c) The length/type field (i.e., the first two octets) within the mac_service_data_unit parameter is set to the IEEE 802.3 MAC Control EtherType value assigned in 31.4.1.3.
d) The remainder of the mac_service_data_unit is set to the concatenation of the Extension Opcode, Organizationally Unique Identifier (OUI) or Company ID (CID)[273] assigned to the organization by the IEEE, and the organization-specific data.
e) The frame_check_sequence is omitted.

MAC Control sublayer entities that transmit or receive EXTENSION frames shall pass them through without additional processing.

31C.3 Receive operation

The opcode–independent MAC Control sublayer Receive state diagram accepts and parses valid frames received from the MAC sublayer. MAC Control sublayer entities that implement the EXTENSION operation shall implement the Receive state diagram specified in this subclause. The functions specified in this subclause are performed upon receipt of a valid Control frame containing the EXTENSION opcode and define the function called by the INITIATE MAC CONTROL FUNCTION state of Figure 31–4 (see 31.5.3).

[273]Details defining the format of OUIs and CIDs can be found in IEEE Std 802 Overview and Architecture. Interested applicants should contact the IEEE Standards Department, Institute of Electrical and Electronics Engineers, https://standards.ieee.org/develop/regauth/, 445 Hoes Lane, Piscataway, NJ 08854, USA.

31C.4 Protocol implementation conformance statement (PICS) proforma for MAC Control organization specific extension operation[274]

31C.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 31A, MAC Control organization specific extension operation, shall complete the following PICS proforma in addition to the PICS of Clause 31.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

31C.4.2 Identification

31C.4.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations, other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).

Annex 31D

(normative)

MAC Control PFC operation

31D.1 PFC description

The Priority-based Flow Control (PFC) operation is used to inhibit transmission of data frames on one or more priorities for a specified period of time. The behavior of a MAC Control client supporting PFC operation is specified in IEEE Std 802.1Q. A MAC Control client wishing to inhibit transmission of data frames from the link partner generates a MA_CONTROL.request primitive specifying:

a) The globally assigned 48-bit multicast address 01-80-C2-00-00-01.
b) The PFC opcode.
c) A request_operand list with two operands: priority_enable_vector and time_vector. (See 31D.2.)

Unlike the MAC Control PAUSE operation, the inhibition of frames for the PFC operation occurs in the MAC Control client. Upon receiving a PFC frame, the only action in MAC Control is to generate a MA_CONTROL.indication primitive with the indication_operand list specified in Table 31A–9.

The PFC operation does not inhibit transmission of MAC Control frames.

PFC operation shall not be enabled on DTEs configured to the half-duplex mode of operation. PFC is intended for use over full-duplex point-to-point links. Use on shared media such as EPON is out of the scope of this standard.

The globally assigned 48-bit multicast address 01-80-C2-00-00-01 has been assigned for use in MAC Control frames. Bridges conformant to IEEE Std 802.1Q will not forward frames sent to this multicast destination address, regardless of the state of the bridge's ports, and whether or not the bridge implements the MAC Control sublayer. To allow PFC full duplex flow control, stations implementing the PFC operation shall instruct the MAC (e.g., through layer management) to enable reception of frames with destination address equal to this multicast address.

NOTE—By definition, an IEEE 802.3 LAN operating in full duplex mode comprises exactly two stations, thus there is no ambiguity regarding the destination DTE's identity. The use of a well-known multicast address relieves the MAC Control sublayer and its client from having to know, and maintain knowledge of, the individual 48-bit address of the other DTE in a full duplex environment.

31D.2 Parameter semantics

The PFC opcode takes the following request_operand_list:

priority_enable_vector:

A 2-octet vector. The most significant octet is reserved (i.e., set to zero on transmission and ignored on receipt). Each bit of the least significant octet indicates if the corresponding field in the time_vector parameter is valid. The bits of the least significant octet are named e[0] (the least significant bit) to e[7] (the most significant bit). Bit e[n] refers to Priority n. For each e[n] bit set to one, the corresponding time[n] value is valid. For each e[n] bit set to zero, the corresponding time[n] value is invalid.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

time_vector:

A list of eight 2-octet fields named time[0] to time[7]. The eight time[n] values are always present regardless of the value of the corresponding e[n] bit. Each time[n] field is a 2-octet, unsigned integer containing the length of time for which the receiving station is requested to inhibit transmission of data frames associated with Priority n. The field is transmitted most significant octet first, and least significant octet second. The time[n] fields are transmitted sequentially, with time[0] transmitted first and time[7] transmitted last. Each time[n] value is measured in units of pause_quanta, equal to the time required to transmit 512 bits of a frame at the data rate of the MAC. Each time[n] field can assume a value in the range of 0 to 65 535 pause_quanta.

31D.3 PFC transmit

The state machines in 31D.3 follow the conventions in 21.5. (See 25.1.1 for an example statement. That also covers the timer conventions from 14 which apply here.)

Upon receipt of a MA_CONTROL.request primitive containing the PFC opcode from a MAC client, the MAC Control sublayer calls the MAC sublayer MAC:MA_DATA.request service primitive with the following parameters:

a) The destination_address is set equal to the destination_address parameter of the MA_CONTROL.request primitive. This parameter is currently restricted to the value specified in 31D.1.
b) The source_address is set equal to the 48-bit individual address of the station.
c) The length/type field (i.e., the first two octets) within the mac_service_data_unit parameter is set to the IEEE 802.3 MAC Control EtherType value assigned in 31.4.1.3.
d) The remainder of the mac_service_data_unit is set equal to the concatenation of the PFC opcode encoding (see Annex 31A), the priority_enable_vector and the time_vector specified in the MA_CONTROL.request primitive, and a field containing zeros of the length specified in 31.4.1.6.
e) The frame_check_sequence is omitted.

Figure 31D–1 depicts the MAC Control PFC Frame transmitted in response to an MA_Control.request primitive with the PFC opcode.

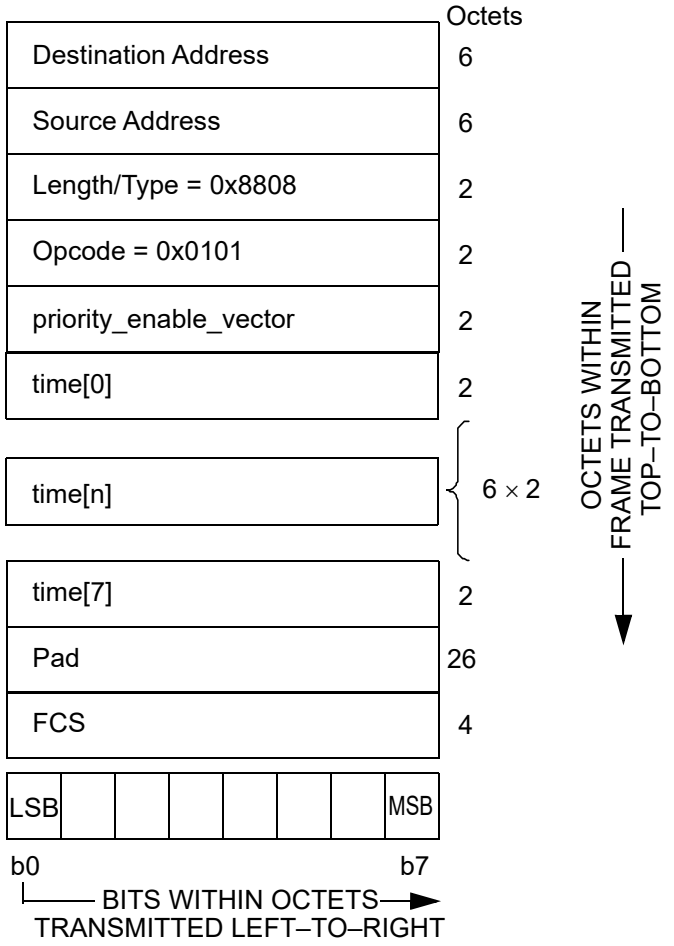

Figure 31D–1—MAC Control EXTENSION Frame

31D.4 Transmit state diagram for PFC operation

MAC Control sublayer entities that transmit PFC frames shall implement the Transmit state diagram specified in this subclause.

31D.4.1 Constants

pfc_command
: The 2-octet encoding of the PFC opcode, as specified in Annex 31A.

phys_Address
: A 48-bit value, equal to the unicast address of the station implementing the MAC Control sublayer.

reserved_multicast_address
: The 48-bit address specified in 31D.1 item a).

802.3_MAC_Control
: The 16 bit EtherType field assignment for IEEE 802.3 MAC Control specified in 31.4.1.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

31D.4.2 Variables

transmitEnabled
: A Boolean set by network management to indicate that the station is permitted to transmit on the network.

  Values: true; Transmitter is enabled by management
  false; Transmitter is disabled by management

pfc_operand_list
: The priority_enable_vector and time_vector from the MA_CONTROL.request.

pfc_mac_service_data_unit
: The concatenation of IEEE 802.3_MAC_Control, pfc_command, priority_enable_vector, time_vector, zeros.

31D.4.3 Messages

MA_CONTROL.request
: The service primitive used by a client to request a MAC Control sublayer function with the specified request_operands.

MCF:MA_DATA.request
: The service primitive used by a client to request MAC data transmission with the specified parameters.

MAC:MA_DATA.request
: The service primitive issued by the MAC Control sublayer to transmit a MAC frame with the specified parameters. The action invoked is not considered to end until the transmission of the frame by the MAC has concluded and the ability of the MAC control layer to determine this is implementation dependent.

31D.4.4 Transmit state diagram for PFC operation

Figure 31B–1 depicts the Transmit state diagram for a MAC Control sublayer entity implementing the PFC operation.

31D.5 PFC receive

The opcode-independent MAC Control sublayer Receive state diagram accepts and parses valid frames received from the MAC sublayer. The functions specified in this subclause are performed upon receipt of a valid Control frame containing the PFC opcode, and define the function called by the INITIATE MAC CONTROL FUNCTION state of Figure 31–4. (See 31.5.3.) Upon receipt of a valid MAC Control frame with the opcode indicating PFC and the destination address indicating the globally assigned multicast address specified in 31D.1, the MAC Control sublayer generates the MA_CONTROL.indication to the MAC Control Client.

31D.6 Receive state diagram for PFC operation

MAC Control sublayer entities that transmit PFC frames shall implement the Receive state diagram specified in this subclause.

Annex 32A

(informative)

Use of cabling systems with nominal differential characteristic impedance of 120 Ω or 150 Ω

The 100BASE-T2 standard specifies only the use of 100 Ω link segments for conformance. Since ISO/IEC 11801: 1995 also recognizes 120 Ω and 150 Ω cabling, this informative annex specifies the conditions for using cabling systems with nominal characteristic impedances of 120 Ω and 150 Ω by 100BASE-T2 conformant stations.

The use of cabling with a characteristic impedance outside the range specified in 32.7.2.2 will generally increase the mismatching effects in the link components if directly coupled to the PHY without a impedance transforming balun and results in the following consequences:

a) Increased echo due primarily to poorer hybrid performance
b) Increased cabling attenuation roughness due to increased reflections
c) Increased transmitter launch amplitude
d) Possible non-linearities in transmitter

The effect of increased echo and reflection is more than compensated by use of Category 4 or higher 120 Ω cabling or 150 Ω cabling consistent with ISO/IEC 11801 specifications. The increased transmitter launch level will not be an additional noise or EMC problem on these quality cabling. Manufacturers intending to support a direct connection of 120 Ω or 150 Ω cabling to the 100BASE-T2 PHY have to ensure that the transmitters can tolerate the impedance without additional non-linearity.

If baluns are used instead of a direct connection, care has to be taken to ensure that the corner frequencies of the baluns do not substantially interfere with the 100BASE-T2 signals. In practice, a lower corner frequency less than 100 kHz and an upper corner frequency greater than 30 MHz should be adequate for use with Category 4 or higher 120 Ω cabling or 150 Ω cabling consistent with ISO/IEC 11801 specifications.

CAUTION

Users of the present annex are further advised to check with the manufacturer of the particular 100BASE-T2 devices they intend to use with a 120 Ω or 150 Ω link whether those devices can operate correctly on cabling with Zc as high as 120 Ω ± 15 Ω and 150 Ω ± 15 Ω.

Annex 33A

(informative)

PSE-PD stability

33A.1 Recommended PSE design guidelines and test setup

In order to prevent potential oscillations between the PSE and PD, the sum of the PSE port output impedance (Zo_port), the cable impedance (Zc), the PD input port circuitry impedance (Zpd_cir) and the PD EMI output filter impedance (Z_emi) should be lower than the PD power supply input impedance (Zin_ps_pd). This subclause focuses on the PSE part.

Port output impedance consists of two parts:

a) PSE power supply output impedance (Zo_ps), which is a function of the load (P_{Port}), and
b) Series elements (Z_ser) that connect the PSE power supply output to the port.

Therefore, the total Port output impedance during normal powering mode is Zo_port = Zo_ps + Z_ser.

In order to maintain PSE-PD stability, the following guidelines apply:

c) Zo_ps max = 0.3 Ω. at frequencies up to 100 kHz at $P_{port} = P_{Type}$ as defined in Table 33–11.
   Zo_ps can be extracted from Z_{port} by measuring V_{Port} / I_{Port} (with an external power dynamic analyzer system) as a function of frequency and subtracting from Z_{port} the value of Zser (f = DC) which is limited by the value of Zser at DC (low frequency).
d) If Zo_ps < Zo_ser and V_{Port} is kept to V_{Port} min and V_{Port} max as defined in Table 33–11 during dynamic load changes from 10 Hz to 100 kHz, then the value of Zo_ps is not limited.

Compliance to the above requirements should be made by measuring the port output impedance from 10 Hz to 100 kHz with a load of P_{Type} as defined in Table 33–11 at short cable length, or by presenting simulation results.

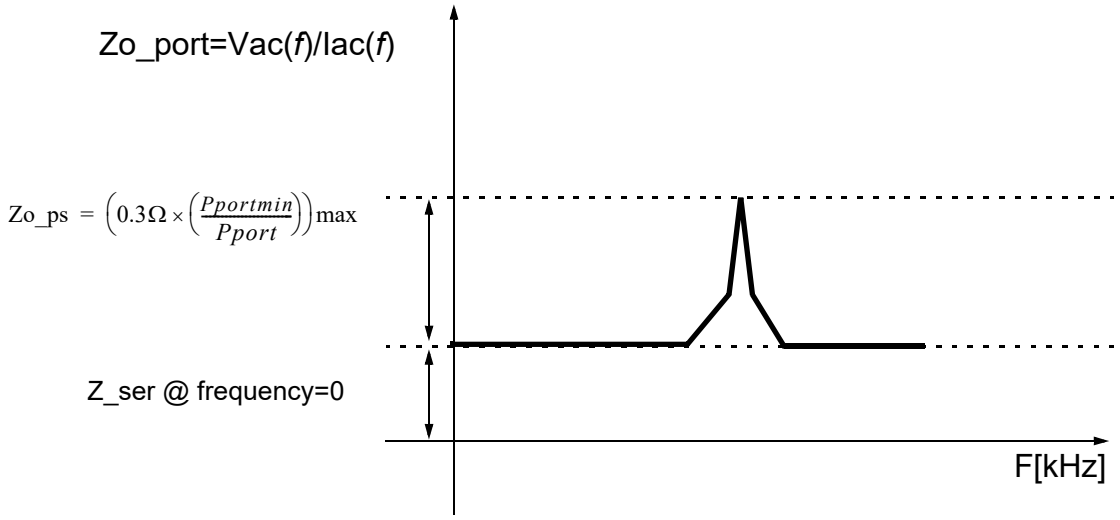

Figure 33A–3—Test requirements for measuring Zo_port

33A.2 Recommended PD design guidelines

PD port input impedance consists of the following two parts:

a) PD port input circuits including the EMI filter (Zin_ser), and
b) PD power supply input impedance (Zin_ps_pd), which is fed by the output of the EMI filter (Zo_emi).

In order to maintain stability with the PSE, the PD power supply input impedance (Zin_ps_pd) should be higher than the output impedance of the total network including the PD EMI output filter impedance fed by the cable (MDI) output impedance, which is fed by the PSE port output impedance.

The worst-case scenario is when the cable (MDI) length is zero (in terms of lower damping factor).

The access to the PD input power supply is not possible through the PD port for evaluating the various impedances and derivation of the above parameters. Because of this, measuring the PD input impedance is a complicated task and the following guidelines should be followed by the PD vendor:

c) The PD power supply input impedance (Zin_ps_pd) at max load of $P_{port} = P_{Port}$ max as defined in Table 33–18 should be higher than 30 Ω at any frequency up to the PD power supply crossover frequency. If the PD power supply is consuming less than $P_{port} = P_{Port}$ max as defined in Table 33–18, then Zin_ps_pd min = $30 \times P_{Port}$ max / P_{port}.
d) The PD power supply EMI filter output impedance should be Zo_emi = 2.7 Ω max. If the PD power supply is consuming less than $P_{port} = P_{Port}$ max, then Zo_emi = $2.7 \times P_{Port}$ max / P_{port}.

See Figure 33A–1 for the PSE-PD system impedance allocation.

Annex 36A

(informative)

Jitter test patterns

This annex defines test patterns for 1000BASE-X PMDs. The applicability of these patterns is specified in the relevant PMD clauses. The patterns may be implemented at a bit, code-group, or frame level and may be used for transmitter testing. The receiver may not have the capability to accept these diagnostic sequences; however, system debug can be improved if a receiver is able to test for one or more of these patterns and report bit errors (e.g., 8B/10B decoder errors) back to the user.

36A.1 High-frequency test pattern

The intent of this test pattern is to test random jitter (RJ) at a BER of 10^{-12}, and also to test the asymmetry of transition times. This high-frequency test pattern generates a one, or light on, for a duration of 1 bit time, followed by a zero, or light off, for a duration of 1 bit time. This pattern repeats continuously for the duration of the test. For example: 10101010101010101010101010101010101010...

NOTE—This pattern can be generated by the repeated transmission of the D21.5 code-group. Disparity rules are followed.

36A.2 Low-frequency test pattern

The intent of this test pattern is to test low-frequency RJ and also to test PLL tracking error. This low frequency test pattern generates a one, or light on, for a duration of 5 bit times, followed by a zero, or light off, for a duration of 5 bit times. This pattern repeats continuously for the duration of the test. For example: 11111000001111100000111110000011111100000...

NOTE—This pattern can be generated by the repeated transmission of the K28.7 code-group. Disparity rules are followed.

36A.3 Mixed frequency test pattern

The intent of this test pattern is to test the combination of RJ and deterministic jitter (DJ). This mixed frequency test pattern generates a one, or light on, for a duration of 5 bit times, followed by a zero, or light off, for a duration of 1 bit times, followed by a one for 1 bit time followed by a zero for 1 bit time followed by a one for 2 bit times followed by a zero for 5 bit times followed by a one for 1 bit time followed by a zero for 1 bit time followed by a one for 1 bit time followed by a zero for 2 bit times. This pattern repeats continuously for the duration of the test. For example: 11111010110000010100111110101100000101000...

NOTE—This pattern can be generated by the repeated transmission of the K28.5 code-group. Disparity rules are followed.

36A.4 Long continuous random test pattern

The long continuous random test pattern is a random test pattern intended to provide broad spectral content and minimal peaking that can be used for the measurement of jitter at either a component or system level.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The derivation of this pattern may be found in *Fibre Channel Jitter Working Group Technical Report* [B24]. This technical report modified the original RPAT as defined by Fibre Channel so that it would maintain its intended qualities but fit into a Fibre Channel frame. This annex uses similar modifications to fit the same RPAT into an IEEE 802.3 frame.

The long continuous random test pattern consists of a continuous stream of identical packets, separated by a minimum IPG. Each packet is encapsulated within SPD and EPD delimiters as specified in Clause 36 in the ordinary way. The contents of each packet is composed of the following octet sequences, as observed at the GMII, before 8B/10B coding.

Each packet in the long continuous random test pattern consists of 8 octets of PREAMBLE/SFD, followed by 1512 data octets (126 repetitions of the 12-octet modified RPAT sequence), plus 4 CRC octets, followed by a minimum IPG of 12 octets of IDLE.

PREAMBLE/SFD:

END

36A.5 Short continuous random test pattern

The short continuous random test pattern is a random test pattern intended to provide broad spectral content and minimal peaking that can be used for the measurement of jitter at either a component or system level.

NOTE—The derivation of this pattern may be found in *Fibre Channel Jitter Working Group Technical Report* [B24]. This technical report modified the original RPAT as defined by Fibre Channel so that it would maintain its intended qualities but fit into a Fibre Channel frame. This annex uses similar modifications to fit the same RPAT into an IEEE 802.3 frame.

The short continuous random test pattern consists of a continuous stream of identical packets, separated by a minimum IPG. Each packet is encapsulated within SPD and EPD delimiters as specified in Clause 36 in the ordinary way. The contents of each packet is composed of the following octet sequences, as observed at the GMII, before 8B/10B coding.

Each packet in the short continuous random test pattern consists of 8 octets of PREAMBLE/SFD, followed by 348 data octets (29 repetitions of the 12-octet modified RPAT sequence), plus 4 CRC octets, followed by a minimum IPG of 12 octets of IDLE.

The format of this packet is such that the PCS will generate the following ordered sets for the IPG: /T/ /R/ /I1/ /I2/ /I2/ /I2/ /I2/

Annex 36B

(informative)

8B/10B transmission code running disparity calculation examples

Detection of a invalid code-group in the 8B/10B transmission code does not necessarily indicate that the code-group in which the error was detected was the one in which the error occurred. Invalid code-groups may result from a prior error that altered the running disparity of the bit stream but that did not result in a detectable error at the code-group in which the error occurred. The examples shown in Tables 36B–1 and 36B–2 exhibit this behavior. The example shown in Table 36B–3 exhibits the case where a bit error in a received code-group is detected in that code-group, affects the next code group, and error propagation is halted upon detection of the running disparity error.

Table 36B–1—RD error detected two code-groups following error

Stream	Code-group			Code-group			Code-group		
	RD	RD	RD	RD	RD	RD	RD	RD	RD
Transmitted code-group	–	D21.1	–	D10.2	–	D23.5	+		
Transmitted bit stream	–	101010 - 1001	–	010101 – 0101	–	111010 + 1010	+		
Received bit stream	–	101010 - 10**1**1[a]	+	010101 + 0101	+	111010 +[b] 1010	+		
Received code-group	–	D21.0	+	D10.2	+	invalid code-group[b]	+[c]		

[a]Bit error introduced (1001 ⇒ 10**1**1)
[b]Nonzero disparity blocks have to alternate in polarity (+ ⇒ –). In this case, RD does not alternate (+ ⇒ +), the received code group is not found in the Current RD+ column in either Table 36–1a–e or Table 36–2, and an invalid code-group is recognized.
[c]Running disparity is calculated on the received code-group regardless of the validity of the received code-group. Nonzero disparity blocks prevent the propagation of errors and normalize running disparity to the transmitted bit stream (i.e., equivalent to the received bit stream had an error not occurred).

Table 36B–2—RD error detected in next code-group following error

Stream	Code-group			Code-group			Code-group		
	RD	RD	RD	RD	RD	RD	RD	RD	RD
Transmitted code-group	–	D21.1	–	D23.4	–	D23.5	+		
Transmitted bit stream	–	101010 – 1001	–	111010 + 0010	–	111010 + 1010	+		
Received bit stream	–	101010 – 10**1**1[a]	+	111010 +[b] 0010	–	111010 + 1010	+		
Received code-group	–	D21.0	+	invalid code-group[b]	–	D23.5	+		

[a]Bit error introduced (1001 ⇒ 10**1**1)
[b]Nonzero disparity blocks have to alternate in polarity (+ ⇒ –).

Table 36B–3—A single bit error affects two received code-groups

Stream	Code-group			Code-group			Code-group		
	RD		RD		RD			RD	
Transmitted code-group	–	D3.6 (FCS3)	–	K29.7 (/T/)		–	K23.7 (/R/)		–
Transmitted bit stream	–	110001 - 0110	–	101110 + 1000		–	111010 + 1000		–
Received bit stream	–	110001 - 011**1**[a]	+[b]	101110	+[c] 1000	–	111010 + 1000		–
Received code-group	–	invalid code-group[d]	+	invalid code-group[e]		–	K23.7 (/R/)		–

[a]Bit error introduced (0110 ⇒ 011**1**).
[b]Nonzero disparity blocks have to alternate in polarity (– ⇒ +). Received RD differs from transmitted RD.
[c]Nonzero disparity blocks have to alternate in polarity (+ ⇒ –). Invalid code-group due to RD error since RD remains at +.
[d]Received code-group is not found in either Table 36–1a–e or Table 36–2.
[e]Nonzero disparity blocks prevent the propagation of errors and normalize running disparity to the transmitted bit stream (i.e. equivalent to the received bit stream had an error not occurred). All code-groups contained in PCS End_of_Packet delimiters (/T/R/R or /T/R/K28.5/) include nonzero disparity blocks.

Annex 38A

(informative)

Fiber launch conditions

38A.1 Overfilled Launch

Overfilled Launch (OFL), as described in IEC 60793-1-4 [B32], is the standard launch used to define optical fiber bandwidth. This launch uniformly overfills the fiber both angularly and spatially. It excites both radial and azimuthal modes of the fiber equally, thus providing a reproducible bandwidth which is insensitive to small misalignments of the input fiber. It is also relatively insensitive to microbending and macrobending when they are not sufficient to affect power distribution carried by the fiber. A restricted launch gives a less reproducible bandwidth number and is dependent on an exact definition of the launch. Overfilled launch is commonly used to measure the bandwidth of LED-based links.

38A.2 Radial Overfilled Launch (ROFL)

A Radial Overfilled Launch is created when a multimode optical fiber is illuminated by the coherent optical output of a source operating in its lowest order transverse mode in a manner that excites predominantly the radial modes of the multimode fiber. This contrasts with the OFL, which is intended to excite both radial and azimuthal modes of the fiber equally. In practice an ROFL is obtained when

a) A spot of laser light is projected onto the core of the multimode fiber,
b) The laser spot is approximately symmetrical about the optical center of the multimode fiber,
c) The optical axis of both the fiber and the laser beam are approximately aligned,
d) The angle of divergence of the laser beam is less than the numerical aperture of the multimode fiber,
e) The laser spot is larger than the core of the multimode fiber.

An ROFL cannot be created using a multi-transverse mode laser or by simply projecting a speckle pattern through an aperture.

Annex 40A

(informative)

Additional cabling design guidelines

This annex provides additional cabling guidelines when installing a new Category 5/Class D balanced cabling system or using an existing Category 5/Class D balanced cabling system. These guidelines are intended to supplement those in Clause 40. 1000BASE-T is designed to operate over 4-pair twisted-pair cabling systems that meet the requirements described in ANSI/TIA/EIA-568-A-1995 (Category 5) and ISO/IEC 11801:1995 (Class D), and the additional transmission parameters of return loss, ELFEXT loss, and MDELFEXT loss specified in 40.7. There are additional steps that may be taken by network designers that provide additional operating margins and ensure the objective BER of 10^{-10} is achieved. Cabling systems that meet or exceed the specifications in 40.7 for a worst case 4-connector topology are recommended for new installations. Whether installing a new Category 5/Class D balanced cabling system or reusing one that is already installed, it is highly recommended that the cabling system be measured/certified before connecting 1000BASE-T equipment following the guidelines in ANSI/EIA/TIA 568-B1 Annex D.

40A.1 Alien crosstalk

40A.1.1 Multipair cabling (i.e., greater than 4-pair)

Multiple Gigabit Ethernet links [(n*4-Pair) with n greater than 1] should not share a common sheath as in a 25-pair binder group in a multipair cable. When the multipair cable is terminated into compliant connecting hardware (TIA does not specify 25 position connecting hardware), the NEXT loss contributions between the adjacent 4-pair Gigabit Ethernet link, from connecting hardware and the cable combined, cannot be completely cancelled.

40A.1.2 Bundled or hybrid cable configurations

Another source of alien crosstalk can occur in a bundled or hybrid cable configuration where two or more 4-pair cables are assembled together.

In order to limit the noise coupled between adjacent 1000BASE-T link segments in a bundled or hybrid cable configuration, the PSNEXT loss between a 1000BASE-T duplex channel in a link segment and all duplex channels in adjacent 1000BASE-T link segments should be greater than $35 - 15*\log(f/100)$ (dB) at all frequencies from 1 MHz to 100 MHz.

40A.2 Cabling configurations

The primary application for the Clause 40 specification is expected to be between a workstation and the local telecommunications closet. In commercial buildings this application is generally referred to as the horizontal cabling subsystem. As specified in ISO/IEC 11801:1995 the maximum length of a horizontal subsystem building wiring channel is 100 m. The channel consists of cords, cables, and connecting hardware. The maximum configuration for this channel is shown in Figure 40A–1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

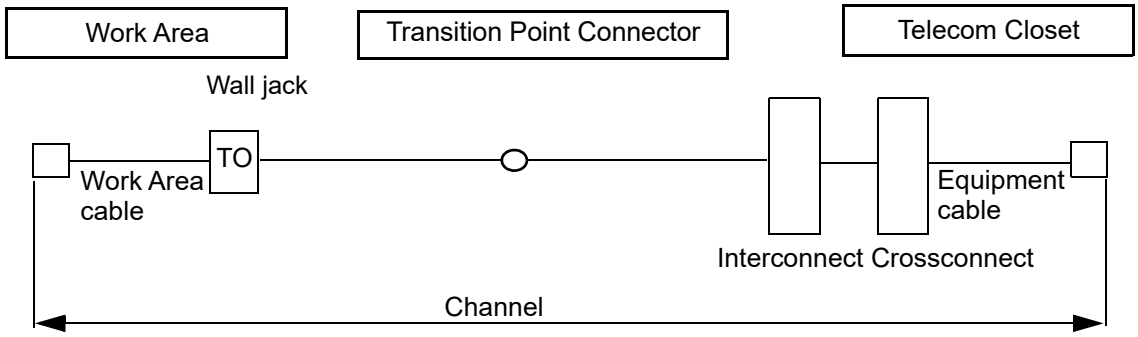

Figure 40A–1—Maximum horizontal subsystem configuration

On the other hand, a minimum configuration can be achieved by removing the patch cord and transition point, which is shown in Figure 40A–2.

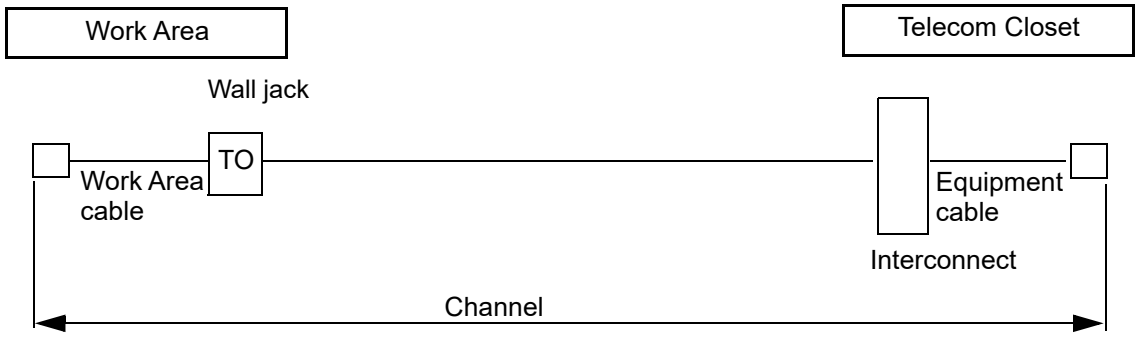

Figure 40A–2—Minimum horizontal subsystem configuration

1000BASE-T is designed to operate over a channel that meets the specifications of 40.7 and the channel configuration shown in Figure 40A–1. However, if the channel specifications of 40.7 cannot be met when using the channel configuration shown in Figure 40A–1, the configuration shown in Figure 40A–2 is recommended. This optimized channel for a 1000BASE-T link segment deletes the transition point and runs an equipment patch cord directly between the LAN equipment and the connector termination of the permanent link. This reduces the number of connectors and their associated crosstalk in the link. The minimum link configuration:

a) Minimizes crosstalk, both near-end and far-end, which maximizes the BER margin; and
b) Minimizes link insertion loss.

Annex 40B

(informative)

Description of cable clamp

This annex describes the cable clamp used in the common-mode noise rejection test of 40.6.1.3.3, which is used to determine the sensitivity of the 1000BASE-T receiver to common-mode noise from the link segment. As shown in Figure 40B–1, the clamp is 300 mm long, 58 mm wide, 54 mm high with a center opening of 6.35 mm (0.25 in). The clamp consists of two halves that permit the insertion of a cable into the clamp.

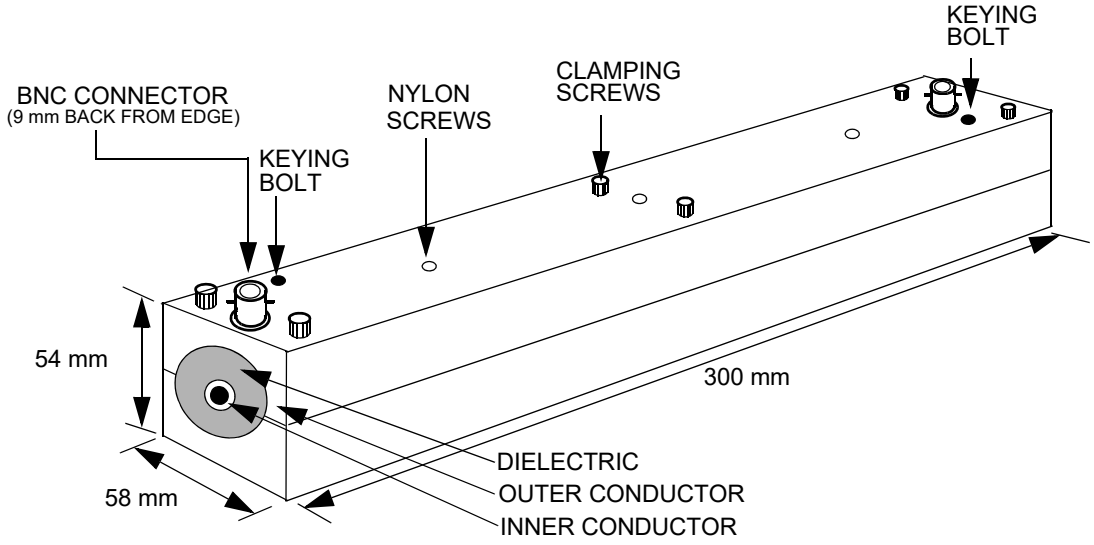

Figure 40B–1—Cable clamp

The clamp has a copper center conductor and an aluminum outer conductor with a high density polyethylene dielectric. The following is a review of the construction and materials of the clamp:

a) *Inner conductor*—Copper tubing with an inner diameter of 6.35 mm (0.25 in) and an outer diameter of 9.4 mm (0.37 in).
b) *Outer conductor*—Aluminum bar that is 300 mm long and approximately 54 mm by 58 mm. The bar is milled to accept the outer diameter of the dielectric material.
c) *Dielectric*—High Density Polyethylene (Residual, TypeF) with dielectric constant of 2.32. An outside diameter of 33.5 mm and an inner diameter that accepts the outside diameter of the copper inner conductor.
d) *Connectors*—BNC connectors are located 9 mm (0.39 in) from each end of the clamp and are recessed into the outer conductor. The center conductor of the connector is connected to the inter conductor as shown in Figure 40B–2.
e) *Clamping screws*—Six screws are used to connect the two halves of the clamp together after the cable has been inserted. Although clamping screws are shown in Figure 40B–1, any clamping method may be used that ensures the two halves are connected electrically and permits quick assembly and disassembly.
f) *Nylon screws*—Used to align and secure the inner conductor and dielectric to the outer conductor. The use and location of the screws is left to the manufacturer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

g) *Keying bolts*—Two studs used to align the two halves of the clamp.

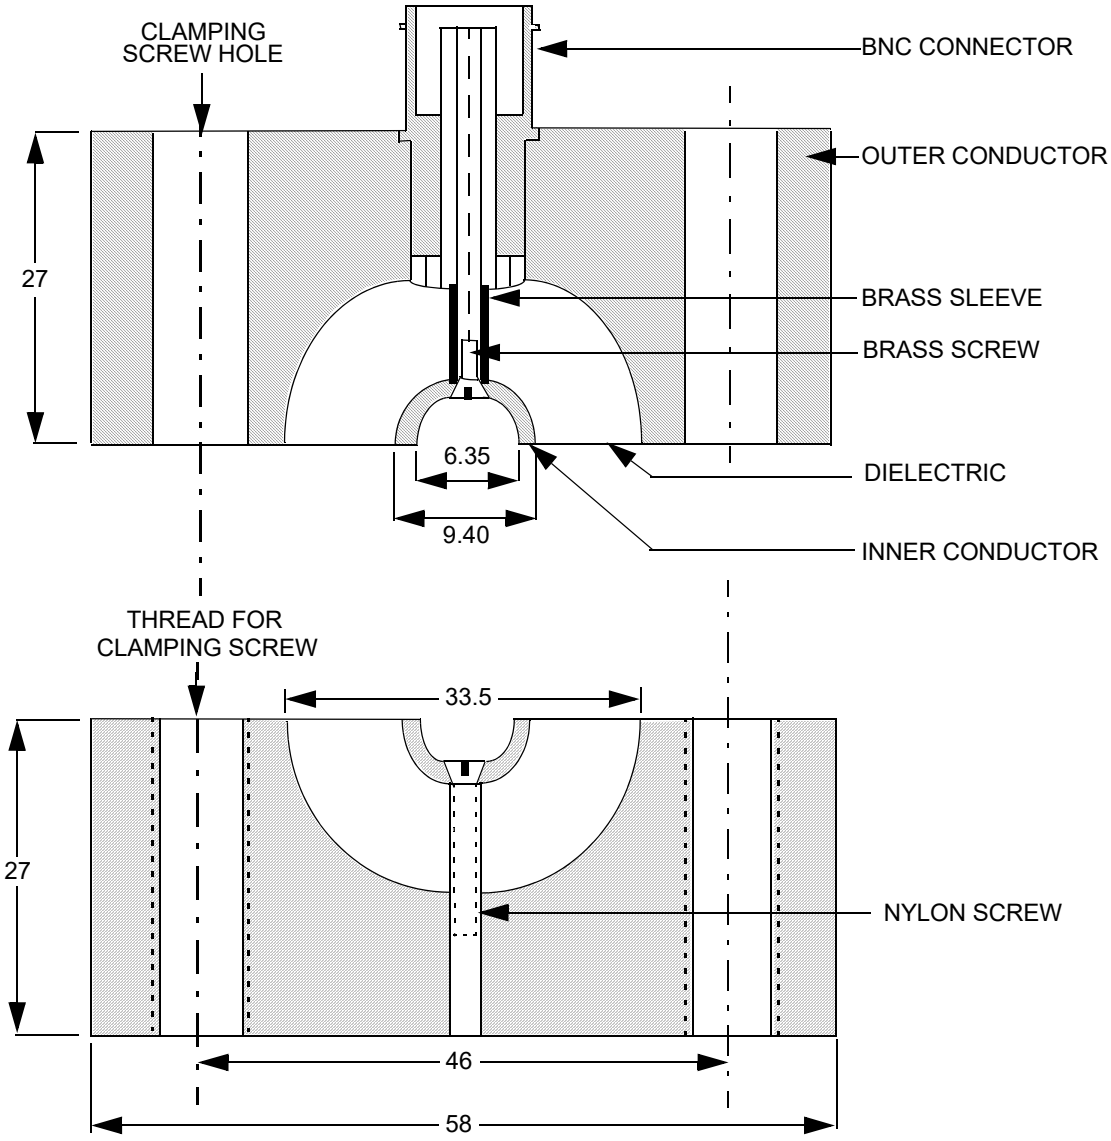

Figure 40B–2—Cross-section of cable clamp

As shown in Figure 40B–2 the inner conductor on the bottom half of the clamp extends slightly (~ 0.1mm) above the dielectric to ensure there is good electrical connection with the inner conductor of the top half of the clamp along the full length of the conductor when the two halves are clamped together.

The electrical parameters of the clamp between 1MHz and 250 MHz are as follows:

a) Insertion loss: < 0.2 dB

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Return loss: > 20.0 dB

40B.1 Cable clamp validation

In order to ensure the cable clamp described above is operating correctly, the following test procedure is provided. Prior to conducting the following test shown in Figure 40B–3, the clamp should be tested to ensure the insertion loss and return loss are as specified above. The cable clamp validation test procedure uses a well-balanced 4-pair Category 5 unshielded test cable or better that meets the specifications of 40.7. The test hardware consists of the following:

a) *Resistor network*—Network consists of three 50 ±0.1% Ω resistors; two resistors are connected in series as a differential termination for cable pairs and the other resistor is connected between the two and the ground plane as a common-mode termination.
b) *Balun*—3 ports, laboratory quality with a 100 Ω differential input, 50 Ω differential output, and a 50 Ω common-mode output:
   Insertion Loss (100 Ω balanced <->50 Ω unbalanced): <1.2 dB (1-350MHz)
   Return Loss: >20 dB (1-350 MHz)
   Longitudinal Balance: >50 dB (1-350 MHz)
c) *Test cable*—4-pair 100 Ω UTP category 5 balanced cable at least 30 m long.
d) *Chokes (2)*—Wideband Ferrite Material:
   Inter-diameter: 6.35 to 6.86 mm
   Impedance: 250 Ω @ 100 MHz
e) *Ground plane*—Copper sheet or equivalent.
f) *Signal generator*
g) *Oscilloscope*
h) *Receiver*

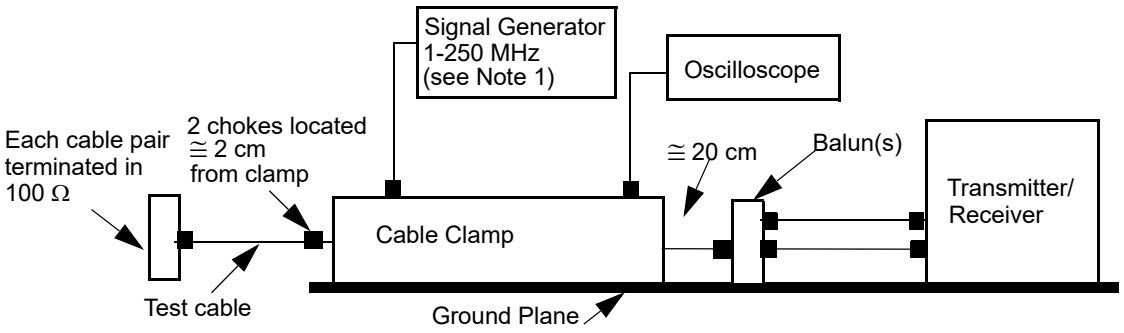

Figure 40B–3—Cable clamp validation test configuration

With the test cable inserted in the cable clamp, a signal generator with a 50 Ω output impedance is connected to one end of the cable clamp and an oscilloscope with a 50 Ω input impedance is connected to the other end. The signal generator shall be capable of providing a sine wave signal of 1 MHz to 250 MHz. The output of the signal generator is adjusted for a voltage of 1.0 Vrms (2.83 Vpp) at 20 MHz on the oscilloscope. The remainder of the test is conducted without changing the signal generator voltage. The cable pairs not connected to the balun are terminated in a resistor network, although when possible it is recommended that each cable pair be terminated in a balun. It very important that the cable clamp, balun, receiver, and resistor networks have good contact with the ground plane. The two chokes, which are located next to each other, are

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

located approximately 2.0 cm from the clamp. The cable between the clamp and the balun should be straight and not in contact with the ground plane.

The differential-mode and common-mode voltage outputs of the balun should meet the limits shown in Table 40B–1 over the frequency range 1 MHz to 250 MHz for each cable pair. The differential mode voltage at the output of the balun has to be increased by 3 dB to take into account the 100-to-50 impedance matching loss of the balun.

Table 40B–1—Common- and differential-mode output voltages

Frequency (*f*)	Common-mode voltage	Differential-mode voltage
1-30 MHz	<0.1+0.97(f/30) Vpp	<2.4 + 19.68 (f/30) mVpp
30-80 MHz	<1.07 Vpp	<22 mVpp
80-250 MHz	<1.07 – 0.6 (f-80)/170 Vpp	<22 mVpp

NOTE—Prior to conducting the validation test the cable clamp should be tested without the cable inserted to determine the variation of the signal generator voltage with frequency at the output of the clamp. The signal generator voltage should be adjusted to 1 Vrms (2.83 Vpp) at 20 MHz on the oscilloscope. When the frequency is varied from 20 MHz to 250 MHz, the voltage on the oscilloscope should not vary more than ±7.5%. If the voltage varies more than ±7.5%, then a correction factor has to be applied at each measurement frequency.

Annex 40C

(informative)

Add-on interface for additional Next Pages

This annex describes a technique for implementing Auto-Negotiation for 1000BASE-T when the implementer wishes to send additional Next Pages (other than those required to configure for 1000BASE-T operation). To accomplish this mode of Auto-Negotiation, the implementer has to ensure that the three Next Pages required for 1000BASE-T configuration are sent first.

The add-on interface described in this annex shows one technique for supporting the transmission of additional Next Pages. This mechanism utilizes the existing Clause 28 Auto-Negotiation mechanism and variables defined in Clause 28. Its purpose is merely to provide optional NEXT PAGE WAIT responses to the Auto-Negotiation Arbitration state diagram (see Figure 28–18).

The add-on interface for Auto-Negotiation is intended to interface directly between the defined registers and the Auto-Negotiation mechanism defined in Clause 28. The mechanism described includes five main blocks (see Figure 40C–1).

The first three blocks are used by the MASTER-SLAVE resolution function. They are used to generate and store random seeds and to resolve the status of the MASTER-SLAVE relationship. Their operation is described later in this annex. The final two blocks, the transmit state diagram for the 1000BASE-T Next Page exchange and the receive state diagram for the 1000BASE-T Next Page exchange, are described in this annex.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

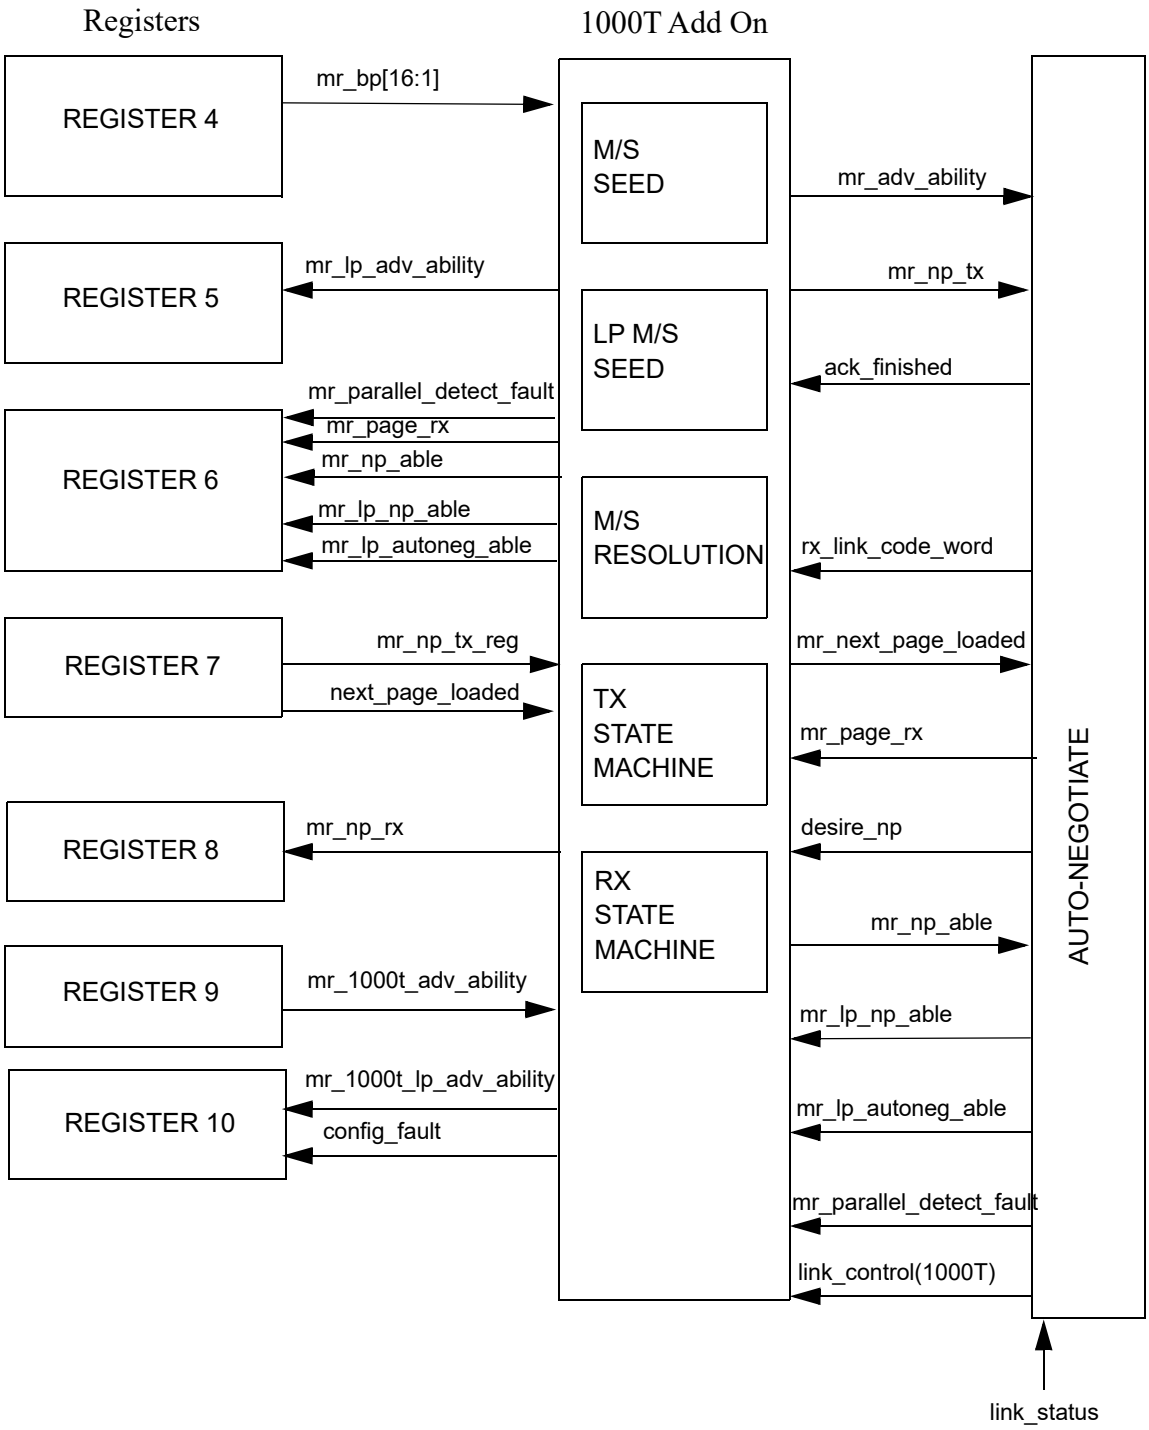

Figure 40C–1—Auto-Negotiate add-on diagram for 1000BASE-T

NOTE—When the exchange of Next Pages is complete, the MASTER-SLAVE relationship can be determined using Table 40–5 with the 1000BASE-T Technology Ability Next Page bit values specified in Table 40–4 and information received from the link partner. This process is conducted at the entrance to the FLP LINK GOOD CHECK state shown in the Auto-Negotiation Arbitration state diagram (Figure 28–18).

40C.1 State variables

ATMP_CNT
: This variable is used to count the number of failed MASTER-SLAVE resolutions. It has a maximum value of 7.

config_fault
: This variable indicates the result of the MASTER-SLAVE resolution function.

desire_1000T_adv
: The local device desires a 1000BASE-T link.
Values: true; bits 9.8 or 9.9 do not contain a logic zero.
false; bits 9.8 and 9.9 both contain a logic zero.

mr_bp
: This variable is used as an intermediate signal from register 4. Normally register 4 would directly source the mr_adv_ability information. This information is now sourced from the transmit state machine.

mr_1000t_adv_ability
: A 16-bit array used to store and indicate the contents of register 9.

mr_1000t_lp_adv_ability
: A 16-bit array used to write information to register 10.

mr_np_tx_reg
: This variable is an intermediate signal from register 7. Normally register 7 would directly source the information to the Auto-Negotiation function via mr_np_tx. This information is now sourced from the transmit state diagram.

mr_np_rx
: A 16-bit array used to write information to register 8.
Values: Zeros; data bit is logical zero.
One; data bit is logical one.

next_page_loaded
: This variable is an intermediate signal from register 7. Normally register 7 would directly source the information to the Auto-Negotiation function via mr_next_page_loaded. This information is now sourced from the transmit state diagram.

reg_random
: An 11-bit array used to store the received random seed from the link partner. It is used by the MASTER-SLAVE resolution function.

All other signals are defined in Clause 28.

40C.2 State diagrams

40C.2.1 Auto-Negotiation Transmit state diagram add-on for 1000BASE-T

The Auto-Negotiation transmit state diagram add-on (see Figure 40C–2) is responsible for sending the Base Page, 1000BASE-T Next Pages, as well as additional Next Pages as specified by the management interface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1000BASE-T Next Pages will automatically be sent by the PHY whenever there are no additional Next Pages to be sent. If the user desires to send additional Next Pages, then the user has to first send three pages of any format. Management will automatically replace these three pages with the appropriate 1000BASE-T Message Page and the two following unformatted pages and then will send the additional Next Pages as specified by the user. All other steps are performed by the management interface. The management interface is now required to complete the Next Page exchange by sourcing its own NULL page. This is shown in Figure 40C–2 for illustration only.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

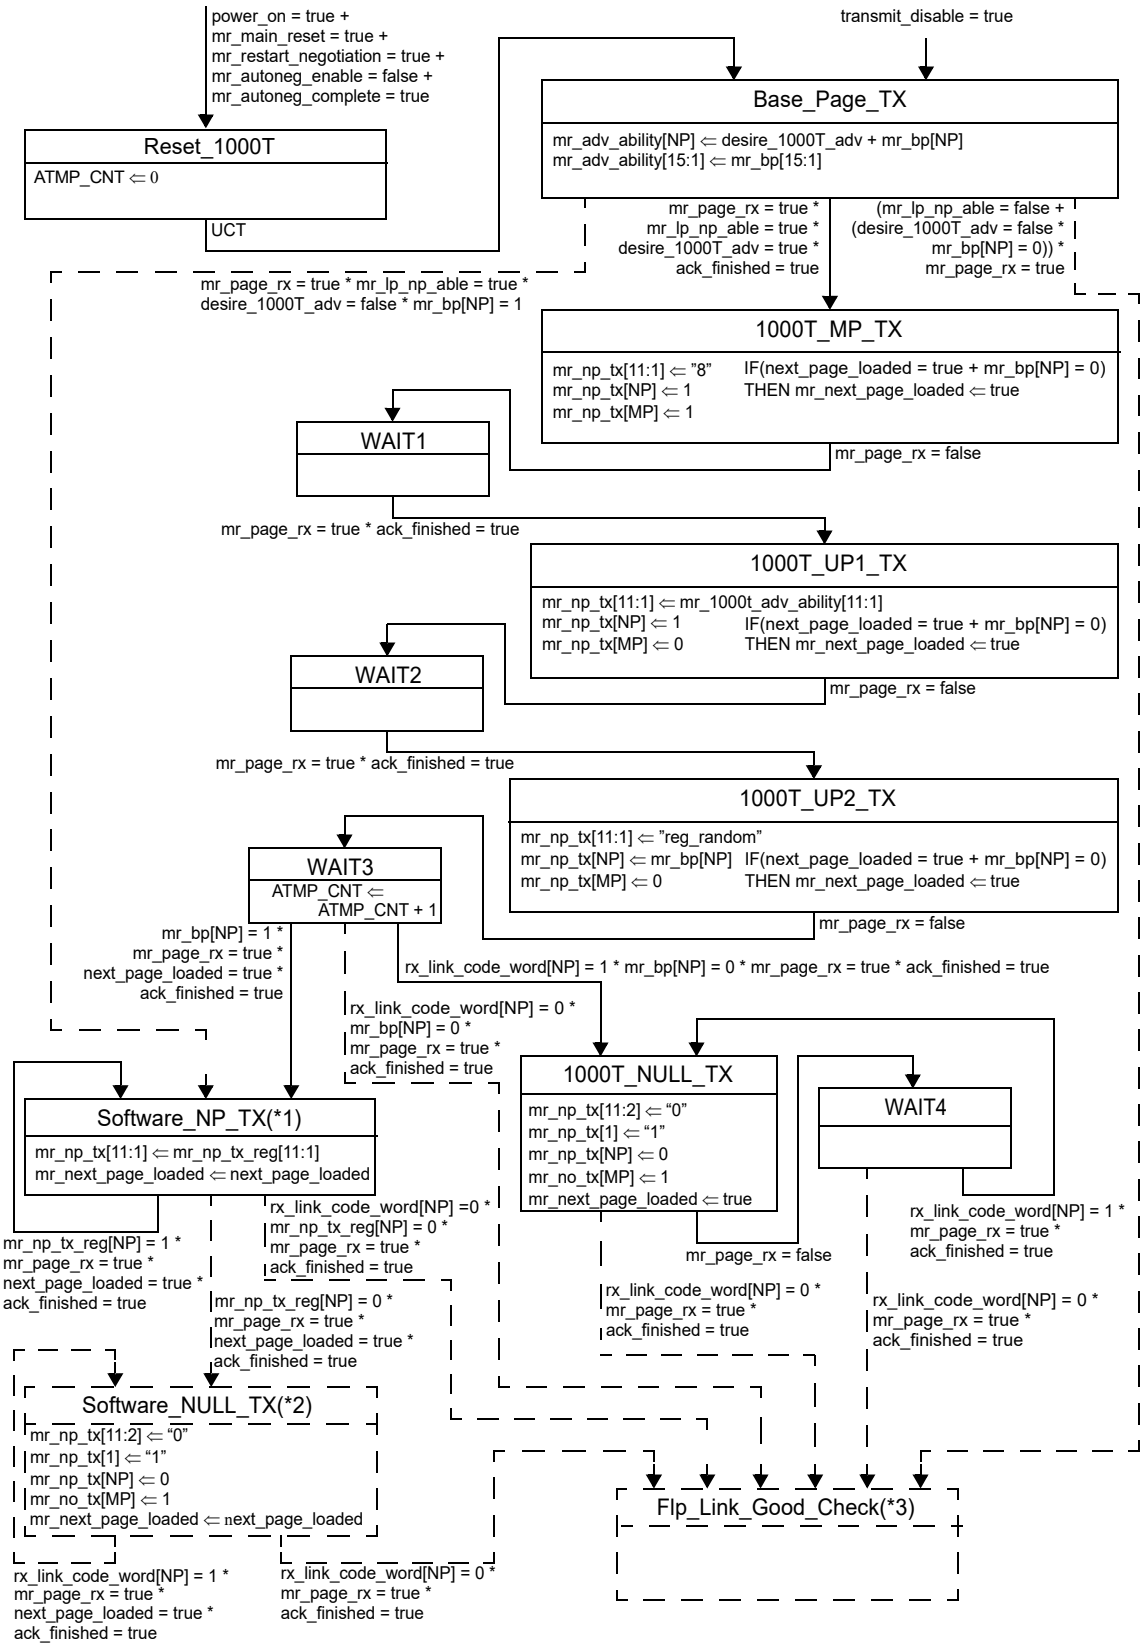

Figure 40C–2—Auto-Negotiation Transmit state diagram add-on for 1000BASE-T

NOTES for Figure 40C–2

1—(Software_NP_TX) If the user desires to send additional Next Pages, then the contents of the first three Next Pages will be overwritten by the three 1000BASE-T Next Pages. In this case, the user is responsible for stepping through the Next Page sequence (by creating the initial three Next Pages to be overwritten by the three 1000BASE-T Next Pages); otherwise the process is automatic. (next_page_loaded signals clear operation as per Clause 28.)

2—(Software_NULL_TX) This is shown for illustration only. This is done in software and is required.

3—(Flp_Link_Good_Check) This is shown for illustration only. This state is from the Auto-Negotiation Arbitration state diagram and indicates the conclusion of pages being sent. (The transition desire_1000T_adv = false is to show sequence for non 1000BASE-T implementations.)

40C.2.2 Auto-Negotiation Receive state diagram add-on for 1000BASE-T

The Auto-Negotiation receive state diagram add-on for 1000BASE-T Next Pages (see Figure 40C–3) is responsible for receiving the Base Page, 1000BASE-T Next Pages, and any additional Next Pages received. 1000BASE-T Next Pages will automatically be received whenever the user does not wish to participate in Next Page exchanges. In this case, the appropriate 1000BASE-T message page and its two unformatted pages will automatically be received and stored in their appropriate registers. Any additional Next Pages received will still be placed in register 8, but will be overwritten automatically when a new page is received. The net result is that the management interface does not need to poll registers 6 and 8. The information in register 8 will be meaningless in this case. If the user desires to participate in additional Next Page exchanges via setting the appropriate bit in register 4, the user now becomes responsible (as was previously the case) for defining how this will be accomplished. In this situation, the first three Next Pages received may be 1000BASE-T and should be discarded. This information will automatically be stored internally in the appropriate register 10 and reg_random. The management interface/user can ignore the information received for the 1000BASE-T Next Pages.

Diagram of Data Flow

This annex contains diagrams of the data flow from the MAC to the MDI in the transmit direction and from the MDI to the MAC in the receive direction. The diagrams are provided as a reference, and the corresponding clause should be reviewed for the complete information.

44A.1 10GBASE-R bit ordering

Figure 44A–1 shows the bit ordering on the LAN serial transmit data path.

Figure 44A–2 shows the bit ordering on the LAN serial receive data path.

The 10GBASE-R diagrams reference the following clauses: 46 (XGMII and RS), 47 (XGXS and XAUI), 49 (64B/66B PCS), and 51 (serial PMA).

44A.2 10GBASE-W serial bit ordering

Figure 44A–3 shows the bit ordering on the WAN serial transmit data path.

Figure 44A–4 shows the bit ordering on the WAN serial receive data path.

The 10GBASE-W serial diagrams reference the following clauses: 46 (XGMII and RS), 47 (XGXS and XAUI), 49 (64B/66B PCS), 50 (WIS), and 51 (serial PMA).

44A.3 10GBASE-LX4 bit ordering

Figure 44A–5 shows the bit ordering on the LAN WDM transmit path.

Figure 44A–6 shows the bit ordering on the LAN WDM receive path.

The 10GBASE-LX4 diagrams reference the following clauses: 46 (XGMII and RS) and 48 (8B/10B PCS and PMA).

44A.4 Loopback locations

Figure 44A–7 diagrams the impact of the various loopback signals on the generation of signal detect and local fault. Clause 46 describes the handling of local fault via the XGMII. If the WIS is not present, the PMA_SIGNAL.indication passes directly from the PMA sublayer to the PCS as is the case in 10GBASE-X and 10GBASE-R devices.

Figure 44A–7 represents an implementation of loopback where loopback is implemented in accordance with the recommendation that it exercises as much of the circuitry in the sublayer as possible. If the loopback is implemented above part of the circuitry in a sublayer, then any data valid signals produced below the loopback point should be ignored during loopback as are any data valid signals from below the sublayer. For instance, if loopback in a WIS implementation was done above the framer, then data valid signals from the framer should be logically OR'ed with loopback.

Annex 45A

(informative)

Clause 45 MDIO electrical interface

45A.1 MDIO driver

It is possible to implement the MDIO electrical driver using an open drain driver, as the MDIO signal is pulled up to 1.2 V using a resistor. This is shown in Figure 45A–1.

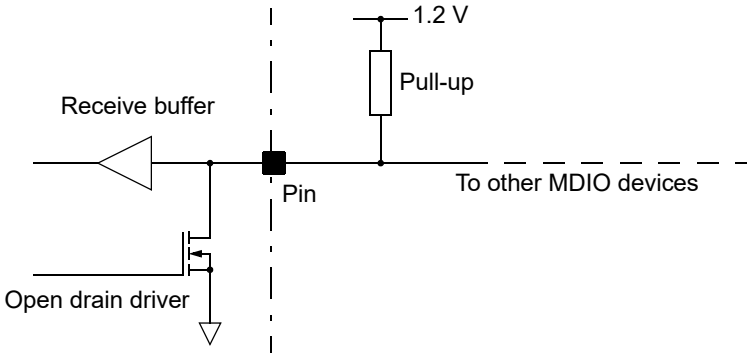

Figure 45A–1—Use of open drain driver for MDIO electrical interface

45A.2 Single Clause 45 electrical interface

As the Clause 45 MDIO electrical interface is significantly different from the Clause 22 MII Management electrical interface, it is not possible to directly attach a Clause 45 MMD to a Clause 22 MII Management Interface. Clause 45 MMDs that include Clause 22 registers may have their Clause 22 registers accessed via the Clause 45 electrical interface. This obviates the requirement to provide a Clause 22 compliant electrical interface in such systems. This is shown in Figure 45A–2.

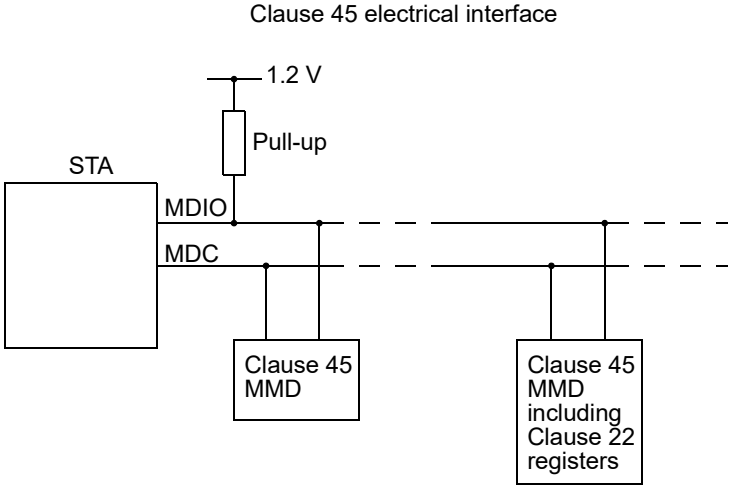

Figure 45A–2—Support of Clause 22 registers via the Clause 45 MDIO interface

45A.3 Clause 45 electrical interface for STA with Clause 22 electrical interface to PHYs

If Clause 22 PHYs are to be attached to a Clause 45 MDIO interface, then a voltage translation device is required. One possible solution is a protocol aware voltage translation device. This arrangement is shown in Figure 45A–3. Such a translation device has to correctly drive both the Clause 45 MDIO interface and the Clause 22 MII Management interface using the voltages and timings specified in the appropriate clause. In order to drive the interfaces correctly, the device needs to have knowledge of the Clause 22 PHY addresses present on the Clause 22 Management interface. When any PHY attached to the Clause 22 MII Management interface is driving the MDIO, the translation device has to drive the Clause 45 MDIO interface with the same logical state that is being driven on to the Clause 22 Management interface by the PHY. Whenever the STA drives the Clause 45 MDIO interface, the translation device has to drive the Clause 22 Management interface with the same logical state that is being driven on to the Clause 45 MDIO interface. In addition, the translation device has to drive the Clause 45 MDC on to the Clause 22 Management interface. Even though the Clause 45 MDIO frames using the ST=00 frame code will also be driven on to the Clause 22 MII Management interface, the Clause 22 PHYs will ignore the frames.

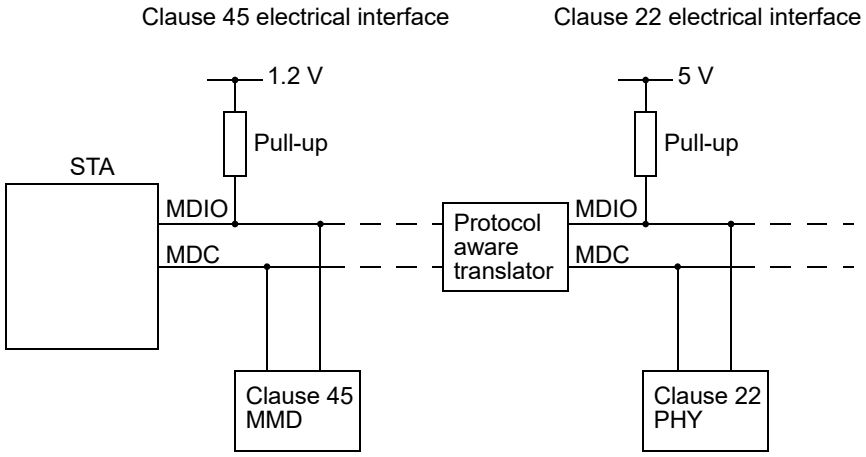

Figure 45A–3—Protocol aware voltage translator between Clause 45 and Clause 22

45A.4 Clause 22 electrical interface for STA with Clause 45 electrical interface to MMDs

If Clause 45 MMDs are to be attached to a Clause 22 MII management interface, then a voltage translation device is required. One possible solution is a protocol aware voltage translation device. This arrangement is shown in Figure 45A–4. Such a translation device has to correctly drive both the Clause 22 MII Management interface and the Clause 45 MDIO interface using the voltages and timings specified in the appropriate clause. In order to drive the interfaces correctly, the device needs to have knowledge of any Clause 22 PHY addresses present within MMDs attached to the Clause 45 MDIO Management interface. When any Clause 45 MMD, including embedded Clause 22 PHYs, attached to the Clause 45 MDIO Management interface is driving the MDIO, the translation device has to drive the Clause 22 MII Management interface with the same logical state that is being driven on to the Clause 45 MDIO interface by the PHY. Whenever the STA drives the Clause 22 MII Management interface, the translation device has to drive the Clause 45 MDIO interface with the same logical state that is being driven on to the Clause 22 MII Management interface. In addition, the translation device has to drive the Clause 22 MII Management interface MDC on to the Clause 45 MDIO interface. The Clause 22 MII Management interface has to be capable of generating the MDIO frame structure specified in Clause 45. Even though the Clause 45 MDIO

frames using the ST=00 frame code will be driven on to the Clause 22 MII Management interface, the Clause 22 PHYs will ignore such frames.

Annex 48A

(normative)

Jitter test patterns

This annex defines test patterns that allow the 10GBASE-X PHY described in Clause 48 to test either its attached PMD described in Clause 53 or its XAUI interface described in Clause 47 for compliance in a system environment, or for unspecified diagnostic purposes. The patterns may be implemented at a bit, code-group or frame level and may be used for transmitter testing. The receiver may not have the capability to accept these diagnostic sequences; however, system debug can be improved if a receiver is able to test for one or more of these patterns and report bit errors (e.g., 8B/10B decoder errors) back to the user.

48A.1 High-frequency test pattern

The intent of this test pattern is to test random jitter (RJ) at a BER of 10^{-12}, and also to test the asymmetry of transition times. This pattern is not intended for jitter compliance testing. This high-frequency test pattern generates a one, or light on, for a duration of 1 unit interval (UI), followed by a zero, or light off, for a duration of 1 UI. This pattern repeats continuously on each lane for the duration of the test. For example, 10101010101010101010101010101010101010...

NOTE—This pattern can be generated by the repeated transmission of the D21.5 code-group on each lane. Disparity rules are followed.

48A.2 Low-frequency test pattern

The intent of this test pattern is to test low-frequency RJ and also to test PLL tracking error. This pattern is not intended for jitter compliance testing. This low-frequency test pattern generates a one, or light on, for a duration of 5 UI, followed by a zero, or light off, for a duration of 5 UI. This pattern repeats continuously on each lane for the duration of the test. For example, 11111000001111100000111110000011111100000...

NOTE—This pattern can be generated by the repeated transmission of the K28.7 code-group on each lane. Disparity rules are followed.

48A.3 Mixed-frequency test pattern

The intent of this test pattern is to test the combination of RJ and deterministic jitter (DJ) due to high-frequency ISI. This pattern is not intended for jitter compliance testing. This mixed-frequency test pattern generates a one, or light on, for a duration of 5 UI, followed by a zero, or light off, for a duration of 1 UI, followed by a one for 1 UI followed by a zero for 1 UI followed by a one for 2 UI followed by a zero for 5 UI followed by a one for 1 UI followed by a zero for 1 UI followed by a one for 1 UI followed by a zero for 2 UI. This pattern repeats continuously on each lane for the duration of the test. For example, 11111010110000010100111110101100000101000...

NOTE—This pattern can be generated by the repeated transmission of the K28.5 code-group on each lane. Disparity rules are followed.

48A.4 Continuous random test pattern (CRPAT)

The continuous random test pattern is intended to provide broad spectral content and minimal peaking that can be used for the measurement of jitter at either a component or system level. This pattern is not intended for jitter compliance testing.

NOTE—The basis of this pattern may be found in NCITS TR-25:1999 [B42], “Fibre Channel - Methodologies for Jitter Specification”. This annex uses similar modifications to fit the RPAT test pattern into an IEEE 802.3 frame.

The continuous random test pattern consists of a continuous stream of identical packets, separated by a minimum IPG. Each packet is encapsulated within delimiters as specified in Clause 48 in the ordinary way. The contents of each packet is composed of the following octet sequences, as observed at the XGMII, before 8B/10B coding.

Each packet in the continuous random test pattern consists of 8 octets of PREAMBLE/SFD, followed by 1488 data octets (124 repetitions of the 12-octet modified RPAT sequence), plus 4 CRC octets, followed by a minimum IPG of 12 octets of IDLE.

48A.5 Continuous jitter test pattern (CJPAT)

The continuous jitter test pattern is intended to expose a receiver's CDR to large instantaneous phase jumps. The pattern alternates repeating low-transition density patterns with repeating high-transition density patterns. The repeating code-group durations should be longer than the time constants in the receiver clock recovery circuit. This assures that the clock phase has followed the systematic pattern jitter and the data sampling circuitry is exposed to large systematic phase jumps. This stresses the timing margins in the received eye. The following pattern is intended for receive jitter compliance testing.

NOTE—The basis of this pattern may be found in NCITS TR-25:1999 [B42]. This annex uses similar modifications to fit the JTPAT test pattern into an IEEE 802.3 frame.

The continuous jitter test pattern consists of a continuous stream of identical packets, separated by a minimum IPG. Each packet is encapsulated within delimiters, as specified in Clause 48, in the ordinary way. The contents of each packet is composed of the following octet sequences, as observed at the XGMII, before 8B/10B coding.

Each packet in the continuous jitter test pattern consists of 8 octets of PREAMBLE/SFD, followed by 1504 data octets, plus 4 CRC octets, followed by a minimum IPG of 12 octets of IDLE.

48A.5.1 Continuous jitter test pattern (CJPAT) 10 bit values

The following tables depict a 10-bit encoding for CJPAT. This is the encoding which will occur when each lane has negative disparity before the Start column. The actual 10-bit encoding sent when CJPAT is transmitted will be one of 16 encodings depending upon the disparity of each lane at the beginning of the packet. CJPAT has been designed to produce the same disparity on each lane after the Terminate column as that lane had before the Start column. When CJPAT is sent continuously, two of the sixteen possible encodings will occur because Idle will either leave the disparity the same or flip the disparity on all lanes.

Annex 48B

(informative)

Jitter test methods

This annex specifies the definitions and measurement requirements for the jitter specification of the XGXS and XAUI described in Clause 47, the 10GBASE-LX4 PMD described in Clause 53 and the 10GBASE-CX4 PMD described in Clause 54. These measurement methods and specifications are intended to be used for jitter and wander compliance testing, but are not definitive.

While jitter specifications are required to be met for all lanes during operation, the methods described in this annex are written for testing of a single lane. Each lane can be tested with these methods individually or concurrently.

48B.1 BER and jitter model

Measurement of BER within a data eye is not only the fundamental indicator of signal quality, it is a valuable tool to infer jitter properties. Insight into the relationship between jitter, eye opening and error ratio can be gained through mathematical modeling.

48B.1.1 Description of dual Dirac mathematical model

Figure 48B–1 considers a typical eye diagram that may be seen on an oscilloscope. For the purpose of discussion, assume that an ideal trigger source is used so that the eye is accurately depicted. Jitter is indicated by distributed transitions (crossings) of the threshold as the data toggles between logic states. Histograms of transition regions can be taken at the threshold level. The width of the histograms can then be estimated, including standard deviation, etc.

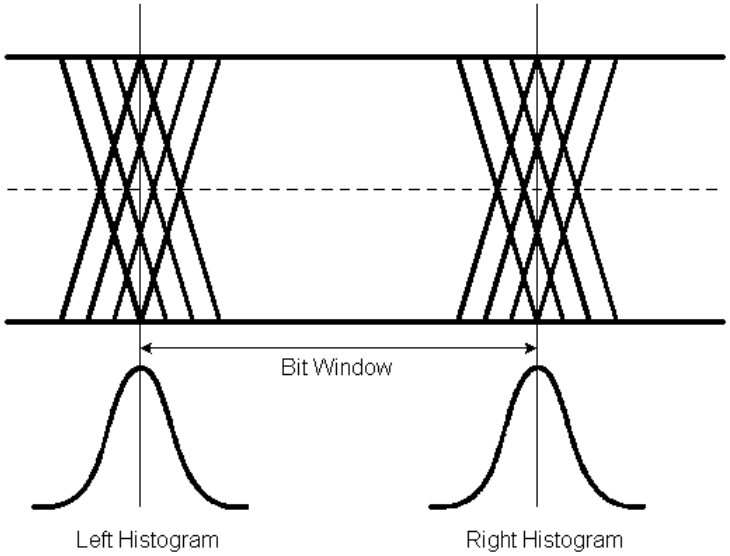

Figure 48B–1—Eye Diagram sketch

The histograms represent probability density functions (PDFs) of the jitter and statistically describe the locations in time of the transitions. The PDFs are placed with their means at the ideal transition times of the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

logic states. To simplify matters, the time scale is given in terms of unit intervals (UI) with 0.5 located at the exact center of the eye. The means of the two PDFs are at 0 and +1 UI.

Ideally, the receiver samples the eye at the center where the tails of the transition histograms are small, as shown in Figure 48B–2. To calculate the probability of either transition causing an error due to jitter, the area under its PDF tail on the errored side of the sample point (time) has to be calculated. This is the complementary cumulative distribution function, or CDF. For the left hand PDF, the tail is integrated from to the sample point to $+\infty$; the right hand PDF's tail is integrated from $-\infty$ to the sample point. The overall probability of transition error is the sum of the two CDFs. It is assumed that the tails of the neighboring bits do not contribute to the probability of error.

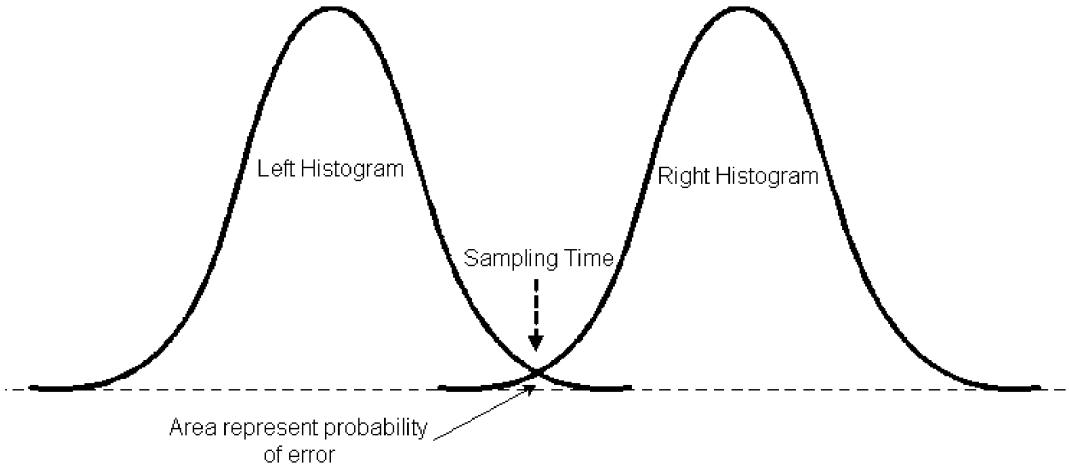

Figure 48B–2—Eye sampling and probability of error

To determine the BER, the probability of a transition-caused error is multiplied by the probability of a transition occurring. Nominally, the latter may be seen as the average transition density. This model assumes typical data streams have a transition density of 50%.

To demonstrate these concepts, define a general jitter PDF, $JT(\tau, W, \sigma)$, centered at 0, where τ is time, W is the peak-to-peak value of deterministic jitter, and σ is the rms value of random jitter. The left PDF histogram (centered at 0) causes bit errors as:

$$BER_{left}(\tau_{sample}, W, \sigma) = \Gamma_{transistion} \cdot \int_{\infty}^{\tau_{sample}} JT(\tau, W, \sigma)\delta\tau \tag{48B-1}$$

where τ_{sample} is the sampling instant in time, and $\Gamma_{transistion}$ is the transition density. Similarly, the right PDF histogram (shifted and centered at 1 UI) causes bit errors as

$$BER_{right}(\tau_{sample}, W, \sigma) = \Gamma_{transistion} \cdot \int_{-\infty}^{\tau_{sample}} JT(\tau - UI, W, \sigma)\delta\tau \tag{48B-2}$$

The sum of these two functions provides the total (BER) due to jitter,

$$BER_{total}(\tau_{sample}, W, \sigma) = BER_{left}(\tau_{sample}, W, \sigma) + BER_{right}(\tau_{sample}, W, \sigma) \tag{48B-3}$$

In the BERT scan, BER is measured as the sample point, τ_{sample}, is swept between the two eye crossings. The probability of error as a function of the sample point is commonly known as a BER bathtub curve.

48B.1.2 Random Jitter

For random or Gaussian jitter (RJ) only the standard deviation, σ, is necessary to define the PDF

$$RT(\tau, \sigma) = \frac{1}{\sqrt{2\pi}} \cdot \frac{1}{\sigma} \cdot e^{-\left(\frac{\tau^2}{2\sigma^2}\right)} \tag{48B-4}$$

The CDF for this Gaussian PDF function is the complementary error function (erfc).

48B.1.3 Addition of Deterministic Jitter

Total jitter is composed of both random and deterministic components. The DJ component can be defined, as for RJ, by a PDF, where the combined total jitter PDF is a convolution of the DJ and RJ PDFs.

Simple peak-to-peak is insufficient as the measurement of DJ. An overall weighting function that captures not only the peak-to-peak but also the shape of the density function is required. This may be known as "effective DJ." For purposes of simplicity, effective DJ in this annex is based on the dual Dirac function, where it is assumed that the DJ PDF is comprised only of a pair of delta functions. Other PDFs are certainly possible, however, in the prediction of low BERs, this simplification is sufficient. All references to DJ in Clauses 47 and 53 should be understood as effective DJ.

An example of effective DJ is duty cycle distortion (DCD), which when convolved with RJ results in two Gaussian functions, one centered at each of the two delta functions.

The magnitude of the DJ, is given as peak-to-peak amplitude, *W*. Therefore, each delta function is offset from the mean crossing position by the peak value of DJ, *W*/2. The PDF for deterministic jitter, centered at 0, is therefore defined as:

$$JT(\tau, W, \sigma) = \frac{\delta\left(\tau, -\frac{W}{2}\right)}{2} + \frac{\delta\left(\tau, \frac{W}{2}\right)}{2} \tag{48B-5}$$

When convolved with random jitter, the PDF, centered at 0, becomes:

$$JT(\tau, W, \sigma) = \frac{1}{2\sqrt{2\pi}} \cdot \frac{1}{\sigma} \cdot \left(e^{-\left(\frac{\left(\tau - \frac{W}{2}\right)^2}{2\sigma^2}\right)} + e^{-\left(\frac{\left(\tau + \frac{W}{2}\right)^2}{2\sigma^2}\right)} \right) \tag{48B-6}$$

48B.1.4 Effects of jitter high-pass filtering and CJPAT on deterministic jitter

It is understood that CDRs track low-frequency jitter, and that including this effect in the specifications could ease requirements on clock oscillators (lower cost designs tend to exhibit low-frequency RJ), serializer (SERDES, same advantage) designs and switching power supplies, layouts, bypassing, etc. All jitter specifications include the effects of a high-pass filter (to suppress the significance of low-frequency jitter) to emulate CDR tracking.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

It is also realized that, due to frequency content, long complex patterns cause phenomena that are not observed with short patterns—data dependent jitter (DDJ, a form of DJ) can have extreme ranges of frequency content from well below to well above the CDR corner frequencies. Effects are usually seen in both transmitters and receivers. Jitter test patterns are specified in Annex 48A.

48B.2 Jitter tolerance test methodologies

An important measurement in determining link integrity is the characterization of a receiver's (i.e., CDR's) ability to tolerate jittered inputs yet recover error-free data. This is accomplished by inputting a well-controlled, jittered signal to a CDR while measuring the BER at the output of the CDR. As the source signal is modified in amplitude and spectral content, the change in BER is measured. This subclause describes some useful test methodologies for testing a receiver's jitter tolerance.

48B.2.1 Calibration of a signal source using the BERT scan technique

The jitter model described in 48B.1 can be used to calibrate the signal source for tolerance measurements as well as to provide a method for extrapolating lower BER. In this approach, curve fitting of the dual Dirac model onto bathtub curves derived from BERT Scans give the jitter content.

Figure 48B–3 shows an example of how to generate controlled amounts of jitter in a signal to be used for tolerance measurement.[276] Three sources of jitter are provided: Deterministic (DDJ and sinusoidal (SJ)) and Gaussian (RJ). Each of these is added to the serial signal generated by a BERT Pattern Generator. A sinewave generator modulates the clock to the Pattern Generator to provide Sinusoidal jitter modulation from 10 Hz to 20 MHz. A filter or cable adds deterministic jitter. A white noise source[277] with a bandwidth greater than 500 MHz[278] is added to the signal to provide random jitter.

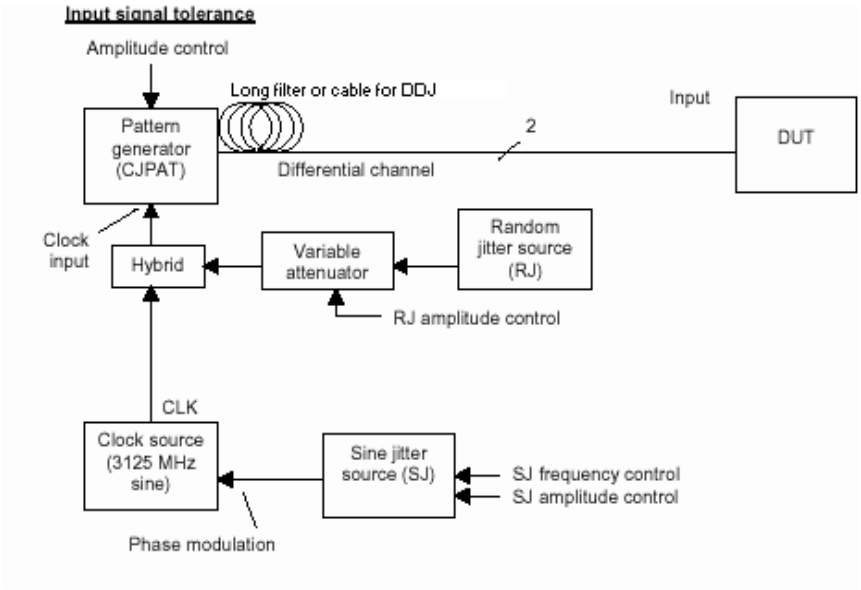

Figure 48B–3—BERT Jitter Tolerance Source

[276]Beware of instrument noise floors and data dependencies, as these may lead to test signals with less stress than intended.

[277]RJ has to be Gaussian and not clipped out to >BER being tested (spec is 1E-12). Simply measuring the rms value does not guarantee that the tails exist and that the Rx will be sufficiently stressed as specified.

[278]The spectrum of the portion of RJ that is calibrated has to be from greater than 20MHz. The sketch as shown assumes the pattern generator passes clock input jitter through to the data with >>20 MHz BW. This may not be the case. The RJ spectrum need not be white above 20 MHz, but a wider spectrum is preferred.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Amplitude calibration is not possible on a scope due to the low probability of the peak-to-peak RJ effects. For better visibility for amplitude calibration, the RJ portion may be temporarily replaced with an equivalent amount of peak-to-peak SJ to bring TJ up to the same specified output jitter level, allowing the desired amplitude value to be met.[279,280]

If the clock data recovery circuit of the system under test has a corner frequency above the maximum sine wave generator frequency, be sure to increase the amount of the applied deterministic jitter by the amount of the specified high-frequency value sinusoidal jitter.

When calibrating the jitter tolerance test setup, the effects of high pass filtering in the time/jitter domain need to be understood and included per the specifications. Per 48B.1.4, high pass filtering can have profound effects on pattern dependent jitter (it will increase measured DJ with patterns such as CJPAT) and also track out jitter below the specified corner frequency. [281]

After complete, calibration has to be verified using the methods described in 48B.3 and iterated as needed until the required specifications are met.

It should be noted that the XAUI is a differential input and calibration of the test signal is performed using the differential signal. If test equipment only provides single-ended possibilities, care should be taken to calibrate and test with a balun to convert differential signals to single-ended signals. Single-ended signals should not be directly used, due to the possibility of asymmetric characteristics.

48B.3 Jitter output test methodologies

Three viable methodologies for measuring jitter output are described in this subclause. They are as follows:

a) Time domain measurement using an oscilloscope to characterize the data eye.
b) Time domain measurement using BERT scan by moving of the data sampling point within the data eye.
c) Time interval analysis based on accurate measurement of the time interval between threshold crossings of the transmitter waveform;

48B.3.1 Time domain measurement—Scope and BERT scan

It is easy to grasp that if the eye is larger than the eye mask, it has to be ok. This is not necessarily true. Given the probabilistic nature of random jitter, it is necessary either to test for an extended amount of time to reach a high confidence level for achieving 1×10^{-12} BER or to perform some kind of statistical extrapolation.

48B.3.1.1 Jitter high pass filtering (using Golden PLL)

Due to the issues mentioned in 48B.1.4, when testing either at the component level or the system level, the test clock should be derived from the data with a given high-pass filter function of the jitter using, for example, a golden PLL.

[279]Amplitude calibration should be done before addition of SJ, as SJ is designed to add margin into the design. This footnote is not referring to the suggestion of temporarily substituting SJ and RJ during amplitude calibration, but to the SJ that is required as part of the specifications.
[280]It may be required to add amplification to achieve the required test signal amplitude.
[281]Beware of autocorrelation effects.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Given a typical test setup, the serial bit pattern is transmitted to the input of a BERT and a golden PLL. The golden PLL extracts a reference clock to trigger the sampling scope or clock the BERT.

48B.3.1.2 Time domain scope measurement

Time domain measurement uses the high-speed sampling scopes to view the jitter output data eye. Most high-speed sampling scopes today provide features to collect and present data on the output jitter. Some oscilloscopes provide a feature to compare the measured data to an "eye mask." An eye mask is a specification for allowed eye opening. The advantage of an eye mask is that it tests for amplitude as well as timing compliance. The general physical media transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram at any of the compliance measurement points. These characteristics include rise time, fall time, pulse overshoot, pulse undershoot, and ringing, all of which prevent excessive degradation of the receiver sensitivity. For the purpose of an assessment of the transmit signal, it is important to not only consider the eye opening, but also the overshoot and undershoot limitations. The parameters specifying the mask of the transmitter diagram (eye mask) can be found in the clause of the applicable Physical Layer specification whether it be copper or fiber physical media. The eye mask, through its use of a specified time range in which the transmit signal can change state from the logic low to logic high levels, is also specifying a measure of the allowed jitter.

It is strongly advised not to use the eye mask to verify that total jitter is within specification because of the nature of the test. The eye mask test is generally a short test, and thus the eye diagram is not captured for a sufficient time to capture the full extent of the random jitter's peak-to-peak value. It is necessary to capture the eye pattern for a sufficient period to insure the full extent of the deterministic jitter is captured by the test instrument. Since the peak-to-peak of the random jitter for a BER of 1×10^{-12} is 14 times the sigma, it is not possible to capture the full extent of random jitter's peak-to-peak value due to the low sampling rate.

48B.3.1.3 BERT scan

As implied by the jitter model in 48B.1, a BERT scan approach can provide random and deterministic jitter components and provides a mechanism to extrapolate to lower BER (less than 1×10^{-12}) without impossibly long test times due to the inherent high sampling rate.

48B.3.1.3.1 Approximate curve-fitting for BERT scan

48B.3.1.3 describes a technique for using a BERT scan to determine eye opening and jitter. For highest accuracy, the bathtub curve should be measured over a high number points at low BER and curve-fitted with a least-squares method to estimate equivalent DJ, RJ, and TJ values. However, a simple and fast method for estimating these values may be applied using only two measurement points.

The following steps describe a process for estimating equivalent RJ, DJ, and TJ values from a two point BERT scan measurement:

a) Measure the eye opening at 2 different BER, BER_0 @τ_0 and BER_1 @τ_1 (e.g., 10^{-9} and 10^{-5}).

b) For each BER_n, determine the associated Q_n from the inverse normal cumulative probability distribution, adjusted for transition density, e.g., $Q = 3.94$ for BER = 10^{-5}, and $Q = 5.77$ for BER = 10^{-9}, where transition density is assumed to be 0.5.

c) Calculate the individual jitter components using the equations for Random Jitter and Deterministic Jitter, and then calculate the total jitter for the given BER = 10^{-12}, using the following three equations:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Random Jitter—

$$RJ_{RMS} = 0.5\left|\frac{t_1 - t_0}{Q_1 - Q_0}\right| \quad (48B\text{-}7)$$

Deterministic Jitter—

$$DJ = UI - t_0 - (2Q_0 RJ_{RMS}) \quad (48B\text{-}8)$$

Total Jitter—

$$TJ = DJ + 13.8 \cdot RJ_{RMS} \quad (48B\text{-}9)$$

The minimum value for measured BER is constrained by test time (10 errors are suggested as an absolute minimum to get reasonable statistical confidence); the maximum value is constrained by potential departure of actual results from the assumed curve fit shape (BER = 10^{-5} should be the maximum value used).

48B.3.2 Time Interval Analysis

Time Interval Analysis (TIA) uses many accurate, single-shot, edge-to-edge time measurements. The statistics of these measurements can be used to perform jitter calculations. True random jitter (RJ) and true deterministic jitter (DJ) can be measured using this technique on repeated patterns as well as random data streams. From the true RJ and DJ measurements, an error probability density function, or bathtub curve can be generated. Using the bathtub curve, effective DJ and effective RJ can be calculated. There are two measurement methods defined for executing this test:

a) TIA with Golden PLL
b) TIA armed on pattern trigger

Each method uses the basic TIA methodology, but with different schemes for acquiring the data. In the first method, the TIA is used with a Golden PLL, as described in 48B.3.1.1, and time measurements are made from the recovered reference clock to the data transitions. The low-frequency content that would be tracked by the receiver is presented on the reference clock, and thus eliminated from the jitter data before being presented to the TIA. The second method is used to acquire data when a Golden PLL is not available, or, when jitter on just the data is desired. This method requires a pattern trigger to synchronize the jitter measurements relative to a specific location in the pattern. The TIA can extract the pattern trigger from the data based on a unique bit sequence or pattern length.

48B.3.2.1 TIA with Golden PLL

In this option, a Golden PLL is required to provide a reference clock derived from the data stream to trigger the TIA. This scheme effectively removes low-frequency content from the measured data in a manner similar to that done in a receiver. The configuration used for this option is shown in Figure 48B–4 (note that only a single channel is shown). The Golden PLL in Figure 48B–4 is shown with a differential input; other approaches are possible, but it is important that the balance of the data signals is not disturbed and that both phases are included in clock recovery. A Golden PLL is used for each data signal so as to ensure proper CDR modeling on each data signal. Each Golden PLL is intended to track low-frequency jitter content occurring on the data signal applied to the input stage of that PLL. It cannot be assumed that the clock extracted from one data signal can be used for the other signals since the low-frequency jitter content may be different. Some TIA models have this algorithm integrated internally in the instrument, and some TIA models have integrated Golden PLL or high-pass filtering algorithms.

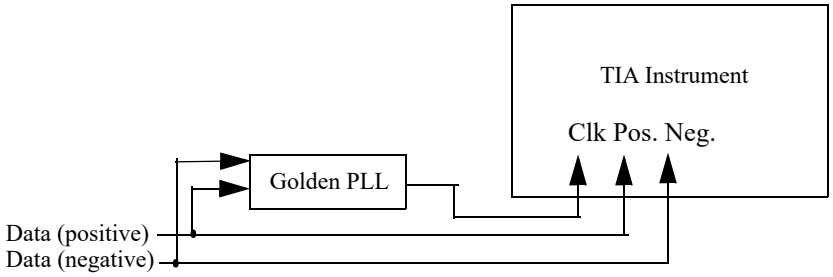

Figure 48B–4—TIA with Golden PLL configured for jitter measurement

48B.3.2.1.1 Test method

The TIA is capable of measuring the time from the data transitions to the reference clock as extracted with the Golden PLL. This results in a clock to data histogram that describes the jitter occurring on the data transitions relative to the reference clock (as is the case with a bit clock triggered BERT measurement). RJ can be estimated by fitting a Gaussian curve to the tail region of the histogram. DJ can be estimated by measuring the separation of the means of the fitted Gaussian curves. Some sampling TIA instruments have built in algorithms specifically designed for this process, and can automatically estimate RJ, DJ, and TJ in this configuration. Figure 48B–5 shows a typical clock to data histogram for a communication signal. Note the highlighted curves that represent the fitted Gaussian curves. Also note that the rising edges are treated separately from the falling edges so as to accurately group the jitter contributors. This is critical in cases where the cross point of the data signal is not at the measured voltage. In Figure 48B–5, the rising edge histogram is shifted to the right of the falling edge histogram, indicating that the cross point was below the test voltage. The outer most histogram on a given side is used for the RJ and DJ calculations for that side of the histogram. Each side is treated independently.

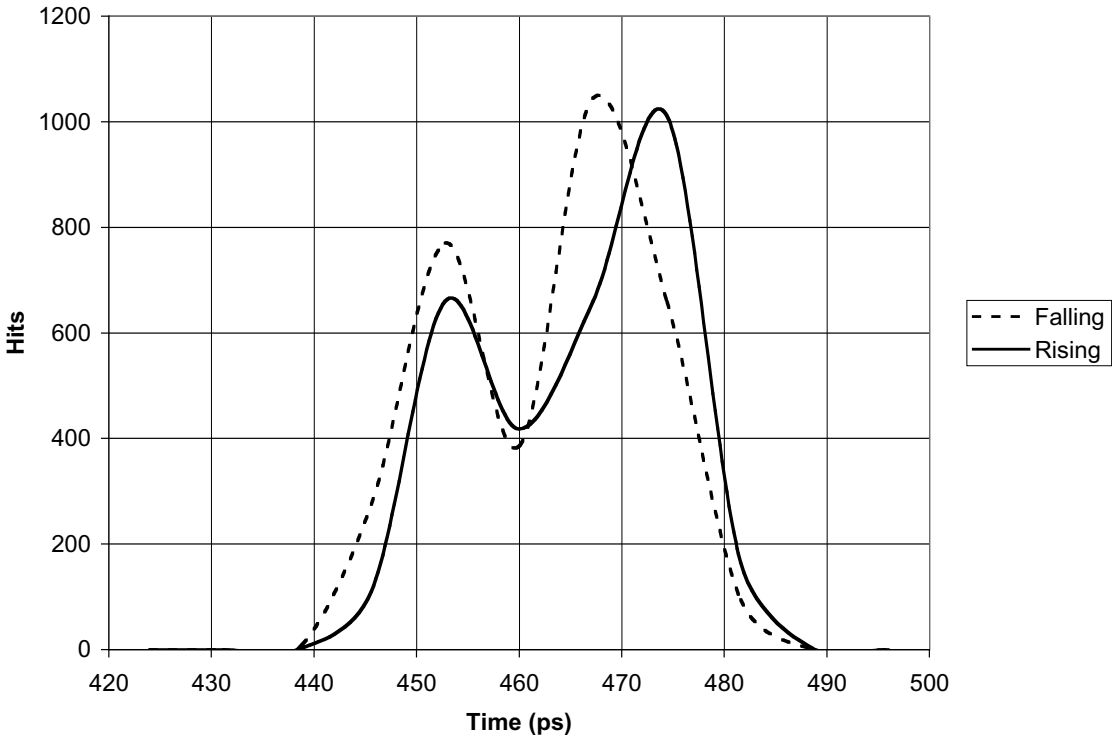

Figure 48B–5—Typical clock to data histogram with fitted Gaussian curves

Jitter values such as DJ, RJ, and TJ can also be displayed on the plot corresponding to 1E-12 BER as shown in Figure 48B–5. Effective Jitter is calculated from the bathtub curve using the same calculations used by the BERT scan method described in 48B.3.1.3.1. To quantify the quality of the measurement, a goodness of fit calculation can be made which compares the quality of the fit of the Gaussian to the actual histogram. Acceptable goodness-of-fit values (χ) for probability confidence level (approximately 1E-4) should be in the range of $0.8 < \chi < 1.2$. The measured DJ and TJ values using this method can be compared against the maximum jitter as specified.

48B.3.2.2 TIA with pattern trigger

The basic setup for this option is shown in Figure 48B–6 (note that only one channel is shown). The pattern trigger can be generated internally to the TIA based on the identification of a unique bit sequence within the data stream or pattern length of the repeated pattern. No measurements are made from the pattern trigger. All measurements are made within the data signal thereby eliminating any error attributed to the bit clock. The high-pass filter characteristic of the Golden PLL is applied using a DSP algorithm thereby eliminating the need for external hardware. Some TIA instruments have this algorithm fully integrated.

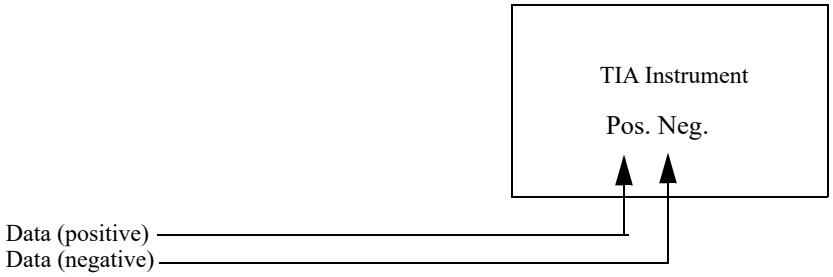

Figure 48B–6—TIA with pattern trigger configured for jitter measurement

48B.3.2.2.1 Test method

All time measurement are made from the same reference edge within the data pattern. This edge is identified by the pattern trigger. Thousands of measurements are made of each transition within the data pattern relative to the reference edge. Histograms for each transition are captured from this data. An FFT of the autocorrelation algorithm of the variance information from these histograms is used to extract SJ. Using the tail fit algorithm described in 48B.3.2.1.1, RJ is measured from each of these histograms and the results plotted in the FFT display. The RJ, bounded by the high-pass filter function is calculated from the FFT of the autocorrelation function. Data dependent jitter is measured from the histograms of each transition based on the displacement of each histogram mean relative to integer multiples of the measured bit period. TJ is calculated and the bathtub curve generated based on the convolution of the RJ PDF, DDJ PDF, and the SJ PDF. This method directly measures the DJ PDF and thereby does not need to assume that the DJ PDF is a dual Dirac function. Effective DJ and Effective RJ is calculated from the bathtub curve using the same formulas used for the BERT scan method, thereby ensuring correlation. Some TIA instruments have this algorithm fully integrated, simplifying the measurement methodology.

48B.3.2.3 Approximate curve fitting for TIA bathtub curve

Since the TIA is capable of measuring true DJ and its probability density function (PDF), the TIA can accurately display total jitter (TJ) as a function of BER in the form of an error probability density function, or bathtub curve. From the Error PDF, the effective DJ can be estimated using the same curve fit technique described in 48B.3.1.3.1.

Annex 50A

(informative)

Thresholds for Severely Errored Second calculations

This annex provides tables of threshold values that may be used to determine the generation of Section, Line and Path Severely Errored Second (SES) events for various error ratios. An SES event is deemed to have occurred when the number of bit errors, detected via the corresponding Bit Interleaved Parity (BIP) check, exceeds some predefined threshold value when accumulated over a 1 s interval; reporting of an SES event indicates that the actual bit error ratio on the medium has increased to a point where Station Management has to be notified. These threshold values are referred to as *x* in the Layer Management definitions in Clause 30. This annex also defines the terms “Path Block Error” and “Far End Path Block Error.”

The values in these tables are derived according to the algorithms given in Annex C of ANSI T1.231-1997.

50A.1 Section SES threshold

The Section SES threshold is referenced as *x* in 30.8.1.1.3.

Table 50A–1 gives the values to be used for the Section SES threshold in order to report Section SES events at various limiting bit error ratios. A BER of 10^{-6} corresponds to the default Section SES threshold of 8554 in 30.8.1.1.3.

Table 50A–1—Section SES

BER	Threshold, *x*
10^{-6}	8554
10^{-7}	980
10^{-8}	99
10^{-9}	10
10^{-10}	1

50A.2 Line SES threshold

The Line SES threshold is referenced as *x* in 30.8.1.1.11.

Table 50A–2 gives the values to be used for the Line SES threshold in order to report Line SES events at various limiting bit error ratios. A BER of 10^{-6} corresponds to the default Line SES threshold of 9835 in 30.8.1.1.11.

50A.3 Path SES threshold

The Path SES threshold is referenced as *x* in 30.8.1.1.19.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 50A–2—Line SES

BER	Threshold, *x*
10^{-6}	9835
10^{-7}	984
10^{-8}	98
10^{-9}	10
10^{-10}	1

Table 50A–3 gives the values to be used for the Path SES threshold in order to report Path SES events at various limiting bit error ratios. The default Path SES threshold of 2400 in 30.8.1.1.19 corresponds to a situation where 30% of all the SPEs being received have parity errors detected via the Path BIP checks.

Table 50A–3—Path SES

Fraction of SPEs with parity errors	Threshold, *x*
30%	2400
25%	2000
20%	1600
15%	1200
10%	800

50A.4 Definition of Path Block Error

A Path Block Error (see Section 8.1.1.1.2 of ANSI T1.231-1997) is declared when one or more of the 8 BIP-8 parity bits that are computed over the received Synchronous Payload Envelope, and compared to the B3 octet of the Path Overhead, are found to be in error. At most one Path Block Error can be declared per WIS frame (i.e., a maximum rate of 8000 counts per second), regardless of the actual number of parity errors detected using a particular B3 octet.

50A.5 Definition of Far End Path Block Error

A Far End Path Block Error is declared when the G1 octet extracted from a received WIS frame indicates that the far end WIS has detected one or more BIP-8 parity errors in the SPE of a previously transmitted WIS frame. The far end WIS reports these parity errors via the REI-P field of the G1 octet. At most one Far End Path Block Error can be declared per received WIS frame (i.e., a maximum rate of 8000 counts per second), regardless of the actual number of parity errors reported in the REI-P field of a particular G1 octet.

Annex 55A

(normative)

LDPC details

55A.1 Generator matrix

The generator matrix, G, uniquely specifies the mapping of information bits to codewords. G.txt contains a representation of G. G.txt contains 1723 rows, one for each row of G. Each row has numbers ranging from 0 to 2047 separated by spaces. Each number represents the column index of the "1" entries in the specific row. All other entries of G are "0" and are not referenced in G.txt. G.txt is available online in the file matrices.zip.[282]

55A.2 Sparse parity check matrix H

Codewords that are generated using G are in the null space of a sparse parity check matrix H. The H matrix is available in machine readable format in file H.txt. This H matrix was obtained by permuting the columns of another sparse matrix using the permutations specified in col_swap.txt. The file row_swap.txt describes row permutations of H that can put it in pseudo-lower triangular form.[282]

For further information on LDPC codes, see Gallagher [B26].

Annex 55B

(informative)

Additional cabling design guidelines for 10GBASE-T

This annex provides additional cabling guidelines for 10GBASE-T deployment on balanced copper cabling systems as specified in 55.7. These guidelines are intended to supplement those in Clause 55.

55B.1 Alien crosstalk considerations

The noise coupled between the adjacent link segments illustrated in Figure 55B–3 and Figure 55B–4 is referred to as alien crosstalk (Figure 55B–1).

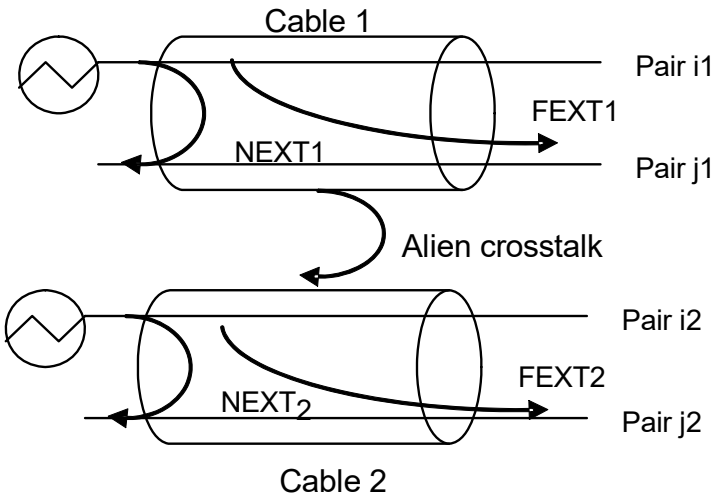

Figure 55B–1—Alien crosstalk coupling between link segments

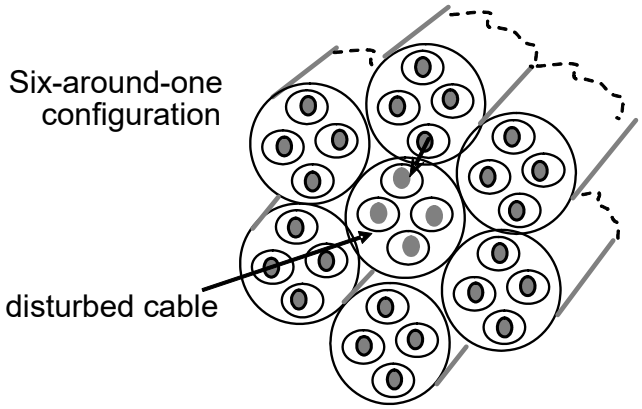
The alien crosstalk noise levels are dependent on the number and proximity of adjacent cables and connectors. The alien crosstalk link segment specifications of PS ANEXT and PS AELFEXT given in 55.7 are based on the alien crosstalk measurements between cabling channels configured in a six-around-one orientation where the disturbed cable is the central cable and adjacent to all of the other disturbing cables. The alien crosstalk coupling between a cable and six adjacent cables tightly bound in a six-around-one configuration exhibits a “worst case”.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



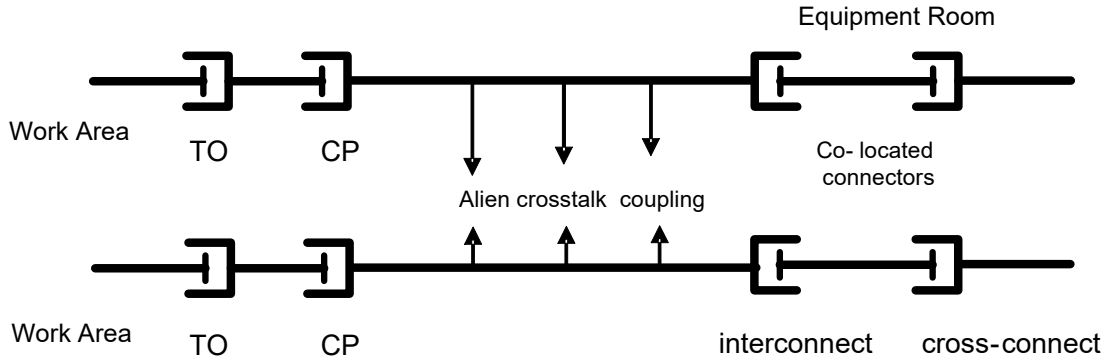


Figure 55B–2—Six-around-one cable configuration

The alien crosstalk coupling is a function of the distance between the cabling components. Removing or loosening cable bindings, separating equipment and patch cordage, and utilizing non-adjacent connectors all have a significant impact on reducing the levels of alien crosstalk noise.

In many topologies, the cables are only bundled together for relatively short distances and laid in cable trays. The star wiring topology, where the cables are distributed radially from a centralized telecommunication closet to each work area, reduces the distances over which link segments are in close proximity.

55B.1.1 Alien crosstalk mitigation

10GBASE-T is designed to operate over a channel that meets the specifications of 55.7 and the channel configuration shown Figure 55B–3. However, if the channel specifications of 55.7 cannot be met when using the channel configuration shown in Figure 55B–3, the configuration shown in Figure 55B–4 is recommended. This optimized channel for a 10GBASE-T link segment deletes the consolidation point or optional transition point and runs an equipment patch cord directly between the LAN equipment and the connector termination of the permanent link. This reduces the number of connectors and cordage and their associated alien crosstalk.

CP = consolidation point connector
TO = telecommunication outlet connector

Figure 55B–3—Maximum horizontal cabling configuration

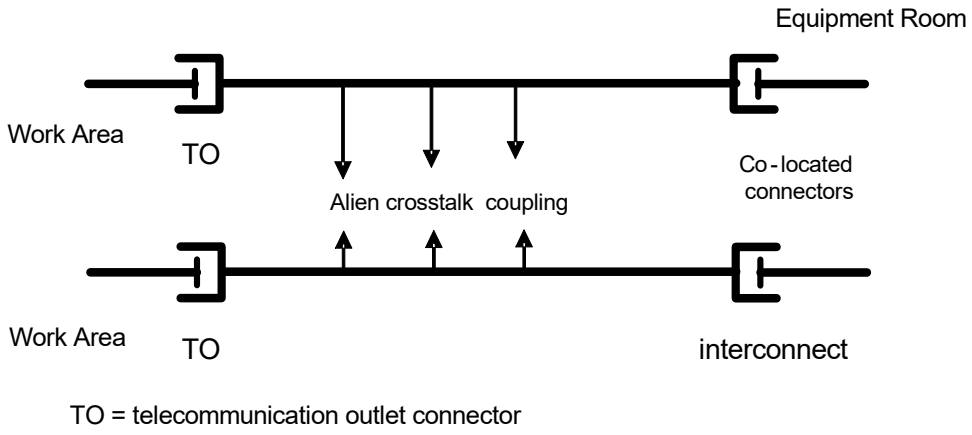

Figure 55B–4—Minimum horizontal cabling configuration

55B.1.2 Alien crosstalk mitigation procedure

This annex provides procedures and cabling guidelines designed to mitigate the alien crosstalk in the event that the alien crosstalk transmission parameters given in 55.7 are not met. For more information on mitigation techniques, see TIA TSB-155-A and ISO/IEC TR 24750.

The mitigation actions outlined below are based on four connector channels. In the majority of initially non-compliant cases, fewer than all corrective actions are required. Select the option(s) that is most appropriate for your situation.

a) When selective deployment of 10GBASE-T is possible, non-adjacent patch panel positions in the equipment room should be used. The adjacent positions may be used for other applications.
b) Reduce the number of co-located connectors by implementing an interconnect configuration to attach equipment to the horizontal cabling rather than a cross-connect. In general, connectors and cordage in the work area are not co-located.
c) Reduce the alien crosstalk coupling in the first 5 m to 20 m of the horizontal cabling by separating the equipment cords and the patch cords and un-bundling the horizontal cabling: in the case of a telecommunications room un-bundle the cabling to the point it exits the telecommunications room. A significant portion of the ANEXT coupling occurs in less than the first 20 m of cabling.
d) An alternative to separating equipment cords is to utilize equipment cords sufficiently specified to mitigate the alien crosstalk coupling.
e) Replace connectors with Category 6A/Class E_A.

