB = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

g) The conditions for receiver aggressor lanes do not apply.

114.8 Safety, installation, environment, and labeling

All equipment subject to this clause shall conform to the applicable requirements of 112.8.

114.9 Fiber optic cabling model

The fiber optic cabling model for 25GBASE-LR and 25GBASE-ER is as specified for 100GBASE-LR4 and 100GBASE-ER4 in 88.10 with the exceptions that Table 88–14 is replaced by Table 114–11 and the maximum channel insertion loss for 25GBASE-ER is specified by Table 114–12.

Table 114–11—Fiber optic cabling (channel) characteristics

Description	25GBASE-LR	25GBASE-ER		Unit
Operating distance (max)	10	30	40	km
Channel insertion loss[a, b] (max)	6.3	See Table 114–12		dB
Channel insertion loss (min)	0	10[c]		dB
Positive dispersion[b] (max)	22.6	27.6	36.8	ps/nm
Negative dispersion[b] (min)	–27.9	–83.7	–111.6	ps/nm
DGD_max[d]	8	10.3	10.3	ps
Optical return loss (min)	21	21	21	dB

[a]These channel insertion loss values include cable, connectors, and splices.
[b]Over the wavelength range 1295 nm to 1325 nm for 25GBASE-LR and 1295 nm to 1310 nm for 25GBASE-ER.
[c]Channel insertion loss (min) may be implemented with an optical attenuator.
[d]DGD_max is the maximum differential group delay that the system is required to tolerate.

Table 114–12—Maximum channel insertion loss versus number of discrete reflectances for 25GBASE-ER

Maximum channel insertion loss (dB)		Number of discrete reflectances > –55 dB and ≤ –35 dB										
		0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
Number of discrete reflectances > –35 dB and ≤ –26 dB	**0**	18	18	18	17.9	17.9	17.9	17.8	17.8	17.8	17.7	17.7
	1	17.9	17.9	17.9	17.8	17.8	17.7	17.7	17.6	17.6	17.5	—[a]
	2	17.8	17.8	17.7	17.7	17.6	17.6	17.5	17.4	17.4	—[a]	—[a]
	3	17.7	17.6	17.6	17.4	17.4	17.3	—[a]	—[a]	—[a]	—[a]	—[a]
	4	17.5	17.4	17.3	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]
	> 4	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]	—[a]

[a]The indicated combination of reflectances is not supported.

114.10 Characteristics of the fiber optic cabling (channel)

The characteristics of the fiber optic cabling (channel) for 25GBASE-LR and 25GBASE-ER are as specified for 100GBASE-LR4 and 100GBASE-ER4 in 88.11 with the following exceptions:

— Table 88–14 is replaced by Table 114–11.

— For 25GBASE-LR, the maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 114–13 corresponding to the number of discrete reflectances above –55 dB within the channel.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— For 25GBASE-ER, the maximum value of channel insertion loss is dependent on the number and maximum value of the discrete reflectances within the channel as given in Table 114–12. Discrete reflectances below –55 dB may be ignored when determining the supported channel insertion loss.

Table 114–13—Maximum value of each discrete reflectance for 25GBASE-LR

Number of discrete reflectances above –55 dB[a]	Maximum value for each discrete reflectance for 25GBASE-LR
1 to 4	–26 dB
6	–30 dB
8	–32 dB
10	–34 dB

[a]For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

114.11 Requirements for interoperation between 25GBASE-LR and 25GBASE-ER

The 25GBASE-LR and 25GBASE-ER PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 25GBASE-LR given in 114.9 are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 114–14 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 114–14—Channel insertion loss requirements for interoperation

Direction	Min loss	Max loss	Unit
25GBASE-LR transmitter to 25GBASE-ER receiver	6.2	13.3	dB
25GBASE-ER transmitter to 25GBASE-LR receiver	4	10.3	dB

114.12 Protocol implementation conformance statement (PICS) proforma for Clause 114, Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-LR and 25GBASE-ER[192]

114.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 114, Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-LR and 25GBASE-ER, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

114.12.2 Identification

114.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

114.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 114, Physical Medium Dependent (PMD) sublayer and medium, types 25GBASE-LR and 25GBASE-ER
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[192]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

115. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and Physical Medium Dependent (PMD) sublayer, types 1000BASE-RHA, 1000BASE-RHB, and 1000BASE-RHC

115.1 Overview

1000BASE-H comprises a Physical Coding Sublayer (PCS) and a Physical Medium Attachment (PMA) sublayer that supports Physical Medium Dependent (PMD) sublayers for operation at 1000 Mb/s over duplex plastic optical fiber (POF) as the transmission medium. The following three port types with different PMDs are defined: 1000BASE-RHA, 1000BASE-RHB, and 1000BASE-RHC (collectively referred to as 1000BASE-RHx).

1000BASE-RHA specifications are driven by the requirements of home and other consumer networks. Connection of the PMD to the step index plastic optical fiber (SI-POF) medium is typically not a mated connector. Rather, a bare duplex cable is attached with a clamp in the PMD receptacle.

1000BASE-RHB specifications are driven by the requirements for industrial applications. Connection of PMD to the SI-POF medium is typically with a PMD receptacle and mated plug. A harsh environment is expected (e.g., extended temperature range, dust), and the connector is typically terminated in the field to facilitate flexible equipment interconnection layout.

1000BASE-RHC specifications are driven by requirements for automotive applications. Connection of PMD to the SI-POF medium is with a PMD receptacle and mated plug. PMD and in-line connectors and the cable have to support specific requirements for installation in a vehicle: Kojiri-safe, dust protection, vibration robustness, tensile strength, etc.

115.1.1 Features

The following are the features of the 1000BASE-H set of PHYs:

a) Specified to operate with the GMII (Clause 35).
b) Full duplex operation.
c) Support for BER of 10^{-12} or better.
d) Communication side-channel for PHY management, operations, administration, and maintenance between link partners.
e) Operation in automotive, industrial, and home network environments.

115.1.2 Conventions

The notation used in the state diagrams in this clause follows the conventions in 21.5. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

115.1.3 Relationship of 1000BASE-RHx to other standards

The relationship between a 1000BASE-RHx PHY, the ISO Open Systems Interconnection (OSI) Reference Model, and the IEEE 802.3 Ethernet Model is shown in Figure 115–1. The physical layer connects one Annex 4A Media Access Control (MAC) to the medium. This clause specifies the Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA), and Physical Medium Dependent (PMD) components of the Physical Layer device (PHY).

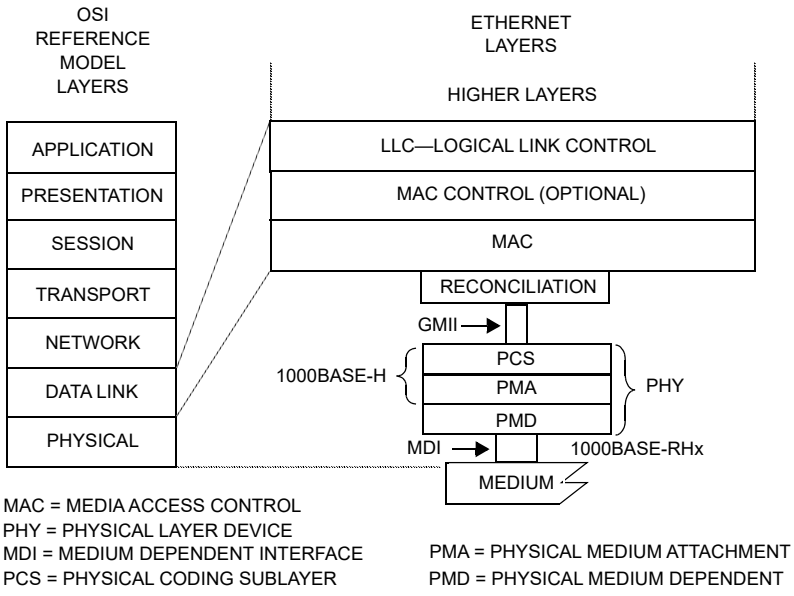

Figure 115–1—1000BASE-RHx PHY relationship to the ISO/IEC Open Systems Interconnection (OSI) Reference Model and the IEEE 802.3 Ethernet Model

115.1.4 Relationship to other Gigabit Ethernet PHY types

1000BASE-RHx PHY types are specified with the PCS interfacing to a GMII. Physical implementation of the GMII is optional. System operation from the perspective of signals at the MDI and management objects are identical whether the GMII is implemented or not. The MII Management Interface used with the initial set of Gigabit Ethernet PHYs is not used for 1000BASE-RHx PHY types.

115.1.5 Operation of 1000BASE-RHx

1000BASE-RHx PHY types support full duplex operation only, using two plastic optical fibers as the medium. Each fiber is used for unidirectional transmission with the 1000BASE-RHx port on one end of the link segment transmitting on one fiber and receiving on the second fiber. A cross-over in the cabling connects the local PMD transmitter to the link partner's PMD receiver, and the link partner's PMD transmitter to the local PMD receiver. The PMD TX and PMD RX compose the PMD sublayer.

The topology of 1000BASE-RHx is illustrated in Figure 115–2.

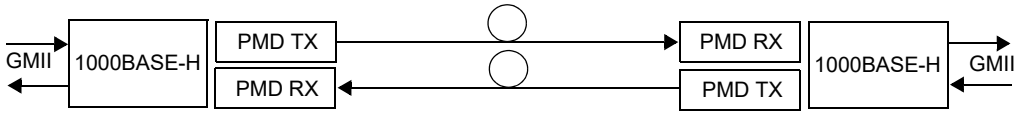

Figure 115–2—1000BASE-RHx topology

The 1000BASE-H PCS encapsulates and decapsulates the transmit and receive GMII data streams using a series of fixed length Transmit Blocks. A frame on the GMII can be contained in one or more Transmit Blocks. GMII frame boundaries have no correlation to Transmit Block boundaries.

Transmit Blocks also include pilot signals and control information. This information keeps the receiver clock aligned with the transmitter, supports channel equalization, and provides link monitoring. These signals and control information are inserted at fixed locations within the Transmit Block interrupting the transmission of the GMII data stream also included in the Transmit Block. Encapsulation of the GMII data stream within the Transmit Block also includes forward error correction encoding in fixed-length codewords inserted at fixed locations.

115.2 Physical Coding Sublayer (PCS)

The 1000BASE-H PCS couples a Gigabit Media Independent Interface (GMII), see Clause 35, to the Physical Medium Attachment (PMA) sublayer.

The PCS transmit function includes several steps. The GMII transmit data stream is encapsulated and encoded into 65-bit blocks called Physical Data Blocks (PDB) and then scrambled. After that, the scrambled data is encoded and mapped using a Multi-Level Coset Code (MLCC) block-oriented encoder, which generates fixed-length codewords of PAM16 symbols. The resultant MLCC codewords are symbol-by-symbol scrambled and then time division multiplexed with control information fields using various sub-blocks to create Transmit Blocks. The control information fields in Transmit Blocks are encoded differently, but the symbol time is equal for both the PAM16 symbols carrying information from the GMII and the encoded control information fields. Symbols are transmitted at a nominal rate of 325 MBd.

The PCS receive function comprises symbol descrambling and decoding of the MLCC codewords and the control information with error correction and detection.The resultant information obtained from MLCC codewords decoding is descrambled recovering the original PDB sequence that is finally processed to extract the GMII receive data stream. The decoded control information is also provided to the PMA sublayer for control of local and remote PHYs.

115.2.1 Transmit Block

The Transmit Block is the basic structure for transmission of data and control information for 1000BASE-H. On an active link, Transmit Blocks shall be transmitted continuously to allow receivers to maintain synchronization and equalizers to maintain alignment to the channel conditions.

The Transmit Block shall consist of 1 pilot S1 sub-block (S1), 13 pilot S2 sub-blocks ($S2_0$, $S2_1$, ..., $S2_{12}$), 14 physical header subframe sub-blocks (PHS_0, PHS_1, …, PHS_{13}), and 28 payload data sub-blocks (numbered 0 through 27), which are temporally ordered as indicated in Figure 115–4. (The top part of the figure provides detail on the beginning of a Transmit Block and the bottom part of the figure the end of a Transmit Block.) The symbols composing any sub-block shall be transmitted to the PMA at the symbol rate.

The GMII data stream is encoded into the payload data sub-blocks in a stream of fixed length Transmit Blocks. Payload data sub-blocks are modified in LPI mode of operation as described in 115.4.

Each pilot S1 sub-block, pilot $S2_x$ sub-block, and PHS_x sub-block is composed of 160 symbols. For these sub-blocks the first 16 symbols (prefix) and the last 16 symbols (postfix) are zeros (see 115.3.3.1).

Each payload data sub-block is composed of 7904 symbols that span 8 MLCC codewords of 988 symbols each. The transmission of MLCC codewords are aligned with the start of the payload data sub-blocks. Since the Transmit Block includes 28 payload data sub-blocks, a total of 224 MLCC codewords (CW_0, CW_1, …, CW_{223}) are transmitted. This gives a total of 221 312 payload data symbols.

The resulting length of a Transmit Block is 225 792 symbols. Because the nominal symbol rate is 325 MBd, a Transmit Block is transmitted nominally every 694.7446 μs.

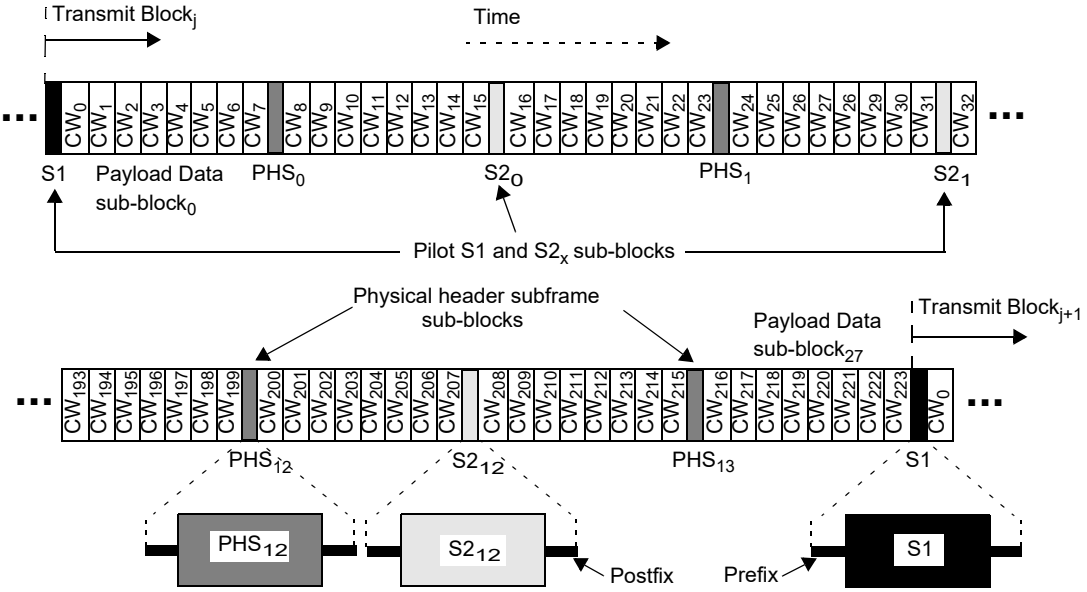

Figure 115–4—1000BASE-H Transmit Block

Transmit Blocks are generated by the multiplexer from the four data paths shown in Figure 115–5. The symbols of pilot S1, pilot $S2_x$, PHS_x, and payload data sub-blocks are generated in a different manner. Though the implementation method is not constrained, the input from each data path to the multiplexer may logically be viewed as a symbol FIFO, with the multiplexer selecting the appropriate data path symbols sequentially to create a sub-block. The sequence of sub-blocks results in the Transmit Block temporal order illustrated in Figure 115–4.

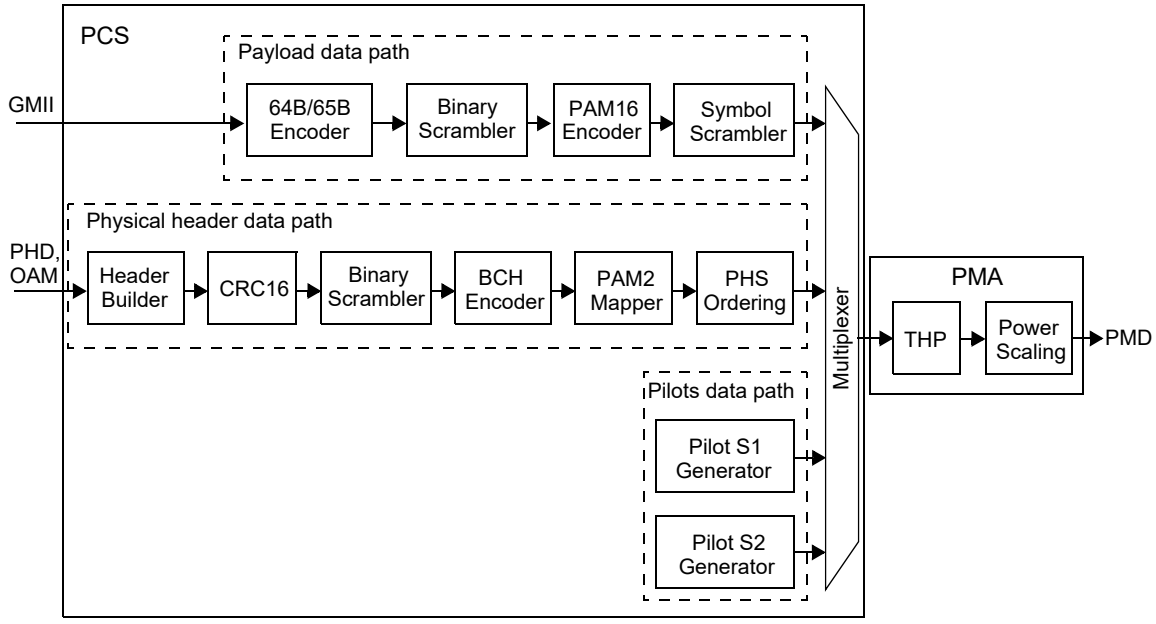

Figure 115–5—Transmit Block generation

115.2.2 Pilots data path

Pilots S1 and S2 are predefined signals transmitted in fixed allocated time slots of the Transmit Block intended to be used by the receiver for initialization and continuous tracking purposes based on data-aided signal processing. A pilot signal S1 is transmitted at the beginning of each Transmit Block as shown in Figure 115–4 and is intended for symbol synchronization and timing recovery. Pilot S2 is divided into a series of sub-blocks ($S2_x$, x = 0 through 12) that are distributed along the Transmit Block. Pilot $S2_x$ sub-blocks are intended to facilitate timing recovery, channel estimation, and equalization by the receiver.

115.2.2.1 Pilot S1 generator

A pilot S1 sub-block is transmitted at the beginning of each Transmit Block as shown in Figure 115–4. Figure 115–6 illustrates the pilot S1 generator.

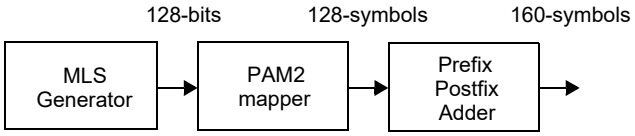

Figure 115–6—Pilot S1 generator

The S1 generator shall produce an output of one pilot S1 sub-block per Transmit Block equivalent to the following steps:

a) A maximum length sequence (MLS) generator that produces the same output as the following code is used to generate a 128-bit binary sequence.[193, 194] This code produces the same 128-bit binary sequence as the shift register shown in Figure 115–7 when the shift register is initialized for each pilot S1 sub-block generation with hexadecimal value of 0x172DB9D, where the leftmost digit of the initialization value corresponds to the initial value of register element r[0] and is taken to generate the first bit of the pilot S1.

```
function out = lfsr(len, seed)
  % Reset
  r = double(dec2bin(hex2dec(seed))) - double('0');
  r = [zeros(1, 25-length(r)) r];
  % Output generation
  for i = 1:len
    out(i) = r(1);
    r      = [mod(r(22)+r(25),2) r(1:24)];
  end
end
```

The variable *len* is the length of the sequence to be generated (*len* = 128 for S1), the variable *out* is the binary output sequence, and the variable seed is the initialization value of the shift register (*seed* = '172DB9D').

b) The bits generated in the previous step are mapped into PAM2 symbols so that bits with value 0 are mapped to {–1} and bits with value 1 are mapped to {+1}.

c) The resulting 128-symbol sequence is prefixed and postfixed by a sequence of 16 zero {0} symbols, thus obtaining the 160 symbol length for S1 sub-block.

[193]This code is written in the MATLAB programming language (see 1.3); however, use of this language does not indicate an endorsement of MATLAB by IEEE and, as such, any tool can be used to perform this calculation.

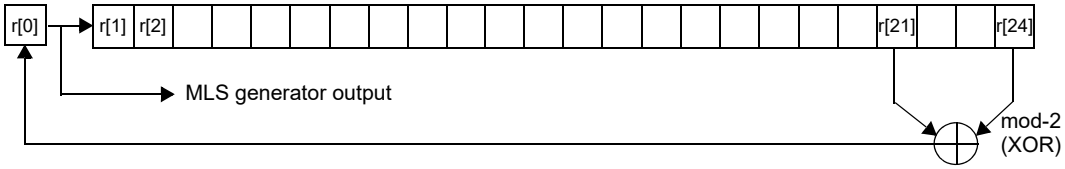

Figure 115–7—MLS generator

115.2.2.2 Pilot S2 generator

A pilot $S2_x$ sub-block is transmitted between every other payload data sub-block, alternating with PHS_x sub-blocks as shown in Figure 115–4. Figure 115–8 illustrates the pilot $S2_x$ sub-block generator.

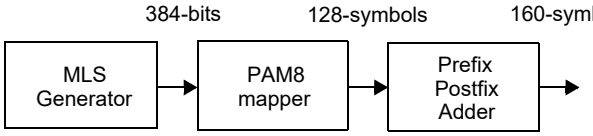

Figure 115–8—Pilot $S2_x$ sub-block generator

The S2 generator shall produce an output of 13 pilot $S2_x$ sub-blocks per Transmit Block equivalent to the following steps:

a) An MLS generator that produces the same output as the shift register shown in Figure 115–7 is used to generate 13 binary sequences of 384-bit length. The shift register is initialized for each pilot $S2_x$ sub-block generation as indicated in Table 115–1. MLS initialization and operation are as described in 115.2.2.1.

Table 115–1—Shift register initialization for $S2_x$ sub-blocks

$S2_x$ sub-block	Shift register initialization	$S2_x$ sub-block	Shift register initialization
$S2_0$	0x0945286	$S2_7$	0x050DF4E
$S2_1$	0x0F00D43	$S2_8$	0x164252F
$S2_2$	0x1AA60F3	$S2_9$	0x1E587FB
$S2_3$	0x0D89E10	$S2_{10}$	0x02CD3AD
$S2_4$	0x0DEBAC8	$S2_{11}$	0x0EE9512
$S2_5$	0x16913D1	$S2_{12}$	0x1ABFA53
$S2_6$	0x13EACDB		

b) A PAM8 mapper generates a sequence of 128 PAM8 symbols from each binary sequence generated in the previous step. The binary sequence is divided into 3-bit groups and a PAM8 symbol is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

generated from each 3-bit group according to Equation (115–1). Bit $b[0]$ is the first of each 3-bit group received from the MLS generator and S the value of the PAM8 symbol.

$$S = 2b[0] + 4b[1] + 8b[2] - 7 \quad (115–1)$$

c) Each sequence of 128 PAM8 symbols is prefixed and postfixed by a sequence of 16 zero symbols, thus obtaining the 160 symbol length for each pilot $S2_x$ sub-block.

115.2.3 Physical header encoding and scrambling

The Physical Header Data (PHD) consists of 704 bits carrying physical layer control information (see 115.3.4). The PHD is scrambled, encoded, and modulated prior to transmission as illustrated in Figure 115–9. The PHD is protected by appending a 16-bit CRC code (CRC16) for extra error detection capability after decoding. The resulting sequence of 720 bits is scrambled and encoded with a (896, 720) BCH code for error correction. The 896 coded bits are mapped to generate the resulting 1792-symbol physical header subframe (PHS), which is ordered in 14 pieces regularly distributed along the Transmit Block (PHS_0 through PHS_{13}) as indicated in Figure 115–4.

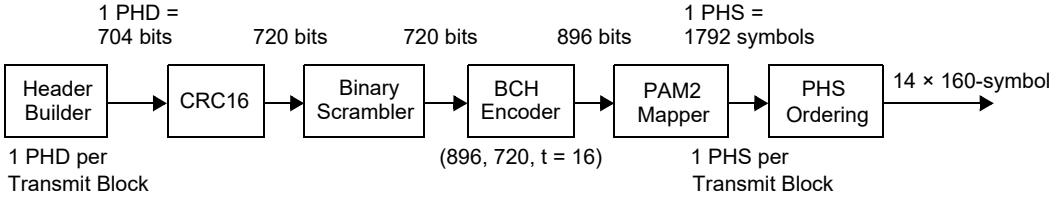

Figure 115–9—Physical header encoding and scrambling

115.2.3.1 Physical header CRC16

The 704 PHD bits from Header Builder are repeated without change and appended with 16 cyclic redundancy check bits (CRC16) for extra error detection capability after BCH decoding. The appended CRC16 shall be computed from the PHD bits and shall produce the same result as the implementation shown in Figure 115–10. The generator polynomial is $(x + 1)(x^{15} + x + 1)$. The shift register elements S_0, ..., S_{15}, shall be initialized with the value of 0x0000 for each PHD. The 704 PHD bits, in transmit bit order, are then used to compute the CRC16 with the multiplexer configured to CRCgen. After the 704 bits have been serially processed, the multiplexer is configured to CRCout and the 16 stored values are the CRC16. CRC16 is transmitted in order from S15 to S0.

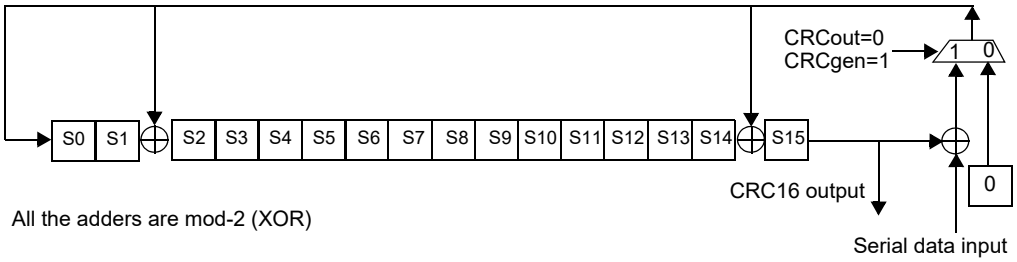

Figure 115–10—Physical header CRC16

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.2.3.2 Physical header binary scrambler

The 720 bits from the CRC16 functional block shall be scrambled prior to transmission using a binary scrambler that produces the same result as the implementation shown in Figure 115–11. The shift register shall be initialized with the value of 0x068D332 for each Transmit Block, where the leftmost digit corresponds to the initial value of register element r[0]. The initial value of r[0] is xor-ed with the first bit from the CRC16 functional block to generate the first input bit to the BCH encoder. See 115.2.2.1 for the formal definition of the shift register.

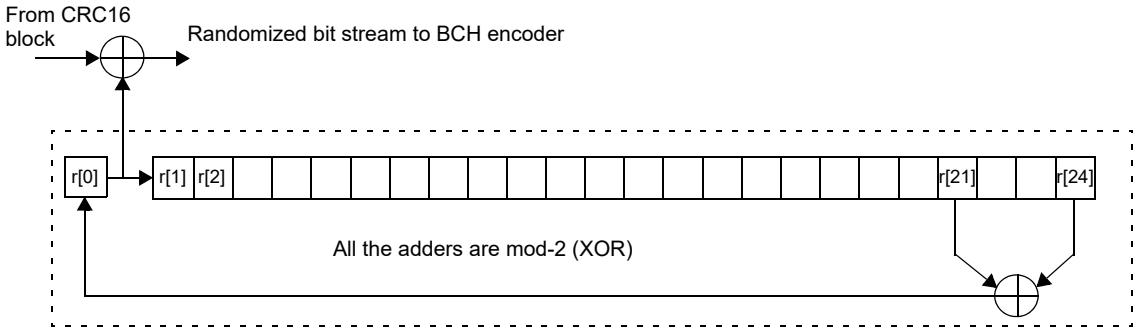

Figure 115–11—Physical header binary scrambler

115.2.3.3 Physical header BCH encoder

The scrambled 720 information bits shall be systematically encoded into 896 bits length codewords by means of a BCH (896, 720) encoder. The BCH code (896, 720) is a shortened version of the primitive BCH code (2047, 1871). It is a BCH code over Galois Field GF(2^{11}), and the error correction capability of such code is $t = 16$ bits. The number of parity bits is $p = 176$ bits. Shortening is implemented by prefixing to the 720 information bits a sequence of 1151 bits with value zero. The zero prefix sequence is not transmitted and is only used to calculate the parity from the primitive code.

The BCH code is specified by the coefficients of the generator polynomial of Equation (115–2), where $g(i)$ takes values 0 or 1.

$$G(x) = \sum_{i=0}^{p} g(i)x^i \tag{115–2}$$

The order of $G(x)$ is $p = 176$. The 177 coefficients of $G(x)$ are given by the following hexadecimal number:

0x0001 A3E8 171D BCA4 EE1E 7CDC A7DA FB8D 8F39 8072 8516 6007

with $g(0)$ being the rightmost bit.

The parity calculation shall produce the same result as the shift register implementation shown in Figure 115–19. The delay elements $s_0, s_1, \ldots, s_{p-1}$ in Figure 115–19 shall be initialized to zero before encoding. See 115.2.4.3.2 for detailed BCH encoder operation.

115.2.3.4 Physical header modulation

The 896 bits from the BCH encoder shall be mapped into 1792 PAM2 symbols so that bits with value 0 are mapped to 2 consecutive symbols {+1, –1}, and bits with value 1 are mapped to 2 consecutive symbols {–1, +1}.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.2.3.5 Physical header ordering

The 1792-symbol PHS sequence shall be divided for transmission into 14 pieces of 128 symbols each, regularly distributed along the Transmit Block (PHS_0 through PHS_{13}) as indicated in Figure 115–4, preserving the symbol ordering. Each piece shall be prefixed and postfixed by zero valued symbol sequences of 16 symbols length, thus obtaining the 160 symbol length of each PHS_x.

115.2.4 Payload data encoding and scrambling

The incoming data from the GMII are encapsulated and encoded into 65-bit blocks (64B/65B encoder in Figure 115–12) for transmission. The 64B/65B generates 705 600 bits per Transmit Block that are scrambled. The scrambled binary sequence is then encoded for forward error correction by a block oriented MLCC encoder that generates a 988-symbol codeword per 3150 input information bits. A total number of 224 MLCC codewords (CW_0, CW_1, …, CW_{223}) are transmitted per Transmit Block grouped in 28 payload data sub-blocks each spanning 8 MLCC codewords as specified in 115.2.1. Each payload data sub-block is composed of 8 × 988 = 7904 PAM16 symbols. The 7904 × 28 = 221 312 PAM16 symbols of a Transmit Block are symbol-by-symbol scrambled before being transmitted to the PMA sublayer.

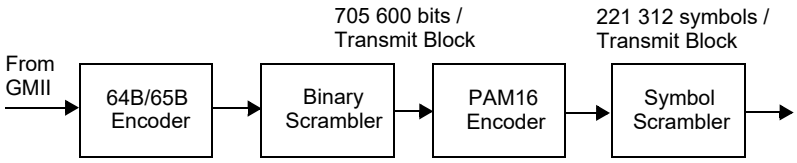

Figure 115–12—Payload data encoding and scrambling

115.2.4.1 GMII data stream encoding

The 64B/65B encoder generates a stream of 65-bit PDBs, which are serially transmitted to the binary scrambler. The nominal bit-rate of the output of the 64B/65B encoder is (65/64) × 1000 = 1015.625 Mb/s.

115.2.4.1.1 64B/65B encoding

The GMII detailed in Clause 35 supports the 1000 Mb/s operation of 1000BASE-H. It includes 8-bit transmit and receive data paths (i.e., TXD<7:0> and RXD<7:0>). Two additional signals in each direction (i.e., TX_EN, TX_ER and RX_DV, RX_ER) are used in conjunction with the data paths to delimit Ethernet packets, indicate errors, and convey other control information. The eight data and two control signals are specified relative to and sampled by a clock (GTX_CLK and RX_CLK for transmit and receive respectively).

In the transmit direction, eight consecutive GMII transfers (a GMII Chunk) are combined and then prepended by a control bit (Type) to create the PDB. TXD <7:0>, TX_EN, and TX_ER compose each GMII transfer. Two different types of PDBs, PDB.DATA and PDB.CTRL, are encoded from the set of GMII transfers defined in Table 115–2. The GMII transfers shown in Table 115–2 are the subset of permissible GMII encodings of Table 35–1 used for full duplex operation.

If the GMII Chunk only contains eight normal data transmission transfers, a PDB.DATA is generated. If the GMII Chunk contains at least one of the other three GMII control transfers shown in Table 115–2, a PDB.CTRL is generated. Both PDB.DATA and PDB.CTRL are composed of a Type bit followed by eight octets.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 115–2—Supported TX GMII encodings

TX_EN	TX_ER	TXD<7:0>	CTRL<1:0>	Description
1	0	00 through FF	—	Normal data transmission
0	0	00 through FF	01	Control: normal inter-frame (idle)
0	1	01	10	Control: assert low power idle (LPI)
1	1	00 through FF	00	Control: transmit error propagation

The format of a PDB.DATA is shown in Figure 115–13. It consists of 65 bits, the first bit being the Type bit (with a value of 0) followed by eight consecutive GMII data transfers (normal data transmission as shown in Table 115–2). The eight data octets are transmitted in the same order as they were received from the GMII. Bits in an octet are transmitted from least to most significant bit.

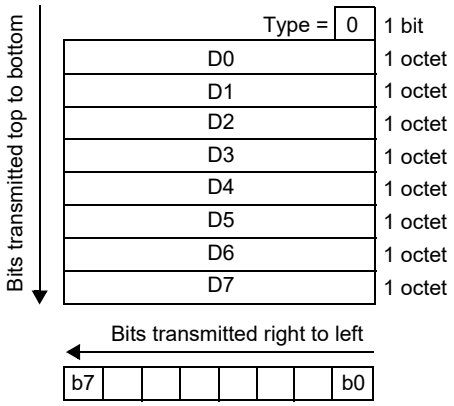

Figure 115–13—PDB.DATA format

The format of a PDB.CTRL is shown in Figure 115–14. It consists of 65 bits, encoding 8 GMII transfers [(LEN + 1) GMII control transfers and (7 – LEN) GMII data transfers, where LEN ranges from 0 through 7] preceded by the Type bit that is set to 1. The Type bit is transmitted first, followed by the 8 data and control octets generated by the encoding method described next. Bits in an octet are transmitted from least to most significant bit.

The processing of a GMII Chunk is as follows. Data octets (normal data transmission in Table 115–2) retain the value of TXD<7:0> in the GMII transfer, but every GMII control transfer is encoded in a control 8-bit byte (CB) with the following contents:

— CTRL<1:0> (CB<7:6>): This field encodes the content of the GMII control transfer as specified in Table 115–2.
— OFS<2:0> (CB<5:3>): This field indicates the offset (in GMII transfers) from the beginning of the GMII Chunk to the location of the first GMII control transfer in the GMII Chunk. This field has the same value for all CBs contained in the PDB.CTRL. The OFS value range is 0 through 7.
— LEN<2:0> (CB<2:0>): This field is the count of GMII control transfers in the GMII Chunk minus 1. This field takes the same value for all CBs contained in the PDB.CTRL. The LEN value range is 0 through 7.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

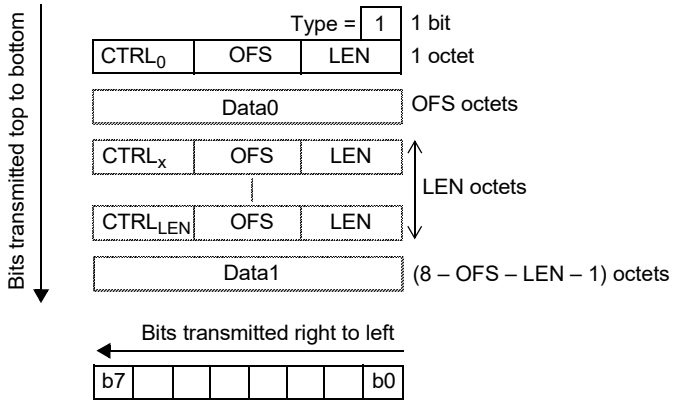

Figure 115–14—PDB.CTRL format

The octets within the PDB.CTRL are reordered as follows:

a) The CB built from the first GMII control transfer is transmitted as the first in PDB.CTRL. (This CB might encode the first GMII transfer of the GMII Chunk, or the CB might correspond to another GMII transfer of the GMII Chunk.)

b) The other seven PDB.CTRL octets are transmitted in order [not including the first CB if it was moved per step a)].

Each dotted box in Figure 115–14 represents a sequence of octets. The number of octets in a dotted box may be zero. Data0 contains OFS octets. If OFS is zero, Data0 is null. The number of CBs shown below Data0 is specified by LEN. If LEN is zero, no CB is located between Data0 and Data1. Data1 similarly may or may not be null depending on the portion of the GMII Chunk captured. Data1 completes the 8 octets included in a PDB.CTRL. It is null if 8 total octets preceded it.

NOTE—Some common example sequences of GMII transfers that illustrate the PDB.CTRL encoding include the following:

1) A GMII Chunk that only captures IPG, PDB.CTRL only includes CBs, and not Data0 or Data1.

2) A GMII Chunk that captures the end of a packet and beginning of IPG results in the first IPG GMII control transfer converted to a CB being moved ahead of the end of the packet data that is transmitted in Data0. If any more IPG GMII control transfers were captured in the GMII Chunk, they are located in the dotted boxes with control fields $CTRL_x$ through $CTRL_{LEN}$. Data1 is null.

3) A GMII Chunk that captures the end of IPG and beginning of a packet does not move any CB during encoding. The IPG is encoded in the first CB, Data0 is null and the CBs with control fields labeled $CTRL_x$ through $CTRL_{LEN}$ hold the remaining CBs encoding the IPG. The beginning of packet then appears in Data1.

4) A GMII Chunk that captures the end of a packet, shortened IPG (six or less IPG transfers), and beginning of a packet. The first IPG GMII transfer is encoded as a CB and moved ahead similar to example 2, and would have the end of packet GMII data transfer(s) in Data0, Other IPG GMII transfers are encoded as CBs in $CTRL_x$ through $CTRL_{LEN}$ and the beginning of the next packet data in Data1.

Because the minimum length of an Ethernet packet is longer than 7 octets, all the GMII control transfers in a GMII Chunk of a correct packet are contiguous. Consequently, all the CBs beyond the first are also contiguous within the PDB.CTRL.

When there are non-contiguous GMII control transfers within a GMII Chunk, the GMII data transfers between the GMII control transfers belong to an erroneous Ethernet packet. In this case, these GMII data

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transfers are replaced by GMII control transfers encoding error propagation as a previous step to the PDB.CTRL encoding. The resulting GMII Chunk is then encoded following the previous description.

A minimum delay of 8 GTX_CLK cycles at the GMII is necessary for the 64B/65B encoding, because the 64B/65B encoder requires the reception of a full GMII Chunk to start generating the first bit of the corresponding PDB.

The formal definition of the 64B/65B encoding is in 115.2.4.1.2.

115.2.4.1.2 64B/65B encoding formal definition

The 64B/65B encoder shall produce the same result as the following code.[195, 196]

```
% Variables definition
GMII.TX_ER    % GMII TX_ER signal, 1xL row vector
GMII.TX_EN    % GMII TX_EN signal, 1xL row vector
GMII.TXD      % GMII TXD bus, 1xL row vector
PCS_ENC_EN    % tx_gmii_enable (see 115.3.5.1) value for each GMII transfer,
              % 1xL vector
PDB.TYPE      % PDB type field, 1x(L/8) row vector
PDB.PAYLOAD   % PDB payload field, 8x(L/8) matrix

% 64B/65B encoding procedure
GMII.TX_EN = GMII.TX_EN & PCS_ENC_EN;
GMII.TX_ER = GMII.TX_ER & PCS_ENC_EN;

for i = 0:8:length(GMII.TXD)-1,
  TC = (GMII.TX_EN(i+1:i+8)*2 + GMII.TX_ER(i+1:i+8)) ~= 2;

  if any(TC)
    % There are at least one control byte in the 8-bytes GMII Chunk
    % The PDB is a PDB.CTRL
    PDB.TYPE(i/8 + 1) = 1;

    if any(~TC(min(find(TC)):max(find(TC))))
      % The control bytes are not contiguous in the GMII Chunk.
      % Replace data bytes that lie within control bytes with error code.
      LL=i+min(find(TC));
      UL=i+max(find(TC));
      GMII.TX_ER(LL:UL) = GMII.TX_EN(LL:UL)|GMII.TX_ER(LL:UL);

      TC(min(find(TC)):max(find(TC))) = 1;
    end

    % Valid GMII Chunk
    % OFS field computation
    OFS = min(find(TC)) - 1

    % LEN field computation
    LEN = sum(TC) - 1

    % Build the PDB.CTRL payload
    for j = 1:8,
      if TC(j)
        if ~GMII.TX_EN(i+j) & ~GMII.TX_ER(i+j)
          % Normal inter-frame

    PDB.PAYLOAD(:, i/8 + 1) = GMII.TXD(i+1:i+8).';
  end
end
```

115.2.4.1.3 PDB alignment with Transmit Block

Since the number of information bits in a Transmit Block (705 600 bits) is not a multiple of the PDB length, in general PDBs are not aligned to the start of a Transmit Block. The PHY transmitter shall encode the number of bits between the first payload bit of Transmit Block j+1 and the start of the first PDB encoded in Transmit Block j+1 in the field PHD.TX.NEXT.PDB.OFFSET of the PHD of Transmit Block j. With this control information the receiver is able to align the PCS decoder for the Transmit Block j+1 once the PHD_j (part of Transmit Block j) is fully received and decoded. This is illustrated in Figure 115–15.

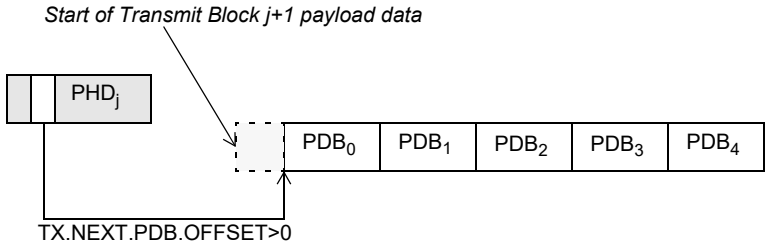

Figure 115–15—PDB alignment

The offset to the start of the first PDB in Transmit Block j+1, $\Delta(j+1)$ is calculated from the offset of the Transmit Block j, $\Delta(j)$ by using the Equation (115–3).

$$\Delta(j+1) = \mathrm{mod}(40 + \Delta(j), 65) \tag{115–3}$$

Modulo operator is defined per Equation (115–4), where floor(a) denotes the greatest integer less than or equal to the real number a.

$$\mathrm{mod}(y, x) = y - x \times \mathrm{floor}\left(\frac{y}{x}\right) \tag{115–4}$$

115.2.4.2 Payload data binary scrambler

The 705 600 bits per Transmit Block from the 64B/65B encoder shall be scrambled prior to transmission using a binary scrambler that produces the same result as the implementation shown in Figure 115–16. The shift register shall be initialized with a hexadecimal value of 0x17C9C58 for each Transmit Block, where the leftmost digit corresponds to the initial value of register element r[0]. The initial value of r[0] is xor-ed with the first bit from the 64B/65B encoder to generate the first bit of the binary sequence that feeds the PAM16 encoder. See 115.2.2.1 for the formal definition of the shift register.

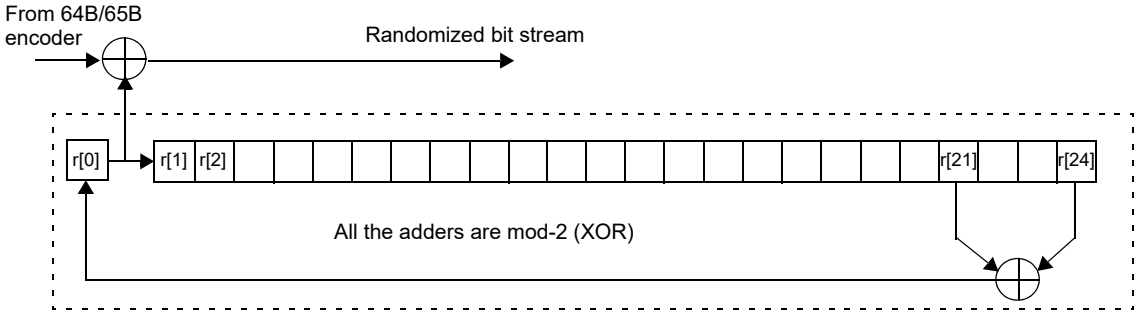

Figure 115–16—Payload data binary scrambler

115.2.4.3 PAM16 encoder

After being encapsulated and scrambled, the GMII data stream is encoded into PAM16 symbols. A two-level, block-oriented MLCC based on two-dimensional constellations is used to transmit the information with high spectral efficiency. The information is partitioned in such a way that the bits more likely to be corrupted by noise are protected by a binary BCH code, and those bits less likely to be corrupted are not additionally protected.

Figure 115–17 shows the essential parts of the MLCC encoder. A block of 3150-bit per codeword is split between the two levels that compose the encoder in an interleaved manner. The bits in the first level are encoded with a (1976, 1668) BCH code and the second level is not encoded. Bits composing the BCH codeword in the first level are mapped onto symbols of a QAM16 constellation. Bits in the second level are mapped onto symbols of a rotated QAM8 constellation. After the mapping, the two levels produce 494 2D symbols per codeword. Symbols from each level are processed by a first lattice transformation and then added to carry out the coset partitioning. The output of the adder is further processed by a second lattice transformation that produces symbols onto a rotated QAM128 constellation. Finally, in-phase and quadrature components of QAM128 symbols are multiplexed in time to generate 988 PAM16 symbols per codeword.

115.2.4.3.1 MLCC demultiplexer

The 3150 information bits to be encoded in an MLCC codeword shall be demultiplexed in two flows, where the bits $7 \times k + j$, for all k from 0 through 416 and all j from 0 through 3, are transferred to the BCH encoder of the first MLCC level, and the bits $7 \times k + j$, for all k from 0 through 416 and all j from 4 through 6, and the bits from 2919 through 3149 are transferred to the second MLCC level, preserving the relative bit ordering in each flow.

Figure 115–18 illustrates the operation of the MLCC demultiplexer. In Figure 115–18, bit quadruples a_i with i from 0 through 416 and bit triples b_i with i from 0 through 493 are the portions of information transferred to the first and to the second MLCC level, respectively. The term “4b” stands for 4-bit groups, and the term “3b” stands for 3-bit groups.

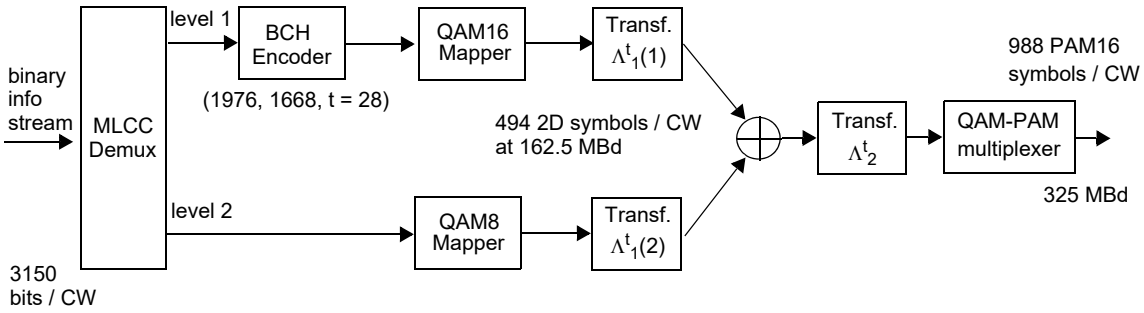

Figure 115–17—Two level coset encoder

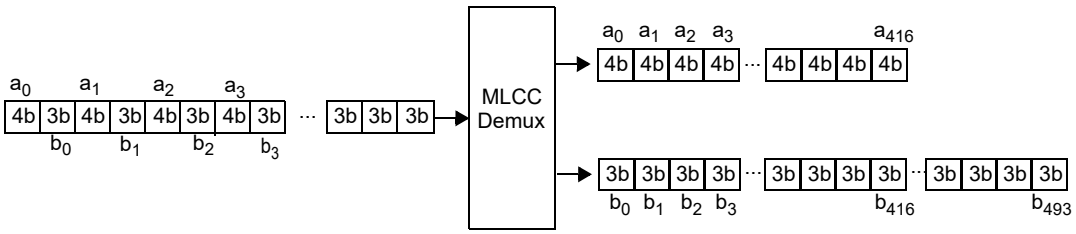

Figure 115–18—MLCC demultiplexing process

115.2.4.3.2 Payload BCH encoder

The 1668 information bits of the first level shall be systematically encoded into 1976 code bits by means of a BCH $(n, k) = (1976, 1668)$ encoder. This BCH code is a shortened version of the primitive BCH code (2047, 1739). It is a BCH code over Galois field GF(2^{11}), and the error correction capability of such code is $t = 28$. The number of parity bits is $p = 308$ bits. Shortening is implemented by prefixing to the 1668 information bits a sequence of 71 bits with value zero. The zero prefix sequence is not transmitted and is only used to calculate the parity from the primitive code.

The BCH code is specified by the coefficients of generator polynomial $G(x)$ of Equation (115–5), where $g(i)$ takes values 0 or 1. The order of $G(x)$ is $p = 308$.

$$G(x) = \sum_{i=0}^{p} g(i)x^i \tag{115–5}$$

The 309 coefficients of $G(x)$ are given by the following hexadecimal number:

0x0014 B624 90DF 0781 4D88 99E9 B9DB 6267 00D3 7A90
49DB C0C4 484A D6C5 49AB AE7E 6F58 A406 CF86 C0BD,

with $g(0)$ being the rightmost bit of the second line.

The parity calculation shall produce the same result as the shift register implementation shown in Figure 115–19. The delay elements $s_0, s_1, \ldots, s_{p-1}$ shall be initialized to zero before encoding. All the k bits

composing the information message are used to calculate the parity and enter the BCH encoder in the same order provided by the MLCC demultiplexer with the multiplexers indicated in Figure 115–19 connected with BCHgen selected. After all the k bits have been serially processed, the multiplexers are configured to select BCHout and the p stored values $s_0, s_1, \ldots, s_{p-1}$ are the parity bits. The parity bits are then transmitted in order from s_{p-1} to s_0.

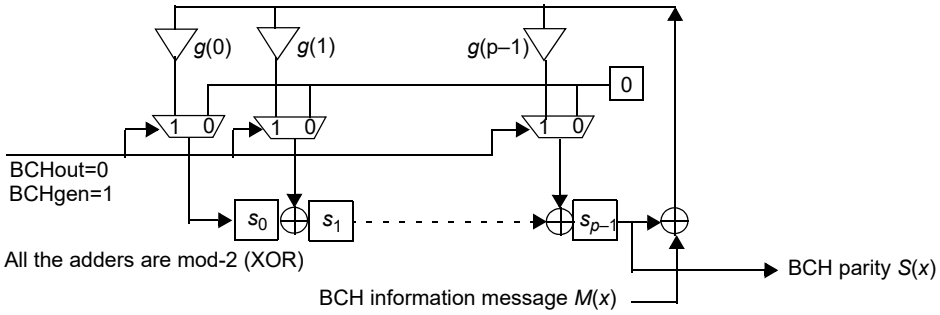

Figure 115–19—BCH encoder

The parity bits are transmitted after the information message $M(x) = m_0 + m_1x + m_2x^2 + \ldots + m_{k-1}x^{k-1}$, where m_{k-1} is the first bit of the message. To encode the message, $M(x)$ is first multiplied by x^{n-k} and the result is then divided by the generator polynomial $G(x)$. The remainder of the division of $M(x)x^{n-k}$ by $G(x)$ defines the parity $S(x) = s_0 + s_1x + s_2x^2 + \ldots + s_{p-1}x^{p-1}$, where $p = n - k$. The transmitted codeword $C(x)$ is formed by combining $M(x)$ and $S(x)$ per Equation (115–6),

$$C(x) = S(x) + M(x)x^{n-k} = s_0 + s_1x + s_2x^2 + \ldots + s_{n-k-1}x^{n-k-1} + m_0x^{n-k} + \ldots + m_{k-1}x^{n-1} \quad (115\text{–}6)$$

which shows that the codeword is produced in the required systematic form.

115.2.4.3.3 QAM16 mapper

Codewords resulting from the BCH encoding shall be mapped by means of a QAM16 mapper (see Figure 115–17) that generates 494 QAM16 symbols per 1976 bits of the MLCC codeword, doing 4-bit groups that are then mapped per Table 115–3. Bit $b[0]$ is the first received bit of each 4-bit group and S_I and S_Q are the in-phase (I) component and the quadrature (Q) component, respectively, of the QAM16 two-dimensional constellation.

Table 115–3—4B mapping to QAM16

$b[3]$	$b[2]$	$b[1]$	$b[0]$	S_I	S_Q	$b[3]$	$b[2]$	$b[1]$	$b[0]$	S_I	S_Q

$b[3]$	$b[2]$	$b[1]$	$b[0]$	S_I	S_Q	$b[3]$	$b[2]$	$b[1]$	$b[0]$	S_I	S_Q
0	1	1	0	+3	–1	1	1	1	0	+3	+1
0	1	1	1	+1	–1	1	1	1	1	+1	+1

115.2.4.3.4 QAM8 mapper

The uncoded bit stream from the MLCC demultiplexer shall be mapped by means of a QAM8 mapper (as illustrated in Figure 115–17) that generates 494 QAM8 symbols per 1482 bits of the MLCC codeword, doing 3-bit groups that are then mapped per Table 115–4. Bit $b[0]$ is the bit of each 3-bit group received first in time and S_I and S_Q are the in-phase (I) component and the quadrature (Q) component, respectively, of the QAM8 two-dimensional constellation.

Table 115–4—3B mapping to QAM8

$b[2]$	$b[1]$	$b[0]$	S_I	S_Q	$b[2]$	$b[1]$	$b[0]$	S_I	S_Q
0	0	0	–3	–3	1	0	0	+3	–1
0	0	1	–1	–1	1	0	1	+1	–3
0	1	0	–3	+1	1	1	0	+3	+3
0	1	1	–1	+3	1	1	1	+1	+1

115.2.4.3.5 First lattice transformation

The QAM16 symbols given by the S_I and S_Q components shall be further processed by a symbol-by-symbol lattice transformation ($\Lambda_1^t(1)$ in Figure 115–17) according to Equation (115–7) and Equation (115–8). The label $t11$ indicates the result of the lattice transformation $\Lambda_1^t(1)$.

$$S_I^{t11} = \frac{1}{2}(3 + S_I) \tag{115–7}$$

$$S_Q^{t11} = \frac{1}{2}(3 + S_Q) \tag{115–8}$$

The QAM8 symbols given by the S_I and S_Q components shall be further processed by a symbol-by-symbol lattice transformation ($\Lambda_1^t(2)$in Figure 115–17) according to Equation (115–9) and Equation (115–10). The label $t12$ indicates the result of the lattice transformation $\Lambda_1^t(2)$.

$$S_I^{t12} = S_I - S_Q \tag{115–9}$$

$$S_Q^{t12} = 6 + S_I + S_Q \tag{115–10}$$

115.2.4.3.6 Lattice addition

The symbols from the first lattice transformation of the first and second levels shall be added symbol-by-symbol according to Equation (115–11) and Equation (115–12). The resulting in-phase and quadrature

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

components of the lattice addition are hereafter labeled as S_I^a and S_Q^a respectively. The label *a* indicates the result of the lattice addition.

$$S_I^a = S_I^{t11} + S_I^{t12} \tag{115–11}$$

$$S_Q^a = S_Q^{t11} + S_Q^{t12} \tag{115–12}$$

115.2.4.3.7 Second lattice transformation

The symbols from lattice addition shall be further processed by a symbol-by-symbol lattice transformation (Λ_2^t in Figure 115–17) according to Equation (115–13) and Equation (115–14). The output symbols that result of the second lattice transformation belong to a rotated QAM128 constellation. The label *t*2 indicates the result of the lattice transformation Λ_2^t.

$$S_I^{t2} = 2\text{mod}(S_I^a + S_Q^a, 16) - 15 \tag{115–13}$$

$$S_Q^{t2} = 2\text{mod}(-S_I^a + S_Q^a, 16) - 15 \tag{115–14}$$

Modulo operator is per definition of Equation (115–4).

115.2.4.3.8 QAM to PAM multiplexer

The QAM to PAM multiplexer shall generate 988 PAM16 symbols from 494 QAM128 symbols produced by the second lattice transformation per MLCC codeword, alternating the in-phase (*I*) component and the quadrature (*Q*) component, S_I^{t2} and S_Q^{t2}, respectively, of QAM128 symbols, starting the codeword with the *I* component of the first QAM symbol and ending the codeword with the *Q* component of the last QAM symbol. The PAM16 symbols generated in this way belong to the set {–15, –13, …, +13, +15}.

115.2.4.4 Payload data symbol scrambler

The 221 312 PAM16 symbols per Transmit Block from the PAM16 encoder block of Figure 115–12 shall be scrambled prior to transfer to the PMA transmit function using a scrambler implementation that produces the same output as the following steps:

a) An MLS generator that produces the same output as the shift register shown in Figure 115–7 is used to generate a 1 991 808-bit binary sequence per Transmit Block. The shift register is initialized for each Transmit Block with hexadecimal value of 0x155D559. MLS initialization and operation are as described in 115.2.2.1.

b) A mapper generates two 221 312-symbol sequences, *v* and *s*, per each binary sequence generated in the previous step, doing 9-bit groups that are then mapped so that 1 symbol of *v* and 1 symbol of *s* are generated per 9-bit group according to Equation (115–15) and Equation (115–16). Bits *b*[0] and *b*[8] are the bits of each 9-bit group received first and last in time, respectively, from the MLS generator.

$$v = -16 + 2\sum_{i=0}^{3} b[i]2^i \tag{115–15}$$

$$s = -1 + 2b[8] \tag{115–16}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) The sequences *v* and *s*, generated in the previous step, are combined symbol-by-symbol basis with the payload symbols from PAM16 encoder, *x*, to generate a 221 312-symbol scrambled sequence, *y*, according to Equation (115–17) and Equation (115–18). Modulo operator is per definition of Equation (115–4).

$$u = v + s \times x \tag{115–17}$$

$$y = \mathrm{mod}(u + 16, 32) - 16 \tag{115–18}$$

Figure 115–20 illustrates the payload data symbol scrambling process.

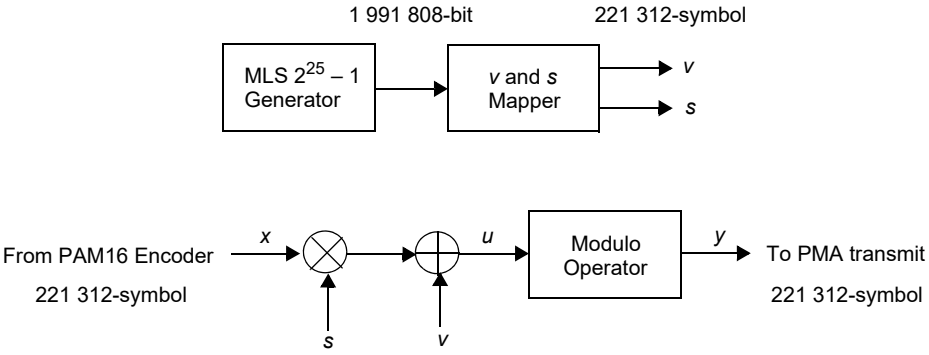

Figure 115–20—Payload data symbol scrambler

115.2.5 PCS receive function

The PCS receive function accepts equalized symbols provided by the PMA receive function. The PCS receive function knows to which part of the received Transmit Block the symbols belong, based on the symbol time alignment information provided by the clock recovery function of the PMA receive function (see 115.3.2 and 115.3.5.3). The PCS receive function shall carry out the PHD decoding, the PAM16 decoding of payload sub-blocks, and the 64B/65B decoding of payload data.

The PHD decoding comprises detection and demapping of the received PAM2 symbols, BCH decoding for error correction, binary data descrambling, and CRC16 checking for each received PHD. Only when the CRC16 computation indicates that the received PHD is correct shall the contents of the different PHD fields be available to the PMA state diagrams and to the other PCS receive functions that use this information.

The received PAM16 symbols belonging to the payload data sub-blocks are first symbol-descrambled, and the resulting symbols are MLCC decoded, with error correction and error detection. If during MLCC decoding it is detected that a codeword contains errors that could not be corrected, the resulting bits belonging to that codeword shall be marked as corrupt. The bit stream is then binary descrambled.

Using the PHD.NEXT.PDB.OFFSET field of the decoded PHD (see 115.2.4.1.3, Figure 115–15) carried in the previous Transmit Block, the PCS receiver shall determine the alignment of the first PDB of a Transmit Block to extract the PDBs from the descrambled bit stream. The PDBs are then finally processed by the 64B/65B decoder to extract the GMII receive data stream. The 64B/65B decoding also includes the information that indicates the parts of the bit stream that have been determined to be corrupted (i.e., belong to MLCC codewords that cannot be corrected). Such corrupted data is signaled on the RX GMII by setting RX_ER = 1.

```

115.3 Physical Medium Attachment (PMA) sublayer

The Physical Medium Attachment sublayer includes the transmit and receive functions and the protocols for management of the 1000BASE-H link. This management includes exchange of information that is encoded within the PHD and the state diagrams that control both the local and remote PHYs. PHD information is encoded into the PHS as defined in 115.2.3. PMA operational information is gathered and organized for transmission by the Header Builder (see Figure 115–9).

115.3.1 PMA transmit function

The PMA transmit function comprises the Tomlinson-Harashima precoding for the payload data sub-blocks and the power scaling for the pilot S1, pilot $S2_x$, PHS_x, and payload data sub-blocks. The resultant payload PAM16 symbols from PCS transmit function are THP processed to compensate intersymbol interference produced in the communication channel. The THP processing is not applied to pilot S1, pilot $S2_x$, and PHS_x sub-blocks. The power scaling, with different factors, is performed producing similar dynamic range in every part of the Transmit Block before the symbols are transmitted to the PMD sublayer.

115.3.1.1 Payload data Tomlinson-Harashima precoding

The PAM16 symbols from the payload data symbol scrambler (see 115.2.4.4), x, shall be processed by the Tomlinson-Harashima precoder (THP) to produce a precoded sequence of symbols, y, according to Equation (115–19), Equation (115–20), and Equation (115–21):

$$v(m) = \sum_{i=0}^{8} c(i)y(m-i-1) \tag{115–19}$$

$$u(m) = x(m) + v(m) \tag{115–20}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$y(m) = \mathrm{mod}(u(m) + 16, 32) - 16 \quad (115–21)$$

where the modulo operator is defined in Equation (115–4). The THP precoded symbols can take any value in the interval $-16 \le y(m) < +16$. The coefficients of the finite-impulse-response (FIR) feedback filter $c(i)$ are set from the PHD received from the link partner (see 115.3.6). The length of the feedback filter is 9 taps. The state of the feedback filter shall be reset before the transmission of any payload data sub-block. The Tomlinson-Harashima precoder is illustrated in Figure 115–21.

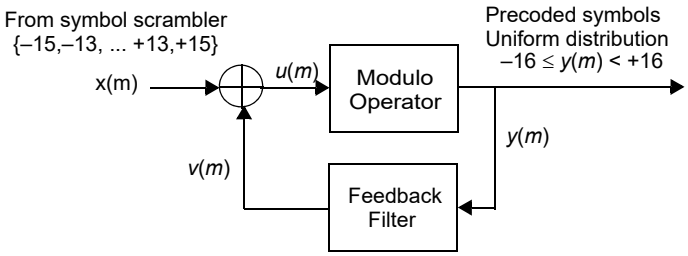

Figure 115–21—Tomlinson-Harashima precoding block diagram

115.3.1.2 Transmit power scaling

The symbols of pilot S1, pilot $S2_x$, PHS_x sub-blocks, and payload data sub-blocks shall be scaled before transmission to the PMD transmit function, by multiplying the symbols by the corresponding scaling factor specified in Table 115–5. As indicated in Table 115–5, the scaling factor used for each symbol depends on the part of the Transmit Block to which the symbol belongs.

Power scaling shall be performed directly to the symbols received from the PCS transmit for pilot S1, pilot $S2_x$, and PHS_x sub-blocks. For the payload data sub-blocks, the power scaling shall be performed to the output symbols of the Tomlinson-Harashima precoder.

Table 115–5—Transmit power scaling factors

Transmit Block part	Scaling factor
Pilot S1 sub-blocks	255/256
Pilot $S2_x$ sub-blocks	9/64
PHS_x sub-blocks	255/256
THP processed payload data sub-blocks	1/16

115.3.2 PMA receive function

The PMA receive function comprises clock recovery for correct time sampling of received symbols and adaptive channel equalization.

The PMA performs clock recovery on the received signal. The clock recovery includes coarse timing recovery for symbol synchronization and fine timing recovery to provide a stable clock to sample the received signal from the PMD with a suitable phase for reliable reception (see 115.3.7.1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Equalization is performed using the adaptive THP protocol (115.3.6) coordinated between the receiver and link partner transmitter to condition the transmitted signal for the characteristics of the fiber optic channel. The receiver estimates the coefficients that are to be used by the remote PHY transmitter to precode the payload data sub-blocks [coefficients $c(i)$ in 115.3.1.1]. This estimation should be based on received pilot $S2_X$ sub-blocks.

In general, harmonic distortion that affects the received signal can exist due to the non-linear response of the PMD photonics. The PMA receiver should implement non-linear channel response compensation in addition to the THP protocol. For estimation of the filters that linearize the channel, the PHY should also use the received pilot $S2_X$ sub-blocks. The channel linearization technique is up to the implementer but is to be fully implemented in the PHY receiver; it does not require coordination with the link partner transmission.

115.3.3 Interface to the PMD

The interface between the PMA and the PMD are signals for which no specific implementation is specified.

115.3.3.1 Signals transmitted to the PMD

Any signal transmitted to the PMD by the PMA transmitter can be expressed in a general form independent of the specific part of the Transmit Block (see 115.2.1) as follows:

$$x(n) = SF(n) \times F_M\left(a(n) + \sum_{i=0}^{8} x(n-i-1)c(i)\right) \tag{115–22}$$

where, $a(n)$ is a PAM-M modulation symbol that can take its value from the set $\{-M+1, -M+3, \ldots +M-3, +M-1\}$ to be transmitted at time instants $n \times T_s$, where T_s is the transmit symbol period (nominally $T_s = 1000/325$ ns), $SF(n)$ is the power scaling factor specified in Table 115–5 for each part of the Transmit Block according to 115.3.1.2, $c(i)$ are the coefficients of the THP specified in 115.3.1.1, and the nonlinear operation $F_M(\alpha) = \text{mod}(\alpha + M, 2M) - M$ corresponds to moving the signal $\alpha(n)$ to a reduced signal $\beta(n) = \alpha(n) + 2M \times m(n)$ with the integer $m(n)$ chosen for each sample such that the output lies in the interval $-M \le \beta(n) < M$, when THP is used.

When a pilot S1 sub-block or PHS_X sub-block is transmitted, $M = 2$. For generation of an $S2_X$ sub-block, $M = 8$. For the zero symbol sequences that prefix and postfix each pilot S1 sub-block, pilot $S2_X$ sub-block, and PHS_X sub-block, $a(n) = 0$.

When payload data sub-blocks are transmitted, $M = 16$. Only for this part of the Transmit Block can the coefficients $c(i)$ take a value different than zero, when the THP coefficients provided by the link partner are used according to the protocols defined in 115.3.6.

For any part of the Transmit Block, after scaling, the transmitter output signal $x(n)$ fits $-1 \le x(n) < +1$.

115.3.3.2 Signals received from PMD

Signals received from the PMD can be expressed as pulse-amplitude modulated signals that have been filtered by a non-linear channel and corrupted by noise as follows in Equation (115–23):

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$y(n) = w_{o0} + \sum_{l_1=0}^{L} w_{o1}(l_1)x(n-l_1) + \sum_{l_1=0}^{L}\sum_{l_2=0}^{L} w_{o2}(l_1, l_2)x(n-l_1)x(n-l_2) + \ldots$$
$$\ldots + \sum_{l_1=0}^{L}\sum_{l_2=0}^{L}\ldots\sum_{l_P=0}^{L} w_{oP}(l_1, l_2, \ldots l_P)x(n-l_1)x(n-l_2)\ldots x(n-l_P) + N(n) \quad (115\text{–}23)$$

where the received signal $y(n)$ is sampled by the PMA receive function with the recovered clock, at the optimum phase and with a frequency equal to the transmit symbol clock with nominal value of 325 MBd. $x(n)$ is the transmitted signal from the PMA transmit function to the PMD transmit function, $N(n)$ is the additive noise from PMD receiver due optical signal conversion, and w_{ox} are the kernels of a truncated Volterra series that represents the non-linear response of the communication channel.

The received signal $y(n)$ of Equation (115–23) includes the effect of the end-to-end communication channel composed of all the elements from the PMA transmitter to the PMA receiver, including the conversion to optical signal carried out by the PMD transmitter, the fiber optic channel, and the conversion from optical signal carried out by the PMD receive function.

115.3.4 Physical Header Data (PHD)

The PHD shall consist of the fields detailed in Table 115–6.

Table 115–6—PHD definition

Field name	Description	Number of bits	Valid values
PHD.TX.NEXT.MODE	Transmission mode of the next Transmit Block, indicated to link partner to align its reception (see 115.5.1)	3	0: normal transmission 1: zeros transmission for BER test 2 through 7: reserved
PHD.TX.NEXT.THP.SETID	Identifier of the THP coefficients set that will be used to transmit the next Transmit Block (see 115.3.6.2)	2	0: next Transmit Block is not THP processed 1, 2, 3: THP set identifier
PHD.TX.NEXT.PDB.OFFSET	Encodes the number of bits between the first payload bit of the next Transmit Block and the start of the first PDB in that block (see 115.2.4.1.3). Offset 0 indicates the first PDB starts aligned to first payload bit of Transmit Block	7	0x00 through 0x40
PHD.RX.REQ.THP.SETID	Requested THP coefficients set identifier (see 115.3.6.3)	2	0: no request to apply the THP coefficients received in PHD.RX.REQ.THP.COEF[8:0] 1, 2, 3: THP set identifier

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 115–6—PHD definition *(continued)*

Field name	Description	Number of bits	Valid values
PHD.RX.REQ.THP.COEF[0]	Requested THP coefficients when PHD.RX.REQ.THP.SETID is not equal to 0 (see 115.3.6.3). These are the 9 coefficients $c(i)$ requested to be used in transmission according to Equation (115–19) (see 115.3.1.1)	12	Fixed-point formatted (12, 2) (see 115.3.8)
PHD.RX.REQ.THP.COEF[1]		12	Fixed-point formatted (12, 2)
PHD.RX.REQ.THP.COEF[2]		12	Fixed-point formatted (12, 2)
PHD.RX.REQ.THP.COEF[3]		12	Fixed-point formatted (12, 2)
PHD.RX.REQ.THP.COEF[4]		12	Fixed-point formatted (12, 2)
PHD.RX.REQ.THP.COEF[5]		12	Fixed-point formatted (12.2)
PHD.RX.REQ.THP.COEF[6]		12	Fixed-point formatted (12, 2)
PHD.RX.REQ.THP.COEF[7]		12	Fixed-point formatted (12, 2)
PHD.RX.REQ.THP.COEF[8]		12	Fixed-point formatted (12, 2)
PHD.RX.LINKSTATUS	Indicates whether the local PHY is able to receive PAM16 symbols belonging to payload data sub-blocks with reliability. The value of this field is determined by the PHY quality monitor state diagram (see 115.3.7.4). The local PHY uses this received PHD field to determine the value of the variable rem_rcvr_status (see 115.3.5.4)	1	0: NOT_OK 1: OK
PHD.RX.HDRSTATUS	Indicates whether the local PHY is able to receive the PHD from its link partner with reliability. The value of this field is determined by the local PHD reception monitor state diagram. The local PHY uses this received PHD field to determine the value of the variable rem_rcvr_hdr_lock (see 115.3.5.5)	1	0: NOT_OK 1: OK
PHD.RX.LINKMARGIN	The value of this field is determined by the PHY quality monitor state diagram (see 115.3.7.4) in response to link margin estimation as defined in 115.3.7.2. Upon PHD reception, the field is stored in bits 3.521.7:0 (see 45.2.3.56.1)	8	This field is fixed-point formatted (8, 3) and is provided in $\log_2$ units (see 115.3.7.2). See 115.3.8 for fixed-point format.
PHD.CAP.LPI	This field indicates the PHY supports and has enabled EEE, and that it is able to transmit and receive Low Power Idle (see 115.4)	1	0: EEE is not supported or is disabled 1: EEE is supported and is enabled

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 115–6—PHD definition *(continued)*

Field name	Description	Number of bits	Valid values
PHD.CAP.OAM	This field indicates the PHY supports and has enabled 1000BASE-H OAM, and that it is able to transmit and receive management information by using the PHD.OAM.* fields (see 115.9)	1	0: 1000BASE-H OAM is not supported or is disabled 1: 1000BASE-H OAM is supported and is enabled
	Reserved	58	0
PHD.OAM.DATA0	1000BASE-H OAM message data field 0. See 115.9	12	0x000 through 0xFFF
PHD.OAM.MSGT	1000BASE-H OAM message identification bit. See 115.9	1	0 or 1
PHD.OAM.MERT	1000BASE-H OAM STA read identification bit (see 115.9)	1	0 or 1
PHD.OAM.PHYT	1000BASE-H OAM PHY reception identification bit (see 115.9)	1	0 or 1
	Reserved	1	0
PHD.OAM.DATA1	1000BASE-H OAM message data field 1 (see 115.9)	16	0x0000 through 0xFFFF
PHD.OAM.DATA2	1000BASE-H OAM message data field 2	16	0x0000 through 0xFFFF
PHD.OAM.DATA3	1000BASE-H OAM message data field 3	16	0x0000 through 0xFFFF
PHD.OAM.DATA4	1000BASE-H OAM message data field 4	16	0x0000 through 0xFFFF
PHD.OAM.DATA5	1000BASE-H OAM message data field 5	16	0x0000 through 0xFFFF
PHD.OAM.DATA6	1000BASE-H OAM message data field 6	16	0x0000 through 0xFFFF
PHD.OAM.DATA7	1000BASE-H OAM message data field 7	16	0x0000 through 0xFFFF
PHD.OAM.DATA8	1000BASE-H OAM message data field 8	16	0x0000 through 0xFFFF
	Reserved	368	0

The fields PHD.TX.NEXT.* are used by the local PHY to provide the link partner with information about the next Transmit Block, so that the remote PHY can align its reception.

The fields PHD.RX.* are transmitted to inform the link partner of the status of the local reception. Specifically, the fields PHD.RX.REQ.THP.SETID and PHD.RX.REQ.THP.COEF[8:0] allow the PHY to request the update of link partner THP coefficients (see 115.3.6). Additionally, PHD.RX.LINKSTATUS indicates whether payload data sub-blocks are being received with reliability, and PHD.RX.HDRSTATUS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

signals the correct/incorrect reception of PHDs. The field PHD.RX.LINKMARGIN is used to report the link margin.

PHD.RX.REQ.THP.COEF[8:0] and PHD.RX.LINKMARGIN fields are fixed-point formatted (12, 2) and (8, 3), respectively. See 115.3.8 for fixed-point format definition.

PHD.CAP.* fields indicate if the local PHY is using optional features. PHD.CAP.LPI is used by the PHY to advertise that Energy-Efficient Ethernet (EEE) is supported and that it is enabled, and the field PHD.CAP.OAM signals that the PHY implements the capability to run the 1000BASE-H OAM message exchange protocol and that it is enabled.

PHD.OAM.* fields are used to transmit and receive 1000BASE-H OAM messages.

All the PHD fields are transmitted from the least to the most significant bit and are transmitted from top to bottom of Table 115–6.

Each PHY has to deal with transmit and receive PHDs simultaneously. The prefix LOCPHD refers to the fields of the PHD to be included in the next Transmit Block transmitted to the link partner (from the local PHY). LOCPHD fields assigned by the state diagrams shall be sampled at the start of a Transmit Block by the Header Builder to create the PHS included in that current Transmit Block.

The prefix REMPHD refers to the fields of the most recent PHD received, decoded, and validated from the link partner (from the remote PHY). The new values of REMPHD fields shall be available to the state diagrams and registers immediately after reception, decoding, and validation of the entire PHS (PHS_0 to PHS_{13}) and before the reception of the Transmit Block that includes that PHS is completed.

115.3.5 PHY control

115.3.5.1 PHY control state variables

hdr_crc16_status
: Result of the CRC16 evaluation for a received PHD from the link partner; this variable is assigned for each received PHD.
  Values: OK: The most recent received PHD is correct as determined by CRC16 verification
  NOT_OK: The most recent received PHD is not correct as determined by CRC16 verification

hdr_fail_count
: Variable used to count the reception of contiguous erroneous PHDs.

link_control
: Variable that controls PMA functional operation. All state diagrams respond to the open-ended link_control = DISABLE.
  Values: DISABLE: Prevent operation of PMA sublayer
  ENABLE: Permit operation of PMA sublayer

link_status
: Variable that is set by the link monitor state diagram and used by PHY TX and PHY RX control state diagrams to control the 64B/65B encoder and 64B/65B decoder operation.
  Values: OK: The link has been established between link partners with data reliability in both communication directions
  FAIL: Link is not established (one or both directions are not providing reliable payload data decoding)

loc_rcvr_hdr_lock
: Variable set by the local PHD reception monitor state diagram to indicate the reliability of PHD reception.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: OK: Local PHD reception is reliable
NOT_OK: Local PHD reception is unreliable

loc_rcvr_status

Variable set by the PHY quality monitor state diagram to indicate correct or incorrect payload data decoding by the local PHY receiver.

Values: OK: Payload data reception by the local PHY is reliable
NOT_OK: Payload data reception by the local PHY is unreliable

new_rxblock_event

Signal sent by the PHY receiver to indicate the start of reception of a new Transmit Block. This event persists only long enough to cause one state diagram transition.

new_rxphd_event

Signal sent by the PHY receiver to indicate the complete reception (including data decoding and CRC16 checking) of a new PHD from the link partner. This event persists only long enough to cause one state diagram transition.

pma_reset

Variable that causes reset of all PMA functions. PMA reset occurs with power on or the PHY reset being set to one (bit 1.0.15). All state diagrams respond to the open-ended pma_reset = ON.

Values: ON: Reset is asserted
OFF: Reset is deasserted

rcvr_clock_lock

Variable set by the PMA receive clock recovery function to indicate that the clock has been properly recovered from the received signal.

Values: OK: Clock is stable and phase adjusted for sampling the received signal
NOT_OK: Clock has not been recovered from the received signal and/or it is not stable

rcvr_hdr_lock

Variable set by the PHD monitor state diagram to indicate the reliability of both the PHD transmission from local to remote PHY and the PHD reception from remote to local PHY.

Values: OK: PHD transmission and reception are reliable
NOT_OK: PHD transmission or reception are unreliable

rcvr_thp_lock

Variable set by the THP REQ state diagram (see 115.3.6.3) to indicate whether the Tomlinson-Harashima precoding is initialized, therefore the PHY is receiving payload data sub-blocks THP processed with the coefficients that were requested by the THP REQ state diagram.

Values: OK: THP is initialized; payload data are received THP processed
NOT_OK: THP is not initialized

rem_rcvr_hdr_lock

Variable set by the remote PHD reception monitor state diagram to indicate the reliability of PHD reception in the remote PHY (link partner).

Values: OK: Link partner PHD reception is reliable
NOT_OK: Link partner PHD reception is unreliable

rem_rcvr_status

Variable set by the link monitor state diagram. It indicates the receiver status of the remote (link partner) PHY payload data decoding.

Values: OK: Payload data reception by the remote PHY is reliable
NOT_OK: Payload data reception by the remote PHY is unreliable

rx_gmii_enable

Variable set by the PHY RX control state diagram to control the 64B/65B decoder operation (see 115.2.5).

Values: TRUE: The 64B/65B decoder receives PDBs from the link partner and decodes them into GMII receive data stream transfers

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

FALSE: The 64B/65B decoder does not decode received PDBs from the link partner

s1_synch

Variable set by the PMA receive clock recovery function to indicate synchronization with the start of Transmit Blocks.

Values: OK: Synchronization based on pilot S1 signal has been achieved
NOT_OK: Synchronization has not been achieved

tx_enable

Variable set by the PHY TX control state diagram to enable PCS and PMA transmission.

Values: TRUE: PCS and PMA transmission is enabled
FALSE: PCS and PMA transmission is disabled

tx_gmii_enable

Variable set by the PHY TX control state diagram to control the 64B/65B encoder operation (see 115.2.4.1.2).

Values: TRUE: The 64B/65B encoder encodes the GMII transmit data stream transfers into PDBs
FALSE: The 64B/65B encoder does not encode the GMII transmit data stream. Normal inter-frame is encoded in transmitted PDBs

tx_gmii_idle

Variable that indicates the idle status of the GMII transmit data path.

Values: TRUE: The value of TX_EN signal of the current GMII transfer in GMII transmit stream is 0
FALSE: The value of TX_EN signal of the current GMII transfer in GMII transmit stream is 1

115.3.5.2 PHY TX control state diagram

Transmit operation shall conform to the PHY TX control state diagram in Figure 115–22.

Upon reset or disable of the PMA, PHY transmit operation is disabled (state PMATX_DISABLE_TX). Once the PMA is enabled (link_control = ENABLE), the local PHY starts sending Transmit Blocks as explained in 115.2.1 (state PMA_ENABLE_TX), so that the remote PHY can perform clock recovery and train its equalizers (tx_enable ⇐ TRUE).

While establishing the bi-directional link, the 64B/65B PCS encoder does not encode the GMII transmit stream (tx_gmii_enable ⇐ FALSE). Once the bidirectional link is established, the 64B/65B encoder checks, and if necessary, waits until the GMII transmit data stream transfer is not part of a packet or error propagation (link_status = OK * tx_gmii_idle = TRUE); and then begins encoding the GMII transmit stream into PDBs (tx_gmii_enable ⇐ TRUE in state PMATX_PCS_DATA). If one of the link partners fails to receive payload data sub-blocks with reliability (link_status = FAIL), the 64B/65B PCS encoder does not encode the GMII transmit stream until the bidirectional link is re-established.

115.3.5.3 PHY RX control state diagram

Receive operation shall conform to the PHY RX control state diagram in Figure 115–23.

Upon reset or disable of the PMA, PHY receive operation is disabled. Once the PMA is enabled (link_control = ENABLE), the PHY receiver begins link establishment by recovering clock from the received signal. The clock recovery comprises two stages. The first stage is coarse timing recovery in PMARX_TIMING_COARSE, where symbol synchronization shall be performed using the a priori known pilot signal contained in the S1 sub-block at the beginning of each received Transmit Block (see Figure 115–4). After symbol synchronization is achieved (s1_synch = OK), fine timing recovery shall be carried out in order to provide a stable clock that samples the received signal with a suitable phase for reliable reception

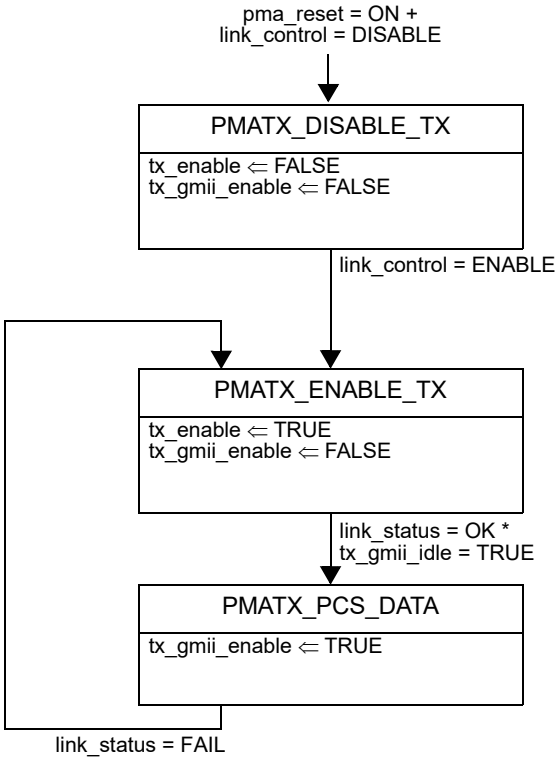

Figure 115–22—PHY TX control state diagram

(see 115.3.7.1). Fine timing recovery can be implemented with data-aided algorithms that use the received pilot S1 and pilot $S2_x$ sub-blocks.

When clock is stable (rcvr_clock_lock = OK), the PHY receiver shall train the equalizers based on the received pilot $S2_x$ sub-blocks in order to compensate the intersymbol interference caused by the communication channel. Blind tracking algorithms for timing recovery can be enabled after the equalizer training has finished.

Once the equalizers have been properly estimated, the PHY receiver processes each PHD from the link partner to determine if PHD reception is reliable in both directions. The state diagrams that monitor the reliability of PHD reception are described in 115.3.5.5.

As soon as both link partners detect reliable PHD reception (rcvr_hdr_lock = OK), the PHY receiver shall initialize the THP following the state diagram explained in 115.3.6.3. Once the local PHY is receiving payload data sub-blocks THP processed with the coefficients that were requested to the link partner (rcvr_thp_lock = OK), it has to determine according to the state diagram described in 115.3.7.3 whether this reception is reliable.

Once a bidirectional link is established (link_status = OK), the 64B/65B PCS decoder begins to decode the received PDBs onto the GMII receive data stream (rx_gmii_enable ⇐ TRUE). Furthermore, both link partners are able to properly use the PHD to carry out continuous adaptation of THP coefficients.

If one of the link partners fails to receive payload data sub-blocks with reliability (link_status = FAIL), the 64B/65B PCS decoder does not decode PDBs received from link partner into the GMII receive stream (rx_gmii_enable ⇐ FALSE) until the bidirectional link is re-established (link_status = OK).

115.3.5.4 Link monitor state diagram

Link status shall be determined as specified by the link monitor state diagram in Figure 115–24. The state diagram determines the value of link_status and rem_rcvr_status state variables.

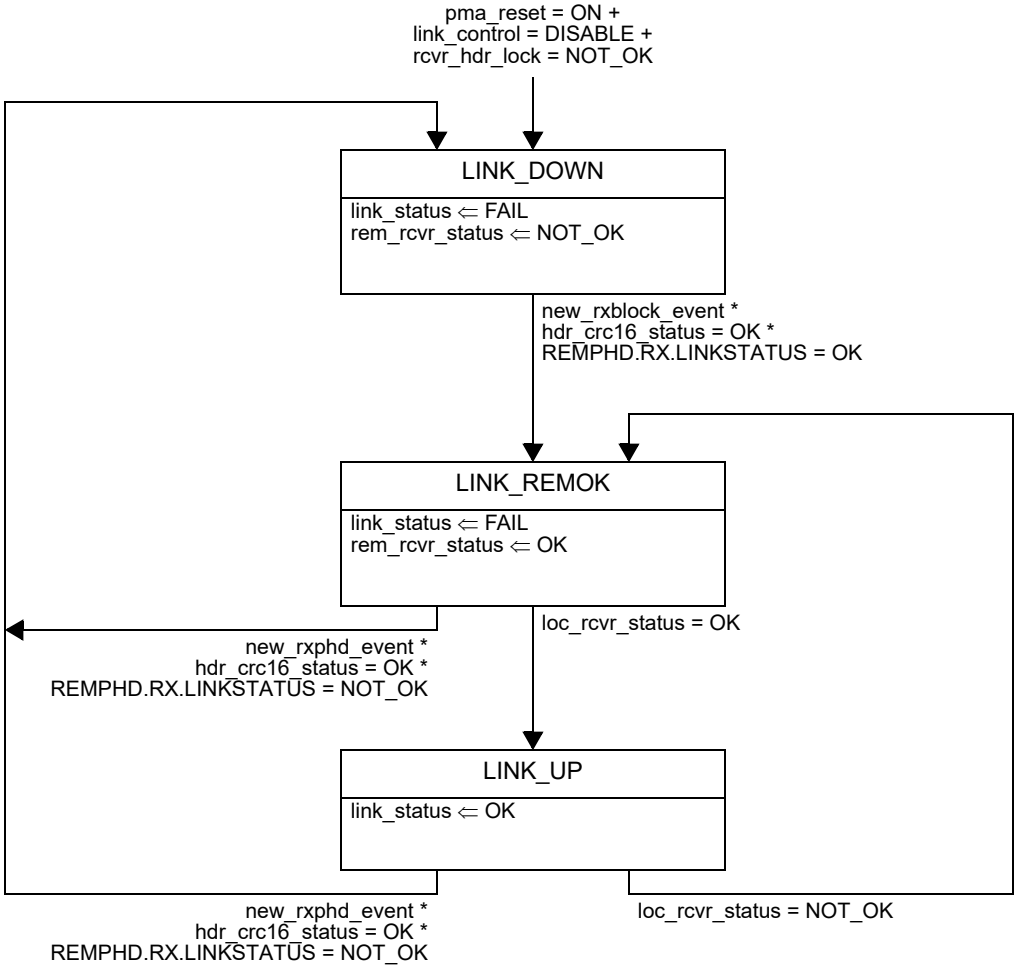

Figure 115–24—Link monitor state diagram

Upon reset, disable of the PMA or unreliable PHD communication, the link is lost (link_status ⇐ FAIL) and the remote receiver status is unknown (rem_rcvr_status ⇐ NOT_OK). When the remote PHY indicates reliable reception (REMPHD.RX.LINKSTATUS = OK), the state diagram transitions to the LINK_REMOK state synchronously on the event of receiving a new Transmit Block (new_rxblock_event). Once in this state, the bidirectional link is established (link_status ⇐ OK) when local reliable reception is signaled by the PHY quality monitor state diagram (loc_rcvr_status = OK).

If the local PHY fails to receive payload data sub-blocks with reliability (loc_rcvr_status = NOT_OK) but the remote PHY reception is indicated as reliable (REMPHD.RX.LINKSTATUS = OK), the bidirectional link is lost and the state diagram transitions to LINK_REMOK state that waits for the local receiver reliability is recovered. If the remote PHY receiver indicates that it does not operate with reliability (REMPHD.RX.LINKSTATUS = NOT_OK), the bidirectional link is lost and the state diagram transitions to LINK_DOWN state in any case.

115.3.5.5 PHD monitor state diagrams

The reliability of PHD reception and transmission shall be determined by the PHD monitor state diagrams in Figure 115–25, Figure 115–26, and Figure 115–27.

The local PHD reception monitor state diagram of Figure 115–25 monitors the PHD reception reliability for the local PHY and indicates it via the variable loc_rcvr_hdr_lock. Upon reset or disable of the PMA, or if the local PHY fails to reliably receive PHDs (loc_rcvr_hdr_lock ⇐ NOT_OK), this is indicated to the link partner by assigning NOT_OK to the field LOCPHD.RX.HDRSTATUS. In the state LOCHDR_UNLOCK, the receiver waits for reception of a valid PHD (i.e., one with correct CRC16) on entry, and the variable hdr_fail_count (the count of contiguous PHDs received with errors) is reset (hdr_fail_count ⇐ 0).

In LOCHDR_UNLOCK, reception of one correct PHD triggers the transition to the state LOCHDR_LOCK. On entry to LOCHDR_LOCK the variable loc_rcvr_hdr_lock and the field LOCPHD.RX.HDRSTATUS are assigned the value OK. The PHY keeps checking the CRC16 of received PHDs, incrementing hdr_fail_count with each erroneous PHD (in state LOCHDR_EVAL_FAIL) and resetting hdr_fail_count with each valid PHD (in state LOCHDR_EVAL_RESET). If hdr_fail_count reaches the limit of 2, or the clock recovery function detects that the PHY has lost synchronization, then the state transitions back to LOCHDR_UNLOCK.

The remote PHD reception monitor state diagram of Figure 115–26 monitors PHD reception reliability reports from the remote PHY and indicates the status via the variable rem_rcvr_hdr_lock. Upon reset, disable of the PMA or unreliable local PHD reception, the status variable rem_rcvr_hdr_lock is assigned the value NOT_OK pending the arrival of a new PHD from the link partner (REMHDR_WAIT state). From then on, the value of the variable rem_rcvr_hdr_lock is updated with the value of the field REMPHD.RX.HDRSTATUS (rem_rcvr_hdr_lock ⇐ REMPHD.RX.HDRSTATUS).

The PHD monitor state diagram of Figure 115–27 indicates via the variable rcvr_hdr_lock if both link partners are reliably receiving PHDs. Upon reset or disable of the PMA, the PHD communication is unreliable (rcvr_hdr_lock ⇐ NOT_OK). Whenever a new PHD is received from the link partner, the status of both the local (variable loc_rcvr_hdr_lock) and remote (variable rem_rcvr_hdr_lock) PHD reception are updated as indicated in Figure 115–25 and Figure 115–26, respectively.

A transition from the HDR_UNLOCK state to the HDR_LOCK state takes place when both the local and the remote PHYs are reliably receiving PHDs (loc_rcvr_hdr_lock = OK and rem_rcvr_hdr_lock = OK). The value OK is then assigned to the variable rcvr_hdr_lock to signal the reliable transmission and reception of PHDs. Subsequently, if either of the link partners fail to receive PHDs reliably (loc_rcvr_hdr_lock = NOT_OK or rem_rcvr_hdr_lock = NOT_OK), a transition to HDR_UNLOCK occurs resulting in assigning NOT_OK to the rcvr_hdr_lock variable.

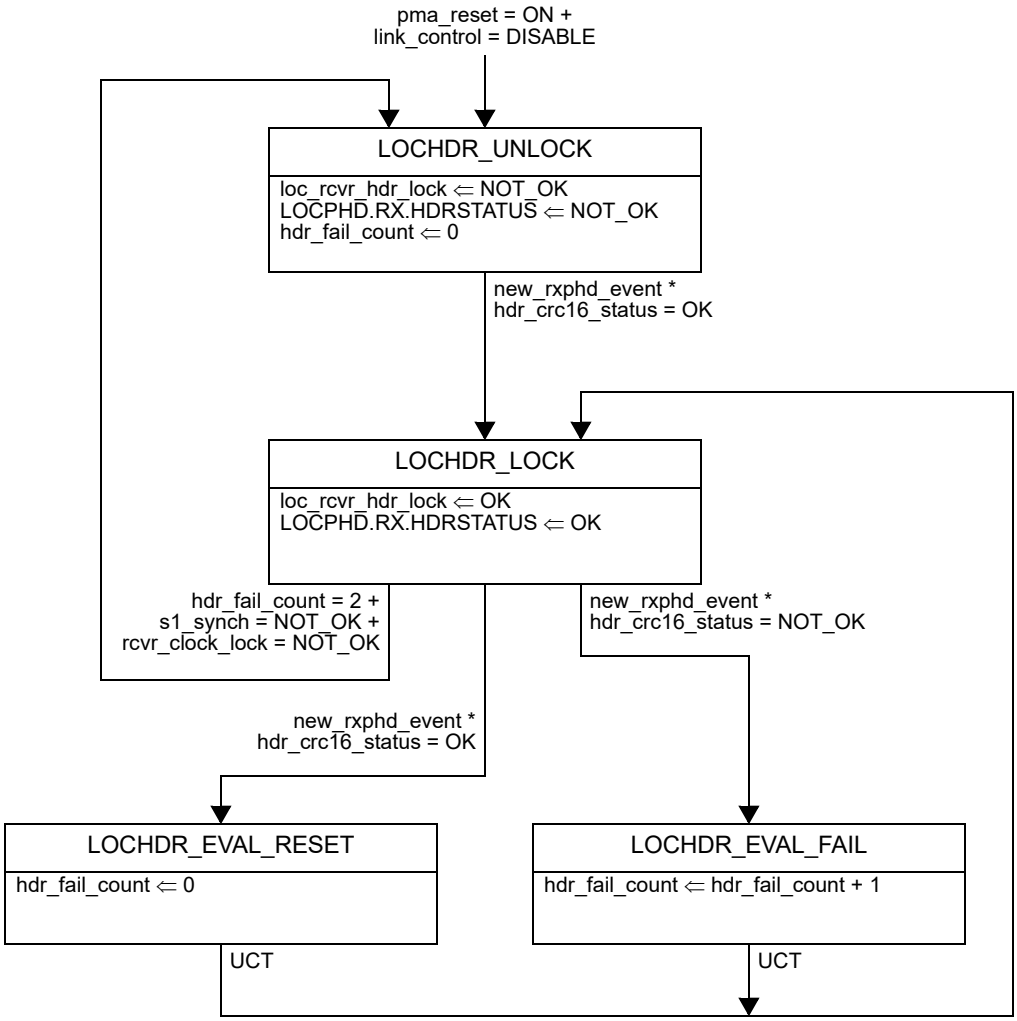

Figure 115–25—Local PHD reception monitor state diagram

115.3.6 Adaptive THP protocol

The receiver estimates the coefficients (see 115.3.2) that are used by the remote PHY transmitter for THP processing of the payload data sub-blocks [coefficients $c(i)$ in 115.3.1.1]. The state diagrams that control THP coefficients allow for dynamic adaptation of the coefficients before and after the link is established. The PHY receiver may dynamically determine variations in the channel response and request the partner to use a new set of THP coefficients. The methods to determine the channel response variation and estimate THP coefficients are implementation dependent.

The local receiver assigns a set identifier (integer number higher than 0 and lower than 4) to each new estimation to unambiguously identify it, and uses it to request the remote transmitter to apply a given set of coefficients for THP by using the field LOCPHD.RX.REQ.THP.SETID. The set of coefficients itself is sent to the link partner by using the fields LOCPHD.RX.REQ.THP.COEF[8:0].

Once the local receiver has performed the request, it waits until the remote transmitter signals via REMPHD.TX.NEXT.THP.SETID that payload data in the next Transmit Block is THP processed with the

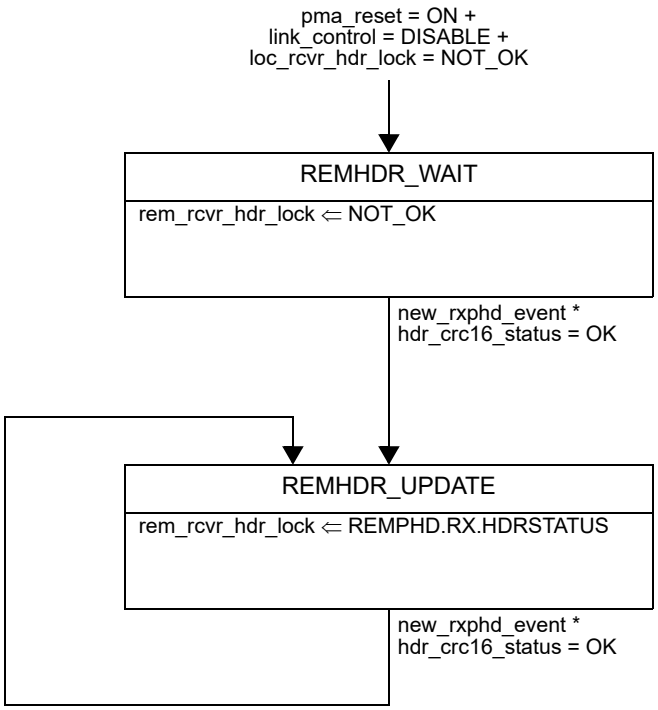

Figure 115–26—Remote PHD reception monitor state diagram

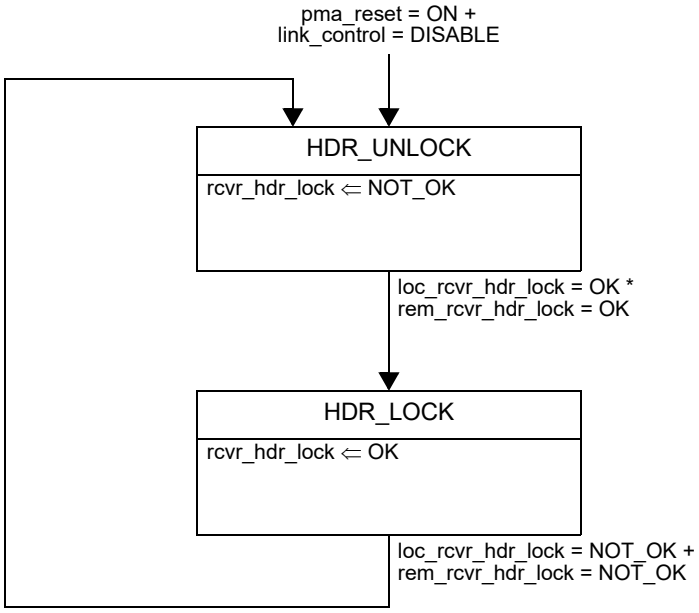

Figure 115–27—PHD monitor state diagram

requested set of coefficients. From then on, the local receiver adapts its circuitry according to the THP coefficients used at the remote transmitter and is allowed to perform a new request to change them.

A formal definition of the THP coefficients adaptation protocol is provided in the form of state diagrams in the following subclauses.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.3.6.1 Adaptive THP state variables

The following defines all the variables used in the adaptive THP state diagrams that have not been previously introduced:

est_thp_coef
: Variable set by the PHY receiver that contains the coefficients estimated to compensate inter-symbol interference by means of Tomlinson-Harashima Precoding. est_thp_coef is a set of 9 real numbers.
Values: Real numbers that take values such that $-2 \le$ est_thp_coef $< +2$

loc_thp_coef
: Variable set by the adaptive THP TX state diagram. It contains the local coefficients used by the PHY for THP processing of payload data sub-blocks. loc_thp_coef is a set of 9 real numbers representing the coefficients of the feedback filter of THP [$c(i)$ in 115.3.1.1].
Values: Real numbers that take values such that $-2 \le$ loc_thp_coef $< +2$

new_thp_coef_event
: Signal sent by the PHY receiver to indicate the estimation of a new set of THP coefficients is available. This event persists only long enough to cause one state diagram transition.

new_txblock_event
: Signal sent by the PHY transmitter to indicate the start of a new Transmit Block. This event persists only long enough to cause one state diagram transition.

req_thp_coef
: Variable set by the adaptive THP TX state diagram when a correct PHD is received. This variable holds the coefficients requested by the link partner to be used for THP processing of the payload data sub-blocks. req_thp_coef is a set of 9 real numbers in fixed-point format (see 115.3.8) as the fields REMPHD.RX.REQ.THP.COEF[8:0].
Values: Real numbers that take values such that $-2 \le$ req_thp_coef $< +2$

req_thp_setid
: Variable set by the adaptive THP TX state diagram when a correct PHD is received. It is the set identifier assigned to the THP coefficients requested by the link partner.
Values: 0: No request to change the THP coefficients
1, 2, 3: Requested set identifier

thp_coef
: Variable set by the adaptive THP REQ state diagram to store the last THP coefficients requested to the link partner. thp_coef is a set of 9 real numbers.
Values: Real numbers that take values such that $-2 \le$ thp_coef $< +2$

thp_setid
: Variable set by the adaptive THP REQ state diagram to store the last THP set identifier requested to the link partner.
Values: 0: Reset value
1, 2, 3: Set identifier

115.3.6.2 Adaptive THP TX state diagram

The update of the THP filter coefficients per link partner requests shall conform to the Adaptive THP TX state diagram in Figure 115–28.

Upon reset, disable of the PMA or unreliable PHD communication, transmitted payload data is no longer THP processed (THPTX_DISABLE state). This causes THP coefficients to be set to zero (loc_thp_coef $\Leftarrow$ 0) and the field LOCPHD.TX.NEXT.THP.SETID is assigned the value 0 to indicate to the remote PHY that THP is disabled.

Once the transmission and reception of PHDs are reliable (rcvr_hdr_lock = OK), the local PHY waits for a request to adapt its THP coefficients from the link partner (THPTX_WAITFOR_REQ state).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

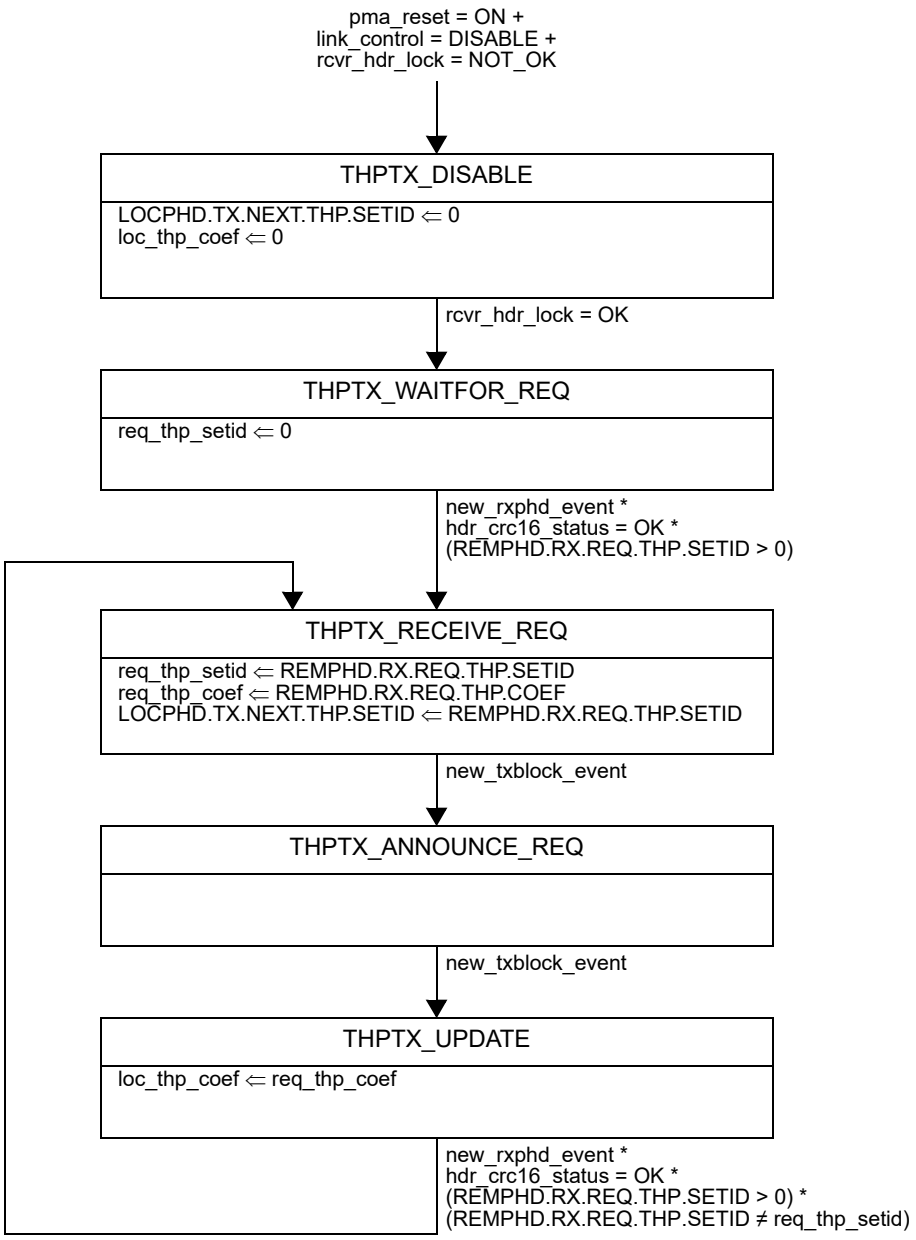

Figure 115–28—Adaptive THP TX state diagram

As soon as the value of the field REMPHD.RX.REQ.THP.SETID is not equal to zero, the field REMPHD.RX.REQ.THP.COEF also contains a THP coefficients adaptation request from the link partner. The local PHY stores both the set identifier associated with the request (req_thp_setid ⇐ REMPHD.RX.REQ.THP.SETID) and the requested coefficients (req_thp_coef ⇐ REMPHD.RX.REQ.THP.COEF). This corresponds to the state THPTX_RECEIVE_REQ.

Triggered with the start of a new Transmit Block a transition to THPTX_ANNOUNCE_REQ occurs, where the local PHY announces that requested coefficients are to be used (LOCPHD.TX.NEXT.THP.SETID ⇐ req_thp_setid assignment of previous state).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

After the announcement, the start of another new Transmit Block triggers the state transition to THPTX_UPDATE, and payload data sub-blocks of Transmit Blocks are then THP processed with the requested set of coefficients (loc_thp_coef ⇐ req_thp_coef) until a request to change THP coefficients from the link partner becomes effective. This happens when the value of the field REMPHD.RX.REQ.THP.SETID is not equal to zero and is different from the value of the variable req_thp_setid, and the new set of coefficients is stored, announced, and applied as previously explained.

115.3.6.3 Adaptive THP REQ state diagram

The requests to the link partner to update the THP filter coefficients shall conform to the Adaptive THP REQ state diagram in Figure 115–29.

Upon reset, disable of the PMA or unreliable PHD communication, the local PHY is not able to receive THP processed payload data sub-blocks (rcvr_thp_lock ⇐ NOT_OK). This is signaled to the remote PHY by assigning 0 to the field LOCPHD.RX.REQ.THP.SETID.

Once the transmission and reception of PHDs are reliable (rcvr_hdr_lock = OK) and the first set of THP coefficients are ready from the estimator (new_thp_coef_event) a transition to THPREQ_STORE occurs.

In this state, the newly estimated coefficients are stored (thp_coef ⇐ est_thp_coef) and assigned a set identifier. The set identifier is calculated based on the identifier previously requested as thp_setid ⇐ mod(thp_setid, 3) + 1, with modulo operator as defined in Equation (115–4).

The request for changing the set of THP coefficients is included in the next Transmit Block PHD (transition to THPREQ_REQUEST state). More precisely, the field LOCPHD.RX.REQ.THP.SETID indicates the associated set identifier, and the set of coefficients itself is transmitted by using the field LOCPHD.RX.REQ.THP.COEF[8:0].

In THPREQ_REQUEST, the local PHY receiver waits for the link partner to signal that the THP request has been accepted (the link partner starts using the requested coefficients for THP processing on its next Transmit Block). Once this event occurs (new_rxphd_event and hdr_crc16_status = OK and REMPHD.TX.NEXT.THP.SETID = thp_setid), a transition to THPREQ_WAITFOR_RX follows.

In THPREQ_WAITFOR_RX, the PHY receiver waits for the next Transmit Block received from the link partner. Once this event occurs, a transition to THPREQ_UPDATE is taken, where the value OK is assigned to the state variable rcvr_thp_lock, indicating that payload data sub-blocks are received with THP processing. In the THPREQ_UPDATE state the PMA receiver also adapts its circuitry to match the THP coefficients used at the remote transmitter.

Whenever a new set of THP coefficients from the estimator is available, it is stored and requested as explained previously. The local PHY receiver is not allowed to make a new THP request until the previous THP request has been acknowledged by the link partner, even if a new set of coefficients is available from the estimator.

115.3.7 PHY quality monitor

115.3.7.1 PHY quality criterion

Payload data reception is reliable when the BCH frame error ratio (BFER) is less than 8.8×10^{-11} after BCH decoding.

Copyright © 2022 IEEE. All rights reserved.

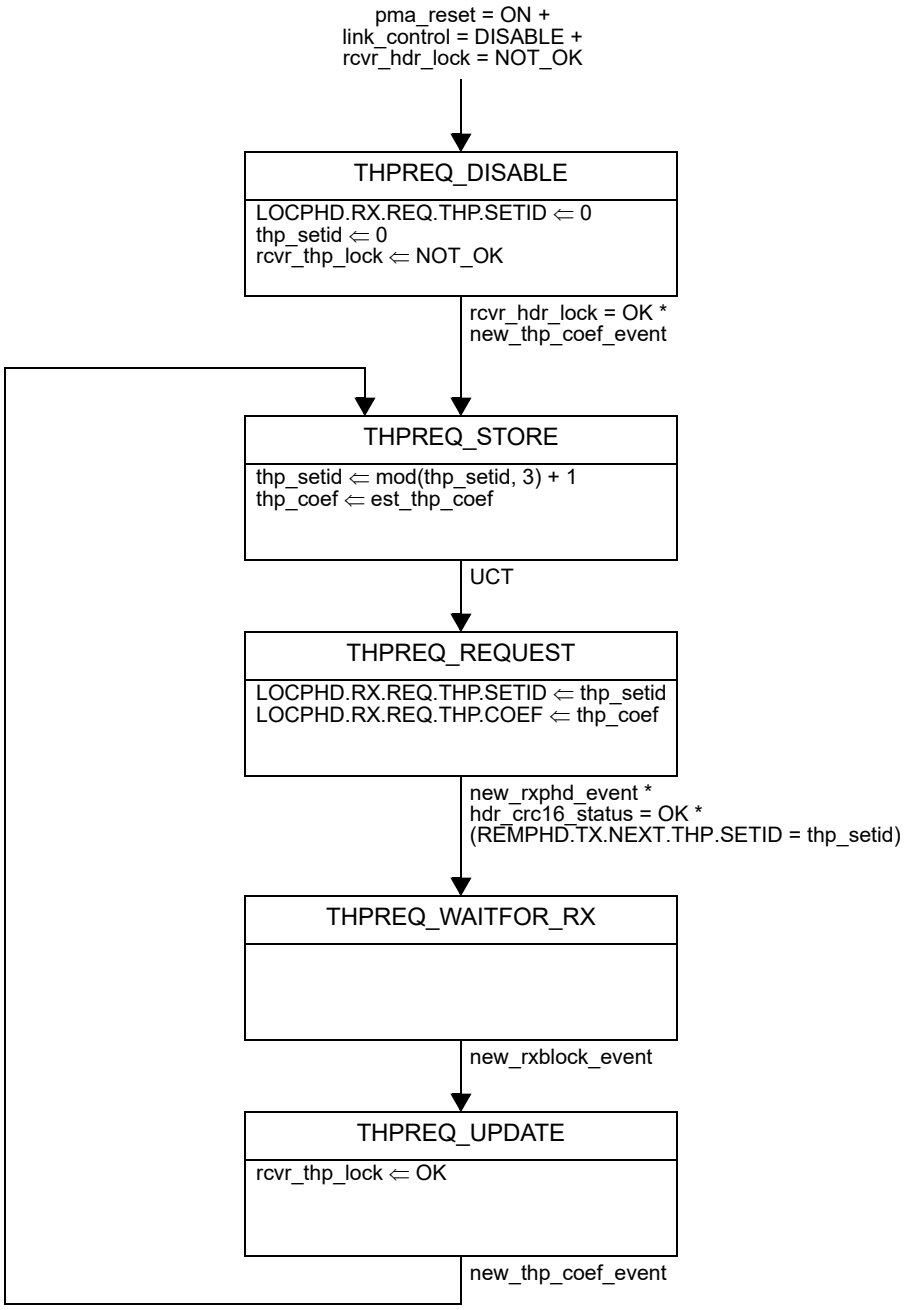

Figure 115–29—Adaptive THP REQ state diagram

115.3.7.2 PHY quality assessment

The assessment of the previously defined PHY quality criterion may be based on estimation of the noise variance at the PAM16 decoder decision points $E[n_d^2]$, which expressed in base-2 logarithmic units has to be lower than a given threshold T_{LM} to enable reliable local reception of payload data. If the condition $\log_2(E[n_d^2]) < T_{LM}$ holds, the variable loc_rcvr_status is assigned the value OK. The noise variance at the PAM16 decoder can be estimated either by measuring the Modulation Error Ratio (MER) at the decision points or measuring the ratio of corrected bits per codeword carried out by the BCH decoder of MLCC

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

level 1 (see 115.2.4.3). The value of the threshold and the information used to estimate the PAM16 decoder noise variance is implementation dependent.

As defined in 115.3.4, the local PHY reports the link margin to the link partner by using the field LOCPHD.RX.LINKMARGIN. The link margin (*LM*) is defined as the SNR margin relative to the SNR required for reception of coded PAM16 with a quality per the specification in 115.3.7.1. Link margin is formally defined per Equation (115–24).

$$LM = T_{LM} - \log_2(E[n_d^2]) \quad (115–24)$$

In LPI mode of operation, the PHY can use the reception of pilot $S2_x$ sub-blocks contained in the refresh periods to estimate the link margin at the PAM16 decoder decision points.

115.3.7.3 PHY quality monitor state variables

The following defines all the variables used in the PHY quality monitor state diagram that have not been previously introduced:

new_link_margin_event
: Signal sent by the PHY receiver to indicate a new estimation of detector link margin is available. This event persists only long enough to cause one state diagram transition.

link_margin
: Variable set by the PHY receiver containing the value of the last link margin estimation.

  Values: Any value determined per Equation (115–24) with $E[n_d^2]$ and T_{LM} as defined in 115.3.7.2

115.3.7.4 PHY quality monitor state diagram

The variable loc_rcvr_status (see 115.3.5.1), which indicates if the local PHY is reliably receiving payload data per the specifications of 115.3.7.1 shall be determined as specified by the PHY quality monitor state diagram in Figure 115–30.

Upon reset, disable of the PMA or loss of PHD lock, the PHY quality monitor functionality is disabled (PMAMON_DISABLE state), and the state variable loc_rcvr_status is assigned the value NOT_OK. This is indicated to the link partner by assigning the value NOT_OK to the field LOCPHD.RX.LINKSTATUS. Additionally, the reported link margin is set to 0x80 (the smallest value representable in 8-bit signed format, see 115.3.8).

Once the local PHY begins to receive payload data sub-blocks that are properly THP processed (rcvr_thp_lock = OK), the state diagram waits for the first estimate of the link margin to be available (PMAMON_WAITING state). From then on, whenever a new estimate of the link margin is available (new_link_margin_event), it is evaluated. If link margin is larger than zero, the local reception of payload data sub-blocks is reliable.

Reliable local reception is indicated to the link partner by assigning OK to the field LOCPHD.RX.LINKSTATUS (state PMAMON_OK). After at least one locally transmitted Transmit Block, the local receiver status is signaled to the link monitor state diagram (loc_rcvr_status ⇐ OK) synchronously on the event of start of a new Transmit Block (state PMAMON_UPDATE).

Otherwise, when link margin is smaller than or equal to zero, unreliable receive link status is signaled (loc_rcvr_status ⇐ NOT_OK). This corresponds to the state PMAMON_FAIL. The local receiver status is always indicated to the link partner by using the field LOCPHD.RX.LINKSTATUS. The measured link margin is also reported via the field LOCPHD.RX.LINKMARGIN.

115.3.8 Fixed-point format formal definition

The notation (m, n) is used to represent an m-bit binary word, which is to be interpreted as a signed twos complement fixed-point rational, where n is the number of bits used to represent the integer part (sign bit included) and (m – n) bits are used to represent the fractional part. Given an m-bit binary word, it is assumed that $1 \leq n \leq m$.

Any 1000BASE-H compliant PHY shall conform to the fixed-point encoding and the fixed-point decoding provided by the codes in 115.3.8.1 and 115.3.8.2, respectively, for the fixed-point representation of Clause 45 registers and PHD fields (see 115.3.4).[199, 200]

115.3.8.1 Fixed-point encoding

```
% Parameters:
%      fdata: Row data vector in floating-point format
%      m    : Word length # of bits
%      n    : Integer part # of bits, including sign
%      rdata: Fixed-point format data vector

function rdata = float2fix(fdata, m, n)
  bdata = round(fdata*2^(m-n));
  bdata = min(bdata, 2^(m-1) - 1);
  bdata = max(bdata, -2^(m-1));
  idx_n = find(bdata < 0);
  rdata = bdata;
  rdata(idx_n) = 2^m + rdata(idx_n);
  rdata = bitand(rdata, 2^m - 1);
end
```

115.3.8.2 Fixed-point decoding

```
% Parameters:
%      rdata: Row data vector in fixed-point format
%      m    : Word length # of bits
%      n    : Integer part # of bits, including sign
%      fdata: Floating-point format data vector

function fdata = fix2float(rdata, m, n)
  % Sign extension
  bdata = bitand(rdata, 2^m - 1);
  idx_n = find(bitand(bdata, 2^(m-1)) ~= 0);
  bdata(idx_n) = bdata(idx_n) - 2^m;

  % Fix to float conversion
  fdata = bdata / (2^(m - n));
end
```

115.4 Energy-Efficient Ethernet (EEE)

Each PHY shall advertise its EEE ability to the link partner in the field PHD.CAP.LPI (see Table 115–6). PHD.CAP.LPI = 1 advertisement indicates to the link partner that the local PHY can generate Transmit Blocks as specified for the LPI mode of operation, it is able to accept Transmit Blocks from the link partner that conform to LPI operation (see 45.2.3.54.15), and that EEE is enabled (see 45.2.3.53.4).

EEE shall be operational only when both link partners indicate PHD.CAP.LPI = 1. If either link partner PHY does not advertise EEE ability (PHD.CAP.LPI = 0), then the link operates in normal mode in both

[199]This code is written in the MATLAB programming language (see 1.3); however, use of this language does not indicate an endorsement of MATLAB by IEEE and, as such, any tool can be used to perform this calculation.

transmit and receive directions even if "Assert LPI" encoding is detected on the GMII. When two link partners do not agree on enabling EEE capability, the PCS encoding transparently carries the LPI signaling GMII to GMII, but the PHY does not enter LPI mode.

As shown in Figure 115–31, 1000BASE-H LPI mode consists of alternating refresh and quiet periods. Refresh is provided by transmitting all the pilot S1, pilot $S2_x$, and PHS_x sub-blocks; and quiet is provided by suspending transmission of the payload data sub-blocks. In quiet periods, the local PHY may turn off much of the PCS, PMA, and PMD transmitter. No optical power is injected into the fiber during these periods of quiet resulting in reduced power consumption. LPI mode is only entered or exited aligned to the beginning of a payload data sub-block.

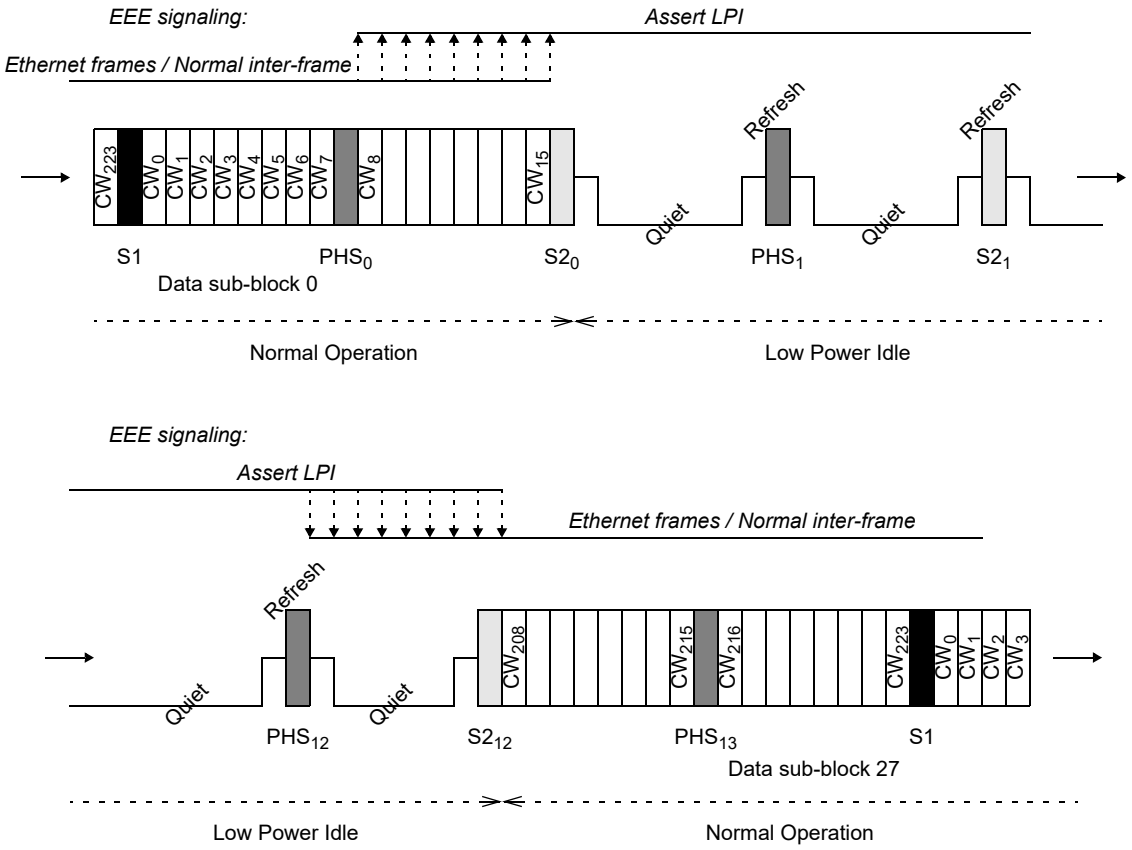

Figure 115–31— LPI operation

Pilot and PHS_x sub-blocks serve as refresh signals allowing the receiver to update adaptive filters and timing circuits in order to maintain link integrity. These sub-blocks are generated as in normal mode (see 115.2.1).

The PHY receiver detects if its link partner is operating in LPI mode based on the received signal at the beginning of each payload data sub-block. The PHY transmitter indicates to its link partner that it is entering a quiet period by the transmission of 130 contiguous zero value symbols. These follow the normal 16 zero postfix of the pilot or PHS_x sub-block. The extra zero symbols are used by the remote PHY receiver to detect that a quiet period follows, allowing the PMD receive function to save the state of circuitry and switch off the optical signal translation before the optical power is switched off at the transmitter. The transmitter then enters its quiet state until 130 symbol times before the end of the payload data sub-block, where the transmitter inserts 130 zero value symbols before the transmission of the pilot or PHS_x sub-block. This allows the link partner to prepare for reception of the sub-block that acts as a refresh signal.

115.4.1 LPI mode transmit operation

The transmit operation of a 1000BASE-H compliant PHY in LPI mode produces alternating quiet and refresh periods as shown in Figure 115–31. LPI operating mode shall only be entered once the link has been established (link_status = OK). When an "Assert LPI" transfer occurs on the GMII, the local PCS encodes the "Assert LPI" signal into a PDB as defined in Table 115–2.

The PHY transmitter shall enter LPI mode at the beginning of the next payload data sub-block, once a PDB that contains an encoded "Assert LPI" has been completely transmitted to its link partner, unless the GMII signals normal inter-frame before the end of the current payload data sub-block.

The PHY transmitter shall be enabled periodically to transmit pilot and PHS_x sub-blocks (refresh signals) at the same time as they would be transmitted in normal operating mode.

During LPI mode, the transmitter shall replace any payload data sub-block with the following:

a) Transmission of 130 zero symbols, to indicate entry to quiet (pcspma_tx = ON, see 115.4.3)
b) No output optical power during 7644 symbols (quiet, pcspma_tx = OFF)
c) Transmission of 130 zero symbols, to prepare the remote receiver for pilot and PHS_x sub-blocks used as refresh signals (pcspma_tx = ON)

The PHY transmitter shall exit LPI mode and resume normal operation at the start of the next payload data sub-block after the reception of normal inter-frame transfers on the GMII.

The 64B/65B encoder shall preserve timing during quiet mode. The time alignment of transmitted PDBs relative to FEC codewords when the PHY re-enters normal operation is the same as it would have been in the absence of LPI mode. This preserves the PCS decoder synchronization of the link partner and coherence with information encoded in the field PHD.TX.NEXT.PDB.OFFSET.

The payload data binary scrambler of 115.2.4.2, and the payload data symbol scrambler of 115.2.4.4 shall preserve timing during quiet mode. When the PHY re-enters normal operation, the scramblers values are the same as they would have been in the absence of LPI mode.

Unlike some other EEE PHYs, neither sleep nor wake specific signals are used to enter and leave the LPI mode of operation. Instead, sleep is indicated to the link partner by the transmission of 130 zero symbols that replace the beginning of a payload data sub-block. Wake is implicit in the presence of normal PAM16 Tomlinson-Harashima precoded signal at the beginning of a payload data sub-block.

115.4.2 LPI mode receive operation

The receive operation of a 1000BASE-H compliant PHY in LPI mode processes alternating quiet and refresh periods as shown in Figure 115–31.

The PHY receiver shall enter LPI mode upon detection of a sequence of zero symbols instead of PAM16-THP signal at the beginning of a payload data sub-block, consequently encoding "Assert LPI" in GMII transfers. Some receive functionality may be disabled to reduce power consumption.

NOTE—"Assert LPI" can also be encoded on the GMII receive stream due to the reception of PDBs containing LPI signaling from the link partner (this, for example, is the case of LPI assertion on the GMII transmit stream in the middle of a payload data sub-block transmission).

In LPI mode, the PHY receiver can use received pilot S1, pilot $S2_x$, and PHS_x sub-blocks, periodically sent by the link partner, to update adaptive coefficients and timing circuits and to determine the values of state variables loc_rcvr_status and link_margin.

The PHY receiver shall exit the LPI mode upon detection of PAM16-THP signal at the beginning of a payload data sub-block, returning to normal operation and sending the received payload to the GMII. The 64B/65B decoder shall resume normal operation after LPI mode, starting aligned to the boundary of the first complete PDB received from the beginning of the payload data sub-block. At this PDB, the local PHY begins to send normal inter-frame encoding on the GMII, since this is the initial information received from the remote PHY and the link returns the nominal operational mode.

115.4.3 PMD power control state variables

The following defines all the variables used in PMD power control state diagrams that have not been previously introduced:

lpi_cap
: Controls LPI functionality.
Values: TRUE: Both local and remote PHY have EEE ability and EEE functionality is enabled in both PHYs
FALSE: Either local or remote PHY do not have EEE ability or it is disabled

pcspma_tx
: State variable that indicates the symbols transmission from PMA.
Values: ON: Enable PCS and PMA transmit (during normal operation or LPI refresh periods)
OFF: Disable PCS and PMA transmit (LPI quiet periods)

pcspma_rx
: State variable that indicates the symbols reception by PMA.
Values: ON: Enable PCS and PMA receive (during normal operation or LPI refresh periods)
OFF: Disable PCS and PMA receive (LPI quiet periods)

rx_pwr
: Controls the PMD receive function.
Values: ON: The PMD receive function receives signal at MDI and transfer to the PMA receiver
OFF: The PMD receive function ignores signal at the MDI, saves the internal state of the circuitry, and may reduce power consumption

sd_inh
: Indicates to the PMD signal detect function to be, or not, inhibited.
Values: TRUE: The PMD signal detect function is inhibited
FALSE: The PMD signal detect function operates normally

tx_pwr
: Controls the PMD transmitter.
Values: ON: The PMD generates signal at the MDI
OFF: The PMD does not generate signal at the MDI, and may reduce power consumption

115.4.4 PMD power control state diagrams

Power control of PMD transmit function via tx_pwr shall conform to the PMD TX power control state diagram in Figure 115–32. Power control of PMD receive function via rx_pwr and sd_inh shall conform to the PMD RX power control state diagram in Figure 115–33.

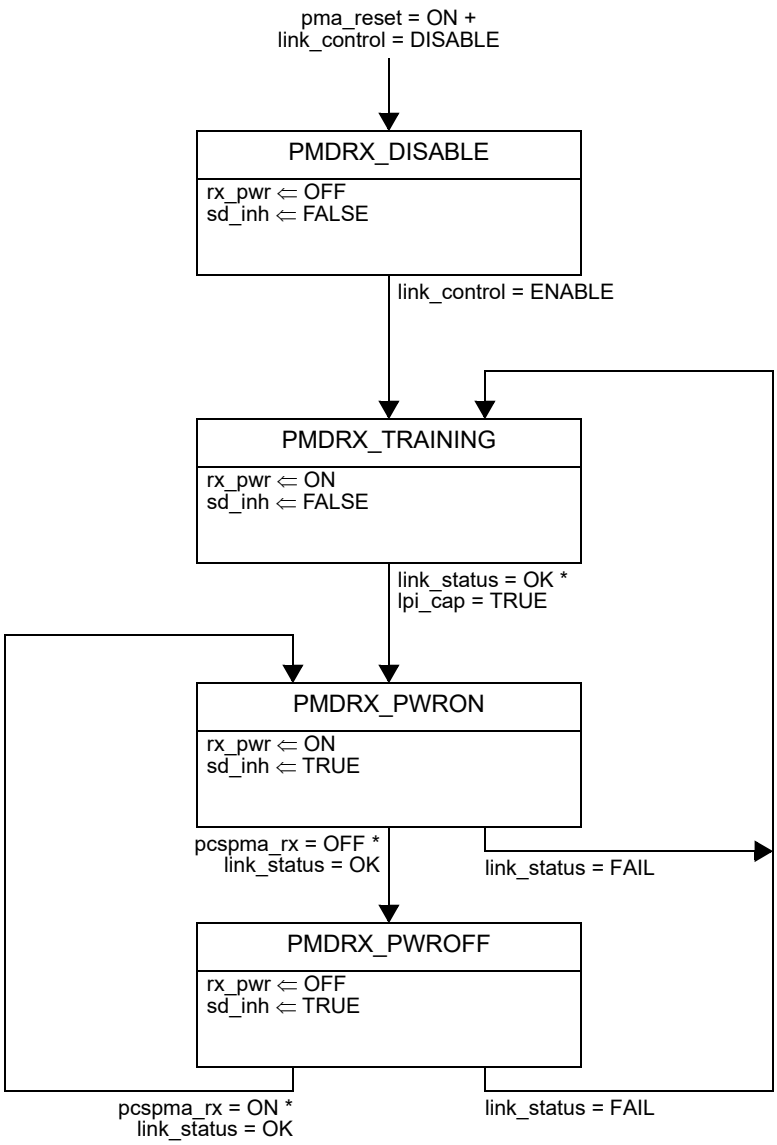

Figure 115–33—PMD RX power control state diagram

115.5 Test modes

The test mode 1 through test mode 6 shall be provided to allow PMD optical measurement requirements defined in 115.6.4 and BER testing.

These test modes shall be configured by setting the 1000BASE-H PCS control register, operation mode bits defined in 45.2.3.53. The test modes only change the symbols provided to the transmitter circuitry and do not alter the optical and jitter characteristics at the MDI from those of normal (non-test mode) operation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.5.1 Test mode 1

Test mode 1 is for measurement of the bit error ratio (BER) of the link including the PCS, PMA, and PMD sublayers of two PHYs in the 1000BASE-H set and a fiber optic cable connected to them. This mode reuses the normal (non-test) mode with a zero data stream.

Operating in this test mode, the PHY shall configure the PCS transmitter to input an all zeros bit stream to the binary scrambler and ignore GMII. In the absence of errors, a zero data sequence is expected after the receiver binary descrambler. Any non-zero data bit received shall be counted as an error to be computed in the BER. The 64B/65B encoder is not used when the PCS transmitter is configured in test mode 1.

PMA and PMD functions shall operate as in normal mode (non-test) establishing the bidirectional link independent of the special configuration of the binary scrambler in PCS.

The PHY shall announce to the link partner the test mode 1 using the field PHD.TX.NEXT.MODE (see 115.3.4). The operating mode of the transmitter encoded in the field PHD.TX.NEXT.MODE is selected at PMA reset, and does not change value unless a PMA reset takes place. The receiver shall reconfigure its circuitry to support the signaled operating mode, for normal operation (the 64B/65B decoder is connected to the binary descrambler), or for BER test (a counter connected to the binary descrambler).

115.5.2 Test mode 2

When test mode 2 is enabled, the PMA shall transmit one {+1} symbol followed by one {–1} symbol continually with the transmitted symbols timed from its local symbol clock. The resulting transmitter output signal is a 162.5 MHz square wave.

115.5.3 Test mode 3

When test mode 3 is enabled, the PMA shall transmit 10 {+1} symbols followed by 10 {–1} symbols continually with the transmitted symbols timed from its local symbol clock. The transmitter output is a 16.25 MHz square wave.

115.5.4 Test mode 4

For test mode 4 definition, let $q1$ be the sub-sequence composed by 20 {+1} symbols followed by 10 {–1} symbols, and $q2$ the sub-sequence composed by 10 {+1} symbols followed by 20 {–1} symbols. When test mode 4 is enabled, the PMA shall transmit a sequence composed by 250 times the sub-sequence $q1$ followed by 250 times the sub-sequence $q2$ continually, being the transmitted symbols timed from its local symbol clock.

115.5.5 Test mode 5

When test mode 5 is enabled, the PMA shall continually transmit {0} symbols timed from its local symbol clock. The transmitter output is a dc signal.

115.5.6 Test mode 6

When test mode 6 is enabled, the PMA shall transmit the sequence of symbols s_n generated by the scrambler generator polynomials per Equation (115–25) and Equation (115–26).

$$g_0(x) = 1 + x^9 + x^{11} \quad (115–25)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$g_1(x) = 1 + x^7 + x^9 + x^{10} + x^{11} \quad (115–26)$$

The two maximum-length shift registers used to generate the sequences defined by these polynomials shall be updated once per symbol interval (nominally 1000/325 ns). The reset value of both shift registers shall be 0x7FF, so the content of both registers start aligned to all ones when the PHY is configured to generate the test mode 6 pattern.

The bits stored in the shift register at a particular time n are denoted $Scr0_n[10:0]$ for the scrambler defined per Equation (115–25). At each symbol period this shift register is advanced by one bit and one new bit represented by $Scr0_n[0]$ is generated. Bits $Scr0_n[10]$ and $Scr0_n[8]$ are exclusive OR'd together to generate the next $Scr0_n[0]$ bit.

The bits stored in the shift register at a particular time n are denoted $Scr1_n[10:0]$ for the scrambler defined per Equation (115–26). At each symbol period this shift register is advanced by one bit and one new bit represented by $Scr1_n[0]$ is generated. Bits $Scr1_n[10]$, $Scr1_n[9]$, $Scr1_n[8]$, and $Scr1_n[6]$ are exclusive OR'd together to generate the next $Scr1_n[0]$ bit.

The bit sequences $x00_n$, $x01_n$, $x02_n$, and $x03_n$ generated from combinations of bits of the two scramblers shall be used to generate the PAM16 symbols, $y0_n$, according to Equation (115–27).

$$\begin{aligned} x00_n &= Scr1_n[0] \\ x01_n &= Scr1_n[1] \wedge Scr0_n[4] \\ x02_n &= Scr1_n[2] \wedge Scr0_n[9] \\ x03_n &= Scr1_n[0] \wedge Scr0_n[10] \\ y0_n &= x00_n + 2 \times x01_n + 4 \times x02_n + 8 \times x03_n \end{aligned} \quad (115–27)$$

The bit sequences $x10_n$, $x11_n$, $x12_n$, and $x13_n$ generated from combinations of bits of the two scramblers shall be used to generate the PAM16 symbols, $y1_n$, according to Equation (115–28).

$$\begin{aligned} x10_n &= Scr0_n[0] \\ x11_n &= Scr0_n[1] \wedge Scr1_n[4] \\ x12_n &= Scr0_n[2] \wedge Scr1_n[9] \\ x13_n &= Scr0_n[0] \wedge Scr1_n[10] \\ y1_n &= x10_n + 2 \times x11_n + 4 \times x12_n + 8 \times x13_n \end{aligned} \quad (115–28)$$

From $y0_n$ and $y1_n$, the PAM256 symbols s_n shall be generated according to Equation (115–29). The transmitter shall time the transmit symbols s_n from its local symbol clock.

$$s_n = \frac{1}{256}(2 \times (16 \times y0_n + y1_n) - 255) \quad (115–29)$$

115.6 Physical Medium Dependent (PMD) sublayer

115.6.1 PMD service interface

The following specifies the services provided by a PMD connected to 1000BASE-H. The PMD sublayer service interface is described in an abstract manner and does not imply any particular implementation.

The PMD service interface supports the exchange of analog signals between PMA and PMD sublayers. The PMD translates the transmit and receive PMA signals to and from optical signals suitable for the specified medium.

The following primitives are defined:

PMD_COMSIGNAL.request
PMD_COMSIGNAL.indication
PMD_TXPWR.request
PMD_RXPWR.request
PMD_RXDETECT.indication
PMD_SDINH.request

115.6.1.1 PMD_COMSIGNAL.request

This primitive defines the transfer of an analog signal amplitude from the PMA to the PMD.

115.6.1.1.1 Semantics of the primitive

PMD_COMSIGNAL.request(tx_signal)

During transmission, this primitive conveys to the PMD via the parameter tx_signal, the amplitude of the output signal to be produced by the PMD transmit function.

115.6.1.1.2 When generated

The PMA generates PMD_COMSIGNAL.request(tx_signal) synchronously with every transmit clock cycle.

115.6.1.1.3 Effect of receipt

Upon receipt of this primitive the PMD converts tx_signal into the MDI optical signal (see 115.6.2.2).

115.6.1.2 PMD_COMSIGNAL.indication

This primitive defines the transfer of an analog signal amplitude from the PMD to the PMA.

115.6.1.2.1 Semantics of the primitive

PMD_COMSIGNAL.indication(rx_signal)

This primitive conveys to the PMA via the parameter rx_signal the relative amplitude of the optical signal received by the PMD at the MDI (see 115.6.2.3).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.6.1.2.2 When generated

The PMD_COMSIGNAL.indication(rx_signal) is continuously generated by the PMD in the form of an analog signal.

115.6.1.2.3 Effect of receipt

Upon receipt of this primitive the PMA performs clock recovery for correct time sampling of received symbols and adaptive channel equalization (see 115.3.2).

115.6.1.3 PMD_TXPWR.request

This primitive is used for optional EEE capability. The primitive is generated to request no optical output power during quiet periods of LPI mode, or to request optical signal being generated at the MDI during refresh periods of LPI mode or for normal operation of the PHY transmitter.

115.6.1.3.1 Semantics of the primitive

PMD_TXPWR.request(tx_pwr)

The tx_pwr parameter can take one of the two values: ON or OFF.

ON: The PMD transmit function generates signals at the MDI.

OFF: The PMD transmit function does not generate signal at the MDI.

115.6.1.3.2 When generated

The PMD_TXPWR.request(tx_pwr) is generated by the PMA transmitter whenever the value of tx_pwr changes as specified by the state diagram of Figure 115–32 (see 115.4.4).

115.6.1.3.3 Effect of receipt

PMD_TXPWR.request(OFF) requests the PMD transmit function to produce no optical output power, and PMD_COMSIGNAL.request(tx_signal) is ignored.

PMD_TXPWR.request(ON) requests the PMD transmit function to respond to PMD_COMSIGNAL.request(tx_signal) with generation of normal optical output.

115.6.1.4 PMD_RXPWR.request

This primitive is used for optional EEE capability. It is generated to request the PMD receive function to transition between being able to respond to received optical signals and a minimum power consumption state.

115.6.1.4.1 Semantics of the primitive

PMD_RXPWR.request(rx_pwr)

The rx_pwr parameter can take one of two values: ON or OFF.

ON: The PMD receive function responds to the received MDI optical signal.

OFF: The PMD receive function ignores the received MDI optical signal.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.6.1.4.2 When generated

The PMD_RXPWR.request(rx_pwr) is generated by the PMA receiver whenever the value of rx_pwr changes as specified by the state diagram of Figure 115–33 (see 115.4.4).

115.6.1.4.3 Effect of receipt

PMD_RXPWR.request(OFF) requests the PMD receive function to ignore the received MDI signal and reduce power consumption.

PMD_RXPWR.request(ON) requests the PMD receive function to respond to the received MDI signal.

115.6.1.5 PMD_RXDETECT.indication

This primitive is generated by the PMD signal detect function to indicate the status of the receive optical signal from the MDI as specified in 115.6.2.4.

115.6.1.5.1 Semantics of the primitive

PMD_RXDETECT.indication(signal_detect)

The signal_detect parameter can take one of two values: OK or FAIL, indicating whether the PMD is detecting average optical power over a threshold (see 115.6.2.4) at the receiver (OK) or not (FAIL). When signal_detect = FAIL, then the rx_signal is undefined.

NOTE—signal_detect = OK does not guarantee that rx_signal provides high enough quality to allow the PHY to establish the link. It just indicates that average optical power present at the MDI exceeds a threshold. A signal_detect = OK indication with sufficient average optical power allows the PHY partners to start establishing the link and still not meet the BFER objective (see 115.3.7.1), then the PHY indicates link_status = FAIL.

115.6.1.5.2 When generated

The PMD signal detect function generates this primitive to indicate a change in the value of signal_detect.

115.6.1.5.3 Effect of receipt

PMD_RXDETECT.indication(OK) indicates that the PMD receive function is able to respond to PMD_RXPWR.request primitives (that request the PMD receive function to respond or not to the MDI signal). PMD_RXDETECT.indication(OK) also indicates to the PMA receive function that optical signal is being received from the MDI and that the link may be established with a link partner. PMD_RXDETECT.indication(OK) may be used to wake up from deep sleep in a system that includes a 1000BASE-RHx PHY.

PMD_RXDETECT.indication(FAIL) indicates the PMD receive function is not responding to the received MDI signal. PMD_RXDETECT.indication(FAIL) also indicates to the PMA receive function that optical signal is not being received so link establishment cannot be initiated. PMD_RXDETECT.indication(FAIL) may be used to transition a system that includes a 1000BASE-RHx PHY into deep sleep.

115.6.1.6 PMD_SDINH.request

This primitive supports EEE operation and is generated to request enable or inhibit of the PMD signal detect function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.6.1.6.1 Semantics of the primitive

PMD_SDINH.request(sd_inh)

The sd_inh parameter can take one of the two values: TRUE or FALSE.

TRUE: The PMD signal detect function is inhibited.

FALSE: The PMD signal detect function responds to the received MDI optical signal.

115.6.1.6.2 When generated

The PMD_SDINH.request(sd_inh) is generated by the PMA receiver whenever the value of sd_inh changes as specified by the state diagram of Figure 115–33 (see 115.4.4).

115.6.1.6.3 Effect of receipt

PMD_SDINH.request(FALSE) requests normal PMD signal detect operation.

PMD_SDINH.request(TRUE) requests the PMD signal detect function to inhibit processing of the received optical signal. This keeps PMD_RXDETECT.indication(signal_detect) = OK, independently of optical signal level received at MDI.

115.6.2 PMD functional specifications

115.6.2.1 PMD block diagram

For purpose of system conformance, the PMD sublayer is defined at the following points, depicted in Figure 115–34. The optical transmit signal is defined at the output end of 1 meter of plastic optical fiber consistent with the link segment type connected to the MDI. All the specified transmitter measurements are made at TP2. The optical receive signals are specified and measured at the output of the fiber optic cabling (TP3), which in a link segment is connected to the receiver.

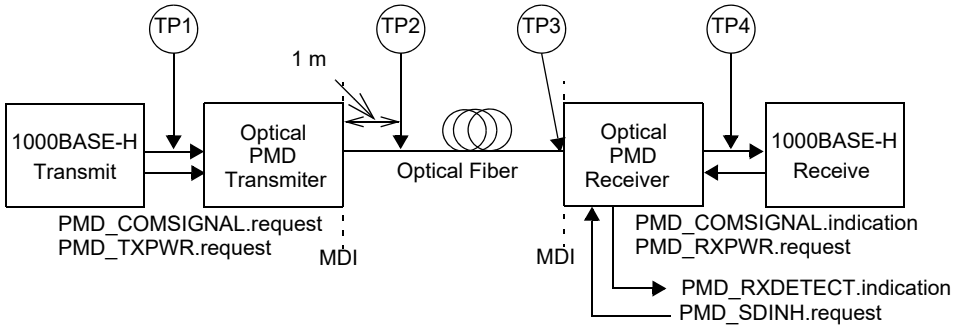

Figure 115–34—1000BASE-RHx PHY block diagram

TP1 and TP4 are standardized reference points for use by implementers to certify component conformance. The specifications of the PMD service interface (TP1 and TP4) are not system compliance points of this standard (these are not readily testable in a system implementation).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.6.2.2 PMD transmit function

The PMD transmit function translates abstract PMD service primitives into optical signals. The transmit signal characteristics at the MDI are specified in 115.6.3.1.

The PMD transmit function shall translate the amplitude parameter tx_signal (see 115.6.1.1) into optical signal p at TP2 according to the following function:

$$p = \frac{P_1 - P_0}{2} \times \text{tx_signal} + \frac{P_1 + P_0}{2} \tag{115–30}$$

where P_0 and P_1 are respectively the minimum and maximum optical power at TP2, and the parameter tx_signal fits $-1 \leq \text{tx_signal} < +1$ (see 115.3.3.1).

According to Equation (115–30), the maximum amplitude of tx_signal is translated into the highest optical power (P_1) at TP2 and the minimum amplitude of tx_signal is translated into the lowest optical power (P_0) at TP2.

Optionally, the PMD transmit function shall turn on and turn off the optical output as required by the PMD_TXPWR.request primitive. The transition times from receipt of this primitive until it takes effect at the MDI are specified in 115.6.3.1.

115.6.2.3 PMD receive function

The PMD receive function shall translate the optical signal received at the MDI into the analog signal amplitude provided by the abstract PMD_COMSIGNAL.indication(rx_signal) primitive. The receive signal at the MDI is specified in 115.6.3.3.

Optionally, the PMD receive function responds to or ignores the receive MDI signal during optional LPI mode, as requested by the PMD_RXPWR.request primitive.

PMD_RXPWR.request(OFF) shall cause the PMD receive function to save the internal state of the circuitry to not be affected by the received optical signal during quiet periods of LPI mode. The PMD receive function ignores the received MDI signal and may reduce its power consumption. The PMD receive function saves state to be able to quickly restart translation of received MDI signal during the LPI mode refresh periods or when normal operation is resumed.

The PMD receive function shall respond to the MDI optical signal in response to receiving a PMD_RXPWR.request(ON). This allows the PMD to process the refresh signals in LPI mode and when normal operation of the PHY is resumed. The transition times from receipt of a PMD_RXPWR.request primitive until it takes effect in the PMD receive function are specified in 115.6.3.3.

115.6.2.4 PMD signal detect function

The PMD signal detect function determines the value of the signal_detect parameter of the PMD_RXDETECT.indication primitive, which is signaled when the value of signal_detect changes.

The value of the signal_detect parameter shall be generated in response to the average optical power present at the MDI and the sd_inh parameter according to the conditions defined in Table 115–7. The PMD receive function is not required to verify whether a compliant 1000BASE-H signal is being received. This standard imposes no response time requirements on the generation of the signal_detect parameter.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 115–7—Signal detect value definitions

sd_inh	Receive conditions	Signal detect value
FALSE	AOP at TP3 < –35 dBm	FAIL
FALSE	AOP at TP3 > –29 dBm	OK
FALSE	–35 dBm < AOP at TP3 < –29 dBm	Unspecified (uncertainty range)
TRUE	Any value of AOP at TP3	OK

115.6.3 PMD to MDI optical specifications

Different PMD to MDI optical specifications are provided for the three port types 1000BASE-RHA, 1000BASE-RHB, and 1000BASE-RHC.

1000BASE-RHA and 1000BASE-RHB PHYs have to be able to operate in a fiber optic channel type I. A 1000BASE-RHC PHY has to be able to operate in the fiber optic channel type II and type III. Fiber optic channel type I, type II, and type III are defined in 115.7.

115.6.3.1 Transmitter optical specifications

A 1000BASE-RHx transmitter shall meet the specifications at TP2 defined in Table 115–8 and the modal power distribution (MPD) shall be higher than the lower bound limits defined in Table 115–9 per measurement techniques defined in 115.6.4. Specification for transmit MPD is illustrated in Figure 115–35 and the measurement method is provided in 115.6.4.11.

Table 115–8—Transmit optical characteristics (RHA, RHB, and RHC)

Parameter	Symbol	Units	Value/Criteria					
			Min			Max		
			RHA	RHB	RHC	RHA	RHB	RHC
Average optical power	AOP	dBm	–6	–7	–9	1		
Average optical power of OFF transmitter	AOP_{OFF}	dBm	—			–35		
Optical return loss tolerance	ORLT	dB	—			14		
Extinction ratio	ER	dB	11			15		
Center wavelength	λ_c	nm	635			665		
Spectral width	λ_w	nm	—			20		
Rise time (10% – 90%)	t_r	ns	—			3		
Fall time (90% – 10%)	t_f	ns	—			3		
Rising-edge overshoot	OS_{rise}	%	0			20		
Falling-edge overshoot	OS_{fall}	%	0			$\frac{100}{10^{ER/10}-1}$ [a]		
Positive output droop	DO^+	dB	0			0.8

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 115–8—Transmit optical characteristics (RHA, RHB, and RHC) *(continued)*

Parameter	Symbol	Units	Value/Criteria					
			Min			Max		
			RHA	RHB	RHC	RHA	RHB	RHC
Negative output droop	DO^{-}	dB	–0.7			0		
Timing jitter	t_J	ps	—			10		
2nd order harmonic distortion	HD_2	dB	—			–20		
3rd order harmonic distortion	HD_3	dB	—			–23		
4th order harmonic distortion	HD_4	dB	—			–34		
Residual distortion	RD	dB	—			–40		
Relative intensity noise	RIN	dB/Hz	—			–134		
Off transition time (from tx_pwr = OFF to AOP_{OFF})	t_{off}	ns	—			100		
On transition time (from tx_pwr = ON to active operation)	t_{on}	ns	—			1500		

[a]Maximum permitted falling-edge overshoot depends on the actual transmit ER. The equation gives the maximum permitted falling-edge overshoot as a function of the actual ER (dB).

Table 115–9—Transmit MPD lower bound limits per EAF (RHA, RHB, and RHC)

Angle (°)	EAF	Angle (°)	EAF	Angle (°)	EAF
0.0	0.00	10.0	0.41	27.5	0.97
1.0	0.00	15.0	0.70	30.0	0.99
2.5	0.03	20.0	0.83	35.0	1.00
5.0	0.11	22.5	0.89		
7.5	0.24	25.0	0.93		

Average optical power depends on the operation mode of the PHY transmitter (normal or LPI). AOP is defined as the average optical power at TP2 when the PMD transmit function receives primitive PMD_TXPWR.request(ON) (normal operation and LPI refresh signals). AOP_{OFF} corresponds to the optical power when the PMD transmit function receives the primitive PMD_TXPWR.request(OFF) (LPI quiet periods or link_control = DISABLE). The AOP_{OFF} maximum value is compatible with the PMD signal detect function specified in 115.6.2.4.

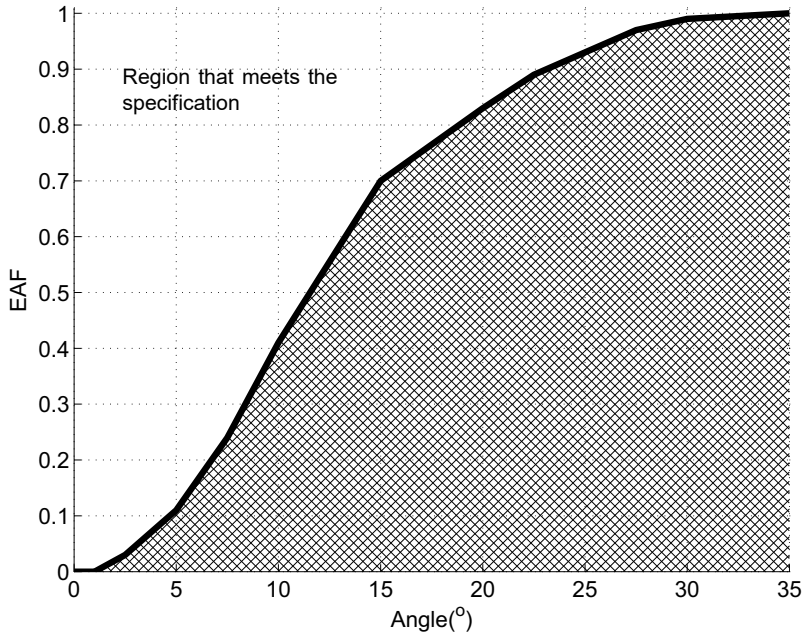

Figure 115–35—Illustration of the transmit MPD lower bound limits per EAF of Table 115–9

115.6.3.2 Transmit clock frequency

The symbol transmission rate of the PHY shall be 325.00 MBd ± 0.01%.

115.6.3.3 Receiver optical specifications

A 1000BASE-RHx receiver shall meet the specifications at TP3 defined in Table 115–10 per measurement techniques defined in 115.6.4. Each 1000BASE-RHx PHY is specified for one or two of three specified fiber optic channels (type I, type II, or type III).

A 1000BASE-RHx PHY shall be able to establish a reliable link per the specification in 115.3.7.1 throughout the average optical power (AOP) range between the minimum and maximum limit defined in Table 115–10, for signals received at the MDI that were transmitted from a remote transmitter within the specifications of 115.6.3.1, and have passed through a fiber optic channel specified in 115.7. Under these conditions, a 1000BASE-RHx PHY shall provide a BER less than 10^{-12} operating in test mode 1 (see 115.5.1), and a frame error ratio less than 1.1×10^{-10} for continuous transmission of 64-octet Ethernet frames transmitted with minimum IPG at GMII interface operating in normal (non-test) mode. These specifications apply to a complete 1000BASE-RHx link composed by two interconnected partners with their respective PCS, PMA, and PMD sublayers.

Table 115–10—Receive optical characteristics (RHA, RHB, and RHC)

Parameter	Symbol	Units	Value/Criteria							
			Min				Max			
			RHA	RHB	RHC		RHA	RHB	RHC	
			Fiber optic channel							
			Type I	Type I	Type II	Type III	Type I	Type I	Type II	Type III
Average optical power for reliable link establishment	AOP[a]	dBm	–17	–17	–17	–18.5	1			
Receiver reflectance	RR[b]	dB	—				–14			
Wavelength range	λ	nm	600				700			
Off transition time (from rx_pwr = OFF to quiet mode)	t_{off}	ns	—				200			
On transition time (from rx_pwr = ON to active operation)	t_{on}	ns	—				400			

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal that has a power level equal to the average receive optical power (max) plus at least 1 dB.
[b] See 1.4 for definition of reflectance.

115.6.3.4 Receiver boundary condition tests

The following boundary condition tests verify the receiver optical specifications defined in 115.6.3.3. A 1000BASE-RHx PHY shall be able to establish a reliable link as specified in 115.6.3.3 under boundary conditions defined in 115.6.3.4.1 and 115.6.3.4.2.

115.6.3.4.1 Receiver minimum AOP test

This test operates the 1000BASE-RHx PHY receiver in minimum AOP conditions as defined in Table 115–11. For this test, the responses of channel type I, type II, and type III are defined by the lower bound limits specified in Table 115–13, Table 115–14, and Table 115–15, respectively. Parameters of Table 115–8 and Table 115–10 that are not specified in Table 115–11 can take any value in the specification ranges.

115.6.3.4.2 Receiver maximum AOP test

This test operates a 1000BASE-RHx PHY receiver in maximum AOP conditions as defined in Table 115–12. The local receiver under test is connected to the remote transmitter by means of a plastic optical fiber of 1 meter or less consistent with the specifications of 115.7. Parameters of Table 115–8 and Table 115–10 that are not specified in Table 115–12 can take any value in the specification ranges.

Table 115–11—Parameters for receiver minimum AOP test

Parameter		Symbol	Units	Value/Criteria			
				RHA	RHB	RHC	
				Fiber optic channel			
				Type I	Type I	Type II	Type III
Transmitter	Extinction ratio	ER	dB	11			
	Fall time (90% – 10%)	t_f	ns	3			
	Rising-edge overshoot	OS_{rise}	%	0			
	Falling-edge overshoot	OS_{fall}	%	0			
Receiver	Receive average optical power	AOP	dBm	–17	–17	–17	–18.5

Table 115–12—Parameters for receiver maximum AOP test

Parameter		Symbol	Units	Value/Criteria		
				RHA	RHB	RHC
Transmitter	Extinction ratio	ER	dB	15		
Receiver	Receive average optical power	AOP	dBm	1		
	Receiver reflectance	RR[a]	dB	–14		

[a]See 1.4 for definition of reflectance.

115.6.4 Optical measurement requirements

All the optical measurements of the transmitter shall be made at TP2 (at the end of a 1m length of POF cable consistent with the link segment type). The optical measurements for the receiver shall be made at TP3.

The transmitter testing methodology assumes that a 1000BASE-RHx PMD is not tested standalone, but is always considered as part of a complete Physical Layer device (i.e., PCS and PMA sublayers are also included). TP1 is not used as a stimulus point; rather, the complete PHY is instructed through management to generate signals that are measured at TP2.

115.6.4.1 Center wavelength measurement

The center wavelength shall meet the specifications according to IEC 61280-1-3, under normal (non-test) mode conditions using a valid 1000BASE-H transmit signal as specified in 115.3.3.1. For this measurement, the PHY is not connected to any link partner, therefore the bidirectional link cannot be established, MLCC codewords are not THP processed, and LPI mode is disabled.

115.6.4.2 Spectral width measurement

The spectral width (RMS) shall meet the specifications according to IEC 61280-1-3, using the same test conditions as for center wavelength measurement (see 115.6.4.1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.6.4.3 Average Optical Power (AOP) measurement

The AOP shall meet the specifications at TP2 and TP3 measured with a large area photo-detector able to couple all the output optical power from the optical fiber, using the same test conditions as 115.6.4.1.

115.6.4.4 Transmitter rise and fall time measurements

The transmitter rise and fall time measurements shall meet the specifications according to the following measurements procedure, using an electrical oscilloscope after optical to electrical conversion or an optical oscilloscope with a minimum bandwidth of 812.5 MHz (–3 dB cut-off frequency):

a) The PHY is configured in test mode 3 (see 115.5.3).
b) Rise time is measured as the time taken for the optical signal to transition from value ($0.1 \times P_1 + 0.9 \times P_0$) to value ($0.1 \times P_0 + 0.9 \times P_1$) and stay above the second value.
c) Fall time is measured as the time taken for the optical signal to transition from value ($0.1 \times P_0 + 0.9 \times P_1$) to value ($0.1 \times P_1 + 0.9 \times P_0$) and stay below the second value.

P_1 is the steady-state value that the optical signal reaches after a rising-edge transition and before the next falling-edge. P_1 (mW) is the average optical power measured over a 2 ns window centered 15 ns after the rising-edge crossing of the optical signal with the average optical power (AOP) level. Similarly, P_0 is the steady-state value that the optical signal reaches after a falling-edge transition and before the next rising-edge. P_0 (mW) is the average optical power measured in a 2 ns window centered 15 ns after the falling-edge AOP crossing.

115.6.4.5 Transmitter extinction ratio (*ER*) measurement

The transmitter extinction ratio (*ER*) shall meet the specifications per Equation (115–31) calculated from the optical power measurements P_1 and P_0, which are defined and measured as specified in 115.6.4.4, using the same test setup, apparatus requirements, and PHY operation mode as 115.6.4.4.

$$ER = 10 \times \log_{10}\left(\frac{P_1}{P_0}\right) \text{ (dB)} \tag{115–31}$$

115.6.4.6 Transmitter overshoot measurements

The transmitter overshoot shall meet the specifications according to Equation (115–32) and Equation (115–33) for rising edge overshoot and falling edge overshoot, respectively, using the same test setup, apparatus requirements, and PHY operation mode as 115.6.4.4.

$$OS_{\text{rise}} = \frac{P_{\max} - P_1}{P_1 - P_0} \tag{115–32}$$

$$OS_{\text{fall}} = \frac{P_0 - P_{\min}}{P_1 - P_0} \tag{115–33}$$

$P_{\max}$ (mW) is the maximum measured value of the optical signal in the time interval between a rising-edge AOP crossing and next falling-edge AOP crossing. Similarly, $P_{\min}$ (mW) is the minimum measured value in the time interval between consecutive falling and rising edges. P_0 and P_1 are defined and measured as specified in 115.6.4.4.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

115.6.4.7 Transmitter output droop measurements

The transmitter output droop shall meet the specifications according to the following measurements steps, using the same test setup and apparatus requirements as 115.6.4.4:

a) A reference of extinction ratio, ER_0, is measured as specified in 115.6.4.5.
b) The PHY is configured in test mode 4 (see 115.5.4).
c) The maximum extinction ratio (ER_{max}) and the minimum extinction ratio (ER_{min}) are measured during a period of time of at least 47 μs (which assures sampling over more than a complete test mode 4 pattern). ER_{max} is calculated from the measured P_1 and P_0 values where the ratio between them is maximum. Similarly, ER_{min} is calculated from the measured P_1 and P_0 values, where the ratio between them is minimum. P_0 and P_1 are defined and measured as specified in 115.6.4.4.
d) The positive output droop DO^+ and the negative output droop DO^- are calculated as $DO^+ = ER_{max} - ER_0$ and $DO^- = ER_{min} - ER_0$, respectively.

115.6.4.8 Transmitter distortion measurement

The transmitter distortion is determined by the following four parameters:

a) Second order harmonic distortion (HD_2).
b) Third order harmonic distortion (HD_3).
c) Fourth order harmonic distortion (HD_4).
d) Residual distortion (RD).

These four parameters HD_2, HD_3, HD_4, and RD, shall meet the specifications according to the following procedure:

1) The PHY is configured in test mode 6 (see 115.5.6).
2) Transmitted waveform is captured at TP2 using the same test setup and apparatus requirements as 115.6.4.4 with data acquisition capabilities. To reduce frequency deviation between the transmitter and the clock used to sample the transmit waveform, the test instrument and the device under test may share the same clock reference.
3) A block of consecutive samples is processed with the code given below or an equivalent.[201, 202] The captured block of signal is at least 13 μs long and is sampled with the minimum sampling rate of 3.25 GSamples/s (10 times the transmit symbol rate of nominal 325 MBd). The code assumes the data acquisition clock is frequency locked to the DUT transmit clock.

