NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

55.12.1.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 55, Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, type 10GBASE-T
Identification of amendments and corrigenda to this PICS proforma which have been completed as part of this PICS	
Have any Exceptions items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[108] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so it can be used for its intended purpose and may further publish the completed PICS.

55.12.2 Major capabilities/options

Item	Feature	Subclause	Status	Support	Value/Comment
XGE	XGMII compatibility interface	46, 55.1.5	O	Yes [ ] No [ ]	Compatibility interface is supported
*LT	Support of loop timing		O	Yes [ ] No [ ]	
*EEE	Support of EEE capability		O	Yes [ ] No [ ]	55.1.3.3
*FR	Support of Fast Retrain capability		O	Yes [ ] No [ ]	55.4.2.5.15
*INS	Installation / cabling	55.7	O	Yes [ ] No [ ]	Items marked with INS include installation practices and cabling specifications not applicable to a PHY manufacturer

55.12.3 Physical Coding Sublayer (PCS)

Item	Feature	Subclause	Status	Support	Value/Comment
PCT1	PCS Transmit function state diagram	55.3.2.2	M	Yes [ ]	See Figure 55–16
PCT2	PCS Transmit function state diagram with EEE states	55.3.2.2	EEE:M	Yes [ ]	See Figure 55–16 and Figure 55–17
PCT3	SEND_Z Operation	55.3.2.2	M	Yes [ ]	PMA_TXMODE.indication message
PCT4	SEND_N Operation	55.3.2.2	M	Yes [ ]	PMA_TXMODE.indication message
PCT5	SEND_T Operation	55.3.2.2	M	Yes [ ]	PMA_TXMODE.indication message
PCT6	PCS Transmit bit ordering	55.3.2.2.4	M	Yes [ ]	See Figure 55–6 and Figure 55–8
PCT7	Invalid control code handling	55.3.2.2.6	M	Yes [ ]	
PCT8	/I/ insertion and deletion	55.3.2.2.9	M	Yes [ ]	
PCT9	/LI/ insertion and deletion	55.3.2.2.10	EEE:M	Yes [ ]	
PCT10	/O/ deletion	55.3.2.2.13	M	Yes [ ]	
PCT11	Scrambler as MASTER	55.3.2.2.16	M	Yes [ ]	
PCT12	Scrambler as SLAVE	55.3.2.2.16	M	Yes [ ]	
PCT13	CRC8	55.3.2.2.17	M	Yes [ ]	See Figure 55–11
PCT14	LDPC encoding	55.3.2.2.18	M	Yes [ ]	Generator matrix is described in Annex 55A
PCT15	DSQ128 mapping	55.3.2.2.19	M	Yes [ ]	
PCT16	EEE Transmit function state diagram	55.3.2.2.22	EEE:M	Yes [ ]	See Figure 55–20

Item	Feature	Subclause	Status	Support	Value/Comment
PCT17	LP_IDLE input to scrambler during LPI mode	55.3.2.2.22	EEE:M	Yes [ ]	
PCT18	lpi_tx_mode control	55.3.2.2.22	EEE:M	Yes [ ]	
PCT19	PCS test pattern mode	55.3.3	M	Yes [ ]	See Figure 55–6
PCT20	PMA training - MASTER scrambler	55.3.4	M	Yes [ ]	
PCT21	PMA training - SLAVE scrambler	55.3.4	M	Yes [ ]	
PCT22	PMA training scrambler initial state	55.3.4	M	Yes [ ]	In no case shall the scrambler state be initialized to all zeros
PCT23	LPI active pair and refresh_active signals	55.3.5.1	EEE:M	Yes [ ]	
PCT24	Alert signaling in place of refresh signaling	55.3.5.3	EEE:M	Yes [ ]	
PCT25	Slave synchronization	55.3.5.1	EEE:M	Yes [ ]	
PCT26	Quiet launch power	55.3.5.2	EEE:M	Yes [ ]	
PCT27	LPI sleep timer	55.3.6.2.3	EEE:M	Yes [ ]	
PCT28	LPI alert timer	55.3.6.2.3	EEE:M	Yes [ ]	
PCT29	LPI wake timer	55.3.6.2.3	EEE:M	Yes [ ]	
PCT30	LPI rx wake timer	55.3.6.2.3	EEE:M	Yes [ ]	
PCT31	LPI tx wake timer	55.3.6.2.3	EEE:M	Yes [ ]	
PCT32	LPI scrambler	55.3.5.3	EEE:M	Yes [ ]	The training sequence without periodic re-initialization described in 55.3.5 shall be used
PCT33	Disable scrambler reinitialization	55.3.5.3	EEE:M	Yes [ ]	
PCT34	Refresh using THP	55.3.5.3	EEE:M	Yes [ ]	
PCT35	Reset THP at the start of refresh	55.3.5.3	EEE:M	Yes [ ]	
PCT36	Master alert on pair A, other pairs silent	55.3.5.3	EEE:M	Yes [ ]	
PCT37	Slave alert on pair C, other pairs silent	55.3.5.3	EEE:M	Yes [ ]	
PCT38	Inactive pairs transmit zeros	55.3.5.3	EEE:M	Yes [ ]	
PCT39	ENCODE function	55.3.6.2.4	M	Yes [ ]	Encode the block as specified in 55.3.2.2.2
PCT40	PCS loopback setup	55.3.7.3	M	Yes [ ]

55.12.3.1 PCS Receive functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCR1	PCS Receive function state diagram	55.3.2.3	M	Yes [ ]	See Figure 55–18 and state variables as specified in 55.3.6.2.
PCR2	PCS Receive bit ordering	55.3.2.3.1	M	Yes [ ]	See Figure 55–7
PCR3	Descrambling as MASTER	55.3.2.3.2	M	Yes [ ]	
PCR4	Descrambling as SLAVE	55.3.2.3.2	M	Yes [ ]	
PCR5	PMA training descrambler - MASTER	55.3.4.3	M	Yes [ ]	
PCR6	PMA training descrambler - SLAVE	55.3.4.3	M	Yes [ ]	
PCR7	DECODE operation	55.3.6.2.4	M	Yes [ ]	Decode the block as specified in 55.3.4
PCR8	LFER monitor	55.3.6.3	M	Yes [ ]	See state diagrams in Figure 55–15, Figure 55–16 and Figure 55–18.

55.12.3.2 Other PCS functions

Item	Feature	Subclause	Status	Support	Value/Comment
PCO1	PCS Reset function	55.3.2.1	M	Yes [ ]	

55.12.4 Physical Medium Attachment (PMA)

Item	Feature	Subclause	Status	Support	Value/Comment
PMF1	PMA Reset function	55.4.2.1	M	Yes [ ]	
PMF2	PMA transmission	55.4.2.2	M	Yes [ ]	
PMF3	Transmitter clocking	55.4.2.2	M	Yes [ ]	All driven by TX_TCLK
PMF4	PMA Transmit mapping	55.4.2.2	M	Yes [ ]	Per mathematical description given in 55.4.3.1
PMF5	PMA Transmit electrical compliance	55.4.2.2	M	Yes [ ]	See PMA electrical specifications given in 55.5
PMF6	Clocking as MASTER	55.4.2.2	M	Yes [ ]	Source the transmit clock TX_TCLK from a local clock
PMF7	Clocking as SLAVE in loop timed mode	55.4.2.2	M	Yes [ ]	Source the transmit clock TX_TCLK from the recovered clock

Item	Feature	Subclause	Status	Support	Value/Comment
PMF8	Transmit fault mapping	55.4.2.2	O	Yes [ ]	Contribute to the transmit fault bit as specified in 45.2.1.7.4
PMF9	Generates alert signal	55.4.2.2	EEE:M	Yes [ ]	Generates the alert signal defined in 55.4.2.2.1
PMF10	Generates link failure signaling	55.4.2.2	FR:M	Yes [ ] No [ ]	Generates the link failure signal defined in 55.4.2.2.2
PMF11	PMA Receive function performance	55.4.2.4	M	Yes [ ]	LDPC frame error ratio of less than 3.2×10^{-9}
PMF12	Receive fault mapping	55.4.2.4	O	Yes [ ]	Contribute to the receive fault bit as specified in 45.2.1.7.5
PMF13	Implement alert_detect	55.4.2.4	EEE:M	Yes [ ]	Generates alert_detect when the alert signal is detected at the receiver
PMF14	Detect link failure signaling	55.4.2.4	FR:M	Yes [ ] No [ ]	Sets link_fail_detect to true when the link failure signal is detected
PMF15	PHY Control function	55.4.2.5	M	Yes [ ]	See state diagram in Figure 55–28 and state diagrams in Figure 55–29 and Figure 55–30
PMF16	InfoField	55.4.2.5	M	Yes [ ]	All subclauses from 55.4.2.5.1 to 55.4.2.5.13
PMF17	THP initialization	55.4.2.5.14	M	Yes [ ]	Last 16 symbols of PMA_Coeff_Exch
PMF18	PBO exchange	55.4.2.5.14	M	Yes [ ]	
PMF19	Slave PBO setting	55.4.2.5.14	M	Yes [ ]	Slave's PBO final setting within two levels (4 dB) of the MASTER's PBO level
PMF20	THP coefficient exchange	55.4.2.5.14	M	Yes [ ]	
PMF21	Recommended startup sequence timing	55.4.2.5.14	O	Yes [ ] No [ ]	See Table 55–9
PMF22	Implements fast retrain state diagram	55.4.2.5.15	FR:M	Yes [ ] No [ ]	
PMF23	Behavior after fast retrain request	55.4.2.5.15	FR:M	Yes [ ] No [ ]	Transmit PAM2 within 9 LDPC frame periods following link failure request
PMF24	Behavior after fast retrain signal detection	55.4.2.5.15	FR:M	Yes [ ] No [ ]	Transmit PAM2 within 9 LDPC frame periods following link failure signal detection
PMF25	Link Monitor	55.4.2.6	M	Yes [ ]	See state diagram in Figure 55–31
PMF26	Refresh monitor state diagram	55.4.2.7	EEE:M	Yes [ ] No [ ]	Implements state diagram of Figure 55–32
PMF27	Recommended fast retrain sequence timing	55.4.2.5.15	FR:O	Yes [ ] No [ ]	See Table 55–10

Item	Feature	Subclause	Status	Support	Value/Comment
PMF28	Clock Recovery function	55.4.2.8	M	Yes [ ]	
PMF29	MDIX for EEE refreshes and alert	55.4.4	EEE:M	Yes [ ]	
PMF30	Symbol response	55.4.3.1	M	Yes [ ]	Per electrical specifications given in 55.5
PMF31	THP filter coefficient setting	55.4.3.1	M	Yes [ ]	Fixed after startup
PMF32	PMA Transmit power backoff settings	55.4.3.1	M	Yes [ ]	
PMF33	Minimum power backoff requested	55.4.3.1	M	Yes [ ]	Per Table 55–11
PMF34	Automatic configuration	55.4.4	M	Yes [ ]	Comply with the specifications of 40.4.4.1 and 40.4.4.2
PMF35	Pair/Polarity swap detection and correction	55.4.4	M	Yes [ ]	
PMF36	PMA_CONFIG.indication generation	55.4.5.1	M	Yes [ ]	
PMF37	Maxwait_timer expiration	55.4.5.2	M	Yes [ ]	
PMF38	Minwait_timer expiration	55.4.5.2	M	Yes [ ]	

55.12.5 Management interface

Item	Feature	Subclause	Status	Support	Value/Comment
MF1	Support for Auto-Negotiation	55.6.1	M	Yes [ ]	See Clause 28
MF2	MASTER and SLAVE operation	55.6.1	M	Yes [ ]	Capable of operating either as MASTER or SLAVE
MF3	Extended Next Page support	55.6.1	M	Yes [ ]	
MF4	Optimized FLP timing	55.6.1	M	Yes [ ]	
MF5	Management registers	55.6.1.1	M	Yes [ ]	As defined in Table 55–14
MF6	10GBASE-T Extended Next Page bit assignments	55.6.1.2	M	Yes [ ]	As defined in Table 55–15
MF7	EEE advertisement	55.6.1.2	EEE:M	Yes [ ]	As defined in Table 55–15
MF8	Fast retrain ability advertisement	55.6.1.2	FR:M	Yes [ ]	As defined in Table 55–15
MF9	MASTER-SLAVE resolution with both or neither devices supporting loop timing	55.6.2	M	Yes [ ]	As defined in Table 55–16
MF10	MASTER-SLAVE resolution with one device supporting loop timing	55.6.2	M	Yes [ ]	Device supporting loop timing forced to SLAVE

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Item	Feature	Subclause	Status	Support	Value/Comment
MF11	Resolution completion	55.6.2	M	Yes [ ]	Successful completion of resolution treated as MASTER-SLAVE configuration resolution complete.
MF12	Seed counter	55.6.2	M	Yes [ ]	Counter provided to track number of seed attempts
MF13	Counter set to zero at startup	55.6.2	M	Yes [ ]	
MF14	Counter increment	55.6.2	M	Yes [ ]	
MF15	Counter reset	55.6.2	M	Yes [ ]	After resolution is complete
MF16	Bit 7.33.15 set to zero after resolution is complete	55.6.2	M	Yes [ ]	After resolution is complete
MF17	Resolution fault declared	55.6.2	M	Yes [ ]	After generation of seven seeds
MF18	MASTER-SLAVE fault condition	55.6.2	M	Yes [ ]	Condition occurs when both devices manually select MASTER or SLAVE
MF19	MASTER-SLAVE fault condition bit	55.6.2	M	Yes [ ]	Set to one upon fault condition
MF20	MASTER-SLAVE fault resolution	55.6.2	M	Yes [ ]	Fault condition treated as MASTER-SLAVE resolution complete
MF21	MASTER-SLAVE fault condition indication	55.6.2	M	Yes [ ]	link_status_10GigT set to FAIL

55.12.6 PMA electrical specifications

Item	Feature	Subclause	Status	Support	Value/Comment
PME1	Electrical isolation	55.5.1	M	Yes [ ]	Conforms to J.1
PME2	Test modes supported	55.5.2	M	Yes [ ]	
PME3	Test mode enablement	55.5.2	M	Yes [ ]	Per management register settings shown in Table 55–12
PME4	The test modes only change the data symbols	55.5.2	M	Yes [ ]	
PME5	Provide a means to enable the test modes	55.5.2	O	Yes [ ]	Mandatory for PHYs without MDIO
PME6	Test mode 1 operation	55.5.2	M	Yes [ ]	
PME7	Test mode 2 operation	55.5.2	M	Yes [ ]	
PME8	Test mode 3 operation, pair D	55.5.2	LT:M	Yes [ ] N/A [ ]	Mandatory for PHY that supports loop timing
PME9	Test mode 3 operation, pairs A, B and C	55.5.2	M	Yes [ ]	Transmit silence

Item	Feature	Subclause	Status	Support	Value/Comment
PME10	Test mode 4 waveform	55.5.2	M	Yes [ ]	Tones per Table 55–13
PME11	Test mode 4 levels	55.5.2	M	Yes [ ]	
PME12	Test mode 5 operation	55.5.2	M	Yes [ ]	
PME13	Test mode 6 operation	55.5.2	M	Yes [ ]	
PME14	Test mode 7 operation	55.5.2	M	Yes [ ]	
PME15	Text fixture 3 isolation	55.5.2	M	Yes [ ]	>30 dB between signals on any of {pairs A, B, C} and pair D
PME16	Transmitter nominal load	55.5.3	M	Yes [ ]	
PME17	AC-coupling to the MDI	55.5.3	M	Yes [ ]	
PME18	Droop test	55.5.3.1	M	Yes [ ]	
PME19	SFDR of transmitter	55.5.3.2	M	Yes [ ]	
PME20	Transmitter jitter as MASTER	55.5.3.3	M	Yes [ ]	
PME21	Transmitter jitter as loop-timed SLAVE	55.5.3.3	LT: M	N/A [ ] Yes [ ]	Applicable only if loop timing is supported
PME22	Transmit power level	55.5.3.4	M	Yes [ ]	
PME23	Transmitter PSD	55.5.3.4	M	Yes [ ]	
PME24	MASTER symbol rate	55.5.3.5	M	Yes [ ]	
PME25	Maximum short term rate of frequency variation during LPI	55.5.3.5	EEE:M	Yes [ ]	Less than 0.1 ppm/s
PME26	Maximum short term rate of frequency variation when switching to and from LPI	55.5.3.5	EEE:M	Yes [ ]	Less than 0.1 ppm/s
PME27	BER over a 55.7 compliant link	55.5.4.1	M	Yes [ ]	
PME28	Receiver frequency tolerance	55.5.4.2	M	Yes [ ]	
PME29	Alien noise tolerance	55.5.4.4	M	Yes [ ]	

55.12.7 Characteristics of the link segment

Item	Feature	Subclause	Status	Support	Value/Comment
LKS1	MDI compatibility	55.7	M	Yes [ ]	
LKS2	Insertion loss of each duplex channel	55.7.2.1	M	Yes [ ]	See Equation (55–11)
LKS3	Return loss	55.7.2.3	M	Yes [ ]	See (55–12)
LKS4	NEXT loss within pairs in a link segment	55.7.2.4.1	M	Yes [ ]	See (55–13)
LKS5	Power sum NEXT loss	55.7.2.4.2	M	Yes [ ]	See (55–14)
LKS6	Worst pair ELFEXT loss	55.7.2.4.4	M	Yes [ ]	See (55–18)

Item	Feature	Subclause	Status	Support	Value/Comment
LKS7	Power sum ELFEXT loss	55.7.2.4.5	M	Yes [ ]	See (55–20)
LKS8	Propagation delay	55.7.2.5	M	Yes [ ]	
LKS9	Delay skew	55.7.2.6	M	Yes [ ]	
LKS10	Delay skew change	55.7.2.6	M	Yes [ ]	
LKS11	Power sum ANEXT loss	55.7.3.1.1	M	Yes [ ]	See (55–23)
LKS12	Average PS ANEXT loss	55.7.3.1.1	M	Yes [ ]	See (55–25)
LKS13	PSANEXT_constant	55.7.3.1.2	M	Yes [ ]	See (55–26)
LKS14	IL(250) used in PSANEXT_ constant equation	55.7.3.1.2	M	Yes [ ]	Actual measured insertion loss at 250 MHz
LKS15	PS AELFEXT loss	55.7.3.2.1	M	Yes [ ]	See (55–32)
LKS16	Average PS AELFEXT loss	55.7.3.2.1	M	Yes [ ]	See (55–34)
LKS17	PSAELFEXT_constant	55.7.3.2.2	M	Yes [ ]	See (55–35)
LKS18	IL(250) used in PSAELFEXT_ constant equation	55.7.3.2.2	M	Yes [ ]	Actual measured insertion loss at 250 MHz
LKS19	Alien crosstalk margin *YL*	55.7.3.3	M	Yes [ ]	Greater than zero

55.12.8 MDI requirements

Item	Feature	Subclause	Status	Support	Value/Comment
MDI1	MDI connector	55.8.1	M	Yes [ ]	Eight-pin connectors meeting the requirements of IEC 60603-7-4 (unscreened) or IEC 60603-7-5 (screened)
MDI2	Cabling connector	55.8.1	M	Yes [ ]	Plug
MDI3	PHY connector	55.8.1	M	Yes [ ]	Jack (as opposed to plug)
MDI4	MDI connector jack plus plug performance	55.8.2	M	Yes [ ]	
MDI5	Mated MDI connector FEXT loss	55.8.2	M	Yes [ ]	Per (55–53)
MDI6	MDI power down	55.8.2	M	Yes [ ]	
MDI7	MDI return loss	55.8.2.1	M	Yes [ ]	
MDI8	MDI impedance balance	55.8.2.2	M	Yes [ ]	
MDI9	MDI fault tolerance to short circuits	55.8.2.3	M	Yes [ ]	No damage with an indefinite short
MDI10	Recovery from short	55.8.2.3	M	Yes [ ]	
MDI11	Short circuit current	55.8.2.3	M	Yes [ ]	Less than 300 mA

Item	Feature	Subclause	Status	Support	Value/Comment
MDI12	Connection to PSE	55.8.2.3	M	Yes [ ]	No damage to PHY
MDI13	Connection to PSE	55.8.2.3	M	Yes [ ]	No damage to PSE
MDI14	Common-mode impulse tolerance	55.8.2.3	M	Yes [ ]	1000 V common-mode impulse of either polarity

55.12.9 General safety and environmental requirements

Item	Feature	Subclause	Status	Support	Value/Comment
ENV1	Conformance to safety specifications	55.9.1	M	Yes [ ]	Conforms to J.2
ENV2	Installation isolation integrity	55.9.3	INS:M	N/A [ ] Yes [ ]	No electrical contact with unintended conductors or ground
ENV3	Phone voltage immunity	55.9.4	M	Yes [ ]	
ENV4	Electromagnetic compatibility	55.9.5	INS:M	N/A [ ] Yes [ ]	With local and national codes

55.12.10 Timing requirements

Item	Feature	Subclause	Status	Support	Value/Comment
TR1	Delay	55.11	M	Yes [ ]

56. Introduction to Ethernet for subscriber access networks

56.1 Overview

Ethernet for subscriber access networks, also referred to as "Ethernet in the First Mile," or EFM, combines a minimal set of extensions to the IEEE 802.3 Media Access Control (MAC) and MAC Control sublayers with a family of Physical Layers. These Physical Layers include optical fiber and voice grade copper cable Physical Medium Dependent sublayers (PMDs) for point-to-point (P2P) connections in subscriber access networks. EFM also introduces the concept of Ethernet Passive Optical Networks (EPONs), in which a point-to-multipoint (P2MP) network is implemented over an optical distribution network (ODN), along with extensions to the MAC Control sublayer and Reconciliation sublayer as well as optical fiber PMDs to support this topology. Furthermore, EFM introduces the concept of EPON Protocol over Coax (EPoC) networks, in which a P2MP network is implemented over a coax cable distribution network (CCDN), along with extensions to the MAC Control sublayer and Reconciliation sublayer as well as EPoC PMDs to support this topology.

In addition, a mechanism for network Operations, Administration, and Maintenance (OAM) is included to facilitate network operation and troubleshooting.

The relationships between these EFM elements and the ISO/IEC Open System Interconnection (OSI) reference model are shown in Figure 56–1 and Figure 56–2 for point-to-point topologies, Figure 56–3 for 1G-EPON topologies, Figure 56–4 for 10/10G-EPON topologies, Figure 56–5 for 10/1G-EPON topologies, Figure 56–6 for EPoC topologies, and Figure 56–7 for Nx25G-EPON topologies.

An important characteristic of EFM is that only full duplex links are supported. A simplified full duplex MAC is defined in Annex 4A for use in EFM networks. P2MP applications use this simplified full duplex MAC. EFM Copper applications may use either this simplified full duplex MAC or the Clause 4 MAC operating in half duplex mode as described in 61.1.4.1.2. All other EFM P2P applications may use either this simplified full duplex MAC or the Clause 4 MAC operating in full duplex mode.

The EFM architecture is further extended in:

— Clause 75 and Clause 76 by the addition of 10G–EPON.
— Clause 100, Clause 101, and Clause 102 by the addition of EPoC.
— Clause 141, Clause 142, and Clause 143 by the addition of Nx25G-EPON.

56.1.1 Summary of P2P sublayers

EFM P2P supports operation at several different bit rates, depending on the characteristics of the underlying medium.

56.1.1.1 P2P fiber media

The 100BASE-X Physical Coding Sublayer (PCS) and Physical Medium Attachment (PMA) sublayers are used to support a bit rate of 100 Mb/s as defined in 66.1. 100BASE-LX10 extends the reach of 100BASE-X to achieve 10 km over conventional single-mode two-fiber cabling.

The 1000BASE-X PCS and PMA sublayers are used to support a bit rate of 1000 Mb/s as defined in 66.2.

The 10GBASE-R PCS, RS-FEC, and PMA sublayers are used to support a bit rate of 10 Gb/s as defined in Clause 158.

The 25GBASE-R PCS, RS-FEC, and PMA sublayers are used to support a bit rate of 25 Gb/s as defined in Clause 159.

The 50GBASE-R PCS, RS-FEC, and PMA sublayers are used to support a bit rate of 50 Gb/s as defined in Clause 160.

56.1.1.2 P2P copper media

The P2P copper links support a variety of bit rates, depending on the span and the signal-to-noise ratio (SNR) characteristics of the medium as described in Clause 61 and Clause 63.

The 2BASE-TL P2P link supports a nominal bit rate of 2 Mb/s at a nominal reach of 2700 meters (see Annex 63B for a more detailed discussion of bit rates and reach).

The 10PASS-TS P2P link supports a nominal bit rate of 10 Mb/s at a nominal reach of 750 meters (see Annex 62B for a more detailed discussion of bit rates and reach).

56.1.2 Summary of P2MP sublayers

For P2MP optical fiber topologies, EFM supports the following systems:

a) PON with a nominal MAC data rate of 1 Gb/s in both downstream and upstream directions (1G-EPON), shared amongst the population of Optical Network Units (ONUs) attached to the P2MP topology. The P2MP PHYs use the 1000BASE-PX Physical Coding Sublayer (PCS), the Physical Medium Attachment (PMA) sublayer defined in Clause 65 and an optional forward error correction (FEC) function defined in Clause 65.
b) PON with a nominal MAC data rate of 10 Gb/s in both the downstream and upstream directions (10/10G-EPON) as well as PON with the nominal MAC data rate of 10 Gb/s in the downstream direction and 1 Gb/s in the upstream direction (10/1G-EPON), shared amongst the population of

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ONUs attached to the P2MP topology, and collectively referred to as 10G-EPON. The P2MP PHYs for the 10/10G-EPON use the 10GBASE-PR PCS and PMA (see Clause 76). The P2MP PHYs for 10/1G-EPON use the 10GBASE-PRX PCS and PMA (see Clause 76). EPONs using a nominal 10 Gb/s bit rate use a mandatory FEC function defined in Clause 76 in any direction running at the 10 Gb/s bit rate.

c) PON with a nominal MAC data rate of 25 Gb/s in the downstream direction and 10 Gb/s in the upstream direction (25/10G-EPON), 25 Gb/s in both the downstream and upstream directions (25/25G-EPON), 50 Gb/s in the downstream direction and 10 Gb/s in the upstream direction (50/10G-EPON), 50 Gb/s in the downstream direction and 25 Gb/s in the upstream direction (50/25G-EPON), and 50 Gb/s in both the downstream and upstream directions (50/50G-EPON), shared amongst the population of ONUs attached to the P2MP topology, and collectively referred to as Nx25G-EPON. The P2MP PHYs for the 25/10G-EPON and 25/25G-EPON use a single channel in each direction. The P2MP PHYs for the 50/10G-EPON and 50/25G-EPON use two channels in the downstream direction and a single channel in the upstream direction. The P2MP PHYs for the 50/50G-EPON use two channels in each direction. Each PMA channel in the downstream direction operates at a 25.78125 GBd line rate. Each PMA channel in the upstream direction operates at either a 25.78125 GBd or a 10.3125 GBd line rate. Each channel implements a mandatory FEC function in each direction (see Clause 142).

For P2MP coaxial topologies, EFM supports EPoC operating with a nominal bit rate of up to 10 Gb/s in the downstream direction and up to 1.6 Gb/s in the upstream direction. The P2MP EPoC PHYs use the 10GPASS-XR Physical Coding Sublayer (PCS), the Physical Medium Attachment (PMA) sublayer, and the mandatory forward error correction (FEC) function defined in Clause 101.

56.1.2.1 Multipoint MAC Control Protocol (MPCP)

The Multipoint MAC Control Protocol (MPCP) for 1G-EPON uses messages, state diagrams, and timers, as defined in Clause 64, to control access to a P2MP topology: Clause 77 defines the messages, state diagrams, and timers required to control access to a P2MP ODN topology in 10G-EPON; and Clause 144 defines the messages, state diagrams, and timers required to control access to a P2MP ODN topology in Nx25G-EPON. The issues related to coexistence of 1G-EPON and 10G-EPON on the same fiber plant are described in 77.4.

Every P2MP ODN topology consists of one Optical Line Terminal (OLT) and one or more ONUs, as shown in Figure 56–3, Figure 56–4, Figure 56–5, and Figure 56–7 for 1G-EPON, 10/10G-EPON, 10/1G-EPON, and Nx25G-EPON, respectively. One of several instances of the MPCP in the OLT communicates with the instance of the MPCP in the ONU. A pair of MPCPs that communicate between the OLT and ONU are a distinct and associated pair.

The MPCP for EPoC uses messages, state diagrams, and timers, as defined in Clause 103 to control access to a P2MP CCDN topology.

Every P2MP CCDN topology consists of one CLT plus one or more CNUs, as shown in Figure 56–6. One of several instances of the MPCP in the CLT communicates with the instance of the MPCP in the CNU. A pair of MPCPs that communicate between the CLT and CNU are a distinct and associated pair.

56.1.2.2 Reconciliation Sublayer (RS) and media independent interfaces

The Clause 22 RS and MII, Clause 35 RS and GMII, Clause 46 RS and XGMII, Clause 106 RS and 25GMII, and Clause 132 RS and 50GMII are all employed for the same purpose in EFM, that being the interconnection between the MAC sublayer and the PHY sublayers. Extensions to the Clause 35 RS for P2MP topologies are described in Clause 65, the RS for 10G-EPON P2MP topologies is described in Clause 76, the RS for Nx25G-EPON P2MP topologies is described in Clause 143, and the RS for EPoC P2MP topologies is described in Clause 101.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The combination of MPCP and the extension of the Reconciliation Sublayer (RS) for P2P Emulation allows an underlying P2MP network to appear as a collection of point-to-point links to the higher protocol layers (at and above the MAC Client).

The MPCP achieves this by providing a Logical Link Identification (LLID) in each packet by replacing two octets of the preamble.

This is described in Clause 65 for EPON, in Clause 76 for 10G-EPON, in Clause 143 for Nx25G-EPON, and in Clause 101 for EPoC. EFM Copper links use the MII of Clause 22 operating at 100 Mb/s. This is described in 61.1.4.1.2.

56.1.3 Physical Layer signaling systems

EFM extends the family of 100BASE-X Physical Layer signaling systems to include 100BASE-LX10 (long wavelength), plus the combination of the 100BASE-BX10-D (Bi-directional long wavelength Downstream) and the 100BASE-BX10-U (Bi-directional long wavelength Upstream), as defined in Clause 58. All of these systems employ the 100BASE-X PCS and PMA as defined in Clause 66.

EFM also extends the family of 1000BASE-X Physical Layer signaling systems to include 1000BASE-LX10 (long wavelength), plus the combination of the 1000BASE-BX10-D (Bi-directional long wavelength Downstream) and the 1000BASE-BX10-U (Bi-directional long wavelength Upstream), as defined in Clause 59. All of these systems employ the 1000BASE-X PCS and PMA as defined in Clause 66. 1000BASE-LX10 is interoperable with 1000BASE-LX on single-mode and multimode fiber, and offers greater reach than 1000BASE-LX on single-mode fiber.

EFM extends the family of 10GBASE-R Physical Layer signaling systems to include the following combinations of bidirectional PMDs defined in Clause 158:

— 10GBASE-BR10-D and 10GBASE-BR10-U
— 10GBASE-BR20-D and 10GBASE-BR20-U
— 10GBASE-BR40-D and 10GBASE-BR40-U

EFM extends the family of 25GBASE-R Physical Layer signaling systems to include the following combinations of bidirectional PMDs defined in Clause 159:

— 25GBASE-BR10-D and 25GBASE-BR10-U
— 25GBASE-BR20-D and 25GBASE-BR20-U
— 25GBASE-BR40-D and 25GBASE-BR40-U

EFM extends the family of 50GBASE-R Physical Layer signaling systems to include the following combinations of bidirectional PMDs defined in Clause 160:

— 50GBASE-BR10-D and 50GBASE-BR10-U
— 50GBASE-BR20-D and 50GBASE-BR20-U
— 50GBASE-BR40-D and 50GBASE-BR40-U

For P2MP topologies, EFM introduces a family of Physical Layer signaling systems that are derived from 1000BASE-X, but which include extensions to the RS, PCS and PMA, along with an optional forward error correction (FEC) capability, as defined in Clause 65. The family of P2MP Physical Layer signaling systems includes the combination of 1000BASE-PX10-D (Passive Optical Network Downstream 10 km), plus 1000BASE-PX10-U (PON Upstream 10 km), the combination of 1000BASE-PX20-D (PON Downstream 20 km) plus 1000BASE-PX20-U (PON Upstream 20 km), the combination of 1000BASE-PX30-D (PON Downstream 20 km) plus 1000BASE-PX30-U (PON Upstream 20 km), and the combination of 1000BASE-PX40-D (PON Downstream 20 km) plus 1000BASE-PX40-U (PON Upstream 20 km), as defined in Clause 60.

Additionally, EFM introduces a family of Physical Layer signaling systems which are derived from 10GBASE–R, but which include RS, PCS and PMA sublayers adapted for 10G-EPON, along with a

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mandatory FEC capability, as defined in Clause 76. All of these systems employ the PMD defined in Clause 75. The family of P2MP Physical Layer signaling systems utilizes 10GBASE-R signaling for the downstream direction while supporting both 10GBASE-R and 1000BASE-X upstream signaling in the following series of PMD combinations:

a) 10GBASE–PR–D1 and 10GBASE–PR–U1, creating a PR10 power budget, with 10 Gb/s downstream and 10 Gb/s upstream data rates, supporting a reach of at least 10 km and a split ratio of at least 1:16.
b) 10GBASE–PR–D2 and 10GBASE–PR–U1, creating a PR20 power budget, with 10 Gb/s downstream and 10 Gb/s upstream data rates, supporting a reach of at least 20 km and a split ratio of at least 1:16 or the reach of at least 10 km and the split ratio of at least 1:32.
c) 10GBASE–PR–D3 and 10GBASE–PR–U3, creating a PR30 power budget, with 10 Gb/s downstream and 10 Gb/s upstream data rates, supporting a reach of at least 20 km and a split ratio of at least 1:32.
d) 10GBASE–PR–D4 and 10GBASE–PR–U4, creating a PR40 power budget, with 10 Gb/s downstream and 10 Gb/s upstream data rates, supporting a reach of at least 20 km and a split ratio of at least 1:64.
e) 10/1GBASE–PRX–D1 and 10/1GBASE–PRX–U1, creating a PRX10 power budget, with 10 Gb/s downstream and 1 Gb/s upstream data rates, supporting a reach of at least 10 km and a split ratio of at least 1:16.
f) 10/1GBASE–PRX–D2 and 10/1GBASE–PRX–U2, creating a PRX20 power budget, with 10 Gb/s downstream and 1 Gb/s upstream data rates, supporting a reach of at least 20 km and a split ratio of at least 1:16.
g) 10/1GBASE–PRX–D3 and 10/1GBASE–PRX–U3, creating a PRX30 power budget, with 10 Gb/s downstream and 1 Gb/s upstream data rates, supporting a reach of at least 20 km and a split ratio of at least 1:32.
h) 10/1GBASE–PRX–D4 and 10/1GBASE–PRX–U4, creating a PRX40 power budget, with 10 Gb/s downstream and 1 Gb/s upstream data rates, supporting a reach of at least 20 km and a split ratio of at least 1:64.

All 10G-EPON PMDs are defined in Clause 75.

Additionally, EFM introduces a family of Physical Layer signaling systems that are derived from 25GBASE–R, but which include RS, PCS and PMA sublayers adapted for Nx25G-EPON, along with a mandatory FEC function, as defined in Clause 142. All these systems employ PMDs defined in Clause 141.

Moreover, EFM introduces a Physical Layer signaling system derived from 10GBASE-R, but which includes RS, PCS, and PMA sublayers adapted for EPoC, along with a mandatory FEC capability, as defined in Clause 101. This system employs the PMD defined in Clause 100. EPoC uses a PHY Link for Physical Layer signaling as defined in Clause 102.

For copper cabling, EFM introduces a family of Physical Layer signaling systems. There are two distinct signaling systems specified for copper cabling. Both of them share a set of common functions and interfaces as described in Clause 61. Clause 61 also includes an optional specification that supports combined operation on multiple copper pairs, affording greater data rate capability for a given link span. Underlying these functions, two Physical Layer signaling system specific PMAs and PMDs are described in Clause 62 and Clause 63. Non-loaded cable is a requirement of the signaling methods employed.

For high-speed applications, the 10PASS-TS signaling system is defined in Clause 62. 10PASS-TS relies on a technique referred to as Frequency Division Duplexing (FDD) to accomplish full duplex communication on a single wire pair. 10PASS-TS is a passband signaling system derived from the Very high-speed Digital Subscriber Line (VDSL) standard defined in ATIS-0600424, using Multiple Carrier Modulation (MCM, also referred to as Discrete Multi-Tone or DMT). This PHY supports a nominal full duplex data rate of 10 Mb/s, hence the identifier 10PASS-TS. For the 10PASS-TS PHY, two subtypes are defined: 10PASS-TS-O and 10PASS-TS-R. A connection can be established only between a 10PASS-TS-O PHY on one end

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

of the voice-grade copper line, and a 10PASS-TS-R PHY on the other end. In public networks, a 10PASS-TS-O PHY is used at a central office (CO), a cabinet, or other centralized distribution point; a 10PASS-TS-R PHY is used at the subscriber premises. In private networks, the network administrator will designate one end of each link as the network end. A PHY implementation may be equipped to support both subtypes and provide means to be configured as a 10PASS-TS-O or a 10PASS-TS-R.

For long distance applications, the 2BASE-TL signaling system is defined in Clause 63. 2BASE-TL is a baseband signaling system derived from the Single-Pair High-Speed Digital Subscriber Line (SHDSL) standards defined by ITU-T. The 2BASE-TL PMD supports a nominal full duplex data rate of approximately 2 Mb/s. As is the case with the 10PASS-TS PHY, the 2BASE-TL PHY consists of two subtypes: 2BASE-TL-O (network end) and 2BASE-TL-R (subscriber end).

System considerations for Ethernet subscriber access networks are described in Clause 67.

Specifications unique to the operation of each Physical Layer device are shown in Table 56–1.

Table 56–1—Summary of EFM Physical Layer signaling systems

56.1.4 Management

Managed objects, attributes, and actions are defined for all EFM components in Clause 30.

In addition to the management objects, attributes, and actions defined in Clause 30, EFM introduces Operations, Administration, and Maintenance (OAM) for subscriber access networks to Ethernet. OAM, as defined in Clause 57, includes a mechanism for communicating management information using OAM frames, as well as functions for performing low-level diagnostics on a per link basis in an Ethernet subscriber access network.

56.1.5 Unidirectional transmission

In contrast to previous editions of IEEE Std 802.3, in certain circumstances a DTE is allowed to transmit frames while not receiving a satisfactory signal. It is necessary for an EPON OLT or EPoC CLT to do this to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

bring an ODN or CCDN into operation (although it is highly inadvisable for an EPON ONU or EPoC CNU to transmit without receiving). Clause 66 describes optional modifications to the 100BASE-X PHY, 1000BASE-X PHY and 10GBASE RS so that a DTE may signal remote fault using OAMPDUs. When unidirectional operation is not enabled, the sublayers in Clause 66 are precisely the same as their equivalents in Clause 24, Clause 36, and Clause 46.

56.2 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

56.3 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE 802.3, Clause 57 through Clause 66, demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the EFM PICS conforms to the same notation and conventions used in 100BASE-T (see 21.6).

57. Operations, Administration, and Maintenance (OAM)

57.1 Overview

57.1.1 Scope

This clause defines the Operations, Administration, and Maintenance (OAM) sublayer, which provides mechanisms useful for monitoring link operation such as remote fault indication and remote loopback control. In general, OAM provides network operators the ability to monitor the health of the network and quickly determine the location of failing links or fault conditions. The OAM described in this clause provides data link layer mechanisms that complement applications that may reside in higher layers.

OAM information is conveyed in Slow Protocol frames (see Annex 57A) called OAM Protocol Data Units (OAMPDUs). OAMPDUs contain the appropriate control and status information used to monitor, test and troubleshoot OAM-enabled links. OAMPDUs traverse a single link, being passed between peer OAM entities, and as such, are not forwarded by MAC clients (e.g., bridges or switches).

OAM does not include functions such as station management, bandwidth allocation, or provisioning functions, which are considered outside the scope of this standard.

For the remainder of this clause, the term OAM is specific to the link level OAM described here.

57.1.2 Summary of objectives and major concepts

This subclause provides details and functional requirements for the OAM objectives:

a) Remote Failure Indication
   1) A mechanism is provided to indicate to a peer that the receive path of the local DTE is non-operational.
   2) Physical Layer devices using Clause 66 may support unidirectional operation that allows OAM remote failure indication during fault conditions.
   3) Subscriber access Physical Layer devices using Clause 65 support unidirectional operation in the direction from OLT to ONU that allows OAM remote failure indication from OLT during fault conditions.
   4) Physical Layer devices other than those listed above do not support unidirectional operation allowing OAM remote failure indication during fault conditions. Some Physical Layer devices have specific remote failure signaling mechanisms in the Physical Layer.

b) Remote Loopback—A mechanism is provided to support a data link layer frame-level loopback mode.

c) Link Monitoring
   1) A mechanism is provided to support event notification that permits the inclusion of diagnostic information.
   2) A mechanism is provided to support polling of any variable in the Clause 30 MIB.

d) Miscellaneous
   1) Implementation and activation of OAM is optional.
   2) A mechanism is provided that performs OAM capability discovery.
   3) An extension mechanism is provided and made available for higher layer management applications.

These objectives support a subset of the user-plane OAM requirements found in ITU-T Y.1730 [B50].

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.1.3 Summary of non-objectives

This subclause explicitly lists certain functions that are not addressed by OAM. These functions, while valuable, do not fall within the scope of this standard.

a) Management functions not pertaining to a single link such as protection switching and station management are not covered by this clause. Such functions could be addressed using the extension mechanism.
b) Provisioning and negotiation functions such as bandwidth allocation, rate adaptation and speed/ duplex negotiation are not supported by OAM.
c) Issues related to privacy of OAM data and authentication of OAM entities are beyond the scope of this standard.
d) The ability to set/write remote MIB variables is not supported.

57.1.4 Positioning of OAM within the IEEE 802.3 architecture

OAM comprises an optional sublayer between a superior sublayer (e.g., MAC client or optional Link Aggregation) and a subordinate sublayer (e.g., MAC or optional MAC Control sublayer). Figure 57–1 shows the relationship of the OAM sublayer to the ISO/IEC (IEEE) OSI reference model.

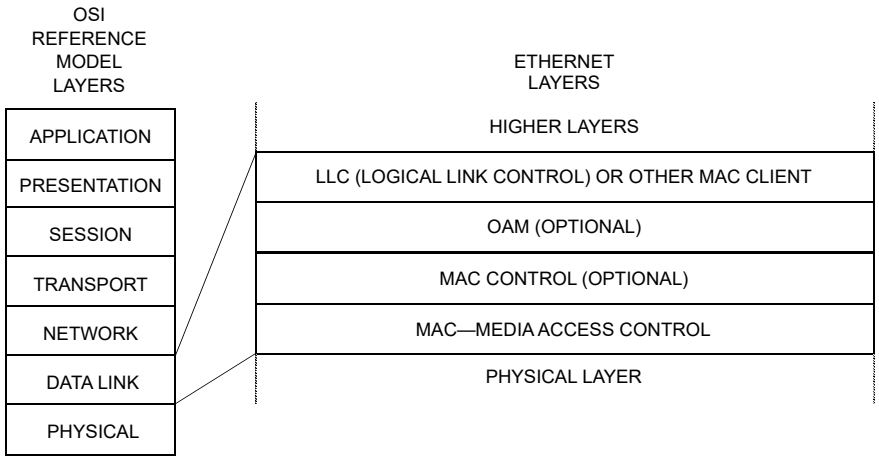

Figure 57–1—OAM sublayer relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

57.1.5 Compatibility considerations

57.1.5.1 Application

OAM is intended for point-to-point and emulated point-to-point IEEE 802.3 links. Implementation of OAM functionality is optional. A conformant implementation may implement the optional OAM sublayer for some ports within a system while not implementing it for other ports.

57.1.5.2 Interoperability between OAM capable DTEs

A DTE is able to determine whether or not a remote DTE has OAM functionality enabled. The OAM Discovery mechanism ascertains the configured parameters, such as maximum allowable OAMPDU size, and supported functions, such as OAM remote loopback, on a given link.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.1.5.3 MAC Control PAUSE

MAC Control PAUSE, commonly referred to as Flow Control as defined in Annex 31B, inhibits the transmission of all MA_DATA.request service primitives, including OAMPDUs. This may delay or prevent the signaling of critical events such as unrecoverable failure conditions and link faults.

57.1.5.4 Interface to MAC Control client

MAC Control clients that generate MA_CONTROL.request service primitives (and which expect MA_CONTROL.indication service primitives in response) are not acted upon by the OAM sublayer. They communicate directly with the MAC Control entity as though no OAM sublayer exists.

57.1.5.5 Frame loss during OAM remote loopback

Invocations of OAM remote loopback may result in frame loss. OAM remote loopback is an intrusive operation that prevents a link from passing frames between the MAC client of the local DTE and the MAC client of the remote DTE. Refer to 57.2.11 for a complete description of OAM remote loopback operation.

57.1.6 State diagram conventions

Many of the functions specified in this clause are presented in state diagram notation. All state diagrams contained in this clause use the notation and conventions defined in 21.5. In the event of a discrepancy between the text description and the state diagram formalization of a function, the state diagrams take precedence.

57.2 Functional specifications

57.2.1 Interlayer service interfaces

Figure 57–2 depicts the usage of interlayer interfaces by the OAM sublayer.

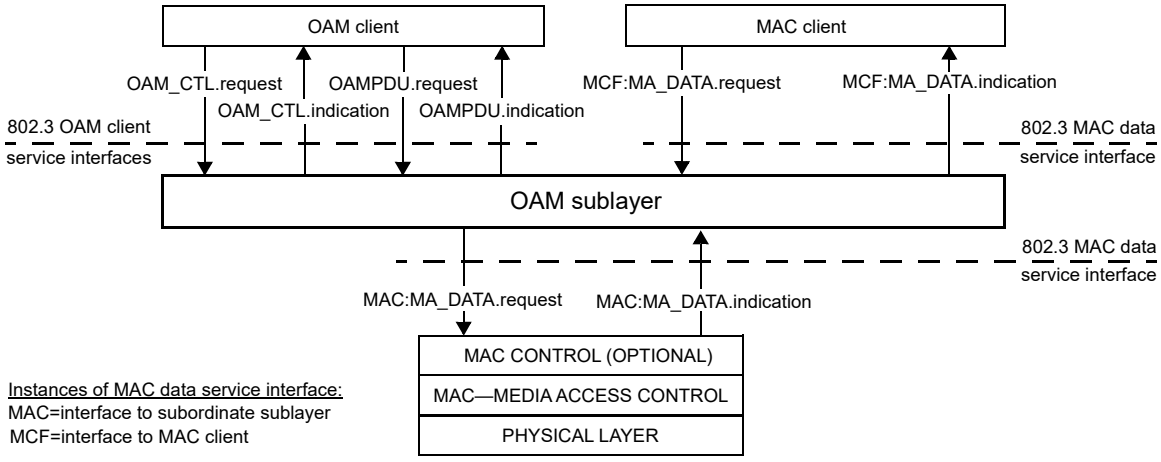

Figure 57–2—OAM sublayer support of interlayer service interfaces

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.2 Principles of operation

OAM employs the following principles and concepts:

a) The OAM sublayer presents a standard IEEE 802.3 MAC service interface to the superior sublayer. Superior sublayers include MAC client and Link Aggregation.
b) The OAM sublayer employs a standard IEEE 802.3 MAC service interface to the subordinate sublayer. Subordinate sublayers include MAC and MAC Control.
c) Frames from superior sublayers are multiplexed within the OAM sublayer with OAMPDUs.
d) The OAM sublayer parses received frames and passes OAMPDUs to the OAM client. In general, non-OAMPDUs are passed to the superior sublayer. When in OAM remote loopback mode, non-OAMPDUs are looped back to the subordinate sublayer. When the peer OAM entity is in OAM remote loopback mode, non-OAMPDUs are discarded by the OAM sublayer so that higher layer functions (e.g., bridging) do not process the looped back frames.
e) Knowledge of the underlying Physical Layer device is not required by the OAM sublayer.
f) OAMPDUs traverse a single link and are passed between OAM client entities or OAM sublayer entities. OAMPDUs are not forwarded by OAM clients.
g) OAM is extensible through the use of an Organization Specific OAMPDU, Organization Specific Information TLV, and Organization Specific Event TLV. These can be used for functions outside the scope of this standard.

57.2.3 Instances of the MAC data service interface

A superior sublayer such as the MAC client communicates with the OAM sublayer using the standard MAC data service interface specified in Clause 2. Similarly, the OAM sublayer communicates with a subordinate sublayer such as the MAC Control or MAC using the same standard service interfaces.

Since this clause uses two instances of the MAC data service interface, it is necessary to introduce a notation convention so that the reader can be clear as to which interface is being referred to at any given time. A prefix is therefore assigned to each service primitive, indicating which of the two interfaces is being invoked, as depicted in Figure 57–2. The prefixes are as follows:

a) MCF:, for primitives issued on the interface between the superior sublayer and the OAM sublayer (MCF is an abbreviation for MAC client frame)
b) MAC:, for primitives issued on the interface between the underlying subordinate sublayer (e.g., MAC) and the OAM sublayer

57.2.4 Responsibilities of OAM client

The OAM client plays an integral role in establishing and managing OAM on a link. The OAM client enables and configures the OAM sublayer entity. During the OAM Discovery process (see 57.3.2.1), the OAM client monitors received OAMPDUs from the remote DTE and based upon local and remote state and configuration settings allows OAM functionality to be enabled on the link.

After OAM has been established, the OAM client is responsible for adhering to the OAMPDU response rules. For example, the OAM client does not respond to illegal requests such as Variable Request and Loopback Control OAMPDUs from Passive DTEs. The OAM client is also expected to manage the OAM remote loopback mode (see 57.2.11). It does so by reacting to particular OAMPDUs and altering local configuration parameters.

Link events are signalled between peer OAM client entities. The OAM client transfers events by sending and receiving particular OAMPDUs. To increase the likelihood that a specific event is received by the remote DTE, the OAM client may send the event multiple times.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.5 OAM client interactions

The OAM sublayer entity communicates with the OAM client using the following new interlayer service interfaces:

OAMPDU.request
OAMPDU.indication
OAM_CTL.request
OAM_CTL.indication

The OAMPDU.request, OAMPDU.indication, OAM_CTL.request and OAM_CTL.indication service primitives described in this subclause are mandatory.

57.2.5.1 OAMPDU.request

57.2.5.1.1 Function

This primitive defines the transfer of data from an OAM client entity to a peer OAM client entity.

57.2.5.1.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
OAMPDU.request      (
                    source_address,
                        flags,
                        code,
                        data
                        )
```

The source_address parameter specifies an individual MAC address. The flags parameter is used to create the Flags field within the OAMPDU to be transmitted. Only the indications corresponding to the Flags field bits 15:3 are contained in the flags parameter since the indications corresponding to Flags field bits 2:0 are contained in the OAM_CTL.request service primitive. The code parameter is used to create the Code field within the OAMPDU to be transmitted. The data parameter is used to create the Data field within the OAMPDU to be transmitted.

57.2.5.1.3 When generated

This primitive is generated by the OAM client entity whenever an OAMPDU is to be transferred to a peer entity. This can be in response to a request from the peer entity or from data generated internally to the OAM client.

57.2.5.1.4 Effect of receipt

The receipt of this primitive will cause the OAM sublayer entity to insert all OAMPDU specific fields, including DA, SA, Length/Type and Subtype, and pass the properly formed OAMPDU to the lower protocol layers for transfer to the peer OAM client entity according to the transmit rules as described in 57.3.2.2.6.

57.2.5.2 OAMPDU.indication

57.2.5.2.1 Function

This primitive defines the transfer of data from an OAM sublayer entity to an OAM client entity.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.5.2.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
OAMPDU.indication    (
                         source_address,
                         flags,
                         code,
                         data
                         )
```

The source_address parameter is the MAC source address of the incoming OAMPDU. The flags parameter is the entire Flags field of the incoming OAMPDU. The code parameter is the Code field of the incoming OAMPDU. The data parameter is the Data field of the incoming OAMPDU.

57.2.5.2.3 When generated

This primitive is passed from the OAM sublayer entity to the OAM client entity to indicate the arrival of an OAMPDU to the local OAM sublayer entity that is destined for the OAM client. Such OAMPDUs are reported only if they are validly formed and received without error.

57.2.5.2.4 Effect of receipt

The effect of receipt of this primitive by the OAM client is unspecified.

57.2.5.3 OAM_CTL.request

57.2.5.3.1 Function

This primitive defines the transfer of control information from an OAM client entity to an OAM sublayer entity.

57.2.5.3.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
OAM_CTL.request      (
                         local_unidirectional,
                         local_link_status,
                         local_dying_gasp,
                         local_critical_event,
                         local_satisfied,
                         remote_state_valid,
                         remote_stable,
                         local_mux_action,
                         local_par_action,
                         information_data
                              )
```

When set, the local_unidirectional parameter is used to indicate the sending station supports transmission of OAMPDUs on unidirectional links as supported by some physical coding layers (see 57.2.12).

The local_link_status, local_dying_gasp, and local_critical_event parameters are used to indicate immediate event situations that should be transmitted to the peer OAM entity. The local_link_status parameter is used

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to convey the status of the link as determined by the underlying Physical Layer. When set to FAIL, the local_link_status parameter will cause the OAM sublayer entity to transmit an Information OAMPDU with the Link Fault bit of the Flags field set and no Information TLVs. The local_dying_gasp parameter is used to signal a local unrecoverable failure condition. When set, the local_dying_gasp parameter will cause the OAM sublayer to transmit an Information OAMPDU with the Dying Gasp bit of the Flags field set. The local_critical_event parameter is used to signal an unspecified critical link event condition. When set, the local_critical_event parameter will cause the OAM sublayer to transmit an Information OAMPDU with the Critical Event bit of the Flags field set.

The local_satisfied, remote_state_valid, and remote_stable parameters are used in the Discovery process. The local_satisfied parameter is set by the OAM client as a result of comparing its local configuration and the remote configuration found in the received Local Information TLV (see 57.3.2.1).

The local_mux_action and local_par_action parameters are used to control the state of the Multiplexer and Parser functions of the OAM sublayer (see 57.3.3 and 57.3.4).

The information_data parameter contains the Local Information TLV fields, and, if available, the Remote Information and Organization Specific Information TLV fields, to be included in Information OAMPDUs generated by the Transmit process (see 57.3.2.2).

57.2.5.3.3 When generated

This primitive is passed from the OAM client entity to the OAM sublayer to update control information.

57.2.5.3.4 Effect of receipt

The receipt of this primitive will cause the OAM sublayer to generate Information OAMPDUs or update specific fields of future Information OAMPDUs. Also, OAM functions will be re-evaluated based upon any changing control information.

57.2.5.4 OAM_CTL.indication

57.2.5.4.1 Function

This primitive defines the transfer of control information from an OAM sublayer entity to an OAM client entity.

57.2.5.4.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
OAM_CTL.indication      (
                        local_pdu,
                        local_stable,
                        local_lost_link_timer_done
                            )
```

The local_pdu and local_stable parameters are used by the OAM sublayer to indicate to the OAM client state information in the Discovery process (see 57.3.2.1). The local_lost_link_timer_done parameter is used to convey the expiration of the local_lost_link_timer.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.5.4.3 When generated

This primitive is passed from the OAM sublayer entity to the OAM client entity to indicate local state information has changed.

57.2.5.4.4 Effect of receipt

The effect of receipt of this primitive by the OAM client is unspecified.

57.2.6 Instances of the OAM internal service interface

The OAM sublayer communicates internally using the OAM internal service interface. Since two instances of the OAM internal service interface are used, it is necessary to introduce a notation convention so that the reader can be clear as to which interface is being referred to at any given time. A prefix is therefore assigned to each service primitive, indicating which of the two interfaces is being invoked (see Figure 57–3). The prefixes are as follows:

a) LBF:, for primitives issued on the interface between the Parser and the Multiplexer (LBF is an abbreviation for loopback frame).
b) CTL:, for primitives issued on the interface between the Control and other OAM functions (CTL is an abbreviation for Control function).

57.2.7 Internal block diagram

Figure 57–3 depicts the major blocks within the OAM sublayer and their interrelationships.

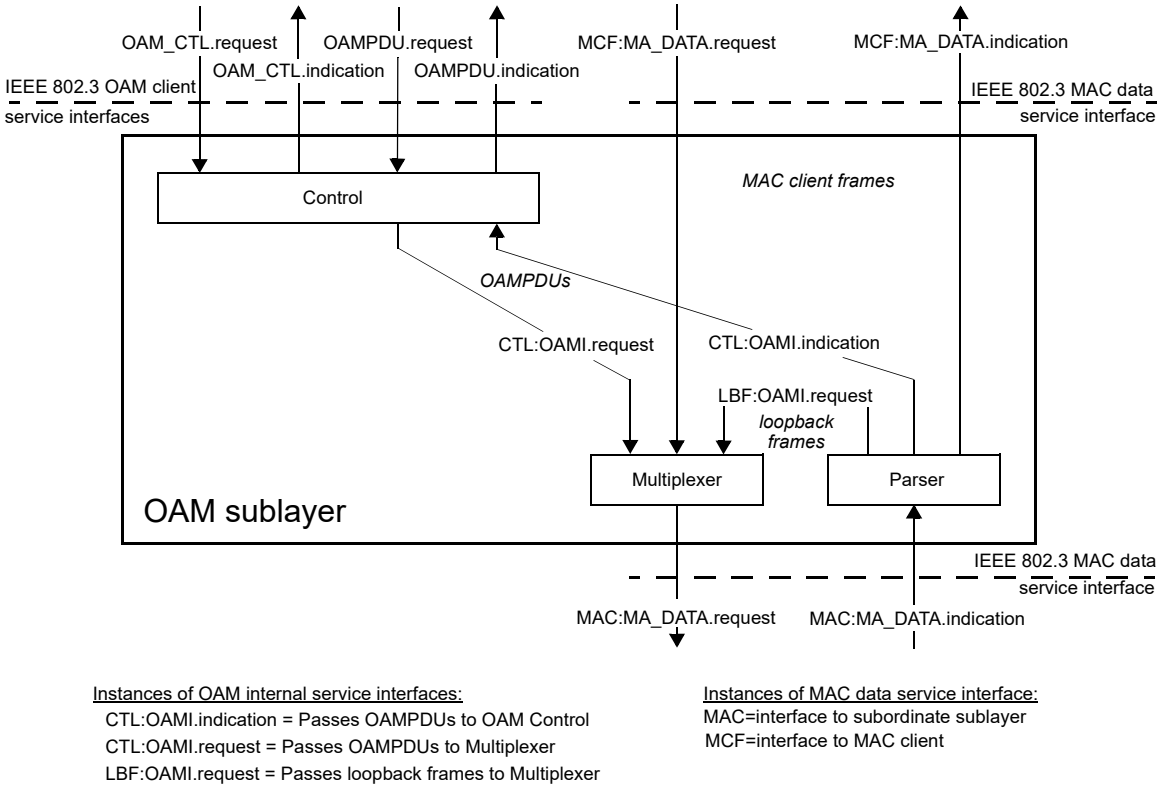

Figure 57–3—OAM sublayer block diagram

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.8 OAM internal interactions

The OAM sublayer entity employs the following new internal service interfaces:
OAMI.request
OAMI.indication

The OAMI.request and OAMI.indication service primitives described in this subclause are mandatory.

57.2.8.1 OAMI.request

57.2.8.1.1 Function

This primitive defines the transfer of frames to the Multiplexer function internal to the OAM sublayer.

57.2.8.1.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
OAMI.request        (
                    destination_address,
                    source_address,
                    oam_service_data_unit,
                        frame_check_sequence
                        )
```

The destination_address parameter specifies the Slow Protocols Multicast Address. The source_address parameter has to specify an individual MAC address. The oam_service_data_unit parameter specifies the OAM service data unit to be transmitted within the OAM sublayer entity. This parameter includes the Length/Type, Subtype, Flags, Code and Data/Pad fields. There is sufficient information associated with the oam_service_data_unit for the OAM sublayer entity to determine the length of the data unit. The frame_check_sequence parameter, if present, has to specify the frame check sequence field for the frame (see 3.2.9).

57.2.8.1.3 When generated

This primitive is generated by the Parser function whenever a frame is intended to be looped back to the remote DTE via the Multiplexer function. This primitive is also generated by the Control function whenever an OAMPDU is to be conveyed to the peer OAM entity via the Multiplexer function, internal to the OAM sublayer.

57.2.8.1.4 Effect of receipt

The receipt of this primitive will cause the Multiplexer function to pass the properly formed frame, subject to Figure 57–7, to the subordinate sublayer via the MAC data service interface (see 57.2.3).

57.2.8.2 OAMI.indication

57.2.8.2.1 Function

This primitive defines the transfer of frames to the Control function internal to the OAM sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.8.2.2 Semantics of the service primitive

The semantics of the primitive are as follows:

```
OAMI.indication     (
                        destination_address,
                        source_address,
                        oam_service_data_unit,
                        frame_check_sequence,
                        reception_status
                        )
```

The destination_address parameter is the Slow Protocols Multicast Address as specified by the DA field of the incoming frame. The source_address parameter is an individual address as specified by the SA field of the incoming frame. The oam_service_data_unit parameter specifies the OAM service data unit as received by the internal OAM function. The frame_check_sequence parameter, if present, is the cyclic redundancy check value (see 3.2.9) as specified by the FCS field of the incoming frame. The reception_status parameter is used to pass status information to the internal OAM function. Values for the reception_status parameter can be found in 4.3.2.

57.2.8.2.3 When generated

This primitive is generated whenever the Parser function intends to pass a received OAMPDU to the Control function, internal to the OAM sublayer. Frames are reported only if they are validly formed and received without error.

57.2.8.2.4 Effect of receipt

The receipt of this primitive will cause the Control function to update internal state variables and pass the OAMPDU to the OAM client via the OAMPDU.indication service primitive (see 57.2.5.2).

57.2.9 Modes

DTEs incorporating the OAM sublayer support Active and/or Passive mode. When OAM is enabled, a DTE capable of both Active and Passive modes shall select either Active or Passive. Table 57–1 contains the behavior of Active and Passive mode DTEs.

Table 57–1—Active and passive mode behavior

Capability	Active DTE	Passive DTE
Initiates OAM Discovery process	Yes	No
Reacts to OAM Discovery process initiation	Yes	Yes
Required to send Information OAMPDUs	Yes	Yes
Permitted to send Event Notification OAMPDUs	Yes	Yes
Permitted to send Variable Request OAMPDUs	Yes	No
Permitted to send Variable Response OAMPDUs	Yes[a]	Yes
Permitted to send Loopback Control OAMPDUs	Yes	No
Reacts to Loopback Control OAMPDUs	Yes[a]	Yes
Permitted to send Organization Specific OAMPDUs	Yes	Yes

[a]Requires the peer DTE to be in Active mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.9.1 Active mode

DTEs configured in Active mode initiate the exchange of Information OAMPDUs as defined by the Discovery state diagram (see Figure 57–5). Once the Discovery process completes, Active DTEs are permitted to send any OAMPDU while connected to a remote OAM peer entity in Active mode. Active DTEs operate in a limited respect if the remote OAM entity is operating in Passive mode (see Table 57–1). Active devices should not respond to OAM remote loopback commands and variable requests from a Passive peer.

57.2.9.2 Passive mode

DTEs configured in Passive mode do not initiate the Discovery process. Passive DTEs react to the initiation of the Discovery process by the remote DTE. This eliminates the possibility of passive to passive links. Passive DTEs shall not send Variable Request or Loopback Control OAMPDUs.

57.2.10 OAM events

OAM defines a set of events that may impact link operation. OAM contains mechanisms to communicate such events to the remote DTE. The following sections provide an overview of these events and mechanisms.

57.2.10.1 Critical link events

Table 57–2 lists the defined critical link events. Critical link events are carried within the Flags field of each OAMPDU. Refer to 57.4.2.1 for the definition and encoding of the Flags field.

Table 57–2—Critical link event

Critical link event	Description
Link fault	The PHY has determined a fault has occurred in the receive direction of the local DTE.
Dying gasp	An unrecoverable local failure condition has occurred.
Critical event	An unspecified critical event has occurred.

NOTE—The definition of the specific faults comprising the Critical Event, Dying Gasp, and Link Fault flags is implementation specific and beyond the scope of this standard.

57.2.10.2 Link events

Link events are signaled via Link Event TLVs that are defined in 57.5.3. Examples of link events include Errored Symbol Period Event and Errored Frame Event.

57.2.10.3 Local event procedure

Local events are communicated to the remote DTE via one of two mechanisms described as follows:

a) Critical link events, defined in 57.2.10.1, are communicated to the OAM sublayer via the OAM_CTL.request service primitive. The OAM sublayer shall respond to critical link events by setting or clearing the appropriate bits within the Flags field on any subsequently generated OAMPDUs of any type.
b) The OAM client sends an Event Notification OAMPDU (see 57.4.3.2) containing a Link Event TLV (see Table 57–12) for every event not yet signaled to the remote DTE. The OAM client uses the OAMPDU.request service primitive to send Event Notification OAMPDUs. The OAM client may send duplicate Event Notification OAMPDUs to increase the probability of reception at the remote DTE on deteriorating links.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.10.4 Remote event procedure

Remote events are detected by the local OAM client via one of two mechanisms described as follows:

a) Critical link events, defined in 57.2.10.1, shall be detected by the local OAM sublayer via the Flags field of any received OAMPDU. The OAM sublayer signals the Flags field to the OAM client using the OAMPDU.indication service primitive. When receiving Information OAMPDUs indicating Link Fault from the remote DTE, it is recommended that the local OAM client set the local_link_status parameter in the OAM_CTL.request service primitive to OK. This avoids the situation where both ends of a link are in a deadlock condition where neither DTE will be capable of receiving frames.
b) All other link events shall be detected by the local OAM sublayer via the reception of an Event Notification OAMPDU and the subsequent passing of the OAMPDU to the OAM client via the OAMPDU.indication service primitive. The OAM client discards any duplicate received Event Notification OAMPDU.

57.2.11 OAM remote loopback

OAM provides an optional data link layer frame-level loopback mode, which is controlled remotely. OAM remote loopback can be used for fault localization and link performance testing. Statistics from both the local and remote DTE can be queried and compared at any time while the remote DTE is in OAM remote loopback mode. These queries can take place before, during or after loopback frames have been sent to the remote DTE. In addition, an implementation may analyze loopback frames within the OAM sublayer to determine additional information about the health of the link (i.e., determine which frames are being dropped due to link errors). Figure 57–4 shows the path of frames traversing the layer stack of both the local and remote DTEs.

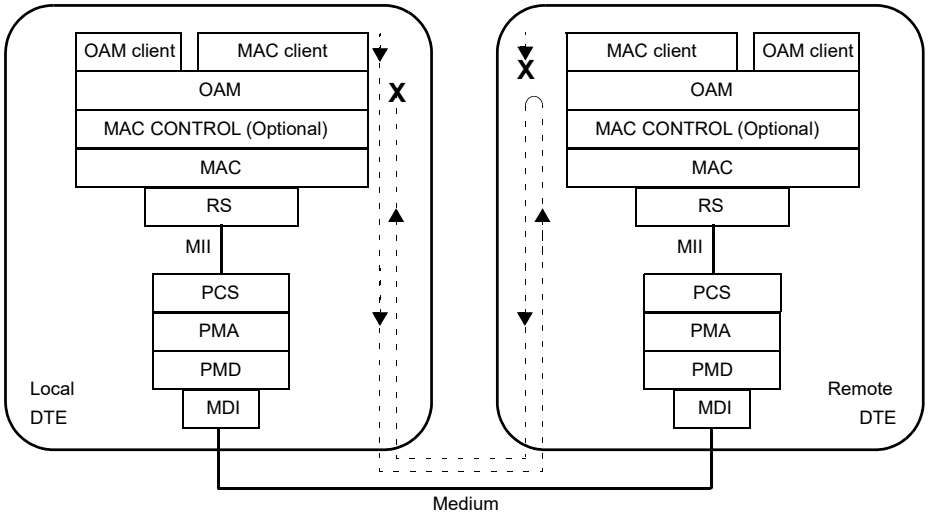

Figure 57–4—OAM remote loopback

57.2.11.1 Initiating OAM remote loopback

To initiate OAM remote loopback, the local OAM client sets its local_mux_action parameter to DISCARD and the local_par_action parameter to DISCARD via the OAM_CTL.request service primitive. The local OAM client sends a Loopback Control OAMPDU (see 57.4.3.5) with the Enable OAM Remote Loopback command. After receiving the Loopback Control OAMPDU, the remote OAM client first sets its local_par_action parameter to LB and its local_mux_action parameter to DISCARD via the OAM_CTL.request service primitive, and then sends an Information OAMPDU with updated state

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

information reflecting its local_par_action set to LB and its local_mux_action parameter set to DISCARD. On the reception of an Information OAMPDU from the remote OAM client with updated state information, the local OAM client sets the local_mux_action to FWD.

If an OAM client has sent a Loopback Control OAMPDU and is waiting for the peer DTE to respond with an Information OAMPDU that indicates it is in OAM remote loopback mode, and that OAM client receives an OAM remote loopback command from the peer device, the following procedures are recommended:

a) If the local DTE has a higher source_address than the peer, it should enter OAM remote loopback mode at the command of its peer.
b) If the local DTE has a lower source_address than the peer, it should ignore the OAM remote loopback command from its peer and continue as if it were never received.

If OAM clients do not follow these guidelines, it may be possible for two OAM clients to issue simultaneous OAM remote loopback commands with indeterminate results.

57.2.11.2 During OAM remote loopback

This subclause elaborates on Figure 57–4 and describes the flow of frames within the local and remote DTEs and across the link during OAM remote loopback mode. While in OAM remote loopback mode:

a) The local DTE transmits frames from the MAC client and OAMPDUs from the local OAM client or OAM sublayer.
b) Within the remote OAM sublayer entity, every non-OAMPDU, including other Slow Protocol frames, is looped back without altering any field of the frame.
c) OAMPDUs received by the remote DTE are passed to the remote OAM client.
d) Both DTEs are required to send OAMPDUs to the peer DTE in order to keep the Discovery process from re-starting. Both are also permitted to send other OAMPDUs to the peer DTE.
e) Frames received by the local DTE are parsed by the OAM sublayer. OAMPDUs are passed to the OAM client and all other frames are discarded.

57.2.11.3 Exiting OAM remote loopback

When the local DTE wishes to end the OAM remote loopback test, the local OAM client sets its local_mux_action parameter to DISCARD. The local OAM client then sends a Loopback Control OAMPDU with the Disable OAM Remote Loopback command. After receiving a Loopback Control OAMPDU with the Disable OAM Remote Loopback command, the remote OAM client first sets the local_par_action and local_mux_action parameters to FWD via the OAM_CTL.request service primitive and then sends an Information OAMPDU with updated state information reflecting the local_par_action and local_mux_action parameters set to FWD. After receiving an Information OAMPDU with local_par_action and local_mux_action set to FWD, the local OAM client sets its local_par_action and local_mux_action parameters to FWD via the OAM_CTL.request service primitive. The remote Parser resumes passing received non-OAMPDUs up to the MAC client and the local Multiplexer resumes forwarding any frames sourced by the local MAC client.

57.2.11.4 Loss of OAMPDUs during OAM remote loopback

There is the possibility of OAMPDU loss before, during and after OAM remote loopback tests. Of particular interest to the operation of OAM remote loopback is the loss of Loopback Control OAMPDUs and Information OAMPDUs. The local OAM client is able to determine whether or not the remote OAM client received Loopback Control OAMPDUs by examining all received Information OAMPDUs. Since Information OAMPDUs are continually sent to keep the OAM Discovery process from restarting, the occasional loss of an Information OAMPDU should not adversely impact the operation of OAM remote loopback mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.2.11.5 Loss of frames during OAM remote loopback

While the link is operating in OAM remote loopback mode, MAC client frames originating from the remote DTE are not transmitted by the remote OAM sublayer entity. Depending upon the remote DTE's implementation of OAM remote loopback, not every frame received is guaranteed to be looped back to the local DTE. Clock differences between the local and remote DTEs may also be a source of lost frames, as the delta in the rate of frames transmitted and received may overrun buffers within either DTE. As always, frames that incur errors during transit will be dropped by the MAC sublayer receiving the frame. Also, OAMPDUs inserted by the remote DTE impacts the bandwidth available to loopback frames. Implementations should take into account the topology (e.g., emulated point-to-point, asymmetrical links) when determining the rate at which to send frames during OAM remote loopback. When a bi-directional link has asymmetric data rates, frame loss may occur if the receive bandwidth is less than the transmit bandwidth.

Loopback frames that are discarded by the OAM sublayer within the remote DTE are counted and, if Clause 30 is present, are reflected in 30.3.6.1.46. This helps determine the health of the link by distinguishing between frames discarded due to link errors and those discarded within the OAM sublayer.

57.2.11.6 Timing considerations for OAM remote loopback

For effective OAM remote loopback operation, it is necessary to place an upper bound on the response time of the remote OAM client after receiving Loopback Control OAMPDUs.

To ensure correct operation, the OAM client needs to, within one second of receiving a Loopback Control OAMPDU with the Enable OAM Remote Loopback command

a) Set its local_par_action parameter to LB and the local_mux_action to DISCARD via the OAM_CTL.request service primitive.
b) Send an Information OAMPDU.

To ensure correct operation, the OAM client needs to, within one second of receiving a Loopback Control OAMPDU with the Disable OAM Remote Loopback command

c) Set its local_par_action and local_mux_action parameters to FWD via the OAM_CTL.request service primitive.
d) Send an Information OAMPDU.

It is possible for the remote MAC client to send frames before the remote OAM client can send the Information OAMPDU instructing the local DTE to change its local_par_action variable. As a result these remote MAC client frames will be discarded by the local DTE.

57.2.12 Unidirectional OAM operation

OAM provides an OAMPDU-based mechanism to notify the remote DTE when one direction of a link is non-operational and therefore data transmission is disabled. The ability to operate a link in a unidirectional mode for diagnostic purposes supports the maintenance objective of failure detection and notification.

Some Physical Layer devices support Unidirectional OAM operation (see 22.2.4.1.12, 22.2.4.2.8, and Clause 66). When a link is operating in Unidirectional OAM mode, the OAM sublayer ensures that only Information OAMPDUs with the Link Fault critical link event indication set and no Information TLVs are sent once per second across the link.

57.3 Detailed functions and state diagrams

As depicted in Figure 57–3, the OAM sublayer comprises the following functions:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) ***Multiplexer.*** This function is responsible for passing frames received from the superior sublayer (e.g., MAC client sublayer), OAMPDUs from the Control function and loopback frames from the Parser, to the subordinate sublayer (e.g., MAC sublayer).
b) ***Parser.*** This function distinguishes among OAMPDUs, MAC client frames and loopback frames and passes each to the appropriate entity (Control, superior sublayer and Multiplexer, respectively).
c) ***Control.*** This function is responsible for providing the interface between the OAM client entity and the functions internal to the OAM sublayer. It incorporates the Discovery process which detects the existence and capabilities of OAM at the remote DTE. Also, it includes the Transmit process, which governs the transmission of OAMPDUs to the Multiplexer function and a set of Receive rules, which govern the reception of OAMPDUs.

57.3.1 State diagram variables

57.3.1.1 Constants

OAM_subtype
: The value of the Subtype field for OAMPDUs (see Table 57A–3).

Slow_Protocols_Multicast
: The value of the Slow Protocols Multicast Address. (see Table 57A–1.)

Slow_Protocols_Type
: The value of the Slow Protocols Length/Type field. (see Table 57A–2.)

57.3.1.2 Variables

BEGIN
: A variable that resets the functions within OAM.
Values: TRUE; when the OAM sublayer is reset, or when local_oam_enable is set to DISABLE.
FALSE; When (re-)initialization has completed and local_oam_enable is set to ENABLE.

ind_DA
ind_SA
ind_mac_service_data_unit
ind_reception_status
: The parameters of the MA_DATA.indication service primitive, as defined in Clause 2.

ind_subtype
: The value of the octet following the Length/Type field in a Slow Protocol frame (see Annex 57A).
Value: Integer

local_critical_event
: A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This indicates the DTE has experienced an unspecified critical event condition.
Values: FALSE; A critical event condition has not occurred.
TRUE; A critical event condition has occurred.

local_dying_gasp
: A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This indicates the DTE has experienced an unrecoverable failure condition.
Values: FALSE; An unrecoverable local failure condition has not occurred.
TRUE; An unrecoverable local failure condition has occurred.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

local_link_status

A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This indicates the status of the established link (see 67.6.3).

Values: FAIL; A link fault condition does exist.
OK; A link fault condition does not exist.

local_lost_link_timer_done

A parameter of the OAM_CTL.indication service primitive, as defined in 57.2.5.4. This is used to indicate the local_lost_link_timer has expired.

Values: TRUE; local_lost_link_timer has expired.
FALSE; local_lost_link_timer has not expired.

local_mux_action

A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This governs the flow of frames from the MAC client through the Multiplexer function (see 57.3.3).

Values: FWD; Multiplexer passes MAC client frames to subordinate sublayer.
DISCARD; Multiplexer discards MAC client frames.

local_oam_enable

Used to enable and disable the OAM sublayer entity. If Clause 30 is present, this maps to 30.3.6.1.2 aOAMAdminState.

Values: DISABLE; The interface acts as it would if it had no OAM sublayer.
ENABLE; The interface employs the OAM sublayer and its functions.

local_oam_mode

Used to configure the OAM sublayer entity in either Active or Passive mode. If Clause 30 is present, this maps to 30.3.3.2 aOAMMode.

Values: PASSIVE; The OAM sublayer entity is configured in Passive mode.
ACTIVE; The OAM sublayer entity is configured in Active mode.

local_par_action

A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This governs the flow of non-OAMPDUs through the Parser function (see 57.3.4).

Values: FWD; Parser passes received non-OAMPDUs to superior sublayer.
LB; Parser passes received non-OAMPDUs to Multiplexer during remote loopback test.
DISCARD; Parser discards received non-OAMPDUs.

local_pdu

This is used to govern the transmission and reception of OAMPDUs as part of the Discovery process (see 57.3.2.1).

Values: LF_INFO; Only Information OAMPDUs with the Link Fault critical link event set and without Information TLVs are allowed to be transmitted; only Information OAMPDUs are allowed to be received.
RX_INFO; No OAMPDUs are allowed to be transmitted; only Information OAMPDUs are allowed to be received.
INFO; Only Information OAMPDUs are allowed to be transmitted and received.
ANY; Any permissible OAMPDU is allowed to be transmitted and received (see Table 57–1).

local_satisfied

A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This indicates the OAM client finds the local and remote OAM configuration settings are agreeable.

Values: FALSE; OAM client either has not seen or is not satisfied with local and remote settings.
TRUE; OAM client is satisfied with local and remote settings.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

local_stable
: A variable set by the Discovery state diagram (see Figure 57–5). This is used to indicate local OAM client acknowledgment of and satisfaction with remote OAM state information.
Values: FALSE; Indicates that local DTE either has not seen or is unsatisfied with remote state information.
TRUE; Indicates that local DTE has seen and is satisfied with remote state information.

local_unidirectional
: A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This indicates the DTE is capable of sending OAMPDUs when the link in the receive direction is not operational.
Values: FALSE; DTE is unable to send OAMPDUs when receive path is not operational.
TRUE; DTE is capable of sending OAMPDUs when receive path is not operational.

pdu_limit
: This variable represents the maximum number of OAMPDUs that are allowed to be transmitted in one second. The value of the pdu_limit variable is equal to the value of the aSlowProtocolFrameLimit attribute (see 30.3.1.1.38).

pdu_req
: This represents a request to send an OAMPDU and is used within the Transmit state diagram (see Figure 57–6).
Values: NONE: No OAMPDU.request
CRITICAL: OAMPDU.request with one or more critical link event OAM_CTL.request parameters set (local_dying_gasp, local_link_status, local_critical_event).
NORMAL: OAMPDU.request with no critical link event(s) set.

remote_stable
: A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. OAM client extracts remote state information from received OAMPDUs. This is used to indicate remote OAM client acknowledgment of and satisfaction with local OAM state information.
Values: FALSE; Indicates that remote DTE either has not seen or is unsatisfied with local state information.
TRUE; Indicates that remote DTE has seen and is satisfied with local state information.

remote_state_valid
: A parameter of the OAM_CTL.request service primitive, as defined in 57.2.5.3. This is used to indicate OAM client has received remote state information found within Local Information TLVs of received Information OAMPDUs.
Values: FALSE; Indicates that OAM client has not seen remote state information.
TRUE; Indicates that OAM client has seen remote state information.

req_DA
req_SA
req_mac_service_data_unit
req_frame_check_sequence
: The parameters of the MA_DATA.request service primitive, as defined in Clause 2.

57.3.1.3 Messages

CTL:OAMI.indication
: The service primitive used to pass a received frame to an internal OAM function with the specified parameters.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

CTL:OAMI.request
LBF:OAMI.request
The service primitives used to transmit a frame with the specified parameters.

MAC:MA_DATA.indication
MCF:MA_DATA.indication
The service primitives used to pass a received frame to a client with the specified parameters.

MAC:MA_DATA.request
MCF:MA_DATA.request
The service primitives used to transmit a frame with the specified parameters.

MADI
Alias for
MA_DATA.indication(ind_DA, ind_SA, ind_mac_service_data_unit, ind_reception_status)

MADR
Alias for
MA_DATA.request(req_DA, req_SA, req_mac_service_data_unit, req_frame_check_sequence)

OAMII
Alias for
OAMI.indication(DA, SA, oam_service_data_unit, frame_check_sequence, reception_status)

OAMIR
Alias for
OAMI.request(DA, SA, oam_service_data_unit, frame_check_sequence)

RxOAMPDU
Alias for ind_DA = Slow_Protocols_Multicast * ind_Length/Type = Slow_Protocols_Type * ind_subtype = OAM_subtype

rxOK
Alias for ind_reception_status = receiveOK

valid_pdu_req
Alias for the following term:
(local_pdu≠RX_INFO * pdu_req=NORMAL * pdu_cnt≠0)
+ (local_pdu=ANY * pdu_req=CRITICAL)

57.3.1.4 Counters

pdu_cnt
This counter is used to limit the number of OAMPDUs transmitted per second and ensure at least one OAMPDU is sent each second within the Transmit state diagram (see Figure 57–6).

57.3.1.5 Timers

All timers operate in the manner described in 14.2.3.2 with the following addition. A timer is reset and stops counting upon entering a state where 'stop x_timer' is asserted.

local_lost_link_timer
Timer used to reset the Discovery state diagram (see Figure 57–5).
Duration: 5 s ± 10%.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

pdu_timer
: Timer used to ensure OAM sublayer adheres to maximum number of OAMPDUs per second and emits at least one OAMPDU per second.
Duration: 1 s ± 10%.

57.3.2 Control

The Control function provides the interfaces with the OAM client necessary to transmit and receive OAMPDUs and convey control and status parameters. The Control function also contains the Discovery process, which enables OAM to be established on a link, and the Transmit process, which governs the transmission of OAMPDUs to the Multiplexer block. Rules governing the reception of OAMPDUs are also contained within the Control function.

57.3.2.1 OAM Discovery

OAM provides a mechanism to detect the presence of an OAM sublayer at the remote DTE. This mechanism is called Discovery. OAM sublayer entities shall implement the OAM Discovery state diagram shown in Figure 57–5.

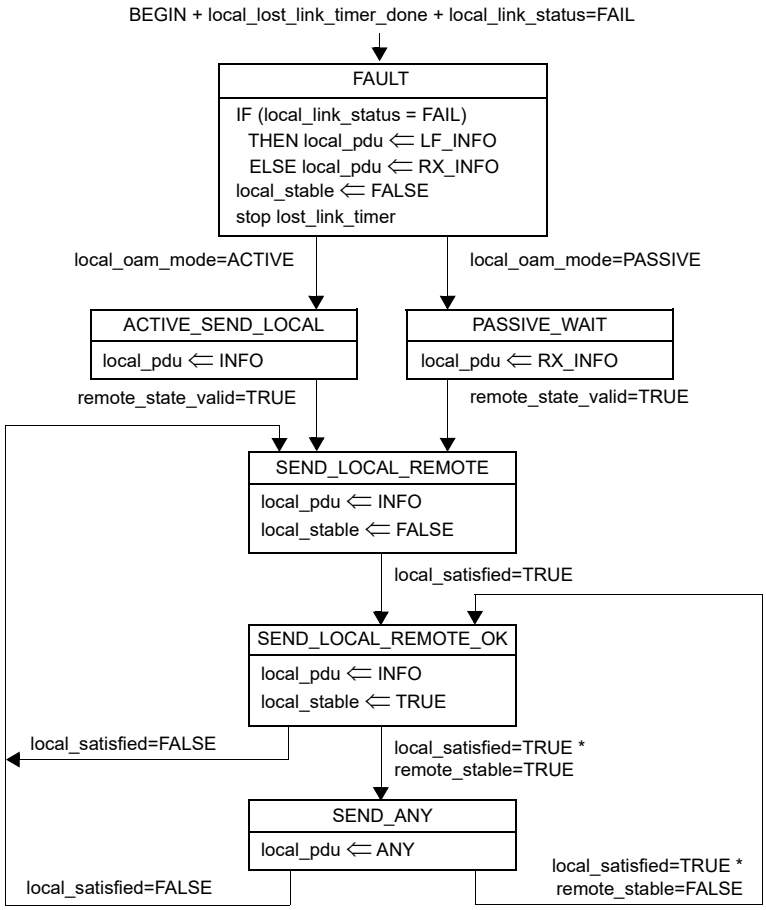

Figure 57–5—OAM Discovery state diagram

In each state, the OAM sublayer sends specified OAMPDUs in a periodic fashion, normally once a second. When local_pdu is set to LF_INFO, the OAM sublayer sends Information OAMPDUs with the Link Fault bit of the Flags field set and without any Information TLVs. When local_pdu is set to RX_INFO, the OAM

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

sublayer does not send any OAMPDUs. When local_pdu is set to INFO, only Information OAMPDUs are sent. When local_pdu is set to ANY, all permissible OAMPDUs may be sent, subject to the restrictions found in Table 57–1.

57.3.2.1.1 FAULT state

Upon entering the FAULT state, local_pdu is set based on the value of local_link_status. If it is set to FAIL, local_pdu is set to LF_INFO, otherwise is it set to RX_INFO. Then, local_stable is set to FALSE and local_lost_link_timer is stopped. While local_link_status is set to FAIL, the DTE will remain in this state indicating to the remote DTE there is link fault. This is accomplished by sending Information OAMPDUs once per second with the Link Fault bit of the Flags field set and no Information TLVs in the Data field. The unidirectional transmission of Information OAMPDUs is supported by some physical coding sublayers (see 57.2.12).

If OAM is reset, disabled, the local_lost_link_timer expires or the local_link_status equals FAIL, the Discovery process returns to the FAULT state.

57.3.2.1.2 ACTIVE_SEND_LOCAL state

Once local_link_status is set to OK, the DTE evaluates local_oam_mode. A DTE configured in Active mode (see 57.2.9.1) sends Information OAMPDUs that only contain the Local Information TLV (see 57.5.2.1). This state is called ACTIVE_SEND_LOCAL. While in this state, the local DTE waits for Information OAMPDUs received from the remote DTE.

57.3.2.1.3 PASSIVE_WAIT state

A DTE configured in Passive mode (see 57.2.9.2) waits until receiving Information OAMPDUs with Local Information TLVs before sending any Information OAMPDUs with Local Information TLVs. This state is called PASSIVE_WAIT. By waiting until first receiving an Information OAMPDU with the Local Information TLV, a Passive DTE cannot complete the OAM Discovery process when connected to another Passive DTE.

57.3.2.1.4 SEND_LOCAL_REMOTE state

Once the local DTE has received an Information OAMPDU with the Local Information TLV from the remote DTE, the local DTE begins sending Information OAMPDUs that contain both the Local and Remote Information TLVs. This state is called SEND_LOCAL_REMOTE. If at any time the settings on either the local or remote DTE change resulting in the local OAM client becoming unsatisfied with the settings, the Discovery process returns to the SEND_LOCAL_REMOTE state.

57.3.2.1.5 SEND_LOCAL_REMOTE_OK state

If the local OAM client deems the settings on both the local and remote DTEs are acceptable, it enters the SEND_LOCAL_REMOTE_OK state. If at any time the settings on the local OAM client change resulting in the remote OAM client becoming unsatisfied with the settings, the OAM Discovery process returns to the SEND_LOCAL_REMOTE_OK state.

57.3.2.1.6 SEND_ANY state

Finally, once an OAMPDU has been received indicating the remote device is satisfied with the respective settings, the local device enters the SEND_ANY state. This is the expected normal operating state for OAM on fully operational links.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.3.2.1.7 Sending Discovery status to peer

The Local Stable and Local Evaluating bits of the Flags field communicate the status of the local Discovery process to the peer. When the OAM Discovery process is started, the local DTE sets the Local Stable to 0 and Local Evaluating bits to 1 indicating OAM Discovery has not completed.

If, after learning of the remote OAM settings, the local OAM client determines it is unsatisfied it sets the Local Stable and Local Evaluating bits to 0 indicating Discovery cannot successfully complete. If the local OAM client is satisfied, the local DTE sets the Local Stable bit to 1 and Local Evaluating bit to 0 indicating the local OAM client is satisfied.

When Local Stable is set to 1 and Local Evaluating is set to 0 and Remote Stable is set to 1 and Remote Evaluating is set to 0 indicating that both OAM clients are satisfied, the OAM Discovery process has successfully completed and local_pdu is set to ANY. See Table 57–3 for more information.

57.3.2.2 Transmit

OAM sublayer entities shall implement the Transmit state diagram shown in Figure 57–6.

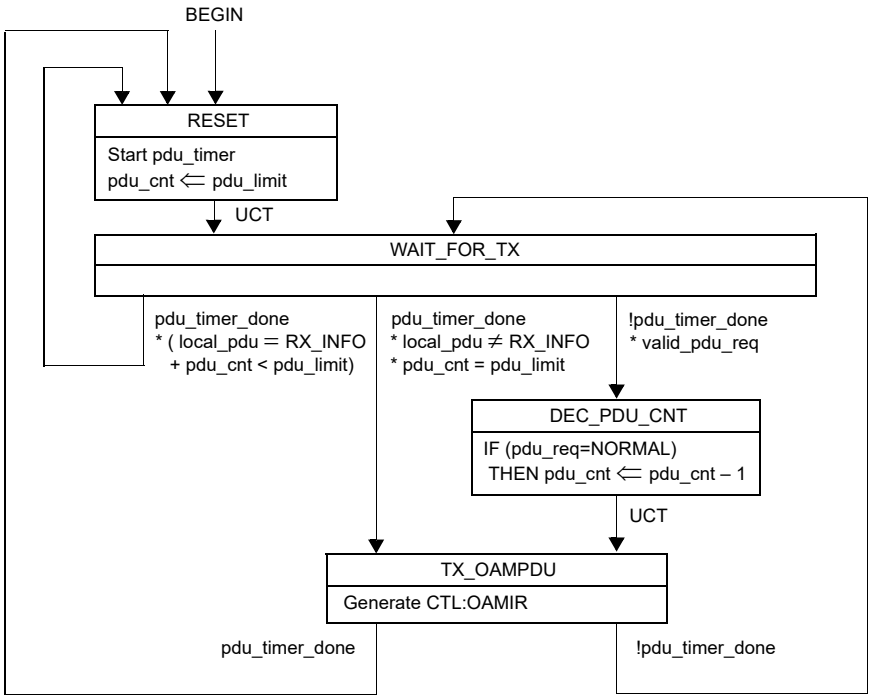

Figure 57–6—Transmit state diagram

57.3.2.2.1 RESET state

Upon initialization, the RESET state is entered. A one second timer is started called pdu_timer. The pdu_cnt variable is reset with a value of ten, the maximum number of OAMPDUs that may be sent in one second. Following RESET, the WAIT_FOR_TX state is entered.

57.3.2.2.2 WAIT_FOR_TX state

While in the WAIT_FOR_TX state, the Transmit process waits for the occurrence of one of three conditions. These three conditions are summarized as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Expiration of pdu_timer:
   1) With one or more OAMPDUs sent within the last second
   2) Without any OAMPDUs being sent within the last second and without a valid pending request to send an OAMPDU
b) Valid request to send an OAMPDU present

57.3.2.2.3 Expiration of pdu_timer

While in the WAIT_FOR_TX state, if the pdu_timer expires and one or more OAMPDUs have been sent within the last second, the Transmit process transitions to the RESET state. If, however, the pdu_timer expires and no OAMPDUs have been sent within the last second and there is no valid request to send an OAMPDU present, the Transmit process transitions to the TX_OAMPDU state sending an Information OAMPDU. This prevents the Discovery process from restarting. If local_pdu is set to LF_INFO, the Transmit process ensures the Information OAMPDU has the Link Fault bit of the Flags field set and has no Information TLVs in the Data field.

If, however, the OAM sublayer entity is configured to not send any OAMPDUs, as indicated by the local_pdu variable set to RX_INFO, the Transmit function will simply restart the pdu_timer by returning to the RESET state.

57.3.2.2.4 Valid request to send an OAMPDU

While in the WAIT_FOR_TX state, if a valid request to send an OAMPDU is present, the Transmit process transmits the requested OAMPDU in the TX_OAMPDU state. If the Flags field of the OAMPDU to be sent does not contain any critical link events, the pdu_cnt variable is decremented in the DEC_PDU_CNT state. A valid request is either one of the following:

a) An OAMPDU.request service primitive from the OAM client with the local_pdu variable set to INFO or ANY and pdu_cnt not equal to zero.
b) An OAM_CTL.request service primitive from the OAM client with one or more critical event parameters set and the local_pdu variable set to ANY. When the local_pdu variable is set to ANY, the Discovery process has completed and is in the SEND_ANY state. The Discovery process needs to complete before critical events, other than Link Fault, may be sent to the peer OAM entity.

57.3.2.2.5 TX_OAMPDU state

The TX_OAMDPU state generates the CTL:OAMI.request service primitive, which requests the transmission of an OAMPDU to the Multiplexer process. After generating the request, the Transmit process returns to the RESET state if the pdu_timer is expired or the WAIT_FOR_TX state if the pdu_timer has not expired.

57.3.2.2.6 Transmit rules

The following rules govern the generation of the CTL:OAMIR service primitive:

a) While local_pdu is set to LF_INFO, only Information OAMPDUs with the Link Fault bit of the Flags field set and without any Information TLVs shall be generated.
b) While local_pdu is set to RX_INFO, CTL:OAMIR service primitives shall not be generated.
c) While local_pdu is set to INFO, only Information OAMPDUs shall be generated.
d) While local_pdu is set to ANY:
   1) An OAM_CTL.request service primitive with one or more of the critical link event parameters set shall generate a CTL:OAMIR service primitive, requesting the transmission of an Information OAMPDU with the appropriate bit(s) of the Flags field set.
   2) An OAMPDU.request service primitive shall generate a CTL:OAMIR service primitive, requesting the transmission of the particular OAMPDU.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.3.2.3 Receive rules

CTL:OAMII service primitives indicate a received OAMPDU and in turn generate an OAMPDU.indication service primitive to the OAM client entity subject to the following rules:

a) When local_pdu is not set to ANY, Information OAMPDUs shall be passed to the OAM client and non-Information OAMPDUs are discarded.
b) When local_pdu is set to ANY, all OAMPDUs, including those with unknown Code fields shall be passed to the OAM client.[109] It is anticipated that the OAM client will ignore unknown or unsupported OAMPDUs.

57.3.3 Multiplexer

OAM sublayer entities shall implement the Multiplexer state diagram shown in Figure 57–7.

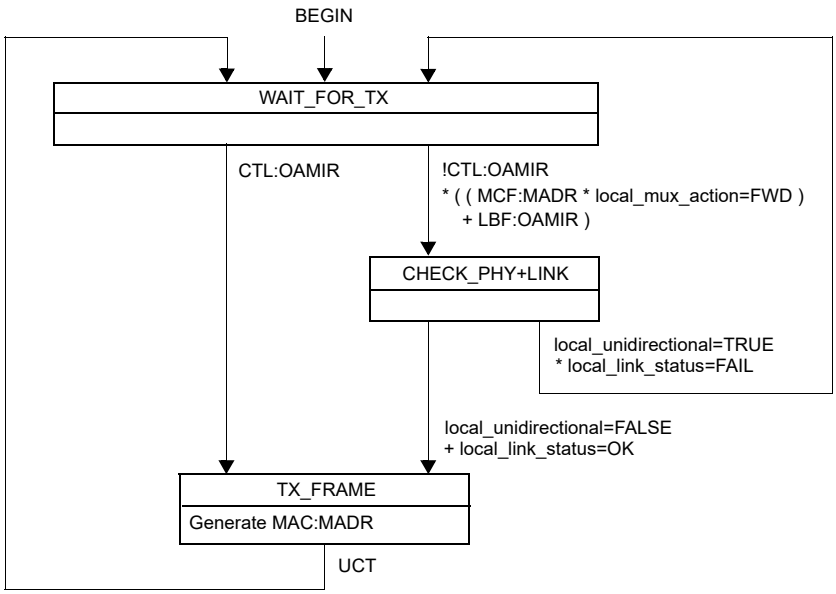

Figure 57–7—Multiplexer state diagram

57.3.3.1 WAIT_FOR_TX state

Upon initialization, the WAIT_FOR_TX state is entered. While in the WAIT_FOR_TX state, the Multiplexer waits for the occurrence of one of two conditions. These two conditions are summarized as follows:

a) Valid request to send an OAMPDU present
b) Valid request to forward a MAC client frame or loopback frame from Parser

57.3.3.1.1 Valid request to send an OAMPDU

While in the WAIT_FOR_TX state, if a request to send an OAMPDU is present, the Multiplexer function transmits the requested OAMPDU in the TX_FRAME state.

[109]The behavior of the OAM sublayer is different in this regard from the behavior of the MAC Control sublayer (see Clause 31 and Clause 64).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.3.3.1.2 Valid request to forward or loopback frame

While in the WAIT_FOR_TX state, if a valid request to forward or loop back a frame is present and no request to send an OAMPDU is present, the Multiplexer will then check the status of the underlying Physical Layer and unidirectional configuration (in the CHECK_PHY+LINK state) and either transmit the frame in the TX_FRAME state or simply return to the WAIT_FOR_TX state.

A valid request to forward a frame from the superior sublayer is indicated by the variable MCF:MADR with the Multiplexer configured to forward frames as indicated by the local_mux_action variable set to FWD. A request to loop back a frame from the Parser function is indicated by the variable LBF:OAMIR. When either request occurs, the local_unidirectional variable needs to be FALSE or the local_link_status variable needs to be OK in order for the frame to be sent to the subordinate sublayer via the TX_FRAME state. Since only Information OAMPDUs with the Link Fault critical link event indication set and no Information TLVs are sent on a unidirectional link, the status of the link is evaluated to ensure the same behavior as devices that do not support the optional Unidirectional OAM capability. When the local_link_status variable is OK, the MAC client frame will be transmitted regardless of the Unidirectional OAM capability or setting (see 57.2.12).

57.3.3.2 TX_FRAME state

Once the Multiplexer process reaches the TX_FRAME state, it shall provide transparent pass-through of frames submitted by the superior sublayer, the Transmit process and the Parser process. The transmission of an OAMPDU shall not affect the transmission of a frame that has been submitted to the subordinate sublayer (i.e., the MAC's TransmitFrame function is synchronous, and is never interrupted). After the frame has been sent to the subordinate sublayer, the Multiplexer process returns to the WAIT_FOR_TX state.

57.3.4 Parser

OAM sublayer entities shall implement the Parser state diagram shown in Figure 57–8.

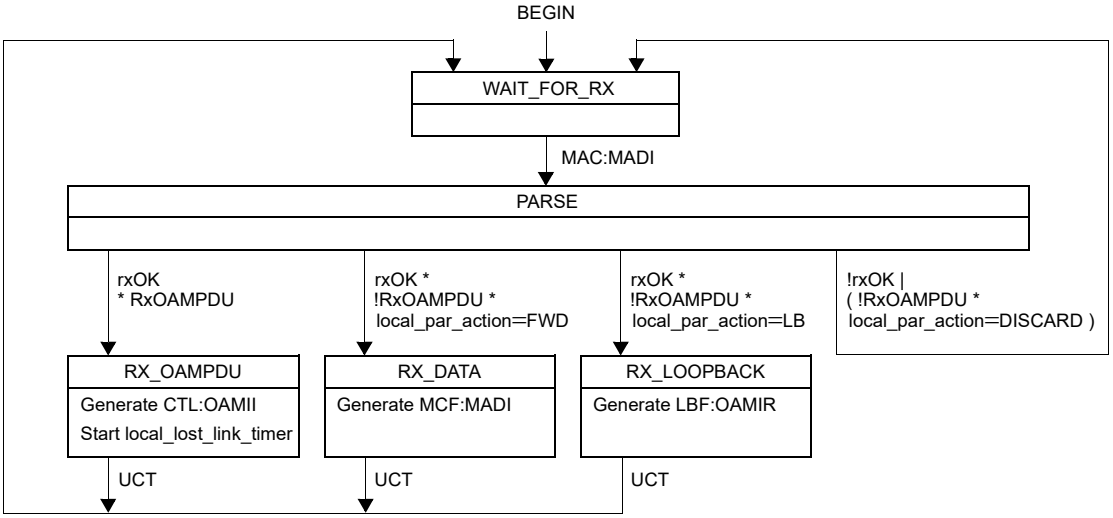

Figure 57–8—Parser state diagram

The Parser decodes frames received from the subordinate sublayer, passes OAMPDUs to the Control function, MAC client frames to the superior sublayer and loopback frames to the Multiplexer function. After reset, the Parser function enters the WAIT_FOR_RX state. The reception of a frame is detected when the MAC:MADI service primitive occurs. When a frame is received, the Parser function enters the PARSE state.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.3.4.1 Reception of OAMPDU

The RX_OAMPDU state is entered when the receive frame is identified as an OAMPDU. Received OAMPDUs are sent to the OAM Control function via the CTL:OAMII service primitive. Following the receive rules in 57.3.2.3, the OAM Control function then passes the received OAMPDU to the OAM client. In addition, the local_lost_link_timer is reset. The Parser function then returns to the WAIT_FOR_RX state.

57.3.4.2 Reception of non-OAMPDUs

Received non-OAMPDUs are handled according to the setting of the local_par_action parameter. Refer to 57.2.11 for a complete description of OAM remote loopback operation and the local_par_action variable.

57.3.4.2.1 Reception of non-OAMPDU in FWD mode

The RX_DATA state is entered if the frame is determined to not be an OAMPDU and the local_par_action variable is set to FWD. The received frame is passed up to the superior sublayer via the MCF:MADI service primitive. The Parser then returns to the WAIT_FOR_RX state.

57.3.4.2.2 Reception of non-OAMPDU in LB mode

The RX_LOOPBACK state is entered if the frame is determined to not be an OAMPDU and the local_par_action parameter is set to LB. The received loopback frame is passed to the Multiplexer function via the LBF:OAMIR service primitive to be looped back to the remote DTE. After the frame is passed to the Multiplexer function, the Parser function returns to the WAIT_FOR_RX state.

57.3.4.2.3 Reception of non-OAMPDU in DISCARD mode

If the local_par_action parameter is set to DISCARD, the Parser function simply returns to the WAIT_FOR_RX state.

57.4 OAMPDUs

57.4.1 Ordering and representation of octets

All OAMPDUs comprise an integral number of octets. When the encoding of (an element of) an OAMPDU is depicted in a diagram:

a) Octets are transmitted from top to bottom.
b) Within an octet, bits are shown with bit 0 to the left and bit 7 to the right.
c) When consecutive octets are used to represent a binary number, the octet transmitted first has the more significant value.
d) When consecutive octets are used to represent a MAC address, the least significant bit of the first octet is assigned the value of the first bit of the MAC address, the next most significant bit the value of the second bit of the MAC address, and so on for all the octets of the MAC address.

When the encoding of an element of an OAMPDU is depicted in a table, the least significant bit is bit 0.

The bit/octet ordering of any Organizationally Unique Identifier (OUI) or Company ID (CID) field within an OAMPDU is identical to the bit/octet ordering of the OUI portion of the DA/SA. Additional detail defining the format of OUIs and CIDs can be found in IEEE Std 802 Overview and Architecture.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.4.2 Structure

The OAMPDU structure shall be as shown in Figure 57–9.

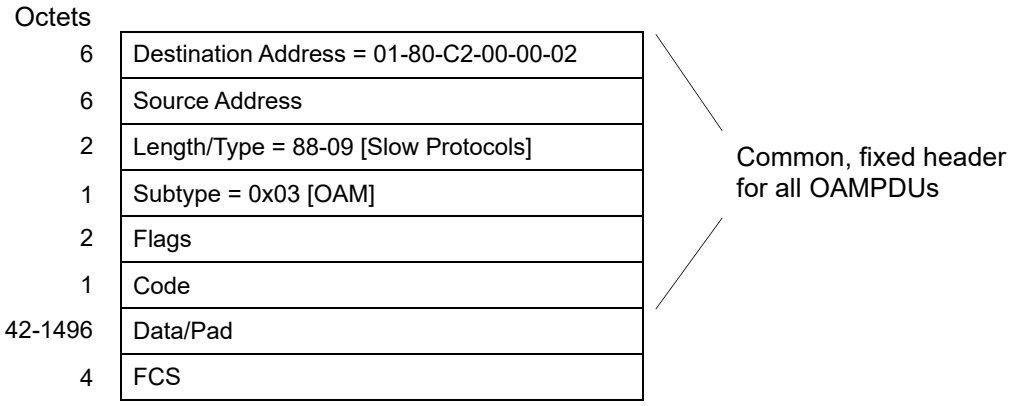

Figure 57–9—OAMPDU frame structure

OAMPDUs shall have the following fields:

a) ***Destination Address*** (DA). The DA in OAMPDUs is the Slow_Protocols_Multicast address. Its use and encoding are specified in Annex 57A.
b) ***Source Address*** (SA). The SA in OAMPDUs carries the individual MAC address associated with the port through which the OAMPDU is transmitted.
c) ***Length/Type***. The Length/Type in OAMPDUs carries the Slow_Protocols_Type field value as specified in 57A.4.
d) ***Subtype***. The Subtype field identifies the specific Slow Protocol being encapsulated. OAMPDUs carry the Subtype value 0x03.
e) ***Flags***. The Flags field contains status bits as defined in 57.4.2.1.
f) ***Code***. The Code field identifies the specific OAMPDU. The use and encoding of this field is specified in Table 57–4.
g) ***Data/Pad***. This field contains the OAMPDU data and any necessary pad. Implementations shall support OAMPDUs at least minFrameSize in length.
h) ***FCS***. This field is the Frame Check Sequence, as defined in Clause 4.

57.4.2.1 Flags field

The Flags field is encoded as individual bits within two octets as shown in Table 57–3. Additional diagnostic information may be sent using the Event Notification OAMPDU.

Table 57–3—Flags field

Bit(s)	Name	Description
15:7	Reserved	Reserved bits shall be set to zero when sending an OAMPDU, and should be ignored on reception for compatibility with future use of reserved bits.
6	Remote Stable	When remote_state_valid is set to TRUE, the Remote Stable and Remote Evaluating values shall be a copy of the last valid received Local Stable and Local Evaluating values from the remote OAM peer. Otherwise, the Remote Stable and Remote Evaluating bits shall be set to 0.
5	Remote Evaluating	

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 57–3—Flags field *(continued)*

Bit(s)	Name	Description
4	Local Stable	Local Stable and Local Evaluating form a two-bit encoding shown below: 4:3 0x0 = Local DTE Unsatisfied, Discovery can not complete 0x1 = Local DTE Discovery process has not completed 0x2 = Local DTE Discovery process has completed 0x3 = Reserved. This value shall not be sent. If the value 0x3 is received, it should be ignored and not change the last received value.
3	Local Evaluating	
2	Critical Event	1 = A critical event has occurred. 0 = A critical event has not occurred.
1	Dying Gasp	1 = An unrecoverable local failure condition has occurred. 0 = An unrecoverable local failure condition has not occurred.
0	Link Fault	The PHY has detected a fault has occurred in the receive direction of the local DTE (e.g., link, Physical Layer). 1 = Local device's receive path has detected a fault. 0 = Local device's receive path has not detected a fault.

NOTE—The definition of the specific faults comprising the Critical Event, Dying Gasp, and Link Fault flags is implementation specific and beyond the scope of this standard.

57.4.2.2 Code field

The value of the Code field is set by the Transmit process in the Control function for Information OAMPDUs it generates. The OAM client sets the Code field for all OAMPDUs it generates. Table 57–4 contains the defined OAMPDU codes.

Table 57–4—OAMPDU codes

Code	OAMPDU	Comment	Source
00	Information	Communicates local and remote OAM information.	OAM client / OAM sublayer
01	Event Notification	Alerts remote DTE of link event(s).	OAM client
02	Variable Request	Requests one or more specific MIB variables.	OAM client
03	Variable Response	Returns one or more specific MIB variables.	OAM client
04	Loopback Control	Enables/disables OAM remote loopback.	OAM client
05-FD	Reserved	Reserved	OAM client
FE	Organization Specific	Organization Specific Extensions, distinguished by Organizationally Unique Identifier.	OAM client
FF	Reserved	Reserved	OAM client

57.4.3 OAMPDU descriptions

The local OAM sublayer communicates with the remote OAM sublayer via OAMPDUs. OAMPDUs are identified with a specific code. OAMPDUs are formatted as compliant IEEE 802.3 frames, where the IEEE 802.3 frame header format is described in Clause 3. OAMPDUs are further defined, as shown in Figure 57–9, to include a Subtype field, a Flags field, and a Code field following the IEEE 802.3 defined Length/Type field. The Data field begins in a fixed location within the OAMPDU. The Data field contents are unique to the particular OAMPDU. The following sections provide a detailed description of each OAMPDU and its corresponding Data field. All received OAMPDUs, including those with reserved Code fields, are passed to the OAM client. OAMPDUs with reserved Code field values shall not be transmitted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.4.3.1 Information OAMPDU

The Information OAMPDU, identified by the Code field 0x00, is used to send OAM state information to the remote DTE. The Information OAMPDU frame structure shall be as depicted in Figure 57–10.

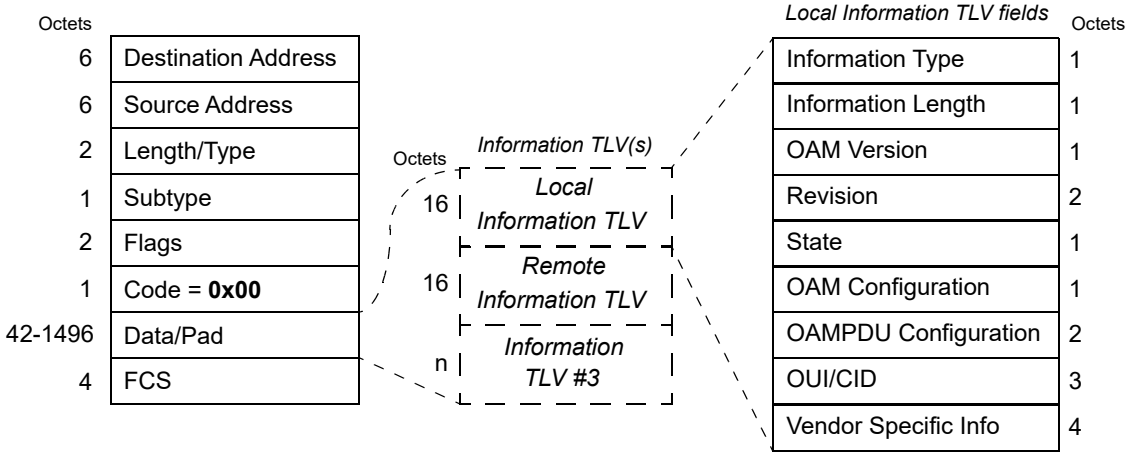

Figure 57–10—Information OAMPDU frame structure

When local_pdu is set to LF_INFO, the Information OAMPDU Data field shall not have any Information TLVs. When local_pdu is not set to LF_INFO, the Information OAMPDU Data field shall consist of the Local Information TLV (see 57.5.2.1) immediately following the Code field. In addition, if the Discovery state diagram variable remote_state_valid is TRUE, the Data field shall also contain the Remote Information TLV (see 57.5.2.2), immediately following the Local Information TLV and may also contain other Information TLVs found in Table 57–6.

57.4.3.2 Event Notification OAMPDU

The optional Event Notification OAMPDU, identified with the Code field set to 0x01, is used to alert the remote DTE of link events introduced in 57.2.10.2. The Event Notification OAMPDU frame structure shall be as depicted in Figure 57–11.

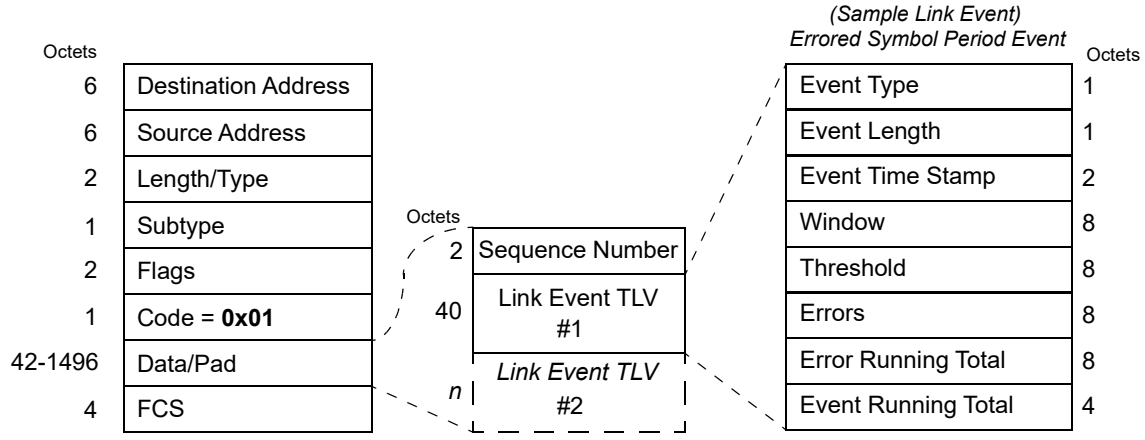

Figure 57–11—Event Notification OAMPDU frame structure

The first two octets of the Data field shall contain a Sequence Number, encoded as a 16-bit unsigned integer. As described in 57.2.3, the OAM client may send duplicate Event Notification OAMPDUs to increase the likelihood the remote DTE receives a particular event. The OAM client increments the Sequence Number

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

for each unique Event Notification OAMPDU formed by the OAM client. A particular Event Notification OAMPDU may be sent multiple times with the same sequence number. It is recommended that any duplicate Event Notification OAMPDUs follow its original without a different, intervening Event Notification OAMPDU. A duplicate Event Notification OAMPDU should not be transmitted if a new Event Notification OAMPDU has already followed the original OAMPDU. Any particular event can be signaled in only one unique Event Notification OAMPDU (though that OAMPDU may be transmitted multiple times). Upon receiving an Event Notification OAMPDU, the OAM client compares the Sequence Number with the last received Sequence Number. If equal, the current event is a duplicate and is ignored by the OAM client.

Following the Sequence Number field, the Data field shall contain one or more optional Link Event TLVs which may provide useful information for troubleshooting events and faults. Link Event TLVs are defined in 57.5.3.

57.4.3.3 Variable Request OAMPDU

The optional Variable Request OAMPDU, identified with a Code field of 0x02, is used to request one or more MIB variables from the remote DTE. The Variable Request OAMPDU frame structure shall be as depicted in Figure 57–12.

The Variable Request OAMPDU Data field shall contain one or more Variable Descriptors. Variable Descriptors are defined in 57.6.1.

The Variable Request OAMPDU Data field may contain one or more Variable Containers, to determine the scope of subsequent Variable Descriptors, as described in 57.6.2.

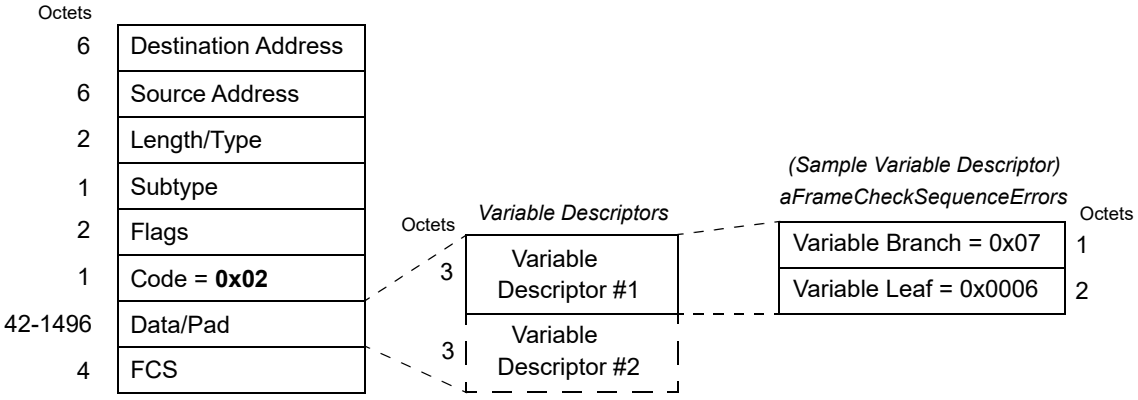

Figure 57–12—Variable Request OAMPDU frame structure

57.4.3.4 Variable Response OAMPDU

The optional Variable Response OAMPDU, identified with the Code field of 0x03, is used to return one or more MIB variables. The Variable Response OAMPDU frame structure shall be as depicted in Figure 57–13.

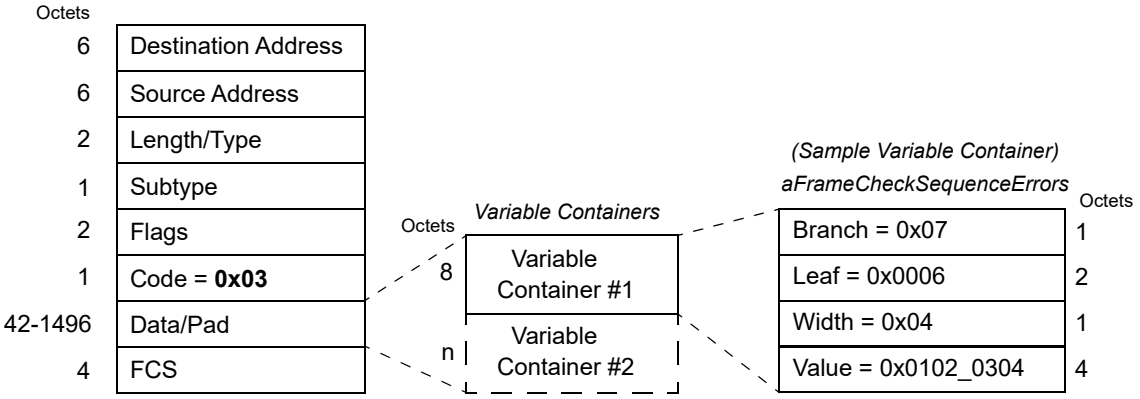

Figure 57–13—Variable Response OAMPDU frame structure

The Variable Response OAMPDU Data field shall contain one or more Variable Containers. Variable Containers are defined in 57.6.2. A Variable Response OAMPDU needs to be sent by the OAM client within one second of receipt of a Variable Request OAMPDU. If a DTE is unable to retrieve one or more variables, it needs to respond within one second and indicate the appropriate error(s) as found in Table 57–17. If a DTE is unable to retrieve one or more attributes within a package or object, it needs to either a) return the appropriate Variable Indication for the particular attribute(s) and return all other requested variables or b) return a Variable Indication for the entire package or object.

57.4.3.5 Loopback Control OAMPDU

The optional Loopback Control OAMPDU, identified with the Code field set to 0x04, is used to control the remote DTE's OAM remote loopback state. The Loopback Control OAMPDU frame structure shall be as depicted in Figure 57–14.

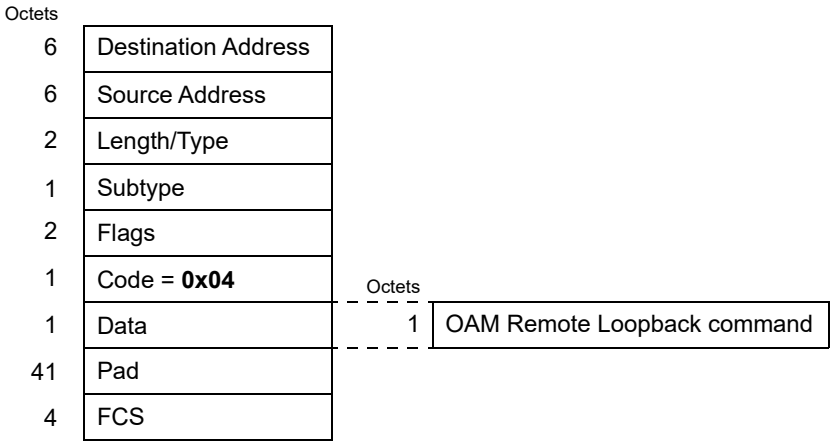

Figure 57–14—Loopback Control OAMPDU frame structure

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Loopback Control OAMPDU Data field shall consist of an OAM remote loopback command. Table 57–5 lists the defined OAM remote loopback commands.

Table 57–5—OAM remote loopback commands

Command	Description
0x00	Reserved — shall not be transmitted, should be ignored on reception by OAM client
0x01	Enable OAM Remote Loopback
0x02	Disable OAM Remote Loopback
0x03–0xFF	Reserved — shall not be transmitted, should be ignored on reception by OAM client

For a complete description of OAM remote loopback refer to 57.2.11.

57.4.3.6 Organization Specific OAMPDU

The optional Organization Specific OAMPDU, identified with the Code field set to 0xFE, is used for organization specific extensions. The Organization Specific OAMPDU frame structure shall be as depicted in Figure 57–15.

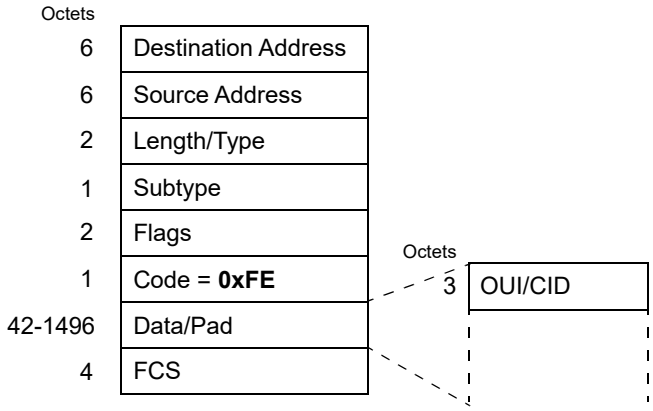

Figure 57–15—Organization Specific OAMPDU frame structure

The first three octets of the Organization Specific OAMPDU Data field shall contain the Organizationally Unique Identifier (OUI) or Company ID (CID).[110] The format and function of the rest of the Organization Specific OAMPDU Data field is dependent on OUI or CID value and is beyond the scope of this standard.

57.5 OAM TLVs

57.5.1 Parsing

The OAM client parses OAM TLVs. All OAM TLVs contain a single octet Type field and a single octet Length field. The Length field encompasses the entire TLV including the Type and Length fields. TLV processing should follow these recommendations:

a) Detection of a TLV type 0x00 should indicate there are no more TLVs to process (the length and value of the Type 0x00 TLV can be ignored).
b) TLVs with lengths 0x00 or 0x01 should be considered invalid, and the OAMPDU should be considered to have no more TLVs.
c) TLVs with unknown or unexpected types should be ignored.

[110]Interested applicants should contact the IEEE Standards Department, Institute of Electrical and Electronics Engineers, 445 Hoes Lane, Piscataway, NJ 08854, USA, https://standards.ieee.org/regauth/index.html.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) If the length of a TLV is less than that defined for the Type, that TLV should be ignored and the rest of the frame may be ignored. If the length of a TLV is greater than that defined for the Type, the expected fields of the TLV should be processed, and the remainder of the frame after the TLV should also be processed.
e) If a TLV length indicates that the TLV extends beyond the frame (e.g., the length cannot fit into the frame given its length and starting point), then the TLV should be ignored.

57.5.2 Information TLVs

This subclause contains the definitions for Information TLVs. Information TLVs are found in Information OAMPDUs. Table 57–6 contains the defined Information TLVs.

Table 57–6—Information TLV types

Type	Description
0x00	*End of TLV marker*
0x01	Local Information
0x02	Remote Information
0x03–0xFD	Reserved—shall not be transmitted, should be ignored on reception by OAM client
0xFE	Organization Specific Information
0xFF	Reserved—shall not be transmitted, should be ignored on reception by OAM client

The following subclauses describe the defined Information TLVs.

57.5.2.1 Local Information TLV

The Local Information TLV shall have the following fields:

a) ***Information Type*** = *Local Information*. This one-octet field indicates the nature of the data carried in this TLV-tuple. The encoding of this field is found in Table 57–6.
b) ***Information Length***. The one-octet field indicates the length (in octets) of this TLV-tuple. Local Information TLV uses a length value of 16 (0x10).
c) ***OAM Version***. This one-octet field indicates the version supported by the DTE. This field shall contain the value 0x01 to claim compliance with Version 1 of this protocol.
d) ***Revision.*** This two-octet field indicates the current revision of the Information TLV. The value of this field shall start at zero and be incremented each time something in the Information TLV changes. Upon reception of an Information TLV from a peer, an OAM client may use this field to decide if it needs to be processed (an Information TLV that is identical to the previous Information TLV does not need to be parsed as nothing in it has changed).
e) ***State***. This one-octet field contains OAM state information and shall be as shown in Table 57–7.
f) ***OAM Configuration***. This one-octet field contains OAM configuration variables and shall be as shown in Table 57–8.
g) ***OAMPDU Configuration***. This two-octet field contains OAMPDU configuration variables and shall be as shown in Table 57–9 and encoded as specified in 57.4.1 c).
h) ***OUI/CID***. This three-octet field contains the 24-bit Organizationally Unique Identifier or Company ID and shall be as shown in Table 57–10.
i) ***Vendor Specific Information***. This four-octet field contains the Vendor Specific Information field and shall be as shown in Table 57–11.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 57–7—State field

Bit(s)	Name	Description
7:3	Reserved	In Local Information TLVs, reserved bits shall be set to zero when sending an OAMPDU, and should be ignored on reception for compatibility with future use of reserved bits.
2	Multiplexer Action	0 = Device is forwarding non-OAMPDUs to the lower sublayer (local_mux_action = FWD). 1 = Device is discarding non-OAMPDUs (local_mux_action = DISCARD).
1:0	Parser Action	00 = Device is forwarding non-OAMPDUs to higher sublayer (local_par_action = FWD). 01 = Device is looping back non-OAMPDUs to the lower sublayer (local_par_action = LB). 10 = Device is discarding non-OAMPDUs (local_par_action = DISCARD). 11 = Reserved. In Local Information TLVs, this value shall not be sent. If the value 11 is received, it should be ignored and not change the last received value.

Table 57–8—OAM Configuration field

Bit(s)	Name	Description
7:5	Reserved	In Local Information TLVs, reserved bits shall be set to zero when sending an OAMPDU, and should be ignored on reception for compatibility with future use of reserved bits.
4	Variable Retrieval	1 = DTE supports sending Variable Response OAMPDUs. 0 = DTE does not support sending Variable Response OAMPDUs.
3	Link Events	1 = DTE supports interpreting Link Events. 0 = DTE does not support interpreting Link Events.
2	OAM Remote Loopback Support	1 = DTE is capable of OAM remote loopback mode. 0 = DTE is not capable of OAM remote loopback mode.
1	Unidirectional Support	1 = DTE is capable of sending OAMPDUs when the receive path is non-operational. 0 = DTE is not capable of sending OAMPDUs when the receive path is non-operational.
0	OAM Mode	1 = DTE configured in Active mode. 0 = DTE configured in Passive mode.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 57–9—OAMPDU Configuration field

Bit(s)	Name	Description
15:11	Reserved	In Local Information TLVs, reserved bits shall be set to zero when sending an OAMPDU, and should be ignored on reception for compatibility with future use of reserved bits.
10:0	Maximum OAMPDU Size	11-bit field which represents the largest OAMPDU, in octets, supported by the DTE. This value is compared to the remote's Maximum OAMPDU Size and the smaller of the two is used. The minimum value of this field is minFrameSize / 8. The maximum value of this field is equal to maxBasicFrameSize, which is defined in 4.4.2. Prior to exchanging Maximum OAMPDU Size and agreeing upon a maximum OAMPDU size, a DTE sends OAMPDUs of length minFrameSize / 8. The OAMPDUs transmitted by a DTE are limited by both the local DTE's Maximum OAMPDU Size and the remote DTE's Maximum OAMPDU Size as indicated in received Information OAMPDUs. A DTE is not required to change the value transmitted in this field after negotiation to an agreed size as each end will dynamically determine the correct maximum OAMPDU size to use.

Table 57–10—OUI/CID field

Bit(s)	Name	Description
23:0	OUI/CID[a]	24-bit Organizationally Unique Identifier or Company ID of the vendor.

[a]Organizations that have previously received OUIs or CIDs from the IEEE Registration Authority should use one of their allocated OUIs or CIDs consistently in this field.

Table 57–11—Vendor Specific Information field

Bit(s)	Name	Description
31:0	Vendor Specific Information	32-bit identifier that may be used to differentiate a vendor's product models/versions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.5.2.2 Remote Information TLV

The Remote Information TLV shall be a copy of the last received Local Information TLV from the remote OAM peer, with the exception of the Information Type field. The encoding of this field is found in Table 57–6.

57.5.2.3 Organization Specific Information TLV

The Organization Specific Information TLV shall have the following fields:

a) ***Information Type*** = *Organization Specific Information*. This one-octet field indicates the nature of the data carried in this TLV-tuple. The encoding of this field is found in Table 57–6.
b) ***Information Length*****.** This one-octet field indicates the length (in octets) of this TLV-tuple. The length of an Organization Specific Information TLV is unspecified.
c) ***Organizationally Unique Identifier or Company ID.*** This three-octet field shall contain the 24-bit Organizationally Unique Identifier (OUI) or Company ID (CID).
d) ***Organization Specific Value*****.** This field indicates the value of the Organization Specific Information TLV. This field's length and contents are unspecified.

57.5.3 Link Event TLVs

This subclause contains the definitions for Link Event TLVs. Link Event TLVs are found in Event Notification OAMPDUs. Table 57–12 contains the defined Link Event TLVs.

Table 57–12—Link Event TLV type value

Type	Description
0x00	*End of TLV marker*
0x01	Errored Symbol Period Event
0x02	Errored Frame Event
0x03	Errored Frame Period Event
0x04	Errored Frame Seconds Summary Event
0x05–0xFD	Reserved—shall not be transmitted, should be ignored on reception by OAM client
0xFE	Organization Specific Event
0xFF	Reserved—shall not be transmitted, should be ignored on reception by OAM client

The following subclauses describe the defined Link Event TLVs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.5.3.1 Errored Symbol Period Event TLV

The Errored Symbol Period Event TLV counts the number of symbol errors that occurred during the specified period. The period is specified by the number of symbols that can be received in a time interval on the underlying Physical Layer. This event is generated if the symbol error count is equal to or greater than the specified threshold for that period.

The Errored Symbol Period Event TLV shall have the following fields:

a) ***Event Type*** = *Errored Symbol Period Event*. This one-octet field indicates the nature of the information carried in this TLV-tuple. The encoding of this field is found in Table 57–12.

b) ***Event Length*****.** This one-octet field indicates the length (in octets) of this TLV-tuple. Errored Symbol Period Event uses a length value of 40 (0x28).

c) ***Event Time Stamp.*** This two-octet field indicates the time reference when the event was generated, in terms of 100 ms intervals, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.35. When received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.42.

d) ***Errored Symbol Window*****.** This eight-octet field indicates the number of symbols in the period, encoded as a 64-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.35. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.42.
   1) The default value is the number of symbols in one second for the underlying Physical Layer.
   2) The lower bound is the number of symbols in one second for the underlying Physical Layer.
   3) The upper bound is the number of symbols in one minute for the underlying Physical Layer.

e) ***Errored Symbol Threshold*****.** This eight-octet field indicates the number of errored symbols in the period is required to be equal to or greater than in order for the event to be generated, encoded as a 64-bit unsigned integer. When generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.35. When received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.42.
   1) The default value is one symbol error.
   2) The lower bound is zero symbol errors.
   3) The upper bound is unspecified.

f) ***Errored Symbols*****.** This eight-octet field indicates the number of symbol errors in the period, encoded as a 64-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.35. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.42.

g) ***Error Running Total*****.** This eight-octet field indicates the sum of symbol errors since the OAM sublayer was reset. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.35. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.42.

h) ***Event Running Total*****.** This four-octet field indicates the number of Errored Symbol Period Event TLVs that have been generated since the OAM sublayer was reset, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.35. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.42.

This event is generated at the end of the event window rather than when the threshold is crossed.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.5.3.2 Errored Frame Event TLV

The Errored Frame Event TLV counts the number of errored frames detected during the specified period. The period is specified by a time interval. This event is generated if the errored frame count is equal to or greater than the specified threshold for that period. Errored frames are frames that had transmission errors as detected at the Media Access Control sublayer as communicated via the reception_status parameter of the MA_DATA.indication service primitive. Refer to 4.2.9 for the definition of detectable transmission errors during reception.

The Errored Frame Event TLV shall have the following fields:

a) ***Event Type*** = *Errored Frame Event*. This one-octet field indicates the nature of the information carried in this TLV-tuple. The encoding of this field is found in Table 57–12.
b) ***Event Length*****.** This one-octet field indicates the length (in octets) of this TLV-tuple. Errored Frame Event uses a length value of 26 (0x1A).
c) ***Event Time Stamp.*** This two-octet field indicates the time reference when the event was generated, in terms of 100 ms intervals, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.37. When received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.43.
d) ***Errored Frame Window*****.** This two-octet field indicates the duration of the period in terms of 100 ms intervals, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.37. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.43.
    1) The default value is one second.
    2) The lower bound is one second.
    3) The upper bound is one minute.
e) ***Errored Frame Threshold*****.** This four-octet field indicates the number of detected errored frames in the period is required to be equal to or greater than in order for the event to be generated, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.37. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.43.
    1) The default value is one frame error.
    2) The lower bound is zero frame errors.
    3) The upper bound is unspecified.
f) ***Errored Frames*****.** This four-octet field indicates the number of detected errored frames in the period, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.37. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.43.
g) ***Error Running Total*****.** This eight-octet field indicates the sum of errored frames that have been detected since the OAM sublayer was reset. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.37. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.43.
h) ***Event Running Total*****.** This four-octet field indicates the number of Errored Frame Event TLVs that have been generated since the OAM sublayer was reset, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.37. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.43.

This event is generated at the end of the event window rather than when the threshold is crossed.

57.5.3.3 Errored Frame Period Event TLV

The Errored Frame Period Event TLV counts the number of errored frames detected during the specified period. The period is specified by a number of received frames. This event is generated if the errored frame count is greater than or equal to the specified threshold for that period (for example, if the errored frame count is greater than or equal to 10 for the last 1 000 000 frames received). Errored frames are frames that had transmission errors as detected at the Media Access Control sublayer as communicated via the reception_status parameter of the MA_DATA.indication service primitive. Refer to 4.2.9 for the definition of detectable transmission errors during reception.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Errored Frame Period Event TLV shall have the following fields:

a) ***Event Type*** = *Errored Frame Period Event*. This one-octet field indicates the nature of the information carried in this TLV-tuple. The encoding of this field is found in Table 57–12.
b) ***Event Length*****.** This one-octet field indicates the length (in octets) of this TLV-tuple. Errored Frame Period Event uses a length value of 28 (0x1C).
c) ***Event Time Stamp.*** This two-octet field indicates the time reference when the event was generated, in terms of 100 ms intervals, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.39. When received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.44.
d) ***Errored Frame Window*****.** This four-octet field indicates the duration of period in terms of frames, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.39. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.44.
    1) The default value is the number of minFrameSize frames that can be received in one second on the underlying Physical Layer.
    2) The lower bound is the number of minFrameSize frames that can be received in 100 ms on the underlying Physical Layer.
    3) The upper bound is the number of minFrameSize frames that can be received in one minute on the underlying Physical Layer.
e) ***Errored Frame Threshold*****.** This four-octet field indicates the number of errored frames in the period is required to be equal to or greater than in order for the event to be generated, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.39. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.44.
    1) The default value is one frame error.
    2) The lower bound is zero frame errors.
    3) The upper bound is unspecified.
f) ***Errored Frames*****.** This four-octet field indicates the number of frame errors in the period, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.39. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.44.
g) ***Error Running Total*****.** This eight-octet field indicates the sum of frame errors that have been detected since the OAM sublayer was reset. When this event is generated by the local DTE and if Clause 30 is present, this maps to 330.3.6.1.39. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.44.
h) ***Event Running Total*****.** This four-octet field indicates the number of Errored Frame Period Event TLVs that have been generated since the OAM sublayer was reset, encoded as a 32-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.39. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.44.

This event is generated at the end of the event window rather than when the threshold is crossed.

57.5.3.4 Errored Frame Seconds Summary Event TLV

The Errored Frame Seconds Summary Event TLV counts the number of errored frame seconds that occurred during the specified period. The period is specified by a time interval. This event is generated if the number of errored frame seconds is equal to or greater than the specified threshold for that period. An errored frame second is a one second interval wherein at least one frame error was detected. Errored frames are frames that had transmission errors as detected at the Media Access Control sublayer and communicated via the reception_status parameter of the MA_DATA.indication service primitive. Refer to 4.2.9 for the definition of detectable transmission errors during reception.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Errored Frame Seconds Summary Event TLV shall have the following fields:

a) ***Event Type*** = *Errored Frame Seconds Summary Event*. This one-octet field indicates the nature of the information carried in this TLV-tuple. The encoding of this field is found in Table 57–12.
b) ***Event Length*****.** This one-octet field indicates the length (in octets) of this TLV-tuple. Errored Frame Seconds Summary Event uses a length value of 18 (0x12).
c) ***Event Time Stamp.*** This two-octet field indicates the time reference when the event was generated, in terms of 100 ms intervals, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.41. When received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.45.
d) ***Errored Frame Seconds Summary Window*****.** This two-octet field indicates the duration of the period in terms of 100 ms intervals, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.41. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.45.
    1) The default value is 60 seconds.
    2) The lower bound is 10 seconds.
    3) The upper bound is 900 seconds.
e) ***Errored Frame Seconds Summary Threshold*****.** This two-octet field indicates the number of errored frame seconds in the period is required to be equal to or greater than in order for the event to be generated, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.41. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.45.
    1) The default value is one errored second.
    2) The lower bound is zero errored seconds.
    3) The upper bound is unspecified.
f) ***Errored Frame Seconds Summary*****.** This two-octet field indicates the number of errored frame seconds in the period, encoded as a 16-bit unsigned integer. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.41. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.45.
g) ***Error Running Total*****.** This four-octet field indicates the sum of errored frame seconds that have been detected since the OAM sublayer was reset. When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.41. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.45.
h) ***Event Running Total*****.** This four-octet field indicates the number of Errored Frame Seconds Summary Event TLVs that have been generated since the OAM sublayer was reset, encoded as a 32-bit unsigned integer.When this event is generated by the local DTE and if Clause 30 is present, this maps to 30.3.6.1.41. When this event is received from the remote DTE and if Clause 30 is present, this maps to 30.3.6.1.45.

This event is generated at the end of the event window rather than when the threshold is crossed.

57.5.3.5 Organization Specific Event TLVs

The optional Organization Specific Event TLV may be used by organizations to define extensions to the Event mechanisms in this clause. Organization Specific Event TLVs shall have the following fields:

a) ***Event Type*** = *Organization Specific Event*. This one-octet field indicates the nature of the information carried in this TLV-tuple. The encoding of this field is found in Table 57–12.
b) ***Event Length*****.** This one-octet field indicates the length (in octets) of this TLV-tuple. The length of the Organization Specific Event is unspecified.
c) ***Organizationally Unique Identifier.*** This three-octet field shall contain a 24-bit Organizationally Unique Identifier.
d) ***Organization Specific Value*****.** This field indicates the value of the Organization Specific Event. This field's length and contents are unspecified.

57.6 Variables

MIB variables are queried through the use of Variable Request OAMPDUs and returned through the use of Variable Response OAMPDUs. Variable Request OAMPDUs, defined in 57.4.3.3, use data structures called Variable Descriptors (see 57.6.1). An OAM client may request one or more variables in each Variable Request OAMPDU.

Variable Response OAMPDUs, defined in 57.4.3.4, use data structures called Variable Containers (see 57.6.2). Each returned Variable Container resides within a single Variable Response OAMPDU. If a Variable Container does not fit within a Variable Response OAMPDU, an error code is returned. In returning requested variables, an OAM client generates at least one and perhaps additional Variable Response OAMPDUs per received Variable Request OAMPDU. The following subclauses describe the format of Variable Descriptors and Variable Containers.

See 57.6.3 for a description of the parsing rules for Variable Descriptors and Variable Containers.

57.6.1 Variable Descriptors

A Variable Descriptor is used to request MIB attributes, objects and packages and uses the encodings found in Annex B of IEEE Std 802.3.1. The Variable Descriptor structure shall be as shown in Table 57–13.

Table 57–13—Variable Descriptor format

Octet(s)	Name	Description
1	Variable Branch	As defined in Annex B of IEEE Std 802.3.1, Variable Branches may reference attributes, objects or packages. If an object or package is referenced, only the attributes within the object or package shall be found within the Variable Container. Actions shall not be found within Variable Containers.
2	Variable Leaf	The Variable Leaf field is derived from the encodings found in Annex B of IEEE Std 802.3.1.

57.6.2 Variable Containers

Variable Containers are used to return MIB attributes, objects and packages. One or more Variable Containers may exist in the Data field of a Variable Response OAMPDU (see 57.4.3.4).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

57.6.2.1 Format of Variable Containers when returning attributes

The Variable Container structure for an attribute shall be as shown in Table 57–14.

Table 57–14—Variable Container format when returning an attribute

Octet(s)	Name	Description
1	Variable Branch	Derived from the encodings found in Annex B of IEEE Std 802.3.1, Variable Branches may reference attributes, objects or packages. If an object or package is referenced, only the attributes within the object or package shall be found within the Variable Container. Actions shall not be found within Variable Containers.
2	Variable Leaf	The Variable Leaf field is derived from the encodings found in Annex B of IEEE Std 802.3.1.
1	Variable Width	When bit 7 = 1, bits 6:0 represent a Variable Indication. Refer to Table 57–17 for the encoding of bits 6:0. There is no Variable Value field when bit 7 = 1. When bit 7 = 0, bits 6:0 represent the length of the Variable Value field in octets. An encoding of 0x00 equals 128 octets. All other encodings represent actual lengths.
varies	Variable Value	The Variable Value field may be 1 to 128 octets in length. Its width is determined by the Variable Width field.

The first field is the one-octet Variable Branch field. The second field is the two-octet Variable Leaf field. See Table 57–16 for examples of Variable Branch and Variable Leaves. The third field is the dual purpose one-octet Variable Width field. This field either contains the actual width of the attribute or a Variable Indication providing information as to the reason this particular attribute could not be returned. See Table 57–17 for the defined Variable Indications. If the Variable Width field contains a width value, the fourth field is the Variable Value field, which contains the attribute. This field may be up to 128 octets in length. Octets of the attribute are ordered most significant first, followed by each successive octet. If the Variable Width field contains a Variable Indication, the Variable Value field does not exist.

Additionally, a special Variable Container with Variable Branch and Leaf values corresponding to an object identification number (such as 7/330 for a PME ID, or 7/282 for an EPON LLID), Variable Width equal to 2, and Variable Value equal to a 2-octet identification number, may be used in a Variable Request OAMPDU to select a particular instance of a managed object of which multiple instances exist in the remote MIB.

The Variable Value identifies which instance is being addressed. Subsequent Variable Descriptors shall be understood to target the attributes of the selected instance until an other instance selector is received or the Variable Request OAMPDU ends. Each instance selector shall be acknowledged with a Variable Container indicating the same Branch/Leaf and the identifier that was selected, preceding the concerned variables. If no explicit instance selection has taken place, all instances of the concerned object are addressed. In this case, each subsequent Variable Descriptor shall be understood to consecutively target the attributes of all existing instances until an instance selector is received or the Variable Request OAMPDU ends.

The Variable Containers returned by the far-end OAM client may be transmitted in one or more OAMPDUs, respecting the OAMPDU size limitations.

NOTE—In the case of PME Aggregation, each PME is identified by a bit position in a 32-bit string during the Handshake process. This position should be transformed into a number between 0 and 31 before transmission in the Variable Value field.

57.6.2.2 Format of Variable Containers when returning packages and objects

The Variable Container structure for packages and objects shall be as shown in Table 57–15.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 57–15—Variable Container format when returning packages and objects

Octet(s)	Name	Description
1	Variable Branch	Derived from the encodings found in Annex B of IEEE Std 802.3.1, Variable Branches may reference attributes, objects or packages. If an object or package is referenced, only the attributes within the object or package shall be found within the Variable Container. Actions shall not be found within Variable Containers.
2	Variable Leaf	The Variable Leaf field is derived from the encodings found in Annex B of IEEE Std 802.3.1.
1	Variable Width	When bit 7 = 1, bits 6:0 represent a Variable Indication. Refer to Table 57–17 for the encoding of bits 6:0. There is no Variable Value field when bit 7 = 1. When bit 7 = 0, bits 6:0 represent the length of the Variable Value field in octets. An encoding of 0x00 equals 128 octets. All other encodings represent actual lengths.
varies	Variable Value	The Variable Value field may be 1 to 128 octets in length. Its width is determined by the Variable Width field.

A package is defined as a set of MIB attributes and/or actions. An object is a set of packages, which in turn are made up of MIB attributes and/or actions. Variable Containers provide an efficient method for returning packages and objects. Objects are returned in the order they are listed in Annex B of IEEE Std 802.3.1.

The Variable Container structure for packages and objects is similar to the structure for attributes. The first field is the one-octet Variable Branch field for the specific package or object being returned. The second field is the two-octet Variable Leaf field for the specific package or object being returned. See Table 57–16 for examples of Variable Branch and Variable Leaves. The third field is the dual purpose one-octet Variable Width field of the first attribute within the package or object being returned. This field either contains the actual width of the attribute or a Variable Indication providing information as to the reason this particular attribute could not be returned. See Table 57–17 for the defined Variable Indications. If the Variable Width field contains a width value, the fourth field is the Variable Value field, which contains the first attribute of the package or object being returned. This field may be up to 128 octets in length. Octets of the attribute are ordered most significant first, followed by each successive octet. If the Variable Width field contains a Variable Indication, the Variable Value field does not exist.

For each successive attribute within the package, the third field (Variable Width) and fourth field (Variable Value), if applicable, are repeated.

For each successive attribute within each successive package of the object, the third field (Variable Width) and fourth field (Variable Value), if applicable, are repeated.

57.6.3 Parsing

The OAM client parses Variable Descriptors and Variable Containers. All Variable Descriptors/Containers contain a one-octet Variable Branch field and a two-octet Variable Leaf field. Variable Descriptor/Container processing should follow these recommendations:

a) Detection of a Variable Branch field equal to 0x00 should indicate there are no more Variable Descriptors/Containers to process (subsequent fields can be ignored).
b) Variable Branch or Variable Leaf fields with unknown or unexpected values should be ignored.
c) If a Variable Width field indicates Variable Container extends beyond the frame (e.g., the length cannot fit into the frame given its length and starting point), then the Variable Container should be ignored.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) Detection of a Variable Indication value equal to 0x40 should indicate there are no more attributes within the object to process.
e) Detection of a Variable Indication value equal to 0x60 should indicate there are no more objects within the package to process.
f) Detection of a Variable Container in a Variable Request OAMPDU indicates that subsequent Variable Descriptors shall be applied to the instance of the managed object corresponding to the identification number expressed in the Variable Value field of the Variable Container. In the corresponding Variable Response OAMPDU, a Variable Container indicating the selected instance shall immediately precede the Variable Containers pertaining to objects of which a particular instance was selected.

57.6.4 Variable Branch/Leaf examples

Table 57–16 contains a set of example branch and leaf values for attributes, packages and objects.

Table 57–16—Variable Branch/Leaf examples

Variable Type	Variable Name	Variable	
		Branch	Leaf
attribute	aFramesTransmittedOK	0x07	0x0002
attribute	aFramesReceivedOK	0x07	0x0005
package	pMandatory	0x04	0x0001
package	pRecommended	0x04	0x0002
object	oMACEntity	0x03	0x0001
object	oPHYEntity	0x03	0x0002

57.6.5 Variable Indications

If a DTE is unable to retrieve one or more variables, the Variable Container is used to return the appropriate Variable Indication for the particular variable(s). The Variable Indications are defined in Table 57–17.

Table 57–17—Variable indications

Coding	Indication
0x00	Reserved - shall not be transmitted, should be ignored on reception by OAM client.
0x01	Length of requested Variable Container(s) exceeded OAMPDU data field.
0x02 to 0x1F	Reserved—shall not be transmitted, should be ignored on reception by OAM client.
Attribute Indications	
0x20	Requested attribute was unable to be returned due to an undetermined error.
0x21	Requested attribute was unable to be returned because it is not supported by the local DTE.
0x22	Requested attribute may have been corrupted due to reset.
0x23	Requested attribute unable to be returned due to a hardware failure.
0x24	Requested attribute experienced an overflow error.
0x25 to 0x3F	Reserved—shall not be transmitted, should be ignored on reception by OAM client.
Object Indications	
0x40	End of object indication.

Table 57–17—Variable indications *(continued)*

Coding	Indication
0x41	Requested object was unable to be returned due to an undetermined error.
0x42	Requested object was unable to be returned because it is not supported by the local DTE.
0x43	Requested object may have been corrupted due to reset.
0x44	Requested object unable to be returned due to a hardware failure.
0x45 to 0x5F	Reserved—shall not be transmitted, should be ignored on reception by OAM client.
Package Indications	
0x60	End of package indication.
0x61	Requested package was unable to be returned due to an undetermined error.
0x62	Requested package was unable to be returned because it is not supported by the local DTE.
0x63	Requested package may have been corrupted due to reset.
0x64	Requested package unable to be returned due to a hardware failure.
0x65 to 0x7F	Reserved—shall not be transmitted, should be ignored on reception by OAM client.

57.7 Protocol implementation conformance statement (PICS) proforma for Clause 57, Operations, Administration, and Maintenance (OAM)[111]

57.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 57, Operations, Administration, and Maintenance (OAM), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

57.7.2 Identification

57.7.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

57.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 57, Operations, Administration, and Maintenance (OAM)
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[111] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

58. Physical Medium Dependent (PMD) sublayer and medium, type 100BASE-LX10 (Long Wavelength) and 100BASE-BX10 (Bi-Directional Long Wavelength)

58.1 Overview

The 100BASE-LX10 and 100BASE-BX10 PMD sublayers provide point-to-point 100 Mb/s Ethernet links over a pair of single-mode fibers or an individual single-mode fiber, respectively, up to at least 10 km. They complement 100BASE-TX (twisted-pair cable, see Clause 25) and 100BASE-FX (multimode fiber, see Clause 26).

This clause specifies the 100BASE-LX10 PMD and the 100BASE-BX10 PMDs for operation over single-mode fiber. A PMD is connected to the 100BASE-X PMA of 66.1, and to the medium through the MDI. A PMD is optionally combined with the management functions that may be accessible through the management interface defined in Clause 22 or by other means.

Table 58–1 shows the primary attributes of each PMD type.

Table 58–1—Classification of 100BASE-LX10 and 100BASE-BX10

Description	100BASE-LX10	100BASE-BX10-D	100BASE-BX10-U	Unit
Fiber type	B1.1, B1.3 SMF[a]			
Number of fibers	2	1		
Typical transmit direction	Any	Downstream	Upstream	
Nominal transmit wavelength	1310	1550	1310	nm
Minimum range	0.5 m to 10 km			
Maximum channel insertion loss[b]	6.0	5.5	6.0	dB

[a]Specified in IEC 60793-2.
[b]At the nominal wavelength.

A 100BASE-LX10 link uses 100BASE-LX10 PMDs at each end while a 100BASE-BX10 link uses a 100BASE-BX10-D PMD at one end and a 100BASE-BX10-U PMD at the other. Typically, the 1550 nm band is used to transmit away from the center of the network (“downstream”) and the 1310 nm band towards the center (“upstream”), although this arrangement, or the notion of hierarchy, is not required. The suffixes “D” and “U” indicate the PMDs at each end of a link which transmit in these directions and receive in the opposite directions.

Two optional temperature ranges are defined; see 58.8.4 for further details. Implementations may be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

58.1.1 Goals and objectives

The following are the objectives of 100BASE-LX10 and 100BASE-BX10:

a) Point-to-point on optical fiber
b) 100BASE-X up to at least 10 km over single-mode fiber (SMF)
c) BER better than or equal to 10^{-12} at the PHY service interface

58.1.2 Positioning of this PMD set within the IEEE 802.3 architecture

Figure 58–1 depicts the relationships of the PMD (shown shaded) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

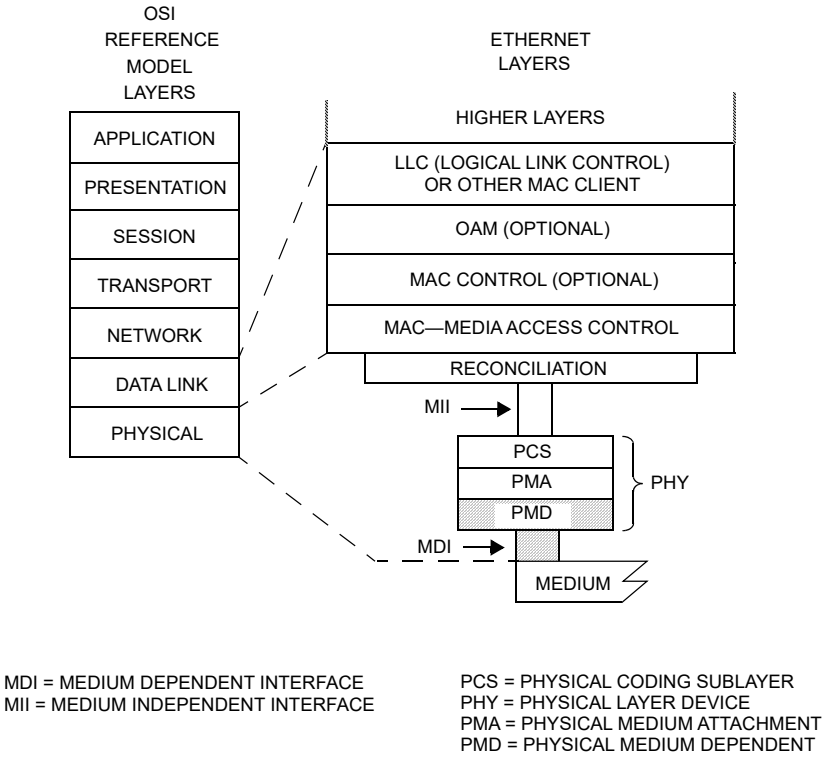

Figure 58–1—100BASE-LX10 and 100BASE-BX10 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

58.1.3 Terminology and conventions

The following list contains references to terminology and conventions used in this clause:

Basic terminology and conventions, see 1.1 and 1.2.

Normative references, see 1.3.

Definitions, see 1.4.

Abbreviations, see 1.5.

Informative references shown referenced in the format [Bn], see Annex A.

Introduction to 100 Mb/s baseband networks, see Clause 21.

Introduction to Ethernet for subscriber access networks, see Clause 56

58.1.4 Physical Medium Dependent (PMD) sublayer service interface

The following specifies the services provided by the 100BASE-LX10 and 100BASE-BX10 PMDs. These PMD sublayer service interfaces are described in an abstract manner and do not imply any particular implementation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PMD service interface supports the exchange of NRZI encoded 4B/5B bit streams between the PMA and PMD entities. The PMD translates the serialized data of the PMA to and from signals suitable for the specified medium.

The following primitives are defined:

PMD_UNITDATA.request

PMD_UNITDATA.indication

PMD_SIGNAL.indication

58.1.4.1 Delay constraints

Delay requirements which affect the PMD layer are specified in 24.6. Of the budget, up to 12 ns is allocated for each of the transmit and receive functions of the PMD to account for those cases where the PMD includes a pigtail.

58.1.4.2 PMD_UNITDATA.request

This primitive defines the transfer of a serial data stream from the PMA to the PMD.

The semantics of the service primitive are PMD_UNITDATA.request(tx_bit). The data conveyed by PMD_UNITDATA.request is a continuous stream of bits where the tx_bit parameter can take one of two values: ONE or ZERO. The PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal 125 MBd signaling speed. Upon receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals at the MDI.

58.1.4.3 PMD_UNITDATA.indication

This primitive defines the transfer of data from the PMD to the PMA.

The semantics of the service primitive are PMD_UNITDATA.indication(rx_bit). The data conveyed by PMD_UNITDATA.indication is a continuous stream of bits where the rx_bit parameter can take one of two values: ONE or ZERO. The PMD continuously sends a stream of bits to the PMA corresponding to the signals received from the MDI.

58.1.4.4 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

The semantics of the service primitive are PMD_SIGNAL.indication(SIGNAL_DETECT). The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting light at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication(rx_bit) is undefined. The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT.

NOTE—SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA.indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the specified bit error ratio.

58.2 PMD functional specifications

The 100BASE-X PMDs perform the transmit and receive functions that convey data between the PMD service interface and the MDI.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

58.2.1 PMD block diagram

The PMD sublayer is defined at the four reference points shown in Figure 58–2. Two points, TP2 and TP3, are compliance points. TP1 and TP4 are reference points for use by implementers. The optical transmit signal is defined at the output end of a patch cord (TP2), between 2 and 5 m in length, of single-mode fiber. Unless specified otherwise, all transmitter measurements and tests defined in 58.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) connected to the receiver. Unless specified otherwise, all receiver measurements and tests defined in 58.7 are made at TP3.

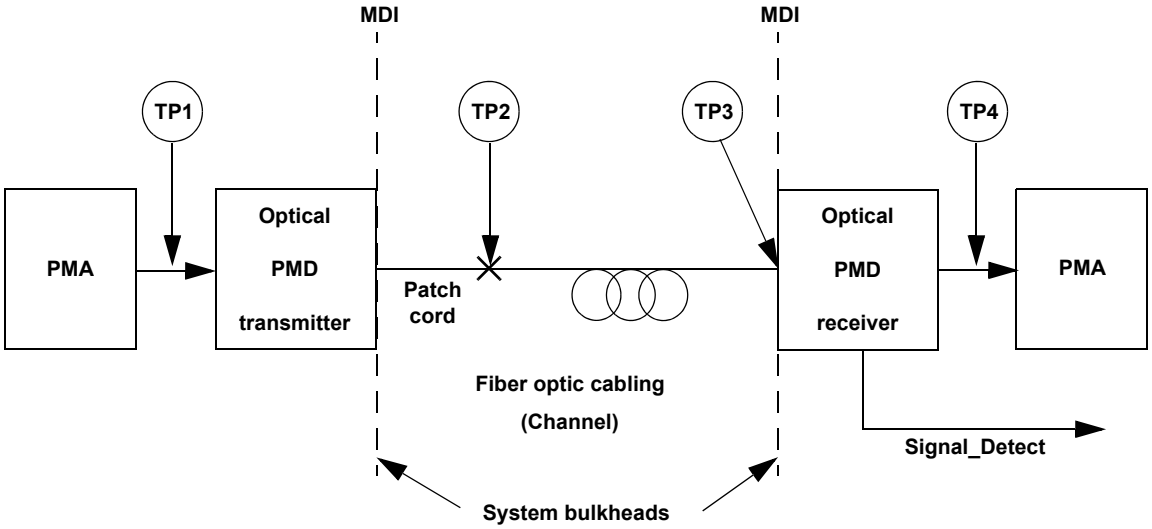

Figure 58–2—100BASE-X block diagram

The electrical specifications of the PMD service interface (TP1 and TP4) are not system compliance points (these are not readily testable in a system implementation). It is expected that in many implementations, TP1 and TP4 will be common between 100BASE-LX10, 100BASE-BX10-D, 100BASE-BX10-U, and 100BASE-FX (multimode fiber, see Clause 26).

58.2.2 PMD transmit function

The PMD transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the optical specifications in this clause. The higher optical power level should correspond to tx_bit = ONE.

NOTE—Because the NRZI coding distinguishes between a transition and no transition on the line, as opposed to 0 and 1, an inverted signal is usable.

58.2.3 PMD receive function

The PMD receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher optical power level should correspond to rx_bit = ONE.

NOTE—Because the NRZI coding distinguishes between a transition and no transition on the line, as opposed to 0 and 1, an inverted signal is usable.

58.2.4 100BASE-LX10 and 100BASE-BX10 signal detect function

The PMD signal detect function shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence.

The value of the SIGNAL_DETECT parameter for 100BASE-LX10 and 100BASE-BX10 shall be generated according to the conditions defined in Table 58–2. The PMD receiver is not required to verify whether a compliant 100BASE-LX10 signal or 100BASE-BX10 signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 58–2—100BASE-LX10 and 100BASE-BX10 SIGNAL_DETECT value definition

Receive conditions		SIGNAL_DETECT value
100BASE-LX10	**100BASE-BX10**	
Average input optical power ≤ Signal detect threshold (min) in Table 58–4	Average input optical power ≤ Signal detect threshold (min) in Table 58–6	FAIL
Average input optical power ≥ Receiver sensitivity (max) in Table 58–4 with a compliant 100BASE-LX10 signal input	Average input optical power ≥ Receiver sensitivity (max) in Table 58–6 with a compliant 100BASE-BX10 signal input at the specified receiver wavelength	OK
All other conditions		Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD due to cross talk, power supply noise, etc.

Various implementations of the signal detect function are permitted by this standard, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the optical signal and implementations that respond to the average optical power of the modulated optical signal.

58.3 PMD to MDI optical specifications for 100BASE-LX10

The operating range for 100BASE-LX10 is defined in Table 58–1. A 100BASE-LX10 compliant transceiver operates over the media types listed in Table 58–1 according to the specifications described in 58.9. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant.

NOTE—In this subclause and 58.4, the specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is explained in 58.7.6.

58.3.1 Transmitter optical specifications

The 100BASE-LX10 transmitter's signaling speed, operating wavelength, spectral width, average launch power, extinction ratio, return loss tolerance, OMA, eye and TDP shall meet the specifications defined in Table 58–3 per measurement techniques described in 58.7. Its $RIN_{12}OMA$ should meet the value listed in Table 58–3 per measurement techniques described in 58.7.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 58–3—100BASE-LX10 transmit characteristics

Description	Type B1.1, B1.3 SMF	Unit
Transmitter type[a]	Longwave laser	
Signaling speed (range)	125 ± 50 ppm	MBd
Operating wavelength range[b]	1260 to 1360	nm
RMS spectral width (max)	7.7	nm
Average launch power (max)	–8	dBm
Average launch power (min)	–15	dBm
Average launch power of OFF transmitter (max)	–45	dBm
Extinction ratio (min)	5	dB
$RIN_{12}OMA$[c] (max)	–110	dB/Hz
Optical return loss tolerance (max)	12	dB
Launch OMA (min)	–14.8 (33.1)	dBm (μW)
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3, Y4}	{0.18, 0.29, 0.35, 0.35, 0.38, 0.4, 0.55}	UI
Transmitter and dispersion penalty (max)	4.5	dB
Decision timing offsets for transmitter and dispersion penalty (min)	±1.6	ns

[a]The nominal transmitter type is not intended to be a requirement on the source type, and any transmitter meeting the transmitter characteristics specified may be substituted for the nominal transmitter type.
[b]The great majority of the transmitted spectrum has to fall within the operating wavelength range, see 58.7.2.
[c]The $RIN_{12}OMA$ recommendation is not mandatory.

58.3.2 Receiver optical specifications

The 100BASE-LX10 receiver's signaling speed, operating wavelength, damage, overload, sensitivity, reflectance and signal detect shall meet the specifications defined in Table 58–4 per measurement techniques defined in 58.7. Its stressed receive characteristics should meet the values listed in Table 58–4 per measurement techniques described in 58.7.11. The receiver sensitivity includes the extinction ratio penalty.

A compliant receiver may be shown to deliver an error ratio lower than that in the table at the received power shown in the table, or shown to deliver an error ratio lower than 10^{-10} at a received power 1 dB lower than the value in the table. Sensitivity measurement is described in 58.7.10. Similarly, stressed receiver conformance may be shown for the error ratio and power shown in the table, or for 10^{-10} and 1 dB lower power. The 10^{-10} limits are more demanding but can be verified more accurately with reasonable test times.

Table 58–4—100BASE-LX10 receive characteristics

Description	Type B1.1, B1.3 SMF	Unit
Signaling speed (range)	125 ± 50 ppm	MBd
Operating wavelength range	1260 to 1360	nm
Bit error ratio (max)	10^{-12}

Table 58–4—100BASE-LX10 receive characteristics *(continued)*

Description	Type B1.1, B1.3 SMF	Unit
Average received power[a] (max)	–8	dBm
Receiver sensitivity (max)	–25	dBm
Receiver sensitivity as OMA (max)	–24.8 (3.3)	dBm (μW)
Receiver reflectance[b] (max)	–12	dB
Stressed receiver sensitivity[c]	–20.1	dBm
Stressed receiver sensitivity as OMA (max)	–19.9 (10.2)	dBm (μW)
Vertical eye-closure penalty[d] (min)	3.7	dB
Stressed eye jitter (min)	0.25	UI pk-pk
Jitter corner frequency	20	kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	0.05, 0.15	UI
Signal detect threshold (min)	–45	dBm

[a]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having a power level equal to the average received power (max) plus at least 1 dB.
[b]See 1.4 for definition of reflectance.
[c]The stressed receiver sensitivity is optional.
[d]Vertical eye closure penalty and the jitter specifications are test conditions for measuring stressed receiver sensitivity. They are not required characteristics of the receiver.

58.4 PMD to MDI optical specifications for 100BASE-BX10

The operating range for 100BASE-BX10 is defined in Table 58–1. A 100BASE-BX10-D or 100BASE-BX10-U compliant transceiver operates over the media types listed in Table 58–1 according to the specifications described in 58.9. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant.

NOTE—In this subclause and 58.3, the specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is explained in 58.7.6.

58.4.1 Transmit optical specifications

The 100BASE-BX10 transmitters' signaling speed, operating wavelength, spectral width, average launch power, extinction ratio, return loss tolerance, OMA, eye and TDP shall meet the specifications defined in Table 58–5 per measurement techniques described in 58.7. Its RIN_{12}OMA should meet the value listed in Table 58–5 per measurement techniques described in 58.7.7.

Table 58–5—100BASE-BX10 transmit characteristics

Description	100BASE-BX10-D	100BASE-BX10-U	Unit
Nominal transmitter type[a]	Longwave laser		
Signaling speed (range)	125 ± 50 ppm		MBd
Operating wavelength range[b]	1480 to 1580	1260 to 1360	nm
RMS spectral width (max)	4.6	7.7	nm

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 58–5—100BASE-BX10 transmit characteristics *(continued)*

Description	100BASE-BX10-D	100BASE-BX10-U	Unit
Average launch power (max)	–8		dBm
Average launch power (min)	–14		dBm
Average launch power of OFF transmitter (max)	–45		dBm
Extinction ratio (min)	6.6		dB
$RIN_{12}OMA$[c] (max)	–110		dB/Hz
Optical return loss tolerance (max)	12		dB
Launch OMA (min)	–12.9 (51.0)		dBm (μW)
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3, Y4}	{0.18, 0.29, 0.35, 0.35, 0.38, 0.4, 0.55}		UI
Transmitter and dispersion penalty (max)	4.5		dB
Decision timing offsets for transmitter and dispersion penalty (min)	±1.6		ns

[a]The nominal transmitter type is not intended to be a requirement on the source type, and any transmitter meeting the transmitter characteristics specified may be substituted for the nominal transmitter type.
[b]The great majority of the transmitted spectrum has to fall within the operating wavelength range, see 58.7.2.
[c]The $RIN_{12}OMA$ recommendation is not mandatory.

58.4.2 Receiver optical specifications

The 100BASE-BX10 receivers' signaling speed, operating wavelength, damage, overload, sensitivity, reflectance and signal detect shall meet the specifications defined in Table 58–6 per measurement techniques defined in 58.7. Its stressed receive characteristics should meet the values listed in Table 58–6 per measurement techniques described in 58.7.11. The receiver sensitivity includes the extinction ratio penalty.

Table 58–6—100BASE-BX10 receive characteristics

Description	100BASE-BX10-D	100BASE-BX10-U	Unit
Signaling speed (range)	125 ± 50 ppm		MBd
Operating wavelength range[a]	1260 to 1360	1480 to 1600	nm
Bit error ratio (max)	10^{-12}		
Average received power[b] (max)	–8		dBm
Receiver sensitivity (max)	–28.2		dBm
Receiver sensitivity as OMA (max)	–27.1 (1.94)		dBm (μW)
Receiver reflectance[c] (max)	–12		dB
Stressed receiver sensitivity[d]	–23.3		dBm
Stressed receiver sensitivity as OMA (max)	–22.3 (6.0)		dBm (μW)
Vertical eye-closure penalty[e] (min)	3.8		dB

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 58–6—100BASE-BX10 receive characteristics *(continued)*

Description	100BASE-BX10-D	100BASE-BX10-U	Unit
Stressed eye jitter (min)	0.25		UI pk-pk
Jitter corner frequency	20		kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	0.05, 0.15		UI
Signal detect threshold (min)	–45		dBm

[a]The receiver wavelength range of 100BASE-BX10-U is wider than the associated transmitter to allow interoperation with existing implementations of 100 Mb/s bi-directional transceivers.
[b]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having a power level equal to the average received power (max) plus at least 1 dB.
[c]See 1.4 for definition of reflectance.
[d]The stressed receiver sensitivity is optional.
[e]Vertical eye closure penalty and jitter specifications are test conditions for measuring stressed receiver sensitivity. They are not required characteristics of the receiver.

A compliant receiver may be shown to deliver an error ratio lower than that in the table at the received power shown in the table, or shown to deliver an error ratio lower than 10^{-10} at a received power 1 dB lower than the value in the table. Sensitivity measurement is described in 58.7.10. Similarly, stressed receiver conformance may be shown for the error ratio and power shown in the table, or for 10^{-10} and 1 dB lower power. The 10^{-10} limits are more demanding but can be verified more accurately with reasonable test times.

58.5 Illustrative 100BASE-LX10 and 100BASE-BX10 channels and penalties

Illustrative channels and penalties for 100BASE-LX10 and 100BASE-BX10 are shown in Table 58–7.

NOTE—The budgets include an allowance for –12 dB reflection at the receiver.

Table 58–7—Illustrative 100BASE-LX10 and 100BASE-BX10 channels and penalties

Description	100BASE-LX10	100BASE-BX10-D	100BASE-BX10-U	Unit
Fiber type	B1.1, B1.3 SMF			
Measurement wavelength for fiber	1310	1550	1310	nm
Nominal distance	10			km
Available power budget	10	14.2		dB
Maximum channel insertion loss[a]	6.0	5.5	6.0	dB
Allocation for penalties[b]	4.0	8.7	8.2	dB

[a]The maximum channel insertion loss is based on the cable attenuation at the target distance and nominal measurement wavelength. The channel insertion loss also includes the loss for connectors, splices and other passive components.
[b]The allocation for penalties is the difference between the available power budget and the channel insertion loss; insertion loss difference between nominal and worst-case operating wavelength is considered a penalty. For 100BASE-X, it is possible for the allocation for penalties to be less than the TDP limit, as some penalties measured by TDP may arise in the receiver and need not be counted twice.

58.6 Jitter at TP1 and TP4 for 100BASE-LX10 and 100BASE-BX10

Jitter at TP1 and TP4 for 100BASE-LX10 and 100BASE-BX10 is informatively described in 58B.1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

58.7 Optical measurement requirements

The following subclauses describe definitive patterns and test procedures for certain PMDs of this standard. implementers using alternative verification methods need to ensure adequate correlation and allow adequate margin such that specifications are met by reference to the definitive methods.

All optical measurements, except TDP and RIN, shall be made through a short patch cable, between 2 m and 5 m in length.

NOTE—58.7.5, 58.7.6, 58.7.7, 58.7.9, 58.7.10, 58.7.11, and 58.7.12 apply to Clause 58, Clause 59, and Clause 60. Clause 59 (1000BASE-LX10) uses multimode fiber, although Clause 58 (100BASE-LX10 and 100BASE-BX10) and Clause 60 (1000BASE-PX10 and 1000BASE-PX20) do not.

58.7.1 Test patterns

Compliance is to be achieved in normal operation. The definitive patterns for testing are shown in Table 58–8.

Table 58–8—List of test patterns and tests

Test pattern	Test	Related subclause
Valid 100BASE-X signal	Wavelength Spectral width	58.7.2
Valid balanced NRZI encoded 4B/5B bit stream	Optical power	58.7.3
Idle or far-end fault indication (see Clause 24)	Extinction ratio OMA RIN_xOMA	58.7.4 58.7.5 58.7.7
Optical frame-based test pattern of 58.7.1.1	Eye mask TDP Receiver sensitivity Stressed receiver sensitivity Jitter measurements	58.7.8 58.7.9 58.7.10 58.7.11 58.7.12

58.7.1.1 100BASE-X optical frame-based test pattern

Transmit eye mask, TDP and sensitivity are to be assured against the test pattern defined below. This represents an extremely untypical pattern. The BER in service can be expected to be lower than with the test pattern. In this clause, extinction ratio, OMA and RIN_xOMA are referred to the idle pattern (1010… for 4B/5B NRZI) or the nearly identical far-end fault indication.

The following test pattern is intended for frame-based testing of the 100BASE-LX10 and 100BASE-BX10 PMDs. It contains compliant Ethernet frames with adequate user defined fields to allow them to be passed through a system to the point of the test. Further information on frame-based testing is included in Annex 58A. The test suite and the recommended patterns are shown in Table 58–8.

NOTE—Users are advised to take care that the system under test is not connected to a network in service.

The test pattern shall be constructed as follows.

A test pattern for base line wander is composed of a sequence of three frames continuously repeated. Each frame has a 1500 octet length client data field and a zero length pad field. The contents of the destination address, source address, length/type fields and the first 32 octets of the client data field are at the discretion of the tester and may be implementation specific. The remaining 1468 octets of the client data field are filled with symbols with an even number of ones in the 4B/5B encoded data prior to NRZI transmission as shown in Table 58–9.

Frames are separated by a near minimum interpacket gap (IPG) of 14 octets.

Within the limits of the three bit maximum run length of the 4B/5B code this sequence gives a near worst case ISI pattern and provides alternating periods of high and low transition density to test clock and data recovery (CDR) performance.

The first 32 octets of the client data field are configured such that, after the frame check sequence (FCS) is added, there are an even number of ones in the first two packets and an odd number of ones in the third packet. This results in a six frame sequence on the line (after NRZI) with three frames containing near 40% ones density and three frames with near 60% ones density. Table 58–10 shows a pattern, nearly identical to the pattern in Table 58–9, that ends in 0 rather than 1 and can be used to join a 40% section to a 60% section. The "flipping" content causes a different frame check sequence which in turn causes the following idle to be inverted.

When transmitted with a near minimum interpacket gap the resulting data stream has baseline wander at 1.35 kHz. In the example shown, IEEE Std 802.2 logical link control headers are used to form TEST command PDUs with null DSAP and SSAP addresses.

Table 58–9—Example unbalanced pattern

Item	Number of octets	Code-group name or hexa-decimal value	TXD<3:0>[a] (binary)		4B/5B encoded (binary)		NRZI encoded (binary)			
			1st nibble	2nd nibble	1st code-group[b]	2nd code-group	40% mark ratio		60% mark ratio

Table 58–9—Example unbalanced pattern *(continued)*

Item	Number of octets	Code-group name or hexa-decimal value	TXD<3:0>[a] (binary)		4B/5B encoded (binary)		NRZI encoded (binary)			
			1st nibble	2nd nibble	1st code-group[b]	2nd code-group	40% mark ratio		60% mark ratio	
Frame check sequence 3	1	9E	1110	1001	11100	10011	10111	00010	01000	11101
Frame check sequence 4	1	59	1001	0101	10011	01011	11101	10010	00010	01101
End-of-stream delimiter (ESD)	1	/T/R/			01101	00111	01001	11010	10110	00101

[a]See Table 24–2.
[b]The five bit code-groups are transmitted left most bit first.
[c]Use of the example broadcast address may cause problems in a system test; any unicast address is preferable. Other source and destination addresses may be chosen.
[d]The first row precedes the second row and the sub-sequence is repeated 16 times. This pattern can be varied to cause the disparity to remain the same or flip.
[e]The frame check sequence for another pattern may be calculated following 3.2.9 and Clause 24.

Table 58–10—Example unbalanced pattern to flip polarity

Item	Number of octets	Code-group name or hexa-decimal value	TXD<3:0> (binary)		4B/5B encoded (binary)		NRZI encoded (binary)			
			1st nibble	2nd nibble	1st code-group	2nd code-group	40% mark ratio		60% mark ratio	
Idle, SSD, preamble, SFD, DA, SA, Length/ type, DSAP, SSAP, Control	38	As in Table 58–9								
Flipping	1	05	0101	0000	01011	11110	10010	10100	01101	01011
Implementation specific, and pattern	1496	As in Table 58–9								
Frame check sequence 1	1	0B	1011	0000	10111	11110	11010	10100	00101	01011
Frame check sequence 2	1	E2	0010	1110	10100	11100	11000	10111	00111	01000
Frame check sequence 3	1	08	1000	0000	10010	11110	00011	01011	11100	10100
Frame check sequence 4	1	3B	1011	0011	10111	10101	00101	11001	11010	00110
End-of-stream delimiter (ESD)	1	/T/R/			01101	00111	10110	00101	01001	11010

NOTE—While it is expected that these frames will be counted by a DTE under test, the likelihood of additional behavior means that the DTE should not be connected to a network in service while being tested.

58.7.2 Wavelength and spectral width measurements

The wavelength and spectral width (RMS) shall meet specifications according to the centroidal wavelength and RMS spectral width definitions in IEC 61280-1-3, under modulated conditions using a valid 100BASE-X signal.

NOTE—The great majority of the transmitted spectrum has to fall within the operating wavelength range. The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.

58.7.3 Optical power measurements

Optical power shall meet specifications according to the methods specified in IEC 61280-1-1. A measurement may be made with the port transmitting any valid balanced NRZI encoded 4B/5B bit stream.

58.7.4 Extinction ratio measurements

Extinction ratio shall meet specifications according to IEC 61280-2-2 with the port transmitting the NRZI encoded 4B/5B idle pattern (1010…) or far-end fault indication, that may be interspersed with OAM packets per 57A.2 and with minimal back reflections into the transmitter, lower than –20 dB. The extinction ratio is expected to be similar for other valid balanced NRZI encoded 4B/5B bit streams. The test receiver has the frequency response as specified for the transmitter optical waveform measurement.

58.7.5 Optical modulation amplitude (OMA) measurements (optional)

The normative way of measuring transmitter characteristics is extinction ratio and mean power. The following clause is intended to inform on how the OMA measurement is performed.

In this clause, OMA is the difference in optical power for “1” and “0” levels of the optical signal in an idle (10101… for 100BASE-LX10 and 100BASE-BX10) sequence or far-end fault indication. It may be found using waveform averaging or histogram means. The measurement is recommended to be equivalent to that described below.

The recommended technique for measuring optical modulation amplitude is illustrated in Figure 58–3. A fourth-order Bessel-Thomson filter as specified for measuring the transmitter concerned is to be used with the O/E converter. The measurement system consisting of the O/E converter, the filter and the oscilloscope is calibrated at the appropriate wavelength for the transmitter under test.

With the device under test transmitting the idle pattern or far-end fault indication, use the following procedure to measure optical modulation amplitude:

a) Configure the test equipment as illustrated in Figure 58–3.
b) Measure the mean optical power P_1 of the logic “1” as defined over the center 20% of the time interval, here 1 UI long, where the signal is in the high state.
c) Measure the mean optical power P_0 of the logic “0” as defined over the center 20% of the time interval, here 1 UI long, where the signal is in the low state.
d) $OMA = P_1 - P_0$.

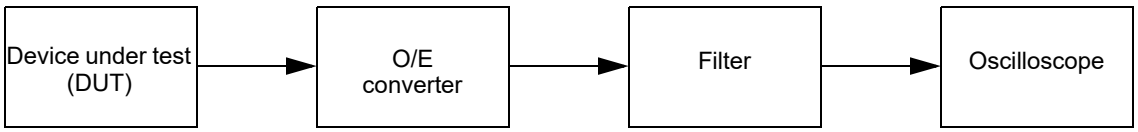

Figure 58–3—Recommended test equipment for measurement of optical modulation amplitude

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A method of approximating OMA is shown in Figure 58–9.

Similarly, the optical power measure A_N is to be measured with a square wave pattern consisting of four to eleven consecutive ones followed by an equal run of zeros. Five ones followed by five zeros is convenient (the /H/ code-group in Clause 24, or K28.7 in 1000BASE-X which is the "Low-frequency test pattern" of 36A.2). The OMA of Clause 52 is A_N, and OMA here may differ.

NOTE—This OMA measurement procedure applies to Clause 58, Clause 59, and Clause 60.

58.7.6 OMA relationship to extinction ratio and power measurements

Annex 58B provides information on how OMA, extinction ratio, and mean power, are related to each other (see 58B.2).

58.7.7 Relative intensity noise optical modulation amplitude (RIN_xOMA) measuring procedure

This procedure describes a component test that may not be appropriate for a system level test depending on the implementation. If used, the procedure is performed as described in 58.7.7.1, 58.7.7.2, and 58.7.7.3.

NOTE—This RIN_xOMA measurement procedure applies to Clause 58, Clause 59, and Clause 60.

58.7.7.1 General test description

The test arrangement is shown in Figure 58–4. The optical path between the Device Under Test (DUT) and the detector has a single discrete reflection with the specified optical return loss as seen by the DUT.

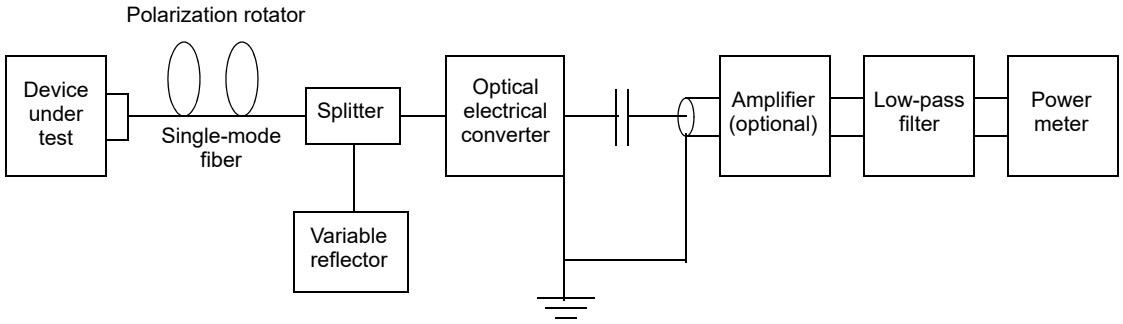

Figure 58–4—RIN_xOMA measurement setup

Both the OMA power and noise power are measured by AC-coupling the O/E converter into the electrical power meter. If needed, an amplifier may be used to boost the signal to the power meter. A low-pass filter is used between the photo detector and the power meter to limit the noise measured to the passband appropriate to the data rate of interest. In order to measure the noise, the modulation to the DUT is turned off.

58.7.7.2 Component descriptions

The optical path and detector combination is configured for a single dominant reflection with an optical return loss as specified in the appropriate transmitter table, e.g., Table 58–3. (The optical return loss may be determined by the method of FOTP-107.) The length of the fiber is not critical but should be in excess of 2 m.

The polarization rotator is capable of transforming an arbitrary orientation elliptically polarized wave into a fixed orientation linearly polarized wave.

If necessary, the noise may be amplified to a level consistent with accurate measurement by the power meter.

The upper –3 dB limit of the measurement apparatus is as specified for the transmitter optical waveform test. The bandwidth used in the RIN calculation takes the low-frequency cutoff of the DC-blocking capacitor into consideration. The low-frequency cutoff is recommended to be less than 1 MHz. The filter should be placed in the circuit as the last component before the power meter so that any high-frequency noise components generated by the detector/amplifier are eliminated. If the power meter used has a very wide bandwidth, care should be taken to ensure that the filter does not lose its rejection at extremely high frequencies.

The RMS electrical power meter should be capable of being zeroed in the absence of input optical power to remove any residual noise.

58.7.7.3 Test procedure

Use the following procedure to test relative intensity noise optical modulation amplitude:

a) With the DUT disconnected, zero the power meter;
b) Connect the DUT, turn on the laser, and ensure that the laser is not modulated;
c) Operate the polarization rotator while observing the power meter output to maximize the noise read by the power meter. Note the maximum power, P_N;
d) Turn on the modulation to the laser using the pattern specified for the PMD type (e.g., in 58.7.1 and 59.7.1) and note the power measurement, P_M. It may be necessary to change or remove the effective reflection to obtain an accurate reading;
e) Calculate RIN from the observed electrical signal power and noise power by use of Equation (0–1).

$$RIN_xOMA = 10 \times \log_{10}\frac{P_N}{BW \times P_M} \text{ [dB/Hz]} \quad (0–1)$$

where:

RIN_xOMA = Relative Intensity Noise referred to optical modulation amplitude measured with x dB reflection,
P_N = Electrical noise power in Watts with modulation off,
P_M = Electrical power in Watts with modulation on,
BW = Low-pass bandwidth of apparatus – high-pass bandwidth of apparatus due to DC-blocking capacitor [noise bandwidth of the measuring system (Hz)].

For testing multimode components or systems, the polarization rotator is removed from the setup and the single-mode fiber replaced with a multimode fiber. Step c) of the test procedure is eliminated.

58.7.8 Transmitter optical waveform (transmit eye)

The required transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 58–5 for 100BASE-LX10 and 100BASE-BX10. Compliance is to be assured during system operation. The transmitter optical waveform of a port transmitting the test pattern specified for the PMD type, e.g., in 58.7.1, shall meet specifications according to the methods specified below.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

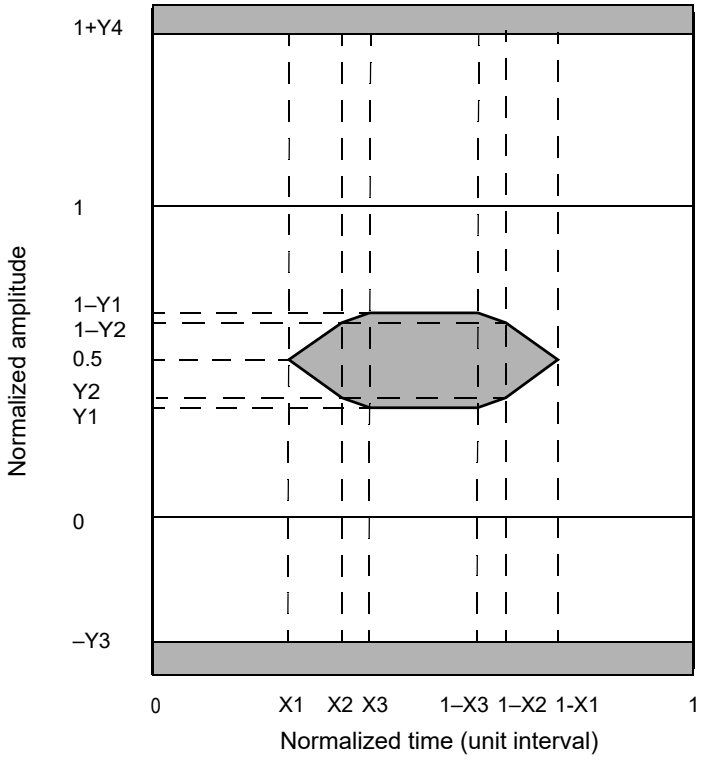

Figure 58–5—Transmitter eye mask definition

NOTE—This transmitter optical waveform measurement procedure applies to Clause 58, Clause 59, and Clause 60.

Normalized amplitudes of 0 and 1 represent the amplitudes of logic ZERO and ONE respectively. These are defined by the means of the lower and upper halves of the central 0.2 UI of the eye. 0 and 1 on the unit interval scale are to be determined by the eye crossing means. A clock recovery unit (CRU) may be used to trigger the scope for mask measurements as shown in Figure 58–6. It should have a high-frequency corner bandwidth of less than or equal to the jitter corner frequency in the appropriate table for the transmitter's peer receiver, e.g., Table 58–4 or Table 58–6, and a slope of –20 dB/decade. The CRU tracks acceptable levels of low frequency jitter and wander. The frequency response of the measurement instrument (e.g., oscilloscope) extends substantially lower than the test pattern repetition frequency. A DC-coupled instrument is convenient.

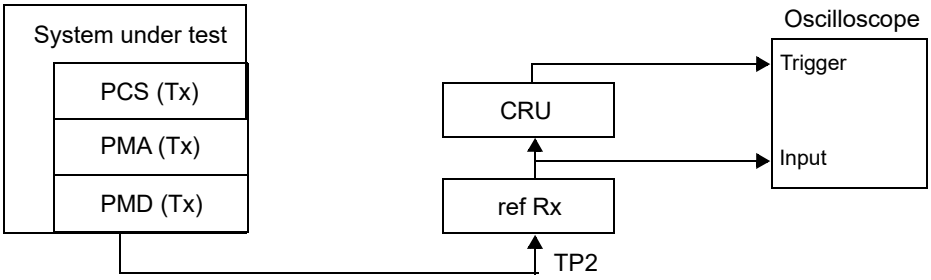

Figure 58–6—Transmitter optical waveform test block diagram

For 100BASE-LX10 and 100BASE-BX10, the eye is measured with respect to the mask of the eye using a receiver with a fourth-order Bessel-Thomson response with nominal f_r of 116.64 MHz as specified for STM-

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

1 in ITU-T G.957, with the tolerances there specified. Receiver responses for other PMD types are specified in the appropriate clause. The Bessel-Thomson receiver is not intended to represent the noise filter used within a compliant optical receiver, but is intended to provide uniform measurement conditions at the transmitter.

The transmitter shall achieve a hit ratio lower than 5×10^{-5} hits per sample, where "hits" are the number of samples within the grey areas of Figure 58–5, and the sample count is the total number of samples from 0 UI to 1 UI.

NOTE—As an example, if an oscilloscope records 1350 samples/screen, and the timebase is set to 0.2 UI/div with 10 divisions across the screen, and the measurement is continued for 200 waveforms, then a transmitter with an expectation of less than 6.75 hits is compliant:

$$5 \times 10^{-5} \times 200 \times \frac{1350}{(0.2 \times 10)} = 6.75 \quad (0–2)$$

Likewise, if a measurement is continued for 1000 waveforms, then an expectation of less than 33.75 hits is compliant. An extended measurement is expected to give a more accurate result, and a single reading of 6 hits in 200 waveforms would not give a statistically significant pass or fail. Measurements to "zero hits," which involve finding the position of the worst single sample in the measurement, have degraded reproducibility because random processes cause the position of such a single low-probability event to vary.

The hit ratio limit has been chosen to avoid misleading results due to transmitter and oscilloscope noise, and to give the best correlation to transmitter penalty; see 58.7.9.5.

Further information on optical eye pattern measurement procedures may be found in IEC 61280-2-2.

58.7.9 Transmitter and dispersion penalty (TDP) measurement

The TDP of a port transmitting the appropriate test pattern test shall meet specifications according to the methods specified below. The transmitter and dispersion penalty (TDP) measurement tests for transmitter impairments with chromatic effects for a transmitter to be used with single-mode fiber, and for transmitter impairments with modal (not chromatic) dispersion effects for a transmitter to be used with multimode fiber. Possible causes of impairment include intersymbol interference, jitter, RIN and mode partition noise. Meeting the separate requirements (e.g., eye mask, spectral characteristics) does not in itself guarantee the TDP. The procedure tests for pattern dependent effects; for 100BASE-LX10 and 100BASE-BX10, a standardized element of pattern dependent baseline wander is included in the reference channel.

Transmitter and dispersion penalty may be measured with apparatus shown in Figure 58–7, consisting of a reference transmitter, the transmitter under test, a controlled optical reflection, an optical attenuator, a test fiber, and a reference receiver system containing a reference receiver front end (optical to electrical converter), a transversal filter to emulate multimode fiber, if appropriate, and a bit error ratio tester. All BER and sensitivity measurements are made with the test patterns specified for the PMD type, e.g., in 58.7.1

NOTE 1—This TDP measurement procedure applies to Clause 58, Clause 59, and Clause 60.

NOTE 2—Multimode fiber is not used with 100BASE-LX10 or 100BASE-BX10.

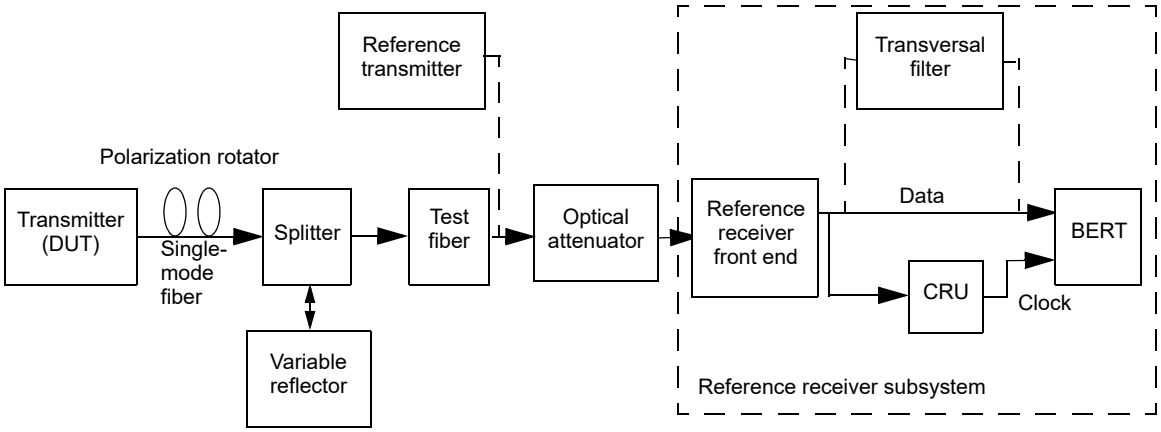

Figure 58–7—Test setup for measurement of transmitter and dispersion penalty

58.7.9.1 Reference transmitter requirements

The reference transmitter is a high-quality instrument-grade device, which can be implemented by a CW laser modulated by a high-performance modulator. It should meet the following basic requirements:

a) The rise/fall times should be less than 0.15 UI at 20% to 80%.
b) The output optical eye is symmetric and with good margin to the eye mask test for the transmitter (PMD) type under test.
c) In the center 20% region of the eye, the worst-case vertical eye closure penalty, as defined in 58.7.11.2, is less than 0.5 dB.
d) Jitter less than 0.20 UI peak-peak.
e) $RIN_{12}OMA$ should be minimized to less than –120 dB/Hz for 100BASE-X and –125 dB/Hz for 1000BASE-X.

58.7.9.2 Channel requirements

The transmitter is tested using an optical and electrical channel that meets the requirements specified for the PMD type listed in Table 58–11. A transmitter is to be compliant with a total dispersion at least as negative as the “minimum dispersion” and at least as positive as the “maximum dispersion” columns specified for the wavelength of the device under test. This may be achieved with a channel or channels consisting of fibers with lengths chosen to meet the dispersion requirements.

To verify that the fiber has the correct amount of dispersion, the measurement method defined in IEC 60793-1-42 may be used. The measurement is made in the linear power regime of the fiber.

When emulating a multimode fiber link, the optical channel is a 2 m to 5 m patch cord meeting the appropriate specifications. In this case, the link bandwidth is emulated in the electrical domain.

The channel provides a maximum optical return loss specified as “Optical return loss tolerance (maximum)” in the specification of the transmitter under test. For a single-mode fiber channel, the state of polarization of the back reflection is adjusted to create the greatest RIN. The methods of 58.7.7.2 and 58.7.7.3 may be used.

The BERT’s receiver sensitivity needs to be adequate to meet the BER with the worst-case test signal and minimum attenuation.

Table 58–11—Transmitter compliance channel specifications

PMD transmitter wavelength, fiber type	Optical channel			Electrical channel
	Dispersion[a] (ps/nm)		Optical return loss[b] (max)	Differential delay (ps)
	Minimum	Maximum		
1310 nm band for SMF	$0.02325 \cdot L^{c} \cdot \lambda \cdot [1-(1324/\lambda)^4]$	$0.02325 \cdot L \cdot \lambda \cdot [1-(1300/\lambda)^4]$	See ORLT in Transmitter spec	N/A
1550 nm band for SMF	0	$0.02325 \cdot L \cdot \lambda \cdot [1-(1300/\lambda)^4]$		N/A

[a]The dispersion is specified for the actual wavelength of the device under test.
[b]The optical return loss is applied with respect to TP2.
[c]L is the upper operating range limit (reach) as defined e.g. in Table 58–1.

58.7.9.3 Reference receiver requirements

The reference receiver system should have the bandwidth specified for the transmitter optical waveform measurement for the transmitter under test. The sensitivity of the reference receiver system should be limited by Gaussian noise. The receiver system should have minimal threshold offset, deadband, hysteresis, deterministic jitter or other distortions. Decision sampling should be instantaneous with minimal uncertainty and setup/hold properties. When testing 100BASE-X optical transmitters, the receiver should have a passband not extending below 10 kHz at the –3 dBe (electrical) point, so as to emulate the pattern-induced baseline wander expected in a compliant receiver.

For all transmitter and dispersion penalty measurements, determination of the center of the eye is required. The center of the eye is defined as the time halfway between the left and right sampling points within the eye where the measured BERs are equal to each other, and greater than or equal to 10^{-3} (the BER at the eye center is much lower). The decision threshold is to occur at the average signal level.

For a transmitter to be used with multimode fiber the reference receiver is followed by a transversal filter with two equal amplitude paths with a differential delay as specified for the transmitter. In this case, the receiver front end should be operating in its linear regime (not clipping). For a transmitter to be used with single-mode fiber, the transversal filter is not used.

The clock recovery unit (CRU) used in the TDP measurement has a corner frequency of less than or equal to the jitter tolerance frequency specified for the appropriate receiver (the peer PMD to the transmitter under test), and a slope of 20 dB/decade. When using a clock recovery unit as a clock for BER measurements, passing of low-frequency jitter from the data to the clock removes this low-frequency jitter from the measurement.

The nominal sensitivity of the reference receiver system, S, is measured in OMA using the apparatus described above but with a short patchcord in place of the test fiber and without any transversal filter. The sensitivity S has to be corrected for any significant reference transmitter impairments including any vertical eye closure. It should be measured while sampling at the eye center or corrected for off-center sampling. It is calibrated at the wavelength of the transmitter under test. For 100BASE-LX10 and 100BASE-BX10, TDP includes a pattern dependent penalty. It may be inconvenient or impossible to obtain reference transmitters and receivers which are immune to this penalty. For these cases, S may be measured with a benign pattern e.g., PRBS7.

58.7.9.4 Test procedure

To measure the transmitter and dispersion penalty (TDP) the following procedure is used. The sampling instant is displaced from the eye center by the amount specified for decision timing offsets in e.g., Table 58–3 or Table 58–5. The following procedure is repeated for early and late decision and the larger TDP value is used:

a) Configure the test equipment as described above and illustrated in Figure 58–7.
b) Adjust the attenuation of the optical attenuator to obtain a BER of 10^{-12}. Extrapolation techniques may be used with care.
c) Record the optical power in OMA at the input to the reference receiver, P_DUT, in dBm.
d) If P_DUT is larger than S, the transmitter and dispersion penalty (TDP) for the transmitter under test is the difference between P_DUT and S, TDP = P_DUT – S. Otherwise the transmitter and dispersion penalty is zero, TDP = 0.

It is to be ensured that the measurements are made in the linear power regime of the fiber.

58.7.9.5 Approximate measures of TDP

Approximate measures of TDP are informatively described in 58B.3.

58.7.10 Receiver sensitivity measurements

Receiver sensitivity is defined for an ideal input signal. The test signal should have negligible impairments such as intersymbol interference (ISI), jitter and RIN (but see the end of this subclause). The test pattern shall be as specified in 58.7.1, 59.7.1 or 60.9.1 as appropriate. Sensitivity is defined by the specified bit error ratio, which may be determined by counting bit or byte errors or errored frames. Extrapolation techniques may be used with care. Sensitivity is measured at a low but compliant extinction ratio, and correction made for any difference between the measurement extinction ratio and the specified minimum extinction ratio. This assurance should be met with asynchronous data flowing out of the optical transmitter of the system under test. The output data pattern from the transmitter of the system under test is the same pattern as defined for this measurement.

The sampling point is set by the system under test. While this standard applies to complete data terminal equipment (DTE), the test may be used as a diagnostic for testing components with appropriate margin, in which case the sampling point should be set at the average optical power level and at the specified timing offsets from the eye center, which may be found as the mid-point between the 10^{-3} BER points.

An implementer may use a combination of extrapolation and margin to assure compliance. This can entail a statistical analysis which could be implementation specific. As an example, with a small margin, it might not be advisable to extrapolate beyond a limited optical power difference; this represents an extrapolation in BER terms which varies according to circumstance.

In the case of 100BASE-X, systematic baseline wander of the input signal is to be expected. This may be generated with AC-coupling above 10 kHz within the transmitter, and/or with the interfering signal technique as described in 58.7.11.2. A standardized baseline wander of ± OMA/10 is defined for these PMD types. This causes some jitter in the test signal, which is acceptable.

For 100BASE-LX10 and 100BASE-BX10 only, sensitivities are defined for 10^{-12} and 10^{-10} bit error ratios. It is sufficient to show compliance to either of these. The 10^{-10} limit is the more demanding but can be verified more accurately with reasonable test times.

NOTE—This receiver sensitivity measurement applies to Clause 58, Clause 59, and Clause 60.

58.7.11 Stressed receiver conformance test

The stressed receiver conformance test is intended to screen against receivers with poor frequency response or timing characteristics that could cause errors when combined with a distorted but compliant signal at TP3. Modal (MMF) or chromatic (SMF) dispersion can cause distortion. Stressed receiver tolerance testing may be performed in accordance with the requirements of 58.7.11.1, 58.7.11.2, and 58.7.11.3. If this test is applied the receiver shall be compliant to for example Table 58–4.

A receiver should receive a conditioned input signal that combines vertical eye closure and jitter according to this clause with BER specified in the receiver tables. This assurance should be met with asynchronous data flowing out of the optical transmitter of the system under test. The output data pattern from the transmitter of the system under test is to be the same pattern as defined for this measurement.

NOTE 1—The length of the test pattern, low signaling rate and narrow rate tolerance of 100BASE-X means that the input and output patterns beat very slowly. Long test times or a slight modification to the length of one pattern may be appropriate.

NOTE 2—This stressed receiver conformance test applies to Clause 58, Clause 59, and Clause 60.

58.7.11.1 Stressed receiver conformance test block diagram

A block diagram for the receiver conformance test is shown in Figure 58–8. A pattern generator continuously generates a signal or test pattern as specified for the receiver under test, e.g., in 58.7.1. The optical test signal is conditioned (stressed) using the methodology, as defined in 58.7.11.2, while applying sinusoidal jitter, as specified e.g., in 58.7.11.4. The receiver of the system under test is tested for conformance by counting bit or byte errors or errored frames. The optical power penalty for the stressed eye is intended to be similar to its vertical eye closure penalty. This is not necessarily the same as the highest TDP anticipated in service, but represents a standardized test condition for the receiver.

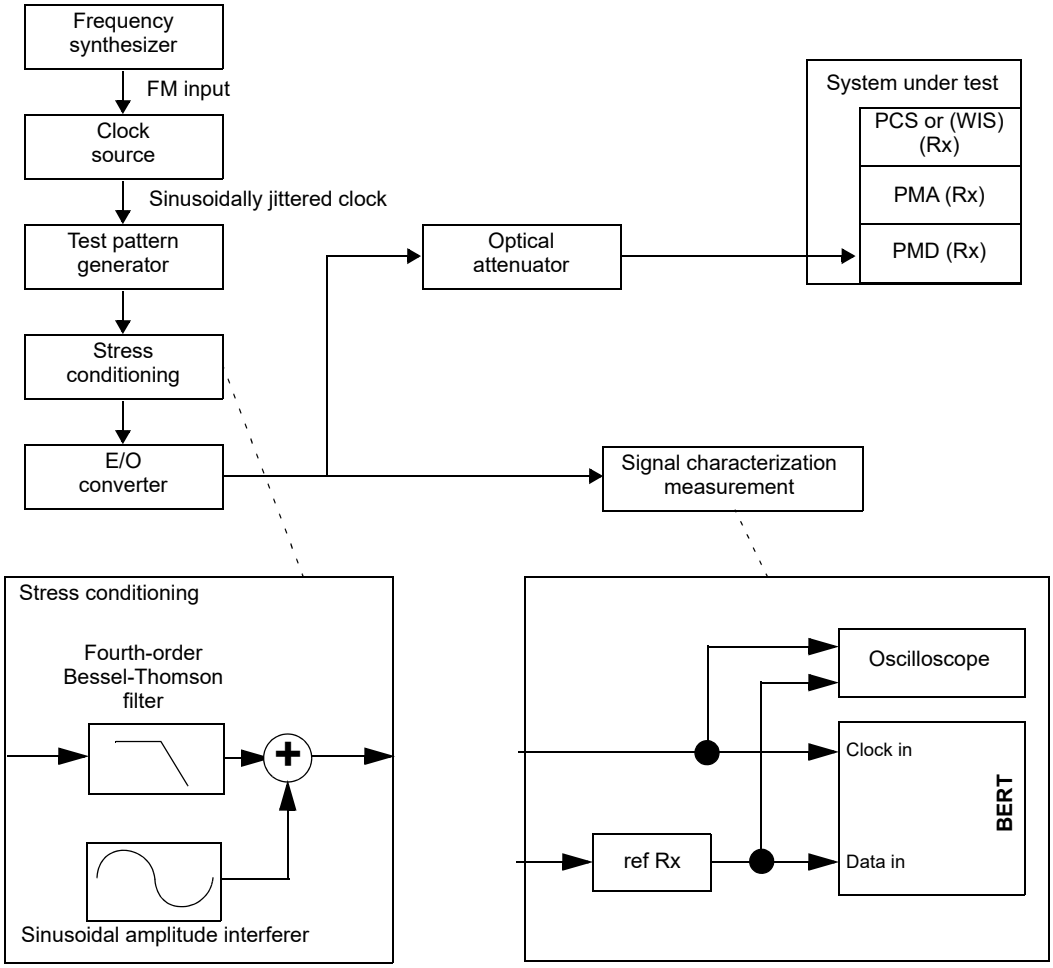

Figure 58–8—Stressed receiver conformance test block diagram

A suitable test set is needed to characterize and verify that the signal used to test the receiver has the appropriate characteristics. The test fiber called out for single-mode fiber based PMD layers and the transversal filter called out to emulate multimode fiber are not needed to characterize the receiver input signal; nor are they used during testing.

The fourth-order Bessel-Thomson filter is used to create ISI-induced vertical eye closure. The sinusoidal amplitude interferer causes additional eye closure, but in conjunction with the slowed edge rates from the filter, also causes jitter. The nature of the jitter is intended to emulate instantaneous bit shrinkage that can occur with DDJ. This type of jitter cannot be created by simple phase modulation. The sinusoidal phase modulation represents other forms of jitter and also verifies that the receiver under test can track low-frequency jitter.

For improved visibility for calibration, it is imperative that the Bessel-Thomson filter and all other elements in the signal path (cables, DC blocks, E/O converter, etc.) have wide and smooth frequency response and linear phase response throughout the spectrum of interest. Overshoot and undershoot should be minimized. If this is achieved, then data dependent effects should be minimal, and short data patterns can be used for calibration with the benefit of providing much improved trace visibility on sampling oscilloscopes. Actual patterns for testing the receiver are specified in the appropriate clause.

To further improve visibility for calibration, random noise effects, such as RIN and random clock jitter, should also be minimized. A small amount of residual noise and jitter from all sources is unavoidable, but should be less than 0.25 UI peak-peak of jitter.

The test pattern generator, filter and E/O converter should together have a frequency response to result in the appropriate level of initial ISI eye closure before the sinusoidal terms are added. The E/O converter should have a linear response if electrical summing is used, linearity of all elements including the E/O modulator is critical. Summing with an optical coupler after the modulator is an option that eases linearity requirements, but requires a second source for the interfering signal, will complicate settings of extinction ratio, and will add more RIN. In either case, a typical optical transmitter with built-in driver is not linear and not suitable.

The vertical and horizontal eye closures to be used for receiver conformance testing are verified using an optical reference receiver with the response specified for the appropriate transmitter (the peer PMD to the receiver under test) e.g., in 58.7.8. Use of standard tolerance filters may significantly degrade this calibration. Care should be taken to ensure that all the light from the fiber is collected by the fast photo detector and (if using multimode fiber) that there is negligible mode selective loss, especially in the optical attenuator and the optical coupler, if used. The reference receiver and oscilloscope should achieve adequately low noise and jitter.

The clock output from the clock source in Figure 58–8 will be modulated with the sinusoidal jitter. To use an oscilloscope to calibrate the final stressed eye jitter that includes the sinusoidal jitter component, a separate clock source (clean clock of Figure 58–8) is required that is synchronized to the source clock, but not modulated with the jitter source.

58.7.11.2 Stressed receiver conformance test signal characteristics and calibration

The conformance test signal is used to validate that the PMD receiver meets BER requirements with near worst case waveforms at TP3 including pulse width shrinkage, power, simulated channel penalties, and a swept frequency sinusoidal jitter contribution.

Signal characteristics are described below along with a suggested approach for calibration.

The test signal includes vertical eye closure and high-probability jitter components. Vertical eye closure is measured at the time center of the eye (halfway between 0 and 1 on the unit interval scale as determined by the eye crossing means) and is the vertical eye closure penalty (VECP) when calculated relative to the measured A_N value. J is measured at the average optical power, which can be obtained with AC-coupling. The values of these components are defined as below by their histogram results. The vertical eye closure penalty is given in Equation (0–3):

$$\text{Vertical eye closure penalty [dB, optical]} = 10 \times \log_{10}\frac{A_N}{A_O} \tag{0–3}$$

where, A_O is the amplitude of the eye opening and A_N is the normal amplitude without ISI, as shown in Figure 58–9. A_N can be approximated with histograms as suggested in Figure 58–9. However, the definition for A_N is given in 58.7.5.

For this test, VECP is defined by the 99.95th percentile of the histogram of the lower half of the signal and the 0.05th percentile of the histogram of the upper half of the signal, and jitter is defined by the 0.5th and 99.5th percentiles of the jitter histogram. Histograms should include at least 10 000 hits, and should be about 1%-width in the direction not being measured. Residual low-probability noise and jitter should be minimized—that is, the outer slopes of the final histograms should be as steep as possible down to very low probabilities.

The following steps describe a suggested method for calibrating a stressed eye generator:

a) Set the signaling speed of the test-pattern generator as specified for the appropriate transmitter. Sinusoidal interference and jitter signals should be turned off at this point.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Turn on the calibration pattern. A repetitive pattern may be used for calibration if the conditions described in 58.7.11.1 are met, but this increases the risk that the longer test pattern used during testing will overstress the device under test.
c) Set the extinction ratio to approximately the extinction ratio (minimum) value as specified for the appropriate transmitter. If optical summing is used, the extinction ratio may need to be adjusted after the sinusoidal interference signal is added below.
d) Measure the settled signal amplitude A_N of the test signal (without attenuation). A_N may be measured according to 58.7.5 using a square wave pattern, although for the purposes of this clause, OMA is to be measured with a different pattern; A_N and OMA are not likely to be equal.
e) The requirements for vertical eye closure and jitter of the stressed eye test signal are given by the vertical eye closure penalty (VECP) and stressed eye jitter (J) values given in the appropriate receiver specification table.

   There are three components involved in calibration for vertical closure and J. These are a linear phase filter, sinusoidal interference, and sinusoidal jitter.

   In general, the majority of the vertical eye closure penalty value should be created by use of a linear phase, low jitter filter (such as Bessel-Thomson). In the case of 100BASE-X, the majority of the vertical eye closure penalty value should be created by baseline wander or sinusoidal interference. The filter should be tested with the prescribed test patterns to verify that residual jitter is small, less than 0.25 UI peak-peak. If not, the stress may be more than desired, leading to conservative results. However, compensation is not allowed. Once done, revert to the calibration pattern, if different than the specified test pattern.

   Any remaining vertical eye closure required has to be created with sinusoidal interference or sinusoidal jitter.

   To emulate the effects of DCD or data-dependent jitter, at least 0.05 but no more than 0.15 UI peak-peak of pulse shrinkage jitter should have been achieved. This imposes a limit of less than 1.2 dB of vertical closure from sinusoidal interference, applied after vertical closure created by filtering.

   The frequency of the sinusoidal interference may be set at any frequency between B / 100 and B / 5 where B is the signaling speed, although care should be taken to avoid a harmonic relationship between the sinusoidal interference, the sinusoidal jitter, the signaling speed and the pattern repetition rate.
   Sinusoidal jitter (phase modulation) has to be added according to the appropriate jitter specification. For calibration purposes, sinusoidal jitter frequencies should be well within the flat portion of the template above the corner frequency.

   Iterate the filter bandwidth and the settings for sinusoidal interference and/or jitter until all constraints are met, including jitter (J), vertical eye closure penalty (VECP), and that sinusoidal jitter above the corner frequency is as specified.

   Verify that the optical power penalty for the stressed eye (relative to the reference transmitter per 58.7.9.1) is greater than or equal to VECP.
f) Decrease the amplitude with the optical attenuator until the OMA complies with the OMA values specified for the receiver under test.
g) For testing, turn on the actual required test pattern(s).

Care should be taken when characterizing the signal used to make receiver tolerance measurements. In the case of a transmit jitter measurement, excessive and/or uncalibrated noise/jitter in the test system makes it more difficult to meet the specification and may have a negative effect on yield but will not impact interoperability. Running the receiver tolerance test with a signal that is under-stressed may result in the deployment of non-compliant receivers. Care should be taken to minimize and/or correct for the noise/jitter

[a]This measure of OMA on the eye of the conformance test signal differs between 100BASE-X, 1000BASE-X and 10GBASE-R/W.
[b]This is also OMA for 10GBASE-R/W.

Figure 58–9—Required characteristics of the conformance test signal at TP3

introduced by the reference receiver, filters, oscilloscope, and BERT. While the details of measurement and test equipment are beyond the scope of this standard it is recommended that the implementers fully characterize their test equipment and apply appropriate guard bands to ensure that the receive input signal meets the specified requirements.

58.7.11.3 Stressed receiver conformance test procedure

The test apparatus is set up as described in 58.7.11.1 and 58.7.11.2. The sinusoidal jitter is then stepped across the specified frequency and amplitude range while monitoring errors at the receiver. The BER is to be compliant at all jitter frequencies in the specified frequency range. This method does not result in values for jitter contributed by the receiver. It does, however, ensure that a receiver meeting the requirements of this test will operate with the worst-case optical input.

58.7.11.4 Sinusoidal jitter for receiver conformance test

The sinusoidal jitter is used to test receiver jitter tolerance. Sinusoidal jitter may vary over a magnitude range as required to accurately calibrate a stressed eye per 58.7.11.2. The range is limited by the constraints of Table 58–12 as illustrated in Figure 58–10, where *f2*, *SJ1,* and *SJ2* are specified in the appropriate receiver table: Table 58–4, Table 58–6, Table 59–6, Table 59–8, Table 60–5, Table 60–6, or Table 60–14. The frequency *f2* is specified as “Jitter corner frequency” in the receiver tables. *SJ1* and *SJ2* are defined as “sinusoidal jitter limits for stressed receiver conformance test (min, max)” in e.g., Table 58–4.

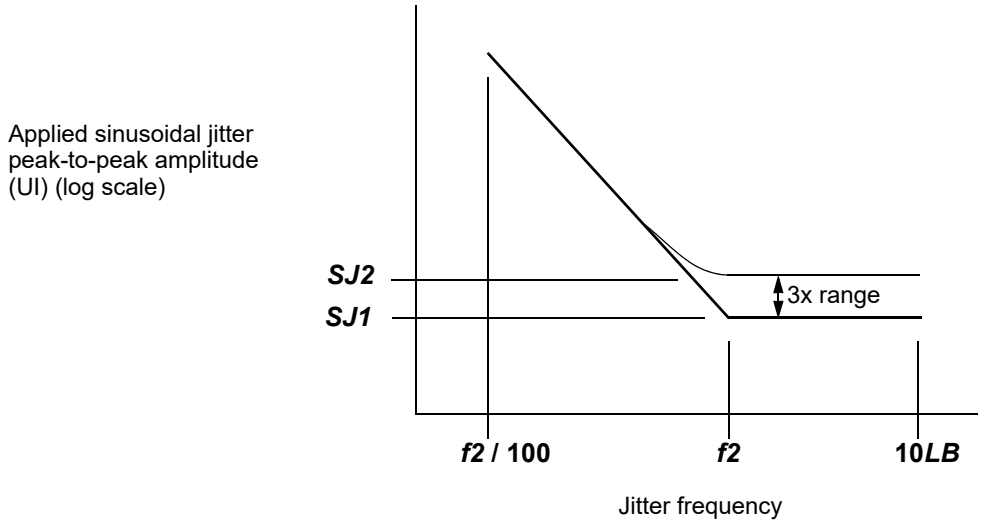

Figure 58–10—Illustration of the mask of the sinusoidal component of jitter tolerance

Table 58–12—Applied sinusoidal jitter

Frequency range	Sinusoidal jitter (UI pk-pk)
$f < f2 / 100$	N/A
$f2 / 100 < f \leq f2$	$0.05 \times f2 / f + S - 0.05$[a]
$f2 < f < 10 \times LB$[b]	$SJ1 \leq S \leq SJ2$[a]

[a]S is the magnitude of sine jitter actually used in the calibration of the stressed eye per the methods of 58.7.11.2.
[b]LB = Loop Bandwidth; Upper frequency bound for added sine jitter should be at least 10 times the loop bandwidth of the receiver being tested.

58.7.12 Jitter measurements

Jitter measurements are informatively described in 58B.4.

58.8 Environmental, safety, and labeling

58.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

58.8.2 Laser safety

100BASE-LX10 and 100BASE-BX10 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore. Conformance to additional laser safety standards may be required for operation within specific geographical regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation shall explicitly define requirements and usage restrictions on the host system necessary to meet these safety certifications.

58.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

58.8.4 Environment

Two optional temperature ranges are defined in Table 58–13. Implementations shall be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

Table 58–13—Component case temperature classes

Class	Low temperature (°C)	High temperature (°C)
Warm extended	–5	+85
Cool extended	–40	+60
Universal extended	–40	+85

Reference Annex 67A for additional environmental information.

58.8.5 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 100BASE-BX10-U).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 58.8.2.

Compliant systems and field pluggable components shall be clearly labeled with the operating temperature range over which their compliance is ensured.

58.9 Characteristics of the fiber optic cabling

The 100BASE-LX10 and 100BASE-BX10 fiber optic cabling shall meet the dispersion specifications of IEC 60793-2 and ITU-T G.652, or the requirements of Table 58–14 where they differ. The fiber cable attenuation is for information only; the end-to-end channel loss shall meet the requirements of Table 58–1. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. The fiber optic cabling spans from one MDI to another MDI, as shown in Figure 58–11.

58.9.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 58–11.

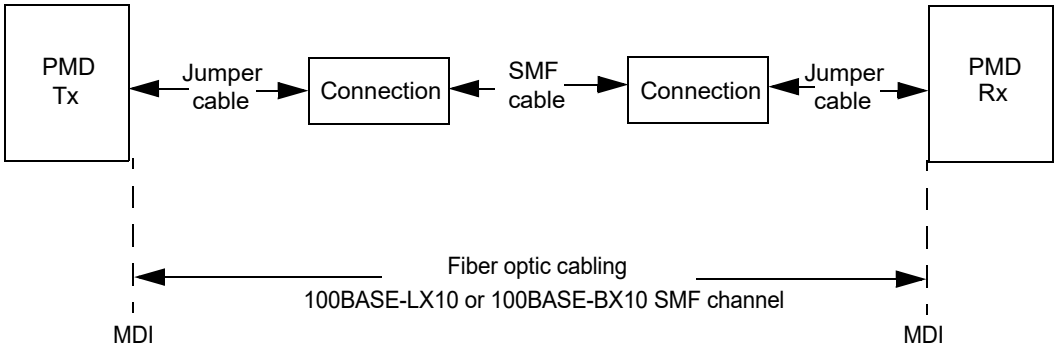

Figure 58–11—Fiber optic cabling model

The maximum channel insertion losses shall meet the requirements specified in Table 58–1. The minimum loss for 100BASE-LX10 and 100BASE-BX10 is zero. A channel may contain additional connectors or other optical elements as long as the optical characteristics of the channel, such as attenuation, dispersion and reflections, meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

NOTE—In extreme cases with minimum length links (less than 2 m), care may be taken to avoid excess optical power delivered through cladding modes to the receiver.

58.9.2 Optical fiber and cable

The fiber optic cable requirements are satisfied by the fibers specified in IEC 60793-2, Types B1.1 (dispersion un-shifted single-mode) and B1.3 (low water peak single-mode) and ITU-T G.652, or by the requirements of Table 58–14 where they differ.

Table 58–14—Optical fiber and cable characteristics

Description[a]	B1.1, B1.3 SMF		Unit
Nominal fiber specification wavelength[b]	1310	1550	nm
Cabled optical fiber attenuation (max)[c]	0.4	0.35	dB/km
Zero dispersion wavelength (λ_0)[d]	$1300 \le \lambda_0 \le 1324$		nm
Dispersion slope (max) (S_0)	0.093		ps/nm^2km

[a]The fiber dispersion values are normative, all other values in the table are optional.
[b]Wavelength specified is the nominal fiber specification wavelength which is the typical measurement wavelength. Power penalties at other wavelengths are accounted for.
[c]Attenuation values are not mandatory requirements. Attenuation for single-mode optical fiber cables is defined in ITU-T G.652.
[d]See IEC 60793 or G.652 for correct use of zero dispersion wavelength and dispersion slope.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

58.9.3 Optical fiber connection

The maximum link distances for single-mode fiber are calculated based on an allocation of 2 dB total connection and splice loss. Connections with different loss characteristics may be used provided the requirements of Table 58–1 are met.

The maximum discrete reflectance of e.g., a connection or splice shall be less than –26 dB.

58.9.4 Medium Dependent Interface (MDI)

The 100BASE-LX10, 100BASE-BX10-D or 100BASE-BX10-U PMD is coupled to the fiber optic cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" (as shown in Figure 58–11). Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

The MDI carries the signal in both directions. For 100BASE-BX10 it couples a single fiber and for 100BASE-LX10 it couples dual fibers.

When the MDI is a remateable connection it shall meet the interface performance specifications of IEC 61753-1.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 58.2.1, not at the MDI.

58.10 Protocol implementation conformance statement (PICS) proforma for Clause 58, Physical Medium Dependent (PMD) sublayer and medium, type 100BASE-LX10 (Long Wavelength) and 100BASE-BX10 (Bi-Directional Long Wavelength)[112]

58.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 58, Physical Medium Dependent (PMD) sublayer and medium, type 100BASE-LX10 and 100BASE-BX10, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

58.10.2 Identification

58.10.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

58.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 58, Physical Medium Dependent (PMD) sublayer and medium, type 100BASE-LX10 and 100BASE-BX10
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

59. Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-LX10 (Long Wavelength) and 1000BASE-BX10 (Bi-Directional Long Wavelength)

59.1 Overview

The 1000BASE-LX10 and 1000BASE-BX10 PMD sublayers provide point-to-point (P2P) 1000BASE-X links over a pair of fibers or a single fiber, respectively, up to 10 km.

This clause specifies the 1000BASE-LX10 PMD for both single-mode and multimode fiber, and the 1000BASE-BX10 PMD for single-mode fiber. A PMD is connected to the 1000BASE-X PMA of 66.2, and to the medium through the MDI. A PMD is optionally combined with the management functions that may be accessible through the management interface defined in Clause 22 or by other means.

Table 59–1 shows the primary attributes of each PMD type.

Table 59–1—Classification of 1000BASE-LX10 and 1000BASE-BX10 PMDs

Description	1000BASE-LX10		1000BASE-BX10-D	1000BASE-BX10-U	Unit
Fiber type[a]	B1.1, B1.3 SMF	50, 62.5 µm MMF	B1.1, B1.3 SMF		
Number of fibers	2	2	1		
Typical transmit direction	N/A		Downstream	Upstream	
Nominal transmit wavelength	1310	1310	1490	1310	nm
Minimum range	0.5 m to 10 km	0.5 m to 550 m[b]	0.5 m to 10 km		
Maximum channel insertion loss[c]	6.0	2.4	5.5	6.0	dB

[a]Per IEC 60793-2.
[b]See Table 59–14 for fiber and cable characteristics.
[c]At the nominal operating wavelength.

A 1000BASE-LX10 link uses 1000BASE-LX10 PMDs at each end while a 1000BASE-BX10 link uses a 1000BASE-BX10-D PMD at one end and a 1000BASE-BX10-U PMD at the other. Typically the 1490 nm band is used to transmit away from the center of the network (“downstream”) and the 1310 nm band towards the center (“upstream”), although this arrangement, or the notion of hierarchy, is not required. The suffixes “D” and “U” indicate the PMDs at each end of a link that transmit in these directions and receive in the opposite directions.

1000BASE-LX10 is interoperable with 1000BASE-LX (see Clause 38). If used on single-mode fiber, operation is not ensured by this standard beyond the reach given in Table 38–6.

Two optional temperature ranges are defined; see 59.8.4 for further details. Implementations may be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

59.1.1 Goals and objectives

The following are the objectives of 1000BASE-LX10 and 1000BASE-BX10:

a) Point-to-point on optical fiber
b) 1000BASE-LX extended temperature range optics
c) 1000BASE-X up to 10km over SM fiber
d) BER better than or equal to 10^{-12} at the PHY service interface

59.1.2 Positioning of 1000BASE-LX10 and 1000BASE-BX10 PMDs within the IEEE 802.3 architecture

Figure 59–1 depicts the relationships of the PMD (shown shaded) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

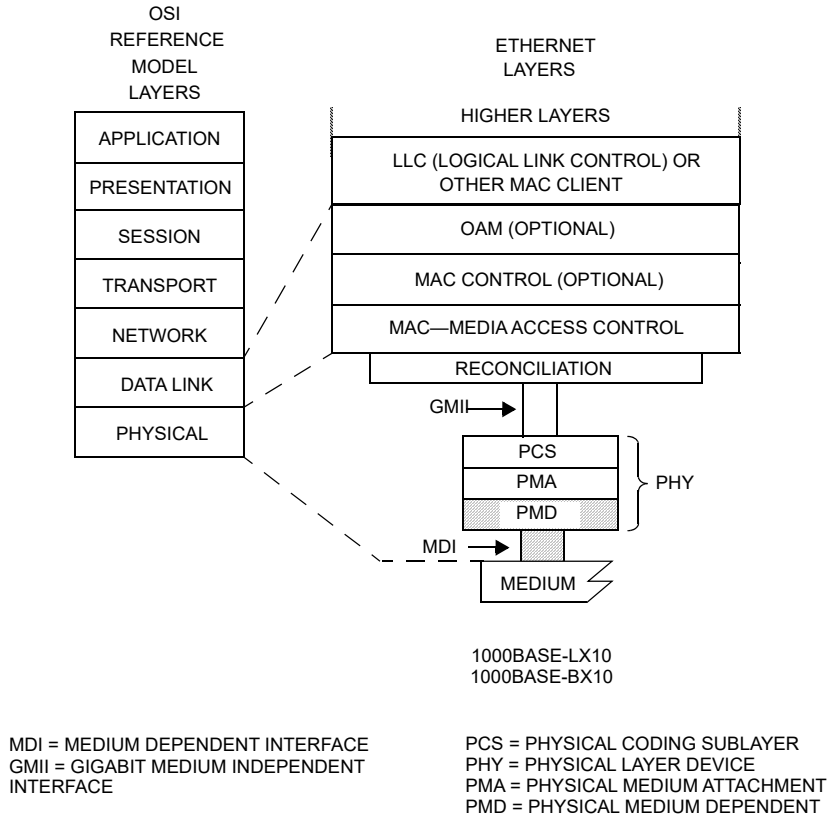

Figure 59–1—1000BASE-LX10 and 1000BASE-BX10 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

59.1.3 Terminology and conventions

The following list contains references to terminology and conventions used in this clause:

Basic terminology and conventions, see 1.1 and 1.2.

Normative references, see 1.3.

Definitions, see 1.4.

Abbreviations, see 1.5.

Informative references, see Annex A.

Introduction to 1000 Mb/s baseband networks, see Clause 34.

Introduction to Ethernet for subscriber access networks, see Clause 56.

59.1.4 Physical Medium Dependent (PMD) sublayer service interface

The following specifies the services provided by the 1000BASE-LX10 and 1000BASE-BX10 PMDs. These PMD sublayers are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded 8B/10B code-groups between the PMA and PMD entities. The PMD translates the serialized data of the PMA to and from signals suitable for the specified medium.

The following primitives are defined:

PMD_UNITDATA.request

PMD_UNITDATA.indication

PMD_SIGNAL.indication

59.1.5 Delay constraints

Delay requirements from the MDI to the GMII which include the PMD layer are specified in Clause 36. Of the budget, up to 20 ns is allocated for each of the transmit and receive functions of the PMD to account for those cases where the PMD includes a pigtail.

59.1.5.1 PMD_UNITDATA.request

This primitive defines the transfer of a serial data stream from the PMA to the PMD.

The semantics of the service primitive are PMD_UNITDATA.request(tx_bit). The data conveyed by PMD_UNITDATA.request is a continuous stream of bits where the tx_bit parameter can take one of two values: ONE or ZERO. The PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal 1.25 GBd signaling speed. Upon receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals at the MDI.

59.1.5.2 PMD_UNITDATA.indication

This primitive defines the transfer of data from the PMD to the PMA.

The semantics of the service primitive are PMD_UNITDATA.indication(rx_bit). The data conveyed by PMD_UNITDATA.indication is a continuous stream of bits where the rx_bit parameter can take one of two values: ONE or ZERO. The PMD continuously sends a stream of bits to the PMA corresponding to the signals received from the MDI.

59.1.5.3 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

The semantics of the service primitive are PMD_SIGNAL.indication(SIGNAL_DETECT). The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting light at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication(rx_bit) is undefined. The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT.

SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA.indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the specified bit error ratio.

59.2 PMD functional specifications

The 1000BASE-X PMDs perform the transmit and receive functions that convey data between the PMD service interface and the MDI.

59.2.1 PMD block diagram

The PMD sublayer is defined at the four reference points shown in Figure 59–2. Two points, TP2 and TP3, are compliance points. TP1 and TP4 are reference points for use by implementers. The optical transmit signal is defined at the output end of a patch cord (TP2), between 2 m and 5 m in length, of a fiber type consistent with the link type connected to the transmitter. If a single-mode fiber offset-launch mode-conditioning patch cord is used, the optical transmit signal is defined at the end of this single-mode fiber offset-launch mode-conditioning patch cord at TP2. Unless specified otherwise, all transmitter measurements and tests defined in 59.7 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) connected to the receiver. Unless specified otherwise, all receiver measurements and tests defined in 59.7 are made at TP3.

The electrical specifications of the PMD service interface (TP1 and TP4) are not system compliance points (these are not readily testable in a system implementation). It is expected that in many implementations, TP1 and TP4 will be common between 1000BASE-X PMD types.

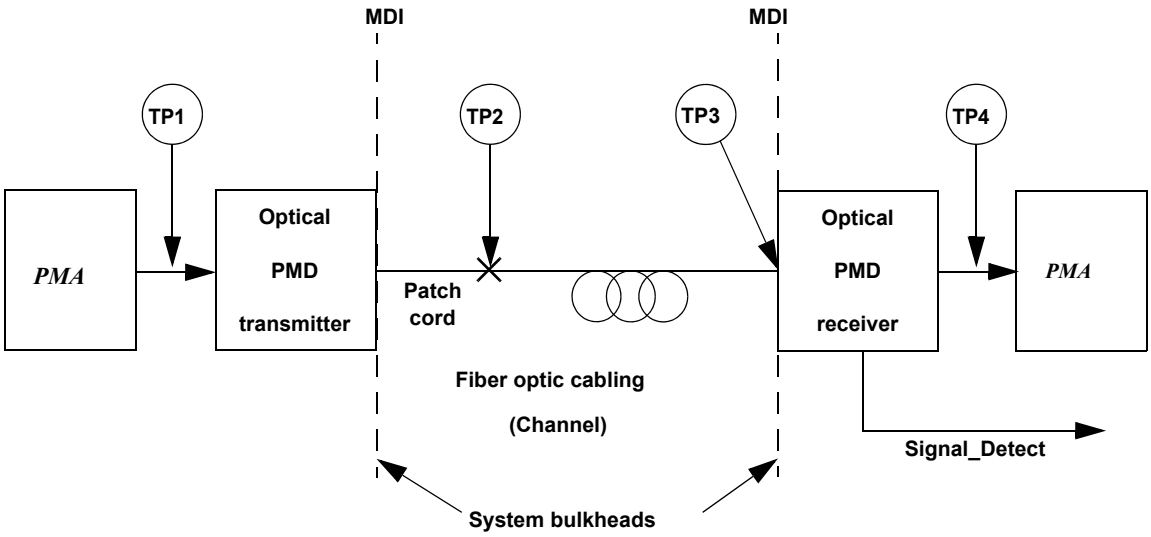

Figure 59–2—1000BASE-X block diagram

59.2.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the optical specifications in this clause. The higher optical power level shall correspond to tx_bit =ONE.

59.2.3 PMD receive function

The PMD receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher optical power level shall correspond to rx_bit =ONE.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

59.2.4 PMD signal detect function

The PMD signal detect function shall report to the PMD service interface using the message PMD_SIGNAL.indication(SIGNAL DETECT) which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 59–2. The PMD receiver is not required to verify whether a compliant 1000BASE-X signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the input optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD due to cross talk, power supply noise, etc.

Various implementations of the Signal Detect function are permitted by this standard, including implementations which generate the SIGNAL_DETECT parameter values in response to the amplitude of the 8B/10B modulation of the optical signal and implementations which respond to the average optical power of the 8B/10B modulated optical signal.

Table 59–2—1000BASE-LX10 and 1000BASE-BX10 SIGNAL_DETECT value definition

Receive conditions		Signal_detect value
1000BASE-LX10	**1000BASE-BX10**	
Average input optical power ≤ signal detect threshold (min) in Table 59–5	Average input optical power ≤ signal detect threshold (min) in Table 59–7	FAIL
Average input optical power ≥ receiver sensitivity (max) in Table 59–5 with a compliant 1000BASE-LX or 1000BASE-LX10 signal input	Average input optical power ≥ receiver sensitivity (max) in Table 59–7 with a compliant 1000BASE-BX10 signal input at the specified receiver wavelength	OK
All other conditions		Unspecified

59.3 PMD to MDI optical specifications for 1000BASE-LX10

The operating range for 1000BASE-LX10 is defined in Table 59–1. A 1000BASE-LX10 compliant transceiver operates over the media types listed in Table 59–1 according to the specifications described in 59.9. A transceiver that exceeds the operational range requirement while meeting all other optical specifications is considered compliant.

NOTE—In this subclause and Table 59–5, the specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is explained in 58.7.6.

59.3.1 Transmitter optical specifications

The 1000BASE-LX10 transmitter's signaling speed, operating wavelength, spectral width, average launch power, extinction ratio, return loss tolerance, OMA, eye and TDP shall meet the specifications defined in Table 59–3 per measurement techniques described in 59.7. Its $RIN_{12}OMA$ should meet the value listed in Table 59–3 per measurement techniques described in 58.7.7. To ensure that the specifications of Table 59–3 are met with MMF links, the 1000BASE-LX10 transmitter output shall be coupled through a single-mode fiber offset-launch mode-conditioning patch cord, as defined in 59.9.5.The maximum RMS spectral width vs. center wavelength for 1000BASE-LX10 is shown in Table 59–4 and Figure 59–3. The equation used to generate these values is included in 59.7.2. The values in bold are normative, the others optional.

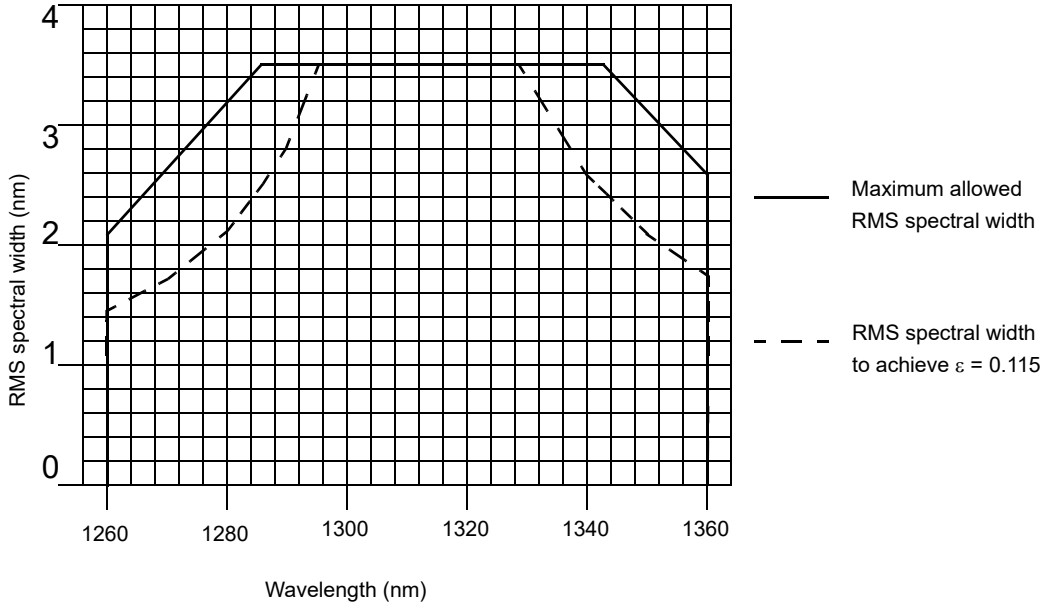

Figure 59–3—1000BASE-LX-10 Transmitter spectral limits

Table 59–3—1000BASE-LX10 transmit characteristics

Description	SMF	50 µm MMF	62.5 µm MMF	Unit
Nominal transmitter type[a]	Longwave Laser			
Signaling speed (range)	1.25 ± 100 ppm			GBd
Operating wavelength range[b]	1260 to 1360			nm
T rise /T fall (max, 20–80% response time)	0.30			ns
RMS spectral width (max)	See Table 59–4			nm
Average launch power (max)	–3			dBm
Average launch power (min)	–9	–11.0	–11.0	dBm
Average launch power of OFF transmitter (max)	–45			dBm
Extinction ratio (min)	6			dB
$RIN_{12}OMA$ (max)	–113			dB/Hz
Optical return loss tolerance (max)	12			dB
Launch OMA (min)	–8.7 (130)	–10.2 (100)	–10.2 (100)	dBm (µW)
Transmitter eye mask definition {X1, X2, Y1, Y2, Y3}	0.22, 0.375, 0.20, 0.20, 0.30			UI

Table 59–3—1000BASE-LX10 transmit characteristics *(continued)*

Description	SMF	50 µm MMF	62.5 µm MMF	Unit
Decision timing offsets for transmitter and dispersion penalty (min)	±80			ps
Transmitter reflectance (max)	–6			dB
Transmitter and dispersion penalty, TDP (max)	3.3	3.5		dB
Differential delay, reference receiver for TDP (min)[c]	NA	367		ps

[a]The nominal device type is not intended to be a requirement on the source type, and any device meeting the transmitter characteristics specified may be substituted for the nominal device type.
[b]The great majority of the transmitted spectrum has to fall within the operating wavelength range. The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.
[c]Delay is calculated as Td = L/(3.BWf) where BWf is defined to –3 dB (optical). 1000BASE-LX is rated for 550 m of 500 MHz.km fiber while 1000BASE-LX also covered 550 m of 400 MHz.km fiber, but this is now seen as a historical bandwidth requirement.

Table 59–4—1000BASE-LX10 and 1000BASE-BX10 transmitter spectral limits

Center wavelength	RMS spectral width (max)[a]	RMS spectral width to achieve ε ≤0.115 (optional)
nm	**nm**	**nm**
1260	**2.09**	1.43
1270	**2.52**	1.72
1280	**3.13**	2.14
1286	**3.50**	2.49
1290		2.80
1297		3.50
1329		
1340		2.59
1343		2.41
1350	**3.06**	2.09
1360	**2.58**	1.76
1480 to 1500	**0.88**	0.60

[a]These limits for the 1000BASE-LX10 transmitter are illustrated in Figure 59–3. Limits at intermediate wavelengths may be found by interpolation.

59.3.2 Receiver optical specifications

The 1000BASE-LX10 receiver's signaling speed, operating wavelength, damage, overload, sensitivity, stressed receive characteristics, reflectance, and signal detect shall meet the specifications defined in Table 59–5 per measurement techniques defined in 59.7.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 59–5—1000BASE-LX10 receive characteristics

Description	Value	Unit
Signaling speed (range)	1.25 ± 100 ppm	GBd
Wavelength (range)	1260 to 1360	nm
Average receive power (max)	–3	dBm
Receive sensitivity (max)	–19.5	dBm
Receiver sensitivity as OMA (max)	–18.7 (13.4)	dBm (μW)
Bit error ratio (max)	10^{-12}	
Receiver reflectance (max)[a]	–12	dB
Stressed receive sensitivity (max)	–15.4	dBm
Stressed receiver sensitivity as OMA (max)	–14.6 (35)	dBm (μW)
Vertical eye-closure penalty (min)	3.6	dB
Receive electrical 3 dB upper cutoff frequency (max)	1500	MHz
Signal detect threshold (min)	–45	dBm
Stressed eye jitter (min)[b]	0.3	UI pk-pk
Jitter corner frequency	637	kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	0.05, 0.15	UI

[a]See 1.4 for definition of reflectance.
[b]Vertical eye closure penalty and jitter specifications are test conditions for measuring stressed receiver sensitivity. They are not required characteristics of the receiver.

59.4 PMD to MDI optical specifications for 1000BASE-BX10-D and 1000BASE-BX10-U

The operating range for 1000BASE-BX10-D and 1000BASE-BX10-U is defined in Table 59–1. A 1000BASE-BX10 compliant transceiver operates over all single-mode fibers listed in Table 59–1. A transceiver that exceeds the operational range requirement while meeting all other optical specifications is considered compliant.

NOTE—In this subclause and 59.3, the specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is explained in 58.7.6.

59.4.1 Transmit optical specifications

The 1000BASE-BX10-D and 1000BASE-BX10-U transmitter's signaling speed, operating wavelength, spectral width, average launch power, extinction ratio, return loss tolerance, OMA, eye and TDP shall meet the specifications defined in Table 59–6 per measurement techniques described in 59.7. Its $RIN_{12}OMA$ should meet the value listed in Table 59–6 per measurement techniques described in 59.7.7.

Table 59–6—1000BASE-BX10-D and 1000BASE-BX10-U transmit characteristics

Description	1000BASE-BX10-D	1000BASE-BX10-U	Unit
Nominal transmitter type[a]	Longwave Laser		
Signaling speed (range)	1.25 ± 100 ppm		GBd
Operating wavelength range[b]	1480 to 1500	1260 to 1360	nm
RMS spectral width (max)	See Table 59–4		nm
Average launch power (max)	–3		dBm
Average launch power (min)	–9		dBm
Average launch power of OFF transmitter (max)	–45		dBm
Extinction ratio (min)	6		dB
$RIN_{12}OMA$ (max)	–113		dB/Hz
Optical return loss tolerance (max)	12		dB
Launch OMA	–8.2 (151)		dBm (μW)
Transmitter eye mask definition {X1, X2, Y1, Y2, Y3}	0.22, 0.375, 0.20, 0.20, 0.30		UI
Transmitter reflectance (max)	–10	–6	dB
Transmitter and dispersion penalty, TDP (max)	3.3		dB
Decision timing offsets for transmitter and dispersion penalty (min)	± 80		ps

[a]The nominal device type is not intended to be a requirement on the source type, and any device meeting the transmitter characteristics specified may be substituted for the nominal device type.

[b]The great majority of the transmitted spectrum has to fall within the operating wavelength range. The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

59.4.2 Receiver optical specifications

The 1000BASE-BX10-D and 1000BASE-BX10-U receiver's signaling speed, operating wavelength, damage, overload, sensitivity, reflectance and signal detect shall meet the specifications defined in Table 59–7 per measurement techniques defined in 59.7. Its stressed receive characteristics should meet the values listed in Table 59–7 per measurement techniques described in 59.7.11.

Table 59–7—1000BASE-BX10-D and 1000BASE-BX10-U receive characteristics

Description	1000BASE-BX10-D	1000BASE-BX10-U	Unit
Signaling speed (range)	1.25 ± 100 ppm		GBd
Wavelength (range)	1260 to 1360	1480 to 1500	nm
Bit error ratio (max)	10^{-12}		
Average receive power (max)	–3		dBm
Receive sensitivity (max)	–19.5		dBm
Receiver sensitivity as OMA (max)	–18.7 (13.4)		dBm (μW)
Receiver reflectance (max)	–12		dB
Stressed receive sensitivity (max)[a]	–15.4		dBm
Stressed receiver sensitivity as OMA (max)	–14.6 (35)		dBm (μW)
Vertical eye-closure penalty (min)[b]	2.6		dB
Receive electrical 3 dB upper cutoff frequency (max)	1500		MHz
Signal detect threshold (min)	–45		dBm
Stressed eye jitter (min)	0.3		UI pk-pk
Jitter corner frequency	637		kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	0.05, 0.15		UI

[a]The stressed receiver sensitivity is optional.
[b]Vertical eye closure penalty and jitter specifications are test conditions for measuring stressed receiver sensitivity. They are not required characteristics of the receiver.

59.5 Illustrative 1000BASE-LX10 and 1000BASE-BX10 channels and penalties

The illustrative channel and penalties for 1000BASE-LX10 and 1000BASE-BX10 PMDs are shown in Table 59–8.

NOTE—The budgets include an allowance for –12 dB reflection at the receiver.

59.6 Jitter specifications

Informative jitter specifications are described in 59A.1.

59.7 Optical measurement requirements

All optical measurements, except TDP and RIN, shall be made through a short patch cable, between 2 m and 5 m in length.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 59–8—Illustrative 1000BASE-LX10 and 1000BASE-BX10 channel and penalties

PMD type	1000BASE-LX10		1000BASE-BX10-D	1000BASE-BX10-U	Unit
Fiber type	B1.1, B1.3 SMF	50µm, 62.5µm MMF	B1.1, B1.3 SMF		
Measurement wavelength for fiber	1310	1300	1550	1310	nm
Nominal distance	10	0.55	10		km
Available power budget	10.5	8.5	10.5		dB
Maximum channel insertion loss[a]	6.0	2.4	5.5	6.0	dB
Allocation for penalties[b]	4.5	6.1	5.0	4.5	dB

[a]The maximum channel insertion loss is based on the cable attenuation at the target distance and nominal measurement wavelength. The channel insertion loss also includes the loss for connectors, splices and other passive components.

[b]The allocation for penalties is the difference between the available power budget and the channel insertion loss; insertion loss difference between nominal and worst-case operating wavelength is considered a penalty.

The following sections describe definitive patterns and test procedures for certain PMDs of this standard. implementers using alternative verification methods need to ensure adequate correlation and allow adequate margin such that specifications are met by reference to the definitive methods.

59.7.1 Test patterns

The frame-based test patterns defined here are suitable for testing all Clause 59 and Clause 60 PMDs. Further information on frame-based testing in included in Annex 58A. The test suite and the patterns are shown in Table 59–9.

Table 59–9—List of test patterns and tests

Test pattern	Tests	Related subclauses
Any valid 8B/10B encoded signal	Eye mask Optical power Central wavelength Spectral width	59.7.8 59.7.3 59.7.2 59.7.2
Idles	Extinction ratio $RIN_{12}OMA$ OMA	59.7.4 59.7.7
Random pattern test frame	Receiver sensitivity Stressed receiver sensitivity Receiver 3dB upper cutoff frequency TDP	59.7.11 59.7.14 59.7.15 59.7.10
Jitter pattern test frame	All jitter tests	59.7.12

The following test patterns are intended for frame-based testing of the 1000BASE-X PMDs of Clause 59 and Clause 60. They are compliant Ethernet packets with adequate user defined fields to allow them to be routed through a system to the point of the test. The common portions of the frames are given in Table 59–10.

NOTE—Users are advised to take care that the system under test is not connected to a network in service.

Two payloads are defined. The first, which emulates a random pattern with broad spectral content and minimal peaking, is shown in Table 59–11.

Source address	6	User defined	User defined	User defined
Length/Type	2	User defined	User defined	User defined
First portion of MAC client data	32	User defined	User defined	User defined
Second portion of MAC client data	456	See Table 59–11 or Table 59–12	See Table 59–11 or Table 59–12	See Table 59–11 or Table 59–12
Frame check sequence[d]	4	As required by frame	As required by frame	As required by frame
EPD (/T/R/)[e]	2	N/A[b]	010001 0111 000101 0111	101110 1000 111010 1000
Idle (/I1/ or /I2/)[e]	2	N/A[b]	110000 0101 101001 0110	001111 1010 100100 0101
Idle (/I2/)[e]	10	N/A[b]	N/A[f]	001111 1010 100100 0101

[a]The binary bits are transmitted left most bit first.
[b]The SPD, EPD, and Idle code-groups are generated by the PCS and their hexadecimal octet values have no meaning without relation to the signals transmitted across the GMII.
[c]Except when operating in a half-duplex mode, it is not possible to transmit an SPD with a positive starting disparity. The first code-group that could begin with a positive running disparity would be the second octet of the destination address.
[d]The frame check sequence may be calculated using the method described in 3.2.9.
[e]The first row precedes the second row.
[f]The first idle code-group following the frame will be an /I1/ if the running disparity is positive and an /I2/ if the running disparity is negative. All subsequent idle code-groups will be /I2/.

Table 59–11—Payload for random pattern test frame

Number of octets	Hexadecimal	8B/10B encoded binary	
		Starting disparity +	Starting disparity –

Phase Jump, Repeat 4 times for 8 bytes	EB	110100 1110	110100 1000
	F4	001011 0001	001011 0111
Low Transition Density, Repeat 96 times for 192 bytes	7E	011110 0011	100001 1100
	7E	100001 1100	011110 0011
Phase Jump, Repeat one time for 8 bytes	F4	001011 0111	001011 0001
	EB	110100 1000	110100 1110
	F4	001011 0111	001011 0001
	EB	110100 1000	110100 1110
	F4	001011 0111	001011 0001
	EB	110100 1000	110100 1110
	F4	001011 0111	001011 0001
	AB	110100 1010	110100 1010
High Transition Density, Repeat 20 times for 20 bytes	B5	101010 1010	101010 1010
Phase Jump, Repeat 4 times for 8 bytes	EB	110100 1000	110100 1110
	F4	001011 0111	001011 0001

This pattern has areas of high and low transition density to aggravate jitter susceptibility.

Frames are separated by a near minimum interpacket gap (IPG) of 14 octets.

59.7.2 Wavelength and spectral width measurements

The wavelength and spectral width (RMS) shall meet the specifications according to the centroidal wavelength and RMS spectral width definitions in IEC 61280-1-3, under modulated conditions using a valid 1000BASE-X signal.

NOTE 1—The great majority of the transmitted spectrum has to fall within the operating range. The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.

NOTE 2—The 20 dB width for SLM lasers is taken as 6.07 times the RMS width.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The interaction between the transmitter and the chromatic dispersion of the fiber is accounted for by a parameter ε (epsilon), which is defined as the product of 10^{-3} times the signaling speed (in GBd) times the path dispersion (in ps/nm) times the RMS spectral width (in nm).

$$\varepsilon = \text{dispersion} \times \text{length} \times \text{RMS spectral width} \times \text{signaling speed} \times 10^{-3} \quad (0–1)$$

A maximum ε close to 0.168 is imposed by column 2 of Table 59–5. If the spectral width is kept below the limits of column 3, ε will not exceed 0.115, and the chromatic dispersion penalty is expected to be below 2 dB. The chromatic dispersion penalty is a component of transmitter and dispersion penalty (TDP) which is specified in Table 59–3, Table 59–6 and described in 58.7.9.

59.7.3 Optical power measurements

Optical power shall meet specifications according to the methods specified in ANSI/TIA/EIA-455-95. A measurement may be made with the port transmitting any valid encoded 8B/10B data stream.

59.7.4 Extinction ratio measurements

Extinction ratio shall meet specifications according to IEC 61280-2-2 with the port transmitting a repeating idle pattern /I2/ ordered set (see 36.2.4.12) that may be interspersed with OAM packets per 57A.2, and with minimal back reflections into the transmitter, lower than –20 dB. The /I2/ ordered set is defined in Clause 36, and is coded as /K28.5/D16.2/, which is binary 001111 1010 100100 0101 within idles. The extinction ratio is expected to be similar for other valid 8B/10B bit streams. The test receiver has the frequency response as specified for the transmitter optical waveform measurement.

59.7.5 OMA measurements (optional)

58.7.5 provides a reference technique for performing OMA measurements.

59.7.6 OMA relationship to extinction ratio and power measurements

Annex 58B provides information on how OMA, extinction ratio, and mean power, are related to each other (see 58B.2).

59.7.7 Relative intensity noise optical modulation amplitude ($RIN_{12}OMA$)

$RIN_{12}OMA$ is the ratio of noise to modulated optical signal in the presence of a back reflection. The measurement procedure is described in 58.7.7.

59.7.8 Transmitter optical waveform (transmit eye)

The required transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 59–4.

The measurement procedure is described in 58.7.8 and references therein.

The eye shall comply to the mask of the eye using a fourth-order Bessel-Thomson receiver response with f_r= 0.9375 GHz, and where the relative response vs. relative frequency is defined in ITU-T G.957, Table B.2 (STM-16 values), along with the allowed tolerances for its physical implementation.

NOTE 1—This Bessel-Thomson filter is not intended to represent the noise filter used within an optical receiver, but is intended to provide uniform measurement conditions on the transmitter.

NOTE 2—The fourth-order Bessel-Thomson filter is reactive. In order to suppress reflections, a 6 dB attenuator may be required at the filter input and/or output.

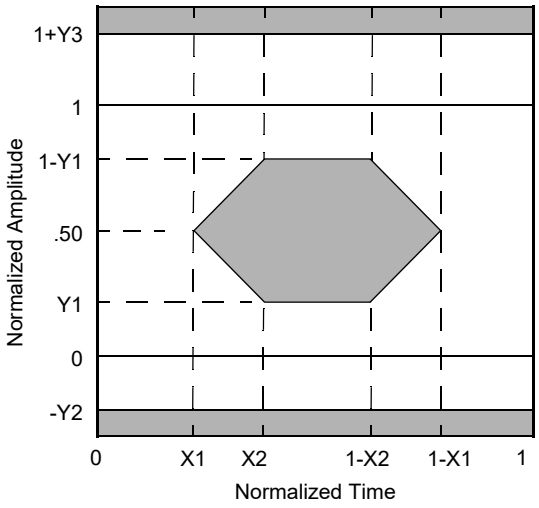

Figure 59–4—Transmitter eye mask definition

59.7.9 Transmit rise/fall characteristics

Optical response time specifications are based on unfiltered waveforms. Some lasers have overshoot and ringing on the optical waveforms, which, if unfiltered, reduce the accuracy of the 20–80% response times. For the purpose of standardizing the measurement method, measured waveforms shall conform to the mask defined in 59.7.8. If a filter is needed to conform to the mask, the filter response should be removed using Equation (0–2):

$$T_{\text{rise, fall}} = \sqrt{(T_{\text{rise, fall, measured}})^2 - (T_{\text{rise, fall, filter}})^2} \quad (0–2)$$

where the filter may be different for rise and fall. Any filter should have an impulse response equivalent to a fourth-order Bessel-Thomson filter. The fourth-order Bessel-Thomson filter describe in 59.7.8 may be a convenient filter for this measurement, however its low bandwidth adversely impacts the accuracy of the rise and fall time measurements.

59.7.10 Transmitter and dispersion penalty (TDP)

This measurement tests for transmitter impairments with modal (not chromatic) dispersion effects for a transmitter to be used with multimode fiber, and for transmitter impairments with chromatic effects for a transmitter to be used with single-mode fiber. Possible causes of impairment include intersymbol interference, jitter, RIN and mode partition noise. Meeting the separate requirements (e.g., eye mask, spectral characteristics) does not in itself guarantee the transmitter and dispersion penalty (TDP). The TDP limit shall be met. See 59.7.9 for details of the measurement.

59.7.11 Receive sensitivity measurements

Receiver sensitivity is defined for the random pattern test frame (see 59.7.1) and an ideal input signal quality with the specified extinction ratio. The measurement procedure is described in 58.7.10. The sensitivity shall be met for the bit error ratio defined in Table 59–5 or Table 59–7 as appropriate. Stressed sensitivity is described in 59.7.14 and 58.7.11.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

59.7.12 Total jitter measurements

Total jitter measurements are informatively described in 59A.2.

59.7.13 Deterministic or high probability jitter measurement

Deterministic or high probability jitter measurement is informatively described in 59A.3.

59.7.14 Stressed receiver conformance test

The stressed receiver conformance test is intended to screen against receivers with poor frequency response or timing characteristics which could cause errors when combined with a distorted but compliant signal at TP3. Modal (MMF) or chromatic (SMF) dispersion can cause distortion. The conformance test signal uses the random pattern test frame and is conditioned by applying deterministic jitter and intersymbol interference. If the option for stressed receiver compliance is chosen, the receiver shall meet the specified bit error ratio at the power level and signal quality defined in Table 59–5 and Table 59–7 as appropriate, according to the measurement procedures of 58.7.11.

59.7.15 Measurement of the receiver 3 dB electrical upper cutoff frequency

The receiver 3 dB electrical upper cutoff frequency shall meet specifications according to the methods specified below. The test setup is shown in Figure 59–5. The test is performed with a laser that is suitable for analog signal transmission. The laser is modulated by a digital data signal. In addition to the digital modulation, the laser is modulated with an analog signal. The analog and digital signals should be asynchronous. The data pattern to be used for this test is the random pattern test frame defined in 59.7.1. The frequency response of the laser needs to be sufficient to allow it to respond to both the digital modulation and the analog modulation. The laser should be biased so that it remains linear when driven by the combined signals. Alternatively the two signals may be combined in the optical domain.

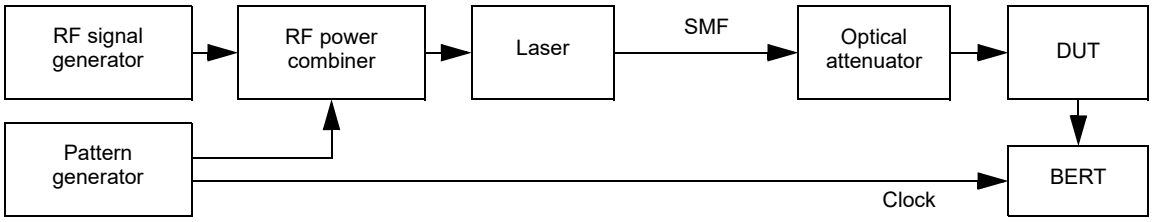

Figure 59–5—Test setup for receiver bandwidth measurement

The 3 dB upper cutoff frequency is measured using the following steps a) through e):

a) Calibrate the frequency response characteristics of the test equipment including the analog radio frequency (RF) signal generator, RF power combiner, and laser source. Measure the laser's extinction ratio according to 59.7.4. With the exception of extinction ratio, the optical source shall meet the requirements of Clause 59.
b) Configure the test equipment as shown in Figure 59–5. Take care to minimize changes to the signal path that could affect the system frequency response after the calibration in step a. Connect the laser output with no RF modulation applied to the receiver under test through an optical attenuator and taking into account the extinction ratio of the source, set the optical power to a level that approximates the stressed receive sensitivity level in Table 59–5 for 1000BASE-LX10 and in Table 59–7 for 1000BASE-BX10.
c) Locate the center of the eye with the BERT. Turn on the RF modulation while maintaining the same average optical power established in step b).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

d) Measure the necessary RF modulation amplitude (in dBm) required to achieve a constant BER (e.g., 10^{-8}) for a number of frequencies.
e) The receiver 3 dB electrical upper cutoff frequency is that frequency where the corrected RF modulation amplitude (the measured amplitude in step d) corrected with the calibration data in step a) increases by 3 dB (electrical). If necessary, interpolate between the measured response values.

59.8 Environmental, safety, and labeling specifications

59.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

59.8.2 Laser safety

1000BASE-BX10 and 1000BASE-LX10 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore. Conformance to additional laser safety standards may be required for operation within specific geographical regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance and service. This documentation shall explicitly define requirements and usage restrictions on the host system necessary to meet these safety certifications.

59.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulations, be followed in every instance in which such practices are applicable.

59.8.4 Environment

Reference Annex 67A for additional environmental information.

Two optional temperature ranges are defined in Table 59–13. Implementations shall be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

Table 59–13—Component case temperature classes

Class	Low temperature (°C)	High temperature (°C)
Warm extended	–5	+85
Cool extended	–40	+60
Universal extended	–40	+85

59.8.5 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 1000BASE-BX10-U).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 59.8.2.

Compliant systems and field pluggable components shall be clearly labeled with the operating temperature range over which their compliance is ensured.

59.9 Characteristics of the fiber optic cabling

The 1000BASE-BX10 and 1000BASE-LX10 fiber optic cabling shall meet the dispersion and modal bandwidth specifications defined in IEC 60793-2 and ITU-T G.652, or the requirements of Table 59–14 where they differ. The fiber cable attenuation is shown for information only; the end-to-end channel loss shall meet the requirements of Table 59–1. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. The fiber optic cabling spans from one MDI to another MDI, as shown in Figure 59–6.

59.9.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 59–6.

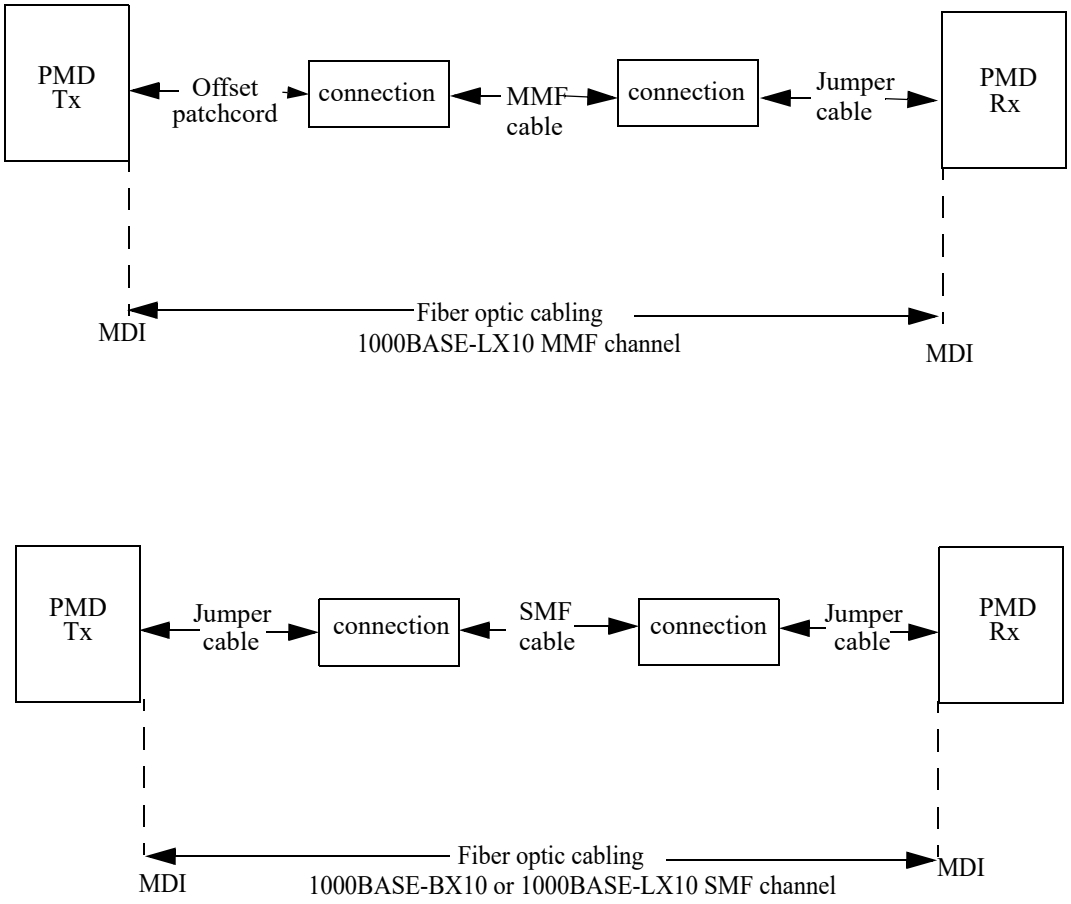

Figure 59–6—Fiber optic cable model

The maximum channel insertion loss shall meet the requirements specified in Table 59–1. The minimum loss for 1000BASE-BX10 and 100BASE-LX10 is zero. A channel may contain additional connectors or

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

other optical elements as long as the optical characteristics of the channel, such as attenuation, dispersion and reflections, meet the specifications. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-1 one-cord method for multimode cabling and IEC 61280-4-2 one-cord reference method for single-mode cabling. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

59.9.2 Optical fiber and cable

The fiber optic cable requirements are satisfied by the fibers specified in IEC 60793-2 Type B1.1 (dispersion un-shifted single-mode fiber) and Type B1.3 (low water peak single-mode fiber) and ITU-T G.652, or by the requirements of Table 59–14 where they differ.

Table 59–14—Optical fiber and cable characteristics

Description[a]	B1.1, B1.3 SMF		50 µm MMF	62.5 µm MMF	Unit
Nominal fiber specification wavelength[b]	1310	1550	1300		nm
Cabled optical fiber attenuation (max)[c]	0.4	0.35	1.5		dB/km
Modal Bandwidth (min; overfilled launch)	N/A		500[d]		MHz· km
Zero dispersion wavelength[e]	$1300 \le \lambda_0 \le 1324$		$1295 \le \lambda_0 \le 1320$	$1320 \le \lambda_0 \le 1365$	nm
Dispersion slope (max)	0.093		0.11 for $1300 \le \lambda_0 \le 1320$ and $0.001(\lambda_0\text{-}1190)$ for $1295 \le \lambda_0 \le 1300$	0.11 for $1320 \le \lambda_0 \le 1348$ and $0.001(1458\text{-}\lambda_0)$ for $1348 \le \lambda_0 \le 1365$	ps /nm^2 · km

[a]The fiber dispersion values are normative, all other values in the table are optional.
[b]The wavelength specified is the nominal fiber specification wavelength which is the typical measurement wavelength. Power penalties at other wavelengths are accounted for.
[c]Attenuation values are optional. Attenuation for single-mode optical fiber cables is defined in ITU-T G.652 and for multimode fiber cables is defined in ISO/IEC 11801.
[d]1000BASE-LX10 is rated for 550 m of 500 MHz·km fiber, while 1000BASE-LX also covered 550 m of 400 MHz·km, but this now seen as a historical bandwidth requirement.
[e]See IEC 60793 or G.652 for correct use of zero dispersion wavelength and dispersion slope.

59.9.3 Optical fiber connection

The maximum link distances for multimode fiber are calculated based on the allocation of 1.5 dB total connection and splice loss. Connections with different loss characteristics may be used provided the requirements of Table 59–1 are met.

The maximum link distances for single-mode fiber are calculated based on the allocation of 2 dB total connection and splice loss for 1000BASE-LX10 and 1000BASE-BX10. Connections with different loss characteristics may be used provided the requirements of Table 59–1 are met.

The maximum discrete reflectance for multimode connections shall be less than –20 dB.

The maximum discrete reflectance for single-mode connections shall be less than –26 dB.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

59.9.4 Medium Dependent Interface (MDI)

The 1000BASE-LX10 or 1000BASE-BX10 PMD is coupled to the fiber cabling at the MDI. The MDI is the interface between the PMD and the "fiber optic cabling" as shown in Figure 59–6. Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a remateable connection, it shall meet the interface performance specifications of IEC 61753-1. The MDI carries the signal in both directions. For 1000BASE-BX10 it couples a single fiber and for 1000BASE-LX10 it couples dual fibers.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 59.2.1, not at the MDI.

59.9.5 Single-mode fiber offset-launch mode-conditioning patch cord for MMF operation of 1000BASE-LX10

This subclause specifies an example embodiment of a mode conditioner for 1000BASE-LX10 operation with MMF cabling. The mode conditioner consists of a single-mode fiber permanently coupled off-center to a graded index fiber. This example embodiment of a patch cord is not intended to exclude other physical implementations of offset-launch mode conditioners. However, any implementation of an offset-launch mode conditioner used for 1000BASE-LX10 shall meet the specifications of Table 59–15. The offset launch shall be contained within the patch cord assembly and is not adjustable by the user.

NOTE—The single-mode fiber offset-launch mode-conditioning patch cord described in Clause 38 may be used, although its labeling and coloring requirements are not mandatory here. See 38.11.4.

Table 59–15—Single-mode fiber offset-launch mode conditioner specifications

Description	62.5 μm MMF	50 μm MMF	Unit
Maximum insertion loss	0.5	0.5	dB
Coupled power ratio (CPR)	28 < CPR < 40	12 < CPR < 20	dB
Optical center offset between SMF and MMF	17 < Offset < 23	10 < Offset < 16	μm
Maximum angular offset	1	1	degree

Patch cord connectors and ferrules for the single-mode-to-multimode offset launch shall have single-mode tolerances, float, and other mechanical requirements according to IEC 61754-1.

The single-mode fiber used in the construction of the single-mode fiber offset-launch mode conditioner shall meet the requirements of 59.9.2. The multimode fiber used in the construction of the single-mode fiber offset-launch mode conditioner shall be of the same type as the cabling over which the 1000BASE-LX10 link is to be operated. If the cabling is 62.5 μm MMF then the MMF used in the construction of the mode conditioner is of type 62.5 μm MMF. If the cabling is 50 μm MMF, then the MMF used in the construction of the mode conditioner is of type 50 μm MMF.

Figure 59–7 shows an example of an embodiment of the single-mode fiber offset-launch mode-conditioning patch cord. This patch cord consists of duplex fibers including a single-mode-to-multimode offset launch fiber connected to the transmitter MDI and a second conventional graded index MMF connected to the receiver MDI. The preferred configuration is a plug-to-plug patch cord since it maximizes the power budget margin of the 1000BASE-LX10 link. The single-mode end of the patch cord is labeled "To Equipment". The multimode end of the patch cord is labeled "To Cable". The recommended color identifier of the single-mode fiber connector is blue. The recommended color identifier of all multimode fiber connector plugs is

beige. The patch cord assembly is labeled “Offset-launch mode-conditioning patch cord assembly”. Labeling identifies which size multimode fiber is used in the construction of the patch cord. The keying of this duplex optical plug ensures that the single-mode fiber end is automatically aligned to the transmitter MDI.

59.10 Protocol implementation conformance statement (PICS) proforma for Clause 59, Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-LX10 (Long Wavelength) and 1000BASE-BX10 (Bi-Directional Long Wavelength)[113]

59.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 59, Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-LX10 and type 1000BASE-LX10, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

59.10.2 Identification

59.10.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1, 3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

59.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 59, Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-LX10 and 1000BASE-BX10
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[113] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

59.10.3.2 PMD to MDI optical specifications for 1000BASE-LX10

Item	Feature	Subclause	Value/Comment	Status	Support
LX1	1000BASE-LX10 transmitter	59.3.1	Transmitter meets specifications in Table 59–3.	LX:M	Yes [ ] N/A [ ]
LX2	Offset-launch mode-conditioning patch cord	59.3.1	Required for LX10 multimode operation.	OFP:M	Yes [ ] N/A [ ]
LX3	1000BASE-LX10 receiver	59.3.2	Receiver meets mandatory specifications in Table 59–5.	LX:M	Yes [ ] N/A [ ]
LX4	1000BASE-LX10 stressed receiver sensitivity	59.3.2	Receiver meets mandatory specifications in Table 59–5.	LX:M	Yes [ ] N/A [ ]

59.10.3.3 PMD to MDI optical specifications for 1000BASE-BX10-D

Item	Feature	Subclause	Value/Comment	Status	Support
BXD1	1000BASE-BX10-D transmitter	59.4.1	Transmitter meets specifications in Table 59–6.	BXD:M	Yes [ ] N/A [ ]
BXD2	1000BASE-BX10-D receiver	59.4.2	Receiver meets mandatory specifications in Table 59–7.	BXD:M	Yes [ ] N/A [ ]
BXD3	1000BASE-BX10-D stressed receiver sensitivity	59.4.2	Receiver meets specifications in Table 59–7.	BXD:O	Yes [ ] No [ ] N/A [ ]

59.10.3.4 PMD to MDI optical specifications for 1000BASE-BX10-U

Item	Feature	Subclause	Value/Comment	Status	Support
BXU1	1000BASE-BX10-U transmitter	59.4.1	Transmitter meets specifications in Table 59–6.	BXU:M	Yes [ ] N/A [ ]
BXU2	1000BASE-BX10-U receiver	59.4.2	Receiver meets mandatory specifications in Table 59–7.	BXU:M	Yes [ ] N/A [ ]
BXU3	1000BASE-BX10-U stressed receiver sensitivity	59.4.2	Receiver meets specifications in Table 59–7.	BXU:O	Yes [ ] No [ ] N/A [ ]

59.10.3.5 Optical Measurement requirements

Item	Feature	Subclause	Value/Comment	Status	Support
OM1	Measurement cable		2 m to 5 m in length.	M	Yes [ ]
OM2	Test patterns	59.7.1	See Table 59–9.	M	Yes [ ]
OM3	Wavelength and spectral width	59.7.2	Per the centroidal wavelength and RMS spectral width definitions in IEC 61280-1-3 under modulated conditions.	M	Yes [ ]
OM4	Average optical power	59.7.3	Per ANSI/TIA/EIA-455-95.	M	Yes [ ]
OM5	Extinction ratio	59.7.4	Per IEC 61280-2-2 with minimal back reflections and fourth-order Bessel-Thomson receiver.	M	Yes [ ]
OM6	$RIN_{12}OMA$	58.7.7	As described in 58.7.7.	M	Yes [ ]
OM7	Transmit optical waveform (transmit eye)	59.7.8	Per ANSI/TIA/EIA-526-4A with test pattern and fourth-order Bessel-Thomson receiver.	M	Yes [ ]
OM8	Transmit rise/fall characteristics	59.7.9	Waveforms conform to mask in Figure 59–4, measure from 20% to 80%, using patch cable per 59.7.	LX:M	Yes [ ]
OM9	Transmitter and dispersion penalty	59.7.10	As described in 58.7.9.	M	Yes [ ]
OM10	Receive sensitivity	59.7.11	With specified pattern.	M	Yes [ ]
*OM11	Stressed receiver conformance	59.7.14	As described in 59.7.14.	O	Yes [ ] N/A[ ]
OM12	Receiver 3dB electrical upper cutoff frequency	59.7.15	As described in 59.7.15.	M	Yes [ ]

59.10.3.6 Environmental, safety, and labeling specifications

Item	Feature	Subclause	Value/Comment	Status	Support
ES1	General safety	59.8.1	Conforms to J.2.	M	Yes [ ]
ES2	Laser safety—IEC Hazard Level 1	59.8.2	Conform to Hazard Level 1 laser requirements defined in IEC 60825-1 and IEC 60825-2.	M	Yes [ ]
ES3	Documentation	59.8.2	Explicitly define requirements and usage restrictions to meet safety certifications.	M	Yes [ ]
ES4	Operating temperature range labeling	59.8.5	If required, label range over which compliance is ensured.	M	Yes [ ] N/A[ ]

59.10.3.7 Characteristics of the fiber optic cabling

Item	Feature	Subclause	Value/Comment	Status	Support
FO1	Fiber optic cabling	59.9	Meets specifications in Table 59–14.	INS:M	Yes [ ] N/A [ ]
FO2	End-to-end channel loss	59.9.1	Meet the requirements specified in Table 59–1.	INS:M	Yes [ ] N/A [ ]
FO3	Maximum discrete reflectance for multimode connections	59.9.3	Less than –20 dB.	INS:M	Yes [ ] N/A [ ]
FO4	Maximum discrete reflectance for single-mode connections	59.9.3	Less than –26 dB.	INS:M	Yes [ ] N/A [ ]
FO5	MDI requirements	59.9.4	Meet the interface performance specifications of IEC 61753-1, if remateable.	INS:O	Yes [ ] No[ ] N/A [ ]

59.10.3.8 Offset-launch mode-conditioning patch cord

Item	Feature	Subclause	Value/Comment	Status	Support
LPC1	Offset-launch mode-conditioning patch cord	59.9.5	Meet conditions of 59.9.5.	OFP:M	Yes [ ] N/A [ ]
LPC2	Single-mode mechanics in offset-launch mode-conditioning patch cords	59.9.5	IEC 61754-1:1997 [B33] grade 1 ferrule.	OFP:M	Yes [ ] N/A [ ]
LPC3	Single-mode fiber in offset-launch mode-conditioning patch cords	59.9.5	Per 59.9.5.	OFP:M	Yes [ ] N/A [ ]
LPC4	Multimode fiber in offset-launch mode-conditioning patch cords	59.9.5	Same type as used in cable plant.	OFP:M	Yes [ ] N/A [ ]

60. Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-PX (long wavelength passive optical networks)

60.1 Overview

The 1000BASE-PX10, 1000BASE-PX20, 1000BASE-PX30, and 1000BASE-PX40 PMD sublayers provide point-to-multipoint (P2MP) 1000BASE-X connections over passive optical networks (PONs). The 1000BASE-PX10 PMD sublayers support a reach of at least 10 km whereas the 1000BASE-PX20, 1000BASE-PX30, and 1000BASE-PX40 PMD sublayers support a reach of at least 20 km. The 1000BASE-PX10 and 1000BASE-PX20 PMD sublayers support a typical split ratio of 1:16. The 1000BASE-PX30 PMD sublayers support a typical split ratio of 1:32. The 1000BASE-PX40 PMD sublayers support a typical split ratio of 1:64. In an Ethernet PON, a single downstream (D) PMD broadcasts to multiple upstream (U) PMDs and receives bursts from each "U" PMD over a single branched topology, single-mode fiber network. The same fibers are used simultaneously in both directions. This clause specifies a single-mode fiber medium and the following PMDs (including MDI): 1000BASE-PX10-D, 1000BASE-PX10-U, 1000BASE-PX20-D, 1000BASE-PX20-U, 1000BASE-PX30-D, 1000BASE-PX30-U, 1000BASE-PX40-D, and 1000BASE-PX40-U. A 1000BASE-PX-U PMD or a 1000BASE-PX-D PMD is connected to the appropriate 1000BASE-X PMA of Clause 65, and to the medium through the MDI. A PMD is optionally combined with the management functions that may be accessible through the management interface defined in Clause 22 or by other means.

A 1000BASE-PX10 link uses a 1000BASE-PX10-U PMD at one end and a 1000BASE-PX10-D PMD at the other. A 1000BASE-PX20 link uses a 1000BASE-PX20-U PMD at one end and a 1000BASE-PX20-D PMD at the other. A 1000BASE-PX30 link uses a 1000BASE-PX30-U PMD at one end and a 1000BASE-PX30-D PMD at the other. A 1000BASE-PX40 link uses a 1000BASE-PX40-U PMD at one end and a 1000BASE-PX40-D PMD at the other. A 1000BASE-PX20-D PMD is interoperable with a 1000BASE-PX10-U PMD. This allows certain upgrade possibilities from 10 km to 20 km PONs.

Two optional temperature ranges are defined; see 60.10.4 for further details. Implementations may be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

Table 60–1 shows the primary attributes of each PMD type.

60.1.1 Goals and objectives

All 1000BASE-PX PMDs share the objectives of:

a) Point-to-multipoint on optical fiber.
b) BER better than or equal to 10^{-12} at the PHY service interface.
c) 1000 Mb/s on one single-mode fiber.

1000BASE-PX10 has an objective of operating at the distance of at least of 10 km and at a split ratio of at least of 1:16. 1000BASE-PX20 has an objective of operating at the distance of at least of 20 km and at a split ratio of at least of 1:16. 1000BASE-PX30 has an objective of operating at the distance of at least of 20 km and at a split ratio of at least of 1:32. 1000BASE-PX40 has an objective of operating at the distance of at least of 20 km and at a split ratio of at least of 1:64.

60.1.2 Positioning of this PMD set within the IEEE 802.3 architecture

Figure 60–1 depicts the relationships of the PMD (shown shaded) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

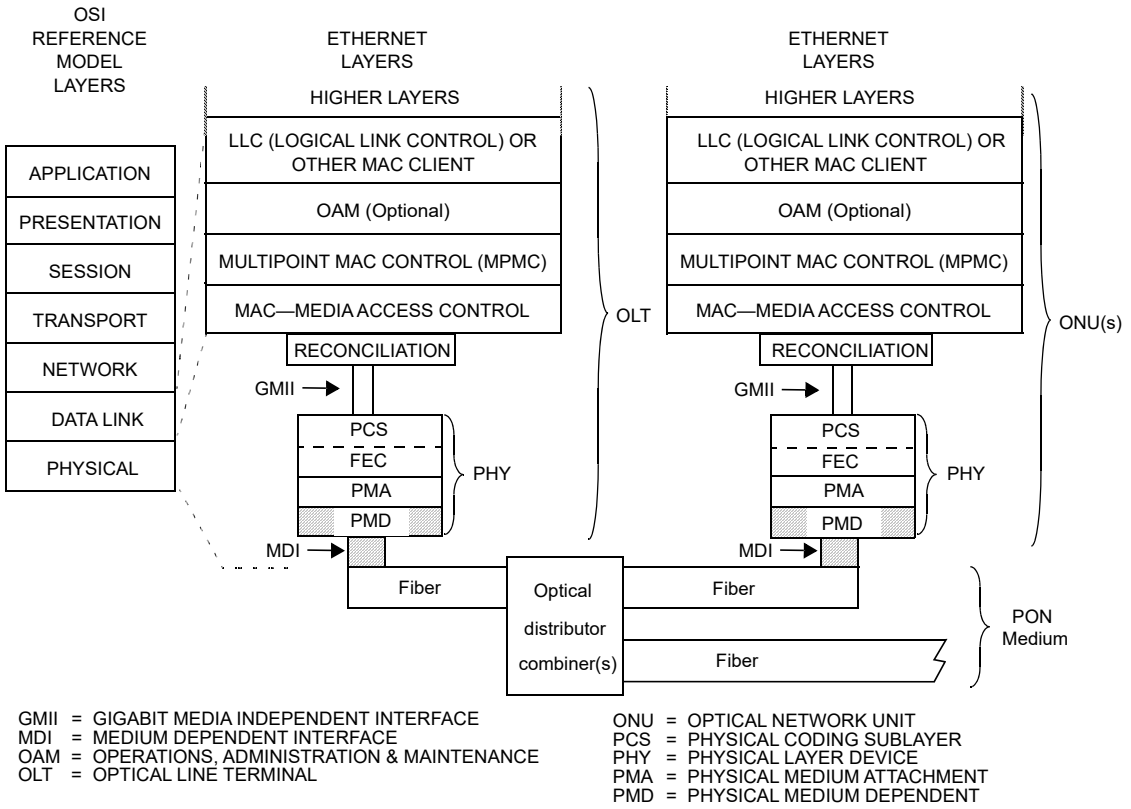

Figure 60–1—P2MP PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

60.1.3 Terminology and conventions

The following list contains references to terminology and conventions used in this clause:

Basic terminology and conventions, see 1.1 and 1.2.

Normative references, see 1.3.

Definitions, see 1.4.

Abbreviations, see 1.5.

Informative references, see Annex A.

Introduction to 1000 Mb/s baseband networks, see Clause 34.

Introduction to Ethernet for subscriber access networks, see Clause 56.

60.1.4 Physical Medium Dependent (PMD) sublayer service interface

The following specifies the services provided by the 1000BASE-PX10, 1000BASE-PX20, 1000BASE-PX30, and 1000BASE-PX40 PMDs.

These PMD sublayer service interfaces are described in an abstract manner and do not imply any particular implementation. The PMD Service Interface supports the exchange of 8B/10B code-groups between the PMA and PMD entities. The PMD translates the serialized data of the PMA to and from signals suitable for the specified medium. The following primitives are defined:

PMD_UNITDATA.request

PMD_UNITDATA.indication

PMD_SIGNAL.request

PMD_SIGNAL.indication

Table 60–1—PMD types specified in this clause

Description	1000BASE-PX10-U	1000BASE-PX10-D	1000BASE-PX20-U	1000BASE-PX20-D	1000BASE-PX30-U	1000BASE-PX30-D	1000BASE-PX40-U	1000BASE-PX40-D	Unit
Fiber type	IEC 60793–2 B1.1, B1.3 SMF				IEC 60793–2 B1.1, B1.3 SMF ITU–T G.652, G.657 SMF				
Number of fibers	1				1				
Nominal transmit wavelength	1310	1490	1310	1490	1310	1490	1310	1490	nm
Transmit direction[a]	US	DS	US	DS	US	DS	US	DS	
Minimum range[b]	0.5 m to 10 km		0.5 m to 20 km						
Maximum channel insertion loss[c]	20	19.5	24	23.5	29		33		dB
Minimum channel insertion loss[d]	5		10		15		18		dB

[a]US stands for Upstream, DS stands for Downstream.
[b]In an FEC enabled link, the minimum range may be increased, or, links with a higher channel insertion loss may be used.
[c]At nominal transmit wavelength.
[d]The differential insertion loss for a link is the difference between the maximum and minimum channel insertion loss, and not applicable to 1000BASE-PX30 and 1000BASE-PX40.

60.1.5 Delay constraints

Delay requirements from the MDI to the GMII which include the PMD layer are specified in Clause 36. Of the budget, up to 20 ns is allocated for each of the transmit and receive functions of the PMD to account for those cases where the PMD includes a pigtail.

60.1.5.1 PMD_UNITDATA.request

This primitive defines the transfer of a serial data stream from the PMA to the PMD.

The semantics of the service primitive are PMD_UNITDATA.request(tx_bit). The data conveyed by PMD_UNITDATA.request is a continuous stream of bits. The tx_bit parameter can take one of two values: ONE or ZERO. The PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal 1.25 GBd signaling speed. Upon receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals at the MDI.

60.1.5.2 PMD_UNITDATA.indication

This primitive defines the transfer of data from the PMD to the PMA.

The semantics of the service primitive are PMD_UNITDATA.indication(rx_bit). The data conveyed by PMD_UNITDATA.indication is a continuous stream of bits. The rx_bit parameter can take one of two values: ONE or ZERO. The PMD continuously sends a stream of bits to the PMA corresponding to the signals received from the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

60.1.5.3 PMD_SIGNAL.request

In the upstream direction, this primitive is generated by the PCS to turn on and off the transmitter according to the granted time. A signal for laser control is generated in 65.3.1.1.

The semantics of the service primitive are PMD_SIGNAL.request(tx_enable). The tx_enable parameter can take on one of two values: ENABLE or DISABLE, determining whether the PMD transmitter is on (enabled) or off (disabled). The PCS generates this primitive to indicate a change in the value of tx_enable. Upon receipt of this primitive, the PMD turns the transmitter on or off as appropriate.

60.1.5.4 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

The semantics of the service primitive are PMD_SIGNAL.indication(SIGNAL_DETECT). The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting light at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication(rx_bit) is undefined. The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT. If the MDIO interface is implemented, then PMD_global_signal_detect shall be continuously set to the value of SIGNAL_DETECT.

NOTE—SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA.indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the specified bit error ratio. PMD_SIGNAL.indication(SIGNAL_DETECT) has different characteristics for upstream and downstream links, see 60.2.4.

60.2 PMD functional specifications

The 1000BASE-PX PMDs perform the transmit and receive functions that convey data between the PMD service interface and the MDI.

60.2.1 PMD block diagram

The PMD sublayer is defined at the four reference points shown in Figure 60–2 where the first digit represents the downstream direction and the second the upstream. Two points, TP2 and TP3, are compliance points. TP1 and TP4 are reference points for use by implementers. The optical transmit signal is defined at the output end of a patch cord (TP2), between 2 m and 5 m in length, of a fiber type consistent with the link type connected to the transmitter. Unless specified otherwise, all transmitter measurements and tests defined in 60.9 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) connected to the receiver. Unless specified otherwise, all receiver measurements and tests defined in 60.9 are made at TP3.

The electrical specifications of the PMD service interface (TP1 and TP4) are not system compliance points (these are not readily testable in a system implementation). It is expected that in many implementations, TP1 and TP4 will be common between 1000BASE-PX PMDs.

60.2.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the optical specifications in this clause. The higher optical power level shall correspond to tx_bit = ONE.

In the upstream direction, the flow of bits is interrupted according to PMD_SIGNAL.request(tx_enable). This implies three optical levels, 1, 0, and dark, the latter corresponding to the transmitter being in the OFF state.

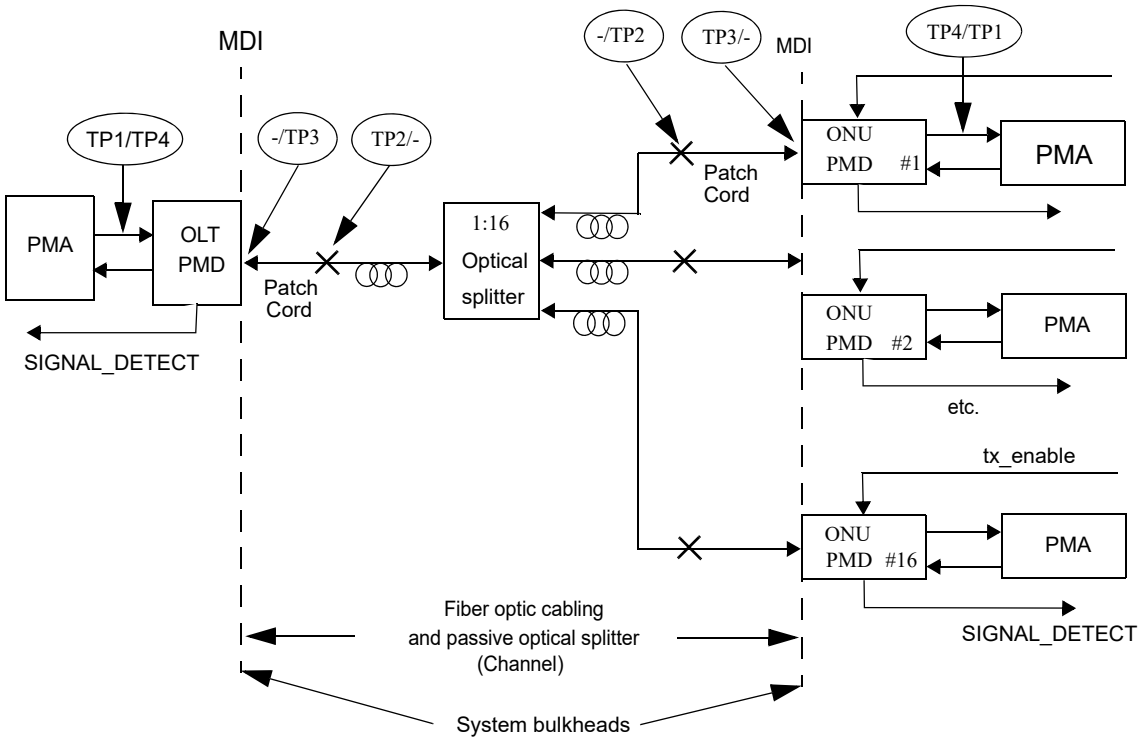

Figure 60–2—1000BASE-PX block diagram

60.2.3 PMD receive function

The PMD Receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher optical power level shall correspond to rx_bit = ONE.

60.2.4 PMD signal detect function

60.2.4.1 ONU PMD signal detect (downstream)

The PMD Signal Detect function for the continuous mode downstream signal shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 60–2 for 1000BASE-PX. The PMD receiver is not required to verify whether a compliant 1000BASE-PX signal is being received.

60.2.4.2 OLT PMD signal detect (upstream)

The response time for the PMD Signal Detect function for the burst mode upstream signal may be longer or shorter than a burst length, thus, it may not fulfill the traditional requirements placed on Signal Detect. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence. The signal detect function in the OLT may be realized in the PMD or PMA layer.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 60–2 for 1000BASE-PX. The PMD receiver is not required to verify whether a compliant 1000BASE-PX signal is being received.

60.2.4.3 1000BASE-PX Signal detect functions

The Signal Detect value definitions for the 1000BASE-PX PMDs are shown in Table 60–2.

Table 60–2—1000BASE-PX SIGNAL_DETECT value definition

PMD type	Receive conditions	SIGNAL_DETECT value
1000BASE-PX10	Average input optical power ≤ Signal Detect Threshold (min) in Table 60–5 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 60–5 with a compliant 1000BASE-X signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified
1000BASE-PX20	Average input optical power ≤ Signal Detect Threshold (min) in Table 60–8 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 60–8 with a compliant 1000BASE-X signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified
1000BASE-PX30	Average input optical power ≤ Signal Detect Threshold (min) in Table 60–9 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 60–9 with a compliant 1000BASE-X signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified
1000BASE-PX40	Average input optical power ≤ Signal Detect Threshold (min) in Table 60–12 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 60–12 with a compliant 1000BASE-X signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified

60.2.5 PMD transmit enable function for ONU

PMD_SIGNAL.request(tx_enable) is defined for the two ONU PMDs. PMD_SIGNAL.request(tx_enable) is asserted prior to data transmission by the ONU PMDs.

60.3 PMD to MDI optical specifications for 1000BASE-PX10-D and 1000BASE-PX10-U

The operating range for 1000BASE-PX10 is defined in Table 60–1. A 1000BASE-PX10 compliant transceiver supports all media types listed in Table 60–16 according to the specifications described in 60.11. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., a single-mode solution operating at 10.5 km meets the minimum range requirement of 0.5 m to 10 km for 1000BASE-PX10).

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

60.3.1 Transmitter optical specifications

The 1000BASE-PX10-D and 1000BASE-PX10-U transmitter's specifications described in Table 60–3 are normative requirements, per measurement techniques described in 60.9, with the exception of $RIN_{15}OMA$ which is an optional requirement per measurement techniques described in 60.9.7.

Table 60–3—1000BASE-PX10-D and 1000BASE-PX10-U transmit characteristics

Description	1000BASE-PX10-D	1000BASE-PX10-U	Unit
Nominal transmitter type[a]	Longwave Laser	Longwave Laser	
Signaling speed (range)	1.25 ± 100 ppm	1.25 ± 100 ppm	GBd
Wavelength[b] (range)	1480 to 1500	1260 to 1360	nm
RMS spectral width (max)	see Table 60–4		nm
Average launch power (max)	+2	+4	dBm
Average launch power (min)	–3	–1	dBm
Average launch power of OFF transmitter (max)	–39	–45	dBm
Extinction ratio (min)	6	6	dB
$RIN_{15}OMA$ (max)	–118	–113	dB/Hz
Launch OMA (min)	–2.2 (0.6)	–0.22 (0.95)	dBm (mW)
Transmitter eye mask definition {X1, X2, Y1, Y2, Y3}	{0.22, 0.375, 0.2, 0.2, 0.3}	{0.22, 0.375, 0.2, 0.2, 0.3}	UI
T_{on} (max)	N/A	512	ns
T_{off} (max)	N/A	512	ns
Optical return loss tolerance (max)	15	15	dB
Optical return loss of ODN (min)	20	20	dB
Transmitter reflectance (max)	–10	–6	dB
Transmitter and dispersion penalty (max)	1.3	2.8	dB
Decision timing offset for transmitter and dispersion penalty (min)	± 0.1	± 0.125	UI

[a]The nominal transmitter type is not intended to be a requirement on the source type, and any device meeting the transmitter characteristics specified may be substituted for the nominal transmitter type.
[b]This represents the range of centre wavelength ±1σ of the rms spectral width.

The maximum RMS spectral width vs. wavelength for 1000BASE-PX10 is shown in Table 60–4 and for 1000BASE-PX10-U in Figure 60–3. The equation used to generate these values is included in 60.9.2. The central column values are normative, the right hand column is optional.

Table 60–4—1000BASE-PX10-D and 1000BASE-PX10-U transmitter spectral limits

Center Wavelength	RMS spectral width (max)[a]	RMS spectral width to achieve epsilon $\varepsilon \leq$ **0.115 (optional)**
nm	**nm**	**nm**
1260	**2.09**	1.43
1270	**2.52**	1.72
1280	**3.13**	2.14

Table 60–4—1000BASE-PX10-D and 1000BASE-PX10-U transmitter spectral limits *(continued)*

Center Wavelength	RMS spectral width (max)[a]	RMS spectral width to achieve epsilon $\varepsilon \leq 0.115$ (optional)
nm	**nm**	**nm**
1286	**3.50**	2.49
1290		2.80
1297		3.50
1329		
1340		2.59
1343		2.41
1350	**3.06**	2.09
1360	**2.58**	1.76
1480 to 1500	**0.88**	0.60

[a]These limits for the 1000BASE-PX10-U transmitter are illustrated in Figure 60–3. The equation used to calculate these values is detailed in 60.9.2. Limits at intermediate wavelengths may be found by interpolation.

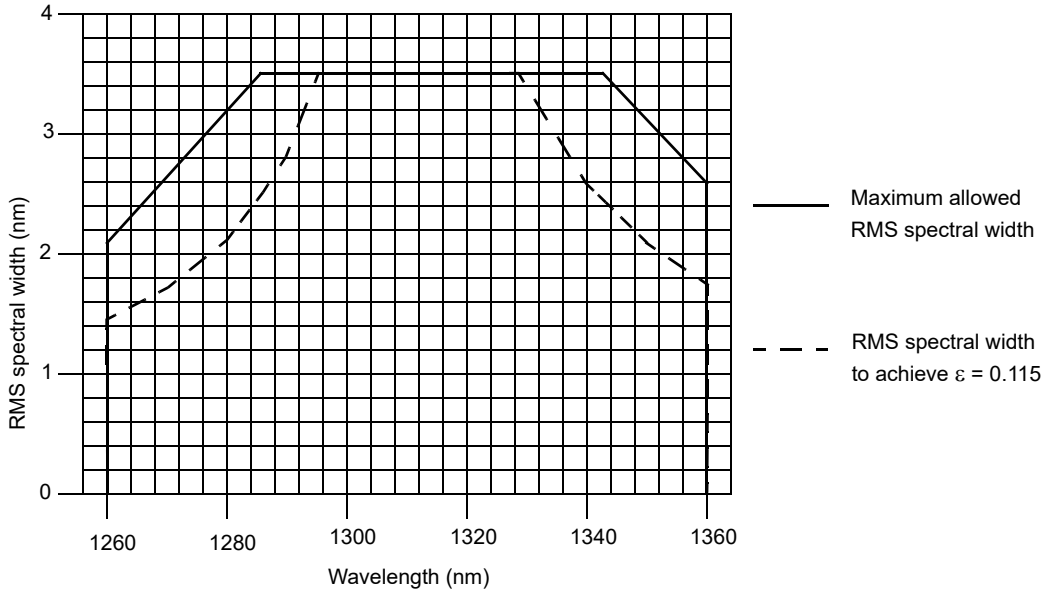

Figure 60–3—1000BASE-PX10-U transmitter spectral limits

60.3.2 Receiver optical specifications

The 1000BASE-PX10-D and 1000BASE-PX10-U receiver shall meet the specifications defined in Table 60–5 per measurement techniques defined in 60.9.10 with the following exceptions. The stressed receive sensitivity (OMA) should meet the values listed in Table 60–5 per measurement techniques described in 60.9.11. Either the damage threshold included in Table 60–5 shall be met, or, the receiver shall

be labeled to indicate the maximum optical input power level to which it can be continuously exposed without damage. The vertical eye-closure penalty, the stressed eye jitter, the jitter corner frequency, and the sinusoidal jitter limits are test conditions for measuring stressed receiver sensitivity and are not required characteristics of the receiver.

Table 60–5—1000BASE-PX10-D and 1000BASE-PX10-U receive characteristics

Description	1000BASE-PX10-D	1000BASE-PX10-U	Unit
Signaling speed (range)	1.25 ± 100 ppm	1.25 ± 100 ppm	GBd
Wavelength (range)	1260 to 1360	1480 to 1500	nm
Bit error ratio (max)	10^{-12}		
Average receive power (max)	–1	–3	dBm
Damage threshold (max)	+4	+2	dBm
Receiver sensitivity (max)	–24	–24	dBm
Receiver sensitivity OMA (max)	–23.2 (5)	–23.2 (5)	dBm (μW)
Signal detect threshold (min)	–45	–44	dBm
Receiver reflectance (max)	–12	–12	dB
Stressed receive sensitivity (max)	–22.3	–21.4	dBm
Stressed receive sensitivity OMA (max)	–21.5 (7)	–20.7 (8.6)	dBm (μW)
Vertical eye-closure penalty (min)	1.2	2.2	dB
$T_{receiver_settling}$ (max)	400	N/A	ns
Stressed eye jitter (min)	0.25	0.25	UI pk-pk
Jitter corner frequency	637	637	kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	(0.05, 0.15)	(0.05, 0.15)	UI

60.4 PMD to MDI optical specifications for 1000BASE-PX20-D and 1000BASE-PX20-U

The operating range for 1000BASE-PX20 is defined in Table 60–1. A 1000BASE-PX20 compliant transceiver supports all media types listed in Table 60–16 according to the specifications described in 60.11.2. A transceiver that exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., a single-mode solution operating at 20.5 km meets the minimum range requirement of 0.5 m to 20 km for 1000BASE-PX20).

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is explained in 58.7.6.

60.4.1 Transmitter optical specifications

The 1000BASE-PX20-D and 1000BASE-PX20-U transmitter's specifications described in Table 60–6 are normative requirements, per measurement techniques described in 60.9, with the exception of $RIN_{15}OMA$ which is an optional requirement per measurement techniques described in 60.9.7.

Table 60–6—1000BASE-PX20-D and 1000BASE-PX20-U transmit characteristics

Description	1000BASE-PX20-D	1000BASE-PX20-U	Unit
Nominal transmitter type[a]	Longwave Laser	Longwave Laser	
Signaling speed (range)	1.25 ± 100 ppm	1.25 ± 100 ppm	GBd
Wavelength[b] (range)	1480 to 1500	1260 to 1360	nm
RMS spectral width (max)	see Table 60–7		nm
Average launch power (max)	+7	+4	dBm
Average launch power (min)	+2	–1	dBm
Average launch power of OFF transmitter (max)	–39	–45	dBm
Extinction ratio (min)	6	6	dB
$RIN_{15}OMA$ (max)	–115	–115	dB/Hz
Launch OMA (min)	2.8 (1.9)	–0.22 (0.95)	dBm (mW)
Transmitter eye mask definition {X1, X2, Y1, Y2, Y3}	{0.22, 0.375, 0.2, 0.2, 0.3}	{0.22, 0.375, 0.2, 0.2, 0.3}	UI
T_{on} (max)	N/A	512	ns
T_{off} (max)	N/A	512	ns
Optical return loss tolerance (max)	15	15	dB
Optical return loss of ODN (min)	20	20	dB
Transmitter reflectance (max)	–10	–10	dB
Transmitter and dispersion penalty (max)	2.3	1.8	dB
Decision timing offset for transmitter and dispersion penalty (min)	± 0.1	± 0.125	UI

[a]The nominal transmitter type is not intended to be a requirement on the source type, and any device meeting the transmitter characteristics specified may be substituted for the nominal transmitter type.
[b]This represents the range of centre wavelength ±1σ of the rms spectral width.

The maximum RMS spectral width vs. wavelength for 1000BASE-PX20 is shown in Table 60–7 and for 1000BASE-PX20-U in Figure 60–4. The equation used to generate these values is included in 60.9.2. The central column values are normative, the right hand column is optional.

60.4.2 Receiver optical specifications

The 1000BASE-PX20-D and 1000BASE-PX20-U receiver shall meet the specifications defined in Table 60–8 per measurement techniques defined in 60.9.10 with the following exceptions. The stressed receive sensitivity (OMA) should meet the values listed in Table 60–8 per measurement techniques

60.5 PMD to MDI optical specifications for 1000BASE-PX30-D and 1000BASE-PX30-U

The operating range for 1000BASE-PX30 is defined in Table 60–1. A 1000BASE-PX30 compliant transceiver supports all media types listed in Table 75–14 according to the specifications described in 75.9. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., a single-mode solution operating at 20.5 km meets the minimum range requirement of 0.5 m to 20 km for 1000BASE-PX30).

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

60.5.1 Transmitter optical specifications

The 1000BASE-PX30-D and 1000BASE-PX30-U transmitter's specifications described in Table 60–9 are normative requirements, per measurement techniques described in 60.8, with the exception of $RIN_{15}OMA$ which is an optional requirement, per measurement techniques described in 60.9.7.

The maximum RMS spectral width vs. wavelength for 1000BASE-PX30 is shown in Table 60–10 and for 1000BASE-PX30-U in Figure 60–5. 1000BASE-PX30-D transmitter uses a DFB laser, and 1000BASE-PX30-U transmitter can use either a DFB or Fabry-Perot laser. If 1000BASE-PX30-U PMD employs a DFB laser, Side Mode Suppression Ratio requirement shown in Table 60–9 is mandatory. If 1000BASE-PX30-U PMD employs a Fabry-Perot laser, RMS spectral width requirement shown in Table 60–10 and Figure 60–5 is mandatory. The equation used to generate these values is included in 60.9.2. The central column values are normative, the right hand column is optional.

Table 60–9—1000BASE-PX30-D and 1000BASE-PX30-U transmit characteristics

Description	1000BASE-PX30-D	1000BASE-PX30-U	Unit
Nominal transmitter type[a]	Longwave Laser	Longwave Laser	
Signaling speed (range)	1.25 ± 100 ppm	1.25 ± 100 ppm	GBd
Wavelength[b] (range)	1480 to 1500	1260 to 1360	nm
Side Mode Suppression Ratio	30	30[c]	dB
RMS spectral width (max)	N/A	see Table 60–10[c]	nm
Average launch power (max)	7	5.62	dBm
Average launch power (min)	3	0.62	dBm
Average launch power of OFF transmitter (max)	–39	–45	dBm
Extinction ratio (min)	6	6	dB
$RIN_{15}OMA$ (max)	–115	–115	dB/Hz
Launch OMA (min)	3.78 (2.39)	1.4 (1.38)	dBm (mW)
Transmitter eye mask definition {X1, X2, Y1, Y2, Y3}	{0.22, 0.375, 0.2, 0.2, 0.3}	{0.22, 0.375, 0.2, 0.2, 0.3}	UI
T_{on} (max)	N/A	512	ns
T_{off} (max)	N/A	512	ns
Optical return loss tolerance (max)	15	15	dB
Optical return loss of ODN (min)	20	20	dB
Transmitter reflectance (max)	–10	–10	dB
Transmitter and dispersion penalty (max)	1	1.4	dB
Decision timing offset for transmitter and dispersion penalty (min)	±0.1	±0.125	UI

[a]The nominal transmitter type is not intended to be a requirement on the source type, and any device meeting the transmitter characteristics specified may be substituted for the nominal transmitter type.
[b]This represents the range of centre wavelength ±1σ of the rms spectral width.
[c]If 1000BASE-PX30-U PMD employs a DFB laser, Side Mode Suppression Ratio is mandatory. If it employs a Fabry-Perot laser, RMS spectral width requirement is mandatory.

Table 60–10—1000BASE-PX30-U transmitter spectral limits

Center wavelength	RMS spectral width (max)[a]	RMS spectral width to achieve epsilon $\varepsilon \leq 0.08$ (optional)
nm	nm	nm
1260	0.59	0.5
1270	0.7	0.59
1280	0.87	0.74
1290	1.14	0.97
1300	1.64	1.39
1304	1.98	1.67
1305	2.09	1.77
1308	2.4	2
1317	2.4	2
1320	2.07	1.75
1321	1.98	1.67
1330	1.4	1.18
1340	1.06	0.89
1350	0.86	0.72
1360	0.72	0.61
1480 to 1500	0.25	0.21

[a]These limits for the 1000BASE–PX30–U transmitter are illustrated in Figure 60–5. The equation used to calculate these values is detailed in 60.9.2. Limits at intermediate wavelengths may be found by interpolation.

60.5.2 Receiver optical specifications

The 1000BASE-PX30-D and 1000BASE-PX30-U receiver shall meet the specifications defined in Table 60–11 per measurement techniques defined in 60.9.10 with the following exceptions. The stressed receive sensitivity OMA (max) should meet the value listed in Table 60–11 per measurement techniques described in 60.9.11. Either the damage threshold included in Table 60–11 shall be met, or, the receiver shall be labeled to indicate the maximum optical input power level to which it can be continuously exposed without damage. The vertical eye-closure penalty, the stressed eye jitter, the jitter corner frequency, and the sinusoidal jitter limits are test conditions for measuring stressed receiver sensitivity and are not required characteristics of the receiver.

60.6 PMD to MDI optical specifications for 1000BASE-PX40-D and 1000BASE-PX40-U

The operating range for 1000BASE-PX40 is defined in Table 60–1. A 1000BASE-PX40 compliant transceiver supports all media types listed in Table 75–14 according to the specifications described in 75.9. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant (e.g., a single-mode solution operating at 20.5 km meets the minimum range requirement of 0.5 m to 20 km for 1000BASE-PX40).

Table 60–11—1000BASE-PX30-D and 1000BASE-PX30-U receive characteristics *(continued)*

Description	1000BASE-PX30-D	1000BASE-PX30-U	Unit
$T_{receiver_settling}$ (max)[b]	400	N/A	ns
Stressed eye jitter (min)	0.28	0.25	UI pk-pk
Jitter corner frequency	637	637	kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	(0.05, 0.15)	(0.05, 0.15)	UI

[a]Direct ONU–OLT connection may result in damage of the receiver.
[b]$T_{receiver_settling}$ represents an upper bound. Optics with better performance may be used in compliant implementations, since the OLT notifies the ONUs of its requirements in terms of the $T_{receiver_settling}$ time via the syncTime parameter.

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

60.6.1 Transmitter optical specifications

The 1000BASE-PX40-D and 1000BASE-PX40-U transmitter's specifications described in Table 60–12 are normative requirements, per measurement techniques described in 60.9, with the exception of $RIN_{15}OMA$ which is an optional requirement, per measurement techniques described in 60.9.7.

Table 60–12—1000BASE-PX40-D and 1000BASE-PX40-U transmit characteristics

Description	1000BASE-PX40-D	1000BASE-PX40-U	Unit
Nominal transmitter type[a]	Longwave Laser	Longwave Laser	
Signaling speed (range)	1.25 ± 100 ppm	1.25 ± 100 ppm	GBd
Wavelength (range)	1480 to 1500	1290 to 1330	nm
Side Mode Suppression Ratio (min)[b]	30		dB
Average launch power (max)	10	6	dBm
Average launch power (min)	4	2	dBm
Average launch power of OFF transmitter (max)	–39	–45	dBm
Extinction ratio (min)	6	6	dB
$RIN_{15}OMA$ (max)	–115	–115	dB/Hz
Launch OMA (min)	4.78 (3.01)	2.78 (1.9)	dBm (mW)
Transmitter eye mask definition {X1, X2, Y1, Y2, Y3}	{0.22, 0.375, 0.2, 0.2, 0.3}	{0.22, 0.375, 0.2, 0.2, 0.3}	UI
T_{on} (max)	N/A	512	ns
T_{off} (max)	N/A	512	ns
Optical return loss tolerance (max)	15	15	dB
Optical return loss of ODN (min)	20	20	dB
Transmitter reflectance (max)	–10	–10	dB
Transmitter and dispersion penalty (max)	1	1	dB
Decision timing offset for transmitter and dispersion penalty (min)	±0.1	±0.125	UI

[a]The nominal device type is not intended to be a requirement on the source type, and any device meeting the transmitter characteristics specified may be substituted for the nominal device type.

[b]Transmitter is a single longitudinal mode device. Chirp is allowed such that the total penalty does not exceed that found in Table 60–14.

60.6.2 Receiver optical specifications

The 1000BASE-PX40-D and 1000BASE-PX40-U receiver shall meet the specifications defined in Table 60–13 per measurement techniques defined in 60.9.10 with the following exceptions. The stressed receive sensitivity OMA (max) should meet the value listed in Table 60–13 per measurement techniques described in 60.9.11. Either the damage threshold included in Table 60–13 shall be met, or, the receiver shall be labeled to indicate the maximum optical input power level to which it can be continuously exposed without damage. The vertical eye-closure penalty, the stressed eye jitter, the jitter corner frequency, and the sinusoidal jitter limits are test conditions for measuring stressed receiver sensitivity and are not required characteristics of the receiver.

Table 60–13—1000BASE-PX40-D and 1000BASE-PX40-U receive characteristics

Description	1000BASE-PX40-D	1000BASE-PX40-U	Unit
Signaling speed (range)	1.25 ± 100 ppm	1.25 ± 100 ppm	GBd
Wavelength (range)	1260 to 1360	1480 to 1500	nm
Bit error ratio (max)	10^{-12}		
Average receive power (max)	–12	–8	dBm
Damage threshold (max)[a]	–6	–3	dBm
Receiver sensitivity (max)	–32	–30	dBm
Receiver sensitivity OMA (max)	–31.22 (0.76)	–29.22 (1.2)	dBm (μW)
Signal detect threshold (min)	–45	–44	dBm
Receiver reflectance (max)	–12	–12	dB
Stressed receive sensitivity (max)	–31	–29	dBm
Stressed receive sensitivity OMA (max)	–30.22 (0.95)	–28.22 (1.51)	dBm (μW)
Vertical eye-closure penalty (min)	2.2	1.5	dB
$T_{receiver_settling}$ (max)[b]	400	N/A	ns
Stressed eye jitter (min)	0.28	0.25	UI pk-pk
Jitter corner frequency	637	637	kHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	(0.05, 0.15)	(0.05, 0.15)	UI

[a]Direct ONU–OLT connection may result in damage of the receiver.
[b]$T_{receiver_settling}$ represents an upper bound. Optics with better performance may be used in compliant implementations, since the OLT notifies the ONUs of its requirements in terms of the $T_{receiver_settling}$ time via the syncTime parameter.

60.7 Illustrative 1000BASE-PX channels and penalties

Illustrative power budget for 1000BASE-PX10, 1000BASE-PX20, 1000BASE-PX30, and 1000BASE-PX40 channels are shown in Table 60–14.

Table 60–14—Illustrative 1000BASE-PX channel insertion loss and penalties

Description[a]	1000BASE -PX10		1000BASE -PX20		1000BASE -PX30		1000BASE -PX40		Unit
	US	DS	US	DS	US	DS	US	DS	
Fiber type	IEC 60793–2 B1.1, B1.3 SMF				IEC 60793–2 B1.1, B1.3 SMF ITU-T G.652, G.657 SMF				
Measurement wavelength for fiber	1310	1550[b]	1310	1550[b]	1310	1550[b]	1310	1550[b]	nm
Nominal distance	10		20						km
Available power budget[c]	23	21	26	26	30.4	30	34	34	dB
Channel insertion loss (max)[d]	20	19.5	24	23.5	29		33		dB
Channel insertion loss (min)[e]	5		10		15		18		dB
Allocation for penalties[f]	3	1.5	2	2.5	1.4	1	1	1	dB
Optical return loss of ODN (min)	20								dB

[a]US stands for Upstream, DS stands for Downstream.
[b]The nominal transmit wavelength is 1490 nm.
[c]In an FEC enabled link, when not operating at the dispersion limit, the available power budget is increased by 2.5 dB.
[d]The channel insertion loss is based on the cable attenuation at the target distance and nominal measurement wavelength. The channel insertion loss also includes the loss for connectors, splices and other passive components such as splitters.
[e]The power budgets for PX10, PX20, PX30, and PX40 links are such that a minimum insertion loss is assumed between transmitter and receiver. This minimum attenuation is required for PMD testing.
[f]The allocation for penalties is the difference between the available power budget and the channel insertion loss; insertion loss difference between nominal and worst case operating wavelength is considered a penalty. This allocation may be used to compensate for transmission related penalties. Further details are given in 60.9.2.

NOTE—The budgets include an allowance for –12 dB reflection at the receiver.

60.8 Jitter at TP1 to TP4 for 1000BASE-PX

Jitter at TP1 to TP4 for 1000BASE-PX is informatively described in Annex 60A.

60.9 Optical measurement requirements

The following sections describe definitive patterns and test procedures for certain PMDs of this standard. implementers using alternative verification methods need to ensure adequate correlation and allow adequate margin such that specifications are met by reference to the definitive methods. All optical measurements, except TDP and $RIN_{15}OMA$, shall be made through a short patch cable between 2 m and 5 m in length.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

60.9.1 Frame-based test patterns

Subclause 59.7.1 provides suitable patterns for frame-based testing.

NOTE—Users are advised to take care that the system under test is not connected to a network in service.

60.9.2 Wavelength, spectral width, and side mode suppression ratio (SMSR) measurements

The wavelength, spectral width (RMS), and SMSR shall meet specifications according to the centroidal wavelength, RMS spectral width, and SMSR definitions in IEC 61280-1-3, under modulated conditions using a valid 1000BASE-X signal.

NOTE 1—The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.

NOTE 2—The 20 dB width for SLM lasers is taken as 6.07 times the RMS width.

The interaction between the transmitter and the chromatic dispersion of the fiber is accounted for by a parameter ε (epsilon), which is defined as the product of 10^{-3} times the signaling speed (in GBd) times the path dispersion (in ps/nm) times the RMS spectral width (in nm).

$$\varepsilon = \text{dispersion} \times \text{length} \times \text{RMS spectral width} \times 10^{-3} \quad (60–1)$$

For the 1000BASE-PX10-D and 1000BASE-PX10-U links, a maximum ε close to 0.168 is imposed by the middle column of Table 60–4. If the spectral width is kept below the limits of the right hand column, ε will not exceed 0.115, and the chromatic dispersion penalty is expected to be below 2 dB when all link parameters are simultaneously at worst case values. For the 1000BASE-PX20-D and 1000BASE-PX20-U links, a maximum ε close to 0.115 is imposed by the middle column of Table 60–7. If the spectral width is kept below the limits of the right hand column, ε will not exceed 0.10, and the chromatic dispersion penalty is expected to be below 1.5 dB when all link parameters are simultaneously at worst case values.

For the 1000BASE-PX30-D and 1000BASE-PX30-U links, a maximum ε close to 0.095 is imposed by the middle column of Table 60–10. If the spectral width is kept below the limits of the right hand column, ε will not exceed 0.08, and the chromatic dispersion penalty is expected to be below 0.9 dB when all link parameters are simultaneously at worst case values.

The chromatic dispersion penalty is a component of transmitter and dispersion penalty (TDP), which is specified in Table 60–3, Table 60–6, Table 60–9, and Table 60–12, and described in 58.7.9.

60.9.3 Optical power measurements

Optical power shall meet specifications according to the methods specified in IEC 61280-1-1. A measurement may be made with the port transmitting any valid encoded 8B/10B data stream.

60.9.4 Extinction ratio measurements

Extinction ratio shall meet specifications according to IEC 61280-2-2 with the port transmitting a repeating idle pattern /I2/ ordered set (see 36.2.4.12) that may be interspersed with OAM packets per 57A.2, and with minimal back reflections into the transmitter, lower than –20 dB. The /I2/ ordered set is defined in Clause 36, and is coded as /K28.5/D16.2/, which is binary 001111 1010 100100 0101 within idles. The extinction ratio is expected to be similar for other valid 8B/10B bit streams. The test receiver has the frequency response as specified for the transmitter optical waveform measurement.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

60.9.5 OMA measurements (optional)

Subclause 58.7.5 provides a reference technique for performing OMA measurements.

60.9.6 OMA relationship to extinction ratio and power measurements

Annex 58B provides information on how OMA, extinction ratio and mean power are related to each other (see 58B.2).

60.9.7 Relative intensity noise optical modulation amplitude ($RIN_{15}OMA$)

$RIN_{15}OMA$ is the ratio of noise to modulated optical signal in the presence of a back reflection. The measurement procedure is described in 58.7.7.

60.9.8 Transmitter optical waveform (transmit eye)

The required transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 60–6.

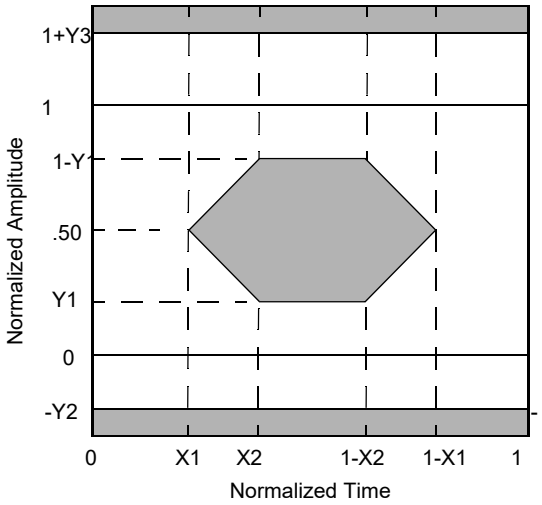

Figure 60–6—Transmitter eye mask definition

The measurement procedure is described in 58.7.8 and references therein.

The eye shall comply to the mask of the eye using a fourth-order Bessel-Thomson receiver response with f_r = 0.9375 GHz, and where the relative response vs. relative frequency is defined in ITU-T G.957, Table B.2 (STM-16 values), along with the allowed tolerances for its physical implementation.

NOTE 1—This Bessel-Thomson filter is not intended to represent the noise filter used within an optical receiver, but is intended to provide uniform measurement conditions on the transmitter.

NOTE 2—The fourth-order Bessel-Thomson filter is reactive. In order to suppress reflections, a 6 dB attenuator may be required at the filter input and/or output.

60.9.9 Transmitter and dispersion penalty (TDP)

TDP measurement tests for transmitter impairments with chromatic effects for a transmitter to be used with single-mode fiber. Possible causes of impairment include intersymbol interference, jitter, RIN and mode partition noise. Meeting the separate requirements (e.g., eye mask, spectral characteristics) does not in itself

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

guarantee the transmitter and dispersion penalty (TDP). The TDP limit shall be met. See 58.7.9 for details of the measurement.