Annex 57A

(normative)

Requirements for support of Slow Protocols

57A.1 Introduction and rationale

There are two distinct classes of protocols used to control various aspects of the operation of IEEE 802.3 devices. They are as follows:

a) Protocols such as the MAC Control PAUSE operation (Annex 31B) that need to process and respond to PDUs rapidly in order to avoid performance degradation. These are likely to be implemented as embedded hardware functions, making it relatively unlikely that existing equipment could be easily upgraded to support additional such protocols.

   NOTE—This consideration was one of the contributing factors in the decision to use a separate group MAC address to support LACP and the Marker protocol, rather than re-using the group MAC address currently used for PAUSE frames.

b) Protocols such as LACP, with less stringent frequency and latency requirements. These may be implemented in software, with a reasonable expectation that existing equipment be upgradeable to support additional such protocols, depending upon the approach taken in the original implementation.

In order to place some realistic bounds upon the demands that might be placed upon such a protocol implementation, this annex defines the characteristics of this class of protocols and identifies some of the behaviors that an extensible implementation needs to exhibit.

57A.2 Slow Protocol transmission characteristics

Protocols that make use of the addressing and protocol identification mechanisms identified in this annex are subject to the following constraints:

a) The number of frames transmitted in any one-second period per Slow Protocol subtype shall not exceed aSlowProtocolFrameLimit (see 30.3.1.1.38).
b) The maximum number of Slow Protocols subtypes is 10.
c) The MAC Client data generated by any of these protocols shall be no larger than maxBasicDataSize (see 4.2.7.1). It is recommended that the maximum length for a Slow Protocol frame be limited to 128 octets.

The effect of these restrictions is to restrict the bandwidth consumed and performance demanded by this set of protocols; by default the maximum traffic loading that would result is 100 maximum length frames per second per point-to-point link and 100 maximum length frames per ONU for point-to-multipoint topologies.

57A.3 Addressing

The Slow_Protocols_Multicast address has been allocated exclusively for use by Slow Protocols PDUs; its value is identified in Table 57A–1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 57A–1—Slow_Protocols_Multicast address

Name	Value
Slow_Protocols_Multicast address	01-80-C2-00-00-02

NOTE 1—This address is within the range used by IEEE Std 802.1Q for link-constrained protocols. As such, frames sent to this address will not be forwarded by conformant MAC Bridges; its use is restricted to a single link.

NOTE 2—Although the two currently existing Slow Protocols (i.e., LACP and the Marker protocol) always use this MAC address as the destination address in transmitted PDUs, this may not be true for all Slow Protocols. In some yet-to-be-defined protocol, unicast addressing may be appropriate and necessary. Rather, the requirement is that this address not be used by any protocols that are not Slow Protocols.

57A.4 Protocol identification

All Slow Protocols use type interpretation of the Length/Type field, and use the Slow_Protocols_Type value as the primary means of protocol identification; its value is shown in Table 57A–2.

Table 57A–2—Slow_Protocols_Type value

Name	Value
Slow_Protocols_Type	88-09

The first octet of the MAC Client data following the Length/Type field is a protocol subtype identifier that distinguishes between different Slow Protocols. Table 57A–3 identifies the semantics of this subtype.

Table 57A–3—Slow Protocols subtypes

Protocol Subtype value	Protocol name
0	Unused—Illegal value
1	Link Aggregation Control Protocol (LACP)
2	Link Aggregation—Marker Protocol
3	Operations, Administration, and Maintenance (OAM)
4	Reserved for future use
5	Reserved for future use
6	Reserved for future use
7	Reserved for future use
8	Reserved for future use
9	Reserved for future use
10	Organization Specific Slow Protcol (OSSP)
11–255	Unused—Illegal values

Copyright © 2022 IEEE. All rights reserved.

NOTE—Although this mechanism is defined as part of an IEEE 802.3 standard, it is the intent that the reserved code points in this table will be made available to protocols defined by other working groups within IEEE 802, should this mechanism be appropriate for their use.

57A.5 Handling of Slow Protocol frames

Any received MAC frame that carries the Slow_Protocols_Type field value is assumed to be a Slow Protocol frame. An implementation that claims conformance to this standard shall handle all Slow Protocol frames as follows:

a) Discard any Slow Protocol frame that carries an illegal value of Protocol Subtype (see Table 57A–3). Such frames shall not be passed to the MAC Client.

b) Pass any Slow Protocol frames that carry Protocol Subtype values that identify supported Slow Protocols to the protocol entity for the identified Slow Protocol.

c) Pass any Slow Protocol frames that carry Protocol Subtype values that identify unsupported Slow Protocols to the MAC Client.

NOTE—The intent of these rules is twofold. First, they rigidly enforce the maximum number of Slow Protocols, ensuring that early implementations of this mechanism do not become invalidated as a result of "scope creep." Second, they make it clear that the appropriate thing to do in any embedded frame parsing mechanism is to pass frames destined for unsupported protocols up to the MAC Client rather than discarding them, thus allowing for the possibility that, in soft configurable systems, the MAC Client might be enhanced in the future in order to support protocols that were not implemented in the hardware.

57A.6 Protocol implementation conformance statement (PICS) proforma for Annex 57A, Requirements for support of Slow Protocols[283]

57A.6.1 Introduction

The supplier of an implementation that is claimed to conform to Annex 57A shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

57A.6.2 Identification

57A.6.2.1 Implementation identification

Supplier (Note 1)	
Contact point for inquiries about the PICS (Note 1)	
Implementation Name(s) and Version(s) (Notes 1 and 3)	
Other information necessary for full identification—e.g., name(s) and version(s) of machines and/or operating system names (Note 2)	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

57A.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 57A, Requirements for support of Slow Protocols.
Identification of amendments and corrigenda to the PICS proforma that have been completed as part of the PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21: the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

Annex 57B

(normative)

Organization specific slow protocol (OSSP)

The organization specific slow protocol (OSSP) provides a standardized means for organizations to define their own slow protocols outside the scope of this standard. The requirements defined in Annex 57A apply to these slow protocols.

57B.1 Transmission and representation of octets

An organization specific slow protocol data unit (OSSPDU) comprises an integral number of octets. The bits in each octet are numbered from 0 to 7, where 0 is the least significant bit. When consecutive octets are used to represent a numerical value, the most significant octet is transmitted first, followed by successively less significant octets.

57B.1.1 OSSPDU frame structure

The OSSPDU frame structure shall be as depicted in Figure 57B–1. In this figure:

a) Octets are transmitted from top to bottom.
b) Within an octet, bits are shown with bit 0 to the left and bit 7 to the right, and are transmitted from left to right.
c) When consecutive octets are used to represent a binary number, the octet transmitted first has the more significant value.
d) When consecutive octets are used to represent a MAC address, the least significant bit of the first octet is assigned the value of the first bit of the MAC address, the next most significant bit the value of the second bit of the MAC address, and so on through the eighth bit. Similarly the least significant through most significant bits of the second octet are assigned the value of the ninth through seventeenth bits of the MAC address, and so on for all the octets of the MAC address.
e) OSSPDUs are at least minFrameSize in length.

A OSSPDU shall have the following fields:

f) *Destination Address (DA).* The DA in OSSPDUs is the Slow_Protocols_Multicast address. Its use and encoding are specified in Annex 57A.
g) *Source Address (SA).* The SA in OSSPDUs is the individual MAC address associated with the port through which the OSSPDU is transmitted.
h) *Length/Type.* The Length/Type in OSSPDUs carries the Slow_Protocols_Type field value specified in 57A.4.
i) *Subtype.* The Subtype field identifies the specific Slow Protocol being encapsulated. OSSPDUs carry the Subtype value 0x0A as specified in Annex 57A.
j) *Organizationally Unique Identifier (OUI) or Company ID (CID).* The OUI/CID field contains the OUI or CID to identify the Organization Specific Data. The bit/octet ordering of the OUI/CID field within an OSSPDU is identical to the bit/octet ordering of the OUI portion of the DA/SA.
k) *Organization Specific Data*. The format and function of the Organization Specific Data field is dependent on the value of the OUI/CID field and is beyond the scope of this standard.
l) *FCS.* This field is the Frame Check Sequence, typically generated by the underlying MAC.

57B.2 Protocol implementation conformance statement (PICS) proforma for Annex 57B, Organization specific slow protocol (OSSP)[284]

57B.2.1 Introduction

The supplier of an implementation that is claimed to conform to Annex 57B shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

57B.2.2 Identification

57B.2.2.1 Implementation identification

Supplier (Note 1)	
Contact point for inquiries about the PICS (Note 1)	
Implementation Name(s) and Version(s) (Notes 1 and 3)	
Other information necessary for full identification—e.g., name(s) and version(s) of machines and/or operating system names (Note 2)	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

57B.2.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 57B, Organization specific slow protocol (OSSP).
Identification of amendments and corrigenda to the PICS proforma that have been completed as part of the PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21: the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

Annex 58A

(informative)

Frame-based testing

The use of the frame-based test patterns described in Clause 58, Clause 59, and Clause 60 provides for the most general testing of the external interfaces. They combine patterns appropriate for testing the desired parameters with a flexible frame structure that allows the test pattern to be passed through a compliant system. However, the frame-based nature of the patterns may cause difficulties with some bit oriented test systems if care is not taken.

The concern is that streams of data that are passed through a system under test may have their inter-frame gap altered by rate control mechanisms. This changes the bit sequence, even in the presence of no errors, and causes difficulties with bit sequence oriented test systems. There are several methods of addressing this issue. The solutions fall roughly into the following three categories:

a) Error detection internal to the equipment under test
b) Use of frame-based test equipment
c) Synchronized systems

An example of the first type of test where the internal error detection would be used is a receiver sensitivity test. The input pattern may be generated by any method, including a bit oriented serial pattern generator or a frame-based pattern generator. Errored frames would be rejected internal to the system under test based on FCS errors. This type of test has the advantage of testing all of the components of an input interface. The error count may be made by accessing the error counters internal to the system under test.

The number of bit errors may be assumed to be the same as the number of frame errors to a 90% confidence level as long as frame error ratio is less than 0.2. The bit error ratio may be determined by dividing the frame error ratio by the number of bits in the test frame that are used in the computation of the FCS.

If the internal error counters are not accessible, the test frames may be passed to an output port and the number of received frames may the counted. Any missing frames may be assumed to have had errors. The frame count may be made by conventional frame-based test equipment. The missing frames render the use of bit stream oriented test equipment inappropriate.

When testing transmitter outputs, frames may be passed to the port under test from another port in the system under test. In this case, loss of frames within the system is not expected and testing may be done using a bit oriented test system by making the system synchronous. This may be done by recovering the clock from the output under test and using this as a clock source for the input. If there are no variable delays in the system under test, such as variable queuing delays, the input data stream will be reproduced in the output and conventional Bit Error Ratio Testing (BERT) systems may be used. In the case of 100BASE-X, the output bit stream may be inverted.

Two frame-based alternatives avoid the need for synchronization. The first is to use a frame-based tester for both the pattern generation and the error detection. The optical signal will need to be received by an optical receiver with the proper characteristics for the specific test. The processed data stream would then be sent to the frame-based receiver to determine possible frame errors.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Another method would be to use a bit oriented test system suitable for burst mode operation. This type of tester will examine only the frame contents for errors. Two methods are used for determining the frame contents. An external gating signal may be used. This has to be triggered by the data source and include any latency associated with the system under test. Alternately, the test set may recognize the frame boundaries in the incoming data stream.

As the behavior above the MAC is not specified by this standard, the system under test might not be able to forward, return or respond to incoming frames at line rate. Diluting the frame rate is thought to be acceptable for 1000BASE-X but for 100BASE-X testing, groups of 12 frames should be kept together. A system might emit additional frames from a port and may need to be configured so that it does not.

NOTE—Users are advised to take care that the system under test is not connected to a network in service.

Annex 58B

(informative)

Jitter, OMA, and TDP

58B.1 Jitter at TP1 and TP4 for 100BASE-LX10 and 100BASE-BX10

The entries in Table 58B–1 represent high-frequency jitter (above 20 kHz) and do not include low frequency jitter or wander. The informative Table 58B–1 shows jitter specifications which may be of interest to implementers. High probability jitter at TP2 is constrained by the eye mask. Total jitter at TP3 (and therefore at TP2 also) is constrained by the error detector timing offsets. High levels of high probability jitter at TP2, TP3 and TP4 are expected, caused by high probability baseline wander. The jitter difference between TP2 and TP3 is expected to be lower than for higher speed PMDs.

Table 58B–1—100BASE-LX10 and 100BASE-BX10 jitter budget

[a]	Total jitter		High probability jitter (*W*)	
Reference point	**UI**	**ns**	**UI**	**ns**
TP1	0.09	0.72	0.05	0.40
TP2	0.40	3.2	0.305	2.44
TP3	0.43	3.54	0.305	2.44
TP4	0.51	4.04	0.305	2.44

[a]Informative jitter values are chosen to be compatible with the limits for eye mask and TDP (see 58.7.9). Because of the way the different components may interact, the differences in jitter between test points cannot be used to indicate a performance level of the intervening sections.

Total jitter in this table is defined at 10^{-12} BER. In a commonly used model,

$$TJ_{12} = 14.1\sigma + W \text{ at } 10^{12} \quad (58B–1)$$

The total jitter at 10^{-10} BER may be calculated assuming

$$TJ_{10} = 12.7\sigma + W \quad (58B–2)$$

NOTE—As an example, TJ_{10} at TP1 is 0.085 UI (0.69 ns).

W is similar but not necessarily identical to deterministic jitter (DJ). A jitter measurement procedure is described in 58B.4. Jitter at TP2 or TP3 is defined with a receiver of the same bandwidth as specified for the transmitted eye.

58B.2 OMA relationship to extinction ratio and power measurements

This subclause is intended to inform on how the three quantities OMA, extinction ratio, and mean power, are related to each other.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Optical modulation amplitude (OMA) is the difference between light levels for “1” and “0”. Extinction ratio is the ratio between light levels for “1” and “0”. If a signal contains equal density of “1” and “0” bits, and does not suffer from duty cycle distortion, the mean power is close to the mean of the light levels for “1” and “0”.

$$OMA = P_1 - P_0 \tag{58B–3}$$

OMA may be expressed in Watts or dBm.

$$ER = \frac{P_1}{P_0} \tag{58B–4}$$

Extinction ratio may be expressed in dB, as $10 \times \log_{10} (P_1 / P_0)$, or directly as a ratio. Sometimes extinction ratio is defined as P_0 / P_1.

$$P_{mean} \approx \frac{P_0 + P_1}{2} \tag{58B–5}$$

Mean power may be expressed in Watts or dBm.

P_1 and P_0 are usually measured with a standardized instrument bandwidth to reduce the effects of overshoot. It should be noted that the values of P_1 and P_0 depend on the measurement technique and pattern to be used, which vary with PMD type. For some PMD types, e.g. 10GBASE, different patterns leading to different values of P_1 and P_0 are used for OMA on the one hand, and extinction ratio on the other.

Aside from these differences:

$$P_1 \approx 2 \times P_{mean} \times \frac{ER}{ER + 1} \tag{58B–6}$$

$$P_0 \approx 2 \times \frac{P_{mean}}{ER + 1} \tag{58B–7}$$

$$OMA \approx 2 \times P_{mean} \times \frac{ER - 1}{ER + 1} \tag{58B–8}$$

Receiver sensitivity, which is an optical power, can be expressed in OMA or mean power terms according to the same relations.

NOTE—The OMA relationship to extinction ratio and power measurements applies to Clause 52, Clause 53, Clause 58, Clause 59, and Clause 60.

58B.3 Approximate measures of TDP

Transmitter and dispersion penalty may be considered as a transmitter penalty (TP) followed by a dispersion penalty, which is also attributable to the transmitter. Measurements at TP2 can reveal the transmitter penalty. TP can be related to eye mask margin (MM) as follows.

In the absence of any noise or significant jitter,

$$TP = 10 \times \log_{10}\left(\frac{1}{H}\right) \tag{58B–9}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$MM = \frac{H - M}{1 - M} \quad (58B–10)$$

where H is height of inner eye and M is the height of the central polygon of the mask.

Transmitter noise or noise-like impairments degrade both apparent MM and actual TP. To obtain a useful correlation between the two, MM is defined to an appropriate percentile of measured samples, to give the right weight to this noise; see 58.7.8. Oscilloscope noise degrades apparent MM only. This would distort the correlation, but in many measurement circumstances the error is reduced at the appropriate percentile. The one-dimensional statistics of MM measurement and the hit ratio are related by the frequency of relevant bit patterns in a stream (typically 1/4 of bits are flanked by two opposite bits) and by a factor related to mask dimensions.

This approach could be applied to a situation with combinations of noise of jitter.

It may be feasible to correlate TDP to eye measurements at TP3. However, the signal at TP3 is weaker, so oscilloscope noise is more of a concern.

The following suggestions apply to 100 Mb/s optical PMDs.

In practice it may be necessary to do without the clock recovery unit at 100 Mb/s. Experimentally, timing stability at this rate may be acceptable, and the jitter due to the CRU could be accounted for by adjusting the eye mask length and the TDP decision timing offsets.

A significant component of TDP is baseline wander. A wander of ± OMA/10 will be created by many receivers if it is not already present in the transmitted signal. Higher levels of pattern dependent penalty can in some cases be estimated from the mask margin (if necessary, by ignoring the upper and lower mask regions). The mask margin may also be measured with an AC-coupled measurement instrument with a high-pass filter of 10 kHz. It is likely that compliant implementations will pass the transmitter mask with both DC and AC-coupling. Certain implementations may be characterized by comparing the transmitted signal with the STM-1 mask, using a benign pattern such as PRBS7.

The accuracy of these approaches have not been established by the committee. Oscilloscope measurements at TP3 may be degraded by instrument noise.

58B.4 Jitter measurements

A jitter measurement method for use at 100 Mb/s or 1000 Mb/s is described in this subclause. The measurement is performed after any relevant fiber dispersion (at virtual TP3). The test pattern is specified in 58.7.1 or 59.7.1 as appropriate.

The transmit jitter is tested using a bit error ratio tester (BERT), where the tester scans the eye opening horizontally (varying the decision time) at the average optical power, at a virtual TP3 (hereafter referred to as simply TP3) and measures the bit error ratio at each point in time. The plot of BER as a function of sampling time is called the “bathtub curve.” The channel and receiver are as specified in e.g., 58.7.9.2 and 58.7.9.3. The receiver includes a defined filter function. The test pattern is the same as for receiver sensitivity measurements.

NOTE—The parameter W may also be estimated from jitter histograms using an oscilloscope. Jitter of an optical signal is measured with a test optical receiver with the receiver bandwidth specified (e.g., for eye mask conformance) for the transmitter under test concerned.

The experimental curve is compared with a mask defined by Equation (58B–11) and Equation (58B–12) and illustrated in Figure 58B–1:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\log_{10}(BER) \le A - B\left(\frac{t - 0.5W}{\sigma}\right)^2 \quad (58B–11)$$

$$\log_{10}(BER) \le A - B\left(\frac{1 - t - 0.5W}{\sigma}\right)^2 \quad (58B–12)$$

where:

$$A = -1.75, B = \frac{\log_{10}(e)}{2} \approx 0.217$$

and t is the decision time specified in unit intervals (UI). $t = 0$ at the mean crossing time, which may be estimated as the mid-point between the 10^{-3} BER points.

The BER mask is defined for $10^{-12} < \text{BER} < 10^{-6}$. All points on the BER "bathtub curve" have to fall within the white area or below. It can be seen that in the case of an asymmetric measured bathtub curve, the worse side determines W and σ.

W ("high probability jitter") and deterministic jitter (DJ) are not necessarily the same, but may be similar. The quantity σ can be similar to random jitter (RJ) although it is determined by low probability pattern dependent jitter also. "Total jitter" (TJ) is taken to be $W + 14\sigma$.

.

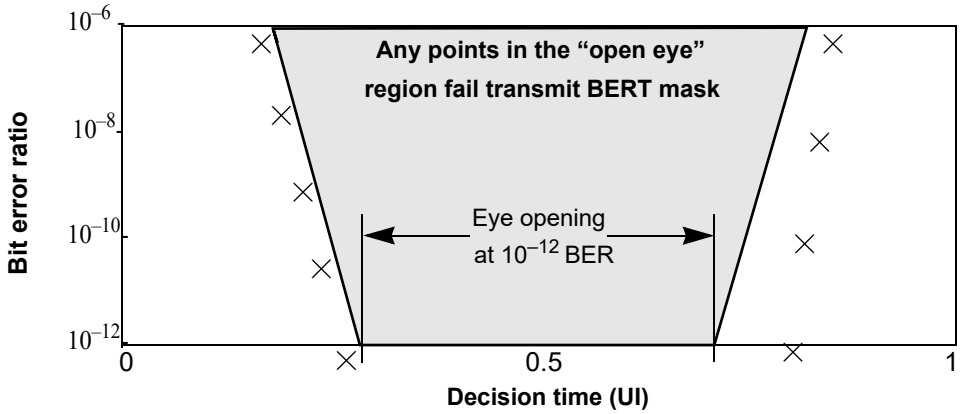

Figure 58B–1—Example transmit BER mask at TP3

NOTE—This jitter measurement method applies to Clause 58, Clause 59, and Clause 60.

Annex 59A

(informative)

Jitter budget and measurements

59A.1 Jitter specifications

The entries for the 1000BASE-LX10 jitter budget on MMF in Table 59A–1 and the 1000BASE-LX10 and 1000BASE-BX10 jitter budget on SMF in Table 59A–2 represent high-frequency jitter (above 637 kHz) and do not include low frequency jitter or wander. All values are informative.

Table 59A–1—1000BASE-LX10 jitter budget on MMF

	Total jitter		*W*	
Reference point	**UI**	**ps**	**UI**	**ps**
TP1	0.240	192	0.100	80
TP1 to TP2	0.284	227	0.100	80
TP2	0.431	345	0.200	160
TP2 to TP3	0.170	136	0.050	40
TP3	0.510	408	0.250	200
TP3 to TP4	0.332	266	0.212	170
TP4	0.749	599	0.462	370

W is similar but not necessarily identical to deterministic jitter (DJ). A jitter measurement procedure is described in 58B.4. Other jitter measurements are described in 59A.2 and 59A.3. Jitter at TP2 or TP3 is defined with a receiver of the same bandwidth as specified for the transmitted eye.

Table 59A–2—1000BASE-LX10 and 1000BASE-BX10 jitter budget on SMF

	Total jitter		*W*	
Reference point	**UI**	**ps**	**UI**	**ps**
TP1	0.240	192	0.100	80
TP1 to TP2	0.334	267	0.150	120
TP2	0.481	385	0.250	200
TP2 to TP3	0.119	95	0	0
TP3	0.510	408	0.250	200
TP3 to TP4	0.332	266	0.212	170
TP4	0.749	599	0.462	370

NOTE—Informative jitter values are chosen to be compatible with the limits for eye mask and TDP (see 58.7.9). A margin between the total jitter at TP4 and the eye opening imposed by the decision point offsets for TDP is intended to allow for the performance of test equipment used for TDP measurement, to avoid very involved jitter calibrations.

Total jitter in this table is defined at 10^{-12} BER. In a commonly used model,

$$TJ = 14.1\sigma + DJ \text{ at } 10^{-12} \quad (59A–1)$$

59A.2 Total jitter measurements

Total jitter measurements may be made according to the method in ANSI INCITS 230-1994 (R1999) (FC-PH), Annex A, A.4.2, or according to 58B.4. Total jitter at TP2 should be measured utilizing a BERT (bit error ratio tester). References to use of the Bessel-Thomson filter should substitute use of the Bessel-Thomson filter defined in 59.7.8. The test should utilize the mixed frequency test pattern specified in 59.7.1.

Total jitter at TP4 should be measured using the conformance test signal at TP3, as specified in 59.7.14. The optical power should be at the stressed receive sensitivity level in Table 59–5 for 1000BASE-LX10 and in Table 59–7 for 1000BASE-BX10. This power level should be corrected if the extinction ratio differs from the specified extinction ratio (minimum). Measurements at TP4 should be taken directly without additional Bessel-Thomson filters.

Jitter measurement may use a clock recovery unit (commonly referred to in the industry as a “golden PLL”) to remove low-frequency jitter from the measurement as shown in Figure 59A–1. The clock recovery unit has a low-pass filter with 20 dB/decade rolloff with –3 dB point of 637 kHz. For this measurement, the recovered clock will run at the signaling speed. The golden PLL is used to approximate the PLL in the deserializer function of the PMA. The PMA deserializer is able to track a large amount of low-frequency jitter (such as drift or wander) below its bandwidth. This low-frequency jitter would create a large measurement penalty, but does not affect operation of the link.

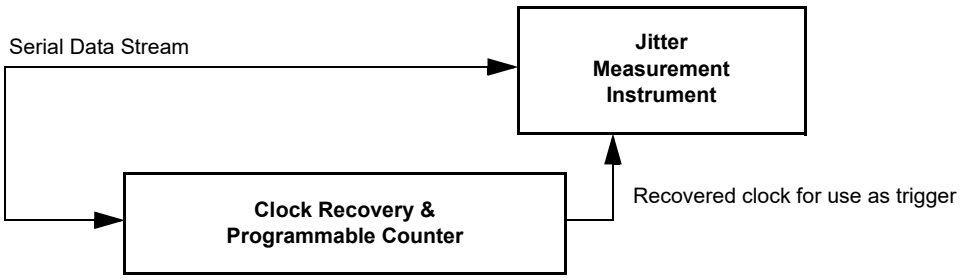

Figure 59A–1—Utilization of clock recovery unit during measurement

59A.3 Deterministic or high probability jitter measurement

Deterministic jitter may be measured according to ANSI INCITS 230-1994 (FC-PH), Annex A, A.4.3, DJ Measurement or high probability jitter may be measured according to 58B.4. The test utilizes the mixed frequency test pattern specified in 36A.3. This method utilizes a digital sampling scope to measure actual vs. predicted arrival of bit transitions of the 36A.3 data pattern (alternating K28.5 code-groups).

It is convenient to use the clock recovery unit described in 59A.2 for purposes of generating a trigger for the test equipment. This recovered clock should have a frequency equivalent to 1/20th of the signaling speed.

Measurements at TP2 and TP3 use the filter specified in 59.7.8, measurements at TP1 and TP4 do not use this filter.

Annex 60A

(informative)

Jitter at TP1 to TP4 for 1000BASE-PX

The entries in Table 60A–1 and Table 60A–2 represent high-frequency jitter (above 637 kHz) and do not include low frequency jitter or wander. They are two sided (peak-to-peak) measures. Table 60A–1 applies to the downstream direction (D to U) while Table 60A–2 applies to the upstream direction (U to D). All values are informative.

Table 60A–1—1000BASE-PX downstream jitter budget

	Total jitter		Deterministic jitter

For the 1000BASE-PX upstream jitter budget, the jitter transfer function is defined by Equation (60A–2) where the value is given in Figure 60A–1 when input sinusoidal jitter according to the mask defined in

Copyright © 2022 IEEE. All rights reserved.

58.7.11.4 and values in Table 60–5, Table 60–8, Table 60–11, and Table 60–13 are applied to the receiver input of the ONU. Two sets of upstream jitter values are defined in Table 60A–2, one set corresponds to testing the upstream link with no jitter on the downstream (jitter generation) and the other set with maximum jitter on the downstream (generated and transferred jitter).

NOTE—Informative jitter values are chosen to be compatible with the limits for eye mask and TDP (see 58.7.9).

Total jitter in this table is defined at 10^{-12} BER. In a commonly used model,

$$TJ = 14.1\sigma + DJ \text{ at } 10^{12} \tag{60A–1}$$

W is similar but not necessarily identical to deterministic jitter (DJ). A jitter measurement procedure is described in 58B.4. Other jitter measurements are described in 59A.2 and 59A.3. Jitter at TP2 or TP3 is defined with a receiver of the same bandwidth as specified for the transmitted eye.

$$\text{Jitter Transfer} = 20\log_{10}\left[\frac{\text{Jitter on upstream signal (UI)}}{\text{Jitter on downstream signal (UI)}}\right] \tag{60A–2}$$

Annex 61A

(informative)

EFM Copper examples

61A.1 Purpose and scope

The purpose of this informative annex is to provide practical examples of the use of

a) Aggregation Discovery, for aggregated operation of 10PASS-TS PHYs (Clause 62) or 2BASE-TL PHYs (Clause 63); see 61A.2.
b) 64/65-octet encapsulation, as specified in 61.3.3; see 61A.3.

61A.2 Aggregation Discovery example

An example procedure for PME aggregation discovery is described for system components as shown in Figure 61A–1, connected as in Figure 61A–2. Additional information on example discovery transactions are shown in Figure 61A–3. An example procedure for discovering this connectivity follows:

a) -O system writes remote_discovery_register to value *alpha* (*alpha* may be any 48-bit value, but would benefit from being locally unique e.g. MAC address) using PME-1.
b) -O system reads remote_discovery_register for all other PMEs.
c) -O system discovers that PME-2, PME-6 and PME-7 are associated with the same remote MAC device as PME-1.
d) -O system writes remote_discovery_register to value *alpha* using PME-3— the next non-associated PME.
e) -O system reads remote_discovery_register for all other PMEs.
f) -O system expects that PME-1, PME-2, PME-3, PME-6 and PME-7 will already be written to value *alpha*.
g) -O system discovers that no other PME is associated with the same remote MAC device as PME-3.
h) -O system writes remote_discovery_register to value *alpha* using PME-4—the next non-associated PME.
i) -O system reads remote_discovery_register for all other PMEs.
j) -O system expects that PME-1, PME-2, PME-3, PME-4, PME-6 and PME-7 will already be written to value *alpha*.
k) -O system discovers that PME-5, PME-9 and PME-11 are associated with the same remote MAC device as PME-4.
l) This procedure repeats for all of the PMEs connected to -O system.

An alternate example procedure for discovering this connectivity uses two different 48-bit values:

m) -O system writes remote_discovery_register to value *alpha* (*alpha* may be any 48-bit value, but would benefit from being locally unique e.g. MAC address) using PME-1.
n) -O system reads remote_discovery_register for all other PMEs.
o) -O system discovers that PME-2, PME-6 and PME-7 are associated with the same remote MAC device as PME-1.
p) -O system rewrites remote_discovery_register to value *beta* (*beta* may be any 48-bit value, different to *alpha*) using PME-1.
q) -O system writes remote_discovery_register to value *alpha* using PME-3— the next non-associated PME.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

r) -O system reads remote_discovery_register for all other PMEs.
s) -O system discovers that no other PME is associated with the same remote MAC device as PME-3.
t) -O system rewrites remote_discovery_register to value *beta* using PME-3.
u) -O system writes remote_discovery_register to value *alpha* using PME-4—the next non-associated PME.
v) -O system reads remote_discovery_register for all other PMEs.
w) -O system discovers that PME-5, PME-9 and PME-11 are associated with the same remote MAC device as PME-4.
x) -O system rewrites remote_discovery_register to value *beta* using PME-4.
y) This procedure repeats for all of the PMEs connected to -O system.

NOTE— This procedure can be expanded at the -O end to provide up to 32 unique alpha values. The -O end would then write a different alpha value on each port and then read all remote_discovery_register. Since the write operation is an atomic write, only one alpha value for each remote PCS will be written. All other subsequent write operations on that PCS will fail.

Observe also that a large and complex -O system may perform multiple discovery operations in parallel by using multiple unique 48-bit values for writing the remote_discovery_register.

Annex 61B

(informative)

Handshake codepoints for 2BASE-TL and 10PASS-TS

61B.1 Purpose and scope

This annex contains the G.994.1 “standard information field” codepoints to be used by 2BASE-TL and 10PASS-TS in the procedures described in 61.4.

61B.2 Level-1 S field codepoints for 2BASE-TL and 10PASS-TS

The Npar(1) codepoints common to 2BASE-TL and 10PASS-TS are specified in Table 10 of G.994.1.

The SPar(1) codepoints to be used by 2BASE-TL and 10PASS-TS transceivers are specified in ITU-T Recommendation G.994.1. The EFM-specific codepoints are shown in Table 61B–1 for information only.

Table 61B–1—Standard information field — SPar(1) coding – Octet 4

Bits								
8	7	6	5	4	3	2	1	**SPar(1)s – Octet 4**
x	x	1	x	x	x	x	x	2BASE-TL
x	1	x	x	x	x	x	x	10PASS-TS
x	0	0	0	0	0	0	0	No parameters in this octet

61B.3 Codepoints for 2BASE-TL

61B.3.1 Level-2 S field codepoints for 2BASE-TL

Table 61B–2 through Table 61B–5 contain the level-2 codepoints specific to 2BASE-TL.

To support a wide range of data rates and multiple encodings, this section introduces a new way to encode data rates in G.994.1 code points. This method of encoding rates is used for both the PMMS rates and the training rates. Data rates are encoded as a set of ranges, where each range is expressed as a 3-tuple (minimum, maximum, step). The 3-tuple represents all rates of the form (m + ks)(64 kb/s) where m is the minimum value, s is the step value, and k is the set of all integers greater than or equal to zero such that m+ks is less than or equal to the maximum value. Thus, for example, the 3-tuple (40, 70, 10) represents the rates (40)(64 kb/s), (50)(64 kb/s), (60)(64 kb/s), and (70)(64 kb/s).

Each data rate parameter can be expressed as a set of between 1 to 8 ranges, where the supported rates are the union of those supported by the individual ranges. Thus, for example, the 3-tuples (20,30,4), (40,70,10) represent the rates (20)(64 kb/s), (24)(64 kb/s), (28)(64 kb/s), (40)(64 kb/s), (50)(64 kb/s), (60)(64 kb/s), and (70)(64 kb/s). If all bits of the extended base data rate minimum and maximum are set to zero, then those rates are not supported for line probe. If only one range of rates is required, then only the octets associated with (min1,max1,step1) shall be sent.

Also, in many cases, the values in the data range 3-tuple can be less than or equal to 89 (representing the maximum data rate of 5696 kb/s supported by 2BASE-TL). When using G.994.1 code point representation, only 6 bits are available for the value of an NPar(3). To support numbers greater than 63, the value has to be

split across multiple octets. When encoding a data range using G.994.1, 4 octets are used, where the first octet contains the highest order bit from each of the values in the 3-tuple.

The following definition is added to the G.994.1 code point definitions in 6.4.1 of G.991.2 for the support of the extended data rates specified in this subclause.

Extended Base Data Rate These octets are used to specify payload rates, as follows:

- The PMMS octets indicate rates for line probing segments. Note that while PMMS uses 2-PAM modulation, the PMMS symbol rates are specified assuming 32 TC-PAM encoding, so the PMMS symbol rate (in kbaud) would be equal to the (payload data rate (kb/s) + 8 kb/s)/4. Valid values for minimum and maximum shall be between 4 and 89, inclusive, and valid values for step shall be between 1 and 89, inclusive. The variables j_5 and j_6 associated with the PMMS rates shall be independent, and shall range from 2 to 8, inclusive. If only one range of rates is required, then only the octets associated with (min1,max1,step1) shall be sent. If more than one range of rates is required, then j_5*4 and j_6*4 correspond to the number of octets sent.
- The training parameter octets indicate extended payload data rates supported.
- In CLR, upstream training parameters indicate which data mode rates the 2BASE-TL-R is capable of transmitting and downstream training parameters indicate which data mode rates the 2BASE-TL-R is capable of receiving. If the optional line probe is used, the receiver training parameters will be further limited by the probe results. Valid values for minimum and maximum shall be between 3 and 60, inclusive, for 16-TCPAM and between 12 and 89, inclusive, for 32-TCPAM. Valid values for step shall be between 1 and 89, inclusive. The variables j_1, j_2, j_3, and j_4 associated with the training rates shall be independent, and shall range from 2 to 8, inclusive. If only one range of rates is required, then only the octets associated with (min1,max1,step1) shall be sent. If more than one range of rates is required, then j_1*4, j_2*4, j_3*4, and j_4*4 correspond to the number of octets sent.
- In CL, downstream training parameters indicate which data mode rates the 2BASE-TL-O is capable of transmitting and upstream training parameters indicate which data mode rates the 2BASE-TL-O is capable of receiving. Valid values for minimum and maximum shall be between 3 and 60, inclusive, for 16-TCPAM and between 12 and 89, inclusive, for 32-TCPAM. Valid values for step shall be between 1 and 89, inclusive. The variables j_1, j_2, j_3, and j_4 associated with the training rates shall be independent, and shall range from 2 to 8, inclusive. If only one range of rates is required, then only the octets associated with (min1,max1,step1) shall be sent. If more than one range of rates

is required, then j_1*4, j_2*4, j_3*4, and j_4*4 correspond to the number of octets sent. If optional line probe is used, the receiver training parameters will be further limited by the probe results.

— Data rate selections shall be specified in MP and MS messages by setting the maximum and minimum rates to the same value.

Table 61B–2—Standard information field – 2BASE-TL NPar(2) coding – Octet 1

Bits								
8	7	6	5	4	3	2	1	**2BASE-TL NPar(2)s – Octet 1**

61B.5 Protocol implementation conformance statement (PICS) proforma for Annex 61B, Handshake codepoints for 2BASE-TL and 10PASS-TS[285]

61B.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 61B, Handshake codepoints for 2BASE-TL and 10PASS-TS, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

61B.5.2 Identification

61B.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., names and versions for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

61B.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 61B, Handshake codepoints for 2BASE-TL and 10PASS-TS.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

61B.5.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
HSCP	Handshake Codepoints	61B	The coding rules for 2BASE-TL handshake messages are implemented.	M	Yes [ ]

[285] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

61B.5.4 2BASE-TL handshake coding rules

Item	Feature	Subclause	Value/Comment	Status	Support
HSCP-1	PMMS coding	61B.3.1	Values for min and max are between 4 and 89, inclusive.	M	Yes [ ]
HSCP-2	PMMS coding	61B.3.1	Valid values for step are between 1 and 89, inclusive.	M	Yes [ ]
HSCP-3	PMMS coding	61B.3.1	The variables j_5 and j_6 associated with the PMMS rates are independent, and range from 2 to 8, inclusive.	M	Yes [ ]
HSCP-4	PMMS coding	61B.3.1	If only one range of rates is required, then only the octets associated with (min1,max1,step1) are sent.	M	Yes [ ]
HSCP-5	CLR coding	61B.3.1	Valid values for minimum and maximum are between 3 and 60, inclusive, for 16-TCPAM and between 12 and 89, inclusive, for 32-TCPAM.	M	Yes [ ]
HSCP-6	CLR coding	61B.3.1	Valid values for step are between 1 and 89, inclusive.	M	Yes [ ]
HSCP-7	CLR coding	61B.3.1	The variables j_1, j_2, j_3 and j_4 associated with the training rates are independent, and range from 2 to 8, inclusive.	M	Yes [ ]
HSCP-8	CLR coding	61B.3.1	If only one range of rates is required, then only the octets associated with (min1,max1,step1) is sent. If more than one range of rates is required, then j_1*4, j_2*4, j_3*4 and j_4*4 correspond to the number of octets sent.	M	Yes [ ]
HSCP-9	CL coding	61B.3.1	Valid values for minimum and maximum are between 3 and 60, inclusive, for 16-TCPAM and between 12 and 89, inclusive, for 32-TCPAM.	M	Yes [ ]
HSCP-10	CL coding	61B.3.1	Valid values for step are between 1 and 89, inclusive.	M	Yes [ ]
HSCP-11	CL coding	61B.3.1	The variables j_1, j_2, j_3 and j_4 associated with the training rates are independent, and range from 2 to 8, inclusive.	M	Yes [ ]
HSCP-12	CL coding	61B.3.1	If only one range of rates is required, then only the octets associated with (min1,max1,step1) is sent. If more than one range of rates is required, then j_1*4, j_2*4, j_3*4 and j_4*4 correspond to the number of octets sent.	M	Yes [ ]
HSCP-13	SPar(2) coding	61B.3.1	Only one of the bits 2BASE-TL training mode and 2BASE-TL PMMS mode is set at any given time.	M	Yes [ ]
HSCP-14	SPar(2) coding	61B.3.1	The Regenerator silent period bit is set to 0_b if the 2BASE-TL PMMS mode NPar(2) bit is set to 1_b or the 2BASE-TL Training mode NPar(2) bit is set to 1_b.	M	Yes [ ]

Annex 62A

(normative)

PMD profiles for 10PASS-TS

62A.1 Introduction and rationale

Annex 62A defines the PMD profiles for 10PASS-TS. These profiles define the transmission characteristics of the PHY on the media. 10PASS-TS PHYs are required to operate across varying media quality, regulatory and noise environments.

The profiles defined in this clause have two purposes. The first is to describe a bounded set of operating modes that a party might choose from when implementing, integrating and installing 10PASS-TS equipment. 10PASS-TS PHYs are inherently flexible in their transmission capabilities. The possible combination of transmission parameters are nearly infinite. The defined profiles collect a small subset of these parameters into modes that work well in most deployments. For deployments that require an operating mode not defined in this Annex, profiles can be overridden by setting PHY PMD registers directly, via Clause 45 for example. Informative Annex 62C contains examples of such user-defined modes of operation.

The second purpose of profiles is to define a set of operating modes against which PHY performance compliance may be tested. The topic of performance compliance is addressed for 10PASS-TS in Annex 62B.

62A.2 Relationship to other clauses

Clause 30 describes how the selection of Annex 62A profiles is exported to a management entity.

Clause 45 registers describe an optional mechanism for configuring a 10PASS-TS PHY to use a particular profile. The register settings for each profile are contained in 62A.4.

62A.3 Profile definitions

The following sections define the mandatory profiles for 10PASS-TS operation, in terms of bandplan, PSD mask, UPBO Reference PSD, notching parameters and payload rate.

62A.3.1 Bandplan and PSD mask profiles

The spectral characteristics of 10PASS-TS communication on the copper medium are defined by a choice of bandplans and PSD Masks.

Each of 5 standard frequency bands (Band 0, D1, U1, D2, U2) used for 10PASS-TS communication are defined in a bandplan. 10PASS-TS PHYs operating in the same cable bundle should use the same bandplan to ensure spectral compatibility. Furthermore, the selection of bandplan may be governed by regional regulations that pertain to the deployment. While all 10PASS-TS PHYs may operate in any of the below bandplans, installers should be aware of any regulations that might restrict their choice of modes. Bandplan profiles specify the use of 2, 3, 4, or 5 standard frequency bands.

PSD Masks further define the spectral environment by specifying the maximum transmit power spectral density at a given frequency. Like bandplans, the PSD mask should be selected to be compatible with applicable regulations and to match other PHYs operating in the same cable bundle.

Profiles are defined here for various regulatory environments as well as for private installation. Additionally, operation with a bandplan or PSD mask not defined in this clause is supported by configuration through Clause 45 registers. All 10PASS-TS PHYs shall be capable of operating in all profiles listed in this clause.

[a]For each band in the bandplan, the Band Assignment indicates the use or direction of communication for that band. U=upstream, D=downstream, x=band is unused. Bands are listed in this order: 0/1/2/3/4.
[b]This profile uses a 5th band (12 MHz—16.5 MHz) for downstream transmission at –60 dBm/Hz.

62A.3.2 Bandplan definitions

The management entity should load the appropriate Clause 45 registers according to the bandplan specified by the selected profile. 62A.4 contains examples of the use of Clause 45 registers for the purpose of setting profiles.

The VDSL bandplans defined in ITU-T Recommendation G.993.1 shall be supported by all 10PASS-TS PMDs. These bandplans are represented for information in Table 62A-2.

Table 62A-2—Bandplans defined by ITU-T Recommendation G.993.1

Plan	Band 0 (optional) US/DS	Band D1	Band U1	Band D2	Band U2
Bandplan A (formerly Plan 998)	25 kHz – 138 kHz	138 kHz – 3.75 MHz	3.75 Mhz – 5.2 MHz	5.2 MHz – 8.5 MHz	8.5 MHz – 12 MHz
Bandplan B (formerly Plan 997)	25 kHz – 138 kHz	138 kHz – 3.0 MHz	3.0 MHz – 5.1 MHz	5.2 MHz – 7.05 MHz	7.05 MHz – 12 MHz
Bandplan C[a]	25 kHz – 138 kHz	138 kHz – 2.5MHz	2.5 MHz – 3.75 MHz	3.75 MHz – *Fx*	*Fx* – 12MHz
Annex F[b,c]	25 kHz – 138 kHz	138 kHz – 3.75 MHz	3.75 Mhz – 5.2 MHz	5.2 MHz – 8.5 MHz	8.5 MHz – 12 MHz

[a]Bandplan C is characterized by a variable split frequency between band D2 and band U2, represented as "*Fx*". 10PASS-TS shall support operation in Bandplan C for $Fx = 3750\ \text{kHz} + n \times 250\ \text{kHz}$, where $0 \le n \le 33$.
[b]Subsets composed of at least one downstream band and one upstream band among D1, U1, D2 and U2 may be implemented.
[c]Band 1D starts at 640 kHz when operating in the frequency region above TCM-ISDN DSL band. Band 1D starts at 1.104 MHz when operating with PSD reduction function in the frequency region below 1.104 Mhz.

62A.3.3 PSD mask definitions

The management entity should load the appropriate Clause 45 registers according to the PSD Mask specified by the selected profile. 62A.4 contains examples of the use of Clause 45 registers for the purpose of setting profiles.

The VDSL PSD Masks defined in ITU-T Recommendation G.993.1, ATIS-0600424 and ETSI TS 101 270-1 shall be supported by all 10PASS-TS PMDs.

NOTE—The reference documents in which the PSD Masks are specified also specify the relationship between PSD Mask and PSD template, and the appropriate method to assess compliance with a PSD Mask or a PSD template.

62A.3.4 UPBO Reference PSD Profiles

Upstream Power Back-Off (UPBO) is defined in 62.3.4.1. Its operation requires the specification of a Reference PSD, by means of which the 10PASS-TS-R calculates the maximum upstream transmit PSD.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Different UPBO Reference PSDs have been standardized in ATIS-0600424 and ETSI TS 101 270-1, as shown in Table 62A-3. 10PASS-TS implementations shall support all UPBO Reference PSDs listed in Table 62A-3. The 10PASS-TS PHY shall additionally allow a profile value of "0" to be selected, which indicates that UPBO is to be disabled.

Table 62A-3—UPBO Reference PSD Profiles
(*f* is in MHz, the PSD level is in dBm/Hz)

#	Reference PSD			1U	2U
1	ATIS-0600424	Noise A	M1	$-60-22.00\sqrt{f}$	$-60-17.18\sqrt{f}$
2			M2	$-53-24.47\sqrt{f}$	$-54-18.93\sqrt{f}$
3		Noise F	M1	$-60-18.54\sqrt{f}$	$-60-16.865\sqrt{f}$
4			M2	$-53-21.19\sqrt{f}$	$-54-18.69\sqrt{f}$
5	ETSI TS 101 270-1	Noise A&B		$-47.3-28.01\sqrt{f}$	$-54-19.22\sqrt{f}$
6		Noise C		$-47.3-21.14\sqrt{f}$	$-54-16.29\sqrt{f}$
7		Noise D		$-47.3-26.21\sqrt{f}$	$-54-17.36\sqrt{f}$
8		Noise E		$-47.3-27.27\sqrt{f}$	$-54-18.1\sqrt{f}$
9		Noise F		$-47.3-19.77\sqrt{f}$	$-54-15.77\sqrt{f}$

62A.3.5 Band Notch Profiles

In certain deployments, 10PASS-TS operation may interfere with nearby amateur radio equipment. The Band Notch profiles specify notches that 10PASS-TS PHYs shall add to their transmit PSDs when selected. When a notch is activated, the transmitter shall reduce its PSD to less than –80 dBm/Hz in the frequencies of the notch. More than one notch may be activated at one time.

All Band Notches specified in the following standards shall be supported:

a) ITU-T Recommendation G.993.1 Annex F, Table F-5
b) ATIS-0600424, Annex A
c) ETSI TS1 101 270 subclause 9.3.3.6.1

The Band Notch Profiles are listed for information in Table 62A-4. This table includes notches that are above 12MHz, that are therefore outside the scope of this standard.

62A.3.6 Payload rate profiles

The Payload Rate Profile describes the payload bitrate as seen at the MII interface.

The Payload Rate Profile consists of a payload rate for each of the downstream and upstream directions. The profile is specified in the format Drate/Urate as the payload bitrate that the PHY link shall provide, where *Drate* and *Urate* are expressed in Mb/s. For example a Payload Rate Profile of 10/2.5 corresponds to a downstream payload rate of 10 Mb/s and an upstream payload rate of 2.5 Mb/s. *Drate* values of 2.5, 5, 7.5, 10, 12.5, 15, 25, 35, 50, 70, and 100 shall be supported where the loop environment, bandplan and PSD mask allow this. *Urate* values of 2.5, 5, 7.5, 10, 12.5, 15, 25, 35, and 50 shall be supported where the loop environment, bandplan and PSD mask allow this. This leads to a total of 9 symmetric and 90 asymmetric Payload Rate Profiles.

The selected Payload Rate Profile sets a target for the PHY's operation. If the payload rates of the selected profile cannot be achieved based on the loop environment, bandplan and PSD mask, the PHY shall drop the link.

62A.3.7 Complete profiles

The complete PMD operation of the 10PASS-TS PHY can be selected by choosing one Bandplan and PSD Mask profile, one UPBO Reference PSD profile, one Payload Rate profile, and any number of Band Notch profiles.

62A.3.8 Default profile

A 10PASS-TS device that is not managed (i.e., no management functions are provided, or enabled) shall operate in the default profile and the default mode specified in this subclause and summarized in Table 62A-5.

Table 62A-5—Default profile and default mode settings

Profile / Setting	Value
Payload bitrate profile	10/10
Bandplan and PSD mask profile	#1
Band notch profiles	#2, #6, #10, and #11
UPBO reference PSD profile	#3
Reed-Solomon setting	(240, 224)
Interleaver setting	I=30, M=62

The default profile shall consist of the 10/10 payload bitrate profile, bandplan and PSD mask profile #1, band notch profiles #2, #6, #10, and #11 enabled, and UPBO reference PSD profile #3.

In addition, the default mode of 10PASS-TS implementations shall use Reed-Solomon setting (240, 224)[286], and interleaver setting I=30, M=62.

NOTE—The default profile may not be spectrally compatible to any particular regional requirement, nor may it be the optimal profile for a particular cable segement.

62A.4 Register settings

Tables 62A-6 through 62A-8 contain the register settings required to implement the profiles described in this Annex. The referenced registers are defined in 45.2.

Table 62A-6 contains the MCM tone group definitions to be used in order to support the band plan profiles described in 62A.3.2. For each of the listed tone groups, the Tone Active and/or Tone Direction bits in the 10P MCM tone control parameter register shall be set according to the use indicated in the first column of the table.

Table 62A-6—MCM register settings implementing bandplan profiles

Band Allocation	Band Plan A 10P MCM Tone Group Register		Band Plan B 10P MCM Tone Group Register		Band Plan C 10P MCM Tone Group Register		Band Plan Ann. F 10P MCM Tone Group Register	
	lower	upper	lower	upper	lower	upper	lower	upper
0 (upstream, downstream or not used)	0007_{16}	$001F_{16}$	0007_{16}	$001F_{16}$	0007_{16}	$001F_{16}$	0007_{16}	$001F_{16}$
1D (downstream)	0021_{16}	0365_{16}	0021_{16}	$02B7_{16}$	0021_{16}	0243_{16}	0021_{16}	0365_{16}
1U (upstream)	0367_{16}	$04B5_{16}$	$02B9_{16}$	$049E_{16}$	0245_{16}	0365_{16}	0367_{16}	$04B5_{16}$
2D (downstream)	$04B7_{16}$	$07B2_{16}$	$04A0_{16}$	0662_{16}	0367_{16}	fx1[a]	$04B7_{16}$	$07B2_{16}$
2U (upstream)	$07B4_{16}$	$0ADE_{16}$	0664_{16}	$0ADE_{16}$	fx2[b]	$0ADE_{16}$	$07B4_{16}$	$0ADE_{16}$
3D (downstream)[c]	$0ADF_{16}$	$0EF2_{16}$	—	—	—	—	—	—

[a]Values for fx1 shall be in the range 0369_{16} to $0ADA_{16}$
[b]Values for fx2 shall be in the range (fx1 + 2) to $0ADE_{16}$
[c]Band 3D is only used in Band Plan and PSD Mask profile #30.

Unlike the other parameters governed by the profiles specified in the Annex, PSDs are typically defined by means of a functional expression, rather than a set of values. Transmit PSDs and Reference PSDs typically vary for each individual tone. A pseudo-C procedure for setting a PSD profile and a Reference PSD profile is shown in Equation (62A–1) below. It assumes the existence of the functions getPSDLevel(float frequencyInKHz) and getReferencePSD(float frequencyInKHz) specifying the transmit PSD and Reference PSD respectively, both expressed as a floating-point value in dBm/Hz. Registers are addressed by means of pointers ToneGroupRegister, ToneControlParameterRegister and ToneControlActionRegister.

```
for (int tone=0;tone<4096;tone++) {
 ToneGroupRegister[0] = tone;                // set lower bound of tone group
 ToneGroupRegister[1] = tone;                // set upper bound of tone group
                                             // to the same value
 short TxPSD = floor(4*(getPSDLevel(tone*4.3125)+100)) & 0x01FF;
                                             // convert to 9-bit value
 ToneControlParameterRegister[1] &= 0xFFFC;  // clear first two bits of PSD level
 ToneControlParameterRegister[2] &= 0x01FF;  // clear remaining 7 bits of PSD level
 ToneControlParameterRegister[1] |= TxPSD >> 7;// store first two bits of PSD level
 ToneControlParameterRegister[2] |= (TxPSD << 9) & 0xFE00;
                                             // store remaining 7 bits of PSD level
 short RefPSD = floor(4*(getReferencePSD(tone*4.3125)+100)) & 0x01FF;
                                             // convert to 9-bit value
 ToneControlParameterRegister[2] &= 0xFFE0;  // clear Reference PSD level
 ToneControlParameterRegister[2] |= RefPSD;  // store Reference PSD level
 *ToneControlActionRegister |= 0x0020;       // refresh contents of the selected
                                             // tones entries in table
}
*ToneControlActionRegister |= 0x0002;        // activates PSD level setting as in
                                             // ToneControlParameterRegister
*ToneControlActionRegister |= 0x0001;        // activates UPBO Ref. PSD level
                                             // setting as in
                                             // ToneControlParameterReg          (62A–1)
```

Functions specifying standard transmit PSDs can be found in the documents referenced in 62A.3.3. Functions specifying UPBO Reference PSDs can be found in Table 62A-3.

Table 62A-7 contains the MCM tone group definitions to be used in order to support the band notch profiles described in 62A.3.5. For each of the listed tone groups, the Tone Active bit in the 10P MCM tone control parameter register shall be cleared to activate the corresponding band notch.

Table 62A-7—MCM register settings implementing band notch profiles

Band Notch Profile	10P MCM Tone Group Register	
	lower	upper
1	$01A3_{16}$	$01A7_{16}$
2	$01A3_{16}$	$01D0_{16}$
3	$01B9_{16}$	$01BB_{16}$
4	$032B_{16}$	$033D_{16}$
5	$032B_{16}$	0371_{16}
6	$032B_{16}$	$03A0_{16}$
7	0364_{16}	0366_{16}
8	$036E_{16}$	0372_{16}
9	0656_{16}	$066E_{16}$
10	0656_{16}	$069D_{16}$
11	0925_{16}	0932_{16}

Table 62A-8 contains the MCM register settings for the payload rate profiles listed in 62A.3.6. When operating under a payload rate profile, the minimum and maximum data rates in the 10P MCM upstream/ downstream data rate configuration registers shall be set to the same value.

Table 62A-8—MCM register settings implementing payload rate profiles

Profile (payload rate in Mb/s)	Downstream Data Rate Configuration Register setting (bits 15:0)	Upstream Data Rate Configuration Register setting (bits 15:0)
2.5	0027_{16}	0027_{16}

62A.5 Protocol implementation conformance statement (PICS) proforma for Annex 62A, PMD profiles for 10PASS-TS[287]

62A.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 62A, PMD profiles for 10PASS-TS, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

62A.5.2 Identification

62A.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., names and versions for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

62A.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 62A, PMD profiles for 10PASS-TS.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[287] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

Annex 62B

(normative)

Performance guidelines for 10PASS-TS PMD profiles

62B.1 Introduction and rationale

Annex 62B defines performance guidelines for 10PASS-TS PMD profiles. The definition of these guidelines is challenging due to the varying nature of the access network. The access network has large variations in cable characteristics from region to region. In addition, the make-up of a cable can encompass multiple cable gauges and/or different configuration of bridged taps. Finally, services may vary from region to region creating different noise scenarios. Typically, deployment guidelines are a function of the telecommunications operator, which is operating a loop and the regional spectrum management policies, which govern deployment on that loop.

Given that one cannot test every possible combination of loop make-up and noise conditions, the performance guidelines are covered from two perspectives. Firstly, 62B.3 lists a suite of artificial tests crafted to test the 10PASS-TS PHYs under representative worst-case noise and loop conditions. Secondly, 62B.4 defines a deployment guideline rule which allows a service provider to determine whether a given loop will support a given profile.

62B.2 Relationship to other clauses

Annex 62A lists a set of PMD profiles for 10PASS-TS. Clause 30 describes how the selection of Annex 62A profiles is exported to a management entity. Clause 45 registers describe an optional mechanism for configuring a 10PASS-TS PHY to use a particular profile. The register settings for each profile are contained in 62A.4.

62B.3 Performance test cases

The performance test cases are derived from the standard definition of test loops in ATIS-0600424.2004(S2015), section 12.1, the noise models are defined in ATIS-0600424.2004(S2015), section 12.2 and the profiles are defined in 62A.3.1. In all cases the PHYs shall attain link in the specified profile in the presence of noise and impairments and maintain link with a Bit Error Ratio less than 10^{-7} with the noise raised by 6dB.

During the test the PHY shall meet the requirements of the bandplan, PSD and Upstream Power Back Off (where appropriate) specified. The control of the profile shall be through the Clause 30 MIB if supported. If the PHY under test includes any implementation options defined in the reference document (but out of scope for this standard) these options shall be disabled in such a manner as to render the behavior identical to implementations without such options.

If a PHY is capable of operating as both CO-subtype and CPE-subtype then both modes of operation shall be tested. If the PHY is capable of supporting PME aggregation then each PME shall be capable of passing the performance tests independently.

Table 62B-1 lists the performance test cases. The test loops are described in ATIS-0600424.2004(S2015), section 12.1. For tests using test loop “VDSL1” the table specifies which of the two cable types (TP1 or TP2) is used. The length value refers to the dimension “x”, “y”, “z”, “u” or “v” depending on the test loop. If “notch” is specified to be “on” then the RF notches specified in ATIS-0600424.2004 (S2015)/Trial-Use, part 1, Annex 1 are applied as described in section 13.3.3. If “UPBO” is specified to be “on” then the Power Back Off specified in 62.3.4.4 is applied. The noise model applied will be noise model “A” or “F” as

described in ATIS-0600424.2004(S2015), section 12.2.1.1. The definition of self crosstalk is in section 12.2.1.4.1.

Table 62B-1—Test cases for 10PASS-TS

Test	Test Loop	L (m)	Profile	Payload Data Rate down/up (Mb/s)	Notch	UPBO	Noise Model[a]
1	TP1	750	13	10/10	—	5	AWGN
2	TP2	750	13	10/10	—	5	ETSI A
3	TP2	300	1	10/10	—	1	ATIS-0600424 A
4	TP2	200	16	50/50	—	—	AWGN
5	TP2	100	16	35/25	—	—	self
6	TP1	650	6	25/5	—	—	self
7	TP2	700	17	15/15	—	—	self
8	TP1	1000	8	15/2.5	—	—	self
9	TP2	400	4	12.5/12.5	—	—	self
10	TP2	750	4	7.5/7.5	—	—	self
11	TP2	1000	23	5/5	—	—	self
12	TP2	1200	23	2.5/2.5	—	—	self
13	TP2	150	16	50/50	2, 5, 9, 11	—	AWGN
14	TP2	100	16	35/25	2, 5, 9, 11	—	self
15	TP1	650	6	25/5	2, 6, 10, 11	—	self
16	TP2	600	17	15/15	2, 5, 9, 11	—	self
17	TP1	1000	8	15/2.5	2, 6, 10, 11	—	self
18	TP2	400	4	12.5/12.5	2, 6, 10, 11	—	self
19	TP2	750	4	7.5/7.5	2, 6, 10, 11	—	self
20	TP2	900	23	5/5	2, 5, 9, 11	—	self
21	TP2	1200	23	2.5/2.5	2, 5, 9, 11	—	self
22	TP2	150	30	100/25	—	—	AWGN

[a]"AWGN" means that only white gaussian noise at -140 dBm/Hz is present. "Self" means that the equivalent crosstalk generated by 20 10PASS-TS transceivers operating in the same mode (assuming the same loop length and the same UPBO configuration) as the device under test is present in addition to white gaussian noise at -140 dBm/Hz. "ATIS-0600424 A" means that alien crosstalk according to ATIS-0600424 Noise Model A is present in addition to white gaussian noise at –140 dBm/Hz. "ETSI A" means that alien crosstalk according to ETSI TS 101 270-1 Noise Model A is present in addition to white gaussian noise. Self crosstalk and alien crosstalk are not to be applied simultaneously.

62B.3.1 Additional tests

Additional testing to prove the requirements for link establishment, UPBO, burst noise immunity, link state and error reporting, etc. may be performed using any test scenarios from Table 62B-1.

62B.4 Deployment guidelines

The relationship between specific cable parameters and performance is complex and cannot be guaranteed. The performance tests described in section 62B.3 are designed to ensure that compliant PHYs will achieve a similar level of performance when applied in similar environments. The tests are designed to represent realistic worst case conditions but real world installations may sometimes experience worse performance for apparently similar conditions.

Annex A of ETSI TS1 101 270-1 (1999) contains some additional information regarding performance expectations related to cable parameters.

62B.5 Protocol implementation conformance statement (PICS) proforma for Annex 62B, Performance guidelines for 10PASS-TS PMD profiles[288]

62B.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 62B, Performance guidelines for 10PASS-TS PMD profiles, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

62B.5.2 Identification

62B.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., names and versions for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

62B.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 62B, Performance guidelines for 10PASS-TS PMD profiles.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[288] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

Annex 62C

(informative)

10PASS-TS Examples

62C.1 Introduction

Annex 62A contains profiles for deployment of 10PASS-TS in typical environments, as well as for testing purposes. Certain situations may require the full use of the 10PASS-TS PHY's flexibility, going beyond what is offered by the predefined profiles, in order to obtain optimal performance. Examples of such circumstances:

a) the 10PASS-TS system shares a cable bundle with a legacy system; the PSD mask can be configured to minimize crosstalk between 10PASS-TS and the legacy system
b) for a specific application, a particular symmetry ratio is required, which is not easily obtained with the standard band plans
c) the desired payload bit rates are beyond the ones that can be set by means of the standard payload rate profiles
d) other unanticipated situations

To use this flexibility, the 10PASS-TS equipment is configured by means of the appropriate Clause 45 registers. This Annex provides examples of such configurations.

62C.2 Bandplan configuration

Example situation: a user wishes to implement a custom bandplan for a 10PASS-TS deployment in a private network, in order to minimize near-end crosstalk to and from a certain legacy system.

Band plans can be configured by selecting any group of tones in the Tone Group register (45.2.1.53), and allocating them to either upstream or downstream by setting the tone direction bit to the appropriate value (0 = downstream, 1 = upstream) in the Tone Control Parameter register (45.2.1.54). This procedure is repeated until the desired number of frequency bands has been allocated. The new configuration is applied by writing binary 1 to the Change Tone Direction bit in the Tone Control Action register (45.2.1.55).

An example of a custom bandplan and PSD is shown in Figure 62C–1 (the solid line represents the upstream PSD, the dashed line represents the downstream PSD). The overall transmission power is assumed to be 14.5 dBm in either direction which is similar to the ATIS-0600424 M2 mask and SHDSL transmit power. The example defined here is such that it should meet VDSL compatibility requirements for up to 1524 m (5000 ft).

The example PSD was tested for spectral compatibility with existing VDSL systems using ITU-T Bandplan A (formerly known as plan 998). The spectral compatibility guideline was obtained by assuring that the new service will not disturb the guaranteed data rates for VDSL basis system as shown in Table 62C–1.

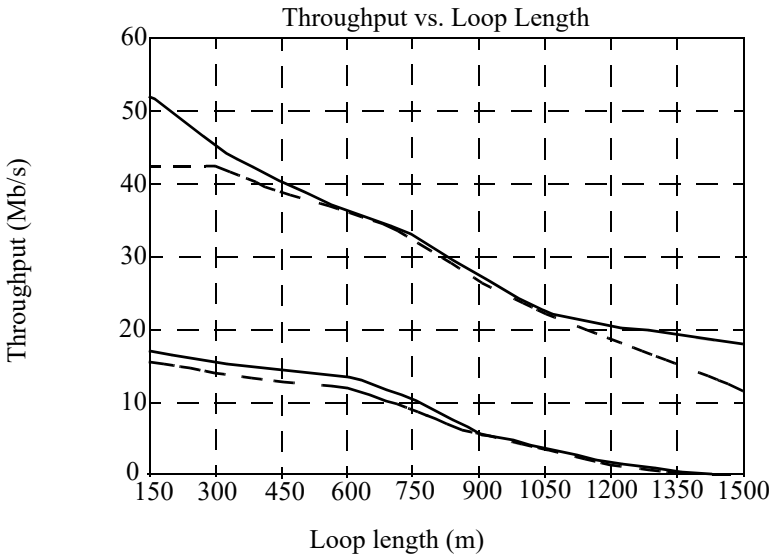

Figure 62C–4—Simulated performance of a VDSL system (using ITU-T Bandplan A) in the presence of 12 disturbers using the example PSD of this subclause and 12 disturbers using ATIS-0600417 mask SM class 6.

NOTE—Dashed line = minimum VDSL performance required for spectral compatibility; solid line = simulated VDSL performance in presence of new disturbers.

62C.2.1 Plan A with variable LF region

As an additional example, this subclause describes a modified version of ITU-T Bandplan A (formerly known as 998) with variable low-frequency region. Its target is to improve the reach of symmetric bitrates using 10PASS-TS or VDSL.

Plan A with variable LF region is shown in Figure 62C–5. The transition frequency between band 0 (used in upstream) and band 1D can be varied between 25 kHz and 490 kHz to boost the upstream channel bitrate. This principle is similar to the variable bandwidth capability of 2BASE-TL and SHDSL. A supporting PSD which observes spectral compatibility requirements is described in 62C.3.2.

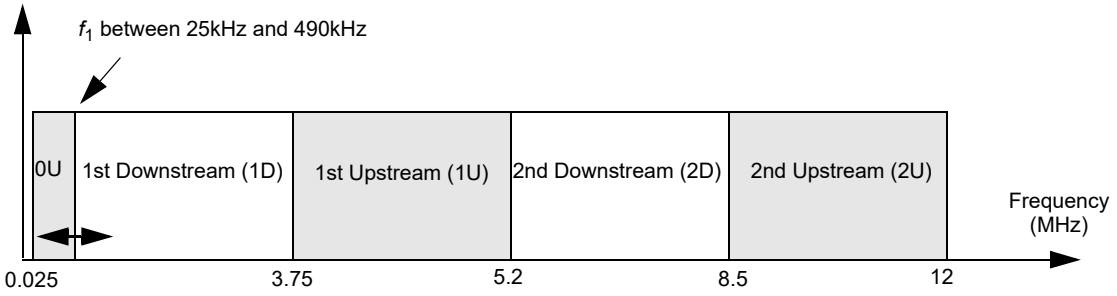

Figure 62C–5—Plan A with variable LF region

This family of bandplans can be implemented by assigning the appropriate tones to upstream and downstream, as shown in Table 62C–2.

Table 62C–2—Implementation of Plan A with variable LF region

Band	Tone Group
0 (upstream)	$6 \rightarrow \lfloor f_1/(4.3125\text{kHz}) \rfloor$
1D (downstream)	$\lceil f_1/(4.3125\text{kHz}) \rceil \rightarrow 869$
1U (upstream)	$870 \rightarrow 1205$
2D (downstream)	$1206 \rightarrow 1970$
2U (upstream)	$1972 \rightarrow 2782$

62C.3 PSD mask configuration

62C.3.1 General procedure

Example situation: a mixed (transitional) deployment where certain subscribers are served with a 10PASS-TS line from a central office (longer lines), while others are served with a 10PASS-TS line from a cabinet (shorter lines). In order to guarantee high link quality for all subscribers, the transmit PSDs from the cabinet are reduced to mimic a longer line (downstream power back-off).

The properties of the different tones are configured by means of the Tone Group register (1.x.15:0; 1.x + 1.15:0, defined in 45.2.1.53). The 8-bit PSD Level field in the Tone Control Parameter register (45.2.1.54) is used to set the TX PSD level for the selected group of tones. Given the tone spacing of 4.3125 kHz, a very fine-grained PSD control is possible. To implement a gradual frequency-dependent power back-off, a narrow sliding window is defined in the Tone Group register; each time the window is moved towards higher frequencies, the allowed TX PSD for that frequency range is set. The new configuration is applied by writing binary 1 to the Change PSD Level bit in the Tone Control Action register (45.2.1.55). This approach is illustrated by the algorithm in Equation (62C–1).[289]

```
for (tone=0;tone<4096;tone+=16) {
 ToneGroupRegister[0] = tone;
 ToneGroupRegister[1] = tone+16;
 ToneControlParameterRegister[1] &= 0xFFFC; // clear first 2 bits
 ToneControlParameterRegister[2] &= 0x01FF; // clear last 7 bits
 ToneControlParameterRegister[1] |= TxPSD[tone] >> 7;
 ToneControlParameterRegister[2] |= (TxPSD[tone] << 9) & 0xFE00;
}
*ToneControlActionRegister |= 0x0002; // activate PSD level setting
```

(62C–1)

62C.3.2 PSD Masks for Plan A with variable LF region

As an additional example, this –subclause describes PSD masks for Plan A with variable LF region, as introduced in 62C.2.1.

In band 0 (up to f_1 between 25 kHz and 490 kHz), the PSD is limited to –50 dBm/Hz, as is the case for 2.32 Mb/s SHDSL.

The PSD in bands 1D, 1U, 2D and 2U is limited to comply with mask M2 as defined in ATIS-0600424.

[289]Variables and pointers are used as described in 62A.4.

Annex 63A

(normative)

PMD Profiles for 2BASE-TL

63A.1 Introduction and rationale

Annex 63A defines the PMD profiles for 2BASE-TL. These profiles define the transmission characteristics of the PHY on the media. 2BASE-TL PHYs are required to operate across varying media quality, regulatory and noise environments. The profiles defined in this clause have two purposes.

The first is to describe a bounded set of operating modes that a party might choose from when implementing, integrating and installing 2BASE-TL equipment. 2BASE-TL PHYs are inherently flexible in their transmission capabilities. The defined profiles collect a subset of these parameters into modes that work well in most deployments. For deployments that require an operating mode not defined in this Annex, profiles can be overridden by setting PHY PMD registers directly, via Clause 45 for example.

The second purpose of the profiles is to define a set of operating modes against which PHY performance compliance may be tested. The topic of performance compliance is addressed for 2BASE-TL in Annex 63B.

63A.2 Relationship to other clauses

Clause 30 describes how the selection of Annex 63A profiles is exported to a management entity.

Clause 45 registers describe an optional mechanism for configuring a 2BASE-TL PHY to use a particular profile. The register settings for each profile are contained in 63A.4.

63A.3 Profile definitions

A 2BASE-TL profile is characterized by 4 parameters: data rate, power, constellation size and region. Different regions have different constraints on the PHY. ITU-T Recommendation G.991.2 distinguishes 3 regions and lists regional requirements in three annexes labeled A, B, C. Reference Annex A generally describes those specifications that are unique to SHDSL systems operating under conditions such as those typically encountered within the North American network; Reference Annex B, within European networks; and Reference Annex C, within networks with existing TCM-ISDN service.

The profiles of Table 63A–1 will generate a net data rate greater than 2 Mb/s at the MII interface on 1 to 4 pairs. Note that the profiles are defined on a single pair basis. The aggregation mechanism is specified in Clause 61. The data rate is the closest multiple of 64 kb/s greater than a net data rate of 2 Mb/s plus the corresponding 64/65-octet encapsulation overhead divided by the number of pairs. The line rate has an additional 8 kb/s of SHDSL overhead.

The default profile shall be profile #7 (Annex B).

63A.4 Register settings

This subclause contains Clause 45 register settings required to comply with the profiles defined in 63A.3. The 2B general parameter register (see 45.2.1.61) selects a region. The 2B PMD parameters register (see 45.2.1.62) selects values for data rate, power and constellation size. The 2B extended PMD parameters registers (see 45.2.1.76) define four additional data range sets to be used in conjunction with the 2B PMD parameters registers when additional PMD configuration detail is desired. Detailed register settings are shown in Table 63A–2.

Table 63A–2—2BASE-TL register settings

63A.5 Protocol implementation conformance statement (PICS) proforma Annex 63A, PMD Profiles for 2BASE-TL[290]

63A.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 63A, PMD Profiles for 2BASE-TL, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

63A.5.2 Identification

63A.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., names and versions for machines and/or operating systems; System Name(s)	

NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification.

NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).

63A.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 63A, 2BASE-TL PMD profiles.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

Annex 63B

(normative)

Performance guidelines for 2BASE-TL PMD profiles

63B.1 Introduction and rationale

This annex defines performance guidelines for 2BASE-TL PMD profiles. The definition of those guidelines is challenging due to the varying nature of the access network. The access network has large variations in cable characteristics from region to region. In addition, the make-up of a cable can encompass multiple cable gauges and/or different configuration of bridged taps. Finally, services may vary from region to region creating different noise scenarios. Typically, deployment guidelines are a function of the telecommunications operator, which is operating a loop and the regional spectrum management policies, which govern deployment on that loop.

Given that one cannot test every possible combination of loop make-up and noise conditions, the performance guidelines are covered from two perspectives. Firstly, 63B.3 lists a suite of artificial tests crafted to test the 2BASE-TL PHYs under representative worst-case noise and loop conditions. Secondly, 63B.4 defines a deployment guideline rule which allows a service provider to determine whether a given loop will support a given profile.

63B.2 Relationship to other clauses

Annex 63A lists a set of PMD profiles for 2BASE-TL.

Clause 30 describes how the selection of Annex 63A profiles is exported to a management entity.

Clause 45 registers describe an optional mechanism for configuring a 2BASE-TL PHY to use a particular profile. The register settings for each profile are contained in 63A.4.

63B.3 Performance test cases.

The profiles associated with the 5696, 3072, 1024, 704 and 512 kb/s (profiles 1, 2, 4, 5, and 6) shall satisfy the tests described in Table 63B-1. The same test methodology defined in G.991.2 Annex A shall be applied. The test cases are numbered 57 to 78 to differentiate them from the existing tests 1 to 56 in Table A-1 of G.991.2. Profile 3 shall successfully pass the corresponding tests described in Table A-1 of G.991.2.

Table 63B-1—Additional tests for the Annex A data rate

Test	Test loop	L (km)	Test unit	Payload data rate (kb/s)	PSD	Interferer Combination	Required Margin (dB)
57	S	2.80	2BASE-TL-O	1024	symmetric	49-HDSL	5 + Δ*
58	BT1-C	2.47	2BASE-TL-O	1024	symmetric	49-SHDSL_768_sym	5 + Δ*
59	BT1-C	2.47	2BASE-TL-O	1024	symmetric	49-HDSL	5 + Δ*
60	S	2.83	2BASE-TL-R	1024	symmetric	49-HDSL	5 + Δ*
61	BT1-R	2.47	2BASE-TL-R	1024	symmetric	49-SHDSL_768_sym	5 + Δ*
62	BT1-R	2.47	2BASE-TL-R	1024	symmetric	49-HDSL	5 + Δ*

Table 63B-1—Additional tests for the Annex A data rate *(continued)*

Test	Test loop	L (km)	Test unit	Payload data rate (kb/s)	PSD	Interferer Combination	Required Margin (dB)
63	S	3.44	2BASE-TL-O	704	symmetric	49-HDSL	5 + Δ*
64	BT1-C	3.17	2BASE-TL-O	704	symmetric	49-SHDSL_768_sym	5 + Δ*
65	BT1-C	3.17	2BASE-TL-O	704	symmetric	49-HDSL	5 + Δ*
66	S	3.44	2BASE-TL-R	704	symmetric	49-HDSL	5 + Δ*
67	BT1-R	3.17	2BASE-TL-R	704	symmetric	49-SHDSL_768_sym	5 + Δ*
68	BT1-R	3.17	2BASE-TL-R	704	symmetric	49-HDSL	5 + Δ*
69	S	4.08	2BASE-TL-O	512	symmetric	49-HDSL	5 + Δ*
70	BT1-C	3.75	2BASE-TL-O	512	symmetric	49-SHDSL_768_sym	5 + Δ*
71	BT1-C	3.75	2BASE-TL-O	512	symmetric	49-HDSL	5 + Δ*
72	S	4.08	2BASE-TL-R	512	symmetric	49-HDSL	5 + Δ*
73	BT1-R	3.75	2BASE-TL-R	512	symmetric	49-SHDSL_768_sym	5 + Δ*
74	BT1-R	3.75	2BASE-TL-R	512	symmetric	49-HDSL	5 + Δ*
75	S	1.37	2BASE-TL-O	3072	symmetric	49-SHDSL_2304 (case 11)	5 + Δ*
76	S	1.37	2BASE-TL-R	3072	symmetric	49-SHDSL_2304 (case 11)	5 + Δ*
77	S	0.85	2BASE-TL-O	5696	symmetric	24-HDSL2+24-T1 (case 4)	5 + Δ*
78	S	0.85	2BASE-TL-R	5696	symmetric	24-HDSL2+24-T1 (case 14)	5 + Δ*

Profiles 7 and 8 shall be tested using tests B-1 to B-4 defined in Table 63B-2. The same test methodology defined in G.991.2 Annex B shall be applied. Profile 9, 10 and 12 shall be tested using the tests defined in Annex B of ITU-T Recommendation G.991.2. The loops defined in Annex B do not scale as well as the loops of Annex A because they are defined in terms of insertion loss at a given frequency (with a granularity of 0.5 dB), rather than a length in meters. The 704 kb/s data rate (profile 11) is expected to successfully pass the test associated with the 768 kb/s data rate. Therefore, for Annex B testing, the 704 kb/s data rate shall be tested using the 768 kb/s test.

Table 63B-2—Additional tests for the Annex B data rate

Test	Test loop	L (km)	Test unit	Payload data rate (kb/s)	PSD	Interferer Combination[a]	Required Margin (dB)
B-1	Loop 2	1.37	2BASE-TL-O	3072	symmetric	C2048sD2	5 + Δ*
B-2	Loop 2	1.37	2BASE-TL-R	3072	symmetric	R1536sB2	5 + Δ*
B-3	Loop 2	0.85	2BASE-TL-O	5696	symmetric	C2304sD2	5 + Δ*
B-4	Loop 2	0.85	2BASE-TL-R	5696	symmetric	R2048sA2	5 + Δ*

[a]The following nomenclature is used to describe Annex B noise shapes: ABBBCDE; where A is the Side (either C or R), BBB, the rate, C the PSD type (either ‘s’ for symmetric or ‘a’ for asymmetric), D the Noise type (A,B,C or D) and E, the loop number (from 1 to 7).

63B.4 Deployment Guidelines

The ITU-T G.991.2 defines an equivalent loop attenuation which can be used to determine whether a cable insertion loss function 1/H(f), can support a given profile associated with a nominal transmit signal power spectral density S(f). The loop attenuation should not be confused with another popular metric called the loop insertion loss at a given frequency. The latter specifies the insertion loss of the loop at a single frequency while the former weights the transmitted signal PSD and insertion loss of the loop over a frequency range corresponding to the transmitted signal bandwidth. The loop attenuation provides a more precise estimate of the loop capability to support a given data rate.

The SHDSL Loop Attenuation shall be defined as follows (section 9.5.5.7.5 of G.991.2):

$$LoopAtten_{SHDSL}(H) = \frac{2}{f_{\text{Baud}}}\left(\int_{0}^{\frac{f_{\text{Baud}}}{2}} 10\log\left[\sum_{n=0}^{1} S(f - nf_{\text{Baud}})\right] df - \int_{0}^{\frac{f_{\text{Baud}}}{2}} 10\log\left[\sum_{n=0}^{1} S(f - nf_{\text{Baud}})\left|H(f - nf_{\text{Baud}})\right|^2\right] df \right) \quad \text{(63B–1)}$$

where f_{Baud} is the symbol rate, $1/H(f)$ is the insertion loss of the loop, and $S(f)$ is the nominal transmit PSD.

Table 63B-3 lists the maximum loop attenuation for a margin of 5 dB assuming the presence of 49 and 12 self-interferers for the profiles defined in Annex 63A. The 49 self-interferer case corresponds to a very conservative deployment reach.

Assuming a data rate of 2048 kb/s, the deployment reach for AWG24 gauge cable corresponds to 2.8 km for the 49-self number and 3.2 km for the 12-self number.

Table 63B-3—Loop attenuation guideline

Profile	Data rate (kb/s)	Maximum SHDSL Loop Attenuation for 49-self-interferers	Maximum SHDSL Loop Attenuation for 12-self-interferers
2 and 7	2048	24.0	27.7
3 and 8	1024	28.6	32.1
4 and 9	704	31.0	34.7
5 and 10	512	33.1	36.7

Annex 67A

(informative)

Environmental characteristics for Ethernet subscriber access networks

67A.1 Introduction

The purpose of EFM and its distinction from traditional Ethernet networks, is that it specifies functionality required for the subscriber access network, i.e., public network access. Network design considerations for "public" access that may differ from traditional Ethernet LANs include the operations, administration and management (OAM) function, and the regulatory requirements, as well as the environmental factors that are addressed in this annex. This annex applies to Clause 56 through Clause 67 with particular relevance for Clause 58, Clause 59, and Clause 60.

The optical link is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). implementers are expected to indicate in their literature the operating environmental conditions to facilitate selection, installation, and maintenance, and may also give summary information on a product label. The normative specifications of this standard are understood to apply over the range of conditions defined by the implementer.

This informative annex provides information, to both the design engineer and the eventual user of specific product implementations, on the environmental factors to be considered when designing EFM network topologies. It is intended to record the assumptions used in developing the specifications contained in the normative specifications. The following sections give an example of likely deployment of the different Physical Layer types, followed by a discussion of temperature issues. Informative references may be found in Annex A.

It is believed that the most critical environmental factor on an Ethernet terminal will be temperature and that the most temperature sensitive element in a link is the semiconductor laser. The temperature sensitivity of these components may impact potential deployment scenarios if not considered. The remaining environmental factors (humidity, vibration, etc.) are not considered to be of such major importance and may be handled by conventional design practice. Therefore, the remainder of this annex addresses temperature.

67A.1.1 Terminal deployment scenarios

The terminal equipment of a link may or may not be in a weather-protected environment. 100BASE-LX10 and 1000BASE-LX10 links may be widely deployed with conventional building cabling for general purpose IT applications, as well as in Ethernet subscriber access applications. The other link types in Table 67A–1 are intended for Ethernet subscriber access applications. The table gives an example deployment scenario. Other scenarios are also supported by this standard, and may be deployed in significant numbers.

This example scenario places the customer premises equipment in a non-weather-protected position, e.g. the outside wall of a house, to allow ease of access for installation and maintenance. Where the premises is a large building such as a hotel, apartment block or office, a weather-protected space such as a basement within the building may be accessible enough.

It is expected that the physical format of the equipment at each end of the link will be different; however, this is outside the scope of the standard. The Physical Layer type (e.g., 2BASE-TL) and the PMD type (e.g., 1000BASE-PX20-U) are classifications of the signal on the line, and do not imply a temperature range or physical format.

Table 67A–1—Informative deployment examples

Head end (nearer the center of the network)	Customer premises (nearer the periphery of the network)
Weather-protected	Not weather-protected or weather-protected
100BASE-LX10	100BASE-LX10
100BASE-BX10-D	100BASE-BX10-U
1000BASE-LX10	1000BASE-LX10
1000BASE-BX10-D	1000BASE-BX10-U
1000BASE-PX10-D	1000BASE-PX10-U
1000BASE-PX20-D	1000BASE-PX20-U
10PASS-TS-O	10PASS-TS-R
2BASE-TL-O	2BASE-TL-R

67A.2 Temperature

Large portions of Ethernet subscriber access optical and copper links are expected to operate in environmental conditions consistent with the outside plant. However, it is recognized that the exact requirements for a particular deployment will vary greatly depending on the geographic location, system structure, and governing regulations. It is also recognized that portions of the network may be deployed in more benign and protected environments and that in some geographic location the outside environment may also be considered benign.

There are many factors. The temperatures in coastal regions are not usually extreme. Tropical regions are usually hot or hot and wet. The widest temperature swings are found in dry regions in the interior of large continents, e.g. central North America or central Asia. High altitude may reduce the efficacy of air cooling systems. To an extent, this is offset by the typically cooler air temperature at high altitude. Direct sunshine can add up to 1120 W/m^2 heating - see Table 1 of ETSI EN 300 019-1-3 [B21].

As a reference, Table 67A–2 shows the annual extreme air temperature values for the nine classes of climates from IEC 60721-2-1 [B31].

The climate is the basic determining factor in the component temperature. However, the temperature of the equipment using the component is significantly modified by a number of factors related to the location of the equipment. Some of these are:

— Is the equipment location weather-protected or non-weather-protected
— Is the building temperature controlled
— Are locations without temperature control subject to solar heating

Equipment temperatures for a number of locations from ETSI and Telcordia documents are shown in Table 67A–3.

An additional factor is the internal thermal design of the equipment using the optical component. The component temperature will be higher than the equipment ambient and the increase will be implementation dependant. For equipment with the complexity of EFM systems an internal temperature rise of 15 ºC to 20 ºC may be anticipated.

Table 67A–2—Informative listing of climate types

Type of climate	Low temperature (°C)	High temperature (°C)
Extremely cold (except the Central Antarctic)	–65	+32
Cold	–50	+32
Cold temperate	–33	+34
Warm temperate	–20	+35
Warm dry	–20	+40
Mild warm dry	–5	+40
Extremely warm dry	+3	+55
Warm damp	+5	+40
Warm damp, equable	+13	+35

Table 67A–3—Informative listing of equipment temperature ranges

Climate or location	Specified ambient temperature	Reference
Weather-protected		
Telecom control rooms	15 – 30°C	ETSI Class 3.6
Temperature controlled	5 – 40°C (–5 – 45°C with cooling failure)	ETSI Class 3.1
Controlled - long term	5 – 40°C (–5 – 50°C short term)	Telcordia GR-63 [B29]
Partly temperature-controlled	–5 – 45°C	ETSI Class 3.2
Not temperature-controlled	–25 – 55°C	ETSI Class 3.3
Sheltered locations	–40 – 40°C	ETSI Class 3.5
Extended/uncontrolled	–40 – 46°C (-40 to 65°C inside enclosure)	Telcordia GR-487 [B28], GR-468 [B27]
Sites with heat trap	–40 – 70°C	ETSI Class 3.4
Non-weather-protected		
Temperate	–33 – 40°C	ETSI Class 4.1
Extended	–45 – 45°C	ETSI Class 4.1E
Extremely cold	–65 – 35°C	ETSI Class 4.2L
Extremely warm dry	–20 – 55°C	ETSI Class 4.2H

67A.3 Temperature impact on optical components

Components are often commercially available in two grades, 0 to 70°C and –40 to 85°C, although optoelectronic components are also available in –20 or –10 to 85°C grade, depending on format. The GBIC MSA requires an operating temperature range of 0 to 50°C in moving air. Because of the varied physical format of equipment and components, the reader is advised to refer to specific product literature or multi source agreements for precise information.

The most temperature sensitive sub-component in an Ethernet terminal is expected to be the semiconductor laser, if for a fiber optic link. There are two categories of laser presently commonplace in the Physical Layers addressed here; Fabry-Perot (FP), a type of multi longitudinal mode (MLM) laser, and distributed feedback (DFB), a type of single longitudinal mode (SLM) laser.

Fabry-Perot lasers may have a temperature coefficient of wavelength around 0.45 nm/K, so the operating wavelength of a particular FP may vary by 55 nm over the range –40 to 85°C. The operating wavelength windows within this standard are generally 100 nm wide where FPs are anticipated, allowing adequate margin for manufacturing tolerances. To allow for the widest variety of implementation the spectral width is specified as a function of wavelength where appropriate. However, the requirement for low error ratios over substantial distances of fiber, as specified by transmitter and dispersion penalty (TDP), forces the implementer of 1000 Mb/s FP laser based implementations to pay careful attention to both wavelength and spectral width to avoid excessive mode partition noise. In practice, the full range of wavelengths in the standard is not actually available for use because at the temperature extremes the required spectral width would be too narrow. It can be seen that the wider the temperature range required, the more precisely the wavelength and spectral width has to be contained to achieve a particular reach. This may have an impact on cost. This consideration would be expected to apply to 1000BASE-LX10, 1000BASE-BX10-U and 1000BASE-PX10-U.

Where the dispersion of the link or the wavelength limits are more demanding than can be met cost-effectively with FPs, DFBs may be used. They may have a temperature coefficient of wavelength under 0.1 nm/K and much narrower spectral widths than FPs. Because only a single longitudinal mode is present, a DFB does not suffer from mode partition noise. DFBs are generally more expensive than FPs. A DFB's lasing wavelength varies at 0.1 nm/K while its gain peak varies at around 0.45 nm/K. At extremes of temperature these two wavelengths are far apart and the laser may perform poorly. For this reason, DFBs for extended temperature range may be more expensive again. This consideration would be expected to apply to 1000BASE-BX10-D, 1000BASE-PX10-D, and 1000BASE-PX20.

67A.3.1 Component case temperature recommendations

67A.2 discussed the temperature progression from climate to equipment to component. 67A.3 discussed the impact of temperature, and particularly temperature range, on the design and cost of laser based optical components. In order to balance these two effects, contain costs, and yet cover the widest range of climates to allow access to the greatest markets the following recommendations are made.

Two component case temperature ranges, and by inference a third, are developed. These are defined as follows:

- Warm Extended: Intended for outdoor application in warmer climate locations.
- Cool Extended: Intended for outdoor applications in cooler climate locations.
- Universal Extended: (This is not a separate class, but is defined by simultaneously complying with the Warm and Cool Extended temperature ranges) This is a combination of the requirements for the Warm Extended and Cool Extended Classes and is intended for general outdoor applications in areas with wide seasonal variations or those designs intended for deployment in multiple geographic locations.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The recommended component case temperature ranges for these two classes are shown in Table 67A–4.

Table 67A–4—Component case temperature class recommendations

Class	Low temperature (°C)	High temperature (°C)
Warm extended	–5	+85
Cool extended	–40	+60
Universal extended	–40	+85

It will be noted that the recommendations of Table 67A–4 do not address the extremely cold climates of Table 67A–2 or the cold non-weather-protected equipment requirements of Table 67A–3. In these geographic locations it is common practice to avoid non-weather-protected locations for systems of EFM complexity and place the equipment indoors.

These temperature ranges are optional and conformance with these ranges is not required. This allows lower cost components to be had for those applications that require less extreme temperature ranges. This may be done by taking advantage of the reduced wavelength change to ease the central wavelength tolerance and spectral width requirements from the trade-off curves and more particularly, the TDP limit. This allows equipment and component suppliers, at their discretion, to develop systems and components that tolerate less severe environmental conditions that they view as suitable for their market as long as the PMD is consistent with the PICS proforma of the relevant clause. This limitation assures interoperability while allowing the equipment to be developed for specific markets. It is to be noted that the PMD specifications included in the optics Clause 58, Clause 59, and Clause 60 are based on a temperature range of –40 to 85°C in terms of the wavelength ranges and spectral widths defined.

Annex 69A

(normative)

Interference tolerance testing

69A.1 Introduction

A major problem in communicating across crowded backplanes is interference. The interfering signal can come from a variety of sources including:

a) Crosstalk from other data channels running the same kind of signals as the channel of interest. This type of interference is usually subdivided into:
   1) Far-end crosstalk (FEXT) coming from data traveling in the same general direction as the channel of interest.
   2) Near-end crosstalk (NEXT) originating from a channel with a transmitter near the receiver of the channel of interest.
b) Self interference caused by reflections due to impedance discontinuities, stubs, etc. This is a form of intersymbol interference (ISI) that is beyond what a reasonable equalizer can compensate.
c) Alien crosstalk which is defined to be interference from unrelated sources such as clocks, other kinds of data, power supply noise, etc.

For the channel to work, the receiver has to be able to extract correct data from the lossy channel in the presence of interference. The ability of the receiver to extract data in the presence of interference is an important characteristic of the receiver and needs to be measured. This ability is called interference tolerance.

69A.2 Test setup

The interference tolerance test is performed with the setup shown in Figure 69A–1.

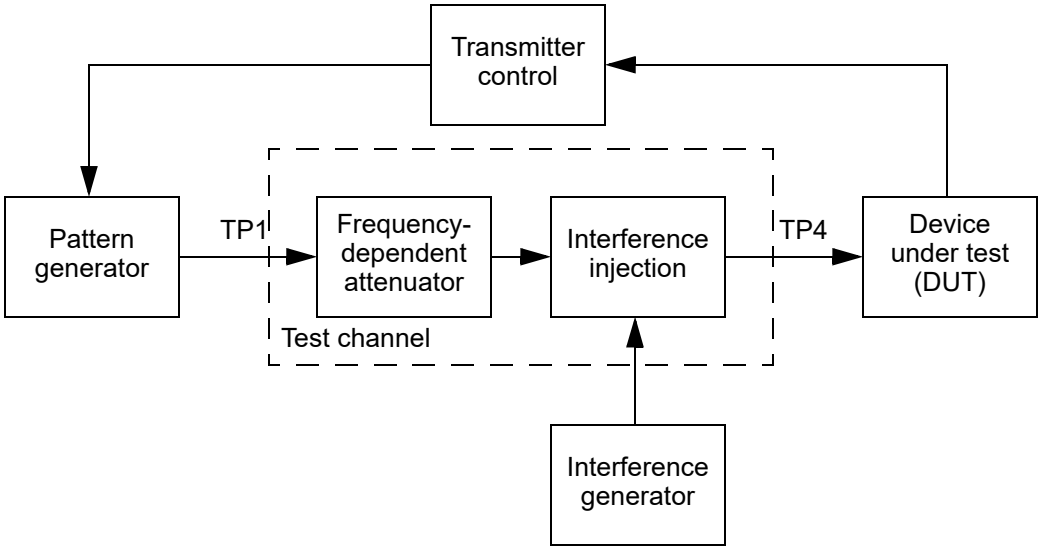

Figure 69A–1—Interference tolerance test setup

69A.2.1Pattern generator

For 1000BASE-KX and 10GBASE-KX4, the amplitude delivered by the pattern generator to the test channel shall be no greater than the specified minimum transmitter output amplitude for the port type being tested adjusted by a gain b_{TC} as defined in 69A.2.2.

For 2.5GBASE-KX, the peak-to-peak amplitude delivered by the pattern generator, as measured on a sequence of alternating ones and zeros, shall be no more than 800 mV, adjusted by a gain b_{TC} as defined in 69A.2.2.

For 5GBASE-CR, 10GBASE-KR, and 40GBASE-KR4, the peak-to-peak amplitude delivered by the pattern generator, as measured on a sequence of alternating ones and zeros, shall be no more than 800 mV, adjusted by a gain b_{TC} as defined in 69A.2.2, regardless of equalization setting.

The applied transition time at the pattern generator output shall be no less than the minimum value specified for the port type being tested. If the transition time of the pattern generator is less than the minimum specified applied transition time, an equivalent stress may be introduced in the test channel. The test channel, defined in 69A.2.2, is chosen so that the insertion loss of the test channel has a specific relationship to the maximum fitted attenuation, A_{max}, defined in 69B.4.2. If the minimum specified applied transition time is T_r(min), and the transition time of the pattern generator is T_r, then the test channel may be used to generate an equivalent stress by incrementing the parameter b_3 in A_{max} by Δb_3 as defined in Equation (69A–1).

$$\Delta b_3 = 6.8 \times (T_r(\min)^2 - T_r^2) \quad (69A–1)$$

The signaling speed of the pattern generator shall be offset ±100 ppm relative to the nominal signaling speed of the port type being tested.

The pattern generator shall have jitter on its output. This jitter shall consist of sinusoidal jitter at a frequency no less than 1/250 of signaling speed, duty cycle distortion, and random jitter. The random jitter shall be measured at the output of a single pole high-pass filter with cut-off frequency at 1/250 of the signaling speed. The sinusoidal jitter, duty cycle distortion, and random jitter shall each be no less than the amount specified for the port type being tested.

The pattern generator may include equalization depending on the port type being tested. For 1000BASE-KX and 2.5GBASE-KX, the pattern generator shall not include equalization. For 5GBASE-KR, equalization equivalent to a two-tap transversal filter meeting the requirements of Table 130–4 shall be included. For 10GBASE-KX4, the pattern generator shall include equalization such that the differential output template defined in 71.7.1.6 is met. For 10GBASE-KR, equalization equivalent to a three-tap transversal filter meeting the requirements of 72.7.1.10 shall be included.

69A.2.2Test channel

The test channel is a 100 Ω differential system consisting of a frequency-dependent attenuator and an interference injection block.

The interference injection block may be a pair of directional couplers, a pair of pick-off tees, or any other component, as long as the combination of the interference injection block and the frequency-dependent attenuator satisfies the requirements of the test channel.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The frequency dependent attenuator is recommended to be constructed in such a way that it accurately represents the insertion loss and group delay characteristics of differential traces on an FR-4 printed circuit board.

The test channel is specified with respect to transmission magnitude response, IL_{TC}, and return loss. Assuming the transmission magnitude response is measured at N uniformly-spaced frequencies f_n spanning the frequency range f_1 to f_2, the transmission magnitude is described by two parameters, m_{TC} and b_{TC}, as defined in Equation (69A–2) through Equation (69A–7).

$$m_X = \frac{1}{N}\sum_n A_{max}(f_n) \tag{69A–2}$$

$$m_Y = \frac{1}{N}\sum_n IL_{TC}(f_n) \tag{69A–3}$$

$$m_{XY} = \frac{1}{N}\sum_n A_{max}(f_n) IL_{TC}(f_n) \tag{69A–4}$$

$$m_{XX} = \frac{1}{N}\sum_n A_{max}(f_n) A_{max}(f_n) \tag{69A–5}$$

$$m_{TC} = \frac{m_{XY} - m_X m_Y}{m_{XX} - m_X m_X} \tag{69A–6}$$

$$b_{TC} = m_Y - m_{TC} m_X \tag{69A–7}$$

The values f_1 and f_2 are a function of the port type under test (see Table 69B–1 and Table 69B–2) and A_{max} is defined in 69B.4.2.

The test channel shall have m_{TC} greater than the minimum value specified for the port type under test and the test being performed. The test channel return loss, as measured at TP1 (see Figure 69A–1) and TP4 (see Figure 69A–1), shall be greater than or equal to 20 dB from f_{min} to f_2.

69A.2.3Interference generator

The interference generator is a broadband noise generator capable of producing white Gaussian noise with adjustable amplitude. The power spectral density shall be flat to ±3 dB from f_1 to 0.5 times the signaling speed for the port type under test with a crest factor of no less than 5. The noise shall be measured at the output of a filter connected to TP4. The filter for this measurement shall have no more than a 40 dB/decade roll-off and a 3 dB cut-off frequency at least 0.5 times the signaling speed.

69A.2.4Transmitter control

For 10GBASE-KR testing, the pattern generator is controlled by transmitter control. Transmitter control responds to inputs from the receiver to adjust the equalization of the pattern generator. The receiver may communicate through its associated transmitter, using the protocol described in 72.6.10, or by other means. For 2.5GBASE-KX and 5GBASE-KR testing, transmitter control is not used.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

69A.3 Test methodology

For 10GBASE-KR testing, the pattern generator shall first be configured to transmit the training pattern defined in 72.6.10.2. During this initialization period, the DUT shall configure the pattern generator equalizer, via transmitter control, to the coefficient settings it would select using the protocol described in 72.6.10. During training, the broadband noise measured at TP4 (see Figure 69A–1) shall have RMS amplitude less than 1 mV. Training patterns and transmitter control are not used for 2.5GBASE-KX and 5GBASE-KR testing.

The pattern generator shall be configured to transmit the test pattern defined for the port type under test.

The broadband noise source shall then be set to the amplitude specified for the port type being tested, as measured at TP4 (see Figure 69A–1). The measured BER shall be less than the target BER specified for the port type under test.

The interference tolerance test parameters are specified in Table 70–7 for 1000BASE-KX, in Table 71–7 for 10GBASE-KX4, in Table 128–6 for 2.5GBASE-KX, in Table 130–6 for 5GBASE-KR, and in Table 72–10 for 10GBASE-KR and 40GBASE-KR4.

Annex 69B

(informative)

Interconnect characteristics

69B.1 Overview

Backplane Ethernet is primarily intended to operate over differential, controlled impedance traces up to 1 m, including two connectors, on printed circuit boards residing in a backplane environment. The performance of such an interconnect is highly dependent on implementation.

69B.2 Reference model

The backplane interconnect is defined between test points TP1 and TP4 as shown in Figure 69B–1. The transmitter and receiver blocks include all off-chip components associated with the respective block. For example, external AC-coupling capacitors, if required, are to be included in the receiver block.

Informative characteristics and methods of calculation for the insertion loss, insertion loss deviation, return loss, crosstalk, and the ratio of insertion loss to crosstalk between TP1 and TP4 are defined in 69B.4.3, 69B.4.4, 69B.4.5, 69B.4.6, and 69B.4.6.4 respectively. These characteristics may be applied to a specific implementation of the full path (including transmitter and receiver packaging and supporting components) for a complete assessment of system performance and the interaction of these components.

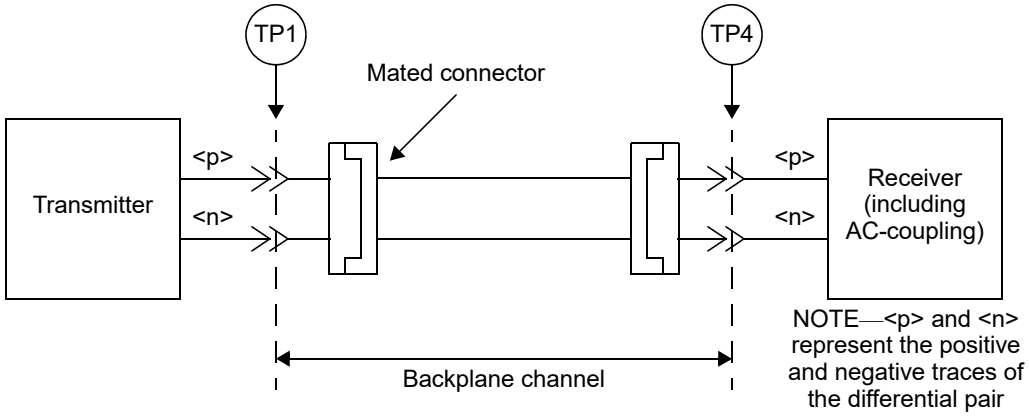

Figure 69B–1—Interconnect reference model

69B.3 Characteristic impedance

The recommended differential characteristic impedance of circuit board trace pairs is 100 Ω ± 10%.

The total differential skew from TP1 to TP4 is recommended to be less than the minimum transition time for port type of interest.

69B.4 Channel parameters

69B.4.1 Overview

A series of informative parameters are defined for use in backplane channel evaluation. These parameters address the channel insertion loss and crosstalk.

The informative parameters for channel insertion loss are based on the amount of loss allowed for a given level of interference as verified by the interference tolerance test procedure defined in Annex 69A.

The informative parameters for channel insertion loss are summarized in Table 69B–1 and Table 69B–2.

The maximum fitted attenuation (A_{max}) due to trace skin effect and dielectric properties is defined in 69B.4.2. The maximum insertion loss (IL_{max}) is defined in 69B.4.3. The maximum deviation of insertion loss from the best-fit attenuation (ILD) is defined in 69B.4.4. The minimum return loss (RL_{min}) is defined in 69B.4.5. The limit on crosstalk in relation to insertion loss (ICR_{min}) is defined in 69B.4.6.4. All of the different parameters have to be considered together in evaluating the overall channel performance.

Table 69B–1—Insertion loss parameters for 1000BASE-KX, 10GBASE-KX4, 10GBASE-KR, and 40GBASE-KR4

Parameter	1000BASE-KX	10GBASE-KX4	10GBASE-KR 40GBASE-KR4	Units
f_{min}	0.05			GHz
f_{max}	15.00			GHz
b_1	2.00×10^{-5}			
b_2	1.10×10^{-10}			
b_3	3.20×10^{-20}			
b_4	-1.20×10^{-30}			
f_1	0.125	0.312	1.000	GHz
f_2	1.250	3.125	6.000	GHz
f_a	0.100	0.100	0.100	GHz
f_b	1.250	3.125	5.15625	GHz

Table 69B–2—Insertion loss parameters for 2.5GBASE-KX and 5GBASE-KR

Parameter	2.5GBASE-KX	5GBASE-KR	Units
f_{min}	0.05		GHz
f_{max}	2.34375	3.8671875	GHz
b_1	2.4×10^{-5}		
b_2	1.3×10^{-10}		
b_3	4.9×10^{-20}		
b_4	-1.9×10^{-30}		
f_1	0.312	0.5	GHz
f_2	1.5625	2.578125	GHz
f_a	0.1		GHz
f_b	1.5625	2.578125	GHz

69B.4.2 Fitted attenuation

The fitted attenuation, A, is defined to be the least mean squares line fit to the insertion loss computed over the frequency range f_1 to f_2. Assuming the transmission magnitude response is measured at N uniformly-spaced frequencies f_n spanning the frequency range f_1 to f_2, the least mean squares line fit procedure is defined by Equation (69B–1) through Equation (69B–5).

$$f_{avg} = \frac{1}{N}\sum_n f_n \tag{69B–1}$$

$$IL_{avg} = \frac{1}{N}\sum_n IL(f_n) \tag{69B–2}$$

$$m_A = \frac{\sum_n (f_n - f_{avg})(IL(f_n) - IL_{avg})}{\sum_n (f_n - f_{avg})^2} \tag{69B–3}$$

$$b_A = IL_{avg} - m_A f_{avg} \tag{69B–4}$$

$$A(f) = m_A f + b_A \tag{69B–5}$$

It is recommended that the fitted attenuation of the channel be less than or equal to A_{max} as defined by the Equation (69B–6), where f is expressed in Hz and the coefficients b_1 through b_4 are given in Table 69B–1 and Table 69B–2.

$$A(f) \le A_{max}(f) = 20\log_{10}(e) \times (b_1\sqrt{f} + b_2 f + b_3 f^2 + b_4 f^3) \tag{69B–6}$$

for $f_1 \le f \le f_2$. The fitted attenuation limit is illustrated in Figure 69B–2 and Figure 69B–3.

69B.4.3 Insertion loss

Insertion loss is defined as the magnitude, expressed in decibels, of the differential response measured from TP1 to TP4. For 1000BASE-KX, 10GBASE-KX4, 10GBASE-KR, and 40GBASE-KR, it is recommended that the insertion loss magnitude, *IL*, be within the high confidence region defined by Equation (69B–7) and Equation (69B–8).

$$IL(f) \le IL_{\max}(f) = A_{\max}(f) + 0.8 + 2.0\times10^{-10} f \quad \text{(69B–7)}$$

for $f_{\min} \le f \le f_2$

$$IL(f) \le IL_{\max}(f) = A_{\max}(f) + 0.8 + 2.0\times10^{-10} f_2 + 1\times10^{-8}(f - f_2) \quad \text{(69B–8)}$$

for $f_2 < f \le f_{\max}$

For 2.5GBASE-KX, it is recommended that the insertion loss magnitude, *IL*, be within the high confidence region defined by Equation (69B–9).

$$IL(f) \le \left\{ \begin{array}{cc} 0.668 + 3.755\sqrt{f} + 3.608f & f_{\min} \le f < f_2 \\ -23.753 + 22.242f & f_2 \le f < f_{\max} \end{array} \right\} \text{ (dB)} \quad \text{(69B–9)}$$

For 5GBASE-KR, it is recommended that the insertion loss magnitude, *IL*, be within the high confidence region defined by Equation (69B–10).

$$IL(f) \le \left\{ \begin{array}{cc} 0.668 + 3.755\sqrt{f} + 3.608f & f_{\min} \le f < f_2 \\ -18.753 + 13.48f & f_2 \le f < f_{\max} \end{array} \right\} \text{ (dB)} \quad \text{(69B–10)}$$

The values of $f_{\min}$, f_2, and $f_{\max}$ are given in Table 69B–1 and Table 69B–2 and $A_{\max}$ is given in Equation (69B–6). The insertion loss limit is illustrated in Figure 69B–4 through Figure 69B–8.

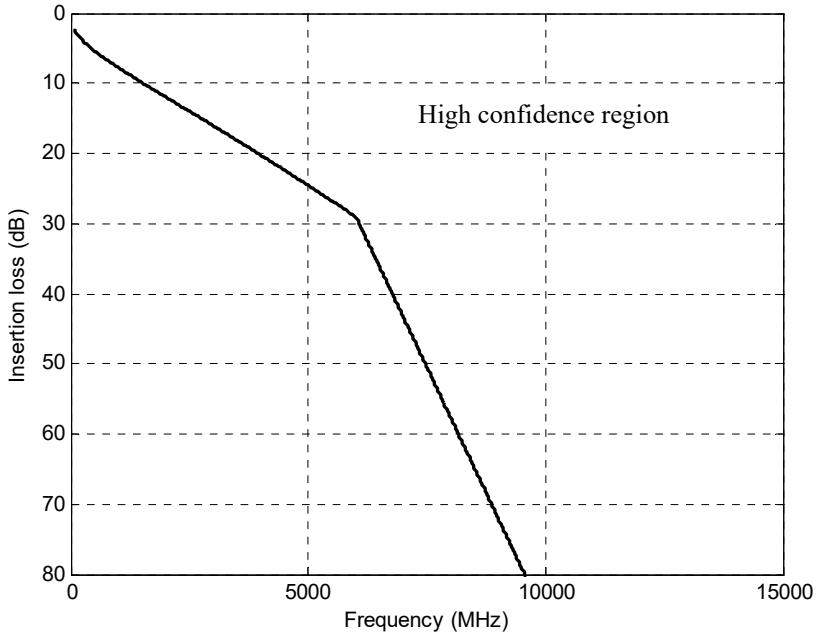

Figure 69B–8—Insertion loss limit for 10GBASE-KR and 40GBASE-KR4

69B.4.4 Insertion loss deviation

The insertion loss deviation, as defined by Equation (69B–11), is the difference between the insertion loss and the fitted attenuation defined in 69B.4.2.

$$ILD(f) = IL(f) - A(f) \tag{69B–11}$$

For 100BASE-KX, 10GBASE-KX4, 10GBASE-KR, and 40GBASE-KR, it is recommended that *ILD* be within the high confidence region defined by Equation (69B–12) and Equation (69B–13).

$$ILD(f) \geq ILD_{\min}(f) = -1.0 - 0.5\times10^{-9}f \tag{69B–12}$$

$$ILD(f) \leq ILD_{\max}(f) = 1.0 + 0.5\times10^{-9}f \tag{69B–13}$$

for $f_1 \leq f \leq f_2$.

For 2.5GBASE-KX and 5GBASE-KR, it is recommended that ILD be within the high confidence region defined by Equation (69B–14) and Equation (69B–15).

$$ILD(f) \geq ILD_{min}(f) = -1.0 - 0.7\times10^{-9}f \tag{69B–14}$$

$$ILD(f) \leq ILD_{max}(f) = 1.0 + 0.7\times10^{-9}f \tag{69B–15}$$

for $f_1 \leq f \leq f_2$.

The recommendation applies over the frequency range $f_1 \le f \le f_2$. The values of f_1 and f_2 are dependent on port type and are given in Table 69B–1 and Table 69B–2. The insertion loss deviation limits for each port type is illustrated in Figure 69B–9 and Figure 69B–10.

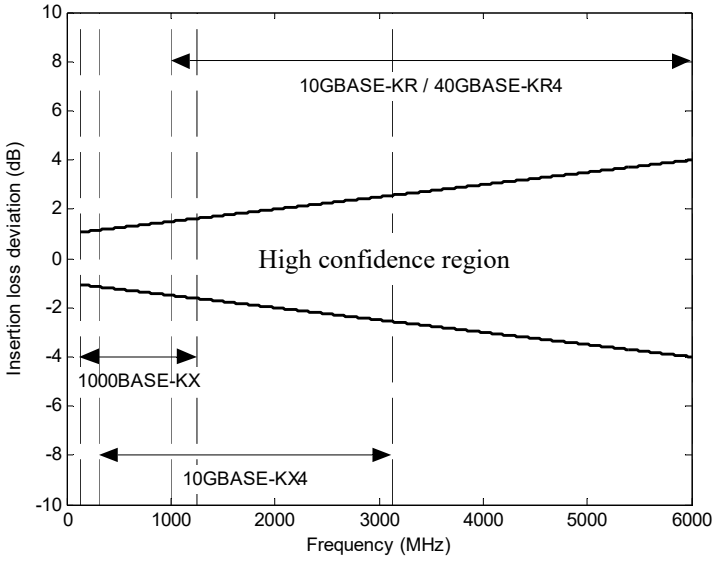

Figure 69B–9—Insertion loss deviation limits for 1000BASE-KX, 10GBASE-KX4, 10GBASE-KR, and 40GBASE-KR4

69B.4.5 Return loss

It is recommended that the channel return loss, *RL*, measured in dB at TP1 and TP4, be greater than or equal to $RL_{\min}$ as defined by Equation (69B–16) through Equation (69B–18).

$$RL(f) \geq RL_{\min}(f) = 12 \tag{69B–16}$$

for 50 MHz $\leq f <$ 275 MHz and

$$RL(f) \geq RL_{\min}(f) = 12 - 6.75\log_{10}\left(\frac{f}{275\ \text{MHz}}\right) \tag{69B–17}$$

for 275 MHz $\leq f <$ 3000 MHz and

$$RL(f) \geq RL_{\min}(f) = 5 \tag{69B–18}$$

for 3000 MHz $\leq f \leq$ 10312.5 MHz.

The recommendation applies from 50 MHz to the signaling speed of the PHY type of interest. The return loss limit is illustrated in Figure 69B–11 and Figure 69B–12.

69B.4.6 Crosstalk

The following equations and informative model assume that aggressors and victim are driven by a compliant PHY of any type.