```
% Post processing code for 1000BASE-RH transmitter distortion

% Read captured data file, min 13 us long, min 3.25GSample/sec,
% high resolution capture
fid  = fopen('RawData.bin', 'r');
xcap = fread(fid, inf, 'double');
fclose(fid);
xcap = reshape(xcap, 1, []);

% Set the over sampling ratio (min 10)
osr = 10;
[HD2 HD3 HD4 RD] = txdist(xcap,osr);
```

115.6.4.9 Transmitter timing jitter measurement

The transmitter timing jitter shall meet the specifications per the following measurement procedure:

a) The PHY is configured in test mode 2 (115.5.2).
b) RMS (Root Mean Square) jitter of the crossing events of transmit signal with the average optical power is measured relative to the corresponding edges of an unjittered clock reference with a frequency of 162.5 MHz (one half the symbol rate), over an interval of 2 ms ± 10%.

The measurement device connected to TP2 shall meet the following specifications:

1) Capture capability.
2) High-frequency low-pass corner of at least 32.5 MHz with slope of –20 dB/decade.
3) Low-frequency high-pass corner of maximum 1 kHz with slope of +20 dB/decade.
4) The unjittered reference is a constant frequency clock extracted from each record of captured output at TP2, and is based on linear regression of frequency and phase that produces a minimum Time Interval Error.

115.6.4.10 Transmitter relative intensity noise (RIN) measurement

This test might not be an appropriate system level test in all implementations, but all implementations shall meet the specified performance. The PHY is configured in test mode 5 (115.5.5). RIN is measured according to 58.7.7 with the following exceptions:

a) The low-pass filter bandwidth is 162.5 MHz (one half the symbol rate).
b) Step d) of the test procedure in 58.7.7.3 is replaced by measuring the value of the photocurrent of the optical to electrical converter I_{oe}.
c) Step e) of the test procedure in 58.7.7.3 is replaced by using the following equation to evaluate RIN:

$$RIN = 10 \times \log_{10}\left(\frac{P_N}{BW \times I_{oe}^{\ 2} \times R}\right) - G \text{ (dB/Hz)} \quad (115\text{–}34)$$

where

RIN	is the relative intensity noise
P_N	is the electrical noise power in Watts with modulation off
BW	is the low-pass bandwidth of the apparatus – high-pass bandwidth of the apparatus due to dc blocking capacitor
I_{oe}	is the photocurrent of the optical to electrical converter
R	is the effective load impedance of the optical to electrical converter (for example, a 50 Ω detector load in parallel with a 50 Ω power meter would give R equal to 25)
G	is the gain in dB of any amplifier in the noise measurement path

115.6.4.11 Transmitter modal power distribution measurement

The modal power distribution (MPD) at TP2 shall meet the specifications of 115.6.3.1 using an encircled angular flux (EAF) measurement method based on two-dimensional far field pattern data captured at TP2, which conforms to IEC 61300-3-53, defined for step-index multimode fibers.

When making this measurement the PHY is configured in normal (non-test) operation. A measured MPD meets the specification when it is higher than the lower bound limits defined for every angle. For the angle points not specified in Table 115–9, the EAF lower bound limit is calculated by linear interpolation.

115.7 Characteristics of the fiber optic cabling (channel)

The fiber optic cabling model is shown in Figure 115–36.

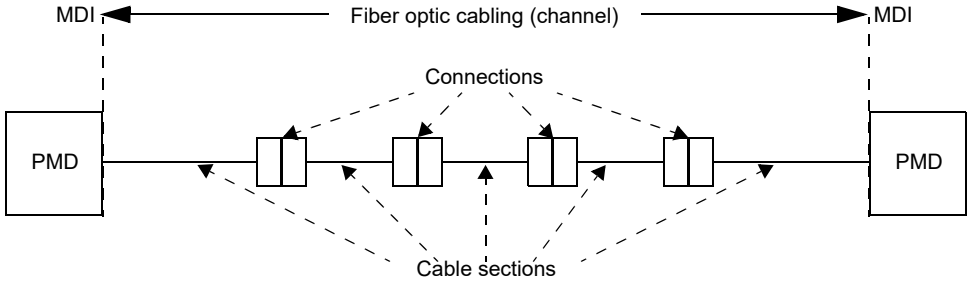

Figure 115–36—Fiber optic cabling model (channel)

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1000BASE-RHx operation requires fiber optic cable meeting the requirements of IEC 60793-2-40 sub-category A4a.2 multimode plastic optical fibers with appropriate augmentation as specified in this subclause. The link segment uses two optical fibers, one for each direction (see 115.1.5), and is composed of one or more cable sections and their in-line connections. The fiber optic cabling model (channel) defined here is a simplex fiber optic link segment, which is sufficient for testing purposes. The term channel is used here for consistency with generic cabling standards.

The following three different fiber optic channel types are specified:

a) Fiber optic channel type I supports reliable link per the specifications of 115.6.3.3 with reach up to at least 50 m. The fiber optic channel type I shall meet a maximum insertion loss of 9.5 dB without in-line connections and the transfer function specification of 115.7.1, per measurement techniques defined in 115.7.4 and 115.7.5, and under spectral distribution and launching modal power distribution at TP2 specified per EAF lower bound limits in 115.6.3.1.
b) Fiber optic channel type II supports reliable link per the specifications of 115.6.3.3 with reach up to at least 40 m. The fiber optic channel type II shall meet a maximum insertion loss of 8 dB without in-line connections and the transfer function specification of 115.7.2, per measurement techniques defined in 115.7.4 and 115.7.5, and under spectral distribution and launching modal power distribution at TP2 specified per EAF lower bound limits in 115.6.3.1. The parameters of this channel type include additional considerations for the environmental conditions of the intended application.
c) Fiber optic channel type III supports reliable link per the specifications of 115.6.3.3 with reach up to at least 15 m. The fiber optic channel type III shall meet a maximum insertion loss of 3 dB without in-line connections and the transfer function specification of 115.7.3, per measurement techniques defined in 115.7.4 and 115.7.5, and under spectral distribution and launching modal power distribution at TP2 specified per EAF lower bound limits in 115.6.3.1. The parameters of this channel type include additional considerations for the environmental conditions of the intended application.

NOTE—It may be possible to construct compliant fiber optic cables longer than indicated. Length of a fiber optic cable does not imply compliance to specifications.

The fiber optic channel transfer function captures the frequency-dependent propagation of the light through the fiber that is caused by the modal and chromatic dispersion. The transfer function is specified in magnitude normalized at dc and is given as a lower bound limit. Any fiber optic channel including in-line connections shall meet the transfer function specification of each type.

The number of supported in-line connections is not normative but instead depends on the specific in-line connection technology and the unallocated link margin (see 115.7.6).

115.7.1 Transfer function of fiber optic channel type I

The transfer function of a fiber optic channel is compliant with type I when it is higher than the lower bound limits of Table 115–13 for any frequency less than or equal to 162.5 MHz. For the frequency points not specified, the transfer function is calculated by linear interpolation. The transfer function lower bound limits of a fiber optic channel type I are illustrated in Figure 115–37.

Table 115–13—Transfer function lower bound limits for fiber optic channel type I

Frequency (MHz)	Transfer function magnitude (dB)	Frequency (MHz)	Transfer function magnitude (dB)
0	0.0	70	–4.0
10	–0.1	85	–5.4
20	–0.3	105	–6.9
30	–0.7	125	–7.8
40	–1.3	145	–8.7
50	–2.1	162.5	–9.5
60	–3.0		

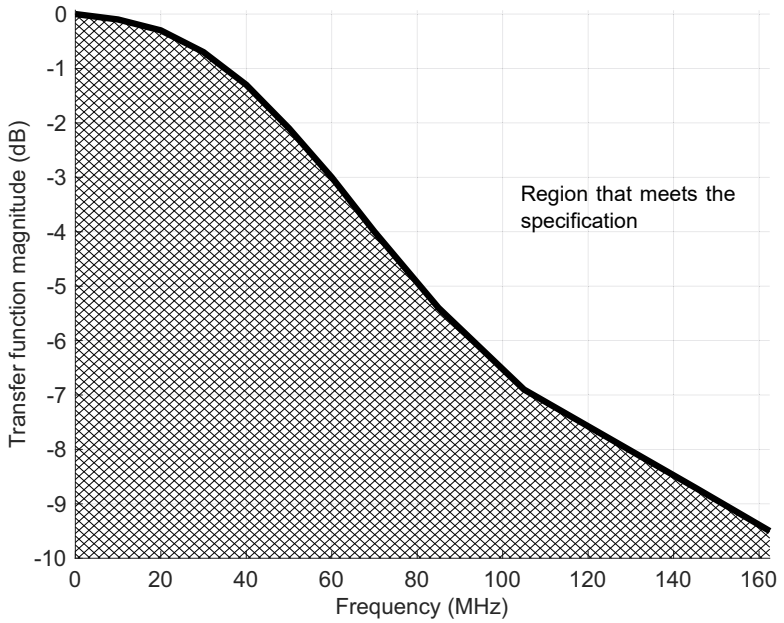

Figure 115–37—Transfer function illustration for fiber optic channel type I

115.7.2 Transfer function of fiber optic channel type II

The transfer function of a fiber optic channel is compliant with type II when it is higher than the lower bound limits of Table 115–14 for any frequency less than or equal to 162.5 MHz. For the frequency points not specified, the transfer function is calculated by linear interpolation. The transfer function lower bound limits of a fiber optic channel type II are illustrated in Figure 115–38.

Table 115–14—Transfer function lower bound limits for fiber optic channel type II

Frequency (MHz)	Transfer function magnitude (dB)	Frequency (MHz)	Transfer function magnitude (dB)
0	0	70	–2.2
10	–0.1	85	–3.2
20	–0.2	105	–4.8
30	–0.4	125	–6.2
40	–0.7	145	–7.4
50	–1.1	162.5	–8.1
60	–1.6

115.7.3 Transfer function of fiber optic channel type III

The transfer function of a fiber optic channel is compliant with type III when it is higher than the lower bound limits of Table 115–15 for any frequency less than or equal to 162.5 MHz. For the frequency points not specified, the transfer function is calculated by linear interpolation. The transfer function lower bound limits of a fiber optic channel type III are illustrated in Figure 115–39.

Table 115–15—Transfer function lower bound limits for fiber optic channel type III

Frequency (MHz)	Transfer function magnitude (dB)
0	0
50	–0.1
85	–0.5
125	–1.4
162.5	–2.5

115.7.4 Fiber optic channel insertion loss measurement

The fiber optic channel shall meet the insertion loss specification per measurement according to ISO/IEC 14763-3, under spectral distribution and launch modal power distribution at TP2 specified per EAF lower bound limits in 115.6.3.1.

115.7.5 Fiber optic channel transfer function measurement

The fiber optic channel shall meet the transfer function specification per measurement according to IEC 60793-1-41:2010, under spectral distribution and launch modal power distribution at TP2 specified per EAF lower bound limits in 115.6.3.1.

115.7.6 Worst-case 1000BASE-RHx link power budget

Table 115–16 shows the worst-case link power budget and the unallocated link margin for a 1000BASE-RHx PHY, which are derived from the transmitter and the receiver optical specifications as well as fiber optic channel specifications provided in 115.6.3.1, 115.6.3.3, and 115.7, respectively.

Table 115–16—Worst case link power budget

Parameter	Units	RHA	RHB	RHC	
		Fiber optic channel			
		Type I	Type I	Type II	Type III
Link power budget (min)	dB	11	10	8	9.5
Channel insertion loss without in-line connections (max)	dB	9.5	9.5	8	3
Unallocated link margin (min)[a]	dB	1.5	0.5	0	6.5

[a] Unallocated link margin may be used for in-line connections (connectors). Maximum 1.5 dB insertion loss per in-line connection is assumed.

115.8 Medium Dependent Interface (MDI)

The 1000BASE-RHx PMD is coupled to the fiber optic cabling through a connection at the Medium Dependent Interface (MDI). The MDI mechanical interface for 1000BASE-RHA is defined in 115.8.1. An MDI mechanical interface is not specified for 1000BASE-RHB and 1000BASE-RHC.

The transmit signal characteristics are defined at the output end of a 1 meter length (TP2) of plastic optical fiber. The optical receive signal is defined at the output of the fiber optic cabling (TP3). Therefore, both the transmitter and the receiver optical characteristics are specified including the MDI mechanical implementation.

115.8.1 MDI mechanical interface for 1000BASE-RHA

The 1000BASE-RHA PMD and the associated MDI receptacle are coupled to the prepared fiber optic cabling without a plug.

The 1000BASE-RHA MDI receptacle shall be a duplex housing consisting of two separated slots (transmit and receive). Viewed from the link segment side of the connection, the 1000BASE-RHA MDI receptacle

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

shall properly indicate with labeling the slot of the transmitter and the slot of the receiver. Figure 115–40 illustrates example MDI receptacle with labeling.

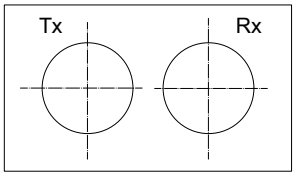

Figure 115–40—Example MDI receptacle (link segment side view)

The 1000BASE-RHA MDI receptacle shall accept link segment duplex cable compliant with specifications of buffered A4 fibers per IEC 60794-2-41.

The 1000BASE-RHA MDI receptacle shall have defined open and close states. The close state shall provide a stable and resilient connection by utilizing a retention mechanism with a minimum steady-state retention force of 4 N aligned with the center line of the receptacle hole in the direction of cable extraction for polyethylene (PE) jacket buffered fibers. Retention force per test procedure of IEC 61300-2-4 shall result in a loss of less than 0.4 dB of the AOP coupled by the PMD transmitter into the fiber while the load is applied and after the load is removed.

The duplex POF cable needs to be properly prepared and split into two single jacketed fibers for connection to the 1000BASE-RHA MDI receptacle.

The POF cable is normally prepared without polishing by using a POF cutting tool. The cutting tool may clamp the POF cable, without damaging the jacket, to prevent movement when cutting it (e.g., with a razor blade). The cutting tool shall provide the following results:

— The resultant fiber end facets are perpendicular to the cable axis with end angle error less than 2.5º.
— The flatness of the fiber end facet produces an insertion loss of less than 1.5 dB, per butt coupling of the two resultant fiber segments.

The duplex cable is split to enable the following:

— Full insertion and guidance inside the MDI receptacle slot
— Bend radius over 25 mm

The 1000BASE-RHA MDI receptacle vendor shall clearly indicate the minimum split length needed for a suitable connection. The left side of Figure 115–41 illustrates the duplex POF cable splitting and the right side illustrates the fiber cable connection to 1000BASE-RHA MDI receptacle.

One of the jackets of the duplex POF cable shall have marking. A possible marking is illustrated in Figure 115–41. Such marking can facilitate installation when the optical transmitters of the link partners are off. There may be specific application marking requirements.

Two different installation scenarios can be considered for correct link segment crossover—the scenario where visible transmit light is used and the scenario where the fiber cable marking is used.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

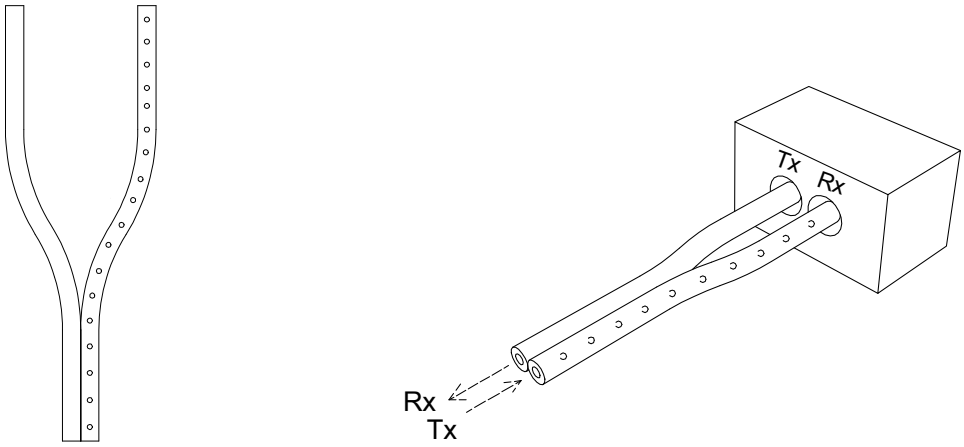

Figure 115–41—Duplex POF cable splitting and connection to the 1000BASE-RHA MDI receptacle

When the remote link partner is transmitting, the fiber used by the link partner to transmit can be easily distinguished because of the 1000BASE-RHA visible light. This fiber is connected to the local receiver, and the other fiber of duplex cable is connected from the local transmitter to the remote receiver. When the remote link partner is not transmitting, the cable specific marking can be used to implement a single crossover between the link partners identifying the correct insertion of the fiber ends into the MDI receptacle.

115.9 1000BASE-H Operations, Administration, and Maintenance (1000BASE-H OAM) channel

The optional 1000BASE-H OAM channel provides a mechanism to reliably exchange messages between station management entity (STA) peers attached to link partners. The 1000BASE-H OAM message exchange occurs in the PCS, as part of the PHD, and does not impact the normal GMII to GMII data transmission. Moreover, the 1000BASE-H OAM message exchange is not affected by EEE operation.

The 1000BASE-H OAM channel utilizes 1000BASE-H OAM transmit and receive registers accessible via the MDIO as well as capabilities specified in the following channel descriptions. All MDIO accessible registers for 1000BASE-H OAM operation are specified in 45.2.3.51 and 45.2.3.52.

The 1000BASE-H OAM channel uses several control bits (MSGT, MERT, PHYT) for message identification, message delivery notification, and flow control.

115.9.1 1000BASE-H OAM message transmission protocol

When the STA connected to the local PHY needs to transmit a new message it shall follow these steps:

a) Wait until bit TXO_REQ of register 3.500 is zero, which indicates that the 1000BASE-H OAM transmit registers are free and that a new 1000BASE-H OAM message can be written.
b) Write the 128 user data bits of the 1000BASE-H OAM message into registers 3.501 through 3.508.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) Write the first 12 bits of the 1000BASE-H OAM message to the bits TXO_DATA0 of register 3.500, also setting bit TXO_REQ to one at the same time to request the transmission of the new message.

When the local PHY accepts the message for transmission, it simultaneously does the following operations:

1) Set the bit TXO_REQ of register 3.500 to zero.
2) Change the bit TXO_MSGT of register 3.500, and copy the new value to LOCPHD.OAM.MSGT.
3) Copy the rest of the message to LOCPHD fields. Bits TXO_DATA0 of register 3.500 are copied to the field LOCPHD.OAM.DATA0. The contents of registers 3.501 through 3.508 are copied to the fields LOCPHD.OAM.DATA1 through LOCPHD.OAM.DATA8.

The local PHY does not accept a new message for transmission until the previous 1000BASE-H OAM message has been accepted by the remote PHY. This happens when the field REMPHD.OAM.PHYT is equal to the field LOCPHD.OAM.MSGT.

Upon PHY reset, all the LOCPHD fields that comprise the 1000BASE-H OAM channel and all the bits in 1000BASE-H OAM transmit registers 3.500 through 3.508 are set to zero.

The fields LOCPHD.OAM.MSGT and LOCPHD.OAM.DATAx always maintain the values corresponding to the last message accepted by the local PHY for transmission, or the reset value if either 1000BASE-H OAM is not enabled or no message has been accepted for transmission since the last PHY reset.

115.9.2 1000BASE-H OAM channel status

There can be up to three outstanding 1000BASE-H OAM messages in the channel from the transmitting PHY to the receiver of the link partner: the message written in the 1000BASE-H OAM transmit registers that is waiting for transmission, the message being currently transmitted by the local PHY, and the message available in the 1000BASE-H OAM receive registers of the remote PHY that is waiting for processing by the remote STA.

The status of the three possible outstanding 1000BASE-H OAM messages can be decoded from the values of the control bits of register 3.500. Table 115–17 shows all the possible values of the four control bits, and the corresponding status of the three possible outstanding 1000BASE-H OAM messages.

Table 115–17—List of all possible 1000BASE-H OAM message status

TXO_ REQ	TXO_ MSGT	TXO_ PHYT	TXO_ MERT	Message K + 1 status	Message K status	Message K – 1 status
0	a	a	a	Not written by local STA	Sent by local PHY ACK by remote PHY ACK by remote STA	Sent by local PHY ACK by remote PHY ACK by remote STA
0	a	!a	!a	Not written by local STA	Sent by local PHY No ACK by remote PHY No ACK by remote STA	Sent by local PHY ACK by remote PHY ACK by remote STA
0	a	a	!a	Not written by local STA	Sent by local PHY ACK by remote PHY No ACK by remote STA	Sent by local PHY ACK by remote PHY ACK by remote STA

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 115–17—List of all possible 1000BASE-H OAM message status *(continued)*

TXO_ REQ	TXO_ MSGT	TXO_ PHYT	TXO_ MERT	Message K + 1 status	Message K status	Message K – 1 status
0	a	!a	a	Not written by local STA	Sent by local PHY No ACK by remote PHY No ACK by remote STA	Sent by local PHY ACK by remote PHY No ACK by remote STA
1	a	a	a	Written by local STA Pending transmission by local PHY	Sent by local PHY ACK by remote PHY ACK by remote STA	Sent by local PHY ACK by remote PHY ACK by remote STA
1	a	!a	!a	Written by local STA Pending transmission by local PHY	Sent by local PHY No ACK by remote PHY No ACK by remote STA	Sent by local PHY ACK by remote PHY ACK by remote STA
1	a	a	!a	Written by local STA Pending transmission by local PHY	Sent by local PHY ACK by remote PHY No ACK by remote STA	Sent by local PHY ACK by remote PHY ACK by remote STA
1	a	!a	a	Written by local STA Pending transmission by local PHY	Sent by local PHY No ACK by remote PHY No ACK by remote STA	Sent by local PHY ACK by remote PHY No ACK by remote STA

The control bits can be either 0 or 1, the symbol ! denotes logical not. Message K is the message currently being transmitted by the local PHY to the remote PHY; its associated message identification bit takes the value ‘a’ as indicated by bit TXO_MSGT. Correspondingly, message K – 1 is the previous message that was transmitted by the local PHY to the remote PHY. Its associated message identification bit takes the value ‘!a’. Finally message K + 1 corresponds to the 1000BASE-H OAM message being composed or yet to be accepted for transmission by the local PHY. Its associated message identification bit takes the value ‘!a’.

115.9.3 1000BASE-H OAM message reception protocol

When the local PHY receives a new 1000BASE-H OAM message as part of REMPHD fields and the 1000BASE-H OAM receive registers are free, it does the following operations:

a) Copy the content of the new message to the 1000BASE-H OAM receive registers.
b) Set the bit RXO_VAL of register 3.509 to one, indicating the presence of a new message in the 1000BASE-H OAM receive registers to the STA attached to the PHY.
c) Copy the value of the field REMPHD.OAM.MSGT to the field LOCPHD.OAM.PHYT to indicate to the remote PHY that the new message has been received by the PHY.

When the STA connected to the local PHY reads a new 1000BASE-H OAM message, it shall follow these steps:

1) Wait until the bit RXO_VAL of register 3.509 is one, which indicates that a new 1000BASE-H OAM message is in the 1000BASE-H OAM receive registers.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

2) When RXO_VAL is one, read the bits RXO_MSGT and RXO_DATA0 of the new 1000BASE-H OAM message, as they are also stored in register 3.509.
3) Read the rest of the message that is stored in registers 3.510 through 3.517. Reading the register 3.517 last is necessary for integrity of the 1000BASE-H OAM message. (The read of register 3.517 triggers the acknowledgment to the remote partner of the 1000BASE-H OAM that message has been read by the local attached STA, and indicates to the local PHY the 1000BASE-H OAM receive registers are available for a new 1000BASE-H OAM message.)

When the local STA reads register 3.517, the local PHY copies the MSGT bit of the message that has been read by the STA to the field LOCPHD.OAM.MERT.

Upon PHY reset, the fields LOCPHD.OAM.PHYT, LOCPHD.OAM.MERT, and all the bits of the 1000BASE-H OAM receive registers are reset to zero.

The field LOCPHD.OAM.PHYT always maintains the value corresponding to the last message copied to the 1000BASE-H OAM receive registers, or zero when 1000BASE-H OAM is disabled or no message has been copied to the 1000BASE-H OAM receive registers since the last PHY reset.

The field LOCPHD.OAM.MERT always maintains the value corresponding to the last message processed by the STA, or zero when 1000BASE-H OAM is disabled or no message has been processed by the STA since the last PHY reset.

115.9.4 1000BASE-H OAM channel state diagrams descriptions

115.9.4.1 1000BASE-H OAM control state variables

The following defines all the variables used in the 1000BASE-H OAM channel state diagrams that have not been previously introduced:

oam_cap
: Enables 1000BASE-H OAM channel functionality. This variable is set to TRUE when PHD.CAP.OAM of both transmit and receive PHD is TRUE. Otherwise, it is FALSE.
Values: TRUE: Both local and remote PHY have 1000BASE-H OAM ability and 1000BASE-H OAM functionality is enabled in both PHYs
FALSE: Either local or remote PHY does not have 1000BASE-H OAM ability or it is disabled

read_RXOAM_DATA8_event
: Event indicating that the 1000BASE-H OAM receive register 3.517 has been read. This event persists only long enough to cause one state diagram transition.

rxphd_mert
: Variable equivalent to the field REMPHD.OAM.MERT.
Values: 0 and 1

rxphd_msgt
: Variable equivalent to the field REMPHD.OAM.MSGT. It contains the message identification bit of the 1000BASE-H OAM message.
Values: 0 and 1

rxphd_oamudat
: Variable equivalent to the fields REMPHD.OAM.DATAx. It is the payload of the 1000BASE-H OAM message.
Values: Any value

rxphd_phyt
: Variable equivalent to the field REMPHD.OAM.PHYT.
Values: 0 and 1

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rxr_msgt

Variable equivalent to the bit RXO_MSGT of register 3.509. This bit is the message identification bit of the message contained in the 1000BASE-H OAM receive registers.

Values: 0 and 1

rxr_oamudat

Variable equivalent to the RXO_DATA0 field of register 3.509 concatenated with the RXO_DATA1 trough RXO_DATA8 of 1000BASE-H OAM receive registers 3.510 through 3.517.

Values: Any value

rxr_rxval

Variable equivalent to the bit RXO_VAL of register 3.509 that indicates the presence of a valid message in the 1000BASE-H OAM receive registers.

Values: 1: There is a valid message in the receive registers, which is pending for processing by the local STA
0: There is no valid message in the receive registers

txphd_mert

Variable equivalent to the field LOCPHD.OAM.MERT. It informs the remote PHY of the message identification bit of the last message that has been received by the local STA.

Values: 0 and 1

txphd_msgt

Identifier of the message being transmitted by the local PHY. This variable is equivalent to the field LOCPHD.OAM.MSGT.

Values: 0 and 1

txphd_oamudat

Variable equivalent to the content of the field LOCPHD.OAM.DATAx.

Values: Any value

txphd_phyt

Variable equivalent to the field LOCPHD.OAM.PHYT. It indicates to the remote PHY the message identification bit of the last valid message written to the receive registers.

Values: 0 and 1

txr_mert

Variable equivalent to the bit TXO_MERT of register 3.500. This bit is updated in OAMTX_TRANSMIT state to reflect the identifier of the last message that has been acknowledged by the remote STA.

Values: It alternates between values 0 and 1

txr_msgt

Variable equivalent to the bit TXO_MSGT of register 3.500. This bit is updated in OAMTX_TRANSMIT state to reflect the message identification bit of the message being sent by the local PHY.

Values: It alternates between values 0 and 1

txr_oamudat

Variable equivalent to the TXO_DATA0 field of register 3.500 concatenated with the TXO_DATA1 trough TXO_DATA8 of 1000BASE-H OAM transmit registers 3.501 through 3.508.

Values: Any value

txr_phyt

Variable equivalent to the bit TXO_PHYT of register 3.500. This bit is updated in OAMTX_TRANSMIT state to reflect the identifier of the last message that has been acknowledged by the remote PHY.

Values: It alternates between values 0 and 1

txr_txreq

Variable equivalent to the bit TXO_REQ of register 3.500. It indicates if the local STA is requesting the transmission of a new 1000BASE-H OAM message.

Values: 0: There is no message transmission request

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1: A new message has been written into the 1000BASE-H OAM transmit registers and transmission is requested

115.9.4.2 1000BASE-H OAM transmit control state diagram

The PHY operation for 1000BASE-H OAM message transmission shall conform to the 1000BASE-H OAM transmit control state diagram in Figure 115–42.

Upon reset (bit 1.0.15 set to one), disable of the PMA or determination of unreliable PHD communication, 1000BASE-H OAM transmit registers are reset (OAMTX_RESET state). Moreover, the LOCPHD fields of the 1000BASE-H OAM message are reset.

Once the transmission and reception of PHDs is reliable (rcvr_hdr_lock = OK), and the 1000BASE-H OAM channel is enabled, the local PHY waits for a new 1000BASE-H OAM message transmission request from the local STA (OAMTX_NEWMSG_WAIT state). Whenever a new valid PHD is received from the remote PHY, the local PHY updates the bit TXO_MERT of register 3.500 with the value of the field REMPHD.OAM.MERT and the bit TXO_PHYT of register 3.500 with the value of the field REMPHD.OAM.PHYT.

As soon as the first 1000BASE-H OAM message transmission is requested by the local STA (txr_txreq = 1), the local PHY accepts it, entering the OAMTX_TRANSMIT state. This causes the content of transmit registers 3.501 through 3.508 and the 12-bit TXO_DATA0 field of register 3.500 to be copied to the corresponding fields LOCPHD.OAM.DATAx. Simultaneously, field LOCPHD.OAM.MSGT is changed and copied to bit TXO_MSGT of register 3.500, and bit TXO_REQ of register 3.500 is cleared to zero. Thus, the local PHY indicates to the attached STA the MSGT assigned to the message and also that the 1000BASE-H OAM transmit registers are free to accept a new message.

From then on, the local PHY keeps transmitting the same 1000BASE-H OAM message within the PHD until the remote PHY acknowledges its reception (OAMTX_PHYT_WAIT state). Simultaneously, whenever a new valid PHD is received from the remote PHY, the local PHY updates the bits TXO_PHYT and TXO_MERT of register 3.500 with the values of the fields REMPHD.OAM.PHYT and REMPHD.OAM.MERT, respectively. As soon as the 1000BASE-H OAM message that is being currently transmitted within the PHD is acknowledged by the remote PHY, the local PHY can accept a new 1000BASE-H OAM message for transmission. The transition from state OAMTX_PHYT_WAIT to state OAMTX_NEWMSG_WAIT occurs when the values of fields REMPHD.OAM.PHYT and LOCPHD.OAM.MSGT are equal (rxphd_phyt = txphd_msgt).

115.9.4.3 1000BASE-H OAM receive control state diagram

The PHY operation for 1000BASE-H OAM message reception shall conform to the 1000BASE-H OAM receive control state diagram in Figure 115–43.

Upon reset (bit 1.0.15 set to one), disable of the PMA or determination of unreliable PHD reception, 1000BASE-H OAM receive registers are reset (OAMRX_RESET state). Moreover, fields LOCPHD.OAM.MERT and LOCPHD.OAM.PHYT are assigned the value zero.

Once the transmission and reception of PHDs are reliable (rcvr_hdr_lock = OK), the local PHY waits until the field REMPHD.OAM.MSGT is different from the bit RXO_MSGT of register 3.509. This indicates that a new 1000BASE-H OAM message has been received from the remote PHY. As soon as this event occurs, transition from state OAMRX_NEWMSG_WAIT to state OAMRX_RXR_UPDT takes place.

In the state OAMRX_RXR_UPDT, the content of the fields REMPHD.OAM.DATAx are stored in 1000BASE-H OAM receive registers 3.510 to 3.517 and the bits RXO_DATA0 of register 3.509. Simultaneously bit RXO_VAL of register 3.509 is set to 1, and the bit RXO_MSGT of register 3.509 is

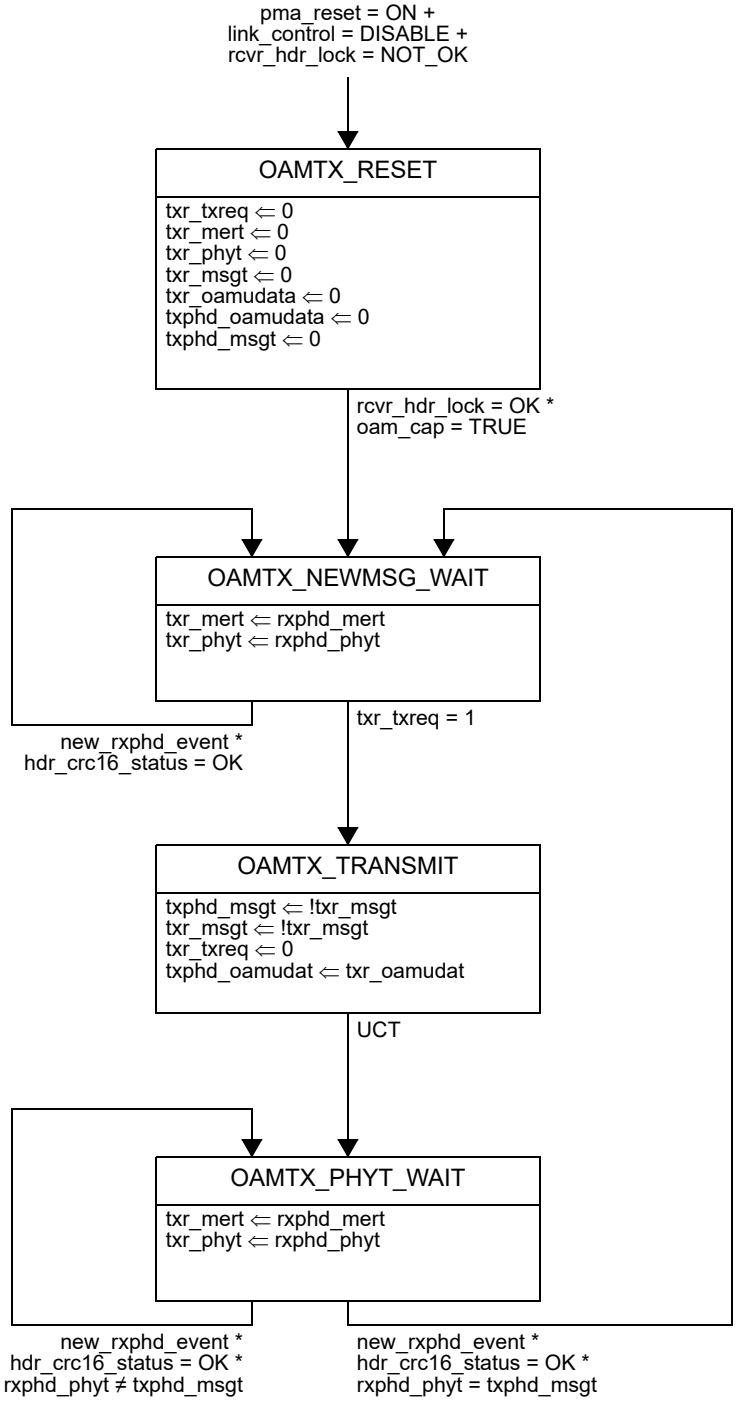

Figure 115–42—PHY 1000BASE-H OAM transmit control state diagram

updated with value of the field REMPHD.OAM.MSGT. Additionally, the local PHY notifies the remote PHY of the reception of the message by setting the field LOCPHD.OAM.PHYT to the value of the field REMPHD.OAM.MSGT (txphd_phyt ⇐ rxphd_msgt).

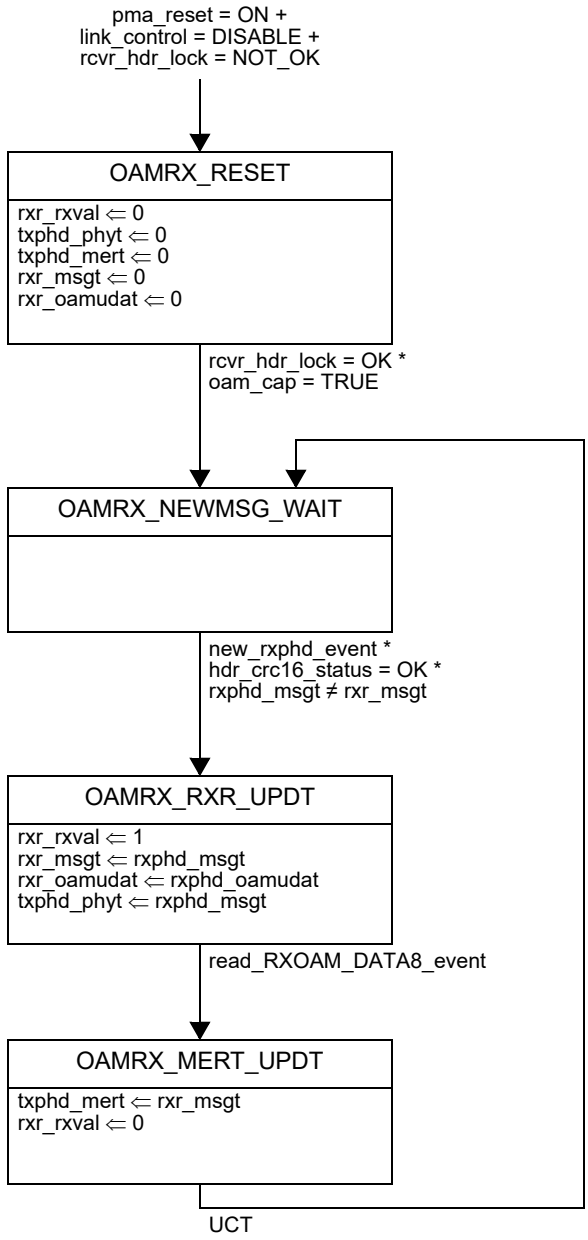

Figure 115–43—PHY 1000BASE-H OAM receive control state diagram

OAMRX_RXR_UPDT state transitions to OAMRX_MERT_UPDT state only when register 3.517 is read (read_OAMDATA8_event), so the 1000BASE-H OAM receive registers are locked until this event. State OAMRX_MERT_UPDT sets the bit RXO_VAL of register 3.509 to 0 indicating that no valid message is stored in the 1000BASE-H OAM receive registers. Also, the local PHY notifies the link partner of reception of the message by the local STA by setting the field LOCPHD.OAM.MERT to the value of the bit RXO_MSGT of register 3.509 (txphd_mert ⇐ rxr_msgt).

The local PHY then waits for a new message to be received (OAMRX_NEWMSG_WAIT).

115.10 Loopback modes

1000BASE-H loopback modes shall be selected using bits 3.518.12:10. Loopback modes support a MAC transmit-to-self that includes selected portions of the local PHY or the local and the remote PHYs.

The default value and value upon reset (bit 1.0.15 = 1) shall be no loopback (3.518.12:10 = 000).

When GMII level loopback mode is selected (3.518.12:10 = 001), the 1000BASE-H PCS shall accept data on the transmit data path from the GMII, looping the data back to the receive path of the GMII. In this mode, the PCS transmitter and receiver are not part of the communication path, and the loopback functionality is provided independent of a link having been established with the link partner. Operations of PCS, PMA, and PMD sublayers are not specified in this loopback mode.

When PMD interface level loopback mode is selected (3.518.12:10 = 010), the loopback shall be implemented near the PMD service interface, completely exercising the PCS and PMA as in normal operation, although the PMA receiver ignores signals from the PMD receive function. PMD operation is not specified in this loopback mode.

When line loopback mode is selected (3.518.12:10 = 011), received data shall be processed and looped back near the GMII interface toward the link partner with data going back through the PCS and PMA transmit path. Received signal is equalized, decoded, and decapsulated by the PMA and PCS. Then the received data stream is forwarded to the GMII receive interface as well as to the PCS transmitter. The GMII transmit interface signals are ignored during line loopback operation. The line loopback is only operative when a bidirectional link has been established. The PCS, PMA, and PMD functions work as in normal operation. The data loopback is implemented between the output of the PCS 64B/65B decoder and the input of the encoder.

115.11 Management interface

PHYs in the 1000BASE-H set shall provide the management capabilities described in this clause and the functionality provided by the referenced Clause 45 registers and bits.

The optional MDIO capability of Clause 45 describes several variables that provide control and status for and about the PHY. If the MDIO is not implemented, an implementation shall include the functionality provided by the specified MDIO registers.

PHYs in the 1000BASE-H set use some generic control bits common with other IEEE 802.3 PHY types. PHY variables shall be mapped as shown in Table 115–18. PHYs in the 1000BASE-H set also use specific registers (1.11, 1.22, 1.900, and 3.500 through 3.522).

In addition to the normal operation capabilities specified elsewhere in this clause, test modes and loopback modes use these registers and bits to facilitate testing.

115.12 Environmental specifications

115.12.1 Temperature classes

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling appropriate to the intended environment (e.g., automotive, industrial, or home networking). A compliant 1000BASE-RHx PHY shall clearly indicate the operating temperature range of Table 115–19 over which their compliance is claimed.

Table 115–18—1000BASE-H variable mapping

MDIO variable/value	PMA/PMD register	Register bit number	PMA/PMD variable/value
Reset = 1	PMA/PMD control 1	1.0.15	pma_reset = ON
Reset = 0	PMA/PMD control 1	1.0.15	pma_reset = OFF
Low Power = 1	PMA/PMD control 1	1.0.11	link_control = DISABLE
Low Power = 0	PMA/PMD control 1	1.0.11	link_control = ENABLE
Global PMD receive signal detect = 1	PMD receive signal detect	1.10.0	signal_detect = OK
Global PMD receive signal detect = 0	PMD receive signal detect	1.10.0	signal_detect = FAIL
Global PMD transmit disable = 1	PMD transmit disable	1.9.0	link_control = DISABLE
Global PMD transmit disable = 0	PMD transmit disable	1.9.0	link_control = ENABLE

Table 115–19—1000BASE-RHx temperature classes

Class	Low temperature (°C)	High temperature (°C)
Regular	0	+70
Extended I	–40	+85
Extended A	–40	+105

115.12.2 General safety

All equipment subject to this clause shall conform to IEC 60950-1 (for IT and motor vehicle applications) and to ISO 26262 (for motor vehicle applications only, if required by the given application). All equipment subject to this clause might additionally be required to conform to applicable local, state, or national motor vehicle standards or as agreed to between the customer and supplier.

115.12.3 Environmental safety

All equipment in automotive applications integrating a PHY subject to this clause shall conform to the potential environmental stresses with respect to their mounting location, as defined in the following specifications:

a) General loads: ISO 16750-1
b) Electrical loads: ISO 16750-2, ISO 7637-2:2008, and ISO 8820-1
c) Mechanical loads: ISO 16750-3, ASTM D4728, and ISO 12103-1
d) Climatic loads: ISO 16750-4, IEC 60068-2-1, IEC 60068-2-27, IEC 60068-2-30, IEC 60068-2-38, IEC 60068-2-52, IEC 60068-2-64, and IEC 60068-2-78
e) Chemical loads: ISO 16750-5 and ISO 20653

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Automotive environmental conditions are generally more severe than those found in many commercial environments.

The targeted application environment(s) require careful analysis.

115.12.4 Electromagnetic compatibility

A system integrating the 1000BASE-RHx PHY shall comply with all applicable local and national codes. In addition, the system might need to comply with more stringent requirements as agreed to between the customer and the supplier, for the limitation of electromagnetic interference. A 1000BASE-RHx PHY shall meet EMC requirements according to ISO 11452 and CISPR 25 test methods for radio frequency (RF) immunity and RF emissions. When used in an automotive environment, a 1000BASE-RHx PHY shall meet the following motor vehicle EMC requirements:

a) Radiated/Conducted Emissions: CISPR 25, IEC 61967-1/4, and IEC 61000-4-21
b) Radiated/Conducted Immunity: ISO 11452, IEC 62132-1/4, and IEC 61000-4-21
c) Electrostatic Discharge: ISO 10605 and IEC 61000-4-2/3
d) Electrical Disturbances: IEC 62215-3 and ISO 7637-2/3

Exact test setup and test limit values may be adapted to each specific application, subject to agreement between the customer and the supplier.

115.12.5 Optical safety

1000BASE-RHx transceivers shall be Hazard Level 1 laser certified under any condition of operation, including an LED as the optical signal source. This includes single fault conditions whether coupled into a fiber or out of an open bore. Transceivers shall be certified to be in conformance with IEC 60825-1 and IEC 60825-2.

Conformance to additional laser safety standards might be required for operation within specific geographic regions.

115.13 Delay constraints

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The sum of the transmit and receive data delays of a 1000BASE-RHx PHY shall not exceed 6500 bit-times. Transmit data delay is measured from the input of a given unit of data at the GMII to the presentation of the same unit of data by the PHY to the MDI. Receive data delay is measured from the input of a given unit of data at the MDI to the presentation of the same unit of data by the PHY to the GMII.

NOTE 1—The transmit and receive delays are not independently testable in a system implementation, and only the total delay from GMII to GMII is testable.

NOTE 2—The physical medium interconnecting two PHYs introduces additional delay (approximately 5 bit-times per meter of POF). In-line connections can also introduce additional delay.

115.14 Protocol implementation conformance statement (PICS) proforma for Clause 115, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and Physical Medium Dependent (PMD) sublayer, types 1000BASE-RHA, 1000BASE-RHB, and 1000BASE-RHC[203]

115.14.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 115, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and Physical Medium Dependent (PMD), types 1000BASE-RHA, 1000BASE-RHB, and 1000BASE-RHC shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

115.14.2 Identification

115.14.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

115.14.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 115, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and Physical Medium Dependent (PMD) sublayer, types 1000BASE-RHA, 1000BASE-RHB, and 1000BASE-RHC
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[203] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

115.14.4 Physical Coding Sublayer (PCS)

Item	Feature	Subclause	Value/Comment	Status	Support
PCS1	Transmit Block transmission	115.2.1	Transmit Blocks transmitted continuously on active link	M	Yes [ ]
PCS2	Transmit Block format	115.2.1	Transmit Block format as specified	M	Yes [ ]
PCS3	Transmit Block symbols rate	115.2.1	Transmit Block symbols transmitted to the PMA at the symbol rate	M	Yes [ ]
PCS4	Pilot S1 generator	115.2.2.1	Pilot S1 generated as specified	M	Yes [ ]
PCS5	Pilot S2 generator	115.2.2.2	Generate 13 $S2_x$ sub-blocks per Transmit Block as specified	M	Yes [ ]
PCS6	Physical header CRC16 input	115.2.3.1	CRC16 computed from PHD bits	M	Yes [ ]
PCS7	Physical header CRC16 operation	115.2.3.1	CRC16 complies with Figure 115–10	M	Yes [ ]
PCS8	Physical header CRC16 initialization	115.2.3.1	CRC16 shift register initialized to 0x0000	M	Yes [ ]
PCS9	Physical header scrambler	115.2.3.2	Scrambler produces same results as Figure 115–11	M	Yes [ ]
PCS10	Physical header scrambler initialization	115.2.3.2	Scrambler shift register initialized with 0x068D332	M	Yes [ ]
PCS11	Physical header BCH encoder	115.2.3.3	720 bits systematically encoded into 896 bits with BCH encoder	M	Yes [ ]
PCS12	Physical header BCH encoder operation	115.2.3.3	BCH parity same as Figure 115–19	M	Yes [ ]
PCS13	Physical header BCH encoder initialization	115.2.3.3	BCH delay elements initialized to zero before encoding	M	Yes [ ]
PCS14	Physical header modulation	115.2.3.4	Physical header modulated as specified	M	Yes [ ]
PCS15	Physical header ordering, division	115.2.3.5	PHS divided in 14 pieces of 128-symbol each, preserving symbol ordering	M	Yes [ ]
PCS16	Physical header ordering, prefixing and postfixing	115.2.3.5	PHS_x pieces prefixed and postfixed with 16 {0} symbols	M	Yes [ ]
PCS17	64B/65B encoder	115.2.4.1.2	Same result of code	M	Yes [ ]
PCS18	PDB alignment signaling	115.2.4.1.3	PDB offset from beginning of first payload sub-block of Transmit Block j+1 indicated in PHD of Transmit Block j	M	Yes [ ]
PCS19	Payload data binary scrambler operation	115.2.4.2	Scrambler produces same result as Figure 115–16	M	Yes [ ]
PCS20	Payload data binary scrambler initialization	115.2.4.2	Scrambler shift register initialized with 0x17C9C58 per Transmit Block	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
PCS21	MLCC demultiplexer	115.2.4.3.1	3150 bits per codeword are demultiplexed in two flows as specified	M	Yes [ ]
PCS22	Payload BCH encoder	115.2.4.3.2	1668 bits of first level systematically encoded into 1976 bits with BCH encoder	M	Yes [ ]
PCS23	Payload BCH encoder operation	115.2.4.3.2	BCH encoder produces same results as Figure 115–19	M	Yes [ ]
PCS24	Payload BCH encoder initialization	115.2.4.3.2	BCH delay elements initialized to zero before encoding	M	Yes [ ]
PCS25	QAM16 mapper	115.2.4.3.3	First level BCH coded bits mapped into QAM16 symbols per codeword as specified	M	Yes [ ]
PCS26	QAM8 mapper	115.2.4.3.4	Second level bits mapped into QAM8 symbols per codeword as specified	M	Yes [ ]
PCS27	First lattice transformation to first level QAM16 symbols	115.2.4.3.5	QAM16 symbols processed symbol-by-symbol per Equation (115–7) and Equation (115–8)	M	Yes [ ]
PCS28	First lattice transformation to second level QAM8 symbols	115.2.4.3.5	QAM8 symbols processed symbol-by-symbol per Equation (115–9) and Equation (115–10)	M	Yes [ ]
PCS29	Lattice addition	115.2.4.3.6	MLCC level 1 and level 2 symbols are added per Equation (115–11) and Equation (115–12)	M	Yes [ ]
PCS30	Second lattice transformation	115.2.4.3.7	Symbols from lattice adder processed symbol-by-symbol per Equation (115–13) and Equation (115–14)	M	Yes [ ]
PCS31	QAM to PAM multiplexer	115.2.4.3.8	988 PAM16 symbols generated from 494 QAM128 symbols per codeword as specified	M	Yes [ ]
PCS32	Payload data symbol scrambler	115.2.4.4	PAM16 payload data symbols scrambled as specified	M	Yes [ ]
PCS33	PCS receive function	115.2.5	Do PHD decoding, PAM16 decoding, and 64B/65B decoding	M	Yes [ ]
PCS34	PCS receive function, decoded PHD fields	115.2.5	PHD data discarded when CRC16 fails	M	Yes [ ]
PCS35	PCS receive function, MLCC decoding failure	115.2.5	Bits of MLCC marked as uncorrectable to 64B/65B decoder, when MLCC decoder is unable to correct	M	Yes [ ]
PCS36	PCS receive function, PHD alignment	115.2.5	Receiver determines alignment of received PDBs by using decoded PHD as specified	M	Yes [ ]
PCS37	64B/65B decoder	115.2.5	Same result of code	M	Yes [ ]

115.14.5 Physical Medium Attachment (PMA)

Item	Feature	Subclause	Value/Comment	Status	Support
PMA1	Payload data THP	115.3.1.1	Payload data is THP processed per Equation (115–19), Equation (115–20), and Equation (115–21)	M	Yes [ ]
PMA2	Payload data THP, reset	115.3.1.1	Payload data THP state is reset before any payload data sub-block	M	Yes [ ]
PMA3	Transmit power scaling	115.3.1.2	Symbols of Transmit Block scaled with scaling factors per Table 115–5 before transmission to PMD	M	Yes [ ]
PMA4	Transmit power scaling, pilot S1, pilot $S2_x$ and PHS_x sub-blocks	115.3.1.2	Scaling factor directly applied to symbols from PCS transmit	M	Yes [ ]
PMA5	Transmit power scaling, payload data sub-blocks	115.3.1.2	Scaling factor applied to symbols from THP	M	Yes [ ]
PMA6	PHD content	115.3.4	PHD content as detailed in Table 115–6	M	Yes [ ]
PMA7	Transmit PHD commit point	115.3.4	PHD fields assigned by state diagrams are sampled at the start of a Transmit Block and transmitted in that current Transmit Block	M	Yes [ ]
PMA8	Receive PHD commit point	115.3.4	Received PHD fields are available to state diagrams and registers after reception, decoding, and validation of the entire PHS, and before Transmit Block reception is completed	M	Yes [ ]
PMA9	PHY TX control state diagram	115.3.5.2	Transmit operation conforms to Figure 115–22	M	Yes [ ]
PMA10	PHY RX control state diagram	115.3.5.3	Receive operation conforms to Figure 115–23	M	Yes [ ]
PMA11	Coarse timing recovery	115.3.5.3	Establish symbol synchronization and coarse timing recovery using pilot S1 signal	M	Yes [ ]
PMA12	Fine timing recovery	115.3.5.3	Perform fine timing recovery after symbol synchronization (s1_synch = OK) to provide stable receiver sampling clock	M	Yes [ ]
PMA13	Equalizer training using S2	115.3.5.3	After rcvr_clock_lock = OK train equalizers using received pilot $S2_x$ sub-blocks	M	Yes [ ]
PMA14	THP initialization	115.3.5.3	Initialize THP per 115.3.6.3 after rcvr_hdr_lock = OK	M	Yes [ ]
PMA15	Link monitor state diagram	115.3.5.4	Link status determined per Figure 115–24	M	Yes [ ]

115.14.7 Test modes

Item	Feature	Subclause	Value/Comment	Status	Support
TM1	Test modes	115.5	Test mode 1 through test mode 6 implemented	M	Yes [ ]
TM2	Selecting test modes	115.5	Selected with operation mode bits of the 1000BASE-H PCS control register	M	Yes [ ]
TM3	Test mode 1, PCS transmit operation	115.5.1	All zero bits sourced to binary scrambler and GMII ignored	M	Yes [ ]
TM4	Test mode 1, PCS receive operation	115.5.1	Any one bit at binary descrambler output counted as error	M	Yes [ ]
TM5	Test mode 1, PMA and PMD operation	115.5.1	PMA and PMD functions operate as in normal (non-test) mode	M	Yes [ ]
TM6	Test mode 1, transmit announcement	115.5.1	Announce to link partner using PHD.TX.NEXT.MODE as specified	M	Yes [ ]
TM7	Test mode 1 and normal mode PCS receive reconfiguration	115.5.1	PCS receive function reconfigured per PHD.TX.NEXT.MODE	M	Yes [ ]
TM8	Test mode 2 signal pattern	115.5.2	PMA transmits one {+1} symbol followed by one {–1}, continually, symbols timed with local symbol clock	M	Yes [ ]
TM9	Test mode 3 signal pattern	115.5.3	PMA transmits 10 {+1} symbol followed by 10 {–1}, continually, symbols timed with local symbol clock	M	Yes [ ]
TM10	Test mode 4 signal pattern	115.5.4	PMA transmits 250 times sequence $q1$ followed by 250 times sequence $q2$, continually, symbols timed with local symbol clock	M	Yes [ ]
TM11	Test mode 5 signal pattern	115.5.5	PMA transmits {0} symbols timed with local symbol clock	M	Yes [ ]
TM12	Test mode 6 signal pattern, scrambler generator polynomials	115.5.6	PMA transmit sequence s_n generated using scrambler generator polynomials per Equation (115–25) and Equation (115–26)	M	Yes [ ]
TM13	Test mode 6 signal pattern, shift registers update rate	115.5.6	Maximum-length shift registers updated once per symbol interval	M	Yes [ ]
TM14	Test mode 6 signal pattern, shift registers reset	115.5.6	Maximum-length shift registers reset to 0x7FF before pattern generation	M	Yes [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
TM15	Test mode 6 signal pattern, intermediate $y0_n$ generation	115.5.6	$y0_n$ sequence of PAM16 symbols generated per Equation (115–27), from $Scr0_n$[10:0] and $Scr1_n$[10:0]	M	Yes [ ]
TM16	Test mode 6 signal pattern, intermediate $y1_n$ generation	115.5.6	$y1_n$ sequence of PAM16 symbols generated per Equation (115–28), from $Scr0_n$[10:0] and $Scr1_n$[10:0]	M	Yes [ ]
TM17	Test mode 6 signal pattern, s_n generation	115.5.6	s_n sequence of PAM256 symbols generated per Equation (115–29), from $y0_n$ and $y1_n$	M	Yes [ ]
TM18	Test mode 6 symbol clock reference	115.5.6	s_n sequence of PAM256 symbols timed with local symbol clock	M	Yes [ ]

115.14.8 Physical Medium Dependent (PMD)

Item	Feature	Subclause	Value/Comment	Status	Support
PMD1	PMD transmit function, symbol to optical signal	115.6.2.2	tx_signal amplitude translated to optical power signal per function of Equation (115–30)	M	Yes [ ]
PMD2	PMD transmit function, power control	115.6.2.2	Turn on and turn off optical power output per PMD_TXPWR.request	EEE:M	Yes [ ] N/A [ ]
PMD3	PMD receive function	115.6.2.3	Translate optical signal in MDI into analog signal provided by PMD_COMSIGNAL.indication	M	Yes [ ]
PMD4	PMD receive function, PMD_RXPWR.request(OFF)	115.6.2.3	PMD_RXPWR.request(OFF) causes save of PMD receiver state so not affected by optical signal during LPI quiet periods	EEE:M	Yes [ ] N/A [ ]
PMD5	PMD receive function, PMD_RXPWR.request(ON)	115.6.2.3	PMD_RXPWR.request(ON) resumes optical signal processing of PMD receiver	EEE:M	Yes [ ] N/A [ ]
PMD6	PMD signal detect function	115.6.2.4	signal_detect generated in response to MDI AOP and sd_inh per Table 115–7	M	Yes [ ]

115.14.9 PMD to MDI optical specifications

Item	Feature	Subclause	Value/Comment	Status	Support
PMI1	Transmitter optical specifications	115.6.3.1	PHY transmitter meets Table 115–8 specifications measured at TP2 per techniques of 115.6.4	M	Yes [ ]
PMI2	Transmitter modal power distribution	115.6.3.1	Modal power distribution at TP2 is higher than lower bound limits of Table 115–9 per technique of 115.6.4.11	M	Yes [ ]
PMI3	Symbol transmission rate	115.6.3.2	Be within the range 325.00 MBd ± 0.01%	M	Yes [ ]
PMI4	Receiver optical specifications	115.6.3.3	PHY receiver meets Table 115–10 specifications measured at TP3 per techniques 115.6.4	M	Yes [ ]
PMI5	Damage threshold	115.6.3.3	Receiver tolerate, without damage, continuous exposure to an optical input signal having a power level as specified in Table 115–10	M	Yes [ ]
PMI6	Reliable link establishment	115.6.3.3	PHY able to establish a reliable link per 115.3.7.1 throughout minimum to maximum AOP range of Table 115–10, for received signals that were transmitted per 115.6.3.1 and have passed through a fiber optic channel per 115.7	M	Yes [ ]
PMI7	Error ratio	115.6.3.3	PHY provides a BER less than 10^{-12} in test mode 1 and a frame error ratio less than 1.1×10^{-10} for continuous transmission of 64-octet Ethernet frames in normal (non-test) mode, throughout minimum to maximum AOP range of Table 115–10, for received signals that were transmitted per 115.6.3.1 and have passed through a fiber optic channel per 115.7	M	Yes [ ]
PMI8	Receiver boundary conditions	115.6.3.4	PHY establishes reliable link as specified in 115.6.3.3 under conditions of 115.6.3.4.1 and 115.6.3.4.2	M	Yes [ ]

115.14.10 Optical measurement requirements

Item	Feature	Subclause	Value/Comment	Status	Support
OM1	Transmitter measurements location	115.6.4	All transmitter measurements made at TP2	M	Yes [ ]
OM2	Receiver measurements location	115.6.4	All receive measurements made at TP3	M	Yes [ ]
OM3	Center wavelength measurement	115.6.4.1	Center wavelength meets specifications per IEC 61280-1-3 under normal (non-test) operation mode signal	M	Yes [ ]
OM4	Spectral width measurement	115.6.4.2	Spectra width meets specifications per IEC 61280-1-3 under normal (non-test) operation mode signal	M	Yes [ ]
OM5	Average Optical Power (AOP) measurement	115.6.4.3	AOP meets specifications per 115.6.4.3	M	Yes [ ]
OM6	Transmitter rise and fall time measurements	115.6.4.4	Transmitter rise and fall time meets specifications per 115.6.4.4	M	Yes [ ]
OM7	Transmitter extinction ratio measurement	115.6.4.5	Transmitter extinction ratio meets specifications per 115.6.4.5	M	Yes [ ]
OM8	Transmitter overshoot measurement	115.6.4.6	Transmitter overshoot meets specifications per 115.6.4.6	M	Yes [ ]
OM9	Transmitter output droop measurement	115.6.4.7	Transmitter output droop meets specifications per 115.6.4.7	M	Yes [ ]
OM10	Transmitter distortion measurement	115.6.4.8	Transmitter distortion meets specifications per 115.6.4.8	M	Yes [ ]
OM11	Transmitter timing jitter measurement procedure	115.6.4.9	Transmitter jitter meets specifications per procedure of 115.6.4.9	M	Yes [ ]
OM12	Transmitter timing jitter measurement device	115.6.4.9	Transmitter jitter meets specifications using a measurement device per 115.6.4.9	M	Yes [ ]
OM13	Transmitter relative intensity noise (RIN) measurement	115.6.4.10	Transmitter RIN meets specifications per 115.6.4.10	M	Yes [ ]
OM14	Transmitter modal power distribution (MPD) measurement	115.6.4.11	Transmitter MPD meets specifications per 115.6.4.11	M	Yes [ ]

115.14.11 Characteristics of the fiber optic cabling (channel)

Item	Feature	Subclause	Value/Comment	Status	Support
CH1	Fiber optic channel type I	115.7	Insertion loss is less than 9.5 dB without in-line connections, and transfer function meet specification per 115.7.1, per techniques of 115.7.4 and 115.7.5, under spectral distribution and MPD at TP2 per 115.6.3.1	M	Yes [ ]
CH2	Fiber optic channel type II	115.7	Insertion loss is less than 8 dB without in-line connections, and transfer function meet specification per 115.7.2, per techniques of 115.7.4 and 115.7.5, under spectral distribution and MPD at TP2 per 115.6.3.1	M	Yes [ ]
CH3	Fiber optic channel type III	115.7	Insertion loss is less than 3 dB without in-line connections, and transfer function meet specification per 115.7.3, per techniques of 115.7.4 and 115.7.5, under spectral distribution and MPD at TP2 per 115.6.3.1	M	Yes [ ]
CH4	Transfer function with in-line connections	115.7	Meet transfer function specifications of the particular type with in-line connections	M	Yes [ ]
CH5	Insertion loss measurement	115.7.4	Fiber optic channel meets insertion loss per ISO/IEC 14763-3	M	Yes [ ]
CH6	Transfer function measurement	115.7.5	Fiber optic channel meets transfer function per IEC 60793-1-41:2010	M	Yes [ ]

115.14.12 Medium dependent interface (MDI)

Item	Feature	Subclause	Value/Comment	Status	Support
MDI1	MDI receptacle duplex	115.8.1	MDI receptacle provides two separate slots: transmit and receive	RHA:M	Yes [ ]
MDI2	MDI receptacle labeling	115.8.1	MDI receptacle indicate with labeling the slots of the transmitter and the receiver	RHA:M	Yes [ ]
MDI3	MDI receptacle link segment acceptance	115.8.1	MDI receptacle accepts duplex cable compliant with IEC 60794-2-41	RHA:M	Yes [ ]
MDI4	MDI receptacle states	115.8.1	MDI receptacle has open and close states	RHA:M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Value/Comment	Status	Support
MDI5	MDI receptacle cable retention	115.8.1	MDI receptacle has a retention mechanism of cable with a retention force of 4 N aligned with the cable insertion in the direction of cable extraction for PE jacket cables	RHA:M	Yes [ ]
MDI6	MDI receptacle cable retention test procedure	115.8.1	MDI receptacle provides a retention force per IEC 61300-2-40 with AOP loss of less than 0.4 dB	RHA:M	Yes [ ]
MDI7	Cutting tool result	115.8.1	Cutting tool provides flat fiber end facets perpendicular to cable axis as specified	RHA:M	Yes [ ]
MDI8	MDI receptacle cable split length indication	115.8.1	MDI receptacle vendor indicates minimum cable split length for suitable connection	RHA:M	Yes [ ]
MDI9	Cable marking	115.8.1	Duplex POF cable has marking on one of the jackets	RHA:M	Yes [ ]

115.14.13 1000BASE-H Operations, Administration, and Maintenance (1000BASE-H OAM) channel

Item	Feature	Subclause	Value/Comment	Status	Support
OC1	STA write of 1000BASE-H OAM message	115.9.1	STA creates a new message to be transmitted per specified steps	BHOAM:M	Yes [ ] N/A [ ]
OC2	STA read of 1000BASE-H OAM message	115.9.3	STA reads a new received message per specified steps	BHOAM:M	Yes [ ] N/A [ ]
OC3	1000BASE-H OAM transmit	115.9.4.2	PHY operation for 1000BASE-H OAM message transmission conforms to Figure 115–42	BHOAM:M	Yes [ ] N/A [ ]
OC4	1000BASE-H OAM receive	115.9.4.3	PHY operation for 1000BASE-H OAM message reception conforms to Figure 115–43	BHOAM:M	Yes [ ] N/A [ ]

115.14.14 Loopback modes

Item	Feature	Subclause	Value/Comment	Status	Support
LB1	Loopback mode selection	115.10	Selected using bits 3.518.12:10	M	Yes [ ]
LB2	Loopback mode reset	115.10	Default and reset value is no loopback	M	Yes [ ]
LB3	GMII level loopback	115.10	GMII TX looped back to GMII RX	M	Yes [ ]
LB4	PMD interface level loopback	115.10	Transmit path looped back to receive path near PMD service interface, with PCS and PMA operating as in normal mode, and the PMA receive ignoring PMD receive signals	M	Yes [ ]
LB5	Line loopback	115.10	Receive data looped back to transmit path (toward link partner) near GMII interface	M	Yes [ ]

115.14.15 Management Interface

Item	Feature	Subclause	Value/Comment	Status	Support
MI1	1000BASE-RHx management	115.11	Provide Clause 115 management capabilities and functionality provided by referenced Clause 45 registers and bits	M	Yes [ ]
MI2	MDIO registers functionality	115.11	Provide control and status functionalities of MDIO registers	M	Yes [ ]
MI3	MDIO interface mapping	115.11	Implement variable to register mapping as specified in Table 115–18	MDIO:M	Yes [ ] N/A [ ]

115.14.16 Environmental specifications

Item	Feature	Subclause	Value/Comment	Status	Support
E1	Temperature class indication	115.12.1	PHY indicates the operating temperature range of Table 115–19 over which their compliance is claimed	M	Yes [ ]
E2	Conformance to IEC 60950-1	115.12.2	For IT and motor vehicle applications	M	Yes [ ]
E3	Conformance to ISO 26262	115.12.2	For motor vehicle applications only, if required by the given application	AE:O	Yes [ ] No [ ] N/A [ ]

Item	Feature	Subclause	Value/Comment	Status	Support
E4	Environmental safety	115.12.3	Conform to environmental stresses as specified in 115.12.3	AE:M	Yes [ ] N/A [ ]
E5	Electromagnetic compatibility	115.12.4	Comply with all applicable local and national codes	M	Yes [ ]
E6	EMC requirements	115.12.4	EMC meets specifications per ISO 11452 and CISPR 25 test methods	M	Yes [ ]
E7	Motor vehicle EMC require-ments	115.12.4	Meet motor vehicle EMC requirements as specified in 115.12.4	AE:M	Yes [ ] N/A [ ]
E8	Optical safety	115.12.5	Hazard Level 1 certified under any operating contition	M	Yes [ ]
E9	Optical safety certification	115.12.5	Conformant to IEC 60825-1 and IEC 60825-2	M	Yes [ ]

115.14.17 Delay constraints

Item	Feature	Subclause	Value/Comment	Status	Support
DLY1	Delay constraint	115.13	Sum of the transmit and receive data delays does not exceed 6500 bit times	M	Yes [ ]

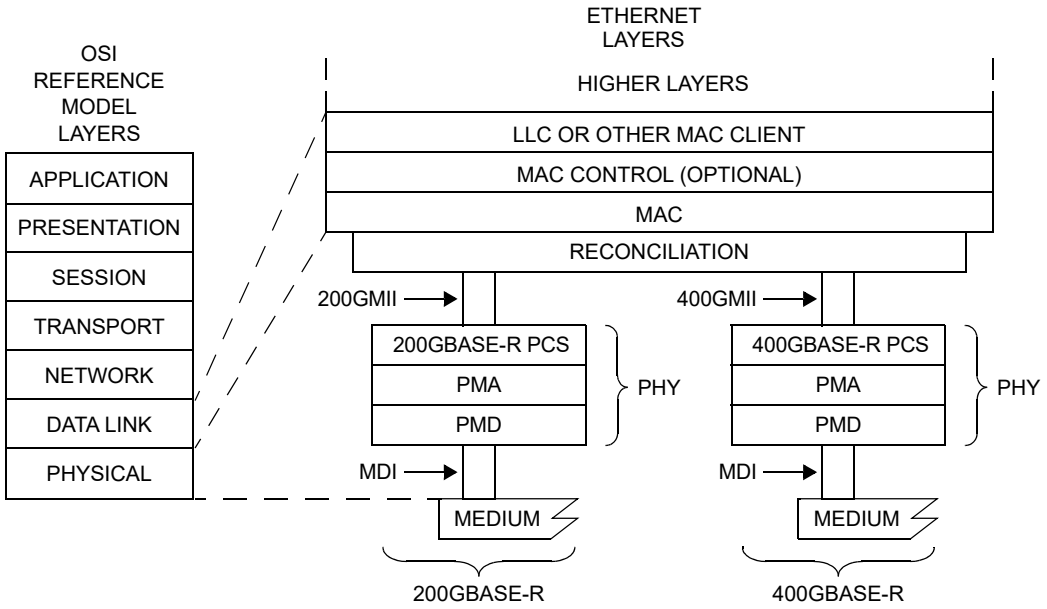
116. Introduction to 200 Gb/s and 400 Gb/s networks

116.1 Overview



116.1.1 Scope

This clause describes the general requirements for 200 Gigabit and 400 Gigabit Ethernet.

200 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 200 Gb/s, coupled with any IEEE 802.3 200GBASE Physical Layer implementation and is defined for full duplex operation only. 400 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 400 Gb/s, coupled with any IEEE 802.3 400GBASE Physical Layer implementation and is defined for full duplex operation only.

116.1.2 Relationship of 200 Gigabit and 400 Gigabit Ethernet to the ISO OSI reference model

200 Gigabit and 400 Gigabit Ethernet couples the IEEE 802.3 MAC to a family of 200 Gb/s and 400 Gb/s Physical Layer devices. The relationships among 200 Gigabit and 400 Gigabit Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 116–1.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 116–1—Architectural positioning of 200 Gigabit and 400 Gigabit Ethernet

While this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience. The only exceptions are as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) The 200GMII and 400GMII, which, when implemented as logical interconnection points between the MAC sublayer and the Physical Layer device (PHY), use a 64-bit wide data path as specified in Clause 117. Physical instantiations of this interface may use other data-path widths.

b) The management interface, which, when physically implemented as the MDIO/MDC (Management Data Input/Output and Management Data Clock) at an observable interconnection port, uses a bit-wide data path as specified in Clause 45.

c) The PMA service interface, which, when physically implemented as 400GAUI-16 (400 Gb/s sixteen-lane Attachment Unit Interface) at an observable interconnection port, uses a 16-lane data path as specified in Annex 120B or Annex 120C.

d) The PMA service interface, which, when physically implemented as 200GAUI-8 (200 Gb/s eight-lane Attachment Unit Interface) or 400GAUI-8 (400 Gb/s eight-lane Attachment Unit Interface) at an observable interconnection port, uses an 8-lane data path as specified in Annex 120B, Annex 120C, Annex 120D, or Annex 120E.

e) The PMA service interface, which, when physically implemented as 200GAUI-4 (200 Gb/s four-lane Attachment Unit Interface) at an observable interconnection port, uses a 4-lane data path as specified in Annex 120D or Annex 120E.

f) The MDI as specified in Clause 123 for 400GBASE-SR16 uses a 16-lane data path.

g) The MDIs as specified in:

— Clause 122 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8
— Clause 138 for 400GBASE-SR8
— Clause 150 for 400GBASE-SR4.2

all use an 8-lane data path.

h) The MDIs as specified in:

— Clause 121 for 200GBASE-DR4
— Clause 122 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4
— Clause 124 for 400GBASE-DR4
— Clause 136 for 200GBASE-CR4
— Clause 137 for 200GBASE-KR4
— Clause 138 for 200GBASE-SR4
— Clause 151 for 400GBASE-FR4 and 400GBASE-LR4-6

all use a 4-lane data path.

116.1.3 Nomenclature

The nomenclature employed by the 200 Gb/s and 400 Gb/s Physical Layer is explained as follows.

The alpha-numeric prefix 200GBASE in the port type (e.g., 200GBASE-R) represents a family of Physical Layer devices operating at a speed of 200 Gb/s. The alpha-numeric prefix 400GBASE in the port type (e.g., 400GBASE-R) represents a family of Physical Layer devices operating at a speed of 400 Gb/s.

200GBASE-R represents a family of Physical Layer devices using the Physical Coding Sublayer for 200 Gb/s operation over multiple PCS lanes (see Clause 119). Physical Layer devices listed in Table 116–1 are defined for operation at 200 Gb/s.

400GBASE-R represents a family of Physical Layer devices using the Physical Coding Sublayer for 400 Gb/s operation over multiple PCS lanes (see Clause 119). Physical Layer devices listed in Table 116–2 are defined for operation at 400 Gb/s.

Table 116–1—200 Gb/s PHYs

Name	Description
200GBASE-KR4	200 Gb/s PHY using 200GBASE-R encoding over four lanes of an electrical backplane (see Clause 137)
200GBASE-CR4	200 Gb/s PHY using 200GBASE-R encoding over four lanes of twinaxial copper cable (see 1.4.559 and Clause 136)
200GBASE-SR4	200 Gb/s PHY using 200GBASE-R encoding over four lanes of multimode fiber (see Clause 138)
200GBASE-DR4	200 Gb/s PHY using 200GBASE-R encoding over four lanes of single-mode fiber, with reach up to at least 500 m (see Clause 121)
200GBASE-FR4	200 Gb/s PHY using 200GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 2 km (see Clause 122)
200GBASE-LR4	200 Gb/s PHY using 200GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 10 km (see Clause 122)
200GBASE-ER4	200 Gb/s PHY using 200GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 40 km (see Clause 122)

Table 116–2—400 Gb/s PHYs

Name	Description
400GBASE-SR16	400 Gb/s PHY using 400GBASE-R encoding over sixteen lanes of multimode fiber, with reach up to at least 100 m (see Clause 123)
400GBASE-SR8	400 Gb/s PHY using 400GBASE-R encoding over eight lanes of multimode fiber, with reach up to at least 100 m (see Clause 138)
400GBASE-SR4.2	400 Gb/s PHY using 400GBASE-R encoding over eight lanes on multimode fiber in a bidirectional WDM format, with reach up to at least 150 m (see Clause 150)
400GBASE-DR4	400 Gb/s PHY using 400GBASE-R encoding over four lanes of single-mode fiber, with reach up to at least 500 m (see Clause 124)
400GBASE-FR8	400 Gb/s PHY using 400GBASE-R encoding over eight WDM lanes on single-mode fiber, with reach up to at least 2 km (see Clause 122)
400GBASE-FR4	400 Gb/s PHY using 400GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 2 km (see Clause 151)
400GBASE-LR4-6	400 Gb/s PHY using 400GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 6 km (see Clause 151)
400GBASE-LR8	400 Gb/s PHY using 400GBASE-R encoding over eight WDM lanes on single-mode fiber, with reach up to at least 10 km (see Clause 122)
400GBASE-ER8	400 Gb/s PHY using 400GBASE-R encoding over eight WDM lanes on single-mode fiber, with reach up to at least 40 km (see Clause 122)

116.1.4 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. Table 116–3, Table 116–4, and Table 116–5 specify the correlation between PHY types and clauses. Implementations conforming to one or more PHY types meet the requirements of the corresponding clauses.

Table 116–3—PHY type and clause correlation (200GBASE copper)

PHY type	Clause[a]										
	73	78	117		118	119	120	120B	120D	136	137
	Auto-Negotiation	EEE	RS	200GMII	200GMII Extender	200GBASE-R PCS	200GBASE-R PMA	200GAUI-8 C2C	200GAUI-4 C2C	200GBASE-CR4 PMD	200GBASE-KR4 PMD
200GBASE-KR4	M	O	M	O	O	M	M	O	O		M
200GBASE-CR4	M	O	M	O	O	M	M	O	O	M	

[a]O = Optional, M = Mandatory.

Table 116–4—PHY type and clause correlation (200GBASE optical)

PHY type	Clause[a]														
	78	117		118	119	120	120B	120C	120D	120E	121	122			138
	EEE	RS	200GMII	200GMII Extender	200GBASE-R PCS	200GBASE-R PMA	200GAUI-8 C2C	200GAUI-8 C2M	200GAUI-4 C2C	200GAUI-4 C2M	200GBASE-DR4 PMD	200GBASE-FR4 PMD	200GBASE-LR4 PMD	200GBASE-ER4 PMD	200GBASE-SR4 PMD
200GBASE-SR4	O	M	O	O	M	M	O	O	O	O					M
200GBASE-DR4	O	M	O	O	M	M	O	O	O	O	M				
200GBASE-FR4	O	M	O	O	M	M	O	O	O	O		M			
200GBASE-LR4	O	M	O	O	M	M	O	O	O	O			M		
200GBASE-ER4	O	M	O	O	M	M	O	O	O	O				M	

[a] O = Optional, M = Mandatory.

[a] O = Optional, M = Mandatory.

116.2 Summary of 200 Gigabit and 400 Gigabit Ethernet sublayers

116.2.1 Reconciliation Sublayer (RS) and Media Independent Interface

The Media Independent Interface (Clause 117) provides a logical interconnection between the MAC sublayer and Physical Layer devices (PHYs). The Media Independent Interface is not intended to be physically instantiated, rather it can logically connect layers within a device.

The 200GMII supports 200 Gb/s operation and the 400GMII supports 400 Gb/s operation through its 64-bit-wide transmit and receive data paths. The Reconciliation Sublayer (RS) provides a mapping between the signals provided at the Media Independent Interface (200GMII and 400GMII) and the MAC/PLS service definition.

While the 200GMII and 400GMII are optional interfaces, they are used extensively in this standard as a basis for functional specification and provides a common service interface for the physical coding sublayer defined in Clause 119.

116.2.2 200GMII and 400GMII Extender Sublayers (200GXS and 400GXS)

The 200 Gigabit 200GMII Extender Sublayer (200GXS) is part of the 200GMII Extender (Clause 118). It is identical in function to the 200GBASE-R PCS in Clause 119 with the exceptions defined in Clause 118. The 400 Gigabit 400GMII Extender Sublayer (400GXS) is part of the 400GMII Extender (Clause 118). It is identical in function to the 400GBASE-R PCS in Clause 119 with the exceptions defined in Clause 118.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The optional 200GMII Extender (Clause 118) can be inserted between the Reconciliation Sublayer and the PHY to transparently extend the reach of the 200GMII. The optional 400GMII Extender (Clause 118) can be inserted between the Reconciliation Sublayer and the PHY to transparently extend the reach of the 400GMII.

116.2.3 Physical Coding Sublayer (PCS)

The terms 200GBASE-R and 400GBASE-R refer to a specific family of Physical Layer implementations based upon the 64B/66B data coding method specified in Clause 119 and the PMA specifications defined in Clause 120. Clause 119 PCSs perform encoding (decoding) of data from (to) the 200GMII or 400GMII to 256B/257B code blocks, apply FEC, distribute the data to multiple lanes, and transfer the encoded data to the PMA.

The 200GBASE-R PCS has almost the same functionality as the 200GXS, and therefore may be configured as a 200GXS in order to implement part of the optional 200GMII Extender (see Clause 118). The 400GBASE-R PCS has almost the same functionality as the 400GXS, and therefore may be configured as a 400GXS in order to implement part of the optional 400GMII Extender (see Clause 118).

116.2.4 Physical Medium Attachment (PMA) sublayer

The PMA provides a medium-independent means for the PCS to support the use of a range of physical media. The 200GBASE-R and 400GBASE-R PMAs perform the mapping of transmit and receive data streams between the PCS and PMA via the PMA service interface, and the mapping and multiplexing of transmit and receive data streams between the PMA and PMD via the PMD service interface. In addition, the PMA performs retiming of the received data stream when appropriate, optionally provides data loopback at the PMA or PMD service interface, and optionally provides test pattern generation and checking.

The 200GBASE-R and 400GBASE-R PMAs are specified in Clause 120.

116.2.5 Physical Medium Dependent (PMD) sublayer

The Physical Medium Dependent sublayer is responsible for interfacing to the transmission medium. The PMD is located just above the Medium Dependent Interface (MDI). The MDI, logically subsumed within each PMD subclause, is the actual medium attachment for the various supported media.

The 200GBASE-R PMDs and their corresponding media are specified in Clause 121, Clause 122, and Clause 136 through Clause 138. The 400GBASE-R PMDs and their corresponding media are specified in Clause 122 through Clause 124, Clause 138, and Clause 150.

116.2.6 Management interface (MDIO/MDC)

The optional MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMDs) and Station Management (STA) entities.

116.2.7 Management

Managed objects, attributes, and actions are defined for all 200 Gigabit and 400 Gigabit Ethernet components. These items are defined in Clause 30.

116.3 Service interface specification method and notation

The service interface specification for the 200GBASE-R and 400GBASE-R Physical Layers is as per the definition in 1.2.2. Note that the 200GBASE-R and 400GBASE-R inter-sublayer service interfaces use

multiple scalar REQUEST and INDICATION primitives, to indicate the transfer of multiple independent streams of data units, as defined in 116.3.1 through 116.3.3.

116.3.1 Inter-sublayer service interface

The inter-sublayer service interface is described in an abstract manner and does not imply any particular implementation. The inter-sublayer service interface primitives are defined as follows:

IS_UNITDATA_*i*.request
IS_UNITDATA_*i*.indication
IS_SIGNAL.indication

The IS_UNITDATA_*i*.request (where $i = 0$ to n – 1, and n is the number of streams of data units) primitive is used to define the transfer of multiple streams of data units from a sublayer to the next lower (closer to the medium) sublayer. The IS_UNITDATA_*i*.indication (where $i = 0$ to n – 1, and n is the number of streams of data units) primitive is used to define the transfer of multiple streams of data units from a sublayer to the next higher (closer to the MAC) sublayer. The IS_SIGNAL.indication primitive is used to define the transfer of signal status from a sublayer to the next higher sublayer.

116.3.2 Instances of the Inter-sublayer service interface

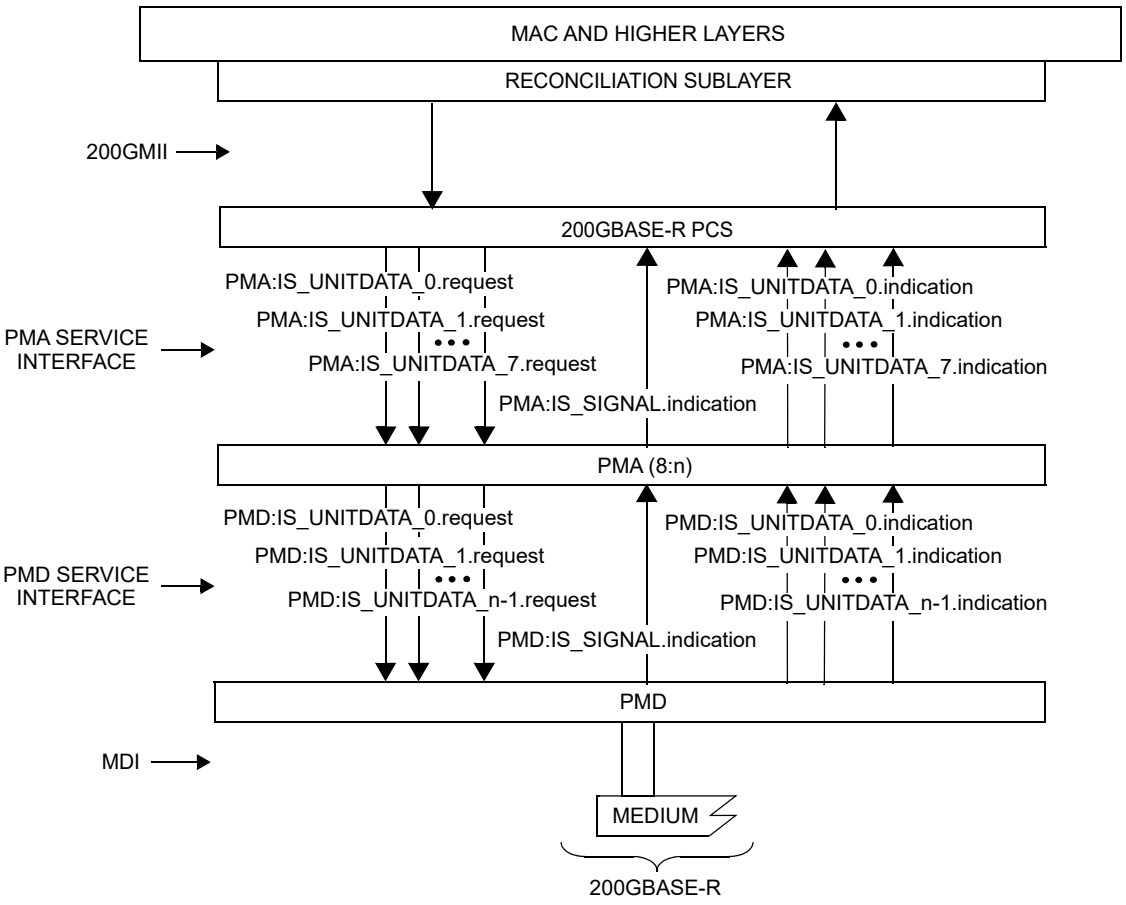
The inter-sublayer interface can be instantiated between different sublayers, hence a prefix notation is defined to identify a specific instance of an inter-sublayer service interface. The following prefixes are defined:

a) PMD:—for primitives issued on the interface between the PMD sublayer and the PMA sublayer called the PMD service interface.
b) PMA:—for primitives issued on the interface between the PMA sublayer and the PCS, DTE 200GXS, DTE 400GXS, or PMA sublayer above called the PMA service interface.
c) PHY XS:—for primitives issued on the interface between the PMA sublayer and the PHY 200GXS sublayer or PHY 400GXS sublayer called the PHY XS service interface.

Examples of inter-sublayer service interfaces for 200GBASE-R and 400GBASE-R with their corresponding instance names are illustrated in Figure 116–2 and Figure 116–3, respectively. For example, the primitives for one instance of the inter-sublayer service interface, named the PMD service interface, are identified as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication.

Primitives for other instances, of inter-sublayer interfaces, are represented in a similar manner as described above.



116.3.3 Semantics of inter-sublayer service interface primitives

The semantics of the inter-sublayer service interface primitives for the 200GBASE-R and 400GBASE-R sublayers are described in 116.3.3.1 through 116.3.3.3.

116.3.3.1 IS_UNITDATA_*i*.request

The IS_UNITDATA_*i*.request (where $i = 0$ to n – 1) primitive is used to define the transfer of multiple streams of data units from a sublayer to the next lower sublayer, where n is the number of parallel streams of data units.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
n = NUMBER OF PARALLEL STREAMS OF DATA UNITS

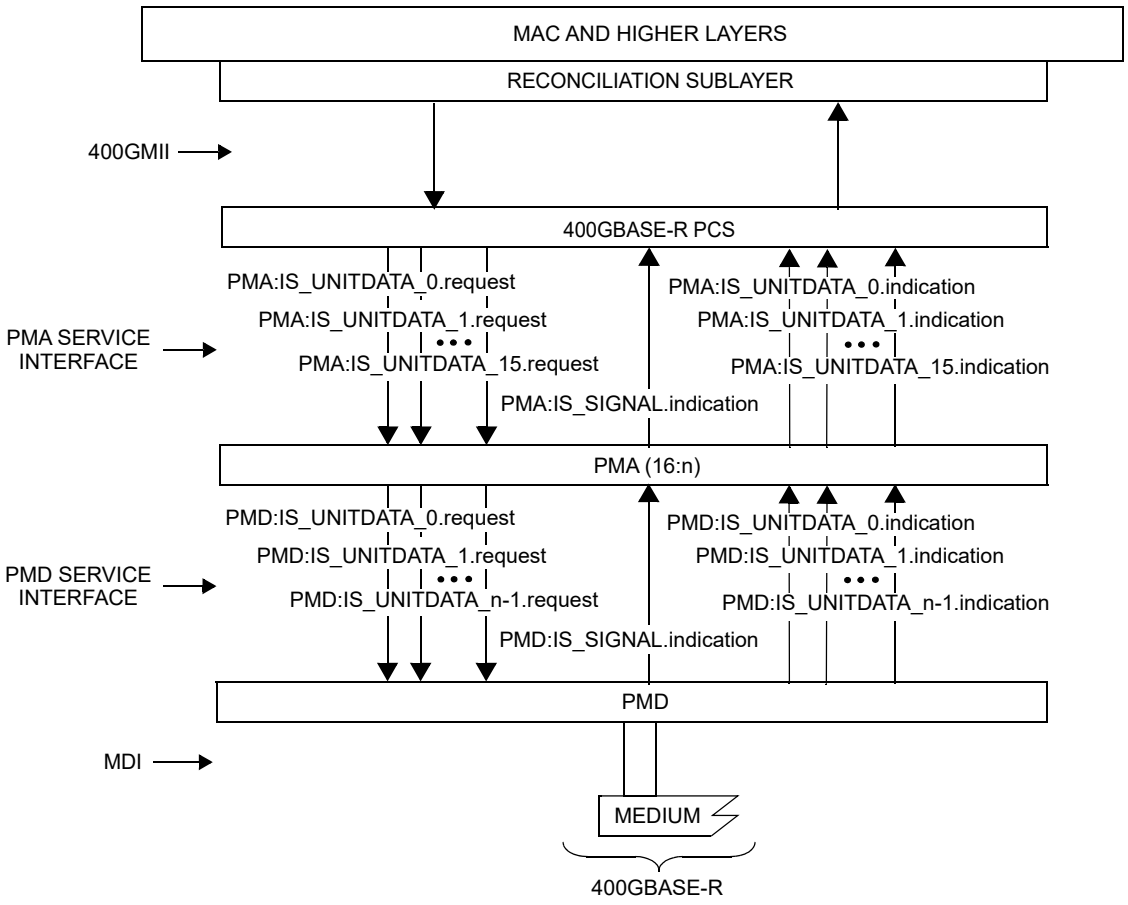

Figure 116–2—200GBASE-R inter-sublayer service interfaces

116.3.3.1.1 Semantics of the service primitive

IS_UNITDATA_0.request(tx_symbol)
IS_UNITDATA_1.request(tx_symbol)
...
IS_UNITDATA_n–1.request(tx_symbol)

The data conveyed by IS_UNITDATA_0.request to IS_UNITDATA_n–1.request consists of n parallel continuous streams of encoded symbols, one stream for each lane. Depending on the specific instance of the inter-sublayer service interface each of the tx_symbol parameters can either take one of two values: zero or one; or take one of four values: zero, one, two, or three.

400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
n = NUMBER OF PARALLEL STREAMS OF DATA UNITS

Figure 116–3—400GBASE-R inter-sublayer service interfaces

116.3.3.1.2 When generated

The sublayer continuously sends n parallel symbol streams IS_UNITDATA_*i*.request(tx_symbol) to the next lower sublayer, each at a nominal signaling rate defined by a specific instance of the inter-sublayer service interface.

116.3.3.1.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

116.3.3.2 IS_UNITDATA_*i*.indication

The IS_UNITDATA_*i*.indication (where i = 0 to n – 1) primitive is used to define the transfer of multiple streams of data units from the sublayer to the next higher sublayer, where n is the number of parallel streams of data units.

116.3.3.2.1 Semantics of the service primitive

IS_UNITDATA_0.indication(rx_symbol)
IS_UNITDATA_1.indication(rx_symbol)
...
IS_UNITDATA_n–1.indication(rx_symbol)

The data conveyed by IS_UNITDATA_0.indication to IS_UNITDATA_n–1.indication consists of n parallel continuous streams of encoded symbols, one stream for each lane. Depending on the specific instance of the inter-sublayer service interface each of the rx_symbol parameters can either take one of two values: zero or one; or take one of four values: zero, one, two, or three.

116.3.3.2.2 When generated

The sublayer continuously sends n parallel symbol streams IS_UNITDATA_*i*.indication(rx_symbol) to the next higher sublayer, each at a nominal signaling rate defined by a specific instance of the inter-sublayer service interface.

116.3.3.2.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

116.3.3.3 IS_SIGNAL.indication

The IS_SIGNAL.indication primitive is generated by the sublayer to the next higher sublayer to indicate the status of the receive process. This primitive is generated by the receive process to propagate the detection of severe error conditions (e.g., no valid signal being received by the sublayer that generates this primitive) to the next higher sublayer.

116.3.3.3.1 Semantics of the service primitive

IS_SIGNAL.indication(SIGNAL_OK)

The SIGNAL_OK parameter can take on one of two values: OK or FAIL. A value of FAIL denotes that invalid data is being presented (rx_symbol parameters undefined) by the sublayer to the next higher sublayer. A value of OK does not guarantee valid data is being presented by the sublayer to the next higher sublayer.

116.3.3.3.2 When generated

The sublayer generates the IS_SIGNAL.indication primitive to the next higher sublayer whenever there is change in the value of the SIGNAL_OK parameter.

116.3.3.3.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

116.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

Table 116–6 and Table 116–7 contain the values of maximum sublayer delay (sum of transmit and receive delays at one end of the link) in bit times as specified in 1.4 and pause_quanta as specified in 31B.2 for 200 Gigabit and 400 Gigabit Ethernet, respectively. If a PHY contains an Auto-Negotiation sublayer, the delay of the Auto-Negotiation sublayer is included within the delay of the PMD and medium.

Table 116–6—Sublayer delay constraints (200GBASE)

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
200G MAC, RS, and MAC Control	49 152	96	245.76	See 117.1.4.
200GBASE-R PCS or 200GXS[d]	160 256	313	801.28	See 119.5.
200GBASE-R PMA	18 432	36	92.16	See 120.5.4.
200GBASE-KR4 PMD	8 192	16	40.96	Includes allocation of 20 ns for one direction through backplane medium. See 137.5.
200GBASE-CR4 PMD	8 192	16	40.96	Includes allocation of 20 ns for one direction through cable medium. See 137.5.
200GBASE-SR4 PMD	4 096	8	20.48	See 138.3.
200GBASE-DR4 PMD	4 096	8	20.48	Includes 2 m of fiber. See 121.3.1.
200GBASE-FR4 PMD	4 096	8	20.48	Includes 2 m of fiber. See 122.3.1.
200GBASE-LR4 PMD	4 096	8	20.48	Includes 2 m of fiber. See 122.3.1.
200GBASE-ER4 PMD	4 096	8	20.48	Includes 2 m of fiber. See 122.3.1.

[a] For 200GBASE-R, 1 bit time (BT) is equal to 5 ps. (See 1.4.215 for the definition of bit time.)
[b] For 200GBASE-R, 1 pause_quantum is equal to 2.56 ns. (See 31B.2 for the definition of pause_quanta.)
[c] Should there be a discrepancy between this table and the delay requirements of the relevant sublayer clause, the sublayer clause prevails.
[d] If an implementation includes the 200GMII extender, the delay associated with the 200GMII extender includes two 200GXS sublayers.

Table 116–7—Sublayer delay constraints (400GBASE)

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
400G MAC, RS, and MAC Control	98 304	192	245.76	See 117.1.4.
400GBASE-R PCS or 400GXS[d]	320 000	625	800	See 119.5.
400GBASE-R PMA	36 864	72	92.16	See 120.5.4.
400GBASE-SR16 PMD	8 192	16	20.48	Includes 2 m of fiber. See 123.3.1.
400GBASE-SR8 PMD	8 192	16	20.48	Includes 2 m of fiber. See 138.3.1.
400GBASE-SR4.2 PMD	8 192	16	20.48	Includes 2 m of fiber. See 150.3.1.
400GBASE-DR4 PMD	8 192	16	20.48	Includes 2 m of fiber. See 124.3.1.

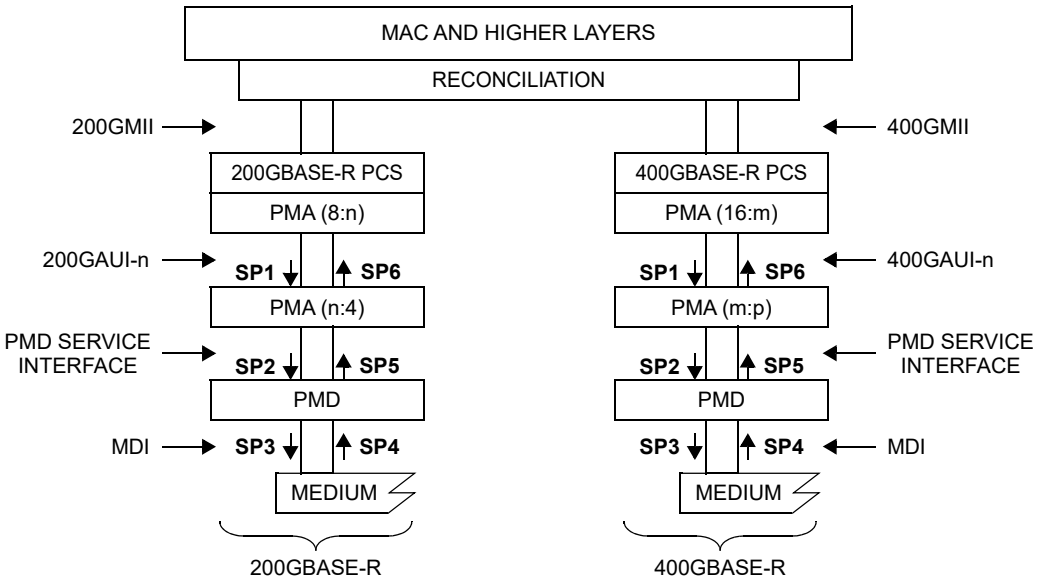
Table 116–7—Sublayer delay constraints (400GBASE) *(continued)*

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
400GBASE-FR8 PMD	8 192	16	20.48	Includes 2 m of fiber. See 122.3.1.
400GBASE-FR4 PMD	8 192	16	20.48	Includes 2 m of fiber. See 151.3.1.
400GBASE-LR4-6 PMD	8 192	16	20.48	Includes 2 m of fiber. See 151.3.1.
400GBASE-LR8 PMD	8 192	16	20.48	Includes 2 m of fiber. See 122.3.1.
400GBASE-ER8 PMD	8 192	16	20.48	Includes 2 m of fiber. See 122.3.1.

[a] For 400GBASE-R, 1 bit time (BT) is equal to 2.5 ps. (See 1.4.215 for the definition of bit time.)
[b] For 400GBASE-R, 1 pause_quantum is equal to 1.28 ns. (See 31B.2 for the definition of pause_quanta.)
[c] Should there be a discrepancy between this table and the delay requirements of the relevant sublayer clause, the sublayer clause prevails.
[d] If an implementation includes the 400GMII extender, the delay associated with the 400GMII extender includes two 400GXS sublayers.

See 80.4 for the calculation of bit time per meter of fiber or electrical cable.

See 31B.3.7 for PAUSE reaction timing constraints for stations at operating speeds of 200 Gb/s and 400 Gb/s.



116.5 Skew constraints

Skew (or relative delay) can be introduced between lanes by both active and passive elements of a 200GBASE-R or 400GBASE-R link. Skew is defined as the difference between the times of the earliest PCS lane and latest PCS lane for the one to zero transition of the alignment marker sync bits. The PCS deskew function (see 119.2.5.1) compensates for all lane-to-lane Skew observed at the receiver. The Skew between the lanes is kept within limits as shown in Table 116–8 so that the transmitted information on the lanes can be reassembled by the receive PCS.

Skew Variation may be introduced due to variations in electrical, thermal or environmental characteristics. Skew Variation is defined as the change in Skew between any PCS lane and any other PCS lane over the entire time that the link is in operation. From the time the link is brought up, Skew Variation is limited so that each PCS lane always traverses the same lane between any pair of adjacent sublayers while the link remains in operation.

The maximum Skew and Skew Variation at physically instantiated interfaces is specified at Skew points SP1, SP2, and SP3 for the transmit direction and SP4, SP5, and SP6 for the receive direction as illustrated in Figure 116–4 (single 200GAUI-n or 400GAUI-n interface) and Figure 116–5 (multiple 200GAUI-n or 400GAUI-n interfaces).

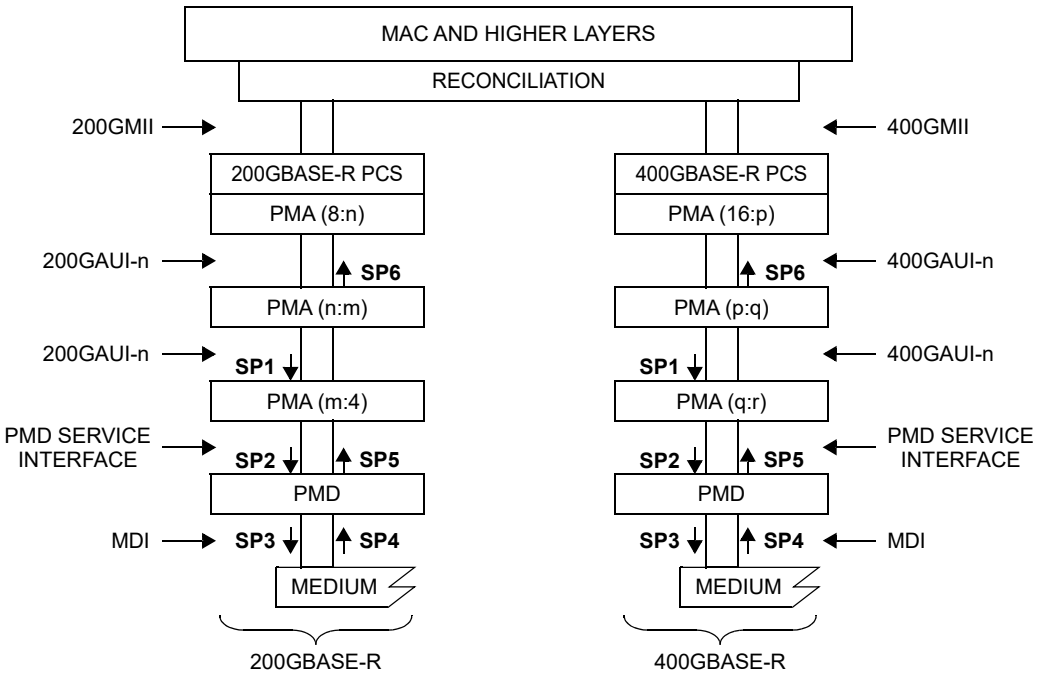
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
n = 8 or 4
m = 16 or 8
p = 16, 8, or 4

Figure 116–4—200GBASE-R and 400GBASE-R Skew points for single 200GAUI-n or 400GAUI-n

In the transmit direction, the Skew points are defined in the following locations:

— SP1 on the 200GAUI-n/400GAUI-n interface, at the input of the PMA closest to the PMD;
— SP2 on the PMD service interface, at the input of the PMD;
— SP3 at the output of the PMD, at the MDI.



In the receive direction, the Skew points are defined in the following locations:

— SP4 at the MDI, at the input of the PMD;
— SP5 on the PMD service interface, at the output of the PMD;
— SP6 on the 200GAUI-n/400GAUI-n interface, at the output of the PMA closest to the 200GBASE-R/400GBASE-R PCS or DTE 200GXS/400GXS.

The allowable limits for Skew are shown in Table 116–8 and the allowable limits for Skew Variation are shown in Table 116–9.

The Skew requirements for the PCS, PMA and PMD sublayers are specified in the respective clauses as noted in Table 116–8 and Table 116–9.

[b] The symbol ≈ indicates approximate equivalent of maximum Skew Variation in UI based on 1 UI equals 18.82353 ps at PMD lane signaling rate of 53.125 GBd.
[c] Should there be a discrepancy between this table and the Skew requirements of the relevant sublayer clause, the sublayer clause prevails.

116.6 FEC Degrade

FEC degrade is a feature allowing for the optional detection of a non-service affecting link degradation condition based on exceeding a threshold for FEC corrected errors. If there are multiple FEC decoders in a given direction of transmission between the MAC sublayers at each end of the link, a Local Degrade condition is cascaded in that direction of transmission to convey the fact that one or more FEC decoders in the path have exceeded their threshold of FEC corrected errors. If any FEC decoder in a given direction of transmission exceeds its provisioned threshold for FEC corrected errors, a Remote Degrade condition is indicated in the opposite direction of transmission from the PCS or XS closest to the MAC.

Figure 116–6 illustrates the signaling of the Remote Degraded condition in the case that there is no Clause 118 extender sublayer present between the MAC and the PCS. Note that the PCS will not initiate the signaling for local degrade in this configuration as there are no additional FEC decoders in the receive direction between the PCS and the MAC.

116.7 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

Multiple states of a function that have a transition to a common state utilizing different qualifiers (for example, multiple exit conditions to an IDLE or WAIT state) may be indicated by a shared arrow. An exit transition arrow connects to the shared arrow, and the qualifier is met prior to termination of the transition arrow on the shared arrow. The shared arrow has no qualifier.

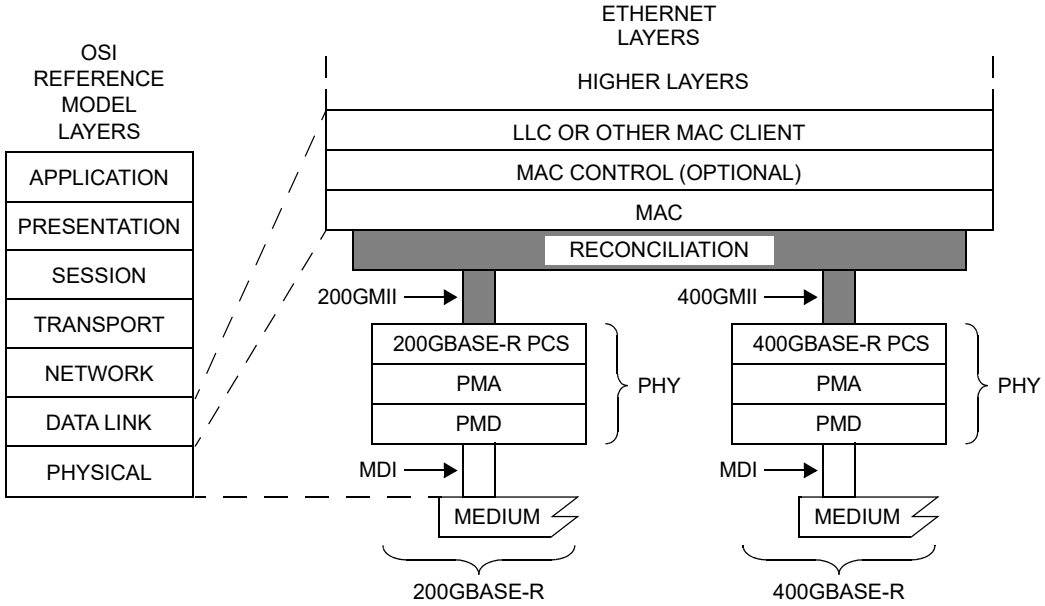
116.8 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 117 through Clause 124, and related annexes demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.



A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the 200 Gigabit and 400 Gigabit Ethernet PICS conforms to the same notation and conventions used in 21.6.

117. Reconciliation Sublayer (RS) and Media Independent Interface for 200 Gb/s and 400 Gb/s operation (200GMII and 400GMII)

117.1 Overview

This clause defines the characteristics of the Reconciliation Sublayer (RS) and the Media Independent Interface between Ethernet media access controllers and various PHYs. Figure 117–1 shows the relationship of the RS and Media Independent Interface to the ISO/IEC OSI reference model.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 117–1—RS and MII relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

The 200GMII and the 400GMII are optional logical interfaces between the MAC sublayer and the Physical Layer device (PHY). The 200GXS/400GXS sublayer in conjunction with the 200GAUI-n/400GAUI-n interface may be used to optionally extend the 200GMII/400GMII.

The RS adapts the bit serial protocols of the MAC to the parallel format of the PCS service interface. Though the 200GMII and 400GMII are optional interfaces, they are used in this standard as a basis for specification. The Physical Coding Sublayer (PCS) is specified to the 200GMII/400GMII, so if not implemented, a conforming implementation shall behave functionally as if the RS and 200GMII/400GMII were implemented.

The 200GMII/400GMII have the following characteristics:

a) The 200GMII supports a speed of 200 Gb/s.
b) The 400GMII supports a speed of 400 Gb/s.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) Data and delimiters are synchronous to a clock reference.

d) They provide independent 64-bit wide transmit and receive data paths.

e) They support full duplex operation only.

117.1.1 Summary of major concepts

The following are the major concepts of the 200GMII/400GMII:

a) The 200GMII/400GMII are functionally similar to other media independent interfaces that have been defined for lower speeds, as they all define an interface allowing independent development of MAC and PHY logic.

b) The RS converts between the MAC serial data stream and the parallel data paths of the 200GMII/400GMII.

c) The RS maps the signal set provided at the 200GMII/400GMII to the PLS service primitives provided at the MAC.

d) Each direction of data transfer is independent and serviced by data, control, and clock signals.

e) The RS generates continuous data or control characters on the transmit path and expects continuous data or control characters on the receive path.

f) The RS participates in link fault detection and reporting by monitoring the receive path for status reports that indicate an unreliable link, and generating status reports on the transmit path to report detected link faults to the DTE on the remote end of the connecting link.

g) The 200GMII/400GMII may also support Low Power Idle (LPI) signaling for PHY types supporting Energy Efficient Ethernet (EEE) (see Clause 78).

h) The 200GMII/400GMII can be extended through the use of a pair of 200GXS/400GXS sublayers (DTE XS and PHY XS) with a 200GAUI-n/400GAUI-n between them.

117.1.2 Application

This clause applies to the interface between the MAC and PHY. This logical interface is used to provide media independence so that an identical media access controller may be used with supported PHY types.

117.1.3 Rate of operation

The 200GMII is specified to support 200 Gb/s operation. The 400GMII is specified to support 400 Gb/s operation.

117.1.4 Delay constraints

The maximum cumulative MAC Control, MAC, and RS delay (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 117–1. A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

Table 117–1—Delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
200 Gb/s MAC, RS, and MAC Control	49 152	96	245.76
400 Gb/s MAC, RS, and MAC Control	98 304	192	245.76

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

117.1.5 Allocation of functions

The allocation of functions at the 200GMII/400GMII balances the need for media independence with interface simplicity. The 200GMII/400GMII provides media independence by separating the Data Link and Physical Layers of the OSI seven-layer reference model.

117.1.6 200GMII/400GMII structure

The 200GMII/400GMII structure is identical to the CGMII structure specified in 81.1.6.

117.1.7 Mapping of 200GMII/400GMII signals to PLS service primitives

The Reconciliation Sublayer (RS) shall map the signals provided at the 200GMII/400GMII to the PLS service primitives defined in Clause 6. The PLS service primitives provided by the RS and described here behave in exactly the same manner as defined in Clause 6. Full duplex operation only is implemented at either 200 Gb/s or 400 Gb/s, therefore, PLS service primitives supporting CSMA/CD operation are not mapped through the RS to the 200GMII/400GMII. This behavior and restrictions are the same as described in 22.7, with the details of the signaling described in 117.3. LPI_REQUEST shall not be set to ASSERT unless the attached link has been operational for at least one second (i.e., link_status = OK, according to the underlying PCS/PMA).

EEE capability requires the use of the MAC defined in Annex 4A for simplified full duplex operation (with carrier sense deferral). This provides full duplex operation but uses the carrier sense signal to defer transmission until the system returns from its low power state.

Mappings for the following primitives are defined for 200 Gb/s and 400 Gb/s operation:

PLS_DATA.request
PLS_DATA.indication
PLS_CARRIER.indication
PLS_SIGNAL.indication
PLS_DATA_VALID.indication

The RS maps all primitives in an identical manner as the CGMII does and as specified in 81.1.7.

117.2 200GMII/400GMII data stream

The 200GMII/400GMII data stream has the same characteristics as the CGMII data stream described in 81.2.

117.3 200GMII/400GMII functional specifications

The 200GMII/400GMII functions identically to the CGMII specified in 81.3.

117.4 LPI Assertion and Detection

LPI assertion and detection function identically to the CGMII specified in 81.4, with the single exception that the PMA stop signaling described in 81.4.4 is not applicable.

117.5 Protocol implementation conformance statement (PICS) proforma for Clause 117, Reconciliation Sublayer (RS) and Media Independent Interface for 200 Gb/s and 400 Gb/s operation (200GMII and 400GMII)[204]

117.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 117, Reconciliation Sublayer (RS) and Media Independent Interface for 200 Gb/s and 400 Gb/s operation (200GMII and 400GMII), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

117.5.2 Identification

117.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

117.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 117, Reconciliation Sublayer (RS) and Media Independent Interface for 200 Gb/s and 400 Gb/s operation (200GMII and 400GMII)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

118. 200GMII Extender, 400GMII Extender, 200GMII Extender Sublayer (200GXS), and 400GMII Extender Sublayer (400GXS)

118.1 Overview

This clause defines the functional characteristics for the optional 200GMII Extender and 200GMII Extender Sublayer (200GXS), and also for the optional 400GMII Extender and 400GMII Extender Sublayer (400GXS). Figure 118–1 shows the relationship of the 200GMII/400GMII Extender and 200GXS/400GXS sublayer with other sublayers to the ISO Open System Interconnection (OSI) reference model.

The 200GMII/400GMII Extender allows the extension of the 200GMII/400GMII to the PCS via a physical instantiation. The 200GMII/400GMII Extender is composed of a 200GXS/400GXS at the RS end, a 200GXS/400GXS at the PHY end with a physical instantiation of 200GAUI-n/400GAUI-n between two adjacent PMA sublayers.

A 200GMII/400GMII Extender with the optional Energy-Efficient Ethernet (EEE) capability (see Clause 78) encodes and decodes Low Power Idle (LPI) signals. The assertion of LPI at the 200GMII/400GMII is encoded in the transmitted symbols. Detection of LPI encoding in the received symbols is indicated as LPI at the 200GMII/400GMII.

200GAUI-n = 200 Gb/s n-LANE ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
200GXS = 200GMII EXTENDER SUBLAYER
400GAUI-n = 400 Gb/s n-LANE ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
400GXS = 400GMII EXTENDER SUBLAYER
DTE = DATA TERMINAL EQUIPMENT
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 118–1—200GXS and 400GXS relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

118.1.1 Summary of major concepts

The following is a list of the major concepts of the 200GMII/400GMII Extender:

a) Simple signal mapping to the 200GMII/400GMII
b) The optional 200GMII/400GMII Extender can be inserted between the Reconciliation Sublayer and the PHY to transparently extend the reach of the 200GMII/400GMII
c) Independent transmit and receive data paths
d) The 200GXS/400GXS leverages all functions in the Clause 119 PCS and supports physical instantiations of the 200GAUI-n/400GAUI-n
e) Optionally extends LPI signaling to the PHY for EEE

118.1.2 200GXS/400GXS Sublayer

The 200GXS, if implemented, shall be identical in function to the 200GBASE-R PCS in Clause 119 with the addition of the functions defined in 118.2. A single device may be configured as either a 200GXS or the 200GBASE-R PCS and may be managed through different optional management registers.

The 400GXS, if implemented, shall be identical in function to the 400GBASE-R PCS in Clause 119 with the addition of the functions defined in 118.2. A single device may be configured as either a 400GXS or the 400GBASE-R PCS and may be managed through different optional management registers.

118.1.3 200GAUI-n/400GAUI-n

A 200GMII Extender may use any of the following electrical interfaces for the connection between its PMA sublayers (200GAUI-n), as shown in Figure 118–1:

— 200GAUI-8 chip-to-chip (Annex 120B)
— 200GAUI-8 chip-to-module (Annex 120C)
— 200GAUI-4 chip-to-chip (Annex 120D)
— 200GAUI-4 chip-to-module (Annex 120E)

A 400GMII Extender may use any of the following electrical interfaces for the connection between its PMA sublayers (400GAUI-n), as shown in Figure 118–1:

— 400GAUI-16 chip-to-chip (Annex 120B)
— 400GAUI-16 chip-to-module (Annex 120C)
— 400GAUI-8 chip-to-chip (Annex 120D)
— 400GAUI-8 chip-to-module (Annex 120E)

118.2 FEC Degrade

The propagation of FEC degrade signaling across PCS and XS sublayers is described in 116.6 and is based on the optional FEC degrade signaling described in Clause 119 with the changes described for the DTE XS in 118.2.1 and for the PHY XS in 118.2.2.

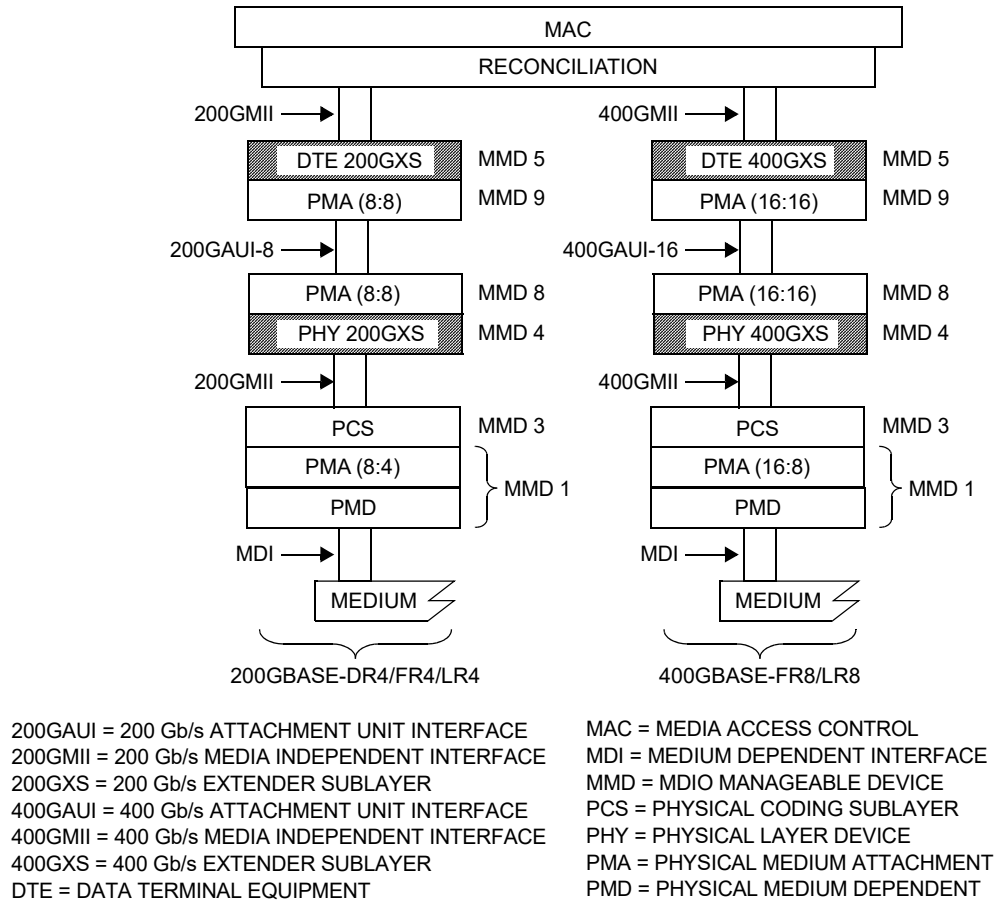
118.2.1 DTE XS FEC Degrade signaling

The variable tx_am_sf is set as follows:

tx_am_sf<2:0> = {FEC_degraded_SER + rx_local_degraded,0,0}

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

118.2.2 PHY XS FEC Degrade signaling



The variable tx_am_sf is set as follows:

tx_am_sf<2:0> = {PCS:rx_rm_degraded, PCS:FEC_degraded_SER + PCS:rx_local_degraded, 0}

Where PCS:rx_rm_degraded, PCS:FEC_degraded_SER, and PCS:rx_local_degraded are the rx_rm_degraded, FEC_degraded_SER, and rx_local_degraded variables from the adjacent PCS.

118.3 200GXS and 400GXS partitioning example

A partitioning example and MMD numbering using the 200GXS and 400GXS is shown in Figure 118–2.

200GAUI = 200 Gb/s ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
200GXS = 200 Gb/s EXTENDER SUBLAYER
400GAUI = 400 Gb/s ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
400GXS = 400 Gb/s EXTENDER SUBLAYER
DTE = DATA TERMINAL EQUIPMENT
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 118–2—Example 200GBASE-DR4/FR4/LR4 and 400GBASE-FR8/LR8 PMA layering with 200GXS and 400GXS

118.4 200GXS and 400GXS MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the 200GXS or 400GXS. If MDIO is implemented, it shall map MDIO PHY XS and DTE XS control bits to Clause 119 control variables as shown in Table 118–1 and Table 118–3, respectively. Similarly, if MDIO is implemented, it shall map MDIO PHY XS and DTE XS status bits to Clause 119 status variables as shown in Table 118–2 and Table 118–4, respectively.

118.5 Protocol implementation conformance statement (PICS) proforma for Clause 118, 200GMII Extender, 400GMII Extender, 200GMII Extender Sublayer (200GXS), and 400GMII Extender Sublayer (400GXS)[205]

118.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 118, 200GMII Extender, 400GMII Extender, 200GMII Extender Sublayer (200GXS), and 400GMII Extender Sublayer (400GXS), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

118.5.2 Identification

118.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

118.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 118, 200GMII Extender, 400GMII Extender, 200GMII Extender Sublayer (200GXS), and 400GMII Extender Sublayer (400GXS)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[205] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

118.5.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
MII	200GMII or 400GMII logical interface	117, 118.1	Logical interface is supported	O	Yes [ ] No [ ]
*PHYXS	PHY 200GXS or PHY 400GXS	118.1		O/2	Yes [ ] No [ ]
*DTEXS	DTE 200GXS or DTE 400GXS	118.1		O/2	Yes [ ] No [ ]
*200GXS	Using the XS for 200GBASE-R	118.1.2		O.1	Yes [ ] No [ ]
*400GXS	Using the XS for 400GBASE-R	118.1.2		O.1	Yes [ ] No [ ]
*MD	MDIO	45, 118.4	Registers and interface supported	O	Yes [ ] No [ ]
*BI	Bypass indication	119.2.5.3	Capability is supported	O	Yes [ ] No [ ]
DC	Delay constraints	119.5	Conforms to delay constraints specified in 119.5	M	Yes [ ]
EEE	EEE capability	119.2.3.3	Capability is supported	O	Yes [ ] No [ ]
JTM	Supports test-pattern mode	119.2.1, 119.2.4.9		M	Yes [ ]
FDD	Support for optional FEC degraded detection	119.2.5.3	In the FEC decoder can optionally detect FEC SER degraded at a programmable threshold	O	Yes [ ] No [ ]

118.5.4 PICS proforma tables for 200GMII Extender, 400GMII Extender, 200GMII Extender Sublayer (200GXS), and 400GMII Extender Sublayer (400GXS)

118.5.4.1 Transmit function

Item	Feature	Subclause	Value/Comment	Status	Support
TF1	64B/66B to 256B/257B transcoder	119.2.4.2	tx_xcoded<256:0> constructed per 119.2.4.2	M	Yes [ ]
TF2	Transmission bit ordering	119.2.4.8	First bit transmitted is bit 0	M	Yes [ ]
TF3	Pad value	119.2.4.4	PRBS9	M	Yes [ ]
TF4	Alignment marker insertion	119.2.4.4		M	Yes [ ]
TF5	Pre-FEC distribution	119.2.4.5	Distribute the data to two FEC codewords	M	Yes [ ]
TF6	Reed-Solomon encoder	119.2.4.6	RS(544,514)	M	Yes [ ]
TF7	Symbol distribution	119.2.4.7	Distribution is based on 10b symbols	M	Yes [ ]

118.5.4.2 Receive function

Item	Feature	Subclause	Value/Comment	Status	Support
RF1	Skew tolerance	119.2.5.1	Maximum Skew of 180 ns between PCS lanes and a maximum Skew Variation of 4 ns	M	Yes [ ]
RF2	Lane reorder and de-interleave	119.2.5.2	Order the PCS lanes according to the PCS lane number and de-interleave the FEC codewords	M	Yes [ ]
RF3	Reed-Solomon decoder	119.2.5.3	Corrects any combination of up to *t*=15 symbol errors in a codeword	M	Yes [ ]
RF4	Reed-Solomon decoder	119.2.5.3	Capable of indicating when a codeword was not corrected.	M	Yes [ ]
RF5	Error monitoring while error indication is bypassed	119.2.5.3	When the number of symbol errors in a block of 8192 codewords exceeds 5560 assert hi_ser for 60 ms to 75 ms	BI:M	Yes [ ] N/A [ ]
RF6	256B/257B to 64B/66B transcoder	119.2.5.7	rx_coded_*j*<65:0>, *j*=0 to 3 constructed per 119.2.5.7	M	Yes [ ]

118.5.4.3 64B/66B coding rules

Item	Feature	Subclause	Value/Comment	Status	Support
C1	Encoder (and ENCODE function) implements the code as specified	119.2.3, 119.2.6.2.3		M	Yes [ ]
C2	Decoder (and DECODE function) implements the code as specified	119.2.3, 119.2.6.2.3		M	Yes [ ]
C3	Only valid block types are transmitted	119.2.3.2		M	Yes [ ]
C4	Invalid block types are treated as an error	119.2.3.2		M	Yes [ ]
C5	Only valid control characters are transmitted	119.2.3.3		M	Yes [ ]
C6	Invalid control characters are treated as an error	119.2.3.3		M	Yes [ ]
C7	Idles do not interrupt data	119.2.3.5		M	Yes [ ]
C8	IDLE control code insertion and deletion	119.2.3.5	Insertion or Deletion in groups of 8 /I/s	M	Yes [ ]
C9	Sequence ordered set deletion	119.2.3.8	Only one whole ordered set of two consecutive sequence ordered sets may be deleted	M	Yes [ ]

118.5.4.4 Scrambler and descrambler

Item	Feature	Subclause	Value/Comment	Status	Support
S1	Scrambler	119.2.4.3	Performs as shown in Figure 49–8	M	Yes [ ]
S2	Descrambler	119.2.5.6	Performs as shown in Figure 49–10	M	Yes [ ]

118.5.4.5 Alignment markers

Item	Feature	Subclause	Value/Comment	Status	Support
AM1	Alignment marker insertion	119.2.4.4	Alignment markers are inserted periodically as in 119.2.4.4	M	Yes [ ]
AM2	Alignment marker form	119.2.4.4	Alignment markers are formed as described in 119.2.4.4	M	Yes [ ]
AM3	Lane mapping	119.2.4.4	PCS lane number is captured	MD:M	Yes [ ] N/A [ ]
AM4	Alignment marker removal	119.2.5.5	Alignment markers are removed prior to descrambling as described in 119.2.5.5	M	Yes [ ]

118.5.5 Test-pattern modes

Item	Feature	Subclause	Value/Comment	Status	Support
JT1	Scrambled idle transmit test-pattern generator is implemented	119.2.4.9		M	Yes [ ]

118.5.6 Bit order

Item	Feature	Subclause	Value/Comment	Status	Support
B1	Transmit bit order	119.2.4.8	Placement of bits into the PCS lanes as shown in Figure 119–10 or Figure 119–11	M	Yes [ ]

118.5.7 Management

Item	Feature	Subclause	Value/Comment	Status	Support
M1	Equivalent access to XS management objects is provided	119.3		!MD:O	Yes [ ] No [ ] N/A [ ]
M2	Mapping of MDIO control bits and MDIO status bits for PHY 200GXS or PHY 400GXS	118.4	See Table 118–1 and Table 118–2	MD*PHY XS:M	Yes [ ] N/A [ ]
M3	Mapping of MDIO control bits and MDIO status bits for DTE 200GXS or DTE 400GXS	118.4	See Table 118–3 and Table 118–4	MD*DTEX S:M	Yes [ ] N/A [ ]

118.5.7.1 State diagrams

Item	Feature	Subclause	Value/Comment	Status	Support
SM1	Alignment marker lock	119.2.6	Implements 8 alignment marker lock processes as depicted in Figure 119–12	200GXS: M	Yes [ ] N/A [ ]
SM2	Alignment marker lock	119.2.6	Implements 16 alignment marker lock processes as depicted in Figure 119–12	400GXS: M	Yes [ ] N/A [ ]
SM3	The SLIP function evaluates all possible block positions	119.2.6.2.3		M	Yes [ ]
SM4	PCS synchronization state diagram	119.2.6	Meets the requirements of Figure 119–13	M	Yes [ ]
SM5	Transmit process	119.2.6	Meets the requirements of Figure 119–14	M	Yes [ ]
SM6	Receive process	119.2.6	Meets the requirements of Figure 119–15	M	Yes [ ]

118.5.7.2 Loopback

Item	Feature	Subclause	Value/Comment	Status	Support
L1	Supports loopback	119.4		M	Yes [ ]
L2	When in loopback, transmits what it receives from the 200GMII/400GMII	119.4		M	Yes [ ]
L3	When in loopback, ignore all data presented by the PMA sublayer	119.4		M	Yes [ ]

119. Physical Coding Sublayer (PCS) for 64B/66B, type 200GBASE-R and 400GBASE-R

119.1 Overview

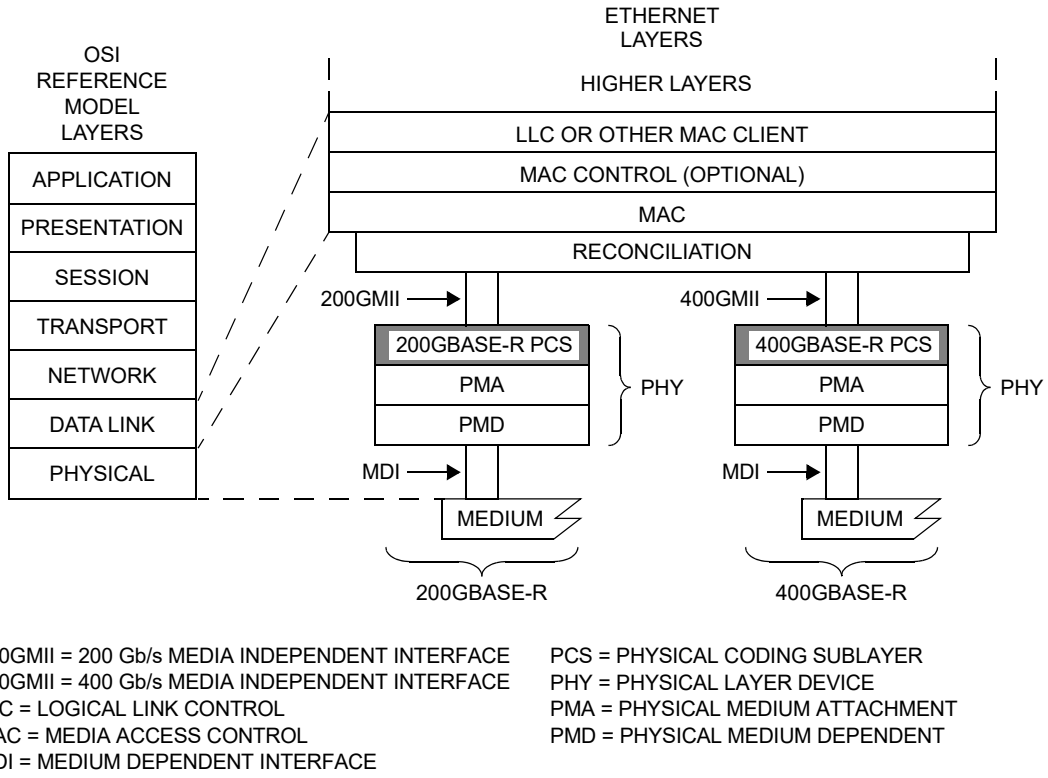
119.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) that is common to two families of Physical Layer implementation known as 200GBASE-R and 400GBASE-R. The 200GBASE-R PCS is a sublayer of the 200 Gb/s PHYs listed in Table 116–1. The 400GBASE-R PCS is a sublayer of the 400 Gb/s PHYs listed in Table 116–2. The terms 200GBASE-R and 400GBASE-R are used when referring generally to Physical Layers using the PCS defined in this clause. Both 200GBASE-R and 400GBASE-R are based on a 64B/66B code. The 64B/66B code supports transmission of data and control characters. The 64B/66B code is then transcoded to 256B/257B encoding to reduce the overhead and make room for forward error correction (FEC). The 256B/257B encoded data is then FEC encoded before being transmitted. Data distribution is introduced to support multiple lanes in the Physical Layer. Part of the distribution includes the periodic insertion of an alignment marker, which allows the receive PCS to align data from multiple lanes.

119.1.2 Relationship of 200GBASE-R and 400GBASE-R to other standards

Figure 119–1 depicts the relationship of the 200GBASE-R and 400GBASE-R sublayers (shown shaded), the Ethernet MAC and Reconciliation Sublayers, and the higher layers.

This clause borrows heavily from Clause 82 and Clause 91. 64B/66B encoding is reused with the addition of transcoding and PCS FEC.



119.1.3 Physical Coding Sublayer (PCS)

The PCS service interface is the Media Independent Interface (200GMII/400GMII), which is defined in Clause 117. The 200GMII provides a uniform interface to the Reconciliation Sublayer for all 200 Gb/s PHY implementations. The 400GMII provides a uniform interface to the Reconciliation Sublayer for all 400 Gb/s PHY implementations.

The 200GBASE-R and 400GBASE-R PCSs provide all services required by the 200GMII/400GMII, including the following:

a) Encoding (decoding) of eight 200GMII/400GMII data octets to (from) 66-bit blocks (64B/66B).
b) Transcoding from 66-bit blocks to (from) 257-bit blocks.
c) Reed-Solomon encoding (decoding) the 257-bit blocks.
d) Transferring encoded data to (from) the PMA.
e) Compensation for any rate differences caused by the insertion or deletion of alignment markers or due to any rate difference between the 200GMII/400GMII and PMA through the insertion or deletion of idle control characters.
f) Determining when a functional link has been established and informing the management entity via the MDIO when the PHY is ready for use.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 119–1—200GBASE-R and 400GBASE-R PCS relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

119.1.4 Inter-sublayer interfaces

The upper interface of the PCS may connect to the Reconciliation Sublayer through the 200GMII/400GMII. The lower interface of the PCS connects to the PMA sublayer to support a PMD. The 200GBASE-R PCS has a nominal rate at the PMA service interface of 26.5625 Gtransfers/s on each of 8 PCS lanes, which provides capacity for the MAC data rate of 200 Gb/s. The 400GBASE-R PCS has a nominal rate at the PMA service interface of 26.5625 Gtransfers/s on each of 16 PCS lanes, which provides capacity for the MAC data rate of 400 Gb/s.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience.

119.1.4.1 PCS service interface (200GMII/400GMII)

The PCS service interface allows the 200GBASE-R or 400GBASE-R PCS to transfer information to and from a PCS client. The PCS client is the Reconciliation Sublayer. The PCS Service Interface is precisely defined as the Media Independent Interface (200GMII/400GMII) in Clause 117.

119.1.4.2 Physical Medium Attachment (PMA) service interface

The PMA service interface for the PCS is described in an abstract manner and does not imply any particular implementation. The PMA Service Interface supports the exchange of encoded data between the PCS and PMA sublayer. The PMA service interface is defined in 120.3 and is an instance of the inter-sublayer service interface definition in 116.3.

119.2 Physical Coding Sublayer (PCS)

119.2.1 Functions within the PCS

The 200GBASE-R and 400GBASE-R PCS are composed of the PCS Transmit and PCS Receive processes. The PCS shields the Reconciliation Sublayer (and MAC) from the specific nature of the underlying channel. The PCS transmit channel can operate in normal mode or test-pattern mode.

When communicating with the 200GMII/400GMII, the PCS uses an eight octet-wide, synchronous data path, with packet delineation being provided by transmit control signals (TXC<n> = 1) and receive control signals (RXC<n> = 1). When communicating with the PMA, the 200GBASE-R PCS uses 8 encoded bit streams (also known as PCS lanes) and the 400GBASE-R PCS uses 16 encoded bit streams. Per direction (RX or TX), the PCS lanes originate from a common clock but may vary in phase and skew dynamically. The PMA sublayer operates independently of block and packet boundaries. The PCS provides the functions necessary to map packets between the 200GMII/400GMII format and the PMA service interface format.

When the transmit channel is in normal mode, the PCS Transmit process continuously generates 66-bit blocks based upon the TXD <63:0> and TXC <7:0> signals on the 200GMII/400GMII. The 66-bit blocks are transcoded to 257-bit blocks to reduce the line coding overhead. The transcoded blocks are then scrambled to control clock content and baseline wander. Alignment markers are periodically added to the data stream. The data stream is distributed to two 5140-bit blocks and then FEC encoded to control errors. The two FEC codewords are then interleaved before data is distributed to individual PCS lanes.

Transmit data-units are sent to the service interface via the PMA:IS_UNITDATA_*i*.request primitive.

When the transmit channel is in test-pattern mode, a test pattern is packed into the transmit data-units that are sent to the PMA service interface via the PMA:IS_UNITDATA_*i*.request primitive.

The PCS Synchronization process continuously monitors PMA:IS_SIGNAL.indication(SIGNAL_OK). When SIGNAL_OK indicates OK, then the PCS synchronization process accepts data-units via the PMA:IS_UNITDATA_*i*.indication primitive. It attains alignment marker lock based on the common marker (CM) portion that is periodically transmitted on every PCS lane. After alignment markers are found on all PCS lanes, the individual PCS lanes are identified using the unique marker portion (UM) and then re-ordered and deskewed. Note that a particular transmit PCS lane can be received on any receive lane of the service interface due to the skew and multiplexing that occurs in the path.

The PCS deskew process deskews, aligns and reorders the individual PCS lanes, forms a single stream, and sets the align_status flag to indicate whether the PCS has obtained alignment. The PCS then de-interleaves and processes the FEC codewords. Next the PCS re-interleaves the corrected FEC codewords on a 10-bit basis to form a single stream. The PCS then removes alignment markers, descrambles the data, transcodes the data back to 64B/66B and then decodes the 64B/66B encoded data.

The PCS shall provide transmit test-pattern mode for the scrambled idle pattern (see 119.2.4.9).

119.2.2 Use of blocks

The PCS maps 200GMII/400GMII signals into 66-bit blocks, and vice versa, using a 64B/66B coding scheme. The PCS functions ENCODE and DECODE generate, manipulate, and interpret blocks as defined in 119.2.3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

119.2.3 64B/66B code

The PCS uses 64B/66B coding to support transmission of control and data characters. The 64B/66B codestream is then transcoded into a 256B/257B stream and FEC bits are added in this PCS before transmission.

119.2.3.1 Notation conventions

For values shown as binary, the leftmost bit is the first transmitted bit.

64B/66B encodes 8 data octets or control characters into a block. Blocks containing control characters also contain a block type field. Data octets are labeled D_0 to D_7. The control characters /I/ and /E/ are labeled C_0 to C_7. The control character /Q/ for a sequence ordered set is labeled as O_0 since it is only valid on the first octet of the 200GMII/400GMII. The control character for start is labeled as S_0 for the same reason. The control character for terminate is labeled as T_0 to T_7. The four trailing zero data octets in ordered sets are labeled as Z_4 to Z_7.

One 200GMII/400GMII transfer provides eight characters that are encoded into one 66-bit transmission block. The subscript in the above labels indicates the position of the character in the eight characters from the 200GMII/400GMII transfer.

Contents of block type fields, data octets, and control characters are shown as hexadecimal values. The LSB of the hexadecimal value represents the first transmitted bit. For instance, the block type field 0x1E is sent from left to right as 01111000. The bits of a transmitted or received block are labeled TxB<65:0> and RxB<65:0>, respectively, where TxB<0> and RxB<0> represent the first transmitted bit. The value of the sync header is shown as a binary value. Binary values are shown with the first transmitted bit (the LSB) on the left.

119.2.3.2 64B/66B block structure

Blocks consist of 66 bits. The first two bits of a block are the synchronization header (sync header). Blocks are either data blocks or control blocks. The sync header is 01 for data blocks and 10 for control blocks. The remainder of the block contains the payload.

Data blocks contain eight data characters. Control blocks begin with an 8-bit block type field that indicates the format of the remainder of the block. For control blocks containing a Start, Terminate, or ordered set, that character is implied by the block type field. Other control characters are encoded in a 7-bit control code. Each control block encodes eight characters.

The format of the blocks is as shown in Figure 82–5. In the figure, the column labeled Input Data shows, in abbreviated form, the eight characters used to create the 66-bit block. These characters are either data characters or control characters and, when transferred across the 200GMII/400GMII, the corresponding TXC or RXC bit is set accordingly. Within the Input Data column, D_0 through D_7 are data octets and are transferred with the corresponding TXC or RXC bit set to zero. All other characters are control characters and are transferred with the corresponding TXC or RXC bit set to one. The single bit fields (thin rectangles with no label in the figure) are sent as zero and ignored upon receipt.

All values of block type field not listed in Figure 82–5 are invalid; they shall not be transmitted and shall be considered an error if received.

119.2.3.3 Control codes

The same set of control characters are supported by the 200GMII/400GMII and the PCS. The representations of the control characters are the control codes. The 200GMII/400GMII encodes a control

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

character into an octet (an eight bit value). The PCS encodes the start and terminate control characters implicitly by the block type field. The PCS encodes the ordered set control codes using the block type field. The PCS encodes each of the other control characters into a 7-bit control code.

The control characters and their mappings to 200GBASE-R/400GBASE-R control codes and 200GMII/400GMII control codes are specified in Table 82–1. All 200GMII/400GMII and 200GBASE-R/400GBASE-R control code values that do not appear in the table shall not be transmitted and shall be considered an error if received. The ability to transmit or receive Low Power Idle (LPI) is required for PHYs that support EEE (see Clause 78). If EEE has not been negotiated, LPI shall not be transmitted and shall be treated as an error if received.

119.2.3.4 Valid and invalid blocks

The valid and invalid blocks are identical to those in 82.2.3.5 with the exception that it is a 200GMII/400GMII data stream instead of XLGMII/CGMII.

119.2.3.5 Idle (/I/)

Idle and LPI control characters are identical to those in 82.2.3.6.

119.2.3.6 Start (/S/)

Start control characters are identical to those in 82.2.3.7.

119.2.3.7 Terminate (/T/)

The terminate control characteristics are identical to those in 82.2.3.8.

119.2.3.8 Ordered set (/O/)

Ordered sets are specified identically as in 82.2.3.9.

119.2.3.9 Error (/E/)

In both the 64B/66B encoder and decoder, the /E/ is generated whenever an /E/ is detected. The /E/ is also generated when invalid blocks are detected. The /E/ allows the PCS to propagate detected errors. See R_TYPE and T_TYPE function definitions in 119.2.6.2.3 for further information.

119.2.4 Transmit

119.2.4.1 Encode and rate matching

The PCS generates 66-bit blocks based upon the TXD<63:0> and TXC<7:0> signals received from the 200GMII/400GMII. One 200GMII/400GMII data transfer is encoded into one 66-bit block. If the transmit PCS spans multiple clock domains, it may also perform clock rate compensation via the deletion of idle control characters or sequence ordered sets or the insertion of idle (or LPI) control characters.

Idle (or LPI) control characters or sequence ordered sets are removed, if necessary, to accommodate the insertion of the alignment markers. See 119.2.3.5 and 119.2.3.8 for the deletion and insertion rules, and 119.2.4.4 for more details on alignment markers.

The transmit PCS generates blocks as specified in the transmit state diagram as shown in Figure 119–14. The contents of each block are contained in a vector tx_coded<65:0>, which is passed to the transcoder. tx_coded<1:0> contains the sync header and the remainder of the bits contain the block payload.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The stream of 66-bit blocks generated by this process, together with the FEC_degraded_SER and rx_local_degraded bits should be used as the reference signal for mapping to OTN.

119.2.4.2 64B/66B to 256B/257B transcoder

The transcoder constructs a 257-bit block, tx_xcoded<256:0>, from a group of four 66-bit blocks, tx_coded_*j*<65:0> where *j*=0 to 3. For each group of four 66-bit blocks, *j*=3 corresponds to the most recently received block. Bit 0 in each 66-bit block is the first bit received and corresponds to the first bit of the synchronization header.

NOTE—This transcoder differs from that described in 91.5.2.5, there is no scrambling of the first 5 bits since this clause scrambles the complete 257-bit blocks after transcoding.

If for all *j*=0 to 3, tx_coded_*j*<0>=0 and tx_coded_*j*<1>=1, tx_xcoded<256:0> shall be constructed as follows:

a) tx_xcoded<0> = 1

b) tx_xcoded<(64*j*+64):(64*j*+1)> = tx_coded_*j*<65:2> for *j*=0 to 3

If for all *j*=0 to 3, tx_coded_*j*<0> ≠ tx_coded_*j*<1> (valid synchronization header) and for any *j*=0 to 3, tx_coded_*j*<0>=1 and tx_coded_*j*<1>=0, tx_xcoded<256:0> shall be constructed as follows:

a1) tx_xcoded<0> = 0

b1) tx_xcoded<*j*+1> = tx_coded_*j*<1> for *j*=0 to 3

c1) Let *c* be the smallest value of *j* such that tx_coded_*c*<0>=1. In other words, tx_coded_*c* is the first 66-bit control block that was received in the current group of four blocks.

d1) Let tx_payloads<(64*j*+63):64*j*> = tx_coded_*j*<65:2> for *j*=0 to 3

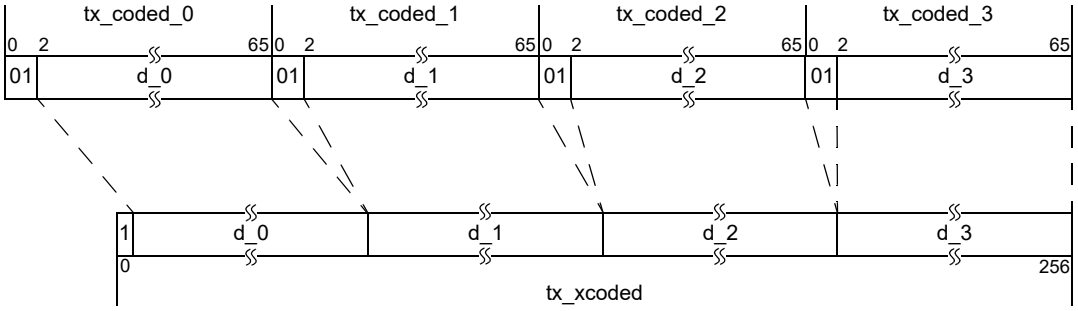
e1) Omit tx_coded_*c*<9:6>, which is the second nibble (based on transmission order) of the block type field for tx_coded_*c,* from tx_xcoded per the following expressions.
tx_xcoded<(64*c*+8):5> = tx_payloads<(64*c*+3):0>
tx_xcoded<256:(64*c*+9)> = tx_payloads<255:(64*c*+8)>

If for any *j*=0 to 3, tx_coded_*j*<0> = tx_coded_*j*<1> (invalid synchronization header), tx_xcoded<256:0> shall be constructed as follows:

a2) tx_xcoded<0> = 0

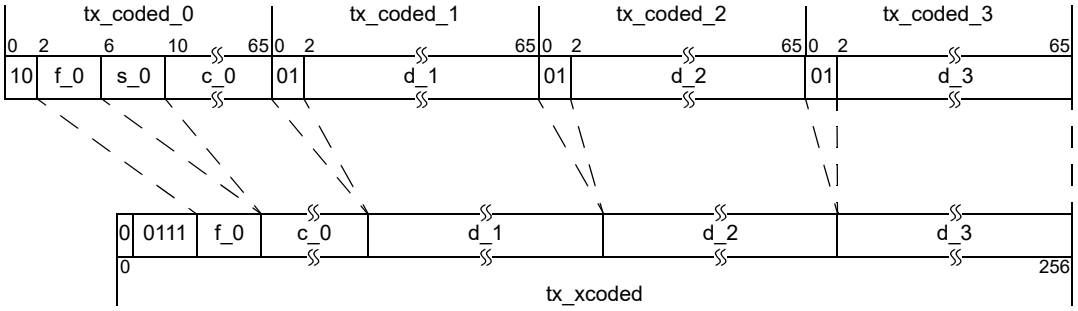
b2) tx_xcoded<*j*+1> = 1 for *j*=0 to 3

c2) Let tx_payloads<(64*j*+63):64*j*> = tx_coded_*j*<65:2> for *j*=0 to 3



d2) Omit the second nibble (based on transmission order) of tx_coded_0 per the following expressions.
tx_xcoded<8:5> = tx_payloads<3:0>
tx_xcoded<256:9> = tx_payloads<255:8>

Several examples of the construction of tx_xcoded<256:0> are shown in Figure 119–3. In Figure 119–3, d_*j* indicates the *j*th 66-bit block contains only data octets, c_*j* indicates the *j*th 66-bit block contains one or more control characters, f_*j* denotes the first nibble of the block type field for 66-bit block *j*, and s_*j* denotes the second nibble of the block type field for 66-bit block *j*.



For each 257-bit block, bit 0 shall be the first bit transmitted.

119.2.4.3 Scrambler

The transcoded 257-bit block, tx_xcoded<256:0>, shall be scrambled with a self-synchronizing scrambler to generate tx_scrambled<256:0>. The scrambler polynomial is identical to that in Clause 49, see Equation (49–1) for the definition of the polynomial.

119.2.4.4 Alignment marker mapping and insertion

In order to support deskew and reordering of the individual PCS lanes at the receive PCS, alignment markers corresponding to PCS lanes are periodically inserted after being processed by the alignment marker mapping function. The alignment marker mapping function compensates for the operation of the symbol distribution function and rearranges the alignment marker bits so that they appear on the PCS lanes intact and in the desired sequence. This preserves the properties of the alignment markers (e.g. DC balance, transition density) and provides a deterministic pattern for the purpose of synchronization.

For the 200GBASE-R PCS, an alignment marker group is composed of the alignment markers for all 8 PCS lanes plus an additional 65-bit pad and a 3-bit status field to yield the equivalent of four 257-bit blocks. For the 400GBASE-R PCS, an alignment marker group is composed of the alignment markers for all 16 PCS lanes plus an additional 133-bit pad and a 3-bit status field to yield the equivalent of eight 257-bit blocks. The alignment marker group is aligned to the beginning of two FEC messages, and interrupts any data transfer that is already in progress. The pad bits at the end of the alignment marker group shall be set to a free running PRBS9 pattern, defined by the polynomial $x^9 + x^5 + 1$. The initial value of the PRBS9 pattern generator may be any pattern other than all zeros.

Room for the alignment marker group is created by the transmit PCS (see 119.2.4.1). Special properties of the alignment marker group are that it is not scrambled, does not conform to the encoding rules as outlined in Figure 82–5 and is not transcoded. This is possible because the alignment marker group is added after encoding, transcoding, and scrambling, and removed before descrambling, transcoding, and 64B/66B decoding. The alignment marker group is not scrambled, which allows the receiver to directly search for and find the individual alignment markers, deskew the PCS lanes, and reassemble the aggregate stream before FEC decoding is performed. The alignment markers are formed from a known pattern that is defined to be balanced and with many transitions and therefore scrambling is not necessary.

The format of each PCS lane's alignment marker is shown in Figure 119–4. There is a portion that is common across all alignment markers (designated as CM_0 to CM_5), a unique portion per PCS lane (designated as UM_0 to UM_5), and finally a unique pad per PCS lane (designated as UP_0 to UP_2). Common synchronization logic independent of the received PCS lane number can be used with the common portion of the alignment marker. The unique pad (UP0 to UP2) within the alignment markers and the PRBS9 pad at the end of the alignment maker group are ignored on receive.

The content of the alignment markers shall be as shown in Table 119–1 for the 200GBASE-R PCS and as shown in Table 119–2 for the 400GBASE-R PCS. The contents depend on the PCS lane number and the octet number, with CM_0 through CM_5 being identical across all alignment markers to allow for common synchronization across lanes. The format shown in Table 119–1 defines how the alignment markers appear on a given PCS lane. In the FEC codewords, they appear in a permuted format due to the codeword interleaving that occurs before FEC codewords are distributed to PCS lanes.

The transmit alignment marker status field allows the local PCS to communicate the status of the FEC degraded feature to the remote PCS. If there is no extender sublayer between the PCS and the MAC, it is set as follows:

tx_am_sf<2:0> = {FEC_degraded_SER + rx_local_degraded,0,0}

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If there is a Clause 118 extender sublayer between the PCS and the MAC, it is set as follows:

tx_am_sf<2:0> = {PHY_XS:rx_rm_degraded, PHY_XS:FEC_degraded_SER, 0}

Where PHY_XS:rx_rm_degraded and PHY_XS:FEC_degraded_SER are the rx_rm_degraded and FEC_degraded_SER variables from the adjacent PHY_XS sublayer.

See 119.2.5.3 for more information on the optional FEC degrade feature.

119.2.4.4.1 AM creation for the 200GBASE-R PCS

For the 200GBASE-R PCS, the alignment marker mapping function creates a set of 8 alignment markers, and in combination with an additional 65-bit PRBS9 pad and a 3-bit status field, the PCS generates an alignment marker group. Let am_*x*<119:0> be the alignment marker for PCS lane *x*, *x*=0 to 7, where bit 0 is the first bit transmitted. The alignment markers shall be mapped to am_mapped<959:0> in a manner that yields the same result as the following process.

For *x*=0 to 7, am_*x*<119:0> is constructed as follows:

am_*x*<119:0> is set to CM_0, CM_1, CM_2, UP_0, CM_3, CM_4, CM_5, UP_1, UM_0, UM_1, UM_2, UP_2, UM_3, UM_4 and UM_5, as shown in Figure 119–4 (bits 119:0) using the values in Table 119–1 for PCS lane number *x*.

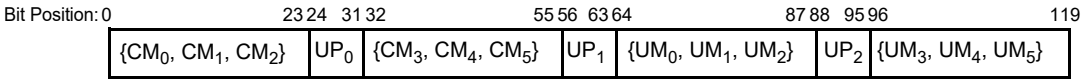

Figure 119–4—Alignment marker format

Table 119–1—200GBASE-R alignment marker encodings

PCS lane number	Encoding[a] {CM_0,CM_1,CM_2,UP_0,CM_3,CM_4,CM_5,UP_1,UM_0,UM_1,UM_2,UP_2,UM_3,UM_4,UM_5}
0	0x9A,0x4A,0x26,0x05,0x65,0xB5,0xD9,0xD6,0xB3,0xC0,0x8C,0x29,0x4C,0x3F,0x73

2	0x9A,0x4A,0x26,0x46,0x65,0xB5,0xD9,0xFE,0x3E,0xF3,0x56,0x01,0xC1,0x0C,0xA9
3	0x9A,0x4A,0x26,0x5A,0x65,0xB5,0xD9,0x84,0x86,0x80,0xD0,0x7B,0x79,0x7F,0x2F
4	0x9A,0x4A,0x26,0xE1,0x65,0xB5,0xD9,0x19,0x2A,0x51,0xF2,0xE6,0xD5,0xAE,0x0D
5	0x9A,0x4A,0x26,0xF2,0x65,0xB5,0xD9,0x4E,0x12,0x4F,0xD1,0xB1,0xED,0xB0,0x2E
6	0x9A,0x4A,0x26,0x3D,0x65,0xB5,0xD9,0xEE,0x42,0x9C,0xA1,0x11,0xBD,0x63,0x5E
7	0x9A,0x4A,0x26,0x22,0x65,0xB5,0xD9,0x32,0xD6,0x76,0x5B,0xCD,0x29,0x89,0xA4

[a] Each octet is transmitted LSB to MSB.

As an example, the variable am_0 is sent as (left most bit sent first, showing the first 32 bits transmitted of am_0):

01011001 01010010 01100100 10100000

The variable am_mapped is then derived from 10-bit interleaving the group of 8 alignment markers am_*x* per the following procedure:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For all *k*=0 to 11
  For all *j*=0 to 3
    if even(*k*)
      am_mapped<80*k*+20*j*+9:80*k*+20*j*> = am_{2*j*}<10*k*+9:10*k*>
      am_mapped<80*k*+20*j*+19:80*k*+20*j*+10> = am_{2*j*+1}<10*k*+9:10*k*>
    else
      am_mapped<80*k*+20*j*+9:80*k*+20*j*> = am_{2*j*+1}<10*k*+9:10*k*>
      am_mapped<80*k*+20*j*+19:80*k*+20*j*+10> = am_{2*j*}<10*k*+9:10*k*>

The additional 65-bit pad is appended to variable am_mapped as follows:

am_mapped<1024:960> = PRBS9<64:0>

In this expression, PRBS9<0> is the first PRBS9 bit output of the 65-bit pad.

The 3-bit transmit alignment marker status field is then appended to the variable am_mapped as follows:

am_mapped<1027:1025> = tx_am_sf<2:0>

Alignment marker mapping is shown in Figure 119–5.

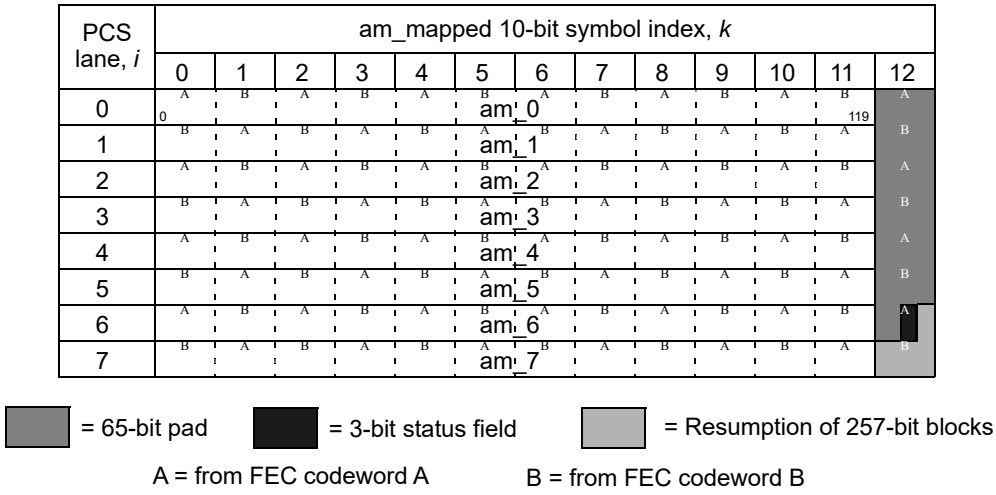

Figure 119–5—200GBASE-R alignment marker mapping to PCS lanes

The alignment marker group am_mapped<1027:0> shall be inserted so it appears in the output stream every 81 920 × 257-bit blocks. The variable tx_scrambled_am<10279:0> is constructed in one of two ways. Let the set of vectors tx_scrambled_*i*<256:0> represent consecutive values of tx_scrambled<256:0>.

For a 10280-bit block with an alignment marker group inserted:

tx_scrambled_am<1027:0> = am_mapped<1027:0>
For all *i*=0 to 35
  tx_scrambled_am<257*i*+1284:257*i*+1028> = tx_scrambled_*i*<256:0>

For a 10280-bit block without an alignment marker group:
For all *i*=0 to 39
  tx_scrambled_am<257*i*+256:257*i*> = tx_scrambled_*i*<256:0>

Alignment marker repetition rate is shown in Figure 119–6.

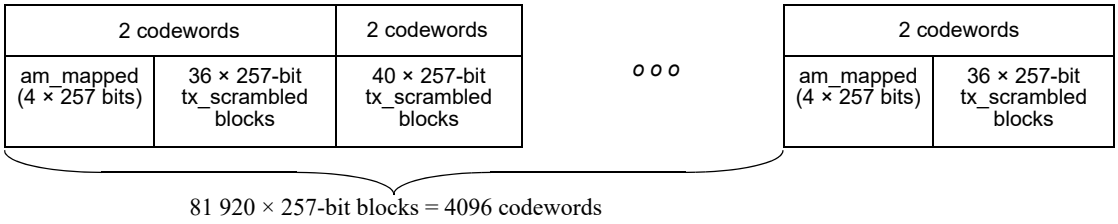

Figure 119–6—200GBASE-R alignment marker insertion period

119.2.4.4.2 AM creation for the 400GBASE-R PCS

For the 400GBASE-R PCS, the alignment marker mapping function creates a set of 16 alignment markers, and in combination with an additional 133-bit PRBS9 pad and a 3-bit status field, the PCS generates an alignment marker group.

Let am_*x*<119:0> be the alignment marker for PCS lane *x*, *x*=0 to 15, where bit 0 is the first bit transmitted. The alignment markers shall be mapped to am_mapped<1919:0> in a manner that yields the same result as the following process.

For *x*=0 to *15*, am_*x*<119:0> is constructed as follows:

am_*x*<119:0> is set to CM_0, CM_1, CM_2, UP_0, CM_3, CM_4, CM_5, UP_1, UM_0, UM_1, UM_2, UP_2, UM_3, UM_4 and UM_5, as shown in Figure 119–4 (bits 119:0) using the values in Table 119–2 for PCS lane number *x*.

Table 119–2—400GBASE-R alignment marker encodings

As an example, the variable am_0 is sent as (left most bit sent first, showing the first 32 bits transmitted of am_0):

01011001 01010010 01100100 01101101

The variable am_mapped is then derived from 10-bit interleaving the group of 16 alignment markers am_*x* per the following procedure:

For all *k*=0 to 11
  For all *j*=0 to 7
    if even(*k*)
      am_mapped<160*k*+20*j*+9:160*k*+20*j*> = am_{2*j*}<10*k*+9:10*k*>
      am_mapped<160*k*+20*j*+19:160*k*+20*j*+10> = am_{2*j*+1}<10*k*+9:10*k*>
    else
      am_mapped<160*k*+20*j*+9:160*k*+20*j*> = am_{2*j*+1}<10*k*+9:10*k*>
      am_mapped<160*k*+20*j*+19:160*k*+20*j*+10> = am_{2*j*}<10*k*+9:10*k*>

The additional 133-bit pad is appended to variable am_mapped as follows:

am_mapped<2052:1920> = PRBS9<132:0>

In this expression, PRBS9<0> is the first PRBS9 bit output of the 133-bit pad.

The 3-bit transmit alignment marker status field is then appended to the variable am_mapped as follows:

am_mapped<2055:2053> = tx_am_sf<2:0>

Alignment marker mapping is shown in Figure 119–7.

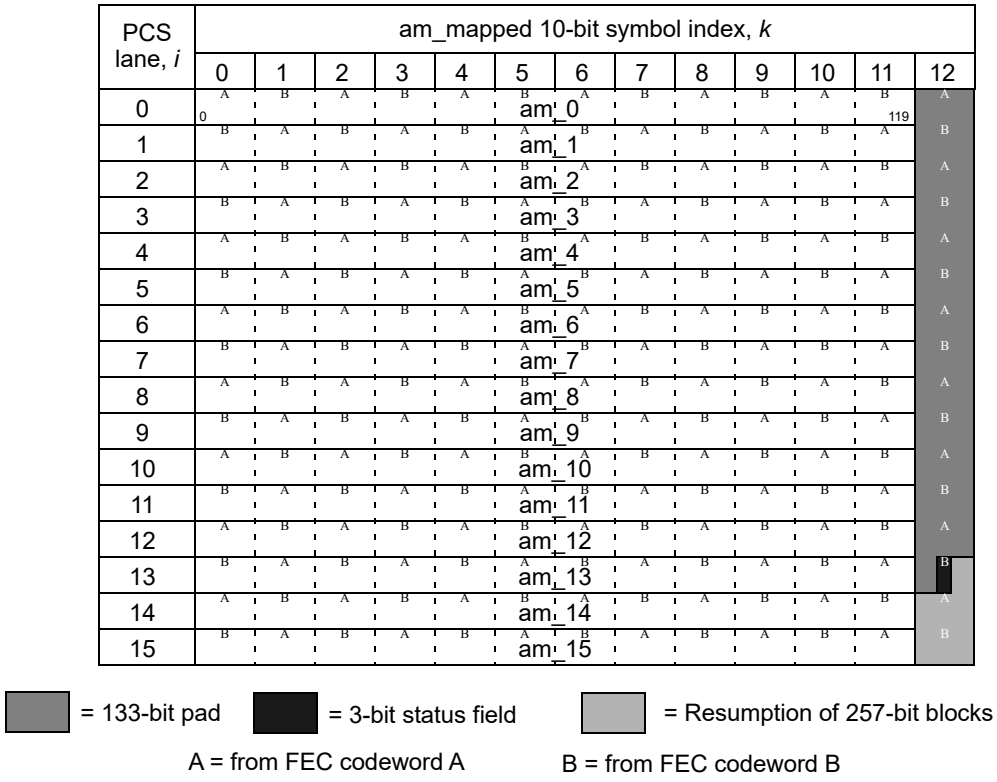

Figure 119–7—400GBASE-R alignment marker mapping to PCS lanes

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The alignment marker group am_mapped<2055:0> shall be inserted so it appears in the output stream every 163 840 × 257-bit blocks. The variable tx_scrambled_am<10279:0> is constructed in one of two ways. Let the set of vectors tx_scrambled_*i*<256:0> represent consecutive values of tx_scrambled<256:0>.

For a 10280-bit block with an alignment marker group inserted:
tx_scrambled_am<2055:0> = am_mapped<2055:0>
For all *i*=0 to 31
  tx_scrambled_am<257*i*+2312:257*i*+2056> = tx_scrambled_*i*<256:0>

For a 10280-bit block without an alignment marker group:
For all *i*=0 to 39
  tx_scrambled_am<257*i*+256:257*i*> = tx_scrambled_*i*<256:0>

Alignment marker repetition rate is shown in Figure 119–8.

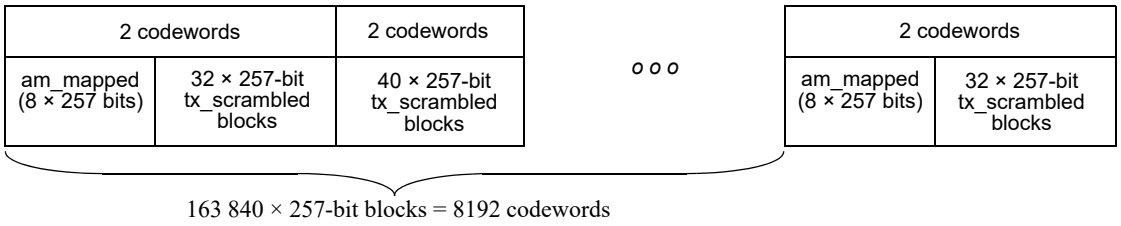

Figure 119–8—400GBASE-R alignment marker insertion period

119.2.4.5 Pre-FEC distribution

In order to improve error correction capability, each set of two consecutive Reed-Solomon FEC codewords is interleaved before being distributed to form the PCS lanes. To enable this interleaving, the Pre-FEC distribution function receives a 10280-bit block tx_scrambled_am, and shall perform a 10-bit symbol round robin distribution to form two 514-symbol FEC messages, m_A and m_B, which are subsequently each encoded by the RS FEC. The following describes the 10-bit round robin distribution process.

For all *i*=0 to 513

m_A<(513–*i*)> = tx_scrambled_am<(20*i*+9):(20*i*)>
m_B<(513–*i*)> = tx_scrambled_am<(20*i*+19):(20*i*+10)>

119.2.4.6 Reed-Solomon encoder

The PCS sublayer employs a Reed-Solomon code operating over the Galois Field GF(2^{10}) where the symbol size is 10 bits. The encoder processes *k* message symbols to generate 2*t* parity symbols, which are then appended to the message to produce a codeword of *n*=*k*+2*t* symbols. For the purposes of this clause, a particular Reed-Solomon code is denoted RS(*n*,*k*).

The PCS shall implement an RS(544,514) based FEC encoder. The PCS distributes a group of 40 × 257-bit blocks from tx_scrambled_am on a 10-bit round robin basis into two 5140-bit message blocks, $m_A$and m_B, as described in 119.2.4.5. These are then encoded using RS(544,514) encoder into codeword A and codeword B, respectively. The RS(544,514) code is based on the generating polynomial given by Equation (119–1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$g(x) = \prod_{j=0}^{2t-1}(x-\alpha^j) = g_{2t}x^{2t} + g_{2t-1}x^{2t-1} + \ldots + g_1 x + g_0 \quad (119\text{–}1)$$

In Equation (119–1), α is a primitive element of the finite field defined by the polynomial $x^{10}+x^3+1$.

Equation (119–2) defines the message polynomial $m(x)$ whose coefficients are the message symbols m_{k-1} to m_0.

$$m(x) = m_{k-1}x^{n-1} + m_{k-2}x^{n-2} + \ldots + m_1 x^{2t+1} + m_0 x^{2t} \quad (119\text{–}2)$$

Each message symbol m_i is the bit vector $(m_{i,9}, m_{i,8}, \ldots, m_{i,1}, m_{i,0})$, which is identified with the element $m_{i,9}\alpha^9 + m_{i,8}\alpha^8 + \ldots + m_{i,1}\alpha + m_{i,0}$ of the finite field. The message symbols are composed of the variable m_A for codeword A and m_B for codeword B (including a group of alignment markers when appropriate). The first symbol input to the encoder is m_{k-1}.

Equation (119–3) defines the parity polynomial $p(x)$ whose coefficients are the parity symbols p_{2t-1} to p_0.

$$p(x) = p_{2t-1}x^{2t-1} + p_{2t-2}x^{2t-2} + \ldots + p_1 x + p_0 \quad (119\text{–}3)$$

The parity polynomial is the remainder from the division of $m(x)$ by $g(x)$. This may be computed using the shift register implementation illustrated in Figure 119–9. The outputs of the delay elements are initialized to zero prior to the computation of the parity for a given message. After the last message symbol, m_0, is processed by the encoder, the outputs of the delay elements are the parity symbols for that message.

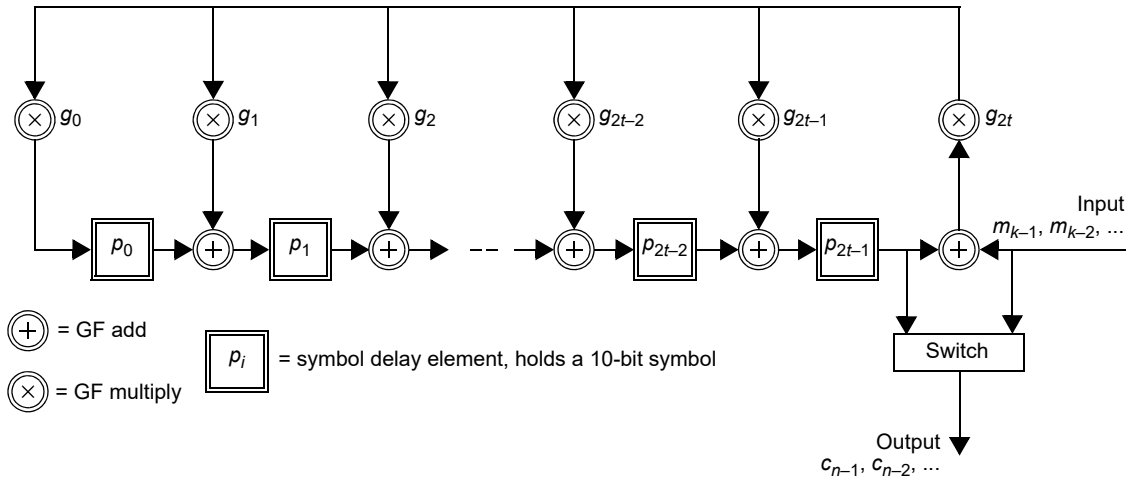

Figure 119–9—Reed-Solomon encoder functional model

The codeword polynomial $c(x)$ is then the sum of $m(x)$ and $p(x)$ where the coefficient of the highest power of x, $c_{n-1} = m_{k-1}$ is first and the coefficient of the lowest power of x, $c_0 = p_0$ is last.

The coefficients of the generator polynomial for the RS(544,514) code are presented in Table 119–3. Example codewords for the RS(544,514) code are provided in Annex 119A.

Table 119–3—Coefficients of the generator polynomial g_i (decimal)

i	g_i	i	g_i	i	g_i
0	523	11	883	22	565
1	834	12	503	23	108
2	128	13	942	24	1
3	158	14	385	25	552
4	185	15	495	26	230
5	127	16	720	27	187
6	392	17	94	28	552
7	193	18	132	29	575
8	610	19	593	30	1
9	788	20	249		
10	361	21	282		

119.2.4.7 Symbol distribution

Once the data has been FEC encoded, two FEC codewords (c_A<543:0> and c_B<543:0>) are interleaved on a 10-bit basis before the data is distributed to each PCS lane.

The interleaving of two codewords for the 200GBASE-R PCS shall follow this procedure:

For all k=0 to 135
For all j=0 to 3
    if even(k)
        tx_out<$8k+2j$> = c_A<$543-4k-j$>
        tx_out<$8k+2j+1$> = c_B<$543-4k-j$>
    else
        tx_out<$8k+2j$> = c_B<$543-4k-j$>
        tx_out<$8k+2j+1$> = c_A<$543-4k-j$>

The interleaving of two codewords for the 400GBASE-R PCS shall follow this procedure:

For all k=0 to 67
For all j=0 to 7
    if even(k)
        tx_out<$16k+2j$> = c_A<$543-8k-j$>
        tx_out<$16k+2j+1$> = c_B<$543-8k-j$>
    else
        tx_out<$16k+2j$> = c_B<$543-8k-j$>
        tx_out<$16k+2j+1$> = c_A<$543-8k-j$>

Once the data has been Reed-Solomon encoded and interleaved, it shall be distributed to 8 PCS lanes for a 200GBASE-R PCS and to 16 PCS lanes for a 400GBASE-R PCS, one 10-bit symbol at a time, from the lowest to the highest PCS lane. The first bit transmitted from each 10-bit symbol is bit 0.

119.2.4.9 Test-pattern generators

The PCS shall have the ability to generate a scrambled idle test pattern which is suitable for receiver tests and for certain transmitter tests. When a scrambled idle pattern is enabled, the test pattern is generated by the PCS. The test pattern is an idle control block (block type=0x1E) with all idles as defined in Figure 82–5. The test pattern is sent continuously and is transcoded, scrambled, alignment markers are inserted and finally encapsulated by the FEC.

When the transmit channel is operating in test-pattern mode, the encoded bit stream is distributed to the PCS Lanes as in normal operation (see 119.2.4.7).

If a Clause 45 MDIO is implemented, then control of the test-pattern generation is from the BASE-R PCS test-pattern control register (bit 3.42.3).

119.2.5 Receive function

119.2.5.1 Alignment lock and deskew

The receive PCS forms *n* separate bit streams by concatenating the bits from each of the *n* PMA:IS_UNITDATA_*i*.indication primitives in the order they are received (where *n* = 8 for a 200GBASE-R PCS and *n* = 16 for a 400GBASE-R PCS). It obtains lock to the alignment markers as specified by the alignment marker lock state diagram shown in Figure 119–12. Note that alignment marker lock is achieved before FEC codewords are processed and therefore the alignment markers are processed in a high error probability environment.

After alignment marker lock is achieved on each of the *n* lanes (bit streams), all inter-lane Skew is removed as specified by the PCS synchronization state diagram shown in Figure 119–13. The PCS receive function shall support a maximum Skew of 180 ns, and maximum Skew Variation of 4 ns, between PCS lanes.

119.2.5.2 Lane reorder and de-interleave

PCS lanes can be received on different lanes of the service interface from which they were originally transmitted. The PCS receive function shall order the PCS lanes according to the PCS lane number. The PCS lane number is defined by the unique portion (UM_0 to UM_5) of the alignment marker that is mapped to each PCS lane (see 119.2.4.4).

After all PCS lanes are aligned, deskewed, and reordered, the two FEC codewords are de-interleaved to reconstruct the original stream of two FEC codewords.

119.2.5.3 Reed-Solomon decoder