60.9.10 Receive sensitivity measurement

Receiver sensitivity is defined for the random pattern test frame and an ideal input signal quality with the specified extinction ratio. The measurement procedure is described in 58.7.10. The sensitivity shall be met for the bit error ratio defined in Table 60–5, Table 60–8, Table 60–11, or Table 60–13 as appropriate.

60.9.11 Stressed receive conformance test

The stressed receiver conformance test is intended to screen against receivers with poor frequency response or timing characteristics which could cause errors when combined with a distorted but compliant signal at TP3. Modal (MMF) or chromatic (SMF) dispersion can cause distortion. The conformance test signal uses the random pattern test frame and is conditioned by applying deterministic jitter and intersymbol interference. If the option for stressed receiver compliance is chosen, the receiver shall meet the specified bit error ratio at the power level and signal quality defined in Table 60–5, Table 60–8, Table 60–11, and Table 60–13 as appropriate, according to the measurement procedures of 58.7.11.

60.9.12 Jitter measurements

Jitter measurements are informatively described in 58B.4.

60.9.13 Other measurements

60.9.13.1 Laser On/Off timing measurement

T_{on} is defined in 60.9.13.1.1, value is less than 512 ns (defined in Table 60–3, Table 60–6, Table 60–9, and Table 60–12).

$T_{receiver_settling}$ is defined in 60.9.13.2.1, value is less than 400 ns (defined in Table 60–5, Table 60–8, Table 60–11, and Table 60–13).

T_{CDR} is defined in 65.3.2.1, value is less than 400 ns (defined in 60.2.2).

$T_{code_group_align}$ is defined in 36.3.2.4, value is less than 4 ten-bit code-groups.

T_{off} is defined in 60.9.13.1.1, value is less than 512 ns (defined in Table 60–3, Table 60–6, Table 60–9, and Table 60–12).

60.9.13.1.1 Definitions

T_{on} is denoted as the time beginning from the falling edge of the tx_enable line to the ONU PMD and ending at the time that the optical signal at TP2 of the ONU PMD is within 15% of its steady state parameters (average launched power, wavelength, RMS spectral width, transmitter and dispersion penalty, optical return loss tolerance, jitter, $RIN_{15}OMA$, extinction ratio and eye mask opening) as defined in Table 60–3 for 1000BASE-PX10-U, Table 60–6 for 1000BASE-PX20-U, Table 60–9 for 1000BASE-PX30-U, and Table 60–12 for 1000BASE-PX40-U. T_{on} is presented in Figure 60–7. The data transmitted may be any valid 8B/10B symbols.

T_{off} is denoted as the time beginning from the rising edge of the tx_enable line to the ONU PMD and ending at the time that the optical signal at TP2 of the ONU PMD reaches the specified average launch power of off transmitter as defined in Table 60–3 for 1000BASE-PX10-U, Table 60–6 for 1000BASE-PX20-U,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 60–9 for 1000BASE-PX30-U, and Table 60–12 for 1000BASE-PX40-U. T_{off} is presented in Figure 60–7. The data transmitted may be any valid 8B/10B symbols.

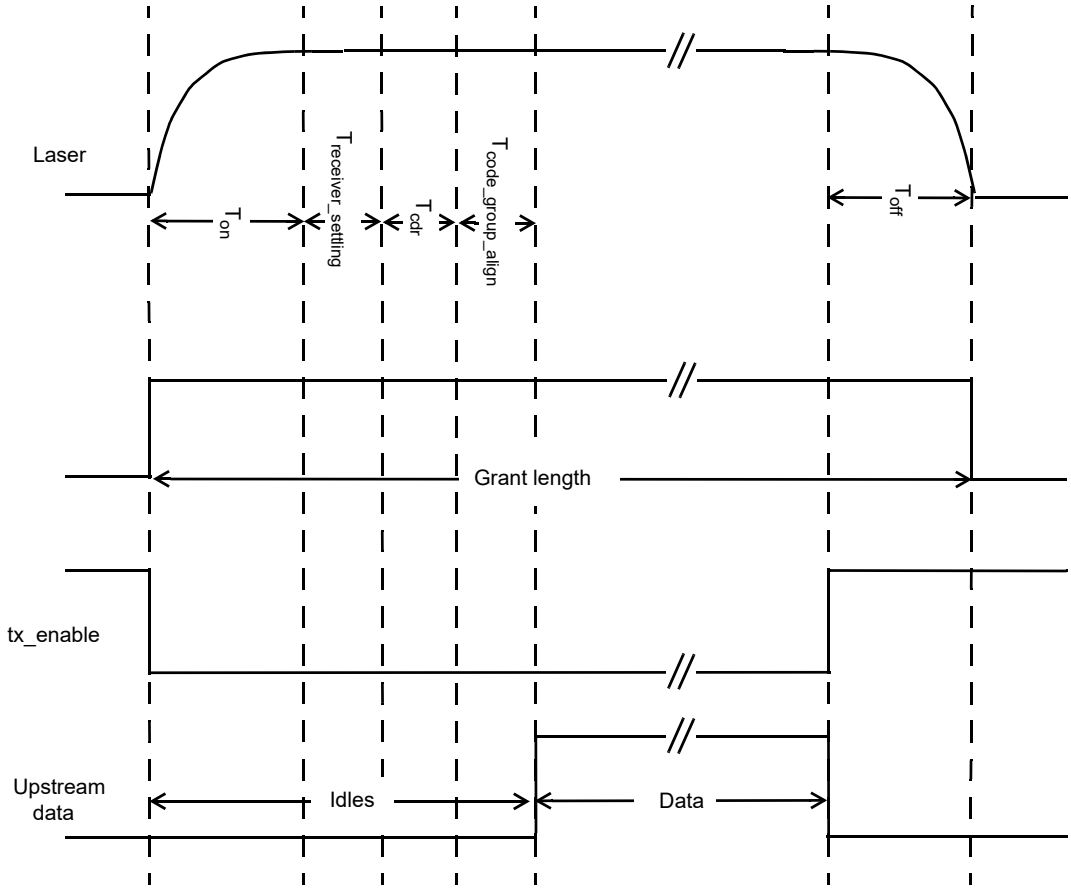

Figure 60–7—P2MP timing parameter definition

60.9.13.1.2 Test specification

The test setup for measuring T_{on} and T_{off} is described in Figure 60–8. An O/E converter is used to convert the optical signal at TP3 to an electrical signal at TP4 where it is assumed that the response time of the converter is considerably shorter that the T_{on} value under measurement. A scope, with a variable delay, can measure the time from the tx_enable trigger to the time the optical signal reaches all its specified conditions. The delay to the scope trigger is adjusted until the point that the received signal meets all its specified conditions. This is the T_{on} in question.

A non-rigorous way to describe this test setup would be: for a PMD with a declared T_{on} and T_{off}, measure all PMD optical parameter after T_{on} and T_{off} from the tx_enable trigger, ensuring conformance to within 15% of the steady state values. Notice that only the steady state optical OFF power has to be verified when measuring T_{off} time, since that is the only relevant parameter.

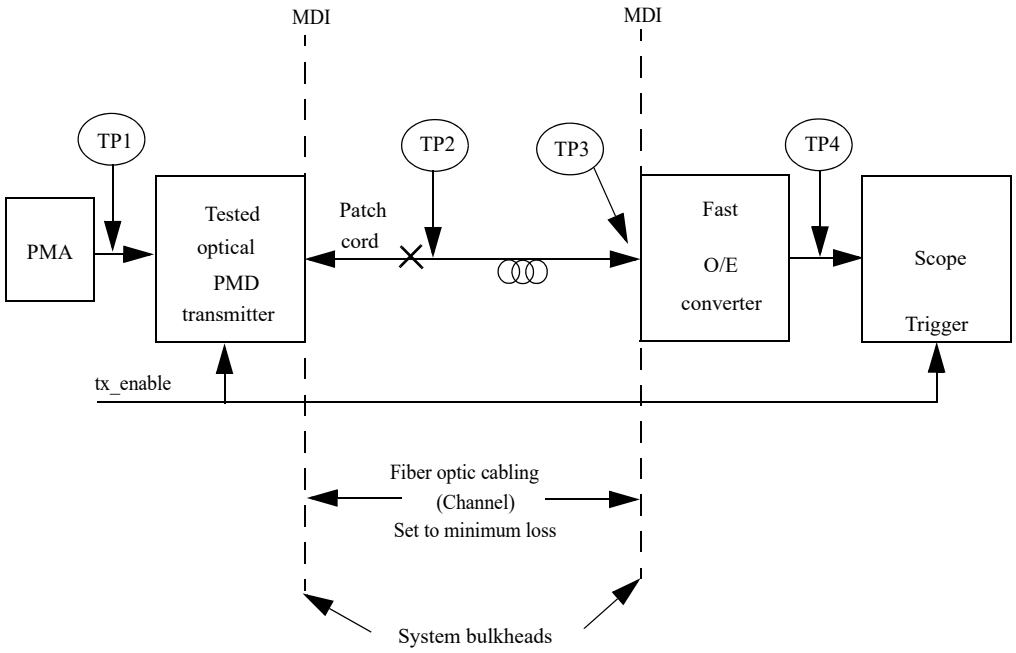

Figure 60–8—ONU PMD Laser on/off time measurement setup

60.9.13.2 Receiver settling timing measurement

60.9.13.2.1 Definitions

$T_{receiver_settling}$ is denoted as the time beginning from the time that the optical power in the receiver at TP3 reaches the conditions specified in 38.6.11, 58.7.11.2 and ending at the time that the electrical signal after the PMD at TP4, reaches within 15% of its steady state parameter, (average power, jitter), see Table 60–5, Table 60–8, Table 60–11, and Table 60–13. $T_{receiver_settling}$ is presented in Figure 60–7. The data transmitted may be any valid 8B/10B symbols (or a specific power synchronization sequence). The optical signal at TP3, at the beginning of the locking, may have any valid 8B/10B pattern, optical power level, jitter, or frequency shift matching the standard specifications.

60.9.13.2.2 Test specification

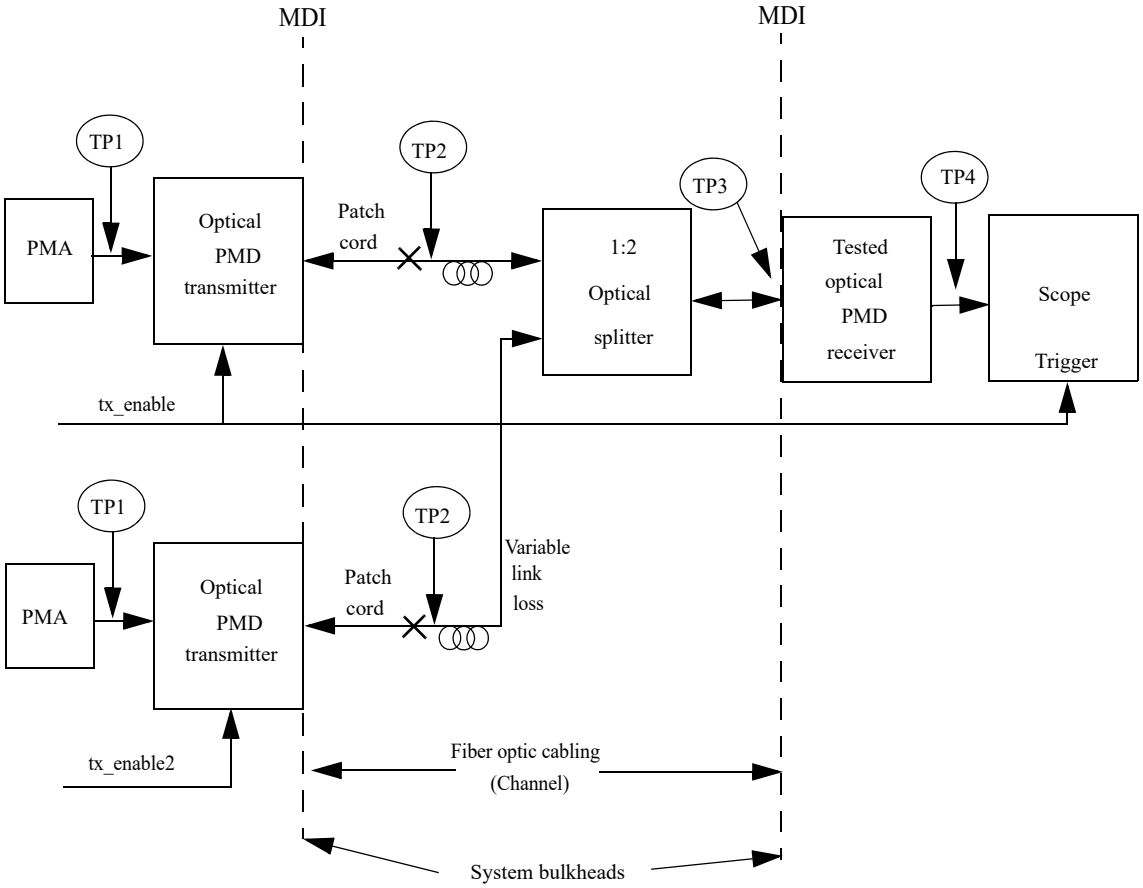

Figure 60–9—Receiver settling time measurement setup

Figure 60–9 illustrates the test setup for the OLT PMD receiver (upstream) $T_{receiver_settling}$ time. The optical PMD transmitter has well-known parameters, with a fixed known T_{on} time. After T_{on} time the parameters of the reference transmitter, at TP2 and therefore at TP3, reach within 15% of its steady state values as specified in Table 60–3 for 1000BASE-PX10-U, Table 60–6 for 1000BASE-PX20-U, Table 60–9 for 1000BASE-PX30-U, and Table 60–12 for 1000BASE-PX40-U.

Define $T_{receiver_settling}$ time as the time from the tx_enable assertion, minus the known T_{on} time, to the time the electrical signal at TP4 reaches within 15% of its steady state conditions.

Conformance should be assured for an optical signal at TP3 with any level of its specified parameters before the tx_enable assertion. Especially the $T_{receiver_settling}$ time has to be met in the following scenarios:

— Switching from a ‘weak’ (minimal received power at TP3) ONU to a ‘strong’ (maximal received power at TP3) ONU, with minimal guard band between.
— Switching from a ‘strong’ ONU to a ‘weak’ ONU, with minimal guard band between.
— Switching from noise level, with maximal duration interval, to ‘strong’ ONU power level.

The following procedure is a non-rigorous way to verify the declared $T_{receiver_settling}$ time.

a) Use a reference transmitter with a known T_{on}.
b) For the PMD receiver under test, measure all PMD receiver electrical parameters at TP8 after $T_{receiver_settling}$ from the tx_enable trigger minus the reference transmitter T_{on}.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) Verify the conformance of the measured parameters to within 15% of their specified steady state values.

60.10 Environmental, safety, and labeling

60.10.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

60.10.2 Laser safety

1000BASE-PX10, 1000BASE-PX20, 1000BASE-PX30, and 1000BASE-PX40 optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825-1 and IEC 60825-2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore. Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product's laser, safety features, labeling, use, maintenance, and service. This documentation shall explicitly define requirements and usage restrictions on the host system necessary to meet these safety certifications.

60.10.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

60.10.4 Environment

Reference Annex 67A for additional environmental information.

Two optional temperature ranges are defined in Table 60–15. Implementations shall be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

Table 60–15—Component case temperature classes

Class	Low temperature (°C)	High temperature (°C)
Warm extended	–5	+85
Cool extended	–40	+60
Universal extended	–40	+85

60.10.5 PMD labeling requirements

It is recommended that each PHY (and supporting documentation) be labeled in a manner visible to the user, with at least the applicable safety warnings and the applicable port type designation (e.g., 1000BASE-PX10-U).

Labeling requirements for Hazard Level 1 lasers are given in the laser safety standards referenced in 60.10.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each systems and field pluggable component shall be clearly labeled with its operating temperature range over which their compliance is ensured.

60.11 Characteristics of the fiber optic cabling

The 1000BASE-PX fiber optic cabling shall meet the dispersion specifications defined in IEC 60793-2 and ITU-T G.652, or the requirements of Table 60–16 where they differ. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. It also includes a connector plug at each end to connect to the MDI. The fiber optic cabling spans from one MDI to another MDI, as shown in Figure 60–10.

60.11.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 60–10.

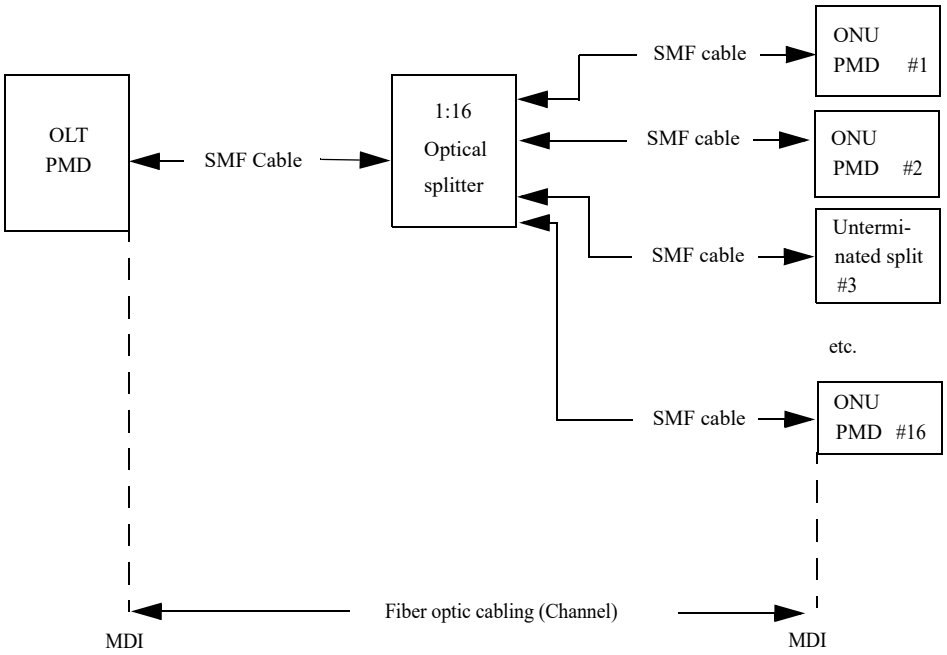

Figure 60–10—Fiber optic cable model

NOTE—The 1:16 optical splitter may be replaced by a number of smaller 1:n splitters such that a different topology may be implemented while preserving the link characteristics and power budget as defined in Table 60–14.

The maximum channel insertion losses shall meet the requirements specified in Table 60–1. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280-4-2 one-cord reference method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

60.11.2 Optical fiber and cable

The fiber optic cable requirements for 1000BASE-PX10 and 1000BASE-PX20 are satisfied by the fibers specified in IEC 60793-2 Type B1.1 (dispersion un-shifted single-mode fiber) and Type B1.3 (low water peak single-mode fiber) and ITU-T G.652, or by the requirements of Table 60–16 where they differ.

The fiber optic cable requirements for 1000BASE-PX30 and 1000BASE-PX40 are satisfied by the fibers specified in IEC 60793–2 Type B1.1 (dispersion un–shifted single-mode fiber), Type B1.3 (low water peak

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

single-mode fiber), ITU-T G.652, and ITU-T G.657 (bend–insensitive single-mode fiber), or by the requirements of Table 75–14 where they differ.

60.11.3 Optical fiber connection

Table 60–16—Optical fiber and cable characteristics

Description[a]	Type B1.1, B1.3 SMF		Unit
Nominal wavelength[b]	1310	1550	nm
Cabled optical fiber attenuation (max)[c]	0.4	0.35	dB/km
Zero dispersion wavelength[d]	$1300 \le \lambda_0 \le 1324$		nm
Dispersion slope (max)	0.093		ps / nm^2 · km

[a]The fiber dispersion values are normative, all other values in the table are optional.
[b]Wavelength specified is the nominal wavelength and typical measurement wavelength. Power penalties at other wavelengths are accounted for.
[c]Attenuation for single-mode optical fiber cables is defined in ITU-T G.652.
[d]See IEC 60793 or ITU-T G.652.

An optical fiber connection as shown in Figure 60–10 consists of a mated pair of optical connectors. The 1000BASE-PX is coupled to the fiber optic cabling through an optical connection and any optical splitters into the MDI optical receiver, as shown in Figure 60–10. The channel insertion loss includes the loss for connectors, splices and other passive components such as splitters, see Table 60–14.

The link attenuations have been calculated on the assumption of 14.5 dB for a 16:1 splitter; 3.5 dB, 4 dB, 7.5 dB, or 8 dB (at the appropriate measurement wavelength where these attenuations are a combination of the minimum range given in Table 60–1 and the values in Table 60–16) for cabled optical fiber attenuation and 1.5 dB for connectors and splices. For example, this allocation supports three connections with an average insertion loss equal to 0.5 dB (or less) per connection, or two connections with a maximum insertion loss of 0.75 dB. Other arrangements, such as a shorter link length and a higher split ratio in the case of 1000BASE-PX20, may be used provided the requirements of Table 60–1 are met.

The maximum discrete reflectance for single-mode connections shall be less than –26 dB.

60.11.4 Medium Dependent Interface (MDI)

The 1000BASE-PX10, 1000BASE-PX20, 1000BASE-PX30, or 1000BASE-PX40 PMD is coupled to the fiber cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” as shown in Figure 60–10. Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a remateable connection, it shall meet the interface performance specifications of IEC 61753-1. The MDI carries the signal in both directions for 1000BASE-PX10, 1000BASE-PX20, 1000BASE-PX30, and 1000BASE-PX40 and couples to a single fiber.

NOTE—Transmitter compliance testing is performed at TP2 as defined in 60.2.1, not at the MDI.

60.12 Protocol implementation conformance statement (PICS) proforma for Clause 60, Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-PX (long wavelength passive optical networks)[114]

60.12.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 60, Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-PX (long wavelength passive optical networks), shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

60.12.2 Identification

60.12.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

60.12.2.2 Protocol Summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 60, Physical Medium Dependent (PMD) sublayer and medium, type 1000BASE-PX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement

61. Physical Coding Sublayer (PCS), Transmission Convergence (TC) sublayer, and common specifications, type 10PASS-TS and type 2BASE-TL

61.1 Overview

This clause specifies the Physical Coding Sublayer (PCS), Transmission Convergence sublayer (TC), and handshaking mechanisms that are common to a family of Physical Layer implementations for Ethernet over voice-grade copper known as 10PASS-TS and 2BASE-TL. These PHYs deliver a minimum of 10 Mb/s over distances of up to 750 m, and a minimum of 2 Mb/s over distances of up to 2700 m, using a single copper pair. Optionally, transmission over multiple copper pairs is supported.

The copper category of EFM PHYs is based on Digital Subscriber Line (DSL) PMDs defined for use in the access network according to ATIS T1, ETSI, and ITU-T standards. These systems are intended to be used in public as well as private networks; therefore they shall be capable of compliance with appropriate regulatory, governmental and regional requirements.

Unlike the specified copper categories for 10BASE-T, 100BASE-T, and 1000BASE-T, existing common carrier voice-grade copper has channel characteristics that are very diverse. Therefore it is conventional to discuss the channel behavior only in terms of averages, standard deviations and percentage worst case.

The 10PASS-TS and 2BASE-TL EFM Copper PHYs, in conjunction with the MAC specified in Clause 4 and Annex 4A, are used for point-to-point communications on a subscriber access network, typically between centralized distribution equipment, such as a Central Office (CO), and equipment located at the subscriber premises [Customer Premises Equipment, (CPE)].

For the 10PASS-TS and 2BASE-TL EFM Copper PHYs, two subtypes are defined: 10PASS-TS-O and 10PASS-TS-R are the subtypes of 10PASS-TS; 2BASE-TL-O and 2BASE-TL-R are the subtypes of 2BASE-TL. A connection can only be established between a 10PASS-TS-O PHY on one end of the voice-grade copper line, and a 10PASS-TS-R PHY on the other end, or between a 2BASE-TL-O PHY on one end and a 2BASE-TL-R PHY on the other end. In public networks, a 10PASS-TS-O or 2BASE-TL-O PHY is used at a CO, a cabinet or other centralized distribution point; a 10PASS-TS-R or 2BASE-TL-R PHY is used as CPE. In private networks, the network administrator will designate one end of each link as the network end. In this clause, 10PASS-TS-O and 2BASE-TL-O are collectively referred to as “CO-subtypes”; 10PASS-TS-R and 2BASE-TL-R are collectively referred to as “CPE-subtypes”. The CO and CPE subtypes of a 10PASS-TS or 2BASE-TL PHY may be implemented in a single physical device.

10PASS-TS and 2BASE-TL PHYs do not provide support for unidirectional links as described in 57.2.12. If a particular anomaly or failure occurs in either downstream or upstream, sublayer-specific signaling will alert the remote end of this condition. In the case of a sustained anomaly or failure, the link will reinitialize.

61.1.1 Scope

This clause defines the Physical Coding Sublayer (PCS) and Transmission Convergence (TC) sublayer for 2BASE-TL and 10PASS-TS. The PCS has similarities to other IEEE 802.3 PCS types, but also differs since new sublayers are added within the PCS sublayer to accommodate the operation of Ethernet over access network copper channels. The TC contains additional functions specific to the EFM Copper PHYs. This clause also defines the common startup and handshaking mechanism used by both PHYs. Parts of register 3.0, parts of register 3.4, and registers 3.60 through 3.73 specified in Clause 45 may be used to control the PCS specified in this clause. The remaining PCS registers defined in Clause 45 do not have any effect on the PCS specified in this clause. Parts of register 6.0 and registers 6.16 through 6.23 specified in Clause 45 may be used to control the TC sublayer specified in this clause.

61.1.2 Objectives

The following are the objectives for 2BASE-TL and 10PASS-TS:

a) To provide 100 Mb/s burst data rate at the MII using Rate Matching.
b) To provide support for simultaneous transmission and reception without interference.
c) To provide for operating over unshielded voice grade twisted pair cable.
d) To provide a communication channel with a mean BER at the PMA service interface of less than 10^{-7} with a noise margin of 6 dB (10PASS-TS) or 5 dB (2BASE-TL).
e) To provide optional support for operation on multiple pairs.
f) To provide functional layering in the PCS which ensures compatibility with the layering and frame interfaces for xDSL systems, including a γ-interface based on that used for the PTM-TC sublayer as defined in ITU-T Recommendation G.993.1.

61.1.3 Relation of 2BASE-TL and 10PASS-TS to other standards

The relation of 2BASE-TL and 10PASS-TS to other standards is shown schematically in Figure 61–1.

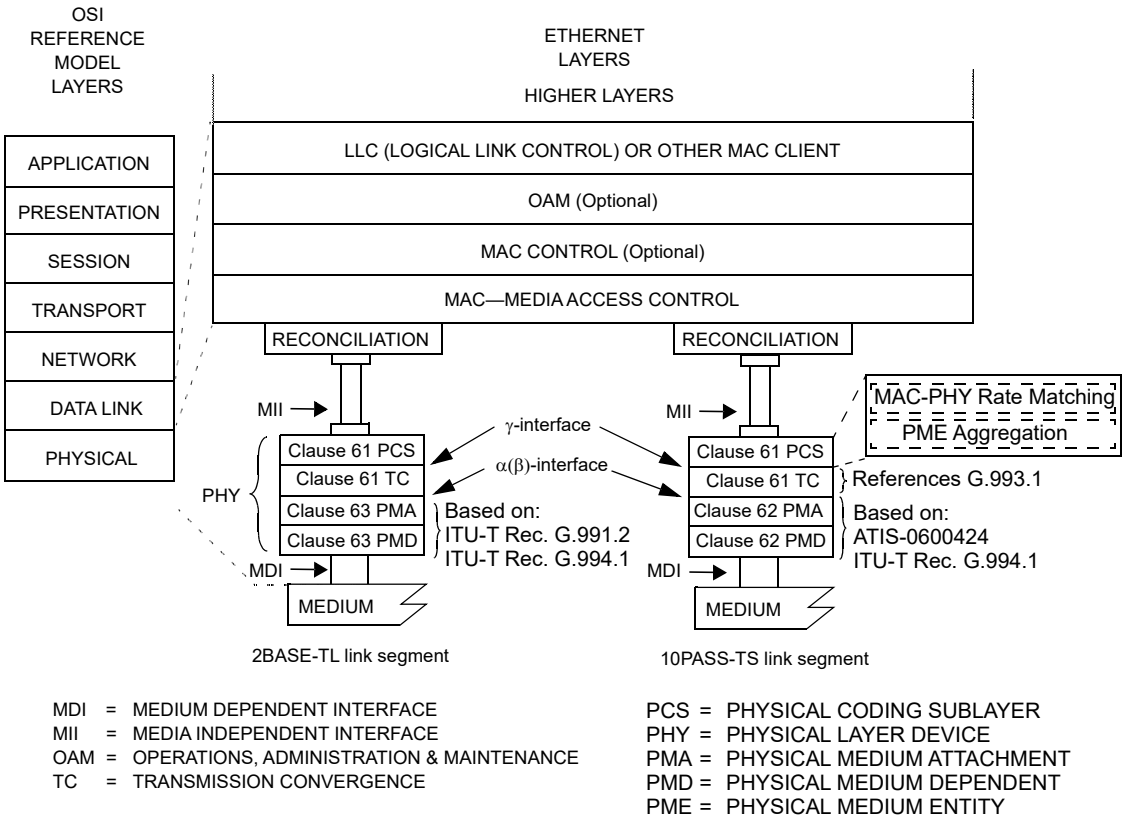

Figure 61–1—Relation of this clause to other standards

NOTE—The PCS shown in the 2BASE-TL PHY and the PCS shown in the 10PASS-TS PHY are two instances of one unique PCS, specified in this clause. The TC shown in the 2BASE-TL PHY and the TC shown in the 10PASS-TS PHY are two instances of one unique TC, specified in this clause.

61.1.4 Summary

61.1.4.1 Summary of Physical Coding Sublayer (PCS) specification

The Physical Coding Sublayer (PCS) for 2BASE-TL and 10PASS-TS contains two functions: MAC-PHY rate matching and PME aggregation. The functional position of the PCS is shown in Figure 61–2.

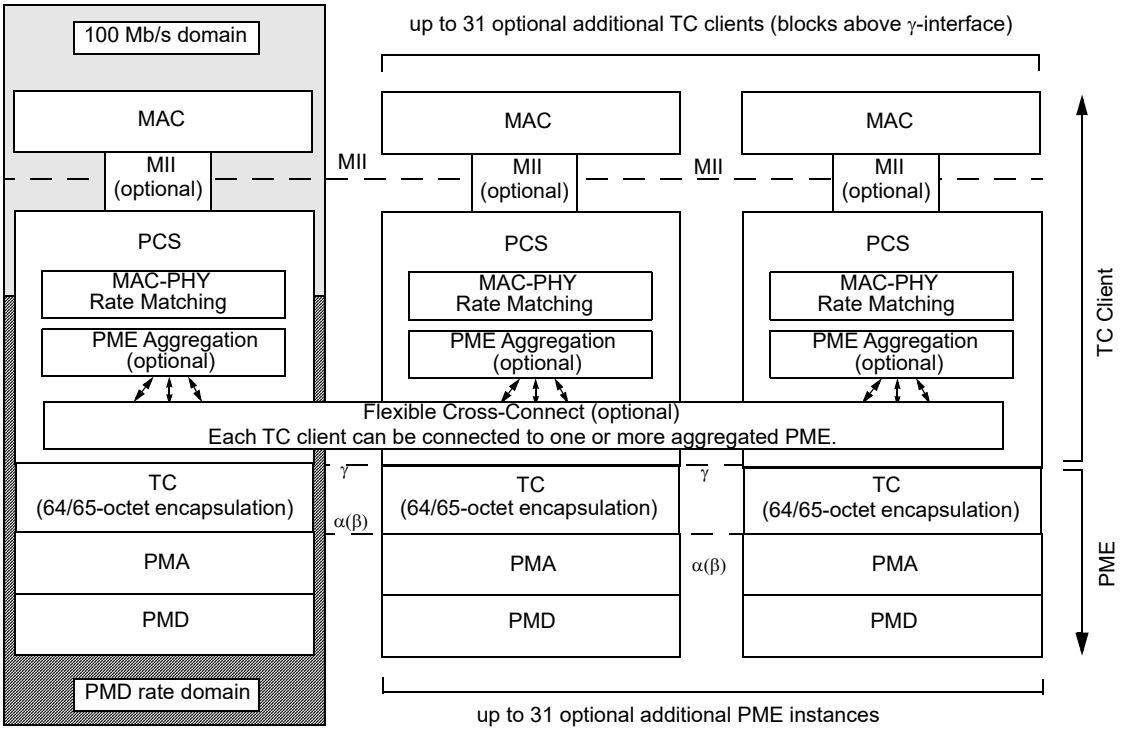

Figure 61–2—Overview of PCS functions

The γ-interface and α(β)-interface are specified in 61.3.1 and 61.3.2, respectively. They are generic interfaces used in various xDSL specifications, such as the ones referenced in Clause 62 and Clause 63. The α(β)-interface is a simple octet-synchronous data interface; the γ-interface adds protocol-awareness (in the case of the TC sublayer defined in this Clause, the γ-interface can signal packet boundaries).

The bit rates in the shaded area labeled "PMD rate domain" are derived from the DSL bit rates. Data is transferred across the γ-interface at the rate imposed by the lower layers. The bit rates in the shaded area labeled "100 Mb/s domain" are synchronous to the MII rate. Data is transferred across the MII at the rate of one nibble per MII clock cycle. The MAC-PHY rate matching function adjusts the inter packet gap so that the net data rate across these interface matches the sum of rates across the γ-interfaces.[115]

In the transmit direction, frames are transferred from the MAC to the PCS across the MII when the MAC-PHY rate matching function allows this. In the PCS, preamble and SFD octets are removed. If the optional PME aggregation function (PAF) is present, the MAC frame is fragmented by the PAF, and fragments are forwarded, optionally through a flexible cross-connect, towards each of the aggregated Physical Medium Entity (PME) instances via their γ-interfaces. If the PAF is not present, the data frame is forwarded to the TC sublayer via the γ-interface. The TC sublayer accepts data from the MAC-PHY rate matching function or the PAF, at the rate at which it can be processed by the TC sublayer, by asserting Tx_Enbl on the γ-interface.

[115]Bit rate domains and physical clock domains do not necessarily coincide. The TC sublayer receives a clock signal from the PMA via the α(β)-interface, and a clock signal from the optional PAF or the MAC-PHY Rate Matching function via the γ-interface. The TC provides matching between these two clock domains.

In the receive direction the TC sublayer pushes data to the PAF (if present) or the MAC-PHY rate matching function by asserting Rx_Enbl on the γ-interface. If multiple links are aggregated, the PAF reassembles the received fragments into data frames. Preamble and SFD octets are generated and prepended to the data frame prior to passing it up to the MAC across the MII. The MAC-PHY Rate Matching function may delay the transfer of the frame to avoid simultaneous transfer of Transmit and Receive frames if required.

NOTE—The MAC_PHY rate matching function and PME Aggregation function both require some form of frame buffer for many implementations. It is recommended that these frame buffers should be sized to accommodate maximum length envelope frames (see 3.2.7).

61.1.4.1.1 Implementation of Media Independent Interface

10PASS-TS and 2BASE-TL specify the optional use of the MII electrical interface as defined in Clause 22 (see also 61.1.5.2). 10PASS-TS and 2BASE-TL do not utilize the MII management interface as described in 22.2.4. The use of the MDIO interface specified in Clause 45 or an equivalent management interface is recommended.

Notwithstanding the specifications in 22.2.2.9, CRS may be asserted by a full-duplex EFM Copper PHY to reduce the effective MAC rate to that of the PHY.

61.1.4.1.2 Summary of MAC-PHY Rate Matching specification

The 10PASS-TS and 2BASE-TL PCS is specified to work with a MAC operating at 100 Mb/s using the MII as defined in Clause 22. The PCS matches the MAC's rate of data transmission to the transmission data rate of the medium, if slower. This is achieved using deference as defined in Annex 4A.

The MAC transmits data at a rate of 100 Mb/s, which is buffered by the PCS before being transmitted onto the medium. Prior to transmission, the MAC checks the carrierSense variable (mapped from the MII signal CRS), and will not transmit another frame as long as carrierSense is asserted. In order to prevent the PCS's transmit buffer from overflowing, the PCS keeps CRS asserted until it has space to receive a maximum length frame. The PCS forces COL to logic zero to prevent the MAC from dropping the frame and performing a re-transmission.

The transmitter MAC-PHY Rate Matching function strips the Preamble and SFD fields from the MAC frame, and forwards the resulting data frame to the PME Aggregation Function or to the TC sublayer.

For reception the PHY buffers a complete frame, prepends the Preamble and SFD fields, and sends it to the MAC at 100 Mb/s.

It is recognized that some MAC implementations have to be configured for half duplex operation to support deference (according to 4.2.3.2.1), and that these may not allow the simultaneous transmission and reception of data while operating in half duplex mode. To permit operation with these MACs the PHY has an operating mode where MAC data transmission is deferred using CRS when received data is sent from the PHY to the MAC. This mode of operation is defined in Figure 61–8, which describes the MAC-PHY rate matching receive state diagram. This state diagram gives receive frames priority over transmitted frames to ensure the receive buffer does not overflow.

The definition of MAC-PHY rate matching is presented in 61.2.1.

61.1.4.1.3 Summary of PME Aggregation specification

An optional PME Aggregation Function (PAF) allows one or more PMEs to be combined together to form a single logical Ethernet link. The PAF is located in the PCS, between the MAC-PHY Rate Matching function and the TC sublayer. It interfaces with the PMEs across the γ-interface, and to the MAC-PHY Rate Matching function using an abstract interface. The definition of the PAF is presented in 61.2.2.

61.1.4.1.4 Overview of management

Ethernet OAM (Clause 57) runs over a MAC service which uses a PHY consisting of either a single physical link, or more than one physical 2BASE-TL or 10PASS-TS links, aggregated as described in 61.2.2. The Ethernet OAM operates as long as there is at least one PME in the PHY that is operational. The physical xDSL PMEs in Clause 62 and Clause 63 each have their own management channel that operates per loop (eoc, VOC and IB for 10PASS-TS; EOC and IB for 2BASE-TL).

61.1.4.2 Summary of Transmission Convergence (TC) specification

The Transmission Convergence sublayer (TC) resides between the γ-interface of the PCS and α(β)-interface of the PMA. It is intended to convert the data frame to be sent into the format suitable to be mapped into PMA, and to recognize the received frame at the other end of the link. Since PMA and MII clocks may be unequal, the TC also provides clock rate matching. The definition of the TC sublayer is presented in 61.3.

61.1.4.3 Summary of handshaking and PHY control specification

Both 2BASE-TL and 10PASS-TS use handshake procedures defined in ITU-T G.994.1 at startup. Devices implementing both 2BASE-TL and 10PASS-TS port types may use ITU-T G.994.1 to determine a common mode of operation.

61.1.5 Application of 2BASE-TL, 10PASS-TS

61.1.5.1 Compatibility considerations

The PCS, TC, PMA, and the MDI are defined to provide compatibility among devices designed by different manufacturers. Designers are free to implement circuitry within the PCS, TC, and PMA in an application-dependent manner provided the MDI and MII specifications are met.

61.1.5.2 Incorporating the 2BASE-TL, 10PASS-TS PHY into a DTE

When the PHY is incorporated within the physical bounds of a DTE, conformance to the MII is optional, provided that the observable behavior of the resulting system is identical to that of a system with a full MII implementation. For example, an integrated PHY may incorporate an interface between PCS and MAC that is logically equivalent to the MII, but does not have the full output current drive capability called for in the MII specification.

61.1.5.3 Application and examples of PME Aggregation

The PME Aggregation Function defined in 61.2.2 allows multiple PME instances to be aggregated together to form one logical link underneath one MII (or MAC). Additionally, the control mechanism allows multi-MAC devices to be built with flexible connections between the MACs and the PMEs. Clause 45 defines a mechanism for addressing and controlling this flexible connectivity. The relationship between the flexible connectivity and the other functions within the PCS is shown in Figure 61–2.

The connection relationship between the PCS instances (including MIIs) and the PME instances is defined in two registers: PME_Available_register (see 45.2.3.29) and PME_Aggregate_register (see 45.2.3.30). The PME_Available_register controls which PMEs may be aggregated into a particular PCS (and MII). This register value is limited by the physical connectivity in the device, may be further constrained by management, and is additionally constrained as PMEs are aggregated into other PCSs (which causes their bit to be cleared to zero in the PCS instances that they are not aggregated into). The register represents the potential for connectivity into this PCS at the particular point in time. The PME_Aggregate_register indicates the actual connectivity, i.e., which PMEs are being aggregated into the particular PCS.

NOTE—The addressing of PCS instances is independent of the addressing of PME instances in order to support the flexible connectivity. Each PCS consumes one of the 32 available port addresses.

Bits corresponding to the same PME may appear in multiple PME_Available_registers but the PME_Aggregate_register for each MII shall be set such that each PME is only actively connected to at most

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

one MII. A particular bit set in one PME_Aggregate_register shall exclude the same corresponding bit in all other PME_Aggregate_registers for the same MDIO connected system.

61.1.5.3.1 Addressing PCS and PME instances

The addressing of the MDIO management interface is defined in 45.1. It is assumed that the reader is familiar with the definition of this interface. The examples here assume that only three MMDs are used: PCS (MMD = 3), TC (MMD = 6), and PMA/PMD (MMD = 1). The combination of TC, PMA and PMD is shown as PME in Figure 61–3. The difference between these examples and the example shown in 45.1 is that the PCS instances are addressed independently of the PME instances. Up to 32 PCS instances and up to 32 PME instances may be addressed by one MDIO bus. These instances may make up one or more aggregateable subdomains. The connection of the MDIO bus to the MMDs is shown in Figure 61–3.

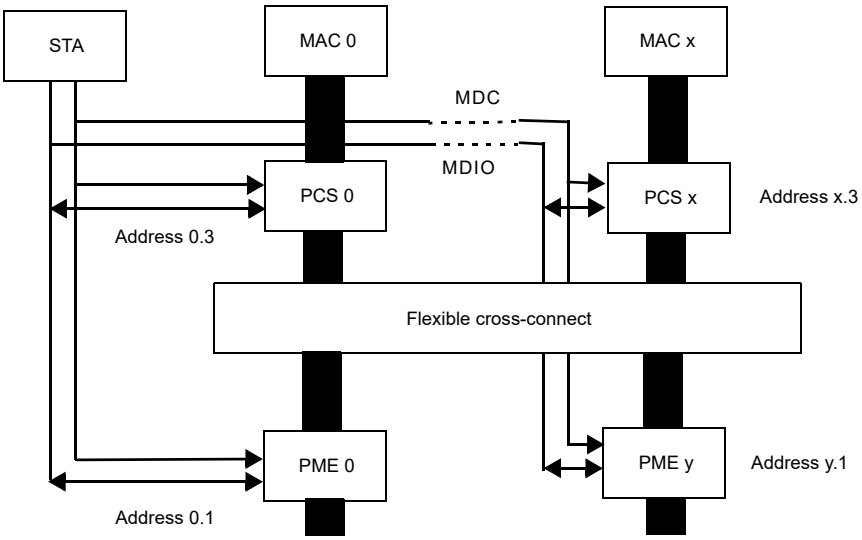

Figure 61–3—Connection of MDIO bus to MMD instances

In the example shown in Figure 61–3 there is no necessary connection between the PCS address and the PME address. The number of PCS instances may be different from the number of PME instances.

61.1.5.3.2 Indicating PME aggregation capability

The PME aggregation capability is indicated by the state of the PME_Available_register (see 45.2.3.29). An instance of this register is readable for each PAF instance *x* at register addresses *x*.3.62 and *x*.3.63. (Device address 3 of every port *x* is assigned to the PCS. The PAF specific registers reside under the *x*.3 register tree, because the PAF is part of the PCS as shown in Figure 61–2.) A bit is set in this register corresponding to the PME address for each PME which can be aggregated through the PAF in that PCS. Some examples are given that show register contents and connectivity for some popular configurations:

a) Simple two PME per MII connections, 32 PMEs are available for aggregation into 16 MIIs (PCS instances). PME_Available_register contents are shown in Table 61–1. A diagram of the connectivity is shown in Figure 61–4.
b) Pairs of 4-to-1 connections, 32 PMEs are available for aggregation into 16 MIIs (PCS instances) in a manner that allows each PME to connect to one of 2 MIIs and each MII to aggregate up to 4 PMEs. PME_Available_register contents are shown in Table 61–2. A diagram of the connectivity is shown in Figure 61–5.
c) 24-to-12 fully flexible connections, 24 PMEs are available for aggregation into 12 MIIs (PCS instances) in a manner that allows any PME to connect to any MII. PME_Available_register

contents are shown in Table 61–3. No connectivity diagram is shown as any connection is possible between PMEs and MIIs.

[a]A mapping in which the same PME is available for connection to several PCS instances (as shown) is only allowed at the CO-side.

61.1.5.3.3 Setting PME aggregation connection

The PME aggregation connection is set using the PME_Aggregate_register (see 45.2.3.30). This register is writeable for each PCS instance (x) at register addresses x.3.64 and x.3.65. A bit is set in this register corresponding to the PME address for each PME that is to be aggregated through that PCS. Some examples are given that show register contents and connectivity for some popular configurations:

a) Simple two PME per MII connections (as shown in example a above), the first MII aggregates 2 PMEs, the second MII only connects through 1 PME, as does the sixteenth. PME_Aggregate_register contents are shown in Table 61–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Pairs of 4-to-1 connections (as shown in example b above), the first MII aggregates 3 PMEs, the second MII only connects through 1 PME, the sixteenth MII aggregates 2 PMEs. PME_Aggregate_register contents are shown in Table 61–5.
c) 24-to-12 fully flexible connections (as shown in example c above), the first MII aggregates 5 PMEs, the second MII only connects through the 24th PME, the eleventh MII is not used, twelfth MII aggregates 2 PMEs. PME_Aggregate_register contents are shown in Table 61–6.

Table 61–4—PME_Aggregate_register contents (example a)

[a]The PME Aggregation functions have to be performed when PAF_enable is set, even if only 1 bit is set in the PME_Aggregate_register.

61.1.5.4 Support for handshaking

It is the goal of the ITU-T that all specifications for digital transceivers for use on public telephone network copper subscriber lines use ITU-T G.994.1 for startup. ITU-T G.994.1 procedures allow for a common startup mechanism for identification of available features, exchange of capabilities and configuration information, and selection of operating mode. As the two loop endpoints are usually separated by a large distance (e.g., in separate buildings) and often owned and installed by different entities, ITU-T G.994.1 also aids in diagnosing interoperability problems. ITU-T G.994.1 codespaces have been assigned by ITU-T to ATIS T1, ETSI, and IEEE 802.3 in support of this goal.

The description of how ITU-T G.994.1 procedures are used for Ethernet in the First Mile handshaking and PHY control are contained in 61.4.

61.2 PCS functional specifications

61.2.1 MAC-PHY Rate Matching functional specifications

61.2.1.1 MAC-PHY Rate Matching functions

The PHY shall use CRS to match the MAC's faster rate of data transmission to the PHY's slower rate.

Upon receipt of a MAC frame on the MII, the PHY shall discard the Preamble and SFD fields, and transmit the resulting data frame across the physical link.

The PHY shall prepend the Preamble and the SFD fields to a received frame before sending it to the MAC.

The PHY shall support a mode of operation where it does not send data to the MAC while the MAC is transmitting (see MII receive during transmit register, defined in 45.2.3.28).

If the PAF is disabled or not present, transmit frames shall not be forwarded to the TC sublayer unless TC_link_state is true for the whole frame. If the PAF is enabled, transmit fragments shall not be forwarded from the PAF to a TC sublayer unless the TC_link_state value of that TC sublayer instance is true for the whole fragment.

NOTE—This implies that in the absence of an active PAF, frames being transmitted over the MII when TC_link_state becomes true are never forwarded to the TC sublayer. A frame being transmitted over the MII when TC_link_state becomes false is aborted.

61.2.1.2 MAC-PHY Rate Matching functional interfaces

61.2.1.2.1 MAC-PHY Rate Matching – MII signals

MII signals are defined in 22.2.2 and listed in Table 23–1 in 23.2.2.1.

COL shall be forced to logic zero by the PCS.

CRS behaves as defined in 61.2.1.3.2.

61.2.1.2.2 MAC-PHY Rate Matching–Management entity signals

See 61.2.3.

61.2.1.3 MAC-PHY Rate Matching state diagrams

61.2.1.3.1 MAC-PHY Rate Matching state diagram constants

No constants are defined for the MAC-PHY rate matching state diagrams.

61.2.1.3.2 MAC-PHY Rate Matching state diagram variables

CRS
: CRS signal of the MII as specified in Clause 22. It is asserted when either of crs_tx or crs_rx are true: CRS ⇐ crs_tx + crs_rx

crs_and_tx_en_infer_col
: True if a reduced-pin MAC-PHY interface is present that infers a collision when TX_EN and CRS are both true simultaneously.

crs_rx
: Asserted by the MAC-PHY rate matching receive state diagram to control CRS

crs_tx
: Asserted by the MAC-PHY rate matching transmit state diagram to control CRS

power_on
: 'power_on' is true while the device is powering up. It becomes false once the device has

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

reached full power. Values:
FALSE; The device is completely powered (default).
TRUE; The device has not been completely powered.

Reset
: True when the PCS is reset via control register bit 3.0.15.

RX_DV
: RX_DV signal of the MII as specified in Clause 22

rx_frame_available
: Set when the PHY's receive FIFO contains one or more complete frames

transferFrameCompleted
: Variable of type Boolean
TRUE if the transmission of the received frame over the MII has been completed,
FALSE otherwise.
The variable returns to the default state (FALSE) upon entry into any state.

tx_buffer_available
: Set when the PHY's transmit FIFO has space to receive a maximum length packet from the MAC

TX_EN
: TX_EN signal of the MII as specified in Clause 22

tx_rx_simultaneously
: False if the MAC is configured in half duplex mode to support deference and it is not capable of transmitting and receiving simultaneously in this mode.

61.2.1.3.3 MAC-PHY Rate Matching state diagram timers

ipg_timer
: Timer used to generate a gap between receive packets across the MII.
Duration: 960 ns, tolerance ±100 ppm.

rate_matching_timer
: Timer used in rate matching state diagram
Duration: 1120 ns, tolerance ±100 ppm.

The rate_matching_timer operates in a manner consistent with 14.2.3.2. The timer is restarted on entry to the WAIT_FOR_TIMER_DONE state with the action: 'Start rate_matching_timer'. It is then tested in the exit condition with the expression "rate_matching_timer_done".

The duration is set to 1120 ns to allow 960 ns for the inter frame gap plus 160 ns for the MAC to recognize CRS. 160 ns is equivalent to 16 bit times and is consistent with the assumptions about MAC performance listed in Table 21–2 in 21.7.

61.2.1.3.4 MAC-PHY Rate Matching state diagram functions

transferFrame()
: This function transmits a packet to the MAC across the MII, according to the MII protocol as described in 22.2. This function generates RX_DV to delimit the frame in accordance with 22.2.2.6. Upon completion of frame transfer to the MAC, this function sets the variable transferFrameCompleted to TRUE.

61.2.1.3.5 MAC-PHY Rate Matching state diagrams

The state diagrams for the MAC-PHY Rate Matching functions are shown in Figure 61–6, Figure 61–7, and Figure 61–8.

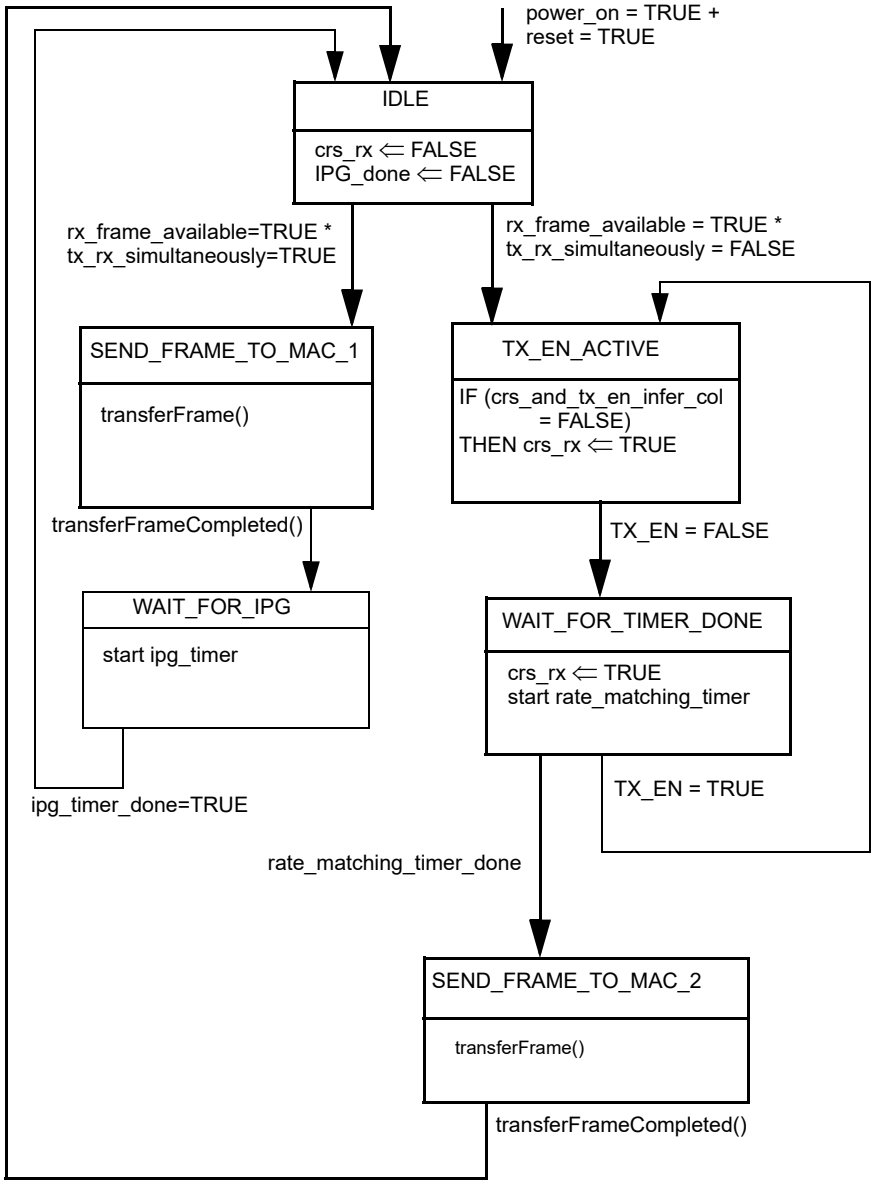

Figure 61–8—MAC-PHY rate matching receive state diagram

61.2.2 PME Aggregation functional specifications

This subclause defines an optional PME Aggregation Function (PAF) for use with Ethernet MACs in EFM copper PHYs. PME Aggregation allows one or more PMA/PMDs to be combined together to form a single logical Ethernet link.

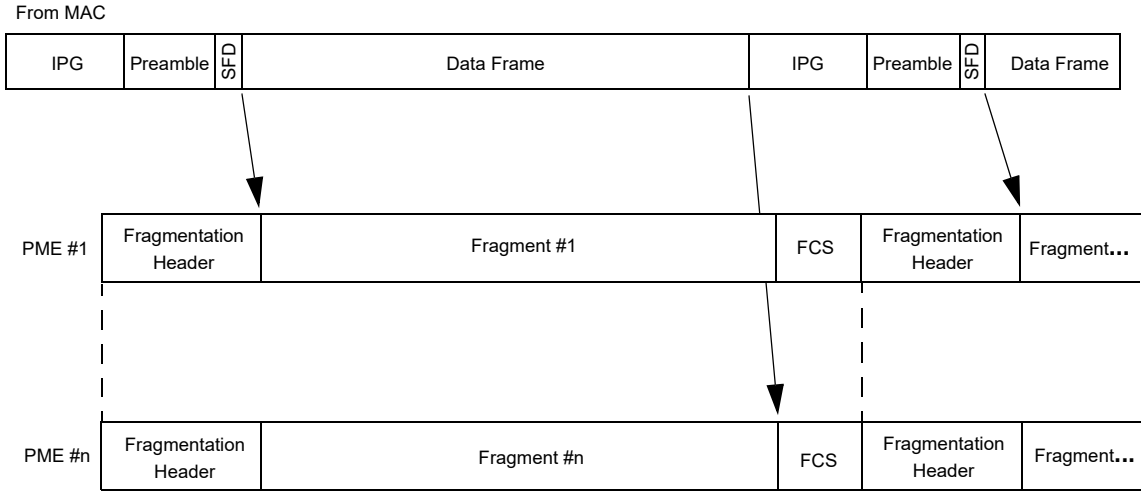
The PAF is located between the MAC-PHY Rate Matching function and the TC sublayer as shown in Figure 61–2. The PAF interfaces with the TC sublayer instances across the γ-interface. The PAF interfaces to the MAC-PHY Rate Matching function using an abstract interface whose physical realization is left to the implementer, provided the requirements of this standard are met.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The PME Aggregation function has the following characteristics:

a) Supports aggregation of up to 32 PMA/PMDs
b) Supports individual PMA/PMDs having different data rates
c) Ensures low packet latency and preserves packet sequence
d) Scalable and resilient to PME failure
e) Independent of type of EFM copper PHY
f) Allows vendor discretionary algorithms for fragmentation

61.2.2.1 PAF Enable and Bypass



For systems that do not have the ability to aggregate loops PAF_available will not be asserted. Additionally, a system may have PAF_available asserted but PAF_enable will be deasserted to indicate that aggregation is not activated.

In both of these cases, the entire data frame is passed across the γ-interface to the TC sublayer without any fragmentation and without fragmentation header. On the receive end, entire data frames are transferred from the γ-interface to the MAC-PHY rate matching function without any reference to the PAF error detecting rules (see 61.2.2.7). If an error has been detected by the FCS in the TC then the MAC-PHY rate matching function shall assert RX_ER during at least one octet of the frame across the MII.

Systems that have the ability to aggregate but are not enabled for aggregation will have the connectivity between the PCS and one PME set either by default, by local management (for CO-subtype devices) or by remote management (for CPE-subtype devices). This will define which γ-interface is used for the transfer of non-fragmented frames. Refer to 61.2.2.8.3 for the function of PAF_available and PAF_enable and Clause 45 for access to these registers.

61.2.2.2 PME Aggregation functions

The PME Aggregation functions provide a fragmentation procedure at the transmitter and a reassembly procedure at the receiver. The fragmentation and reassembly procedures take a data frame and partition it into one or more fragments as shown in Figure 61–9. Each fragment is given a fragmentation header and transmitted over a specific TC sublayer instance. A Frame Check Sequence, known as the TC-CRC, is added to each fragment by the TC sublayer. The fragmentation header has the format shown in Figure 61–10. Short data frames can be transported over a single fragment, and consequently both StartOfPacket and EndOfPacket can be set to '1' simultaneously.

NOTE—This is one example of how a frame may be fragmented across multiple PMEs.

Figure 61–9—Data frame fragmentation

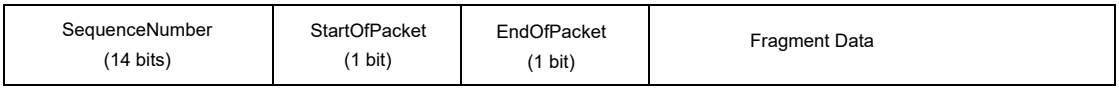

Figure 61–10—Fragment format

61.2.2.3 PME Aggregation Transmit function

The PME Aggregation transmit functions uses the following algorithm:

a) Select an active PME (i.e., one with TC_link_state asserted, see 61.3.1) for the next transmission.
b) Select the number of octets to transmit on that PME (shall not be less than minFragmentSize nor greater than maxFragmentSize, see 61.2.2.6).
c) Increment by one (modulo 2^{14}) and set fragment sequence number in the Fragmentation Header. There is a single sequence number stream for each aggregation, not one per PME. It is this sequence number stream that the receiver uses for fragment reassembly.
d) Set the start-of-packet and end-of-packet bits in the Fragmentation Header as appropriate.
e) Transmit fragment to the TC sublayer.

It is important to note that the selection of the next PME to use in transmission [step a)] and the number of octets to transmit [step b)] is implementation dependent. However, implementations shall follow the restrictions as outlined in 61.2.2.6.

61.2.2.4 PME Aggregation Receive function

The PME aggregation receive function requires per-PME queues as well as a per-MAC fragment buffer for fragment reassembly. The algorithm assumes only "good" fragments are placed on the per-PME receive queues ("bad" fragments are discarded according to the rules in 61.2.2.7).

The sequence number rolls over after it reaches the maximum value, thus all sequence number comparisons shall use "split horizon" calculations. Split horizon calculations are defined for comparisons that are valid for numbers that roll over after reaching the maximum value. Generically, "x is less than y" is defined as $x < y \le x +$ (maxSequenceNumber+1)/2.

61.2.2.4.1 Expected sequence number

During initial startup and in the event of certain errors, the receive algorithm has to determine which sequence number is expected next (expectedFragmentSequenceNumber). When the link state is changed to UP, the expected sequence number is unknown and no errors in fragment sequencing (see 61.2.2.7.2) shall be recorded.

61.2.2.4.2 PME Aggregation Receive function state diagram variables

The following variables are used in the PME Aggregation Receive function state diagram.

allQueuesNonEmpty
: variable of type Boolean that indicates whether any active queue is currently empty.
TRUE if none of the active queues is currently empty
FALSE if at least one active queue is currently empty

expectedFragmentSequenceNumber
: the sequence number expected in the receive process that would not result in a fragment error, initialized to the smallest sequence number of fragments at the head of per-PME queues when either all active queues are non-empty or at least one queue has been non-empty for maxDifferentialDelay bit times at the bit rate of the PMD associated with that queue

frameLengthOverflow
: variable of type Boolean, indicating that the reassembly buffer is overflowing due to a received frame that is too long, as described in 61.2.2.7.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TRUE if the overflow condition exists
FALSE during normal operation

missingStartOfPacket
: variable of type Boolean, indicating that a fragment was received with the StartOfPacket bit deasserted while the packet assembly function was between frames (i.e., waiting for a Start of Packet).

nextFragmentSequenceNumber
: smallest sequence number of fragments at the head of per-PME queues

noFragmentProcessed_Timer
: variable of type Boolean that indicates whether at least one active queue has been non-empty for maxDifferentialDelay bit times at the bit rate of the PMD associated with that queue. Each fragment processed on any queue restarts all per-queue timers.
TRUE if a timeout of maxDifferentialDelay bit times has expired
FALSE if the timeout of maxDifferentialDelay bit times has not yet expired

oneQueueNonEmpty_Timer
: variable of type Boolean that indicates whether at least one active queue has been non-empty for at least maxDifferentialDelay bit times.
TRUE if at least one active queue has been non-empty for at least maxDifferentialDelay bit times
FALSE otherwise

smallestFragmentSequenceNumber
: smallest sequence number of fragments at the head of per-PME queues

unexpectedEndOfPacket
: variable of type Boolean, indicating that a fragment was received with the EndOfPacket bit asserted and the StartofPacket bit deasserted while the packet assembly function was between frames (i.e., waiting for a Start of Packet)

unexpectedStartOfPacket
: variable of type Boolean, indicating that a fragment is received with the StartOfPacket bit asserted while the packet assembly function was mid-frame (i.e., waiting for an End of Packet)

The following functions are used in the PME Aggregation Receive function state diagram.

errorDetection()
: function comprising the process described in 61.2.2.7.2

fragmentError()
: function comprising the process described in 61.2.2.7.3

61.2.2.4.3 PME Aggregation Receive function state diagram

The receive function executes the algorithm as shown in Figure 61–11. The initial state of the state diagram is INITIALIZING. This state is entered when at least one TC_link_state is asserted for the first time after system power-on, and each time when at least one TC_link_state is asserted after all having been deasserted for any reason.

61.2.2.4.4 PME Aggregation Receive function state diagram description

Aggregation receive algorithm is as follows:

a) Determine the nextFragmentSequenceNumber via the algorithm in 61.2.2.4.1.
b) If the nextFragmentSequenceNumber is equal to the expectedFragmentSequenceNumber, process that fragment and continue to step c). If (nextFragmentSequenceNumber is less than expectedFragmentSequenceNumber) or (all the active PME queues are non-empty and nextFragmentSequenceNumber ≠ expectedFragmentSequenceNumber) or (any PME queue has been non-empty for maxDifferentialDelay bit times without any fragment being processed) follow the fragment sequence error handling rules described in 61.2.2.7.2 before returning to normal fragment processing.

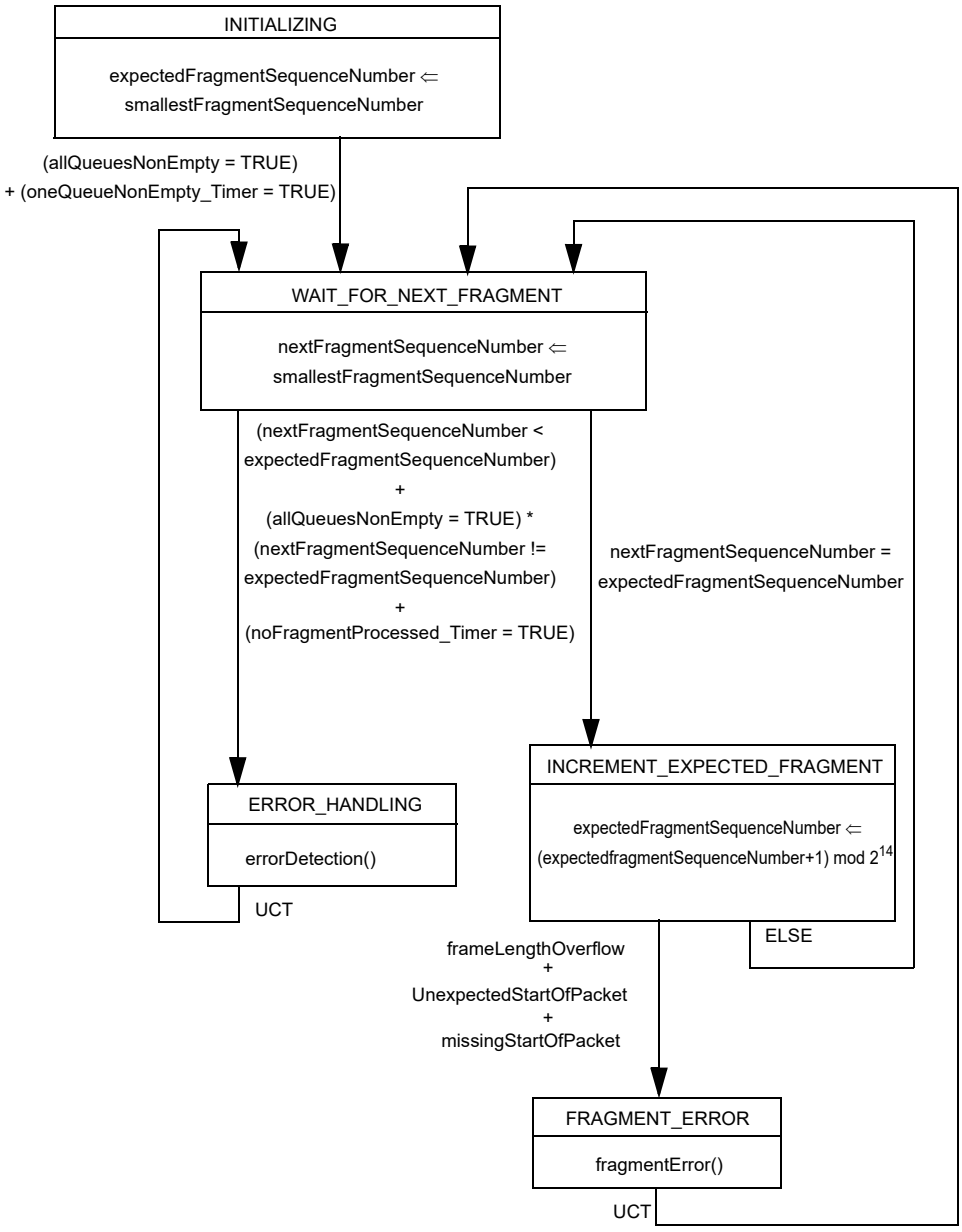

Figure 61–11—Aggregation receive function

c) Accept the fragment into the fragment buffer. If (accepting the fragment into the fragment buffer causes a frame length overflow) or (the fragment is an unexpected start of packet) or (the fragment is an unexpected end of packet) or (the fragment has the StartOfPacket bit deasserted when the start of a new packet is expected) then follow the error handling procedures described in 61.2.2.7.3. Else if that fragment is an end-of-packet, pass the packet to the MAC-PHY Rate Matching layer.
d) Increment (modulo 2^{14}) the expectedFragmentSequenceNumber.
e) Repeat processing.

61.2.2.5 PME Aggregation restrictions

In order to guarantee correct receiver operation, a transmitter has to ensure that pairs in an aggregate group obey certain restrictions.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—These restrictions ensure that buffer sizes for receivers of 2^{14} bits per PME are sufficient.

One factor is the differential latency between multiple PMEs in an aggregated group. Differential latency measures the variation in the time required to transmit across different PMEs. To normalize the latency measurement for high and low speed links it is measured in bit times. A differential latency between two PMEs is defined as the number of bits, N, that can be sent across the fast link, in the time that it takes one maxFragmentSize fragment to be sent across the slow link. Large differential latencies generate greater variance in bit delivery times across aggregated PMEs, which in turn require large sequence number ranges. The PMD control of aggregated links controls the maximum latency difference between any two aggregated links. This is achieved by configuring the bit rate, error correction and interleaving functions in the PMA/PMD of each link. The burst noise protection offered by the error correction and interleaving[116] functions is directly proportional to the latency, therefore it is logical that multiple aggregated links in the same environment should be optimized to have similar latencies. Differences in electrical length will not contribute significantly to the differential latency; no additional per-PME buffer size is required for this variation.

NOTE 2—The value for differential latency for two identical links will be 4096 bit times because the definition includes the length of a maximum size fragment.

The speed ratio of the links also restricts what PMEs can be aggregated together. The speed ratio is defined as the ratio of the bit rate of the faster link divided by the bit rate of the slower link.

The restrictions that govern which PMEs can be aggregated are as follows:

a) The differential latency between any two PMEs in an aggregated group shall be no more than maxDifferentialDelay.
b) The highest ratio of speeds between any two aggregated links shall be maxSpeedRatio. A speed ratio of 4 may only be used if the latency is controlled to meet the restriction.

Table 61–7 specifies the values for constants maxDifferentialDelay and maxSpeedRatio.

Table 61–7—PME Aggregation constants

Constant name	Value
maxDifferentialDelay	15 000 bit times
maxSpeedRatio	4

61.2.2.6 PME Aggregation transmit function restrictions

There are factors that limit the freedom of the transmission algorithm specified in 61.2.2.3.

A first factor is the size of the fragments being transmitted across the PMEs. Very small fragments require larger sequence number ranges as there can be more fragments within the same number of bit times.

Another restriction on the size of the fragments, is that fragments shall be a multiple of 4 octets in size when possible.

The restrictions for the transmission algorithm in 61.2.2.3 are:

a) Fragments shall not be less than minFragmentSize not including PAF header.

[116]Interleaving is the relevant issue here, since it affects latency. While 2BASE-TL does not have block error correction, it does use trellis coding, which is sometimes considered forward error correction.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Fragments shall not be more than maxFragmentSize not including PAF header.
c) The fragment size, not including PAF header, shall be a multiple of 4 octets except for the last fragment of a data frame.

NOTE—A fragment size of maxFragmentSize may only be used if the latency is controlled to meet the restriction a) in 61.2.2.5.

These restrictions allow the use of a 14-bit sequence number space. As a consequence, the maximum sequence number is $2^{14} - 1$ (maxSequenceNumber).

Table 61–8 specifies the values for constants maxFragmentSize and minFragmentSize.

Table 61–8—Fragment size constants

Constant name	Value
maxFragmentSize	512 octets
minFragmentSize	64 octets

61.2.2.7 Error-detecting rules

There are three classes of error detected by the PAF: Errors during fragment reception; Errors in fragment sequencing; and Errors during packet reassembly. In the case of an error detected by the PAF, it sends the frame or part of frame to the MAC with RX_ER asserted. When the PAF is unable to reconstruct or partially reconstruct a frame due to such errors, it sends a garbage frame up to the MAC, in order to allow higher-layer event counters to register the error. The garbage frame shall consist of 64 octets of 00 (including CRC). Preamble and SFD are prepended before the frame is sent to the MII according to 61.2.1.1.

The rules described in this subclause are applied by the functions errorDetection() and fragmentError() referenced in Figure 61–11.

61.2.2.7.1 Errors during fragment reception

The receive TC function passes all decapsulated fragments to the PAF across the γ-interface. If the TC detects an error in the encapsulation, it asserts Rx_Err on the γ-interface. If the TC detects an error in the TC-CRC, it asserts Rx_Err on the γ-interface. Asserting Rx_Err during fragment reception invalidates the entire fragment.

For each PMA α(β)-interface, the per-PMA buffering mechanism shall discard the fragment if any of the following conditions occur:

a) Rx_Err is asserted during the reception of the fragment across the γ-interface.
b) The fragment is too small — less than minFragmentSize as defined in 61.2.2.6.
c) The fragment is too large — more than maxFragmentSize as defined in 61.2.2.6.
d) The fragment would cause the per-PMA received buffer to overflow.

The PAF shall then assert one of the following per-PMA error flags as appropriate:

— TC_PAF_RxErrorReceived
— TC_PAF_FragmentTooSmall
— TC_PAF_FragmentTooLarge
— TC_PAF_Overflow

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

61.2.2.7.2 Errors in fragment sequencing

If nextFragmentSequenceNumber is outside the range (expectedFragmentSequenceNumber through expectedFragmentSequenceNumber + (maxSequenceNumber+1)/2) then assert PAF_BadFragmentReceived. Discard the fragment, do not increment ExpectedFragmentSequenceNumber.

If all active PMA buffers are non empty and nextFragmentSequenceNumber is greater than expectedFragmentSequenceNumber then assert PAF_LostFragment, set expectedFragmentSequenceNumber equal to nextFragmentSequenceNumber.

If any PMA buffer is non empty for maxDifferentialDelay bit times (for that PMA/PMD) and no fragment is transferred then assert PAF_LostFragment, set expectedFragmentSequenceNumber equal to nextFragmentSequenceNumber.

Having detected one of the above fragment sequencing errors, the packet assembly function shall act as follows:

— If the packet assembly function was mid-frame (i.e., waiting for an End of Packet), the first part of the frame shall be transferred across the MII, then assert RX_ER signal on the MII, abort frame transfer and flush PMA buffers until the next Start of Packet is received.
— If the packet assembly function was between frames (i.e., waiting for a Start of Packet), assert RX_ER signal on the MII and send a garbage frame as defined in 61.2.2.7 to the MAC.

61.2.2.7.3 Errors in packet reassembly

If a fragment is received with the StartofPacket bit deasserted while the packet assembly function was between frames (i.e., waiting for a Start of Packet), discard the offending fragment, assert RX_ER signal on the MII and send a garbage frame as defined in 61.2.2.7 to the MAC. Assert PAF_LostStart.

If a fragment is received with the StartOfPacket bit asserted while the packet assembly function was mid-frame (i.e., waiting for an End of Packet), the first part of the frame shall be transferred across the MII, then assert RX_ER signal on the MII, abort frame transfer and flush the PMA buffers, starting the next frame with the Start of Packet fragment just received. Assert PAF_LostEnd.

If a fragment is received while the packet assembly function was mid-frame (i.e., waiting for an End of Packet) and would cause the frame size to exceed the maximum supported frame size (see 4.2.4.2.1) then the first part of the frame, excluding the error causing fragment, shall be transferred across the MII, then assert RX_ER signal on the MII, abort frame transfer and flush PMA buffers until the next Start of Packet is received. Assert PAF_LostEnd.

61.2.2.8 PME aggregation functional interfaces

The PAF interfaces with the TC sublayer instances across the γ-interface. The PAF interfaces to the MAC-PHY Rate Matching function using an abstract interface whose physical realization is left to the implementer, provided the requirements of this standard are met.

61.2.2.8.1 PME aggregation–γ-interface signals

The PAF interfaces with the PMA/PMDs across the γ-interface. The γ-interface specification is defined in 61.3.1. This subclause specifies the data, synchronization and control signals that are transmitted between the TC sublayer and the PAF.

61.2.2.8.2 PME aggregation–management entity signals

The management entity signals pertaining to PME aggregation are specified in 61.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

61.2.2.8.3 PME aggregation register functions

If an MDIO interface is provided (see Clause 22 and Clause 45), PME aggregation registers are accessed via that interface. If not, it is recommended that an equivalent access be provided.

Clause 45 defines one bit each in the EFM 10P/2B capability register and the 10P/2B PCS control register to control the PAF function (see 45.2.3.27 and 45.2.3.28 respectively). PAF_available is used to indicate that the system has the capability to aggregate PMEs, PAF_enable is used to control whether this ability is enabled or not. In all cases, the PAF_available bit is read-only; the PAF_enable bit is read-only when the PAF_available bit is not asserted.

For CO-subtype devices, both the PAF_available and the PAF_enable bits are only accessible locally, the PAF_enable bit is writeable.

For CPE-subtype devices, both the PAF_available and the PAF_enable bits are locally read only and remotely readable. Additionally, the PAF_enable bit is remotely writeable.

Clause 45 defines access to two registers which relate to the PME aggregation function: the PME_Available_register (see 45.2.3.29) and the PME_Aggregate_register (see 45.2.3.30). Additionally the remote_discovery_register and Aggregation_link_state_register shall be implemented.

NOTE—The remote_discovery_register is a variable which is defined for CPE-subtypes only. It is used during the PME aggregation discovery process. The Aggregation_link_state_register is a variable with significance for the PCS only. These variables have no associated management interface registers.

The PME_Available_register is read-only for CO-subtype and may be writeable for CPE-subtype (in order to restrict CPE-subtype connection capability according to 45.2.3.29). It indicates whether an aggregateable link is possible between this PCS and multiple PMDs. For a device that does not support aggregation of multiple PMEs, a single bit of this register shall be set and all other bits clear. The position of bits indicating aggregateable PME links correspond to the PMA/PMD sub-address defined in Clause 45.

For CPE-subtype devices, the PME_Available_register may optionally be writeable by the local management entity. The reset state of the register reflects the capabilities of the device. The management entity (through Clause 45 access) may clear bits which are set, in order to limit the mapping between MII and PME for PME aggregation. For CPE-subtype devices, PMD links shall not be enabled (such that it shall not respond to or initiate any G.994.1 handshaking sessions, on any of its PMEs) until the PME_Available register has been set to limit the connectivity such that each PME maps to at most one MII (see 45.2.3.29). This condition is necessary so that remote commands from the network-end which affect PCS registers have a defined target. PMDs that are not associated to any PCS shall not respond to or initiate any G.994.1 handshaking signals. Multiple PMEs per MII are allowed.

The PME_Aggregate_register is defined in Clause 45. For CO-subtype devices, access to this register is through Clause 45 register read and write mechanisms. For CPE-subtype devices the register may be read locally through Clause 45, and reads and writes shall be allowed from remote devices via the remote access signals passed across the γ-interface from the PMA (see 61.3.1). The operation of the PME_Aggregate_register for CPE-subtype devices is defined as follows:

a) If the remote_discovery_register is clear then the PME_Aggregate_register shall be cleared.
b) If write_remote_Aggregation_reg is asserted, the contents of remote_write_data bit zero is written to PME_Aggregate_register in the bit location corresponding to the PMA/PMD from which the request was received. Acknowledge_read_write is asserted for one octet clock cycle.
c) If read_remote_Aggregation_reg is asserted, the contents of PME_Aggregate_register are placed onto remote_read_data_bus, bits 31 through 0. Unsupported bits are written as zero if the full width of PME_Aggregate_register is not supported. Acknowledge_read_write is asserted for one octet clock cycle.

61.2.2.8.4 PME aggregation discovery register functions

The remote_discovery_register shall be implemented for CPE-subtype devices. The remote_discovery_register shall support atomic write operations and reads from remote devices via the remote access signals passed across the γ-interface from the PMA (see 61.3.1). The operation of the remote_discovery_register for CPE-subtype devices is defined as follows:

a) If read_remote_discovery_reg is asserted, which corresponds to a "Get" command as described in 61.4.7.1, the contents of remote_discovery_register are placed onto remote_read_data_bus. Acknowledge_read_write is asserted for one octet clock cycle[117].
b) If write_remote_discovery_reg is asserted, which corresponds to a "Set if Clear" command as described in 61.4.7.1, the action depends on the contents of remote_discovery_register. If the remote_discovery_register is currently clear (no bits asserted), the contents of the remote_write_data bus are placed into the remote_discovery_register. The new contents of remote_discovery_register are placed on the remote_read_data_bus. Acknowledge_read_write is asserted for one octet clock cycle. Else if the remote_discovery_register is not currently clear (any bit asserted), no data is written. The old contents of remote_discovery_register are placed on the remote_read_data_bus. NAcknowledge_read_write is asserted for one octet clock cycle. If multiple write_remote_discovery_reg signals are asserted (from multiple γ-interfaces) they shall be acted upon serially.
c) If clear_remote_discovery_reg is asserted, which corresponds to a "Clear if Same" command as described in 61.4.7.1, the action depends on the contents of remote_discovery_register. If the contents of the remote_write_data bus match that of the remote_discovery_register, the remote_discovery_register is cleared, the PME_Aggregate_register is cleared, the new contents of remote_discovery_register are placed on the remote_read_data_bus, and Acknowledge_read_write is asserted for one octet clock cycle. If the contents of the remote_write_data bus do not match that of the remote_discovery_register, the remote_discovery_register is unchanged; its contents are placed on the remote_read_data_bus; and NAcknowledge_read_write is asserted for one octet clock cycle.
d) If the logical AND of the Aggregation_link_state_register and the PME_Aggregate_register is clear then a timeout counter shall be started. If this condition continues for 30 seconds (the timeout period) then the remote_discovery_register shall be cleared.

A single device may be implemented which has multiple MIIs and (therefore) multiple PCS instances. There shall be one remote_discovery_register per PCS instance. The PME_Available_register shall be set prior to the enabling of links so that each PMA/PMD is linked to only one PCS. Access to the remote_discovery_register (read or write) shall be restricted to PMA/PMD instances for which the corresponding PME_Available_register bit is asserted.

The Aggregation_link_state_register is a pseudo-register corresponding to the TC_link_state bits from each γ-interface in the appropriate bit positions according to the PMA/PMD from which the signal is received. Bits corresponding to unsupported aggregation connections are zero.

The remote access mechanisms for the PME aggregation registers are defined in 61.4.7.

61.2.3 PCS sublayer: Management entity signals

The management interface has pervasive connections to all functions. Operation of the management control lines MDC and MDIO is specified in Clause 22 and Clause 45, and requirements for managed objects inside the PCS and PMA are specified in Clause 30.

The following MAC-PHY Rate Matching function signals are mapped to Clause 45 registers:

[117]If the CPE device fails to respond, NAcknowledge_read_write is asserted with remote_read_data_bus set to 000000000000_{16}.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

tx_rx_simultaneously
: this signal is asserted by the management entity to indicate that the MAC which is connected to the PHY is capable of receiving and transmitting simultaneously while in half-duplex mode. The corresponding register ("MII receive during transmit") is defined in 45.2.3.28.

crs_and_tx_en_infer_col
: this signal is asserted by the management entity to indicate that the MAC uses simultaneous detection of TX_EN and CRS to infer a collision. This signal is used in the rate matching state diagrams (Figure 61–7 and Figure 61–8). The corresponding register ("TX_EN and CRS infer a collision") is defined in 45.2.3.28.

The following PAF signals are mapped to Clause 45 registers or cause Clause 45 counters to increment:

PAF_available
: this signal indicates to the management whether the PAF function is available for use. The corresponding register is defined in 45.2.3.27.1.

PAF_enable
: this signal is asserted by the management entity to indicate that the PAF function is enabled. The corresponding register is defined in 45.2.3.28.3.

TC_PAF_RxErrorReceived
: (for each PMA, γ-interface) this signal is asserted to indicate that a fragment has been received across the γ-interface with Rx_Err asserted. The errored fragment has been discarded. The corresponding register is defined in 45.2.3.31.

TC_PAF_FragmentTooSmall
: (for each PMA, γ-interface) this signal is asserted to indicate that a fragment has been received across the γ-interface that was smaller than the minFragmentSize defined. The errored fragment has been discarded. The corresponding register is defined in 45.2.3.32.

TC_PAF_FragmentTooLarge
: (for each PMA, γ-interface) this signal is asserted to indicate that a fragment has been received across the γ-interface that was larger than the maxFragmentSize defined. The errored fragment has been discarded. The corresponding register is defined in 45.2.3.33.

TC_PAF_Overflow
: (for each PMA, γ-interface) this signal is asserted to indicate that a fragment has been received across the γ-interface that would have caused the receive buffer to overflow. The errored fragment has been discarded. The corresponding register is defined in 45.2.3.34.

PAF_BadFragmentReceived
: this signal is asserted to indicate that a fragment has been received that does not fit into the sequence expected by the frame assembly function. The errored fragment has been discarded and the frame buffer flushed to the next valid frame start. The corresponding register is defined in 45.2.3.35.

PAF_LostFragment
: this signal is asserted to indicate that a fragment (or fragments) expected according to sequence has not been received by the frame assembly function. The missing fragment (or fragments) has been skipped and the frame buffer flushed to the next valid frame start. The corresponding register is defined in 45.2.3.36.

PAF_LostStart
: this signal is asserted to indicate that the packet reassembly function did not receive a StartOf Packet indicator in the appropriate sequence. The corresponding register is defined in 45.2.3.37.

PAF_LostEnd
: this signal is asserted to indicate that the packet reassembly function did not receive an EndOfPacket indicator in the appropriate sequence. The corresponding register is defined in 45.2.3.38.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PCS_link_state
: this signal is asserted to indicate that at least one TC_link_state in the assigned aggregation group is up.

Additionally, the following PAF register is mapped to a Clause 45 register:

remote_discovery_register
: this register is implemented in CPE-subtype devices. It is written or read by the PME via the γ-interface. The PME relays this information to and from the associated CO-subtype device via the handshake messages described in 61.4.7. The CO-subtype device interprets the contents of the remote_discovery_register to determine which remote PMEs connect to the same PCS and may be aggregated. The corresponding Clause 45 register is defined in 45.2.6.6.1.

61.3 TC sublayer functional specifications

The functional model of the TC sublayer is presented in Figure 61–12. The term "TPS-TC" (Transport Protocol Specific - Transmission Convergence) is used in ITU-T Recommendation G.993.1. In this context the term "TC" (Transmission Convergence) is sufficient as no other types of TC are defined in this subclause (e.g., PMS-TC).

Because the PAF function is optional, either entire data frames or data frame fragments may be passed across the γ-interface. In this section, the term "fragment" will be used to describe either fragments or data frames depending on the existence of the PAF.

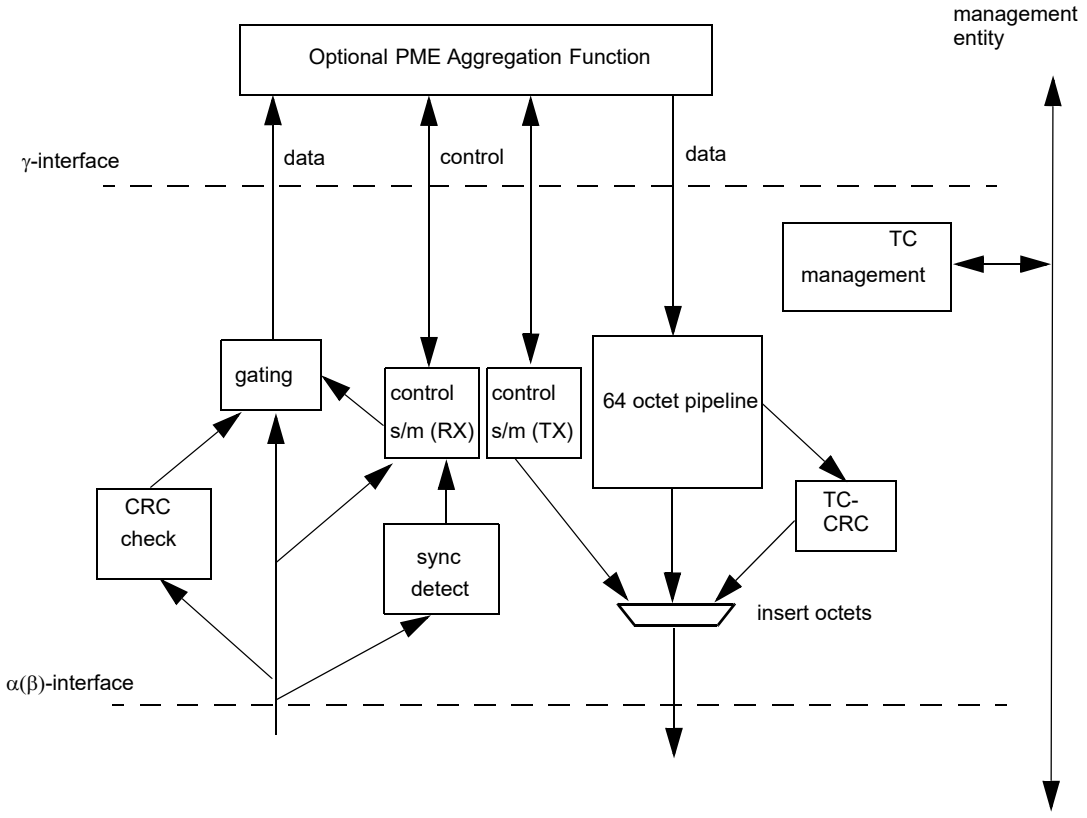

Figure 61–12—Functional diagram of TC sublayer

61.3.1 The γ-interface

The γ-interface is specified by incorporating section H.3.1 and all subsections of ITU-T Recommendation G.993.1 (Annex H) by reference, with the following exceptions and additions:

The PCS shall assert Tx_Avbl when an entire data fragment is available for transmission, and de-assert Tx_Avbl when there are no data fragments to transmit. Tx_Avbl shall never be de-asserted during the transmission of a data fragment.

OAM Information flow across the γ-interface supports access to registers referenced in Clause 45. Refer to Clause 45 for a complete description of access to TC, PMA and PMD registers from the MDIO interface.

Additional signals, which would be represented in the referenced document section H.3.1.4, are described in Table 61–9. Some of these signals may be unused when Clause 45 is not implemented.

Table 61–9—Additional γ-interface signals for OAM[a]

Signal	Size	Description	Direction
TC_link_state	1 bit	Control signal asserted when link is active and framing has synchronized according to the definition in 61.3.3 (TC_synchronized = TRUE) and remote_TC_out_of_sync (see 61.3.3.7) is not asserted.	TC → PCS
write_remote_aggregation_reg[b]	1 bit	Control signal to write PME_Aggregate_register. Active (min) 1 octet clock cycle	to PCS
write_remote_discovery_reg[b]	1 bit	Control signal to write remote_discovery_register. Active (min) 1 octet clock cycle	to PCS
clear_remote_discovery_reg[b]	1 bit	Control signal to clear remote_discovery_register. Active (min) 1 octet clock cycle	to PCS
read_remote_aggregation_reg[b]	1 bit	Control signal to read PME_Aggregate_register. Active (min) 1 octet clock cycle	to PCS
read_remote_discovery_reg[b]	1 bit	Control signal to read remote_discovery_register. Active (min) 1 octet clock cycle	to PCS
remote_write_data_bus[b]	48 bit	Data bus for writing to PME aggregation registers. Valid during octet clock cycle when write control is asserted	to PCS
remote_read_data_bus[b]	48 bit	Data bus for the results of a read or atomic write function. Valid during octet clock cycle when Acknowledge_read_write or NAcknowledge read_write is asserted	from PCS
Acknowledge_read_write[b]	1 bit	Control signal responding (positively) to read or write. Active 1 octet clock cycle	from PCS
NAcknowledge read_write[b]	1 bit	Control signal responding (negatively) to read or write. Active 1 octet clock cycle	from PCS

[a]The term "OAM" as used here refers to the OAM facilities as defined in the referenced G.993.1 document.
[b]These signals are defined only if PAF is implemented, and then only in CPE subtypes. They are used only during G.994.1 handshake. For CO subtypes, pervasive access by management may be used to obtain the corresponding information. In case of read/write collision the PAF has to process the read/write-requests sequentially.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

61.3.2 The α(β)-interface

The α(β)-interface is specified by incorporating section 7.1 and all subsections of ITU-T Recommendation G.993.1 by reference.

NOTE—An identical α(β)-interface is defined in ITU-T G.991.2.

The α and β reference points define interfaces between the PCS and PMA in the 2BASE-TL-O/10PASS-TS-O and the 2BASE-TL-R/10PASS-TS-R, respectively. Both interfaces are functional, application independent and identical. Both interfaces are defined by the following signal flow:

a) Data flow
b) Synchronization flow
c) OAM flow[118]

61.3.2.1 α(β) data flow: reference G.993.1 section 7.1.1

Referenced as is, with the additions shown in Table 61–10.

Table 61–10— Additional α(β)-Interface signals

Signal(s)	Size	Description	Direction
PMA_receive_synchronized	1 bit	Receive PMA state diagram synchronized	PMA → TC
PMA_PMD_type	8 bit[a]	Signal indicating PMA/PMD mode of operation. Defined values: 00_{16} — 10PASS-TS CO subtype 01_{16} — 2BASE-TL CO subtype 02_{16}–$7B_{16}$ — reserved for allocation by IEEE 802.3 $7C_{16}$–$7F_{16}$ — assigned for allocation by ATIS T1E1.4 80_{16} – 10PASS-TS CPE subtype 81_{16} – 2BASE-TL CPE subtype 82_{16}–FB_{16} — reserved for allocation by IEEE 802.3 FC_{16}–FF_{16} — assigned for allocation by ATIS T1E1.4	PMA → TC

[a]NOTE—The MSB of this octet-wide signal is used to differentiate between CO-subtype and CPE-subtype.

61.3.2.2 α(β) synchronization flow

The synchronization flow comprises the following synchronization signals:

a) Transmission data flow octet synchronization (Osync_t)
b) Reception data flow octet synchronization (Osync_r)
c) Transmit and receive data flow bit-synchronization (Clk_t, Clk_r), optional
d) Transmit and receive data flow frame-synchronization (Fsync_t, Fsync_r), optional
e) Receive PMA state diagram synchronized (PMA_receive_synchronized)

The synchronization signals are asserted by the PMA and directed towards the PCS. The synchronization flow signals are described in Table 61–10.

[118]The term “OAM” as used here refers to the OAM facilities as defined in the referenced G.993.1 document.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

61.3.2.3 α(β) OAM flow[119]

The OAM Flow across the α(β)-interface exchanges OAM information between the PHY-OAM entity, the PMA and the PMD. The OAM flow is bi-directional and transports line related primitives, parameters, configuration setup and maintenance signals or commands.

Refer to Clause 62 and Clause 63 for definitions of the G.994.1 messaging, Operation Channel (OC) and Indicator Bits (IB) mechanisms for accessing remote parameters.

Refer to Annex 61A for an example of aggregation discovery.

61.3.3 TC functions

The TC shall provide full transparent transfer of data fragments between γ_O-interface and γ_R-interface (except non-correctable errors caused by the transmission medium). It shall also provide fragment integrity and fragment error monitoring capability.

In the transmit direction, the TC receives fragments from the PCS via the γ-interface. An additional 16- or 32-bit CRC is calculated on the data and appended. The TC then performs 64/65-octet encapsulation, and sends the resulting codewords to the PMA via the α(β)-interface. In the receive direction, the TC receives codewords from the PMA via α(β)-interface, recovers the transported TC fragment, checks the CRC, and submits the extracted fragment to the PCS via the γ-interface.

An implementation is shown in Figure 61–13 and some example timing diagrams are shown in Figure 61–14.

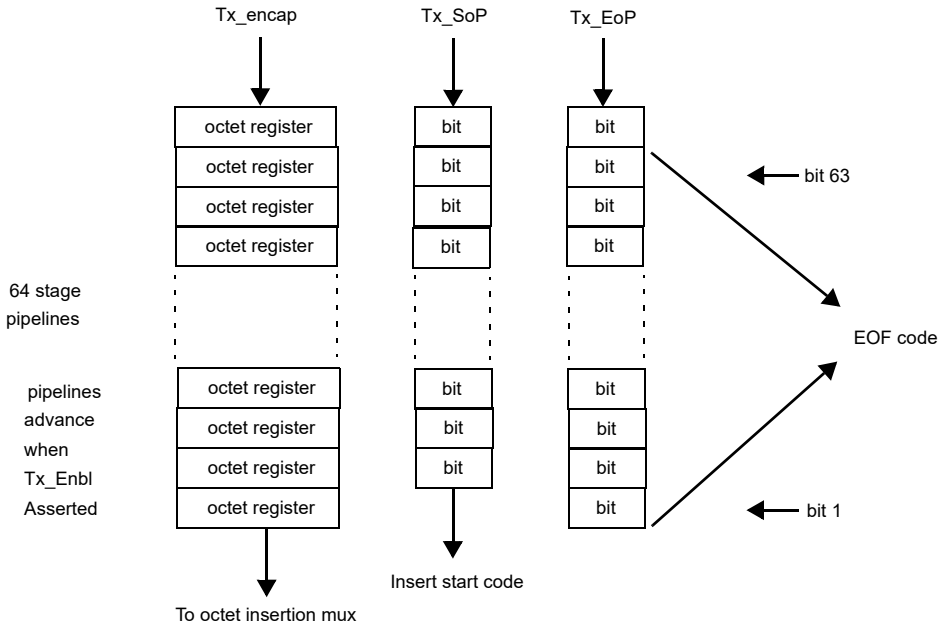

Figure 61–13—Example transmit pipeline

61.3.3.1 TC encapsulation and coding

A TC fragment consists of a fragment, followed by a 16- or 32-bit CRC (referred to as the TC-CRC) as defined in 61.3.3.3.

[119]The term "OAM" as used here refers to the OAM facilities as defined in the referenced G.993.1 document.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

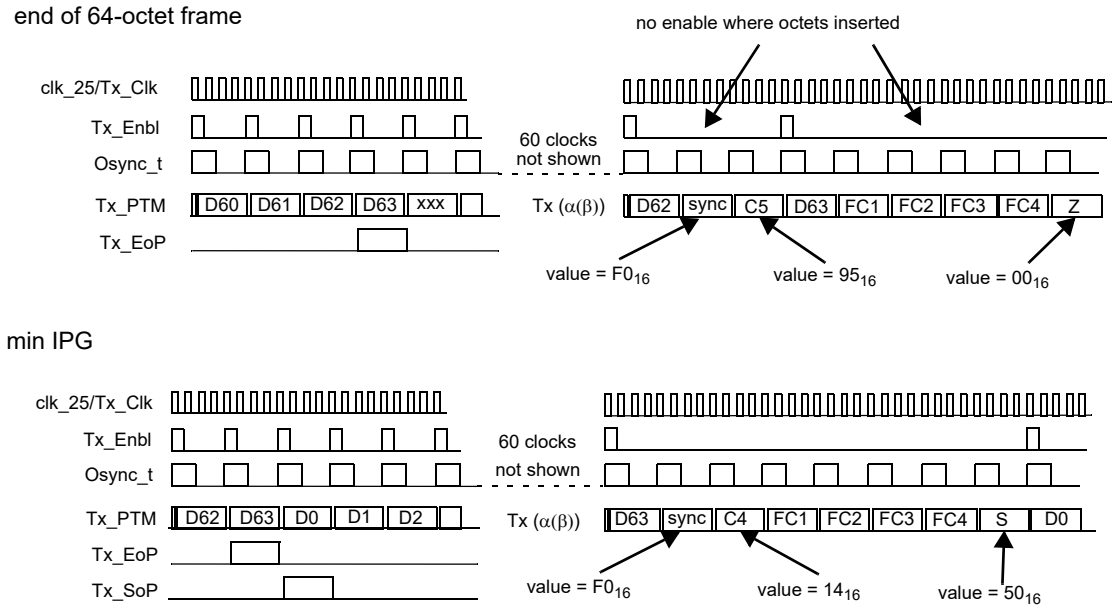

Figure 61–14—Example transmit timing

The TC coding function generates codewords with a fixed length of 65 octets (64/65-octet coding). A codeword consists of a Sync Octet and one of the following combinations:

a) all data: all of the octets in the codeword belong to the same TC fragment.
b) end of frame (go to idle): up to 63 octets in the codeword belong to the same TC fragment, the rest of the codeword consists of Idle octets.
c) end of frame (start new frame): up to 62 octets in the codeword belong to the same TC fragment, a number of Idle octets and a single Start of Frame octet precede the first data octets of the next TC fragment.
d) idle: all of the octets in the codeword are Idle octets.
e) idle (start new frame): a number of Idle octets and a single Start of Frame octet precede up to 63 data octets of the next TC fragment.
f) out-of-sync idle: all of the octets in the codeword are idle octets and the 64/65-octet receive state diagram is out-of-sync (TC_synchronized = FALSE).

Both transmit and receive data may be transferred across both the α(β) and the γ-interfaces at rates that are different from the rate across the MII; the frame buffering is managed in the sublayer above the γ-interface. The TC layer uses the γ-interface flow control signal, Tx_Enbl, to slow transmit data to the rate required for the encapsulated data across the α(β)-interface. The TC layer uses the γ-interface flow control signal, Rx_Enbl, to allow idle cycles in the flow of receive data across the γ-interface.

When a fragment arrives from the γ-interface while an End of Frame codeword is being transmitted, a Start of Frame octet shall be inserted prior to the transmission of data octets belonging to the next fragment. The Start of Frame octet *S* is distinct from the Idle octet *Z.* Valid locations for *S* are any valid location for *Z*, and the presence of an *S* rather than a *Z* octet indicates that what follows is the commencement of data for a new fragment.

No new fragment shall be transmitted when TC_link_state = FALSE (TC_link_state is defined in 61.3.3.7). If a fragment is being transmitted when TC_link_state becomes false, the End of Frame codeword completing the fragment shall not contain an *S* symbol after the end of the fragment. If an Idle codeword is being transmitted when TC_link_state becomes false, it shall be completed with *Z* symbols only. After the completed End of Frame or Idle codeword, only All Idle or All Idle Out-of-Sync codewords shall be

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

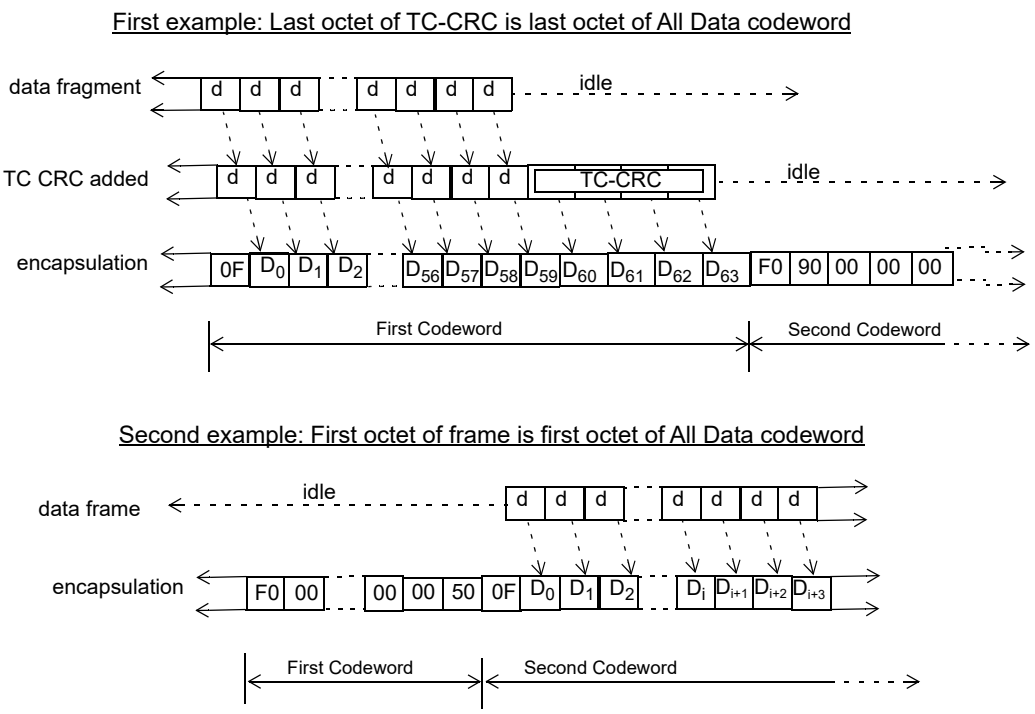
transmitted until TC_link_state becomes TRUE again. After TC_link_state becomes true again, transmission of data can restart when a new fragment is available for transmission over the gamma-interface.

The data and sync format of the encapsulated data is shown in Table 61–11.

Table 61–11—Codeword formats

Type	Frame Data	Sync Octet	Octet fields 1–64									
all data	*DDDD—DDDD*	$0F_{16}$	D_0	D_1	D_2	D_3	D_4	D_5	...	D_{61}	D_{62}	D_{63}
end of frame	contains k *D*'s, where k = 0 to 63	$F0_{16}$	C_k	D_0	D_1	D_2	D_3	...	D_{k-1}	*Z*	...	*Z*
start of frame while transmitting	contains last k *D*'s of 1st frame, where k=0 to 62; & first j *D*'s of 2nd frame, where j=0 to 62-k	$F0_{16}$	C_k	D_0	...	D_{k-1}	*Z*	...	*S*	D_0	...	D_{j-1}
all idle	ZZZZ—ZZZZ	$F0_{16}$	*Z*	*Z*	*Z*	*Z*	*Z*	*Z*	...	*Z*	*Z*	*Z*
start of frame while idle	contains k *D*'s, where k=0 to 63, and contains j Z's, where j=63-k	$F0_{16}$	*Z*	*Z*	*S*	D_0	D_1	...	...	D_{k-3}	D_{k-2}	D_{k-1}
all idle out-of-sync	YZZZ—ZZZZ	$F0_{16}$	*Y*	*Z*	*Z*	*Z*	*Z*	*Z*	...	*Z*	*Z*	*Z*

The end of a TC fragment is always marked with an "end of frame" or "start of frame while transmitting" codeword; e.g., the received sequence [All Data codeword][All Idle codeword] is considered a sequencing error. When any of the following events occur, signal TC_coding_error shall be asserted:



a) An incorrect octet is received when a Sync Octet is expected.
b) Outside a fragment, the received octet following a valid $F0_{16}$ sync is not a *Z*, *Y*, *S*.
c) Inside a fragment, the received octet following a valid $F0_{16}$ sync is not a valid value of C_k.
d) *Z* or *S* is expected, and a value different from *Z* and *S* is received.

Signal remote_TC_out_of_sync shall be asserted when *Y* is received after an expected $F0_{16}$ sync symbol, and remain asserted until the beginning of a codeword other than All Idle Out-of-Sync is detected.

NOTE—When the local TC is not synchronized (TC_synchronized = FALSE), it may fail to detect incoming "All Idle Out-of-Sync" codewords. However, this does not affect the behavior of the local TC, which is sending "All Idle Out-of-Sync" codewords itself. Higher sublayers only use the combined signal TC_link_state, defined in 61.3.1.

Figure 61–15 illustrates two interesting examples. In the first example, the last 60 octets of a data frame, plus the 4 encapsulation CRC octets, are transmitted in an All Data codeword. In other words, the end of the (TC-CRC-augmented) frame coincides with the end of the codeword. In this case, the next codeword begins with Sync Octet equal to $F0_{16}$, C_k equal to C_0 (90_{16}). The second codeword indicates an End Of Frame, but with no additional data; in other words, the data in the previous codeword were the last of the frame. In the second example, the first octet of a frame is aligned with the first octet of an All Data codeword.

All octets other than D_x are written in hexadecimal notation.

Figure 61–15—TC Encapsulation examples

The values of the TC control characters are shown in Table 61–12.

Table 61–12—TC control character values

Character	Value
Z	00_{16}
C_k, k=0–63	$C_k = k+10_{16}$, with MSB set so that resulting value has even parity; $C_0=90_{16}$, $C_1=11_{16}$, $C_2=12_{16}$, $C_3=93_{16}$, ... $C_{62}=4E_{16}$, $C_{63}=CF_{16}$
Y	$D1_{16}$
S	50_{16}
R	All other values[a]

[a]See the state diagram for the 64/65-octet receive function (Figure 61–19) for required action when receiving reserved codewords.

61.3.3.2 Sync insertion and transmit control

The transmit data path needs a 64 stage pipeline in order to generate the appropriate sync octet along with an end-of-frame indicator when required. The flow control signal, Tx_Enbl, is used to slow the flow of data across the γ-interface to cater for the difference in clock speed between the α(β)-interface and the γ-interface and also to allow for the insertion of sync octets and CRC codes into the data stream.

A simple implementation may use a 64 bit pipeline for the Tx_EOP control signal. In that case, an end of frame sync code ($F0_{16}$, then C_k) would be inserted whenever a bit is set in stages 63 to 1 of the pipeline

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

(stage 64 is the first stage). The value of C_k inserted would be such that k is equal to the stage number of the bit that is set.

Some implementations may optimize the insertions of idles between fragments. In particular an implementation may remove idle characters between fragments to increase the effective bandwidth of the channel.

If PMA/PMD link status is not Up (i.e. either Down or Initializing), the TC sublayer shall transmit only Out-of-Sync Idle codewords. The PMA/PMD link status is defined in 45.2.1.29.4.

61.3.3.3 TC-CRC functions

The TC-CRC is generated for the entire payload fragment including any attached header (from PAF), including the Ethernet CRC; i.e., the TC-CRC is computed over octets from the first octet of the PAF header (if present), or the first octet of the DestinationAddress (in the case where the PAF header not present), to the last octet of the Ethernet CRC (for a frame) or the last octet of the fragment (if PAF fragmentation is operating), inclusive. The TC-CRC is added to the data stream after the end of the fragment in the transmit direction. The TC-CRC is checked against the last 2 or 4 octets of the fragment in the receive direction. If the receive TC-CRC is incorrect then Rx_Err is asserted to signal that the fragment is errored.

The encoding for 2BASE-TL is defined by the following generating polynomial in Equation (61–1).

$$x^{32}+x^{28}+x^{27}+x^{26}+x^{25}+x^{23}+x^{22}+x^{20}+x^{19}+ \quad (61–1)$$
$$x^{18}+x^{14}+x^{13}+x^{11}+x^{10}+x^{9}+x^{8}+x^{6}+1 =$$
$$(x+1)(x^{31}+x^{30}+x^{29}+x^{28}+x^{26}+x^{24}+x^{23}+x^{21}+x^{20}+x^{18}+x^{13}+x^{10}+x^{8}+x^{5}+x^{4}+x^{3}+x^{2}+x+1)$$

The encoding for 10PASS-TS is defined by the following generating polynomial in Equation (61–2).[120]

$$x^{16}+x^{12}+x^{5}+1 \quad (61–2)$$

Mathematically, the TC-CRC value corresponding to a given payload fragment (including any attached header) is defined by the following procedure:

a) The first 32 bits (in the case of 2BASE-TL) or the first 16 bits (in the case of 10PASS-TS) of the payload are complemented.
b) The n bits of the payload are then considered to be the coefficients of a polynomial M(x) of degree n–1. (e.g., the first bit of the fragment corresponds to the x^{n-1} term and the last bit of the fragment corresponds to the x^0 term.)
c) $M(x)$ is multiplied by x^{32} (in the case of 2BASE-TL), or by x^{16} (in the case of 10PASS-TS), and divided by $G(x)$, the TC-CRC polynomial, producing a remainder $R(x)$ of degree 31 (in the case of 2BASE-TL), or degree 15 (in the case of 10PASS-TS).
d) The coefficients of $R(x)$ are considered to be a 32-bit sequence (in the case of 2BASE-TL), or a 16-bit sequence (in the case of 10PASS-TS).
e) The bit sequence is complemented and the result is the TC-CRC.

In the case of 2BASE-TL, the 32 bits of the TC-CRC value are placed so that the x^{31} term is the bit in position b_8 on the α(β)-interface (as shown in Figure 61–16) of the first octet, and the x^0 term is the bit in position b_1 on the α(β)-interface (as shown in Figure 61–16) of the last octet. (The bits of the CRC are thus transmitted in the order x^{31}, x^{30},.., x^1, x^0.) At the receiver, a payload received without error will result in the remainder $1C2D19ED_{16}$ when divided by $G(x)$.

[120]For 10PASS-TS, a 16-bit TC-CRC is sufficient for detecting payload errors, as the error-detecting capabilities of its Reed-Solomon decoder is also employed (see 62.2.2). In 2BASE-TL PHYs, a Reed-Solomon decoder is not present, hence a stronger TC-CRC is required.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In the case of 10PASS-TS, the 16 bits of the TC-CRC value are placed so that the x^{15} term is the bit in position b_8 on the α(β)-interface (as shown in Figure 61–16) of the first octet, and the x^0 term is the bit in position b_1 on the α(β)-interface (as shown in Figure 61–16) of the last octet. (The bits of the CRC are thus transmitted in the order x^{15}, x^{14},.., x^1, x^0.) At the receiver, a payload received without error will result in the remainder $1D0F_{16}$ when divided by $G(x)$.

If, in the transmitter, the TX_Err signal is asserted during the transmission of the fragment across the γ-interface, the last octet of the TC-CRC shall be ones-complemented (i.e., intentionally corrupted by inverting all the bits of the last octet).

61.3.3.4 Bit ordering

In the transmitter, after encapsulation into 64/65-octet codewords, bits within each octet are labeled from b_1 to b_8, with the MSB labeled as b_1, the LSB labeled as b_8, and intervening bits labeled accordingly. In keeping with the labeling convention for the α(β)-interface in ITU-T Recommendations, bit b_8 is regarded as the MSB at the α(β)-interface, and is transmitted first if the α(β)-interface is serial by implementation.

Observe that the TC functionality defines a correspondence between the LSB at the γ-interface and b_8, between the next-order bit and b_7, etc., in order to conform to the Ethernet bit order convention of transmitting LSB first. See also H.4.1.1 in Annex H of ITU-T Recommendation G.993.1. In transmitting and calculating the TC-CRC, the octets at the γ-interface are processed LSB first.

61.3.3.5 Sync detection

The sync detection function serves two purposes. Firstly, the synchronization is acquired from the incoming data stream, the sync detection function controls the initial acquisition and maintenance of the synchronization. Secondly, the sync detection is needed so that the receive control state diagram can extract framing information from the receive data stream and remove the sync characters and CRC codes. The sync detection state diagram is shown in Figure 61–17.

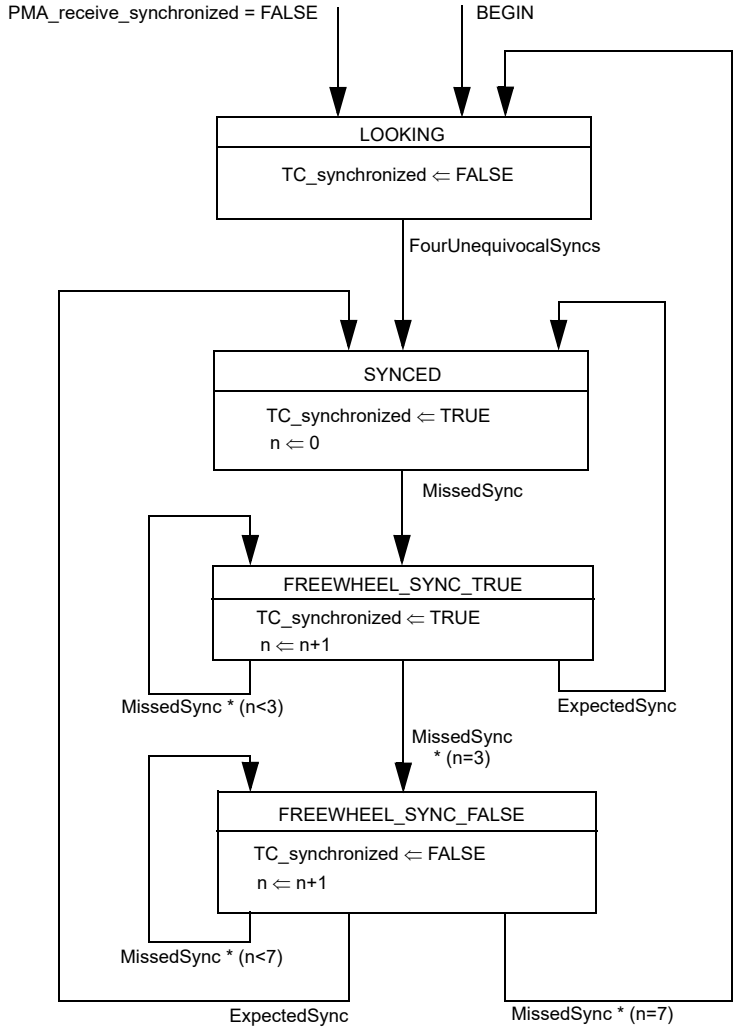

Figure 61–17—Sync detect state diagram

61.3.3.5.1 State diagram variables

BEGIN

A variable that resets the functions within the sync detection function (see 45.2.1.1.1.)
TRUE when the TC sublayer is reset.
FALSE when (re-)initialization has completed.

ExpectedSync

variable of type Boolean, TRUE indicating the occurrence of a sync character in the correct position in the octet stream. The default value of this variable is FALSE; the value of the variable resets to FALSE on every state transition.

FourUnequivocalSyncs

variable of type Boolean, TRUE indicating the occurrence of a 196-octet sequence with the following two characteristics:

a)the sequence is of the form <sync><data><sync><data><sync><data><sync>, where each <sync> is $0F_{16}$ or $F0_{16}$ and each <data> is 64 octets of any value;
b)the pattern <sync><data><sync><data><sync> occurs nowhere in the sequence, where <sync> and <data> are as defined in (a, unless the <sync> values are coincident with those in (a;

The default value of this variable is FALSE; the value of the variable resets to FALSE on every state transition.

MissedSync

variable of type Boolean, TRUE indicating the occurrence of a non-sync character in the octet stream position where a sync character is expected. The default value of this variable is FALSE; the value of the variable resets to FALSE on every state transition.

n

variable of type integer, counting the occurrences of MissedSync = TRUE, used to determine when to leave state FREEWHEEL_SYNC_TRUE or FREEWHEEL_SYNC_FALSE.

PMA_receive_synchronized

signal of the α(β)-interface, see 61.3.2.

TC_synchronized

variable of type Boolean, TRUE indicating that the state diagram is in state SYNCED or FREEWHEEL_SYNC_TRUE. This variable is used to calculate the value of signal TC_link_state on the γ-interface (see 61.3.1), and to generate “All Idle Out Of Sync” codewords in the 64/65-octet transmit function (see Figure 61–18).

61.3.3.5.2 State diagram

The receiver shall implement the sync detect state diagram shown in Figure 61–17.

61.3.3.6 Receive control

The receive control function removes the sync characters and encapsulation CRC octets from the data stream and passes it upward across the γ-interface. If TC_synchronized = false then signal RX_Enbl shall be de-asserted. If a CRC error is detected the receive controller shall assert signal TC_CRC_error. The receive controller shall assert signal RX_Err at the γ-interface during at least one octet of a fragment as it is passed up across the γ-interface, if TC_CRC_error is asserted, or if the fragment contains data from a block of data in which the PMA detected errors, but did not correct them (the means by which the PHY passes this information from the PMA to the TC is unspecified).

61.3.3.7 State diagrams for 64/65-octet encapsulation

This subclause contains the state diagrams for the 64/65-octet encapsulation function. Only the signals that affect the operation of the state diagrams are explicitly mentioned in the state diagrams. Other signals are to be set and read in accordance with the specifications of the γ-interface (see 61.3.1) and the α(β)-interface (see 61.3.2).

61.3.3.7.1 Transmit state diagram

The following variables are used in the state diagram.

BEGIN
: A variable that resets the functions within the sync detection function.
TRUE when the TC-sublayer is reset.
FALSE when (re-)initialization has completed.

k
: variable of type integer, used to keep track of the number of octets used in the current codeword, not including the sync symbols

loop
: variable of type Boolean, keeping track of the fact that an Out-of-Sync Idle codeword is being transmitted, thus preventing a Start-of-Frame to occur within this codeword (initial value is TRUE).

TC_link_state
: variable of type Boolean, indicating the current state of the TC_link_state signal on the γ-interface

TC_link_stateCHANGE
: This function monitors the TC_link_state variable for a state change. The function is set to TRUE on state change detection.
Values:
TRUE; A TC_link_state variable state change has been detected.
FALSE; A TC_link_state variable state change has not been detected (default).

NOTE—TC_link_stateCHANGE is set by this function definition; it is not set explicitly in the state diagrams. TC_link_stateCHANGE evaluates to its default value upon state entry.

TC_synchronized
: variable of type Boolean, indicating whether synchronization has been acquired (as used in Figure 61–17)

Tx_Avbl
: variable of type Boolean, indicating the current state of the Tx_Avbl (transmit data available) signal on γ-interface

Tx_EoP
: variable of type Boolean, indicating the current state of the Tx_EoP (end of packet) signal on γ-interface

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following functions are used in the state diagram:

flushBuffer()
: function that removes any octets that have been pulled from the PCS by the function pullOctet() from the transmit fifo.

pullOctet()
: function that receives a single octet of data from the γ-interface. This function takes one cycle of the Tx_Enbl (transmit enable) signal (see 61.3.1) to complete. At the end of a fragment, this function returns the octets of the TC-CRC in the order specified in 61.3.3.3.

transmitAllDataSync()
: function that transmits the all-data sync symbol ($0F_{16}$) to the α(β)-interface. This function takes one cycle of the Osync_t signal (see 61.3.3.2) to complete.

transmitC(int k)
: function that transmits the C_k symbol as specified in Table 61–10 to the α(β)-interface. This function takes one cycle of the Osync_t signal (see 61.3.3.2) to complete.

transmitData()
: function that transmits all data currently in the transmit fifo to the α(β)-interface. This function takes one cycle of the Osync_t signal (see 61.3.3.2) per octet of data transmitted to complete.

transmitS()
: function that transmits the *S* symbol as specified in Table 61–12 to the α(β)-interface. This function takes one cycle of the Osync_t signal (see 61.3.3.2) to complete.

transmitSync()
: function that transmits the regular sync symbol ($F0_{16}$) to the α(β)-interface. This function takes one cycle of the Osync_t signal (see 61.3.3.2) to complete.

transmitZ(int k, Boolean loop)
: function that transmits the *Y* symbol ($D1_{16}$) to the α(β)-interface if (k=1) and (loop=TRUE), and transmits the *Z* symbol (00_{16}) to the α(β)-interface otherwise. This function takes one cycle of the Osync_t signal (see 61.3.3.2) to complete.

Figure 61–18 specifies the 64/65-octet encapsulation (transmit) function.

61.3.3.7.2 Receive state diagram

The following variables are used in the state diagram.

B
: variable of type octet, used to store a single received octet

C
: variable of type octet, used to store a received C_k symbol

codingViolation
: variable of type Boolean, used to mark detection of a coding violation when a sync octet was expected

expectedSync
: variable of type Boolean, used to mark successful sync octet detections, which are counted towards achieving synchronization as specified in Figure 61–17. The default value of this variable is FALSE; it returns to FALSE on every state transition.

k
: variable of type integer, used to keep track of the number of octets received in the current codeword, not including the sync symbols

kmax
: variable of type integer, used to store the decoded value of a C_k symbol

missedSync
: variable of type Boolean, used to mark unsuccessful sync octet detections, which are counted towards losing synchronization as specified in Figure 61–17. The default value of this variable is FALSE; it returns to FALSE on every state transition.

remote_TC_out_of_sync
: variable of type Boolean, representing the state of the remote TC synchronization state diagram (see 45.2.6.13).
TRUE if the remote TC has lost synchronization according to 61.3.3.5
FALSE if the remote TC has acquired synchronization according to 61.3.3.5

Rx_Err
: variable of type Boolean, representing the corresponding signal (receive error) on the γ-interface

TC_coding_error
: when this signal is asserted, the TPS-TC coding violations counter register is incremented (see 45.2.6.12). The default value of this variable is FALSE; it returns to FALSE on every state transition. If TC_coding_error becomes true during the reception of a fragment, Rx_Err is asserted on the γ-interface to signal this condition to the PCS, thus invalidating the entire fragment.

TC_synchronized
: variable of type Boolean, identical to the variable TC_synchronized defined in 61.3.3.7.1.

TC_synchronizedCHANGE
: This function monitors the TC_synchronized variable for a state change. The function is set to TRUE on state change detection.
Values:
TRUE; A TC_synchronized variable state change has been detected.
FALSE; A TC_synchronized variable state change has not been detected (default).

NOTE—TC_synchronizedCHANGE is set by this function definition; it is not set explicitly in the state diagrams. TC_synchronizedCHANGE evaluates to its default value upon state entry.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following functions are used in the state diagram.

decode(octet B)
: function that decodes the C_k symbol as specified in Table 61–12. A return value between 0 and 63 indicates a valid C_k symbol was read.

receiveOctet()
: function that receives a single octet of data over the α(β)-interface. This function takes one cycle of the Osync_r signal (see 61.3.2.2) to complete.

sendOctetToPCS()
: function that sends a single octet of data over an internal γ-interface to an intermediate fifo. The size of the intermediate fifo is more than 2 octets for 10PASS-TS and more than 4 octets for 2BASE-TL. Data is transmitted at the same rate from the intermediate fifo to the PCS (if present) over the γ-interface. This function takes one cycle of the Rx_clk (receive clock) signal (see 61.3.1) to complete. At the end of a fragment, the fifo contains the TC_CRC octets. The TC_CRC octets are never forwarded over the γ-interface. After verification of the TC_CRC octets, the result of the TC_CRC verification is signalled to the PCS (if present) over the γ-interface.

Figure 61–19 specifies the 64/65-octet decapsulation (receive) function.

61.3.3.8 TC sublayer management entity signals

The following TC sublayer signals are mapped to Clause 45 registers or cause Clause 45 counters to increment:

remote_TC_out_of_sync
: (for each PMA, γ-interface) this signal is asserted to indicate that the remote TC has signaled loss-of-sync. See Figure 61–19 and 45.2.6.13.

TC_synchronized
: (for each PMA, γ-interface) this signal is asserted to indicate that the state diagram has achieved codeword synchronization. See Figure 61–17 and 45.2.6.10.

TC_CRC_error
: (for each PMA, γ-interface) this signal is asserted to indicate that the synchronization state diagram has detected a false CRC code for a received frame (see 45.2.6.11).

TC_coding_error
: (for each PMA, γ-interface) this signal is asserted to indicate that a coding violation has been detected in the received octet stream (see 45.2.6.12).

61.4 Handshaking and PHY control specification for type 2BASE-TL and 10PASS-TS

61.4.1 Overview

This subclause defines the startup and handshaking procedures by incorporating ITU-T Recommendation G.994.1 by reference, with the exceptions listed below. Where there is conflict between specifications in G.994.1 and those in this standard, those of this standard will prevail. The G.994.1 parameter values and options to be used by 2BASE-TL and 10PASS-TS are specified here.

At the time of publication, G.994.1 Revision 3 (2004) is in force. Earlier Revisions of this Recommendation shall not be implemented in 2BASE-TL or 10PASS-TS.

61.4.2 Replacement of 1, “Scope”

61.4.2.1 Scope

This subclause defines signals, messages, and procedures for exchanging these between 2BASE-TL and 10PASS-TS port types, when the modes of operation of the equipment need to be automatically established and selected, but before signals are exchanged which are specific to a particular port type.

The startup procedures defined here are compatible with those used by other equipment on the public access network, such as DSL transceivers compliant with ITU-T Recommendations. For interrelationships of this subclause with ITU-T G.99x-series Recommendations, see ITU-T Series G Supplement 50 [B49].

The principal characteristics of this subclause are as follows:

a) Use over metallic local loops
b) Provisions to exchange capabilities information between DSL equipment and EFM PHYs to identify common modes of operation
c) Provisions for equipment at either end of the loop to select a common mode of operation or to request the other end to select the mode
d) Provisions for exchanging non-standard information between equipment
e) Provisions to exchange and request service and application related information
f) Support for both duplex and half-duplex transmission modes
g) Support for multi-pair operation
h) Provisions for equipment at the remote end of the loop (xTU-R) to propose a common mode of operation

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

61.4.2.2 Purpose

It is the goal of the ITU-T that all specifications for digital transceivers for use on public telephone network copper subscriber lines use G.994.1 for startup. G.994.1 procedures allow for a common mechanism for identification of available features, exchange of capabilities and configuration information, and selection of operating mode. As the two loop endpoints are usually separated by a large distance (e.g., in separate buildings) and often owned and installed by different entities, G.994.1 also aids in diagnosing interoperability problems. G.994.1 codespaces have been assigned by ITU-T to ATIS, ETSI, and IEEE 802.3 in support of this goal.

In private networks, the management entity may additionally use G.994.1 tones or messages to autoconfigure the subtype (CO or CPE) in devices which implement both (see 61.1).

61.4.3 Changes to 6.1, “Description of signals”

NOTE 4 and NOTE 5 are not applicable.

Replace paragraph 3 of 6.1.1, “4.3125 kHz signaling family” with the following.

The carrier sets in this family are mandatory for the port types listed in Table 61–13. One or more carriers listed in Reference Table 1 or Reference Table 3 may be transmitted in addition to the mandatory carrier set listed in Table 61–13. Carriers not listed in Reference Table 1 or Reference Table 3 shall not be transmitted.

Table 61–13—Mandatory carrier sets

Port Types	Carrier set designation
10PASS-TS	V43

Replace paragraph 3 of section 6.1.2, “4 kHz signaling family” with the following.

The carrier sets in this family are mandatory for the port types listed in Table 61–14. One or more carriers listed in Reference Table 1 or Reference Table 3 may be transmitted in addition to the mandatory carrier set listed in Table 61–14. Carriers not listed in Reference Table 1 or Reference Table 3 shall not be transmitted.

Table 61–14—Mandatory carrier sets

Port Types	Carrier set designation
2BASE-TL	A4

61.4.4 Changes to 9.4, “Standard information field (S)”

Paragraphs 1–5: referenced as is.

Table 11.1 to Table 11.52 and Table 11.57 and beyond are not applicable.

The Standard information field (S) codepoints specified in Annex 61B shall be used in the transactions specified in this subclause.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

61.4.5 Changes to 9.5, “Non-standard information field (NS)”

Add this paragraph: The contents of the NS information field are outside the scope of this standard.

61.4.6 Applicability of Annex A–B and Appendix I–VI

Annex A / G.994.1—Support for legacy non-G.994.1 devices—Not applicable

Annex B / G.994.1—Operation over multiple wire pairs—Not applicable to the multipair operation for EFM

Appendix I / G.994.1—Not applicable

Appendix II / G.994.1—Provider Code contact Information —Referenced as is

Appendix III / G.994.1—Support for legacy DMT-based devices —Not applicable

Appendix IV / G.994.1—Procedure for the assignment of additional G.994.1 parameters—Not applicable

Appendix V / G.994.1—Rules for code point table numbering—Not applicable

Appendix VI / G.994.1—Bibliography

61.4.7 PME Aggregation – remote access of PME Aggregation registers

As the CO-subtype accesses PME Aggregation registers (i.e., remote_discovery_register and PME_Aggregate_register) in the CPE-subtype prior to training and establishment of the PMD-to-PMD link, it is performed using G.994.1 handshake messages.

The G.994.1 handshake messages described in this subclause shall assert the “Ethernet bonding” NPar(2) codepoint if and only if PAF_available is asserted. The “TDIM Bonding” NPar(2) bit shall be deasserted. In addition, the “Ethernet bonding” NPar(2) codepoint shall be asserted by the -O device in an MS message if and only if PAF_enable is asserted.

NOTE 1—A G.994.1 session including configuration of the PME Aggregation Function may violate the maximum activation time specified for SHDSL transceivers by ITU-T Recommendation G.991.2.

NOTE 2—In the transactions specified in this subclause, each CLR message may be preceded by MR/REQ-CLR messages. Each CL message is followed by an ACK(1). These messages are not shown in the diagrams.

61.4.7.1 Remote_discovery_register

2BASE-TL-R and 10PASS-TS-R PHYs shall assert the PME Aggregation Discovery SPar(2) bit in all G.994.1 CLR messages, if and only if its local PAF_available bit is set. CPE-subtypes shall place the contents of the remote_discovery_register in the corresponding NPar(3) bits in the outgoing CLR message, with the “Clear if Same” NPar(3) set to zero.

In response to a “Get” command, the CO-subtype shall perform a G.994.1 capabilities exchange with the CPE-subtype. The contents of the NPar(3) remote_discovery_register bits in the CLR message received from the CPE-subtype shall be reported as the result. The CL message sent by the CO-subtype in response to the CLR shall have the PME Aggregation Discovery SPar(2) bit set to zero.

In response to a “Set if Clear” command, the CO-subtype shall perform two back-to-back G.994.1 capabilities exchanges with the CPE-subtype. The contents of the NPar(3) remote_discovery_register bits in the first CLR message received from the CPE-subtype shall be ignored. The CL message sent by the CO-subtype in response to this first CLR shall have the PME Aggregation Discovery SPar(2) bit set to one, the Clear if Same NPar(3) bit set to zero, and the NPar(3) remote_discovery_register bits set to the CO-subtype

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PME Aggregation Discovery Code register. The CPE-subtype shall set the remote_discovery register to this value if it is currently clear. The contents of the NPar(3) remote_discovery_register bits in the CLR message received from the CPE-subtype during the second capabilities exchange shall be reported as the result. The CL message sent by the CO-subtype in response to this second CLR shall have the PME Aggregation Discovery SPar(2) bit set to zero.

In response to a “Clear if Same” command, the CO-subtype shall perform two back-to-back G.994.1 capabilities exchanges with the CPE-subtype. The contents of the NPar(3) remote_discovery_register bits in the first CLR message received from the CPE-subtype shall be ignored. The CL message sent by the CO-subtype in response to this first CLR shall have the PME Aggregation Discovery SPar(2) bit set to one, the Clear if Same NPar(3) bit set to one, and the NPar(3) remote_discovery_register bits set to the CO-subtype PME Aggregation Discovery Code register. The CPE-subtype shall clear the remote_discovery register if it is currently equal to this value. The contents of the NPar(3) remote_discovery_register bits in the CLR message received from the CPE-subtype during the second capabilities exchange shall be reported as the result. The CL message sent by the CO-subtype in response to this second CLR shall have the PME Aggregation Discovery SPar(2) bit set to zero.

Figure 61–20 illustrates the relevant sequences of G.994.1 transactions.

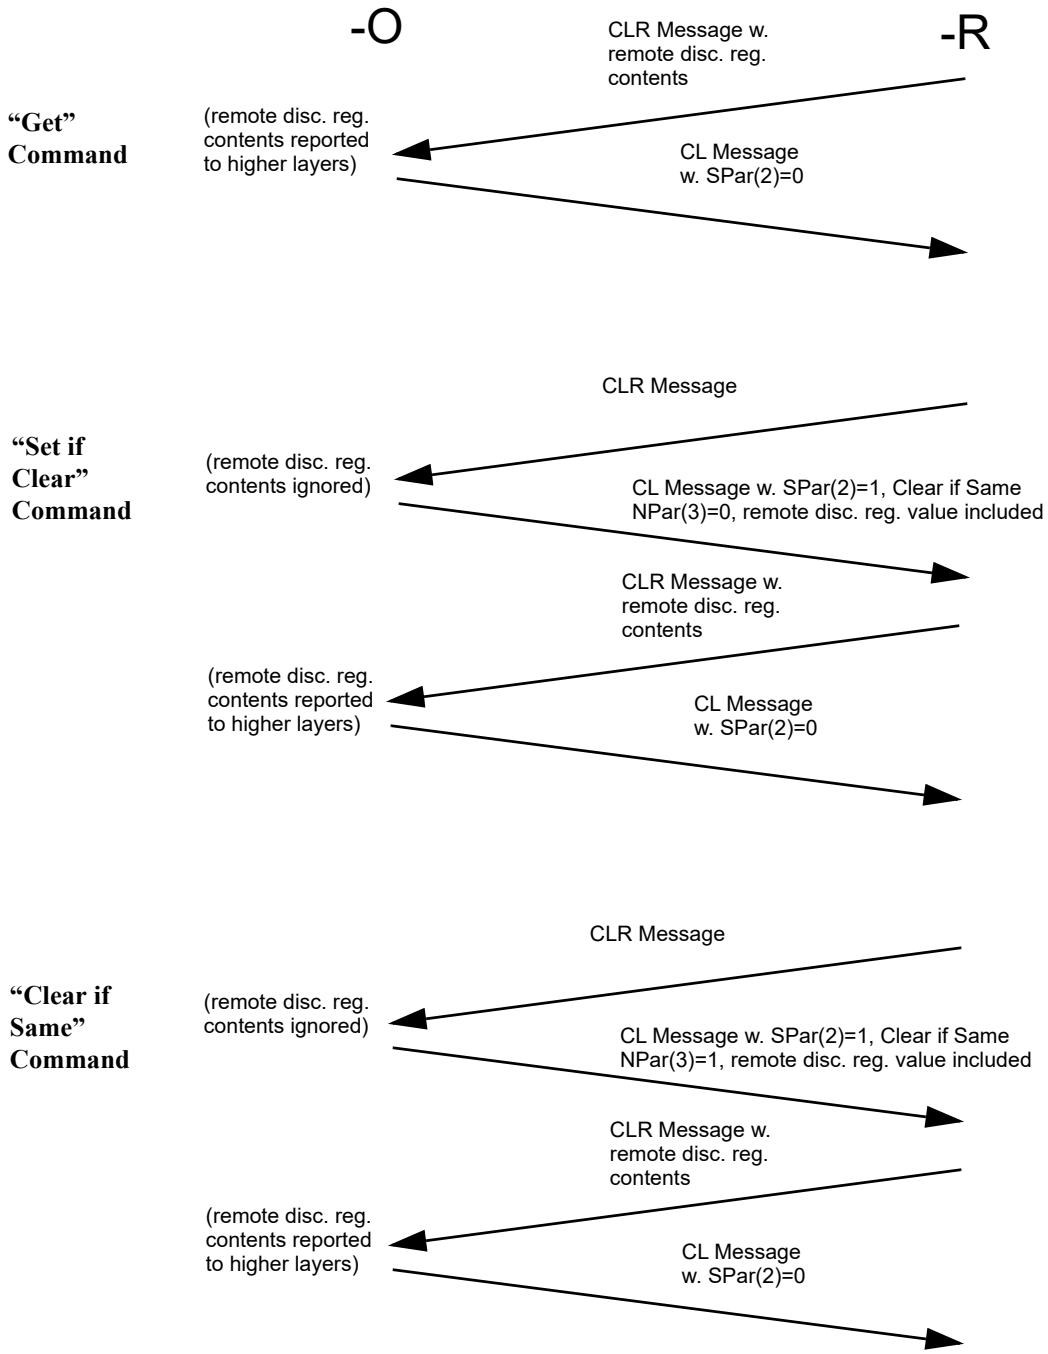

Figure 61–20—G.994.1 transactions for remote_discovery_register access

61.4.7.2 PME_Aggregate_register

2BASE-TL-R and 10PASS-TS-R PHYs shall assert the PME Aggregation SPar(2) bit in all G.994.1 CLR messages, if and only if its local PAF_available bit is set. CPE-subtypes shall place the contents of the PME_Aggregate_register in the corresponding NPar(3) bits in the outgoing CLR message.

In response to a "get" command, the CO-subtype shall perform a G.994.1 capabilities exchange with the CPE-subtype. The contents of the NPar(3) PME_Aggregate_register bits in the CLR message received from the CPE-subtype shall be reported as the result. The CL message sent by the CO-subtype in response to the CLR shall have the PME Aggregation SPar(2) bit set to zero.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

In response to a “set” command, the CO-subtype shall perform two back-to-back G.994.1 capabilities exchanges with the CPE-subtype. The contents of the NPar(3) PME_Aggregate_register bits in the first CLR message received from the CPE-subtype shall be ignored. The CL message sent by the CO-subtype in response to this first CLR shall have the PME Aggregation SPar(2) bit set to one and the NPar(3) PME_Aggregate_register bit zero. The -R device sets the bit position in the PME_Aggregate_register corresponding to the PME upon which the G.994.1 exchange takes place. The contents of the NPar(3) PME_Aggregate_register bits in the CLR message received from the CPE-subtype during the second capabilities exchange shall be reported as the result. The CL message sent by the CO-subtype in response to this second CLR shall have the PME Aggregation SPar(2) bit set to zero.

61.4.7.3 Timing and preferred transactions

This subclause is applicable to devices in which 10PASS-TS and/or 2BASE-TL are the only G.994.1-initiated PHYs implemented and enabled. Startup procedures for devices that include additional G.994.1-initiated modes of operation are outside the scope of this standard.

NOTE 1—Handshake operations specified in this subclause occur autonomously in the PHY, without intervention of the STA. They may however be triggered by an STA using the management interface.

If the PMA/PMD link control bit is set to 1 in the -O device (Table 45–31), or discovery register operations are initiated (Table 45–367), or link partner aggregation register operations are initiated (Table 45–370), the -O device initiates G.994.1 startup procedures by transmitting C-TONES.

If the PMA/PMD link control bit is set to 1 in the -R device (Table 45–31), the -R device initiates G.994.1 startup procedures by transmitting R-TONES-REQ.

At the conclusion of G.994.1 startup, the -R device shall begin G.994.1 transactions by transmitting an MR message. The -O device responds by sending C-TONES if the Ignore incoming handshake register bit (see 45.2.1.11) is set to 0_b.

If the G.994.1 session was initiated by the PMA/PMD link control bit (signifying that the link is to be brought up) in either the -O or -R device, then the -O device shall respond with an MS message specifying the configured mode of operation. However, if the PMA/PMD type selection bits in the -O device are set to the value 0011 or 0100, and a capabilities exchange has not previously taken place, the -O device shall instead respond with an REQ-CLR so that a capabilities exchange is performed. Following the final message of the capabilities exchange [i.e., an ACK(1)], the -R device once again sends an MR message. The -O device shall respond with an MS message specifying the configured mode of operation.

If the G.994.1 session was initiated in response to discovery register operations (Table 45–367), or link partner aggregation register operations (Table 45–370), then the -O device shall respond with an REQ-CLR message (MR received before) or with a CL message (CLR received before). This is then followed by one or two capability exchanges as described in the previous two subclauses. Following the final message of the final capabilities exchange [i.e., an ACK(1)], the CPE device once again sends an MR message. If neither the PMA/PMD control bit nor the discovery or link partner aggregation register operations are activated within the next 0.5 seconds, the -O shall transmit an MS message with the SPar(1) silent bit set.

NOTE 2—It is understood that the entire activation sequence consisting of PAF Discovery, PAF and line activation is time-consuming, therefore 2BASE-TL and 10PASS-TS devices are encouraged to exchange only relevant information in G.994.1 sessions during various stages of initialization.

61.5 Link segment characteristics

As stated in 61.1, the channel characteristics of voice grade copper are very diverse. Some typical channels are defined as part of the Performance Guidelines contained in Annex 62B (for 10PASS-TS) and Annex 63B (for 2BASE-TL). These annexes also define the reference performance levels for each PHY in these conditions. Behavior in other voicegrade installations may be interpolated or extrapolated from that set of references.

61.6 MDI specification

The MDI interface for 10PASS-TS and the Service Splitter and Electrical Characteristics for 10PASS-TS are defined in 62.3.5.

The Electrical Characteristics of the MDI interface for 2BASE-TL are defined in 63.3.2.

The local regulations may dictate interface characteristics in addition to or in place of some or all of these requirements.

61.7 System considerations

Both EFM Copper port types are defined for full duplex operation only, although certain MACs may still require to be configured for half duplex operation in order to respond to the carrier Sense signal, as required by the specification of MAC-PHY Rate Matching. The requirements of 31B.1 restrict the transmission of PAUSE frames to DTEs configured to the full duplex mode of operation. If PAUSE frames are used on an EFM Copper link, consideration should be given to the link latency, and the fact that the MAC-PHY Rate Matching mechanism can interfere with the expected operation of the PAUSE frame mechanism.

NOTE—It is recognized that an EFM Copper system may have to comply with additional requirements and/or restrictions outside the scope of this standard (see 61.6 and 61.8 for examples) in order to be allowed to be connected to a public infrastructure in a certain geographic area or regulatory environment. These additional requirements and/or restrictions may prohibit operation under certain profiles, or degrade the performance of the system when working under certain profiles.This may limit the system's compliance with this standard, as compliant systems support all profiles (see Annex 62A for 10PASS-TS and Annex 63A for 2BASE-TL) and meet all performance guidelines (see Annex 62B for 10PASS-TS and Annex 63B for 2BASE-TL).

A compliant CPE-side system cannot distinguish a CO-side system designed to operate under a limited set of profiles from a fully compliant CO-side system, as the selection of profiles is under control of the CO-side. A CPE-side system designed to operate under a limited set of profiles cannot be guaranteed to correctly interoperate with compliant CO-side systems.

It is recommended that vendors of systems that support a limited set of profiles provide PICS forms to indicate which profiles are supported, in order to allow users to assess the impact on interoperability.

61.8 Environmental specifications

The requirements of 14.7 should be considered as baseline Environmental Specifications for types 10PASS-TS and type 2BASE-TL. Since equipment specified in this Clause will typically be deployed into public network environments, the specific requirements of the network operator or the local authority having jurisdiction shall prevail in all cases, and shall be considered in the development of such equipment. Such requirements may be statutory and may include product safety, electromagnetic compatibility and protection of the public network against harms from attached equipment.

61.9 PHY labeling

It is recommended that PHY equipment (and supporting documentation) be labeled in a manner visible to the user with at least the following parameters:

a) PMA/PMD (sub-)type. A type (e.g., 10PASS-TS) can be specified if both -O and -R subtypes are supported. A subtype should be specified (e.g. 10PASS-TS-R) if only a single subtype is supported.
b) PAF capability if supported. The following information should be provided: number of MII/PCS ports provided; maximum number of PMEs per MII/PCS; total number of PMEs. For example:
    1) x8 or 1x8:8 for a single MII port with 8 PMEs
    2) 2x2:4 for a device with 2 MII ports and 4 PMEs, which can be aggregated up to 2 PMEs per port
    3) 4x4:4 for a device with 4 MII ports and 4 PMEs, which can be aggregated up to 4 PMEs per port
c) Homologation information
d) Applicable safety warnings

61.10 Protocol implementation conformance statement (PICS) proforma for Clause 61, Physical Coding Sublayer (PCS), Transmission Convergence (TC) sublayer, and common specifications type 10PASS-TS, 2BASE-TL[121]

61.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 61, Physical Coding Sublayer (PCS), Transmission Convergence (TC) sublayer, and common specifications type 10PASS-TS, 2BASE-TL, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

61.10.2 Identification

61.10.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification--e.g., names and versions for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

61.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 61, Physical Coding Sublayer (PCS) and common specifications, type 10PASS-TS and 2BASE-TL.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[121] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

61.10.3 Major capabilities/options

Item	Feature	Subclause	Value/Comment	Status	Support
RM	MAC-PHY Rate Matching	61.2.1	CRS deference mechanism supported.	M	Yes [ ]
TC	64/65-octet Encapsulation	61.3	The Ethernet-specific TPS-TC, between α(β)-interface and γ-interface is implemented.	M	Yes [ ]
*PAF	PME Aggregation	61.2.2	Up to 32 PMA/PMD instances can be aggregated into a single MAC.	O	Yes [ ] No [ ]
HS	Support for G.994.1 handshake	61.4	PHY uses G.994.1 handshake to identify remote transceiver and exchange capabilities.	M	Yes [ ]
*2BO	2BASE-TL-O subtype	61, 63	The 2BASE-TL CO subtype is implemented.	O.1	Yes [ ] No [ ]
*2BR	2BASE-TL-R subtype	61, 63	The 2BASE-TL CPE subtype is implemented.	O.1	Yes [ ] No [ ]
*10PO	10PASS-TS-O subtype	61, 62	The 10PASS-TS CO subtype is implemented.	O.1	Yes [ ] No [ ]
*10PR	10PASS-TS-R subtype	61, 62	The 10PASS-TS CPE subtype is implemented.	O.1	Yes [ ] No [ ]

61.10.4 PICS proforma tables for the Physical Coding Sublayer (PCS), Transmission Convergence (TC) sublayer, and common specifications type 10PASS-TS, 2BASE-TL

61.10.4.1 MAC-PHY Rate Matching

Item	Feature	Subclause	Value/Comment	Status	Support
RM-1	MAC-PHY Rate Matching functions	61.2.1.1	The PHY uses CRS to match the MAC's faster rate of data transmission to the PHY's slower rate.	M	Yes [ ]
RM-2	MAC-PHY Rate Matching functions	61.2.1.1	Upon receipt of a MAC frame from the MII, the PHY discards the Preamble and SFD fields, and transmits the resulting data frame across the physical link.	M	Yes [ ]
RM-3	MAC-PHY Rate Matching functions	61.2.1.1	The PHY prepends the Preamble and the SFD fields to a received frame before sending it to the MAC.	M	Yes [ ]
RM-4	MAC-PHY Rate Matching functions	61.2.1.1	The PHY supports a mode of operation where it does not send data to the MAC while the MAC is transmitting.	M	Yes [ ]

61.10.4.2 64/65-octet Encapsulation

Item	Feature	Subclause	Value/Comment	Status	Support
TC-1	The γ-interface	61.3.1	The PAF asserts Tx_Avbl when it has a whole data fragment available for transmission, and de-assert Tx_Avbl when there are no data fragments to transmit.	M	Yes [ ]
TC-2	TC functions	61.3.3	The TC provides full transparent transfer of data frames between γ_O-interface and γ_R-interface.	M	Yes [ ]
TC-3	TC functions	61.3.3	The TC provides fragment integrity and fragment error monitoring capability.	M	Yes [ ]
TC-4	TC functions	61.3.3	The bit rate of data transport in the upstream and downstream directions are set independently of each other to any eligible value up to the maximum rate determined by the PMD.	M	Yes [ ]
TC-5	TC Encapsulation and Coding	61.3.3.1	When a frame arrives from the γ-interface while an End of Frame codeword is being transmitted, a Start of Frame octet is inserted prior to the transmission of data octets belonging to the next frame.	M	Yes [ ]
TC-6	Sync detection	61.3.3.5	The synchronization is acquired from the incoming data stream.	M	Yes [ ]
TC-7	Sync detection	61.3.3.5.2	The receiver implements the sync detect state diagram shown in Figure 61–17.	M	Yes [ ]
TC-8	Receive control	61.3.3.6	If TC_synchronized = false then signal RX_Enbl is de-asserted.	M	Yes [ ]
TC-9	Receive control	61.3.3.6	If a TC-CRC error is detected, the receive controller asserts signal RX_Err during at least one octet of the fragment as it is passed up across the γ-interface.	M	Yes [ ]
TC-10	Receive control	61.3.3.6	If the fragment contains data from a block in which the PMA detected errors but did not correct them, the receive controller asserts signal RX_Err during at least one octet of a fragment as it is passed up across the γ-interface.	M	Yes [ ]

61.10.4.3 PME Aggregation[122]

Item	Feature	Subclause	Value/Comment	Status	Support
PAF-1	PME Aggregation Receive function	61.2.2.4	When the link state is changed to UP, the expected sequence number is unknown and no frame sequence errors are recorded.	*PAF:M	Yes [ ]
PAF-2	PME Aggregation Transmit Function Restrictions	61.2.2.6	The differential latency between any two PMEs in an aggregated group is no more than 15 000 bit times.	*PAF:M	Yes [ ]
PAF-3	PME Aggregation Transmit Function Restrictions	61.2.2.6	Fragments are not less than 64 octets.	*PAF:M	Yes [ ]
PAF-4	PME Aggregation Transmit Function Restrictions	61.2.2.6	Fragments are not more than 512 octets.	*PAF:M	Yes [ ]
PAF-5	PME Aggregation Transmit Function Restrictions	61.2.2.6	The highest ratio of speeds between any two aggregated links is 4.	*PAF:M	Yes [ ]
PAF-6	PME Aggregation Transmit Function Restrictions	61.2.2.6	The fragment size is a multiple of 4 octets except for the last fragment of a data frame.	*PAF:M	Yes [ ]
PAF-7	Error-detecting Rules	61.2.2.7	For each PMA, the per-PMA buffering mechanism discards the fragment if any of the listed conditions occur, and asserts the PAF error flags as appropriate. If the packet assembly function was mid-frame, the first part of the frame is transferred across the MII, then the RX_ER signal is asserted on the MII, the frame transfer is aborted and PMA buffers are flushed until the next Start of Packet is received.	*PAF:M	Yes [ ]
PAF-8	Error-detecting Rules	61.2.2.7	If a fragment is received with the StartOfPacket bit asserted while the packet assembly function was mid-frame, the first part of the frame is transferred across the MII, then the RX_ER signal is asserted on the MII, the frame transfer is aborted and PMA buffers are flushed until the next Start of Packet is received.	*PAF:M	Yes [ ]
PAF-9	PME aggregation register functions	61.2.2.8.3	The remote_discovery_register and Aggregation_link_state_register are implemented.	*PAF:M	Yes [ ]
PAF-10	PME aggregation register functions	61.2.2.8.3	The PME_Available_register is read-only.	*PAF: *2BO:M *10PO:M	Yes [ ]

[122]All items listed in this section are only applicable if the optional PME Aggregation Function is supported.

Copyright © 2022 IEEE. All rights reserved.

62. Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 10PASS-TS

62.1 Overview

62.1.1 Scope

This clause specifies the 10PASS-TS Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD) for voice grade twisted-pair wiring. In order to form a complete 10PASS-TS PHY, the 10PASS-TS PMA and PMD are integrated with the TC and PCS of Clause 61. Parts of register 3.0, parts of register 3.4, and registers 3.60 through 3.73 specified in Clause 45 may be used to control the PCS of Clause 61. Parts of register 6.0 and registers 6.16 through 6.23 specified in Clause 45 may be used to control the TC sublayer of Clause 61. Registers 1.16 through 1.71 may be used to control the 10PASS-TS PMA and PMD.

62.1.2 Objectives

The following are the objectives for the 10PASS-TS PMA and PMD:

a) To provide 10Mb/s encapsulated packet data rate at the α(β)-interface.
b) To provide full duplex operation.
c) To provide for operating over non-loaded voice grade twisted pair cable at distances up to 750 m.
d) To provide a communication channel with a mean bit error ratio, at the α(β)-interface, of less than one part in 10^7 with 6 dB noise margin.

62.1.3 Relation of 10PASS-TS to other standards

The specifications of 10PASS-TS PMA and PMD are based on the VDSL transceiver specified in ATIS-0600424.

62.1.4 Summary of Physical Medium Attachment (PMA) specification

This layer is defined by the α(β)-interface and the I-interface.

62.1.4.1 α(β)-interface

A complete definition of the α(β)-interface is contained in 61.3.2.

62.1.4.2 I-interface

The I_O and I_R reference points define interfaces between the PMA and PMD in the 10PASS-TS-O and 10PASS-TS-R, respectively. Both interfaces are functional, application independent and identical. Both interfaces are defined by the following signal flows:

a) Data flow
b) Synchronization flow

62.1.4.2.1 I Data Flow

The data flow consists of the following two octet-oriented streams, both with the PMA frame format, with the bit rates defined by the PMD transmission profile:

a) Transmitted data (Tx)
b) Received data (Rx)

If data streams are implemented serially, the MSB of each octet is sent first.

Each stream bit rate value is set during PMD configuration.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

62.1.4.2.2 I Synchronization Flow

The synchronization flow consists of the transmitted and received octet synchronization signals (Clko_t, Clko_r). Optional transmit and receive bit-synchronization signals (Clkp_t, Clkp_r) are defined too.

Synchronization signals are asserted by the PMD and directed towards the PMA.

The synchronization flow signals are described in Table 62–1.

Table 62–1—I-interface signals

Signal(s)	Description	Direction	Notes
Data signals			
Tx	Transmitted data stream	PMA → PMD	Transmission frame format.
Rx	Received data stream	PMA ← PMD	
Synchronization signals			
Clko_t	Transmitted octet timing	PMA ← PMD	
Clko_r	Received octet timing	PMA ← PMD	
Clkp_t	Transmitted bit timing	PMA ← PMD	Optional
Clkp_r	Received bit timing	PMA ← PMD	Optional

62.2 PMA functional specifications

For the purpose of transmission over a serial implementation of the α(β)-interface or the I-interface, bit b_8 as defined in Figure 61–16 is considered MSB and shall therefore be transmitted first. However, for the purpose of all serial processing (e.g., scrambling, CRC calculation) bit b_8 is considered LSB and shall therefore be the first bit processed. Thus, the outside world MSB is considered as the 10PASS-TS LSB.

62.2.1 PMA functional diagram

Figure 62–1 shows a diagram of the PMA sublayer.

62.2.2 PMA functional specifications

The 10PASS-TS PMA is specified by incorporating the VDSL standard, ATIS-0600424, by reference, with the modifications noted below. This standard provides support for voice-grade twisted pair. For improved legibility in this clause, ATIS-0600424, will henceforth be referred to as MCM-VDSL.

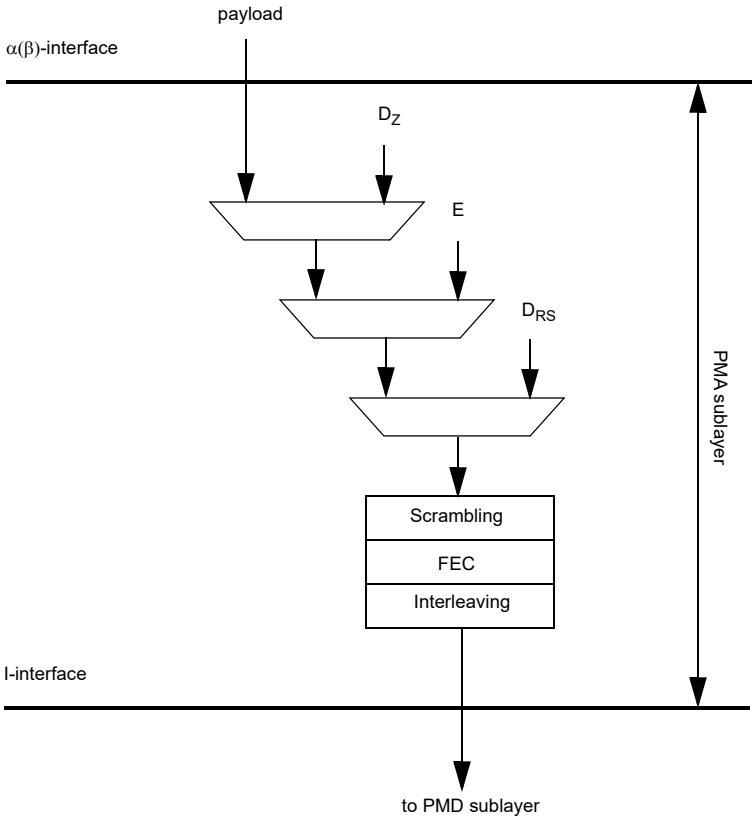

Figure 62–1—Diagram of PMA sublayer

62.2.3 General exceptions

The 10PASS-TS PMA is precisely the PMS-TC specified in MCM-VDSL, with the following general modifications:

a) There are minor terminology differences between this standard and MCM-VDSL that do not cause ambiguity. The terminology used in 10PASS-TS was chosen to be consistent with other IEEE 802 standards, rather than with MCM-VDSL. Terminology is both defined and consistent within each standard. Special note should be made of the interpretations shown in Table 62–2.
b) The 10PASS-TS PMA does not support the “fast path”.

Table 62–2—Interpretation of general MCM-VDSL terms and concepts

MCM-VDSL term or concept	Interpretation for 10PASS-TS
PMS-TC	PMA
VTU-O, LT	10PASS-TS-O
VTU-R, NT	10PASS-TS-R
Transmission medium dependent interface	MDI
U1-interface (splitter present)	
U2-interface (splitter absent)	

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

62.2.4 Specific requirements and exceptions

The 10PASS-TS PMA shall comply to the requirements of MCM-VDSL Section 9.3 with the exceptions listed below. Where there is conflict between specifications in MCM-VDSL and those in this standard, those of this standard shall prevail.

62.2.4.1 Replacement of 9.3.1, “PMS-TC functional diagram”

Replace 9.3.1 of MCM-VDSL by the PMA functional diagram in 62.2.1.

62.2.4.2 Changes to 9.3.3, “Forward error correction”

Referenced as is, with the exception of required Reed-Solomon encoder and interleaver settings.

The mandatory settings in MCM-VDSL (144,128) and (240,224) shall be supported. Other values are out of scope.

The following interleaver parameters shall be supported:

a) For (*N*,*K*)=(144,128) the following values for *M* and *I* shall be supported: *I*=36 and *M* between 2 and 52
b) For (*N*,*K*)=(240,224) the following values for *M* and *I* shall be supported: *I*=30 and *M* between 2 and 62

Other settings for *M* and *I* are out of scope.

62.2.4.3 Changes to 9.3.5, “Framing”

Referenced as is, with following exceptions:

a) The “fast” buffer is not supported
b) There shall be 1 VOC byte per packet; other values of V as defined in 9.3.5.5 are outside the scope of this standard
c) 9.3.5.5.4 (NTR) is not applicable
d) In Table 9-4 (9.3.5.5.3), following changes apply
    1) bits B2, B3 of Byte #2 are reserved
    2) bits B1, B2, B3, B4 of Byte #3 shall be set to 0

Additional text: the signal PMA_receive_synchronized, defined in 61.3.2.2, shall be asserted when 10PASS-TS is in the state “STEADY_STATE_TRANSMISSION” (see Figure 62–4), and deasserted when 10PASS-TS is in any other state.

62.3 PMD functional specifications

62.3.1 PMD Overview

The 10PASS-TS PMD functional model is presented in Figure 62–2. In the transmit direction, the PMD layer receives frames from the PMA layer. It sends a DMT modulated signal towards the physical medium over the MDI.

The bytes within the frame are encoded to a set of QAM constellation points that are used to modulate the carriers of the DMT symbol. The time-domain symbol is cyclically extended and then windowed to reduce sidelobe energy.

In the receive direction, a modulated signal is received from the transmission medium over the MDI. The PMD layer outputs a data frame to the PMA layer. The receiver is responsible for equalization and demodulation of the signal.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

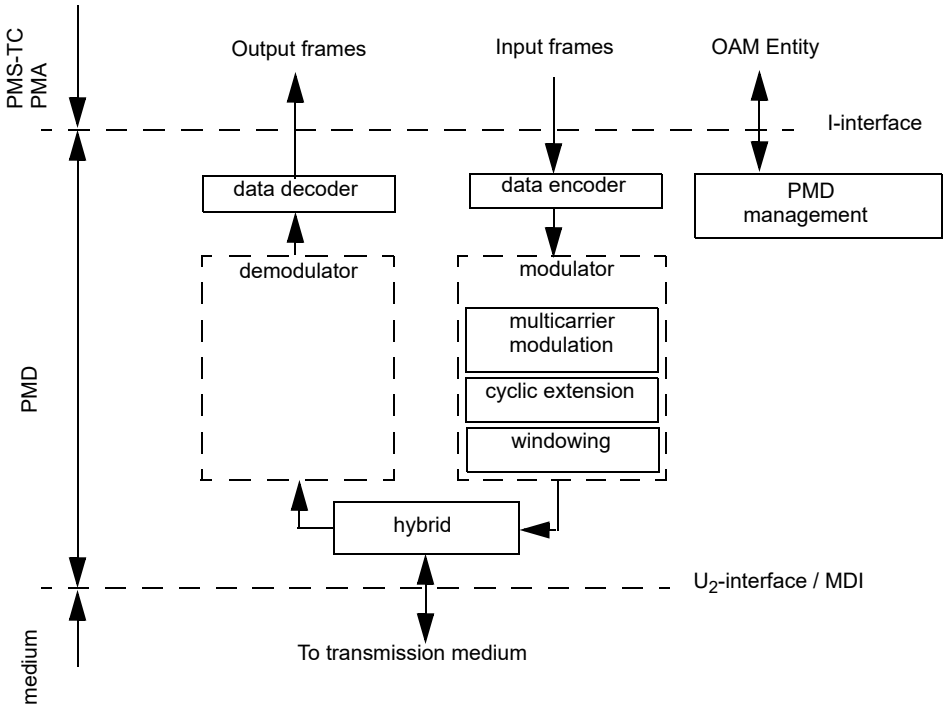

Figure 62–2—Functional diagram of PMD sublayer

62.3.2 PMD functional specifications

The 10PASS-TS PMD (and MDI) is specified by incorporating the MCM-VDSL standard, ATIS-0600424, by reference, with the modifications noted below. This standard provides support for voice-grade twisted pair.

62.3.3 General exceptions

The 10PASS-TS PMD is precisely the PMD specified as MCM-VDSL, with the following general modifications:

There are minor terminology differences between this standard and MCM-VDSL that do not cause ambiguity. The terminology used in 10PASS-TS was chosen to be consistent with other IEEE 802 standards, rather than with MCM-VDSL. Terminology is both defined and consistent within each standard. Special note should be made of the interpretations shown in Table 62–3.

62.3.4 Specific requirements and exceptions

The 10PASS-TS PMD (including MDI) shall comply to the requirements of MCM-VDSL Section 8 [Physical medium dependent (PMD) sublayer], Section 10 (Operations and maintenance), Section 11 (Link activation and deactivation) and Section 18 (Normative Annex 4—Handshake procedure for VDSL) with the exceptions listed below. Section 12 (Test procedures and requirements), Section 13 (Physical conditions), Section 14 (Environmental conditions), Section 15 (Normative Annex 1: International amateur bands), Section 16 (Informative Annex 2: VDSL PSD templates figures), Section 17 (Informative Annex 3: Utopia implementation of the ATM-TC interface), Section 19 (Informative Annex 5: FMT implementation), Section 20 (Informative Annex 6: 8.625 kHz tone spacing), Section 21 (Normative Annex 7: Electrical characteristics of service splitter at remote subscriber end), Section 22 (Informative Annex 8: Electrical characteristics of service splitter at network end), and Section 23 (Informative Annex 9: Alien crosstalk descriptions), are outside the scope of this standard. Where there is conflict between specifications

Table 62–3—Interpretation of general MCM-VDSL terms and concepts

MCM-VDSL term or concept	Interpretation for 10PASS-TS
PMS-TC	PMA
VTU-O, LT	10PASS-TS-O
VTU-R, NT	10PASS-TS-R
Transmission medium dependent interface	MDI
U1-interface (splitter present)	
U2-interface (splitter absent)	

in MCM-VDSL and those in this standard, those of this standard shall prevail. Optional specifications in MCM-VDSL are out of scope unless explicitly referenced in this document as mandatory. If out-of-scope optional features are implemented, the mode of operation of the PHY cannot be labeled "10PASS-TS" when these features are activated.

NOTE—If optional features are implemented, their use is negotiated during initialization.

62.3.4.1 Replacement of 8.2.1, "Multi-carrier Modulation"

10PASS-TS transceivers shall use Frequency Division Duplexing (FDD) to separate upstream and downstream transmission. 10PASS-TS transceivers shall support modulation of N_{SC} = 4096 subcarriers (n = 4). Disjoint subsets of the N_{SC} subcarriers shall be defined for use in the downstream and upstream directions. These subsets are determined by the choice of frequency plan. The exact subsets of subcarriers used to modulate data in each direction shall be determined during initialization and shall be based on management system settings and the signal-to-noise ratios (SNRs) of the subchannels. In many cases the number of subcarriers used in a direction will be less than the maximum number allowed by the partitioning.

Frequency plans are defined in Annex 62A. In standard frequency plans, frequency bands are allocated as shown in Figure 62–3. The values of the splitting frequencies are given in Annex 62A. Adherence to a particular frequency plan may be mandatory under local regulations when 10PASS-TS is deployed in public networks. Other frequency plans, for use in private networks, can be supported by means of Clause 45 register settings (see Annex 62C for examples).

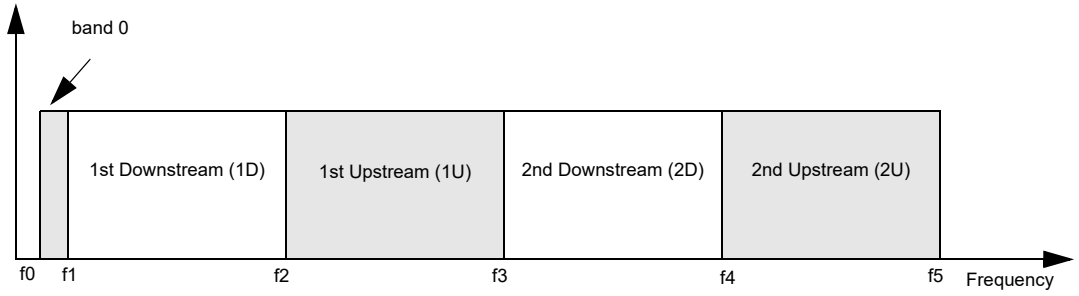

Figure 62–3—10PASS-TS band allocation

8.2.1.1 (Tone Spacing) is referenced as is.

8.2.1.2 (Data Sub Carriers) is referenced as is.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

8.2.1.3 (IDFT modulation) is referenced as is.

62.3.4.2 Changes to 8.2.2, “Cyclic extension”

8.2.2 of MCM-VDSL is further restricted by the following normative text:

The cyclic extension length is specified by the value of parameter *m*. In 10PASS-TS, support for the values $m = 10$, $m = 20$, and $m = 40$ is mandatory. The value $m=20$ is the default setting. Support for other values is out of scope.

62.3.4.3 Changes to 8.2.3, “Synchronization”

8.2.3.1 of MCM-VDSL is further clarified by the following text:

Support for pilot tones is mandatory. 10PASS-TS-O PHYs shall support the transmission of a pilot tone on any downstream tone.

8.2.3.2 (Loop Timing) is referenced as is.

8.2.3.3 (Timing Advance) is referenced as is.

8.2.3.4 of MCM-VDSL is replaced with the following:

The use of synchronous mode as defined in MCM-VDSL 8.2.3.4 may improve operation in certain binder environments and is a system implementation item that is outside the scope of this standard.

62.3.4.4 Replacement of 8.2.4, “Power back-off in the upstream direction”

To mitigate the effects of FEXT from short lines into long lines in distributed cable topologies, upstream power back-off shall be applied. Transceivers shall be capable of performing frequency-dependent power back-off.

It shall be possible to temporarily disable UPBO for performance testing purposes (as required by Annex 62B). In normal operation, only one UPBO mode shall be supported as described below:

a) It shall be possible for the network management system to set the limiting transmit PSD template PSD_0 for the 10PASS-TS-R to one of the standard transmit PSD templates as defined in the applicable section of 62A.3.3.
b) The 10PASS-TS-R shall perform UPBO autonomously, i.e., without sending any significant information to the 10PASS-TS-O until the UPBO is applied.
c) After UPBO has been applied as described in item b), the 10PASS-TS-O shall be capable of adjusting the transmit PSD selected by the 10PASS-TS-R; the adjusted transmit PSD shall be subject to the limitations given in the applicable section of 62A.3.3.

To enable the 10PASS-TS-R to initiate a connection with the 10PASS-TS-O, which will occur before UPBO has been applied, the 10PASS-TS-R shall be allowed to cause more degradation to other loops than expected when using the mode described below.

NOTE—Initiation refers to a request from the 10PASS-TS-R to start the initialization of the link. The particular method is in MCM-VDSL 11.2.

The 10PASS-TS-R shall explicitly estimate the electrical length of its line, kl_0, and use this value to calculate the transmit PSD template $TxPSD(kl_0,f)$. The 10PASS-TS-R shall then adapt its transmit signal PSD to conform to the template $TxPSD(kl_0,f)$ and the corresponding PSD mask, which is defined in the applicable section of 62A.3.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The transmit PSD template shall be calculated as shown in Equation (62–1):

$$TxPSD(kl_0,f) = \min (PSD_REF(f) + LOSS(kl_0,f), PSD_0), \text{ in dBm/Hz} \quad (62–1)$$

where PSD_0 as defined in item a) in the previous list, and:

$$LOSS = kl_0 \, \text{sqrt}(f), \text{ in dB} \quad (62–2)$$

where the *LOSS* function is an approximation of the loop attenuation (insertion loss).

NOTE—The estimation of the electrical length should be sufficiently accurate to avoid spectrum management problems and additional performance loss.

PSD_REF will depend on the limiting transmit PSD template PSD_0 and on the noise model that is relevant for a given deployment scenario. The values of *PSD_REF* depend on the selected UPBO Reference PSD profile, as shown in Table 62A-3. The same bandwidth as for all regular transmit PSD masks defined in the applicable section of 62A.3.3 shall be used to check the conformance of *TxPSD* with power back-off. The general methodology for testing PSD conformance is defined in 6.1 of ATIS-0600417.2003 (S2015). Conformance with the PSD template shall be verified using a 100 kHz sliding window in the in-band frequency range below 1 MHz and a 1 MHz sliding window in the in-band frequency range above 1 MHz.

PSD_REF shall be input via the management interface (by means of the UPBO Reference PSD field in the 10P tone control parameter register, see 45.2.1.54) and shall be transmitted from the 10PASS-TS-O to the 10PASS-TS-R.

The 10PASS-TS-R shall estimate the insertion losses of the upstream bands based on the received downstream signals. From this, the shape of the *LOSS* function (or, equivalently, the electrical length) as defined above shall be derived. The 10PASS-TS-R shall then compute the transmit PSD by dividing the reference PSD in the upstream bands by the estimated *LOSS* function. Next, the 10PASS-TS-R shall take a tone-by-tone minimum of this computed PSD and the maximum allowed transmit PSD in the upstream direction. The result shall be used as the initial upstream transmit PSD. The PSD received by the 10PASS-TS-O should approximate the reference PSD. Upon receiving signals from the 10PASS-TS-R, the 10PASS-TS-O shall compare the actual received PSD to the reference PSD. If necessary, it shall instruct the 10PASS-TS-R to fine-tune its PSD.

The 10PASS-TS-O shall also have the capability to directly impose a maximum allowed transmit PSD at the 10PASS-TS-R. This maximum transmit PSD shall also be input via the management interface and shall be transmitted from 10PASS-TS-O to 10PASS-TS-R in the early stages of the initialization. The 10PASS-TS-O shall allow the operator to select one of these two methods. If the PBO is defined as a maximum transmit PSD at the 10PASS-TS-R, the 10PASS-TS-R shall adjust its transmit PSD such that it does not exceed the maximum allowed transmit PSD. The restrictions specified in the previous paragraph shall also apply in this case (i.e., the 10PASS-TS-O shall not impose a transmit PSD mask that violates the mask specified there).

62.3.4.5 Changes to 8.2.5, “Constellation encoder”

In 8.2.5 of MCM-VDSL, the constraints on B_{max_d} and B_{max_u} are replaced by the following constraints:

$$B_{max_d} = 12 \quad (62–3)$$

$$B_{max_u} = 12 \quad (62–4)$$

62.3.4.6 Band notch profiles

The requirements specified in 62A.3.5 are to be met.

All other subclauses in MCM-VDSL Clause 8 are referenced as is.

62.3.4.8 Changes to 11.1, “VDSL Link State and Timing Diagram”

See Figure 62–4.

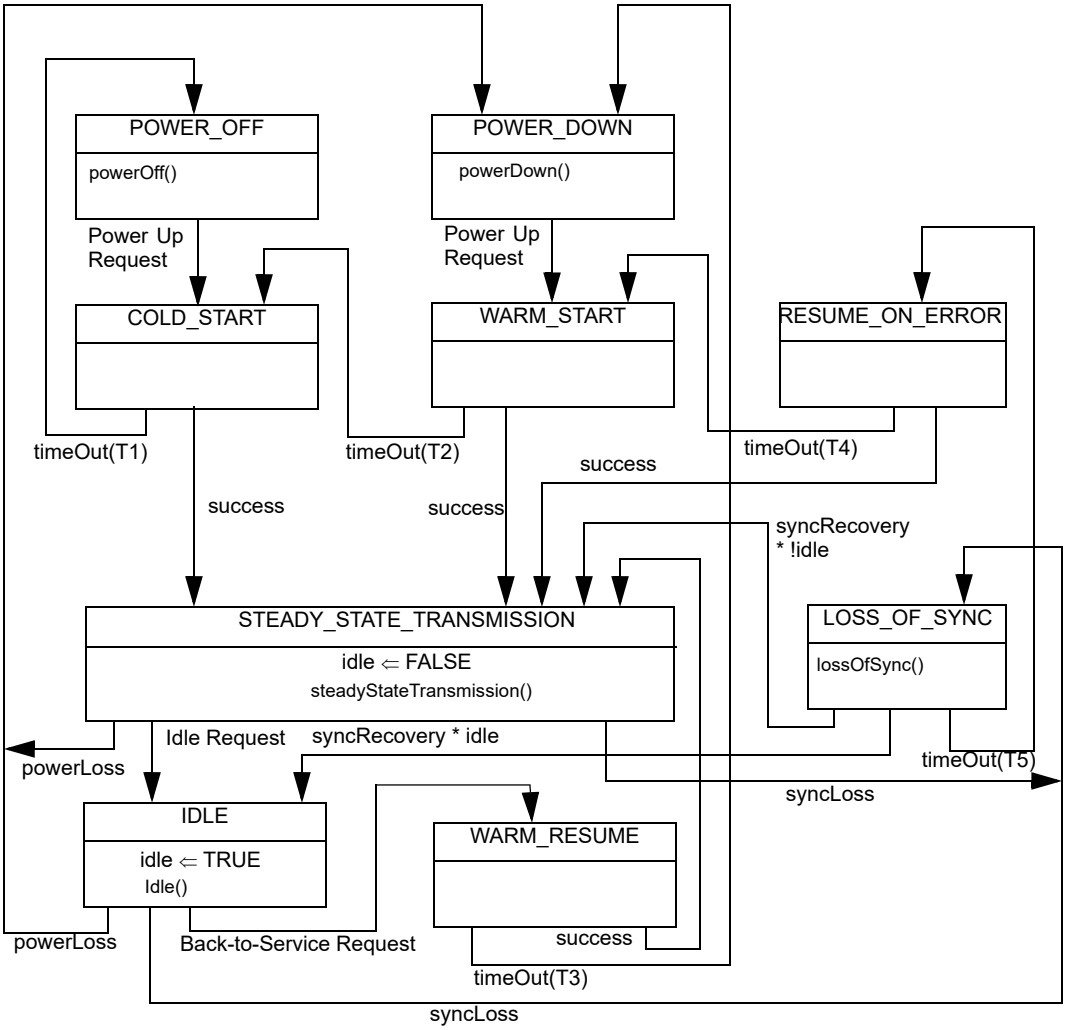

Figure 62–4—Link state and timing diagram

The function timeOut (time) returns FALSE upon entry of the associated state, and returns TRUE as soon as the interval specified by the argument “time” has expired. In addition, the state diagram uses following variables and constants:

T1
: Constant indicating the maximum cold-start activation time, equal to 10 000 ms

T2
: Constant indicating the maximum warm-start activation time, equal to 5000 ms

T3
: Constant indicating the maximum warm-resume activation time, equal to 100 ms

T4
: Constant indicating the maximum resume-on-error activation time, equal to 300 ms

T5
: Constant indicating the maximum sync-loss recovery time, equal to 200 ms

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

idle Variable that indicates if the PMD has transitioned from STEADY_STATE_TRANSMISSION to IDLE. The idle variable becomes TRUE when the PMD enters the IDLE state, and becomes FALSE when the PMD enters the STEADY_STATE_TRANSMISSION mode.

success
Variable that is TRUE if and only if the procedures in the associated state were completed without error.

The following procedures are introduced to represent the actions associated with various states, as defined in MCM-VDSL.

powerOff()
See description of *Power-off* in MCM-VDSL section 11.1.1.1

steadyStateTransmission()
See description of *Steady-State Transmission* in MCM-VDSL section 11.1.1.1

lossOfSync()
See description of *Loss of Sync (Loss of Signal)* in MCM-VDSL section 11.1.1.1

powerDown()
See description of *Power Down* in MCM-VDSL section 11.1.1.1

idle()
See description of *Idle* in MCM-VDSL section 11.1.1.1

The remaining actions and transitions are documented in MCM-VDSL section 11.1, referenced as is.

62.3.4.9 Changes to section 18 (Annex 4), “Handshake procedure for VDSL”

62.3.4.9.1 Replacement of 18.1, “Introduction”

The 10PASS-TS handshake procedure is based on ITU-T Recommendation G.994.1 (G.hs). The carrier set used is specified in 61.3. During the handshake procedure, the following parameters shall be transmitted:

a) The size of IDFT/DFT;
b) the initial length of the cyclic extension;
c) flags indicating the use of the optional band, 25–138 kHz.

The parameters above shall be encoded using the information fields specified in 61.4.

62.3.4.9.2 Replacement of 18.2, “Description of signals”

The carrier set and signals used are specified in 61.4.

62.3.4.9.3 Replacement of 18.3, “Message coding format”

The message coding format and field definition tables are specified in 61.4.

62.3.4.9.4 Replacement of 18.4.1, “Handshake - 10PASS-TS-O”

The detailed procedures for handshake at the 10PASS-TS-O are defined in Recommendation G.994.1. A 10PASS-TS-O, after power-up, loss of signal, recovery from errors during the initialization procedure, shall enter the initial G.994.1 state C-SILENT1. The 10PASS-TS-O may transition to the Initialization Reset Procedure under instruction from the network. From either state, operation shall proceed according to the procedures defined in G.994.1.

If Recommendation G.994.1 procedures select 10PASS-TS as the mode of operation, the 10PASS-TS-O shall transition to state O-QUIET at the conclusion of G.994.1 operation.

A 10PASS-TS-O wishing to indicate 10PASS-TS capabilities during in a G.994.1 CL message shall do so by setting to 1_b the Level 1 SPar(1)10PASS-TS bit as defined in G.994.1. The NPar(2) and SPar(2) fields corresponding to the "10PASS-TS" Level 1 bit are defined in 61.4. For each Level 2 SPar(2) bit set to 1_b, a corresponding NPar(3) field shall also be present. These NPar(3) fields are defined in 61.4. The Level 2 bits in a CL message are defined in Table 62–5 and Table 62–6.

Table 62–5—10PASS-TS-O CL message NPar(2) bit definitions

NPar(2) bit	Definition
Upstream use of 25 kHz–138 kHz band	If set to 1_b, signifies that the 10PASS-TS-O is capable of using the band between 25 kHz and 138 kHz and that the band can be used for the upstream transmission.
Downstream use of 25 kHz–138 kHz band	If set to 1_b, signifies that the 10PASS-TS-O is capable of using the band between 25 kHz and 138 kHz and that the band can be used for the downstream transmission.
EOC-Clear	If set to 1_b, signifies that the 10PASS-TS-O supports transmission and reception of G.997.1 OAM frames.

Table 62–6—10PASS-TS-O CL message SPar(2) bit definitions

NPar(2) bit	Definition
Used bands in upstream	The use of this bit is optional. If set to 1_b, indicates the used upstream bands. The optional band between 25 kHz and 138 kHz shall not be included.
Used bands in downstream	The use of this bit is optional. If set to 1_b, indicates the used downstream bands. The optional band between 25 kHz and 138 kHz shall not be included.
IDFT/DFT size	Always set to 1_b in a CL message. Indicates the maximum IDFT/DFT size that 10PASS-TS-O can support. The value shall be present in the corresponding NPar(3) field.
Initial length of *CE*	If set to 0_b, it signifies that the 10PASS-TS-O can support only the mandatory cyclic extension length of $40*2^n$ for a number of tones equal to $256*2^n$. If set to 1_b in a CL message, it indicates the initial sample length of the cyclic extension that 10PASS-TS-O can support. It also signifies that the 10PASS-TS-O can support CE lengths other than the mandatory length. The value shall be present in the corresponding NPar(3) field. If one of the modems supports only the mandatory value, then this value shall be used.
RFI bands	The use of this bit is optional. If set to 1_b, indicates the RFI bands.

A PHY selecting 10PASS-TS mode of operation in a G.994.1 MS message shall do so by setting to 1_b the Level 1 SPar(1) 10PASS-TS-O bit as defined in G.994.1. The NPar(2) and SPar(2) fields corresponding to this bit are defined in 61.3. For each Level 2 SPar(2) bit set to 1b, a corresponding NPar(3) field shall also be present, as defined in 61.3. The Level 2 bits in an MS message from the 10PASS-TS-O are defined in Table 62–7 and Table 62–8.

If both bits Upstream use of optional band and Downstream use of optional band are enabled in the CL and CLR message, one and only one of the bits shall be set to 1_b in an MS message sent from the 10PASS-TS-O, and the use of the band between 25 kHz and 138 kHz is at the 10PASS-TS-O's discretion. If the 10PASS-TS-O and 10PASS-TS-R have no common usage of the optional band, both bits shall be set to 0_b in an MS message sent from the 10PASS-TS-O.

Table 62–7—10PASS-TS-O MS message NPar(2) bit definitions

NPar(2) bit	Definition
Upstream use of 25 kHz–138 kHz band	Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. It signifies that the band between 25 kHz and 138 kHz shall be used for the upstream transmission.
Downstream use of 25 kHz–138 kHz band	Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. It signifies that the band between 25 kHz and 138 kHz shall be used for the downstream transmission.
EOC-Clear	Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. Signifies that both 10PASS-TS-O and 10PASS-TS-R may transmit and receive G.997.1 OAM frames.

Table 62–8—10PASS-TS-O MS message SPar(2) bit definitions

NPar(2) bit	Definition
Used bands in upstream	Always set to 0_b in an MS message.
Used bands in downstream	Always set to 0_b in an MS message.
IDFT/DFT size	Always set to 1_b in an MS message. Indicates the maximum IDFT/DFT size that both 10PASS-TS-O and 10PASS-TS-R can support. The value shall be present in the corresponding NPar(3) field.
Initial length of *CE*	Set to 0_b if and only if this bit was set to 0_b in the last previous CL message or the last previous CLR message, or both. It signifies that both 10PASS-TS-O and 10PASS-TS-R shall use only the mandatory cyclic extension length. Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. It indicates the initial sample length of the cyclic extension. It also signifies that both 10PASS-TS-O and 10PASS-TS-R can support CE lengths other than the mandatory length. The value shall be given in the corresponding NPar(3) field.
RFI bands	Always set to 0_b in an MS message.

62.3.4.9.5 Replacement of 18.4.2, “Handshake - 10PASS-TS-R”

The detailed procedures for handshake at the 10PASS-TS-R are defined in Recommendation G.994.1. An 10PASS-TS-R, after power-up, loss of signal, recovery from errors during the initialization procedure, shall enter the initial G.994.1 state R-SILENT0. Upon command from the host controller, the 10PASS-TS-R shall initiate handshaking by invoking the Initialization Reset Procedure. Operation shall then proceed according to the procedures defined in G.994.1.

If Recommendation G.994.1 procedures select 10PASS-TS as the mode of operation, the 10PASS-TS-R shall transition to state R-QUIET at the conclusion of G.994.1 operation.

A 10PASS-TS-R wishing to indicate 10PASS-TS capabilities during in a G.994.1 CLR message shall do so by setting to 1_b the Level 1 SPar(1) 10PASS-TS bit as defined in G.994.1. The NPar(2) and SPar(2) fields corresponding to the “10PASS-TS” Level 1 bit are defined in 61.4. For each Level 2 SPar(2) bit set to 1_b, a corresponding NPar(3) field shall also be present. These NPar(3) fields are defined in 61.4. The Level 2 bits in a CLR message are defined in Table 62–9 and Table 62–10.

Table 62–9—10PASS-TS-R CLR message NPar(2) bit definitions

NPar(2) bit	Definition
Upstream use of 25 kHz–138 kHz band	If set to 1_b, signifies that the 10PASS-TS-R is capable of using the band between 25 kHz and 138 kHz and that the band can be used for the upstream transmission.
Downstream use of 25 kHz–138 kHz band	If set to 1_b, signifies that the 10PASS-TS-R is capable of using the band between 25 kHz and 138 kHz and that the band can be used for the downstream transmission.
EOC-Clear	If set to 1_b, signifies that the 10PASS-TS-R supports transmission and reception of G.997.1 OAM frames.

Table 62–10—10PASS-TS-R CLR message SPar(2) bit definitions

NPar(2) bit	Definition
Used bands in upstream	Always set to 0_b in a CLR message.
Used bands in downstream	Always set to 0_b in a CLR message.
IDFT/DFT size	Always set to 1_b in a CLR message. Indicates the maximum IDFT/ DFT size that 10PASS-TS-R can support. The value shall be present in the corresponding NPar(3) field.
Initial length of *CE*	If set to 0_b, it signifies that the 10PASS-TS-R can support only the mandatory cyclic extension length of 40×2^n for a number of tones equal to 256×2^n. If set to 1_b in a CLR message, it indicates the initial sample length of the cyclic extension that 10PASS-TS-R can support. It also signifies that the 10PASS-TS-R can support CE lengths other than the mandatory length. The value shall be present in the corresponding NPar(3) field. If one of the modems supports only the mandatory value, then this value shall be used.
RFI bands	Always set to 0_b in a CLR message.

A 10PASS-TS-R selecting 10PASS-TS mode of operation in a G.994.1 MS message shall do so by setting to 1_b the Level 1 SPar(1) 10PASS-TS bit as defined in G.994.1. The NPar(2) and SPar(2) fields corresponding to this bit are defined in 61.4. For each Level 2 SPar(2) bit set to 1_b, a corresponding NPar(3) field shall also be present, as defined in 61.4. The Level 2 bits in an MS message from the 10PASS-TS-R are defined in Table 62–11 and Table 62–12.

If both bits Upstream use of optional band and Downstream use of optional band are enabled in the CL and CLR message, one and only one of the bits shall be set to 1_b in an MS message sent from the 10PASS-TS-R, and the use of the band between 25 kHz and 138 kHz shall be at the 10PASS-TS-R's discretion. If the 10PASS-TS-O and 10PASS-TS-R have no common usage of the optional band, both bits shall be set to 0_b in an MS message sent from the 10PASS-TS-R.

62.3.5 Transmission medium interface characteristics

This subclause specifies the interface between the transceiver and the transmission medium (U2 reference point). The interface at U1 reference point (see MCM-VDSL Section 5.1 for VDSL reference model) is specified by the corresponding characteristics of the service splitter. The definition of the service splitter is outside the scope of this standard. Relevant specifications may be found in MCM-VDSL Clause 21 and Clause 22.

Table 62–11—10PASS-TS-R MS message NPar(2) bit definitions

NPar(2) bit	Definition
Upstream use of 25 kHz–138 kHz band	Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. It signifies that the band between 25 kHz and 138 kHz shall be used for the upstream transmission.
Downstream use of 25 kHz–138 kHz band	Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. It signifies that the band between 25 kHz and 138 kHz shall be used for the downstream transmission.
EOC-Clear	Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. Signifies that both 10PASS-TS-O and 10PASS-TS-R may transmit and receive G.997.1 OAM frames.

Table 62–12—10PASS-TS-R MS message SPar(2) bit definitions

NPar(2) bit	Definition
Used bands in upstream	Always set to 0_b in an MS message.
Used bands in downstream	Always set to 0_b in an MS message.
IDFT/DFT size	Always set to 1_b in an MS message. Indicates the maximum IDFT/DFT size that both 10PASS-TS-O and 10PASS-TS-R can support. The value shall be present in the corresponding NPar(3) field.
Initial length of *CE*	Set to 0_b if and only if this bit was set to 0_b in the last previous CL message or the last previous CLR message, or both. It signifies that both 10PASS-TS-O and 10PASS-TS-R shall use only the mandatory cyclic extension length. Set to 1_b if and only if this bit was set to 1_b in both the last previous CL message and the last previous CLR message. It indicates the initial sample length of the cyclic extension. It also signifies that both 10PASS-TS-O and 10PASS-TS-R can support CE lengths other than the mandatory length. The value shall be given in the corresponding NPar(3) field.
RFI bands	Always set to 0_b in an MS message.

62.3.5.1 Transmit signal characteristics

62.3.5.1.1 Wide-band power

The average wide-band power of the transmitted 10PASS-TS signal measured over the frequency range between 25 kHz to 12 MHz shall be no greater than the values listed in Table 62–13 when terminated with resistive impedance of $R_V = 100\ \Omega$.

NOTE 1—For compliance with this requirement, the 10PASS-TS transceiver is terminated with the impedance R_V and configured to transmit pseudo-random data with any repetitive framing patterns enabled.

NOTE 2—Power is measured across the termination resistance of R_V. No energy is inserted into the POTS/ISDN port of the splitter (if applied) during this test.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 62–13—10PASS-TS maximum transmit power

Central office deployment scenario		Cabinet deployment scenario	
Downstream [dBm]	**Upstream [dBm]**	**Downstream [dBm]**	**Upstream [dBm]**
14.5	14.5	11.5	14.5

62.3.5.1.2 Power spectral density (PSD)

Transmit PSD is characterized by the PSD template and PSD mask. PSD templates and masks are defined in Annex 62A.

62.3.5.1.3 Egress control

To avoid potential harm to amateur radio service due to radiated emission from 10PASS-TS, it shall be possible to reduce the PSD of the transmit signal within the amateur radio bands. Specifications for egress power control are described in Annex 62A.

62.3.5.2 Termination impedance

A termination impedance of $R_v = 100\ \Omega$ (purely resistive, either source or load) shall be used over the entire 10PASS-TS frequency band for both the 10PASS-TS-O and 10PASS-TS-R when matching to the metallic wire-pair.

This termination impedance approximates (and is based upon) the insertion-point impedance of the 10PASS-TS test loop. It enables a compromise high-frequency impedance match to the various types of unshielded cable in metallic access networks.

62.3.5.3 Return loss

The return loss requirement is defined to limit signal power uncertainties due to the tolerance of the line interface impedance. The return loss *RL* specifies the amount of reflected differential signal upon a reference impedance R_V

$$RL = 20 \times \log\left|\frac{Z + R_V}{Z - R_V}\right| \tag{62–5}$$

where Z is the internal impedance of the VTU. Note that in Equation (62–5), the log is taken to base 10, such that *RL* is expressed in dB.

The in-band return loss value of the 10PASS-TS transceiver shall be greater than or equal to 12 dB. The out-of-band return loss value shall be greater than or equal or 3 dB. In-band and out-of-band frequencies are defined by the frequency plan as shown in Figure 62–3 and by the transmit direction.

The value of 12 dB assumes a flat transmit PSD is applied over the entire in-band region. Requirements may be relaxed in the frequency ranges of reduced PSD values. The exact value requirements are outside the scope of this standard.

The return loss shall be measured on a resistive test load of $R_V = 100\ \Omega$ while the tested implementation of the 10PASS-TS transceiver is powered.

NOTE—If a splitter is used, the return-loss requirements should be met for the full range of possible values of the POTS/ISDN port termination.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

62.3.5.4 Output signal balance

Output signal balance (*OSB*) is a measure of unwanted longitudinal signals at the output of the transceiver, as defined by Equation (62–6). The longitudinal output voltage (V_{cm}) to the differential output voltage (V_{diff}) ratio shall be measured while the 10PASS-TS transmitter is active in accordance with ITU-T Recommendation G.117 and ITU-T Recommendation O.9.

$$OSB = 20\log\left|\frac{V_{diff}}{V_{cm}}\right| \tag{62–6}$$

The *OSB* of the 10PASS-TS transceiver shall be equal to or greater than 35 dB in the entire 10PASS-TS band.

NOTE—The equipment balance should be better than the anticipated cable balance in order to minimize the unwanted emissions and susceptibility to external RFI. The typical worst case balance for an aerial drop-wire has been observed to be in the range 30 dB – 35 dB, therefore the balance of the 10PASS-TS equipment should be equal or better.

62.4 Protocol implementation conformance statement (PICS) proforma for Clause 62, Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 10PASS-TS[123]

62.4.1 Introduction

The supplier of a protocol implementation that claimed to conform to Clause 62, Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 10PASS-TS, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

62.4.2 Identification

62.4.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification--e.g., names and versions for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

62.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 62, Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 10PASS-TS.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[123] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

62.4.4.2 MCM-VDSL based PMD

Item	Feature	Subclause	Value/Comment	Status	Support
10PPMD-1	Specific requirements and exceptions	62.3.4	The PMD complies to the requirements of MCM-VDSL Section 8, Section 10, Section 11, and Section 12, with the exceptions listed.	M	Yes [ ]
10PPMD-2	Duplexing and Modulation	62.3.4.1	The PMD uses Frequency Division Duplexing to separate upstream and downstream transmission.	M	Yes [ ]
10PPMD-3	Duplexing and Modulation	62.3.4.1	The PMD supports modulation of N_{SC} = 4096 subcarriers.	M	Yes [ ]
10PPMD-4	Duplexing and Modulation	62.3.4.1	The PMD supports modulation of B_{max_d} = 12 bits per downstream subcarrier and B_{max_u} = 12 bits per upstream subcarrier.	M	Yes [ ]
10PPMD-5	Duplexing and Modulation	62.3.4.1	Disjoint subsets of the N_{SC} subcarriers are defined for use in the downstream and upstream directions.	M	Yes [ ]
10PPMD-6	Duplexing and Modulation	62.3.4.1	The exact subsets of subcarriers used to modulate data in each direction are determined during initialization, based on management system settings and the signal-to-noise ratios of the subchannels.	M	Yes [ ]
10PPMD-7	Duplexing and Modulation	62.3.4.1	The use of the band between 25 kHz and 138 kHz is negotiated during the initialization to indicate if the capability exists and select one of the following options: use for upstream transmission, use for downstream transmission, not used.	M	Yes [ ]
10PPMD-8	Duplexing and Modulation	62.3.4.1	10PASS-TS-O PMD supports the transmission of a pilot tone on any downstream tone.	M	Yes [ ]
10PPMD-9	Upstream Power Back-Off	62.3.4.1	Upstream power back-off is applied to mitigate the effects of FEXT from short lines into long lines in distributed cable topologies.	M	Yes [ ]
10PPMD-10	Upstream Power Back-Off	62.3.4.1	The PMD is capable of performing frequency-dependent power back-off.	M	Yes [ ]
10PPMD-11	Upstream Power Back-Off	62.3.4.1	It is possible for the network management system to set the limiting transmit PSD template PSD_0 for the 10PASS-TS-R to one of the standard transmit PSD templates as defined in the applicable section of 62A.3.4.	M	Yes [ ]
10PPMD-12	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-R PMD performs UPBO autonomously, i.e., without sending any significant information to the 10PASS-TS-O until the UPBO is applied.	M	Yes [ ]
10PPMD-13	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-O is capable of adjusting the transmit PSD selected by the 10PASS-TS-R, after UPBO has been applied. The adjusted transmit PSD is subject to the limitations given in the applicable section of 62A.3.3.	M	Yes [ ]

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

10PPMD-14	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-R estimates the insertion losses of the upstream bands based on the received downstream signals. The 10PASS-TS-R explicitly estimates the electrical length of its line, kl_0, and uses this value to calculate the transmit PSD template TxPSD per Equation (62–1) and Equation (62–2).	M	Yes [ ]
10PPMD-15	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-R adapts its transmit signal PSD to conform to the template TxPSD and the corresponding PSD mask which is defined in the applicable section of 62A.3.3. The same bandwidth as for all regular transmit PSD masks defined in the applicable section of 62A.3.3 are used to check the conformance of TxPSD with power back-off. Conformance with the PSD template is verified using a 100 kHz sliding window in the in-band frequency range below 1 MHz and a 1 MHz sliding window in the in-band frequency range above 1 MHz.	M	Yes [ ]
10PPMD-16	Upstream Power Back-Off	62.3.4.1	PSD_REF is input via the management interface.	M	Yes [ ]
10PPMD-17	Upstream Power Back-Off	62.3.4.1	PSD_REF is transmitted from the 10PASS-TS-O to the 10PASS-TS-R.	M	Yes [ ]
10PPMD-18	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-R takes a tone-by-tone minimum of this computed PSD and the maximum allowed transmit PSD in the upstream direction. The result is used as the initial upstream transmit PSD.	M	Yes [ ]
10PPMD-19	Upstream Power Back-Off	62.3.4.1	Upon receiving signals from the 10PASS-TS-R, the 10PASS-TS-O compares the actual received PSD to the reference PSD. If necessary, it instructs the 10PASS-TS-R to fine-tune its PSD.	M	Yes [ ]
10PPMD-20	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-O has the capability to directly impose a maximum allowed transmit PSD at the 10PASS-TS-R.	M	Yes [ ]
10PPMD-21	Upstream Power Back-Off	62.3.4.1	The maximum transmit PSD is input via the management interface.	M	Yes [ ]
10PPMD-22	Upstream Power Back-Off	62.3.4.1	The maximum transmit PSD is transmitted from 10PASS-TS-O to 10PASS-TS-R during initialization.	M	Yes [ ]
10PPMD-23	Upstream Power Back-Off	62.3.4.1	The 10PASS-TS-O allows the operator to select between the UPBO method based on Reference PSD and the UPBO method based on maximum transmit PSD.	M	Yes [ ]
10PPMD-24	Handshake	62.3.4.9	The handshake uses the 4.3125 kHz signaling family and the duplex transmission mode.	M	Yes [ ]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

10PPMD-25	Handshake	62.3.4.9	The handshake proceeds as specified in 61.4.	M	Yes [ ]
10PPMD-26	Wide-band power	62.3.5.1.1	The average wide-band power of the transmitted 10PASS-TS signal measured over the frequency range between 25 kHz to 12 MHz is no greater than the values listed in Table 62–13 when terminated with resistive impedance of RV = 100 Ohm.	M	Yes [ ]
10PPMD-27	Egress control	62.3.5.1.3	To avoid potential harm to amateur radio service due to radiated emission from 10PASS-TS, it is possible to reduce the PSD of the transmit signal within the amateur radio bands.	M	Yes [ ]
10PPMD-28	Termination impedance	62.3.5.2	A termination impedance of Rv = 100 Ohm is used over the entire 10PASS-TS frequency band for both the 10PASS-TS-O and 10PASS-TS-R when matching to the metallic wire-pair.	M	Yes [ ]
10PPMD-29	Return loss	62.3.5.3	The in-band return loss value of the 10PASS-TS transceiver are greater than or equal to 12 dB.	M	Yes [ ]
10PPMD-30	Return loss	62.3.5.3	The out-of-band return loss value are greater than or equal or 3 dB.	M	Yes [ ]
10PPMD-31	Return loss	62.3.5.3	Requirements are relaxed in the frequency ranges of reduced PSD values.	O	Yes [ ] No [ ]
10PPMD-32	Return loss	62.3.5.3	The return loss are measured on a resistive test load of R_V = 100 Ohm while the tested implementation of the 10PASS-TS transceiver is powered.	M	Yes [ ]
10PPMD-33	Output signal balance	62.3.5.4	The longitudinal output voltage to the differential output voltage ratio is measured while the VTU transmitter is active in accordance with ITU-T Recommendation G.117 and ITU-T Recommendation O.9.	M	Yes [ ]
10PPMD-34	Output signal balance	62.3.5.4	The OSB of the 10PASS-TS transceiver is equal to or greater than 35 dB in the entire 10PASS-TS band.	M	Yes [ ]

63. Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 2BASE-TL

63.1 2BASE-TL Overview

63.1.1 Scope

This clause specifies the 2BASE-TL Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD) sublayer for voice grade twisted-pair wiring. In order to form a complete 2BASE-TL PHY, the 2BASE-TL PMA and PMD are integrated with the TC and PCS of Clause 61. Parts of register 3.0, parts of register 3.4 and registers 3.60 through 3.73 specified in Clause 45 may be used to control the PCS of Clause 61. Parts of register 6.0 and registers 6.16 through 6.23 specified in Clause 45 may be used to control the TC sublayer of Clause 61. Registers 1.16 through 1.42 and 1.80 through 1.109 specified in Clause 45 may be used to control the 2BASE-TL PMA and PMD.

63.1.2 Objectives

The following are the objectives for the 2BASE-TL PMA and PMD:

a) To provide 2 Mb/s encapsulated packet data rate at the α(β)-interface.

b) To provide full duplex operation.

c) To provide for operating over non-loaded voice grade twisted pair cable at distances up to 2700 m.

d) To provide a communication channel with a mean bit error ratio, at the α(β)-interface, of less than one part in 10^7 with 5 dB noise margin.

63.1.3 Relation of 2BASE-TL to other standards

The specifications of the 2BASE-TL PMA and PMD are based on the SHDSL transceiver (PMD and PMS-TC) specified in ITU-T Recommendation G.991.2.

Item	Feature	Subclause	Value/Comment	Status	Support

63.1.4 Summary of Physical Medium Attachment (PMA) specification

This layer is defined by the α(β)-interface and the I-interface. Figure 63–1 shows a functional diagram of the 2BASE-TL PMA layer functionality. The payload is formed into a 2BASE-TL PMA frame with overhead added (for example, the PME aggregation Header). The framed data is then scrambled and sent to the PMD sublayer. One distinguishes between the data mode PMA specification that is used during normal data operation and the activation PMA specification that is used when the PMD is training.

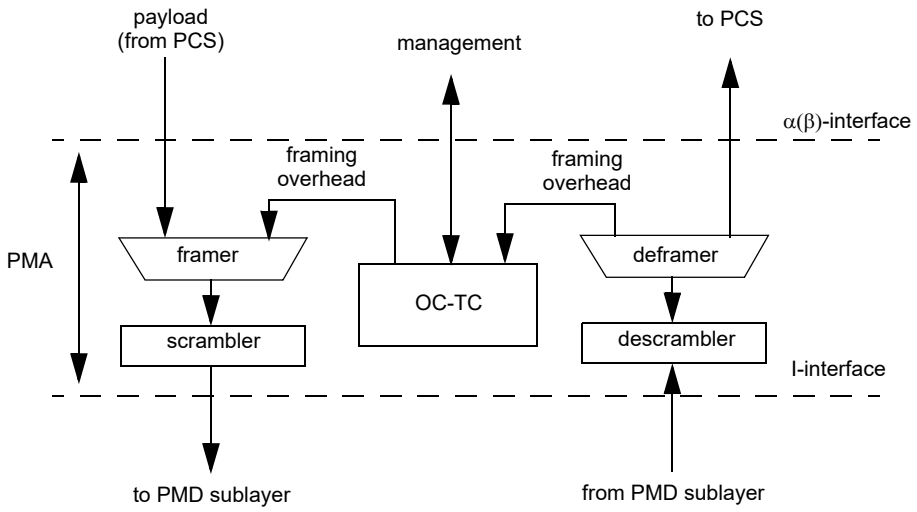

Figure 63–1—Diagram of PMA sublayer

63.1.4.1 α(β)-interface

A complete definition of the α(β)-interface is contained in 61.3.2. The signal PMA_receive_synchronized, defined in 61.3.2.2, shall be asserted when the LOSW bit is set to 0 (see 63.2.2.2), and deasserted when the LOSW is set to 1.

63.1.4.2 The I-interface

The I_O and I_R reference points define interfaces between the PMA and PMD in the 2BASE-TL-O and 2BASE-TL-R, respectively. Both interfaces are functional, application independent and identical. Both interfaces are defined by the following signal flows:

a) Data flow
b) Synchronization flow

The specification of the I-interface is implicit in ITU-T Recommendation G.991.2.

63.1.4.2.1 The I Data Flow

The data flow consists of two octet-oriented streams, both with the PMA frame format, with the bit rates defined by the PMD transmission profile:

a) Transmit data (Tx)
b) Receive data (Rx)

If data streams are implemented serially, the LSB of each octet (i.e., b_8 of Figure 61–16) shall be sent first. In section 7.1.1 of G.991.2, with i = 0, the payload blocks are made of a stream of octets. Each octet consists of 8 bits. The first bit of each octet (i.e., lowest frame bit number in an octet) maps to b_8 in Figure 61–16 and the last bit of each octet maps to b_1 of Figure 61–16.

Each stream bit rate value is set during PMD configuration.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

63.1.4.2.2 I Synchronization Flow

The synchronization flow consists of the transmitted and received octet synchronization signals (Clko_t, Clko_r). Optional transmit and receive bit-synchronization signals (Clkp_t, Clkp_r) are defined too.

Synchronization signals are asserted by the PMD and directed towards the PMA.

The synchronization signals are described in Table 63–1.

Table 63–1—I-interface signals

Signal(s)	Description	Direction	Notes
Data Signals			
Tx	Transmit data stream	PMA → PMD	Transmission frame format.
Rx	Receive data stream	PMA ← PMD	
Synchronization Signals			
Clko_t	Transmitted octet timing	PMA ← PMD	
Clko_r	Received octet timing	PMA ← PMD	
Clkp_t	Transmitted bit timing	PMA ← PMD	Optional
Clkp_r	Received bit timing	PMA ← PMD	Optional

63.1.4.3 Operation Channel (OC)

The OC-TC function of the PMA shall receive the EOC and overhead indicators over the OC-TC interface. For each 2BASE-TL PMA frame, the OC shall deliver a fixed number of embedded operations channel (EOC) and overhead indicators bits to the framer. These bits shall be included in the overhead sections of the 2BASE-TL PMA frames.

63.1.5 Summary of Physical Medium Dependent (PMD) specification

The PMD specification is based on Pulse Amplitude Modulation (PAM) and is divided into three consecutive phases, summarized as follows:

a) Preactivation: during this phase, the PMDs determine each other capabilities and the bit rate they will operate at in data mode. Reference section 6.3.1 (included in this standard per 63.3.2.2) describes the preactivation reference model. The preactivation uses G.994.1 as a handshake mechanism to exchange parameters in accordance with the specifications in 61.4. It also offers an optional line probing capability. The line probe uses 2-level PAM signals to determine a suitable bit rate to run at on the copper link.
b) Activation: during this phase, the PMDs train and exchange information necessary to adapt and operate the various filters and processes necessary during data mode operation. Reference section 6.2.1 describes the Activation reference model. The activation uses 2-level PAM to train the various filters.
c) Data Mode: once pre-activation and activation are complete, the PMD can start transmitting payload data. Reference section 6.1.1 describes the Data Mode reference model.

NOTE—Line activation takes place after entire discovery and PME aggregation operation.

63.2 2BASE-TL PMA functional specifications

The 2BASE-TL PMA is specified by incorporating the SHDSL standard, ITU-T Recommendation G.991.2 (02/2001) with the changes specified in G.991.2 Amendment 1 (11/2001), by reference, with the modifications noted below. This standard provides support for voice-grade twisted pair. For improved legibility in this clause, ITU-T Recommendation G.991.2 and G.991.2 Amendment 1, will henceforth be referred to as G.991.2.

63.2.1 General exceptions

The 2BASE-TL PMA is precisely the PMS-TC specified in G.991.2, with the following general modifications:

a) There are minor terminology differences between this standard and G.991.2 that do not cause ambiguity. The terminology used in 2BASE-TL was chosen to be consistent with other IEEE 802 standards, rather than with G.991.2. Terminology is both defined and consistent within each standard. Special note should be made of the interpretations shown in Table 63–2.

Table 63–2—Interpretation of general G.991.2 terms and concepts

G.991.2 term or concept	Interpretation for 2BASE-TL
PMS-TC	PMA
STU-C, LT	2BASE-TL-O
STU-R, NT	2BASE-TL-R
Transmission medium dependent interface, U-interface	MDI
byte	octet

b) The 2BASE-TL PMA supports only one channel of user data with an associated γ-interface.
c) The 2BASE-TL PMA does not support the optional “four-wire mode”. Operation over multiple pairs is optional; if implemented, multi-pair operation shall comply to the specifications in 61.2.2.
d) The 2BASE-TL PMA does not support “plesiochronous mode”.
e) The 2BASE-TL PMA shall be octet oriented; hence, the bit oriented parameter *i* defined for Equation (63–1) shall be equal to *0* in all cases.
f) The 2BASE-TL PMA does not support the notion of “sub-blocks” in the Payload Block. Each payload block consists of a contiguous sequence of 12*n* octets, with parameter *n* as defined for Equation (63–1).

63.2.2 Specific requirements and exceptions

The 2BASE-TL PMA shall comply to the requirements of G.991.2 Section 7 and Section 9 with the exceptions listed below. Where there is conflict between specifications in G.991.2 and those in this standard, those of this standard shall prevail.

Implementation of optional specifications in G.991.2 is not required for compliance with this standard. Reference Section 8 (TPS-TC Layer Functional Characteristics), Reference Annex D (Signal Regenerator Operation), Reference Annex E (Application-specific TPS-TC Framing) and Reference Appendices I, II, and III are out of scope for 2BASE-TL PMA. Deployment of compatible versions of G.991.2 Annex D is an implementation specific option for the purposes of 2BASE-TL.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

63.2.2.1 Changes to 7.1, “Data Mode Operation”

Reference 7.1.1 (Frame Structure) is replaced with the following:

Table 7-1 of the Reference summarizes the SHDSL frame structure. Complete bit definitions may be found in Reference 7.1.2. The size of each payload block is defined as k bits, where $k = 96n$. The payload rate r (in kb/s) is given by Equation (63–1) and Equation (63–3), with $i = 0$. The value of n is limited by Equation (63–2) and Equation (63–4).

Reference 7.1.2.6 (Stuff Indicator bits) is replaced with the following:

2BASE-TL operates in synchronous mode, therefore *sbid1* and *sbid2* are spare bits.

Reference 7.1.2.7 (Stuffing Bits) is replaced with the following:

2BASE-TL operates in synchronous mode, therefore *stb1* and *stb2* shall be present in every frame, and *stb3* and *stb4* shall not be present.

Reference 7.1.4 (Frame synchronization) is replaced with the following:

The precise manner in which frame synchronization is acquired or maintained is the choice of the receiver designer. Since different frame synchronization algorithms may require different values for the bits of the FSW, a provision has been made to allow the receiver to inform the far end transmitter of the particular values that are to be used for this field in the transmitted PMS-TC frame.

All other subsections of Reference 7.1 are referenced as is.

63.2.2.2 Changes to Section 9, “Management”

Referenced as is, with the exception of 9.5.5.6 where Message IDs 17 “ATM Cell Status Request”, 20 “ISDN Request”, 145 “ATM Cell Status Information” and 148 “ISDN Response” are out of scope.

63.2.2.3 Relation between the 2BASE-TL registers and the SHDSL management functions

The parameters of the various 2BASE-TL registers of the -R device, defined in Clause 45, are gathered via the SHDSL management. SNR margin, code violations, ES, SES, LOSW, UAS, SNR margin defect, Loop attenuation defect and loss of sync word failure shall be obtained in the following way:

The 2BASE-TL-O shall send a Status Request (Msg ID 11) EOC message. If there has been any change in performance status other than SNR margin since the last time a unit was polled, the peer 2BASE-TL-R shall respond with an SHDSL Network Side Performance Status (Msg ID 140) EOC message.

The following octets and bits are then mapped to the Clause 45 registers (see Table 63–3):

Otherwise, the peer 2BASE-TL-R shall respond with a Status/SNR (Msg ID 139) EOC message, in which the SNR margin is communicated in octet 2.

Loop attenuation and SNR margin threshold for both 2BASE-TL-O and 2BASE-TL-R devices shall be set in the Clause 45 register of the 2BASE-TL-O device; the 2BASE-TL-R thresholds will be passed to the 2BASE-TL-R using message ID 3.

The segment defect is defined in section 9.2.4 and uses a dedicated framing bit rather than the EOC messaging.

The retrieval of the remote vendor ID is defined in G.997.1. The use of this mechanism is outside the scope of this standard.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 63–3—Mapping of registers to "Network Side Performance Status" EOC message octets

register	octets / bits
LOSW failure	octet 2 / bit 1
Loop attenuation defect	octet 2 / bit 2
SNR margin defect	octet 2 / bit 3
SNR margin	octet 3
Loop attenuation	octet 4
ES	octet 5
SES	octet 6
Code violations	octet 7 and 8
LOSW	octet 9
UAS	octet 10
See footnote[a]	octet 11

[a]Bit 6 and 7 of octet 11 indicate that either an overflow or reset condition has occurred on any of the code violations / ES/ SES / LOSW / UAS registers.

NOTE—The code violation, ES, SES, LOSW, and UAS in SHDSL are modulo counters. The absolute value of the counter is meaningless, however the difference in between two consecutive readings provides the change in code violation/ES/SES/LOSW/UAS. If there are no changes in the performance registers, message ID 139 rather than 140 will be sent by the 2BASE-TL-R. It only contains the SNR value and none of the other parameters.

63.3 2BASE-TL PMD functional specifications

The 2BASE-TL PMD (and MDI) is specified by incorporating the SHDSL standard, ITU-T Recommendation G.991.2 (02/2001) with the changes specified in G.991.2 Amendment 1 (11/2001), by reference, with the modifications noted below. This standard provides support for voice-grade twisted pair. For improved legibility in this clause, ITU-T Recommendation G.991.2 and G.991.2 Amendment 1, will henceforth be referred to as G.991.2.

63.3.1 General exceptions

The 2BASE-TL PMD is precisely the PMD specified in G.991.2, with the following general modifications:

a) There are minor terminology differences between this standard and G.991.2 that do not cause ambiguity. The terminology used in 2BASE-TL was chosen to be consistent with other IEEE 802 standards, rather than with G.991.2. Terminology is both defined and consistent within each standard. Special note should be made of the interpretations shown in Table 63–4.
b) The 2BASE-TL PMD does not support the optional "four-wire mode". Operation over multiple pairs is optional; if implemented, multi-pair operation shall comply to the specifications in 61.2.2.
c) The 2BASE-TL PMD does not support "plesiochronous mode".
d) The 2BASE-TL PMD shall be octet oriented; hence, the bit oriented parameter *i* defined for Equation (63–1) shall be equal to *0* in all cases.
e) The 2BASE-TL PMD shall support the use of the 32-TCPAM constellation for specific rates (see 63.3.2.1).
f) The 2BASE-TL PMD shall support the use of the enhanced SHDSL[124] extended bandwidths.

[124]"Enhanced SHDSL" refers to 32TC-PAM modulation and higher values of n as defined in Equation (63–2) and Equation (63–4), which are not part of ITU-T Recommendation G.991.2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 63–4—Interpretation of general G.991.2 terms and concepts

G.991.2 term or concept	Interpretation for 2BASE-TL
PMS-TC	PMA
STU-C, LT	2BASE-TL-O
STU-R, NT	2BASE-TL-R
Transmission medium dependent interface, U-interface	MDI

63.3.2 Specific requirements and exceptions

The 2BASE-TL PMD (including MDI) shall comply to the requirements of G.991.2 Section 5 (Transport Capacity), Section 6 (PMD Layer Functional Characteristics), Section 10 (Clock Architecture), Section 11 (Electrical Characteristics), Section 12 (Conformance Testing) with the exceptions listed below. The 2BASE-TL PMD supports the requirements of G.991.2 Annex A (Regional Requirements - Region 1) and Annex B (Regional Requirements - Region 2) with the exception of performance requirements, which are replaced by Annex 63B. Where there is conflict between specifications in G.991.2 and those in this standard, those of this standard shall prevail.

Implementation of optional specifications in G.991.2 is not required for compliance with this standard. Reference Section 8 (TPS-TC Layer Functional Characteristics), Reference Annex D (Signal Regenerator Operation), Reference Annex E (Application-specific TPS-TC Framing), and Reference Appendices I, II, and III are out of scope for the 2BASE-TL PMD.

63.3.2.1 Replacement of section 5, “Transport Capacity”

This recommendation specifies a two-wire operational mode for 2BASE-TL transceivers that is capable of supporting user (payload) data rates from 192 kb/s to 3.840 Mb/s, using the 16-TCPAM constellation, and 768 kb/s to 5.696 Mb/s, using the 32-TCPAM constellation. The allowed rates r (in kb/s), using the 16-TCPAM constellation, are given by Equation (63–1):

$$r = n \times 64 + i \times 8 \tag{63–1}$$

where

$$3 \le n \le 60\,. \tag{63–2}$$

The allowed rates r (in kb/s), using the 32-TCPAM constellation, are given by Equation (63–3):

$$r = n \times 64 + i \times 8 \tag{63–3}$$

where

$$12 \le n \le 89 \tag{63–4}$$

In all cases, i is restricted to the value of 0. See 63.3.2.4, 63.3.2.5 and 63.3.2.6 for details of specific regional requirements.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

63.3.2.2 Changes to section 6, "PMD Layer Functional Characteristics"

Referenced as is, with the exception of subsection 6.4 (G.994.1 Preactivation Sequence), which is supplanted by 61.4.

Section 6.1.2.3 is superseded by the following text:

Mapper:

The $K + 1$ bits $Y_K(m)$, ..., $Y_1(m)$, and $Y_0(m)$ shall be mapped to a level $x(m)$. In section 6.1.2.3 of G.991.2, the mapper function is specified for 16-TCPAM. This text extends that mapping to include both 16- and 32-TCPAM encodings. Table 63–5 shows the bit to level mapping for 16 and 32 level mapping.

Table 63–5—Mapping of bits to PAM levels

$Y_4(m)$	$Y_3(m)$	$Y_2(m)$	$Y_1(m)$	$Y_0(m)$	32-PAM (5 Bits)	16-PAM (4 Bits)
0	0	0	0	0	–31/32	–15/16
0	0	0	0	1	–29/32	–13/16
0	0	0	1	0	–27/32	–11/16
0	0	0	1	1	–25/32	–9/16
0	0	1	0	0	–23/32	–7/16
0	0	1	0	1	–21/32	–5/16
0	0	1	1	0	–19/32	–3/16

63.3.2.3 Changes to section 10, “Clock Architecture”

Referenced as is, with the exception of Reference Table 10-1, which is replaced by Table 63–6.

Table 63–6—Clock synchronization configurations

Mode number	2BASE-TL-O symbol clock reference	2BASE-TL-R symbol clock reference	Example application	Mode
3a	Transmit data clock	Received symbol clock	Main application is synchronous transport in both directions.	Synchronous

63.3.2.4 Changes to Annex A, “Regional Requirements—Region 1”

63.3.2.4.1 General Changes

Referenced as is, with the exception of optional support for asymmetric PSD masks. Asymmetric PSD masks are not supported by 2BASE-TL.

Section A.5.3 “Span Powering” is out of scope.

63.3.2.4.2 Additional requirement: wetting current

The 2BASE-TL-R shall be capable of sustaining 20 mA of wetting (sealing) current. The maximum rate of change of the wetting current shall be no more than 20 mA per second.

NOTE—The -R device cannot be guaranteed to operate correctly if more than 20 mA (tip to ring) is sourced.

63.4 Protocol implementation conformance statement (PICS) proforma for Clause 63, Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 2BASE-TL[125]

63.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 63, Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 2BASE-TL, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

63.4.2 Identification

63.4.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., names and versions for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

63.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 63, Physical Medium Attachment (PMA) and Physical Medium Dependent (PMD), type 2BASE-TL.
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[125] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

64. Multipoint MAC Control

64.1 Overview

This clause deals with the mechanism and control protocols required in order to reconcile the P2MP topology into the Ethernet framework. The P2MP medium is a passive optical network (PON), an optical network with no active elements in the signal's paths from source to destination. The only interior elements used in a PON are passive optical components, such as optical fiber, splices, and splitters. When combined with the Ethernet protocol, such a network is referred to as Ethernet passive optical network (EPON).

P2MP is an asymmetrical medium based on a tree (or tree-and-branch) topology. The DTE connected to the trunk of the tree is called optical line terminal (OLT) and the DTEs connected at the branches of the tree are called optical network units (ONU). The OLT typically resides at the service provider's facility, while the ONUs are located at the subscriber premises.

In the downstream direction (from the OLT to an ONU), signals transmitted by the OLT pass through a 1:N passive splitter (or cascade of splitters) and reach each ONU. In the upstream direction (from the ONUs to the OLT), the signal transmitted by an ONU would only reach the OLT, but not other ONUs. To avoid data collisions and increase the efficiency of the subscriber access network, ONU's transmissions are arbitrated. This arbitration is achieved by allocating a transmission window (grant) to each ONU. An ONU defers transmission until its grant arrives. When the grant arrives, the ONU transmits frames at wire speed during its assigned time slot.

A simplified P2MP topology example is depicted in Figure 64–1. Clause 67 provides additional examples of P2MP topologies.

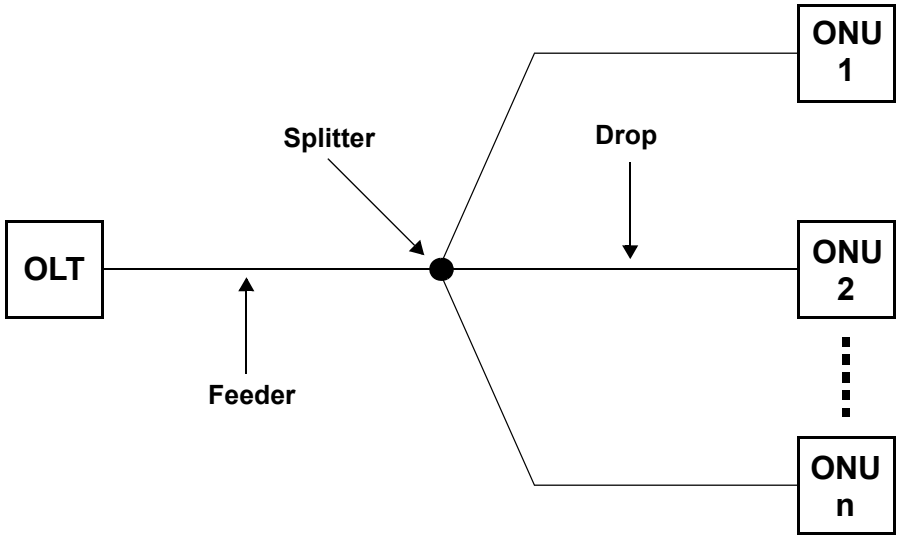

Figure 64–1—PON topology example

Topics dealt with in this clause include allocation of upstream transmission resources to different ONUs, discovery and registration of ONUs into the network, and reporting of congestion to higher layers to allow for dynamic bandwidth allocation schemes and statistical multiplexing across the PON.

This clause does not deal with topics including bandwidth allocation strategies, authentication of end-devices, quality-of-service definition, provisioning, or management.

This clause specifies the multipoint control protocol (MPCP) to operate an optical multipoint network by defining a Multipoint MAC Control sublayer as an extension of the MAC Control sublayer defined in Clause 31, and supporting current and future operations as defined in Clause 31 and annexes.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each PON consists of a node located at the root of the tree assuming the role of OLT, and multiple nodes located at the tree leaves assuming roles of ONUs. The network operates by allowing only a single ONU to transmit in the upstream direction at a time. The MPCP located at the OLT is responsible for timing the different transmissions. Reporting of congestion by the different ONUs may assist in optimally allocating the bandwidth across the PON.

Automatic discovery of end stations is performed, culminating in registration through binding of an ONU to an OLT port by allocation of a Logical Link ID (see LLID in 65.1.3.3.2), and dynamic binding to a MAC connected to the OLT.

The Multipoint MAC Control functionality shall be implemented for subscriber access devices containing point-to-multipoint Physical Layer devices defined in Clause 60.

64.1.1 Goals and objectives

The goals and objectives of this clause are the definition of a point-to-multipoint Ethernet network utilizing an optical medium.

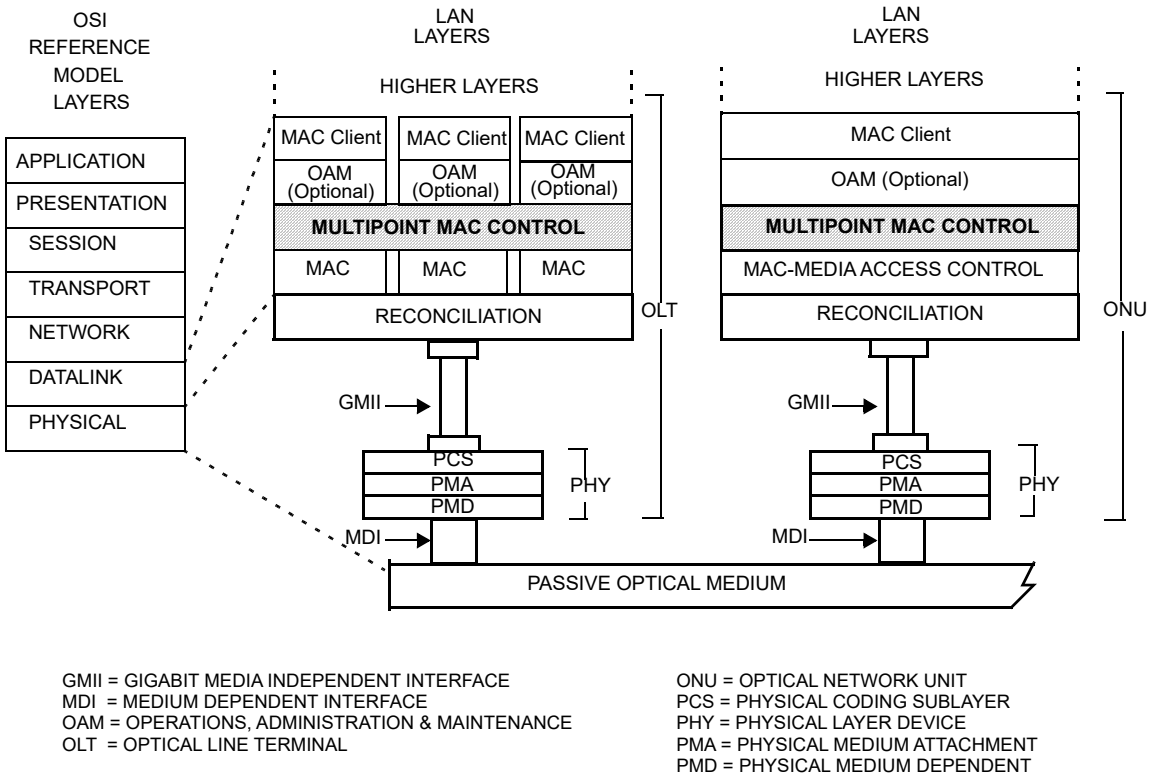
Specific objectives met include the following:

a) Support of Point-to-Point Emulation (P2PE) as specified
b) Support multiple LLIDs and MAC Clients at the OLT
c) Support a single LLID per ONU
d) Support a mechanism for single copy broadcast
e) Flexible architecture allowing dynamic allocation of bandwidth
f) Use of 32 bit timestamp for timing distribution
g) MAC Control based architecture
h) Ranging of discovered devices for improved network performance
i) Continuous ranging for compensating round trip time variation

64.1.2 Position of Multipoint MAC Control within the IEEE 802.3 hierarchy

Multipoint MAC Control defines the MAC control operation for optical point-to-multipoint networks. Figure 64–2 depicts the architectural positioning of the Multipoint MAC Control sublayer with respect to the MAC and the MAC Control client. The Multipoint MAC Control sublayer takes the place of the MAC Control sublayer to extend it to support multiple clients and additional MAC control functionality.

Multipoint MAC Control is defined using the mechanisms and precedents of the MAC Control sublayer. The MAC Control sublayer has extensive functionality designed to manage the real-time control and manipulation of MAC sublayer operation. This clause specifies the extension of the MAC Control mechanism to manipulate multiple underlying MACs simultaneously. This clause also specifies a specific protocol implementation for MAC Control.



The Multipoint MAC Control sublayer is specified such that it can support new functions to be implemented and added to this standard in the future. MultiPoint Control Protocol (MPCP), the management protocol for P2MP is one of these protocols. Non-real-time, or quasi-static control (e.g., configuration of MAC operational parameters) is provided by Layer Management. Operation of the Multipoint MAC Control sublayer is transparent to the MAC.

As depicted in Figure 64–2, the layered system instantiates multiple MAC entities, using a single Physical Layer. The individual MAC instances offer a Point-to-point emulation service between the OLT and the ONU. An additional MAC is instantiated to communicate to all ONUs at once. This instance takes maximum advantage of the broadcast nature of the downstream channel by sending a single copy of a frame that is received by all ONUs. This MAC instance is referred to as single copy broadcast (SCB).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The ONU only requires one MAC instance since frame filtering operations are done at the RS layer before reaching the MAC. Therefore, MAC and layers above are emulation-agnostic at the ONU (see 65.1.3.3).

Although Figure 64–2 and supporting text describe multiple MACs within the OLT, a single unicast MAC address may be used by the OLT. Within the EPON Network, MACs are uniquely identified by their LLID which is dynamically assigned by the registration process.

GMII = GIGABIT MEDIA INDEPENDENT INTERFACE
MDI = MEDIUM DEPENDENT INTERFACE
OAM = OPERATIONS, ADMINISTRATION & MAINTENANCE
OLT = OPTICAL LINE TERMINAL
ONU = OPTICAL NETWORK UNIT
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT

64.1.4 Service interfaces

The MAC Client communicates with the Control Multiplexer using the standard service interface specified in 2.3. Multipoint MAC Control communicates with the underlying MAC sublayer using the standard service interface specified in 4A.3.2. Similarly, Multipoint MAC Control communicates internally using primitives and interfaces consistent with definitions in Clause 31.

64.1.5 State diagram conventions

The body of this standard comprises state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2 augmented as follows:

a) [start x_timer, y] sets expiration of *y* to timer *x_timer*.
b) [stop x_timer] aborts the timer operation for *x_timer* asserting *x_timer_not_done* indefinitely.

The state diagrams use an abbreviation MACR as a shorthand form for MA_CONTROL.request and MACI as a shorthand form for MA_CONTROL.indication.

The vector notations used in the state diagrams for bit vector use 0 to mark the first received bit and so on (for example data[0:15]), following the conventions of 3.1 for bit ordering. When referring to an octet vector, 0 is used to mark the first received octet and so on (for example m_sdu[0..1]).

a < *b:* A function that is used to compare two (cyclic) time values. Returned value is true when *b* is larger than *a* allowing for wrap around of *a* and *b*. The comparison is made by subtracting *b* from *a* and testing the MSB. When MSB(*a*-*b*) = 1 the value true is returned, else false is returned. In addition, the following functions are defined in terms of *a* < *b*:
a > *b* is equivalent to !(*a* < *b* or *a* = *b*)
a ≥ *b* is equivalent to !(*a* < *b*)
a ≤ *b* is equivalent to !(*a* > *b*)

64.2 Multipoint MAC Control operation

As depicted in Figure 64–3, the Multipoint MAC Control functional block comprises the following functions:

a) *Multipoint Transmission Control*. This block is responsible for synchronizing Multipoint MAC Control instances associated with the Multipoint MAC Control. This block maintains the Multipoint MAC Control state and controls the multiplexing functions of the instantiated MACs.
b) *Multipoint MAC Control Instance n*. This block is instantiated for each MAC and respective MAC and MAC Control clients associated with the Multipoint MAC Control. It holds all the variables and state associated with operating all MAC Control protocols for the instance.
c) *Control Parser*. This block is responsible for parsing MAC Control frames, and interfacing with Clause 31 entities, the opcode specific blocks, and the MAC Client.
d) *Control Multiplexer*. This block is responsible for selecting the source of the forwarded frames.
e) *Clause 31 Annexes*. This block holds MAC Control actions as defined in Clause 31 annexes for support of legacy and future services.
f) *Discovery, Report and Gate Processing*. These blocks are responsible for handling the MPCP in the context of the MAC.

64.2.1 Principles of Multipoint MAC Control

As depicted in Figure 64–3, Multipoint MAC Control sublayer may instantiate multiple Multipoint MAC Control instances in order to interface multiple MAC and MAC Control clients above with multiple MACs below. A unique unicast MAC instance is used at the OLT to communicate with each ONU. The individual MAC instances utilize the point-to-point emulation service between the OLT and the ONU as defined in 65.1.

At the ONU, a single MAC instance is used to communicate with a MAC instance at the OLT. In that case, the Multipoint MAC Control contains only a single instance of the Control Parser/Multiplexer function.

Multipoint MAC Control protocol supports several MAC and client interfaces. Only a single MAC interface and Client interface is enabled for transmission at a time. There is a tight mapping between a MAC service interface and a Client service interface. In particular, the assertion of the MAC:MA_DATA.indication primitive in MAC *j* leads to the assertion of the MCF:MA_DATA.indication primitive to Client *j*. Conversely, the assertion of the request service interface in Client *i* leads to the assertion of the MAC:MA_DATA.request primitive of MAC *i*. Note that the Multipoint MAC sublayer need not receive and transmit packets associated with the same interface at the same time. Thus the Multipoint MAC Control acts like multiple MAC Controls bound together with common elements.

The scheduling algorithm is implementation dependent, and is not specified for the case where multiple transmit requests happen at the same time.

The reception operation is as follows. The Multipoint MAC Control instances generate MAC:MA_DATA.indication service primitives continuously to the underlying MAC instances. Since these MACs are receiving frames from a single PHY only one frame is passed from the MAC instances to Multipoint MAC Control. The MAC instance responding to the MAC:MA_DATA.indication is referred to as the enabled MAC, and its service interface is referred to as the enabled MAC interface. The MAC passes to the Multipoint MAC Control sublayer all valid frames. Invalid frames, as specified in 3.4, are not passed to the Multipoint MAC Control sublayer in response to a MAC:MA_DATA.indication service primitive.

The enabling of a transmit service interface is performed by the Multipoint MAC Control instance in collaboration with the Multipoint Transmission Control. Frames generated in the MAC Control are given priority over MAC Client frames, in effect, prioritizing the MA_CONTROL primitive over the MCF:MA_DATA primitive, and for this purpose MCF:MA_DATA.request primitives may be delayed, discarded or modified in order to perform the requested MAC Control function. For the transmission of this frame, the Multipoint MAC Control instance enables forwarding by the MAC Control functions, but the MAC Client interface is not enabled. The reception of a frame in a MAC results in generation of the MAC:MA_DATA.indication primitive on that MAC's interface. Only one receive MAC interface will be enabled at any given time since there is only one PHY interface.

The information of the enabled interfaces is stored in the controller state variables, and accessed by the Multiplexing Control block.

The Multipoint MAC Control sublayer uses the services of the underlying MAC sublayer to exchange both data and control frames.

Receive operation (MAC:MA_DATA.indication) at each instance:

a) A frame is received from the underlying MAC.
b) The frame is parsed according to Length/Type field
c) MAC Control frames are demultiplexed according to opcode and forwarded to the relevant processing functions
d) Data frames (see 31.5.1) are forwarded to the MAC Client by asserting MCF:MA_DATA.indication primitives

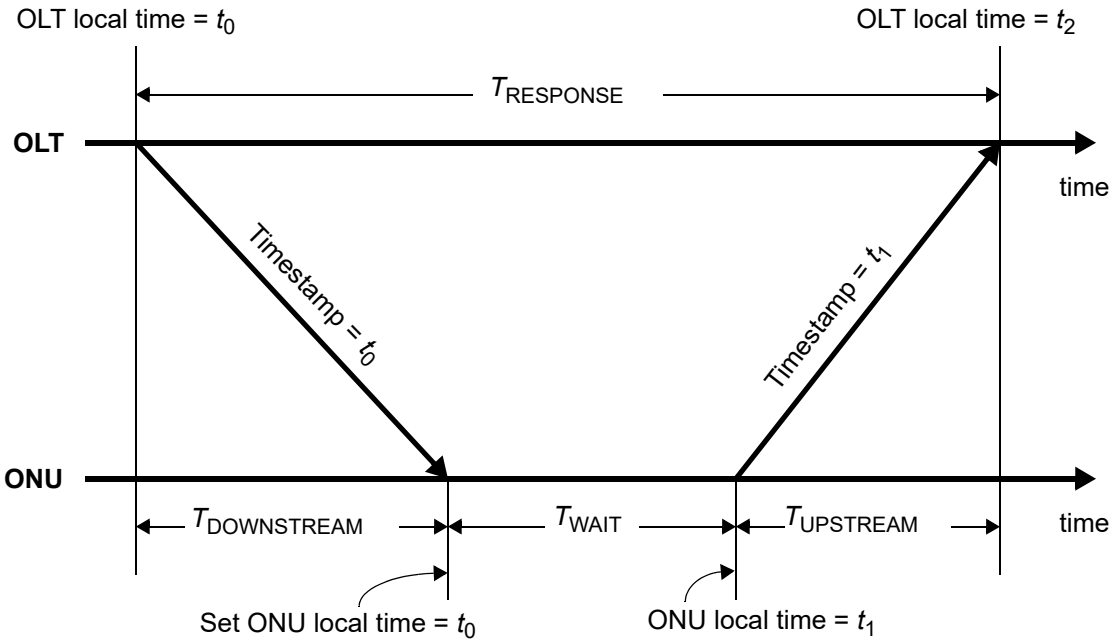
Transmit operation (MAC:MA_DATA.request) at each instance:

e) The MAC Client signals a frame transmission by asserting MCF:MA_DATA.request, or

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

f) A protocol processing block attempts to issue a frame, as a result of a previous MA_CONTROL.request or as a result of an MPCP event that generates a frame.
g) When allowed to transmit by the Multipoint Transmission Control block, the frame is forwarded.

64.2.1.1 Ranging and Timing Process



Both the OLT and the ONU have 32-bit counters that increment every 16 ns. These counters provide a local time stamp. When either device transmits an MPCPDU, it maps its counter value into the timestamp field. The time of transmission of the first octet of the MPCPDU frame from the MAC Control to the MAC is taken as the reference time used for setting the timestamp value.

When the ONU receives MPCPDUs, it sets its counter according to the value in the timestamp field in the received MPCPDU.

When the OLT receives MPCPDUs, it uses the received timestamp value to calculate or verify a round trip time between the OLT and the ONU. The RTT is equal to the difference between the timer value and the value in the timestamp field. The calculated RTT is notified to the client via the MA_CONTROL.indication primitive. The client can use this RTT for the ranging process.

A condition of *timestamp drift error* occurs when the difference between OLT's and ONU's clocks exceeds some predefined threshold. This condition can be independently detected by the OLT or an ONU. The OLT detects this condition when an absolute difference between new and old RTT values measured for a given ONU exceeds the value of guardThresholdOLT (see 64.2.2.1), as shown in Figure 64–10. An ONU detects the timestamp drift error condition when absolute difference between a timestamp received in an MPCPDU and the localTime counter exceeds guardThresholdONU (see 64.2.2.1), as is shown in Figure 64–11.

$T_{DOWNSTREAM}$ = downstream propagation delay

$T_{UPSTREAM}$ = upstream propagation delay

T_{WAIT} = wait time at ONU = t_1 - t_0

$T_{RESPONSE}$ = response time at OLT = t_2 - t_0

$$RTT = T_{DOWNSTREAM} + T_{UPSTREAM} = T_{RESPONSE} - T_{WAIT} = (t_2 - t_0) - (t_1 - t_0) = t_2 - t_1$$

Figure 64–4—Round trip time calculation

64.2.2 Multipoint transmission control, Control Parser, and Control Multiplexer

The purpose of the multipoint transmission control is to allow only one of the multiple MAC clients to transmit to its associated MAC and subsequently to the RS layer at one time by only asserting one transmitEnable signal at a time.

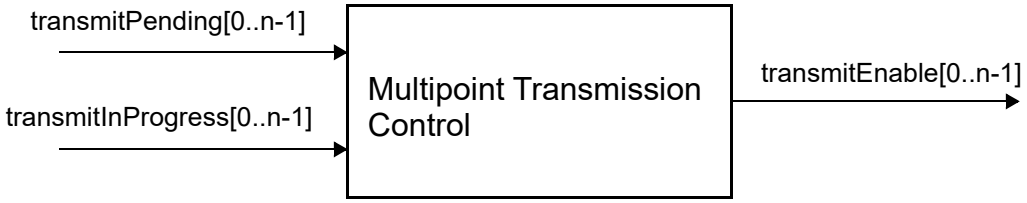

Figure 64–5—Multipoint Transmission Control Service Interfaces

Copyright © 2022 IEEE. All rights reserved.

Multipoint MAC Control Instance n function block communicates with the Multipoint Transmission Control using transmitEnable[n], transmitPending[n], and transmitInProgress[n] state variables (see Figure 64–3).

The Control Parser is responsible for opcode independent parsing of MAC frames in the reception path. By identifying MAC Control frames, demultiplexing into multiple entities for event handling is possible. Interfaces are provided to existing Clause 31 entities, functional blocks associated with MPCP, and the MAC Client.

The Control Multiplexer is responsible for forwarding frames from the MAC Control opcode-specific functions and the MAC Client to the MAC. Multiplexing is performed in the transmission direction. Given multiple MCF:MA_DATA.request service primitives from the MAC Client, and MA_CONTROL.request primitives from the MAC Control Clients, a single MAC:MA_DATA.request service primitive is generated for transmission. At the OLT, multiple MAC instances share the same Multipoint MAC Control, as a result, the transmit block is enabled based on an external control signal housed in Multipoint Transmission Control for transmission overlap avoidance. At the ONU the Gate Processing functional block interfaces for upstream transmission administration.

64.2.2.1 Constants

defaultOverhead

This constant holds the size of packet transmission overhead. This overhead is measured in units of time quanta.

TYPE: integer
VALUE: 6

guardThresholdOLT

This constant holds the maximal amount of drift allowed for a timestamp received at the OLT. This value is measured in units of time_quantum (16 bit times).

TYPE: integer
VALUE: 12

guardThresholdONU

This constant holds the maximal amount of drift allowed for a timestamp received at the ONU. This value is measured in units of time_quantum (16 bit times)

TYPE: integer
VALUE: 8

MAC_Control_type

The value of the Length/Type field as defined in 31.4.1.3.

TYPE: integer
VALUE: 0x8808

tailGuard

This constant holds the value used to reserve space at the end of the upstream transmission at the ONU in addition to the size of last MAC service data unit (m_sdu) in units of octets. Space is allocated for the MAC overheads including: preamble, SFD, DA, SA, Length/Type, FCS, and the End of Packet Delimiter (EPD). The sizes of the above listed MAC overhead items are described in 3.1.1. The size of the EPD is described in 36.2.4.14.

TYPE: integer
VALUE: 29

time_quantum

The unit of time_quantum is used by all mechanisms synchronized to the advancement of the localTime variable. All variables that represent counters and time intervals are defined using time_quantum. Each time_quantum is 16 ns.

TYPE: integer
VALUE: 16

tqSize

This constant represents time_quantum in octet transmission times.

TYPE: integer
VALUE: 2

64.2.2.2 Counters

localTime

This variable holds the value of the local timer used to control MPCP operation. This variable is advanced by a timer at 62.5 MHz, and counts in time_quanta. At the OLT the counter shall track the transmit clock, while at the ONU the counter shall track the receive clock. For accuracy of receive clock, see 65.3.1.2. It is reloaded with the received timestamp value (from the OLT) by the Control Parser (see Figure 64–11). Changing the value of this variable while running using Layer Management is highly undesirable and is unspecified.

TYPE: 32 bit unsigned

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

64.2.2.3 Variables

BEGIN

This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset.

TYPE: Boolean

data_rx

This variable represents a 0-based bit array corresponding to the payload of a received MPCPDU. This variable is used to parse incoming MPCPDU frames.

TYPE: bit array

data_tx

This variable represents a 0-based bit array corresponding to the payload of an MPCPDU being transmitted. This variable is used to access payload of outgoing MPCPDU frames, for example to set the timestamp value.

TYPE: bit array

fecEnabled

This variable represents whether the FEC function is enabled. If FEC function is enabled, this variable equals true, otherwise it equals false.

TYPE: Boolean

flags_rx

This variable holds the value of the Flags field from the last received MPCPDU.

TYPE: 8-bit unsigned

newRTT

This variable temporary holds a newly-measured Round Trip Time to the ONU. The new RTT value is represented in units of time_quanta.

TYPE:16 bit unsigned

nextTxTime

This variable represents a total transmission time of next packet and is used to check whether the next packet fits in the remainder of ONU's transmission window. The value of nextTxTime includes packet transmission time, tailGuard defined in 64.2.2.1, and FEC parity data overhead, if FEC is enabled. This variable is measured in units of time quanta.

TYPE: 16 bit unsigned

opcode_rx

This variable holds an opcode of the last received MPCPDU.

TYPE: 16 bit unsigned

opcode_tx

This variable holds an opcode of an outgoing MPCPDU.

TYPE: 16 bit unsigned

RTT

This variable holds the measured Round Trip Time to the ONU. The RTT value is represented in units of time_quanta.

TYPE: 16 bit unsigned

stopTime

This variable holds the value of the localTime counter corresponding to the end of the nearest grant. This value is set by the Gate Processing function as described in 64.3.5.

TYPE: 32 bit unsigned

timestamp

This variable holds the value of timestamp of the last received MPCPDU frame.

TYPE: 32 bit unsigned

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

timestampDrift

This variable is used to indicate whether an error is signaled as a result of uncorrectable timestamp drift.

TYPE: Boolean

transmitAllowed

This variable is used to control PDU transmission at the ONU. It is set to true when the transmit path is enabled, and is set to false when the transmit path is being shut down. transmitAllowed changes its value according to the state of the Gate Processing functional block.

TYPE: Boolean

transmitEnable[j]

These variables are used to control the transmit path in a Multipoint MAC Control instance at the OLT. Setting them to on indicates that the selected instance is permitted to transmit a frame. Setting it to off inhibits the transmission of frames in the selected instance. Only one of transmitEnable[j] should be set to on at a time.

TYPE: Boolean

transmitInProgress[j]

This variable indicates that the Multipoint MAC Control instance *j* is in a process of transmitting a frame.

TYPE: Boolean

transmitPending[j]

This variable indicates that the Multipoint MAC Control instance *j* is ready to transmit a frame.

TYPE: Boolean

64.2.2.4 Functions

abs(n)

This function returns the absolute value of the parameter n.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

FEC_Overhead(length)

This function calculates the size of additional overhead to be added by the FEC encoder while encoding a frame of size length. Parameter length represents the size of an entire frame including preamble, SFD, DA, SA, Length/Type, and FCS. As specified in 65.2.3, FEC encoder adds 16 parity octets for each block of 239 data octets. Additionally, 26 code-groups are required to accommodate IPG and longer start-of-frame and end-of-frame sequences, which are used to allow reliable packet boundary detection in presence of high bit error ratio. The function returns the value of FEC overhead in units of time quanta. The following formula is used to calculate the overhead:

$$FEC_Overhead = 13 + \left\lceil \frac{length}{239} \right\rceil \times 8$$

NOTE—The notation $\lceil x \rceil$ represents a *ceiling* function, which returns the value of its argument *x* rounded up to the nearest integer.

select

This function selects the next Multipoint MAC Control instance allowed to initiate transmission of a frame. The function returns an index to the transmitPending array for which the value is not false. The selection criteria in the presence of multiple active elements in the list is implementation dependent.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SelectFrame()

This function enables the interface, which has a pending frame. If multiple interfaces have frames waiting at the same time, only one interface will be enabled. The selection criteria is not specified, except for the case when some of the pending frames have Length/Type = MAC_Control. In this case, one of the interfaces with a pending MAC Control frame shall be enabled.

sizeof(sdu)

This function returns the size of the sdu in octets.

transmissionPending()

This function returns true if any of the Multipoint MAC Control instances has a frame waiting to be transmitted. The function can be represented as

transmissionPending() = transmitPending[0] +
transmitPending[1] +
... +
transmitPending[n-1]

where n is the total number of Multipoint MAC Control instances.

64.2.2.5 Timers

packet_initiate_timer

This timer is used to delay frame transmission from MAC Control to avoid variable MAC delay while MAC enforces IPG after a previous frame. In addition, when FEC is enabled, this timer increases interframe spacing just enough to accommodate the extra parity data to be added by the FEC encoder.

64.2.2.6 Messages

MAC:MA_DATA.indication(DA, SA, m_sdu, receiveStatus)

The service primitive is defined in 31.3.

MCF:MA_DATA.indication(DA, SA, m_sdu, receiveStatus)

The service primitive is defined in 31.3.

MAC:MA_DATA.request (DA, SA, m_sdu)

The service primitive is defined in 31.3. The action invoked by this service primitive is not considered to end until the transmission of the frame by the MAC has concluded. The ability of the MAC control layer to determine this is implementation dependent.

MCF:MA_DATA.request (DA, SA, m_sdu)

The service primitive is defined in 31.3.

64.2.2.7 State diagrams

The Multipoint transmission control function in the OLT shall implement state diagram shown in Figure 64–9. Control parser function in the OLT shall implement state diagram shown in Figure 64–10. Control parser function in the ONU shall implement state diagram shown in Figure 64–11. Control multiplexer function in the OLT shall implement state diagram shown in Figure 64–12. Control multiplexer function in the ONU shall implement state diagram shown in Figure 64–13.

64.3 Multipoint Control Protocol (MPCP)

As depicted in Figure 64–3, the Multipoint MAC Control functional block comprises the following functions:

a) *Discovery Processing*. This block manages the discovery process, through which an ONU is discovered and registered with the network while compensating for RTT.
b) *Report Processing*. This block manages the generation and collection of report messages, through which bandwidth requirements are sent upstream from the ONU to the OLT.
c) *Gate Processing*. This block manages the generation and collection of gate messages, through which multiplexing of multiple transmitters is achieved.

As depicted in Figure 64–3, the layered system may instantiate multiple MAC entities, using a single Physical Layer. Each instantiated MAC communicates with an instance of the opcode specific functional blocks through the Multipoint MAC Control. In addition some global variables are shared across the multiple instances. Common state control is used to synchronize the multiple MACs using MPCP procedures. Operation of the common state control is generally considered outside the scope of this document.

64.3.1 Principles of Multipoint Control Protocol

Multipoint MAC Control enables a MAC Client to participate in a point-to-multipoint optical network by allowing it to transmit and receive frames as if it was connected to a dedicated link. In doing so, it employs the following principles and concepts:

a) A MAC client transmits and receives frames through the Multipoint MAC Control sublayer.
b) The Multipoint MAC Control decides when to allow a frame to be transmitted using the client interface Control Multiplexer.
c) Given a transmission opportunity, the MAC Control may generate control frames that would be transmitted in advance of the MAC Client's frames, utilizing the inherent ability to provide higher priority transmission of MAC Control frames over MAC Client frames.
d) Multiple MACs operate on a shared medium by allowing only a single MAC to transmit upstream at any given time across the network using a time-division multiple access (TDMA) method.
e) Such gating of transmission is orchestrated through the Gate Processing function.
f) New devices are discovered in the network and allowed transmission through the Discovery Processing function.
g) Fine control of the network bandwidth distribution can be achieved using feedback mechanisms supported in the Report Processing function.
h) The operation of P2MP network is asymmetrical, with the OLT assuming the role of master, and the ONU assuming the role of slave.

64.3.2 Compatibility considerations

64.3.2.1 PAUSE operation

Even though MPCP is compatible with flow control, optional use of flow control may not be efficient in the case of large propagation delay. If flow control is implemented, then the timing constraints in Annex 31B supplement the constraints found at 64.3.2.4.

NOTE—MAC at an ONU can receive frames from unicast channel and SCB channel. If the SCB channel is used to broadcast data frames to multiple ONUs, the ONU's MAC may continue receiving data frames from SCB channel even after the ONU has issued a PAUSE request to its unicast remote-end.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

64.3.2.2 Optional Shared LAN Emulation

By combining P2PE, suitable filtering rules at the ONU, and suitable filtering and forwarding rules at the OLT, it is possible to emulate an efficient shared LAN. Support for shared LAN emulation is optional, and requires an additional layer above the MAC, which is out of scope for this document. Thus, shared LAN emulation is introduced here for informational purposes only.

Specific behavior of the filtering layer at the RS is specified in 65.1.3.3.2.

64.3.2.3 Multicast and single copy broadcast support

In the downstream direction, the PON is a broadcast medium. In order to make use of this capability for forwarding broadcast frames from the OLT to multiple recipients without multiple duplication for each ONU, the SCB and multicast LLID support is introduced.

The OLT has at least one MAC associated with every ONU. In addition one more MAC at the OLT is marked as the SCB MAC. Moreover, the OLT has a multicast MAC associated with each defined multicast LLID. The SCB MAC handles all downstream broadcast traffic, but is never used in the upstream direction for client traffic, except for client registration. Similarly, the multicast MACs handle downstream multicast traffic, but are never used in the upstream direction for client traffic. Optional higher layers may be implemented to perform selective broadcast and multicast of frames. Such layers may require additional MACs (multicast MACs) to be instantiated in the OLT for some or all ONUs increasing the total number of MACs beyond the number of ONUs + 1.

When connecting the SCB MAC or a multicast MAC to an IEEE 802.1Q bridge port it is possible that loops may be formed due to the broadcast or multicast nature of the associated LLIDs. Thus it is recommended that this MAC not be connected to an IEEE 802.1Q bridge port.

SCB channel configuration as well as filtering and marking of frames for support of SCB is defined in 65.1.3.3.2.

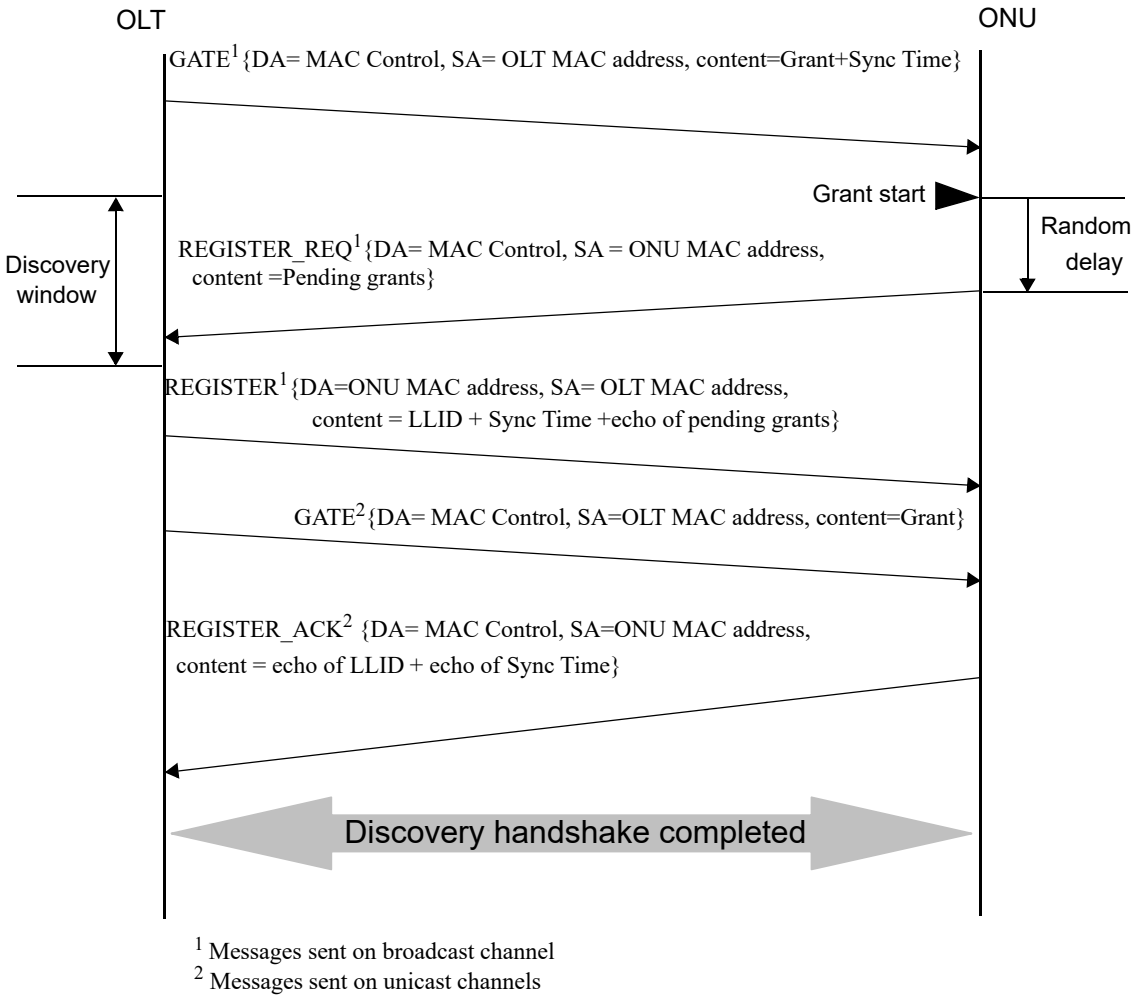
64.3.2.4 Delay requirements

The MPCP protocol relies on strict timing based on distribution of timestamps. A compliant implementation needs to guarantee a constant delay through the MAC and PHY in order to maintain the correctness of the timestamping mechanism. The actual delay is implementation dependent, however, a complying implementation shall maintain a delay variation of no more than 16 bit times through the implemented MAC stack.

The OLT shall not grant less than 1024 time_quanta into the future, in order to allow the ONU processing time when it receives a gate message. The ONU shall process all messages in less than this period. The OLT shall not issue more than one message every 1024 time_quanta to a single ONU. The unit of time_quantum is defined as 16 ns.

64.3.3 Discovery Processing

Discovery is the process whereby newly connected or off-line ONUs are provided access to the PON. The process is driven by the OLT, which periodically makes available Discovery Time Windows during which off-line ONUs are given the opportunity to make themselves known to the OLT. The periodicity of these windows is unspecified and left up to the implementer. The OLT signifies that a discovery period is occurring by broadcasting a discovery gate message, which includes the starting time and length of the discovery window. Off-line ONUs, upon receiving this message, wait for the period to begin and then transmit a REGISTER_REQ message to the OLT. Discovery windows are unique in that they are the only times where multiple ONUs can access the PON simultaneously, and transmission overlap can occur. In



Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

order to reduce transmission overlaps, a contention algorithm is used by all ONUs. Measures are taken to reduce the probability for overlaps by artificially simulating a random distribution of distances from the OLT. Each ONU shall wait a random amount of time before transmitting the REGISTER_REQ message that is shorter than the length of the discovery time window. It should be noted that multiple valid REGISTER_REQ messages can be received by the OLT during a single discovery time period. Included in the REGISTER_REQ message is the ONU's MAC address and number of maximum pending grants. Upon receipt of a valid REGISTER_REQ message, the OLT registers the ONU, allocating and assigning new port identities (LLIDs), and bonding corresponding MACs to the LLIDs.

The next step in the process is for the OLT to transmit a Register message to the newly discovered ONU, which contains the ONU's LLID, and the OLT's required synchronization time. Also, the OLT echoes the maximum number of pending grants. The OLT now has enough information to schedule the ONU for access to the PON and transmits a standard GATE message allowing the ONU to transmit a REGISTER_ACK. Upon receipt of the REGISTER_ACK, the discovery process for that ONU is complete, the ONU is registered and normal message traffic can begin. It is the responsibility of Layer Management to perform the MAC bonding, and start transmission from/to the newly registered ONU. The discovery message exchange is illustrated in Figure 64–14.

There may exist situations when the OLT requires that an ONU go through the discovery sequence again and reregister. Similarly, there may be situations where an ONU needs to inform the OLT of its desire to deregister. The ONU can then reregister by going through the discovery sequence. For the OLT, the REGISTER message may indicate a value, Reregister or Deregister, that if either is specified will force the receiving ONU into reregistering. For the ONU, the REGISTER_REQ message contains the Deregister bit that signifies to the OLT that this ONU should be deregistered.

64.3.3.1 Constants

No constants defined.

64.3.3.2 Variables

BEGIN
: This variable is defined in 64.2.2.3.

data_rx
: This variable is defined in 64.2.2.3.

data_tx
: This variable is defined in 64.2.2.3.

grantEndTime
: This variable holds the time at which the OLT expects the ONU grant to complete. Failure of a REGISTER_ACK message from an ONU to arrive at the OLT before grantEndTime is a fatal error in the discovery process, and causes registration to fail for the specified ONU, who may then retry to register. The value of grantEndTime is measured in units of time_quantum.
: TYPE: 32-bit unsigned

insideDiscoveryWindow
: This variable holds the current status of the discovery window. It is set to true when the discovery window opens, and is set to false when the discovery window closes.
: TYPE: Boolean

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

localTime
: This variable is defined in 64.2.2.2.

opcode_rx
: This variable is defined in 64.2.2.3.

opcode_tx
: This variable is defined in 64.2.2.3.

pendingGrants
: This variable holds the maximum number of pending grants that an ONU is able to queue.
TYPE: 16 bit unsigned

registered
: This variable holds the current result of the Discovery Process. It is set to true once the discovery process is complete and registration is acknowledged.
TYPE: Boolean

syncTime
: This variable holds the time required to stabilize the receiver at the OLT. It counts time_quanta units from the point where transmission output is stable to the point where synchronization has been achieved. The value of syncTime includes gain adjustment interval ($T_{receiver_settling}$), clock synchronization interval (T_{CDR}), and code-group alignment interval ($T_{code_group_align}$), as specified in 60.9.13.2. The OLT conveys the value of syncTime to ONUs in Discovery GATE and REGISTER messages. During the synchronization time only IDLE patterns can be transmitted by an ONU.
TYPE: 16 bit unsigned

timestampDrift
: This variable is defined in 64.2.2.3.

64.3.3.3 Functions

None.

64.3.3.4 Timers

discovery_window_size_timer
: This timer is used to wait for the event signaling the end of the discovery window.
VALUE: The timer value is set dynamically based on the parameters received in a DISCOVERY GATE message.

mpcp_timer
: This timer is used to measure the arrival rate of MPCP frames in the link. Failure to receive frames is considered a fatal fault and leads to deregistration.

64.3.3.5 Messages

MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: The service primitive is defined in 2.3.2.

MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, GATE, discovery, start, length, discovery_length, sync_time)
: The service primitive used by the MAC Control client at the OLT to initiate the Discovery Process. This primitive takes the following parameters:

DA:	multicast or unicast MAC address.
GATE:	opcode for GATE MPCPDU as defined in Table 31A–1.
discovery:	flag specifying that the given GATE message is to be used for discovery only.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

start: start time of the discovery window.
length: length of the grant given for discovery.
discovery_length: length of the discovery window process.
sync_time: the time interval required to stabilize the receiver at the OLT.

MA_CONTROL.request(DA, GATE, grant_number, start[4], length[4], force_report[4])

This service primitive is used by the MAC Control client at the OLT to issue the GATE message to an ONU. This primitive takes the following parameters:

DA: multicast MAC Control address as defined in Annex 31B.
GATE: opcode for GATE MPCPDU as defined in Table 31A–1.
grant_number: number of grants issued with this GATE message. The number of grants ranges from 0 to 4.
start[4]: start times of the individual grants. Only the first grant_number elements of the array are used.
length[4]: lengths of the individual grants. Only the first grant_number elements of the array are used.
force_report[4]: flags indicating whether a REPORT message should be generated in the corresponding grant. Only the first grant_number elements of the array are used.

MA_CONTROL.request(DA, REGISTER_REQ, status)

The service primitive used by a client at the ONU to request the Discovery Process to perform a registration. This primitive takes the following parameters:

DA: multicast MAC Control address as defined in Annex 31B.
REGISTER_REQ: opcode for REGISTER_REQ MPCPDU as defined in Table 31A–1.
status: This parameter takes on the indication supplied by the flags field in the REGISTER_REQ MPCPDU as defined in Table 64–3.

MA_CONTROL.indication(REGISTER_REQ, status, flags, pending_grants, RTT)

The service primitive issued by the Discovery Process to notify the client and Layer Management that the registration process is in progress. This primitive takes the following parameters:

REGISTER_REQ: opcode for REGISTER_REQ MPCPDU as defined in Table 31A–1.
status: This parameter holds the values incoming or retry. Value incoming is used at the OLT to signal that a REGISTER_REQ message was received successfully. The value retry is used at the ONU to signal to the client that a registration attempt failed and will be repeated.
flags: This parameter holds the contents of the flags field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process is in the OLT.
pending_grants: This parameters holds the contents of the pending_grants field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

RTT: The measured round trip time to/from the ONU is returned in this parameter. RTT is stated in time_quanta units. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

MA_CONTROL.request(DA, REGISTER, LLID, status, pending_grants)

The service primitive used by the MAC Control client at the OLT to initiate acceptance of an ONU. This primitive takes the following parameters:

DA: Unicast MAC address or multicast MAC Control address as defined in Annex 31B.

REGISTER: opcode for REGISTER MPCPDU as defined in Table 31A–1.

LLID: This parameter holds the logical link identification number assigned by the MAC Control client.

status: This parameter takes on the indication supplied by the flags field in the REGISTER MPCPDU as defined in Table 64–4.

pending_grants: This parameters echoes back the pending_grants field that was previously received in the REGISTER_REQ message.

MA_CONTROL.indication(REGISTER, SA, LLID, status)

This service primitive is issued by the Discovery Process at the OLT or an ONU to notify the MAC Control client and Layer Management of the result of the change in registration status. This primitive takes the following parameters:

REGISTER: opcode for REGISTER MPCPDU as defined in Table 31A–1.

SA This parameter represents is the MAC address of the OLT.

LLID This parameter holds the logical link identification number assigned by the MAC Control client.

status This parameter holds the value of accepted/denied/deregistered/reregistered.

MA_CONTROL.request(DA, REGISTER_ACK, status)

This service primitive is issued by the MAC Control clients at the ONU and the OLT to acknowledge the registration. This primitive takes the following parameters:

DA: multicast MAC Control address as defined in Annex 31B.

REGISTER_ACK: opcode for REGISTER_ACK MPCPDU as defined in Table 31A–1.

status: This parameter takes on the indication supplied by the flags field in the REGISTER MPCPDU as defined in Table 64–5.

MA_CONTROL.indication(REGISTER_ACK, SA, LLID, status, RTT)

This service primitive is issued by the Discovery Process at the OLT to notify the client and Layer Management that the registration process has completed. This primitive takes the following parameters:

REGISTER_ACK: opcode for REGISTER_ACK MPCPDU as defined in Table 31A–1.

SA This parameter represents the MAC address of the reciprocating device (ONU address at the OLT, and OLT address at the ONU).

LLID This parameter holds the logical link identification number assigned by the MAC Control client.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

status	This parameter holds the value of accepted/denied/reset/ deregistered.
RTT	The measured round trip time to/from the ONU is returned in this parameter. RTT is stated in time_quanta units. This parameter holds a valid value only when the invoking Discovery Process is in the OLT

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

64.3.3.6 State diagram

Discovery process in the OLT shall implement the discovery window setup state diagram shown in Figure 64–18, request processing state diagram as shown in Figure 64–19, register processing state diagram as shown in Figure 64–20, and final registration state diagram as shown in Figure 64–21. The discovery process in the ONU shall implement registration state diagram as shown in Figure 64–22.

Instantiation of state diagrams as described in Figure 64–18, Figure 64–19, and Figure 64–20 is performed only at the Multipoint MAC Control instance attached to the broadcast LLID. Instantiation of state diagrams as described in Figure 64–21 and Figure 64–22 is performed for every Multipoint MAC Control instance, except the instance attached to the broadcast channel.

64.3.4 Report Processing

The Report Processing functional block has the responsibility of dealing with queue report generation and termination in the network. Reports are generated by higher layers and passed to the MAC Control sublayer by the MAC Control clients. Status reports are used to signal bandwidth needs as well as for arming the OLT watchdog timer.

Reports shall be generated periodically, even when no request for bandwidth is being made. This keeps a watchdog timer in the OLT from expiring and deregistering the ONU. For proper operation of this mechanism the OLT shall grant the ONU periodically.

The Report Processing functional block, and its MPCP protocol elements are designed for use in conjunction with an IEEE 802.1P capable bridge.

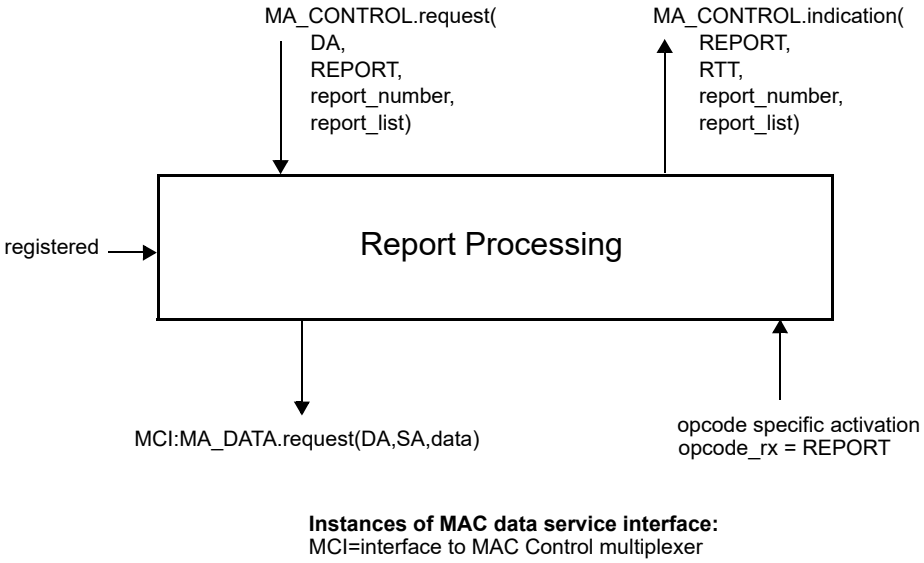

Figure 64–23—Report Processing service interfaces

64.3.4.1 Constants

None

64.3.4.2 Variables

BEGIN
: This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset.
TYPE: Boolean

data_rx
: This variable is defined in 64.2.2.3.

data_tx
: This variable is defined in 64.2.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mpcp_timeout
: This variable represents the maximum allowed interval of time between two MPCPDU messages. Failure to receive at least one frame within this interval is considered a fatal fault and leads to deregistration. This variable is expressed in units of time_quanta.
  TYPE 32-bit unsigned
  VALUE 03-B9-AC-A0 (1 s, default value)

opcode_rx
: This variable is defined in 64.2.2.3.

opcode_tx
: This variable is defined in 64.2.2.3.

registered
: This variable is defined in 64.3.3.2.

report_timeout
: This variable represents the maximum allowed interval of time between two REPORT messages generated by the ONU, expressed in units of time_quanta.
  TYPE 32-bit unsigned
  VALUE 00-2F-AF-08 (50 ms, default value)

64.3.4.3 Functions

None.

64.3.4.4 Timers

report_periodic_timer
: ONUs are required to generate REPORT MPCPDUs with a periodicity of less than report_timeout value. This timer counts down time remaining before a forced generation of a REPORT message in an ONU.

mpcp_timer
: This timer is defined in 64.3.3.4.

64.3.4.5 Messages

MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, REPORT, report_number, report_list)
: This service primitive is used by a MAC Control client to request the Report Process at the ONU to transmit a queue status report. This primitive may be called at variable intervals, independently of the granting process, in order to reflect the time varying aspect of the network. This primitive uses the following parameters:

  DA: multicast MAC Control address as defined in Annex 31B.
  REPORT: opcode for REPORT MPCPDU as defined in Table 31A–1.
  report_number: the number of queue status report sets located in report list. The report_number value ranges from 0 to a maximum of 13.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

report_list: the list of queue status reports. A queue status report consists of two fields: valid and status. The parameter valid, is a Boolean array with length of 8, '0' or false indicates that the corresponding status field is not present (the length of status field is 0), while '1' or true indicates that the corresponding status field is present (the length of status field is 2 octets). The index of the array is meant to reflect the same numbered priority queue in the IEEE 802.1P nomenclature.