69B.4.6.1 Power sum differential near-end crosstalk (PSNEXT)

The differential near-end crosstalk at TP4 is calculated as the power sum of the individual NEXT aggressors (*PSNEXT*). *PSNEXT* is computed as shown in Equation (69B–19), where $NEXT_n$ is the crosstalk loss, in dB, of aggressor *n*. Note that for the case of a single aggressor, *PSNEXT* will be the crosstalk loss for that single aggressor.

$$PSNEXT(f) = -10\log\left(\sum_n 10^{-NEXT_n(f)/10}\right) \quad \text{(69B–19)}$$

69B.4.6.2 Power sum differential far-end crosstalk (PSFEXT)

The differential far-end crosstalk at TP4 is calculated as the power sum of the individual FEXT aggressors (*PSFEXT*). *PSFEXT* is computed as shown in Equation (69B–20), where $FEXT_{\mathrm{n}}$ is the crosstalk loss, in dB, of aggressor *n*. Note that for the case of a single aggressor, *PSFEXT* will be the crosstalk loss for that single aggressor.

$$PSFEXT(f) = -10\log\left(\sum_n 10^{-FEXT_n(f)/10}\right) \quad \text{(69B–20)}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

69B.4.6.3 Power sum differential crosstalk

The differential crosstalk at TP4 is calculated as the power sum of the individual NEXT and FEXT aggressors (*PSXT*). *PSXT* may be computed as shown in the following equation:

$$PSXT(f) = -10\log(10^{-PSNEXT(f)/10} + 10^{-PSFEXT(f)/10}) \quad (69B–21)$$

69B.4.6.4 Insertion loss to crosstalk ratio (ICR)

Insertion loss to crosstalk ratio (*ICR*) is the ratio of the insertion loss, measured from TP1 to TP4, to the total crosstalk measured at TP4. *ICR* may be computed from *IL* and *PSXT* as shown in the following equation:

$$ICR(f) = -IL(f) + PSXT(f) \quad (69B–22)$$

Assuming ICR is computed at N uniformly-spaced frequencies f_n spanning the frequency range f_a to f_b, ICR_{fit} may be computed using Equations (69B–23) through (69B–27). The values of f_a and f_b are dependent on port type and are provided in Table 69B–1.

$$x_{avg} = \frac{1}{N}\sum_n \log(f_n) \quad (69B–23)$$

$$ICR_{avg} = \frac{1}{N}\sum_n ICR(f_n) \quad (69B–24)$$

$$m_{ICR} = \frac{\sum_n (\log(f_n) - x_{avg})(ICR(f_n) - ICR_{avg})}{\sum_n (\log(f_n) - x_{avg})^2} \quad (69B–25)$$

$$b_{ICR} = ICR_{avg} - m_{ICR}x_{avg} \quad (69B–26)$$

$$ICR_{fit}(f) = m_{ICR}\log(f) + b_{ICR} \quad (69B–27)$$

It is recommended that ICR_{fit} be greater than or equal to ICR_{min}. For 1000BASE-KX, 10GBASE-KX4, 10GBASE-KR, and 40GBASE-KR, ICR_{min} is defined by Equation (69B–28). For 2.5GBASE-KX and 5GBASE-KR, ICR_{min} is defined by Equation (69B–29).

$$ICR_{fit}(f) \geq ICR_{min}(f) = 23.3 - 18.7\log_{10}\left(\frac{f}{5\text{ GHz}}\right) \quad (69B–28)$$

$$ICR_{fit}(f) \geq ICR_{min}(f) = 28 - 18\log_{10}\left(\frac{f}{2\text{ GHz}}\right) \quad (69B–29)$$

ICR_{min} is defined over the frequency range $f_a \leq f \leq f_b$. ICR_{fit} accounts for the worst-case differences in characteristics (e.g. amplitude, transition times) between the victim and aggressor transmitters. It also assumes a 3 dB signal-to-noise ratio penalty related to insertion loss deviation.

The insertion loss to crosstalk ratio limit for each port type is illustrated in Figure 69B–13 and Figure 69B–14.

Annex 73A

(normative)

Next page message code field definitions

This Annex defines the Next Page message code fields for devices using Clause 73 Auto-Negotiation. The message code field of a message page used in Next Page exchange shall be used to identify the meaning of a message. Table 73A–1 identifies the types of messages that may be sent. As new messages are developed, this table will be updated accordingly.

The Message code field uses an 11-bit binary encoding that allows 2048 messages to be defined. All message codes not specified are reserved for IEEE use or allocation.

Table 73A–1—Message code field values

Message code	M 10	M 9	M 8	M 7	M 6	M 5	M 4	M 3	M 2	M 1	M 0	Message code description
1	0	0	0	0	0	0	0	0	0	0	1	Null Message
5	0	0	0	0	0	0	0	0	1	0	1	Organizationally Unique Identifier Tagged Message
6	0	0	0	0	0	0	0	0	1	1	0	AN device Identifier Tag Code
10	0	0	0	0	0	0	0	1	0	1	0	EEE Technology Message Code. EEE capability is advertised using unformatted message code field in the Message Next Page (see 73A.4).

73A.1 Message code 1—Null Message code

The Null Message code shall be transmitted during Next Page exchange when the Local Device has no further messages to transmit and the Link Partner is still transmitting valid Next Pages. See 73.7.7 for more details.

73A.2 Message code 5—Organizationally Unique Identifier (OUI) tag code

The OUI tag code message shall consist of a Message Next Page with the message code field 000 0000 0101 followed by one Unformatted Next Page defined as follows. The unformatted code field of Message Next Page 5 shall contain the most significant 11 bits of the OUI or CID (bits 23:13) in bits 26:16 (bits U10 to U0) with the most significant OUI or CID bit in bit 26 (bit U10) of the unformatted code field, the next 11 most significant bits of the OUI or CID (bits 12:2) in bits 42:32 (bit U26 to U16) with the most significant bit in bit 42 (bit U26). The unformatted code field of the Unformatted Next Page shall contain the remaining least significant 2 bits of the OUI or CID (bits 1:0) in bits 10:9 (U10 and U9) with OUI or CID bit 1 in bit 10 (bit U10) with the bits 8:0, 26:16 (bits U8 to U0, U21 to U11) as a user-defined user code value that is specific to the OUI or CID transmitted. The remaining unformatted code field bits in the Message Next Page and the Unformatted Next Page shall be sent as zero and ignored on receipt.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For example, assume that a manufacturer's IEEE-assigned OUI/CID value is AC-DE-48 and the manufacturer-selected user-defined user code associated with the OUI or CID is 0xCE1FC (binary 1100 1110 0001 1111 1100). The message code values generated from these two numbers is encoded into the message Next Page and Unformatted Next Page codes, as specified in Figure 73A–1. For clarity, the position of the M bit[292] is illustrated.

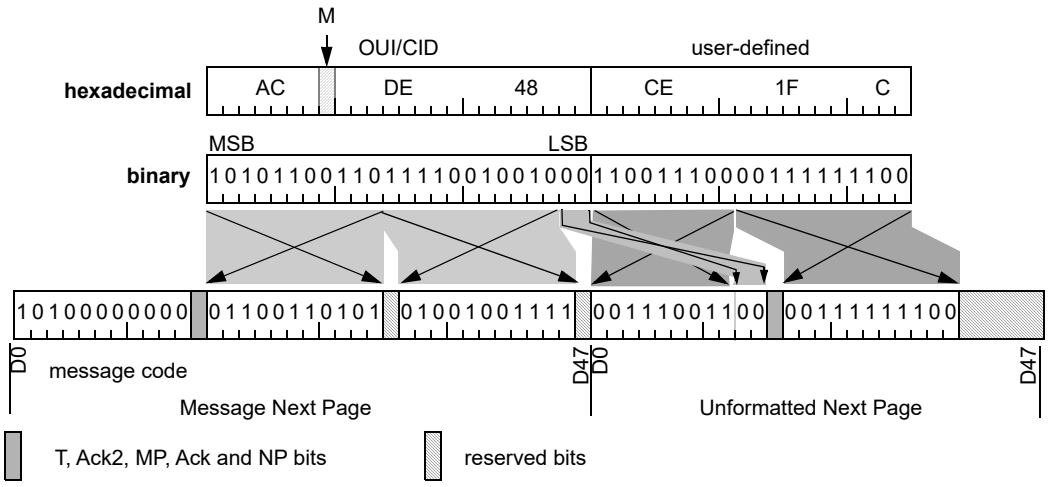

Figure 73A–1—Message code 5 sequence

NOTE—Figure 73A–1 shows the order Next Pages are transmitted, with the first transmitted Next Page shown in the leftmost position. This bits within each page are shown with the first transmitted bit (i.e., least significant bit) in the leftmost position. This is the same convention for bit order in the figures of Clause 73. Figure 28C–1 uses the opposite convention for bit order.

73A.3 Message code 6—AN device identifier tag code

The AN device ID tag code message shall consist of a Message Next Page with the message code field 000 0000 0110 followed by one Unformatted Next Page defined as follows. The unformatted fields of this message contain the AN device identifier. If a Clause 45 MDIO is implemented, the AN device identifier is accessible through registers 7.2 and 7.3 (see 45.2.7.3).

The unformatted code field of Message Next Page 6 shall contain the most significant 11 bits of the AN device identifier (7.2.15:5) in bits 26:16 (bits U0 to U10) with the most significant AN device identifier bit in bit 26 (bit U10) of the unformatted code field, and the next 11 most significant bits of the AN device identifier (bits 7.2.4:0 to 7.3.15:10) in bits 42:32 (bit U26 to U16) with the most significant bit in bit 42 (bit U26) of the unformatted code field. The unformatted code field of the Unformatted Next Page shall contain the remaining least significant 10 bits of the AN device identifier (bits 7.3.9:0) in bits 10:1 (bit U10 to U1). Bits 0, 26:16 (bits U0, U21 to U11) of the unformatted code field of the Unformatted Next Page shall contain a user-defined user code value that is specific to the device identifier transmitted. The remaining unformatted code field bits in the Message Next Page and the Unformatted Next Page shall be sent as zero and ignored on receipt.

[292]See IEEE Std 802, subclause 9.3

73A.4 Message code 10—EEE technology message code

Multiple clauses use Next Page message code 10 as an identifier for EEE technology. The EEE technology code message shall consist of only a Message Next Page. The message code field, 000 0000 1010, shall be contained in bits 10:0. The contents of the unformatted code bits U31:U0 (D47:D16) shall be as defined in 45.2.7.14.

EEE capability negotiation is defined in 78.3.

Annex 74A

(informative)

FEC block encoding examples

This annex provides an example FEC block encoding with (2112, 2080) code. See Table 74–1 for the format of the FEC block. The length of the FEC block is 2112 bits. Each FEC block contains 32 rows of 65 bits each; 64 bits of payload and 1 bit transcoding overhead (T bits). At the end of each block there is 32-bit overhead or parity check bits.

The data pattern in this annex is represented in a tabular form. For the tables within this annex the contents are transmitted from left to right within each row and from top to bottom between rows. The first bit out on the wire starts at the top left hand corner. Note that there is both binary representation and hexadecimal symbol representation in the table; in case of the hex symbol, the most significant bit of each hex symbol is sent first.

74A.1 Input to the FEC (2112,2080) Encoder

Table 74A–1 provides an example 64B/66B block stream at the input to the FEC (2112,2080) encoder. The example shows a stream of 32 64B/66B symbols generated from the output of the PCS layer when the link was sending out IDLE symbols.

74A.3 Output of the FEC (2112,2080) Encoder after scrambling with PN-2112 sequence

Table 74A–3 provides the data stream at the output of the FEC (2112,2080) encoder after the data is scrambled with the PN-2112 sequence as described in 74.7.4.4.1. The corresponding 2112 bit FEC block input to the scrambler is as described in Table 74A–2. The example shows the stream of data in 64 bit format (33 64b symbols) generated from the output of the FEC (2112,2080) encoder after the PN-2112 scrambler.

74A.5 Output of the FEC (2112,2080) Encoder to Support Rapid Block during the wake state in EEE (optional)

If the optional EEE function is supported (see Clause 78) then the reverse gearbox of the remote FEC encoder will be receiving unscrambled data. PCS sublayer will be encoding /I/ during the wake state, which produces the deterministic FEC frame.

Table 74A–5 provides the data stream at the output of the FEC (2112,2080) encoder after the data is scrambled with the PN-2112 sequence as described in 74.7.4.4.1. The example shows the stream of data in 64 bit format (33 64b symbols) generated from the output of the FEC (2112,2080) encoder after the PN-2112 scrambler.

74A.6 Output of the FEC (2112,2080) Encoder to Support Rapid Block during the refresh state in EEE (optional)

If the optional EEE capability is supported (see Clause 78) then the reverse gearbox of the remote FEC encoder will be receiving unscrambled data. PCS sublayer will be encoding /LI/ during the refresh state, which produces the deterministic FEC frame.

Table 74A–6 provides the data stream at the output of the FEC (2112,2080) encoder after the data is scrambled with the PN-2112 sequence as described in 74.7.4.4.1. The example shows the stream of data in 64 bit format (33 64b symbols) generated from the output of the FEC (2112,2080) encoder after the PN-2112 scrambler.

Annex 75A

(informative)

Dual-rate receiver implementation

75A.1 Overview

The OLT receiver supports burst mode operation. If the OLT supports a single upstream data rate e.g., only 1 Gb/s or 10 Gb/s, the receiver can be designed to handle the designated upstream data rate and line code. However, if the OLT supports both 1 Gb/s and 10 Gb/s upstream data rates, the OLT receiver supports both data rates via TDMA.

From a topological point of view, the PMD has a single optical input, sensitive to 1260–1360 nm signal, and two corresponding derived electrical outputs: 1.25 GBd and 10.3125 GBd. Thus, at a certain point in the implementation it is necessary to introduce a signal split, where the location of such a signal split is an implementation choice. The incoming signal can be split in the optical domain and fed into two, independent photodetectors as shown in Figure 75A–1(a). Alternatively, the signal can be detected using a single photodetector as shown in Figure 75A–1(b) and then split in the electrical domain after the transimpedance amplifier (TIA) block.

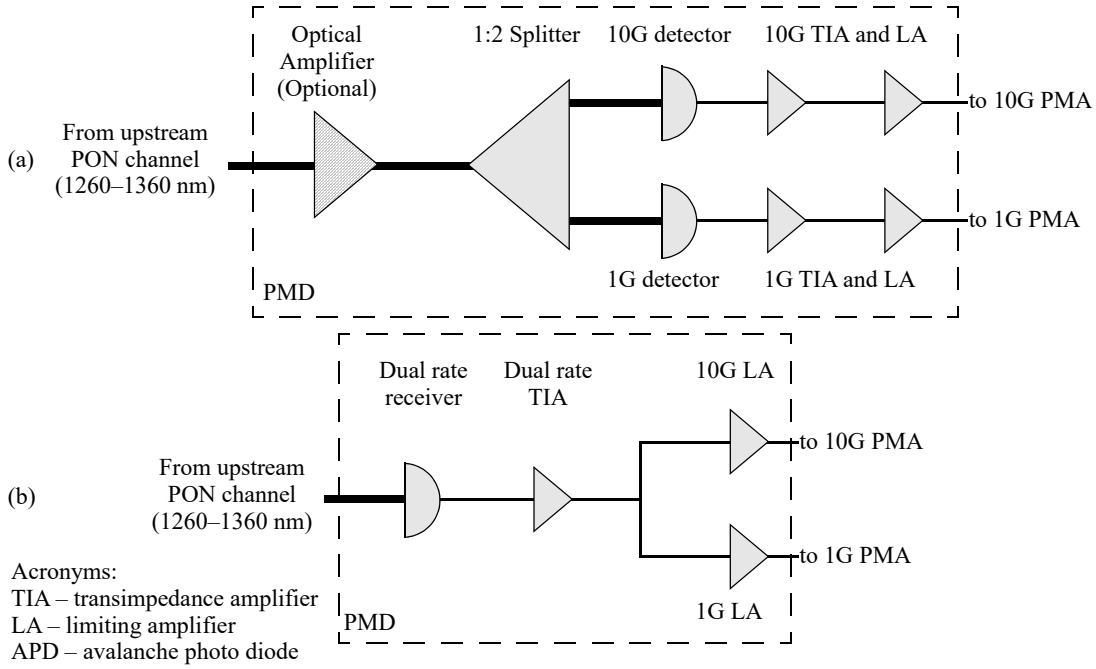

Figure 75A–1—Dual-rate PMD topologies with the split in the (a) optical domain, (b) electrical domain

When the incoming signal is split in the optical domain, it is possible to design each PMD channel specifically to match the signaling speed, offering optimum sensitivity for both 1 Gb/s and 10 Gb/s signals. However, the additional 1:2 optical splitter presented in Figure 75A–1(a) degrades the sensitivity of the

PMD by introducing additional loss and lowering the power of the optical signal. Such a sensitivity reduction may be tolerable in the PX10/PR10/PRX10 type PMDs, but the more stringent power budgets including PX20, PR20, PRX20, PX30, PR30, PRX30, PX40, PR40, and PRX40, may be very challenging or even impossible to implement with such an additional loss on the OLT receiver side.

When the incoming signal is split in the electrical domain, only one photodetector and one TIA unit is used. The resulting optical sensitivity theoretically can be maintained without the need for optical amplification, reducing the complexity of the OLT receiver. However, the photodetector and TIA cope with both data rates in quick succession, switching between 1 Gb/s and 10 Gb/s bursts during the guardband. The key aspect here is that the detector-TIA bandwidth directly affects the sensitivity. If the circuit parameters of the detector-TIA can be rapidly adapted to the correct value, optimum sensitivity can be maintained. There are several implementation choices in this regard, three examples of which are shown in Figure 75A–2(a)–(c):

a) This implementation fixes the detector parameters at some predefined value, resulting in the reduction of the OLT receiver sensitivity by approximately 2 dB. However, it should be noted that this penalty can be divided in such a way that both 1 Gb/s and 10 Gb/s sensitivities are 1 dB lower than their ideal values.
b) This implementation fixes the avalanche photo diode (APD) bias, but switches the TIA transimpedance depending on the target signaling speed for the given incoming burst, resulting in the reduction of the receiver sensitivity by approximately 1 dB. The said sensitivity penalty could be subdivided to both data rates by setting the APD bias to a compromise value.
c) This implementation switches both the APD bias and the TIA transimpedance depending on the signaling speed of the incoming burst. This results in ideal performance at both 1 Gb/s and 10 Gb/s data rates. However, it is the most complex implementation in terms of the number of elements and the control complexity.

In the case of dynamic detector designs, it is necessary to determine the data rate of the incoming burst before adjusting the dynamic detector to match the target data rate.

In general, the PMD layer does not have prior knowledge of which data rate is used in the given burst; such information is available only to the MAC Client and is not available to the PMD sublayer. Therefore, some sort of data rate detector circuit should be utilized. One of the simple methods is based on measuring the spectral energy content of the received signal at frequencies well above 1.25 GHz (e.g., in the range of 2–10 GHz). The 1 Gb/s signal has very little energy in this frequency range, while the 10 Gb/s signal has ample energy there. Thus, the presence of 5 GHz energy indicates that a 10 Gb/s signal is incident.

In the dual-rate PMD topologies with the split in the electrical domain, the 10 Gb/s detector and TIA are implemented for receiving both 1 Gb/s and 10 Gb/s signals. Therefore, the damage threshold (max) of the 1/10 Gb/s dual-rate receiver should comply with the 10 Gb/s receiver specification in Table 75–6. Those values for 1000BASE–PX10–D in Table 60–5, for 1000BASE–PX20–D in Table 60–8, for 1000BASE–PX30–D in Table 60–11, and for 1000BASE–PX40–D in Table 60–13, and also those of 10/1GBASE–PRX–D1, 10/1GBASE–PRX–D2, 10/1GBASE–PRX–D3, and 10/1GBASE–PRX–D4 in Table 75–5 cannot be applied for dual-rate OLT receivers.

Annex 75B

(informative)

Illustrative channels and penalties for 10GBASE-PR and 10/1GBASE-PRX power budget classes

75B.1 Overview

Illustrative power budgets for PR10, PR20, PR30, and PR40 power budget classes are shown in Table 75B–1. Illustrative power budgets for PRX10, PRX20, PRX30, and PRX40 power budget classes are shown in Table 75B–2.

NOTE—The budgets include an allowance for –12 dB reflection at the receiver.

75B.2 Wavelength allocation

The wavelength allocation plan for 10G–EPON systems is specified below.

75B.2.1 Downstream wavelength allocation

The 1 Gb/s downstream transmission uses the 1480–1500 nm wavelength band, as specified in Clause 60. The 10 Gb/s downstream transmission uses the 1575–1580 nm wavelength band, as specified in Clause 75. An OLT supporting both downstream channels may multiplex the output of the two transmitters using a WDM coupler, while the optical filters at an ONU are tuned to receive only one downstream wavelength.

Table 75B–1—Illustrative 10GBASE–PR channel insertion loss and penalties (symmetric-rate, 10 Gb/s power budget classes)

Description[a]	PR10		PR20		PR30		PR40		Unit
	US	DS	US	DS	US	DS	US	DS	
Fiber Type[b]	IEC 60793–2 B1.1, B1.3 SMF ITU–T G.652, G.657 SMF								
Measurement wavelength for fiber	1270	1577[c]	1270	1577[c]	1270	1577[c]	1270	1577[c]	nm
Nominal distance[d]	10		20		20		20		km
Available power budget[e]	23	21.5	27	25.5	32	30.5	35	34.5	dB
Channel insertion loss (max)[f]	20		24		29		33		dB
Channel insertion loss (min)[g]	5		10		15		18		dB
Allocation for penalties[h]	3	2.5[i]	3	1.5	3	1.5	2	1.5	dB
Optical return loss of ODN (min)	20								dB

[a]US stands for Upstream, DS stands for Downstream.
[b]Other fiber types are acceptable if the resulting ODN meets channel insertion loss and dispersion requirements.
[c]The nominal transmit wavelength is 1577 nm.
[d]Nominal distance refers to the expected maximum distance a PMD is capable of achieving in a typical ODN. Numerous ODN implementation practices may result in longer or shorter distances being actually achievable in a user's network.
[e]The available power budget assumes a BER at the PMD service interface of 10^{-3}. The required BER of 10^{-12} at the PCS service interface is achieved by the FEC function of the PCS.
[f]The channel insertion loss is based on the cable attenuation at the target distance and nominal measurement wavelength. The channel insertion loss also includes the loss for connectors, splices and other passive components such as splitters.
[g]The power budgets for PR10, PR20, PR30, and PR40 power budget classes are such that a minimum insertion loss is assumed between transmitter and receiver. This minimum attenuation is required for PMD testing.
[h]The allocation for penalties is the difference between the available power budget and the channel insertion loss; insertion loss difference between nominal and worst case operating wavelength is considered a penalty. This allocation may be used to compensate for transmission related penalties. Further details are given in 75.7.2.
[i]The extra 1 dB of penalty here is to unify the downstream Tx and Rx specifications.

Available power budget	23	21.5[e]	26	25.5[e]	30.4	30.5[e]	34	34.5[e]	dB
Channel insertion loss (max)[f]	20		24		29		33		dB
Channel insertion loss (min)[g]	5		10		15		18		dB
Allocation for penalties[h]	3	2.5[i]	2	1.5	1.4	1.5	1	1.5	dB
Optical return loss of ODN (min)	20								dB

[a]US stands for Upstream, DS stands for Downstream.
[b]Other fiber types are acceptable if the resulting ODN meets channel insertion loss and dispersion requirements.
[c]The nominal transmit wavelength is 1577 nm.
[d]Nominal distance refers to the expected maximum distance a PMD is capable of achieving in a typical ODN. Numerous ODN implementation practices may result in longer or shorter distances being actually achievable in a user's network.
[e]The available power budget assumes a BER at the PMD service interface of 10^{-3}. The required BER of 10^{-12} at the PCS service interface is achieved by the FEC function of the PCS.
[f]The channel insertion loss is based on the cable attenuation at the target distance and nominal measurement wavelength. The channel insertion loss also includes the loss for connectors, splices and other passive components such as splitters.
[g]The power budgets for PRX10, PRX20, PRX30, and PRX40 power budget classes are such that a minimum insertion loss is assumed between transmitter and receiver. This minimum attenuation is required for PMD testing.
[h]The allocation for penalties is the difference between the available power budget and the channel insertion loss; insertion loss difference between nominal and worst case operating wavelength is considered a penalty. This allocation may be used to compensate for transmission related penalties. Further details are given in 75.7.2.
[i]The extra 1 dB of penalty here is to unify the downstream Tx and Rx specifications.

75B.2.2 Upstream wavelength allocation

The 1 Gb/s upstream transmission uses the 1260 to 1360 nm wavelength band for 1000BASE–PX10–U, 1000BASE–PX20–U, 1000BASE–PX30–U, 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2, and 10/1GBASE–PRX–U3 compliant ONUs, and the 1290 to 1330 nm wavelength for 1000BASE–PX40–U and 10/1GBASE–PRX–U4 compliant ONUs, as specified in Clause 60. The 10 Gb/s upstream transmission uses the 1260 to 1280 nm wavelength band, as specified in Clause 75. The two wavelength bands overlap, thus WDM channel multiplexing cannot be used to separate the 1G upstream links operating in 1260 to 1360 nm wavelength band from 10G upstream links operating in 1260 to 1280 nm wavelength band.

An OLT supporting both upstream data rates uses TDMA techniques to avoid collisions between transmissions originating from different ONUs, resulting in a dual-rate burst–mode reception as discussed in 75.6.

Annex 75C

(informative)

Jitter at TP1 to TP8 for 10GBASE–PR and 10/1GBASE–PRX

75C.1 Overview

The jitter values at frequencies above 4 MHz are listed in Table 75C–1 for PR10, PR20, PR30, PR40, PRX10, PRX20, PRX30, and PRX40 downstream and in Table 75C–2 for PR10, PR20, PR30, and PR40 upstream. Those in Table 75C–3 relate to the jitter frequencies above 637 kHz for PRX10, PRX20, PRX30, and PRX40 upstream.

Table 75C–1—10GBASE–PR and 10/1GBASE–PRX downstream jitter budgets

Reference point	DJ (UI p–p)	RJ (UI p–p)	TJ (UI p–p)
TP1	0.09	0.14	0.23
TP2	0.19	0.20	0.39
TP3	0.24	0.20	0.44
TP4	0.42	0.34	0.76

NOTE 1—Jitter measurements should be performed at nominal operating conditions.
NOTE 2—BER conditions for TP1, TP2, and TP3 are 10^{-12}, for TP4 is 10^{-3}.
NOTE 3—All jitter values relate to high frequency (>4 MHz) jitter.
NOTE 4—0.1 UI of sinusoidal jitter stress is assumed at the receiver.
NOTE 5—The Gaussian jitter is assumed to be a weak function of BER.

The upstream jitter transfer function is defined Equation (75C-1). The jitter gain curve and the corresponding jitter gain values are shown in Figure 75C–1 where the jitter gain P and the jitter corner frequency f_c are specified in Table 75C–4 for PR10, PR20, PR30, and PR40, and in Table 75C–5 for PRX10, PRX20, PRX30, and PRX40, respectively.

Annex 76A

(informative)

FEC Encoding example

76A.1 Introduction and rationale

This Annex provides an example of FEC encoding with RS (255,223) code. See 76.3.2.4.3 for the format of the FEC codeword.[293]

76A.2 64B/66B block input

Table 76A–1 provides an example of a 64B/66B block stream received at the input to the RS (255,223) encoder. The example shows a stream of 27 scrambled 64B/66B blocks generated from the output of the PCS layer when the link was sending out Idles.

The 66 bit blocks in the Table 76A–1 are transmitted from left to right within each row and from top to bottom between rows. The 64 bit payload portion of the 66 bit block is described as a series of hexadecimal octets—the left-most octet of each payload portion is transmitted first. Bits within each octet of the payload are transmitted in least-significant bit-first order (i.e., the right-most bit of each octet is transmitted first). Thus, the first ten bits transmitted are: 10 0100 0000 …

76A.8 64B/66B Parity Blocks for Transmit

Table 76A–7 illustrates the 64B/66B blocks carrying parity that are generated by the RS (255,223) encoder for the input blocks in Table 76A–6 above. The RS (255,223) encoder inserts the parity blocks into the transmission stream to the gearbox subsequent to its transmission of the corresponding input 66 bit blocks (as described in 76.3.2.4).

The 66 bit blocks in the Table 76A–7 are transmitted from left to right within each row and from top to bottom between rows. The 64 bit payload portion of the 66 bit block is described as a series of hexadecimal octets—the left-most octet of each payload portion is transmitted first. Bits within each octet of the payload are transmitted in least-significant bit-first order (i.e., the right-most bit of each octet is transmitted first).

Thus, the first 18 bits of the parity blocks transmitted are: 00 0111 1110 0100 0110 …

Annex 83A

(normative)

40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10)

83A.1 Overview

This annex defines the functional and electrical characteristics for the optional 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10). Figure 83A–1 shows the relationships of the XLGMII, PMA, XLAUI, and PMD for 40 Gb/s and CGMII, PMA, CAUI-10, and PMD for 100 Gb/s.

CAUI-10 = 100 Gb/s TEN-LANE ATTACHMENT UNIT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLAUI = 40 Gb/s ATTACHMENT UNIT INTERFACE
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

NOTE 1—OPTIONAL OR OMITTED DEPENDING ON PHY TYPE
NOTE 2—CONDITIONAL BASED ON PMD TYPE

Figure 83A–1—Example relationship of XLAUI and CAUI-10 to IEEE 802.3 Ethernet model

The purpose of the optional XLAUI or CAUI-10 is to provide a flexible chip-to-chip and chip-to-module interconnect for 40 Gb/s or 100 Gb/s components. Annex 83A provides compliance requirements for

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

XLAUI/CAUI-10 transmitters and receivers while Annex 83B specifies the electrical requirements for the chip-to-module interconnection.

The XLAUI/CAUI-10 allows interconnect distances of approximately 25 cm over printed circuit board including one connector, see 83A.4.

An example application of CAUI-10 includes providing a physical connection between a ten-lane 100 Gb/s PMA and a 10:4 PMA mapping element. An example application of XLAUI is to provide lane extension for interfacing MAC and PHY components in a 40 Gb/s Ethernet system distributed across a circuit board.

The optional XLAUI/CAUI-10 interface has the following characteristics:

a) Independent transmit and receive data paths
b) Differential AC-coupled signaling with low voltage swing
c) Self-timed interface
d) Shared technology with other 40 Gb/s or 100 Gb/s interfaces
e) Utilization of 64B/66B coding

83A.1.1 Summary of major concepts

The following is a list of the major concepts of XLAUI and CAUI-10:

a) The optional XLAUI/CAUI-10 interface can be inserted between PMA layers in the IEEE 802.3 Ethernet model to transparently enable chip-to-chip communication
b) The XLAUI is organized into four lanes, the CAUI-10 is organized into ten lanes
c) The XLAUI/CAUI-10 interface is a parallel electrical interface with each lane running at a nominal rate of 10.3125 Gb/s

83A.1.2 Rate of operation

The XLAUI interface supports the 40 Gb/s data rate and the CAUI-10 interface supports the 100 Gb/s data rate. For 40 Gb/s applications, the data stream shall be presented in four lanes as described in Clause 83. For 100 Gb/s applications, the data stream shall be presented in ten lanes as described in Clause 83. The data is 64B/66B coded. The nominal signaling rate for each lane in both 40 Gb/s and 100 Gb/s applications shall be 10.3125 Gb/s.

83A.2 XLAUI/CAUI-10 link block diagram

XLAUI/CAUI-10 link is illustrated in Figure 83A–2. XLAUI/CAUI-10 channel is defined from the transmit pad to the receive pad including any AC-coupling in the path.

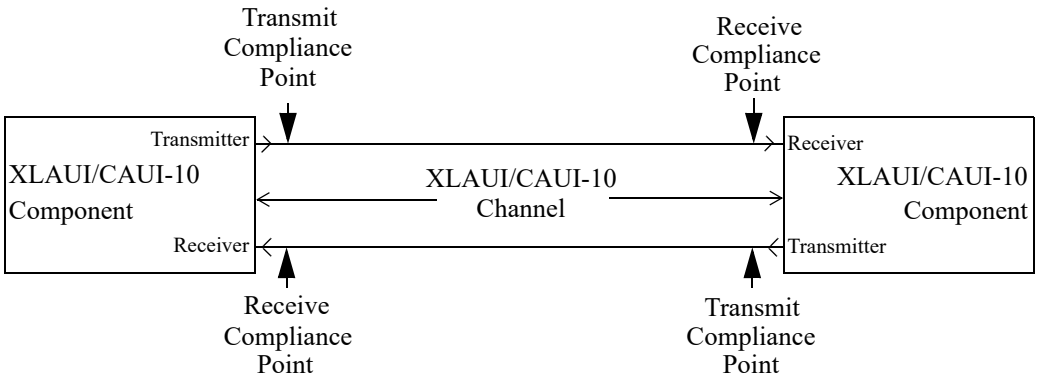

Figure 83A–2—Definition of transmit and receive compliance points

83A.2.1 Transmitter compliance points

The reference differential insertion loss, expressed in decibels, between the transmitter and the transmit compliance point is defined in Equation (83A–1) and illustrated in Figure 83A–3. The effects of differences between the actual insertion loss and the reference insertion loss are to be accounted in the measurements.

$$Insertion_loss(f) = -0.00086 + 0.2286\sqrt{f} + 0.08386f \quad \text{dB} \qquad 0.01 \le f \le 11.1 \qquad \text{(83A–1)}$$

where

Insertion_loss(*f*) is the differential insertion loss at frequency *f*
f is the frequency in GHz

83A.2.2 Receiver compliance points

The reference differential insertion loss, expressed in decibels, between the receiver compliance point and the receiver is defined in Equation (83A–2) and illustrated in Figure 83A–4. The effects of differences between the actual insertion loss and the reference insertion loss are to be accounted in the measurements.

$$Insertion_loss(f) = -0.00086 + 0.2286\sqrt{f} + 0.08386f \quad \text{dB} \qquad 0.01 \le f \le 11.1 \qquad \text{(83A–2)}$$

where

Insertion_loss(*f*) is the differential insertion loss at frequency *f*
f is the frequency in GHz

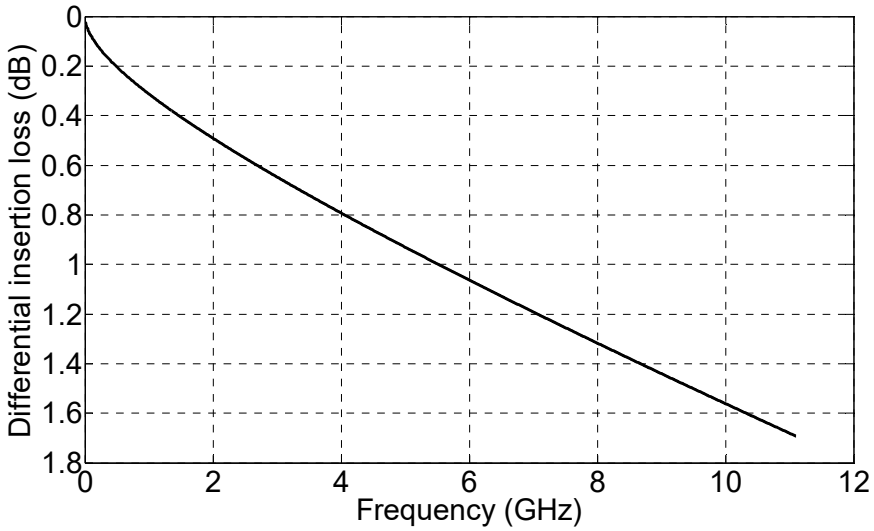

Figure 83A–4—Insertion loss between receive compliance point and receiver

83A.3 XLAUI/CAUI-10 electrical characteristics

The electrical characteristics of the XLAUI/CAUI-10 interface are specified such that they can be applied within a variety of 40 Gb/s Ethernet or 100 Gb/s Ethernet equipment types. The electrical characteristics for XLAUI/CAUI-10 shall meet the specifications defined in 83A.3.1, 83A.3.2, 83A.3.4, and 83A.3.5.

83A.3.1 Signal levels

The XLAUI/CAUI-10 is a low-swing AC-coupled differential interface. AC-coupling allows for interoperability between components operating from different supply voltages. Differential signal swings are defined in the following subclauses, and depend on several factors such as transmitter de-emphasis and transmission line losses.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

83A.3.2 Signal paths

The XLAUI/CAUI-10 signal paths are point-to-point connections. Each path corresponds to a XLAUI/CAUI-10 lane, and is composed of two complementary signals making a balanced differential pair. For XLAUI, there are four differential paths in each direction for a total of eight pairs, or sixteen connections. For CAUI-10, there are ten differential paths in each direction for a total of twenty pairs, or 40 connections.

83A.3.3 EEE operation

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78, 78.1.3.3.1), then the inter-sublayer service interface includes four additional primitives as described in 83.3 and may also support CAUI-10 shutdown.

If the EEE capability includes XLAUI/CAUI-10 shutdown (see 78.5.2), then when aui_tx_mode (see 83.5.11.3) is set to ALERT, the transmit direction sublayer sends a repeating 16-bit pattern, hexadecimal 0xFF00, which is transmitted across the XLAUI/CAUI-10. This sequence is transmitted regardless of the value of tx_bit presented by the PMA:IS_UNITDATA_i.request primitive or the rx_bit presented by the PMA:IS_UNITDATA_i.indication primitive. When aui_tx_mode is QUIET, the transmit direction XLAUI/CAUI-10 transmitter is disabled as specified in 83A.3.4.1.1. Similarly when the received aui_tx_mode is set to ALERT, the receive direction sublayer sends a repeating 16-bit pattern, hexadecimal 0xFF00, which is transmitted across the XLAUI/CAUI-10. This sequence is transmitted regardless of the value of tx_bit presented by the PMA:IS_UNITDATA_i.request primitive or the rx_bit presented by the PMA:IS_UNITDATA_i.indication primitive. When the received aui_tx_mode is QUIET, the receive direction XLAUI/CAUI-10 transmitter is disabled as specified in 83A.3.4.1.1.

83A.3.4 Transmitter characteristics

The XLAUI/CAUI-10 transmitter characteristics measured at the transmitter compliance point are specified in Table 83A–1. The XLAUI/CAUI-10 signaling rate shall be the signaling rate defined in Table 83A–1.

Table 83A–1—Transmitter characteristics

Parameter	Subclause reference	Value	Units
Signaling rate per lane (range)	—	10.3125 ± 100 ppm	GBd
Single-ended output voltage maximum minimum	83A.3.4.1	 4 –0.4	 V V
Maximum differential output voltage, peak-to-peak	83A.3.4.1	760	mV
Minimum de-emphasis	83A.3.4.1	4.4	dB
Maximum de-emphasis	83A.3.4.1	7	dB
Minimum VMA	83A.3.4.1	See Equation (83A–4)	mV
Maximum termination mismatch at 1 MHz	86A.5.3.2	5	%
Maximum output AC common-mode voltage, RMS	86A.5.3.1	15	mV
Minimum output rise and fall time (20% to 80%)	83A.3.4.2	24	ps
Differential output return loss	83A.3.4.3	See Equation (83A–5)	dB

Table 83A–1—Transmitter characteristics *(continued)*

Parameter	Subclause reference	Value	Units
Common-mode output return loss	83A.3.4.4	See Equation (83A–6)	dB
Maximum Total Jitter	83A.3.4.5	0.32	UI
Maximum Deterministic Jitter	83A.3.4.5	0.17	UI
Transmitter eye mask definition X1	83A.3.4.5	0.16	UI
Transmitter eye mask definition X2	83A.3.4.5	0.38	UI
Transmitter eye mask definition Y1	83A.3.4.5	200	mV
Transmitter eye mask definition Y2	83A.3.4.5	380	mV

83A.3.4.1 Output amplitude

Driver differential output amplitude shall be less than the maximum differential output voltage defined in Table 83A–1 including any transmit de-emphasis. DC-referenced logic levels are not defined since the receiver is AC-coupled. Single-ended output voltage shall be within the range specified in Table 83A–1 with respect to ground.

De-emphasis shall be greater than the minimum de-emphasis and less than the maximum de-emphasis defined in Table 83A–1. De-emphasis is defined as the ratio between the amplitude following a transition and the amplitude during a non-transition bit as seen in Equation (83A–3). VMA is defined in 86A.5.3.5 using the square wave or PRBS9 (Pattern 4) defined in Table 86–11.

See Figure 83A–5 for an illustration of absolute driver output voltage limits, definition of differential peak-to-peak amplitude, and definition of the parameters used to calculate de-emphasis. SLi<P> and SLi<N> are positive and negative sides of a differential signal pair for lane i (i = 0, 1, 2, 3 for XLAUI. For CAUI-10 i = 0:9).

$$\text{De-emphasis (dB)} = 20\log_{10}\left(\frac{\text{Differential peak-to-peak amplitude}}{\text{VMA}}\right) \quad \text{(83A–3)}$$

$$\text{Minimum VMA (mV)} = (234.64 - 2.13x + 0.18x^2) \times 1.32(10^{-y/20}) \quad \text{(83A–4)}$$

where

x is the rise or fall time (whichever is larger) in ps
y is de-emphasis value in dB

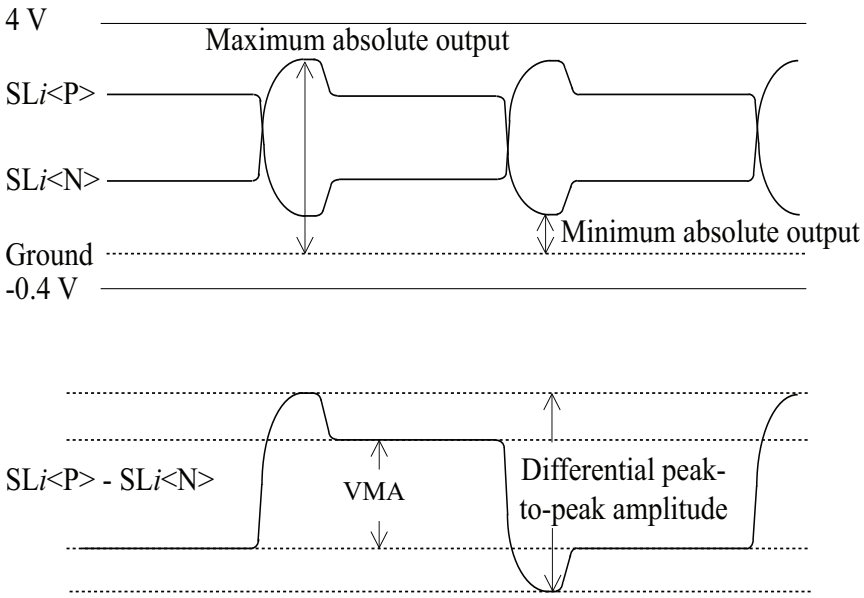

Figure 83A–5—Driver output voltage limits and definitions

83A.3.4.1.1 Amplitude and swing

For EEE capability with XLAUI/CAUI-10 shutdown, the XLAUI/CAUI-10 transmitter lane's differential peak-to-peak output voltage shall be less than 30 mV within 500 ns of aui_tx_mode changing to QUIET in the relevant direction. Furthermore, the XLAUI/CAUI-10 transmitter lane's differential peak-to-peak output voltage shall be greater than 720 mV within 500 ns of aui_tx_mode ceasing to be QUIET in the relevant direction.

83A.3.4.2 Rise/fall time

Differential rise/fall times shall be greater than the minimum output rise and fall time defined in Table 83A–1, as measured from the 20% to the 80% levels. Shorter transitions may result in excessive high-frequency components and increase EMI and crosstalk. The upper limit is defined by the transmit eye mask shown in Figure 83A–8. Rise/fall time is measured with de-emphasis off as defined in 83A.5.1. Rise/fall time measurements are taken using a square wave test pattern as defined in 83.5.10.

83A.3.4.3 Differential output return loss

Differential output return loss shall meet the requirements defined in Table 83A–1. Differential output return loss is given in Equation (83A–5) and is illustrated Figure 83A–6. Differential output return loss includes contributions from on-chip circuitry, chip packaging, and any off-chip components related to the driver. This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements is 100 Ω. The maximum termination mismatch at 1 MHz shall be less than the requirement defined in Table 83A–1.

$$Return_loss(f) \geq \begin{cases} 12 & 0.01 \leq f < 2.125 \\ 6.5 - 13.33\log_{10}\left(\frac{f}{5.5}\right) & 2.125 \leq f \leq 11.1 \end{cases} \text{ (dB)} \quad \text{(83A–5)}$$

where

Return_loss(*f*) is the differential output return loss at frequency *f*
f is the frequency in GHz

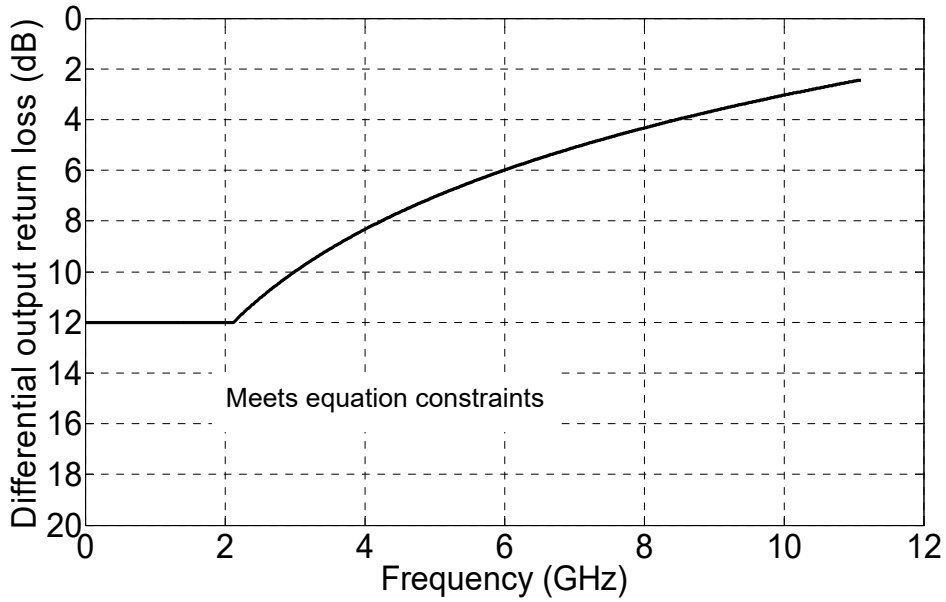

Figure 83A–6—Differential output return loss

83A.3.4.4 Common-mode output return loss

Common-mode output return loss shall meet the requirements defined in Table 83A–1. Common-mode output return loss is given in Equation (83A–6) and is illustrated in Figure 83A–7. Common-mode output return loss includes contributions from on-chip circuitry, chip packaging, and any off-chip components related to the driver. This output impedance requirement applies to all valid output levels. The reference impedance for common-mode return loss measurements is 25 Ω.

$$Return_loss(f) \geq \begin{cases} 9 & 0.01 \leq f < 2.125 \\ 3.5 - 13.33\log_{10}\left(\frac{f}{5.5}\right) & 2.125 \leq f < 7.1 \\ 2 & 7.1 \leq f \leq 11.1 \end{cases} \text{ (dB)} \quad \text{(83A–6)}$$

83A.3.4.5 Transmitter eye mask and transmitter jitter definition

The measured transmit signal at the transmit compliance point shall meet the eye template specified in Figure 83A–8 and Table 83A–1. The template measurement requirements are specified in 83A.5.1. The measured jitter at the transmit compliance point shall be less than the maximum Total Jitter as defined in Table 83A–1 and a maximum Deterministic Jitter as defined in Table 83A–1. Jitter and eye mask measurement requirements are described in 83A.5.1 and are conducted with de-emphasis off.

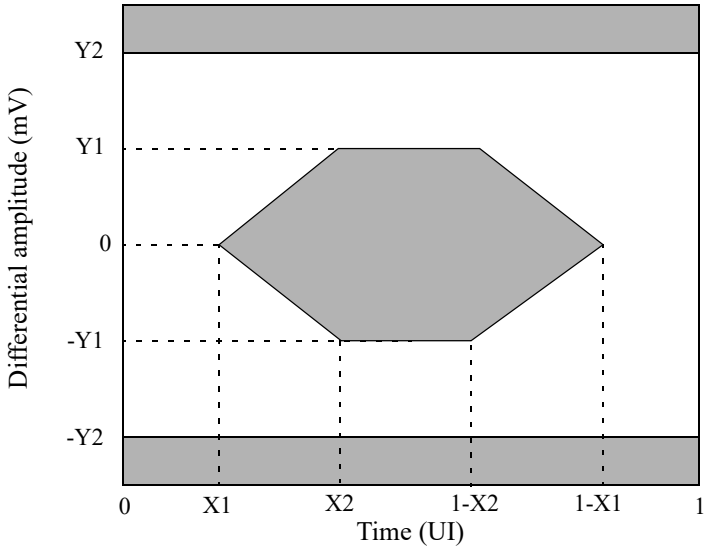

Figure 83A–8—Transmitter eye mask

83A.3.4.6 Global transmit disable function

Global transmit disable is optional for EEE capability. The transmit disable function shall turn off all transmitter lanes for a physically instantiated AUI in either the ingress or the egress direction. In the egress direction, the PMA may turn off all the transmitter lanes for the egress direction XLAUI/CAUI-10 if PEASE is asserted and aui_tx_mode is QUIET. In the ingress direction, the PMA may turn off all the transmitter lanes for the ingress direction XLAUI/CAUI-10 if PIASE is asserted and the received aui_tx_mode is QUIET. In both directions, the transmit disable function shall turn on all transmitter lanes after the appropriate direction aui_tx_mode changes to any state other than QUIET within a time and voltage level specified in 83A.3.4.1.1.

83A.3.5 Receiver characteristics

Receiver characteristics at the receiver compliance point are specified in Table 83A–2 and detailed in 83A.3.5.1 through 83A.3.5.6.

83A.3.5.1 Bit error ratio

The receiver shall operate with a BER of better than 10^{-12} in the presence of a compliant input signal as defined in 83A.3.5.2.

NOTE—A transmitter capable of operating at TJ = 0.3 UI and DJ = 0.16 UI and receiver capable of operating at stress jitter tolerance of TJ = 0.64 UI and DJ= 0.41 UI would have sufficient margin for operation at approximately BER 10^{-15}.

Table 83A–2—Receiver characteristics

Parameter	Subclause reference	Value	Units
Signaling rate per lane (range)	—	10.3125 ± 100 ppm	GBd
Minimum input AC common-mode voltage tolerance, RMS	86A.5.3.1	20	mV
Minimum input rise and fall time tolerance (20% to 80%)	83A.3.4.2	24	ps
Differential input return loss	83A.3.5.3	See Equation (83A–7)	dB
Differential to common-mode input return loss	83A.3.5.4	See Equation (83A–8)	dB
Stressed receiver tolerance			
Minimum Total Input Jitter Tolerance	83A.3.5.2	0.62	UI
Minimum Deterministic Input Jitter Tolerance	83A.3.5.2	0.42	UI
Receiver eye mask definition X1	83A.3.5.2	0.31	UI
Receiver eye mask definition X2	83A.3.5.2	0.5	UI
Receiver eye mask definition Y1	83A.3.5.2	42.5	mV
Receiver eye mask definition Y2	83A.3.5.2	425	mV

83A.3.5.2 Input signal definition

A compliant input signal to a XLAUI/CAUI-10 receiver has characteristics determined by a compliant XLAUI/CAUI-10 driver and channel. The input signal definition satisfies the eye mask defined in Table 83A–2 and Figure 83A–9. Input signal jitter does not exceed the jitter tolerance requirements specified in 83A.3.5.6. Stressed receiver measurement requirements are specified in 83A.5.2.

83A.3.5.3 Differential input return loss

Differential input return loss shall meet the requirements defined in Table 83A–2. Differential input return loss is given in Equation (83A–7) and is illustrated in Figure 83A–10. Differential input return loss includes contributions from on-chip circuitry, chip packaging, and any off-chip components related to the receiver. The reference impedance for differential return loss measurements is 100 Ω.

$$Return_loss(f) \geq \begin{cases} 12 & 0.01 \leq f < 2.125 \\ 6.5 - 13.33\log_{10}\left(\frac{f}{5.5}\right) & 2.125 \leq f \leq 11.1 \end{cases} \quad \text{(dB)} \qquad \text{(83A–7)}$$

where

Return_loss(*f*) is the differential input return loss at frequency *f*
f is the frequency in GHz

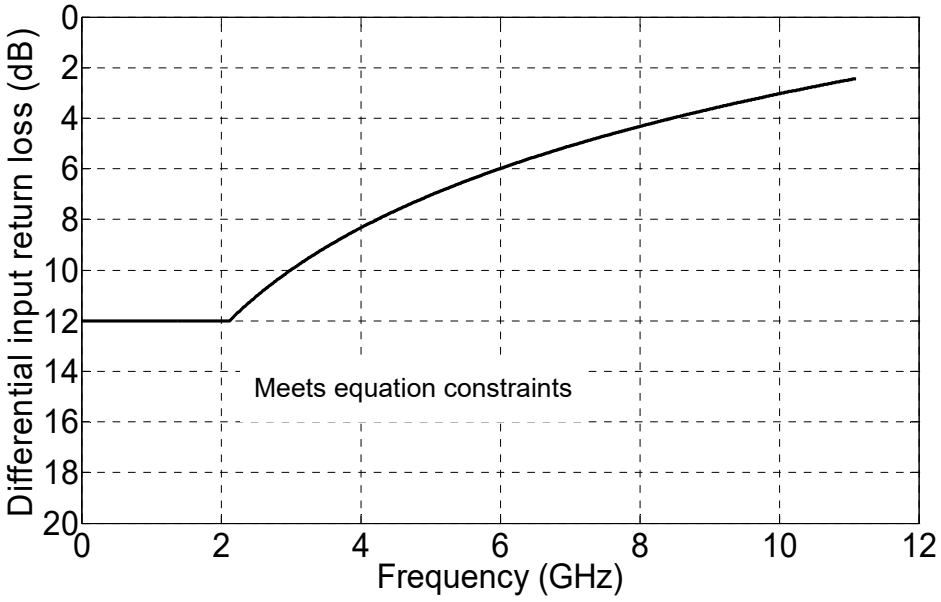

Figure 83A–10—Differential input return loss

83A.3.5.4 Differential to common-mode input return loss

Differential to common-mode input return loss shall meet the requirements defined in Table 83A–2. Differential to common-mode input return loss is given in Equation (83A–8) and is illustrated in Figure 83A–11. Differential to common-mode input return loss includes contributions from on-chip circuitry, chip packaging, and any off-chip components related to the receiver. The reference impedance for differential return loss measurements is 100 Ω. The reference impedance for common-mode return loss measurements is 25 Ω.

$$Return_loss(f) \geq 15 \qquad 0.01 \leq f < 11.1 \qquad \text{(dB)} \qquad \text{(83A–8)}$$

Return_loss(*f*) is the differential to common-mode input return loss at frequency *f*
f is the frequency in GHz

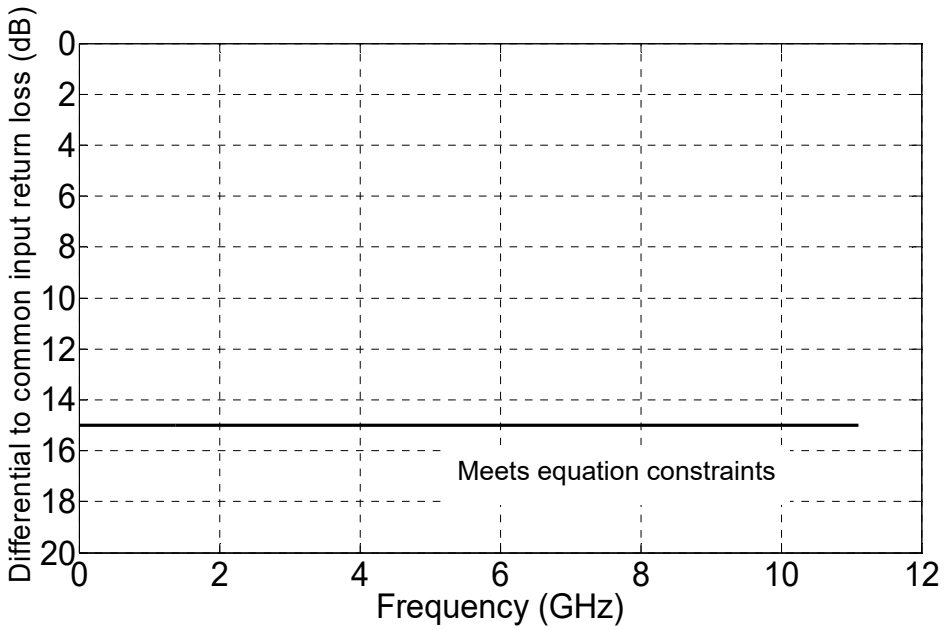

Figure 83A–11—Differential to common-mode input return loss

83A.3.5.5 AC-coupling

The XLAUI/CAUI-10 receiver shall be AC-coupled to the XLAUI/CAUI-10 transmitter to allow for maximum interoperability between various 10 Gb/s components. AC-coupling is considered to be part of the receiver for the purposes of this specification except when interfacing with modules defined in Annex 83B or explicitly stated otherwise. It should be noted that there may be various methods for AC-coupling in actual implementations.

83A.3.5.6 Jitter tolerance

The XLAUI/CAU-10 receiver shall have a peak-to-peak total jitter amplitude tolerance of at least the minimum total input jitter tolerance defined in Table 83A–2. This total jitter is composed of two components: deterministic jitter and random jitter. Deterministic jitter tolerance shall be at least the minimum deterministic input jitter tolerance defined in Table 83A–2. The XLAUI/CAUI-10 receiver shall tolerate sinusoidal jitter with any frequency and amplitude defined by the mask of Figure 83A–12. This sub-component of deterministic jitter is intended to ensure margin for low-frequency jitter, wander, noise, crosstalk, and other variable system effects.

83A.3.5.7 Global energy detect function

The global energy detect function is mandatory for EEE capability with the deep sleep mode option and XLAUI/CAUI-10 shutdown. The global energy detect function indicates whether or not signaling energy is being received on the physical instantiation of the inter sublayer interface (in each direction as appropriate). The energy detection function may be considered a subset of the signal indication logic. If no energy is being received on the XLAUI/CAUI-10 for the ingress direction, SIGNAL_DETECT is set to FAIL following a transition from aui_rx_mode = DATA to aui_rx_mode = QUIET. When aui_rx_mode = QUIET, SIGNAL_DETECT shall be set to OK within 500 ns following the application of a signal at the receiver

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

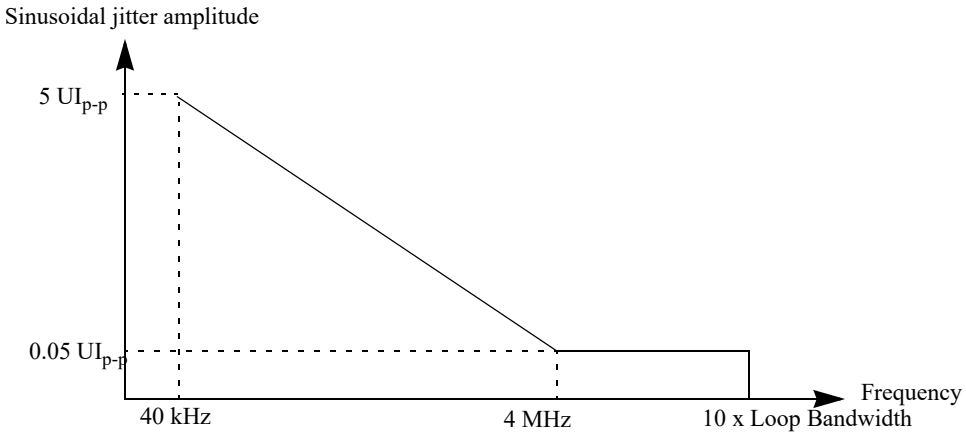

Figure 83A–12—Single-tone sinusoidal jitter mask

input that corresponds to an ALERT signal driven from the XLAUI/CAUI-10 link partner. While aui_rx_mode = QUIET, SIGNAL_DETECT changes from FAIL to OK only after the valid ALERT signal is received.

83A.4 Interconnect characteristics

This subclause describes recommended characteristics which are used to characterize a XLAUI/CAUI-10 channel as shown in Figure 83A–2. The value for differential insertion loss is summarized in Equation (83A–9) and illustrated in Figure 83A–13. The value for minimum return loss is summarized in Equation (83A–10) and illustrated in Figure 83A–14. The channel is terminated with 100 Ω differential impedance. Other impairments such as crosstalk can have a material impact on the link performance and should be minimized.

$$Insertion_loss(f) < \left\{ \begin{array}{ll} 0.15 + 1.39\sqrt{f} + 1.4f & 0.01 \le f < 7 \\ -15.86 + 4.2f & 7 \le f \le 11.1 \end{array} \right\} \text{ (dB)} \quad \text{(83A–9)}$$

where

Insertion_loss(*f*) is the differential insertion loss at frequency *f*
f is the frequency in GHz

$$Return_loss(f) \ge \left\{ \begin{array}{ll} 12.5 & 0.01 \le f < 5 \\ 12.5 - 27.5\log_{10}\left(\frac{f}{5}\right) & 5 \le f \le 11.1 \end{array} \right\} \text{ (dB)} \quad \text{(83A–10)}$$

where

Return_loss(*f*) is the differential input return loss at frequency *f*
f is the frequency in GHz

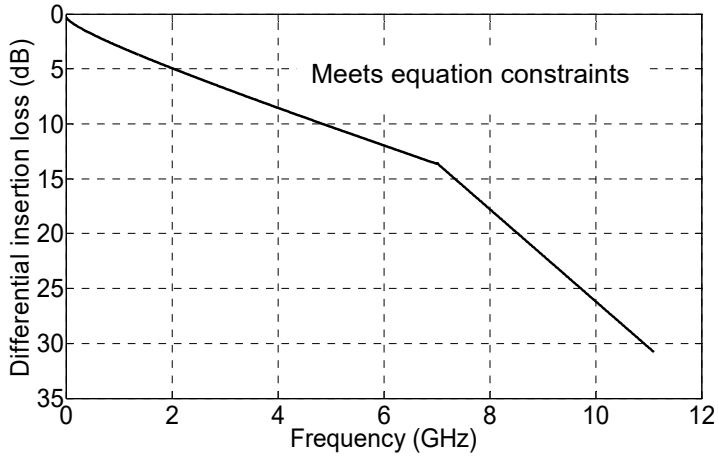

Figure 83A–13—Differential insertion loss

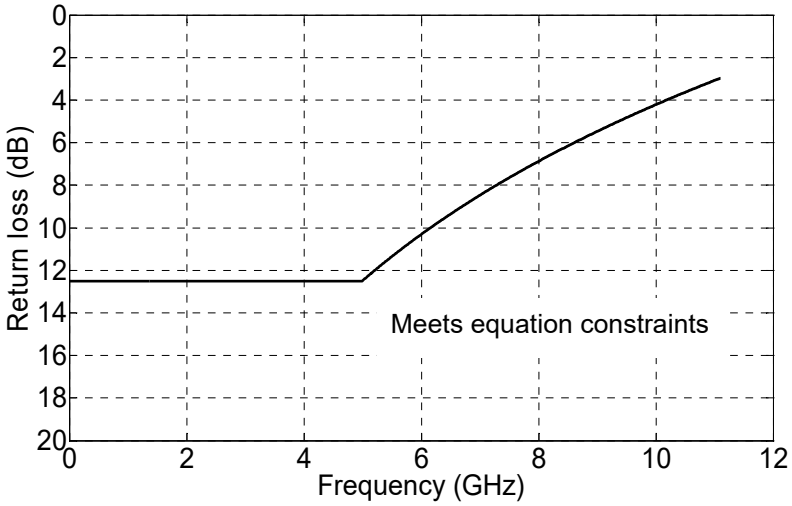

Figure 83A–14—Differential input return loss

The XLAUI/CAUI-10 is primarily intended as a point-to-point interface of up to approximately 25 cm between integrated circuits using controlled impedance traces on low-cost printed circuit boards (PCBs). Longer reaches for the XLAUI/CAUI-10 may be achieved by the use of better PCB materials, as the performance of an actual XLAUI/CAUI-10 interconnect is highly dependent on the implementation.

83A.4.1 Characteristic impedance

The recommended differential characteristic impedance of circuit board trace pairs is 100 Ω ± 10%.

83A.5 Electrical parameter measurement methods

This subclause describes the measurement methodology that is to be used to verify XLAUI/CAUI-10 compliance. Eye templates are measured with AC-coupling and centered at 0 V differential. The signal waveform, eye, and jitter may be measured using a receiver with at least an equivalent 12 GHz low-pass filter response. Jitter values and eye masks are specified for BER 10^{-12}.

83A.5.1 Transmit jitter

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in Annex 48B.3. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 4 MHz is applied to the jitter. The test pattern for jitter measurements shall be PRBS31 test pattern in 83.5.10 or scrambled idle in 82.2.11. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal. De-emphasis shall be off during jitter testing. Transmit de-emphasis off state is defined by any setting that gives optimal performance for transmitter jitter and eye mask evaluation. All XLAUI/CAUI-10 transmitter lanes shall be active and all XLAUI/CAUI-10 receive lanes shall be receiving maximum amplitude and fastest rise time (as defined in Table 83A–1) during transmit jitter testing to ensure maximum lane-lane crosstalk is included in the jitter evaluation.

83A.5.2 Receiver tolerance

The XLAUI/CAUI-10 jitter tolerance test setup in Figure 83A–15 or its equivalent shall meet the receiver eye mask defined in Table 83A–2. Applied jitter is measured using the methodology described in Annex 48B.3. Deterministic jitter is added to a clean test pattern by adding sinusoidal jitter as defined in 83A.3.5.6, along with low-pass filter stress, followed by a limiting function, and frequency-dependent attenuation. The low-pass filter stress is added until the 0.34 UI Deterministic Jitter is achieved. Frequency-dependent attenuation is then added using PCB trace or frequency-dependent attenuation which emulates PCB loss. Frequency-dependent attenuation is added until 0.42 UI Deterministic Jitter is achieved. Random jitter is added to the test signal using an interference generator which is a broadband noise source capable of producing white Gaussian noise with adjustable amplitude. The power spectral density shall be flat to ±3 dB from 50 MHz to 6 GHz with a crest factor of no less than 5. The amplitude and output jitter of the filter stress plus limiter and random jitter injection shall meet the receiver eye mask defined in Table 83A–2. All XLAUI/CAUI-10 lanes shall be active during jitter tolerance testing. The PRBS31 pattern defined in 83.5.10 or scrambled idle defined in 82.2.11 is used for evaluating XLAUI/CAUI-10 jitter tolerance.

83A.6 Environmental specifications

83A.6.1 General safety

Equipment subject to this annex shall conform to the general safety requirements in J.2.

83A.6.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

83A.6.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

83A.6.4 Electromagnetic compatibility

A system integrating the XLAUI/CAUI-10 shall comply with applicable local and national codes for the limitation of electromagnetic interference.

83A.6.5 Temperature and humidity

A system integrating the XLAUI/CAUI-10 is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

83A.7 Protocol implementation conformance statement (PICS) proforma for Annex 83A, 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10)[294]

83A.7.1 Introduction

The supplier of a XLAUI/CAUI-10 implementation that is claimed to conform to Annex 83A, 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the same, can be found in Clause 21.

83A.7.2 Identification

83A.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

83A.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 83A, 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[294]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

Annex 83B

(normative)

Chip-to-module 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10)

83B.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10). The purpose of this annex is to provide electrical characteristics and associated compliance points for pluggable module applications that use the XLAUI/CAUI-10 interface and shall use the same number of lanes and signaling rate defined in Annex 83A. Figure 83B–3 and Table 83B–1 summarize an example differential insertion loss budget associated with the chip-to-module application. The insertion loss of Equation (83A–9), excluding a 0.5 dB connector loss at 5.15625 GHz, is linearly scaled to 7.9 dB loss at 5.15625 GHz for the host XLAUI/CAUI-10 component, and 2.1 dB loss at 5.15625 GHz for the module as per Table 83B–1 and Equation (83B–1) for the host and Equation (83B–2) for the module. Tradeoffs can be made between the host PCB insertion loss and the connector loss. Equation (83B–1) is illustrated in Figure 83B–1 and Equation (83B–2) is illustrated in Figure 83B–2.

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.111 + 1.046\sqrt{f} + 1.05f & 0.01 \le f < 7 \\ -11.82 + 3.15f & 7 \le f \le 11.1 \end{array} \right\} \text{ (dB)} \qquad \text{(83B–1)}$$

where

Insertion_loss(*f*) is the differential insertion loss at frequency *f*
f is the frequency in GHz

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.03 + 0.278\sqrt{f} + 0.28f & 0.01 \le f < 7 \\ -3.155 + 0.84f & 7 \le f \le 11.1 \end{array} \right\} \text{ (dB)} \qquad \text{(83B–2)}$$

where

Insertion_loss(*f*) is the differential insertion loss at frequency *f*
f is the frequency in GHz

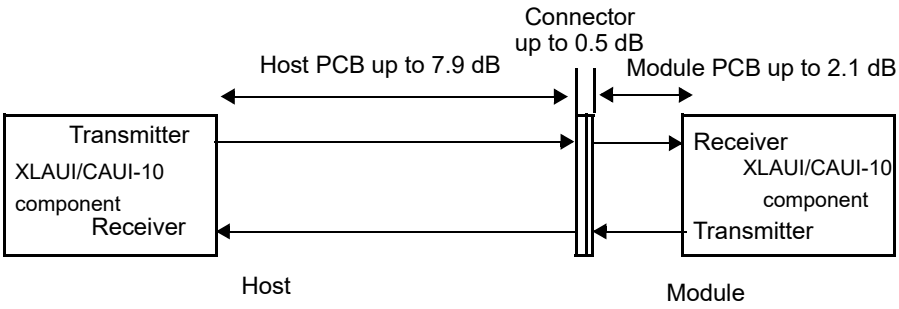

Figure 83B–3—Chip-to-module loss budget at 5.15625 GHz

Table 83B–1—Chip-to-module loss budget

Section	Differential insertion loss max. (at 5.15625 GHz)
Host XLAUI/CAUI-10 component to connector	7.9 dB
Connector loss	0.5 dB
Connector to module XLAUI/CAUI-10 component	2.1 dB

83B.2 Compliance point specifications for chip-to-module XLAUI/CAUI-10

The chip-to-module XLAUI/CAUI-10 interface specifies compliance points around the module connector as depicted in Figure 83B–5 and Figure 83B–7. Chip-to-module devices shall meet the electrical characteristics defined in 83B.2, 83B.2.1, 83B.2.2, and 83B.2.3. Compliance points are defined to ensure interoperability between hosts and modules. A Module Compliance Board (MCB) is used to isolate the characteristics of the module, and a Host Compliance Board (HCB) is used to isolate the characteristics of the host. Figure 83B–5 and Figure 83B–7 include the loss associated with the HCB and MCB at 5.15625 GHz.

The reference differential insertion loss of the HCB PCB is given in Equation (83B–3) and illustrated in Figure 83B–4. The effects of differences between the insertion loss of an actual HCB and the reference insertion loss are to be accounted in the measurements.

$$Insertion_loss(f) = 0.017 + 0.5\sqrt{f} + 0.1836f \qquad 0.01 \le f \le 11.1 \qquad \text{(83B–3)}$$

where

$Insertion_loss(f)$ is the differential insertion loss at frequency f
f is the frequency in GHz

83B.2.1 Module specifications

A module that uses XLAUI/CAUI-10 to interface with a host shall meet the characteristics outlined in Table 83B–2 and Table 83B–3 when measured using the MCB and HCB (where the HCB is used to calibrate

inputs to the module). Table 83B–2 also lists the equivalent test points for the XLPPI/CPPI (see Figure 86–3).

Modules may support additional de-emphasis states, but the specification of additional states is outside the scope of this standard. De-emphasis shall be off during eye mask and jitter testing. Module electrical output de-emphasis off state is the optimal setting for module electrical output jitter and eye mask evaluation. AC-coupling for both Tx and Rx paths shall be located in the module.

Table 83B–2—Specifications at module compliance points

Reference	Compliance point		Value	Unit
Minimum module differential input return loss	MCB input	TP1	See Equation (83B–5)	dB
Module input tolerance signal	HCB output	TP1a	See 83A.5.2	
Module output signal	MCB output	TP4	See Table 83B–3	
Minimum module differential output return loss	MCB output	TP4	See Equation (83B–5)	dB

$$Return_loss(f) \geq \begin{cases} 12 - 2\sqrt{f} & 0.01 \leq f < 2.19 \\ 5.56 - 8.7\log_{10}\left(\frac{f}{5.5}\right) & 2.19 \leq f \leq 11.1 \end{cases} \text{ (dB)} \qquad (83B–5)$$

where

Return_loss(*f*) is the differential input return loss at frequency *f*
f is the frequency in GHz

Minimum module differential input/output return loss is illustrated in Figure 83B–8.

$$\text{Minimum VMA (mV)} = (-110 - 2.13x + 0.32x^2) \times (10^{-y/20}) \quad (83B–6)$$

where

x is the rise or fall time, or 38, (whichever is larger) in ps
y is de-emphasis value in dB

83B.2.2 Host specifications

A host that uses XLAUI/CAUI-10 to interface with a module shall meet the characteristics outlined in Table 83B–4 and Table 83B–5 when measured using the HCB and MCB (where MCB is used to calibrate inputs to the host). Table 83B–4 also lists the equivalent test points for the XLPPI/CPPI.

Table 83B–4—Specifications at host compliance points

Reference	Compliance point		Value	Unit
Host output signal specifications	HCB output	TP1a	See Table 83B–5	
Minimum host differential output return loss	HCB output	TP1a	See Equation (83B–7)	dB
Minimum host differential input return loss	HCB input	TP4a	See Equation (83B–7)	dB
Host input tolerance signal	MCB output	TP4	See 83B.2.3	

$$Return_loss(f) \geq \begin{cases} 12 - 2\sqrt{f} & 0.01 \leq f < 2.19 \\ 5.56 - 8.7\log_{10}\left(\frac{f}{5.5}\right) & 2.19 \leq f \leq 11.1 \end{cases} \text{ (dB)} \quad (83B–7)$$

where

$Return_loss(f)$ is the differential input/output return loss at frequency f
f is the frequency in GHz

Minimum host differential input/output return loss is illustrated in Figure 83B–9.

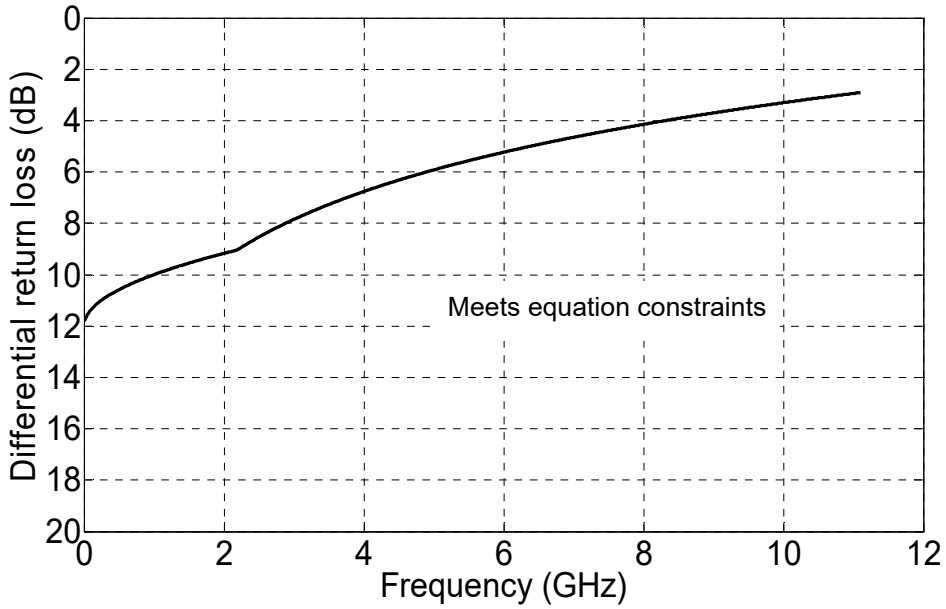

Figure 83B–9—Host input/output return loss

Table 83B–5—Host electrical output

Parameter	Subclause reference	Value	Units
Maximum output AC common-mode voltage, RMS	86A.5.3.1	20	mV
Minimum output rise and fall time (20% to 80%)	83A.3.4.2	24	ps
Maximum Total Jitter	83A.3.4.5	0.62	UI
Maximum Deterministic Jitter	83A.3.4.5	0.42	UI
Host electrical output eye mask definition X1	83A.3.4.5	0.31	UI
Host electrical output eye mask definition X2	83A.3.4.5	0.5	UI
Host electrical output eye mask definition Y1	83A.3.4.5	42.5	mV
Host electrical output eye mask definition Y2	83A.3.4.5	425	mV

83B.2.3 Host input signal tolerance

Host XLAUI/CAUI-10 jitter tolerance evaluation shall be defined by a stressed input signal that comprises 0.25 UI Deterministic Jitter, and 0.15 UI random jitter for BER 10^{-12}. Deterministic Jitter is added to a clean test pattern as sinusoidal jitter defined in 83A.3.5.6. The limited low-pass filter stress is added until the 0.22 UI Deterministic Jitter is achieved. Frequency-dependent attenuation is then added using PCB trace or frequency-dependent attenuation that emulates PCB loss. Frequency-dependent attenuation is added until 0.25 UI Deterministic Jitter is achieved. Random jitter is added to the test signal using an interference generator, which is a broadband noise source capable of producing white Gaussian noise with adjustable

amplitude. The power spectral density shall be flat to ±3 dB from 50 MHz to 6 GHz with a crest factor of no less than 5. Figure 83B–10 depicts a XLAUI/CAUI-10 jitter tolerance test setup. The amplitude and output jitter of the filter stress plus limiter and random jitter injection shall meet the receiver eye mask illustrated in Figure 83A–9 with the values for X1, X2, Y1, Y2 given in Table 83B–3. All XLAUI/CAUI-10 lanes shall be active during jitter tolerance testing. The PRBS31 pattern defined in 83.5.10 or scrambled idle defined in 82.2.11 is used for evaluating XLAUI/CAUI-10 jitter tolerance.

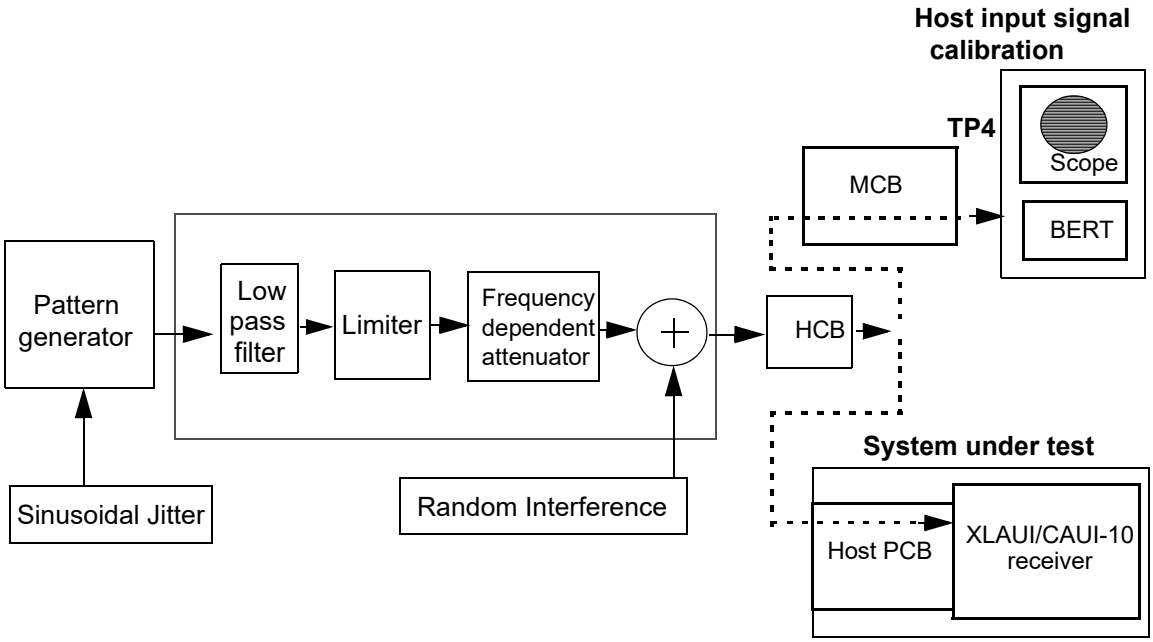

Figure 83B–10—Stressed-eye and jitter tolerance test setup

83B.3 Environmental specifications

83B.3.1 General safety

Equipment subject to this annex shall conform to the general safety requirements in J.2.

83B.3.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

83B.3.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

83B.3.4 Electromagnetic compatibility

A system integrating the XLAUI/CAUI-10 shall comply with applicable local and national codes for the limitation of electromagnetic interference.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

83B.3.5 Temperature and humidity

A system integrating the XLAUI/CAUI-10 is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

83B.4 Protocol implementation conformance statement (PICS) proforma for Annex 83B, Chip-to-module 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10)[295]

83B.4.1 Introduction

The supplier of a chip to module XLAUI/CAUI-10 implementation that is claimed to conform to Annex 83B, Chip-to-module 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the same, can be found in Clause 21.

83B.4.2 Identification

83B.4.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

83B.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 83B, Chip-to-module 40 Gb/s Attachment Unit Interface (XLAUI) and 100 Gb/s ten-lane Attachment Unit Interface (CAUI-10)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

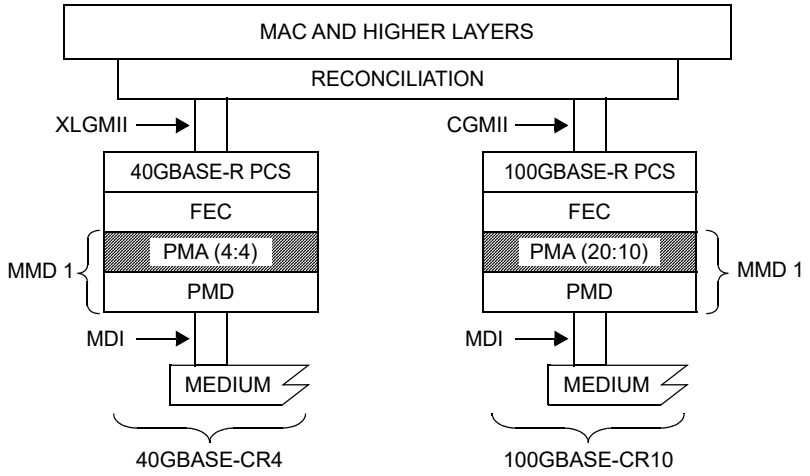
Annex 83C

(informative)

PMA sublayer partitioning examples



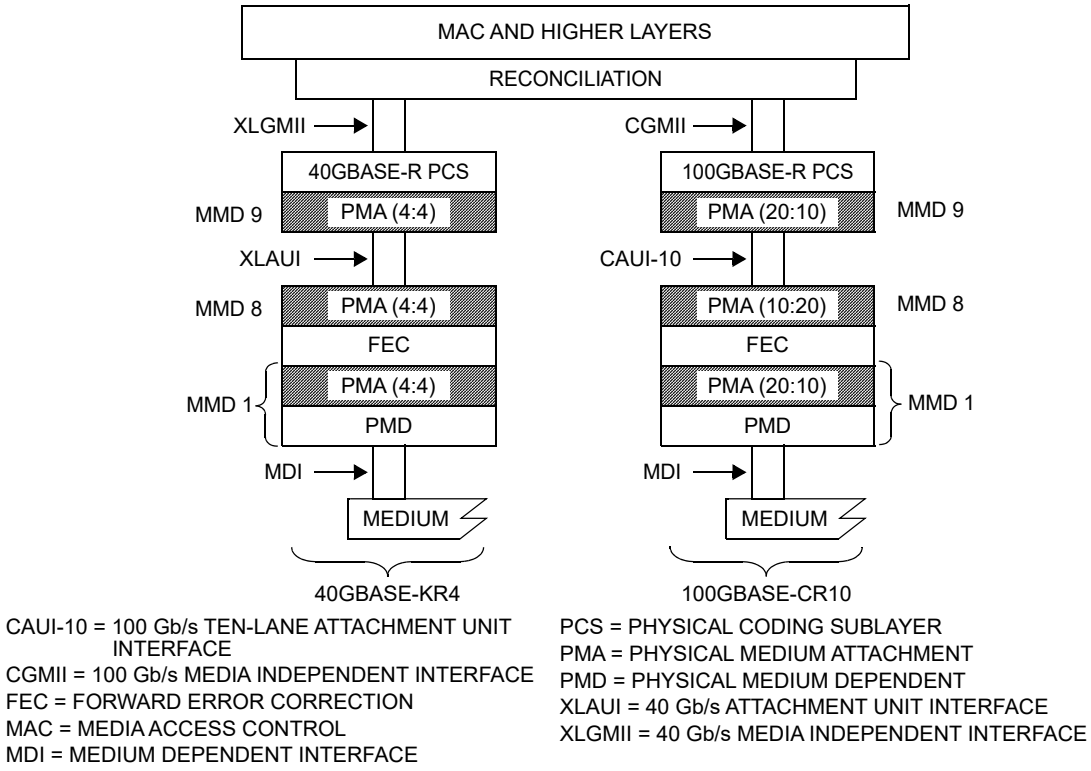
The following subclauses provide various partitioning examples. Partitioning guidelines and MMD numbering conventions are described in 83.1.4.

83C.1 Partitioning examples with FEC

The example of BASE-R FEC (see Clause 74) implemented in a separate device from either the PCS or the PMD is illustrated in Figure 83–2.

83C.1.1 FEC implemented with PCS

Figure 83C–1 depicts an example of FEC implemented with the PCS sublayer.



CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

Figure 83C–1—Example FEC implemented with PCS

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

83C.1.2 FEC implemented with PMD

Figure 83C–2 depicts an example of FEC implemented with the PMD sublayer.

CAUI-10 = 100 Gb/s TEN-LANE ATTACHMENT UNIT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLAUI = 40 Gb/s ATTACHMENT UNIT INTERFACE
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

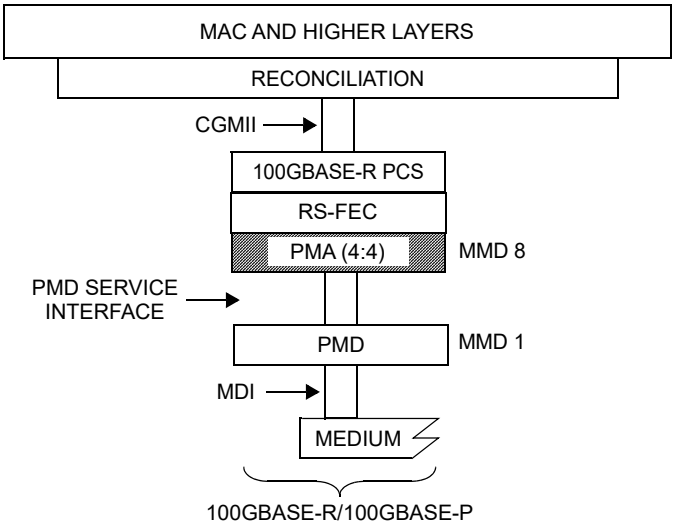


Figure 83C–2—Example FEC implemented with PMD

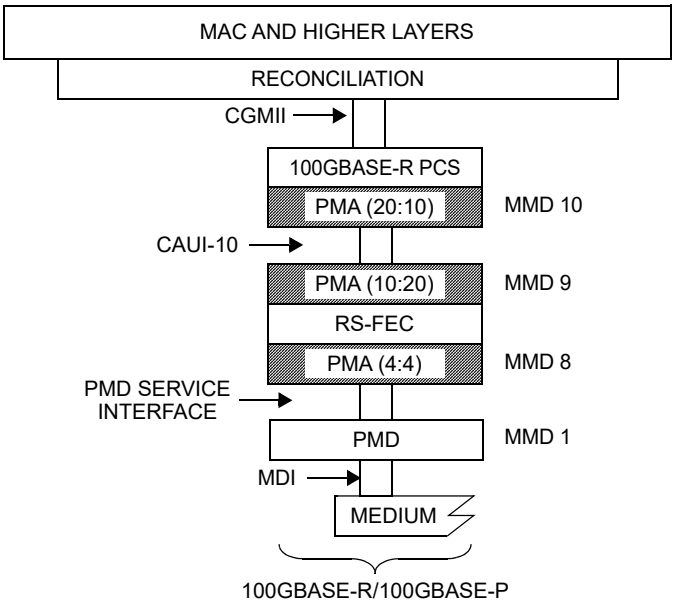
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

83C.2 Partitioning examples with RS-FEC

83C.2.1 Single PMA sublayer with RS-FEC

Figure 83C–3 depicts an example of a single PMA sublayer with RS-FEC.



CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 83C–3—Example single PMA sublayer with RS-FEC

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

83C.2.2 Single CAUI-10 with RS-FEC

Figure 83C–4 depicts an example of a single CAUI-10 interface with RS-FEC.

CAUI-10 = 100 Gb/s TEN-LANE ATTACHMENT UNIT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

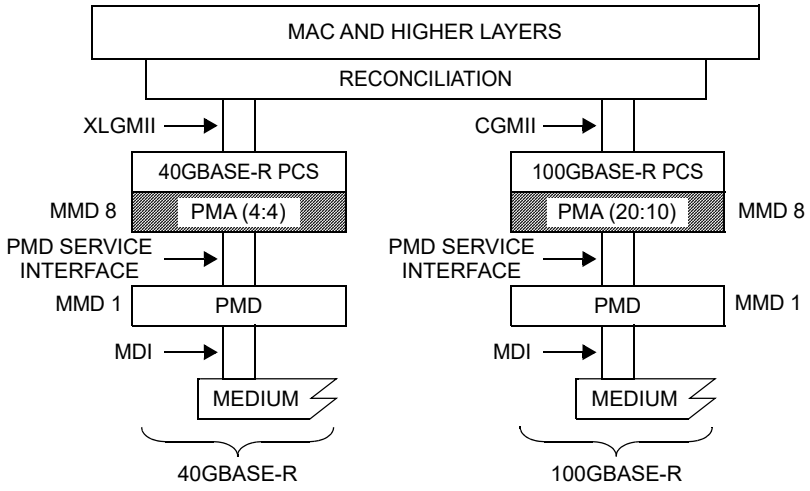


Figure 83C–4—Example single CAUI-10 with RS-FEC

Annex 83D

(normative)

Chip-to-chip 100 Gb/s four-lane Attachment Unit Interface (CAUI-4)

83D.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-chip 100 Gb/s four-lane Attachment Unit Interface (CAUI-4). Figure 83D–1 shows an example relationship of the CAUI-4 chip-to-chip interface to the ISO/IEC Open System Interconnection (OSI) reference model. The chip-to-chip interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with electrical interconnect of approximately 25 cm in length.

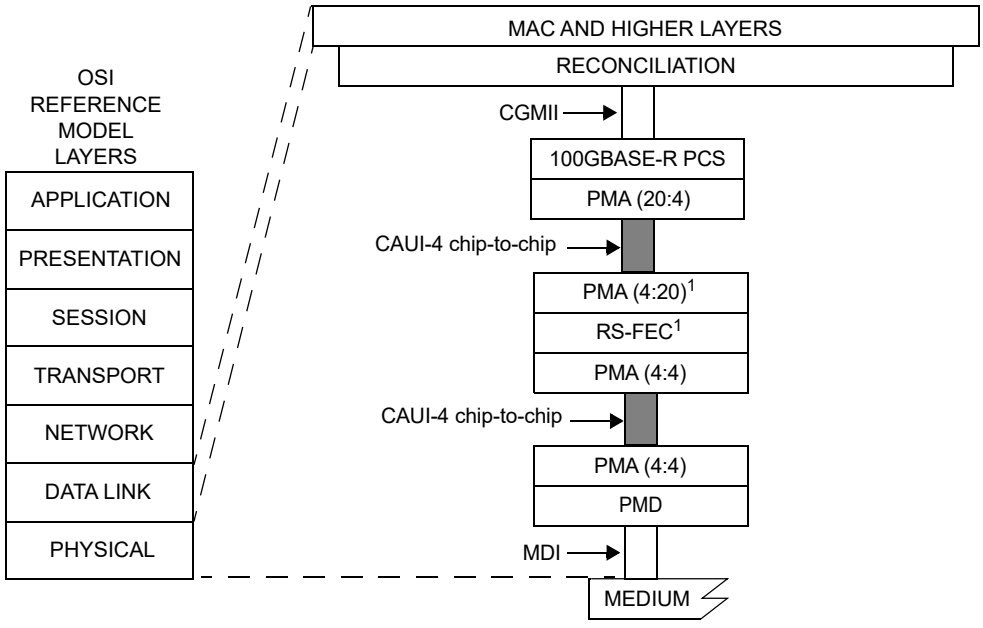

Figure 83D–1—Example CAUI-4 chip-to-chip relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The CAUI-4 bidirectional link is described in terms of a CAUI-4 transmitter, a CAUI-4 channel, and a CAUI-4 receiver. Figure 83D–2 depicts a typical CAUI-4 application, and Equation (83D–1) (illustrated in Figure 83D–3) summarizes the recommended differential insertion loss budget associated with the chip-to-chip application. The CAUI-4 chip-to-chip interface comprises independent data paths in each direction. Each data path contains four differential lanes, which are AC-coupled. The nominal signaling rate for each lane is 25.78125 GBd. The CAUI-4 transmitter on each end of the link is adjusted to an appropriate setting

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 83D.3.3.2 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

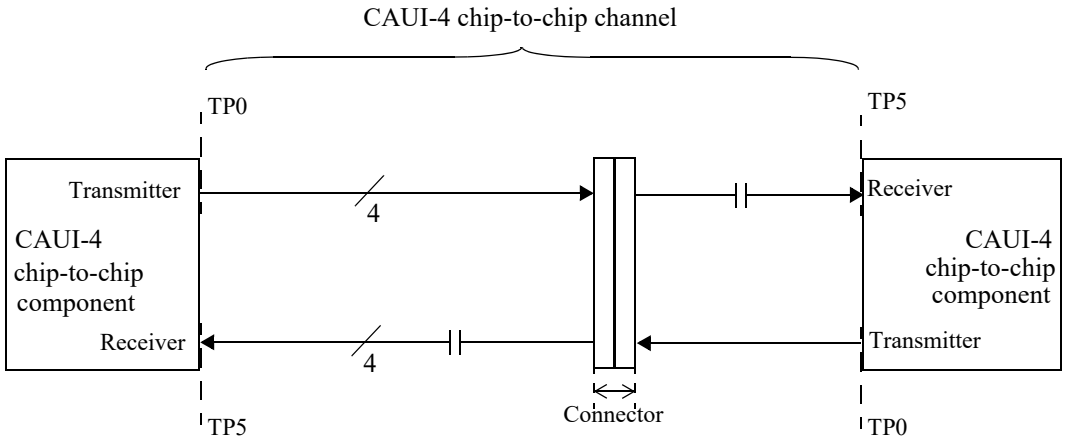

Figure 83D–2—Typical CAUI-4 chip-to-chip application

The normative channel compliance is through CAUI-4 COM as described in 83D.4. Actual channel loss could be higher or lower than that given by Equation (83D–1) due to the channel ILD, return loss, and cross-talk.

$$Insertion_loss(f) \le \left\{ \begin{array}{cc} 1.083 + 2.543\sqrt{f} + 0.761f & 0.01 \le f < 12.89 \\ -17.851 + 2.936f & 12.89 \le f < 25.78 \end{array} \right\} \text{ (dB)} \qquad (83D–1)$$

where

f	is the frequency in GHz
Insertion_loss(f)	is the recommended CAUI-4 chip-to-chip insertion loss

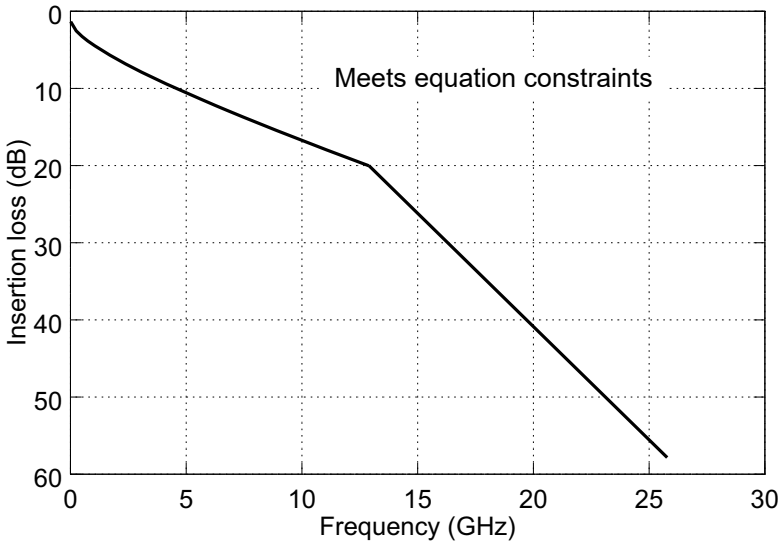

Figure 83D–3—CAUI-4 chip-to-chip channel insertion loss

83D.2 CAUI-4 chip-to-chip compliance point definition

The electrical characteristics for the CAUI-4 chip-to-chip interface are defined at compliance points for the transmitter (TP0a) and receiver (TP5a), respectively. The location of TP0a and electrical characteristics of the test fixture used to measure transmitter characteristics are defined in Figure 93–5 and 93.8.1.1, respectively. The location of TP5a and electrical characteristics of the test fixture used to measure the receiver are defined in Figure 93–10 and 93.8.2.1, respectively.

83D.3 CAUI-4 chip-to-chip electrical characteristics

83D.3.1 CAUI-4 transmitter characteristics

A CAUI-4 chip-to-chip transmitter shall meet the specifications defined in Table 83D–1 if measured at TP0a. While the CAUI-4 chip-to-chip transmitter requirements are similar to those in Clause 93, they differ in that they do not assume transmitter training or a back-channel communications path. Also, the transmit output waveform is not manipulated via the PMD control function described in 93.7.12, but may optionally be manipulated via the feedback mechanism described in 83D.3.3.2.

A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all transmitter signal measurements, unless otherwise specified.

[a]The state of the transmit equalizer is controlled by management interface.
[b]The values of the parameters are measured as defined in the referenced subclause except that the values of N_p and N_w are 5.
[c]Effective bounded uncorrelated jitter and effective total uncorrelated jitter are measured as defined in 92.8.3.8.2 except that the range for fitting $CDFL_i$ and $CDFR_i$, as defined in 92.8.3.8.2 c), shall be from 10^{-6} to 10^{-4}.
[d]Effective total uncorrelated jitter, peak-to-peak is specified to a 10^{-15} probability.

83D.3.1.1 Transmitter equalization settings

The CAUI-4 chip-to-chip transmitter includes programmable equalization to compensate for the frequency-dependent loss of the channel and to facilitate data recovery at the receiver. The functional model for the transmit equalizer is the three tap transversal filter shown in Figure 83D–4. The transmitter output equalization is characterized using the linear fit method described in 93.8.1.5.1 where the state of the CAUI-4 transmit output is manipulated via management.

The variable *Local_eq_cm1* controls the weight of the pre-cursor tap c(–1), by changing the ratio c(–1)/(|c(–1)|+|c(0)|+|c(1)|). The valid values of *Local_eq_cm1* and the corresponding ratios are specified in Table 83D–2. The variable *Local_eq_c1* controls the weight of the post-cursor tap c(1), by changing the ratio c(1)/(|c(–1)|+|c(0)|+|c(1)|). The valid values of *Local_eq_c1* and the corresponding ratios are specified in Table 83D–3. *Local_eq_cm1* and *Local_eq_c1* are independent of each other and independent on each lane. Each successive step in *Local_eq_cm1* and *Local_eq_c1* value shall result in a monotonic change in transmitter equalization.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If a Clause 45 MDIO is implemented, *Local_eq_cm1* and *Local_eq_c1* for each lane (0 through 3) and direction (transmit and receive) are accessible through registers 1.180 through 1.187 (see 45.2.1.112 through 45.2.1.115).

3	–0.15 ±0.04

83D.3.2 Optional EEE operation

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78 and 78.3), then the inter-sublayer service interface includes four additional primitives as described in 83.3 and may also support CAUI-4 shutdown.

If the EEE capability includes CAUI-4 shutdown (see 78.5.2), then when aui_tx_mode (see 83.5.11.3) is set to ALERT, the transmit direction sublayer sends a repeating 16-bit pattern, hexadecimal 0xFF00, which is transmitted across the CAUI-4. This sequence is transmitted regardless of the value of tx_bit presented by the PMA:IS_UNITDATA_i.request primitive or the rx_bit presented by the PMA:IS_UNITDATA_i.indication primitive. When aui_tx_mode is QUIET, the transmit direction CAUI-4 transmitter is disabled as specified below. Similarly when the received aui_tx_mode is set to ALERT, the receive direction sublayer sends a repeating 16-bit pattern, hexadecimal 0xFF00, which is transmitted across the CAUI-4. This sequence is

Table 83D–3—Post-cursor equalization

Local_eq_c1 value	*c*(1) ratio $\left(\frac{c(1)}{\lvert c(-1)\rvert + \lvert c(0)\rvert + \lvert c(1)\rvert}\right)$
0	0 ±0.04
1	–0.05 ±0.04
2	–0.1 ±0.04
3	–0.15 ±0.04
4	–0.2 ±0.04
5	–0.25 ±0.04

transmitted regardless of the value of tx_bit presented by the PMA:IS_UNITDATA_i.request primitive or the rx_bit presented by the PMA:IS_UNITDATA_i.indication primitive. When the received aui_tx_mode is QUIET, the receive direction CAUI-4 transmitter is disabled as specified below.

For EEE capability with CAUI-4 shutdown, the CAUI-4 transmitter lane's differential peak-to-peak output voltage shall be less than 30 mV within 500 ns of aui_tx_mode changing to QUIET in the relevant direction. Furthermore, the CAUI-4 transmitter lane's differential peak-to-peak output voltage shall be greater than 720 mV within 500 ns of aui_tx_mode ceasing to be QUIET in the relevant direction.

Global transmit disable is optional for EEE capability. The transmit disable function shall turn off all transmitter lanes for a physically instantiated AUI in either the ingress or the egress direction. In the egress direction, the PMA may turn off all the transmitter lanes for the egress direction CAUI-4 if PEASE is asserted and aui_tx_mode is QUIET. In the ingress direction, the PMA may turn off all the transmitter lanes for the ingress direction CAUI-4 if PIASE is asserted and the received aui_tx_mode is QUIET. In both directions, the transmit disable function shall turn on all transmitter lanes after the appropriate direction aui_tx_mode changes to any state other than QUIET within a time and voltage level specified in this subclause.

83D.3.3 CAUI-4 receiver characteristics

A CAUI-4 chip-to-chip receiver shall meet the specifications defined in Table 83D–4 if measured at TP5a.

Table 83D–4—CAUI-4 receiver characteristics at TP5a

Parameter	Subclause reference	Value	Units
Differential input return loss (min)	93.8.2.2	Equation (93–3)	dB
Differential to common-mode input return loss	93.8.2.2	Equation (93–5)	dB
Interference tolerance	83D.3.3.1	Table 83D–5	—

83D.3.3.1 Receiver interference tolerance

The receiver shall satisfy the requirements for interference tolerance defined in Table 83D–5. The interference tolerance test uses the method described in Annex 93C as specified by 93.8.2.3, with the following exceptions:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) The parameters in Table 83D–5 replace the parameters in Table 93–6.

b) The transmitter taps are set via management (see 83D.3.1.1) to the settings that provide the lowest BER.

c) Sinusoidal jitter is added to the test transmitter by modulating the clock source.

Table 83D–5—Receiver interference tolerance parameters

Parameter	Test 1 values			Test 2 values			Units
	Min	Max	Target	Min	Max	Target	
Bit error ratio[ab]	—	10^{-15}		—	10^{-15}		—
Applied pk-pk sinusoidal jitter			Table 8 8–13			Table 8 8–13	
Insertion loss at 12.89 GHz[c]	19.5	20.5		9.5	10.5		dB
Coefficients of fitted insertion loss[d] a_0 a_1 a_2 a_4	 –1 0 0 0	 2 2.937 1.599 0.03		 –1 0 0 0	 1 0.817 0.801 0.01		 dB dB/GHz$^{1/2}$ dB/GHz dB/GHz^2
RSS_DFE2[e]	0.05	—		0.025	—		—
COM including effects of broad-band noise	—	—	2	—	—	2	dB

[a]Bit error ratio replaces the RS symbol error ratio measurement in 93.8.2.3.
[b]Maximum BER assumes errors are not correlated to ensure sufficiently high mean time to false packet acceptance (MTTFPA) assuming 64B/66B coding. Actual implementation of the receiver is beyond the scope of this standard.
[c]Measured between TPt and TP5 (see Figure 93C–4).
[d]Coefficients are calculated from the insertion loss measured between TPt and TP5 (see Figure 93C–4) using the method in 93A.3 with f_{min} = 0.05 GHz, and f_{max} = 25.78125 GHz, and maximum Δf = 0.01 GHz.
[e]RSS_DFE2 is equivalent to RSS_DFE4 described in 93A.2 except that n_1=2 and n_2=5.

83D.3.3.2 Transmitter equalization feedback (optional)

Transmitter equalization feedback is an optional capability for a CAUI-4 chip-to-chip receiver. If implemented, it shall operate as described in this subclause.

Transmitter equalization feedback is generated for each lane (0 through 3) and direction (transmit and receive) independently. The variables that control transmitter equalization feedback are specific for each lane and direction.

A CAUI-4 chip-to-chip receiver may generate a request to change the transmit equalization coefficients of the remote transmitter to new values by setting the *Request_flag* variable to 1. The variables *Requested_eq_cm1* and *Requested_eq_c1* indicate the request values of *Local_eq_cm1* and *Local_eq_c1*, respectively, in the remote transmitter (see Table 83D–2 and Table 83D–3). The requested setting may be generated from the remote CAUI-4 chip-to-chip transmitter's equalization setting, which is stored in variables *Remote_eq_cm1* and *Remote_eq_c1*, and from information internal to the receiver, in an implementation specific manner.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When a CAUI-4 chip-to-chip receiver does not request a change of the remote transmitter's transmit equalization setting, it sets the *Request_flag* variable to 0. A CAUI-4 chip-to-chip receiver that does not implement transmitter equalization feedback always sets *Requests_flag* to 0.

If a Clause 45 MDIO is implemented, the variables *Request_flag, Requested_eq_cm1, Requested_eq_c1, Remote_eq_cm1,* and *Remote_eq_c1* for each lane and direction are accessible through registers 1.180 through 1.187 (see 45.2.1.112 through 45.2.1.115).

83D.3.4 Global energy detect function for optional EEE operation

The global energy detect function is mandatory for EEE capability with the deep sleep mode option and CAUI-4 shutdown. The global energy detect function indicates whether or not signaling energy is being received on the physical instantiation of the inter sublayer interface (in each direction as appropriate). The energy detection function may be considered a subset of the signal indication logic. If no energy is being received on the CAUI-4 for the ingress direction, SIGNAL_DETECT is set to FAIL following a transition from aui_rx_mode = DATA to aui_rx_mode = QUIET. When aui_rx_mode = QUIET, SIGNAL_DETECT shall be set to OK within 500 ns following the application of a signal at the receiver input that corresponds to an ALERT signal driven from the CAUI-4 link partner. While aui_rx_mode = QUIET, SIGNAL_DETECT changes from FAIL to OK only after the valid ALERT signal is received.

83D.4 CAUI-4 chip-to-chip channel characteristics

The Channel Operating Margin (COM), computed using the procedure in Annex 93A and the parameters in Table 83D–6, shall be greater than or equal to 2 dB. This minimum value allocates margin for practical limitations on the receiver implementation as well as the allowed transmitter equalization coefficients.

Table 83D–6—COM parameter values

Parameter	Symbol	Value	Units
Signaling rate	f_b	25.78125	GBd

83D.5 Example usage of the optional transmitter equalization feedback

83D.5.1 Overview

If implemented, transmitter equalization feedback from a CAUI-4 chip-to-chip receiver may be used to tune the equalization settings of the transmitter at the other end of the CAUI-4 chip-to-chip link to the values requested by the receiver. An example of a possible transmitter equalization tuning process using transmitter equalization feedback is provided in this subclause.

In this example, two components, A and B, are connected by a CAUI-4 chip-to-chip link, such that A is closest to the PCS and B is closest to the PMD. Clause 45 MDIO is implemented by both components, with component A at device address 11 and component B at device address 10. Transmitter equalization feedback is implemented by either component A, component B, or both. One Station Management (STA) controls both components.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Figure 83D–5 depicts the components of the CAUI-4 chip-to-chip link and the registers used during the tuning procedure.

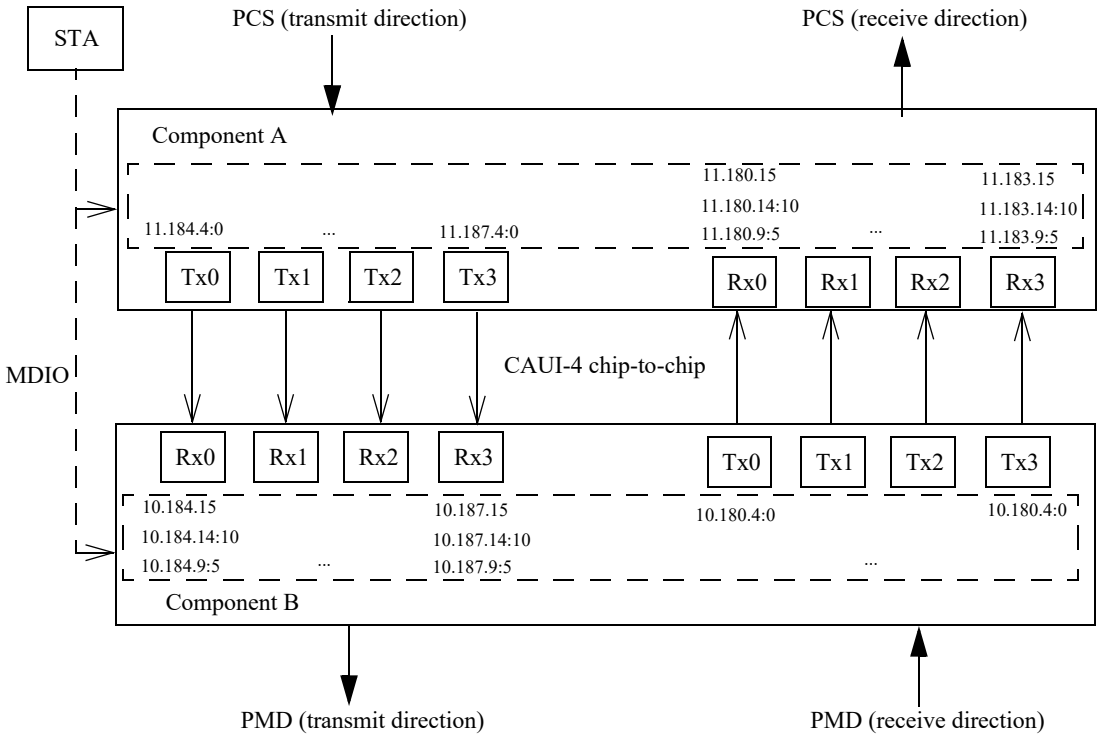

Figure 83D–5—Example transmitter equalization feedback components and registers

The STA performs the procedures described in 83D.5.2 and 83D.5.3 to tune lane 0 equalization settings in both sides of the CAUI-4 chip-to-chip link. When these procedures are completed, the STA uses similar procedures to tune equalization settings in lanes 1 through 3. When all lanes are tuned, the STA may repeat the process with another pair of components connected by CAUI-4 chip-to-chip.

NOTE—Using non-optimal transmitter equalization settings (or changing them) during the tuning procedure may interrupt data communication. The CAUI-4 bit error ratio is assumed to meet the requirements of 83D.3.3.1 upon completion of the tuning process.

83D.5.2 Tuning equalization settings on lane 0 in the transmit direction

1) Read *Local_eq_cm1* (11.184.1:0) and *Local_eq_c1* (11.184.4:2) from component A.
2) Write *Local_eq_cm1* and *Local_eq_c1* read from component A to *Remote_eq_cm1* (10.184.6:5) and *Remote_eq_c1* (10.184.9:7), respectively, in component B.
3) Read *Request_flag* (10.184.15), *Requested_eq_cm1* (10.184.11:10), and *Requested_eq_c1* (10.184.14:12) from component B.
4) If *Request_flag* is 0, go to tuning equalization settings on lane 0 in the Receive direction (83D.5.3).
5) If *Request_flag* is 1, write *Requested_eq_cm1* and R*equested_eq_c1* read from component B to *Local_eq_cm1* (11.184.1:0) and *Local_eq_c1* (11.184.4:2), respectively, in component A.
6) Go to step 1).

83D.5.3 Tuning equalization settings on lane 0 in the receive direction

1) Read *Local_eq_cm1* (10.180.1:0) and *Local_eq_c1* (10.180.4:2) from component B.
2) Write *Local_eq_cm1* and *Local_eq_c1* read from component B to *Remote_eq_cm1* (11.180.6:5) and *Remote_eq_c1* (11.180.9:7), respectively, in component A.
3) Read *Request_flag* (11.180.15), *Requested_eq_cm1* (11.180.11:10), and *Requested_eq_c1* (11.180.14:12) from component A.
4) If *Request_flag* is 0, proceed to tuning lane 1.
5) If *Request_flag* is 1, write *Requested_eq_cm1* and *Requested_eq_c1* read from component A to *Local_eq_cm1* (10.180.1:0) and *Local_eq_c1* (10.180.4:2), respectively, in component B.
6) Go to step 1).

83D.6 Protocol implementation conformance statement (PICS) proforma for Annex 83D, Chip-to-chip 100 Gb/s four-lane Attachment Unit Interface (CAUI-4)[296]

83D.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 83D, Chip-to-chip 100 Gb/s four-lane Attachment Unit Interface (CAUI-4), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

83D.6.2 Identification

83D.6.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

83D.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 83D, Chip-to-chip 100 Gb/s four-lane Attachment Unit Interface (CAUI-4)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[296]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Annex 83E

(normative)

Chip-to-module 100 Gb/s four-lane Attachment Unit Interface (CAUI-4)

83E.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 100 Gb/s four-lane Attachment Unit Interface (CAUI-4). Figure 83E–1 shows the relationship of the CAUI-4 chip-to-module interface to the ISO/IEC Open System Interconnection (OSI) reference model. The chip-to-module interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable module interfaces.

CAUI-4 = 100 Gb/s FOUR-LANE ATTACHMENT UNIT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION

Figure 83E–1—Example CAUI-4 chip-to-module relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The CAUI-4 link is described in terms of a host CAUI-4 component, a CAUI-4 channel with associated insertion loss, and a module CAUI-4 component. Figure 83E–2 and Equation (83E–1) depict a typical CAUI-4 application and summarize the differential insertion loss budget associated with the chip-to-module application, which is shown in Figure 83E–3. The CAUI-4 chip-to-module interface comprises independent data paths in each direction. Each data path contains four differential lanes, which are AC-coupled within the module. The nominal signaling rate for each lane is 25.78125 GBd. The chip-to-module interface is

defined using a specification and test methodology that is similar to that used for CEI-28G-VSR defined in OIF-CEI-03.1 [B57].

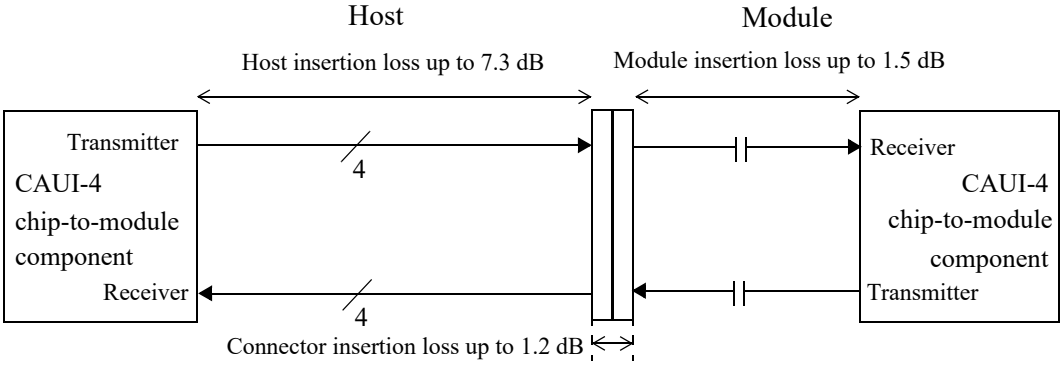

Figure 83E–2—Chip-to-module insertion loss budget at 12.89 GHz

$$Insertion_loss(f) \le \begin{cases} 1.076(0.075 + 0.537\sqrt{f} + 0.566f) & 0.01 \le f < 14 \\ 1.076(-18 + 2f) & 14 \le f < 18.75 \end{cases} \text{ (dB)} \qquad (83E–1)$$

where

f is the frequency in GHz
Insertion_loss(f) is the CAUI-4 chip-to-module insertion loss

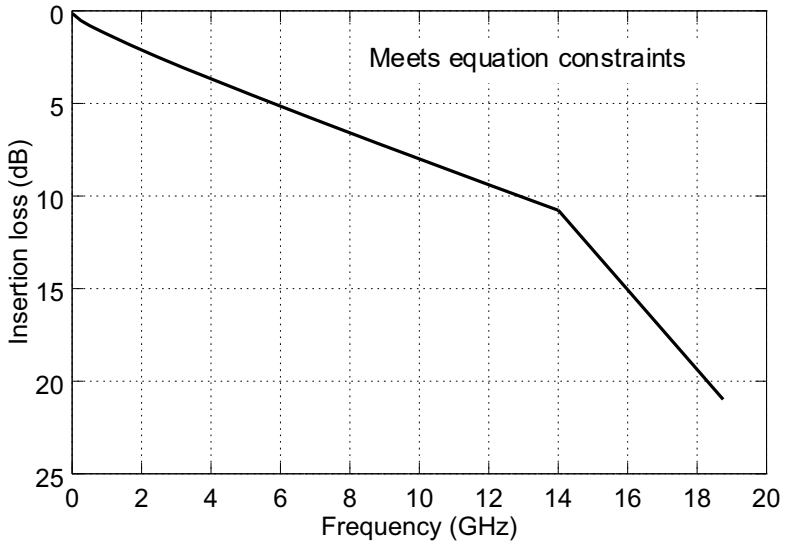

Figure 83E–3—CAUI-4 chip-to-module channel insertion loss

83E.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 10^{-15} with any errors sufficiently uncorrelated to ensure an acceptably high mean time to false packet acceptance (MTTFPA) assuming 64B/66B coding.