The Reed-Solomon decoder extracts the message symbols from the codeword, corrects them as necessary, and discards the parity symbols.

The Reed-Solomon decoder shall be capable of correcting any combination of up to t=15 symbol errors in a codeword. The Reed-Solomon decoder shall also be capable of indicating when an errored codeword was not corrected. The probability that the decoder fails to indicate a codeword with t+1 errors as uncorrected is not expected to exceed 10^{-16}. This limit is also expected to apply for t+2 errors, t+3 errors, and so on.

If bypass error indication is not supported or not enabled, when the Reed-Solomon decoder determines that a codeword contains errors that were not corrected, it shall cause the PCS receive function to set every 66-bit block within the two associated codewords to an error block (set to EBLOCK_R). This may be achieved by setting the synchronization header to 11 for all 66-bit blocks created from these codewords by the 256B/257B to 64B/66B transcoder.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Reed-Solomon decoder may optionally provide the ability to bypass the error indication feature to reduce the delay contributed by the FEC function. The presence of this option is indicated by the assertion of the FEC_bypass_indication_ability variable (see 119.3). When the option is provided it is enabled by the assertion of the FEC_bypass_indication_enable variable (see 119.3).

When FEC_bypass_indication_enable is asserted, additional error monitoring is performed by the Reed-Solomon decoder to reduce the likelihood that errors in a packet are not detected. The Reed-Solomon decoder counts the number of symbol errors detected on all PCS lanes in consecutive non-overlapping blocks of 8192 codewords. When the number of symbol errors in a block of 8192 codewords exceeds 5560, the Reed-Solomon decoder shall assert hi_ser for a period of 60 ms to 75 ms.

The Reed-Solomon decoder may optionally provide the ability to signal a degradation of the received signal. The presence of this option is indicated by the assertion of the FEC_degraded_SER_ability variable (see 119.3). When the option is provided it is enabled by the assertion of the FEC_degraded_SER_enable variable (see 119.3).

When FEC_degraded_SER_enable is asserted, additional error monitoring is performed by the PCS. The Reed-Solomon decoder counts the number of symbol errors detected on all PCS lanes in consecutive non-overlapping blocks of FEC_degraded_SER_interval codewords (see 119.3.1), where the least significant bit of FEC_degraded_SER_interval is ignored (evaluated as 0) to make the number of codewords even. If the decoder determines that a codeword is uncorrectable, the number of symbol errors detected is increased by 16. When the number of symbol errors exceeds the threshold set in FEC_degraded_SER_activate_threshold (see 119.3.1), the FEC_degraded_SER bit (see 119.3.1) is set. At the end of each interval, if the number of symbol errors is less than FEC_degraded_SER_deactivate_threshold, the FEC_degraded_SER bit is cleared. If either FEC_degraded_SER_ability or FEC_degraded_SER_enable is de-asserted then the FEC_degraded_SER bit is cleared.

119.2.5.4 Post FEC interleave

After the Reed-Solomon decoder processes the data, data is interleaved on a 10-bit basis into rx_scrambled_am from two codewords corresponding to 40 transcoded blocks in order to recreate the transmitted data stream.

119.2.5.5 Alignment marker removal

For the 200GBASE-R PCS, every 81 920 x 257-bit blocks (corresponds to 4096 codewords) the first 1028 bits of rx_scrambled_am blocks is the vector am_rx<1027:0> where bit 0 is the first bit received. The specific codewords that include this vector are indicated by the alignment lock and deskew function. The 3-bit receive alignment marker status field is assigned from the variable am_rx as follows:

rx_am_sf<2:0> = am_rx<1027:1025>

For the 400GBASE-R PCS, every 163 840 x 257-bit blocks (corresponds to 8192 codewords) the first 2056 bits of rx_scrambled_am blocks is the vector am_rx<2055:0> where bit 0 is the first bit received. The specific codewords that include this vector are indicated by the alignment lock and deskew function. The 3-bit receive alignment marker status field is assigned from the variable am_rx as follows:

rx_am_sf<2:0> = am_rx<2055:2053>

The vector am_rx shall be removed from rx_scrambled_am to create rx_scrambled prior to descrambling.

119.2.5.6 Descrambler

The descrambler shall process rx_scrambled<256:0> to reverse the effect of the scrambler using the polynomial given in Equation (49–1).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

119.2.5.7 256B/257B to 64B/66B transcoder

The transcoder extracts a group of four 66-bit blocks, rx_coded_*j*<65:0> where *j*=0 to 3, from each 257-bit block rx_xcoded<256:0>. Bit 0 of the 257-bit block is the first bit received.

If rx_xcoded<0> is 1, rx_coded_*j*<65:0> for *j*=0 to 3 shall be derived as follows.

a) rx_coded_*j*<65:2> = rx_xcoded<(64*j*+64):(64*j*+1)> for *j*=0 to 3

b) rx_coded_*j*<0>=0 and rx_coded_*j*<1>=1 for all *j*=0 to 3

If rx_xcoded<0> is 0 and any rx_xcoded<*j*+1>=0 for *j*=0 to 3, rx_coded_*j*<65:0> for *j*=0 to 3 shall be derived as follows.

a1) Let *c* be the smallest value of *j* such that rx_xcoded<*j*+1>=0. In other words, rx_coded_*c* is the first 66-bit control block in the resulting group of four blocks.

b1) Let rx_payloads be a vector representing the payloads of the four 66-bit blocks. It is derived using the following expressions:
rx_payloads<(64*c*+3):0> = rx_xcoded<(64*c*+8):5>
rx_payloads<(64c+7):(64c+4)> is set to a value derived by cross-referencing rx_payloads<(64c+3):64c> using Figure 82–5. For example, if rx_payloads<(64c+3):64c> is 0xE then rx_payloads<(64c+7):(64c+4)> is 0x1. If no match to rx_payloads<(64c+3):64c> is found, rx_payloads<(64c+7):(64c+4)> is set to 0000
rx_payloads<255:(64*c*+8)> = rx_xcoded<256:(64*c*+9)>

c1) rx_coded_*j*<65:2> = rx_payloads<(64*j*+63):64*j*> for *j*=0 to 3

d1) If rx_xcoded<*j*+1>=0, rx_coded_*j*<0>=1 and rx_coded_*j*<1>=0 for *j*=0 to 3

e1) If rx_xcoded<*j*+1>=1, rx_coded_*j*<0>=0 and rx_coded_*j*<1>=1 for *j*=0 to 3

f1) If rx_payloads<(64c+7):(64c+4)> = 0000, rx_coded_c<1>=1 (invalidate synchronization header)

If rx_xcoded<0> is 0 and all rx_xcoded<*j*+1>=1 for *j*=0 to 3, rx_coded_*j*<65:0> for *j*=0 to 3 shall be derived as follows.

a2) Set *c* = 0

b2) Let rx_payloads be a vector representing the payloads of the four 66-bit blocks. It is derived using the following expressions.
rx_payloads<(64*c*+3):0> = rx_xcoded<(64*c*+8):5>
rx_payloads<(64*c*+7):(64*c*+4)> = 0000
rx_payloads<255:(64*c*+8)> = rx_xcoded<256:(64*c*+9)>

c2) rx_coded_*j*<65:2> = rx_payloads<(64*j*+63):(64*j*)> for *j*=0 to 3

d2) rx_coded_*j*<0>=0 and rx_coded_*j*<1>=0 for *j*=0 and 2

e2) rx_coded_*j*<0>=1 and rx_coded_*j*<1>=1 for *j*=1 and 3

The 66-bit blocks are transmitted in order from *j*=0 to 3. Bit 0 of each block is the first bit transmitted.

NOTE—The stream of 66-bit blocks generated by this process is used as the reference signal for de-mapping from OTN. See ITU-T G.709.

119.2.5.8 Decode and rate matching

The receive PCS decodes blocks to produce RXD<63:0> and RXC<7:0> for transmission to the 200GMII/400GMII. One 200GMII/400GMII data transfer is decoded from each block. The receive PCS may insert idle control characters to compensate for the removal of alignment markers. If the receive PCS spans multiple clock domains, it may also perform clock rate compensation via the deletion of idle control characters or sequence ordered sets or the insertion of idle control characters (see 82.2.3.6 and 82.2.3.9 for insertion and deletion rules).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PCS receive decodes blocks as specified in the receive state diagram shown in Figure 119–15.

119.2.6 Detailed functions and state diagrams

119.2.6.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, functions, and counters. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

119.2.6.2 State variables

119.2.6.2.1 Constants

EBLOCK_R<71:0>
: 72-bit vector to be sent to the 200GMII/400GMII containing /E/ in all the eight character locations.

EBLOCK_T<65:0>
: 66-bit vector to be sent to the transcoder containing /E/ in all the eight character locations.

LBLOCK_R<71:0>
: 72-bit vector to be sent to the 200GMII/400GMII containing one Local Fault ordered set. The Local Fault ordered set is defined in 119.3.

LBLOCK_T<65:0>
: 66-bit vector to be sent to the transcoder containing one Local Fault ordered set.

119.2.6.2.2 Variables

align_status
: A variable set by the PCS synchronization process to reflect the status of PCS lane-to-lane alignment. Set to true when all lanes are synchronized and aligned and set to false when the PCS synchronization process is not complete.

all_locked
: A Boolean variable that is set to true when amps_lock<*x*> is true for all *x* and is set to false when amps_lock<*x*> is false for any *x*.

amp_counter_done
: Boolean variable that indicates that amp_counter has reached its terminal count.

amp_match
: Boolean variable that holds the output of the function AMP_COMPARE.

amp_valid
: Boolean variable that is set to true if the received 120-bit block is a valid alignment marker payload. The alignment marker payload, mapped to a PCS lane according to the process described in 119.2.4.4, consists of 96 known bits. The 48 bits of the common marker portion are compared on a nibble-wise basis (12 comparisons). If 9 or more nibbles in the candidate block match the corresponding known nibbles in the common portion of the alignment marker payload, the candidate block is considered a valid alignment marker payload.

amps_lock<*x*>
: Boolean variable that is set to true when the receiver has detected the location of the alignment marker payload sequence for a given lane on the PMA service interface, where *x* = 0:7 for 200GBASE-R and *x* = 0:15 for 400GBASE-R

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

current_pcsl

A variable that holds the PCS lane number corresponding to the current alignment marker payload that is recognized on a given lane of the PMA service interface. It is compared to the variable first_pcsl to confirm that the location of the alignment marker payload sequence has been detected. The PCS lane number is determined by the alignment marker payloads based on the mapping defined in 119.2.4.4. The 48 bits that are in the positions of the unique marker bits in the received alignment marker payload are compared to the expected values for a given payload position and PCS lane on a nibblewise basis (12 comparisons). If 9 or more nibbles in the candidate block match the corresponding known nibbles for any payload position on a given PCS lane, then the PCS lane number is assigned accordingly. If a match is not found, then the AMP_COMPARE function sets amp_match to false.

cw_A_bad

A Boolean variable that is set to true if the Reed-Solomon decoder (see 119.2.5.3) fails to correct the current FEC codeword A and is set to false otherwise.

cw_B_bad

A Boolean variable that is set to true if the Reed-Solomon decoder (see 119.2.5.3) fails to correct the current FEC codeword B and is set to false otherwise.

deskew_done

A Boolean variable that is set to true when pcs_enable_deskew is set to true and the deskew process is completed. Otherwise, this variable is set to false.

first_pcsl

A variable that holds the PCS lane number that corresponds to the first alignment marker payload that is recognized on a given lane of the PMA service interface. It is compared to the PCS lane number corresponding to the second alignment marker payload that is tested.

hi_ser

When FEC_bypass_indication_enable is set to one, this bit is set to one for a period of 60 ms to 75 ms if the number of RS-FEC symbol errors in a window of 8192 codewords exceeds the threshold (see 119.2.5.3), and is set to zero otherwise. When FEC_bypass_indication_enable is set to zero, this bit is set to zero. This variable is mapped to the bit defined in 45.2.3.61 (3.801.2).

pcs_alignment_valid

Boolean variable that is set to true if all PCS lanes are aligned. PCS lanes are considered to be aligned when amps_lock<*x*> is true for all *x*, each PCS lane is locked to a unique alignment marker payload sequence (see 119.2.4.4), and the PCS lanes are deskewed. Otherwise, this variable is set to false.

pcs_enable_deskew

A Boolean variable that enables and disables the PCS synchronization process. Received bits may be discarded whenever deskew is enabled. It is set to true when deskew is enabled and set to false when deskew is disabled.

pcs_lane_mapping<*x*>

A variable that holds the value of the pcs_lane received on physical lane *x*.

PCS_status

A Boolean variable that is true when align_status is true and is false otherwise.

reset

Boolean variable that controls the resetting of the PCS sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS sublayer into low-power mode.

restart_lock

Boolean variable that is set by the PCS synchronization process to restart the alignment marker lock process on all PCS lanes. It is set to true after 3 consecutive uncorrected codewords are received (3_BAD state) and set to false upon entry into the LOSS_OF_ALIGNMENT state.

rx_coded<65:0>

Vector containing the input to the 64B/66B decoder. The format for this vector is shown in Figure 82–5. The leftmost bit in the figure is rx_coded<0> and the rightmost bit is rx_coded<65>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_local_degraded
: Boolean variable that is asserted true when the receiver detects rx_am_sf<1> asserted true for two consecutive alignment marker periods. It is deasserted when rx_am_sf<1> is deasserted for two consecutive alignment marker periods. If a Clause 45 MDIO is implemented, the status of this variable is reflected in bit 3.801.6.

rx_raw<71:0>
: Vector containing one 200GMII/400GMII transfer. RXC<0> through RXC<7> are from rx_raw<0> through rx_raw<7>, respectively. RXD<0> through RXD<63> are from rx_raw<8> through rx_raw<71>, respectively.

rx_rm_degraded
: Boolean variable that is asserted true when the receiver detects rx_am_sf<2> asserted true for two consecutive alignment marker periods. It is deasserted when rx_am_sf<2> is deasserted for two consecutive alignment marker periods. If a Clause 45 MDIO is implemented, the status of this variable is reflected in bit 3.801.5.

signal_ok
: Boolean variable that is set based on the most recently received value of PMA:IS_SIGNAL.indication(SIGNAL_OK). It is true if the value was OK and false if the value was FAIL.

slip_done
: Boolean variable that is set to true when the SLIP requested by the alignment marker lock state diagram has been completed indicating that the next candidate 120-bit block position can be tested.

test_amp
: Boolean variable that is set to true when a candidate block position is available for testing and false when the FIND_1ST state is entered.

test_cw
: Boolean variable that is set to true when a new FEC codeword is available for decoding and is set to false when the TEST_CW state is entered.

tx_coded<65:0>
: Vector containing the output from the 64B/66B encoder. The format for this vector is shown in Figure 82–5. The leftmost bit in the figure is tx_coded<0> and the rightmost bit is tx_coded<65>.

tx_raw<71:0>
: Vector containing one 200GMII/400GMII transfer. TXC<0> through TXC<7> are placed in tx_raw<0> through tx_raw<7>, respectively. TXD<0> through TXD<63> are placed in tx_raw<8> through tx_raw<71>, respectively.

119.2.6.2.3 Functions

AMP_COMPARE
: This function compares the values of first_pcsl and current_pcsl to determine if a valid alignment marker payload sequence has been detected and returns the result of the comparison using the variable amp_match. If current_pcsl and first_pcsl both found a match and indicate the same PCS lane number, amp_match is set to true.

DECODE(rx_coded<65:0>)
: Decodes the 66-bit vector returning rx_raw<71:0>, which is sent to the 200GMII/400GMII. The DECODE function shall decode the block as specified in 119.2.3.

ENCODE(tx_raw<71:0>)
: Encodes the 72-bit vector returning tx_coded<65:0>. The ENCODE function shall encode the block as specified in 119.2.3.

R_TYPE(rx_coded<65:0>)
: This function classifies the current rx_coded<65:0> vector as belonging to one of the following types, depending on its contents. The classification results are returned via the r_block_type variable.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: C; The vector contains a sync header of 10 and one of the following:
a) A block type field of 0x1E and eight valid control characters other than /E/ or /LI/;
b) A block type field of 0x4B.
LI; For EEE capability, the LI type is supported where the vector contains a sync header of 10, a block type field of 0x1E and eight control characters of 0x06 (/LI/).
S; The vector contains a sync header of 10 and the following:
a) A block type field of 0x78.
T; The vector contains a sync header of 10, a block type field of 0x87, 0x99, 0xAA, 0xB4, 0xCC, 0xD2, 0xE1 or 0xFF and all control characters are valid.
D; The vector contains a sync header of 01.
E; The vector does not meet the criteria for any other value.

Valid control characters are specified in Table 82–1.

NOTE—A PCS that does not support EEE classifies vectors containing one or more /LI/ control characters as type E.

R_TYPE_NEXT

This function classifies the 66-bit rx_coded vector that immediately follows the current rx_coded<65:0> vector as belonging to one of the five types defined in R_TYPE, depending on its contents. It is intended to perform a prescient end of packet check. The classification results are returned via the r_block_type_next variable.

SLIP

Causes the next candidate block position to be tested. The precise method for determining the next candidate block position is not specified and is implementation dependent. However, an implementation shall ensure that all possible block positions are evaluated.

T_TYPE = (tx_raw<71:0>)

This function classifies each 72-bit tx_raw vector as belonging to one of the following types depending on its contents. The classification results are returned via the t_block_type variable.

Values: C; The vector contains one of the following:
a) Eight valid control characters other than /O/, /S/, /T/, /LI/, and /E/;
b) One valid ordered set.
LI; For EEE capability, this vector contains eight /LI/ characters.
S; The vector contains an /S/ in its first character, and all characters following the /S/ are data characters.
T; The vector contains a /T/ in one of its characters, all characters before the /T/ are data characters, and all characters following the /T/ are valid control characters other than /O/, /S/ and /T/.
D; The vector contains eight data characters.
E; The vector does not meet the criteria for any other value.

A tx_raw character is a control character if its associated TXC bit is asserted. A valid control character is one containing an 200GMII/400GMII control code specified in Table 82–1. A valid ordered set consists of a valid /O/ character in the first character and data characters in the seven characters following the /O/. A valid /O/ is any character with a value for O code in Table 82–1.

NOTE—A PCS that does not support EEE classifies vectors containing one or more /LI/ control characters as type E.

119.2.6.2.4 Counters

amp_bad_count
: Counts the number of consecutive alignment markers that don't match the expected values for a given PCS lane.

amp_counter
: This counter counts the interval of *i* FEC codewords containing normal alignment marker payload sequences (where *i* is 4096 for the 200GBASE-R PCS, and 8192 for the 400GBASE-R PCS).

cw_A_bad_count
: Counts the number of consecutive uncorrected FEC codewords for codeword A. This counter is set to zero when an FEC codeword A is received and cw_A_bad is false.

cw_B_bad_count
: Counts the number of consecutive uncorrected FEC codewords for codeword B. This counter is set to zero when an FEC codeword B is received and cw_B_bad is false.

119.2.6.3 State diagrams

The 200GBASE-R PCS shall implement eight alignment marker lock processes and the 400GBASE-R PCS shall implement sixteen alignment marker lock processes as depicted in Figure 119–12. An alignment marker lock process operates independently on each lane. The alignment marker lock state diagram shown in Figure 119–12 determines when the PCS has obtained alignment marker lock to the received bit stream for a given lane of the service interface. Each alignment marker lock process looks for two valid alignment markers 278 528 × 10-bit Reed-Solomon symbols apart, on a per PCS lane basis, to gain alignment marker lock. When the alignment marker lock process achieves lock for a lane, and if a Clause 45 MDIO is implemented, the PCS shall record the PCS lane number received on that lane of the service interface in the appropriate lane mapping register (3.400 to 3.415). Once in lock, a lane goes out of alignment marker lock when restart_lock is signaled (this occurs when the PCS synchronization process determines that three uncorrectable codewords in a row are seen) or when the alignment marker lock process sees five alignment markers in a row that fail to match the expected pattern on a given lane.

The PCS shall run the synchronization process as depicted in Figure 119–13. The PCS synchronization process is responsible for determining if the PCS is capable of presenting coherent data to the 200GMII/400GMII. The synchronization process ensures that all PCS lanes have alignment marker lock, are locked to different alignment markers, and that the Skew is within the boundaries of what the PCS can deskew. The synchronization process, along with the alignment marker lock process, are restarted if three consecutive FEC codewords from the same codeword (A or B) are uncorrectable.

The Transmit state diagram shown in Figure 119–14 controls the encoding of 66-bit transmitted blocks. It makes exactly one transition for each 66-bit transmit block processed. Though the Transmit state diagram sends Local Fault ordered sets when reset is asserted, the scrambler is not guaranteed to be operational during reset. Thus, the Local Fault ordered sets may not appear on the PMA service interface.

The Receive state diagram shown in Figure 119–15 controls the decoding of received blocks. It makes exactly one transition for each receive 66-bit block processed.

The PCS shall perform the functions of alignment marker lock, PCS synchronization, Transmit, and Receive as specified in the respective state diagrams.

119.3 PCS management

The following objects apply to PCS management. If an MDIO Interface is provided (see Clause 45), they are accessed via that interface. If not, it is recommended that an equivalent access is provided.

119.3.1 PCS MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PCS. If MDIO is implemented, it shall map MDIO control bits to PCS control variables, as shown in Table 119–4, and MDIO status bits to PCS status variables, as shown in Table 119–5.

Table 119–4—MDIO/PCS control variable mapping

MDIO control variable	PCS register name	Register/bit number	PCS control variable
Reset	PCS control 1 register	3.0.15	reset
Loopback	PCS control 1 register	3.0.14	Loopback
Transmit test-pattern enable	BASE-R PCS test-pattern control register	3.42.3	tx_test_mode
LPI_FW	EEE control and capability	3.20.0	LPI_FW
PCS FEC bypass indication enable	PCS FEC control register	3.800.1	FEC_bypass_indication_enable
PCS FEC degraded SER enable	PCS FEC control register	3.800.2	FEC_degraded_SER_enable
PCS FEC degraded SER activate threshold	PCS FEC degraded SER activate threshold register	3.806, 3.807	FEC_degraded_SER_activate_threshold
PCS FEC degraded SER deactivate threshold	PCS FEC degraded SER deactivate threshold register	3.808, 3.809	FEC_degraded_SER_deactivate_threshold
PCS FEC degraded SER interval	PCS FEC degraded SER interval	3.810, 3.811	FEC_degraded_SER_interval

Table 119–5—MDIO/PCS status variable mapping

MDIO status variable	PCS register name	Register/bit number	PCS status variable
BASE-R and MultiGBASE-T receive link status	BASE-R and MultiGBASE-T PCS status 1 register	3.32.12	PCS_status
Lane *x* aligned	Multi-lane BASE-R PCS alignment status 3 and 4 registers	3.52.7:0 3.53.7:0	am_lock<*x*>
PCS lane alignment status	Multi-lane BASE-R PCS alignment status 1 register	3.50.12	align_status
Lane *x* mapping	Lane *x* mapping register	3.400 through 3.415	pcs_lane_mapping<*x*>
PCS FEC bypass indication ability	PCS FEC status register	3.801.1	FEC_bypass_indication_ability

Copyright © 2022 IEEE. All rights reserved.

Table 119–5—MDIO/PCS status variable mapping *(continued)*

MDIO status variable	PCS register name	Register/bit number	PCS status variable
PCS FEC corrected codewords	PCS FEC corrected codewords counter register	3.802, 3.803	FEC_corrected_cw_counter
PCS FEC uncorrected codewords	PCS FEC uncorrected codewords counter register	3.804, 3.805	FEC_uncorrected_cw_counter
PCS FEC symbol errors, PCS lanes 0 to *x*	PCS FEC symbol error counter register, lanes 0 to *x*	3.600 to 3.631	FEC_symbol_error_counter_*i*
Tx LPI indication	PCS status 1	3.1.9	Tx LPI indication
Tx LPI received	PCS status 1	3.1.11	Tx LPI received
Rx LPI indication	PCS status 1	3.1.8	Rx LPI indication
Rx LPI received	PCS status 1	3.1.10	Rx LPI received
EEE wake error counter	EEE wake error counter	3.22	Wake_error_counter
PCS FEC degraded SER ability	PCS FEC status register	3.801.3	FEC_degraded_SER_ability
PCS FEC degraded SER	PCS FEC status register	3.801.4	FEC_degraded_SER
Local degraded SER received	PCS FEC status register	3.801.6	rx_local_degraded
Remote degraded SER received	PCS FEC status register	3.801.5	rx_rm_degraded
PCS FEC high SER	PCS FEC status register	3.801.2	hi_ser

119.3.2 FEC_corrected_cw_counter

A corrected FEC codeword is a codeword that contains errors and was corrected. FEC_corrected_cw_counter is a 32-bit counter that counts once for each corrected FEC codeword processed when align_status is true. This variable is mapped to the registers defined in 45.2.3.62 (3.802, 3.803).

119.3.3 FEC_uncorrected_cw_counter

An uncorrected FEC codeword is a codeword that contains errors that were not corrected. FEC_uncorrected_cw_counter is a 32-bit counter that counts once for each uncorrected FEC codeword processed when align_status is true. This variable is mapped to the registers defined in 45.2.3.63 (3.804, 3.805).

119.3.4 FEC_symbol_error_counter_*i*

FEC_symbol_error_counter_*i* (where *i*=0 to 7 for the 200GBASE-R PCS and *i*=0 to 15 for the 400GBASE-R PCS) are 32-bit counters that count once for each 10-bit symbol corrected on PCS lane *i* when align_status is true. These variables are mapped to the registers defined in 45.2.3.58 and 45.2.3.59 (3.600 to 3.631).

119.4 Loopback

When the PCS is in loopback, the PCS shall accept data on the transmit path from the 200GMII/400GMII and return it on the receive path to the 200GMII/400GMII. In addition, the PCS shall transmit what it receives from the 200GMII/400GMII to the PMA sublayer, and shall ignore all data presented to it by the PMA sublayer. If a Clause 45 MDIO is implemented, then the PCS is placed in the loopback when the loopback bit from the PCS control 1 register (bit 3.0.14) is set to a one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

119.5 Delay constraints

The maximum delay contributed by the 200GBASE-R PCS (sum of transmit and receive delays at one end of the link) shall be no more than 160 256 BT (313 pause_quanta or 801.28 ns). The maximum delay contributed by the 400GBASE-R PCS (sum of transmit and receive delays at one end of the link) shall be no more than 320 000 BT (625 pause_quanta or 800 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

119.6 Auto-Negotiation

The following requirements apply to a PCS used with a 200GBASE-CR4 or 200GBASE-KR4 PMD where support for the Auto-Negotiation process defined in Clause 73 is mandatory. The PCS shall support the AN_LINK.indication(link_status) primitive (see 73.9). The parameter link_status shall take the value FAIL when PCS_status=false and the value OK when PCS_status=true. The primitive shall be generated when the value of link_status changes.

119.7 Protocol implementation conformance statement (PICS) proforma for Clause 119, Physical Coding Sublayer (PCS) for 64B/66B, type 200GBASE-R and 400GBASE-R[206]

119.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 119, Physical Coding Sublayer (PCS) for 64B/66B, type 200GBASE-R and 400GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

119.7.2 Identification

119.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

119.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 119, Physical Coding Sublayer (PCS) 64B/66B, type 200GBASE-R and 400GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[206] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

120. Physical Medium Attachment (PMA) sublayer, type 200GBASE-R and 400GBASE-R

120.1 Overview

120.1.1 Scope

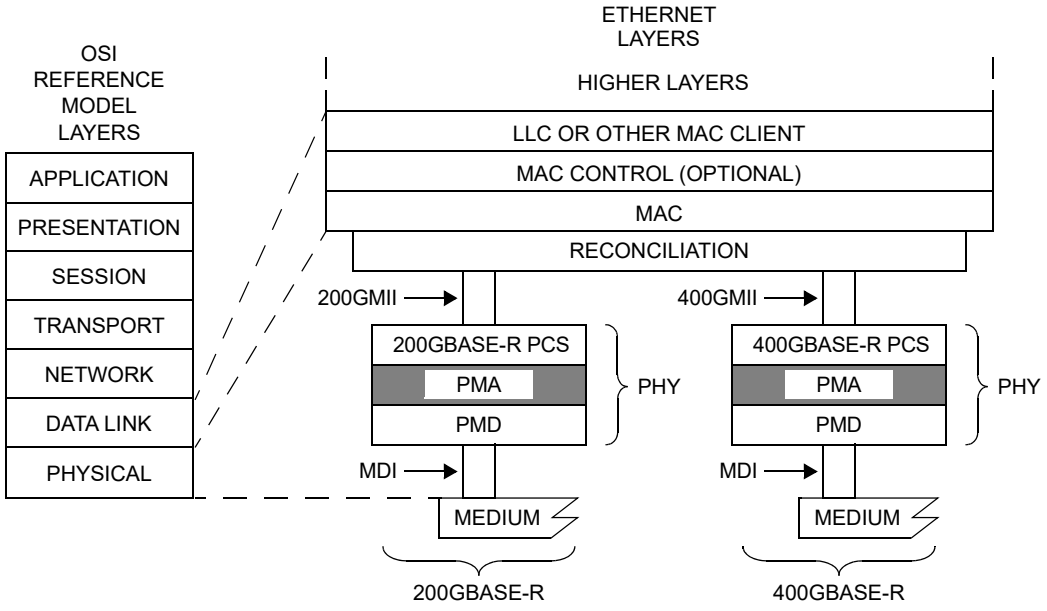
This clause specifies the Physical Medium Attachment sublayer (PMA) for the families of 200 Gb/s and 400 Gb/s Physical Layer implementations, known as 200GBASE-R and 400GBASE-R. The PMA allows the PCS (specified in Clause 119) to connect in a media-independent way with a range of physical media, or for the DTE XS to connect to the PHY XS (specified in Clause 118). The 200GBASE-R PMA(s) can support any of the 200 Gb/s PMDs in Table 116–1, and the 400GBASE-R PMA(s) can support any of the 400 Gb/s PMDs in Table 116–2. The terms 200GBASE-R and 400GBASE-R are used when referring generally to Physical Layers using the PMA defined in this clause.

200GBASE-R and 400GBASE-R can be extended to support any full duplex medium requiring only that the PMD be compliant with the appropriate PMA interface.

The interfaces for the inputs of the 200GBASE-R and 400GBASE-R PMAs are defined in an abstract manner and do not imply any particular implementation. For 200GBASE-R PMAs, electrical interfaces connecting PMA sublayers, known as 200GAUI-n, are defined in Annex 120B, Annex 120C, Annex 120D, and Annex 120E. For 400GBASE-R PMAs, electrical interfaces connecting PMA sublayers, known as 400GAUI-n, are defined in Annex 120B, Annex 120C, Annex 120D, and Annex 120E.

120.1.2 Position of the PMA in the 200GBASE-R and 400GBASE-R sublayers

Figure 120–1 shows the relationship of the PMA sublayer (shown shaded) with other sublayers to the ISO Open System Interconnection (OSI) reference model.



120.1.3 Summary of functions

The following is a summary of the principal functions implemented (when required) by the PMA in both the transmit and receive directions:

a) Adapt the PCSL formatted signal to the appropriate number of abstract or physical lanes.
b) Provide per input-lane clock and data recovery.
c) Provide bit-level multiplexing.
d) Provide clock generation.
e) Provide signal drivers.
f) Optionally provide local loopback to/from the PMA service interface.
g) Optionally provide remote loopback to/from the PMD service interface.
h) Optionally provide test-pattern generation and detection.
i) Tolerate Skew Variation.
j) Perform PAM4 encoding and decoding for 200GBASE-R PMAs where the number of physical lanes is 4, and for 400GBASE-R PMAs where the number of physical lanes is 4 or 8.

In addition, the PMA provides receive link status information in the receive direction.

120.1.4 PMA sublayer positioning

An implementation may use one or more PMA sublayers to adapt the number and rate of the PCS lanes to the number and rate of the PMD lanes. The number of PMA sublayers required depends on the partitioning of functionality for a particular implementation. An example is illustrated in Figure 120–2. Additional examples are illustrated in Annex 120A. Each PMA maps the PCSLs from p PMA input lanes to q PMA output lanes in the Tx direction, and from q PMA input lanes to p PMA output lanes in the Rx direction.

Management Data Input/Output (MDIO) Manageable Device (MMD) addresses 1, 8, 9, and 10 are available for addressing multiple instances of PMA sublayers (see Table 45–1 for MMD device addresses). If the PMA sublayer that is closest to the PMD is packaged with the PMD, it shares MMD 1 with the PMD. More addressable instances of PMA sublayers, each one separated from lower addressable instances by chip-to-chip interfaces, may be implemented and addressed allocating MMD addresses to PMAs in increasing numerical order going from the PMD toward the MAC. The example shown in Figure 120–2 could be implemented with three addressable instances: MMD 1 addressing the lowest PMA sublayer (co-packaged with the PMD), MMD 8 addressing the PMA sublayer above the 200GAUI-4 below the 200GAUI-8 or above the 400GAUI-8 below the 400GAUI-16, and MMD 9 addressing the PMA sublayer below the PCS.

The number of input lanes and the number of output lanes for a PMA are always divisors of the number of PCSLs. For PMA sublayers supporting 200GBASE-R PMDs, the number of PCSLs is 8. For PMA sublayers supporting 400GBASE-R PMDs, the number of PCSLs is 16.

Figure 120–2—Example 200GBASE-R and 400GBASE-R PMA layering

The following guidelines apply to the partitioning of PMAs:

a) The inter-sublayer service interface, defined in 116.3.1, is used for the PMA service interfaces supporting a flexible architecture with multiple PMA sublayers.
   1) An instance of this interface can only connect service interfaces with the same number of lanes, where the lanes operate at the same rate.

b) 200GAUI-n is a physical instantiation of the connection between two adjacent 200GBASE-R PMA sublayers with the exception of the inst:IS_SIGNAL.indication which is carried outside of this physically instantiated interface. 400GAUI-n is a physical instantiation of the connection between two adjacent 400GBASE-R PMA sublayers with the exception of the inst:IS_SIGNAL.indication which is carried outside of this physically instantiated interface.
   1) As physical instantiations, these define electrical and timing specification as well as requiring a receive re-timing function.
   2) 200GAUI-8 is a 26.5625 GBd by 8 lane NRZ physical instantiation of the 200 Gb/s connection. 400GAUI-16 is a 26.5625 GBd by 16 lane NRZ physical instantiation of the 400 Gb/s connection.
   3) 200GAUI-4 is a 26.5625 GBd by 4 lane PAM4 physical instantiation of the 200 Gb/s connection. 400GAUI-8 is a 26.5625 GBd by 8 lane PAM4 physical instantiation of the 400 Gb/s connection.

c) The abstract inter-sublayer service interface can be physically instantiated as a 200GAUI-n or 400GAUI-n, using associated PMAs to map to the appropriate number of lanes.

d) Opportunities for optional test-pattern generation, optional test-pattern detection, optional local loopback and optional remote loopback are dependent upon the location of the PMA sublayer in the implementation. See Figure 120–5.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

e) A minimum of one PMA sublayer is required in a PHY.

f) A maximum of four PMA sublayers are addressable as MDIO MMDs.

120.2 PMA interfaces

All PMA variants for 200GBASE-R and 400GBASE-R are based on a generic specification of a bit mux function that applies to all input/output lane counts and each direction of transmission. Each direction of transmission may employ one or more such bit muxes to adapt from the appropriate number of input lanes to the appropriate number of output lanes as illustrated in Figure 120–3.

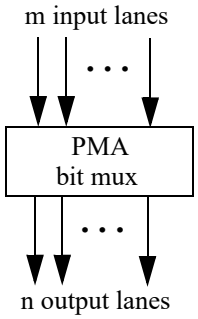

Figure 120–3—PMA bit mux used in both Tx and Rx directions

Conceptually, the PMA bit mux operates in one direction of transmission by demultiplexing PCSLs from m PMA input lanes and remultiplexing them into n PMA output lanes. The mapping of PCSLs from input to output lanes is not specified. See 120.5.2 and Figure 120–4 for details.

Figure 120–5 provides the functional block diagram of a PMA. The parameters of a PMA include the following:

— The numbers of input and output lanes in each direction.

— Whether the PMA is adjacent to a physically instantiated interface (200GAUI-n or 400GAUI-n above or below).

— Whether the PMA is adjacent to the PCS or DTE XS.

— Whether the PMA is adjacent to the PMD or PHY XS.

120.3 PMA service interface

The PMA service interface for 200GBASE-R and 400GBASE-R is an instance of the inter-sublayer service interface defined in 116.3.1. The PMA service interface primitives are summarized as follows:

PMA:IS_UNITDATA_*i*.request(tx_symbol)
PMA:IS_UNITDATA_*i*.indication(rx_symbol)
PMA:IS_SIGNAL.indication(SIGNAL_OK)

For a PMA service interface with p lanes, the primitives are defined for $i = 0$ to $p - 1$.

If the PMA client is the PCS or DTE XS, the PMA continuously sends eight (for 200GBASE-R) or sixteen (for 400GBASE-R) parallel bit streams to the PCS, each at the nominal signaling rate of the PCSL.

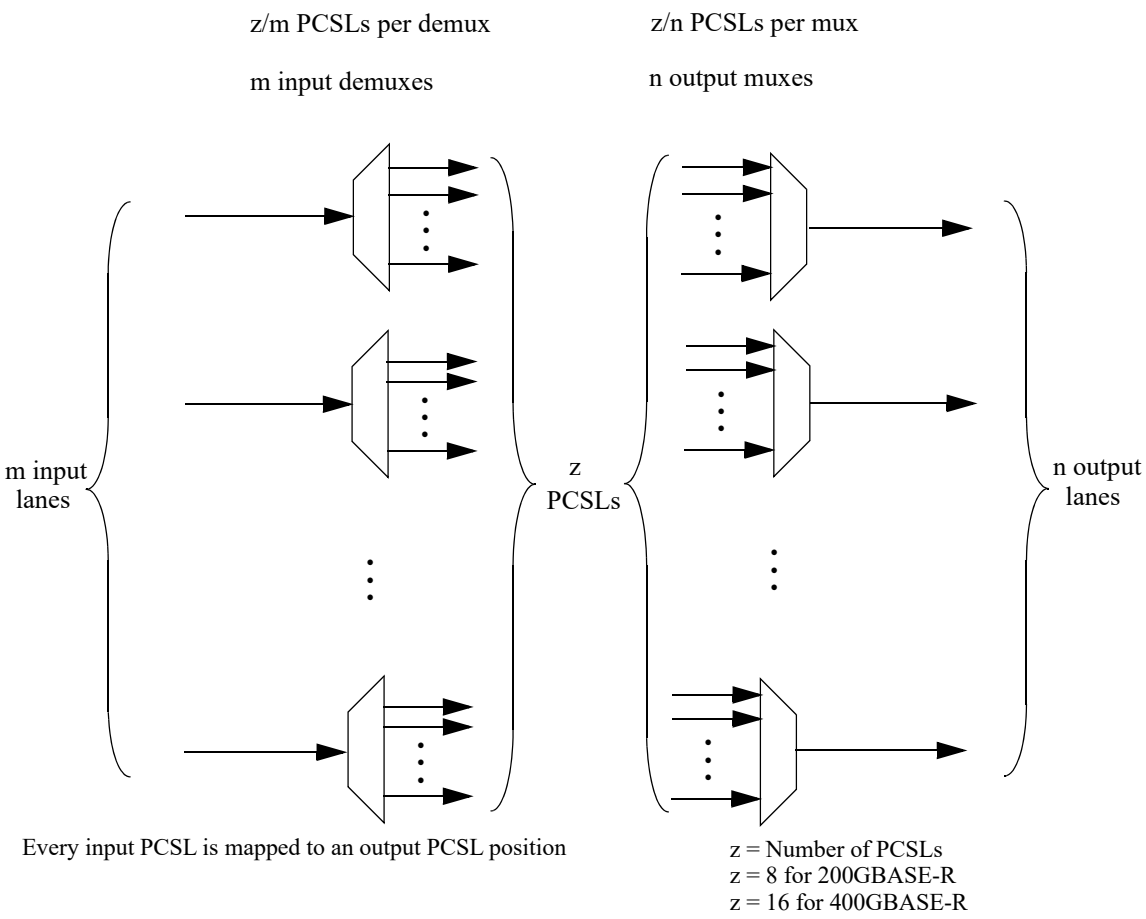

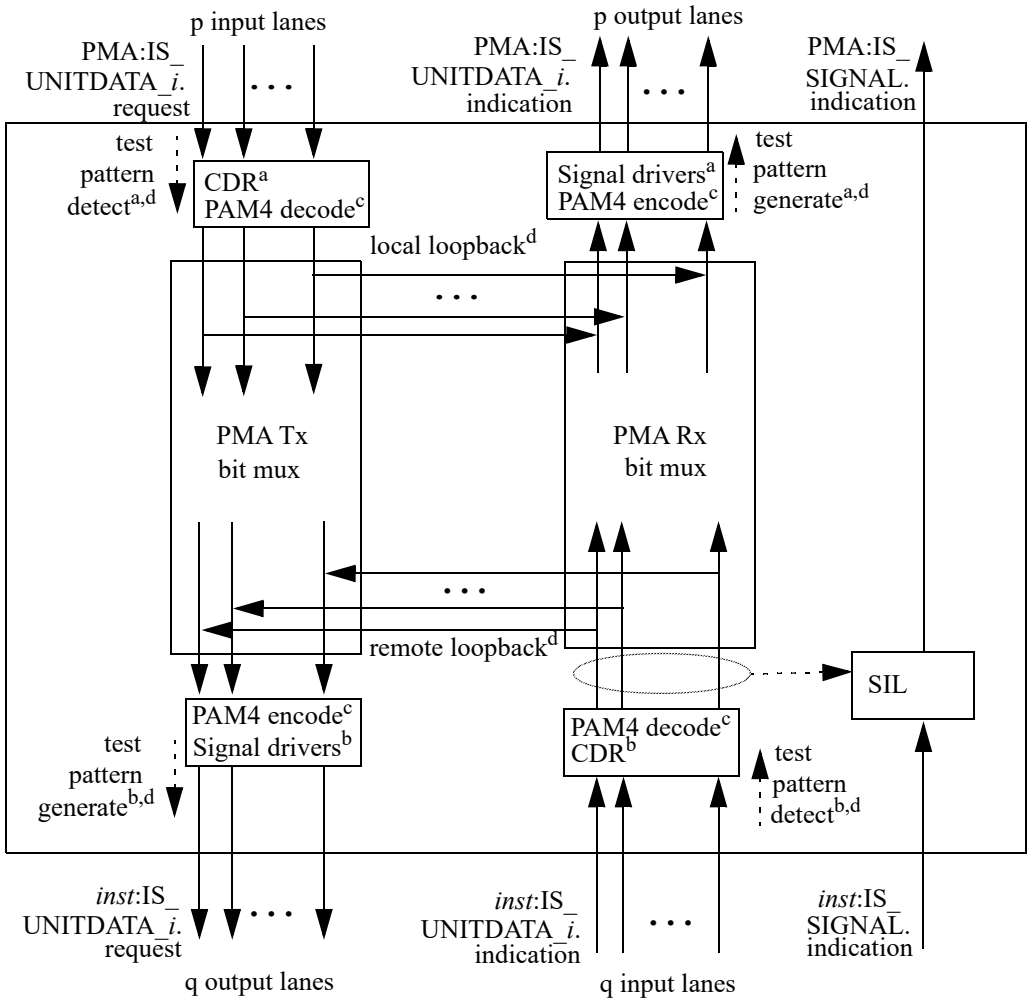

Figure 120–4—PMA bit mux operation used in both Tx and Rx directions

If a PMA client is another PMA, a 200GBASE-R PMA with p=8 or a 400GBASE-R PMA with p=16 physical input lanes receives bits from one PCSL on each of its input lanes. A 200GBASE-R PMA with p=4 physical input lanes receives PAM4 symbols on each of its input lanes at the PCSL rate, each symbol formed from two bits. A 400GBASE-R PMA with p=4 or p=8 physical input lanes receives PAM4 symbols on each of its input lanes at 8/p times the PCSL rate, each symbol formed from two bits. The bit stream represented by the input symbols carries z/p bit-multiplexed PCSLs on each physical input lane, where z=8 for 200GBASE-R and z=16 for 400GBASE-R. Skew may exist between different PCSLs received on the same physical input lane even though all PCSLs originate from the same synchronous source, so there is independence of arrival of bits from each PCSL on each physical input lane.

In the Tx direction, if the symbol from a PMA:IS_UNITDATA_*i*.request primitive is received over a physically instantiated interface (200GAUI-n or 400GAUI-n), clock and data are recovered on the lane receiving the symbol. If necessary, PAM4 symbols are converted to pairs of bits. Bits are routed through the PMA to an output lane through a process that may demultiplex PCSLs from the input, perform any necessary buffering to tolerate Skew Variation across input lanes, and multiplex PCSLs to output lanes. If necessary, pairs of bits on output lanes are converted to PAM4 symbols. The symbols are sent on an output lane to the sublayer below using the *inst*:IS_UNITDATA_*k*.request (*k* not necessarily equal to *i*) primitive (see 120.4).

inst PMD, PMA, or PHY_XS, depending on which sublayer is below this PMA
SIL Signal Indication Logic

[a] If physically instantiated interface (200GAUI-n or 400GAUI-n) immediately above this PMA.
[b] If physically instantiated interface (200GAUI-n or 400GAUI-n) immediately below this PMA, or if this is the closest PMA to the PMD.
[c] If number of input or output lanes is 4 for a 200GBASE-R PMA, or 4 or 8 for a 400GBASE-R PMA.
[d] Optional.

Figure 120–5—PMA Functional Block Diagram

The PMA passes symbols from the input lanes to the output lanes in the Rx direction when data is being received from every input lane from the sublayer below the PMA that has a PCSL that is routed to a particular output lane at the PMA service interface, and (if necessary), buffers are filled to allow tolerating the Skew Variation that may appear between the input lanes. PCSLs are demultiplexed from the input lanes, remultiplexed to the output lanes, and symbols are transferred over each output lane to the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive. If necessary, PAM4 symbols are converted to pairs of bits on the input lanes and/or pairs of bits are converted to PAM4 symbols on the output lanes.

The PMA:IS_SIGNAL.indication primitive is generated through a set of Signal Indication Logic (SIL) that reports signal health based on receipt of the *inst*:IS_SIGNAL.indication from the sublayer below, data being received on all of the input lanes from the sublayer below, buffers filled (if necessary) to accommodate Skew Variation, and symbols being sent to the PMA client on all of the output lanes. When these conditions

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

are met, the SIGNAL_OK parameter sent to the PMA client via the PMA:IS_SIGNAL.indication primitive has the value OK. Otherwise, the SIGNAL_OK primitive has the value FAIL. In the case where the sublayer below the PMA is a PHY XS the PMA does not receive a PHY_XS:IS_SIGNAL.indication as an input to the SIL.

120.4 Service interface below PMA

Since the architecture supports multiple PMA sublayers for various PMD lane counts and device partitioning, there are several different sublayers that may appear below a PMA, including the PMD, an extender sublayer, or another PMA. The variable *inst* represents whichever sublayer appears below the PMA (e.g., another PMA or PMD).

The sublayer below the PMA utilizes the inter-sublayer service interface defined in 116.3. The service interface primitives provided to the PMA are summarized as follows:

inst:IS_UNITDATA_*i*.request(tx_symbol)
inst:IS_UNITDATA_*i*.indication(rx_symbol)
inst:IS_SIGNAL.indication(SIGNAL_OK)

The number of lanes q for the service interface matches the number of lanes expected by the PMA. The *inst*:IS_UNITDATA_*i* primitives are defined for each lane $i = 0$ to $q - 1$ of the service interface below the PMA. Note that electrical and timing specifications of the service interface are defined if the interface is physically instantiated (e.g., 200GAUI-n or 400GAUI-n), otherwise the service interface is specified only abstractly. The interface between the PMA and the sublayer below consists of q lanes for data transfer and a status indicating a good signal from the sublayer below the PMA (see Figure 120–5).

The PMA transfers symbols from the input lanes to the output lanes in the Tx direction when data is being received via the PMA:IS_UNITDATA_*i*.request primitive from every input lane from the PMA client at the PMA service interface (see 120.3) that has a PCSL that is routed to this output lane, and (if necessary), buffers are filled to provide the ability to tolerate the Skew Variation that may appear between the input lanes from the PMA client. PCSLs are demultiplexed from the input lanes, remultiplexed to the output lanes, and symbols are transferred over each output lane to the sublayer below the PMA.

In the Rx direction, if the symbol is received over a physically instantiated interface (200GAUI-n, 400GAUI-n, or physically instantiated PMD service interface), clock and data are recovered on the lane receiving the symbol. If necessary, PAM4 symbols received on the input lanes are converted to pairs of bits. The bits are routed through the PMA to an output lane toward the PMA client through a process that may demultiplex PCSLs from the input, perform any necessary buffering to tolerate Skew Variation across input lanes, and multiplex PCSLs to output lanes. If necessary, pairs of bits are converted to PAM4 symbols on the output lanes. Each symbol is sent on an output lane to the PMA client using the PMA:IS_UNITDATA_*k*.indication (*k* not necessarily equal to *i*) primitive at the PMA service interface.

In the case where the sublayer below the PMA is a PHY XS, there is an additional primitive:

PHY_XS:IS_SIGNAL.request(SIGNAL_OK)

The PHY_XS:IS_SIGNAL.request primitive is generated through a set of SIL that reports signal health based on data being received on all of the input lanes from the sublayer above, buffers filled (if necessary) to accommodate Skew Variation, and symbols being sent to the PHY XS on all of the output lanes. When these conditions are met, the SIGNAL_OK parameter sent to the PHY XS via the PHY_XS:IS_SIGNAL.request primitive has the value OK. Otherwise, the SIGNAL_OK primitive has the value FAIL.

120.5 Functions within the PMA

The purpose of the PMA is to adapt the PCSL formatted signal to an appropriate number of abstract or physical lanes, to recover clock from the received signal (if appropriate), and optionally to provide test signals and loopback. Each input (Tx direction) or output (Rx direction) lane between the PMA and the PMA client carries one or more PCSLs that are bit-multiplexed. All input and output lanes between the PMA and the PMA client carry the same number of PCSLs and operate at the same nominal signaling rate. Likewise, each input (Rx direction) or output (Tx direction) lane between the PMA and the sublayer below the PMA carries one or more PCSLs that are bit-multiplexed. All input and output lanes between the PMA and the sublayer below the PMA carry the same number of PCSLs and operate at the same nominal signaling rate. As described in 120.1.4, the number of input lanes and the number of output lanes for a given PMA are divisors of 8 for 200GBASE-R, or 16 for 400GBASE-R, which are the number of PCSLs for the respective PHYs. The symbols received from input lanes or sent on output lanes are bits for 200GBASE-R interfaces where the number of lanes is 8, or 400GBASE-R interfaces where the number of lanes is 16. The symbols received from input lanes or sent on output lanes are PAM4 symbols for 200GBASE-R interfaces where the number of lanes is 4, or 400GBASE-R interfaces where the number of lanes is 8 or 4.

120.5.1 Per input-lane clock and data recovery

If the interface between the PMA client and the PMA is physically instantiated as 200GAUI-n or 400GAUI-n, the PMA shall meet the electrical and timing specifications in Annex 120B, Annex 120C, Annex 120D, or Annex 120E as appropriate. If the interface between the sublayer below the PMA and the PMA is physically instantiated as 200GAUI-n or 400GAUI-n, the PMA shall meet the electrical and timing specifications at the service interface below the PMA as specified in Annex 120B, Annex 120C, Annex 120D, or Annex 120E as appropriate.

Test patterns that are intended for transmitter testing, such as square wave, may not be correctly recovered by an adjacent PMA.

120.5.2 Bit-level multiplexing

The PMA provides bit-level multiplexing in both the Tx and Rx directions. In the Tx direction, the function is performed among the bits received from the PMA client via the PMA:IS_UNITDATA_*i*.request primitives (for PMA client lanes $i = 0$ to $p - 1$) with the result sent to the service interface below the PMA using the *inst*:IS_UNITDATA_*i*.request primitives (for service interface lanes $i = 0$ to $q - 1$), referencing the functional block diagram shown in Figure 120–5. The bit multiplexing behavior is illustrated in Figure 120–4.

The aggregate signal carried by the group of input lanes or the group of output lanes is arranged as a set of PCSLs. The number of PCSLs z is 8 for 200GBASE-R interfaces and 16 for 400GBASE-R interfaces. The nominal bit rate R of each PCSL is 26.5625 Gb/s.

For a PMA with m input lanes (Tx or Rx direction), each input lane carries, bit multiplexed, z/m PCSLs. Each input lane has a nominal bit rate of 26.5625 × z/m Gb/s. Note that the signaling (Baud) rate is equal to the bit rate when the number of physical lanes is 8 for 200GBASE-R or 16 for 400GBASE-R (bits are sent or received on the lanes). The Baud rate is equal to half of the bit rate when the number of physical lanes is 4 for 200GBASE-R or the number of physical lanes is 8 or 4 for 400GBASE-R (PAM4 symbols are sent or received on the lanes). If necessary, PAM4 symbols are converted to pairs of bits on the input lanes and/or pairs of bits are converted to PAM4 symbols on the output lanes. If bit x received on an input lane belongs to a particular PCSL, the next bit of that same PCSL is received on the same input lane at bit position $x+(z/m)$. The z/m PCSLs may arrive in any sequence on a given input lane.

For a PMA with n output lanes (Tx or Rx direction), each output lane carries, bit multiplexed, z/n PCSLs. Each output lane has a nominal signaling rate of 26.5625 × z/n Gb/s. Each PCSL is mapped from a position

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

in the sequence on one of the m input lanes to a position in the sequence on one of the n output lanes. If bit *x* sent on an output lane belongs to a particular PCSL, the next bit of that same PCSL is sent on the same output lane at bit position *x* + (z/n). The PMA shall maintain the chosen sequence of PCSLs on all output lanes while it is receiving a valid stream of bits on all input lanes.

Each PCSL received in any temporal position on an input lane is transferred into a temporal position on an output lane. As the PCS (see Clause 119) has fully flexible receive logic, an implementation is free to perform the mapping of PCSLs from input lanes to output lanes without constraint. Figure 120–6 illustrates one possible bit ordering for a 400GBASE-R 8:4 PMA bit mux. Other bit orderings are also valid.

Note that since the number of input lanes and output lanes for a 200GBASE-R or 400GBASE-R PMA is always a power of two, many PMAs converting between different numbers of lanes normally simply multiplex two or four input lanes to one output lane, or demultiplex two or four output lanes from one input lane. However, any PMA implementation which produces an allowable order of bits from all PCSLs on the output lanes is valid.

NOTE—PMA output lanes composed of some specific combinations of four PCSLs with specific skew offsets (e.g., 400GBASE-R PCSLs 0, 2, 4, and 10 with delays 0, 1, 0, and 2 bits, respectively) may have reduced transition density.

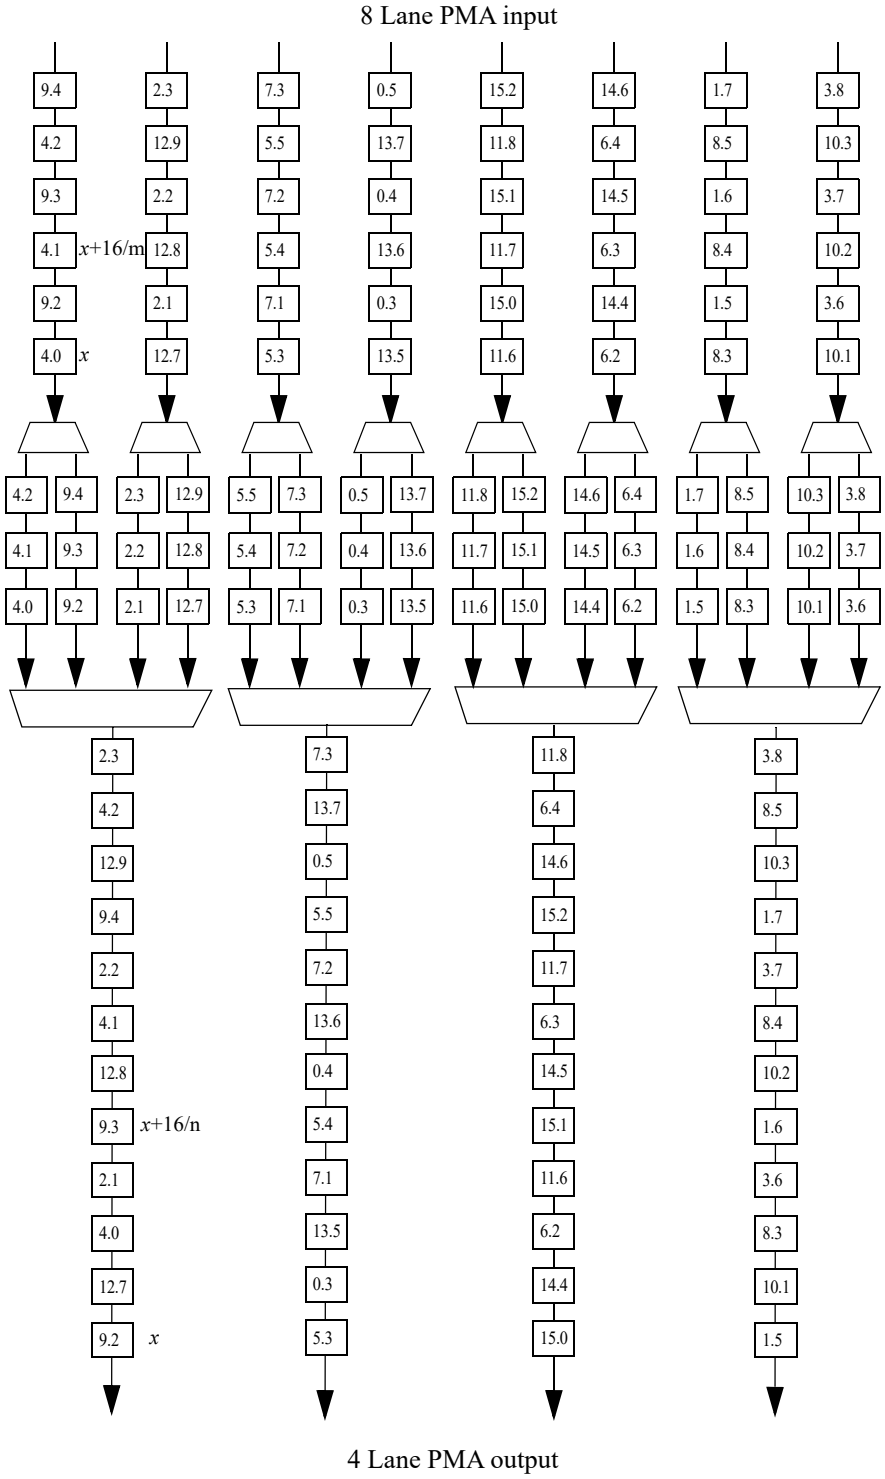
120.5.3 Skew and Skew Variation

The Skew (relative delay) between the PCSLs is kept within limits so that the information on the lanes can be reassembled by the PCS.

Any PMA that combines PCSLs from different input lanes onto the same output lane is required to tolerate Skew Variation between the input lanes without changing the PCSL positions on the output. Skew and Skew Variation are defined in 116.5. The limits for Skew and Skew Variation at physically instantiated interfaces are specified at Skew points SP1 and SP2 in the transmit direction and SP5 and SP6 in the receive direction as defined in 116.5 and illustrated in Figure 116–4 and Figure 116–5.

120.5.3.1 Skew generation toward SP1

In an implementation with one or more physically instantiated 200GAUI-n or 400GAUI-n interfaces, the PMA that sends data in the transmit direction toward the 200GAUI-n or 400GAUI-n that is closest to the PMD (SP1 in Figure 116–4 and Figure 116–5) shall produce no more than 29 ns of Skew between PCSLs toward the 200GAUI-n or 400GAUI-n, and no more than 200 ps of Skew Variation.



120.5.3.2 Skew tolerance at SP1

In an implementation with one or more physically instantiated 200GAUI-n or 400GAUI-n interfaces, the PMA service interface that receives data in the transmit direction from the 200GAUI-n or 400GAUI-n (SP1 in Figure 116–4 and Figure 116–5) shall tolerate the maximum amount of Skew Variation allowed at SP1 (200 ps) between input lanes while maintaining the bit ordering and position of each PCSL on each PMA lane in the transmit direction (toward the PMD).

120.5.3.3 Skew generation toward SP2

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, the PMA adjacent to the PMD service interface shall generate no more than 43 ns of Skew, and no more than 400 ps of Skew Variation between output lanes toward the PMD service interface (SP2 in Figure 116–4 and Figure 116–5). If there is a physically instantiated 200GAUI-n or 400GAUI-n as well, then the Skew measured at SP1 is limited to no more than 29 ns of Skew and no more than 200 ps of Skew Variation.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

120.5.3.4 Skew tolerance at SP5

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, the PMA adjacent to the PMD service interface (SP5) shall tolerate the maximum amount of Skew Variation allowed at SP5 (3.6 ns) between output lanes from the PMD service interface while maintaining the bit ordering and position of each PCSL on each PMA lane in the receive direction (toward the MAC).

120.5.3.5 Skew generation at SP6

In an implementation with one or more physically instantiated 200GAUI-n or 400GAUI-n interfaces, at SP6 (the receive direction of the 200GAUI-n or 400GAUI-n closest to the PCS), the PMA or group of PMAs between the PMD and the 200GAUI-n or 400GAUI-n closest to the PCS shall deliver no more than 160 ns of Skew, and no more than 3.8 ns of Skew Variation between output lanes toward the 200GAUI-n or 400GAUI-n in the Rx direction.

If there is a physically instantiated PMD service interface that allows the Skew to be measured, the Skew measured at SP5 is limited to no more than 145 ns of Skew and no more than 3.6 ns of Skew Variation. If there is no physically instantiated PMD service interface, the Skew measured at SP4 is limited to no more than 134 ns of Skew, and no more than 3.4 ns of Skew Variation.

120.5.3.6 Skew tolerance at SP6

In an implementation with one or more physically instantiated 200GAUI-n or 400GAUI-n interfaces, the PMA between the 200GAUI-n or 400GAUI-n closest to the PCS and the PCS shall tolerate the maximum amount of Skew Variation allowed at SP6 (3.8 ns) between input lanes while maintaining the bit order and position of PCSLs on lanes sent in the receive direction towards the MAC.

120.5.4 Delay constraints

The maximum cumulative delay contributed by up to four PMA stages in a PHY (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 120–1. A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 116.4 and its references.

Table 120–1—Delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
200GBASE-R PMA	18 432	36	92.16
400GBASE-R PMA	36 864	72	92.16

120.5.5 Clocking architecture

A PMA with m input lanes and n output lanes shall clock the output lanes such that the bit rate of the output lanes is m/n times the bit rate of the input lanes. For input or output lanes encoded as PAM4 (for 200GBASE-R, where the number of input or output lanes is 4, or for 400GBASE-R, where the number of input or output lanes is 4 or 8), the symbol rate is half of the bit rate. This applies in both the Tx and Rx directions of transmission. In the case where the interfaces between the PMA client and the PMA and/or the PMA and the sublayer below the PMA are physically instantiated, the PMA may derive its input clock(s)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

from the electrical interface on one or more of the input lanes, and generate the output clock(s) with an appropriate PLL multiplier/divider circuit.

NOTE—For a PMA where the signaling rate on each output lane is higher than the signaling rate on each input lane, any low frequency jitter on the input lanes may result in more jitter relative to the UI on the output lanes.

There is no requirement that the PMA clock all output lanes in unison. Examples of independent clocking of output lanes include the following:

— The case where the number of input and output lanes are equal (the PMA is provided for retiming and regeneration of the signal). This may be implemented without any rearrangement of PCSLs between input lanes and output lanes (although rearrangements are allowed), and such a PMA may be implemented by driving each output lane using the clock recovered from the corresponding input lane.
— Since the number of PCSLs is a power of 2, whenever the number of input and output lanes are unequal, each input lane could be mapped to multiple output lanes (in the case where the number of output lanes is greater), or multiple input lanes could be mapped to a single output lane.

120.5.6 Signal drivers

For cases where the interface between the PMA client and the PMA, or between the PMA and the sublayer below the PMA represent a physically instantiated interface, the PMA provides electrical signal drivers for that interface. The electrical and jitter/timing specifications for these interfaces appear in

— Annex 120B, which specifies the 200GAUI-8 and 400GAUI-16 interfaces for chip-to-chip applications.
— Annex 120C, which specifies the 200GAUI-8 and 400GAUI-16 interfaces for chip-to-module applications.
— Annex 120D, which specifies the 200GAUI-4 and 400GAUI-8 interfaces for chip-to-chip applications.
— Annex 120E, which specifies the 200GAUI-4 and 400GAUI-8 interfaces for chip-to-module applications.

For 200GAUI-8 or 400GAUI-16, the modulation format is NRZ. For 200GAUI-4 or 400GAUI-8, the modulation format is PAM4.

120.5.7 PAM4 Encoding

120.5.7.1 Gray mapping for PAM4 encoded lanes

For output lanes encoded as PAM4 (for 200GBASE-R, where the number of output lanes is 4, or for 400GBASE-R, where the number of output lanes is 4 or 8), the PMA transmit process shall map consecutive pairs of bits {A, B}, where A is the bit arriving first, to a Gray-coded symbol as follows:

{0, 0} maps to 0,
{0, 1} maps to 1,
{1, 1} maps to 2, and
{1, 0} maps to 3.

For input lanes encoded as PAM4 (for 200GBASE-R, where the number of input lanes 4, or for 400GBASE-R, where the number of input lanes is 4 or 8), the PMA receive process shall map Gray-coded PAM4 symbols to pairs of bits {A, B} where A is considered to be the first bit as follows:

0 maps to {0, 0},
1 maps to {0, 1},

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

2 maps to {1, 1}, and
3 maps to {1, 0}.

120.5.7.2 Precoding for PAM4 encoded lanes

The precoding specifications in this subclause apply to the input and output lanes of a PMA that are connected to the service interface of a 200GBASE-R PMD that includes the PMD control function defined in 136.8.11 (200GBASE-CR4 or 200GBASE-KR4).

The PMA shall provide 1/(1+D) mod 4 precoding capability on each transmit lane and may optionally provide 1/(1+D) mod 4 decoding capability on each receive lane. Precoding is implemented as specified in 135.5.7.2.

The precoder is enabled independently on the Tx output (toward the PMD) and the Rx input (from the PMD) on each lane (0, 1, 2, and 3). Precoding is enabled and disabled using variables precoder_tx_out_enable_*i* and precoder_rx_in_enable_*i* (where *i* is 0, 1, 2, or 3).

If a Clause 45 MDIO is implemented, the variables precoder_tx_out_enable_*i* and precoder_rx_in_enable_*i* are accessible through register 1.600 and 1.601 (see 45.2.1.139 and 45.2.1.140).

If the PMA is connected to the service interface of a PMD that includes the PMD control function and training is enabled by the management variable mr_training_enable (see 136.7), then precoder_tx_out_enable_*i* and precoder_rx_in_enable_*i* shall be set as determined by the PMD control function in the LINK_READY state on lane *i* (see 136.8.11.7.5 and Figure 136–7). The method by which the PMD control function affects these variables is implementation dependent.

If the PMA is connected to the service interface of a PMD that includes the PMD control function and training is disabled by the management variable mr_training_enable, then precoder_tx_out_enable_*i*, precoder_rx_in_enable_*i*, precoder_tx_in_enable_*i*, and precoder_rx_out_enable_*i* are set as required by the implementation.

120.5.8 Link status

The PMA shall provide link status information to the PMA client using the PMA:IS_SIGNAL.indication primitive. The PMA continuously monitors the link status reported by the service interface below from the *inst*:IS_SIGNAL.indication primitive, and uses this as input to Signal Indication Logic (SIL) to determine the link status to report to the layer above. Other inputs to the SIL may include the status of clock and data recovery on the lanes from the service interface below the PMA and whether buffers/FIFOs have reached the required fill level to accommodate Skew Variation so that data is being sent on the output lanes.

120.5.9 PMA local loopback mode (optional)

PMA local loopback mode is optional. If it is implemented, it shall be as described in this subclause (120.5.9).

The PMA sublayer may provide a local loopback function. The function involves looping back each input lane to the corresponding output lane. Each bit received from the PMA:IS_UNITDATA_*i*.request(tx_symbol) primitive is looped back in the direction of the MAC using the PMA:IS_UNITDATA_*i*.indication(rx_symbol) primitive.

During local loopback, the PMA performs normal bit muxing of PCSLs per 120.5.2 onto the lanes in the Tx direction toward the service interface below the PMA.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Ability to perform this function is indicated by the Local_loopback_ability status variable. If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.8.0 (45.2.1.7.15). A device is placed in local loopback mode when the Local_loopback_enable control variable is set to one, and removed from local loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD control 1 register (bit 1.0.0, see 45.2.1.1.5).

120.5.10 PMA remote loopback mode (optional)

PMA remote loopback mode is optional. If implemented, it shall be as described in this subclause (120.5.10).

Remote loopback, if provided, should be implemented in a PMA sublayer close enough to the PMD to maintain the bit sequence on each individual PMD lane. When remote loopback is enabled, each symbol received over a lane of the service interface below the PMA via *inst*:IS_UNITDATA_*i*.indication is looped back to the corresponding output lane toward the PMD via *inst*:IS_UNITDATA_*i*.request. Note that the service interface below the PMA can be provided by the PHY XS, PMD, or another PMA sublayer.

During remote loopback, the PMA performs normal bit muxing of PCSLs per 120.5.2 onto the lanes in the Rx direction towards the PMA client.

The ability to perform this function is indicated by the 200G_Remote_loopback_ability and 400G_Remote_loopback_ability status variables for the 200GBASE-R PMA and 400GBASE-R PMA, respectively. If a Clause 45 MDIO is implemented, the 200G_Remote_loopback_ability and 400G_Remote_loopback_ability variables are accessible through bit 1.23.15 (45.2.1.21.1) and bit 1.24.15 (45.2.1.22.1), respectively. A device is placed in remote loopback mode when the Remote_loopback_enable control variable is set to one, and removed from remote loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD Control register 1 (bit 1.0.1, see 45.2.1.1.4).

120.5.11 PMA test patterns (optional)

Where the output lanes of the PMA appear on a physically instantiated interface 200GAUI-n, 400GAUI-n or the PMD service interface (whether or not it is physically instantiated), the PMA may optionally generate and detect test patterns. These test patterns are used to test adjacent layer interfaces for an individual PMA sublayer or to perform testing between a physically instantiated interface of a PMA sublayer and external testing equipment.

120.5.11.1 Test patterns for NRZ encoded signals

For a 200GBASE-R PMA with 8 output lanes or a 400GBASE-R PMA with 16 output lanes using 2-level NRZ encoding, the test patterns in this clause may be supported.

The ability to generate each of the respective test patterns in each direction of transmission are indicated by the PRBS9_Tx_generator_ability, PRBS9_Rx_generator_ability, PRBS31_Tx_generator_ability, PRBS31_Rx_generator_ability, and Square_wave_ability status variables, which if a Clause 45 MDIO is implemented are accessible through bits 1.1500.5, 1.1500.4, 1.1500.3, 1.1500.1, and 1.1500.12, respectively (see 45.2.1.169).

120.5.11.1.1 PRBS31 test pattern

The ability to check PRBS31 test patterns in each direction of transmission are indicated by the PRBS31_Tx_checker_ability and PRBS31_Rx_checker_ability status variables, which, if a Clause 45 MDIO is implemented, are accessible through bits 1.1500.2 and 1.1500.0, respectively (see 45.2.1.169).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If supported, when send Tx PRBS31 test pattern is enabled by the PRBS31_enable and PRBS_Tx_gen_enable control variables, the PMA shall generate a PRBS31 pattern (as defined in 49.2.8) on each of the lanes toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. To avoid correlated crosstalk, it is highly recommended that the PRBS31 patterns generated on each lane be generated from independent, random seeds or at a minimum offset of 20 000 UI between the PRBS31 sequence on any lane and any other lane. When send Tx PRBS31 test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Tx_gen_enable control variables are accessible through bits 1.1501.7 and 1.1501.3 (see 45.2.1.170).

If supported, when send Rx PRBS31 test pattern is enabled by the PRBS31_enable and PRBS_Rx_gen_enable control variables, the PMA shall generate a PRBS31 pattern on each of the lanes toward the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive. While this test pattern is enabled, the PMA also generates PMA:IS_SIGNAL.indication(SIGNAL_OK) toward the PMA client independent of the link status at the service interface below the PMA. When send Rx PRBS31 test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Rx_gen_enable control variables are accessible through bits 1.1501.7 and 1.1501.1 (see 45.2.1.170).

If supported, when check Tx PRBS31 test pattern mode is enabled by the PRBS31_enable and PRBS_Tx_check_enable control variables, the PMA shall check for the PRBS31 pattern on each of the lanes received from the PMA client via the PMA:IS_UNITDATA_*i*.request primitive. The checker shall increment the test-pattern error counter by one for each incoming bit error in the PRBS31 pattern for isolated single bit errors. Implementations should be capable of counting at least one error whenever one or more errors occur in a sliding 1000-bit window. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Tx_check_enable control variables are accessible through bits 1.1501.7 and 1.1501.2 (see 45.2.1.170). The Tx test-pattern error counters Ln0_PRBS_Tx_test_err_counter through Ln15_PRBS_Tx_test_err_counter count, per lane, errors in detecting the PRBS31 pattern on the lanes from the PMA client. If a Clause 45 MDIO is implemented, these counters are accessible through registers 1.1600 through 1.16015 (see 45.2.1.173). When check Tx PRBS31 test pattern is disabled, the PMA expects normal traffic and test-pattern error counting does not continue. While in check Tx PRBS31 test-pattern mode, bit multiplexing continues as described in 120.5.2. Note that bit multiplexing of per-lane PRBS31 may produce a signal which is not meaningful for downstream sublayers.

If supported, when check Rx PRBS31 test-pattern mode is enabled by the PRBS31_enable and PRBS_Rx_check_enable control variables, the PMA shall check for the PRBS31 pattern on each of the lanes received from the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.indication primitive. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Rx_check_enable control variables are accessible through bits 1.1501.7 and 1.1501.0 (see 45.2.1.170). The Rx test-pattern error counters Ln0_PRBS_Rx_test_err_counter through Ln15_PRBS_Rx_test_err_counter count, per lane, errors in detecting the PRBS31 pattern on the lanes from the service interface below the PMA. If a Clause 45 MDIO is implemented, these counters are accessible through registers 1.1700 through 1.1715 (see 45.2.1.174). While in check Rx PRBS31 test-pattern mode, the PMA:IS_SIGNAL.indication primitive does not indicate a valid signal. When check Rx PRBS31 test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2.

120.5.11.1.2 PRBS9 test pattern

If supported, when send Tx PRBS9 test-pattern mode is enabled by the PRBS9_enable and Tx_gen_enable control variables, the PMA shall generate a PRBS9 pattern (as defined in Table 68–6) on each lane toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. If a Clause 45 MDIO is implemented, the PRBS9_enable and Tx_gen_enable control variables are accessible through bits 1.1501.6 and 1.1501.3 (see 45.2.1.170). When send Tx PRBS9 test-pattern mode is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If supported, when send Rx PRBS9 test-pattern mode is enabled by the PRBS9_enable and Rx_gen_enable control variables, the PMA shall generate a PRBS9 pattern on each lane toward the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive. The PMA also generates PMA:IS_SIGNAL.indication(SIGNAL_OK) toward the PMA client independent of the link status at the service interface below the PMA. If a Clause 45 MDIO is implemented, the PRBS9_enable and Rx_gen_enable control variables are accessible through bits 1.1501.6 and 1.1501.1 (see 45.2.1.170). When send Rx PRBS9 test-pattern mode is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2.

Note that PRBS9 is intended to be checked by external test gear, and no PRBS9 checking function is provided within the PMA.

120.5.11.1.3 Square wave test pattern

Transmit square wave test-pattern mode optionally applies to each lane of the Tx direction PMA towards a physically instantiated 200GAUI-8, 400GAUI-16 or towards an NRZ PMD service interface whether or not it is physically instantiated. The ability to perform this function is indicated by the Square_wave_ability status variable. If a Clause 45 MDIO is implemented, the Square_wave_ability status variable is accessible through the Square wave test ability bit 1.1500.12 (see 45.2.1.169). If implemented, the transmit square wave test-pattern mode is enabled by control variables Square_wave_enable_0 through Square_wave_enable_15. If a Clause 45 MDIO is implemented, these control variables are accessible through the square wave testing control and status register bits 1.1510.0 through 1.1510.15 (limited to the number of lanes of the service interface below the PMA, see 45.2.1.171). When enabled, the PMA shall generate a square wave test pattern (8 ones followed by 8 zeros) on the square wave enabled lanes toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. Lanes for which square wave is not enabled transmit normal data resulting from the bit multiplexing operations described in 120.5.2 or test patterns as determined by other registers. When transmit square wave test pattern is disabled for all lanes, the PMA performs normal operation performing bit multiplexing as described in 120.5.2 or transmit test patterns as determined by other registers.

120.5.11.2 Test patterns for PAM4 encoded signals

For a 200GBASE-R PMA with 4 output lanes or a 400GBASE-R PMA with 4 or 8 output lanes using PAM4 encoding, the test patterns described in this clause may optionally be supported.

The patterns PRBS13Q and square wave (quaternary) can be enabled on a lane-by-lane basis. The patterns PRBS31Q and SSPRQ can be enabled on all lanes of an interface at once. If per-lane pattern(s) are enabled for a subset of the lanes and a per-interface pattern is also enabled, the per-lane patterns are generated only on the indicated lanes and the per-interface pattern is generated on the remaining lanes. The behavior if more than one per-lane pattern is enabled for the same lane or more than one per-interface pattern is enabled is not defined.

120.5.11.2.1 PRBS13Q test pattern

A PMA may optionally include a PRBS13Q pattern generator as specified in this subclause. The ability to perform this function is indicated by the PRBS13Q_gen_Tx_ability and PRBS13Q_gen_Rx_ability status variables, reflecting the ability to send this test pattern in the direction towards the PMD and towards the MAC, respectively. If a Clause 45 MDIO is implemented, the PRBS13Q_gen_Tx_ability and PRBS13Q_gen_Rx_ability status variables are accessible through the PRBS13Q Tx generator ability and PRBS13Q Rx generator ability bits 1.1500.11 and 1.1500.10 (see 45.2.1.169).

When the PRBS13Q test pattern enabled, it replaces the signal on the output lane(s) for which it is enabled. The PRBS13Q test pattern is a repeating 8191-symbol sequence formed by Gray coding pairs of bits from two repetitions of the PRBS13 pattern into PAM4 symbols as described in 120.5.7.1. The PRBS pattern

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

generator produces the same result as the implementation shown in Figure 94–6, which implements the generator polynomial shown in Equation (94–3). Since the PRBS13 pattern is an odd number of bits in length, bits which are mapped as the first bit of a PAM4 symbol during one repetition of the PRBS13 sequence are mapped as the second bit of a PAM4 symbol during the next repetition of the PRBS13 sequence, and bits which are mapped as the second bit of a PAM4 symbol are mapped as the first bit of the following symbol in the next repetition of the PRBS13 sequence. For example, if the PRBS13 generator used to create the PRBS13Q sequence is initialized to a seed value of 0000010101011 (with the leftmost bit in S0 and the rightmost in S12), the PRBS13Q sequence begins with the following Gray coded PAM4 symbols, transmitted left to right: 10313202201111301031212312100121021210231311 12.

The PRBS13Q test pattern is enabled in the transmit direction by the Tx_gen_enable and PRBS13Q_enable_0 through PRBS13Q_enable_7 control variables (in the downstream direction towards the PMD), and in the receive direction by the Rx_gen_enable and PRBS13Q_enable_0 through PRBS13Q_enable_7 control variables (in the upstream direction towards the MAC). If the optional Clause 45 MDIO is implemented, the Tx_gen_enable and Rx_gen_enable control variables are accessible through the Tx generator enable and Rx generator enable bits 1.1501.3 and 1.1501.1 (see 45.2.1.170), and the PRBS13_enable_0 through PRBS13_enable_7 control variables are accessible through bits 1.1512.0 through 1.1512.7 (see 45.2.1.172).

120.5.11.2.2 PRBS31Q test pattern

A PMA may optionally include a PRBS31Q pattern generator as specified in this subclause. The ability to generate PRBS31Q patterns in each direction of transmission are indicated by the PRBS31Q_gen_Tx_ability and PRBS31Q_gen_Rx_ability status variables, reflecting the ability to send this test pattern in the direction towards the PMD and towards the MAC, respectively. The ability to check PRBS31Q patterns in each direction of transmission are indicated by the PRBS31Q_Tx_checker_ability and PRBS31Q_Rx_checker_ability status variables. If a Clause 45 MDIO is implemented, the PRBS31Q_gen_Tx_ability, PRBS31Q_gen_Rx_ability, PRBS31Q_Tx_checker_ability and PRBS31Q_Rx_checker_ability status variables are accessible through the PRBS31Q Tx generator ability, PRBS31Q Rx generator ability, PRBS31Q Tx checker ability, and PRBS31Q Rx checker ability bits 1.1500.9, 1.1500.7, 1.1500.8, and 1.1500.6 (see 45.2.1.169).

The PRBS31Q test pattern is a repeating 2^{31}–1-symbol sequence formed by Gray coding pairs of bits from two repetitions of the PRBS31 pattern defined in 49.2.8 into PAM4 symbols as described in 120.5.7.1. Since the PRBS31 pattern is an odd number of bits in length, bits that are mapped as the first bit of a PAM4 symbol during one repetition of the PRBS31 sequence are mapped as the second bit of a PAM4 symbol during the next repetition of the PRBS31 sequence, and bits that are mapped as the second bit of a PAM4 symbol during one repetition of the PRBS31 sequence are mapped as the first bit of the following symbol in the next repetition of the PRBS31 sequence. For example, if the PRBS31 generator used to create the PRBS31Q sequence is initialized to a seed value of all ones, the PRBS31Q sequence begins with the following Gray coded PAM4 symbols, transmitted left to right: 22222222222220122222222222200022222222222012012 22. To avoid correlated crosstalk, it is highly recommended that the PRBS31 patterns used to generate the PRBS31Q pattern on each lane are generated from independent, random seeds, or at a minimum offset of 20 000 UI between the PRBS31 sequence used to generate the PRBS31Q pattern on any lane and any other lane. A PRBS31Q pattern checker operates by converting PAM4 symbols received on each input lane to pairs of bits as described in 120.5.7.1 and then using a PRBS31 pattern checker on the resulting bit stream. The checker shall increment the test-pattern error counter by one for each incoming bit error in the PRBS31 pattern for isolated single bit errors. Implementations should be capable of counting at least one error whenever one or more errors occur in a sliding 1000-bit window.

If supported, when send Tx PRBS31Q test pattern is enabled by the PRBS31Q_pattern_enable and PRBS_Tx_gen_enable control variables, the PMA shall generate a PRBS31Q pattern on each of the lanes toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. When send Tx

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PRBS31Q test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2. If a Clause 45 MDIO is implemented, the PRBS31Q_pattern_enable and PRBS_Tx_gen_enable control variables are accessible through bits 1.1501.13 and 1.1501.3 (see 45.2.1.170).

If supported, when send Rx PRBS31Q test pattern is enabled by the PRBS31Q_pattern_enable and PRBS_Rx_gen_enable control variables, the PMA shall generate a PRBS31Q pattern on each of the lanes toward the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive. The PMA also generates PMA:IS_SIGNAL.indication(SIGNAL_OK) toward the PMA client independent of the link status at the service interface below the PMA. If a Clause 45 MDIO is implemented, the PRBS31Q_pattern_enable and PRBS_Rx_gen_enable control variables are accessible through bits 1.1501.13 and 1.1501.1 (see 45.2.1.170). When send Rx PRBS31Q test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2.

If supported, when check Tx PRBS31Q test pattern mode is enabled by the PRBS31Q_pattern_enable and PRBS_Tx_check_enable control variables, the PMA checks for the PRBS31Q pattern on each of the lanes received from the PMA client via the PMA:IS_UNITDATA_*i*.request primitive. If a Clause 45 MDIO is implemented, the PRBS31Q_pattern_enable and PRBS_Tx_check_enable control variables are accessible through bits 1.1501.13 and 1.1501.2 (see 45.2.1.170). The Tx test-pattern error counters Ln0_PRBS_Tx_test_err_counter through either Ln3_PRBS_Tx_test_error_counter or Ln7_PRBS_Tx_test_error_counter (depending on whether the number of lanes is 4 or 8) count, per lane, errors in detecting the PRBS31 pattern resulting from converting the PAM4 symbols received on each lane to pairs of bits. If a Clause 45 MDIO is implemented, these counters are accessible through registers 1.1600 through 1.1603 or 1.1607 (depending on whether the number of lanes is 4 or 8) (see 45.2.1.173). When check Tx PRBS31Q test pattern is disabled, the PMA expects normal traffic and test pattern error counting does not continue. While in check Tx PRBS31Q mode, bit multiplexing continues as described in 120.5.2. Note that bit multiplexing of per-lane PRBS31Q may produce a signal which is not meaningful for downstream sublayers.

If supported, when check Rx PRBS31Q test pattern mode is enabled by the PRBS31Q_pattern_enable and PRBS_Rx_check_enable control variables, the PMA checks for the PRBS31Q pattern on each of the lanes received from the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.indication primitive. If a Clause 45 MDIO is implemented, the PRBS31Q_pattern_enable and PRBS_Rx_check_enable control variables are accessible through bits 1.1501.13 and 1.1501.0 (see 45.2.1.170). The Rx test-pattern error counters Ln0_PRBS_Rx_test_err_counter through either Ln3_PRBS_Rx_test_error_counter or Ln7_PRBS_Rx_test_error_counter (depending on whether the number of lanes is 4 or 8) count, per lane, errors in detecting the PRBS31 pattern resulting from converting the PAM4 symbols received on each lane to pairs of bits. If a Clause 45 MDIO is implemented, these counters are accessible through registers 1.1700 through 1.1703 or 1.1707 (depending on whether the number of lanes is 4 or 8) (see 45.2.1.174). While in check Rx PRBS31Q mode, the PMA:IS_SIGNAL.indication primitive does not indicate a valid signal. When check Rx PRBS31Q test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 120.5.2.

120.5.11.2.3 SSPRQ test pattern

A PMA may optionally include a short stress pattern random quaternary (SSPRQ) test pattern generator as specified in this subclause. The ability to perform this function is indicated by the SSPRQ_gen_Tx_ability status variable, reflecting the ability to send this test pattern in the direction towards the PMD. If a Clause 45 MDIO is implemented, the SSPRQ_gen_Tx_ability status variable is accessible through the SSPRQ Tx generator ability bit 1.1500.13 (see 45.2.1.169).

The SSPRQ pattern is a repeating 2^{16}–1 PAM4 symbol sequence constructed as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Bit sequence A is a 32768-bit sequence composed of three sections of the PRBS31 binary sequence (see 120.5.11.1.1) according to Table 120–2.

Table 120–2—SSPRQ bit sequence A

Pattern	Seed	Length
PRBS31	0x00000002	10924 bits
	0x34013FF7	10922 bits
	0x0CCCCCCC	10922 bits

— Each section of PRBS31 is generated as if produced by the shift register implementation shown in Figure 49–9 and the seed is a 31-bit hexadecimal value used to preset S30 through S0 (S30 is set to the MSB and S0 is set to the LSB) prior to the generation of the PRBS31 sequence for the indicated length of bits.

— Bit sequence B is a 65534-bit sequence formed by removing the first and last binary bit from a sequence consisting of two repetitions of bit sequence A.

— PAM4 sequence 1 is a 16384-symbol sequence formed by Gray coding bit sequence A according to 120.5.7.1.

— PAM4 sequence 2 is a 16384-symbol sequence formed by Gray coding bit sequence A according to 120.5.7.1, and then inverting each PAM4 symbol by replacing each PAM4 symbol *n* with the value 3–*n*.

— PAM4 sequence 3 is a 16383-symbol sequence formed by Gray coding the first 32766 bits of bit-sequence B according to 120.5.7.1.

— PAM4 sequence 4 is a 16384-symbol sequence formed by Gray coding the last 32768 bits of bit-sequence B according to 120.5.7.1, and then inverting each PAM4 symbol by replacing each PAM4 symbol *n* with the value 3–*n*.

— The repeating SSPRQ pattern formed by concatenating PAM4 sequences 1, 2, 3 and 4.

NOTE—A CSV file containing the entire PAM4 symbol sequence for the SSPRQ test pattern is available at https://standards.ieee.org/downloads/802.3/.

If supported, when send SSPRQ test pattern is enabled by the SSPRQ_pattern_enable control variable, the PMA shall generate an SSPRQ pattern on each of its lanes in the Tx direction towards the PMD with at least a 31 UI delay between the SSPRQ pattern on one lane and any other lane. If a Clause 45 MDIO is implemented, the SSPRQ_pattern_enable control variable is accessible through the SSPRQ pattern enable bit 1.1501.14 (see 45.2.1.170).

120.5.11.2.4 Square wave (quaternary) test pattern

Transmit square wave (quaternary) test-pattern mode optionally applies to each lane of the Tx direction PMA towards a physically instantiated 200GAUI-4, 400GAUI-8 or towards a PAM4 PMD service interface whether or not it is physically instantiated.

The ability to perform this function is indicated by the Square_wave_ability status variable. If a Clause 45 MDIO is implemented, the Square_wave_ability status variable is accessible through the Square wave test ability bit 1.1500.12 (see 45.2.1.169). If implemented, the transmit square wave test-pattern mode is enabled by control variables Square_wave_enable_0 through Square_wave_enable_8. If a Clause 45 MDIO is implemented, these control variables are accessible through the square wave testing control and status register bits 1.1510.0 through 1.1510.15 (limited to the number of lanes of the service interface below the PMA, see 45.2.1.171). When enabled, the PMA shall generate a square wave test pattern (8 threes followed

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

by 8 zeros) on the square wave enabled lanes toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. Lanes for which square wave is not enabled transmit normal data resulting from the bit multiplexing operations described in 120.5.2 or test patterns as determined by other registers. When transmit square wave test pattern is disabled for all lanes, the PMA performs normal operation performing bit multiplexing as described in 120.5.2 or transmit test patterns as determined by other registers.

NOTE—A square wave transmitted over a 200GAUI-4 or 400GAUI-8 may not be correctly forwarded to the PMD transmitter output.

120.6 PMA MDIO function mapping

The optional MDIO capability described in Clause 45 describes several variables that provide control and status information for and about the PMA. Since a given implementation may employ more than one PMA sublayer, the PMA control and status information is organized into multiple addressable instances, one for each possible PMA sublayer. See 45.2.1 and 120.1.4 for the allocation of MMD addresses to PMA sublayers. Control and status registers for MMD 8, 9, and 10 use the Extended PMA control and status registers at identical locations to those for MMD 1.

Mapping of MDIO control variables to PMA control variables is shown in Table 120–3. Mapping of MDIO status variables to PMA status variables is shown in Table 120–4. Mapping of MDIO counter to PMA counters is shown in Table 120–5. These tables provide the register and bit numbers for the PMA addressed as MMD 1. For implementations with multiple PMA sublayers, additional PMA sublayers use the corresponding register and bit numbers in MMDs 8, 9, and 10 as necessary.

Table 120–3—MDIO/PMA control variable mapping

MDIO variable	PMA/PMD register name	Register/ bit number	PMA control variable
PMA remote loopback	PMA/PMD control 1	1.0.1	Remote_loopback_enable
PMA local loopback	PMA/PMD control 1	1.0.0	Local_loopback_enable
Lane 0 Tx output precoder enable	PMA precoder control Tx output	1.600.0	precoder_tx_out_enable_0
Lane 1 Tx output precoder enable	PMA precoder control Tx output	1.600.1	precoder_tx_out_enable_1

120.7 Protocol implementation conformance statement (PICS) proforma for Clause 120, Physical Medium Attachment (PMA) sublayer, type 200GBASE-R and 400GBASE-R[207]

120.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 120, Physical Medium Attachment (PMA) sublayer, type 200GBASE-R and 400GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

120.7.2 Identification

120.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

120.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 120, Physical Medium Attachment (PMA) sublayer, type 200GBASE-R and 400GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[207] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

121. Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-DR4

121.1 Overview

This clause specifies the 200GBASE-DR4 PMD together with the single-mode fiber medium. The optical signal generated by this PMD type is modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 121–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 121–1—Physical Layer clauses associated with the 200GBASE-DR4 PMD

Associated clause	200GBASE-DR4
117—RS	Required
117—200GMII[a]	Optional
118—200GMII Extender	Optional
119—PCS	Required
120—PMA	Required
120B—Chip-to-chip 200GAUI-8	Optional
120C—Chip-to-module 200GAUI-8	Optional
120D—Chip-to-chip 200GAUI-4	Optional
120E—Chip-to-module 200GAUI-4	Optional
78—Energy Efficient Ethernet	Optional

[a] The 200GMII is an optional interface. However, if the 200GMII is not implemented, a conforming implementation behaves functionally as though the RS and 200GMII were present.

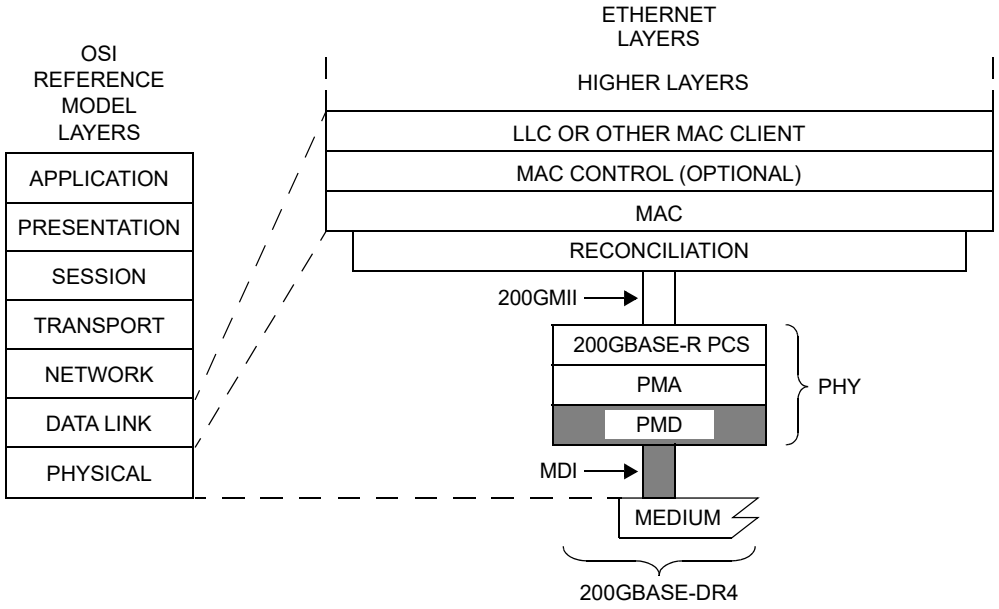

Figure 121–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 200 Gb/s Ethernet is introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

200GBASE-DR4 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

121.1.1 Bit error ratio

The bit error ratio (BER) when processed according to Clause 120 shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when processed according to Clause 120 and then Clause 119. For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
DR = PMD FOR SINGLE-MODE FIBER — 500 m

Figure 121–1—200GBASE-DR4 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

121.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 200GBASE-DR4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 116.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 200GBASE-DR4 PMD has four parallel symbol streams, hence $i = 0$ to 3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the transmit direction, the PMA continuously sends four parallel symbol streams to the PMD, one per lane, each at a nominal signaling rate of 26.5625 GBd. The PMD then converts these streams of data units into the appropriate signals on the MDI.

In the receive direction, the PMD continuously sends four parallel symbol streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service interface primitive defined in 116.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 121.1.1.

121.3 Delay and Skew

121.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 200GBASE-DR4 PMD including 2 m of fiber in one direction shall be no more than 4096 bit times (8 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

121.3.2 Skew constraints

The Skew (relative delay between the lanes) and Skew Variation are kept within limits so that the information on the lanes can be reassembled by the PCS. Skew and Skew Variation are defined in 116.5 and specified at the points SP1 to SP6 shown in Figure 116–4 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 116.5. The measurements of Skew and Skew Variation are defined in 86.8.3.1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

121.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 121–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 121–3.

Table 121–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 3 to PMD transmit disable 0	PMD transmit disable register	1.9.4 to 1.9.1	PMD_transmit_disable_3 to PMD_transmit_disable_0

Table 121–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 3 to PMD receive signal detect 0	PMD receive signal detect register	1.10.4 to 1.10.1	PMD_signal_detect_3 to PMD_signal_detect_0

121.5 PMD functional specifications

The 200GBASE-DR4 PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

121.5.1 PMD block diagram

The PMD block diagram is shown in Figure 121–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 121.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 121.11.3). Unless specified otherwise, all receiver measurements and tests defined in 121.8 are made at TP3.

TP1<0:3> and TP4<0:3> are optional reference points that may be useful to implementors for testing components (these test points will not typically be accessible in an implemented system).

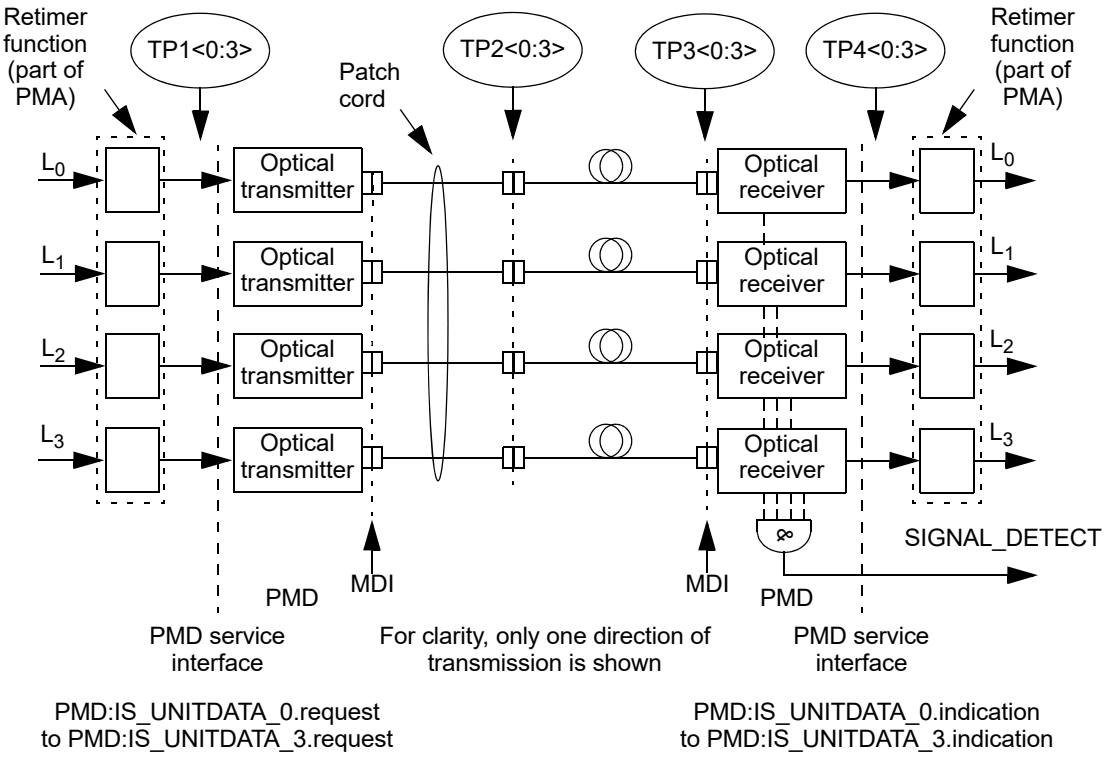

Figure 121–2—Block diagram for 200GBASE-DR4 transmit/receive paths

121.5.2 PMD transmit function

The PMD Transmit function shall convert the four symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate optical signals. The four optical signals shall then be delivered to the MDI, which contains four parallel light paths for transmit, according to the transmit optical specifications in this clause. The highest optical power level in each signal shall correspond to tx_symbol = three and the lowest shall correspond to tx_symbol = zero.

121.5.3 PMD receive function

The PMD Receive function shall convert the four parallel optical signals received from the MDI into separate symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_symbol = three and the lowest shall correspond to rx_symbol = zero.

121.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 116.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all four lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 121–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMD receiver is not required to verify whether a compliant 200GBASE-DR4 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 121–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –16 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) Table 121–7) AND (compliant 200GBASE–R signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

121.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where i represents the lane number in the range 0:3, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 121–4.

121.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

121.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 121–6.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

121.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitters in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 121–6.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane for testing purposes.

121.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

121.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

121.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

121.6 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for 200GBASE-DR4. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the physical ordering of the lanes, as the PCS sublayer is capable of receiving the lanes in any arrangement. The positioning of transmit and receive lanes at the MDI is specified in 121.11.3.1.

121.7 PMD to MDI optical specifications for 200GBASE-DR4

The operating range for the 200GBASE-DR4 PMD is defined in Table 121–5. A 200GBASE-DR4 compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 121–14. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 200GBASE-DR4 PMD operating at 600 m meets the operating range requirement of 2 m to 500 m).

Table 121–5—200GBASE-DR4 operating range

PMD type	Required operating range
200GBASE-DR4	2 m to 500 m

121.7.1 200GBASE-DR4 transmitter optical specifications

The 200GBASE-DR4 transmitter shall meet the specifications defined in Table 121–6 per the definitions in 121.8.

Table 121–6—200GBASE-DR4 transmit characteristics

Description	Value	Unit
Signaling rate, each lane (range)	26.5625 ± 100 ppm	GBd
Modulation format	PAM4	—
Lane wavelength (range)	1304.5 to 1317.5	nm
Side-mode suppression ratio (SMSR), (min)	30	dB
Average launch power, each lane (max)	3	dBm
Average launch power, each lane[a] (min)	–5.1	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	2.8	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min)[b]	–3	dBm
Launch power in OMA_{outer} minus TDECQ, each lane (min)	–4.4	dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	3.2	dB
TDECQ – $10\log_{10}(C_{eq})$[c] (max)	3.2	dB
Average launch power of OFF transmitter, each lane (max)	–16	dBm
Extinction ratio, each lane (min)	3.5	dB
Transmitter transition time (max)	34	ps
$RIN_{21.4}OMA$ (max)	–132	dB/Hz
Optical return loss tolerance (max)	21.4	dB
Transmitter reflectance[d] (max)	–26	dB

[a] Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] Even if the TDECQ < 1.4 dB, the OMA_{outer} (min) has to exceed this value.
[c] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d] Transmitter reflectance is defined looking into the transmitter.

121.7.2 200GBASE-DR4 receive optical specifications

The 200GBASE-DR4 receiver shall meet the specifications defined in Table 121–7 per the definitions in 121.8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 121–7—200GBASE-DR4 receive characteristics

Description	Value	Unit
Signaling rate, each lane (range)	26.5625± 100 ppm	GBd
Modulation format	PAM4	—
Lane wavelengths (range)	1304.5 to 1317.5	nm
Damage threshold[a], each lane	4	dBm
Average receive power, each lane (max)	3	dBm
Average receive power, each lane[b] (min)	–8.1	dBm
Receive power (OMA_{outer}), each lane (max)	2.8	dBm
Receiver reflectance (max)	–26	dB
Receiver sensitivity (OMA_{outer}), each lane[c] (max)	Equation (121–13)	dBm
Stressed receiver sensitivity (OMA_{outer}), each lane[d] (max)	–4.3	dBm
Conditions of stressed receiver sensitivity test:[e]		
Stressed eye closure for PAM4 (SECQ), lane under test	3.2	dB
SECQ – $10\log_{10}(C_{eq})$[f] (max), lane under test	3.2	dB
OMA_{outer} of each aggressor lane	2.8	dBm

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level. The receiver does not have to operate correctly at this input power.
[b] Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity (OMA_{outer}), each lane (max) is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB.
[d] Measured with conformance test signal at TP3 (see 121.8.10) for the BER specified in 121.1.1.
[e] These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.
[f] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.

121.7.3 200GBASE-DR4 illustrative link power budget

An illustrative power budget and penalties for 200GBASE-DR4 channels are shown in Table 121–8.

Table 121–8—200GBASE-DR4 illustrative link power budget

Parameter	Value	Unit
Power budget (for max TDECQ)	6.3	dB
Operating distance	500	m
Channel insertion loss[a]	3	dB
Maximum discrete reflectance	See 121.11.2.2	dB
Allocation for penalties[b] (for max TDECQ)	3.3	dB
Additional insertion loss allowed	0	dB

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

[a] The channel insertion loss is calculated using the maximum distance specified in Table 121–5 and cabled optical fiber attenuation of 0.5 dB/km at 1304.5 nm plus an allocation for connection and splice loss given in 121.11.2.1.
[b] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

121.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

121.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 121–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 121–10 may be used to perform that test. The test patterns used in this clause are shown in Table 121–9.

Table 121–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle	119.2.4.9
6	SSPRQ	120.5.11.2.3

Table 121–10—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 200GBASE-R signal	121.8.2
Side mode suppression ratio	3, 5, 6 or valid 200GBASE-R signal	121.8.2
Average optical power	3, 5, 6 or valid 200GBASE-R signal	121.8.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	121.8.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	121.8.5
Extinction ratio	4 or 6	121.8.6
Transmitter transition time	Square wave or 6	121.8.7
$RIN_{21.4}OMA$	Square wave	121.8.8
Stressed receiver conformance test signal calibration	6	121.8.10.2
Stressed receiver sensitivity	3 or 5	121.8.10

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

121.8.2 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR of each optical lane shall be within the range given in Table 121–6 if measured per IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 121–10.

121.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 121–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern defined in Table 121–10.

121.8.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} of each lane shall be within the limits given in Table 121–6. The OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 121–10 as the difference between the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 121–3.

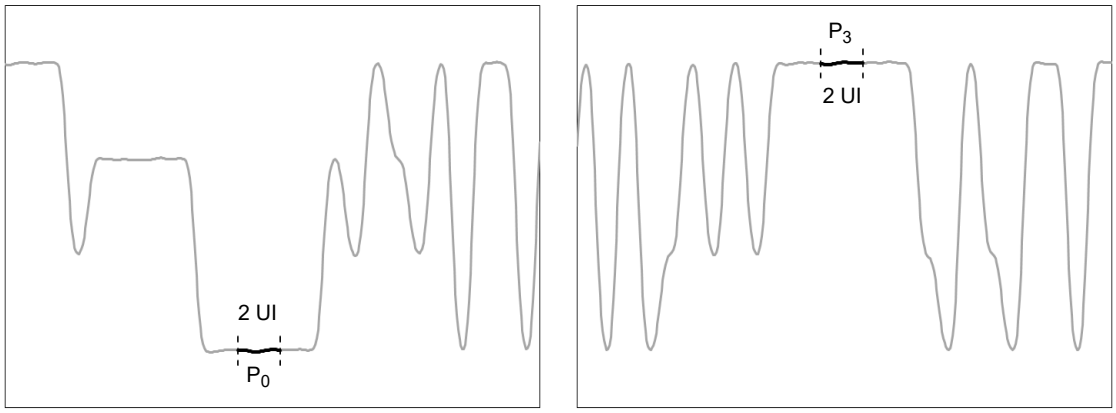

Figure 121–3—Example power levels P_0 and P_3 from PRBS13Q test pattern

121.8.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

The TDECQ and TDECQ – $10\log_{10}(C_{eq})$ of each lane shall be within the limits given in Table 121–6 if measured using the methods specified in 121.8.5.1, 121.8.5.2, and 121.8.5.3.

TDECQ is a measure of each optical transmitter's vertical eye closure when transmitted through a worst case optical channel (specified in 121.8.5.2), as measured through an optical to electrical converter (O/E) and oscilloscope with the combined frequency response given in 121.8.5.1, and equalized with the reference equalizer (as described in 121.8.5.4). The reference receiver and equalizer may be implemented in software or may be part of an oscilloscope.

Table 121–10 specifies the test patterns to be used for measurement of TDECQ.

121.8.5.1 TDECQ conformance test setup

A block diagram for the TDECQ conformance test is shown in Figure 121–4. Other equivalent measurement implementations may be used with suitable calibration.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each optical lane is tested individually with all other lanes in operation and all lanes using the same test pattern. There shall be at least 31 UI delay between the test pattern on one lane and the pattern on any other lane, so that the symbols on each lane are not correlated within the PMD. The optical splitter and variable reflector are adjusted so that each transmitter is tested with the optical return loss specified in Table 121–11. The state of polarization of the back reflection is adjusted to create the greatest RIN. Each optical lane is tested with the optical channel described in 121.8.5.2. The combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz, and at frequencies above 1.5 × 26.5625 GHz, the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The test pattern (specified in Table 121–10) is transmitted repetitively by the optical lane under test and the oscilloscope is set up to capture the complete pattern for TDECQ analysis as described in 121.8.5.3. The clock recovery unit (CRU) has a corner frequency of 4 MHz and a slope of 20 dB/decade. The CRU can be implemented in hardware or software depending on oscilloscope technology.

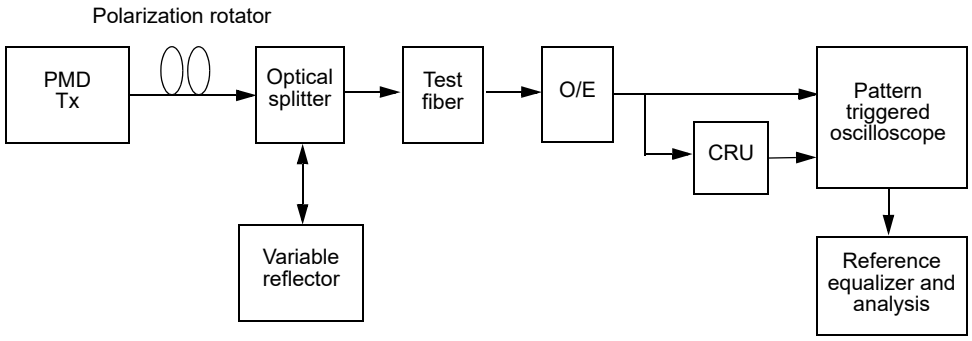

Figure 121–4—TDECQ conformance test block diagram

121.8.5.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 121–11.

Table 121–11—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
200GBASE-DR4	$0.011625\times\lambda\times[1-(1324/\lambda)^4]$	$0.011625\times\lambda\times[1-(1300/\lambda)^4]$	Minimum	21.4 dB	0.5 ps

[a] The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes 500 m for 200GBASE-DR4.
[b] There is no intent to stress the sensitivity of the O/E converter associated with the oscilloscope.
[c] The optical return loss is applied at TP2.

A 200GBASE-DR4 transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 121–11 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 121–11. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 121–11.

121.8.5.3 TDECQ measurement method

The standard deviation of the noise of the O/E and oscilloscope combination, σ_S, is determined with no optical input signal and the same settings as used to capture the histograms described below.

OMA_{outer} is measured according to 121.8.4 on the equalized signal.

The test pattern specified for TDECQ (see Table 121–10) is transmitted repetitively by the optical lane under test and the oscilloscope is set up to capture samples from all symbols in the complete pattern without averaging.

If an equivalent-time sampling oscilloscope is used, the impact of the sampling process and the reference equalizer on transmitter noise has to be compensated for, so that the correct magnitude of noise is present at the output of the equalizer.

The captured waveform is processed to find the largest noise that could be combined with the signal by an ideal reference receiver when optimally equalized by a reference equalizer. The optimal equalizer tap coefficients are dependent on the amount of noise that can be added to the signal, so finding the noise that can be added and the optimal equalizer setting is an iterative process. One way of doing this, using estimated PAM4 symbol error ratio as the figure of merit for the equalized signal, is described below.

The reference equalizer (specified in 121.8.5.4) is applied to the waveform. The sum of the equalizer tap coefficients is equal to 1. An eye diagram is formed from the equalized captured waveform.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The average optical power (P_{ave}) of the equalized eye diagram is determined, and the 0 UI and 1 UI crossing points are determined by the average of the eye diagram crossing times, as measured at P_{ave}, as illustrated in Figure 121–5.

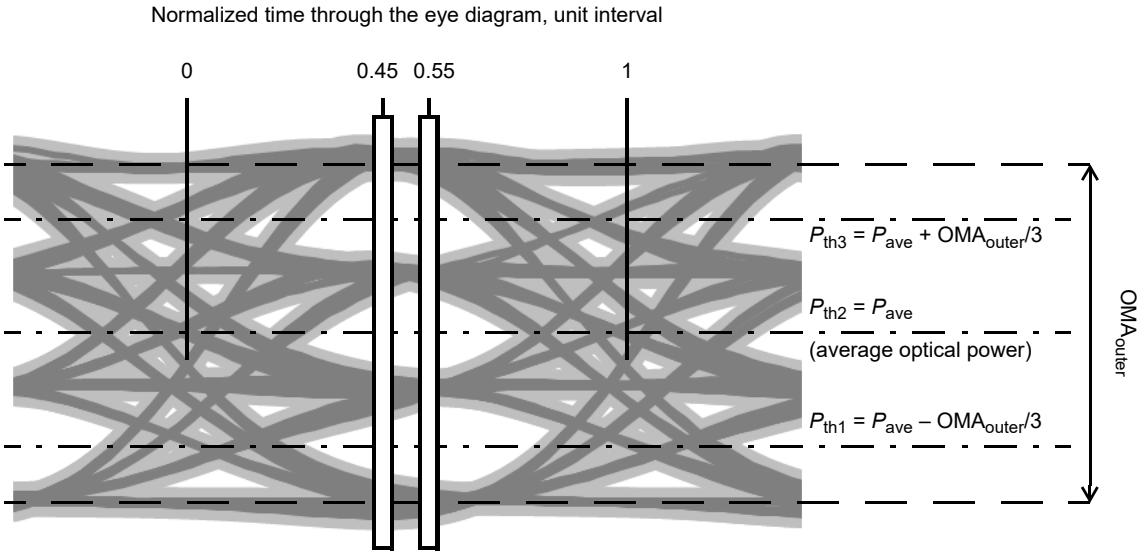

Figure 121–5—Illustration of the TDECQ measurement

Two vertical histograms are measured through the eye diagram, nominally centered at 0.45 UI and 0.55 UI. Each of the histogram windows spans all of the modulation levels of the eye diagram, as illustrated in Figure 121–5. The precise time position of the pair of histograms is adjusted to minimize TDECQ while keeping the histograms spaced 0.1 UI apart.

Each histogram window has a width of 0.04 UI. Each histogram window has outer height boundaries which are set beyond the extremes of the eye diagram (so that no further samples would be captured by increasing the vertical separation of the height boundaries).

The sub-eye threshold levels P_{th1}, P_{th2}, and P_{th3}, are determined from the OMA_{outer} and the average optical power of the eye diagram (P_{ave}) as defined in Equation (121–1), Equation (121–2), and Equation (121–3) and illustrated in Figure 121–5.

$$P_{th1} = P_{ave} - \frac{OMA_{outer}}{3} \quad (121–1)$$

$$P_{th2} = P_{ave} \quad (121–2)$$

$$P_{th3} = P_{ave} + \frac{OMA_{outer}}{3} \quad (121–3)$$

Each captured histogram is processed to, in effect, combine the PAM4 waveform with noise, in order to produce an estimate of the partial PAM4 symbol error ratio (SER) for each sub-eye. One way of doing this is described below.

The left and right histograms are each normalized, and can be represented as a series of equally spaced optical power values (y_i) with separation Δy, each with an associated fraction $F(y_i)$, equal to the number of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

samples captured in that power interval divided by the total number of samples in that histogram. The sum of all $F(y_i)$ for each histogram is equal to 1.

From the left normalized histogram $F(y_i)$, three cumulative probability functions are created, $CF_{L1}(y_i)$, $CF_{L2}(y_i)$, and $CF_{L3}(y_i)$, one around each sub-eye threshold. The right histogram is treated similarly to create three cumulative probability functions $CF_{R1}(y_i)$, $CF_{R2}(y_i)$, and $CF_{R3}(y_i)$. $CF_{L1}(y_i)$ is defined in Equation (121–4).

$$CF_{L1}(y_i) = \begin{cases} \sum_{y=P_{\text{th1}}}^{y_i} F(y) \text{ for } y_i \geq P_{\text{th1}} \\ \sum_{y=y_i}^{P_{\text{th1}}} F(y) \text{ for } y_i < P_{\text{th1}} \end{cases} \quad (121\text{–}4)$$

Each element of the cumulative probability function, $CF_{L1}(y_i)$, is multiplied by a value $G_{\text{th1}}(y_i)$, and then summed to calculate an approximation for SER_{L1}, the partial SER for threshold 1. Each element of the cumulative probability function, $CF_{L2}(y_i)$, is multiplied by a value $G_{\text{th2}}(y_i)$, and then summed to calculate an approximation for SER_{L2}. Each element of the cumulative probability function, $CF_{L3}(y_i)$, is multiplied by a value $G_{\text{th3}}(y_i)$, and then summed to calculate an approximation for SER_{L3}. The sum of the three partial SERs is the SER associated with the left histogram, SER_L.

Each element of the cumulative probability function, $CF_{R1}(y_i)$, is multiplied by a value $G_{\text{th1}}(y_i)$, and then summed to calculate an approximation for SER_{R1}, the partial SER for threshold 1. $CF_{R2}(y_i)$ and $CF_{R3}(y_i)$ are treated similarly to calculate SER_{R2}, and SER_{R3}, the partial SERs for threshold 2 and threshold 3. The sum of the three partial SERs is the SER associated with the right histogram, SER_R.

$G_{\text{th1}}(y_i)$ is equivalent to a Gaussian probability density function with an RMS value of σ_G, centered around the sub-eye threshold P_{th1}. $G_{\text{th1}}(y_i)$ is given by Equation (121–5) and can be estimated by Equation (121–6).

$$G_{\text{th1}}(y_i) = \int_{y_i-\frac{\Delta y}{2}}^{y_i+\frac{\Delta y}{2}} \frac{1}{C_{\text{eq}}\sigma_G\sqrt{2\pi}} \times \text{e}^{-\left(\frac{y-P_{\text{th1}}}{C_{\text{eq}}\sigma_G\sqrt{2}}\right)^2} dy \quad (121\text{–}5)$$

$$G_{\text{th1}}(y_i) = \frac{1}{C_{\text{eq}}\sigma_G\sqrt{2\pi}} \times \text{e}^{-\left(\frac{y_i-P_{\text{th1}}}{C_{\text{eq}}\sigma_G\sqrt{2}}\right)^2} \times \Delta y \quad (121\text{–}6)$$

$G_{\text{th2}}(y_i)$ and $G_{\text{th3}}(y_i)$ are similar Gaussian probability density functions with the same RMS value of σ_G, centered around the sub-eye thresholds P_{th2} and P_{th3} respectively. $G_{\text{th2}}(y_i)$ and $G_{\text{th3}}(y_i)$ are given by Equation (121–7) and Equation (121–8) respectively.

$$G_{\text{th2}}(y_i) = \int_{y_i-\frac{\Delta y}{2}}^{y_i+\frac{\Delta y}{2}} \frac{1}{C_{\text{eq}}\sigma_G\sqrt{2\pi}} \times \text{e}^{-\left(\frac{y-P_{\text{th2}}}{C_{\text{eq}}\sigma_G\sqrt{2}}\right)^2} dy \quad (121\text{–}7)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$G_{\text{th3}}(y_i) = \int_{y_i - \frac{\Delta y}{2}}^{y_i + \frac{\Delta y}{2}} \frac{1}{C_{\text{eq}}\sigma_G\sqrt{2\pi}} \times \text{e}^{-\left(\frac{y - P_{\text{th3}}}{C_{\text{eq}}\sigma_G\sqrt{2}}\right)^2} dy \quad (121\text{–}8)$$

where

C_{eq} is a coefficient which accounts for the reference equalizer noise enhancement

The value of C_{eq} can be calculated from the product of the normalized noise power density spectrum $N(f)$ at the input of the reference equalizer and the normalized frequency response $H_{\text{eq}}(f)$ of the reference equalizer, as shown in Equation (121–9).

$$C_{\text{eq}} = \sqrt{\int_f N(f) \times |H_{\text{eq}}(f)|^2 df} \quad (121\text{–}9)$$

where

$N(f)$ is the normalized noise power density spectrum equivalent to white noise filtered by a fourth-order Bessel-Thomson response filter with a 3 dB bandwidth of 13.28125 GHz.

and

$$\int_f N(f)df = H_{\text{eq}}(f = 0) = 1 \quad (121\text{–}10)$$

The equalizer tap coefficients are iteratively adjusted and SER_L and SER_R calculated until the largest of SER_L and SER_R is minimized. Then, if the larger of SER_L and SER_R is greater than the target SER of 4.8×10^{-4}, the value of σ_G is decreased and the process of equalizer optimization is repeated; If the larger of SER_L and SER_R is lower than the target SER of 4.8×10^{-4}, then the value of σ_G is increased and the process of equalizer optimization is repeated.

P_{th1}, P_{th2}, and P_{th3} are varied from their nominal values by up to ±1% of $\text{OMA}_{\text{outer}}$ in order to optimize TDECQ. The same three thresholds are used for both the left and the right histogram.

When the larger of SER_L and SER_R is equal to the target SER of 4.8×10^{-4}, and the value of σ_G cannot be increased by further optimization of the equalizer tap coefficients or the sub-eye threshold levels, then TDECQ is calculated.

The RMS noise, R, that could be added by a receiver is given by Equation (121–11).

$$R = \sqrt{\sigma_G{}^2 + \sigma_S{}^2} \quad (121\text{–}11)$$

TDECQ is given by Equation (121–12).

$$TDECQ = 10\log_{10}\left(\frac{OMA_{\text{outer}}}{6} \times \frac{1}{Q_t R}\right) \quad (121\text{–}12)$$

where

OMA_{outer} is the Outer Optical Modulation Amplitude as defined in 121.8.4

Q_t is 3.414 consistent with the BER and target symbol error ratio for Gray coded PAM4

121.8.5.4 TDECQ reference equalizer

The reference equalizer for 200GBASE-DR4 is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 121–6. The sum of the equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3, has the largest magnitude tap coefficient, which is constrained to be at least 0.8.

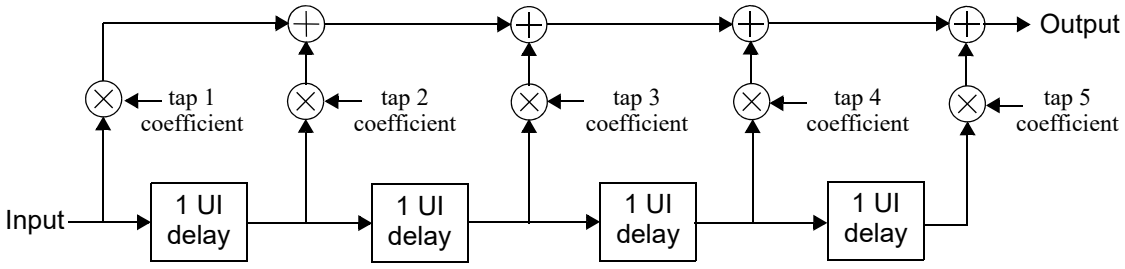

Figure 121–6—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver equalizer implementation.

121.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 121–6 if measured using a test pattern specified for extinction ratio in Table 121–10. The extinction ratio of a PAM4 optical signal is defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 121–3.

121.8.7 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 121–6 if measured using a test pattern specified for transmitter transition time in Table 121–10.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with response defined as follows. The combined response of the O/E converter and oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz. At frequencies above 1.5 × 26.5625 GHz, the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 121.8.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence, and the falling edge is that within the 33333000000 symbol sequence.

121.8.8 Relative intensity noise ($RIN_{21.4}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 21.4 dB.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm.

c) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 26.6 GHz).

d) The test pattern is according to Table 121–10.

121.8.9 Receiver sensitivity

Receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (121–13), which is illustrated in Figure 121–7.

$$RS = \max(-6.1, SECQ - 7.5) \quad \text{(dBm)} \tag{121–13}$$

where

RS is the receiver sensitivity

SECQ is the SECQ of the transmitter used to measure the receiver sensitivity

The normative requirement for receivers is stressed receiver sensitivity.

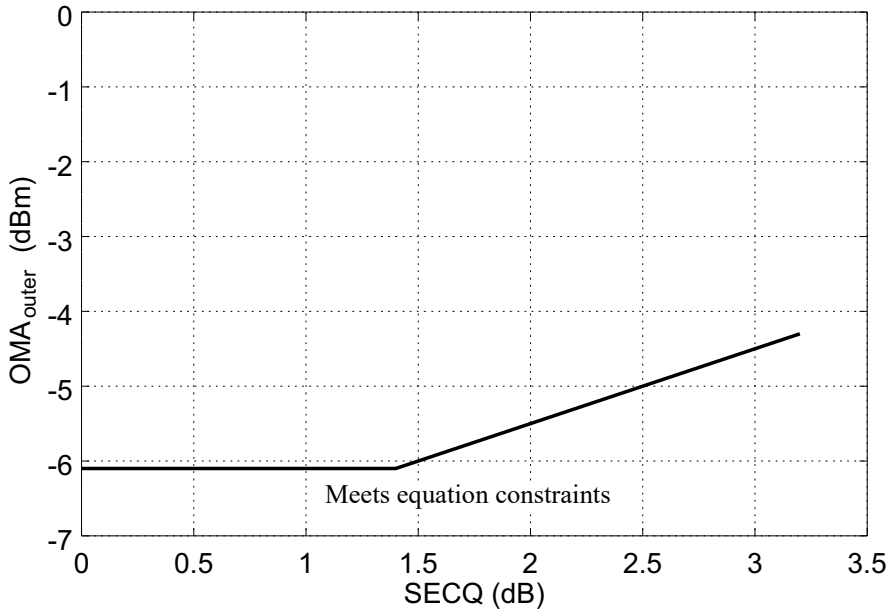

Figure 121–7—Illustration of receiver sensitivity

121.8.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 121–7 if measured using the method defined in 121.8.10.1 and 121.8.10.3, with the conformance test signal at TP3 as described in 121.8.10.2, using the test pattern specified for stressed receiver sensitivity in Table 121–10. The BER is required to be met for the lane under test on its own.

Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Any of the patterns specified for stressed receiver sensitivity in Table 121–10 is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.

121.8.10.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 121–8. The patterns used for the received conformance signal are specified in Table 121–10. The optical test signal is conditioned (stressed) using the stressed receiver methodology defined in 121.8.10.2 and has sinusoidal jitter applied as specified in 121.8.10.4. A suitable test set is needed to characterize the signal used to test the receiver. Stressed receiver conformance test signal verification is described in 121.8.10.3.

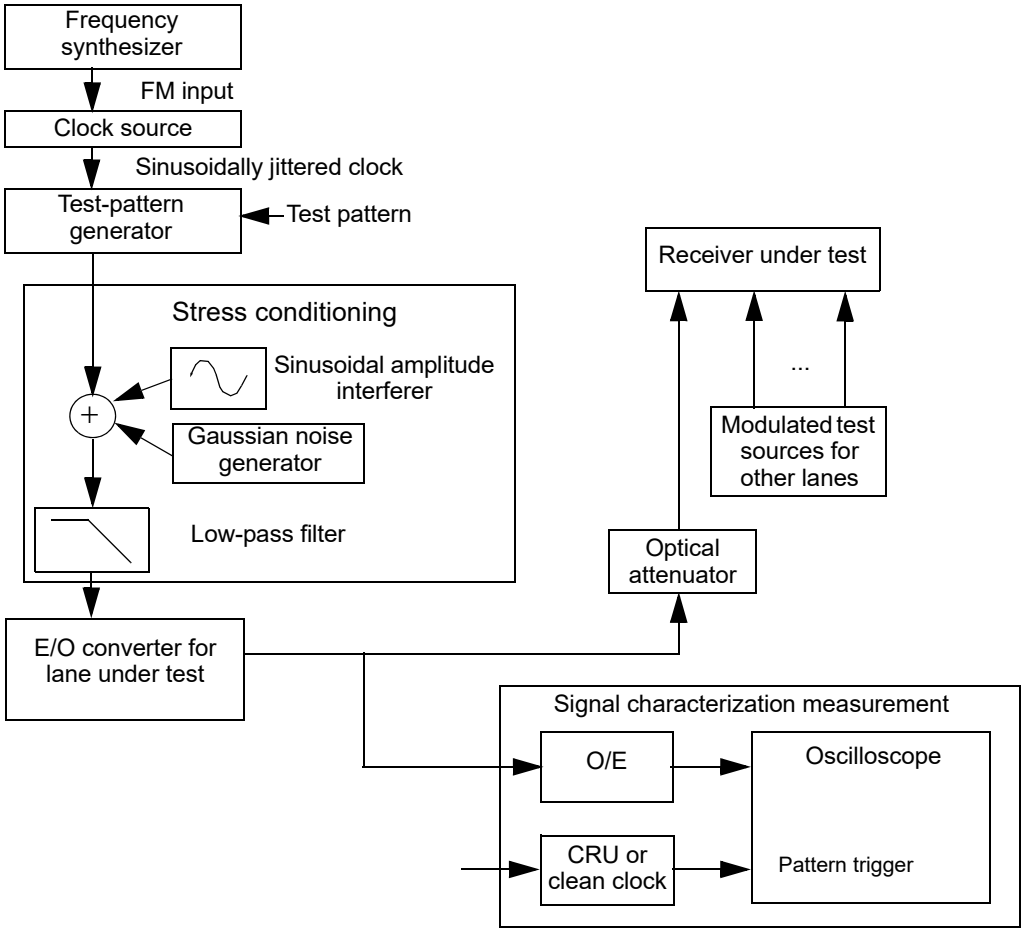

Figure 121–8—Stressed receiver conformance test block diagram

The low-pass filter is used to create ISI. The sinusoidal amplitude interferer causes additional eye closure, but in conjunction with the finite edge rates, also causes some jitter.

The sinusoidally jittered clock represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter. The sinusoidal amplitude interferer may be set at any frequency between 100 MHz and 2 GHz, although care should be taken to avoid harmonic relationships between the sinusoidal interferer, the sinusoidal jitter, the signaling rate, and the pattern repetition rate. The Gaussian noise generator, the amplitude of the sinusoidal interferer, and the low-pass filter are adjusted so that the SECQ specified in Table 121–7 is met, according to the methods specified in 121.8.10.2.

For improved visibility for calibration, all elements in the signal path (cables, DC blocks, E/O converter, etc.) should have wide and smooth frequency response, and linear phase response, throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be negligible.

121.8.10.2 Stressed receiver conformance test signal characteristics and calibration

The conformance test signal is used to validate that each lane of the PMD receiver meets BER requirements with near worst-case waveforms at TP3.

The primary parameters of the stressed receiver conformance test signal are its stressed eye closure (SECQ), and the sinusoidal jitter applied, as specified in 121.8.10.4. The SECQ of the stressed receiver conformance test signal is measured according to 121.8.5, except that the test fiber is not used. An example stressed receiver conformance test setup is shown in Figure 121–8; however, alternative test setups that generate equivalent stress conditions may be used.

The following steps describe a possible method for setting up and calibrating a stressed receiver conformance test signal when using a stressed receiver conformance test setup as shown in Figure 121–8:

1) Set the signaling rate of the test pattern generator to meet the requirements in Table 121–6.
2) With the sinusoidal jitter, sinusoidal interferer, and the Gaussian noise generator turned off, set the extinction ratio of the E/O converter to approximately the minimum specified in Table 121–6.
3) The required value of SECQ is given in Table 121–7. Sinusoidal jitter is added as specified in Table 121–12.

When calibrating the conformance signal, the sinusoidal jitter frequency should be between 50 MHz and 10 times LB as defined in Table 121–12. Sinusoidal jitter amplitude may be calibrated by measuring the jitter on the oscilloscope, while transmitting the square wave pattern, as defined in Table 121–9, and using a clean clock in place of the CRU to trigger the oscilloscope.

Iterate the adjustments of the sinusoidal interferer, the Gaussian noise generator, and extinction ratio, until the required value of SECQ is met, while also meeting the following conditions:

— The extinction ratio is approximately the minimum specified in Table 121–6;
— The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 121–6;
— With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_{21.4}OMA$ of the conformance test signal is no greater than the value specified in Table 121–6;
— The value of SECQ − $10\log_{10}(C_{eq})$ is less than the value specified in Table 121–7; and
— Sinusoidal jitter is as specified in Table 121–12.

Each receiver lane is conformance tested in turn. The source for the lane under test is adjusted to supply a signal at the input to the receiver under test at the “Stressed receiver sensitivity (OMA_{outer}), each lane (max)” specified in Table 121–7, and the test sources for the other lanes are set to the “OMA_{outer} of each aggressor lane” specified in Table 121–7.

NOTE—A compliant PMD receiver is expected to meet the stressed receiver sensitivity requirements with a calibrated conformance test signal regardless of the proportion of the dB value of the SECQ that is due to the frequency response of the combination of the low-pass filter and the E/O converter.

121.8.10.3 Stressed receiver conformance test signal verification

The SECQ of the stressed receiver conformance test signal is measured according to 121.8.5, except that the test fiber is not used. The clock output from the clock source in Figure 121–8 is modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye jitter that includes the sinusoidal

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

jitter component, a separate clock source (clean clock of Figure 121–8) is required that is synchronized to the source clock, but not modulated with the jitter source.

Care should be taken when characterizing the test signal because excessive noise/jitter in the measurement system would result in an input signal that does not fully stress the receiver under test. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. The noise/jitter introduced by the O/E, filters, and oscilloscope should be negligible or the results should be corrected for its effects. While the details of test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands so that the stressed receiver conformance input signal meets the stress and sinusoidal jitter specified in 121.8.10.2 and 121.8.10.4.

121.8.10.4 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. The amplitude of the applied sinusoidal jitter is dependent on frequency as specified in Table 121–12 and is illustrated in Figure 121–9.

Table 121–12—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak (UI)
$f < 40$ kHz	Not specified
40 kHz $< f \leq$ 4 MHz	2×10^5 Hz/ f
4 MHz $< f <$ 10 LB[a]	0.05

[a] LB = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

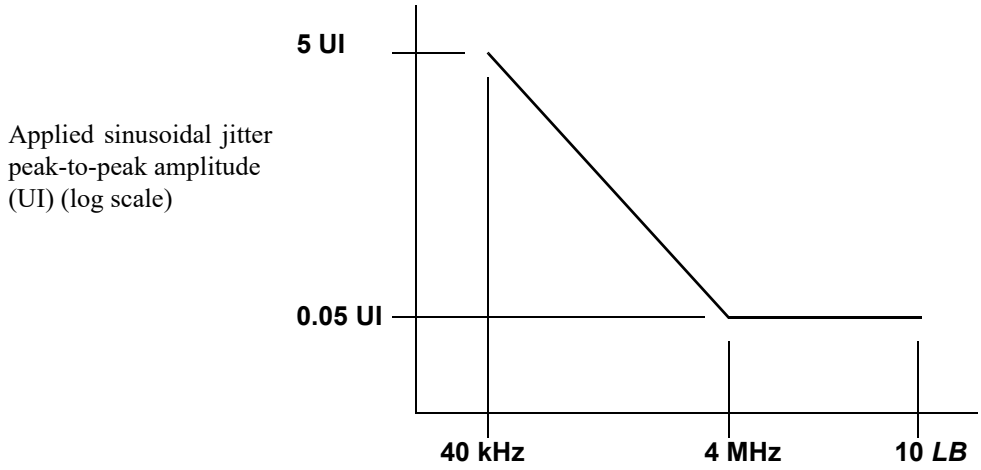

Figure 121–9—Illustration of the mask of the sinusoidal component of jitter tolerance

121.9 Safety, installation, environment, and labeling

121.9.1 General safety

All equipment subject to this clause shall conform to IEC 60950-1.

121.9.2 Laser safety

200GBASE-DR4 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[208]

121.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

121.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 200GBASE-DR4 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

121.9.5 Electromagnetic emission

A system integrating a 200GBASE-DR4 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

121.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

[208] A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

121.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 200GBASE-DR4).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 121.9.2.

121.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 121–10.

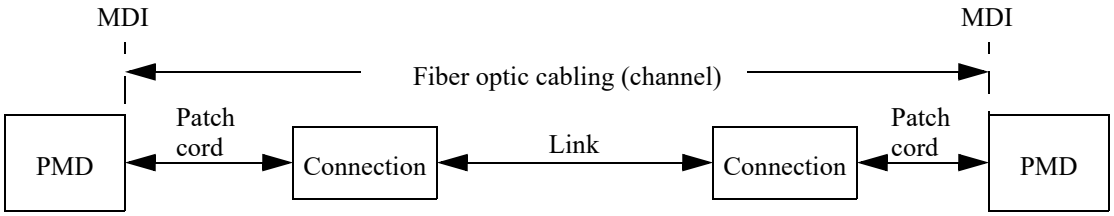

Figure 121–10—Fiber optic cabling model

The channel insertion loss is given in Table 121–13. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 121–13—Fiber optic cabling (channel) characteristics

Description	200GBASE-DR4	Unit
Operating distance (max)	500	m
Channel insertion loss[a, b](max)	3	dB
Channel insertion loss (min)	0	dB
Positive dispersion[b] (max)	0.8	ps/nm
Negative dispersion[b] (min)	–0.93	ps/nm
DGD_max[c]	2.24	ps
Optical return loss (min)	37	dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1304.5 nm to 1317.5 nm.
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

121.11 Characteristics of the fiber optic cabling (channel)

The 200GBASE-DR4 fiber optic cabling shall meet the specifications defined in Table 121–14. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

121.11.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion un-shifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 121–14 where they differ.

Table 121–14—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.5[a]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \leq \lambda_0 \leq 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a] The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3.

121.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 121–10, consists of a mated pair of optical connectors.

121.11.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 2.75 dB total connection and splice loss. For example, this allocation supports five connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 121–13 are met.

121.11.2.2 Maximum discrete reflectance

The maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 121–15 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

121.11.3 Medium Dependent Interface (MDI)

The 200GBASE-DR4 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” (as shown in Figure 121–10). The 200GBASE-DR4 PMD is coupled to the fiber optic cabling through one connector plug into the MDI optical receptacle as shown in Figure 121–12. Example constructions of the MDI include the following:

a) PMD with a connectorized fiber pigtail plugged into an adapter
b) PMD receptacle

Table 121–15—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance
1	–37 dB
2	–42 dB
4	–45 dB
6	–47 dB
8	–48 dB
10	–49 dB

121.11.3.1 Optical lane assignments

The four transmit and four receive optical lanes of 200GBASE-DR4 shall occupy the positions depicted in Figure 121–11 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains eight active lanes within twelve total positions. The transmit optical lanes occupy the left-most four positions. The receive optical lanes occupy the right-most four positions. The four center positions are unused.

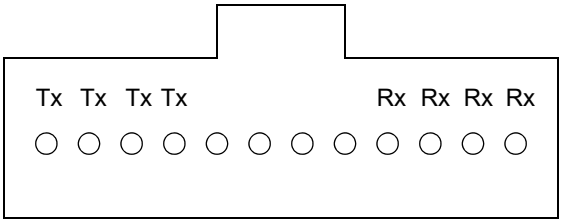

Figure 121–11—200GBASE-DR4 optical lane assignments

121.11.3.2 Medium Dependent Interface (MDI) requirements

The MDI shall meet the dimensional specifications of IEC 61754-7-1 interface 7-1-9: *MPO device receptacle, angled interface*. The plug terminating the optical fiber cabling shall meet the dimensional specifications of IEC 61754-7-1 interface 7-1-1: *MPO female plug connector, down-angled interface for 2 to 12 fibres*. The MDI shall optically mate with the plug on the optical fiber cabling. Figure 121–12 shows an MPO female plug connector with down-angled interface, and an MDI as an active device receptacle with angled interface.

The MDI shall meet the interface performance specifications of IEC 61753-021-2 for performance level D/2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 121.5.1, not at the MDI.

121.12 Protocol implementation conformance statement (PICS) proforma for Clause 121, Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-DR4[209]

121.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 121, Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-DR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

121.12.2 Identification

121.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

121.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 121, Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-DR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[209] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

122. Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8

122.1 Overview

This clause specifies the 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs together with the single-mode fiber medium. The optical signals generated by these six PMD types are modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 122–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 122–1—Physical Layer clauses associated with the 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs

Associated clause	200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4	400GBASE-FR8, 400GBASE-LR8, 400GBASE-ER8
117—RS	Required	Required
117—200GMII[a]	Optional	Not applicable
117—400GMII[a]	Not applicable	Optional
118—200GMII Extender	Optional	Not applicable
118—400GMII Extender	Not applicable	Optional
119—PCS for 200GBASE-R	Required	Not applicable
119—PCS for 400GBASE-R	Not applicable	Required
120—PMA for 200GBASE-R	Required	Not applicable
120—PMA for 400GBASE-R	Not applicable	Required
120B—Chip-to-chip 200GAUI-8	Optional	Not applicable
120B—Chip-to-chip 400GAUI-16	Not applicable	Optional
120C—Chip-to-module 200GAUI-8	Optional	Not applicable
120C—Chip-to-module 400GAUI-16	Not applicable	Optional
120D—Chip-to-chip 200GAUI-4	Optional	Not applicable
120D—Chip-to-chip 400GAUI-8	Not applicable	Optional
120E—Chip-to-module 200GAUI-4	Optional	Not applicable
120E—Chip-to-module 400GAUI-8	Not applicable	Optional
78—Energy Efficient Ethernet	Optional	Optional

[a] 200GMII and 400GMII are optional interfaces. However, if the appropriate interface is not implemented, a conforming implementation behaves functionally as though the RS and 200GMII or 400GMII were present.

Figure 122–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 200 Gb/s and 400 Gb/s Ethernet are introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

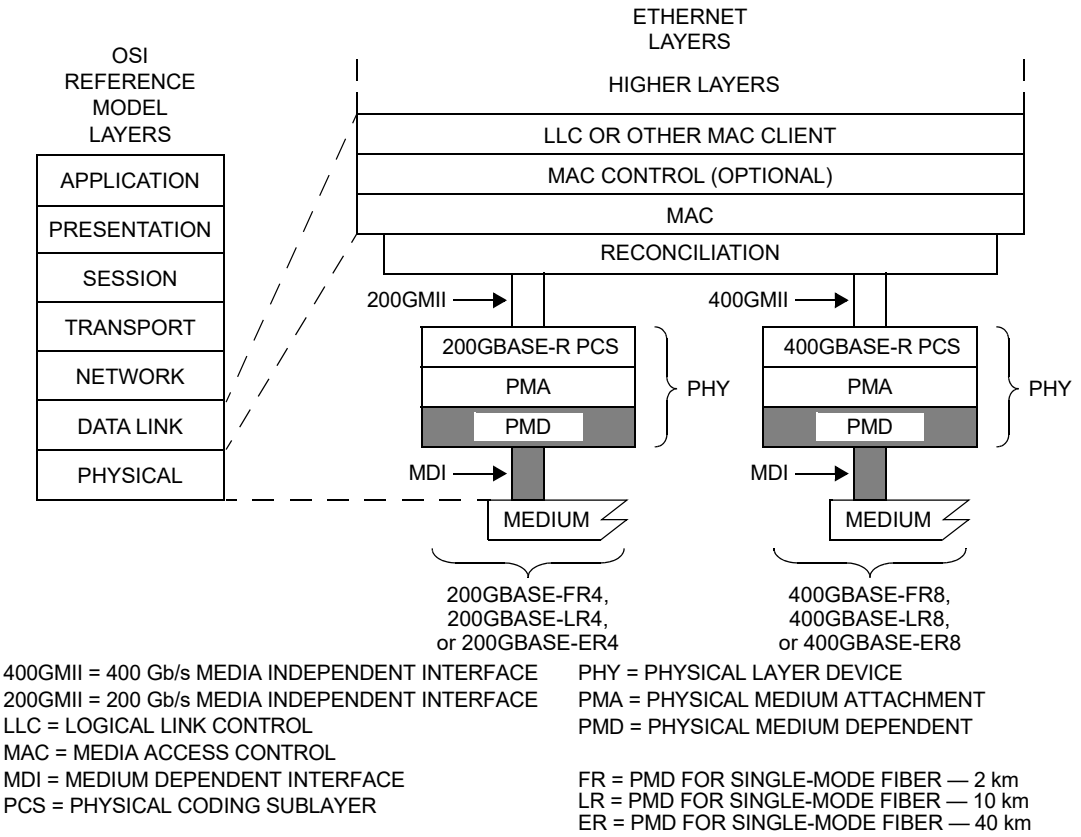

Figure 122–1—200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 use four lanes, while 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 use eight lanes. In this clause, where there are four or eight items (depending on PMD type) such as lanes, the items are numbered from 0 to $n - 1$, and an example item is numbered i. Thus n is 4 or 8.

200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

122.1.1 Bit error ratio

The bit error ratio (BER) when processed according to Clause 120 shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when processed according to Clause 120 and then Clause 119. For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

122.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 116.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 PMDs have four parallel symbol streams, in which case $i = 0$ to 3, and the 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs have eight parallel symbol streams, in which case $i = 0$ to 7.

In the transmit direction, the PMA continuously sends n parallel symbol streams to the PMD, one per lane, each at a nominal signaling rate of 26.5625 GBd. The PMD then converts these streams of data units into the appropriate signals on the MDI.

In the receive direction, the PMD continuously sends n parallel symbol streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service interface primitive defined in 116.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 122.1.1.

122.3 Delay and Skew

122.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 200GBASE-FR4, 200GBASE-LR4, or 200GBASE-ER4 PMD including 2 m of fiber in one direction shall be no more than 4096 bit times (8 pause_quanta or 20.48 ns). The sum of the transmit and receive delays at one end of the link contributed by the 400GBASE-FR8, 400GBASE-LR8, or 400GBASE-ER8 PMD including 2 m of fiber in one direction shall be no more than 8192 bit times (16 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

122.3.2 Skew constraints

The Skew (relative delay between the lanes) and Skew Variation are kept within limits so that the information on the lanes can be reassembled by the PCS. Skew and Skew Variation are defined in 116.5 and specified at the points SP1 to SP6 shown in Figure 116–4 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 116.5. The measurements of Skew and Skew Variation are defined in 87.8.2.

122.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 122–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 122–3.

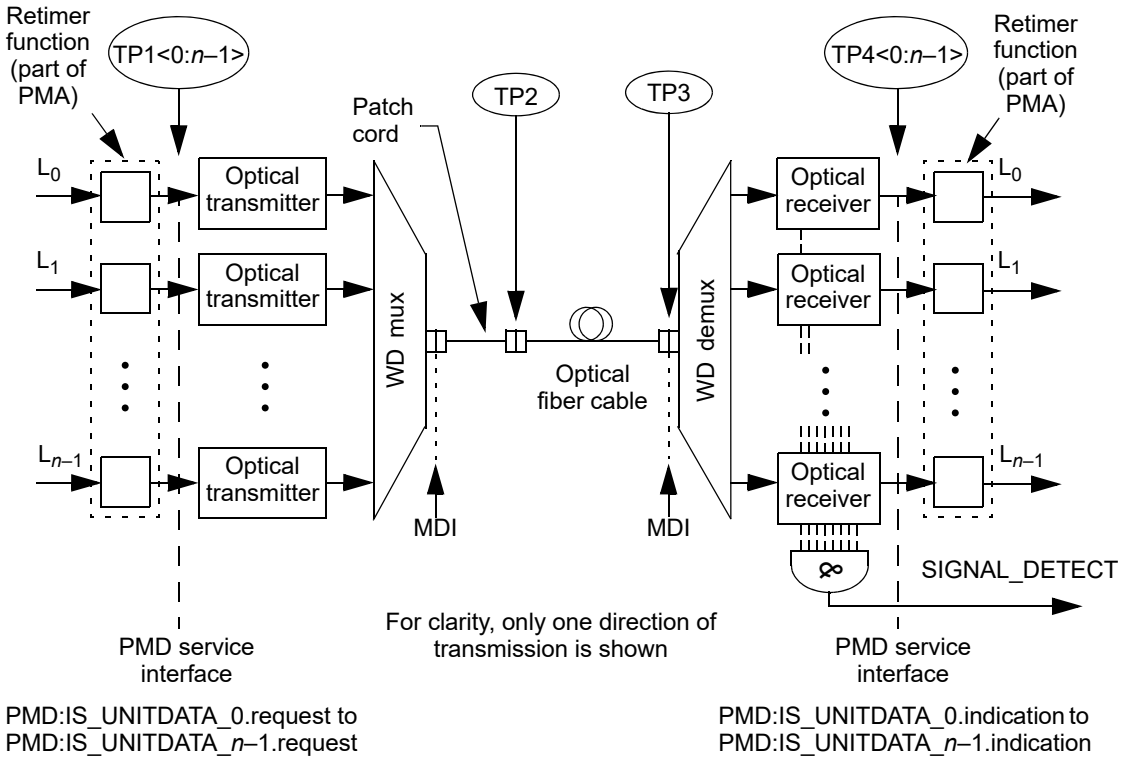
Table 122–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable *n*–1 to PMD transmit disable 0	PMD transmit disable register	1.9.8 to 1.9.1	PMD_transmit_disable_*n*–1 to PMD_transmit_disable_0

122.5 PMD functional specifications

The 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

122.5.1 PMD block diagram



The PMD block diagram is shown in Figure 122–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 122.8 are made at TP2. The optical receive signal is defined at

Table 122–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect *n*–1 to PMD receive signal detect 0	PMD receive signal detect register	1.10.8 to 1.10.1	PMD_signal_detect_*n*–1 to PMD_signal_detect_0

the output of the fiber optic cabling (TP3) at the MDI (see 122.11.3). Unless specified otherwise, all receiver measurements and tests defined in 122.8 are made at TP3.

NOTE—Specification of the retimer function and the electrical implementation of the PMD service interface is beyond the scope of this standard.

Figure 122–2—Block diagram for 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 transmit/receive paths

TP1<0:*n*–1> and TP4<0:*n*–1> are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

122.5.2 PMD transmit function

The PMD Transmit function shall convert the *n* symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_*n*–1.request into *n* separate optical signals. The *n* optical signals shall then be wavelength division multiplexed and delivered to the MDI, all according to the transmit optical specifications in this clause. The highest optical power level in each signal shall correspond to tx_symbol = three and the lowest shall correspond to tx_symbol = zero.

122.5.3 PMD receive function

The PMD Receive function shall demultiplex the composite optical signal received from the MDI into *n* separate optical signals. The *n* optical signals shall then be converted into *n* symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_*n*–1.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_symbol = three and the lowest shall correspond to rx_symbol = zero.

122.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 116.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all *n* lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 122–4. The PMD receiver is not required to verify whether a compliant 200GBASE-R or 400GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 122–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 122–11 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 or Table 122–12 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8) AND (compliant 200GBASE-R or 400GBASE–R signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

122.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:*n*–1, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 122–4.

122.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

122.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

122.5.8 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function allows the optical transmitters in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and 0:7 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method shall be provided to independently disable each transmit lane for testing purposes.

122.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

122.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

122.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

122.6 Wavelength-division-multiplexed lane assignments

The wavelength range for each lane of the 200GBASE-FR4 PMD is defined in Table 122–5. The 200GBASE-FR4 center wavelengths are members of the CWDM wavelength grid defined in ITU-T G.694.2 and are spaced at 20 nm.

The wavelength range for each lane of the 200GBASE-LR4 and 200GBASE-ER4 PMDs is defined in Table 122–6. The wavelength range for each lane of the 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs is defined in Table 122–7. The 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 center frequencies are members of the frequency grid for 100 GHz spacing and above defined in ITU-T G.694.1 and are spaced at multiples of 800 GHz.

Table 122–5—200GBASE-FR4 wavelength-division-multiplexed lane assignments

Lane	Center wavelength	Wavelength range
L_0	1271 nm	1264.5 to 1277.5 nm
L_1	1291 nm	1284.5 to 1297.5 nm
L_2	1311 nm	1304.5 to 1317.5 nm
L_3	1331 nm	1324.5 to 1337.5 nm

Table 122–6—200GBASE-LR4 and 200GBASE-ER4 wavelength-division-multiplexed lane assignments

Lane	Center frequency	Center wavelength	Wavelength range
L_0	231.4 THz	1295.56 nm	1294.53 to 1296.59 nm
L_1	230.6 THz	1300.05 nm	1299.02 to 1301.09 nm
L_2	229.8 THz	1304.58 nm	1303.54 to 1305.63 nm
L_3	229 THz	1309.14 nm	1308.09 to 1310.19 nm

NOTE—There is no requirement to associate a particular electrical lane with a particular optical lane, as the PCS is capable of receiving lanes in any arrangement.

Table 122–7—400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 wavelength-division-multiplexed lane assignments

Lane	Center frequency	Center wavelength	Wavelength range
L_0	235.4 THz	1273.54 nm	1272.55 to 1274.54 nm
L_1	234.6 THz	1277.89 nm	1276.89 to 1278.89 nm
L_2	233.8 THz	1282.26 nm	1281.25 to 1283.27 nm
L_3	233 THz	1286.66 nm	1285.65 to 1287.68 nm
L_4	231.4 THz	1295.56 nm	1294.53 to 1296.59 nm
L_5	230.6 THz	1300.05 nm	1299.02 to 1301.09 nm
L_6	229.8 THz	1304.58 nm	1303.54 to 1305.63 nm
L_7	229 THz	1309.14 nm	1308.09 to 1310.19 nm

122.7 PMD to MDI optical specifications for 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8

The operating ranges for the 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 PMDs are defined in Table 122–8. A 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, or 400GBASE-ER8 compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 122–18. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 400GBASE-FR8 PMD operating at 2.5 km meets the operating range requirement of 2 m to 2 km).

The 200GBASE-ER4 PMD interoperates with the 200GBASE-LR4 PMD provided that the channel requirements defined in 122.12 are met.

The 400GBASE-LR8 PMD interoperates with the 400GBASE-FR8 PMD provided that the channel requirements for 400GBASE-FR8 are met.

The 400GBASE-ER8 PMD interoperates with the 400GBASE-FR8 PMD provided that the channel requirements defined in 122.13 are met.

The 400GBASE-ER8 PMD interoperates with the 400GBASE-LR8 PMD provided that the channel requirements defined in 122.14 are met.

Table 122–8—200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 operating ranges

PMD type	Required operating range
200GBASE-FR4 and 400GBASE-FR8	2 m to 2 km
200GBASE-LR4 and 400GBASE-LR8	2 m to 10 km
200GBASE-ER4 and 400GBASE-ER8	2 m to 30 km
	2 m to 40 km[a]

[a] Links longer than 30 km for the same link power budget are considered engineered links. Attenuation for such links needs to be less than the worst case specified for IEC 60793-2-50 type B1.1, type B1.3, or type B6_a single-mode fiber.

122.7.1 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 transmitter optical specifications

The 200GBASE-FR4 transmitter shall meet the specifications defined in Table 122–9 per the definitions in 122.8. The 200GBASE-LR4 transmitter shall meet the specifications defined in Table 122–9 per the definitions in 122.8. The 200GBASE-ER4 transmitter shall meet the specifications defined in Table 122–9 per the definitions in 122.8. The 400GBASE-FR8 transmitter shall meet the specifications defined in Table 122–10 per the definitions in 122.8. The 400GBASE-LR8 transmitter shall meet the specifications defined in Table 122–10 per the definitions in 122.8. The 400GBASE-ER8 transmitter shall meet the specifications defined in Table 122–10 per the definitions in 122.8.

Table 122–9—200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 transmit characteristics

Description	200GBASE-FR4	200GBASE-LR4	200GBASE-ER4	Unit
Signaling rate, each lane (range)	26.5625 ± 100 ppm			GBd
Modulation format	PAM4			—
Lane wavelengths (range)	1264.5 to 1277.5 1284.5 to 1297.5 1304.5 to 1317.5 1324.5 to 1337.5	1294.53 to 1296.59 1299.02 to 1301.09 1303.54 to 1305.63 1308.09 to 1310.19		nm
Side-mode suppression ratio (SMSR), (min)	30			dB
Total average launch power (max)	10.7	11.3	12.6	dBm
Average launch power, each lane (max)	4.7	5.3	6.6	dBm
Average launch power, each lane[a] (min)	–4.2	–3.4	0.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	4.5	5.1	7.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min)[b]	–1.2	–0.4	3.4	dBm
Difference in launch power between any two lanes (OMA_{outer}) (max)	4			dB
Launch power in OMA_{outer} minus TDECQ, each lane (min): for extinction ratio ≥ 4.5 dB for extinction ratio < 4.5 dB	 –2.6 –2.5	 –1.8 –1.7	 2 —	 dBm dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	3.1	3.2	3.2	dB
TDECQ $-10\log_{10}(C_{eq})$[c] (max)	3.1	3.2	3.2	dB
Average launch power of OFF transmitter, each lane (max)	–30			dBm
Extinction ratio, each lane (min)	3.5		6	dB
Transmitter transition time (max)	34			ps
$RIN_{17.1}OMA$ (max)	–132	—	—	dB/Hz
$RIN_{15.6}OMA$ (max)	—	–132	—	dB/Hz