The parameter status is an array of 16-bit unsigned integer values. This array consists only of entries whose corresponding bit in field valid is set to true.

MA_CONTROL.indication(REPORT, RTT, report_number, report_list)

The service primitive issued by the Report Process at the OLT to notify the MAC Control client and higher layers the queue status of the MPCP link partner. This primitive may be called multiple times, in order to reflect the time-varying aspect of the network. This primitive uses the following parameters:

REPORT: opcode for REPORT MPCPDU as defined in Table 31A–1.

RTT: this parameter holds an updated round trip time value which is recalculated following each REPORT message reception.

report_number: the number of queue status report sets located in report list. The report_number value ranges from 0 to a maximum of 13.

report_list: the list of queue status reports. A queue status report consists of two fields: valid and status. The parameter valid, is a Boolean array with length of 8, '0' or false indicates that the corresponding status field is not present (the length of status field is 0), while '1' or true indicates that the corresponding status field is present (the length of status field is 2 octets). The index of the array is meant to reflect the same numbered priority queue in the 802.1P nomenclature.
The parameter status is an array of 16-bit unsigned integer values. This array consists only of entries whose corresponding bit in field valid is set to true.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

64.3.4.6 State diagram

The report process in the OLT shall implement the report processing state diagram as shown in Figure 64–24. The report process in the ONU shall implement the report processing state diagram as shown in Figure 64–25. Instantiation of state diagrams as described is performed for Multipoint MAC Control instances attached to unicast LLIDs only.

64.3.5 Gate Processing

A key concept pervasive in Multipoint MAC Control is the ability to arbitrate a single transmitter out of a plurality of ONUs. The OLT controls an ONU's transmission by the assigning of grants.

The transmitting window of an ONU is indicated in GATE message where start time and length are specified. An ONU will begin transmission when its localTime counter matches start_time value indicated in the GATE message. An ONU will conclude its transmission with sufficient margin to ensure that the laser is turned off before the grant length interval has elapsed.

Multiple outstanding grants may be issued to each ONU. The OLT shall not issue more than the maximal supported maximal outstanding grants as advertised by the ONU during registration (see pending grants in 64.3.6.3).

In order to maintain the watchdog timer at the ONU, grants are periodically generated. For this purpose empty GATE messages may be issued periodically.

When registered, the ONU ignores all gate messages where the discovery flag is set.

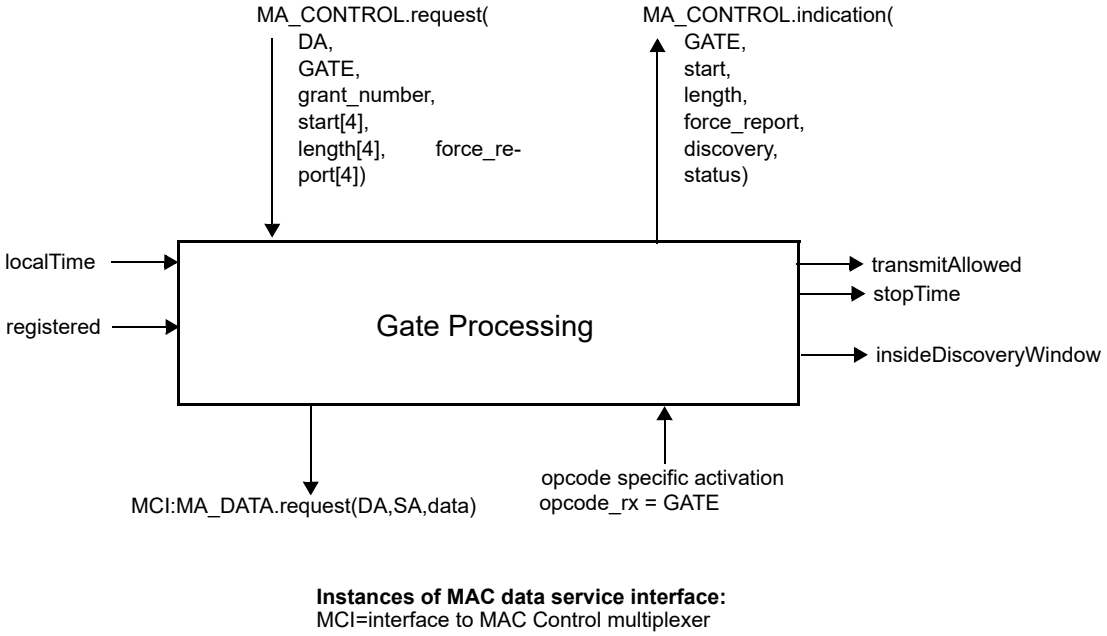

Figure 64–26—Gate Processing service interface

64.3.5.1 Constants

discoveryGrantLength

This constant represents the duration of ONU's transmission during discovery attempt. The value of discoveryGrantLength includes MPCPDU transmission time and tailGuard as defined in 64.2.2.1. discoveryGrantLength is represented in units of time_quanta.

TYPE: 32 bit unsigned
VALUE: 00-00-00-26 (608 ns)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

laserOffTime

This constant holds the time required to terminate the laser. It counts in time_quanta units the time period required for turning off the PMD, as specified in 60.9.13.1.

TYPE: 32 bit unsigned
VALUE: 00-00-00-20 (512 ns)

laserOnTime

This constant holds the time required to initiate the PMD. It counts in time_quanta units the time period required for turning on the PMD, as specified in 60.9.13.1.

TYPE: 32 bit unsigned
VALUE: 00-00-00-20 (512 ns)

max_future_grant_time

This constant holds the time limiting the future time horizon for a valid incoming grant.

TYPE: 32 bit unsigned
VALUE: 03-B9-AC-A0 (1 s)

min_processing_time

This constant is the time required for the ONU processing time.

TYPE: 32 bit unsigned
VALUE: 00-00-04-00 (16.384 us)

tqSize

This constant is defined in 64.2.2.1.

64.3.5.2 Variables

BEGIN

This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset.

TYPE: Boolean

counter

This variable is used as a loop iterator counting the number of incoming grants in a GATE message.

TYPE: integer

currentGrant

This variable is used for local storage of a pending grant state during processing. It is dynamically set by the Gate Processing functional block and is not exposed.

The state is a structure field composed of multiple subfields.

TYPE: structure {

DA	48 bit unsigned, a.k.a MAC address type
start	32 bit unsigned
length	16 bit unsigned
force_report	Boolean
discovery	Boolean}

data_rx

This variable is defined in 64.2.2.3.

data_tx

This variable is defined in 64.2.2.3.

effectiveLength

This variable is used for temporary storage of a normalized net time value. It holds the net effective length of a grant normalized for elapsed time, and compensated for the periods required to turn the laser on and off, and waiting for receiver lock.

TYPE: 32 bit unsigned

fecEnabled

This variable is defined in 64.2.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

gate_timeout

This variable represents the maximum allowed interval of time between two GATE messages generated by the OLT to the same ONU, expressed in units of time_quanta.

TYPE 32-bit unsigned
VALUE 00-2F-AF-08 (50 ms, default value)

grantList

This variable is used for storage of the list of pending grants. It is dynamically set by the Gate Processing functional block and is not exposed. Each time a grant is received it is added to the list.

The list elements are structure fields composed of multiple subfields.

The list is indexed by the start subfield in each element for quick searches.

TYPE: list of elements having the structure define in currentGrant

insideDiscoveryWindow

This variable is defined in 64.3.3.2.

maxDelay

This variable holds the maximum delay that can be applied by an ONU before sending the REGISTER MPCPDU. This delay is calculated such that the ONU would have sufficient time to transmit the REGISTER message and its associated overhead (FEC parity date, end-of-frame sequence, etc.) and terminate the laser before the end of the discovery grant.

TYPE 16 bit unsigned

nextGrant

This variable is used for local storage of a pending grant state during processing. It is dynamically set by the Gate Processing functional block and is not exposed. The content of the variable is the next grant to become active.

TYPE: element having same structure as defined in currentGrant

nextStopTime

This variable holds the value of the localTime counter corresponding to the end of the next grant.

TYPE: 32 bit unsigned

registered

This variable is defined in 64.3.3.2.

stopTime

This variable is defined in 64.2.2.3.

syncTime

This variable is defined in 64.3.3.2.

transmitAllowed

This variable is defined in 64.2.2.3.

64.3.5.3 Functions

empty(list)

This function is use to check whether the list is empty. When there are no elements queued in the list, the function returns true. Otherwise, a value of false is returned.

InsertInOrder(sorted_list, inserted_element)

This function is used to queue an element inside a sorted list. The queueing order is sorted. In the condition that the list is full the element may be discarded. The length of the list is dynamic and its maximal size equals the value advertised during registration as maximum number of pending grants.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

IsBroadcast(grant)

This function is used to check whether its argument represents a broadcast grant, i.e., grant given to multiple ONUs. This is determined by the destination MAC address of the corresponding GATE message. The function returns the value true when MAC address is a global assigned MAC Control address as defined in Annex 31B, and false otherwise.

PeekHead(sorted_list)

This function is used to check the content of a sorted list. It returns the element at the head of the list without dequeuing the element.

Random(r)

This function is used to compute a random integer number uniformly distributed between 0 and r. The randomly generated number is then returned by the function.

RemoveHead(sorted_list)

This function is used to dequeue an element from the head of a sorted list. The return value of the function is the dequeued element.

64.3.5.4 Timers

gntStTmr

This timer is used to wait for the event signaling the start of a grant window.
VALUE: The timer value is dynamically set according to the signaled grant start time.

gntWinTmr

This timer is used to wait for the event signaling the end of a grant window.
VALUE: The timer value is dynamically set according to the signaled grant length.

gate_periodic_timer

The OLT is required to generate GATE MPCPDUs with a periodicity of less than gate_timeout value. This timer counts down time remaining before a forced generation of a GATE message in the OLT.

mpcp_timer

This timer is defined in 64.3.3.4.

rndDlyTmr

This timer is used to measure a random delay inside the discovery window. The purpose of the delay is to apriori reduce the probability of transmission overlap during the registration process, and thus lowering the expectancy of registration time in the PON.
VALUE: A random value less than the net discovery window size less the REGISTER_REQ MPCPDU frame size less the idle period and laser turn on and off delays less the preamble size less the IFG size. The timer value is set dynamically based on the parameters passed from the client.

64.3.5.5 Messages

MA_DATA.request (DA, SA, m_sdu)

The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, GATE, grant_number, start[4], length[4], force_report[4])

This service primitive is defined in 64.3.3.5.

MA_CONTROL.indication(GATE, start, length, force_report, discovery, status)

This service primitive issued by the Gate Process at the ONU to notify the MAC Control client and higher layers that a grant is pending. This primitive is invoked multiple times when a single GATE message arrives with multiple grants. It is also generated at the start and end of each grant as it becomes active. This primitive uses the following parameters:

GATE: opcode for GATE MPCPDU as defined in Table 31A–1.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

start:	start time of the grant. This parameter is not present when the status value is deactive.
length:	length of the grant. This parameter is not present when the status value is deactive.
force_report:	flags indicating whether a REPORT message should be transmitted in this grant. This parameter is not present when the status value is deactive.
discovery:	This parameter holds the value true when the grant is to be used for the discovery process, and false otherwise. This parameter is not present when the status value is deactive.
status:	This parameter takes the value *arrive* on grant reception, *active* when a grant becomes active, and *deactive* at the end of a grant.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

64.3.5.6 State diagrams

The gating process in the OLT shall implement the gate processing state diagram as shown in Figure 64–26. The gating process in the ONU shall implement the gate processing state diagram as shown in Figure 64–27. Instantiation of state diagrams as described is performed for all Multipoint MAC Control instances.

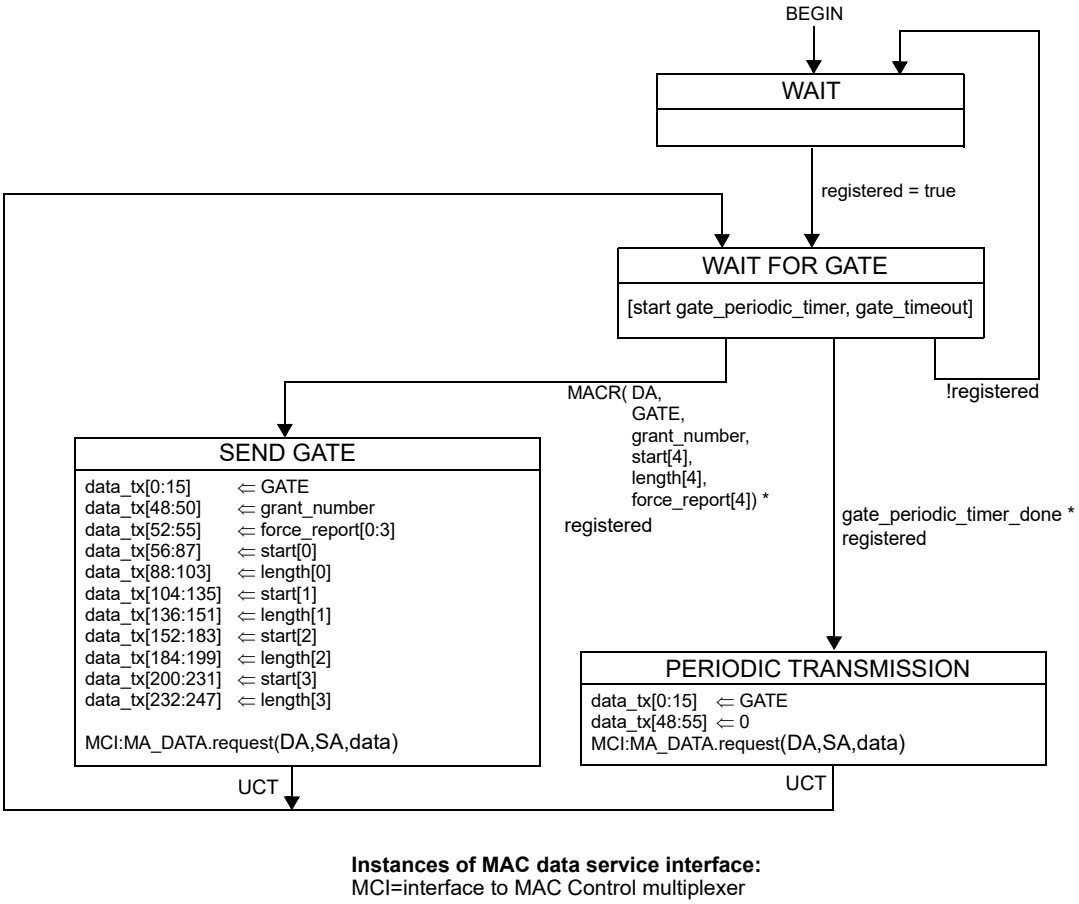

Figure 64–27—Gate Processing state diagram at OLT

64.3.6 MPCPDU structure and encoding

The MPCPDU structure shall be as shown in Figure 64–30, and is further defined in the following definitions:

a) Destination Address (DA). The DA in MPCPDU is the MAC Control Multicast address as specified in the annexes to Clause 31, or the individual MAC address associated with the port to which the MPCPDU is destined.
b) Source Address (SA). The SA in MPCPDU is the individual MAC address associated with the port through which the MPCPDU is transmitted. For MPCPDUs originating at the OLT end, this can be the address any of the individual MACs. These MACs may all share a single unicast address, as explained in 64.1.2.
c) Length/Type. The Length/Type in MPCPDU carries the MAC_Control_Type field value as specified in 31.4.1.3.
d) Opcode. The opcode identifies the specific MPCPDU being encapsulated. Values are defined in Table 31A–1.
e) Timestamp. The timestamp field conveys the content of the localTime register at the time of transmission of the MPCPDUs. This field is 32 bits long, and counts 16 bit transmissions. The timestamp counts time in 16 bit time granularity.
f) Data/Reserved/PAD. These 40 octets are used for the payload of the MPCPDUs. When not used they would be filled with zeros on transmission, and be ignored on reception.
g) FCS. This field is the Frame Check Sequence, typically generated by the underlying MAC.

Based on the MAC instance used to generate the specific MPCPDU, the appropriate LLID shall be generated by the RS.

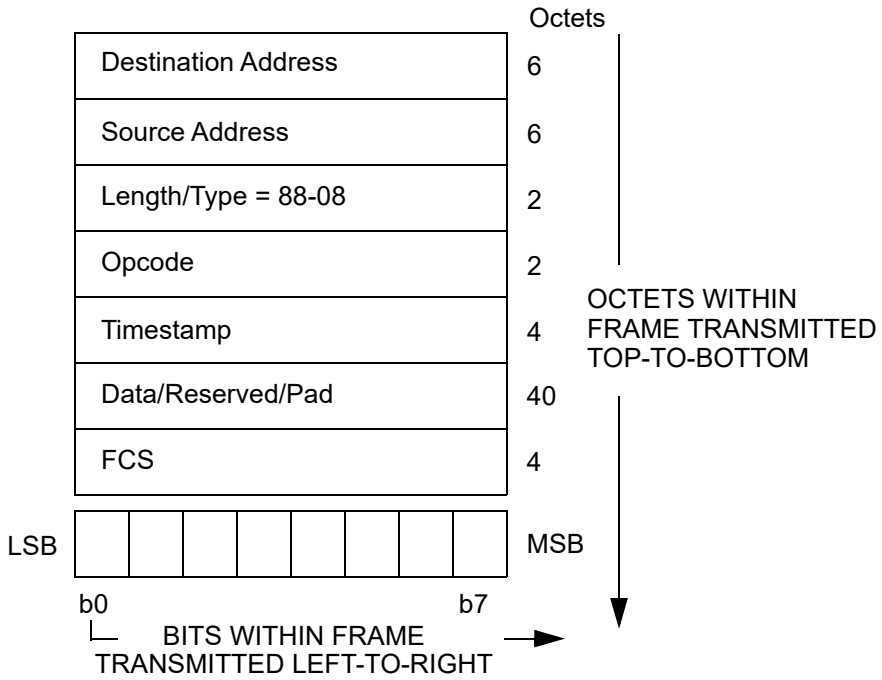

Figure 64–30—Generic MPCPDU

64.3.6.1 GATE description

The purpose of GATE message is to grant transmission windows to ONUs for both discovery messages and normal transmission. Up to four grants can be included in a single GATE message. The number of grants can also be set to zero for using the GATE message as an MPCP keep alive from OLT to the ONU.

The GATE MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the GATE MPCPDU is 0x0002.
b) Flags. This is an 8 bit flag register that holds the following flags: The Number of grants field contains the number of grants, composed of valid Length, Start Time pairs in this MPCPDU. This is a number between 0 and 4. Note: when Number of grants is set to 0, sole purpose of message is conveying of timestamp to ONU.
   The Discovery flag field indicates that the signaled grants would be used for the discovery process, in which case a single grant shall be issued in the gate message.
   The Force Report flag fields ask the ONU to issue a REPORT message related to the corresponding grant number at the corresponding transmission opportunity indicated in this GATE.
c) Grant #n Length. Length of the signaled grant, this is an 16 bit unsigned field. The length is counted in 16 bit time increments. There are 4 Grants that are possibly packed into the GATE MPCPDU. The laserOnTime, syncTime, and laserOffTime are included in and thus consume part of Grant #n Length.
d) Grant #n Start Time. Start time of the grant, this is an 32 bit unsigned field. The start time is compared to the local clock, to correlate the start of the grant. Transmitted values shall satisfy the condition Grant #n Start Time < Grant #n + 1 Start Time for consecutive grants within the same GATE MPCPDU.
e) Sync Time. This is an unsigned 16 bit value signifying the required synchronization time of the OLT receiver. During the synchronization time the ONU shall send IDLE code-pairs. The value is counted in 16 bit time increments. The advertised value includes synchronization requirement on all receiver elements including PMD, PMA and PCS. This field is present only when the gate is a discovery gate, as signaled by the Discovery flag and is not present otherwise.
f) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception when constructing a complying MPCP protocol implementation. The size of this field depends on the used Grant #n Length/Start Time entry-pairs, and varies in length from 13–39 accordingly.

Table 64–1—GATE MPCPDU Number of grants/Flags Fields

Bit	Flag Field	Values
0–2	Number of grants	0–4
3	Discovery	0—Normal GATE 1—Discovery GATE
4	Force Report Grant 1	0—No action required 1—A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 1
5	Force Report Grant 2	0—No action required 1—A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 2
6	Force Report Grant3	0—No action required 1—A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 3
7	Force Report Grant 4	0—No action required 1—A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 4

The GATE MPCPDU shall be generated by a MAC Control instance mapped to an active ONU, and as such shall be marked with a unicast type of LLID, except when the discovery flag is set where the MAC Control instance is mapped to all ONUs and such frame is marked by the broadcast LLID.

64.3.6.2 REPORT description

REPORT messages have several functionalities. Time stamp in each REPORT message is used for round trip (RTT) calculation. In the REPORT messages ONUs indicate the upstream bandwidth needs they request per IEEE 802.1Q priority queue. REPORT messages are also used as keep-alives from ONU to OLT. ONUs issue REPORT messages periodically in order to maintain link health at the OLT as defined in 64.3.4. In addition, the OLT may specifically request a REPORT message.

The REPORT MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the REPORT MPCPDU is 0x0003.
b) Number of Queue Sets. This field specifies the number of requests in the REPORT message. A REPORT frame may hold multiple sets of Report bitmap and Queue #n as specified in the Number of Queue Sets field
c) Report bitmap. This is an 8 bit flag register that indicates which queues are represented in this REPORT MPCPDU.

Table 64–2—REPORT MPCPDU Report bitmap fields

Bit	Flag Field	Values
0	Queue 0	0—queue 0 report is not present 1—queue 0 report is present
1	Queue 1	0—queue 1 report is not present 1—queue 1 report is present
2	Queue 2	0—queue 2 report is not present 1—queue 2 report is present
3	Queue 3	0—queue 3 report is not present 1—queue 3 report is present
4	Queue 4	0—queue 4 report is not present 1—queue 4 report is present
5	Queue 5	0—queue 5 report is not present 1—queue 5 report is present
6	Queue 6	0—queue 6 report is not present 1—queue 6 report is present
7	Queue 7	0—queue 7 report is not present 1—queue 7 report is present

d) Queue #n Report. This value represents the length of queue# n at time of REPORT message generation. The reported length shall be adjusted to account for the necessary inter-frame spacing and FEC parity data overhead, if FEC is enabled. The Queue #n Report field is an unsigned 16 bit integer representing transmission request in units of time quanta. This field is present only when the corresponding flag in the Report bitmap is set.
e) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception when constructing a complying MPCP protocol implementation. The size of this field depends on the used Queue Report entries, and accordingly varies in length from 0 to 39.

The REPORT MPCPDU shall be generated by a MAC Control instance mapped to an active ONU, and as such shall be marked with a unicast type of LLID.

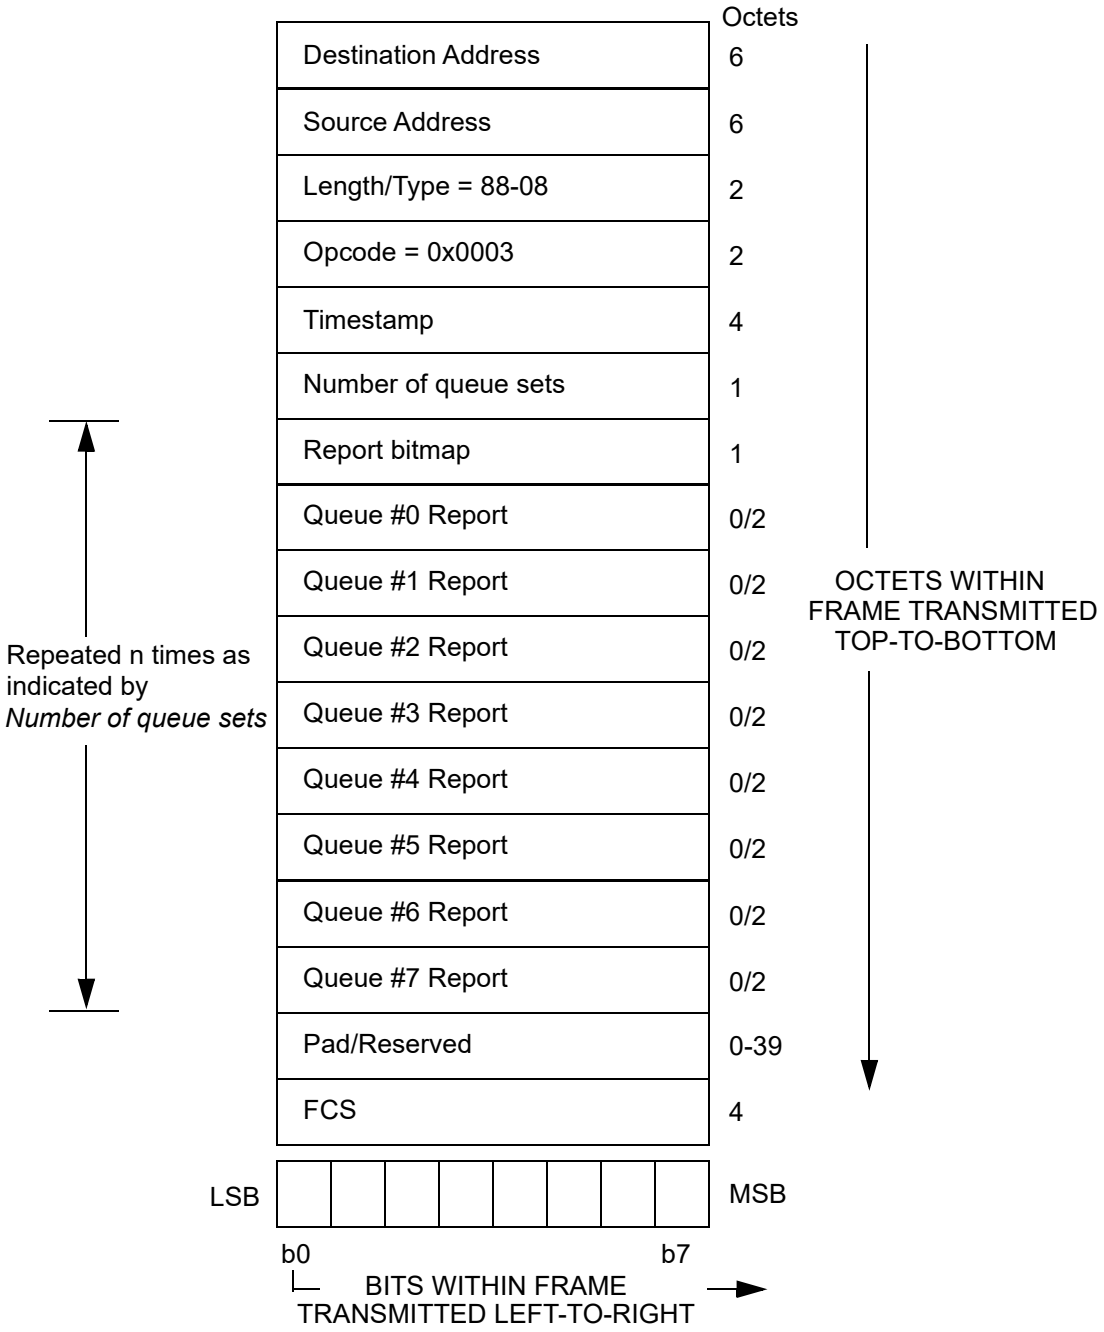

Figure 64–32—REPORT MPCPDU

64.3.6.3 REGISTER_REQ description

The REGISTER_REQ MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the REGISTER_REQ MPCPDU is 0x0004.
b) Flags. This is an 8 bit flag register that indicates special requirements for the registration.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

.

Table 64–3—REGISTER_REQ MPCPDU Flags fields

Value	Indication	Comment
0	Reserved	Ignored on reception.
1	Register	Registration attempt for ONU.
2	Reserved	Ignored on reception.
3	Deregister	This is a request to deregister the ONU. Subsequently, the MAC is deallocated and the LLID may be reused.
4–255	Reserved	Ignored on reception.

c) Pending grants. This is an unsigned 8 bit value signifying the maximum number of future grants the ONU is configured to buffer. The OLT should not grant the ONU more than this maximum number of Pending grants vectors composed of {start, length, force_report, discovery} into the future.
d) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception when constructing a complying MPCP protocol implementation.

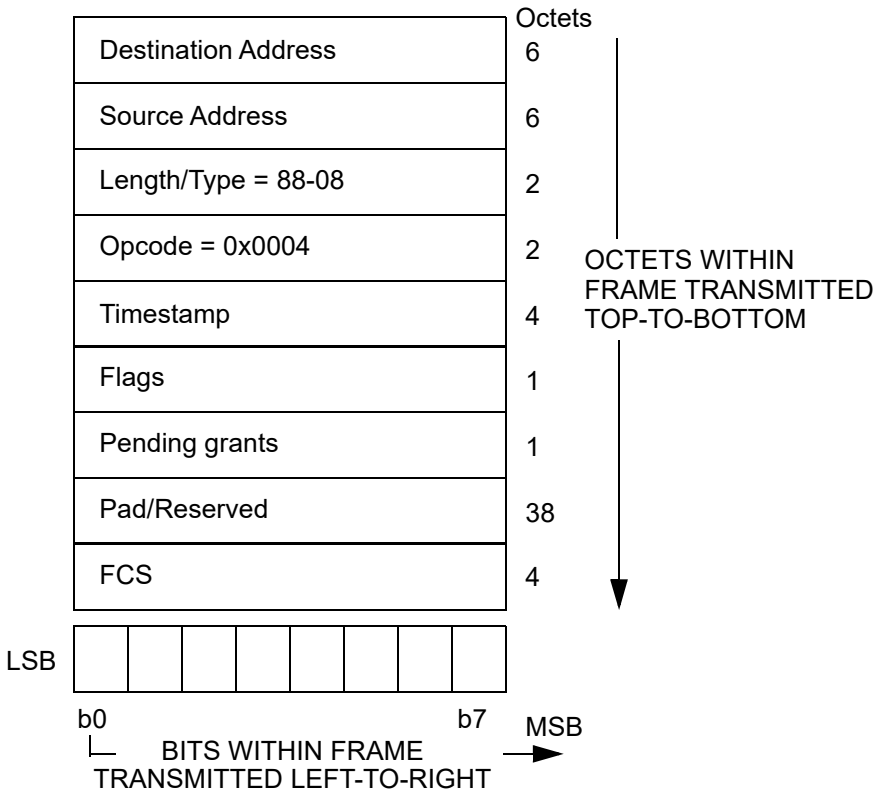

Figure 64–33—REGISTER_REQ MPCPDU

The REGISTER_REQ MPCPDU shall be generated by a MAC Control instance mapped to an undiscovered ONU, and as such shall be marked with a broadcast type of LLID.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

64.3.6.4 REGISTER description

The REGISTER MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) DA. The destination address used shall be an individual MAC address.
b) Opcode. The opcode for the REGISTER MPCPDU is 0x0005.
c) Assigned Port. This field holds a 16 bit unsigned value reflecting the LLID of the port assigned following registration.
d) Flags. this is an 8 bit flag register that indicates special requirements for the registration.

Table 64–4—REGISTER MPCPDU Flags field

Value	Indication	Comment
0	Reserved	Ignored on reception.
1	Reregister	The ONU is explicitly asked to re-register.
2	Deregister	This is a request to deallocate the port and free the LLID. Subsequently, the MAC is deallocated.
3	Ack	The requested registration is successful.
4	Nack	The requested registration attempt is denied by the higher-layer-entity.
5–255	Reserved	Ignored on reception.

e) Sync Time. This is an unsigned 16 bit value signifying the required synchronization time of the OLT receiver. During the synchronization time the ONU transmits only IDLE code-pairs. The value is counted in 16 bit time increments. The advertised value includes synchronization requirement on all receiver elements including PMD, PMA and PCS.
f) Echoed pending grants. This is an unsigned 8 bit value signifying the number of future grants the ONU may buffer before activating. The OLT should not grant the ONU more than this number of grants into the future.
g) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception when constructing a complying MPCP protocol implementation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

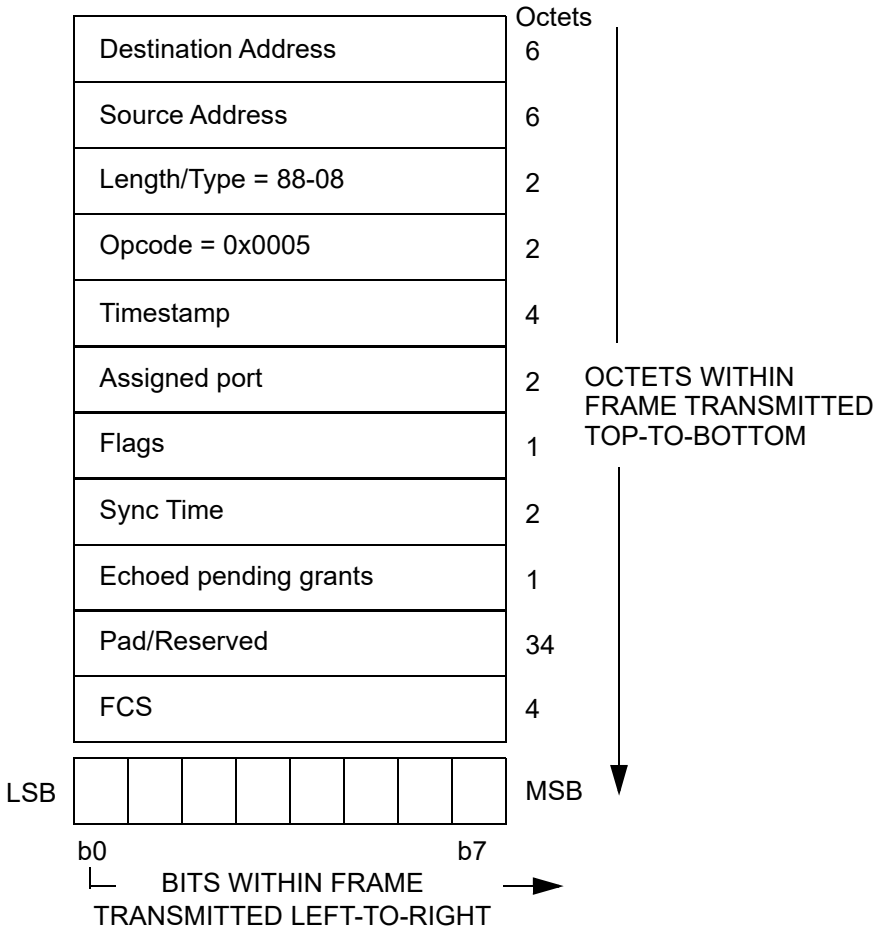

Figure 64–34—REGISTER MPCPDU

The REGISTER MPCPDU shall be generated by a MAC Control instance mapped to all ONUs and such frame is marked by the broadcast LLID.

64.3.6.5 REGISTER_ACK description

The REGISTER_ACK MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the REGISTER_ACK MPCPDU is 0x0006.
b) Flags. This is an 8-bit flag register that indicates special requirements for the registration.Echoed assigned port. This field holds a 16 bit unsigned value reflecting the LLID of the port assigned following registration.
c) Echoed Sync Time. This is an unsigned 16 bit value echoing the required synchronization time of the OLT receiver as previously advertised (see 64.3.6.4).
d) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored at reception when constructing a complying MPCP protocol implementation.

64.4 Protocol implementation conformance statement (PICS) proforma for Clause 64, Multipoint MAC Control[126]

64.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 64 Multipoint MAC Control, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

64.4.2 Identification

64.4.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

64.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 64, Multipoint MAC Control
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[126]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

65. Extensions of the Reconciliation Sublayer (RS) and Physical Coding Sublayer (PCS)/Physical Media Attachment (PMA) for 1000BASE-X for multipoint links and forward error correction

This clause describes functions for use in a 1000BASE-PX point-to-multipoint (P2MP) networks. This is an optical multipoint network that connects multiple DTEs using a single shared fiber. The architecture is asymmetrical, based on a tree and branch topology utilizing passive optical splitters. This type of network requires that the Multipoint MAC Control sublayer exists above the MACs, as described in Clause 64.

65.1 Extensions of the Reconciliation Sublayer (RS) for point-to-point emulation

65.1.1 Overview

This subclause extends Clause 35 to enable multiple data link layers to interface with a single Physical Layer. The number of MACs supported is limited only by the implementation. It is acceptable for only one MAC to be connected to this Reconciliation Sublayer. Figure 65–1 shows the relationship of this RS to the ISO/IEC OSI reference model. The mapping of GMII signals to PLS service primitives is described in 35.2.1.

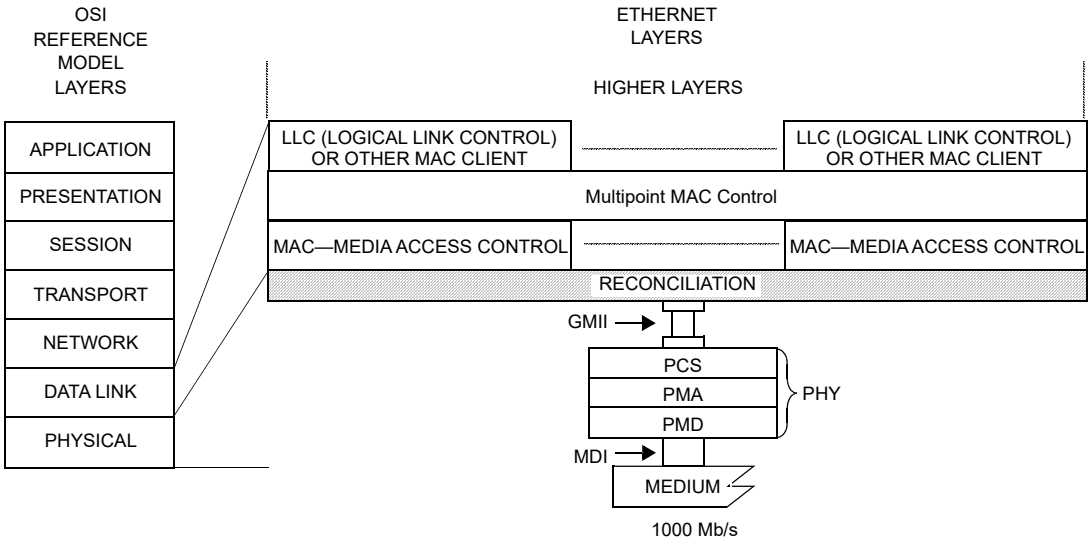

Figure 65–1—RS location in the OSI protocol stack

65.1.2 Principle of operation

A successful registration process, described in 64.3.3, results in the assignment of values to the MODE and LLID variables associated with a MAC. This may be one of many MACs in an Optical Line Terminal (OLT) or a single MAC in an Optical Network Unit (ONU). The MODE and LLID variables are used to identify a packet transmitted from that MAC and how received packets are directed to that MAC. The PCS of OLT shall operate in unidirectional mode as defined in 66.2.2.

As described in 64.1.2, multiple MACs within an OLT are bound to a single GMII, while at the ONU a single MAC is bound to the GMII. The multipoint control protocol (MPCP) ensures that only one MAC is transmitting at any one time. Correspondingly, only one PLS_DATA.request primitive is active at any time. The active PLS_DATA.request is mapped to the GMII signals, TXD<7:0>, TX_EN, TX_ER, and

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

GTX_CLK. The RS replaces octets of preamble with the values of the transmitting MAC's MODE and LLID variables.

In the receive direction, these MODE and LLID values, embedded within the preamble, identify the MAC to which this frame should be directed. The RS establishes a temporal mapping of the GMII signals, RXD<7:0>, RX_ER, RX_CLK, and RX_DV, to the correct PLS_DATA.indication and PLS_DATA_VALID.indication primitives.

65.1.3 Functional specifications

The variables below provide a mapping between MODE and LLID variables and multiple MACs. While the usage of this mapping is less interesting in the ONU, it is critical in the OLT. This mapping is used to replace transmitted preambles with MODE and LLID fields as well as to steer received packets to the appropriate MAC.

65.1.3.1 Variables

enable
: Value: Boolean
: This variable shall be TRUE for an ONU MAC. For an OLT MAC, this variable is defined as below:
: TRUE when management has assigned a value to mode and logical_link_id. Indicates the MAC is enabled to receive frames.
: FALSE when the MAC is not in use.

mode
: Value: 1 bit
: This variable shall be 0 for an ONU MAC and may be 0 or 1 for an OLT MAC.
: When the LLID is used to emulate a single copy broadcast or multicast channel, this variable will be set to 1. When emulating a unicast channel, this variable will be set to 0.

logical_link_id
: Value: 15 bits
: This variable shall be set to the broadcast value of 0x7FFF for the unregistered ONU MAC.
: Enabled OLT MACs may use any value for this variable. If the optional multicast LLID feature is supported, the OLT may use a multicast_link_id along with the mode bit 0.
: Registered ONU MACs may use any value other than 0x7FFF or a multicast_link_id for this variable.

multicast_link_id
: Value: 15 bits
: Enabled OLT MACs that support the optional multicast LLID feature may use any value for this variable. This variable is used, along with a mode bit reset to 0, to derive the multicast LLID.

65.1.3.2 Transmit

The transmit function of this extended RS replaces some of the octets of the preamble as transmitted by the MAC with several fields: SLD (start of LLID delimiter), LLID and CRC8. The SLD field is used by the receiver function to locate the LLID and CRC8 fields. The LLID field identifies the source or destination MAC. The CRC8 field provides a level of integrity on the LLID field. Table 65–1 shows the replacement mapping.

Table 65–1—Preamble/SFD replacement mapping

Offset	Field	Preamble/SFD	Modified preamble/SFD
1	—	0x55	same
2	—	0x55	same
3	SLD	0x55	0xD5
4	—	0x55	same
5	—	0x55	same
6	LLID[15:8]	0x55	<mode, logical_link_id[14:8]>[a]

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 65–1—Preamble/SFD replacement mapping *(continued)*

Offset	Field	Preamble/SFD	Modified preamble/SFD
7	LLID[7:0]	0x55	<logical_link_id[7:0]>[b]
8	CRC8	0xD5	The 8-bit CRC calculated over offsets 3 through 7

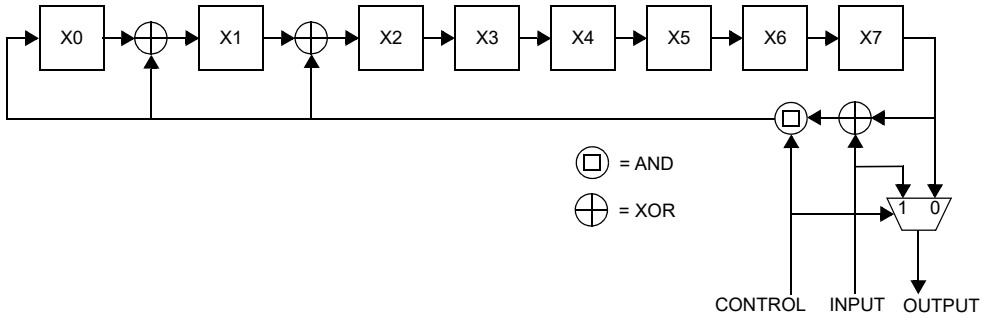
[a]mode maps to TXD[7], logical_link_id[14] maps to TXD[6], logical_link_id[8] maps to TXD[0]
[b]logical_link_id[7] maps to TXD[7], logical_link_id[0] maps to TXD[0]

65.1.3.2.1 SLD

The SLD field is one octet in length and replaces the third octet of the preamble.

NOTE—The 1000BASE-X PCS transmit function replaces the first octet of preamble with the /S/ code-group or it discards the first octet and replaces the second octet of preamble with the /S/ code-group. This decision is based upon the even or odd alignment of the PCS's transmit state diagram (see Figure 36–5). The 1000BASE-X PCS receive function replaces the /S/ code-group with an octet of preamble. The third octet of preamble is the first octet passed through the 1000BASE-X PHY without modification.

65.1.3.2.2 LLID



The LLID field is two octets in length and replaces the last two octets of preamble. The LLID field is a concatenation of the mode and logical_link_id variables for the associated MAC.

65.1.3.2.3 CRC-8

The CRC8 field contains an 8-bit cyclic redundancy check value. This value is computed as a function of the contents of the modified preamble beginning with the SLD field (offset 3) through the LLID field (offset 7). The encoding is defined by the generating polynomial shown in Equation (65–1):

$$G(x) = x^8 + x^2 + x + 1 \tag{65–1}$$

This CRC calculation shall produce the same result as the serial implementation shown in Figure 65–2. Before calculation begins, the shift register shall be initialized to the value 0x00. The content of the shift register is transmitted without inversion.

CONTROL = 1 when shifting the modified preamble and calculating the CRC
CONTROL = 0 when transmitting the CRC8 field

Figure 65–2—CRC8 field generation

65.1.3.3 Receive function

The receive function of this extended RS is responsible for the following functions:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) Locate the SLD field.
b) Use the location of the SLD field to locate the CRC8 field and verify that the received value matches the CRC calculated using the received data.
c) Use the location of the SLD field to locate the LLID field and parse it to determine the destination MAC.
d) If the packet is not discarded due to incorrect CRC or unknown LLID, then replace the SLD and LLID fields with normal preamble and the CRC8 field with the SFD and transfer the packet to the appropriate MAC.
e) Otherwise, discard the entire packet, replacing it with normal inter-frame.

Table 65–2 shows the mapping of the modified preamble/SFD to RXD.

Table 65–2—Preamble/SFD replacement mapping

Signal	Bit values of octets received through GMII[a]									
RXD0	X	1[b]	1	1[c]	1	1	logical_link_id[8][d]	logical_link_id[0][e]	X7[f]	D0[g]
RXD1	X	0	0	0	0	0	logical_link_id[9]	logical_link_id[1]	X6	D1
RXD2	X	1	1	1	1	1	logical_link_id[10]	logical_link_id[2]	X5	D2
RXD3	X	0	0	0	0	0	logical_link_id[11]	logical_link_id[3]	X4	D3
RXD4	X	1	1	1	1	1	logical_link_id[12]	logical_link_id[4]	X3	D4
RXD5	X	0	0	0	0	0	logical_link_id[13]	logical_link_id[5]	X2	D5
RXD6	X	1	1	1	1	1	logical_link_id[14]	logical_link_id[6]	X1	D6
RXD7	X	0	0	1	0	0	mode	logical_link_id[7]	X0	D7
RX_DV	0	1	1	1	1	1	1	1	1	1

[a]Leftmost octet is the first received
[b]This octet may be missing per 1000BASE-X PCS transmit state diagram (see Figure 36–5)
[c]SLD field
[d]First octet of LLID field
[e]Second octet of LLID field
[f]CRC8 field
[g]D0 through D7 is the first octet of the PDU (first octet of the Destination Address)

65.1.3.3.1 SLD

Recall that the 1000BASE-X transmit function has to maintain an even alignment for its Start_of_Packet delimiters. It may replace the first octet of preamble with the /S/ code-group and pass the second octet unchanged or it may discard the first octet of preamble and replace the second octet of preamble with the /S/ code-group. The SLD is transmitted in the third octet. These are the only two possibilities considered when parsing the incoming octet stream for the SLD. If the SLD field is not found then the packet shall be discarded. If the packet is transferred, the SLD shall be replaced with a normal preamble octet and the one or two octets preceding the SLD and the two octets following the SLD are passed without modification.

65.1.3.3.2 LLID

The third and fourth octets following the SLD contain the mode and logical_link_id values. These values are acted upon differently for OLTs and ONUs.

If the device is an OLT then the following comparison is made:

a) The received mode bit is ignored.
b) If the received logical_link_id value matches 0x7FFF and an enabled MAC exists with a logical_link_id variable with the same value then the comparison is considered a match to that MAC.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) If the received logical_link_id value is any value other than 0x7FFF and an enabled MAC exists with a mode variable with a value of 0 and a logical_link_id variable with a value matching the received logical_link_id value then the comparison is considered a match to that MAC.

If the device is an ONU then the following comparison is made:

d) If the received mode bit is 0 and the received logical_link_id value matches the logical_link_id variable then the comparison is considered a match.
e) If the received mode bit is 1 and the received logical_link_id value does not match the logical_link_id variable, or the received logical_link_id matches 0x7FFF, then the comparison is considered a match.
f) If the device supports the multicast LLID feature, the received mode bit is 0 and the received logical_link_id value matches an assigned multicast_link_id, then the comparison is considered a match.

If no match is found, then the packet shall be discarded within the RS. If a match is found, then the packet is intended to be transferred. If the packet is transferred, then both octets of the LLID field shall be replaced with normal preamble octets.

65.1.3.3.3 CRC-8

The octet following the LLID field contains the CRC8 field. The value of this field is compared against the calculated CRC of the received octets, beginning with the SLD field and ending with the last octet of the LLID field. If the received and calculated CRC values do not match, then the packet shall be discarded. If the values match then the packet is transferred. If the packet is transferred, then the CRC8 field shall be replaced with the SFD.

65.2 Extensions of the physical coding sublayer for data detection and forward error correction

65.2.1 Overview

This subclause extends the physical coding sublayer Clause 36 to support burst mode operation of the point-to-multipoint physical medium. This subclause also specifies an optional forward error correction (FEC) mechanism to increase the optical link budget or the fiber distance. Figure 65–3 shows the relationship between the extended PCS sublayer and the ISO/IEC OSI reference model. Auto-Negotiation, as defined in Clause 37, establishes a point-to-point handshaking mechanism for allowing 1000BASE-X devices to achieve a highest common denominator link. The P2MP aspect of a 1000BASE-PX network prohibits the use of the auto-negotiation protocol.

NOTE—Many implementations of the transmit and receive buffers might be dependent on the maximum length of frame supported. It is recommended that these frame buffers should be sized to accommodate maximum length envelope frames (see 3.2.7). It is also recommended that the FEC function should accommodate maximum length envelope frames, requiring up to 9 FEC code blocks per frame.

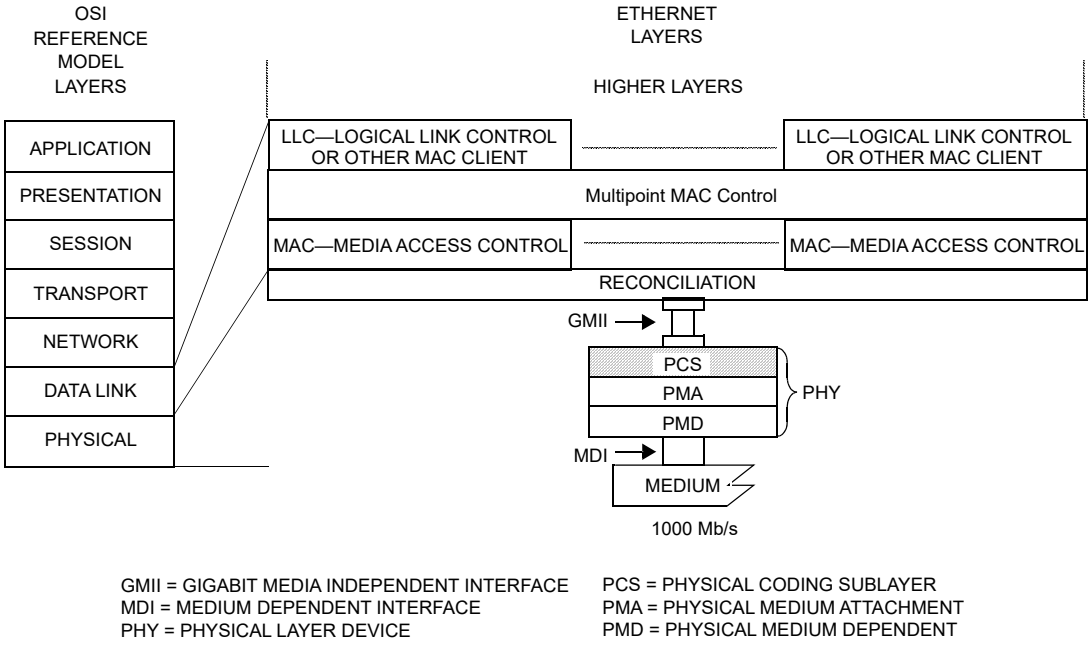

Figure 65–3—PCS location in the OSI protocol stack

65.2.2 Burst-mode operation

To avoid spontaneous emission noise from near ONUs obscuring signal from a distant ONU, the ONUs' lasers should be turned off between their transmissions. To control the laser, the PCS is extended to detect the presence of transmitted data and generate the PMD_SIGNAL.request(tx_enable) primitive to turn the laser on and off at the correct times. This function is performed by the Data Detector shown in the functional block diagram in Figure 65–4.

65.2.2.1 Principle of operation

The Data Detector contains a delay line (FIFO buffer) storing code-groups to be transmitted. The length of the FIFO buffer shall be chosen such that the delay introduced by the buffer together with any delay introduced by the PMA sublayer is long enough to turn the laser on and to allow a predefined number of idle characters to be transmitted. This number of idle characters is needed by the receiver to adjust its gain ($T_{receiver_settling}$), synchronize its receiving clock (T_{CDR}), and complete the synchronization process (T_{sync}).

Upon initialization, the FIFO buffer is filled with /I/ ordered sets and the laser is turned off. When the first code-group that is not /I/ arrives at the buffer, the Data Detector sets the PMD_SIGNAL.request(tx_enable) primitive to the value ON, instructing the PMD sublayer to start the process of turning the laser on (see Figure 65–4).

When the buffer empties of data (i.e., contains only /I/ ordered sets), the Data Detector sets the PMD_SIGNAL.request(tx_enable) primitive to the value OFF, instructing the PMD sublayer to start the process of turning the laser off. Between packets, /I/ or /R/ ordered sets will arrive at the buffer. If the number of these /I/ or /R/ ordered sets is insufficient to fill the buffer then the laser is not turned off.

Figure 65–5 shows the relationship of filling the buffer and the generation of laser_control. In the OLT, the laser always remains turned on. Correspondingly, therefore the OLT's Data Detector does not need a delay line or buffer in the data path for this purpose.

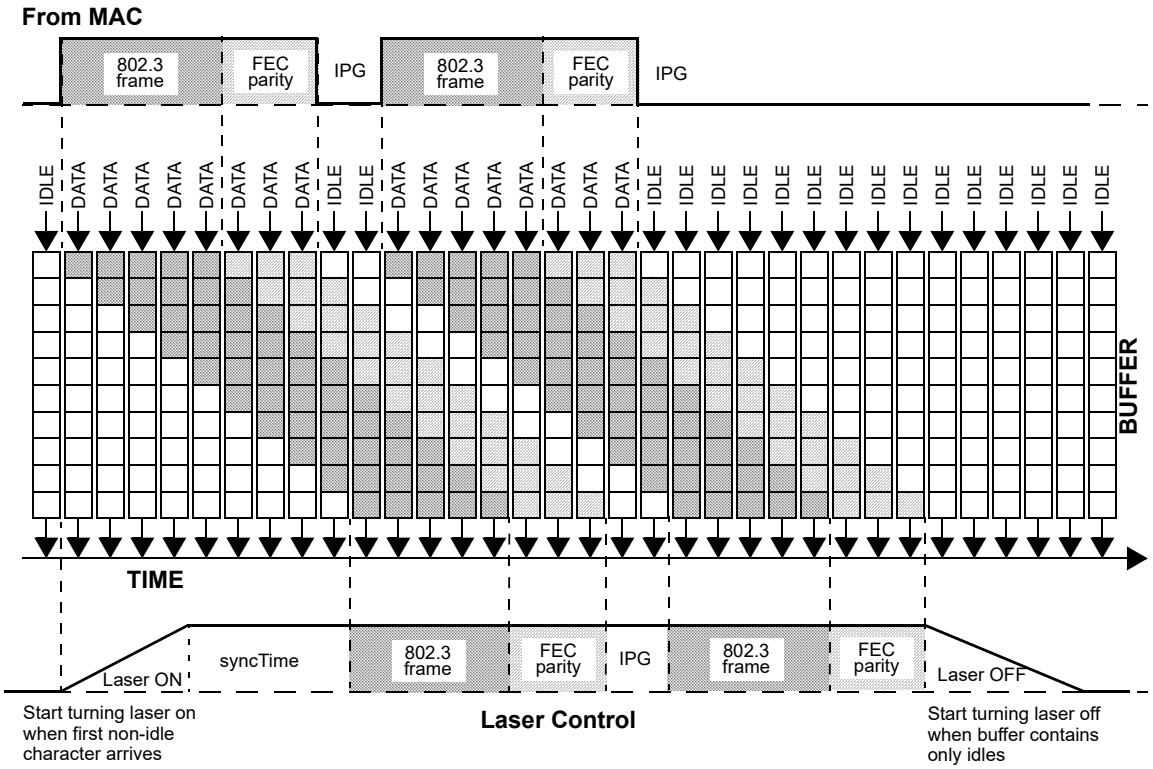

Figure 65–5—Laser control as a function of buffer fill

65.2.2.2 Detailed functions and state diagrams

The body of this clause comprises state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams in this clause follows the conventions in 21.5. State diagram variables follow the conventions of 21.5.2 except when the variable has a default value. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set.

65.2.2.2.1 Variables

BEGIN

TYPE: Boolean

This variable is used when initiating operation of the state diagram. It is set to true following initialization and every reset.

DelayBound

TYPE: 16-bit unsigned

DEFAULT VALUE: 00-6A (106 code-groups = 848 ns)

This represents the delay sufficient to initiate the laser and to stabilize the receiver at the OLT. The default value of DelayBound is based on default values of laserOnTime (64.3.5.1) and SyncTime (64.3.3.2). This variable is only used by the ONU.

dtx_code-group

A 10-bit vector representing one code-group, as specified in Tables 36–1a through 36–2, which has been prepared for transmission by the Data Detector process. This vector is conveyed to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the PMA as the parameter of a PMA_UNITDATA.request(dtx_code-group) service primitive. The element dtx_code-group<0> is the first bit transmitted and dtx_code-group<9> is the last bit transmitted.

laser_control

This variable represents the status of the laser. The value on corresponds to the laser being turned on, and the value off corresponds to laser being off.

TYPE: Boolean.

tx_code-group

A 10-bit vector of bits representing one code-group, as specified in Table 36–1a–e or Table 36–2, which has been prepared for transmission by the PCS Transmit process. The element tx_code-group<0> is the first tx_bit transmitted; tx_code-group<9> is the last tx_bit transmitted.

65.2.2.2.2 Functions

IsIdle(tx_code-group)

This function is used to determine whether tx_code-group is a code-group in /I/, the IDLE ordered set, or /C/, the Configuration ordered set. This function returns true if tx_code-group is /K28.5/ or any code-group that follows a /K28.5/ or any two consecutive /D/ code-groups that follow /K28.5/D21.5/ or /K28.5/D2.2/. Otherwise, the IsIdle function returns false.

FIFO.RemoveHead()

This function removes the first code-group from the FIFO buffer and advances all remaining code-groups one position ahead. This function returns the 10-bit vector representing the removed code-group.

FIFO.Append(tx_code-group)

This function appends a new 10-bit vector to the end of the FIFO buffer.

65.2.2.2.3 Messages

PMD_SIGNAL.request(tx_enable)

This primitive is used to turn the laser on and off at the PMD sublayer. In the OLT, this primitive shall always take the value ON. In the ONU, the value of this variable is controlled by the Data detector state diagram (see Figure 65–6).

PUDR

Alias for PMA_UNITDATA.request(tx_code-group<9:0>).

65.2.2.2.4 Counters

IdleLength

This counter represents the length of the consecutive interval of idles ending with the most recent tx_code-group. If the most recent tx_code-group represents a non-idle character, the IdleLength is reset to 0.

TYPE: 32-bit unsigned

65.2.2.3 State diagrams

The Data Detector shall be implemented for an ONU as depicted in Figure 65–6, including compliance with the associated state variables as specified in 65.2.2.2.

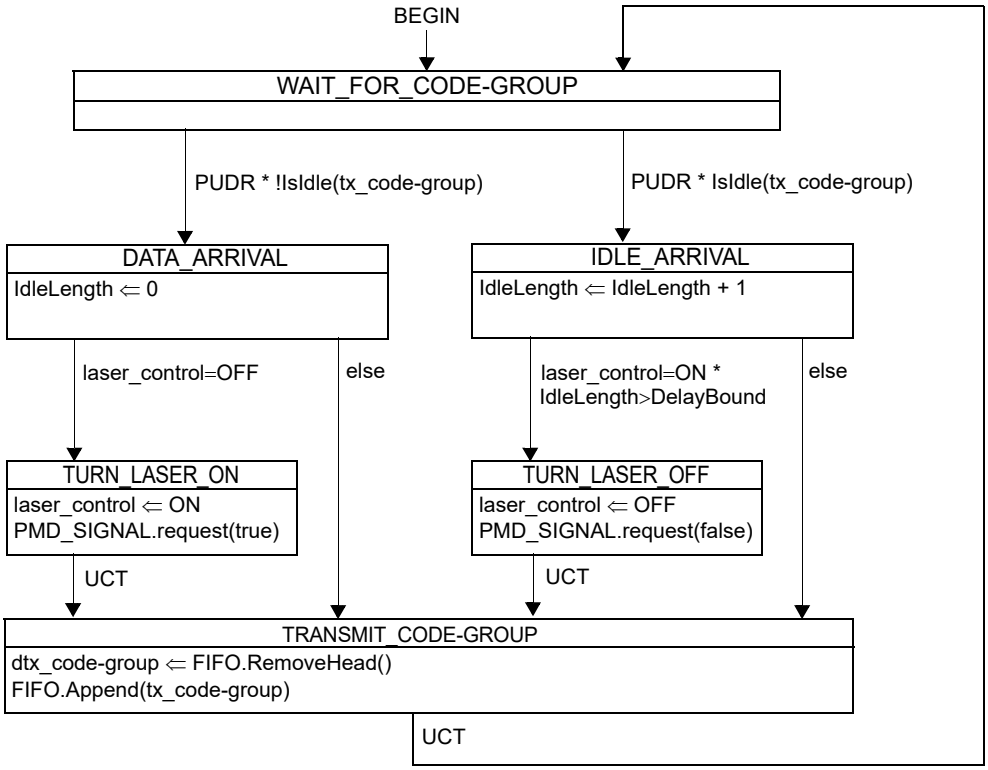

Figure 65–6—ONU data decoder state diagram

65.2.3 Forward error correction

This subclause specifies an optional forward error correction (FEC) mechanism to increase the optical link budget or the fiber distance. The FEC appends to the Ethernet frame additional data that is a result of a set of non-binary arithmetic functions (known as Galois arithmetic) performed on the data of the Ethernet frame. This additional data (known as the FEC parity octets) is used to correct errors at the receiving end of the link that may occur when the data is transferred through the link.

The FEC function comprises three functional blocks: FEC Encoder, FEC Decoder, and FEC Synchronization, as shown in Figure 65–4. These blocks have ten-bit interfaces (TBIs) to both sides and can be omitted for implementations not requiring FEC. Though the FEC functionality is optional, if implemented for operation over a multipoint optical link, it shall behave as specified in 65.2.3.

The following are the objectives of FEC:

a) Keep frame format compliant to 1000BASE-X PCS.
b) Support optional functionality.
c) Allow backwards compatibility with legacy 1000BASE-X devices.
d) Support BER objective of 10^{-12} at PCS.
e) Support BER objective of 10^{-4} at FEC sublayer.

65.2.3.1 FEC code

The FEC code specification, properties and performance analysis are specified in ITU-T G.975.

The FEC code used is a linear cyclic block code - the Reed-Solomon code (255,239,8) over the Galois Field of GF(2^8) - a non-binary code operating on 8-bit symbols. The code encodes 239 information symbols and adds 16 parity symbols. The code is systematic—meaning that the information symbols are not disturbed in any way in the encoder and the parity symbols are added separately to each block.

The code is the systematic form of the RS code based on the generating polynomial $G(x) = \prod_{i=0}^{15}(x - \alpha^i)$

where α is equal to 0x02 and is a root of the binary primitive polynomial $x^8+x^4+x^3+x^2+1$.

A codeword of the systematic code is presented by $D(x) + P(x) = G(x) * L(x)$ where:

$D(x)$ is the data vector – $D(x)=D_{238}X^{254} + ... + D_0X^{16}$. D_{238} is the first data octet and D_0 is the last.

$P(x)$ is the parity vector – $P(x)=P_{15}X^{15} + ... + P_0$. P_{15} is the first parity octet and P_0 is the last.

A data octet (d_7, d_6, ..., d_1, d_0) is identified with the element: $d_7*\alpha^7 + d_6*\alpha^6 + ... d_1*\alpha^1 + d_0$ in GF(2^8), the finite field with 2^8 elements. The code has a correction capability of up to eight symbols.

NOTE—For the (255,239,8) Reed-Solomon code, the symbol size equals one octet. d_0 is identified as the LSB and d_7 is identified as the MSB bit in accordance with the conventions of 3.1.1.

The FEC decoder shall replace all octets in an uncorrectable block with /V/ to clearly propagate the error condition to the PCS.

65.2.3.2 FEC frame format

The frame format of an FEC coded Ethernet frame is herein described.

65.2.3.2.1 Placing parity octets

Ethernet packets are received from the PCS. The data is partitioned into 239-symbol frames (blocks), with the first block beginning with the first symbol after the /S/ code-group and the last block ending with the last symbol before the /T/ code-group. Each block is encoded using the (255,239,8) Reed-Solomon encoder, which results in an additional 16 parity symbols for each block. The block plus the associated 16 parity symbols form the 255 symbol Reed-Solomon codeword. The additional 16 parity symbols, which are generated from this encoding process for each block, are gathered and added at the end of the packet.

65.2.3.2.2 Shortened last block

When dividing the data into blocks there might be a case where the last block is shorter than 239 symbols. This block is noted as a shortened block. A shortened block of length r octets results in the data vector assignment of D_{238} to D_r as zeros and D_{r-1} to D_0 as valid data, where D_{r-1} is the first octet of the shortened block and D_0 is the last. This full size block is then encoded and the 16 parity symbols are generated. The data is then sent without the zero symbols. At the receiver, the decoder completes the block again into the full block (by adding back the zeros) for decoding.

65.2.3.2.3 Special frame markers

The Ethernet frame consists of a number of blocks plus special frame start and stop markers. In order to decode the FEC code, the receiver first has to synchronize on the Ethernet frame. The Ethernet frame

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

markers are not protected by the FEC code and are exposed to higher BER. Therefore, special start and stop marker symbols are added at the beginning and the end of the FEC coded frame that are capable of being correctly detected in a high noise environment. The special symbol noise immunity is made possible by the implementation of a simple correlator. The marker framing sequences used are at least 5 octets long, long enough to be detected with very high probability. The start FEC framing sequence is denoted by /S_FEC/ and the end FEC framing sequence is denoted by /T_FEC/.

In order to determine that an FEC coded frame has started, the input symbol stream is scanned for a match with the /S_FEC/ ordered set with fewer than d/2 errors. In order to determine that an FEC coded frame has ended, the input symbol stream is scanned for a match with the /T_FEC_O/ or /T_FEC_E/ ordered sets with fewer than d/2 errors.

The value chosen for d is 10, the number of bits that are different between these ordered sets and any other regularly occurring five consecutive code-groups when considered in the 10-bit domain.

The sequence can flow through non-FEC PCS transparently (in a False_Carrier_Sense mode).

The start and end symbols are constructed from 8B/10B code-groups:

— /S_FEC/ - start of FEC coded packet - /K28.5/D6.4/K28.5/D6.4/S/
— /T_FEC_E/ - end of FEC coded packet with even alignment. If the starting running disparity is positive, the /T_FEC_E/ has the following pattern: /T/R/K28.5/D10.1/T/R/. If the starting running disparity is negative, the T_FEC_E has the following pattern: /T/R/K28.5/D29.5/T/R/.
— /T_FEC_O/ - end of FEC coded packet with odd alignment - /T/R/R/I/T/R/

/S/, /T/, /R/ and /I/ are described in Table 36–3. The /I/ in both the /T_FEC_E/ and the /T_FEC_O/ ordered sets can be either an /I1/ (a disparity correcting IDLE) or an /I2/ (a disparity preserving IDLE).

Figure 65–7 describes the FEC coded Ethernet frame. Between the FCS and PARITY fields, the T_FEC can be either the /T_FEC_E/ or the /T_FEC_O/ ordered set. After the PARITY field, the T_FEC can only be a /T_FEC_E/ ordered set.

Figure 65–7—FEC coded Ethernet frame

65.2.3.3 FEC sublayer operation

This section describes the functionality and operation of the FEC sublayer.

65.2.3.3.1 Principles of operation

At transmission, the FEC sublayer receives the packets from the PCS, performs the FEC coding, appends the parity octets in place of the stretched IPG and sends the data to the PMA. At reception, the FEC sublayer receives the data from the PMA, performs the octet alignment, detects the Start FEC Framing Sequence, decodes the FEC code, correcting data where necessary and possible, replaces the parity octets with IDLE and sends the data to the PCS.

NOTE—To ensure correct MPCP operation, the FEC function maintains constant and equal delay for all code-groups and all signals transmitted from PMA to PCS. Timing effects of adding FEC function should be indistinguishable from an increased propagation delay.

65.2.3.3.2 Functional block diagram

As depicted in Figure 65–4, the FEC sublayer comprises a transmit side and a receive side. The following sections define the functionality of each block in the sublayer. See 36.3.3 for a complete description of the TBI.

65.2.3.3.3 Transmission

Figure 65–8 describes a block diagram of the FEC sublayer transmit data path. The packet delimiters of the packets from the PCS are detected. The /I/I/S/ is replaced with the /S_FEC/ ordered set. The data in the frame is then 8B/10B decoded so that the FEC coding can take place and the parity octets buffered. The /T/R/I/I/ or /T/R/R/I/I/ is detected and replaced with the /T_FEC_E/ or /T_FEC_O/, respectively. Then the parity octets and another /T_FEC_E/ is appended, replacing the stretched interframe spacing.

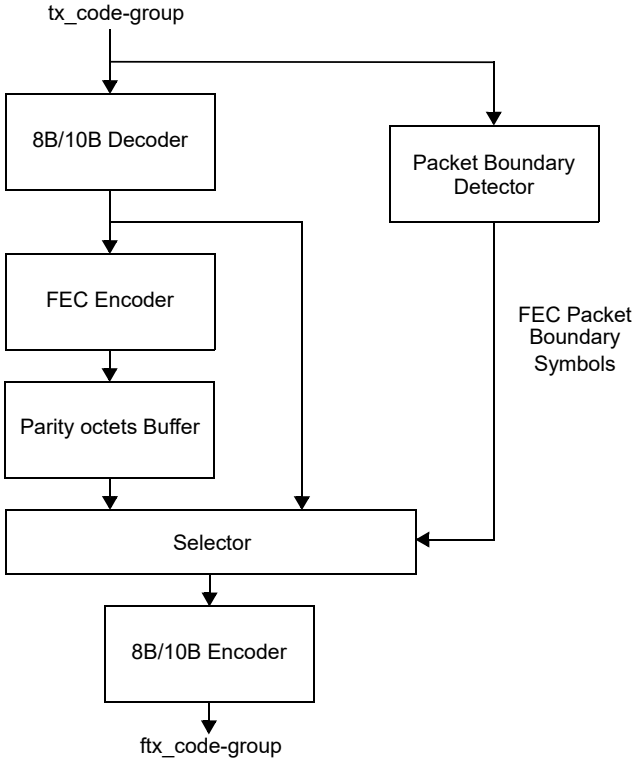

Figure 65–8—Transmit block diagram

The FEC Transmit process continually generates code-groups based upon information provided in the PMA_UNITDATA.request primitive with the tx_code-group<9:0> parameter, sending them immediately to the PMA Service Interface via the same primitive with the ftx_code-group<9:0> parameter.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

65.2.3.3.4 Reception

Figure 65–9 describes the receive synchronization block diagram of the FEC sublayer receive data path. The FEC Synchronization process continually accepts code-groups via the PMA_UNITDATA.indication service primitive and conveys received code-groups to the FEC Receive process via the SYNC_UNITDATA.indicate service primitive. The FEC Synchronization process sets the sync_status flag to indicate whether the PMA is functioning dependably (as well as can be determined without exhaustive error-ratio analysis).

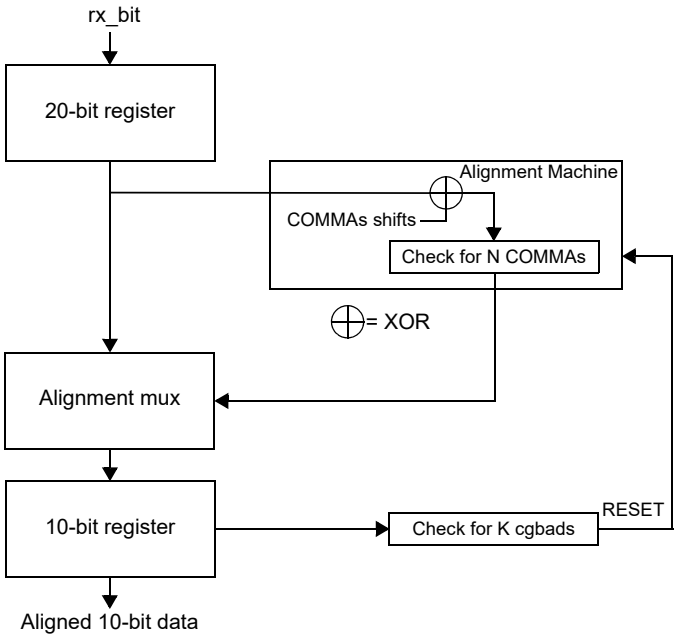

Figure 65–9—Receive synchronization block diagram

Figure 65–10 describes a block diagram of the FEC sublayer receive data path. The FEC Receive process continuously accepts code-groups via the SYNC_UNITDATA.indicate service primitive. It fills a buffer with these code-groups, converting an /S_FEC/ with fewer than d/2 errors to /I/I/S/ and converting all /T_FEC/ with fewer than d/2 errors to a clean /T_FEC/. This buffer exists in order to store all necessary data until the parity octets are available for performing data correction. Data correction is performed within the buffer. While emptying the buffer, the parity octets, along with the latter /T/R/ of the first /T_FEC/ and the entire second /T_FEC/ are converted to /I/.

NOTE—Under specific conditions, the PCS may generate a large number of FALSE_CARRIER events. FEC encryption only protects Ethernet frames. The IDLEs are not FEC-protected. During idle periods, excessive bit errors may results in FALSE_CARRIER events. Additionally, when FEC and non-FEC devices are combined in the same EPON, a non-FEC device will treat FEC parity data as FALSE_CARRIER events.

65.2.3.4 Detailed functions and state diagrams

The body of this clause comprises state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams in this clause follows the conventions in 21.5. State diagram variables follow the conventions of 21.5.2 except when the variable has a default value. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set.

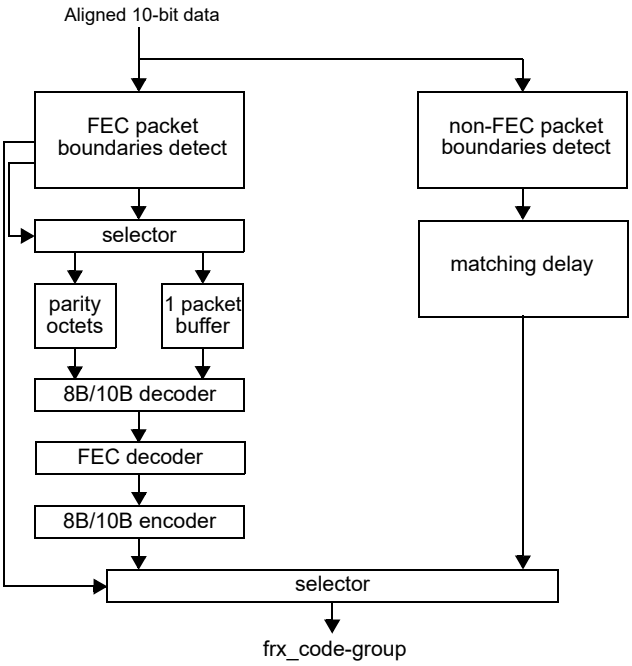

Figure 65–10—Receive data block diagram

65.2.3.4.1 State variables

65.2.3.4.2 Notation conventions

/x/

Denotes the constant code-group specified in 36.2.5.1.2 (valid code-groups have to follow the rules of running disparity as per 36.2.4.5 and 36.2.4.6).

[/x/]

Denotes the latched received value of the constant code-group (/x/) specified in 36.2.5.1.2 and conveyed by the SYNC_UNITDATA.indicate message described in 36.2.5.1.6.

65.2.3.4.3 Constants

/COMMA/

The set of special code-groups that include a comma as specified in 36.2.4.9 and listed in Table 36–2.

/D/

The set of 256 code-groups corresponding to valid data, as specified in 36.2.4.11.

/Dx.y/

One of the set of 256 code-groups corresponding to valid data, as specified in 36.2.4.11.

/I/

The IDLE ordered set group, comprising either the /I1/ or /I2/ ordered sets, as specified in 36.2.4.12.

/INVALID/

The set of invalid data or special code-groups, as specified in 36.2.4.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

/Kx.y/
: One of the set of 12 code-groups corresponding to valid special code-groups, as specified in Table 36–2.

/R/
: The code-group used as either: End_of_Packet delimiter part 2; End_of_Packet delimiter part 3; Carrier_Extend; and /I/ alignment.

/S/
: The code-group corresponding to the Start_of_Packet delimiter (SPD) as specified in 36.2.4.14.

/T/
: The code-group used for the End_of_Packet delimiter part 1.

/V/
: The Error_Propagation code-group, as specified in 36.2.4.17.

65.2.3.4.4 Variables

buffer
: The Receive process buffer of undefined length containing code-groups.

buffer_head
: The code-group at the head of the Receive process buffer.

cgbad
: Alias for the following terms: ((rx_code-group∈/INVALID/) + (rx_code-group=/COMMA/ *rx_even=TRUE)) * PMA_UNITDATA.indication

cggood
: Alias for the following terms: !((rx_code-group∈/INVALID/) + (rx_code-group=/COMMA/ *rx_even=TRUE)) * PMA_UNITDATA.indication

fec_encode
: A Boolean set by the FEC Transmit process to indicate the status of the RS_Encode(Data) function.

  Values: TRUE; data is acted upon by the RS_Encode(Data) function.
  FALSE; data is not being acted upon by the RS_Encode(Data) function.

ftx_bit
: A binary parameter used to convey data from the PMA to the PMD via the PMD_UNITDATA.request service primitive as specified in 60.1.5.1.

  Values: ZERO; Data bit is a logical zero.
  ONE; Data bit is a logical one.

ftx_code-group<9:0>
: A vector of bits representing one code-group, as specified in Table 36–1a through Table 36–2, which has been prepared for transmission by the FEC Transmit process. This vector is conveyed to the PMA as the parameter of a PMA_UNITDATA.request(ftx_code-group) service primitive. The element ftx_code-group<0> is the first ftx_bit transmitted; ftx_code-group<9> is the last ftx_bit transmitted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

parity<D7:D0>

An 8-bit array that contains the current parity bits to be encoded in the FEC Transmit Process. The elements within the array are updated with the next 8-bits to be encoded upon each entry into the XMIT_PARITY state.

Values for each element in the array: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

parity_buffer_empty

A Boolean set by the FEC Transmit process to indicate if more parity octets need to be encoded.

Values: TRUE; No more parity octets need to be encoded.
FALSE; More parity octets need to be encoded.

rx_disparity

A Boolean set by the FEC Receive process to indicate the running disparity at the end of code-group reception as a binary value. Running disparity is described in 36.2.4.3.

Values: POSITIVE
NEGATIVE

rx_even

A Boolean set by the FEC Synchronization process to designate received code-groups as either even- or odd-numbered code-groups as specified in 36.2.4.2.

Values: TRUE; Even-numbered code-group being received.
FALSE; Odd-numbered code-group being received.

rx_code-group<9:0>

A 10-bit vector represented by the most recently received code-group from the PMA. The element rx_code-group<0> is the least recently received (oldest) rx_bit; rx_code-group<9> is the most recently received rx_bit (newest). When code-group alignment has been achieved, this vector contains precisely one code-group.

signal_detect

A Boolean set by the PMD continuously via the PMD_SIGNAL.indication(signal_detect) message to indicate the status of the incoming link signal.

Values: FAIL; A signal is not present on the link.
OK; A signal is present on the link.

sync_status

A parameter set by the FEC Synchronization process to reflect the status of the link as viewed by the receiver.

Values: FAIL; The receiver is not synchronized to code-group boundaries.
OK; The receiver is synchronized to code-group boundaries.

tx_bit

A binary parameter used to convey data from the PMA to the PMD via the PMD_UNITDATA.request service primitive as specified in 60.1.5.1.

Values: ZERO; Data bit is a logical zero.
ONE; Data bit is a logical one.

tx_code-group<9:0>

A vector of bits representing one code-group, as specified in Table 36–1a–e or Table 36–2, which has been prepared for transmission by the PCS Transmit process. This vector is conveyed to the PMA as the parameter of a PMD_UNITDATA.request(tx_bit) service

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

primitive. The element tx_code-group<0> is the first tx_bit transmitted; tx_code-group<9> is the last tx_bit transmitted.

tx_disparity
: A Boolean set by the FEC Transmit process to indicate the running disparity at the end of code-group transmission as a binary value. Running disparity is described in 36.2.4.3.

  Values: POSITIVE
  NEGATIVE

65.2.3.4.5 Functions

check_ahead_tx
: Prescient function used by the FEC Transmit process to find the Start_of_Packet in order to replace the Start_of_Packet and its two preceding IDLE ordered sets with /S_FEC/.

check_ahead_rx
: Prescient function used by the FEC Receive process to find the /S_FEC/ and /T_FEC/, with fewer than d/2 errors.

DECODE ([/x/])
: In the PCS Receive process, this function takes as its argument the latched value of rx_code-group<9:0> ([/x/]) and the current running disparity, and returns the corresponding GMII RXD<7:0>, rx_Config_Reg<D7:D0>, or rx_Config_Reg<D15:D8> octet, per Table 36–1a–e. DECODE also updates the current running disparity per the running disparity rules outlined in 36.2.4.4.

ENCODE(x)
: In the PCS Transmit process, this function takes as its argument (x), where x is a GMII TXD<7:0>, tx_Config_Reg<D7:D0>, or tx_Config_Reg<D15:D8> octet, and the current running disparity, and returns the corresponding ten-bit code-group per Table 36–1a–e. ENCODE also updates the current running disparity per Table 36–1a–e.

POP_BUFFER
: Removes the octet at the head of the Receive process buffer, making the next octet available.

RS_Encode(Data)
: This function is used to encode the Reed-Solomon (255,239,8) code. The encoder encodes the 239 octets data frame and generates 16 parity octets for each data frame. Before being passed to the Reed-Solomon encoder, this function passes the data through DECODE([/x/]).

RS_Decode(Data)
: This function is used to decode the Reed-Solomon (255,239,8) code. The decoder decodes the 255 symbols data frame and generates 239 corrected data octets for each frame and an error signal.

signal_detectCHANGE
: In the PCS Synchronization process, this function monitors the signal_detect variable for a state change. The function is set upon state change detection.

  Values: TRUE; A signal_detect variable state change has been detected.
  FALSE; A signal_detect variable state change has not been detected (default).

65.2.3.4.6 Counters

good_cgs
: Count of consecutive valid code-groups received.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

loop_count
: A 3-bit counter used to keep track of the number of loops in the receive synchronization process.

65.2.3.4.7 Messages

FEC_UNITDATA.indicate(frx_code-group<9:0>)
: A signal sent by the FEC Receive process conveying the next code-group received over the medium.

FUDI
: Alias for FEC_UNITDATA.indicate(frx_code-group<9:0>).

PMA_UNITDATA.indication(rx_code-group<9:0>)
: A signal sent by the PMA Receive process conveying the next code-group received over the medium (see 36.3.1.2).

PMA_UNITDATA.request(tx_code-group<9:0>)
: A signal sent to the PMA or FEC Transmit process conveying the next code-group ready for transmission over the medium (see 36.3.1.1).

PUDI
: Alias for PMA_UNITDATA.indication(rx_code-group<9:0>).

PUDR
: Alias for PMA_UNITDATA.request(tx_code-group<9:0>).

SUDI
: Alias for SYNC_UNITDATA.indicate(parameters).

SYNC_UNITDATA.indicate(parameters)
: A signal sent by the FEC Synchronization process to the FEC Receive process conveying the following parameters:

  Parameters: [/x/]; the latched value of the indicated code-group (/x/);
  EVEN/ODD; The latched state of the rx_even variable;

  Value: EVEN; Passed when the latched state of rx_even=TRUE.
  ODD; Passed when the latched state of rx_even=FALSE.

65.2.3.5 State diagrams

65.2.3.5.1 Transmit state diagram

The FEC shall implement its transmit process as depicted in Figure 65–11, including compliance with the associated state variables as specified in 65.2.3.4.1.

65.2.3.5.2 Receive synchronization state diagram

The FEC shall implement its synchronization process as depicted in Figure 65–12, including compliance with the associated state variables in 65.2.3.4.1.

65.2.3.5.3 Receive state diagram

The FEC shall implement its receive process as depicted in Figure 65–13 and Figure 65–14, including compliance with the associated state variables in 65.2.3.4.1.

It is expected that the FEC decoding is performed while the data is in the buffer.

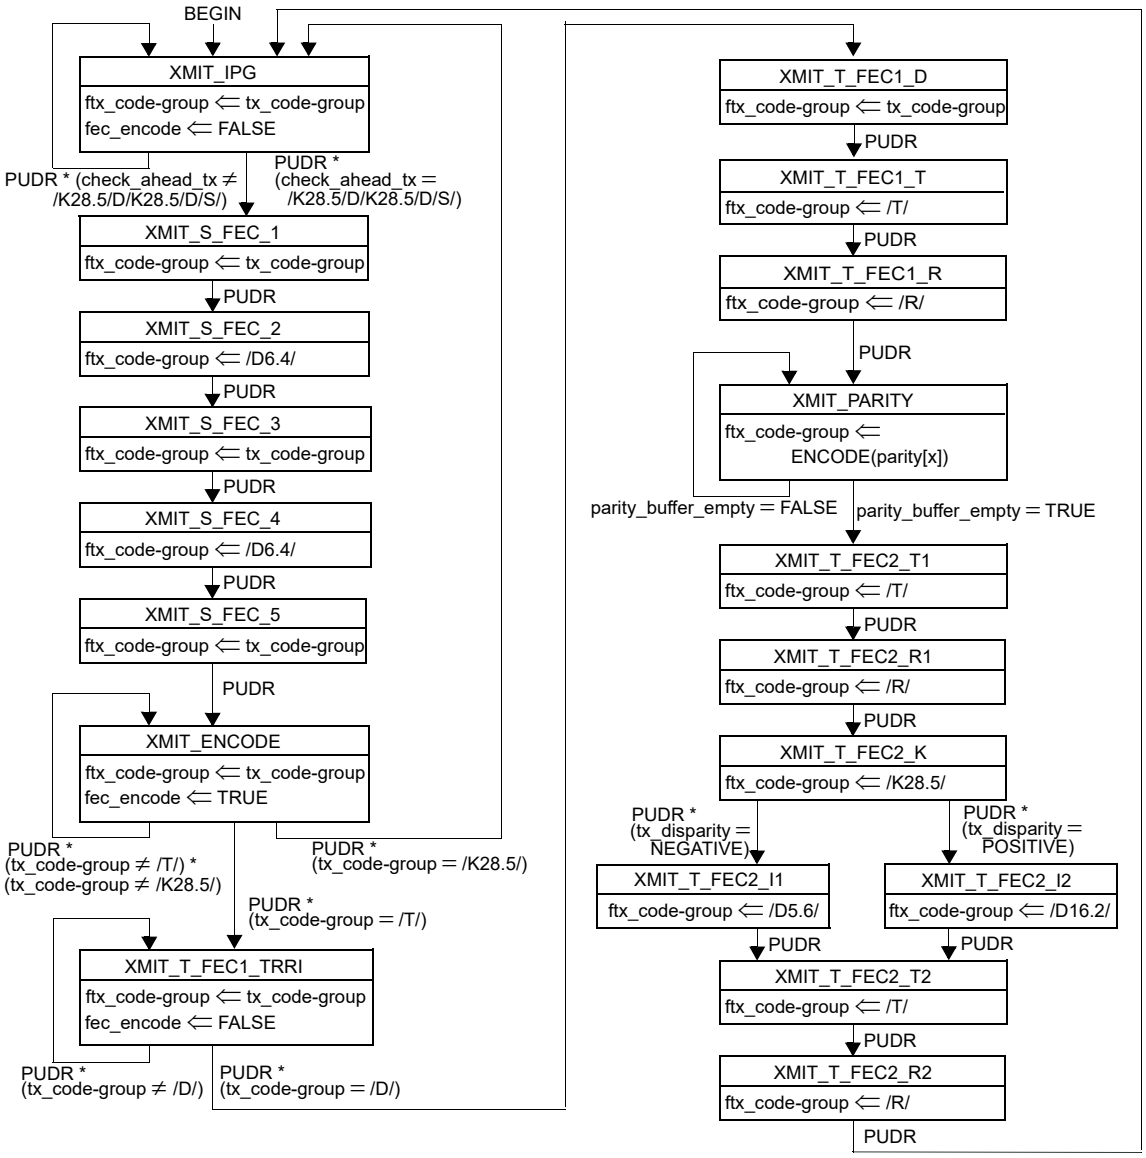

Figure 65–11—Transmit state diagram

65.2.3.6 Error monitoring capability

The following counters apply to FEC sublayer management and error monitoring. If an MDIO interface is provided (see Clause 22), it is accessed via that interface. If not, it is recommended that an equivalent access be provided. These counters are reset to zero upon read or upon reset of the FEC sublayer. When a counter reaches all ones, it stops counting. The counters' purpose is to help monitor the quality of the link.

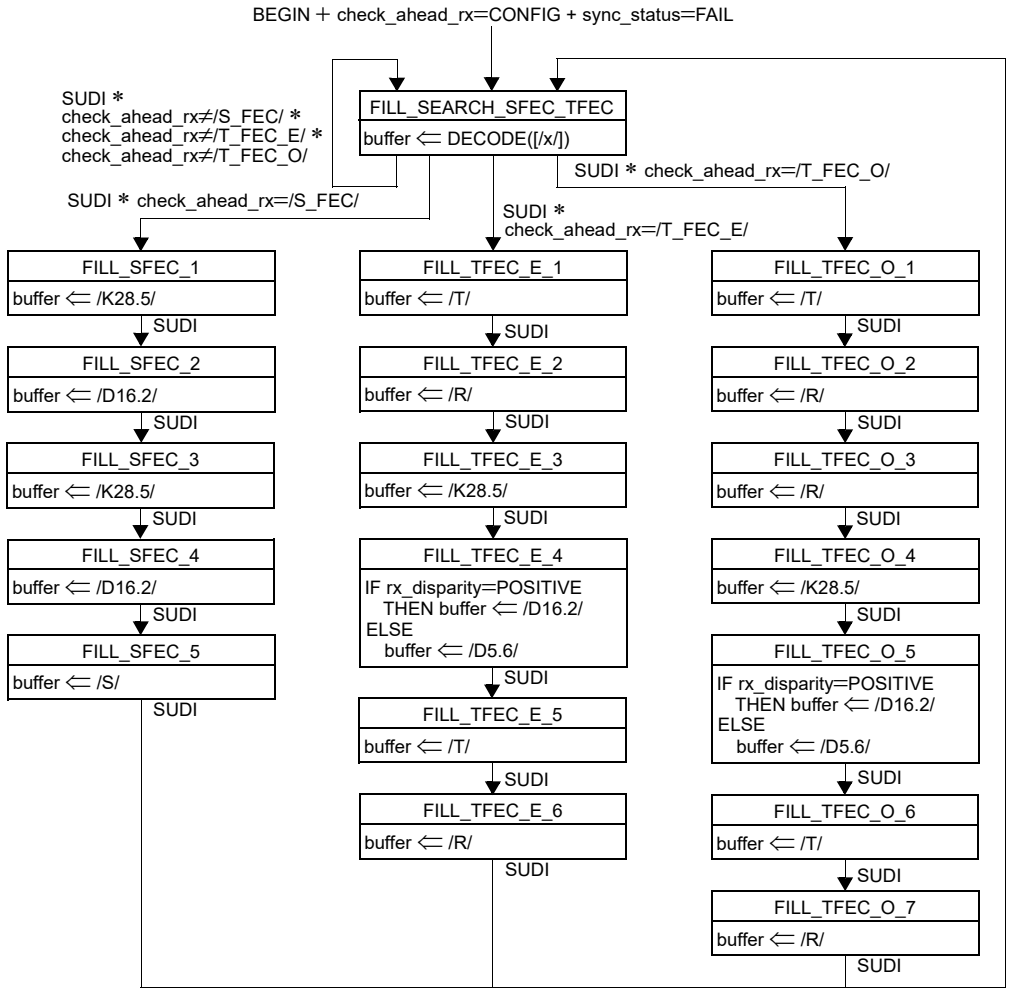

Figure 65–13—Receive buffer-fill state diagram

65.2.3.6.1 buffer_head_coding_violation_counter

32-bit counter. buffer_head_coding_violation_counter counts once for each invalid code-group received directly from the link. This variable is provided by a management interface that may be mapped to the 45.2.10.4 register (29.9.15:0).

65.2.3.6.2 FEC_corrected_blocks_counter

32-bit counter. FEC_corrected_blocks_counter counts once for each corrected FEC blocks in the decoding. This variable is provided by a management interface that may be mapped to the 45.2.10.5 register (29.10.15:0).

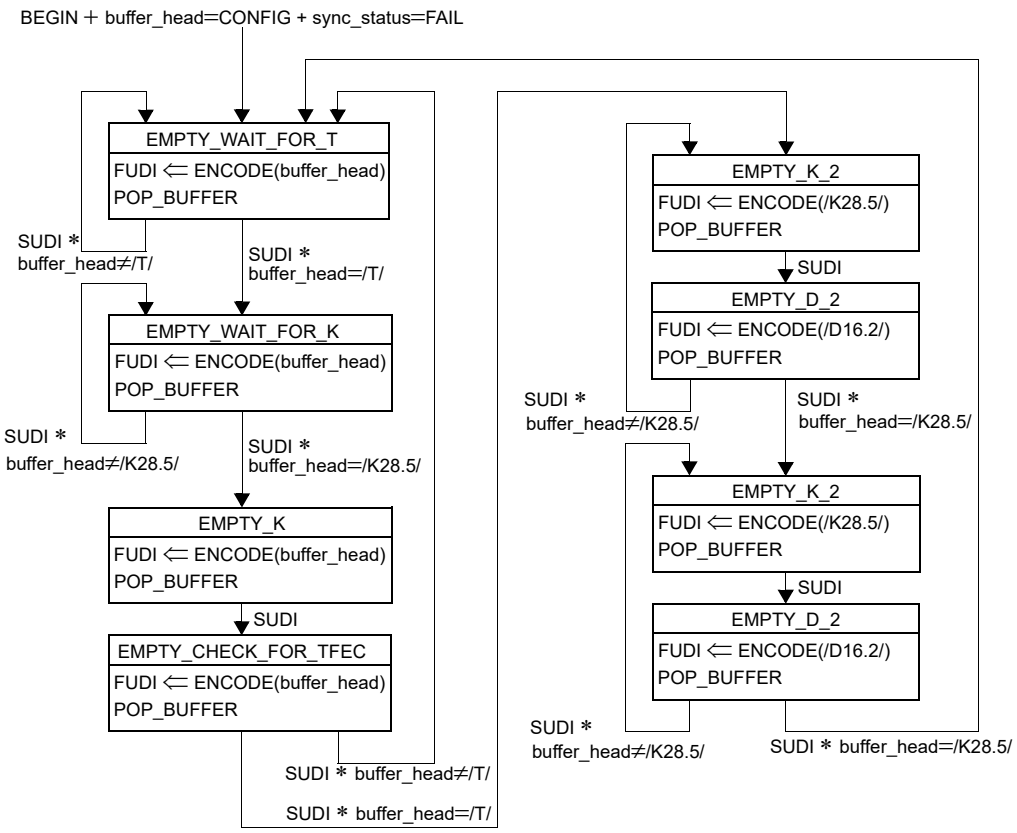

Figure 65–14—Receive buffer-empty state diagram

65.2.3.6.3 FEC_uncorrected_Blocks_counter

32-bit counter. FEC_uncorrected_blocks_counter counts once for each uncorrected FEC blocks in the decoding. This variable is provided by a management interface that may be mapped to the 45.2.10.6 register (29.11.15:0).

65.3 Extensions to PMA for 1000BASE-PX

In addition to the requirements defined in Clause 36, P2MP operation imposes the following requirement on the PMA sublayer of the OLT and ONU.

65.3.1 Extensions for 1000BASE-PX-U

65.3.1.1 Physical Medium Attachment (PMA) sublayer interfaces

In addition to the primitives of Clause 36, the following primitive is defined:

PMD_SIGNAL.request(tx_enable)

This primitive controls PMD emission of light. It is generated by the PCS's data detector (see 65.2.2.2.3) and the effect of its receipt is defined in 60.1.5.3. This primitive is received from the PCS and passed in timely fashion and without modification to the PMD. It takes the following parameter:

tx_enable The tx_enable parameter can take one of two values, ON or OFF.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

65.3.1.2 Loop-timing specifications for ONUs

ONUs shall operate at the same time basis as the OLT, i.e., the ONU TX clock tracks the ONU RX clock. Jitter transfer masks are defined in 60.8.

65.3.2 Extensions for 1000BASE-PX-D

65.3.2.1 CDR lock timing measurement

A PMA instantiated in an OLT becomes synchronized at the bit level within 400 ns (T_{CDR}) and code-group level within an additional 32 ns ($T_{code_group_alignment}$) of the appearance of a valid 1000BASE-X IDLE pattern at TP4 when the PMA_TX_CLK frequency is equal to twice the PMA_RX_CLK frequency.

65.3.2.1.1 Definitions

CDR Lock Time (denoted T_{CDR}) is defined as a time interval required by the receiver to acquire phase and frequency lock on the incoming data stream. T_{CDR} is measured as the time elapsed from the moment when electrical signal after the PMD at TP4 reaches the conditions specified in 60.9.13.2.1 for receiver settling time to the moment when the phase and frequency are recovered and jitter is maintained for a network with BER of no more than 10^{-12} for non-FEC systems, or no more than 10^{-4} for FEC enabled systems.

The combined value of measured T_{CDR} and $T_{code_group_alignment}$ shall not exceed 432 ns.

65.3.2.1.2 Test specification

Figure 60–2 illustrates the tests setup for the OLT PMA receiver (upstream) T_{CDR} time. The test assumes that there is an optical PMD transmitter at the ONU with well known parameters, having a fixed known T_{on} time as defined in 60.9.13.1, and an optical PMD receiver at the OLT with well-known parameters, having a fixed known $T_{receiver_settling}$ time as defined in 60.9.13.2. After $T_{on} + T_{receiver_settling}$ time the parameters at TP4 reach within 15% of their steady state values.

Measure T_{CDR} as the time from the tx_enable assertion, minus the known $T_{on} + T_{receiver_settling}$ time, to the time the electrical signal at the output of the PMA reaches up to phase difference from the input signal of the transmitting PMA, assuring BER of 10^{-12} for non-FEC systems, or BER of 10^{-4} for FEC enabled systems, and maintaining its jitter specifications. The signal throughout this test, is the 1000BASE-X IDLE pattern.

A non-rigorous way to describe this test setup would be (using a transmitter PMD at the ONU, with a known T_{on} time and a receiver PMD at the OLT, with a known $T_{receiver_settling}$ time):

For a tested PMA receiver with a declared T_{CDR} time, measure the phase and jitter of the recovered PMA receiver signal after T_{CDR} time from the tx_enable trigger minus the reference $T_{on} + T_{receiver_settling}$ time, ensuring synchronization to the ONU PMA input signal and conformance to the specified steady state phase, frequency, and jitter values for BER of 10^{-12} for non-FEC systems, or BER of 10^{-4} for FEC enabled systems.

65.3.3 Delay variation requirements

The MPCP relies on strict timing based on the distribution of timestamps. The actual delay is implementation dependent but an implementation shall maintain a combined delay variation through RS, PCS, and PMA sublayers of no more than 16 bit times so as to comply with this mechanism.

65.4 Protocol implementation conformance statement (PICS) proforma for Clause 65, Extensions of the Reconciliation Sublayer (RS) and Physical Coding Sublayer (PCS)/Physical Media Attachment (PMA) for 1000BASE-X for multipoint links and forward error correction[127]

65.4.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 65, Extensions of the Reconciliation Sublayer (RS) and Physical Coding Sublayer (PCS)/Physical Media Attachment (PMA) for 1000BASE-X for multipoint links and forward error correction, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

65.4.2 Identification

65.4.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

65.4.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 65, Extensions of the Reconciliation Sublayer (RS) and Physical Coding Sublayer (PCS)/Physical Media Attachment (PMA) for 1000BASE-X for multipoint links and forward error correction
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)

66. Extensions of the 10 Gb/s Reconciliation Sublayer (RS), 100BASE-X PHY, and 1000BASE-X PHY for unidirectional transport

In the absence of unidirectional operation, the sublayers in this clause are precisely the same as their equivalents in Clause 24, Clause 36, and Clause 46. Otherwise, this clause describes additions and modifications to the 100BASE-X, 1000BASE-X, 10GBASE-R, 10GBASE-W, and 10GBASE-X Physical Layers, making them capable of unidirectional operation, which is required to initialize a 1000BASE-PX network, and allows the transmission of Operations, Administration and Management (OAM) frames regardless of whether the PHY has determined that a valid link has been established.

However, unidirectional operation may only be enabled under very limited circumstances. Before enabling this mode, the MAC shall be operating in full-duplex mode and Auto-Negotiation, if applicable, shall be disabled. In addition, the OAM sublayer above the MAC (see Clause 57) shall be present and enabled or (for 1000BASE-X), the PCS shall be part of a 1000BASE-PX-D PHY (see Clause 60 and Clause 64). Unidirectional operation shall not be invoked for a PCS that is part of a 1000BASE-PX-U PHY (except for out-of-service test purposes or where the PON contains just one ONU). Failure to follow these restrictions results in an incompatibility with the assumptions of IEEE 802.1 protocols, a PON that cannot initialize, or collisions, which are unacceptable in the P2MP protocol.

66.1 Modifications to the physical coding sublayer (PCS) and physical medium attachment (PMA) sublayer, type 100BASE-X

66.1.1 Overview

This subclause specifies the 100BASE-X PCS and PMA for support of subscriber access networks.

66.1.2 Functional specifications

The 100BASE-X PCS and PMA for subscriber access networks shall conform to the requirements of the 100BASE-X PCS specified in 24.2 and the 100BASE-X PMA specified in 24.3 with the following exception: The 100BASE-X PCS for subscriber access networks may have the ability to transmit data regardless of whether the PHY has determined that a valid link has been established. The following are the detailed changes to Clause 24 in order to support this additional ability.

66.1.2.1 Variables

Insert a new variable among those already described in 24.2.3.2:

mr_unidirectional_enable
: A control variable that enables the unidirectional mode of operation. This variable is provided by a management interface that may be mapped to the Clause 22 Control register Unidirectional enable bit (0.5).

  Values: FALSE; Unidirectional capability is not enabled
  TRUE; Unidirectional capability is enabled

66.1.2.2 Transmit state diagram

The description of the transmit state diagram is changed to include the contribution of the new mr_unidirectional_enable variable. The third paragraph of 24.2.4.2 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

> The indication of link_status ≠ OK by the ~~PMA at any time~~ PMA, when mr_unidirectional_enable = FALSE, causes an immediate transition to the IDLE state and supersedes any other Transmit process operations. When mr_unidirectional_enable = TRUE, the Transmit process ignores the value of link_status. This enables the ability to transmit data from the MII when link_status ≠ OK.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Additionally, the functionality of Figure 24–13 shall be changed as represented by Figure 66–1.

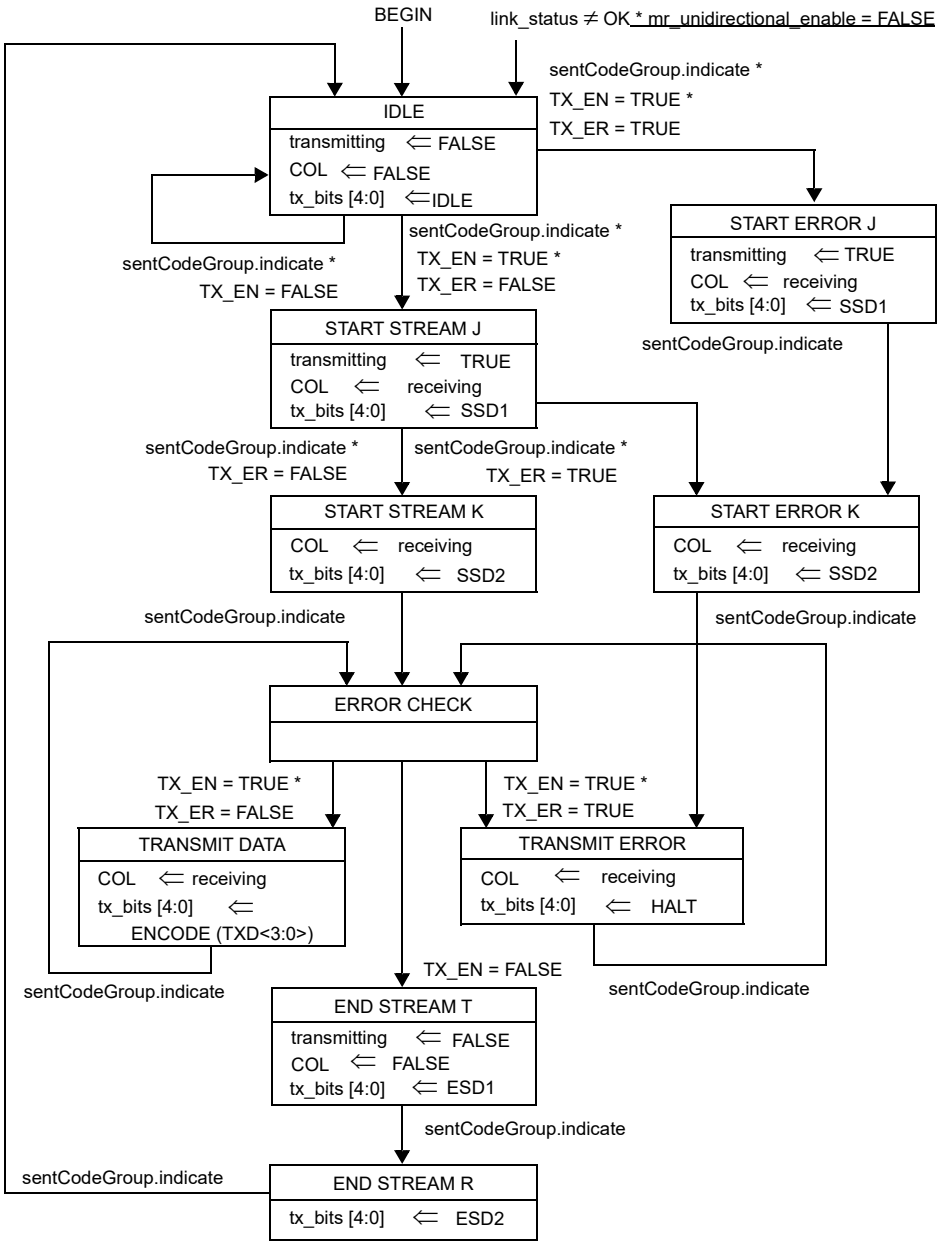

Figure 66–1—Transmit state diagram

66.1.2.3 Far-end fault generate

The description of the far-end fault generate state diagram is also changed to include the contribution of the new mr_unidirectional_enable variable. The first paragraph of 24.3.4.5 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

> Far-End Fault Generate simply passes tx_code-bits to the TX process when signal_status=ON or when mr_unidirectional_enable=TRUE. When signal_status=OFF and mr_unidirectional_enable=FALSE, it repetitively generates each cycle of the Far-End Fault Indication until signal_status is reasserted or mr_unidirectional_enable is set to TRUE.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Additionally, the functionality of Figure 24–16 shall be changed as represented by Figure 66–2.

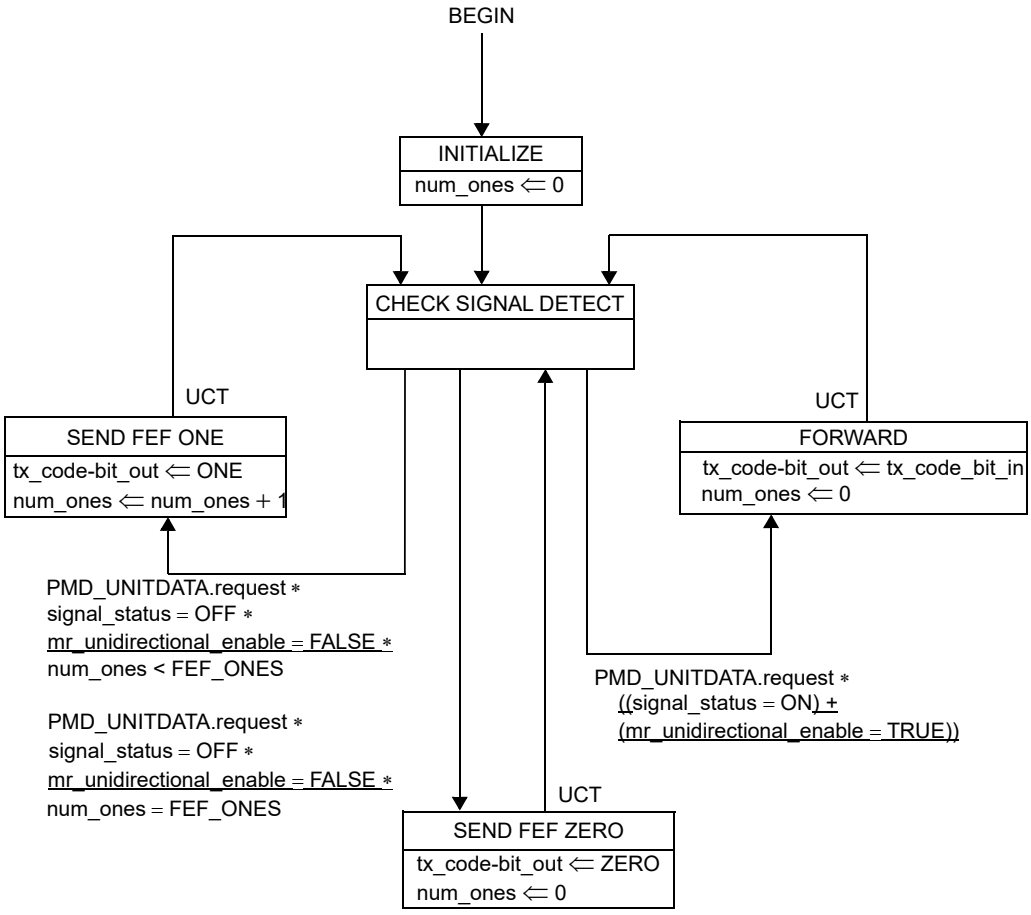

Figure 66–2—Far-End Fault Generate state diagram

66.2 Modifications to the physical coding sublayer (PCS) and physical medium attachment (PMA) sublayer, type 1000BASE-X

66.2.1 Overview

This subclause specifies the 1000BASE-X PCS and PMA for support of subscriber access networks.

66.2.2 Functional specifications

The 1000BASE-X PCS for subscriber access networks shall conform to the requirements of the 1000BASE-X PCS specified in 36.2 with the following exception: The 1000BASE-X PCS for subscriber access networks may have the ability to transmit data regardless of whether the PHY has determined that a valid link has been established. The 1000BASE-X PMA for subscriber access networks shall conform to the requirements of the 1000BASE-X PMA specified in 36.3 with no changes. The following are the detailed changes to Clause 36 in order to support this additional ability.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

66.2.2.1 Variables

Insert a new variable among those already described in 36.2.5.1.3:

mr_unidirectional_enable

A control variable that enables the unidirectional mode of operation. This variable is provided by a management interface that may be mapped to the Clause 22 Control register Unidirectional enable bit (0.5).

Values: FALSE; Unidirectional capability is not enabled
TRUE; Unidirectional capability is enabled

Additionally, modify the existing xmit variable from 36.2.5.1.3 as follows (~~strikethroughs~~ show deleted text and underscores show inserted text):

xmit

When mr_unidirectional_enable=FALSE, xmit is d~~D~~efined in 37.3.1.1. When mr_unidirectional_enable=TRUE, xmit always takes the value DATA.

66.2.2.2 Transmit

The description of the transmit state diagram is changed to include the contribution of the new mr_unidirectional_enable variable. The second paragraph of 36.2.5.2.1 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

The Transmit ordered set process continuously sources ordered sets to the Transmit code-group process. When mr_unidirectional_enable = TRUE, the Auto-Negotiation process xmit flag always takes the value DATA and the Auto-Negotiation process is never invoked. Otherwise, when initially invoked, and when the Auto-Negotiation process xmit flag indicates CONFIGURATION, the Auto-Negotiation process is invoked. When the Auto-Negotiation process xmit flag indicates IDLE, and between packets (as delimited by the GMII), /I/ is sourced. Upon the assertion of TX_EN by the GMII when the Auto-Negotiation process xmit flag indicates DATA, the SPD ordered set is sourced. Following the SPD, /D/ code-groups are sourced until TX_EN is deasserted. Following the de-assertion of TX_EN, EPD ordered sets are sourced. If TX_ER is asserted when TX_EN is deasserted and carrier extend error is not indicated by TXD, /R/ ordered sets are sourced for as many GTX_CLK periods as TX_ER is asserted with a delay of two GTX_CLK periods to first source the /T/ and /R/ ordered sets. If carrier extend error is indicated by TXD during carrier extend, /V/ ordered sets are sourced. If TX_EN and TX_ER are both de-asserted, the /R/ ordered set may be sourced, after which the sourcing of /I/ is resumed. If, while TX_EN is asserted, the TX_ER signal is asserted, the /V/ ordered set is sourced except when the SPD ordered set is selected for sourcing.

66.2.2.3 Transmit state diagram

The 1000BASE-X PCS for subscriber access networks shall implement the transmit process as depicted in Figure 36–5 and Figure 36–6, including compliance with the associated state variables as specified in 36.2.5.1 and as modified in 66.2.2.1.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

66.3 Modifications to the reconciliation sublayer (RS) for P2P 10 Gb/s operation

66.3.1 Overview

This subclause specifies the 10 Gb/s RS for support of P2P subscriber access networks.

66.3.2 Functional specifications

The 10 Gb/s RS for subscriber access networks shall conform to the requirements of the 10 Gb/s RS specified in Clause 46 with the following exception: The 10 Gb/s RS for subscriber access networks may have the ability to transmit data regardless of whether the PHY has determined that a valid link has been established. The following are the detailed changes to Clause 46 in order to support this additional ability.

66.3.2.1 Link fault signaling

The description of the link fault signaling functional specification is changed to include the contribution of the new mr_unidirectional_enable variable. The second paragraph of 46.3.4 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

> Sublayers within the PHY are capable of detecting faults that render a link unreliable for communication. Upon recognition of a fault condition a PHY sublayer indicates Local Fault status on the data path. When this Local Fault status reaches an RS, the RS tests the unidirectional_enable variable. If this variable is FALSE, the RS stops sending MAC data, and continuously generates a Remote Fault status on the transmit data path (possibly truncating a MAC frame being transmitted). If this variable is TRUE, the RS continues to allow the transmission of MAC data but replaces IPG with a Remote Fault status. When Remote Fault status is received by an RS, the RS tests the unidirectional_enable variable. If this variable is FALSE, the RS stops sending MAC data, and continuously generates Idle control characters. If this variable is TRUE, the RS continues to allow the transmission of MAC data. When the RS no longer receives fault status messages, it returns to normal operation, sending MAC data.

66.3.2.2 Variables

Insert a new variable among those already described in 46.3.4.2:

unidirectional_enable

A control variable that enables the unidirectional mode of operation.

Values: FALSE; Unidirectional capability is not enabled
TRUE; Unidirectional capability is enabled

66.3.2.3 State diagram

The description of what the RS outputs onto TXC<3:0> and TXD<31:0> is changed to include the contribution of the new mr_unidirectional_enable variable. The lettered list of 46.3.4.3 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

a) link_fault = OK
The RS shall send MAC frames as requested through the PLS service interface. In the absence of MAC frames, the RS shall generate Idle control characters.

b) link_fault = Local Fault
If unidirectional_enable=FALSE, t~~T~~he RS shall continuously generate Remote Fault Sequence ordered sets.
If unidirectional_enable=TRUE, the RS shall send MAC frames as requested through the PLS service interface. After a MAC frame and before transition to generation of Remote Fault Sequence

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

the RS shall ensure a column of idles has been sent. In the absence of MAC frames, the RS shall generate Remote Fault Sequence ordered sets.

c) link_fault = Remote Fault
If unidirectional_enable=FALSE, t~~T~~he RS shall continuously generate Idle control characters.
If unidirectional_enable=TRUE, the RS shall send MAC frames as requested through the PLS service interface. In the absence of MAC frames, the RS shall generate Idle control characters.

66.4 Modifications to the RS for P2MP 10 Gb/s operation

66.4.1 Overview

This subclause specifies the 10 Gb/s RS for support of P2MP subscriber access networks.

66.4.2 Functional specifications

The 10 Gb/s RS for P2MP subscriber access networks shall conform to the requirements of the 10 Gb/s RS specified in Clause 46 with the following exception: The 10 Gb/s RS for P2MP subscriber access networks may have the ability to transmit data regardless of whether the PHY has determined that a valid link has been established. The following are the detailed changes to Clause 46 in order to support this additional ability.

66.4.2.1 Link fault signaling

The description of the link fault signaling functional specification is changed to include the contribution of the new unidirectional_enable variable. The second paragraph of 46.3.4 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

Sublayers within the PHY are capable of detecting faults that render a link unreliable for communication. The nature of the P2MP link allows for some of these fault conditions to be ignored. Upon recognition of a fault condition a PHY sublayer indicates Local Fault status on the data path. When this Local Fault status reaches an RS, the RS tests the unidirectional_enable variable. If this variable is FALSE, the RS stops sending MAC data, and continuously generates ~~a Remote Fault status~~ Idle control characters on the transmit data path (possibly truncating a MAC frame being transmitted). If this variable is TRUE, the RS continues to allow the transmissions of MAC data. When Remote Fault status is received by an RS, the RS tests the unidirectional_enable variable. If this variable is FALSE, the RS stops sending MAC data, and continuously generates Idle control characters. If this variable is TRUE, the RS continues to allow the transmission of MAC data. When the RS no longer receives fault status messages, it returns to normal operation, sending MAC data.

66.4.2.2 Variables

Insert a new variable among those already described in 46.3.4.2:

unidirectional_enable
A control variable that enables the unidirectional mode of operation.
Values:FALSE; Unidirectional capability is not enabled
TRUE; Unidirectional capability is enabled

66.4.2.3 State diagram

The description of what the RS outputs onto TXC<3:0> and TXD<31:0> is changed to include the contribution of the new unidirectional_enable variable. The lettered list of 46.3.4.3 is changed to read (~~strikethroughs~~ show deleted text and underscores show inserted text):

66.5 Protocol implementation conformance statement (PICS) proforma for Clause 66, Extensions of the 10 Gb/s Reconciliation Sublayer (RS), 100BASE-X PHY, and 1000BASE-X PHY for unidirectional transport[128]

66.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 66, Extensions of the 10 Gb/s Reconciliation Sublayer (RS), 100BASE-X PHY, and 1000BASE-X PHY for unidirectional transport, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

66.5.2 Identification

66.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

66.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 66, Extensions of the 10 Gb/s Reconciliation Sublayer (RS), 100BASE-X PHY, and 1000BASE-X PHY for unidirectional transport

67. System considerations for Ethernet subscriber access networks

67.1 Overview

This clause provides information on building Ethernet subscriber access networks, also referred to as "Ethernet in the First Mile" or EFM networks.

EFM encompasses a family of technologies that vary in media type and signaling speed. EFM is designed to be deployed in networks of one or multiple EFM media type(s) as well as interact with mixed 10/100/1000/10000 Mb/s Ethernet networks. Any network topology defined in IEEE Std 802.3 can be used within the subscriber premises and then connected to an Ethernet subscriber access network via an IEEE Std 802.1Q compliant bridge, or a router.

Further, within a given EFM domain, the specific EFM technologies allow for a variety of topologies affording the subscriber access network maximum flexibility. For example, a 1000BASE-PX10 P2MP system with 16 ONUs can be built with a 1:16 splitter or as a tree-and-branch network utilizing more than one splitter.

The design of multiple-domain networks is governed by the rules defining each of the transmission systems incorporated into the design. The physical size of a network is limited by the characteristics of individual network components. These characteristics include the media lengths and type.

Table 67–1 summarizes the various EFM media characteristics.

Table 67–1—Characteristics of the various EFM network media segments

Media type	Rate	Number of PHYs per segment	Nominal reach (km)
Optical 100 Mb/s fiber segment (100BASE-LX10, 100BASE-BX10)	100 Mb/s	2	10
Optical 1000 Mb/s fiber segment (1000BASE-LX10, 1000BASE-BX10)	1 Gb/s	2	10
Optical 1000 Mb/s P2MP segment (1000BASE-PX10)	1 Gb/s[a]	17[b,c]	10
Optical 1000 Mb/s P2MP segment (1000BASE-PX20)		17[b,c]	20
Optical 1000 Mb/s P2MP segment (1000BASE-PX30)		33[b,c]	20
Optical 1000 Mb/s P2MP segment (1000BASE-PX40)		65[b,c]	20
Optical 10/1 Gb/s P2MP segment (10/1GBASE-PRX10)	10 / 1 Gb/s[d]	17[b,c]	10
Optical 10/1 Gb/s P2MP segment (10/1GBASE-PRX20)		17[b,c]	20
Optical 10/1 Gb/s P2MP segment (10/1GBASE-PRX30)		33[b,c]	20
Optical 10/1 Gb/s P2MP segment (10/1GBASE-PRX40)		65[b,c]	20

Table 67–1—Characteristics of the various EFM network media segments *(continued)*

Media type	Rate	Number of PHYs per segment	Nominal reach (km)
Optical 10 Gb/s P2MP segment (10GBASE-PR10)	10 Gb/s[e]	17[b,c]	10
Optical 10 Gb/s P2MP segment (10GBASE-PR20)		17[b,c]	20
Optical 10 Gb/s P2MP segment (10/1GBASE-PR30)		33[b,c]	20
Optical 10 Gb/s P2MP segment (10GBASE-PR40)		65[b,c]	20
Copper high-speed segment (10PASS-TS)	10 Mb/s[f]	2	0.75
Copper long reach segment (2BASE-TL)	2 Mb/s[c]	2	2.7
EPoC coaxial segment (10GPASS-XR)	Up to 10 Gb/s downstream	variable[g]	2.9[h]
	Up to 1.6 Gb/s upstream	variable[g]	2.9[h]
Optical Nx25-EPON P2MP segment (50/50-PQ20*, 50/25-PQ20*, 25/25-PQ20*) [i]	50 / 50 Gb/s [j] 50 / 25 Gb/s 25 / 25 Gb/s	17[b,c]	20
		33[b,c]	10
Optical Nx25-EPON P2MP segment (50/10-PQ20*, 25/25-PQ20*) [i]	50 / 10 Gb/s [j] 25 / 10 Gb/s	17[b,c]	20
		33[b,c]	10
Optical Nx25-EPON P2MP segment (50/50-PQ30*, 50/25-PQ30*, 25/25-PQ30*) [i]	50 / 50 Gb/s [j] 50 / 25 Gb/s 25 / 25 Gb/s	33[b,c]	20
Optical Nx25-EPON P2MP segment (50/10-PQ30*, 25/25-PQ30*) [i]	50 / 10 Gb/s [j] 25 / 10 Gb/s	33[b,c]	20

[a]1 Gb/s in downstream direction, 1 Gb/s in upstream direction.
[b]P2MP segments may be implemented with a trade off between link span and split ratio listed. Refer to 67.2.1.
[c]The number of PHYs in the P2MP segment includes the OLT PHY.
[d]10 Gb/s in downstream direction, 1 Gb/s in upstream direction (asymmetric data rate in 10/1G-EPON).
[e]10 Gb/s in downstream direction, 10 Gb/s in upstream direction (symmetric data rate in 10/10G-EPON).
[f]Nominal rate stated at the nominal reach in this table. Rate and reach can vary depending on the plant. For 2BASE-TL please refer to Annex 63B for more information. For 10PASS-TS, please refer to Annex 62A for more information.
[g] Based on the cable operator's CCDN configuration, the number of PHYs will be the CLT PHY plus each CNU PHY.
[h] Maximal differential distance between CNUs. Reach may vary depending on the CCDN.
[i]For brevity, the two Nx25G-EPON PMD coexistence class designators "X" and "G" have been abbreviated in this table with an asterisk ("*") as they are equivalent with respect to rate, number of PHYs per segment, and nominal reach (see 141.1.3 and 141.2.5).
[j]For Nx25G-EPON possible downstream rates are either 25 Gb/s or 50 Gb/s and possible upstream rates are 10 Gb/s, 25 Gb/s, or 50 Gb/s. The format shown in the table is the downstream rate followed by a forward slash ("/") followed by the upstream rate (see 141.2.2).

67.2 Discussion and examples of EFM P2MP topologies

This subclause discusses EFM P2MP topologies. For P2MP PON architecture, this subclause details flexibility of trading off split ratio for link span. This subclause also shows some examples of different P2MP PON topologies.

67.2.1 Trade off between link span and split ratio for P2MP PON architecture

While the P2MP PON PMDs are nominally described in terms of a link span of either 10 km or 20 km with a 1:16 split ratio, other link spans and split ratios can be implemented provided that the requirements of Table 60–1 are met.

67.2.2 Single splitter topology for P2MP PON architecture

A P2MP PON topology implemented with a single optical splitter is shown in Figure 67–1.

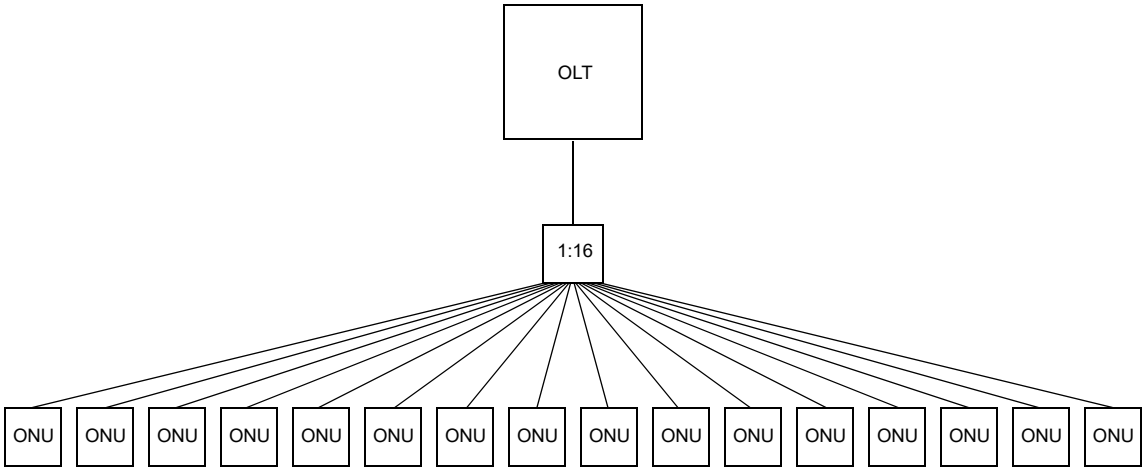

Figure 67–1—Single splitter topology

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

67.2.3 Tree-and-branch topology for P2MP PON architecture

A P2MP PON topology implemented with a tree-and-branches of optical splitters is shown in Figure 67–2.

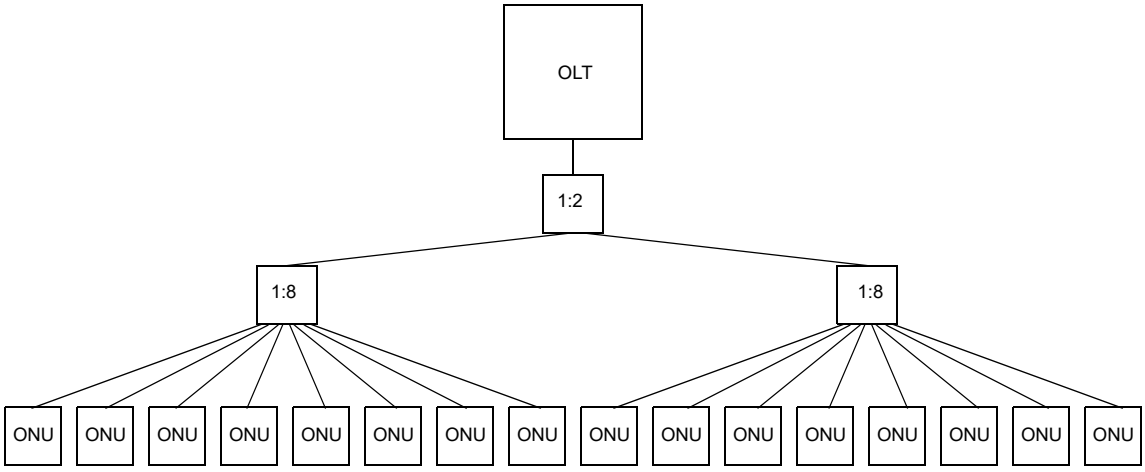

Figure 67–2—Tree-and-branch topology

67.2.4 Interoperability between certain 1000BASE-PX10 and 1000BASE-PX20

1000BASE-PX20-D PMD is interoperable with a 1000BASE-PX10-U PMD, this allows certain upgrade possibilities from 10 km to 20 km P2MP networks.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

67.3 Hybrid media topologies

Hybrid media topologies, such as those shown in Figure 67–3, can be implemented using a combination of P2P or P2MP optical links and copper links.

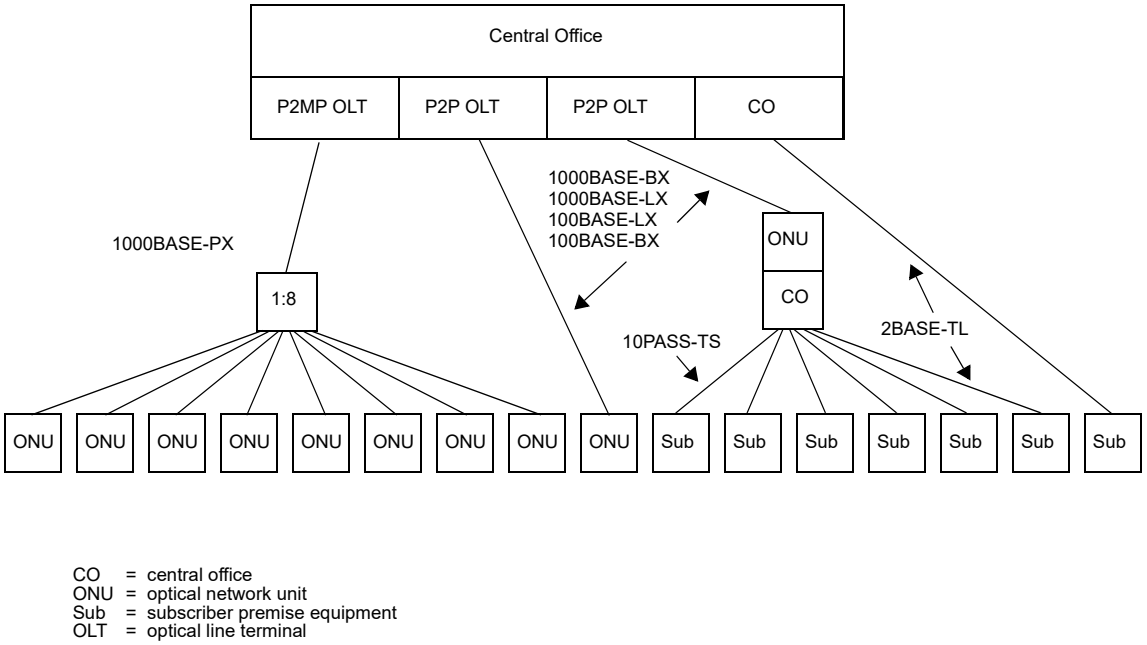

Figure 67–3—Hybrid media topologies

67.4 Topology limitations

The physical size of EFM networks is not limited by the round-trip collision propagation delay. Instead, the maximum link length between DTEs is limited by the signal transmission characteristics of the specific link.

67.5 Deployment restrictions for subscriber access copper

10PASS-TS and 2BASE-TL PHYs have been specified to allow deployment on public access networks. Non-loaded cable is a requirement of the signaling methods employed. The 10PASS-TS do not preclude coexistence with POTS. However, it is important that systems are designed and configured to comply with all appropriate regulatory, governmental and regional requirements. Refer to Annex 62A (10PASS-TS) and Annex 63A (2PASS-TL) for further information regarding configuration profiles.

67.6 Operations, Administration, and Maintenance

All P2P and emulated P2P links, including all of the EFM network media segments, support the optional OAM sublayer as defined in Clause 57. 2BASE-TL and 10PASS-TS PHYs do not support unidirectional links as defined in 57.2.6 (see 61.1).

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

67.6.1 Unidirectional links

Some Physical Layer devices have the optional ability to encode and transmit data while one direction of the link is non-operational.

This ability should be used only when the OAM sublayer is present and enabled or for a 1000BASE-PX-D, 10/1GBASE-PRX, 10GBASE-PR PHY, or 10GPASS-XR-D PHY. Otherwise, MAC Client frames will be sent across a unidirectional link potentially causing havoc with bridge and other higher layer protocols. The feature should not be enabled for 1000BASE-PX-U, 10/1GBASE-PRX-U, 10GBASE-PR-U PHYs, or 10GPASS-XR-U PHYs in service, to avoid simultaneous transmission by more than one ONU or CNU.

67.6.2 Active and Passive modes

A device may be configured to be in either Active or Passive OAM mode. At least one end of a given link is required to be in Active mode.

In an access network, customer premises devices will commonly be configured as Passive devices. All other devices in an access network will commonly be configured as Active devices. For a detailed description of Active and Passive mode, refer to 57.2.6.

67.6.3 Link status signaling in P2MP networks

In P2MP networks the local_link_status parameter should reflect the status of a logical link associated with the underlying instance of Multipoint MAC Control. This is achieved by mapping the local_link_status parameter to variable 'registered' defined in 64.3.3.2 for 1G-EPON links, in 77.3.3.2 for 10G-EPON links, and in 103.3.3.2 for EPoC links as follows:

local_link_status = OK if registered = true

local_link_status = FAIL if registered = false

68. Physical medium dependent (PMD) sublayer type 10GBASE-LRM

68.1 Overview

This clause specifies the 10GBASE-LRM PMD and the associated multimode fiber media. In order to form a complete Physical Layer, the PMD is combined with the sublayers appropriate for 10GBASE-R, as specified in Table 52–2, and optionally with the management functions that may be accessible through the management interface defined in Clause 45.

Figure 68–1 depicts the relationships of the PMD (shown hatched) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model. Clause 44 contains an introduction to 10 Gigabit Ethernet and the relationship of the 10GBASE-LRM PMD to other sublayers. Further relevant information may be found in Clause 1 (i.e., terminology and conventions, references, definitions and abbreviations) and Annex A (i.e., bibliography, entries referenced here in the format [B*n*]).

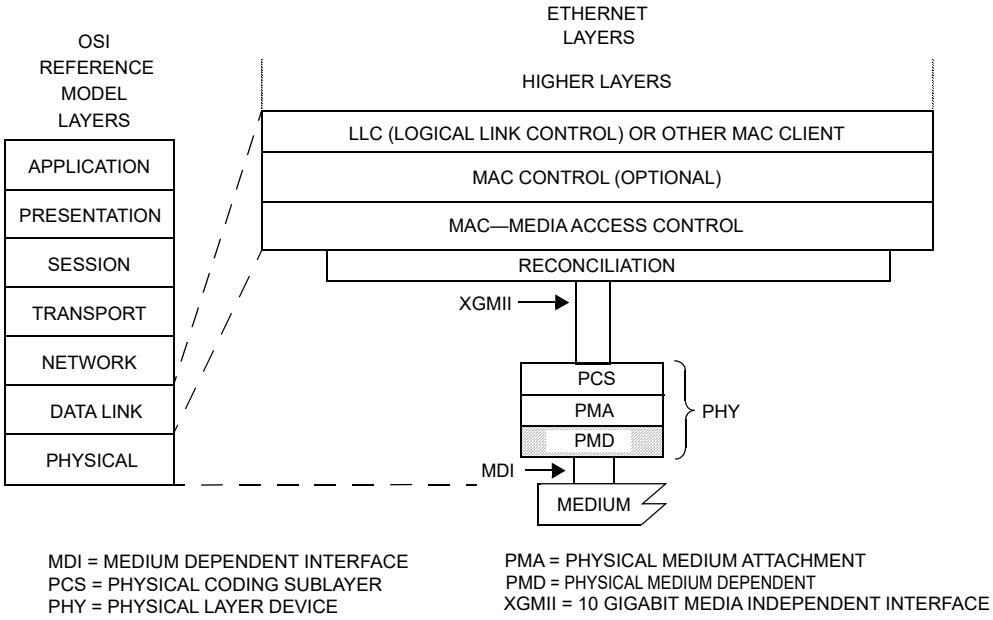

Figure 68–1—10GBASE-LRM PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

68.1.1 Physical Medium Dependent (PMD) sublayer service interface

The PMD service interface is the 10GBASE-R PMD service interface as described in 52.1.1.

68.2 Delay constraints

An upper bound to the delay through the PMA and PMD is required for predictable operation of the MAC Control PAUSE operation. The PMA and PMD shall incur a round-trip delay (transmit and receive) of not more than 9216 bit times, or 18 pause_quanta, while including two meters of fiber. A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 44.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

68.3 PMD MDIO function mapping

If present, the 10GBASE-LRM PMD MDIO function mapping shall be as specified in 52.3.

68.4 PMD functional specifications

The 10GBASE-LRM PMD performs the transmit and receive functions that convey data between the PMD service interface and the MDI.

68.4.1 PMD block diagram

For the purposes of system conformance, the PMD sublayer is standardized at test points TP2 and TP3, as shown in Figure 68–2. The optical transmit signal is defined at the output end of a patch cord (TP2), of between 2 m and 5 m in length. The optical launch condition at TP2 is either the preferred launch or the alternative launch (at the user's choice), as specified in 68.5.1. A compliant PMD shall support both options. The launch is selected by using either a single-mode fiber offset-launch mode-conditioning patch cord or a regular multimode fiber patch cord inserted between the MDI and TP2, consistent with the media type. Unless specified otherwise, all transmitter measurements and tests defined in 68.6 are made at TP2. The optical receive signal is defined at the output of the fiber optic cabling (TP3) that is the input to the MDI of the optical receiver. Unless specified otherwise, for all receiver measurements and tests defined in 68.6, the test stimulus is applied at TP3.

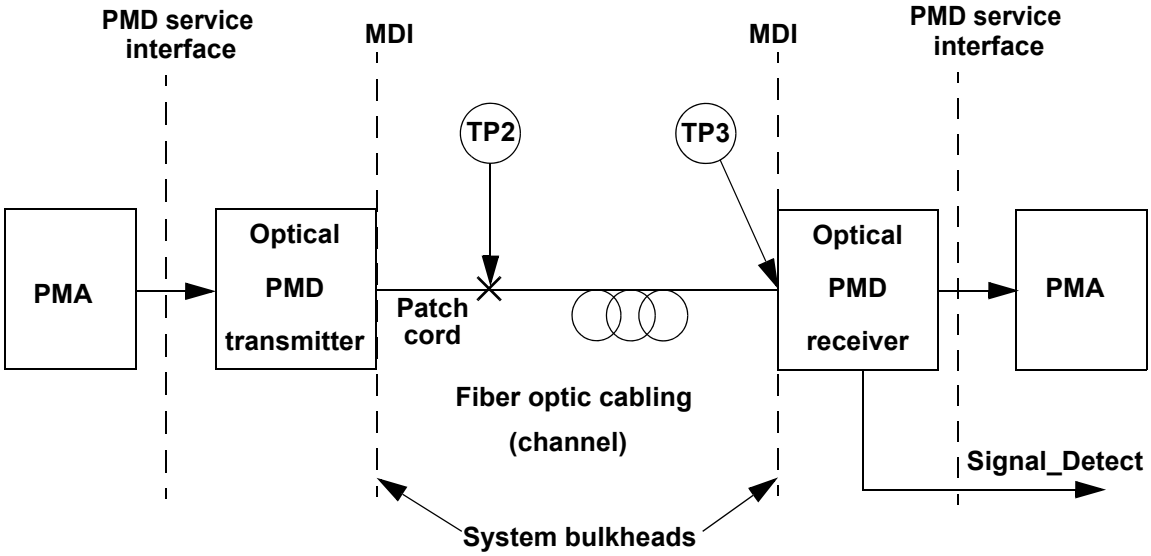

Figure 68–2—Block diagram

68.4.2 PMD transmit function

The PMD transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the optical specifications in this clause. The higher optical power level shall correspond to tx_bit = ONE.

68.4.3 PMD receive function

The PMD receive function shall convey the bits received from the MDI according to the optical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher optical power level shall correspond to rx_bit = ONE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

68.4.4 PMD signal detect function

The PMD signal detect function shall report to the PMD service interface using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence. If the MDIO interface is implemented, then PMD_global_signal_detect (1.10.0) shall be continuously set to the value of SIGNAL_DETECT as described in 45.2.1.9.7.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 68–1. The PMD receiver is not required to verify whether a compliant 10GBASE-R signal is being received. This standard imposes no response time requirements on the generation of the SIGNAL_DETECT parameter.

Table 68–1—SIGNAL_DETECT value definition

Receive conditions	SIGNAL_DETECT value
Input average power < –30 dBm	FAIL
Compliant 10GBASE-R input signal with optical power in OMA > stressed sensitivity in OMA in Table 68–5	OK
All other conditions	Unspecified

As a consequence of the requirements for the setting of the SIGNAL_DETECT parameter, implementations need to provide adequate margin between the optical power level at which the SIGNAL_DETECT parameter is set to OK, and the inherent noise level of the PMD due to crosstalk, power supply noise, etc.

Various implementations of the signal detect function are permitted, including implementations that generate the SIGNAL_DETECT parameter values in response to the amplitude of the modulation of the received optical signal and implementations that respond to the average power of the received optical signal.

68.4.5 PMD_reset function

If the MDIO interface is implemented, and if PMD_reset is asserted, the PMD shall be reset as specified in 45.2.1.1.1.

68.4.6 PMD_fault function

If the MDIO is implemented, PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation-specific fault.

68.4.7 PMD_global_transmit_disable function

The PMD_global_transmit_disable function is optional. When asserted, this function shall turn off the optical transmitter so that it meets the requirements of the average launch power of OFF transmitter in Table 68–3.

If a PMD_transmit_fault (optional) is detected, then the PMD_global_transmit_disable function should also be asserted.

If the MDIO interface is implemented, then this function shall map to the PMD_global_transmit_disable bit as specified in 45.2.1.8.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

68.4.8 PMD_transmit_fault function

The PMD_transmit_fault function is optional. The faults detected by this function are implementation specific, but should not include the assertion of the PMD_global_transmit_disable function.

If a PMD_transmit_fault (optional) is detected, then the PMD_global_transmit_disable function should also be asserted.

If the MDIO interface is implemented, then this function shall be mapped to the PMD_transmit_fault bit as specified in 45.2.1.7.4.

68.4.9 PMD_receive_fault function

The PMD_receive_fault function is optional. PMD_receive_fault is the logical OR of NOT SIGNAL_DETECT and any implementation-specific fault.

If the MDIO interface is implemented, then this function shall contribute to the PMA/PMD receive fault bit as specified in 45.2.1.7.5.

68.5 PMD to MDI optical specifications

The operating ranges for 10GBASE-LRM are given in Table 68–2. A PMD that exceeds the operational range requirements given in this clause, while meeting all other specifications, is considered compliant.

Table 68–2—10GBASE-LRM fiber types and operating ranges

Multimode fiber type[a]	ISO/IEC 11801:2002 fiber type	Operating range (m)	Maximum channel insertion loss (dB)[b]
62.5 μm 160/500[c]		0.5 to 220	1.9
62.5 μm 200/500	OM1	0.5 to 220	1.9
50 μm 500/500	OM2	0.5 to 220	1.9
50 μm 400/400		0.5 to 100	1.7
50 μm 1500/500[d]	OM3	0.5 to 220	1.9

[a]Each fiber type is identified by its core diameter followed by a pair of OFL bandwidth values separated by "/". The OFL bandwidths are in MHz · km and are for 850 nm and 1300 nm respectively.
[b]Channel insertion loss includes cabled optical fiber attenuation and an allocation of 1.5 dB for connectors.
[c]160/500, 62.5 μm fiber is commonly referred to as "FDDI-grade" fiber.
[d]The OM3 fiber specification includes the 850 nm laser launch bandwidth in addition to the OFL bandwidths.

68.5.1 Transmitter optical specifications

The 10GBASE-LRM transmitter shall meet the specifications given in Table 68–3 and Figure 68–3, per definitions in 68.6.

68.5.2 Characteristics of signal within, and at the receiving end of, a compliant 10GBASE-LRM channel

Table 68–4 gives the characteristics of a signal within, and at the receiving end of, a compliant 10GBASE-LRM channel. A signal with power in OMA and average power not within the ranges given cannot be compliant. However, a signal with power values within the ranges is not necessarily compliant.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

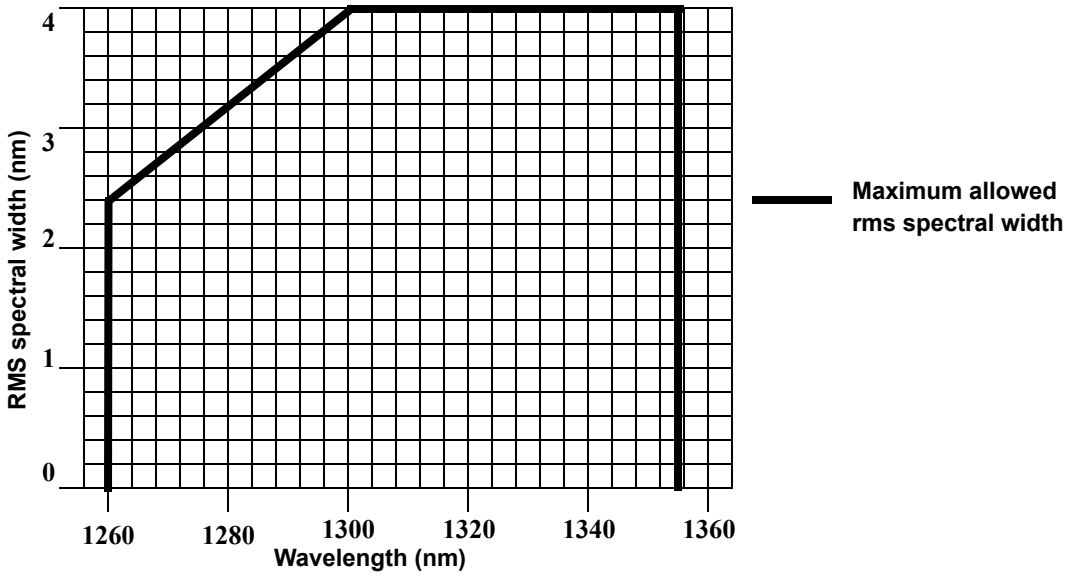

Figure 68–3—10GBASE-LRM Transmitter spectral limits

68.5.3 Receiver optical specifications

The 10GBASE-LRM receiver shall meet the specifications given in Table 68–5, per definitions in 68.6.

68.5.3.1 Dynamic response

Channel responses are expected to vary with time at rates of up to 10 Hz. It is highly recommended that receivers tolerate such time varying channel responses.

68.6 Definitions of optical parameters and measurement methods

The following definitions and measurement methods apply to the transmitter and receiver optical parameters given in Table 68–3 and Table 68–5.

68.6.1 Test patterns and related subclauses for optical parameters

Compliance is to be achieved in normal operation. Table 68–6 gives the test patterns to be used in each measurement, unless otherwise specified, and also lists references to the subclauses in which each parameter is defined. The test patterns include pattern 1, pattern 2, pattern 3, and square waves, defined in 52.9.1.1 and 52.9.1.2, as well as the PRBS9 pattern.

NOTE—The longer test patterns are designed to emulate system operation; however, they do not form valid 10GBASE-R frames.

68.6.2 Optical modulation amplitude (OMA)

For the purposes of Clause 68, OMA is defined by the measurement method given in 52.9.5, and as illustrated in Figure 68–4. The mean logic ONE and mean logic ZERO values are measured over the center 20% of the two time intervals of the square wave. The OMA is the difference between these two means.

NOTE—An estimate of the OMA value is provided by the variable Measured OMA in 68.6.6.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

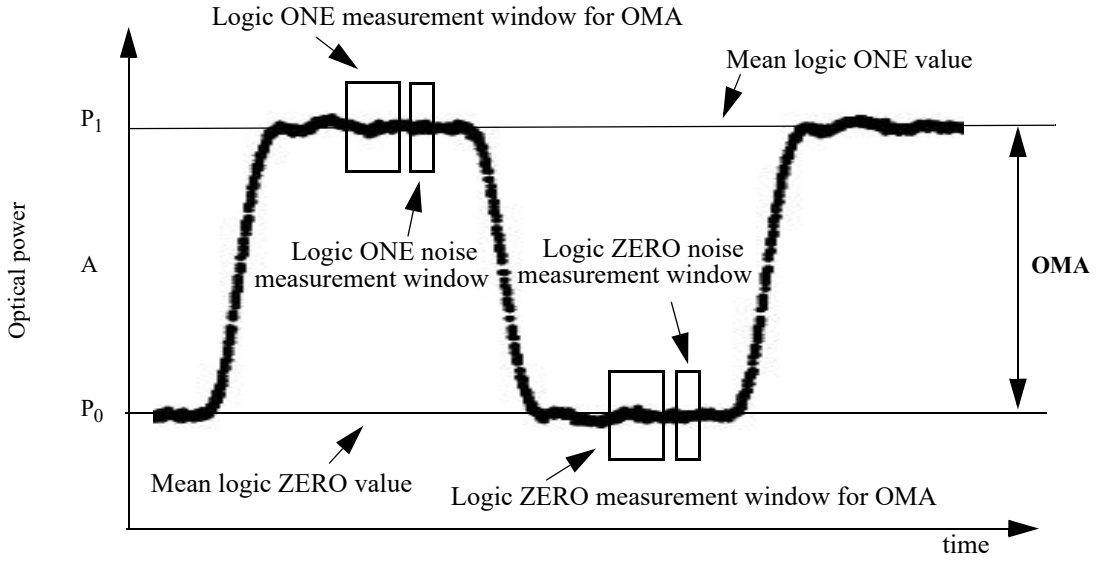

Figure 68–4—Positions of logic ZERO and logic ONE measurement windows for OMA and transmitter noise measurements

68.6.3 Extinction ratio measurement

The extinction ratio shall meet specifications according to 52.9.4.

NOTE—Extinction ratio and OMA are defined with different test patterns (see Table 68–6).

68.6.4 Relationship between OMA, extinction ratio and average power

The relationship between OMA, extinction ratio and average power is described in 58B.2.

NOTE—The difference between Clause 68 and Clause 58 measurement methods for OMA causes the equations in 58B.2 to become approximations for transmitter signals with undershoot, overshoot, or intersymbol interference. It is recommended that these equations not be used for signals at TP3. Figure 68–5 illustrates the approximate region of transmitter compliance and also the approximate relationships between OMA, extinction ratio, and average power.

68.6.5 Transmitter optical waveform—transmitter eye mask

The required transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 68–6. Compliance is to be assured with pattern 1 or 3 defined in 52.9.1. Measurements during system operation or with other patterns, such as a 2^{23}– 1 PRBS or a valid 10GBASE-R signal, are likely to give very similar results. The transmitter optical waveform of a port transmitting the test pattern specified in Table 68–6 shall meet specifications according to the methods specified below.

Normalized amplitudes of 0 and 1 represent the amplitudes of logic ZERO and ONE respectively. These are defined by the means of the lower and upper halves of the central 0.2 UI of the eye. Normalized times of 0 and 1 on the unit interval scale are determined by the eye crossing means measured at the average value of the optical eye pattern. A clock recovery unit (CRU) should be used to trigger the oscilloscope for mask measurements, as shown in Figure 52–9. It should have a high-frequency corner bandwidth of 4 MHz and a slope of –20 dB/decade. The CRU tracks acceptable levels of low-frequency jitter and wander.

The eye is measured with respect to the mask using a receiver with the fourth-order Bessel-Thomson response with nominal f_r of 7.5 GHz as specified for STM-64 in ITU-T G.691, with the tolerances there specified. The Bessel-Thomson receiver is not intended to represent the noise filter used within a compliant

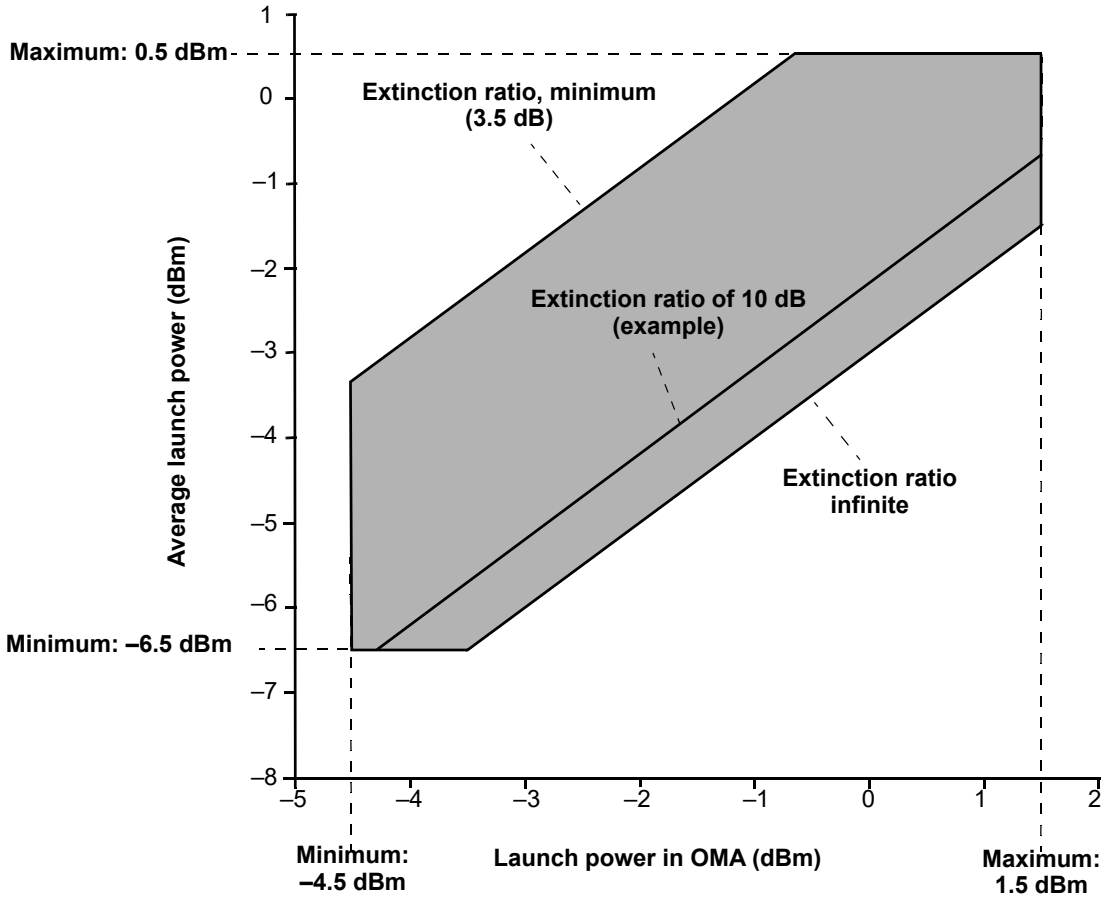

Figure 68–5—Illustration of approximate region of transmitter compliance (shown shaded)

optical receiver, but is intended to provide uniform measurement conditions at the transmitter. The nominal transfer function is given in Equation (52–2) and Equation (52–3).

The transmitter shall achieve a hit ratio lower than 5×10^{-5} hits per sample, where "hits" are the number of samples within the grey areas of Figure 68–6, and the sample count is the total number of samples from 0 UI to 1 UI. Some illustrative examples are provided in 68.6.5.1.

Further information on optical eye pattern measurement procedures may be found in IEC 61280-2-2.

68.6.5.1 Examples of transmitter eye mask acceptable hit count

If an oscilloscope records 1350 samples/screen, and the time-base is set to 0.2 UI per division with 10 divisions across the screen, and the measurement is continued for 200 waveforms, then a transmitter with an expectation of less than 6.75 hits is compliant. i.e.,

$$\frac{5 \times 10^{-5} \times 200 \times 1350}{0.2 \times 10} = 6.75 \tag{68–1}$$

Likewise, if a measurement is continued for 1000 waveforms, then an expectation of less than 33.75 hits is compliant. An extended measurement is expected to give a more accurate result, and a single reading of 6 hits in 200 waveforms would not give a statistically significant pass or fail. Measurements to "zero hits,"

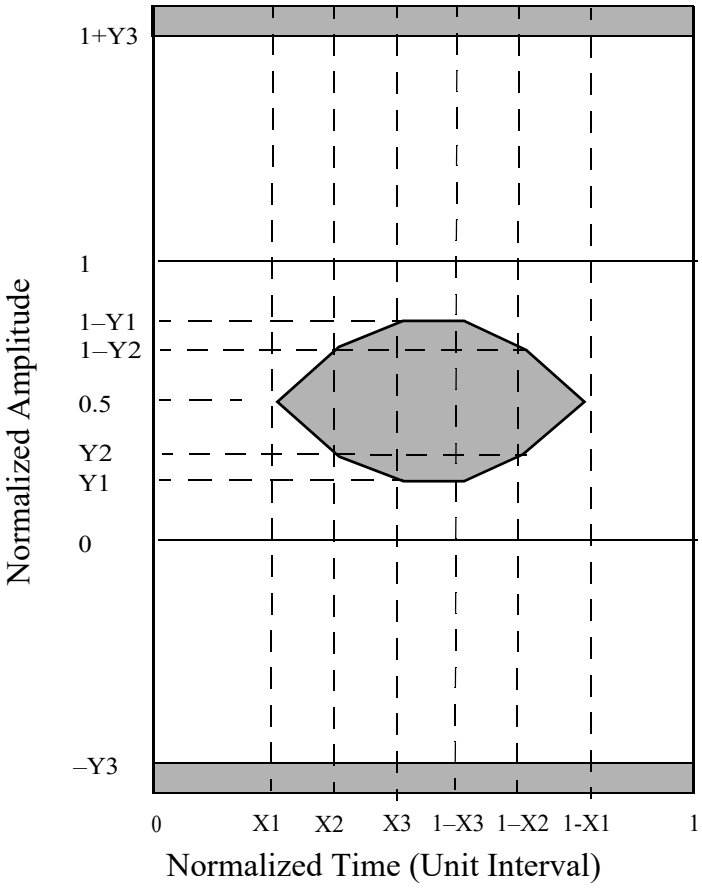

Figure 68–6—Transmitter eye mask definition

which involve finding the position of the worst single sample in the measurement, have degraded reproducibility because random processes cause the position of such a single low-probability event to vary.

The hit ratio limit has been chosen to avoid misleading results due to transmitter and oscilloscope noise.

68.6.6 Transmitter waveform and dispersion penalty (TWDP)

The transmitter waveform shall meet the transmitter waveform and dispersion penalty (TWDP) specification given in Table 68–3.

TWDP is a measure of the deterministic dispersion penalty due to a particular transmitter with reference emulated multimode fibers and receiver. Figure 68–7 shows the TWDP measurement configuration. A waveform from TP2 of the system under test is captured for analysis using an oscilloscope having a fourth-order, 7.5 GHz Bessel-Thomson response.

68.6.6.1 TWDP measurement procedure

The system under test repetitively transmits a test pattern, as specified in Table 68–6. The waveform is captured using averaging to avoid a pessimistic estimate of TWDP. An effective sample rate of at least seven samples per unit interval is required. If test pattern 1 is transmitted, then the specified sub-pattern is to be captured. If PRBS9 is used, then the entire pattern is to be captured.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

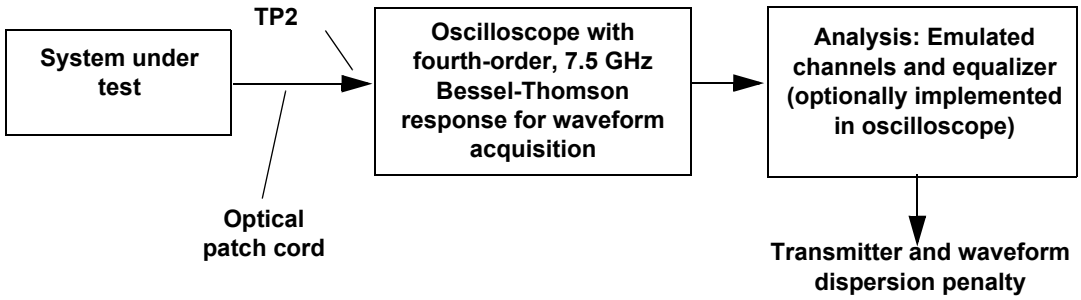

Figure 68–7—Transmitter waveform and dispersion penalty measurement configuration

NOTE—The algorithm assumes 16 samples per unit interval. Interpolation is required for a waveform not captured with 16 samples per unit interval. Use of the $\sin(x)/x$ method or the cubic spline method is recommended. Linear interpolation is not recommended.

The captured waveform is analyzed using the algorithm given below, or equivalent. This algorithm analyses the waveform in combination with each of three emulated channels, equivalent to those given in Table 68–5 for the comprehensive stressed receiver specifications, and with an emulated reference receiver equalizer. A penalty is computed for each of the three emulated channels and the TWDP value is the largest of the three penalty results.

The reference equalizer is a decision feedback equalizer with defined tap number and spacing, as specified in 68.6.6.2. This is not intended to represent the equalizer used within an optical receiver, but is intended to provide uniform measurement conditions at the transmitter.

See Swenson, et al. [B63] for a detailed explanation of the TWDP algorithm.

Table 68–3—10GBASE-LRM transmit characteristics

Description	Type	Value	Unit
Signaling speed	nom	10.3125	GBd
Signaling speed variation from nominal	max	± 100	ppm
Center wavelength	range	1260 to 1355	nm
RMS spectral width[a] at 1260 nm RMS spectral width between 1260 nm and 1300 nm RMS spectral width between 1300 nm and 1355 nm	max max max	2.4 Figure 68–3 4	nm nm nm
Launch power in OMA[b]	max	1.5	dBm
Launch power in OMA[b]	min	–4.5	dBm
Average launch power[b]	max	0.5	dBm
Average launch power[b]	min	–6.5	dBm
Average launch power[b] of OFF transmitter	max	–30	dBm
Extinction ratio	min	3.5	dB
Peak launch power[bc]	max	3	dBm
$RIN_{20}OMA$	max	–128	dB/Hz
Eye mask parameters {X1, X2, X3, Y1, Y2, Y3}		{0.25, 0.40, 0.45, 0.25, 0.28, 0.80}	
Transmitter waveform and dispersion penalty (TWDP)	max	4.7	dB
Uncorrelated jitter (rms)	max	0.033	UI
Optical launch for OM1 and 160/500, 62.5 µm fiber Preferred[d] Encircled flux[e] for alternative launch	— min min	 62.5 µm mode-conditioning patch cord, as specified in 68.9.3 30% within 5 µm radius 81% within 11 µm radius	
Optical launch for OM2, and 400/400, 50 µm fiber Preferred[d] Encircled flux[e] for alternative launch	— min min	 50 µm mode-conditioning patch cord, as specified in 68.9.3 30% within 5 µm radius 81% within 11 µm radius	
Optical launch for OM3, 50 µm, fiber Encircled flux[e]	 min min	 30% within 5 µm radius 81% within 11 µm radius	
Optical return loss tolerance	min	20	dB

[a]RMS spectral width is the standard deviation of the spectrum.
[b]The OMA, average launch power and peak launch power specifications apply at TP2. This is after each type of patch cord. For information: Patch cord losses, between MDI and TP2, differ. The range of losses have to be accounted for to ensure compliance to TP2.
[c]Peak optical power can be determined as the maximum value from the waveform capture for the TWDP test, or equivalent method.
[d]The PMD has to support both the preferred and alternative launch types by the use of a single-mode fiber offset-launch mode-conditioning patch cord, or a regular multimode fiber patch cord, between the MDI and TP2.

Table 68–5—10GBASE-LRM receive characteristics

Description		Type	Value	Unit
Signaling speed		nom	10.3125	GBd
Signaling speed variation from nominal		max	±100	ppm
Center wavelength		range	1260 to 1355	nm
Stressed sensitivity in OMA		—	–6.5	dBm
Stressed sensitivity in OMA for symmetrical test		—	–6	dBm
Overload in OMA		—	1.5	dBm
Conditions of comprehensive stressed receiver tests:				
	Bandwidth of Gaussian white noise source[a]	min	10	GHz
	Test transmitter signal to noise ratio, Q_{sq} [b]	—	26.3	
	Tap spacing, Δt, of ISI generator	—	0.75	UI
	Pre-cursor tap weights {A1, A2, A3, A4}	—	{0.158, 0.176, 0.499, 0.167}	
	Symmetrical tap weights {A1, A2, A3, A4}	—	{0.00, 0.513, 0.00, 0.487}	
	Post-cursor tap weights {A1, A2, A3, A4}	—	{0.254, 0.453, 0.155, 0.138}	
Conditions of simple stressed receiver test:				
	Signal rise and fall times (20% to 80%)	—	115	ps
Conditions of receiver jitter tolerance test:				
	Jitter frequency and peak to peak amplitude	—	(75, 5)	(kHz, UI)
	Jitter frequency and peak to peak amplitude	—	(375, 1)	(kHz, UI)
Received average power for damage[c]		—	1.5	dBm
Receiver reflectance		max	–12	dB

[a]Bandwidth of Gaussian white noise source refers to the –3 dB (electrical) frequency of the noise spectrum before any subsequent filtering.
[b]Transmitter signal to noise ratio, Q_{sq}, is defined in 68.6.7 and its use here is qualified by 68.6.9.3.
[c]The receiver shall be able to tolerate, without damage, continuous exposure to an optical input signal having this average received power level.

Table 68–6—Test-pattern definitions and related subclauses

Test	Pattern	Related subclause
Transmitter OMA (modulated optical power)	Square	68.6.2
Calibration of OMA for receiver tests	Square, eight ONEs and eight ZEROs	68.6.9 and 68.6.10

68.6.7 Transmitter signal to noise ratio

The system under test shall meet the RIN_xOMA specification, given in Table 68–3 as $RIN_{20}OMA$, when measured using the procedure given in 58.7.7. A different measurement procedure for the same quantity, giving approximately the same results, uses the setup shown in Figure 68–8 and proceeds as follows:

a) Measure OMA, using a square wave and following the method of 68.6.2

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) Using the same square wave, measure the rms noise over flat regions of the logic ONE and logic ZERO portions of the square wave, as indicated in Figure 68–4, compensating for noise in the measurement system. The optical path and detector combination are configured for a single dominant reflection with the reflector adjusted to produce an optical return loss, as seen by the system under test, equal to the optical return loss tolerance (min) specified in Table 68–3. The length of the single-mode fiber is not critical, but should be in excess of 2 m. The polarization rotator is capable of transforming an arbitrary orientation elliptically polarized wave into a fixed orientation linearly polarized wave, and should be adjusted to maximize the noise. The receiver of the system under test should be receiving a signal that is asynchronous to that being transmitted. If possible, means should be used to prevent noise of frequency less than 1 MHz from affecting the result. Q_{sq} is given by Equation (68–2):

$$Q_{sq} = \frac{\text{OMA}}{\text{logic ONE noise (rms)} + \text{logic ZERO noise (rms)}} \tag{68–2}$$

where OMA and rms noise are measured in the same linear units of optical power, for example mW.

c) RIN_xOMA is then computed using the relationship shown in Equation (68–3):

$$RIN_xOMA = -20 \times \log_{10}(Q_{sq}) - 10 \times \log_{10}(BW) \quad \text{dB/Hz} \tag{68–3}$$

where BW is the low-pass bandwidth of oscilloscope minus high-pass bandwidth of the measurement system. For the specified measurement setup, BW is approximately 7.5×10^9 Hz.

Q_{sq} may be computed from the RIN_xOMA using the relationship shown in Equation (68–4):

$$Q_{sq} = 10^{-RINxOMA/20} / \sqrt{BW} \tag{68–4}$$

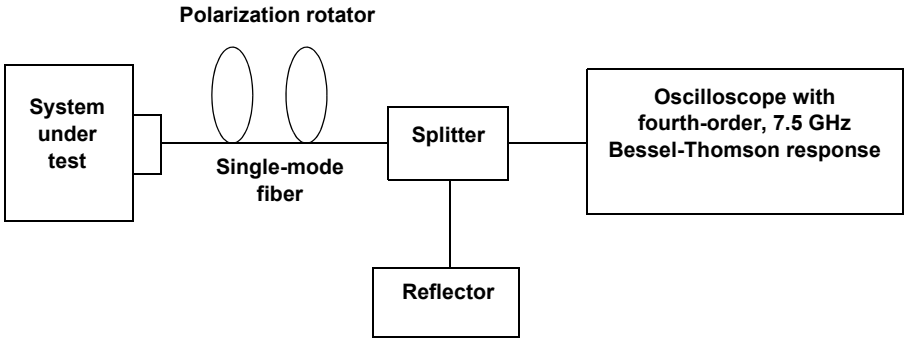

Figure 68–8—Transmitter signal to noise measurement setup

68.6.8 Transmitter uncorrelated jitter

Uncorrelated jitter refers to the component of jitter in the transmitted optical signal that is not correlated to the transmitter data.

The uncorrelated jitter specification of Table 68–3 shall be met when measured using an oscilloscope with a fourth-order, 7.5 GHz Bessel-Thomson response. The test pattern specified in Table 68–6 is used. A clock recovery unit (CRU) should be used to trigger the oscilloscope as shown in Figure 52–9. It should have a high frequency corner bandwidth of 4 MHz and a slope of –20 dB/decade. The CRU tracks acceptable levels

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

of low-frequency jitter and wander. The oscilloscope is to be synchronized to the data pattern. The receiver of the system under test should be receiving a signal that is asynchronous to that being transmitted.

Figure 68–9 illustrates two measurement window positions, one on a rising edge, the other on a falling edge and both placed at the average power level of the pattern. The uncorrelated jitter (rms) is given by the RMS value of the standard deviations of the two distributions, as shown in Equation (68–5):

$$\text{Uncorrelated jitter (rms)} = \sqrt{(\sigma_r^2 + \sigma_f^2)/2} \tag{68–5}$$

where

σ_r is the standard deviation of the jitter on the rising edge

σ_f is the standard deviation of the jitter on the falling edge

Compensation for measurement system jitter is encouraged.

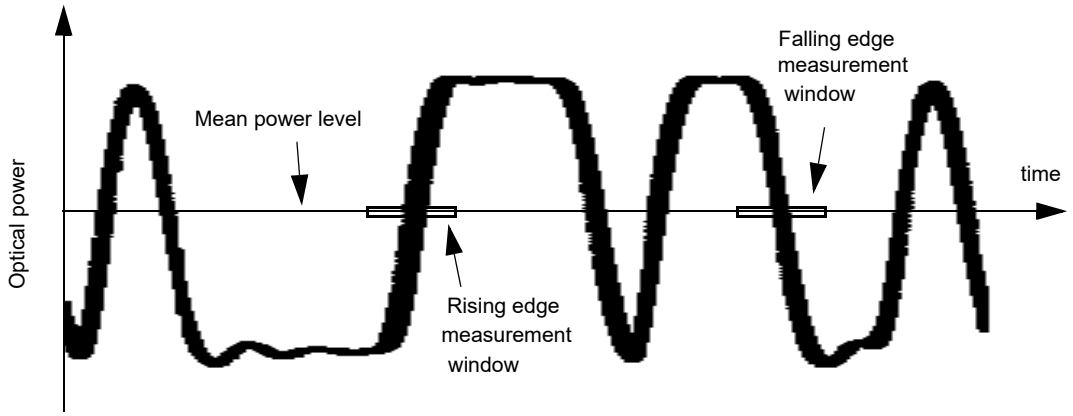

Figure 68–9—Measurement windows for transmitter uncorrelated jitter

68.6.9 Comprehensive stressed receiver sensitivity and overload

The PMD's receiver shall satisfy the comprehensive stressed receiver sensitivity and comprehensive stressed receiver overload specifications given in Table 68–5. These parameters are defined by reference to the procedures of 68.6.9.1 to 68.6.9.4. A BER of better than 10^{-12} shall be achieved with asynchronous transmission from the system under test. The received and transmitted patterns are the same, and as specified in Table 68–6 for the comprehensive stressed receiver sensitivity and the comprehensive stressed receiver overload.

68.6.9.1 Comprehensive stressed receiver sensitivity and overload test block diagram

Figure 68–10 shows the reference block diagram for the comprehensive stressed receiver test. As shown in the figure, an electrical signal is created using a pattern generator with pattern according to Table 68–6, and impaired by the following:

Gaussian low-pass filter

a) Gaussian white noise source
b) Intersymbol interference (ISI)

NOTE—Gaussian noise that extends, positively and negatively, to at least seven times its rms value is adequate.

The resulting electrical signal is converted to an optical signal using a linear electrical/optical converter, and the optical waveform is connected to an optical attenuator, and to the receiver under test via a mode-conditioning patch cord of the type defined in 38.11.4 or 59.9.5 for use with 62.5/125 μm fiber.

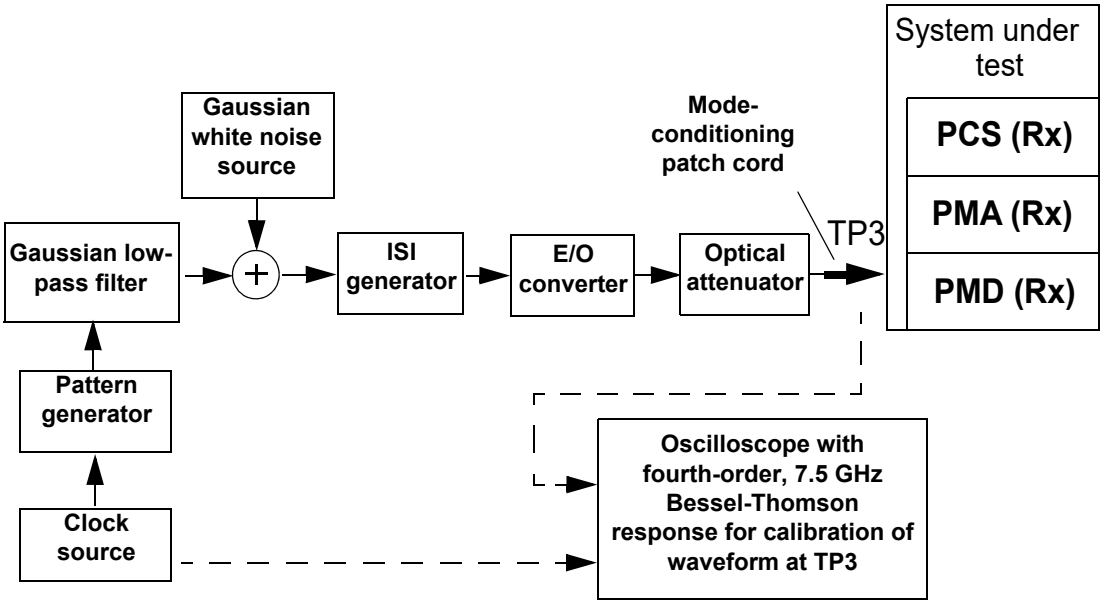

Figure 68–10—Reference measurement configuration for comprehensive stressed receiver sensitivity and overload test