83E.2 CAUI-4 chip-to-module compliance point definitions

The electrical characteristics for the CAUI-4 chip-to-module interface are defined at compliance points for the host and module, respectively. Reference test fixtures, called compliance boards, are used to access the electrical specification parameters. Figure 83E–4 depicts the location of compliance points when measuring host CAUI-4 compliance. The output of the Host Compliance Board (HCB) is used to verify the host electrical output signal at TP1a. Similarly, the input of the HCB at TP4a is used to verify the host input compliance.

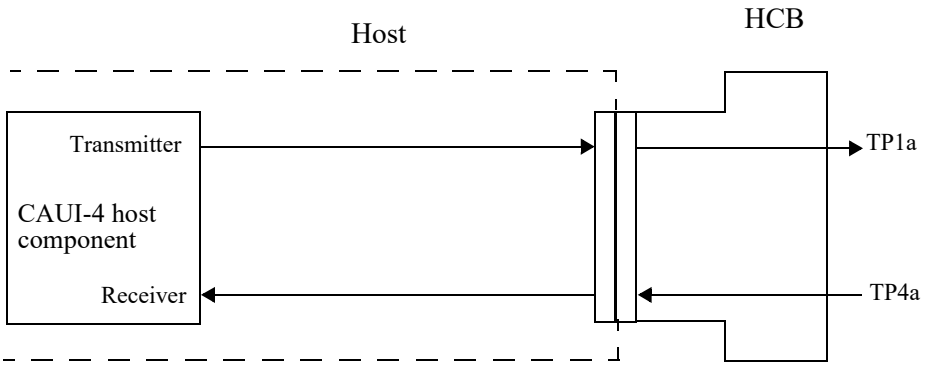

Figure 83E–4—Host CAUI-4 compliance points

Figure 83E–5 depicts the location of compliance points when measuring module CAUI-4 compliance. The output of the Module Compliance Board (MCB) is used to verify the module electrical output signal at TP4. Similarly, the input of the MCB at TP1 is used to verify the module input compliance. Additional details on the requirements for the MCB and HCB are given in 83E.4.1.

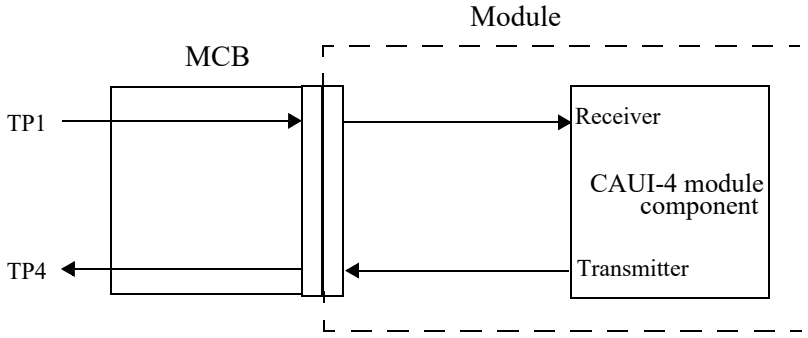

Figure 83E–5—Module CAUI-4 compliance points

83E.3 CAUI-4 chip-to-module electrical characteristics

83E.3.1 CAUI-4 host output characteristics

A CAUI-4 host output shall meet the specifications defined in Table 83E–1 if measured at TP1a.

Table 83E–1—CAUI-4 host output characteristics at TP1a

Parameter	Reference	Value	Units
Signaling rate per lane (range)	83E.3.1.1	25.78125 ± 100 ppm	GBd
DC common-mode output voltage (max)	83E.3.1.2	2.8	V
DC common-mode output voltage (min)	83E.3.1.2	–0.3	V
Single-ended output voltage (max)	83E.3.1.2	3.3	V
Single-ended output voltage (min)	83E.3.1.2	–0.4	V
AC common-mode output voltage (max, RMS)	83E.3.1.2	17.5	mV
Differential peak-to-peak output voltage (max) Transmitter disabled Transmitter enabled	83E.3.1.2	 35 900	mV
Eye width (min)	83E.3.1.6	0.46	UI
Eye height A, differential (min)	83E.3.1.6	95	mV
Eye height B, differential (min)	83E.3.1.6	80	mV
Differential output return loss (min)	83E.3.1.3	Equation (83E–2)	dB
Common-to-differential-mode output return loss (min)	83E.3.1.3	Equation (83E–3)	dB
Differential termination mismatch (max)	83E.3.1.4	10	%
Transition time (min, 20% to 80%)	83E.3.1.5	10	ps

A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all output signal measurements, unless otherwise specified.

83E.3.1.1 Signaling rate and range

The CAUI-4 signaling rate is 25.78125 GBd ± 100 ppm per lane. This translates to a nominal unit interval of 38.787879 ps.

83E.3.1.2 Signal levels

The differential output voltage v_{di} is defined to be the difference between the single-ended output voltages, SL*i*<p> minus SL*i*<n>. The common-mode voltage v_{cmi} is defined to be one half of the sum of SL*i*<p> and SL*i*<n>. These definitions are illustrated by Figure 83E–6.

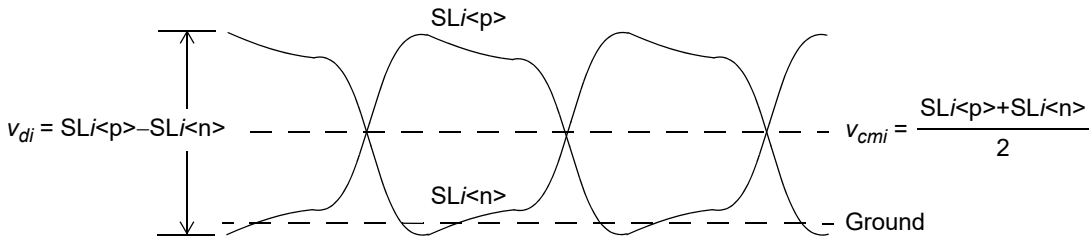

Figure 83E–6—Voltage definitions

The peak-to-peak differential output voltage is less than or equal to 900 mV. The peak-to-peak differential output voltage is less than or equal to 35 mV when the transmitter is disabled.

The DC common-mode output voltage and AC common-mode output voltage are defined with respect to signal ground.

83E.3.1.3 Output return loss

The differential output return loss, in dB, of the output is shown in Equation (83E–2) and illustrated in Figure 83E–7. This output requirement applies to all valid output levels. The reference impedance for differential return loss measurements is 100 Ω.

$$RLd(f) \geq \begin{cases} 9.5 - 0.37f & 0.01 \leq f < 8 \\ 4.75 - 7.4\log_{10}\left(\frac{f}{14}\right) & 8 \leq f < 19 \end{cases} \text{ (dB)} \quad \text{(83E–2)}$$

where

f	is the frequency in GHz
RLd	is the CAUI-4 chip-to-module host output differential return loss

Common-to-differential-mode output return loss, in dB, is shown in Equation (83E–3) and illustrated in Figure 83E–8.

$$RLdc(f) \geq \begin{cases} 22 - 20\left(\frac{f}{25.78}\right) & 0.01 \leq f < 12.89 \\ 15 - 6\left(\frac{f}{25.78}\right) & 12.89 \leq f < 19 \end{cases} \text{ (dB)} \quad \text{(83E–3)}$$

where

f	is the frequency in GHz
$RLdc$	is the CAUI-4 chip-to-module output common-to-differential-mode output return loss

83E.3.1.6 Host output eye width and eye height

Figure 83E–9 depicts an example host output eye width and eye height test configuration. Host output eye width and eye height are measured at TP1a using compliance boards defined in 83E.2. The host output eye is measured using a reference receiver with a continuous time linear equalizer (CTLE) defined in 83E.3.1.6.1. The recommended CTLE peaking value is used for host output eye measurements. In addition, it is provided to the module via the variable *Recommended_CTLE_value.* If a Clause 45 MDIO is implemented, this variable is accessible in the module through register 1.179 (see 45.2.1.111). Eye width and eye height measurement methodology is described in 83E.4.2. All counter-propagating signals shall be asynchronous to the co-propagating signals using Pattern 5 (with or without FEC encoding), Pattern 3, or a valid 100GBASE-R signal. Patterns 3 and 5 are described in Table 86–11. For the case where Pattern 3 is used with a common clock, there is at least 31 UI delay between the PRBS31 patterns on one lane and any other lane. The crosstalk generator is calibrated at TP4 with target differential peak-to-peak amplitude of 900 mV and target transition time of 12 ps.

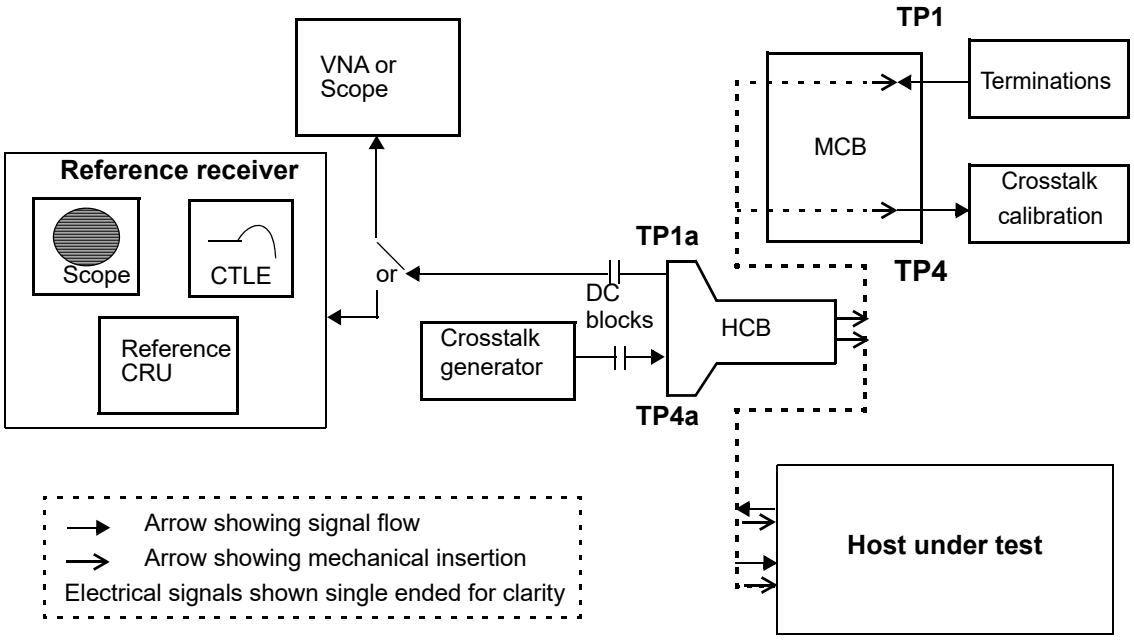

Figure 83E–9—Example host output test configuration

83E.3.1.6.1 Reference receiver for host output eye width and eye height evaluation

The reference receiver is used to measure host eye width and eye height. The reference receiver includes a selectable continuous time linear equalizer (CTLE), which is described by Equation (83E–4) with coefficients given in Table 83E–2 and illustrated in Figure 83E–10. The equalizer may be implemented in software; however, the measured signal is not averaged.

$$H(f) = \frac{GP_1P_2}{Z_1} \times \frac{\mathrm{j}2\pi f + Z_1}{(\mathrm{j}2\pi f + P_1)(\mathrm{j}2\pi f + P_2)} \tag{83E–4}$$

where

$H(f)$ is the CTLE transfer function
G is the CTLE gain

83E.3.2 CAUI-4 module output characteristics

A CAUI-4 module output shall meet the specifications defined in Table 83E–3 if measured at TP4. A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all output signal measurements, unless otherwise specified.

Table 83E–3—CAUI-4 module output characteristics at TP4

Parameter	Reference	Value	Units
Signaling rate per lane (range)	83E.3.1.1	25.78125 ± 100 ppm	GBd
AC common-mode output voltage (max, RMS)	83E.3.1.2	17.5	mV
Differential output voltage (max)	83E.3.1.2	900	mV
Eye width (min)	83E.3.2.1	0.57	UI
Eye height, differential (min)	83E.3.2.1	228	mV
Vertical eye closure (max)	83E.4.2.1	5.5	dB
Differential output return loss (min)	83E.3.1.3	Equation (83E–2)	dB
Common-to-differential-mode output return loss (min)	83E.3.1.3	Equation (83E–3)	dB
Differential termination mismatch (max)	83E.3.1.4	10	%
Transition time (min, 20% to 80%)	83E.3.1.5	12	ps
DC common-mode voltage tolerance (min)[a]	83E.3.1.2	–350	mV
DC common-mode voltage tolerance (max)[a]	83E.3.1.2	2850	mV

[a]DC common-mode voltage is generated by the host. A compliant module meets the output specifications with any DC common-mode voltage within the specified range applied at TP4. The specification includes effects of ground offset voltage.

83E.3.2.1 Module output eye width and eye height

Module output eye width is greater than 0.57 UI. Module output eye height is greater than 228 mV. Figure 83E–11 depicts an example module output eye width and eye height test configuration. Module output eye width and eye height are measured at TP4 using compliance boards defined in 83E.2. The module output eye is measured using a reference receiver with a continuous time linear equalizer (CTLE) defined in 83E.3.2.1.1. Eye width and eye height measurement methodology is described in 83E.4.2. All counter-propagating signals shall be asynchronous to the co-propagating signals using Pattern 5 (with or without FEC encoding), Pattern 3, or a valid 100GBASE-R signal. Patterns 3 and 5 are described in Table 86–11. For the case where Pattern 3 is used with a common clock, there is at least 31 UI delay between the PRBS31 patterns on one lane and any other lane. The crosstalk generator is calibrated at TP1a with target differential peak-to-peak amplitude of 900 mV and target transition time of 19 ps.

83E.3.2.1.1 Reference receiver for module output eye width and eye height evaluation

A reference receiver is used to measure module eye width and eye height. The reference receiver includes a selectable continuous time linear equalizer (CTLE), which is described by Equation (83E–4) with coefficients given in the first two rows of Table 83E–2. The equalizer may be implemented in software; however, the measured signal is not averaged. Either of the two equalizer settings may be used to meet the output eye width and eye height requirement.

83E.3.3.1 Input return loss

The differential input return loss, in dB, of the input is shown in Equation (83E–5) and illustrated in Figure 83E–12. The reference impedance for differential return loss measurements is 100 Ω.

$$RLd(f) \geq \left\{ \begin{array}{ll} 9.5 - 0.37f & 0.01 \leq f < 8 \\ 4.75 - 7.4\log_{10}\left(\frac{f}{14}\right) & 8 \leq f < 19 \end{array} \right\} \text{ (dB)} \qquad \text{(83E–5)}$$

where

f	is the frequency in GHz
RLd	is the CAUI-4 chip-to-module input differential return loss

Differential-to-common-mode input return loss, in dB, of the input is shown in Equation (83E–6) and illustrated in Figure 83E–13.

$$RLcd(f) \geq \left\{ \begin{array}{ll} 22 - 20\left(\frac{f}{25.78}\right) & 0.01 \leq f < 12.89 \\ 15 - 6\left(\frac{f}{25.78}\right) & 12.89 \leq f < 19 \end{array} \right\} \text{ (dB)} \qquad \text{(83E–6)}$$

where

f	is the frequency in GHz
$RLcd$	is the CAUI-4 chip-to-module input differential-to-common-mode input return loss

83E.3.3.2 Host stressed input test

The host stressed input tolerance is measured using the procedure defined in 83E.3.3.2.1. The input shall satisfy the input tolerance defined in Table 83E–5.

Table 83E–5—Host stressed input parameters

Parameter	Value
Eye width	0.57 UI
Applied pk-pk sinusoidal jitter	Table 88–13
Eye height	228 mV

83E.3.3.2.1 Host stressed input test procedure

The host stressed input test is summarized in Figure 83E–14. The stressed signal is applied at TP4a and is calibrated at TP4. A reference CRU with a corner frequency of 10 MHz and slope of 20 dB/decade is used to calibrate the stressed signal using Pattern 4 (PRBS9, see Table 86–11 and Table 68–6). The reference receiver includes a selectable CTLE given by Equation (83E–4) and the first two rows of Table 83E–2. The stressed signal is generated by adding sinusoidal jitter, random jitter, and bounded uncorrelated jitter to a clean signal. The amount of applied peak-to-peak sinusoidal jitter used for the host stressed input test is given in Table 83E–5. Bounded uncorrelated jitter provides a source of bounded high probability jitter uncorrelated with the pattern. This jitter stress source may not be present in all stressed pattern generators or bit error ratio testers. It can be generated by driving the pattern generator external jitter modulation input with a filtered PRBS pattern. The PRBS pattern length should be between PRBS7 and PRBS9. The PRBS signaling rate should be approximately 1/10 of the stressed signal's signaling rate (i.e., approximately

Copyright © 2022 IEEE. All rights reserved.

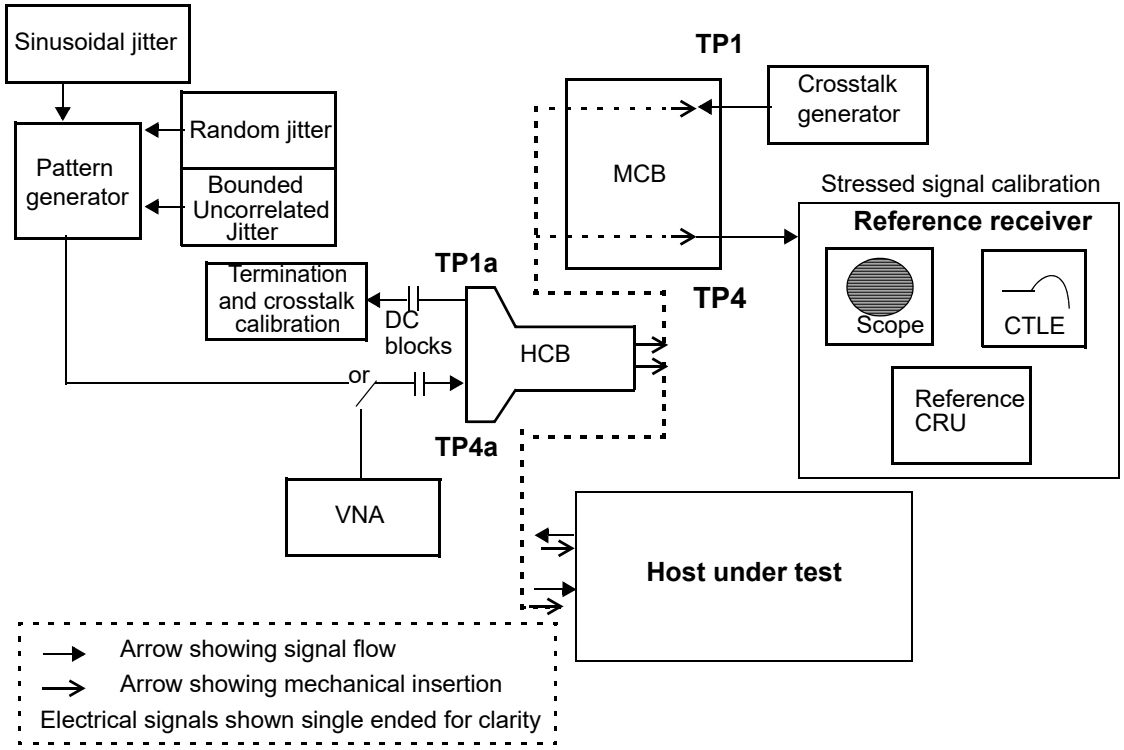

Figure 83E–14—Example host stressed input test

2.578 GBd). The clock source for the PRBS generator is asynchronous to the pattern generator clock source to assure non-correlation of the jitter. The low pass filter that operates on the PRBS pattern to generate the bounded uncorrelated jitter should exhibit 20 dB/decade roll-off with a –3 dB corner frequency between 150 MHz and 300 MHz. This value also has to be below the upper frequency limit of the pattern generator external modulator input. Random jitter and bounded uncorrelated jitter are added such that the output of the pattern generator approximates a jitter profile given in Table 83E–6.

Table 83E–6—Pattern generator jitter characteristics

Parameter	Value
Total Jitter (pk-pk)[a]	0.28 UI
Random Jitter (pk-pk)[b]	0.15 UI
Max even-odd jitter (pk-pk)[c]	0.035 UI

[a]Total Jitter at BER of 10^{-15}
[b]Random Jitter at BER of 10^{-15}
[c]As defined in 92.8.3.8.1

The counter propagating crosstalk signals during calibration of the stressed signal are asynchronous with target amplitude of 900 mV peak-to-peak differential and 20% to 80% target transition time of 19 ps as measured at TP1a. The crosstalk signal transition time is calibrated with Pattern 4. The pattern is changed to Pattern 5 (with or without FEC encoding), Pattern 3, or a valid 100GBASE-R signal for amplitude calibration and the stressed input test. Patterns 3, 4, and 5 are described in Table 86–11. For the case where Pattern 3 is used with a common clock, there is at least 31 UI delay between the PRBS31 patterns on one

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

lane and any other lane. Any one of these patterns is sufficient as a crosstalk aggressor with all lanes active during the stressed input test.

Eye height and eye width, extrapolated to a probability of 10^{-15}, are then measured at TP4 based on the eye measurement methodology given in 83E.4.2. Random jitter and the pattern generator output amplitude are adjusted (without exceeding the differential pk-pk input voltage tolerance specification as shown in Table 83E–4) to result in the eye height and eye width given in Table 83E–5 using the reference receiver with the setting of the CTLE that maximizes the product of eye height and eye width.

A host input stressed signal should have a vertical eye closure in the range of 4.5 dB to 5.5 dB with a target value of 5 dB.

The pattern is then changed to Pattern 5 (with or without FEC encoding), Pattern 3, or a valid 100GBASE-R signal for the input test, which is conducted by inserting the HCB into the host under test.

83E.3.4 CAUI-4 module input characteristics

A CAUI-4 module input shall meet the specifications defined in Table 83E–7 if measured at the appropriate test point.

Table 83E–7—CAUI-4 module input characteristics

Parameter	Reference	Test point	Value	Units
Signaling rate per lane (range)	83E.3.1.1	TP1	25.78125 ± 100 ppm	GBd

Module stressed input test[a]	83E.3.4.1	TP1a	See 83E.3.4.1	
Single-ended voltage tolerance range (min)	83E.3.1.2	TP1a	–0.4 to 3.3	V
DC common-mode voltage tolerance (min)[b]	83E.3.1.2	TP1	–350	mV
DC common-mode voltage tolerance (max)[b]	83E.3.1.2	TP1	2850	mV

[a]Meets BER specified in 83E.1.1.
[b]DC common-mode voltage is generated by the host. A compliant module meets the input specifications with any DC common-mode voltage within the specified range applied at TP1. The specification includes effects of ground offset voltage.

83E.3.4.1 Module stressed input test

The module stressed input tolerance is measured using the procedure defined in 83E.3.4.1.1. The input shall satisfy the input tolerance defined in Table 83E–8.

Parameter	Value
Eye width	0.46 UI
Applied pk-pk sinusoidal jitter	Table 88–13
Eye height	95 mV

83E.3.4.1.1 Module stressed input test procedure

The module stressed input test is summarized in Figure 83E–15. The stressed signal is applied at TP1 and is calibrated at TP1a. A reference CRU with a corner frequency of 10 MHz and slope of 20 dB/decade is used to calibrate the stressed signal using Pattern 4. The reference receiver includes a selectable CTLE given by Equation (83E–4) and Table 83E–2. The stressed signal is generated by adding sinusoidal jitter, random jitter, and bounded uncorrelated jitter to a clean signal, followed by frequency-dependent attenuation. The frequency-dependent attenuator represents the host channel and may be implemented with PCB traces. The amount of applied peak-to-peak sinusoidal jitter used for the module stressed input test is given in Table 83E–8. Bounded uncorrelated jitter provides a source of bounded high probability jitter uncorrelated with the pattern. This jitter stress source may not be present in all stressed pattern generators or bit error ratio testers. It can be generated by driving the pattern generator external jitter modulation input with a filtered PRBS pattern. The PRBS pattern length should be between PRBS7 and PRBS9. The PRBS signaling rate should be approximately 1/10 of the stressed signal's signaling rate (i.e., approximately 2.578 GBd). The clock source for the PRBS generator is asynchronous to the pattern generator clock source to assure non-correlation of the jitter. The low pass filter that operates on the PRBS pattern to generate the bounded uncorrelated jitter should exhibit 20 dB/decade roll-off with a –3 dB corner frequency between 150 MHz

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

and 300 MHz. This value also has to be below the upper frequency limit of the pattern generator external modulator input. Random jitter and bounded uncorrelated jitter are added such that the output of the pattern generator approximates a jitter profile given in Table 83E–9. The target pattern generator 20% to 80% transition time in the module stressed input test is 9.5 ps. The return loss of the test system as measured at TP1 meets the specification given in Equation (83E–2).

Table 83E–9—Pattern generator jitter characteristics

Parameter	Value
Total Jitter (pk-pk)[a]	0.28 UI
Random Jitter (pk-pk)[b]	0.15 UI
Max even-odd jitter (pk-pk)[c]	0.035 UI

[a]Total Jitter at BER of 10^{-15}.
[b]Random Jitter at BER of 10^{-15}.
[c]As defined in 92.8.3.8.1.

The counter propagating crosstalk signals during calibration of the stressed signal are asynchronous with target amplitude of 900 mV peak-to-peak differential and 20% to 80% target transition time of 12 ps as measured at TP4. The crosstalk signal transition time is calibrated with Pattern 4. The pattern is changed to Pattern 5 (with or without FEC encoding), Pattern 3, or a valid 100GBASE-R signal for amplitude calibration and the stressed input test. Patterns 3, 4, and 5 are described in Table 86–11. For the case where Pattern 3 is used with a common clock, there is at least 31 UI delay between the PRBS31 patterns on one lane and any other lane. Any one of these patterns is sufficient as a crosstalk aggressor with all lanes being active during the stressed input test.

Two levels of frequency-dependent attenuation are used for the module stressed input test: high loss and low loss. For the high loss case, frequency-dependent attenuation is added such that the loss at 12.89 GHz from the output of the pattern generator to TP1a is 13.8 dB. The 13.8 dB loss represents 10.25 dB channel loss with an additional allowance for host transmitter package loss. Eye height and eye width, extrapolated to a probability of 10^{-15}, are then measured at TP1a based on the eye measurement methodology given in 83E.4.2. Random jitter and the pattern generator output amplitude are adjusted (without exceeding the differential pk-pk input voltage tolerance specification as shown in Table 83E–7) to result in the eye height and eye width given in Table 83E–8 using the reference receiver with the setting of the CTLE that maximizes the product of eye height and eye width. For the low loss case, discrete frequency-dependent attenuation is removed such that the connection from the output of the pattern generator to TP1a comprises the mated HCB/MCB pair as described in 83E.4.1. Eye height and eye width at TP1a are then adjusted in the same way as described for the high loss case. In both the low loss and high loss cases, the module under test is provided with the reference CTLE setting used to meet eye width and eye height requirements via the variable *Recommended_CTLE_value*. If a Clause 45 MDIO is implemented, this variable is accessible through register 1.179 (see 45.2.1.111). The pattern is then changed to Pattern 5 (with or without FEC encoding), Pattern 3, or a valid 100GBASE-R signal for the input test, which is conducted by inserting the module into the MCB. The module CAUI-4 receiver under test shall meet the BER requirement as described in 83E.1.1 using three *Recommended_CTLE_value* values for both the high loss test and low loss test:

a) The CTLE setting used to meet eye width and eye height requirements
b) The value 1 dB higher if present in Table 83E–2
c) The value 1 dB lower if present in Table 83E–2

Modules may optionally elect not to use the *Recommended_CTLE_value.*

83E.4 CAUI-4 measurement methodology

This subclause describes common measurement tools and methodologies to be used for the CAUI-4 chip-to-module interface. Details of HCB and MCB characteristics are given in 83E.4.1 and details of the eye diagram measurement methodology are given in 83E.4.2.

83E.4.1 HCB/MCB characteristics

HCB characteristics are described in 92.11.1 where the HCB performs the equivalent function as the TP2 or TP3 test fixture. The MCB characteristics are described in 92.11.2 where the MCB performs the equivalent functionality as the cable assembly test fixture.

83E.4.2 Eye width and eye height measurement method

Eye diagrams in CAUI-4 chip-to-module are measured using a reference receiver. The reference receiver includes a fourth-order Bessel-Thomson low-pass filter response with 33 GHz 3 dB bandwidth, and a selectable continuous time linear equalizer (CTLE) to measure eye height and width. The pattern used for output eye diagram measurements is Pattern 4. The following procedure should be used to obtain eye height and eye width parameters:

1) Capture Pattern 4 using a clock recovery unit with a corner frequency of 10 MHz and slope of 20 dB/decade and a minimum sampling rate of 3 samples per bit. Collect sufficient samples equivalent to at least 4 million bits to allow for construction of a normalized cumulative distribution function (CDF) to a probability of 10^{-6} without extrapolation.
2) Apply the reference receiver including the appropriate CTLE to the captured signal. For modules, any single CTLE setting as described in 83E.3.2.1.1 that meets both eye width and eye height requirements is acceptable. For host compliance, the CTLE peaking in the reference receiver shall be set to three values:
   a) The recommended CTLE peaking value provided by the host
   b) The value 1 dB higher if present in Table 83E–2
   c) The value 1 dB lower if present in Table 83E–2

   A compliant host passes both the eye width and eye height A limit specified in Table 83E–1 using at least one of the settings and passes eye height B in Table 83E–1 at all of the two or three settings.
3) Use the differential equalized signal from step 2) to construct the CDF of the jitter zero crossing for both the left edge (CDFL) and right edge (CDFR), as a distance from the center of the eye. Calculate the eye width (EW6) as the difference in time between CDFR and CDFL with a value of 10^{-6}. CDFL and CDFR are calculated as the cumulative sum of histograms of the zero crossing samples at the left and right edges of the eye normalized by the total number of sampled bits. For a pattern with 50% transition density the maximum value for the CDFL and CDFR would be 0.5. The CDFL and CDFR are equivalent to bath tub curves where the BER is plotted versus sampling time.
4) Leveraging the Dual-Dirac jitter model described in 48B.1.1, estimate the random jitter. Calculate the best linear fit in Q-scale over the range of probabilities of 10^{-4} to 10^{-6} of the CDFL and CDFR to yield the random jitter on the left edge (RJL) and the random jitter on the right edge (RJR), respectively. The eye width is then given by Equation (83E–7).

$$EW15 = EW6 - 3.19 \times (RJR + RJL) \quad \text{(83E–7)}$$

where

$EW15$	is the eye width extrapolated to 10^{-15} probability
$EW6$	is the eye width at 10^{-6} probability
RJL	is the RMS value of the jitter estimated from CDFL
RJR	is the RMS value of the jitter estimated from the CDFR

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

5) Use the differential equalized signal from step 2) to construct the CDF of the signal voltage in the central 5% of the eye, for both logic 1 (CDF1) and logic 0 (CDF0), as a distance from the center of the eye. Calculate the eye height (EH6) as the difference in voltage between CDF1 and CDF0 with a value of 10^{-6}. CDF0 and CDF1 are calculated as the cumulative sum of histograms of the voltage at the top and bottom of the eye normalized by the total number of sampled bits. For a well-balanced number of ones and zeros, the maximum value for CDF0 and CDF1 will be 0.5.

6) Apply the Dual-Dirac and tail fitting techniques to CDF1 and CDF0 to estimate the noise at the middle of the eye. Calculate the best linear fit in Q-scale over the range of probabilities of 10^{-4} and 10^{-6} of CDF1 and CDF0 to yield relative noise one (RN1) and relative noise zero (RN0). The eye height is then given by Equation (83E–8)

$$EH15 = EH6 - 3.19 \times (RN0 + RN1) \quad \text{(83E–8)}$$

where

$EH15$	is the eye height extrapolated to 10^{-15} probability
$EH6$	is the eye height at 10^{-6} probability
$RN1$	is the RMS value of the noise estimated from CDF1
$RN0$	is the RMS value of the noise estimated from CDF0

83E.4.2.1 Vertical eye closure

Vertical eye closure is calculated using Equation (83E–9).

$$VEC = 20\log\left(\frac{AV}{EH15}\right) \quad \text{(83E–9)}$$

where

VEC	is vertical eye closure in dB
AV	is the eye amplitude of the equalized waveform. Eye amplitude is defined as the mean value of logic one minus the mean value of logic zero in the central 5% of the eye
$EH15$	is given in Equation (83E–8)

83E.5 Protocol implementation conformance statement (PICS) proforma for Annex 83E, Chip-to-module 100 Gb/s four-lane Attachment Unit Interface (CAUI-4)[297]

83E.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 83E, Chip-to-module 100 Gb/s four-lane Attachment Unit Interface (CAUI-4), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

83E.5.2 Identification

83E.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

83E.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 83E, Chip-to-module 100 Gb/s four-lane Attachment Unit Interface (CAUI-4)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[297]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Annex 85A

(informative)

40GBASE-CR4 and 100GBASE-CR10 TP0 and TP5 test point parameters

85A.1 Overview

Annex 85A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system. TP0 and TP5 test points are illustrated in the 40GBASE-CR4 and 100GBASE-CR10 link block diagram of Figure 85–2.

85A.2 Transmitter characteristics at TP0

The specifications at TP0 are summarized in Table 85A–1.

Table 85A–1—Transmitter characteristics at TP0 summary

Parameter	Subclause reference	Value	Units
Signaling rate, per lane	85.8.3.9	10.3125 ± 100 ppm	GBd
Unit interval nominal	85.8.3.9	96.969697	ps
Differential peak-to-peak output voltage (max) with Tx disabled		30	mV
Common-mode voltage limits	72.7.1.4	0 to 1.9	V
Differential output return loss (min)	72.7.1.5	See Equation (72–4) and Equation (72–5)	dB
Common-mode output return loss (min)	72.7.1.6	See Equation (72–6)and Equation (72–7)	dB
AC common-mode output voltage (max, RMS)		30	mV
Transition time (20%–80%)	72.7.1.7	24 to 47	ps
Max output jitter (peak-to-peak)[a] Random jitter[b] Deterministic jitter Duty Cycle Distortion[c] Total jitter	72.7.1.9	 0.15 0.15 0.035 0.28	 UI UI UI UI

[a]Jitter is measured with emphasis off.
[b]Jitter is specified at BER 10^{-12}.
[c]Duty Cycle Distortion is considered part of the deterministic jitter distribution.

85A.3 Receiver characteristics at TP5

The receiver characteristics at TP5 are summarized in Table 85A–2.

Table 85A–2—Receiver characteristics at TP5 summary

Parameter	Subclause reference	Value	Units
Bit error ratio	85.8.4.3	10^{-12}	
Signaling rate, per lane	85.8.4.4	10.3125 ± 100 ppm	GBd
Unit interval (UI) nominal	85.8.4.4	96.969697	ps
Receiver coupling	85.8.4.5	AC	
Differential input peak-to-peak amplitude (max)	72.7.2.4	1200[a]	mV
Differential input return loss (min)[b]	72.7.2.5	See Equation (72–4) and Equation (72–5)	dB
Differential to common-mode input return loss	85.8.4	10 min from 10 MHz to 10 GHz	dB

[a]The receiver shall tolerate amplitudes up to 1600 mV without permanent damage.
[b]Relative to 100 Ω differential.

85A.4 Transmitter and receiver differential printed circuit board trace loss

With the insertion loss TP0 to TP2 or TP3 to TP5 given in 85.8.3.4 and an assumed mated connector loss of 1.74 dB, the maximum insertion loss allocation for the transmitter and receiver differential controlled impedance printed circuit boards for each differential lane (i.e., the maximum value of the sum of the insertion losses from TP0 to the MDI host receptacle and from TP5 to the MDI host receptacle) are determined using Equation (85A–1). The maximum insertion loss allocation for the transmitter and receiver differential controlled impedance printed circuit boards is 7 dB at 5.15625 GHz. The maximum insertion loss for the transmitter or the receiver differential controlled impedance printed circuit board is one half of the maximum insertion loss $IL_{PCBmax}(f)$.

$$IL_{\mathrm{PCB}}(f) \le IL_{\mathrm{PCBmax}}(f) \;=\; (0.3)[20\log_{10}(\mathrm{e})(b_1\sqrt{f} + b_2 f + b_3 f^2 + b_4 f^3)] \;\; (\mathrm{dB}) \qquad (85\text{A}–1)$$

for 10 MHz ≤ f ≤ 7500 MHz.

where

f is the frequency in Hz
$IL_{\mathrm{PCB}}(f)$ is the insertion loss for the transmitter and receiver PCB
$IL_{\mathrm{PCBmax}}(f)$ is the maximum insertion loss for the transmitter and receiver PCB
b_1 2×10^{-5}
b_2 1.1×10^{-10}
b_3 3.2×10^{-20}
b_4 -1.2×10^{-30}
e ≈ 2.71828

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The minimum insertion loss allocation for the transmitter and receiver differential controlled impedance printed circuit boards for each differential lane (i.e., the minimum value of the sum of the insertion losses from TP0 to MDI receptacle and TP5 to MDI receptacle) are determined using Equation (85A–2) and the coefficients b_1 through b_4 are given in Equation (85A–1). The minimum insertion loss for the transmitter or the receiver differential controlled impedance printed circuit board is one half of the minimum insertion loss $IL_{\mathrm{PCBmin}}(f)$.

$$IL_{\mathrm{PCB}}(f) \geq IL_{\mathrm{PCBmin}}(f) = (0.0574)[20\log_{10}(\mathrm{e})(b_1\sqrt{f} + b_2 f + b_3 f^2 + b_4 f^3)] \text{ (dB)} \quad (85\text{A–}2)$$

for 10 MHz $\leq f \leq$ 7500 MHz.

where

f is the frequency in Hz
$IL_{\mathrm{PCB}}(f)$ is the insertion loss for the transmitter and receiver PCB
$IL_{\mathrm{PCBmin}}(f)$ is the minimum insertion loss for the transmitter and receiver PCB

85A.5 Channel insertion loss

This subclause provides information on channel insertion losses for intended topologies ranging from 0.5 m to 7 m in length. The maximum channel insertion loss associated with the 7 m topology is determined using Equation (85A–3). The channel insertion loss associated with the 0.5 m topology and a maximum host channel is determined by Equation (85A–4). The channel insertion loss budget at 5.15625 GHz is illustrated in Figure 85A–1.

The maximum channel insertion loss is determined using Equation (85A–3). The maximum channel insertion loss is 24.44 dB at 5.15625 GHz.

$$IL_{\mathrm{Chmax}}(f) = IL_{\mathrm{Camax}}(f) + 2IL_{\mathrm{Host}}(f) - 2IL_{\mathrm{MatedTF}}(f) \text{ (dB)} \quad (85\text{A–}3)$$

for 50 MHz $\leq f \leq$ 7500 MHz.

where

f is the frequency in MHz
$IL_{\mathrm{Ch}max}(f)$ is the maximum channel insertion loss between TP0 and TP5
$IL_{\mathrm{Camax}}(f)$ is the maximum cable assembly insertion loss using Equation (85–19)
$IL_{\mathrm{Host}}(f)$ is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (85–14)
$IL_{\mathrm{MatedTF}}(f)$ is the maximum insertion loss of the mated test fixture using Equation (85–36)

The channel insertion loss between TP0 and TP5 representative of a 0.5 m cable assembly and a maximum host channel is determined using Equation (85A–4).

$$(IL_{\mathrm{Ch0.5}m}(f) = 0.275IL_{\mathrm{Camax}}(f) + 2IL_{\mathrm{Host}}(f) - 2IL_{\mathrm{MatedTF}}(f) \text{ (dB)} \quad (85\text{A–}4)$$

for 50 MHz $\leq f \leq$ 7500 MHz.

where

f is the frequency in MHz

$IL_{\mathrm{Ch0.5}m}(f)$ is the channel insertion loss between TP0 and TP5 representative of a 0.5 m cable assembly and a maximum host channel

$IL_{\mathrm{Camax}}(f)$ is the maximum cable assembly insertion loss from TP1 to TP4 using Equation (85–19)

$IL_{\mathrm{Host}}(f)$ is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (85–14)

$IL_{\mathrm{MatedTF}}(f)$ is the maximum insertion loss of the mated test fixture using Equation (85–36)

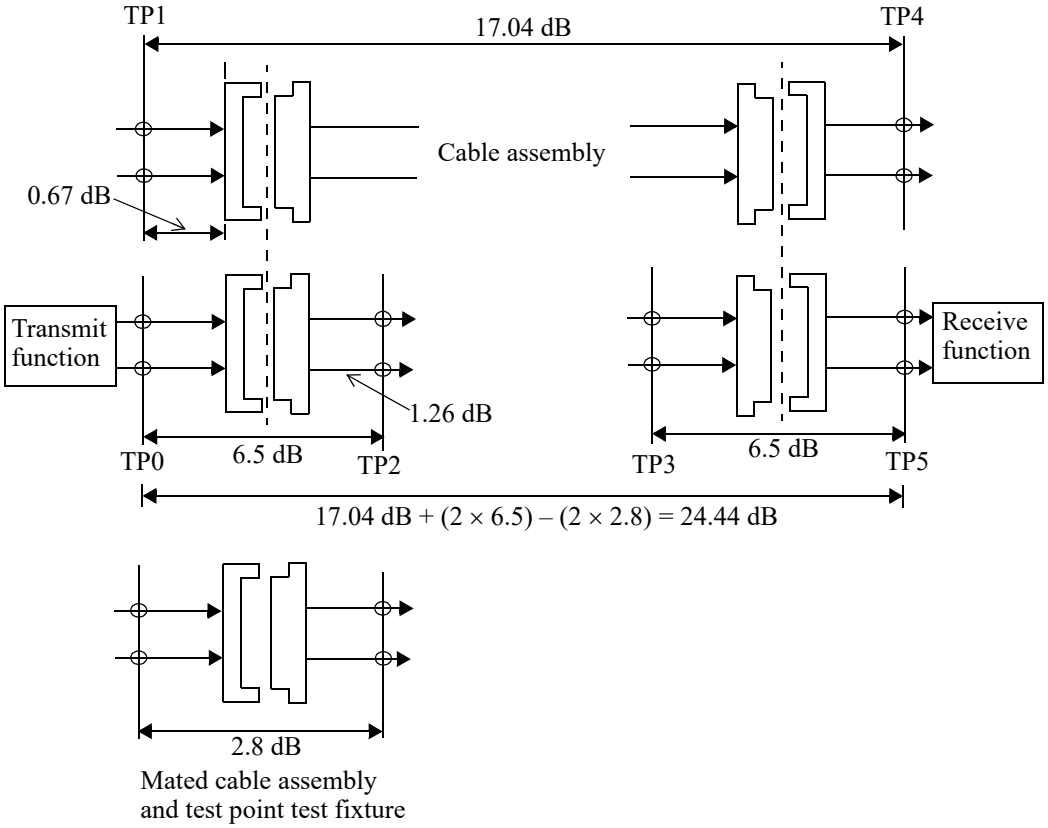

Figure 85A–1—Illustration of channel insertion loss budget at 5.15625 GHz

85A.6 Channel return loss

The return loss of each lane of the 40GBASE-CR4 or 100GBASE-CR10 channel is recommended to meet the values determined using Equation (85–25).

85A.7 Channel insertion loss deviation (ILD)

The channel insertion loss deviation is the difference between the channel insertion loss and the fitted channel insertion loss is determined using Equation (85A–5).

$$ILD(f) = IL_{\mathrm{Ch}}(f) - IL_{\mathrm{fitted}}(f) \text{ (dB)} \quad (85A–5)$$

where

f is the frequency in MHz

$ILD(f)$ is the channel insertion loss deviation at frequency f

$IL_{\text{fitted}}(f)$ is defined in Equation (85–19)

Given the channel insertion loss is at N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 7500 MHz with a maximum frequency spacing of 10 MHz, the coefficients of the fitted channel insertion loss are determined using Equation (85–20) and Equation (85–21).

The channel insertion loss deviation is recommended to be within the region defined by Equation (85–23) and Equation (85–24) for all frequencies from 50 MHz to 7500 MHz.

85A.8 Channel integrated crosstalk noise (ICN)

Since four lanes or ten lanes are used to transfer data between PMDs, the near-end crosstalk (NEXT) that is coupled into a victim receiver will be from the four or ten adjacent transmitters. The channel multiple disturber NEXT loss, $MDNEXT_loss_1(f)$, is specified using the individual NEXT losses as shown in Equation (85–26).

In addition, the far-end Crosstalk (FEXT) that is coupled into a receiver will be from the three or nine other transmitters adjacent to the victim transmitter. The channel multiple disturber FEXT loss, $MDFEXT_loss(f)$, is specified using the individual FEXT losses as shown in Equation (85–27).

Given the channel $MDNEXT_loss(f)$ and $MDFEXT_loss(f)$ measured over N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 10000 MHz with a maximum frequency spacing of 10 MHz, the RMS value of the integrated crosstalk noise is determined using Equation (85–28) through Equation (85–32) and the parameters shown in Table 85–11.

The total integrated crosstalk RMS noise voltage of the channel is recommended to meet the values determined using Equation (85A–6) illustrated in Figure 85A–2.

$$\sigma_{x,\,ch} \leq \left\{ \begin{array}{ll} 10 & 3 \leq IL \leq 7.5 \\ 13.4 - 0.45IL & 7.5 < IL \leq 24.44 \end{array} \right\} \quad \text{(mV)} \qquad \text{(85A–6)}$$

where IL is the value of the channel insertion loss in dB at 5.15625 GHz.

Annex 86A

(normative)

Parallel Physical Interface (nPPI) for 40GBASE-SR4 and 40GBASE-LR4 (XLPPI) and 100GBASE-SR10 (CPPI)

86A.1 Overview

The Parallel Physical Interface (nPPI) is an optional instantiation of the PMD service interface for the PMDs in Clause 86, which is described in 86.2 and 80.3, or for the 40GBASE-LR4 PMD service interface described in 87.2 and 80.3. It allows the construction of compact optical transceiver modules for 40GBASE-SR4, 40GBASE-LR4, or 100GBASE-SR10 with no clock and data recovery circuits inside. The 40 Gb/s Parallel Physical Interface (XLPPI, four lanes) is used with 40GBASE-SR4 or 40GBASE-LR4, and the 100 Gb/s Parallel Physical Interface (CPPI, ten lanes) with 100GBASE-SR10. The term “nPPI” denotes either or both.

The PMD and PMA attached to the nPPI are required to comply with the delay, Skew, and Skew Variation requirements in 86.3, 83.5.3, and 83.5.4 as appropriate. The PMD MDIO function mapping given in 86.4 may apply. The PMD functional specifications are as given in 86.5.

This annex is arranged as follows: following the overview, a reminder of the block diagram, a brief introduction to the test points, and lane assignments, 86A.4 contains the electrical specifications for nPPI from host to module (Tx side) and then module to host (Rx side). Test points, compliance boards, and electrical parameters are defined in 86A.5. The host PCB (“channel”) response recommendation is provided in 86A.6. Safety, installation, environment, and labeling is addressed in 86A.7 and PICS is provided in 86A.8. This annex is very closely related to Clause 86.

86A.2 Block diagram and test points

The PMD block diagram is shown in Figure 86–2. Figure 86–3 shows the test points.

The nPPI is standardized at the test points described in 86.8.1. The transmit side electrical signal (host electrical output and module electrical input) is defined at the output of the Host Compliance Board (TP1a), and other specifications of the module electrical input port are defined at the input of the Module Compliance Board (TP1). The receive side electrical signal (module electrical output and host electrical input) is defined at the output of the Module Compliance Board (TP4), and other specifications of the host electrical input port are defined at the input of the Host Compliance Board (TP4a). Test points and compliance boards are defined more thoroughly in 86A.5.1.

86A.3 Lane assignments

There are no lane assignments (within a group of transmit or receive lanes) for XLPPI or CPPI. While it is expected that a PMD will map electrical lane *i* to optical lane *i* and vice versa, there is no need to define the physical ordering of the lanes, as the PCS is capable of receiving the lanes in any arrangement.

86A.4 Electrical specifications for nPPI

The signaling rate for a lane of an XLPPI or CPPI interface shall be as defined in Table 86–2. 86A.4.1 and 86A.4.2 specify the host to module (Tx side) and module to host (Rx side) respectively of the nPPI. Parameters are defined in 86A.5 and 86.8. A recommended PCB ("channel") response for the host (PMA) is provided in 86A.6. Test points are defined in 86A.5.1.

86A.4.1 nPPI host to module electrical specifications

Each output lane and signal of the nPPI host (PMA), if measured at TP1a (see 86A.5.1) with the specified crosstalk signals applied on all input lanes, shall meet the specifications of Table 86A–1 per the definitions in 86A.5. Each lane of the nPPI module (PMD) electrical input, if measured at TP1 and TP1a with all Rx lanes (module output) operating, shall meet the specifications of Table 86A–2 per the definitions in 86A.5. The module electrical input shall be AC-coupled, i.e., it shall present a high DC common-mode impedance at TP1. There may be various methods for AC-coupling in actual implementations.

Table 86A–1—nPPI host electrical output specifications at TP1a

Parameter description	Min	Max	Units	Conditions
Single ended output voltage	–0.3	4	V	Referred to signal common
AC common-mode output voltage	—	15	mV	RMS
Termination mismatch at 1 MHz	—	5	%	
Differential output return loss	See 86A.4.1.1	—	dB	
Output transition time, 20% to 80%	28	—	ps	
J2 Jitter output	—	0.17	UI	
J9 Jitter output	—	0.29	UI	
Data Dependent Pulse Width Shrinkage (DDPWS)	—	0.07	UI	
Q_{sq} for XLPPI	45	—	V/V	
Q_{sq} for CPPI	43	—	V/V	
	Specification values			
Eye mask coordinates: X1, X2 Y1, Y2	0.11, 0.31 95, 350		UI mV	Hit ratio = 5×10^{-5}
Crosstalk source VMA, each input lane	700		mV	At TP4
Crosstalk source transition times, 20% to 80%	34		ps	At TP4

Table 86A–2—nPPI module electrical input specifications at TP1 and TP1a

Parameter description	Test point	Min	Max	Units	Conditions
Single ended input voltage tolerance[a]	TP1a	–0.3	4	V	Referred to TP1 signal common
AC common-mode input voltage tolerance	TP1a	15	—	mV	RMS
Differential input return loss	TP1	See 86A.4.1.1	—	dB	10 MHz to 11.1 GHz
Differential to common-mode input return loss	TP1	10	—	dB	10 MHz to 11.1 GHz
J2 Jitter tolerance	TP1a	0.17	—	UI	
J9 Jitter tolerance	TP1a	0.29	—	UI	
Data Dependent Pulse Width Shrinkage (DDPWS) tolerance	TP1a	0.07	—	UI	
		Specification values			
Eye mask coordinates: X1, X2 Y1, Y2	TP1a	0.11, 0.31 95, 350		UI mV	Hit ratio = 5×10^{-5}
Crosstalk calibration signal VMA	TP4	850		mV	While calibrating compliance signal[b]
Crosstalk calibration signal transition times, 20% to 80%	TP4	34		ps	

[a] The single ended input voltage tolerance is the allowable range of the instantaneous input signals.
[b] The crosstalk calibration signals are applied to the mated HCB-MCB at TP4a and measured at TP4 following the same principles as the host electrical input calibration (see 86A.5.3.8.5). They are removed before testing.

86A.4.1.1 Differential return losses at TP1 and TP1a

From 10 MHz to 11.1 GHz, the magnitude in decibels of the module differential input return loss at TP1 and the host differential output return loss at TP1a (see 86A.5.1) shall not exceed the limit given in Equation (86A–1) and illustrated in Figure 86A–1.

$$Return_loss(f) \geq \begin{cases} 12 - 2\sqrt{f} & 0.01 \leq f < 4.11 \\ 6.3 - 13\log_{10}\left(\frac{f}{5.5}\right) & 4.11 \leq f \leq 11.1 \end{cases} \text{ dB} \qquad (86A–1)$$

where
$Return_loss(f)$ is the return loss at frequency f
f is the frequency in GHz

86A.4.2 nPPI module to host electrical specifications

Each electrical output lane and signal of the nPPI module (PMD), if measured at TP4 shall meet the specifications of Table 86A–3 per the definitions in 86A.5 while the specified crosstalk sources are applied to the module's electrical input Each lane of the nPPI host (PMA) input shall meet the specifications of Table 86A–4 at TP4 and/or TP4a per the definitions in 86A.5. The module electrical output shall be AC-coupled, i.e., it shall present a high DC common-mode impedance at TP4. There may be various methods for AC-coupling in actual implementations..

Table 86A–3—nPPI module electrical output specifications at TP4

Parameter description	Min	Max	Units	Conditions
Single ended output voltage tolerance	–0.3	4	V	Referred to signal common
AC common-mode output voltage (RMS)	—	7.5	mV	
Termination mismatch at 1 MHz	—	5	%	
Differential output return loss	See 86A.4.2.1	—	dB	10 MHz to 11.1 GHz
Output transition time, 20% to 80%	28	—	ps	
J2 Jitter output	—	0.42	UI

[a] The host is required to tolerate (work correctly with) input signals with instantaneous voltages anywhere in the specified range.
[b] The specification values are test conditions for measuring signal tolerance and are not characteristics of the host (see 86A.5.3.8).

86A.5 Definitions of electrical parameters and measurement methods

Test points are defined in 86A.5.1, compliance boards in 86A.5.1.1, test patterns in 86A.5.2 and parameters in 86A.5.3 and 86.8. Multi-lane testing considerations are given in 86.8.2.1.

86A.5.1 Test points and compliance boards

Figure 86–3 shows the six test points for 40GBASE-SR4 and 100GBASE-SR10. These are TP1, TP1a, TP2, TP3, TP4, and TP4a; four of these are Skew points SP2, SP3, SP4, and SP5 as shown. For 40GBASE-LR4, points TP1, TP1a, TP4, TP4a, SP2, and SP5 are in equivalent positions. Figure 86–3 also shows the substitution of compliance boards for module (PMD) or host (PMA). These compliance boards are defined to connect generic test equipment to the module and host for test purposes. The module can be plugged into

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the Module Compliance Board (MCB), which has specified electrical parameters. The Host Compliance Board (HCB), which also has specified electrical parameters, can plug into the host. The MCB and the HCB can be plugged together for calibration of compliance signals and to check the electrical parameters of the boards. Table 86A–5 shows the parameters or signals measured at each point. Also, TP0 and TP5 define the host ends of the electrical channel, at the PMA IC.

All electrical measurements and parameters are defined as through HCB and/or MCB as appropriate, with corrections if necessary.

CAUTION

A PMD with an nPPI interface is AC-coupled; however, an HCB is not. The user should take care that the test equipment does not improperly load or damage a host under test.

Table 86A–5—Parameters defined at each test point

Test point	Direction	Parameter
TP1	Looking downstream into module transmitter input	Module transmitter input return loss
TP1a	Looking upstream into host transmitter output	Host transmitter output signal and output return loss, module transmitter compliance signal calibration, host receiver compliance crosstalk signal calibration
TP4	Looking upstream into module receiver output	Module receiver output signal and output return loss, host receiver compliance signal calibration
TP4a	Looking downstream into host receiver input	Host receiver input return loss

86A.5.1.1 Compliance board parameters

The electrical characteristics of the HCB and MCB are given in 86A.5.1.1.1 and 86A.5.1.1.2. If boards are used that do not match the specifications given, the measurement results for nPPI shall be corrected for the differences between the actual HCB or MCB's properties and the reference differential insertion losses given in 86A.5.1.1.1. As it may be impractical to correct eye measurements for a board with differential insertion loss outside the limits given in 86A.5.1.1.2, such boards shall not be used. Boards that do not meet the specifications for mated HCB-MCB in 86A.5.1.1.2 shall not be used.

86A.5.1.1.1 Reference insertion losses of HCB and MCB

The reference differential insertion loss in decibels of the HCB and of the MCB, excluding the module connector, are given in Equation (86A–3) and Equation (86A–4) respectively, and illustrated in Figure 86A–2.

For the HCB,

$$Insertion_loss(f) = 0.01 + 0.3\sqrt{f} + 0.11f \quad \text{dB} \qquad 0.01 \le f \le 11.1 \qquad \text{(86A–3)}$$

where

$Insertion_loss(f)$ is the insertion loss at frequency f
f is the frequency in GHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

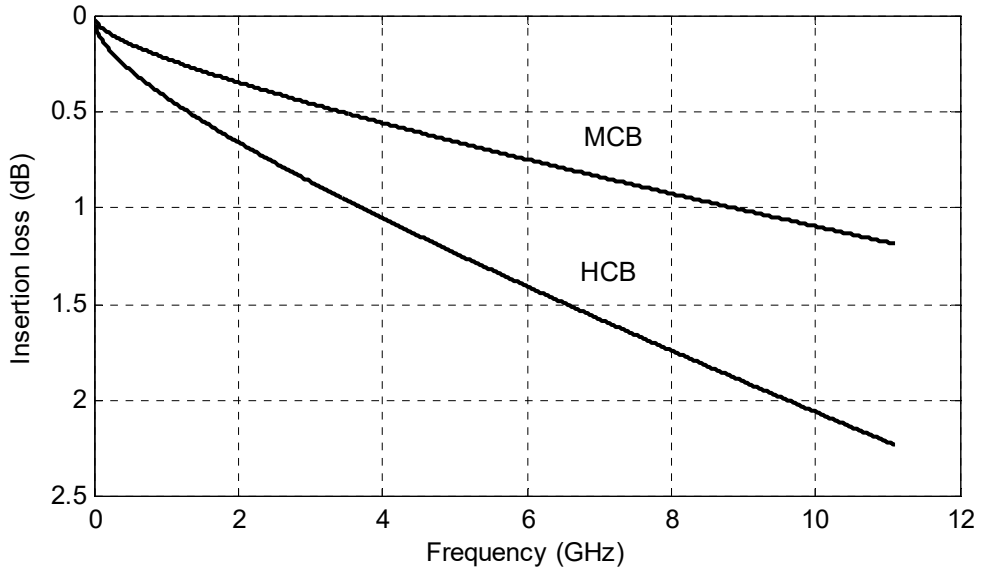

Figure 86A–2—Reference differential insertion losses of HCB, MCB excluding connector

For the MCB,

$$Insertion_loss(f) = 0.0006 + 0.16\sqrt{f} + 0.0587f \quad \text{dB} \qquad 0.01 \le f \le 11.1 \tag{86A–4}$$

where

Insertion_loss(*f*) is the insertion loss at frequency *f*
f is the frequency in GHz

86A.5.1.1.2 Electrical specifications of mated HCB and MCB

The limits on the differential insertion loss in decibels of the mated HCB and MCB (in either direction) are given in Equation (86A–5) (which defines the minimum insertion loss) and Equation (86A–6) (which defines the maximum insertion loss). These limits are illustrated in Figure 86A–3.

$$Insertion_loss(f) \ge -0.11 + 0.46\sqrt{f} + 0.16f \quad \text{dB} \qquad 0.01 \le f \le 11.1 \tag{86A–5}$$

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.029 + 0.861\sqrt{f} + 0.158f & 0.01 \le f < 5.5 \\ 0.2 + 0.65f & 5.5 \le f \le 11.1 \end{array} \right\} \quad \text{dB} \tag{86A–6}$$

where

Insertion_loss(*f*) is the insertion loss at frequency *f*
f is the frequency in GHz

The limit on the differential return loss in decibels of the mated HCB and MCB, looking into the HCB or looking into the MCB, is given in Equation (86A–7), and illustrated in Figure 86A–4.

where

Return_loss(*f*) is the return loss at frequency *f*
f is the frequency in GHz

The limit on the common-mode return loss in decibels of the mated HCB and MCB is given in Equation (86A–8) and illustrated in Figure 86A–4.

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 12 - 2.8f & 0.01 \leq f < 2.5 \\ 5.2 - 0.08f & 2.5 \leq f \leq 15 \end{array} \right\} \text{ dB} \quad \text{(86A–8)}$$

where

Return_loss(*f*) is the return loss at frequency *f*
f is the frequency in GHz

The limit on the differential to common-mode conversion loss in decibels of the mated HCB and MCB, for input to HCB and output from MCB, or input to MCB and output from HCB, is given in Equation (86A–9) and illustrated in Figure 86A–5.

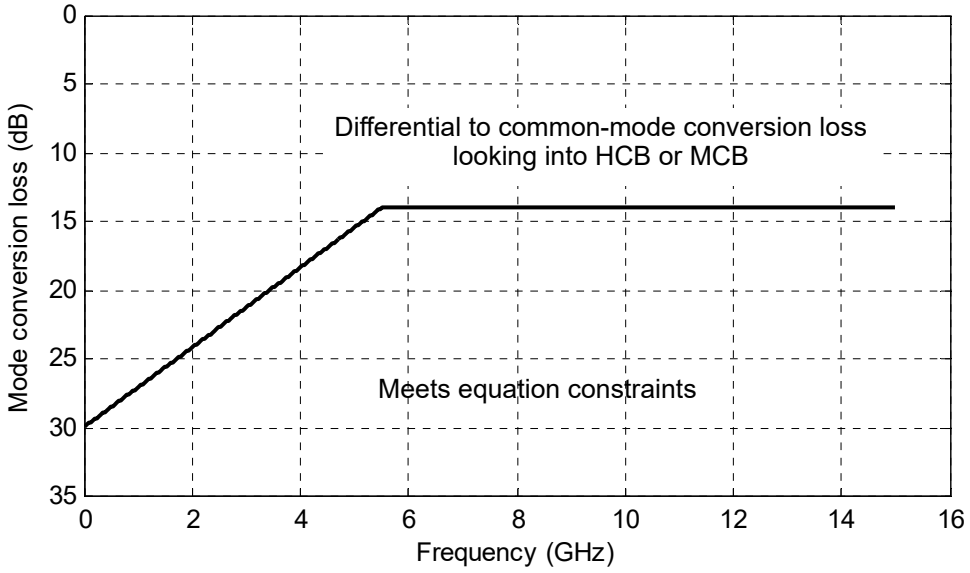

Figure 86A–5—Differential to common-mode conversion loss limit of mated HCB-MCB

$$Mode_conversion_loss(f) \geq \left\{ \begin{array}{ll} 30 - 2.91f & 0.01 \leq f < 5.5 \\ 14 & 5.5 \leq f \leq 15 \end{array} \right\} \text{ dB} \quad \text{(86A–9)}$$

where

Mode_conversion_loss(*f*) is the mode conversion loss at frequency *f*
f is the frequency in GHz

The limits on integrated crosstalk noise of the mated HCB and MCB for XLPPI and CPPI are as specified in 85.10.9.4 for 40GBASE-CR4 and 100GBASE-CR10 respectively, with the exception that the frequency range is 0.01 GHz to 12 GHz.

86A.5.2 Test patterns and related subclauses

While compliance is to be achieved in normal operation, specific test patterns are defined for measurement consistency and to enable measurement of some parameters. Table 86–11 lists the defined test patterns, and Table 86A–6 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. Multi-lane testing considerations are

Table 86A–6—Test patterns and related subclauses

Parameter	Pattern	Related subclause
J2 Jitter	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.3.3.1
J9 Jitter	3 or 5	86.8.3.3.2
Data Dependent Pulse Width Shrinkage (DDPWS)	4	86A.5.3.4
AC common-mode voltage	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86A.5.3.1
Transition time	Square wave or 4	86A.5.3.3
Electrical waveform (eye mask)	3, 5, or valid 40GBASE-SR4 or 100GBASE-SR10 signal	86.8.3.2, 86A.5.3.6
Q_{sq}	Square wave or 4	86A.5.3.5
Host electrical receiver signal tolerance	3 or 5	86A.5.3.8

given in 86.8.2.1. As Pattern 3 is more demanding than Pattern 5 (which itself is the same or more demanding than other 40GBASE-R or 100GBASE-R bit streams) an item which is compliant using Pattern 5 is considered compliant even if it does not meet the required limit using Pattern 3.

86A.5.3 Parameter definitions

In addition to the parameter definitions in the following subclause, some definitions with dual use (both optical and electrical) are given in 86.8.3.

86A.5.3.1 AC common-mode voltage

The common-mode voltage of a differential signal at any time is the average of signal+ and signal– at that time. RMS AC common-mode voltage may be calculated by applying the histogram function over 1 UI to the common-mode signal. As AC common-mode generation is very sensitive to the cable or oscilloscope delay mismatch, it is recommended to delay match the oscilloscope inputs for any measurements.

86A.5.3.2 Termination mismatch

Termination mismatch is the percentage difference between the two low-frequency impedances to common of a differential electrical port. Termination mismatch is defined as shown in Equation (86A–10).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\Delta Z_M = 2 \times \frac{|Z_p - Z_n|}{Z_p + Z_n} \times 100\ \% \quad (86A–10)$$

Termination mismatch can be measured by applying a low-frequency test tone to the differential inputs as shown in Figure 86A–6. The test frequency has to be high enough to overcome the high pass effects of any AC-coupling capacitors. The measured differential output or input impedance is designated by Z_{diff}.

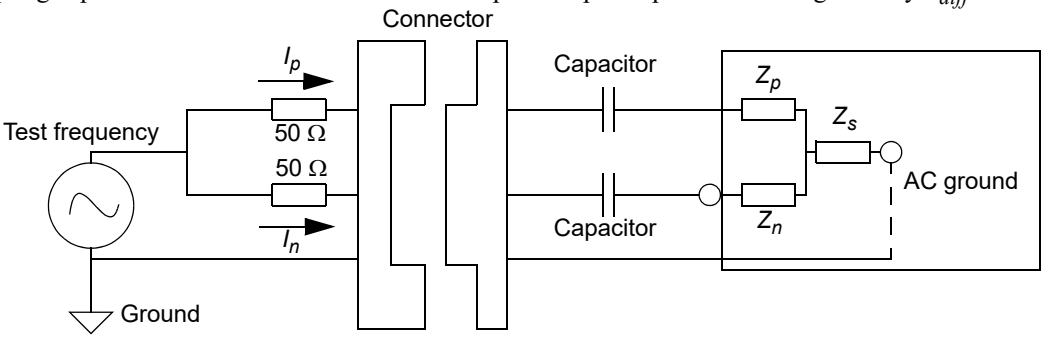

Figure 86A–6—Measurement of AC termination mismatch

For a 100 Ω port, low-frequency termination mismatch is then given by Equation (86A–11).

$$\Delta Z_M = 2 \times \frac{|I_p - I_n|}{I_p + I_n} \times \frac{Z_{diff} + 100}{Z_{diff}} \times 100\ \% \quad (86A–11)$$

where I_p and I_n are the currents flowing into the port as shown in Figure 86A–6.

Z_s is the effective series impedance between the terminations Z_p and Z_n and the AC ground.

86A.5.3.3 Transition time

In this annex, transition times (rise and fall times) are defined as the time between the 20% and 80% times, or 80% and 20% times, respectively, of isolated edges.

If the test pattern is the square wave with eight ones and eight zeros, the 0% level and the 100% level are as defined by the OMA measurement procedure (see 68.6.2).

If the test pattern is PRBS9, the transitions within sequences of five zeros and four ones, and nine ones and five zeros, respectively, are measured. These are bits 10 to 18 and 1 to 14, respectively, where bits 1 to 9 are the run of nine ones. In this case, the 0% level and the 100% level may be estimated as ZeroLevel and ZeroLevel + MeasuredOMA in the TWDP code (see 68.6.6.2), or by the average signal within windows from –3 UI to –2 UI and from 2 UI to 3 UI relative to the edge.

For electrical signals, the waveform is observed through a 12 GHz low-pass filter response (such as a Bessel-Thomson response).

NOTE—This definition is not the same as the rise and fall times typically reported by an oscilloscope from an eye diagram, which take all the edges into account.

86A.5.3.4 Data Dependent Pulse Width Shrinkage (DDPWS)

An oscilloscope, time interval analyzer, or other instrument with equivalent capability may be used to measure DDPWS. A clock recovery unit (CRU) as defined in 86.8.3.2 is used to trigger the oscilloscope. A repeating PRBS9 pseudo-random test pattern, 511 bits long, is used. For electrical jitter measurements, the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

measurement bandwidth is 12 GHz (such as a Bessel-Thomson response). If the measurement bandwidth affects the result, it can be corrected for by post-processing. However, a bandwidth above 12 GHz is expected to have little effect on the results.

The crossing level is the average value of the entire waveform being measured. The instrument is synchronized to the pattern repetition frequency and the waveforms or the crossing times are averaged sufficiently to remove the effects of random jitter and noise in the system. The PRBS9 pattern has 128 positive-going transitions and 128 negative-going transitions. The crossing times t_1 to t_{256} of each transition of the averaged waveform (when the averaged waveform crosses the crossing level) are found as shown in Figure 86A–7.

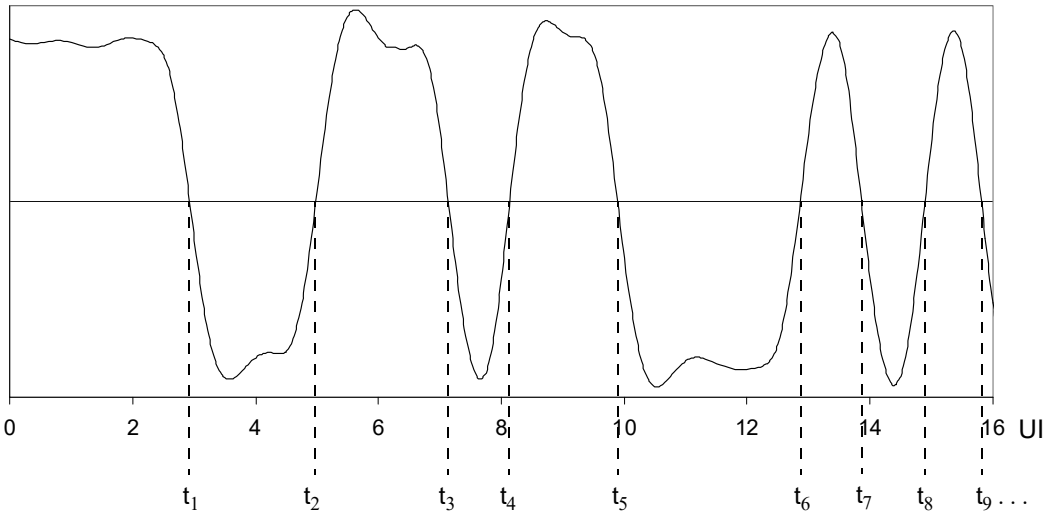

Figure 86A–7—Data Dependent Pulse Width Shrinkage test method

The DDPWS is the difference between one symbol period and the minimum of all the differences between pairs of adjacent transitions as follows in Equation (86A–12).

$$DDPWS = \mathrm{T} - \min(t_2 - t_1, t_3 - t_2, \ldots\ldots t_{256+1} - t_{256}) \quad (86A–12)$$

where T is one symbol period.

Note that the difference from the next edge in the repeating sequence, t_{256+1}, is also considered.

86A.5.3.5 Signal to noise ratio Q_{sq}

Q_{sq} is a measure of signal to noise ratio. For an electrical signal, it is analogous to Q_{sq} defined for an optical signal in 68.6.7, and it relates the low-frequency signal amplitude to the noise in an electrical –3 dB bandwidth of 12 GHz. It is defined with all co-propagating and counter-propagating crosstalk sources active, using one of patterns 3, 5, or a valid 40GBASE-SR4 or 100GBASE-SR10 signal. The input lanes of the item under test are receiving signals that are asynchronous to those being output.

Q_{sq} may be measured using an oscilloscope as follows:

a) The Voltage Modulation Amplitude (VMA) of the output lane is measured, using a square wave (8 ones, 8 zeros) or PRBS9 (Pattern 4). VMA is the difference between the 0% level and the 100% level defined in 86A.5.3.3; it is defined by analogy to OMA (see 68.6.2) but with a 12 GHz observation bandwidth.

b) Using the same pattern, the RMS noise over flat regions of the logic one and logic zero portions of the signal (see Figure 68–4 for the analogous optical measurement), is measured, compensating for noise in the measurement system. If possible, means should be used to prevent noise of frequency less than 1 MHz from affecting the result.
c) Q_{sq} is given by Equation (86A–13).

$$Q_{sq} = VMA / (n1 + n0) \quad (86A–13)$$

where

n1 is the RMS noise of logic one
n0 is the RMS noise of logic zero

86A.5.3.6 Eye mask for TP1a and TP4

The eye mask is defined by parameters X1, X2, Y1, and Y2. Unlike the optical eye mask, the vertical dimensions are fixed rather than scaled to the signal. Figure 83A–8 (an example of a hexagonal eye mask such as at TP1a) and Figure 83A–9 (a diamond mask such as at TP4) show the meaning of the parameters X1, X2, Y1 and Y2. The eye is defined as measured using a receiver with an electrical –3 dB bandwidth of 12 GHz (such as a Bessel-Thomson response). Further requirements are given in 86.8.3.2.

86A.5.3.7 Reference impedances for electrical measurements

The reference impedance for differential electrical measurements is 100 Ω and the reference impedance for common-mode electrical measurements is 25 Ω.

86A.5.3.8 Host input signal tolerance

To be compliant the host input signal tolerance shall satisfy the requirements of 86A.5.3.8.1 to 86A.5.3.8.6.

86A.5.3.8.1 Introduction

This subclause provides guidance for jitter tolerance testing at the host input (PMA) compliance point TP4/TP4a. Compliance is required with input jitter, vertical eye closure (Y1), and vertical peak level (Y2) as specified in Table 86A–4. Compliance is defined at an interface BER (the average of the BERs of all the lanes when stressed) of 10^{-12}. There are two test conditions: one each for the sensitivity and overload vertical eye parameters conditions. The reference test procedure is described in detail for a single stressed lane. Each Rx lane is tested in turn while all lanes are operated. Aggressor lanes are operated with the VMA specified in Table 86A–4.

86A.5.3.8.2 Test equipment and setup

A jitter tolerance test configuration is shown in Figure 86A–8. A test source is used to continuously generate the test signal. The test signal is conditioned within the guidelines outlined in 86A.5.3.8.3 to exhibit the appropriate jitter stress.

An RF attenuator or other output amplitude control of the test source may be required to set the vertical eye opening of the stressed eye.

The test equipment measured at TP4a looking towards the test signal source has better than 20 dB output return loss up to 12 GHz. The output return loss of the test system when measured at TP4 with the Module Compliance Board (looking towards the test signal source) is 2 dB better than the specifications of Table 86A–3 up to 8 GHz and 1 dB better up to 11 GHz.

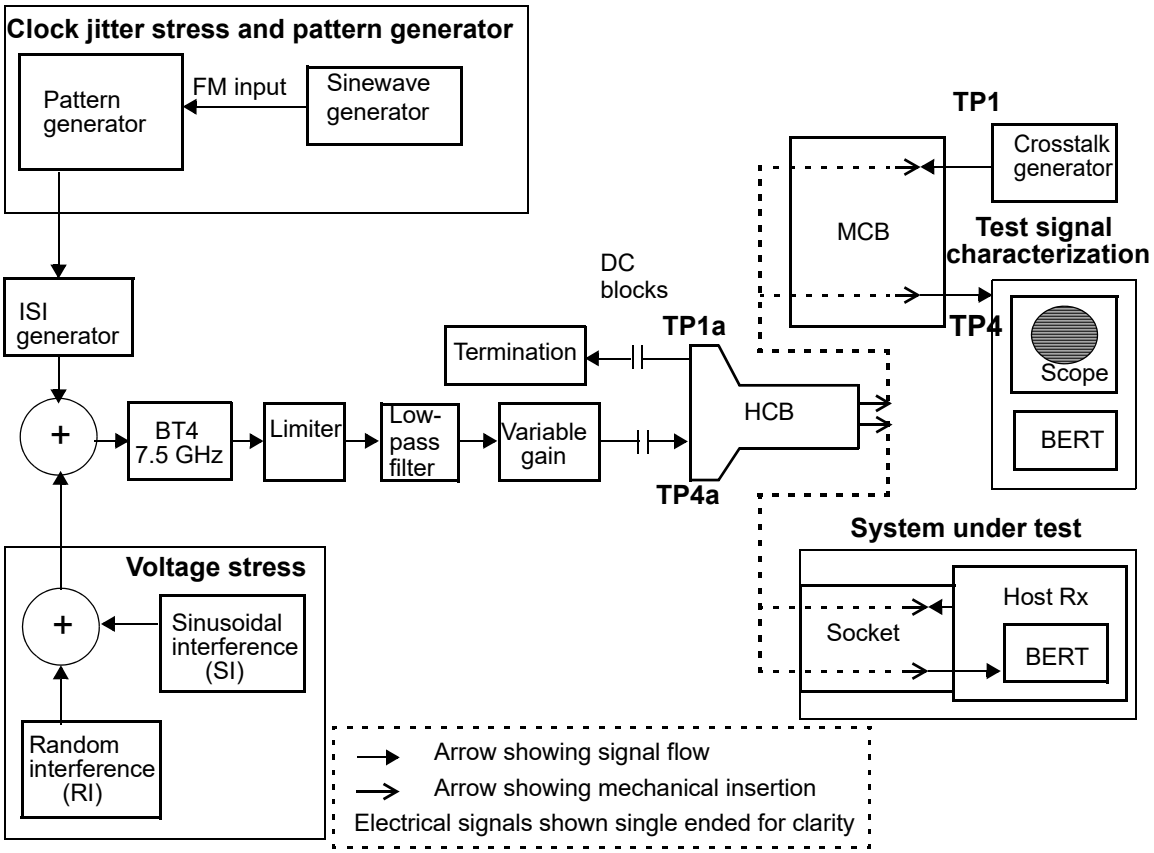

Figure 86A–8—Example jitter tolerance test configuration

86A.5.3.8.3 Stressed eye jitter characteristics

This subclause describes required test signal characteristics along with considerations and suggested approaches for test signal generation. The test signal is generated by the functions shown in Figure 86A–8 or by equivalent means. Figure 86A–9 illustrates how the jitter parameters in Table 86A–4 map to the jitter components in the stressed-eye test signal.

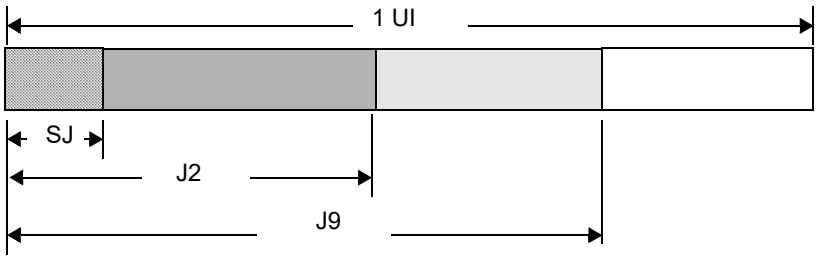

Figure 86A–9—Stressed eye jitter components

The 0.05 UI Sinusoidal Jitter (SJ) component of J2 Jitter is defined for frequencies much higher than the CDR bandwidth (e.g., ~20 MHz). At lower frequencies, the CDR has to track additional applied SJ as detailed in the relevant specifications (see Figure 86A–10 and 52.8.1).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The balance of the J2 Jitter is created by the following mechanisms: an ISI generator, sinusoidal interference (SI), and random interference (RI), all passed through a limiting function.

The test signal at TP4 has DDPWS as defined by Table 86A–4. Any duty cycle distortion (DCD) in the test signal does not exceed 0.02 UI. DCD is the difference between the mean position of all falling edges and the mean position of all rising edges of a waveform. It is measured at the average level of the waveform in a 12 GHz bandwidth, using Pattern 3 (PRBS31), Pattern 4 (PRBS9), Pattern 5, or a valid 40GBASE-SR4 or 100GBASE-SR10 signal.

The ISI generator may be implemented by a low-pass filter, length of FR4 trace, length of coax cable, or other equivalent method. It is required that the resulting signal be passed through a limiter function. A suitable limiter function may be implemented using a discrete limiting amplifier followed by a low-pass filter and an attenuator. The low-pass filter emulates the bandwidth and/or slew rate of a practical limiter. The attenuator is used to set the output amplitude to minimum and maximum values allowed by the eye mask coordinates of Table 86A–4.

A voltage stress is to be applied before the limiter function. This stress is composed of a single tone sinusoidal interferer (SI) in the frequency range 100 MHz to 2 GHz and a broadband noise source (RI) with a minimum power spectrum –3 dB point of 6 GHz and minimum crest factor of 7. It is the intent that this combination of voltage stress and limiting function introduce pulse-shrinkage jitter behavior. However, no more than 20% of the J2 Jitter is created by the sinusoidal interferer.

Jitter generation mechanisms for the pattern generator are typically based on phase modulation of the clock source, edge modulation of a variable delay line or a combination thereof.

Any approach that modulates or creates the appropriate levels and frequencies of the jitter components is acceptable.

86A.5.3.8.4 Calibration

Calibration of the test signal is performed using the guidelines for test setup in 86A.5.3.8.2 and illustrated in Figure 86A–8. The aim of the calibration is to achieve a test signal exhibiting jitter stress in accordance with Table 86A–4.

The test signal is calibrated differentially into standard instrumentation loads. If complementary single-ended signals are used, they are carefully matched in both amplitude and phase.

For accurate calibration, it is imperative that all elements in the signal path (cables, DC blocks, etc.) have wide and smooth frequency response as well as linear phase response throughout the spectrum of interest. Baseline wander and overshoot/undershoot are minimized.

An AC-coupling –3 dB corner frequency of 20 kHz is expected to be adequate to eliminate baseline wander effects; however, high-frequency performance is critical and should not be sacrificed by the AC-coupling.

Given random jitter and the nature of the long test patterns, low probability jitter events will likely be present. It is recommended for jitter calibration that a technique that can accurately measure low probability events be used to avoid overly stressful test conditions.

It is recommended that the actual compliance test pattern be used during calibration. For jitter stress calibration it is permissible, however, to use any appropriate test pattern that still results in the creation of a compliance test pattern with the appropriate jitter stress.

86A.5.3.8.5 Calibration procedure

The vertical eye opening and peak level are set approximately to the levels specified in Table 86A–4.

With an applied calibration test pattern and no additional jitter stress applied, the intrinsic J2 Jitter and J9 Jitter of the test source due to intrinsic noise and finite bandwidth effects are measured. At this stage, J2 Jitter is less than 0.15 UI and J9 Jitter less than 0.25 UI.

SJ is added until the J2 Jitter increases by 0.05 UI above this intrinsic J2 Jitter level. The SJ jitter frequency is well above the CDR bandwidth and asynchronous to the characteristic frequencies of the signal.

Next, additional high probability jitter as specified in 86A.5.3.8.3 is added by the ISI generator until at least 80% of the J2 Jitter has been created. The sinusoidal interferer amplitude is then turned on and adjusted until the required level of J2 Jitter is achieved. The frequency of any sinusoidal interferer is asynchronous to the characteristic frequencies of the signal.

A compliant test signal exhibits Data Dependent Pulse Width Shrinkage (defined in 86A.5.3.4) as specified in Table 86A–4. This is measured with noise and clock-jitter sources turned off.

Once the required level of J2 Jitter has been achieved, turn on the crosstalk source that is set such that at the output of the Host Compliance Board, the amplitude and the transition time are as given in Table 86A–4. The crosstalk pattern is Pattern 3 (PRBS31), Pattern 5, or a valid 40GBASE-SR4 or 100GBASE-SR10 signal, and is asynchronous with the test signal. Then the RI (random interference) voltage stress is added until the specified value of J9 Jitter is achieved.

If necessary, the sine interferer is readjusted to obtain the required level of J2 Jitter and if the sinusoidal interferer is changed then the random interferer is readjusted to obtain the required level of J9 Jitter. Iterative adjustments of the sinusoidal interferer and random interferer are made until the required values of both J2 Jitter and J9 Jitter are achieved.

If necessary, the vertical eye opening is readjusted to required levels.

The vertical eye opening and peak level specifications are verified.

Care should be taken when characterizing the signal used to make receiver tolerance measurements. The intrinsic noise and jitter introduced by the calibration measurement equipment (e.g., filters, oscilloscope and BERT) have to be accounted for and controlled. If equipment imperfections affect the results materially, corrections such as root-sum-of-squares deconvolution of Gaussian noise and jitter are used.

86A.5.3.8.6 Test procedure

Testing is performed differentially through a Host Compliance Board (see 86A.5.1).

Using a test signal arranged according to 86A.5.3.8.2 and calibrated according to 86A.5.3.8.5, operate the system with the test pattern specified in Table 86A–6. Each lane is tested in turn while all are operated. Aggressor lanes are operated with the VMA specified in Table 86A–4. The BERs of all the lanes when stressed are averaged to form the interface BER. See 86.8.2.1.

All signals and reference clocks that operate during normal operation are active during the test including all the other host lanes in both directions. The test signal and the host's transmitted signals are asynchronous. The host transmits Pattern 3 (PRBS31), Pattern 5, or a valid 40GBASE-SR4 or 100GBASE-SR10 signal. The sinusoidal jitter is stepped across the frequency and amplitude range according to Table 86A–7 and illustrated in Figure 86A–10, while monitoring the BER of the lane(s). The interface BER of a compliant host receiver remains below 10^{-12}.

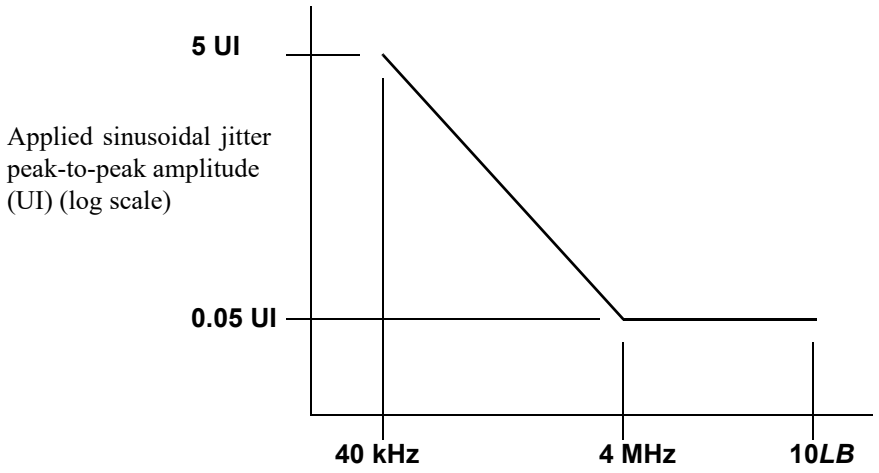

Figure 86A–10—Mask of the sinusoidal component of jitter tolerance

Table 86A–7—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter, peak-to-peak, (UI)
$f < 40$ kHz	Not specified
40 kHz $\le f <$ 4 MHz	2×10^5 Hz / f
4 MHz $\le f \le 10\ LB$[a]	0.05

[a]*LB* = loop bandwidth; upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

86A.6 Recommended electrical channel

The recommended limits for the differential insertion loss in decibels of the host PCB and connector mated to the HCB, between the PMA IC (TP0 or TP5) and TP1a or TP4a, are given in Equation (86A–14) and Equation (86A–15), and illustrated in Figure 86A–11. It is recommended that

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.5 & 0.01 \le f < 0.11 \\ 0.114 + 0.8914\sqrt{f} + 0.846f & 0.11 \le f < 7 \\ -35.91 + 6.3291f & 7 \le f < 8 \\ 14.72 & 8 \le f \le 11.1 \end{array} \right\} \text{ dB} \qquad (86A–14)$$

and

$$Insertion_loss(f) \ge \left\{ \begin{array}{ll} -0.22 + 0.46f & 0.01 \le f < 7 \\ 3 & 7 \le f \le 11.1 \end{array} \right\} \text{ dB} \qquad (86A–15)$$

where

Insertion_loss(*f*) is the insertion loss at frequency *f*
f is the frequency in GHz

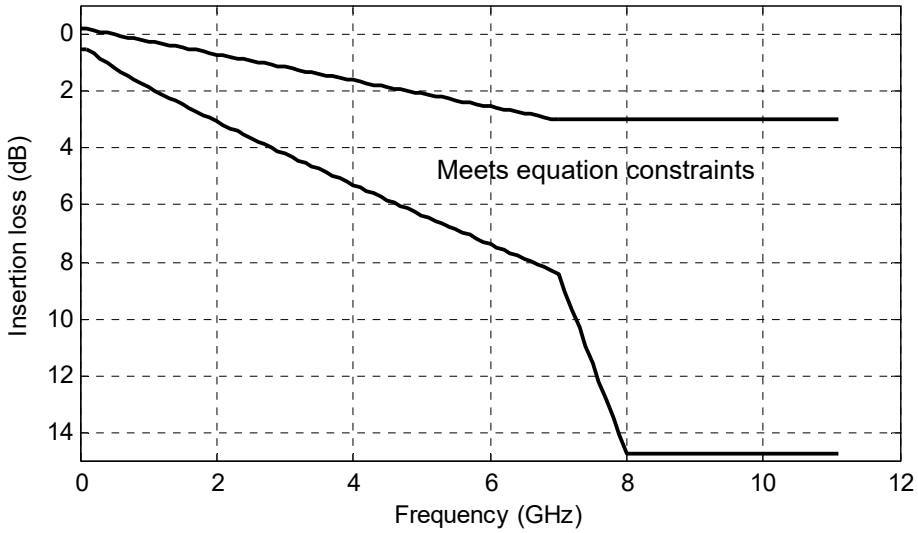

Figure 86A–11—Recommended insertion loss limits of host PCB, connector and HCB

The recommended maximum loss of the host PCB only (without connector or HCB) at 5.15625 GHz is 4.4 dB.

86A.7 Safety, installation, environment, and labeling

86A.7.1 General safety

Equipment subject to this annex shall conform to the general safety requirements in J.2.

86A.7.2 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

86A.7.3 Environment

The 40GBASE–SR4 and 100GBASE–SR10 operating environment specifications are as defined in 52.11, as defined in 52.11.1 for electromagnetic emission, and as defined in 52.11.2 for temperature, humidity, and handling.

86A.7.4 PMD labeling

The 40GBASE–SR4 and 100GBASE–SR10 labeling recommendations and requirements are as defined in 52.12.

86A.8 Protocol implementation conformance statement (PICS) proforma for Annex 86A, Parallel Physical Interface (nPPI) for 40GBASE-SR4 and 40GBASE-LR4 (XLPPI) and 100GBASE-SR10 (CPPI)[298]

86A.8.1 Introduction

The supplier of an XLPPI/CPPI implementation that is claimed to conform to Annex 86A, Parallel Physical Interface (nPPI) for 40GBASE-SR4 and 40GBASE-LR4 (XLPPI) and 100GBASE-SR10 (CPPI), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the same, can be found in Clause 21.

86A.8.2 Identification

86A.8.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

86A.8.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 86A, Parallel Physical Interface (nPPI) for 40GBASE-SR4 and 40GBASE-LR4 (XLPPI) and 100GBASE-SR10 (CPPI)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

Annex 91A

(informative)

RS-FEC codeword examples

This annex provides example RS-FEC codewords produced by the 64B/66B to 256B/257B transcoding and Reed-Solomon encoding defined in Clause 91. This annex presents data in a tabular form. The contents of the tables are transmitted from left to right within each row starting from the top row and ending at the bottom row. The tables contain both binary and hexadecimal representations of the data. For the hexadecimal representation, the most significant bit of each hex symbol is transmitted first.

91A.1 Input to the 64B/66B to 256B/257B transcoder

Table 91A–1 contains a sequence of 80 66-bit blocks corresponding to the PCS transmission of Idle control characters. The initial value of the scrambler was set to bits 6 to 63 of the first 64-bit payload in the first row of Table 74A–2. Bit 6 is assigned to S57 and bit 63 is assigned to S0 (see 49.2.6).

Table 91A–1—64B/66B to 256B/257B transcoder input

91A.2 Output of the RS(528,514) encoder

Table 91A–2 contains a RS(528,514) codeword. Each row of Table 91A–1 is a set of four 66-bit blocks that is converted to one 257-bit block using the procedure defined in 91.5.2.5. The resulting set of 20 257-bit blocks constitute the message portion of the codeword. The parity is computed using the encoder defined in 91.5.2.7 and is appended to the message to complete the codeword.

91A.4 Reed-Solomon encoder model

This annex also includes a model of the Reed-Solomon encoder, defined in 91.5.2.7, written in the C programming language. To emulate the RS(528,514) encoder, declare global variables per 91A.4.1. To emulate the RS(544,514) encoder, declare global variables per 91A.4.2. The generic components of the model are defined in 91A.4.3 to 91A.4.6.

91A.4.1 Global variable declarations for RS(528,514)

These global variables define the codeword size (in symbols) and generator polynomial coefficients (see Table 91–1) for the RS(528,514) code. Elements of GF(2^{10}) are presented as decimal values.

```
long n_symbols = 528;
unsigned long generator_polynomial[1024] =
   {904,6,701,32,656,925,900,614,391,592,265,945,290,432};
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

91A.4.2 Global variable declarations for RS(544,514)

These global variables define the codeword size and generator polynomial coefficients for the RS(544,514) code.

```
long n_symbols = 544;
unsigned long generator_polynomial[1024] =
   {575,552,187,230,552,1,108,565,282,249,593,132,94,720,495,385,942,503,883,36
   1,788,610,193,392,127,185,158,128,834,523};
```

91A.4.3 Other global variable declarations

The following global variables are declared for both RS(528,514) and RS(544,514). The field polynomial is assigned its decimal representation (1033 corresponds to $x^{10}+x^3+1$).

```
long polynomial = 1033;
long k_symbols = 514;
long check_symbols;
unsigned long codeword[1024];
```

91A.4.4 GF(2^{10}) multiplier function

This function implements multiplication over GF(2^{10}) using the expansion and reduction algorithm.

```
unsigned long multiply(long aa, long bb)
{
   unsigned long expand = 0;
   long k;

   for (k = 0; k < 10; k++)
   {
      if (bb & (1 << k))
         expand = expand ^ (aa << k);
   }

   for (k = 0; k < 9; k++)
   {
      if ((expand >> (18-k)) & 1)
         expand = expand ^ (polynomial << (8-k));
   }

   return expand;
}
```

91A.4.5 Reed-Solomon encoder function

This function implements the Reed-Solomon encoder. It uses the multiply() function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

```
void encode()
{
    long k, j;
    unsigned long multiplier;
    unsigned long generator_vector[1024];
    unsigned long encoder_divide[1024];

    for (k = 0; k < check_symbols; k++)
        encoder_divide[k] = 0;

    for (k = 0; k < k_symbols; k++)
    {
        multiplier = codeword[k] ^ encoder_divide[0];

        for (j = 0; j < check_symbols; j++)
            generator_vector[j] = multiply(multiplier, generator_polynomial[j]);

        for (j = 0; j < check_symbols-1; j++)
            encoder_divide[j] = generator_vector[j] ^ encoder_divide[j+1];

        encoder_divide[check_symbols-1] = generator_vector[check_symbols-1];

        for (j = 0; j < check_symbols; j++)
            codeword[j+k_symbols] = encoder_divide[j];
    }
}
```

91A.4.6 Main function

This sample main function defines a hypothetical message consisting of a countdown from 1023 to 510 (514 Reed-Solomon symbols). It then computes the parity and produces a codeword using the encode() function. The resulting codeword is printed to the console.

```
void main()
{
    long k;
    check_symbols = n_symbols-k_symbols;

    //*** Generate simple message symbols ***
    for (k = 0; k < k_symbols; k++)
        codeword[k] = 1023-k;

    encode();