$RIN_{15}OMA$ (max)	—	—	–132	dB/Hz
Optical return loss tolerance (max)	17.1	15.6	15	dB
Transmitter reflectance[d] (max)	–26			dB

[a] Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] Even if the TDECQ < 1.4 dB for an extinction ratio of ≥ 4.5 dB or TDECQ < 1.3 dB for an extinction ratio of < 4.5 dB, the OMA_{outer} (min) has to exceed this value.
[c] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d] Transmitter reflectance is defined looking into the transmitter.

Description	400GBASE-FR8	400GBASE-LR8	400GBASE-ER8	Unit
Signaling rate, each lane (range)	26.5625 ± 100 ppm			GBd
Modulation format	PAM4			—
Lane wavelengths (range)	1272.55 to 1274.54 1276.89 to 1278.89 1281.25 to 1283.27 1285.65 to 1287.68 1294.53 to 1296.59 1299.02 to 1301.09 1303.54 to 1305.63 1308.09 to 1310.19			nm
Side-mode suppression ratio (SMSR), (min)	30			dB
Total average launch power (max)	13.2		14.6	dBm
Average launch power, each lane[a] (max)	5.3		5.6	dBm
Average launch power, each lane[b] (min)	–3.5	–2.8	–0.6	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	5.5	5.7	6.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min)[c]	–0.5	0.2	2.4	dBm
Difference in launch power between any two lanes (OMA_{outer}) (max)	4			dB
Launch power in OMA_{outer} minus TDECQ, each lane (min): for extinction ratio ≥ 4.5 dB for extinction ratio < 4.5 dB	 –1.9 –1.8	 –1.2 –1.1	 1 —	 dBm dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	2.9	3.1	3.4	dB
TDECQ $-10\log_{10}(C_{eq})$[d] (max)	2.9	3.1	3.4	dB
Average launch power of OFF transmitter, each lane (max)	–30			dBm
Extinction ratio, each lane (min)	3.5		6	dB
Transmitter transition time (max)	34			ps
$RIN_{17.1}OMA$ (max)	–132	—	—	dB/Hz
$RIN_{15.6}OMA$ (max)	—	–132	—	dB/Hz
$RIN_{15}OMA$ (max)	—	—	–132	dB/Hz
Optical return loss tolerance (max)	17.1	15.6	15	dB
Transmitter reflectance[e] (max)	–26			dB

[a] As the total average launch power limit has to be met, not all of the lanes can operate at the maximum average launch power, each lane.
[b] Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Even if the TDECQ < 1.4 dB for an extinction ratio of ≥ 4.5 dB or TDECQ < 1.3 dB for an extinction ratio of < 4.5 dB, the OMA_{outer} (min) has to exceed this value.
[d] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[e] Transmitter reflectance is defined looking into the transmitter.

122.7.3 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 illustrative link power budgets

Illustrative power budgets and penalties for 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 channels are shown in Table 122–13.

Table 122–13—200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 illustrative link power budgets

Parameter	200GBASE-FR4	400GBASE-FR8	200GBASE-LR4	400GBASE-LR8	200GBASE-ER4		400GBASE-ER8		Unit
Power budget (for maximum TDECQ): for extinction ratio ≥ 4.5 dB for extinction ratio < 4.5 dB	7.4 7.5	7.2 7.3	10 10.1	9.9 10	21.7 —		21.9 —		dB dB
Operating distance	2		10		30	40[a]	30	40[a]	km
Channel insertion loss (max)	4[b]		6.3		15	18	15	18	dB
Channel insertion loss (min)	0				10		10		dB
Maximum discrete reflectance	See 122.11.2.2								dB
Allocation for penalties[c] (for maximum TDECQ): for extinction ratio ≥ 4.5 dB for extinction ratio < 4.5 dB	3.4 3.5	3.2 3.3	3.7 3.8	3.6 3.7	3.7 —		3.9 —		dB dB
Additional insertion loss allowed	0		0		3	0	3	0	dB

[a] Links longer than 30 km are considered engineered links. Attenuation for such links needs to be less than the worst case for cables containing IEC 60793-2-50 type B1.1, type B1.3, or type B6_a single-mode cabled optical fiber.

[b] The channel insertion loss is calculated using the maximum distance specified in Table 122–8 for 200GBASE-FR4 and 400GBASE-FR8 and fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 122.11.2.1.

[c] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

122.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

122.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 122–15 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 122–15 may be used to perform that test. The test patterns used in this clause are shown in Table 122–14.

Table 122–14—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle	119.2.4.9
6	SSPRQ	120.5.11.2.3

Table 122–15—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 200GBASE-R or 400GBASE-R signal	122.8.2
Side mode suppression ratio	3, 5, 6 or valid 200GBASE-R or 400GBASE-R signal	122.8.2
Average optical power	3, 5, 6 or valid 200GBASE-R or 400GBASE-R signal	122.8.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	122.8.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	122.8.5
Extinction ratio	4 or 6	122.8.6
Transmitter transition time	Square wave or 6	122.8.7
$RIN_{17.1}OMA$, $RIN_{15.6}OMA$, and $RIN_{15}OMA$	Square wave	122.8.8
Stressed receiver conformance test signal calibration	6	122.8.10.2
Stressed receiver sensitivity	3 or 5	122.8.10

122.8.2 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR of each optical lane shall be within the ranges given in Table 122–5 for 200GBASE-FR4, in Table 122–6 for 200GBASE-LR4 and 200GBASE-ER4 and in Table 122–7 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8, if measured per IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 122–15.

122.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 if measured using the methods given in IEC 61280-1-1, with the sum of the optical power from all of the lanes not under test below –30 dBm, per the test setup in Figure 53–6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

122.8.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} of each lane shall be within the limits given in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8. The OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 122–15. It is the difference between the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 122–3. For this measurement the sum of the optical power from all of the lanes not under test is below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.

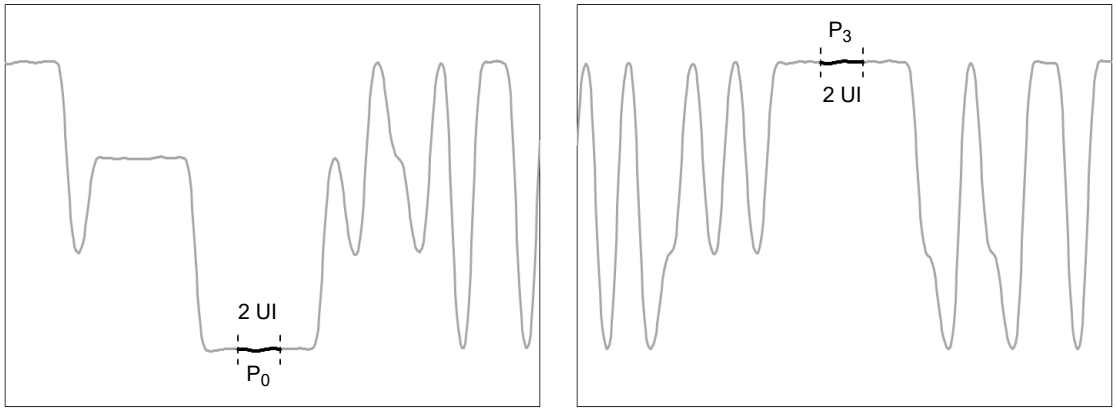

Figure 122–3—Power levels P_0 and P_3 from PRBS13Q test pattern

122.8.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

The TDECQ and TDECQ – $10\log_{10}(C_{eq})$ of each lane shall be within the limits given in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 if measured using the methods specified in 122.8.5.1, 122.8.5.2, and 122.8.5.3.

TDECQ is a measure of each optical transmitter's vertical eye closure when transmitted through a worst case optical channel (specified in 122.8.5.2), as measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a reference receiver, and equalized with the reference equalizer (as described in 122.8.5.4). The reference receiver and equalizer may be implemented in software or may be part of the oscilloscope.

Table 122–15 specifies the test patterns to be used for measurement of TDECQ.

122.8.5.1 TDECQ conformance test setup

A block diagram for the TDECQ conformance test is shown in Figure 122–4. Other equivalent measurement implementations may be used with suitable calibration.

Each optical lane is tested individually with all other lanes in operation and all lanes using the same test pattern. There shall be at least 31 UI delay between the test pattern on one lane and the pattern on any other lane, so that the symbols on each lane are not correlated within the PMD. The optical splitter and variable reflector are adjusted so that each transmitter is tested with the optical return loss specified in Table 122–16. The state of polarization of the back reflection is adjusted to create the greatest RIN. The optical filter is used to separate the lane under test from the others. Each optical lane is tested with the optical channel described in 122.8.5.2. The combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz, and at frequencies above 1.5 × 26.5625 GHz, the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The optical filter passband ripple shall be limited to 0.5 dB peak-to-peak and the isolation is chosen such that the ratio of the power in the lane being measured to the sum of the powers of all of the other lanes is greater than 20 dB (see ITU-T G.959.1 Annex B).

The test pattern (specified in Table 122–15) is transmitted repetitively by the optical lane under test and the oscilloscope is set up to capture the complete pattern for TDECQ analysis as described in 122.8.5.3. The clock recovery unit (CRU) has a corner frequency of 4 MHz and a slope of 20 dB/decade. The CRU can be implemented in hardware or software depending on oscilloscope technology.

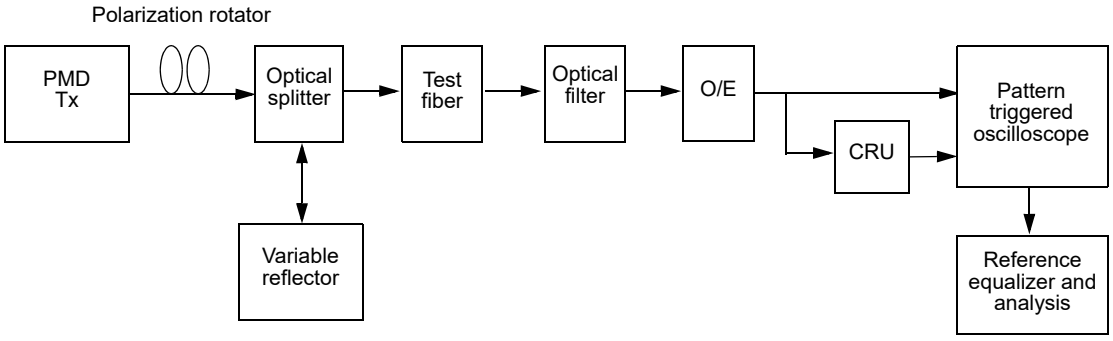

Figure 122–4—TDECQ conformance test block diagram

122.8.5.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 122–16.

Table 122–16—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
200GBASE-FR4 or 400GBASE-FR8	$0.0465 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.0465 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	17.1 dB	0.8 ps
200GBASE-LR4 or 400GBASE-LR8	$0.2325 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.2325 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	15.6 dB	0.8 ps
200GBASE-ER4 or 400GBASE-ER8	$0.93 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.93 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	15 dB	0.8 ps

[a] The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes 2 km for 200GBASE-FR4 and 400GBASE-FR8, 10 km for 200GBASE-LR4 and 400GBASE-LR8, and 40 km for 200GBASE-ER4 and 400GBASE-ER8.
[b] There is no intent to stress the sensitivity of the O/E converter associated with the oscilloscope.
[c] The optical return loss is applied at TP2.

A 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, or 400GBASE-ER8 transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 122–16 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 122–16. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 122–16.

122.8.5.3 TDECQ measurement method

TDECQ for 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 is measured as described in 121.8.5.3 with the exception that the reference equalizer is as specified in 122.8.5.4.

122.8.5.4 TDECQ reference equalizer

The reference equalizer for 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 122–5. The sum of the equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3 has the largest magnitude tap coefficient, which is constrained to be at least 0.8.

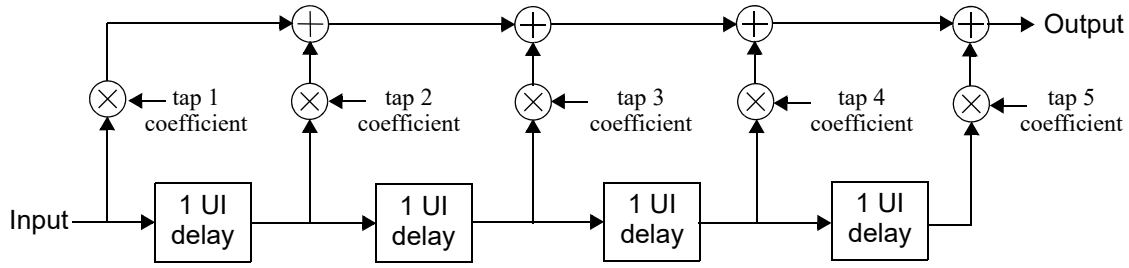

Figure 122–5—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver equalizer implementation.

122.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 if measured using a test pattern specified for extinction ratio in Table 122–15 with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test. The extinction ratio of a PAM4 optical signal is defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 122–3.

122.8.7 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8, if measured using a test pattern specified for transmitter transition time in Table 122–15.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with response defined as follows. The combined response of the O/E converter and oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz. At frequencies above 1.5 × 26.5625 GHz, the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 121.8.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence, and the falling edge is that within the 33333000000 symbol sequence.

122.8.8 Relative intensity noise ($RIN_{17.1}OMA$, $RIN_{15.6}OMA$, and $RIN_{15}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 17.1 dB for 200GBASE-FR4 and 400GBASE-FR8, 15.6 dB for 200GBASE-LR4 and 400GBASE-LR8, and 15 dB for 200GBASE-ER4 and 400GBASE-ER8.

b) Each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm, or if other lanes are operating, a suitable optical filter may be used to separate the lane under test.

c) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 26.6 GHz).

d) The test pattern is according to Table 122–15.

122.8.9 Receiver sensitivity

For 200GBASE-FR4, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.1 dB. Receiver sensitivity should meet Equation (122–1), which is illustrated in Figure 122–6.

For 200GBASE-LR4, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (122–2), which is illustrated in Figure 122–6.

For 200GBASE-ER4, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (122–3), which is illustrated in Figure 122–6.

$$RS = \max(-5.5, SECQ - 6.9) \quad \text{(dBm)} \tag{122–1}$$

$$RS = \max(-7.2, SECQ - 8.6) \quad \text{(dBm)} \tag{122–2}$$

$$RS = \max(-15.1, SECQ - 16.5) \quad \text{(dBm)} \tag{122–3}$$

where

RS is the receiver sensitivity

SECQ is the SECQ of the transmitter used to measure the receiver sensitivity

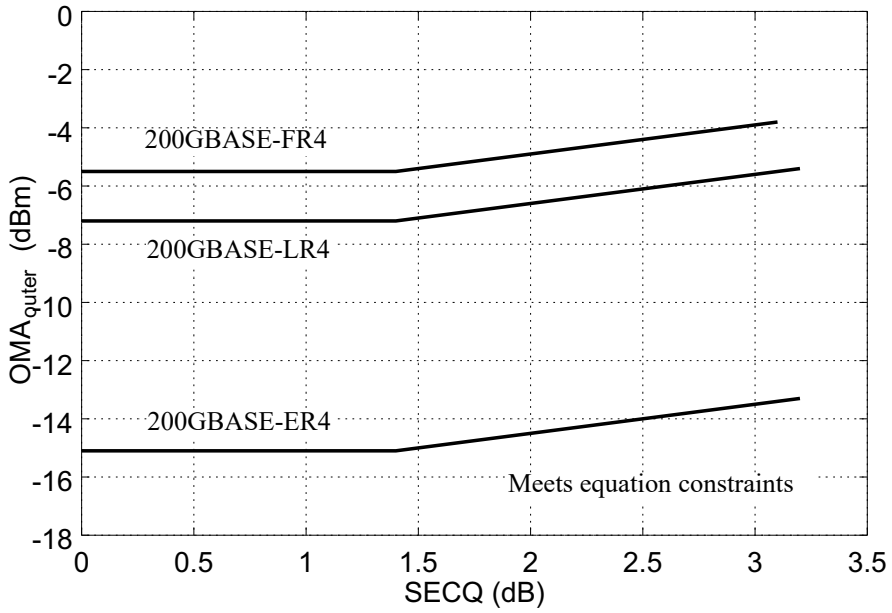

Figure 122–6—Illustration of receiver sensitivity for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4

For 400GBASE-FR8, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 2.9 dB. Receiver sensitivity should meet Equation (122–4), which is illustrated in Figure 122–7.

For 400GBASE-LR8, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.1 dB. Receiver sensitivity should meet Equation (122–5), which is illustrated in Figure 122–7.

For 400GBASE-ER8, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.4 dB. Receiver sensitivity should meet Equation (122–6), which is illustrated in Figure 122–7.

$$RS = \max(-4.8, SECQ - 6.2) \quad \text{(dBm)} \tag{122–4}$$

$$RS = \max(-6.6, SECQ - 8) \quad \text{(dBm)} \tag{122–5}$$

$$RS = \max(-16.1, SECQ - 17.5) \quad \text{(dBm)} \tag{122–6}$$

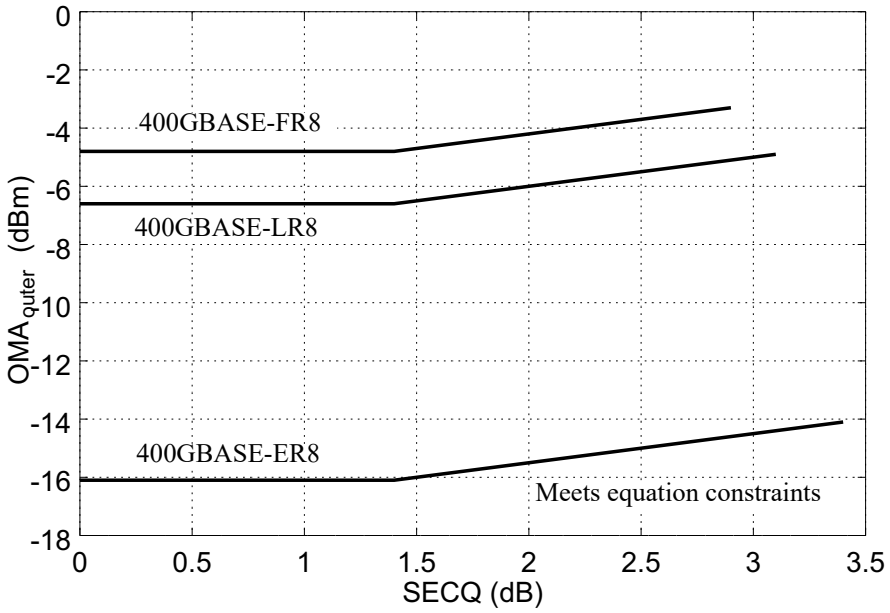

Figure 122–7—Illustration of receiver sensitivity for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8

The normative requirement for receivers is stressed receiver sensitivity.

122.8.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 122–11 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–12 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 if measured using the method defined in 122.8.10.1 and 122.8.10.3, with the conformance test signal at TP3 as described in 122.8.10.2, using the test pattern specified for SRS in Table 122–15. The BER is required to be met for the lane under test on its own.

Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Any of the patterns specified for SRS in Table 122–15 is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.

122.8.10.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 122–8. The patterns used for the received conformance signal are specified in Table 122–15. The optical test signal is conditioned (stressed) using the stressed receiver methodology defined in 122.8.10.2 and has sinusoidal jitter applied as specified in 121.8.10.4. A suitable test set is needed to characterize the signal used to test the receiver. Stressed receiver conformance test signal verification is described in 122.8.10.3.

The low-pass filter is used to create ISI. The sinusoidal amplitude interferer causes additional eye closure, but in conjunction with the finite edge rates, also causes some jitter.

The sinusoidally jittered clock represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter. The sinusoidal amplitude interferer may be set at any frequency between

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

100 MHz and 2 GHz, although care should be taken to avoid harmonic relationships between the sinusoidal interferer, the sinusoidal jitter, the signaling rate, and the pattern repetition rate. The Gaussian noise generator, the amplitude of the sinusoidal interferer, and the low-pass filter are adjusted so that the SECQ specified in Table 122–11 or Table 122–12 is met, according to the methods specified in 122.8.10.2.

For improved visibility for calibration, all elements in the signal path (cables, DC blocks, E/O converter, etc.) should have wide and smooth frequency response, and linear phase response, throughout the spectrum of interest. Baseline wander and overshoot and undershoot should be negligible.

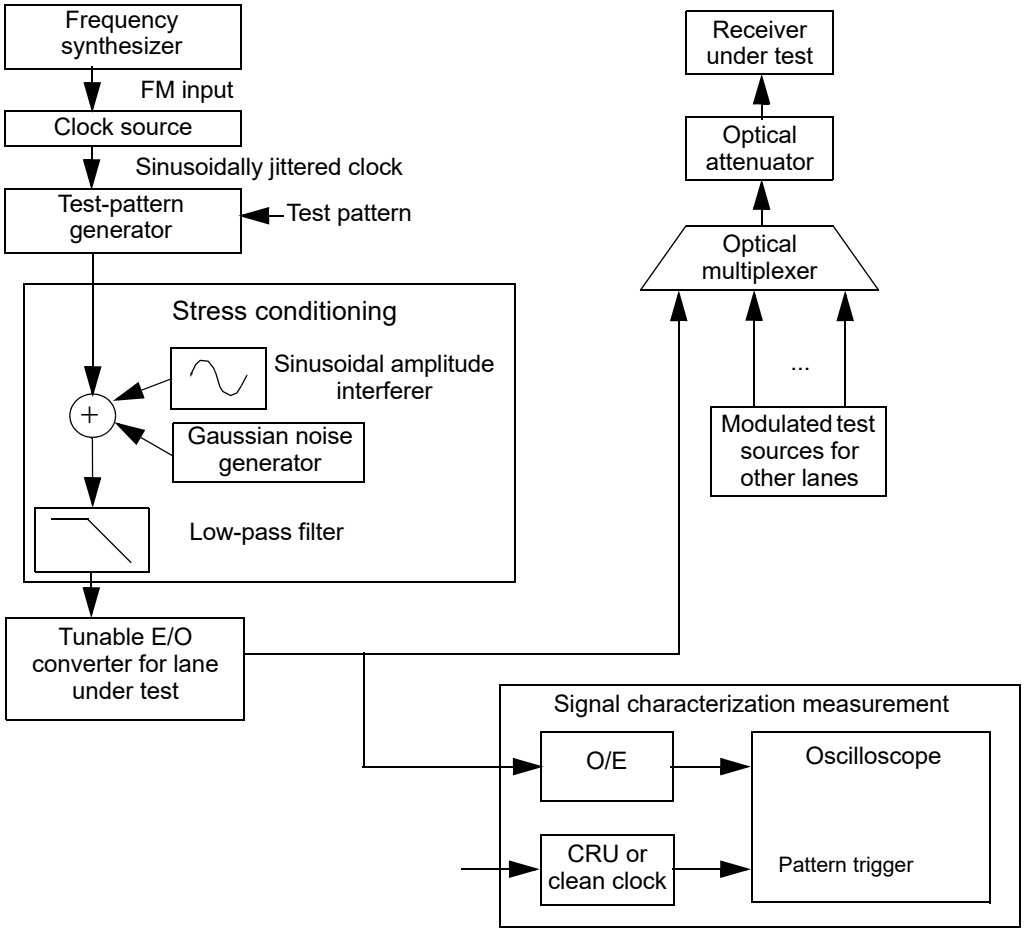

Figure 122–8—Stressed receiver conformance test block diagram

122.8.10.2 Stressed receiver conformance test signal characteristics and calibration

The stressed receiver conformance test signal characteristics and calibration methods are as described in 121.8.10.2 with the following exceptions:

— The SECQ of the stressed receiver conformance test signal is measured according to 122.8.5, except that the test fiber is not used. The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.

— An example stressed receiver conformance test setup is shown in Figure 122–8; however, alternative test setups that generate equivalent stress conditions may be used.

— With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_{xx.x}$OMA of the SRS test source should be no greater than the value specified in Table 122–9 for

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.

— The signaling rate of the test pattern generator and the extinction ratio of the E/O converter are as given in Table 122–9 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–10 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.

— The required values of the "Stressed receiver sensitivity (OMA_{outer}), each lane (max)", "Stressed eye closure for PAM4 (SECQ), lane under test", "SECQ – $10\log_{10}(C_{eq})$ (max), lane under test", and "OMA_{outer} of each aggressor lane" are as given in Table 122–11 for 200GBASE-FR4, 200GBASE-LR4, and 200GBASE-ER4 and in Table 122–12 for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.

122.8.10.3 Stressed receiver conformance test signal verification

The SECQ of the stressed receiver conformance test signal is measured according to 122.8.5, except that the test fiber is not used. The clock output from the clock source in Figure 122–8 is modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye jitter that includes the sinusoidal jitter component, a separate clock source (clean clock of Figure 122–8) is required that is synchronized to the source clock, but not modulated with the jitter source.

Care should be taken when characterizing the test signal because excessive noise/jitter in the measurement system would result in an input signal that does not fully stress the receiver under test. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. The noise/jitter introduced by the O/E, filters, and oscilloscope should be negligible or the results should be corrected for its effects. While the details of test equipment are beyond the scope of this standard, it is recommended that the implementer fully characterize the test equipment and apply appropriate guard bands so that the stressed receiver conformance input signal meets the stress and sinusoidal jitter specified in 122.8.10.2 and 121.8.10.4.

122.9 Safety, installation, environment, and labeling

122.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

122.9.2 Laser safety

200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, and 400GBASE-LR8 optical transceivers shall conform to Hazard Level 1 laser requirements and 400GBASE-ER8 optical transceivers shall conform to Hazard Level 1M laser requirements, as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[210]

[210]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

122.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

122.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, or 400GBASE-ER8 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

122.9.5 Electromagnetic emission

A system integrating a 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, or 400GBASE-ER8 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

122.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

122.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 400GBASE-FR8).

Labeling requirements for Hazard Level 1 and Hazard Level 1M lasers are given in the laser safety standards referenced in 122.9.2.

122.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 122–9.

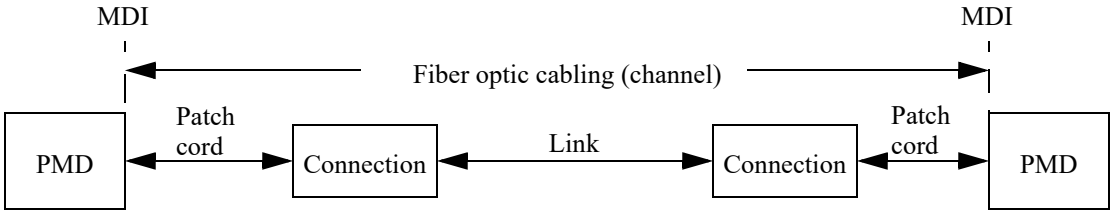

Figure 122–9—Fiber optic cabling model

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The channel insertion loss is given in Table 122–17. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 122–17—Fiber optic cabling (channel) characteristics

Description	200GBASE-FR4	400GBASE-FR8	200GBASE-LR4	400GBASE-LR8	200GBASE-ER4		400GBASE-ER8		Unit
Operating distance (max)	2		10		30	40	30	40	km
Channel insertion loss[a,b] (max)	4		6.3[c]		18		18		dB
Channel insertion loss (min)	0		0		10[d]				dB
Positive dispersion[b] (max)	6.7	1.9	9.5		28	37	28	37	ps/nm
Negative dispersion[b] (min)	–11.9	–10.2	–28.4	–50.8	–85	–114	–151	–201	ps/nm
DGD_max[e]	3		8		10.3				ps
Optical return loss (min)	25		22		19				dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1264.5 nm to 1337.5 nm for 200GBASE-FR4, 1294.53 nm to 1310.19 nm for 200GBASE-LR4 and 200GBASE-ER4, and 1272.55 nm to 1310.19 nm for 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8.
[c] Using 0.46 dB/km at 1272.55 nm attenuation for optical fiber cables derived from Appendix I of ITU-T G.695 may not support operation at 10 km for 400GBASE-LR8 under worst case conditions.
[d] Channel insertion loss (min) may be implemented with an optical attenuator.
[e] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

122.11 Characteristics of the fiber optic cabling (channel)

The 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8 fiber optic cabling shall meet the specifications defined in Table 122–17. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

122.11.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion un-shifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 122–18 where they differ.

122.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 122–9, consists of a mated pair of optical connectors.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 122–18—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.47[a] or 0.5[b]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \le \lambda_0 \le 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a] The 0.47 dB/km at 1264.5 nm attenuation for optical fiber cables is derived from Appendix I of ITU-T G.695.
[b] The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3. Using 0.5 dB/km may not support operation at 10 km for 200GBASE-LR4 or 400GBASE-LR8 or at 40 km for 200GBASE-ER4 or 400GBASE-ER8.

122.11.2.1 Connection insertion loss

The maximum link distance for 200GBASE-LR4, 200GBASE-ER4, 400GBASE-LR8, and 400GBASE-ER8 is based on an allocation of 2 dB total connection and splice loss. For example, this allocation supports four connections with an average insertion loss per connection of 0.5 dB. The maximum link distance for 200GBASE-FR4 and 400GBASE-FR8 is based on an allocation of 3 dB total connection and splice loss. Connections with different loss characteristics may be used provided the requirements of Table 122–17 are met.

122.11.2.2 Maximum discrete reflectance

The maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 122–19 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

Table 122–19—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance		
	200GBASE-FR4 or 400GBASE-FR8	200GBASE-LR4 or 400GBASE-LR8	200GBASE-ER4 or 400GBASE-ER8
1	–25 dB	–22 dB	–19 dB
2	–31 dB	–29 dB	–27 dB
4	–35 dB	–33 dB	–32 dB
6	–38 dB	–35 dB	–35 dB
8	–40 dB	–37 dB	–37 dB
10	–41 dB	–39 dB	–39 dB

122.11.3 Medium Dependent Interface (MDI) requirements

The 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, or 400GBASE-ER8 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 122–9). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1-1 and IEC 61753-021-2.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 122.5.1, not at the MDI.

122.12 Requirements for interoperation between 200GBASE-ER4 and 200GBASE-LR4

The 200GBASE-ER4 and 200GBASE-LR4 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 200GBASE-LR4 are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 122–20 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 122–20—Channel insertion loss requirements for interoperation between 200GBASE-ER4 and 200GBASE-LR4

Direction	Min loss	Max loss	Unit
200GBASE-ER4 transmitter to 200GBASE-LR4 receiver	2.3	10.1	dB
200GBASE-LR4 transmitter to 200GBASE-ER4 receiver	8.7	14.2	dB

122.13 Requirements for interoperation between 400GBASE-ER8 and 400GBASE-FR8

The 400GBASE-ER8 and 400GBASE-FR8 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 400GBASE-FR8 are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 122–21 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 122–21—Channel insertion loss requirements for interoperation between 400GBASE-ER8 and 400GBASE-FR8

Direction	Min loss	Max loss	Unit
400GBASE-ER8 transmitter to 400GBASE-FR8 receiver	0.7	6.9	dB
400GBASE-FR8 transmitter to 400GBASE-ER8 receiver	9.7	15.1	dB

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

122.14 Requirements for interoperation between 400GBASE-ER8 and 400GBASE-LR8

The 400GBASE-ER8 and 400GBASE-LR8 PMDs can interoperate with each other (over an engineered link) provided that the fiber optic cabling (channel) characteristics for 400GBASE-LR8 are met, with the exception of the maximum and minimum channel insertion loss values, which are given in Table 122–22 for the two link directions separately. Attenuators may be used to achieve the required losses.

Table 122–22—Channel insertion loss requirements for interoperation between 400GBASE-ER8 and 400GBASE-LR8

Direction	Min loss	Max loss	Unit
400GBASE-ER8 transmitter to 400GBASE-LR8 receiver	0.7	8.5	dB
400GBASE-LR8 transmitter to 400GBASE-ER8 receiver	9.7	15.8	dB

122.15 Protocol implementation conformance statement (PICS) proforma for Clause 122, Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8[211]

122.15.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 122, Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

122.15.2 Identification

122.15.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

122.15.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 122, Physical Medium Dependent (PMD) sublayer and medium, type 200GBASE-FR4, 200GBASE-LR4, 200GBASE-ER4, 400GBASE-FR8, 400GBASE-LR8, and 400GBASE-ER8
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[211] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

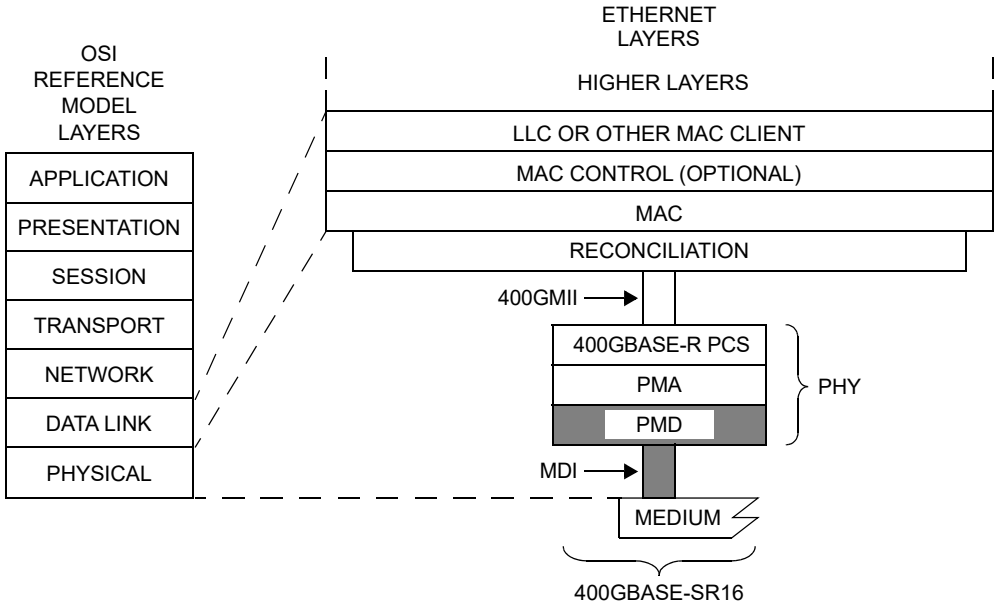
123. Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR16

123.1 Overview

This clause specifies the 400GBASE-SR16 PMD together with the multimode fiber medium. The PMD sublayer provides a point-to-point 400 Gb/s Ethernet link over 16 pairs of multimode fiber, up to at least 100 m. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 123–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 123–1—Physical Layer clauses associated with the 400GBASE-SR16 PMD

Associated clause	400GBASE-SR16
117—RS	Required
117—400GMII[a]	Optional
118—400GMII Extender	Optional
119—PCS	Required
120—PMA	Required
120B—Chip-to-chip 400GAUI-16	Optional
120C—Chip-to-module 400GAUI-16	Optional
120D—Chip-to-chip 400GAUI-8	Optional
120E—Chip-to-module 400GAUI-8	Optional
78—Energy Efficient Ethernet	Optional



[a] The 400GMII is an optional interface. However, if the 400GMII is not implemented, a conforming implementation behaves functionally as though the RS and 400GMII were present.

Figure 123–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 400 Gb/s Ethernet is introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

400GBASE-SR16 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions and abbreviations) and Annex A (bibliography, referenced as [B1], [B2], etc.).

400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
SR = PMD FOR MULTIMODE FIBER

Figure 123–1—400GBASE-SR16 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

123.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when processed according to Clause 119. For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

123.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 400GBASE-SR16 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMD service interface is an instance of the inter-sublayer service interface defined in 116.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 400GBASE-SR16 PMD has 16 parallel bit streams, hence $i = 0$ to 15.

In the transmit direction, the PMA continuously sends 16 parallel bit streams to the PMD, one per lane, each at a nominal signaling rate of 26.5625 GBd. The PMD converts these streams of bits into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends 16 parallel bit streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service primitive defined in 116.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 123.1.1.

123.3 Delay and Skew

123.3.1 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The sum of the transmit and receive delays at one end of the link contributed by the 400GBASE-SR16 PMD including 2 m of fiber in one direction shall be no more than 8192 bit times (16 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

123.3.2 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the PCS sublayer. Skew and Skew Variation are defined in 116.5 and specified at the points SP1 to SP6 shown in Figure 116–4 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For more information on Skew and Skew Variation see 116.5. The measurements of Skew and Skew Variation are defined in 86.8.3.1.

123.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 123–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 123–3.

Table 123–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 15	PMD transmit disable extension register	1.27.0	PMD_transmit_disable_15
PMD transmit disable 14 to PMD transmit disable 0	PMD transmit disable register	1.9.15 to 1.9.1	PMD_transmit_disable_14 to PMD_transmit_disable_0

Table 123–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 15	PMD receive signal detect extension register	1.28.0	PMD_signal_detect_15
PMD receive signal detect 14 to PMD receive signal detect 0	PMD receive signal detect register	1.10.15 to 1.10.1	PMD_signal_detect_14 to PMD_signal_detect_0

123.5 PMD functional specifications

The 400GBASE-SR16 PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

123.5.1 PMD block diagram

The PMD block diagram is shown in Figure 123–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a multimode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 123.8 are made at TP2. The optical receive signal is defined at

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the output of the fiber optic cabling (TP3) at the MDI (see 123.11.3). Unless specified otherwise, all receiver measurements and tests defined in 123.8 are made at TP3.

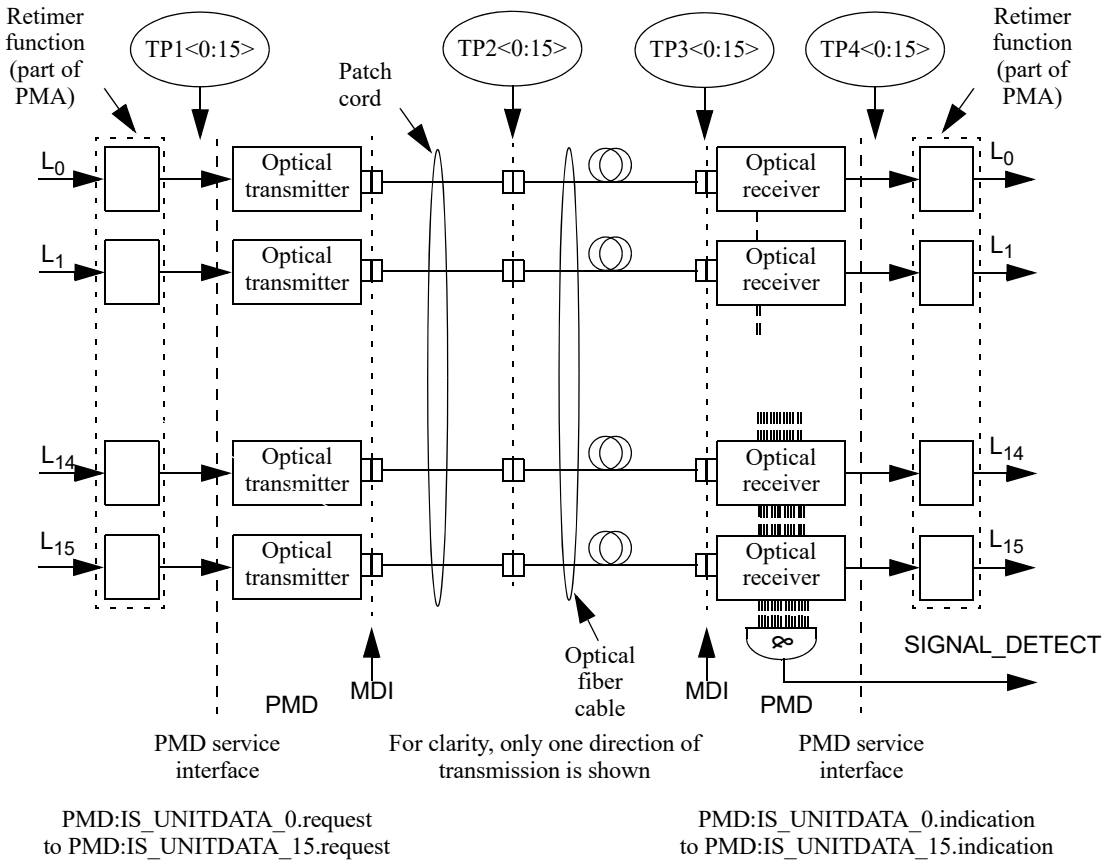

Figure 123–2—Block diagram for 400GBASE-SR16 transmit/receive paths

TP1 and TP4 are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

123.5.2 PMD transmit function

The PMD Transmit function shall convert the 16 bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_15.request into 16 optical signals. The optical signals shall then be delivered to the MDI which contains 16 parallel light paths for transmit, according to the transmit optical specifications in this clause. The higher optical power level in each signal shall correspond to tx_symbol = one.

123.5.3 PMD receive function

The PMD Receive function shall convert the 16 optical signals received from the MDI into separate bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_15.indication, all according to the receive optical specifications in this clause. The higher optical power level in the signal shall correspond to rx_symbol = one.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

123.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 116.3.

SIGNAL_DETECT shall be an indicator of the presence of the optical signals on all 16 lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 123–4. The PMD receiver is not required to verify whether a compliant 400GBASE-SR16 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 123–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 95–7) AND (compliant 400GBASE-SR16 signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the PMD global signal detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signals and implementations that respond to the average optical power of the modulated optical signals. When the MDIO is implemented, the SIGNAL_DETECT value shall be continuously set in response to the magnitude of the optical signals, according to the requirements of Table 123–4.

123.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:15, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 123–4.

123.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

123.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 95–6.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

123.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitter in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:15) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 95–6.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane.

123.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

123.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set PMD_transmit_fault to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

123.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

123.6 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for 400GBASE-SR16. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the physical ordering of the lanes, as the PCS sublayer is capable of receiving the lanes in any arrangement. The positioning of transmit and receive lanes at the MDI is specified in 123.11.3.

123.7 PMD to MDI optical specifications for 400GBASE-SR16

The operating range for the 400GBASE-SR16 PMD is defined in Table 123–5. A 400GBASE-SR16 compliant PMD operates on 50/125 μm multimode fibers, type A1a.2 (OM3), type A1a.3 (OM4), or type A1a.4 (OM5), according to the specifications defined in Table 123–6. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 400GBASE-SR16 PMD operating at 120 m meets the operating range requirement of 0.5 m to 100 m). The operating range shown in Table 123–5 is the same as 100GBASE-SR4 (See Clause 95).

Table 123–5—400GBASE-SR16 operating range

PMD type	Required operating range[a]
400GBASE-SR16	0.5 m to 70 m for OM3
	0.5 m to 100 m for OM4
	0.5 m to 100 m for OM5

[a] The PCS FEC correction function may not be bypassed for any operating distance.

123.7.1 400GBASE-SR16 transmitter optical specifications

The optical characteristics of each lane of a 400GBASE-SR16 transmitter shall be the same as those of a single lane of 100GBASE-SR4, as specified in Table 95–6 and 95.7.1, with the exception that the "signaling rate, each lane" is 26.5625 GBd ± 100 ppm, TDEC is as specified in 123.8.5, and the BER requirement is as specified in 123.1.1.

123.7.2 400GBASE-SR16 receive optical specifications

The optical characteristics of each lane of a 400GBASE-SR16 receiver shall be the same as those of a single lane of 100GBASE-SR4, as specified in Table 95–7 and 95.7.2, with the exception that the "signaling rate, each lane" is 26.5625 GBd ± 100 ppm, stressed receiver sensitivity is as specified in 123.8.8, and the BER requirement is as specified in 123.1.1.

123.7.3 400GBASE-SR16 illustrative link power budget

The illustrative power budget and penalties for each lane of a 400GBASE-SR16 link are the same as those of a single lane of 100GBASE-SR4, as specified in Table 95–8 and 95.7.3.

123.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified. Optical parameters and measurement methods for 400GBASE-SR16 are the same as for 100GBASE-SR4.

123.8.1 Test patterns for optical parameters

The test patterns used in this clause shall be the same as those used for 100GBASE-SR4, as described in 95.8.1 and shown in Table 95–9, with the exception that pattern 5 defined in 82.2.11 is encoded by Clause 119 PCS for 400GBASE-SR16. Table 95–10 as modified by this subclause (123.8.1) shows the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined.

123.8.2 Center wavelength and spectral width

The center wavelength and RMS spectral width shall be within the range given in Table 95–6 if measured per IEC 61280-1-3. The transmitter is modulated using one of the test patterns specified in Table 95–10 as modified by 123.8.1.

123.8.3 Average optical power

The average optical power shall be within the limits given in Table 95–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using one of the test patterns specified in Table 95–10 as modified by 123.8.1.

123.8.4 Optical Modulation Amplitude (OMA)

OMA shall be within the limits given in Table 95–6 if measured as defined in 52.9.5 for measurement with a square wave (8 ones, 8 zeros) test pattern or as defined in 68.6.2 (from the variable MeasuredOMA in 68.6.6.2) for measurement with a PRBS9 test pattern. See 123.8.1 for test pattern information.

123.8.5 Transmitter and dispersion eye closure (TDEC)

TDEC is a measure of the optical transmitter's vertical eye closure, as described in 95.8.5. TDEC shall be within the limits given in Table 95–6 if measured using the methods specified in 95.8.5.1 and 95.8.5.2, with the exceptions that the clock recovery unit (CRU) has a corner frequency of 4 MHz and in Equation (95–6), 3.8906R is replaced by 3.4917R, for consistency with the BER of 2.4×10^{-4} given in 123.1.1. Table 95–10 as modified by 123.8.1 specifies the test patterns to be used for measurement of TDEC.

123.8.6 Extinction ratio

The extinction ratio shall be within the limits given in Table 95–6 if measured using the methods specified in IEC 61280-2-2. The extinction ratio is measured using one of the test patterns specified for extinction ratio in Table 95–10 as modified by 123.8.1.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 95–10).

123.8.7 Transmitter optical waveform (transmit eye)

The transmitter optical waveform of a port transmitting the test pattern specified in Table 95–10 as modified by 123.8.1 shall meet the transmitter eye mask coordinates and hit ratio specified in Table 95–6 if measured according to the methods specified in 95.8.7 with the exception that the clock recovery unit's high frequency corner bandwidth is 4 MHz.

123.8.8 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 95–7 if measured using the methods defined in 95.8.8 with the following exceptions:

- The signaling rate of the test pattern generator is set to the rate defined in 123.7.2.
- The clock recovery unit (CRU) has a corner bandwidth of 4 MHz.
- Sinusoidal jitter is added as specified in Table 87–13 instead of Table 95–11.
- When using 95.8.5 to measure the SEC of the stressed receiver conformance test signal, the BER requirement is as specified in 123.1.1 and 3.4917R replaces 3.8906R in Equation (95–6).
- The hit ratio for the stressed receiver eye mask definition is changed from 5×10^{-5} to 2.4×10^{-4}.

123.9 Safety, installation, environment, and labeling

123.9.1 General safety

All equipment subject to this clause shall conform to IEC 60950-1.

123.9.2 Laser safety

400GBASE-SR16 optical transceivers shall conform to Hazard Level 1M laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[212]

123.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

123.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 400GBASE-SR16 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate, in the literature associated with the PHY, the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

123.9.5 Electromagnetic emission

A system integrating a 400GBASE-SR16 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

123.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

[212]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

123.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 400GBASE-SR16).

Labeling requirements for Hazard Level 1M lasers are given in the laser safety standards referenced in 123.9.2.

123.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 123–3. The fiber type and length are the same as 100BASE-SR4 (see Clause 95).

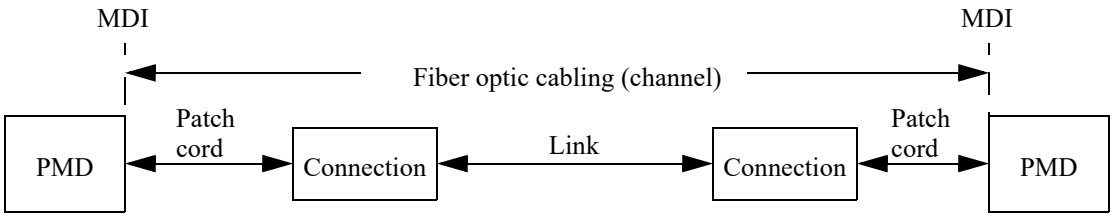

Figure 123–3—Fiber optic cabling model

The channel insertion loss is given in Table 123–6. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, modal dispersion, reflections and losses of all connectors and splices meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method. As OM4 and OM5 optical fiber meet the requirements for OM3, a channel compliant to the "OM3" column may use OM4 or OM5 optical fiber, or a combination of OM3, OM4, and OM5. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 123–6—Fiber optic cabling (channel) characteristics for 400GBASE-SR16

Description	OM3	OM4	OM5	Unit
Operating distance (max)	70	100	100	m
Channel insertion loss[a] (max)	1.8	1.9	1.9	dB
Channel insertion loss (min)	0			dB

[a] These channel insertion loss values include cable loss plus 1.5 dB allocated for connection and splice loss, over the wavelength range 840 nm to 860 nm.

123.11 Characteristics of the fiber optic cabling (channel)

The 400GBASE-SR16 fiber optic cabling shall meet the specifications defined in Table 123–6. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. The requirements for the optical fiber, connection insertion loss, and maximum discrete reflectance are the same as 100GBASE-SR4 (see Clause 95).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

123.11.1 Optical fiber cable

The fiber contained within the 400GBASE-SR16 fiber optic cabling shall comply with the specifications and parameters of Table 123–7. A variety of multimode cable types may satisfy these requirements, provided the resulting channel also meets the specifications of Table 123–6.

Table 123–7—Optical fiber and cable characteristics

Description	OM3[a]	OM4[b]	OM5[c]	Unit
Nominal core diameter	50			μm
Nominal fiber specification wavelength	850			nm
Effective modal bandwidth (min)[d]	2000	4700		MHz.km
Cabled optical fiber attenuation (max)	3.5			dB/km
Zero dispersion wavelength (λ_0)	$1295 \le \lambda_0 \le 1340$		$1297 \le \lambda_0 \le 1328$	nm
Chromatic dispersion slope (max) (S_0)	0.105 for $1295 \le \lambda_0 \le 1310$ and $0.000375 \times (1590 - \lambda_0)$ for $1310 \le \lambda_0 \le 1340$		$-412/(840(1-(\lambda_0/840)^4))$ for $1297 \le \lambda_0 \le 1328$	ps/nm^2 km

[a] IEC 60793-2-10 type A1a.2.
[b] IEC 60793-2-10 type A1a.3.
[c] IEC 60793-2-10 type A1a.4.
[d] When measured with the launch conditions specified in Table 95–6.

123.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 123–3, consists of a mated pair of optical connectors.

123.11.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 1.5 dB total connection and splice loss. For example, this allocation supports three connections with an average insertion loss per connection of 0.5 dB. Connections with lower loss characteristics may be used provided the requirements of Table 123–6 are met. However, the loss of a single connection shall not exceed 0.75 dB.

123.11.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

123.11.3 Medium Dependent Interface (MDI)

The 400GBASE-SR16 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 123–3). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

123.11.3.1 Optical lane assignments

The 16 transmit and 16 receive optical lanes of 400GBASE-SR16 shall occupy the positions depicted in Figure 123–4 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains 32 active lanes. The transmit optical lanes occupy the upper 16 positions. The receive optical lanes occupy the lower 16 positions.

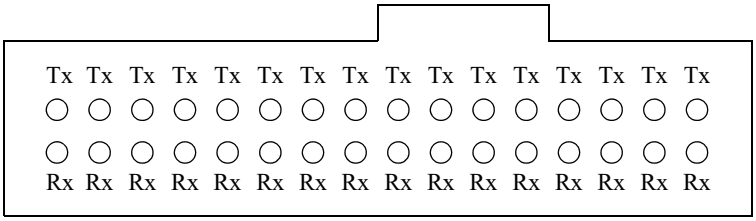

Figure 123–4—400GBASE-SR16 optical lane assignments

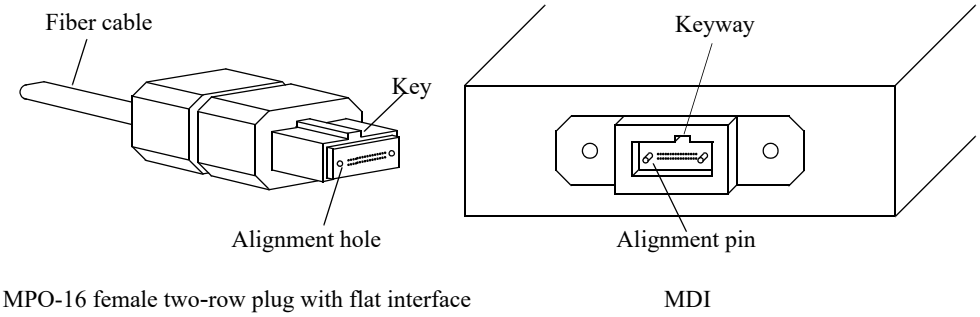

Figure 123–5—MPO-16 female two-row plug with flat interface, and an MDI

123.11.3.2 Medium Dependent Interface (MDI) requirements

The MDI adapter or receptacle shall meet the dimensional specifications for designation FOCIS 18 A-k-0 as defined in ANSI/TIA-604-18. The plug terminating the optical fiber cabling shall meet the dimensional specifications of designation FOCIS 18 P-2x16-1-0-2-2 as defined in ANSI/TIA-604-18. The MDI shall optically mate with the plug on the optical fiber cabling. Figure 123–5 shows an MPO-16 female two-row plug with flat interface, and an MDI. The MDI shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2 for performance Class Cm/2m.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 123.5.1, not at the MDI.

123.12 Protocol implementation conformance statement (PICS) proforma for Clause 123, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR16[213]

123.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 123, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR16, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

123.12.2 Identification

123.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

123.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 123, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-SR16
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[213]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

124. Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-DR4

124.1 Overview

This clause specifies the 400GBASE-DR4 PMD together with the single-mode fiber medium. The optical signal generated by this PMD type is modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 124–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 124–1—Physical Layer clauses associated with the 400GBASE-DR4 PMD

Associated clause	400GBASE-DR4
117—RS	Required
117—400GMII[a]	Optional
118—400GMII Extender	Optional
119—PCS	Required
120—PMA	Required
120B—Chip-to-chip 400GAUI-16	Optional
120C—Chip-to-module 400GAUI-16	Optional
120D—Chip-to-chip 400GAUI-8	Optional
120E—Chip-to-module 400GAUI-8	Optional
78—Energy Efficient Ethernet	Optional

[a] The 400GMII is an optional interface. However, if the 400GMII is not implemented, a conforming implementation behaves functionally as though the RS and 400GMII were present.

Figure 124–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 400 Gb/s Ethernet is introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

400GBASE-DR4 PHYs with the optional Energy Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

124.1.1 Bit error ratio

The bit error ratio (BER) when processed according to Clause 120 shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when processed according to Clause 120 and then Clause 119. For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

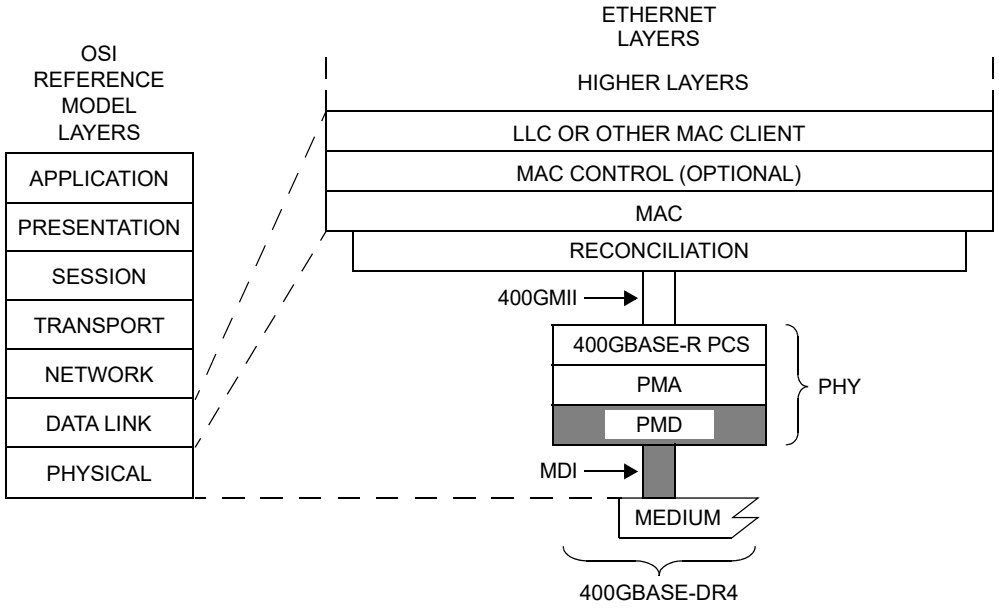

Figure 124–1—400GBASE-DR4 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

124.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 400GBASE-DR4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The PMD service interface is an instance of the inter-sublayer service interface defined in 116.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 400GBASE-DR4 PMD has four parallel symbol streams, hence $i = 0$ to 3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the transmit direction, the PMA continuously sends four parallel symbol streams to the PMD, one per lane, each at a nominal signaling rate of 53.125 GBd. The PMD then converts these streams of data units into the appropriate signals on the MDI.

In the receive direction, the PMD continuously sends four parallel symbol streams to the PMA corresponding to the signals received from the MDI, one per lane, each at a nominal signaling rate of 53.125 GBd. See NOTE at the end of 120.5.2 concerning the transition density of lanes operating at this nominal signaling rate.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication(SIGNAL_OK) inter-sublayer service interface primitive defined in 116.3.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 124.1.1.

124.3 Delay and Skew

124.3.1 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the 400GBASE-DR4 PMD including 2 m of fiber in one direction shall be no more than 8192 bit times (16 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 116.4 and its references.

124.3.2 Skew constraints

The Skew (relative delay between the lanes) and Skew Variation are kept within limits so that the information on the lanes can be reassembled by the PCS. Skew and Skew Variation are defined in 116.5 and specified at the points SP1 to SP6 shown in Figure 116–4 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 116.5. The measurements of Skew and Skew Variation are defined in 86.8.3.1.

124.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

control variables to PMD control variables shall be as shown in Table 124–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 124–3.

Table 124–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable 3 to PMD transmit disable 0	PMD transmit disable register	1.9.4 to 1.9.1	PMD_transmit_disable_3 to PMD_transmit_disable_0

Table 124–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect 3 to PMD receive signal detect 0	PMD receive signal detect register	1.10.4 to 1.10.1	PMD_signal_detect_3 to PMD_signal_detect_0

124.5 PMD functional specifications

The 400GBASE-DR4 PMD performs the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

124.5.1 PMD block diagram

The PMD block diagram is shown in Figure 124–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 124.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 124.11.3). Unless specified otherwise, all receiver measurements and tests defined in 124.8 are made at TP3.

TP1<0:3> and TP4<0:3> are optional reference points that may be useful to implementors for testing components (these test points will not typically be accessible in an implemented system).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

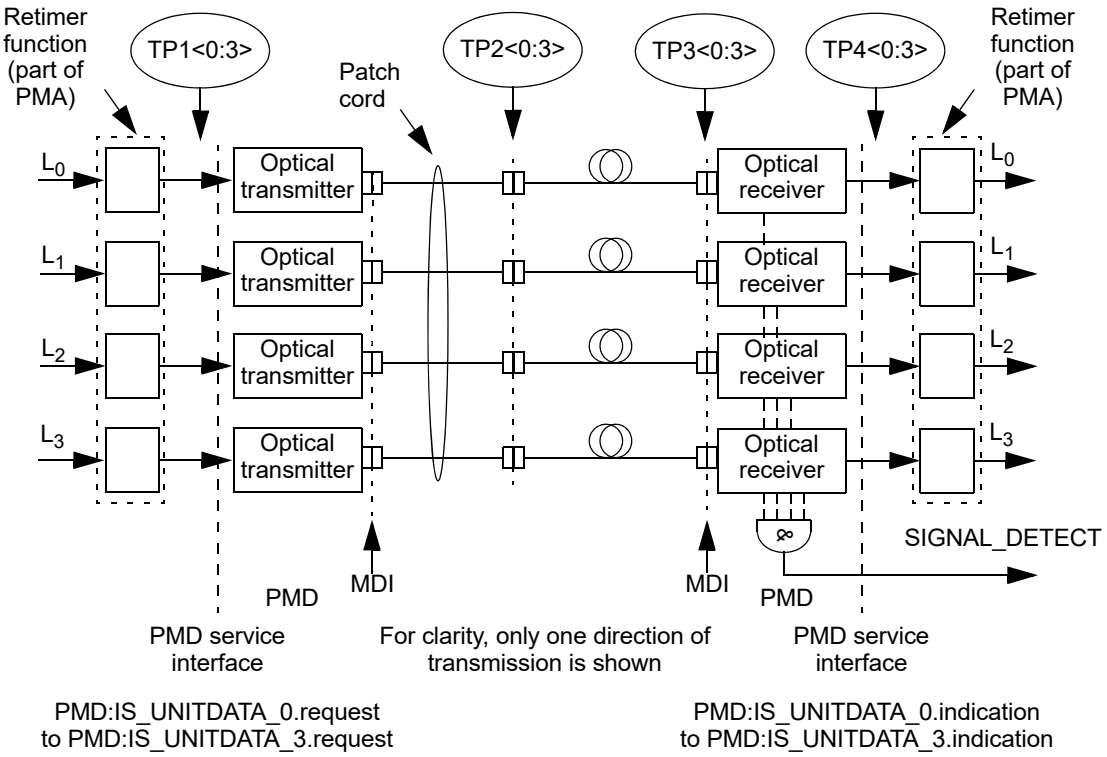

Figure 124–2—Block diagram for 400GBASE-DR4 transmit/receive paths

124.5.2 PMD transmit function

The PMD Transmit function shall convert the four symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate optical signals. The four optical signals shall then be delivered to the MDI, which contains four parallel light paths for transmit, according to the transmit optical specifications in this clause. The highest optical power level in each signal shall correspond to tx_symbol = three and the lowest shall correspond to tx_symbol = zero.

124.5.3 PMD receive function

The PMD Receive function shall convert the four parallel optical signals received from the MDI into separate symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication, all according to the receive optical specifications in this clause. The higher optical power level in each signal shall correspond to rx_symbol = three and the lowest shall correspond to rx_symbol = zero.

124.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 116.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all four lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 124–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMD receiver is not required to verify whether a compliant 400GBASE-DR4 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 124–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –15 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) Table 124–7) AND (compliant 400GBASE–R signal input)]	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

124.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:3, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 124–4.

124.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

124.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 124–6.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

124.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitters in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 124–6.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane for testing purposes.

124.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

124.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

124.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

124.6 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for 400GBASE-DR4. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the physical ordering of the lanes, as the PCS sublayer is capable of receiving the lanes in any arrangement. The positioning of transmit and receive lanes at the MDI is specified in 124.11.3.1.

124.7 PMD to MDI optical specifications for 400GBASE-DR4

The operating range for the 400GBASE-DR4 PMD is defined in Table 124–5. A 400GBASE-DR4 compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 124–12. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 400GBASE-DR4 PMD operating at 600 m meets the operating range requirement of 2 m to 500 m).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 124–5—400GBASE-DR4 operating range

PMD type	Required operating range
400GBASE-DR4	2 m to 500 m

124.7.1 400GBASE-DR4 transmitter optical specifications

The 400GBASE-DR4 transmitter shall meet the specifications defined in Table 124–6 per the definitions in 124.8.

Table 124–6—400GBASE-DR4 transmit characteristics

Description	Value	Unit
Signaling rate, each lane (range)	53.125 ± 100 ppm	GBd
Modulation format	PAM4	—
Lane wavelength (range)	1304.5 to 1317.5	nm
Side-mode suppression ratio (SMSR), (min)	30	dB
Average launch power, each lane (max)	4	dBm
Average launch power, each lane[a] (min)	–2.9	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	4.2	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min)[b]	–0.8	dBm
Launch power in OMA_{outer} minus TDECQ, each lane (min)	–2.2	dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	3.4	dB
TDECQ – $10\log_{10}(C_{eq})$[c] (max)	3.4	dB
Average launch power of OFF transmitter, each lane (max)	–15	dBm
Extinction ratio, each lane (min)	3.5	dB
Transmitter transition time (max)	17	ps
$RIN_{21.4}OMA$ (max)	–136	dB/Hz
Optical return loss tolerance (max)	21.4	dB
Transmitter reflectance[d] (max)	–26	dB

[a] Average launch power, each lane (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] Even if the TDECQ < 1.4 dB, the OMA_{outer} (min) has to exceed this value.
[c] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d] Transmitter reflectance is defined looking into the transmitter.

124.7.2 400GBASE-DR4 receive optical specifications

The 400GBASE-DR4 receiver shall meet the specifications defined in Table 124–7 per the definitions in 124.8. See NOTE at the end of 120.5.2 concerning the transition density of lanes operating at this nominal signaling rate.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 124–7—400GBASE-DR4 receive characteristics

Description	Value	Unit
Signaling rate, each lane (range)	53.125 ± 100 ppm	GBd
Modulation format	PAM4	—
Lane wavelengths (range)	1304.5 to 1317.5	nm
Damage threshold[a], each lane	5	dBm
Average receive power, each lane (max)	4	dBm
Average receive power, each lane[b] (min)	–5.9	dBm
Receive power (OMA_{outer}), each lane (max)	4.2	dBm
Receiver reflectance (max)	–26	dB
Receiver sensitivity (OMA_{outer}), each lane[c] (max)	Equation (124–1)	dBm
Stressed receiver sensitivity (OMA_{outer}), each lane[d] (max)	–1.9	dBm
Conditions of stressed receiver sensitivity test:[e]		
Stressed eye closure for PAM4 (SECQ), lane under test	3.4	dB
SECQ – $10\log_{10}(C_{eq})$[f] (max), lane under test	3.4	dB
OMA_{outer} of each aggressor lane	4.2	dBm

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level. The receiver does not have to operate correctly at this input power.
[b] Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity (OMA_{outer}), each lane (max) is optional and is defined for a transmitter with a value of SECQ up to 3.4 dB.
[d] Measured with conformance test signal at TP3 (see 124.8.10) for the BER specified in 124.1.1.
[e] These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.
[f] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.

124.7.3 400GBASE-DR4 illustrative link power budget

An illustrative power budget and penalties for 400GBASE-DR4 channels are shown in Table 124–8.

Table 124–8—400GBASE-DR4 illustrative link power budget

Parameter	Value	Unit
Power budget (for max TDECQ)	6.5	dB
Operating distance	500	m
Channel insertion loss[a]	3	dB
Maximum discrete reflectance	See 124.11.2.2	dB
Allocation for penalties[b] (for max TDECQ)	3.5	dB
Additional insertion loss allowed	0	dB

[a] The channel insertion loss is calculated using the maximum distance specified in Table 124–5 and cabled optical fiber attenuation of 0.5 dB/km at 1304.5 nm plus an allocation for connection and splice loss given in 124.11.2.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

[b] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

124.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

124.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 124–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 124–10 may be used to perform that test. The test patterns used in this clause are shown in Table 124–9.

Table 124–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle	119.2.4.9
6	SSPRQ	120.5.11.2.3

Table 124–10—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 400GBASE-R signal	124.8.2
Side mode suppression ratio	3, 5, 6 or valid 400GBASE-R signal	124.8.2
Average optical power	3, 5, 6 or valid 400GBASE-R signal	124.8.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	124.8.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	124.8.5
Extinction ratio	4 or 6	124.8.6
Transmitter transition time	Square wave or 6	124.8.7
$RIN_{21.4}OMA$	Square wave	124.8.8
Stressed receiver conformance test signal calibration	6	124.8.10
Stressed receiver sensitivity	3 or 5	124.8.10

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

124.8.2 Wavelength and side mode suppression ratio (SMSR)

The wavelength and SMSR of each optical lane shall be within the range given in Table 124–6 if measured per IEC 61280-1-3. The lane under test is modulated using the test pattern defined in Table 124–10.

124.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 124–6 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using the test pattern defined in Table 124–10.

124.8.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} of each lane shall be within the limits given in Table 124–6. The OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 124–10 as the difference between the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 124–3.

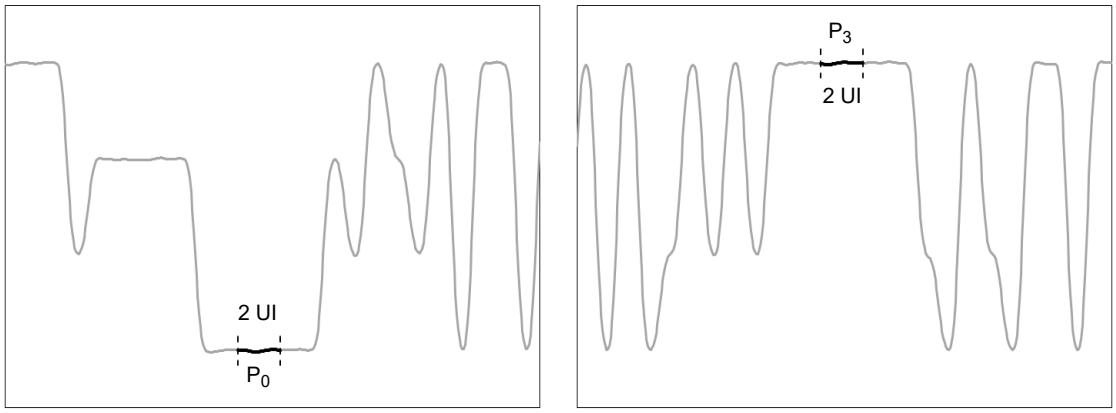

Figure 124–3—Example power levels P_0 and P_3 from PRBS13Q test pattern

124.8.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

The TDECQ and TDECQ – $10\log_{10}(C_{eq})$ of each lane shall be within the limits given in Table 124–6 if measured using the methods specified in 121.8.5.1, 121.8.5.2, and 121.8.5.3 using a reference equalizer as described in 121.8.5.4 where T is the symbol period for 400GBASE-DR4, with the following exceptions:

— The signaling rate of the test pattern generator is as given in Table 124–6 and uses the test pattern specified for TDECQ in Table 124–10.

— The combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 26.5625 GHz with a fourth-order Bessel-Thomson response to at least 1.3 × 53.125 GHz, and at frequencies above 1.3 × 53.125 GHz, the response should not exceed –20 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

— The normalized noise power density spectrum $N(f)$ is equivalent to white noise filtered by a fourth-order Bessel-Thomson response filter with a 3 dB bandwidth of 26.5625 GHz.

124.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 124–6 if measured using a test pattern specified for extinction ratio in Table 124–10. The extinction ratio of a PAM4 optical signal is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 124–3.

124.8.7 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 124–6 if measured using a test pattern specified for transmitter transition time in Table 124–10.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with response defined as follows. The combined response of the O/E converter and oscilloscope has a 3 dB bandwidth of approximately 26.5625 GHz with a fourth-order Bessel-Thomson response to at least 1.3 × 53.125 GHz. At frequencies above 1.3 × 53.125 GHz, the response should not exceed –20 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 124.8.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence, and the falling edge is that within the 33333000000 symbol sequence.

124.8.8 Relative intensity noise ($RIN_{21.4}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 21.4 dB.
b) Each lane may be tested individually with the sum of the optical power from all of the lanes not under test being below –30 dBm.
c) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 53.2 GHz).
d) The test pattern is according to Table 124–10.

124.8.9 Receiver sensitivity

Receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.4 dB. Receiver sensitivity should meet Equation (124–1), which is illustrated in Figure 124–4.

$$RS = \max(-3.9, SECQ - 5.3) \quad \text{(dBm)} \tag{124–1}$$

where

RS	is the receiver sensitivity
$SECQ$	is the SECQ of the transmitter used to measure the receiver sensitivity

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The normative requirement for receivers is stressed receiver sensitivity.

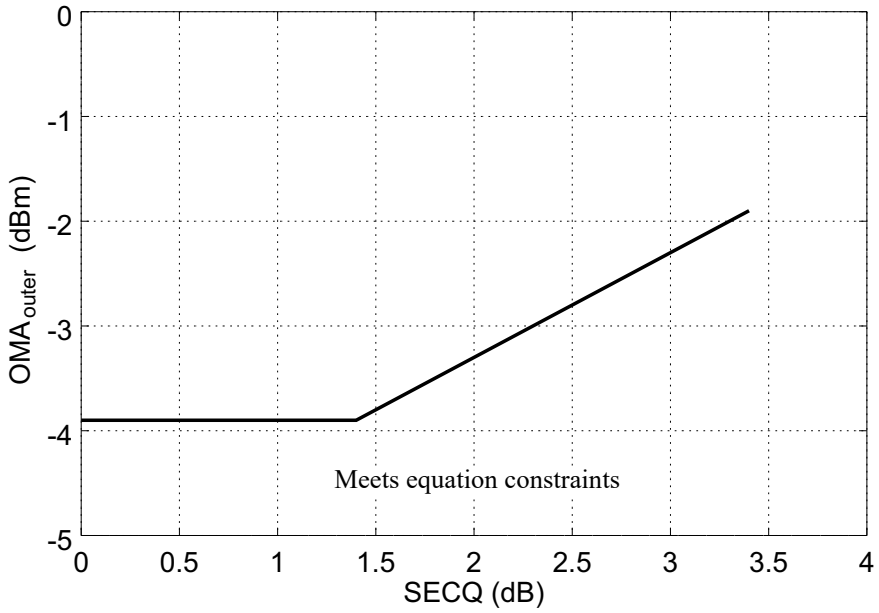

Figure 124–4—Illustration of receiver sensitivity

124.8.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 124–7 if measured using the method defined in 121.8.10 with the following exceptions:

- The SECQ of the stressed receiver conformance test signal is measured according to 124.8.5, except that the test fiber is not used. The transition time of the stressed receiver conformance test signal is no greater than the value specified in Table 124–6.
- With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_{21.4}OMA$ of the SRS test source should be no greater than the value specified in Table 124–6.
- The signaling rate of the test pattern generator and the extinction ratio of the E/O converter are as given in Table 124–6 using test patterns specified in Table 124–10.
- The required values of the "Stressed receiver sensitivity (OMA_{outer}), each lane (max)", "Stressed eye closure for PAM4 (SECQ), lane under test", "SECQ – $10\log_{10}(C_{eq})$ (max), lane under test", and "OMA_{outer} of each aggressor lane" are as given in Table 124–7.

124.9 Safety, installation, environment, and labeling

124.9.1 General safety

All equipment subject to this clause shall conform to IEC 60950-1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

124.9.2 Laser safety

400GBASE-DR4 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[214]

124.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

124.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 400GBASE-DR4 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate in the literature associated with the PHY the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

[214]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

124.9.5 Electromagnetic emission

A system integrating a 400GBASE-DR4 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

124.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

124.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 400GBASE-DR4).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 124.9.2.

124.10 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 124–5.

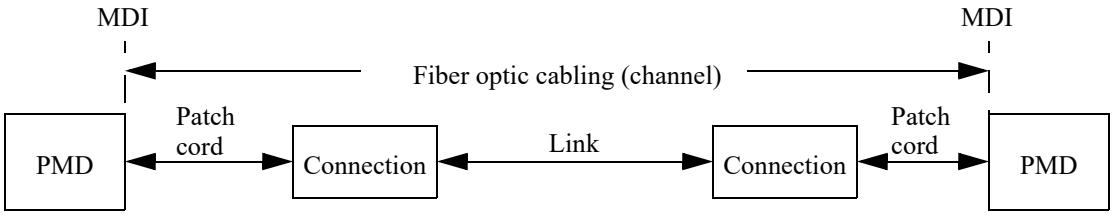

Figure 124–5—Fiber optic cabling model

The channel insertion loss is given in Table 124–11. A channel may contain additional connectors as long as the optical characteristics of the channel, such as attenuation, dispersion, reflections, and polarization mode dispersion meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

124.11 Characteristics of the fiber optic cabling (channel)

The 400GBASE-DR4 fiber optic cabling shall meet the specifications defined in Table 124–12. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

124.11.1 Optical fiber cable

The fiber optic cable requirements are satisfied by cables containing IEC 60793-2-50 type B1.1 (dispersion un-shifted single-mode), type B1.3 (low water peak single-mode), or type B6_a (bend insensitive) fibers or the requirements in Table 124–12 where they differ.

Table 124–11—Fiber optic cabling (channel) characteristics

Description	400GBASE-DR4	Unit
Operating distance (max)	500	m
Channel insertion loss[a,b] (max)	3	dB
Channel insertion loss (min)	0	dB
Positive dispersion[b] (max)	0.8	ps/nm
Negative dispersion[b] (min)	–0.93	ps/nm
DGD_max[c]	2.24	ps
Optical return loss (min)	37	dB

[a] These channel insertion loss values include cable, connectors, and splices.
[b] Over the wavelength range 1304.5 nm to 1317.5 nm.
[c] Differential Group Delay (DGD) is the time difference at reception between the fractions of a pulse that were transmitted in the two principal states of polarization of an optical signal. DGD_max is the maximum differential group delay that the system is required to tolerate.

Table 124–12—Optical fiber and cable characteristics

Description	Value	Unit
Nominal fiber specification wavelength	1310	nm
Cabled optical fiber attenuation (max)	0.5[a]	dB/km
Zero dispersion wavelength (λ_0)	$1300 \le \lambda_0 \le 1324$	nm
Dispersion slope (max) (S_0)	0.093	ps/nm^2 km

[a] The 0.5 dB/km attenuation is provided for Outside Plant cable as defined in ANSI/TIA 568-C.3.

124.11.2 Optical fiber connection

An optical fiber connection, as shown in Figure 124–5, consists of a mated pair of optical connectors.

124.11.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 2.75 dB total connection and splice loss. For example, this allocation supports five connections with an average insertion loss per connection of 0.5 dB. Connections with different loss characteristics may be used provided the requirements of Table 124–11 are met.

124.11.2.2 Maximum discrete reflectance

The maximum value for each discrete reflectance shall be less than or equal to the value shown in Table 124–13 corresponding to the number of discrete reflectances above –55 dB within the channel. For numbers of discrete reflectances in between two numbers shown in the table, the lower of the two corresponding maximum discrete reflectance values applies.

Table 124–13—Maximum value of each discrete reflectance

Number of discrete reflectances above –55 dB	Maximum value for each discrete reflectance
1	–37 dB
2	–42 dB
4	–45 dB
6	–47 dB
8	–48 dB
10	–49 dB

124.11.3 Medium Dependent Interface (MDI)

The 400GBASE-DR4 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 124–5). The 400GBASE-DR4 PMD is coupled to the fiber optic cabling through one connector plug into the MDI optical receptacle as shown in Figure 124–7. Example constructions of the MDI include the following:

a) PMD with a connectorized fiber pigtail plugged into an adapter
b) PMD receptacle

124.11.3.1 Optical lane assignments

The four transmit and four receive optical lanes of 400GBASE-DR4 shall occupy the positions depicted in Figure 124–6 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains eight active lanes within twelve total positions. The transmit optical lanes occupy the left-most four positions. The receive optical lanes occupy the right-most four positions. The four center positions are unused.

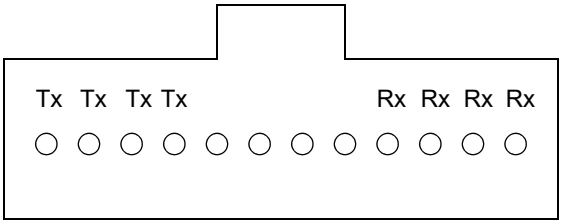

Figure 124–6—400GBASE-DR4 optical lane assignments

124.11.3.2 Medium Dependent Interface (MDI) requirements

The MDI shall meet the dimensional specifications of IEC 61754-7-1 interface 7-1-9: *MPO device receptacle, angled interface*. The plug terminating the optical fiber cabling shall meet the dimensional specifications of IEC 61754-7-1 interface 7-1-1: *MPO female plug connector, down-angled interface for 2 to 12 fibres*. The MDI shall optically mate with the plug on the optical fiber cabling. Figure 124–7 shows an MPO female plug connector with down-angled interface, and an MDI as an active device receptacle with angled interface.

The MDI shall meet the interface performance specifications of IEC 61753-021-2 for performance level D/2.

124.12 Protocol implementation conformance statement (PICS) proforma for Clause 124, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-DR4[215]

124.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 124, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-DR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

124.12.2 Identification

124.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

124.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 124, Physical Medium Dependent (PMD) sublayer and medium, type 400GBASE-DR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[215]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

125. Introduction to 2.5 Gb/s and 5 Gb/s networks

125.1 Overview

125.1.1 Scope

This clause describes the general requirements for 2.5 Gigabit and 5 Gigabit Ethernet. 2.5 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 2.5 Gb/s, coupled with any IEEE 802.3 2.5GBASE Physical Layer implementation. 5 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 5 Gb/s, coupled with any IEEE 802.3 5GBASE Physical Layer implementation. 2.5 Gb/s and 5 Gb/s Physical Layer devices, such as those specified in Table 125–1, provide a bit error ratio (BER) better than or equal to 10^{-12} at the MAC/PLS service interface.

2.5 Gigabit and 5 Gigabit Ethernet are defined for full duplex operation only.

125.1.2 Relationship of 2.5 Gigabit and 5 Gigabit Ethernet to the ISO OSI reference model

2.5 Gigabit and 5 Gigabit Ethernet couple the IEEE 802.3 MAC to a family of 2.5 Gb/s and 5 Gb/s Physical Layers. The relationships among 2.5 Gigabit and 5 Gigabit Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 125–1. While this standard defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience. The only exceptions are as follows:

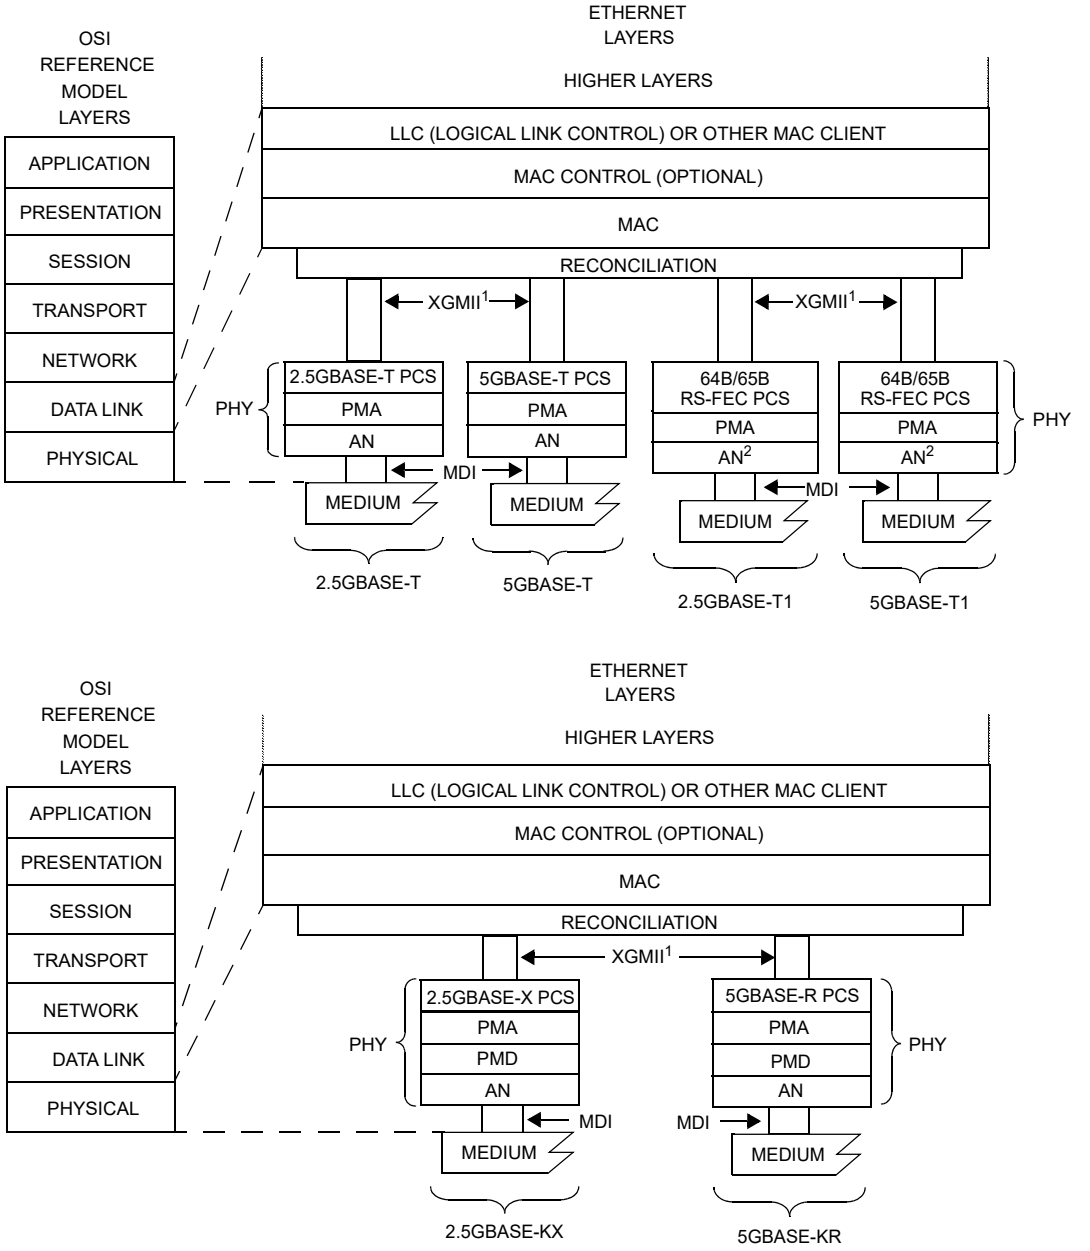
a) The XGMII, which, when implemented as a logical interconnection port between the MAC sublayer and the Physical Layer device (PHY), uses a 32-bit-wide data path as specified in Clause 46.

b) The management interface, which, when physically implemented as the MDIO/MDC (Management Data Input/Output and Management Data Clock) at an observable interconnection port, uses a bit wide data path as specified in Clause 45.

c) The MDI as specified in Clause 126 for 2.5GBASE-T and 5GBASE-T uses a 4-lane data path.

d) The MDI as specified in Clause 128 for 2.5GBASE-KX and Clause 130 for 5GBASE-KR uses a single-lane data path.

e) The MDI as specified in Clause 149 for 2.5GBASE-T1 and 5GBASE-T1 uses a single-lane data path.



125.1.3 Nomenclature

The nomenclature employed by the 2.5 Gigabit and 5 Gigabit Physical Layers is explained in the following paragraphs.

The alpha-numeric prefix 2.5GBASE in the port type (e.g., 2.5GBASE-T) represents a family of Physical Layer devices operating at a speed of 2.5 Gb/s. The alpha-numeric prefix 5GBASE in the port type (e.g., 5GBASE-T) represents a family of Physical Layer devices operating at a speed of 5 Gb/s.

2.5GBASE-T represents Physical Layer devices using Clause 126 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, for transmitting 2.5 Gb/s Ethernet over a point-to-point 4-pair balanced twisted-pair medium. 2.5GBASE-T uses low density parity check (LDPC) FEC in its Physical Coding Sublayers mapped to a PAM16 constellation for transmission on 4-pair, twisted-pair copper cabling.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

AN = AUTO-NEGOTIATION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PHY = PHYSICAL LAYER DEVICE
PMD = PHYSICAL MEDIUM DEPENDENT
XGMII = 10 GIGABIT MEDIA INDEPENDENT INTERFACE
NOTE 1 – XGMII IS OPTIONAL
NOTE 2 – AUTO-NEGOTIATION IS OPTIONAL

Figure 125–1—Architectural positioning of 2.5 Gigabit and 5 Gigabit Ethernet

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

5GBASE-T represents Physical Layer devices using Clause 126 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, for transmitting 5 Gb/s Ethernet over a point-to-point 4-pair balanced twisted-pair medium. 5GBASE-T uses low density parity check (LDPC) FEC in its Physical Coding Sublayers mapped to a PAM16 constellation for transmission on 4-pair, twisted-pair copper cabling.

2.5GBASE-X refers to a specific family of Physical Layer devices based upon the 8B/10B data coding method specified in Clause 127. The 2.5GBASE-X family is composed of 2.5GBASE-KX.

5GBASE-R refers to a specific family of Physical Layer devices based upon the 64B/66B data coding method specified in Clause 129. The 5GBASE-R family is composed of 5GBASE-KR.

2.5GBASE-T1 represents Physical Layer devices using Clause 149 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, for transmitting 2.5 Gb/s Ethernet over a point-to-point single balanced pair of conductors. 2.5GBASE-T1 uses Reed-Solomon FEC in its Physical Coding Sublayers mapped to PAM4 for transmission on a single balanced pair of conductors.

5GBASE-T1 represents Physical Layer devices using Clause 149 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, for transmitting 5 Gb/s Ethernet over a point-to-point single balanced pair of conductors. 5GBASE-T1 uses Reed-Solomon FEC in its Physical Coding Sublayers mapped to PAM4 for transmission on a single balanced pair of conductors.

125.1.4 Physical Layer signaling systems

Physical Layer devices listed in Table 125–1 are defined for operation at 2.5 Gb/s and 5 Gb/s.

Table 125–1—2.5 Gb/s and 5 Gb/s PHYs

Name	Description
2.5GBASE-KX	2.5 Gb/s PHY using 2.5GBASE-X encoding over one lane of an electrical backplane (see Clause 128)
2.5GBASE-T	2.5 Gb/s PHY using LDPC encoding and PAM16 modulation over balanced twisted-pair structured cabling systems (see Clause 126)
2.5GBASE-T1	2.5 Gb/s PHY using Reed–Solomon encoding and PAM4 modulation over a single balanced pair of conductors (see Clause 149)
5GBASE-KR	5 Gb/s PHY using 5GBASE-R encoding over one lane of an electrical backplane (see Clause 130)
5GBASE-T	5 Gb/s PHY using LDPC encoding and PAM16 modulation over balanced twisted-pair structured cabling systems (see Clause 126)
5GBASE-T1	5 Gb/s PHY using Reed–Solomon encoding and PAM4 modulation over a single balanced pair of conductors (see Clause 149)

5GBASE-T1		M	O		O	O										M

[a]O = Optional, M = Mandatory.

125.2 Summary of 2.5 Gigabit and 5 Gigabit Ethernet sublayers

125.2.1 Reconciliation Sublayer (RS) and Media Independent Interface

2.5 Gigabit and 5 Gigabit Ethernet use the 10 Gigabit Media Independent Interface defined in Clause 46, with the clock scaled to their respective data rates. The physical instantiation of the Media Independent Interface is optional, and can be used to logically connect layers within a device.

The XGMII supports 2.5 Gb/s and 5 Gb/s operation, in addition to 10 Gb/s operation, through its 32-bit wide transmit and receive data paths. The Reconciliation Sublayer (RS) provides a mapping between the signals provided at the Media Independent Interface (XGMII) and the MAC/PLS service definition.

While XGMII is an optional interface, it is used extensively in this standard as a basis for functional specification and provides a common service interface for the Physical Coding Sublayers defined in Clause 126.

125.2.2 Physical Coding Sublayer (PCS)

2.5GBASE-T and 5GBASE-T PHYs contain a 65B-LDPC PCS that maps the data transferred across the XGMII interface to 64B/65B blocks encoded in a 2048-bit LDPC frame. This LDPC frame is then mapped to 512 Gray-coded PAM16 symbols for transfer to the 4-lane PMA.

2.5GBASE-X uses the PCS specified in Clause 127, and 5GBASE-R uses the PCS specified in Clause 129.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

2.5GBASE-T1 and 5GBASE-T1 use the PCS specified in Clause 149.

125.2.3 Physical Medium Attachment sublayer (PMA)

The PMA provides a medium-independent means for the PCS to support the use of a range of physical media. The 2.5GBASE-T and 5GBASE-T PMAs perform the mapping of transmit and receive data streams between the PCS and PMA via the PMA service interface. The PMA provides a medium-independent means for the PCS to support the use of a range of physical media.

In the case of BASE-T, the 2.5GBASE-T and 5GBASE-T PMAs perform the mapping of transmit and receive data streams between the PCS and PMA via the PMA service interface, and the mapping and multiplexing of transmit and receive data streams between the PMA and MDI. In addition, the PMAs perform retiming of the received data stream when appropriate.

2.5GBASE-X uses the PMA specified in Clause 127, and 5GBASE-R uses the PMA specified in Clause 129.

2.5GBASE-T1 and 5GBASE-T1 use the PMA specified in Clause 149.

125.2.4 Auto-Negotiation

125.2.4.1 Auto-Negotiation, type BASE-T

Auto-Negotiation (Clause 28) is used by 2.5GBASE-T and 5GBASE-T devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for joint operation. Auto-Negotiation is performed upon link startup through the use of a special sequence of fast link pulses.

125.2.4.2 Auto-Negotiation, type Backplane

Auto-Negotiation (Clause 73) is used by 2.5GBASE-X and 5GBASE-R devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for joint operation. Auto-Negotiation is performed upon link startup through the use of differential Manchester encoding.

125.2.4.3 Auto-Negotiation, type single differential-pair media

Auto-Negotiation (Clause 98) may be used by 2.5GBASE-T1 and 5GBASE-T1 devices to detect the abilities (modes of operation) supported by the device at the other end of a link segment, determine common abilities, and configure for joint operation. Auto-Negotiation is performed upon link startup through the use of half-duplex differential Manchester encoding.

The use of Clause 98 Auto-Negotiation is optional for 2.5GBASE-T1 and 5GBASE-T1 PHYs.

125.2.5 Management interface (MDIO/MDC)

The optional MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMD) and Station Management (STA) entities.

125.2.6 Management

Managed objects, attributes, and actions are defined for all 2.5 Gigabit and 5 Gigabit Ethernet components. These items are defined in Clause 30.

125.3 Delay Constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices. Table 125–3 contains the values of maximum sublayer delay (sum of transmit and receive delays at one end of the link) in bit times as specified in 1.4 and pause_quanta as specified in 31B.2. If a PHY contains an Auto-Negotiation sublayer, the delay of the Auto-Negotiation sublayer is included within the delay of the PMD and medium.

See 31B.3.7 for PAUSE reaction timing constraints for stations at operating speeds of 2.5 Gb/s and 5 Gb/s.

Table 125–3—Sublayer delay constraints

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
2.5GBASE-KX PHY	1 024	2	409.6	See 127.5 and 128.4.
2.5GBASE-T PHY	12 800	25	5120	Does not include delay of cable medium. See 126.11.
2.5GBASE-T1 PHY	10 240	20	4096	See 149.10.
5GBASE-R PCS PMA	3 584	7	716.8	See 129.5.
5GBASE-KR PMD	512	1	102.4	See 130.4.
5GBASE-T PHY	14 336	28	2867.2	Does not include delay of cable medium. See 126.11.
5GBASE-T1 PHY no interleave	10 240	20	2048	See 149.10.
5GBASE-T1 PHY 2x interleave	13 824	27	2764.8	See 149.10.

[a] For 2.5GBASE-T, 2.5GBASE-X, and 2.5GBASE-T1, 1 bit time (BT) is equal to 400 ps and for 5GBASE-T, 5GBASE-R, and 5GBASE-T1, 1 bit time (BT) is equal to 200 ps. (See 1.4.215 for the definition of bit time.)
[b] For 2.5GBASE-T, 2.5GBASE-X, and 2.5GBASE-T1, 1 pause_quantum is equal to 204.8 ns and for 5GBASE-T, 5GBASE-R, and 5GBASE-T1, 1 pause_quantum is equal to 102.4 ns. (See 31B.2 for the definition of pause_quanta.)
[c] Should there be a discrepancy between this table and the delay requirements of the relevant sublayer clause, the sublayer clause prevails.

126. Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 2.5GBASE-T and 5GBASE-T

126.1 Overview

The 2.5GBASE-T and 5GBASE-T PHYs are members of the 2.5 Gb/s and 5 Gb/s Ethernet family of high-speed network specifications respectively. The 2.5GBASE-T PCS, PMA, and baseband medium specifications are intended for operation over balanced twisted-pair structured cabling systems. The 5GBASE-T PCS, PMA, and baseband medium specifications are intended for operation over balanced twisted-pair structured cabling systems. 2.5GBASE-T and 5GBASE-T signaling both require four pairs of balanced cabling as specified in ISO/IEC 11801:2002 and ANSI/TIA-568-C.2.

This clause defines the types 2.5GBASE-T and 5GBASE-T PCS, PMA sublayers, and Medium Dependent Interfaces (MDI). Together, the PCS and PMA sublayers define a Physical Layer device (PHY). Functional, electrical, and mechanical specifications for the type 2.5GBASE-T PMA, 5GBASE-T PMA, and MDI are provided in this clause. This clause also specifies the baseband media used with 2.5GBASE-T and 5GBASE-T. Management functions are optionally accessible through the management interface defined in Clause 45, or equivalent. Please refer to Table 125–2 for associated sublayers and options for assembling a 2.5 Gb/s or 5 Gb/s system with the 2.5GBASE-T or 5GBASE-T PHY, respectively.

This clause also specifies 2.5GBASE-T and 5GBASE-T Low Power Idle (LPI) as part of Energy-Efficient Ethernet (EEE). This allows the PHY to enter a low power mode of operation during periods of low link utilization as described in Clause 78.

2.5GBASE-T and 5GBASE-T PHYs may optionally support a fast retrain mechanism. Implementation of the fast retrain option is recommended. Configurations wishing to disable fast retrain on the link may do so by advertising lack of support during link startup, thus preventing the link partner from attempting fast retrain and potentially dropping the link, see 45.2.7.10.

126.1.1 Nomenclature

The 2.5GBASE-T and 5GBASE-T PHYs described in this clause represent two distinct PHY types that share the same PCS, PMA, and MDI specifications subject to frequency scaling. In order to efficiently describe the two PHYs, the nomenclature 2.5G/5GBASE-T is used to describe specifications that apply to both the 2.5GBASE-T and 5GBASE-T PHYs. Additionally, for parameters that scale with the PHYs data rate, the parameter S is used for scaling. For 2.5GBASE-T, $S = 0.5$ and for 5GBASE-T, $S = 1$.

126.1.2 Relationship of 2.5GBASE-T and 5GBASE-T to other standards

The relationships between the 2.5GBASE-T and 5GBASE-T PHYs, the ISO Open Systems Interconnection (OSI) reference model, and the IEEE 802.3 Ethernet model are shown in Figure 126–1. The PHY sublayers (shown shaded) in Figure 126–1 connect the IEEE 802.3 Ethernet MAC to the medium. The 2.5GBASE-T and 5GBASE-T PHY service interface is the XGMII, which is defined in Clause 46.

.

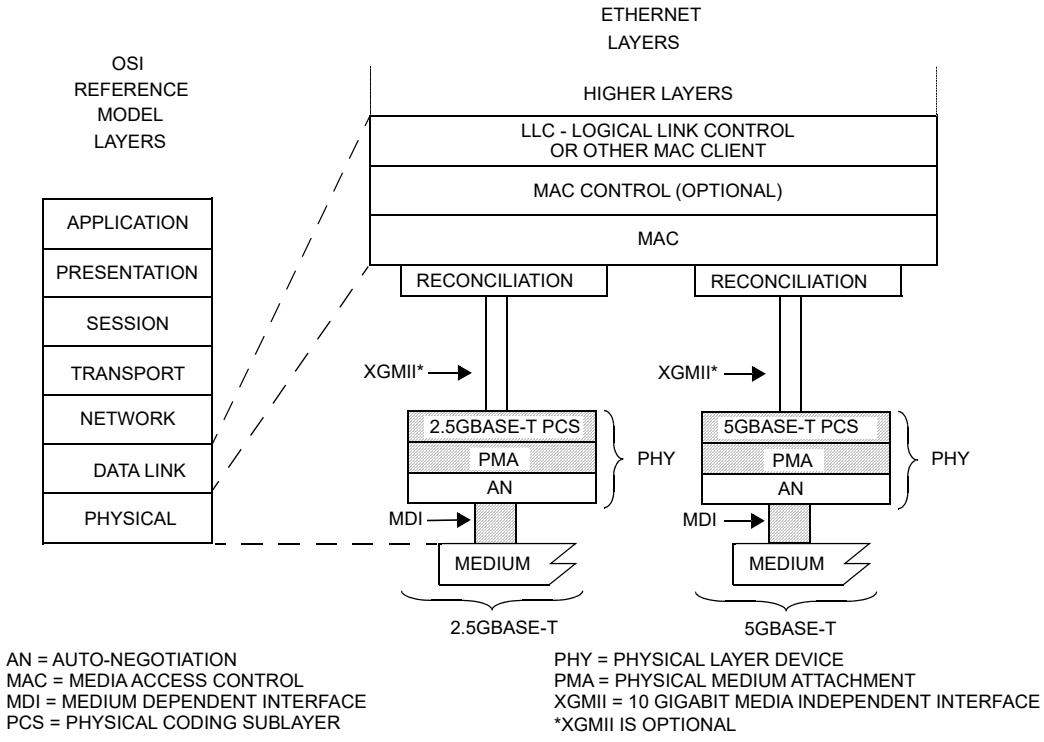

Figure 126–1—Types 2.5GBASE-T and 5GBASE-T PHYs relationship to the ISO Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

126.1.3 Operation of 2.5GBASE-T and 5GBASE-T

The 2.5GBASE-T PHY and 5GBASE-T PHY each employ full duplex baseband transmission over four pairs of balanced twisted-pair structured cabling. The aggregate data rates of 2.5 Gb/s or 5 Gb/s are achieved by transmitting one-quarter of the aggregate data rate in each direction simultaneously on each wire pair, as follows in Figure 126–2. Baseband 16-level PAM signaling with a modulation rate of 200 MBd for 2.5GBASE-T and 400 MBd for 5GBASE-T is used on each of the wire pairs. Ethernet data and control characters are encoded at a rate of 3.125 information bits per PAM16 symbol, along with auxiliary bits. Each transmitted PAM16 symbol is considered as a single one-dimensional (1D) symbol. After link startup, PHY frames consisting of 512 PAM16 symbols are continuously transmitted. The PAM16 symbols are determined by 4-bit labels, each comprising 4 LDPC-encoded bits. The 512 PAM16 symbols of one PHY frame are transmitted as 4×128 PAM16 symbols over the four wire pairs. Data and Control symbols are embedded in a framing scheme that runs continuously after startup of the link. For 2.5GBASE-T, the modulation symbol rate of 200 MBd results in a symbol period of 5 ns, and for 5GBASE-T, the modulation symbol rate of 400 MBd results in a symbol period of 2.5 ns.

A 2.5GBASE-T or 5GBASE-T PHY can be configured either as a MASTER PHY or as a SLAVE PHY. The MASTER-SLAVE relationship between two stations sharing a link segment is established during Auto-Negotiation (see Clause 28, 126.6, Annex 28B, Annex 28C, and Annex 28D). The MASTER PHY uses a local clock to determine the timing of transmitter operations. The MASTER-SLAVE relationship includes loop timing. The SLAVE PHY recovers the clock from the received signal and uses it to determine the timing of transmitter operations, i.e., it performs loop timing, as illustrated in Figure 126–3.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

2.5GBASE-T and 5GBASE-T PHYs optionally provide support for LPI as part of EEE (see Clause 78). This extension allows PHYs to enter an LPI mode when either the local or link partner system requests low power operation. The transmit and receive functions may enter and leave the LPI mode independently so that both symmetric and asymmetric operation is supported. While the PHY is in the LPI mode, the PHY periodically transmits a refresh signal to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variation in the timing of the link or the underlying channel characteristics. An easily detectable alert signal is transmitted to signal an end to the LPI mode. The alert signal is followed by a wake signal to enable a rapid transition back to the normal operational mode.

2.5GBASE-T and 5GBASE-T PHYs may optionally support a fast retrain mechanism. This function allows PHYs to quickly recover from link degradation without a normal two-second retrain.

The PCS and PMA are summarized in 126.1.3.1 and 126.1.3.2. The EEE capability is summarized in 126.1.3.3. Figure 126–3 shows the functional block diagram.

126.1.3.1 Summary of Physical Coding Sublayer (PCS)

The 2.5GBASE-T or 5GBASE-T PCS couples a 10 Gigabit Media Independent Interface (XGMII), as described in Clause 46, to the 2.5GBASE-T or 5GBASE-T Physical Medium Attachment (PMA) sublayer.

In addition to the normal mode of operation, the PCS supports a training mode. Furthermore, the PCS contains a management interface.

In the transmit direction (see Figure 126–6), in normal mode, the PCS receives eight XGMII data octets provided by two consecutive transfers on the XGMII service interface on TXD<31:0> and groups them into 64-bit blocks with the 64-bit block boundaries aligned with the boundary of the two XGMII transfers. Each group of eight octets along with the data/control indications is transcoded into a 65-bit block. The resulting 65-bit blocks are scrambled and assembled in a group of 25 blocks, yielding an Ethernet payload of $25 \times 65 = 1625$ bits. Additionally, 97 zero-bits are appended, and a leading auxiliary bit is added to obtain a block of 1723 bits.

The 1723 bits are encoded by a systematic LDPC(1723,2048) encoder, which adds 325 LDPC check bits to form an LDPC codeword of 2048 coded bits. The 97 zero-bits are then replaced with vendor-defined random data. Implementers are cautioned that insufficient randomization can impact meeting PMA PSD mask requirements (see 126.5.3.4 for transmit PSD mask definition). The resulting 2048 bit LDPC frame is then divided into 512 4-bit labels, which are mapped into PAM16 modulation symbols.

The obtained PHY frame of 512 PAM16 symbols is passed on to the PMA as PMA_UNITDATA.request. The PMA transmits the PAM16 symbols over the four wire pairs in the form of 128 constituent PAM16 symbols per pair.

In the receive direction (see Figure 126–7), in normal mode, the PCS processes code-groups received from the remote PHY via the PMA in 128 four-dimensional (4D) symbol blocks and maps them to the XGMII service interface in the receive path. In this receive processing scheme, symbol clock synchronization is done by the PMA Receive function.

The signals provided by the PCS at the XGMII conform to the interface requirements of Clause 46.

Details of the PCS functions and state diagrams are covered in 126.3. The interface to the PMA is an abstract message-passing interface specified in 126.2.

126.1.3.2 Summary of Physical Medium Attachment (PMA) sublayer

The PMA couples messages from the PCS service interface onto the balanced cabling physical medium via the Medium Dependent Interface (MDI) and provides the link management and PHY Control functions. The PMA provides full duplex communications at $400 \times S$ MBd over four pairs of balanced cabling up to 100 m in length.

The PMA Transmit function comprises four transmitters to generate continuous time analog signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD, as described in 126.4.3.1. In normal mode, each 4D symbol received from the PCS Transmit function undergoes multiple stages of processing. First the symbol goes through a Tomlinson-Harashima precoder (THP), which maps the PAM16 input (as described in 126.3.2.2.18) in each dimension of the 4D symbol into a quasi-continuous discrete-time value in the range $-16 \le x < 16$. This THP-processed 4D symbol stream may be further processed by a digital transmit filter and is then passed on to four digital-to-analog converters (DACs). The DAC outputs may be further processed with continuous time filters to roll off the high-frequency spectral response to limit high-frequency emissions and are then applied to each of the four balanced pairs via the MDI port.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMA Receive function comprises four independent receivers for pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD, as described in 126.4.3.2. The receivers are responsible for acquiring symbol timing and, when operating in normal mode, for canceling echo, near-end crosstalk, far-end crosstalk, and equalizing the signal. The 4D symbols are provided to the PCS Receive function via the PMA_UNITDATA.indication message. The PMA also contains functions for Link Monitor.

The PMA PHY Control function generates signals that control the PCS and PMA sublayer operations. PHY Control begins following the completion of Auto-Negotiation and provides the startup functions required for successful 2.5GBASE-T and 5GBASE-T operation. PHY Control determines whether the PHY operates in a normal mode, enabling data transmission over the link segment, or whether the PHY sends special PAM2 code-groups that are used in the training mode.

PMA functions and state diagrams are specified in 126.4. PMA electrical specifications are given in 126.5.

The PMA sublayer may also support a fast retrain function. The fast retrain function is specified in 126.4.2.5.16.

126.1.3.3 Summary of EEE capability

A 2.5GBASE-T or 5GBASE-T PHY may optionally support the EEE capability, as described in 78.1.4. The EEE capability is a mechanism by which 2.5GBASE-T and 5GBASE-T PHYs are able to reduce power consumption during periods of low link utilization. PHYs can enter this mode of operation after reaching PCS data mode. Each direction of the full duplex link is able to enter and exit the LPI mode independently, supporting symmetric and asymmetric LPI operation. This allows power savings when only one side of the full duplex link is in a period of low utilization. No data frames are lost or corrupted during the transition to or from the LPI mode.

In the transmit direction, the transition to the LPI transmit mode begins when the PCS transmit function detects an LPI control character in all four lanes of two consecutive transfers of TXD[31:0] that is then mapped into a single 64B/65B block, according to the position in the 2.5GBASE-T or 5GBASE-T LDPC frame. Following this event a sleep signal is transmitted by the PMA. The sleep signal is composed of LDPC frames that contain only LP_IDLE 64B/65B blocks. The sleep signal indicates to the link partner that the transmit function of the PHY is entering the LPI transmit mode. Immediately after the transmission of the sleep frames, the transmit function of the local PHY enters the LPI transmit mode. While the transmit function is in the LPI mode the PHY may disable data path and control logic to save additional power. Periodically the transmit function of the local PHY transmits refresh frames that are used by the link partner to update adaptive filters and timing circuits in order to maintain link integrity. The LPI mode begins with quiet signaling or with a full refresh period. Partial refreshes (defined as a refresh signal shorter than eight LDPC frames) that immediately follow the transition to the LPI mode are replaced with quiet signaling. The quiet-refresh cycle continues until the PCS function detects IDLE characters on the XGMII. These characters signal to the PHY that the LPI transmit mode should end. The PMA Transmit function in the PHY then sends an alert message to the link partner. The alert signal begins on a LDPC 2-frame 256 4D-symbol boundary aligned to the inversion on pair A during PMA training, but has no fixed relationship to the quiet-refresh cycle. The alert signal wakes the link partner from sleep. The alert signal is followed by a wake signal, composed of LDPC frames containing only IDLE 64B/65B blocks. After a short recovery time the normal operational mode is resumed.

In the receive direction the transition to the LPI mode is triggered when the PCS Receive function detects LPI control characters within received LDPC frames. This indicates that the link partner is about to enter the LPI transmit mode. Following these frames the link partner ceases transmission and begins quiet-refresh signaling. During the quiet time it is highly recommended that the local receiver power off circuits to reduce power consumption. Periodically the link partner transmits refresh frames that are used by the receiver to update adaptive coefficients and timing circuits. This quiet-refresh cycle continues until the link partner transmits the alert signal, initiating a transition back to the normal operational mode. The alert signal is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

detected in the PMA and signals that normal data frames will follow. The alert signal is followed by a wake signal that allows the local receiver time to prepare for the normal operational mode. The wake signal is composed of repeated IDLE 64B/65B blocks. After a short recovery time the normal operational mode is resumed.

Support for the EEE capability is advertised in the Infofield (Octet 12 bit 7) during link startup. Transitions to and from the LPI transmit mode are controlled via XGMII signaling. Transitions to and from the LPI receive mode are controlled by the link partner using sleep, alert, and wake signaling.

The PCS 64B/65B Transmit state diagram in Figure 126–14 and Figure 126–15 includes additional states for EEE. The PCS 64B/65B Receive state diagram in Figure 126–16 and Figure 126–17 includes additional states for EEE. The EEE Transmit state diagram is contained in the PCS Transmit function and is specified in Figure 126–18.

126.1.4 Signaling

2.5GBASE-T and 5GBASE-T signaling is performed by the PCS generating continuous code-group sequences that the PMA transmits over each wire pair. The signaling scheme achieves a number of objectives including:

a) Forward error correction (FEC) coded symbol mapping for data.
b) Algorithmic mapping from TXD<31:0> and TXC<3:0> to 4D symbols in the transmit path.
c) Algorithmic mapping from the received 4D signals on the MDI port to RXD<31:0> and RXC<3:0> on the XGMII interface.
d) Uncorrelated symbols in the transmitted symbol stream.
e) No correlation between symbol streams traveling both directions on any pair combination.
f) No correlation between symbol streams on pairs BI_DA, BI_DB, BI_DC, and BI_DD.
g) Block framing and other control signals.
h) Ability to signal the status of the local receiver to the remote PHY to indicate that the local receiver is not operating reliably and requires retraining.
i) Ability to automatically detect and correct for pair swapping and crossover connections.
j) Ability to automatically detect and correct for incorrect polarity in the connections.
k) Ability to automatically correct for differential delay variations across the wire-pairs.
l) Ability to support refresh, quiet and alert signaling during LPI operation.

The PHY operates in two modes—normal mode or training mode. In normal mode, PCS generates a continuous stream of 4D symbols that are transmitted via the PMA at one of eight power levels. In training mode, the PCS is directed to generate only PAM2 symbols for transmission by the PMA, which enable the receiver at the other end to train until it is ready to operate in normal mode. (See 126.3.2.2 for description of PCS transmit modes.)

PHYs may also support the EEE capability as described in 126.1.3.3. Transitions to the LPI mode are supported after reaching normal mode.

126.1.5 Interfaces

All 2.5GBASE-T and 5GBASE-T PHY implementations are compatible at the MDI and at the XGMII, if implemented. Implementation of the XGMII is optional. Designers are free to implement circuitry within the PCS and PMA in an application-dependent manner provided that the MDI and XGMII (if the XGMII is implemented) specifications are met. System operation from the perspective of signals at the MDI and management objects are identical whether the XGMII is implemented or not.

126.1.6 Conventions in this clause

The body of this clause contains state diagrams, including definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5.

Default initializations, unless specified, are left to the implementer.

126.2 2.5GBASE-T and 5GBASE-T service primitives and interfaces

2.5GBASE-T and 5GBASE-T transfer data and control information across the following four service interfaces:

a) 10 Gigabit Media Independent Interface (XGMII)
b) Technology Dependent Interface
c) PMA service interface
d) Medium dependent interface (MDI)

The XGMII is specified in Clause 46; the Technology Dependent Interface is specified in Clause 28. The PMA service interface is defined in 126.2.2 and the MDI is defined in 126.8.

126.2.1 Technology Dependent Interface

2.5GBASE-T and 5GBASE-T use the following service primitives to exchange status indications and control signals across the Technology Dependent Interface as specified in Clause 28:

PMA_LINK.request (link_control)

PMA_LINK.indication (link_status)

126.2.1.1 PMA_LINK.request

This primitive allows the Auto-Negotiation algorithm to enable and disable operation of the PMA as specified in 28.2.6.2.

126.2.1.1.1 Semantics of the primitive

PMA_LINK.request (link_control)

The link_control parameter can take on one of three values: SCAN_FOR_CARRIER, DISABLE, or ENABLE.

SCAN_FOR_CARRIER	Used by the Auto-Negotiation algorithm prior to receiving any fast link pulses. During this mode the PMA reports link_status=FAIL. PHY processes are disabled.
DISABLE	Set by the Auto-Negotiation algorithm in the event fast link pulses are detected. PHY processes are disabled. This allows the Auto-Negotiation algorithm to determine how to configure the link.
ENABLE	Used by Auto-Negotiation to turn control over to the PHY for data processing functions.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.2.1.1.2 When generated

Auto-Negotiation generates this primitive to indicate a change in link_control as described in Clause 28.

126.2.1.1.3 Effect of receipt

This primitive affects operation of the PMA Link Monitor function as defined in 126.4.2.6.

126.2.1.2 PMA_LINK.indication

This primitive is generated by the PMA to indicate the status of the underlying medium as specified in 28.2.6.1. This primitive informs the Auto-Negotiation algorithm about the status of the underlying link.

126.2.1.2.1 Semantics of the primitive

PMA_LINK.indication (link_status)

The link_status parameter can take on one of two values: FAIL or OK.

FAIL	No valid link established.
OK	The Link Monitor function indicates that a valid 2.5GBASE-T or 5GBASE-T link is established. Reliable reception of signals transmitted from the remote PHY is possible.

126.2.1.2.2 When generated

The PMA generates this primitive to indicate a change in link_status in compliance with the state diagram given in Figure 126–29.

126.2.1.2.3 Effect of receipt

Auto-Negotiation uses this primitive to detect a change in link_status as described in Clause 28.

126.2.2 PMA service interface

2.5GBASE-T and 5GBASE-T use the following service primitives to exchange symbol vectors, status indications, and control signals across the service interfaces:

PMA_TXMODE.indication (tx_mode)

PMA_CONFIG.indication (config)

PMA_UNITDATA.request (tx_symb_vector)

PMA_UNITDATA.indication (rx_symb_vector)

PMA_SCRSTATUS.request (scr_status)

PMA_PCSSTATUS.request (pcs_status)

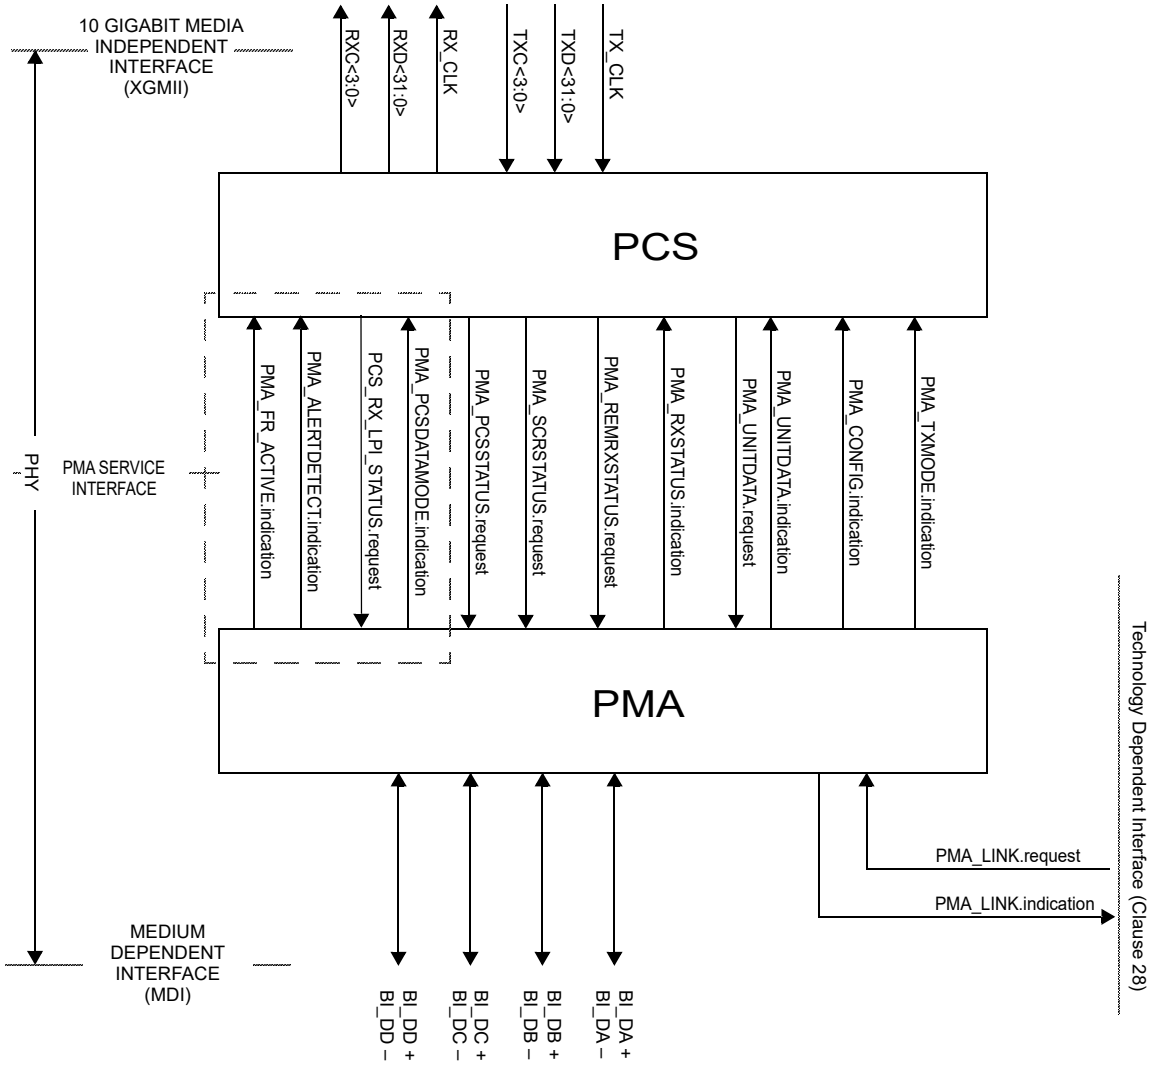
PMA_RXSTATUS.indication (loc_rcvr_status)

PMA_REMRXSTATUS.request (rem_rcvr_status)

EEE-capable PHYs additionally support the following service primitives:

PMA_ALERTDETECT.indication (alert_detect)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



PCS_RX_LPI_STATUS.request (rx_lpi_active)

PMA_PCSDATAMODE.indication (PCS_data_mode)

Fast retrain capable PHYs additionally support the following service primitive:

PMA_FR_ACTIVE.indication (fr_active)

The use of these primitives is illustrated in Figure 126–4. Connections from the management interface (signals MDC and MDIO) to the sublayers are pervasive and are not shown in Figure 126–4.

NOTE 1—PMA_PCSDATAMODE.indication is required only for the EEE or fast retrain capabilities.

NOTE 2—PMA_ALERTDETECT.indication and PCS_RX_LPI_STATUS.request are only required for the EEE capability.

NOTE 3—PMA_FR_ACTIVE.indication is only required for the fast retrain capability.

Figure 126–4—2.5GBASE-T and 5GBASE-T service interfaces

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.2.2.1 PMA_TXMODE.indication

The transmitter in a 2.5GBASE-T or 5GBASE-T link normally sends over the four pairs, 4D symbols that represent an XGMII data stream with framing, scrambling and encoding of data, control information, or idles.

126.2.2.1.1 Semantics of the primitive

PMA_TXMODE.indication (tx_mode)

PMA_TXMODE.indication specifies to PCS Transmit via the parameter tx_mode what sequence of code-groups the PCS should be transmitting. The parameter tx_mode can take on one of the following three values of the form:

SEND_N	This value is continuously asserted when transmission of sequences of 4D symbols representing an XGMII data stream in normal mode.
SEND_T	This value is continuously asserted in case transmission of sequences of code-groups representing the training mode is to take place.
SEND_Z	This value is continuously asserted in case transmission of zeros is required.

126.2.2.1.2 When generated

The PMA PHY Control function generates PMA_TXMODE.indication messages to indicate a change in tx_mode.

126.2.2.1.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 126.3.2.2.

126.2.2.2 PMA_CONFIG.indication

Each PHY in a 2.5GBASE-T or 5GBASE-T link is capable of operating as a MASTER PHY and as a SLAVE PHY. MASTER-SLAVE configuration is determined during Auto-Negotiation (126.6.1). The result of this negotiation is provided to the PMA.

126.2.2.2.1 Semantics of the primitive

PMA_CONFIG.indication (config)

PMA_CONFIG.indication specifies to PCS and PMA Transmit via the parameter config whether the PHY operates as a MASTER PHY or as a SLAVE PHY. The parameter config can take on one of the following two values of the form:

MASTER	This value is continuously asserted when the PHY operates as a MASTER PHY.
SLAVE	This value is continuously asserted when the PHY operates as a SLAVE PHY.

126.2.2.2.2 When generated

PMA generates PMA_CONFIG.indication messages to indicate a change in config.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.2.2.2.3 Effect of receipt

PCS and PMA Clock Recovery perform their functions in MASTER or SLAVE configuration according to the value assumed by the parameter config.

126.2.2.3 PMA_UNITDATA.request

This primitive defines the transfer of code-groups in the form of the tx_symb_vector parameter from the PCS to the PMA. The code-groups are obtained in the PCS Transmit function using the encoding rules defined in 126.3.2.2 to represent XGMII data and control streams or other sequences.

126.2.2.3.1 Semantics of the primitive

PMA_UNITDATA.request (tx_symb_vector)

During transmission, the PMA_UNITDATA.request simultaneously conveys to the PMA via the parameter tx_symb_vector the value of the symbols to be sent over each of the four transmit pairs BI_DA, BI_DB, BI_DC, and BI_DD. For EEE-capable PHYs, the vector also requests the PMA to send the ALERT signal during LPI. The tx_symb_vector parameter takes on the following form:

SYMB_4D	A vector of four multi-level symbols, one for each of the four transmit pairs BI_DA, BI_DB, BI_DC, and BI_DD. In normal operation, each symbol may take on one of the values in the set {–15, –13, –11, –9, –7, –5, –3, –1, 1, 3, 5, 7, 9, 11, 13, 15}. The symbols may additionally take the value 0 when zeros are to be transmitted in the following two cases: 1) when PMA_TXMODE.indication is SEND_Z during PMA training, and 2) after data mode is reached, the transmit function is in the LPI transmit mode and lpi_tx_mode is QUIET
ALERT	A vector used to indicate that the PMA should transmit the alert sequence. ALERT is asserted for a time equal to 8 LDPC frames.

The symbols that are elements of tx_symb_vector are called, according to the pair on which each is transmitted, tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD].

126.2.2.3.2 When generated

The PCS generates PMA_UNITDATA.request synchronously with every transmit clock cycle.

126.2.2.3.3 Effect of receipt

Upon receipt of this primitive the PMA transmits on the MDI the signals corresponding to the indicated symbols after processing with the THP, the transmit filter and other specified PMA Transmit processing. The parameter tx_symb_vector is also used by the PMA Receive function to process the signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD for canceling the echo and near-end crosstalk (NEXT).

126.2.2.4 PMA_UNITDATA.indication

This primitive defines the transfer of code-groups in the form of the rx_symb_vector parameter from the PMA to the PCS.

126.2.2.4.1 Semantics of the primitive

PMA_UNITDATA.indication (rx_symb_vector)

During reception the PMA_UNITDATA.indication simultaneously conveys to the PCS via the parameter rx_symb_vector the values of the symbols detected on each of the four receive pairs BI_DA, BI_DB, BI_DC, and BI_DD. The rx_symb_vector parameter takes on the following form:

SYMB_4D A vector of the four 1D symbols that is the receiver's best estimate of the symbols that were sent by the remote transmitter across the four pairs with reliability measures.

126.2.2.4.2 When generated

The PMA generates PMA_UNITDATA.indication (SYMB_4D) messages synchronously every four symbols received at the MDI. The nominal rate of the PMA_UNITDATA.indication primitive is $S \times 400$ MHz, as governed by the recovered clock.

126.2.2.4.3 Effect of receipt

The effect of receipt of this primitive is unspecified.

126.2.2.5 PMA_SCRSTATUS.request

This primitive is generated by PCS Receive to communicate the status of the descrambler for the local PHY. The parameter scr_status conveys to the PMA Receive function the information that the training mode descrambler has achieved synchronization.

126.2.2.5.1 Semantics of the primitive

PMA_SCRSTATUS.request (scr_status)

The scr_status parameter can take on one of the following two values of the form:

OK The training mode descrambler has achieved synchronization.

NOT_OK The training mode descrambler is not synchronized.

126.2.2.5.2 When generated

PCS Receive generates PMA_SCRSTATUS.request messages to indicate a change in scr_status.

126.2.2.5.3 Effect of receipt

The effect of receipt of this primitive is specified in 126.4.2.4, 126.4.2.5, and 126.4.6.1.

126.2.2.6 PMA_PCSSTATUS.request

This primitive is generated by PCS Receive to indicate the fully operational state of the PCS for the local PHY. The parameter pcs_status conveys to the PMA Receive function the information that the PCS is operating reliably in data mode.

126.2.2.6.1 Semantics of the primitive

PMA_PCSSTATUS.request (pcs_status)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The pcs_status parameter can take on one of the following two values of the form:

OK	The PCS is operating reliably in data mode.
NOT_OK	The PCS is not operating reliably in data mode.

126.2.2.6.2 When generated

PCS Receive generates PMA_PCSSTATUS.request messages to indicate a change in pcs_status.

126.2.2.6.3 Effect of receipt

The effect of receipt of this primitive is specified in 126.4.6.

126.2.2.7 PMA_RXSTATUS.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY. The parameter loc_rcvr_status conveys to the PCS Transmit, PCS Receive, PMA PHY Control function, and Link Monitor the information on whether the status of the overall receive link is satisfactory or not. Note that loc_rcvr_status is used by the PCS Receive decoding functions. The criterion for setting the parameter loc_rcvr_status is left to the implementer. It can be based, for example, on observing the mean-square error at the decision point of the receiver and detecting errors during reception of symbol streams.

126.2.2.7.1 Semantics of the primitive

PMA_RXSTATUS.indication (loc_rcvr_status)

The loc_rcvr_status parameter can take on one of the following two values of the form:

OK	This value is asserted and remains true during reliable operation of the receive link for the local PHY.
NOT_OK	This value is asserted whenever operation of the link for the local PHY is unreliable.

126.2.2.7.2 When generated

PMA Receive generates PMA_RXSTATUS.indication messages to indicate a change in loc_rcvr_status on the basis of signals received at the MDI.

126.2.2.7.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 126–26 and in 126.2 and 126.4.6.3.

126.2.2.8 PMA_REMRXSTATUS.request

This primitive is generated by PCS Receive to indicate the status of the receive link at the remote PHY as communicated by the remote PHY via its encoding of its loc_rcvr_status parameter. The parameter rem_rcvr_status conveys to the PMA PHY Control function the information on whether reliable operation of the remote PHY is detected or not. The criterion for setting the parameter rem_rcvr_status is left to the implementer. It can be based, for example, on asserting rem_rcvr_status is NOT_OK until loc_rcvr_status is OK and then asserting the detected value of rem_rcvr_status after proper PCS Receive decoding is achieved.

126.2.2.8.1 Semantics of the primitive

PMA_REMRXSTATUS.request (rem_rcvr_status)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The rem_rcvr_status parameter can take on one of the following two values of the form:

OK	The receive link for the remote PHY is operating reliably.
NOT_OK	Reliable operation of the receive link for the remote PHY is not detected.

126.2.2.8.2 When generated

The PCS generates PMA_REMRXSTATUS.request messages to indicate a change in rem_rcvr_status on the basis of signals received at the MDI.

126.2.2.8.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 126–26.

126.2.2.9 PMA_ALERTDETECT.indication

This primitive is generated by PMA Receive to indicate the status of the receive link at the local PHY when rx_lpi_active is TRUE. The parameter alert_detect conveys to the PCS receive function information regarding the detection of the LPI alert signal by the PMA receive function. The criterion for setting the parameter alert_detect is left to the implementer.

126.2.2.9.1 Semantics of the primitive

PMA_ALERTDETECT.indication (alert_detect)

The alert_detect parameter can take on one of the following two values of the form:

TRUE	The alert signal has been reliably detected at the local receiver.
FALSE	The alert signal at the local receiver has not been detected.

126.2.2.9.2 When generated

The PMA generates PMA_ALERTDETECT.indication messages to indicate a change in the alert_detect status.

126.2.2.9.3 Effect of receipt

The effect of receipt of this primitive is specified in 126.3.2.3, Figure 126–16, and Figure 126–17.

126.2.2.10 PCS_RX_LPI_STATUS.request

When the PHY supports the EEE capability this primitive is generated by the PCS receive function to indicate the status of the receive link at the local PHY. The parameter PCS_RX_LPI_STATUS.request conveys to the PCS transmit and PMA receive functions information regarding whether the receive function is in the LPI receive mode. The parameter is generated by the Receive 64B/65B state diagram in Figure 126–16.

126.2.2.10.1 Semantics of the primitive

PCS_RX_LPI_STATUS.request (rx_lpi_active)

The rx_lpi_active parameter can take on one of the following two values of the form:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TRUE	The receive function is in the LPI receive mode.
FALSE	The receive function is not in the LPI receive mode.

126.2.2.10.2 When generated

The PCS generates PCS_RX_LPI_STATUS.request messages to indicate a change in the rx_lpi_active variable as determined by the receive state diagram in Figure 126–16.

126.2.2.10.3 Effect of receipt

The effect of receipt of this primitive is specified in 126.3.2.3 and Figure 126–30.

126.2.2.11 PMA_PCSDATAMODE.indication

This primitive indicates whether or not the PCS state diagrams are able to transition from their initialization states. The pcs_data_mode variable is generated by the PMA PHY Control function. It is passed to the PCS Control function via the PMA_PCSDATAMODE.indication primitive.

126.2.2.11.1 Semantics of the primitive

PMA_PCSDATAMODE.indication (pcs_data_mode)

The pcs_data_mode parameter can take on one of the following two values of the form:

TRUE	PHY is in state PCS_Data (see Figure 126–26).
FALSE	PHY is not in state PCS_Data (see Figure 126–26).

126.2.2.11.2 When generated

The PMA PHY Control function generates PMA_PCSDATAMODE.indication messages continuously.

126.2.2.11.3 Effect of receipt

Upon receipt of this primitive, the PCS performs its transmit function as described in 126.3.2.2.

126.2.2.12 PMA_FR_ACTIVE.indication

This primitive indicates whether or not the PMA is currently performing a fast retrain. The fr_active variable is generated by the PMA PHY Control function. It is passed to the PCS Receive Control function via the PMA_FR_ACTIVE.indication primitive. This primitive is only supported by PHYs with the fast retrain capability.

126.2.2.12.1 Semantics of the primitive

PMA_FR_ACTIVE.indication (fr_active)

The fr_active parameter can take on one of the following two values of the form:

TRUE	PHY is currently performing a fast retrain.
FALSE	PHY is not currently performing a fast retrain.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.2.2.12.2 When generated

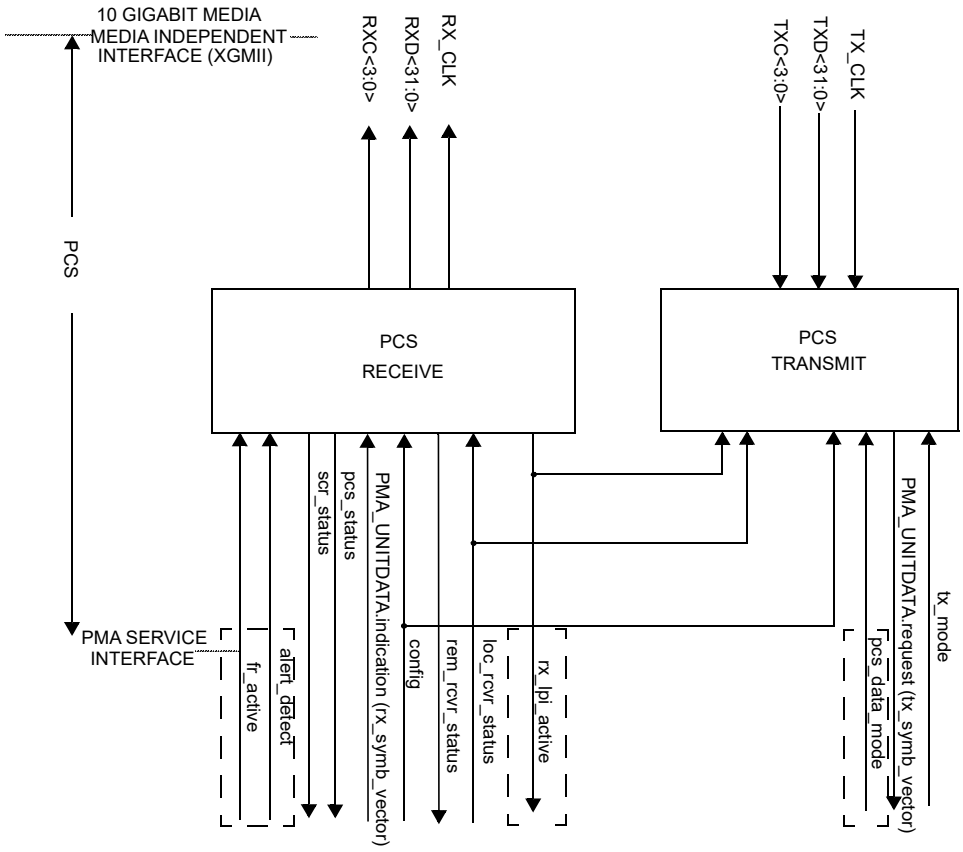
The PMA PHY Control function generates PMA_FR_ACTIVE.indication messages continuously.

126.2.2.12.3 Effect of receipt

The effect of receipt of this primitive is specified in Figure 126–16.

126.3 Physical Coding Sublayer (PCS)

126.3.1 PCS service interface (XGMII)



The PCS service interface allows the 2.5GBASE-T or 5GBASE-T PCS to transfer information to and from a PCS client. The PCS Interface is precisely defined as the 10 Gigabit Media Independent Interface (XGMII) in Clause 46.

126.3.2 PCS functions

The PCS comprises one PCS Reset function and two simultaneous and asynchronous operating functions. The PCS operating functions are: PCS Transmit and PCS Receive. All operating functions start immediately after the successful completion of the PCS Reset function.

The PCS reference diagram, Figure 126–5, shows how the two operating functions relate to the messages of the PCS-PMA interface. Connections from the management interface (signals MDC and MDIO) to other layers are pervasive and are not shown in Figure 126–5.

NOTE 1—pcs_data_mode is required only for the EEE or fast retrain capabilities.
NOTE 2—alert_detect and rx_lpi_active are only required for the EEE capability.
NOTE 3—fr_active is only required for the fast retrain capability.

Figure 126–5—PCS reference diagram

126.3.2.1 PCS Reset function

PCS Reset initializes all PCS functions. The PCS Reset function shall be executed whenever one of the following conditions occur:

a) Power on (see 126.3.6.2.2).
b) The receipt of a request for reset from the management entity.

PCS Reset sets pcs_reset = true while any of the above reset conditions hold true. All state diagrams take the open-ended pcs_reset branch upon execution of PCS Reset. The reference diagrams do not explicitly show the PCS Reset function.

126.3.2.2 PCS Transmit function

The PCS Transmit function shall conform to the PCS 64B/65B Transmit state diagram in Figure 126–14 and the PCS Transmit bit ordering in Figure 126–6.

Dashed rectangles in Figure 126–14 and Figure 126–15 are used to indicate states and state transitions in the PCS 64B/65B Transmit state diagram that shall be supported by PHYs with the EEE capability. PHYs without the EEE capability do not support these transitions.

When communicating with the XGMII, the PCS uses a 4-octet-wide, synchronous data path, with packet delimiting being provided by transmit control signals and receive control signals. Alignment to 64B/65B is performed in the PCS. The PMA sublayer operates independently of block and packet boundaries. The PCS provides the functions necessary to map packets between the XGMII format and the PMA service interface format.

When the transmit channel is in normal mode, the PCS Transmit process continuously generates 65B blocks based upon the TXD <31:0> and TXC <3:0> signals on the XGMII. The subsequent functions of the PCS Transmit process then scramble the bits of the 65B blocks, pack the resulting scrambled blocks, append 97 zeros, and attach a leading aux channel bit, all of which are then processed by a low density parity check (LDPC) encoder. The appended zeros are then replaced by vendor discretionary randomized bits. The resulting 2048-bit LDPC frame is then mapped into PAM16 symbols. Transmit data-units are sent to the PMA service interface via the PMA_UNITDATA.request primitive.

In each symbol period, when communicating with the PMA, the PCS Transmit generates a code-group (A_n, B_n, C_n, D_n) that is transferred to the PMA via the PMA_UNITDATA.request primitive. The PMA transmits symbols A_n, B_n, C_n, D_n over wire-pairs BI_DA, BI_DB, BI_DC, and BI_DD respectively. The integer, n, is a time index that is introduced to establish a temporal relationship between different symbol periods. A symbol period, T, is 2.5/S ns.

If a PMA_TXMODE.indication message has the value SEND_Z, PCS Transmit passes a vector of zeros at each symbol period to the PMA via the PMA_UNITDATA.request primitive.

If a PMA_TXMODE.indication message has the value SEND_T, PCS Transmit generates sequences of code-groups (TA_n, TB_n, TC_n, TD_n) defined in 126.3.4.2 to the PMA via the PMA_UNITDATA.request primitive. These code-groups are used for training mode and only transmit the values {–9, 9} to keep the transmit power in the training mode the same as the transmit power in normal mode.

During training mode an Infofield is transmitted at regular intervals containing messages for startup operation. By this mechanism, a PHY indicates the status of its own receiver to the link partner and makes requests for remote transmitter settings. (See 126.4.2.5.)

In the normal mode of operation, the PMA_TXMODE.indication message has the value SEND_N, and the PCS Transmit function uses a 65B-LDPC coding to generate at each symbol period code-groups that represent data or control. During transmission, the 65B encoded bits are scrambled by the PCS using a PCS scrambler, 97 zero bits and an auxiliary bit are added, then frames are encoded into a code-group of 4D symbols and transferred to the PMA. During data encoding, PCS Transmit utilizes an LDPC frame encoder.

After reaching the normal mode of operation, EEE-capable PHYs may enter the LPI transmit mode under the control of the MAC via the XGMII. The EEE Transmit state diagram is contained within the PCS Transmit function. The EEE capability is described in 126.3.2.2.19.

126.3.2.2.1 Use of blocks

The PCS translates between XGMII signals and 65-bit blocks inserted within an LDPC frame using a 65B-LDPC coding scheme. The PAM2 PMA training frame synchronization allow establishment of LDPC frame and 65B boundaries by the PCS Synchronization process. Blocks and frames are unobservable and have no meaning outside the PCS. During the LPI mode, LDPC frame boundaries delimit sleep, wake, refresh, quiet, and alert cycles. The PCS functions ENCODE and DECODE generate, manipulate, and interpret blocks and frames as provided by the rules in 126.3.2.2.2.

126.3.2.2.2 65B-LDPC transmission code

The PCS uses a transmission code to improve the transmission characteristics of information to be transferred across the link and to support transmission of control and data characters. In addition, the code enables the receiver to achieve PCS synchronization alignment on the incoming PHY bit stream.

The relationship of block bit positions to XGMII, PMA, and other PCS constructs is illustrated in Figure 126–6 for transmit and Figure 126–7 for receive. These figures illustrate the processing of a multiplicity of blocks containing 8 data octets. See 126.3.2.2.5 for information on how blocks containing control characters are mapped.

126.3.2.2.3 Notation conventions

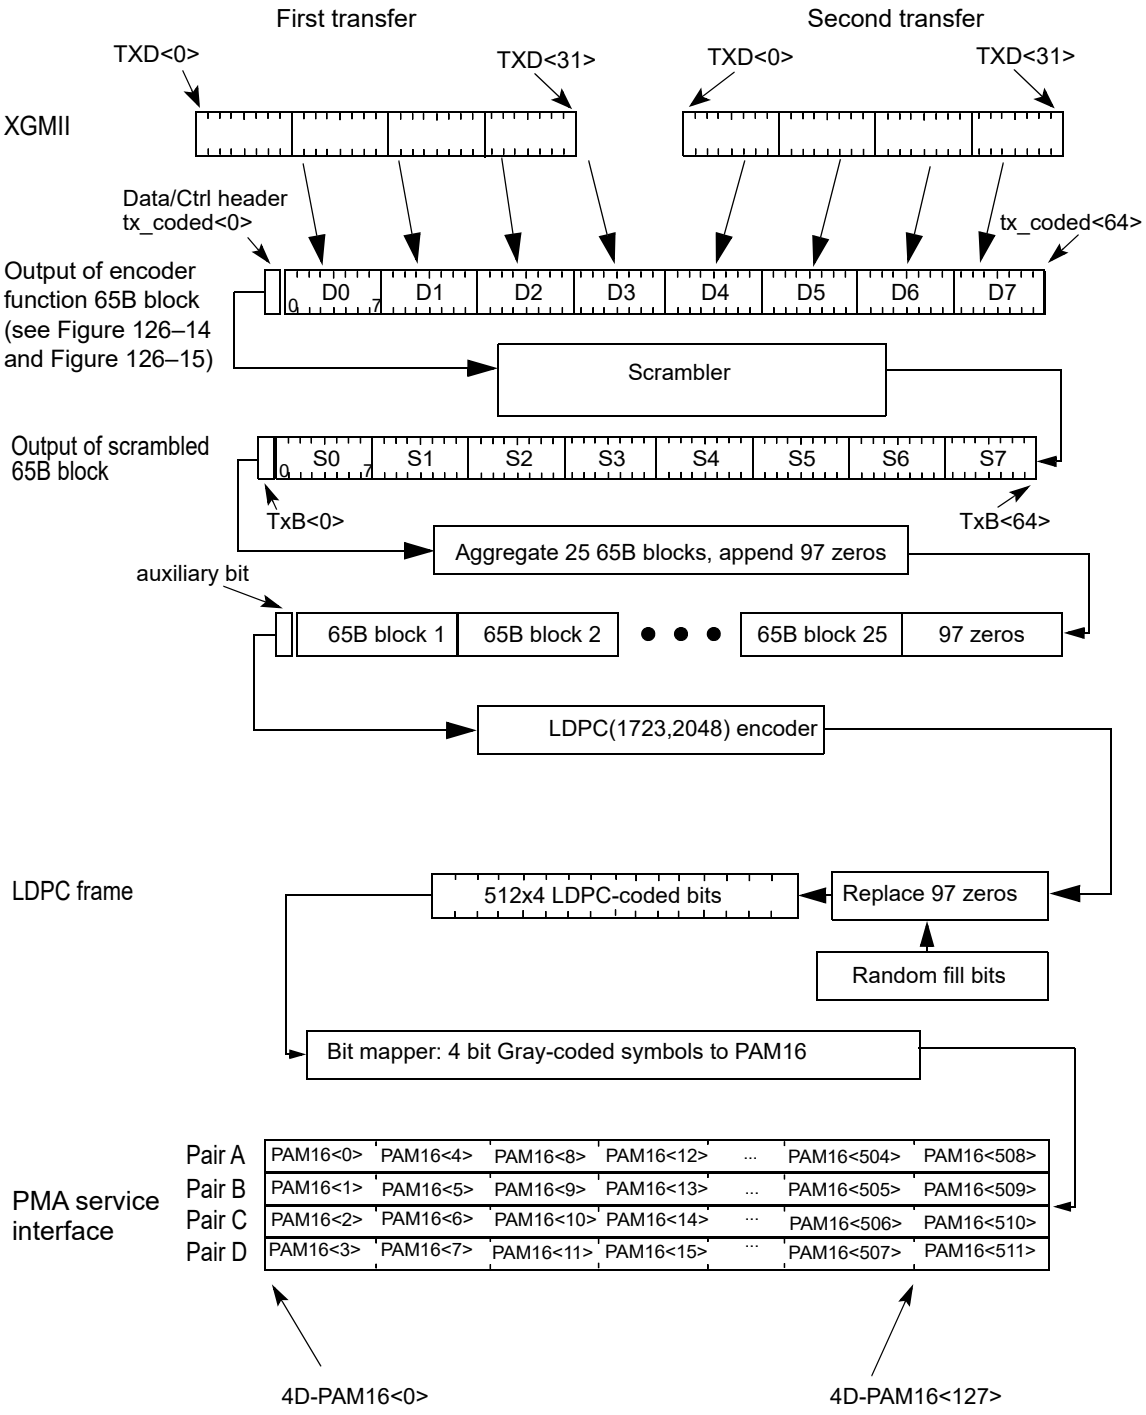
For values shown as binary, the leftmost bit is the first transmitted bit.

64B/65B encodes 8 data octets or control characters into a block. Blocks containing control characters also contain a block type field. Data octets are labeled D_0 to D_7. Control characters other than /O/, /S/, and /T/ are labeled C_0 to C_7. The control character for ordered set is labeled as O_0 or O_4 since it is only valid on the first octet of the XGMII. The control character for start is labeled as S_0 or S_4 for the same reason. The control character for terminate is labeled as T_0 to T_7.

Two consecutive XGMII transfers provides eight characters that are encoded into one 65-bit transmission block. The subscript in the above labels indicates the position of the character in the eight characters from the XGMII transfers.

Contents of block type fields, data octets and control characters are shown in hexadecimal notation. The LSB of the equivalent binary value represents the first transmitted bit. For instance, the block type field 0x1E is sent from left to right as 01111000. The bits of a transmitted or received block are labeled TxB<64:0> and RxB<64:0> respectively where TxB<0> and RxB<0> represent the first transmitted bit. The value of the data/ctrl header is shown as a binary value. Binary values are shown with the first transmitted bit (the LSB) on the left.

126.3.2.2.4 Transmission order



The PCS Transmit bit ordering shall conform to Figure 126–6. Note that this figure shows the mapping from XGMII to 64B/65B block for a block containing eight data characters.

126.3.2.2.5 Block structure

Blocks consist of 65 bits. The first bit of a block is the data/ctrl header. Blocks are either data blocks or control blocks. The data/ctrl header is 0 for data blocks and 1 for control blocks. The remainder of the block contains the payload.

Data blocks contain eight data characters. Control blocks begin with an 8-bit block type field that indicates the format of the remainder of the block. For control blocks containing a Start or Terminate character, that

character is implied by the block type field. Other control characters are encoded in a 7-bit control code or a 4-bit O Code. Each control block contains eight characters.

The format of the blocks is as follows in Figure 126–8. In the figure, the column labeled Input Data shows, in abbreviated form, the eight characters used to create the 65-bit block. These characters are either data characters or control characters and, when transferred across the XGMII interface, the corresponding TXC or RXC bit is set accordingly. Within the Input Data column, D_0 through D_7 are data octets and are transferred with the corresponding TXC or RXC bit set to zero. All other characters are control octets and are transferred with the corresponding TXC or RXC bit set to one. The single bit fields (thin rectangles with no label in the figure) are sent as zero and ignored upon receipt.

Bits and field positions are shown with the least significant bit on the left. Hexadecimal numbers are shown prepended with '0x', and with the least significant digit on the right. For example the block type field 0x1E is sent as 01111000 representing bits 1 through 8 of the 65-bit block. The least significant bit for each field is placed in the lowest numbered position of the field.

All unused values of block type field are reserved.[216]

126.3.2.2.6 Control codes

The same set of control characters are supported by the XGMII, 2.5GBASE-T and 5GBASE-T PCS. The representations of the control characters are the control codes. The XGMII encodes a control character into an octet (an 8-bit value). The 2.5GBASE-T and 5GBASE-T PCS encode the start and terminate control characters implicitly by the block type field. The 2.5GBASE-T and 5GBASE-T PCS encode the ordered set control codes using a combination of the block type field and a 4-bit O code for each ordered set. The 2.5GBASE-T and 5GBASE-T PCS encode each of the other control characters into a 7-bit C code.

The control characters and their mappings to 2.5GBASE-T and 5GBASE-T control codes and XGMII control codes are specified in Table 126–1. All XGMII, 2.5GBASE-T, and 5GBASE-T control code values that do not appear in the table shall not be transmitted and shall be treated as an error if received.

126.3.2.2.7 Ordered sets

Ordered sets are used to extend the ability to send control and status information over the link such as remote fault and local fault status. Ordered sets consist of a control character followed by three data characters. Ordered sets always begin on the first octet of the XGMII. One kind of ordered set is used for 2.5 and 5 Gigabit Ethernet—the sequence ordered set (see 46.3.4). The sequence ordered set control character is denoted /Q/. An additional ordered set, the signal ordered set, has been reserved and it begins with another control code. The 4-bit O field encodes the control code. See Table 126–1 for the mappings.

126.3.2.2.8 Idle (/I/)

Idle control characters (/I/) are transmitted when idle control characters are received from the XGMII. Idle characters may be added or deleted by the PCS to adapt between clock rates. /I/ insertion and deletion shall occur in groups of 4. /I/s may be added following idle or ordered sets. They shall not be added while data is being received. When deleting /I/s, the first four characters after a /T/ shall not be deleted.

[216]The block type field values have been chosen to have a 4-bit Hamming distance between them. The only unused value that maintains the Hamming distance is 0x00.

126.3.2.2.9 LPI (/LI/)

Low power idle (LPI) control characters (/LI/) on the XGMII indicate that the LPI client is requesting operation in the LPI transmit mode. A continuous stream of LPI control characters (/LI/) is used to maintain a link in the LPI transmit mode. Idle control characters (/I/) are used to transition from the LPI transmit mode to the normal mode. PHYs that support EEE respond to the LPI XGMII control characters using the procedure outlined in 126.1.3.3. LPI characters may be added or deleted by the PCS to adapt between clock rates. /LI/ insertion and deletion shall occur in groups of four. /LI/s may be added following low power idle characters. They shall not be added while data is being received.

If EEE is not supported, then /LI/ is not a valid control character.

126.3.2.2.10 Start (/S/)

The start control character (/S/) indicates the start of a packet. This delimiter is only valid on the first octet of the XGMII (TXD<7:0> and RXD<7:0>). Receipt of an /S/ on any other octet of TXD indicates an error. Block type field values implicitly encode an /S/ as the fifth or first character of the block. These are the only characters of a block on which a start can occur.

126.3.2.2.11 Terminate (/T/)

The terminate control character (/T/) indicates the end of a packet. Since packets may be any length, the /T/ can occur on any octet of the XGMII interface and within any character of the block. The location of the /T/ in the block is implicitly encoded in the block type field. A valid end of packet occurs when a block containing a /T/ is followed by a control block that does not contain a /T/.

126.3.2.2.12 ordered set (/O/)

The ordered set control characters (/O/) indicate the start of an ordered set. There are two kinds of ordered sets: the sequence ordered set and the signal ordered set (which is reserved). When it is necessary to designate the control character for the sequence ordered set specifically, /Q/ is used. /O/ is only valid on the first octet of the XGMII. Receipt of an /O/ on any other octet of TXD indicates an error. Block type field

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

values implicitly encode an /O/ as the first or fifth character of the block. The 4-bit O code encodes the specific /O/ character for the ordered set.

Sequence ordered sets may be deleted by the PCS to adapt between clock rates. Such deletion shall only occur when two consecutive sequence ordered sets have been received and shall delete only one of the two. Only Idles may be inserted for clock compensation. Signal ordered sets are not deleted for clock compensation.

126.3.2.2.13 Error (/E/)

The /E/ is sent whenever an /E/ is received. The /E/ allows physical sublayers such as the PCS to propagate received errors. See R_BLOCK_TYPE and T_BLOCK_TYPE function definitions in 126.3.6.2.4 for further information.

126.3.2.2.14 Transmit process

The transmit process generates blocks based upon the TXD<31:0> and TXC<3:0> signals received from the XGMII. Two XGMII data transfers are encoded into each block. 50 XGMII data transfers are encoded into an LDPC frame. It takes 128 PMA_UNITDATA transfers to send an LDPC frame of data. Therefore, if the PCS is connected to an XGMII and PMA sublayer where the ratio of their transfer rates is exactly 25:64, then the transmit process does not need to perform rate adaptation. Where the XGMII and PMA sublayer data rates are not synchronized to that ratio, the transmit process needs to insert idles, delete idles, or delete sequence ordered sets to adapt between the rates.

The transmit process generates blocks as specified in the PCS 64B/65B Transmit state diagram (see Figure 126–16 and Figure 126–17). The contents of each block are contained in a vector tx_coded<64:0>, which is passed to the scrambler. tx_coded<0> contains the data/ctrl header and the remainder of the bits contain the block payload.

126.3.2.2.15 PCS Scrambler

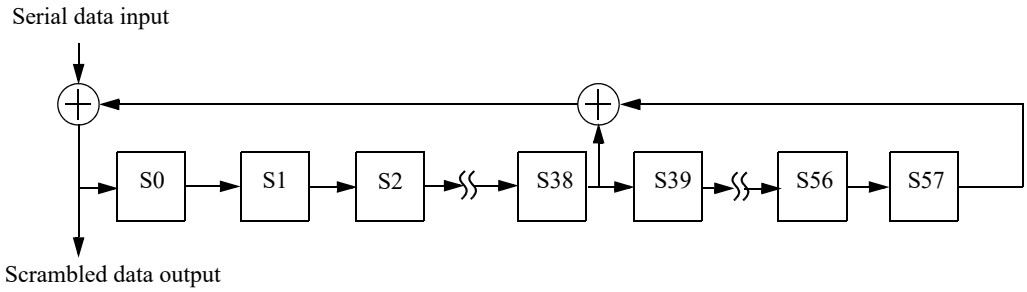
The payload of the PCS PHY frame is scrambled with a self-synchronizing scrambler. The scrambler for the MASTER shall produce the same result as the implementation shown in Figure 126–9. This implements the scrambler polynomial:[217]

$$G(x) = 1 + x^{39} + x^{58} \quad (126–1)$$

The scrambler for the SLAVE shall produce the same result as the implementation shown in Figure 126–9. This implements the scrambler polynomial:

$$G(x) = 1 + x^{19} + x^{58} \quad (126–2)$$

The initial seed values for the MASTER and SLAVE are left to the implementer. The scrambler is run continuously on all payload bits.



126.3.2.2.16 LDPC framing and LDPC encoder

The resulting payload of scrambled 25 65B blocks, followed by the 97 zero bits and preceded by 1 auxiliary bit results in a total payload of 25 × 65 + 97 +1 = 1723 bits. The use of the auxiliary bit is for vendor-specific

[217]The convention here, which considers the most recent bit into the scrambler to be the lowest order term, is consistent with most references and with other scramblers shown in this standard. Some references consider the most recent bit into the scrambler to be the highest order term and would therefore identify this as the inverse of the polynomial in Equation (126–1). In case of doubt, note that the conformance requirement is based on the representation of the scrambler in the figure rather than the polynomial equation.

PCS scrambler employed by the MASTER

PCS scrambler employed by the SLAVE

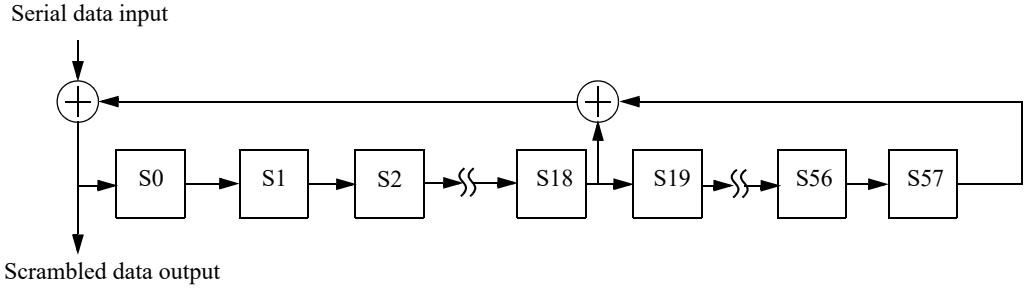

Figure 126–9—MASTER and SLAVE PCS scramblers

communication is outside the scope of this document. For the purposes of this standard it is ignored by the link partner. The 1723 bits shall be encoded by the LDPC(1723, 2048) generator matrix G. G is described in Annex 55A.

The LDPC encoding takes the 1723 bit input code vector $x = [x_0\ x_1\ x_2\ ...\ x_{1722}]$, and shall generate the 2048 bit codeword c represented by the matrix multiplication $c = x \times G$. For both x and c the leftmost element of the vector is the first bit into the LDPC encoder and the first transmitted bit.

126.3.2.2.17 Substitution for zero-bit fill

The 2048 LDPC-coded bits output from the LDPC encoder in Figure 126–6 are then divided into three groups: the first 1626 bits, representing the auxiliary bit and the 25 scrambled 65B blocks of Ethernet payload; the subsequent 97 bits, representing the zero-fill added prior to encoding, and the subsequent 325 LDPC check bits. The group of 97 zero-fill bits are then replaced by vendor discretionary, randomized bits. The randomized fill bits should approximate the autocorrelation properties of the PCS scrambler described in 126.3.2.2.15, so as not to generate tones violating the transmit spectral PSD masks in 126.5.3.4.

126.3.2.2.18 PAM16 bit mapping

The LDPC frame shall be mapped four bits at a time in bit order of transmission into Gray-coded PAM-16 as follows in Table 126–2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 126–2—PAM16 to Gray coded PAM16 mapping

Bits ($b_0b_1b_2b_3$)	Hex	Level
0100	0x4	+15
0101	0x5	+13
0111	0x7	+11
0110	0x6	+9
0010	0x2	+7
0011	0x3	+5
0001	0x1	+3
0000	0x0	+1
1000	0x8	–1
1001	0x9	–3
1011	0xB	–5
1010	0xA	–7
1110	0xE	–9
1111	0xF	–11
1101	0xD	–13
1100	0xC	–15

126.3.2.2.19 EEE capability

The optional 2.5GBASE-T or 5GBASE-T EEE capability allows compliant PHYs to transition to an LPI mode of operation when link utilization is low.

PHYs that support EEE shall conform to the EEE transmit state diagram, shown in Figure 126–18, within the PCS.

When PCS_Reset is asserted or pcs_data_mode is not asserted, the state diagram enters the TX_NORMAL state.

When a complete 64B/65B block of LPI characters is generated by the PCS transmit function, the PHY transmits the sleep signal to indicate to the link partner that it is transitioning to the LPI transmit mode. If the sleep signal begins on an even LDPC frame boundary aligned to the inversion on pair A during PMA training, then it contains 18 full LDPC frames each composed entirely of LDPC encoded LP_IDLE blocks. If the sleep signal does not begin on an even LDPC frame boundary, then it contains one to two LDPC frames partially composed of LP_IDLE blocks followed by 18 LDPC frames fully composed of LP_IDLE blocks.

Following the transmission of the sleep signal, quiet-refresh signaling begins, as described in 126.3.5.

After the sleep signal is transmitted LPI control characters shall be input to the PCS scrambler continuously until the PCS Transmit Function exits the LPI transmit mode.

While the PMA asserts SEND_N, the lpi_tx_mode variable shall control the transmit signal through the PMA_UNITDATA.request primitive described as follows:

When the PHY is not in the PCS_Data state, the lpi_tx_mode variable is ignored.

When the lpi_tx_mode variable takes the value NORMAL and the PMA asserts SEND_N, the PCS passes coded data to the PMA via the PMA_UNITDATA.request primitive as described in 126.3.2.2.

When the lpi_tx_mode variable takes the value QUIET and the PMA asserts SEND_N, the PCS passes zeros to the PMA through the PMA_UNITDATA.request primitive.

When the lpi_tx_mode variable takes the value REFRESH_A and the PMA asserts SEND_N, the PCS passes the PMA training signal to the PMA on pair A, to allow both the local and remote PHY to refresh adaptive filters and timing loops. The PCS passes zeros to all other pairs in this condition. REFRESH_B, REFRESH_C and REFRESH_D operate in an analogous manner for the other pairs.

When the lpi_tx_mode variable takes the value ALERT and the PMA asserts SEND_N, the PCS passes the ALERT vector to the PMA.

The quiet-refresh cycle is repeated until codewords other than LP_IDLE are detected at the XGMII. These codewords indicate that the local system is requesting a transition back to the normal operational mode. Following this event, the PMA_UNITDATA.request parameter tx_symb_vector is set to the value ALERT. The alert signal is not synchronized with respect to the quiet-refresh cycle but shall be synchronized so that the alert signal from the PMA begins on a LDPC 2-frame 256 4D-symbol boundary aligned to the inversion on pair A during PMA training.

The PHY also transitions back to the normal operation mode if an error condition occurs. This error condition is defined as the detection of any characters other than LPI or IDLE at the XGMII.

After the alert signal the PCS completes the transition from LPI mode to normal mode by sending a wake signal containing lpi_wake_time LDPC frames composed of IDLE 64B/65B blocks.

lpi_wake_time is a fixed parameter that is defined as 18 LDPC frames as follows in Table 126–3. The maximum PHY wake time when wake is requested before sleep has been completely transmitted is 14.72/S μs (lpi_wake_timer=T_{w_phy} as defined by Clause 78). The maximum PHY wake time when wake is requested after sleep has been completely transmitted is 8.96/S μs.

Table 126–3—LPI wake time

lpi_wake_time	lpi_wake_timer when wake starts before sleep signal is complete		lpi_wake_timer when wake starts after sleep signal is complete	
(frames)	(frames)	(μs)	(frames)	(μs)
18	46	14.72/S	28	8.96/S

126.3.2.3 PCS Receive function