The characteristics of the stressed test signal are defined in 68.6.9.2 and are based upon the parameters in Table 68–5. These parameters and the definition in 68.6.9.2 describe an ISI generator as a tapped delay line with four weighted taps, having equally spaced delays and with impulse response as illustrated in Figure 68–11.

Any implementation of the measurement configuration may be used, provided that the resulting signal and noise in the optical domain match those defined here. This consideration includes the shaping of the noise by the ISI generator.

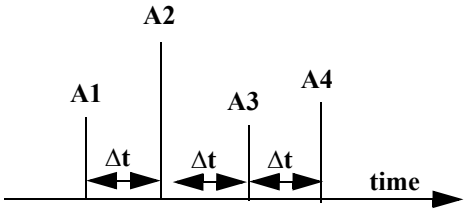

Figure 68–11—Illustration of parameters defining ISI generator impulse responses

68.6.9.2 Comprehensive stressed receiver test signal characteristics

The comprehensive stressed receiver test signal impairments are specified in Table 68–5 as the conditions of the comprehensive stressed receiver tests. These conditions include three sets of ISI parameters that are applied in turn. The ISI impaired test signal is defined by Equation (68–6):

$$S_{\mathrm{ISI}}(t) = S(t) * G_{47}(t) * \left[\sum_{i=1}^{4} A_i \times \delta(t - i \times \Delta t) \right] \tag{68–6}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where

$S(t)$ is an ideal NRZ test pattern signal specified in Table 68–6
$G_{47}(t)$ is a Gaussian low-pass filter with a 20% to 80% step response of 47 ps
A_i are the amplitudes of the four impulses
Δt is their spacing
δ is the Dirac delta function
* denotes convolution

The impulse spacing, and the amplitudes of the impulses for the three different test cases, are specified in Table 68–5.

The test signal is also impaired by broadband white Gaussian noise with a minimum bandwidth specified in Table 68–5 and with the amplitude adjusted such that Q_{sq} of the test signal, without ISI impairment, is as specified in Table 68–5.

Two different optical signal powers, in OMA, are used for the comprehensive stressed receiver sensitivity test. For the test with pre-cursor ISI tap weights, and the test with the post-cursor ISI tap weights, the OMA is set to the stressed sensitivity in OMA, given in Table 68–5. For the test with the symmetrical ISI tap weights, the OMA is set to the stressed sensitivity in OMA for symmetrical test, given in Table 68–5. For all three tests, the minimum extinction ratio specified in Table 68–3 is used.

For the comprehensive stressed receiver overload test, the OMA is set to the overload in OMA, given in Table 68–5, and with the maximum average power specified in Table 68–3.

68.6.9.3 Comprehensive stressed receiver test signal calibration

The test signal is calibrated as follows, using an optical reference receiver with a multimode compatible input and a 7.5 GHz fourth-order ideal Bessel-Thomson response.

The extinction ratio of the optical output is calibrated with the Gaussian low-pass filter but without the ISI generator.

Without ISI impairment due to the ISI generator, the level of the Gaussian noise is adjusted such that Q_{sq} is as specified in Table 68–5. See 68.6.7 for the definition of signal to noise ratio Q_{sq}.

The ISI generator is configured and calibrated for each of the three ISI cases specified in Table 68–5. The calibration of the ISI may be done with any portion of a repeating test signal. One convenient example is an isolated ONE bit with at least ten ZERO bits before and after. The ISI generator is adjusted such that the signal, S_{meas}, recorded on the reference receiver is given by Equation (68–7):

$$S_{meas}(t) = S_{cal}(t) * G_{47}(t) * \left[\sum_{i=1}^{4} A_i \times \delta(t - i \times \Delta t) \right] * BT4_{7.5GHz}(t) \quad (68–7)$$

where

S_{cal} is an ideal NRZ calibration test signal
G_{47}, A_i , Δt, and * are defined as in 68.6.9.2
$BT4_{7.5GHz}(t)$ is the impulse response of an ideal 7.5 GHz fourth-order Bessel-Thomson filter representing the optical reference receiver response

In practice, the bandwidth of, or need for, the Gaussian low-pass filter shown in block diagram of Figure 68–10 is determined by the characteristics of the signal source, ISI generator and E/O converter such that the final measured signal has the overall pulse response given by Equation (68–7).

Figure 68–12 illustrates the required measured test signals for the three cases specified in Table 68–5, where the test signal, S_{cal}, is a single ONE bit (rectangular pulse with 1 UI width) surrounded by ZEROs. Table 68–7 gives the tabulated amplitude vs. time for these curves.

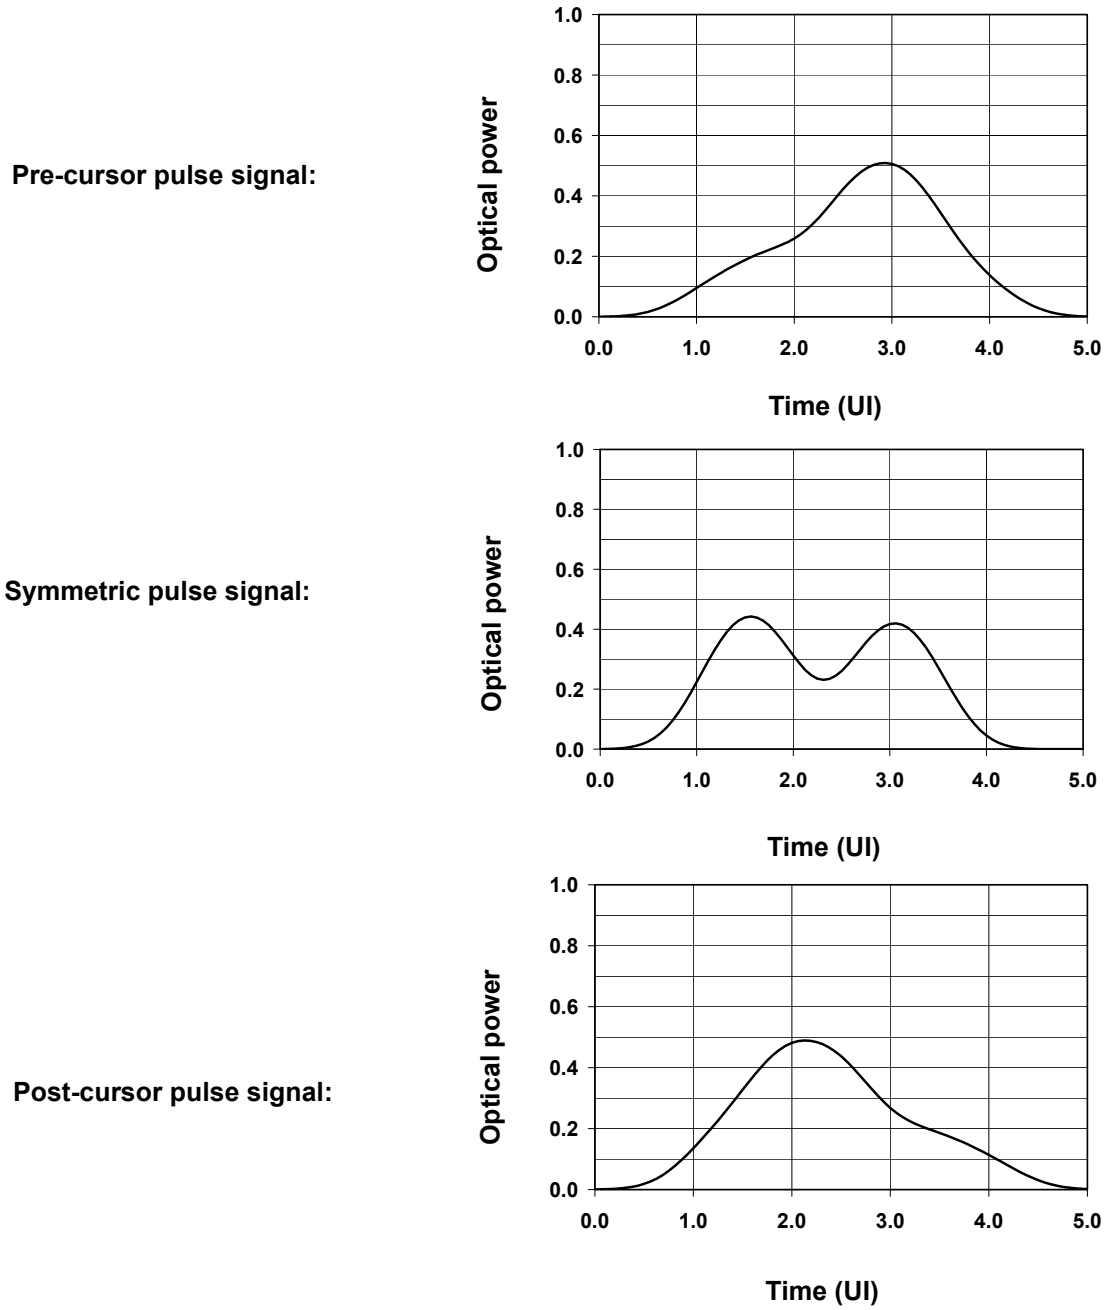

Figure 68–12—Comprehensive stressed receiver test pulse signals (i.e., signals corresponding to an isolated ONE bit)

NOTE—The optical powers have been normalized to correspond to waveforms with OMA of one.

NOTE—The TWDP values without simulated channels, which are measured using the same method as TWDP except that the simulated fiber stressors are set to (0,1,0,0), are 4.1 dB, 3.9 dB, and 4.2 dB for the pre-cursor, symmetrical and post-cursor tests, respectively. Significant differences from these values indicate problems with the test equipment (possibly nonlinearities) and that the test will not provide valid results. For small differences, the ISI generator should be adjusted to obtain the expected values. Also, one should ensure that the test system has adequate low-frequency response to avoid baseline wander problems with the longer test patterns used for the test.

With the ISI generator present, the Q_{sq} values are as follows for the three different ISI impairments—precursor: 45.6; symmetrical: 37.2; post-cursor: 47.0. Significant differences from these values indicate problems with the test equipment (possibly noise sources within the ISI generator), and the test will not provide valid results. For small differences, the amplitude of the added Gaussian white noise should be adjusted to obtain the expected values.

The attenuator setting is determined by measuring the OMA of the impaired test signal according to 68.6.2.

68.6.9.4 Comprehensive stressed receiver test procedure

The three ISI impairments defined in Table 68–5 and 68.6.9.2, together with the appropriate OMA values, also as specified in Table 68–5, define six discrete signal conditions.

With the test system setup as described in 68.6.9.2 and 68.6.9.3, for each case, select the required ISI impairment and set the attenuator and Gaussian white noise source to obtain either the stressed sensitivity in OMA, stressed sensitivity in OMA for symmetrical test or overload in OMA, with the appropriate noise, as specified in Table 68–5. Set the pattern generator to one of the patterns specified in Table 68–6 for these measurements. Connect the test signal to the system receiver TP3 and a BER of better than 10^{-12} shall be achieved for each case.

68.6.10 Simple stressed receiver sensitivity and overload (optional)

The simple stressed receiver sensitivity and simple stressed receiver overload are optional and compliance is not required. If measured, the receiver under test will be expected to satisfy the simple stressed receiver sensitivity and simple stressed receiver overload specifications in Table 68–5.

Figure 68–13 gives the block diagram for the simple stressed receiver test. A pattern generator output is impaired by a low-pass filter and the resulting electrical signal is converted to an optical signal using a linear electrical/optical converter. Other signal impairments, such as jitter and RIN, should be negligible. The optical waveform is connected to an optical attenuator, and to the receiver under test via a mode-conditioning patch cord of the type defined in 38.11.4 or 59.9.5 for use with 62.5/125 μm fiber.

The filter should be chosen so as to produce an optical output with the rise and fall times given in Table 68–5, and dominated by a fourth-order Bessel-Thomson response. The rise and fall times of the test signal are defined as measured with a 7.5 GHz Bessel-Thomson reference receiver and with the square wave pattern used for calibrating OMA for the comprehensive stressed receiver test of 68.6.9.

Other implementations may be used provided that the resulting signal in the optical domain matches that created using the implementation described.

NOTE—The TWDP without simulated channels, which is measured using the same method as TWDP except that the simulated fiber stressors are set to (0, 1, 0, 0), for this test signal is 4 dB.

For the two OMA values (i.e., the stressed sensitivity in OMA, and the overload in OMA, both specified in Table 68–5), a BER of better than 10^{-12} should be achieved. For the simple stressed receiver sensitivity test, the minimum extinction ratio specified in Table 68–3 is used. For the simple stressed receiver overload test, the maximum average power specified in Table 68–3 is used.

68.6.11 Receiver jitter tolerance

The receiver jitter tolerance specification given in Table 68–5 shall be met when measured as described here. This specification addresses the need for the receiver to track low-frequency jitter without the occurrence of errors.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

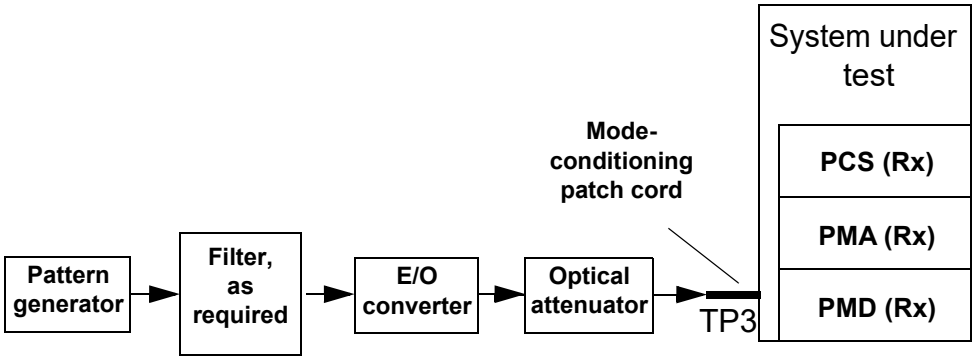

Figure 68–13—Measurement configuration for simple stressed receiver sensitivity test (optional)

Figure 68–14 gives the measurement configuration for the receiver jitter tolerance test. An optical pattern generator output is impaired by frequency modulation of the generating clock. The optical waveform is connected to the receiver under test via an optical attenuator and mode-conditioning patch cord suitable for 62.5/125 μm fiber.

Two jitter frequency and amplitude combinations are specified in Table 68–5. These are applied as the conditions of two separate receiver jitter tolerance tests. For each, the power in OMA at the receiver is adjusted, using the optical attenuator, to be equal to the stressed sensitivity in OMA, also given in Table 68–5, and a BER of better than 10^{-12} shall be achieved.

Various implementations may be used, provided that the resulting jitter in the optical domain matches that specified. Phase or frequency modulation may be applied to induce the sinusoidal jitter, and the modulation may be applied to the clock source or to the data stream itself.

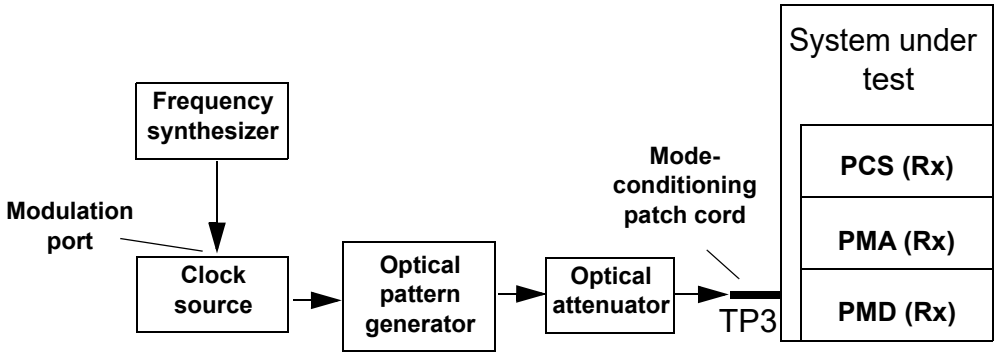

Figure 68–14—Measurement configuration for receiver jitter tolerance test

68.7 Safety, installation, environment, and labeling

68.7.1 Safety

The 10GBASE-LRM environmental specifications are as defined in 52.10.1 for general safety, and as defined in 52.10.2 for laser safety.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

68.7.2 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

NOTE—The preferred launch (as specified in Table 68–3) is expected to provide more stable operation. It is recommended that link stability be confirmed by physical manipulation of the transmitter patch cord.

68.7.3 Environment

The 10GBASE-LRM operating environment specifications are as defined in 52.11, as defined in 52.11.1 for electromagnetic emission, and as defined in 52.11.2 for temperature, humidity, and handling.

68.7.4 PMD labeling

The 10GBASE-LRM labeling recommendations and requirements are as defined in 52.12.

68.8 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 38–7.

A channel may contain additional connectors or other optical elements as long as the optical characteristics of the channel such as attenuation, dispersion, reflections, modal bandwidth and total connector loss meet the specifications. Insertion loss measurements of installed multimode fiber cables are made in accordance with IEC 61280-4-1 one-cord method. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term channel is used here for consistency with generic cabling standards.

68.9 Characteristics of the fiber optic cabling (channel)

The channel consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. The fiber optic cabling shall meet the requirements of Table 68–8.

Table 68–8—Fiber optic cabling (channel)

Description	Type	Value	Unit
Cabled optical fiber insertion loss at 1300 nm	max	0.4	dB
Losses of all connectors and splices	max	1.5	dB

68.9.1 Optical fiber and cable

The optical fiber shall meet the requirements of IEC 60793-2-10 and the requirements given in Table 68–9, where they differ. Multimode cables chosen from IEC 60794-2-11 or IEC 60794-3-12 may be suitable.

68.9.2 Optical fiber connections

An optical fiber connection, as shown in Figure 38–7, consists of a mated pair of optical connectors.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 68–9—Optical fiber and cable

Description	Type	Value	Unit
Cabled optical fiber attenuation at 1300 nm	max	1.5	dB/km
Modal bandwidth at 1300 nm	min	Value used as 1300 nm modal bandwidth portion of fiber identifier in Table 68–2	MHz · km
Zero dispersion wavelength (λ_0) for 62.5 μm MMF	range	$1320 \le \lambda_0 \le 1365$	nm
Chromatic dispersion slope for 62.5 μm MMF	max	0.11 for $1320 \le \lambda_0 \le 1348$ and $0.001(1458 - \lambda_0)$ for $1348 \le \lambda_0 \le 1365$	ps/nm^2 · km
Zero dispersion wavelength (λ_0) for 50 μm MMF	range	$1295 \le \lambda_0 \le 1320$	nm
Chromatic dispersion slope for 50 μm MMF	max	0.11 for $1300 \le \lambda_0 \le 1320$ and $0.001(\lambda_0 - 1190)$ for $1295 \le \lambda_0 \le 1300$	ps/nm^2 · km

68.9.2.1 Connection insertion loss

The insertion loss is specified for a connection, which consists of a mated pair of optical connectors.

The maximum link distances for multimode fiber are calculated based on an allocation of 1.5 dB total connector and splice loss. For example, this allocation supports three connections with an insertion loss equal to 0.5 dB (or less) per connection, or two connections (as shown in Figure 38–7) with an insertion loss equal to 0.75 dB per connection. Connections with different loss characteristics may be used provided the requirements of Table 68–8 are met.

68.9.2.2 Maximum discrete reflectance

The maximum discrete reflectance shall be less than –20 dB.

68.9.3 Single-mode fiber offset-launch mode-conditioning patch cord

Single-mode fiber offset-launch mode-conditioning patch cords shall satisfy the requirements of 38.11.4 or 59.9.5. Any discrete reflectance within the patch cord shall be less than –20 dB.

68.10 Protocol implementation conformance statement (PICS) proforma for Clause 68, Physical medium dependent (PMD) sublayer type 10GBASE-LRM[132]

68.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Physical medium dependent (PMD) sublayer type 10GBASE-LRM, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

68.10.2 Identification

68.10.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

68.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 68, Physical medium dependent (PMD) sublayer type 10GBASE-LRM
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[132]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that if can be used for its intended purpose and may further publish the completed PICS.

69. Introduction to Ethernet operation over electrical backplanes

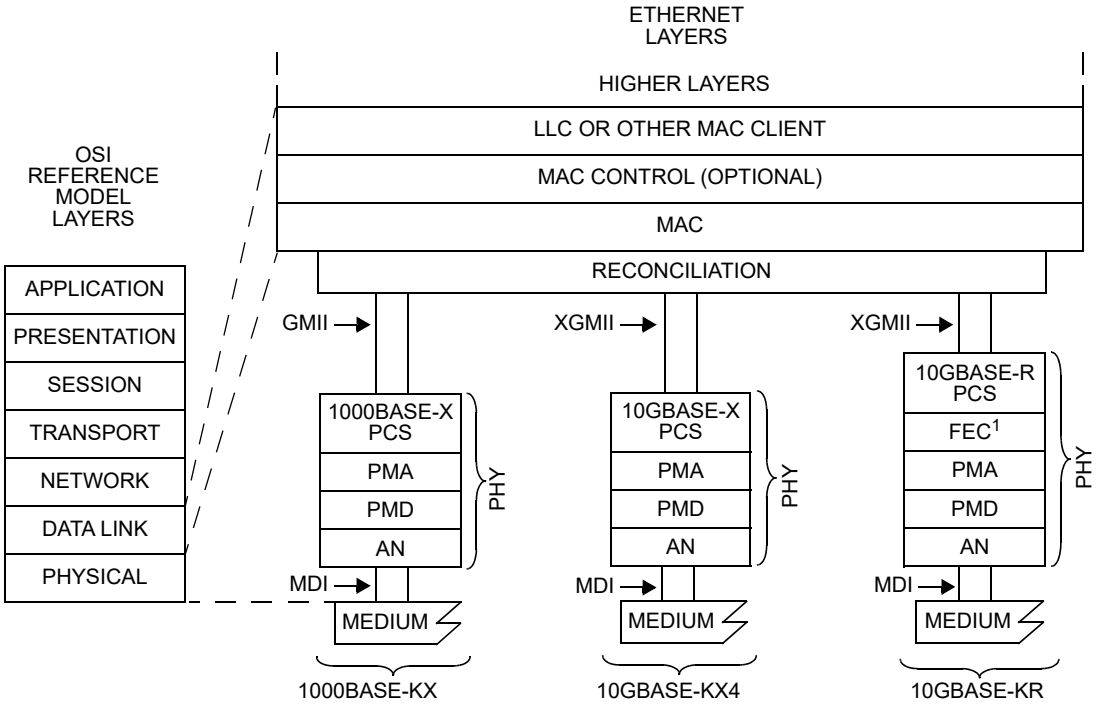
69.1 Overview

69.1.1 Scope

Ethernet operation over electrical backplanes, also referred to as “Backplane Ethernet,” combines the IEEE 802.3 Media Access Control (MAC) and MAC Control sublayers with a family of Physical Layers defined to support operation over a modular chassis backplane.

Backplane Ethernet supports the IEEE 802.3 full duplex MAC operating at 1000 Mb/s, 2.5 Gb/s, 5 Gb/s, 10 Gb/s, 25 Gb/s, 40 Gb/s, 50 Gb/s, 100 Gb/s, or 200 Gb/s. The following Physical Layers are supported:

— 1000BASE-KX for 1 Gb/s operation over a single lane
— 2.5GBASE-KX for 2.5 Gb/s operation over a single lane
— 5GBASE-KR for 5 Gb/s operation over a single lane
— 10GBASE-KX4 for 10 Gb/s operation over four lanes
— 10GBASE-KR for 10 Gb/s operation over a single lane
— 25GBASE-KR and 25GBASE-KR-S for 25 Gb/s operation over a single lane
— 40GBASE-KR4 for 40 Gb/s operation over four lanes
— 50GBASE-KR for 50 Gb/s operation over a single lane
— 100GBASE-KR4 and 100GBASE-KP4 for 100 Gb/s operation over four lanes
— 100GBASE-KR2 for 100 Gb/s operation over two lanes
— 200GBASE-KR4 for 200 Gb/s operation over four lanes



Auto-Negotiation enables PHY selection amongst Backplane Ethernet Physical Layer signaling systems.

Energy Efficient Ethernet (EEE) is optionally supported for all Backplane Ethernet PHYs.

69.1.2 Relationship of Backplane Ethernet to the ISO OSI reference model

Backplane Ethernet couples the IEEE 802.3 MAC to a family of Physical Layers defined for operation over electrical backplanes. The relationships among Backplane Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 69–1, Figure 69–2, Figure 69–3, Figure 69–4, and Figure 69–5.

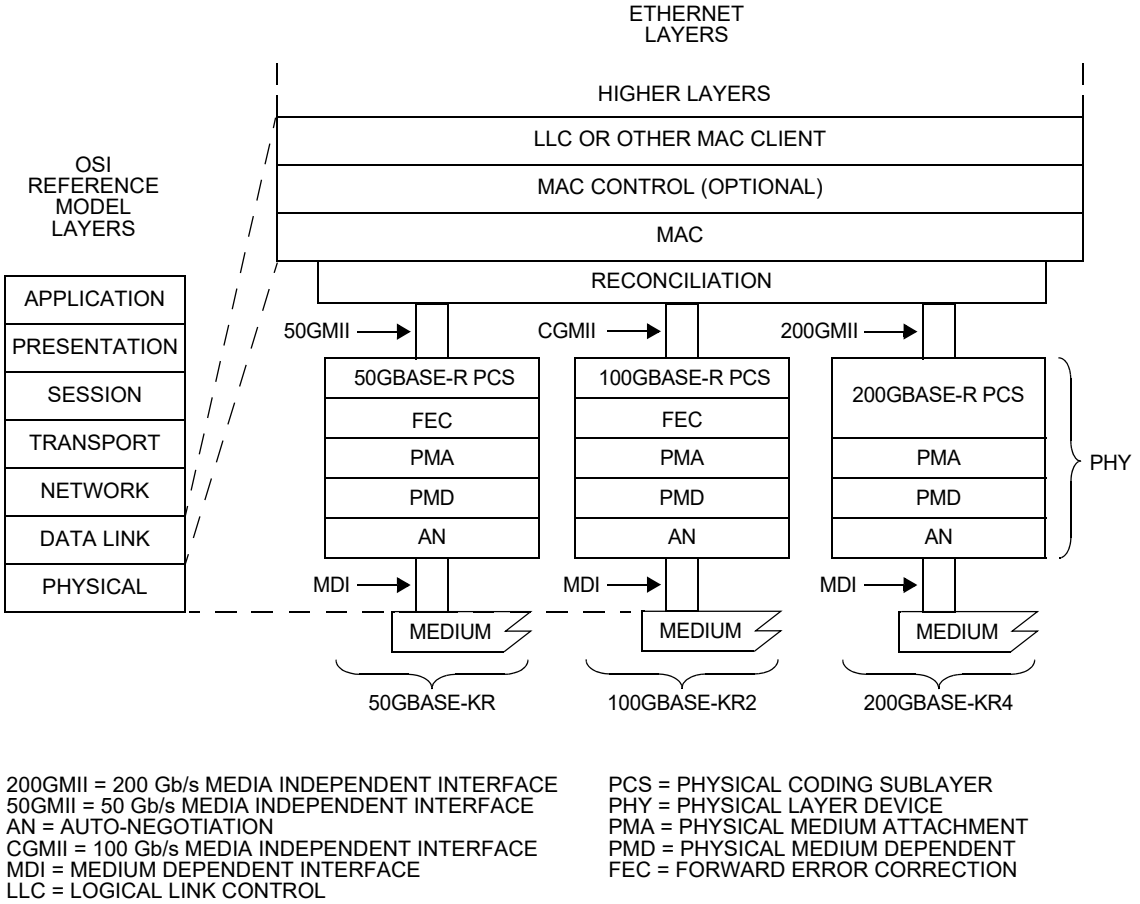

Figure 69–5—Architectural positioning of 50 Gb/s, 100 Gb/s, and 200 Gb/s PAM4 Backplane Ethernet

While this specification defines interfaces in terms of bits, octets, and frames, implementers may choose other data-path widths for implementation convenience. Exceptions are described in the clauses related to specific Backplane Ethernet PHY types.

69.2 Summary of Backplane Ethernet Sublayers

69.2.1 Reconciliation sublayer and media independent interfaces

The Clause 35 RS and GMII, the Clause 46 RS and XGMII, the Clause 106 RS and 25GMII, the Clause 81 RS, XLGMII, and CGMII, the Clause 132 RS and 50GMII, and the Clause 117 RS and 200GMII are employed for the same purpose in Backplane Ethernet, that being the interconnection between the MAC sublayer and the PHY.

69.2.2 Management interface

The MDIO/MDC management interface (Clause 45) is intended to provide an interconnection between MDIO Manageable Devices (MMD) and Station Management (STA) entities.

69.2.3 Physical Layer signaling systems

Backplane Ethernet extends the family of 1000BASE-X Physical Layer signaling systems to include 1000BASE-KX. This embodiment specifies operation at 1 Gb/s over two differential, controlled impedance pairs of traces (one pair for transmit, one pair for receive). This system employs the 1000BASE-X PCS and PMA as defined in Clause 36. The 1000BASE-KX PMD is defined in Clause 70.

Backplane Ethernet also extends the family of 2.5GBASE-X Physical Layer signaling systems to include 2.5GBASE-KX. This embodiment specifies operation at 2.5 Gb/s over two differential, controlled impedance pairs of traces (one pair for transmit, one pair for receive). This system employs the 2.5GBASE-X PCS and PMA as defined in Clause 127. The 2.5GBASE-KX PMD is defined in Clause 128.

Backplane Ethernet also extends the family of 5GBASE-R Physical Layer signaling systems to include 5GBASE-KR. This embodiment specifies 5 Gb/s operation over two differential, controlled impedance pairs of traces (one pair for transmit, one pair for receive). This system employs the 5GBASE-R PCS and PMA as defined in Clause 129. The 5GBASE-KR PMD is defined in Clause 130.

Backplane Ethernet also extends the family of 10GBASE-X Physical Layer signaling systems to include 10GBASE-KX4. This embodiment is based on XAUI with 10GBASE-CX4 extensions and specifies 10 Gb/s operation over four differential paths in each direction for a total of eight pairs. This system employs the 10GBASE-X PCS and PMA as defined in Clause 48. The 10GBASE-KX4 PMD is defined in Clause 71.

Backplane Ethernet also extends the family of 10GBASE-R Physical Layer signaling systems to include the 10GBASE-KR. This embodiment specifies 10 Gb/s operation over two differential, controlled impedance pairs of traces (one pair for transmit, one pair for receive). This system employs the 10GBASE-R PCS as defined in Clause 49 and the serial PMA as defined in Clause 51. The 10GBASE-KR PMD is defined in Clause 72. The 10GBASE-KR PHY may optionally include 10GBASE-R forward error correction (FEC), as defined in Clause 74.

Backplane Ethernet also specifies 25GBASE-KR and 25GBASE-KR-S. The 25GBASE-KR embodiment employs the PCS defined in Clause 107, the BASE-R FEC defined in Clause 74, the RS-FEC defined in Clause 108, the PMA defined in Clause 109, and the PMD defined in Clause 111, and specifies 25 Gb/s operation over one differential path in each direction. The 25GBASE-KR-S embodiment employs the PCS defined in Clause 107, the BASE-R FEC defined in Clause 74, the PMA defined in Clause 109, and the PMD defined in Clause 111, and specifies 25 Gb/s operation over one differential path in each direction.

Backplane Ethernet also specifies 40GBASE-KR4. This embodiment employs the PCS defined in Clause 82, the PMA defined in Clause 83, and the PMD defined in Clause 84 and specifies 40 Gb/s operation over four differential paths in each direction for a total of eight pairs.

Backplane Ethernet also specifies 50GBASE-KR, 100GBASE-KR2, and 200GBASE-KR4. The 50GBASE-KR embodiment employs the PCS defined in Clause 133, the RS-FEC defined in Clause 134, the PMA defined in Clause 135, and the PMD defined in Clause 137, and specifies 50 Gb/s operation using 4-level PAM over one differential path in each direction. The 100GBASE-KR2 embodiment employs the PCS defined in Clause 82, the RS-FEC defined in Clause 91, the PMA defined in Clause 135, and the PMD defined in Clause 137, and specifies 100 Gb/s operation using 4-level PAM over two differential paths in each direction. The 200GBASE-KR4 embodiment employs the PCS defined in Clause 119, the PMA defined in Clause 120, and the PMD defined in Clause 137, and specifies 200 Gb/s operation using 4-level PAM over four differential paths in each direction.

Backplane Ethernet also specifies 100GBASE-KR4 for 100 Gb/s operation using 2-level pulse amplitude modulation (PAM) over four differential signal pairs in each direction for a total of eight pairs where the insertion loss of each pair does not exceed 35 dB at 12.9 GHz. The embodiment of 100GBASE-KR4

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

employs the PCS defined in Clause 82, the RS-FEC defined in Clause 91, the PMA defined in Clause 83, and the PMD defined in Clause 93.

Backplane Ethernet also specifies 100GBASE-KP4 for 100 Gb/s operation using 4-level PAM over four differential signal pairs in each direction for a total of eight pairs where the insertion loss of each pair does not exceed 33 dB at 7 GHz. The embodiment of 100GBASE-KP4 employs the PCS defined in Clause 82, the RS-FEC defined in Clause 91, and the PMA and PMD defined in Clause 94.

Table 69–1 specifies the correlation between nomenclature and clauses for 1 Gb/s and 10 Gb/s backplane Ethernet. For other backplane PHY types, refer to Table 125–2 (2.5 Gb/s and 5 Gb/s), Table 105–1 (25 Gb/s), Table 80–2 (40 Gb/s), Table 131–2 (50 Gb/s), Table 80–3 (100 Gb/s), and Table 116–3 (200 Gb/s).

Table 69–1—Nomenclature and clause correlation for 1 Gb/s and 10 Gb/s Backplane Ethernet Physical Layers

Nomenclature	Clause													
	35		36	46		48	49	51	70	71	72	73	74	78
	RS	GMII	1000BASE-X PCS/PMA	RS	XGMII	10GBASE-X PCS/PMA	10GBASE-R PCS	Serial PMA	1000BASE-KX PMD	10GBASE-KX4 PMD	10GBASE-KR PMD	Auto-Negotiation	BASE-R FEC	Energy-Efficient Ethernet (EEE)
1000BASE-KX	M[a]	O[a]	M						M			M		O
10GBASE-KX4				M	O	M				M		M		O
10GBASE-KR				M	O		M	M			M	M	O	O

[a]O = Optional, M = Mandatory

69.2.4 Auto-Negotiation

Auto-Negotiation provides a linked device with the capability to detect the abilities (modes of operation) supported by the device at the other end of the link, determine common abilities, and configure for joint operation.

Auto-Negotiation for Backplane Ethernet is based on the Clause 28 definition of Auto-Negotiation for twisted-pair link segments. Auto-Negotiation for Backplane Ethernet utilizes an extended Base Page and Next Page format and modifies the timers to allow rapid convergence. Furthermore, Auto-Negotiation does not utilize Fast Link Pulses (FLPs) for link codeword signaling and instead uses a signaling more suitable for electrical backplanes.

Auto-Negotiation for Backplane Ethernet is defined in Clause 73.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

69.2.5 Management

Managed objects, attributes, and actions are defined for all Backplane Ethernet components. These items are defined in Clause 30.

69.2.6 Low-Power Idle

With the optional EEE feature, described in Clause 78, Backplane Ethernet PHYs can achieve lower power consumption during periods of low link utilization. The EEE capabilities are advertised during Auto-Negotiation for Backplane Ethernet. The Backplane Ethernet LPI allows each link direction to enter sleep, refresh, or wake states asymmetric from the other direction.

69.3 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

Table 69–2 contains the values of maximum sublayer round-trip (sum of transmit and receive) delay for the 1000BASE-KX port types in bit time as specified in 1.4.

Table 69–2—Round-trip delay constraints for 1000BASE-KX

Sublayer	Maximum (bit time)	Notes
MAC Control, MAC, and RS	696	
1000BASE-X PCS, PMA, and PMD	328	See 36.5.1
Medium	16	See 70.4
Total delay	1040[a]	

[a]Per 31B.3.7, a station incorporating the 1000BASE-KX PHY will not begin to transmit a new frame more than two pause_quanta after the reception of a valid PAUSE frame that contains a non-zero value of pause_time, as measured at the MDI.

Table 69–3 contains the values of maximum sublayer round-trip (sum of transmit and receive) delay for the 10GBASE-KX4 and 10GBASE-KR port types in bit time as specified in 1.4 and pause_quanta as specified in 31B.2.

For 2.5GBASE-KX, normative delay specifications may be found in 127.5 and 128.4. For 5GBASE-KR, normative delay specifications may be found in 129.5 and 130.4. They are also referenced in 125.3.

For 25GBASE-KR and 25GBASE-KR-S, normative delay specifications may be found in 106.1.4, 107.4, 109.5, and 111.4, and also referenced in 105.5.

For 40GBASE-KR4, normative delay specifications may be found in 81.1.4, 82.5, 83.5.4, and 84.4 and also referenced in 80.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For 50GBASE-KR, normative delay specifications may be found in 132.1.4, 133.3, 135.5.4, and 137.5, and also referenced in 131.4.

For 100GBASE-KR4, normative delay specifications may be found in 81.1.4, 82.5, 83.5.4, 91.4, and 93.4 and also referenced in 80.4.

For 100GBASE-KP4, normative delay specifications may be found in 81.1.4, 82.5, 91.4, and 94.3.3 and also referenced in 80.4.

For 100GBASE-KR2, normative delay specifications may be found in 81.1.4, 82.5, 135.5.4, and 137.5, and also referenced in 80.4.

For 200GBASE-KR4, normative delay specifications may be found in 117.1.4, 119.5, 120.5.4, and 137.5, and also referenced in 116.4.

Table 69–3—Round-trip delay constraints for 10GBASE-KX4 and 10GBASE-KR

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Notes
MAC Control, MAC, and RS	8192	16	See 46.1.4
XGXS and XAUI	4096	8	Round-trip of 2 XGXS and trace for both directions, see 47.2.2
10GBASE-X PCS and PMA	2048	4	See 48.5
10GBASE-R PCS	3584	7	See 49.2.15
10GBASE-R FEC	6144	12	See 74.6
10GBASE-KX4 PMD[a]	512	1	See 71.3
10GBASE-KR PMA and PMD[a]	1024	2	See 72.4

[a]The 10GBASE-KX4 PMD and 10GBASE-KR PMA and PMD delays include the delay associated with the backplane medium.

69.4 State diagrams

In the case of any ambiguity between the text and the state diagrams, the state diagrams take precedence.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

69.5 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 70 through Clause 74, Clause 84, Clause 91, Clause 93, Clause 94, Clause 108, Clause 111, Clause 119, Clause 128, Clause 130, Clause 134, Clause 137, and related annexes demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each

clause as appropriate. Each of the Backplane Ethernet PICS uses the notation and conventions specified in 21.6.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70. Physical Medium Dependent sublayer and baseband medium, type 1000BASE-KX

70.1 Overview

This clause specifies the 1000BASE-KX PMD and baseband medium. When forming a complete PHY, a PMD shall be combined with the appropriate sublayers (see Table 70–1), and with the management functions that are optionally accessible through the management interface defined in Clause 45.

Table 70–1—Physical Layer clauses associated with the 1000BASE-KX PMD

Associated clause	1000BASE-KX
35—GMII[a]	Optional
36—1000BASE-X PCS/PMA	Required
73—Auto-Negotiation for Backplane Ethernet	Required
78—Energy-Efficient Ethernet	Optional

[a]The GMII is an optional interface. However, if the GMII is not implemented, a conforming implementation behaves functionally as though the RS and GMII were present.

The Clause 36 PCS/PMA when used with 1000BASE-KX PMD shall support full duplex operation only.

A 1000BASE-KX PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization. The “Assert LPI” request at the GMII is encoded in the transmitted symbols. Detection of LPI signaling in the received symbols is indicated as “Assert LPI” at the GMII. Upon the detection of “Assert LPI” at the GMII, an energy-efficient 1000BASE-KX PHY continues transmitting for a predefined period, then ceases transmission and deactivates transmit functions to conserve energy. The PHY periodically transmits during this quiet period to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variations in the timing of the link or the underlying channel characteristics. If, during the quiet or refresh periods, normal interframes resume at the GMII, the PHY reactivates transmit functions and initiates transmission. This transmission will be detected by the remote PHY, causing it to also exit the LPI mode.

70.2 Physical Medium Dependent (PMD) service interface

The 1000BASE-KX PMD performs the following three functions in support of the matching service interface primitives of 38.1.1: Transmit, Receive, and Signal Detect.

The PMD provides the following service interface signals if EEE is supported:

PMD_RXQUIET.request(rx_quiet)
PMD_TXQUIET.request(tx_quiet)

These messages signals are defined for the PCS in 36.2.5.1.6.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70.2.1 PMD_RXQUIET.request

This primitive is generated by the PCS Receive Process when EEE is supported to indicate that the input signal is quiet and the PMA and PMD receiver may go into low power mode. See 36.2.4.13. When EEE is not supported, the primitive is never invoked and the PMD behaves as if rx_quiet = FALSE.

70.2.1.1 Semantics of the service primitive

PMD_RXQUIET.request (rx_quiet)

The rx_quiet parameter takes on one of two values: TRUE or FALSE.

70.2.1.2 When generated

The PCS generates this primitive to request the appropriate PMD receive LPI state.

70.2.1.3 Effect of receipt

This variable is from the receive process of the PCS to control the power-saving function of the local PMD receiver. The 1000BASE-KX PHY receiver should put unused functional blocks into a low power state to save energy.

70.2.2 PMD_TXQUIET.request

This primitive is generated by the PCS Transmit Process when EEE is supported to indicate that the PMA and PMD transmit functions may go into a low power mode and to disable the PMD transmitter. See 70.6.5. When EEE is not supported, the primitive is never invoked and the PMD behaves as if tx_quiet = FALSE.

70.2.2.1 Semantics of the service primitive

PMD_TXQUIET.request (tx_quiet)

The tx_quiet parameter takes on one of two values: TRUE or FALSE.

70.2.2.2 When generated

The PCS generates this primitive to request the appropriate PMD transmit LPI state.

70.2.2.3 Effect of receipt

This primitive affects operation of the PMD Transmit disable function as described in 70.6.5. The 1000BASE-KX PHY transmitter should put unused functional blocks into a lower power state to save energy.

70.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD shall support the AN service interface primitive AN_LINK.indication as defined in 73.9. (See 36.2.5.2.7.)

70.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

sublayer, and PHY implementers consider the delay maxima, and that network planners and administrators consider the delay constraints regarding the physical topology and concatenation of devices. A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 69.3

The sum of transmit and receive delays contributed by the 1000BASE-KX PCS, PMA, and PMD shall be no more than 328 bit times. It is assumed that the round-trip delay through the medium is 16 bit times.

70.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If the MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 70–2, and MDIO status variables to PMD status variables as shown in Table 70–3.

Table 70–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	Control register 1	1.0.15	PMD_reset
PMD Transmit Disable	1000BASE-KX/2.5GBASE-KX control register	1.160.0	PMD_transmit_disable

Table 70–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	Status register 1	1.1.7	PMD_fault
Transmit fault ability	1000BASE-KX/2.5GBASE-KX status register	1.161.13	PMD_Transmit_fault_ability
Receive fault ability	1000BASE-KX/2.5GBASE-KX status register	1.161.12	PMD_Receive_fault_ability
Transmit fault	1000BASE-KX/2.5GBASE-KX status register	1.161.11	PMD_transmit_fault
Receive fault	1000BASE-KX/2.5GBASE-KX status register	1.161.10	PMD_receive_fault
PMD transmit disable ability	1000BASE-KX/2.5GBASE-KX status register	1.161.8	PMD_transmit_disable_ability
Signal detect from PMD	1000BASE-KX/2.5GBASE-KX status register	1.161.0	PMD_signal_detect

70.6 PMD functional specifications

The 1000BASE-KX PMD performs the following three functions in support of the matching service interface primitives of 38.1.1: Transmit, Receive, and Signal Detect (see service interface definition in 70.2).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70.6.1 Link block diagram

For purposes of system conformance, the PMD sublayer is standardized at test points TP1 and TP4 as shown in Figure 70–1. The transmitter and receiver blocks include all off-chip components associated with the respective block. For example, external AC-coupling capacitors, if required, are to be included in the receiver block.

The electrical path from the transmitter block to TP1, and from TP4 to the receiver block, will affect link performance and the measured values of electrical parameters used to verify conformance to this specification. It is therefore recommended that this path be carefully designed.

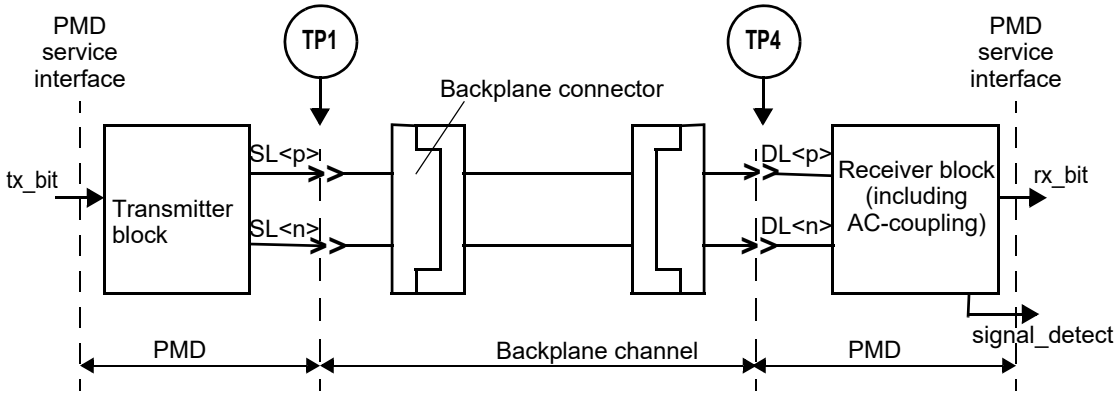

Figure 70–1—Link block diagram

70.6.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according electrical specifications in 70.7.1. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = ONE.

70.6.3 PMD receive function

The PMD Receive function shall convey the bits received at the MDI in accordance with the electrical specifications of 70.7.2 to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = ONE.

70.6.4 PMD signal detect function

For 1000BASE-KX operation PMD signal detect is mandatory if EEE is supported. When EEE is not supported, the PMD signal detect is optional for 1000BASE-KX and its definition is beyond the scope of this specification. When PMD signal detect is not implemented, the value of SIGNAL_DETECT shall be set to OK for purposes of management and signaling of the primitive.

If EEE is supported, a local PMD signal detect function shall report to the PMD service interface using the message PMD_SIGNAL.indication(SIGNAL_DETECT). This message is signaled continuously. For EEE, the SIGNAL_DETECT parameter can take on one of two values, OK or FAIL, indicating whether the PMD is detecting electrical energy at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication is undefined. The signal energy from a compliant transmitter shall set

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SIGNAL_DETECT to OK within 750 ns when transitioning from LPI quiet to active and set SIGNAL_DETECT to FAIL within 750 ns when transitioning from active to LPI quiet.

70.6.5 PMD transmit disable function

The PMD_transmit_disable function is mandatory if EEE is supported and is otherwise optional. When implemented, it allows the transmitter to be disabled with a single variable.

a) When the PMD_transmit_disable variable is set to ONE, this function shall turn off the transmitter such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 70–4.
b) If a PMD_fault (70.6.7) is detected, then the PMD may turn off the electrical transmitter.
c) Loopback, as defined in 70.6.6, shall not be affected by PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off the transmitter after tx_quiet is asserted within the time and voltage level specified in 70.7.1.5. The PMD_transmit_disable function shall turn on the transmitter after tx_quiet is de-asserted within a time and voltage level specified in 70.7.1.5.

70.6.6 Loopback mode

Loopback mode shall be provided for the 1000BASE-KX PMA/PMD by the transmitter and receiver of a device as a test function to the device. When loopback mode is selected, transmission requests passed to the transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. Transmitter operation shall be independent of loopback mode. A device has to be explicitly placed in loopback mode because loopback mode is not the normal mode of operation of a device. The method of implementing loopback mode is not defined by this standard.

Control of the loopback function is specified in 45.2.1.1.5.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

70.6.7 PMD fault function

If the MDIO is implemented, and the PMD has detected a local fault, the PMD shall set PMD_fault to ONE; otherwise, the PMD shall set PMD_fault to ZERO.

70.6.8 PMD transmit fault function

If the MDIO is implemented, and the PMD has detected a local fault on the transmitter, the PMD shall set the PMD_transmit_fault variable to ONE; otherwise, the PMD shall set PMD_transmit_fault to ZERO.

70.6.9 PMD receive fault function

If the MDIO is implemented, and the PMD has detected a local fault on the receiver, the PMD shall set the PMD_receive_fault variable to ONE; otherwise, the PMD shall set PMD_receive_fault to ZERO.

70.6.10 PMD LPI function

The PMD LPI function responds to the transitions between Active, Sleep, Quiet, Refresh, and Wake states via the PMD_TXQUIET and PMD_RXQUIET requests. Implementation of the function is optional. EEE

capabilities and parameters are advertised during the Backplane Auto-negotiation as described in 45.2.7.14. The transmitter on the local device informs the link partner's receiver when to sleep, refresh, and wake. The local receiver's transitions are controlled by the link partner's transmitter and change independently from the local transmitter's states and transitions.

The transmitter sends /LI/ ordered sets during the sleep and refresh states, disables the transmitter during quiet, and forwards /I/ during the wake phase.

If EEE is supported, the PMD transmit function enters into a low power mode when tx_quiet is set to TRUE and exits when tx_quiet is set to FALSE. While tx_quiet is TRUE the PMD transmitter functional blocks should be deactivated to conserve energy. The PMD receive function enters into a low power mode when rx_quiet is set to TRUE and exits when rx_quiet is set to FALSE. While rx_quiet is TRUE the PMD receiver functional blocks should be deactivated to conserve energy.

70.7 1000BASE-KX electrical characteristics

70.7.1 Transmitter characteristics

Transmitter characteristics at TP1 are summarized in Table 70–4 and detailed in 70.7.1.1 through 70.7.1.9.

Table 70–4—Transmitter characteristics for 1000BASE-KX

Parameter	Subclause reference	Value	Units
Signaling speed	70.7.1.3	1.25 ± 100 ppm	GBd
Differential peak-to-peak output voltage	70.7.1.5	800 to 1600	mV
Differential peak-to-peak output voltage (max.) with TX disabled	70.6.5	30	mV
DC common-mode voltage limits	70.7.1.5	–0.4 to 1.9	V
Common-mode voltage deviation (max) during LPI	70.7.1.5	150	mV
Differential output return loss (min.)	70.7.1.6	[See Equation (70–1) and Equation (70–2)]	dB
Transition time[a] (20%–80%)	70.7.1.7	60 to 320	ps
Output jitter (max. peak-to-peak) Deterministic jitter[b] Random jitter Total jitter[c]	70.7.1.8	 0.10 0.15 0.25	 UI UI UI

[a]Transition time parameters are recommended values, not compliance values.
[b]Deterministic jitter is already incorporated into the differential output template.
[c]At BER 10^{-12}.

70.7.1.1 Test fixtures

The test fixture of Figure 70–2, or its functional equivalent, is required for measuring the transmitter specifications described in 70.7.1, with the exception of return loss.

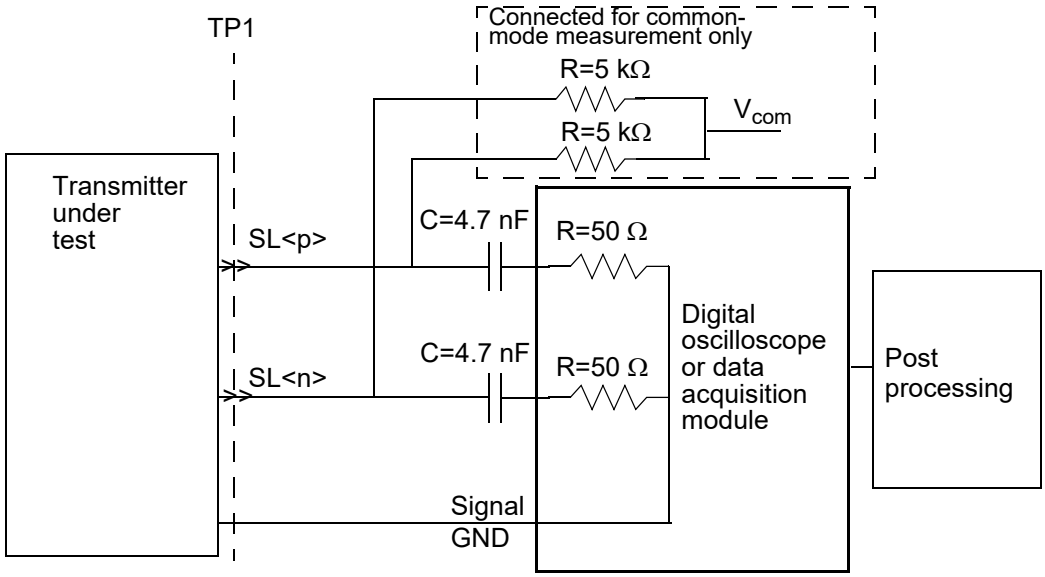

Figure 70–2—Transmit test fixture for 1000BASE-KX

70.7.1.2 Test fixture impedance

The differential load impedance applied to the transmitter output by the test fixture depicted in Figure 70–2 shall be 100 Ω with a return loss greater than 20 dB from 50 MHz to 625 MHz.

70.7.1.3 Signaling speed

The 1000BASE-KX signaling speed shall be 1.25 GBd ± 100 ppm.

70.7.1.4 Differential output eye mask

The transmitter differential output signal is defined at TP1, as shown in Figure 70–2. The transmitter output waveform shall fall within the eye mask shown in Figure 70–3 for the jitter test frame defined in 59.7.1. Voltage and time coordinates for mask points on Figure 70–3 are given in Table 70–5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

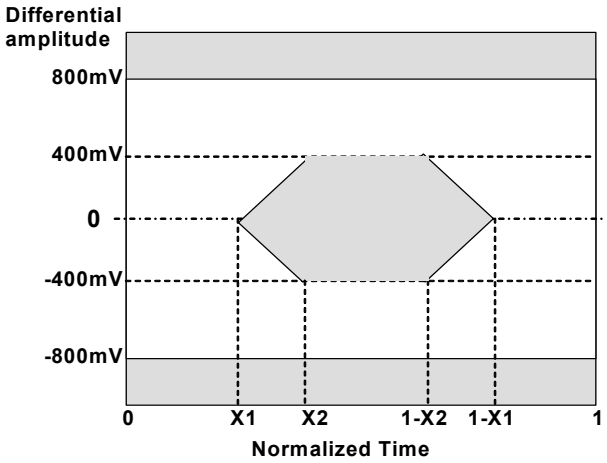

Figure 70–3—Absolute eye diagram mask at TP1 for 1000BASE-KX

Table 70–5—Transmitted eye mask at TP1 for 1000BASE-KX

Symbol	Value	Units
X1	0.125	Unit intervals (UI)
X2	0.325	Unit intervals (UI)

70.7.1.5 Output amplitude

While transmitting the test pattern specified in 36A.2, the transmitter differential peak-to-peak output voltage shall be between 800 mV and 1600 mV. See Figure 70–4 for an illustration of the definition of differential peak-to-peak output voltage. DC-referenced voltage levels are not defined since the receiver is AC-coupled. The common-mode voltage of SL<p> and SL<n> shall be between –0.4 V and 1.9 V with respect to signal ground as measured at V_{com} in Figure 70–2.

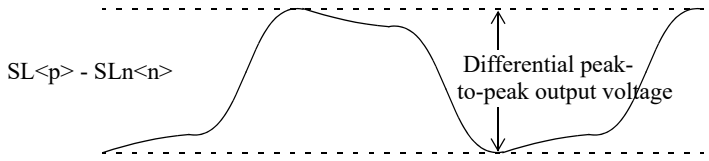

Figure 70–4—Transmitter differential peak-to-peak output voltage definition

NOTE—SL<p> and SL<n> are the positive and negative sides of the differential signal pair respectively.

For EEE capability, the transmitter's differential peak-to-peak output voltage shall be less than 30 mV within 500 ns of tx_quiet being asserted. Furthermore, the transmitters differential peak-to-peak output voltage shall be greater than 720 mV within 500 ns of tx_quiet being de-asserted. The transmitter output shall be fully compliant within 5 μs after tx_quiet is set to FALSE. During LPI, the common-mode shall be maintained to within ±150 mV of the pre-LPI value.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70.7.1.6 Differential output return loss

For frequencies from 50 MHz to 1250 MHz, the differential return loss, in dB with f in MHz, of the transmitter shall meet the requirements of Equation (70–1) and Equation (70–2). This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$\text{ReturnLoss}(f) \geq 10 \tag{70–1}$$

for 50 MHz ≤ f < 625 MHz and

$$\text{ReturnLoss}(f) \geq 10 - 10 \times \log\left(\frac{f}{625}\right) \tag{70–2}$$

for 625 MHz ≤ f ≤ 1250 MHz.

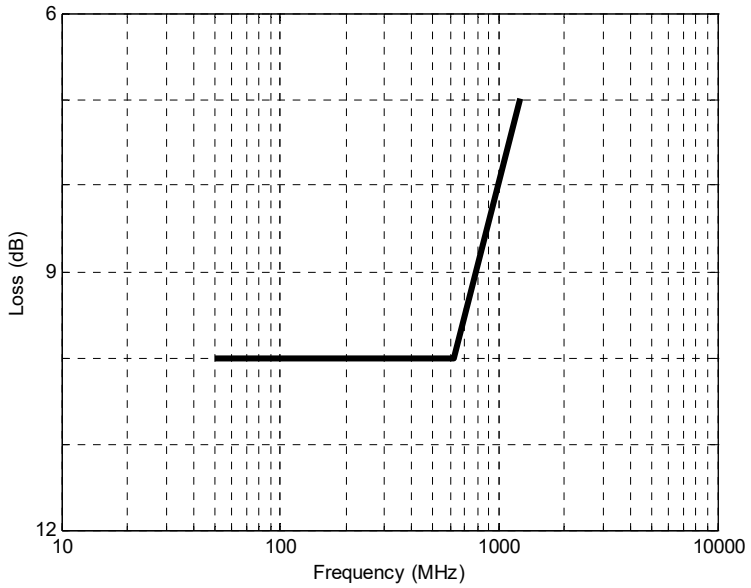

Figure 70–5—Differential return loss

70.7.1.7 Transition time

The rising edge transition time is recommended to be no less than 60 ps as measured at the 20% and 80% levels of the peak-to-peak differential value of the waveform using the high-frequency test pattern of 36A.1.

The falling edge transition time is recommended to be no less than 60 ps as measured at the 80% and 20% levels of the peak-to-peak differential value of the waveform using the high-frequency test pattern of 36A.1.

The maximum transition time is recommended to be no more than 320 ps.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70.7.1.8 Transmit jitter

The transmitter shall have a maximum total jitter of 0.25 UI peak-to-peak and a maximum deterministic component of 0.10 UI peak-to-peak. Jitter specifications include all but 10^{-12} of the jitter population. Transmit jitter test requirements are specified in 70.7.1.9.

70.7.1.9 Transmit jitter test requirements

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in Annex 48B. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 750 kHz is applied to the jitter. The data pattern for jitter measurements shall be the jitter test frame described in 59.7.1. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal.

70.7.2 Receiver characteristics

Receiver characteristics at TP4 are summarized in Table 70–6 and detailed in 70.7.2.1 through 70.7.2.5.

Table 70–6—Receiver characteristics for 1000BASE-KX

Parameter	Subclause reference	Value	Units
Bit error ratio	70.7.2.1	10^{-12}	
Signaling speed	70.7.2.2	1.25 ± 100 ppm	GBd
Receiver coupling	70.7.2.3	AC	
Differential input peak-to-peak amplitude (max.)	70.7.2.4	1600	mV
Differential input return loss (min.)	70.7.2.5	[See Equation (70–1) and Equation (70–2)]	dB

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70.7.2.1 Receiver interference tolerance

The receiver interference tolerance shall be measured as described in Annex 69A with the parameters specified in Table 70–7. The data pattern for the interference tolerance test shall be the jitter pattern test frame as defined in 59.7.1. The receiver shall satisfy the requirements for interference tolerance specified in Annex 69A.

Table 70–7—1000BASE-KX interference tolerance parameters

Parameter	Value	Units
Target BER	10^{-12}	
m_{TC}[a] (min.)	1.0	
Amplitude of broadband noise (min. RMS)	8.6	mV
Applied transition time (20%–80%, min.)	320	ps
Applied sinusoidal jitter (min. peak-to-peak)	0.10	UI
Applied random jitter (min. peak-to-peak)[b]	0.15	UI
Applied duty cycle distortion (min. peak-to-peak)	0.0	UI

[a]m_{TC} is defined in Equation (69A–6) of Annex 69A.
[b]Applied random jitter is specified at a BER of 10^{-12}.

70.7.2.2 Signaling speed range

A 1000BASE-KX receiver shall comply with the requirements of Table 70–7 for any signaling speed in the range 1.25 GBd ± 100 ppm. The corresponding unit interval is nominally 800 ps.

70.7.2.3 AC-coupling

The receiver shall be AC-coupled to the backplane to allow for maximum interoperability between various PMD components. AC-coupling is considered to be part of the receiver for the purposes of this specification unless explicitly stated otherwise. It should be noted that there may be various methods for AC-coupling in actual implementations.

NOTE—It is recommended that the maximum value of the coupling capacitors be limited to 4.7 nF. This will limit the inrush currents to the receiver that could damage the receiver circuits when repeatedly connected to transmit modules with a higher voltage level.

70.7.2.4 Input signal amplitude

Receivers shall accept differential input signal peak-to-peak amplitudes produced by compliant transmitters connected without attenuation to the receiver, and still meet the BER requirement specified in 70.7.2.1. Note that this may be larger than the 1600 mV differential maximum of 70.7.1.5 due to the actual transmitter output and receiver input impedances. The input impedance of a receiver can cause the minimum signal into a receiver to differ from that measured when the receiver is replaced with a 100 Ω test load. Since the receiver is AC-coupled, the absolute voltage levels with respect to the receiver ground are dependent on the receiver implementation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

70.7.2.5 Differential input return loss

For frequencies from 50 MHz to 1250 MHz, the differential return loss, in dB with f in MHz, of the receiver shall meet the requirements of Equation (70–1) and Equation (70–2). The reference impedance for differential return loss measurements shall be 100 Ω.

70.8 Interconnect characteristics

Informative interconnect characteristics for 1000BASE-KX are provided in Annex 69B.

70.9 Environmental specifications

70.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

70.9.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

70.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

70.9.4 Electromagnetic compatibility

A system integrating the 1000BASE-KX PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

70.9.5 Temperature and humidity

A system integrating the 1000BASE-KX PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

70.10 Protocol implementation conformance statement (PICS) proforma for Clause 70, Physical Medium Dependent (PMD) sublayer and baseband medium, type 1000BASE-KX[132]

70.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 70, Physical Medium Dependent (PMD) sublayer and baseband medium type 1000BASE-KX, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

70.10.2 Identification

70.10.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

70.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 70, Physical Medium Dependent (PMD) sublayer and baseband medium type 1000BASE-KX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[132]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

71. Physical Medium Dependent sublayer and baseband medium, type 10GBASE-KX4

71.1 Overview

This clause specifies the 10GBASE-KX4 PMD and the baseband medium. When forming a complete PHY, a PMD shall be connected to the appropriate sublayers (see Table 71–1), and with the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

The XAUI, defined by Clause 47, is intended for chip-to-chip applications for lengths up to approximately 0.5 m. 10GBASE-KX4 is intended for backplane applications up to 1 m in length.

Table 71–1—Physical Layer clauses associated with the 10GBASE-KX4 PMD

Associated clause	10GBASE-KX4
46—XGMII[a]	Optional
47—XGXS and XAUI	Optional
48—10GBASE-X PCS/PMA	Required
73—Auto-Negotiation for Backplane Ethernet	Required
78—EEE	Optional

[a]The XGMII is an optional interface. However, if the XGMII is not implemented, a conforming implementation behaves functionally as though the RS and XGMII were present.

A 10GBASE-KX4 PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization. The “Assert LPI” request at the XGMII is encoded in the transmitted symbols. Detection of LPI signaling in the received symbols is indicated as “Assert LPI” at the XGMII. Upon the detection of “Assert LPI” at the XGMII, an energy-efficient 10GBASE-KX4 PHY continues transmitting for a predefined period, then ceases transmission and deactivates transmit functions to conserve energy. The PHY periodically transmits during this quiet period to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variations in the timing of the link or the underlying channel characteristics. If, during the quiet or refresh periods, normal interframes resume at the XGMII, the PHY reactivates transmit functions and initiates transmission. This transmission will be detected by the remote PHY, causing it to also exit the LPI mode.

71.2 Physical Medium Dependent (PMD) service interface

The 10GBASE-KX4 PMD utilizes the PMD service interface defined in 53.1.1.

The following primitives are defined on the PMD Service Interface when EEE is supported:

PMD_RXQUIET.request(rx_quiet)
PMD_TXQUIET.request(tx_quiet)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

These messages are defined for the PCS in 48.2.6.1.7.

71.2.1 PMD_RXQUIET.request

This primitive is generated by the PCS Receive Process when EEE is supported to indicate that the input signal is quiet and the PMA and PMD receiver may go into a low power mode. When EEE is not supported, the primitive is never invoked and the PMD behaves as if rx_quiet = FALSE.

71.2.1.1 Semantics of the service primitive

PMD_RXQUIET.request (rx_quiet)

The rx_quiet parameter takes on one of two values: TRUE or FALSE.

71.2.1.2 When generated

The PCS generates this primitive to request the appropriate PMD receive LPI state.

71.2.1.3 Effect of receipt

This variable is from the Receive process of the PCS to control the power-saving function of the local receiver. The 10GBASE-KX4 PHY receiver should put unused functional blocks into a low power state to save energy.

71.2.2 PMD_TXQUIET.request

This primitive is generated by the PCS Transmit Process when EEE is supported to indicate that the PMA and PMD transmit functions may go into a low power mode and to disable the PMD transmitter. When EEE is not supported, the primitive is never invoked and the PMD behaves as if tx_quiet = FALSE.

71.2.2.1 Semantics of the service primitive

PMD_TXQUIET.request (tx_quiet)

The tx_quiet parameter takes on one of two values: TRUE or FALSE.

71.2.2.2 When generated

The PCS generates this primitive to request the appropriate PMD transmit LPI state.

71.2.2.3 Effect of receipt

This primitive affects operation of the PMD Transmit disable function as described in 71.6.6. The 10GBASE-KX4 PHY transmitter should put unused functional blocks into a lower power state to save energy.

71.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD shall support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 48.2.7.)

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

71.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementers consider the delay maxima, and that network planners and administrators consider the delay constraints regarding the physical topology and concatenation of devices. A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 69.3.

The sum of transmit and receive delays contributed by the 10GBASE-KX4 PMD and medium shall be no more than 512 bit times or 1 pause_quanta. It is assumed that the round-trip delay through the medium is 160 bit times.

71.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If the MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 71–2 and MDIO status variables to PMD status variables as shown in Table 71–3.

Table 71–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	Control register 1	1.0.15	PMD_reset
Global PMD transmit disable	Transmit disable register	1.9.0	Global_PMD_transmit_disable
Transmit disable 3	Transmit disable register	1.9.4	PMD_transmit_disable_3
Transmit disable 2	Transmit disable register	1.9.3	PMD_transmit_disable_2
Transmit disable 1	Transmit disable register	1.9.2	PMD_transmit_disable_1
Transmit disable 0	Transmit disable register	1.9.1	PMD_transmit_disable_0

71.6 PMD functional specifications

The 10GBASE-KX4 PMD performs the transmit and receive functions that convey data between the PMD service interface and the MDI, and provides various management functions if the optional MDIO is implemented.

71.6.1 Link block diagram

For purposes of system conformance, the PMD sublayer is standardized at test points TP1 and TP4 as shown in Figure 71–1. The transmitter and receiver blocks include all off-chip components associated with the respective block. For example, external AC-coupling capacitors, if required, are to be included in the receiver block.

Table 71–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	Status register 1	1.1.7	PMD_fault
Transmit fault	Status register 2	1.8.11	PMD_transmit_fault
Receive fault	Status register 2	1.8.10	PMD_receive_fault
Global PMD Receive signal detect	Receive signal detect register	1.10.0	Global_PMD_signal_detect
PMD signal detect 3	Receive signal detect register	1.10.4	PMD_signal_detect_3
PMD signal detect 2	Receive signal detect register	1.10.3	PMD_signal_detect_2
PMD signal detect 1	Receive signal detect register	1.10.2	PMD_signal_detect_1
PMD signal detect 0	Receive signal detect register	1.10.1	PMD_signal_detect_0

The electrical path from the transmitter block to TP1, and from TP4 to the receiver block, will affect link performance and the measured values of electrical parameters used to verify conformance to this specification. It is therefore recommended that this path be carefully designed.

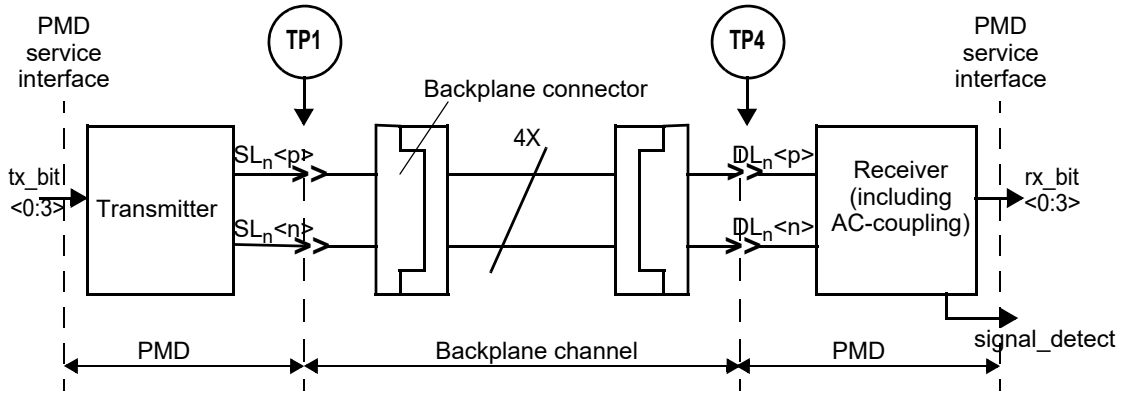

Figure 71–1—Link block diagram

71.6.2 PMD Transmit function

The PMD Transmit function shall convert the four logical bit streams requested by the PMD service interface message PMD_UNITDATA.request (tx_bit<0:3>) into four separate electrical signals. The four electrical signals shall then be delivered to the MDI, all according to the specifications in 71.7.1. A positive output voltage of SLn<p> minus SLn<n> (differential voltage) shall correspond to tx_bit = ONE.

The PMD shall convey the bits received from the PMD service interface using the message PMD_UNITDATA.request(tx_bit<0:3>) to the MDI lanes, where SL0<p>/<n> corresponds to tx_bit<0>, SL1<p>/<n> to tx_bit<1>, SL2<p>/<n> to tx_bit<2>, and SL3<p>/<n>) = tx_bit<3>.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

71.6.3 PMD Receive function

The PMD Receive function shall convert the four electrical signals from the MDI into four logical bit streams for delivery to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit<0:3>), all according to the receive electrical specifications in 71.7.2. A positive input voltage level in each signal of DLn<p> minus DLn<n> (differential voltage) shall correspond to a rx_bit = ONE.

The PMD shall convey the bits received from the MDI lanes to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit<0:3>), where rx_bit<0:3> = (DL0<p>/<n>, DL1<p>/<n>, DL2<p>/<n>, DL3<p>/<n>).

71.6.4 Global PMD signal detect function

For 10GBASE-KX4 operation Global PMD signal detect is mandatory if EEE is supported. When EEE is not implemented, the PMD signal detect is optional for 10GBASE-KX4 and its definition is beyond the scope of this standard. When Global PMD signal detect is not implemented, the value of SIGNAL_DETECT shall be set to OK for purposes of management and signaling of the primitive.

If EEE is supported, a local PMD signal detect function shall report to the PMD service interface using the message PMD_SIGNAL.indication(SIGNAL_DETECT). This message is signaled continuously. For EEE, the SIGNAL_DETECT parameter can take on one of two values, OK or FAIL, indicating whether the PMD is detecting electrical energy at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication(rx_lane<3:0>) is undefined. The signal energy from a compliant transmitter shall set SIGNAL_DETECT to OK within 750 ns when transitioning from LPI quiet to active and set SIGNAL_DETECT to FAIL within 750 ns when transitioning from active to LPI quiet.

71.6.5 PMD lane-by-lane signal detect function

When the MDIO is implemented, each PMD_signal_detect_n value, where n represents the lane number in the range 0:3, shall report the value of SIGNAL_DETECT for the corresponding lane when signal detect is implemented, or OK otherwise.

71.6.6 Global PMD transmit disable function

The Global_PMD_transmit_disable function is mandatory if EEE is supported and is otherwise optional. When implemented, it allows all of the transmitters to be disabled with a single variable.

a) When the Global_PMD_transmit_disable variable is set to ONE, this function shall turn off all of the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 71–4.
b) If a PMD_fault (71.6.9) is detected, then the PMD may turn off the electrical transmitter in all lanes.
c) Loopback, as defined in 71.6.8, shall not be affected by Global_PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off all transmitter lanes after tx_quiet is asserted within a time and voltage level specified in 71.7.1.4. The PMD_transmit_disable function shall turn on all transmitter lanes after tx_quiet is de-asserted within a time and voltage level specified in 71.7.1.4.

71.6.7 PMD lane-by-lane transmit disable function

The PMD_transmit_disable_n function shall be implemented. It allows the electrical transmitters in each lane to be selectively disabled.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) When a PMD_transmit_disable_n variable is set to ONE, this function shall turn off the transmitter associated with that variable such that the corresponding transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 71–4.
b) If a PMD_fault (71.6.9) is detected, then the PMD may turn off the electrical transmitter in all lanes.
c) Loopback, as defined in 71.6.8, shall not be affected by PMD_transmit_disable_n.

NOTE—Turning off a transmitter can be disruptive to a network.

71.6.8 Loopback mode

Loopback mode shall be provided for the 1000BASE-KX4 PMA/PMD by the transmitter and receiver of a device as a test function to the device. When loopback mode is selected, transmission requests passed to the transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. Transmitter operation shall be independent of loopback mode. A device has to be explicitly placed in loopback mode because loopback mode is not the normal mode of operation of a device. The method of implementing loopback mode is not defined by this standard.

Control of the loopback function is specified in 45.2.1.1.5.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

71.6.9 PMD fault function

If the MDIO is implemented, and the PMD has detected a local fault on any of the transmit or receive paths, the PMD shall set PMD_fault to ONE; otherwise, the PMD shall set PMD_fault to ZERO.

71.6.10 PMD transmit fault function

If the MDIO is implemented, and the PMD has detected a local fault on any transmit lane, the PMD shall set the PMD_transmit_fault variable to ONE; otherwise, the PMD shall set PMD_transmit_fault to ZERO.

71.6.11 PMD receive fault function

If the MDIO is implemented, and the PMD has detected a local fault on any receive lane, the PMD shall set the PMD_receive_fault variable to ONE; otherwise, the PMD shall set PMD_receive_fault to ZERO.

71.6.12 PMD LPI function

The PMD LPI function responds to transitions between Active, Sleep, Quiet, Refresh, and Wake states via the PMD_TXQUIET and PMD_RXQUIET requests. Implementation of the function is optional. EEE capabilities and parameters, as described in 45.2.7, is advertised during the Backplane Auto-negotiation. The transmitter on the local device will inform the link partner’s receiver when to sleep, refresh, and wake. The local receiver transitions are controlled by the link partner’s transmitter and can change independent of the local transmitter states and transitions.

The transmitter sends /LI/ ordered sets during the sleep and refresh states, disables the transmitter during quiet, and forwards ||I|| during the wake phase.

If EEE is supported, the PMD transmit function enters into a low power mode when tx_quiet is set to TRUE and exits when tx_quiet is set to FALSE. While tx_quiet is TRUE the PMD transmitter functional blocks should be deactivated to conserve energy. The PMD receive function enters into a low power mode when rx_quiet is set to TRUE and exits when rx_quiet is set to FALSE. While rx_quiet is TRUE, the PMD receiver functional blocks should be deactivated to conserve energy.

71.7 Electrical characteristics for 10GBASE-KX4

71.7.1 Transmitter characteristics

Transmitter characteristics at TP1 are summarized in Table 71–4.

Table 71–4—Transmitter characteristics for 10GBASE-KX4

Parameter	Subclause reference	Value	Units
Signaling speed, per lane	71.7.1.3	3.125 ± 100 ppm	GBd
Differential peak-to-peak output voltage	71.7.1.4	800 to 1200	mV
Differential peak-to-peak output voltage (max.) with TX disabled	71.6.6, 71.6.7	30	mV
Common-mode voltage limits	71.7.1.4	–0.4 to 1.9	V
Common-mode voltage deviation (max) during LPI	71.7.1.4	150	mV
Differential output return loss (min.)	71.7.1.5	[See Equation (71–1) and Equation (71–2)]	dB
Differential output template	71.7.1.6	[See Figure 71–5 and Table 71–5]	V
Transition time[a] (20%–80%)	71.7.1.7	60 to 130	ps
Output jitter (max. peak-to-peak) Random jitter Deterministic jitter Total jitter[b]	71.7.1.8	 0.27 0.17 0.35	 UI UI UI

[a]Transition time parameters are recommended values, not compliance values.
[b]At BER 10^{-12}.

71.7.1.1 Test fixtures

The test fixture of Figure 71–2, or its functional equivalent, is required for measuring the transmitter specifications described in 71.7.1, with the exception of return loss.

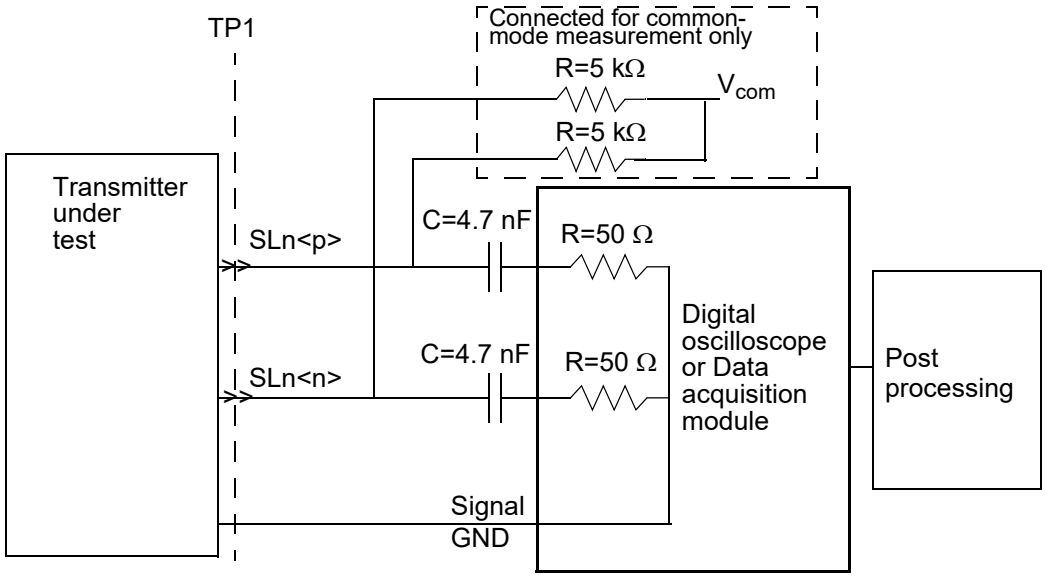

Figure 71–2—Transmit test fixture for 10GBASE-KX4

71.7.1.2 Test fixture impedance

The differential load impedance applied to the transmitter output by the test fixture depicted in Figure 71–2 shall be 100 Ω with a return loss greater than 20 dB from 100 MHz to 2000 MHz.

71.7.1.3 Signaling speed

The 10GBASE-KX4 signaling speed shall be 3.125 GBd ±100 ppm. The corresponding unit interval is nominally 320 ps.

71.7.1.4 Output amplitude

While transmitting the test pattern specified in 48A.2,

1) The transmitter maximum differential peak-to-peak output voltage shall be less than 1200 mV.
2) The minimum differential peak-to-peak output voltage shall be greater than 800 mV.
3) The maximum difference between any two lanes' differential peak-to-peak output voltage shall be less than or equal to 150 mV.

See Figure 71–3 for an illustration of the definition of differential peak-to-peak output voltage.

DC-referenced voltage levels are not defined since the receiver is AC-coupled. The common-mode voltage of SLn<p> and SLn<n> shall be between –0.4 V and 1.9 V with respect to signal ground as measured at V_{com} in Figure 71–2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

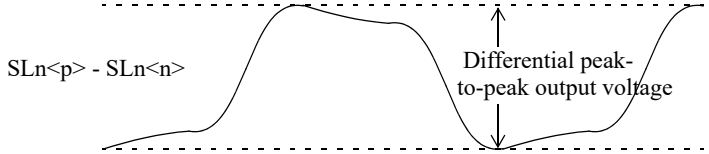

Figure 71–3—Transmitter differential peak-to-peak output voltage definition

NOTE—SLn<p> and SLn<n> are the positive and negative sides of the differential signal pair for Lane n (n = 0,1,2,3).

For EEE capability, the transmitter lane's differential peak-to-peak output voltage shall be less than 30 mV within 500 ns of tx_quiet being asserted. Furthermore, the transmitter lane's differential peak-to-peak output voltage shall be greater than 720 mV within 500 ns of tx_quiet being de-asserted. The transmitter output shall be fully compliant within 5 μs after tx_quiet is set to FALSE. During LPI, the common-mode shall be maintained to within ± 150 mV of the pre-LPI value.

71.7.1.5 Output return loss

For frequencies from 100 MHz to 2000 MHz, the differential return loss, in dB with f in MHz, of the transmitter shall meet the requirements of Equation (71–1) and Equation (71–2). This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$\text{ReturnLoss}(f) \geq 10 \tag{71–1}$$

for 100 MHz ≤ f < 625 MHz and

$$\text{ReturnLoss}(f) \geq 10 - 10 \times \log_{10}\left(\frac{f}{625}\right) \tag{71–2}$$

for 625 MHz ≤ f ≤ 2000 MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The minimum differential output return loss is shown in Figure 71–4.

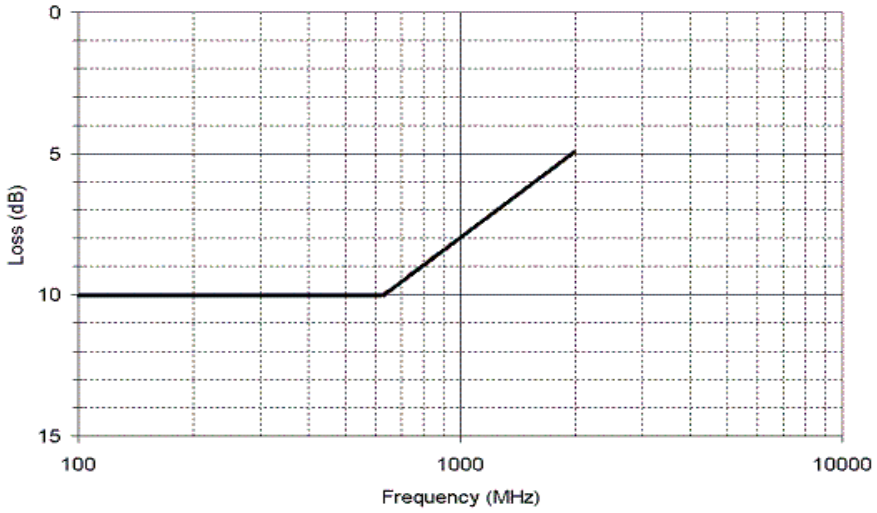

Figure 71–4—Minimum differential output return loss

71.7.1.6 Differential output template

The transmitter differential output signal is defined at TP1, as shown in Figure 71–2 and Figure 71–3. The transmitter shall provide equalization such that the output waveform falls within the template shown in Figure 71–5 for the test pattern specified in 48A.2, with all other transmitters active. All other transmitters shall be terminated with a load meeting the requirements described in 71.7.1.2. Voltage and time coordinates for inflection points on Figure 71–5 are given in Table 71–5. The waveform under test shall be normalized by using the following procedure:

a) Align the output waveform under test, to achieve the best fit along the horizontal time axis.
b) Calculate the +1 low frequency level as V_{lowp} = average of any two successive unit intervals (2UI) between 2.5 UI and 5.5 UI.
c) Calculate the 0 low frequency level as V_{lowm} = average of any two successive unit intervals (2UI) between 7.5 UI and 10.5 UI.
d) Calculate the vertical offset to be subtracted from the waveform as $V_{off} = (V_{lowp} + V_{lowm}) / 2$.
e) Calculate the vertical normalization factor for the waveform as $V_{norm} = (V_{lowp} – V_{lowm}) / 2$.
f) Calculate the normalized waveform as:
Normalized_Waveform = (Original_Waveform – V_{off}) × (0.69/V_{norm}).
g) Align the Normalized_Waveform under test, to achieve the best fit along the horizontal time axis.

71.7.1.7 Transition time

The rising edge transition time is recommended to be between 60 ps and 130 ps as measured at the 20% and 80% levels of the peak-to-peak differential value of the waveform using the high-frequency test pattern of 48A.1. The falling edge transition time is recommended to be between 60 ps and 130 ps as measured at the 80% and 20% levels of the peak-to-peak differential value of the waveform using the high-frequency test pattern of 48A.1.

71.7.1.8 Transmit jitter

The transmitter shall have a maximum total jitter of 0.350 UI peak-to-peak, a maximum deterministic component of 0.170 UI peak-to-peak, and a maximum random component of 0.270 UI peak-to-peak. Jitter specifications include all but 10^{-12} of the jitter population. Transmit jitter test requirements are specified in 71.7.1.9.

71.7.1.9 Transmit jitter test requirements

Transmit jitter is defined with respect to the transmitter differential output signal at TP1, as shown in Figure 71–2 and Figure 71–5, and the test procedure resulting in a BER bathtub curve such as that described in Annex 48B. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 1.875 MHz is applied to the jitter. The data pattern for jitter measurements shall be the jitter tolerance test pattern defined in Annex 48A.5. For this test, all other transmitters shall be active and terminated with a load meeting the requirements described in 71.7.1.2. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal.

71.7.2 Receiver characteristics

Receiver characteristics at TP4 are summarized in Table 71–6 and detailed in 71.7.2.1 through 71.7.2.5.

Table 71–6—Receiver characteristics

Parameter	Subclause reference	Value	Units
Bit error ratio	71.7.2.1	10^{-12}	
Signaling speed, per lane	71.7.2.2	3.125 ± 100 ppm	GBd
Unit interval (UI) nominal	71.7.2.2	320	ps
Receiver coupling	71.7.2.3	AC	
Differential input peak-to-peak amplitude (maximum)	71.7.2.4	1600	mV
EEE Signal Detect deactivation time (T_{SD}) from active to LPI quiet	71.6.4	750	ns
EEE Signal Detect activation time (T_{SA}) from LPI quiet to active	71.6.4	750	ns
Differential input return loss[a] (minimum)	71.7.2.5	[See Equation (71–1) and Equation (71–2)]	dB

[a]Relative to 100 Ω differential.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

71.7.2.1 Receiver interference tolerance

The receiver interference tolerance shall be measured as described in Annex 69A with the parameters specified in Table 71–7. The data pattern for the interference tolerance test shall be the continuous jitter test pattern as defined in Annex 48A.5. The receiver shall satisfy the requirements for interference tolerance specified in Annex 69A.

Table 71–7—10GBASE-KX4 interference tolerance parameters

Parameter	Value	Units
Target BER	10^{-12}	
m_{TC}[a] (min.)	1.0	
Amplitude of broadband noise (min. RMS)	8.1	mV
Applied transition time (20%–80%, min.)	130	ps
Applied sinusoidal jitter (min. peak-to-peak)	0.17	UI
Applied random jitter (min. peak-to-peak)[b]	0.18	UI
Applied duty cycle distortion (min. peak-to-peak)	0.0	UI

[a]m_{TC} is defined in Equation (69A–6) of Annex 69A.
[b]Applied random jitter is specified at a BER of 10^{-12}.

71.7.2.2 Signaling speed

The 10GBASE-KX4 signaling speed shall be 3.125 GBd ± 100 ppm. The corresponding unit interval is nominally 320 ps.

71.7.2.3 AC-coupling

The 10GBASE-KX4 receiver shall be AC-coupled to the backplane to allow for maximum interoperability between various 10 Gb/s components. AC-coupling is considered to be part of the receiver for the purposes of this specification unless explicitly stated otherwise. It should be noted that there may be various methods for AC-coupling in actual implementations.

NOTE—It is recommended that the maximum value of the coupling capacitors be limited to 4.7 nF. This will limit the inrush currents to the receiver that could damage the receiver circuits when repeatedly connected to transmit modules with a higher voltage level.

71.7.2.4 Input signal amplitude

10GBASE-KX4 receivers shall accept differential input signal peak-to-peak amplitudes produced by compliant transmitters connected without attenuation to the receiver, and still meet the BER requirement specified in 71.7.2.1. Note that this may be larger than the 1200 mV differential maximum of 71.7.1.4 due to the actual transmitter output and receiver input impedances. The input impedance of a receiver can cause the minimum signal into a receiver to differ from that measured when the receiver is replaced with a 100 Ω test load. Since the channel is AC-coupled, the absolute voltage levels with respect to the receiver ground are dependent on the receiver implementation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

71.7.2.5 Differential input return loss

For frequencies from 100 MHz to 2000 MHz, the differential return loss, in dB with *f* in MHz, of the receiver shall be greater than or equal to Equation (71–1) and Equation (71–1). The reference impedance for differential return loss measurements is 100 Ω.

71.8 Interconnect characteristics

Informative interconnect characteristics for 10GBASE-KX4 are provided in Annex 69B.

71.9 Environmental specifications

71.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

71.9.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

71.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

71.9.4 Electromagnetic compatibility

A system integrating the 10GBASE-KX4 PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

71.9.5 Temperature and humidity

A system integrating the 10GBASE-KX4 PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

71.10 Protocol implementation conformance statement (PICS) proforma for Clause 71, Physical Medium Dependent (PMD) sublayer and baseband medium, type 10GBASE-KX4[133]

71.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 71, Physical Medium Dependent (PMD) sublayer and baseband medium type 10GBASE-KX4, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

71.10.2 Identification

71.10.2.1 Implementation identification

72. Physical Medium Dependent sublayer and baseband medium, type 10GBASE-KR

72.1 Overview

This clause specifies the 10GBASE-KR PMD and the baseband medium. When forming a complete PHY, a PMD shall be connected to the appropriate sublayers (see Table 72–1), and with the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 72–1—Physical Layer clauses associated with the 10GBASE-KR PMD

Associated clause	10GBASE-KR
46—XGMII[a]	Optional
47—XGXS and XAUI	Optional
49—10GBASE-R PCS	Required
51—10-Gigabit Serial PMA	Required
73—Auto-Negotiation for Backplane Ethernet	Required
74—BASE-R FEC	Optional
78—Energy-Efficient Ethernet	Optional

[a]The XGMII is an optional interface. However, if the XGMII is not implemented, a conforming implementation behaves functionally as though the RS and XGMII were present.

A 10GBASE-KR PHY with the optional Energy-Efficient Ethernet (EEE) capability may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization. The “Assert LPI” request at the XGMII is encoded in the transmitted symbols. Detection of LPI signaling in the received symbols is indicated as “Assert LPI” at the XGMII. Upon the detection of “Assert LPI” at the XGMII, an energy-efficient 10GBASE-KR PHY continues transmitting for a predefined period, then ceases transmission and deactivates transmit functions to conserve energy. The PHY periodically transmits during this quiet period to allow the remote PHY to refresh its receiver state (e.g., timing recovery, adaptive filter coefficients) and thereby track long-term variations in the timing of the link or the underlying channel characteristics. If, during the quiet or refresh periods, normal interframes resume at the XGMII, the PHY reactivates transmit functions and initiates transmission. This transmission will be detected by the remote PHY, causing it to also exit the LPI mode.

72.2 Physical Medium Dependent (PMD) service interface

The 10GBASE-KR PMD utilizes the PMD service interface defined in 52.1.1. The PMD service interface is summarized as follows:

a) PMD_UNITDATA.request (as defined in 52.1.1)
b) PMD_UNITDATA.indication (as defined in 52.1.1)
c) PMD_SIGNAL.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If EEE is supported, the following primitives are also defined on the PMD Service Interface:

PMD_RX_MODE.request(rx_mode)
PMD_TX_MODE.request(tx_mode)

These messages affect the PCS variables as described in 49.2.13.2.2.

72.2.1 PMD_RX_MODE.request

This primitive is generated by the PCS Receive Process when EEE is supported to indicate that the input signal is quiet and the PMA and PMD receiver may go into a low power mode. When EEE is not supported, the primitive is never invoked and the PMD behaves as if rx_mode = DATA.

72.2.1.1 Semantics of the service primitive

PMD_RX_MODE.request (rx_mode)

The rx_mode parameter takes on one of two values: QUIET or DATA.

72.2.1.2 When generated

The PCS generates this primitive to request the appropriate PMD receive LPI state.

72.2.1.3 Effect of receipt

When rx_mode is QUIET, the PMD receive function may deactivate functional blocks to conserve energy. When rx_mode is DATA, the PMD receive function operates normally.

72.2.2 PMD_TX_MODE.request

This primitive is generated by the PCS Transmit Process when EEE is supported to indicate that the PMA and PMD transmit functions may go into a low power mode and to disable the PMD transmitter. See subclause 72.6.5. When EEE is not supported, the primitive is never invoked and the PMD behaves as if tx_mode = DATA.

72.2.2.1 Semantics of the service primitive

PMD_TX_MODE.request (tx_mode)

The tx_mode parameter takes on one of three values: QUIET, ALERT, or DATA.

72.2.2.2 When generated

The PCS generates this primitive to request appropriate PMD transmit LPI state.

72.2.2.3 Effect of receipt

When tx_mode is QUIET, the PMD Transmit function may deactivate functional blocks to conserve energy. When tx_mode is ALERT, the PMD Transmit function transmits the alert pattern. And when it is DATA, the PMD Transmit function operates normally.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD shall support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 49.2.16.)

72.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementers consider the delay maxima, and that network planners and administrators consider the delay constraints regarding concatenation of devices. A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 69.3.

The sum of the transmit and the receive delays contributed by the 10GBASE-KR PMD and medium shall be no more than 1024 bit times. It is assumed that the round-trip delay through the medium is 160 bit times.

72.5 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 72–2, and MDIO status variables to PMD status variables as shown in Table 72–3.

Table 72–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	Control register 1	1.0.15	PMD_reset
Global PMD Transmit Disable	Transmit disable register	1.9.0	Global_PMD_transmit_disable
Restart training	BASE-R PMD control register	1.150.0	mr_restart_training
Training enable	BASE-R PMD control register	1.150.1	mr_training_enable

72.6 PMD functional specifications

72.6.1 Link block diagram

For purposes of system conformance, the PMD sublayer is standardized at test points TP1 and TP4 as shown in Figure 72–1. The transmitter and receiver blocks include all off-chip components associated with the respective block. For example, external AC-coupling capacitors, if required, are to be included in the receiver block.

The electrical path from the transmitter block to TP1, and from TP4 to the receiver block, will affect link performance and the measured values of electrical parameters used to verify conformance to this standard. Therefore, it is recommended that this path be carefully designed.

Table 72–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	Status register 1	1.1.7	PMD_fault
Transmit fault	Status register 2	1.8.11	PMD_transmit_fault
Receive fault	Status register 2	1.8.10	PMD_receive_fault
Global PMD Receive signal detect	Receive signal detect register	1.10.0	Global_PMD_signal_detect
Receiver status	BASE-R PMD status register	1.151.0	rx_trained
Frame lock	BASE-R PMD status register	1.151.1	frame_lock
Startup protocol status	BASE-R PMD status register	1.151.2	training
Training failure	BASE-R PMD status register	1.151.3	training_failure

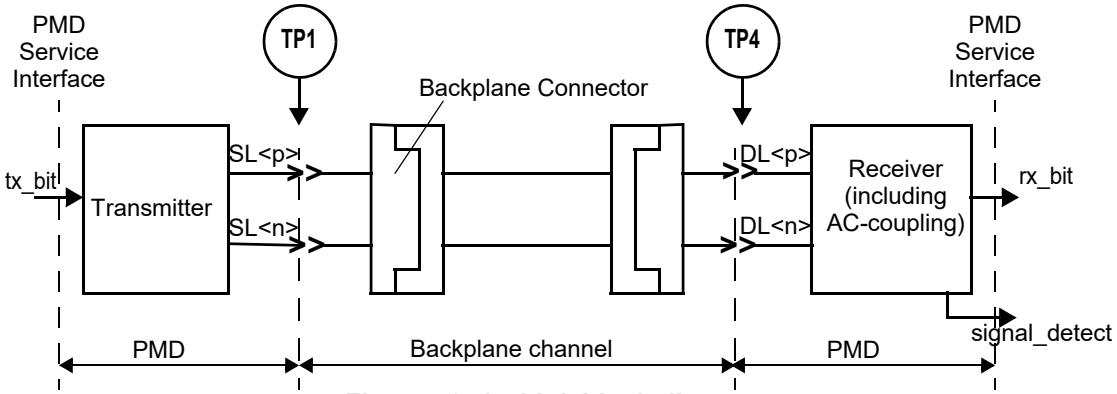

Figure 72–1—Link block diagram

72.6.2 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the specifications in this clause. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = ONE.

If the optional Energy-Efficient Ethernet (EEE) capability is supported (see Clause 78) then when tx_mode is set to ALERT, the PMD will transmit a repeating 16-bit pattern, hexadecimal 0xFF00. When tx_mode is ALERT, the transmitter equalizer taps are set to the preset state specified in 72.6.10.2.3.1. When tx_mode is DATA, the driver coeffcients are restored to their states resolved during training.

72.6.3 PMD receive function

The PMD Receive function shall convey the bits received from the MDI according to the electrical specifications in this clause to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = ONE.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.6.4 PMD signal detect function

The Global PMD signal detect function shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is used by 10GBASE-KR to indicate the successful completion of the startup protocol. When the PHY supports the optional EEE capability, PMD_SIGNAL.indication is also used to indicate when the ALERT signal is detected, which corresponds to the beginning of a refresh or a wake. If the MDIO interface is implemented, then Global_PMD_signal_detect (1.10.0) shall be continuously set to the value of SIGNAL_DETECT as described in 45.2.1.9.7.

The value of the SIGNAL_DETECT is defined by the training state diagram shown in Figure 72–5 when the PHY does not support the EEE capability or if the PHY supports the EEE capability and rx_mode is set to DATA. When the PHY supports the EEE capability, SIGNAL_DETECT is set to FAIL following a transition from rx_mode = DATA to rx_mode = QUIET. When rx_mode = QUIET, SIGNAL_DETECT shall be set to OK within 500 ns following the application of a signal at the receiver input that is the output of a channel that satisfies the requirements of all the parameters of both interference tolerance test channels defined in 72.7.2.1 when driven by a square wave pattern with a period of 16 unit intervals and peak-to-peak differential output amplitude of 720 mV. While rx_mode = QUIET, SIGNAL_DETECT changes from FAIL to OK only after a valid ALERT signal is applied to the channel.

SIGNAL_DETECT shall be set to FAIL following system reset or the manual reset of the training state diagram. Upon completion of training, SIGNAL_DETECT shall be set to OK.

If training is disabled by management and EEE is not implemented, SIGNAL_DETECT shall be set to OK.

72.6.5 PMD transmit disable function

The Global_PMD_transmit_disable function is mandatory if EEE is supported and is otherwise optional. When this function is supported, it shall meet the requirements of this subclause.

a) When the Global_PMD_transmit_disable variable is set to ONE, this function shall turn off the transmitter such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 72–6.
b) If a PMD_fault (72.6.7) is detected, then the PMD may turn off the electrical transmitter.
c) Loopback, as defined in 72.6.6, shall not be affected by Global_PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off the transmitter after tx_mode is set to QUIET within a time and voltage level specified in 72.7.1.4. The PMD_transmit_disable function shall turn on the transmitter after tx_mode is set to DATA or ALERT within the time and voltage level specified in 72.7.1.4.

If the MDIO interface is implemented, then this function shall map to the Global_PMD_transmit_disable bit as specified in 45.2.1.8.7.

72.6.6 Loopback mode

Loopback mode shall be provided for the 10GBASE-KR PMD by the transmitter and receiver of a device as a test function to the device. When loopback mode is selected, transmission requests passed to the transmitter are shunted directly to the receiver, overriding any signal detected by the receiver on its attached link. Note, this bit does not affect the state of the transmitter. The method of implementing loopback mode is not defined by this standard.

Control of the loopback function is specified in 45.2.1.1.5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

72.6.7 PMD_fault function

If the MDIO is implemented, PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault.

72.6.8 PMD transmit fault function

The PMD_transmit_fault function is optional. The faults detected by this function are implementation specific, but should not include the assertion of the Global_PMD_transmit_disable function.

If a PMD_transmit_fault (optional) is detected, then the Global_PMD_transmit_disable function should also be asserted.

If the MDIO interface is implemented, then this function shall be mapped to the PMD_transmit_fault bit as specified in 45.2.1.7.4.

72.6.9 PMD receive fault function

The PMD_receive_fault function is optional. The faults detected by this function are implementation specific.

If the MDIO interface is implemented, then this function shall contribute to PMA/PMD receive fault bit as specified in 45.2.1.7.5.

72.6.10 PMD control function

72.6.10.1 Overview

The PMD control function generates the control actions required to bring the PMD from initialization to a mode in which data may be exchanged with the link partner.

The PMD control function implements the 10GBASE-KR startup protocol. This protocol facilitates timing recovery and equalization while also providing a mechanism through which the receiver can tune the transmit equalizer to optimize performance over the backplane interconnect. The protocol supports these mechanisms through the continuous exchange of fixed-length training frames.

If EEE is supported, the PMD control function responds to PCS requests to transition in and out of quiet states.

72.6.10.2 Training frame structure

The training frame is a fixed length structure that is sent continuously during training. The training frame, shown in Figure 72–2, is 548 octets in length and contains a control channel and training pattern.

The control channel is signaled using differential Manchester encoding (DME) at a signaling rate equal to one quarter of the 10GBASE-KR signaling rate. Since each DME symbol contains two DME transition positions and each transition position is four 10GBASE-KR UI, one control channel bit is transmitted every eight 10GBASE-KR UI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Differential Manchester encoding guarantees transition density and DC balance while the reduced rate of transmission facilitates reception over non-optimally equalized channels.[134]

Training frames are delimited by a fixed 4 octet frame marker.

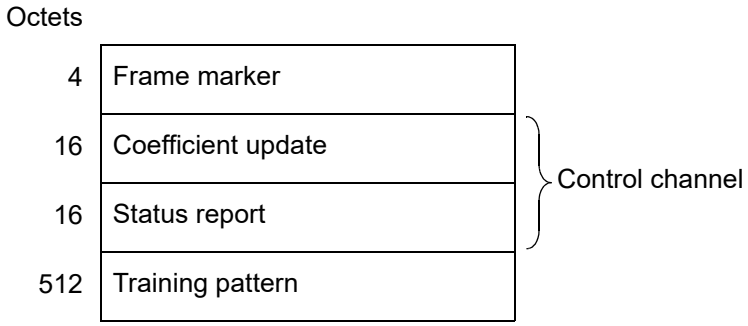

Figure 72–2—Training frame structure

72.6.10.2.1 Frame marker

Frames are delimited by the 32-bit pattern, hexadecimal 0xFFFF0000 (ones transmitted first), as expressed in 10.3125 Gbd symbols. This pattern does not appear in the control channel or the training pattern and therefore serves as a unique indicator of the start of a training frame.

72.6.10.2.2 Control channel encoding

The control channel shall be transmitted using differential Manchester encoding (DME). The rules of differential Manchester encoding are as follows:

a) A data transition shall occur at each cell boundary.
b) A mid-cell data transition shall be used to signal a logical one.
c) The absence of a mid-cell data transition shall be used to signal a logical zero.

If a coding violation is detected within the bounds of the control channel in a given training frame, the contents of the control channel for that frame shall be ignored.

The data cell length shall be 8 10GBASE-KR UI. Therefore, the total length of the control channel is 256 10GBASE-KR UI.

72.6.10.2.3 Coefficient update field

The coefficient update field carries correction information from the local receiver to the link partner transmit equalizer. The field consists of preset controls, initialization controls, and coefficient updates for three transmit equalizer taps. The format of the coefficient update field shall be as shown in Table 72–4. Cell 15 of the coefficient update field sent shall be transmitted first. The preset, initialize, and coefficient updates are set by the receiver adaptation process. The algorithm employed by the receiver adaptation process is beyond the scope of this standard.

[134]The differential Manchester encoding defined for Backplane Ethernet is different from that defined in IEEE Std 802.5™.

Table 72–4—Coefficient update field

Cell(s)	Name	Description
15:14	Reserved	Transmitted as 0, ignored on reception.
13	Preset	1 = Preset coefficients 0 = Normal operation
12	Initialize	1 = Initialize coefficients 0 = Normal operation
11:6	Reserved	Transmitted as 0, ignored on reception.
5:4	Coefficient (+1) update	5 4 1 1 = reserved 0 1 = increment 1 0 = decrement 0 0 = hold
3:2	Coefficient (0) update	3 2 1 1 = reserved 0 1 = increment 1 0 = decrement 0 0 = hold
1:0	Coefficient (–1) update	1 0 1 1 = reserved 0 1 = increment 1 0 = decrement 0 0 = hold

72.6.10.2.3.1 Preset

The preset control is sent to request that the coefficients be set to a state where equalization is turned off. When received, the pre-cursor ($k = -1$) and post-cursor ($k = +1$) coefficients shall be set to a zero value and the main ($k = 0$) coefficient shall be set to its maximum value. The preset control shall only be initially sent when all coefficient status fields indicate not_updated, and will then continue to be sent until the status for all coefficients indicates updated or maximum. At that point, the outgoing preset control shall be set to zero. Maximum status shall be returned when the main coefficient is updated. Maximum status shall be returned for the pre-cursor and/or post-cursor coefficients when the coefficient is updated and zero is its maximum supported value. Updated status shall be returned for the pre-cursor and/or post-cursor coefficients when the coefficient is updated and it supports additional settings above the value zero.

A new request to preset or initialize shall not be sent until the incoming status messages for all coefficients revert to not_updated. Preset shall not be sent in combination with initialize or coefficient increment/decrement requests.

72.6.10.2.3.2 Initialize

The initialize control is sent to request that the coefficients be set to configure the transmit equalizer to its INITIALIZE state. When received, the taps shall be set such that the transmit output meets the conditions defined in 72.6.10.4.2. The initialize control shall only be initially sent when all coefficient status fields indicate not_updated, and will then continue to be sent until no coefficient status field indicates not_updated.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Updated status shall be returned for each coefficient when the coefficient update is completed. At that point, the outgoing initialize control shall be set to zero.

A new request to preset or initialize shall not be sent until the incoming status messages for all coefficients revert to not_updated. Initialize shall not be sent in combination with coefficient increment/decrement requests or preset.

72.6.10.2.3.3 Coefficient (*k*) update

Each coefficient, *k*, is assigned a 2-bit field describing a requested update. Three request encodings are defined: increment, decrement, and hold. The default state for a given tap is hold, which corresponds to no change in the coefficient. The increment or decrement encodings are transmitted to request that the corresponding coefficient be increased or decreased. The amount of change implemented by the transmitter in response to the coefficient update request shall meet the requirements of Table 72–7 and 72.7.1.10. An increment or decrement request shall continue to be transmitted until the update status for that tap (as defined in 72.6.10.2.4.5) indicates updated, maximum, or minimum. At that point, the outgoing requests for that tap shall be set to hold.

A new request to increment or decrement shall not be sent before the incoming status messages for that tap revert to not_updated. Coefficient increment/decrement shall not be sent in combination with initialize or preset.

The valid range for *k* is –1 to +1 where *k* = 0 denotes the main tap. The encoding of the coefficient update shall be as shown in Table 72–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.6.10.2.4 Status report field

The status report field is used to signal state information from the local PMD to the link partner. The format of the status report field shall be as shown in Table 72–5. Cell 15 of the status report field shall be transmitted first.

Table 72–5—Status report field

Cell(s)	Name	Description
15	Receiver ready	1 = The local receiver has determined that training is complete and is prepared to receive data. 0 = The local receiver is requesting that training continue.
14:6	Reserved	Transmitted as 0, ignored on reception.
5:4	Coefficient (+1) status	5 4 1 1 = maximum 1 0 = minimum 0 1 = updated 0 0 = not_updated
3:2	Coefficient (0) status	3 2 1 1 = maximum 1 0 = minimum 0 1 = updated 0 0 = not_updated
1:0	Coefficient (–1) status	1 0 1 1 = maximum 1 0 = minimum 0 1 = updated 0 0 = not_updated

72.6.10.2.4.4 Receiver ready

The receiver ready bit is used to signal the local receiver state to the link partner. When asserted, the receiver ready bit indicates that the local receiver has concluded training and is prepared to receive data. When de-asserted, the receiver ready bit indicates that the local receiver is requesting that training continue. The format of the receiver ready bit shall be as shown in Table 72–5.

72.6.10.2.4.5 Coefficient (*k*) status

Each coefficient, *k*, is assigned a 2-bit field describing the status of pending updates to the coefficient. Four status encodings are defined: not updated, updated, maximum, and minimum.

These status encodings indicate the corresponding state of the coefficient update state diagram for coefficient *k*.

The valid range for *k* is –1 to +1 where *k* = 0 denotes the main tap. The encoding of the coefficient update shall be as shown in Table 72–5.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.6.10.2.5 Coefficient update process

Each coefficient, k, has an associated coefficient update state diagram that controls updates of the coefficient and generates the tap update status field.

The default state for a given tap is not_updated. An increment or decrement request will only be acted upon when the state of the tap is not_updated. Upon execution of a received increment or decrement request, the status is reported as updated, maximum, or minimum. Maximum is reported if a received increment request causes the tap value to reach its maximum limit, or if it is already at that limit. Minimum is reported if a received decrement request causes the tap value to reach its minimum limit, or if it is already at that limit.

Once the updated, maximum, or minimum state is reported it continues to be reported until a hold request is received, after which the status reverts to not_updated.

The coefficient update process responds to coefficient requests as specified in the state diagram shown in Figure 72–6.

72.6.10.2.6 Training pattern

The training pattern shall be a 512 octet pattern consisting of 4094 bits from the output of a pseudo-random bit sequence of order 11 (PRBS11) generator followed by two zeros. The PRBS11 pattern generator shall produce the same result as the implementation shown in Figure 72–3. This implements the generator polynomial shown in Equation (72–1).

$$G(x) = 1 + x^9 + x^{11} \tag{72–1}$$

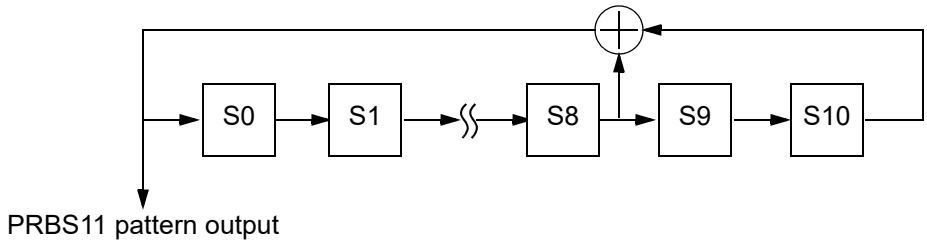

Figure 72–3—PRBS11 pattern generator

The pseudo-random generator shall have a random seed at the start of the training pattern. Each bit of the training pattern is transmitted as a single 10.3125 GBd symbol.

72.6.10.3 State variables

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

72.6.10.3.1 Variables

coefficient
: Integer variable containing a value that should be used as the tap coefficient.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

dec

Boolean variable that is set to TRUE when a training frame has been completely received and the coefficient update field of that frame for this coefficient is decrement, and is set to FALSE on reception of any other value.

frame_lock

Boolean variable that is set to TRUE when the receiver acquires training frame delineation and is set to FALSE otherwise.

frame_offset

Boolean variable that is set to TRUE after receiving one full training frame (548 octets) from the current frame start position. The Boolean variable is set to FALSE when the GET_NEW_MARKER state is entered. The current frame start position is indicated by a transition into the GET_NEW_MARKER state when the Boolean variable is set to FALSE.

hold

Boolean variable that is set to TRUE when a training frame has been completely received and the coefficient update field of that frame for this coefficient is hold, and neither preset or initialize are activated, and is set to FALSE on reception of any other value.

inc

Boolean variable that is set to TRUE when a training frame has been completely received and the coefficient update field of that frame for this coefficient is increment, and set to FALSE on reception of any other value.

initialize

Boolean variable that is set to TRUE when a training frame has been completely received and the initialize field of that frame is set to one and the preset field is set to zero, and is set to FALSE otherwise.

local_rx_ready

Boolean variable that is set to TRUE by the training state diagram when rx_trained is asserted and is set to FALSE otherwise. This value is transmitted as the receiver ready bit on all outgoing training frames.

marker_valid

Boolean variable that is set to TRUE when the candidate frame marker matches the specified frame marker pattern and is set to FALSE when the candidate frame marker does not match the specified frame marker pattern.

max_limit

Integer variable containing the maximum tap coefficient value, subject to the constraints detailed in 72.7.1.10.

min_limit

Integer variable containing the minimum tap coefficient value, subject to the constraints detailed in 72.7.1.10.

mr_restart_training

Boolean variable used by system management to restart the 10GBASE-KR startup protocol. When set to TRUE, it forces the training state diagram to the INITIALIZE state.

mr_training_enable

Boolean variable used by system management to enable or disable the 10GBASE-KR startup

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

protocol. It is set to TRUE when the startup protocol is enabled and set to FALSE when the startup protocol is disabled.

new_coeff
: Integer variable containing the result of increment/decrement operations on the coefficient value

new_marker
: Boolean variable that is set to TRUE when a new candidate frame marker is available for testing and FALSE when the TEST_MARKER state is entered. A new marker is available for testing when the training frame lock process has accumulated one frame marker (4 octets) from a candidate frame start position.

preset
: Boolean variable that is set to TRUE when a training frame has been completely received and the preset field of that frame is set to one and is set to FALSE if set to zero.

remote_rx_ready
: Boolean variable that is set to FALSE upon entry into the SEND_TRAINING state. The value of remote_rx_ready shall not be set to TRUE until no fewer than three consecutive training frames have been received with the receiver ready bit asserted.

reset
: Boolean variable that controls the resetting of the PMA/PMD. It is set to TRUE whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PMA/PMD into low-power mode.

rx_trained
: Boolean variable that is set to TRUE when the remote transmit and local receive equalizers have been optimized and normal data transmission may commence and set to FALSE otherwise.

signal_detect
: Boolean variable that is set to TRUE when the training process is complete and is set to FALSE otherwise. The value of signal_detect is reported to the PMA sublayer via the PMD_SIGNAL.indication primitive.

slip_done
: Boolean variable that is set to TRUE when the SLIP requested by the Frame Lock State Diagram has been completed indicating that the next candidate frame sync position can be tested.

training
: Boolean variable that is set to TRUE to indicate that the 10GBASE-KR startup protocol is in progress and is set to FALSE when training has completed.

training_failure
: Boolean variable that is set to TRUE when the training state diagram has timed out due to expiration of the max_wait_timer while in the SEND_TRAINING, TRAIN_LOCAL, or TRAIN_REMOTE states and is set to FALSE otherwise.

update_status
: Value to be transmitted in the Coefficient Status field for this coefficient in the next transmitted training frame, as defined in Table 72–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.6.10.3.2 Timers

max_wait_timer
: This timer is started in the INITIALIZE state of the training state diagram. If the max_wait_timer expires the training state diagram will enter the TRAINING_FAILURE state. The value of max_wait_timer shall be 500 ms ± 1%.

wait_timer
: This timer is started when the local receiver is trained and detects that the remote receiver is ready to receive data. The local PMD will deliver wait_timer additional training frames to ensure that the link partner correctly detects the local receiver state. The value of wait_timer shall be between 100 and 300 training frames.

72.6.10.3.3 Counters

bad_markers
: Count of the number of consecutive frame marker mis-matches.

good_markers
: Count of the number of consecutive frame marker matches.

72.6.10.3.4 Functions

COEFF_UPDATE(coefficient, preset, initialize, inc, dec)
: Returns an updated coefficient based on the contents of the coefficient update field in the training frame. Sets a fixed coefficient value, or adds, or subtracts from the current coefficient value to create the updated coefficient. If multiple actions are requested in the coefficient update field, then the priority is:
  1) preset
  2) initialize
  3) inc/dec

  Values: preset; If preset is TRUE then the function returns the coefficient value equivalent to no equalization [$c(-1)$ and $c(1)$ coefficients are set to zero, $c(0)$ set to maximum].
  initialize; If initialize is TRUE, then the function returns the coefficient value such that the transmit output meets the conditions defined in 72.6.10.4.2.
  inc; If inc is TRUE then the function returns (coefficient + step).
  dec; If dec is TRUE then the function returns (coefficient – step).

  The requirements for the value of step are defined in 72.7.1.10 and Table 72–7.

SLIP
: Causes the next candidate frame sync position to be tested. The precise method for determining the next candidate frame sync position is not specified and is implementation dependent. However, an implementation shall ensure that all possible bit positions are evaluated.

TRANSMIT(TRAINING, DATA)
: Controls the output of the TRANSMIT functional block.

  Values: TRAINING; the transmit block output is a continuous stream of training frames as defined in 72.6.10.2.
  DATA; the transmit block output is determined by the value of the input tx_bit.

72.6.10.4 State diagrams

72.6.10.4.1 Frame lock

The 10GBASE-KR PMD shall implement the Frame Lock state diagram as depicted in Figure 72–4 including compliance with the associated state variables as specified in 72.6.10.3. The frame lock state diagram determines when the PMD control function has detected the frame boundaries in the received data stream.

72.6.10.4.2 Training

The 10GBASE-KR PMD shall implement the Training state diagram as depicted in Figure 72–5 including compliance with the associated state variables as specified in 72.6.10.3. The training state diagram defines the operation of the 10GBASE-KR startup protocol. When the training state diagram enters the INITIALIZE state, the transmitter equalizer shall be configured such that R_{pre} and R_{pst} are 1.29 ± 10% and 2.57 ± 10% respectively. R_{pre} and R_{pst} are defined in 72.7.1.11. At the start of training the initial value of c(0) shall be set such that the constraints of 72.7.1.11 are satisfied and the peak-to-peak differential output voltage shall be greater than or equal to 800 mV for a 1010 pattern.

72.6.10.4.3 Coefficient update

For each tap, the 10GBASE-KR PMD shall implement an instance of the coefficient update state diagram as depicted in Figure 72–6 including compliance with the associated state variables as specified in 72.6.10.3. The coefficient update state diagram defines the process for updating transmit equalizer coefficients in response to requests from the link partner, and also defines the coefficient update status to be reported in outgoing training frames.

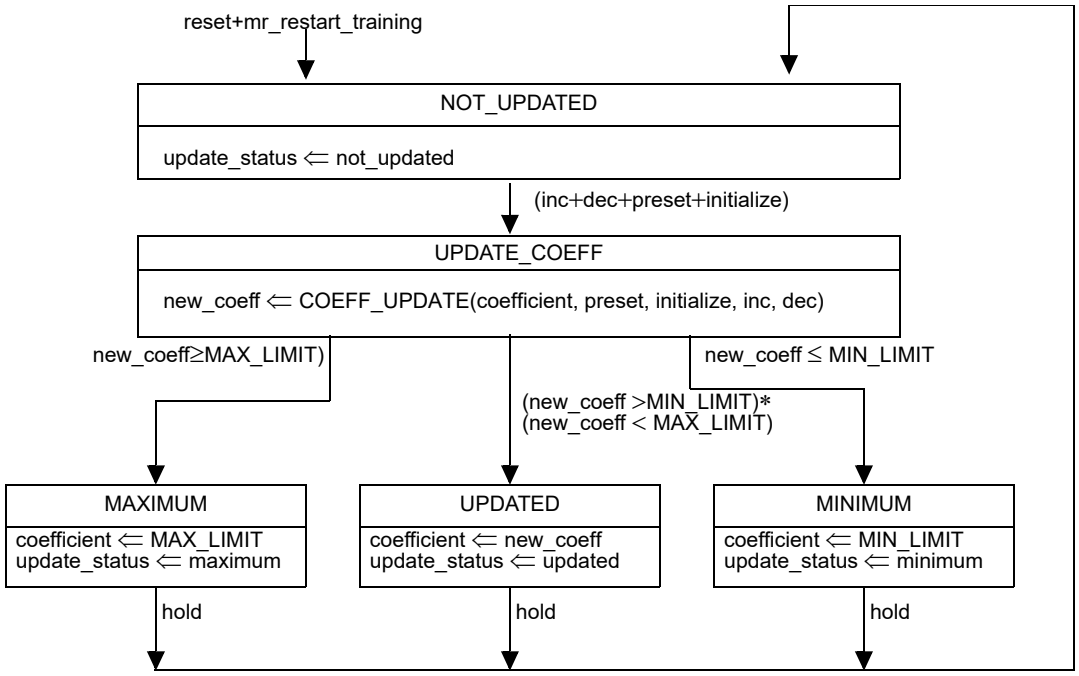

Figure 72–6—Coefficient update state diagram

72.6.11 PMD LPI function

The PMD LPI function responds to the transitions between Active, Sleep, Quiet, Refresh, and Wake states via the PMD_TX_MODE and PMD_RX_MODE requests. Implementation of the function is optional. EEE capabilities and parameters will be advertised during the Backplane Auto-negotiation, as described in 45.2.7.14. The transmitter on the local device will inform the link partner's receiver when to sleep, refresh and wake. The local receiver transitions are controlled by the link partner's transmitter and can change independent of the local transmitter states and transitions.

72.7 10GBASE-KR electrical characteristics

72.7.1 Transmitter characteristics

Transmitter characteristics at TP1 are summarized in Table 72–6 and detailed in 72.7.1.1 through 72.7.1.11.

Table 72–6—Transmitter characteristics for 10GBASE-KR

Parameter	Subclause reference	Value	Units
Signaling speed	72.7.1.3	10.3125 ± 100 ppm	GBd
Differential peak-to-peak output voltage (max.)	72.7.1.4	1200	mV
Differential peak-to-peak output voltage (max.) with TX disabled	72.6.5	30	mV
Common-mode voltage limits	72.7.1.4	0 to 1.9	V
Common-mode voltage deviation (max) during LPI	72.7.1.4	150	mV
Differential output return loss (min.)	72.7.1.5	[See Equation (72–4) and Equation (72–5)]	dB
Common-mode output return loss (min.)	72.7.1.6	[See Equation (72–6) and Equation (72–7)]	dB
Transition time (20%–80%)	72.7.1.7	24 to 47	ps
Max output jitter (peak-to-peak) Random jitter[a] Deterministic jitter Duty Cycle Distortion[b] Total jitter	72.7.1.9	 0.15 0.15 0.035 0.28	 UI UI UI UI

[a]Jitter is specified at BER 10^{-12}.
[b]Duty Cycle Distortion is considered part of the deterministic jitter distribution.

72.7.1.1 Test fixture

The test fixture of Figure 72–7 or its functional equivalent, is required for measuring the transmitter specifications described in 72.7.1, with the exception of return loss.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

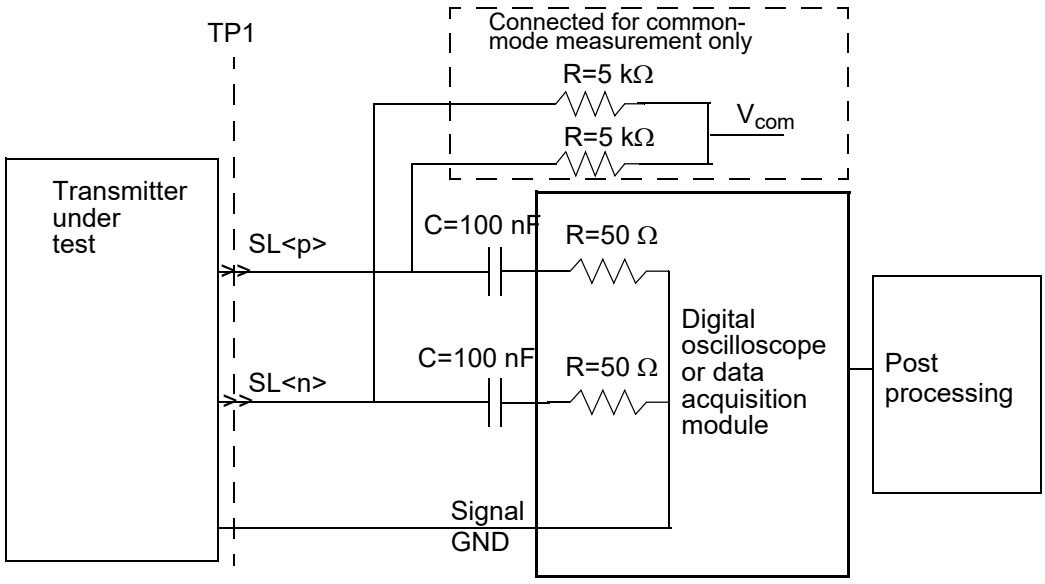

Figure 72–7—Transmit test fixture for 10GBASE-KR

72.7.1.2 Test fixture impedance

The differential load impedance applied to the transmitter output by the test fixture depicted in Figure 72–7 shall be 100 Ω. The differential return loss, in dB with f in MHz, of the test fixture shall meet the requirements of Equation (72–2) and Equation (72–3).

$$ReturnLoss(f) \geq 15 \tag{72–2}$$

for 100 MHz ≤ f < 5000 MHz

$$ReturnLoss(f) \geq 15 - 26.57\log_{10}\left(\frac{f}{5000\ \text{MHz}}\right) \tag{72–3}$$

for 5000 MHz ≤ f ≤ 10000 MHz

72.7.1.3 Signaling speed

The 10GBASE-KR signaling speed shall be 10.3125 GBd ± 100 ppm.

72.7.1.4 Output amplitude

The differential output voltage is constrained via the transmitter output waveform requirements specified in 72.7.1.10. For a 1010 pattern, the peak-to-peak differential output voltage shall be less than 1200 mV, regardless of equalization setting. The transmitter output voltage shall be less than 30 mV peak-to-peak when disabled. The differential output voltage test pattern shall consist of no fewer than eight symbols of alternating polarity.

NOTE 1—The required test patterns may be found in the training pattern field of the training frames or test patterns 2 or 3 as defined in 52.9.1.1.

NOTE 2—See Figure 72–8 for an illustration of the definition of differential peak-to-peak output voltage.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

DC-referenced voltage levels are not defined since the receiver is AC-coupled. The common-mode voltage of SL<p> and SL<n> shall be between 0 V and 1.9 V with respect to signal ground as measured at V_{com} in Figure 72–7.

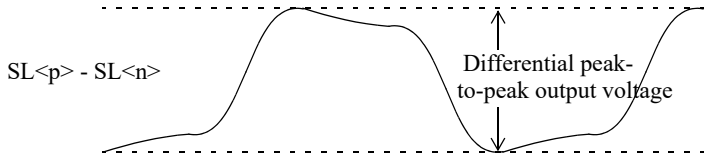

Figure 72–8—Transmitter differential peak-to-peak output voltage definition

NOTE—SL<p> and SL<n> are the positive and negative sides of the differential signal pair.

For EEE capability, the transmitter's differential peak-to-peak output voltage shall be less than 30 mV within 500 ns of tx_mode being set to QUIET and remain so while tx_mode is set to QUIET. Furthermore, the transmitter's differential peak-to-peak output voltage shall be greater than 720 mV within 500 ns of tx_mode being set to ALERT. The transmitter output shall be fully compliant within 5 μs after tx_mode is set to DATA. During LPI mode, the common-mode shall be maintained to within ± 150 mV of the pre-LPI value.

72.7.1.5 Differential output return loss

For frequencies from 50 MHz to 7500 MHz, the differential return loss, in dB with f in MHz, of the transmitter shall meet the requirements of Equation (72–4) and Equation (72–5). This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$ReturnLoss(f) \geq 9 \tag{72–4}$$

for 50 MHz ≤ f < 2500 MHz

$$ReturnLoss(f) \geq 9 - 12\log_{10}\left(\frac{f}{2500\ \text{MHz}}\right) \tag{72–5}$$

for 2500 MHz ≤ f ≤ 7500 MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The minimum differential output return loss is shown in Figure 72–9.

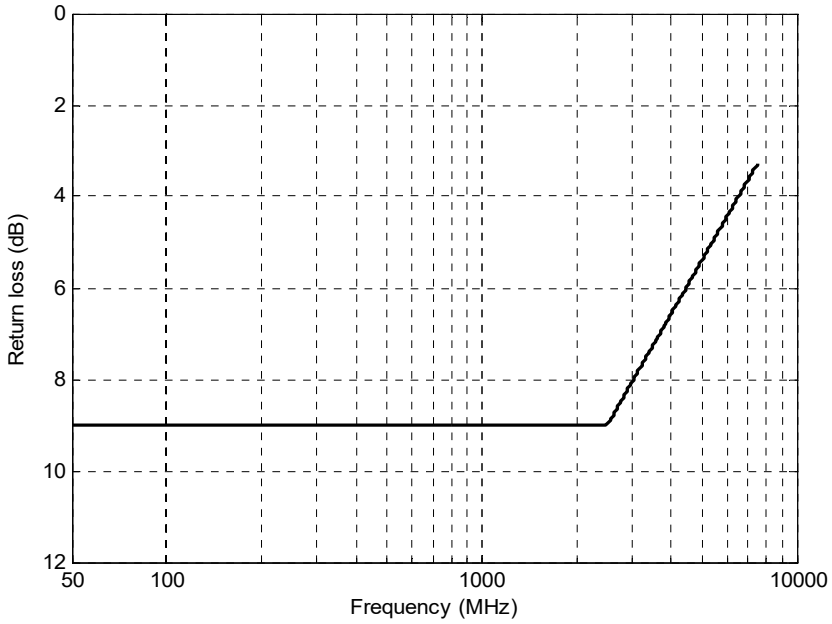

Figure 72–9—Minimum differential output return loss

72.7.1.6 Common-mode output return loss

The transmitter common-mode return loss shall meet the requirements of Equation (72–6) and Equation (72–7). The reference impedance for common-mode return loss measurements is 25 Ω.

$$ReturnLoss(f) \geq 6 \tag{72–6}$$

for 50 MHz ≤ f < 2500 MHz

$$ReturnLoss(f) \geq 6 - 12\log_{10}\left(\frac{f}{2500\ \text{MHz}}\right) \tag{72–7}$$

for 2500 MHz ≤ f ≤ 7500 MHz

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The minimum common-mode output return loss is shown in Figure 72–10.

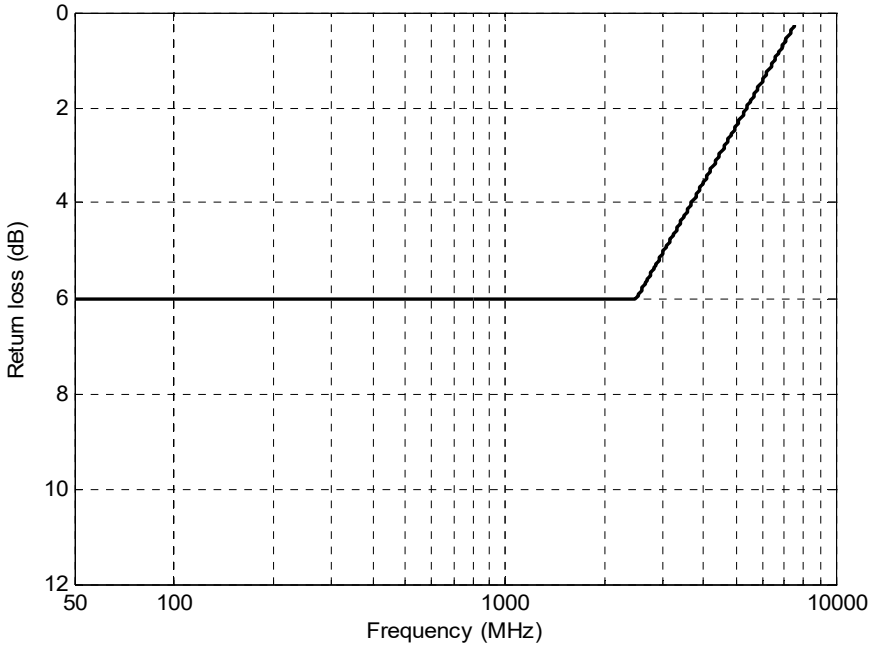

Figure 72–10—Minimum common-mode output return loss

72.7.1.7 Transition time

The rising and falling edge transition times shall be between 24 ps and 47 ps as measured at the 20% and 80% levels referenced to v_2 and v_5 as defined in 72.7.1.11. Measurement is done using the square wave test pattern defined in 52.9.1.2, with no equalization and a run of at least eight consecutive ones. Transmit equalization may be disabled by asserting the preset control defined in Table 45–77 and 45.2.1.97.3.

72.7.1.8 Transmit jitter test requirements

Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in Annex 48B.3. For the purpose of jitter measurement, the effect of a single-pole high-pass filter with a 3 dB point at 4 MHz is applied to the jitter. The data pattern for jitter measurements shall be test patterns 2 or 3 as defined in 52.9.1.1. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal. Equalization shall be off during jitter testing. Transmit equalization may be disabled by asserting the preset control defined in Table 45–77 and 45.2.1.97.3.

The duty cycle distortion test pattern shall consist of no fewer than eight symbols of alternating polarity (e.g., a 10101010… bit sequence).

NOTE—The required test patterns may be found in the training pattern field of the training frames or test patterns 2 or 3 as defined in 52.9.1.1.

72.7.1.9 Transmit jitter

The transmitter shall have a maximum total jitter of 0.28 UI peak-to-peak, composed of a maximum deterministic component of 0.15 UI peak-to-peak and a maximum random component of 0.15 UI peak-to-peak. Duty cycle distortion (DCD) is considered a component of deterministic jitter and shall not exceed 0.035 UI peak-to-peak. The peak-to-peak duty cycle distortion is defined as the absolute value of the difference in the mean pulse width of a 1 pulse or the mean pulse width of a 0 pulse (as measured at the mean of the high and

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

low voltage levels in a repeating 0101 bit sequence) and the nominal pulse width. Jitter specifications are specified for BER 10^{-12}. Transmit jitter test requirements are specified in 72.7.1.8.

72.7.1.10 Transmitter output waveform

The 10GBASE-KR transmitter includes programmable equalization to compensate for frequency-dependent loss in the backplane channel and facilitate data recovery at the receiver. This equalization may be accomplished with a three-tap finite impulse response (FIR) structure as shown in Figure 72–11. The actual implementation of the transmit equalizer, including the incorporation of additional taps, is beyond the scope of this standard.

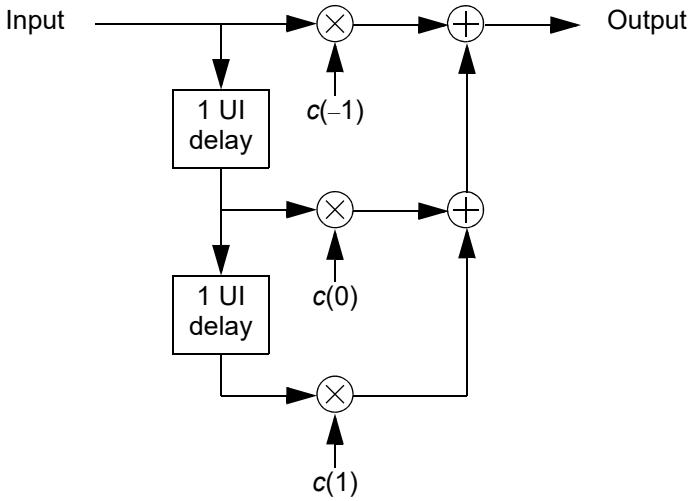

Figure 72–11—Transmit equalizer example

Transmit equalizer performance is specified in terms of the voltages defined in 72.7.1.11. It should be noted that the valid ranges of the $c(1)$ and $c(–1)$ coefficients may include positive and negative values. A value of zero is used to turn off equalization for the tap.

72.7.1.11 Transmitter output waveform requirements

The test pattern for the transmitter output waveform is the square wave test pattern defined in 52.9.1.2, with a run of at least eight consecutive ones. The transmitter output waveform test is based on the voltages v_1 through v_6, Δv_2, and Δv_5, which shall be measured as shown in Figure 72–12 and described below.

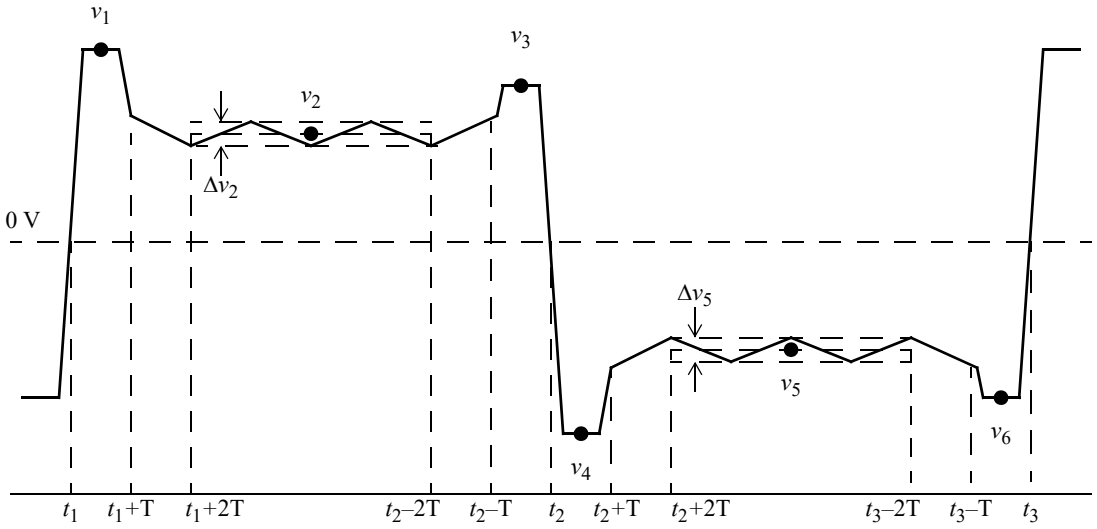

Figure 72–12—Transmitter output waveform

T	=	symbol period
t_1	=	zero-crossing point of the first rising edge of the AC-coupled signal
t_2	=	zero-crossing point of the falling edge of the AC-coupled signal
t_3	=	zero-crossing point of the second rising edge of the AC-coupled signal
v_1	=	maximum voltage measured in the interval t_1 to t_1 + T
v_2	=	positive steady-state voltage measured as the average voltage in the interval t_1 + 2T to t_2 – 2T
v_3	=	maximum voltage measured in the interval t_2 – T to t_2
v_4	=	minimum voltage measured in the interval t_2 to t_2 + T
v_5	=	negative steady-state voltage measured as the average voltage in the interval t_2 + 2T to t_3 – 2T
v_6	=	minimum voltage measured in the interval t_3 – T to t_3
Δv_2	=	positive voltage ripple measured as the peak-to-peak value of the difference between the voltage in the range t_1 + 2T to t_2 – 2T and v_2
Δv_5	=	negative voltage ripple measured as the peak-to-peak value of the difference between the voltage in the range t_2 + 2T to t_3 – 2T and v_5

From these voltages, the pre- and post-cursor equalization ratios R_{pre} and R_{pst} are derived from Equation (72–8) and Equation (72–9).

$$R_{pre} = \frac{v_3}{v_2} \tag{72–8}$$

$$R_{pst} = \frac{v_1}{v_2} \tag{72–9}$$

The state of the transmitter equalizer and hence the transmitter output waveform is manipulated via the protocol defined in 72.6.10 or via management. The changes in the transmitter output waveform resulting from coefficient update requests shall meet the requirements stated in Table 72–7. The coefficient update requests in Table 72–7 are to be followed by a coefficient update equal to hold for all taps. The results shall be verified after the coefficient status for all taps is reported as not_updated.

Table 72–7—Transmitter output waveform requirements related to coefficient update

Coefficient update[a]			Requirements[b]		
$c(1)$	$c(0)$	$c(-1)$	$v_1(k) - v_1(k-1)$ (mV)	$v_2(k) - v_2(k-1)$ (mV)	$v_3(k) - v_3(k-1)$ (mV)
increment	hold	hold	–20 to –5	5 to 20	5 to 20
decrement	hold	hold	5 to 20	–20 to –5	–20 to –5
hold	increment	hold	5 to 20	5 to 20	5 to 20
hold	decrement	hold	–20 to –5	–20 to –5	–20 to –5
hold	hold	increment	5 to 20	5 to 20	–20 to –5
hold	hold	decrement	–20 to –5	–20 to –5	5 to 20

[a]Step size requirements for the tap under test apply regardless of the current value of the other taps.
[b]This difference is measured relative to the voltage prior to the assertion coefficient update k equal to hold.

For any coefficient update, the magnitudes of the changes in v_1, v_2, and v_3 shall be within 5 mV of each other. When sufficient increment or decrement updates have been applied to a given tap, it will reach a maximum or minimum limit governed by the coefficient range or by restrictions placed on minimum steady-state or maximum peak voltage, and the coefficient status is reported accordingly. The transmitter output waveform shall meet the requirements of Table 72–8 for all of the limiting cases represented in the table. Implementation of $c(-1)$ or $c(1)$ coefficient values greater than zero or less than the minimum defined by R_{pre} (min) and R_{pst} (min) is optional. A coefficient may be disabled by first asserting the preset control defined in Table 45–215 and 45.2.1.97, then manipulating the other coefficients as required by the test.

Table 72–8—Transmitter output waveform requirements related to coefficient status

Coefficient status			Requirements		
$c(1)$	$c(0)$	$c(-1)$	R_{pre}	R_{pst}	v_2 (mV)
disabled	minimum	disabled	0.90 to 1.10	0.90 to 1.10	220 to 330
disabled	maximum	disabled	0.95 to 1.05	0.95 to 1.05	400 to 600
minimum	minimum	disabled	—	4.00 (min)	—