    for (k = 0; k < n_symbols; k++)
        printf("%ld ", codeword[k]);
}
```

Annex 92A

(informative)

100GBASE-CR4 TP0 and TP5 test point parameters and channel characteristics

92A.1 Overview

Annex 92A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system. TP0 and TP5 test points are illustrated in the 100GBASE-CR4 link block diagram of Figure 92–2. It also provides information on channel characteristics.

92A.2 Transmitter characteristics at TP0

The transmitter characteristics at TP0 are constrained at TP0a by 93.8.1.

92A.3 Receiver characteristics at TP5

The receiver characteristics at TP5 are constrained at TP5a by 93.8.2.

92A.4 Transmitter and receiver differential printed circuit board trace loss

The recommended maximum insertion loss allocation for the transmitter or receiver differential controlled impedance printed circuit boards is determined using Equation (92A–1) and illustrated in Figure 92A–1. Note that the recommended maximum insertion loss allocation for the transmitter or receiver differential controlled impedance printed circuit boards is 6.81 dB at 12.8906 GHz. The recommended maximum insertion loss allocation for the transmitter or receiver differential controlled impedance printed circuit boards is consistent with the insertion loss TP0 to TP2 or TP3 to TP5 given in 92.8.3.6 and an assumed mated connector loss of 1.69 dB.

$$IL_{\mathrm{PCB}}(f) \le IL_{\mathrm{PCBmax}}(f) \;=\; 0.5(0.0694 + 0.4248\sqrt{f} + 0.9322f) \quad \text{(dB)} \qquad \text{(92A–1)}$$

for 0.01 GHz $\le f \le$ 19 GHz.

where

f	is the frequency in GHz
$IL_{\mathrm{PCB}}(f)$	is the insertion loss for the transmitter and receiver PCB
$IL_{\mathrm{PCBmax}}(f)$	is the recommended maximum insertion loss for the transmitter and receiver PCB

The minimum insertion loss allocation for the transmitter and receiver differential controlled impedance printed circuit boards for each differential lane (i.e., the minimum value of the sum of the insertion losses from TP0 to MDI receptacle or TP5 to MDI receptacle) is determined using Equation (92A–2) and illustrated in Figure 92A–1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$IL_{PCB}(f) \geq IL_{PCBmin}(f) = 0.086(0.0694 + 0.4248\sqrt{f} + 0.9322f) \quad \text{(dB)} \qquad \text{(92A–2)}$$

for 0.01 GHz ≤ f ≤ 19 GHz.

where

f	is the frequency in GHz
$IL_{PCB}(f)$	is the insertion loss for the transmitter and receiver PCB
$IL_{PCBmin}(f)$	is the minimum insertion loss for the transmitter and receiver PCB

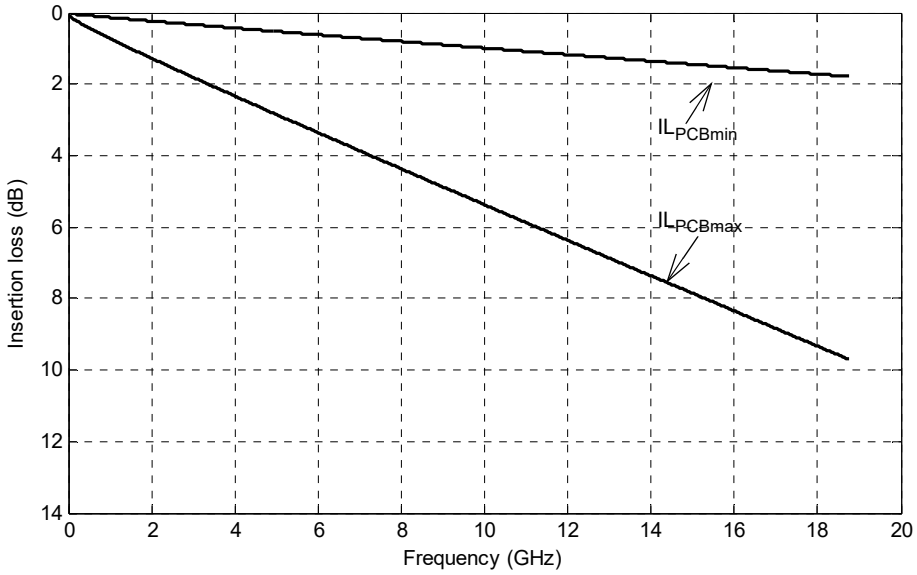

Figure 92A–1—Insertion Loss Tx or Rx PCB max and min

92A.5 Channel insertion loss

This subclause provides information on channel insertion losses for intended topologies ranging from 0.5 m to 5 m in length. The maximum channel insertion loss associated with the 5 m topology is determined using Equation (92A–3). The channel insertion loss associated with the 0.5 m topology and a maximum host channel is determined by Equation (92A–5). The channel insertion loss budget at 12.8906 GHz for the 5 m topology is illustrated in Figure 92A–2.

The maximum channel insertion loss for the 5 m topology is determined using Equation (92A–3). The maximum channel insertion loss is 35 dB at 12.8906 GHz.

$$IL_{\text{Chmax35dB}}(f) = IL_{\text{Camax5m}}(f) + 2IL_{\text{Host}}(f) - 2IL_{\text{MatedTF}}(f) \quad \text{(dB)} \tag{92A–3}$$

for 0.05 GHz ≤ f ≤ 19 GHz.

where

f	is the frequency in GHz
$IL_{\text{Chmax35dB}}(f)$	is the maximum channel insertion loss between TP0 and TP5 representative of a 5 m cable assembly and a maximum host channel
$IL_{\text{Camax5m}}(f)$	is the maximum 5 m cable assembly insertion loss.
$IL_{\text{Host}}(f)$	is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (92–8)
$IL_{\text{MatedTF}}(f)$	is the nominal insertion loss of the mated test fixture using Equation (92A–4)

The nominal insertion loss of the mated test fixture is determined using Equation (92A–4).

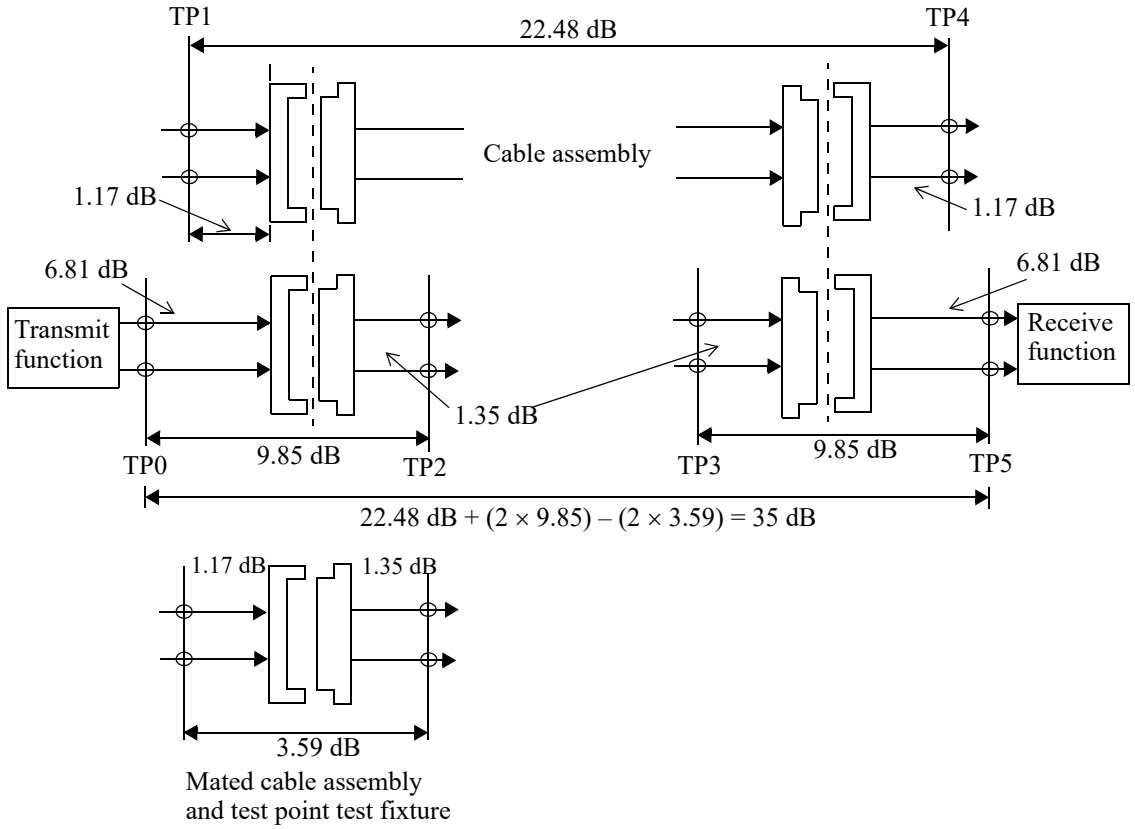
$$IL_{\text{MatedTF}}(f) = 0.1148\sqrt{f} + 0.287f \quad \text{(dB)} \tag{92A–4}$$

for 0.01 GHz ≤ f ≤ 25 GHz.

where

f	is the frequency in GHz
$IL_{\text{MatedTF}}(f)$	is the nominal insertion loss of the mated test fixture.

The channel insertion loss between TP0 and TP5 representative of a 0.5 m cable assembly and a maximum host channel is determined using Equation (92A–5).



$$IL_{\text{Ch0.5m}}(f) = IL_{\text{Camin0.5m}}(f) + 2IL_{\text{Host}}(f) - 2IL_{\text{MatedTF}}(f) \quad \text{(dB)} \tag{92A–5}$$

for 0.05 GHz ≤ f ≤ 19 GHz.

where

f	is the frequency in GHz
$IL_{\text{Ch0.5m}}(f)$	is the channel insertion loss between TP0 and TP5 representative of a 0.5 m cable assembly and a maximum host channel
$IL_{\text{Camin0.5m}}(f)$	is the minimum 0.5 m cable assembly insertion loss given in Equation (92–26) and illustrated in Figure 92–12.
$IL_{\text{Host}}(f)$	is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (92–8)
$IL_{\text{MatedTF}}(f)$	is the nominal insertion loss of the mated test fixture using Equation (92A–4)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The connector insertion loss is 1.07 dB for the mated test fixture. The host connector is allocated 0.62 dB of additional margin.

Figure 92A–2—35 dB channel insertion loss budget at 12.8906 GHz

92A.6 Channel return loss

The return loss of each lane of the 100GBASE-CR4 channel is recommended to meet the values determined using Equation (92–27).

92A.7 Channel Operating Margin (COM)

The Channel Operating Margin (COM) for the channel between TP0 and TP5, computed using the procedure in 93A.1 and the parameters in Table 93–8, is recommended to be greater than or equal to 3 dB.

NOTE—For cable lengths greater than 4 m, a frequency step (Δf) no larger than 5 MHz is recommended.

Annex 93A

(normative)

Specification methods for electrical channels

93A.1 Channel Operating Margin

The Channel Operating Margin (COM) is a figure of merit for a channel derived from a measurement of its scattering parameters. COM is related to the ratio of a calculated signal amplitude to a calculated noise amplitude as defined by Equation (93A–1).

$$COM = 20\log_{10}(A_s/A_{ni}) \quad (93A–1)$$

COM shall be calculated using the method described in this annex. The signal amplitude A_s is defined in 93A.1.6 and the noise amplitude A_{ni} is defined in 93A.1.7.

Figure 93A–1 illustrates the reference model that is the basis for the calculation for COM. The parameters used to calculate COM are listed in Table 93A–1. The values assigned to these parameters are defined by the Physical Layer specification that invokes the method (see Table 93A–2).

93A.1.1 Measurement of the channel

The channel consists of a victim signal path plus some number of far-end and near-end crosstalk paths. The total number of paths for a given channel is denoted as K and, by convention, the path index k=0 corresponds to the victim path. The number of crosstalk paths is a function of the structure of the system. All significant contributors to the channel crosstalk should be included in the calculation of COM.

Each signal path is represented by a set of frequency-dependent scattering parameters. For the purpose of the calculation of COM, references to scattering parameters correspond to the differential-mode scattering parameters. The scattering parameters measured at frequency f are presented as the 2 x 2 matrix $S(f)$ as defined by Equation (93A–2).

$$S(f) = \begin{bmatrix} s_{11}(f) & s_{12}(f) \\ s_{21}(f) & s_{22}(f) \end{bmatrix} \quad \text{(93A–2)}$$

The relationship between $S(f)$ and other commonly cited characteristics is as follows. The insertion loss is the magnitude in dB of either $1/s_{12}(f)$ or $1/s_{21}(f)$. The input and output return loss are the magnitude in dB of $1/s_{11}(f)$ and $1/s_{22}(f)$, respectively.

The scattering parameters for the victim signal path are measured from TP0 to TP5. The scattering parameters for each crosstalk path are measured from the package-to-board interface of the aggressor transmitter to TP5. The frequency-dependent scattering matrix for signal path k is denoted as $S^{(k)}(f)$. The reference impedance for scattering parameter measurements is 100 Ω.

It is recommended that the scattering parameters be measured with uniform frequency step no larger than Δf from a start frequency no larger than $f_{\min}$ to a stop frequency of at least the signaling rate f_b.

93A.1.2 Transmitter and receiver device package models

Each signal path in the channel is augmented to reflect the likely influence of transmitter and receiver device packages. The device package models are two-port networks defined by their scattering parameters. The scattering parameters are calculated using the method defined in 93A.1.2.1 through 93A.1.2.4.

Each signal path in the channel is represented by the scattering matrix $S^{(k)}$. The augmented signal path is denoted as $S_p^{(k)}$ and is defined by Equation (93A–3).

$$S_p^{(k)} = \text{cascade}(\text{cascade}(S^{(tp)}, S^{(k)}), S^{(rp)}) \quad \text{(93A–3)}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The function cascade() is defined in 93A.1.2.1. $S^{(tp)}$ and $S^{(rp)}$ are defined in 93A.1.2.4. If k corresponds to a near-end crosstalk path, $S^{(tp)}$ is calculated with the smallest value of z_p specified by the clause that invokes this method.

93A.1.2.1 Cascade connection of two-port networks

The connection of a pair of two-port networks x and y such that port 2 of network x is connected to port 1 of network y may be represented by an equivalent two-port network z. Port 1 of network z corresponds to port 1 of network x and port 2 network z corresponds to port 2 of network y. The scattering parameters of network z are given in terms of the scattering parameters of networks x and y by Equation (93A–4) through Equation (93A–7).

$$s_{11}^{(z)} = s_{11}^{(x)} + \frac{s_{21}^{(x)} s_{11}^{(y)} s_{12}^{(x)}}{1 - s_{22}^{(x)} s_{11}^{(y)}} \tag{93A–4}$$

$$s_{12}^{(z)} = \frac{s_{12}^{(x)} s_{12}^{(y)}}{1 - s_{22}^{(x)} s_{11}^{(y)}} \tag{93A–5}$$

$$s_{21}^{(z)} = \frac{s_{21}^{(x)} s_{21}^{(y)}}{1 - s_{22}^{(x)} s_{11}^{(y)}} \tag{93A–6}$$

$$s_{22}^{(z)} = s_{22}^{(y)} + \frac{s_{12}^{(y)} s_{22}^{(x)} s_{21}^{(y)}}{1 - s_{22}^{(x)} s_{11}^{(y)}} \tag{93A–7}$$

For the purpose of this annex, this set of operations is referred to using the shorthand notation $S^{(z)} = \text{cascade}(S^{(x)}, S^{(y)})$.

93A.1.2.2 Two-port network for a shunt capacitance

The scattering parameters for a shunt capacitance with value C are defined by Equation (93A–8) where $j = \sqrt{-1}$ and $\omega = 2\pi f$.

$$S(C) = \frac{1}{2 + j\omega C R_0} \begin{bmatrix} -j\omega C R_0 & 2 \\ 2 & -j\omega C R_0 \end{bmatrix} \tag{93A–8}$$

The scattering parameters for the device capacitance C_d are denoted as $S^{(d)} = S(C_d)$ and the scattering parameters for the board capacitance C_p are denoted as $S^{(p)} = S(C_p)$.

93A.1.2.3 Two-port network for the package transmission line

The scattering parameters for the package transmission line model are a function of the complex propagation coefficient defined by Equation (93A–9), Equation (93A–10), and Equation (93A–11) and the reflection coefficient defined by Equation (93A–12). The values of the parameters that appear in these equations are defined in Table 93A–3. Where a value for Z_c is not provided by the clause that invokes this method, it takes the value 78.2 Ω. The units of f are GHz.

$$\gamma(f) = \left\{ \begin{array}{cc} \gamma_0 & f = 0 \\ \gamma_0 + \gamma_1\sqrt{f} + \gamma_2(f)f & f > 0 \end{array} \right\} \quad \text{(93A–9)}$$

$$\gamma_1 = a_1(1 + j) \quad \text{(93A–10)}$$

$$\gamma_2(f) = a_2(1 - j(2/\pi)\log_e(f/1\ \text{GHz})) + j2\pi\tau \quad \text{(93A–11)}$$

$$\rho = \frac{Z_c - 2R_0}{Z_c + 2R_0} \quad \text{(93A–12)}$$

Table 93A–3—Transmission line model parameters and values

Parameter	Value	Units
γ_0	0	1/mm
a_1	1.734×10^{-3}	$ns^{1/2}$/mm
a_2	1.455×10^{-4}	ns/mm
τ	6.141×10^{-3}	ns/mm

The scattering parameters for a package transmission line of length z_p are defined by Equation (93A–13) and Equation (93A–14). The units of z_p are mm.

$$s_{11}^{(l)}(f) = s_{22}^{(l)}(f) = \frac{\rho(1 - \exp(-\gamma(f)2z_p))}{1 - \rho^2\exp(-\gamma(f)2z_p)} \quad \text{(93A–13)}$$

$$s_{21}^{(l)}(f) = s_{12}^{(l)}(f) = \frac{(1 - \rho^2)\exp(-\gamma(f)z_p)}{1 - \rho^2\exp(-\gamma(f)2z_p)} \quad \text{(93A–14)}$$

The transmission line scattering parameter matrix is then denoted as $S^{(l)}$.

93A.1.2.4 Assembly of transmitter and receiver device package models

The scattering parameters for the transmitter device package model $S^{(tp)}$ are the result of the cascade connection of the device capacitance, package transmission line, and board capacitance as defined by Equation (93A–15).

$$S^{(tp)} = \text{cascade}(\text{cascade}(S^{(d)}, S^{(l)}), S^{(p)}) \quad \text{(93A–15)}$$

Similarly, the scattering parameters for the receiver device package model $S^{(rp)}$ are the result of the cascade connection of the board capacitance, package transmission line, and device capacitance as defined by Equation (93A–16).

$$S^{(rp)} = \text{cascade}(\text{cascade}(S^{(p)}, S^{(l)}), S^{(d)}) \quad \text{(93A–16)}$$

93A.1.3 Path terminations

The input to each signal path is terminated by an impedance defined by the reflection coefficient Γ_1. The output of each signal path is terminated by an impedance defined by the reflection coefficient Γ_2.

The reflection coefficients Γ_1 and Γ_2 are defined by Equation (93A–17).

$$\Gamma_1 = \Gamma_2 = \frac{R_d - R_0}{R_d + R_0} \tag{93A–17}$$

The voltage transfer function of the terminated signal path is defined by Equation (93A–18) where $\Delta S(f) = s_{11}(f)s_{22}(f) - s_{12}(f)s_{21}(f)$.

$$H_{21}(f) = \frac{s_{21}(f)(1-\Gamma_1)(1+\Gamma_2)}{1 - s_{11}(f)\Gamma_1 - s_{22}(f)\Gamma_2 + \Gamma_1\Gamma_2\Delta S(f)} \tag{93A–18}$$

The voltage transfer function for the signal path represented by $S_p^{(k)}(f)$ is denoted $H_{21}^{(k)}(f)$.

93A.1.4 Filters

The voltage transfer function for each signal path $H_{21}^{(k)}(f)$ (see 93A.1.3) is multiplied by a set of filter transfer functions to yield $H^{(k)}(f)$ as shown in Equation (93A–19).

$$H^{(k)}(f) = H_{ffe}(f)H_t(f)H_{21}^{(k)}(f)H_r(f)H_{ctf}(f) \tag{93A–19}$$

The receiver noise filter $H_r(f)$ is defined in 93A.1.4.1, the transmitter transition time filter $H_t(f)$ is defined by Equation (93A–46) where T_r is 0 unless defined otherwise for the Physical Layer specification that invokes this method, the transmitter equalizer $H_{ffe}(f)$ is defined in 93A.1.4.2, and the receiver equalizer $H_{ctf}(f)$ is defined in 93A.1.4.3.

The filtered voltage transfer function $H^{(k)}(f)$ is used to compute the pulse response (see 93A.1.5).

93A.1.4.1 Receiver noise filter

$H_r(f)$ is a noise filter defined by Equation (93A–20).

$$H_r(f) = \frac{1}{1 - 3.414214(f/f_r)^2 + (f/f_r)^4 + j2.613126(f/f_r - (f/f_r)^3)} \tag{93A–20}$$

93A.1.4.2 Transmitter equalizer

$H_{ffe}(f)$ is defined by Equation (93A–21) and is intended to represent the transmitter equalizer. If k corresponds to a near-end crosstalk path, then $c(-2)$, $c(-1)$, and $c(1)$ are all zero regardless of the values used for the other paths. The value of the "cursor" coefficient $c(0)$ is set to $1 - |c(-2)| - |c(-1)| - |c(1)|$ for any value of $c(-2)$, $c(-1)$, and $c(1)$. If the value of $c(0)$ is less than the specified minimum value, the corresponding combination of $c(-2)$, $c(-1)$, and $c(1)$ is considered invalid and is not used to calculate COM.

$$H_{ffe}(f) = \sum_{i=-2}^{1} c(i)\exp\left(-j2\pi(i+2)\frac{f}{f_b}\right) \tag{93A–21}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

93A.1.4.3 Receiver equalizer

$H_{ctf}(f)$ is defined by Equation (93A–22). Where values for g_{DC2} and f_{LF} are not provided by the clause that invokes this method, g_{DC2} takes the value 0 and f_{LF} takes the value 1.

$$H_{ctf}(f) = \frac{\left(10^{\frac{g_{DC}}{20}} + j\frac{f}{f_z}\right)\left(10^{\frac{g_{DC2}}{20}} + j\frac{f}{f_{LF}}\right)}{\left(1 + j\frac{f}{f_{p1}}\right)\left(1 + j\frac{f}{f_{p2}}\right)\left(1 + j\frac{f}{f_{LF}}\right)} \quad (93A–22)$$

93A.1.5 Pulse response

The pulse response of a signal path is defined to be the output of the path following the application of a rectangular pulse one unit interval in duration at its input. First define the function $X(f)$ per Equation (93A–23) where $\mathrm{sinc}(x) = \sin(\pi x)/(\pi x)$ and $T_b = 1/f_b$ is the unit interval.

$$X(f) = A_t T_b \mathrm{sinc}(fT_b) \quad (93A–23)$$

$X(f)$ is a function of A_t, which in turn is based on the path index k. If k=0, i.e., the victim path, then $A_t = A_v$. If k corresponds to a far-end crosstalk path, then $A_t = A_{fe}$. If k corresponds to a near-end crosstalk path, then $A_t = A_{ne}$.

The pulse response $h^{(k)}(t)$ is derived from the voltage transfer function $H^{(k)}(f)$ (see 93A.1.4) using Equation (93A–24).

$$h^{(k)}(t) = \int_{-\infty}^{\infty} X(f)H^{(k)}(f)\exp(j2\pi ft)df \quad (93A–24)$$

NOTE 1—COM is expected to be computed from measurements at discrete frequencies that cover a limited span (see 93A.1.1). The inverse Fourier transform depicted in Equation (93A–24) is likely to be implemented as a discrete Fourier transform and the filtered voltage transfer function may need to be extrapolated (both to DC and to one half of the sampling frequency) for this computation. The extrapolation method and sampling frequency should be chosen carefully to limit the error in the COM computation.

NOTE 2—The time span of the pulse response in unit intervals, N, is limited in practice by frequency step Δf ($N = f_b/\Delta f$) but in general should be set to include all significant components of the pulse response.

93A.1.6 Determination of variable equalizer parameters

COM is a function of the variables $c(-2)$, $c(-1)$, $c(1)$, g_{DC}, and g_{DC2}. The following procedure is used to determine the values of these variables that are used to calculate COM.

a) Compute the pulse response $h^{(k)}(t)$ of each signal path k for a given $c(-2)$, $c(-1)$, $c(1)$, g_{DC}, and g_{DC2} using the procedure defined in 93A.1.5.
b) Define t_s to be the time that satisfies Equation (93A–25). If there are multiple values of t_s that satisfy the equation, then the first value prior to the peak of $h^{(0)}(t)$ is selected. The coefficients of the decision feedback equalizer $b(n)$ are computed as shown in Equation (93A–26). If N_b is 0, then the $b(n)$ is considered to be zero for all n.
c) Define A_s to be $R_{LM}h^{(0)}(t_s)/(L–1)$.
d) Compute σ_{TX}^2 per Equation (93A–30) and Equation (93A–29). This represents the noise output from the transmitter.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

e) Compute $h_{ISI}(n)$ per Equation (93A–27). This represents the residual intersymbol interference (ISI) after decision feedback equalization. The corresponding ISI amplitude variance σ_{ISI}^2 is computed per Equation (93A–31) and Equation (93A–29).

f) Compute the slope of the pulse response of the victim path $h_J(n)$ as shown in Equation (93A–28). The variance of the amplitude error due to timing jitter σ_J^2 is computed per Equation (93A–32) and Equation (93A–29).

g) The variance of the amplitude for path k is given by Equation (93A–33) where the phase index m can assume any integer value from 0 to M–1. Denote the value of m that maximizes the variance for path k as i. The variance of the amplitude for the combination of all crosstalk paths σ_{XT}^2 is then computed using Equation (93A–34), which is the sum of the maximum variances for the individual paths k=1 to K–1.

h) Compute the variance of the noise at the output of the receive equalizer σ_N^2 based on the one-sided spectral density η_0 referred to the receiver noise filter input per Equation (93A–35).

i) Compute the figure of merit (FOM) per Equation (93A–36).

$$h^{(0)}(t_s - T_b) = h^{(0)}(t_s + T_b) - h^{(0)}(t_s)b(1) \tag{93A–25}$$

$$b(n) = \begin{Bmatrix} -b_{\max}(n) & h^{(0)}(t_s + nT_b)/h^{(0)}(t_s) < -b_{\max}(n) \\ b_{\max}(n) & h^{(0)}(t_s + nT_b)/h^{(0)}(t_s) > b_{\max}(n) \\ h^{(0)}(t_s + nT_b)/h^{(0)}(t_s) & \text{otherwise} \end{Bmatrix} \tag{93A–26}$$

$$h_{ISI}(n) = \begin{Bmatrix} 0 & n = 0 \\ h^{(0)}(t_s + nT_b) - h^{(0)}(t_s)b(n) & 1 \le n \le N_b \\ h^{(0)}(t_s + nT_b) & \text{otherwise} \end{Bmatrix} \tag{93A–27}$$

$$h_J(n) = \frac{h^{(0)}(t_s + (n + 1/M)T_b) - h^{(0)}(t_s + (n - 1/M)T_b)}{2/M} \tag{93A–28}$$

$$\sigma_X^2 = \frac{L^2 - 1}{3(L - 1)^2} \tag{93A–29}$$

$$\sigma_{TX}^2 = [h^{(0)}(t_s)]^2 10^{-SNR_{TX}/10} \tag{93A–30}$$

$$\sigma_{ISI}^2 = \sigma_X^2 \sum_n h_{ISI}^2(n) \tag{93A–31}$$

$$\sigma_J^2 = (A_{DD}^2 + \sigma_{RJ}^2)\sigma_X^2 \sum_n h_J^2(n) \tag{93A–32}$$

$$[\sigma_m^{(k)}]^2 = \sigma_X^2 \sum_n [h^{(k)}((m/M + n)T_b)]^2 \tag{93A–33}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\sigma_{XT}^2 = \sum_{k=1}^{K-1} [\sigma_i^{(k)}]^2 \quad (93A–34)$$

$$\sigma_N^2 = \eta_0 \int_0^\infty \left| H_r(f) H_{ctf}(f) \right|^2 df \quad (93A–35)$$

$$FOM = 10\log_{10}\left(\frac{A_s^2}{\sigma_{TX}^2 + \sigma_{ISI}^2 + \sigma_J^2 + \sigma_{XT}^2 + \sigma_N^2} \right) \quad (93A–36)$$

The FOM is calculated for each permitted combination of $c(-2)$, $c(-1)$, $c(1)$, g_{DC}, and g_{DC2} values per Table 93A–1, where any parameters not provided by the clause that invokes this method are set to 0. The combination of values that maximizes the FOM, including the corresponding value of t_s, is used for the calculation of the interference and noise amplitude in 93A.1.7 and the calculation of COM in 93A.1.

93A.1.7 Interference and noise amplitude

Given the values of $c(-1)$, $c(1)$, g_{DC}, g_{DC2}, and t_s derived in 93A.1.6, compute the combined interference and noise distribution $p(y)$ per 93A.1.7.3. The corresponding cumulative distribution function is $P(y)$ as defined by Equation (93A–37).

$$P(y) = \int_{-\infty}^{y} p(y) dy \quad (93A–37)$$

The noise amplitude, A_{ni}, is the magnitude of the value of y_0 that satisfies the relationship $P(y_0) = DER_0$ where DER_0 is the target detector error ratio. The detector error ratio is the probability that the detector fails to identify the signal level that was transmitted.

In 93A.1.7.1 through 93A.1.7.3, "*" denotes convolution, which is defined by Equation (93A–38).

$$f(t) * g(t) = \int_{-\infty}^{\infty} f(\tau) g(t - \tau) d\tau \quad (93A–38)$$

93A.1.7.1 Interference amplitude distribution

The interference amplitude distribution is computed from the sampled pulse response $h(n)$ with the assumption that the transmitted symbols are independent, identically distributed random variables and that the symbols are uniformly distributed across the set of L possible values. For the purpose of this subclause, $h(n)$ is a general notation that corresponds to $A_{DD}h_f(n)$ (see 93A.1.7.2), $h_{ISI}(n)$, or $h^{(k)}((i / M + n)T_b)$ (see 93A.1.7.3).

Equation (93A–39) defines the nth component of the interference amplitude distribution function where $\delta(y)$ is the Dirac delta function.

$$p_n(y) = \frac{1}{L} \sum_{l=0}^{L-1} \delta\left(y - \left(\frac{2l}{L-1} - 1 \right) h(n) \right) \quad (93A–39)$$

The set of N such components are combined via convolution to obtain the complete interference amplitude distribution. Initialize $p(y)$ to $\delta(y)$ and then evaluate Equation (93A–40) sequentially for n=0 to N–1.

$$p(y) = p(y) * p_n(y) \quad (93A–40)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—COM is expected to be numerically computed using a quantized amplitude axis y. The amplitude step Δy introduces quantization error in the calculated distribution function that is compounded by subsequent convolutions with other quantized distribution functions. It is recommended that Δy be no larger than 0.1% of A_s or 0.01 mV, whichever is smaller.

NOTE 2—It is recommended that components of the pulse response whose amplitude is less than 0.1% of A_s be ignored as they likely correspond to measurement noise or numerical artifacts.

93A.1.7.2 Noise amplitude distribution

The calculation of COM includes two noise terms that are described in terms of their distribution function. The first term has a Gaussian amplitude distribution function with zero mean and variance σ_G^2. The variance is defined by Equation (93A–41) where $H_r(f)$ is defined in 93A.1.4.1, $H_{ctf}(f)$ is defined in 93A.1.4.3, and σ_X^2 and $h_J(n)$ are defined in 93A.1.6.

$$\sigma_G^2 = \sigma_{TX}^2 + \sigma_{RJ}^2\sigma_X^2\sum_n h_J^2(n) + \eta_0\int_0^\infty \left|H_r(f)H_{ctf}(f)\right|^2 df \tag{93A–41}$$

The amplitude distribution of the Gaussian noise term is defined by Equation (93A–42).

$$p_G(y) = \frac{\exp(-y^2/(2\sigma_G^2))}{\sqrt{2\pi\sigma_G^2}} \tag{93A–42}$$

The second term is denoted as p_{DD} and is related to the amplitude noise resulting from dual-Dirac jitter. It is computed using the procedure defined in 93A.1.7.1 with $h(n) = A_{DD}h_J(n)$.

The components are combined using convolution to yield the overall noise amplitude distribution function as defined in Equation (93A–43).

$$p_n(y) = p_G(y) * p_{DD}(y) \tag{93A–43}$$

93A.1.7.3 Combination of interference and noise distributions

Compute the intersymbol interference amplitude distribution using the procedure defined in 93A.1.7.1 with $h(n) = h_{ISI}(n)$ as defined by Equation (93A–27) and denote the result as $p(y)$.

The contributions of the K–1 crosstalk paths to the total interference are included as follows. Determine the phase index $m = i$ that maximizes the variance of the amplitude for path k as defined by Equation (93A–33). Compute the interference amplitude distribution using the procedure defined in 93A.1.7.1 with $h(n) = h^{(k)}((i / M + n)T_b)$ and denote the result as $p^{(k)}(y)$.

Compute $p^{(k)}(y)$ and evaluate Equation (93A–44) sequentially for integer values k=1 to K–1.

$$p(y) = p(y) * p^{(k)}(y) \tag{93A–44}$$

The noise distribution $p_n(y)$ defined in 93A.1.7.2 is then included to yield the combined interference and noise amplitude distribution as shown in Equation (93A–45).

$$p(y) = p(y) * p_n(y) \tag{93A–45}$$

93A.2 Test channel calibration using COM

A generalized block diagram of the interference tolerance test channel is shown in Figure 93A–2.

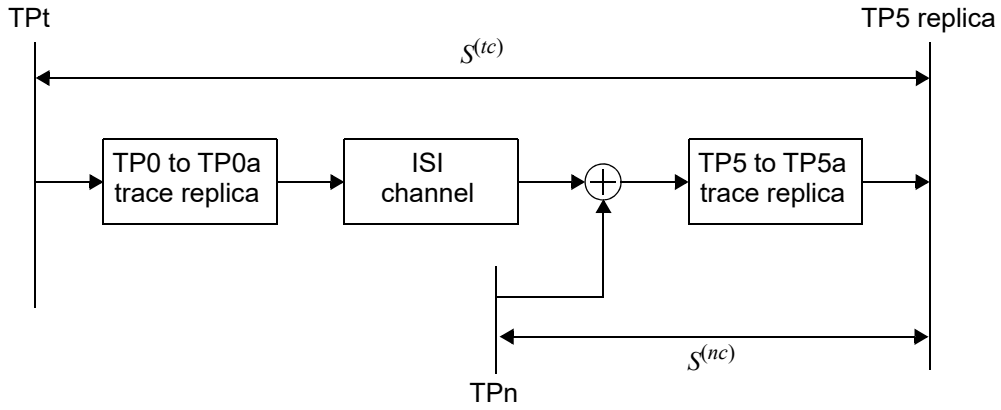

Figure 93A–2—Generalized interference tolerance test channel

The signal path from the test transmitter connected at TPt to the receiver under test connected at TP5 consists of replicas of the test fixture traces, a controlled ISI channel, and the means by which additive broadband noise is coupled into the path. This path is represented by the scattering parameters $S^{(tc)}$ measured from TPt to the TP5 replica. The signal path from the broadband noise source connected at TPn to the receiver consists of the means of broadband noise coupling and a replica of TP5 to TP5a test fixture trace. This path is represented by scattering parameters $S^{(nc)}$ measured from TPn to the TP5 replica.

COM is used to calibrate the interference tolerance test channel. The values assigned to the parameters listed in Table 93A–1 are defined by the Physical Layer specification that invokes this method.

The calculations defined in 93A.1 are evaluated for $S^{(tc)}$ with the following exceptions.

If the test transmitter presents a high-quality termination, e.g., it is a piece of test equipment, the transmitter device package model $S^{(tp)}$ is omitted from the calculation of $S_p^{(k)}$ and the filtered voltage transfer function $H^{(k)}(f)$ in 93A.1.4 includes the filter $H_t(f)$ defined by Equation (93A–46) where T_r is the 20% to 80% transition time in ns (see 86A.5.3.3) of the signal as measured at TP0a and f is frequency in GHz.

$$H_t(f) = \exp(-2(\pi f T_r / 1.6832)^2) \tag{93A–46}$$

The approximate voltage transfer function for the path from TPn to the output of the receiver equalizer is defined by Equation (93A–47).

$$H^{(ne)}(f) = s_{21}^{(nc)}(f)\, s_{21}^{(rp)}(f) H_r(f)\, H_{ctf}(f) \tag{93A–47}$$

The broadband noise source applies noise at TPn that has a Gaussian amplitude distribution with zero mean and standard deviation σ_{bn}. The power spectral density of the noise is flat from $-f_b / 2$ to $f_b / 2$ and is zero elsewhere. The standard deviation of the noise at the receiver equalizer output σ_{ne} is defined by Equation (93A–48).

$$\sigma_{ne}^2 = \frac{2\sigma_{bn}^2}{f_b} \int_0^{f_b/2} \left| H^{(ne)}(f) \right|^2 df \tag{93A–48}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Equation (93A–41) defines the standard deviation of the Gaussian noise amplitude distribution function. When COM is used to calibrate the interference tolerance test channel, this definition is replaced by Equation (93A–49). The value of σ_{bn} is adjusted until the target COM value is achieved.

$$\sigma_G^2 = \sigma_{TX}^2 + \sigma_{RJ}^2\sigma_X^2\sum_n h_J^2(n) + \eta_0\int_0^\infty \left|H_r(f)H_{ctf}(f)\right|^2 df + \sigma_{ne}^2 \tag{93A–49}$$

An additional figure of merit for the test channel is the root-sum-square of the magnitude terms n_1 to n_2 of the equalized pulse response where n_2 is less than or equal to N_b. This measure of the relative usage of the decision feedback equalizer is defined by Equation (93A–50).

$$u_b(n_1, n_2) = \frac{1}{A_s}\sqrt{\sum_{n=n_1}^{n_2}\left(h^{(0)}(t_s + nT_b)\right)^2} \tag{93A–50}$$

The shorthand notation RSS_DFE4 is used to represent $u_b(4, N_b)$.

93A.3 Fitted insertion loss

The fitted insertion loss as a function of frequency is given by Equation (93A–51).

$$IL_{fitted}(f) = a_0 + a_1\sqrt{f} + a_2 f + a_4 f^2 \tag{93A–51}$$

Denote the insertion loss, in dB, measured at frequency f_n as $IL(f_n)$. Given the insertion loss measured at N uniformly-spaced frequencies from start frequency $f_{\min}$ to stop frequency $f_{\max}$ with step no larger than Δf, the coefficients for the fitted insertion loss shall be calculated as follows.

Define the weighted frequency matrix F using Equation (93A–52).

$$F = \begin{bmatrix} 10^{-IL(f_1)/20} & \sqrt{f_1}10^{-IL(f_1)/20} & f_1 10^{-IL(f_1)/20} & f_1^2 10^{-IL(f_1)/20} \\ 10^{-IL(f_2)/20} & \sqrt{f_2}10^{-IL(f_2)/20} & f_2 10^{-IL(f_2)/20} & f_2^2 10^{-IL(f_2)/20} \\ \cdots & \cdots & \cdots & \cdots \\ 10^{-IL(f_N)/20} & \sqrt{f_N}10^{-IL(f_N)/20} & f_N 10^{-IL(f_N)/20} & f_N^2 10^{-IL(f_N)/20} \end{bmatrix} \tag{93A–52}$$

Define the weighted insertion loss vector L using Equation (93A–53).

$$L = \begin{bmatrix} IL(f_1)10^{-IL(f_1)/20} \\ IL(f_2)10^{-IL(f_2)/20} \\ \cdots \\ IL(f_N)10^{-IL(f_N)/20} \end{bmatrix} \tag{93A–53}$$

The fitted insertion loss coefficients are then given by Equation (93A–54).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_4 \end{bmatrix} = (F^T F)^{-1} F^T L \quad \text{(93A–54)}$$

The values assigned to f_{min}, f_{max}, and Δf are defined by the Physical Layer specification that invokes this method.

93A.4 Insertion loss deviation

The insertion loss deviation $ILD(f)$ is the difference between the measured insertion loss $IL(f)$ and the fitted insertion loss $IL_{fitted}(f)$ (see 93A.3) as shown in Equation (93A–55).

$$ILD(f) = IL(f) - IL_{fitted}(f) \quad \text{(93A–55)}$$

A figure of merit for a channel that is based on $ILD(f)$ is given by Equation (93A–56). In Equation (93A–56), f_n are the frequencies considered in the computation of the fitted insertion loss and $W(f_n)$ is the weight at each frequency as defined by Equation (93A–57).

$$FOM_{ILD} = \left[\frac{1}{N}\sum_n W(f_n) ILD^2(f_n)\right]^{1/2} \quad \text{(93A–56)}$$

$$W(f_n) = \text{sinc}^2(f_n/f_b)\left[\frac{1}{1+(f_n/f_t)^4}\right]\left[\frac{1}{1+(f_n/f_r)^8}\right] \quad \text{(93A–57)}$$

The variable f_b is the signaling rate. The 3 dB transmit filter bandwidth f_t is inversely proportional to the 20% to 80% rise and fall time T_t. The constant of proportionality is 0.2365 (e.g., $T_t f_t = 0.2365$; with f_t in Hertz and T_t in seconds). The variable f_r is the 3 dB reference receiver bandwidth.

The values assigned to f_b, T_t, and f_r are defined by the Physical Layer specification that invokes this method.

93A.5 Effective Return Loss

Effective Return Loss (ERL) is a figure of merit for the electromagnetic wave reflection from a device or a channel input or output. ERL shall be calculated using the method described in this annex.

The parameters used to calculate ERL are listed in Table 93A–4. The values assigned to these parameters are defined by the Physical Layer specification that invokes the ERL method.

93A.5.1 Pulse time-domain reflection signal

ERL is derived from a unity pulse time-domain reflection signal, PTDR(t). PTDR(t) is defined at the test points defined in the Physical Layer specification that invokes the ERL method. PTDR(t) may be acquired directly from an appropriately filtered time domain reflectometer (TDR), or derived mathematically from measured differential scattering parameters $S(f)$ and transmitter and receiver filters, according to the procedure in this subclause. See 93A.1.1 for scattering parameters measurement recommendations including frequency step, start frequency, and stop frequency.

Table 93A–4—ERL parameters

Parameter	Reference	Symbol	Units
Signaling rate	93A.1.1	f_b	GBd
Transition time associated with a pulse	93A.2	T_r	ns
Receiver 3 dB bandwidth	93A.1.4.1	f_r	GHz
Number of signal levels	93A.1.6	L	—
Length of the reflection signal		N	UI
Number of samples per unit interval	93A.1.6	M	—
Equalizer length associated with reflection signal	93A.5.2	N_{bx}	UI
Incremental available signal loss factor	93A.5.2	β_x	GHz
Permitted reflection from a transmission line external to the device under test	93A.5.2	ρ_x	—
Target detector error ratio	93A.1.7	DER_0	—

The filtered return loss, $H_{ii}(f)$, is defined by Equation (93A–58).

$$H_{ii}(f) = H_t(f)s_{ii}(f)H_r(f) \quad \text{(93A–58)}$$

where

f is the frequency in GHz
$H_r(f)$ is defined by Equation (93A–20)
$H_t(f)$ is defined by Equation (93A–46)
i is the port index of the scattering parameters, 1 or 2

The pulse TDR signal, PTDR(t), is defined by Equation (93A–59).

$$PTDR(t) = \int_{-\infty}^{\infty} X(f)H_{ii}(f)\exp(j2\pi ft)df \quad \text{(93A–59)}$$

where

t is the time in ns starting from the peak of the injected pulse
$X(f)$ is defined by Equation (93A–23) with A_t set to 1

93A.5.2 Effective reflection waveform

The effective reflection waveform, $R_{eff}(t)$, is computed by time gating and weighting the PTDR waveform, PTDR(t), according to Equation (93A–60). $R_{eff}(t)$ is a pure number.

$$R_{eff}(t) = PTDR(t) \times G_{rr}(t) \times G_{loss}(t) \quad \text{(93A–60)}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where $G_{rr}(t)$ and $G_{loss}(t)$ are time gating weighting functions defined in Equation (93A–61) and Equation (93A–62) with t in nanoseconds.

$$G_{rr}(t) = \begin{cases} 0 & t < T_{fx} \\ \rho_x(1+\rho_x)\exp\left(-\dfrac{[(t-T_{fx})f_b-(N_{bx}+1)]^2}{(N_{bx}+1)^2}\right) & T_{fx} \le t < T_{fx}+\dfrac{N_{bx}+1}{f_b} \\ 1 & t \ge T_{fx}+\dfrac{N_{bx}+1}{f_b} \end{cases} \quad \text{(93A–61)}$$

where

t	is the time in ns starting from the peak of the injected pulse
T_{fx}	is twice the propagation delay in ns associated with the test fixture, obtained by measurement or inspection
ρ_x, f_b, N_{bx}	are supplied by the clause that invokes this method

$$G_{loss}(t) = \begin{cases} 0 & t < T_{fx} \\ 10^{\frac{\frac{\beta_x}{f_b}[(t-T_{fx})f_b-(N_{bx}+1)]}{20}} & T_{fx} \le t < T_{fx}+\dfrac{N_{bx}+1}{f_b} \\ 1 & t \ge T_{fx}+\dfrac{N_{bx}+1}{f_b} \end{cases} \quad \text{(93A–62)}$$

where

t	is the time in ns starting from the peak of the injected pulse
T_{fx}	is twice the propagation delay in ns associated with the test fixture, obtained by measurement or inspection
β_x, f_b, N_{bx}	are supplied by the clause that invokes this method

93A.5.3 Sampled effective reflection

The sampled effective reflection for each phase m is computed per Equation (93A–63).

$$h^{(m)}(n) = R_{eff}\left(T_{fx}+\frac{n+m/M}{f_b}\right) \quad \text{(93A–63)}$$

where

n	is an integer ranging from 0 to N–1
m	is an integer ranging from 0 to M–1
N and M	are supplied by the clause that invokes this method

The standard deviation of the distribution of the reflection signal for each phase m, $\sigma^{(m)}{}_h$, is defined by Equation (93A–64).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\sigma^{(m)}{}_h = \sqrt{\sum_{n=1}^{N} h^{(m)}(n)^2} \quad \text{(93A–64)}$$

where

m is an integer ranging from 0 to *M*–1
N and *M* are supplied by the clause that invokes this method

93A.5.4 x-quantile of the reflection distribution

The reflection signal distribution $p(y)$ is computed from the sampled effective reflection using the procedure defined in 93A.1.7.1, with $h(n) = h^{(m)}(n)$, where m maximizes $\sigma^{(m)}{}_h$. The value of L in Equation (93A–39) is supplied by the clause that invokes this method. The corresponding cumulative distribution function $P(y)$ is calculated from $p(y)$ using Equation (93A–37).

The x-quantile of the distribution, $P^{-1}(x)$, is the value of y that satisfies the relationship $P(y)=x$.

93A.5.5 ERL

ERL is defined as $-20 \times \log_{10} P^{-1}(DER_0)$ where DER_0 is the target detector error ratio.

Annex 93B

(informative)

Electrical backplane reference model

This annex describes additional informative test points that may used to partition the electrical backplane channel. See Figure 93B–1 and Table 93B–1

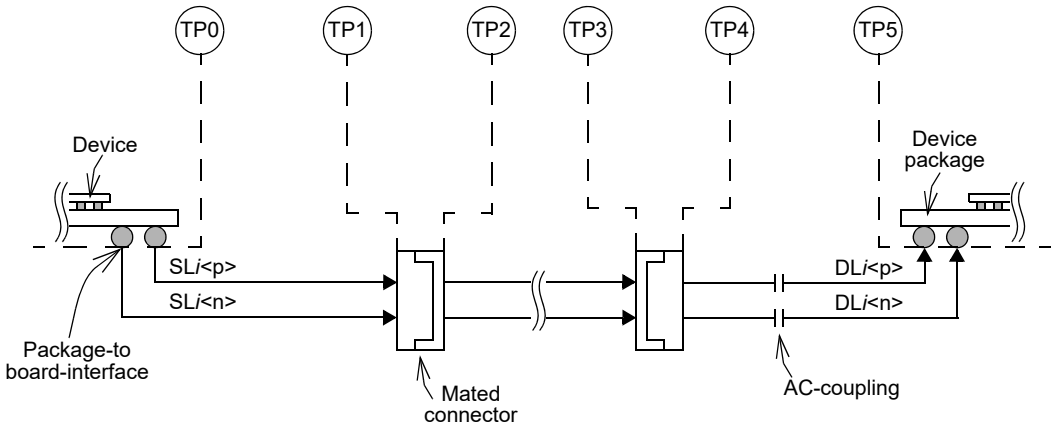

Figure 93B–1—Reference model (one direction from one lane is illustrated)

Table 93B–1—Description of channel components

Test points	Description
TP0 to TP1	The printed circuit board between the transmitter and the separable connector closest to the transmitter. TP1 is defined to be the interface between the board and connector plug.
TP2 to TP3	The electrical path from the separable connector closest to the transmitter to the separable connector closest to the receiver. TP2 and TP3 are defined to be the interface between connector receptacle and the printed circuit board.
TP4 to TP5	The printed circuit board between the receiver and the separable connector closest to the receiver. TP4 is defined to be the interface between the board and connector plug. It is recommended that the AC-coupling capacitors are implemented between TP4 and TP5
TP0 to TP5	The electrical backplane channel as defined in 93.9 or 111.9. TP0 and TP5 are defined to be the interface between the device package and the printed circuit board.

Annex 93C

(normative)

Receiver interference tolerance

This annex defines a test setup (see 93C.1) and method (see 93C.2) for testing receiver interference tolerance. The PMD clause that invokes this method specifies the following items:

a) Constraint limit values for peak-to-peak voltage, the pre-cursor peaking ratio, and the post-cursor peaking ratio for test setup,
b) Lower frequency bound for the noise spectral density constraints (f_{NSD1}),
c) Jitter parameters to be measured in test method step 3,
d) Target Channel Operating Margin (COM) and RSS_DFE4 values for the test system in test method step 7,
e) COM parameter table in test method step 7,
f) Jitter transformation method in test method step 7,
g) Test pattern in test method step 9, and
h) Test system frequency response.

NOTE—The intent of the interference tolerance test is to ensure that the PHY receiver operates correctly with transmitter parameters anywhere within the specified limits including the case where all parameters are at the specified limits. Testing of the receiver with transmitter parameters beyond the specified limits may be helpful to determine margin or to provide comparative metrics, but failure of the receiver to operate correctly under these conditions is not to be interpreted as non-compliance.

93C.1 Test setup

The interference tolerance test is performed with the setup shown in Figure 93C–2 or its equivalent. Calibration and characterization of the various elements in the test setup is accomplished using the test configurations in Figure 93C–3, Figure 93C–4, Figure 93C–5, and Figure 93C–6.

The transmitter is functionally and parametrically compliant to the requirements of the invoking PMD clause. The ISI channel emulates the frequency dependent loss of a backplane channel. The channel noise source emulates crosstalk, transmitter noise, and unequalizable signal distortions introduced by a channel.

The transmitter output, as measured at TP0a, meets all transmitter specifications as indicated by the invoking PMD clause. In addition, the transmitter output, as measured at TP0a, is constrained such that for any transmitter equalizer setting the maximum differential peak-to-peak voltage, the pre-cursor peaking ratio, and the post-cursor peaking ratio are constrained as indicated by the PMD clause that invokes this method.

The channel noise source has an adjustable output such that the level may be set according to the test procedure. The noise produced by the channel noise source is measured directly at the output of the noise source (see Figure 93C–6). The noise is Gaussian with a crest factor of at least 5. The noise spectral density, $NSD(f)$, is normalized and constrained according to the relations in Equation (93C–1), where f_b is the symbol rate and f_{NSD1} is specified by the PMD clause that invokes this method. $NSD(f)$ is in units of V^2/Hz. The average noise spectral density, NSD_{average}, is determined according Equation (93C–2). An example constraint template with f_{NSD1} equal to $0.08f_b$ is illustrated in Figure 93C–1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\left.\begin{aligned} 10\log_{10}\left(\frac{NSD(f)}{NSD_{average}}\right) &< 3 \\ 10\log_{10}\left(\frac{NSD(f)}{NSD_{average}}\right) &> -3(1 - 1.2f/f_b) \end{aligned}\right\} f_{NSD1} \le f \le f_b/2 \quad \text{(93C–1)}$$

$$NSD_{average} = \frac{\int_{f_{NSD1}}^{f_b/2} NSD(f)df}{f_b/2 - f_{NSD1}} \quad \text{(93C–2)}$$

The receiver on one lane at a time is tested for compliance. The input to the receiver on each of the other lanes is generated by a transmitter with similar levels and equalization settings and transmitted through a similar channel, such that the input signals are similar to the input signal on the lane under test.

NOTE—FEXT and NEXT in the test setup are not accounted for in the test channel calibration (see 93A.2). It is recommended that the test setup be designed to minimize these effects.

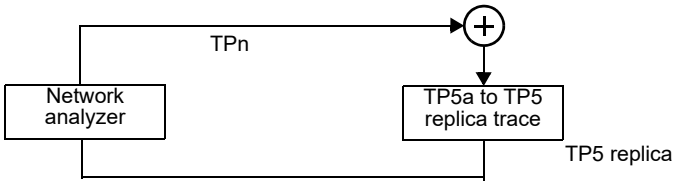

Figure 93C–5—Interference tolerance channel noise path test setup

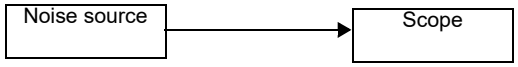

Figure 93C–6—Interference tolerance channel noise level test setup

93C.2 Test method

The interference tolerance test is performed using the following method:

1) Set the channel noise source to zero.
2) Using the test setup in Figure 93C–2, initiate the training sequence, allow the training sequence to complete, and retain the resulting transmitter tap coefficients.
3) Measure the jitter parameters relevant to the PMD clause that invokes this method that are to be used to set the value of σ_{RJ} and A_{DD} in step 7.
4) Measure the noise parameters relevant to the PMD clause that invokes this method that are to be used to set the value SNR_{TX}.
5) Using the test setup in Figure 93C–4 (also see Figure 93A–2), measure the scattering parameters, $S^{(tc)}$, of the test channel (TPt to TP5 replica).
6) Using the test setup in Figure 93C–5 (also see Figure 93A–2), measure the scattering parameters, $S^{(nc)}$, of the noise addition network (TPn to TP5 replica).
7) Using the procedure defined in 93A.2: (a) determine the receiver noise level, σ_{bn}, required to achieve the COM value specified in the PMD clause that invokes this method, and (b) verify that RSS_DFE4 is greater than or equal to the value specified in the PMD clause that invokes this method. The procedure is based on the calculation of COM, which uses the parameters defined in the COM parameter table in the PMD clause that invokes this method with the following exceptions. The value of σ_{RJ} and A_{DD} are set based on a transformation of measured parameters as specified in the PMD clause that invokes this method. The value of SNR_{TX} is set based on a transformation of the measured parameters specified in the PMD clause that invokes this method. In the COM computation the transmitter package model is included only if a compliant transmitter with a similar termination is used. If a transmitter with high quality termination is used, in the COM calculation, the termination is modeled as ideal and a Gaussian low pass filter is added to Equation (93A–19), which has the same 20% to 80% transition time as the transmitter measured at TP0a.
8) Using the test setup in Figure 93C–6, measure the channel noise voltage σ_{bnm} and adjust it so that it equals σ_{bn} determined in step 7. The channel noise voltage is determined from the measured $NSD(f)$ according to Equation (93C–3).
9) Using the test setup in Figure 93C–2, the transmitter taps as determined in step 2, and the channel noise as determined in step 7, configure the transmitter to transmit the test pattern specified in the PMD clause that invokes this method. Also configure the transmitters of the PMD under test to transmit the same test pattern, with their transmitters in the preset condition.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

10) Measure the FEC symbol error ratio on the receiver under test using the errored symbol counter, FEC_symbol_error_counter_*i*, where *i* is the lane number of the receiver under test.

$$\sigma_{bnm} = \sqrt{\int_0^{f_b/2} NSD(f)df} \quad \text{(93C–3)}$$

A test system with frequency response specified in the PMD clause that invokes this method is to be used for measurement of the signal applied by the pattern generator and for measurements of the broadband noise.

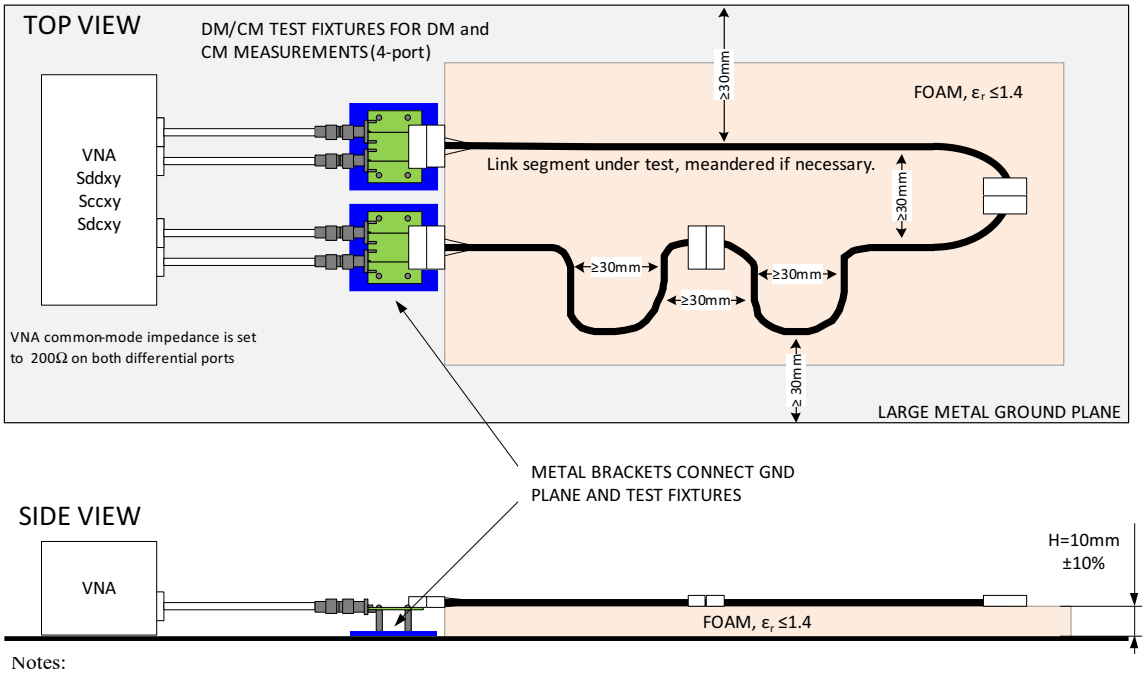
Annex 97A

(normative)

Common-mode conversion test methodology

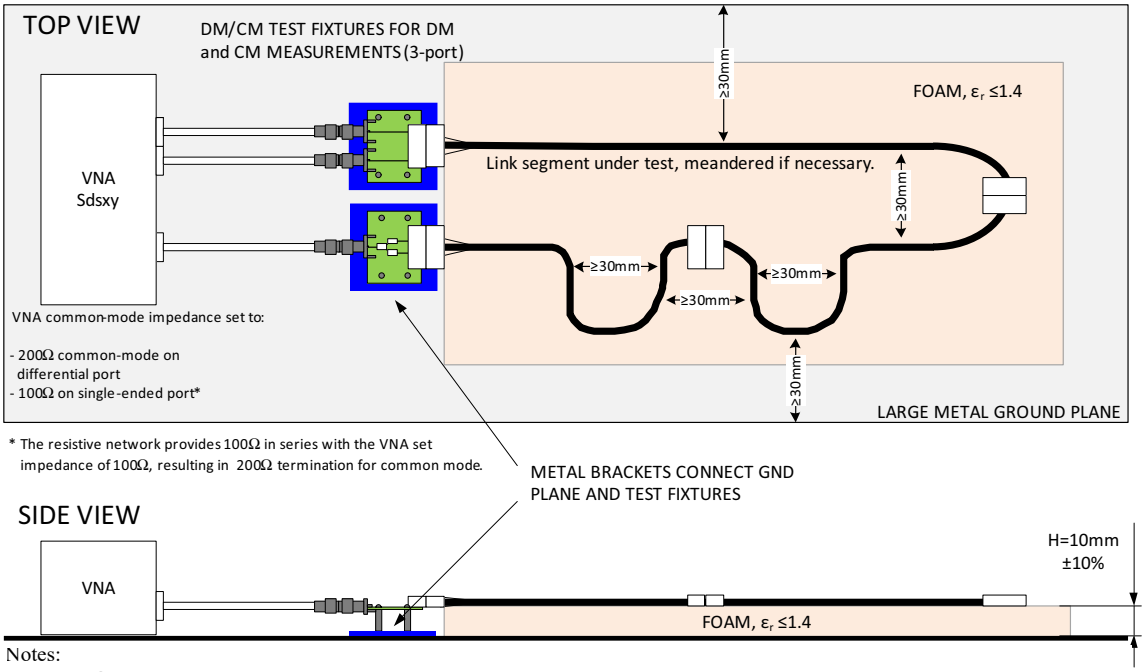


97A.1 Introduction

This annex describes the test methodologies that shall be used to measure the 1000BASE-T1 link segment differential-to-common-mode conversion loss specified in 97.6.1.4.

97A.2 Test configuration and measurement

The common-mode conversion loss is measured in a specified test environment to ensure repeatability. Individual test fixtures are illustrated in Figure 97A–1 and Figure 97A–2. The 1000BASE-T1 link segment is placed on a reference plane raised 10 mm from the surface of the ground plane.



To avoid ground-plane edge effects the 1000BASE-T1 link segment is placed 30 mm from the edge of the ground plane, this same spacing is used between adjacent sections of the same link segment to avoid unwanted coupling. The link segment parameters specified in 97.6 are to be measured using Annex 97A methodology.

Notes:
1. Two DM/CM test fixtures are used for all 4-port differential-mode and common-mode measurements.
2. Brackets provide reference “0V” for CM at the ends of DUT and VNA cables.
3. The entire setup is on a large metal GND plane, which extends at least 30 mm beyond the setup.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Notes:
1. The 50 Ω 0.1% resistors are RF-type DMS 0805 or smaller, e.g., Vishay FC series thing-film resistors.
2. Brackets provide reference “0V” for CM at the ends of DUT and VNA cables.
3. The entire setup is on a large metal GND plane, which extends at least 30 mm beyond the setup.

97A.3 Protocol implementation conformance statement (PICS) proforma for Annex 97A, Common-mode conversion test methodology[299]

97A.3.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 97A, Common-mode conversion test methodology, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

97A.3.2 Identification

97A.3.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. Annex 97B

(normative)

Alien Crosstalk Test Procedure

97B.1 Introduction

Annex 97B describes a procedure for measuring ANEXT loss and AFEXT loss between pairs of adjacent link segments consisting of cables and in-line connectors.

The procedure is required to assess the alien crosstalk performance of the link segments as specified in 97.6.3 and 97.6.4. This procedure is intended for use in the laboratory, to evaluate that the link segments complies with the PSANEXT loss and PSAACRF requirements, when properly installed.

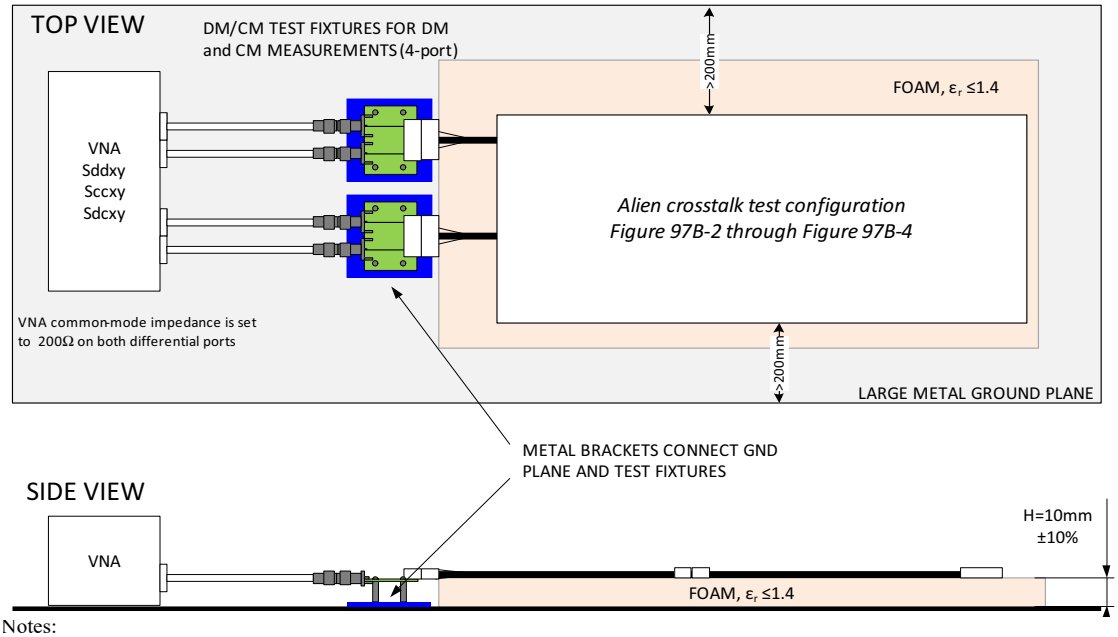
97B.1.1 Alien crosstalk test configurations

The limits for PSANEXT and PSAACRF are based on the alien crosstalk test configurations in Figure 97B–2, Figure 97B–3, Figure 97B–4, and Figure 97B–5. The automotive link segment test configurations are derived from two automotive industry use cases representative of common scenarios.

Measurements to be performed at 23°C ± 5°C relative humidity 25% to 75%.

Multiport test fixtures are used for multiport link segments. The number of disturbing ports to be included in the power sum calculation is dependent on the configuration. Significant connectors may be located in the same or other mounting systems in close proximity and are assessed as follows. For any given configuration, the determination of which ports to be included can be made based on the ANEXT loss contribution to the disturbed port. If at any frequency point the ANEXT measurement is less than 90 dB, then the entire ANEXT loss and PSAACRF response of that connector combination shall be included in the overall power sum result.

Link segment ends not under test are terminated in 100 Ω differential mode and 200 Ω common mode.



97B.2 Alien crosstalk coupled between type A link segments

The use case 1 alien crosstalk test configuration consists of three link segments of 5 m length and two in-line connectors, equally spaced at 1.66 m distance.

The use case 2 alien crosstalk test configuration consists of 5 link segments bundled together over a 5 m length with the center link segment extending unbundled for 3 m. The 3 m unbundled section includes 2 in-line connectors in addition to the 2 in-line connectors in the 5 m bundled section.

The alien crosstalk measurements are to be performed utilizing the test setup and methodology specified in Annex 97B.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Notes:
1. Two DM/CM test fixtures are used for all 4-port differential-mode and common-mode measurements.
2. Brackets provide reference “0V” for CM at the ends of DUT and VNA cables.
3. The entire setup is on a large metal GND plane, which extends at least 200 mm beyond the setup.

Figure 97B–1—Alien crosstalk test setup

97B.3 Cable bundling

The cable bundle shall be placed on dielectric insulation material (εR < 1.4) of 10 mm height over conducting ground plane. The cables are uniformly fixed in their position by means of cable straps or adhesive tape to keep the cables attached together with a maximum distance between the fixation devices of 30 cm.

The measurement test fixtures are to be connected to the reference ground plane by means of conducting stands, copper braid, or foil.

If it is necessary to split up the wiring harness at the end of the bundle in order to accommodate the measurement fixtures, the length of the area split up is limited to the maximum of 30 cm.

An example of cable bundling for the 2-around–1 alien crosstalk test configuration is illustrated in Figure 97B–4.

An example of cable bundling for the 4-around–1 alien crosstalk test configuration is illustrated in Figure 97B–5. For use case 2, the link segment extending unbundled for 3 m is centered in the cable bundle e.g., cable 2 in Figure 97B–5.

Annex 98A

(normative)

Selector Field definitions

98A.1 Introduction

The Selector Field, S[4:0] in the link codeword, shall be used to identify the type of message being sent by Auto-Negotiation. The following table identifies the types of messages that may be sent. The Selector Field uses a 5-bit binary encoding, which allows 32 messages to be defined. All unspecified combinations are reserved. Reserved combinations shall not be transmitted.

Table 98A–1—Selector Field Encoding

S4	S3	S2	S1	S0	Selector description
0	0	0	0	0	Reserved
0	0	0	0	1	IEEE Std 802.3
0	0	0	1	X	Reserved
0	0	1	X	X	Reserved
0	1	X	X	X	Reserved
1	X	X	X	X	Reserved

Annex 98B

(normative)

IEEE 802.3 Selector Base Page definition

98B.1 Introduction

This annex provides the Technology Ability Field bit assignments, Priority Resolution table, and Message Page transmission conventions relative to the IEEE 802.3 Selector Field value within the Base Page encoding for devices using Clause 98 Auto-Negotiation.

The Technology Ability Field is inserted into the Priority Resolution hierarchy and made a part of the Auto-Negotiation process. The relative hierarchy of the existing technologies is designed in such a way that backward compatibility with existing Auto-Negotiation implementations is maintained.

Reserved bits shall be transmitted as zeros. This is to ensure that devices implemented using the current priority table forward updated priority tables.

98B.2 Selector field value

The value of the IEEE 802.3 Selector Field is S[4:0] = 00001.

98B.3 Technology Ability Field bit assignments

The Technology Ability Field consists of bits D21 through D47 (A0–A26, respectively) in the IEEE 802.3 Selector Base Page. Table 98B–1 summarizes bit assignments in the Technology Ability Field. Note that the order of the bits within the Technology Ability Field has no relationship to the relative priority of the technologies.

Table 98B–1—Technology Ability Field bit assignments

bit	Selector description
A0	100BASE-T1 ability
A1	10BASE-T1S full duplex ability
A2	1000BASE-T1 ability
A3	2.5GBASE-T1 ability
A4	5GBASE-T1 ability
A5	10GBASE-T1 ability
A6 through A8	Reserved
A9	10BASE-T1L capability
A10 through A21	Reserved

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 98B–1—Technology Ability Field bit assignments *(continued)*

bit	Selector description
A22	10BASE-T1S half duplex capability
A23	10BASE-T1L increased transmit level request
A24	10BASE-T1L increased transmit/receive level ability
A25	10BASE-T1L EEE ability
A26	Reserved

98B.3.1 10BASE-T1L-specific bit assignments

Configuration of 10BASE-T1L specific bits A23, A24, and A25 are specified in 146.6.

98B.4 Priority Resolution

Since a local device and a link partner may have multiple abilities in common, a prioritization scheme exists to ensure that the highest common denominator ability is chosen. The following list shall represent the relative priorities of the technologies supported by the IEEE 802.3 Selector Field value, where priorities are listed from highest to lowest:

— 10GBASE-T1
— 5GBASE-T1
— 2.5GBASE-T1
— 1000BASE-T1
— 100BASE-T1
— 10BASE-T1S full duplex
— 10BASE-T1S half duplex
— 10BASE-T1L

98B.5 Message Page transmission convention

Each series of Unformatted Pages shall be preceded by a Message Page containing a message code that defines how the following Unformatted Pages is used.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Annex 98C

(normative)

Next Page Message Code Field definitions

98C.1 Introduction

This Annex defines the Next Page message code fields for devices using Clause 98 Auto-Negotiation. The Message Code Field of a message page used in Next Page exchange shall be used to identify the meaning of a message. Table 98C–1 identifies the types of messages that may be sent.

The Message Code Field uses an 11-bit binary encoding that allows 2048 messages to be defined. All message codes not specified shall be reserved.

Table 98C–1—Message Code Field values

Message code	M10	M9	M8	M7	M6	M5	M4	M3	M2	M1	M0	Message code description
0	0	0	0	0	0	0	0	0	0	0	0	Reserved
1	0	0	0	0	0	0	0	0	0	0	1	Null Message
2 to 4												Reserved
5	0	0	0	0	0	0	0	0	1	0	1	Organizationally Unique Identifier Tagged Message
6	0	0	0	0	0	0	0	0	1	1	0	AN device Identifier Tag Code
7 to 2047	1	1	1	1	1	1	1	1	1	1	1	Reserved

98C.2 Message code 1—Null Message code

The Null Message code shall be transmitted during Next Page exchange when the Local Device has no further messages to transmit and the Link Partner is still transmitting valid Next Pages. See 98.2.4.3 for more details.

98C.3 Message code 5—Organizationally Unique Identifier (OUI) tag code

The OUI tag code message shall consist of a Message Next Page with the message code field 000 0000 0101 followed by one Unformatted Next Page defined as follows. The unformatted code field of Message Next Page 5 shall contain the most significant 11 bits of the OUI or CID (bits 23:13) in bits 26:16 (bits U0 to U10) with the most significant OUI or CID bit in bit 26 (bit U10) of the unformatted code field, the next 11 most significant bits of the OUI or CID (bits 12:2) in bits 42:32 (bit U26 to U16) with the most significant bit in bit 42 (bit U26). The unformatted code field of the Unformatted Next Page shall contain the remaining least significant 2 bits of the OUI or CID (bits 1:0) in bits 10:9 (U10 and U9) with OUI or CID bit 1 in bit 10 (bit U10) with the bits 8:0, 26:16 (bits U8 to U0, U21 to U11) as a user-defined user code value that is specific to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the OUI or CID transmitted. The remaining unformatted code field bits in the Message Next Page and the Unformatted Next Page shall be sent as zero and ignored on receipt.

For example, assume that a manufacturer's IEEE-assigned OUI/CID value is AC-DE-48 and the manufacturer-selected user-defined user code associated with the OUI or CID is 1100 1110 0001 1111 1100_2. The message code values generated from these two numbers is encoded into the message Next Page and Unformatted Next Page codes, as specified in Figure 98C–1. For clarity, the position of the M bit[301] is illustrated.

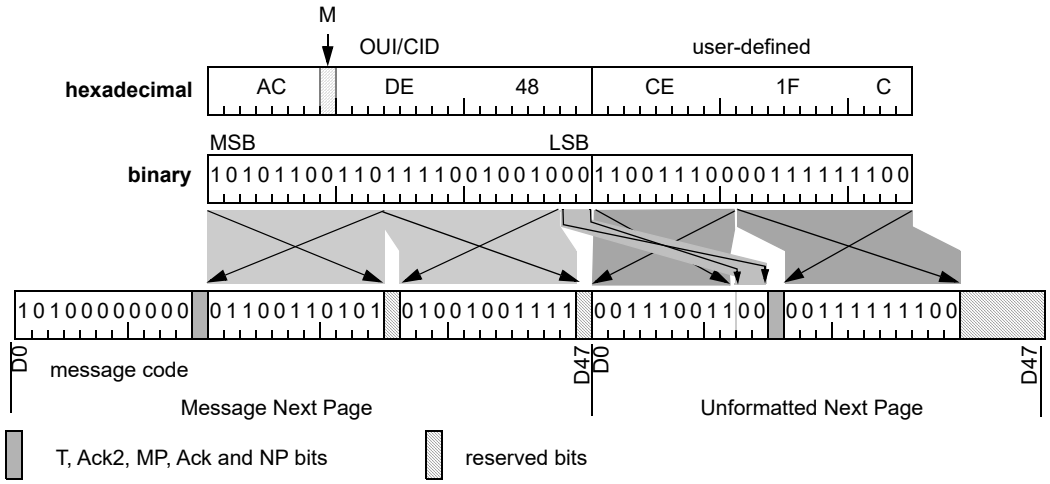

Figure 98C–1—Message code 5 sequence

NOTE—Figure 98C–1 shows the order Next Pages are transmitted, with the first transmitted Next Page shown in the leftmost position. This bits within each page are shown with the first transmitted bit (i.e., least significant bit) in the leftmost position. This is the same convention for bit order in the figures of Clause 98. Figure 28C–1 uses the opposite convention for bit order.

98C.4 Message code 6—AN device identifier tag code

The AN device ID tag code message shall consist of a Message Next Page with the message code field 000 0000 0110 followed by one Unformatted Next Page defined as follows. The unformatted fields of this message contain the AN device identifier (registers 7.2 and 7.3). The unformatted code field of Message Next Page 6 shall contain the most significant 11 bits of the AN device identifier (7.2.15:5) in bits 26:16 (bits U0 to U10) with the most significant AN device identifier bit in bit 26 (bit U10) of the unformatted code field, and the next 11 most significant bits of the AN device identifier (bits 7.2.4:0 to 7.3.15:10) in bits 42:32 (bit U26 to U16) with the most significant bit in bit 42 (bit U26) of the unformatted code field. The unformatted code field of the Unformatted Next Page shall contain the remaining least significant 10 bits of the AN device identifier (bits 7.3.9:0) in bits 10:1 (bit U10 to U1). Bits 0, 26:16 (bits U0, U21 to U11) of the unformatted code field of the Unformatted Next Page shall contain a user-defined user code value that is specific to the device identifier transmitted. The remaining unformatted code field bits in the Message Next Page and the Unformatted Next Page shall be sent as zero and ignored on receipt.

Annex 100A

(normative)

EPoC OFDM channel model

100A.1 Topology

The normative EPoC baseline channel conditions and OFDM channel parameters are referenced to the topology shown in Figure 100A–1. Numerous other topologies are possible that may exhibit better or worse performance than that shown in Figure 100A–1. When operating in a network that does not meet the parameters given in Table 100A–1 and Figure 100A–1 degraded performance is expected.

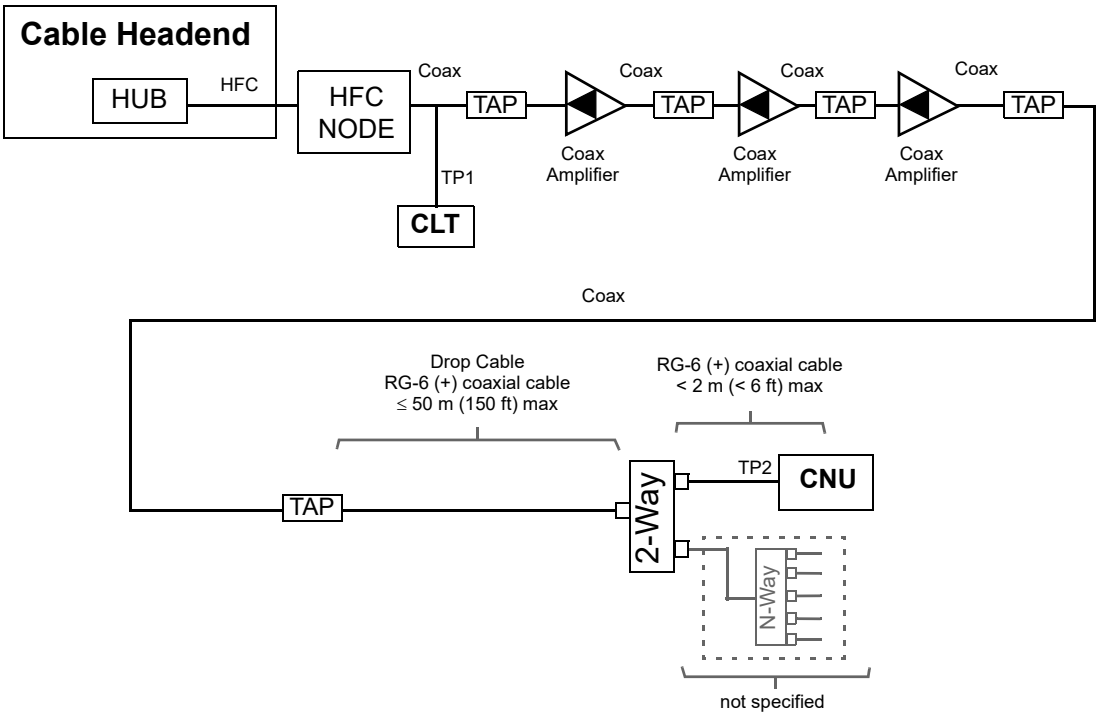

Figure 100A–1—EPoC network topology

NOTE—Additional information on cable coaxial network topology can be found in Modern Cable Television Technology [B55] and SCTE Measurement Recommended Practices for Cable Systems [B61].

100A.2 Downstream channel parameters

Devices designed to the EPoC PHY standard shall meet or exceed normative performance when operated in any network that meets or exceeds the parameters given in Table 100A–1 regardless of the network topology. The normative network operating parameters for the downstream direction in an EPoC network are

given in Table 100A–1. These parameters are based on the following conditions:

— HFC downstream spectrum of 1 GHz.
— An amplifier cascade depth of N+3 (HFC Node plus CLT plus three coax amplifiers as in Figure 100A–1).
— A channel loading of 48 Analog TV channels (32 removed for EPoC) + 75 digital TV channels + 1 EPoC band (digital PSD@ –6 dBc).
— An HFC optical architecture of linear optics operating at 1310 nm (nominal link length) legacy with the EPoC RF coupled after HFC Node.
— A home architecture of up to the maximum drop cable length and one 2-way splitter.

100A.3 Upstream channel parameters

Devices designed to the EPoC PHY standard shall meet or exceed normative performance when operated in any network that meets or exceeds the parameters given in Table 100A–2 regardless of the network topology. The normative network operating parameters for the upstream direction in an EPoC network are given in Table 100A–2. These parameters are based on the following conditions:

— HFC upstream spectrum of 300 MHz.
— An amplifier cascade depth of N+3 (HFC Node plus CLT plus three coax amplifiers as in Figure 100A–1).
— A channel loading of remote transmitter and receiver.
— Head end architecture is not applicable as this section only address EPoC upstream path.
— A home architecture of up to the maximum drop cable length and one 2-way splitter.

Table 100A–2—Upstream EPoC channel parameters

Parameter	Nominal Conditions	Units
Spectrum		
Frequency range	100 to 292	MHz
OFDM modulated spectrum	190	MHz

100A.4 Protocol implementation conformance statement (PICS) proforma for Annex 100A, EPoC OFDM channel model[302]

100A.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 100A, EPoC OFDM channel model, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

100A.4.2 Identification

100A.4.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).

Annex 109A

(normative)

Chip-to-chip 25 Gigabit Attachment Unit Interface (25GAUI C2C)

109A.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-chip 25 Gigabit Attachment Unit Interface (25GAUI C2C). Figure 109A–1 shows an example relationship of the 25GAUI C2C interface to the ISO/IEC Open System Interconnection (OSI) reference model. The 25GAUI C2C interface provides electrical characteristics and associated compliance points that can optionally be used when designing systems with electrical interconnect of approximately 25 cm in length.

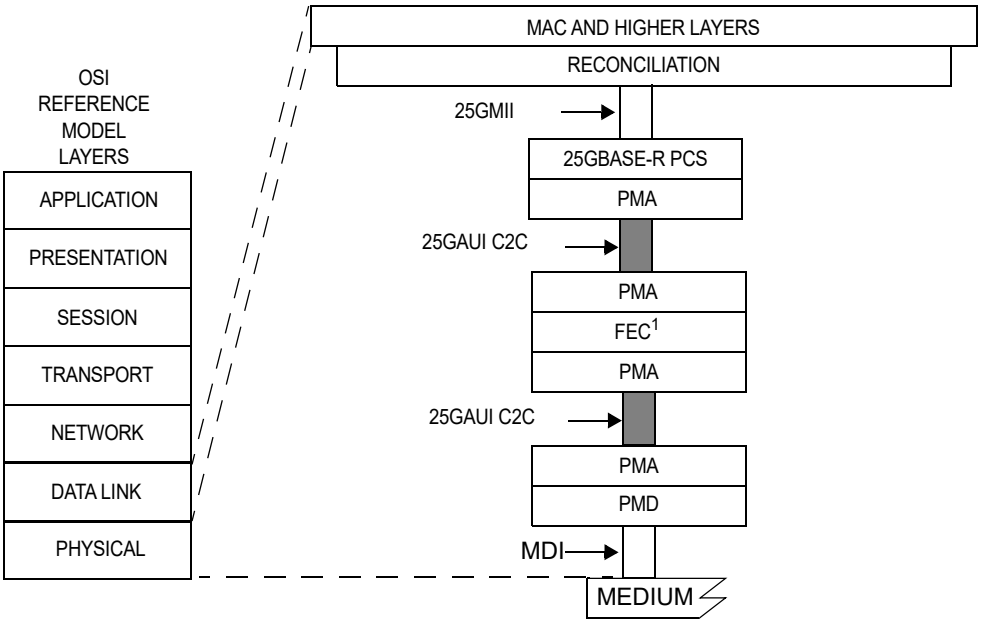

Figure 109A–1—Example 25GAUI C2C relationship to the ISO/IEC Open System Interconnection reference model and the IEEE 802.3 Ethernet model

The 25GAUI C2C bidirectional link is described in terms of a 25GAUI C2C transmitter, a 25GAUI C2C channel, and a 25GAUI C2C receiver. Figure 109A–2 depicts a typical 25GAUI C2C application, and Equation (83D–1) (illustrated in Figure 83D–3) summarizes the recommended differential insertion loss budget associated with the chip-to-chip application. The 25GAUI C2C interface comprises independent, differential data paths in each direction, which are AC-coupled. The nominal signaling rate is 25.78125 GBd. The 25GAUI C2C transmitter on each end of the link is adjusted to an appropriate setting based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 83D.3.3.2 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

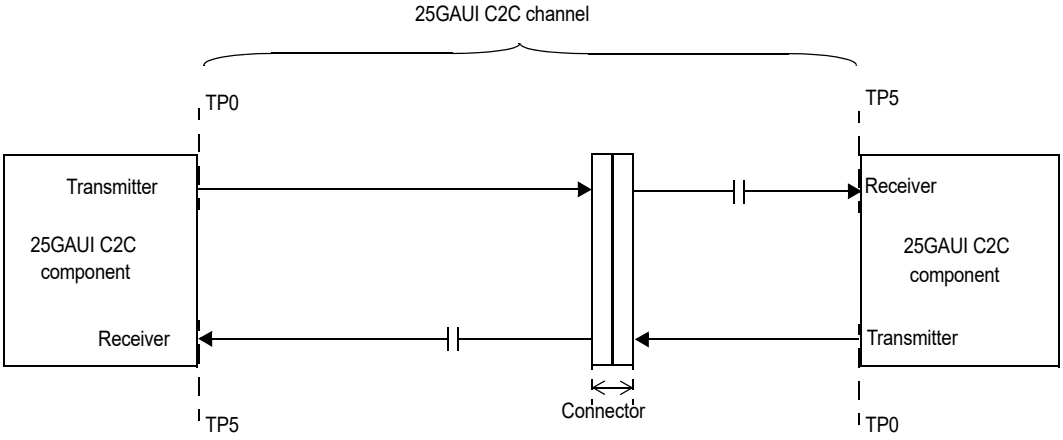

Figure 109A–2—Typical 25GAUI C2C application

The normative channel compliance is through 25GAUI C2C channel operating margin (COM) as described in 83D.4. Actual channel loss could be higher or lower than that given by Equation (83D–1) due to the channel ILD, return loss, and crosstalk.

109A.2 25GAUI C2C compliance point definition

The compliance points for the 25GAUI C2C interface are defined in 83D.2.

109A.3 25GAUI C2C electrical characteristics

109A.3.1 25GAUI C2C transmitter characteristics

A 25GAUI C2C transmitter shall meet all specifications of a single CAUI-4 lane as specified in 83D.3.1.

109A.3.2 25GAUI C2C receiver characteristics

A 25GAUI C2C receiver shall meet all specifications in Table 83D–4 for a single CAUI-4 lane. If the receiver supports the optional transmitter equalization feedback, it shall meet all requirements in 83D.3.3.2.

109A.3.3 Optional EEE operation

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78 and 78.3) then the inter-sublayer service interface includes four additional primitives as described in 83.3 and may also support 25GAUI shutdown (see 78.5.2).

If the EEE capability includes 25GAUI shutdown then the transmitter shall meet all requirements in 83D.3.2 and the receiver shall meet all requirements in 83D.3.4.

109A.4 25GAUI C2C channel characteristics

The 25GAUI C2C channel shall meet the requirements specified in 83D.4.

109A.5 Protocol implementation conformance statement (PICS) proforma for Annex 109A, Chip-to-chip 25 Gigabit Attachment Unit Interface (25GAUI C2C)[303]

109A.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 109A, Chip-to-chip 25 Gigabit Attachment Unit Interface (25GAUI C2C), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

109A.5.2 Identification

109A.5.2.1 Implementation identification

Supplier[1]

Annex 109B

(normative)

Chip-to-module 25 Gigabit Attachment Unit Interface (25GAUI C2M)

109B.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 25 Gigabit Attachment Unit Interface (25GAUI C2M). Figure 109B–1 shows the relationship of the 25GAUI C2M interface to the ISO/IEC Open System Interconnection (OSI) reference model. The 25GAUI C2M interface provides electrical characteristics and associated compliance points that can optionally be used when designing systems with pluggable module interfaces.

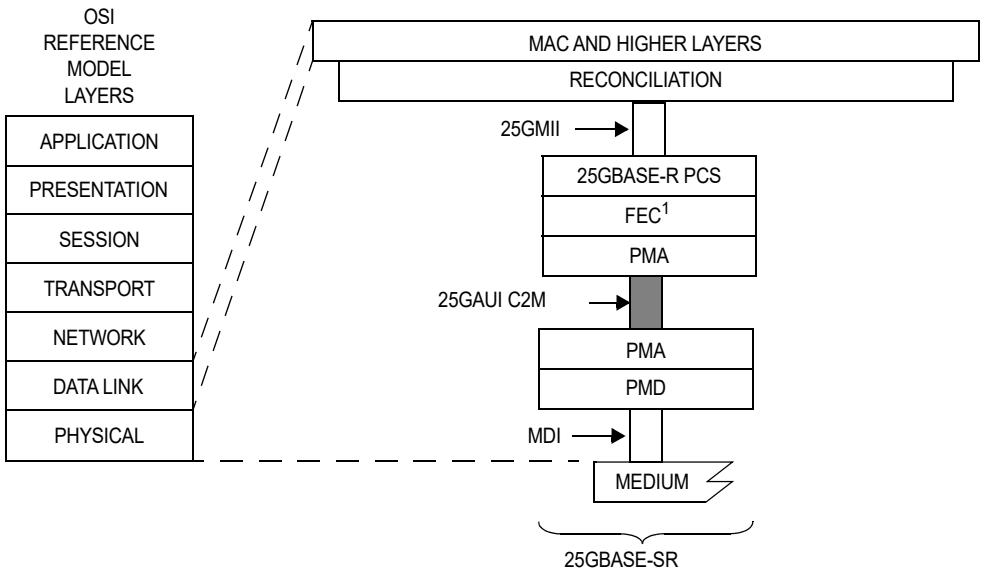

Figure 109B–1—Example 25GAUI C2M relationship to the ISO/IEC Open System Interconnection reference model and the IEEE 802.3 Ethernet model

The 25GAUI C2M link is described in terms of a host 25GAUI C2M component, a 25GAUI C2M channel with associated insertion loss, and a module 25GAUI C2M component.

For module form factors with more than one 25GAUI C2M lane, each lane comprises a separate 25GAUI C2M interface with independent management.

Figure 109B–2 depicts a typical 25GAUI C2M application with loss budget per section. The supported insertion loss budget is characterized by Equation (83E–1) and illustrated in Figure 83E–3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 25GAUI C2M interface comprises independent data paths in each direction. Each data path contains a differential pair that is AC-coupled within the module. The nominal signaling rate is 25.78125 GBd. The 25GAUI C2M interface is defined using a specification and test methodology that is similar to that used for CEI-28G-VSR defined in OIF-CEI-03.1 [B57].

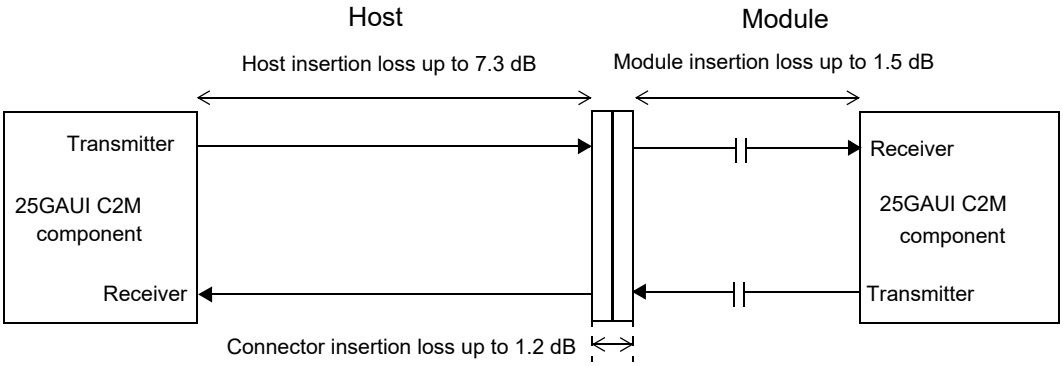

Figure 109B–2—25GAUI C2M insertion loss budget at 12.89 GHz

109B.1.1 Bit error ratio

For a PHY without the RS-FEC sublayer (Clause 108), the 25GAUI C2M bit error ratio (BER) is less than 10^{-15} with any errors sufficiently uncorrelated to ensure an acceptably high mean time to false packet acceptance (MTTFPA) assuming 64B/66B coding.

For a PHY with the RS-FEC sublayer (Clause 108), the 25GAUI C2M bit error ratio is less than 10^{-6} with any errors sufficiently uncorrelated to ensure a frame loss ratio (see 1.4.344) of less than 6.2×10^{-10} for 64-octet frames with minimum interpacket gap when processed according to Clause 108.

109B.2 25GAUI C2M compliance point definitions

25GAUI C2M compliance points are defined in 83E.2. The HCB and MCB for a four-lane connector (e.g., QSFP28) are described and specified in 92.11.2. The HCB and MCB for a single-lane connector (e.g., SFP28) are described and specified in Annex 110B.

109B.3 25GAUI C2M electrical characteristics

109B.3.1 25GAUI C2M host output characteristics

A 25GAUI C2M host output shall meet all specifications in 83E.3.1.

109B.3.2 25GAUI C2M module output characteristics

A 25GAUI C2M module output shall meet all specifications in 83E.3.2 with the exception of eye height, eye width, and vertical eye closure.

A 25GAUI C2M module output also shall meet the eye height, eye width, and vertical eye closure specified in 109B.3.2.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

109B.3.2.1 25GAUI C2M module output eye opening

Figure 83E–11 depicts an example module output eye test configuration. The module output eye is measured at TP4, as shown in Figure 83E–5. The module output eye is measured using a reference receiver with a continuous-time linear equalizer (CTLE) defined in 83E.3.2.1.1. The crosstalk generator is calibrated at TP1a with target differential peak-to-peak amplitude of 900 mV and target transition time of 19 ps.

For a PHY that includes an RS-FEC sublayer (Clause 108), the module output eye opening shall meet the eye opening requirements in either 109B.3.2.1.1 or 109B.3.2.1.2.

For a PHY that does not include an RS-FEC sublayer, the module output eye opening shall meet the eye opening requirements in 109B.3.2.1.1.

109B.3.2.1.1 Eye opening using measurement method A

Module output eye width (*EW15*) shall be greater than 0.57 UI. Module output eye height (*EH15*) shall be greater than 228 mV. Module output vertical eye closure (*VEC*) shall be less than 5.5 dB.

Eye width, eye height, and vertical eye closure are measured using the methodology described in 83E.4.2.

The input (counter-propagating) signal is asynchronous with the output signal and is modulated with a scrambled idle pattern (82.2.11), a PRBS31 pattern (49.2.8), or a valid 25GBASE-R signal.

109B.3.2.1.2 Eye opening using measurement method B

Module output eye width (*EW8*) shall be greater than 0.57 UI. Module output eye height (*EH8*) shall be greater than 228 mV. Module output vertical eye closure (*VEC8*) shall be less than 5 dB.

Eye width, eye height, and vertical eye closure are measured using the methodology described in 109B.4.1.

The input (counter-propagating) signal is asynchronous with the output signal and is modulated with a scrambled idle pattern (82.2.11) with RS-FEC encoding, a PRBS31 pattern (49.2.8), or a valid 25GBASE-R signal with RS-FEC encoding.

109B.3.3 25GAUI C2M host input characteristics

A 25GAUI C2M host input shall meet all specifications in 83E.3.3.

109B.3.4 25GAUI C2M module input characteristics

The 25GAUI C2M module input shall meet all specifications in 83E.3.3, with the exception of the module stressed input test. Channel equalization is provided by an equalizer in the module that uses the reference CTLE setting provided by the host or an adaptive equalizer in the module that does not use the setting provided by the host.

For a PHY that includes an RS-FEC sublayer, the 25GAUI C2M module input shall meet the module stressed input test requirements in either 109B.3.4.1 or 109B.3.4.2.

For a PHY that does not include an RS-FEC sublayer (Clause 108), the 25GAUI C2M module input shall meet the module stressed input test requirements in 109B.3.4.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

109B.3.4.1 Module stressed input test using measurement method A

The module stressed input tolerance is measured using the procedure defined in 83E.3.4.1.

109B.3.4.2 Module stressed input test using measurement method B

The module stressed input tolerance is measured using the procedure defined in 83E.3.4.1.1 with the following exceptions. The input eye height and eye width are measured according to the method in 109B.4.1. The stressed input signal shall satisfy the input tolerance defined in Table 109B–1. The module receiver shall operate with a BER of better than 10^{-6} in the presence of a compliant stressed input signal.

Table 109B–1—Module stressed input parameters for method B

Parameter	Value
Eye width (EW8)	0.46 UI
Applied pk-pk sinusoidal jitter	Table 88–13
Eye height (EH8)	95 mV

109B.4 25GAUI C2M measurement methodology

109B.4.1 Eye width, eye height, and eye closure measurement method B

Eye width and eye height are measured using the methodology described in 83E.4.2 with the following exceptions:

a) For step 1, collect sufficient samples equivalent to at least 400 000 bits to allow for construction of a normalized cumulative distribution function (CDF) to a probability of 10^{-5} without extrapolation.

b) For step 4, calculate the best linear fit in Q-scale over the range of probabilities of 10^{-3} to 10^{-5} of CDFL and CDFR and calculate the eye width (*EW8*) using Equation (109B–1).

c) For step 6, calculate the best linear fit in Q-scale over the range of probabilities of 10^{-3} and 10^{-5} of CDF1 and CDF0 and calculate the eye height (*EH8*) using Equation (109B–2).

d) Measure the eye amplitude (*AV*) of the equalized waveform. Eye amplitude is defined as the mean value of logic one minus the mean value of logic zero in the central 5% of the eye. Calculate the vertical eye closure (*VEC8*) using Equation (109B–3).

$$EW8 = EW5 - 1.35\,(RJR + RJL) \quad (109B–1)$$

where

EW8 is the eye width extrapolated to 10^{-8} probability
EW5 is the eye width at 10^{-5} probability
RJL is the RMS value of the jitter estimated from CDFL
RJR is the RMS value of the jitter estimated from CDFR

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$EH8 = EH5 - 1.35\ (RN0 + RN1) \quad (109B–2)$$

where

EH8 is the eye height extrapolated to 10^{-8} probability
EH5 is the eye height at 10^{-5} probability
RN1 is the RMS value of the noise estimated from CDF1
RN0 is the RMS value of the noise estimated from CDF0

$$VEC8 = 20\ \log_{10}(\mathrm{AV}/EH8) \quad (109B–3)$$

where

VEC8 is vertical eye closure in dB, extrapolated to 10^{-8} probability
AV is the eye amplitude of the equalized waveform
EH8 is the eye height defined in Equation (109B–2)

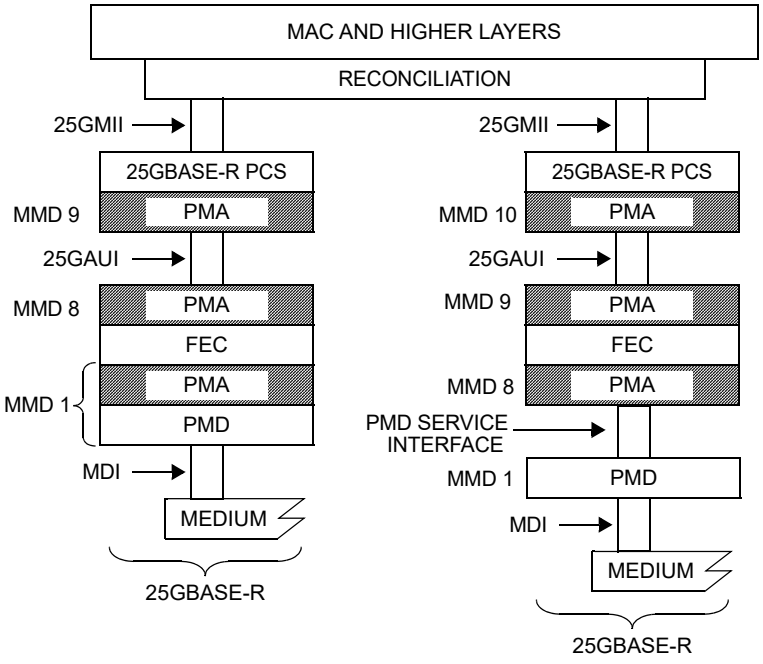
Annex 109C

(informative)

25GBASE-R PMA sublayer partitioning examples

The following figures provide various partitioning examples using the PMA, PMA service interface, and 25GAUI (see Figure 109C–1 through Figure 109C–6). Partitioning guidelines and MMD numbering conventions are described in 109.1.4. These partitioning examples are informative and do not specify a particular sublayer combination for any PHY. Specific and compliant sublayer combinations for a particular PHY are provided in the appropriate normative clause.



An example of an FEC (e.g., Clause 74, Clause 108) implemented in a separate device from either the PCS or the PMD is illustrated in Figure 109–3.

25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Annex 110A

(informative)

TP0 and TP5 test point parameters and channel characteristics for 25GBASE-CR and 25GBASE-CR-S

110A.1 Overview

Annex 110A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system. TP0 and TP5 test points are illustrated in the 25GBASE-CR and 25GBASE-CR-S link block diagram of Figure 110–2. This annex also provides information on channel characteristics.

110A.2 Transmitter characteristics at TP0

The transmitter characteristics at TP0 are constrained at TP0a by 93.8.1, with the exception that the value of linear fit pulse peak (min.) is $0.75 \times v_f$.

110A.3 Receiver characteristics at TP5

The receiver characteristics at TP5 are constrained at TP5a by 93.8.2.

110A.4 Transmitter and receiver differential printed circuit board trace loss

The recommended maximum and minimum printed circuit board trace insertion losses are specified in 92A.4.

110A.5 Channel insertion loss

This subclause provides information on channel insertion losses for the maximum-loss and minimum-loss cabling topologies.

The maximum channel insertion loss associated with the CA-25G-L, CA-25G-S, and CA-25G-N topologies is determined using Equation (110A–1). The channel insertion loss budget at 12.8906 GHz for the CA-25G-L topology is illustrated in Figure 110A–1. Loss budget parameters for all cable topologies are provided in Table 110A–1.

$$IL_{\mathrm{Chmax}}(f) = IL_{\mathrm{Camax}}(f) + 2IL_{\mathrm{Host}}(f) - 2IL_{\mathrm{MatedTF}}(f) \quad \text{(dB)} \qquad (110A–1)$$

for $0.05\ \mathrm{GHz} \le f \le 19\ \mathrm{GHz}$.

where

f	is the frequency in GHz
$IL_{\mathrm{Chmax}}(f)$	is the maximum channel insertion loss between TP0 and TP5

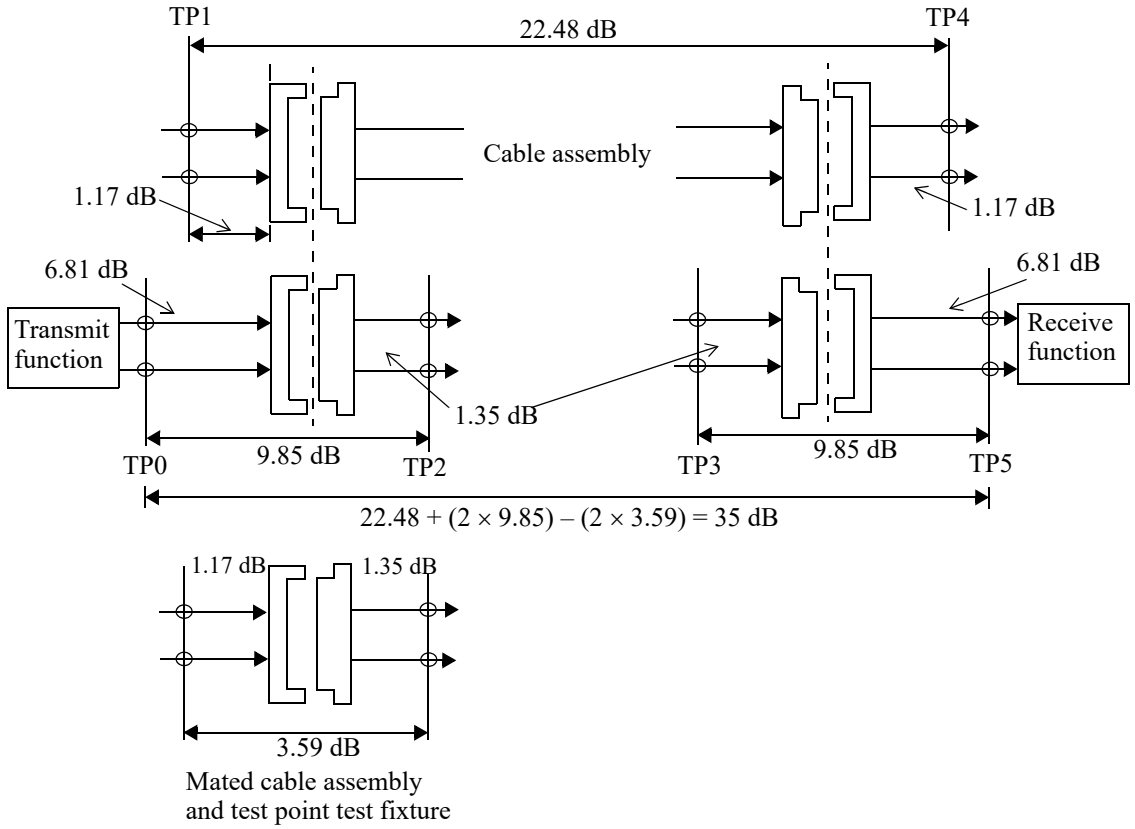
Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$IL_{Camax}(f)$ is the maximum cable assembly insertion loss (TP1 to TP4) for each topology (see Table 110–10)
$IL_{Host}(f)$ is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (92–8)
$IL_{MatedTF}(f)$ is the nominal insertion loss of the mated test fixture using Equation (92A–4)

The channel insertion loss associated with the 0.5 m topology and a maximum host channel is determined by Equation (110A–2).

$$IL_{Ch0.5m}(f) = IL_{Camin}(f) + 2IL_{Host}(f) - 2IL_{MatedTF}(f) \quad \text{(dB)} \qquad (110A–2)$$

for 0.05 GHz ≤ f ≤ 19 GHz.



where
f is the frequency in GHz
$IL_{Ch0.5m}(f)$ is the channel insertion loss between TP0 and TP5 representative of a 0.5 m cable assembly and a maximum host channel
$IL_{Camin}(f)$ is the minimum cable assembly insertion loss (TP1 to TP4) given in Equation (92–26) and illustrated in Figure 92–12
$IL_{Host}(f)$ is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (92–8)
$IL_{MatedTF}(f)$ is the nominal insertion loss of the mated test fixture using Equation (92A–4)

The loss budget parameter values at 12.8906 GHz are provided in Table 110A–1.

Table 110A–1—Cable insertion loss budget values at 12.8906 GHz

Parameter	CA-25G-L	CA-25G-S	CA-25G-N	Units
IL_{Chmax}	35	29	28.02	dB
IL_{Camax}	22.48	16.48	15.50	dB
$IL_{Ch0.5m}$	20.52			dB
IL_{Camin}	8			dB
IL_{Host}	9.85			dB
$IL_{MatedTF}$	3.59			dB

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The connector insertion loss is 1.07 dB for the mated test fixture. The host connector is allocated 0.62 dB of additional margin.

Figure 110A–1—35 dB channel insertion loss budget at 12.8906 GHz

110A.6 Channel return loss

The recommended return loss of the 25GBASE-CR and 25GBASE-CR-S channels is specified in 92A.6.

110A.7 Channel Operating Margin (COM)

The Channel Operating Margin (COM) for the channel between TP0 and TP5, computed using the procedure in 93A.1 and the parameters in Table 110–11, is recommended to be greater than or equal to the Channel Operating Margin (min.) value in Table 110–11 for the cable assembly type being used.

Annex 110B

(normative)

Test fixtures for 25GBASE-CR, 25GBASE-CR-S, and 25GAUI C2M

110B.1 Test fixtures

Transmitter and receiver measurements at TP2 or TP3 for 25GBASE-CR and 25GBASE-CR-S PHYs in an SFP28 host form factor (see 110C.2.1), and at TP1a or TP4a for the 25GAUI C2M host (see 109B.2), are made utilizing the test fixture specified in 110B.1.1. Transmitter and receiver measurements at TP2 or TP3 for 25GBASE-CR and 25GBASE-CR-S PHYs in a QSFP28 host form factor (see 110C.2.2) are made utilizing the test fixture specified in 92.11.1.

Cable assembly measurements for the SFP28-SFP28 form factor (see 110C.3.1) are made between TP1 and TP4 with cable assembly test fixtures as specified in 110B.1.2 on both ends. Cable assembly measurements for the QSFP28-QSFP28 form factor (see 110C.3.2) are made between TP1 and TP4 with cable assembly test fixtures as specified in 92.11.2 on both ends. Cable assembly measurements for the QSFP28-4×SFP28 form factor (see 110C.3.3) are made between TP1 and TP4 with a cable assembly test fixture as specified in 110B.1.2 for each connector on the SFP28 end, and with a cable assembly test fixture as specified in 92.11.2 for the QSFP28 end.

The test fixtures are specified in a mated state to enable connections to measurement equipment. The reference insertion loss of the mated test fixtures is 3.59 dB (see 110A.5). The requirements in the referenced subclauses are not the MDI connector specifications for an implemented design.

110B.1.1 SFP28 TP2 or TP3 test fixture

The TP2 or TP3 test fixture, also known as Host Compliance Board (HCB), is required for measuring the transmitter specifications in 110.7.2 at TP2 and the receiver return loss at TP3. The TP2 and TP3 test points are illustrated in Figure 110–2.

This test fixture is also required for verifying 25GAUI C2M host output characteristics in 109B.3.1 at TP1a and host input characteristics in 109B.3.3 at TP4a. The TP1a and TP4a test points are illustrated in Figure 83E–4.

The test fixture printed circuit board reference insertion loss is given in Equation (92–34). The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the host measurements.

110B.1.2 SFP28 Cable assembly test fixture

The cable assembly test fixture, also known as Module Compliance Board (MCB), is required for measuring the cable assembly specifications in 110.10 at TP1 and TP4. The TP1 and TP4 test points are illustrated in Figure 110–2.

This test fixture is also required for verifying 25GAUI C2M module output characteristics in 109B.3.2 at TP1 and module input characteristics in 109B.3.4 at TP4. The TP1 and TP4 test points are illustrated in Figure 83E–5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The test fixture printed circuit board reference insertion loss is given in Equation (92–35). The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the cable assembly or module measurements.

110B.1.3 SFP28 Mated test fixtures

The TP2 or TP3 and cable assembly test fixtures are specified in a mated state illustrated in Figure 92–18. The mated test fixtures specifications are listed in 92.11.3.

110B.1.3.1 Mated test fixtures differential insertion loss