The PCS Receive function shall conform to the PCS 64B/65B receive state diagram in Figure 126–16 and Figure 126–17 and the PCS Receive bit ordering in Figure 126–7 including compliance with the associated state variables as specified in 126.3.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PCS Receive function accepts received code-groups provided by the PMA Receive function via the parameter rx_symb_vector. The PCS receiver uses knowledge of the encoding rules to correctly align the 65B-LDPC frames. The randomized bits are replaced with known zeros. The received 65B-LDPC frames are decoded with error correction; the auxiliary bit and the trailing zero-fill bits are then stripped; descrambling is then performed. This process generates the 64B/65B block vector rx_coded<64:0>, which is then decoded to form the XGMII signals RXD<31:0> and RXC<3:0> as specified in the PCS 64B/65B Receive state diagram (see Figure 126–16 and Figure 126–17). Two XGMII data transfers are decoded from each block. Where the XGMII and PMA sublayer data rates are not synchronized to a 25:64 ratio, the receive process inserts idles, deletes idles, or deletes sequence ordered sets to adapt between rates.

During PMA training mode, PCS Receive checks the received PAM2 framing and signals the reliable acquisition of the descrambler state by setting the scr_status parameter of the PMA_SCRSTATUS.request primitive to OK.

When the PCS Synchronization process has obtained synchronization, the LDPC frame error ratio (LFER) monitor process monitors the signal quality asserting hi_lfer if excessive LDPC frame errors are detected (LDPC parity error). If 40 consecutive LDPC frame errors are detected, the block_lock flag is de-asserted. When block_lock is asserted and hi_lfer is de-asserted, the PCS Receive process continuously accepts blocks. The PCS Receive process monitors these blocks and generates RXD <31:0> and RXC <3:0> on the XGMII.

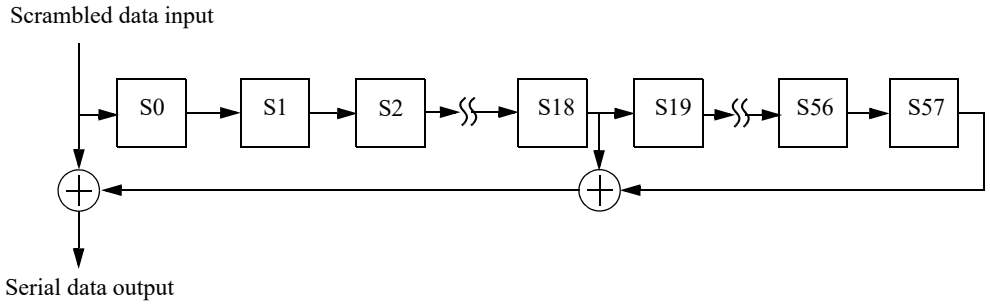
When the receive channel is in training mode, the PCS Synchronization process continuously monitors PMA_RXSTATUS.indication (loc_rcvr_status). When loc_rcvr_status indicates OK, then the PCS Synchronization process accepts data-units via the PMA_UNITDATA.indication primitive. It attains frame and block synchronization based on the PMA training frames and conveys received blocks to the PCS Receive process. The PCS Synchronization process sets the block_lock flag to indicate whether the PCS has obtained synchronization. The PMA training sequence includes 1 bit pattern on pair A every 256 PAM2 symbols, which is aligned with the PCS boundary of two LDPC frames. When the PCS Synchronization process is synchronized to this pattern, block_lock is asserted.

PHYs with the EEE capability support transition to the LPI mode when the PHY has successfully completed training and pcs_data_mode is TRUE. Transitions to and from the LPI mode are allowed to occur independently in the transmit and receive functions. The PCS receive function is responsible for detecting transitions to and from the LPI receive mode and indicating these transitions using signals defined in 126.2.2.

The link partner signals a transition to the LPI mode of operation by transmitting 18 LDPC frames composed entirely of 64B/65B blocks of /LI/. When blocks of /LI/ are detected at the output of the 64B/65B decoder, rx_lpi_active is asserted by the PCS receive function and the /LI/ character is continuously asserted at the receive XGMII. These frames may be preceded by a frame composed partially of /LI/ characters. After these frames the link partner begins transmitting zeros, and it is recommended that the receiver power down receive circuits to reduce power consumption. The receive function uses LDPC frame counters to maintain synchronization with the remote PHY and receives periodic refresh signals that are used to update coefficients, so that the integrity of adaptive filters and timing loops in the PMA is maintained. LPI signaling is defined in 126.3.5. The quiet-refresh cycle continues until the PMA asserts alert_detect to indicate that the alert signal has been reliably detected. After the alert signal the link partner transmits repeated /I/ characters, representing a wake signal. The PHY receive function sends /I/ to the XGMII for 18 LDPC frame periods and then resumes normal operation.

126.3.2.3.1 Frame and block synchronization

When the receive channel is operating in normal mode, the frame and block synchronization function receives data via 4D-PAM16 PMA_UNITDATA.indication primitives. It shall form a 4D-PAM16 stream from the primitives by concatenating requests with the PAM16s of each primitive in order from



Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_symb_vector<0> to rx_symb_vector<127> (see Figure 126–7). It obtains block_lock to the LDPC frames during the PAM2 training pattern using synchronization bits provided on pair A. The 65-bit blocks are extracted based on their location in the LDPC frame.

126.3.2.3.2 PCS descrambler

The descrambler processes the payload to reverse the effect of the scrambler using the same polynomial. It shall produce the same result as the implementations shown in Figure 126–10 for the MASTER and the SLAVE.

PCS descrambler employed by the MASTER

PCS descrambler employed by the SLAVE

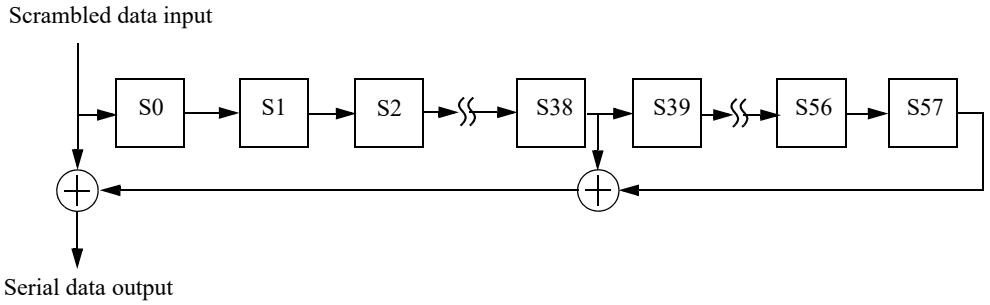


Figure 126–10—MASTER and SLAVE PCS descramblers

126.3.2.3.3 Invalid blocks

A block is invalid if any of the following conditions exists:

a) The block type field contains a reserved value.
b) Any control character contains a value not in Table 126–1.
c) Any O code contains a value not in Table 126–1.
d) The block contains information from the payload of an invalid received PHY frame or the first 64B/65B block following an invalid received PHY frame.

The PCS Receive function shall check the integrity of the LDPC parity bits defined in 126.3.2.2.16. If the check fails the PHY frame is invalid.

R_BLOCK_TYPE of an invalid block is set to E.

126.3.3 Test-pattern generators

The test-pattern generator mode is provided for enabling joint testing of the local transmitter, the channel and remote receiver. When the transmit PCS is operating in test-pattern mode it shall transmit continuously as illustrated in Figure 126–6, with the input to the scrambler set to zero and the initial condition of the scrambler set to any non-zero value. When the receiver PCS is operating in test-pattern mode it shall receive continuously as illustrated in Figure 126–7. After acquiring the self-synchronizing scrambler state, the output of the received scrambled values should ideally be zero. Any nonzero values correspond to receiver bit errors. This mode is further described as test mode 7 in 126.5.2.

126.3.4 PMA training side-stream scrambler polynomials

The PCS Transmit function employs side-stream scrambling for generating 2-level PAM PMA training sequences as follows in Figure 126–11. An implementation of MASTER and SLAVE PHY side-stream scramblers is shown in the "Main PN sequence" box. The bits stored in the shift register delay line at time n are denoted by $Scr_n[32:0]$. At each symbol period, the shift register is advanced by one bit, and one new bit represented by $Scr_n[0]$ is generated. The transmitter side-stream scrambler is reset upon execution of the PCS Reset function. If PCS Reset is executed, all bits of the 33-bit vector representing the side-stream scrambler state are arbitrarily set. The initialization of the scrambler state is left to the implementer. In no case shall the scrambler state be initialized to all zeros.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Main PN sequence:

$$Scr_n[32:1] = Scr_{n-1}[31:0]$$

$$Scr_n[0] = \begin{cases} Scr_{n-1}[12] + Scr_{n-1}[32] & \text{if PMA_CONFIG=MASTER} \\ Scr_{n-1}[19] + Scr_{n-1}[32] & \text{if PMA_CONFIG=SLAVE} \end{cases}$$

Derived sequences:

$$Sa_n = \begin{cases} Scr_n[0] \oplus 1 & \text{if } n \bmod 256 = 0 \\ Scr_n[0] & \text{otherwise} \end{cases}$$

$$Sb_n = Scr_n[3] \oplus Scr_n[8]$$

$$Sc_n = Scr_n[6] \oplus Scr_n[16]$$

$$Sd_n = Scr_n[9] \oplus Scr_n[14] \oplus Scr_n[19] \oplus Scr_n[24]$$

Figure 126–11—A realization of PMA training PAM2 sequences

126.3.4.1 Generation of bits Sa_n, Sb_n, Sc_n, Sd_n

PMA training signal encoding rules are based on the generation, at time *n*, of the four bits Sa_n, Sb_n, Sc_n, Sd_n. These four bits are generated in a systematic fashion using the bits in $Scr_n[32:0]$, and an auxiliary generating polynomial. For both MASTER and SLAVE PHYs, they are obtained by the same linear combinations of bits stored in the transmit scrambler shift register delay line. These four bits are derived from elements of the same maximum-length shift register sequence of length $2^{33}-1$ as $Scr_n[0]$, but shifted in time. The associated delays are all large and different so that there is no short-term correlation among the bits Sa_n, Sb_n, Sc_n, Sd_n. The four bits are generated using the bit $Scr_n[0]$ and the equations in Figure 126–11 in the "Derived sequences" box.

126.3.4.2 Generation of 4D symbols TA_n, TB_n, TC_n, TD_n

The four bits Sa_n, Sb_n, Sc_n, Sd_n are mapped to a 4D symbol (TA_n, TB_n, TC_n, TD_n) as follows in Figure 126–11.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The inversion on pair A at 256 intervals ($n = k \times 256, k = 0, 1, 2, \ldots$) defines the LDPC boundary during data mode.

Notice that over the repeating time intervals of 16384 and of length 128, $m \times 16384 - 128 \le n < m \times 16384, m = 1, 2, 3, \ldots$, the PMA training pattern in pair A is XOR'ed with the Infofield. Thus, pair A transmits the Infofield, which communicates to the remote transceiver settings of THP and power backoff and other control information.

126.3.4.3 PMA training mode descrambler polynomials

The PHY shall acquire descrambler state synchronization to the PAM2 training sequence and report success through scr_status. For side-stream descrambling, the MASTER PHY shall employ the receiver descrambler generator polynomial $g'_M(x) = 1 + x^{20} + x^{33}$ and the SLAVE PHY shall employ the receiver descrambler generator polynomial $g'_S(x) = 1 + x^{13} + x^{33}$.

126.3.5 LPI signaling

PHYs with EEE capability have transmit and receive functions that can enter and leave the LPI mode independently. The PHY can transition to the LPI mode when the PHY has successfully completed training and pcs_data_mode is TRUE. The transmit function of the PHY initiates a transition to the LPI transmit mode when it generates 64B/65B blocks composed entirely of LPI control characters, as described in 126.3.2.2.19. The transmit function of the link partner signals the transition using the sleep signal. When the transmitter begins to send the sleep signal, it asserts tx_lpi_active and the transmit function enters the LPI transmit mode.

Within the LPI mode PHYs use a repeating quiet-refresh cycle (see Figure 126–12). The first part of this cycle is known as the quiet period and lasts for a time lpi_quiet_time equal to 120 LDPC frame periods. The quiet period is defined in 126.3.5.2. The second part of this cycle is known as the refresh period and lasts for a time lpi_refresh_time equal to 8 LDPC frame periods. The refresh period is defined in 126.3.5.3. A cycle composed of one quiet period and one refresh period is known as a single pair LPI cycle and lasts for a time lpi_qr_time equal to 128 LDPC frame periods. The time taken to complete a quiet-refresh cycle for all four pairs is known as a complete LPI cycle.

lpi_offset, lpi_quiet_time, lpi_refresh_time, lpi_qr_time, and lpi_allpairs_qr_time are timing parameters that are integer multiples of the LDPC frame period. lpi_offset is a fixed value equal to lpi_qr_time/2 that is used to ensure refresh signals are appropriately offset by the link partners.

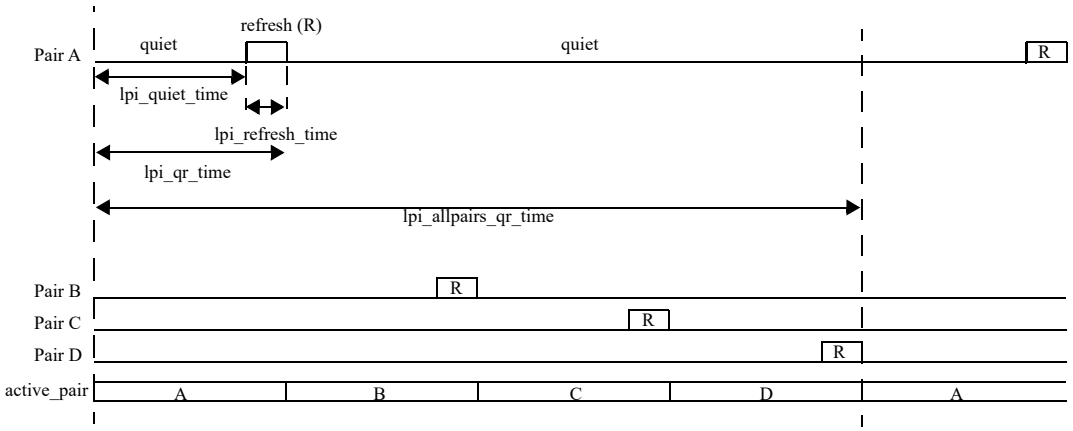

Figure 126–12—Timing periods for LPI signals

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PHYs begin the transition from the LPI receive mode when the alert signal is detected by the PMA as defined in 126.4.2.4.

126.3.5.1 LPI Synchronization

To maximize power savings, maintain link integrity, and ensure interoperability, EEE-capable PHYs synchronize refresh intervals during the LPI mode. The transition to PCS_Test is used as a fixed timing reference for the link partners. Refresh signaling is derived by counting LDPC frames from the transition to PCS_Test.

In initial training, normal retraining, and fast retraining, with or without the EEE capability being supported, the master and slave signal when they transition to PCS_Test using the transition counter following the procedure described in 126.4.2.5.15.

A EEE-capable PHY in slave mode is responsible for synchronizing its PMA training frame to the master's PMA training frame during the transition to PMA_Training_Init_S. The slave shall ensure that its PMA training frames are synchronized to the master's PMA training frames within two LDPC frames, measured at the slave MDI on pair A. In addition, the slave shall initialize its transition counter so that it transitions to PCS_Test within two LDPC frames of the master PHY's transition to PCS_Test, measured at the slave PHY's MDI on pair A. This mechanism ensures that the refresh offset is bounded to a small value at both MDI interfaces, thus ensuring there is no overlap of master and slave signals when both transmit and receive are in the LPI mode.

Following the transition to PCS_Test, the PCS counts transmitted and received LDPC frames, and uses these counters to generate refresh and pair control signals for the transmit and receive functions. The transmitted LDPC frame count is named tx_ldpc_frame_cnt. The received LDPC frame count is named rx_ldpc_frame_cnt.

The master and slave shall derive the active pair and refresh_active signals from the LDPC frame counters as follows in Table 126–4 and Table 126–5.

Table 126–4—Synchronization logic derived from slave signal LDPC frame count

Slave-side variable	Master-side variable	for master u=rx_ldpc_frame_cnt for slave u=tx_ldpc_frame_cnt
tx_refresh_active=true	rx_refresh_active=true	lpi_offset – lpi_refresh_time ≤ mod(u,lpi_qr_time) < lpi_offset
tx_lpi_full_refresh=true	N/A	lpi_offset – lpi_refresh_time = mod(u,lpi_qr_time)
tx_active_pair=PAIR_A	rx_active_pair=PAIR_A	lpi_offset + lpi_qr_time ≤ u < lpi_offset + 2 × lpi_qr_time
tx_active_pair=PAIR_B	rx_active_pair=PAIR_B	lpi_offset + 2 × lpi_qr_time ≤ u < lpi_offset + 3 × lpi_qr_time
tx_active_pair=PAIR_C	rx_active_pair=PAIR_C	lpi_offset + 3 × lpi_qr_time ≤ u < 4 × lpi_qr_time OR 0 ≤ u < lpi_offset
tx_active_pair=PAIR_D	rx_active_pair=PAIR_D	lpi_offset ≤ u < lpi_offset + lpi_qr_time

Table 126–5—Synchronization logic derived from master signal LDPC frame count

Slave-side variable	Master-side variable	for master v=tx_ldpc_frame_cnt for slave v=rx_ldpc_frame_cnt
rx_refresh_active=true	tx_refresh_active=true	lpi_quiet_time ≤ mod(v,lpi_qr_time)
N/A	tx_lpi_full_refresh=true	lpi_quiet_time = mod(v,lpi_qr_time)
rx_active_pair=PAIR_A	tx_active_pair=PAIR_A	0 ≤ v < lpi_qr_time
rx_active_pair=PAIR_B	tx_active_pair=PAIR_B	lpi_qr_time ≤ v < 2 × lpi_qr_time
rx_active_pair=PAIR_C	tx_active_pair=PAIR_C	2 × lpi_qr_time ≤ v < 3 × lpi_qr_time
rx_active_pair=PAIR_D	tx_active_pair=PAIR_D	3 × lpi_qr_time ≤ v < 4 × lpi_qr_time

126.3.5.2 Quiet period signaling

During the quiet period the transmitters on all four pairs should be turned off. Average launch power (as measured from 56 LDPC frames after a refresh period to 56 LDPC frames before the next refresh period on the same lane) for each Transmitter shall be less than –41 dBm. This requirement does not apply to the periods when the alert signal is transmitted as defined in 126.4.2.2.1.

126.3.5.3 Refresh period signaling

During the LPI mode 2.5GBASE-T and 5GBASE-T PHYs use staggered, out-of-phase refresh signaling to maximize power savings. Two-level PAM refresh symbols are generated using the PMA side-stream scrambler polynomials described in 126.3.4 and exactly as is shown in Figure 126–11 with the exception that the Infofield consists of a sequence of 128 zeros. The training sequence described in 126.3.4 shall be used during the LPI mode, with the scramblers free-running from PCS Reset.

Refresh signals shall be sent using the THP filter as described in 126.4.3.1. At the start of each refresh signal the THP feedback delay line shall be initialized with zeros.

While a transmit function is in the LPI transmit mode only one of the transmit pairs is active during a refresh period. tx_symb_vector for all transmit pairs that are not active shall be set to zero.

When tx_symb_vector has the value ALERT and the PHY is master, the transmitter on pair A shall be active and all other pairs shall be quiet. When tx_symb_vector has the value ALERT and the PHY is slave, the transmitter on pair C shall be active and all other pairs shall be quiet. If lpi_tx_mode=REFRESH_A on a MASTER PHY or lpi_tx_mode=REFRESH_C on a SLAVE PHY, and tx_symb_vector has the value ALERT, then the alert signaling shall be transmitted in place of the refresh signaling where the signals overlap.

126.3.6 Detailed functions and state diagrams

126.3.6.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

126.3.6.2 State diagram parameters

126.3.6.2.1 Constants

EBLOCK_R<71:0>
: 72 bit vector to be sent to the XGMII interface containing /E/ in all the eight character locations.

EBLOCK_T<64:0>
: 65 bit vector to be sent to the LDPC encoder containing /E/ in all the eight character locations.

LBLOCK_R<71:0>
: 72 bit vector to be sent to the XGMII interface containing two Local Fault ordered sets. The Local Fault ordered set is defined in 46.3.4.

LBLOCK_T<64:0>
: 65 bit vector to be sent to the LDPC encoder containing two Local Fault ordered sets.

LPBLOCK_R<71:0>
: 72 bit vector to be sent to the XGMII containing /LI/ in all the eight character locations.

LPBLOCK_T<64:0>
: 65 bit vector to be sent to the LDPC encoder containing /LI/ in all the eight character locations.

IBLOCK_R<71:0>
: 72 bit vector to be sent to the XGMII containing /I/ in all the eight character locations.

IBLOCK_T<64:0>
: 65 bit vector to be sent to the LDPC encoder containing /I/ in all the eight character locations.

UBLOCK_R<71:0>
: 72 bit vector to be sent to the XGMII containing two Link Interruption ordered sets. The Link Interruption ordered set is defined in 46.3.4.

126.3.6.2.2 Variables

lfer_test_lf
: Boolean variable that is set true when a new LDPC frame is available for testing and false when LFER_TEST_LF state is entered. A new LDPC frame is available for testing when the Block Sync process has accumulated enough symbols from the PMA to evaluate the next LDPC frame.

block_lock
: Boolean variable that is set true when receiver acquires block delineation.

hi_lfer
: Boolean variable that is asserted true when the lfer_cnt reaches 16 errors in one lfer_timer interval.

pcs_reset
: Boolean variable that controls the resetting of the PCS. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS into low-power mode.

rx_coded<64:0>
: Vector containing the input to the 64B/65B decoder. The format for this vector is shown in Figure 126–8. The leftmost bit in the figure is rx_coded<0> and the rightmost bit is rx_coded<64>.

rx_raw<71:0>
: Vector containing two successive XGMII output transfers. RXC<3:0> for the first transfer are taken from rx_raw<3:0>. RXC<3:0> for the second transfer are taken from rx_raw<7:4>. RXD<31:0> for the first transfer are taken from rx_raw<39:8>. RXD<31:0> for the second transfer are taken from rx_raw<71:40>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

lf_valid
: Boolean indication that is set true if received LDPC frame is valid. LDPC frame is valid if and only if all parity checks of the LDPC code are satisfied.

tx_coded<64:0>
: Vector containing the output from the 64B/65B encoder. The format for this vector is shown in Figure 126–8. The leftmost bit in the figure is tx_coded<0> and the rightmost bit is tx_coded<64>.

tx_raw<71:0>
: Vector containing two successive XGMII transfers. TXC<3:0> for the first transfer are placed in tx_raw<3:0>. TXC<3:0> for the second transfer are placed in tx_raw<7:4>. TXD<31:0> for the first transfer are placed in tx_raw<39:8>. TXD<31:0> for the second transfer are placed in tx_raw<71:40>.

The following variables are required for PHYs that support the EEE capability:

tx_lpi_active
: A Boolean variable that is set true when the PHY transmit function is operating in the LPI transmit mode and during transitions to and from the LPI transmit mode (i.e., at any time when the PHY is transmitting sleep, alert, wake, or quiet-refresh signaling). It is set false otherwise.

tx_lpi_qr_active
: A Boolean variable that is set true during the LPI transmit mode, when the PHY is transmitting quiet-refresh signaling. Set false otherwise.

rx_lpi_active
: A Boolean variable that is set true when the PHY receive function is operating in the LPI receive mode and set false otherwise. The LPI receive mode begins when the sleep signal is detected and lasts until the alert signal is detected. When the EEE capability is not supported, rx_lpi_active is set false.

tx_lpi_req
: A Boolean variable that is set true when the LPI client indicates that it is requesting operation in the LPI transmit mode via the XGMII and set false otherwise.

alert_detect
: Indicates that an alert signal from the link partner has been received at the MDI as indicated by PMA_ALERTDETECT.indication(alert_detect).

tx_lpi_alert_active
: A Boolean variable that is set true when the PHY is transmitting ALERT signaling. Set false otherwise.

rx_lpi_wake
: A Boolean variable that is set true when the PHY receiver is in the WAKE state and sending IDLE to the XGMII. Set false otherwise. When the EEE capability is not supported, rx_lpi_wake is set false.

tx_active_pair
: A variable indicating the transmit active pair during the LPI transmit mode. The variable may take the values PAIR_A, PAIR_B, PAIR_C, PAIR_D. This variable is defined in 126.3.5.1.

lpi_tx_mode
: A variable indicating the signaling to be used from the PCS to the PMA across the PMA_UNITDATA.request (tx_symb_vector) interface.
lpi_tx_mode controls tx_symb_vector only when tx_mode is set to SEND_N.
The variable is set to NORMAL when (!tx_lpi_qr_active * !tx_lpi_alert_active), indicating that the PCS is in the normal mode of operation and encodes code-groups as described in Figure 126–14 and Figure 126–15.
The variable is set to REFRESH_A when (tx_lpi_qr_active * (tx_active_pair=PAIR_A) * tx_refresh active).
The variable is set to REFRESH_B when (tx_lpi_qr_active * (tx_active_pair=PAIR_B) * tx_refresh active).
The variable is set to REFRESH_C when (tx_lpi_qr_active * (tx_active_pair=PAIR_C) *

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_refresh active).
The variable is set to REFRESH_D when (tx_lpi_qr_active * (tx_active_pair=PAIR_D) * tx_refresh active).
The variable is set to QUIET when (tx_lpi_qr_active * (!tx_refresh_active + tx_lpi_initial_quiet)).
The variable is set to ALERT when (tx_lpi_alert_active).

tx_refresh_active
: A Boolean value. This variable is set true following the logic described in 126.3.5.1.

tx_lpi_full_refresh
: A Boolean value. This variable is set true following the logic described in 126.3.5.1.

tx_lpi_initial_quiet
: A Boolean value. This variable is set true when the transmit function enters the LPI transmit mode and a partial refresh is replaced by quiet signaling.

ldpc_two_frame_done
: A Boolean value. This variable is set true when the final symbol of each even LDPC frame aligned to the inversion on pair A during PMA training is transmitted and is set false otherwise.

The following variable is only required for PHYs that support the fast retrain capability:

fr_sigtype
: If fast retrain is supported, this variable controls the block type the PMA sends on the receive path during fast retrain. If MDIO is supported, this variable is set based on the value in 1.147.2:1 as follows:
  00 IBLOCK_R
  01 LBLOCK_R
  10 UBLOCK_R
  11 Reserved
  If MDIO is not supported, an equivalent method of controlling fast retrain functionality should be provided.

126.3.6.2.3 Timers

State diagram timers follow the conventions described in 14.2.3.2.

lfer_timer
: Timer that is triggered every 125/*S* μs +1%, –25%. When the timer reaches its terminal count it sets lfer_timer_done = TRUE.

The following timers are required for PHYs that support the EEE capability:

lpi_tx_sleep_timer
: This timer defines the time the local transmitter sends the sleep signal to the link partner.
  Values: The condition lpi_tx_sleep_timer_done becomes true upon timer expiration.
  Duration: This timer shall have a period equal to 18 LDPC frame periods.

lpi_tx_alert_timer
: This timer defines the time the local transmitter transmits the alert signal.
  Values: The condition lpi_tx_alert_timer_done becomes true upon timer expiration.
  Duration: This timer shall have a period equal to 8 LDPC frame periods.

lpi_tx_wake_timer
: This timer defines the time the local transmitter transmits the wake signal.
  Values: The condition lpi_tx_wake_timer_done becomes true upon timer expiration.
  Duration: This timer shall have a period equal to lpi_wake_time LDPC frame periods.

lpi_rx_wake_timer
: This timer defines the time the receiver sends IDLE blocks to the XGMII after the alert signal is detected.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: The condition lpi_rx_wake_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to lpi_wake_time LDPC frame periods.

126.3.6.2.4 Functions

DECODE(rx_symb_vector<64:0>)

In the PCS Receive process, this function takes as its argument 65-bit rx_coded<64:0> from the LDPC decoder and decodes the 65B-LDPC bit vector returning a vector rx_raw<71:0>, which is sent to the XGMII. The DECODE function shall decode the block based on code specified in 126.3.2.2.2.

ENCODE(tx_raw<71:0>)

Encodes the 72-bit vector received from the XGMII, returning 65-bit vector tx_coded. The ENCODE function shall encode the block as specified in 126.3.2.2.2.

R_BLOCK_TYPE = {C, S, T, D, E, I, LI, LII}

When the EEE capability is not supported, this function classifies each 65-bit rx_coded vector as belonging to one of the five types {C, S, T, D, E} depending on its contents.

When the EEE capability is supported, this function classifies each 65-bit rx_coded vector as belonging to the eight types depending on its contents. A vector may simultaneously belong to the C and I types when it contains eight valid control characters that are all /I/, but in every other case the vector belongs to only one type.

Values: C; The vector contains a data/ctrl header of 1 and one of the following:

a) A block type field of 0x1E and eight valid control characters other than /E/ and /LI/;
b) A block type field of 0x2D or 0x4B, a valid O code, and four valid control characters;
c) A block type field of 0x55 and two valid O codes.

S; The vector contains a data/ctrl header of 1 and one of the following:

a) A block type field of 0x33 and four valid control characters;
b) A block type field of 0x66 and a valid O code;
c) A block type field of 0x78.

T; The vector contains a data/ctrl header of 1, a block type field of 0x87, 0x99, 0xAA, 0xB4, 0xCC, 0xD2, 0xE1, or 0xFF and all control characters are valid.

D; The vector contains a data/ctrl header of 0.

I; If the optional EEE capability is supported, then the I type is a special case of the C type where the vector contains a data/ctrl header of 1, a block type field of 0x1E, and eight control characters of /I/.

LI: If the optional EEE capability is supported, then the LI type occurs when the vector contains a data/ctrl header of 1, a block type field of 0x1E, and eight control characters of /LI/.

LII: If the optional EEE capability is supported, then the LII type occurs when the vector contains a data/ctrl header of 1, a block type field of 0x1E, and one of the following:

a) Four control characters of /LI/ followed by four control characters of /I/;
b) Four control characters of /I/ followed by four control characters of /LI/.

E; The vector does not meet the criteria for any other value.

A valid control character is one containing a 2.5G/5GBASE-T control code specified in Table 126–1. A valid O code is one containing an O code specified in Table 126–1.

R_TYPE(rx_coded<64:0>)

Returns the R_BLOCK_TYPE of the rx_coded<64:0> bit vector.

R_TYPE_NEXT

Prescient end of packet check function. It returns the R_BLOCK_TYPE of the rx_coded vector immediately following the current rx_coded vector.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

T_BLOCK_TYPE = {C, S, T, D, E, I, LI, LII}

When the EEE capability is not supported, this function classifies each 72-bit tx_raw vector as belonging to one of the five types {C, S, T, D, E} depending on its contents.

When the EEE capability is supported, this function classifies each 72-bit tx_raw vector as belonging to the eight types depending on its contents. A vector may simultaneously belong to the C and I types when it contains eight valid control characters that are all /I/, but in every other case the vector belongs to only one type.

Values: C; The vector contains one of the following:

a) Eight valid control characters other than /O/, /S/, /T/, /E/, and /LI/;
b) One valid ordered set and four valid control characters other than /O/, /S/, and /T/;
c) Two valid ordered sets.

S; The vector contains an /S/ in its first or fifth character, any characters before the S character are valid control characters other than /O/, /S/, and /T/ or form a valid ordered set, and all characters following the /S/ are data characters.

T; The vector contains a /T/ in one of its characters, all characters before the /T/ are data characters, and all characters following the /T/ are valid control characters other than /O/, /S/ and /T/.

D; The vector contains eight data characters.

I; If the optional EEE capability is supported, then the I type is a special case of the C type where the vector contains eight control characters of /I/.

LI: If the optional EEE capability is supported, then the LI type occurs when the vector contains eight control characters of /LI/.

LII: If the optional EEE capability is supported, then the LII type occurs when the vector contains one of the following:

a) Four control characters of /LI/ followed by four control characters of /I/;
b) Four control characters of /I/ followed by four control characters of /LI/.

E; The vector does not meet the criteria for any other value.

A tx_raw character is a control character if its associated TXC bit is asserted. A valid control character is one containing an XGMII control code specified in Table 126–1. A valid ordered set consists of a valid /O/ character in the first or fifth characters and data characters in the three characters following the /O/. A valid /O/ is any character with a value for O code in Table 126–1.

T_TYPE(tx_raw<71:0>)

Returns the T_BLOCK_TYPE of the tx_raw<71:0> bit vector.

T_TYPE_NEXT

Prescient end of packet check function. It returns the FRAME_TYPE of the tx_raw vector immediately following the current tx_raw vector.

126.3.6.2.5 Counters

lfer_cnt

Count up to a maximum of 16 of the number of invalid LDPC frames within the current lfer_timer period.

The following counters are required for PHYs that support the EEE capability:

tx_ldpc_frame_cnt

An integer value that counts transmit LDPC frame periods. The counter is reset when the first symbol of the first LDPC frame crosses the MDI on pair A in the transmit direction after normal training or fast retraining. It is incremented after the last symbol of each transmitted LDPC frame. tx_ldpc_frame_cnt is reset to 0 when tx_ldpc_frame_cnt = lpi_qr_time × 4.

rx_ldpc_frame_cnt

An integer value that counts receive LDPC frame periods. The counter is reset when the first symbol of the first LDPC frame crosses the MDI on pair A in the receive direction after normal

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

training or fast retraining. It is incremented after the last symbol of each received LDPC frame. rx_ldpc_frame_cnt is reset to 0 when rx_ldpc_frame_cnt = lpi_qr_time × 4.

lpi_rxw_err_cnt

An integer value that counts the number of receive wake on error conditions. lpi_rxw_err_cnt is reset to zero during PCS_Test. The counter is reflected in register 3.22 (see 45.2.3.12).

126.3.6.3 State diagrams

The LFER Monitor state diagram shown in Figure 126–13 monitors the received signal for high LDPC frame error ratio.

The 64B/65B Transmit state diagram shown in Figure 126–14 controls the encoding of 65B transmitted blocks. It makes exactly one transition for each 65B transmit block processed. Though the Transmit state diagram sends Local Fault ordered sets when reset is asserted, the scrambler and 65B-LDPC may not be operational during reset. Thus, the Local Fault ordered sets may not appear on the PMA service interface.

The 64B/65B Receive state diagram shown in Figure 126–16 controls the decoding of 65B received blocks. It makes exactly one transition for each receive block processed except for the transition from RX_WE to RX_E, which occurs immediately after the RX_WE processes are complete.

The PCS shall perform the functions of LFER Monitor, Transmit, and Receive as specified in these state diagrams. The PCS shall not perform the LFER Monitor function during LPI receive operation from the time that the PCS 64B/65B Receiver enters the state RX_L, until the state RX_W is exited.

Transitions surrounded by dashed rectangles indicate requirements for 2.5GBASE-T and 5GBASE-T EEE-capable implementations.

126.3.7 PCS management

The following objects apply to PCS management. If an MDIO Interface is provided (see Clause 45), they are accessed via that interface. If not, it is recommended that an equivalent access be provided.

126.3.7.1 Status

pcs_status

Indicates whether the PCS is in a fully operational state. It is only true if block_lock is true and hi_lfer is false. This status is reflected in MDIO register 3.32.12. A latch low view of this status is reflected in MDIO register 3.1.2 and a latch high of the inverse of this status, Receive fault, is reflected in MDIO register 3.8.10.

block_lock

Indicates the state of the block_lock variable. This status is reflected in MDIO register 3.32.0. A latch low view of this status is reflected in MDIO register 3.33.15.

hi_lfer

Indicates the state of the hi_lfer variable. This status is reflected in MDIO register 3.32.1. A latch high view of this status is reflected in MDIO register 3.33.14.

Rx LPI indication

For EEE capability, this variable indicates the current state of the receive LPI function. This flag is set to TRUE (register bit set to one) when the PCS 64B/65B Receive state diagram (Figure 126–17) is in the RX_L or RX_W states. This status is reflected in MDIO register 3.1.8. A latch high view of this status is reflected in MDIO register 3.1.10 (Rx LPI received).

Tx LPI indication

For EEE capability, this variable indicates the current state of the transmit LPI function. This flag is set to TRUE (register bit set to one) when the PCS 64B/65B Transmit state diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

(Figure 126–15) is in the TX_L or TX_W states. This status is reflected in MDIO register 3.1.9. A latch high view of this status is reflected in MDIO register 3.1.11 (Tx LPI received).

126.3.7.2 Counters

The following counters are reset to zero upon read and upon reset of the PCS. When they reach all ones, they stop counting. Their purpose is to help monitor the quality of the link.

lfer_count
: 6-bit counter that counts each time LFER_BAD_LF state is entered. This counter is reflected in MDIO register bits 3.33.13:8. The counter is reset when register 3.33 is read by management. Note that this counter counts a maximum of 16 counts per lfer_timer period since the LFER_BAD_LF can be entered a maximum of 16 times per lfer_timer window.

errored_block_count
: 8-bit counter. When the receiver is in normal mode, errored_block_count counts once for each time RX_E state is entered. This counter is reflected in MDIO register bits 3.33.7:0.

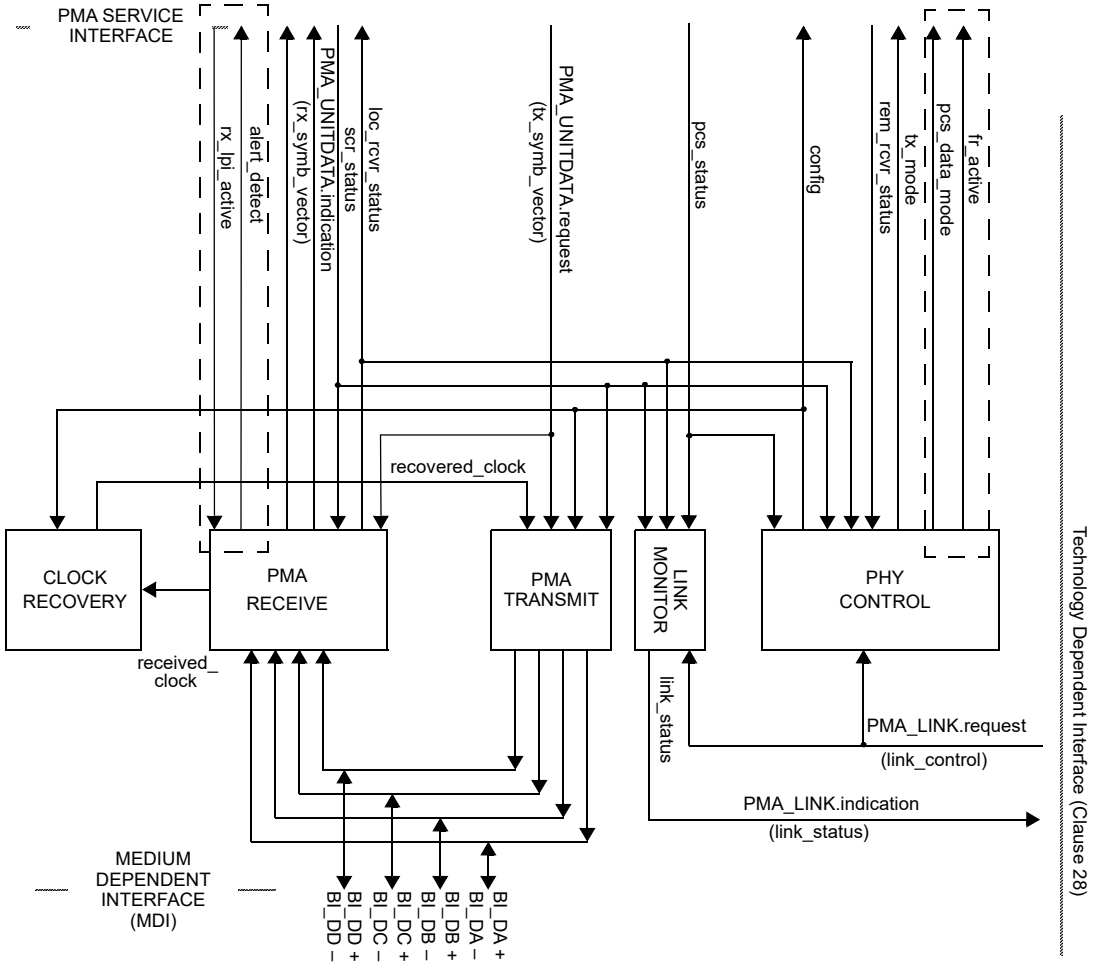
126.3.7.3 Loopback



The PCS shall be placed in loopback mode when the loopback bit in MDIO register 3.0.14 is set to a one. In this mode, the PCS shall accept data on the transmit path from the XGMII and return it on the receive path to the XGMII. In addition, the PCS shall transmit a continuous stream of 65B-LDPC encoded 4D-PAM16 symbols to the PMA sublayer, and shall ignore all data presented to it by the PMA sublayer.

126.4 Physical Medium Attachment (PMA) sublayer

126.4.1 PMA functional specifications

The PMA couples messages from a PMA service interface specified in 126.2.2 to the 2.5GBASE-T and 5GBASE-T baseband media, specified in 126.7.

The interface between PMA and the baseband medium is the Medium Dependent Interface (MDI), which is specified in 126.8.

NOTE 1—The recovered_clock arc is shown to indicate delivery of the recovered clock signal back to PMA TRANSMIT for loop timing.

NOTE 2—pcs_data_mode is required only for the EEE or fast retrain capabilities alert_detect and rx_lpi_active are only required for the EEE capability fr_active is only required for the fast retrain capability.

126.4.2 PMA functions

The PMA sublayer comprises one PMA Reset function and five simultaneous and asynchronous operating functions. The PMA operating functions are PHY Control, PMA Transmit, PMA Receive, Link Monitor, and Clock Recovery. All operating functions are started immediately after the successful completion of the PMA Reset function.

The PMA reference diagram, Figure 126–19, shows how the operating functions relate to the messages of the PMA Service interface and the signals of the MDI. Connections from the management interface, comprising the signals MDC and MDIO, to other layers are pervasive and are not shown in Figure 126–19.

126.4.2.1 PMA Reset function

The PMA Reset function shall be executed whenever one of the two following conditions occur:

a) Power on (see 126.3.6.2.2)
b) The receipt of a request for reset from the management entity

All state diagrams take the open-ended pma_reset branch upon execution of PMA Reset. The reference diagrams do not explicitly show the PMA Reset function.

126.4.2.2 PMA Transmit function

The PMA Transmit function comprises four synchronous transmitters to generate four pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD. While send_fail is FALSE and ALERT is not indicated by tx_symb_vector, PMA Transmit shall continuously transmit onto the MDI pulses modulated by the symbols given by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and tx_symb_vector[BI_DD], respectively after processing with the THP, optional transmit filtering, digital to analog conversion (DAC) and subsequent analog filtering. When ALERT is indicated by tx_symb_vector, the alert signal is transmitted as specified in 126.4.2.2.1. When send_fail is TRUE, the link failure signal is transmitted as specified in 126.4.2.2.2. The four transmitters shall be driven by the same transmit clock, TX_TCLK. The signals generated by PMA Transmit shall follow the mathematical description given in 126.4.3.1, and shall comply with the electrical specifications given in 126.5.

When the PMA_CONFIG.indication parameter config is MASTER, for both normal and LPI operation, the PMA Transmit function shall source TX_TCLK from a local clock source while meeting the transmit jitter requirements of 126.5.3.3. The MASTER/SLAVE relationship includes loop timing. If the PMA_CONFIG.indication parameter config is SLAVE, the PMA Transmit function shall source TX_TCLK from the recovered clock of 126.4.2.8 while meeting the jitter requirements of 126.5.3.3.

The PMA Transmit fault function is optional. The faults detected by this function are implementation specific. If the MDIO interface is implemented, then this function shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

EEE-capable PHYs shall generate the alert signal as defined in 126.4.2.2.1. PHYs that support the fast retrain capability shall generate the link failure signal as defined in 126.4.2.2.2. If ALERT is indicated by tx_symb_vector at the same time as send_fail is TRUE, then link failure signaling is transmitted.

126.4.2.2.1 Alert signal

PHYs that support the optional EEE capability transmit the following PAM2 sequence when the PMA_UNITDATA.request parameter is set to ALERT. The alert signal is sent for a total of 8 LDPC frame periods and begins on a LDPC 2-frame 256 4D-symbol boundary aligned to the inversion on pair A during

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA training. The alert signal is transmitted without THP filtering. The alert signal is transmitted on pair A when the PHY operates as a MASTER. The alert signal is transmitted on pair C when the PHY operates as a SLAVE. All other pairs transmit quiet as described in 126.3.5.

When the PMA_CONFIG.indication(config) is MASTER the alert signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xpr_master =

9 9 –9 –9 –9 –9 –9 –9 9 9 –9 –9 9 9 9 9

9 9 9 9 –9 –9 9 9 9 9 –9 –9 9 9 –9 –9

–9 –9 –9 –9 –9 –9 9 9 –9 –9 –9 –9 –9 –9 9 9

–9 –9 –9 –9 –9 –9 –9 –9 9 9 –9 –9 9 9 –9 –9

–9 –9 9 9 9 9 9 9 9 9 9 9 –9 –9 –9 –9

9 9 –9 –9 –9 –9 9 9 9 9 –9 –9 9 9 –9 –9

–9 –9 –9 –9 –9 –9 –9 –9 9 9 9 9 –9 –9 9 9

9 9 –9 –9 9 9 –9 –9 9 9 9 9 –9 –9 –9 –9

When the PMA_CONFIG.indication(config) is SLAVE the alert signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xpr_slave =

–9 –9 –9 –9 9 9 9 9 –9 –9 9 9 –9 –9 9 9

9 9 –9 –9 9 9 9 9 –9 –9 –9 –9 –9 –9 –9 –9

–9 –9 9 9 –9 –9 9 9 9 9 –9 –9 –9 –9 9 9

–9 –9 –9 –9 9 9 9 9 9 9 9 9 9 9 –9 –9

–9 –9 9 9 –9 –9 9 9 –9 –9 –9 –9 –9 –9 –9 –9

9 9 –9 –9 –9 –9 –9 –9 9 9 –9 –9 –9 –9 –9 –9

–9 –9 9 9 –9 –9 9 9 9 9 –9 –9 9 9 9 9

9 9 9 9 –9 –9 9 9 –9 –9 –9 –9 –9 –9 9 9

The alert signal is followed by a wake signal composed of repeated IDLE characters encoded using the 64B/65B encoding technique. At the start of the wake signal all THP feedback delay lines are initialized with zeros.

126.4.2.2.2 Link failure signal

PHYs that support the fast retrain capability transmit the link failure signal under the control of the Fast Retrain state diagram. The link failure signal indicates to the link partner that a link failure has been detected and that the link partners should begin the fast retrain procedure.

The link failure signal is sent for 8 LDPC frames and begins on an even LDPC frame boundary aligned to the inversion on pair A during PMA training. The link failure signal is transmitted without THP filtering. The link failure signal is transmitted on pair A when the PHY operates as a MASTER. The link failure signal is transmitted on pair C when the PHY operates as a SLAVE. All other pairs transmit quiet as described in 126.3.5.

When the PMA_CONFIG.indication(config) is MASTER, the link failure signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xfr_master = xpr_master × (−1)

When the PMA_CONFIG.indication(config) is SLAVE the link failure signal is composed of 7 repetitions of the following 128 symbol PAM2 sequence, followed by 128 zero symbols.

xfr_slave = xpr_slave × (−1)

126.4.2.3 PMA transmit disable function

126.4.2.3.1 Global PMA transmit disable function

The Global_PMA_transmit_disable function allows all of the transmitters to be disabled. It is used in either of the following cases:

a) When a Global_PMA_transmit_disable variable is set to TRUE, this function shall turn off all of the transmitters so that the each transmitter Average Launch Power of the OFF Transmitter is less than –53 dBm.
b) If a PMA_transmit_fault is detected, then the PMA may set the Global_PMA_transmit_disable to TRUE, turning off the transmitter on each pair.

126.4.2.3.2 PMA pair by pair transmit disable function

The PMA_transmit_disable function allows the transmitters on each pair to be selectively disabled.

When a PMA_transmit_disable_N variable is set to TRUE, this function shall turn off the transmitter associated with that variable so that the transmitter Average Launch Power of the OFF Transmitter is less than –53 dBm.

126.4.2.3.3 PMA MDIO function mapping

The MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMA. Mapping of MDIO control variables to PMA control variables is shown in Table 126–6. Mapping of MDIO status variables to PMA status variables is shown in Table 126–7.

Table 126–6—MDIO/PMA control variable mapping

MDIO control variable	PMA register name	Register/bit number	PMA control variable
Reset	Control register 1	1.0.15	PMA_reset
Global PMD transmit disable	Transmit disable register	1.9.0	Global_PMA_transmit_disable
Transmit disable pair D	Transmit disable register	1.9.4	PMA_transmit_disable_D
Transmit disable pair C	Transmit disable register	1.9.3	PMA_transmit_disable_C
Transmit disable pair B	Transmit disable register	1.9.2	PMA_transmit_disable_B
Transmit disable pair A	Transmit disable register	1.9.1	PMA_transmit_disable_A

Table 126–7—MDIO/PMA status variable mapping

MDIO status variable	PMA register name	Register/bit number	PMA status variable
Fault	Status register 1	1.1.7	PMA_fault
Transmit fault	Status register 2	1.8.11	PMA_transmit_fault
Receive fault	Status register 2	1.8.10	PMA_receive_fault

126.4.2.4 PMA Receive function

The PMA Receive function comprises four independent receivers for pulse-amplitude modulated signals on each of the four pairs BI_DA, BI_DB, BI_DC, and BI_DD. The PMA Receive contains the circuits necessary to both detect symbol sequences from the signals received at the MDI over receive pairs BI_DA, BI_DB, BI_DC, and BI_DD and to present these sequences to the PCS Receive function. The signals received at the MDI are described mathematically in 126.4.3.2. The PMA translates the signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD into the PMA_UNITDATA.indication parameter rx_symb_vector. The quality of these symbols shall allow an LFER of less than 3.2×10^{-9} after LDPC decoding, over a channel meeting the requirements of 126.7. The receiver shall correct for differential delay variations of up to 50 ns across the wire-pairs. The delay skew is removed by computing the relative received delay of the four known transmit patterns described in 126.3.4.

To achieve the indicated performance, it is highly recommended that PMA Receive include the functions of signal equalization, echo and crosstalk cancellation. The sequence of code-groups assigned to tx_symb_vector is needed to perform echo and self near-end crosstalk cancellation.

The PMA Receive function uses the scr_status parameter and the state of the equalization, cancellation, estimation, and LPI functions to determine the quality of the receiver performance, and generates the loc_rcvr_status variable accordingly. The precise algorithm for generation of loc_rcvr_status is implementation dependent.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The receiver uses the sequence of symbols during the training sequence to detect and correct for pair swaps and crossovers. The receiver pairs BI_DA, BI_DB, BI_DC, and BI_DD may be connected in any manner described in 126.4.4 to the corresponding transmit pairs. The receiver also detects and corrects for polarity mismatches on any pairs and corrects for differential delay variations across the wire-pairs.

The PMA Receive fault function is optional. The PMA Receive fault function is the logical OR of the link_status = FAIL and any implementation specific fault. If the MDIO interface is implemented, then this function shall contribute to the receive fault bit specified in 45.2.1.7.5.

PMA receive functions that support the optional EEE capability shall generate alert_detect when the alert signal is detected at the receiver. The PMA receive function asserts alert_detect after the entire alert signal (7 LDPC frame periods of the xpr_master or xpr_slave sequence and 1 frame of silence) has been detected. The alert signal is specified in 126.4.2.2.1. The criterion used to generate alert_detect is left to the implementer.

PHYs that support the fast retrain capability shall set link_fail_detect to TRUE when the link failure signal is reliably detected at the receiver. The PMA receive function asserts link_fail_detect after the entire link failure signal (7 LDPC frame periods of the xfr_master or xfr_slave sequence and 1 frame of silence) has been detected. The link failure signal is specified in 126.4.2.2.2. The criterion used to generate link_fail_detect is left to the implementer. It is highly recommended that the generation of link_fail_detect is qualified with repeated errored frames at the LDPC decoder output.

126.4.2.5 PHY Control function

PHY Control generates the control actions that are needed to bring the PHY into a mode of operation during which frames can be exchanged with the link partner. PHY Control shall comply with the state diagram description given in Figure 126–26.

During PMA training (includes PMA_Training_Init_M, PMA_Training_Init_S, PMA_PBO_Exch, PMA_Coeff_Exch, and PMA_Fine_Adjust states in Figure 126–26), PHY Control information is exchanged between link partners with a 16 octet Infofield, which is XOR'ed with the last 128 bits of the PMA 16384 PAM2 frame on pair A (see Figure 126–11). The link partner is not required to decode every Infofield transmitted but is required to decode Infofields at a rate that enables the correct actions to timer expiration times, transition counter values, etc. described in Figure 126–26, Figure 126–27, and Figure 126–28.

The 16 octet Infofield shall include the fields in 126.4.2.5.2 through 126.4.2.5.14, also shown in the overview Figure 126–20, and the more detailed Figure 126–21, Figure 126–22, and Figure 126–23.

126.4.2.5.1 Infofield notation

For all the Infofield notation below, Reserved<bit location> represents any unused values and shall be set to zero and ignored by the link partner. For all PBO Infofield values below, the PBO<6:4> are unsigned 3-bit values 000, 001, 010, 011, 100, 101, 110, and 111 shall indicate power backoffs of 0 dB, 2 dB, 4 dB, 6 dB, 8 dB, 10 dB, 12 dB, and 14 dB respectively. The Infofield is transmitted following the notation described in 126.3.2.2.3 where the LSB of each octet is sent first and the octets are sent in increasing number order (that is, the LSB of Octet 1 is sent first).

126.4.2.5.2 Start of Frame Delimiter

The start of Frame Delimiter consist of 4 octets [Octet 1<7:0>, Octet 2<7:0>, Octet 3<7:0>, Octet 4<7:0>] and shall use the hexadecimal value 0xBBA70000. 0xBB corresponds to Octet 1<7:0> and so forth.

126.4.2.5.3 Current transmitter settings

Current transmitter setting (1 octet). Represented by Octet 5{Valid<7>, PBO<6:4>, Reserved<3:0>} and shown in Figure 126–24. Used to announce the current fixed PBO setting during PMA_Training_Init_M, PMA_Training_Init_S and PMA_PBO_Exch, and the current programmable PBO setting during PMA_Coeff_Exch. For every other state this octet is set to zero and ignored by the link partner. The bit Valid shall be set to one if the corresponding octet information is valid and shall be set to zero if it the octet information is not valid. If Valid is set to zero, the octet is ignored by the link partner.

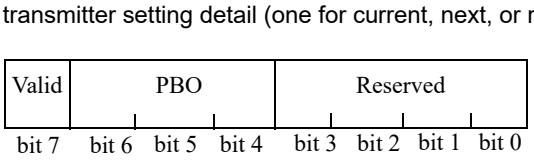

Figure 126–24—Infofield transmitter setting format

126.4.2.5.4 Next transmitter settings

Next transmitter setting (1 octet). Represented by Octet 6{Valid<7>, PBO<6:4>, Reserved<3:0>} and shown in Figure 126–24. Used to announce the next programmable PBO setting during PMA_PBO_Exch that takes effect upon entering PMA_Coeff_Exch state. For every other state, this octet is set to zero and ignored by the link partner. The bit Valid shall be set to one if the corresponding octet information is valid and shall be set to zero if it the octet information is not valid. If Valid is set to zero, the octet is ignored by the link partner.

126.4.2.5.5 Requested transmitter settings

Requested remote transmitter setting (1 octet). Represented by Octet 7{Valid<7>, PBO<6:4>, Reserved<3:0>} and shown in Figure 126–24. Used to request the remote transmitter programmable PBO setting during PMA_PBO_Exch that takes effect upon entering PMA_Coeff_Exch state. For every other state, this octet is set to zero and ignored by the link partner. The bit Valid shall be set to one if the corresponding octet information is valid and shall be set to zero if it the octet information is not valid. If Valid is set to zero, the octet is ignored by the link partner.

126.4.2.5.6 Message field

Message field (1 octet). For the MASTER, this field is represented by Octet 8{PMA_state<7:6>, loc_rcvr_status<5>, en_slave_tx<4>, trans_to_Coeff_Exch<3>, Coeff_exchange<2>, trans_to_Fine_Adjust<1>, trans_to_PCS_Test<0>}. For the SLAVE, this field is represented by Octet 8{PMA_state<7:6>, loc_rcvr_status<5>, timing_lock_OK<4>, trans_to_Coeff_Exch<3>, Coeff_exchange<2>, trans_to_Fine_Adjust <1>, trans_to_PCS_Test<0>}.

The two state-indicator bits PMA_state<7:6> shall indicate the state of the transmitting transceiver to the link partner as follows: PMA_state<7:6>=00 indicates PMA_Training_Init_M or PMA_Training_Init_S, PMA_state<7:6>=01 indicates PMA_PBO_Exch, PMA_state<7:6>=10 indicates PMA_Coeff_Exch, and PMA_state<7:6>=11 indicates PMA_Fine_Adjust.

All possible Message field settings are listed in Table 126–8 for the MASTER and Table 126–9 for the SLAVE. No other value shall be transmitted, and all other values shall be ignored at the receiver. The Message field setting for the first transmitted PMA frame shall be the first row of Table 126–8 for the MASTER and the first row of Table 126–9 for the SLAVE. Moreover, for a given Message field setting, the following Message field setting shall be the same Message field setting or the Message field setting corresponding to a row below the current setting. When loc_rcvr_status=OK the Infofield variable is set to loc_rcvr_status<5>=1 and set to 0 otherwise.

126.4.2.5.7 SNR_margin

SNR_margin (4 bits). Represented by Octet 9<7:4>, which reports received decision point SNR margin in 1/2 dB steps. SNR_margin is relative to the SNR required for reception of LDPC-coded PAM16 at an LDPC frame error ratio of less than 3.2×10^{-9}. The SNR_margin<7:4> 4-bit values, 0010, 0011, 0100, 0101, 0110, 0111, 1000, 1001, 1010, 1011, 1100, 1101, 1110 shall indicate the decision point SNR margin values of –1.5,

–1, –0.5, 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5 dB respectively. The value 0001 shall indicate a margin of –2 dB or less, and the value 1111 shall indicate 5 dB or more. Finally, the value 0000 shall indicate that the SNR margin value is unknown.

126.4.2.5.8 Transition counter

Transition counter (10 bits). Represented by the 1.25 octets [Octet 9<1:0>, Octet 10<7:0>]. When configured as Transition counter (Coeff_exchange<2>=0 and a transition is announced to PMA_Coeff_Exch, PMA_Fine_Adjust or PCS_Test) this field is used as a 10-bit counter that counts the number of remaining frames until the next transition (PMA_Coeff_Exch, PMA_Fine_Adjust, PCS_Test).

126.4.2.5.9 Coefficient exchange handshake

Coefficient exchange handshake (12 bits). Represented by the 1.5 octets [Octet 9<3:0>, Octet 10<7:0>]. If Coeff_exchange<2>=1, this field is configured as a Coefficient exchange handshake and is used as a handshake control channel during programmable THP coefficient exchange. The details of the coefficient exchange are described in 126.4.2.5.15.

126.4.2.5.10 Ability fields

Ability field (1 octet). Represented by Octet 12{EEE Ability<7>, THP Bypass Request<6>,Fast Retrain<5>, Reserved<4:0>}. Used to advertise the abilities of the PHY during the PMA_PBO_Exch state when Message<7:6> = 01.

For every other state, this octet is set to zero and ignored by the link partner. The Ability bits are defined as follows:

Octet 12<4:0> = Reserved

Octet 12<5> = Fast Retrain

0 = Fast Retrain not supported

1 = Fast Retrain supported

Octet 12<6> = THP Bypass Request in PMA_Coeff_Exch state

0 = Local device requests link partner not to bypass THP during fast retrain

1 = Local device requests link partner to bypass THP during fast retrain

Octet 12<7> = EEE Ability

0 = EEE not supported

1 = EEE supported.

126.4.2.5.11 Reserved fields

All Infofield fields denoted Reserved in Figure 126–21, Figure 126–22, and Figure 126–23 are reserved for future use. This includes Octet 11 and Octet 12 when Coeff_exchange<2>=0 and Message<7:6> is not equal to 01; Octet 9<3:2> when transition counter is announced; and [Octet 9<3:0>, Octet 10<7:0>] when no transition is announced and no coefficients are exchanged.

126.4.2.5.12 Vendor-specific field

If Coeff_exchange<2>=0, Octet 13 and Octet 14 are vendor-specific fields. If during Auto-Negotiation both transceivers agree on the use of the two vendor-specific octets, they may be used as a PHY communication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

channel; otherwise they are set to zero and ignored by the link partner. They are represented by Octet 13<7:0> and Octet 14<7:0>.

126.4.2.5.13 Coefficient field

The Coefficient field (4 octets) is represented by Octet 11<7:0>, Octet 12<7:0>, Octet 13<7:0>, and Octet 14<7:0>. When Coeff_exchange<2>=1, this field is used to exchange programmable THP coefficients. It transmits four 8-bit THP coefficients out of the total of 64 (16 coefficients over each of the 4 pairs). The order is pair A, coefficients 0:3, followed by coefficients 4:7, followed by 8:11 and 12:15. For all cases the first coefficient (indices 0, 4, 8, and 12) is mapped to Octet 11, the second coefficient (indices 1, 5, 9, 13) is mapped to Octet 12 and so on. The same coefficient order is followed to transmit the coefficients for pair B, followed by pair C, and finally pair D. The details of the coefficient exchange are described in 126.4.2.5.15.

126.4.2.5.14 CRC16

CRC16 (2 octets). This field shall contain the CRC16 value calculated using the polynomial $(x+1)(x^{15}+x+1)$ of the previous 10 octets, Octet 5<7:0>, Octet 6<7:0>, Octet 7<7:0>, Octet 8<7:0>, Octet 9<7:0>, Octet 10<7:0>, Octet 11<7:0>, Octet 12<7:0>, Octet 13<7:0>, and Octet 14<7:0>. The CRC16 shall produce the same result as the implementation shown in Figure 126–25. In Figure 126–25 the 16 delay elements S0,..., S15, shall be initialized to zero. Afterwards Octet 5 through Octet 14 are used to compute the CRC16 with the switch set to CRCgen in Figure 126–25. After all the 10 octets have been processed, the switch is set to CRCout and the 16 values stored in the delay elements are transmitted in the order illustrated, first S15, followed by S14, and so on, until the final value S0.

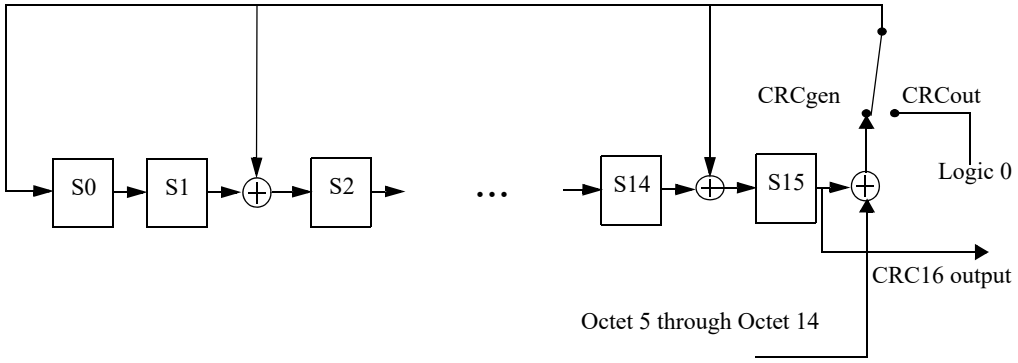

Figure 126–25—CRC16

126.4.2.5.15 Startup sequence

The startup sequence shall comply with the state diagram description given in Figure 126–26 and the transition counter state diagrams Figure 126–27 and Figure 126–28.

During Auto-Negotiation, PHY Control is in the DISABLE_2.5G/5GBASE-T_TRANSMITTER state and the transmitters are disabled. During normal training, prior to enabling the transmitter, the THP coefficients are set to zero.

When the Auto-Negotiation process asserts link_control=ENABLE, PHY Control enters the INIT_MAXWAIT_TIMER state. Upon entering this state, the maxwait_timer is started and PHY Control enters the SILENT state, which starts the minwait_timer and forces transmission of zeros by setting tx_mode=SEND_Z.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In MASTER mode, after expiration of the minwait_timer, PHY Control transitions to the PMA_Training_Init_M state.

Upon entering the PMA_Training_Init_M and PMA_Training_Init_S states, the PHY Control forces transmission into the training mode by asserting tx_mode=SEND_T, which includes the transmission of Infofields.

Upon entering state PMA_Training_Init_M, the MASTER starts transmission with a fixed transmit power level, PBO=4 (corresponding to a power backoff of 8 dB). The PBO variable is communicated to the link partner via the current transmitter octet of the Infofield.

Initially the MASTER is not ready for the SLAVE to respond and sets en_slave_tx=0, which is communicated to the link partner via the Infofield. After the MASTER has sufficiently converged the necessary circuitry, the MASTER sets en_slave_tx=1 to allow the SLAVE to transition to PMA_Training_Init_S.

In SLAVE mode, PHY Control transitions to the PMA_Training_Init_S state only after the SLAVE PHY acquires timing, converges its equalizers, acquires its descrambler state and sets loc_SNR_margin=OK. The SLAVE shall respond using the fixed PBO transmit power level, PBO=4 (corresponding to a power backoff of 8 dB). For PHYs with the EEE capability, further requirements for this transition are described in 126.3.5.1.

While in states PMA_Training_Init_S, PMA_PBO_Exch, or PMA_Coeff_Exch, whenever a SLAVE operating in loop timing mode loses the MASTER timing reference (for example, after transmit power level transitions) it sets timing_lock_OK=0, which is communicated to the link partner via the Infofield. Otherwise, timing_lock_OK is set to one.

In MASTER mode, PHY Control enters the PMA_PBO_Exch state after loc_SNR_margin=OK and in SLAVE mode PHY Control enters the PMA_PBO_Exch state after the loc_SNR_margin=OK and minwait_timer expires. In the PMA_PBO_Exch state while Infofield Message<7:6> = 01, the PHY advertises EEE and Fast Retrain capability in octet 12 of the Infofield. When both the local device and remote device advertise EEE capability then EEE is supported. When both the local device and remote device advertise Fast Retrain capability then Fast Retrain is supported. In the PMA_PBO_Exch state, after the MASTER has computed the final desired programmable PBO level, it shall request a PBO change using the requested transmitter setting in the Infofield (octet 7). In SLAVE mode, after the MASTER has requested the desired PBO level, the SLAVE shall request a desired PBO level that is within two levels (within 4 dB) of the requested MASTER PBO level.

Following PBO exchange for both transceivers, each PHY shall announce the next PBO setting using the next transmitter setting (octet 6). Afterwards, each PHY announces a transition to the PMA_Coeff_Exch state using the trans_to_Coeff_Exch=1 and transition_count as described in 126.4.5.1. MASTER initiates the transition to PMA_Coeff_Exch count with the trans_to_Coeff_Exch=1 flag and a transition counter value of $S \times 2^8$. The SLAVE responds prior to the MASTER transition counter reaching $S \times 2^5$ by setting trans_to_Coeff_Exch=1 flag and a transition counter value matching the MASTER. The PMA frame after each transceiver transition_count reaches zero, the PHYs shall enter the PMA_Coeff_Exch state and enable the requested PBO. Therefore, both PHYs enter the PMA_Coeff_Exch state within one PMA frame.

While both MASTER and SLAVE are in state PMA_Coeff_Exch, when either end has computed the programmable THP settings, the programmable THP coefficient exchange process can begin, using the 1.5-octet Coefficient exchange handshake and the 4-octet Coefficient field as follows:

a) During PMA_Coeff_Exch each PHY begins a coefficient exchange by setting the Coeff_Exchange flag to 1 in the Message field.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) During coefficient exchange, the transition counter bits are used as the Coefficient Exchange Handshake
   1) Octet 9{Reserved<3:0>}: unused
   2) Coefficient Pair Received, Octet 10<7:6>: 01 for local transmitter pair A, 10 for B, 11 for C and 00 for D (default). This is the handshake to tell the remote unit the last coefficients received.
   3) Coefficient Group Received, Octet 10<5:4>: 01 for coefficients 0:3, 10 for 4:7, 11 for 8:11 and 00 for 12:15 (default). This is the handshake to tell the remote unit the last coefficients received.
   4) Coefficient Pair Sent, Octet 10<3:2>: 01 for remote transmitter pair A, 10 for B, 11 for C and 00 for D (default). This is the handshake to tell the remote unit the current coefficients being sent.
   5) Coefficient Group Sent, Octet 10<1:0>: 01 for 0:3, 10 for 4:7, 11 for 8:11 and 00 for 12:15 (default). This is the handshake to tell the remote unit the current coefficients being sent.

c) The Coefficient field is used to send four 8-bit coefficients in each frame designated by the Coefficient Pair Sent and Coefficient Group Sent bits. The coefficient format is as follows:
   1) 8 bits per coefficient. Use one octet per coefficient in twos complement notation
   2) Coefficient range is –2.0 to 1.984375 in steps of 0.015625
   3) The sign of the coefficients shall be consistent with Equation (126–3)

d) Each PHY begins the exchange by sending pair A coefficients 0:3 with Coefficient Pair Sent=01 and Coefficient Group Sent=01.

e) The remote unit acknowledges by setting Coefficient Pair Received=01 and Coefficient Group Received=01.

f) Following each acknowledgment, the PHY increments through the Coefficient Group and then Coefficient Pair settings until Coefficient Pair Sent=00 and Coefficient Group Sent=00 and Coefficient Pair Received=00 and Coefficient Group Received=00. At this time, coefficient exchange is done and both PHYs set Coeff_Exchange=0.

Following coefficient exchange for both transceivers, each PHY announces a transition to the PMA_Fine_Adjust state (trans_to_Fine_Adjust=1) and starts the transition_count as described in 126.4.5.1. During the first PMA frame after the transition_count reaches zero, the PHYs enter the PMA_Fine_Adjust state and enable the THP precoders with the requested coefficients. At the closure of the THP feedback loop, the initial state of the THP feedback filters shall be the last 16 symbols from the state PMA_Coeff_Exch.

The THP coefficients and PBO setting may not be changed during PMA_Fine_Adjust. The final convergence of the adaptive filter parameters is completed in the PMA_Fine_Adjust state.

After the PHY completes successful training and establishes proper receiver operations, PCS Transmit conveys this information to the link partner via transmission of the parameter Infofield value loc_rcvr_status. The link partner's value for loc_rcvr_status is stored in the local device parameter rem_rcvr_status. When the condition loc_rcvr_status=OK and rem_rcvr_status=OK is satisfied, each PHY announces a transition to the PCS_Test state (trans_to_PCS_Test=1) and start the transition counter as described in 126.4.5.1. For PHYs with the EEE capability, further requirements for this transition are described in 126.3.5.1.

The normal mode of operation corresponds to the PCS_Data state, where PHY Control asserts tx_mode=SEND_N and transmission of data over the link can take place.

PHY Control may force the transmit scrambler state to be initialized to an arbitrary value by requesting the execution of the PCS Reset function defined in 126.3.2.1.

The operation of the maxwait_timer requires that the PHY complete the startup sequence from state SILENT to PMA_Fine_Adjust in the PHY Control state diagram (Figure 126–26) in less than 2000 ms to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

avoid link_status being changed to FAIL by the Link Monitor state diagram (Figure 126–29). To ensure interoperability the timing in Table 126–10 should be observed.

After reaching the PCS_Data state, PHYs with the EEE capability can transition to the LPI receive mode under the control of the link partner and to the LPI transmit mode under control of the local LPI client.

Table 126–10—Recommended startup sequence timing

Master	Recommended maximum time (ms)	Recommended average time (ms)	Slave
SILENT plus (PMA_Training_Init_M state AND en_slave_tx = 0)	350	315	SILENT
(PMA_Training_Init_M state AND en_slave_tx = 1) plus PMA_PBO_Exch state	480	432	PMA_Training_Init_S state plus PMA_PBO_Exch state
PMA_Coeff_Exch state	100	90	PMA_Coeff_Exch state with timing_lock_OK=0
	520	468	Total for PMA Coeff Exch state
PMA_Fine_Adjust state	650	585	PMA_Fine_Adjust state
Total	2000	1800	

126.4.2.5.16 Fast retrain function

PHYs that support the fast retrain capability shall conform to the fast retrain state diagram shown in Figure 126–31. PHYs may request a fast retrain by setting the variable loc_fr_req to TRUE. This causes the transmission of an easily-detected link failure signal specified in 126.4.2.2.2. After completing the link failure signal the PHY shall transition to the PMA_INIT_FR state followed immediately by the PMA_Coeff_Exch state. If the link partner requested THP bypass for fast retrain the PHY bypasses the THP (or set THP coefficients to zero). Otherwise the PHY shall keep its THP turned on with its previously exchanged coefficients, and send PAM2 signaling within a time period equivalent to 18 LDPC frame periods.

After the detection of the link failure signal, a PHY shall transition to the PMA_Coeff_Exch state and respond with PAM2 signaling within a time period equivalent to 18 LDPC frame periods after receiving the link failure signal.

The PAM2 symbols are generated using the PMA sidestream scrambler polynomials shown in Figure 126–11. The training sequence described in 126.3.4 shall be used during fast retraining, with the scramblers free-running from PCS Reset.

Note that reliable traffic on the transmitter may be interrupted when the local receiver requests a fast retrain.

Following the link failure signal, the two link partners transition back to the PMA_Coeff_Exch state and follow the training procedure described in 126.4.2.5.15, with the exception that the initial Infofield countdown values are reduced as indicated in Figure 126–27 and Figure 126–28.

To ensure interoperability the training times in Table 126–11 should be observed during the fast retrain.

Table 126–11—Recommended fast retrain sequence timing

State	Recommended maximum time (ms)
PMA_Coeff_Exch state	20
PMA_Fine_Adjust state	10

126.4.2.6 Link Monitor function

Link Monitor determines the status of the underlying receive channel and communicates it via the variable link_status. Failure of the underlying receive channel typically causes the PMA's clients to suspend normal operation.

The Link Monitor function shall comply with the state diagram of Figure 126–29.

Upon power on, reset, or release from power down, the Auto-Negotiation algorithm sets link_control=SCAN_FOR_CARRIER and, during this period, sends fast link pulses to signal its presence to a remote station. If the presence of a remote station is sensed through reception of fast link pulses, the Auto-Negotiation algorithm sets link_control=DISABLE and exchanges Auto-Negotiation information with the remote station. During this period, link_status=FAIL is asserted. If the presence of a remote 2.5GBASE-T or 5GBASE-T station is established, the Auto-Negotiation algorithm permits full operation by setting link_control=ENABLE. As soon as reliable transmission is achieved, the variable link_status=OK is asserted, upon which further PHY operations can take place.

126.4.2.7 Refresh Monitor function

The Refresh monitor is required for PHYs that support the EEE capability. The Refresh monitor operates when the PHY is in the LPI receive mode. The Refresh monitor shall comply with the state diagram of Figure 126–17. The function forces a link retrain if a refresh signal is not reliably detected within a moving time window equivalent to 50 complete quiet-refresh cycles (nominally equal to 16.384/*S* ms), when the PHY is in the lower power receive mode.

126.4.2.8 Clock Recovery function

The Clock Recovery function couples to all four receive pairs. It may provide independent clock phases for sampling the signals on each of the four pairs.

The Clock Recovery function shall provide clocks suitable for signal sampling on each line so that the LDPC FER indicated in 126.4.2.4 is achieved. The received clock signal should be stable and ready for use when training has been completed (loc_rcvr_status=OK). The received clock signal is supplied to the PMA Transmit function by received_clock.

126.4.3 MDI

Communication through the MDI is summarized in 126.4.3.1 and 126.4.3.2.

126.4.3.1 MDI signals transmitted by the PHY

The symbols to be transmitted by the PMA on the four pairs BI_DA, BI_DB, BI_DC, and BI_DD are denoted by tx_symb_vector[BI_DA], tx_symb_vector[BI_DB], tx_symb_vector[BI_DC], and

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_symb_vector[BI_DD], respectively. The modulation scheme used over each pair is PAM16. PMA Transmit generates a pulse-amplitude modulated signal on each pair in the following form:

$$x_n = M\left(a_n - \sum_{k=1}^{16} x_{n-k} c_k\right) = a_n + 32m_n - \sum_{k=1}^{16} x_{n-k} c_k \quad (126\text{–}3)$$

$$s(t) = \sum_{n=0}^{\infty} x_n h_T(t - nT) \quad (126\text{–}4)$$

In Equation (126–3), a_n is the PAM16 modulation symbol from the set {–15, –13, –11, –9, –7, –5, –3, –1, 1, 3, 5, 7, 9, 11, 13, 15} to be transmitted at time nT. Each of the 16 THP coefficients c_1, c_2,..., c_{16} per wire pair is represented in two's complement form by 8 bits described in 126.4.2.5. The nonlinear THP operation given by $M(\alpha) = (\alpha + 16) mod 32 - 16$ corresponds to changing the modulation symbol a_n to an augmented modulation symbol $\tilde{a}_n = a_n + 32m_n$ with the integer m_n chosen such that the THP output lies in the interval $-16 \le x_n < 16$. Equation (126–4) describes the convolution of the THP output signals with the transmitter symbol response $h_T(t)$ to obtain the transmit signal $s(t)$ at the MDI. The values of the programmable THP coefficients are exchanged in the Infofield during PMA_Coeff_Exch. The THP filter coefficients shall be fixed after startup.

The nominal power (denoted *Ptx*) and the symbol response of the PMA transmitted signal $s(t)$, shall comply with the electrical specifications given in 126.5. When the link segment does not experience the maximum insertion loss (IL), each transceiver indicates to the link partner that the link partner PMA Transmit signal shall be reduced in increments of 2 dB. The minimum power backoff level requested shall comply with the power backoff schedule in Table 126–12. If a given receiver has sufficient decision point SNR margin, it may choose to request from the link partner larger power backoff (up to 14 dB) than shown in Table 126–12. Additionally, the Slave shall select a PBO level as described in the PMA_PBO_Exch state of 126.4.2.5.15. The PMA Transmit shall be capable of eight power backoff settings in approximately 2 dB steps. The difference between each consecutive power setting shall be 2 ± 0.25 dB, and each step shall be centered at 2 × *n* dB (*n* = 0 to 7) reduction from nominal, with a maximum error of ± 1 dB.

The received signal power at the MDI, *P* (dBm), in Table 126–12, should be the estimate of the average received power across all four pairs from the remote transmitter when the link partner PMA Transmit is at nominal power (after accounting for local transmitter power). If the remote transmitter is not at nominal power during the measurement, the estimate of the received power should be incremented by the amount of power backoff of the link partner transmitter during the measurement. Nominal power refers to the transmit power without any power backoff and is specified in 126.5.3.4. The estimate of the received signal power is stored in registers 1.141 to 1.144 as described in 45.2.1. The values in the length, *L* (m), column in Table 126–12 are for reference only (not required for power backoff evaluation).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 126–12—Power backoff schedule

5GBASE-T		
Received signal power at MDI, *P* (dBm)	**Length *L*(m) (reference)**	**Minimum power backoff (dB)**
$-5.8 < P$	$0 \le L < 35$	8
$-7.0 < P \le -5.8$	$35 \le L < 45$	6
$-9.2 < P \le -7.0$	$45 \le L < 65$	4
$-11 < P \le -9.2$	$65 \le L < 85$	2
$P \le -11$	$85 \le L$	0
2.5GBASE-T		
Received signal power at MDI, *P* (dBm)	**Length *L*(m) (reference)**	**Minimum power backoff (dB)**
$-4.3 < P$	$0 \le L < 45$	2
$P \le -4.3$	$45 \le L$	0

126.4.3.2 Signals received at the MDI

Signals received at the MDI can be expressed for each pair as pulse-amplitude modulated signals that are corrupted by noise as follows:

$$r(t) = \sum_{n=0}^{\infty} \tilde{a}_n h_R(t - nT) + w(t) \quad (126–5)$$

In Equation (126–5), $\tilde{a}_n$ are the augmented PAM16 modulation symbols described in 126.4.3.1, $h_R(t)$ denotes the symbol response of the overall channel from the THP precoder to the MDI at the receiver, and $w(t)$ represents the contribution of various noise sources including uncancelled crosstalk. The four signals received on pairs BI_DA, BI_DB, BI_DC, and BI_DD are processed within the PMA Receive function to yield the received symbols rx_symb_vector.

126.4.4 Automatic MDI/MDI-X configuration

Automatic MDI/MDI-X configuration is intended to eliminate the need for crossover cables between similar devices. Automatic MDI/MDI-X configuration is required for 2.5GBASE-T and 5GBASE-T devices and shall comply with 40.4.4.1 and 40.4.4.2.

Having established MDI/MDI-X configuration, the receiver shall detect and correct for several configurations of pair swaps and crossovers and arbitrary polarity swaps. The receiver pairs BI_DA, BI_DB, BI_DC, and BI_DD might be connected to the corresponding transmit pairs in any of the following ways with arbitrary polarity:

a) No crossover
b) A/B crossover only
c) C/D crossover only
d) A/B crossover and C/D crossover

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For EEE-capable PHYs, the MDI/MDIX function configuration shall apply to refresh and alert signaling. For PHYs with the fast retrain capability, the MDI/MDIX function configuration shall apply to link failure signaling.

126.4.5 State variables

126.4.5.1 State diagram variables

coeff_exchange_done
: This variable reports that both transceivers have received the corresponding coefficients from the link partner.
Values: TRUE: The coefficient exchange has completed.
FALSE: The coefficient exchange has not completed.

config
: The PMA shall generate this variable continuously and pass it to the PCS via the PMA_CONFIG.indication primitive.
Values: MASTER or SLAVE.

link_control
: The link_control parameter generated by Auto-Negotiation and passed to the PMA via the PMA_LINK.request primitive (see 126.2.1.1).

link_status
: The link_status parameter set by PMA Link Monitor state diagram and communicated through the PMA_LINK.indication primitive.
Values: OK or FAIL.

loc_rcvr_status
: Variable set by the PMA Receive function to indicate correct or incorrect operation of the receive link for the local PHY.
Values: OK: The receive link for the local PHY is operating reliably.
NOT_OK: Operation of the receive link for the local PHY is unreliable.

loc_SNR_margin
: This variable reports whether the local device has sufficient SNR margin to continue to the next state. The criterion for setting the parameter loc_SNR_margin is left to the implementer.
Values: OK: The local device has sufficient SNR margin.
NOT_OK: The local device does not have sufficient SNR margin.

master_transition_counter
: This variable reports the current value of the MASTER's transition counter reported in the Infofield defined in 126.4.2.5.
Values: 0 to 2^9.

MessageField_IF
: This variable reports that a receiver has successfully received and decoded the Infofield from the remote device. This variable takes on the value contained in the Message field. If the Message field cannot be decoded or no explicit action is outstanding the value Null is returned.
Values: trans_to_Coeff_Exch, trans_to_Fine_Adjust, trans_to_PCS_Test or Null.

PBO
: PBO is a variable that can take any integer value from 0 to 7 and indicates the power backoff level. Denoting *Ptx* as the maximum nominal power, the PBO values are as follows:
Values: 0, 1, 2, 3, 4, 5, 6, 7, which correspond to transmit power levels of
Ptx, *Ptx*–2 dB, *Ptx*–4 dB, *Ptx*–6 dB, *Ptx*–8 dB, *Ptx*–10 dB, *Ptx*–12 dB, *Ptx*–14 dB respectively.

PBO_next
: PBO_next is a variable that can take any integer value from 0 to 7 and indicates the next power backoff level to be used at the local transmitter. The value is taken from the fixed set of values during PMA_Training_Init_M and PMA_Training_Init_S as described in 126.4.2.5. The value is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

taken from the decoded value of the link partner Infofield during PMA_PBO_Exch
Values:0, 1, 2, 3, 4, 5, 6, 7, which correspond to transmit power levels of
Ptx, *Ptx*–2 dB, *Ptx*–4 dB, *Ptx*–6 dB, *Ptx*–8 dB, *Ptx*–10 dB, *Ptx*–12 dB, *Ptx*–14 dB respectively.

PBO_tx

PBO_tx is a variable that can take any integer value from 0 to 7 and indicates the power backoff level currently used at the local transmitter.
Values:0, 1, 2, 3, 4, 5, 6, 7, which correspond to transmit power levels of
Ptx, *Ptx*–2 dB, *Ptx*–4 dB, *Ptx*–6 dB, *Ptx*–8 dB, *Ptx*–10 dB, *Ptx*–12 dB, *Ptx*–14 dB respectively.

PBO_exchange_done

This variable reports that both transceivers have received the corresponding PBO levels from the link partner.
Values:TRUE: The PBO exchange has completed.
FALSE: The PBO exchange has not completed.

pcs_status

The pcs_status parameter generated by the PCS and passed to the PMA via the PMA_PCSSTATUS.request primitive (see 126.2.2.6).

pma_reset

Allows reset of the PHY Control and Link Monitor state diagrams.
Values:ON or OFF.

rem_rcvr_status

Variable set by the PCS Receive function to indicate whether correct operation of the receive link for the remote PHY is detected or not.
Values:OK: The receive link for the remote PHY is operating reliably.
NOT_OK: Reliable operation of the receive link for the remote PHY is not detected.

THP_next

THP_next is a variable that contains sixteen 8-bit values and describes the next transmitter setting of the THP coefficients. It refers to the programmable THP coefficients selected during coefficient exchange described in 126.4.2.5.
Values:16 coefficients of 8-bit values each. Range is –2.0 to 1.984375 in steps of 0.015625.

THP_tx

THP_tx is a variable that contains sixteen 8-bit values and describes the current transmitter setting of the THP coefficients. It refers to the programmable THP coefficients selected during the coefficient exchange described in 126.4.2.5.
Values:16 coefficients of 8-bit values each. Range is –2.0 to 1.984375 in steps of 0.015625.

trans_to_Coeff_Exch

Message field variable defined in 126.4.2.5 that flags a transition by the local device to the PMA_Coeff_Exch state.
Values:1: The local device transitions to the PMA_Coeff_Exch state on expiration of the transition counter.
0: The local device does not transition to the PMA_Coeff_Exch state.

trans_to_Fine_Adjust

Message field variable defined in 126.4.2.5 that flags a transition by the local device to the PMA_Fine_Adjust state.
Values:1: The local device transitions to the PMA_Fine_Adjust state on expiration of the transition counter.
0: The local device does not transition to the PMA_Fine_Adjust state.

trans_to_PCS_Test

Message field variable defined in 126.4.2.5 that flags a transition by the local device to the PCS_Test state.
Values:1: The local device transitions to the PCS_Test state on expiration of the transition counter.
0: The local device does not transition to the PCS_Test state.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transition_count

This variable reports the value of the transition counter contained in the Infofield sent to the remote device. Transition_count has to comply with the state diagram description given in 126.4.6.2. When the Message field contains a flag for a state transition, the transition counter denotes the remaining number of Infofield until the next state transition. MASTER initiates the transition to PMA_Coeff_Exch count with the trans_to_Coeff_Exch=1 flag and a counter value of $S \times 2^8$. The SLAVE responds prior to the counter reaching $S \times 2^5$ with the same flag and a count value matching the MASTER. Then both PHY's transition to PMA_Coeff_Exch within one PMA frame. The same sequence is performed in the transition to PMA_Fine_Adjust state and PCS_Test state using the trans_to_Fine_Adjust=1 and trans_to_PCS_Test=1 flags respectively. In EEE-capable PHYs, synchronization of the PMA frames is tightly controlled as described in 126.3.5.1. When the Message field does not contain a flag for a state transition, the transition counter is set to zero and ignored by the receiver.

Values:0 to 2^9.

tx_mode

PCS Transmit sends code-groups according to the value assumed by this variable.

Values: SEND_N: This value is continuously asserted when transmission of sequences of code-groups representing a XGMII data stream take place.

SEND_T: This value is continuously asserted when transmission of sequences of code-groups representing the sequences of code-groups (TA_n, TB_n, TC_n, TD_n) defined in 126.3.4.2 is to take place.

SEND_Z: This value is asserted when transmission of zero code-groups is to take place.

The following variables are required only for PHYs that support the EEE capability:

lpi_refresh_detect

Set TRUE when the receiver has reliably detected refresh signaling and FALSE otherwise. The exact criteria left to the implementer.

pcs_data_mode

Generated by the PMA PHY Control function and indicates whether or not the local PHY may transition its PCS state diagrams out of their initialization states. The current value of the pcs_data_mode is passed to the PCS via the PMA_PCSDATAMODE.indicate primitive. In the absence of the optional EEE and fast retrain capabilities, the PHY operates as if the value of this variable is TRUE.

mtc

mtc is the transition count for a MASTER PHY during normal training and fast retraining. mtc shall be equal to $S \times 2^8$ for normal training and $S \times 2^5$ for fast retrain.

stc

stc is the transition count for a SLAVE PHY during normal training and fast retraining. stc shall be equal to $S \times 2^5$ for normal training and $S \times 2^4$ for fast retrain.

The following six variables are required only for PHYs that support the fast retrain capability:

fr_enable

This variable is set to TRUE if fast retrain is supported. The variable is set to FALSE otherwise. If MDIO is supported, this variable is based on the value of 1.147.0 with the value of TRUE corresponding to 1.147.0 set to 1. If MDIO is not supported, an equivalent method of controlling fast retrain functionality should be provided.

loc_fr_req

Set TRUE when the receiver has detected a link failure condition and is requesting a fast retrain; set FALSE otherwise.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

loc_fr_detect
: Set TRUE when the receiver has reliably detected the link failure signal. It is highly recommended that loc_fr_detect is qualified with the reception of errored blocks at the LDPC decoder output. Set FALSE when the link failure signal is not detected.

send_link_fail
: When TRUE indicates that the PMA should send the link failure signal. When FALSE the variable has no effect.

fr_active
: Set TRUE when the PHY is performing a fast retrain and set FALSE otherwise.

fast_retrain_flag
: Set TRUE after the PHY generates or detects a link failure signal and set FALSE otherwise.

126.4.5.2 Timers

All timers operate in the manner described in 14.2.3.2.

maxwait_timer
: A timer used to limit the amount of time during which a receiver dwells in the SILENT and TRAINING states. The timer shall expire 2000 ms ± 10 ms after being started. This timer is used jointly in the PHY Control and Link Monitor state diagrams. The maxwait_timer is tested by the Link Monitor to force link_status to be set to FAIL if the timer expires and loc_rcvr_status is NOT_OK. See Figure 126–26 and Figure 126–29.

minwait_timer
: A timer used to determine the minimum amount of time the PHY Control stays in the SILENT, PMA_Training_Init_S, PCS_Test and PCS_Data states. The timer shall expire 1 ms ± 0.1 ms after being started.

The following timer is required only for PHYs that support the EEE capability:

lpi_refresh_rx_timer
: This timer is used to monitor link quality during the LPI receive mode. If the PHY does not reliably detect reliable refresh signaling before this timer expires then a full retrain is performed.
Values: The condition lpi_refresh_rx_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 50 complete quiet-refresh signal periods, equivalent to 8.192/*S* ms.

The following two timers are required only for PHYs that support the fast retrain capability:

link_fail_sig_timer
: Determines the period of time the PHY sends the link failure signal.
Values: The condition link_fail_sig_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 8 LDPC frame periods.

fr_maxwait_timer
: Determines the period of time the PHY has to transition its PCS Control State to PCS_Test following a fast retrain before the fast retrain is aborted and a full retrain performed.
Values: The condition fr_maxwait_timer_done becomes true upon timer expiration.
Duration: This timer shall have a period equal to 30 ms.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

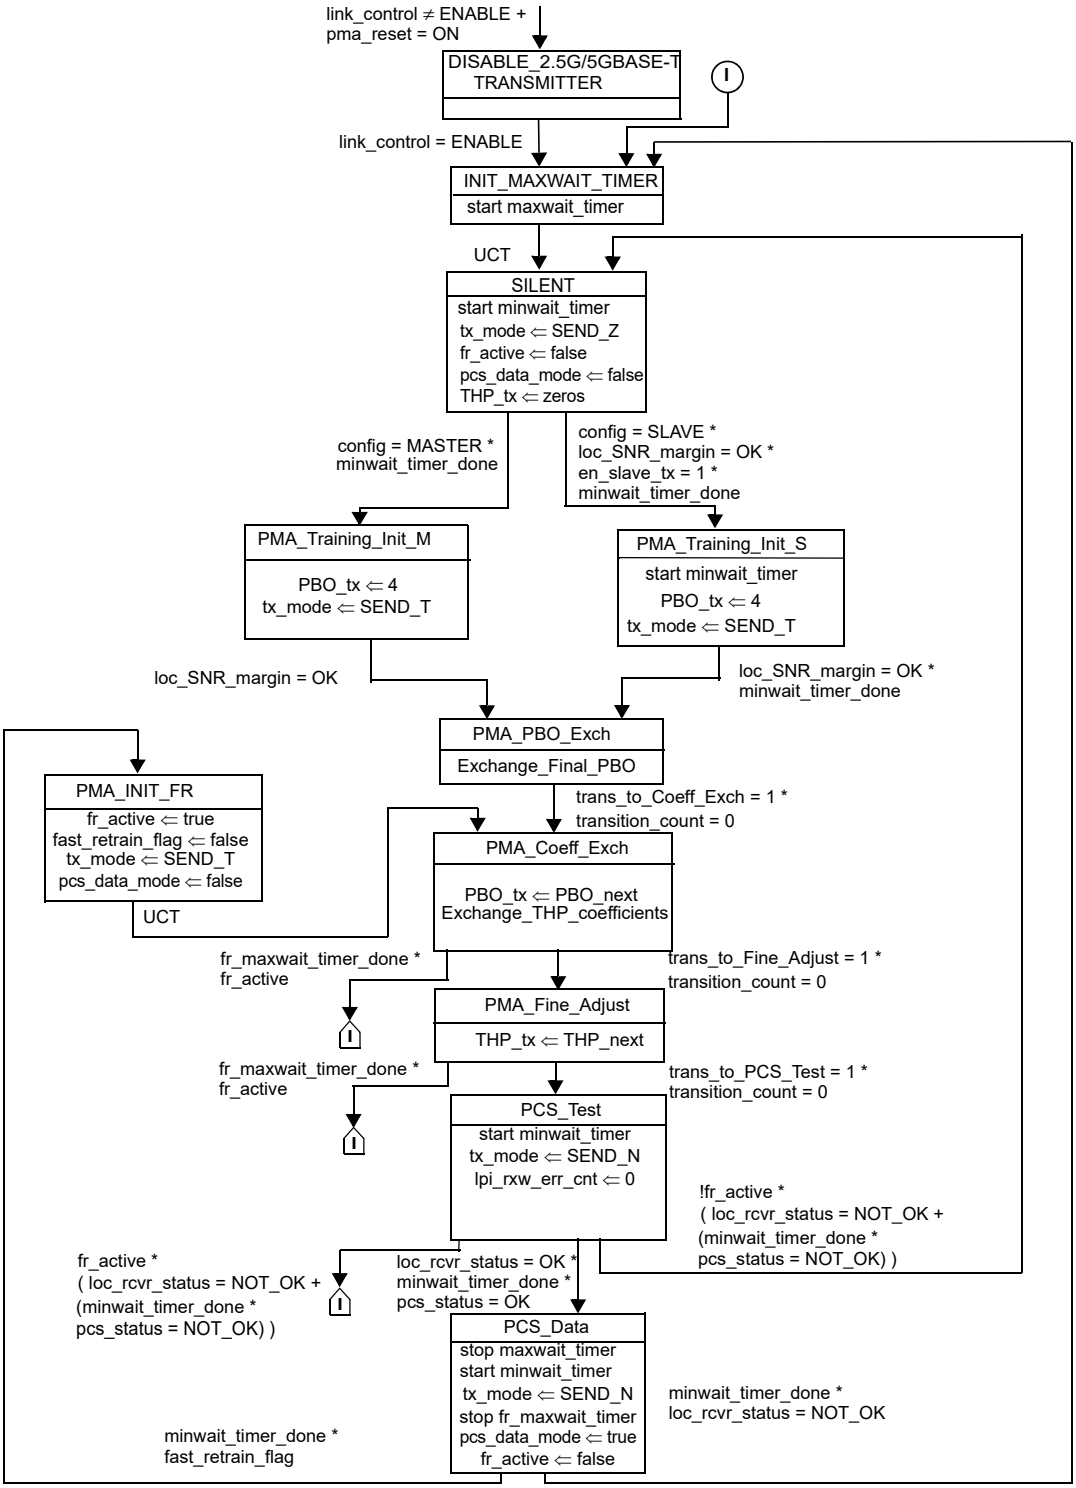
126.4.5.3 Functions

Exchange_Final_PBO
: This function transmits and receives the final PBO settings using the Infofield as described in 126.4.2.5.

Exchange_THP_Coefficients
: This function compiles and sends to the link partner and receives from the link partner the desired programmable THP coefficients using the Infofield as described in 126.4.2.5.

126.4.5.4 Counters

The following two counters are required only for PHYs that support the fast retrain capability:



fr_tx_counter
: Counts the number of times the PHY initiates a fast link retrain by transmitting the link failure signal. This counter is reflected in MDIO register 1.147.10:6 specified in 45.2.1.94.2.

fr_rx_counter
: Counts the number of times the PHY begins a fast link retrain in response to the detection of link failure signaling from the link partner. This counter is reflected in MDIO register 1.147.15:11 specified in 45.2.1.94.1.

126.5 PMA electrical specifications

This subclause defines the electrical characteristics of the PMA and specifies PMA-to-MDI interface tests.

126.5.1 Electrical isolation

A PHY with a MDI that is a PI (see 33.1.3) shall meet the isolation requirements defined in 33.4.1 or 145.4.1.

A PHY with a MDI that is not a PI shall provide electrical isolation between the port device circuits, including frame ground (if any) and all MDI leads. This electrical isolation shall meet the isolation requirements as specified in J.1.

126.5.2 Test modes

The test modes described next shall be provided to allow for testing of the transmitter waveform, transmitter distortion, transmitted jitter, transmitter droop, and BER testing.

For a PHY with an MDIO management interface, these modes shall be enabled by setting bits 1.132.15:13 (MultiGBASE-T test mode register) of the MDIO Management register set as follows in Table 126–13. These test modes shall only change the data symbols provided to the transmitter circuitry and shall not alter

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the electrical and jitter characteristics of the transmitter and receiver from those of normal (non-test mode) operation. PHYs without a MDIO shall provide a means to enable these modes for conformance testing.

Table 126–13—MDIO management register settings for test modes

1.132.15	1.132.14	1.132.13	Mode
0	0	0	Normal operation.
0	0	1	Test mode 1—Setting of MASTER transmitter required by SLAVE for transmit jitter test in SLAVE mode.
0	1	0	Test mode 2—Transmit jitter test in MASTER mode.
0	1	1	Test mode 3—Transmit jitter test in SLAVE mode.
1	0	0	Test mode 4—Transmit distortion test.
1	0	1	Test mode 5—Normal operation with no power backoff. This is for the PSD mask and power level test.
1	1	0	Test mode 6—Transmitter droop test mode.
1	1	1	Test mode 7—Pseudo-random test mode for BER Monitor.

Test mode 1 is a mode provided for enabling testing of timing jitter on a SLAVE transmitter. When test mode 1 is enabled, the PHY shall transmit the PMA training pattern (PRBS 33) continually from all four transmitters with the THP turned off, with no power backoff and with the transmitted symbols timed from its local clock source.

Test mode 2 is for transmitter jitter testing when transmitter is in MASTER timing mode. When test mode 2 is enabled, the PHY shall transmit {two +16 symbols followed by two –16 symbols} continually from all four transmitters with the THP turned off, with no power backoff and with the transmitted symbols timed from its local clock source. The transmitter output is a $S \times 100$ MHz signal.

When test mode 3 is enabled on a PHY, the PHY shall transmit, with THP turned off, the data symbol sequence {two +16 symbols followed by two –16 symbols} repeatedly on pair D with the symbols timed from its recovered receive data clock in SLAVE timing mode. A PHY operates in test mode 3 when there is no input signal on pair D. The transmitter output is a $S \times 100$ MHz signal on pair D and shall be silence on pairs A, B, and C.

Test mode 4 is for transmitter nonlinear distortion testing. When test mode 4 is enabled, the PHY shall transmit, with the THP turned off, transmitted symbols, timed from a transmit clock (as specified in 126.5.3.5) in the MASTER timing mode, defined by the bits1.132.12:10 and Table 126–14.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 126–14—MDIO management register settings for transmit frequencies in Test mode 4

1.132.12	1.132.11	1.132.10	Output waveform frequencies in MHz
			Two tone frequency pairs
0	0	0	Reserved
0	1	1	Reserved
1	1	1	Reserved
0	0	1	$S \times (400/1024) \times 47$, $S \times (400/1024) \times 53$
0	1	0	$S \times (400/1024) \times 101$, $S \times (400/1024) \times 103$
1	0	0	$S \times (400/1024) \times 179$, $S \times (400/1024) \times 181$
1	0	1	$S \times (400/1024) \times 277$, $S \times (400/1024) \times 281$
1	1	0	$S \times (400/1024) \times 397$, $S \times (400/1024) \times 401$

The peak-to-peak levels used in this test shall correspond to the ±16 symbol levels and the relative amplitudes of the tones in a two-tone pair shall be within 0.5 dB of each other.

Test mode 5 is for checking whether the transmitter is compliant with the transmit PSD mask and the transmit power level. When test mode 5 is enabled, the PHY shall transmit as in normal operation but with the power backoff disabled.

Test mode 6 is for testing transmitter droop. When test mode 6 is enabled, the PHY shall transmit the following sequence of data symbols A_n, B_n, C_n, D_n, of 126.4.3.1 continually from all four transmitters, with the THP turned off:

{One hundred twenty eight +16 followed by one hundred twenty eight –16 symbols}.

Test mode 7 is for enabling measurement of the bit error ratio of the link including the LDPC encoder/decoder, the transmit and receive analog front ends of the PHY and a cable connecting two PHYs. This mode shall use the 2.5GBASE-T and 5GBASE-T scrambler and is defined in detail in 126.3.3.

126.5.2.1 Test fixtures

The following fixtures (illustrated by Figure 126–32, Figure 126–33, and Figure 126–34), or their functional equivalents, can be used for measuring the transmitter specifications described in 126.5.3.

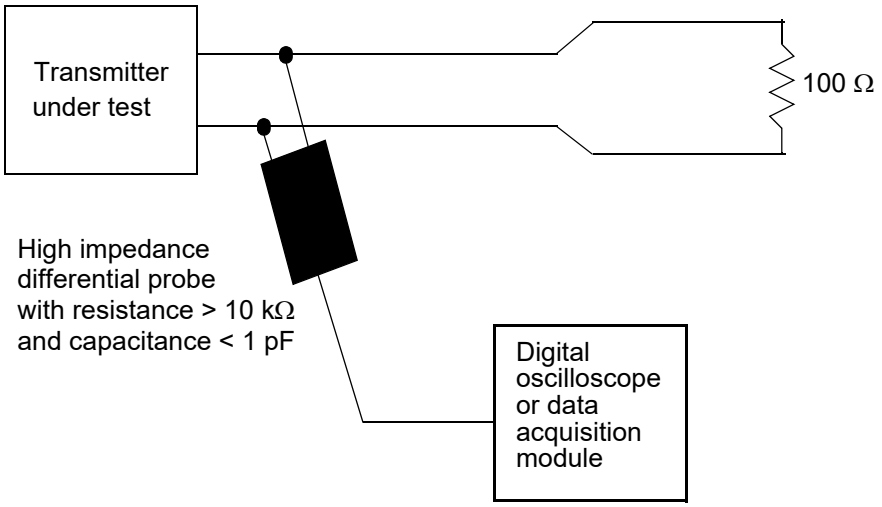

Figure 126–32—Transmitter test fixture 1 for transmitter droop measurement

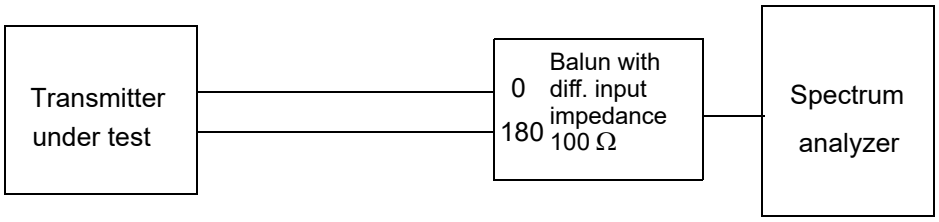

Figure 126–33—Transmitter test fixture 2 for linearity measurement, power spectral density measurement and transmit power level measurement

The high impedance probe shown in Figure 126–32 in transmitter test fixture 1 has resistance > 10 KΩ and capacitance < 1 pF over the frequency range of 1 MHz to $S \times 200$ MHz. Figure 126–33 includes a power summer or balun device to couple the 100 Ω differential output of the transmitter to the 50 Ω single-ended input typically found in a spectrum analyzer input. The center frequency (f_c) of the band pass filter shown in Figure 126–34 is $S \times 100$ MHz ± 200 kHz and the band pass filter noise bandwidth (B_n) is 2 MHz ± 200 kHz. The center frequency (f_c) of the band pass filter shown in Figure 126–35 is 45 MHz ± 200 kHz and the band pass filter noise bandwidth (B_n) is 2 MHz ± 200 kHz.

126.5.3 Transmitter electrical specifications

The PMA provides the Transmit function specified in 126.4.2.2 in accordance with the electrical specifications of this clause. The PMA shall operate with AC-coupling to the MDI.

Where a load is not specified, the transmitter shall meet the requirements of this clause with a 100 Ω resistive differential load connected to each transmitter output.

126.5.3.1 Maximum output droop

With the transmitter in test mode 6 and using the transmitter test fixture 1, the magnitude of both the positive and negative droop shall be less than (7.5 + 5/*S*)%, measured with respect to an initial value at 10 ns after the zero crossing and a final value at (10 + 160/*S*) ns after the zero crossing.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.5.3.2 Transmitter nonlinear distortion

When in test mode 4 and observing the spectrum of the differential signal output at the MDI using transmitter test fixture 2, for each pair, with no intervening cable, the transmitter nonlinear distortion mask is defined as follows:

The SFDR of the transmitter, with dual tone inputs as specified in test mode 4, shall meet the requirement shown in Equation (126–6).

$$\text{SFDR} \geq \quad 2.5 + \ \min\{52, 58 - 20 \times \log_{10}(f/25)\} \tag{126–6}$$

where

f is the maximum frequency of the two test tones in MHz
SFDR is the ratio in dB of the minimum RMS value of either input tone to the RMS value of the worst intermodulation product in the frequency range of 1 MHz to $S \times 200$ MHz

Additionally, for 2.5GBASE-T, when in test mode 4, at 0 dB PBO, and observing the spectrum of the differential signal output at the MDI using transmitter test fixture 4, for each pair, while injecting a 45 MHz sine wave from the signal generator so that it has an amplitude 7 dB below the peak of the transmitter at the MDI, with no intervening cable, the transmitter nonlinear distortion mask is defined as follows: The SFDR of the transmitter, with dual tone inputs as specified in test mode 4, shall meet the requirement shown in Equation (126–7).

$$\text{SFDR} \geq \quad -5.5 + \ \min\{52, 58 - 20 \times \log_{10}(f/25)\} \tag{126–7}$$

where

f is the maximum frequency of the two test tones in MHz
SFDR is the ratio in dB of the minimum RMS value of either input tone to the RMS value of the worst intermodulation product in the frequency range of 1 MHz to 100 MHz

This specification on transmit linearity is derived from the requirement for interoperability with the far-end device.

126.5.3.3 Transmitter timing jitter

When in test mode 2, the PHY transmits {two +16 symbols followed by two –16 symbols} continually with the THP turned off and with no power backoff. In this mode, the transmitter output should be a $S \times 100$ MHz signal and the RMS period jitter measured at the PHY MDI output shall be less than 7.2 ps for 5GBASE-T and 10.0 ps for 2.5GBASE-T. The RMS period jitter is measured as per the test configuration shown in Figure 126–34 over an integration time interval of $2/S$ ms ± 10%.

The SLAVE mode RMS period jitter test is measured using the test configuration shown in Figure 126–34. For this test, the MASTER PHY is in test mode 1 and the SLAVE PHY is in test mode 3. The MASTER is transmitting the PMA training pattern (PRBS 33) to the SLAVE PHY on pairs A, B, and C. The SLAVE PHY is in loop timing mode, synchronizing its transmit clock to the signals received from the MASTER PHY on pairs A, B, and C. In this configuration, the transmitter output on pair D should be a $S \times 100$ MHz signal and the RMS period jitter measured at the SLAVE PHY MDI output shall be less than 7.2 ps for 5GBASE-T and 10.0 ps for 2.5GBASE-T. The RMS period jitter is measured over an integration time interval of $2/S$ ms ± 10%.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RMS period jitter over an integration time interval of $2/S$ ms ± 10% is defined as the root mean square period difference from the average period ($T - T_{avg}$), accumulated over a sample size of 200 000 ± 20 000, as shown in Equation (126–8).

$$\text{RMS period jitter} = \sqrt{\frac{\sum[(T - T_{avg})^2]}{\text{Sample size}}} \tag{126–8}$$

126.5.3.4 Transmitter power spectral density (PSD) and power level

In test mode 5 (normal operation with no power backoff), the transmit power shall be in the range 1.0 dBm to 3.0 dBm and the power spectral density of the transmitter, measured into a 100 Ω, load using the test fixture shown in Figure 126–33 shall be between the upper and lower masks specified in Equation (126–9) and Equation (126–10). In the highest frequency segment, the PSD mask is the maximum of the PSD specified for 2.5G/5GBASE-T, or 6 dB less than that specified in Clause 55 by Equation (55–9). The masks are shown in Figure 126–36.

$$\text{PSD1}(f) \leq \begin{cases} -77.7 - 10 \times \log_{10}(S) & \text{dBm/Hz} \quad 0 < 2\frac{f}{S} \leq 70 \\ -77.7 - 10 \times \log_{10}S - \frac{\left(2\frac{f}{S} - 70\right)}{80} & \text{dBm/Hz} \quad 70 < 2\frac{f}{S} \leq 150 \\ -78.7 - 10 \times \log_{10}S - \frac{\left(2\frac{f}{S} - 150\right)}{58} & \text{dBm/Hz} \quad 150 < 2\frac{f}{S} \leq 730 \\ -78.7 - 10 \times \log_{10}S - \frac{\left(2\frac{f}{S} - 330\right)}{40} & \text{dBm/Hz} \quad 730 < 2\frac{f}{S} \leq 1822 - 400 \times \log_{10}(S) \\ -116 & \text{dBm/Hz} \quad S \times (911 - 200 \times \log_{10}(S)) < f \leq 3000 \end{cases}$$

$$\text{UpperPSD}(f) \leq \max(\text{PSD1}(f), (\text{Equation 55-9}) - 6\ \text{dB})$$

(126–9)

and

$$\text{Lower PSD}\ (f) \geq \begin{cases} -82.2 - 10 \times \log_{10}(S) & \text{dBm/Hz} \quad 5 < 2\frac{f}{S} \leq 50 \\ -82.2 - 10 \times \log_{10}S - \frac{\left(2\frac{f}{S} - 50\right)}{50} & \text{dBm/Hz} \quad 50 < 2\frac{f}{S} \leq 200 \\ -85.2 - 10 \times \log_{10}S - \frac{\left(2\frac{f}{S} - 200\right)}{25} & \text{dBm/Hz} \quad 200 < 2\frac{f}{S} \leq 400 \end{cases} \tag{126–10}$$

where

f is in MHz

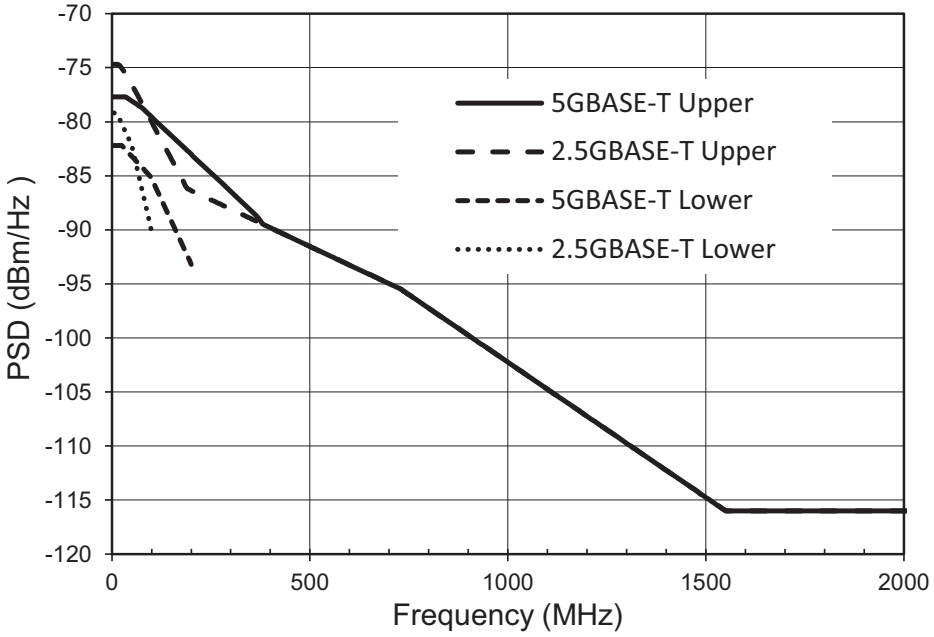

Figure 126–36—Transmitter power spectral density mask

126.5.3.5 Transmit clock frequency

The symbol transmission rate on each pair of the MASTER PHY shall be within the range $S \times 400$ MHz ± 50 ppm.

For a MASTER PHY, when the transmitter is in the LPI transmit mode or when the receiver is in the LPI receive mode the transmitter clock short-term rate of frequency variation shall be less than 0.1 ppm/second. The short-term frequency variation limit shall also apply when switching to and from the LPI mode.

126.5.4 Receiver electrical specifications

The PMA provides the Receive function specified in 126.4.2.4 in accordance with the electrical specifications of this clause using cabling that is within the limits specified in 126.7.

126.5.4.1 Receiver differential input signals

Differential signals received at the MDI that were transmitted from a remote transmitter within the specifications of 126.5.3 and have passed through a link specified in 126.7 shall be received with a BER less than 10^{-12} after LDPC decoding, and sent to the XGMII after link reset completion. This specification can be verified by a frame error ratio less than 7.8×10^{-9} for 800 octet frames with minimum IPG or greater than 220 octet IPG.

126.5.4.2 Receiver frequency tolerance

The receive feature shall properly receive incoming data, per the requirements of 126.5.4.1, with a symbol rate within the range $S \times 400$ MHz ± 50 ppm.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.5.4.3 Rejection of External EM Fields

When the cabling system is subjected to electromagnetic fields, currents are generated that may be converted to interference. This specification is provided to limit the sensitivity of the PMA receiver to external EM fields picked up by the cabling and interconnect system. It provides an assessment method of the electromagnetic performance of the link segment and the PHY, including the MDI.

An 80 MHz to 1000 MHz test can be made based on the cable clamp test described in Annex 113A, a 30 meter plug-terminated link segment that meets the requirements of 126.7, and suitable broadband ferrites. All components that are exposed to the induced fields should remain over the ground reference plane. A sine wave with the amplitude held constant over the whole frequency range from 80 MHz to 1000 MHz, with the amplitude calibrated so that the signal power measured at the output of the clamp does not exceed 6 dBm, is used to generate the external electromagnetic field and corresponding currents.

A system integrating a 2.5GBASE-T or 5GBASE-T PHY may perform this test to evaluate anticipated performance in regulatory test environments. Operational requirements of the transceiver during the test are determined by the manufacturer.

NOTE—The 6 dBm limit includes the 10% frequency-dependent variation mentioned in 113A.3.

126.5.4.4 Alien crosstalk noise rejection

While receiving data from a transmitter compliant with specifications in 126.5.3, through a 100 m link segment compliant with the specifications in 126.7, a receiver shall operate with an Ethernet frame error ratio less than 7.8×10^{-9} for 800 octet frames with either a minimum IPG or greater than 220 octet IPG with four noise sources at the specified levels representing alien crosstalk, one connected to each of the four pairs. Independent noise sources should be injected into each MDI input using couplers that do not significantly alter the link segment characteristics. The injected noise shall have a flat spectrum within the following limits: a 3 dB bandwidth extending over at least 10 MHz to $200 \times S$ MHz and a power spectral density such that at the MDI port of the device under test the power spectral density of the injected noise is –137 dBm/Hz and –125 dBm/Hz for 5GBASE-T and 2.5GBASE-T, respectively. A flat noise source is chosen to model the sum of all alien noise sources. See Figure 126–37.

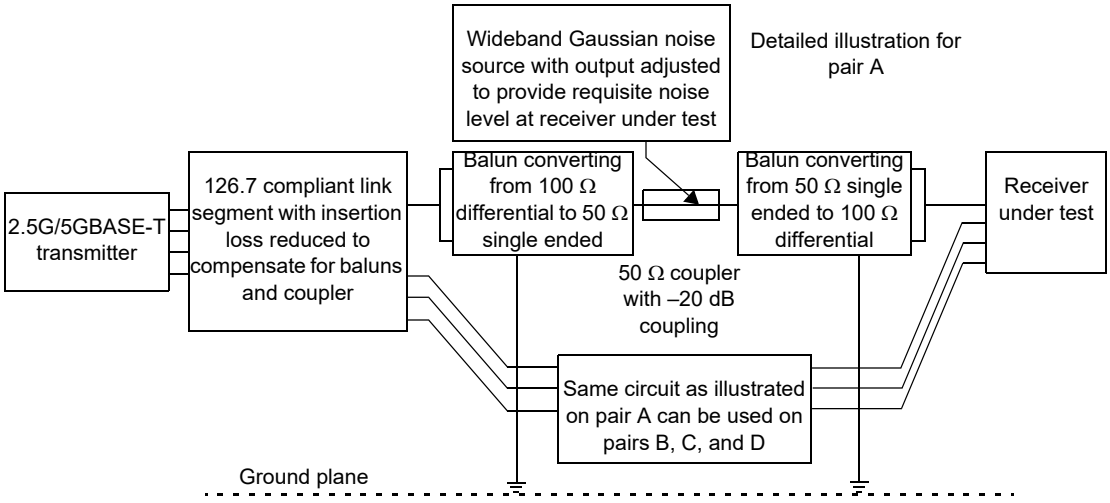

Figure 126–37—Alien crosstalk noise rejection test

The structure shown for injecting the noise in Figure 126–37 is illustrative and alternative approaches are possible. The loss of the coupling structure shown in Figure 126–37, which consists of two baluns and a

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

coupler, is approximately 2.5 dB. The overall insertion loss of the link segment together with the insertion loss of the coupling structure should be adjusted to match the insertion loss specified in 126.7.2.1 to within ± 0.5 dB. The balun-coupler-balun structure shown in Figure 126–37 can be replaced by resistively coupling a balanced noise source to the twisted pair using 500 Ω resistors. In either case, calibration of the test setup is required to confirm the overall insertion loss and the injected noise power at the MDI of the receiver under test.

126.6 Management interfaces

2.5GBASE-T and 5GBASE-T make extensive use of the management functions that may be provided by the MDIO (Clause 45), and the communication and self-configuration functions provided by Auto-Negotiation (Clause 28). Additional Auto-Negotiation requirements are set forth within this subclause.

126.6.1 Support for Auto-Negotiation

All 2.5GBASE-T and 5GBASE-T PHYs shall provide support for Auto-Negotiation (Clause 28) and shall be capable of operating as MASTER or SLAVE. All 2.5GBASE-T and 5GBASE-T PHYs shall provide support for Extended Next Pages as defined in 28.2.3.4.2 and shall support and use optimized FLP Burst to FLP burst timing as defined in 28.2.1.1.1, and nlp_link_test_min_timer and link_fail_inhibit_timer as defined in 28.3.2.

Auto-Negotiation is performed as part of the initial set-up of the link, and allows the PHYs at each end to advertise their capabilities (speed, PHY type, half or full duplex) and to automatically select the operating mode for communication on the link. Auto-Negotiation signaling is used for the following primary purposes for 2.5GBASE-T and 5GBASE-T:

a) To negotiate that the PHY is capable of supporting 2.5GBASE-T or 5GBASE-T transmission.
b) To determine the MASTER-SLAVE relationship between the PHYs at each end of the link.

126.6.1.1 2.5GBASE-T and 5GBASE-T use of registers during Auto-Negotiation

When Clause 45 registers are implemented, a 2.5GBASE-T and 5GBASE-T PHYs shall use the management register definitions and values specified in Table 126–15.

Table 126–15—2.5GBASE-T and 5GBASE-T registers

Register	Bit	Name	Description	Type[a]

126.6.1.2 2.5GBASE-T and 5GBASE-T Auto-Negotiation page use

2.5GBASE-T and 5GBASE-T PHYs shall exchange a MultiGBASE-T and 1000BASE-T formatted Extended Next Page, as specified in Table 126–16, immediately following the exchange of the Base Page.

Note that the Acknowledge 2 bit is not utilized and has no meaning when used for the 2.5GBASE-T and 5GBASE-T message page exchange.

126.6.1.3 Sending Next Pages

Implementers who do not wish to send additional Extended Next Pages (i.e., Extended Next Pages in addition to those required to perform PHY configuration as defined in this clause) can use Auto-Negotiation as defined in Clause 28. Implementers who wish to send additional Extended Next Pages may do so using the AN XNP transmit registers. See 45.2.7.8.

126.6.2 MASTER-SLAVE configuration resolution

Since both PHYs that share a link segment are capable of being MASTER or SLAVE, a prioritization scheme exists to ensure that the correct mode is chosen. The MASTER-SLAVE relationship shall be determined during Auto-Negotiation using Table 126–17 with the 2.5GBASE-T and 5GBASE-T Technology Ability Next Page bit values specified in Table 126–16 and information received from the link partner. This process is conducted at the entrance to the FLP LINK GOOD CHECK state shown in the Arbitration state diagram (see Figure 28–18).

The following four equations are used to determine these relationships:

manual_MASTER = U11 * U12
manual_SLAVE = U11 * !U12
single-port device = !U11 * !U13
multiport device = !U11 * U13

where

U11 is bit 11 of MultiGBASE-T and 1000BASE-T Technology message code
U12 is bit 12 of MultiGBASE-T and 1000BASE-T Technology message code
U13 is bit 13 of MultiGBASE-T and 1000BASE-T Technology message code (see Table 126–16)

A 2.5GBASE-T or 5GBASE-T PHY is capable of operating either as the MASTER or SLAVE. In the scenario of a link between a single-port device and a multiport device, the preferred relationship is for the multiport device to be the MASTER PHY and the single-port device to be the SLAVE. However, other

topologies may result in contention. The resolution function of Table 126–17 is defined to handle any relationship conflicts.

The resolution shown in Table 126–17 shall be used.

Table 126–17—2.5GBASE-T and 5GBASE-T MASTER-SLAVE configuration resolution table

Local device type	Remote device type	Local device resolution	Remote device resolution
single-port device	multiport device	SLAVE	MASTER
single-port device	manual_MASTER	SLAVE	MASTER
manual_SLAVE	manual_MASTER	SLAVE	MASTER
manual_SLAVE	multiport device	SLAVE	MASTER
multiport device	manual_MASTER	SLAVE	MASTER
manual_SLAVE	single-port device	SLAVE	MASTER
multiport device	single-port device	MASTER	SLAVE
multiport device	manual_SLAVE	MASTER	SLAVE
manual_MASTER	manual_SLAVE	MASTER	SLAVE
manual_MASTER	single-port device	MASTER	SLAVE
single-port device	manual_SLAVE	MASTER	SLAVE
manual_MASTER	multiport device	MASTER	SLAVE
multiport device	multiport device	The device with the higher seed value is configured as MASTER, otherwise SLAVE	The device with the higher seed value is configured as MASTER, otherwise SLAVE
single-port device	single-port device	The device with the higher seed value is configured as MASTER, otherwise SLAVE	The device with the higher seed value is configured as MASTER, otherwise SLAVE
manual_SLAVE	manual_SLAVE	MASTER-SLAVE configuration fault	MASTER-SLAVE configuration fault
manual_MASTER	manual_MASTER	MASTER-SLAVE configuration fault	MASTER-SLAVE configuration fault

A 2.5GBASE-T or 5GBASE-T multiport device has higher priority than a single-port device to become the MASTER. In the case where both devices are of the same type, e.g., both devices are multiport devices, the device with the higher MASTER-SLAVE seed bits (SB0, ..., SB10), where SB10 is the MSB, shall become the MASTER and the device with the lower seed value shall become the SLAVE. In case both devices have the same seed value, both should assert link_status_2p5GigT = FAIL for 2.5GBASE-T and link_status_5GigT = FAIL for 5GBASE-T (as defined in 28.3.1) to force a new cycle through Auto-Negotiation. Successful completion of the MASTER-SLAVE resolution shall be treated as MASTER-SLAVE configuration resolution complete.

The method of generating a random or pseudorandom seed is left to the implementer. The generated random seeds should belong to a sequence of independent, identically distributed integer numbers with a uniform distribution in the range of 0 to 2^{11}– 2. The algorithm used to generate the integer should be designed to minimize the correlation between the number generated by any two devices at any given time. A seed

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

counter shall be provided to track the number of seed attempts. The seed counter shall be set to zero at startup and shall be incremented each time a seed is generated. When MASTER-SLAVE resolution is complete, the seed counter shall be reset to 0 and bit 7.33.15 shall be set to zero. A MASTER-SLAVE resolution fault shall be declared if resolution is not reached after the generation of seven seeds.

The MASTER-SLAVE manual configuration enable bit (control register bit 7.32.15) and the MASTER-SLAVE config value bit (control register bit 7.32.14) are used to manually set a device to become the MASTER or the SLAVE. In case both devices are manually set to become the MASTER or the SLAVE, this condition shall be flagged as a MASTER-SLAVE configuration fault condition; thus the MASTER-SLAVE configuration fault bit (status register bit 7.33.15) shall be set to logical one. The MASTER-SLAVE configuration fault condition shall be treated as MASTER-SLAVE configuration resolution complete and link_status_2p5GigT, for 2.5GBASE-T, or link_status_5GigT, for 5GBASE-T, shall be set to FAIL, because the MASTER-SLAVE relationship was not resolved. This forces a new cycle through Auto-Negotiation after the link_fail_inhibit_timer has expired. Determination of MASTER-SLAVE values occur on the entrance to the FLP LINK GOOD CHECK state (Figure 28–18) when the highest common denominator (HCD) technology is 2.5GBASE-T or 5GBASE-T. The resulting MASTER-SLAVE value is used by the 2.5GBASE-T or 5GBASE-T PHY Control (126.4.2.5).

If MASTER-SLAVE manual configuration is disabled (bit 7.32.15 is set to 0) and the local device detects that both the local device and the remote device are of the same type (either multiport device or single-port device) and that both have generated the same random seed, it generates and transmits a new random seed for MASTER-SLAVE negotiation by setting link_status to FAIL and cycling through the Auto-Negotiation process again.

The MASTER-SLAVE configuration process returns one of the three following outcomes:

a) *Successful:* Bit 7.33.15 of the MultiGBASE-T status register is set to logical zero and bit 7.33.14 is set to logical one for MASTER resolution or for logical zero for SLAVE resolution. 2.5GBASE-T or 5GBASE-T return control to Auto-Negotiation (at the entrance to the FLP LINK GOOD CHECK state in Figure 28–18) and passes the value MASTER or SLAVE to PMA_config.indication (see 126.2.2.2).
b) *Unsuccessful:* link_status_2p5GigT (2.5GBASE-T) or link_status_5GigT (5GBASE-T) is set to FAIL and Auto-Negotiation restarts (see Figure 28–18).
c) *Fault detected:* Bit 7.33.15 of the MultiGBASE-T status register is set to logical one to indicate that a configuration fault has been detected. This bit also is set when seven attempts to configure the MASTER-SLAVE relationship via the seed method have failed. When a fault is detected, link_status_2p5GigT (2.5GBASE-T) or link_status_5GigT (5GBASE-T) is set to FAIL, causing Auto-Negotiation to cycle through again.

NOTE—MASTER-SLAVE arbitration only occurs if 2.5GBASE-T, 5GBASE-T, 10GBASE-T, 25GBASE-T, 40GBASE-T, or 1000BASE-T is selected as the highest common denominator.

126.7 Link segment characteristics

2.5GBASE-T and 5GBASE-T are designed to operate over Category 5e/Class D 4-pair balanced cabling that meets the additional requirements specified in this subclause. Each of the 2.5GBASE-T four pairs supports an effective data rate of 625 Mb/s per pair, in each direction simultaneously. Each of the 5GBASE-T four pairs supports an effective data rate of 1250 Mb/s per pair, in each direction simultaneously. The term “link segment” used in this clause refers to four twisted pairs operating in full duplex termed “duplex channels.” Specifications for a link segment apply equally to each of the four twisted pairs. All implementations of the balanced cabling link segment specification shall be compatible at the MDI. It is recommended that the guidelines in TIA TSB-5021, ISO/IEC TR 11801-9904, ANSI/TIA-568-C.2, and ISO/IEC 11801:2002/Amendment 1 be considered before the installation of 2.5G/5GBASE-T equipment for any cabling system.

126.7.1 Cabling system characteristics

2.5G/5GBASE-T requires 4 pair Class D cabling with a nominal impedance of 100 Ω., as specified in ISO/IEC 11801:2002. Operation on other classes of cabling may be supported if the link segment meets the requirements of 126.7.

Additionally:

a) 2.5GBASE-T is an ISO/IEC 11801-2002 Class D and ANSI/TIA-568-C.2 Category 5e application, with additional installation requirements and transmission parameters specified in this clause.
b) 5GBASE-T is an ISO/IEC 11801-2002 Class D and ANSI/TIA-568-C.2 Category 5e application, with additional installation requirements and transmission parameters specified in this clause, including extended frequency performance beyond that specified for Class D and Category 5e.
c) Refer to ISO/IEC TR 11801-9904 and TIA TSB-5021 for support of 2.5GBASE-T and 5GBASE-T over installed cabling.
d) Supported cabling types and distances for 2.5GBASE-T and 5GBASE-T are listed in Table 126–18 and Table 126–19 respectively.

126.7.2 Link segment transmission parameters

A link segment consisting of up to 100 m of Category 5e/Class D 4-pair balanced cabling that meets the transmission parameters of this subclause (including extended frequency specifications for 5GBASE-T) provides a reliable medium for support of 2.5GBASE-T and 5GBASE-T. The transmission parameters of the link segment include insertion loss, delay parameters, nominal impedance, NEXT loss, ACRF, and return loss. In addition, the requirements for the alien crosstalk coupled "between" link segments is specified.

Table 126–18 lists the 2.5GBASE-T supported cabling types and distances.

Table 126–18—2.5 GBASE-T Cabling types and distances

Cabling	Supported link segment distances[a, b]	Cabling references
Class D/ Category 5e	100 m	ISO/IEC 11801-2002, ISO/IEC TR 11801-9904, TIA TSB-5021
Class E/ Category 6	100 m	ISO/IEC 11801-2002, ISO/IEC TR 11801-9904, TIA TSB-5021

[a]Supported link segments up to 100 m shall meet the signal-to-alien crosstalk noise margin criteria specified in 126.7.3.1.
[b]A link segment consisting of up to 100 m of Category 6A/Class EA or better will meet the transmission parameters of 126.7 and provide a reliable medium for 2.5GBASE-T without further qualification.

Table 126–19 lists the 5GBASE-T supported cabling types and distances.

Table 126–19—5GBASE-T Cabling types and distances

Cabling	Supported link segment distances[a, b]	Cabling references
Class D/Category 5e	100 m	ISO/IEC 11801-2002, ISO/IEC TR 11801-9904, TIA TSB-5021
Class E/Category 6	100 m	ISO/IEC 11801-2002, ISO/IEC TR 11801-9904, TIA TSB-5021

[a]Supported link segments up to 100 m shall meet the signal-to-alien crosstalk noise margin criteria specified in 126.7.3.1.
[b]A link segment consisting of up to 100 m of Category 6A/Class EA or better will meet the transmission parameters of 126.7 and provide a reliable medium for 5GBASE-T without further qualification.

126.7.2.1 Insertion loss

The insertion loss of each duplex channel shall meet the values determined using Equation (126–11).

$$\text{Insertion loss}(f) \leq 1.02\left(1.967 \times \sqrt{f} + 0.023 \times f + \frac{0.05}{\sqrt{f}}\right) + 4 \times 0.04 \times \sqrt{f} \quad \text{(dB)} \qquad (126\text{–}11)$$

where

f is the frequency in MHz; $1 \leq f \leq 100$ for 2.5GBASE-T; $1 \leq f \leq 250$ for 5GBASE-T

This includes the insertion loss of the balanced cabling pairs, including work area and equipment cables plus connector losses within each duplex channel. The factor of 4 in Equation (126–11) corresponds to the number of connectors in the duplex channel.

126.7.2.2 Differential characteristic impedance

The nominal differential characteristic impedance of each link segment duplex channel, which includes cable cords and connecting hardware, is 100 Ω.

126.7.2.3 Return loss

In order to limit the noise at the receiver due to impedance mismatches in the cabling system, each link segment duplex channel shall meet the values determined using Equation (126–12). The reference impedance for the return loss specification is 100 Ω.

$$\text{Return loss} \geq \left\{ \begin{array}{ll} 17 & 1 \leq f < 20 \\ 17 - 10\log_{10}\left(\frac{f}{20}\right) & 20 \leq f \leq 250 \end{array} \right\} \quad \text{(dB)} \qquad (126\text{–}12)$$

where

f is the frequency in MHz; $1 \leq f \leq 100$ for 2.5GBASE-T; $1 \leq f \leq 250$ for 5GBASE-T

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.7.2.4 Coupling parameters between duplex channels comprising one link segment

In order to limit the noise coupled into a duplex channel from adjacent duplex channels, near-end crosstalk (NEXT) loss and attenuation to crosstalk ratio, far-end (ACRF) are specified for each link segment. In addition, each duplex channel can be disturbed by more than one duplex channel. To ensure the total NEXT loss and FEXT loss coupled into a duplex channel is limited, multiple disturber near-end crosstalk (MDNEXT) and multiple disturber ACRF (MDACRF) are specified.

126.7.2.4.1 Differential near-end crosstalk

Since four duplex channels are used to transfer data between PMAs, the NEXT that is coupled into a data carrying channel is from the three adjacent disturbing duplex channels.

In order to limit the crosstalk at the near end of a link segment, the differential pair-to-pair near-end crosstalk (NEXT) loss between a duplex channel and the other three duplex channels is specified to meet the bit error ratio specified in 126.5.4.1. The NEXT loss between any two duplex channels of a link segment shall meet the values determined using Equation (126–13). Additionally, the NEXT loss between any two 5GBASE-T duplex channels of a link segment shall meet the values determined using Equation (126–14). The factor of 2 in Equation (126–13) and Equation (126–14) corresponds to the number of connectors at the near-end of the duplex channels.

$$\text{NEXT loss}(f) \geq -20\log_{10}\left(10^{\frac{35.3 - 15\log_{10}(f/100)}{-20}} + 2 \times 10^{\frac{43 - 20\log_{10}(f/100)}{-20}}\right) \quad \text{(dB)} \qquad (126\text{–}13)$$

where

f is the frequency in MHz; $1 \leq f \leq 100$

$$\text{NEXT loss}(f) \geq -20\log_{10}\left(10^{\frac{35.3 - 15\log_{10}(f/100)}{-20}} + 2 \times 10^{\frac{43 - 40\log_{10}(f/100)}{-20}}\right) \quad \text{(dB)} \qquad (126\text{–}14)$$

where

f is the frequency in MHz; $100 < f \leq 250$

Calculations that result in NEXT loss values greater than 60 dB shall revert to a requirement of 60 dB minimum.

126.7.2.4.2 Multiple disturber near-end crosstalk (MDNEXT) loss

Since four duplex channels are used to transfer data between PMAs, the NEXT that is coupled into a data carrying channel is from the three adjacent disturbing duplex channels.

To ensure the total NEXT coupled into a duplex channel is limited, multiple disturber NEXT loss is specified as the power sum of the individual NEXT losses. The power sum loss between a duplex channel and the three adjacent disturbers shall meet the values determined using Equation (126–15). Additionally, the power sum of the individual NEXT loss of each 5GBASE-T duplex channel shall meet the values determined using

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Equation (126–16). The factor of 2 in Equation (126–15) and Equation (126–16) corresponds to the number of connectors at the near-end of the duplex channels.

$$\text{MDNEXT loss}(f) \geq -20\log_{10}\left(10^{\frac{32.3-15\log_{10}(f/100)}{-20}} + 2\times 10^{\frac{40-20\log_{10}(f/100)}{-20}}\right) \quad \text{(dB)} \quad (126\text{–}15)$$

where

f is the frequency in MHz; $1 \leq f \leq 100$

$$\text{MDNEXT loss}(f) \geq -20\log_{10}\left(10^{\frac{32.3-15\log_{10}(f/100)}{-20}} + 2\times 10^{\frac{40-40\log_{10}(f/100)}{-20}}\right) \quad \text{(dB)} \quad (126\text{–}16)$$

where

f is the frequency in MHz; $100 < f \leq 250$

Calculations that result in MDNEXT loss values greater than 57 dB shall revert to a requirement of 57 dB minimum.

126.7.2.4.3 Multiple disturber power sum near-end crosstalk (PSNEXT) loss

PS NEXT loss is determined by summing the power of the three individual pair-to-pair differential NEXT loss values over the frequency range 1 MHz to 100 MHz for 2.5GBASE-T and 1 MHz to 250 MHz for 5GBASE-T as follows in Equation (126–17).

$$\text{PSNEXT loss}(f) = \left(-10\log_{10}\sum_{i=1}^{n} 10^{\frac{-NL(f)i}{10}}\right) \quad \text{(dB)} \quad (126\text{–}17)$$

where

$NL(f)i$ is the magnitude in dB of NEXT loss at frequency f (in MHz) of pair combination i

i is the pair-to-pair combination (1 to n)

n is the number of pair-to-pair combinations ($n = 3$)

126.7.2.4.4 Attenuation to crosstalk ratio, far-end (ACRF)

Attenuation to crosstalk ratio, far-end (ACRF) is specified in order to limit the crosstalk at the far end of each link segment duplex channel and meet the bit error ratio objective specified in 126.5.4.1. Far-end crosstalk (FEXT) is crosstalk that appears at the far end of a duplex channel (disturbed channel), which is coupled from another duplex channel (disturbing channel) with the noise source (transmitters) at the near end.

FEXT loss is defined in Equation (126–18).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\text{FEXT loss}(f) = 20\log_{10}\left(\frac{V_{pds}(f)}{V_{pcn}(f)}\right) \quad \text{(dB)} \tag{126–18}$$

and ACRF is defined in Equation (126–19).

$$\text{ACRF}\ (f) = 20\log_{10}\left(\frac{V_{pds}(f)}{V_{pcn}(f)}\right) - \text{SLS_Loss}\ (f)\ \text{(dB)} \tag{126–19}$$

where

V_{pds} is the peak voltage of disturbing signal (near-end transmitter)
V_{pcn} is the peak crosstalk noise at far end of disturbed channel
SLS_Loss is the insertion loss of disturbed channel in dB

The worst pair ACRF between any two duplex channels shall meet the values determined using Equation (126–20). The factor of 4 in Equation (126–20) corresponds to the number of connectors the duplex channels.

$$\text{ACRF} \geq -20\log_{10}\left(10^{\frac{23.8 - 20\log_{10}(f/100)}{-20}} + 4 \times 10^{\frac{35.1 - 20\log_{10}(f/100)}{-20}}\right) \quad \text{(dB)} \tag{126–20}$$

where

f is the frequency in MHz; $1 \leq f \leq 100$ for 2.5GBASE-T; $1 \leq f \leq 250$ for 5GBASE-T

ACRF values that correspond to FEXT loss values of greater than 70 dB are for information only.

126.7.2.4.5 Multiple disturber attenuation to crosstalk ratio, far-end (MDACRF)

Since four duplex channels are used to transfer data between PMAs, the FEXT that is coupled into a data carrying channel is from the three adjacent disturbing duplex channels. To ensure the total FEXT coupled into a duplex channel is limited, multiple disturber ACRF is specified as the power sum of the individual ACRF disturbers. The power sum loss between a duplex channel and the three adjacent disturbers shall meet the values determined using Equation (126–21). The factor of 4 in Equation (126–21) corresponds to the number of connectors the duplex channels.

$$\text{MDACRF} \geq -20\log_{10}\left(10^{\frac{20.8 - 20\log_{10}(f/100)}{-20}} + 4 \times 10^{\frac{32.1 - 20\log_{10}(f/100)}{-20}}\right) \quad \text{(dB)} \tag{126–21}$$

where

f is the frequency in MHz; $1 \leq f \leq 100$ for 2.5GBASE-T; $1 \leq f \leq 250$ for 5GBASE-T

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.7.2.4.6 Multiple disturber power sum attenuation to crosstalk ratio, far-end (PS ACRF)

PS ACRF is determined by summing the power of the three individual pair-to-pair differential ACRF values over the frequency range 1 MHz to 100 MHz for 2.5GBASE-T and 1 MHz to 250 MHz for 5GBASE-T as follows in Equation (126–22):

$$\text{PSACRF}\ (f) = -10\log_{10}\sum_{i=1}^{i=n} 10^{\frac{-ACR(f)i}{10}} \quad \text{(dB)} \qquad (126\text{–}22)$$

where

ACRF(f)i is the magnitude of ACRF at frequency *f* of pair combination *i*
i is the pair-to-pair combination (1 to *n*)
f is the frequency in MHz
n is the number of pair-to-pair combinations (*n* = 3)

126.7.2.5 Maximum link delay

The propagation delay of a link segment shall not exceed 570 ns at all frequencies between 2 MHz and 250 MHz.

126.7.2.6 Link delay skew

The difference in propagation delay, or skew, between all duplex channel pair combinations of a link segment, under all conditions, shall not exceed 50 ns at all frequencies from 2 MHz to 250 MHz. It is a further functional requirement that, once installed, the skew between any two of the four duplex channels due to environmental conditions shall not vary more than 10 ns within the above requirement.

126.7.3 Coupling parameters between link segments

Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. An signal-to-alien crosstalk noise criteria is specified to ensure the total alien NEXT loss and alien FEXT loss coupled between link segments is limited. See TIA TSB-5021 and ISO/IEC TR 11801-9904 for guidance on identifying link segments and use cases for 2.5GBASE-T and 5GBASE-T.

126.7.3.1 Alien crosstalk limited signal-to-noise ratio criteria

Noise coupled between the disturbed duplex channel in a link segment and the disturbing duplex channels in other link segments is referred to as alien crosstalk noise. To ensure the total alien NEXT loss and alien FEXT loss coupled between link segments are limited a figure of merit denoted as the alien crosstalk limited signal-to-noise ratio criteria ($ALSNR_{\text{criteria}}$) is specified. The $ALSNR_{\text{criteria}}$ is the numerical difference between the *ALSNR* derived from measurements of its alien crosstalk and insertion loss parameters, denoted $ALSNR_{\text{link}}$ and the link segment SNR sufficient to support the objective BER, denoted SNR_{linkreq}. SNR_{linkreq} includes SNR margin to account for power backoff uncertainties and the differences between what is theoretically possible and what is feasible in the implementation of receivers. An additional noise term is added to better model receiver losses which change the achievable ALSNR criterion with insertion loss.

The $ALSNR_{\text{criteria}}$ algorithm enables determination of $ALSNR_{\text{link}}$ for disturbed link segments with 2.5G and 5G signaling rates from any number of disturbing link segments with all possible combinations of 1G/2.5G/5G/10G signaling rates. Guidelines for evaluating the ALSNR criterion in installed cabling,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

including the selection of the number of disturbing link segments and signaling rates to consider are addressed in TIA TSB-5021 and ISO/IEC TR 11801-9904.

For a compliant 2.5GBASE-T link segment, $ALSNR_{\text{criteria}}$ shall be greater than zero for every possible permutation of 1000BASE-T and 2.5GBASE-T running on the disturbing link segments. For a compliant 5GBASE-T link segment, $ALSNR_{\text{criteria}}$ shall be greater than zero for every possible permutation of 1000BASE-T, 2.5GBASE-T, 5GBASE-T, and 10GBASE-T on the disturbing link segments.

The $ALSNR_{\text{criteria}}$ may be determined by the result of the following nine-step procedure:

Indices

i is the 1-4 pair of the disturbed link segment

k is the 1-4 pair of the disturbing link segment

m is the index of the disturbing link segment

M is the number of disturbing link segments

Step 1. Measure the insertion loss of all the pairs in the disturbed link segment and the disturbing link segments in the frequency range given by Table 126–20.

Table 126–20—Frequency range of IL measurements

Application running on the disturbed link segment	Frequency range of measurement
2.5GBASE-T	$1 \le f \le 100$ MHz
5GBASE-T	$1 \le f \le 200$ MHz

Denote each pair of the disturbed link segment insertion loss as $IL_disturbed_i$. Denote each pair of the disturbing link segment insertion loss as $IL_disturbing_{k,m}$. Where i denotes the pair of the disturbed link segment, k denotes the pair of the disturbing link segment and M denotes the index number of the disturbing link segment.

NOTE—While disturbing signals may contain higher frequencies, the received power that determines the power backoff is dominated by the power below 100 MHz, for 2.5GBASE-T and 5GBASE-T, and neglecting the frequencies above 100 MHz has no appreciable effect in computing the 2.5GBASE-T or 5GBASE-T power backoff. When 10GBASE-T power backoff is to be computed, frequencies up to at least 200 MHz should be used.

Step 2. Determine the Received Signal Transmit Power including PBO, S_i, for each pair, i, of the disturbed link segment, at each frequency point.

Step 2a. Determine the nominal (i.e., without power backoff) Received Signal Transmit Power for each pair of the disturbed link segment, $RxTPdBmdisturbed_i$ at each frequency point by using Equation (126–23).

$$RxTPdBmdisturbed_i(f) = TemplatePSDdisturbed_i(f) + ILdisturbed_i(f) \quad \text{(dBm/Hz)} \qquad (126\text{–}23)$$

where

$TemplatePSDdisturbed_i$ is provided by Table 126–21, according to which application is running on the disturbed link segment. This is calculated over the frequency range selected in Step 1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 126–21— Template PSD for disturbed link segment

Application running on the disturbed link segment	Template PSD (dBm/Hz)
2.5GBASE-T	$-77.9 + 20\log_{10}\left(\frac{\lvert\sin(\pi f/200)\rvert}{\pi f/200}\right) - 10\log_{10}\left(1+\left(\frac{f}{490}\right)^4\right)$
5GBASE-T	$-80.7 + 20\log_{10}\left(\frac{\lvert\sin(\pi f/400)\rvert}{\pi f/400}\right) - 10\log_{10}\left(1+\left(\frac{f}{490}\right)^4\right)$

Step 2b. Calculate the Received Signal Transmit power, for each pair of the disturbed link segment, *i*, at each frequency point, to a linear magnitude and multiply by the frequency step size in Hz using Equation (126–24).

$$RxTPmWdisturbed_i(f) = \Delta f \left(10^{\frac{(RxTPdBmdisturbed_i(f))}{10}} \right) \quad \text{(mW)} \tag{126–24}$$

where

Δf is the step size between frequency points at that data point in Hz

Step 2c. Determine the Total Received Power in dBm, $TotalRxTPdBmdisturbed_i$, for each pair, *i*, of the disturbed cable using Equation (126–25).

$$TotalRxTPdBmdisturbed_i = 10\log_{10}\left(\sum_{f=fmin}^{fmax} RxTPmWdisturbed_i(f) \right) \quad \text{(dBm)} \tag{126–25}$$

where

fmin and fmax are given in Table 126–20

Step 2d. Determine the power backoff for the disturbed cable, $PBO_{\text{disturbed}}$, by calculating the mean value of $TotalRxTPdBmdisturbed_i$ across the pairs using Equation (126–26), and determine $PBO_{\text{disturbed}}$ from Table 126–12 for 2.5GBASE-T, or for 5GBASE-T, depending on for which PHY the disturbed link segment is being qualified.

For each value of *m*:

$$\overline{RxTPdisturbed} = \frac{\left(\sum_{i=1}^{4} TotalRxTPdBmdisturbed_i \right)}{4} \tag{126–26}$$

Step 2e. Calculate the Received Signal Transmit PSD including PBO, S_i, for each pair of the disturbed link segment at each frequency point by using Equation 126-28.

For *i*=1 to 4:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$S_i(f) = RxTPdBmdisturbed_i(f) - PBO_{\text{disturbed}} \quad (126–27)$$

Step 3. For each disturber type being evaluated on a disturbing link segment, determine the power backoff for the disturber type running on each disturbing link segment, PBO_m. This step involves selecting which application is running on each disturbing link segment (see Step 9 for further details of calculations for all possible permutations).

NOTE 1—The PBO for 1000BASE-T is always 0 dB, and the calculations of this step do not apply.

NOTE 2—When 2.5GBASE-T is running on the disturbed link segment, then the calculations only need to consider 2.5GBASE-T and 1000BASE-T running on the disturbing link segments.

Step 3a. Determine the nominal (i.e., without power backoff applied) Received Signal Transmit Power, $RxTPdBmdisturbing_{k,m}$, for each pair, k, of the disturbing link segment, m, at each frequency point by using Equation (126-29).

$$RxTPdBmdisturbing_{k,m}(f) = TemplatePSD_m(f) + ILdisturbing_{k,m}(f) \text{ (dBm/Hz)} \quad (126–28)$$

where

$TemplatePSD_m(f)$ is provided by Table 126–22, for the disturber type being evaluated

Table 126–22—Template PSD for disturbing link segment

Application running on the disturbed link segment	Template PSD (dBm/Hz)
1000BASE-T	$-72.38 + 20\log_{10}\left(\frac{\lvert\sin(\pi f/125)\rvert}{\pi f/125}\right) - 10\log_{10}\left(1+\left(\frac{f}{100}\right)^2\right) + 10\log_{10}\left(0.625 + 0.375 \times \cos\frac{2\pi f}{125}\right)$
2.5GBASE-T	$-77.9 + 20\log_{10}\left(\frac{\lvert\sin(\pi f/200)\rvert}{\pi f/200}\right) - 10\log_{10}\left(1+\left(\frac{f}{490}\right)^4\right)$
5GBASE-T	$-80.7 + 20\log_{10}\left(\frac{\lvert\sin(\pi f/400)\rvert}{\pi f/400}\right) - 10\log_{10}\left(1+\left(\frac{f}{490}\right)^4\right)$
10GBASE-T	$-80.89 + 20\log_{10}\left(\frac{\lvert\sin(\pi f/800)\rvert}{\pi f/800}\right) - 10\log_{10}\left(1+\left(\frac{f}{490}\right)^4\right)$