The differential insertion loss of the mated test fixtures shall meet the requirements of 92.11.3.1.

The FOM_{ILD} of the mated test fixtures shall meet the requirements of 92.11.3.1.

110B.1.3.2 Mated test fixtures differential return loss

The differential return loss of the mated test fixtures shall meet the requirements of 92.11.3.2.

110B.1.3.3 Mated test fixtures common-mode conversion insertion loss

The common-mode conversion insertion loss of the mated test fixtures shall meet the requirements of 92.11.3.3.

110B.1.3.4 Mated test fixtures common-mode return loss

The common-mode return loss of the mated test fixtures shall meet the requirements of 92.11.3.4.

110B.1.3.5 Mated test fixtures common-mode to differential mode return loss

The common-mode to differential mode return loss of the mated test fixtures shall meet the requirements of 92.11.3.5.

110B.1.3.6 Mated test fixtures integrated near-end crosstalk noise

The integrated near-end crosstalk noise voltage for the disturber near-end crosstalk loss determined according to the method in this subclause shall meet the specification in Table 110B–1.

Table 110B–1—Mated test fixtures integrated near-end crosstalk noise

Parameter	Value	Units
Integrated near-end crosstalk noise voltage	Less than 1.8	mV

Given the disturber near-end crosstalk loss $NEXT_{loss}(f)$ measured over N uniformly spaced frequencies f_n spanning the frequency range 50 MHz to 19 000 MHz with a maximum frequency spacing of 10 MHz, the RMS value of the integrated near-end crosstalk noise is determined using Equation (110B–1) and Equation (110B–2).

The RMS crosstalk noise is characterized at the output of a specified receive filter utilizing a specified transmitter waveform and the measured disturber crosstalk transfer functions. The transmitter and receiver filters

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

are used in Equation (110B–1) to define a weighting function to the multiple-disturber crosstalk in Equation (110B–2). The sinc function is defined by $\mathrm{sinc}(x) = \sin(\pi x)/(\pi x)$.

Define the weight at each frequency f_n using Equation (110B–1).

$$W_{nt}(f_n) = (A_{nt}^2/f_b)\mathrm{sinc}^2(f_n/f_b)\left[\frac{1}{1+(f_n/f_{nt})^4}\right]\left[\frac{1}{1+(f_n/f_r)^8}\right] \quad (110B–1)$$

where the equation parameters are given in Table 110B–2.

Note that the 3 dB transmit filter bandwidth f_{nt} is inversely proportional to the 20% to 80% rise and fall time T_{nt}. The constant of proportionality is 0.2365 (e.g., $T_{nt}f_{nt} = 0.2365$; with f_{nt} in hertz and T_{nt} in seconds). In addition, f_r is the 3 dB reference receiver bandwidth, which is set to 18.75 GHz.

The integrated near-end crosstalk noise σ_{nx} is calculated using Equation (110B–2).

$$\sigma_{nx} = \left[2\Delta f\sum_n W_{nt}(f_n)10^{-NEXT_{loss}(f_n)/10}\right]^{1/2} \quad (110B–2)$$

where Δf is the uniform frequency step of f_n.

The total integrated near-end crosstalk noise for the mated test fixture is computed using the parameters shown in Table 110B–2.

Table 110B–2—Mated test fixture integrated near-end crosstalk noise parameters

Description	Symbol	Value	Units
Symbol rate	f_b	25.78125	GBd
Near-end disturber peak differential output amplitude	A_{nt}	600	mV
Near-end disturber 20% to 80% rise and fall times	T_{nt}	9.6	ps

110B.2 Protocol implementation conformance statement (PICS) proforma for Annex 110B, Test fixtures for 25GBASE-CR, 25GBASE-CR-S, and 25GAUI C2M[305]

110B.2.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 110B, Test fixtures for 25GBASE-CR, 25GBASE-CR-S, and 25GAUI C2M shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

110B.2.2 Identification

110B.2.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

110B.2.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 110B, Test fixtures for 25GBASE-CR, 25GBASE-CR-S, and 25GAUI C2M
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

Annex 110C

(normative)

Host and cable assembly form factors for 25GBASE-CR and 25GBASE-CR-S PHYs

110C.1 Overview

This annex describes form factors for the three cable assemblies specified in 110.10 and for hosts with either 25GBASE-CR or 25GBASE-CR-S Physical Layers.

Hosts have two specified MDI connectors, single-lane (SFP28, specified in 110.11.1) and multi-lane (QSFP28, specified in 92.12). This creates two host interface types and three cable assembly types with different combinations of the connectors at each end. These host and cable assembly types are referred to as form factors, distinguishing both the host receptacle (MDI) and the cable assembly plug.

Cable assemblies have three sets of electrical specifications, denoted CA-25G-L, CA-25G-S, and CA-25G-N, as specified in 110.10. The CA-25G-L specifications are based on a single lane of 100GBASE-CR4 cable assembly (see 92.10), enabling a 5 m length, and are compatible with 25GBASE-CR PHYs that operate in RS-FEC mode. The CA-25G-S specifications enable a shorter length of 3 m with lower loss than CA-25G-L, and are required for compatibility with 25GBASE-CR or 25GBASE-CR-S PHYs that operate in BASE-R FEC mode. The CA-25G-N specifications enable a shorter length of 3 m with lower loss than CA-25G-S, and are required for compatibility with 25GBASE-CR or 25GBASE-CR-S PHYs that operate in no-FEC mode.

The possible combinations of host form factors, cable assembly form factors and lengths are summarized in Table 110C–1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 110C–1—Host and cable assembly combinations

Cable assembly form factor	Cable assembly type	Host, first end	Hosts, second end	Length[a]	FEC modes supported[b]
SFP28 to SFP28 (see 110C.3.1)	CA-25G-L	One, SFP28 form factor (see 110C.2.1)	One, SFP28 form factor (see 110C.2.1)	5 m	RS-FEC
	CA-25G-S			3 m	RS-FEC BASE-R FEC
	CA-25G-N			3 m	RS-FEC BASE-R FEC no FEC
QSFP28 to QSFP28 (see 110C.3.2)	CA-25G-L	One, QSFP28 form factor (see 110C.2.2)	One, QSFP28 form factor (see 110C.2.2)	5 m	RS-FEC
	CA-25G-S			3 m	RS-FEC BASE-R FEC
	CA-25G-N			3 m	RS-FEC BASE-R FEC no FEC
QSFP28 to 4×SFP28 (see 110C.3.3)	CA-25G-L	One, QSFP28 form factor (see 110C.2.2)	Four, SFP28 form factor (see 110C.2.1)	5 m	RS-FEC
	CA-25G-S			3 m	RS-FEC BASE-R FEC
	CA-25G-N			3 m	RS-FEC BASE-R FEC no FEC

[a]Indicates the achievable length of compliant cable assemblies. It may be possible to construct compliant cable assemblies longer than indicated. Length of the cable assembly does not imply compliance to specifications.
[b]FEC mode is selected through Auto-Negotiation (Clause 73). See 110.6.

110C.2 Host form factors

110C.2.1 SFP28 host form factor

A host may use the SFP28 receptacle specified in 110.11.1 as the MDI for each 25GBASE-CR or 25GBASE-CR-S PHY. This is referred to as an SFP28 host form factor.

A SFP28 form factor host can form a single 25 Gb/s link to either another SFP28 form factor host, using a SFP28 to SFP28 form factor cable assembly (see 110C.3.1), or a QSFP28 form factor host (see 110C.2.2), using a QSFP28 to 4×SFP28 form factor cable assembly (see 110C.3.3).

110C.2.2 QSFP28 host form factor

A host may use the QSFP28 receptacle specified in 92.12 as the MDI for up to four 25GBASE-CR or 25GBASE-CR-S PHYs. This is referred to as a QSFP28 host form factor.

A QSFP28 form factor host can form up to four 25 Gb/s links to either another QSFP28 form factor host, using a QSFP28 to QSFP28 form factor cable assembly (see 110C.3.2), or to separate SFP28 form factor hosts (see 110C.2.1) using a QSFP28 to 4×SFP28 form factor cable assembly (see 110C.3.3).

110C.3 Cable assembly form factors

110C.3.1 SFP28 to SFP28 cable assembly form factor

The SFP28 to SFP28 cable assembly has SFP28 plugs, specified in 110.11.1, on both ends. It may be used to connect two SFP28 form factor hosts (see 110C.2.1) with a single 25 Gb/s link. The cable assembly is illustrated in Figure 110C–1.

The electrical characteristics of a cable assembly for this form factor are specified in 110.10, using the definitions in 110.10.7.2.1.

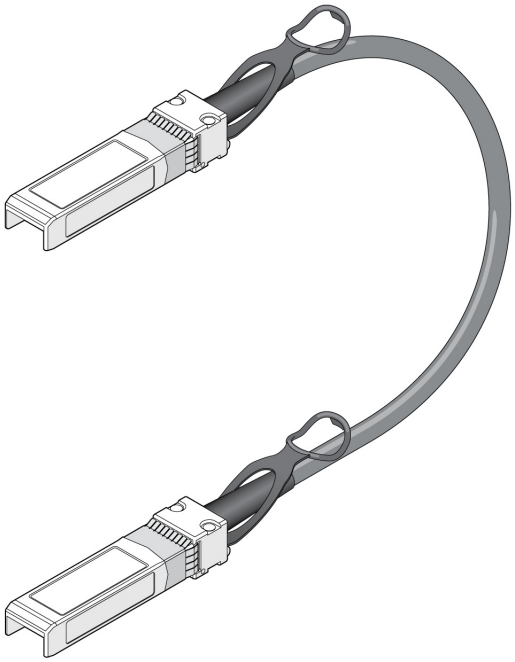

Figure 110C–1—SFP28 to SFP28 cable assembly

110C.3.2 QSFP28 to QSFP28 cable assembly form factor

The QSFP28 to QSFP28 cable assembly has QSFP28 plugs, specified in 92.12, on both ends. It may be used to connect two QSFP28 form factor hosts (see 110C.2.2) with up to four 25 Gb/s links. The cable assembly is illustrated in Figure 110C–2.

The electrical characteristics of a cable assembly for this form factor are specified in 110.10, using the definitions in 110.10.7.2.4.

110C.3.3 QSFP28 to 4×SFP28 cable assembly form factor

The QSFP28 to 4×SFP28 cable assembly has a QSFP28 plug as specified in 92.12 on one end, and four SFP28 plugs as specified in 110.11.1 on the other end. It may be used to connect a QSFP28 form factor host (see 110C.2.2) to up to four SFP28 form factor hosts (see 110C.2.1) with one 25 Gb/s link to each SFP28 host. The cable assembly is illustrated in Figure 110C–3.

Annex 113A

(informative)

Description of cable clamp and test setup

113A.1 Overview

This annex describes an example of a cable clamp and a representative methodology that should be used in common-mode noise rejection, rejection of external EM fields, or similar MultiGBASE-T receiver tests using EM clamp injection techniques, which are used to determine the sensitivity of the PMA receiver to external EM fields introduced by the cabling and interconnect system. Variations of this methodology may also be useful for other testing as applicable for design and development purposes. Refer to the receiver specifications of the PHY under test for specific impairments, impairment source power levels, and relevant frequency ranges.

113A.2 Description of cable clamp

NOTE—The larger inner diameter clamp is described here; see Annex 40B for the description of an alternate clamp for use with smaller diameter cable types.

As shown in Figure 113A–1 and Figure 113A–2 the clamp is 300 mm long, 75 mm wide, 78 mm high with a center opening of 9.53 mm (0.375 in). The clamp consists of two halves that permit the insertion of a cable into the clamp.

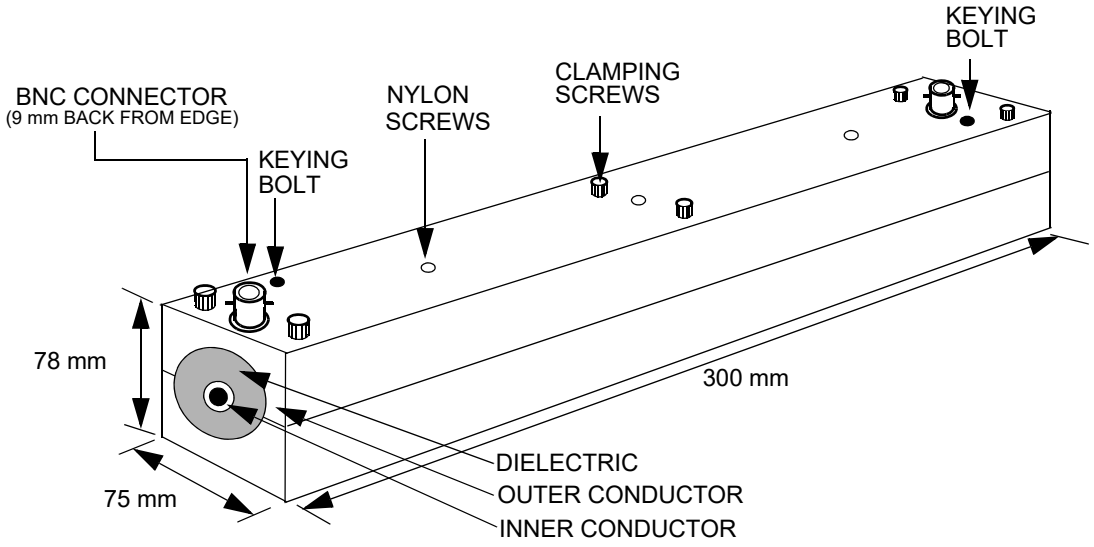

Figure 113A–1—Cable clamp

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The clamp has a copper center conductor and an aluminum outer conductor with a high density polyethylene dielectric. The following is a review of the construction and materials of the clamp:

a) *Inner conductor*—Copper tubing with an inner diameter of 9.53 mm (0.375 in) and an outer diameter of 12.7 mm (0.50 in).

b) *Outer conductor*—Aluminum bar that is 300 mm long and approximately 78 mm by 75 mm. The bar is milled to accept the outer diameter of the dielectric material.

c) *Dielectric*—High density polyethylene (residual, TypeF) with dielectric constant of 2.32. The hollow cylinder has an outside diameter of 45 mm and an inner diameter that accepts the outside diameter of the copper inner conductor.

d) *Connectors*—BNC connectors are located 9 mm (0.39 in) from each end of the clamp and are recessed into the outer conductor. The center conductor of the connector is connected to the inner conductor as shown in Figure 113A–2.

e) *Clamping screws*—Six screws are used to connect the two halves of the clamp together after the cable has been inserted. Although clamping screws are shown in Figure 113A–1, any clamping method may be used that ensures the two halves are connected electrically and permits quick assembly and disassembly.

f) *Nylon screws*—Used to align and secure the inner conductor and dielectric to the outer conductor. The use and location of the screws is left to the manufacturer.

g) *Keying bolts*—Two studs used to align the two halves of the clamp

The inner conductor on the bottom half of the clamp extends slightly (~ 0.1 mm) above the dielectric to ensure there is good electrical connection with the inner conductor of the top half of the clamp along the full length of the conductor when the two halves are clamped together.

The electrical parameters of the clamp between 1 MHz and 2000 MHz are summarized in Table 113A–1.

Table 113A–1—Cable clamp electrical parameters (1 MHz to 2000 MHz)

Frequency range	Insertion loss	Return loss
1 MHz to 250 MHz	< 0.2 dB	> 20.0 dB
250 MHz to 500 MHz	< 1.0 dB	> 7.0 dB
500 MHz to 1000 MHz	< 3.5 dB	> 3.5 dB
1000 MHz to 2000 MHz	< 15.0 dB	> 1.0 dB

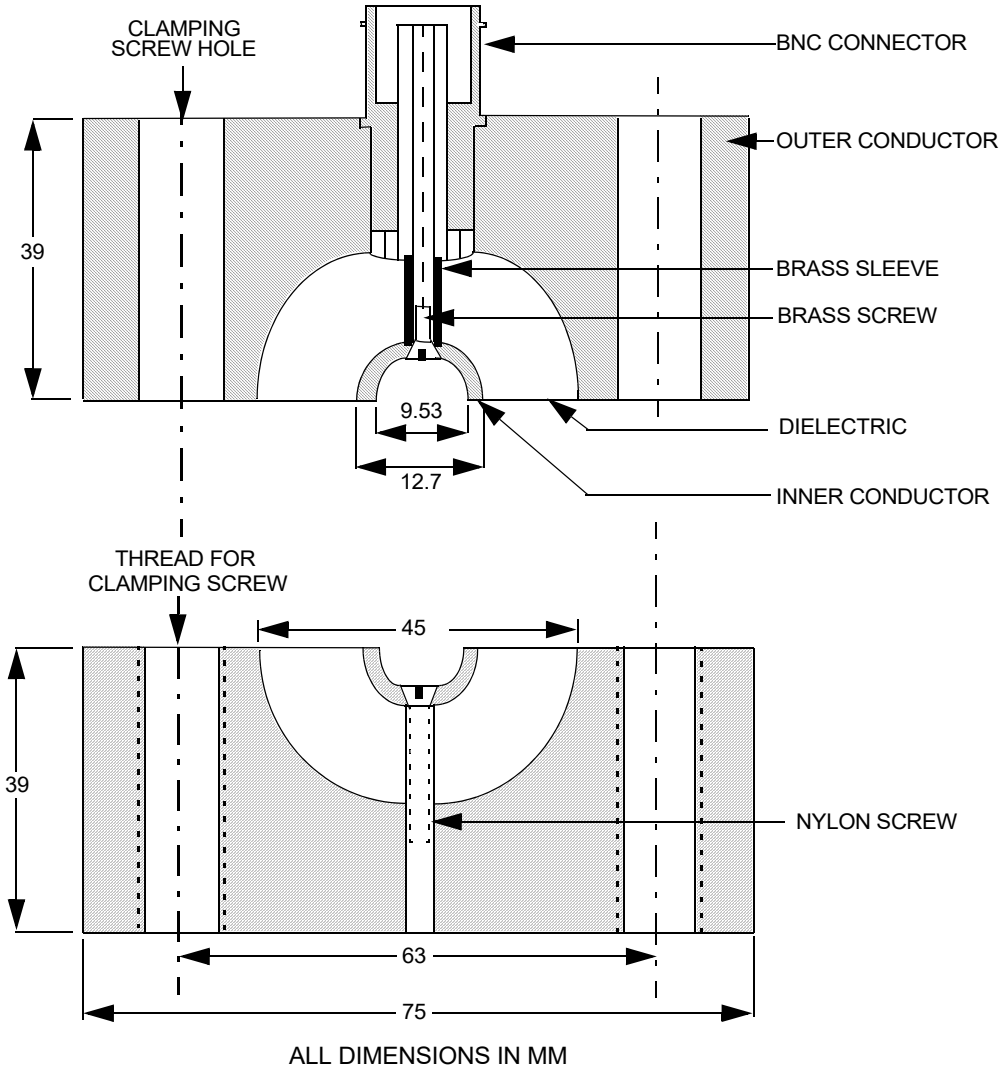

Figure 113A–2—Cross-section of cable clamp

113A.3 Cable clamp measurement, calibration, and validation

In order to ensure the cable clamp is operating correctly, the following electrical measurement, calibration, and validation procedures are provided and should be completed prior to conducting the test described in 113A.4 and illustrated in Figure 113A–4. Note that other methods are allowed providing they can demonstrate equivalent results to the method described in this annex.

Cable clamp electrical measurement—The clamp should be tested to ensure the insertion loss and return loss are as specified in Table 113A–1. Electrical parameters of the clamp are measured between the source connections and without cabling (that is, no cabling inserted in the clamp inner conductor).

Cable clamp calibration—Prior to making validation measurements or performing the test described in 113A.4, the cable clamp should be tested without the cable inserted to determine the variation of the signal generator voltage with frequency at the output of the clamp. The signal generator output should be adjusted to the specified signal power (for example, 6 dBm for 40GBASE-T) at 20 MHz on the signal sensor. The

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

signal generator output frequency is swept incrementally from 1 MHz to 2000 MHz with a step size that should not exceed 1% of the preceding frequency value. When the frequency is varied from 1 MHz to 2000 MHz, the measured power should not vary more than ±10%. If the power varies more than ±10%, then a correction factor may be applied at each measurement frequency. If used, the signal power correction factor should not result in common-mode and differential-mode voltages that exceed the limits defined in Table 113A–2.

Cable clamp validation—This validation procedure is provided to verify proper operation of the test setup before performing any tests. In contrast to the clamp electrical measurement, the cable clamp validation test procedure uses the clamp with cabling that meets the PHY link segment specifications inserted into the clamp.

The validation test hardware consists of the following:

a) Transmitter/receiver—A link partner system, configured for the data rate being evaluated, with the transmitter disabled.

b) Breakout fixture—A passive fixture with an MDI connector jack input and individual outputs for each of the 8 signal wires. Wires of pairs not being measured should be terminated to the ground plane with a 50 Ω resistor.

c) Balun—Three ports, laboratory quality with a 100 Ω balanced differential input (Port 1), a 50 Ω unbalanced single-ended output for the differential component (Port 2), and a 50 Ω unbalanced single-ended output for the common-mode component (Port 3):

   Insertion loss (Port 1 to Port 2): < 4 dB (1 MHz to 2000 MHz)

   Return loss (Port 1): > 8 dB (1 MHz to 3 MHz), > 15 dB (3 MHz to 2000 MHz)

   Common-mode rejection (Port 1 to Port 2):
   > 50 dB (1 MHz to 1000 MHz), > 40 dB up to 2000 MHz

   Common-mode return loss (Port 1): > 8 dB (1 MHz to 2000 MHz)

   Note that other devices for detecting differential and common-mode signals may also be used, provided the performance is demonstrated to be equivalent or better. The use of two separate differential and common-mode signal component measurement configurations is permissible provided the preceding specifications are met for each measurement device. The common-mode reference (termination) impedance may be standard specific. The common-mode return loss requirement does not change, but Z_{ref} (common-mode) may be 50 Ω for shielded and 75 Ω for unshielded applications.

d) 50 Ω resistors—Used to terminate unmeasured conductors.

e) Test cable—A 30 m, 4-pair 100 Ω plug-terminated cable that meets the PHY link segment specifications.

f) Chokes (minimum 5)—Wideband ferrite material:

   Inner diameter: Selected to minimize the gap between the ferrite and the test cable.

   Minimum impedance:
   175 Ω @ 100 MHz, 275 Ω @ 250 MHz, 375 Ω @ 500 MHz, 400 Ω @ 1000 MHz

g) Ground plane—Copper sheet or equivalent large enough to span the equipment interface under test and the clamp, including the portion of the cable between the equipment and the chokes (see Figure 113A–3).

h) Signal generator capable of providing a sine wave signal of 1 MHz to 2000 MHz, with adequate test power for adjustments, low harmonic distortion, and the ability to control and monitor power and frequency transitions.

i) Signal sensor and measurement system—Oscilloscopes, power meters, or spectrum analyzers with at least 4000 MHz bandwidth

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The signal generator may include elements needed to control signal generator performance, harmonic distortion, switching transients, and reflections so as not to influence signal level and frequency content at specified levels.

Figure 113A–3—Cable clamp validation test configuration

With the test cable inserted in the cable clamp, a signal generator with a 50 Ω output impedance is connected to one end of the cable clamp and a signal sensor with a 50 Ω input impedance is connected to the other end.

The signal generator should be capable of providing a sine wave signal of 1 MHz to 2000 MHz. The output of the signal generator is adjusted for the specified signal power at 20 MHz on the signal sensor. The remainder of the test is conducted without changing the signal generator voltage. The cable pairs not connected to the balun (or equivalent measurement network) are terminated in a resistor network. The cable clamp, breakout fixture, and balun are in direct contact with the ground plane in a manner consistent with good RF measurement practices. The chokes are placed on the cable, located next to each other and approximately 2.0 cm from the clamp.

The cable between the clamp and the breakout fixture should be positioned straight from the clamp to the breakout port and not contact the ground plane. Any plug shield contacts should mate with the breakout jack shield. The cable between the transmitter and the cable clamp should be installed either in a linear run or wrapped randomly on a cable rack. The cable rack should be at least 3 m from the cable clamp.

The differential-mode and common-mode voltage outputs of the balun and breakout fixture should meet the limits shown in Table 113A–2 over the frequency range 1 MHz to 2000 MHz for each cable pair.

Table 113A–2—Common- and differential-mode output voltages

Frequency (*f*)	Common-mode voltage	Differential-mode voltage
1 MHz to 30 MHz	< 0.1 + 0.97 (f / 30) Vpp	< 2.4 + 19.68 (f / 30) mVpp
30 MHz to 80 MHz	< 1.07 Vpp	< 22 mVpp (–29 dBm)
80 MHz to 250 MHz	< 1.07 – 0.6 (f-80) / 170 Vpp	< 22 mVpp (–29 dBm)
250 MHz to 2000 MHz	< 470mVpp (–2.6 dBm)	< 22 mVpp (–29 dBm)

After the setup has been validated, the clamp, cabling, and choke positions should remain unchanged when performing any receiver tests.

113A.4 Test setup

Cabling up to the maximum specified length that meets the link segment specification for the PHY under test (for example, 113.7 for 40GBASE-T) is connected between two such PHYs and inserted into the cable clamp. The cable should be terminated on each end with an MDI connector plug specified for the PHY under test (for example, 113.8.1 for 40GBASE-T).

The breakout fixture and balun are replaced by the transmitter/receiver under test, with the system port positioned at the original location of the breakout. The clamp should be located a distance of ~20 cm from the receiver port.

As described in the validation setup, the cable clamp and transmitter/receiver under test should be placed on a common ground plane and the system ground of the receiver should be in direct contact with the ground plane. The chassis grounds of all test equipment used should be connected to the ground plane. A signal generator with a 50 Ω impedance is connected to one end of the clamp and measurement equipment with a 50 Ω input is connected to the other end of the clamp. The signal generator should be capable of providing a sine wave signal of 1 MHz to 2000 MHz or other cable-clamp-coupled impairment as specified. See Figure 113A–4.

The output of the signal generator (as calibrated in 113A.3) is applied to the clamp input to simulate the specified impairment (for example, an external electromagnetic field of approximately 3 V/m). As with the calibration procedure, the signal generator output frequency is swept incrementally over the specified frequency range with a step size that should not exceed 1% of the preceding frequency value and with a dwell time at each step of at least 500 ms. The signal generator output should be controlled between steps to minimize any frequency switching transients.

NOTE—The signal generator may include elements needed to control signal generator performance, harmonic distortion, switching transients, and reflections so as not to influence signal level and frequency content at specified levels.

Annex 115A

(informative)

BCH codeword examples

This annex provides example BCH codewords produced by the physical header BCH encoder and the payload BCH encoder defined in Clause 115. This annex presents data in a tabular form to facilitate reading of data. The contents of the tables are transmitted from left to right within each row starting from the top row and ending at the bottom row. The tables contain hexadecimal representations of the data. For the hexadecimal representation, the most significant bit of each hex symbol is transmitted first.

115A.1 Output of the BCH(896, 720) encoder

Table 115A–1 contains an example output codeword of the systematic BCH(896, 720) encoder defined in 115.2.3.3. Because it is a systematic code, the first 720 bits are copied from the input. The input bits were produced by the physical header binary scrambler from the PHD plus CRC16 (see 115.2.3). The last 176 bits are the parity calculated by the BCH encoder.

Table 115A–1—BCH(896, 720) codeword

115A.2 Output of the BCH(1976, 1668) encoder

Table 115A–2 contains an example output codeword of the systematic BCH(1976, 1668) encoder defined in 115.2.4.3.2.

The BCH codeword in Table 115A–2 corresponds to the first MLCC codeword transmitted in a Transmit Block when a 1000BASE-H based PHY is configured in test mode 1 (see 115.5.1). Because it is a systematic code, the first 1668 bits of the BCH codeword are copied from the input. The input bits were transferred by the MLCC demultiplexer (see 115.2.4.3.1) from the payload data binary scrambler (115.2.4.2) to the BCH encoder. The last 308 bits are the parity calculated by the BCH encoder.

Annex 119A

(informative)

200GBASE-R and 400GBASE-R PCS FEC codeword examples

This annex provides example PCS FEC codewords produced by the 64B/66B to 256B/257B transcoding, scrambling, pre-FEC distribution, and Reed-Solomon encoding defined in Clause 119. This annex presents data in a tabular form. The contents of the tables are hexadecimal representations of the data and are transmitted to the symbol distribution function from left to right within each row starting from the top row and ending at the bottom row. The most significant bit of each hex symbol is transmitted first.

A constant transmission of Idle control characters is sent to the 256B/257B transcoder resulting in a continuous stream of 257-bit blocks, tx_xcoded<0:256>, shown in hex:

tx_xcoded<0:256> = 0070000000000000078000000000000007800000000000000780000000000000

In this example, an alignment marker is due for insertion and the scrambler seed [see Equation (49–1)] just before the 257-bit block was scrambled was:
S<0:57> = 24E6959D0FA5DBD

After scrambling and inserting the alignment marker group am_mapped, the variable tx_scrambled_am is produced as shown in Table 119A–1 for 200GBASE-R and Table 119A–2 for 400GBASE-R. In these tables, italicized characters are alignment markers and bold characters are padding for the alignment markers. Just prior to insertion, the seed of the PRBS9 generator used for padding was P<0:8> = 0x100.

After distributing into two message blocks, and PCS FEC encoding, codewords c_A and c_B are produced. c_A and c_B may be illustrated as two 5440-bit representations cx_A and cx_B as follows:

For all i=0 to 543:
cx_A <(10i+9):(10i)> = c_A<i>
cx_B <(10i+9):(10i)> = c_B<i>

The expanded codewords are shown in Table 119A–3 and Table 119A–4 for 200GBASE-R and Table 119A–5 and Table 119A–6 for 400GBASE-R (bold characters are parity).

The example codewords have tx_am_sf<2:0> = {0,0,0}.

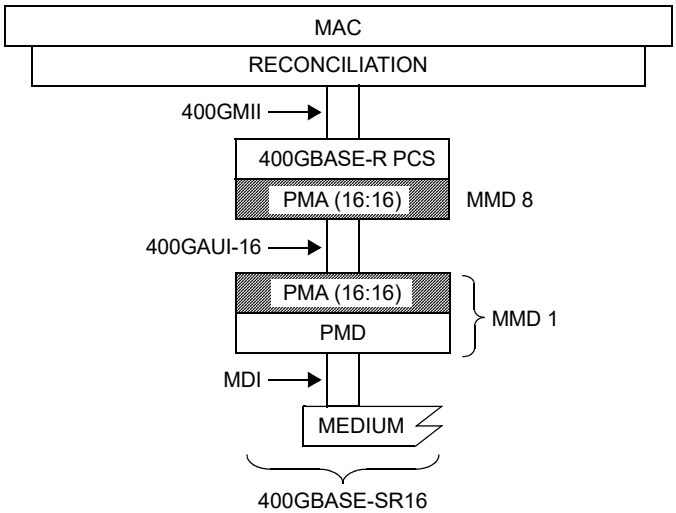
Annex 120A



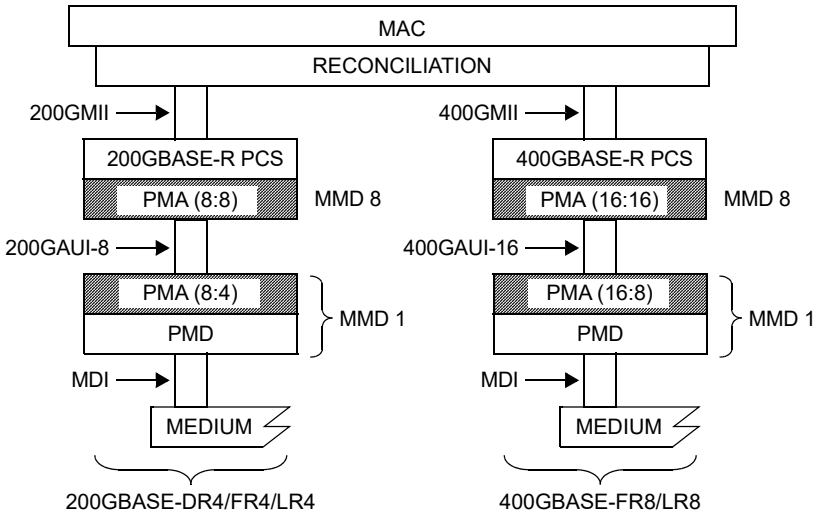
(informative)

200 Gb/s and 400 Gb/s PMA sublayer partitioning examples

The following subclauses provide various partitioning examples. Partitioning guidelines and MMD numbering conventions are described in 120.1.4.

120A.1 Partitioning example supporting 400GBASE-SR16

Figure 120A–1 depicts an example of 400GBASE-SR16 PMA layering with a single 400GAUI-16 chip-to-module interface.



400GAUI = 400 Gb/s ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120A–1—Example 400GBASE-SR16 PMA layering with single 400GAUI-16 chip-to-module interface

120A.2 Partitioning examples supporting 200GBASE-DR4/FR4/LR4 and 400GBASE-FR8/LR8

Figure 120A–2 depicts an example of 200GBASE-DR4/FR4/LR4 or 400GBASE-FR8/LR8 PMA layering with a single 200GAUI-8 or 400GAUI-16 chip-to-module interface.

200GAUI = 200 Gb/s ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
400GAUI = 400 Gb/s ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120A–2—Example 200GBASE-DR4/FR4/LR4 or 400GBASE-FR8/LR8 PMA layering with single 200GAUI-8 or 400GAUI-16 chip-to-module interface

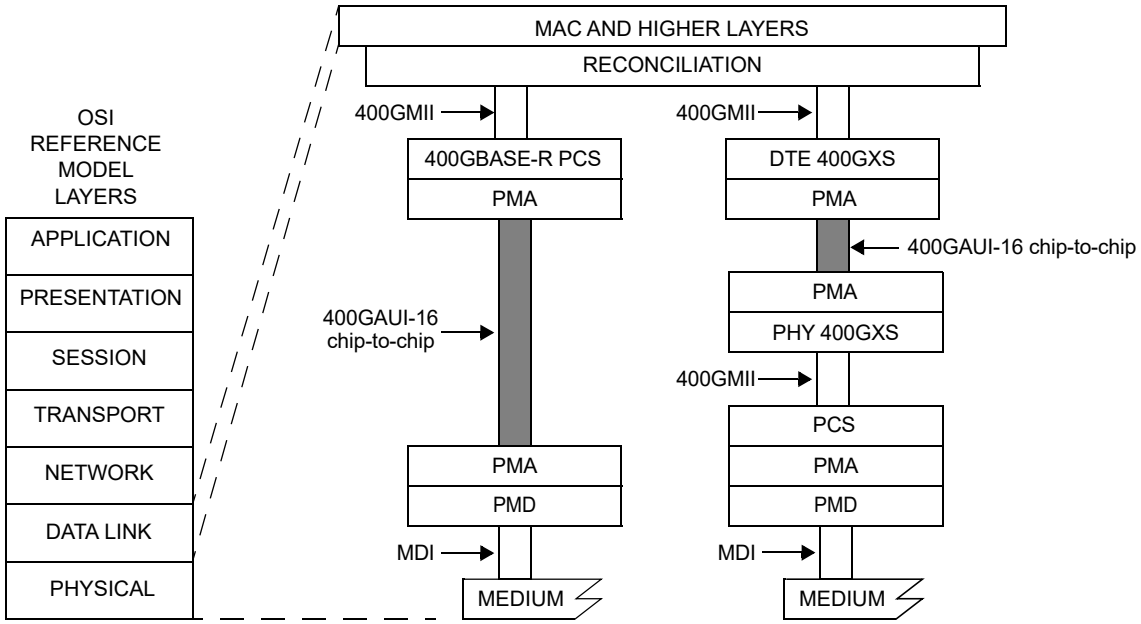
Annex 120B

(normative)

Chip-to-chip 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2C) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2C)

120B.1 Overview



This annex defines the functional and electrical characteristics for the optional chip-to-chip 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2C) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2C). Figure 120B–1 and Figure 120B–2 show example relationships of the 200GAUI-8 and 400GAUI-16 C2C interfaces to the ISO/IEC Open System Interconnection (OSI) reference model, respectively. The 200GAUI-8 and 400GAUI-16 C2C interfaces provide electrical characteristics and associated compliance points, which can optionally be used when designing systems with electrical interconnect of approximately 25 cm in length.

200GAUI-8 = 200 Gb/s EIGHT-LANE ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
200GXS = 200GMII EXTENDER SUBLAYER
DTE = DATA TERMINAL EQUIPMENT
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120B–1—Example 200GAUI-8 chip-to-chip relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

400GAUI-16 = 400 Gb/s SIXTEEN-LANE ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
400GXS = 400GMII EXTENDER SUBLAYER
DTE = DATA TERMINAL EQUIPMENT
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120B–2—Example 400GAUI-16 chip-to-chip relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The 200GAUI-8 C2C link is described in terms of a 200GAUI-8 C2C transmitter, a 200GAUI-8 C2C channel, and a 200GAUI-8 C2C receiver. Figure 120B–3 depicts a typical 200GAUI-8 C2C application, and Equation (83D–1) (illustrated in Figure 83D–3) summarizes the recommended differential insertion loss budget associated with the chip-to-chip application. The 200GAUI-8 C2C interface comprises independent data paths in each direction. Each data path contains eight AC-coupled differential lanes using 2-level NRZ (also known as PAM2) signaling, where the highest differential voltage level corresponds to the symbol one and the lowest level corresponds to the symbol zero. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

The 400GAUI-16 C2C link is described in terms of a 400GAUI-16 C2C transmitter, a 400GAUI-16 C2C channel, and a 400GAUI-16 C2C receiver. Figure 120B–4 depicts a typical 400GAUI-16 C2C application, and Equation (83D–1) (illustrated in Figure 83D–3) summarizes the recommended differential insertion loss budget associated with the chip-to-chip application. The 400GAUI-16 C2C interface comprises independent data paths in each direction. Each data path contains sixteen AC-coupled differential lanes using 2-level NRZ (also known as PAM2) signaling, where the highest differential voltage level corresponds to the symbol one and the lowest level corresponds to the symbol zero. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

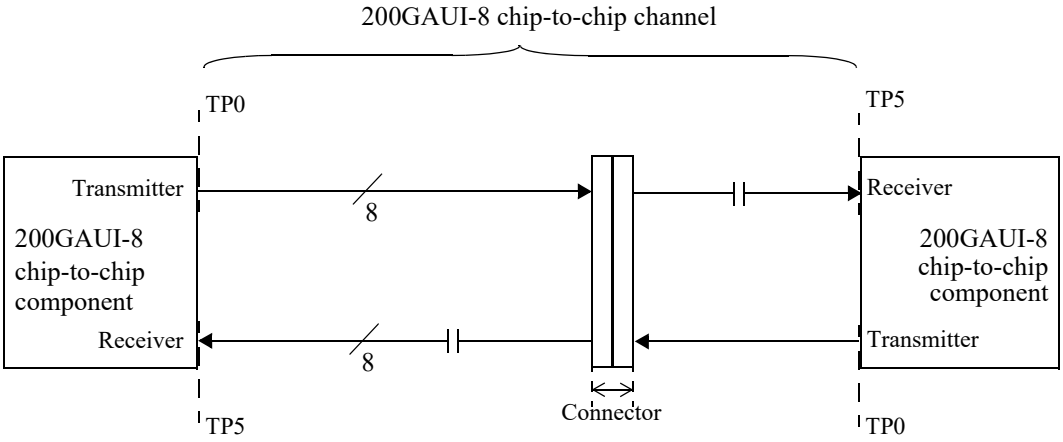

Figure 120B–3—Typical 200GAUI-8 chip-to-chip application

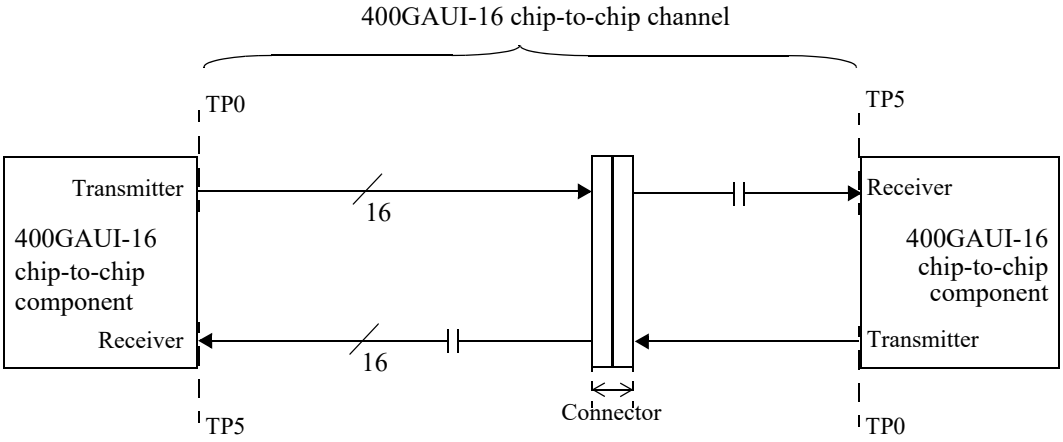

Figure 120B–4—Typical 400GAUI-16 chip-to-chip application

The nominal signaling rate for each lane is 26.5625 GBd. The 200GAUI-8 C2C or 400GAUI-16 C2C transmitter on each end of the link is adjusted to an appropriate setting based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 83D.3.3.2 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

The normative channel compliance is through 200GAUI-8 C2C or 400GAUI-16 C2C channel operating margin (COM) as described in 120B.4. Actual channel loss could be higher or lower than that given by Equation (83D–1) due to the channel ILD, return loss, and crosstalk.

120B.2 200GAUI-8 and 400GAUI-16 chip-to-chip compliance point definition

The compliance points for the 200GAUI-8 and 400GAUI-16 chip-to-chip interfaces are as defined in 83D.2.

120B.3 200GAUI-8 and 400GAUI-16 chip-to-chip electrical characteristics

120B.3.1 200GAUI-8 and 400GAUI-16 C2C transmitter characteristics

A 200GAUI-8 or a 400GAUI-16 chip-to-chip transmitter shall meet all specifications in 83D.3.1 with the following exceptions:

- The signaling rate per lane is 26.5625 GBd ± 100 ppm.
- The value for the "Linear fit pulse peak (min)" in Table 83D–1 is $0.75 \times v_f$.
- The value for the "Effective total uncorrelated jitter, peak-to-peak" in Table 83D–1 is 0.19 UI.
- The value of the probability in Table 83D–1 footnote d is 10^{-6}.
- The high-pass filter used for the jitter measurements in 92.8.3.8 has a 3 dB frequency of 4 MHz.

If a Clause 45 MDIO is implemented, *Local_eq_cm1* and *Local_eq_c1* for each lane (0 through 7 for 200GAUI-8 and 0 through 15 for 400GAUI-16) and direction (transmit and receive) are accessible through registers 1.500 through 1.531 (see 45.2.1.135 through 45.2.1.138).

120B.3.2 200GAUI-8 and 400GAUI-16 C2C receiver characteristics

A 200GAUI-8 or a 400GAUI-16 chip-to-chip receiver shall meet all specifications in 83D.3.3 with the following exceptions:

- The signaling rate per lane is 26.5625 GBd ± 100 ppm.
- The "Bit error ratio" parameter in Table 83D–5 is replaced with "PCS FEC symbol error ratio" with max values of 1.1×10^{-5}.
- The target values for the parameter "COM including effects of broadband noise" in Table 83D–5 are 3 dB.
- The transmitter device package model $S^{(tp)}$ is omitted from Equation (93A–3) in the calculation of COM. The filtered voltage transfer function $H^{(k)}(f)$ calculated in Equation (93A–19) uses the filter $H_t(f)$ defined by Equation (93A–46), where T_r is calculated as $T_r = 1.09 \times T_{\mathrm{rm}} - 4.32$ ps and T_{rm} is the measured 20% to 80% transition time of the signal at TP0a. T_{rm} is measured using the method in 86A.5.3.3, with the exception that the observation filter bandwidth is 33 GHz instead of 12 GHz. T_{rm} is measured with the transmit equalizer turned off (i.e., *Local_eq_cm1* and *Local_eq_c*1 both equal to zero, see 83D.3.1.1).
- Table 83D–5 footnote a is replaced by Table 93–6 footnote a.
- Table 83D–5 footnote b does not apply.
- The "Applied pk-pk sinusoidal jitter" for Test 1 and Test 2 in Table 83D–5 is according to Table 87–13.

If the 200GAUI-8 or 400GAUI-16 chip-to-chip receiver supports the optional transmitter equalization feedback, it shall meet all requirements in 83D.3.3.2. If a Clause 45 MDIO is implemented, the variables *Request_flag*, *Requested_eq_cm1*, *Requested_eq_c1*, *Remote_eq_cm1*, and *Remote_eq_c1* for each lane (0 through 7 for 200GAUI-8 and 0 through 15 for 400GAUI-16) and direction are accessible through registers 1.500 through 1.531 (see 45.2.1.135 through 45.2.1.138).

120B.4 200GAUI-8 and 400GAUI-16 chip-to-chip channel characteristics

The 200GAUI-8 or 400GAUI-16 chip-to-chip channel shall meet the requirements specified in 83D.4 with the following exceptions:

— The signaling rate per lane is 26.5625 GBd ± 100 ppm.

— The "Target detector error ratio" (DER_0) value in Table 83D–6 is 10^{-6}.

— The "Normalized DFE coefficient magnitude limit, for n = 1 to N_b" ($b_{max}(n)$) value in Table 83D–6 is 1.

— The Channel Operating Margin (COM) shall be greater than or equal to 3 dB.

120B.5 Protocol implementation conformance statement (PICS) proforma for Annex 120B, Chip-to-chip 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2C) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2C)[306]

120B.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 120B, Chip-to-chip 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2C) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2C), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

120B.5.2 Identification

120B.5.2.1 Implementation identification

Annex 120C

(normative)

Chip-to-module 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2M) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2M)

120C.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2M) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2M). Figure 120C–1 shows the relationship of the 200GAUI-8 and 400GAUI-16 C2M interfaces to the ISO/IEC Open System Interconnection (OSI) reference model. The chip-to-module interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable module interfaces.

200GAUI-8 = 200 Gb/s EIGHT-LANE ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
400GAUI-16 = 400 Gb/s SIXTEEN-LANE ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120C–1—Example 200GAUI-8 and 400GAUI-16 chip-to-module relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The sublayers (including the PCS and associated FEC) of each PHY that can optionally include a 200GAUI-8 C2M or 400GAUI-16 C2M are summarized in the tables in 116.1.4 and are specified in the corresponding PMD clause. The positioning of the 200GAUI-8 C2M or 400GAUI-16 C2M relative to other sublayers is shown in 120.1 with further examples in Annex 120A.

The 200GAUI-8 C2M link is described in terms of a host 200GAUI-8 C2M component, a 200GAUI-8 C2M channel with associated insertion loss, and a module 200GAUI-8 C2M component. Figure 120C–2 depicts a typical 200GAUI-8 C2M application and summarizes the differential insertion loss budget associated with the chip-to-module application. The supported insertion loss budget is characterized by Equation (83E–1) and illustrated in Figure 83E–3. The 200GAUI-8 C2M interface comprises independent data paths in each direction. Each data path contains eight differential lanes using 2-level NRZ (also known as PAM2) signaling, where the highest differential voltage level corresponds to the symbol one and the lowest level corresponds to the symbol zero. Each lane is AC-coupled within the module.

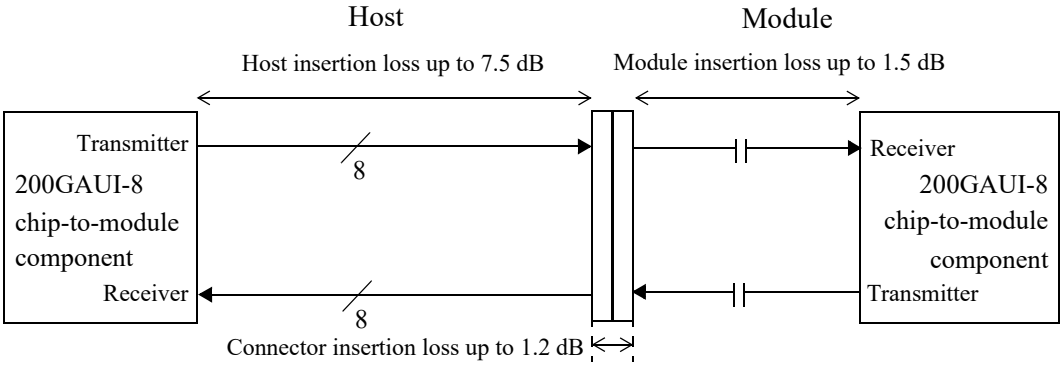

Figure 120C–2—200GAUI-8 chip-to-module insertion loss budget at 13.28 GHz

The 400GAUI-16 C2M link is described in terms of a host 400GAUI-16 C2M component, a 400GAUI-16 C2M channel with associated insertion loss, and a module 400GAUI-16 C2M component. Figure 120C–3 depicts a typical 400GAUI-16 C2M application and summarizes the differential insertion loss budget associated with the chip-to-module application. The supported insertion loss budget is characterized by Equation (83E–1) and illustrated in Figure 83E–3. The 400GAUI-16 C2M interface comprises independent data paths in each direction. Each data path contains sixteen differential lanes using 2-level NRZ (also known as PAM2) signaling, where the highest differential voltage level corresponds to the symbol one and the lowest level corresponds to the symbol zero. Each lane is AC-coupled within the module.

The nominal signaling rate for each lane is 26.5625 GBd. The 200GAUI-8 and 400GAUI-16 chip-to-module interfaces are defined using a specification and test methodology that is similar to that used for CEI-28G-VSR defined in OIF-CEI-03.1 [B57].

120C.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 10^{-6}.

120C.2 200GAUI-8 and 400GAUI-16 chip-to-module compliance point definitions

The compliance points for the 200GAUI-8 and 400GAUI-16 chip-to-module interfaces are as defined in 83E.2.

120C.3 200GAUI-8 and 400GAUI-16 chip-to-module electrical characteristics

120C.3.1 200GAUI-8 and 400GAUI-16 C2M host output characteristics

A 200GAUI-8 or 400GAUI-16 C2M host output shall meet all specifications in 83E.3.1 with the following exceptions:

— The signaling rate per lane is 26.5625 GBd ± 100 ppm.
— The clock recovery unit corner frequency is 4 MHz.

If a Clause 45 MDIO is implemented, the variable *Recommended_CTLE_value* is accessible in the module for lanes 0 through 7 for 200GAUI-8 and 0 through 15 for 400GAUI-16 through registers 1.400 to 1.415 (see 45.2.1.111 and 45.2.1.133).

120C.3.2 200GAUI-8 and 400GAUI-16 C2M module output characteristics

A 200GAUI-8 or a 400GAUI-16 C2M module output shall meet all specifications in 83E.3.2 with the following exceptions:

— The signaling rate per lane is 26.5625 GBd ± 100 ppm.
— The eye height, eye width, and vertical eye closure are as specified in 109B.3.2.1 for a PHY that includes an RS-FEC sublayer.
— The clock recovery unit corner frequency is 4 MHz.

120C.3.3 200GAUI-8 and 400GAUI-16 C2M host input characteristics

A 200GAUI-8 or a 400GAUI-16 C2M host input shall meet all specifications in 83E.3.3 with the following exceptions:

— The signaling rate per lane is 26.5625 GBd ± 100 ppm.
— The BER for the host stressed input test meets the requirement in 120C.1.1 rather than those in 83E.1.1.
— The “Applied pk-pk sinusoidal jitter” in Table 83E–5 is according to Table 87–13.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

120C.3.4 200GAUI-8 and 400GAUI-16 C2M module input characteristics

A 200GAUI-8 or a 400GAUI-16 C2M module input shall meet all specifications in 83E.3.4 with the following exceptions:

— The signaling rate per lane is 26.5625 GBd ± 100 ppm.

— The BER for the module stressed input test meets the requirement in 120C.1.1 rather than those in 83E.1.1.

— The "Applied pk-pk sinusoidal jitter" in Table 83E–8 is according to Table 87–13.

Channel equalization is provided by an equalizer in the module which uses the *Recommended_CTLE_value* provided by the host or an adaptive equalizer in the module which does not use the setting provided by the host.

If a Clause 45 MDIO is implemented, the variable *Recommended_CTLE_value* is accessible in the module for lanes 0 through 7 for 200GAUI-8 and 0 through 15 for 400GAUI-16 through registers 1.400 to 1.415 (see 45.2.1.111 and 45.2.1.133).

120C.4 200GAUI-8 and 400GAUI-16 C2M measurement methodology

The 200GAUI-8 and 400GAUI-16 C2M measurement methodology is as defined in 83E.4 with the following exceptions:

— The module output eye height, eye width, and vertical eye closure are measured as specified in 109B.3.2.1 for a PHY that includes an RS-FEC sublayer.

120C.5 Protocol implementation conformance statement (PICS) proforma for Annex 120C, Chip-to-module 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2M) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2M)[307]

120C.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 120C, Chip-to-module 200 Gb/s eight-lane Attachment Unit Interface (200GAUI-8 C2M) and 400 Gb/s sixteen-lane Attachment Unit Interface (400GAUI-16 C2M), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

120C.5.2 Identification

120C.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]

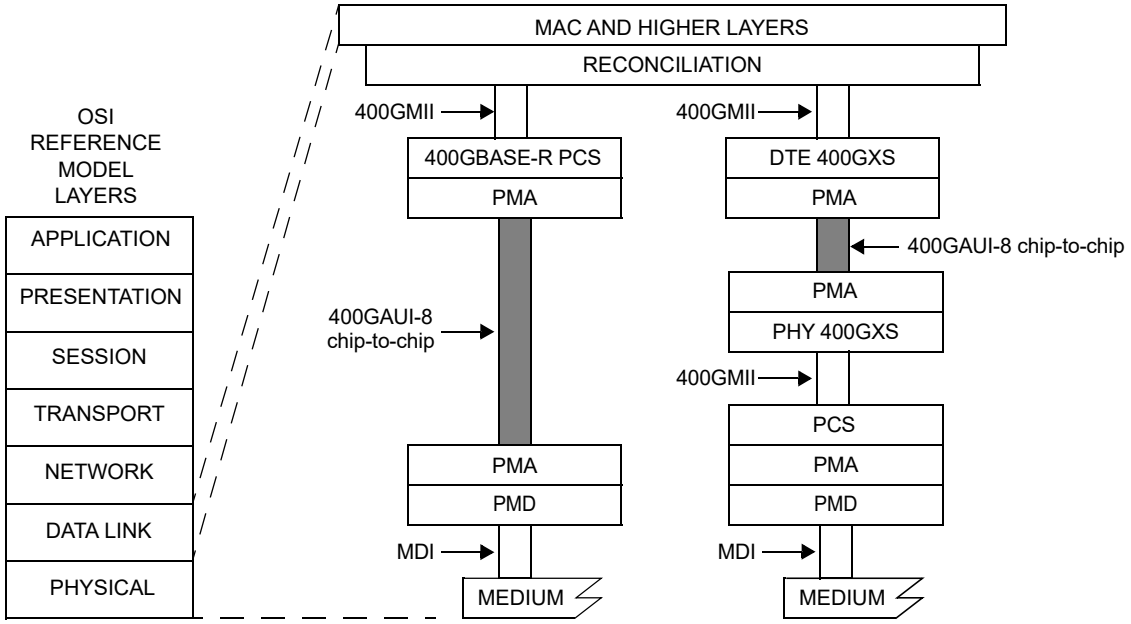
Annex 120D

(normative)

Chip-to-chip 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2C) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2C)

120D.1 Overview



This annex defines the functional and electrical characteristics for the optional chip-to-chip 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2C) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2C). Figure 120D–1 and Figure 120D–2 show example relationships of the 200GAUI-4 and 400GAUI-8 C2C interfaces to the ISO/IEC Open System Interconnection (OSI) reference model, respectively. The 200GAUI-4 and 400GAUI-8 C2C interfaces provide electrical characteristics and associated compliance points, which can optionally be used when designing systems with electrical interconnect of approximately 25 cm in length.

200GAUI-4 = 200 Gb/s FOUR-LANE ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
200GXS = 200GMII EXTENDER SUBLAYER
DTE = DATA TERMINAL EQUIPMENT
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120D–1—Example 200GAUI-4 chip-to-chip relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

400GAUI-8 = 400 Gb/s EIGHT-LANE ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
400GXS = 400GMII EXTENDER SUBLAYER
DTE = DATA TERMINAL EQUIPMENT
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120D–2—Example 400GAUI-8 chip-to-chip relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The 200GAUI-4 C2C link is described in terms of a 200GAUI-4 C2C transmitter, a 200GAUI-4 C2C channel, and a 200GAUI-4 C2C receiver. Figure 120D–3 depicts a typical 200GAUI-4 C2C application, and Equation (120D–1) (illustrated in Figure 120D–5) summarizes the recommended differential insertion loss budget associated with the chip-to-chip application. The 200GAUI-4 C2C interface comprises independent data paths in each direction. Each data path contains four AC-coupled differential lanes using PAM4 signaling, where the highest differential level corresponds to the symbol three and the lowest level corresponds to the symbol zero. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

The 400GAUI-8 C2C link is described in terms of a 400GAUI-8 C2C transmitter, a 400GAUI-8 C2C channel, and a 400GAUI-8 C2C receiver. Figure 120D–4 depicts a typical 400GAUI-8 C2C application, and Equation (120D–1) (illustrated in Figure 120D–5) summarizes the recommended differential insertion loss budget associated with the chip-to-chip application. The 400GAUI-8 C2C interface comprises independent data paths in each direction. Each data path contains eight AC-coupled differential lanes using PAM4 signaling, where the highest differential level corresponds to the symbol three and the lowest level corresponds to the symbol zero. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

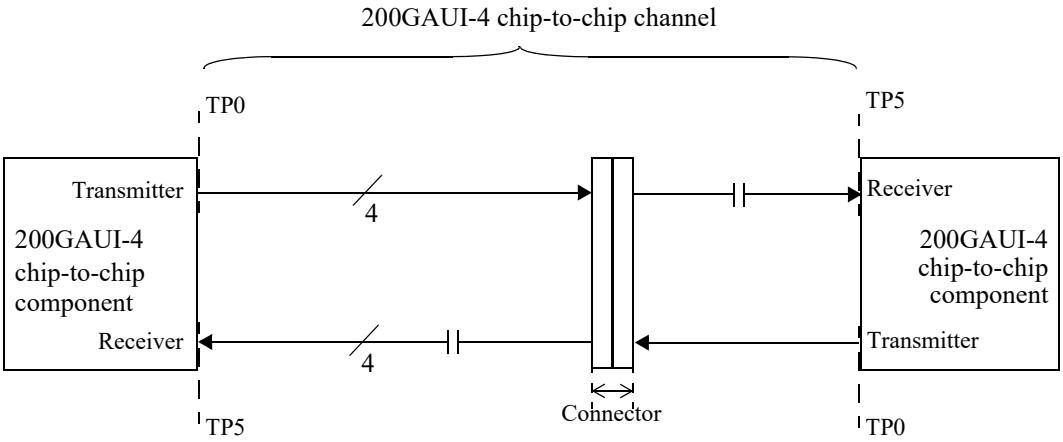

Figure 120D–3—Typical 200GAUI-4 chip-to-chip application

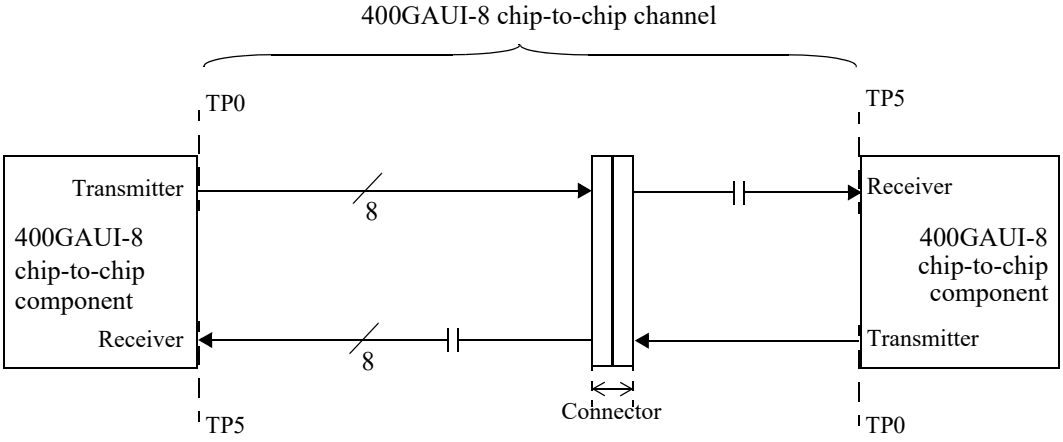

Figure 120D–4—Typical 400GAUI-8 chip-to-chip application

The nominal signaling rate for each lane is 26.5625 GBd. The 200GAUI-4 C2C or 400GAUI-8 C2C transmitter on each end of the link is adjusted to an appropriate setting based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 120D.3.2.3 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

The channel is normatively defined using channel operating margin (COM) as described in 120D.4. Actual channel loss could be higher or lower than that given by Equation (120D–1) due to the channel ILD, return loss, and crosstalk. Note that for this equation the channel loss at the Nyquist frequency is lower than or equal to 20.457 dB.

$$Insertion_loss(f) \le 1.083 + 2.543\sqrt{f} + 0.761f \quad \text{(dB)}$$
$$\text{for } 0.01 \le f \le 26.5625 \qquad \text{(120D–1)}$$

where

f is the frequency in GHz

Insertion_loss(f) is the recommended 200GAUI-4 or 400GAUI-8 chip-to-chip insertion loss

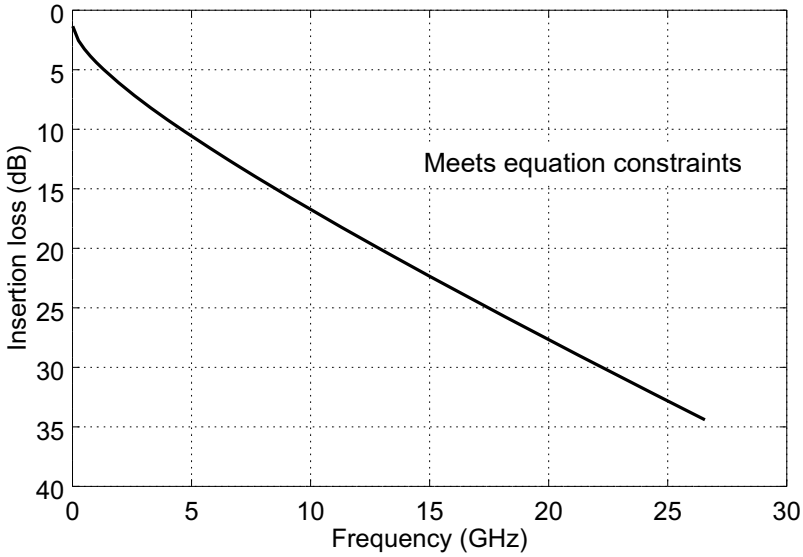

Figure 120D–5—200GAUI-4 or 400GAUI-8 chip-to-chip channel insertion loss

120D.2 200GAUI-4 and 400GAUI-8 chip-to-chip compliance point definition

The electrical characteristics for the 200GAUI-4 and 400GAUI-8 chip-to-chip interfaces are defined at compliance points for the transmitter (TP0a) and receiver (TP5a). The location of TP0a and electrical characteristics of the test fixture used to measure transmitter characteristics are defined in Figure 93–5 and 93.8.1.1, respectively, with the exception that the upper frequency for Equation (93–1) and Equation (93–2) is 26.5625 GHz. The location of TP5a and electrical characteristics of the test fixture used to measure the receiver are defined in Figure 93–10 and 93.8.2.1, respectively, with the exception that the upper frequency for Equation (93–1) and Equation (93–2) is 26.5625 GHz.

120D.3 200GAUI-4 and 400GAUI-8 chip-to-chip electrical characteristics

120D.3.1 200GAUI-4 and 400GAUI-8 C2C transmitter characteristics

A 200GAUI-4 or a 400GAUI-8 chip-to-chip transmitter shall meet the specifications given in Table 120D–1. The transmit output waveform may optionally be manipulated via the feedback mechanism described in 120D.3.2.3.

A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all transmitter signal measurements, unless otherwise specified.

[a]Measurement uses the method described in 93.8.1.3 with the exception that the PRBS13Q test pattern is used.
[b]The state of the transmit equalizer is controlled by management interface.

120D.3.1.1 Transmitter differential output return loss

The differential output return loss, in dB, of the transmitter shall meet Equation (120D–2) where f is the frequency in GHz. This requirement applies to all valid output levels. The reference impedance for differential return loss is $100\,\Omega$. The test fixture return loss may be de-embedded from return loss measurements. For the treatment of the insertion loss of the test fixture see 93.8.1.1.

$$RL_d(f) \geq \begin{cases} 14.25 - f & 0.05 \leq f \leq 6 \\ 8.7 - 0.075f & 6 < f \leq 19 \end{cases} \quad \text{dB} \qquad \text{(120D–2)}$$

The differential return loss limit is illustrated by Figure 120D–6.

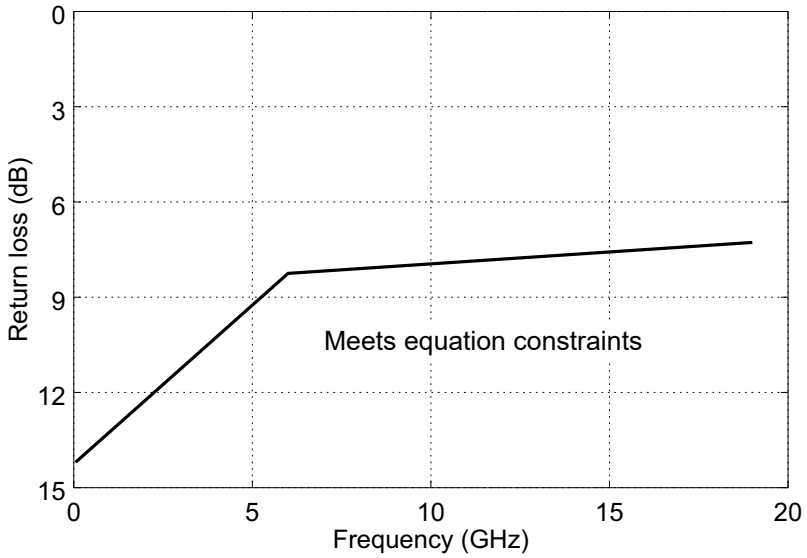

Figure 120D–6—Differential return loss limit

120D.3.1.2 Transmitter linearity

Transmitter linearity is defined as a function of the mean signal level transmitted for each PAM4 symbol level. The mean signal levels of the symbols corresponding to the PAM4 symbol levels 0, 1, 2, and 3 are defined as V_0, V_1, V_2, and V_3 respectively, as defined in 120D.3.1.2.1. The mid-range level V_{mid} is defined by Equation (120D–3). The mean signal levels are then normalized and offset adjusted so that V_{mid} corresponds to 0, V_0 to −1, V_1 to $-ES1$, V_2 to $ES2$, and V_3 to 1. $ES1$ is defined by Equation (120D–4) and $ES2$ is defined by Equation (120D–5).

$$V_{\text{mid}} = \frac{V_0 + V_3}{2} \tag{120D–3}$$

$$ES1 = \frac{V_1 - V_{\text{mid}}}{V_0 - V_{\text{mid}}} \tag{120D–4}$$

$$ES2 = \frac{V_2 - V_{\text{mid}}}{V_3 - V_{\text{mid}}} \tag{120D–5}$$

The level separation mismatch ratio R_{LM} is defined by Equation (120D–6).

$$R_{\text{LM}} = \min((3 \times ES1), (3 \times ES2), (2 - 3 \times ES1), (2 - 3 \times ES2)) \tag{120D–6}$$

120D.3.1.2.1 Measurement of mean signal levels

The signal levels are measured from a waveform captured using the procedure defined in 85.8.3.3.4 while the transmitter is transmitting the PRBS13Q test pattern. The waveform consists of M samples per unit interval and is aligned such that the first M samples of the waveform correspond to the first PAM4 symbol of the test pattern, the second M samples to the second PAM4 symbol, and so on. This allows each sample of the waveform to be associated with a specific PAM4 symbol in the test pattern.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Denote the number of PAM4 symbols in the test pattern as N. Reduce the captured waveform to N samples by choosing the central sample from each unit interval. The central sample is defined as m^{th} sample in a given unit interval where m is the integer closest to $M/2$.

For each PAM4 symbol level x, V_x is the mean value of the waveform samples that correspond to that symbol level.

120D.3.1.3 Linear fit to the measured waveform

The following test procedure shall be followed to determine the linear fit pulse response, linear fit error, and normalized transmitter coefficient values.

For each configuration of the transmit equalizer, capture at least one complete cycle of the PRBS13Q test pattern (120.5.11.2.1) at TP0a per 85.8.3.3.4.

Compute the linear fit pulse response $p(k)$ and linear fit error $e(k)$ from the captured waveform per 85.8.3.3.5 using $N_p = 200$ and $D_p = 2$. The aligned symbols *x(n)* are assigned normalized amplitudes −1, $-ES$, ES, and 1 to represent the PAM4 symbol values 0, 1, 2, and 3 respectively. ES is defined to be $(|ES1| + |ES2|)/2$ where *ES1* and *ES2* are defined in 120D.3.1.2.

Define $r(k)$ to be the linear fit pulse response with *Local_eq_cm1* and *Local_eq_c1* set to zero.

For each configuration of the transmit equalizer, compute the normalized transmit equalizer coefficients, *c(i)*, according to 92.8.3.5.1.

The clock recovery unit (CRU) used in the output waveform measurement has a corner frequency of 4 MHz and a slope of 20 dB/decade

120D.3.1.4 Steady-state voltage and linear fit pulse peak

The linear fit pulse, $p(k)$, is determined according to the linear fit procedure in 120D.3.1.3 with *Local_eq_cm1* and *Local_eq_c1* set to zero. The steady-state voltage v_f is defined to be the sum of the linear fit pulse $p(1)$ through $p(M \times N_v)$ divided by M, determined in step 3 of the linear fit procedure. Here, N_v represents the number of symbols to take into account for the steady-state voltage v_f and has a value of 13.

120D.3.1.5 Transmitter equalization settings

The 200GAUI-4 and 400GAUI-8 chip-to-chip transmitters include programmable equalization to compensate for the frequency-dependent loss of the channel and to facilitate data recovery at the receiver. The functional model for the transmit equalizer is the three tap transversal filter shown in Figure 120D–7. The transmitter output equalization is characterized using the linear fit method described in 120D.3.1.3.

The state of the 200GAUI-4 or 400GAUI-8 C2C transmit output is manipulated via management.

The variable *Local_eq_cm1* controls the weight of the pre-cursor tap $c(-1)$, by changing the ratio $c(-1)/(|c(-1)|+|c(0)|+|c(1)|)$. The valid values of *Local_eq_cm1* and the corresponding ratios are specified in Table 120D–2. The variable *Local_eq_c1* controls the weight of the post-cursor tap $c(1)$, by changing the ratio $c(1)/(|c(-1)|+|c(0)|+|c(1)|)$. The valid values of *Local_eq_c1* and the corresponding ratios are specified in Table 120D–3. *Local_eq_cm1* and *Local_eq_c1* are independent of each other and independent on each lane. Each successive step in *Local_eq_cm1* and *Local_eq_c1* value shall result in a monotonic change in transmitter equalization.

120D.3.1.6 Transmitter output noise and distortion

Signal-to-noise and distortion ratio (SNDR) is measured at the transmitter output using the following method, with transmitters on all lanes enabled, with identical transmit equalizer settings, and the lanes not under test transmitting PRBS31Q or a valid 200GBASE-R or 400GBASE-R signal.

Compute the linear fit to the captured waveform and the linear fit pulse response, $p(k)$, and error, $e(k)$, according to 120D.3.1.3. Denote the standard deviation of $e(k)$ as σ_e.

Using the same configuration of the transmitter equalizer, measure the RMS deviation from the mean voltage at a fixed low-slope point in runs of at least 6 consecutive identical PAM4 symbols. PRBS13Q includes such a run for each of the PAM4 levels. The average of the four measurements is denoted as σ_n.

SNDR is defined by Equation (120D–7) where $p_{\max}$ is the maximum value of $p(k)$.

$$SNDR = 10\log_{10}\left(\frac{p_{\max}^2}{\sigma_e^2 + \sigma_n^2}\right) \quad \text{(120D–7)}$$

120D.3.1.7 Transmitter output residual ISI

SNR_{ISI} is defined by Equation (120D–9) computed from $p_{\max}$ and ISI_{cursors} after these have been re-calculated with the continuous time filter described in 93A.1.4.3 using the parameters in Table 120D–8 applied and optimized for maximum SNR_{ISI}. The SNR_{ISI} specification shall be met for all transmit equalization settings.

$$ISI_{\text{cursors}} = [p(t_p + M \times (N_b + 1)), p(t_p + M \times (N_b + 2)), \ldots, p(t_p + M \times (N_p - D_p - 1))] \quad \text{(120D–8)}$$

$$SNR_{\text{ISI}} = 20\log_{10}\left(\frac{p_{\max}}{\sqrt{\sum(ISI_{\text{cursors}}{}^2)}}\right) \quad \text{(120D–9)}$$

ISI_{cursors} are computed from the linear fit pulse response, $p(k)$ in accordance with 120D.3.1.3, using Equation (120D–8), where

t_p is the index of the linear fit pulse where $p(t_p)$ equals $p_{\max}$
M is the oversampling ratio of the measured waveform and linear fit pulse as defined in 85.8.3.3.4
N_p is the linear fit pulse length given in 120D.3.1.3
N_b is given in Table 120D–8

NOTE—The observed SNR_{ISI} can be significantly influenced by the measurement setup, e.g., reflections in cables and connectors. High-precision measurement and careful calibration of the setup are recommended.

120D.3.1.8 Output jitter

J4u, J_{RMS}, and Even-odd jitter are defined by measurements of 12 specific transitions in a PRBS13Q pattern (see 120.5.11.2.1) in order to exclude correlated jitter. The 12 transitions represent all possible combinations of four identical symbols followed by two different identical symbols as shown in Table 120D–4. The sequences are located by the symbol indices given in the table where symbols 1 to 7 are the run of seven 3s.

The threshold used to define each transition is given in Table 120D–4 where V_0, V_1, V_2, and V_3 are as defined in 120D.3.1.2.

F20	2 to 0 fall	122222 0000002	7282	7287	7288	7294	
R13	1 to 3 rise	011111 331	133	138	139	141	$(V_1+V_3)/2$
F31	3 to 1 fall	23333 112	7905	7909	7910	7912	

The jitter is measured with a clock recovery unit (CRU) with a corner frequency of 4 MHz and a slope of 20 dB/decade. Jitter measurements are performed with transmitters on all lanes enabled and using identical transmitter equalizer settings. Transmitters on lanes not under test transmit PRBS31Q, or a valid 200GBASE-R or 400GBASE-R signal. PRBS31Q is described in 120.5.11.2.2.

The J4u, J_{RMS}, and Even-odd jitter specifications shall be met regardless of the transmit equalization setting.

120D.3.1.8.1 J4u and J_{RMS} jitter

For each transition i, $1 \le i \le 12$, of the transitions specified in Table 120D–4, obtain a set $S_i = \{t_i(1), t_i(2), ...\}$ of transition times modulo the period of the pattern. The 12 sets should be of equal size and the size of all sets should be chosen to enable calculation of J4u (as defined below) with sufficient accuracy.

Calculate the average of each set S_i, $T\text{avg}_i$, and subtract it from all elements of that set, to create a set $S0_i = \{t_i(1) - T\text{avg}_i, t_i(2) - T\text{avg}_i, ...\}$.

Combine the sets $S0_i$, i=1 to 12, to create an estimated probability distribution $f_J(t)$.

J4u is defined as the time interval that includes all but 10^{-4} of $f_J(t)$, from the 0.005th to the 99.995th percentile of $f_J(t)$.

J_{RMS} is defined as the standard deviation of $f_J(t)$.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

120D.3.1.8.2 Even-odd Jitter

For one of the 12 specific transitions in PRBS13Q in Table 120D–4:

a) Trigger once in 3 repeats of the PRBS13Q test pattern
   1) Obtain the mean time ($T3$) for this transition in the first PRBS13Q.
   2) Obtain the mean time ($T4$) for the same transition in the second PRBS13Q.
b) The difference between the two means ($T4 – T3$), is the estimated period of the repeating pattern

For each of the 12 specific transitions in PRBS13Q in Table 120D–4:

a1) Trigger once in 2 repeats of the PRBS13Q test pattern.
   1) Obtain the mean time ($T1$) for the specific transition in the first PRBS13Q.
   2) Obtain the mean time ($T2$) for the same transition in the second PRBS13Q.
b1) Calculate even-odd jitter for this transition as $|(T2 – T1) – (T4 – T3)|$

Even-odd jitter EOJ is the maximum of the 12 measurements.

NOTE 1—Both of ($T2 – T1$) and ($T4 – T3$) are about 8191 UI, which is much larger than the EOJ value. Hence, each of $T1$ through $T4$ should have high precision.

NOTE 2—Even-odd jitter has been referred to as *duty cycle distortion* by other Physical Layer specifications for operation over electrical backplane or twinaxial copper cable assemblies (see 72.7.1.9). The term *even-odd jitter* is used here to distinguish it from the duty cycle distortion referred to by Physical Layer specifications for operation over fiber optic cabling.

120D.3.2 200GAUI-4 and 400GAUI-8 C2C receiver characteristics

A 200GAUI-4 or a 400GAUI-8 chip-to-chip receiver shall meet the specifications given in Table 120D–5.

Table 120D–5—200GAUI-4 and 400GAUI-8 C2C receiver characteristics at TP5a

Parameter	Reference	Value	Units
Differential input return loss (min)	120D.3.1.1	Equation (120D–2)	dB
Differential-to-common-mode input return loss	93.8.2.2	Equation (93–5)	dB
Interference tolerance	120D.3.2.1	Table 120D–6	—
Jitter tolerance	120D.3.2.2	Table 120D–7	—

120D.3.2.1 Receiver interference tolerance

Receiver interference tolerance is defined by the procedure in Annex 93C with the exception that transmitter equalization is configured by management (see 120D.3.2.3) to the settings that provide the lowest PCS FEC symbol error ratio. The receiver on each lane shall meet the PCS FEC symbol error ratio requirement with channels matching the Channel Operating Margin (COM) and loss parameters for Test 1 and Test 2 in Table 120D–6. The following additional considerations apply to the interference tolerance test.

a) The test transmitter is constrained such that for any transmitter equalizer setting the differential peak-to-peak voltage (see 93.8.1.3) is less than or equal to 800 mV.
b) The return loss of the test setup in Figure 93C–4 measured at TP5 replica towards TPt meets the requirements of Equation (93–2).
c) The lower frequency bound for the noise spectral density constraints, f_{NSD1}, is 1 GHz.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) The transmitter device package model $S^{(tp)}$ is omitted from Equation (93A–3) in the calculation of COM. The filtered voltage transfer function $H^{(k)}(f)$ calculated in Equation (93A–19) uses the filter $H_t(f)$ defined by Equation (93A–46), where T_r is calculated as $T_r = 1.09 \times T_{rm} - 4.32$ ps and T_{rm} is the measured 20% to 80% transition time of the signal at TP0a. T_{rm} is measured using the method in 120E.3.1.5. T_{rm} is measured with *Local_eq_cm1* and *Local_eq_c*1 set to zero (see 120D.3.1.5).

e) For the calculation of test channel COM, the following parameters are based on values measured from the test transmitter. The parameter SNR_{TX} is set to the measured value of SNDR with *Np*=13, the parameter R_{LM} is set to the measured value of R_{LM}, and the parameters A_{DD} and σ_{RJ} are calculated from the measured values of J4u and J_{RMS} using Equation (120D–10), and Equation (120D–11), respectively.

f) Other COM parameters are set according to the values in Table 120D–8.

g) COM is calculated using both Test 1 and Test 2 device package model transmission line lengths listed in Table 120D–8 on the receiver side. The value of COM is taken as the lower of the two calculated values.

h) The test pattern is the scrambled idle test pattern defined in 119.2.4.9.

i) As an alternative to using the scrambled idle test pattern and measuring FEC symbol error ratio it is permissible to use the PRBS31Q pattern as described in 120.5.11.2.2 and bit error ratio testing. In this case the required bit error ratio is equal to the required FEC symbol error ratio divided by 10. Note that this requirement can be somewhat more stringent than using the scrambled idle test pattern and measuring FEC symbol error ratio, and therefore failing this test requirement with the PRBS31Q pattern does not necessarily imply a failure of the interference tolerance test.

j) A test system with a fourth-order Bessel-Thomson low pass response with 33 GHz 3 dB bandwidth is to be used for measurement of the signal applied by the pattern generator and for measurements of the broadband noise.

$$A_{DD} = \left(\left(\frac{J4u}{2}\right) + Q4\sqrt{\left((Q4^2+1)\times {J_{RMS}}^2 - \left(\frac{J4u}{2}\right)^2\right)}\right)/(Q4^2+1) \quad (120D–10)$$

$$\sigma_{RJ} = \left(\frac{J4u}{2} - A_{DD}\right)/(Q4) \quad (120D–11)$$

where $Q4$ is 3.8906.

Table 120D–6—Receiver interference tolerance parameters

Parameter	Test 1 (low loss)			Test 2 (high loss)			Units
	Min	Max	Target	Min	Max	Target	
PCS FEC Symbol error ratio[a]	—	10^{-4}	—	—	10^{-4}	—	—
Insertion loss at 13.2813 GHz[b]	9.5	10.5	—	19.5	20.5	—	dB
RSS_DFE4[c]	0.025	—	—	0.05	—	—	—
COM including effects of broadband noise[d]	—	—	3	—	—	3	dB

[a] The FEC symbol error ratio is measured in step 10 of the receiver interference tolerance method defined in 93C.2
[b] Measured between TPt and TP5 (see Figure 93C–4).
[c] RSS_DFE4 is described in 93A.2.
[d] The COM value is the target for the receiver noise level calibration defined in 93C.2 step 7. The channel noise voltage applied in 93C.2 step 8 should be as close as practical to the value needed to produce the target COM. If higher amplitude values are used, this would demonstrate margin to the specification but this is not required for compliance.

120D.3.2.2 Receiver jitter tolerance

Receiver jitter tolerance is verified for each pair of jitter frequency and peak-to-peak amplitude values listed in Table 120D–7. The test setup shown in Figure 93–12, or its equivalent, is used. The test channel meets the insertion loss requirement for Test 2 in Table 120D–6. The synthesizer frequency is set to the specified jitter frequency and the synthesizer output amplitude is adjusted until the specified peak-to-peak jitter amplitude for that frequency is measured at TP0a. The test procedure is the same as the one described in 120D.3.2.1, with the following exceptions:

a) No broadband noise is added.

b) The test channel COM, calculated per items d) through g) in 120D.3.2.1, is at least 3 dB.

c) For the COM parameter calibration described in 120D.3.2.1 item e), the test channel transmitter J_{RMS} and J4u values are measured with the jitter frequency and amplitude set according to Case F from Table 120D–7.

d) As an alternative to using the scrambled idle test pattern and measuring FEC symbol error ratio it is permissible to use the PRBS31Q pattern as described in 120.5.11.2.2 and bit error ratio testing. In this case the required bit error ratio is equal to the required FEC symbol error ratio divided by 10. Note that this requirement can be somewhat more stringent than using the scrambled idle test pattern and measuring FEC symbol error ratio, and therefore failing this test requirement with the PRBS31Q pattern does not necessarily imply a failure of the jitter tolerance test.

The receiver under test shall meet the PCS FEC symbol error ratio requirements for each case in Table 120D–7.

Table 120D–7—200GAUI-4 and 400GAUI-8 C2C receiver jitter tolerance parameters

Parameter	Case A	Case B	Case C	Case D	Case E	Case F	Units
PCS FEC Symbol error ratio	10^{-4}	10^{-4}	10^{-4}	10^{-4}	10^{-4}	10^{-4}	—
Jitter frequency	0.04	0.4	1.333	4	12	40	MHz
Jitter amplitude (pk-pk)	5	0.5	0.15	0.05	0.05	0.05	UI

120D.3.2.3 Transmitter equalization feedback (optional)

Transmitter equalization feedback is an optional capability for a 200GAUI-4 or a 400GAUI-8 chip-to-chip receiver. If implemented, it shall operate as described in this subclause.

Transmitter equalization feedback is generated for each lane (0 through 3 for 200GAUI-4 C2C and 0 through 7 for 400GAUI-8 C2C) and direction (transmit and receive) independently. The variables that control transmitter equalization feedback are specific for each lane and direction.

A 200GAUI-4 or a 400GAUI-8 chip-to-chip receiver may generate a request to change the transmit equalization coefficients of the remote transmitter to new values by setting the *Request_flag* variable to 1. The variables *Requested_eq_cm1* and *Requested_eq_c1* indicate the requested values of *Local_eq_cm1* and *Local_eq_c1*, respectively, in the remote transmitter (see Table 120D–2 and Table 120D–3). The requested setting may be generated from the remote 200GAUI-4 or 400GAUI-8 chip-to-chip transmitter's equalization setting, which is stored in variables *Remote_eq_cm1* and *Remote_eq_c1*, and from information internal to the receiver, in an implementation specific manner.

When a 200GAUI-4 or a 400GAUI-8 chip-to-chip receiver does not request a change of the remote transmitter's transmit equalization setting, it sets the *Request_flag* variable to 0. A 200GAUI-4 or a

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

400GAUI-8 chip-to-chip receiver that does not implement transmitter equalization feedback always sets *Request_flag* to 0.

If a Clause 45 MDIO is implemented, the variables *Request_flag, Requested_eq_cm1, Requested_eq_c1, Remote_eq_cm1,* and *Remote_eq_c1* for each lane and direction are accessible through registers 1.500 through 1.507 for receive, and 1.516 through 1.523 for transmit (see 45.2.1.135 through 45.2.1.138).

An example of a possible transmitter equalization tuning process using transmitter equalization feedback is provided in 83D.5. Note that 400GAUI-8 C2C uses a different number of lanes and both 200GAUI-4 and 400GAUI-8 use a different register set to those in 83D.5.

120D.4 200GAUI-4 and 400GAUI-8 chip-to-chip channel characteristics

120D.4.1 Channel Operating Margin

The Channel Operating Margin (COM), computed using the procedure in 93A.1, where T_r is 13 ps for $H_t(f)$ in Equation (93A–19), and the parameters in Table 120D–8, shall be greater than or equal to 3 dB. This minimum value allocates margin for practical limitations on the receiver implementation as well as the allowed transmitter equalization coefficients.

Table 120D–8—COM parameter values

Parameter	Symbol	Value	Units
Signaling rate	f_b	26.5625	GBd

120D.4.2 Channel return loss

The differential return loss of the channel shall meet Equation (120D–12) if the computed value of the Channel Operating Margin (COM) is less than or equal to 4 dB. For COM greater than 4 dB it is recommended that the differential return loss of the channel meet Equation (120D–12).

$$RL_d(f) \geq \begin{cases} 12 & 0.05 \leq f \leq f_b/4 \\ 12 - 15\log_{10}(4f/f_b) & f_b/4 < f \leq f_b \end{cases} \quad \text{dB} \qquad \text{(120D–12)}$$

where

f is the frequency in GHz
f_b is the signaling rate (26.5625) in GHz
$RL(f)$ is the return loss at frequency f

120D.5 Protocol implementation conformance statement (PICS) proforma for Annex 120D, Chip-to-chip 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2C) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2C)[308]

120D.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 120D, Chip-to-chip 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2C) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2C), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

120D.5.2 Identification

120D.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

120D.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 120D, Chip-to-chip 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2C) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2C)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

Annex 120E

(normative)

Chip-to-module 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2M) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2M)

120E.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2M) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2M). Figure 120E–1 shows the relationship of the 200GAUI-4 and 400GAUI-8 C2M interfaces to the ISO/IEC Open System Interconnection (OSI) reference model. The chip-to-module interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable module interfaces.

200GAUI-4 = 200 Gb/s FOUR-LANE ATTACHMENT UNIT INTERFACE
200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE
400GAUI-8 = 400 Gb/s EIGHT-LANE ATTACHMENT UNIT INTERFACE
400GMII = 400 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 120E–1—Example 200GAUI-4 and 400GAUI-8 chip-to-module relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The sublayers (including the PCS and associated FEC) for each PHY that can optionally include a 200GAUI-4 C2M or 400GAUI-8 C2M are summarized in the tables in 116.1.4 and are specified in the corresponding PMD clause. The positioning of the 200GAUI-4 C2M or 400GAUI-8 C2M relative to other sublayers is shown in 120.1 with further examples in Annex 120A.

The 200GAUI-4 C2M link is described in terms of a host 200GAUI-4 C2M component, a 200GAUI-4 C2M channel with associated insertion loss, and a module 200GAUI-4 C2M component. Figure 120E–2 depicts a typical 200GAUI-4 C2M application and summarizes the differential insertion loss budget associated with the chip-to-module application. The supported insertion loss budget is characterized by Equation (120E–1) and illustrated in Figure 120E–4. The 200GAUI-4 C2M interface comprises independent data paths in each direction. Each data path contains four differential lanes using PAM4 signaling, where the highest differential level corresponds to the symbol three and the lowest level corresponds to the symbol zero. Each lane is AC-coupled within the module.

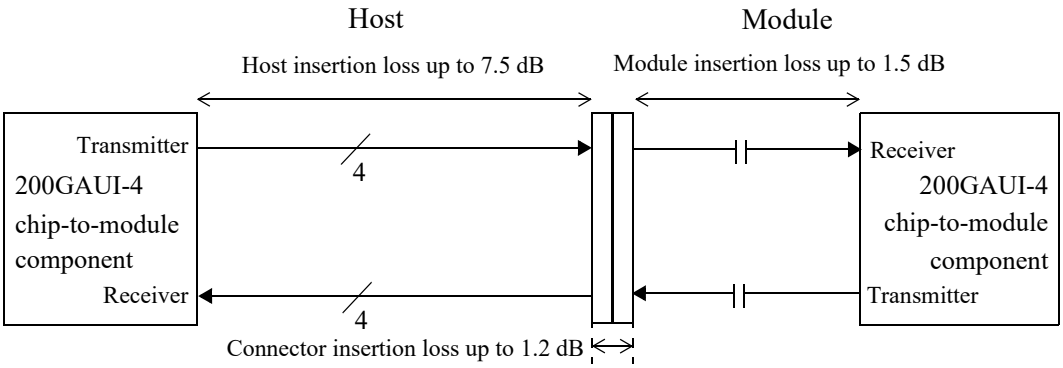

Figure 120E–2—200GAUI-4 chip-to-module insertion loss budget at 13.28 GHz

The 400GAUI-8 C2M link is described in terms of a host 400GAUI-8 C2M component, a 400GAUI-8 C2M channel with associated insertion loss, and a module 400GAUI-8 C2M component. Figure 120E–3 depicts a typical 400GAUI-8 C2M application and summarizes the differential insertion loss budget associated with the chip-to-module application. The recommended insertion loss budget is characterized by Equation (120E–1) and illustrated in Figure 120E–4. The 400GAUI-8 C2M interface comprises independent data paths in each direction. Each data path contains eight differential lanes using PAM4 signaling, where the highest differential level corresponds to the symbol three and the lowest level corresponds to the symbol zero. Each lane is AC-coupled within the module.

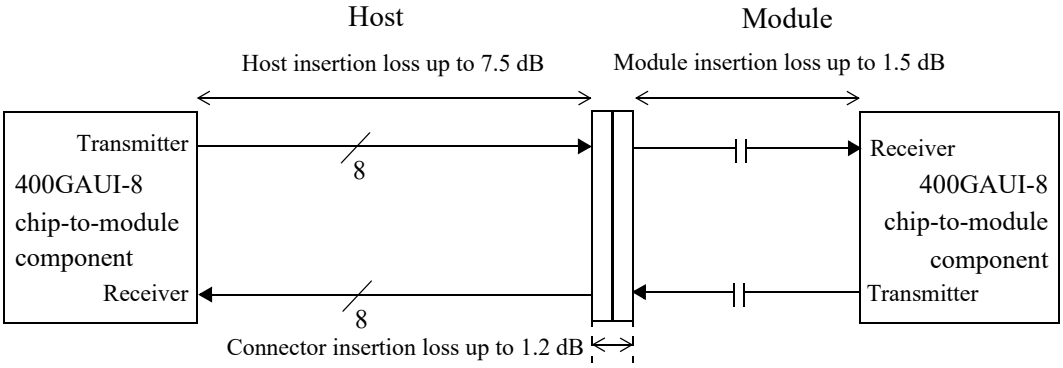

Figure 120E–3—400GAUI-8 chip-to-module insertion loss budget at 13.28 GHz

The nominal signaling rate for each lane is 26.5625 GBd. The chip-to-module interface is defined using a specification and test methodology that is similar to that used for CEI-56G-VSR-PAM defined in OIF-CEI-04.0 [B58].

$$Insertion_loss(f) \le \left\{ \begin{array}{cc} 0.05 + 1.8\sqrt{f} + 0.2705f & 0.01 \le f \le 13.28 \\ -4.0096 + 1.07f & 13.28 < f \le 26.5625 \end{array} \right\} (\text{dB}) \quad (120\text{E–}1)$$

where

f is the frequency in GHz

Insertion_loss(f) is the 200GAUI-4 or 400GAUI-8 chip-to-module insertion loss

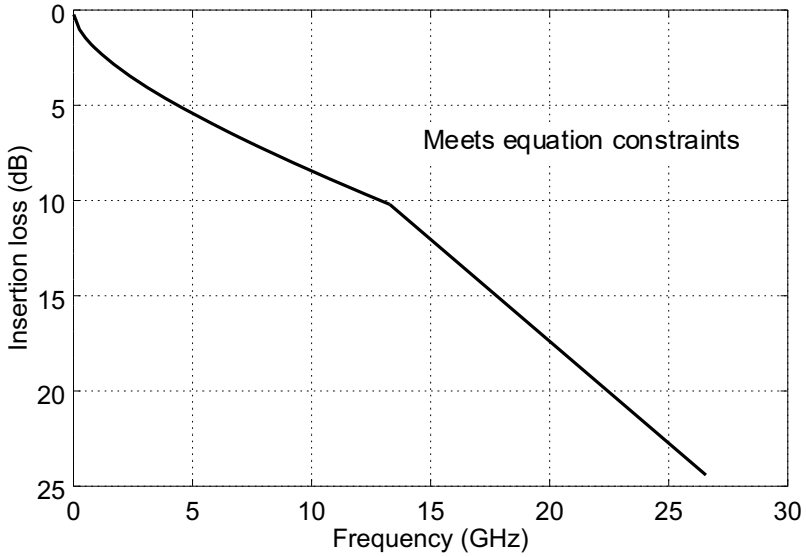

Figure 120E–4—Recommended 200GAUI-4 or 400GAUI-8 chip-to-module channel insertion loss

120E.1.1 Bit error ratio

The bit error ratio (BER) when processed according to Clause 120 shall be less than 10^{-5}.

120E.2 200GAUI-4 and 400GAUI-8 chip-to-module compliance point definitions

The electrical characteristics for the 200GAUI-4 and 400GAUI-8 chip-to-module interfaces are defined at compliance points for the host and module, respectively. Reference test fixtures, called compliance boards, are used to access the electrical specification parameters. Figure 120E–5 depicts the location of compliance points when measuring host 200GAUI-4 or 400GAUI-8 C2M compliance. The output of the Host Compliance Board (HCB) is used to verify the host electrical output signal at TP1a. Similarly, the input of the HCB at TP4a is used to verify the host input compliance.

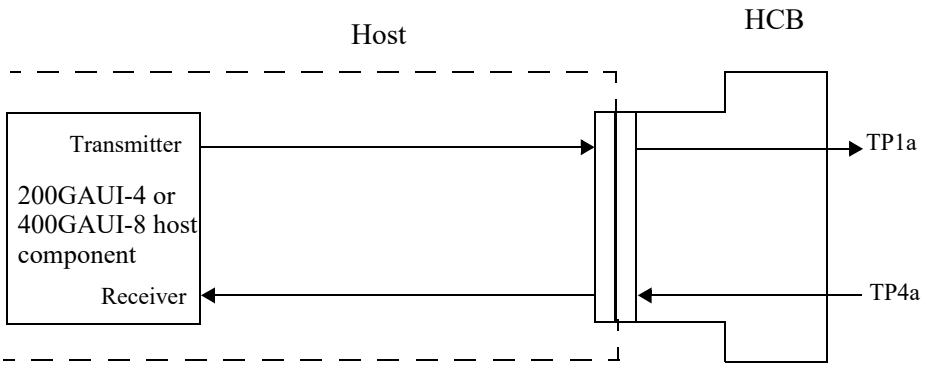

Figure 120E–5—Host 200GAUI-4 or 400GAUI-8 C2M compliance points

Figure 120E–6 depicts the location of compliance points when measuring module 200GAUI-4 or 400GAUI-8 C2M compliance. The output of the Module Compliance Board (MCB) is used to verify the module electrical output signal at TP4. Similarly, the input of the MCB at TP1 is used to verify the module input compliance. Additional details on the requirements for the MCB and HCB are given in 120E.4.1.

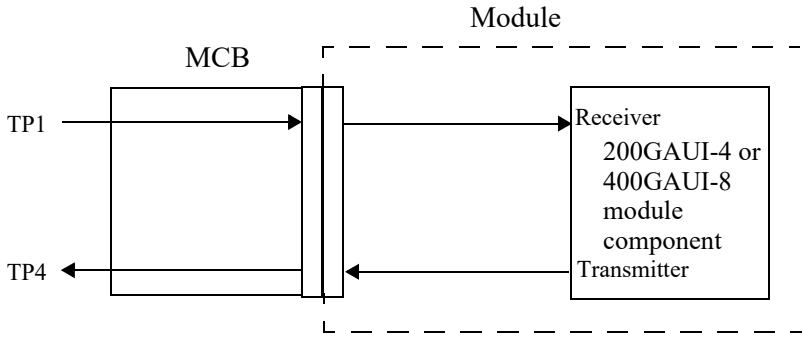

Figure 120E–6—Module 200GAUI-4 or 400GAUI-8 C2M compliance points

120E.3 200GAUI-4 and 400GAUI-8 chip-to-module electrical characteristics

120E.3.1 200GAUI-4 and 400GAUI-8 C2M host output characteristics

A 200GAUI-4 or a 400GAUI-8 C2M host output shall meet the specifications given in Table 120E–1.

A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all output signal measurements, unless otherwise specified.

Table 120E–1—200GAUI-4 and 400GAUI-8 C2M host output characteristics at TP1a

Parameter	Reference	Value	Units
Signaling rate per lane (range)	120E.3.1.1	26.5625 ± 100 ppm	GBd
DC common-mode output voltage (max)	120E.3.1.2	2.8	V
DC common-mode output voltage (min)	120E.3.1.2	–0.3	V
Single-ended output voltage (max)	120E.3.1.2	3.3	V
Single-ended output voltage (min)	120E.3.1.2	–0.4	V
AC common-mode output voltage (max, RMS)	120E.3.1.2	17.5	mV
Differential peak-to-peak output voltage (max) Transmitter disabled Transmitter enabled	120E.3.1.2	 35 880	mV
ESMW (Eye symmetry mask width)	120E.4.2	0.22	UI
Eye height, differential (min)	120E.4.2	32	mV
Vertical eye closure (max)	120E.4.3	12	dB
Differential output return loss (min)	83E.3.1.3	Equation (83E–2)	dB
Common to differential mode conversion return loss (min)	83E.3.1.3	Equation (83E–3)	dB
Differential termination mismatch (max)	120E.3.1.4	10	%
Transition time (min, 20% to 80%)	120E.3.1.5	10	ps

120E.3.1.1 Signaling rate and range

The 200GAUI-4 and 400GAUI-8 C2M signaling rate is 26.5625 GBd ± 100 ppm per lane. This translates to a nominal unit interval of 37.647059 ps.

120E.3.1.2 Signal levels

The differential output voltage v_{di} is defined to be the difference between the single-ended output voltages, SL*i*<p> minus SL*i*<n>. The common-mode voltage v_{cmi} is defined to be one half of the sum of SL*i*<p> and SL*i*<n>. These definitions are illustrated by Figure 120E–7.

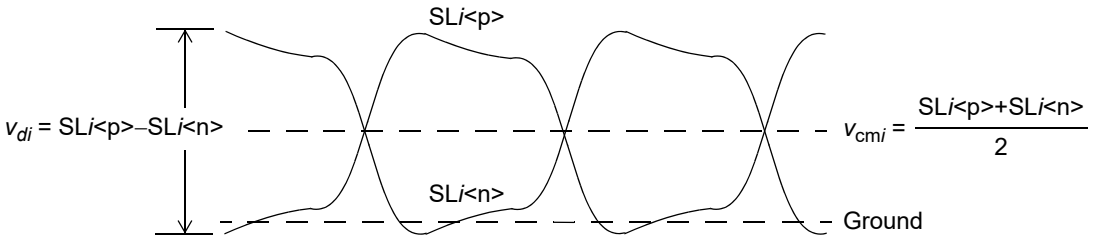

Figure 120E–7—Voltage definitions

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The DC common-mode output voltage and AC common-mode output voltage are defined with respect to signal ground.

Unless otherwise noted, differential and common-mode signal voltages are measured with a PRBS13Q test pattern.

120E.3.1.3 Output return loss

Differential output return loss is defined in 83E.3.1.3.

120E.3.1.4 Differential termination mismatch

Differential termination mismatch is defined in 86A.5.3.2.

120E.3.1.5 Transition time

In this annex, transition times are specified for transitions between three consecutive “zero” symbols and three consecutive “three” symbols, or vice versa. The specified times are between the crossings of 20% and 80% levels of the signal.

The test pattern used is PRBS13Q, the transitions within sequences of three zeros and three threes, and three threes and three zeros, respectively, are measured. These are PAM4 symbols 1820 to 1825 and 2086 to 2091, respectively, where symbols 1 to 7 are the run of seven threes. The 0% level and the 100% level are defined as the average signal within windows from –1.5 UI to –1 UI and from 1.5 UI to 2 UI relative to the edge.

The waveform is observed through a fourth-order Bessel-Thomson low-pass response with a 3 dB bandwidth of 33 GHz.

NOTE—This definition is not the same as the rise and fall times typically reported by an oscilloscope from an eye diagram, which take all the edges into account.

120E.3.1.6 Host output eye width and eye height

Figure 120E–8 depicts an example host output eye width and eye height test configuration. Host output eye width and eye height are measured at TP1a using compliance boards defined in 120E.4.1. The host output eye is measured using a reference receiver with a continuous time linear equalizer (CTLE) defined in 120E.3.1.7. Eye width and eye height measurement methodology is described in 120E.4.2. All counter-propagating signals shall be asynchronous to the co-propagating signals using the PRBS13Q or PRBS31Q pattern, or a valid 200GBASE-R or 400GBASE-R signal. PRBS13Q is described in 120.5.11.2.1. PRBS31Q is described in 120.5.11.2.2. For the case where PRBS13Q or PRBS31Q are used with a common clock, there is at least 31 UI delay between the patterns on one lane and any other lane, so that the symbols on each lane are not correlated. The crosstalk generator is calibrated at TP4 (without the use of a CTLE) with target differential peak-to-peak amplitude of 900 mV and slew time of 12 ps between ± 0.27 V.

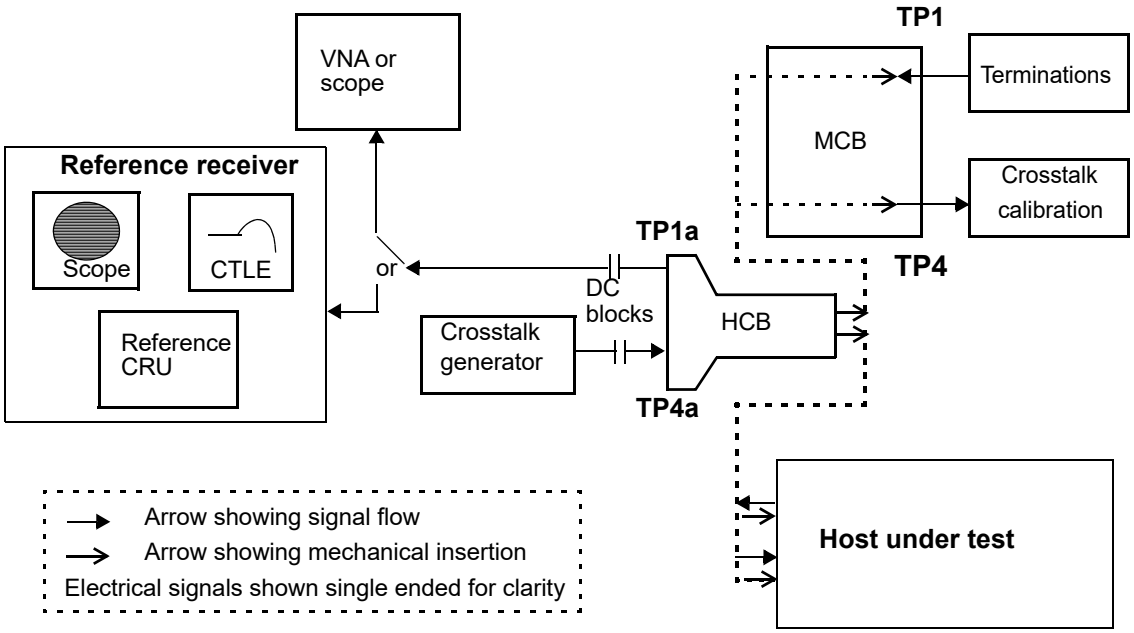

Figure 120E–8—Example host output test configuration

120E.3.1.7 Reference receiver for eye width and eye height evaluation

The reference receiver is used to measure eye width and eye height. The reference receiver includes a selectable continuous time linear equalizer (CTLE), which is described by Equation (120E–2) with coefficients given in Table 120E–2 and illustrated in Figure 120E–9. The equalizer may be implemented in software; however, the measured signal is not averaged.

$$H(f) = \frac{GP_1P_2P_{\mathrm{LF}}}{Z_1Z_{\mathrm{LF}}} \times \frac{\mathrm{j}2\pi f + Z_1}{(\mathrm{j}2\pi f + P_1)(\mathrm{j}2\pi f + P_2)} \times \frac{\mathrm{j}2\pi f + Z_{\mathrm{LF}}}{\mathrm{j}2\pi f + P_{\mathrm{LF}}} \quad (120\text{E–}2)$$

where

$H(f)$	is the CTLE transfer function
G	is the CTLE gain
P_1, P_2	are the CTLE poles in Grad/s
Z_1	is the CTLE zero in Grad/s
P_{LF}	is the low frequency CTLE pole in Grad/s
Z_{LF}	is the low frequency CTLE zero in Grad/s
j	is the square root of –1
f	is the frequency in GHz

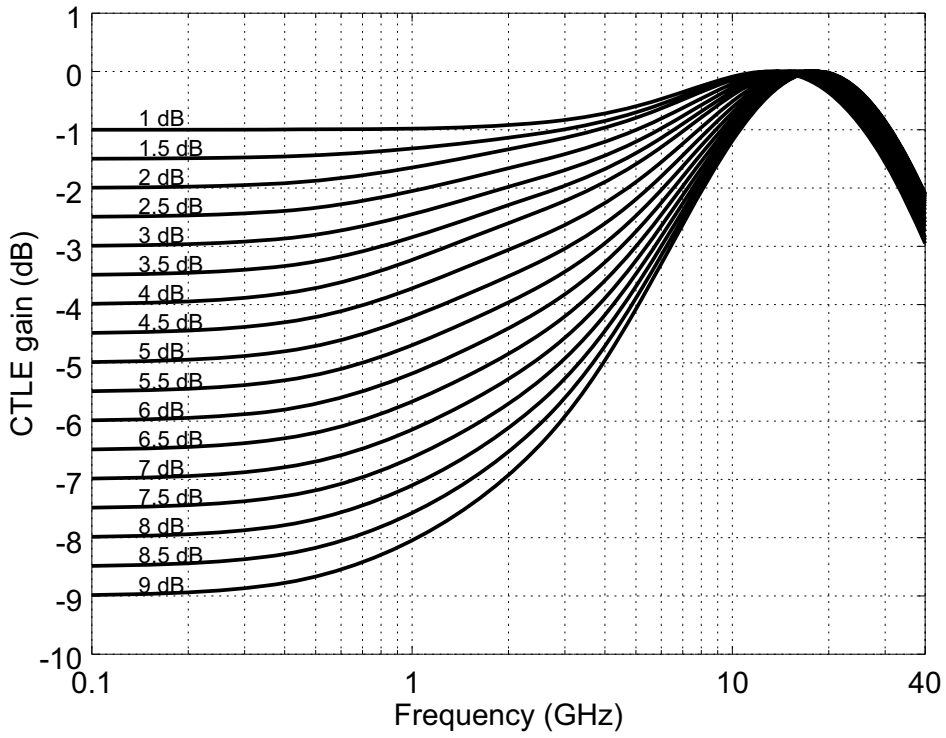

Figure 120E–9—Reference continuous time linear equalizer (CTLE) characteristic

120E.3.2 200GAUI-4 and 400GAUI-8 C2M module output characteristics

A 200GAUI-4 or a 400GAUI-8 C2M module output shall meet the specifications given in Table 120E–3. The low-frequency 3 dB cutoff of the output AC-coupling within the module should be less than 100 kHz. A test system with a fourth-order Bessel-Thomson low-pass response with 33 GHz 3 dB bandwidth is to be used for all output signal measurements, unless otherwise specified.

120E.3.2.1 Module output eye width, eye height, and pre-cursor ISI ratio

Figure 120E–10 depicts an example module output eye width and eye height test configuration. Module output eye width and eye height are measured at TP4 using compliance boards defined in 120E.4.1. The module output eye is measured using a reference receiver with a continuous time linear equalizer (CTLE) defined in 120E.3.2.1.1. Eye width and eye height measurement methodology is described in 120E.4.2. All counter-propagating signals shall be asynchronous to the co-propagating signals using the PRBS13Q or PRBS31Q pattern, or a valid 200GBASE-R or 400GBASE-R signal. PRBS13Q is described in 120.5.11.2.1 and PRBS31Q is described in 120.5.11.2.2. For the case where PRBS13Q or PRBS31Q are used with a common clock, there is at least 31 UI delay between the patterns on one lane and any other lane, so that the symbols on each lane are not correlated. The crosstalk generator is calibrated at TP1a (without the use of a CTLE) with target differential peak-to-peak amplitude of 880 mV and target transition time of 19 ps.

120E.3.2.1.1 Reference receiver for module output evaluation

A reference receiver is used to measure module eye width and eye height. The reference receiver includes a selectable continuous time linear equalizer (CTLE), which is defined in 120E.3.1.7. The equalizer may be implemented in software; however, the measured signal is not averaged.

The near-end eye is measured with the reference receiver. Equalizer settings corresponding to less than or equal to 3 dB of peaking from Table 120E–2 may be used to meet the output eye width and height requirements.

For the far-end eye, the signal measured at TP4 is first convolved with a loss channel (~6.4 dB loss at Nyquist) that represents the worst case channel loss. The loss channel is the host trace defined in 92.10.7.1.1 with Z_p = 151 mm. The reference receiver is then used to measure the eye width and height. Any of the equalizer settings from Table 120E–2 may be used.

120E.3.2.1.2 Far-end pre-cursor ISI ratio

Capture the PRBS13Q waveform corresponding to the far-end eye (see 120E.3.2.1.1) and calculate the linear fit pulse using the procedure defined in 120D.3.1.3. Any setting of the reference CTLE for which the far-end eye width and height satisfy the limits in Table 120E–3, may be used.

The peak amplitude of the linear fit pulse is p_{max}. The pre-cursor ISI p_{pre} is the value of the linear fit pulse 1 UI prior to the time of the pulse peak. The pre-cursor ISI ratio is p_{pre} / p_{max}.

120E.3.3 200GAUI-4 and 400GAUI-8 C2M host input characteristics

A 200GAUI-4 or a 400GAUI-8 C2M host input shall meet the specifications given in Table 120E–4.

Table 120E–4—200GAUI-4 and 400GAUI-8 C2M host input characteristics

Parameter	Reference	Test point	Value	Units
Signaling rate, per lane (range)	120E.3.1.1	TP4a	26.5625 ± 100 ppm	GBd
Differential pk-pk input voltage tolerance (min)	120E.3.1.2	TP4	900	mV

120E.3.3.2 Host stressed input test

The host stressed input tolerance is measured using the procedure defined in 120E.3.3.2.1. The input shall satisfy the input tolerance with the parameters in Table 120E–5.

Table 120E–5—Host stressed input parameters

Parameter	Value
Far-end ESMW (Eye symmetry mask width)	0.2 UI
Far-end Eye width	0.2 UI
Applied pk-pk sinusoidal jitter	Table 120E–6
Far-end Eye height	30 mV

120E.3.3.2.1 Host stressed input test procedure

The host stressed input test is summarized in Figure 120E–11. The stressed signal is applied at TP4a and is calibrated at TP4. A reference CRU with a corner frequency of 4 MHz and slope of 20 dB/decade is used to calibrate the stressed signal using the PRBS13Q Pattern (see 120.5.11.2.1). The reference receiver includes a selectable CTLE as specified in 120E.3.2.1.1. The stressed signal is generated by adding sinusoidal jitter, random jitter, and bounded uncorrelated jitter to a clean signal. The frequency and peak-to-peak amplitude of the sinusoidal jitter used for the host stressed input test is given in Table 120E–6.

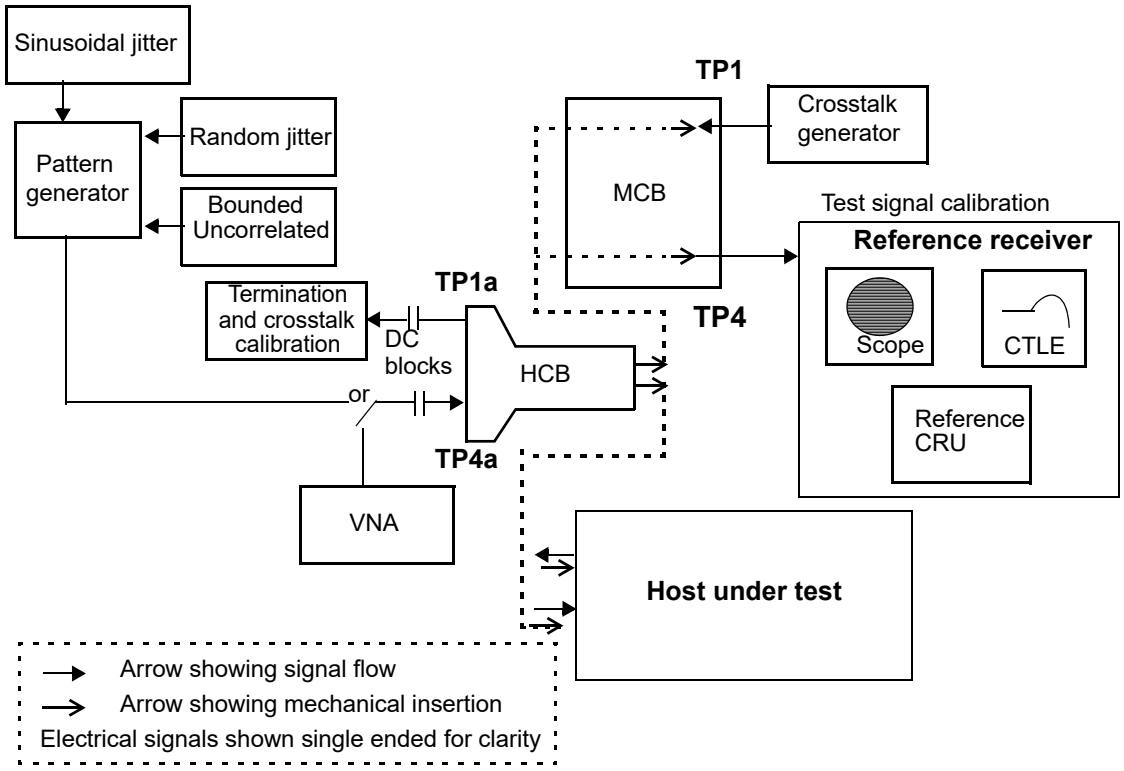

Figure 120E–11—Example host stressed input test

Table 120E–6—Applied sinusoidal jitter

Parameter	Case A	Case B	Case C	Case D	Case E	Case F	Units
Jitter frequency	0.04	0.4	1.333	4	12	40	MHz
Jitter amplitude (pk-pk)	5	0.5	0.15	0.05	0.05	0.05	UI

Bounded uncorrelated jitter provides a source of bounded high probability jitter uncorrelated with the pattern. This jitter stress source may not be present in all stressed pattern generators or bit error ratio testers. It can be generated by driving the pattern generator external jitter modulation input with a filtered PRBS pattern. The PRBS pattern length should be between PRBS7 and PRBS9 with a signaling rate approximately 1/10 of the stressed pattern signaling rate (e.g., 2.65625 GBd). The clock source for the PRBS generator is asynchronous to the pattern generator clock source to assure non-correlation of the jitter. The low-pass filter that operates on the PRBS pattern to generate the bounded uncorrelated jitter should exhibit 20 dB/decade roll-off with a –3 dB corner frequency between 150 MHz and 300 MHz. This value also has to be below the upper frequency limit of the pattern generator external modulator input. Random jitter and bounded uncorrelated jitter are added such that the output of the pattern generator approximates the 200GAUI-4 and 400GAUI-8 C2C output jitter profile given in Table 120D–1.

The counter propagating crosstalk signals during calibration of the stressed signal are asynchronous with target amplitude of 880 mV peak-to-peak differential and 20% to 80% target transition time of 19 ps as measured at TP1a (without the use of a CTLE). The crosstalk signal transition time is calibrated with PRBS13Q. The pattern may be changed to a valid 400GBASE-R signal for amplitude calibration and the stressed input test. The PRBS13Q pattern is described in 120.5.11.2.1. For the case where the PRBS13Q pattern is used with a common clock, there is at least 31 UI delay between the PRBS13Q patterns on one lane and any other lane, so that the symbols on each lane are not correlated. Any one of these patterns is sufficient as a crosstalk aggressor with all lanes active during the stressed input test.

The far-end eye height and eye width, measured to a probability of 10^{-5}, are then measured at TP4 with the reference receiver defined in 120E.3.2.1.1 using the measurement methodology given in 120E.4.2. Note that the reference receiver for far-end eye height and width measurements includes a loss channel. Random jitter and the pattern generator output levels are adjusted (without exceeding the differential pk-pk input voltage tolerance specification as shown in Table 120E–4) to result in the eye height for all three eyes and eye width for the smallest eye given in Table 120E–5 with the setting of the CTLE that maximizes the product of eye height and eye width.

The far-end pre-cursor ISI ratio is measured using the method defined in 120E.3.2.1.2 and it shall meet the specification in Table 120E–3. Pre-emphasis capability is likely to be required in the pattern generator to meet this requirement.

The pattern is then changed to Pattern 5, Pattern 3, or a valid 200GBASE-R/400GBASE-R signal for the input test which is conducted by inserting the HCB into the host under test. Patterns 3 and 5 are described in Table 124–9.

If the test is performed with pattern 3, the host BER may be calculated using the host's PMA test pattern checker (see 120.5.11.2.2). If the test is performed with pattern 5 or a valid 200GBASE-R/400GBASE-R signal, the BER may be calculated using the host's PCS Reed-Solomon decoder error counters (see 119.3.1), as the number of FEC symbol errors divided by the number of received bits. The number of received bits may be estimated based on the test time.

120E.3.4 200GAUI-4 and 400GAUI-8 C2M module input characteristics

A 200GAUI-4 or a 400GAUI-8 C2M module input shall meet the specifications given in Table 120E–7. Channel equalization is provided by an adaptive equalizer in the module.

Table 120E–7—200GAUI-4 and 400GAUI-8 C2M module input characteristics

Parameter	Reference	Test point	Value	Units
Signaling rate per lane (range)	120E.3.1.1	TP1	26.5625 ± 100 ppm	GBd
Differential pk-pk input voltage tolerance (min)[a]	120E.3.1.2	TP1a	900	mV
Differential input return loss (min)	83E.3.3.1	TP1	Equation (83E–5)	dB
Differential-to-common-mode input return loss (min)	83E.3.3.1	TP1	Equation (83E–6)	dB
Differential termination mismatch (max)	120E.3.1.4	TP1	10	%
Module stressed input test[b]	120E.3.4.1	TP1a	See 120E.3.4.1	
Single-ended voltage tolerance range (min)	120E.3.1.2	TP1a	–0.4 to 3.3	V
DC common-mode voltage (min)[c]	120E.3.1.2	TP1	–350	mV
DC common-mode voltage (max)[c]	120E.3.1.2	TP1	2850	mV

[a] With the exception to 120E.3.1.2 that the pattern is PRBS31Q or scrambled idle.
[b] Meets BER specified in 120E.1.1.
[c] DC common-mode voltage generated by the host. Specification includes effects of ground offset voltage.

120E.3.4.1 Module stressed input test

The module stressed input tolerance is measured using the procedure defined in 120E.3.4.1.1. The input shall satisfy the input tolerance with the parameters in Table 120E–8.

Table 120E–8—Module stressed input parameters

Parameter	Value
ESMW (Eye symmetry mask width)	0.22 UI
Eye width	0.22 UI
Applied pk-pk sinusoidal jitter	Table 120E–6
Eye height	32 mV

120E.3.4.1.1 Module stressed input test procedure

The module stressed input test is summarized in Figure 120E–12. The stressed signal is applied at TP1 and is calibrated at TP1a. A reference CRU with a corner frequency of 4 MHz and slope of 20 dB/decade is used to calibrate the stressed signal using a PRBS13Q pattern. The reference receiver includes a selectable CTLE as specified in 120E.3.1.7. The stressed signal is generated by adding sinusoidal jitter, random jitter, and

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bounded uncorrelated jitter to a clean signal, followed by frequency-dependent attenuation. The frequency-dependent attenuator represents the host channel and may be implemented with PCB traces. The amount of applied peak-to-peak sinusoidal jitter used for the module stressed input test is given in Table 120E–6. Bounded uncorrelated jitter provides a source of bounded high probability jitter uncorrelated with the signal stream. This jitter stress source may not be present in all stressed pattern generators or bit error ratio testers. It can be generated by driving the pattern generator external jitter modulation input with a filtered PRBS pattern. The PRBS pattern length should be between PRBS7 and PRBS9 with a signaling rate approximately 1/10 of the stressed pattern signaling rate (e.g., 2.65625 GBd). The clock source for the PRBS generator is asynchronous to the pattern generator clock source to assure non-correlation of the jitter. The low-pass filter that operates on the PRBS pattern to generate the bounded uncorrelated jitter should exhibit 20 dB/decade roll-off with a –3 dB corner frequency between 150 MHz and 300 MHz. This value also has to be below the upper frequency limit of the pattern generator external modulator input. Random jitter and bounded uncorrelated jitter are added such that the output of the pattern generator approximates the 200GAUI-4 and 400GAUI-8 C2C output jitter profile given in Table 120D–1. The target pattern generator 20% to 80% transition time at the input to the test channel in the module stressed input test is 10.5 ps. The return loss of the test system as measured at TP1 meets the specification given in Equation (83E–2).

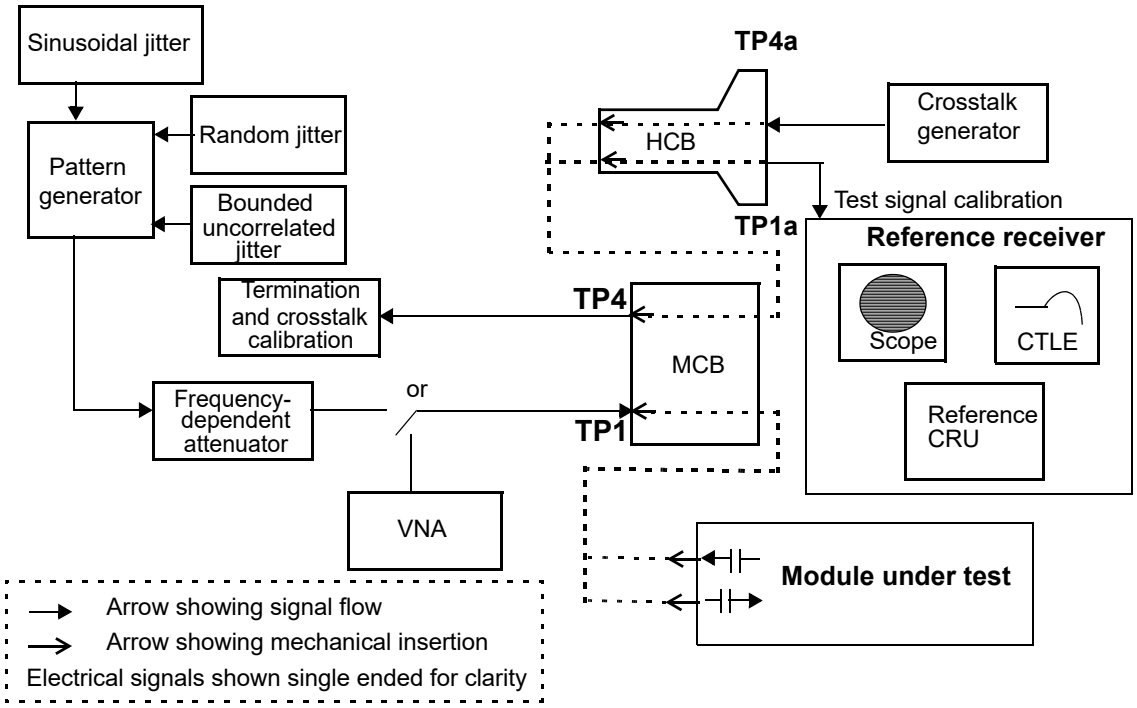

Figure 120E–12—Example module stressed input test

For the high loss case, pre-emphasis capability is likely to be required in the pattern generator to meet the TP1a eye height and eye width specifications.

The counter propagating crosstalk signals during calibration of the stressed signal are asynchronous with target amplitude of 900 mV peak-to-peak differential and target slew time between ± 270 mV of 12 ps as measured at TP4 (without the use of a CTLE). The crosstalk signal transition time is calibrated with a PRBS13Q pattern. The pattern may be changed to a valid 200GBASE-R/400GBASE-R signal for amplitude calibration and the stressed input test. The PRBS13Q pattern is described in 120.5.11.2.1. For the case where the PRBS13Q pattern is used with a common clock, there is at least 31 UI delay between the PRBS13Q patterns on one lane and any other lane, so that the symbols on each lane are not correlated. Any one of these patterns is sufficient as a crosstalk aggressor with all lanes being active during the stressed input test.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Two levels of frequency-dependent attenuation are used for the module stressed input test: high loss and low loss. For the high loss case, frequency-dependent attenuation is added such that the loss at 13.28 GHz from the output of the pattern generator to TP1a is 12.2 dB. The 12.2 dB loss represents 10.5 dB channel loss with an additional allowance for host transmitter package loss. Eye height and eye width are then measured at TP1a based on the eye measurement methodology given in 120E.4.2 and vertical eye closure is measured according to 120E.4.3. Random jitter and the pattern generator output levels are adjusted (without exceeding the differential pk-pk input voltage tolerance specification as shown in Table 120E–7) to result in the eye height for all three eyes and eye width for the smallest eye given in Table 120E–8 using the reference receiver with the setting of the CTLE that maximizes the product of eye height and eye width. This CTLE setting has to be greater than or equal to 7 dB. For the low loss case, discrete frequency-dependent attenuation is removed such that from the output of the pattern generator to TP1a comprises the mated HCB/MCB pair as described in 120E.4.1. Eye height and eye width at TP1a are then adjusted in the same way as described for the high loss case except that the restriction that the CTLE setting has to be greater than or equal to 7 dB does not apply. In both cases, the input vertical eye closure is less than 12 dB.

The pattern is then changed to Pattern 5, Pattern 3, or a valid 200GBASE-R/400GBASE-R signal for the input test, which is conducted by inserting the module into the MCB. Patterns 3 and 5 are described in Table 124–9.

If the test is performed with pattern 3, the module bit errors may be counted using a PMA test pattern checker (see 120.5.11.2.2) if this option is implemented in the module.

If the test is performed with pattern 5 or a valid 200GBASE-R/400GBASE-R signal, the module BER may be calculated by placing the module under test into local loopback (see 120.5.9) and feeding the module output into a compliant host or its equivalent. The BER may then be calculated using the host's PCS Reed-Solomon decoder error counters (see 119.3.1), as the number of FEC symbol errors divided by the number of received bits.

Methods of extracting the received bit pattern and counting errors other than the ones described above may be used if they generate equivalent results.

The number of received bits may be estimated based on the test time.

The module 200GAUI-4 or 400GAUI-8 C2M receiver under test shall meet the BER requirement as described in 120E.1.1 for both the high loss test and low loss test.

120E.4 200GAUI-4 and 400GAUI-8 C2M measurement methodology

This subclause describes common measurement tools and methodologies to be used for the 200GAUI-4 and 400GAUI-8 chip-to-module interface. Details of HCB and MCB characteristics are given in 120E.4.1 and details of the eye diagram measurement methodology are given in 120E.4.2.

120E.4.1 HCB/MCB characteristics

HCB characteristics are described in 92.11.1 where the HCB performs the equivalent function as the TP2 or TP3 test fixture with the exception that the upper frequency of 25 GHz is replaced with 26.5625 GHz. The MCB characteristics are described in 92.11.2 where the MCB performs the equivalent functionality as the cable assembly test fixture with the exception that the upper frequency of 25 GHz is replaced with 26.5625 GHz.

The mated compliance board characteristics are described in 92.11.3 where the MCB and HCB perform the equivalent functionality as the cable assembly test fixtures with the exceptions that the upper frequency of

25 GHz is replaced with 26.5625 GHz, MDNEXT shall be less than 1.5 mV RMS, MDFEXT shall be less than 4.2 mV RMS, ICN shall be less than 4.4 mV RMS, FOM_{ILD} limit is 0.1 dB, and the reference insertion loss is given in Equation (120E–3) for 0.01 GHz ≤ f ≤ 25 GHz.

$$IL(f) = 0.471\sqrt{f} + 0.1194f + 0.002f^2 \quad \text{(dB)} \tag{120E–3}$$

where

f is the frequency in GHz
$IL(f)$ is the mated compliance board reference insertion loss

120E.4.2 Eye width and eye height measurement method

Eye diagrams in 200GAUI-4 and 400GAUI-8 chip-to-module are measured using a reference receiver. The reference receiver includes a fourth-order Bessel-Thomson low-pass filter response with 33 GHz 3 dB bandwidth, and a selectable continuous time linear equalizer (CTLE) to measure eye height and width. The pattern used for output eye diagram measurements is PRBS13Q. Unless specified otherwise the probabilities are relative to the number of PAM4 symbols measured. The following procedure should be used to obtain the eye height and eye width parameters, as illustrated by Figure 120E–13:

1) Capture the PRBS13Q using a clock recovery unit with a corner frequency of 4 MHz and slope of 20 dB/decade. The capture includes a minimum of 3 samples per symbol, or equivalent. Collect sufficient samples equivalent to at least 1.2 million PAM4 symbols to allow for construction of a normalized cumulative distribution function (CDF) to a probability of 10^{-5} without extrapolation.
2) Apply the reference receiver including the appropriate CTLE to the captured signal. For module compliance, any single CTLE setting as described in 120E.3.2.1.1 that meets both eye width and eye height requirements is acceptable. For host compliance, any single CTLE setting as described in 120E.3.1.7 that meets both eye width and eye height requirements is acceptable.
3) Use the differential equalized signal from step 2) to construct the CDF of the signal threshold crossing for both the left edge (MID0CDFL) and right edge (MID0CDFR) of the middle eye, as a function of the distance from the center of the eye. Calculate the time center of the middle eye width (TCmid) as the mid-point in time between MID0CDFR and MID0CDFL with a value of 10^{-3}. MID0CDFL and MID0CDFR are calculated as the cumulative sum of histograms of the zero crossing samples at the left and right edges of the middle eye normalized by the total number of sampled symbols. The MID0CDFL and MID0CDFR are equivalent to bath tub curves where the BER is plotted versus sampling time.
4) Use the differential equalized signal from step 2) to construct the CDF of the signal voltage of the middle eye within 0.025 UI of time TCmid, for both +1/3 (MIDCDF1) and –1/3 (MIDCDF0), as a function of the distance from the center of the eye. Calculate the eye height (Vmid) as the difference in voltage between MIDCDF1 and MIDCDF0 with a value of 10^{-5}. Calculate the voltage center (VCmid) of the middle eye as the mid-point in voltage between MIDCDF1 and MIDCDF0 with a value of 10^{-5}. MIDCDF0 and MIDCDF1 are calculated as the cumulative sum of histograms of the voltage at the top and bottom of the eye normalized by the total number of sampled bits.
5) Using the method in step 4), construct CDFs of signal voltages of the upper eye within 0.025 UI of time TCmid, and calculate the 10^{-5} upper eye height (Vupp). Calculate the voltage center (VCupp) of the upper eye as the mid-point in voltage between UPPCDF1 and UPPCDF0 with a value of 10^{-5}.
6) Using the method in step 4), construct CDFs of signal voltages of the lower eye within 0.025 UI of time TCmid, and calculate the 10^{-5} lower eye height (Vlow). Calculate the voltage center (VClow) of the lower eye as the mid-point in voltage between LOWCDF1 and LOWCDF0 with a value of 10^{-5}.
7) The eye height is defined as the minimum of Vmid, Vupp, and Vlow.

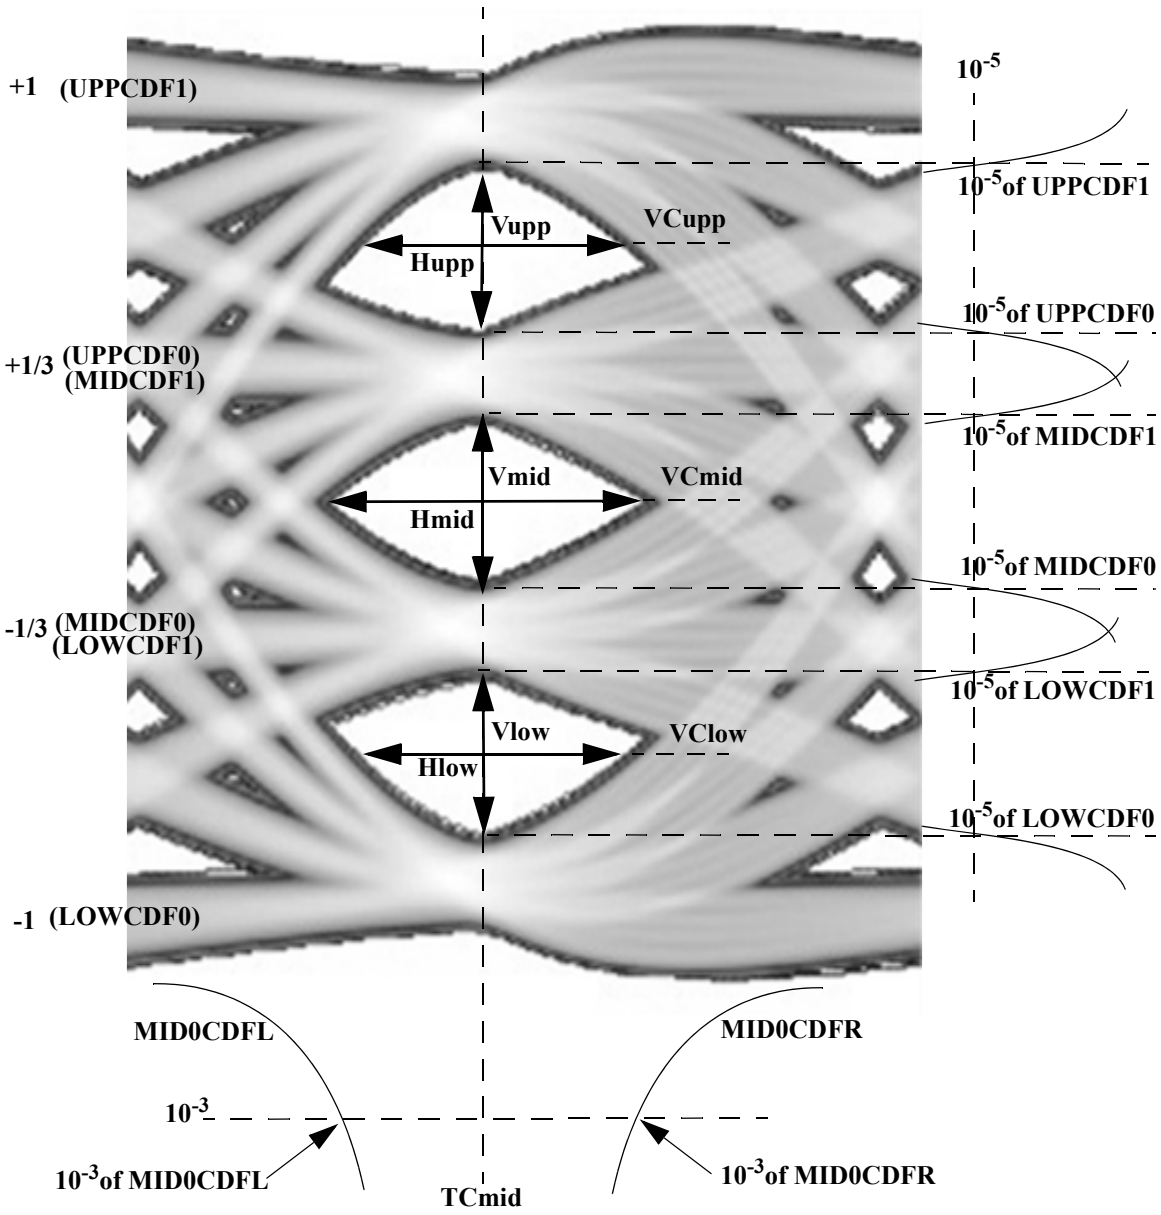

Figure 120E–13—PAM4 eye measurements

8) Use the differential equalized signal from step 2) to construct new CDFs of the signal for both the left edge (MIDCDFL) and right edge (MIDCDFR) of the middle eye at VCmid, as a function of the distance from the center of the eye. Calculate the middle eye width (Hmid) as the difference in time between MIDCDFR and MIDCDFL with a value of 10^{-5}.

9) Using the method in step 8), calculate the 10^{-5} upper eye width (Hupp) sliced at VCupp.

10) Using the method in step 8), calculate the 10^{-5} lower eye width (Hlow) sliced at VClow.

11) The eye width is defined as the minimum of Hmid, Hupp, and Hlow.

12) Check the upper and lower eye alignment to the middle eye. Apply an ESMW wide mask centered on TCmid, as illustrated by Figure 120E–14. The 10^{-5} horizontal openings of the middle eye at VCmid, the upper eye at VCupp, and of the lower eye at VClow all have to extend beyond this mask.

120E.4.3 Vertical eye closure

Vertical eye closure is defined by Equation (120E–4) for a PRBS13Q differential equalized signal captured and processed according to 120E.4.2.

$$VEC = 20\log_{10}\left(\max\left(\frac{AV_{\text{upp}}}{V_{\text{upp}}}, \frac{AV_{mid}}{V_{\text{mid}}}, \frac{AV_{\text{low}}}{V_{\text{low}}}\right)\right) \text{ (dB)} \quad \text{(120E–4)}$$

where

VEC is the vertical eye closure, in dB

V_{upp}	is the 10^{-5} upper eye height per 120E.4.2
V_{mid}	is the 10^{-5} middle eye height per 120E.4.2
V_{low}	is the 10^{-5} lower eye height per 120E.4.2
AV_{upp}	is the amplitude of the upper eye (AVupp), equal to VM3–VM2
AV_{mid}	is the amplitude of the middle eye (AVmid), equal to VM2–VM1
AV_{low}	is the amplitude of the lower eye (AVlow), equal to VM1–VM0
VM3	is the mean of the differential equalized signal above VCupp within 0.025 UI of TCmid
VM2	is the mean of the differential equalized signal between VCupp and VCmid within 0.025 UI of TCmid
VM1	is the mean of the differential equalized signal between VCmid and VClow within 0.025 UI of TCmid
VM0	is the mean of the differential equalized signal below VClow within 0.025 UI of TCmid
VCupp	is the voltage center of the upper eye per 120E.4.2
VCmid	is the voltage center of the middle eye per 1120E.4.2
VClow	is the voltage center of the lower eye per 120E.4.2
TCmid	is the time center of the middle eye width per 120E.4.2

120E.5 Protocol implementation conformance statement (PICS) proforma for Annex 120E, Chip-to-module 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2M) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2M)[309]

120E.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 120E, Chip-to-module 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2M) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2M), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

120E.5.2 Identification

120E.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

120E.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 120E, Chip-to-module 200 Gb/s four-lane Attachment Unit Interface (200GAUI-4 C2M) and 400 Gb/s eight-lane Attachment Unit Interface (400GAUI-8 C2M)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

Annex 127A

(informative)

Compatibility of 2.5GBASE-X PCS/PMA with 1000BASE-X PCS/PMA running 2.5 times faster

This annex discusses the restrictions when operating 2.5GBASE-X PCS/PMA with a 1000BASE-X PCS/PMA link partner running 2.5 times faster. Compatibility of the PMD is outside the scope of this annex. In this annex when 1000BASE-X PCS/PMA is referred to, the 2.5 times speed up is implied.

The 2.5GBASE-X PCS/PMA is specified to be compatible with a link partner running 1000BASE-X PCS/PMA running 2.5 times faster as shown in Figure 127A–1 with some restrictions.

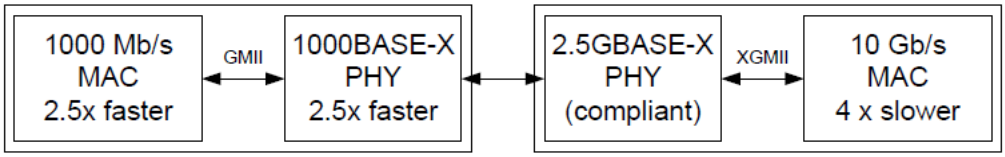

Figure 127A–1—2.5X speed 1000BASE-X to 2.5GBASE-X Link

2.5GBASE-X is defined to operate only in full duplex. Hence the 1000BASE-X PCS can only operate in full duplex. If the half duplex carrier extend or carrier extend with errors is sent by the 1000BASE-X PCS, the 2.5GBASE-X PCS will convert it to receive errors. A /T/R/ or a /T/R/R/ at the end of packet are correctly converted as idles.

The 2.5GBASE-X PCS does not support Clause 37 Auto-Negotiation. Hence, the 1000BASE-X PCS is expected to have its Clause 37 Auto-Negotiation functionality disabled so that the /C/ ordered set will not be transmitted. If a 2.5GBASE-X PCS receives /C/ ordered set, then undefined behavior may occur.

Since the 2.5GBASE-X PCS is attached to an RS that can send out sequence ordered set (/Q/), a compliant 1000BASE-X PCS will interpret each /Q/ ordered set as four /I/ ordered sets. Unlike /I/, /LI/, and /C/ ordered sets, there is no concept of correcting vs preserving the running disparity when /Q/ ordered sets are generated.

Unlike the GMII, there is no false carrier defined in the XGMII. The 2.5GBASE-X PCS Receive process can detect false carriers, but these will be converted to receive errors by the PCS Word Decode process.

It is permissible for a compliant 1000BASE-X PCS transmit process to truncate the first byte of a preamble in order to align the start of packet on the EVEN boundary. The implication of this is the 2.5 Gb/s RS (see 46.3.3.3) has to be able to accept a seven byte preamble on the XGMII with the SFD positioned on lane 2.

Since the start of packet has to align to lane 0 of the XGMII the 2.5 Gb/s RS may delete idle bytes in order to do the alignment. The 1G RS running 2.5 times faster has to be able to handle IPG shrinkage.

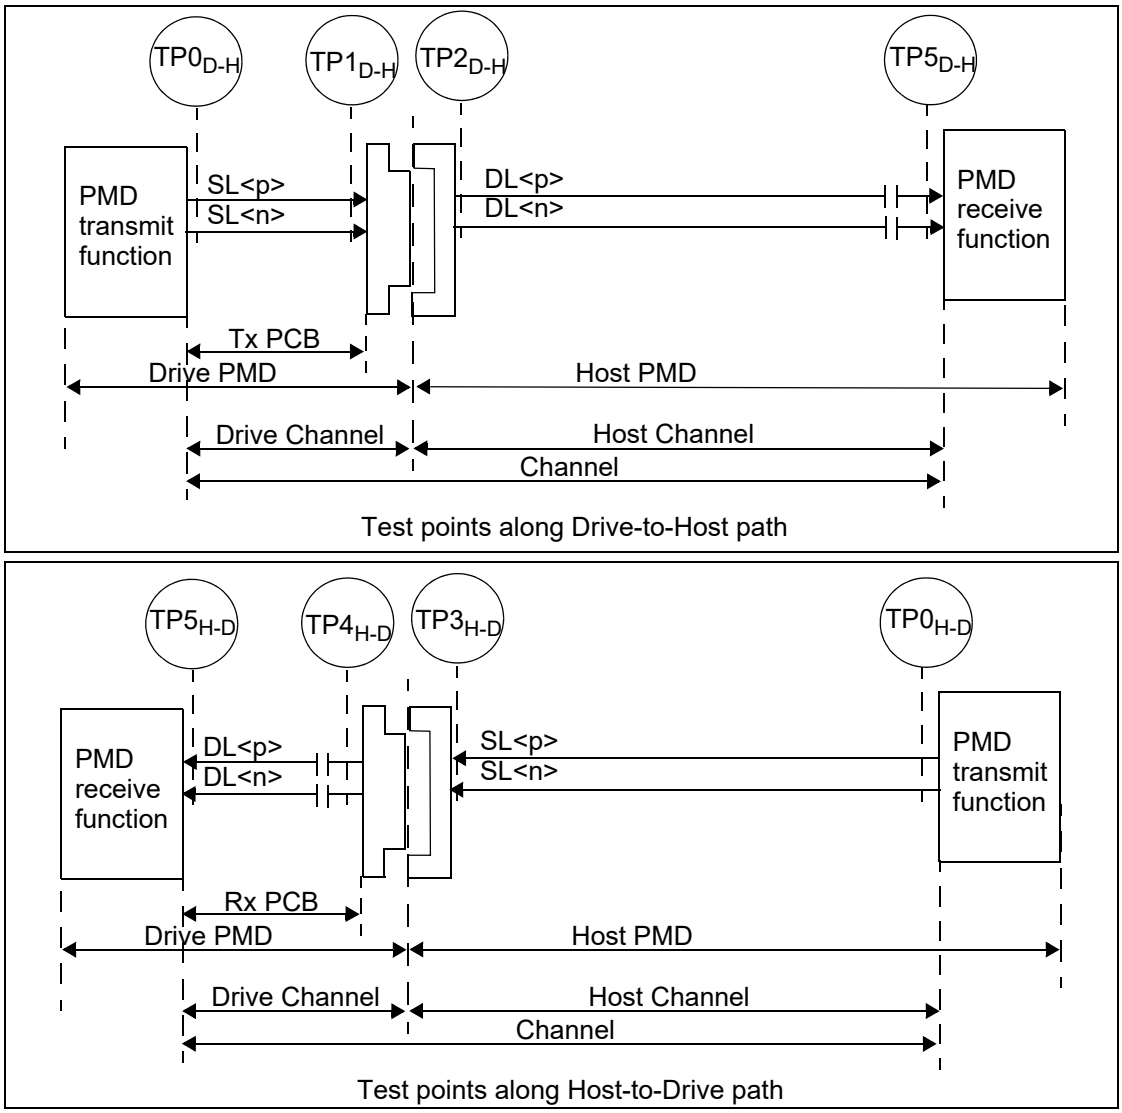
Annex 128A

(normative)

2.5 Gb/s Storage Enclosure Interface (2.5GSEI)

128A.1 Overview

This clause defines the functional and electrical characteristics for 2.5GSEI. This interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable storage drive module interfaces. The compliance point definitions provide a unique partitioning of the channel defined in Annex 69B, such that the test points $TP0_{D\text{-}H}$ and $TP0_{H\text{-}D}$ defined in this annex are equivalent to TP1, and $TP5_{D\text{-}H}$ and $TP5_{H\text{-}D}$ are equivalent to TP4. Figure 128A–1 shows the test point locations associated with 2.5GSEI.



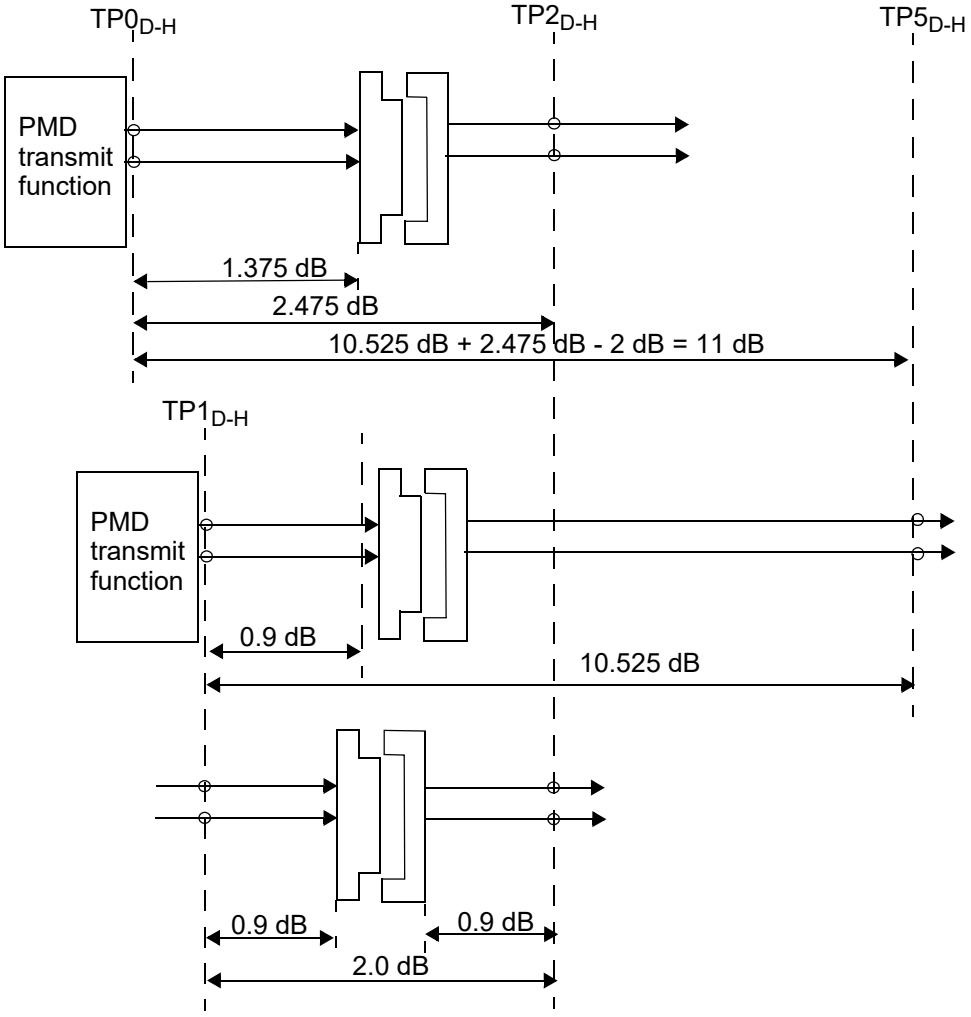


Figure 128A–1—Test points

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 2.5GSEI link is described in terms of a host 2.5GSEI component with associated insertion loss and a drive 2.5GSEI component. Figure 128A–2 (one direction shown) depicts the recommended differential insertion loss budget at 1.5625 GHz for a typical 2.5GSEI application. The recommended maximum differential insertion loss from TP0 to TP5 is given in Equation (128A–1) and depicted in Figure 128A–3. The 2.5GSEI interface consists of independent data paths in each direction. Each data path contains one differential lane, which is AC-coupled on the receiver side. The nominal signaling rate for each lane is 3.125 GBd.

NOTE—The connector insertion loss is 0.2 dB for the mated test fixture.

Figure 128A–2—Insertion loss budget at 1.5625 GHz

$$Insertion_loss(f) \le \begin{cases} 0.668 + 3.755\sqrt{f} + 3.608f & 0.05 \le f < 1.5625 \\ -23.753 + 22.242f & 1.5625 \le f < 2.34375 \end{cases} \text{ (dB)} \qquad (128A–1)$$

where

f is the frequency in GHz

Insertion_loss(f) is chip to chip (C2C) insertion loss

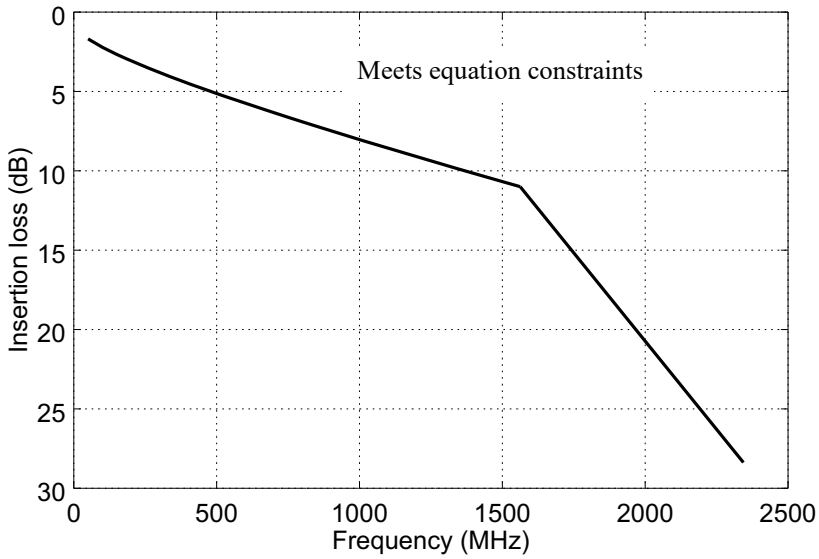

Figure 128A–3—Illustration of recommended maximum differential insertion loss from TP0 to TP5

128A.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 10^{-12} with any errors sufficiently uncorrelated to ensure an acceptably high mean time to false packet acceptance (MTTFPA) assuming 8B/10B coding.

128A.2 2.5GSEI compliance point definitions

The electrical characteristics for 2.5GSEI are defined at compliance points for the host and drive, respectively. Reference test fixtures, called compliance boards, are used to access the electrical specification parameters. Figure 128A–4 depicts the location of compliance points when measuring host 2.5GSEI compliance. The output of the Host Compliance Board (HCB) is used to verify the host electrical output signal at $TP4_{H\text{-}D}$ (see Figure 128A–1). Similarly, the input of the HCB at $TP1_{D\text{-}H}$ (see Figure 128A–2) is used to verify the host input compliance.

Figure 128A–5 depicts the location of compliance points when measuring drive 2.5GSEI compliance. The output of the Drive Compliance Board (DCB) is used to verify the Drive electrical output signal at $TP2_{D\text{-}H}$ (see Figure 128A–5). Similarly, the input of the DCB at $TP3_{H\text{-}D}$ (see Figure 128A–5) is used to verify the Drive input compliance. Additional details on the requirements for the HCB and DCB are given in Annex 128B.

128A.3 2.5GSEI electrical characteristics

128A.3.1 2.5GSEI host output characteristics

A 2.5GSEI host output shall meet the specifications defined in Table 128A–1 if measured at $TP4_{H\text{-}D}$ (see Figure 128A–4).

Table 128A–1—2.5GSEI host output characteristics

Parameter	Subclause reference	Value	Units
Signaling rate	128A.3.1.1	3.125 ± 100 ppm	GBd
Nominal unit interval	128A.3.1.1	320	ps
DC common-mode output voltage (max)	128A.3.1.2	1.9	V
AC common-mode output voltage (max, RMS)	128A.3.1.2	30	mV
Peak-to-peak differential output voltage (min) transmitter enabled	128.7.1.4	580	mV
Peak-to-peak differential output voltage (max) transmitter enabled	128.7.1.4	1200	mV
Peak-to-peak differential output voltage (max) transmitter disabled	128.7.1.4	35	mV
Maximum transition time (20%–80%)	128.7.1.7	460	ps
Differential output return loss (min)	128A.3.1.3	See Equation (128A–2)	dB
Max output jitter (peak-to-peak) Random jitter Deterministic jitter Duty Cycle Distortion[1] Total jitter	128A.3.1.5	 0.2 0.12 0.035 0.32	 UI UI UI UI
Signal-to-noise-and-distortion ratio (min) (SNDR)	128A.3.1.6	25	dB

[1]Duty Cycle Distortion is considered part of deterministic jitter distribution.

A test system, as depicted in Figure 128B–1, with a fourth-order Bessel-Thomson low-pass response with 8 GHz 3 dB bandwidth, is to be used for all output signal measurements, unless otherwise specified.

128A.3.1.1 Signaling rate and range

The 2.5GSEI signaling rate is specified in Table 128A–1. The nominal unit interval is the inverse of the signaling rate.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128A.3.1.2 Signaling levels

The differential output voltage V_d is defined to be the difference between the single-ended output voltages, *SL*<*p*> minus *SL*<*n*>. The common-mode voltage V_{cm} is defined to be one half of the sum of *SL*<*p*> and *SL*<*n*>. These definitions are illustrated by Figure 128A–6.

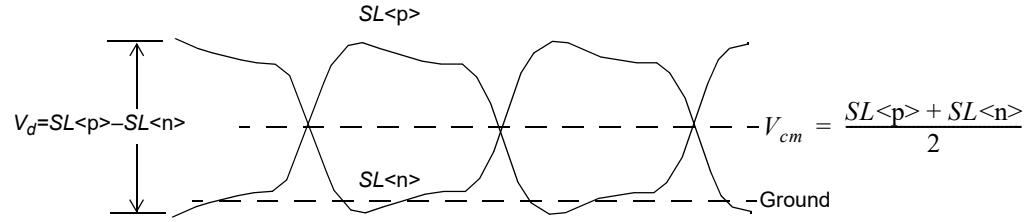

Figure 128A–6—Voltage definitions

The DC common-mode output voltage and AC common-mode output voltage are defined with respect to signal ground.

128A.3.1.3 Output return loss

The differential output return loss, in dB, of the output is shown in Equation (128A–2) and illustrated in Figure 128A–7. This output requirement applies to all valid output levels. The reference impedance for differential return loss measurements is 100 Ω.

$$Return_loss(f) \geq \begin{cases} Return_loss_{min} = 12 & 50 \leq f < 275 \\ Return_loss_{min} = 12 - 6.75\log_{10}\left(\frac{f}{275\text{MHz}}\right) & 275 \leq f < 2343.75 \end{cases} \text{(dB)} \qquad \text{(128A–2)}$$

where

f is the frequency in MHz

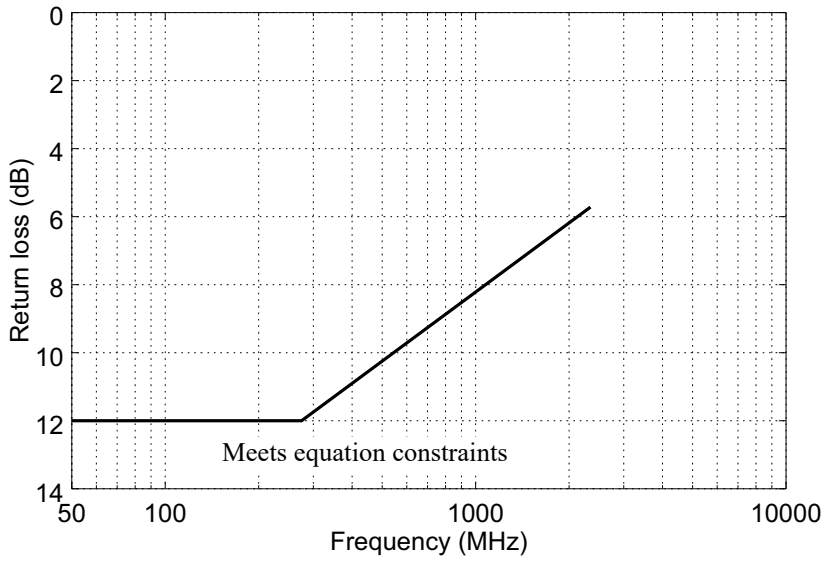

Figure 128A–7—Differential return loss limit

128A.3.1.4 Transmit jitter test requirements

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in 48B.3. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 1.875 MHz is applied to the jitter. The data pattern for jitter measurements shall be the test pattern defined in 48A.2. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal.

128A.3.1.5 Transmit jitter

The transmitter shall have a maximum total jitter, composed of a maximum deterministic component and a maximum random component as shown in Table 128A–1. Duty cycle distortion (DCD) is considered a component of deterministic jitter and shall not exceed the value shown in Table 128A–1. The peak-to-peak duty cycle distortion is defined as the absolute value of the difference in the mean pulse width of a 1 pulse or the mean pulse width of a 0 pulse (as measured at the mean of the high- and low-voltage levels in a clock like repeating bit sequence) and the nominal pulse width. Jitter specifications are specified for BER = 10^{-12}. Transmit jitter test requirements are specified in 128A.3.1.4.

128A.3.1.6 Transmitter output noise and distortion

Signal-to-noise-and-distortion ratio (SNDR) is measured at the transmitter output using the following method:

a) Capture at least one complete cycle of the test pattern PRBS9 as specified in Table 68–6 at $TP4_{H_D}$ (see Figure 128A–4) per 85.8.3.3.4.
b) Apply the reference equalizer from 93A.1.4.3, using the values from Table 128A–2.
c) Compute the linear fit pulse response $p(k)$ and the linear fit error waveform $e(k)$ from the resulting waveform per 85.8.3.3.5 using N_p=3 and D_p = 1. Denote the standard deviation of $e(k)$ as σ_e.
d) Measure the RMS deviation from the mean voltage at a fixed point in a run of at least 8 consecutive identical bits in a suitable pattern. PRBS9 is an example of a pattern that includes runs suitable to perform the measurement. It is recommended that the deviation is measured within the flattest portion of the waveform at a point where the slope is closest to zero. The RMS deviation is measured for a run of zeros and also a run of ones. The average of the two measurements is denoted as σ_n.

Table 128A–2—2.5G host receiver equalizer parameters

Parameter	Symbol	Value	Units
Signaling rate	f_b	3.125 ± 100 ppm	GBd
Continuous time filter, DC gain [1] Minimum value Maximum value Step size	g_{DC}	 –9.5 0 0.5	 dB dB dB
Continuous time filter, zero frequency	f_z	$f_b/2$	GHz
Continuous time filter, pole frequencies	f_{p1} f_{p2}	$f_b/2$ f_b	GHz GHz

[1]The DC gain, gDC, is optimized to satisfy the SNDR requirement.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SNDR is defined by Equation (128A–3).

$$SNDR = 10\log_{10}\left(\frac{p_{max}^{2}}{\sigma_e^{2} + \sigma_n^{2}}\right)\text{dB} \quad (128A–3)$$

where

$p_{\max}$ is the maximum value of $p(k)$

128A.3.2 2.5GSEI host input characteristics

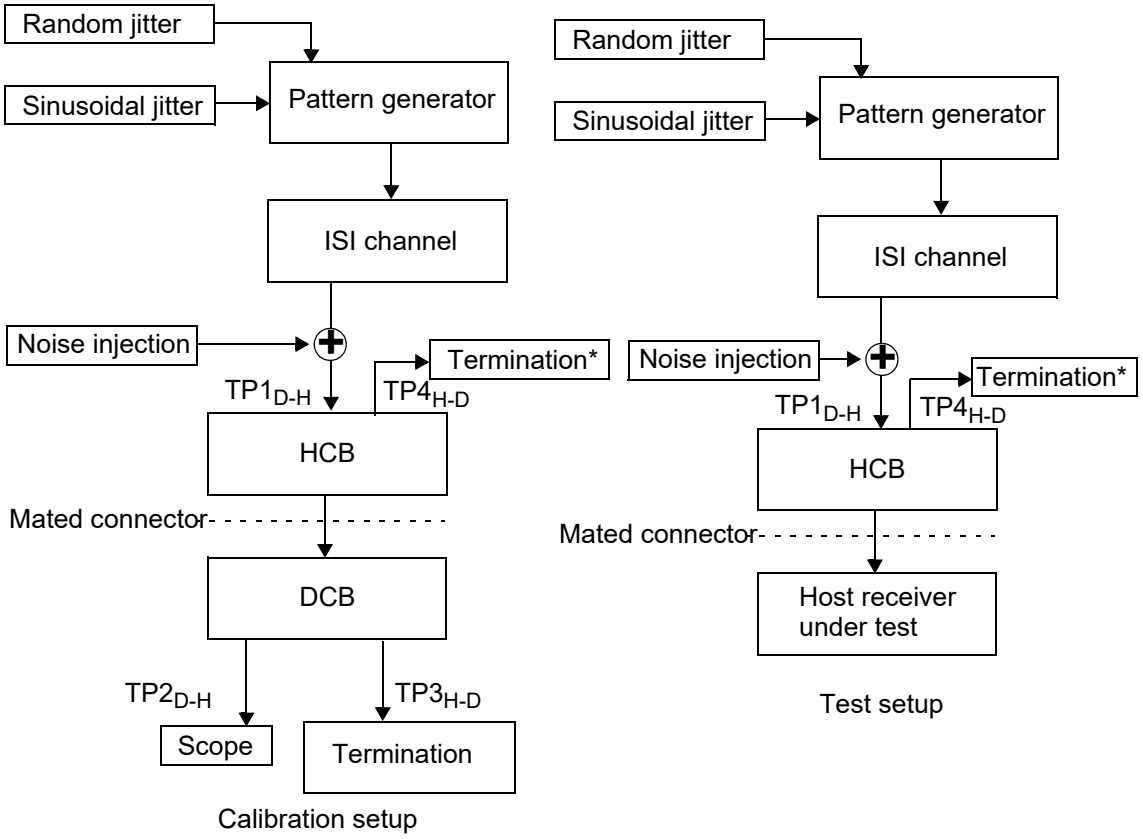
A 2.5GSEI host input shall meet the specifications defined in Table 128A–3 if measured at the appropriate test point.

Table 128A–3—2.5GSEI host input characteristics

Parameter	Subclause reference	Value	Units
Differential input return loss (min)	128A.3.2.1	See Equation (128A–2)	dB
Interference tolerance	128A.3.2.2	—	—
Jitter tolerance	128A.3.2.3	—	—

128A.3.2.1 Input differential return loss

The host input differential return loss shall meet Equation (128A–2) measured at $TP1_{D\text{-}H}$ (see Figure 128A–4).



128A.3.2.2 Receiver interference tolerance

The following considerations apply to the interference tolerance test. The pattern generator is calibrated at $TP2_{D\text{-}H}$ (see Figure 128A–8) to produce the values in the calibration procedure shown below. The channel noise source is a broadband noise generator capable of producing white Gaussian noise with adjustable amplitude. The power spectral density shall be flat to ±3 dB from f_1 in Table 69B–2 to 0.5 times the signaling speed for the port type under test with a crest factor of no less than 5. The noise shall be measured at the output of a filter connected to the output of the noise source. The filter for this measurement shall have no more than a 40 dB per decade roll-off and a 3 dB cut-off frequency shall be equal to 0.5 times the signaling speed. Figure 128A–8 illustrates the calibration and test configurations that are needed for the host interference tolerance test. The data pattern used for the receiver interference tolerance test shall be the test pattern defined in 48A.5. The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 3.125 GBd ± 100 ppm.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 5 dB of loss at 1.5625 GHz as possible.
b) Measure signal through the ISI channel at $TP2_{D\text{-}H}$ (see Figure 128A–8).
c) Adjust the ISI channel to the limit of the maximum transition time in Table 128A–1.
d) Adjust the amplitude to meet the peak-to-peak differential output voltage in Table 128A–1.
e) Adjust noise to meet the required SNDR in Table 128A–1.
f) Adjust pattern generator random jitter to the required value in Table 128A–1.

* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

128A.3.2.3 Receiver jitter tolerance

The following considerations apply to the jitter tolerance test. The transmitter is calibrated at $TP2_{D\text{-}H}$ (see Figure 128A–9) to produce the values in the calibration procedure shown below. Broadband noise is not injected during this test except for what is inherently present in the host. Figure 128A–9 illustrates the calibration and test configurations that are needed for the host jitter tolerance test. The data pattern used for the receiver jitter tolerance test shall be the test pattern defined in 48A.5. The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 3.125 GBd ± 100 ppm.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 5 dB of loss at 1.5625 GHz as possible.
b) Measure signal through the ISI channel at $TP2_{D\text{-}H}$ (see Figure 128A–9).
c) Adjust the ISI channel to the limit of the maximum transition time in Table 128A–1.
d) Adjust the amplitude to meet the Peak-to-peak differential output voltage (min) transmitter enabled in Table 128A–1.
e) Adjust pattern generator random jitter to the required value in Table 128A–1.
f) Adjust sinusoidal jitter until the values in Table 128A–6 are met.

* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

128A.3.3 2.5GSEI drive output characteristics

A 2.5GSEI drive output shall meet the specifications defined in Table 128A–4 if measured at $TP2_{D\text{-}H}$ (see Figure 128A–5).

Table 128A–4—2.5GSEI drive output characteristics

Parameter	Subclause reference	Value	Units
Signaling rate	128A.3.1.1	3.125 ± 100 ppm	GBd
Nominal unit interval	128A.3.1.1	320	ps
DC common-mode output voltage (max)	128A.3.1.2	1.9	V
AC common-mode output voltage (max, RMS)	128A.3.1.2	30	mV
Peak-to-peak differential output voltage (min) transmitter enabled	128.7.1.4	800	mV
Peak-to-peak differential output voltage (max) transmitter enabled	128.7.1.4	1200	mV
Peak-to-peak differential output voltage (max) transmitter disabled	128.7.1.4	35	mV
Maximum transition time (20%-80%)	128.7.1.7	229	ps
Differential output return loss (min)	128A.3.1.3	See Equation (128A–2)	dB
Max output jitter (peak-to-peak) Random jitter Deterministic jitter Duty Cycle Distortion[1] Total jitter	 128A.3.1.5 128A.3.1.5 128A.3.1.5 128A.3.1.5	 0.2 0.12 0.035 0.32	 UI UI UI UI
Signal-to-noise-and-distortion ratio (min) - SNDR	128A.3.1.6	25	dB

[1]Duty Cycle Distortion is considered part of deterministic jitter distribution.

A test system with a fourth-order Bessel-Thomson low-pass response with 8 GHz 3 dB bandwidth is to be used for all output signal measurements, unless otherwise specified.

128A.3.4 2.5GSEI drive input characteristics

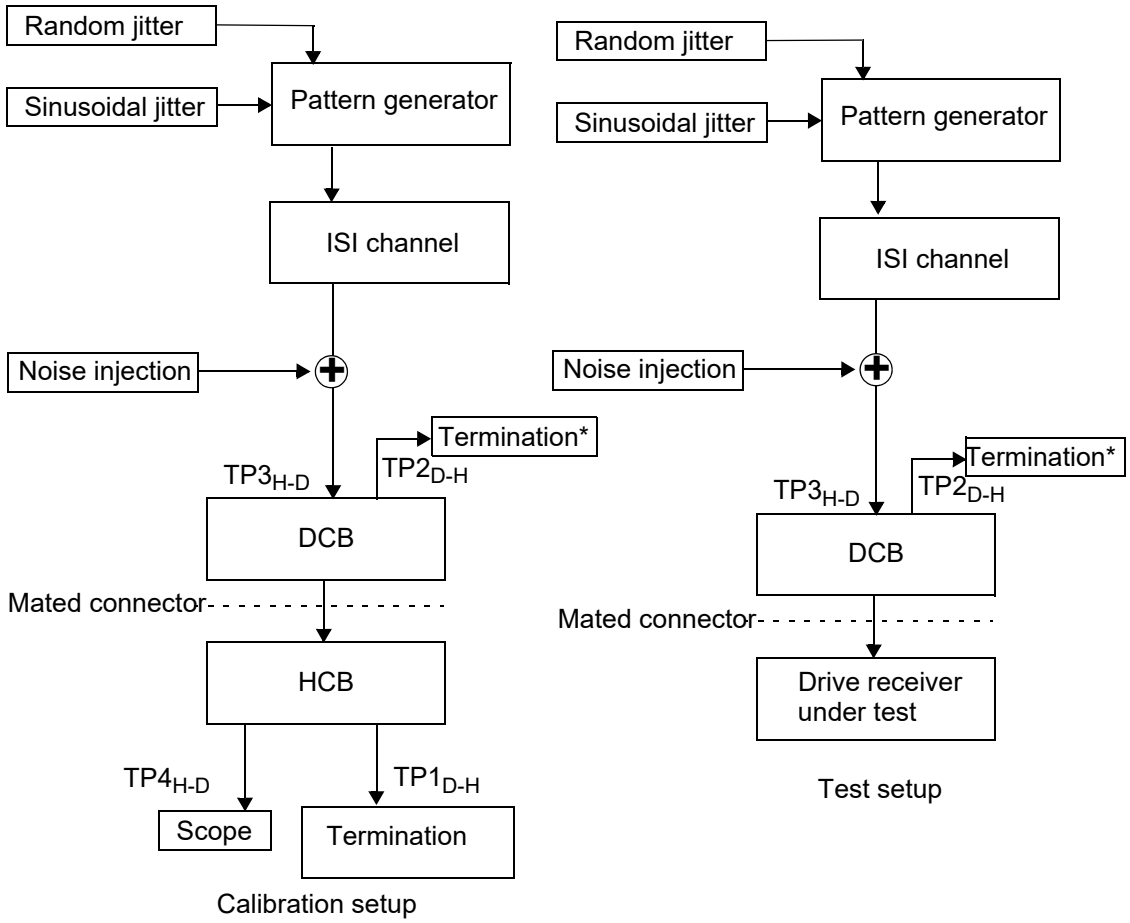
A 2.5GSEI drive input shall meet the specifications defined in Table 128A–5 if measured at the appropriate test point.

Table 128A–5—2.5GSEI drive input characteristics

Parameter	Subclause reference	Value	Units
Differential input return loss (min)	128A.3.4.1	See Equation (128A–2)	dB
Interference tolerance	128A.3.4.2	—	—
Jitter tolerance	128A.3.4.3	—	—

128A.3.4.1 Input differential return loss

The drive input differential return loss shall meet Equation (128A–2) measured at $TP3_{H\text{-}D}$ (see Figure 128A–5).



128A.3.4.2 Receiver interference tolerance

The following considerations apply to the interference tolerance test. The pattern generator is calibrated at $TP4_{H\text{-}D}$ (see Figure 128A–10) to produce the values in the calibration procedure shown below. The channel noise source is a broadband noise generator capable of producing white Gaussian noise with adjustable amplitude. The power spectral density shall be flat to ±3 dB from f_1 in Table 69B–2 to 0.5 times the signaling speed for the port type under test with a crest factor of no less than 5. The noise shall be measured at the output of a filter connected to the output of the noise source. The filter for this measurement shall have no more than a 40 dB per decade roll-off and a 3 dB cut-off frequency shall be equal to 0.5 times the signaling speed. Figure 128A–10 illustrates the calibration and test configurations that are needed for the drive interference tolerance test. The data pattern used for the receiver interference tolerance test shall be the test pattern defined in 48A.5. The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 3.125 GBd ± 100 ppm.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 13.5 dB of loss at 1.5625 GHz as possible.
b) Measure signal through the ISI channel at $TP2_{H\text{-}D}$ (see Figure 128A–10).
c) Adjust the ISI channel to the limit of the maximum transition time in Table 128A–4.
d) Adjust the amplitude to meet the peak-to-peak differential output voltage in Table 128A–4.
e) Adjust noise to meet the required SNDR (see 128A.3.1.6).
f) Adjust pattern generator random jitter to the required value in Table 128A–4.

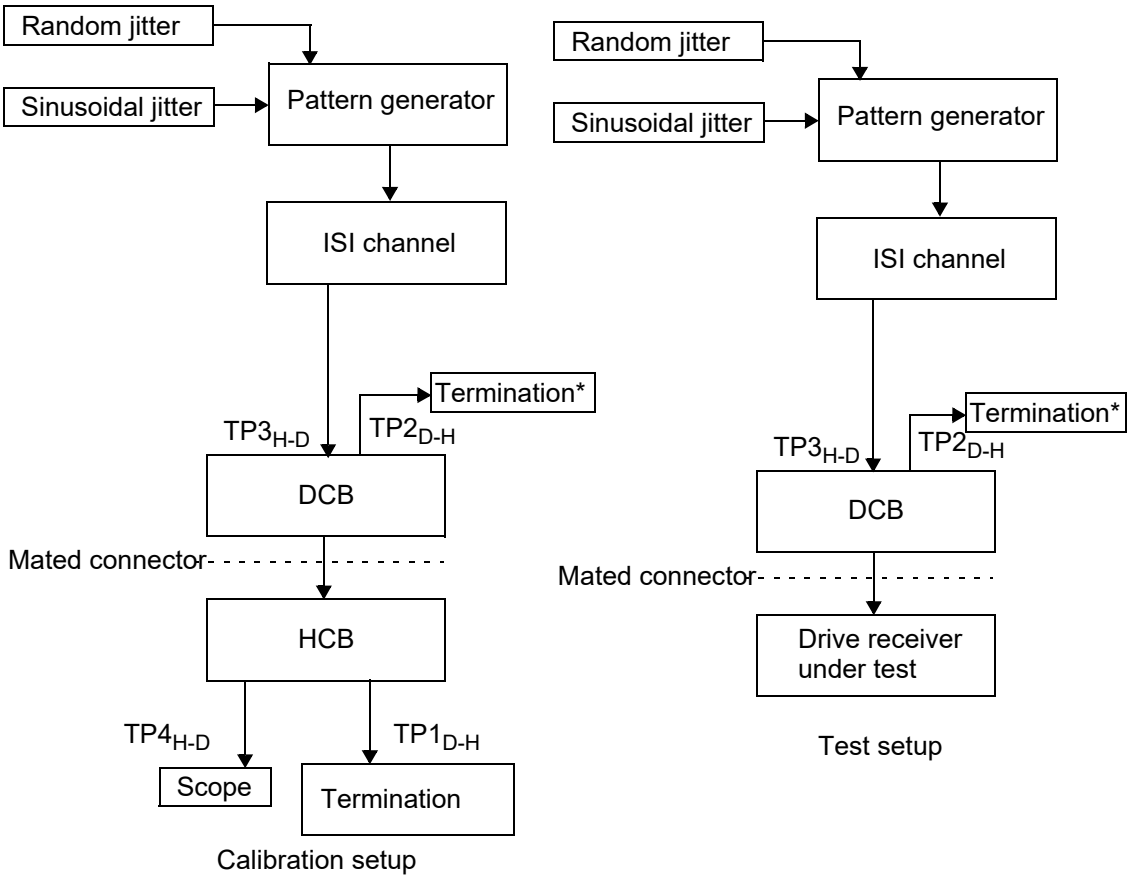
* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

Figure 128A–10—Drive interference calibration and test setup



128A.3.4.3 Receiver jitter tolerance

The following considerations apply to the jitter tolerance test. The transmitter is calibrated at $TP4_{H\text{-}D}$ (see Figure 128A–11) to produce the values in the calibration procedure shown below. Broadband noise is not injected during this test except for what is inherently present in the drive. Figure 128A–11 illustrates the calibration and test configurations that are needed for the drive jitter tolerance test. The data pattern used for the receiver jitter tolerance test shall be the test pattern defined in 48A.5. The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 3.125 GBd ± 100 ppm.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 13.5 dB of loss at 1.5625 GHz as possible.
b) Measure signal through the ISI channel at $TP4_{H\text{-}D}$ (see Figure 128A–11).
c) Adjust the ISI channel to the limit of the maximum transition time in Table 128A–4.
d) Adjust the amplitude to meet the Peak-to-peak differential output voltage (min) transmitter enabled in Table 128A–4.
e) Adjust pattern generator random jitter to the required value in Table 128A–4.
f) Adjust sinusoidal jitter until the values in Table 128A–6 are met.

128A.4 Protocol implementation conformance statement (PICS) proforma for Annex 128A, 2.5 Gb/s Storage Enclosure Interface (2.5GSEI)[310]

128A.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 128A, 2.5 Gb/s Storage Enclosure Interface (2.5GSEI), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

128A.4.2 Identification

128A.4.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

128A.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 128A, 2.5 Gb/s Storage Enclosure Interface (2.5GSEI)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement

Annex 128B

(normative)

Test fixtures for 2.5 Gb/s and 5 Gb/s Storage Enclosure Interfaces

Transmitter and receiver measurements are made utilizing the test fixtures specified in Figure 128B–1. The requirements in this clause are not MDI connector specifications for an implemented design.

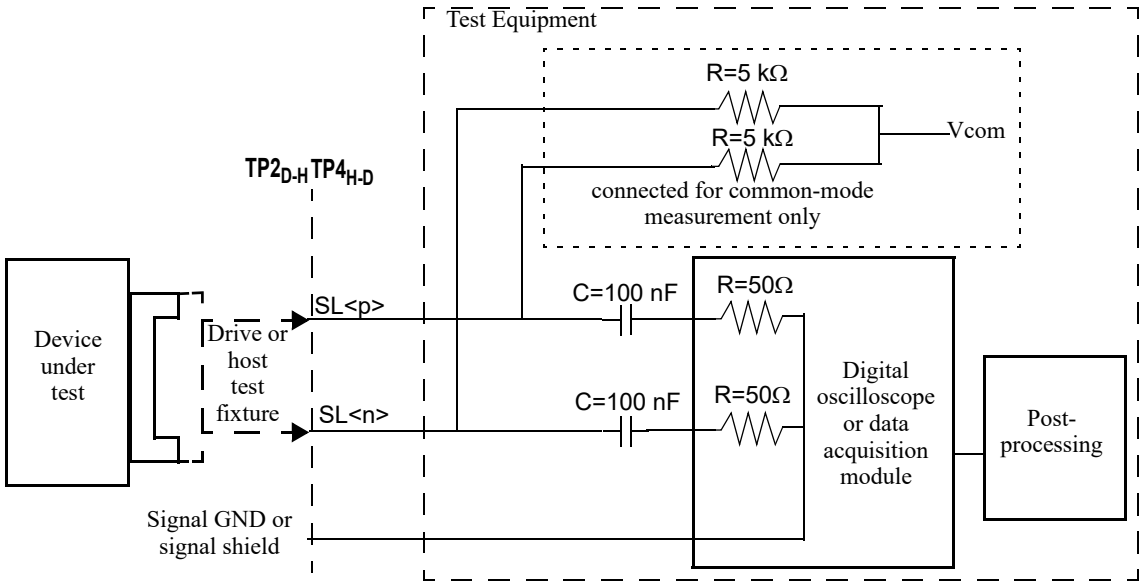

Figure 128B–1—Test configuration

128B.1 Host and drive compliance boards

128B.1.1 Test fixture return loss

The differential return loss, in dB, of the test fixture is specified in a mated state and shall meet the requirements of 128B.2.2.

128B.1.2 Test fixture insertion loss

The test fixture printed circuit board insertion loss values determined using Equation (128B–1) shall be used as the reference test fixture insertion loss.

$$Insertion_loss_{tfref}(f) = 0.44\sqrt{f} + 0.2293f \text{ (dB)} \quad (128B–1)$$

for $0.05 \le f \le 5.15625$

where

f is the frequency in GHz
$Insertion_loss_{tfref}$ is the reference test fixture insertion loss at frequency f

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The reference test fixture insertion loss limit is illustrated in Figure 128B–2.

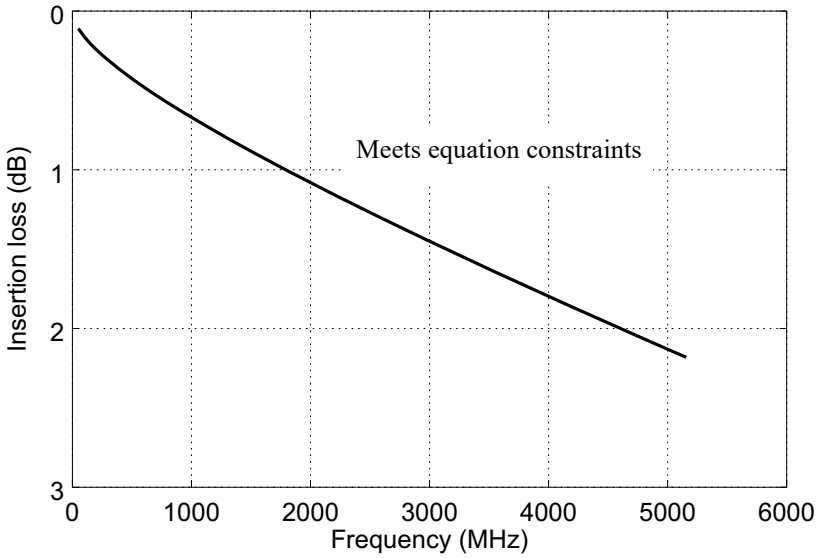

Figure 128B–2—Reference test fixture insertion loss limit

128B.2 Mated test fixtures

The test fixtures are specified in a mated state illustrated in Figure 128B–3. Return loss shall be verified at all test points shown in Figure 128B–3. A connector that meets the following requirements is specified in SFF-8482.

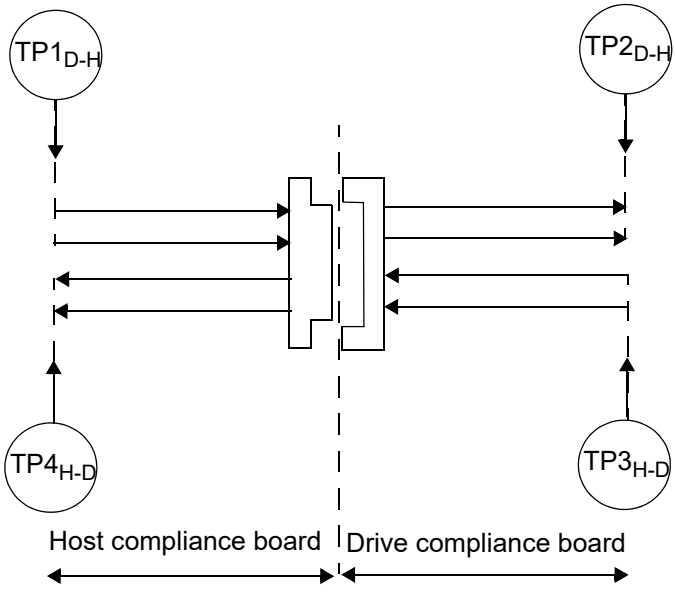

Figure 128B–3—Mated test fixture

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

128B.2.1 Mated test fixtures insertion loss

The insertion loss of the mated test fixtures shall meet the values determined using Equation (128B–2) and Equation (128B–3).

$$Insertion_loss(f) \le Insertion_loss_{MTF_{max}}(f) = \left\{ \begin{array}{ll} 1.6782\sqrt{f} + 0.293f & 0.05 \le f < 2.578125 \\ -2.4145 + 2.2747f & 2.578125 \le f < 5.15625 \end{array} \right\} \text{(dB)} \quad \text{(128B–2)}$$

$$Insertion_loss(f) \le Insertion_loss_{MTF_{min}}(f) = (0.9486\sqrt{f} + 0.1656f) \quad 0.05 \le f \le 5.15625 \text{ (dB)} \quad \text{(128B–3)}$$

where

f	is the frequency in GHz
Insertion_loss(f)	is the test fixture insertion loss at frequency f

The mated test fixture insertion loss limit is illustrated in Figure 128B–4.

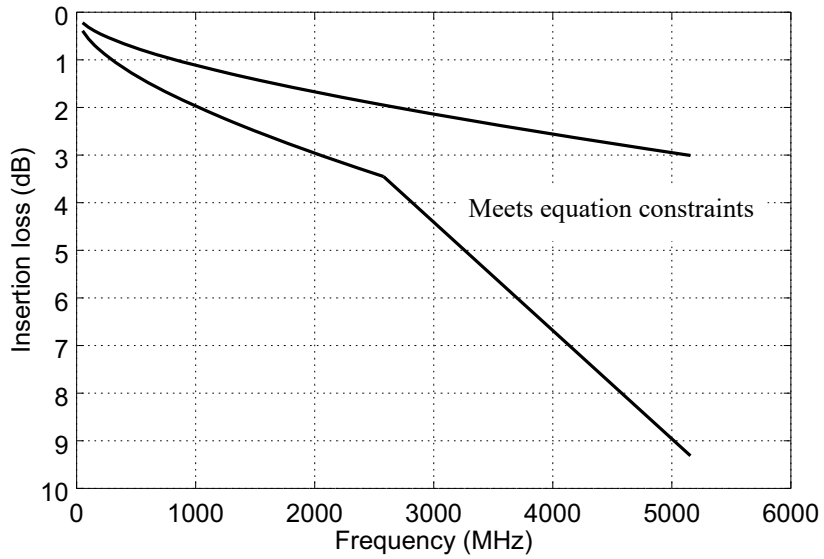

Figure 128B–4—Mated test fixtures insertion loss limit

128B.2.2 Mated test fixtures return loss

The return loss of the mated test fixtures measured at each test fixture interface shall meet the values determined using Equation (128B–4).

$$Return_loss(f) \le Return_loss_{MTF_{max}}(f) = \left\{ \begin{array}{ll} 17 - f & 0.01 \le f < 4 \\ 15 - 0.5f & 4 \le f < 5.15625 \end{array} \right\} (dB) \quad \text{(128B–4)}$$

where

f	is the frequency in GHz
Return_loss(f)	is the insertion loss at frequency f

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The mated test fixture return loss limit is illustrated in Figure 128B–5.

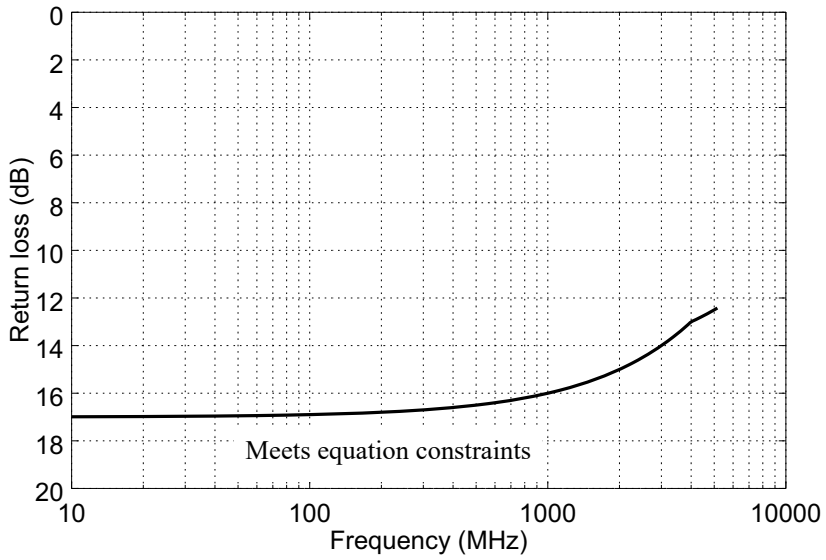

Figure 128B–5—Mated test fixture return loss limit

128B.2.3 Mated test fixtures integrated crosstalk noise

The values of the mated test fixtures integrated crosstalk RMS noise voltages determined using Equation (128B–5) through Equation (128B–7) for the near-end crosstalk loss shall meet the specifications in Table 128B–1.

Table 128B–1—Mated test fixtures integrated crosstalk noise

Parameter	ICN	Units
NEXT integrated crosstalk noise voltage	less than 1.8	mV

128B.2.3.1 Mated test fixture near-end crosstalk (NEXT) loss

ICN is calculated from the *NEXT*. Given the near-end crosstalk loss *NEXT_loss(f)* measured over N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 5.15625 GHz with a maximum frequency spacing of 10 MHz, the RMS value of the integrated crosstalk noise is determined using Equation (128B–5) through Equation (128B–7). The RMS crosstalk noise is characterized at the output of a specified receive filter utilizing a specified transmitter waveform and the measured crosstalk transfer functions. The combined transmitter and receiver filters are defined by Equation (128B–5) as a weighting function to the crosstalk in Equation (128B–6). The sinc function is defined by $\mathrm{sinc}(x) = \sin(\pi x)/(\pi x)$.

Define the weight at each frequency f_n using Equation (128B–5).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$W_{nt}(f_n) = \left(\frac{A_{nt}^2}{f_b}\right)\mathrm{sinc}^2\left(\frac{f_n}{f_b}\right)\left[\frac{1}{1+\left(\frac{f_n}{f_{nt}}\right)^4}\right]\left[\frac{1}{1+\left(\frac{f_n}{f_r}\right)^8}\right] \quad (128B–5)$$

The 3 dB transmit filter bandwidth f_{nt} is inversely proportional to the 20% to 80% rise and fall time T_{nt}. The constant of proportionality is 0.2365 (e.g., $T_{nt}f_{nt} = 0.2365$; with f_{nt} in hertz and T_{nt} in seconds). In addition, f_r is the 3 dB reference receiver bandwidth, which is set to 8 GHz.

The near-end integrated crosstalk noise is calculated using Equation (128B–6).

$$\sigma_{nx} = \left[2\Delta f\sum_n W_{nt}(f_n)10^{\frac{-NEXT_loss(f_n)}{10}}\right]^{1/2} \quad (128B–6)$$

where

Δf	is the uniform frequency step of f_n
NEXT_loss(f)	is the NEXT loss at frequency f in dB

The total integrated crosstalk noise is calculated using Equation (128B–7).

$$\sigma_x = \sigma_{nx} \quad (128B–7)$$

The total integrated crosstalk noise for the mated test fixture is computed using the parameters shown in Table 128B–2.

Table 128B–2—Integrated crosstalk noise characteristics

Parameter	Subclause reference	Value	Units
Symbol rate	f_b	5.51625	GBd
Near-end disturber peak differential output amplitude	A_{nt}	600	mV
Near-end disturber 20% to 80% rise and fall times	T_{nt}	20	ps

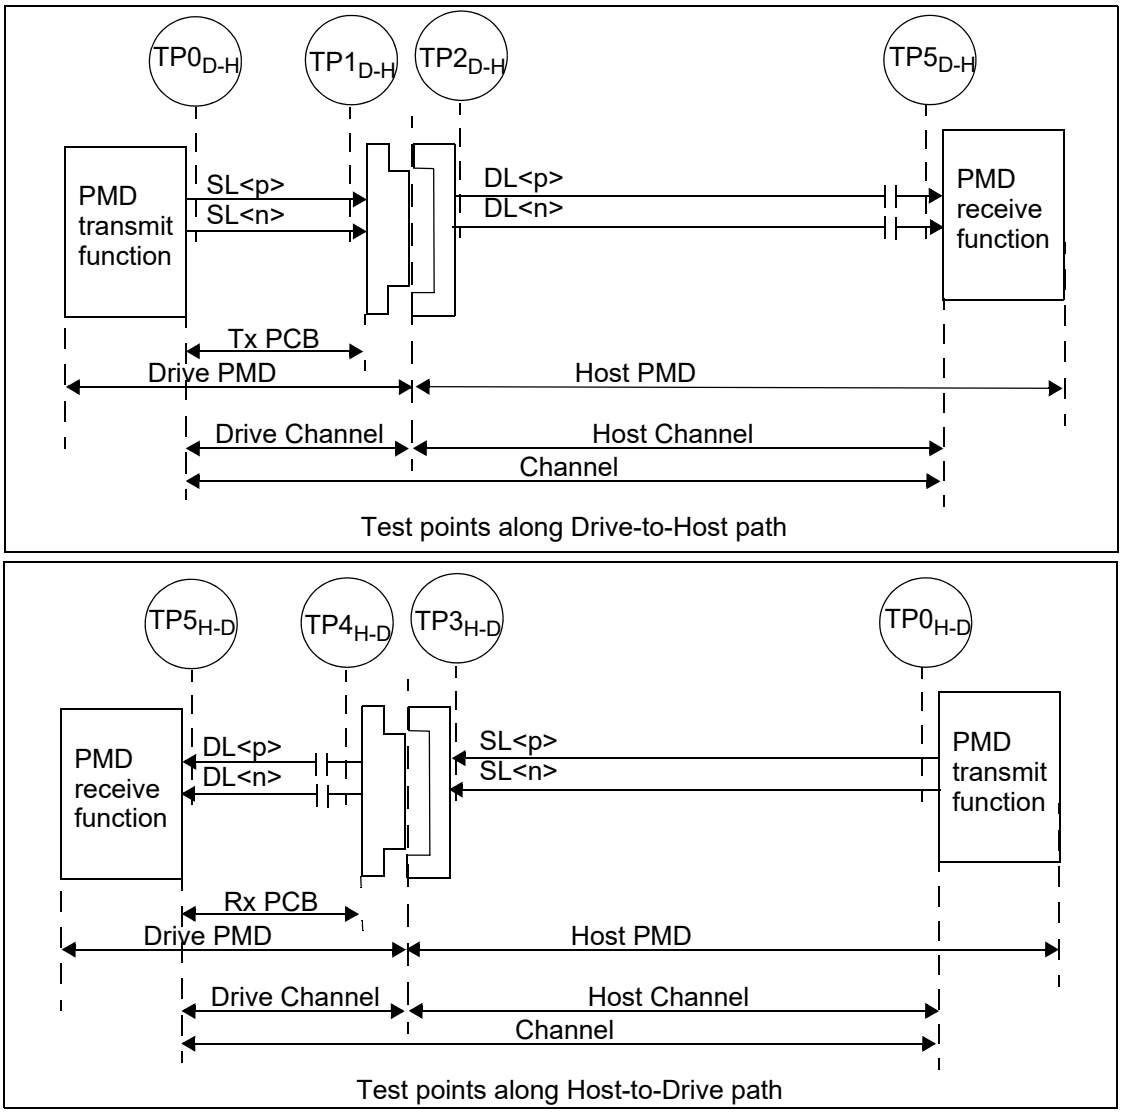
Annex 130A

(normative)

5 Gb/s Storage Enclosure Interface (5GSEI)

130A.1 Overview

This clause defines the functional and electrical characteristics for 5GSEI. This interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable storage drive module interfaces.The compliance point definitions provide a unique partitioning of the channel defined in Annex 69B, such that the test points $TP0_{D\text{-}H}$ and $TP0_{H\text{-}D}$ defined in this Annex are equivalent to TP1 defined in Figure 130–1, and $TP5_{D\text{-}H}$ and $TP5_{H\text{-}D}$ defined in this Annex are equivalent to TP4 defined in Figure 130–1. Figure 130A–1 shows the test point locations associated with 5GSEI.



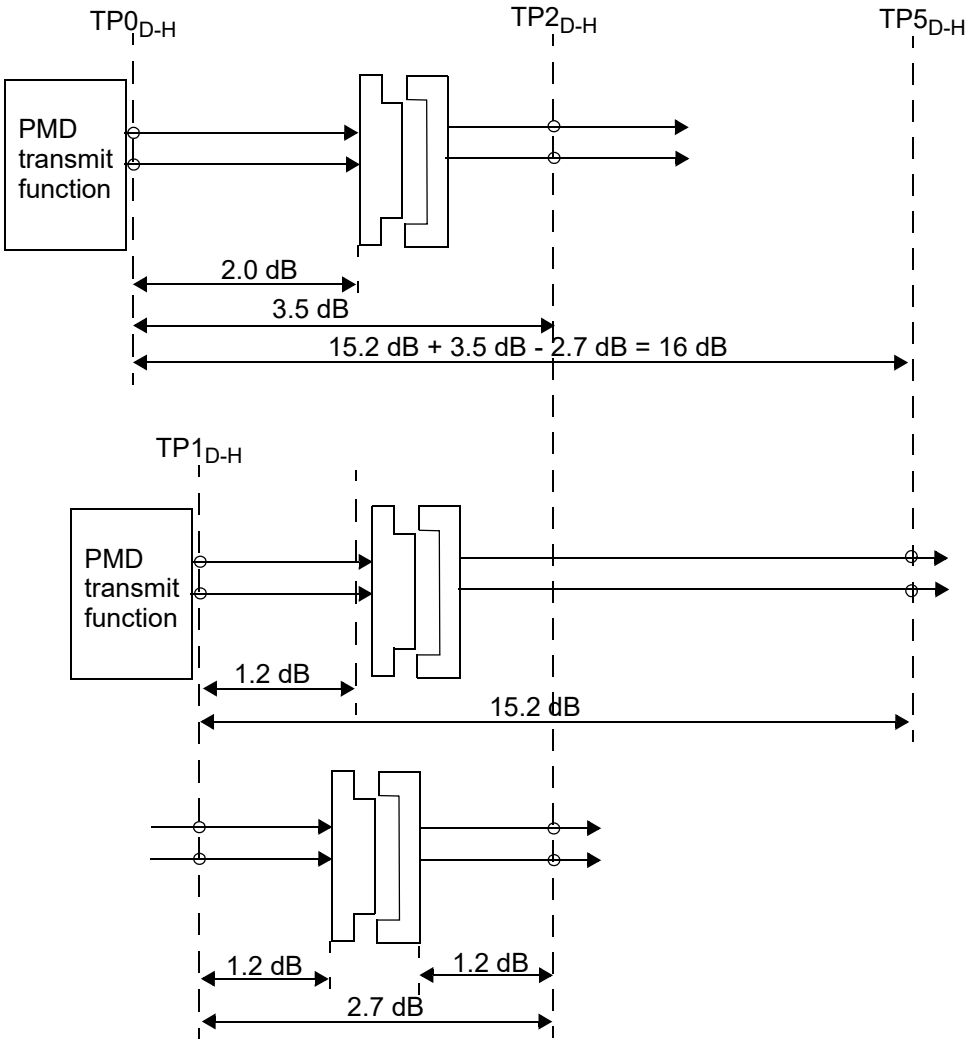


Figure 130A–1—Test points

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 5GSEI link is described in terms of a host 5GSEI component with associated insertion loss and a drive 5GSEI component. Figure 130A–2 (one direction shown) depicts the recommended differential insertion loss budget at 2.578125 GHz for a typical 5GSEI application. The recommended maximum differential insertion loss from TP0 to TP5 is given in Equation (130A–1) and depicted in Figure 130A–3. The 5GSEI interface consists of independent data paths in each direction. Each data path contains one differential lane, which is AC-coupled on the receiver side. The nominal signaling rate for each lane is 5.15625 GBd.

NOTE—The connector insertion loss is 0.3 dB for the mated test fixture.

Figure 130A–2—Insertion loss budget at 2.578125 GHz

$$Insertion_loss(f) \le \begin{cases} 0.668 + 3.755\sqrt{f} + 3.608f & 0.05 \le f < 2.578125 \\ -18.753 + 13.48f & 2.578125 \le f < 3.8671875 \end{cases} \text{ (dB)} \qquad (130A\text{–}1)$$

where

f is the frequency in GHz

Insertion_loss(f) is chip to chip (C2C) insertion loss

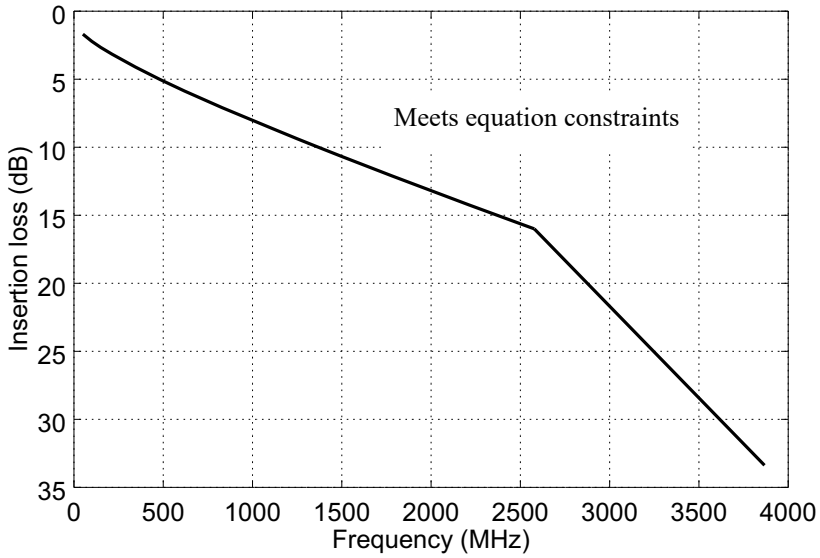

Figure 130A–3—Illustration of recommended maximum differential insertion loss from TP0 to TP5

130A.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 10^{-12} with any errors sufficiently un-correlated to ensure an acceptably high mean time to false packet acceptance (MTTFPA) assuming 64B/66B coding.

130A.2 5GSEI compliance point definitions

The electrical characteristics for 5GSEI are defined at compliance points for the host and drive, respectively. Reference test fixtures, called compliance boards, are used to access the electrical specification parameters. Figure 130A–4 depicts the location of compliance points when measuring host 5GSEI compliance. The output of the Host Compliance Board (HCB) is used to verify the host electrical output signal at $TP4_{H\text{-}D}$. Similarly, the input of the HCB at $TP1_{D\text{-}H}$ is used to verify the host input compliance.

Figure 130A–5 depicts the location of compliance points when measuring drive 5GSEI compliance. The output of the Drive Compliance Board (DCB) is used to verify the drive electrical output signal at $TP2_{D\text{-}H}$. Similarly, the input of the DCB at $TP3_{H\text{-}D}$ is used to verify the drive input compliance. Additional details on the requirements for the HCB and DCB are given in Annex 128B.

130A.3 5GSEI electrical characteristics

130A.3.1 5GSEI host output characteristics

A 5GSEI host output shall meet the specifications defined in Table 130A–1 if measured at $TP4_{H\text{-}D}$ (see Figure 130A–4).

Table 130A–1—5GSEI host output characteristics

Parameter	Subclause reference	Value	Units
Signaling rate	130A.3.1.1	5.15625 ± 100 ppm	GBd
Nominal unit interval	130A.3.1.1	193.9	ps
DC common-mode output voltage (max)	130A.3.1.2	1.9	V
AC common-mode output voltage (max, RMS)	130A.3.1.2	30	mV
Peak-to-peak differential output voltage (min) transmitter enabled	130A.3.1.2	800	mV
Peak-to-peak differential output voltage (max) transmitter enabled	130A.3.1.2	1200	mV
Peak-to-peak differential output voltage (max) transmitter disabled	130A.3.1.2	35	mV
Differential output return loss (min)	130A.3.1.3	See Equation (130A–2)	dB
Output waveform			
Transmitter steady-state voltage, v_f(max)	130A.3.1.4.2	600	mV
Transmitter steady-state voltage, v_f(min)		285	mV
Linear fit pulse peak (min)	130A.3.1.4.2	0.41 × v_f	mV
Pre-cursor coefficient	130A.3.1.4.3	0.65 ± 0.1	—
Max output jitter (peak-to-peak)			
Random jitter	130A.3.1.6	0.15	UI
Deterministic jitter	130A.3.1.6	0.12	UI
Duty Cycle Distortion[1]	130A.3.1.6	0.035	UI
Total jitter	130A.3.1.6	0.27	UI
Signal-to-noise-and-distortion ratio (min) - SNDR	130A.3.1.7	25	dB

[1]Duty Cycle Distortion is considered part of deterministic jitter distribution.

A test system as depicted in Figure 128B–1, with a fourth-order Bessel-Thomson low-pass response with 8 GHz 3 dB bandwidth, is to be used for all output signal measurements, unless otherwise specified.

130A.3.1.1 Signaling rate and range

The 5GSEI signaling rate is specified in Table 130A–1. The nominal unit interval is the inverse of the signaling rate.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

130A.3.1.2 Signaling levels

The differential output voltage V_d is defined to be the difference between the single-ended output voltages, *SL*<*p*> minus *SL*<*n*>. The common-mode voltage V_{cm} is defined to be one half of the sum of *SL*<*p*> and *SL*<*n*>. These definitions are illustrated by Figure 130A–6.

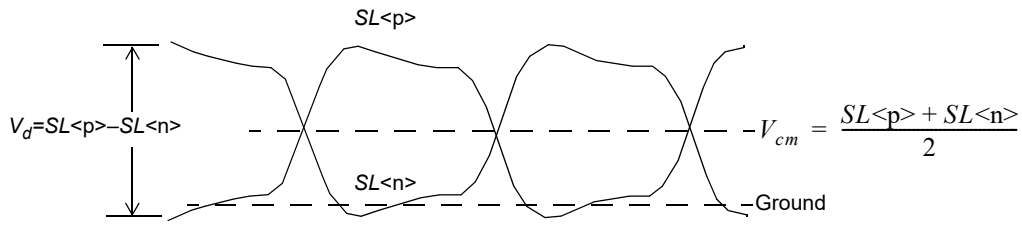

Figure 130A–6—Voltage definitions

The peak-to-peak differential output voltage is specified in Table 130A–1, when the transmitter is enabled and disabled. The DC common-mode output voltage and AC common-mode output voltage are defined with respect to signal ground.

130A.3.1.3 Output return loss

The differential output return loss, in dB, of the output is shown in Equation (130A–2) and illustrated in Figure 130A–7. This output requirement applies to all valid output levels. The reference impedance for differential return loss measurements is 100 Ω.

$$Return_loss(f) \geq \begin{cases} Return_loss_{min}(f) = 12 & 50 \leq f < 275 \\ Return_loss_{min}(f) = 12 - 6.75\log_{10}\left(\frac{f}{275\ \text{MHz}}\right) & 275 \leq f < 3000 \\ Return_loss_{min}(f) = 5 & 3000 \leq f < 3867.1875 \end{cases} \text{ (dB)} \quad (130A\text{–}2)$$

where

f is the frequency in MHz

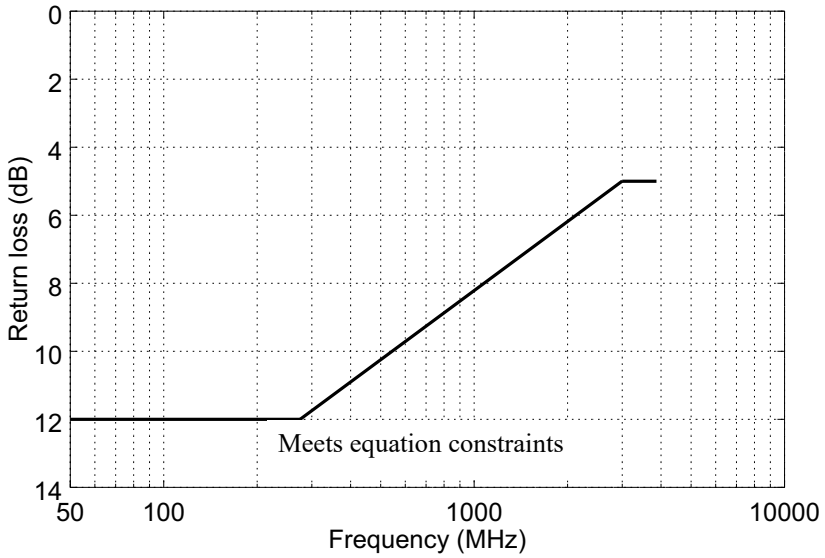

Figure 130A–7—Differential return loss limit

130A.3.1.4 Transmitter output waveform

The 5GSEI transmit function includes programmable equalization to compensate for the frequency dependent loss of the channel and facilitate data recovery at the receiver. The functional model for the transmit equalizer is the two tap transversal filter shown in Figure 130A–8. The state of the transmit equalizer and hence the transmitted output waveform may be manipulated via the management interface.

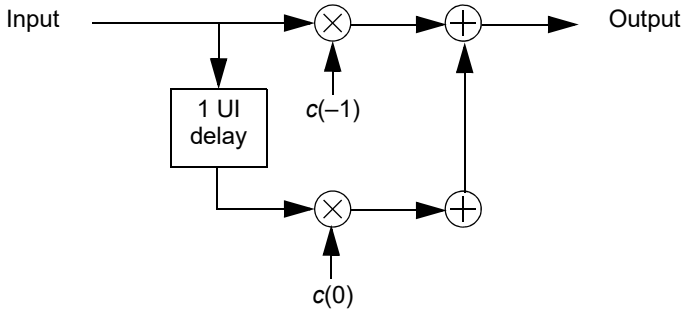

Figure 130A–8—Transmit equalizer functional model

130A.3.1.4.1 Linear fit to the measured waveform

The linear fit pulse response and normalized transmitter coefficient values are characterized using the procedure described in 92.8.3.5.1 with the exception that the measurement is performed at $TP4_{H\text{-}D}$ (see Figure 130A–4) rather than TP2, N_p =8.

130A.3.1.4.2 Steady-state voltage and linear fit pulse peak

The linear fit pulse, $p(k)$, is determined according to 130A.3.1.4.1. The steady-state voltage v_f is defined to be the sum of the linear fit pulse $p(k)$ divided by M, determined in step 3 of the linear fit procedure.

130A.3.1.4.3 Pre-cursor coefficient

The Pre-cursor coefficient, c(-1), is determined according to 130A.3.1.4.1.

130A.3.1.5 Transmit jitter test requirements

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in 48B.3. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 4 MHz is applied to the jitter. The data pattern for jitter measurements shall be a square wave as defined in 52.9.1.2 with 5 consecutive 1's and 0's. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal.

130A.3.1.6 Transmit jitter

The transmitter shall have a maximum total jitter, composed of a maximum deterministic component and a maximum random component as shown in Table 130A–1. Duty cycle distortion (DCD) is considered a component of deterministic jitter and shall not exceed the value shown in Table 130A–1. The peak-to-peak duty cycle distortion is defined as the absolute value of the difference in the mean pulse width of a 1 pulse or the mean pulse width of a 0 pulse (as measured at the mean of the high- and low-voltage levels in a clock like repeating bit sequence) and the nominal pulse width. Jitter specifications are specified for BER = 10^{-12}. Transmit jitter test requirements are specified in 130A.3.1.5.

130A.3.1.7 Transmitter output noise and distortion

Signal-to-noise-and-distortion ratio (SNDR) is measured at the transmitter output using the following method:

a) Capture at least one complete cycle of the test pattern PRBS9 as specified in Table 68–6 at $TP4_{H_D}$ (see Figure 130A–4) per 85.8.3.3.4.

b) Apply the reference equalizer from 93A.1.4.3, using the values from Table 130A–2.

c) Compute the linear fit pulse response $p(k)$ and the linear fit error waveform $e(k)$ from the resulting waveform per 85.8.3.3.5 using N_p=8 and D_p = 1. Denote the standard deviation of $e(k)$ as σ_e.

d) Measure the RMS deviation from the mean voltage at a fixed point in a run of at least 8 consecutive identical bits in a suitable pattern. PRBS9 is an example of a pattern that includes runs suitable to perform the measurement. It is recommended that the deviation is measured within the flattest portion of the waveform at a point where the slope is closest to zero. The RMS deviation is measured for a run of zeros and also a run of ones. The average of the two measurements is denoted as σ_n.

Table 130A–2—5G host receiver equalizer parameters

Parameter	Symbol	Value	Units
Signaling rate	f_b	5.15625 ± 100 ppm	GBd
Continuous time filter, DC gain [1] Minimum value Maximum value Step size	g_{DC}	 –14.5 0 0.5	 dB dB dB
Continuous time filter, zero frequency	f_z	$f_b/2$	GHz
Continuous time filter, pole frequencies	f_{p1} f_{p2}	$f_b/2$ f_b	GHz

[1] The DC gain, gDC, is optimized to satisfy the SNDR requirement.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SNDR is defined by Equation (130A–3).

$$SNDR = 10\log_{10}\left(\frac{p_{max}^{2}}{\sigma_e^{2} + \sigma_n^{2}}\right)\text{dB} \quad (130A–3)$$

where

$p_{\max}$ is the maximum value of $p(k)$

130A.3.2 5GSEI host input characteristics

A 5GSEI host input shall meet the specifications defined in Table 130A–3, measured at $TP1_{D\text{-}H}$ (see Figure 130A–4).

Table 130A–3—5GSEI host input characteristics

Parameter	Subclause reference	Value	Units
Differential input return loss (min)	130A.3.2.1	See Equation (130A–2)	dB
Interference tolerance	130A.3.2.2	Table 130A–4	—
Jitter tolerance	130A.3.2.3	Table 130A–5	—

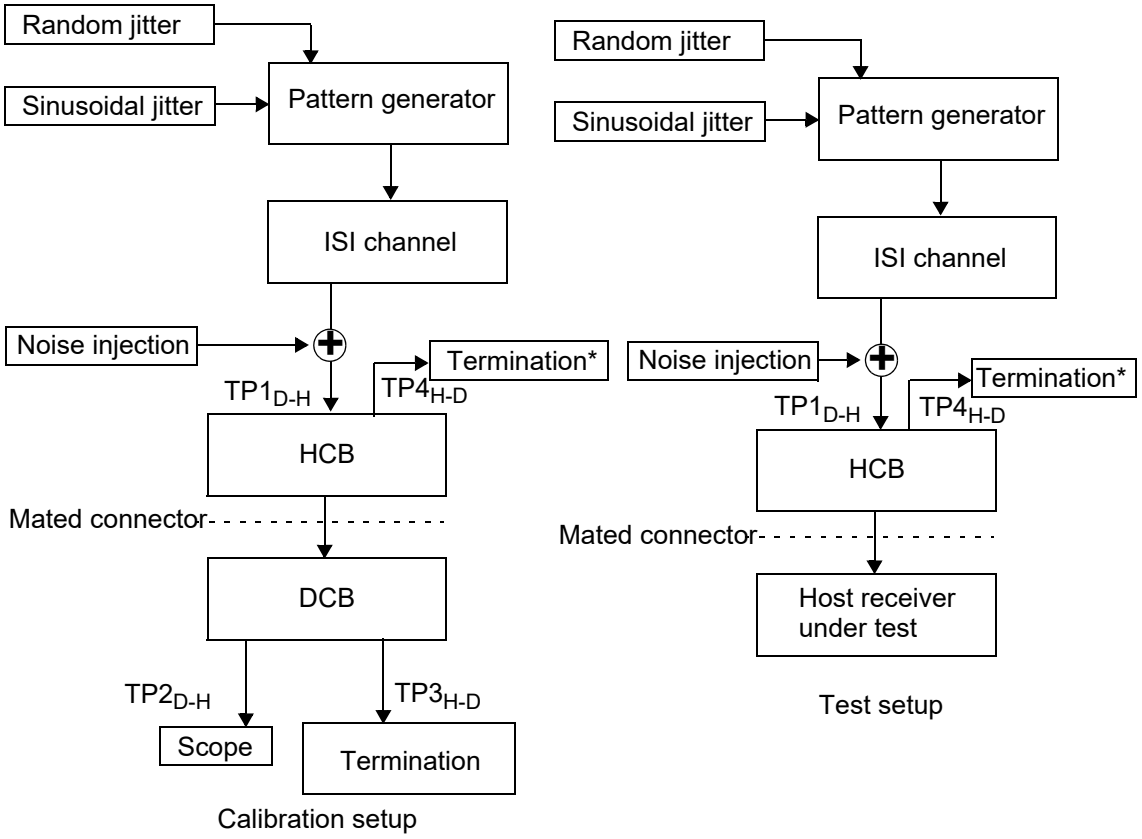
130A.3.2.1 Input differential return loss

The host input differential return loss shall meet Equation (130A–2) measured at $TP1_{D\text{-}H}$ (see Figure 130A–4).

130A.3.2.2 Receiver interference tolerance

The following considerations apply to the interference tolerance test. The pattern generator is calibrated at $TP2_{D\text{-}H}$ (see Figure 130A–9) to produce the values in Table 130A–4. The channel noise source is a broadband noise generator capable of producing white Gaussian noise with adjustable amplitude. The power spectral density shall be flat to ±3 dB from f_1 in Table 69B–2 to 0.5 times the signaling speed for the port type under test with a crest factor of no less than 5. The noise shall be measured at the output of a filter connected to the output of the noise source. The filter for this measurement shall have no more than a 40 dB per decade roll-off and a 3 dB cut-off frequency shall be equal to 0.5 times the signaling speed. Figure 130A–9 illustrates the calibration and test configurations that are needed for the host interference tolerance test. The data pattern used for the receiver interference tolerance test shall be PRBS31 (see 49.2.8). The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 5.15625 GBd ± 100 ppm.

Calibration procedure is as follows:



a) Create a channel (ISI channel + HCB + DCB) with as close to 6 dB of loss at 2.578125 GHz as possible.
b) Measure signal through the ISI channel at $TP2_{D\text{-}H}$ (see Figure 130A–9).
c) Adjust pattern generator output and ISI channel to meet the required linear fit pulse peak and precursor equalization ratio values.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) Adjust pattern generator amplitude to meet the required steady-state voltage.

e) Adjust noise to meet the required SNDR (see 130A.3.1.7).

f) Adjust pattern generator random jitter to the required value and then add sinusoidal jitter at 20 MHz to reach the total jitter requirement.

* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

Figure 130A–9—Host interference calibration and test setup

130A.3.2.3 Receiver jitter tolerance

The following considerations apply to the jitter tolerance test. The transmitter is calibrated at $TP2_{D\text{-}H}$ (see Figure 130A–10) to produce the values in Table 130A–5. Broadband noise is not injected during this test except for what is inherently present in the host. Figure 130A–12 illustrates the calibration and test configurations that are needed for the host jitter tolerance test. The data pattern used for the receiver jitter tolerance test shall be PRBS31 (see 49.2.8). The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 5.15625 GBd ± 100 ppm.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 6 dB of loss at 2.578125 GHz as possible.
b) Measure signal through the ISI channel at $TP2_{D\text{-}H}$ (see Figure 130A–10).
c) Adjust pattern generator output and ISI channel to meet the required linear fit pulse peak and precursor equalization ratio values.
d) Adjust pattern generator amplitude to meet the required steady-state voltage.
e) Adjust pattern generator random jitter to the required value.
f) Adjust sinusoidal jitter until the values in Table 130A–6 are met.

* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

A test system as depicted in Figure 128B–1, with a fourth-order Bessel-Thomson low-pass response with 8 GHz 3 dB bandwidth, is to be used for all output signal measurements, unless otherwise specified.

130A.3.3.1 Linear fit to the measured waveform

The linear fit pulse response and normalized transmitter coefficient values are characterized using the procedure described in 92.8.3.5.1 with the exception that the measurement is performed at $TP2_{D\text{-}H}$ (see Figure 130A–5) rather than TP2, and set $N_p = 8$.

130A.3.3.2 Steady-state voltage and linear fit pulse peak

The linear fit pulse, $p(k)$, is determined according to 130A.3.3.1. The steady-state voltage v_f shall have the limits shown in Table 130A–7.

130A.3.3.3 Precursor coefficient

The Precursor coefficient, c(-1), is determined according to 130A.3.3.1.

130A.3.3.4 Transmitter output noise and distortion

Signal-to-noise-and-distortion ratio (SNDR) is measured at the transmitter output using the following method:

a) Capture at least one complete cycle of the test pattern PRBS9 as specified in Table 68–6 at $TP2_{D_H}$ (see Figure 130A–5) per 85.8.3.3.4.
b) Apply the reference equalizer from 93A.1.4.3, using the values from Table 130A–8
c) Compute the linear fit pulse response $p(k)$ and the linear fit error waveform $e(k)$ from the resulting waveform per 85.8.3.3.5 using N_p=8 and $D_p = 1$. Denote the standard deviation of $e(k)$ as σ_e.
d) Measure the RMS deviation from the mean voltage at a fixed point in a run of at least 8 consecutive identical bits in a suitable pattern. PRBS9 is an example of a pattern that includes runs suitable to perform the measurement. It is recommended that the deviation is measured within the flattest portion of the waveform at a point where the slope is closest to zero. The RMS deviation is measured for a run of zeros and also a run of ones. The average of the two measurements is denoted as σ_n.

Table 130A–8—5G Drive receiver equalizer parameter

Parameter	Symbol	Value	Units
Signaling rate	f_b	5.15625 ± 100 ppm	GBd
Continuous time filter, DC gain [1] Minimum value Maximum value Step size	g_{DC}	 –2.0 0 1	 dB dB dB
Continuous time filter, zero frequency	f_z	$f_b/2$	GHz
Continuous time filter, pole frequencies	f_{p1} f_{p2}	$f_b/2$ f_b	GHz

[1] The DC gain, gDC, is optimized to satisfy the SNDR requirement.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SNDR is defined by Equation (130A–4).

$$SNDR = 10\log_{10}\left(\frac{p_{max}^{2}}{\sigma_e^{2} + \sigma_n^{2}}\right)\text{dB} \quad (130A–4)$$

where

$p_{\max}$ is the maximum value of $p(k)$

130A.3.4 5GSEI drive input characteristics

A 5GSEI drive input shall meet the specifications defined in Table 130A–9, measured at $TP3_{H\text{-}D}$ (see Figure 130A–5).

Table 130A–9—5GSEI drive input characteristics

Parameter	Subclause reference	Value	Units
Differential input return loss (min)	130A.3.4.1	See Equation (130A–2)	dB
Interference tolerance	130A.3.4.2	Table 130A–10	
Jitter tolerance	130A.3.4.3	Table 130A–11	

130A.3.4.1 Input differential return loss

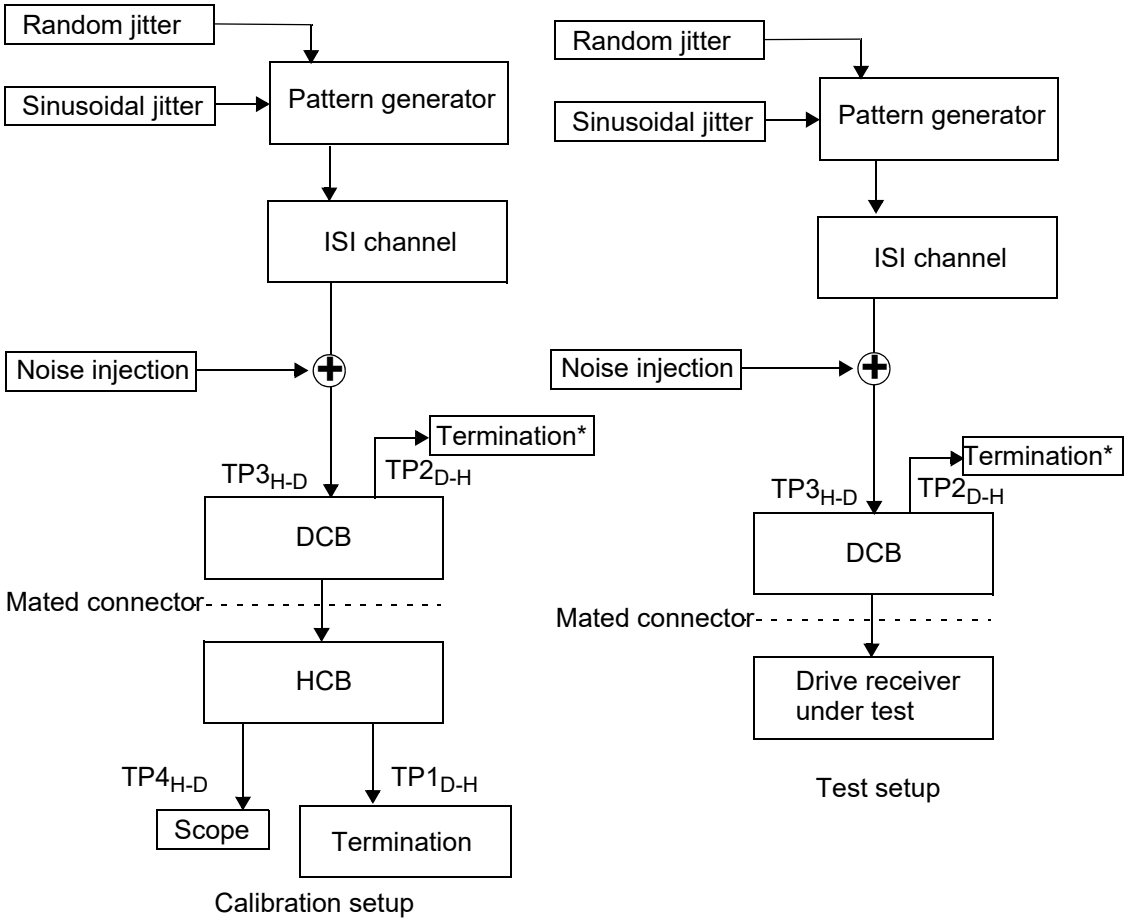
The drive input differential return loss shall meet Equation (130A–2) measured at $TP3_{H\text{-}D}$ (see Figure 130A–5).

130A.3.4.2 Receiver interference tolerance

The following considerations apply to the interference tolerance test. The pattern generator is calibrated at $TP4_{H\text{-}D}$ (see Figure 130A–11) to produce the values in Table 130A–10. The channel noise source is a broadband noise generator capable of producing white Gaussian noise with adjustable amplitude. The power spectral density shall be flat to ±3 dB from f_1 in Table 69B–2 to 0.5 times the signaling speed for the port type under test with a crest factor of no less than 5. The noise shall be measured at the output of a filter connected to the output of the noise source. The filter for this measurement shall have no more than a 40 dB per decade roll-off and a 3 dB cut-off frequency shall be equal to 0.5 times the signaling speed. Figure 130A–11 illustrates the calibration and test configurations that are needed for the drive interference tolerance test. The data pattern used for the receiver interference tolerance test shall be PRBS31 (see 49.2.8). The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 5.15625 GBd ± 100 ppm.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 18.5 dB of loss at 2.578125 GHz as possible.
b) The FOM ILD (see 93A.4) of the channel shall be greater than 1 dB, with f_b set to the signaling rate of Table 130A–7, T_t set to 42 ps, and f_r set to 0.75 x f_b.
c) Measure signal through the ISI channel at $TP4_{H\text{-}D}$ (see Figure 130A–11).



Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) Adjust pattern generator output and ISI channel to meet the required linear fit pulse peak value.

e) Adjust pattern generator amplitude to meet the required steady-state voltage.

f) Adjust noise to meet the required SNDR (see 130A.3.1.7).

g) Adjust pattern generator random jitter to the required value and then add sinusoidal jitter at 20 MHz to reach the total jitter requirement.

* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

130A.3.4.3 Receiver jitter tolerance

The following considerations apply to the jitter tolerance test. The transmitter is calibrated at $TP4_{H\text{-}D}$ (see Figure 130A–12) to produce the values in Table 130A–11. Broadband noise is not injected during this test except for what is inherently present in the drive. Figure 130A–12 illustrates the calibration and test configurations that are needed for the drive jitter tolerance test. The data pattern used for the receiver jitter tolerance test shall be PRBS31 (see 49.2.8). The BER shall be less than or equal to 10^{-12} for any signaling speed in the range of 5.15625 GBd ± 100 ppm.

Calibration procedure is as follows:

a) Create a channel (ISI channel + HCB + DCB) with as close to 18.2 dB of loss at 2.578125 GHz as possible.
b) The FOM ILD (see 93A.4) of the channel shall be greater than 1 dB, with f_b set to the signaling rate of Table 130A–7, T_t set to 42 ps, and f_r set to 0.75 x f_b.
c) Measure signal through the ISI channel at $TP4_{H\text{-}D}$.
d) Adjust pattern generator output and ISI channel to meet the required linear fit pulse peak value.
e) Adjust pattern generator amplitude to meet the required steady-state voltage.
f) Adjust pattern generator random jitter to the required value.
g) Adjust sinusoidal jitter until the values in Table 130A–12 are met.

* The single-ended transmit signals are terminated in 50 Ω to provide a 100 Ω differential termination.

130A.4 Protocol implementation conformance statement (PICS) proforma for Annex 130A, 5 Gb/s Storage Enclosure Interface (5GSEI)[312]

130A.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 130A, 5 Gb/s Storage Enclosure Interface (5GSEI), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

130A.4.2 Identification

130A.4.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

130A.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 130A, 5 Gb/s Storage Enclosure Interface (5GSEI)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

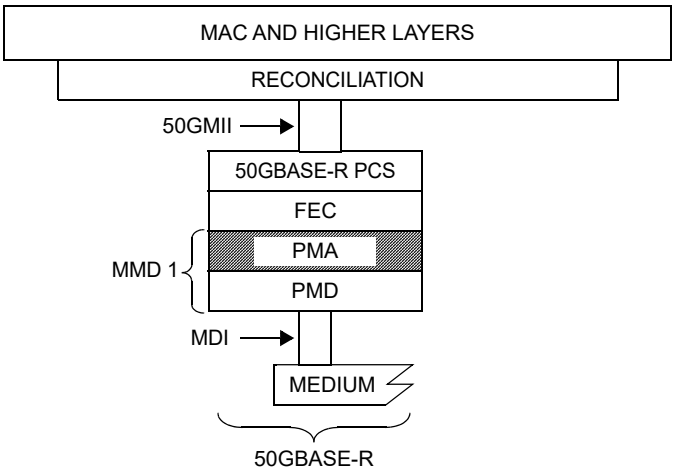
Annex 135A



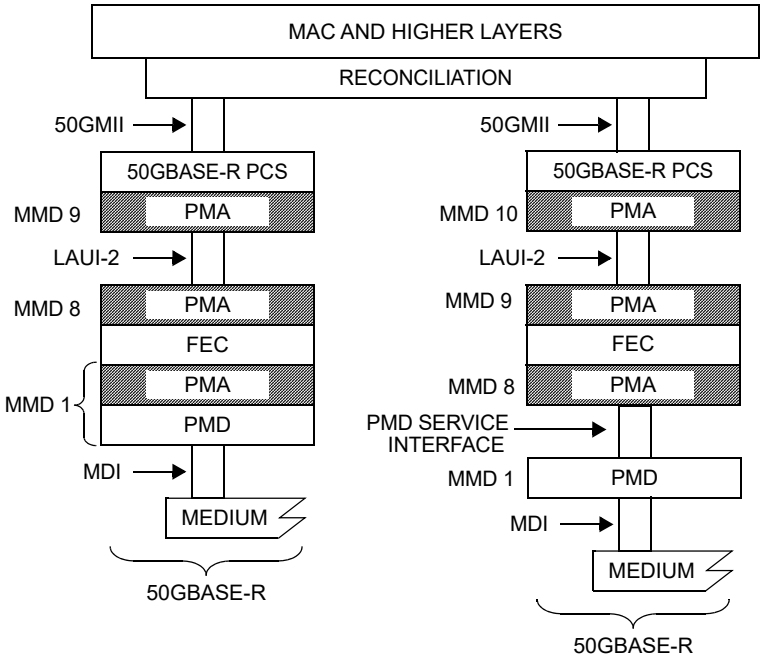
(informative)

50 Gb/s and 100 Gb/s PMA sublayer partitioning examples

The figures in this annex provide various partitioning examples. Partitioning guidelines and MMD numbering conventions are described in 135.1.4. These partitioning examples are informative and do not specify a particular sublayer combination for any PHY. Specific and compliant sublayer combinations for a particular PHY are provided in the appropriate normative clause.

135A.1 Partitioning examples of 50GBASE-R PHYs

Figure 135A–1 depicts an example of an FEC sublayer implemented with the PCS and PMD sublayers.



50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Annex 135B

(normative)

Chip-to-Chip 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2C)

135B.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-chip 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2C). The LAUI-2 C2C interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with electrical interconnect of approximately 25 cm in length.

LAUI-2 C2C is a physical instantiation of the PMA service interface between the PCS and the FEC, as described in 135.1.4. Figure 135B–1 shows an example relationship of the LAUI-2 C2C interface to the ISO/IEC Open System Interconnection (OSI) reference model.

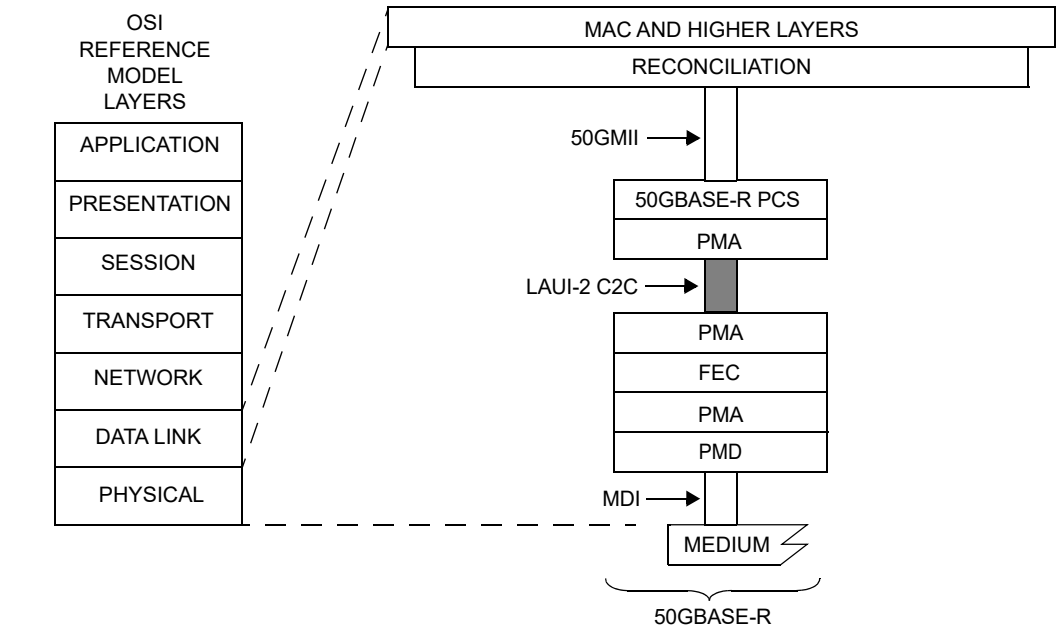

Figure 135B–1—Example LAUI-2 C2C relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The LAUI-2 C2C bidirectional link is described in terms of a LAUI-2 C2C transmitter, a LAUI-2 C2C channel, and a LAUI-2 C2C receiver. Figure 135B–2 depicts a typical LAUI-2 C2C application.

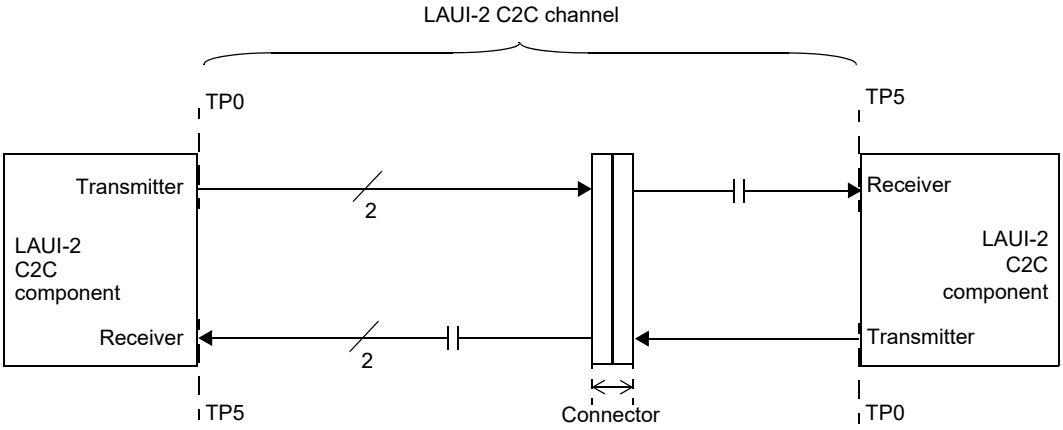

Figure 135B–2—Typical LAUI-2 C2C application

The LAUI-2 C2C interface comprises independent data paths in each direction. Each data path contains two differential lanes, which are AC-coupled. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

LAUI-2 uses NRZ signaling. The nominal signaling rate for each lane is 25.78125 GBd.

The recommended differential insertion loss budget associated with the C2C application can be found in Equation (83D–1) and Figure 83D–3. The normative channel compliance is through LAUI-2 C2C channel operating margin (COM) as described in 83D.4. Actual channel loss could be higher or lower than that given by Equation (83D–1) due to the channel ILD, return loss, and crosstalk.

The LAUI-2 C2C transmitter on each end of the link is adjusted to an appropriate setting based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 83D.3.3.2 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

135B.2 LAUI-2 C2C compliance point definition

The compliance points for the LAUI-2 C2C interface is defined in 83D.2.

135B.3 LAUI-2 C2C electrical characteristics

135B.3.1 LAUI-2 C2C transmitter characteristics

A LAUI-2 C2C transmitter shall meet all specifications for two CAUI-4 lanes in 83D.3.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

135B.3.2 LAUI-2 C2C receiver characteristics

A LAUI-2 C2C receiver shall meet all specifications for two CAUI-4 lanes in 83D.3.3.

If the LAUI-2 C2C receiver supports the optional transmitter equalization feedback, it shall meet all requirements in 83D.3.3.2.

135B.4 LAUI-2 C2C channel characteristics

The LAUI-2 C2C channel shall meet the requirements specified in 83D.4.

Annex 135C

(normative)

Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2M)

135C.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2M). The C2M interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable module interfaces.

LAUI-2 C2M is a physical instantiation of the PMA service interface between the PCS and the FEC, as described in 135.1.4. Figure 135C–1 shows the relationship of the LAUI-2 C2M interface to the ISO/IEC Open System Interconnection (OSI) reference model.

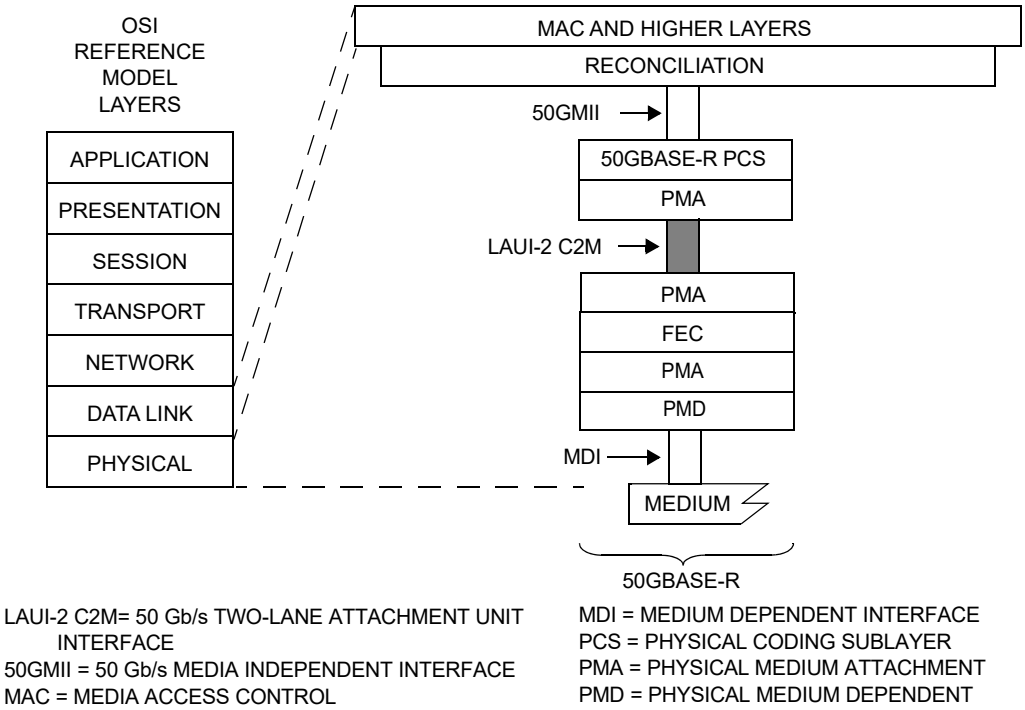

Figure 135C–1—Example LAUI-2 C2M relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The LAUI-2 C2M link is described in terms of a host LAUI-2 C2M component, a LAUI-2 C2M channel with associated insertion loss, and a module LAUI-2 C2M component. Figure 135C–2 depicts a typical LAUI-2 C2M application and summarizes the differential insertion loss budget associated with the C2M application.

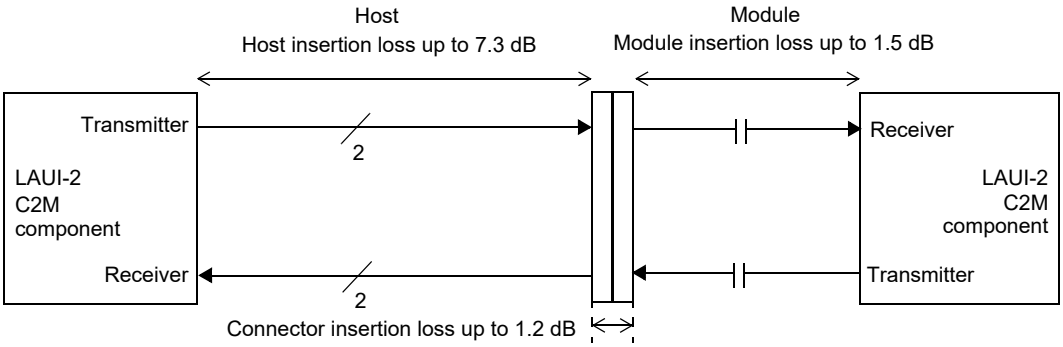

Figure 135C–2—LAUI-2 C2M insertion loss budget at 12.89 GHz

The LAUI-2 C2M interface comprises independent data paths in each direction. Each data path contains two differential lanes, which are AC-coupled within the module.

The LAUI-2 C2M uses NRZ signaling. The nominal signaling rate for each lane is 25.78125 GBd.

The supported insertion loss budget is characterized by Equation (83E–1) and illustrated in Figure 83E–3.

The LAUI-2 C2M interface is defined using a specification and test methodology that is similar to that used for CEI-28G-VSR defined in OIF-CEI-03.1 [B57].

135C.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 10^{-15} with any errors sufficiently uncorrelated to ensure an acceptably high mean time to false packet acceptance (MTTFPA) assuming 64B/66B coding.

135C.2 LAUI-2 C2M compliance point definitions

The compliance points for the LAUI-2 C2M interfaces are as defined for two CAUI-4 lanes in 83E.2.

135C.3 LAUI-2 C2M electrical characteristics

135C.3.1 LAUI-2 C2M host output characteristics

A LAUI-2 C2M host output shall meet all specifications for two CAUI-4 lanes in 83E.3.1.

135C.3.2 LAUI-2 C2M module output characteristics

A LAUI-2 C2M module output shall meet all specifications for two CAUI-4 lanes in 83E.3.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

135C.3.3 LAUI-2 C2M host input characteristics

A LAUI-2 C2M host input shall meet all specifications for two CAUI-4 lanes in 83E.3.3.

135C.3.4 LAUI-2 C2M module input characteristics

A LAUI-2 C2M module input shall meet all specifications for two CAUI-4 lanes in 83E.3.4.

135C.4 LAUI-2 C2M measurement methodology

The LAUI-2 C2M measurement methodology is as defined in 83E.4.

135C.5 Protocol implementation conformance statement (PICS) proforma for Annex 135C, Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2M)[314]

135C.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 135C, Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2M), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

135C.5.2 Identification

135C.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

135C.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 135C, Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (LAUI-2 C2M)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

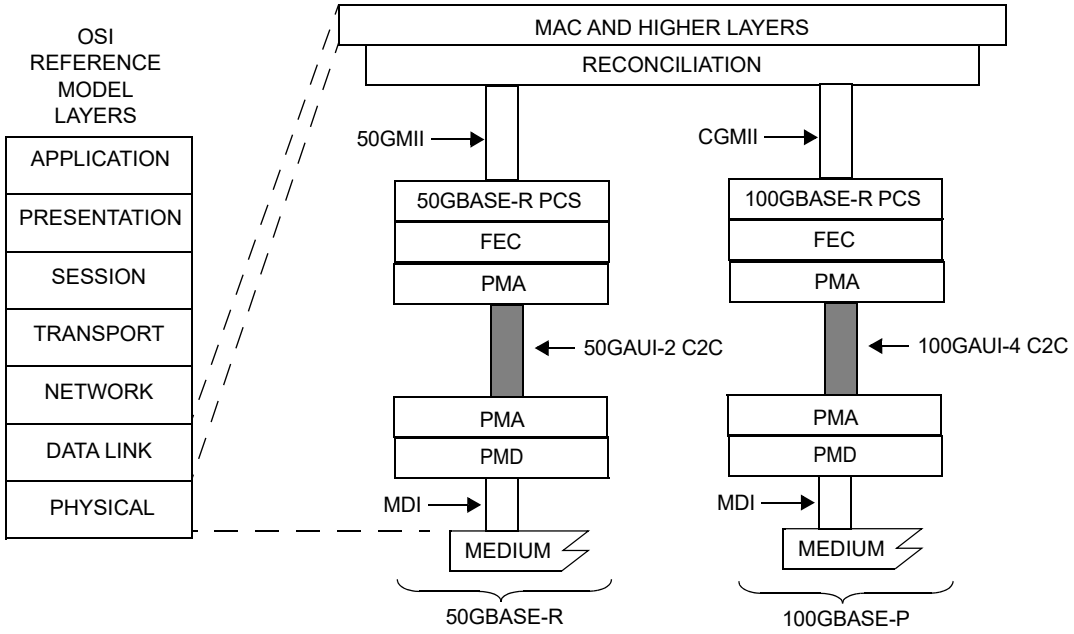
Annex 135D



(normative)

Chip-to-chip 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2C) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2C)

135D.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-chip 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2C) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2C). The 50GAUI-2 C2C and 100GAUI-4 C2C interfaces provide electrical characteristics and associated compliance points, which can optionally be used when designing systems with electrical inter-connect of approximately 25 cm in length.

50GAUI-2 C2C and 100GAUI-4 C2C are physical instantiations of the PMA service interface between the FEC and the PMD, as described in 135.1.4. Figure 135D–1 shows example relationships of the 50GAUI-2 C2C and 100GAUI-4 C2C interfaces to the ISO/IEC Open System Interconnection (OSI) reference model, respectively.

100GAUI-4 C2C= 100 Gb/s FOUR-LANE ATTACHMENT UNIT INTERFACE
50GAUI-2 C2C = 50 Gb/s TWO-LANE ATTACHMENT UNIT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 135D–1—Example 50GAUI-2 C2C and 100GAUI-4 C2C relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The 50GAUI-2 C2C bidirectional link is described in terms of a 50GAUI-2 C2C transmitter, a 50GAUI-2 C2C channel, and a 50GAUI-2 C2C receiver. Figure 135D–2 depicts a typical 50GAUI-2 C2C application.

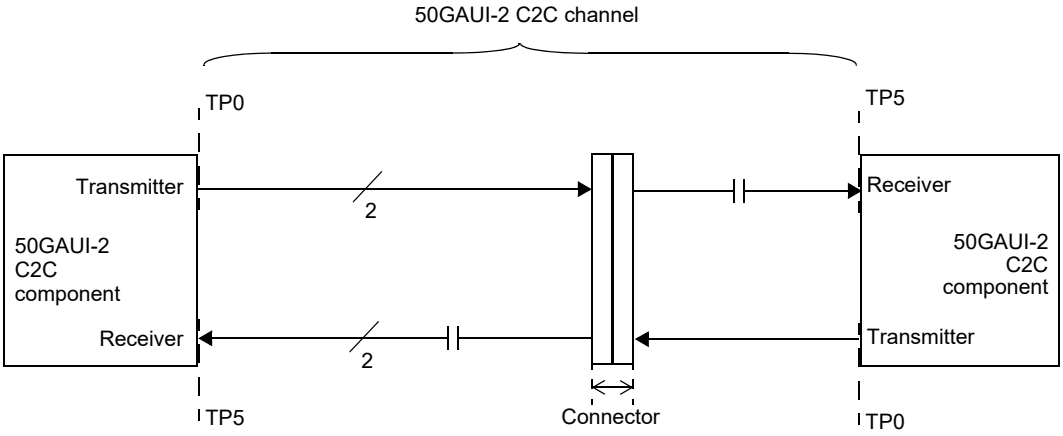

Figure 135D–2—Typical 50GAUI-2 C2C application

The 50GAUI-2 C2C interface comprises independent data paths in each direction. Each data path contains two differential lanes, which are AC-coupled. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

The 100GAUI-4 C2C bidirectional link is described in terms of a 100GAUI-4 C2C transmitter, a 100GAUI-4 C2C channel, and a 100GAUI-4 C2C receiver. Figure 135D–3 depicts a typical 100GAUI-4 C2C application.

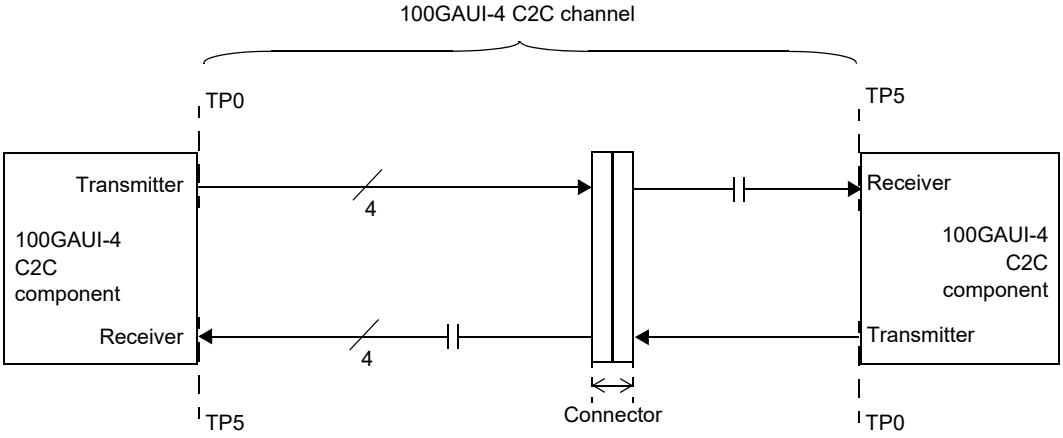

Figure 135D–3—Typical 100GAUI-4 C2C application

The 100GAUI-4 C2C interface comprises independent data paths in each direction. Each data path contains four differential lanes, which are AC-coupled. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

The 50GAUI-2 C2C or 100GAUI-4 C2C use NRZ signaling. The nominal signaling rate for each lane is 26.5625 GBd.

Equation (83D–1) (illustrated in Figure 83D–3) summarizes the recommended differential insertion loss budget associated with the 50GAUI-2 C2C or 100GAUI-4 C2C application. The normative channel compliance is through 50GAUI-2 C2C or 100GAUI-4 C2C channel operating margin (COM) as described in 83D.4. Actual channel loss could be higher or lower than that given by Equation (83D–1) due to the channel ILD, return loss, and crosstalk.

The 50GAUI-2 C2C or 100GAUI-4C2C transmitter on each end of the link is adjusted to an appropriate setting based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 83D.3.3.2 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

135D.2 50GAUI-2 C2C and 100GAUI-4 C2C compliance point definition

The compliance points for the 50GAUI-2 C2C and 100GAUI-4 C2C interfaces are as defined in 83D.2.

135D.3 50GAUI-2 C2C and 100GAUI-4 C2C electrical characteristics

135D.3.1 50GAUI-2 C2C and 100GAUI-4 C2C transmitter characteristics

A 50GAUI-2 C2C or a 100GAUI-4 C2C transmitter shall meet all specifications in 120B.3.1.

135D.3.2 50GAUI-2 C2C and 100GAUI-4 C2C receiver characteristics

A 50GAUI-2 C2C or a 100GAUI-4 C2C receiver shall meet all specifications in 120B.3.2.

135D.4 50GAUI-2 C2C and 100GAUI-4 C2C channel characteristics

The 50GAUI-2 C2C or 100GAUI-4 C2C channel shall meet the requirements specified in 120B.4.

135D.5 Protocol implementation conformance statement (PICS) proforma for Annex 135D, Chip-to-chip 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2C) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2C)[315]

135D.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 135D, Chip-to-chip 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2C) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2C), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

135D.5.2 Identification

135D.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

135D.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 135D, Chip-to-chip 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2C) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2C)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

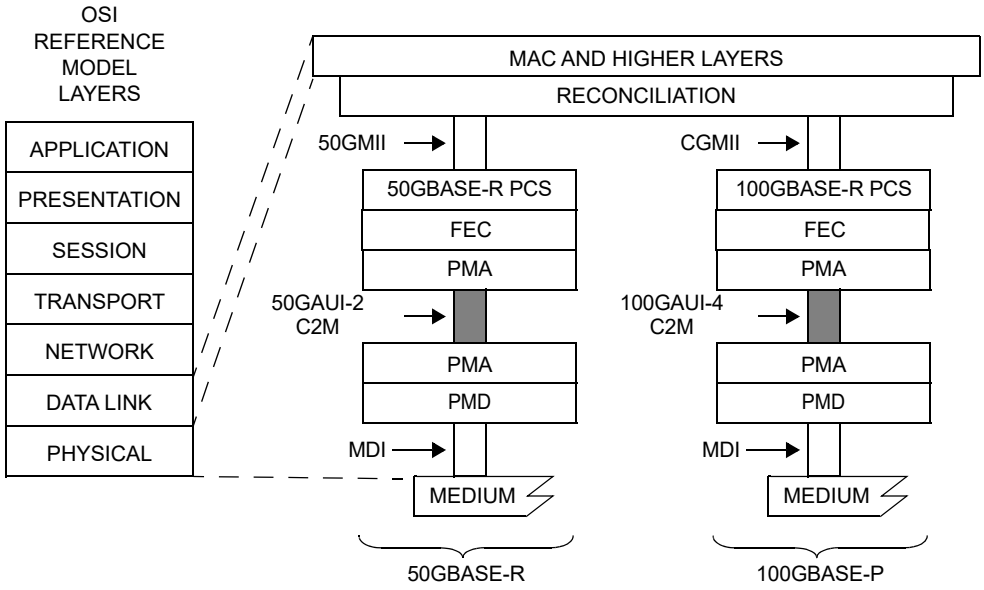
Annex 135E



(normative)

Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2M) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2M)

135E.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2M) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2M). The C2M interface provides electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable module interfaces.

50GAUI-2 C2M and 100GAUI-4 C2M are physical instantiations of the PMA service interface between the FEC and the PMD, as described in 135.1.4. Figure 135E–1 shows the relationship of the 50GAUI-2 C2M and 100GAUI-4 C2M interfaces to the ISO/IEC Open System Interconnection (OSI) reference model.

100GAUI-4 C2M = 100 Gb/s FOUR-LANE ATTACHMENT UNIT INTERFACE
50GAUI-2 C2M = 50 Gb/s TWO-LANE ATTACHMENT UNIT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 135E–1—Example 50GAUI-2 C2M and 100GAUI-4 C2M relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The sublayers (including FEC) for each PHY that can optionally include a 50GAUI-2 C2M or 100GAUI-4 C2M are summarized in the tables in 131.1.4 and 80.1.5, respectively, and are specified in the corresponding PMD clause. The positioning of the 50GAUI-2 C2M and 100GAUI-4 C2M relative to other sublayers is shown in Figure 135–2 with further examples in Annex 135A.

The 50GAUI-2 C2M link is described in terms of a host 50GAUI-2 C2M component, a 50GAUI-2 C2M channel with associated insertion loss, and a module 50GAUI-2 C2M component. Figure 135E–2 depicts a typical 50GAUI-2 C2M application and summarizes the differential insertion loss budget associated with the 50GAUI-2 C2M application.

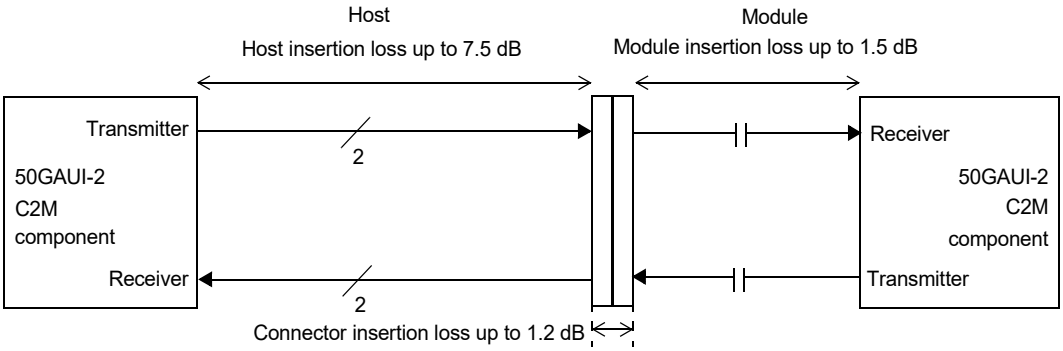

Figure 135E–2—50GAUI-2 C2M insertion loss budget at 13.28 GHz

The 50GAUI-2 C2M interface comprises independent data paths in each direction. Each data path contains two differential lanes, which are AC-coupled within the module.

The 100GAUI-4 C2M link is described in terms of a host 100GAUI-4 C2M component, a 100GAUI-4 C2M channel with associated insertion loss, and a module 100GAUI-4 C2M component. Figure 135E–3 depicts a typical 100GAUI-4 C2M application and summarizes the differential insertion loss budget associated with the C2M application.

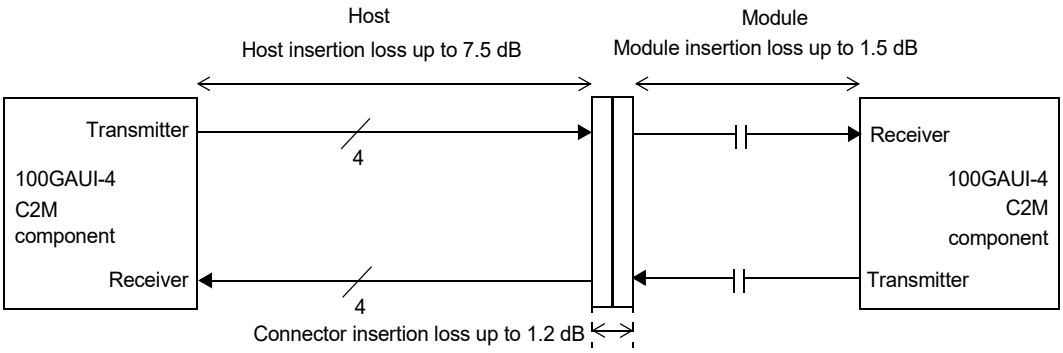

Figure 135E–3—100GAUI-4 C2M insertion loss budget at 13.28 GHz

The 100GAUI-4 C2M interface comprises independent data paths in each direction. Each data path contains four differential lanes, which are AC-coupled within the module.

The 50GAUI-2 C2M and 100GAUI-4 C2M interfaces use NRZ signaling. The nominal signaling rate for each lane is 26.5625 GBd.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The supported insertion loss budget is characterized by Equation (83E–1) and illustrated in Figure 83E–3.

The 50GAUI-2 C2M and 100GAUI-4 C2M interfaces are defined using a specification and test methodology that is similar to that used for CEI-28G-VSR defined in OIF-CEI-03.1 [B57].

135E.1.1 Bit error ratio

The bit error ratio (BER) shall be less than 10^{-6}.

135E.2 50GAUI-2 C2M and 100GAUI-4 C2M compliance point definitions

The compliance points for the 50GAUI-2 C2M and 100GAUI-4 C2M interfaces are as defined in 83E.2.

135E.3 50GAUI-2 C2M and 100GAUI-4 C2M electrical characteristics