Step 3b. Convert the Received Signal Transmit power for each pair, k, of each disturbing link segment, m, at each frequency point to a linear magnitude and multiply by the frequency step size using Equation (126–29).

$$RxTPmWdisturbing_{k,m}(f) = \Delta f \left(10^{\frac{RxTPdBmdisturbing_{k,m}(f)}{10}} \right) \text{ (mW)} \quad (126–29)$$

where

Δf is the step size between frequency points at that data point in Hz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Step 3c. Calculate the Total Received Power in dBm, for each pair, *k*, of each disturbing link segment, *m*, by adding the values at each frequency point and converting to dBm using Equation (126–30).

$$TotalRxTPdBmdisturbing_{k,m} = 10\log_{10}\left(\sum_{f=fmin}^{fmax} RxTPmWdisturbing_{k,m}(f)\right) \quad \text{(dBm)} \quad (126–30)$$

where

fmin and fmax are given in Table 126–20

Step 3d. Determine the power backoff, PBO_m,for each disturbing link segment, *m*, by calculating the mean value of $TotalRxTPdBmdisturbing_{k,m}$ across the pairs, using Equation (126–31) for each link segment, and then determining, PBO_m, from Table 126–12 for 2.5GBASE-T and 5GBASE-T, and Table 55–11 for 10GBASE-T running on the disturbing link segment. The PBO for 1000BASE-T is always 0 dB.

For each value of *m*:

$$\overline{RxTPdisturbing_m} = \frac{\left(\sum_{i=1}^{4} TotalRxTPdBmdisturbing_{k,m}\right)}{4} \quad (126–31)$$

Step 4. Measure the ANEXT and AFEXT combinations for each disturbing link segment, *m*. Each disturbing link segment will provide 16 ANEXT combinations and 16 AFEXT combinations.

Denote the measurements as $\text{ANEXTmeasurement}_{i,k,m}$ and $\text{AFEXTmeasurement}_{i,k,m}$.

where

i is the 1-4 pair of the disturbed link segment
k is the 1-4 pair of the disturbing link segment
m is the 1- *M* index of the disturbing link segment
M is the number of disturbing link segments

Step 5. Calculate the alien crosstalk components including PBO for each alien crosstalk measurement for each disturbing link segment at each frequency point using Equation (126–32) and Equation (126–33). Note that the frequency points are measured or interpolated to the same frequencies used for the insertion loss measurements.

$$\text{ANEXTcomponent}_{i,k,m}(f) = TemplatePSD_m(f) - \text{ANEXTmeasurement}_{i,k,m}(f) - PBO_m \quad \text{(dBm/Hz)} \quad (126–32)$$

$$\text{AFEXTcomponent}_{i,k,m}(f) = TemplatePSD_m(f) - \text{AFEXTmeasurement}_{i,k,m}(f) - PBO_m \quad \text{(dBm/Hz)} \quad (126–33)$$

where

$TemplatePSD_m(f)$ and PBO_m are from Step 3a and Step 3d, respectively

Step 6. Determine the total noise received by each pair, *i*, of the disturbed link segment by the power summation of the ANEXT and AFEXT Components together at each frequency point using Equation (126–34).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$N_i(f) = 10\log_{10}\left(\sum_{m=1}^{M}\left(\sum_{k=1}^{4}\left(10^{\frac{\text{ANEXTcomponent}_{i,k,m}(f)}{10}} + 10^{\frac{\text{AFEXTcomponent}_{i,k,m}(f)}{10}}\right)\right) + 10^{\frac{addnoise}{10}}\right) \text{ (dBm/Hz)} \quad (126\text{–}34)$$

where

addnoise is given in Table 126–23

Table 126–23—Values of *addnoise* noise term

Application running on the disturbed link segment	*addnoise* noise term
2.5GBASE-T	–129 dBm/Hz
5GBASE-T	–135 dBm/Hz

Step 7. Determine the alien signal-to-noise ratio, ALSNR for each pair, *i*, of the disturbed link segment using Equation (126–35).

$$ALSNR_i = \left(\frac{1}{fmax}\right)\sum_{f=fmin}^{fmax}(S_i(f) - N_i(f))\Delta f \qquad \text{(dB)} \quad (126\text{–}35)$$

where

$fmin$ *and* $fmax$ are given in Table 126–20, and Δf is the step size between frequency points at each data point in the same frequency units (e.g., both MHz or both Hz)

Determine the minimum of $ALSNR_i$ across all pairs, providing $ALSNR_{\text{link}}$.

Step 8. Determine the $ALSNR_{\text{criteria}}$ using Equation (126–36).

$$ALSNR_{\text{criteria}} = ALSNR_{\text{link}} - SNR_{\text{linkreq}} \quad (126\text{–}36)$$

where

$SNR_{\text{linkreq}} = 28$ dB

Step 9. Multiplicity

Steps 1–8 determine the $ALSNR_{\text{link}}$ for a given application running on the disturbed link segment, and a given permutation of applications running on the disturbing link segments.

To calculate the worst case permutation of disturbers running on the disturbing link segments, repeat steps 3–8 using every possible permutation of disturbers running on the disturbing link segments, and determine $ALSNR_{\text{criteria}}$ for each permutation of disturbing applications.

126.8 MDI specification

This subclause defines the MDI. The link topology requires a crossover function in a DTE-to-DTE connection. See 126.4.4 for a description of the automatic MDI/MDI-X configuration.

126.8.1 MDI connectors

Eight-pin connectors meeting the requirements of IEC 60603-7-4 (unscreened) or IEC 60603-7-5 (screened) shall be used as the mechanical interface to the balanced cabling. The plug connector shall be used on the balanced cabling and the jack on the PHY. These connectors are depicted (for informational use only) in Figure 126–38 and Figure 126–39. The assignment of PMA signals to connector contacts for PHYs is shown in Table 126–24.

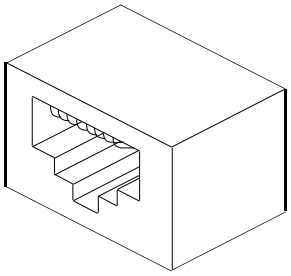

Figure 126–38—MDI connector

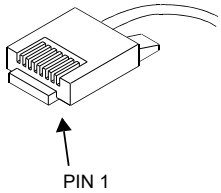

Figure 126–39—Balanced cabling connector

Table 126–24—Assignment of PMA signal to MDI and MDI-X pin-outs

Contact	MDI	MDI-X
1	BI_DA+	BI_DB+
2	BI_DA–	BI_DB–
3	BI_DB+	BI_DA+
4	BI_DC+	BI_DD+
5	BI_DC–	BI_DD–
6	BI_DB–	BI_DA–
7	BI_DD+	BI_DC+
8	BI_DD–	BI_DC–

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.8.2 MDI electrical specifications

The MDI connector (jack) shall meet the following requirements for FEXT, Return Loss, and Impedance Balance when mated with a nominal balanced cabling connector (plug). The mated connection shall meet transmission performance requirements for category 5e connecting hardware found in ANSI/TIA 568-C.2, section 6.8.

NOTE—Use of a compliant test plug as defined in ANSI/TIA 568-C.2, annex C, section C.4.10 will help ensure connecting hardware transmission performance for these purposes.

126.8.2.1 MDI FEXT

The MDI connector (jack) shall meet the FEXT requirements as specified in Equation (126–37) between all contact pair combinations shown in Table 126–24.

$$\text{FEXT loss} \geq 43.1 - 20\log_{10}(f/100) \quad \text{(dB)} \tag{126–37}$$

where

f is the frequency over the range 1 MHz to 100 MHz for 2.5GBASE-T, and 1 MHz to 250 MHz for 5GBASE-T

No spurious signals shall be emitted onto the MDI when the PHY is held in power-down mode (as defined in 22.2.4.1.5), when released from power-down mode, or when external power is first applied to the PHY.

126.8.2.2 MDI return loss

The differential impedance at the MDI for each transmit/receive channel shall be such that any reflection due to differential signals incident upon the MDI from a balanced cabling having a nominal differential characteristic impedance of 100 Ω is attenuated, relative to the incident signal as per the relationship shown in Equation (126–38):

$$\text{Return loss} \geq \begin{cases} 16 & 1 \leq f \leq 40 \quad \text{(dB)} \\ 16 - 10\log_{10}(f/40) & 40 < f \leq f_{\max} \quad \text{(dB)} \end{cases} \tag{126–38}$$

where

f is in MHz
$f_{\max}$ is 125 MHz for 2.5GBASE-T and 250 MHz for 5GBASE-T

126.8.2.3 MDI impedance balance

Impedance balance is a measure of the impedance-to-ground difference between the two MDI contacts used by a duplex link channel and is referred to as common-mode-to-differential-mode impedance balance. MDI impedance balance is specified beyond the Nyquist frequency of the PHY to account for system performance variation. When the transmitter is transmitting random or pseudo-random data, the common-mode-to-differential-mode impedance balance, *Bal*(*f*), of each channel of the MDI shall meet the relationship:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For 2.5GBASE-T: (126–39)

$$Bal(f) \geq \begin{cases} 48 & 1 \leq f < 10 \quad \text{(dB)} \\ 48 - 20\log_{10}(f/10) & 10 \leq f < 20 \quad \text{(dB)} \\ 42 - 15\log_{10}(f/20) & 20 \leq f \leq 125 \quad \text{(dB)} \end{cases}$$

For 5GBASE-T:

$$Bal(f) \geq \begin{cases} 48 & 1 \leq f \leq 30 \quad \text{(dB)} \\ 44 - 19.2\log_{10}(f/50) & 30 < f \leq 250 \quad \text{(dB)} \end{cases}$$

where

f is the frequency in MHz

Test mode 5 may be used to generate an appropriate transmitter output.

The impedance balance is defined as the S parameter measurement of Sdc11 in dB at the MDI.

The impedance balance may be measured with a mixed mode four port network analyzer capable of measuring the common-mode voltage and differential mode voltage of a balanced port. Impedance balance is the S parameter measurement of Sdc11 in dB at the MDI where two ports of the four port network analyzer are connected between two MDI contacts used by a duplex link channel and these two ports are configured as a single balanced port. For this test the PHY ground is connected to the network analyzer ground. The other two ports of the network analyzer are unconnected. The network analyzer should be capable of measuring Sdc11 to at least –60 dB and should use a differential input impedance of 100 Ω and a common-mode impedance of 75 Ω.

During the test the PHY is connected to the MDI as in normal operation.

NOTE—The measurement may use narrow IF bandwidth settings and averaging to better distinguish between impedance balance and the transmitted test pattern.

126.8.2.4 MDI fault tolerance

Each wire pair of the MDI shall, under all operating conditions, withstand without damage the application of short circuits of any wire to any other wire within the 4-pair cable for an indefinite period of time and shall resume normal operation after the short circuit(s) are removed. The magnitude of the current through such a short circuit shall not exceed 300 mA.

A 2.5GBASE-T or 5GBASE-T PHY shall be able to sustain, without damage, connection to a PSE and shall not cause damage to the PSE as defined in 33.2.

Each wire pair shall withstand without damage a 1000 V common-mode impulse of either polarity. The shape of the impulse is 0.3/50 μs (300 ns virtual front time, 50 μs virtual time of half value), as defined in IEC 60060. See Figure 40–34 in 40.8.3.4.

126.9 Environmental specifications

126.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

126.9.2 Network safety

This subclause sets forth a number of recommendations and guidelines related to safety concerns; the list is neither complete nor does it address all possible safety issues. The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

LAN cabling systems described in this subclause are subject to at least four direct electrical safety hazards during their installation and use. These hazards are as follows:

a) Direct contact between LAN components and power, lighting, or communications circuits.
b) Static charge buildup on LAN cabling and components.
c) High-energy transients coupled onto the LAN cabling system.
d) Voltage potential differences between safety grounds to which various LAN components are connected.

Such electrical safety hazards should be avoided or appropriately protected against for proper network installation and performance. In addition to provisions for proper handling of these conditions in an operational system, special measures should be taken to ensure that the intended safety features are not negated during installation of a new network or during modification or maintenance of an existing network.

126.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, including screen management, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable. In addition, Annex 55B provides additional cabling guidelines for 10GBASE-T deployment on balanced copper cabling systems, which may be helpful to 2.5G/5GBASE-T installations.

It is a mandatory requirement that, during installation of the cabling plant, care be taken to ensure that non-insulated network cabling conductors do not make electrical contact with unintended conductors or ground.

126.9.4 Telephone voltages

The use of building wiring brings with it the possibility of wiring errors that may connect telephony voltages to 2.5GBASE-T or 5GBASE-T. Other than voice signals (which are low voltage), the primary voltages that may be encountered are the “battery” and ringing voltages. Although there is no universal standard, the following maximums generally apply:

a) Battery voltage to a telephone line is generally 56 V dc applied to the line through a balanced 400 Ω source impedance.
b) Ringing voltage is a composite signal consisting of an ac component and a dc component. The ac component is up to 175 V peak at 20 Hz to 60 Hz with a 100 Ω source resistance. The dc component is 56 V dc with a 300 Ω to 600 Ω source resistance. Large reactive transients can occur at the start and end of each ring interval.

Although 2.5GBASE-T and 5GBASE-T equipment is not required to survive such wiring hazards without damage, application of any of the above voltages shall not preclude conformance with 126.9.1 and 126.9.2.

126.9.5 Electromagnetic compatibility

A system integrating the 2.5GBASE-T or 5GBASE-T shall comply with applicable local and national codes for the limitation of electromagnetic interference.

126.9.6 Temperature and humidity

A system integrating the 2.5GBASE-T or 5GBASE-T is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

126.10 PHY labeling

It is recommended that each PHY (or supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) Data rate capability and units thereof
b) Power level in terms of maximum current drain (for external PHYs)
c) Port type (i.e., 2.5GBASE-T or 5GBASE-T)
d) Any applicable safety warnings
e) EEE support
f) Fast retrain support

126.11 Delay constraints

In full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementers conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The sum of the transmit and receive data delays for an implementation of a 2.5GBASE-T PHY shall not exceed 12 800 BT. The sum of the transmit and receive data delays for an implementation of a 5GBASE-T PHY shall not exceed 14 336 BT. Transmit data delay is measured from the input of a given unit of data at the XGMII to the presentation of the same unit of data by the PHY to the MDI. Receive data delay is measured from the input of a given unit of data at the MDI to the presentation of the same unit of data by the PHY to the XGMII.

NOTE—The physical medium interconnecting two PHYs introduces additional delay in a link. Equation (80–1) specifies the calculation of delay per meter of electrical cable, which may be converted to bit times using 2.5 BT per ns for 2.5GBASE-T, and 5 BT per ns for 5GBASE-T (see Table 125–3).

126.12 Protocol implementation conformance statement (PICS) proforma for Clause 126—Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 2.5GBASE-T and 5GBASE-T[218]

The supplier of a protocol implementation that is claimed to conform to this clause shall complete the protocol implementation conformance statement (PICS) proforma listed in the following subclauses.

Instructions for interpreting and filling out the PICS proforma may be found in Clause 21.

126.12.1 Identification

126.12.1.1 Implementation identification

Supplier	
Contact point for queries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

126.12.1.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 126, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, types 2.5GBASE-T and 5GBASE-T
Identification of amendments and corrigenda to this PICS proforma which have been completed as part of this PICS	
Have any Exceptions items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[218]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so it can be used for its intended purpose and may further publish the completed PICS.

126.12.8 MDI requirements

Item	Feature	Subclause	Status	Support	Value/Comment
MDI1	MDI connector	126.8.1	M	Yes [ ]	Eight-pin connectors meeting the requirements of IEC 60603-7-4 (unscreened) or IEC 60603-7-5 (screened)
MDI2	Cabling connector	126.8.1	INS:M	Yes [ ] N/A [ ]	Plug
MDI3	PHY connector	126.8.1	M	Yes [ ]	Jack (as opposed to plug)
MDI4	MDI connector jack plus plug performance	126.8.2	INS:M	Yes [ ] N/A [ ]	
MDI5	Mated MDI connector FEXT loss	126.8.2	INS:M	Yes [ ] N/A [ ]	Per Equation (126–37)
MDI6	MDI power down	126.8.2	M	Yes [ ]	
MDI7	MDI return loss	126.8.2.2	M	Yes [ ]	
MDI8	MDI impedance balance	126.8.2.3	M	Yes [ ]	
MDI9	MDI fault tolerance to short circuits	126.8.2.4	M	Yes [ ]	No damage with an indefinite short
MDI10	Recovery from short	126.8.2.4	M	Yes [ ]	
MDI11	Short circuit current	126.8.2.4	M	Yes [ ]	Less than 300 mA
MDI12	Connection to PSE	126.8.2.4	M	Yes [ ]	No damage to PHY
MDI13	Connection to PSE	126.8.2.4	M	Yes [ ]	No damage to PSE
MDI14	Common-mode impulse tolerance	126.8.2.4	M	Yes [ ]	1000 V common-mode impulse of either polarity

127. Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 2.5 Gb/s 8B/10B 2.5GBASE-X

127.1 Overview

127.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) and the Physical Medium Attachment (PMA) sublayer that are common to a family of 2.5 Gb/s Physical Layer implementations known as 2.5GBASE-X. The 2.5GBASE-X PCS and 2.5GBASE-X PMA are sublayers of the 2.5 Gb/s BASE-X PHY listed in Table 125–1. The term 2.5GBASE-X is used when referring generally to Physical Layers using the PCS and PMA defined in this clause.

2.5GBASE-X PCS and PMA sublayers map the interface characteristics of the PMD sublayer (including MDI) to the services expected by the Reconciliation sublayer. 2.5GBASE-X can be extended to support any other full duplex medium requiring only that the medium be compliant at the PMD level.

127.1.2 Relationship of 2.5GBASE-X to other standards

Figure 125–1 depicts the relationships among the 2.5GBASE-X sublayers, Ethernet MAC and reconciliation layers, and the higher layers. The 2.5GBASE-X service interface is the XGMII, which is defined in Clause 46.

127.1.3 Summary of 2.5GBASE-X sublayers

Figure 127–1 shows the relationship of the 2.5GBASE-X PCS sublayer with other sublayers to the ISO Open System Interconnection (OSI) reference model.

127.1.3.1 Physical Coding Sublayer (PCS)

The PCS service interface is the XGMII that provides a uniform interface to the Reconciliation sublayer for all 2.5 Gb/s PHY implementations. The 2.5GBASE-X PCS provides all services required by the XGMII including encoding (decoding) of XGMII data octets to (from) ten-bit code-groups (8B/10B) for communication with the underlying PMA.

127.1.3.2 Physical Medium Attachment (PMA) sublayer

The PMA provides a medium-independent means for the PCS to support the use of serial-bit-oriented physical media. The 2.5GBASE-X PMA performs the following functions:

a) Mapping of transmit and receive code-groups between the PCS and PMA via the PMA Service Interface.
b) Serialization (deserialization) of code-groups for transmission (reception) on the underlying serial PMD.
c) Recovery of clock from the 8B/10B-coded data supplied by the PMD.
d) Mapping of transmit and receive bits between the PMA and PMD via the PMD Service Interface.

127.1.3.3 Physical Medium Attachment (PMA) service interface rates

2.5GBASE-X Physical Layer specification has nominal rate at the PMA service interface of 3.125 Gb/s, which provides MAC data rate of 2.5 Gb/s.

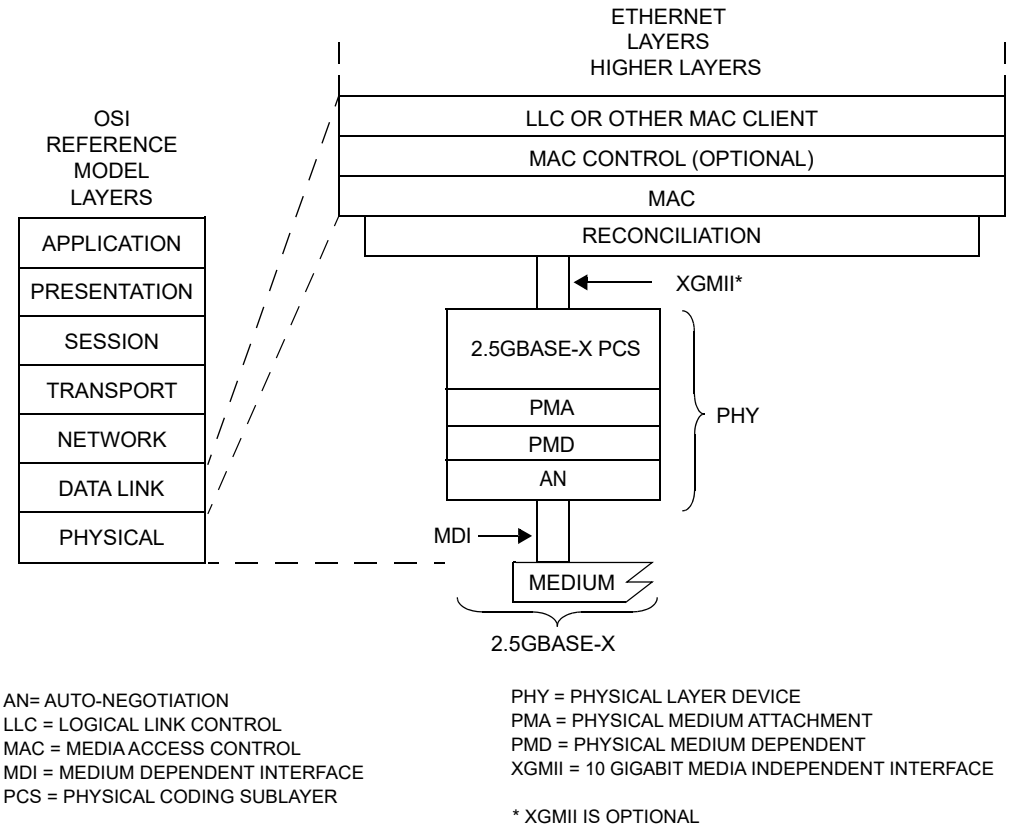

Figure 127–1—2.5GBASE-X PCS and PMA relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

127.1.4 Inter-sublayer interfaces

There are a number of interfaces employed by 2.5GBASE-X. Some (such as the PMA Service Interface) use an abstract service model to define the operation of the interface. An optional physical instantiation of the PCS Interface is the XGMII. Figure 127–2 depicts the relationship and mapping of the services provided by all of the interfaces relevant to 2.5GBASE-X.

While this specification defines interfaces in terms of bits, octets, and code-groups, implementers may choose other data path widths for implementation convenience. The only exception is the XGMII, which, when implemented at an observable interconnection port, uses a 32-bit-wide data path as specified in Clause 46.

127.1.5 Functional block diagram

Figure 127–2 provides a functional block diagram of the 2.5GBASE-X PHY.

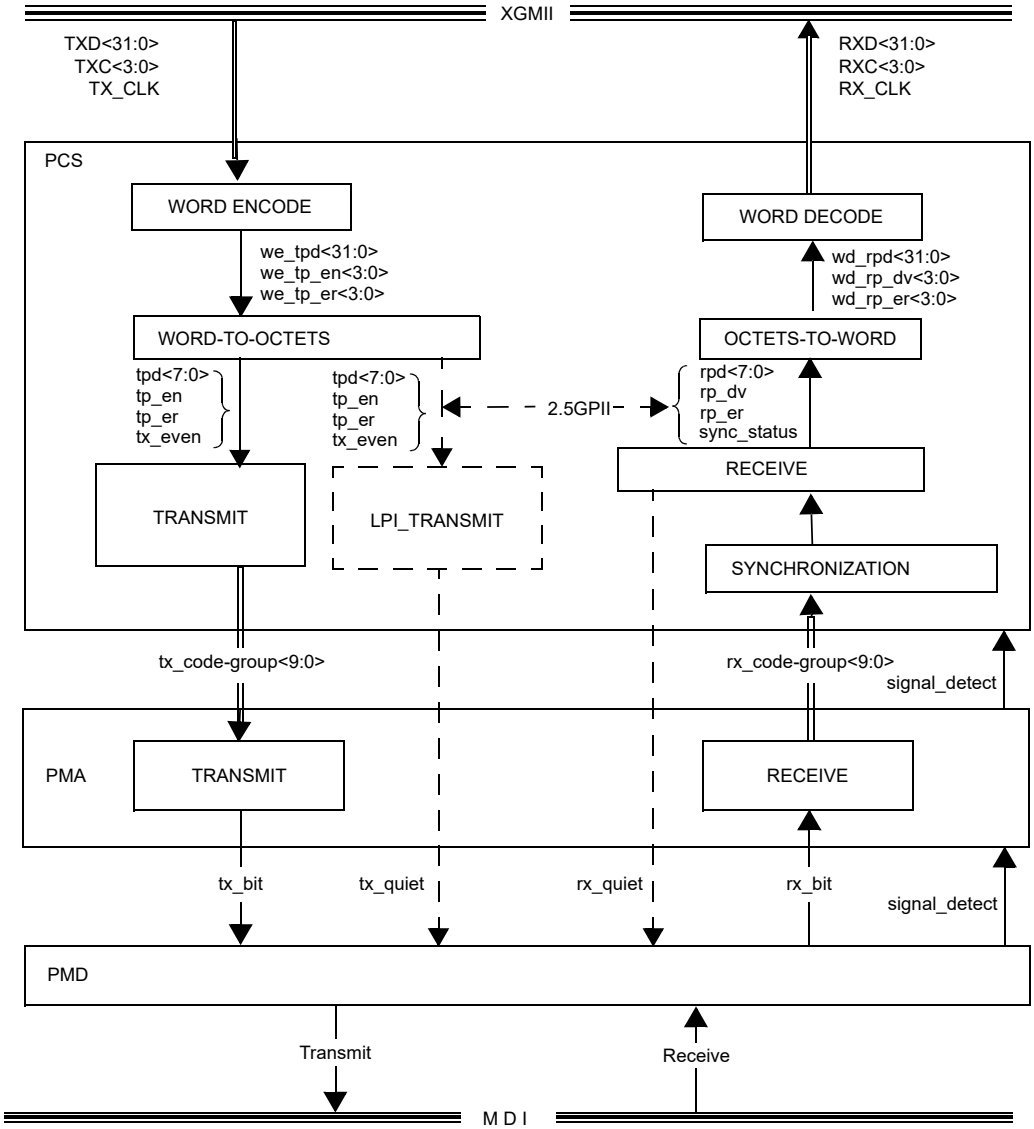

Figure 127–2—Functional block diagram of 2.5GBASE-X PHY

127.2 Physical Coding Sublayer (PCS)

127.2.1 PCS Interface (XGMII)

The PCS Service Interface allows the 2.5GBASE-X PCS to transfer information to and from a PCS client. PCS clients include the MAC (via the Reconciliation sublayer). The PCS Interface is precisely defined as the 10 Gigabit Media Independent Interface (XGMII) in Clause 46.

127.2.2 Functions within the PCS

The PCS includes the Word Encode, Word-to-Octets, Transmit, Synchronization, Receive, Octets-to-Word, and Word Decode processes for 2.5GBASE-X. The PCS shields the RS (and MAC) from the specific nature of the underlying channel.

When communicating with the XGMII, the PCS uses, in each direction, 32 data signals (TXD <31:0> and RXD <31:0>), four control signals (TXC <3:0> and RXC <3:0>), and a clock (TX_CLK and RX_CLK).

When communicating with the PMA, the PCS uses a ten-bit-wide synchronous data path, tx_code-group<9:0> and rx_code-group<9:0>, which conveys ten-bit code-groups. At the PMA Service Interface, code-group alignment and MAC packet delimiting are made possible by embedding special non-data code-groups in the transmitted code-group stream. The PCS provides the functions necessary to map packets between the XGMII format and the PMA service interface format.

The Word Encode process continuously generates four 2.5GPII symbols (we_tpd<31:0>) and associated four bits of transmit enable (we_tp_en<3:0>) and four bits of transmit error (we_tp_er<3:0>) based upon the TXD <31:0> and TXC <3:0> signals on the XGMII, sending them to the Word-to-Octets process.

The Word-to-Octets process takes the four 2.5GPII symbols, and associated transmit enable and transmit error, and transmits one 2.5GPII symbol (tpd<7:0>) and its associated transmit enable (tp_en) and transmit error (tp_er) at a time to the PCS Transmit Process.

The Word-to-Octets process takes the output of the Word Encoder and presents one symbol at a time (tp_en, tp_er, tpd<7:0>) to the PCS transmit process. we_tpd<7:0> is presented first and we_tpd<31:24> is presented last.

The PCS Synchronization process continuously accepts code-groups via the PMA_UNITDATA.indication primitive and conveys received code-groups to the PCS Receive process via the SYNC_UNITDATA.indication primitive. The PCS Synchronization process sets the sync_status flag to indicate whether the PMA is functioning dependably.

The PCS Receive process continuously accepts code-groups via the SYNC_UNITDATA.indication primitive. The PCS Receive process monitors these code-groups and generates rpd<7:0>, rp_dv, and rp_er on the 2.5GPII.

The Octets-to-Word process queues the received 2.5GPII symbols and aligns them in groups of four 2.5GPII symbols. Symbols may be deleted or idle symbols added in order to do the alignment.

The Word Decode process continuously accepts the four 2.5GPII symbols from the Octets-to-Word process and generates RXD <31:0> and RXC <3:0> on the XGMII.

All PCS processes are described in detail in the state diagrams in 127.2.7.2.

127.2.3 PCS used with 2.5GBASE-KX PMD

The following requirements apply to a PCS used with a 2.5GBASE-KX PMD. Support for the Auto-Negotiation process defined in Clause 73 is mandatory. The PCS shall support the primitive AN_LINK.indication(link_status) (see 73.9). The parameter link_status shall take the value FAIL when code_sync_status=FAIL and the value OK when code_sync_status =OK. The primitive shall be generated when the value of link_status changes.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

127.2.4 Use of code-groups

The transmission code used by the PCS, referred to as 8B/10B, is identical to that specified in Clause 36. The PCS maps XGMII characters into an intermediate 2.5GPII which is then mapped to 10-bit code-groups, and vice versa, using the 8B/10B block coding scheme. Implicit in the definition of a code-group is an establishment of code-group boundaries by a PCS Synchronization process. The 8B/10B transmission code as well as the rules by which the PCS ENCODE and DECODE functions generate, manipulate, and interpret code-groups are specified in 127.2.6. The XGMII to 2.5GPII mapping and vice versa are specified in 127.2.5. Code-groups and the 2.5GPII are unobservable and have no meaning outside the PCS.

127.2.5 XGMII to 2.5GPII mapping

The Word Encode, Word-to-Octets, Octets-to-Word, and Word Decode processes together define the XGMII to 2.5GPII mapping. This mapping function formats and serializes/deserializes the data between the four XGMII lanes and the single lane of the PCS transmit/receive process.

127.2.5.1 2.5 Gb/s PCS Internal Interface (2.5GPII)

The 2.5 Gb/s PCS Internal Interface (2.5GPII) is a logical interface that is internal to the 2.5GBASE-X PCS and exists solely for the purposes of defining the 2.5GBASE-X PCS functionality. Physical implementation of the 2.5GPII is optional and is not exposed outside of the PCS.

A 2.5GPII symbol is defined to be a set of tp_en, tp_er, tpd<7:0> variables on the transmit path, and rp_dv, rp_er, rpd<7:0> variables on the receive path. The permissible encodings are shown in Table 127–1 and Table 127–2. The Word Encode and Word Decode processes maps between the four XGMII lanes to four 2.5GPII symbols. The 2.5GPII symbols are indexed as we_tp_en<3:0>, we_tp_er<3:0>, we_tpd<31:0>, wd_rp_dv<3:0>, wd_rp_er<3:0>, and wd_rpd<31:0>. The nominal rate of operation is 78.125 Msymbols/s ± 100 ppm.

The Word-to-Octets and Octets-to-Word processes serializes/de-serializes four 2.5GPII symbols, and their associated enable and error bits, to/from four consecutive single 2.5GPII symbols. The nominal rate of operation of 2.5GPII symbols is 312.5 Msymbols/s ± 100 ppm.

Table 127–1—Permissible encodings of tpd<7:0>, tp_en, tp_er at 2.5GPII

tp_en	tp_er	tpd<7:0>	Description	Mnemonic
0	0	0x00 to 0xFF	Normal Inter-frame	Idle
0	1	0x00	Reserved	
0	1	0x01	Assert LPI	LPI
0	1	0x02 to 0x9B	Reserved	
0	1	0x9C	Sequence	Seq
0	1	0x9D to 0xFF	Reserved

Table 127–2—Permissible encodings of rpd<7:0>, rp_dv, rp_er at 2.5GPII

rp_dv	rp_er	rpd<7:0>	Description	Mnemonic
0	0	0x00 to 0xFF	Normal Inter-frame	Idle
0	1	0x00	Reserved	
0	1	0x01	Assert LPI	LPI
0	1	0x02 to 0x0D	Reserved	
0	1	0x0E	False carrier indication	FCI
0	1	0x0F	Carrier Extend (odd byte packets)	CE
0	1	0x10 to 0x9B	Reserved	
0	1	0x9C	Sequence	Seq
0	1	0x9D to 0xFF	Reserved	
1	0	0x00 to 0xFF	Data	Data X
1	1	0x00 to 0xFF	Receive Error	Err

127.2.5.2 Word Encode

The Word Encode process maps the four XGMII lanes (see Table 46–2) onto four 2.5GPII symbols, and their associated transmit enable and transmit error bits, as shown in Table 127–3. The XGMII encoding is specified in Table 46–3. The 2.5GPII encoding is specified in Table 127–1. The mapping of the sequence ordered set is dependent on the current state of the wencode_state variable as shown in column 5. The state of wencode_state is updated once the mapping occurs per the last column.

A sequence ordered set ||Q|| appears to the PMA as /K28.5/W/K28.5/W/K28.5/W/K28.5/W/. On the 2.5GPII this appears as Seq, Data S0, Seq, Data S1, Seq, Data S2, Seq, Data S3. The same sequence ordered set is assumed to be repeating over multiple XGMII cycles. Every alternating consecutive sequence ordered set on the XGMII is ignored. If a sequence ordered set occurs over odd number of cycles on the XGMII, then the final one will be truncated as Seq, Data S0, Seq, Data S1 and Seq, Data S2, Seq, Data S3 are not sent.

The 24-bit Data X, Data Y, and Data Z from the sequence ordered set is mapped to Data S0, Data S1, Data S2, Data S3 as shown in Equation (127-1).

S0<7> = S3<7> = 0, S1<7> = S2<7> = 1
S0<5:0> = Data X<5:0>
S1<5:0> = Data Y<3:0>, Data X<7:6>
S2<5:0> = Data Z<1:0>, Data Y<7:4>
S3<5:0> = Data Z<7:2>
Sn<6> = Sn<7> if Sn<2> = 0
Sn<6> = Sn<5> if Sn<2> = 1 (127-1)

The signal ordered set |Fsig| uses the same equation except S2<7> is set to 0.

Since sequence ordered set can be sent back to back it is necessary to determine the boundaries of the ordered set. {S0<7>, S1<7>, S2<7>, S3<7>} can be used to determine the boundary. {S0<7>, S1<7>} will always be 01, while the 01 combination will never occur over {S1<7>, S2<7>}, {S2<7>, S3<7>}, or {S3<7>, S0<7>}.

Only 128 combinations of Sn<7:0> are possible. When encoded to their 10-bit equivalent, these 128 code-groups are defined to be in the set of /W/ (see 127.2.7.1.2).

127.2.5.3 Word-to-Octets

The Word-to-Octets process takes the output of the Word Encoder and presents one symbol at a time (tp_en, tp_er, tpd<7:0>) to the PCS transmit process. we_tpd<7:0> is presented first and we_tpd<31:24> is presented last.

The Word-to-Octets process shall be synchronized to the PCS transmit process such that the we_tpd<7:0>and we_tpd<23:16> symbols are presented to the PCS transmit process which will result in the corresponding ordered set to be output to the PMA when the variable tx_even is TRUE and we_tpd<15:8>and we_tpd<31:24> variables when tx_even is FALSE.

127.2.5.4 Octets-to-Word

The Octets-to-Word process de-serializes the output of the PCS receive process to four symbols (wd_rp_dv<3:0>, wd_rp_er<3:0>, wd_rpd<31:0>). wd_rpd<7:0> is the earliest to arrive and wd_rpd<31:24> is the last.

The Octets-to-Word process inserts idle symbols or deletes symbols from the sequence of rpd<7:0> symbols received to achieve the following conditions:

a) A transition of a 2.5GPII idle symbol to a data or error symbol shall place the data or error symbol on wd_rpd<7:0>.
b) A transition of a 2.5GPII idle symbol to a LPI symbol shall place the LPI symbol on either wd_rpd<7:0> or wd_rpd<23:16>.
c) A transition of a 2.5GPII LPI symbol to an idle symbol shall place the idle symbol on either wd_rpd<7:0> or wd_rpd<23:16>.
d) The start of ||Q|| or ||Fsig|| set shall always occur on wd_rpd<7:0>. 127.2.5.2 describes how the start of |Q| and |Fsig| can be determined.

The Octets-to-Word process maintains a Deficit Idle Count (DIC) that represent the cumulative count of idle symbols in rpd<7:0> added or deleted from the sequence of received symbols. The DIC is incremented by one for each idle symbol deleted and decremented by one for each idle symbol added. The DIC shall be bounded to a minimum of 0 and a maximum of 3.

Note that in a properly behaved system, deletion of idle symbols from rpd<7:0> onto wd_rpd<31:0> should only occur at most once at the beginning of link, and afterwards no further insertions or deletions are required. In order to interoperate with the application described in Annex 127A, additional symbol insertions and deletions may be required during normal operation.

The only symbol that may be inserted is a idle symbol. However any symbol may be deleted. Usually this will either be idle or LPI symbols, though in pathological error conditions (e.g., unterminated packet followed immediately with sequence ordered set) some other symbol may be deleted.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

127.2.5.5 Word Decode

The Word Decode process maps the four 2.5GPII symbols onto the four XGMII lanes (see Table 46–2) as shown in Table 127–4. The XGMII encoding is specified in Table 46–4. The seq_s2_s3 variable indicates whether the next four 2.5GPII symbols are of the form Sequence, Data, Sequence, Data. The 2.5GPII encoding is specified in Table 127–2. The mapping is dependent on the current state of the wdecode_state and next_seq_s2_s3 variables as shown in columns 5 and 6. The state of wdecode_state is updated once the mapping occurs per the last column.

The 24-bit Data X, Data Y, and Data Z from the sequence ordered is reconstructed from Data S0, Data S1, Data S2, Data S3 according to Equation (127-2).

$$\begin{aligned} &\text{Data X<7:0> = S1<1:0>, S0<5:0>} \\ &\text{Data Y<7:0> = S2<3:0>, S1<5:2>} \\ &\text{Data Z<7:0> = S3<5:0>, S2<5:4>} \end{aligned} \tag{127-2}$$

127.2.6 8B/10B transmission code

The transmission code used by the PCS, referred to as 8B/10B, is identical to that specified in Clause 36. In addition to the requirements in this clause, a 2.5GBASE-X PCS shall also meet the 8B/10B transmission code requirements specified in 36.2.4.1 through 36.2.4.6, 36.2.4.8, and 36.2.4.9. The relationship of code-group bit positions to PMA and other PCS constructs is illustrated in Figure 127–3.

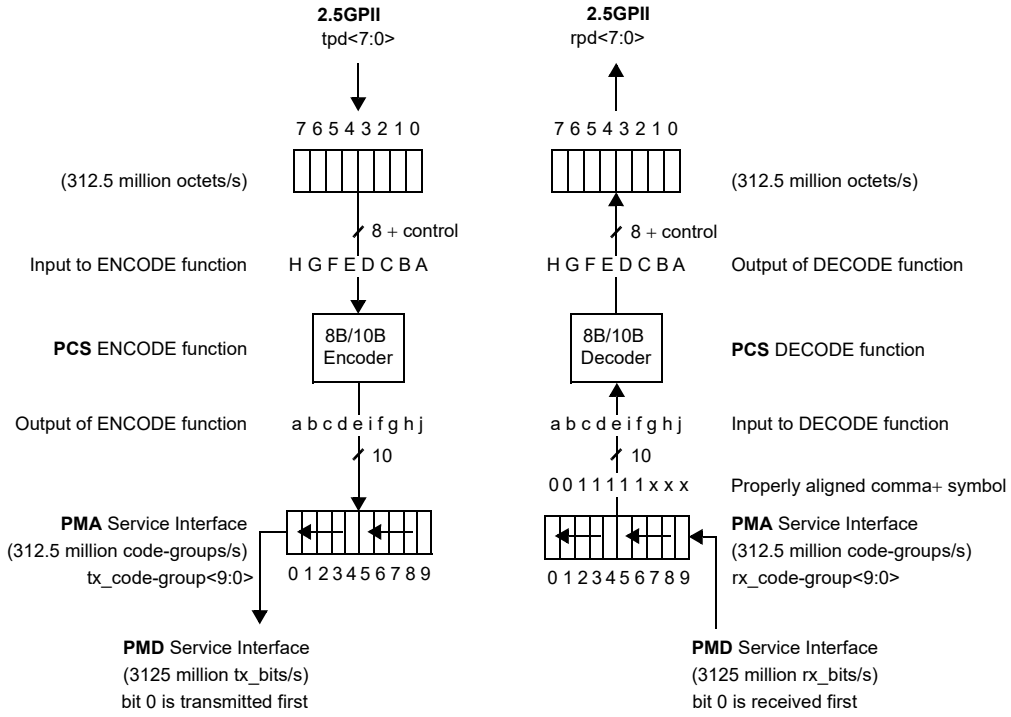

Figure 127–3—PCS 8B/10B reference diagram

127.2.6.1 Notation conventions

The 8B/10B transmission code uses letter notation for describing the bits of an unencoded information octet and a single control variable according to 36.2.4.1.

127.2.6.2 Transmission order

Code-group bit transmission order is illustrated in Figure 127–3 and defined in 36.2.4.2.

127.2.6.3 Generating code-groups and checking the validity of received code

Valid code-groups are defined in 36.2.4.3.

The running disparity rules are defined in 36.2.4.4.

The code-group generation is defined in 36.2.4.5.

The check on the validity of received code-groups is defined in 36.2.4.6.

127.2.6.4 Ordered sets

Table 127–5 lists the defined ordered sets, consisting of a single special code-group or combinations of special and data code-groups. Ordered sets which include /K28.5/ provide the ability to obtain bit and code-group synchronization and establish ordered set alignment (see 36.2.4.9 and 127.3.2.4). Ordered sets provide for the delineation of a packet and synchronization between the transmitter and receiver circuits at opposite ends of a link. Certain PHYs include an option (see 78.3) to transmit or receive /LI/, /LI1/ and /LI2/ to support Energy-Efficient Ethernet (see Clause 78).

Table 127–5—Defined ordered sets

Code	Ordered Set	Number of Code-Groups	Encoding
/I/	**IDLE**		Correcting /I1/, Preserving /I2/
/I1/	IDLE 1	2	/K28.5/D5.6/
/I2/	IDLE 2	2	/K28.5/D16.2/
	Encapsulation		
/R/	Carrier_Extend	1	/K23.7/
/S/	Start_of_Packet	1	/K27.7/
/T/	End_of_Packet	1	/K29.7/
/V/	Error_Propagation	1	/K30.7/
/LI/	**LPI**		Correcting /LI1/, Preserving /LI2/
/LI1/	LPI 1	2	/K28.5/D6.5/
/LI2/	LPI 2	2	/K28.5/D26.4/
	Link Status		
/Q/	Sequence ordered set	8	/K28.5/W0/K28.5/W1/K28.5/W2/ K28.5/W3[a]
	Reserved		
/Fsig/	Signal ordered set	8	/K28.5/W0/K28.5/W1/K28.5/W2/ K28.5/W3[a]

[a] /W0/, /W1/, /W2/, /W3/ are the 10-bit /Dx.y/ version of S0, S1, S2, S3 as defined per 127.2.5.2 and will never have a value of /D5.6/, /D16.2/, /D6.5/, /D26.4/.

Ordered sets are specified according to the following rules:

a) Ordered sets consist of either one, two, or eight code-groups.
b) The first code-group of all ordered sets is always a special code-group.
c) The second code-group of all multi-code-group ordered sets is always a data code-group. The second code-group is used to distinguish the ordered set from all other ordered sets.

127.2.6.5 Comma considerations

The comma considerations are described in 36.2.4.8 and 36.2.4.9.

127.2.6.6 Sequence (/Q/)

A sequence ordered set is used to convey various optional link status such as local fault or remote fault. The 24-bit data of the sequence ordered set on the XGMII,when implemented, are mapped to S0, S1, S2, S3 (see 127.2.5.2), and /W0/, /W1/, /W2/, /W3/ are the 8B/10B mapped version.

S0, S1, S2, S3 are constructed such that each /Wn/ can be mapped to only 128 out of 256 possible /Dx.y/ code-groups. /W/ is defined to be the set of 128 /Dx.y/ code-groups that can appear in a sequence ordered set. /W/ does not contain /D5.6/, /D16.2/, /D6.5/, /D26.4/.

It is possible for the transmitter to send out a truncated sequence ordered set that appears as /K28.5/W0/K28.5/W1/. When a truncated sequence ordered set is received, the Word Decode process will convert it to idles.

127.2.6.7 Data (/D/)

A data code-group, when not used to distinguish or convey information for a defined ordered set, conveys one octet of arbitrary data supplied on the XGMII. The sequence of data code-groups is arbitrary, where any data code-group can be followed by any other data code-group. Data code-groups are coded and decoded but not interpreted by the PCS. Successful decoding of the data code-groups depends on proper receipt of the Start_of_Packet delimiter, as defined in 127.2.6.10 and the checking of validity, as defined in 36.2.4.6.

127.2.6.8 IDLE (/I/)

IDLE ordered sets (/I/) are transmitted continuously and repetitively whenever the XGMII is idle. /I/ provides a continuous fill pattern to establish and maintain clock synchronization. /I/ is emitted from, and interpreted by, the PCS. /I/ consists of one or more consecutively transmitted /I1/ or /I2/ ordered sets, as defined in Table 127–5.

The /I1/ ordered set is defined such that the running disparity at the end of the transmitted /I1/ is opposite that of the beginning running disparity. The /I2/ ordered set is defined such that the running disparity at the end of the transmitted /I2/ is the same as the beginning running disparity. The first /I/ following a packet or a sequence order set restores the current positive or negative running disparity to a negative value. All subsequent /I/s are /I2/ to ensure negative ending running disparity.

Distinct carrier events are separated by /I/s.

A received ordered set that consists of two code-groups, the first of which is /K28.5/ and the second of which is a data code-group other than any of the 128 possible /W/, /D21.5/, or /D2.2/ (or /D6.5/ or /D26.4/ to support EEE capability), is treated as an /I/ ordered set.

127.2.6.9 Low Power Idle (/LI/)

LPI is transmitted in the same manner as IDLE. LPI ordered sets (/LI/) are transmitted continuously and repetitively whenever the XGMII is indicating “Assert LPI”.

127.2.6.10 Start_of_Packet delimiter (SPD)

A Start_of_Packet delimiter (SPD) is used to delineate the starting boundary of a data transmission sequence. Upon initiation of packet transmission, the PCS replaces the first octet of the MAC preamble with

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SPD. Upon initiation of packet reception, the PCS replaces the received SPD delimiter with the data octet value associated with the first preamble octet. A SPD delimiter consists of the code-group /S/, as defined in Table 127–5.

127.2.6.11 End_of_Packet delimiter (EPD)

An End_of_Packet delimiter (EPD) is used to delineate the ending boundary of a packet. The EPD is transmitted by the PCS following the last data octet comprising the FCS of the MAC packet. On reception, EPD is interpreted by the PCS as terminating a packet. A EPD consists of the code-groups /T/R/. If /R/ is transmitted in an even-numbered code-group position, the PCS appends a single additional /R/ to the code-group stream to ensure that the subsequent /I/ is aligned on an even numbered code-group boundary. An /I/ always follows the conclusion of EPD. The /T/R/ or /T/R/R/ occupies part of the region considered by the MAC to be the IPG. The code-group /T/ and /R/ are defined in Table 127–5.

127.2.6.12 Error_Propagation (/V/)

Error_Propagation (/V/) indicates that the PCS client wishes to indicate a transmission error to its peer entity. /V/ is emitted from the PCS when the XGMII indicates transmit error propagation, or when the XGMII presents a mapping that is undefined in Table 127–3 to the Word Encode process. The code group /V/ is defined in Table 127–5.

The presence of Error_Propagation or any invalid code-group on the medium denotes an error condition. Invalid code-groups are not intentionally transmitted onto the medium.

127.2.7 Detailed functions and state diagrams

The body of this subclause comprises state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2.

127.2.7.1 State variables

127.2.7.1.1 Notation conventions

/x/
: Denotes the constant code-group specified in 127.2.7.1.2 (valid code-groups have to follow the rules of running disparity as per 127.2.6.3).

[/x/]
: Denotes the latched received value of the constant code-group (/x/) specified in 127.2.7.1.2 and conveyed by the SYNC_UNITDATA.indication message described in 127.2.7.1.6.

127.2.7.1.2 Constants

/COMMA/
: The set of special code-groups which include a comma as specified in 36.2.4.9 and listed in Table 36–2.

/D/
: The set of 256 code-groups corresponding to valid data, as specified in 127.2.6.7.

/Dx.y/
: One of the set of 256 code-groups corresponding to valid data, as specified in 127.2.6.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

/I/
: The IDLE ordered set group, comprising either the /I1/ or /I2/ ordered sets, as specified in 127.2.6.8.

/INVALID/
: The set of invalid data or special code-groups, as specified in 36.2.4.6.

/Kx.y/
: One of the set of 12 code-groups corresponding to valid special code-groups, as specified in Table 36–2.

/Q/
: Sequence ordered set as specified in 127.2.6.6. A properly formed sequence order set appears as /K28.5/W/K28.5/W/K28.5/W/K28.5/W/. A truncated sequence order set appears as /K28.5/W/K28.5/W/.

/R/
: The code-group used for the second and, if present, the third code-group in an End_of_Packet delimiter as specified in 127.2.6.11.

/S/
: The code-group corresponding to the Start_of_Packet delimiter (SPD) as specified in 127.2.6.10.

/T/
: The code-group used for the first code-group in the End_of_Packet delimiter as specified in 127.2.6.11.

/V/
: The Error_Propagation code-group, as specified in 127.2.6.12.

/W/
: The set of 128 code-groups that is generated by ENCODE(s<7:0>) where for all 128 possible values of x<6:0>
s<7> = x<6>, s<5:0> = x<5:0>,
s<6> is set to x<5> when x<2> = 1; and s<6> is set to x<6> when x<2> = 0
NOTE— /W/ is a subset of /D/.

PL_LIMIT
: The number of 2.5GPII symbols to preload in the Octets-to-Word process after release from the RESET state. The number of symbols to preload is implementation dependent and should be minimized to reduce latency. The minimum number has to be 3 to account for the deficit idle counting in 127.2.5.4.

The following constant is used only for the EEE capability:

/LI/
: The LP_IDLE ordered set group, comprising either the /LI1/ or /LI2/ ordered sets, as specified in 127.2.6.9.

127.2.7.1.3 Variables

assert_seq
: Alias used for sequence ordered set, consisting of the following terms:
tp_en=0 * tp_er=1 * (tpd<7:0> = 0x9C)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

cgbad

Alias for the following terms: ((rx_code-group∈/INVALID/) + (rx_code-group=/COMMA/*rx_even=TRUE)) * PMA_UNITDATA.indication

cggood

Alias for the following terms: !((rx_code-group∈/INVALID/) + (rx_code-group=/COMMA/*rx_even=TRUE)) * PMA_UNITDATA.indication

EVEN

The latched state of the rx_even variable, when rx_even=TRUE, as conveyed by the SYNC_UNITDATA.indication message described in 127.2.7.1.6.

mr_loopback

A Boolean that indicates the enabling and disabling of data being looped back through the PHY. Loopback of data through the PHY is enabled when Control register bit 3.0.14 is set to one.

Values: FALSE; Loopback through the PHY is disabled.
TRUE; Loopback through the PHY is enabled.

mr_main_reset

Controls the resetting of the PCS via control register bit 3.0.15.

Values: FALSE; Do not reset the PCS.
TRUE; Reset the PCS.

ODD

The latched state of the rx_even variable, when rx_even=FALSE, as conveyed by the SYNC_UNITDATA.indication message described in 127.2.7.1.6.

power_on

Condition that is true until such time as the power supply for the device that contains the PCS has reached the operating region. The condition is also true when the device has low power mode set via Control register bit 3.0.11.

Values: FALSE; The device is completely powered (default).
TRUE; The device has not been completely powered.

NOTE—Power_on evaluates to its default value in each state where it is not explicitly set.

rpd<7:0>

Single lane 2.5GPII receive data from the PCS receive process.

wd_rpd<31:0>

Receive data from the Octets-to-Word process. x= 0, 1, 2, 3 for the four sets of 2.5GPII.

rp_dv

Single lane 2.5GPII receive data valid from the PCS receive process.

Values: 0 or 1.

wd_rp_dv<3:0>

Receive data valid from the Octets-to-Word process.

Values: 0 or 1.

rp_er

Single lane 2.5GPII receive error from the PCS receive process.

Values: 0 or 1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

wd_rp_er<3:0>
Receive error from the Octets-to-Word process.

Values: 0 or 1.

rx_bit
A binary parameter conveyed by the PMD_UNITDATA.indication service primitive, as specified in 128.2.2, to the PMA.

Values: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

rx_code-group<9:0>
A 10-bit vector represented by the most recently received code-group from the PMA. The element rx_code-group<0> is the least recently received (oldest) rx_bit; rx_code-group<9> is the most recently received rx_bit (newest). When code-group alignment has been achieved, this vector contains precisely one code-group.

rx_even
A Boolean set by the PCS Synchronization process to designate received code-groups as either even- or odd-numbered code-groups as specified in 127.2.6.2.

Values: TRUE; Even-numbered code-group being received.
FALSE; Odd-numbered code-group being received.

RXC<3:0>
The RXC<3:0> signal of the XGMII as specified in Clause 46. Set by the Word Decode process.

RXD<31:0>
The RXD<31:0> signal of the XGMII as specified in Clause 46. Set by the Word Decode process.

signal_detect
A Boolean set by the PMD continuously via the PMD_SIGNAL.indication(SIGNAL_DETECT) message to indicate the status of the incoming link signal.

Values: FAIL; A signal is not present on the link.
OK; A signal is present on the link.

sync_status
Alias used by the PCS receive state diagram, consisting of the following terms:

sync_status = code_sync_status + rx_lpi_active.

Values: FAIL; A signal is not present on the link.
OK; A signal is present on the link.

NOTE—If EEE is not supported, the variable rx_lpi_active is always false, and this variable is identical to code_sync_status controlled by the synchronization state diagram.

tpd<7:0>
Single lane 2.5GPII transmit data to the PCS transmit process.

tpd_t1<7:0>
The value of tpd<7:0> latched by cg_timer_done = TRUE.

Values: 0 or 1.

we_tpd<31:0>
Transmit data output of the WORD ENCODE process.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tp_en
: Single lane 2.5GPII transmit data enable to the PCS transmit process.

  Values: 0 or 1.

we_tp_en<3:0>
: Transmit data valid output of the WORD ENCODE process.

  Values: 0 or 1.

tp_er
: Single lane 2.5GPII transmit error to the PCS transmit process.

  Values: 0 or 1.

we_tp_er<3:0>
: Transmit error output of the WORD ENCODE process.

  Values: 0 or 1.

tx_bit
: A binary parameter used to convey data from the PMA to the PMD via the PMD_UNITDATA.request service primitive as specified in 128.2.1.

  Values: ZERO; Data bit is a logical zero.
  ONE; Data bit is a logical one.

tx_code-group<9:0>
: A vector of bits representing one code-group, as specified in Table 36–1a through Table 36–1e, or Table 36–2, which has been prepared for transmission by the PCS Transmit process. This vector is conveyed to the PMA as the parameter of the PMD_UNITDATA.request(tx_bit) service primitive. The element tx_code-group<0> is the first tx_bit transmitted; tx_code-group<9> is the last tx_bit transmitted.

tx_disparity
: A Boolean set by the PCS Transmit process to indicate the running disparity at the end of code-group transmission as a binary value. Running disparity is described in 36.2.4.4.

  Values: POSITIVE
  NEGATIVE

tx_even
: A Boolean set by the PCS Transmit process to designate transmitted code-groups as either even or odd numbered code-groups as specified in 127.2.6.2.

  Values: TRUE; Even-numbered code-group being transmitted.
  FALSE; Odd-numbered code-group being transmitted.

tx_o_set
: One of the following defined ordered sets: /T/, /R/, /I/, /S/, /V/, /LI/, or one of the following code-groups: /K28.5/ or /D/.

TXC<3:0>
: The TXC<3:0> signal of the XGMII as specified in Clause 46.

TXD<31:0>
: The TXD<31:0> signal of the XGMII as specified in Clause 46.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

wdecode_state
: Word Decoder State used by the Word Decode process to properly assemble the next XGMII value to output.

  Values: DATA;
  IDLE;
  SEQ;

wencode_state
: Word Encoder State used by the Word Encode process to properly assemble the Sequence ordered set.

  Values: DATA;
  IDLE;
  SEQ;

xgmii_txc_lo<3:0>
: The value of xgmii_txc_lo_neg<3:0> latched by the rising edge of TX_CLK.

xgmii_txc_lo_neg<3:0>
: The value of TXC<3:0> latched by the falling edge of TX_CLK.

xgmii_txc_hi<3:0>
: The value of TXC<3:0> latched by the rising edge of TX_CLK.

xgmii_txd_lo<31:0>
: The value of xgmii_txd_lo_neg<31:0> latched by the rising edge of TX_CLK.

xgmii_txd_lo_neg<31:0>
: The value of TXD<3:0> latched by the falling edge of TX_CLK.

xgmii_txd_hi<31:0>
: The value of TXD<31:0> latched by the rising edge of TX_CLK.

The following variables are used only for the EEE capability:

assert_lpidle
: Alias used for the optional LPI function, consisting of the following terms:

  (tp_en=0 * tp_er=1 * (tpd<7:0> = 0x01))

code_sync_status
: A parameter set by the PCS Synchronization process to reflect the status of the link as viewed by the receiver.

  Values: FAIL; The receiver is not synchronized to code-group boundaries.
  OK; The receiver is synchronized to code-group boundaries.

idle_d
: Alias for the following terms:

  SUDI(![/D21.5/] * ![/D2.2/]) when EEE is not supported, or

  SUDI(![/D21.5/] * ![/D2.2/] * ![/D6.5/] * ![/D26.4/]) when EEE is supported.

rx_lpi_active
: A Boolean variable that is set to TRUE when the receiver is in a low power state and set to FALSE when it is in an active state and capable of receiving data.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

rx_quiet

A Boolean variable set to TRUE while in the RX_QUIET state and set to FALSE otherwise.

tx_quiet

A Boolean variable set to TRUE when the transmitter is in the TX_QUIET state and set to FALSE otherwise. When set to TRUE, the PMD will disable the transmitter as described in 128.6.5.

127.2.7.1.4 Functions

carrier_detect

In the PCS Receive process, this function uses for input the latched code-group ([/x/]) and latched rx_even (EVEN/ODD) parameters of the SYNC_UNITDATA.indication message from the PCS Synchronization process. When SYNC_UNITDATA.indication message indicates EVEN, the carrier_detect function detects carrier when either:

a) A two or more bit difference between [/x/] and both /K28.5/ encodings exists (see Table 36–2); or

b) A two to nine bit difference between [/x/] and the expected /K28.5/ (based on current running disparity) exists.

Values: TRUE; Carrier is detected.
FALSE; Carrier is not detected.

check_end

Prescient End_of_Packet function used by the PCS Receive process. The check_end function returns the current and next two code-groups in rx_code-group<9:0>.

DECODE([/x]/)

In the PCS Receive process, this function takes as its argument the latched value of rx_code-group<9:0> ([/x/]) and the current running disparity, and returns the corresponding 2.5GPII rpd<7:0>, as per Table 36–1a to Table 36–1e. DECODE also updates the current running disparity per the running disparity rules outlined in 36.2.4.4.

ENCODE(x)

In the PCS Transmit process, this function takes as its argument (x), where x is a 2.5GPII tpd<7:0> octet, and the current running disparity, and returns the corresponding ten-bit code-group as per Table 36–1a to Table 36–1e. ENCODE also updates the current running disparity variable tx_disparity per the running disparity rules outlined in 36.2.4.4.

NEXTSEQ

Prescient function used by the Word Decode process that returns whether the next four 2.5GPII symbols presented to the Word Decode process is of the form: Sequence, Data, Sequence, Data.

Values: TRUE; Next four 2.5GPII symbols are Sequence, Data, Sequence, Data.
FALSE; Next four 2.5GPII symbols are not Sequence, Data, Sequence, Data.

signal_detectCHANGE

In the PCS Synchronization process, this function monitors the signal_detect variable for a state change. The function is set upon state change detection.

Values: TRUE; A signal_detect variable state change has been detected.
FALSE; A signal_detect variable state change has not been detected (default).

NOTE—signal_detectCHANGE is set by this function definition; it is not set explicitly in the state diagrams. signal_detectCHANGE evaluates to its default value upon state entry.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SINSERT(x)

Add a single 2.5GPII symbol to the end of a queue that stores the 2.5GPII symbol presented by the receive process. The variable x is the 2.5GPII symbol (rp_dv, rp_er, rpd<7:0>). If x is a null set, then all content in the queue is emptied. The depth of the queue is implementation dependent.

VOID(x)

x ∈ /D/, /T/, /R/, /K28.5/. Substitutes /V/ on a per code-group basis as requested by the 2.5GPII.

If [tp_en=0 * tp_er=1 * tpd<7:0>≠(0000 1111)],

then return /V/;

Else if [tp_en=1 * tp_er=1],

then return /V/;

Else return x.

WALIGN

In the PCS Octets-to-Word process, this function performs the alignment according to 127.2.5.4. Four 2.5GPII symbols (wd_rp_dv<3:0>, wd_rp_er<3:0>, wd_rpd<31:0>) are returned by this function. wd_rpd<7:0> is the earliest to arrive and wd_rpd<31:24> is last. The SINSERT(x) function adds 2.5GPII symbols to the queue. The WALIGN functions removes one to seven 2.5GPII symbols from the front of the queue every time it is called.

When no 2.5GPII symbols are inserted or deleted, this function will return the first four 2.5GPII symbols in the queue and remove them from the queue.

When X 2.5GPII idles symbols are inserted, then X 2.5GPII idles symbols and the first 4 – X 2.5GPII symbols are returned by the function, and the first 4 - X 2.5GPII symbols are removed from the queue.

When X 2.5GPII symbols are deleted, then the first X 2.5GPII symbols are removed from the queue, and the next four in the queue are returned by the function and then removed from the queue.

WDECODE(x, y, z)

In the PCS Word Decode process, this function performs the mapping according to 127.2.5.5. The variable x is four sets of 2.5GPII variables wd_rp_dv<3:0>, wd_rp_er<3:0>, wd_rpd<31:0>, the variable y is the current state of the wdecode_state variable, and the variable z indicates whether the next four 2.5GPII symbols are of the form: Sequence, Data, Sequence, Data.

The output is XGMII RXC<3:0>, RXD<31:0>, wdecode_state.

WENCODE(x, y)

In the PCS Word Encode process, this function performs the mapping according to 127.2.5.2. The variable x is xgmii_txc_lo<3:0> or xgmii_txc_hi<3:0>, xgmii_txd_lo<31:0> or xgmii_txd_hi<31:0>, and the variable y is the current state of the wencode_state variable.

The output is four sets of 2.5GPII variables and the updated state of the wencode_state variable and is ordered as follows: we_tp_en<3:0>, we_tp_er<3:0>, we_tpd<31:0>, wencode_state.

127.2.7.1.5 Counters

good_cgs

Count of consecutive valid code-groups received.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

plcnt

Count of number the number of 2.5GPII symbols to preload in the Octets-to-Word process after release from the RESET state. The number of symbols to preload is implementation dependent and should be minimized to reduce latency.

The following counter is used only for the EEE capability:

wake_error_counter

A counter that is incremented each time that the LPI receive state diagram enters the RX_WTF state indicating that a wake time fault has been detected. The counter is reflected in register 3.22 (see 45.2.3.12).

127.2.7.1.6 Messages

PMA_UNITDATA.indication(rx_code-group<9:0>)

A signal sent by the PMA Receive process conveying the next code-group received over the medium (see 127.3.1.2).

PMA_UNITDATA.request(tx_code-group<9:0>)

A signal sent to the PMA Transmit process conveying the next code-group ready for transmission over the medium (see 127.3.1.1).

PMD_SIGNAL.indication(SIGNAL_DETECT)

A signal sent by the PMD to indicate the status of the signal being received on the MDI.

PUDI

Alias for PMA_UNITDATA.indication(rx_code-group<9:0>).

PUDR

Alias for PMA_UNITDATA.request(tx_code-group<9:0>).

SUDI

Alias for SYNC_UNITDATA.indication(parameters).

SYNC_UNITDATA.indication(parameters)

A signal sent by the PCS Synchronization process to the PCS Receive process conveying the following parameters:

Parameters: [/x/]; the latched value of the indicated code-group (/x/);
EVEN/ODD; the latched state of the rx_even variable;

Value: EVEN; passed when the latched state of rx_even=TRUE.
ODD; passed when the latched state of rx_even=FALSE.

TX_OSET.indication

A signal sent to the PCS Transmit ordered set process from the PCS Transmit code-group process signifying the completion of transmission of one ordered set.

The following messages are used only for the EEE capability:

PMD_RXQUIET.request(rx_quiet)

A signal sent by the PCS/PMA LPI receive state diagram to the PMD. This message is ignored by devices that do not support EEE capability.

Values: TRUE: The receiver is in a quiet state and is not expecting incoming data.
FALSE: The receiver is ready to receive data.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMD_TXQUIET.request(tx_quiet)

A signal sent by the PCS/PMA LPI transmit state diagram to the PMD. This message is ignored by devices that do not support the optional LPI mechanism.

Values: TRUE: The transmitter is in a quiet state and may cease to transmit a signal on the medium.
FALSE: The transmitter is ready to transmit data.

127.2.7.1.7 Timers

cg_timer

A continuous free-running timer. If XGMII is implemented, cg_timer shall expire synchronously with the rising edge of TX_CLK as well as every one-eighth of the TX_CLK cycle time (see tolerance required for TX_CLK in 46.3.1.1). In the absence of XGMII, cg_timer shall expire every 3.2 ns ± 100 ppm.

Values: The condition cg_timer_done becomes true upon timer expiration.

Restart when: immediately after expiration; restarting the timer resets the condition cg_timer_done.

Duration: 3.2 ns nominal.

TX_CLK_timer

A continuous free-running timer. TX_CLK_timer shall expire synchronously with the rising edge of TX_CLK (see tolerance required for TX_CLK in 46.3.1.1).

Restart when: immediately after expiration.

Duration: 25.6 ns nominal.

The following timers are used only for the EEE capability:

rx_tq_timer

This timer is started when the PCS receiver enters the START_TQ_TIMER state. The timer terminal count is set to T_{QR}. When the timer reaches terminal count, it will set the rx_tq_timer_done = TRUE.

rx_tw_timer

This timer is started when the PCS receiver enters the RX_WAKE state. The timer terminal count shall not exceed the maximum value of T_{WR} in Table 127–7. When the timer reaches terminal count, it will set the rx_tw_timer_done = TRUE.

rx_wf_timer

This timer is started when the PCS receiver enters the RX_WTF state, indicating that the receiver has encountered a wake time fault. The rx_wf_timer allows the receiver an additional period in which to synchronize or return to the quiescent state before a link failure is indicated. The timer terminal count is set to T_{WTF}. When the timer reaches terminal count, it will set the rx_wf_timer_done = TRUE.

tx_tq_timer

This timer is started when the PCS transmitter enters the TX_QUIET state. The timer terminal count is set to T_{QL}. When the timer reaches terminal count, it will set the tx_tq_timer_done = TRUE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_tr_timer
: This timer is started when the PCS transmitter enters the TX_REFRESH state. The timer terminal count is set to T_{UL}. When the timer reaches terminal count, it will set the tx_tr_timer_done = TRUE.

tx_ts_timer
: This timer is started when the PCS transmitter enters the TX_SLEEP state. The timer terminal count is set to T_{SL}. When the timer reaches terminal count, it will set the tx_ts_timer_done = TRUE.

127.2.7.2 State diagrams

127.2.7.2.1 Word Encode and Word-to-Octets

The Word Encode process (see 127.2.5.2) and Word-to-Octets process (see 127.2.5.3) are merged into one state diagram depicted in Figure 127–4, including compliance with the associated state variables as specified in 127.2.7.1.

The Word Encode process continuously maps the four XGMII lanes to four 2.5GPII symbols via the WENCODE function in the TX_XGMII_LO and TX_XGMII_HI states. The four 2.5GPII symbols are then serialized and output one at a time by the Word-to-Octets process. The presentation of the 2.5GPII symbols are synchronized to the PCS transmit process such that the 2.5GPII index 0 and 2 symbols are presented to the PCS transmit process which will result in the corresponding ordered set to be output to the PMA when the variable tx_even is TRUE and index 1 and 3 variables when tx_even is FALSE.

127.2.7.2.2 Transmit

The PCS Transmit process is depicted in two state diagrams: PCS Transmit ordered set and PCS Transmit code-group. The PCS shall implement its Transmit process as depicted in Figure 127–5 and Figure 127–6, including compliance with the associated state variables as specified in 127.2.7.1.

The Transmit ordered set process continuously sources ordered sets to the Transmit code-group process. Upon the assertion of tp_en by the 2.5GPII, the SPD ordered set is sourced. Following the SPD, /D/ code-groups are sourced until tp_en is deasserted. Following the de-assertion of tp_en, EPD ordered sets are sourced. If tp_en and tp_er are both deasserted, the /R/ ordered set may be sourced, after which the sourcing of /I/ is resumed. If, while tp_en is asserted, the tp_er signal is asserted, the /V/ ordered set is sourced except when the SPD ordered set is selected for sourcing. If the 2.5GPII indicates sequence, then /Q/ ordered sets are sourced. If the optional EEE is enabled and the 2.5GPII indicates low power idles, then /LI/ ordered sets are sourced.

The Transmit code-group process continuously sources tx_code-group<9:0> to the PMA based on the ordered sets sourced to it by the Transmit ordered set process. The Transmit code-group process determines the proper code-group to source based on even/odd-numbered code-group alignment, running disparity requirements, and ordered set format.

127.2.7.2.3 Synchronization

The PCS shall implement the Synchronization process as depicted in Figure 127–7 including compliance with the associated state variables as specified in 127.2.7.1. The Synchronization process is responsible for determining whether the underlying receive channel is ready for operation. Failure of the underlying channel typically causes the PMA client to suspend normal actions.

A receiver that is in the LOSS_OF_SYNC state and that has acquired bit synchronization attempts to acquire code-group synchronization via the Synchronization process. Code-group synchronization is acquired by the detection of three ordered sets containing commas in their leftmost bit positions without intervening invalid code-group errors. Upon acquisition of code-group synchronization, the receiver enters the SYNC_ACQUIRED_1 state. Acquisition of synchronization ensures the alignment of multi-code-group ordered sets to even-numbered code-group boundaries.

Once synchronization is acquired, the Synchronization process tests received code-groups in sets of four code-groups and employs multiple sub-states, to move between the SYNC_ACQUIRED_1 and LOSS_OF_SYNC states.

For EEE capability the relationship between sync_status and code_sync_status is given by the definition of the sync_status variable in 127.2.7.1.3; otherwise sync_status is identical to code_sync_status.

127.2.7.2.4 Receive

The PCS shall implement its Receive process as depicted in Figure 127–8a and Figure 127–8b, including compliance with the associated state variables as specified in 127.2.7.1. The PCS shall implement Figure 127–8c if the optional EEE is present and enabled.

The PCS Receive process continuously passes rpd<7:0> and sets the rp_dv and rp_er signals to the 2.5GPII based on the received code-group from the PMA.

127.2.7.2.5 Octets-to-Word and Decode

The Octets-to-Word process and Word decode process are merged into one state diagram depicted in Figure 127–9, including compliance with the associated state variables as specified in 127.2.7.1.

The Octets-to-Word process continuously queues the incoming 2.5GPII symbols from the PCS receive process and outputs four 2.5GPII symbols at a time using the WALIGN function. Symbols may be dropped or idles symbols added by the WALIGN function. The Word Decode process continuously maps the four 2.5GPII symbols and presents them on the XGMII using the WDECODE function in the RX_XGMII state.

127.2.7.2.6 LPI state diagram

A PCS that supports the EEE capability shall implement the LPI transmit process as shown in Figure 127–10. The transmit LPI state diagram controls tx_quiet, which disables the transmitter when true.

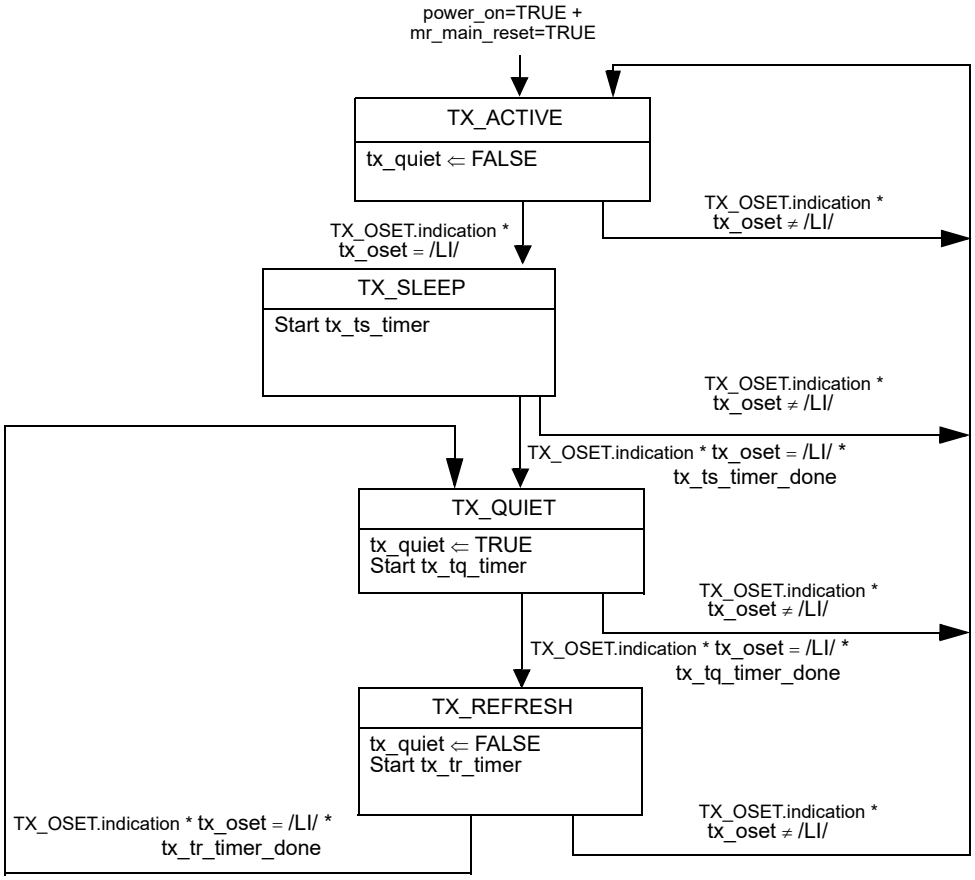

Figure 127–10—LPI Transmit state diagram

The timer values for these state diagrams are shown in Table 127–6 for transmit and Table 127–7 for receive.

Table 127–6—Transmitter LPI timing parameters

Parameter	Description	Min	Max	Units
T_{SL}	Local Sleep Time from entering the TX_SLEEP state to when tx_quiet is set to TRUE	19.9	20.1	µs
T_{QL}	Local Quiet Time from when tx_quiet is set to TRUE to entry into the TX_REFRESH state	2.5	2.6	ms
T_{UL}	Local Refresh Time from entry into the TX_REFRESH state to entry into the TX_QUIET state	19.9	20.1	µs

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 127–7—Receiver LPI timing parameters

Parameter	Description	Min	Max	Units
T_{QR}	The time the receiver waits for signal detect to be set to OK while in the LP_IDLE_D, LPI_K and RX_QUIET states before asserting a rx_fault	3	4	ms
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault (WTF)		11	µs
T_{WTF}	Wake time fault recovery time		1	ms

127.2.7.2.7 LPI status and management

For EEE capability, the PCS indicates to the management system that LPI is currently active in the receive and transmit directions using the status variables shown in Table 36–10.

127.3 Physical Medium Attachment (PMA) sublayer

127.3.1 Service Interface

The PMA provides a Service Interface to the PCS. These services are described in an abstract manner and do not imply any particular implementation. The PMA Service Interface supports the exchange of code-groups between PCS entities. The PMA converts code-groups into bits and passes these to the PMD, and vice versa. It also generates an additional status indication for use by its client.

The following primitives are defined:

PMA_UNITDATA.request(tx_code-group<9:0>)

PMA_UNITDATA.indication(rx_code-group<9:0>)

127.3.1.1 PMA_UNITDATA.request

This primitive defines the transfer of data (in the form of code-groups) from the PCS to the PMA. PMA_UNITDATA.request is generated by the PCS Transmit process.

127.3.1.1.1 Semantics of the service primitive

PMA_UNITDATA.request(tx_code-group<9:0>)

The data conveyed by PMA_UNITDATA.request is the tx_code-group<9:0> parameter defined in 127.2.7.1.3.

127.3.1.1.2 When generated

The PCS continuously sends, at a nominal rate of 312.5 MHz, tx_code-group<9:0> to the PMA.

127.3.1.1.3 Effect of receipt

Upon receipt of this primitive, the PMA generates a series of ten PMD_UNITDATA.request primitives, requesting transmission of the indicated tx_bit to the PMD.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

127.3.1.2 PMA_UNITDATA.indication

This primitive defines the transfer of data (in the form of code-groups) from the PMA to the PCS. PMA_UNITDATA.indication is used by the PCS Synchronization process.

127.3.1.2.1 Semantics of the service primitive

PMA_UNITDATA.indication(rx_code-group<9:0>)

The data conveyed by PMA_UNITDATA.indication is the rx_code-group<9:0> parameter defined in 127.2.7.1.3.

127.3.1.2.2 When generated

The PMA continuously sends one rx_code-group<9:0> to the PCS corresponding to the receipt of each code-group aligned set of ten PMD_UNITDATA.indication primitives received from the PMD. The nominal rate of the PMA_UNITDATA.indication primitive is 312.5 MHz, as governed by the recovered bit clock.

127.3.1.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMA sublayer.

127.3.2 Functions within the PMA

Figure 127–2 and Figure 127–3 depict the mapping of the four octet-wide data path of the XGMII to the ten-bit code-groups of the PMA Service Interface and on to the serial PMD Service Interface. The PMA comprises the PMA Transmit and PMA Receive processes for 2.5GBASE-X.

The PMA Transmit process serializes tx_code-groups into tx_bits and passes them to the PMD for transmission on the underlying medium, according to Figure 127–3. Similarly, the PMA Receive process deserializes rx_bits received from the PMD according to Figure 127–3. The PMA continuously conveys ten bit code-groups to the PCS, independent of code-group alignment. After code-group alignment is achieved, based on comma detection, the PCS converts code-groups into XGMII data octets, according to 127.2.7.2.4 and 127.2.7.2.5.

The proper alignment of a comma used for code-group synchronization is depicted in Figure 127–3.

127.3.2.1 Data delay

The PMA maps a nonaligned one-bit data path from the PMD to an aligned, ten-bit-wide data path to the PCS, on the receive side. Logically, received bits have to be buffered to facilitate proper code-group alignment. These functions necessitate an internal PMA delay of at least ten bit times. In practice, code-group alignment may necessitate even longer delays of the incoming rx_bit stream.

127.3.2.2 PMA transmit function

The PMA Transmit function passes data unaltered (except for serializing) from the PCS directly to the PMD. Upon receipt of a PMA_UNITDATA.request primitive, the PMA Transmit function shall serialize the ten bits of the tx_code-group<9:0> parameter and transmit them to the PMD in the form of ten successive PMD_UNITDATA.request primitives, with tx_code-group<0> transmitted first, and tx_code-group<9> transmitted last.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

127.3.2.3 PMA receive function

The PMA Receive function passes data unaltered (except for deserializing and possible code-group slipping upon code-group alignment) from the PMD directly to the PCS. Upon receipt of ten successive PMD_UNITDATA.indication primitives, the PMA shall assemble the ten received rx_bits into a single ten-bit value and pass that value to the PCS as the rx_code-group<9:0> parameter of the primitive PMA_UNITDATA.indication, with the first received bit installed in rx_code-group<0> and the last received bit installed in rx_code-group<9>. An exception to this operation is specified in 127.3.2.4.

127.3.2.4 Code-group alignment

In the event the PMA sublayer detects a comma+ within the incoming rx_bit stream, it may realign its current code-group boundary, if necessary, to that of the received comma+ as shown in Figure 36–3. This process is referred to in this document as code-group alignment. During the code-group alignment process, the PMA sublayer may delete or modify up to four, but shall delete or modify no more than four, ten-bit code-groups in order to align the correct receive clock and code-group containing the comma+. This process is referred to as code-group slipping.

In addition, the PMA sublayer is permitted to realign the current code-group boundary upon receipt of a comma-pattern.

127.3.3 Loopback mode

Loopback mode shall be provided, as specified in this subclause, by the transmitter and receiver of a device as a test function to the device. When Loopback mode is selected, transmission requests passed to the transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. A device is explicitly placed in Loopback mode (i.e., Loopback mode is not the normal mode of operation of a device). The method of implementing Loopback mode is not defined by this standard.

NOTE—Loopback mode may be implemented either in the parallel or the serial circuitry of a device.

127.3.3.1 Receiver considerations

A receiver may be placed in Loopback mode. Entry into or exit from Loopback mode may result in a temporary loss of synchronization.

127.3.3.2 Transmitter considerations

A transmitter may be placed in Loopback mode. While in Loopback mode, the transmitter output is not defined.

127.3.4 Test functions

A limited set of test functions may be provided as an implementation option for testing of the transmitter function or for testing of an attached receiver.

Some test functions that are not defined by this standard may be provided by certain implementations. Compliance with the standard is not affected by the provision or exclusion of such functions by an implementation. The patterns described in Annex 36A may be used for 2.5GBASE-X except the nominal bit rate is 2.5 times faster and any references to the GMII applies to the XGMII.

A typical test function is the ability to transmit invalid code-groups within an otherwise valid PHY bit stream. Certain invalid PHY bit streams may cause a receiver to lose word and/or bit synchronization. See

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ANSI INCITS 230-1994 (FC-PH), subclause 5.4, for a more detailed discussion of receiver and transmitter behavior under various test conditions.

127.3.4.1 PMA PRBS9 test pattern (optional)

The PMA may optionally generate a PRBS9 test pattern in the transmit direction.

The ability to generate the test pattern is indicated by the PRBS9_Tx_generator_ability status variable, which, if a Clause 45 MDIO is implemented, is accessible through bit 1.1500.5 (see 45.2.1.169).

If supported, when send Tx PRBS9 test-pattern mode is enabled by the PRBS9_enable and PRBS_Tx_gen_enable control variables, the PMA shall generate a PRBS9 pattern (as defined in footnote a of Table 68–6) toward the service interface below the PMA via the PMA_UNITDATA.request primitive. If a Clause 45 MDIO is implemented, the PRBS9_enable and PRBS_Tx_gen_enable control variables are accessible through bits 1.1501.6 and 1.1501.3 (see 45.2.1.170). When send Tx PRBS9 test-pattern mode is disabled, the PMA returns to normal operation.

Note that PRBS9 is intended to be checked by external test gear, and no PRBS9 checking function is provided within the PMA.

127.4 Compatibility considerations

There is no requirement for a compliant device to implement or expose any of the interfaces specified for the PCS or PMA. Implementations of a XGMII shall comply with the requirements as specified in Clause 46.

127.5 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) also demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the backplane channel and concatenation of devices.

The sum of transmit and receive delay contributed by the 2.5GBASE-X PCS and PMA shall be no more than 768 bit-times.

127.6 Environmental specifications

All equipment subject to this clause shall conform to the requirements of 71.9.

127.7 Protocol implementation conformance statement (PICS) proforma for Clause 127, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 2.5 Gb/s 8B/10B 2.5GBASE-X[219]

127.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 127, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 2.5 Gb/s 8B/10B 2.5GBASE-X, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

127.7.2 Identification

127.7.2.1 Implementation identification

Supplier (Note 1)	
Contact point for inquiries about the PICS (Note 1)	
Implementation Name(s) and Version(s) (Notes 1 and 3)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s) (Note 2)	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

127.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 127, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 2.5 Gb/s 8B/10B 2.5GBASE-X
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[219]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

128. Physical Medium Dependent sublayer and baseband medium, type 2.5GBASE-KX

128.1 Overview

This clause specifies the 2.5GBASE-KX PMD and baseband medium. When forming a complete PHY, a PMD shall be combined with the appropriate sublayers (see Table 128–1), and with the management functions that are optionally accessible through the management interface defined in Clause 45. References to the MDI (Media Dependent Interface) should be considered to be TP1 for the transmitter and TP4 for the receiver, as measurement points.

Table 128–1—Physical Layer clauses associated with the 2.5GBASE-KX PMD

Associated clause	2.5GBASE-KX
46—XGMII [a]	Optional
73—Auto-Negotiation for Backplane	Required
78—EEE	Optional
127—2.5GBASE-X PCS/PMA	Required

[a]The XGMII is an optional interface. However, if the XGMII is not implemented, a conforming implementation behaves functionally as though the RS and XGMII were present.

A 2.5GBASE-KX PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

128.2 Physical Medium Dependent (PMD) service interface

The following specifies the services provided by the 2.5GBASE-KX PMDs. These PMD sublayer service interfaces are described in an abstract manner and do not imply any particular implementation.

The PMD Service Interface supports the exchange of bit streams representing 2.5GBASE-X 8B/10B encoded data between the PMA and PMD entities. The PMD translates the serialized data of the PMA to and from signals suitable for the specified medium.

The following primitives are defined:

PMD_UNITDATA.request(tx_bit)
PMD_UNITDATA.indication(rx_bit)
PMD_SIGNAL.indication(SIGNAL_DETECT)

If EEE is supported, the following primitives are also defined on the PMD Service Interface:

PMD_RXQUIET.request(rx_quiet)
PMD_TXQUIET.request(tx_quiet)

These messages affect the PCS variables as described in 127.2.7.1.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128.2.1 PMD_UNITDATA.request

This primitive defines the transfer of a serial data stream from the PMA to the PMD.

128.2.1.1 Semantics of the service primitive

PMD_UNITDATA.request(tx_bit)

The data conveyed by PMD_UNITDATA.request is a continuous stream of bits. The tx_bit parameter can take one of two values: ONE or ZERO.

128.2.1.2 When generated

The PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at the signaling speed for 2.5GBASE-KX PMD types specified in Table 128–4.

128.2.1.3 Effect of receipt

Upon receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals on the MDI.

128.2.2 PMD_UNITDATA.indication

This primitive defines the transfer of a serial data stream from the PMD to the PMA.

128.2.2.1 Semantics of the service primitive

PMD_UNITDATA.indication(rx_bit)

The data conveyed by PMD_UNITDATA.indication is a continuous stream of bits. The rx_bit parameter can take one of two values: ONE or ZERO.

128.2.2.2 When generated

The PMD continuously sends a stream of bits to the PMA corresponding to the signals received from the MDI.

128.2.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

128.2.3 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

128.2.3.1 Semantics of the service primitive

PMD_SIGNAL.indication(SIGNAL_DETECT)

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting signal at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, then rx_bit is undefined, but consequent actions based on PMD_UNITDATA.indication, where necessary, interpret rx_bit as a logic ZERO.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA.indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient signal for a SIGNAL_DETECT = OK indication and still not meet the BER objective.

128.2.3.2 When generated

The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT. If the MDIO interface is implemented, then PMD_global_signal_detect shall be continuously set to the value of SIGNAL_DETECT.

128.2.3.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

128.2.4 PMD_RXQUIET.request

This primitive is generated by the PCS Receive Process when EEE is supported to indicate that the input signal is quiet and the PMA and PMD receiver may go into low power mode. When EEE is not supported, the primitive is never invoked, and the PMD behaves as if rx_quiet = FALSE.

128.2.4.1 Semantics of the service primitive

PMD_RXQUIET.request(rx_quiet)

The rx_quiet parameter takes on one of two values: TRUE or FALSE.

128.2.4.2 When generated

The PCS generates this primitive to request the appropriate PMD receive LPI state.

128.2.4.3 Effect of receipt

This variable is from the receive process of the PCS to control the power-saving function of the local PMD receiver. The 2.5GBASE-KX PHY receiver should put unused functional blocks into a low power state to save energy.

128.2.5 PMD_TXQUIET.request

This primitive is generated by the PCS Transmit Process when EEE is supported to indicate that the PMA and PMD transmit functions may go into a low power mode and to disable the PMD transmitter. See 128.6.5. When EEE is not supported, the primitive is never invoked, and the PMD behaves as if tx_quiet = FALSE.

128.2.5.1 Semantics of the service primitive

PMD_TXQUIET.request(tx_quiet)

The tx_quiet parameter takes on one of two values: TRUE or FALSE.

128.2.5.2 When generated

The PCS generates this primitive to request the appropriate PMD transmit LPI state.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128.2.5.3 Effect of receipt

This primitive affects operation of the PMD Transmit disable function as described in 128.6.5. The 2.5GBASE-KX PHY transmitter should put unused functional blocks into a lower power state to save energy.

128.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD shall support the AN service interface primitive AN_LINK.indication as defined in 73.9.

128.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementers consider the delay maxima, and that network planners and administrators consider the delay constraints regarding the physical topology and concatenation of devices.

The sum of transmit and receive delays contributed by the 2.5GBASE-KX PMD and medium shall be no more than 256 bit times. It is assumed that the round-trip delay through the medium is less than or equal to 80 bit times.

128.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If the MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 128–2 and MDIO status variables to PMD status variables as shown in Table 128–3.

Table 128–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	Control register 1	1.0.15	PMD_reset
PMD Transmit Disable	1000BASE-KX/2.5GBASE-KX control register	1.160.0	PMD_transmit_disable

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 128–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	Status register 1	1.1.7	PMD_fault
Transmit fault ability	1000BASE-KX/2.5GBASE-KX status register	1.161.13	PMD_Transmit_fault_ability
Receive fault ability	1000BASE-KX/2.5GBASE-KX status register	1.161.12	PMD_Receive_fault_ability
Transmit fault	1000BASE-KX/2.5GBASE-KX status register	1.161.11	PMD_transmit_fault
Receive fault	1000BASE-KX/2.5GBASE-KX status register	1.161.10	PMD_receive_fault
PMD transmit disable ability	1000BASE-KX/2.5GBASE-KX status register	1.161.8	PMD_transmit_disable_ability
Signal detect from PMD	1000BASE-KX/2.5GBASE-KX status register	1.161.0	PMD_signal_detect

128.6 PMD functional specifications

128.6.1 Link block diagram

For purposes of system conformance, the PMD sublayer is standardized at test points TP1 and TP4 as shown in Figure 128–1. The transmitter and receiver blocks include all off-chip components associated with the respective block. For example, external AC-coupling capacitors, if required, are to be included in the receiver block.

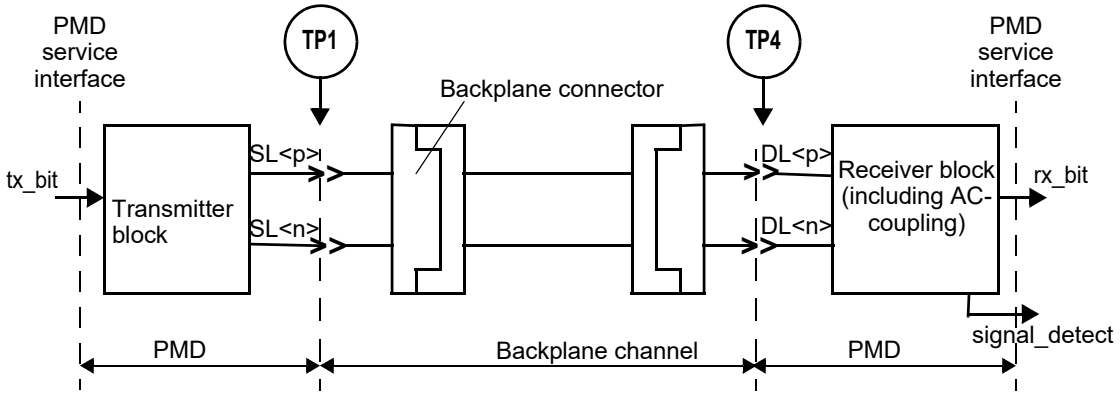

Figure 128–1—Link block diagram

The electrical path from the transmitter block to TP1, and from TP4 to the receiver block, will affect link performance and the measured values of electrical parameters used to verify conformance to this standard. Therefore, it is recommended that this path be carefully designed.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128.6.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the electrical specifications in 128.7.1. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = ONE.

128.6.3 PMD receive function

The PMD Receive function shall convey the bits received at the MDI in accordance with the electrical specifications of 128.7.2 to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = ONE.

128.6.4 PMD signal detect function

For 2.5GBASE-KX operation PMD signal detect is mandatory if EEE is supported. When EEE is not supported, the PMD signal detect is optional for 2.5GBASE-KX, and its definition is beyond the scope of this specification. When PMD signal detect is not implemented, the value of SIGNAL_DETECT shall be set to OK for purposes of management and signaling of the primitive.

If EEE is supported, a local PMD signal detect function shall report to the PMD service interface using the message PMD_SIGNAL.indication(SIGNAL_DETECT). This message is signaled continuously. For EEE, the SIGNAL_DETECT parameter can take on one of two values, OK or FAIL, indicating whether the PMD is detecting electrical energy at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication is undefined. The signal energy from a compliant transmitter shall set SIGNAL_DETECT to OK within 750 ns when transitioning from LPI quiet to active and set SIGNAL_DETECT to FAIL within 750 ns when transitioning from active to LPI quiet.

128.6.5 PMD transmit disable function

The PMD_transmit_disable function is mandatory if EEE is supported and is otherwise optional. When this function is supported, it shall meet the following requirements.

a) When the PMD_transmit_disable variable is set to ONE, this function shall turn off the transmitter such that it drives a constant level (i.e., no transitions) and does not exceed the maximum peak-to-peak differential output voltage specified in Table 128–4.
b) If a PMD_fault (128.6.7) is detected, then the PMD may turn off the electrical transmitter.
c) Loopback, as defined in 128.6.6, shall not be affected by PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off the transmitter after tx_quiet is asserted within the time and voltage level specified in 128.7.1.4. The PMD_transmit_disable function shall turn on the transmitter after tx_quiet is de-asserted within a time and voltage level specified in 128.7.1.4.

128.6.6 Loopback mode

Loopback mode shall be provided for the 2.5GBASE-KX PMA/PMD by the transmitter and receiver of a device as a test function to the device. When loopback mode is selected, transmission requests passed to the transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. Transmitter operation shall be independent of loopback mode. The method of implementing loopback mode within the PMD is not defined by this standard.

Control of the loopback function is specified in 45.2.1.1.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

128.6.7 PMD fault function

If the MDIO is implemented and the PMD has detected a local fault, the PMD shall set PMD_fault to ONE; otherwise, the PMD shall set PMD_fault to ZERO.

128.6.8 PMD transmit fault function

If the MDIO is implemented and the PMD has detected a local fault on the transmitter, the PMD shall set the PMD_transmit_fault variable to ONE; otherwise, the PMD shall set PMD_transmit_fault to ZERO.

128.6.9 PMD receive fault function

If the MDIO is implemented and the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to ONE; otherwise, the PMD shall set PMD_receive_fault to ZERO.

128.6.10 PMD LPI function

The PMD LPI function responds to PMD_TXQUIET and PMD_RXQUIET requests generated by the LPI transmit state diagram (See 127.2.7.2.7) and the LPI receive state diagram (see 49.2.13.3.1 and Figure 49–13). Implementation of the function is optional. EEE capabilities and parameters are advertised during the Backplane Auto-Negotiation as described in 45.2.7.16. The transmitter on the local device informs the link partner's receiver when to sleep, refresh, and wake. The local receiver's transitions are controlled by the link partner's transmitter and change independently from the local transmitter's states and transitions.

If EEE is supported, the PMD transmit function enters into a low power mode when tx_quiet is set to TRUE and exits when tx_quiet is set to FALSE. While tx_quiet is TRUE the PMD transmitter functional blocks should be deactivated to conserve energy. The PMD receive function enters into a low power mode when rx_quiet is set to TRUE and exits when rx_quiet is set to FALSE. While rx_quiet is TRUE the PMD receiver functional blocks should be deactivated to conserve energy.

The "Assert LPI" request at the XGMII is encoded in the transmitted symbols. Detection of LPI signaling in the received symbols is indicated as "Assert LPI" at the XGMII. Upon the detection of "Assert LPI" at the XGMII, an energy-efficient 2.5GBASE-KX PHY continues transmitting for a predefined period, then ceases transmission and deactivates transmit functions to conserve energy. The PHY periodically transmits during this quiet period to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variations in the timing of the link or the underlying channel characteristics. If, during the quiet or refresh periods, normal interframes resume at the XGMII, the PHY reactivates transmit functions and initiates transmission. This transmission will be detected by the remote PHY, causing it to also exit the LPI mode.

128.7 2.5GBASE-KX electrical characteristics

128.7.1 Transmitter characteristics

Transmitter characteristics at TP1 (see Figure 129–1) are summarized in Table 128–4 and detailed in 128.7.1.1 through 128.7.2.

Table 128–4—Transmitter characteristics for 2.5GBASE-KX

Parameter	Subclause reference	Value	Units
Signaling speed	128.7.1.3	3.125 ± 100 ppm	GBd
Peak-to-peak differential output voltage (max)	128.7.1.4	1200	mV
Peak-to-peak differential output voltage (min)	128.7.1.4	800	mV
Peak-to-peak differential output voltage (max) with TX disabled	128.6.5	30	mV
Common-mode voltage limits[c]	128.7.1.4	0 to +1.9	V
Differential output return loss (min)	128.7.1.5	See Equation (128–3)	dB
Common-mode output return loss (min)	128.7.1.6	See Equation (128–4)	dB
Transition time (20%–80%)	128.7.1.7	30 to 100	ps
Maximum Output jitter (peak-to-peak)			
Random jitter	128.7.1.9	0.2	UI
Deterministic jitter	128.7.1.9	0.12	UI
Duty Cycle Distortion[a]	128.7.1.9	0.035	UI
Total jitter[b]	128.7.1.9	0.32	UI

[a]Duty Cycle Distortion is considered part of deterministic jitter distribution.
[b]Jitter is specified at BER 10^{-12}.
[c]Defined with respect to signal ground as measured at Vcom in Figure 128–2.

128.7.1.1 Test fixtures

The test fixture of Figure 128–2, or its functional equivalent, is required for measuring the transmitter specifications described in 128.7.1, with the exception of return loss.

128.7.1.2 Test fixture characteristics

The differential load impedance applied to the transmitter output by the test fixture depicted in Figure 128–2 shall be 100 Ω. The differential return loss, in dB, of the test fixture shall meet the requirements of Equation (128–1) and Equation (128–2).

$$Return_loss(f) \geq 20 \tag{128–1}$$

for 100 MHz ≤ f < 1562.5 MHz and

$$Return_loss(f) \geq Return_loss_{min} = 20 - 20\log_{10}\left(\frac{f}{1562.5\,\text{MHz}}\right) \tag{128–2}$$

for 1562.5 MHz ≤ f ≤ 2000 MHz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

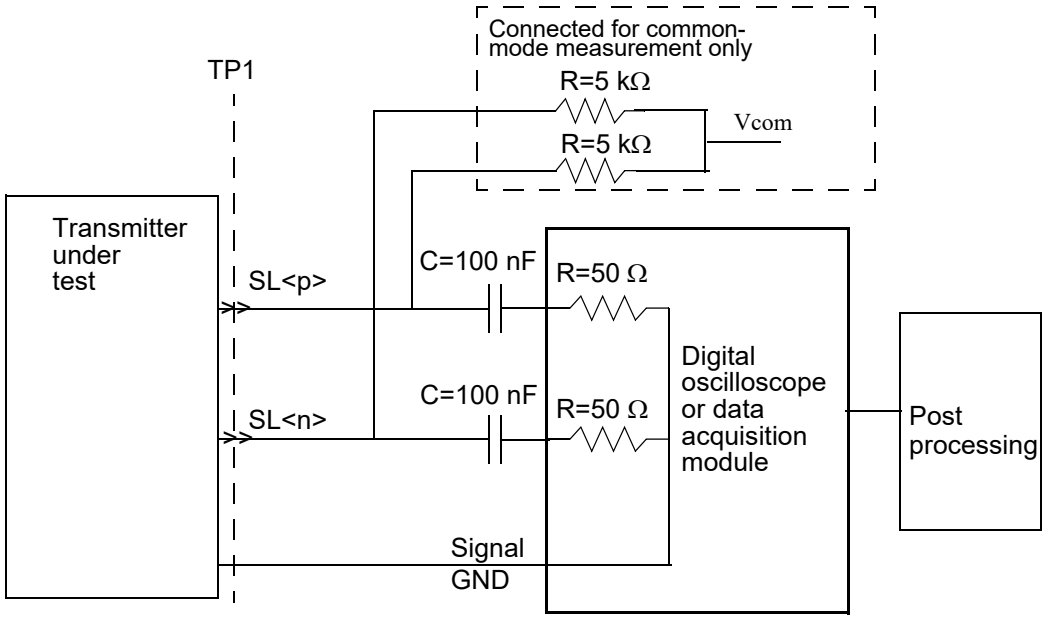

Figure 128–2—Transmit test fixture for 2.5GBASE-KX

128.7.1.3 Signaling speed

The 2.5GBASE-KX signaling speed shall be as specified in Table 128–4.

128.7.1.4 Output amplitude

The peak-to-peak differential output voltage shall be as specified in Table 128–4. See Figure 128–3. The differential output voltage test pattern is the test pattern specified in 48A.2. .

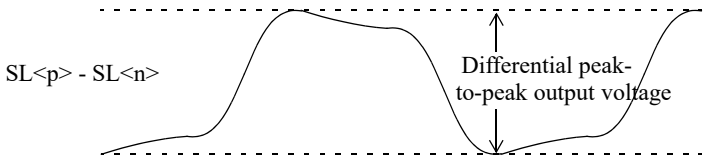

Figure 128–3—Transmitter peak-to-peak differential output voltage definition

NOTE—SL<p> and SL<n> are the positive and negative sides of the differential signal pair.

DC-referenced voltage levels are not defined since the receiver is AC-coupled. The common-mode voltage of SL<p> and SL<n>, with respect to signal ground, as measured at Vcom in Figure 128–2 is specified in Table 128–4.

For EEE capability, the transmitter shall meet the Table 128–4 requirement for Differential peak to peak output voltage when TX is disabled within 500 ns of tx_mode being set to QUIET and remain so while tx_mode is set to QUIET. Furthermore, the transmitter's peak-to-peak differential output voltage shall be greater than 720 mV within 500 ns of tx_mode being set to ALERT. The transmitter output shall be fully compliant within 5 μs after tx_mode is set to DATA. During LPI mode, the common-mode voltage shall be maintained to within ± 150 mV of the pre-LPI value.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128.7.1.5 Differential output return loss

For frequencies from 100 MHz to 2000 MHz, the differential output return loss, in dB, of the transmitter shall meet the requirements of Table 128–4. This output impedance requirement applies to all valid output levels. The reference impedance for differential output return loss measurements shall be 100 Ω.

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 10 & 100 \leq f < 625 \\ 10 - 10\log_{10}(f/625) & 625 \leq f \leq 2000 \end{array} \right\} (\text{dB}) \quad (128\text{–}3)$$

where

f is the frequency in MHz

The minimum differential output return loss is shown in Figure 128–4.

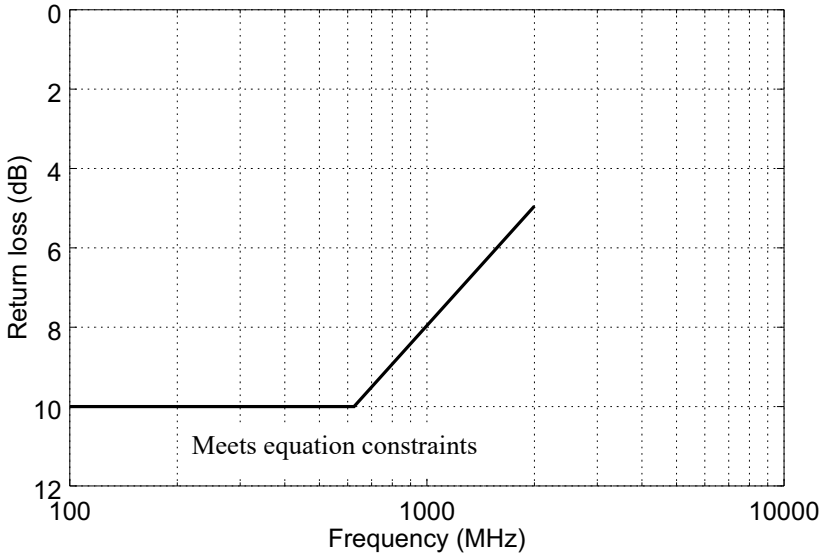

Figure 128–4—Transmitter differential-mode return loss limit

128.7.1.6 Common-mode output return loss

The transmitter common-mode return loss shall meet the requirements of Table 128–4. The reference impedance for common-mode return loss measurements is 25 Ω.

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 7 & 100 \leq f < 625 \\ 7 - 10\log_{10}(f/625) & 625 \leq f \leq 2000 \end{array} \right\} (\text{dB}) \quad (128\text{–}4)$$

where

f is the frequency in MHz

The minimum common-mode output return loss is shown in Figure 128–5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

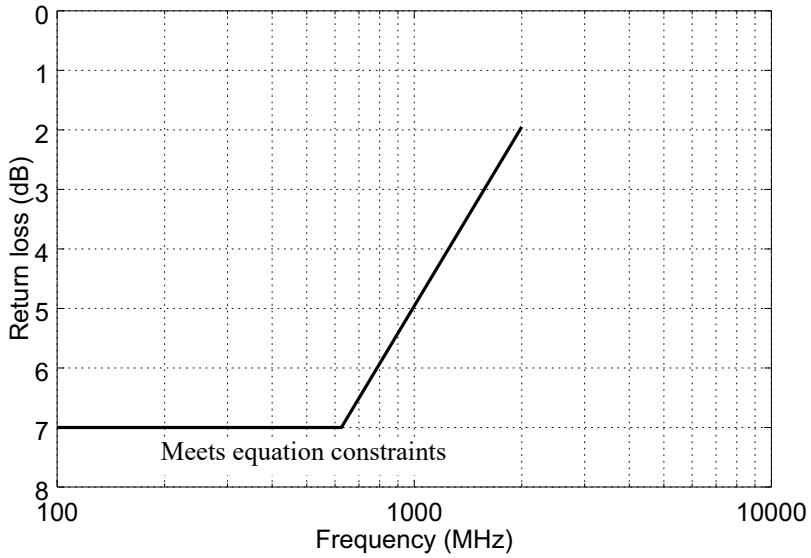

Figure 128–5—Transmitter common-mode return loss limit

128.7.1.7 Transition time

The rising and falling edge transition times shall be as specified in Table 128–4 when measured with respect to the peak-to-peak differential value of the waveform using the high-frequency test pattern of 48A.1.

128.7.1.8 Transmit jitter test requirements

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in 48B.3. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 1.875 MHz is applied to the jitter. The data pattern for jitter measurements shall be a high-frequency test pattern as defined in 48A.1. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal.

The duty cycle distortion test pattern shall be the high-frequency test pattern as defined in 48A.1.

128.7.1.9 Transmit jitter

The transmit jitter shall be as specified in Table 128–4. Duty cycle distortion (DCD) is considered a component of deterministic jitter. The peak-to-peak duty cycle distortion is defined as the absolute value of the difference in the mean pulse width of a 1 pulse or the mean pulse width of a 0 pulse (as measured at the mean of the high and low voltage levels in a repeating 0101 bit sequence) and the nominal pulse width. Jitter specifications are specified for BER = 10^{-12}. Transmit jitter test requirements are specified in 128.7.1.8.

NOTE—Duty cycle distortion (DCD) is also referred to as Even-odd jitter (see 92.8.3.8.1).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128.7.2 Receiver characteristics

Receiver characteristics at TP4 (see Figure 129–1) are summarized in Table 128–5 and detailed in 128.7.2.1 through 128.7.2.5.

Table 128–5—Receiver characteristics for 2.5GBASE-KX

Parameter	Subclause reference	Value	Units
Bit error ratio	128.7.2.1	10^{-12}	
Signaling speed	128.7.2.2	3.125 ± 100 ppm	GBd
Differential input peak-to-peak amplitude (max)[a]	128.7.2.4	1200	mV
Differential input return loss (min)[b]	128.7.2.5	See Equation (128–3)	dB

[a]The receiver shall tolerate amplitudes up to a maximum voltage of 1200mV without permanent damage.
[b]Relative to 100 Ω differential.

128.7.2.1 Receiver interference tolerance

The receiver interference tolerance consists of the test as described in Annex 69A with the parameters specified in Table 128–6. The data pattern for the interference tolerance test shall be the test pattern as defined in 48A.5. The receiver shall satisfy the requirements for interference tolerance specified in Annex 69A for the test.

Table 128–6—2.5GBASE-KX interference tolerance parameters

Parameter	Value	Units
Target BER	10^{-12}	
m_{TC}[a] (min)	1	
Amplitude of broadband noise (min RMS)	8.1	mV
Applied transition time (20%–80%, min)	100	ps
Applied sinusoidal jitter (min peak-to-peak)	0.12	UI
Applied random jitter (min peak-to-peak)[b]	0.2	UI

[a]m_{TC} is defined in Equation (69A–6) in Annex 69A.
[b]Applied random jitter is specified at a BER of 10^{-12}.

128.7.2.2 Signaling speed range

The signaling speed of a 2.5GBASE-KX receiver shall comply with the requirements of Table 128–5.

128.7.2.3 AC-coupling

The 2.5GBASE-KX receiver shall be AC-coupled to the backplane to allow for maximum interoperability between various 2.5 Gb/s components. AC-coupling is considered to be part of the receiver for the purposes of this specification unless explicitly stated otherwise. It should be noted that there may be various methods for AC-coupling in actual implementations.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—It is recommended that the maximum value of the coupling capacitors be limited to 100 nF. This will limit the inrush currents to the receiver that could damage the receiver circuits when repeatedly connected to transmit modules with a higher voltage level.

128.7.2.4 Input signal amplitude

2.5GBASE-KX receivers shall accept differential input signal peak-to-peak amplitudes produced by compliant transmitters connected without attenuation to the receiver, and still meet the BER requirement specified in 128.7.2.1. Note that this may be larger than the differential maximum of 128.7.1.4 due to the actual transmitter output and receiver input impedances. The input impedance of a receiver can cause the minimum signal into a receiver to differ from that measured when the receiver is replaced with a 100 Ω test load. Since the receiver is AC-coupled, the absolute voltage levels with respect to the receiver ground are dependent on the receiver implementation.

128.7.2.5 Differential input return loss

For frequencies from 100 MHz to 2000 MHz, the differential input return loss, in dB, of the receiver shall meet the requirements of Table 128–5.

128.8 Interconnect characteristics

Informative interconnect characteristics are provided in Annex 69B.

128.9 Environmental specifications

128.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

128.9.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

128.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

128.9.4 Electromagnetic compatibility

A system integrating the 2.5GBASE-KX PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

128.9.5 Temperature and humidity

A system integrating the 2.5GBASE-KX PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

128.10 Protocol implementation conformance statement (PICS) proforma for Clause 128, Physical Medium Dependent sublayer and baseband medium, type 2.5GBASE-KX[220]

128.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 128, Physical Medium Dependent sublayer and baseband medium type 2.5GBASE-KX, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

128.10.2 Identification

128.10.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

128.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 128, Physical Medium Dependent sublayer and baseband medium type 2.5GBASE-KX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022)

129. Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 5 Gb/s 64B/66B, type 5GBASE-R

129.1 Overview

129.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) and the Physical Medium Attachment (PMA) Sublayer that is common to a family of 5 Gb/s Physical Layer implementations, known as 5GBASE-R. The 5GBASE-R PCS and 5GBASE-R PMA are sublayers of the 5 Gb/s BASE-R PHY listed in Table 125–1. The term 5GBASE-R is used when referring generally to Physical Layers using the PCS and PMA defined in this clause.

129.1.2 Relationship of 5GBASE-R to other standards

Figure 125–1 depicts the relationships among the 5GBASE-R sublayers, the Ethernet MAC and reconciliation layers, and the higher layers. The 5GBASE-R service interface is the XGMII, which is defined in Clause 46.

The 5GBASE-R PCS is identical to the 10GBASE-R PCS specified in Clause 49 with the exception that the BER Monitor process asserts hi_ber if ber_cnt reaches 16 in a 250 μs period. This differs from the definition in 49.2.13.3 where it asserts hi_ber if ber_cnt reaches 16 in a 125 μs period.

The purpose of the serial PMA is to attach the PMD of choice to its client. The PMA service interface is defined in an abstract manner and does not imply any particular implementation. The nominal bit rate of the PMA is 5.15625 Gb/s.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

129.1.3 Summary of 5GBASE-R sublayers

Figure 129–1 depicts the relationship between the 5GBASE-R PCS and its associated sublayers.

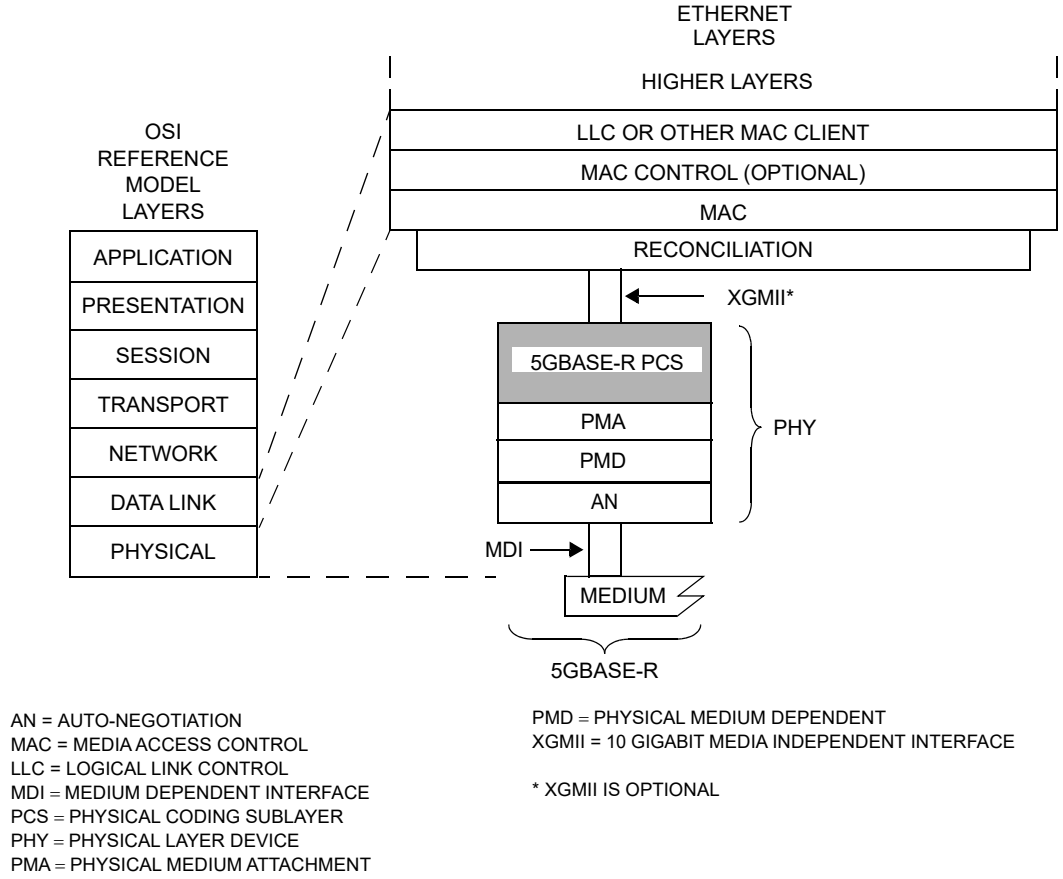

Figure 129–1—5GBASE-R PCS and PMA relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

129.1.3.1 Physical Coding Sublayer (PCS)

The PCS service interface is the XGMII, which is defined in Clause 46 operating at 5 Gb/s. The 5GBASE-R PCS provides all services required by the XGMII, including encoding (decoding) of eight XGMII data octets to (from) 66-bit blocks (64B/66B) for communication with the underlying PMA.

129.1.3.2 Physical Medium Attachment (PMA) sublayer

The PMA provides a medium-independent means for the PCS to support the use of serial-bit oriented physical media. The 5GBASE-R PMA performs the following functions:

In the transmit direction (i.e., transmitting data from the PMA client to the PMD), the PMA performs the following functions:

a) Provide transmit source clock to PMA client
b) Serialization of 16-bit data to serial bit stream.
c) Transmission of serial data to PMD.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the receive direction (i.e., serial data from PMD to the PMA client), the PMA performs the following functions:

a1) Bit clock recovery of serial data from PMD.
b1) Provide receive clock to PMA client.
c1) Deserialization of serial data to16-bit parallel data.
d1) Transmission of parallel data to PMA client.
e1) Provide link status information.

129.1.4 Inter-sublayer interfaces

There are a number of interfaces employed by 5GBASE-R. Some (such as the PMA service interface) use an abstract service model to define the operation of the interface. The PCS service interface is the XGMII running at 5 Gb/s that is defined in Clause 46. The XGMII has an optional physical instantiation.

The upper interface of the PCS may connect to the Reconciliation Sublayer through the XGMII. The lower interface of the PCS connects to the PMA sublayer to support a 5GBASE-KR PMD. The nominal rate of the PMA service interface is 322.265625 Mtransfers/s, which provides capacity for the MAC data rate of 5 Gb/s.

The nominal rate of the PMD service interface is 5.15625 Gb/s.

If the optional Energy-Efficient Ethernet (EEE) capability is supported (see Clause 78, 78.3), then the interface with the PMA sublayer includes rx_mode and tx_mode to control power states in lower sublayers and energy_detect that indicates whether the PMD sublayer has detected a signal at the receiver.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience.

129.2 Physical Coding Sublayer (PCS)

129.2.1 Functions within the PCS

The 5GBASE-R PCS shall have all the functionality of the 10GBASE-R PCS specified in Clause 49.

The BER monitor state diagram shown in Figure 49–15 applies but the definition of “ber_cnt” in 49.2.13.2.4 is replaced with “Count up to a maximum of 16 of the number of invalid sync headers within the current 250 μs period.” and the ber_cnt definition in 49.2.14.2 is similarly modified.

The PCS encodes data and control information into 66-bit blocks. The relationship of block bit positions to the XGMII, PMA, and other PCS constructs is illustrated in Figure 129–2 for transmit and Figure 129–3 for receive (see figures in 129.2.3).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

129.2.2 Notation conventions

For values shown as binary, the leftmost bit is the first transmitted bit.

Two consecutive XGMII transfers provide eight characters that are encoded into one 66-bit transmission block.

129.2.3 Transmission order

Block bit transmission order is illustrated in Figure 129–2 and Figure 129–3. These figures show the mapping from XGMII to 64B/66B block for a block containing eight data characters.

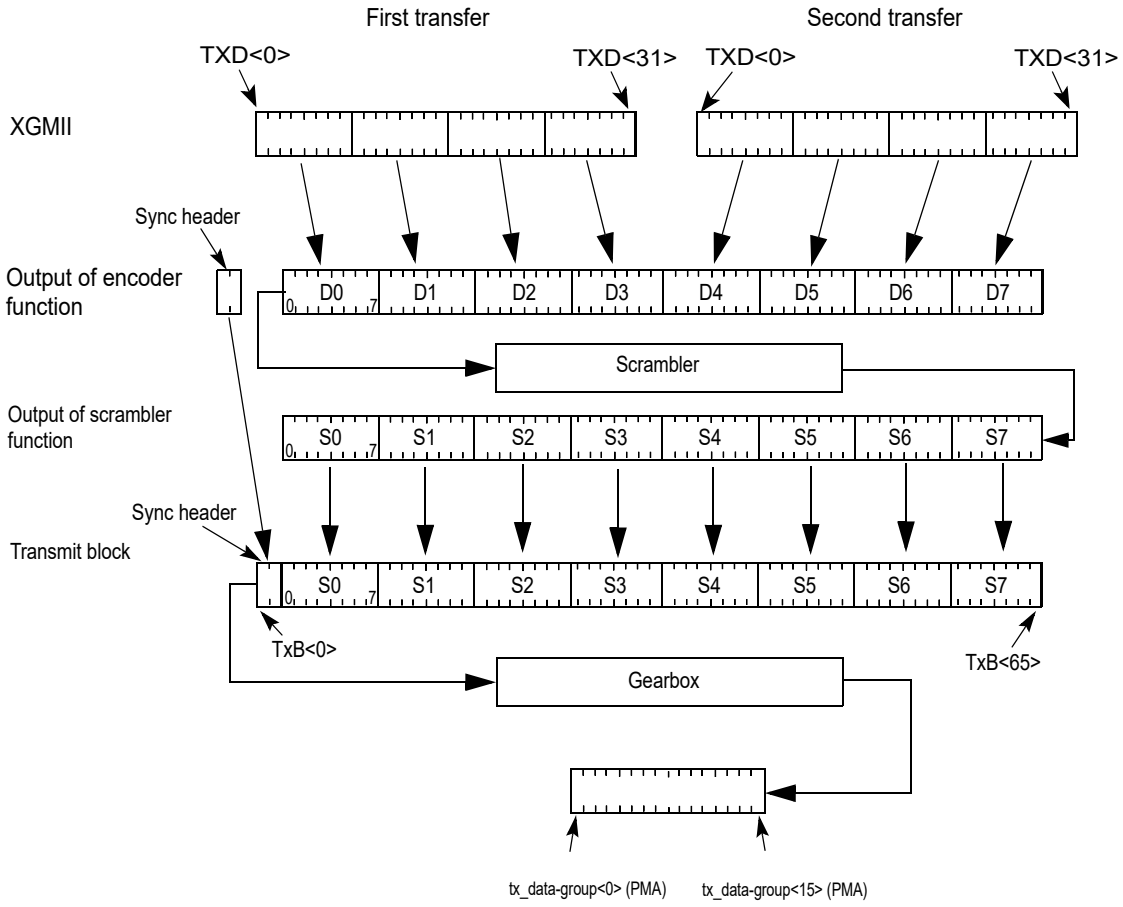

Figure 129–2—PCS Transmit bit ordering

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

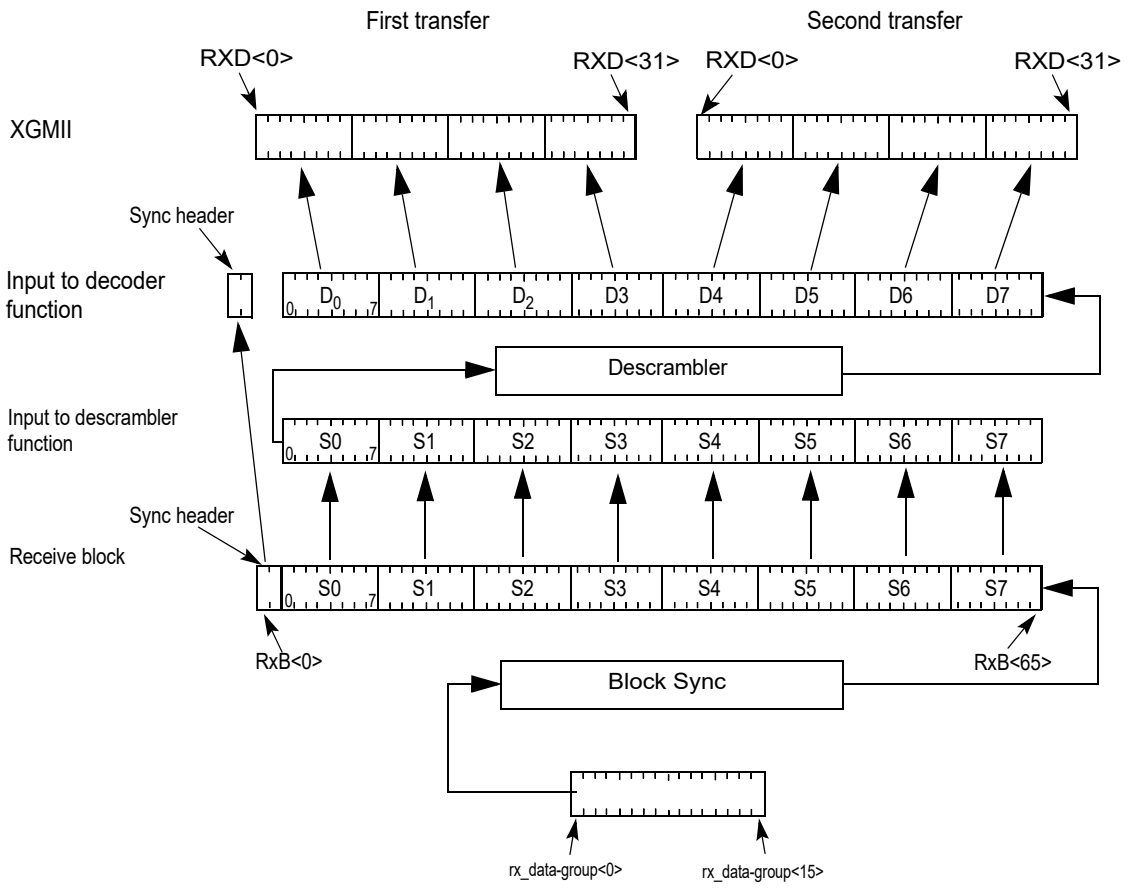

Figure 129–3—PCS Receive bit ordering

129.2.4 Low Power Idle

If the 5GBASE-KR PCS is a part of a PHY configured for EEE operation, the PCS shall follow the state diagrams specified in Figure 49–12 and Figure 49–13.

The LPI functions shall use timer values for these state diagrams as shown in Table 129–1 for transmit and Table 129–2 for receive.

Table 129–1—Transmitter LPI timing parameters

Parameter	Description	Min	Max	Units
T_{SL}	Local Sleep Time from entering the TX_SLEEP state to when tx_mode is set to QUIET	4.9	5.1	µs
T_{QL}	Local Quiet Time from when tx_mode is set to QUIET to entry into the TX_ALERT state	1.7	1.8	ms
T_{WL}	Time spent in the TX_WAKE state	10.9	11.1	µs
T_{1U}	Time spent in the TX_ALERT and TX_SCR_BYPASS states	1.1	1.3	µs

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 129–2—Receiver LPI timing parameters

Parameter	Description	Min	Max	Units
T_{QR}	The time the receiver waits for energy_detect to be set to TRUE while in the RX_SLEEP and RX_QUIET states before asserting receive fault	2	3	ms
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault (when scr_bypass_enable = FALSE)	—	11.5	μs
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault (when scr_bypass_enable = TRUE)	—	13.7	μs
T_{WTF}	Wake time fault recovery time	—	10	ms

129.2.5 PCS used with 5GBASE-KR PMD

The following requirements apply to a PCS used with a 5GBASE-KR PMD. Support for the Auto-Negotiation process defined in Clause 73 is mandatory. The PCS shall support the primitive AN_LINK.indication(link_status) (see 73.9). The parameter link_status shall take the value FAIL when PCS_status=false and the value OK when PCS_status=true. The primitive shall be generated when the value of link_status changes.

129.3 Physical Medium Attachment (PMA) sublayer

129.3.1 Service Interface

The Serial PMA provides a Service Interface to the 5G BASE-R PCS. These services are described in an abstract manner and do not imply any particular implementation. The PMA Service Interface shall support the exchange of data-groups between the PMA and the PMA client. The PMA converts data-groups into bits and passes these to the PMD, and vice versa. It also generates an additional status indication for use by its client.

The following primitives are defined:

PMA_UNITDATA.request(tx_data-group<15:0>)
PMA_UNITDATA.indication (rx_data-group<15:0>)
PMA_SIGNAL.indication(SIGNAL_OK)
PMA_RXMODE.request(rx_mode)
PMA_TXMODE.request(tx_mode)
PMA_ENERGY.indication(energy_detect)

The definitions of these primitives are found in 51.2.

129.3.2 Functions within the PMA

The PMA comprises the PMA Transmit and PMA Receive processes for 5GBASE-R. The PMA Transmit process serializes the tx_data-groups and passes them to the PMD for transmission on the underlying medium. Similarly, the PMA Receive process deserializes received data from the PMD and presents the data as rx_data-groups to the PMA client. The PMA receiver continuously conveys 16-bit data-groups to the PMA client, independent of data-group alignment.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

129.3.2.1 PMA transmit function

The PMA Transmit function passes data unaltered (except for serializing) from the PMA client directly to the PMD. Upon receipt of a PMA_UNITDATA.request primitive, the PMA Transmit function shall serialize the 16 bits of the tx_data-group<15:0> parameter and transmit them to the PMD in the form of 16 successive PMD_UNITDATA.request primitives.

129.3.2.2 PMA receive function

The PMA Receive function passes data unaltered from the PMD directly to the PMA client. Upon receipt of 16 successive PMD_UNITDATA.indication primitives, the PMA shall assemble the 16 received bits into a single 16-bit value and pass that value to the PMA client as the rx_data-group<15:0> parameter of the primitive PMA_UNITDATA.indication. The PMA receive function does not align rx_datagroup<15:0> to the original tx_data-group<15:0> from the remote end of the link.

129.3.3 PMA loopback mode (optional)

PMA loopback is optional. If PMA loopback is implemented, it shall conform to the requirements of 51.8.

129.4 Compatibility considerations

There is no requirement for a compliant device to implement or expose any of the interfaces specified for the PCS or PMA. Implementations of a XGMII shall comply with the requirements as specified in Clause 46.

129.5 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The sum of transmit and receive delay contributed by the 5GBASE-R PCS and PMA shall be no more than 3584 bit-times.

129.6 Environmental specifications

All equipment subject to this clause shall conform to the requirements of 51.9.

129.7 Protocol implementation conformance statement (PICS) proforma for Clause 129, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 5 Gb/s 64B/66B, type 5GBASE-R [221]

129.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 129, Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayer for 5 Gb/s 64B/66B, type 5GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

129.7.2 Identification

129.7.2.1 Implementation identification

129.7.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
XGE	XGMII compatibility interface	129.1.4	Compatibility interface is supported	O	Yes [ ] No [ ]
*MD	MDIO	Clause 45, 49.2.14	Registers and interface supported	O	Yes [ ] No [ ]
PCS	5GBASE-R PCS	129.2.1, 49	Support PCS in Clause 49 as modified in 129.2.1	M	Yes [ ]
BER	BER Monitor test counter	129.2.1, 49	ber_cnt of 16 in a period of 250 µs	M	Yes [ ]
*LPI	Implementation of LPI	Clause 78		O	Yes [ ] No [ ]

129.7.4 PICS Proforma Tables for PCS, type 5GBASE-R

129.7.4.1 Coding rules

Item	Feature	Subclause	Value/Comment	Status	Support
C1	Encoder implements the code as specified	49.2.13.2.3 and 49.2.4		M	Yes [ ]
C2	Decoder implements the code as specified	49.2.13.2.3 and 49.2.4		M	Yes [ ]
C3	IDLE control code insertion and deletion	49.2.4.7	Insertion or Deletion in groups of 4 /I/s	M	Yes [ ]
C4	IDLE control code deletion	49.2.4.7	When deleting /I/s, the first four characters after a /T/ shall not be deleted.	M	Yes [ ]
C5	Sequence ordered set deletion	49.2.4.10	Only one whole ordered set of two consecutive sequence ordered sets may be deleted	M	Yes [ ]

129.7.4.2 Scrambler and Descrambler

Item	Feature	Subclause	Value/Comment	Status	Support
S1	Scrambler	49.2.6	Performs as shown in Figure 49–8	M	Yes [ ]
S2	Descrambler	49.2.10	Performs as shown in Figure 49–10	M	Yes [ ]

129.7.5 Test-pattern modes

Item	Feature	Subclause	Value/Comment	Status	Support
JT1	Square wave and pseudo-random transmit test-pattern generators are implemented	49.2.8	Performs as in 49.2.8	M	Yes [ ]
JT2	Pseudo-random receive test-pattern checker is implemented	49.2.12	Performs as in 49.2.12	M	Yes [ ]
*JT3	Support for PRBS31 test pattern	49.2.8		O	Yes [ ] No [ ]
JT4	PRBS31 test-pattern generator is implemented	49.2.8	Performs as in 49.2.8	JT3:M	Yes [ ] N/A[ ]
JT5	PRBS31 test-pattern checker is implemented	49.2.12	Performs as in 49.2.12	JT3:M	Yes [ ] N/A[ ]
*JT6	Support for PRBS9 transmit test pattern	49.2.8		O	Yes [ ] No [ ]
JT7	PRBS9 transmit test pattern is implemented	49.2.8	Performs as in 49.2.8	JT6:M	Yes [ ] N/A[ ]

129.7.5.1 Bit order

Item	Feature	Subclause	Value/Comment	Status	Support
B1	Transmit bit order	49.2.7	Placement of bits into tx_data-group<15:0> as specified in 49.2.7	M	Yes [ ]
B2	Receive bit order	49.2.9	Placement of bits from rx_data-group<15:0> into blocks as specified in 49.2.9	M	Yes [ ]

129.7.6 Management

Item	Feature	Subclause	Value/Comment	Status	Support
M1	Equivalent access to PCS Management objects is provided	49.2.14		!MD:O	Yes [ ] No [ ] N/A [ ]

129.7.6.1 State diagrams

Item	Feature	Subclause	Value/Comment	Status	Support
SM1	Lock	49.2.13.3	Meets the requirements of Figure 49–14	M	Yes [ ]
SM2	BER Monitor	49.2.13.3	Meets the requirements of Figure 49–15	M	Yes [ ]
SM3	Transmit	49.2.13.3	Meets the requirements of Figure 49–16	M	Yes [ ]
SM4	Receive	49.2.13.3	Meets the requirements of Figure 49–17	M	Yes [ ]

129.7.6.2 Loopback

Item	Feature	Subclause	Value/Comment	Status	Support
LB1	PMA Loopback	129.3.3	Conform to the requirements of 51.8	O	Yes [ ] No [ ]

129.7.6.3 Delay Constraints

Item	Feature	Subclause	Value/Comment	Status	Support
TIM1	PCS Delay Constraint	49.2.15	No more than 3584 BT for sum of transmit and receive path delays	M	Yes [ ]

129.7.6.4 Auto-Negotiation for Backplane Ethernet functions

Item	Feature	Subclause	Value/Comment	Status	Support
AN1	Support for use with a 5GBASE-KR PMD	49.2.16	AN technology dependent interface described in Clause 73	M	Yes [ ]
AN2	AN_LINK.indication primitive	49.2.16 and 129.2.5	Support of the primitive AN_LINK.indication(link_status), when the PCS is used with 5GBASE-KR PMD. Primitive generated when link_status changes.	M	Yes [ ]
AN3	link_status parameter	49.2.16 and 129.2.5	Takes the value OK or FAIL, as described in 49.2.16	M	Yes [ ]
AN4	Generation of AN_LINK.indication primitive	49.2.16 and 129.2.5	Generated when the value of link_status changes	M	Yes [ ]

130. Physical Medium Dependent sublayer and baseband medium, type 5GBASE-KR

130.1 Overview

This clause specifies the 5GBASE-KR PMD and the baseband medium. When forming a complete PHY, a PMD shall be connected to the appropriate sublayers (see Table 130–1), and with the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent. References to the MDI (Media Dependent Interface) should be considered to be TP1 for the transmitter and TP4 for the receiver, as measurement points.

Table 130–1—Physical Layer clauses associated with the 5GBASE-KR PMD

Associated clause	5GBASE-KR
46—XGMII[a]	Optional
73—Auto Negotiation for Backplane	Required
78—EEE	Optional
129—PCS and PMA for 64B/66B	Required

[a]The XGMII is an optional interface. However, if the XGMII is not implemented, a conforming implementation behaves functionally as though the RS and XGMII were present.

A 5GBASE-KR PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization.

130.2 Physical Medium Dependent (PMD) service interface

The following specifies the services provided by the 5GBASE-KR PMDs. These PMD sublayer service interfaces are described in an abstract manner and do not imply any particular implementation.

The PMD Service Interface supports the exchange of encoded and scrambled 64B/66B blocks between the PMA and PMD entities. The PMD translates the serialized data of the PMA to and from signals suitable for the specified medium.

The following primitives are defined:

PMD_UNITDATA.request(tx_bit)
PMD_UNITDATA.indication(rx_bit)
PMD_SIGNAL.indication(SIGNAL_DETECT)

If EEE is supported, the following primitives are also defined on the PMD Service Interface:

PMD_RX_MODE.request(rx_mode)
PMD_TX_MODE.request(tx_mode)

These messages affect the PCS variables as described in 49.2.13.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130.2.1 PMD_UNITDATA.request

This primitive defines the transfer of a serial data stream from the PMA to the PMD.

130.2.1.1 Semantics of the service primitive

PMD_UNITDATA.request(tx_bit)

The data conveyed by PMD_UNITDATA.request is a continuous stream of bits. The tx_bit parameter can take one of two values: ONE or ZERO.

130.2.1.2 When generated

The PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at the signaling speed specified in Table 130–4 for 5GBASE-KR PMD types.

130.2.1.3 Effect of receipt

Upon receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals on the MDI.

130.2.2 PMD_UNITDATA.indication

This primitive defines the transfer of data (in the form of serialized data) from the PMD to the PMA.

130.2.2.1 Semantics of the service primitive

PMD_UNITDATA.indication(rx_bit)

The data conveyed by PMD_UNITDATA.indication is a continuous stream of bits. The rx_bit parameter can take one of two values: ONE or ZERO.

130.2.2.2 When generated

The PMD continuously sends a stream of bits to the PMA corresponding to the signals received from the MDI.

130.2.2.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

130.2.3 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

130.2.3.1 Semantics of the service primitive

PMD_SIGNAL.indication(SIGNAL_DETECT)

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting signal at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication(rx_bit) is undefined.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA.indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient signal for a SIGNAL_DETECT = OK indication and still not meet the BER objective.

130.2.3.2 When generated

The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT. If the MDIO interface is implemented, then PMD_global_signal_detect shall be continuously set to the value of SIGNAL_DETECT.

130.2.3.3 Effect of receipt

The effect of receipt of this primitive by the client is unspecified by the PMD sublayer.

130.2.4 PMD_RX_MODE.request

This primitive is generated by the PCS Receive Process when EEE is supported to indicate that the input signal is quiet and the PMA and PMD receiver may go into a low power mode. When EEE is not supported, the primitive is never invoked, and the PMD behaves as if rx_mode = DATA.

130.2.4.1 Semantics of the service primitive

PMD_RX_MODE.request(rx_mode)

The rx_mode parameter takes on one of two values: QUIET or DATA.

130.2.4.2 When generated

The PCS generates this primitive to request the appropriate PMD receive LPI state.

130.2.4.3 Effect of receipt

When rx_mode is QUIET, the PMD receive function may deactivate functional blocks to conserve energy. When rx_mode is DATA, the PMD receive function operates normally.

130.2.5 PMD_TX_MODE.request

This primitive is generated by the PCS Transmit Process when EEE is supported to indicate that the PMA and PMD transmit functions may go into a low power mode and to disable the PMD transmitter. See 130.6.5. When EEE is not supported, the primitive is never invoked, and the PMD behaves as if tx_mode = DATA.

130.2.5.1 Semantics of the service primitive

PMD_TX_MODE.request(tx_mode)

The tx_mode parameter takes on one of three values: QUIET, ALERT, or DATA.

130.2.5.2 When generated

The PCS generates this primitive to request appropriate PMD transmit LPI state.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130.2.5.3 Effect of receipt

When tx_mode is QUIET, the PMD Transmit function may deactivate functional blocks to conserve energy. When tx_mode is ALERT, the PMD Transmit function transmits the alert pattern. When tx_mode is DATA, the PMD Transmit function operates normally.

130.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD shall support the AN service interface primitive AN_LINK.indication defined in 73.9.

130.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementers consider the delay maxima, and that network planners and administrators consider the delay constraints regarding concatenation of devices.

The sum of the transmit and the receive delays contributed by the 5GBASE-KR PMD and medium shall be no more than 512 bit times. It is assumed that the round-trip delay through the medium is 80 bit times.

130.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 130–2 and MDIO status variables to PMD status variables as shown in Table 130–3.

Table 130–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	Control register 1	1.0.15	PMD_reset
Global PMD Transmit Disable	Transmit disable register	1.9.0	Global_PMD_transmit_disable

Table 130–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	Status register 1	1.1.7	PMD_fault
Transmit fault	Status register 2	1.8.11	PMD_transmit_fault
Receive fault	Status register 2	1.8.10	PMD_receive_fault
Global PMD Receive signal detect	Receive signal detect register	1.10.0	Global_PMD_signal_detect

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130.6 PMD functional specifications

130.6.1 Link block diagram

For purposes of system conformance, the PMD sublayer is standardized at test points TP1 and TP4 as shown in Figure 130–1. The transmitter and receiver blocks include all off-chip components associated with the respective block. For example, external AC-coupling capacitors, if required, are to be included in the receiver block.

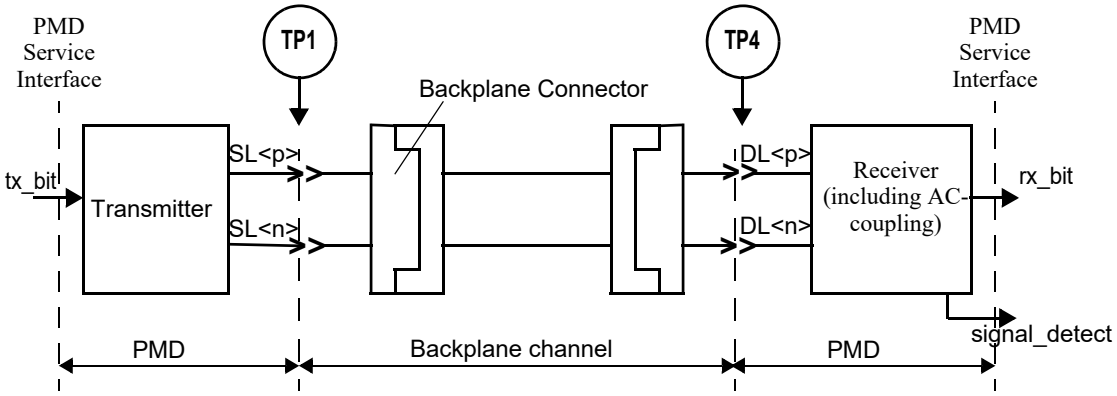

Figure 130–1—Link block diagram

The electrical path from the transmitter block to TP1, and from TP4 to the receiver block, will affect link performance and the measured values of electrical parameters used to verify conformance to this standard. Therefore, it is recommended that this path be carefully designed.

130.6.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the specifications in this clause. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = ONE.

If the optional Energy-Efficient Ethernet (EEE) capability is supported (see Clause 78), then when tx_mode is set to ALERT, the PMD shall transmit a repeating 16-bit pattern, hexadecimal 0xFF00.

130.6.3 PMD receive function

The PMD Receive function shall convey the bits received from the MDI according to the electrical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = ONE.

130.6.4 PMD signal detect function

The Global_PMD_signal_detect function reports to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is used by 5GBASE-R PHYs as an indicator of valid signal presence. SIGNAL_DETECT shall be set to FAIL following system reset.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the PMD signal detect function is implemented, its definition is beyond the scope of this specification. When PMD signal detect is not implemented, the value of SIGNAL_DETECT shall be set to OK for purposes of management and signaling of the primitive. PMD signal detect is mandatory if EEE is supported.

When the PHY supports the optional EEE capability, PMD_SIGNAL.indication is used to indicate when the ALERT signal is detected, which corresponds to the beginning of a refresh or a wake. If the MDIO interface is implemented, then Global_PMD_signal_detect (1.10.0) shall be continuously set to the value of SIGNAL_DETECT as described in 45.2.1.9.7.

When the PHY supports the EEE capability, SIGNAL_DETECT is set to FAIL following a transition from rx_mode = DATA to rx_mode = QUIET. When rx_mode = QUIET, SIGNAL_DETECT shall be set to OK within 500 ns following the application of a signal at the receiver input that is the output of a channel that satisfies the requirements of all the parameters of both interference tolerance test channels defined in 130.7.2.1 when driven by a square wave pattern with a period of 16 unit intervals and peak-to-peak differential output amplitude of 720 mV. While rx_mode = QUIET, SIGNAL_DETECT changes from FAIL to OK only after a valid ALERT signal is applied to the channel.

SIGNAL_DETECT shall be set to FAIL following system reset.

130.6.5 PMD transmit disable function

The Global_PMD_transmit_disable function is mandatory if EEE is supported and is otherwise optional. When this function is supported, it shall meet the following requirements:

a) When the Global_PMD_transmit_disable variable is set to ONE, this function shall turn off the transmitter such that it drives a constant level (i.e., no transitions) and does not exceed the maximum peak-to-peak differential output voltage specified in Table 130–4.
b) If a PMD_fault (130.6.7) is detected, then the PMD may turn off the electrical transmitter.
c) Loopback, as defined in 130.6.6, shall not be affected by Global_PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off the transmitter after tx_mode is set to QUIET within a time and voltage level specified in 130.7.1.4. The PMD_transmit_disable function shall turn on the transmitter after tx_mode is set to DATA or ALERT within the time and voltage level specified in 130.7.1.4.

If the MDIO interface is implemented, then this function shall map to the Global_PMD_transmit_disable bit as specified in 45.2.1.8.7.

130.6.6 Loopback mode

Loopback mode shall be provided for the 5GBASE-KR PMD by the transmitter and receiver of a device as a test function to the device. When loopback mode is selected, transmission requests passed to the transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. This bit does not affect the state of the transmitter. The method of implementing loopback mode within the PMD is not defined by this standard.

Control of the loopback function is specified in 45.2.1.1.5.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130.6.7 PMD_fault function

If the MDIO is implemented, PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault.

130.6.8 PMD transmit fault function

The PMD_transmit_fault function is optional. The faults detected by this function are implementation specific, but should not include the assertion of the Global_PMD_transmit_disable function.

If a PMD_transmit_fault (optional) is detected, then the Global_PMD_transmit_disable function should also be asserted.

If the MDIO interface is implemented, then this function shall be mapped to the PMD_transmit_fault bit as specified in 45.2.1.7.4.

130.6.9 PMD receive fault function

The PMD_receive_fault function is optional. The faults detected by this function are implementation specific.

If the MDIO interface is implemented, then this function shall contribute to PMA/PMD receive fault bit as specified in 45.2.1.7.5.

130.6.10 PMD LPI function

The PMD LPI function responds to the transitions between Active, Sleep, Quiet, Refresh, and Wake states via the PMD_TX_MODE and PMD_RX_MODE requests. Implementation of the function is optional. The PMD LPI function responds to the transitions between Active, Sleep, Quiet, Refresh, and Wake states via the PMD_TX_MODE and PMD_RX_MODE requests. Implementation of the function is optional. EEE capabilities and parameters will be advertised during the Backplane Auto-negotiation, as described in 45.2.7.16. The transmitter on the local device will inform the link partner's receiver when to sleep, refresh and wake. The local receiver transitions are controlled by the link partner's transmitter and can change independent of the local transmitter states and transitions.

The “Assert LPI” request at the XGMII is encoded in the transmitted symbols. Detection of LPI signaling in the received symbols is indicated as “Assert LPI” at the XGMII. Upon the detection of “Assert LPI” at the XGMII, an energy-efficient 5GBASE-KR PHY continues transmitting for a predefined period, then ceases transmission and deactivates transmit functions to conserve energy. The PHY periodically transmits during this quiet period to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variations in the timing of the link or the underlying channel characteristics. If, during the quiet or refresh periods, normal interframes resume at the XGMII, the PHY reactivates transmit functions and initiates transmission. This transmission will be detected by the remote PHY, causing it to also exit the LPI mode.

130.7 5GBASE-KR electrical characteristics

130.7.1 Transmitter characteristics

Transmitter characteristics at TP1 (see Figure 130–1) are summarized in Table 130–4 and detailed in 130.7.1.1 through 130.7.1.10.

Table 130–4—Transmitter characteristics for 5GBASE-KR

Parameter	Subclause reference	Value	Units
Signaling speed	130.7.1.3	5.15625 ± 100 ppm	GBd
Peak-to-peak differential output voltage (max)	130.7.1.4	1200	mV
Peak-to-peak differential output voltage (min)	130.7.1.4	800	mV
Peak-to-peak differential output voltage (max) with TX disabled	130.6.5	30	mV
Pre-cursor equalization ratio (R_{pre})	130.7.1.10	1.25 ± 0.05	
Common-mode voltage limits[c]	130.7.1.4	0 to +1.9	V
Common-mode voltage deviation (max) during LPI	130.7.1.4	150	mV
Differential output return loss (min)	130.7.1.5	See Equation (130–3) and Equation (130–4)	dB
Common-mode output return loss (min)	130.7.1.6	See Equation (130–5) and Equation (130–6)	dB
Transition time (20%–80%)	130.7.1.7	20 to 60	ps
Max output jitter (peak-to-peak) Random jitter[a] Deterministic jitter Duty Cycle Distortion[b] Total jitter	 130.7.1.9 130.7.1.9 130.7.1.9 130.7.1.9	 0.15 0.12 0.035 0.27	 UI UI UI UI

[a]Jitter is specified at BER 10^{-12}.
[b]Duty Cycle Distortion is considered part of the deterministic jitter distribution.
[c]Defined with respect to signal ground as measured at Vcom in Figure 130–2.

130.7.1.1 Test fixture

The test fixture of Figure 130–2, or its functional equivalent, is required for measuring the transmitter specifications described in 130.7.1, with the exception of return loss.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

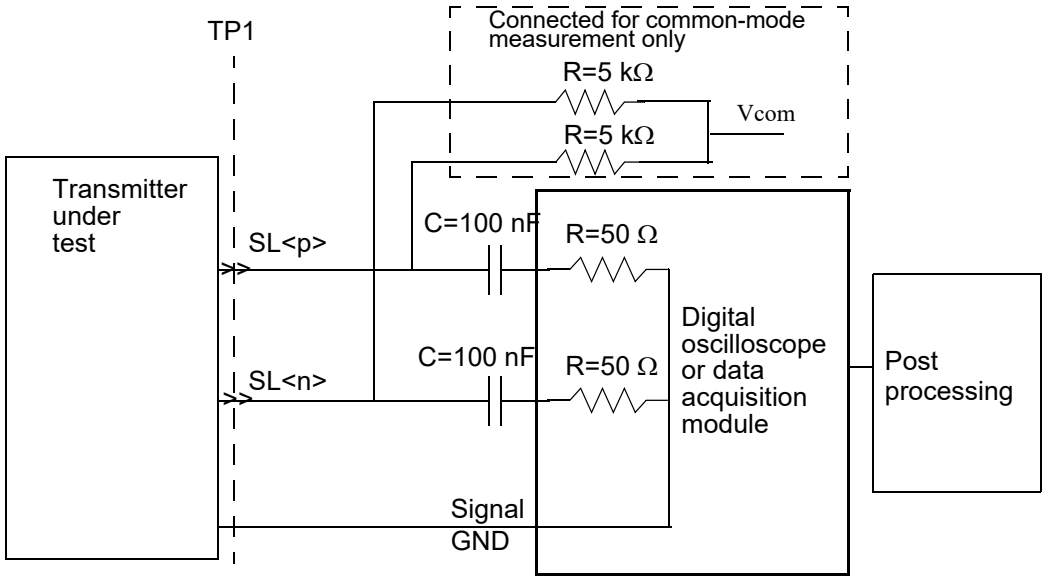

Figure 130–2—Transmit test fixture for 5GBASE-KR

130.7.1.2 Test fixture characteristics

The differential load impedance applied to the transmitter output by the test fixture depicted in Figure 130–2 shall be 100 Ω. The differential return loss, in dB, of the test fixture shall meet the requirements of Equation (130–1) and Equation (130–2).

$$Return_loss(f) \geq 20 \tag{130–1}$$

for 100 MHz ≤ f < 2579 MHz

$$Return_loss(f) \geq Return_loss_{min} = 20 - 26.55\log_{10}\left(\frac{f}{2579\text{MHz}}\right) \tag{130–2}$$

for 2579 MHz ≤ f ≤ 5156.25 MHz

130.7.1.3 Signaling speed

The 5GBASE-KR signaling speed shall be as specified in Table 130–4.

130.7.1.4 Output amplitude

The differential output voltage is constrained via the transmitter output waveform requirements specified in 130.7.1.10. The peak-to-peak differential output voltage shall be as specified in Table 130–4. See Figure 130–3. The differential output voltage test pattern is the square wave test pattern defined in 52.9.1.2, with a run of at least eight consecutive ones followed by an equal number of consecutive zeros.

NOTE—SL<p> and SL<n> are the positive and negative sides of the differential signal pair.

DC-referenced voltage levels are not defined since the receiver is AC-coupled. The common-mode voltage of SL<p> and SL<n>, with respect to signal ground, shall be measured at Vcom in Figure 130–2, with the value as specified in Table 130–4.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

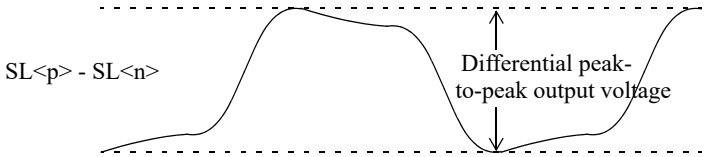

Figure 130–3—Transmitter peak-to-peak differential output voltage definition

For EEE capability, the transmitter shall meet the Table 130–4 requirement for differential peak to peak output voltage when TX is disabled within 500 ns of tx_mode being set to QUIET and remain so while tx_mode is set to QUIET. Furthermore, the transmitter's peak-to-peak differential output voltage shall be greater than 720 mV within 500 ns of tx_mode being set to ALERT. The transmitter output shall be fully compliant within 5 μs after tx_mode is set to DATA. During LPI mode, the common-mode voltage shall not deviate from the pre-LPI value by more than that allowed in Table 130–4.

130.7.1.5 Differential output return loss

For frequencies from 100 MHz to 3750 MHz, the differential output return loss, in dB, of the transmitter shall meet the requirements of Table 130–4. This output impedance requirement applies to all valid output levels. The reference impedance for differential output return loss measurements shall be 100 Ω.

$$Return_loss \geq 10 \tag{130–3}$$

for 100 MHz ≤ f < 1289 MHz and,

$$Return_loss(f) \geq Return_loss_{min} = 10 - 13.275\log_{10}\left(\frac{f}{1289\,\text{MHz}}\right) \tag{130–4}$$

for 1289 MHz ≤ f ≤ 3750 MHz.

The minimum differential output return loss is shown in Figure 130–4.

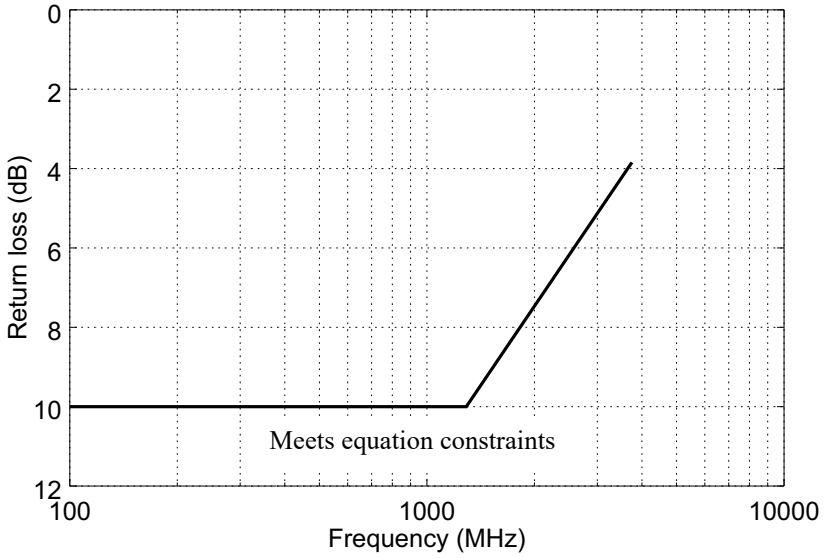

Figure 130–4—Transmit output differential-mode return loss limit

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130.7.1.6 Common-mode output return loss

The transmitter common-mode return loss shall meet the requirements of Table 130–4. The reference impedance for common-mode return loss measurements is 25 Ω.

$$Return_loss \geq 7 \tag{130–5}$$

for 100 MHz ≤ f < 1250 MHz,

$$Return_loss(f) \geq 7 - 13.275 \log_{10}\left(\frac{f}{1250\text{MHz}}\right) \tag{130–6}$$

for 1250 MHz ≤ f ≤ 3750 MHz.

The minimum common-mode output return loss is shown in Figure 130–5.

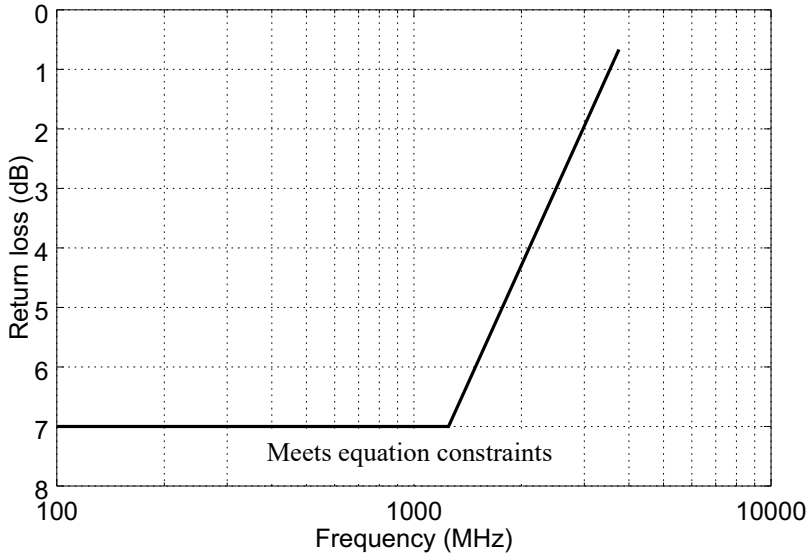

Figure 130–5—Transmit common-mode output return loss limit

130.7.1.7 Transition time

The rising and falling edge transition times shall be as specified in Table 130–4 when measured with respect to v_1 and v_3 as defined in Figure 130–7. Measurement is done using the square wave test pattern defined in 52.9.1.2, with no equalization (bit 1.150.2 in Table 45–75 set to '1') and a run of at least eight consecutive ones followed by an equal number of consecutive zeros.

The BASE-R PMD control register is also used by 5GBASE-KR described in Clause 130 to disable the transmitter equalizer for test purposes. 5GBASE-KR does not use the startup protocol.

130.7.1.8 Transmit jitter test requirements

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in Annex 48B.3. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 4 MHz is applied to the jitter. The data pattern for jitter measurements shall be test

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

patterns 2 or 3 as defined in 52.9.1.1. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal. Equalization shall be off during jitter testing (bit 1.150.2 in Table 45–75 set to '1').

The duty cycle distortion test pattern shall consist of no fewer than eight symbols of alternating polarity (e.g., a 10101010… bit sequence).

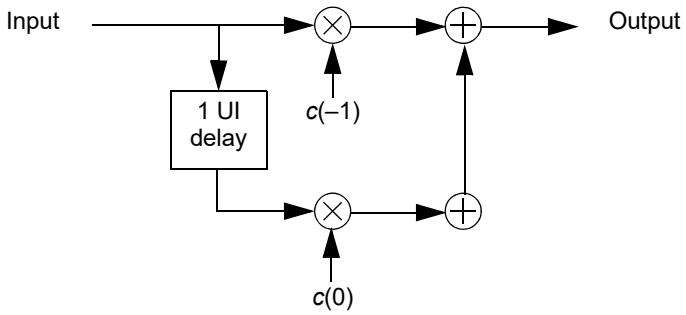
130.7.1.9 Transmit jitter

The transmitter shall be as specified in Table 130–4. Duty cycle distortion (DCD) is considered a component of deterministic jitters. The peak-to-peak duty cycle distortion is defined as the absolute value of the difference in the mean pulse width of a 1 pulse or the mean pulse width of a 0 pulse (as measured at the mean of the high and low voltage levels in a repeating 0101 bit sequence) and the nominal pulse width. Jitter specifications are specified for BER 10^{-12}. Transmit jitter test requirements are specified in 130.7.1.8.

NOTE—Duty cycle distortion (DCD) is also referred to as Even-odd jitter (see 92.8.3.8.1).

130.7.1.10 Transmitter output waveform

The 5GBASE-KR transmitter includes pre-emphasis to compensate for frequency-dependent loss in the backplane channel and facilitate data recovery at the receiver. This equalization may be accomplished with a two-tap finite impulse response (FIR) structure as shown in Figure 130–6.



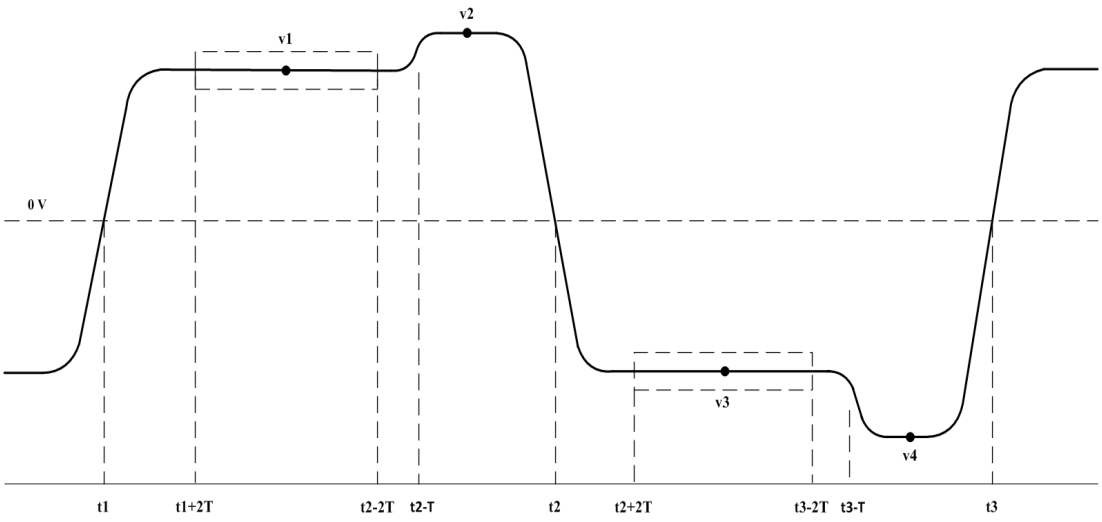


Figure 130–6—Transmit equalizer example

The test pattern for the transmitter output waveform is the square wave test pattern defined in 52.9.1.2, with a run of at least eight consecutive ones followed by an equal number of consecutive zeros. The transmitter output waveform test is based on the voltages v_1 through v_4, which are illustrated in Figure 130–7 and described below. These measurements are used to calculate R_{pre}, defined in Equation (130–7). R_{pre} shall be within the limits specified in Table 130–4.

From these voltages, the pre-equalization ratio R_{pre} is derived from Equation (130–7).

$$R_{pre} = \frac{v_2}{v_1} \tag{130–7}$$

T = symbol period
t_1 = zero-crossing point of the first rising edge of the AC-coupled signal
t_2 = zero-crossing point of the falling edge of the AC-coupled signal
t_3 = zero-crossing point of the second rising edge of the AC-coupled signal
v_1 = positive steady-state voltage measured as the average voltage in the interval t_1 + 2T to t_2 – 2T
v_2 = maximum voltage measured in the interval t_2 – T to t_2
v_3 = negative steady-state voltage measured as the average voltage in the interval t_2 + 2T to t_3 – 2T
v_4 = minimum voltage measured in the interval t_3 – T to t_3

Figure 130–7—Transmitter output waveform

130.7.2 Receiver characteristics

Receiver characteristics at TP4 (see Figure 130–1) are summarized in Table 130–5 and detailed in 130.7.2.1 through 130.7.2.5.

Table 130–5—Receiver characteristics for 5GBASE-KR

Parameter	Subclause reference	Value	Units
Bit error ratio	130.7.2.1	10^{-12}	
Signaling speed	130.7.2.2	5.15625 ± 100 ppm	GBd
Differential input peak-to-peak amplitude (max)	130.7.2.4	1200[a]	mV
Differential input return loss (min)[b]	130.7.2.5	Equation (130–3) and Equation (130–4)	dB

[a]The receiver shall tolerate input amplitudes up to a maximum of 1600 mV without permanent damage.
[b]Relative to 100 Ω differential.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130.7.2.1 Receiver interference tolerance

The receiver interference tolerance consists of two separate tests as described in Annex 69A with the parameters specified in Table 130–6. The data pattern for the interference tolerance test shall be the test patterns 2 or 3 as defined in 52.9.1.1. The receiver shall satisfy the requirements for interference tolerance specified in Annex 69A for both tests.

Table 130–6—5GBASE-KR interference tolerance parameters

Parameter	Test 1 values	Test 2 values	Units
Target BER	10^{-12}	10^{-12}	
m_{TC} (min)[a]	1	0.5	
Amplitude of broadband noise (min RMS)	5.2	12	mV
Applied transition time (20%–80%, min)	60	60	ps
Applied Sinusoidal jitter (min peak-to-peak)	0.115	0.115	UI
Applied random jitter (min peak-to-peak)[b]	0.13	0.13	UI

[a]m_{TC} is defined in Equation (69A–5)in Annex 69A.
[b]Applied random jitter is specified at a BER of 10^{-12}.

130.7.2.2 Signaling speed range

A signaling speed of a 5GBASE-KR receiver shall comply with the requirements of Table 130–5 for any signaling speed in the range 5.15625 GBd ± 100 ppm.

130.7.2.3 AC-coupling

The 5GBASE-KR receiver shall be AC-coupled to the backplane to allow for maximum interoperability between various 5 Gb/s components. AC-coupling is considered to be part of the receiver for the purposes of this specification unless explicitly stated otherwise. There may be various methods for AC-coupling in actual implementations.

NOTE—It is recommended that the maximum value of the coupling capacitors be limited to 100 nF. This will limit the inrush currents to the receiver that could damage the receiver circuits when repeatedly connected to transmit modules with a higher voltage level.

130.7.2.4 Input signal amplitude

5GBASE-KR receivers shall accept differential input signal peak-to-peak amplitudes produced by compliant transmitters connected without attenuation to the receiver, and still meet the BER requirement specified in 130.7.2.1. This may be larger than the differential maximum in 130.7.1.4 due to the actual transmitter output and receiver input impedances. The input impedance of a receiver can cause the minimum signal into a receiver to differ from that measured when the receiver is replaced with a 100 Ω test load. Since the channel is AC-coupled, the absolute voltage levels with respect to the receiver ground are dependent on the receiver implementation.

130.7.2.5 Differential input return loss

For frequencies from 100 MHz to 3750 MHz, the differential input return loss, in dB, of the receiver shall be as specified in Table 130–5.

130.8 Interconnect characteristics

Informative interconnect characteristics are provided in Annex 69B.

130.9 Environmental specifications

130.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

130.9.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

130.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

130.9.4 Electromagnetic compatibility

A system integrating the 5GBASE-KR PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

130.9.5 Temperature and humidity

A system integrating the 5GBASE-KR PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

130.10 Protocol implementation conformance statement (PICS) proforma for Clause 130, Physical Medium Dependent (PMD) sublayer and baseband medium, type 5GBASE-KR[222]

130.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 130, Physical Medium Dependent (PMD) sublayer and baseband medium type 5GBASE-KR, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

130.10.2 Identification

130.10.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

130.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 130, Physical Medium Dependent (PMD) sublayer and baseband medium type 5GBASE-KR
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[222]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

131. Introduction to 50 Gb/s networks

131.1 Overview

131.1.1 Scope

This clause describes the general requirements for 50 Gigabit Ethernet.

50 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 50 Gb/s, coupled with any IEEE 802.3 50GBASE Physical Layer implementation and is defined for full duplex operation only.

50 Gb/s Physical Layer devices, such as those specified in Table 131–1, provide a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap.

131.1.2 Relationship of 50 Gigabit Ethernet to the ISO OSI reference model

50 Gigabit Ethernet couples the IEEE 802.3 MAC to a family of 50 Gb/s Physical Layers. The relationships among 50 Gigabit Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 131–1.

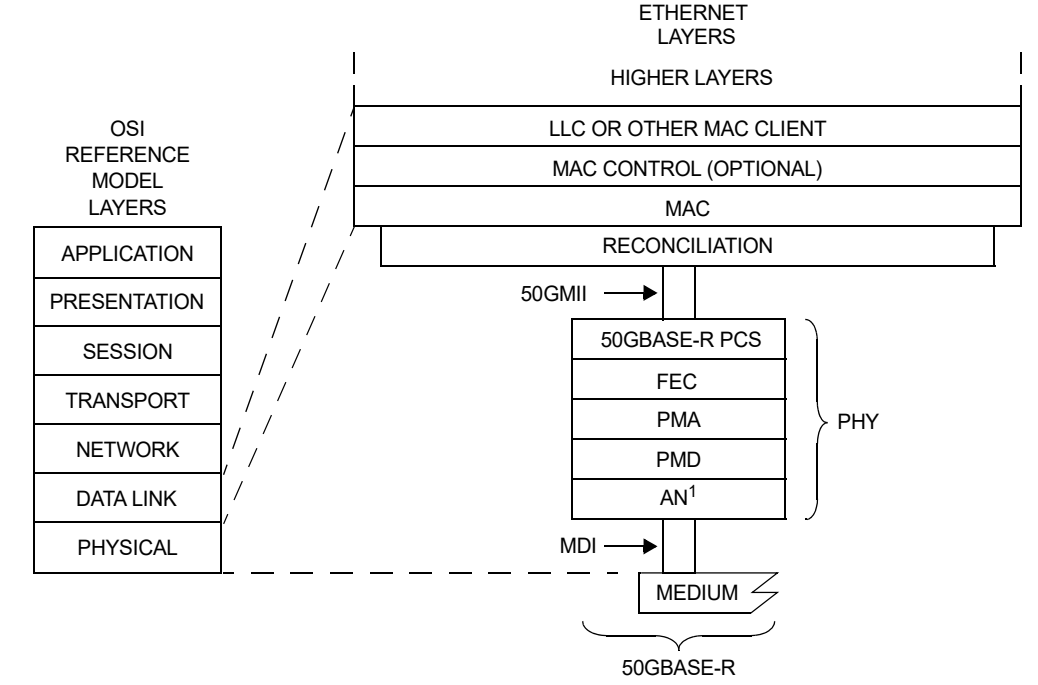

Figure 131–1—Architectural positioning of 50 Gigabit Ethernet

While this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience. The only exceptions are as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) The 50GMII, which, when implemented as logical interconnection point between the MAC sublayer and the Physical Layer device (PHY), uses a 64-bit-wide data path as specified in Clause 132. Physical instantiations of this interface may use other data-path widths.

b) The management interface, which, when physically implemented as the MDIO/MDC (Management Data Input/Output and Management Data Clock) at an observable interconnection port, uses a bit-wide data path as specified in Clause 45.

c) The PMA service interface, which, when physically implemented as LAUI-2, as specified in Annex 135B and Annex 135C, or as 50GAUI-2 (50 Gb/s two-lane Attachment Unit Interface), as specified in Annex 135D and Annex 135E, at an observable interconnection port, uses a two-lane data path.

d) The PMA service interface, which, when physically implemented as 50GAUI-1 (50 Gb/s one-lane Attachment Unit Interface) at an observable interconnection port, uses a one-lane data path as specified in Annex 135F or Annex 135G.

e) The MDI as specified in Clause 136 for 50GBASE-CR, Clause 137 for 50GBASE-KR, Clause 138 for 50GBASE-SR, and Clause 139 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER uses a one-lane data path.

131.1.3 Nomenclature

The nomenclature employed by the 50 Gb/s Physical Layer is explained as follows.

The alpha-numeric prefix 50GBASE in the port type (e.g., 50GBASE-R) represents a family of Physical Layer devices operating at a speed of 50 Gb/s.

50GBASE-R represents a family of Physical Layer devices using the Physical Coding Sublayer (PCS) for 50 Gb/s operation over multiple PCS lanes (see Clause 133). Physical Layer devices listed in Table 131–1 are defined for operation at 50 Gb/s.

Table 131–1—50 Gb/s PHYs

Name	Description
50GBASE-KR	50 Gb/s PHY using 50GBASE-R encoding over an electrical backplane (see Clause 137).
50GBASE-CR	50 Gb/s PHY using 50GBASE-R encoding over twinaxial copper cable (see 1.4.559 and Clause 136).
50GBASE-SR	50 Gb/s PHY using 50GBASE-R encoding over multimode fiber (see Clause 138).
50GBASE-FR	50 Gb/s PHY using 50GBASE-R encoding over single-mode fiber, with reach up to at least 2 km (see Clause 139).
50GBASE-LR	50 Gb/s PHY using 50GBASE-R encoding over single-mode fiber, with reach up to at least 10 km (see Clause 139).
50GBASE-ER	50 Gb/s PHY using 50GBASE-R encoding over single-mode fiber, with reach up to at least 40 km (see Clause 139).

131.1.4 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. Table 131–2 and Table 131–3 specify the correlation between PHY types and clauses. Implementations conforming to one or more PHY types meet the requirements of the corresponding clauses.

Table 131–2—PHY types and clause correlation (50GBASE copper)

PHY type	Clause[a]											
	73	78	132		133	134	135	135B	135D	135F	136	137
	Auto-Negotiation	EEE	RS	50GMII	50GBASE-R PCS	50GBASE-R RS-FEC	50GBASE-R PMA	LAUI-2 C2C	50GAUI-2 C2C	50GAUI-1 C2C	50GBASE-CR PMD	50GBASE-KR PMD
50GBASE-KR	M	O	M	O	M	M	M	O	O	O		M
50GBASE-CR	M	O	M	O	M	M	M	O	O	O	M	

[a]O = Optional, M = Mandatory.

Table 131–3—PHY types and clause correlation (50GBASE optical)

PHY type	Clause[a]															
	78	132		133	134	135	135B	135C	135D	135E	135F	135G	138	139		
	EEE	RS	50GMII	50GBASE-R PCS	50GBASE-R RS-FEC	50GBASE-R PMA	LAUI-2 C2C	LAUI-2 C2M	50GAUI-2 C2C	50GAUI-2 C2M	50GAUI-1 C2C	50GAUI-1 C2M	50GBASE-SR PMD	50GBASE-FR PMD	50GBASE-LR PMD	50GBASE-ER PMD
50GBASE-SR	O	M	O	M	M	M	O	O	O	O	O	O	M			
50GBASE-FR	O	M	O	M	M	M	O	O	O	O	O	O		M		
50GBASE-LR	O	M	O	M	M	M	O	O	O	O	O	O			M	
50GBASE-ER	O	M	O	M	M	M	O	O	O	O	O	O				M

[a]O = Optional, M = Mandatory.

131.2 Summary of 50 Gigabit Ethernet sublayers

131.2.1 Reconciliation Sublayer (RS) and Media Independent Interface (50GMII)

The Media Independent Interface specified in Clause 132 provides a logical interconnection between the MAC sublayer and Physical Layer devices (PHYs). The Media Independent Interface is not intended to be physically instantiated, rather it can logically connect layers within a device.

The 50GMII supports 50 Gb/s operation through its 64-bit-wide transmit and receive data paths. The Reconciliation Sublayer (RS) provides a mapping between the signals provided at the 50GMII and the MAC/PLS service definition.

While the 50GMII is an optional interface, it is used extensively in this standard as a basis for functional specification and provides a common service interface for the physical coding sublayer defined in Clause 133.

131.2.2 Physical Coding Sublayer (PCS)

50GBASE-R PHYs use the PCS specified in Clause 133. The 50GBASE-R PCS performs encoding of data from the 50GMII to 64B/66B code blocks and transfers the encoded data to the PMA (or FEC) and performs decoding of 64B/66B blocks from the PMA (or FEC) and transfers the decoded data to the 50GMII.

131.2.3 Forward error correction (FEC) sublayer

50GBASE-R PHYs use the FEC sublayer specified in Clause 134. The FEC sublayer can be placed between the PCS and PMA sublayers or between two PMA sublayers.

131.2.4 Physical Medium Attachment (PMA) sublayer

The 50GBASE-R PMA specified in Clause 135 provides a medium-independent means for the PCS to support the use of a range of physical media.

The 50GBASE-R PMA performs the mapping of transmit and receive data streams between the PCS and PMA via the PMA service interface, the mapping of transmit and receive data streams between the FEC and the PMA via the PMA service interface, and the mapping and multiplexing of transmit and receive data streams between the PMA and PMD via the PMD service interface. In addition, the PMA performs retiming of the received data stream when appropriate, optionally provides data loopback at the PMA or PMD service interface, and optionally provides test-pattern generation and checking.

131.2.5 Physical Medium Dependent (PMD) sublayer

The Physical Medium Dependent sublayer is responsible for interfacing to the transmission medium. The PMD is located just above the Medium Dependent Interface (MDI). The MDI, logically subsumed within each PMD subclause, is the actual medium attachment for the various supported media.

The 50GBASE-R PMDs and their corresponding media are specified in Clause 136 through Clause 139.

131.2.6 Management interface (MDIO/MDC)

The optional MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMDs) and Station Management (STA) entities.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

131.2.7 Management

Managed objects, attributes, and actions are defined for all 50 Gigabit Ethernet components. These items are defined in Clause 30.

131.3 Service interface specification method and notation

The service interface specification for the 50GBASE-R Physical Layers is as per the definition in 1.2.2. Note that the 50GBASE-R inter-sublayer service interfaces use multiple scalar REQUEST and INDICATION primitives, to indicate the transfer of multiple independent streams of data units, as defined in 131.3.1 through 131.3.3.

131.3.1 Inter-sublayer service interface

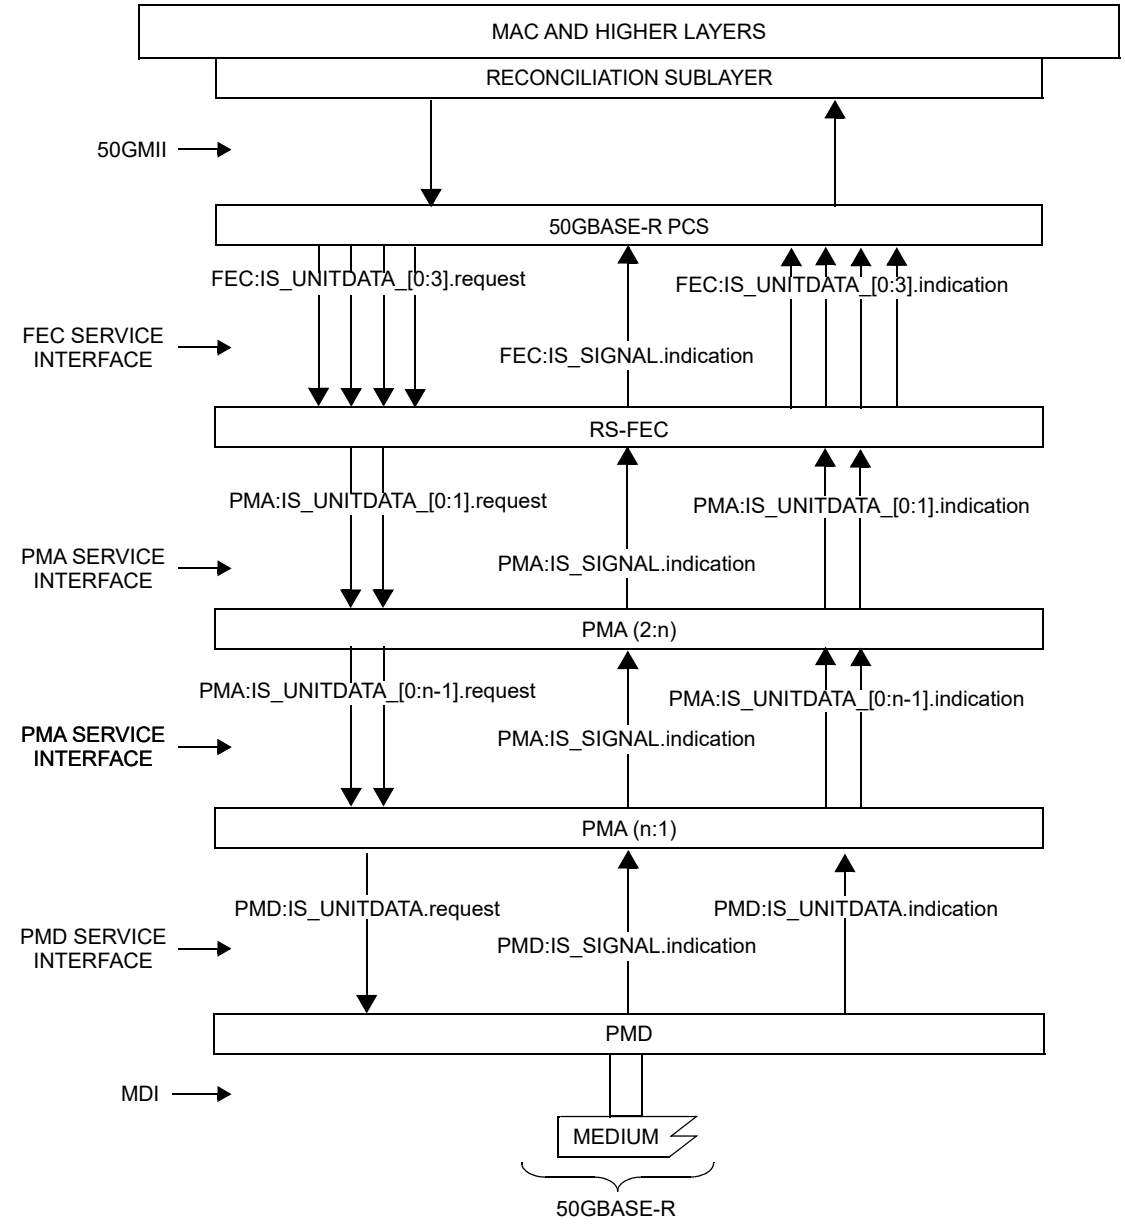
The inter-sublayer service interface is defined in 116.3.1.

131.3.2 Instances of the inter-sublayer service interface

The inter-sublayer interface can be instantiated between different sublayers, hence a prefix notation is defined to identify a specific instance of an inter-sublayer service interface. The following prefixes are defined:

a) PMD:—for primitives issued on the interface between the PMD sublayer and the PMA sublayer called the PMD service interface.
b) PMA:—for primitives issued on the interface between the PMA sublayer and the PCS or the FEC sublayer called the PMA service interface.
c) FEC:—for primitives issued on the interface between the FEC sublayer and the PCS or the PMA sublayer called the FEC service interface.

Examples of inter-sublayer service interfaces for 50GBASE-R with their corresponding instance names are illustrated in Figure 131–2. For example, the primitives for one instance of the inter-sublayer service interface, named the PMD service interface, are identified as follows:



PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication.

Primitives for other instances, of inter-sublayer interfaces, are represented in a similar manner as described above.

131.3.3 Semantics of inter-sublayer service interface primitives

The semantics of the inter-sublayer service interface primitives for the 50GBASE-R sublayers are described in 116.3.3.1 through 116.3.3.3.

131.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices. Table 131–4 contains the values of maximum sublayer delay (sum of transmit and receive delays at one end of the link) in bit times as specified in 1.4 and pause_quanta as specified in 31B.2 for 50 Gigabit Ethernet. If a PHY contains an Auto-Negotiation sublayer, the delay of the Auto-Negotiation sublayer is included within the delay of the PMD and medium.

Table 131–4—Sublayer delay constraints (50GBASE)

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
50G MAC, RS, and MAC Control	16 384	32	327.68	See 132.1.4.
50GBASE-R PCS	11 264	22	225.28	See 133.3.
50GBASE-R RS-FEC	25 600	50	512	See 134.4.
50GBASE-R PMA	4 608	9	92.16	See 135.5.4.
50GBASE-KR PMD	2 048	4	40.96	See 137.5. Includes allocation of 20 ns for the medium.
50GBASE-CR PMD	2 048	4	40.96	See 136.5. Includes allocation of 20 ns for the medium.
50GBASE-SR PMD	1 024	2	20.48	Includes 2 m of fiber. See 138.3.1.
50GBASE-FR PMD	1 024	2	20.48	Includes 2 m of fiber. See 139.3.
50GBASE-LR PMD	1 024	2	20.48	Includes 2 m of fiber. See 139.3.
50GBASE-ER PMD	1 024	2	20.48	Includes 2 m of fiber. See 139.3.
50GBASE-BR10 PMD	1 024	2	20.48	Includes 2 m of fiber. See 160.3.1.
50GBASE-BR20 PMD	1 024	2	20.48	Includes 2 m of fiber. See 160.3.1.
50GBASE-BR40 PMD	1 024	2	20.48	Includes 2 m of fiber. See 160.3.1.

[a]For 50GBASE-R, 1 bit time is equal to 20 ps. (See 1.4.215 for the definition of bit time.)
[b]For 50GBASE-R, 1 pause_quantum is equal to 10.24 ns. (See 31B.2 for the definition of pause_quanta.)
[c]Should there be a discrepancy between this table and the delay requirements of the relevant sublayer clause, the sublayer clause prevails.

See 80.4 for the calculation of bit time per meter of fiber or electrical cable.

See 31B.3.7 for PAUSE reaction timing constraints for stations at operating speeds of 50 Gb/s.

131.5 Skew constraints

Skew (or relative delay) can be introduced between lanes by both active and passive elements of a 50GBASE-R link. Skew is defined as the difference between the times of the earliest PCS lane and latest PCS lane for the one to zero transition of the alignment marker sync bits. The PCS deskew function (see 133.2.3) compensates for all lane-to-lane Skew observed at the receiver. The Skew between the lanes is kept within limits as shown in Table 131–5 so that the transmitted information on the lanes can be reassembled by the receive PCS.

Skew Variation may be introduced due to variations in electrical, thermal or environmental characteristics. Skew Variation is defined as the change in Skew between any PCS lane and any other PCS lane over the entire time that the link is in operation. From the time the link is brought up, Skew Variation is limited to ensure that each PCS lane always traverses the same lane between any pair of adjacent sublayers while the link remains in operation.

The maximum Skew and Skew Variation at physically instantiated interfaces is specified at Skew points SP0, SP1, SP2, and SP3 for the transmit direction and SP4, SP5, SP6, and SP7 for the receive direction as illustrated in Figure 131–3.

50GAUI-n = 50 Gb/s ATTACHMENT UNIT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
LAUI-2 = 50 Gb/s ATTACHMENT UNIT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
n = 1 or 2

Figure 131–3—50GBASE-R Skew points

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the transmit direction, the Skew points are defined in the following locations:

— SP0 on the LAUI-2 interface, at the input of the PMA above the RS-FEC;
— SP1 on the 50GAUI-n interface, at the input of the PMA closest to the PMD;
— SP2 on the PMD service interface, at the input of the PMD;
— SP3 at the output of the PMD, at the MDI.

In the receive direction, the Skew points are defined in the following locations:

— SP4 at the MDI, at the input of the PMD;
— SP5 on the PMD service interface, at the output of the PMD;
— SP6 on the 50GAUI-n interface, at the output of the PMA below the RS-FEC;
— SP7 on the LAUI-2 interface, at the output of the PMA above the RS-FEC.

The allowable limits for Skew are shown in Table 131–5 and the allowable limits for Skew Variation are shown in Table 131–6.

The Skew requirements for the PCS, PMA and PMD sublayers are specified in the respective clauses as noted in Table 131–5 and Table 131–6.

Table 131–5—Summary of Skew constraints

Skew points	Maximum Skew (ns)[a]	Maximum Skew for 50GBASE-R PCS lane (UI)[b]	Maximum Skew for 50GBASE-R FEC lane (UI)[c]	Notes[d]
SP0	29	≈ 374	N/A	See 135.5.3.1
SP1	29	N/A	≈ 770	See 135.5.3.3
SP2	43	N/A	≈ 1142	See 135.5.3.3, 136.6, 137.6, 138.3.2, 139.3
SP3	54	N/A	≈ 1434	See 136.6, 137.6, 138.3.2, 139.3
SP4	134	N/A	≈ 3559	See 136.6, 137.6, 138.3.2, 139.3
SP5	145	N/A	≈ 3852	See 135.5.3.3, 136.6, 137.6, 138.3.2, 139.3
SP6	160	N/A	≈ 4250	See 135.5.3.7
SP7	29	≈ 374	N/A	See 135.5.3.8
At FEC transmit	49	N/A	≈ 1302	See 134.5.2.2
At FEC receive	180	N/A	≈ 4781	See 134.5.2.2
At PCS receive	49	≈ 632	N/A	See 133.2.3

[a]The Skew limit includes 1 ns allowance for PCB traces that are associated with the Skew points.
[b]The symbol ≈ indicates approximate equivalent of maximum Skew in UI based on 1 UI equals 77.5758 ps at PCS lane signaling rate of 12.890625 Gb/s.
[c]The symbol ≈ indicates approximate equivalent of maximum Skew in UI based on 1 UI equals 37.6471 ps at FEC lane signaling rate of 26.5625 Gb/s.
[d]Should there be a discrepancy between this table and the Skew requirements of the relevant sublayer clause, the sublayer clause prevails.

Table 131–6—Summary of Skew Variation constraints

Skew points	Maximum Skew Variation (ns)	Maximum Skew Variation for 25.78125 GBd lane (UI)[a]	Maximum Skew Variation for 26.5625 GBd lane (UI)[b]	Notes[c]
SP0	0.2	≈ 5	N/A	See 135.5.3.1
SP1	0.2	N/A	≈ 5	See 135.5.3.3
SP2	0.4	N/A	≈ 11	See 135.5.3.5
SP3	0.6	N/A	≈ 16	
SP4	3.4	N/A	≈ 90	
SP5	3.6	N/A	≈ 96	See 135.5.3.6
SP6	3.8	N/A	≈ 101	See 135.5.3.7
SP7	0.2	≈ 6	N/A	See 135.5.3.8
At FEC transmit	0.4	N/A	≈ 11	See 134.5.2.2
At FEC receive	4	N/A	≈ 106	See 134.5.2.2
At PCS receive	0.4	≈ 10	N/A	See 133.2.3

[a]The symbol ≈ indicates approximate equivalent of maximum Skew Variation in UI based on 1 UI equals 38.7879 ps at LAUI-2 lane signaling rate of 25.78125 GBd.
[b]The symbol ≈ indicates approximate equivalent of maximum Skew Variation in UI based on 1 UI equals 37.6471 ps at 50GAUI-2 lane signaling rate of 26.5625 GBd.
[c]Should there be a discrepancy between this table and the Skew requirements of the relevant sublayer clause, the sublayer clause prevails.

131.6 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

Multiple states of a function that have a transition to a common state utilizing different qualifiers (for example, multiple exit conditions to an IDLE or WAIT state) may be indicated by a shared arrow. An exit transition arrow connects to the shared arrow, and the qualifier is met prior to termination of the transition arrow on the shared arrow. The shared arrow has no qualifier.

131.7 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 132 through Clause 140, and related annexes demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the 50 Gigabit Ethernet PICS conforms to the same notation and conventions used in 21.6.

132. Reconciliation Sublayer (RS) and Media Independent Interface (50GMII) for 50 Gb/s operation

132.1 Overview

This clause defines the characteristics of the Reconciliation Sublayer (RS) and the Media Independent Interface between Ethernet media access controllers and various PHYs. Figure 132–1 shows the relationship of the RS and Media Independent Interface to the ISO/IEC OSI reference model. The 50 Gb/s RS has identical logical functionality to the 40 Gb/s RS defined in Clause 81.

The 50GMII is an optional logical interface between the MAC sublayer and the Physical Layer device (PHY).

The RS adapts the bit serial protocols of the MAC to the parallel format of the PCS service interface. Though the 50GMII is an optional interface, it is used in this standard as a basis for specification. The Physical Coding Sublayer (PCS) is specified to the 50GMII, so if not implemented, a conforming implementation shall behave functionally as if the RS and 50GMII were implemented.

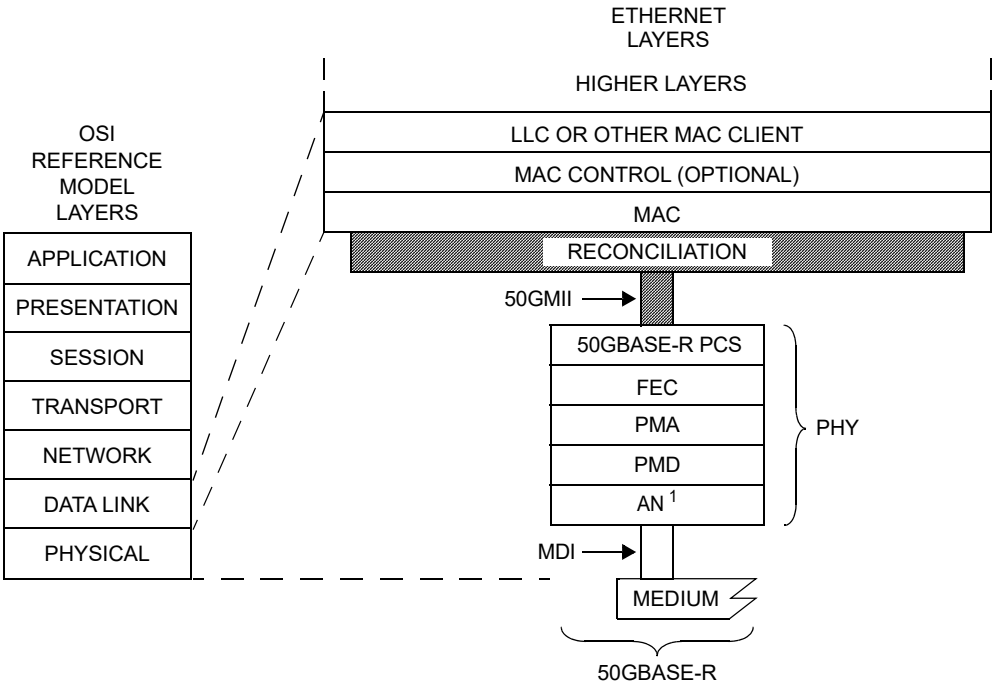
The 50GMII has the following characteristics:

a) The 50GMII supports a speed of 50 Gb/s.
b) Data and delimiters are synchronous to a clock reference.
c) It provides independent 64-bit-wide transmit and receive data paths.
d) It supports full duplex operation only.

132.1.1 Summary of major concepts

The following are the major concepts of the 50GMII:

a) The 50GMII is functionally similar to other media independent interfaces that have been defined for other speeds, as they all define an interface allowing independent development of MAC and PHY logic.
b) The RS converts between the MAC serial data stream and the parallel data paths of the 50GMII.
c) The RS maps the signal set provided at the 50GMII to the PLS service primitives provided at the MAC.
d) Each direction of data transfer is independent and serviced by data, control, and clock signals.
e) The RS generates continuous data or control characters on the transmit path and expects continuous data or control characters on the receive path.
f) The RS participates in link fault detection and reporting by monitoring the receive path for status reports that indicate an unreliable link, and generating status reports on the transmit path to report detected link faults to the DTE on the remote end of the connecting link.
g) The 50GMII may also support Low Power Idle (LPI) signaling for PHY types supporting Energy-Efficient Ethernet (EEE) (see Clause 78).



132.1.2 Application

This clause applies to the interface between the MAC and PHY. This logical interface is used to provide media independence so that an identical media access controller may be used with all 50GBASE PHY types.

132.1.3 Rate of operation

The 50GMII is specified to support 50 Gb/s operation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
AN = AUTO-NEGOTIATION
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 132–1—RS and MII relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

132.1.4 Delay constraints

The maximum cumulative MAC Control, MAC, and RS delay (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 132–1. A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 131.4 and its references.

Table 132–1—Delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
50 Gb/s MAC, RS, and MAC Control	16 384	32	327.68

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

132.1.5 Allocation of functions

The allocation of functions at the 50GMII balances the need for media independence with interface simplicity. The 50GMII maximizes media independence by separating the Data Link and Physical Layers of the OSI seven-layer reference model.

132.1.6 50GMII structure

The 50GMII structure is identical to the XLGMII/CGMII structure specified in 81.1.7.

132.1.7 Mapping of 50GMII signals to PLS service primitives

The Reconciliation Sublayer (RS) shall map the signals provided at the 50GMII to the PLS service primitives defined in Clause 6. The PLS service primitives provided by the RS and described here behave in exactly the same manner as defined in Clause 6. Full duplex operation only is implemented at 50 Gb/s; therefore, PLS service primitives supporting CSMA/CD operation are not mapped through the RS to the 50GMII. This behavior and restrictions are the same as described in 22.7, with the details of the signaling described in 132.3. LPI_REQUEST shall not be set to ASSERT unless the attached link has been operational for at least one second (i.e., link_status = OK, according to the underlying PCS/PMA).

EEE capability requires the use of the MAC defined in Annex 4A for simplified full duplex operation (with carrier sense deferral). This provides full duplex operation but uses the carrier sense signal to defer transmission when the PHY is in its low power state.

Mappings for the following primitives are defined for 50 Gb/s:

PLS_DATA.request
PLS_DATA.indication
PLS_CARRIER.indication
PLS_SIGNAL.indication
PLS_DATA_VALID.indication

The RS maps all primitives in an identical manner as the XLGMII/CGMII does and as specified in 81.1.7.

132.2 50GMII data stream

The 50GMII data stream has the same characteristics as the XLGMII/CGMII data stream described in 81.2.

132.3 50GMII functional specifications

The 50GMII functions identically to the XLGMII/CGMII specified in 81.3.

132.4 LPI assertion and detection

LPI assertion and detection function identically to the XLGMII/CGMII specified in 81.4, with the single exception that the PMA stop signaling is not applicable.

The operation of LPI in the PHY requires that the MAC does not send valid data for a time after LPI has been deasserted as governed by resolved Transmit T_{w_sys} defined in 78.4.2.3.

This wake-up time is enforced by the transmit LPI state diagram using CARRIER_SENSE.indication in an identical manner to that defined in 81.4, with the single exception that the PMA stop signaling described in 81.4.4 is not applicable.

132.5 Protocol implementation conformance statement (PICS) proforma for Clause 132, Reconciliation Sublayer (RS) and Media Independent Interface (50GMII) for 50 Gb/s operation[223]

132.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 132, Reconciliation Sublayer (RS) and Media Independent Interface (50GMII) for 50 Gb/s operation, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

132.5.2 Identification

132.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

132.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 132, Reconciliation Sublayer (RS) and Media Independent Interface (50GMII) for 50 Gb/s operation
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

133. Physical Coding Sublayer (PCS) for 64B/66B, type 50GBASE-R

133.1 Overview

133.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) that is common to a family of 50 Gb/s Physical Layer implementations known as 50GBASE-R. The 50GBASE-R PCS is a sublayer of the 50 Gb/s PHYs listed in Table 131–1.

133.1.2 Relationship of 50GBASE-R to other standards

Figure 133–1 depicts the relationships among the 50GBASE-R sublayers, the Ethernet MAC and Reconciliation Sublayers, and the higher layers.

The 50GBASE-R PCS specifications are based on the 40GBASE-R PCS specifications in Clause 82, with the modifications listed in 133.2 and 133.3.

133.1.3 Summary of 50GBASE-R sublayers

Figure 133–1 shows the relationship of the 50GBASE-R PCS sublayer (shown shaded) with other sublayers to the ISO Open System Interconnection (OSI) reference model.

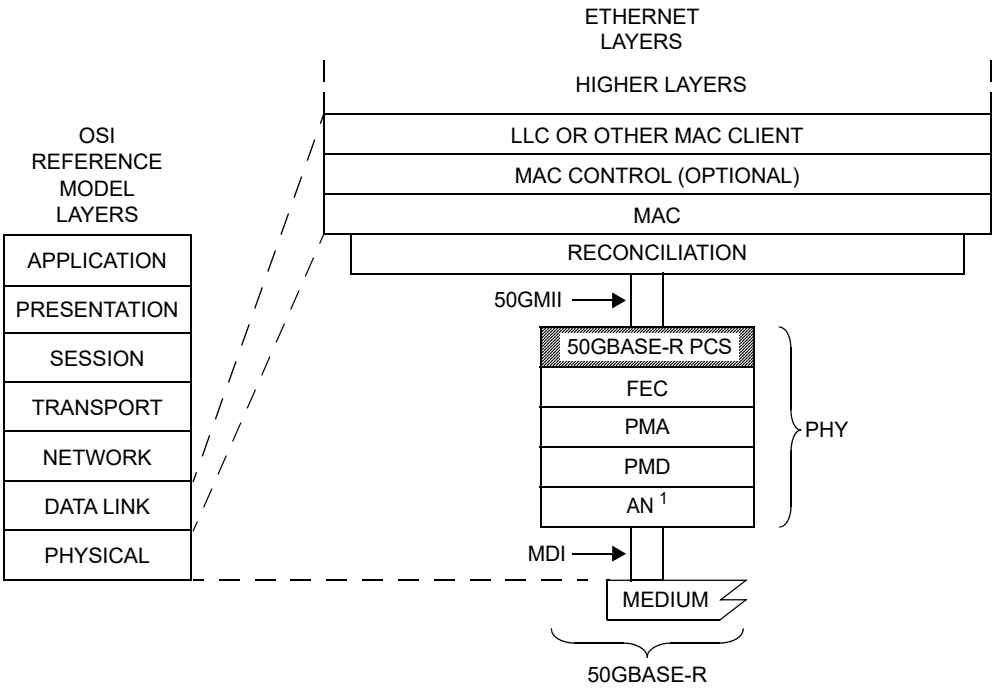
133.1.3.1 Physical Coding Sublayer (PCS)

The PCS service interface is the 50GMII, which is defined in Clause 132. The 50GMII provides a uniform interface to the Reconciliation Sublayer for all 50 Gb/s PHY implementations

The 50GBASE-R PCS provides all services required by the 50GMII.

133.1.4 Inter-sublayer interfaces

The upper interface of the PCS may connect to the Reconciliation Sublayer through the 50GMII.



The lower interface of the PCS connects to the FEC sublayer. If the optional LAUI-2 interface (see 135B.1 and 135C.1) is physically instantiated directly below the PCS sublayer, then the lower interface of the PCS instead connects to the PMA. The 50GBASE-R PCS is based on 4 PCS lanes and has a nominal rate at the FEC or PMA service interface of 12.890625 Gb/s per PCS lane, which provides capacity for the MAC data rate of 50 Gb/s.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience.

133.1.4.1 PCS service interface (50GMII)

The PCS service interface allows the 50GBASE-R PCS to transfer information to and from a PCS client. The PCS client is the Reconciliation Sublayer. The PCS Service Interface is defined as the 50GMII in Clause 132.

PMD = PHYSICAL MEDIUM DEPENDENT
FEC = FORWARD ERROR CORRECTION

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 133–1—50GBASE-R PCS relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

133.1.4.2 Forward error correction (FEC) or Physical Medium Attachment (PMA) service interface

The FEC or PMA service interface for the PCS is described in an abstract manner and does not imply any particular implementation. The FEC or PMA Service Interface supports the exchange of encoded data between the PCS and the FEC or PMA sublayer. The FEC service interface is defined in 134.2. The PMA service interface is defined in 135.3.

133.2 Physical Coding Sublayer (PCS)

133.2.1 Functions within the PCS

The 50GBASE-R PCS shall have all of the functionality of the 40GBASE-R PCS specified in Clause 82 with the following exceptions:

a) The nominal rate at the FEC or PMA service interface is 12.890625 Gb/s per PCS lane, rather than 10.3125 Gb/s per PCS lane.

b) The alignment marker spacing is modified such that alignment markers are inserted after every 20 479 66-bit blocks on each PCS lane, rather than after every 16 383 66-bit blocks on each PCS lane as described in 82.2.7. (See 133.2.2.)

c) The definition of the variables current_am, am_counter, ber_cnt, and xus_timer in the state diagrams defined in 82.2.19 are modified to account for the different alignment marker spacing and the different data rate. (See 133.2.4.)

d) The optional deep sleep mode of EEE is not supported.

133.2.2 Alignment marker insertion

The alignment marker insertion for the 50GBASE-R PCS is identical to the alignment marker insertion for the 40GBASE-R PCS described in 82.2.7, with the exception that the alignment markers shall be inserted after every 20 479 66-bit blocks on each PCS lane, rather than after every 16 383 66-bit blocks on each PCS lane as described in 82.2.7. Alignment marker insertion is illustrated in Figure 133–3 and Figure 133–4.

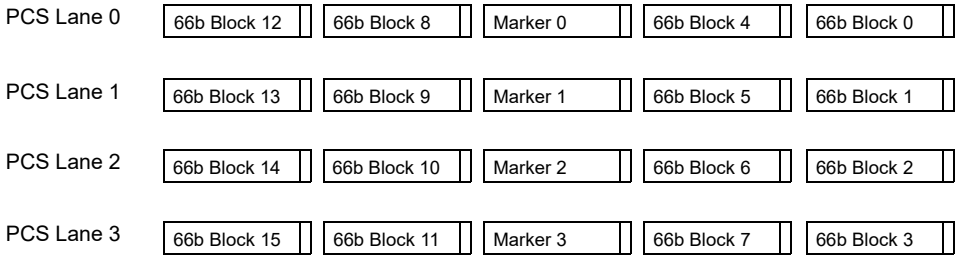

Figure 133–3—Alignment marker insertion

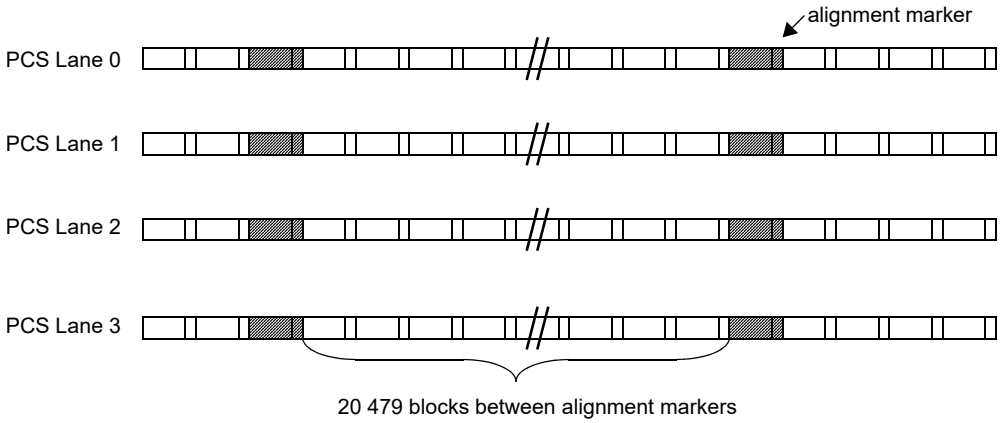

Figure 133–4—Alignment marker insertion period

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The format of the 50GBASE-R PCS alignment markers is identical to the format of the 40GBASE-R PCS alignment markers described in 82.2.7 and shown in Figure 82–9.

The content of the 50GBASE-R PCS alignment markers is identical to the content of the 40GBASE-R PCS alignment markers described in 82.2.7 and shown in Table 82–3.

133.2.3 PCS lane deskew

The 50GBASE-R PCS receiver shall support a maximum Skew of 49 ns and a maximum Skew Variation of 0.4 ns.

Skew and Skew Variation are defined in 131.5.

133.2.4 Detailed functions and state diagrams

The state diagrams are identical to those for the 40GBASE-R PCS defined in 82.2.19 with the exception that some variables, counters and timers are redefined as follows:

current_am
: This variable holds the lane number of the current alignment marker. This is compared to the variable first_am to determine if we have alignment marker lock and is always n × 20 480 66-bit blocks away from the first_am.

am_counter
: This counter counts 66-bit blocks that separate two consecutive alignment markers. The terminal count is 20 479.

ber_cnt
: This counter counts up to a maximum of 97 of the number of invalid sync headers within the current 1 ms period.

xus_timer
: Timer that is triggered every 1 ms +1%, –25%.

133.3 Delay constraints

The maximum delay contributed by the 50GBASE-R PCS (sum of transmit and receive delays at one end of the link) shall be no more than 11 264 bit times (22 pause_quanta or 225.28 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 131.4 and its references.

133.4 Auto-Negotiation

The following requirements apply to a PCS used with a 50GBASE-CR or 50GBASE-KR PMD where support for the Auto-Negotiation process defined in Clause 73 is mandatory. The PCS shall support the primitive AN_LINK.indication(link_status) (see 73.9). The parameter link_status shall take the value FAIL when PCS_status=false and the value OK when PCS_status=true. The primitive shall be generated when the value of link_status changes.

133.5 Protocol implementation conformance statement (PICS) proforma for Clause 133, Physical Coding Sublayer (PCS) for 64B/66B, type 50GBASE-R[224]

133.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 133, Physical Coding Sublayer (PCS) for 64B/66B, type 50GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

133.5.2 Identification

133.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

133.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 133, Physical Coding Sublayer (PCS) for 64B/66B, type 50GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

134. Reed-Solomon forward error correction (RS-FEC) sublayer for 50GBASE-R PHYs

134.1 Overview

134.1.1 Scope

This clause specifies a Reed-Solomon forward error correction (RS-FEC) sublayer for 50GBASE-R PHYs.

The RS-FEC sublayer for 50GBASE-R PHYs is identical to the RS-FEC sublayer for 100GBASE-R PHYs specified in Clause 91 with the following exceptions:

a) The service interface has four PCS lanes instead of 20 PCS lanes, and the nominal rate of each PCS lane is 12.890625 Gb/s rather than 5.15625 Gb/s. (See 134.2.)

b) It only implements the RS(544,514) Reed-Solomon encoder option defined in 91.5.2.7. (See 134.5.2.7.)

c) The output of the Reed-Solomon encoder is distributed to two FEC lanes, rather than the four FEC lanes described in 91.5.2.8.

d) The alignment marker processing is modified to account for the difference in the alignment marker format between the 50GBASE-R PCS (Clause 133) and the 100GBASE-R PCS (Clause 82), for the fact that the alignment markers are mapped to two FEC lanes rather than four FEC lanes, and the alignment marker mapping to the two FEC lanes needs to maintain a 10-bit alignment. (See 134.5.2.6.)

e) The definition of some of the variables and counters for the state diagrams in 91.5.4 are modified to support the different alignment marker spacing and the different number of FEC lanes. (See 134.5.4.)

f) The states identified as optional in the FEC synchronization state diagram in 91.5.4.3 (Figure 91–8) are mandatory for the 50GBASE-R RS-FEC.

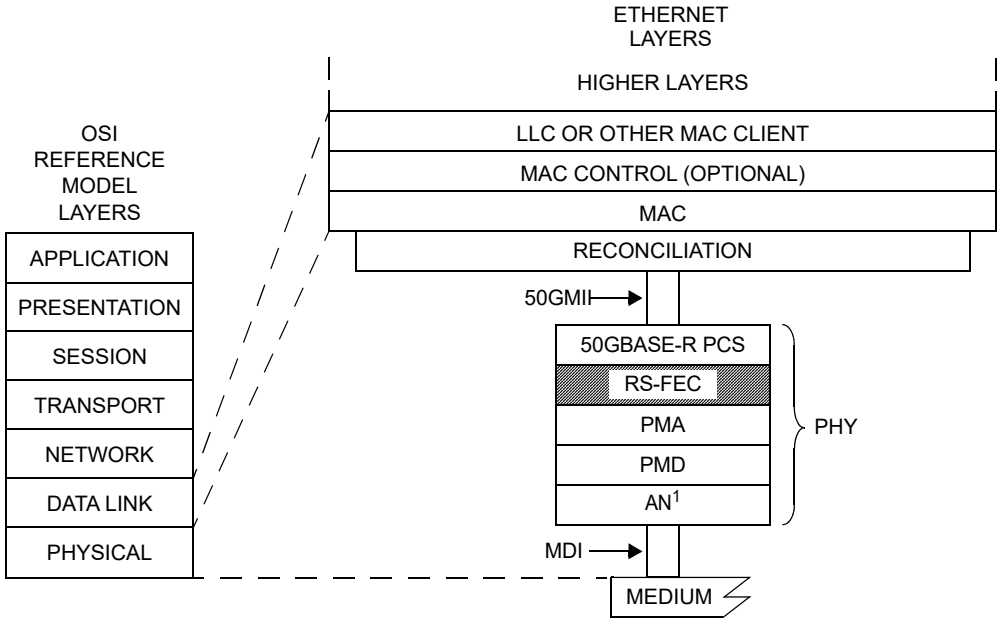
g) The optional EEE deep sleep capability is not supported.

h) The optional FEC bypass correction feature (see 91.5.3.3) is not supported.

134.1.2 Position of RS-FEC in the 50GBASE-R sublayers

Figure 134–1 shows the relationship of the RS-FEC sublayer to the ISO/IEC Open System Interconnection (OSI) reference model.

134.2 FEC service interface



This subclause specifies the services provided by the RS-FEC sublayer. The service interface is described in an abstract manner and does not imply any particular implementation.

The FEC service interface is provided to allow the PCS to transfer information to and from the RS-FEC. The PCS may be connected to the RS-FEC using an optional instantiation of the PMA service interface (see Annex 135B) in which case a PMA is the client of the FEC service interface.

The FEC service interface is an instance of the inter-sublayer service interface defined in 131.3. The FEC service interface primitives are summarized as follows:

FEC:IS_UNITDATA_*i*.request
FEC:IS_UNITDATA_*i*.indication
FEC:IS_SIGNAL.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
AN = AUTO-NEGOTIATION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 134–1—RS-FEC relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The RS-FEC operates on four parallel bit streams, hence i = 0 to 3.

The PCS or PMA continuously sends four parallel bit streams to the RS-FEC, one per PCS lane, each at a nominal signaling rate of 12.890625 Gb/s. The RS-FEC continuously sends four parallel bit streams to the PCS or PMA, one per PCS lane, each at a nominal signaling rate of 12.890625 Gb/s.

The SIGNAL_OK parameter of the FEC:IS_SIGNAL.indication primitive can take one of two values: OK or FAIL. The value is set to OK when the FEC receive function has identified codeword boundaries as indicated by fec_align_status equal to true. That value is set to FAIL when the FEC receive function is unable to reliably establish codeword boundaries as indicated by fec_align_status equal to false. When SIGNAL_OK is FAIL, the rx_symbol parameters of the FEC:IS_UNITDATA_*i*.indication primitives are undefined.

134.3 PMA compatibility

The RS-FEC sublayer requires that the PMA service interface consist of exactly two upstream FEC lanes and exactly two downstream FEC lanes, with each lane running at a nominal signaling rate of 26.5625 Gb/s. Therefore, the RS-FEC sublayer may be a client of the 50GBASE-R PMA sublayer defined in Clause 135, when the PMA service interface width, p, is set to 2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

134.4 Delay constraints

The maximum delay contributed by the RS-FEC sublayer (sum of transmit and receive delays at one end of the link) shall be no more than 25 600 bit times (50 pause_quanta or 512 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 131.4 and its references.

134.5 Functions within the RS-FEC sublayer

134.5.1 Functional block diagram

A functional block diagram of the RS-FEC sublayer is shown in Figure 134–2.

134.5.2 Transmit function

134.5.2.1 PCS Lane block synchronization

The RS-FEC transmit function forms four bit streams by concatenating the bits from each of the four FEC:IS_UNITDATA_*i*.request primitives in the order they are received. It obtains lock to the 66-bit blocks in each bit stream using the sync headers and outputs 66-bit blocks. Block lock is obtained as specified in the block lock state diagram shown in Figure 82–12, but using the variable definitions from 133.2.4.

134.5.2.2 PCS Alignment lock and deskew

Once the RS-FEC transmit function achieves block lock on a PCS lane, it then begins obtaining alignment marker lock as specified by the alignment marker lock state diagram shown in Figure 82–13, but using the variable definitions from 133.2.4. This process identifies the PCS lane number received on a particular lane of the service interface. After alignment marker lock is achieved on all four PCS lanes, all inter-lane Skew is removed as specified by the PCS deskew state diagram shown in Figure 82–14, but using the variable definitions from 133.2.4. The RS-FEC transmit function shall support a maximum Skew of 49 ns and a maximum Skew Variation of 0.4 ns. Skew and Skew Variation are defined in 131.5.

134.5.2.3 PCS Lane reorder

PCS lanes can be received on different lanes of the service interface from which they were originally transmitted due to Skew between lanes and multiplexing by the PMA. The RS-FEC transmit function shall order the PCS lanes according to the PCS lane number.

134.5.2.4 Alignment marker removal

After all PCS lanes are aligned and deskewed, the PCS lanes are multiplexed together in the proper order to reconstruct the original stream of blocks and the alignment markers are removed from the data stream. Note that an alignment marker is always removed when am_lock is true for a given PCS lane even if it does not match the expected alignment marker value (due to a bit error for example). Repeated alignment marker errors result in am_lock being set to false for a given PCS lane, but until that happens it is sufficient to remove the block in the alignment marker position.

As part of the alignment marker removal process, the BIP_3 field is compared to the calculated Bit Interleaved Parity (BIP) value (see 82.2.8) for each PCS lane. If a Clause 45 MDIO is implemented, then the appropriate BIP error counter register (registers 1.230 to 1.233) is incremented by one each time the calculated BIP value does not equal the value received in the BIP_3 field. The bit error ratio in the data received from the local PCS can be estimated by dividing the BIP block error ratio by a factor of 1 351 680.

NOTE—The data received from the local PCS is processed by the RS-FEC transmit function without error correction.

134.5.2.6 Alignment marker mapping and insertion

The alignment markers that were removed per 134.5.2.4 are re-inserted after being processed by the alignment marker mapping function. The alignment marker mapping function compensates for the operation of the symbol distribution function defined in 134.5.2.8 and rearranges the alignment marker bits so that they appear on the FEC lanes intact and in the desired sequence. This preserves the properties of the alignment markers (e.g., DC balance, transition density) and provides a deterministic pattern for the purpose of synchronization at the receiver. The RS-FEC receive function uses knowledge of this mapping to determine the FEC lane that is received on a given lane of the PMA service interface, to compensate for skew between FEC lanes, and to identify RS-FEC codeword boundaries.

The alignment marker mapping function operates on a group of four aligned and reordered alignment markers received from the PCS. Let am_tx_*x*<65:0> be the alignment marker for PCS lane *x*, *x*=0 to 3, where bit 0 is the first bit transmitted. The alignment markers shall be mapped to am_txmapped<256:0> in a manner that yields the same result as the following process.

For *x*=0 to 3, amp_tx_*x*<63:0> is constructed as follows:

— Set $y = 0$ when $x \leq 1$, otherwise set $y = x$.

— amp_tx_*x*<23:0> is set to M_0, M_1, and M_2 as shown in Figure 82–9 (bits 25 to 2) using the values in Table 82–3 for PCS lane number *y*.

— amp_tx_*x*<31:24> = am_tx_*x*<33:26>

— amp_tx_*x*<55:32> is set to M_4, M_5, and M_6 as shown in Figure 82–9 (bits 57 to 34) using the values in Table 82–3 for PCS lane number *y*.

— amp_tx_*x*<63:56> = am_tx_*x*<65:58>

This process replaces the fixed bytes of the alignment markers received from the PCS, possibly with errors, with the values from Table 82–3. In addition it substitutes the fixed bytes of the alignment markers corresponding to PCS lane 1 with the fixed bytes for the alignment marker corresponding to PCS lane 0. The variable bytes of the alignment markers received from the PCS (BIP_3 and BIP_7) are unchanged. This simplifies the synchronization process at the RS-FEC receiver, as the receiver only needs to search for the fixed alignment marker bytes corresponding to PCS lane 0 on each FEC lane.

am_txpayloads<0,129:0> and am_txpayloads<1,125:0> are then constructed from amp_tx as follows:

— am_txpayloads<0, 63:0> = amp_tx_0<63:0>

— am_txpayloads<0, 127:64> = amp_tx_2<63:0>

— am_txpayloads<0, 129:128> = amp_tx_3<57:56>

— am_txpayloads<1, 63:0> = amp_tx_1<63:0>

— am_txpayloads<1, 119:64> = amp_tx_3<55:0>

— am_txpayloads<1, 125:120> = amp_tx_3<63:58>

This process is an intermediate step in the generation of am_txmapped<256:0>, and is illustrated in Figure 134–3.

Given *i*=0 to 1, *k*=0 to 12, and $y=i+2k$, am_txmapped<255:0> is constructed from am_txpayloads as follows:

— If ($y < 25$) then am_txmapped<(10*y*+9):10*y*> = am_txpayloads<*i*, (10*k*+9):10*k*>

— am_txmapped<255:250> = am_txpayloads<1, 125:120>

A 1-bit pad is appended to the mapped alignment markers to yield the equivalent of one 257-bit block. The pad bit, am_txmapped<256>, shall be set to 0 or 1 in an alternating pattern.

am_txmapped<256:0> is inserted into the data path prior to the Reed-Solomon encoder (see Figure 134–4) every $4 \times 20\,480$ 66-bit blocks, corresponding to every 1024 Reed-Solomon codewords. The mapped alignment markers, am_txmapped<256:0> shall be inserted as the first 257 message bits to be transmitted every 1024th codeword. The first 257-bit block inserted after am_txmapped shall correspond to the four 66-bit blocks received on PCS lanes 0, 1, 2, and 3 that immediately followed the alignment marker on each respective PCS lane.

The result of this alignment mapping process is that after Reed-Solomon encoding and symbol distribution (134.5.2.7 and 134.5.2.8 respectively), the alignment marker bit patterns shown in Figure 134–3 appear on the two FEC output lanes and aligned with the start of every 1024th FEC codeword. The FEC receiver uses this information to lock onto the two FEC lanes and to identify the FEC codeword boundaries.

An additional result of this alignment mapping process, is that the BIP_3 and BIP_7 fields from normal PCS alignment markers are carried across the link protected by FEC. These fields cannot be used to monitor errors on the link protected by FEC as 64B/66B to 256B/257B transcoding and Reed-Solomon encoding alters the bit sequence. However, these fields may again be used to monitor errors after the original bit sequence is restored, i.e., following Reed-Solomon decoding and 256B/257B to 64B/66B transcoding.

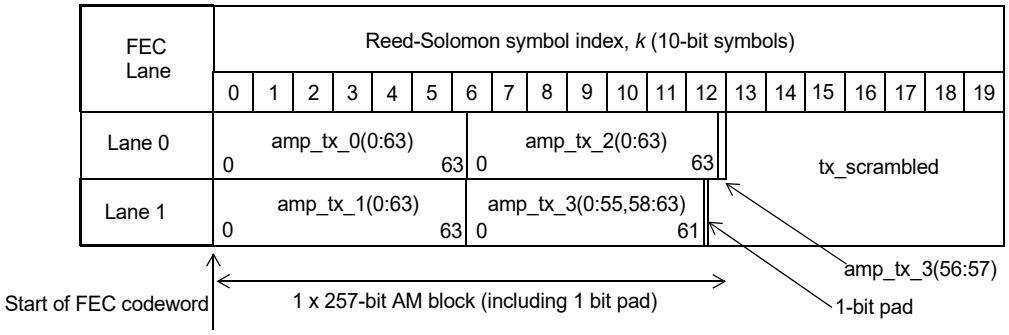

Figure 134–3—Alignment marker mapping to FEC lanes

134.5.2.7 Reed-Solomon encoder

The Reed-Solomon encoder is identical to the RS(544,514) Reed-Solomon encoder defined in 91.5.2.7.

134.5.2.8 Symbol distribution

Once the data has been Reed-Solomon encoded, it is distributed to two FEC lanes, one 10-bit symbol at a time alternating between FEC lanes 0 and 1. The distribution process is shown in Figure 134–4.

134.5.2.9 Transmit bit ordering

The transmit bit ordering is illustrated in Figure 134–4.

134.5.3 Receive function

134.5.3.1 Alignment lock and deskew

The RS-FEC receive function forms two bit streams by concatenating the bits from each of the two PMA:IS_UNITDATA_*i*.indication primitives in the order they are received. It obtains lock to the alignment markers as specified by the FEC synchronization state diagram shown in Figure 91–8, but using the variable definitions from 134.5.4.

After alignment marker lock is achieved on the two FEC lanes, all inter-lane Skew is removed as specified by the FEC alignment state diagram shown in Figure 91–9. The FEC receive function shall support a maximum Skew of 180 ns between FEC lanes and a maximum Skew Variation of 4 ns.

134.5.3.2 FEC Lane reorder

FEC lanes can be received on different lanes of the service interface from which they were originally transmitted. The FEC receive function shall order the FEC lanes according to the FEC lane number (see 134.5.2.6). The FEC lane number is defined by the sequence of alignment markers that are mapped to each FEC lane.

After both FEC lanes are aligned, deskewed, and reordered, the FEC lanes are multiplexed together in the proper order to reconstruct the original stream of FEC codewords.

134.5.3.3 Reed-Solomon decoder

The Reed-Solomon decoder extracts the message symbols from the codeword, corrects them as necessary, and discards the parity symbols.

The RS-FEC sublayer shall be capable of correcting any combination of up to t=15 symbol errors in a codeword. The RS-FEC sublayer shall also be capable of indicating when an errored codeword was not corrected. The probability that the decoder fails to indicate a codeword with t+1 errors as uncorrected is not expected to exceed 10^{-16}. This limit is also expected to apply for t+2 errors, t+3 errors, and so on.

The Reed-Solomon decoder shall indicate errors to the PCS sublayer by intentionally corrupting 66-bit block synchronization headers. When the decoder determines that a codeword contains errors that were not corrected, it ensures that for every other 257-bit block within the codeword starting with the first (1st, 3rd, 5th, etc.), the synchronization header for the first 66-bit block at the output of the 256B/257B to 64B/66B transcoder, rx_coded_0<1:0>, is set to 11. In addition, it shall ensure that rx_coded_0<1:0> corresponding to the second 257-bit block and rx_coded_3<1:0> corresponding to the last (20th) 257-bit block in the codeword are set to 11. Setting rx_coded_0<1:0> to 11 as described causes the PCS to assign R_BLOCK_TYPE=E to the 66-bit block and decode its content as EBLOCK_R (see 49.2.13.2.1 and 49.2.13.2.3). This causes the PCS to discard all frames 64 bytes and larger that are fully or partially contained within the codeword.

134.5.3.3.1 FEC Error indication bypass (optional)

The Reed-Solomon decoder may optionally provide the ability to bypass the error indication feature to reduce the delay contributed by the RS-FEC sublayer. The presence of this option is indicated by the assertion of the FEC_bypass_indication_ability variable (see 134.6.6). When the option is provided it is enabled by the assertion of the FEC_bypass_indication_enable variable (see 134.6.1).

When FEC_bypass_indication_enable is asserted, additional error monitoring is performed by the RS-FEC sublayer to reduce the likelihood that errors in a packet are not detected. The Reed-Solomon decoder counts the number of symbol errors detected in consecutive non-overlapping blocks of 8192 codewords. When the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

number of symbol errors in a block of 8192 codewords exceeds 6380, the Reed-Solomon decoder shall cause synchronization header rx_coded<1:0> of each subsequent 66-bit block that is delivered to the PCS to be assigned a value of 00 or 11 for a period of 60 ms to 75 ms. As a result, the PCS sets hi_ber = true, which inhibits the processing of received packets. When Auto-Negotiation is supported and enabled, assertion of hi_ber causes Auto-Negotiation to restart.

134.5.3.3.2 FEC Degraded SER (optional)

The Reed-Solomon decoder may optionally provide the ability to indicate a degradation of the received signal. The presence of this option is indicated by the assertion of the FEC_degraded_SER_ability variable (see 134.6.8). When the option is provided it is enabled by the assertion of the FEC_degraded_SER_enable variable (see 134.6.2).

When FEC_degraded_SER_enable is asserted, additional error monitoring is performed by the FEC. The Reed-Solomon decoder counts the total number of symbol errors detected in consecutive non-overlapping blocks of FEC_degraded_SER_interval codewords (see 134.6.5). If the decoder determines that a codeword is uncorrectable, the number of symbol errors detected is increased by 16. When the number of symbol errors exceeds the threshold set in FEC_degraded_SER_activate_threshold (see 134.6.3), the FEC_degraded_SER bit (see 134.6.9) is set. At the end of each interval, if the number of symbol errors is less than the threshold set in FEC_degraded_SER_deactivate_threshold (see 134.6.4), the FEC_degraded_SER bit is cleared. The value of the FEC_degraded_SER bit is unspecified if the value of FEC_degraded_SER_activate_threshold is less than the value of FEC_degraded_SER_deactivate_threshold.

If either FEC_degraded_SER_ability or FEC_degraded_SER_enable is deasserted then the FEC_degraded_SER bit is cleared.

134.5.3.4 Alignment marker removal

The first 257 message bits in every 1024th codeword is the vector am_rxmapped<256:0> where bit 0 is the first bit received. The specific codewords that include this vector are indicated by the alignment lock and deskew function (see 134.5.3.1).

The vector am_rxmapped shall be removed prior to transcoding.

134.5.3.5 256B/257B to 64B/66B transcoder

The 256B/257B to 64B/66B transcoder is identical to the transcoder for the 100GBASE-R RS-FEC sublayer defined in 91.5.3.5.

134.5.3.6 Block distribution

After the data has been transcoded, it shall be distributed to four PCS lanes, one 66-bit block at a time in a round robin distribution from the lowest to the highest numbered PCS lanes. The distribution process is shown in Figure 82–6.

134.5.3.7 Alignment marker mapping and insertion

The alignment marker mapping function compensates for operation of the lane reorder function (see 134.5.2.3) to derive the PCS lane alignment markers, am_rx_*x*<65:0> for *x*=0 to 3, from am_rxmapped<256:0> (see 134.5.3.4).

The alignment markers shall be derived from am_rxmapped<256:0> in a manner that yields the same result as the following process.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Given *i*=0 to 1, *k*=0 to 12, and *y*=*i*+2*k*, am_rxpayloads is constructed from am_rxmapped as follows:

— If (*y* < 25) then am_rxpayloads<*i*, (10*k*+9):10*k*> = am_rxmapped<(10*y*+9):10*y*>

— am_rxpayloads<1, 125:120> = am_rxmapped<255:250>

The one bit pad am_rxmapped<256> is ignored by the receiver.

For *x*=0 to 3, amp_rx_*x*<63:0> is constructed from am_rxpayloads as follows:

— amp_rx_0<63:0> = am_rxpayloads<0, 63:0>

— amp_rx_1<63:0> = am_rxpayloads<1, 63:0>

— amp_rx_2<63:0> = am_rxpayloads<0, 127:64>

— amp_rx_3<55:0> = am_rxpayloads<1, 119:64>

— amp_rx_3<57:56> = am_rxpayloads<0, 129:128>

— amp_rx_3<63:58> = am_rxpayloads<1, 125:120>

For *x*=0 to 3, am_rx_*x*<65:0> is constructed as follows:

— am_rx_*x*<0>=1 and am_rx_*x*<1>=0.

— am_rx_*x*<25:2> is set to M_0, M_1, and M_2 as shown in Figure 82–9 using the values in Table 82–3 for PCS lane number *x*.

— am_rx_*x*<33:26> = amp_rx_*x*<31:24>.

— am_rx_*x*<57:34> is set to M_4, M_5, and M_6 as shown in Figure 82–9 using the values in Table 82–3 for PCS lane number *x*.

— am_rx_*x*<65:58> = amp_rx_*x*<63:56>

One vector is mapped to four alignment markers every 1024 Reed-Solomon codewords (see 134.5.3.4). The alignment markers are simultaneously transmitted on the four PCS lanes after every 20 479th column of four 66-bit blocks.

The alignment markers am_rx_0 to am_rx_3 shall be inserted so that they are immediately followed by rx_coded_0 to rx_coded_3, respectively, as derived from the first 257-bit block following am_rxmapped.

134.5.3.8 Receive bit ordering

The receive bit ordering is illustrated in Figure 134–5. This illustration shows the case where the FEC lanes appear across the PMA:IS_UNITDATA_*i*.indication primitives in the correct order.

134.5.4 Detailed functions and state diagrams

The state diagrams, including the associated definitions of variables, functions and counters, are identical to those for the 100GBASE-R RS-FEC sublayer defined in 91.5.4, with the exception that some of the variables and counters are redefined to account for the differences in alignment marker spacing and number of FEC lanes.

In addition, EEE optional deep sleep capability is not supported for 50GBASE-R PHYs and therefore any reference to the optional EEE deep sleep capability in 91.5.4 can be ignored.

134.5.4.1 State diagram conventions

The state diagram conventions are identical to those defined in 91.5.4.1.

134.5.4.2 State variables

134.5.4.2.1 Variables

This following variables are redefined from what is described in 91.5.4.2.1:

amp_valid
: Boolean variable that is set to true if the received 64-bit block is a valid alignment marker payload. The alignment marker payload, mapped to an FEC lane according to the process described in 134.5.2.6, consists of 48 known bits and 16 variable bits (the BIP3 field and its complement BIP7 see 82.2.7). The bits of the candidate block that are in the positions of the known bits in the alignment marker payload are compared on a nibble-wise basis (12 comparisons). If no more than 3 nibbles in the candidate block fail to match the corresponding known nibbles in the alignment marker payload, the candidate block is considered a valid alignment marker payload. Each FEC lane compares the candidate block to the alignment marker payload for PCS lane 0.

amps_lock<*x*>
: Boolean variable that is set to true when the receiver has detected the location of the alignment marker payload sequence for a given lane on the PMA service interface, where $x = 0{:}1$.

fec_lane
: A variable that holds the FEC lane number (0 to 1) received on lane *x* of the PMA service interface when amps_lock<*x*> = true. The FEC lane number is determined by the alignment marker payloads in the 2nd position of the sequence based on the mapping defined in 134.5.2.6. The 48 bits that are in the positions of the known bits in the received alignment marker payload are compared to the expected values for a given payload position and FEC lane on a nibble-wise basis (12 comparisons). If no more than 3 nibbles in the candidate block fail to match the corresponding known nibbles on a given FEC lane, then the FEC lane number is assigned accordingly.

fec_lpi_fw
: Boolean variable that controls the behavior of the Transmit LPI and Receive LPI state diagrams. This variable is set to true when the local PCS is configured to use the fast wake mechanism and set to false otherwise. This variable shall always be set to true.

fec_optional_states
: Boolean variable that is always set to true to indicate that the optional states in the FEC synchronization state diagram in Figure 91–8 are implemented.

134.5.4.2.2 Functions

The functions are identical to those defined in 91.5.4.2.2.

134.5.4.2.3 Counters

This following counters are redefined from what is described in 91.5.4.2.3:

amp_counter
: This counter counts the 1024 FEC codewords that separate the ends of two consecutive normal alignment marker payload sequences. An FEC codeword is 2720 bits per FEC lane.

134.5.4.3 State diagrams

The state diagrams are identical to those defined in 91.5.4.3.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

134.6 RS-FEC MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the RS-FEC. If MDIO is implemented, it shall map MDIO control bits to RS-FEC control variables as shown in Table 134–1, and MDIO status bits to RS-FEC status variables as shown in Table 134–2, and if a separated PMA (see 45.2.1) is connected to the FEC service interface (e.g., if the RS-FEC and PCS are separated via a LAUI-2 interface) it shall map additional MDIO status bits to additional RS-FEC status variables as shown in Table 134–3.

Table 134–1—MDIO/RS-FEC control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
FEC bypass indication enable	RS-FEC control register	1.200.1	FEC_bypass_indication_enable
FEC degraded SER enable	RS-FEC control register	1.200.4	FEC_degraded_SER_enable
FEC degraded SER activate threshold	RS-FEC degraded SER activate threshold register	1.650, 1.651	FEC_degraded_SER_activate_threshold
FEC degraded SER deactivate threshold	RS-FEC degraded SER deactivate threshold register	1.652, 1.653	FEC_degraded_SER_deactivate_threshold
FEC degraded SER interval	RS-FEC degraded SER interval register	1.654, 1.655	FEC_degraded_SER_interval

Table 134–2—MDIO/RS-FEC status variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
FEC bypass indication ability	RS-FEC status register	1.201.1	FEC_bypass_indication_ability
RS-FEC high SER	RS-FEC status register	1.201.2	hi_ser
FEC degraded SER ability	RS-FEC status register	1.201.3	FEC_degraded_SER_ability
FEC degraded SER	RS-FEC status register	1.201.4	FEC_degraded_SER
FEC optional states supported	RS-FEC status register	1.201.7	fec_optional_states
FEC AM lock *x*, *x*=0 to 1	RS-FEC status register	1.201.8:9	amps_lock<*x*>
RS-FEC align status	RS-FEC status register	1.201.14	fec_align_status
FEC corrected codewords	RS-FEC corrected codewords counter register	1.202, 1.203	FEC_corrected_cw_counter
FEC uncorrected codewords	RS-FEC uncorrected codewords counter register	1.204, 1.205	FEC_uncorrected_cw_counter
FEC lane *x* mapping	RS-FEC lane mapping register	1.206	FEC_lane_mapping<*x*>
FEC symbol errors, FEC lanes 0 to 1	RS-FEC symbol error counter register, FEC lanes 0 to 1	1.210 to 1.213	FEC_symbol_error_counter_*i*

Table 134–3—MDIO/RS-FEC status variable mapping for separated PMA

MDIO control variable	PMA/PMD register name	Register/bit number	FEC variable
PCS align status	RS-FEC status register	1.201.15	align_status
BIP errors, PCS lanes 0 to 3	RS-FEC BIP error counter register, PCS lanes 0 to 3	1.230 to 1.233	BIP_error_counter_*i*
PCS lane *x* mapping	PCS lane *x* mapping register	1.250 to 1.253	lane_mapping<*x*>
Block *x* lock	RS-FEC PCS alignment status 1 register	1.280	block_lock<*x*>
Lane *x* aligned	RS-FEC PCS alignment status 3 register	1.282	am_lock<*x*>

The following subclauses define variables that are not otherwise defined, e.g., for use by state diagrams.

134.6.1 FEC_bypass_indication_enable

This variable is set to one to bypass the error indication function (see 134.5.3.3.1) when this ability is supported. When this variable is set to zero, the decoder indicates errors to the PCS sublayer. The default value of this variable is zero. This variable is mapped to the bit defined in 45.2.1.116.4 (1.200.1).

134.6.2 FEC_degraded_SER_enable

This variable enables the FEC decoder to indicate the presence of a degraded SER when the ability is supported (see 134.5.3.3.2). When set to a one, this variable enables degraded SER detection. When set to a zero, degraded SER detection is disabled. Writes to this bit are ignored and reads return a zero if the FEC does not have the ability to signal the presence of a degraded SER. This variable is mapped to the bit defined in 45.2.1.116.1 (1.200.4).

134.6.3 FEC_degraded_SER_activate_threshold

This variable controls the threshold used to set the FEC_degraded_SER bit as defined in 134.5.3.3.2. It is mapped to the registers defined in 45.2.1.146 (1.650, 1.651).

134.6.4 FEC_degraded_SER_deactivate_threshold

This variable controls the threshold used to clear the FEC_degraded_SER bit as defined in 134.5.3.3.2. It is mapped to the registers defined in 45.2.1.147 (1.652, 1.653).

134.6.5 FEC_degraded_SER_interval

This variable controls the interval used to set and clear the FEC_degraded_SER bit as defined in 134.5.3.3.2. It is mapped to the registers defined in 45.2.1.148 (1.654, 1.655).

134.6.6 FEC_bypass_indication_ability

The Reed-Solomon decoder may have the option to bypass the error indication function (see 134.5.3.3.1) to reduce the delay contributed by the RS-FEC sublayer. This variable is set to one to indicate that the decoder has the ability to bypass error indication. The variable is set to zero if this ability is not supported. This variable is mapped to the bit defined in 45.2.1.117.11 (1.201.1).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

134.6.7 hi_ser

This variable is defined when the FEC_bypass_indication_ability variable is set to one. When FEC_bypass_indication_enable is set to one, this bit is set to one if the number of RS-FEC symbol errors in a window of 8192 codewords exceeds the threshold (see 134.5.3.3) and is set to zero otherwise. This variable is mapped to the bit defined in 45.2.1.117.10 (1.201.2).

134.6.8 FEC_degraded_SER_ability

The FEC decoder may have the option to indicate the presence of a degraded SER (see 134.5.3.3.2). This variable is set to one to indicate that the FEC decoder has the ability to indicate the presence of a degraded SER. This variable is set to zero if this ability is not supported. It is mapped to the bit defined in 45.2.1.117.9 (1.201.3).

134.6.9 FEC_degraded_SER

When FEC_degraded_SER_enable is asserted, this variable indicates the presence of a degraded SER as defined in 134.5.3.3.2. This variable is mapped to the bit defined in 45.2.1.117.8 (1.201.4).

134.6.10 fec_optional_states

This variable is always set to true to indicate that the optional states in the FEC synchronization state diagram in Figure 91–8 are implemented. This variable is mapped to the bit defined in 45.2.1.117.8 (1.201.7).

134.6.11 amps_lock<*x*>

These variables are assigned by the FEC alignment state diagram shown in Figure 91–9 (see 91.5.4.3 and 134.5.4). They are mapped to the bits defined in 45.2.1.117 (1.201.8 to 1.201.9 for FEC lanes 0 to 1, respectively).

134.6.12 fec_align_status

This variable assigned by the FEC alignment state diagram shown in Figure 91–9 (see 91.5.4.3). It is mapped to the bit defined in 45.2.1.117.2 (1.201.14).

134.6.13 FEC_corrected_cw_counter

A corrected FEC codeword is a codeword that contains errors and was corrected.

FEC_corrected_cw_counter is a 32-bit counter that counts once for each corrected FEC codeword processed when fec_align_status is true. This variable is mapped to the registers defined in 45.2.1.118 (1.202, 1.203).

134.6.14 FEC_uncorrected_cw_counter

An uncorrected FEC codeword is a codeword that contains errors that were not corrected.

FEC_uncorrected_cw_counter is a 32-bit counter that counts once for each uncorrected FEC codeword processed when fec_align_status is true. This variable is mapped to the registers defined in 45.2.1.119 (1.204, 1.205).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

134.6.15 FEC_lane_mapping<*x*>

When the RS-FEC receive function detects and locks to an alignment marker payload on PMA service interface lane *x*, the FEC lane number corresponding to the detected alignment marker payload is assigned to the variable FEC_lane_mapping<*x*>. These variables are mapped to the register defined in 45.2.1.120 (1.206).

134.6.16 FEC_symbol_error_counter_*i*

FEC_symbol_error_counter_*i*, where *i*=0 to 1, is a 32-bit counter that counts once for each 10-bit symbol corrected on FEC lane *i* when fec_align_status is true. These variables are mapped to the registers defined in 45.2.1.121 and 45.2.1.122 (1.210 to 1.213).

134.6.17 align_status

This variable is assigned the value of rx_align_status as defined by the PCS deskew state diagram shown in Figure 82–14 (see 134.5.2.2). It is mapped to the bit defined in 45.2.1.117.1 (1.201.15).

134.6.18 BIP_error_counter_*i*

BIP_error_counter_*i*, where *i*=0 to 3, is a 16-bit counter that holds the BIP error count for PCS lane *i* as calculated by the RS-FEC transmit function (see 134.5.2.4). These variables are mapped to the registers defined in 45.2.1.123 and 45.2.1.124 (1.230 to 1.233).

134.6.19 lane_mapping<*x*>

When the RS-FEC transmit function detects and locks to an alignment marker on FEC service interface lane *x*, the PCS lane number corresponding to the detected alignment marker is assigned to the variable lane_mapping<*x*>. These variables are mapped to the registers defined in 45.2.1.125 and 45.2.1.126 (1.250 to 1.253).

134.6.20 block_lock<*x*>

These variables are assigned by the block lock state diagram shown in Figure 82–12 (see 134.5.2.1). They are mapped to the registers defined in 45.2.1.127 (1.280).

134.6.21 am_lock<*x*>

These variables are assigned by the alignment marker lock state diagram shown in Figure 82–13 (see 134.5.2.2). They are mapped to the registers defined in 45.2.1.129 (1.282).

134.7 Protocol implementation conformance statement (PICS) proforma for Clause 134, Reed-Solomon forward error correction (RS-FEC) sublayer for 50GBASE-R PHYs[225]

134.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 134, Reed-Solomon forward error correction (RS-FEC) sublayer for 50GBASE-R PHYs, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

134.7.2 Identification

134.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

134.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 134, Reed-Solomon forward error correction (RS-FEC) sublayer for 50GBASE-R PHYs
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[225] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

135. Physical Medium Attachment (PMA) sublayer, type 50GBASE-R and 100GBASE-P

135.1 Overview

135.1.1 Scope

This clause specifies the Physical Medium Attachment sublayer (PMA) for the families of 50 Gb/s and 100 Gb/s PAM4 Physical Layer implementations known as 50GBASE-R (see 131.1.3) and 100GBASE-P (see 80.1.4). The PMA allows the PCS (see Clause 133 and Clause 82) and FEC (see Clause 134 and Clause 91) to connect in a media-independent way with a range of physical media. The 50GBASE-R PMA can support any of the 50 Gb/s PMDs in Table 131–1 and the 100GBASE-P PMA can support any of the 100 Gb/s PAM4 PMDs according to Table 80–3 and Table 80–5.

50GBASE-R and 100GBASE-P PHYs can be extended to support any full duplex medium requiring only that the PMD be compliant with the appropriate PMA interface.

The interfaces for the inputs of the 50GBASE-R and 100GBASE-P PMAs are defined in an abstract manner and do not imply any particular implementation. For 50GBASE-R PMAs, electrical interfaces connecting PMA sublayers, known as LAUI-2 and 50GAUI-n, are defined in Annex 135B through Annex 135G. For 100GBASE-P PMAs, electrical interfaces connecting PMA sublayers, known as 100GAUI-n, are defined in Annex 135D through Annex 135G.

135.1.2 Position of the PMA in the 50GBASE-R and 100GBASE-P sublayers

Figure 135–1 shows the relationship of the PMA sublayer (shown shaded) with other sublayers to the ISO Open System Interconnection (OSI) reference model.

135.1.3 Summary of functions

The following is a summary of the principal functions implemented (when required) by the PMA in both the transmit and receive directions:

a) Adapt the PCSL/FECL-formatted signal to the appropriate number of abstract or physical lanes.
b) Provide per-input-lane clock and data recovery.
c) Provide bit-level multiplexing.
d) Provide clock generation.
e) Provide signal drivers.
f) Optionally provide local loopback to/from the PMA service interface.
g) Optionally provide remote loopback to/from the PMD service interface.
h) Optionally provide test-pattern generation and checking.
i) Tolerate Skew Variation.
j) Perform PAM4 encoding and decoding, including Gray mapping and optional precoding, when required.

PAM4 encoding and decoding is required for 50GBASE-R PMAs where the number of physical lanes is 1 and for 100GBASE-P PMAs where the number of physical lanes is 1 or 2.

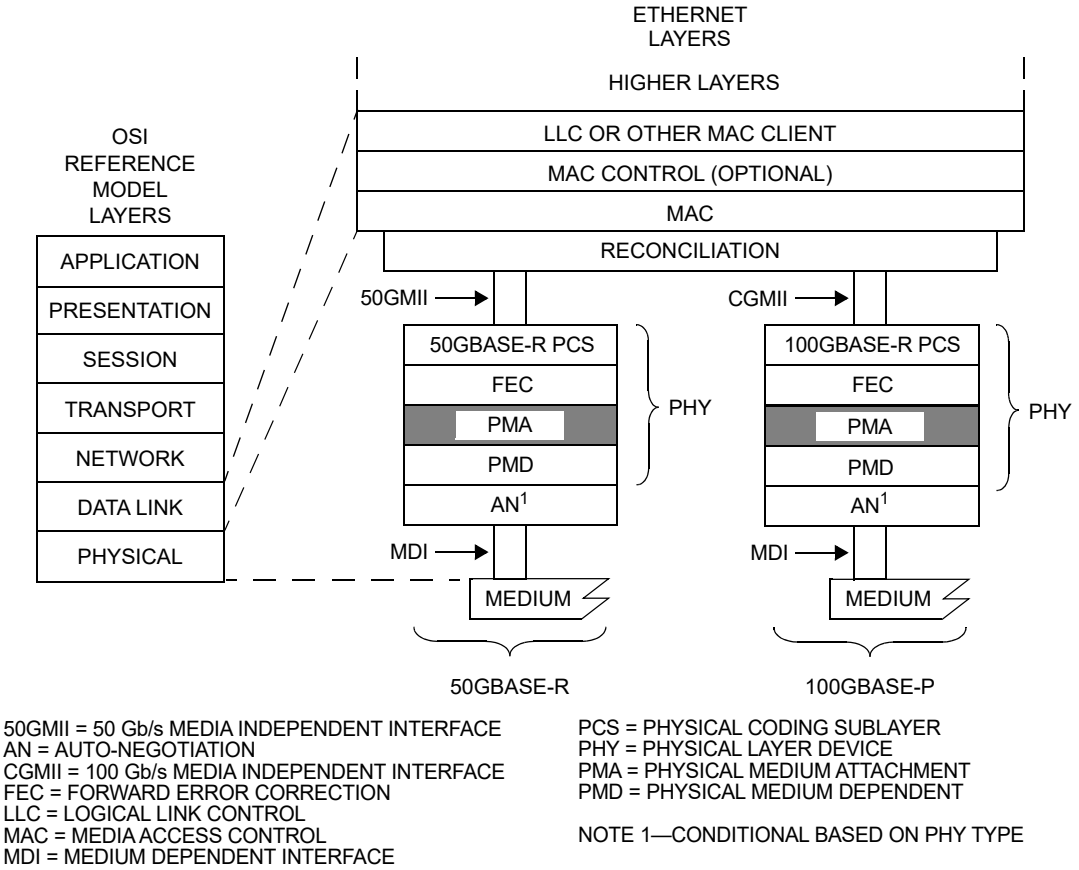

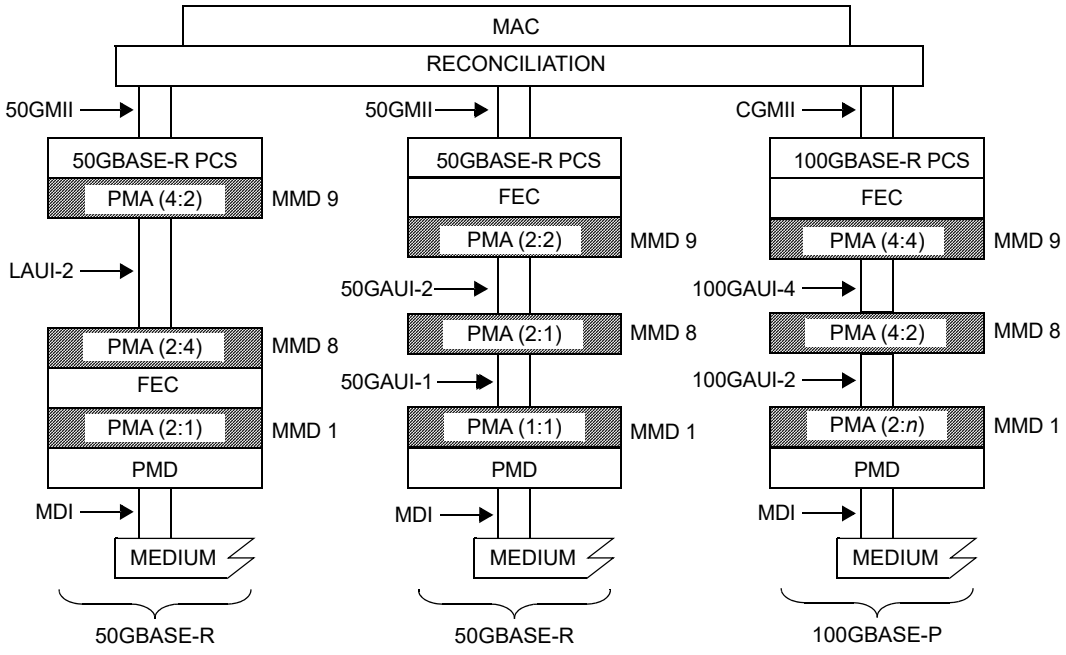

Figure 135–1—50GBASE-R and 100GBASE-P PMA relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

135.1.4 PMA sublayer positioning

An implementation may use one or more PMA sublayers to adapt the number and rate of the PCS lanes to the number and rate of the PMD lanes. The number of PMA sublayers required depends on the partitioning of functionality for a particular implementation. An example is illustrated in Figure 135–2. Additional examples are illustrated in Annex 135A. Each PMA maps the PCSLs/FECLs from p PMA input lanes to q PMA output lanes in the Tx direction, and from q PMA input lanes to p PMA output lanes in the Rx direction.

Management Data Input/Output (MDIO) Manageable Device (MMD) addresses 1, 8, 9, and 10 are available for addressing multiple instances of PMA sublayers (see Table 45–1 for MMD device addresses). If the PMA sublayer that is closest to the PMD is packaged with the PMD, it shares MMD 1 with the PMD. More addressable instances of PMA sublayers, each one separated from lower addressable instances by chip-to-chip interfaces, may be implemented and addressed allocating MMD addresses to PMAs in increasing numerical order going from the PMD toward the MAC. The examples shown in Figure 135–2 could be implemented with three addressable instances: MMD 1 addressing the lowest PMA sublayer (co-packaged with the PMD), MMD 8 addressing the middle PMA sublayer, and MMD 9 addressing the highest PMA sublayer (immediately below the FEC).

100GAUI = 100 Gb/s ATTACHMENT UNIT INTERFACE
50GAUI = 50 Gb/s ATTACHMENT UNIT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
LAUI = 50 Gb/s ATTACHMENT UNIT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

n = 1 or 2

Figure 135–2—Example 50GBASE-R and 100GBASE-P PMA layering

The number of input lanes and the number of output lanes for a PMA are always divisors of the number of PCSLs/FECLs. For PMA sublayers supporting 50GBASE-R PMDs, the number of PCSLs (above the FEC) is 4 and the number of FECLs (below the FEC) is 2. For PMA sublayers supporting 100GBASE-P PMDs, the number of FECLs is 4.

The following guidelines apply to the partitioning of PMAs:

a) The inter-sublayer service interface, defined in 131.3.1, is used for the PMA service interfaces supporting a flexible architecture with multiple PMA sublayers.
   1) An instance of this interface can only connect service interfaces with the same number of lanes, where the lanes operate at the same rate.

b) The abstract PMA service interface can be physically instantiated as a LAUI-2, 50GAUI-n, or 100GAUI-n, using associated PMAs to map to the appropriate number of lanes.

c) For physical instantiations of the PMA service interface, the PMA:IS_SIGNAL.indication is conveyed outside of this physically instantiated interface.

d) Physical instantiations of the PMA service interface define electrical and timing specification as well as requiring a receive re-timing function.

e) LAUI-2 is a physical instantiation of the PMA service interface between two adjacent 50GBASE-R PMA sublayers above the FEC.
   1) LAUI-2 provides bit-multiplexing of 4 PCSLs.
   2) LAUI-2 is a 25.78125 GBd by two-lane NRZ physical instantiation of the 50 Gb/s connection.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

f) 50GAUI-n is a physical instantiation of the PMA service interface between two adjacent 50GBASE-R PMA sublayers below the FEC and contains 2 FECLs.
   1) 50GAUI-n provides bit-multiplexing of 2 FECLs.
   2) 50GAUI-2 is a 26.5625 GBd by two-lane NRZ physical instantiation of the 50 Gb/s connection.
   3) 50GAUI-1 is a 26.5625 GBd by one-lane PAM4 physical instantiation of the 50 Gb/s connection.

g) CAUI-n is a physical instantiation of the PMA service interface between two adjacent 100GBASE-R PMA (see Clause 83) sublayers above the FEC for a 100GBASE-P PHY or between adjacent sublayers below the PCS for a 100GBASE-R PHY. CAUI-n is not specified in this clause, but is listed here for completeness.
   1) CAUI-n provides bit-multiplexing of 20 PCSLs.
   2) CAUI-4 is a 25.78125 GBd by four-lane NRZ physical instantiation of the 100 Gb/s connection. CAUI-4 is specified in Clause 83 and associated annexes.
   3) CAUI-10 is a 10.3125 GBd by ten-lane NRZ physical instantiation of the 100 Gb/s connection. CAUI-10 is specified in Clause 83 and associated annexes.

h) 100GAUI-n is a physical instantiation of the PMA service interface between two adjacent 100GBASE-P PMA sublayers below the FEC for a 100GBASE-P PHY.
   1) 100GAUI-n provides bit-multiplexing of 4 FECLs.
   2) 100GAUI-4 is a 26.5625 GBd by four-lane NRZ physical instantiation of the 100 Gb/s connection.
   3) 100GAUI-2 is a 26.5625 GBd by two-lane PAM4 physical instantiation of the 100 Gb/s connection.

i) Opportunities for optional test-pattern generation, optional test-pattern detection, optional local loopback and optional remote loopback are dependent upon the location of the PMA sublayer in the implementation. See Figure 135–5.

j) A minimum of one PMA sublayer is required in a PHY.

k) A maximum of four PMA sublayers are addressable as MDIO MMDs.

135.2 PMA interfaces

All PMA variants for 50GBASE-R and 100GBASE-P are based on a generic specification of a bit mux function that applies to all input/output lane counts and each direction of transmission. Each direction of transmission may employ one or more such bit muxes to adapt from the appropriate number of input lanes to the appropriate number of output lanes as illustrated in Figure 135–3.

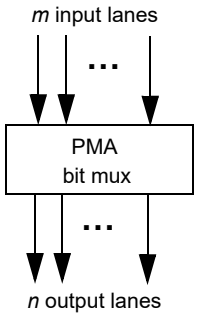

Figure 135–3—PMA bit mux used in both Tx and Rx directions

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Conceptually, the PMA bit mux operates in one direction of transmission by demultiplexing PCSLs/FECLs from *m* PMA input lanes and remultiplexing them into *n* PMA output lanes. The mapping of PCSLs/FECLs from input to output lanes is not specified. See 135.5.2 and Figure 135–4 for details.

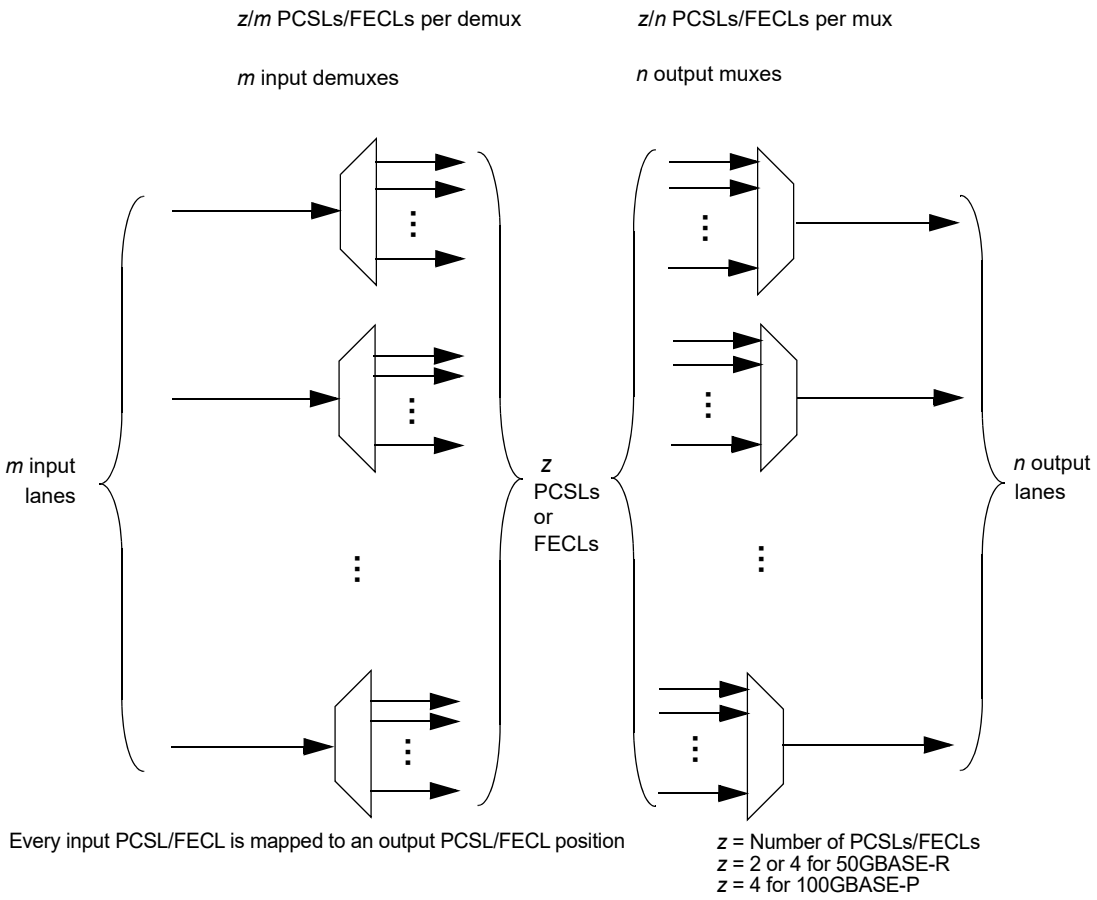

Figure 135–4—PMA bit mux operation used in both Tx and Rx directions

135.3 PMA service interface

The PMA service interface for 50GBASE-R and 100GBASE-P is an instance of the inter-sublayer service interface defined in 131.3.1. The PMA service interface primitives are summarized as follows:

PMA:IS_UNITDATA_*i*.request
PMA:IS_UNITDATA_*i*.indication
PMA:IS_SIGNAL.indication

For a PMA service interface with *p* lanes, the primitives are defined for $i = 0$ to $p - 1$.

If the PMA client is the 50GBASE-R PCS, the PMA continuously sends four parallel bit streams to the PCS, each at the nominal signaling rate of the PCSL.

If a PMA client is another PMA, a 50GBASE-R PMA with p=2 physical input lanes receives NRZ symbols on each of its input lanes at the FECL rate or at 2 times the PCSL rate. A 50GBASE-R PMA with p=1

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

physical input lane receives PAM4 symbols on that input lane at the FECL rate, with each symbol formed from two bits.

If a PMA client is another PMA, 100GBASE-P PMA with *p*=4 physical input lanes receives NRZ symbols on each of its input lanes at the FECL rate. A 100GBASE-P PMA with *p*=1 or *p*=2 physical input lanes receives PAM4 symbols on each of its input lanes at 2 or 1 times, respectively, the FECL rate, with each symbol formed from two bits. The bit stream represented by the input symbols carries *z*/*p* bit-multiplexed FECLs on each physical input lane, where *z*=4 for 100GBASE-P.

Skew may exist between different PCSLs/FECLs received on the same physical input lane even though all PCSLs/FECLs originate from the same synchronous source, so there is independence of arrival of bits from each PCSL/FECL on each physical input lane.

In the Tx direction, if the symbol from a PMA:IS_UNITDATA_*i*.request primitive is received over a physically instantiated interface (LAUI-2, 50GAUI-n, or 100GAUI-n), clock and data are recovered on the lane receiving the symbol. If necessary, PAM4 symbols are converted to pairs of bits. Bits are routed through the PMA to an output lane through a process that may demultiplex PCSLs/FECLs from the input, perform any necessary buffering to tolerate Skew Variation across input lanes, and multiplex PCSLs/FECLs to output lanes. If necessary, pairs of bits on output lanes are converted to PAM4 symbols. The symbols are sent on an output lane to the sublayer below using the *inst*:IS_UNITDATA_*k*.request (*k* not necessarily equal to *i*) primitive (see 135.4).

In the Rx direction, the PMA passes the bits represented by the symbols from the input lane(s) received from the sublayer below the PMA into encoded symbols on the output lanes. If necessary, buffers are filled to allow tolerating the Skew Variation that may appear between the input lanes. PCSLs/FECLs are demultiplexed from the input lanes, remultiplexed to the output lanes, and symbols are transferred over each output lane to the PMA client via the PMA:IS_UNITDATA_i.indication primitive.

The PMA:IS_SIGNAL.indication primitive is generated by a Signal Indication Logic (SIL) function that reports signal health based on receipt of the *inst*:IS_SIGNAL.indication from the sublayer below, data being received on all of the input lanes from the sublayer below, buffers filled (if necessary) to accommodate Skew Variation, and symbols being sent to the PMA client on all of the output lanes. When these conditions are met, the SIGNAL_OK parameter sent to the PMA client via the PMA:IS_SIGNAL.indication primitive has the value OK. Otherwise, the SIGNAL_OK primitive has the value FAIL.

135.4 Service interface below PMA

Since the architecture supports multiple PMA sublayers for various PMD lane counts and device partitioning, there are several different sublayers that may appear below a PMA, including the FEC, PMD, or another PMA. The variable *inst* represents whichever sublayer appears below the PMA (e.g., another PMA, FEC, or PMD).

The sublayer below the PMA utilizes the inter-sublayer service interface defined in 131.3. The service interface primitives provided to the PMA are summarized as follows:

inst:IS_UNITDATA_*i*.request
inst:IS_UNITDATA_*i*.indication
inst:IS_SIGNAL.indication

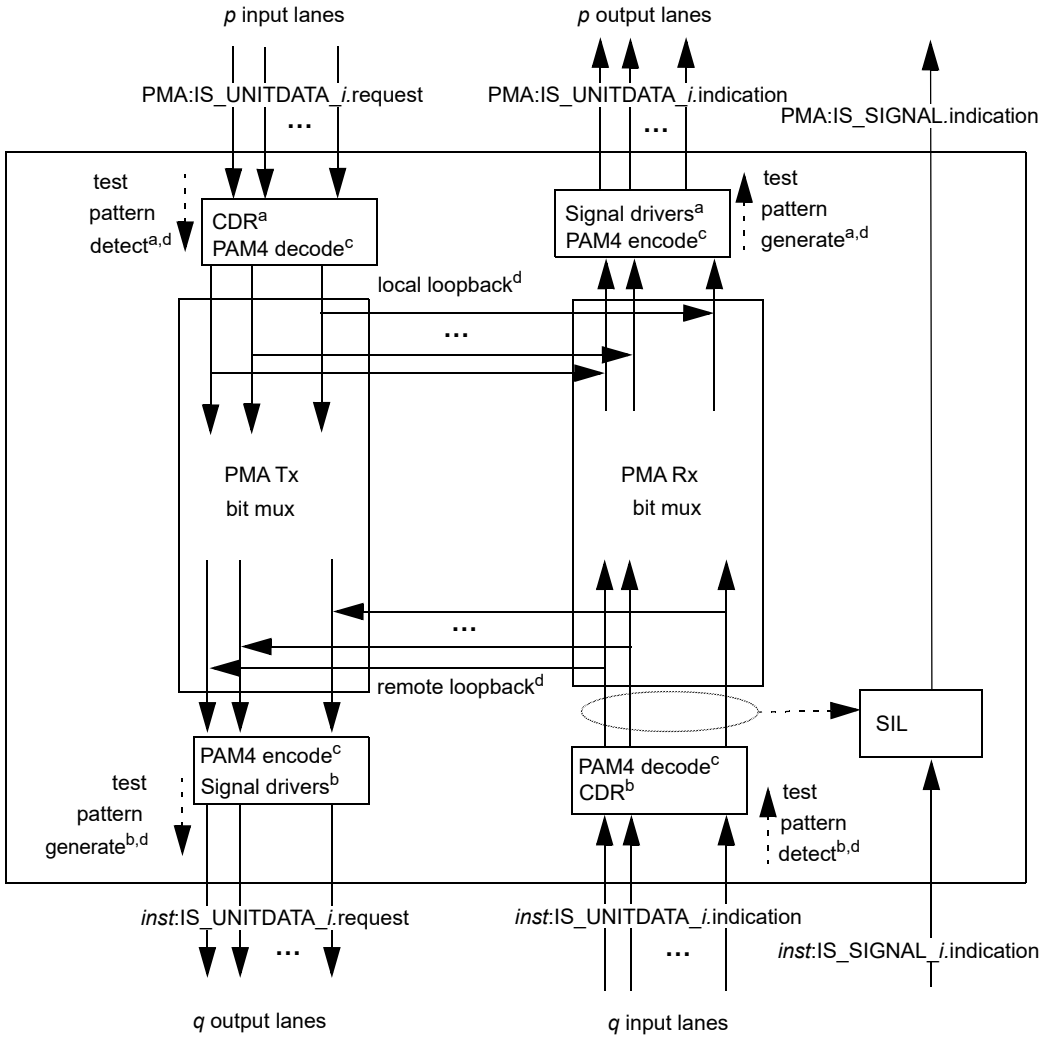
The number of lanes *q* for the service interface matches the number of lanes expected by the PMA. The *inst*:IS_UNITDATA_*i* primitives are defined for each lane $i = 0$ to $q - 1$ of the service interface below the PMA. Note that electrical and timing specifications of the service interface are defined if the interface is physically instantiated (e.g., LAUI-2, 50GAUI-n, or 100GAUI-n), otherwise the service interface is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

specified only abstractly. The interface between the PMA and the sublayer below consists of *q* lanes for data transfer and a status indicating a good signal from the sublayer below the PMA (see Figure 135–5).

In the Tx direction, the PMA passes the bits represented by the symbols from the input lane(s) received via the PMA:IS_UNITDATA_i.request primitive(s) into encoded symbols on the output lanes. If necessary, buffers are filled to provide the ability to tolerate the Skew Variation that may appear between the input lanes from the PMA client. PCSLs/FECLs are demultiplexed from the input lanes, remultiplexed to the output lanes, and symbols are transferred over each output lane to the sublayer below the PMA.

In the Rx direction, if the symbol is received over a physically instantiated interface (50GAUI-n, 100GAUI-n, or physically instantiated PMD service interface), clock and data are recovered on the lane receiving the symbol. If necessary, PAM4 symbols received on the input lanes are converted to pairs of bits. The bits are routed through the PMA to an output lane toward the PMA client through a process that may demultiplex PCSLs/FECLs from the input, perform any necessary buffering to tolerate Skew Variation across input lanes, and multiplex PCSLs/FECLs to output lanes. If necessary, pairs of bits are converted to PAM4 symbols on the output lanes. Each symbol is sent on an output lane to the PMA client using the PMA:IS_UNITDATA_*k*.indication (*k* not necessarily equal to *i*) primitive at the PMA service interface.



135.5 Functions within the PMA

The purpose of the PMA is to adapt the PCSL/FECL-formatted signal to an appropriate number of abstract or physical lanes, to recover clock from the received signal (if appropriate), and optionally to provide test signals and loopback. Each input (Tx direction) or output (Rx direction) lane between the PMA and the PMA client carries one or more PCSLs/FECLs that are bit-multiplexed. All input and output lanes between the PMA and the PMA client carry the same number of PCSLs/FECLs and operate at the same nominal signaling rate. Likewise, each input (Rx direction) or output (Tx direction) lane between the PMA and the sublayer below the PMA carries one or more PCSLs/FECLs that are bit-multiplexed. All input and output lanes between the PMA and the sublayer below the PMA carry the same number of PCSLs/FECLs and operate at the same nominal signaling rate. As described in 135.1.4, the number of input lanes and the number of output lanes for a given PMA are divisors of 2 (below the FEC) or 4 (above the FEC) for 50GBASE-R, or 4 for 100GBASE-P, which are the number of PCSLs/FECLs for the respective PHYs.

Figure 135–5 provides the functional block diagram of a PMA. The parameters of a PMA include the following:

- The numbers of input and output lanes in each direction.
- Whether the PMA is adjacent to a physically instantiated interface (LAUI-2, 50GAUI-n, or 100GAUI-n above or below).
- Whether the PMA is adjacent to the PCS.
- Whether the PMA is adjacent to the PMD.
- Whether the PMA is adjacent to the FEC.

inst = PMD, PMA, depending on which sublayer is below this PMA
SIL = Signal Indication Logic

[a] If LAUI-2, 50GAUI-n, or 100GAUI-n immediately above this PMA.
[b] If LAUI-2, 50GAUI-n, or 100GAUI-n immediately below this PMA or if this is the closest PMA to the PMD.
[c] If number of input or output lanes is 1 for a 50GBASE-R PMA, or 1 or 2 for a 100GBASE-P PMA.
[d] Optional.

Figure 135–5—PMA Functional Block Diagram

135.5.1 Per input-lane clock and data recovery

If the interface between the PMA client and the PMA is physically instantiated as LAUI-2, 50GAUI-n, or 100GAUI-n, the PMA shall meet the electrical and timing specifications above the PMA in Annex 135B through Annex 135G, as appropriate.

If the interface between the sublayer below the PMA and the PMA is physically instantiated as LAUI-2, 50GAUI-n, or 100GAUI-n, the PMA shall meet the electrical and timing specifications below the PMA at the service interface as specified in Annex 135B through Annex 135G, as appropriate.

135.5.2 Bit-level multiplexing

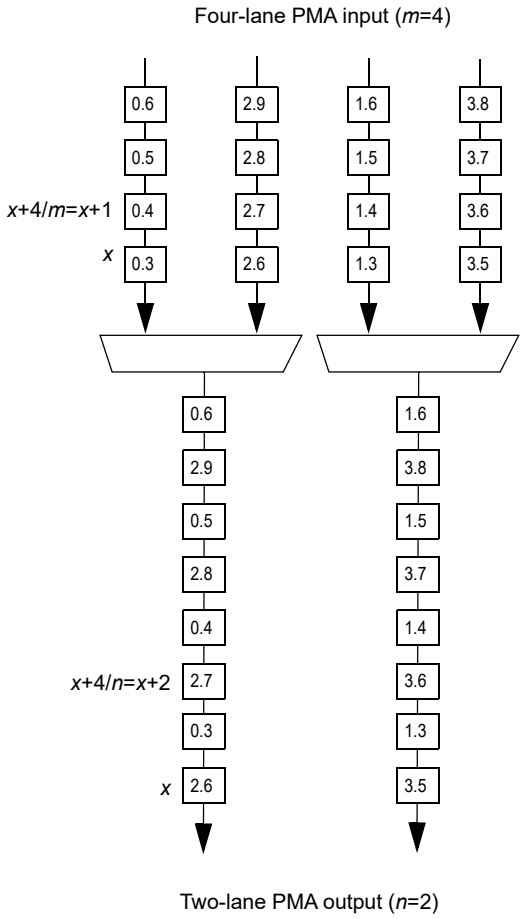
The PMA provides bit-level multiplexing in both the Tx and Rx directions. In the Tx direction, the function is performed among the bits received from the PMA client via the PMA:IS_UNITDATA_*i*.request primitives (for PMA client lanes $i = 0$ to $p - 1$) with the result sent to the service interface below the PMA using the *inst*:IS_UNITDATA_*i*.request primitives (for service interface lanes $i = 0$ to $q - 1$), referencing the functional block diagram shown in Figure 135–5. The bit multiplexing behavior is illustrated in Figure 135–4.

The aggregate signal carried by the group of input lanes or the group of output lanes is arranged as a set of PCSLs/FECLs. The number of PCSLs/FECLs z is 2 FECLs (below the FEC) and 4 PCSLs (above the FEC) for 50GBASE-R interfaces and 4 FECLs for 100GBASE-P interfaces. For 50GBASE-R, the nominal bit rate R_{lane} is 12.890625 Gb/s for each PCSL and 26.5625 Gb/s for each FECL. For 100GBASE-P, the nominal bit rate R_{lane} is 26.5625 Gb/s for each FECL.

For a PMA with m input lanes (Tx or Rx direction), each input lane carries, bit multiplexed, z/m PCSLs/FECLs. Each input lane has a nominal bit rate of $z/m \times R_{\text{lane}}$. Note that the signaling rate is equal to the bit rate when the signal modulation is NRZ. The signaling rate is equal to half of the bit rate when the signal modulation is PAM4. If necessary, PAM4 symbols are converted to pairs of bits on the input lanes and/or pairs of bits are converted to PAM4 symbols on the output lanes. If bit x received on an input lane belongs to a particular PCSL/FECL, the next bit of that same PCSL/FECL is received on the same input lane at bit position $x+(z/m)$. The z/m PCSLs/FECLs may arrive in any sequence on a given input lane.

For a PMA with n output lanes (Tx or Rx direction), each output lane carries, bit multiplexed, z/n PCSLs/FECLs. Each output lane has a nominal signaling rate of $z/n \times R_{\text{lane}}$. Each PCSL/FECL is mapped from a position in the sequence on one of the m input lanes to a position in the sequence on one of the n output lanes. If bit x sent on an output lane belongs to a particular PCSL/FECL, the next bit of that same PCSL/FECL is sent on the same output lane at bit position $x + (z/n)$. The PMA shall maintain the chosen sequence of PCSLs/FECLs on all output lanes while it is receiving a valid stream of bits on all input lanes.

Each PCSL/FECL received in any temporal position on an input lane is transferred into a temporal position on an output lane. As the PCS (see Clause 133 and Clause 82) and FEC (See Clause 91 and Clause 134) have fully flexible receive logic, an implementation is free to perform the mapping of PCSLs/FECLs from input lanes to output lanes without constraint. Figure 135–6 illustrates one possible bit ordering for a 100GBASE-P 4:2 PMA bit mux. Other bit orderings are also valid.



Note that since the number of input lanes and output lanes for a 50GBASE-R or 100GBASE-P PMA is always a power of two, many PMAs converting between different numbers of lanes normally simply multiplex two or four input lanes to one output lane, or demultiplex two or four output lanes from one input lane. However, any PMA implementation which produces an allowable order of bits from all PCSLs/FECLs on the output lanes is valid.

135.5.3 Skew and Skew Variation

The Skew (relative delay) between the PCSLs/FECLs is kept within limits so that the information on the lanes can be reassembled by the PCS and FEC.

Any PMA that combines PCSLs/FECLs from different input lanes onto the same output lane is required to tolerate Skew Variation between the input lanes without changing the PCSL/FECL positions on the output. Skew and Skew Variation are defined in 131.5. The limits for Skew and Skew Variation at physically instantiated interfaces are specified at Skew points SP0, SP1, and SP2 in the transmit direction and SP5, SP6, and SP7 in the receive direction as defined in 131.5 and illustrated in Figure 131–3 for 50GBASE-R and as defined in 80.5 and illustrated in Figure 80–9 for 100GBASE-P.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—*i.k* indicates bit *k* on FECL *i*. Skew may exist between FECLs.

Figure 135–6—Example 4:2 100GBASE-P PMA bit mux

135.5.3.1 Skew generation toward SP0

In an implementation with an instantiated LAUI-2 interface between the PCS and the FEC, the PMA that sends data in the transmit direction toward the LAUI-2 (SP0 in Figure 131–3) shall produce no more than 29 ns of Skew between PCSLs and no more than 0.2 ns of Skew Variation.

135.5.3.2 Skew tolerance at SP0

In an implementation with an instantiated LAUI-2 interface, the PMA service interface that receives data in the transmit direction from the LAUI-2 (SP0 in Figure 131–3) shall tolerate the maximum amount of Skew Variation allowed at SP0 (0.2 ns) between input lanes while maintaining the bit ordering and position of each PCSL on each PMA lane in the transmit direction (toward the PMD).

135.5.3.3 Skew generation toward SP1

In an implementation with one or more physically instantiated 50GAUI-n or 100GAUI-n interfaces, the PMA that sends data in the transmit direction toward the 50GAUI-n or 100GAUI-n that is closest to the PMD (SP1 in Figure 131–3 and Figure 80–9) shall produce no more than 29 ns of Skew between FECLs toward the 50GAUI-n or 100GAUI-n and no more than 0.2 ns of Skew Variation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

135.5.3.4 Skew tolerance at SP1

In an implementation with one or more physically instantiated 50GAUI-n or 100GAUI-n interfaces, the PMA service interface that receives data in the transmit direction from the 50GAUI-n or 100GAUI-n (SP1 in Figure 131–3 and Figure 80–9) shall tolerate the maximum amount of Skew Variation allowed at SP1 (0.2 ns) between input lanes while maintaining the bit ordering and position of each FECL on each PMA lane in the transmit direction (toward the PMD).

135.5.3.5 Skew generation toward SP2

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, the PMA adjacent to the PMD service interface shall generate no more than 43 ns of Skew, and no more than 0.4 ns of Skew Variation between output lanes toward the PMD service interface (SP2 in Figure 80–9 and Figure 131–3). If there is a physically instantiated 50GAUI-n or 100GAUI-n as well, then the Skew measured at SP1 is limited to no more than 29 ns of Skew and no more than 0.2 ns of Skew Variation.

135.5.3.6 Skew tolerance at SP5

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, the PMA adjacent to the PMD service interface (SP5 in Figure 131–3 and Figure 80–9) shall tolerate the maximum amount of Skew Variation allowed at SP5 (0.4 ns) between output lanes from the PMD service interface while maintaining the bit ordering and position of each FECL on each PMA lane in the receive direction (toward the MAC).

135.5.3.7 Skew generation at SP6

In an implementation with one or more physically instantiated 50GAUI-n or 100GAUI-n interfaces, at SP6 (the receive direction of the 50GAUI-n or 100GAUI-n closest to the FEC), the PMA or group of PMAs between the PMD and the 50GAUI-n or 100GAUI-n closest to the FEC shall deliver no more than 160 ns of Skew, and no more than 3.8 ns of Skew Variation between output lanes toward the 50GAUI-n or 100GAUI-n in the Rx direction.

If there is a physically instantiated PMD service interface that allows the Skew to be measured, the Skew measured at SP5 is limited to no more than 145 ns of Skew and no more than 3.6 ns of Skew Variation. If there is no physically instantiated PMD service interface, the Skew measured at SP4 is limited to no more than 134 ns of Skew, and no more than 3.4 ns of Skew Variation.

135.5.3.8 Skew tolerance at SP6

In an implementation with one or more physically instantiated 50GAUI-n or 100GAUI-n interfaces, the PMA between the 50GAUI-n or 100GAUI-n closest to the FEC and the FEC shall tolerate the maximum amount of Skew Variation allowed at SP6 (3.8 ns) between input lanes while maintaining the bit order and position of FECLs on lanes sent in the receive direction towards the MAC.

135.5.3.9 Skew generation at SP7

In an implementation with an instantiated LAUI-2 interface between the PCS and the FEC, the PMA that sends data in the receive direction toward the LAUI-2 (SP7 in Figure 131–3) shall produce no more than 29 ns of Skew between PCSLs and no more than 0.2 ns of Skew Variation.

135.5.3.10 Skew tolerance at SP7

In an implementation with an instantiated LAUI-2 interface between the PCS and the FEC, the PMA service interface that receives data in the receive direction from the LAUI-2 (SP7 in Figure 131–3) shall tolerate the

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

maximum amount of Skew Variation allowed at SP7 (0.2 ns) between input lanes while maintaining the bit ordering and position of each PCSL on each PMA lane in the transmit direction (toward the PMD).

135.5.4 Delay constraints

The maximum cumulative delay contributed by up to three PMA stages in a PHY (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 135–1. A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 131.4 and its references.

Table 135–1—Delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
50GBASE-R PMA	4608	9	92.16
100GBASE-P PMA	9216	18	92.16

135.5.5 Clocking architecture

A PMA with *m* input lanes and *n* output lanes shall clock the output lanes such that the bit rate of the output lanes is *m*/*n* times the bit rate of the input lanes. For input or output lanes encoded as PAM4, the symbol rate is half of the bit rate. This applies in both the Tx and Rx directions of transmission. In the case where the interfaces between the PMA client and the PMA and/or the PMA and the sublayer below the PMA are physically instantiated, the PMA may derive its input clock(s) from the electrical interface on one or more of the input lanes, and generate the output clock(s) with an appropriate PLL multiplier/divider circuit.

NOTE—For a PMA where the signaling rate on each output lane is higher than the signaling rate on each input lane, any low-frequency jitter on the input lanes may result in more jitter relative to the UI on the output lanes.

There is no requirement that the PMA clock all output lanes in unison. Examples of independent clocking of output lanes include the following:

— The case where the number of input and output lanes are equal (the PMA is provided for retiming and regeneration of the signal). This may be implemented without any rearrangement of PCSLs/FECLs between input lanes and output lanes (although rearrangements are allowed). Such a PMA may be implemented by driving each output lane using the clock recovered from the corresponding input lane.

— Since the number of PCSLs/FECLs is a power of 2, whenever the number of input and output lanes are unequal, each input lane could be mapped to multiple output lanes (in the case where the number of output lanes is greater), or multiple input lanes could be mapped to a single output lane.

135.5.6 Signal drivers

For cases where the interface between the PMA client and the PMA or between the PMA and the sublayer below the PMA represent a physically instantiated interface, the PMA provides electrical signal drivers for that interface. The electrical and jitter/timing specifications for these interfaces appear in

— Annex 135B for LAUI-2 C2C applications
— Annex 135C for LAUI-2 C2M applications
— Annex 135D for 50GAUI-2 and 100GAUI-4 C2C applications
— Annex 135E for 50GAUI-2 and 100GAUI-4 C2M applications
— Annex 135F for 50GAUI-1 and 100GAUI-2 C2C applications
— Annex 135G for 50GAUI-1 and 100GAUI-2 C2M applications

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The modulation format is NRZ for LAUI-2, 50GAUI-2, and 100GAUI-4 and the modulation format is PAM4 for 50GAUI-1 and 100GAUI-2.

135.5.7 PAM4 encoding

135.5.7.1 Gray mapping for PAM4 encoded lanes

For output lanes encoded as PAM4, the PMA transmit process shall map consecutive pairs of bits to Gray-coded symbols G(*j*) with one of four levels as specified in 120.5.7.1.

For input lanes encoded as PAM4, the PMA receive process shall map Gray-coded symbols G(*j*) with one of four levels to pairs of bits as specified in 120.5.7.1.

135.5.7.2 Precoding for PAM4 encoded lanes

The precoding specifications in this subclause apply to the input and output lanes of a PMA that are connected to the service interface of a 50GBASE-R or 100GBASE-R PMD that includes the PMD control function defined in 136.8.11 (50GBASE-CR, 50GBASE-KR, 100GBASE-CR2, or 100GBASE-KR2), or are part of a 50GAUI-1 C2C or 100GAUI-2 C2C link.

The PMA shall provide 1/(1+D) mod 4 precoding capability on each output lane and may optionally provide 1/(1+D) mod 4 decoding capability on each input lane.

On each output lane, for each Gray-coded symbol G(*j*), a precoded symbol P(*j*) shall be determined by the following algorithm, where *j* is an index indicating the symbol number:

$$P(j) = (G(j) - P(j\text{-}1)) \bmod 4, \text{ when precoding is enabled} \quad (135\text{–}1)$$

$$P(j) = G(j), \text{ when precoding is disabled} \quad (135\text{–}2)$$

On each input lane, for each precoded symbol P(*j*), a Gray-code symbol G(*j*) shall be determined by the following algorithm:

$$G(j) = (P(j) + P(j\text{-}1)) \bmod 4, \text{ when precoding is enabled} \quad (135\text{–}3)$$

$$G(j) = P(j), \text{ when precoding is disabled} \quad (135\text{–}4)$$

The precoder is enabled independently for the input and output in each direction (Tx direction toward the PMD and Rx direction toward the MAC) and on each lane. Precoding is enabled and disabled using variables precoder_tx_out_enable_*i*, precoder_rx_in_enable_*i,* precoder_rx_out_enable_*i*, and precoder_tx_in_enable_*i*. If a Clause 45 MDIO is implemented, these variables are accessible through registers 1.600, 1.601, 1.602, and 1.603 (see 45.2.1.139 through 45.2.1.142). An example relating the variables with input and outputs is provided in Figure 135–7.

If the PMA is connected to the service interface of a PMD that includes the PMD control function and training is enabled by the management variable mr_training_enable (see 136.7), then precoder_tx_out_enable_*i* and precoder_rx_in_enable_*i* shall be set as determined by the PMD control function in the LINK_READY state on lane *i* (see 136.8.11.7.5 and Figure 136–7). The method by which the PMD control function affects these variables is implementation dependent.

If the PMA is connected to the service interface of a PMD that supports the PMD control function and training is disabled by the management variable mr_training_enable, or if the PMA is part of a 50GAUI-1 C2C or a 100GAUI-2 C2C link, then precoder_tx_out_enable_*i*, precoder_rx_in_enable_*i*,

Copyright © 2022 IEEE. All rights reserved.

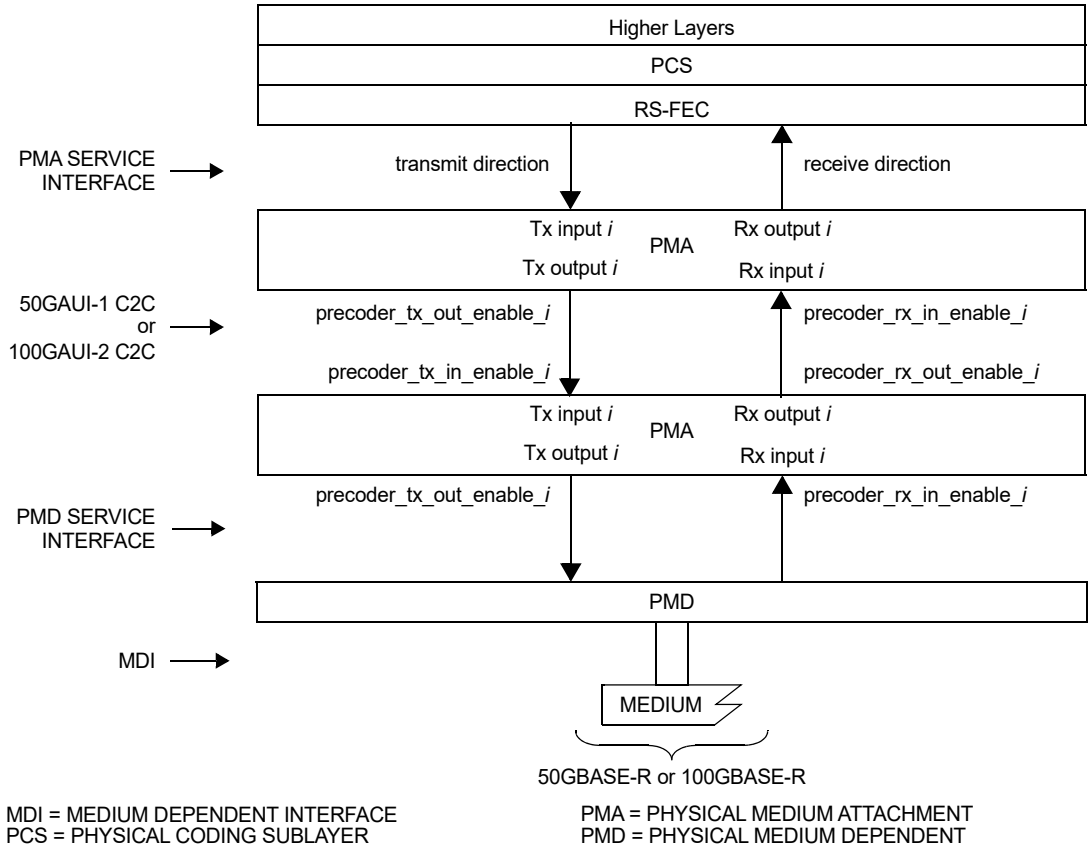

Figure 135–7—Example relating PMA precoder variables to inputs and outputs

precoder_tx_in_enable_*i*, and precoder_rx_out_enable_*i* are set as required by the implementation. The method described in 135F.3.2.1 may be used for 50GAUI-1 C2C or 100GAUI-2 C2C.

135.5.8 PMA local loopback mode (optional)

PMA local loopback mode is optional. If it is implemented, it shall be as specified in this subclause.

The PMA sublayer may provide a local loopback function. The function involves looping back each input lane to the corresponding output lane. Each bit received from the PMA:IS_UNITDATA_*i*.request(tx_symbol) primitive is looped back toward the MAC using the PMA:IS_UNITDATA_*i*.indication(rx_symbol) primitive.

During local loopback, the PMA performs normal bit muxing of PCSLs/FECLs per 135.5.2 onto the lanes in the Tx direction toward the service interface below the PMA.

Ability to perform this function is indicated by the Local_loopback_ability status variable. If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.8.0 (45.2.1.7.15).

A device is placed in local loopback mode when the Local_loopback_enable control variable is set to one, and removed from local loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD control 1 register (bit 1.0.0, see 45.2.1.1.5).

NOTE—Placing a network port into loopback mode can be disruptive to a network.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

135.5.9 PMA remote loopback mode (optional)

PMA remote loopback mode is optional. If implemented, it shall be as described in this subclause.

Remote loopback, if provided, should be implemented in a PMA sublayer close enough to the PMD to maintain the bit sequence on each individual PMD lane. When remote loopback is enabled, each symbol received over a lane of the service interface below the PMA via *inst*:IS_UNITDATA_*i*.indication is looped back to the corresponding output lane toward the PMD via *inst*:IS_UNITDATA_*i*.request. Note that the service interface below the PMA can be provided by the PMD, FEC (LAUI-2 only), or another PMA sublayer.

During remote loopback, the PMA performs normal bit muxing of PCSLs/FECLs per 135.5.2 onto the lanes in the Rx direction towards the PMA client.

The ability to perform this function is indicated by the 50G_Remote_loopback_ability status variable for 50GBASE-R 100G_Remote_loopback_ability status variable for 100GBASE-P.

A device is placed in remote loopback mode when the Remote_loopback_enable control variable is set to one and removed from remote loopback mode when this variable is set to zero.

If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.13.15 (45.2.1.12.1).

If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD Control register 1 (bit 1.0.1, see 45.2.1.1.4).

135.5.10 PMA test patterns (optional)

Where the output lanes of the PMA appear on a physically instantiated interface LAUI-2, 50GAUI-n, 100GAUI-n or the PMD service interface (whether or not it is physically instantiated), the PMA may optionally generate and detect test patterns. These test patterns are used to test adjacent-layer interfaces for an individual PMA sublayer or to perform testing between a physically instantiated interface of a PMA sublayer and external test equipment.

135.5.10.1 Test patterns for NRZ encoded signals

For a 50GBASE-R PMA with NRZ encoding, the test patterns in this subclause may be supported.

135.5.10.1.1 PRBS31 test pattern

A PMA may optionally include a PRBS31 test-pattern generator on output lanes in either direction as specified in 120.5.11.1.1.

A PMA may optionally include a PRBS31 test-pattern checker on input lanes in either direction as specified in 120.5.11.1.1.

135.5.10.1.2 PRBS9 test pattern

A PMA may optionally include a PRBS9 test-pattern generator on output lanes in either direction as specified in 120.5.11.1.2.

135.5.10.1.3 Square-wave test pattern

A PMA may optionally include a square-wave test-pattern generator on output lanes in either direction as specified in 120.5.11.1.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

135.5.10.2 Test patterns for PAM4 encoded signals

For a 50GBASE-R PMA with PAM4 encoding, the test patterns described in this subclause may be supported.

The PRBS13Q and quaternary square wave test patterns are enabled on a lane-by-lane basis. The patterns PRBS31Q and SSPRQ are enabled on all lanes of an interface at once. If a per-lane pattern is enabled on one or more of the lanes and a per-interface pattern is also enabled, the per-lane patterns are generated only on the indicated lanes and the per-interface pattern is generated on the remaining lanes. The behavior if more than one per-lane pattern is enabled for the same lane or more than one per-interface pattern is enabled is not defined.

135.5.10.2.1 PRBS13Q test pattern

A PMA may optionally include a PRBS13Q test-pattern generator as specified in 120.5.11.2.1.

135.5.10.2.2 PRBS31Q test pattern

A PMA may optionally include a PRBS31Q test-pattern generator on output lanes in either direction as specified in 120.5.11.2.2.

A PMA may optionally include a PRBS31Q test-pattern checker on input lanes in either direction as specified in 120.5.11.2.2.

135.5.10.2.3 SSPRQ test pattern

A PMA may optionally include a short stress pattern random quaternary (SSPRQ) test-pattern generator as specified in 120.5.11.2.3.

135.5.10.2.4 Square wave (quaternary) test pattern

Transmit square wave (quaternary) test-pattern generator optionally applies to each lane of the Tx direction PMA towards a physically instantiated 50GAUI-1 or 100GAUI-1, or towards a PAM4 PMD service interface whether or not it is physically instantiated as specified in 120.5.11.2.4.

135.6 PMA MDIO function mapping

The optional MDIO capability described in Clause 45 describes several variables that provide control and status information for and about the PMA. Since a given implementation may employ more than one PMA sublayer, the PMA control and status information is organized into multiple addressable instances, one for each possible PMA sublayer. See 45.2.1 and 135.1.4 for the allocation of MMD addresses to PMA sublayers. Control and status registers for MMD 8, 9, and 10 use the Extended PMA control and status registers at identical locations to those for MMD 1.

Mapping of MDIO control variables to PMA control variables is shown in Table 135–2. Mapping of MDIO status variables to PMA status variables is shown in Table 135–3. Mapping of MDIO counter to PMA counters is shown in Table 135–4. These tables provide the register and bit numbers for the PMA addressed as MMD 1. For implementations with multiple PMA sublayers, additional PMA sublayers use the corresponding register and bit numbers in MMDs 8, 9, and 10 as necessary.

135.7 Protocol implementation conformance statement (PICS) proforma for Clause 135, Physical Medium Attachment (PMA) sublayer, type 50GBASE-R and 100GBASE-P[226]

135.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 135, Physical Medium Attachment (PMA) sublayer, type 50GBASE-R and 100GBASE-P, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

135.7.2 Identification

135.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

135.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 135, Physical Medium Attachment (PMA) sublayer, type 50GBASE-R and 100GBASE-P
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[226]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

136. Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4

136.1 Overview

This clause specifies the 50GBASE-CR PMD, the 100GBASE-CR2 PMD, the 200GBASE-CR4 PMD, and the baseband medium. The specifications for the three PMDs are similar, except for the number of lanes and associated parameters and the MDI.

There are four associated annexes. Annex 136A provides information on parameters with test points that may not be testable in an implemented system. Annex 136B specifies test fixtures. Annex 136C specifies MDIs. Annex 136D describes 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 host and cable assembly form factors.

When forming a complete Physical Layer, a PMD shall be connected as illustrated in Figure 136–1, to the appropriate sublayers (as specified in Table 136–1, Table 136–2, and Table 136–3), to the medium through the appropriate MDI, and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 136–1—Physical Layer clauses associated with the 50GBASE-CR PMD

Associated clause	50GBASE-CR
132—RS	Required
132—50GMII[a]	Optional
133—PCS for 50GBASE-R	Required
134—RS-FEC	Required
135—PMA for 50GBASE-R	Required
135B—LAUI-2 C2C	Optional
135D—50GAUI-2 C2C	Optional
135F—50GAUI-1 C2C	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The 50GMII is an optional interface. However, if the 50GMII is not implemented, a conforming implementation behaves functionally as though the RS and 50GMII were present.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 136–2—Physical Layer clauses associated with the 100GBASE-CR2 PMD

Associated clause	100GBASE-CR2
80—RS	Required
80—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
91—RS-FEC	Required
83—PMA for 100GBASE-R	Optional[b]
83A—CAUI-10	Optional
83D—CAUI-4 C2C	Optional
135—PMA for 100GBASE-P	Required
135D—100GAUI-4 C2C	Optional
135F—100GAUI-2 C2C	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]PMA for 100GBASE-R is required when either CAUI-10 or CAUI-4 is used.

Table 136–3—Physical Layer clauses associated with the 200GBASE-CR4 PMD

Associated clause	200GBASE-CR4
117—RS	Required
117—200GMII[a]	Optional
118—200GMII extender	Optional
119—PCS for 200GBASE-R	Required
120—PMA for 200GBASE-R	Required
120B—200GAUI-8 C2C	Optional
120D—200GAUI-4 C2C	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The 200GMII is an optional interface. However, if the 200GMII is not implemented, a conforming implementation behaves functionally as though the RS and 200GMII were present.

For the 50GBASE-CR and 100GBASE-CR2 PHYs, in order to support the required frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap, the PMD and the adjacent PMA are expected to detect bits from a compliant input signal at a BER lower than 2.4×10^{-4} assuming errors are sufficiently uncorrelated. This BER allocation enables a frame loss ratio lower than 10^{-10} after processing by the RS-FEC (Clause 134 or Clause 91) and the PCS (Clause 133 or Clause 82) if

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

there are negligible errors due to other electrical interfaces (50GAUI-n or 100GAUI-n). If the PMD and PMA create errors that are not sufficiently uncorrelated, the BER is required to be lower as appropriate to maintain a frame loss ratio lower than 10^{-10}.

For the 200GBASE-CR4 PHY, in order to support the required frame loss ratio (see 1.4.344) of less than 6.2×10^{-11} for 64-octet frames with minimum interpacket gap, the PMD and the adjacent PMA are expected to detect bits from a compliant input signal at a BER lower than 2.4×10^{-4} assuming errors are sufficiently uncorrelated. This BER allocation enables a frame loss ratio lower than 9.2×10^{-13} after processing by the PCS (Clause 119) if there are negligible errors due to other electrical interfaces (200GAUI-n). If the PMD and PMA create errors that are not sufficiently uncorrelated, the BER is required to be lower as appropriate to maintain a frame loss ratio lower than 9.2×10^{-13}.

A compliant input signal is a transmitter output of a compliant PHY that has passed through a compliant cable assembly.

50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Figure 136–1 shows the relationship of the 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 PMD sublayers and MDIs to the ISO/IEC Open System Interconnection (OSI) reference model.

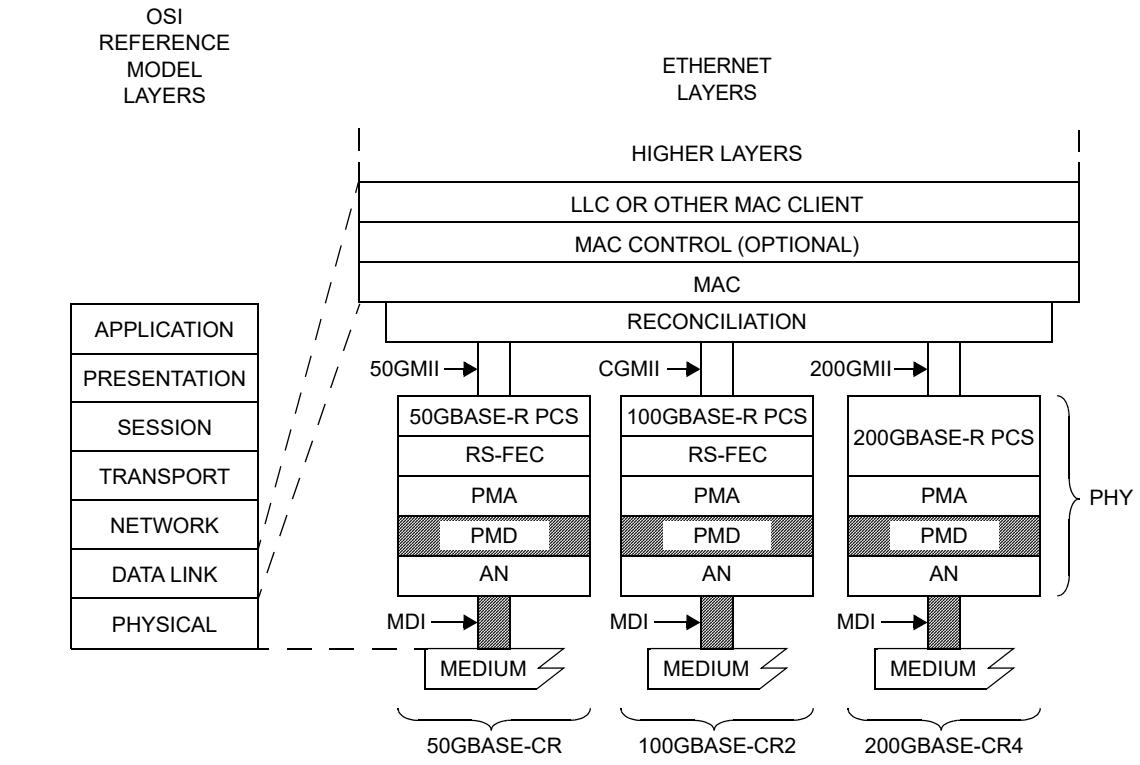
136.2 Conventions

Clause 136 describes three PMDs, 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 PMD, which have one, two, and four lanes, respectively. For efficient description, the parameter n is used to describe the number of lanes in a specific PMD. Accordingly, n = 1 for 50GBASE-CR, n = 2 for 100GBASE-CR2, and n = 4 for 200GBASE-CR4.

The parameter *i* is used as an index or a suffix to identify a specific lane, and takes the values 0 to n – 1.

Within this clause, the unqualified term “PMD” refers to any of 50GBASE-CR PMD, 100GBASE-CR2 PMD, or 200GBASE-CR4 PMD.

136.3 PMD service interfaces



This subclause specifies the services provided by the 50GBASE-CR, 100GBASE-CR2 and 200GBASE-CR4 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The 50GBASE-CR PMD service interface is an instance of the inter-sublayer service interface defined in 131.3, with a single symbol stream (n = 1).

The 100GBASE-CR2 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with the exception that there are two parallel symbol streams (n = 2).

The 200GBASE-CR4 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with four parallel symbol streams (n = 4).

PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 136–1—50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 50GBASE-CR PMD has a single symbol stream, hence $i = 0$.

The 100GBASE-CR2 PMD has two parallel symbol streams, hence $i = 0$ to 1.

The 200GBASE-CR4 PMD has four parallel symbol streams, hence $i = 0$ to 3.

In the transmit direction, the PMA continuously sends n streams of PAM4 symbols to the PMD, one per lane, using the PMD:IS_UNITDATA_*i*.request primitive, at a nominal signaling rate of 26.5625 GBd. The PMD converts these streams of symbols into appropriate signals on the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the receive direction, the PMD continuously sends *n* streams of PAM4 symbols to the PMA, corresponding to the signals received from the MDI, one per lane, using the PMD:IS_UNITDATA_*i*.indication primitive, at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable Global_PMD_signal_detect as defined in 136.8.4. When Global_PMD_signal_detect is one, SIGNAL_OK shall be assigned the value OK. When Global_PMD_signal_detect is zero, SIGNAL_OK shall be assigned the value FAIL. When SIGNAL_OK is FAIL, the PMD:IS_UNITDATA_*i*.indication parameter is undefined.

136.4 PCS requirements for Auto-Negotiation (AN) service interface

The PCSs associated with the 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 PMDs are required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 133.4, 82.6, and 119.6.)

50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR-4 PHYs may be extended using chip-to-chip (C2C) 50GAUI-n/LAUI-2, 100GAUI-n/CAUI-n, and 200GAUI-n, respectively, as physical instantiations of the inter-sublayer service interface between devices. If such extension is used, then the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

136.5 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the PMD and AN including the medium in one direction shall be no more than the maximum delays listed in Table 136–4. It is assumed that the one-way delay through the medium is no more than 20 ns.

Table 136–4—Delay constraints

PMD	Maximum (bit times)[a]	Maximum (pause_quanta)[b]	Maximum (ns)
50GBASE-CR	2048	4	40.96
100GBASE-CR2	4096	8	40.96
200GBASE-CR4	8192	16	40.96

[a]One bit time is equal to 20 ps for 50GBASE-CR, 10 ps for 100GBASE-CR2, and 5 ps for 200GBASE-CR4. (See 1.4.215 for the definition of bit time.)
[b]One pause_quantum is equal to 10.24 ns for 50GBASE-CR, 5.12 ns for 100GBASE-CR2, and 2.56 ns for 200GBASE-CR4. (See 31B.2 for the definition of pause_quanta.)

Descriptions of overall system delay constraints can be found in 131.4 for 50GBASE-CR, in 80.4 for 100GBASE-CR2, and in 116.3 for 200GBASE-CR4.

136.6 Skew constraints

The Skew (relative delay) between the PCS or FEC lanes is kept within limits so that the information on the PCS or FEC lanes can be reassembled by the PCS or FEC. The Skew Variation is also limited to ensure that a given PCS or FEC lane always traverses the same physical lane.

136.6.1 Skew Constraints for 50GBASE-CR

Skew and Skew Variation are defined in 131.5 and specified at the points SP0 to SP7 shown in Figure 131–3.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 135.5.3.5. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

For more information on Skew and Skew Variation, see 131.5. The measurements of Skew and Skew Variation are defined in 89.7.2 with the exception that the measurement clock and data recovery unit high-frequency corner bandwidth is 4 MHz.

136.6.2 Skew Constraints for 100GBASE-CR2 and 200GBASE-CR4

Skew and Skew Variation are defined in 80.5 and 116.5 and specified at the points SP1 to SP6 shown in Figure 80–9 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5 and 116.5.

136.7 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several registers that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control bits to PMD

136.8 PMD functional specifications

136.8.1 Link block diagram

One direction of a 50GBASE-CR, 100GBASE-CR2, or 200GBASE-CR4 link is shown in Figure 136–2.

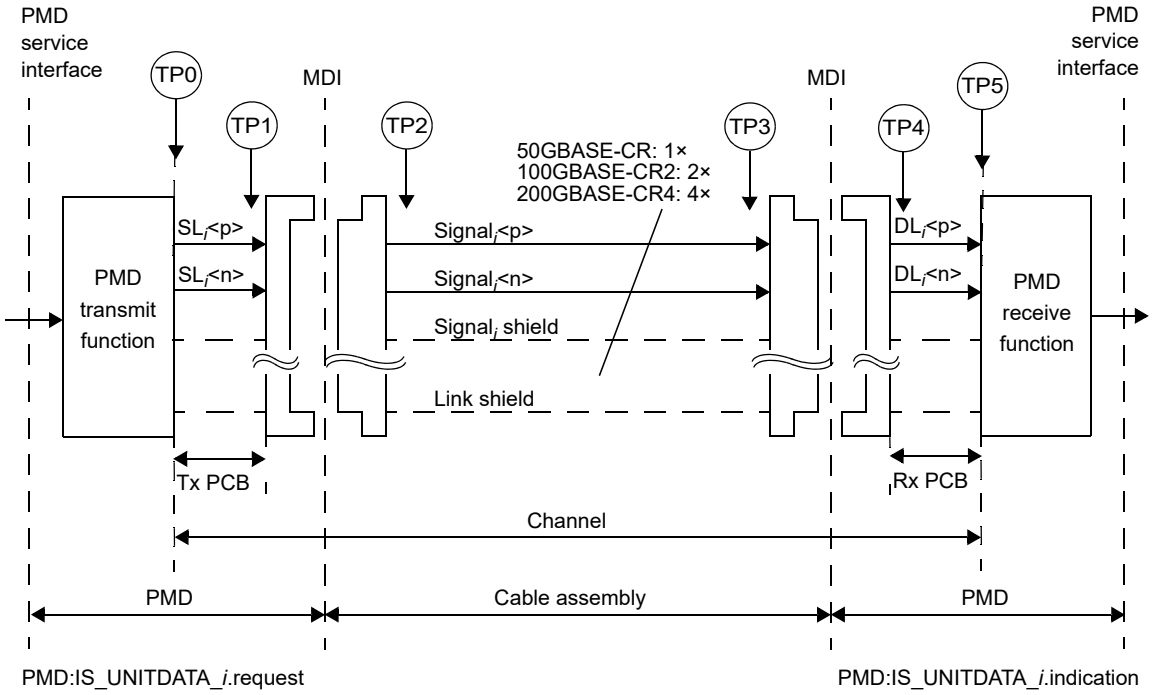

Figure 136–2—50GBASE-CR, 100GBASE-CR2 or 200GBASE-CR4 link (one direction is illustrated)

Note that the source lane (SL) signals SL$_i$<p> and SL$_i$<n> are the positive and negative sides of the transmitter's differential signal pair on lane *i* and the destination lane (DL) signals DL$_i$<p> and DL$_i$<n> are the positive and negative sides of the receiver's differential signal pair on lane *i*.

For purposes of system conformance, the PMD sublayer is standardized at the test points described in this subclause.

The electrical transmit signal is defined at TP2. Unless specified otherwise, all transmitter measurements and tests defined in 136.9.3 are made at TP2 utilizing the test fixture specified in Annex 136B.

The electrical receive signal is defined at TP3. Unless specified otherwise, all receiver measurements and tests defined in 136.9.4 are performed at TP3 utilizing the test fixture specified in Annex 136B.

A mated connector pair has been included in both the transmitter and receiver specifications defined in 136.9.3 and 136.9.4. The recommended maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is provided in 136.9.3.2. Annex 136A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system.

The channel (see 136.10) is defined between the transmitter (TP0) and receiver (TP5) blocks to include the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss, as illustrated in Figure 136–2. All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 136–2. The cable assembly test fixture of 136B.1, or its equivalent, is required for measuring the cable assembly specifications in 136.10 at TP1 and TP4. Two cable assembly test fixtures have been included in the cable assembly specifications defined in 136.10. Transmitter and receiver differential controlled impedance printed circuit board insertion losses defined between TP0 and the MDI and between the MDI and TP5, respectively, are provided informatively in 136A.4.

Table 136–7 describes the defined test points illustrated in Figure 136–2.

Table 136–7—Test points

Test points	Description
TP0 to TP5	The channel including the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss.
TP1 to TP4	All cable assembly measurements are made between TP1 and TP4 as illustrated in Figure 136–2. The cable assembly test fixture of Annex 136B, or its equivalent, is required for measuring the cable assembly specifications in 136.10 at TP1 and TP4.
TP0 to TP2 TP3 to TP5	A mated connector pair has been included in both the transmitter and receiver specifications defined in 136.9.3 and 136.9.4. The recommended maximum insertion loss from TP0 to TP2 or from TP3 to TP5 including the test fixture is provided in 136.9.3.2.
TP2	Unless specified otherwise, all transmitter measurements defined in 136.9.3 are made at TP2 utilizing the test fixture specified in Annex 136B.
TP3	Unless specified otherwise, all receiver measurements and tests defined in 136.9.4 are made at TP3 utilizing the test fixture specified in Annex 136B.

136.8.2 PMD transmit function

The PMD transmit function has three operating modes: DATA, TRAINING, and QUIET. The operating mode is controlled by the PMD control state diagram (Figure 136–7). Support for the QUIET operating mode is only required when the variable use_quiet_in_training (see 136.8.11.7.1) is set to TRUE.

When operating in DATA mode, the PMD transmit function shall convert the symbol stream requested by the PMD service interface message PMD:IS_UNITDATA_*i*.request(tx_symbol) of each lane into an

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

electrical signal, and deliver the electrical signals to the MDI, according to the transmit electrical specifications in 136.9.3. The differential output voltage (SL_i<p> minus SL_i<n>) meets the specifications in 136.9.3.1.1 where the PAM4 symbol values 0, 1, 2, and 3 correspond to the tx_symbol values zero, one, two, and three, respectively, with the highest differential output voltage corresponding to tx_symbol = three and the lowest differential output voltage corresponding to tx_symbol = zero.

When operating in TRAINING mode, the PMD transmit function shall convert the symbol stream generated by the PMD control function of each lane into an electrical signal, and deliver the electrical signals to the MDI, according to the transmit electrical specifications in 136.9.3. The differential output voltage (SL_i<p> minus SL_i<n>) meets the specifications in 136.9.3.1.1, with the highest differential output voltage corresponding to the PAM4 symbol 3 and the lowest differential output voltage corresponding to the PAM4 symbol 0.

When operating in QUIET mode the PMD transmit function shall turn off the transmitter such that the transmitter drives a constant level (i.e., no transitions) and does not exceed the differential peak-to-peak output voltage (max) with Tx disabled in Table 136–11.

136.8.3 PMD receive function

The PMD receive function shall convert the electrical signal from each of the lanes on the MDI into a symbol stream for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_*i*.indication(rx_symbol). The highest differential input voltage (DL_i<p> minus DL_i<n>) shall correspond to rx_symbol = three and the lowest differential input voltage shall correspond to rx_symbol = zero.

136.8.4 PMD global signal detect function

For the 50GBASE-CR PMD, the variable Global_PMD_signal_detect is set to PMD_signal_detect_0 (see 136.8.5). For the 100GBASE-CR2 and 200GBASE-CR4 PMDs, the variable Global_PMD_signal_detect is set to the logical AND of the values of PMD_signal_detect_*i* from each of the PMD lanes.

136.8.5 PMD lane-by-lane signal detect function

The PMD lane-by-lane signal detect function is used by the PMD to indicate the successful completion of the startup protocol by the PMD control function (see 136.8.11). PMD_signal_detect_*i* shall be set to zero when signal_detect on lane *i* is set to false, and to one when signal_detect on lane *i* is set to true. The signal_detect variables are set independently on each lane by the PMD control state diagram (Figure 136–7).

If training is disabled by the management variable mr_training_enable (see 136.7), PMD_signal_detect_*i* shall be set to one for all lanes.

When the MDIO is implemented, this function maps the variables to registers and bits as defined in 136.7.

136.8.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional. When implemented, it allows the transmitters on all lanes to be disabled with a single variable.

When Global_PMD_transmit_disable variable is set to one, this function shall turn off all the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the differential peak-to-peak output voltage (max.) with Tx disabled in Table 136–11.

If a PMD fault (136.8.8) is detected, then the PMD may set Global_PMD_transmit_disable to one.

136.8.7 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the transmitter in each lane to be selectively disabled. When this function is supported, it shall meet the following requirements:

— When a PMD_transmit_disable_*i* variable is set to one, this function shall turn off the transmitter in lane *i* so that it drives a constant level (i.e., no transitions) and does not exceed the differential peak-to-peak output voltage (max.) with Tx disabled in Table 136–11.

— If a PMD fault (136.8.8) is detected, then the PMD may set each PMD_transmit_disable_*i* to one, turning off the transmitter in each lane.

136.8.8 PMD fault function

PMD_fault is the logical-OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault. If the MDIO interface is implemented, then PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

136.8.9 PMD transmit fault function (optional)

The PMD transmit fault function is optional. The faults detected by this function are implementation specific, but the assertion of Global_PMD_transmit_disable is not considered a transmit fault.

If PMD_transmit_fault is set to one, then Global_PMD_transmit_disable should also be set to one.

If the MDIO interface is implemented, then PMD_transmit_fault shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

136.8.10 PMD receive fault function (optional)

The PMD receive fault function is optional. The faults detected by this function are implementation specific. A fault is indicated by setting the variable PMD_receive_fault to one.

If the MDIO interface is implemented, then PMD_receive_fault shall be mapped to the Receive fault bit as specified in 45.2.1.7.5.

136.8.11 PMD control function

The PMD control function performs the PMD startup protocol. This protocol facilitates timing recovery and equalization while providing a mechanism through which the receiver can configure the transmitter to optimize performance. The protocol supports these functions through the continuous exchange of fixed-length training frames.

The PMD shall implement one instance of the PMD control function described in this subclause for each lane. The PMD control functions operate independently on each lane.

136.8.11.1 Training frame structure

The training frame is a sequence of PAM4 symbols whose values correspond to the possible values of the tx_symbol and rx_symbol variables (the PAM4 symbol values 0, 1, 2, and 3 correspond to tx_symbol or rx_symbol values zero, one, two, and three, respectively). The structure of a training frame is shown in Figure 136–3.

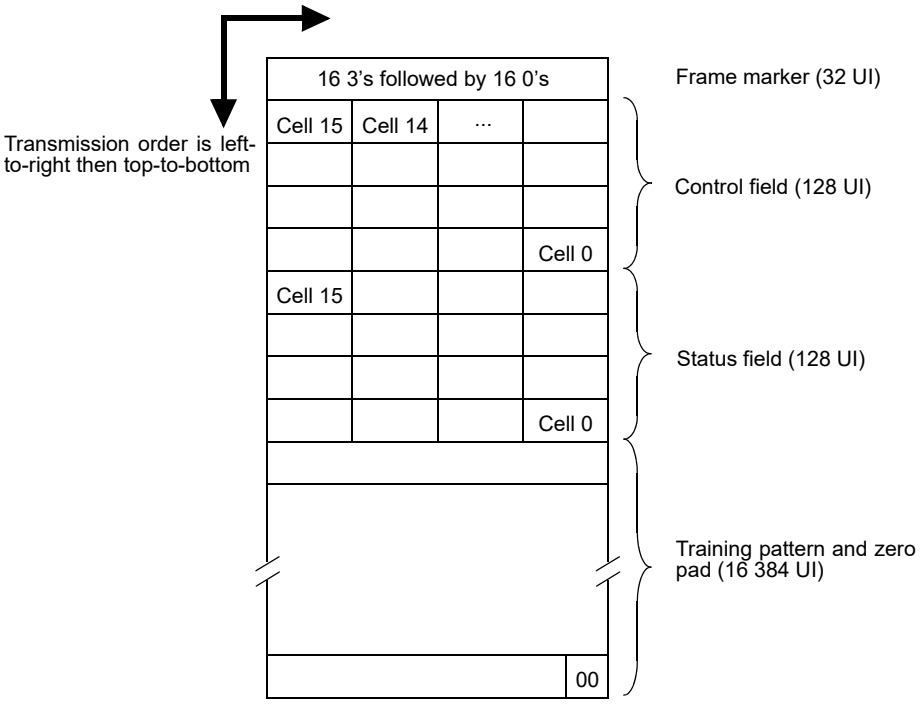

Figure 136–3—Training frame structure

136.8.11.1.1 Frame marker

Training frames are delimited by a specific sequence of PAM4 symbols. The training frame marker is a run of 16 consecutive "3" symbols followed by a run of 16 consecutive "0" symbols. This sequence is not found in the control field, status field, or training pattern and it uniquely identifies the beginning of a training frame.

136.8.11.1.2 Control and status fields

The control field comprises 16 bits with the structure defined in 136.8.11.2. The status field comprises 16 bits with the structure defined in 136.8.11.3.

Each bit of the control and status fields is sent as a differential Manchester encoded (DME) cell, where each cell is eight unit intervals in length. The specific rules for this encoding follow.

a) A transition from 0 to 3 or from 3 to 0 occurs at the start of each cell.
b) A transition from 0 to 3 or from 3 to 0 at the midpoint of a cell, i.e., four unit intervals from the transition at the beginning of the cell, corresponds to a logical one.
c) The absence of a transition at the midpoint of a cell corresponds to a logical zero.

The control field is transmitted immediately after the frame marker. The status field is transmitted immediately after the control field. Within each field, the order of transmission is from bit 15 to bit 0.

When a training frame is received, if a violation of the DME encoding rules is detected within the control field or the status field, the contents of both fields in that frame are ignored.

136.8.11.1.3 Training pattern

The training pattern is the result of a training pattern generator equivalent to the structure shown in Figure 136–4.

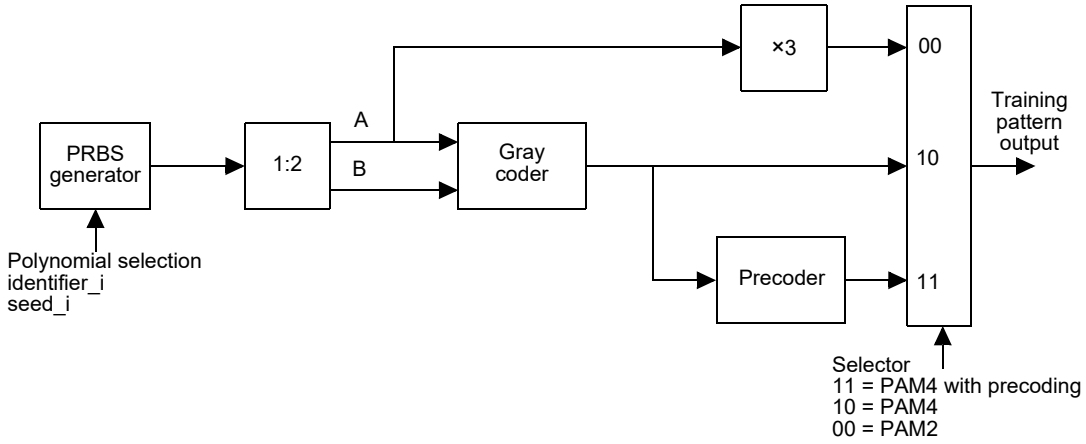

Figure 136–4—Training pattern generator

A set of four PRBS generator polynomials are defined to minimize correlated interference between PMDs, or physical lanes within a PMD, during the startup protocol. The PRBS generator for each lane shall implement each of four generator polynomials defined in Table 136–8. The polynomial used in each lane *i* is selectable by identifier_*i*. The default identifier for each lane is its lane number (e.g., the default value for identifier_0 is 0 which selects polynomial_0). A sample implementation of the PRBS generator for identifier_*i* = 0 is shown in Figure 136–5.

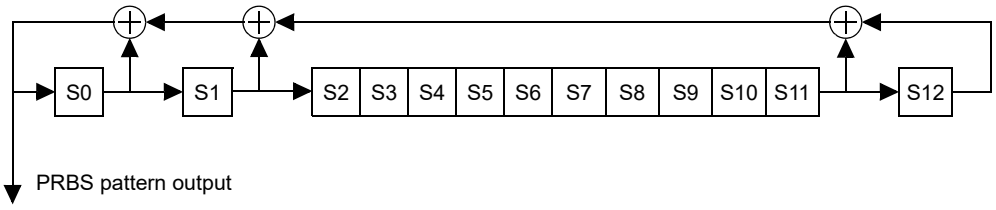

Figure 136–5—Training pattern PRBS generator (identifier_*i* = 0)

At the start of the training pattern, the state of the PRBS generator shall be set to the value seed_*i*. The default value of seed_*i* shall be the value given in Table 136–8 for $p = i$. A seed of all zeros is not valid.

The polynomials for each identifier value p and the default seeds, as well as the first 13 symbols of the training pattern for each modulation and precoding mode, using the default seed, are provided in Table 136–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 136–8—Training patterns

p	Polynomial_*p*, *G*(*x*)	Default seed bits[a]	Initial output, PAM2	Initial output, PAM4	Initial output, PAM4 with precoding
0	$1+x+x^2+x^{12}+x^{13}$	0000010101011	0030330330000	1031320220111[b]	1301200200101
1	$1+x^2+x^3+x^7+x^{13}$	0011101000001	3030303030333	3030213021333	3122012201212
2	$1+x^2+x^4+x^8+x^{13}$	1001000101100	0303333033030	1212332133031	1102120121301
3	$1+x^2+x^5+x^9+x^{13}$	0100010000010	3330300030330	2231210121221	2032013201110

[a]The leftmost bit in the sequence corresponds to the initial value of S0 and the rightmost bit corresponds to the initial value of S12.
[b]This is equivalent to the PRBS13Q test pattern defined in 120.5.11.2.1.

For a given configuration of the PRBS generator, there are three possible training patterns. The construction of each training pattern begins by demultiplexing the PRBS generator output into pairs of bits {A, B} where A corresponds to the 1st, 3rd, 5th, etc. bits output by the PRBS generator and B corresponds to the 2nd, 4th, 6th, etc. bits output by the PRBS generator. There is a new pair of bits each unit interval which implies that the PRBS generator is required to generate bits at twice the signaling rate. Given these pairs of bits, the three different training patterns correspond to three modulation and precoding modes: PAM2, PAM4, PAM4 with precoding.

When the modulation and precoding mode is set to PAM2, the training pattern is the sequence of 16 382 PAM4 symbols derived by mapping only the A bits such that logical 0 is transmitted as 0 and logical 1 is transmitted as 3.

When the modulation and precoding mode is set to PAM4, the training pattern is the sequence of 16 382 PAM4 symbols derived by Gray coding the {A, B} pairs as specified in 135.5.7.1.

When the modulation and precoding mode is set to PAM4 with precoding, the training pattern is the sequence of 16 382 PAM4 symbols derived by Gray coding the {A, B} pairs as specified in 135.5.7.1 and precoding the result as specified in 135.5.7.2. The precoder state is initialized to 0 at the beginning of each training pattern, so that P(j–1)=0 in Equation (135–1) for the first PAM4 symbol of the training pattern.

The modulation and precoding mode is set to PAM2 upon entry to the INITIALIZE state of the PMD control state diagram (see Figure 136–7).

NOTE—Exiting TRAINING mode requires both sides to use PAM4 modulation, thus the request and the status of the modulation and precoding are both required to have values other than PAM2 (either “PAM4” or “PAM4 with precoding”).

136.8.11.1.4 Zero pad

Two “0” symbols are transmitted immediately after the training pattern. This zero pad ensures the training frame is DC balanced and helps to delineate the start of the frame marker for the next training frame.

136.8.11.2 Control field structure

The structure of the control field shall be as shown in Table 136–9.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 136–9—Control field structure

Bit(s)	Name	Description
15:14	Reserved	Transmit as 0, ignore on receipt
13:12	Initial condition request	13 12 1 1 = Preset 3 1 0 = Preset 2 0 1 = Preset 1 0 0 = Individual coefficient control
11:10	Reserved	Transmit as 0, ignore on receipt
9:8	Modulation and precoding request	9 8 1 1 = PAM4 with precoding 1 0 = PAM4 0 1 = Reserved 0 0 = PAM2
7:5	Reserved	Transmit as 0, ignore on receipt
4:2	Coefficient select	4 3 2 1 1 0 = $c(-2)$ 1 1 1 = $c(-1)$ 0 0 0 = $c(0)$ 0 0 1 = $c(1)$
1:0	Coefficient request	1 0 1 1 = No equalization 1 0 = Decrement 0 1 = Increment 0 0 = Hold

136.8.11.2.1 Initial condition request

The initial condition request bits are used to select one of the three predefined transmitter equalizer configurations (presets) specified in 136.9.3.1.3. When the initial condition request bits are 00, the coefficient select and coefficient request bits are used to update the transmitter equalizer configuration.

136.8.11.2.2 Modulation and precoding request

The modulation and precoding request bits are used to request that the link partner transmitter transmit one of the three training pattern formats defined in 136.8.11.1.3.

136.8.11.2.3 Coefficient select

The coefficient select bits are used to identify the coefficient that is the target of a coefficient request. The value of the field is the two's complement encoding of the coefficient index. For example, binary value 111 corresponds to a coefficient index of –1.

136.8.11.2.4 Coefficient request

The coefficient request bits are used to change the value of the coefficient specified by the coefficient select bits. A coefficient may be changed by incrementing or decrementing its value or by setting it to "No equalization". The "No equalization" value is 1 for $c(0)$ and 0 for $c(-2)$, $c(-1)$, and $c(1)$.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136.8.11.3 Status field structure

The structure of the status field is shown in Table 136–10.

Table 136–10—Status field structure

Bit(s)	Name	Description
15	Receiver ready	1 = Training is complete and the receiver is ready for data 0 = Request for training to continue
14:12	Reserved	Transmit as 0, ignore on receipt
11:10	Modulation and precoding status	11 10 1 1 = PAM4 with precoding 1 0 = PAM4 0 1 = Reserved 0 0 = PAM2
9	Receiver frame lock	1 = Frame boundaries identified 0 = Frame boundaries not identified
8	Initial condition status	1 = Updated 0 = Not updated
7	Parity	Even parity bit
6	Reserved	Transmit as 0, ignore on receipt
5:3	Coefficient select echo	5 4 3 1 1 0 = $c(-2)$ 1 1 1 = $c(-1)$ 0 0 0 = $c(0)$ 0 0 1 = $c(1)$
2:0	Coefficient status	2 1 0 1 1 1 = Reserved 1 1 0 = Coefficient at limit and equalization limit 1 0 1 = Reserved 1 0 0 = Equalization limit 0 1 1 = Coefficient not supported 0 1 0 = Coefficient at limit 0 0 1 = Updated 0 0 0 = Not updated

136.8.11.3.1 Receiver ready

The receiver ready bit is used to signal the local receiver state to the link partner. When this bit is 1, it indicates that the local receiver has completed training and is prepared to receive data (local_rx_ready = true). When this bit is 0, it indicates that the local receiver is requesting that training continue (local_rx_ready = false).

136.8.11.3.2 Modulation and precoding status

The modulation and precoding status bits encode the value of local_tp_mode.

136.8.11.3.3 Receiver frame lock

When the receiver frame lock bit is set to 1, the receiver is indicating that it has identified training frame marker positions and is in a state where the response time requirements specified in 136.8.11.6 are met.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Receiver frame lock shall be set to 0 when the variable training is false, and shall not be set to 1 until training and local_tf_lock are both true.

136.8.11.3.4 Initial condition status

The initial condition status bit acknowledges the initial condition request bits received from the link partner. The acknowledgment reflects the value of ic_sts resulting from the procedure described in 136.8.11.4.1.

136.8.11.3.5 Parity bit

The parity bit is calculated based on the other bits in the control field and status field to create even parity for these fields. Even parity ensures that the transmitted control and status fields (see 136.8.11.1.2) are DC balanced. This field is ignored on receipt.

136.8.11.3.6 Coefficient select echo

The coefficient select echo bits acknowledge the coefficient select bits received from the link partner. When a change to the coefficient select bits is detected, the coefficient select echo bits are updated to represent the same coefficient index. This serves as a confirmation to the link partner that subsequent coefficient requests will act on the targeted coefficient.

136.8.11.3.7 Coefficient status

The coefficient status bits acknowledge the coefficient request bits received from the link partner. The acknowledge reflects the value of coef_sts resulting from the procedure described in 136.8.11.4.3.

136.8.11.4 Equalization control

When the PMD control state diagram (Figure 136–7) is in the TRAIN_LOCAL state, a PMD may request its link partner to change the transmitter equalization coefficients, either to predefined initial conditions or by individual coefficient control. The criteria for initiating such requests are implementation dependent.

A new individual coefficient update request or initial condition update request is not initiated until after the prior request has completed.

136.8.11.4.1 Initial condition setting request process

A request to change the initial condition of the link partner's transmitter is made by using the following procedure:

a) Set the initial condition request bits (136.8.11.2.1) to the desired predefined transmitter equalizer configuration (preset) and the coefficient request bits (136.8.11.2.4) to "hold".
b) Wait until the initial condition status bits (136.8.11.3.4) indicate "updated" and the coefficient status bits (136.8.11.3.7) indicate "not updated".
c) Set the initial condition request bits (136.8.11.2.1) to individual coefficient control and the coefficient request bits (136.8.11.2.4) to "hold".
d) Wait until both the initial condition status bits (136.8.11.3.4) and the coefficient status bits (136.8.11.3.7) indicate "not updated".

136.8.11.4.2 Initial condition setting response process

The handling of incoming requests is specified by the coefficient update state diagram (Figure 136–9). The behavior of the UPDATE_IC function is consistent with the following algorithm.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
if ic_req = ind_ctl
   ic_sts = not_upd
else
   if ic_req = preset 1
      Set coefficients to preset 1
   else if ic_req = preset 2
      Set coefficients to preset 2
   else if ic_req = preset 3
      Set coefficients to preset 3
   end if
   ic_sts = updated
end if
```