135E.3.1 50GAUI-2 C2M and 100GAUI-4 C2M host output characteristics

A 50GAUI-2 C2M or 100GAUI-4 C2M host output shall meet all specifications in 120C.3.1.

135E.3.2 50GAUI-2 C2M and 100GAUI-4 C2M module output characteristics

A 50GAUI-2 C2M or a 100GAUI-4 C2M module output shall meet all specifications in 120C.3.2.

135E.3.3 50GAUI-2 C2M and 100GAUI-4 C2M host input characteristics

A 50GAUI-2 C2M or a 100GAUI-4 C2M host input shall meet all specifications in 120C.3.3.

135E.3.4 50GAUI-2 C2M and 100GAUI-4 C2M module input characteristics

A 50GAUI-2 C2M or a 100GAUI-4 C2M module input shall meet all specifications in 120C.3.4.

135E.4 50GAUI-2 C2M and 100GAUI-4 C2M measurement methodology

The 50GAUI-2 C2M and 100GAUI-4 C2M measurement methodology is as defined in 120C.4.

135E.5 Protocol implementation conformance statement (PICS) proforma for Annex 135E, Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2M) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2M)[316]

135E.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 135E, Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2M) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2M), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

135E.5.2 Identification

135E.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

135E.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 135E, Chip-to-module 50 Gb/s two-lane Attachment Unit Interface (50GAUI-2 C2M) and 100 Gb/s four-lane Attachment Unit Interface (100GAUI-4 C2M)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

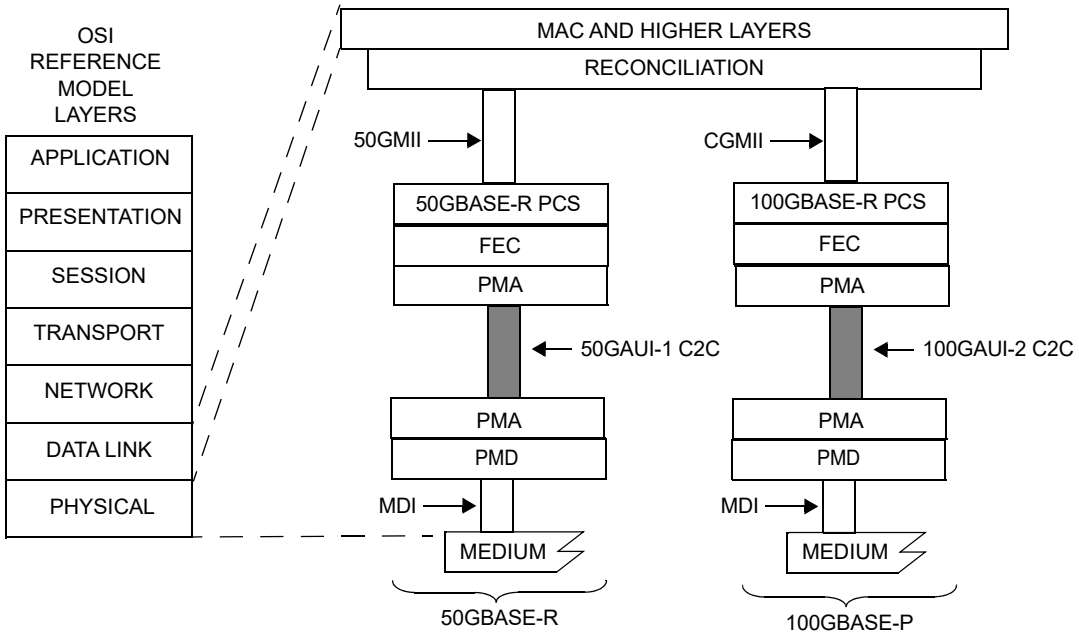
Annex 135F



(normative)

Chip-to-chip 50 Gb/s one-lane Attachment Unit Interface (50GAUI-1 C2C) and 100 Gb/s two-lane Attachment Unit Interface (100GAUI-2 C2C)

135F.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-chip 50 Gb/s one-lane Attachment Unit Interface (50GAUI-1 C2C) and 100 Gb/s two-lane Attachment Unit Interface (100GAUI-2 C2C). The 50GAUI-1 C2C and 100GAUI-2 C2C interfaces provide electrical characteristics and associated compliance points, which can optionally be used when designing systems with electrical inter-connect of approximately 25 cm in length.

50GAUI-1 C2C and 100GAUI-2 C2C are physical instantiations of the PMA service interface between the FEC and the PMD, as described in 135.1.4. Figure 135F–1 shows example relationships of the 50GAUI-1 C2C and 100GAUI-2 C2C interfaces to the ISO/IEC Open System Interconnection (OSI) reference model, respectively.

100GAUI-2 = 100 Gb/s FOUR-LANE ATTACHMENT UNIT INTERFACE
50GAUI-1 = 50 Gb/s ONE-LANE ATTACHMENT UNIT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 135F–1—Example 50GAUI-1 C2C and 100GAUI-2 C2C relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The 50GAUI-1 C2C bidirectional link is described in terms of a 50GAUI-1 C2C transmitter, a 50GAUI-1 C2C channel, and a 50GAUI-1 C2C receiver. Figure 135F–2 depicts a typical 50GAUI-1 C2C application.

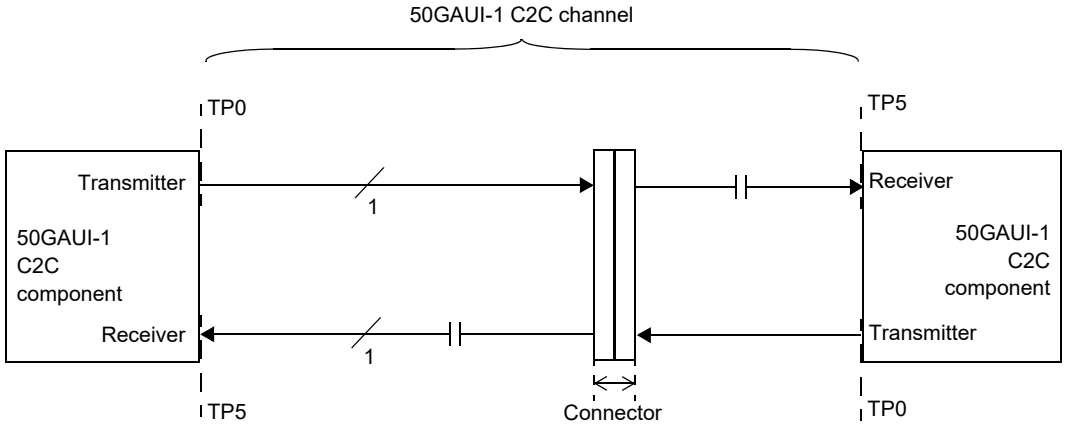

Figure 135F–2—Typical 50GAUI-1 C2C application

The 50GAUI-1 C2C interface comprises independent data paths in each direction. Each data path contains one differential lane, which is AC-coupled. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

The 100GAUI-2 C2C bidirectional link is described in terms of a 100GAUI-2 C2C transmitter, a 100GAUI-2 C2C channel, and a 100GAUI-2 C2C receiver. Figure 135F–3 depicts a typical 100GAUI-2 C2C application.

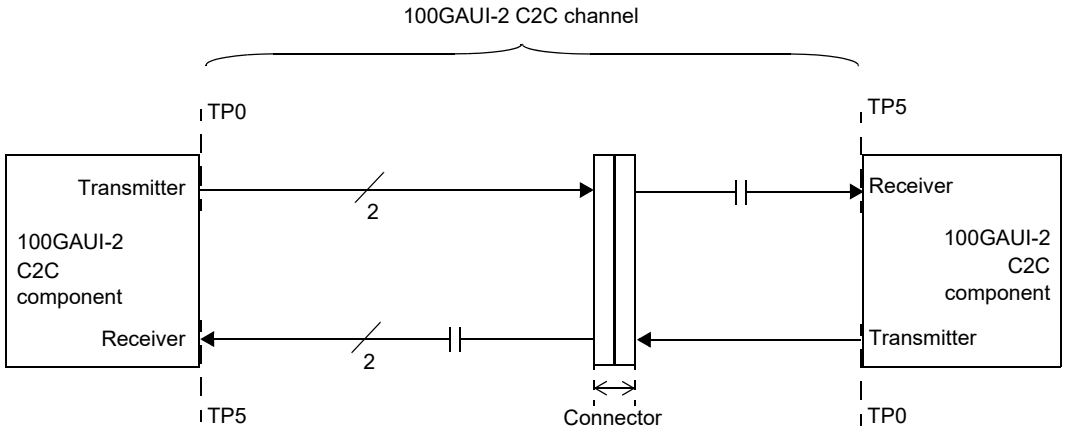

Figure 135F–3—Typical 100GAUI-2 C2C application

The 100GAUI-2 C2C interface comprises independent data paths in each direction. Each data path contains two differential lanes, which are AC-coupled. The low-frequency 3 dB cutoff of the AC-coupling should be less than 100 kHz.

The 50GAUI-1 C2C and 100GAUI-2 C2C use PAM4 signaling. The nominal signaling rate for each lane is 26.5625 GBd.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 50GAUI-2 C2C or 100GAUI-2 C2C channel is specified in 135F.4. The recommended channel insertion loss is described in 120D.1.

The 50GAUI-1 C2C or 100GAUI-2 C2C transmitter on each end of the link is adjusted to an appropriate setting based on channel knowledge. If implemented, the transmitter equalization feedback mechanism described in 120D.3.2.3 may be used to identify an appropriate setting. The adaptive or adjustable receiver performs the remainder of the equalization.

The 50GAUI-1 C2C or 100GAUI-2 C2C transmitter and receiver processing may include precoding as specified in 135F.3.1 and 135F.3.2, respectively. Precoding may be enabled and disabled using the precoder request mechanism specified in 135F.3.2.1.

135F.2 50GAUI-1 C2C and 100GAUI-2 C2C compliance point definition

The compliance points for the 50GAUI-1 C2C and 100GAUI-2 C2C interfaces are as defined in 120D.2.

135F.3 50GAUI-1 C2C and 100GAUI-2 C2C electrical characteristics

135F.3.1 50GAUI-1 C2C and 100GAUI-2 C2C transmitter characteristics

The 50GAUI-1 C2C or 100GAUI-2 C2C transmitter shall support 1/(1+D) mod 4 precoding, as specified in 135.5.7.2, that may be enabled or disabled as required.

A 50GAUI-1 C2C or a 100GAUI-2 C2C transmitter shall meet all specifications in 120D.3.1

135F.3.2 50GAUI-1 C2C and 100GAUI-2 C2C receiver characteristics

The 50GAUI-1 C2C or 100GAUI-2 C2C receiver may optionally support 1/(1+D) mod 4 decoding, as specified in 135.5.7.2, that may be enabled or disabled as required.

A 50GAUI-1 C2C or a 100GAUI-2 C2C receiver shall meet all specifications in 120D.3.2, with precoding enabled on the test transmitter if required by the receiver.

135F.3.2.1 Transmitter precoder request (optional)

The transmitter precoder request is an optional capability for a 50GAUI-1 C2C or 100GAUI-2 C2C receiver. If implemented, it shall operate as described in this subclause.

The transmitter precoder request is generated for each input (Tx and Rx) on each lane. The variables that control the transmitter precoding request are specific for each input and lane.

A 50GAUI-1 C2C or 100GAUI-2 C2C input may generate a request to change the precoder state of the remote output by setting the variable request_precoder_tx_in_flag or request_precoder_rx_in_flag to 1. The variables request_precoder_tx_in_*i* and request_precoder_rx_in_*i* indicate the requested transmitter precoder state for the corresponding interface and lane. A request from a 50GAUI-1 C2C or 100GAUI-2 C2C receiver is generated in an implementation specific manner. An example of a possible precoder update process is provided in 135F.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When a 50GAUI-1 C2C or 100GAUI-2 C2C receiver does not request a change of the remote transmitter's transmit setting, it sets request_precoder_tx_in_flag or request_precoder_rx_in_flag to 0. A 50GAUI-1 C2C or 100GAUI-2 C2C receiver that does not implement transmitter precoder request always sets request_precoder_tx_in_flag or request_precoder_rx_in_flag to 0.

If a Clause 45 MDIO is implemented, the variables request_precoder_rx_in_flag and request_precoder_tx_in_flag are accessible through register 1.604 (see 45.2.1.143), variables request_precoder_rx_in_*i* are accessible through register 1.605 (see 45.2.1.144), and variables request_precoder_tx_in_*i* are accessible through register 1.606 (see 45.2.1.145).

135F.4 50GAUI-1 C2C and 100GAUI-2 C2C channel characteristics

The 50GAUI-1 C2C or 100GAUI-2 C2C channel shall meet the requirements specified in 120D.4.

135F.5 Example usage of the optional transmitter precoder request

135F.5.1 Overview

If implemented, transmitter precoder request from a 50GAUI-1 C2C or 100GAUI-2 C2C receiver may be used to set the precoder configuration for each lane within the link as requested by the receiver. An example of a possible precoder configuration process using the transmitter precoder request is provided in this subclause.

In this example, two components, A and B, are connected by a C2C link, such that A is closest to the PCS and B is closest to the PMD. Clause 45 MDIO is implemented by both components, with component A at device address 11 and component B at device address 10. Transmitter precoder request is implemented by either component A, component B, or both. One Station Management (STA) controls both components.

Figure 135F–4 depicts the components of the C2C link and the registers used during the procedure.

135F.5.2 Configuring precoder setting in the transmit direction

For this example, the following procedure may be used to configure the precoder settings in the transmit direction:

a) For each lane in the link:
   1) Read request_precoder_tx_in_*i* from component B.
   2) Set both precoder_tx_in_enable_*i* of component B and precoder_tx_out_enable_*i* of component A to the read value.
b) If request_precoder_tx_in_flag of component B is 1 then go to step a.
c) Complete.

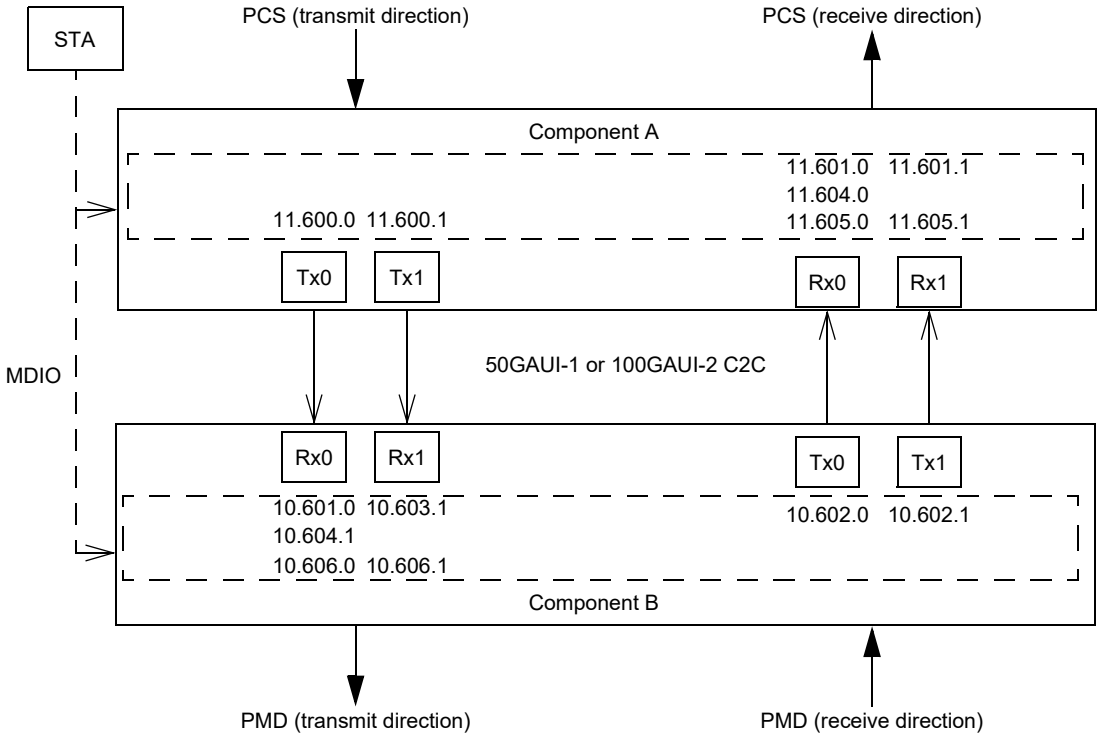

Figure 135F–4—Example transmitter precoder request components and registers

135F.5.3 Configuring precoder setting in the receive direction

For this example, the following procedure may be used to configure the precoder settings in the receive direction:

a) For each lane in the link:
   1) Read request_precoder_rx_in_*i* from component A.
   2) Set both precoder_rx_in_enable_*i* of component A and precoder_rx_out_enable_*i* of component B to the read value.

b) If request_precoder_rx_in_flag of component A is 1 then go to step a.

c) Complete.

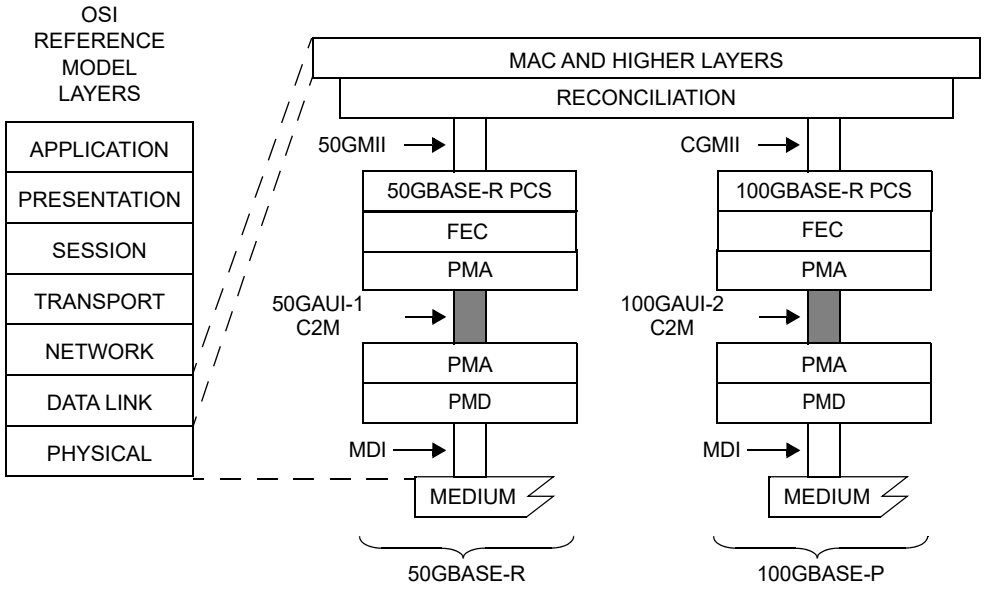
Annex 135G



(normative)

Chip-to-module 50 Gb/s one-lane Attachment Unit Interface (50GAUI-1 C2M) and 100 Gb/s two-lane Attachment Unit Interface (100GAUI-2 C2M)

135G.1 Overview

This annex defines the functional and electrical characteristics for the optional chip-to-module 50 Gb/s one-lane Attachment Unit Interface (50GAUI-1 C2M) and 100 Gb/s two-lane Attachment Unit Interface (100GAUI-2 C2M). The 50GAUI-1 C2M and 100GAUI-2 C2M interfaces provide electrical characteristics and associated compliance points, which can optionally be used when designing systems with pluggable module interfaces.

50GAUI-1 C2M and 100GAUI-2 C2M are physical instantiations of the PMA service interface between the FEC and the PMD, as described in 135.1.4. Figure 135G–1 shows the relationship of the 50GAUI-1 C2M and 100GAUI-2 C2M interfaces to the ISO/IEC Open System Interconnection (OSI) reference model.

100GAUI-2 C2M = 100 Gb/s TWO-LANE ATTACHMENT UNIT INTERFACE
50GAUI-1 C2M = 50 Gb/s ONE-LANE ATTACHMENT UNIT INTERFACE
50GMII = 50 Gb/s MEDIA INDEPENDENT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

Figure 135G–1—Example 50GAUI-1 C2M and 100GAUI-2 C2M relationship to the ISO/IEC Open System Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The sublayers (including FEC) for each PHY that can optionally include a 50GAUI-1 C2M or 100GAUI-2 C2M are summarized in the tables in 131.1.4 and 80.1.5, respectively, and are specified in the corresponding PMD clause. The positioning of the 50GAUI-1 C2M and 100GAUI-2 C2M relative to other sublayers is shown in Figure 135–2 with further examples in Annex 135A.

The 50GAUI-1 C2M link is described in terms of a host 50GAUI-1 C2M component, a 50GAUI-1 C2M channel with associated insertion loss, and a module 50GAUI-1 C2M component. Figure 135G–2 depicts a typical 50GAUI-1 C2M application and summarizes the differential insertion loss budget associated with the 50GAUI-1 C2M application.

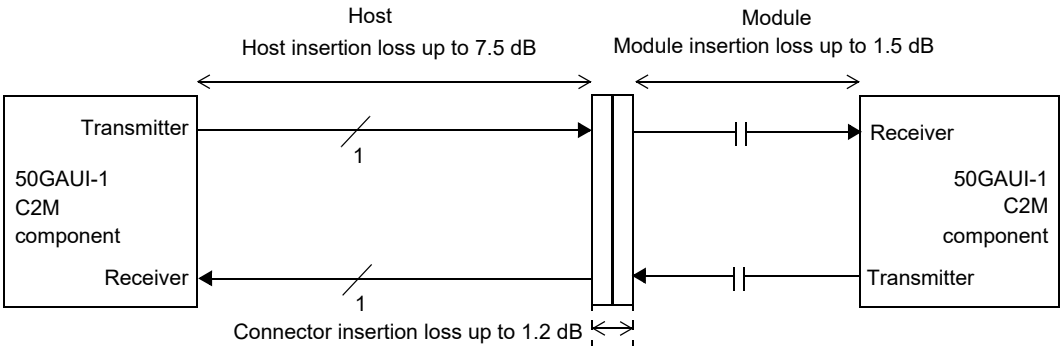


Figure 135G–2—50GAUI-1 C2M insertion loss budget at 13.28 GHz

The 50GAUI-1 C2M interface comprises independent data paths in each direction. The data path contains one differential lane, which is AC-coupled within the module.

The 100GAUI-2 C2M link is described in terms of a host 100GAUI-2 C2M component, a 100GAUI-2 C2M channel with associated insertion loss, and a module 100GAUI-2 C2M component. Figure 135G–3 depicts a typical 100GAUI-2 C2M application and summarizes the differential insertion loss budget associated with the 100GAUI-2 C2M application.

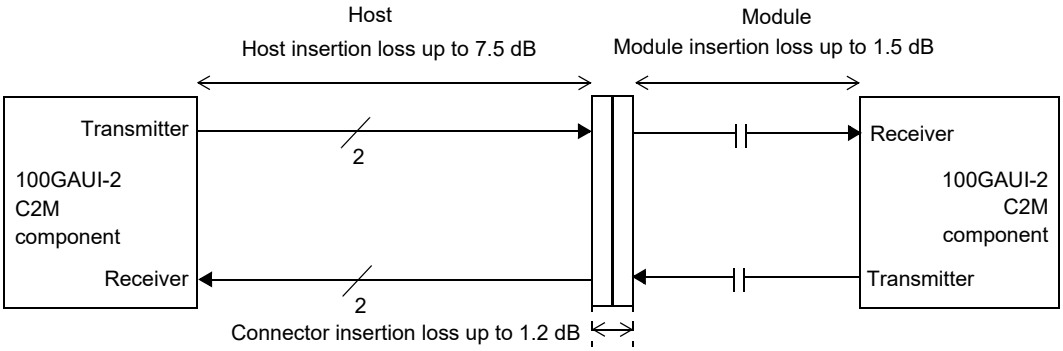

Figure 135G–3—100GAUI-2 C2M insertion loss budget at 13.28 GHz

The 100GAUI-2 C2M interface comprises independent data paths in each direction. Each data path contains two differential lanes, which are AC-coupled within the module.

The 50GAUI-1 C2M and 100GAUI-2 C2M interfaces use PAM4 signaling. The nominal signaling rate for each lane is 26.5625 GBd.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The supported insertion loss budget is characterized by Equation (120E–1) and illustrated in Figure 120E–4.

The 50GAUI-1 C2M and 100GAUI-2 C2M interfaces are defined using a specification and test methodology that is similar to that used for CEI-56G-VSR defined in OIF-CEI-4.0 [B58].

135G.1.1 Bit error ratio

The bit error ratio (BER) when processed according to Clause 135 shall be less than 10^{-5}.

135G.2 50GAUI-1 C2M and 100GAUI-2 C2M compliance point definitions

The compliance points for the 50GAUI-1 C2M and 100GAUI-2 C2M interfaces are as defined in 120E.2.

135G.3 50GAUI-1 C2M and 100GAUI-2 C2M electrical characteristics

135G.3.1 50GAUI-1 C2M and 100GAUI-2 C2M host output characteristics

A 50GAUI-1 C2M or 100GAUI-2 C2M host output shall meet all specifications in 120E.3.1.

135G.3.2 50GAUI-1 C2M and 100GAUI-2 C2M module output characteristics

A 50GAUI-1 C2M or a 100GAUI-2 C2M module output shall meet all specifications in 120E.3.2.

135G.3.3 50GAUI-1 C2M and 100GAUI-2 C2M host input characteristics

A 50GAUI-1 C2M or a 100GAUI-2 C2M host input shall meet all specifications in 120E.3.3.

135G.3.4 50GAUI-1 C2M and 100GAUI-2 C2M module input characteristics

A 50GAUI-1 C2M or a 100GAUI-2 C2M module input shall meet all specifications in 120E.3.4.

135G.4 50GAUI-1 C2M and 100GAUI-2 C2M measurement methodology

The 50GAUI-1 C2M and 100GAUI-2 C2M measurement methodology is as defined in 120E.4.

135G.5 Protocol implementation conformance statement (PICS) proforma for Annex 135G, Chip-to-module 50 Gb/s one-lane Attachment Unit Interface (50GAUI-1 C2M) and 100 Gb/s two-lane Attachment Unit Interface (100GAUI-2 C2M)[318]

135G.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 135G, Chip-to-module 50 Gb/s one-lane Attachment Unit Interface (50GAUI-1 C2M) and 100 Gb/s two-lane Attachment Unit Interface (100GAUI-2 C2M), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

135G.5.2 Identification

135G.5.2.1 Implementation identification

Supplier[1]

Annex 136A

(informative)

TP0 and TP5 test point parameters and channel characteristics for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4

136A.1 Overview

Annex 136A provides information on parameters associated with test points TP0 and TP5 that might not be testable in an implemented system. TP0 and TP5 test points are illustrated in the 50GBASE-CR, 100GBASE-CR2 and 200GBASE-CR4 link block diagram of Figure 136–2. This annex also provides information on channel characteristics.

136A.2 Transmitter characteristics at TP0

The recommended transmitter characteristics at TP0 as measured at TP0a are described in 137.9.2.

136A.3 Receiver characteristics at TP5

The recommended receiver characteristics at TP5 as measured at TP5a are described in 137.9.3.

136A.4 Transmitter and receiver differential printed circuit board trace loss

The recommended maximum and minimum printed circuit board trace insertion losses are specified in Equation (92A–1) and Equation (92A–2), respectively.

Note that the recommended maximum insertion loss allocation for the transmitter or receiver differential controlled impedance printed circuit boards is 7 dB at 13.28 GHz and the recommended minimum insertion loss allocation for the transmitter or receiver differential controlled impedance printed circuit boards is 1.2 dB at 13.28 GHz. The recommended maximum insertion loss allocation for the transmitter or receiver differential controlled impedance printed circuit boards is consistent with the insertion loss TP0 to TP2 or TP3 to TP5 given in Equation (136–5) and an assumed mated connector loss of 1.69 dB.

Note that the recommended maximum insertion loss from TP0 to TP2 or from TP3 to TP5 is 10.07 dB at 13.28 GHz.

136A.5 Channel insertion loss

This subclause provides information on channel insertion losses for the maximum-loss and minimum-loss cabling topologies.

The maximum channel insertion loss associated with the cable assembly is determined using Equation (136A–1). The channel insertion loss budget at 13.28 GHz is illustrated in Figure 136A–1. Loss budget parameters for all cable topologies are provided in Table 136A–1.

$$IL_{Chmax}(f) = IL_{Camax}(f) + 2IL_{Host}(f) - 2IL_{MatedTF}(f) \quad \text{(dB)} \quad \text{(136A–1)}$$

for 0.05 GHz ≤ f ≤ 19 GHz

where

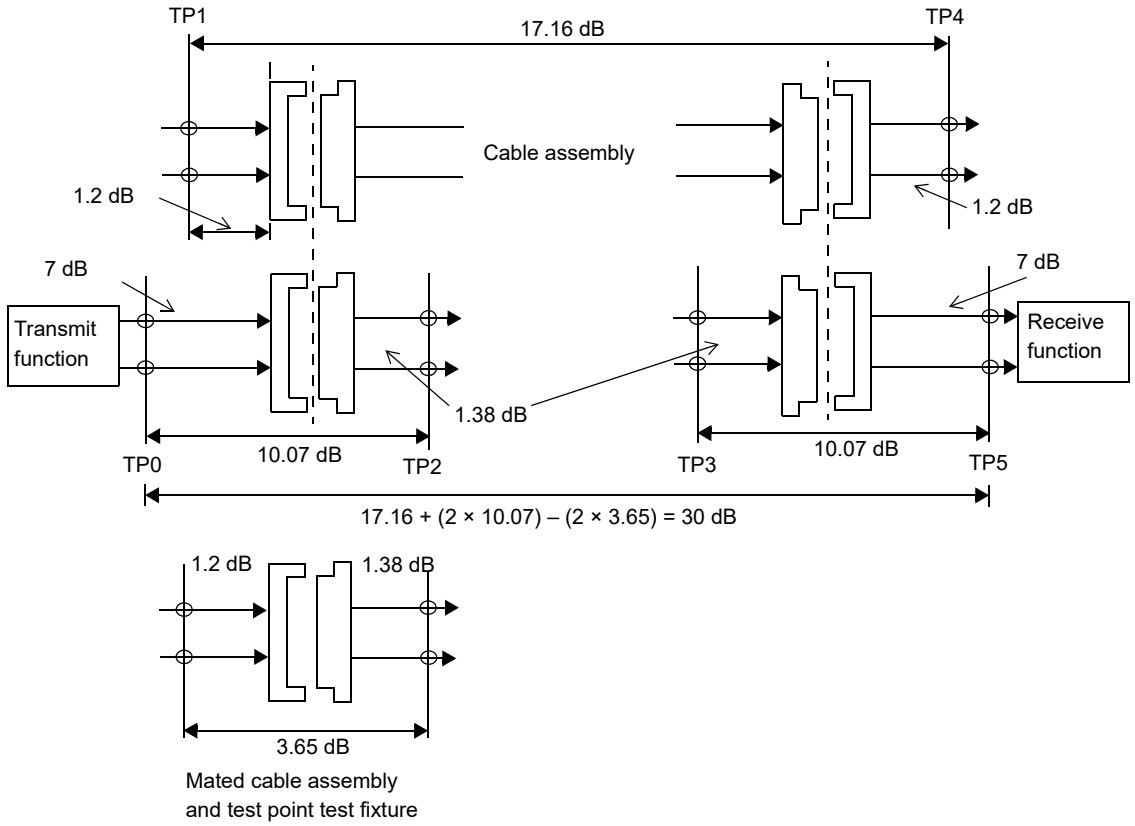
f	is the frequency in GHz
$IL_{Chmax}(f)$	is the maximum channel insertion loss between TP0 and TP5
$IL_{Camax}(f)$	is the maximum cable assembly insertion loss (TP1 to TP4)
$IL_{Host}(f)$	is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (136–5)
$IL_{MatedTF}(f)$	is the reference insertion loss of the mated test fixture using Equation (136B–1).

The channel insertion loss associated with the 0.5 m cable assembly and a maximum host channel is determined by Equation (136A–2).

$$IL_{Ch0.5m}(f) = IL_{Camin}(f) + 2IL_{Host}(f) - 2IL_{MatedTF}(f) \quad \text{(dB)} \quad \text{(136A–2)}$$

for 0.05 GHz ≤ f ≤ 19 GHz

where



f	is the frequency in GHz
$IL_{Ch0.5m}(f)$	is the channel insertion loss between TP0 and TP5 representative of a 0.5 m cable assembly and a maximum host channel
$IL_{Camin}(f)$	is the minimum cable assembly insertion loss (TP1 to TP4) given in Equation (92–26) and illustrated in Figure 92–12
$IL_{Host}(f)$	is the maximum insertion loss from TP0 to TP2 or TP3 to TP5 using Equation (136–5)
$IL_{MatedTF}(f)$	is the reference insertion loss of the mated test fixture using Equation (136B–1).

The loss budget parameter values at 13.28 GHz are provided in Table 136A–1.

Table 136A–1—Insertion loss budget values at 13.28 GHz

Parameter	50GBASE-CR	100GBASE-CR2	200GBASE-CR4	Units
IL_{Chmax}	30			dB
IL_{Camax}	17.16			dB
$IL_{Ch0.5m}$	21.14			dB
IL_{Camin}	8.3			dB
IL_{Host}	10.07			dB
$IL_{MatedTF}$	3.65			dB

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—The connector insertion loss is 1.07 dB for the mated test fixture. The host connector is allocated 0.62 dB of additional margin.

Figure 136A–1—30 dB channel insertion loss budget at 13.28 GHz

136A.6 Channel effective return loss

The 50GBASE-CR, 100GBASE-CR2 and 200GBASE-CR4 channels are recommended to meet the effective return loss specified in 137.10.2.

136A.7 Channel Operating Margin (COM)

The Channel Operating Margin (COM) for the channel between TP0 and TP5, computed using the procedure in 93A.1 and the parameters in Table 137–6, is recommended to be greater than or equal to 3 dB.

Annex 136B

(normative)

Test fixtures for 50GBASE-CR, 100GBASE-CR2, 200GBASE-CR4, 50GAUI-1 C2M, and 100GAUI-2 C2M

136B.1 Test fixtures

Transmitter and receiver measurements at TP2 or TP3 for the 50GBASE-CR PHY in an SFP28 host form factor (see 136D.2.1), and at TP1a or TP4a for the 50GAUI-1 C2M host (see Annex 135G), are made utilizing the test fixture specified in 110B.1.1. Transmitter and receiver measurements at TP2 or TP3 for the 50GBASE-CR, 100GBASE-CR2 or 200GBASE-CR4 PHYs in a multi-lane host form factor (see 136D.2.2), and at TP1a or TP4a for the 100GAUI-2 C2M host (see Annex 135G), are made utilizing the test fixture specified in 136B.1.1.

Cable assembly measurements for the SFP28-SFP28 form factor (see 136D.3.1) are made between TP1 and TP4 with cable assembly test fixtures as specified in 110B.1.2. on both ends. Cable assembly measurements for the multi-lane form factors (see 136D.3.1) are made between TP1 and TP4 with cable assembly test fixtures as specified in 136B.1.1 on both ends. Cable assembly measurements for the multi-lane-SFP28 form factor (see 136D.3.3) are made between TP1 and TP4 with a cable assembly test fixture as specified in 110B.1.2. for each connector on the SFP28 end, and with a cable assembly test fixture as specified in 136B.1.1 for the multi-lane end.

The test fixtures are specified in a mated state to enable connections to measurement equipment. The reference insertion loss of the mated test fixtures is 3.65 dB at 13.28 GHz using Equation (136B–1). The requirements in the referenced subclauses are not the MDI connector specifications for an implemented design.

136B.1.1 Mated test fixtures

The TP2 or TP3 and cable assembly test fixtures are specified in a mated state illustrated in Figure 92–18. The mated test fixtures specifications are listed in 92.11.3 and using the multi-lane integrated crosstalk noise in 136B.1.1.6.

136B.1.1.1 Mated test fixtures differential insertion loss

The differential insertion loss of the mated test fixtures shall meet the requirements of 92.11.3.1.

The FOM_{ILD} of the mated test fixtures shall meet the requirements of 92.11.3.1.

The reference insertion loss of the mated test fixture is determined using Equation (136B–1).

$$IL_{\mathrm{MatedTF}}(f) = 0.471\sqrt{f} + 0.1194f + 0.002f^2 \ \text{(dB)} \qquad \text{(136B–1)}$$

for $0.01\ \text{GHz} \le f \le 25\ \text{GHz}$

where

f is the frequency in GHz

136B.1.1.2 Mated test fixtures differential return loss

The differential return loss of the mated test fixtures shall meet the requirements of 92.11.3.2.

136B.1.1.3 Mated test fixtures common-mode conversion insertion loss

The common-mode conversion insertion loss of the mated test fixtures shall meet the requirements of 92.11.3.3.

136B.1.1.4 Mated test fixtures common-mode return loss

The common-mode return loss of the mated test fixtures shall meet the requirements of 92.11.3.4.

136B.1.1.5 Mated test fixtures common-mode to differential mode return loss

The common-mode to differential mode return loss of the mated test fixtures shall meet the requirements of 92.11.3.5.

136B.1.1.6 Mated test fixtures integrated crosstalk noise

The SFP28 mated test fixture integrated near-end crosstalk noise voltage for the disturber near-end crosstalk loss is determined according to the method in 110B.1.3.6 using the parameters shown in Table 136B–1 and shall meet the specification in Table 136B–2.

Table 136B–1—SFP28 mated test fixture integrated near-end crosstalk noise parameters

Description	Symbol	Value	Units
Symbol rate	f_b	26.5625	GBd
3 dB reference receiver bandwidth	f_r	19.92	GHz
Near-end disturber peak differential output amplitude	A_{nt}	600	mV
Near-end disturber 20% to 80% rise and fall times	T_{nt}	9.27	ps

Table 136B–2—SFP28 mated test fixture integrated near-end crosstalk noise voltage

Parameter	Value	Units
Integrated near-end crosstalk noise voltage	Less than 1.6	mV

The multi-lane mated test fixtures integrated crosstalk RMS noise voltages determined using Equation (92–44) through Equation (92–48) for the multiple disturber near-end crosstalk loss, and the multiple-disturber far-end crosstalk loss shall meet the specifications in Table 136B–4 using the parameters shown in Table 136B–3.

136B.2 Protocol implementation conformance statement (PICS) proforma for Annex 136B, Test fixtures for 50GBASE-CR, 100GBASE-CR2, 200GBASE-CR4, 50GAUI-1 C2M, and 100GAUI-2 C2M[319]

136B.2.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 136B, Test fixtures for 50GBASE-CR, 100GBASE-CR2, 200GBASE-CR4, 50GAUI-1 C2M, and 100GAUI-2 C2M, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

136B.2.2 Identification

136B.2.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

136B.2.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 136B, Test fixtures for 50GBASE-CR, 100GBASE-CR2, 200GBASE-CR4, 50GAUI-1 C2M, and 100GAUI-2 C2M
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

Annex 136C

(normative)

MDIs for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4

136C.1 Overview

This annex defines the Media Dependent Interface (MDI) for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4. The MDI couples the PMD (specified in 136.8 and 136.9) to the cable assembly (specified in 136.11). The PMDs supportable for each MDI connector type are given in Table 136C–1. The QSFP28, microQSFP, QSFP-DD and OSFP are also referred to as multi-lane connectors.

Table 136C–1—Number of PMDs supportable for each connector type

MDI types	50GBASE-CR	100GBASE-CR2	200GBASE-CR4	Reference
SFP28	1	—	—	110.11.1
QSFP28	1, 2, 4	1, 2	1	92.12.1.1
microQSFP	1, 2, 4	1, 2	1	136C.2.3
QSFP-DD	1, 2, 4, 8	1, 2, 4	1, 2	136C.2.4
OSFP	1, 2, 4, 8	1, 2, 4	1, 2	136C.2.5

For 50GBASE-CR, the mechanical interface between the PMD and the cable assembly may be a mated pair of connectors meeting the requirements of 110.11.1 (SFP28), 92.12.1.1 (QSFP), 136C.2.3 (microQSFP), 136C.2.4 (QSFP-DD), or 136C.2.5 (OSFP). The plug connector is used on the cable assembly and the receptacle is used on the PMD.

For 100GBASE-CR2 and 200GBASE-CR4, the mechanical interface between the PMD and the cable assembly is a mated pair of connectors meeting the requirements of 92.12.1.1 (QSFP), 136C.2.3 (microQSFP), 136C.2.4 (QSFP-DD), or 136C.2.5 (OSFP). The plug connector is used on the cable assembly and the receptacle is used on the PMD.

The cable assembly connector shall be the MDI connector plug. The PMD connector shall be the MDI connector receptacle.

The MDI connector electrical performance is consistent with the signal quality and electrical requirements of 136.9 and 136.10.

An MDI connector type may support one or more PMDs. The assignment of PMD signals to connector signals is specified in Table 136C–2, where as an example 0:DL0n refers to the DL0n signal of the first PMD.

The MDI connectors shall have data signal and signal ground contact assignments as specified in Table 136C–3 for the paired transmit and receive lanes (e.g., (SL0, DL0), (SL1, DL1)).

136C.2 MDI connector types

136C.2.1 SFP28

For 50GBASE-CR, the mechanical interface between the PMD and the cable assembly may be a mated pair of connectors meeting the requirements of 110.11.1 (SFP28). SFP28 supports one lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136C.2.2 QSFP28

For 50GBASE-CR, 100GBASE-CR2 or 200GBASE-CR4 the mechanical interface between the PMD and the cable assembly may be a mated pair of connectors meeting the requirements of 92.12.1.1 (QSFP28). QSFP28 supports up to four lanes.

136C.2.3 MicroQSFP

For 50GBASE-CR, 100GBASE-CR2 or 200GBASE-CR4 the mechanical interface between the PMD and the cable assembly may be a mated pair of connectors as defined in the microQSFP MSA.[320] microQSFP supports up to four lanes.

The microQSFP cable assembly connector is the plug illustrated in Figure 136C–1. The microQSFP PMD connector is the receptacle with the mechanical mating interface as illustrated in Figure 136C–2. The connectors have data signal and signal ground contact assignments as specified in Table 136C–3.

136C.2.4 QSFP-DD

For 50GBASE-CR, 100GBASE-CR2, or 200GBASE-CR4 the mechanical interface between the PMD and the cable assembly may be a mated pair of connectors as defined as defined in the QSFP-DD MSA.[321] QSFP-DD supports up to eight lanes.

The QSFP-DD cable assembly connector is the plug illustrated in Figure 136C–3. The QSFP-DD PMD connector is the receptacle with the mechanical mating interface as illustrated in Figure 136C–4. The connectors have data signal and signal ground contact assignments as specified in Table 136C–3.

136C.2.5 OSFP

For 50GBASE-CR, 100GBASE-CR2, or 200GBASE-CR4, the mechanical interface between the PMD and the cable assembly may be a mated pair of connectors as defined in the OSFP MSA.[322] OSFP supports up to eight lanes.

The OSFP cable assembly connector is the plug illustrated in Figure 136C–5. The OSFP PMD connector is the receptacle with the mechanical mating interface as illustrated in Figure 136C–6. The connectors have data signal and signal ground contact assignments as specified in Table 136C–3.

136C.3 Protocol implementation conformance statement (PICS) proforma for Annex 136C, MDIs for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4[323]

136C.3.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 136C, MDIs for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

136C.3.2 Identification

136C.3.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

136C.3.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 136C, MDIs for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

Annex 136D

(informative)

Host and cable assembly form factors for 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4

136D.1 Overview

This annex describes form factors for the cable assemblies specified in 136.11 and for hosts with 50GBASE-CR, 100GBASE-CR2, or 200GBASE-CR4 Physical Layers. Hosts have five specified MDI connectors: single-lane (SFP28 specified in 136C.2.1), four-lane (QSFP28 specified in 136C.2.2 and microQSFP specified 136C.2.3) and eight-lane (QSFP-DD specified in 136C.2.4 and OSFP specified in 136C.2.5). This creates five host interface types and multiple cable assembly types with different combinations of the connectors at each end. These host and cable assembly types are referred to as form factors, distinguishing both the host receptacle (MDI) and the cable assembly plug. Cable assemblies denoted as 50GBASE-CR, 100GBASE-CR2, and 200GBASE-CR4, have a common set of electrical parameters specified in 136.11. The 50GBASE-CR is a single-lane cable assembly enabling a 3 m length (and can also be implemented as a multiple version using a four-lane or eight-lane plug for high density applications). The 100GBASE-CR2 is a two-lane cable assembly enabling a 3 m length (and can also be implemented as a multiple version using a four-lane and eight-lane plug for high density applications). The 200GBASE-CR4 is a four-lane cable assembly enabling a 3 m length.

136D.2 Host form factors

136D.2.1 SFP28 host form factor

A host may use the SFP28 receptacle specified in 110.11.1 as the MDI for each 50GBASE-CR. This is referred to as an SFP28 host form factor.

A SFP28 form factor host can form a single 50 Gb/s link to either another SFP28 form factor host, using an SFP28 to SFP28 form factor cable assembly (see 136D.3.1), or a QSFP28 form factor host (see 136D.2.2), using a QSFP28 to 4×SFP28 form factor cable assembly (see 136D.3.3).

136D.2.2 QSFP28 host form factor

A host may use the QSFP28 receptacle specified in 136C.2.2 as the MDI for one, two, three or four 50GBASE-CR PHYs, one or two 100GBASE-CR2 PHYs, or one 200GBASE-CR4 PHY. This is referred to as a QSFP28 host form factor.

A QSFP28 form factor host can also form up to four 50 Gb/s links to either another QSFP28 form factor host, using a QSFP28 to QSFP28 form factor cable assembly (see 136D.3.2), or four separate SFP28 form factor hosts (see 136D.2.1) using a QSFP28 to 4×SFP28 form factor cable assembly (see 136D.3.3).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136D.2.3 microQSFP host form factor

A host may use the microQSFP receptacle specified in 136C.2.3 as the MDI for one, two, three or four 50GBASE-CR PHYs, one or two 100GBASE-CR2 PHYs, or one 200GBASE-CR4 PHY. This is referred to as a microQSFP host form factor.

A microQSFP form factor host can also form up to four 50 Gb/s links to either another microQSFP form factor host, using a microQSFP to microQSFP form factor cable assembly (see 136D.3.2), or four separate SFP28 form factor hosts (see 136D.2.1) using a microQSFP to 4xSFP28 form factor cable assembly (see 136D.3.3).

136D.2.4 QSFP-DD host form factor

A host may use the QSFP-DD receptacle specified in 136C.2.4 as an MDI for eight 50GBASE-CR PHYs, four 100GBASE-CR2 PHYs, or two 200GBASE-CR4 PHYs. This is referred to as a QSFP-DD host form factor.

136D.2.5 OSFP host form factor

A host may use the OSFP receptacle specified in 136C.2.5 as the MDI for eight 50GBASE-CR PHYs, four 100GBASE-CR2 PHYs, or two 200GBASE-CR4 PHYs. This is referred to as an OSFP host form factor.

136D.3 Cable assembly form factors

A subset of the possible cable assembly form factors are provided as examples in 136D.3.1 through 136D.3.4. The examples are: one-plug to one-plug, one-plug to two-plug, one-plug to four-plug, and one-plug to eight-plug. Cable assembly form factors consisting of any combination of MDIs and number of lanes that meet the requirements of 136.11 are acceptable.

136D.3.1 One-plug to one-plug cable assembly form factor

A one-plug to one-plug cable assembly form factor can use SFP28 plugs as specified in 110.11.1, QSFP28 plugs as specified in 92.12.1.1, microQSFP plugs as specified in 136C.2.3, QSFP-DD plugs as specified in 136C.2.4, or OSFP plugs as specified in 136C.2.5 on both ends. One plug to one plug cables can also have different cable plugs on each end. It may be used to connect the host form factors in 136D.2 with a single or, except for SFP28, multiple 50 Gb/s link.

A SFP28 to SFP28 cable assembly is illustrated in Figure 136D–1. Note that the figure is one example of a one-plug to one-plug cable assembly form factor.

The electrical characteristics of a cable assembly for this form factor are specified in 136.11, using the definitions in 136.11.7.1.1 and 136.11.7.1.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136D.3.2 One-plug to two-plug cable assembly form factor

A one-plug to two-plug cable assembly form factor can use either a QSFP28 plug as specified in 92.12.1.1 or a microQSFP plug as specified in 136C.2.3 on one end, and two QSFP28 or microQSFP plugs on the other end. It may be used to connect a QSFP28 form factor host (see 136D.2.2) or a microQSFP form factor host (see 136D.2.3) on the one-plug end to two QSFP28 or microQSFP form factor hosts on the two-plug end, such that the host on the one-plug end forms two 50GBASE-CR links or one 100GBASE-CR2 link with each of the hosts on the two-plug end.

A QSFP28 to two QSFP28 cable assembly is illustrated in Figure 136D–2. Note that the figure is one example of a one-plug to two-plug cable assembly form factor.

The electrical characteristics of a cable assembly for this form factor are specified in 136.11, using the definitions in 136.11.7.1.1 and 136.11.7.1.2.

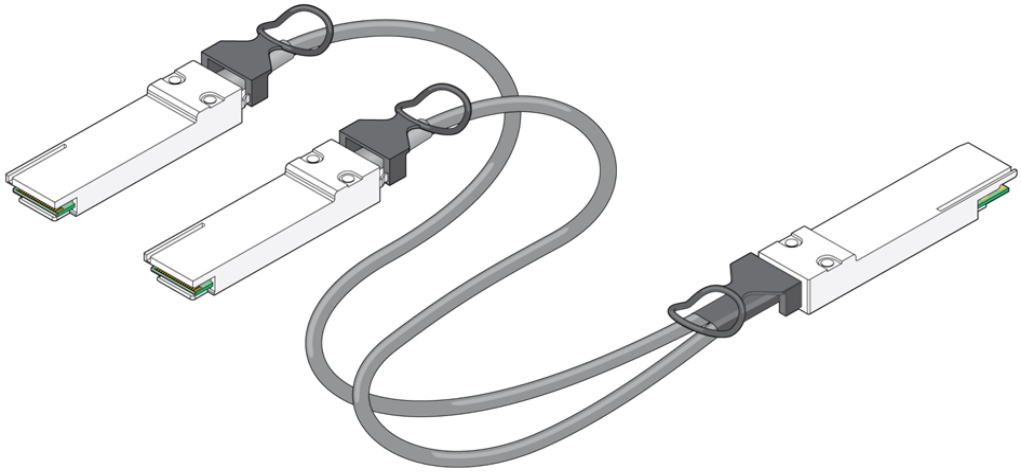

Figure 136D–2—QSFP28 to 2×QSFP28 cable assembly

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136D.3.3 One-plug to four-plug cable assembly form factor

A one-plug to four-plug cable assembly form factor can use either a QSFP28 plug as specified in 92.12.1.1 or a microQSFP plug as specified in 136C.2.3 on one end, and four SFP28 plugs as specified in 110.11.1 on the other end. It may be used to connect a QSFP28 or microQSFP form factor host (see 136D.2.2 or 136D.2.3) to up to four SFP28 form factor hosts (see 136D.2.1) with one 50 Gb/s link to each SFP28 host.

A QSFP28 to four SFP28 cable assembly is illustrated in Figure 136D–3. Note that the figure is one example of a one-plug to four-plug cable assembly form factor.

The electrical characteristics of a cable assembly for this form factor are specified in 136.11, using the definitions in 136.11.7.1.1 and 136.11.7.1.2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

136D.3.4 One-plug to eight-plug cable assembly form factor

A one-plug to eight-plug cable assembly form factor can use either a QSFP-DD plug as specified in 136C.2.4 or an OSFP plug as specified in 136C.2.5 on one end, and eight SFP28 plugs as specified in 110.11.1 on the other end. It may be used to connect a QSFP-DD or OSFP form factor host (see 136D.2.4 or 136D.2.5) to up to eight SFP28 form factor hosts (see 136D.2.1) with one 50 Gb/s link to each SFP28 host.

A QSFP-DD to eight SFP28 cable assembly is illustrated in Figure 136D–4. Note that the figure is one example of a one-plug to eight-plug cable assembly form factor.

The electrical characteristics of a cable assembly for this form factor are specified in 136.11, using the definitions in 136.11.7.1.1 and 136.11.7.1.2.

Annex 142A

(informative)

Encoding example for QC-LDPC(16952,14392) FEC and interleaving

142A.1 Example of initial control seed sequence

For example, from Table 142–5 the control seed sequence for the first user interleaver is:

0xE3-88-B0-9A-74-F4-94-8E-5D-C0-CC-8A-18-9A-B9-B2

which represents the binary sequence:

1 1 1 0 0 0 1 1 1 0 0 0 1 0 0 0 1 0 1 1 0 0 0 0 1 0 0 1 1 0 1 0
0 1 1 1 0 1 0 0 1 1 1 1 0 1 0 0 1 0 0 1 0 1 0 0 1 0 0 0 1 1 1 0
0 1 0 1 1 1 0 1 1 1 0 0 0 0 0 0 1 1 0 0 1 1 0 0 1 0 0 0 1 0 1 0
0 0 0 1 1 0 0 0 1 0 0 1 1 0 1 0 1 0 1 1 1 0 0 1 1 0 1 1 0 0 1 0

From Table 142–4, the switch programming sequence for the first stage of the user interleaver is a circular shift (left rotation) of the above control seed by 17 positions:

Control bit for switch 127 of the first stage
|
0 1 0 1 1 1 0 0 1 1 0 1 1 0 0 1 0 1 1 1 0 0 0 1 1 1 0 0 0 1 0 0
0 1 0 1 1 0 0 0 0 1 0 0 1 1 0 1 0 0 1 1 1 0 1 0 0 1 1 1 1 0 1 0
0 1 0 0 1 0 1 0 0 1 0 0 0 1 1 1 0 0 1 0 1 1 1 0 1 1 1 0 0 0 0 0
0 1 1 0 0 1 1 0 0 1 0 0 0 1 0 1 0 0 0 0 1 1 0 0 0 1 0 0 1 1 0 1
                                                                      |
                                                Control bit for switch 0 of the first stage

From Table 142–4, the switch programming sequence for the second stage of the user interleaver is a circular shift (left rotation) of the above control seed by 34 positions:

Control bit for switch 127 of the first stage
|
1 0 0 0 0 1 1 0 0 0 1 0 0 1 1 0 1 0 1 0 1 1 1 0 0 1 1 0 1 1 0 0
1 0 1 1 1 0 0 0 1 1 1 0 0 0 1 0 0 0 1 0 1 1 0 0 0 0 1 0 0 1 1 0
1 0 0 1 1 1 0 1 0 0 1 1 1 1 0 1 0 0 1 0 0 1 0 1 0 0 1 0 0 0 1 1
1 0 0 1 0 1 1 1 0 1 1 1 0 0 0 0 0 0 1 1 0 0 1 1 0 0 1 0 0 0 1 0
                                                                      |
                                                Control bit for switch 0 of the first stage

142A.2 QC-LDPC FEC encoder test vectors

Five test vectors are provided to assist in the implementation and verification of the FEC encoder and interleaver as presented in 142.4. The locations of each of the vectors in the processing path relative to Figure 142–5 are shown in Figure 142A–1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The description for each of the five test vectors are provided in Table 142A–1. Bit 0 of word 0 of each test vector is first on the wire. The values for Test Vector 1 are shown in Table 142A–2. The values for Test Vector 2 are shown in Table 142A–3. The values for Test Vector 3 are shown in Table 142A–4. The values for Test Vector 4 are shown in Table 142A–5. The values for Test Vector 5 are shown in Table 142A–6.

NOTE—Files containing the test vectors shown in Table 142A–2, Table 142A–3, Table 142A–4, Table 142A–5, and Table 142A–6 are available at https://standards.ieee.org/downloads/802.3/.

Table 142A–1—FEC encoder and interleaver test vector description

Test Vector	Filename	Description
TV 1	ldpc_tv1_pre_zeropadding	56 × 257-bit line coded input, pre-zero padding
TV 2	ldpc_tv2_pre_enc_pre_deintlv	57 × 256 $K + S$ bits, pre-de-interleaving
TV 3	ldpc_tv3_pre_enc_post_deintlv	57 × 256 $K + S$ bits, post-de-interleaving
TV 4	ldpc_tv4_post_enc_pre_intlv	10 × 256 M parity bits pre-interleaving
TV 5	ldpc_tv5_post_enc_post_intlv	10 × 256 M parity bits post-interleaving

Annex 145A

(informative)

Resistance and current unbalance

145A.1 Intra pair resistance unbalance

Operation for all PSE and PD Types requires that the intra-pair resistance unbalance be 3% or less. Resistance unbalance is a measure of the difference between the two conductors of a twisted pair in the 100 Ω balanced cabling system. Resistance unbalance is defined as in Equation (145A–1):

$$R_{unb} = \left\{ \frac{(R_{max} - R_{min})}{(R_{max} + R_{min})} \times 100 \right\}_{\%} \quad (145A–1)$$

where

R_{max} is the resistance of the pair conductor with the highest resistance

R_{min} is the resistance of the pair conductor with the lowest resistance

145A.2 Pair-to-pair unbalance overview

Pair-to-pair current unbalance is caused by unequal resistances in a parallel current path of the same polarity. The PSE, the PD, and the link section connecting those independently contribute to unbalance. A system model for the worst-case instance of this is shown in Figure 145A–1.

R_{PSE_min} or R_{PSE_max} common-mode effective resistance is the resistance of the two internal conductors (including the internal components on each conductor) in a powered pair of the same polarity connected in parallel.

$R_{Ch_unb_min}$ and $R_{Ch_unb_max}$ are respectively the minimum and maximum common-mode link section resistances in the powered pairs of the same polarity from the PSE PI to the PD PI per the model described in Figure 145A–2.

R_{PD_min} and R_{PD_max} are respectively the minimum and maximum common-mode effective PD PI resistances. They account for the effective resistance of the resistive elements, combined with the PD pair-to-pair voltage difference and the effect of system end-to-end pair-to-pair unbalance.

145A.3 Pair-to-pair link section resistance unbalance requirements for 4-pair operation

Operation using 4-pair requires the specification of resistance unbalance between each two pairs of the link section, not greater than 100 mΩ or resistance unbalance of 7 % whichever is a greater unbalance. Resistance unbalance between the link section pairs is a measure of the difference of resistance of the common-mode pairs of conductors used for power delivery. Link section pair-to-pair resistance unbalance is defined by Equation (145A–2):

$$R_{\text{ch_unb}} = \left\{ \frac{(R_{\text{Ch_unb_max}} - R_{\text{Ch_unb_min}})}{(R_{\text{Ch_unb_max}} + R_{\text{Ch_unb_min}})} \times 100 \right\}_{\%} \quad \text{(145A–2)}$$

Operation using 4-pair requires R_{diff} to be less than 100 mΩ or $R_{\text{ch_unb}}$ to be less than 7 %, whichever results in the greater absolute unbalance. R_{diff} is defined in Equation (145A–3).

$$R_{\text{diff}} = \{R_{\text{Ch_unb_max}} - R_{\text{Ch_unb_min}}\} \quad \text{(145A–3)}$$

where

$R_{\text{Ch_unb_max}}$ is the sum of link section pair components with the highest common-mode resistance from the PSE PI to the PD PI

$R_{\text{Ch_unb_min}}$ is the sum of link section pair components with the lowest common-mode resistance from the PSE PI to the PD PI

Link section common-mode resistance is the resistance of the two conductors (including connectors) in a pair, connected in parallel.

The resistance of the common-mode pairs of conductors and connectors $R_{\text{Ch_unb_min}}$ and $R_{\text{Ch_unb_max}}$ are described by Figure 145A–2.

The values for $I_{\text{Unbalance-2P}}$ and the relation between $R_{\text{PSE_max}}$ and $R_{\text{PSE_min}}$, as defined in Equation (145–13), are valid given that $R_{\text{Chan-2P}}$ (see 145.1.3) ranges from 0.2 Ω to 12.5 Ω and that the PD meets 145.3.8.9. In cases where $R_{\text{Chan-2P}}$ is less than 0.2 Ω, or R_{Chan} is less than 0.1 Ω, PSE compliance with $I_{\text{Unbalance-2P}}$ can be evaluated using $R_{\text{load_min}}$ and $R_{\text{load_max}}$ both reduced by $0.5 \times R_{\text{Chan-2P}}$. This compliance will require a reduction in the ratio of $R_{\text{PSE_max}}$ to $R_{\text{PSE_min}}$ defined in Equation (145–13).

145A.4 PSE resistance and current unbalance

End-to-end pair-to-pair resistance/current unbalance refers to the ratio of current differences in powered pairs of the same polarity to the total 4-pair current. The end-to-end pair-to-pair current unbalance is equal to the end-to-end pair-to-pair effective resistance unbalance which refers to the ratio of effective resistance difference in the powered pairs of the same polarity to the sum of the effective resistance elements of both pairs of the same polarity and is shown by Figure 145A–1. Current unbalance can occur in positive and negative powered pairs when a PSE uses all four pairs to source power to a PD.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PSE current unbalance requirements need to be met with R_{load_max} and R_{load_min} applied as defined in Equation (145–14), Equation (145–15), and Table 145–18. A compliant unbalanced load, R_{load_min} and R_{load_max}, consists of the link section and PD effective resistances, including the effects (or influence) of system end-to-end unbalance. See Figure 145–21, Figure 145A–1 and Figure 145A–3 for details.

Equation (145–13) is described in 145.2.10.6.1, specified for the PSE, assures that pair-to-pair current unbalance will be met in the presence of all compliant unbalanced loads (R_{load_min} and R_{load_max}) attached to the PSE PI.

Figure 145–21 illustrates the relationship between effective resistances at the PSE PI as defined by Equation (145–13) and R_{load_min} and R_{load_max} as defined by Equation (145–14), Equation (145–15), and Table 145–18. PSE pair-to-pair voltage difference is specified by $V_{Port_PSE\text{-}2P}$ in Table 145–16.

A method to determine whether R_{PSE_max} and R_{PSE_min} conform to Equation (145–13) is defined in 145A.4.1.

If pair-to-pair balance is actively controlled in a manner that changes effective resistance to achieve balance, then the current unbalance measurement method described in 145.2.10.6.1 should be used.

145A.4.1 Direct R_{PSE} measurement

If there is access to internal circuits, effective resistance may be determined by sourcing current in each path corresponding to maximum P_{Class} operation, and measuring the voltage across all components that contribute to the effective resistance, including circuit board traces and all components passing current to the PSE PI output connection. The effective resistance R_{PSE_min} or R_{PSE_max} is the measured voltage V_{eff}, divided by the current through the path e.g. the effective value of R_{PSE_min} for i_1 is $R_{PSE_min}=V_{eff1} / i_1$ as shown in Figure 145A–1. R_{PSE_min} and R_{PSE_max} values respectively may be different than $R_{pair_PSE_min}$ and $R_{pair_PSE_max}$ values.

The R_{PSE_min} or R_{PSE_max} effective resistance verification procedure is as follows:

1) With the PSE powered on and connected to a constant power sink through the elements shown in Figure 145A–1, which is set to $_{PClass_PD}$ measured at the PD PI, measure the currents i_1, i_2, i_3, and i_4 and the voltages V_{eff1}, V_{eff2}, V_{eff3} and V_{eff4}.
2) Calculate the R_{PSE_min} and R_{PSE_max} values of each pair of the same polarity as follows:
   For the positive pairs:
   $R_1 = R_{PSE_min} = V_{eff1} / i_1$
   $R_2 = R_{PSE_max} = V_{eff2} / i_2$
   For the negative pairs:
   $R_3 = R_{PSE_min} = V_{eff3} / i_3$
   $R_4 = R_{PSE_max} = V_{eff4} / i_4$
3) Verify that R_{PSE_min} and R_{PSE_max} meet Equation (145–13) on each pair of the same polarity.
4) Repeat steps 1 to 3 with $R_{Ch_unb_min}$ and R_{PD_min} exchanged with $R_{Ch_unb_max}$ and R_{PD_max}.

145A.5 PD resistance and current unbalance

$R_{Pair_PD_max}$ and $R_{Pair_PD_min}$ represent PD common-mode input effective resistance of pairs of the same polarity. Common-mode effective resistance is the resistance of two conductors of the same pair and their other components connected in parallel including the effect of PD pair-to-pair voltage difference of pairs with the same polarity (e.g., $V_{f1} - V_{f3}$). The common-mode effective resistance R_n is the measured voltage $V_{eff_pd_n}$, divided by the current through the path as described below and as shown in the example in Figure 145A–3, where *n* is the pair number. PD pair-to-pair voltage difference (e.g. $V_{f1} - V_{f3}$) was limited to 60 mV while generating values for $I_{Unbalance\text{-}2P}$ under worst case conditions.

NOTE—In order to measure the maximum value of $V_{f1} - V_{f3}$, an input current in the range of 1 mA to 10 mA is recommended.

Positive pairs:

$$R_1 = R_{Pair_PD_min} = V_{eff_pd1} / i_1$$
$$R_3 = R_{Pair_PD_max} = V_{eff_pd3} / i_3$$

Negative pairs:

$$R_2 = R_{Pair_PD_min} = V_{eff_pd2} / i_2$$
$$R_4 = R_{Pair_PD_max} = V_{eff_pd4} / i_4$$

Annex 145B

(informative)

Timing diagrams

The following timing diagrams are provided for informative purpose only.

145B.1 CC_DET_SEQ timing diagrams

Each of the following sample timing diagrams show a PSE performing a sequence of connection check, detection, classification, power up and power on events. A PSE implements one or more of the four defined CC_DET_SEQ sequences based on the results of detection, connection check and 4PID.

When the result of the connection check is dual, the Alternatives are controlled by the semi-independent dual-signature state machine. In this case the detection, classification, and power up are not necessarily synchronized between the Alternatives.

145B.1.1 CC_DET_SEQ=0 timing diagrams

CC_DET_SEQ = 0 is the first of four possible connection check and detection sequences.

Figure 145B–1 illustrates a PSE implementing CC_DET_SEQ=0 when the result of connection check is ‘single’.

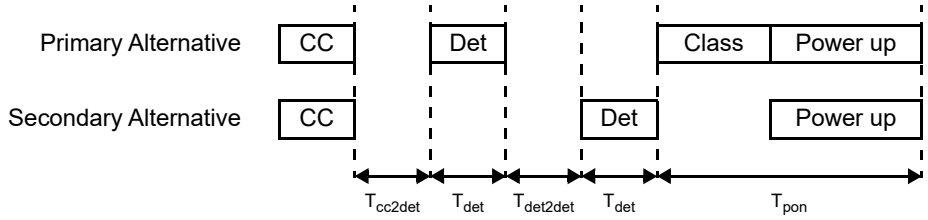

Figure 145B–1—PSE implementing CC_DET_SEQ=0, do_cxn_chk result is single

Figure 145B–2 illustrates a PSE implementing CC_DET_SEQ=0 when the connection check result is dual and Class_4PID_mult_events_sec is TRUE.

Figure 145B–15 shows a Type 3 or Type 4 PSE performing Multiple-Event Physical Layer classification with Autoclass enabled. The Autoclass-enabled PD responds by requesting an Autoclass measurement.

Legend for numbered areas:

1) PSE may not measure I_{Class}, wait for PD to stabilize class current.
2) PSE measures class signature for first class event.
3) PSE may not measure I_{Class}, PD may switch current level during this time.
4) PSE may measure class signature to check if the PD requests Autoclass.

5) PD to set class current during this window.
6) PD to have valid and stable class current for the first class event.
7) PD may switch current level to class_sig_0 if it requests Autoclass.
8) PD to maintain class signature 0 if it requests Autoclass for the duration of the class event.

Annex 145C

(informative)

Power system and parameters

This annex provides additional information for derivation of the system parameters of current and direct current resistance (DCR) given in Table 145–1. This allows analysis of the power delivery system, enabling consideration of applications not operating at the nominal highest current, or maximum DC loop resistance.

145C.1 Constant power

The power system provides constant power to the Powered Device (PD). Powering schematics with the nominal highest current per pair and the maximum DC loop resistance are illustrated in Figure 145C–1 and Figure 145C–2 for a Class 4 PD with a constant power of 25.5 W and in Figure 145C–3 and Figure 145C–4 for a Class 8 PD with a constant power of 71.3 W. Each 4-conductor connection is defined in Clause 145 as a “pairset”.

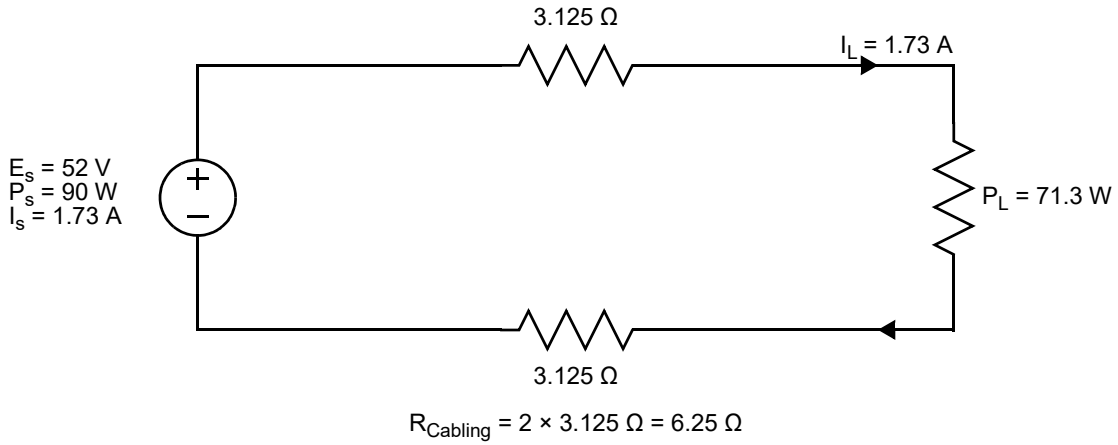

Figure 145C–4—Class 8 powering schematic simplified

145C.2 Current

The value of currents for the example power schematics in Figure 145C–1 through Figure 145C–4 are derived using Equation (145C–1). Note that Equation (145C–1) is of the same form given in Equation (145–3).

$$I_s = \left\{ \frac{E_s - \sqrt{E_s^2 - 4 \times R_{cabling} \times P_L}}{2 \times R_{cabling}} \right\}_A \quad (145C–1)$$

Equation (145C–1) can be applied to all PD Classes. The currents (I_s), calculated using Equation (145C–1), are provided in Table 145C–1 as a function of $R_{Cabling}$ with a constant voltage (52 V) and power (71.3 W) for Class 8.

The maximum value of $R_{Cabling}$ assumes a 100 meter cabling topology along with other worst case elements in the cable plant (see 145C.3). The cable DCR scales linearly such that 50 % of $R_{Cabling}$ is representative of a cabling topology of approximately 50 meters. Note that for a 50 % reduction in the maximum $R_{Cabling}$ (3.125 Ω), equating with approximately 50 meters of cabling, the current decreases from 0.43 A to 0.38 A and the power dissipated in the cabling decreases from 18.7 W to 7.1 W.

Table 145C–1—Current I_s as a function of $R_{Cabling}$

$R_{Cabling}$ (Ω)	I_s (A)	I_{Cond} (A)	$P_{Cabling}$ (W)
0.5	1.39	0.347	0.97
1	1.41	0.352	1.99
1.5	1.43	0.358	3.07
2	1.45	0.363	4.22
2.5	1.48	0.369	5.45

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 145C–1—Current I_s as a function of $R_{Cabling}$ *(continued)*

$R_{Cabling}$ (Ω)	I_s (A)	I_{Cond} (A)	$P_{Cabling}$ (W)
3	1.5	0.375	6.76
3.5	1.53	0.382	8.18
4	1.56	0.389	9.71
4.5	1.59	0.397	11.38
5	1.63	0.406	13.20
5.5	1.66	0.416	15.23
6	1.71	0.427	17.5
6.25	1.73	0.433	18.74

145C.3 Direct current resistance (DCR)

The maximum conductor DCR of 12.5 Ω in Figure 145C–1 and Figure 145C–3 is derived from a cabling topology consisting of the following:

— 90 meters of 24 AWG horizontal cable (0.0938 Ω/m)
— 10 meters of 26 AWG patch cord (0.14 Ω/m)
— Four in-line connectors (0.3 Ω per connector)

The DCR of the 90 meters of cable is adjusted for a temperature increase of 45° C from 20° C to 65° C with a 0.4 % increase per degree C (0.1107 Ω/m), shown in Table 145C–2.

Table 145C–2—Cabling conductor DCR with 24 AWG horizontal cable

deg C	90 meters horizontal cable (Ω) (24 AWG)	4 connectors (Ω) (4 × 0.3 Ω per connector)	10 m patch cord (Ω) (26 AWG)	100 m cabling conductor DCR (Ω)
20	8.44	1.2	1.4	11.04
30	8.78	1.2	1.4	11.38
40	9.12	1.2	1.4	11.72
50	9.46	1.2	1.4	12.06
60	9.79	1.2	1.4	12.39
65	9.96	1.2	1.4	12.56

Using 23 AWG and 22 AWG horizontal cable or lower AWG number patch cords reduces the per meter cable DCR; see Table 145C–3.

Using cable smaller than 26 AWG is not recommended in powering applications.

Table 145C–3—Cable conductor DCR

AWG	Diameter (in)	Resistance per meter (Ω)	Resistance per 100 meter (Ω)	Resistance per 90 meter (Ω)
22	0.025346	0.059	5.9	5.31
23	0.022571	0.0744	7.44	6.7
24	0.0201	0.0938	9.38	8.44

145C.4 Bundled cabling applications

Table 145–1 lists the nominal highest current per pair and the maximum DCR loop resistance. The maximum current is used in ISO/IEC TS 29125, TIA TSB-184A, and the National Electrical Code® (NEC®) (NFPA 70®, 2017 Edition) [B56] to limit the maximum number of 4-pair cables in a bundle. The additional information provided in this Annex will enable considerations for the number of 4-pair cables in a cabling bundle that are not at the nominal highest current or maximum DC loop resistance.

Annex 146A

(informative)

Guidelines for implementation of the 10BASE-T1L PHY in an intrinsically safe application

The principle of intrinsic safety is based on the limitation of voltage, current, power, capacitance, and inductance of electrical circuits. Within hazardous locations, a circuit following the limits of the intrinsic safety standards will not be able to ignite gas or dust atmospheres in case of a short circuit or any other kind of failure.

The additional requirements to achieve equipment protection by intrinsic safety are described by International Standards (e.g., IEC 60079-11). Possible limits of parameters used for intrinsically safe communication circuits can be derived from these standards. The specification of 10BASE-T1L in Clause 146 is intended to be compatible with implementation of such intrinsically safe systems.

In addition, the PHY implementation has a strong impact on intrinsic safety, while using external and discrete components for intrinsic safety related aspects simplifies the certification process. The following implementation choices can simplify the process for certifying 10BASE-T1L PHYs in intrinsically safe systems:

External termination resistors: These can be used to limit the energy and current to or from the intrinsically safe link segment;

Providing separate high impedance receive pins:
External resistors for current and energy limitation can also be added to the receive path.

Figure 146A–1 and Figure 146A–2 show, in principle, two possible implementations on how to feed power onto an intrinsically safe link segment. The circuits should be seen only as examples. It is in the responsibility of the hardware designer to fulfill all relevant standards (especially IEC 60079-0 and IEC 60079-11, but also others), when implementing devices for the use within intrinsically safe applications.

NOTE—The version shown in Figure 146A–2 may be easier to implement within a PHY IC as the hybrid within the PHY IC does not need to adapt to different external resistor values.

Figure 146A–3 shows, in principle, a possible implementation on how to decouple the power from an intrinsically safe link segment. The circuits should be seen only as examples, and values of the components are implementation and application dependent. It is in the responsibility of the hardware designer to fulfill all relevant standards (especially IEC 60079-0 and IEC 60079-11, but also others), when implementing devices for the use within intrinsically safe applications.

Annex 146B

(informative)

Optional power distribution

146B.1 Overview

Annex 146B provides information on the optional powering topologies. The class power requirements are specified in Clause 104.

146B.2 Point-to-point powering topologies

The point-to-point powering topology is defined to enable characterization of the direct current resistance (DCR). The point-to-point powering topology is illustrated in Figure 146B–1.

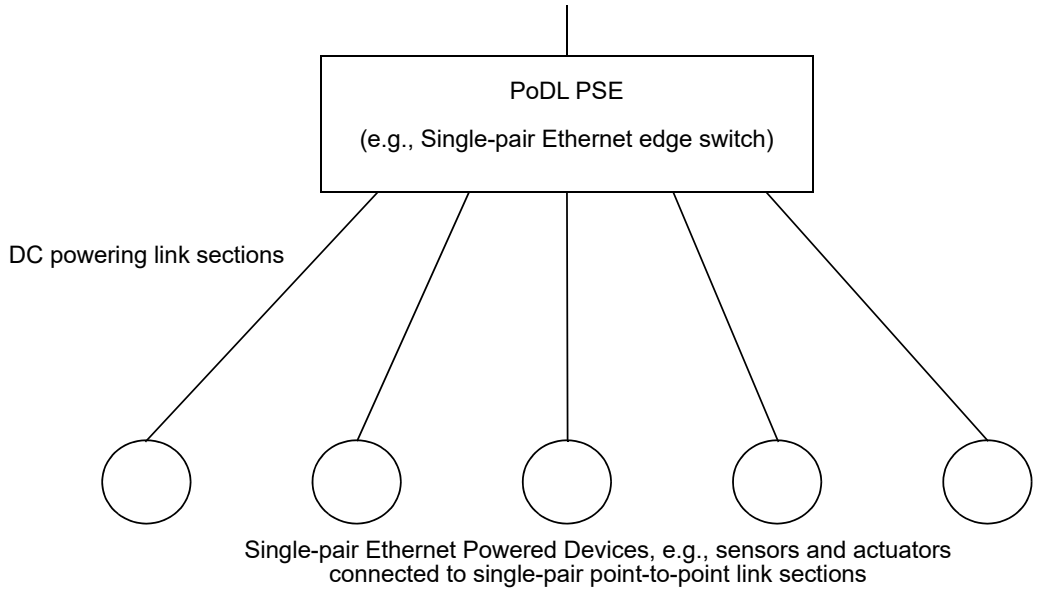

Figure 146B–1—Point-to-point powering topology

The point-to-point link segment DCR characteristics are given in Table 146B–1.

1.14 (17)	0.0185	1123	20.78	41.55	1	42.55
1.02 (18)	0.0233	1000	23.33	46.66	1	47.66
0.91 (19)	0.0294	891	26.20	52.40	1	53.40
0.81 (20)	0.0371	793	29.42	58.84	1	59.84
0.72 (21)	0.0468	706	33.04	66.07	1	67.07
0.64 (22)	0.0590	629	37.10	74.19	1	75.19
0.57 (23)	0.0744	560	41.66	83.31	1	84.31
0.51 (24)	0.0938	499	46.78	93.55	1	94.55
0.40 (26)	0.1492	395	58.98	117.96	1	118.96

146B.3 Powered trunk cable topologies

The “powered trunk cable” topology is illustrated in Figure 146B–2. The trunk link section provides power to the single pair field switches. The trunk link section can also interconnect field switches. The spur link sections provides power to the PDs. Powering trunk topologies are considered “engineered”; therefore, DCR characteristics for specified lengths are not given.

Annex 149A

(normative)

Coupling and screening attenuation test methodology

149A.1 Introduction

This annex describes the test methodologies used to measure 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 link segment coupling and screening attenuation specified in 149.7.1.4 and 149.7.1.5.

149A.2 General test conditions

Coupling and screening attenuation are the main parameters for a shielded differential link segment to define its EMC properties. Coupling and screening attenuation are tested as specified in IEC 62153-4-7 using triaxial tube in tube method.

The usable frequency range of the setup may be limited by the dimensions of the triaxial measurement equipment, as higher order modes may occur. IEC 62153-4-7 provides additional information on how to suppress higher order modes in order not to falsify the measurement result.

These test methods are applicable for temperature and humidity as specified by IEC 62153-4-7.

149A.3 Reference cable assembly

The reference cable assembly is intended to be a simplified representation of the components used within a wiring harness. These include cable, PCB connectors, and in-line connectors. In order to reach sufficient accuracy to measure coupling and screening attenuation, the connectors and cable should be matched in terms of balance and shielding.

This topology serves as a common reference to compare link segments made of different components. It also enables the comparison of results from different test houses.

The reference cable assembly has a nominal length of 1.75 m, including one in-line connector and one PCB connector with termination as shown in Figure 149A–1.

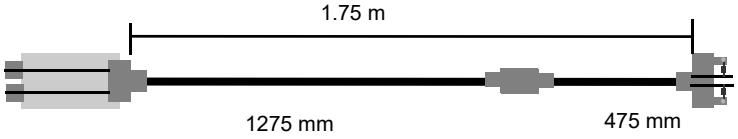

Figure 149A–1—Coupling attenuation reference cable assembly

149A.4 Measurement setup

Figure 149A–2 shows the reference cable assembly within the triaxial tube in tube method measurement setup.

Additional to the nominal lengths, some length tolerances are allowed. The overall assembly length shall be between 1650 mm and 1800 mm. The exposed cable length within the triaxial tube shall be between 900 mm and 1000 mm. Therefore, the cable length from the measurement fixture to the triaxial tube shall be between 650 mm and 900 mm. This allows easy handling while keeping the influence of the feeding cable section on insertion loss and balance low. In addition, both ends of the cable shield should be connected to the reference plane using techniques suitable for RF applications in the frequency range of interest, see 149.7.1.4 and 149.7.1.5,when implementing cable assemblies in vehicles.

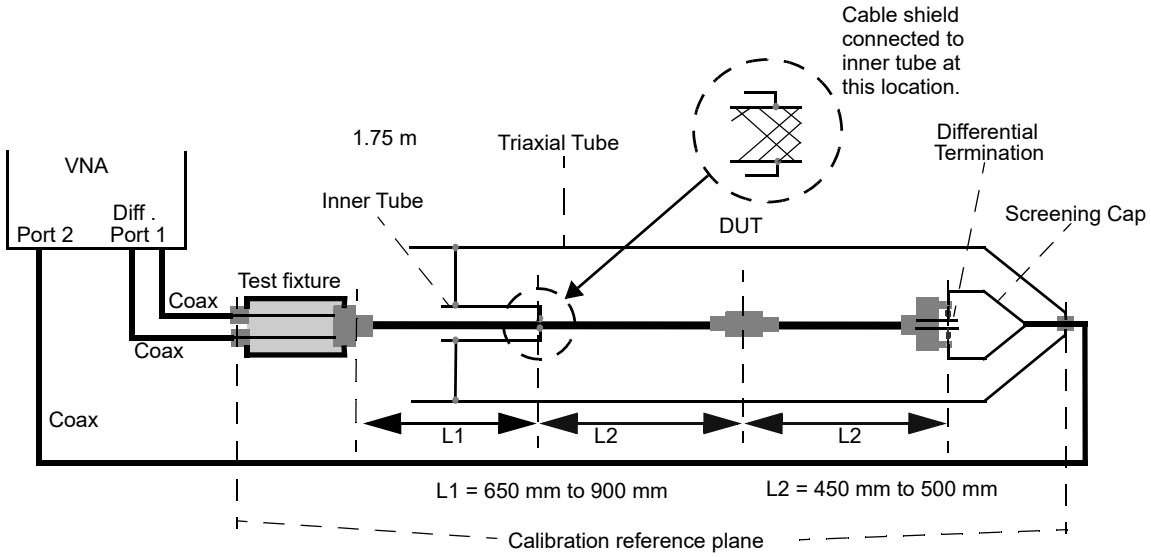

Figure 149A–2—Coupling attenuation reference cable assembly measurement setup

A 3-port vector network analyzer (VNA) measurement setup shall be used without baluns. Two ports of the VNA act as generator and the third port is used as single-ended receiver. For coupling attenuation measurements, the generator port-pair is operated in differential mode. For screening attenuation measurements, the generator port-pair is operated in common mode.

The measurement setup shall be optimized with respect to balance. This includes VNA, accurate and well-balanced test fixture and termination designs, as well as the use of phase stable coaxial cables.

The termination shall be nominal 100 Ω in differential mode and 25 Ω in common mode. The requirements on the single-ended termination of every conductor of the differential pair shall be 50 Ω ± 1% to ground. The two resistors of the differential pair shall be matched to within ±0.1 Ω at DC. The resistors need to be suitable for RF applications in the frequency range under test.

The measurement shall include the transition from the MDI connector to the PCB. Therefore, the termination resistors shall be placed between the signal conductors and ground of a termination housing or equivalent termination fixture as shown in Figure 149A–3. Termination resistors shall not be placed inside the connector in order to omit the transition to the PCB. The termination housing shall be shielded and cover the termination resistors and any signal conductors placed on the bottom of the PCB.

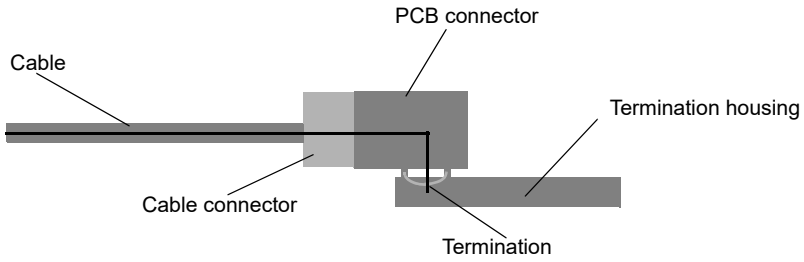

Figure 149A–3—PCB connector and termination

For connectors that provide an additional shield contact from the connector housing to a shielded enclosure, the reference plane at the MDI connector side may be set at the point where the EMC seal is attached. In this case, the connector housing and the transition to the PCB should not be part of the measurement but within the shield cap referenced in Figure 149A–4.

149A.5 Protocol implementation conformance statement (PICS) proforma for Annex 149A, Coupling and screening attenuation test methodology[324]

149A.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Annex 149A, Coupling and screening attenuation test methodology, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

149A.5.2 Identification

149A.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

149A.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Annex 149A, Coupling and screening attenuation test methodology
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[324] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this annex so that it can be used for its intended purpose and may further publish the completed PICS.

Annex 149B

(informative)

OAM status

149B.1 Purpose

This annex describes a suggested assignment of the OAM status bits for use with the Clause 149 MultiGBASE-T1 PHYs. Suggested bit behaviors, shown in state diagrams, and bit assignments in the OAM frame are detailed in this annex for informative purposes to enable consistent use of the OAM channel. Use of these specific assignments and the behaviors described by the state diagrams is implementation dependent.

149B.2 MultiGBASE-T1 OAM status structure

Each MultiGBASE-T1 OAM frame includes a four-octet MultiGBASE-T1 OAM status message. The status bits transmitted in the MultiGBASE-T1 OAM status message represent the state of health of the transmitting device. The information in these bits should be filled automatically, in an implementation-dependent way, rather than through the management entity.

This information is loaded to registers 3.2318 and 3.2319 for transmission, see 45.2.3.83. The information received from the link partner is read from registers 3.2320 and 3.2321, see 45.2.3.84.

Symbol 12	Reserved	1	REC<7:0>							
Symbol 13	Reserved	1	REC<15:8>							

Figure 149B–1—MultiGBASE-T1 OAM status

149B.3 MultiGBASE-T1 status message data

The MultiGBASE-T1 status message is shown in Figure 149B–1. OAM<*x*><*y*> refers to symbol *x*, bit *y* of the BASE-T1 OAM frame. Reserved fields should be set to 0.

The definitions that follow are from the transmitting device's point of view.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149B.3.1 MultiGBASE-T1 status valid

MultiGBASE-T1 status valid is indicated in OAM<10><7>.

— 0: Current OAM frame does not contain valid OAM status data, OAM<10><6:2>.

— 1: Current OAM frame contains valid OAM status data, OAM<10><6:2>.

149B.3.2 Power supply warning

Power supply warning is indicated in OAM<10><6>.

This status bit indicates the state of the local power supply(ies). The definitions of good and near the limit are implementation dependent. It is recommended that this status is set for a minimum of 100 ms.

— 0: Local PHY power supply(ies) is good.

— 1: Local PHY power supply(ies) is near the limit.

149B.3.3 Internal temperature warning

Internal temperature warning is indicated in OAM<10><5>.

This status bit indicates the internal temperature of the PHY. The definitions of good and near the limit are implementation dependent. It is recommended that this status is set for a minimum of 100 ms.

— 0: Local PHY internal temperature is good.

— 1: Local PHY internal temperature is near the limit.

149B.3.4 No MAC messages warning

No MAC messages warning is indicated in OAM<10><4>.

This status bit indicates transmit data is not being received from the MAC. It is recommended that this status is set for a minimum of 100 ms.

— 0: PHY is receiving valid transmit messages from the MAC.

— 1: PHY is not receiving valid transmit messages from the MAC.

149B.3.5 Degraded link segment

Degraded link segment is indicated in OAM<10><3>.

This status is set to indicate the status of the link segment. The definitions of good and degraded are implementation dependent. It is recommended that this status is set for a minimum of 100 ms.

— 0: Link segment is good.

— 1: Link segment is degraded.

149B.3.6 Polarity inversion

Polarity inversion is indicated in OAM<10><2>.

This status is set to indicate the conductors of the pair are swapped and the PHY has accounted for this.

— 0: No polarity inversion detected.

— 1: Polarity inversion detected.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149B.3.7 Vendor-specific field

Vendor-specific field <7:0> is indicated in OAM<11><7:0> and may be used to convey a vendor defined data field.

149B.3.8 Clear REC

Clear REC is indicated in OAM<10><1>.

This status is set to indicate the link partner should clear the receive error counter (REC) in OAM<13:12><7:0>.

— 0: Do not clear REC.

— 1: Clear REC.

149B.3.9 REC cleared

REC cleared is indicated in OAM<10><0>.

This status is set to indicate the REC (in OAM<13:12><7:0>) has been cleared.

— 0: REC has not been cleared and is counting errors.

— 1: REC has been cleared, set to 0x0000, and has resumed counting errors.

149B.3.10 Receive error counter (REC)

REC<15:0> is indicated in OAM<13:12><7:0>.

This two-byte symbol indicates the number of RS-FEC frame block errors, both correctable and uncorrectable, that have been seen by the receiver since the REC was last cleared. This counter should be cleared when clear REC (OAM<10><1>) is received as 1. If the counter reaches 0xFFFF, it stays at 0xFFFF until cleared by clear REC. See Figure 149B–2 and Figure 149B–3 for additional details on the behavior of this counter in conjunction with clear REC and REC cleared.

149B.4 Detailed functions and state diagrams

149B.4.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, counters, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5, along with the extensions described in 145.2.5.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

149B.4.2 State diagram parameters

149B.4.2.1 Variables

mr_rx_rec

The number of RS-FEC block errors, both correctable and uncorrectable, reported by the link partner.

Values:

The value can be any integer from 0 to 65 535, inclusive.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mr_rx_rec_cleared
: Indicates whether the link partner has cleared its REC.
Values:
FALSE: Link partner REC counter has not been cleared.
TRUE: Link partner REC counter has been cleared.

mr_tx_rec_cleared
: Indicates whether the local REC counter has been cleared.
Values:
FALSE: REC counter has not been cleared.
TRUE: REC counter has been cleared.

mr_rx_clear_rec
: Request from the link partner to clear the REC counter.
Values:
FALSE: Link partner is not requesting the REC counter be cleared.
TRUE: Link partner is requesting the REC counter be cleared.

mr_tx_clear_rec
: Request to clear the REC counter in the link partner.
Values:
FALSE: Don’t send request to link partner to clear their REC counter.
TRUE: Send request to link partner to clear their REC counter.

rf_valid
: Defined in 149.3.7.2.2.

149B.4.2.2 Counters

mr_tx_rec
: A count of received RS-FEC block errors, both correctable and uncorrectable.
Values:
The value can be any integer from 0 to 65 535, inclusive.

149B.4.2.3 Messages

RX_FRAME
: Defined in 149.3.7.2.6.

Annex 149C

(informative)

Tx Function to Rx function channel characteristics

149C.1 Overview

Annex 149C provides information on insertion loss and return loss parameters of the channel defined between Tx function and Rx function illustrated in Figure 149C–1.

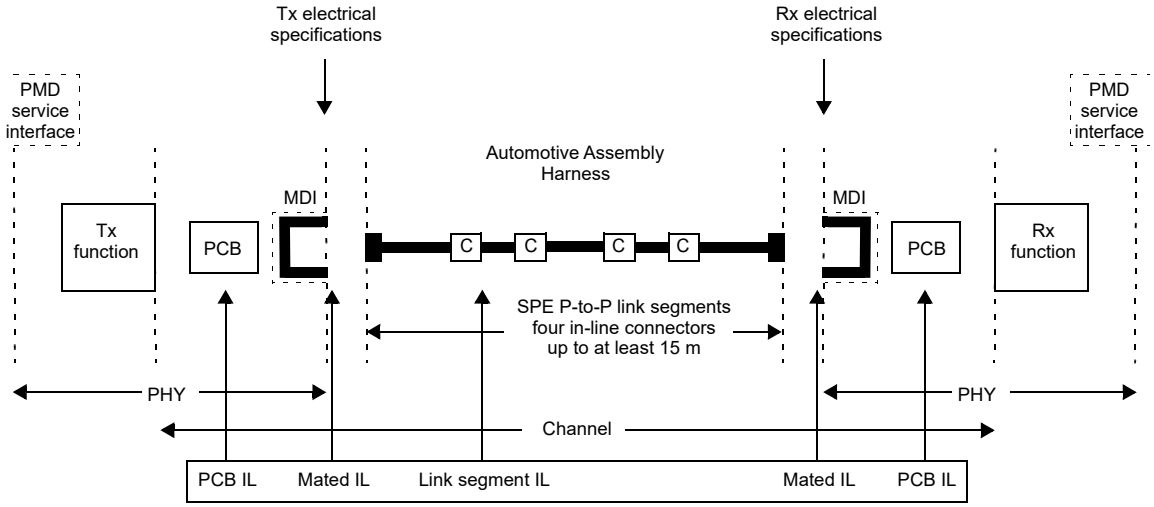

Figure 149C–1—Channel Tx function to Rx function

149C.2 Differential printed circuit board trace loss

The recommended maximum and minimum printed circuit board trace insertion losses are as specified in Equation (149C–1) and Equation (149C–2), respectively.

$$IL_{\mathrm{PCB(76.2mm)}} = \left(0.0071 \times \sqrt{\frac{f}{1000}} + 0.0045 \times \frac{f}{1000}\right) \times 76.2 \text{ (dB)} \quad \text{(149C–1)}$$

$$IL_{\mathrm{PCB(25.4mm)}} = \left(0.0071 \times \sqrt{\frac{f}{1000}} + 0.0045 \times \frac{f}{1000}\right) \times 25.4 \text{ (dB)} \quad \text{(149C–2)}$$

where

f is the frequency in MHz; $1 \le f \le F_{\max}$

$$F_{\max} = 4000 \times S \quad \text{(149C–3)}$$

See Table 149–1 for the definition of *S*.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

149C.3 Channel insertion loss

The channel topology with the 76.2 mm PCB insertion loss is determined using Equation (149C–4), Equation (149C–5), and Equation (149C–6).

$$IL_{\text{channel}} = 2 \times IL_{\text{PCB(76.2mm)}} + 2 \times IL_{\text{MDI}} + IL_{\text{LinkSegment}} \quad (149C–4)$$

$$IL_{\text{MDI}} = 0.1 \times \sqrt{\frac{f}{1000}} \quad (149C–5)$$

$$IL_{\text{LinkSegment}} = 0.002 \times f + 0.68 \times f^{0.45} \quad (149C–6)$$

where

f is the frequency in MHz; $1 \le f \le F_{\max}$

$F_{\max}$ is defined by Equation (149C–3)

The 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 PHYs utilize 4-level pulse amplitude modulation (PAM4) transmitted at 1406.25 MBd, 2812.5 MBd, and 5625 MBd rates, respectively. The channel insertion loss values are given in Table 149C–1 at the specified bandwidth for each PHY type.

Table 149C–1—Channel insertion loss for each PHY type

PHY	Rate MBd	Bandwidth (MHz)	$IL_{\text{PCB(76.2mm)}}$ (dB)	$IL_{\text{LinkSegment}}$ (dB)	IL_{MDI} (dB)	IL_{channel} (dB)
2.5GBASE-T1	1406.25	703.125	0.6948	14.3982	0.084	15.955
5GBASE-T1	2812.5	1406.25	1.1238	20.56	0.119	23.045
10GBASE-T1	5625	2812.5	1.8717	29.8688	0.168	33.948

149C.4 Channel return loss

The channel topology between Tx function and Rx function illustrated in Figure 149C–2 consists of the Tx function to MDI, the link segment, and the MDI to Rx function. The channel return loss can be modeled as a concatenation of the Tx function to MDI return loss, the link segment return loss, and the MDI to Rx function return loss.

Figure 149C–2—Tx/Rx function channel topology

149C.4.1 Tx/Rx function to MDI return loss

An example of an implementation of a Tx/Rx function to MDI topology is given in Figure 149C–3 and Figure 149C–4 with associated parameter values given in Table 149C–2. The implementation enables MDI return loss to be considered as a function of PHY termination impedances, PCB impedances, PCB trace

149C.4.2 Link segment return loss

Link segment return loss can be modeled as a two-port ladder network, as shown in Figure 149C–5 with sections consisting of cable (Z_{cab}) and connector impedances (Z_{con}).

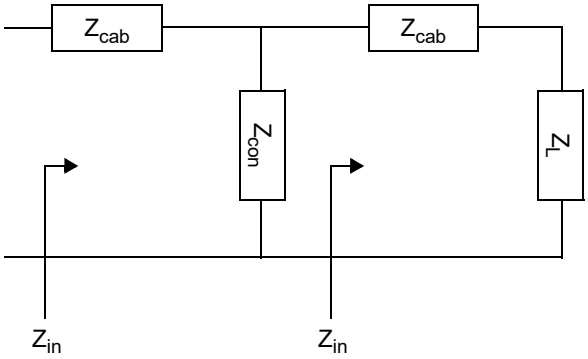

Figure 149C–5—Two–port ladder network

The return loss is derived from the input impedance of the ladder network using Equation (149C–7) and Equation (149C–8). The input impedance is derived using Equation (149C–9) through Equation (149C–12) applied recursively to each section.

$$RL = 20\log_{10}|\Gamma| \tag{149C–7}$$

$$\Gamma = \frac{Z_{in} - Z_s}{Z_{in} + Z_s} \tag{149C–8}$$

$$Z_{in} = Z_o \frac{Z_L + Z_o \tanh(\gamma l)}{Z_o + Z_L \tanh(\gamma l)} \tag{149C–9}$$

$$\gamma = \alpha + j\beta \tag{149C–10}$$

$$\alpha = \frac{\text{Attenuation (dB/m)}}{20\log_{10}(e)} \tag{149C–11}$$

$$\beta = \frac{\omega}{v} \text{ radians/m} \tag{149C–12}$$

where

Z_s is the source impedance
Z_o is the cable (Z_{cab}) or connector (Z_{con}) impedance
Z_L is the initial and recursive impedance
l is the length in m
ω is the angular frequency in radians/s
v is the phase velocity ($c/\sqrt{\text{dielectric constant}}$) in m/s

149C.4.3 Channel return loss concatenation

The return loss for a channel can be modeled as a concatenation of the Tx function to MDI return loss, the link segment return loss, and the MDI to Rx function return loss using the method in 93A.1.2.1.

149C.5 Coupling between ports on multiport designs

When multiple MultiGBASE-T1 PHYs are implemented on the same board, care should be taken to avoid coupling between ports. The coupling between adjacent ports on a multiport MDI connector or between adjacent balanced pairs is recommended to be approximately the same level, but no greater, than that specified for power sum alien near end crosstalk specified in Equation (149–25).

Annex 154A

(informative)

Examples of 100GBASE-ZR compliant DWDM black links

154A.1 Introduction

In implementations of the DWDM black link for 100GBASE-ZR, the channels supporting the full duplex links may be implemented on one fiber per direction, as illustrated in Figure 154A–1, or implemented on one fiber for both directions, as illustrated in Figure 154A–2.

154A.2 Relationship between OSNR and average optical power

The DWDM black link requirements for the 100GBASE-ZR PMD are defined in Table 154–9. The relationship between OSNR and average optical power at TP3 defined in Table 154–9 is illustrated in Figure 154A–3. The operating ranges in Figure 154A–3 can be roughly divided into two areas, one where the OSNR is between 19.5 dB (12.5 GHz) and 35 dB (12.5 GHz) together with an average optical power at TP3 between 0 dBm and –16 dBm and a second range where the OSNR is equal to or larger than 35 dB (12.5 GHz) together with an average optical power at TP3 between 0 dBm and –27 dBm.

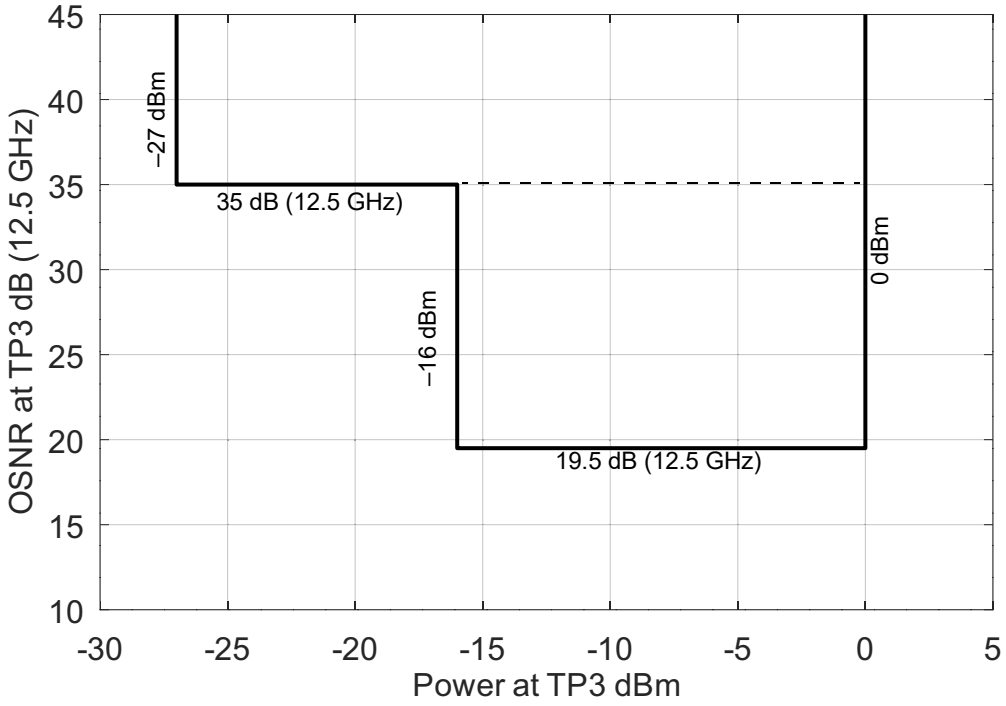

Figure 154A–3—100GBASE-ZR OSNR (TP3) requirements versus average receive power (TP3)

The area for OSNR at TP3 ≥ 35 dB (12.5 GHz) suggests DWDM black links not containing any optical amplifiers, because there is no or negligible reduction of OSNR across the DWDM black link from the minimum transmitter in-band OSNR at TP2 of 35 dB (12.5 GHz). The link performance in this range is generally loss limited.

On the other hand, the area for OSNR at TP3 between 19.5 dB (12.5 GHz) and 35 dB (12.5 GHz) suggests DWDM black links containing one or more optical amplifiers, causing a reduction of the minimum transmitter in-band OSNR at TP2 of 35 dB (12.5 GHz) to the value at TP3. The link performance in this range is generally OSNR limited.

The boundaries shown in Figure 154A–3 indicate the limits of OSNR and average power at TP3 that the DWDM black link should stay within to be compliant to the 100GBASE-ZR requirements. The boundaries also indicate the minimum requirements for a compliant 100GBASE-ZR receiver.

154A.3 Examples of DWDM black link applications with OSNR at TP3 between 19.5 dB (12.5 GHz) and 35 dB (12.5 GHz)

The DWDM black link designed for this region of operation will probably contain one of more optical amplifiers and the achievable distances across the multi-channel fiber between the optical multiplexer and demultiplexer will be determined by the ability of these amplifiers to compensate for the loss of this fiber, while simultaneously meeting the DWDM black link requirements listed in Table 154–9.

For any application over any DWDM black link distance and any number of channels up to 48 the optical amplifier needs to be designed to achieve the DWDM black link output power and OSNR parameter values at TP3 from the DWDM black link input parameter values at TP2, both listed in Table 154A–1. This implies that the channel input power range of –8 dBm to 0 dBm, attenuated by all of the passive components in the DWDM black link, should be amplified to a channel output range of –16 dBm to 0 dBm.

Specifically in an example application of 40 channels over 80 km of single-mode fiber with a loss coefficient of 0.25 dB/km, optical multiplexer and demultiplexer loss of 6 dB each and 2 dB loss for patching panels (between TP2 and TP3), this means that optical amplifiers need to be designed to allow a total DWDM black link passive loss of 34 dB.

This suggests an amplification between 18 dB per DWDM channel (for maximum difference between DWDM black link input and output power of 16 dB) and 42 dB per DWDM channel (for a maximum difference between DWDM black link input and output power of –8 dB).

NOTE—Suitable attenuation coefficients for optical fiber cables operating in the 1550 nm window can be found in Appendix I of ITU-T G.695. For loss calculations an average value of 0.25 dB/km is used in this annex. The loss values for optical multiplexer, optical demultiplexer, and patch panels used in the examples in this annex are conservative. Other loss values may lead to other potential distances.

Table 154A–1—DWDM black link channel power and OSNR requirements for OSNR at TP3 between 19.5 dB (12.5 GHz) and 35 dB (12.5 GHz)

Description	Value	Unit
Average channel power at TP2	–8 to 0	dBm
OSNR at TP2 (min)	35	dB (12.5 GHz)
Average channel power at TP3	–16 to 0	dBm
OSNR at TP3	19.5 to 35	dB (12.5 GHz)

154A.4 Example of DWDM black link applications with OSNR at TP3 greater than or equal to 35 dB (12.5 GHz)

The DWDM black link designed for this region of operation will not cause a reduction of the OSNR from input to output and therefore it can be assumed to be completely passive.

The achievable distances across the fiber between TP2 and TP3 will be determined by the total loss from TP2 to TP3, minus the total loss of the optical multiplexer and demultiplexer and the loss of potentially present patch panel connectors. The maximum allowable loss from TP2 to TP3 can be calculated from the difference between the minimum average receive power (at TP3) and the minimum transmitter average channel output power (at TP2), which is 19 dB.

In Table 154A–2, Table 154A–3, Table 154A–4, and Table 154A–5, four examples of DWDM black link applications with OSNR at TP3 greater than or equal to 35 dB (12.5 GHz), with associated assumptions for losses of optical multiplexer/demultiplexer, patch panel, and cabled fiber loss coefficient, are provided. Different assumptions will give different results of achievable transmission distances. The example in Table 154A–5 is a separate case, because the DWDM black link does not contain an optical multiplexer or optical demultiplexer, so that the fiber plant inside the DWDM black link is not a multi-channel link, but rather a single channel link, and therefore a conventional point-to-point Ethernet application where the PMDs at TP2 and TP3 are connected only via a combination of fiber and optical connectors.

Table 154A–2—40 channel example DWDM black link application with OSNR (TP3) ≥ 35 dB (12.5 GHz)

Description	Value	Unit
Available loss budget TP2 to TP3	19	dB
Allocation for loss of 40 channel optical multiplexer	6	dB
Allocation for loss of 40 channel optical demultiplexer	6	dB
Allocation for loss of patch panels	2	dB
Remaining loss available for multi-channel fiber plant	5	dB
Potential distance for 0.25 dB/km cabled fiber attenuation coefficient	20	km

Table 154A–3—16 channel example DWDM black link application with OSNR (TP3) ≥ 35 dB (12.5 GHz)

Description	Value	Unit
Available loss budget TP2 to TP3	19	dB
Allocation for loss of 16 channel optical multiplexer	4	dB
Allocation for loss of 16 channel optical demultiplexer	4	dB
Allocation for loss of patch panels	2	dB
Remaining loss available for multi-channel fiber plant	9	dB
Potential distance for 0.25 dB/km cabled fiber attenuation coefficient	36	km

Table 154A–4—4 channel example DWDM black link application with OSNR (TP3) ≥ 35 dB (12.5 GHz)

Description	Value	Unit
Available loss budget TP2 to TP3	19	dB
Allocation for loss of 4 channel optical multiplexer	2	dB
Allocation for loss of 4 channel optical demultiplexer	2	dB
Allocation for loss of patch panels	2	dB
Remaining loss available for multi-channel fiber plant	13	dB
Potential distance for 0.25 dB/km cabled fiber attenuation coefficient	52	km