The variables ic_req and ic_sts are defined in 136.8.11.7.1. The transmitter equalizer coefficients corresponding to each of the three presets shall be within the ranges specified in Table 136–12.

The transmitter equalizer is set to preset 1 upon entry to the INITIALIZE state of the PMD control state diagram.

136.8.11.4.3 Coefficient update request process

A request to change an individual equalizer coefficient of the link partner's transmitter is made by using the following procedure:

a) In the transmitted control field, set the initial condition request bits (136.8.11.2.1) to individual control, and set the coefficient select bits (136.8.11.2.3) and coefficient request bits (136.8.11.2.4) to the desired values. This may be done in one step (all fields updated in the same training frame) or sequentially.

b) Wait until the received coefficient status bits (136.8.11.3.7) do not indicate "not updated" and the coefficient select echo bits (136.8.11.3.6) indicate the requested coefficient select value.

c) If the subsequent request is to change the same coefficient or request a new initial condition, set the coefficient request bits (136.8.11.2.4) to "hold" and wait until the received coefficient status bits (136.8.11.3.7) indicate "not updated".

136.8.11.4.4 Coefficient update response process

The handling of incoming requests is specified by the coefficient update state diagram (Figure 136–9). The behavior of the UPDATE_C(k) function is consistent with the following algorithm.

```
if k in k_list

   if coef_req = INCREMENT
      ck_ask = c(k) + ck_stp
   else if coef_req = DECREMENT
      ck_ask = c(k) – ck_stp
   else if coef_req = NO EQUALIZATION
      if k = 0
         ck_ask = 1
      else
         ck_ask = 0
      end if
   else
      ck_ask = c(k)
   end if

   if ck_ask > ck_max
      c(k) = ck_max
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
      if CHECK_EQ(ck_ask,k)
         coef_sts = COEFFICIENT AT LIMIT AND EQUALIZATION LIMIT
      else
         coef_sts = COEFFICIENT AT LIMIT
      end if
   else if ck_ask < ck_min
      c(k) = ck_min
      if CHECK_EQ(ck_ask,k)
         coef_sts = COEFFICIENT AT LIMIT AND EQUALIZATION LIMIT
      else
         coef_sts = COEFFICENT AT LIMIT
      end if
   else if CHECK_EQ(ck_ask,k)
      coef_sts = EQUALIZATION LIMIT
   else
      c(k) = ck_ask
      coef_sts = UPDATED
   end if
else
   coef_sts = COEFFICIENT NOT SUPPORTED
end if
```

The variables coef_req, coef_sts, and k are defined in 136.8.11.7.1. The following additional variables and functions are used.

c(k)
: Variable that contains the current value of the coefficient *c*(k).

ck_ask
: Variable that contains the value of *c*(k) that would result from the requested update.

ck_min
: Variable that contains the minimum supported value of *c*(k).

ck_max
: Variable that contains the maximum supported value of *c*(k).

ck_stp
: Variable that contains the magnitude of the change in *c*(k) for one step up or one step down from its current value.

k_list
: The set of valid transmitter equalizer coefficient indices {–2, –1, 0, 1}.

CHECK_EQ(ck_ask,k)
: Compares the transmitter's steady-state voltage that would result from setting transmit equalization coefficient *c*(k) value to ck_ask, while keeping all other coefficients unchanged, against the transmitter's steady-state voltage (see 136.9.3.1.2) and equalization capability. Returns true if the resulting combination of coefficients would exceed the maximum steady-state voltage or the transmitter's equalization capability. Otherwise returns false.

136.8.11.5 Modulation and precoding setting

When a change to the modulation and precoding request bits is detected, the modulation and precoding mode of the transmitted training pattern (see 136.8.11.1.3) is set accordingly, and the local_tp_mode variable is then set to the value of the modulation and precoding request bits to confirm that the change to the format of the training pattern was completed. local_tp_mode is encoded in the status field (see 136.8.11.3.2).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136.8.11.6 Handshake timing

Changes to the configuration of the transmitter equalizer or the transmitted training pattern may occur at any point between the time the request for the new configuration is received and the time that the request is acknowledged.

When the receiver frame lock bit in the status field of transmitted training frames is set to 1, the time from the receipt of a new request to the acknowledgment of that request shall be less than 2 ms. A new request is defined to be a received training frame whose control field differs from the control field of the preceding training frame. An acknowledgment is defined as the first transmitted training frame that contains a status field encoding that is an appropriate response for the requested action. For example, a change in the coefficient select bits in the control field would be acknowledged by a change in the coefficient select echo bits of the status field. Similarly, a change in the modulation and precoding request bits in the control field would be acknowledged by a change in the modulation and precoding status bits in the status field. All timing measurements are referred to a common reference point within the training frame (e.g., the 3 to 0 transition in the training frame marker).

The timing of requests and acknowledgment is illustrated in Figure 136–6.

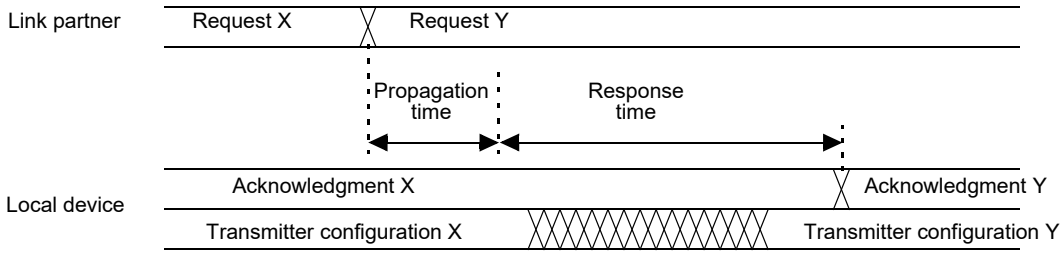

Figure 136–6—Transmitter update timing

136.8.11.7 Variables, functions, timers, counters, and state diagrams

The PMD implements one instance of each of the PMD control state diagrams, and the set of associated variables, functions, counters and timers defined in this subclause, independently for each of the n physical lanes.

136.8.11.7.1 Variables

coef_req

Enumerated variable derived from the “coefficient request” bits from the control field of the received training frames (see 136.8.11.2). This variable may be one of the following values: hold, decrement, increment, no equalization.

coef_sel

Variable derived from the “coefficient select” bits from the control field of the received training frames (see 136.8.11.2). It is assigned a signed integer value that is the two’s complement interpretation of the bits.

coef_sts

Enumerated variable that may be assigned one of the following values (abbreviations used by the state diagram are included in parentheses): not updated (not_upd), updated, coefficient at limit, coefficient not supported, equalization limit, coefficient at limit and equalization limit. The value is assigned by the UPDATE_C(k) function and Coefficient update state diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

(Figure 136–9), and then encoded in the status field of transmitted training frames via the ENCODE_STS function.

ic_req

Enumerated variable derived from the "initial condition request" bits from the control field of the received training frames (see 136.8.11.2). This variable may be assigned one of the following values (abbreviations used by the state diagram are included in parentheses): individual control (ind_ctl), preset 1, preset 2, preset 3.

ic_sts

Enumerated variable that may be assigned one of the following values (abbreviations used by the state diagram are included in parentheses): not updated (not_upd), updated.

k

Variable that stores the most recent value of coef_sel.

local_rx_ready

Boolean variable that is set to true by the training state diagram when local_trained is asserted and is set to false otherwise. This value is encoded as the "receiver ready" bit in the status field of transmitted training frames.

local_tf_lock

Boolean variable that is true when the training frame marker positions have been identified and is false otherwise.

local_tp_mode

Enumerated variable that controls the modulation and precoding mode in the transmitted training pattern (see 136.8.11.1.3) and may be assigned one of the following values: pam2, pam4, pam4 with precoding.

local_trained

Boolean variable that is set to true when the local receiver has determined that the remote transmit and local receive equalizers have been optimized and normal data transmission may commence. It is set to false otherwise. The exact criteria for setting this variable to true are implementation specific.

lost_training_lock

Boolean variable that indicates disruption in the reception of training frames from the link partner. When use_quiet_in_training is TRUE and the PMD control function (see Figure 136–7) is in TRAIN_LOCAL or TRAIN_REMOTE states, this variable is set to TRUE if local_tf_lock is FALSE continuously for a period of 20 ms, and may also be set to TRUE upon detection of an input signal consistent with a transmitter operating in the QUIET operating mode (see 136.8.2). It is set to FALSE otherwise.

marker_valid

Boolean variable that is set to true when the candidate frame marker matches the frame marker pattern defined in 136.8.11.1.1 and is set to false otherwise.

mr_restart_training

Boolean variable used by system management to restart the startup protocol. When set to true, it forces the PMD control state diagram to the INITIALIZE state.

mr_training_enable

Boolean variable used by system management to enable or disable the startup protocol. When set to true it enables the startup protocol, and when set to false it disables the startup protocol.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

new_marker
: Boolean variable that is set to true when a new candidate frame marker is available for testing and is set to false when the TEST_MARKER state is entered. A new frame marker is available for testing when the training frame lock process has accumulated 32 consecutive symbols starting at the candidate frame start position.

remote_rx_ready
: Boolean variable derived from the "receiver ready" bit of the status field of received training frames. The value of remote_rx_ready shall not be set to TRUE until no fewer than three consecutive training frames have been received with the "receiver ready" bit asserted.

remote_tf_lock
: Boolean variable derived from the "receiver frame lock" bit of the status field of received training frames. The value of remote_tf_lock shall not be set to TRUE until no fewer than three consecutive training frames have been received with the "receiver frame lock" bit asserted.

remote_tp_mode
: Enumerated variable that corresponds to the "modulation and precoding status" bits in the status field of received training frames. It may be assigned one of the following values: pam2, pam4, pam4 with precoding.

reset
: Boolean variable that resets the PMD. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PMD into low-power mode. It is false otherwise.

signal_detect
: Boolean variable that is set to true when the training process is complete and is set to false otherwise. The value of signal_detect is used by the PMD lane-by-lane signal detect function (136.8.5).

slip_done
: Boolean variable that is set to TRUE when the SLIP requested by the Training frame lock state diagram (Figure 136–8) is completed indicating that the next candidate frame sync position can be tested.

tf_offset
: Boolean variable that is set to true when receiving one full training frame (16 672 symbols, see 136.8.11.1) following the recent frame start position, such that a new frame marker is expected. Otherwise it is set to false

training
: Boolean variable that is set to true when the startup protocol is in progress and is set to false otherwise.

training_failure
: Boolean variable that is set to true when training failed to complete successfully within the allotted time limit. Otherwise it is set to false.

use_quiet_in_training
: Boolean variable that is TRUE if the PMD control function (see Figure 136–7) can enter the QUIET state. The value of this variable is implementation dependent.

136.8.11.7.2 Functions

ENCODE_STS
: Encodes portions of the status field of transmitted training frames. k is mapped to the coefficient select echo bits, coef_sts is mapped to the coefficient status bits, and ic_sts is mapped to the initial condition status bit.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SLIP

Causes the next candidate frame marker position to be tested. Repeated invocations of SLIP cause all possible positions to be evaluated. The precise method for determining the next candidate frame marker position is implementation dependent and beyond the scope of this standard.

TRANSMIT(tx_mode)

Controls the output of the PMD transmit function on the current lane. When tx_mode = DATA, the PMD transmit function output is the parameter of the PMD:IS_UNITDATA_*i*.request primitive (see 136.3). When tx_mode = TRAINING, the PMD transmit function output is the stream of symbols generated by the PMD control function. When tx_mode = QUIET, the PMD transmitter is turned off, equivalent to setting PMD_transmit_disable_*i* to one (see 136.8.7)

UPDATE_C(k)

Updates the value of *c*(k) based on the current values of the variables k and coef_req. The result of the update is stored in the variable coef_sts. This function implements the algorithm specified in 136.8.11.4.4.

UPDATE_IC

Updates all transmit equalizer coefficients based on the current value of the variable ic_req. The result is stored in the variable ic_sts. This function implements the algorithm specified in 136.8.11.4.2.

136.8.11.7.3 Timers

holdoff_timer

This timer is started when the PMD control state diagram enters the TIMEOUT state or the QUIET state. The terminal count of holdoff_timer is 80 ms ± 2%.

max_wait_timer

This timer sets the limit for how long the PMD startup protocol is allowed to operate. If the timer expires before the LINK_READY state is reached, then a failure to train is indicated. The terminal count of max_wait_timer is 3 s ± 2%.

wait_timer

This timer is started when the local receiver has completed training and detects that the remote receiver is ready to receive data. The local transmitter sends additional training frames until the timer expires to ensure that the link partner correctly detects the local receiver state. The terminal count of wait_timer is between 25 µs and 125 µs, equivalent to approximately 40 to 200 training frames.

136.8.11.7.4 Counters

bad_markers

Count of the number of consecutive frame marker mismatches.

good_markers

Count of the number of consecutive frame marker matches.

136.8.11.7.5 State diagrams

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter indicates that its value is to be incremented.

The PMD control state diagram (Figure 136–7) defines the operation of the startup protocol.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the LINK_READY state is entered with local_tp_mode set to “PAM4 with precoding”, then the PMD shall cause the adjacent PMA to transmit all subsequent data on the corresponding lane with precoding (see 135.5.7.2 and 120.5.7.2).

If the LINK_READY state is entered with remote_tp_mode set to “PAM4 with precoding”, then the PMD shall inform the adjacent PMA that all subsequently received data on the corresponding lane includes precoding (see 135.5.7.2 and 120.5.7.2).

The PMD control state diagram is supported by the training frame lock and coefficient update state diagrams. The training frame lock state diagram (Figure 136–8) determines when the PMD control function has detected training frame boundaries. The coefficient update state diagram (Figure 136–9) defines the process for updating the local transmitter equalizer coefficients in response to requests from the link partner.

136.9 PMD electrical characteristics

136.9.1 AC-coupling

Interoperability between PMD components operating from different supply voltages is facilitated by AC-coupling within the cable assembly (as specified in 136.11).

136.9.2 Signal paths

The MDI transmit and receive paths are point-to-point connections. Each path corresponds to one MDI lane and comprises two complementary signals, which form a balanced differential pair.

For 50GBASE-CR, there is one differential path in each direction for a total of two pairs, or four connections. For 100GBASE-CR2, there are two differential paths in each direction for a total of four pairs, or eight connections. For 200GBASE-CR4, there are four differential paths in each direction for a total of eight pairs, or sixteen connections.

136.9.3 Transmitter characteristics

The transmitter on each lane shall meet the specifications given in Table 136–11 and detailed in the referenced subclauses. Unless specified otherwise, all transmitter measurements are made for each lane separately, at TP2, utilizing the test fixtures specified in Annex 136B, using a test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth. The connection from TP2 to the test equipment is AC-coupled.

Measurement of the DC common-mode voltage is made with a high-impedance connection to TP2 where each conductor of the differential pair is AC-coupled to a 50 Ω termination.

The transmitter characteristics at TP0 are provided informatively in 136A.2.

Table 136–11—Summary of transmitter specifications at TP2

Parameter	Subclause reference	Value	Units
Differential pk-pk output voltage (max.) with Tx disabled[a]	93.8.1.3	30	mV
DC common-mode voltage (max.)[a]	93.8.1.3	1.9	V
AC common-mode RMS output voltage, v_{cmi} (max.)[a]	93.8.1.3	30	mV
Differential pk-pk voltage, v_{di} (max.)[a]	93.8.1.3	1200	mV
Effective return loss (ERL) (min.)	136.9.3.4	See Equation (136–6)	dB
Common-mode to differential mode output return loss (min.)	92.8.3.3	See Equation (92–2)	dB
Common-mode to common-mode output return loss (min.)	92.8.3.4	See Equation (92–3)	dB
Transmitter steady-state voltage, v_f (min.) Transmitter steady-state voltage, v_f (max.)	136.9.3.1.2	0.354 0.6	V
Linear fit pulse peak (min.)	136.9.3.1.2	$0.49 \times v_f$	V
Level separation mismatch ratio R_{LM} (min.)	120D.3.1.2	0.95	—

Table 136–11—Summary of transmitter specifications at TP2 *(continued)*

Parameter	Subclause reference	Value	Units
Transmitter output waveform			
abs step size for $c(-1)$, $c(0)$, and $c(1)$ (min.)	136.9.3.1.4	0.005	—
abs step size for $c(-1)$, $c(0)$, and $c(1)$ (max.)	136.9.3.1.4	0.05	—
abs step size for $c(-2)$ (min.)	136.9.3.1.4	0.005	—
abs step size for $c(-2)$ (max.)	136.9.3.1.4	0.025	—
value at minimum state for $c(-1)$ and $c(1)$ (max.)	136.9.3.1.5	−0.25	—
value at maximum state for $c(-2)$ (min.)	136.9.3.1.5	0.1	—
Signal-to-noise-and-distortion ratio SNDR (min.)	120D.3.1.6	32.2	dB
Output jitter (max.)[b]			
J_{RMS}	120D.3.1.8	0.023	UI
J3u	136.9.3.3	0.115	UI
Even-odd jitter, pk-pk[c]	120D.3.1.8	0.019	UI
Signaling rate		26.5625 ± 100 ppm	GBd
Unit interval nominal		37.64706	ps

[a]Measurement uses the method described in 93.8.1.3 with the exception that the PRBS13Q test pattern is used.
[b]J3u, J_{RMS}, and even-odd jitter measurements are made with a single transmit equalizer setting selected to compensate for the loss of the host channel.
[c]If the measuring instrument is triggered by a clock based on the signaling rate divided by an even number, the even-odd jitter may not be correctly observed.

136.9.3.1 Transmitter output waveform

The transmit function includes programmable equalization to compensate for the frequency-dependent loss of the channel and facilitate data recovery at the receiver. The functional model for the transmit equalizer on each lane is the four-tap transversal filter shown in Figure 136–10.

The state of the transmit equalizer and hence the transmitted output waveform may be manipulated via the PMD control function defined in 136.8.11 or via the management interface. The transmit function responds to a set of commands issued by the link partner's receive function and conveyed by a back-channel communications path. This command set includes instructions to increment, decrement, hold, or set to zero a selected coefficient $c(k)$, where $k = -2$ to 1. In addition, it includes commands to set all coefficients to one of three initial conditions.

In response, the transmit function relays status information to the link partner's receive function. The status messages indicate the selected coefficient index k, the status of the coefficient $c(k)$ (updated, not updated, or at limit), and the status of the initial condition (updated or not updated).

136.9.3.1.1 Linear fit to the measured waveform

The following procedure is used to determine the linear fit pulse response, linear fit error, and normalized transmitter coefficient values.

Set the transmitter under test to transmit the PRBS13Q test pattern (defined in 120.5.11.2.1). For each configuration of the transmit equalizer, capture at least one complete cycle of the test pattern at TP2, as specified in 85.8.3.3.4. The clock recovery unit (CRU) used in the measurement has a corner frequency of 4 MHz and a slope of 20 dB/decade.

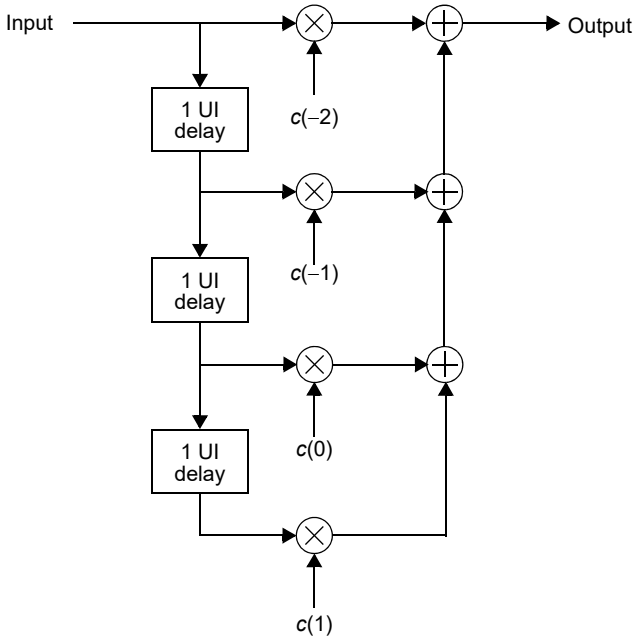

Figure 136–10—Transmit equalizer functional model

In the following calculations, M should be an integer not less than 32. Interpolation of the captured waveform may be used to achieve this.

Compute the linear fit pulse response $p(k)$, k=1 to $M \times N_p$, from the captured waveform, as specified in 85.8.3.3.5, with $N_p = 200$ and $D_p = 3$, where the aligned symbols $x(n)$ are assigned normalized amplitudes −1, −*ES*, *ES*, and 1 to represent the PAM4 symbol values 0, 1, 2, and 3 respectively. *ES* is defined as $(|ES1| + |ES2|)/2$ where *ES1* and *ES2* are calculated according to 120D.3.1.2.

Define $r(k)$ to be the linear fit pulse response when transmit equalizer coefficients have been set to the "pre-set 1" values. The normalized coefficients for any configuration of the transmit equalizer are computed using the following method.

For each value of m in the range $-M/2$ to $M/2-1$ when M is even and $-(M-1)/2$ to $(M-1)/2$ when M is odd:

a) Define an $M \times N_p$-by-4 matrix R_m. The elements of R_m are assigned values per Equation (136–1) where $i = -2$ to 1 and $j = 1$ to $M \times N_p$.

$$R_m(j, i+3) = \left\{ \begin{array}{ll} r(m+j-M\times i) & \text{if } 1 \le m+j-M\times i \le M\times N_p \\ 0 & \text{otherwise} \end{array} \right\} \tag{136–1}$$

b) The normalized coefficients of the transmit equalizer are computed using Equation (136–2).

$$\begin{bmatrix} c_m(-2) \\ c_m(-1) \\ c_m(0) \\ c_m(1) \end{bmatrix} = (R_m^T R_m)^{-1} R_m^T \begin{bmatrix} p(1) \\ \dots \\ p(M\times N_p) \end{bmatrix} \tag{136–2}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) The linear fit pulse response is reconstructed from the matrix R_m and the normalized coefficients using Equation (136–3).

$$\begin{bmatrix} p_m(1) \\ \cdots \\ p_m(M \times N_p) \end{bmatrix} = R_m \begin{bmatrix} c_m(-2) \\ c_m(-1) \\ c_m(0) \\ c_m(1) \end{bmatrix} \quad (136\text{–}3)$$

d) $\varepsilon^2(m)$ is computed using Equation (136–4).

$$\varepsilon^2(m) = \sum_{k=1}^{M \times N_p} (p(k) - p_m(k))^2 \quad (136\text{–}4)$$

The normalized transmit equalizer coefficients $c(i)$ for a given linear fit pulse $p(k)$ are the values $c_m(i)$ for the value of m that minimizes $\varepsilon^2(m)$.

136.9.3.1.2 Steady-state voltage and linear fit pulse peak

The steady-state voltage v_f is defined to be the sum of the linear fit pulse $p(1)$ through $p(M \times N_v)$ divided by M (refer to 85.8.3.3 step 3), where N_v represents the number of symbols to take into account and has a value of 13. The steady-state voltage shall be greater than or equal to 0.354 V and less than or equal to 0.6 V after the transmit equalizer initial condition has been set to preset 1 (no equalization).

The peak value of $p(k)$ shall be greater than $0.49 \times v_f$ after the transmit equalizer initial condition has been set to preset 1 (no equalization).

136.9.3.1.3 Coefficient initialization

When the Coefficient update state diagram (Figure 136–9) is in either the OUT_OF_SYNC state or the NEW_IC state, the coefficients of the transmit equalizer shall be configured to values within the ranges specified in Table 136–12 (according to the value of the variable ic_req). These requirements apply upon the assertion of Initial condition status of "Updated".

Table 136–12—Coefficient initial conditions

Coefficient update state	ic_req	$c(-2)$	$c(-1)$	$c(0)$	$c(1)$
OUT_OF_SYNC	N/A	0 ± 0.025	0 ± 0.05	1 ± 0.05	0 ± 0.05
NEW_IC	preset 1	0 ± 0.025	0 ± 0.05	1 ± 0.05	0 ± 0.05
	preset 2	0 ± 0.025	–0.15 ± 0.05	0.75 ± 0.05	–0.1 ± 0.05
	preset 3	0 ± 0.025	–0.25 ± 0.05	0.75 ± 0.05	0 ± 0.05

136.9.3.1.4 Coefficient step size

When coef_sel is –1, 0, or 1, the change in the normalized transmit equalizer coefficient c(coef_sel) corresponding to a request to "increment" shall be between 0.005 and 0.05, and the change in the normalized

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transmit equalizer coefficient c(coef_sel) corresponding to a request to "decrement" shall be between –0.05 and –0.005.

When coef_sel is –2, the change in the normalized transmit equalizer coefficient c(–2) corresponding to a request to "increment" shall be between 0.005 and 0.025, and the change in the normalized transmit equalizer coefficient c(coef_sel) corresponding to a request to "decrement" shall be between –0.025 and –0.005.

The coefficients other than c(coef_sel) are not expected to change. The absolute change in any coefficient other than c(coef_sel) shall be less than 0.005.

The change in the normalized transmit equalizer coefficient is defined to be the difference in the value measured prior to the assertion of the "increment" or "decrement" request (i.e., coef_req is "Hold") and the value upon the assertion of a coefficient status of "updated".

136.9.3.1.5 Coefficient range

When sufficient "increment" or "decrement" requests have been received for a given coefficient, the coefficient reaches a lower or upper bound based on the range of that coefficient or the combination of coefficients.

With $c(-2)$ and $c(-1)$ both set to zero and both $c(0)$ and $c(1)$ having received sufficient "decrement" requests so that they are at their respective minimum values, $c(1)$ shall be less than or equal to −0.25.

With $c(-2)$ and $c(1)$ set to zero and both $c(-1)$ and $c(0)$ having received sufficient "decrement" requests so that they are at their respective minimum values, $c(-1)$ shall be less than or equal to −0.25.

With $c(-1)$ and $c(1)$ set to zero, $c(0)$ having received sufficient "decrement" requests so that it is at its minimum value, and $c(-2)$ having received sufficient "increment" requests so that it is at its maximum value, $c(-2)$ shall be greater than or equal to 0.1.

NOTE—Any coefficient except c(0) may be set to zero by asserting a coefficient request of "no equalization" for that coefficient, using the control function specified in 136.8.11, or by implementation specific means.

136.9.3.2 Insertion loss, TP0 to TP2 or TP3 to TP5

The recommended maximum insertion loss from TP0 to TP2 or from TP3 to TP5 including the test fixture is given by Equation (136–5). Note that the recommended maximum insertion loss from TP0 to TP2 or from TP3 to TP5 is 10.07 dB at 13.28 GHz.

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.08 + 0.57\sqrt{f} + 0.596f & 0.01 \le f < 14 \\ -19.109 + 2.119f & 14 \le f \le 19 \end{array} \right\} \text{(dB)} \qquad (136\text{–}5)$$

136.9.3.3 J3u jitter

J3u is calculated from a jitter measurement specified in 120D.3.1.8.1. J3u is defined as the time interval that includes all but 10^{-3} of $f_J(t)$, from the 0.05th to the 99.95th percentile of $f_J(t)$.

136.9.3.4 Transmitter effective return loss (ERL)

ERL of the transmitter at TP2 is computed using the procedure in 93A.5 with the values in Table 136–13. Parameters that do not appear in Table 136–13 take values from Table 136–18. The value of T_{fx} is twice the delay associated with the TP2 test fixture being used. N_{bx} is set to the value of N_b in Table 136–18.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 136–13—Transmitter and receiver ERL parameter values

Parameter	Symbol	Value	Units
Transition time associated with a pulse	T_r	0.0189	ns
Incremental available signal loss factor	β_x	1.7	GHz
Permitted reflection from a transmission line external to the device under test	ρ_x	0.3	—
Length of the reflection signal	N	300	UI

Transmitter ERL at TP2 shall meet Equation (136–6).

$$ERL \geq 40\log_{10}\left(\frac{v_f}{\max\limits_{k}(p(k))}\right) \quad \text{(dB)} \tag{136–6}$$

where

v_f is the steady-state voltage, defined in 136.9.3.1.2

$p(k)$ is the linear fit pulse at preset 1 (no equalization) (see 136.9.3.1.2)

136.9.4 Receiver characteristics

The receiver on each lane shall meet the specifications given in Table 136–14 and detailed in the referenced subclauses. Unless specified otherwise, all receiver measurements are made for each lane separately, at TP3, utilizing the test fixtures specified in Annex 136B.

The receiver specifications at TP5 are provided informatively in 136A.3.

Table 136–14—Summary of receiver specifications at TP3

Parameter	Subclause reference	Value	Units
Input amplitude tolerance	136.9.4.1	1200[a]	mV
Interference tolerance	136.9.4.2	Table 136–15	—
Jitter tolerance	136.9.4.3	Table 120D–7	—
Signaling rate	136.9.4.4	26.5625 ± 100 ppm	GBd
ERL (min.)	136.9.4.5	10	dB
Differential to common-mode input return loss	92.8.4.3	Equation (92–21)	dB

[a]Amplitude is measured at TP2.

136.9.4.1 Receiver input amplitude tolerance

When a PMD receiver is connected to a compliant transmitter whose peak-to-peak differential output voltage (see Table 136–11 footnote a) measured at the preset 1 equalizer setting is 1200 mV, using a compliant cable assembly with the minimum insertion loss specified in 136.11.2, the PMD receiver operation shall enable an FEC symbol error ratio better than 10^{-3} assuming errors are sufficiently

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

uncorrelated to support the required frame loss ratio (see 136.1). If errors are not sufficiently uncorrelated, the FEC symbol error ratio shall be lower as appropriate to support the required frame loss ratio.

The receiver is allowed to control the transmitter equalizer coefficients, using the PMD control function defined in 136.8.11 or an equivalent process, to meet these requirements.

136.9.4.2 Receiver interference tolerance

Receiver interference tolerance is measured according to the procedure described in 136.9.4.2.1 through 136.9.4.2.5. Receiver interference tolerance test requirements are specified in Table 136–15.

Two tests are defined. Test 1 includes a low-loss channel. Test 2 includes a high-loss channel. The cable assembly used in the test channel (see 110.8.4.2.2) shall meet the cable assembly Channel Operating Margin (COM) as specified in 136.11.7.

Table 136–15—Interference tolerance test parameters

Parameter	Test 1 (low loss)		Test 2 (high loss)		Units
	Min	Max	Min	Max	
Test pattern	Scrambled idle encoded by RS-FEC				
FEC symbol error ratio required[a]	$< 10^{-3}$				
Test channel insertion loss at 13.28 GHz[b]	14.3	14.8	24.34	24.84	dB
Cable assembly insertion loss at 13.28 GHz	8	10	15.16	17.16	dB
COM[c]	3		3		dB

[a]See 136.9.4.2.5 for definition of FEC symbol error ratio.
[b]Insertion loss between the two test references (see Figure 110–3b).
[c]The COM value is the target value for the SNR_{TX} calibration defined in 136.9.4.2.3 item f. The SNR_{TX} value measured at the Tx test reference should be as close as practical to the value needed to produce the target COM. If lower SNR_{TX} values are used, this would demonstrate margin to the specification but this is not required for compliance.

136.9.4.2.1 Test setup

The interference tolerance test is performed with the setup similar to the one described in 110.8.4.2.1. The test setup includes noise injection for all lanes of the pattern generator.

136.9.4.2.2 Test channel

The test channel is the same as the one defined in 110.8.4.2.2, except that the cable assembly meets the requirements of 136.11 and the cable assembly test fixture meets the requirements of Annex 136B.

136.9.4.2.3 Test channel calibration

The scattering parameters of the test channel are measured at the test references as illustrated in Figure 110–3b using the cable assembly test fixtures specified in Annex 136B.

The insertion loss at 13.28 GHz of the signal path between the test references in Figure 110–3b is within the limits in Table 136–15.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The COM is calculated using the method and parameters of 136.11.7 with the following considerations:

a) The channel signal path is $SCHS_p$ = cascade($S^{(CTSP)}$, $S^{(HOSP)}$), where cascade() is defined in 93A.1.2.1, $S^{(HOSP)}$ is defined in 136.11.7.1.1, and $S^{(CTSP)}$ is the measured channel between the test references in Figure 110–3b.

b) The COM parameters are as modified by Table 136–15.

c) COM is calculated using both Test 1 and Test 2 device package model transmission line lengths listed in Table 136–18 on the receiver side. The value of COM is taken as the lower of the two calculated values.

d) The augmented signal path in 93A.1.2 is replaced by S_p determined from Equation (136–7) (effectively omitting the transmitter device package model $S^{(tp)}$). The filtered voltage transfer function $H^{(k)}(f)$ calculated in Equation (93A–19) uses T_r equal to the 20% to 80% transition time at the Tx test reference. T_r is measured using the method in 120E.3.1.5 with the transmit equalizer turned off (i.e., coefficients set to the preset 1 values, see 136.9.3.1.3).

e) Even-odd jitter, J3u, and J_{RMS} without noise injection (see 136.9.4.2.4) are measured at the Tx test reference and comply with the specification in Table 136–11. In the calculation of COM, A_{DD} and σ_{RJ} are calculated from the measured values of J3u and J_{RMS} using Equation (136–8) and Equation (136–9), replacing the values in Table 136–18. It is recommended to adjust the pattern generator jitter such that J3u and J_{RMS} are as close as practical to their limits in Table 136–11.

f) The SNR_{TX} value that results in the required COM value for the test is calculated. The injected noise (see 136.9.4.2.4) is set such that the SNDR matches the calculated SNR_{TX} value. SNDR is measured at the Tx test reference using the procedure in 120D.3.1.6, with the exception that the linear fit in 120D.3.1.3 is performed with a pulse length (N_p) of 15 UI.

$$S_p = \text{cascade}(SCHS_p, S^{(rp)}) \tag{136–7}$$

where

cascade()	is defined in 93A.1.2.1
$SCHS_p$	is defined in item a) above
$S^{(rp)}$	is defined in 93A.1.2.4

$$A_{DD} = \frac{\frac{J3u}{2} + Q3\sqrt{(Q3^2+1)\times J_{RMS}^2 - \left(\frac{J3u}{2}\right)^2}}{Q3^2+1} \tag{136–8}$$

$$\sigma_{RJ} = \frac{\frac{J3u}{2} - A_{DD}}{Q3} \tag{136–9}$$

where $Q3 = 3.2905$

NOTE 1—$Q3$ is an approximated solution of $Q(Q3) = 5 \times 10^{-4}$, where the Q function is defined in Equation (95–1).

NOTE 2—Calculation of A_{DD} requires that $(Q3^2+1)\times J_{RMS}^2 \geq \left(\frac{J3u}{2}\right)^2$. If this does not hold, a different transmitter should be used in the test setup.

136.9.4.2.4 Pattern generator and noise injection

The pattern generator transmits data to all lanes of the device under test. At the start of transmitter training, the pattern generator output amplitude on all lanes shall be 800 mV peak-to-peak differential when measured on an alternating zero-three pattern. The output amplitude, measured on an alternating zero-three pattern, is not permitted to exceed 800 mV peak-to-peak differential during transmitter training. The output waveform and the ERL of the pattern generator shall comply with 136.9.3.

Broadband noise is added to the signal before the Tx test reference, with noise level set according to step f in 136.9.4.2.3.

The broadband noise required for each lane is calibrated. The noise may be added either to one lane at a time or using multiple noise sources to all lanes at the same time.

136.9.4.2.5 Test procedure

The pattern generator is first configured to transmit the training pattern defined in 136.8.11. During this initialization period, the device under test (DUT) configures the pattern generator transmit equalizer to the coefficient settings it would select using the protocol described in 136.8.11 and the receiver is tuned using its optimization method. The coefficient settings may be communicated via the startup protocol or by other means.

After the pattern generator equalizer has been configured and the receiver tuned, the pattern generator is set to generate the test pattern specified in Table 136–15. During the test, the transmitters in the device under test transmit the same pattern type specified for the test, with equalization turned off (preset 1 condition).

Symbol error ratio is measured using the per-lane RS-FEC symbol error counters (see 91.6) in the adjacent RS-FEC sublayer, or the per-lane PCS symbol error counters (see 119.3.1) in the adjacent PCS, as appropriate.

The FEC symbol error ratio is defined as the sum of the symbol error counters on all lanes divided by the number of symbols transmitted on all lanes, which may be estimated from the test time.

A PHY shall meet the FEC symbol error ratio requirement in all tests defined in Table 136–15 with broadband noise added to all lanes (see 136.9.4.2.4). The FEC symbol error ratio requirement assumes errors are sufficiently uncorrelated to support the required frame loss ratio (see 136.1). If errors are not sufficiently uncorrelated, the FEC symbol error ratio shall be lower as appropriate to support the required frame loss ratio.

NOTE—If noise is applied to each of the n lanes one at a time, results of the n measurements are summed to yield the FEC symbol error ratio. The result may need to be corrected based on the FEC symbol error ratio with no noise added on any lane.

136.9.4.3 Receiver jitter tolerance

136.9.4.3.1 Test setup

Jitter tolerance is measured with a channel meeting the insertion loss of Test 2 as specified in Table 136–15. The pattern generator includes sinusoidal jitter injection.

136.9.4.3.2 Test procedure

The jitter tolerance test procedure is similar to that of 136.9.4.2, with the exception that no noise is injected (i.e., step f in 136.9.4.2.3 is not performed). Instead, jitter with the specified frequency and amplitude is applied to the pattern generator and the jitter amplitude is adjusted to obtain the peak-to-peak jitter specified for that frequency in Table 120D–7 at the Tx test reference (see Figure 110–3a). The test channel COM, calculated per 136.9.4.2.3 with the jitter-stressed transmitter output, shall not be lower than the value in Table 136–15.

A PHY shall meet the FEC symbol error ratio requirement defined in Table 136–15 for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 120D–7 with jitter added to all lanes (see 136.9.4.2.4).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—If jitter is applied to each of the n lanes one at a time, results of the n measurements are summed to yield the FEC symbol error ratio. The result may need to be corrected based on the FEC symbol error ratio with no jitter applied on any lane.

NOTE 2—The A_{DD} (Equation (136–8)) and σ_{RJ} (Equation (136–9)) calculated from transmitter measurements in this test may be higher than the values in Table 136–18. A suitable channel should be chosen in order to meet the COM requirement with these values.

136.9.4.4 Signaling rate range

A PHY shall comply with the receiver requirements of 136.9.4.2 and 136.9.4.3 for any signaling rate in the range 26.5625 GBd ± 100 ppm. This translates to a nominal unit interval of 37.64706 ps.

136.9.4.5 Receiver ERL

ERL of the receiver at TP3 is computed using the procedure in 93A.5 with the values in Table 136–13. Parameters that do not appear in Table 136–13 take values from Table 136–18. The value of T_{fx} is twice the delay associated with the TP3 test fixture being used. N_{bx} is set to the value of N_b in Table 136–18.

Receiver ERL at TP3 shall be greater than or equal to 10 dB.

136.10 Channel characteristics

The channel is defined between TP0 and TP5 to include the transmitter and receiver differential controlled impedance printed circuit board and the cable assembly as illustrated in Figure 136–2. The channel insertion loss, return loss, COM, and the transmitter and receiver differential controlled impedance printed circuit board parameters are provided informatively in 136A.4 through 136A.7.

Channel definitions apply for links between two PHYs of the same type, 50GBASE-CR, 100GBASE-CR2, or 200GBASE-CR4.

136.11 Cable assembly characteristics

Cable assemblies defined in this subclause contain insulated conductors terminated in a connector at each end for use as link segments between MDIs. Cable assemblies are primarily intended as point-to-point links between 50GBASE-CR, 100GBASE-CR2, or 200GBASE-CR4 PHYs using controlled impedance cables.

Three cable assembly types are specified:

a) 50GBASE-CR: Cable assembly that supports single-lane links between two 50GBASE-CR PHYs with achievable cable length of at least 3 m.

b) 100GBASE-CR2: Cable assembly that supports two-lane links between two 100GBASE-CR2 PHYs with achievable cable length of at least 3 m.

c) 200GBASE-CR4: Cable assembly that supports four-lane links between two 200GBASE-CR4 PHYs with achievable cable length of at least 3 m.

NOTE—It may be possible to construct compliant cable assemblies longer than indicated. Length of a cable assembly does not imply compliance to specifications.

50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 cable assembly form factors are described in Annex 136D. There are five possible MDIs which are defined in Annex 136C.

For 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4, the lanes are AC-coupled. The AC-coupling shall be within the cable assembly. It is recommended that it is within the plug connectors. It should be noted that there may be various methods for AC-coupling in actual implementations. The low-frequency 3 dB

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

cutoff of the AC-coupling shall be less than 50 kHz. It is recommended that the value of the coupling capacitors be 100 nF. The capacitor limits the inrush charge and baseline wander.

All cable assembly measurements are to be made between TP1 and TP4 with cable assembly test fixtures as specified in Annex 136B. These cable assembly specifications are based upon twinaxial cable characteristics, but other cable types are acceptable if the specifications of this subclause are met.

Table 136–16 provides a summary of the cable assembly characteristics for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4, and references to the subclauses addressing each parameter.

The specifications for the three cable assembly types are identical except the number of lanes.

Table 136–16—Cable assembly characteristics summary

Description	Reference	Value	Unit
Maximum insertion loss at 13.28 GHz	136.11.2	17.16	dB
Minimum insertion loss at 13.28 GHz	136.11.2	8	dB
Minimum cable assembly ERL[a]	136.11.3	11	dB
Differential to common-mode return loss	136.11.4	Equation (92–28)	dB
Differential to common-mode conversion loss	136.11.5	Equation (92–29)	dB
Common-mode to common-mode return loss	136.11.6	Equation (92–30)	dB
Minimum COM	136.11.7	3	dB

[a]Cable assemblies with a COM greater than 4 dB are not required to meet minimum ERL.

136.11.1 Characteristic impedance and reference impedance

The nominal differential characteristic impedance of the cable assembly is 100 Ω. The differential reference impedance for cable assembly specifications shall be 100 Ω.

136.11.2 Cable assembly insertion loss

The measured insertion loss of a cable assembly shall be greater than or equal to the minimum cable assembly insertion loss given in Equation (92–26) and illustrated in Figure 92–12.

The measured insertion loss at 13.28 GHz of a cable assembly shall be less than or equal to 17.16 dB.

136.11.3 Cable assembly ERL

ERL of the cable assembly at TP1 and at TP4 are computed using the procedure in 93A.5 with the values in Table 136–17. Parameters that do not appear in Table 136–17 take values from Table 136–18. The value of T_{fx} is twice the delay associated with the specific cable assembly test fixture being used. Note that test fixtures are specified in 136B.1. N_{bx} is set to the value of N_b in Table 136–18.

Cable assembly ERL at TP1 and at TP4 shall be greater than or equal to 11 dB for cable assemblies that have a COM less than 4 dB.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 136–17—Cable assembly ERL parameter values

Parameter	Symbol	Value	Units
Transition time associated with a pulse	T_r	0.0189	ns
Incremental available signal loss factor	β_x	1.7	GHz
Permitted reflection from a transmission line external to the device under test	ρ_x	0.25	—
Length of the reflection signal	N	1000	UI

136.11.4 Differential to common-mode return loss

The cable assembly differential to common-mode return loss shall meet the requirements of 92.10.4.

136.11.5 Differential to common-mode conversion loss

The cable assembly differential to common-mode conversion loss shall meet the requirements of 92.10.5.

136.11.6 Common-mode to common-mode return loss

The cable assembly common-mode to common-mode return loss shall meet the requirements of 92.10.6.

136.11.7 Cable assembly Channel Operating Margin

The cable assembly Channel Operating Margin (COM) for each lane is derived from measurements of the cable assembly signal, near-end crosstalk and far-end crosstalk paths. COM is computed using the path calculations defined in 136.11.7.1 and the procedure in 93A.1, where T_r is 12 ps for $H_t(f)$ as used in Equation (93A–19). The specific paths used depend on cable assembly form factor (see Annex 136D), as described in 136.11.7.2.

COM parameter values for the three cable assembly types are provided in Table 136–18.

Test 1 and Test 2 differ in the value of the device package model transmission line length z_p. COM for any channel within the cable assembly shall be greater than or equal to 3 dB for both Test 1 and Test 2.

136.11.7.1 Channel signal and crosstalk path calculations

The channel paths between TP0 and TP5 used for calculation of the cable assembly COM consist of measured cable assembly signal and crosstalk paths, representative transmitter PCB signal paths, and representative receiver PCB signal paths.

The transmitter and receiver PCB signal paths are calculated using the method defined in 93A.1.2.3. The scattering parameters for a PCB are defined by Equation (93A–13), Equation (93A–14), and the parameter values given in Table 92–12, with the exception that Z_c is 100 Ω. The PCB trace length parameter z_p has different value for each specific signal path, as specified in 136.11.7.1.1 and 136.11.7.1.2.

The channel path calculations use the function cascade() defined in 93A.1.2.1.

136.11.7.1.1 Channel signal path

The scattering parameters of the channel signal path from TP0 to TP5 are calculated using Equation (136–10). The transmitter and receiver PCB signal paths are both denoted as $S^{(HOSP)}$ and are calculated from Equation (93A–13) and Equation (93A–14) using z_p = 151 mm in length and the parameter values given in Table 92–12, with the exception that Z_c is 100 Ω, representing an insertion loss of 6.42 dB at 13.28 GHz on each PCB.

$$SCHS_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOSP)}, S^{(CASP)}), S^{(HOSP)}) \quad (136\text{–}10)$$

where

$SCHS_p^{(k)}$ is the channel signal path

$S^{(HOSP)}$ is the host (transmitter or receiver) PCB signal path

$S^{(CASP)}$ is the cable assembly signal path (TP1 to TP4)

k is equal to zero

136.11.7.1.2 Channel crosstalk paths

The MDI is the significant contributor to crosstalk and is included in and characterized by the cable assembly crosstalk measurements. Crosstalk includes a near-end path where the aggressor is the PMD transmitter, and in some cases, additional near-end, far-end, and alien far-end crosstalk paths where the aggressors are other PMD transmitters that are connected to the same cable assembly.

For the channel crosstalk paths, the receiver PCB model is $S^{(HOSP)}$ as defined in 136.11.7.1.1. The aggressor transmitter host PCB model is denoted as $S^{(HOTxSP)}$ and is calculated from Equation (93A–13) and Equation (93A–14) using z_p = 110 mm in length and the parameter values given in Table 92–12, with the exception that Z_c is 100 Ω, representing an insertion loss of 4.68 dB at 13.28 GHz. The transmitter host PCB

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

insertion loss is lower than that used for the signal path, to allow for a reasonable worst-case crosstalk in the COM calculation.

The scattering parameters of the channel near-end crosstalk paths are calculated using Equation (136–11). The scattering parameters of the channel alien far-end crosstalk paths are calculated using Equation (136–12).

$$SCHNXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOTxSP)}, S^{(CANXTk)}), S^{(HOSP)}) \quad (136–11)$$

where

$SCHNXT_p^{(k)}$ is the near-end crosstalk path

$S^{(HOSP)}$ is the host receiver PCB signal path defined in 136.11.7.1.1

$S^{(HOTxSP)}$ is the aggressor transmitter PCB signal path

$S^{(CANXTk)}$ is the cable assembly near-end crosstalk path k (TP1 to TP4)

k is the index of the near-end crosstalk path

$$SCHAFXT_p^{(k)} = \text{cascade}(\text{cascade}(S^{(HOTxSP)}, S^{(CAFXTk)}), S^{(HOSP)}) \quad (136–12)$$

where

$SCHAFXT_p^{(k)}$ is the alien far-end crosstalk path

$S^{(HOSP)}$ is the host receiver PCB signal path defined in 136.11.7.1.1

$S^{(HOTxSP)}$ is the aggressor transmitter PCB signal path

$S^{(CAFXTk)}$ is the cable assembly far-end crosstalk path k (TP1 to TP4)

k is the index of the alien far-end crosstalk path

136.11.7.2 Signal and crosstalk paths used in calculation of COM

Cable assemblies have several form factors, as described in Annex 136D. The choice of signal and crosstalk paths for calculation of COM is specific to each cable assembly form factor, as specified in Table 136–19.

The signal path is calculated using Equation (136–10).

The near-end crosstalk paths are calculated using Equation (136–11), with k values from 1 to n; where n is the number of near-end crosstalk paths given in Table 136–19 for the cable assembly form factor considered.

The far-end crosstalk paths are calculated using Equation (136–12), with k values from 1 to n; where n is the number of far-end crosstalk paths given in Table 136–19 for the cable assembly form factor considered.

Annex 136C specifies the MDIs for 50GBASE-CR, 100GBASE-CR2, 200GBASE-CR4.

The specifications for the cable assembly types are identical except the number of lanes.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The crosstalk paths for each MDI type are given in Table 136–19; the crosstalk paths are from the aggressors given in columns two through four to the victim given in the first column.

Table 136–19—Number of crosstalk paths used in COM

	SFP28		QSFP28 or microQSFP		QSFP-DD or OSFP	
	NEXT	**FEXT**	**NEXT**	**FEXT**	**NEXT**	**FEXT**
SFP28	1	0	1	3	1	7
QSFP28 or microQSFP	4	3	4	3	4	7
QSFP-DD or OSFP	8	7	8	7	8	7

136.12 MDI specifications

The MDI couples the PMD (specified in 136.8 and 136.9) to the cable assembly (specified in 136.11).

50GBASE-CR has five specified MDI connectors: SFP28, QSFP28, microQSFP, QSFP-DD, and OSFP.

100GBASE-CR2 and 200GBASE-CR4 have four specified MDI connectors: QSFP28, microQSFP, QSFP-DD, and OSFP.

Annex 136C specifies the MDIs for 50GBASE-CR, 100GBASE-CR2, 200GBASE-CR4.

136.13 Environmental specifications

All equipment subject to this clause shall conform to the applicable requirements of 14.7.

136.14 Protocol implementation conformance statement (PICS) proforma for Clause 136, Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4[227]

136.14.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 136, Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

136.14.2 Identification

136.14.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

136.14.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 136, Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

137. Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4

137.1 Overview

This clause specifies the 50GBASE-KR PMD, the 100GBASE-KR2 PMD, the 200GBASE-KR4 PMD, and the baseband medium. The specifications for the three PMDs are similar, except for the number of lanes and associated parameters and the MDI.

When forming a complete Physical Layer, a PMD shall be connected as illustrated in Figure 137–1, to the appropriate sublayers (as specified in Table 137–1, Table 137–2, and Table 137–3), to the medium through the appropriate MDI, and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 137–1—Physical Layer clauses associated with the 50GBASE-KR PMD

Associated clause	50GBASE-KR
132—RS	Required
132—50GMII[a]	Optional
133—PCS for 50GBASE-R	Required
134—RS-FEC	Required
135—PMA for 50GBASE-R	Required
135B—LAUI-2 C2C	Optional
135D—50GAUI-2 C2C	Optional
135F—50GAUI-1 C2C	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The 50GMII is an optional interface. However, if the 50GMII is not implemented, a conforming implementation behaves functionally as though the RS and 50GMII were present.

For the 50GBASE-KR and 100GBASE-KR2 PHYs, in order to support the required frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap, the PMD and the adjacent PMA are expected to detect bits from a compliant input signal at a BER lower than 2.4×10^{-4} assuming errors are sufficiently uncorrelated. This BER allocation enables a frame loss ratio lower than 10^{-10} after processing by the RS-FEC (Clause 134 or Clause 91) and the PCS (Clause 133 or Clause 82) if there are negligible errors due to other electrical interfaces (50GAUI-n or 100GAUI-n). If the PMD and PMA create errors that are not sufficiently uncorrelated, the BER is required to be lower as appropriate to maintain a frame loss ratio lower than 10^{-10}.

Table 137–2—Physical Layer clauses associated with the 100GBASE-KR2 PMD

Associated clause	100GBASE-KR2
80—RS	Required
80—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
91—RS-FEC	Required
83—PMA for 100GBASE-R	Optional[b]
83A—CAUI-10	Optional
83D—CAUI-4 C2C	Optional
135—PMA for 100GBASE-P	Required
135D—100GAUI-4 C2C	Optional
135F—100GAUI-2 C2C	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]PMA for 100GBASE-R is required when either CAUI-10 or CAUI-4 is used.

Table 137–3—Physical Layer clauses associated with the 200GBASE-KR4 PMD

Associated clause	200GBASE-KR4
117—RS	Required
117—200GMII[a]	Optional
118—200GMII extender	Optional
119—PCS for 200GBASE-R	Required
120—PMA for 200GBASE-R	Required
120B—200GAUI-8 C2C	Optional
120D—200GAUI-4 C2C	Optional
73—Auto-Negotiation	Required
78—Energy-Efficient Ethernet	Optional

[a]The 200GMII is an optional interface. However, if the 200GMII is not implemented, a conforming implementation behaves functionally as though the RS and 200GMII were present.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For the 200GBASE-KR4 PHY, in order to support the required frame loss ratio (see 1.4.344) of less than 6.2×10^{-11} for 64-octet frames with minimum interpacket gap, the PMD and the adjacent PMA are expected to detect bits from a compliant input signal at a BER lower than 2.4×10^{-4} assuming errors are sufficiently uncorrelated. This BER allocation enables a frame loss ratio lower than 9.2×10^{-13} after processing by the PCS (Clause 119) if there are negligible errors due to other electrical interfaces (200GAUI-n). If the PMD and PMA create errors that are not sufficiently uncorrelated, the BER is required to be lower as appropriate to maintain a frame loss ratio lower than 9.2×10^{-13}.

A compliant input signal is a transmitter output of a compliant PHY that has passed through a compliant channel.

50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4 PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Figure 137–1 shows the relationship of the PMD and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 137–1—50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4 relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

137.2 Conventions

Clause 137 describes three PMDs, 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4, which have one, two, and four lanes, respectively. For efficient description, the parameter n is used to describe the number of lanes in a specific PMD. Accordingly, n = 1 for 50GBASE-KR, n = 2 for 100GBASE-KR2, and n = 4 for 200GBASE-KR4.

The parameter *i* is used as an index or a suffix to identify a specific lane, and takes the values 0 to n – 1.

Within this clause, the unqualified term "PMD" refers to any of 50GBASE-KR PMD, 100GBASE-KR2 PMD, or 200GBASE-KR4 PMD.

137.3 PMD service interfaces

The service interfaces of the 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4 PMDs are identical to those of the 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4 PMDs, respectively (see 136.3).

137.4 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with the PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. The requirements are the same as those specified in 136.4.

137.5 Delay constraints

The sum of the transmit and receive delays at one end of the link contributed by the PMD and AN including the medium in one direction shall be no more than the maximum delays listed in Table 137–4. It is assumed that the one-way delay through the medium is no more than 20 ns.

Table 137–4—Delay constraints

PMD	Maximum (bit times)[a]	Maximum (pause_quanta)[b]	Maximum (ns)
50GBASE-KR	2048	4	40.96
100GBASE-KR2	4096	8	40.96
200GBASE-KR4	8192	16	40.96

[a]One bit time is equal to 20 ps for 50GBASE-KR, 10 ps for 100GBASE-KR2, and 5 ps for 200GBASE-KR4. (See 1.4.215 for the definition of bit time.)
[b]One pause_quantum is equal to 10.24 ns for 50GBASE-KR, 5.12 ns for 100GBASE-KR2, and 2.56 ns for 200GBASE-KR4. (See 31B.2 for the definition of pause_quanta.)

Descriptions of overall system delay constraints can be found in 131.4 for 50GBASE-KR, in 80.4 for 100GBASE-KR2, and in 116.3 for 200GBASE-KR4.

137.6 Skew constraints

The Skew (relative delay) between the PCS or FEC lanes is kept within limits so that the information on the PCS or FEC lanes can be reassembled by the PCS or FEC. The Skew Variation is also limited to ensure that a given PCS or FEC lane always traverses the same physical lane.

137.6.1 Skew Constraints for 50GBASE-KR

Skew and Skew Variation are defined in 131.5 and specified at the points SP0 to SP7 shown in Figure 131–3.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 135.5.3.5. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

For more information on Skew and Skew Variation, see 131.5. The measurements of Skew and Skew Variation are defined in 89.7.2.

137.6.2 Skew Constraints for 100GBASE-KR2 and 200GBASE-KR4

Skew and Skew Variation are defined in 80.5 and 116.5 and specified at the points SP1 to SP6 shown in Figure 80–9 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5 and 116.5.

137.7 PMD MDIO function mapping

The PMD MDIO function mapping requirements for the PMDs defined in this clause are identical to those of 136.7.

137.8 PMD functional specifications

137.8.1 Link block diagram

One direction of a 50GBASE-KR, 100GBASE-KR2, or 200GBASE-KR4 link is shown in Figure 137–2.

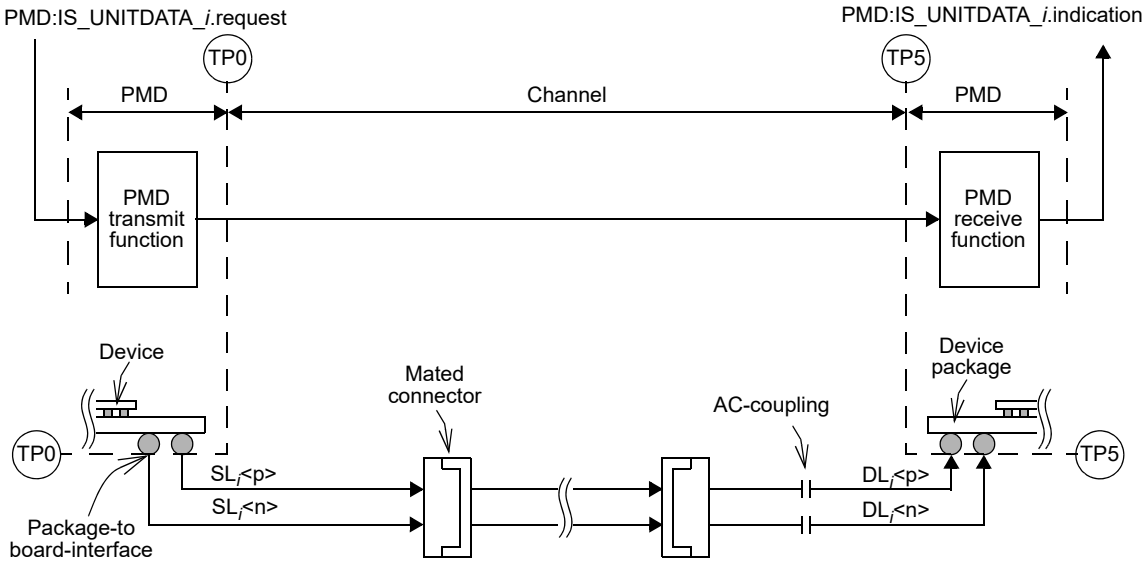

Figure 137–2—50GBASE-KR, 100GBASE-KR2 or 200GBASE-KR4 link (one direction for one lane is illustrated)

137.8.2 PMD transmit function

The PMD transmit function specification is identical to that of 136.8.2 with the exception that electrical signals are delivered to the MDI, according to the transmit electrical specifications in 137.9.2.

137.8.3 PMD receive function

The PMD receive function specification is identical to that of 136.8.3 with the exception that electrical signals are received from the MDI, according to the receive electrical specifications in 137.9.3.

137.8.4 PMD global signal detect function

The PMD global signal detect function specification is identical to that of 136.8.4.

137.8.5 PMD lane-by-lane signal detect function

The PMD lane-by-lane signal detect function specification is identical to that of 136.8.5.

137.8.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional. Its specification is identical to that of 136.8.6.

137.8.7 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional. Its specification is identical to that of 136.8.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

137.8.8 PMD fault function

The PMD fault function specification is identical to that of 136.8.8.

137.8.9 PMD transmit fault function (optional)

The PMD transmit fault function is optional. Its specification is identical to that of 136.8.9.

137.8.10 PMD receive fault function (optional)

The PMD receive fault function is optional. Its specification is identical to that of 136.8.10.

137.8.11 PMD control function

The PMD control function specification is identical to that of 136.8.11.

137.9 Electrical characteristics

137.9.1 MDI

The MDI for the 50GBASE-KR, 100GBASE-KR2 and 200GBASE-KR4 PHYs is an implementation-dependent direct electrical connection between the PMD and the medium. The MDI comprises $2 \times n$ differential pairs, one pair for the transmit function and one pair for the receive function on each lane, marked by TP0 and TP5 in Figure 137–2.

Transmitter and receiver characteristics are defined at TP0a and TP5a.

The location of TP0a and the electrical characteristics of the test fixture used to measure transmitter characteristics are defined in Figure 93–5 and 93.8.1.1, respectively, with the exception that the upper frequency for Equation (93–1) and Equation (93–2) is 26.5625 GHz.

The location of TP5a and the electrical characteristics of the test fixture used to measure receiver characteristics are defined in Figure 93–10 and 93.8.2.1, respectively, with the exception that the upper frequency for Equation (93–1) and Equation (93–2) is 26.5625 GHz.

137.9.2 Transmitter characteristics

The transmitter shall meet the specifications given in Table 120D–1 with a measurement system as specified in 120D.3.1, with the following exceptions:

a) The value of linear fit pulse peak (min) is $0.75 \times v_f$. Linear fit pulse peak is measured with transmit equalization off (preset 1, see 136.9.3.1.3).
b) The output waveform Pre-cursor equalization and Post-cursor equalization parameters are replaced by the “Transmitter output waveform” specifications summarized in Table 136–11 and detailed in 136.9.3.1. The state of the transmit equalization may be manipulated and controlled by the PMD control function specified in 136.8.11, or by equivalent means.
c) The differential output return loss (min) and SNR_{ISI} (min) requirements are replaced by the transmitter effective return loss (ERL) specification in 137.9.2.1.
d) The value of SNDR (min) is 32.5 dB.
e) The J4u limit in Table 120D–1 does not apply. The maximum J3u (see 136.9.3.3) is 0.106 UI.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

137.9.2.1 Transmitter ERL

ERL of the transmitter at TP0a is computed using the procedure in 93A.5 with the values in Table 137–5. Parameters that do not appear in Table 137–5 take values from Table 137–6. The value of T_{fx} is twice the delay from TP0 to TP0a. N_{bx} is set to the value of N_b in Table 137–6.

Table 137–5—Transmitter and receiver ERL parameter values

Parameter	Symbol	Value	Units
Transition time associated with a pulse	T_r	0.0189	ns
Incremental available signal loss factor	β_x	1.7	GHz
Permitted reflection from a transmission line external to the device under test	ρ_x	0.32	—
Length of the reflection signal	N	100	UI

Transmitter ERL at TP0a shall be greater than or equal to 15 dB.

137.9.3 Receiver characteristics

Receiver electrical characteristics are specified at TP5a. The receiver shall meet the specifications given in Table 120D–5 with the following exceptions:

a) PCS FEC symbol error ratio (max) values in Table 120D–6 and Table 120D–7 are all 10^{-3}. For 50GBASE-KR and 100GBASE-KR2, RS-FEC symbol error ratio is used instead of PCS FEC symbol error ratio.

b) Insertion loss at 13.2813 GHz values for Test 1 are 14.5 (min) and 15.5 (max).

c) Insertion loss at 13.2813 GHz values for Test 2 are 29.5 (min) and 30.5 (max).

d) RSS_DFE4 value for Test 1 is 0.05.

e) Receiver jitter tolerance (see 120D.3.2.2) is tested using the test channel used for receiver interference tolerance Test 2 (see item c).

f) The differential input return loss (min) requirements are replaced by the receiver ERL specification in 137.9.3.1.

137.9.3.1 Receiver ERL

ERL of the receiver at TP5a is computed using the procedure in 93A.5 with the values in Table 137–5. Parameters that do not appear in Table 137–5 take values from Table 137–6. The value of T_{fx} is twice the delay from TP5a to TP5. N_{bx} is set to the value of N_b in Table 137–6.

Receiver ERL at TP5a shall be greater than or equal to 15 dB.

137.10 Channel characteristics

The Channel Operating Margin (COM) is computed using the procedure in 93A.1 with the values in Table 137–6, where T_r is 12 ps for $H_t(f)$ as used in Equation (93A–19). COM shall be greater than or equal to 3 dB.

Channels shall have AC-coupling as specified in 93.9.4.

137.10.1 Channel insertion loss

The maximum recommended insertion loss of the channel is given by Equation (137–1).

$$IL(f) \le \left\{ \begin{array}{ll} 1.25 + 3.9\sqrt{f} + 1.095f & 0.01 \le f \le f_b/2 \\ -12.5 + 3.2f & f_b/2 < f \le f_b \end{array} \right\} \text{ (dB)} \qquad (137\text{–}1)$$

where

f is the frequency in GHz
f_b is the signaling rate (26.5625) in GHz
$IL(f)$ is the insertion loss at frequency f

The insertion loss limit is illustrated by Figure 137–3.

137.10.2 Channel ERL

ERL of the channel at TP0 and at TP5 are computed using the procedure in 93A.5 with the values in Table 137–7. Parameters that do not appear in Table 137–7 take values from Table 137–6. The value of T_{fx} is 0. N_{bx} is set to the value of N_b in Table 137–6.

Channel ERL at TP0 and at TP5 shall be greater than or equal to 10 dB.

137.11 Environmental specifications

All equipment subject to this clause shall conform to the applicable requirements of 93.10.

137.12 Protocol implementation conformance statement (PICS) proforma for Clause 137, Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4[228]

137.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 137, Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

137.12.2 Identification

137.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

137.12.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 137, Physical Medium Dependent (PMD) sublayer and baseband medium, type 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[228] *Copyright release for PICS proformas*: Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

138. Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, 400GBASE-SR8

138.1 Overview

This clause specifies the 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 PMDs together with the multimode fiber medium. The optical signals generated by these PMD types are modulated using a 4-level pulse amplitude modulation (PAM4) format. The PMD sublayers provide point-to-point 50, 100, 200, and 400 Gigabit Ethernet links over one, two, four, or eight pairs of multimode fiber, with a reach of up to at least 100 m.

When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA, as shown in Table 138–1, Table 138–2, or Table 138–3, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 138–1—Physical Layer clauses associated with the 50GBASE-SR PMD

Associated clause	50GBASE-SR
132—RS	Required
132—50GMII[a]	Optional
133—PCS	Required
134—RS-FEC	Required
135—PMA for 50GBASE-R	Required
135B—LAUI-2 C2C	Optional
135C—LAUI-2 C2M	Optional
135D—50GAUI-2 C2C	Optional

80—CGMII[a]	Optional
82—PCS for 100GBASE-R	Required
91—RS-FEC[b]	Required
83—PMA for 100GBASE-R	Optional
83A—CAUI-10	Optional
83D—CAUI-4 C2C	Optional
83E—CAUI-4 C2M	Optional
135—PMA for 100GBASE-P	Required
135D—100GAUI-4 C2C	Optional
135E—100GAUI-4 C2M	Optional
135F—100GAUI-2 C2C	Optional
135G—100GAUI-2 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.
[b]The option to bypass the Clause 91 RS-FEC correction function is not supported.

Table 138–3—Physical Layer clauses associated with the 200GBASE-SR4 and 400GBASE-SR8 PMDs

Associated clause	200GBASE-SR4	400GBASE-SR8
117—RS	Required	Required
117—200GMII[a]	Optional	Not applicable
117—400GMII[a]	Not applicable	Optional

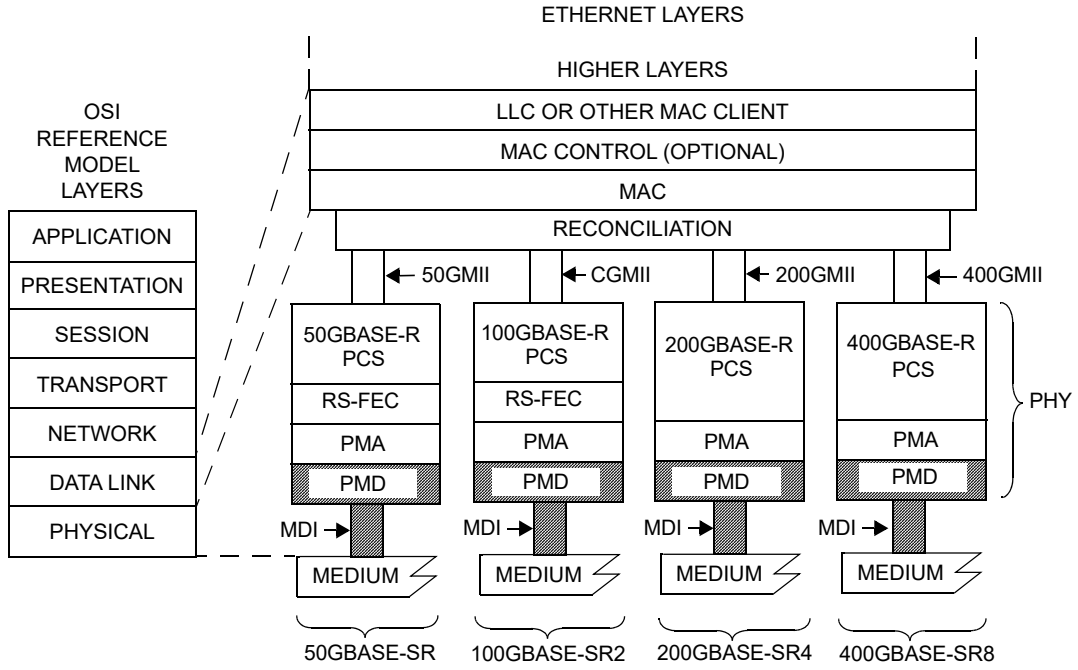
Table 138–3—Physical Layer clauses associated with the 200GBASE-SR4 and 400GBASE-SR8 PMDs *(continued)*

Associated clause	200GBASE-SR4	400GBASE-SR8
120D—200GAUI-4 C2C	Optional	Not applicable
120D—400GAUI-8 C2C	Not applicable	Optional
120E—200GAUI-4 C2M	Optional	Not applicable
120E—400GAUI-8 C2M	Not applicable	Optional
78—Energy-Efficient Ethernet	Optional	Optional



[a]The 200GMII and 400GMII are optional interfaces. However, if the appropriate interface is not implemented, a conforming implementation behaves functionally as though the RS and 200GMII or 400GMII were present.

Figure 138–1 shows the relationship of the PMDs and MDIs (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 50 Gigabit Ethernet is introduced in Clause 131 and the purpose of each PHY sublayer is summarized in 131.2. 100 Gigabit Ethernet is introduced in Clause 80 and the purpose of each PHY sublayer is summarized in 80.2. 200 Gigabit Ethernet and 400 Gigabit Ethernet are introduced in Clause 116 and the purpose of each PHY sublayer is summarized in 116.2.

50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

Further relevant information may be found in Clause 1 (terminology and conventions, references, definitions and abbreviations) and Annex A (bibliography, referenced as [B1], [B2], etc.). The 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 sublayers provide point-to-point 50, 100, 200, and 400 Gigabit Ethernet links over one, two, four, or eight pairs of multimode fiber, up to at least 100 m.

Figure 138–1—50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, 400GBASE-SR8 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

138.1.1 Bit error ratio

For the 50GBASE-SR and 100GBASE-SR2 PMDs, the bit error ratio (BER) when processed by the PMA (Clause 135) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap when additionally processed by the FEC (Clause 134 or Clause 91) and PCS (Clause 133 or Clause 82). For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-10} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces. If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap.

For the 200GBASE-SR4 and 400GBASE-SR8 PMDs, the bit error ratio (BER) when processed by the PMA (Clause 120) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap when additionally processed by the PCS (Clause 119). For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-11} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces. If the error statistics are not sufficiently random to meet this

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

requirement, then the BER shall be less than that required to give a frame loss ratio of less than 1.7×10^{-12} for 64-octet frames with minimum interpacket gap.

138.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The 50GBASE-SR PMD service interface is an instance of the inter-sublayer service interface defined in 131.3, with a single symbol stream (n = 1).

The 100GBASE-SR2 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with two parallel symbol streams (n = 2).

The 200GBASE-SR4 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with four parallel symbol streams (n = 4).

The 400GBASE-SR8 PMD service interface is an instance of the inter-sublayer service interface defined in 116.3, with eight parallel symbol streams (n = 8).

The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 50GBASE-SR PMD has a single symbol stream, hence $i = 0$.

The 100GBASE-SR2 PMD has two parallel symbol streams, hence $i = 0$ to 1.

The 200GBASE-SR4 PMD has four parallel symbol streams, hence $i = 0$ to 3.

The 400GBASE-SR8 PMD has eight parallel symbol streams, hence $i = 0$ to 7.

In the transmit direction, the PMA continuously sends *n* streams of PAM4 symbols to the PMD, one per lane, using the PMD:IS_UNITDATA_*i*.request primitive, at a nominal signaling rate of 26.5625 GBd. The PMD converts these streams of symbols into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends *n* streams of PAM4 symbols to the PMA, corresponding to the signals received from the MDI, one per lane, using the PMD:IS_UNITDATA_*i*.indication primitive, at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable SIGNAL_DETECT parameter as defined in 138.5.4. The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 138.1.1.

138.3 Delay and Skew

138.3.1 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation.

The sum of the transmit and receive delays at one end of the link contributed by the 50GBASE-SR PMD including 2 m of fiber in one direction shall be no more than 1024 bit times (2 pause_quanta or 20.48 ns).

The sum of the transmit and receive delays at one end of the link contributed by the 100GBASE-SR2 PMD including 2 m of fiber in one direction shall be no more than 2048 bit times (4 pause_quanta or 20.48 ns).

The sum of the transmit and receive delays at one end of the link contributed by the 200GBASE-SR4 PMD including 2 m of fiber in one direction shall be no more than 4096 bit times (8 pause_quanta or 20.48 ns).

The sum of the transmit and receive delays at one end of the link contributed by the 400GBASE-SR8 PMD including 2 m of fiber in one direction shall be no more than 8192 bit times (16 pause_quanta or 20.48 ns).

Descriptions of overall system delay constraints and the definitions for bit times and pause_quanta, can be found in 131.4 for 50GBASE-SR, in 80.4 for 100GBASE-SR2, and in 116.4 and its references for 200GBASE-SR4 and 400GBASE-SR8.

138.3.2 Skew constraints

The Skew (relative delay) between the PCS or FEC lanes is kept within limits so that the information on the PCS or FEC lanes can be reassembled by the PCS or FEC. The Skew Variation is also limited to ensure that a given PCS or FEC lane always traverses the same physical lane.

138.3.2.1 Skew Constraints for 50GBASE-SR

Skew and Skew Variation are defined in 131.5 and specified at the points SP0 to SP7 shown in Figure 131–3.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 135.5.3.5. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

For more information on Skew and Skew Variation, see 131.5. The measurements of Skew and Skew Variation are defined in 89.7.2 with the exception that the measurement clock and data recovery unit high-frequency corner bandwidth is 4 MHz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

138.3.2.2 Skew Constraints for 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8

Skew and Skew Variation are defined in 80.5 and 116.5 and specified at the points SP1 to SP6 shown in Figure 80–9 and Figure 116–5.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5 and 116.5.

138.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 138–4, and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 138–5.

Table 138–4—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable
PMD transmit disable *n*–1 to PMD transmit disable 0	PMD transmit disable register	1.9.*n* to 1.9.1	PMD_transmit_disable_*n*–1 to PMD_transmit_disable_0

Table 138–5—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect
PMD receive signal detect *n*–1 to PMD receive signal detect 0	PMD receive signal detect register	1.10.*n* to 1.10.1	PMD_signal_detect_*n*–1 to PMD_signal_detect_0

138.5 PMD functional specifications

The 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

138.5.1 PMD block diagram

The PMD block diagram for 200GBASE-SR8 is shown in Figure 138–2. The block diagrams for 200GBASE-SR4, 100GBASE-SR2, and 50GBASE-SR are equivalent to Figure 138–2, but for four lanes, two lanes, and one lane per direction, respectively.

For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a multimode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 138.8 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 138.10.3). Unless specified otherwise, all receiver measurements and tests defined in 138.8 are made at TP3.

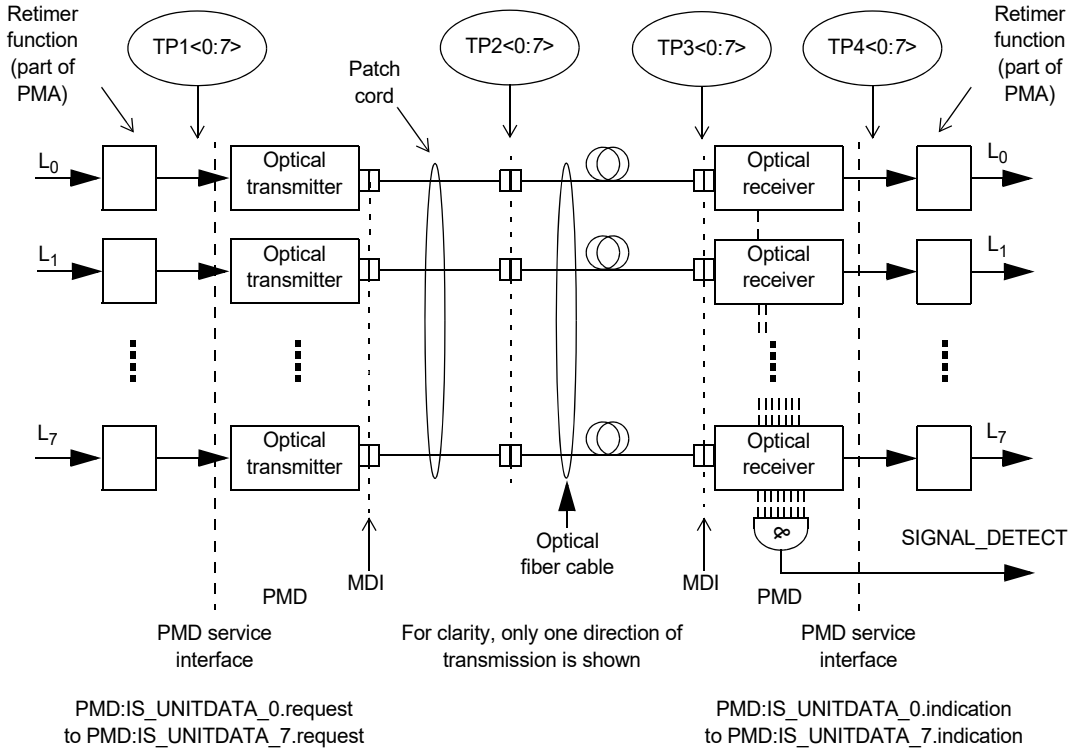

Figure 138–2—Block diagram for 400GBASE-SR8 transmit/receive paths

TP1<0:7> and TP4<0:7> are optional reference points that may be useful to implementers for testing components (these test points will not typically be accessible in an implemented system).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

138.5.2 PMD transmit function

The PMD Transmit function shall convert the one, two, four, or eight symbol streams requested by the PMD service interface messages PMD:IS_UNITDATA_*i*.request into one, two, four, or eight separate optical signals. The 50GBASE-SR PMD has a single symbol stream, hence $i = 0$. The 100GBASE-SR2 PMD has two parallel symbol streams, hence $i = 0$ to 1. The 200GBASE-SR4 PMD has four parallel symbol streams, hence $i = 0$ to 3. The 400GBASE-SR8 PMD has eight parallel symbol streams, hence $i = 0$ to 7. Each optical signal shall then be delivered to the MDI, which contains one, two, four, or eight parallel light paths for transmit, according to the transmit optical specifications in this clause. The four optical power levels in the signal in order from lowest to highest shall correspond to tx_symbol values zero, one, two, and three, respectively.

Editor's note (to be removed after D3.1): According to the resolution of comment I-19, the phrase "signal streams requested by the PMD service interface" was to be changed to "signals requested by the PMD service interface". However, the editor's understanding is that the change should be to "symbol streams requested by the PMD service interface" instead.

138.5.3 PMD receive function

The PMD Receive function shall convert the one, two, four, or eight parallel optical signals received from the MDI into separate symbol streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_7.indication, all according to the receive optical specifications in this clause. The four optical power levels in each signal in order from lowest to highest shall correspond to rx_symbol values zero, one, two, and three, respectively.

138.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 80.3.

SIGNAL_DETECT shall be a global indicator of the presence of optical signals on all lanes. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 138–6. The PMD receiver is not required to verify whether a compliant 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 138–6—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
For any lane; Average optical power at TP3 ≤ –30 dBm	FAIL
For all lanes; [(Optical power at TP3 ≥ average receive power, each lane (min) in Table 138–8) AND (compliant 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 signal input)]	OK
All other conditions	Unspecified

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

138.5.5 PMD lane-by-lane signal detect function

Various implementations of the Signal Detect function are permitted by this standard. When the MDIO is implemented, each PMD_signal_detect_*i*, where *i* represents the lane number in the range 0:7, shall be continuously set in response to the magnitude of the optical signal on its associated lane, according to the requirements of Table 138–6.

138.5.6 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

138.5.7 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows all of the optical transmitters to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off all of the optical transmitters so that each transmitter meets the requirements of the average launch power of the OFF transmitter in Table 138–8.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter in each lane.

138.5.8 PMD lane-by-lane transmit disable function (optional)

The PMD lane-by-lane transmit disable function is optional and allows the optical transmitter in each lane to be selectively disabled.

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:7) is set to one, this function shall turn off the optical transmitter associated with that variable so that the transmitter meets the requirements of the average launch power of the OFF transmitter in Table 138–8.

b) If a PMD_fault is detected, then the PMD may set each PMD_transmit_disable_*i* to one, turning off the optical transmitter in each lane.

If the optional PMD lane-by-lane transmit disable function is not implemented in MDIO, an alternative method may be provided to independently disable each transmit lane.

138.5.9 PMD fault function (optional)

If the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

138.5.10 PMD transmit fault function (optional)

If the PMD has detected a local fault on any transmit lane, the PMD shall set PMD_transmit_fault to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4

138.5.11 PMD receive fault function (optional)

If the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

138.6 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the physical ordering of the lanes, as the RS-FEC or PCS sublayer is capable of receiving the lanes in any arrangement. The positioning of transmit and receive lanes at the MDI is specified in 138.10.3.1.

138.7 PMD to MDI optical specifications for 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8

The operating range for the 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 PMDs is defined in Table 138–7. A compliant PMD operates on 50/125 μm multimode fibers, type A1a.2 (OM3), type A1a.3 (OM4), or type A1a.4 (OM5), according to the specifications defined in Table 138–14. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 50GBASE-SR PMD operating at 120 m meets the operating range requirement of 0.5 m to 100 m).

Table 138–7—Operating range

PMD type	Required operating range[a]
50GBASE-SR 100GBASE-SR2 200GBASE-SR4 400GBASE-SR8	0.5 m to 70 m for OM3
	0.5 m to 100 m for OM4
	0.5 m to 100 m for OM5

[a]The PCS FEC correction function may not be bypassed for any operating distance.

138.7.1 Transmitter optical specifications

Each lane of a 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 transmitter shall meet the specifications in Table 138–8 per the definitions in 138.8.

Table 138–8—Transmit characteristics

Description	Value	Unit
Signaling rate, each lane (range)	26.5625 ± 100 ppm	GBd
Modulation format	PAM4	—
Center wavelength (range)	840 to 860	nm
RMS spectral width[a] (max)	0.6	nm
Average launch power, each lane (max)	4	dBm
Average launch power, each lane (min)	–6.5	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (max)	3	dBm
Outer Optical Modulation Amplitude (OMA_{outer}), each lane (min)[b]	–4.5	dBm
Launch power in OMA_{outer} minus TDECQ (min)	–5.9	dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ), each lane (max)	4.5	dB
TDECQ – $10\log_{10}(C_{eq})$[c], each lane (max)	4.5	dB
Average launch power of OFF transmitter, each lane (max)	–30	dBm
Extinction ratio, each lane (min)	3	dB
Transmitter transition time, each lane (max)	34	ps
$RIN_{12}OMA$ (max)	–128	dB/Hz
Optical return loss tolerance (max)	12	dB
Encircled flux[d]	≥ 86% at 19 μm ≤ 30% at 4.5 μm	—

[a]RMS spectral width is the standard deviation of the spectrum.
[b]Even if the TDECQ < 1.4 dB, the OMA (min) has to exceed this value.
[c]C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d]If measured into type A1a.2 or type A1a.3, or A1a.4, 50 μm fiber, in accordance with IEC 61280-1-4:2009.

138.7.2 Receiver optical specifications

Each lane of a 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 receiver shall meet the specifications in Table 138–9 per the definitions in 138.8.

Table 138–9—Receive characteristics

Description	Value	Unit
Signaling rate, each lane (range)	26.5625 ± 100 ppm	GBd
Modulation format	PAM4	—
Center wavelength (range)	840 to 860	nm

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 138–9—Receive characteristics *(continued)*

Description	Value	Unit
Damage threshold[a] (min)	5	dBm
Average receive power, each lane (max)	4	dBm
Average receive power, each lane[b] (min)	–8.4	dBm
Receive power, each lane (OMA_{outer}) (max)	3	dBm
Receiver reflectance (max)	–12	dB
Stressed receiver sensitivity (OMA_{outer}), each lane[c] (max)	–3.4	dBm
Receiver sensitivity (OMA_{outer}), each lane[d] (max)	Equation (138–1)	dBm
Conditions of stressed receiver sensitivity test:[e]		
Stressed eye closure for PAM4 (SECQ), lane under test	4.5	dB
SECQ – $10\log_{10}(C_{eq})$[f] (max), lane under test	4.5	dB
OMA_{outer} of each aggressor lane[g]	3	dBm

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level on one lane. The receiver does not have to operate correctly at this input power.
[b]Average receive power, each lane (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c]Measured with conformance test signal at TP3 (see 138.8.10) for the BER specified in 138.1.1.
[d]Receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 4.5 dB.
[e]These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.
[f]C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[g]Only applies to 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8.

138.7.3 Illustrative link power budget

An illustrative power budget and penalties for 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 channels are shown in Table 138–10.

Table 138–10—Illustrative link power budget

Parameter	OM3	OM4	OM5	Unit
Effective modal bandwidth at 850 nm[a]	2000	4700		MHz.km
Power budget (for max TDECQ)	6.5			dB
Operating distance	0.5 to 70	0.5 to 100		m
Channel insertion loss[b]	1.8	1.9		dB
Allocation for penalties[c] (for max TDECQ)	4.6			dB
Additional insertion loss allowed	0.1	0		dB

[a]Per IEC 60793-2-10.
[b]The channel insertion loss is calculated using the maximum distance specified in Table 138–7 and cabled optical fiber attenuation of 3.5 dB/km at 850 nm plus an allocation for connection and splice loss given in 138.10.2.2.1.
[c]Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

138.8 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

138.8.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 138–12 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 138–12 may be used to perform that test. The test patterns used in this clause are shown in Table 138–11.

Table 138–11—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle	119.2.4.9
6	SSPRQ	120.5.11.2.3

Table 138–12—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength, spectral width	3, 4, 5, 6, or valid 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 signal	138.8.2
Average optical power	3, 4, 5, 6, or valid 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 signal	138.8.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	138.8.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	138.8.5
Extinction ratio	4 or 6	138.8.6
Transmitter transition time	Square wave or 6	138.8.7
$RIN_{12}OMA$	Square wave	138.8.8
Stressed receiver sensitivity	3, 5, or valid 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 signal	138.8.10

138.8.1.1 Multi-lane testing considerations

Stressed receiver sensitivity is defined for each lane at the BER specified in 138.1.1. Measurements with Pattern 3 (PRBS31Q) allow lane-by-lane BER measurements. In stressed receiver sensitivity measurements, unstressed lanes may be created by setting the power at the receiver under test well above its sensitivity and/or not stressing those lanes with ISI and jitter, or by other means. Each receive lane is stressed in turn while all are operated. All aggressor lanes are operated as specified. Where relevant, parameters are defined with all co-propagating and counter-propagating lanes operational so that crosstalk effects are included. Where not otherwise specified, the maximum amplitude (OMA_{outer}) for a particular situation is used. Alternative test methods that generate equivalent results may be used. While the lanes in a particular direction may share a common clock, the Tx and Rx directions are not synchronous to each other. If Pattern 3 is used for the lanes not under test using a common clock, there is at least 31 UI delay between the PRBS31Q patterns on one lane and any other lane so that the symbols on each lane are not correlated within the PMD.

138.8.2 Center wavelength and spectral width

The center wavelength and RMS spectral width of each optical lane shall be within the range given in Table 138–8 if measured per IEC 61280-1-3. The lane under test is modulated using one of the test patterns specified in Table 138–12.

138.8.3 Average optical power

The average optical power of each lane shall be within the limits given in Table 138–8 if measured using the methods given in IEC 61280-1-1. The average optical power is measured using one of the test patterns defined in Table 138–12.

138.8.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} of each lane shall be within the limits given in Table 138–8 if measured as defined in 121.8.4.

138.8.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

TDECQ is a measure of each optical transmitter's vertical eye closure as measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a combined reference receiver and worst case optical channel, and equalized with the reference equalizer specified in 138.8.5.1. Table 138–9 specifies the test pattern to be used for measurement of TDECQ.

The TDECQ and TDECQ – $10\log_{10}(C_{eq})$ of each lane shall be within the limits given in Table 138–8 if measured using the methods specified in 121.8.5, with the following exceptions:

- The polarization rotator and test fiber shown in Figure 121–4 are not used.
- The optical channel requirements in 121.8.5.2 do not apply. For 400GBASE-SR8, the optical splitter and variable reflector are adjusted so that each transmitter is tested with an optical return loss equal to the "Optical return loss tolerance (max)" given in Table 138–8.
- The combination of the O/E converter and the oscilloscope used to measure the optical waveform has a 3 dB bandwidth of approximately 11.2 GHz with a fourth-order Bessel-Thomson response to at least 1.5×22.4 GHz and at frequencies above 1.5×22.4 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.
- The reference equalizer to be used for TDECQ for 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 is specified in 138.8.5.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

138.8.5.1 TDECQ reference equalizer

The reference equalizer for 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 138–3. The sum of the equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3, has the largest magnitude tap coefficient, which is constrained to be at least 0.8.

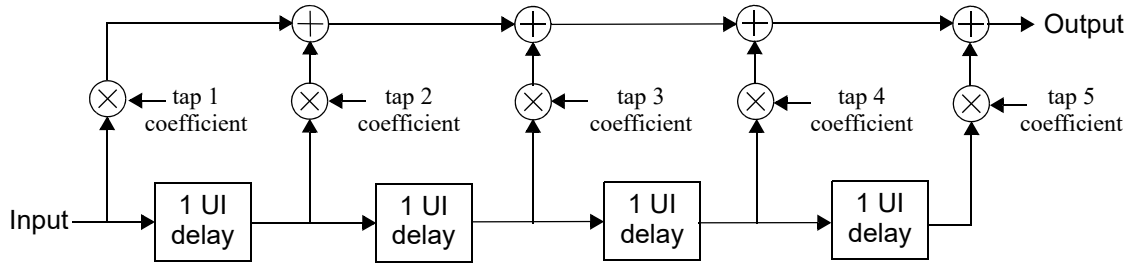

Figure 138–3—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver implementation.

138.8.6 Extinction ratio

The extinction ratio of each lane shall be within the limits given in Table 138–8 if measured using the methods specified in 121.8.6.

138.8.7 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 138–8 if measured using a test pattern specified for transmitter transition time in Table 138–12.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with a combined 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz and at frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 138.8.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence and the falling edge is that within the 33333000000 symbol sequence.

138.8.8 Relative intensity noise ($RIN_{12}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 12 dB.
b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 26.6 GHz).
c) The test pattern is according to Table 138–12.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

138.8.9 Receiver sensitivity

Receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 4.5 dB. Receiver sensitivity should meet Equation (138–1), which is illustrated in Figure 138–4.

$$RS = \max(-6.5, SECQ - 7.9) \quad \text{(dBm)} \tag{138–1}$$

where

RS is the receiver sensitivity

SECQ is the SECQ of the transmitter used to measure the receiver sensitivity

The normative requirement for receivers is stressed receiver sensitivity.

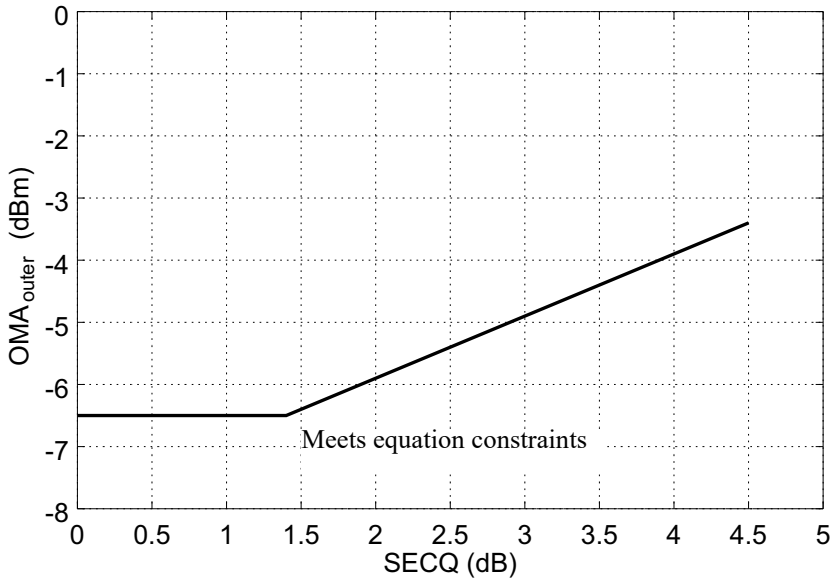

Figure 138–4—Illustration of receiver sensitivity

138.8.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 138–9 if measured using the methodology defined in 121.8.10.1 and 121.8.10.3, with the conformance test signal at TP3 as described in 121.8.5.2, with the following exceptions:

- The SECQ of the stressed receiver conformance test signal is measured according to 138.8.5, except that the combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz and at frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response. The optical splitter and variable reflector shown in Figure 121–4 are not used, and the transition time is no greater than the value specified in Table 138–8.
- With the Gaussian noise generator on and the sinusoidal jitter and sinusoidal interferer turned off, the $RIN_{12}OMA$ of the SRS test source should be no greater than the $RIN_{12}OMA$ (max) specified for the transmit characteristics in Table 138–8.
- The test patterns used for stressed receiver sensitivity are specified in Table 138–12.
- The signaling rate, the required stressed eye closure (SECQ), and the maximum $SECQ - 10\log_{10}(C_{eq})$ of the stressed receiver conformance test signal is as specified in Table 138–9.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— The applied sinusoidal jitter is specified in 138.8.10.1.
— For 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8, the OMA_{outer} of the aggressor lanes is specified in Table 138–9.

The BER is required to be met for each lane under test on its own. Stressed receiver sensitivity is defined with all transmit and receive lanes in operation. Any of the patterns specified for stressed receiver sensitivity in Table 138–12 is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.

138.8.10.1 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. The amplitude of the applied sinusoidal jitter is dependent on frequency as specified in Table 138–13.

Table 138–13—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter peak-to-peak (UI)
$f < 40$ kHz	Not specified
40 kHz $< f \leq 4$ MHz	2×10^5 Hz/f
4 MHz $< f \leq 10$ LB[a]	0.05

[a]LB = loop bandwidth; upper frequency bound for added sinusoidal jitter should be at least 10 times the loop bandwidth of the receiver being tested.

138.9 Safety, installation, environment, and labeling

138.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

138.9.2 Laser safety

50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8 optical transceivers shall conform to Hazard Level 1M laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.[229]

[229]A host system that fails to meet the manufacturer's requirements and/or usage restrictions may emit laser radiation in excess of the safety limits of one or more safety standards. In such a case, the host manufacturer is required to obtain its own laser safety certification.

138.9.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

138.9.4 Environment

Normative specifications in this clause shall be met by a system integrating a 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 PMD over the life of the product while the product operates within the manufacturer's range of environmental, power, and other specifications.

It is recommended that manufacturers indicate, in the literature associated with the PHY, the operating environmental conditions to facilitate selection, installation, and maintenance.

It is recommended that manufacturers indicate, in the literature associated with the components of the optical link, the distance and operating environmental conditions over which the specifications of this clause will be met.

138.9.5 Electromagnetic emission

A system integrating a 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 PMD shall comply with applicable local and national codes for the limitation of electromagnetic interference.

138.9.6 Temperature, humidity, and handling

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

138.9.7 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8).

Labeling requirements for Hazard Level 1M lasers are given in the laser safety standards referenced in 138.9.2.

138.10 Fiber optic cabling model

The fiber optic cabling (channel) contains 1, 2, 4, or 8optical fibers for each direction to support 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8, respectively. The fiber optic cabling interconnects the transmitters at the MDI on one end of the channel to the receivers at the MDI on the other end of the channel. As defined in 138.10.3, the optical lanes appear in defined locations at the MDI but the locations are not assigned specific lane numbers within this standard because any transmitter lane may be connected to any receiver lane.

138.10.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 138–5.

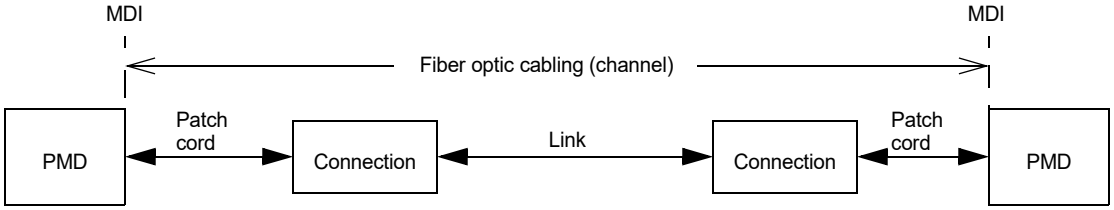

Figure 138–5—Fiber optic cabling model

The channel insertion loss is given in Table 138–14. A channel may contain additional connectors as long as the optical characteristics of the channel (such as attenuation, modal dispersion, reflections and losses of all connectors and splices) meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method. As OM4 and OM5 optical fiber meet the requirements for OM3, a channel compliant to the "OM3" column may use OM4 or OM5 optical fiber, or a combination of OM3, OM4, and OM5. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

Table 138–14—Fiber optic cabling (channel) characteristics

Description	OM3	OM4	OM5	Unit
Operating distance (max)	70	100		m
Cabling Skew (max)[a]	79			ns
Cabling Skew Variation[ab] (max)	2.4			ns
Channel insertion loss[c] (max)	1.8	1.9		dB
Channel insertion loss (min)	0			dB

[a]Applies only to 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8.
[b]An additional 400 ps of Skew Variation could be caused by wavelength changes, which are attributable to the transmitter not the channel.
[c]These channel insertion loss values include cable loss plus 1.5 dB allocated for connection and splice loss, over the wavelength range 840 nm to 860 nm.

138.10.2 Characteristics of the fiber optic cabling (channel)

The fiber optic cabling shall meet the specifications defined in Table 138–14. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together.

138.10.2.1 Optical fiber cable

The fiber contained within the fiber optic cabling shall comply with the specifications and parameters of Table 138–15. A variety of multimode cable types may satisfy these requirements, provided the resulting channel also meets the specifications of Table 138–14.

Table 138–15—Optical fiber and cable characteristics

Description	OM3[a]	OM4[b]	OM5[c]	Unit
Nominal core diameter	50			μm
Nominal fiber specification wavelength	850			nm
Effective modal bandwidth (min)[d]	2000	4700		MHz.km
Cabled optical fiber attenuation (max)	3.5			dB/km
Zero dispersion wavelength (λ_0)	$1295 \le \lambda_0 \le 1340$		$1297 \le \lambda_0 \le 1328$	nm
Chromatic dispersion slope (max) (S_0)	0.105 for $1295 \le \lambda_0 \le 1310$ and $0.000375 \times (1590 - \lambda_0)$ for $1310 \le \lambda_0 \le 1340$		$-412/(840(1 - (\lambda_0/840)^4))$	ps/nm^2 km

[a]IEC 60793-2-10 type A1a.2
[b]IEC 60793-2-10 type A1a.3
[c]IEC 60793-2-10 type A1a.4
[d]When measured with the launch conditions specified in Table 138–8

138.10.2.2 Optical fiber connection

An optical fiber connection, as shown in Figure 138–5, consists of a mated pair of optical connectors.

138.10.2.2.1 Connection insertion loss

The maximum link distance is based on an allocation of 1.5 dB total connection and splice loss. For example, this allocation supports three connections with an average insertion loss per connection of 0.5 dB. Connections with lower loss characteristics may be used provided the requirements of Table 138–14 are met. However, the loss of a single connection shall not exceed 0.75 dB.

138.10.2.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

138.10.3 Medium Dependent Interface (MDI)

The 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, or 400GBASE-SR8 PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 138–5). Examples of an MDI include the following:

a) PMD with a connectorized fiber pigtail plugged into an adapter;

b) PMD receptacle.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 138.5.1, not at the MDI.

138.10.3.1 Optical lane assignments for 100GBASE-SR2, 200GBASE-SR4, and 400GBASE-SR8

The two transmit and two receive optical lanes of 100GBASE-SR2 shall occupy the positions depicted in Figure 138–6 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains four active lanes within 12 total positions. The eight center positions are unused. The transmit optical lanes occupy the leftmost two positions. The receive optical lanes occupy the rightmost two positions.

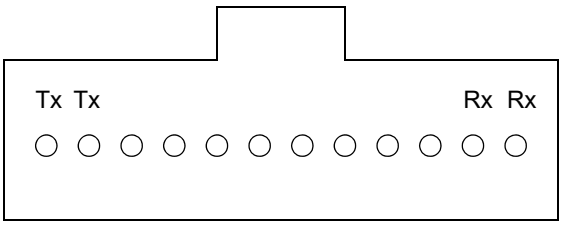

Figure 138–6—Optical lane assignments for 100GBASE-SR2

The four transmit and four receive optical lanes of 200GBASE-SR4 shall occupy the positions depicted in Figure 138–7 when looking into the MDI receptacle with the connector keyway feature on top. The interface contains eight active lanes within 12 total positions. The four center positions are unused. The transmit optical lanes occupy the leftmost four positions. The receive optical lanes occupy the rightmost four positions.

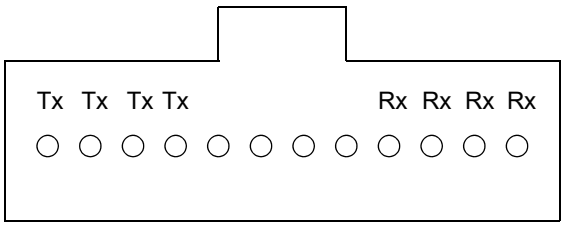

Figure 138–7—Optical lane assignments for 200GBASE-SR4

400GBASE-SR8 has two optical lane assignment options: Option A for a dual-row twelve-fiber interface, and option B for a single-row sixteen-fiber interface.

For a dual-row twelve-fiber interface, the eight transmit and eight receive optical lanes of 400GBASE-SR8 shall occupy the positions depicted in Figure 138–8 (option A) when looking into the MDI receptacle with the connector keyway feature on top. The interface contains sixteen active lanes within 24 total positions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The four center positions in each row are unused. The transmit optical lanes occupy the leftmost four positions in each row. The receive optical lanes occupy the rightmost four positions in each row.

For a single-row sixteen-fiber interface, the eight transmit and eight receive optical lanes of 400GBASE-SR8 shall occupy the positions depicted in Figure 138–8 (option B) when looking into the MDI receptacle with the connector keyway feature on top. The interface contains sixteen active lanes within sixteen total positions. The transmit optical lanes occupy the leftmost eight positions. The receive optical lanes occupy the rightmost eight positions.

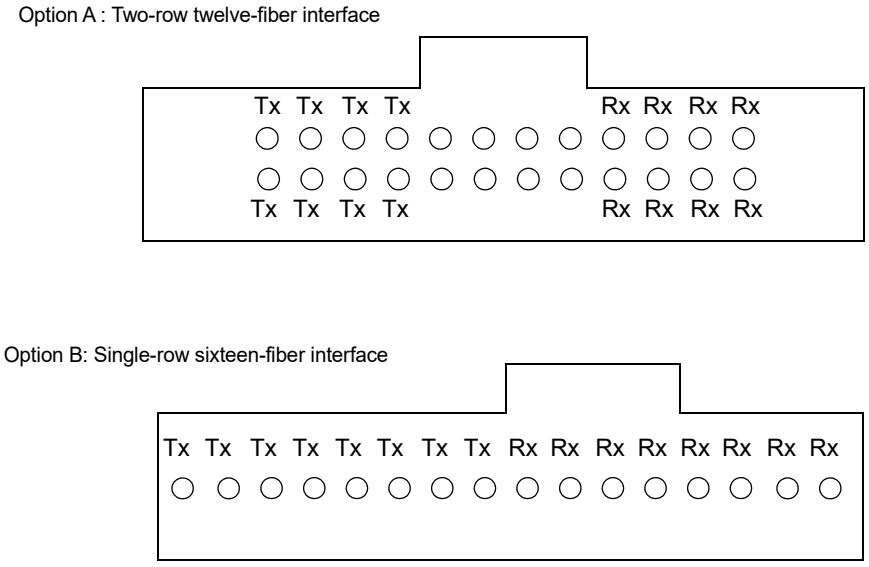

Figure 138–8—Optical lane assignments for 400GBASE-SR8

138.10.3.2 MDI requirements for 50GBASE-SR

The MDI shall optically mate with the compatible plug on the optical fiber cabling. For 50GBASE-SR, when the MDI is a connector plug and receptacle connection, it shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2 for performance grade Bm/2m.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

138.10.3.3 MDI requirements for 100GBASE-SR2 and 200GBASE-SR4

The MDI shall optically mate with the compatible plug on the optical fiber cabling. For 100GBASE-SR2 and 200GBASE-SR4 the MDI adapter or receptacle shall meet the dimensional specifications for interface 7-1-3: *MPO adapter interface - opposed keyway configuration*, or interface 7-1-10: *MPO active device receptacle, flat interface*, as defined in IEC 61754-7-1. The plug terminating the optical fiber cabling shall meet the dimensional specifications of interface 7-1-4: *MPO female plug connector, flat interface for 2 to 12 fibers*, as defined in IEC 61754-7-1. Figure 138–9 shows an MPO female plug connector with flat interface, and an MDI. The MDI connection shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2 for performance grade Bm/2m.

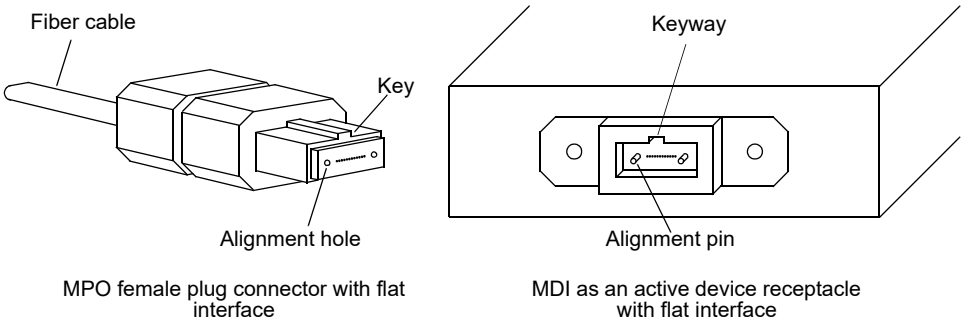

Figure 138–9—MPO female plug with flat interface and MDI active device receptacle with flat interface

138.10.3.4 MDI requirements for 400GBASE-SR8

The MDI shall optically mate with the compatible plug on the optical fiber cabling. The MDI connection shall meet the interface performance specifications of IEC 61753-1 and IEC 61753-022-2 for performance grade Bm/2m. 400GBASE-SR8 has two optical lane assignment options: Option A for a dual-row twelve-fiber interface, and option B for a single-row sixteen-fiber interface.

For Option A, the MDI adapter or receptacle shall meet the dimensional specifications for interface 7-2-3: *MPO adapter interface - opposed keyway* configuration, or interface 7-2-10: *MPO active device receptacle, flat interface*, as defined in IEC 61754-7-2. The plug terminating the optical fiber cabling shall meet the dimensional specifications of interface 7-2-4: *MPO female plug connector, flat interface for 16 to 24 fibers*, as defined in IEC 61754-7-2. The MPO female plug connector and MDI are structurally similar to those depicted in Figure 138–9, but with two rows of fibers.

For Option B, the MDI adapter or receptacle shall meet the dimensional specifications for designation FOCIS 18 A-1-0, or designation FOCIS 18 R-1x16-1-0-1-2-0, as defined in ANSI/TIA-604-18-A. The plug terminating the optical fiber cabling shall meet the dimensional specifications of designation FOCIS 18 P-1x16-1-0-2-2-0, as defined in ANSI/TIA-604-18-A. The MPO female plug connector and MDI are structurally similar to those depicted in Figure 138–9, but with sixteen fibers and an offset keyway as well as a different pin diameter and location.

138.11 Protocol implementation conformance statement (PICS) proforma for Clause 138, Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, 400GBASE-SR8[230]

138.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 138, Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, 400GBASE-SR8, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

138.11.2 Identification

138.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

138.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 138, Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-SR, 100GBASE-SR2, 200GBASE-SR4, 400GBASE-SR8
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[230]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

139. Physical Medium Dependent (PMD) sublayer and medium, type 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER

139.1 Overview

This clause specifies the 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs together with the single-mode fiber medium. The optical signals generated by these three PMD types are modulated using a 4-level pulse amplitude modulation (PAM4) format. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 139–1, to the medium through the MDI and optionally with the management functions that may be accessible through the management interface defined in Clause 45, or equivalent.

Table 139–1—Physical Layer clauses associated with the 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs

Associated clause	50GBASE-FR, 50GBASE-LR, 50GBASE-ER
132—RS	Required
132—50GMII[a]	Optional
133—PCS for 50GBASE-R	Required
134—RS-FEC for 50GBASE-R	Required
135—PMA for 50GBASE-R	Required
135B—LAUI-2 C2C	Optional
135C—LAUI-2 C2M	Optional
135D—50GAUI-2 C2C	Optional
135E—50GAUI-2 C2M	Optional
135F—50GAUI-1 C2C	Optional
135G—50GAUI-1 C2M	Optional
78—Energy-Efficient Ethernet	Optional

[a]50GMII is an optional interface. However, if the appropriate interface is not implemented, a conforming implementation behaves functionally as though the RS and 50GMII were present.

Figure 139–1 shows the relationship of the PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model. 50 Gigabit Ethernet is introduced in Clause 131 and the purpose of each PHY sublayer is summarized in 131.2.

50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PHYs with the optional Energy-Efficient Ethernet (EEE) fast wake capability may enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78). The deep sleep mode of EEE is not supported.

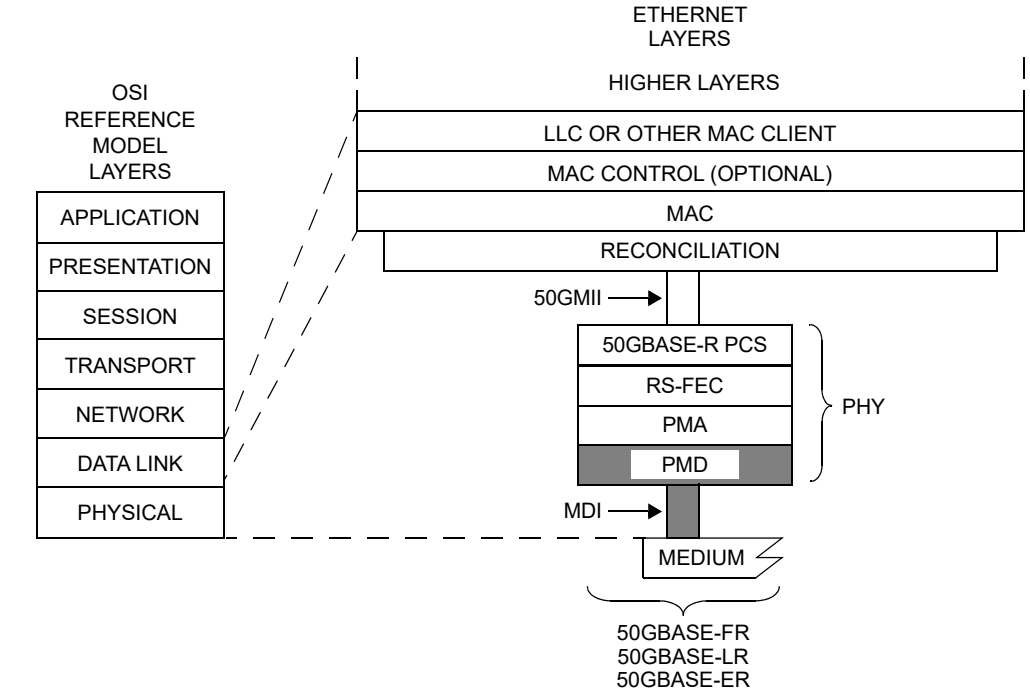

Figure 139–1—50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

139.1.1 Bit error ratio

The bit error ratio (BER) when processed by the PMA (Clause 135) shall be less than 2.4×10^{-4} provided that the error statistics are sufficiently random that this results in a frame loss ratio (see 1.4.344) of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap when additionally processed by the FEC (Clause 134) and PCS (Clause 133). For a complete Physical Layer, the frame loss ratio may be degraded to 6.2×10^{-10} for 64-octet frames with minimum interpacket gap due to additional errors from the electrical interfaces.

If the error statistics are not sufficiently random to meet this requirement, then the BER shall be less than that required to give a frame loss ratio of less than 9.2×10^{-13} for 64-octet frames with minimum interpacket gap.

139.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs. The service interface for these PMDs is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMA entity that resides just above the PMD, and the PMD entity. The PMD translates the encoded data to and from signals suitable for the specified medium.

The 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMD service interface is an instance of the inter-sublayer service interface defined in 131.3, with a single symbol stream (n = 1).

The service interface primitives are summarized as follows:

PMD:IS_UNITDATA_0.request
PMD:IS_UNITDATA_0.indication
PMD:IS_SIGNAL.indication

In the transmit direction, the PMA continuously sends one stream of PAM4 symbols to the PMD using the PMD:IS_UNITDATA_*i*.request primitive, at a nominal signaling rate of 26.5625 GBd. The PMD converts these streams of symbols into appropriate signals on the MDI.

In the receive direction, the PMD continuously sends one stream of PAM4 symbols to the PMA, corresponding to the signals received from the MDI, using the PMD:IS_UNITDATA_*i*.indication primitive, at a nominal signaling rate of 26.5625 GBd.

The SIGNAL_OK parameter of the PMD:IS_SIGNAL.indication primitive corresponds to the variable SIGNAL_DETECT parameter as defined in 139.5.4. The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the rx_symbol parameters are undefined.

NOTE—SIGNAL_DETECT = OK does not guarantee that the rx_symbol parameters are known to be good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the BER defined in 139.1.1.

139.3 Delay and Skew

139.3.1 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The sum of the transmit and receive delays at one end of the link contributed by the 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs including 2 m of fiber in one direction shall be no more than 1024 bit times (2 pause_quanta or 20.48 ns). A description of overall system delay constraints and the definitions for bit times and pause_quantum can be found in 131.4 and its references.

139.3.2 Skew constraints

The Skew (relative delay) between the FEC lanes is kept within limits so that the information on the lanes can be reassembled by the FEC. The Skew Variation is also limited to ensure that a given FEC lane always traverses the same physical lane. Skew and Skew Variation are defined in 131.5 and specified at the points SP0 to SP7 shown in Figure 131–3.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns as defined by 135.5.3.5. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns. Since the signal at the MDI represents a serial bit stream, there is no Skew Variation at this point.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns. Since the signal at the PMD service interface represents a serial bit stream, there is no Skew Variation at this point.

For more information on Skew and Skew Variation, see 131.5. The measurements of Skew and Skew Variation are defined in 89.7.2 with the exception that the measurement clock and data recovery unit high-frequency corner bandwidth is 4 MHz.

139.4 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PMD. If the MDIO interface is implemented, the mapping of MDIO control variables to PMD control variables shall be as shown in Table 139–2 and the mapping of MDIO status variables to PMD status variables shall be as shown in Table 139–3.

Table 139–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	PMD_global_transmit_disable

Table 139–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault
Receive fault	PMA/PMD status 2 register	1.8.10	PMD_receive_fault
Global PMD receive signal detect	PMD receive signal detect register	1.10.0	PMD_global_signal_detect

139.5 PMD functional specifications

The 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs perform the Transmit and Receive functions, which convey data between the PMD service interface and the MDI.

139.5.1 PMD block diagram

The PMD block diagram is shown in Figure 139–2. For purposes of system conformance, the PMD sublayer is standardized at the points described in this subclause. The optical transmit signal is defined at the output end of a single-mode fiber patch cord (TP2), between 2 m and 5 m in length. Unless specified otherwise, all transmitter measurements and tests defined in 139.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) at the MDI (see 139.10.3). Unless specified otherwise, all receiver measurements and tests defined in 139.7 are made at TP3.

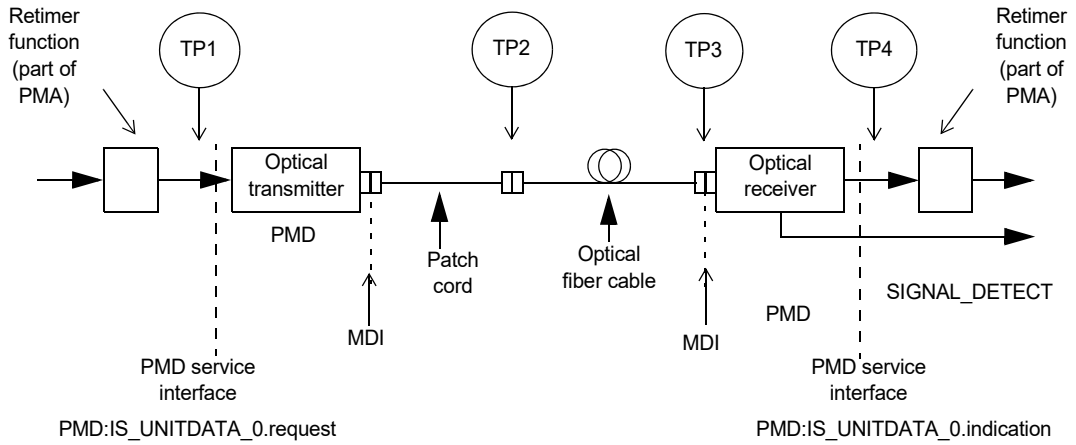

Figure 139–2—Block diagram for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER transmit/receive paths

139.5.2 PMD transmit function

The PMD Transmit function shall convert the symbol stream requested by the PMD service interface messages PMD:IS_UNITDATA_0.request into an optical signal. The optical signal shall then be delivered to the MDI, according to the transmit optical specifications in this clause. The four optical power levels in the signal in order from lowest to highest shall correspond to tx_symbol values zero, one, two, and three, respectively.

139.5.3 PMD receive function

The PMD receive function shall convert the optical signal received from the MDI into a symbol stream for delivery to the PMD service interface using the message PMD:IS_UNITDATA_0.indication, all according to the receive optical specifications in this clause. The four optical power levels in each signal in order from lowest to highest shall correspond to rx_symbol values zero, one, two, and three, respectively.

139.5.4 PMD global signal detect function

The PMD global signal detect function shall report the state of SIGNAL_DETECT via the PMD service interface. The SIGNAL_DETECT parameter is signaled continuously, while the PMD:IS_SIGNAL.indication message is generated when a change in the value of SIGNAL_DETECT occurs. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the inter-sublayer service interface primitives defined in 131.3.

SIGNAL_DETECT shall be a global indicator of the presence of the optical signal. The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 139–4. The PMD receiver is not required to verify whether a compliant 50GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD including the effects of crosstalk, power supply noise, etc.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 139–4—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Average optical power at TP3 ≤ –16 dBm	FAIL
[(Optical power at TP3 ≥ average receive power in Table 139–7) AND (compliant 50GBASE-R signal input)]	OK
All other conditions	Unspecified

Various implementations of the Signal Detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

139.5.5 PMD reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as defined in 45.2.1.1.1.

139.5.6 PMD global transmit disable function (optional)

The PMD global transmit disable function is optional and allows the optical transmitter to be disabled.

a) When the PMD_global_transmit_disable variable is set to one, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of the OFF transmitter in Table 139–6.

b) If a PMD_fault is detected, then the PMD may set the PMD_global_transmit_disable variable to one, turning off the optical transmitter.

139.5.7 PMD fault function (optional)

If the PMD has detected a local fault on the transmit or receive paths, the PMD shall set PMD_fault to one.

If the MDIO interface is implemented, PMD_fault shall be mapped to the fault bit as specified in 45.2.1.2.3.

139.5.8 PMD transmit fault function (optional)

If the PMD has detected a local fault on the transmitter, the PMD shall set the PMD_transmit_fault variable to one.

If the MDIO interface is implemented, PMD_transmit_fault shall be mapped to the transmit fault bit as specified in 45.2.1.7.4.

139.5.9 PMD receive fault function (optional)

If the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to one.

If the MDIO interface is implemented, PMD_receive_fault shall be mapped to the receive fault bit as specified in 45.2.1.7.5.

139.6 PMD to MDI optical specifications for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER

The operating ranges for the 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER PMDs are defined in Table 139–5. A 50GBASE-FR, 50GBASE-LR, or 50GBASE-ER compliant PMD operates on type B1.1, B1.3, or B6_a single-mode fibers according to the specifications defined in Table 139–13. A PMD that exceeds the operating range requirement while meeting all other optical specifications is considered compliant (e.g., a 50GBASE-FR PMD operating at 2.5 km meets the operating range requirement of 2 m to 2 km).

The 50GBASE-LR PMD interoperates with the 50GBASE-FR PMD provided that the channel requirements for 50GBASE-FR are met.

The 50GBASE-ER PMD interoperates with the 50GBASE-FR PMD provided that the channel requirements defined in 139.11 are met.

The 50GBASE-ER PMD interoperates with the 50GBASE-LR PMD provided that the channel requirements defined in 139.12 are met,

Table 139–5—50GBASE-FR, 50GBASE-LR, and 50GBASE-ER operating ranges

PMD type	Required operating range
50GBASE-FR	2 m to 2 km
50GBASE-LR	2 m to 10 km
50GBASE-ER	2 m to 30 km
	2 m to 40 km[a]

[a] Links longer than 30 km for the same link power budget are considered engineered links. Attenuation for such links needs to be less than the worst case specified for IEC 60793-2-50 type B1.1, type B1.3, or type B6_a single-mode fiber.

139.6.1 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER transmitter optical specifications

The 50GBASE-FR transmitter shall meet the specifications defined in Table 139–6 per the definitions in 139.7. The 50GBASE-LR transmitter shall meet the specifications defined in Table 139–6 per the definitions in 139.7. The 50GBASE-ER transmitter shall meet the specifications defined in Table 139–6 per the definitions in 139.7.

Average launch power (max)	3	4.2	6.6	dBm
Average launch power[a] (min)	–4.1	–4.5	0.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}) (max)	2.8	4	7.4	dBm
Outer Optical Modulation Amplitude (OMA_{outer}) (min)[b]	–2.5	–1.5	3.4	dBm
Launch power in OMA_{outer} minus TDECQ (min)	–3.9	–2.9	2	dBm
Transmitter and dispersion eye closure for PAM4 (TDECQ) (max)	3	3.2	3.2	dB
TDECQ – $10\log_{10}(C_{eq})$[c] (max)	3	3.2	3.2	dB
Average launch power of OFF transmitter (max)	–16		–15	dBm
Extinction ratio (min)	3.5		6	dB
Transmitter transition time (max)	34			ps
$RIN_{17.1}OMA$ (max)	–132	—	—	dB/Hz
$RIN_{15.6}OMA$ (max)	—	–132	—	dB/Hz
$RIN_{15}OMA$ (max)	—	—	–132	dB/Hz
Optical return loss tolerance (max)	17.1	15.6	15	dB
Transmitter reflectance[d] (max)	–26			dB

[a] Average launch power (min) is not the principal indicator of signal strength. A transmitter with launch power below this value cannot be compliant; however, a value above this does not ensure compliance.
[b] Even if the TDECQ < 1.4 dB, the OMA_{outer} (min) has to exceed this value.
[c] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.
[d] Transmitter reflectance is defined looking into the transmitter.

139.6.2 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER receive optical specifications

The 50GBASE-FR receiver shall meet the specifications defined in Table 139–7 per the definitions in 139.7.
The 50GBASE-LR receiver shall meet the specifications defined in Table 139–7 per the definitions in 139.7.
The 50GBASE-ER receiver shall meet the specifications defined in Table 139–7 per the definitions in 139.7.

Table 139–7—50GBASE-FR, 50GBASE-LR, and 50GBASE-ER receive characteristics

Description	50GBASE-FR	50GBASE-LR	50GBASE-ER	Unit
Signaling rate (range)	26.5625 ± 100 ppm			GBd
Modulation format	PAM4			—
Wavelengths (range)	1304.5 to 1317.5			nm
Damage threshold[a]	5.2	5.2	–2.4	dBm
Average receive power (max)	3	4.2	–3.4	dBm
Average receive power[b] (min)	–8.1	–10.8	–17.6	dBm
Receive power (OMA_{outer}) (max)	2.8	4	–2.6	dBm
Receiver reflectance (max)	–26			dB
Receiver sensitivity (OMA_{outer})[c] (max)	Equation (139–1)	Equation (139–2)	Equation (139–3)	dBm
Stressed receiver sensitivity (OMA_{outer})[d] (max)	–5.3	–6.6	–13.3	dBm
Conditions of stressed receiver sensitivity test:[e]				
Stressed eye closure for PAM4 (SECQ)	3	3.2	3.2	dB
SECQ – $10\log_{10}(C_{eq})$[f] (max)	3	3.2	3.2	dB

[a] The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average power level.
[b] Average receive power (min) is not the principal indicator of signal strength. A received power below this value cannot be compliant; however, a value above this does not ensure compliance.
[c] Receiver sensitivity (OMA_{outer}) (max) is optional and is defined for a transmitter with a value of SECQ up to 3 dB for 50GBASE-FR and 3.2 dB for 50GBASE-LR and 50GBASE-ER.
[d] Measured with conformance test signal at TP3 (see 139.7.10) for the BER specified in 139.1.1.
[e] These test conditions are for measuring stressed receiver sensitivity. They are not characteristics of the receiver.
[f] C_{eq} is a coefficient defined in 121.8.5.3, which accounts for the reference equalizer noise enhancement.

139.6.3 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER illustrative link power budgets

Illustrative power budgets and penalties for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER channels are shown in Table 139–8.

Table 139–8—50GBASE-FR, 50GBASE-LR, and 50GBASE-ER illustrative link power budgets

Parameter	50GBASE-FR	50GBASE-LR	50GBASE-ER		Unit
Power budget (for maximum TDECQ)	7.4	10.1	21.7		dB
Operating distance	2	10	30	40[a]	km
Channel insertion loss	4[b]	6.3[c]	15	18	dB
Maximum discrete reflectance	See 139.10.2.2	See 139.10.2.2	See 139.10.2.2		dB
Allocation for penalties[d] (for maximum TDECQ)	3.4	3.8	3.7		dB
Additional insertion loss allowed	0	0	3	0	dB

[a] Links longer than 30 km are considered engineered links. Attenuation for such links needs to be less than the worst case for cables containing IEC 60793-2-50 type B1.1, type B1.3, or type B6_a single-mode cabled optical fiber.
[b] The channel insertion loss is calculated using the maximum distance specified in Table 139–5 for 50GBASE-FR and fiber attenuation of 0.5 dB/km plus an allocation for connection and splice loss given in 139.10.2.1.
[c] The channel insertion loss is calculated using the maximum distance specified in Table 139–5 for 50GBASE-LR and fiber attenuation of 0.43 dB/km at 1304.5 nm plus an allocation for connection and splice loss given in 139.10.2.1.
[d] Link penalties are used for link budget calculations. They are not requirements and are not meant to be tested.

139.7 Definition of optical parameters and measurement methods

All transmitter optical measurements shall be made through a short patch cable, between 2 m and 5 m in length, unless otherwise specified.

139.7.1 Test patterns for optical parameters

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 139–10 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Any of the test patterns given for a particular test in Table 139–10 may be used to perform that test. The test patterns used in this clause are shown in Table 139–9.

Table 139–9—Test patterns

Pattern	Pattern description	Defined in
Square wave	Square wave (8 threes, 8 zeros)	120.5.11.2.4
3	PRBS31Q	120.5.11.2.2
4	PRBS13Q	120.5.11.2.1
5	Scrambled idle encoded by RS-FEC	82.2.11[a], 134
6	SSPRQ	120.5.11.2.3

[a]As modified by Clause 133.

Table 139–10—Test-pattern definitions and related subclauses

Parameter	Pattern	Related subclause
Wavelength	Square wave, 3, 4, 5, 6 or valid 50GBASE-R signal	139.7.2
Side-mode suppression ratio	3, 5, 6 or valid 50GBASE-R signal	139.7.2
Average optical power	3, 5, 6 or valid 50GBASE-R signal	139.7.3
Outer Optical Modulation Amplitude (OMA_{outer})	4 or 6	139.7.4
Transmitter and dispersion eye closure for PAM4 (TDECQ)	6	139.7.5
Extinction ratio	4 or 6	139.7.6
Transmitter transition time	Square wave or 6	139.7.7
$RIN_{15.1}OMA$, $RIN_{16.5}OMA$, and $RIN_{15}OMA$	Square wave	139.7.8
Stressed receiver conformance test signal calibration	6	139.7.10.2
Stressed receiver sensitivity	3 or 5	139.7.10

139.7.2 Wavelength and side-mode suppression ratio (SMSR)

The wavelength and SMSR shall be within the ranges given in Table 139–6 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER, if measured per IEC 61280-1-3. The transmitter is modulated using the test pattern defined in Table 139–10.

139.7.3 Average optical power

The average optical power shall be within the limits given in Table 139–6 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER if measured using the methods given in IEC 61280-1-1.

139.7.4 Outer Optical Modulation Amplitude (OMA_{outer})

The OMA_{outer} shall be within the limits given in Table 139–6 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER. The OMA_{outer} is measured using a test pattern specified for OMA_{outer} in Table 139–10 as the difference between the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 139–3.

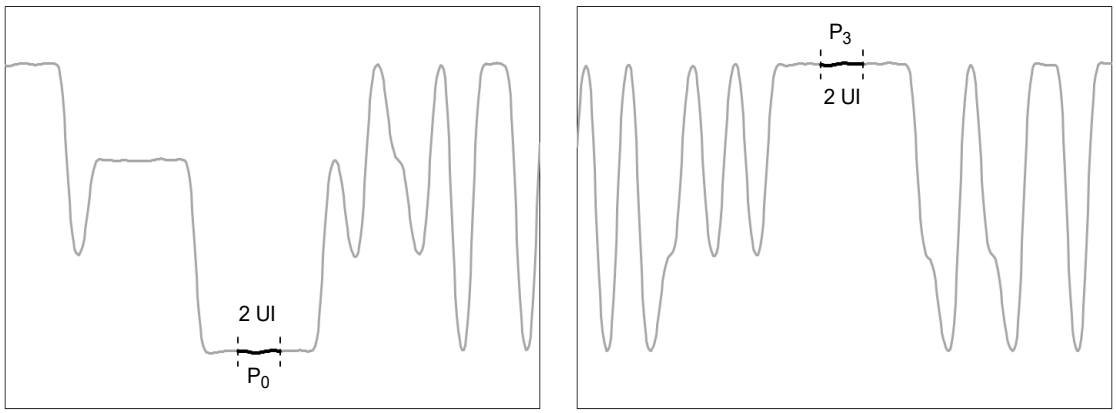

Figure 139–3—Example power levels P_0 and P_3 from PRBS13Q test pattern

139.7.5 Transmitter and dispersion eye closure for PAM4 (TDECQ)

The TDECQ and TDECQ – $10\log_{10}(C_{eq})$ shall be within the limits given in Table 139–6 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER if measured using the methods specified in 139.7.5.1, 139.7.5.2, and 139.7.5.3.

TDECQ is a measure of each optical transmitter's vertical eye closure when transmitted through a worst case optical channel (specified in 139.7.5.2), as measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a reference receiver, and equalized with the reference equalizer (as described in 139.7.5.4). The reference receiver and equalizer may be implemented in software or may be part of the oscilloscope.

Table 139–10 specifies the test patterns to be used for measurement of TDECQ.

139.7.5.1 TDECQ conformance test setup

A block diagram for the TDECQ conformance test is shown in Figure 139–4. Other equivalent measurement implementations may be used with suitable calibration.

The optical splitter and variable reflector are adjusted so that each transmitter is tested with the optical return loss specified in Table 139–11. The state of polarization of the back reflection is adjusted to create the greatest RIN. The signal is tested with the optical channel described in 139.7.5.2. The combination of the O/E converter and the oscilloscope has a 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz and at frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The test pattern (specified in Table 139–11) is transmitted repetitively and the oscilloscope is set up to capture the complete pattern for TDECQ analysis as described in 139.7.5.3. The clock recovery unit (CRU) has a corner frequency of 4 MHz and a slope of 20 dB/decade. The CRU can be implemented in hardware or software depending on oscilloscope technology.

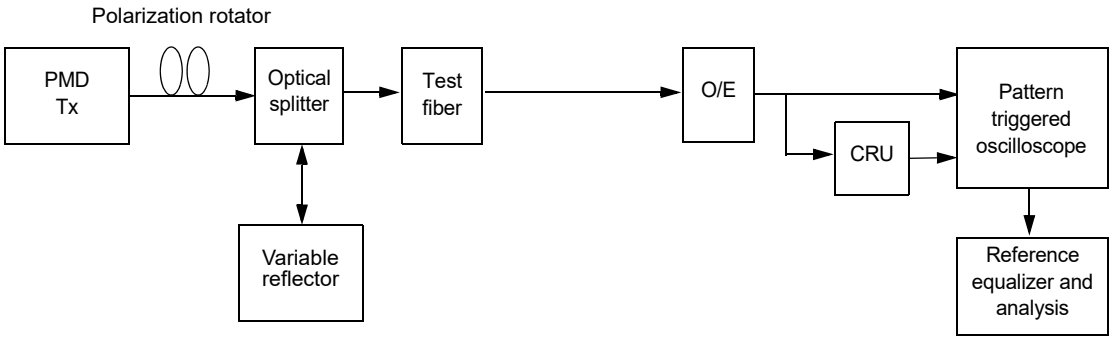

Figure 139–4—TDECQ conformance test block diagram

139.7.5.2 Channel requirements

The transmitter is tested using an optical channel that meets the requirements listed in Table 139–11.

Table 139–11—Transmitter compliance channel specifications

PMD type	Dispersion[a] (ps/nm)		Insertion loss[b]	Optical return loss[c]	Max mean DGD
	Minimum	Maximum			
50GBASE-FR	$0.0465 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.0465 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	17.1 dB	0.8 ps
50GBASE-LR	$0.2325 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.2325 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	15.6 dB	0.8 ps
50GBASE-ER	$0.93 \cdot \lambda \cdot [1 - (1324 / \lambda)^4]$	$0.93 \cdot \lambda \cdot [1 - (1300 / \lambda)^4]$	Minimum	15 dB	0.8 ps

[a]The dispersion is measured for the wavelength of the device under test (λ in nm). The coefficient assumes 2 km for 50GBASE-FR, 10 km for 50GBASE-LR, and 40 km for 50GBASE-ER.
[b]There is no intent to stress the sensitivity of the O/E converter associated with the oscilloscope.
[c]The optical return loss is applied at TP2.

A 50GBASE-FR, 50GBASE-LR, or 50GBASE-ER transmitter is to be compliant with a total dispersion at least as negative as the "minimum dispersion" and at least as positive as the "maximum dispersion" columns specified in Table 139–11 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

The channel provides an optical return loss specified in Table 139–11. The state of polarization of the back reflection is adjusted to create the greatest RIN.

The mean DGD of the channel is to be less than the value specified in Table 139–11.

139.7.5.3 TDECQ measurement method

TDECQ for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER is measured as described in 121.8.5.3 with the exception that the reference equalizer is as specified in 139.7.5.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

139.7.5.4 TDECQ reference equalizer

The reference equalizer for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER is a 5-tap, T-spaced, feed-forward equalizer (FFE), where T is the symbol period. A functional model of the reference equalizer is shown in Figure 139–5. The sum of the equalizer tap coefficients is equal to 1. Tap 1, tap 2, or tap 3, has the largest magnitude tap coefficient, which is constrained to be at least 0.8.

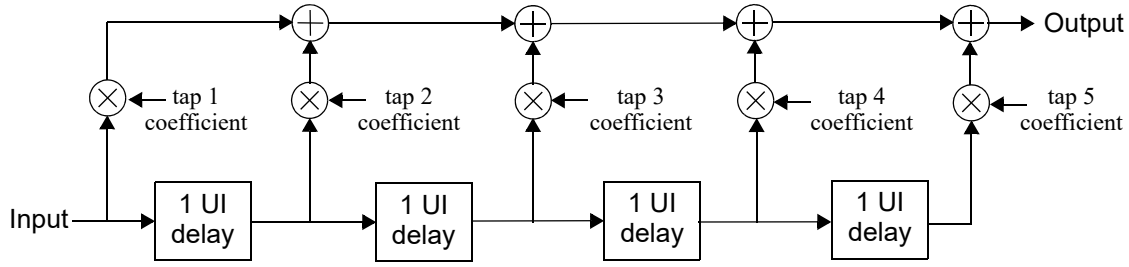

Figure 139–5—TDECQ reference equalizer functional model

NOTE—This reference equalizer is part of the TDECQ test and does not imply any particular receiver equalizer implementation.

139.7.6 Extinction ratio

The extinction ratio shall be within the limits given in Table 139–6 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER if measured using a test pattern specified for extinction ratio in Table 139–10. The extinction ratio of a PAM4 optical signal is defined as the ratio of the average optical launch power level P_3, measured over the central 2 UI of a run of 7 threes, and the average optical launch power level P_0, measured over the central 2 UI of a run of 6 zeros, as shown in Figure 139–3.

139.7.7 Transmitter transition time

The transmitter transition time of each lane shall be within the limits given in Table 139–6 if measured using a test pattern specified for transmitter transition time in Table 139–10.

Transmitter transition time is defined as the slower of the time interval of the transition from 20% of OMA_{outer} to 80% of OMA_{outer}, or from 80% of OMA_{outer} to 20% of OMA_{outer}, for the rising and falling edges respectively, as measured through an O/E converter and oscilloscope with a combined 3 dB bandwidth of approximately 13.28125 GHz with a fourth-order Bessel-Thomson response to at least 1.5 × 26.5625 GHz and at frequencies above 1.5 × 26.5625 GHz the response should not exceed –24 dB. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The 0% level and the 100% level are P_0 and P_3 as defined by the OMA_{outer} measurement procedure (see 139.7.4), with the exception that the square wave test pattern can be used. When the SSPRQ pattern is used, the rising edge used for the measurement is that within the 00000333333 symbol sequence and the falling edge is that within the 33333000000 symbol sequence.

139.7.8 Relative intensity noise ($RIN_{17.1}OMA$, $RIN_{15.6}OMA$, and $RIN_{15}OMA$)

RIN shall be as defined by the measurement methodology of 52.9.6 with the following exceptions:

a) The optical return loss is 17.1 dB for 50GBASE-FR, 15.6 dB for 50GBASE-LR, and 15 dB for 50GBASE-ER.
b) The upper –3 dB limit of the measurement apparatus is to be approximately equal to the signaling rate (i.e., 26.6 GHz).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) The test pattern is according to Table 139–10.

139.7.9 Receiver sensitivity

For 50GBASE-FR, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3 dB. Receiver sensitivity should meet Equation (139–1), which is illustrated in Figure 139–6.

For 50GBASE-LR, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (139–2), which is illustrated in Figure 139–6.

For 50GBASE-ER, receiver sensitivity is optional and is defined for a transmitter with a value of SECQ up to 3.2 dB. Receiver sensitivity should meet Equation (139–3), which is illustrated in Figure 139–6.

$$RS = \max(-6.9, SECQ - 8.3) \quad \text{(dBm)} \tag{139–1}$$

$$RS = \max(-8.4, SECQ - 9.8) \quad \text{(dBm)} \tag{139–2}$$

$$RS = \max(-15.1, SECQ - 16.5) \quad \text{(dBm)} \tag{139–3}$$

where

RS is the receiver sensitivity
SECQ is the SECQ of the transmitter used to measure the receiver sensitivity

The normative requirement for receivers is stressed receiver sensitivity.

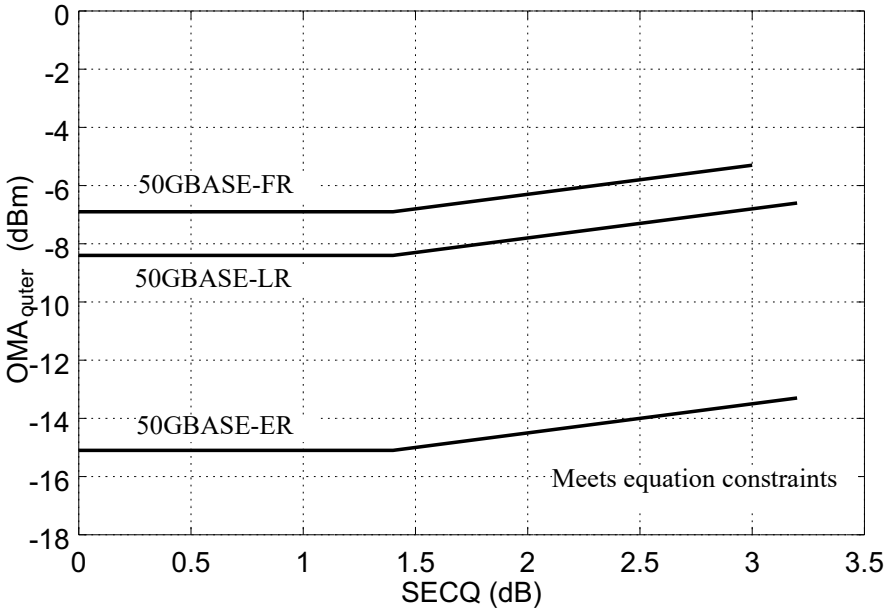

Figure 139–6—Illustration of receiver sensitivity

139.7.10 Stressed receiver sensitivity

Stressed receiver sensitivity shall be within the limits given in Table 139–7 for 50GBASE-FR, 50GBASE-LR, and 50GBASE-ER if measured using the method defined in 139.7.10.1 and 139.7.10.3, with

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the conformance test signal at TP3 as described in 139.7.10.2, using the test pattern specified for SRS in Table 139–10.

Any of the patterns specified for SRS in Table 139–10 is sent from the transmit section of the PMD under test. The signal being transmitted is asynchronous to the received signal.