disabled	minimum	minimum	1.54 (min)	—	—

In addition:

a) The quantities Δv_2 and Δv_5 shall not exceed 40 mV peak-to-peak.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

b) The positive and negative voltages shall match such that each of the quantities min($|v_1 + v_4|/v_1$, $|v_1 + v_4|/|v_4|$), min($|v_2 + v_5|/v_2$, $|v_2 + v_5|/|v_5|$), and min($|v_3 + v_6|/v_3$, $|v_3 + v_6|/|v_6|$) does not exceed 0.05.
c) The quantity v_2 shall be greater than or equal to 40 mV.
d) Any coefficient update equal to decrement applied to any tap that would result in v_2 less than 40 mV shall return a coefficient status value minimum.
e) Any coefficient update equal to decrement that would result in a violation of 72.7.1.4 shall return a coefficient status value minimum for that coefficient.
f) Any coefficient update equal to increment that would result in a violation of 72.7.1.4 shall return a coefficient status value maximum for that coefficient.

72.7.2 Receiver characteristics

Receiver characteristics at TP4 are summarized in Table 72–9 and detailed in 72.7.2.1 through 72.7.2.5.

Table 72–9—Receiver characteristics for 10GBASE-KR

Parameter	Subclause reference	Value	Units
Bit error ratio	72.7.2.1	10^{-12}	
Signaling speed	72.7.2.2	10.3125 ± 100 ppm	GBd
Receiver coupling	72.7.2.3	AC	
Differential input peak-to-peak amplitude (maximum)	72.7.2.4	1200[a]	mV
Differential input return loss (minimum)[b]	72.7.2.5	[See Equation (72–4) and Equation (72–5)]	dB

[a]The receiver shall tolerate amplitudes up to 1600 mV without permanent damage.
[b]Relative to 100 Ω differential.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.7.2.1 Receiver interference tolerance

The receiver interference tolerance shall consist of two separate tests as described in Annex 69A with the parameters specified in Table 72–10. The data pattern for the interference tolerance test shall be the test patterns 2 or 3 as defined in 52.9.1.1. The receiver shall satisfy the requirements for interference tolerance specified in Annex 69A for both tests.

Table 72–10—10GBASE-KR interference tolerance parameters

Parameter	Test 1 values	Test 2 values	Units
Target BER	10^{-12}	10^{-12}	
m_{TC} (min.)[a]	1.0	0.5	
Amplitude of broadband noise (min. RMS)	5.2	12	mV
Applied transition time (20%–80%, min.)	47	47	ps
Applied Sinusoidal jitter (min. peak-to-peak)	0.115	0.115	UI
Applied random jitter (min. peak-to-peak)[b]	0.130	0.130	UI
Applied Duty Cycle Distortion (min. peak-to-peak)	0.035	0.035	UI

[a]m_{TC} is defined in Equation (69A–6) of Annex 69A.
[b]Applied random jitter is specified at a BER of 10^{-12}.

72.7.2.2 Signaling speed range

A 10GBASE-KR receiver shall comply with the requirements of Table 72–9 for any signaling speed in the range 10.3125 GBd ± 100 ppm.

72.7.2.3 AC-coupling

The 10GBASE-KR receiver shall be AC-coupled to the backplane to allow for maximum interoperability between various 10 Gb/s components. AC-coupling is considered to be part of the receiver for the purposes of this specification unless explicitly stated otherwise. It should be noted that there may be various methods for AC-coupling in actual implementations.

NOTE—It is recommended that the maximum value of the coupling capacitors be limited to 100 nF. This will limit the inrush currents to the receiver that could damage the receiver circuits when repeatedly connected to transmit modules with a higher voltage level.

72.7.2.4 Input signal amplitude

10GBASE-KR receivers shall accept differential input signal peak-to-peak amplitudes produced by compliant transmitters connected without attenuation to the receiver, and still meet the BER requirement specified in 72.7.2.1. Note that this may be larger than the 1200 mV differential maximum of 72.7.1.4 due to the actual transmitter output and receiver input impedances. The input impedance of a receiver can cause the minimum signal into a receiver to differ from that measured when the receiver is replaced with a 100 Ω test load. Since the channel is AC-coupled, the absolute voltage levels with respect to the receiver ground are dependent on the receiver implementation.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

72.7.2.5 Differential input return loss

For frequencies from 100 MHz to 7500 MHz, the differential return loss, in dB with *f* in MHz, of the receiver shall be greater than or equal to Equation (72–4) and Equation (72–5). The reference impedance for differential return loss measurements is 100 Ω.

72.8 Interconnect characteristics

Informative interconnect characteristics for 10GBASE-KR are provided in Annex 69B.

72.9 Environmental specifications

72.9.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

72.9.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

72.9.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

72.9.4 Electromagnetic compatibility

A system integrating the 10GBASE-KR PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

72.9.5 Temperature and humidity

A system integrating the 10GBASE-KR PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

72.10 Protocol implementation conformance statement (PICS) proforma for Clause 72, Physical Medium Dependent (PMD) sublayer and baseband medium, type 10GBASE-KR[135]

72.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 72, Physical Medium Dependent (PMD) sublayer and baseband medium type 10GBASE-KR, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

72.10.2 Identification

72.10.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

72.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 72, Physical Medium Dependent (PMD) sublayer and baseband medium type 10GBASE-KR
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[135] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

73. Auto-Negotiation for backplane and copper cable assembly

Auto-Negotiation, as defined in this clause, is specified for use with Ethernet PHYs operating over a backplane and for use with certain Ethernet PHYs operating over a copper cable assembly.

73.1 Auto-Negotiation introduction

While implementation of Auto-Negotiation is mandatory for Backplane Ethernet PHYs, the use of Auto-Negotiation is optional. Parallel detection shall be provided for legacy devices that do not support Auto-Negotiation.

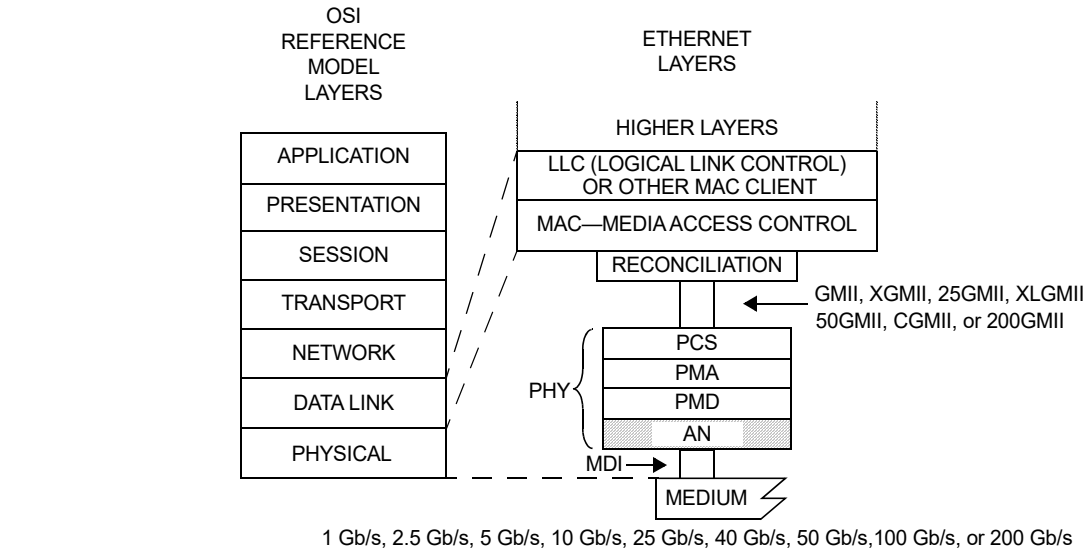
The Auto-Negotiation function allows an Ethernet device to advertise modes of operation it possesses to another device at the remote end of a Backplane Ethernet link and to detect corresponding operational modes the other device may be advertising.

The objective of this Auto-Negotiation function is to provide the means to exchange information between two devices that share a link across a backplane and to automatically configure both devices to take maximum advantage of their abilities. It has the additional objective of supporting a digital signal detect to ensure that the device is attached to a link partner rather than detecting signal due to crosstalk.

Auto-Negotiation is performed using differential Manchester encoding (DME) pages. DME provides a DC-balanced signal. DME does not add packet or upper layer overhead to the network devices.

Auto-Negotiation does not test the link segment characteristics.

This function allows the devices at both ends of a link segment to advertise abilities, acknowledge receipt and discover the common modes of operation that both devices share, and to reject the use of operational modes that are not shared by both devices. Where more than one common mode exists between the two devices, a mechanism is provided to allow the devices to resolve to a single mode of operation using a predetermined priority resolution function. The Auto-Negotiation function allows the devices to switch between the various operational modes in an orderly fashion, permits management to disable or enable the Auto-Negotiation function, and allows management to select a specific operational mode. The Auto-Negotiation function also provides a parallel detection function to allow Backplane Ethernet devices to connect to other Backplane Ethernet devices that have Auto-Negotiation disabled and interoperate with legacy devices that do not support Clause 73 Auto-Negotiation.



It is recommended that a device that has negotiated 1000BASE-KX operation through this clause not perform Clause 37 Auto-Negotiation. A device that performs Clause 37 Auto-Negotiation after having negotiated 1000BASE-KX operation through Clause 73 Auto-Negotiation will not interoperate with a device that does not perform Clause 37 Auto-Negotiation. Therefore, a device that intends to enable Clause 37 Auto-Negotiation after Clause 73 Auto-Negotiation has completed shall ensure through an implementation-specific mechanism that the link partner supports Clause 37 Auto-Negotiation and intends to enable it. If Clause 37 Auto-Negotiation is performed after Clause 73 Auto-Negotiation, then the advertised abilities used in the Clause 37 Auto-Negotiation shall match those advertised abilities used in the Clause 73 Auto-Negotiation.

The Auto-Negotiation functions are listed in 73.3.

73.2 Relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model

The Auto-Negotiation function is provided at the Physical Layer of the ISO/IEC OSI reference model as shown in Figure 73–1. A device that supports multiple modes of operation may advertise its capabilities using the Auto-Negotiation function. The actual transfer of information is observed only at the MDI or on the backplane medium.

200GMII = 200 Gb/s MEDIA INDEPENDENT INTERFACE

Figure 73–1—Location of Auto-Negotiation function within the ISO/IEC OSI reference model

73.3 Functional specifications

The Auto-Negotiation function provides a mechanism to control connection of a single MDI to a single PHY type, where more than one PHY type may exist. A management interface provides control and status of Auto-Negotiation, but the presence of a management agent is not required.

The Auto-Negotiation function shall provide the following:

a) Auto-Negotiation transmit
b) Auto-Negotiation receive
c) Auto-Negotiation arbitration

These functions shall comply with the state diagrams from Figure 73–9 through Figure 73–11. The Auto-Negotiation functions shall interact with the technology-dependent PHYs through the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Technology-Dependent interface (see 73.9). Technology-Dependent PHYs are those supported by the Auto-Negotiation process (see Table 73–4).

When the MDI supports multiple lanes, then lane 0 of the MDI shall be used for Auto-Negotiation and for connection of any single-lane PHYs (e.g., 1000BASE-KX or 10GBASE-KR).

73.4 Transmit function requirements

The Transmit function provides the ability to transmit pages. The first pages exchanged by the local device and its link partner after Power-On, link restart, or renegotiation contain the base link codeword defined in Figure 73–6. The local device may modify the link codeword to disable an ability it possesses, but will not transmit an ability it does not possess. This makes possible the distinction between local abilities and advertised abilities so that multi-ability devices may Auto-Negotiate to a mode lower in priority than the highest common ability.

73.5 DME transmission

Auto-Negotiation's method of communication builds upon the encoding mechanism known as differential Manchester encoding (DME). The DME page encodes the data that is used to control the Auto-Negotiation function. DME pages shall not be transmitted when Auto-Negotiation is complete and the highest common denominator PHY has been enabled.

73.5.1 DME electrical specifications

Transmitter characteristics shall meet the specifications in Table 73–1 at TP1 while transmitting DME pages. Receiver characteristics shall meet the specifications in Table 73–1 at TP4 while receiving DME pages.

Table 73–1—DME electrical characteristics

Parameter	Value	Units
Transmit differential peak-to-peak output voltage	600 to 1200	mV
Receive differential peak-to-peak input voltage	200 to 1200	mV

For any multi-lane PHY, DME pages shall be transmitted only on lane 0. The transmitters on other lanes should be disabled as specified in 71.6.7, 84.7.7, 85.7.7, 92.7.7, 93.7.7, 94.3.6.7, 136.8.7, or 137.8.7.

73.5.2 DME page encoding

A DME page carries a 48-bit Auto-Negotiation page. It consists of 106 evenly spaced transition positions that contain a Manchester violation delimiter, the 48-bit page, and a single pseudo-random bit. The odd-numbered transition positions represent clock information. The even numbered transition positions represent data information. DME pages are transmitted continuously without any idle or gap.

The first eight transition positions contain the Manchester violation delimiter, which marks the beginning of the page. The Manchester violation contains a transition at position 1 and position 5 and no transitions at the remaining positions. The Manchester violation delimiter is the only place where four intervals occur between transitions. This allows the receiver to obtain page synchronization.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Each of the remaining 49 odd-numbered transition positions shall contain a transition. The remaining 49 even-numbered transition positions shall represent data information as follows:

— A transition present in an even-numbered transition position represents a logical one
— A transition absent from an even-numbered transition position represents a logical zero

The first 48 of these positions shall carry the data of the Auto-Negotiation page. The final position carries the pseudo-random bit. The value of the pseudo-random bit shall be derived from a pseudo-random generator as shown in Figure 73–2.

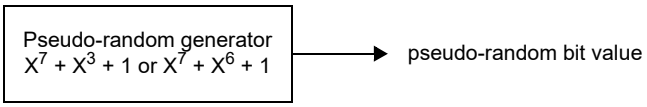

Figure 73–2—DME page bit 49 randomizer

The counter shall increment once per DME page.

The purpose of the 49th bit is to remove the spectral peaks that would otherwise occur when sending the same AN page repeatedly. Randomly choosing between 0 or 1 for one of the DME bits results in randomly inverting or not inverting the encoded page so that repetitions of the same page no longer produce a periodic signal.

Clock transition positions are differentiated from data transition positions by the spacing between them, as shown in Figure 73–3 and enumerated in Table 73–2.

The encoding of data using DME bits in an DME page is illustrated in Figure 73–3.

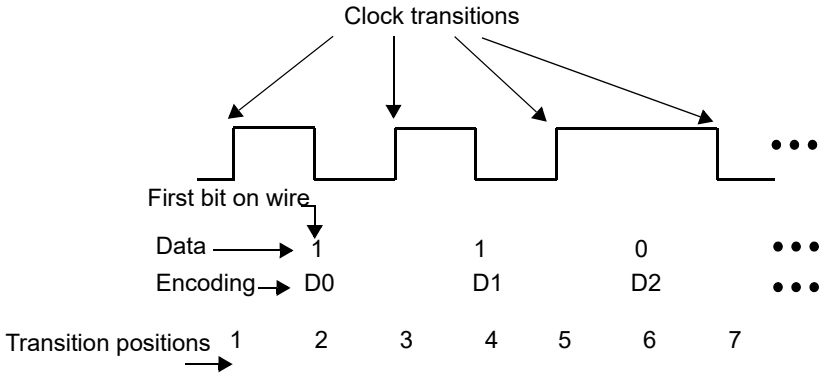

Figure 73–3—Data bit encoding within DME pages

73.5.3 DME page timing

The timing parameters for DME pages shall be followed as in Table 73–2. The transition positions within a DME page are spaced with a period of T1. T2 is the separation between clock transitions. T3 is the time from a clock transition to a data transition representing a one. The period, T1, shall be 3.2 ns ± 0.01%. Transitions shall occur within ± 0.2 ns of their ideal positions.

T5 specifies the duration of a DME page. Since DME pages are sent continuously during Auto-Negotiation, T5 is also the time from the start of one DME page to the start of the next DME page.

The minimum number of transitions and maximum number of transitions in a page is represented by T4.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 73–2 summarizes the timing parameters. The transition timing parameters are illustrated in Figure 73–4.

Table 73–2— DME page timing summary

	Parameter	Min.	Typ.	Max.	Units
T1	Transition position spacing (period)	3.2 –0.01%	3.2	3.2 +0.01%	ns
T2	Clock transition to clock transition	6.2	6.4	6.6	ns
T3	Clock transition to data transition (data = 1)	3.0	3.2	3.4	ns
T4	Transitions in a DME page	51	—	100	—
T5	DME page width	338.8	339.2	339.6	ns
T6	DME Manchester violation delimiter width	12.6	12.8	13.0	ns

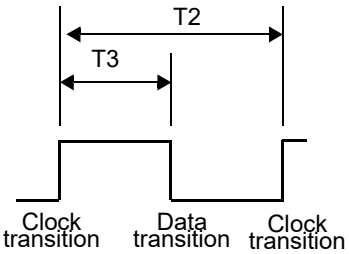

Figure 73–4—DME page transition timing

73.5.3.1 Manchester violation delimiter

A violation is signaled as shown in Figure 73–5.

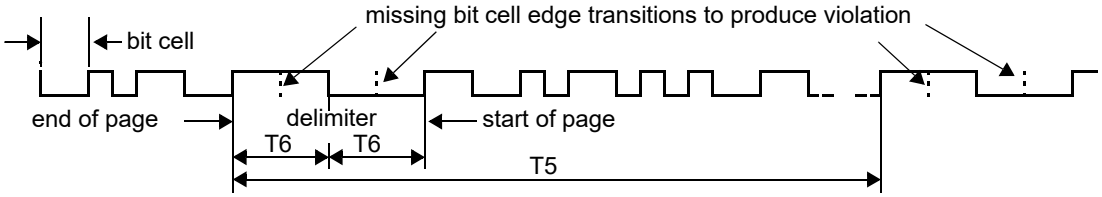

Figure 73–5—Manchester violation

73.6 Link codeword encoding

The base link codeword (Base Page) transmitted within a DME page shall convey the encoding shown in Figure 73–6. The Auto-Negotiation function supports additional pages using the Next Page function. Encoding for the link codeword(s) used in the Next Page exchange are defined in 73.7.7. In a DME page, D0 shall be the first bit transmitted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

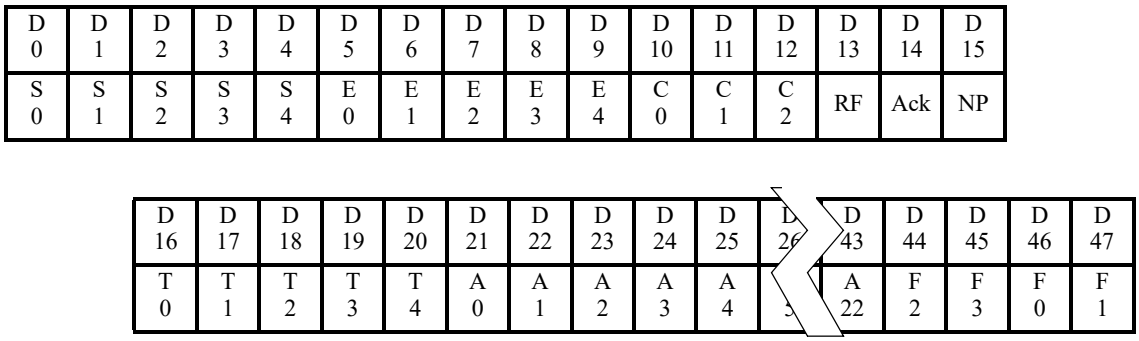

Figure 73–6—Link codeword Base Page

D[4:0] contains the Selector Field. D[9:5] contains the Echoed Nonce field. D[12:10] contains capability bits to advertise capabilities not related to the PHY. C[1:0] is used to advertise pause capability. The remaining capability bit C[2] is reserved. D[15:13] contains the RF, Ack, and NP bits. These bits shall function as specified in 28.2.1.2. D[20:16] contains the Transmitted Nonce field. D[43:21] contains the Technology Ability Field. D[47:44] contains FEC capability (see 73.6.5).

73.6.1 Selector Field

Selector Field (S[4:0]) is a five-bit wide field, encoding 32 possible messages. Selector Field encoding definitions are shown in Annex 28A. Combinations not specified are reserved for future use. Reserved combinations of the Selector Field shall not be transmitted.

The Selector Field for IEEE Std 802.3 is shown in Table 73–3.

Table 73–3—Selector Field Encoding

S4	S3	S2	S1	S0	Selector description
0	0	0	0	1	IEEE Std 802.3

73.6.2 Echoed Nonce Field

Echoed Nonce Field (E[4:0]) is a 5-bit wide field containing the nonce received from the link partner. When Acknowledge is set to logical zero, the bits in this field shall contain logical zeros. When Acknowledge is set to logical one, the bits in this field shall contain the value received in the Transmitted Nonce Field from the link partner.

73.6.3 Transmitted Nonce Field

Transmitted Nonce Field (T[4:0]) is a 5-bit wide field containing a random or pseudo-random number. A new value shall be generated for each entry to the Ability Detect state. The method of generating the nonce is left to the implementer. The transmitted nonce should have a uniform distribution in the range from 0 to $2^5 - 1$. The method used to generate the value should be designed to minimize correlation to the values generated by other devices.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

73.6.4 Technology Ability Field

Technology Ability Field (A[22:0]) is a 23-bit wide field containing information indicating supported technologies specific to the selector field value when used with the Auto-Negotiation for backplane and copper cable assembly. These bits are mapped to individual technologies such that abilities are advertised in parallel for a single selector field value. The Technology Ability Field encoding for the IEEE 802.3 selector with Auto-Negotiation for backplane and copper cable assembly is described in Table 73–4.

Table 73–4—Technology Ability Field encoding

Bit	Technology
A0	1000BASE-KX
A1	10GBASE-KX4
A2	10GBASE-KR
A3	40GBASE-KR4
A4	40GBASE-CR4
A5	100GBASE-CR10
A6	100GBASE-KP4
A7	100GBASE-KR4
A8	100GBASE-CR4
A9	25GBASE-KR-S or 25GBASE-CR-S
A10	25GBASE-KR or 25GBASE-CR
A11	2.5GBASE-KX
A12	5GBASE-KR
A13	50GBASE-KR or 50GBASE-CR
A14	100GBASE-KR2 or 100GBASE-CR2
A15	200GBASE-KR4 or 200GBASE-CR4
A16 through A22	Reserved

Multiple technologies may be advertised in the link codeword. A device shall support the data service ability for a technology it advertises. It is the responsibility of the Arbitration function to determine the common mode of operation shared by a link partner and to resolve multiple common modes.

NOTE—Previous editions of this standard prohibited simultaneous advertisement of PHYs that support operation over electrical backplanes with PHYs that support operation over copper cable assemblies.

25GBASE-KR-S abilities are a subset of 25GBASE-KR abilities, and likewise 25GBASE-CR-S abilities are a subset of 25GBASE-CR abilities. To allow interoperation between 25GBASE-KR-S and 25GBASE-KR PHY types, and between 25GBASE-CR-S and 25GBASE-CR PHY types, a device that supports 25GBASE-KR or 25GBASE-CR should advertise both A9 and A10 ability bits during auto-negotiation.

The fields A[22:16] are reserved for future use. Reserved fields shall be sent as zero and ignored on receive.

73.6.5 FEC capability

FEC (F2, F3, F0, F1) is encoded in bits D44:D47 of the base link codeword. The four FEC bits are used as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) F0 is 10 Gb/s per lane FEC ability
b) F1 is 10 Gb/s per lane FEC requested
c) F2 is 25G RS-FEC requested
d) F3 is 25G BASE-R FEC requested

Bits F2 and F3 are used for resolving FEC operation for 25G PHYs, while bits F0 and F1 are used for 10 Gb/s per lane operation. Bits F0 and F1 are not used for 25G PHYs.

73.6.5.1 FEC resolution for 25G PHYs

For 25G PHYs if neither PHY requests FEC operation in bits F2 or F3 then FEC is not enabled.

For 25GBASE-KR and 25GBASE-CR PHYs if either PHY requests RS-FEC then RS-FEC operation is enabled, otherwise if either PHY requests BASE-R FEC then BASE-R operation is enabled.

For 25GBASE-KR-S and 25GBASE-CR-S PHYs, if either PHY requests RS-FEC or BASE-R FEC then BASE-R operation is enabled. This is because 25GBASE-KR-S and 25GBASE-CR-S PHYs do not support RS-FEC operation.

73.6.5.2 FEC resolution for 10 Gb/s per lane PHYs

For 10 Gb/s per lane operation, when the FEC ability bit F0 is set to logical one, it indicates that the PHY has FEC ability (see Clause 74). When the FEC requested F1 bit is set to logical one, it indicates a request to enable FEC on the link.

Since the local device and the link partner may have set the FEC capability bits differently, the priority resolution function is used to enable FEC in the respective PHYs. The FEC function shall be enabled on the link if 10GBASE-KR, 40GBASE-KR4, 40GBASE-CR4, or 100GBASE-CR10 is the HCD technology (see 73.7.6), both devices advertise FEC ability on the F0 bits, and at least one device requests FEC on the F1 bits; otherwise FEC shall not be enabled.

73.6.5.3 FEC control variables

The variable an_baser_fec_control indicates that BASE-R FEC operation has been negotiated. If the value is false, then BASE-R FEC has not been negotiated. If the value is true, then BASE-R FEC has been negotiated.

The variable an_rs_fec_control indicates that RS-FEC operation has been negotiated. If the value is false, then RS-FEC has not been negotiated. If the value is true, then RS-FEC has been negotiated.

The mapping of these variables to MDIO register bits is defined in Table 73–6.

If mr_autoneg_enable (see 73.10.1) is false, the FEC function is controlled by implementation-dependent means.

73.6.6 Pause Ability

Pause (C0:C1) is encoded in bits D11:D10 of the base link codeword. The two-bit Pause is encoded as follows:

a) C0 is the same as PAUSE as defined in Annex 28B
b) C1 is the same as ASM_DIR as defined in Annex 28B

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The Pause encoding is defined in Clause 28B.2, Table 28B–2. The PAUSE bit indicates that the device is capable of providing the symmetric PAUSE functions as defined in Annex 31B. The ASM_DIR bit indicates that asymmetric PAUSE is supported. The value of the PAUSE bit when the ASM_DIR bit is set indicates the direction the PAUSE frames are supported for flow across the link. Asymmetric PAUSE configuration results in independent enabling of the PAUSE receive and PAUSE transmit functions as defined by Annex 31B. See 28B.3 regarding PAUSE configuration resolution.

73.6.7 Remote Fault

Remote Fault (RF) is encoded in bit D13 of the base link codeword. The default value is logical zero. The Remote Fault bit provides a standard transport mechanism for the transmission of simple fault information. When the RF bit in the AN advertisement register (register 7.16.13) is set to logical one, the RF bit in the transmitted base link codeword is set to logical one. When the RF bit in the received base link codeword is set to logical one, the Remote Fault bit in the AN LP Base Page ability register (register 7.19.13) will be set to logical one, if the management function is present.

73.6.8 Acknowledge

Acknowledge (Ack) is used by the Auto-Negotiation function to indicate that a device has successfully received its link partner's link codeword. The Acknowledge Bit is encoded in bit D14 of link codeword. If no Next Page information is to be sent, this bit shall be set to logical one in the link codeword after the reception of at least three consecutive and consistent DME pages (ignoring the Acknowledge bit value). If Next Page information is to be sent, this bit shall be set to logical one after the device has successfully received at least three consecutive and matching DME pages (ignoring the Acknowledge bit value), and will remain set until the Next Page information has been loaded into the AN XNP transmit register (registers 7.22, 7.23, 7.24). In order to save the current received link codeword, it has to be read from the AN LP XNP ability register (register 7.25, 7.26, 7.27) before the Next Page of transmit information is loaded into the AN XNP transmit register. After the COMPLETE ACKNOWLEDGE state has been entered, the link codeword will be transmitted at least six times.

73.6.9 Next Page

Next Page (NP) is encoded in bit D15 of link codeword. Support of Next Pages is mandatory. If the device does not have any Next Pages to send, the NP bit shall be set to logical zero. If a device wishes to engage in Next Page exchange, it shall set the NP bit to logical one. If a device has no Next Pages to send and its link partner has set the NP bit to logical one, it shall transmit Next Pages with Null message codes and the NP bit set to logical zero while its link partner transmits valid Next Pages. Next page exchanges will occur if either the device or its link partner sets the Next Page bit to logical one. The Next Page function is defined in 73.7.7.

73.6.10 Transmit Switch function

During Auto-Negotiation and prior to entry into the AN_GOOD_CHECK state, the Transmit Switch function shall connect only the DME page generator controlled by the Transmit State Diagram to the MDI.

Upon entry into the AN_GOOD_CHECK state, the Transmit Switch function shall connect the transmit path from a single technology-dependent (highest common denominator) PHY to the MDI.

When a PHY is connected to the MDI through the Transmit Switch function, the signals at the MDI shall conform to all of the PHY's specifications within 20 ms.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

73.7 Receive function requirements

The receive function detects the DME page sequence, decodes the information contained within, and stores the data in rx_link_code_word[48:1]. The receive function incorporates a receive switch to control connection of the DME page receiver or a PHY to the MDI.

73.7.1 DME page reception

To be able to detect the DME bits, the receiver should have the capability to receive DME signals sent with the electrical specifications of the PHY. The DME transmit signal level and receive sensitivity are specified in 73.5.1.

73.7.2 Receive Switch function

During Auto-Negotiation and prior to entry into the AN_GOOD_CHECK state, the Receive Switch function shall connect the DME page receiver to the MDI. For the Parallel Detection function, the Receive Switch function shall also connect the receive path of the 1000BASE-KX and 10GBASE-KX4 PHY to the MDI when those PHYs are present.

Upon entry into the AN_GOOD_CHECK state, the Receive Switch function shall connect the receive path from a single technology-dependent (highest common denominator) PHY to the MDI.

73.7.3 Link codeword matching

The Receive function shall generate ability_match, acknowledge_match, and consistency_match variables as defined in Arbitration state diagram Figure 73–11.

73.7.4 Arbitration function requirements

The Arbitration function is described in Figure 73–11 and ensures proper sequencing of the Auto-Negotiation function using the Transmit function and Receive function. The Arbitration function enables the Transmit function to advertise and acknowledge abilities. Upon indication of acknowledgement, the Arbitration function determines the highest common denominator using the priority resolution function and enables the appropriate technology-dependent PHY via the link_control_[x] variables.

If mr_autoneg_enable (see 73.10.1) is false, enabling the desired technology-dependent PHY is controlled by implementation-dependent means.

73.7.4.1 Parallel Detection function

The local device detects a link partner that supports Auto-Negotiation by DME page detection. The Parallel Detection function allows detection of link partners that support 1000BASE-KX, 2.5GBASE-KX, and 10GBASE-KX4 but have disabled Auto-Negotiation, and detection of legacy devices that can interoperate with 1000BASE-KX, 2.5GBASE-KX, and 10GBASE-KX4 devices, but do not provide Clause 73 Auto-Negotiation.

A local device shall provide Parallel Detection for 1000BASE-KX, 2.5GBASE-KX, and 10GBASE-KX4 if it supports those PHYs. Additionally, parallel detection may be used for 10GBASE-CX4. Parallel detection of 10GBASE-CX4 will be indicated by the setting of the Negotiated Port Type to “10GBASE-KX4 or 10GBASE-CX4” in the management register bit 7.48.2. The means to distinguish between 10GBASE-KX4

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

and 10GBASE-CX4 is implementation dependent. Parallel Detection shall be performed by directing the MDI receive activity to the PHY. This detection may be done in sequence between detection of DME pages and detection of each supported PHY. If at least one of the 1000BASE-KX, 2.5GBASE-KX, or 10GBASE-KX4 establishes link_status=OK, the LINK STATUS CHECK state is entered and the autoneg_wait_timer is started. If exactly one link_status=OK indication is present when the autoneg_wait_timer expires, then Auto-Negotiation shall set link_control=ENABLE for the PHY indicating link_status=OK. If a PHY is enabled, the Arbitration function shall set link_control=DISABLE to all other PHYs and indicate that Auto-Negotiation has completed. On transition to the AN GOOD CHECK state from the LINK STATUS CHECK state, the Parallel Detection function shall set the bit in the AN LP Base Page ability registers (see 45.2.7.7) corresponding to the technology detected by the Parallel Detection function.

If Auto-Negotiation detects link_status=OK from any of the technology-dependent PHYs prior to DME page detection, the autoneg_wait_timer shall start. If more than one technology-dependent PHYs indicate link_status=OK when the autoneg_wait_timer expires, Auto-Negotiation will not allow any data service to be enabled and may signal this as a remote fault to the link partner using the Base Page and will flag this in the local device by setting the Parallel Detection fault bit (45.2.7.2) in the AN Status register.

73.7.5 Renegotiation function

A renegotiation request from any entity, such as a management agent, shall cause the Arbitration function to disable all technology-dependent PHYs and halt any transmit data and link transition activity until the break_link_timer expires. Consequently, the link partner will go into link fail and normal Auto-Negotiation resumes. The local device shall resume Auto-Negotiation after the break_link_timer has expired by issuing DME pages with the Base Page valid in tx_link_code_word[48:1]. Once Auto-Negotiation has completed, renegotiation will take place if the Highest Common Denominator technology that receives link_control=ENABLE returns link_status=FAIL. To allow the PHY an opportunity to determine link integrity using its own link integrity test function, the link_fail_inhibit_timer qualifies the link_status=FAIL indication such that renegotiation takes place if the link_fail_inhibit_timer has expired and the PHY still indicates link_status=FAIL.

73.7.6 Priority Resolution function

Since a local device and a link partner may have multiple common abilities, a mechanism to resolve which mode to configure is required. The mechanism used by Auto-Negotiation is a Priority Resolution function that predefines the hierarchy of supported technologies. The single PHY enabled to connect to the MDI by Auto-Negotiation shall be the technology corresponding to the bit in the Technology Ability Field common

to the local device and link partner that has the highest priority as defined in Table 73–5 (listed from highest priority to lowest priority).

Table 73–5—Priority Resolution

Priority	Technology	Capability
1	200GBASE-KR4 or 200GBASE-CR4	200 Gb/s 4 lane, highest priority
2	100GBASE-KR2 or 100GBASE-CR2	100 Gb/s 2 lane
3	100GBASE-CR4	100 Gb/s 4 lane
4	100GBASE-KR4	100 Gb/s 4 lane
5	100GBASE-KP4	100 Gb/s 4 lane
6	100GBASE-CR10	100 Gb/s 10 lane
7	50GBASE-KR or 50GBASE-CR	50 Gb/s 1 lane
8	40GBASE-CR4	40 Gb/s 4 lane
9	40GBASE-KR4	40 Gb/s 4 lane
10	25GBASE-KR or 25GBASE-CR	25 Gb/s 1 lane
11	25GBASE-KR-S or 25GBASE-CR-S	25 Gb/s 1 lane, short reach
12	10GBASE-KR	10 Gb/s 1 lane
13	10GBASE-KX4	10 Gb/s 4 lane
14	5GBASE-KR	5 Gb/s 1 lane
15	2.5GBASE-KX	2.5 Gb/s 1 lane
16	1000BASE-KX	1 Gb/s 1 lane, lowest priority

The common technology is referred to as the highest common denominator, or HCD, technology. If the local device receives a Technology Ability Field with a bit set that is reserved, the local device shall ignore that bit for priority resolution. Determination of the HCD technology occurs on entrance to the AN GOOD CHECK state. In the event that a technology is chosen through the parallel detection function, that technology shall be considered the highest common denominator (HCD) technology. In the event that there is no common technology, HCD shall have a value of “NULL”, indicating that no PHY receives link_control=ENABLE and link_status[HCD]=FAIL.

NOTE—If both local device and link partner are Backplane Ethernet compliant PHYs, then both ends use abilities exchanged through Clause 73 Auto-Negotiation function. If the Link partner is a legacy device (or has disabled Auto-Negotiation) as indicated by the parallel detect function, then the peer 1 Gb/s devices can opt to use abilities exchanged through Clause 37. This will ensure there are no interoperability issues when connected to a Backplane Ethernet PHY.

73.7.7 Next Page function

The Next Page function uses the Auto-Negotiation arbitration mechanisms to allow exchange of Next Pages of information, which may follow the transmission and acknowledgment procedures used for the base link codeword. The Next Page has both Message code field and Unformatted code fields.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A dual acknowledgment system is used. Acknowledge (Ack) is used to acknowledge receipt of the information; Acknowledge 2 (Ack2) is used to indicate that the receiver is able to act on the information (or perform the task) defined in the message.

The Toggle bit is used to ensure proper synchronization between the local device and the link partner.

Next page exchange occurs after the base link codewords have been exchanged if either end of the link segment set the Next Page bit to logical one indicating that it had at least one Next Page to send. Next page exchange consists of using the normal Auto-Negotiation arbitration process to send Next Page messages.

The Next Page contains two message encodings. The message encodings are defined as follows: message code, which contain predefined 11-bit codes, and unformatted code contains 32 bit codes. Multiple Next Pages with appropriate message codes and unformatted codes can be transmitted to send extended messages. Each series of Next Pages shall have a Message code that defines how the Unformatted codes will be interpreted. Any number of Next Pages may be sent in any order; however, it is recommended that the total number of Next Pages sent be kept small to minimize the link startup time.

Next page transmission ends when both ends of a link segment set their Next Page bits to logical zero, indicating that neither has anything additional to transmit. It is possible for one device to have more pages to transmit than the other device. Once a device has completed transmission of its Next Page information, it shall transmit Next Pages with Null message codes and the NP bit set to logical zero while its link partner continues to transmit valid Next Pages. An Auto-Negotiation able device shall recognize reception of Message Pages with Null message codes as the end of its link partner's Next Page information.

73.7.7.1 Next page encodings

The Next Page shall use the encoding shown in Figure 73–7 and Figure 73–8 for the NP, Ack, MP, Ack2, and T bits. These bits shall function as specified in 28.2.3.4. There are two types of Next Page encodings—message and unformatted. For message Next Pages, the MP bit shall be set to logical one, the 11-bit field D[10:0] shall be encoded as a Message Code Field and D[47:16] shall be encoded as Unformatted Code Field. For Unformatted Next Pages, the MP bit shall be set to logical zero; D[10:0] and D[47:16] shall be encoded as the Unformatted Code Field.

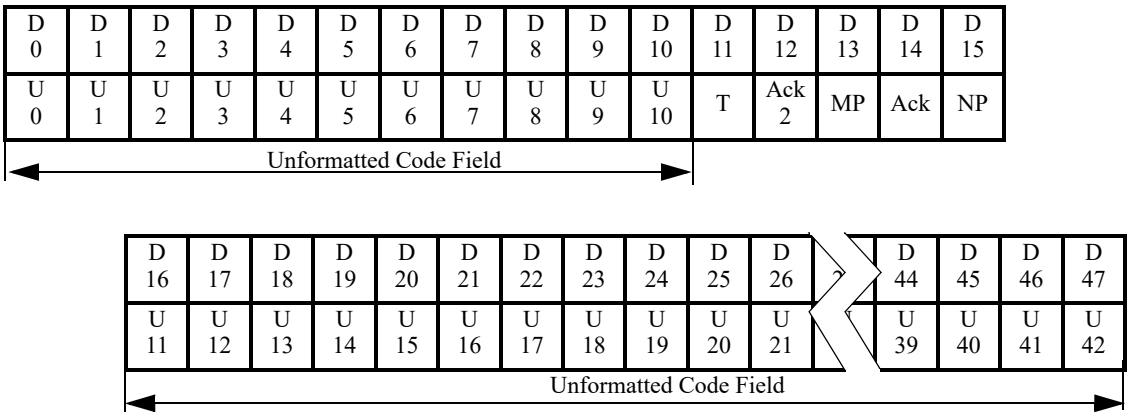

Figure 73–8—Unformatted Next Page

73.7.7.2 Use of Next Pages

Next page exchange will commence after the Base Page exchange if either device requests it by setting the NP bit to logical one.

Next page exchange shall continue until neither device on a link has more pages to transmit as indicated by the NP bit. A Next Page with a Null Message Code Field value shall be sent if the device has no other information to transmit.

A message code can carry either a specific message or information that defines how the corresponding unformatted codes should be interpreted.

73.8 Management register requirements

The management interface is used to communicate Auto-Negotiation information to the management entity. MMD7 of the Clause 45 Management Data Input/Output (MDIO) interface shall be provided as the logical interface to access the device registers for Auto-Negotiation and other management purposes. The Clause 45 MDIO electrical interface is optional. Where no physical embodiment of the MDIO exists, provision of an equivalent mechanism to access the registers is recommended. Table 73–6 provides the mapping of Backplane Ethernet Auto-Negotiation variables to management registers.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 73–6—Backplane Ethernet Auto-Negotiation variable to MDIO register mapping

Variable	Description
mr_adv_ability[48:1]	{7.18.15:0, 7.17.15:0, 7.16.15:0} AN advertisement registers
mr_autoneg_complete	7.1.5 Auto-Negotiation Complete
mr_autoneg_enable	7.0.12 Auto-Negotiation Enable
mr_lp_adv_ability[48:1]	For Base Page: {7.21.15:0, 7.20.15:0, 7.19.15:0} AN LP Base Page ability registers For Next Page(s): {7.27.15:0, 7.26.15:0, 7.25.15:0} AN LP XNP ability registers
mr_lp_autoneg_able	7.1.0 LP Auto-Negotiation Able
mr_main_reset	7.0.15 Reset
mr_next_page_loaded	Set on write to AN XNP Transmit registers; cleared by Arbitration state diagram
mr_np_tx[48:1]	{7.24.15:0, 7.23.15:0, 7.22.15:0} AN XNP Transmit registers
mr_page_rx	7.1.6 Page Received
mr_parallel_detection_fault	7.1.9 Parallel detection Fault
mr_restart_negotiation	7.0.9 Auto-Negotiation Restart
set to 1	7.1.3 Auto-Negotiation Ability
link_control_[x]	{7.48.15:8, 7.48.6:5, 7.48.3:1, 7.49.2:0} Negotiated Port Type
an_baser_fec_control	7.48.4 BASE-R FEC negotiated
an_rs_fec_control	7.48.7 RS-FEC negotiated

73.9 Technology-Dependent interface

The Technology-Dependent interface is the communication mechanism between each technology's PCS and the Auto-Negotiation function. Auto-Negotiation can support multiple technologies, all of which need not be implemented in a given device. Each of these technologies may utilize its own technology-dependent link integrity test function.

73.9.1 AN_LINK.indication

This primitive is generated by the PCS to indicate the status of the underlying medium. The purpose of this primitive is to give the Auto-Negotiation function a means of determining the validity of received code elements.

73.9.1.1 Semantics of the service primitive

AN_LINK.indication(link_status)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The link_status parameter shall assume one of two values: OK or FAIL, indicating whether the underlying receive channel is intact and enabled (OK) or not intact (FAIL).

73.9.1.2 When generated

A technology-dependent PCS generates this primitive to indicate a change in the value of link_status.

73.9.1.3 Effect of receipt

The effect of receipt of this primitive shall be governed by the state diagram of Figure 73–11.

73.10 State diagrams and variable definitions

The notation used in state diagrams follows the conventions in Clause 28. Variables in a state diagram with default values evaluate to the variable default in each state where the variable value is not explicitly set.

Auto-Negotiation shall implement the Transmit state diagram, Receive state diagram and Arbitration state diagram. Additional requirements to these state diagrams are made in the respective functional requirements sections. Options to these state diagrams clearly stated as such in the functional requirements sections or state diagrams shall be allowed. In the case of any ambiguity between stated requirements and the state diagrams, the state diagrams shall take precedence.

73.10.1 State diagram variables

A variable with "_[x]" appended to the end of the variable name indicates a variable or set of variables as defined by "x". "x" may be as follows:

all;	represents all specific technology-dependent PMDs supported in the local device.
1GKX;	represents the 1000BASE-KX PMD.
2.5GKX;	represents the 2.5GBASE-KX PMD.
5GKR;	represents the 5GBASE-KR PMD.
10GKR;	represents the 10GBASE-KR PMD.
10GKX4;	represents the 10GBASE-KX4 or 10GBASE-CX4 PMD.
25GR;	represents the 25GBASE-KR, 25GBASE-KR-S, 25GBASE-CR, or 25GBASE-CR-S PMD.
40GKR4;	represents the 40GBASE-KR4 PMD.
40GCR4;	represents the 40GBASE-CR4 PMD.
50GR;	represents the 50GBASE-KR or 50GBASE-CR PMD.
100GCR10;	represents the 100GBASE-CR10 PMD.
100GKP4;	represents the 100GBASE-KP4 PMD.
100GKR4;	represents the 100GBASE-KR4 PMD.
100GCR4;	represents the 100GBASE-CR4 PMD.
100GR2;	represents the 100GBASE-KR2 or 100GBASE-CR2 PMD.
200GR4;	represents the 200GBASE-KR4 or 200GBASE-CR4 PMD.
HCD;	represents the single technology-dependent PMD chosen by Auto-Negotiation as the highest common denominator technology through the Priority Resolution or

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

parallel detection function.

notHCD; represents all technology-dependent PMDs not chosen by Auto-Negotiation as the highest common denominator technology through the Priority Resolution or parallel detection function.

PD; represents all of the following that are present: 1000BASE-KX PMD, 2.5GBASE-KX PMD, and 10GBASE-KX4 (or 10GBASE-CX4) PMD.

Variables with [48:1] appended to the end of the variable name indicate arrays that can be directly mapped to 48-bit registers. For these variables, "[x]" indexes an element or set of elements in the array, where "[x]" may be as follows:

a) Any integer
b) Any range of integers
c) Any variable that takes on integer values
d) NP; represents the index of the Next Page bit
e) ACK; represents the index of the Acknowledge bit
f) RF; represents the index of the Remote Fault bit

Variables of the form "mr_x", where x is a label, comprise a management interface that is intended to be connected to the Management function. However, an implementation-specific management interface may provide the control and status function of these bits.

ability_match

Indicates that three consecutive link codewords match, ignoring the Acknowledge bit. Three consecutive words are any three words received one after the other, regardless of whether the word has already been used in a word-match comparison or not.

Values: false; three matching consecutive link codewords have not been received, ignoring the Acknowledge bit (default).
true; three matching consecutive link codewords have been received, ignoring the Acknowledge bit.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

ability_match_word [48:1]

A 48-bit array that is loaded upon transition to Acknowledge Detect state with the value of the link codeword that caused ability_match = true for that transition. For each element in the array transmitted.

Values: zero; data bit is logical zero.
one; data bit is logical one.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

ack_finished

Status indicating that the final remaining_ack_cnt link codewords with the Ack bit set have been transmitted.

Values: false; more link codewords with the Ack bit set to logical one have to be transmitted.
true; all remaining link codewords with the Ack bit set to logical one have been transmitted.

ack_nonce_match

Indicates whether the echoed nonce received from the link partner matches the transmitted nonce

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

field sent by the local device. The echoed nonce value from the DME page that caused acknowledge_match to be set is used for this test.

Values false; link partner echoed nonce does not equal local device transmitted nonce.
true; link partner echoed nonce equals local device transmitted nonce.

acknowledge_match

Indicates that three consecutive link codewords match and have the Acknowledge bit set. Three consecutive words are any three words received one after the other, regardless of whether the word has already been used in a word match comparison or not.

Values: false; three matching and consecutive link codewords have not been received with the Acknowledge bit set (default).
true; three matching and consecutive link codewords have been received with the Acknowledge bit set.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

an_link_good

Indicates that Auto-Negotiation has completed.

Values: false; negotiation is in progress (default).
true; negotiation is complete, forcing the Transmit and Receive functions to IDLE.

an_receive_idle

Indicates that the Receive state diagram is in the IDLE or DELIMITER DETECT state.

Values: false; the Receive state diagram is not in the IDLE or DELIMITER DETECT state (default).
true; the Receive state diagram is in the IDLE or DELIMITER DETECT state.

base_page

Status indicating that the page currently being transmitted by Auto-Negotiation is the initial link codeword encoding used to communicate the device's abilities.

Values: false; a page other than base link codeword is being transmitted.
true; the base link codeword is being transmitted.

code_sel

A Boolean random or pseudo-random value uniformly distributed. A new value is generated each time the variable code_sel is used.

Values: zero; a zero has been assigned.
one; a one has been assigned.

complete_ack

Controls the counting of transmitted link codewords that have their Acknowledge bit set.

Values: false; transmitted link codewords with the Acknowledge bit set are not counted (default).
true; transmitted link codewords with the Acknowledge bit set are counted.

consistency_match

Indicates that the ability_match_word same as the link codeword that caused acknowledge_match to be set.

Values: false; the link codeword that caused ability_match to be set is not the same as the link codeword that caused acknowledge_match to be set, ignoring the Acknowledge bit value and the echoed nonce value.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

true; the link codeword that caused ability_match to be set is the same as the link codeword that caused acknowledge_match to be set, ignoring the Acknowledge bit value and the echoed nonce value.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

detect_mv_pair

Status indicating that the receiver has detected the pair of Manchester violations forming a Manchester Violation delimiter—a sequence of three consecutive transitions with 12.8 ns ± 200 ps between each pair of transitions.

Values: false; set to false after any Receive State Diagram state transition (default).
true; Manchester violation pair has been detected.

detect_transition

Status indicating that the receiver has detected a transtion.

Values: false; set to false after any Receive State Diagram state transition (default).
true; set to true when a transition is received.

incompatible_link

Parameter used following Priority Resolution to indicate the resolved link is incompatible with the local device settings. A device's ability to set this variable to true is optional.

Values: false; A compatible link exists between the local device and link partner (default).
true; Optional indication that Priority Resolution has determined no highest common denominator exists following the most recent negotiation.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

link_control_[x]

Controls the connection of each PMD to the MDI. When all PMD transmitters are isolated from the MDI, the AN transmitter is connected to the MDI.

Values: DISABLE; isolates the PMD from the MDI.
SCAN_FOR_CARRIER; connects the PMD receiver to the MDI and isolates the PMD transmitter from the link.
ENABLE; connects the PMD (both transmit and receive) to the MDI.

link_status_[x]

This variable is defined in 73.9.1.

mr_autoneg_complete

Status indicating whether Auto-Negotiation has completed or not.

Values: false; Auto-Negotiation has not completed.
true; Auto-Negotiation has completed.

mr_autoneg_enable

Controls the enabling and disabling of the Auto-Negotiation function.

Values: false; Auto-Negotiation is disabled.
true; Auto-Negotiation is enabled.

mr_adv_ability[48:1]

A 48-bit array that contains the Advertised Abilities link codeword.
For each element within the array:

Values: zero; data bit is logical zero.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

one; data bit is logical one.

mr_lp_adv_ability[48:1]

A 48-bit array that contains the link partner's Advertised Abilities link codeword.
For each element within the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

mr_lp_autoneg_able

Status indicating whether the link partner supports Auto-Negotiation.

Values: false; the link partner does not support Auto-Negotiation.
true; the link partner supports Auto-Negotiation.

mr_main_reset

Controls the resetting of the Auto-Negotiation state diagrams.

Values: false; do not reset the Auto-Negotiation state diagrams.
true; reset the Auto-Negotiation state diagrams.

mr_next_page_loaded

Status indicating whether a new page has been loaded into the AN XNP transmit register (45.2.7.8).

Values: false; a New Page has not been loaded.
true; a New Page has been loaded.

mr_np_tx[48:1]

A 48-bit array that contains the new Next Page to transmit.
For each element within the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

mr_page_rx

Status indicating whether a New Page has been received. A New Page has been successfully received when acknowledge_match=true and consistency_match=true and the link codeword has been written to mr_lp_adv_ability[48:1].

Values: false; a New Page has not been received.
true; a New Page has been received.

mr_parallel_detection_fault

Error condition indicating that while performing parallel detection, either an_receive_idle = false, or zero or more than one of the following indications were present when the autoneg_wait_timer expired. This signal is cleared on read of the AN status register (register 7.1).

1) link_status_ [1GKX] = OK
2) link_status_[10GKX4] = OK

Values: false; Exactly one of the above two indications was true when the autoneg_wait_timer expired, and an_receive_idle = true.
true; either zero or more than one of the above two indications was true when the autoneg_wait_timer expired, or an_receive_idle = false.

mr_restart_negotiation

Controls the entrance to the TRANSMIT DISABLE state to break the link before Auto-Negotiation is allowed to renegotiate via management control.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Values: false; renegotiation is not taking place.
true; renegotiation is started.

nonce_match

Indicates whether the transmitted nonce received from the link partner matches the transmitted nonce field sent by the local device.

Values false; link partner transmitted nonce does not equal local device transmitted nonce.
true; link partner transmitted nonce equals local device transmitted nonce.

np_rx

Flag to hold the value of rx_link_code_word[NP] upon entry to the COMPLETE ACKNOWLEDGE state. This value is associated with the value of rx_link_code_word[NP] when acknowledge_match was last set.

Values zero; local device np_rx bit equals a logical zero.
one; local device np_rx bit equals a logical one.

power_on

Condition that is true until such time as the power supply for the device that contains the Auto-Negotiation state diagrams has reached the operating region or the device has low-power mode set via MMD control register bit 1.120.12.

Values: false; the device is completely powered (default).
true; the device has not been completely powered.

pulse_too_long

Indicates that the receiver has detected successive transitions spaced too far apart for a valid DME page. Transitions separated by more than 20 ns shall cause this indication to be true. Valid Manchester violation delimiters shall not cause this indication to be true.

Values: false; excessively long pulses have not been detected.
true; excessively long pulses have been detected.

pulse_too_short

Indicates that the receiver has detected successive transitions spaced too closely for a valid DME page. Transitions separated by less than 1.6 ns shall cause this indication to be true. Valid Manchester transitions shall not cause this indication to be true.

Values: false; excessively short pulses have not been detected.
true; excessively short pulses have been detected.

rx_link_code_word[48:1]

A 48-bit array that contains the data bits to be received from a DME page.
For each element within the array:

Values: zero; data bit is a logical zero.
one; data bit is a logical one.

rx_nonce[4:0]

A 5-bit array that contains the transmitted nonce received from the DME page that caused ability_match=true.
For each element within the array:

Values: zero; data bit is a logical zero.
one; data bit is a logical one.

single_link_ready

Status indicating that an_receive_idle = true and only one the of the following indications is being

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

received:

1) link_status_[1GKX] = OK
2) link_status_[2.5GKX] = OK
3) link_status_[5GKR] = OK
4) link_status_[10GKX4] = OK
5) link_status_[10GKR] = OK
6) link_status_[25GR] = OK
7) link_status_[40GKR4] = OK
8) link_status_[40GCR4] = OK
9) link_status_[50GR] = OK
10) link_status_[100GCR10] = OK
11) link_status_[100GKP4] = OK
12) link_status_[100GKR4] = OK
13) link_status_[100GCR4] = OK
14) link_status_[100GR2] = OK
15) link_status_[200GR4] = OK

Values: false; either zero or more than one of the above indications are true or an_receive_idle = false.
true; Exactly one of the above indications is true and an_receive_idle = true.

NOTE—This variable is set by this variable definition; it is not set explicitly in the state diagrams.

TD_AUTONEG

Controls the signal sent by Auto-Negotiation on the TD_AUTONEG circuit.

Values: disable; transmission of Auto-Negotiation signals is disabled
idle; Auto-Negotiation maintains the current signal level on the MDI.
mv_delimiter; Auto-Negotiation causes the transmission of the Manchester violation delimiter on the MDI.
transition; Auto-Negotiation causes a transition in the level on the MDI.

toggle_rx

Flag to keep track of the state of the link partner's Toggle bit.

Values: zero; link partner's Toggle bit equals logical zero.
one; link partner's Toggle bit equals logical one.

toggle_tx

Flag to keep track of the state of the local device's Toggle bit.

Values: zero; local device's Toggle bit equals logical zero.
one; local device's Toggle bit equals logical one.

transmit_ability

Controls the transmission of the link codeword containing tx_link_code_word[48:1].

Values: false; any transmission of tx_link_code_word[48:1] is halted (default).
true; the transmit state diagram begins sending tx_link_code_word[48:1].

transmit_ack

Controls the setting of the Acknowledge bit in the tx_link_code_word[48:1] to be transmitted.

Values: false; sets the Acknowledge bit in the transmitted tx_link_code_word[48:1] to a logical zero (default).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

true; sets the Acknowledge bit in the transmitted tx_link_code_word[48:1] to a logical one.

transmit_disable

Controls the transmission of tx_link_code_word[48:1].

Values: false; tx_link_code_word[48:1] transmission is allowed (default).
true; tx_link_code_word[48:1] transmission is halted.

transmit_mv_done

Status indicating that the transmission of the Manchester violation delimiter has been completed.

Values: false; transmission of the Manchester violation is in progress.
true; transmission of the Manchester violation has been completed.

tx_link_code_word[49:1]

A 49-bit array that contains the data bits to be transmitted in an DME page.
tx_link_code_word[48:1] contains the Auto-Negotiation page to be transmitted.
tx_link_code_word[49] contains the pseudo-random bit. This array may be loaded from mr_adv_ability or mr_np_tx.
For each element within the array:

Values: zero; data bit is logical zero.
one; data bit is logical one.

73.10.2 State diagram timers

All timers operate in the manner described in 14.2.3.2.

autoneg_wait_timer

Timer for the amount of time to wait before evaluating the number of link integrity test functions with link_status=OK asserted. The autoneg_wait_timer shall expire 25 ms to 50 ms from the assertion of link_status=OK from the PCS.

break_link_timer

Timer for the amount of time to wait in order to assure that the link partner enters a Link Fail state. The timer shall expire 60 ms to 75 ms after being started.

clock_detect_min_timer

Timer for the minimum time between detection of differential Manchester clock transitions. The clock_detect_min_timer shall expire 4.8 ns to 6.2 ns after being started or restarted.

clock_detect_max_timer

Timer for the maximum time between detection of differential Manchester clock transitions. The clock_detect_max_timer shall expire 6.6 ns to 8.0 ns after being started or restarted.

data_detect_max_timer

Timer for the maximum time between a clock transition and the following data transition. This timer is used in conjunction with the data_detect_min_timer to detect whether the data bit between two clock transitions is a logical zero or a logical one. The data_detect_max_timer shall expire 3.4 ns to 4.8 ns from the last clock transition.

data_detect_min_timer

Timer for the minimum time between a clock transition and the following data transition. This timer is used in conjunction with the data_detect_max_timer to detect whether the data bit between two clock transitions is a logical zero or a logical one. The data_detect_min_timer shall expire 1.6 ns 3.0 ns from the last clock transition.

interval_timer

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Timer for the separation of a transmitted clock pulse from a data bit. The interval_timer shall expire 3.2 ns ± 0.01% from each clock pulse and data bit.

link_fail_inhibit_timer

Timer for qualifying a link_status=FAIL indication or a link_status=OK indication when a specific technology link is first being established. A link will only be considered "failed" if the link_fail_inhibit_timer has expired and the link has still not gone into the link_status=OK state. The link_fail_inhibit_timer shall expire within the timer values given in Table 73–7 after entering the AN LINK GOOD CHECK state.

NOTE—The link_fail_inhibit_timer expiration value has to be greater than the time required for the link partner to complete Auto-Negotiation after the local device has completed Auto-Negotiation plus the time required for the specific technology to enter the link_status=OK state.

page_test_max_timer

Timer for the maximum time between detection of Manchester violation delimiters. This timer is used in conjunction with the page_test_min_timer to detect whether the link partner is transmitting DME pages. The page_test_max_timer shall expire 350 ns to 375 ns after being started or restarted.

page_test_min_timer

Timer for the minimum time between detection of Manchester violation delimiters. This timer is used in conjunction with the page_test_max_timer to detect whether the link partner is transmitting DME pages. The page_test_min_timer shall expire 305 ns 330 ns after being started or restarted.

Table 73–7—Timer min/max value summary

Parameter	Min	Value and tolerance	Max	Units
autoneg_wait_timer	25		50	ms
break_link_timer	60		75	ms
clock_detect_min_timer	4.8		6.2	ns
clock_detect_max_timer	6.6		8.0	ns
data_detect_min_timer	1.6		3.0	ns
data_detect_max_timer	3.4		4.8	ns
interval_timer		3.2 ± 0.01%		ns
link_fail_inhibit_timer (when the link is 50GBASE-KR, 50GBASE-CR, 100GBASE-KR2, 100GBASE-CR2, 200GBASE-KR4 or 200GBASE-CR4)	3.1		3.2	s
link_fail_inhibit_timer (when the link is 10GBASE-KR, 25GBASE-KR, 25GBASE-KR-S, 25GBASE-CR, 25GBASE-CR-S, 40GBASE-KR4, 40GBASE-CR4, 100GBASE-KR4, 100GBASE-KP4, 100GBASE-CR4, or 100GBASE-CR10)	500		510	ms
link_fail_inhibit_timer (when the link is 1000BASE-KX, 2.5GBASE-KX, 5GBASE-KR, or 10GBASE-KX4)	40		50	ms
page_test_min_timer	305		330	ns
page_test_max_timer	350		375	ns

73.10.3 State diagram counters

remaining_ack_cnt

A counter that may take on integer values from 0 to 8. The number of additional link codewords with the Acknowledge Bit set to logical one to be sent to ensure that the link partner receives the acknowledgment.

Values: not_done; positive integers between 0 and 5 inclusive.
done; positive integers 6 to 8 inclusive (default).
init; counter is reset to zero.

rx_bit_cnt

A counter that may take on integer values from 0 to 49. This counter is used to keep a count of data bits received from a DME page and to ensure that when erroneous extra transitions are received, the first 48 bits are kept while the rest are ignored. When this variable reaches 49, enough data bits have been received. This counter does not increment beyond 49 and does not return to 0 until it is reinitialized.

Values: not_done; 0 to 48 inclusive.
done; 49
init; counter is reset to zero.

tx_bit_cnt

A counter that may take on integer values from 1 to 50. This counter is used to keep a count of data bits sent within a DME page. When this variable reaches 50, all data bits have been sent.

Values: not_done; 1 to 49 inclusive.
done; 50.
init; counter is initialized to 1.

73.11 Protocol implementation conformance statement (PICS) proforma for Clause 73, Auto-Negotiation for backplane and copper cable assembly[136]

73.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 73, Auto-Negotiation for backplane and copper cable assembly, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

73.11.2 Identification

73.11.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

73.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 73, Auto-Negotiation for backplane and copper cable assembly
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[136]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

74. Forward error correction (FEC) sublayer for BASE-R PHYs

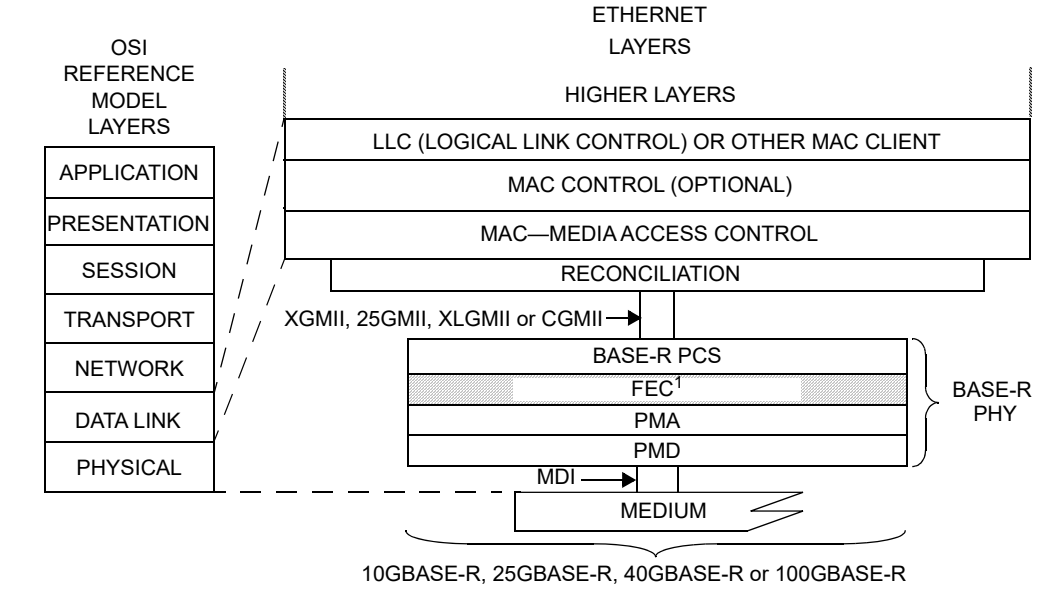
74.1 Overview

This clause specifies a forward error correction (FEC) sublayer for 10GBASE-R and other BASE-R PHYs. The FEC sublayer can be placed in between the PCS and PMA sublayers of the 10GBASE-R and other BASE-R Physical Layer implementations as shown in Figure 74–2, Figure 74–3, Figure 74–4, and Figure 74–5. For a PHY with a multi-lane BASE-R PCS, the FEC sublayer is instantiated for each PCS lane and operates autonomously on a per PCS lane basis. The FEC provides coding gain to increase the link budget and BER performance.

The 10GBASE-KR and 40GBASE-KR4 PHYs described in Clause 72 and Clause 84 optionally use the FEC sublayer to increase the performance on a broader set of backplane channels than are defined in Clause 69. The FEC sublayer provides additional margin to account for variations in manufacturing and environmental conditions.

The 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, and 25GBASE-KR-S PHYs described in Clause 110 and Clause 111 are required to implement the FEC sublayer and may use it with links with a BER of 10^{-8} or better.

The 40GBASE-CR4 and 100GBASE-CR10 PHYs described in Clause 85 optionally use the FEC sublayer to improve the BER performance beyond 10^{-12}.



74.2 Objectives

NOTE—The contents of this subclause have been deleted.

74.3 Relationship to other sublayers

Figure 74–1 depicts the relationships among the BASE-R FEC (shown shaded), the MAC and Reconciliation Sublayers, the BASE-R PCS, PMA and PMD, the ISO/IEC 8802-2 LLC, and the ISO/IEC Open System Interconnection (OSI) reference model.

25GMII = 25 GIGABIT MEDIA INDEPENDENT INTERFACE
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XGMII = 10 Gb/s MEDIA INDEPENDENT INTERFACE
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

NOTE 1—OPTIONAL OR CONDITIONAL BASED ON PHY TYPE

Figure 74–1—BASE-R FEC relationship to ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

74.4 Inter-sublayer interfaces

An FEC service interface is provided to allow the FEC sublayer to transfer information to and from the PCS. An abstract service model is used to define the operation of this interface. For 10GBASE-R, the FEC service interface directly maps to the PMA service interface of the PCS defined in Clause 49 and the lower FEC sublayer interface maps to the service interface provided by the serial PMA sublayer defined in Clause 51. For 25GBASE-R, the FEC service interface is an instance of the inter-sublayer service interface defined in 105.4, as is the PMA service interface defined in 109.2. For 40GBASE-R and 100GBASE-R, the FEC service interface is an instance of the inter-sublayer service interface defined in 80.3 as is the PMA service interface defined in 83.2.

For 25GBASE-R the FEC service interface can either connect to the PCS as illustrated in Figure 74–1 or the PMA as illustrated in Figure 109–3 where the FEC and PCS are in separate devices connected by 25GAUI.

For 40GBASE-R and 100GBASE-R the FEC service interface can either connect to the PCS as illustrated in Figure 74–1 or the PMA as illustrated in Figure 83–2 where the FEC and PCS are in separate devices connected by XLAUI/CAUI-n.

This standard defines these interfaces in terms of bits, octets, data-group, data units, and signals; however, implementers may choose other data-path widths and other control mechanisms for implementation convenience, provided that the implementation adheres to the logical model of the service interface.

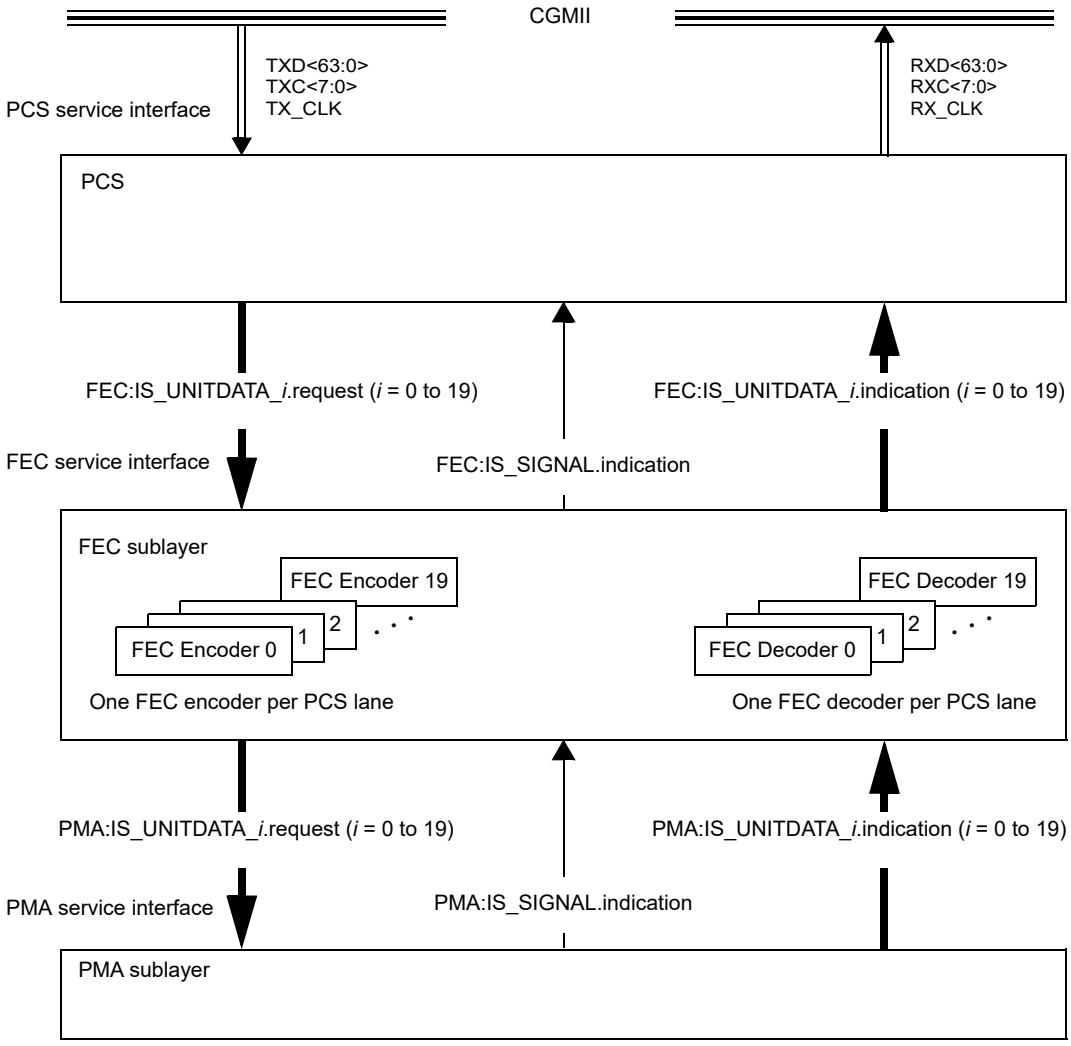

Figure 74–5—Functional block diagram for 100GBASE-R PHY

74.5 FEC service interface

The FEC service interface is provided to allow the PCS to transfer information to and from the FEC. The FEC service interface is equivalent to the PMA service interface for 10GBASE-R and an instance of the inter-sublayer service interface defined in 105.4 for 25GBASE-R, and 80.3 for 40GBASE-R and 100GBASE-R. These services are defined in an abstract manner and do not imply any particular implementation. The FEC service interface supports exchange of data units between PCS entities on either side of a link using request and indication primitives. Data units are mapped into FEC blocks by the FEC and passed to the PMA, and vice versa.

The service primitives are defined differently for 10GBASE-R, for 25GBASE-R, and for 40GBASE-R and 100GBASE-R.

Optional physical instantiations of the PMA service interface have been defined (see Clause 51, Annex 109A, Annex 109B, Annex 83A, Annex 83B, Annex 83D, and Annex 83E). There is XSBI

(10 Gigabit Sixteen-Bit Interface) for 10GBASE-R, 25GAUI for 25GBASE-R, XLAUI for 40GBASE-R and CAUI-n for 100GBASE-R. These physical instantiations, with a PMA if required, may also be used for the FEC service interface.

74.5.1 10GBASE-R service primitives

The following primitives are defined within the FEC service interface:

a) FEC_UNITDATA.request(tx_data-group<15:0>)
b) FEC_UNITDATA.indication(rx_data-group<15:0>)
c) FEC_SIGNAL.indication(SIGNAL_OK)
d) FEC_TX_MODE.request(tx_mode)
e) FEC_RX_MODE.request(rx_mode)
f) FEC_ENERGY.indication(energy_detect)
g) FEC_LPI_ACTIVE.request(rx_lpi_active)

Items d), e), f), and g) are only required for the optional EEE capability.

The FEC service interface directly maps to the PMA service interface of the 10GBASE-R PCS defined in Clause 49. The FEC_UNITDATA.request maps to the PMA_UNITDATA.request primitive, the FEC_UNITDATA.indication maps to the PMA_UNITDATA.indication primitive, and the FEC_SIGNAL.indication maps to the PMA_SIGNAL.indication primitive of the 10GBASE-R PCS.

If the optional Energy-Efficient Ethernet (EEE) capability is supported (see Clause 78) then the interface with the PMA sublayer (or FEC sublayer) includes rx_mode and tx_mode to control power states in lower sublayers and energy_detect that indicates whether the PMD sublayer has detected a signal at the receiver.

74.5.1.1 FEC_UNITDATA.request

This primitive defines the transfer of data in the form of constant-width data units from the PCS to the FEC. The data supplied via FEC_UNITDATA.request is mapped by the FEC Transmit process into the payload capacity of the outgoing FEC block stream.

74.5.1.1.1 Semantics of the service primitive

FEC_UNITDATA.request(tx_data-group<15:0>)

The data conveyed by FEC_UNITDATA.request is a 16-bit vector representing a single data unit that has been prepared for transmission by the 10GBASE-R PCS Transmit process.

74.5.1.1.2 When generated

The 10GBASE-R PCS sends tx_data-group<15:0> to the FEC at a nominal rate of 644.53125 MHz, corresponding to the 10GBASE-R signaling rate of 10.3125 GBd.

74.5.1.1.3 Effect of receipt

Upon receipt of this primitive, the FEC Transmit process maps the data conveyed by the tx_data unit<15:0> parameter into the payload of the transmitted FEC block stream, adds FEC overhead as required, scrambles the data, and transfers the result to the PMA via the PMA_UNITDATA.request primitives.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

74.5.1.2 FEC_UNITDATA.indication

This primitive defines the transfer of received data in the form of constant-width data units from the FEC to the PCS. FEC_UNITDATA.indication is generated by the FEC Receive process in response to FEC block data received from the PMA.

74.5.1.2.1 Semantics of the service primitive

FEC_UNITDATA.indication(rx_data-group<15:0>)

The rx_data-group<15:0> parameter is a 16-bit vector that represents the data unit transferred by the FEC to the 10GBASE-R PCS.

74.5.1.2.2 When generated

The FEC sends one rx_data-group<15:0> to the 10GBASE-R PCS for each 16 bits received from the PMA sublayer. The nominal rate of generation of the FEC_UNITDATA.indication primitive is 644.53125 Mtransfers/s.

74.5.1.2.3 Effect of receipt

The effect of receipt of this primitive by the FEC client is unspecified by the FEC sublayer.

74.5.1.3 FEC_SIGNAL.indication

This primitive is sent by the FEC to the PCS to indicate the status of the Receive process. FEC_SIGNAL.indication is generated by the FEC Receive process in order to propagate the detection of severe error conditions (e.g., no valid signal being received from the PMA sublayer) to the PCS.

74.5.1.3.1 Semantics of the service primitive

FEC_SIGNAL.indication(SIGNAL_OK)

The SIGNAL_OK parameter can take one of two values: OK or FAIL. A value of OK denotes that the FEC Receive process is successfully delineating valid payload information from the incoming data stream received from the PMA sublayer indicated by the fec_signal_ok variable equal to true, and this payload information is being presented to the PCS via the FEC_UNITDATA.indication primitive. A value of FAIL denotes that errors have been detected by the Receive process indicated by the fec_signal_ok variable equal to false, that prevent valid data from being presented to the PCS, in this case the FEC_UNITDATA.indication primitive and its associated rx_data-group<15:0> parameter are meaningless.

74.5.1.3.2 When generated

The FEC generates the FEC_SIGNAL.indication primitive to the 10GBASE-R PCS whenever there is a change in the value of the SIGNAL_OK parameter and FEC block synchronization is achieved.

74.5.1.3.3 Effect of receipt

The effect of receipt of this primitive by the FEC client is unspecified by the FEC sublayer.

74.5.1.4 FEC_ENERGY.indication (optional)

FEC_ENERGY.indication(energy_detect)

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

A Boolean variable that reflects the value of the energy detection primitive PMA_ENERGY.indication.

74.5.1.4.1 Effect of receipt

The effect of receipt of this primitive by the FEC client is unspecified by the FEC sublayer.

74.5.1.5 FEC_LPI_ACTIVE.request (optional)

FEC_LPI_ACTIVE.request(rx_lpi_active)

The rx_lpi_active parameter is a Boolean variable sent from the PCS that is set to TRUE when LPI mode is active at the receiver and set to FALSE otherwise.

74.5.1.5.1 When generated

The generation of this primitive by the FEC client is unspecified by the FEC sublayer.

74.5.1.5.2 Effect of receipt

When rx_lpi_active is TRUE, rapid block lock as specified in 74.7.4.8 will be used to quickly determine the start of the FEC block during EEE REFRESH or WAKE. When rx_lpi_active is FALSE, rapid block lock will not be used.

74.5.1.6 FEC_RX_MODE.request (optional)

FEC_RX_MODE.request(rx_mode)

The rx_mode parameter is a variable sent from the PCS. It is set to QUIET while the receiver is in the RX_QUIET state and is set to DATA otherwise.

74.5.1.6.1 When generated

The generation of this primitive by the FEC client is unspecified by the FEC sublayer.

74.5.1.6.2 Effect of receipt

When rx_mode is QUIET, the FEC decoder logic may deactivate functional blocks to conserve energy. When rx_mode is DATA, the FEC decoder logic operates normally. The value rx_mode is passed to the client layer through PMA_RX_MODE(rx_mode).request.

74.5.1.7 FEC_TX_MODE.request (optional)

FEC_TX_MODE.request(tx_mode)

The tx_mode parameter is a variable sent from the PCS. It is set to QUIET while the transmitter is in the TX_QUIET state, it is set to ALERT while the transmitter is in the TX_ALERT state and is set to DATA otherwise.

74.5.1.7.1 When generated

The generation of this primitive by the FEC client is unspecified by the FEC sublayer.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

74.5.1.7.2 Effect of receipt

When tx_mode is QUIET or ALERT, the FEC encoder logic may deactivate functional blocks to conserve energy. When tx_mode is DATA, the FEC encoder logic operates normally. The value tx_mode is passed to the client layer through PMA_TX_MODE(tx_mode).request.

74.5.2 25GBASE-R service primitives

The FEC service interface for 25GBASE-R is an instance of the inter-sublayer service interface defined in 105.4. The FEC service interface primitives are summarized as follows:

a) FEC:IS_UNITDATA.request
b) FEC:IS_UNITDATA.indication
c) FEC:IS_SIGNAL.indication
d) FEC:IS_TX_MODE.request(tx_mode)
e) FEC:IS_RX_MODE.request(rx_mode)
f) FEC:IS_RX_TX_MODE.indication(rx_tx_mode)
g) FEC:IS_LPI_ACTIVE.request(rx_lpi_active)
h) FEC:IS_ENERGY.indication(energy_detect)

Items d), e), f), g), and h) are only required for the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode.

The 25GBASE-R PCS (or PMA) continuously sends bit streams to the FEC via the tx_bit parameter of the FEC:IS_UNITDATA.request at a nominal signaling rate of 25.78125 GBd.

The FEC continuously sends bit streams to the 25GBASE-R PCS (or PMA) via the rx_bit parameter of the FEC:IS_UNITDATA.indication at a nominal signaling rate of 25.78125 GBd.

The SIGNAL_OK parameter of the FEC:IS_SIGNAL.indication primitive can take one of two values: OK or FAIL. A value of OK denotes that the FEC Receive process is successfully delineating valid payload information from the incoming data stream received from the PMA sublayer indicated by the fec_signal_ok variable equal to true, and this payload information is being presented to the PCS (or PMA) via the FEC:IS_UNITDATA.indication primitive. A value of FAIL denotes that errors have been detected by the Receive process indicated by the fec_signal_ok variable equal to false that prevent valid data from being presented to the PCS, in this case the rx_bit parameter of the FEC:IS_UNITDATA.indication primitive is undefined.

FEC:IS_TX_MODE.request is sourced from the PCS and passed through the FEC to the PMA sublayer. The tx_mode parameter can take the values QUIET, ALERT, or DATA. When tx_mode is QUIET or ALERT, the FEC encoder logic may deactivate functional blocks to conserve energy. When tx_mode is DATA, the FEC encoder logic operates normally.

FEC:IS_RX_MODE.request is sourced from the PCS and passed through the FEC to the PMA sublayer. The rx_mode parameter can take the values QUIET or DATA. When rx_mode is QUIET, the FEC decoder logic may deactivate functional blocks to conserve energy. When rx_mode is DATA, the FEC decoder logic operates normally.

FEC:IS_RX_TX_MODE.indication communicates the rx_tx_mode parameter to a PMA client layer if present. This parameter indicates the value of tx_mode that the PMA sublayer has inferred from the received signal. Without EEE deep sleep capability, the primitive is never generated and the sublayer behaves as if rx_tx_mode = DATA. The parameter rx_tx_mode is assigned one of the following values: DATA, QUIET, or ALERT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The rx_lpi_active parameter in FEC:IS_LPI_ACTIVE.request is a Boolean variable sent from the PCS that is set to TRUE when LPI mode is active at the receiver and set to FALSE otherwise. When TRUE, rx_lpi_active causes rapid FEC block lock as specified in 74.7.4.8 to be used to quickly determine the start of the FEC block during EEE REFRESH or WAKE.

The energy_detect parameter in FEC:IS_ENERGY.indication is a Boolean variable that indicates to the PCS that energy has been detected at the PMD. This signal is passed up through the FEC from the PMA sublayer to the PCS. It has no effect on FEC operation.

74.5.3 40GBASE-R and 100GBASE-R service primitives

The FEC service interface for 40GBASE-R and 100GBASE-R is an instance of the inter-sublayer service interface defined in 80.3. The FEC service interface primitives are summarized as follows:

a) FEC:IS_UNITDATA_*i*.request
b) FEC:IS_UNITDATA_*i*.indication
c) FEC:IS_SIGNAL.indication
d) FEC_TX_MODE.request(tx_mode)
e) FEC_RX_MODE.request(rx_mode)
f) FEC_RX_TX_MODE.indication(rx_tx_mode)
g) FEC_LPI_ACTIVE.request(rx_lpi_active)
h) FEC_ENERGY.indication(energy_detect)

Items d), e), f), g), and h) are only required for the optional EEE capability.

The 40GBASE-R FEC has four parallel bit streams, hence $i = 0$ to 3 for 40GBASE-R and the 100GBASE-R FEC has twenty parallel bit streams, hence $i = 0$ to 19 for 100GBASE-R.

The PCS (or PMA) continuously sends four or twenty parallel bit streams to the FEC, one per PCS lane, each at a nominal signaling rate of 10.3125 GBd for 40GBASE-R and 5.15625 GBd for 100GBASE-R.

This FEC:IS_SIGNAL.indication primitive is sent by the FEC to the PCS (or PMA) to indicate the status of the Receive process. FEC:IS_SIGNAL.indication is generated by the FEC Receive process in order to propagate the detection of severe error conditions (e.g., no valid signal being received from the PMA sublayer) to the PCS (or PMA).

The SIGNAL_OK parameter in FEC:IS_SIGNAL.indication can take one of two values: OK or FAIL. A value of OK denotes that the FEC Receive process is successfully delineating valid payload information from all of the incoming data streams received from the PMA sublayer indicated by the fec_signal_ok variable equal to true, for all data streams, and this payload information is being presented to the PCS (or PMA) via the FEC:IS_UNITDATA_*i*.indication primitive. A value of FAIL denotes that errors have been detected by the Receive process indicated by the fec_signal_ok variable equal to false, in any of the data streams, that prevent valid data from being presented to the PCS (or PMA), in this case the FEC:IS_UNITDATA_*i*.indication primitive is a direct pass through of the PMA:IS_UNITDATA_*i*.indication from the PMA.

If the optional Energy-Efficient Ethernet (EEE) capability is supported (see Clause 78) then the interface with the PMA sublayer (or FEC sublayer) includes rx_mode and tx_mode to control power states in lower sublayers and energy_detect that indicates whether the PMD sublayer has detected a signal at the receiver. If the optional EEE deep sleep capability is supported, rx_tx_mode is passed through the FEC but is not used by it.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The tx_mode parameter in FEC_TX_MODE.request is sent from the PCS. It is set to QUIET while the transmitter is in the TX_QUIET state, it is set to ALERT while the transmitter is in the TX_ALERT state, and is set to DATA otherwise.

The rx_mode parameter in FEC_RX_MODE.request is sent from the PCS. It is set to QUIET while the receiver is in the RX_QUIET state and is set to DATA otherwise.

The FEC_RX_TX_MODE.indication primitive communicates the rx_tx_mode parameter. This parameter indicates the value of tx_mode that the PMA sublayer has inferred from the received signal. Without EEE deep sleep capability, the primitive is never generated and the sublayer behaves as if rx_tx_mode=DATA. The parameter rx_tx_mode is assigned one of the following values: DATA, QUIET, or ALERT.

The rx_lpi_active parameter in FEC_LPI_ACTIVE.request is a Boolean variable sent from the PCS that is set to TRUE when LPI mode is active at the receiver and set to FALSE otherwise.

The energy_detect parameter in FEC_ENERGY.indication is a Boolean variable that indicates to the PCS that energy has been detected at the PMD.

74.6 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices.

The maximum delay contributed by the 10GBASE-R FEC (sum of transmit and receive delays at one end of the link) shall be no more than 6144 BT (or 12 pause_quanta or 614.4 ns).

The maximum delay contributed by the 25GBASE-R FEC (sum of transmit and receive delays at one end of the link) shall be no more than 6144 BT (or 12 pause quanta or 245.76 ns).

The maximum delay contributed by the 40GBASE-R FEC (sum of transmit and receive delays at one end of the link) shall be no more than 24576 BT (or 48 pause_quanta or 614.4 ns).

The maximum delay contributed by the 100GBASE-R FEC (sum of transmit and receive delays at one end of the link) shall be no more than 122880 BT (or 240 pause_quanta or 1228.8 ns).

A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 80.4 and its references.

74.7 FEC principle of operation

On transmission, the FEC sublayer receives data from the PCS, transcodes 64B/66B words, performs the FEC coding/framing, scrambles and sends the data to the PMA. On reception, the FEC sublayer receives data from the PMA, performs descrambling, achieves FEC framing synchronization, decodes the FEC code, correcting data where necessary and possible, re-codes 64B/66B words, and sends the data to the PCS.

74.7.1 FEC code

The FEC code used is a shortened cyclic code (2112, 2080) for error checking and forward error correction. The FEC block length is 2112 bits. The code encodes 2080 bits of payload (or information symbols) and adds 32 bits of overhead (or parity symbols). The code is systematic—meaning that the information symbols

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

are not disturbed in anyway in the encoder and the parity symbols are added separately to the end of each block.

The (2112,2080) code is constructed by shortening the cyclic code (42987, 42955). The shortened cyclic code (2112,2080) is guaranteed to correct an error burst of up to 11 bits per block. It is a systematic code that is well suited for correction of the burst errors typical in a backplane channel (see 69.3) resulting from error propagation in the receive equalizer.

See Blahut [B16] and Lin and Costello [B52] for additional information on cyclic codes and shortened cyclic codes for correcting burst errors.

74.7.2 FEC block format

The format of the FEC block is shown in Table 74–1. The length of the FEC block is 2112 bits. Each FEC block contains 32 rows of 65 bits each; 64 bits of payload and 1 bit transcoding overhead (T bits). At the end of each block there is 32-bit overhead or parity check bits. Transmission is from left to right within each row and from top to bottom between rows. The payload bits carry the information symbols from the PCS layer.

Table 74–1—FEC block format

T_0	64 bit payload Word 0	T_1	64 bit payload Word 1	T_2	64 bit payload Word 2	T_3	64 bit payload Word 3
T_4	64 bit payload Word 4	T_5	64 bit payload Word 5	T_6	64 bit payload Word 6	T_7	64 bit payload Word 7
T_8	64 bit payload Word 8	T_9	64 bit payload Word 9	T_{10}	64 bit payload Word 10	T_{11}	64 bit payload Word 11
T_{12}	64 bit payload Word 12	T_{13}	64 bit payload Word 13	T_{14}	64 bit payload Word 14	T_{15}	64 bit payload Word 15
T_{16}	64 bit payload Word 16	T_{17}	64 bit payload Word 17	T_{18}	64 bit payload Word 18	T_{19}	64 bit payload Word 19
T_{20}	64 bit payload Word 20	T_{21}	64 bit payload Word 21	T_{22}	64 bit payload Word 22	T_{23}	64 bit payload Word 23
T_{24}	64 bit payload Word 24	T_{25}	64 bit payload Word 25	T_{26}	64 bit payload Word 26	T_{27}	64 bit payload Word 27
T_{28}	64 bit payload Word 28	T_{29}	64 bit payload Word 29	T_{30}	64 bit payload Word 30	T_{31}	64 bit payload Word 31
32 parity bits							

Total FEC block length = (32 × 65) + 32 = 2112 bits

74.7.3 Composition of the FEC block

The FEC sublayer does not decrease the symbol rate of the PCS, nor does it increase the signaling rate of the PMD sublayer. Instead, the FEC sublayer compresses the sync bits from the 64B/66B encoded data provided by the PCS to accommodate the addition of 32 parity check bits for every block of 2080 bits.

The BASE-R 64B/66B PCS maps 64 bits of scrambled payload and 2 bits of unscrambled sync header into 66-bit encoded blocks. The 2-bit sync header allows establishment of 64B/66B block boundaries by the PCS sync process. The sync header is 01 for data blocks and 10 for control blocks; the sync header is the only

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

position in the PCS block that always contain a transition and this feature of the code is used to establish 64B/66B block boundaries.

The FEC sublayer compresses the 2 bits of the sync header to 1 transcode bit. The transcode bit carries the state of BASE-R sync bits for the associated payload. This is achieved by eliminating the first bit in 64B/66B block, which is also the first sync bit, and preserving the second bit. The value of the second bit defines the value of the removed first bit uniquely, since it is always an inversion of the first bit. The transcode bits are further scrambled (as explained in 74.7.4.2) to ensure DC balance.

The 32 sequential 64B/66B blocks are transcoded in this fashion, and then 32 bits of FEC parity are computed for them. The 32 transcoded words and the 32 FEC parity bits constitute an FEC block.

The error detection property of the FEC cyclic code is used to establish block synchronization at FEC block boundaries at the receiver. If decoding passes successfully, the FEC decoder produces 32 65-bit words, the first decoded bit of each word being the transcode bit. Then the first sync bit in 64B/66B code is constructed by the inversion of the transcode bit, and the value of the second sync bit is equal to the transcode bit.

74.7.4 Functions within FEC sublayer

The FEC sublayer comprises four functional blocks; FEC Encoder, Reverse Gearbox function, FEC decoder, and FEC block synchronization.

74.7.4.1 Reverse gearbox function

74.7.4.1.1 Reverse gearbox function for 10GBASE-R

The reverse gearbox function adapts between the 66-bit width of the 64B/66B blocks and the 16-bit width of the PCS interface. It receives the 16-bit stream from the PCS interface and converts them back to 66-bit encoded blocks for the FEC Encoder to process. The reverse gearbox function operates in the same manner as the block sync function defined in 49.2.9.

The reverse gearbox function receives data via 16-bit FEC_UNITDATA.request primitive. It will form a bit stream from the primitives by concatenating requests with the bits of each primitive in order to form tx_data-group<0> to tx_data-group<15> (see Figure 49–6). It obtains lock to the 66-bit blocks in the bit stream using the sync headers and outputs 66-bit blocks. Lock is obtained as specified in the block lock state diagram shown in Figure 49–14.

NOTE—Figure 49–6 shows rx_data-group<0> to rx_data-group<15> because the processing depicted in that figure is in the receive function. However, the reverse gearbox in this subclause is part of the transmit function, so it uses tx_-data-group<0> to tx_data-group<15>.

The reverse gearbox functionality is necessary only when the optional PMA compatibility interface named XSBI is implemented between the PCS and FEC functions, since that interface passes data via a 16-bit wide path. When the XSBI is not implemented, the internal data-path width between the PCS and FEC is an implementation choice. Depending on the path width, the reverse gearbox function may not be necessary.

74.7.4.1.2 Reverse gearbox function for 25GBASE-R, 40GBASE-R, and 100GBASE-R

The reverse gearbox function adapts between the 66-bit width of the 64B/66B blocks and the 1-bit wide lane of the 25GBASE-R, 40GBASE-R, or 100GBASE-R PCS to FEC interface (or PMA to FEC interface). It receives the 1-bit stream from the FEC service interface (or PMA service interface) and converts it back to 66-bit encoded blocks for the FEC Encoder to process. The reverse gearbox function, if implemented, shall operate in the same manner as the lane block sync function defined in 82.2.12.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The reverse gearbox function receives data via the 25GBASE-R FEC:IS_UNITDATA.request primitive (or via the PMA:IS_UNITDATA.request primitive) or via the 40GBASE-R and 100GBASE-R FEC:IS_UNITDATA_*i*.request primitive see 74.5.3 (or via the PMA:IS_UNITDATA_*i*.request primitive). It obtains lock to the 66-bit blocks in each bit stream using the sync headers and outputs 66-bit blocks to the FEC encoder function (see 74.7.4.4). PCS lane lock is obtained as specified in the PCS lane lock state diagram shown in Figure 82–12.

The internal data-path width from the PCS or PMA is an implementation choice. Depending on the path width, the reverse gearbox function may not be necessary.

74.7.4.2 FEC Encoder

The FEC encoder connects to the reverse gearbox function using the 66-bit wide data path. The FEC encoder takes 32 × 64B/66B blocks from the reverse gearbox and encodes it into a single FEC block of 2112 bits. The FEC Encoder compresses the two sync bits to one transcode bit as explained in 74.7.3. The transcode bit is then XOR'ed with data bit 8 of the corresponding 64B/66B block. The resulting 32 × 65b = 2080 bits with the block format as shown in Table 74–1 are fed to the (2112,2080) encoder, which produces 32 parity-check bits. The parity check bits are appended to the end of the FEC block. The FEC block is scrambled using the PN-2112 pseudo-noise sequence as described in 74.7.4.4.1. and sent to the PMA interface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

74.7.4.3 FEC transmission bit ordering

The format of the FEC block and the transmit bit ordering is shown in Figure 74–6.

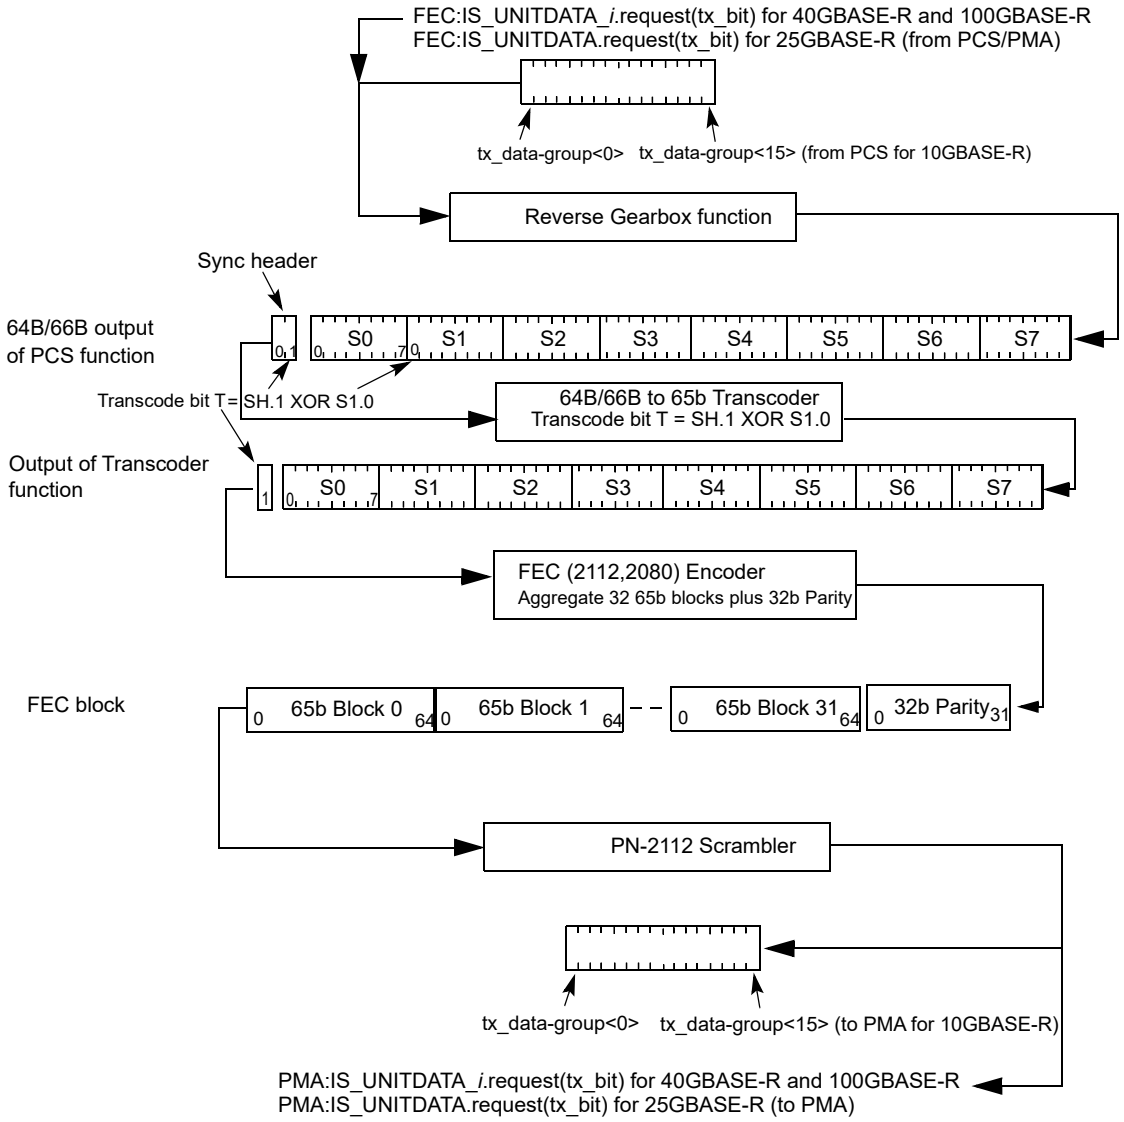

Figure 74–6—FEC Transmit bit ordering

74.7.4.4 FEC (2112,2080) encoder

The block diagram of the FEC Encoder is illustrated in Figure 74–7. The 32 × 65-bit payload blocks are encoded by the (2112, 2080) code. This code is a shortened cyclic code that can be encoded by generator polynomial $g(x)$. The FEC block is scrambled using the PN-2112 pseudo-noise sequence as described in 74.7.4.4.1.

The generator polynomial $g(x)$ for the (2112, 2080) parity-check bits is defined as given in Equation (74–1).

$$g(x) = x^{32} + x^{23} + x^{21} + x^{11} + x^2 + 1 \quad (74–1)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the polynomial representation of information bits is $m(x)$, the codeword $c(x)$ can be calculated in systematic form as given in Equation (74–2) and Equation (74–3).

$$p(x) = x^{32}m(x) \bmod g(x) \tag{74–2}$$

$$c(x) = p(x) + x^{32}m(x) \tag{74–3}$$

(Multiplication by x^{32} is performed using shifts).

Systematic form of the codeword means that first 2080 bits of the codeword are information bits that can be extracted directly.

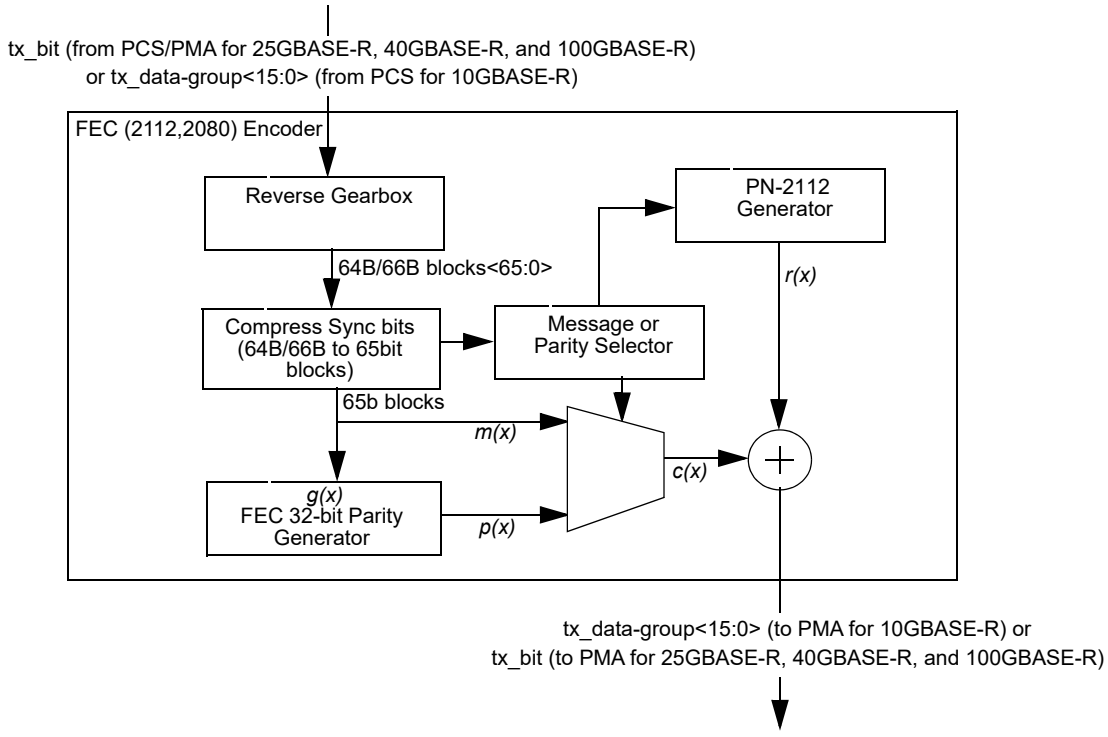

Figure 74–7—FEC (2112,2080) encoding

74.7.4.4.1 PN-2112 pseudo-noise sequence generator

PN-2112 is a pseudo-noise sequence of length 2112 generated by the polynomial *r(x)*, which is equal to the scrambler polynomial defined in 49.2.6 with initial state S57 = 1, Si–1 = Si XOR 1 or simply the binary sequence of 101010…. . Before each FEC block processing (encoding or decoding) the PN-2112 generator is initialized with this state. The PN-2112 generator shall produce the same result as the implementation shown in Figure 74–8. This implements the PN-2112 generator polynomial given in Equation (74–4).

$$r(x) = 1 + x^{39} + x^{58} \tag{74–4}$$

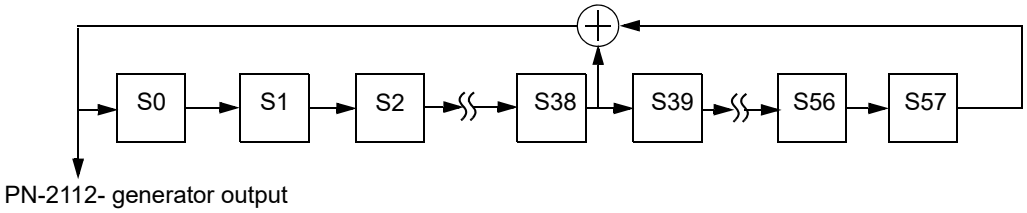

Figure 74–8—PN-2112 generator

Scrambling with the PN-2112 sequence at the FEC codeword boundary is necessary for establishing FEC block synchronization (to ensure that any shifted input bit sequence is not equal to another FEC codeword) and to ensure DC balance.

74.7.4.5 FEC decoder

The FEC decoder establishes FEC block synchronization based on repeated decoding of the received sequence. Decoding and error correction is performed after FEC synchronization is achieved. There is an option for the FEC decoder to indicate any decoding errors to the upper layer.

The FEC decoder recovers and extracts the information bits using the parity-check data. In case of successful decoding the decoder restores the sync bits in each of the 64B/66B blocks sent to the PCS function, by first performing an XOR operation of the received transcode bit with the associated data bit 8 and then generating the two sync bits.

When the decoder for 10GBASE-R or 25GBASE-R is configured to indicate decoding error, the decoder indicates error to the PCS by means of setting both sync bits to the value 11 in the 1st, 9th, 17th, 25th, and 32nd of the 32 decoded 64B/66B blocks from the corresponding errored FEC block, thus forcing the PCS sublayer to consider this block as invalid.

When the decoder for 40GBASE-R or 100GBASE-R is configured to indicate decoding error, the decoder needs to mark errors in more of the 64B/66B blocks to ensure that detected errors are signaled to the MAC for every frame containing an error. The FEC sublayers for 40GBASE-R and 100GBASE-R set both sync bits to the value 11 in all thirty-two 64B/66B blocks to indicate error to the PCS.

The FEC Synchronization process continuously monitors PMA_SIGNAL.indication(SIGNAL_OK) or PMA:IS_SIGNAL.indication(SIGNAL_OK). When SIGNAL_OK indicates OK, the FEC Synchronization process accepts data units via the PMA_UNITDATA.indication primitive or the PMA:IS_UNITDATA_*i*.indication primitives. It attains block synchronization based on the decoding of FEC blocks and conveys received 64B/66B blocks to the PCS Receive process. The FEC Synchronization process sets the sync_status flag to the PCS function to indicate whether the FEC has obtained synchronization.

74.7.4.5.1 FEC (2112,2080) decoding

The FEC decoding function block diagram is shown in Figure 74–9. The decoder processes the 16-bit rx_data-group stream received from the PMA sublayer and descrambles the data using the PN-2112 pseudo-noise sequence as described in 74.7.4.4.1.

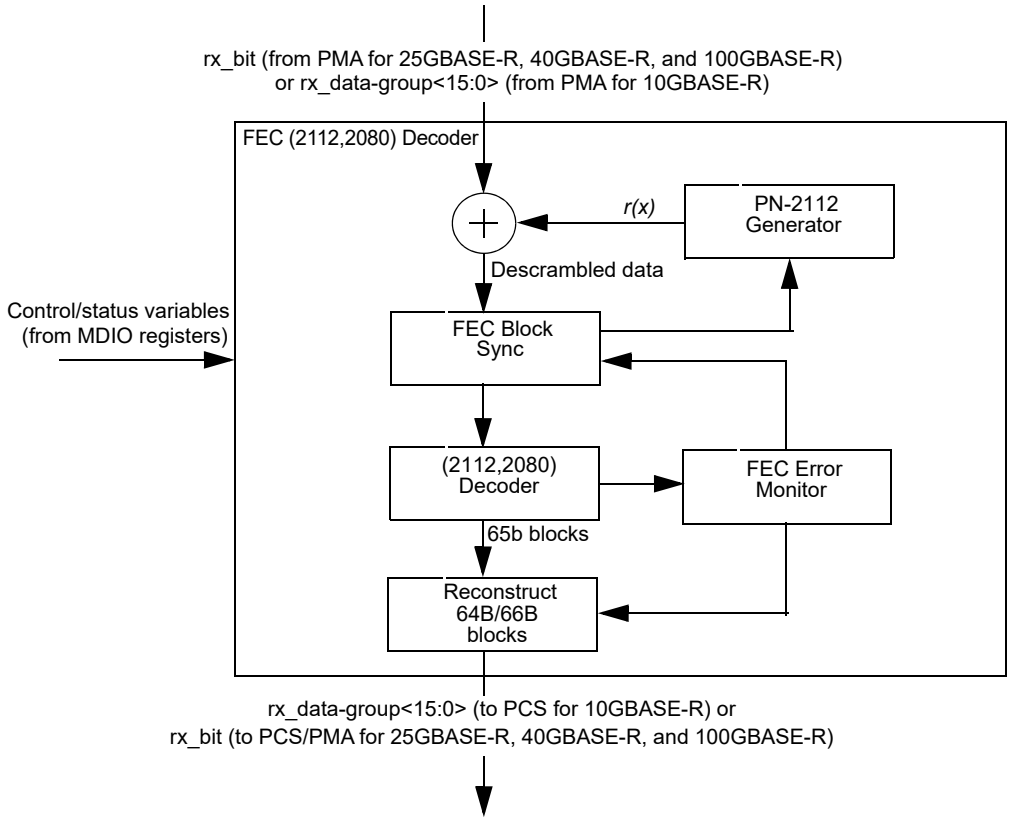

Figure 74–9—FEC (2112,2080) decoding

The synchronization of the 2112 bit FEC block is established using FEC decoding as described in 74.7.4.7. Each of the 32 65-bit data words is extracted from the recovered FEC block and the 2-bit sync is reconstructed for the 64B/66B codes from the transcode bit as shown in Figure 74–10. The FEC decoder provides an option to indicate decoding errors in the reconstructed sync bits. The sync bits {SH.0, SH.1} take the value as described in the following:

a) If decoding is successful (by either the parity match or the FEC block is correctable) and the descrambled received transcode bit (T) is 1 then the sync bits take a value of {SH.0,SH.1} = 01 or if the descrambled received transcode bit (T) is 0 then the sync bits take a value of {SH.0,SH.1} = 10.
b) If the variable FEC_Enable_Error_to_PCS is set to 1 to indicate error to PCS layer and the received FEC block has uncorrectable errors then the sync bits for the 1st, 9th, 17th, 25th, and 32nd of the 32 decoded 64B/66B blocks take a value of {SH.0,SH.1} = 11 for the 10GBASE-R and 25GBASE-R PHY. For the 40GBASE-R and 100GBASE-R PHYs, sync bits in all thirty-two 64B/66B decoded 64B/66B blocks take a value of {SH.0,SH.1} = 11. The sync bits for all other 64B/66B blocks take a value as described in item a) above.
c) If the variable FEC_Enable_Error_to_PCS is set to 0 and the received FEC block has uncorrectable errors then the sync bits take a value as described in item a) above.

This information corresponds to one complete (2112,2080) FEC block that is equal to 32 64B/66B code blocks.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The FEC code (2112, 2080) and its performance is specified in 74.7.1. The FEC (2112,2080) decoder implementations shall be able to correct up to a minimum of 11-bit burst errors per FEC block.

74.7.4.6 FEC receive bit ordering

The format of the FEC block and the receive bit ordering is shown in Figure 74–10.

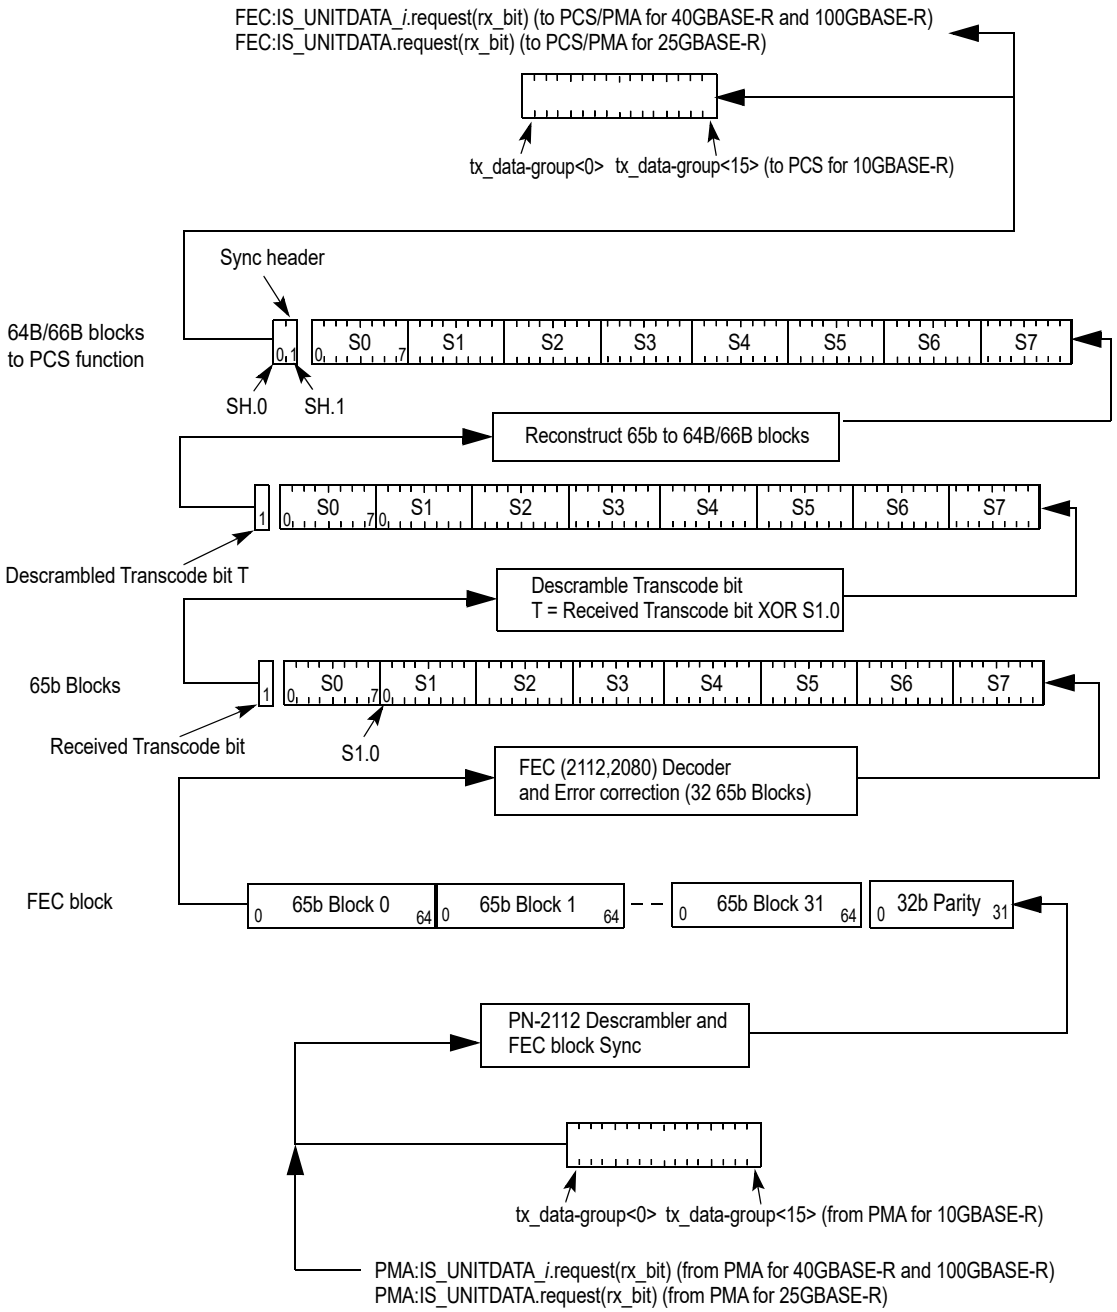

Figure 74–10—FEC Receive bit ordering

74.7.4.7 FEC block synchronization

The receive synchronization of FEC blocks is illustrated by FEC Lock state diagram in Figure 74–11.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Receive FEC block synchronization is achieved using conventional n/m serial locking techniques as described as follows:

a) Test a potential candidate block start position
   1) Descramble block using PN-2112 Generator per 74.7.4.4.1
   2) Evaluate parity for the potential block
      i) If the parity does not match (i.e., the received parity does not match the computed parity), shift candidate start by one bit position and try again.
b) Validate potential block start position has good parity for "n" consecutive blocks
   1) If any of them fail shift candidate start one bit position and start again
   2) If "n" consecutive blocks are received with good parity, report Block Sync
c) Block Sync is established.
d) If "m" consecutive blocks are received with bad parity, drop Block Sync and restart again at item a).

The procedure is repeated at most 2111 times for all bits positions in the 2112 codeword. The values for m and n are as follows: m = 8 and n = 4.

74.7.4.8 FEC rapid block synchronization for EEE (optional)

If the optional EEE capability is supported then during the wake and refresh states the FEC decoder receives one of the two types of deterministic blocks to achieve rapid block synchronization. During these states the reverse gearbox of the remote FEC encoder is receiving unscrambled data from the PCS sublayer via 16-bit FEC_UNITDATA.request primitive.

The Clause 49 and Clause 107 PCS sublayers encode /I/ during the wake state and /LI/ during the refresh state, which produces the two types of deterministic FEC blocks.

If the optional EEE deep sleep capability is supported, then a Clause 82 PCS sublayer also encodes /I/ during the wake state and /LI/ during the refresh state, but in addition inserts Rapid Alignment Markers into each of the PCS Lanes (see 82.2.9). This causes the two types of deterministic FEC blocks to have a number of 65-bit words within the deterministic FEC block replaced with Rapid Alignment Markers, thus not matching the two deterministic patterns as shown in Table 74A–5 and Table 74A–6. The locations of the Rapid Alignment Markers within the Rapid FEC block are consistent for a given entry into the wake or refresh states, but the locations can vary for subsequent entries. This modification to the two deterministic patterns needs to be taken into account by the Rapid FEC Lock implementation.

When rx_lpi_active is TRUE and rx_mode (or rx_tx_mode if appropriate) transitions to DATA, start a hold-off timer whose duration is greater than or equal to 13.7 μs and enable the FEC Rapid block lock mechanism, which attempts to determine the FEC start of block location based on the deterministic pattern. When the rapid block lock is locked, the determined start of block location is used as the FEC lock state diagram candidate start of block location until the rapid block lock loses lock. Assuming the rapid block lock determined the correct start of block location, the FEC lock state diagram achieves lock without requiring subsequent slips. The rapid block lock mechanism is implementation dependent and outside the scope of this standard. The FEC sublayer shall hold off asserting SIGNAL_OK until one of the following two events occurs:

1) Two 65b payload blocks after the transition from deterministic FEC block to normal scrambled FEC block
2) Expiration of the hold-off timer

74.8 FEC MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control, status, abilities/capabilities, error indication information for and about the PHY. If MDIO is implemented, it shall map MDIO variables to FEC variables as shown in Table 74–1.

Table 74–1—MDIO/FEC variable mapping

MDIO variable	PMA/PMD register name	Register/ bit number	FEC variable
BASE-R FEC ability	BASE-R FEC ability register	1.170.0	FEC_ability
BASE-R FEC Error Indication ability	BASE-R FEC ability register	1.170.1	FEC_Error_Indication_ability
FEC Enable	BASE-R FEC control register	1.171.0	FEC_Enable
FEC Enable Error Indication	BASE-R FEC control register	1.171.1	FEC_Enable_Error_to_PCS
FEC corrected blocks	Single-lane PHY BASE-R FEC corrected blocks counter register	1.172, 1.173	FEC_corrected_blocks_counter
FEC uncorrected blocks	Single-lane PHY BASE-R FEC uncorrected blocks counter register	1.174, 1.175	FEC_uncorrected_blocks_counter
FEC corrected blocks, lanes 0 through 19	BASE-R FEC corrected blocks counter register, lanes 0 through 19	1.300 through 1.339	FEC_corrected_blocks_counter_*i*
FEC uncorrected blocks, lanes 0 through 19	BASE-R FEC uncorrected blocks counter register, lanes 0 through 19	1.700 through 1.739	FEC_uncorrected_blocks_counter_*i*

74.8.1 FEC capability

Since the FEC is an optional sublayer, the FEC ability is indicated by the variable FEC_ability for each of the BASE-R PHY types. An MDIO interface or an equivalent management interface shall be provided to access the variable FEC_ability for the BASE-R PHY type. The FEC_ability variable bit is set to a one to indicate that the PHY supports FEC sublayer, it defaults to zero otherwise.

The FEC_ability variable for the BASE-R PHY is mapped to register bit 1.170.0 (refer to 45.2.1.107.1).

The FEC capability between the link partners can be negotiated using the Clause 73 Auto-Negotiation as defined in 73.6.5.

74.8.2 FEC Enable

The FEC sublayer shall have capability to enable or disable the FEC function. An MDIO interface or an equivalent management interface shall be provided to access the variable FEC_Enable for the BASE-R PHY (refer to 45.2.1.108 register bit 1.171.0). When FEC_Enable variable bit is set to a one, this enables the FEC for the BASE-R PHY. When the variable is set to zero, the FEC is disabled in the BASE-R PHY. This

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

variable shall be set to zero upon execution of PHY reset. When the FEC function is disabled, the PHY shall have a mechanism to bypass the FEC Encode and Decode functions so as not to cause additional latency associated with encoding or decoding functions.

74.8.3 FEC Enable Error Indication

The FEC sublayer may have the option to enable the BASE-R FEC decoder to indicate decoding errors to the upper layers (PCS) through the sync bits for the BASE-R PHY as defined in 74.7.4.5, if this ability is supported. An MDIO interface or an equivalent management interface shall be provided to access the variable FEC_Enable_Error_to_PCS. When the variable is set to one, this enables indication of decoding errors through the sync bits to the PCS layer. When set to zero, the error indication function is disabled.

74.8.3.1 FEC Error Indication ability

The FEC error indication ability shall be indicated by the variable FEC_Error_Indication_ability. The variable is set to one to indicate that the BASE-R FEC has the ability to indicate decoding errors to the PCS layer. The variable is set to zero if this ability is not supported by the BASE-R FEC. An MDIO interface or an equivalent management interface shall be provided to access the variable FEC_Error_Indication_ability.

74.8.4 FEC Error monitoring capability

The following counters apply to FEC sublayer management and error monitoring. If an MDIO interface is provided (see Clause 45), it is accessed via that interface. If not, it is recommended that an equivalent access be provided. These counters are reset to zero upon read or upon reset of the FEC sublayer. When a counter reaches all ones, it stops counting. The counters' purpose is to help monitor the quality of the link.

These counters shall be disabled if FEC_LPI_ACTIVE.request(rx_lpi_active) is TRUE.

74.8.4.1 FEC_corrected_blocks_counter

A corrected block is an FEC block that has invalid parity, and has been corrected by the FEC decoder.

FEC_corrected_blocks_counter (for single-lane PHYs) or FEC_corrected_blocks_counter_*i* (for multi-PCS-lane PHYs, where $i = 0$ to 3 for 40 Gb/s and $i = 0$ to 19 for 100 Gb/s,) count once for each corrected FEC block processed when FEC_SIGNAL.indication or FEC:IS_SIGNAL.indication is OK. These are 32-bit counters. These variables are accessed through a management interface that may be mapped to the registers defined in 45.2.1.109 (1.172, 1.173) for single-lane PHYs and 45.2.1.131 (1.300 to 1.339) for multi-lane PHYs.

74.8.4.2 FEC_uncorrected_blocks_counter

An uncorrected block is an FEC block that has invalid parity, and has not been corrected by the FEC decoder.

FEC_uncorrected_blocks_counter (for single-lane PHYs) or FEC_uncorrected_blocks_counter_*i* (for multi-PCS-lane PHYs, where $i = 0$ to 3 for 40 Gb/s and $i = 0$ to 19 for 100 Gb/s,) count once for each uncorrected FEC block processed when FEC_SIGNAL.indication or FEC:IS_SIGNAL.indication is OK. These are 32-bit counters. These variables are accessed through a management interface that may be mapped to the registers defined in 45.2.1.110 (1.174, 1.175) for single-lane PHYs and 45.2.1.149 (1.700 to 1.739) for multi-lane PHYs.

74.9 BASE-R PHY test-pattern mode

The 10GBASE-R PCS and the 25GBASE-R PCS provide test-pattern functionality and the PCS transmit channel and receive channel can each operate in normal mode or test-pattern mode (see 49.2.2). When the 10GBASE-R or 25GBASE-R PHY is configured for test-pattern mode, the FEC function may be disabled by setting the FEC Enable variable to zero, so the test-pattern from the PCS can be sent to the PMA service interface, bypassing the FEC Encode and Decode functions.

The Clause 82 and Clause 107 PCS can also operate in test pattern mode (see 82.2.11 and 107.2.3); however, the scrambled idle test pattern does not require bypassing FEC encode and decode.

74.10 Detailed functions and state diagrams

74.10.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

74.10.2 State variables

74.10.2.1 Constants

m
: Positive integer constant set to value 8.

n
: Positive integer constant set to value 4.

74.10.2.2 Variables

fec_block_lock
: Boolean variable that is set to true when receiver acquires FEC block delineation.

fec_block<2111:0>
: Vector containing 2112 bits of a new FEC block accumulated from the candidate start position received from the PMA and descrambled using PN-2112 as specified in 74.7.4.4.1. For each FEC block processing, the PN-2112 is returned to the initial state as described in 74.7.4.4.1.

fec_signal_ok
: Boolean variable that is set based on the most recently received value of PMA_UNITDATA.indication(SIGNAL_OK) or PMA:IS_SIGNAL.indication(SIGNAL_OK) and fec_block_lock. It is set to true if the fec_block_lock value is true and PMA_UNITDATA.indication(SIGNAL_OK) or PMA:IS_SIGNAL.indication(SIGNAL_OK) value was OK and set to false otherwise. The value is sent to the PCS layer through the primitive FEC_SIGNAL.indication or FEC:IS_SIGNAL.indication as specified in 74.5.1.3 or 74.5.3.

parity_good
: Boolean indication that is set to true if the FEC_PARITY_CHECK function returns “match” and false if the FEC_PARITY_CHECK function returns “no_match”.

parity_invalid
: Boolean indication that is set to true if the FEC_PARITY_CHECK function returns “no_match” and false if the FEC_PARITY_CHECK function returns “match”.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

reset
: Boolean variable that controls the resetting of the FEC sublayer. It is true whenever a reset is necessary, including when reset is initiated from the MDIO during power on.

signal_ok
: Boolean variable that is set based on the most recently received value of PMA_UNITDATA.indication(SIGNAL_OK). It is true if the value was OK and false if the value was FAIL.

slip_done
: Boolean variable that is asserted true when the SLIP requested by the FEC Block Lock state diagram has been completed indicating that the next candidate block sync position can be tested.

test_fec_block
: Boolean variable that is set to true when a new FEC block is available for testing and false when TEST_FEC_BLOCK state is entered. A new FEC block is available for testing when the FEC Block Sync process has accumulated one FEC block from the candidate start position (fec_block<2111:0>) from the PMA to evaluate the parity of the next block.

74.10.2.3 Functions

FEC_PARITY_CHECK(fec_block<2111:0>)
: Computes parity based on the FEC generator polynomial *g(x)* on fec_block<2079:0> and compares it against the received 32-bit parity bits fec_block<2111:2080>. The FEC_PARIY_CHECK function returns “match” if the parity check matches, and returns “no_match” if the computed parity does not match the received parity.

SLIP
: Causes the next candidate FEC block sync position to be tested. The precise method for determining the next candidate block sync position is not specified and is implementation dependent. However, an implementation shall ensure that all possible bit positions are evaluated.

74.10.2.4 Counters

parity_good_cnt
: Count of the number of times the computed parity of received message bits matched the received parity.

parity_invalid_cnt
: Count of the number of times the computed parity of received message bits did not match the received parity.

74.10.3 State diagrams

The FEC sublayer shall implement the FEC Lock state diagram shown in Figure 74–11, including compliance with the associated state variables as specified in 74.10.2. The FEC Lock state diagram determines when the receiver has obtained FEC block lock on the received data stream.

74.11 Protocol implementation conformance statement (PICS) proforma for Clause 74, forward error correction (FEC) sublayer for BASE-R PHYs[137]

74.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.3, Clause 74 forward error correction (FEC) sublayer for BASE-R PHYs, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

74.11.2 Identification

74.11.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Names(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

74.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 74, forward error correction (FEC) sublayer for BASE-R PHYs
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022)	
Date of Statement	

[137] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

75. Physical Medium Dependent (PMD) sublayer and medium for passive optical networks, type 10GBASE–PR and 10/1GBASE–PRX

75.1 Overview

Clause 75 describes Physical Medium dependent (PMD) sublayer for Ethernet Passive Optical Networks operating at the line rate of 10.3125 GBd in either downstream or in both downstream and upstream directions.

75.1.1 Terminology and conventions

The following list contains references to terminology and conventions used in Clause 75:

Basic terminology and conventions, see 1.1 and 1.2.

Normative references, see 1.3.

Definitions, see 1.4

Abbreviations, see 1.5.

Informative references, see Annex A.

Introduction to 1000 Mb/s baseband networks, see Clause 34.

Introduction to 10 Gb/s baseband network, see Clause 44.

Introduction to Ethernet for subscriber access networks, see Clause 56.

EPONs operate over a point-to-multipoint (P2MP) topology, also called a tree or trunk-and-branch topology. The device connected at the root of the tree is called an Optical Line Terminal (OLT) and the devices connected as the leaves are referred to as Optical network Units (ONUs). The direction of transmission from the OLT to the ONUs is referred to as the *downstream* direction, while the direction of transmission from the ONUs to the OLT is referred to as the *upstream* direction.

75.1.2 Goals and objectives

The following are the PMD objectives fulfilled by Clause 75:

a) Support subscriber access networks using point-to-multipoint topologies on optical fiber.
b) Provide Physical Layer specifications:
   1) PHY for PON, 10 Gb/s downstream / 1 Gb/s upstream, on a single SMF
   2) PHY for PON, 10 Gb/s downstream / 10 Gb/s upstream, on a single SMF
c) PHY(s) to have a BER better than or equal to 10^{-12} at the PHY service interface.
d) Define up to four optical power budgets that support split ratios of at least 1:16, 1:32, and 1:64, and distances of at least 10 km and 20 km.

75.1.3 Power budget classes

To support the above-stated objectives, Clause 75 defines the following four power budget classes:

— *Low power budget class* supports P2MP media channel insertion loss of ≤ 20 dB e.g., a PON with the split ratio of at least 1:16 and the distance of at least 10 km.
— *Medium power budget class* supports P2MP media channel insertion loss of ≤ 24 dB e.g., a PON with the split ratio of at least 1:16 and the distance of at least 20 km or a PON with the split ratio of at least 1:32 and the distance of at least 10 km.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— *High power budget class* supports P2MP media channel insertion loss of ≤ 29 dB e.g., a PON with the split ratio of at least 1:32 and the distance of at least 20 km.
— *Extended power budget class* supports P2MP media channel insertion loss of ≤ 33 dB e.g., a PON with the split ratio of at least 1:64 and the distance of at least 20 km.

75.1.4 Power budgets

Each power budget class is represented by PRX-type power budget and PR-type power budget as follows:

— PRX–type power budget describes asymmetric-rate PHY for PON operating at 10 Gb/s downstream and 1 Gb/s upstream over a single SMF [see objective b 1) in 75.1.2].
— PR–type power budget describes symmetric-rate PHY for PON operating at 10 Gb/s downstream and 10 Gb/s upstream over a single SMF [see objective b 2) in 75.1.2].

Each power budget is further identified with a numeric representation of its class, where a value of 10 represents low power budget, a value of 20 represents medium power budget, a value of 30 represents high power budget, and a value of 40 represents extended power budget. Thus, the following power budgets are defined in Clause 75:

— PRX10: asymmetric-rate, low power budget, compatible with PX10 power budget defined in Clause 60.
— PRX20: asymmetric-rate, medium power budget, compatible with PX20 power budget defined in Clause 60.
— PRX30: asymmetric-rate, high power budget, compatible with PX30 power budget defined in Clause 60.
— PRX40: asymmetric-rate, extended power budget, compatible with PX40 power budget defined in Clause 60.
— PR10: symmetric-rate, low power budget, compatible with PX10 power budget defined in Clause 60
— PR20: symmetric-rate, medium power budget, compatible with PX20 power budget defined in Clause 60
— PR30: symmetric-rate, high power budget, compatible with PX30 power budget defined in Clause 60.
— PR40: symmetric-rate, extended power budget, compatible with PX40 power budget defined in Clause 60.

Table 75–1 shows the primary attributes of all power budget types defined in Clause 75.

Table 75–1—Power budgets

Description	Low Power Budget		Medium Power Budget		High Power Budget		Extended Power Budget		Units
	PRX10	PR10	PRX20	PR20	PRX30	PR30	PRX40	PR40	
Number of fibers	1								–
Nominal downstream line rate	10.3125								GBd
Nominal upstream line rate	1.25	10.3125	1.25	10.3125	1.25	10.3125	1.25	10.3125	GBd
Nominal downstream wavelength	1577								nm
Downstream wavelength tolerance	–2, +3								nm
Nominal upstream wavelength	1310	1270	1310	1270	1310	1270	1310	1270	nm
Upstream wavelength tolerance	±50	±10	±50	±10	±50	±10	±20	±10	nm
Maximum reach[a]	≥10		≥20						km
Maximum channel insertion loss	20		24		29		33		dB
Minimum channel insertion loss	5		10		15		18		dB

[a]A compliant system may exceed the maximum reach designed for given power budget as long as optical power budget and other mandatory optical layer specifications are met.

75.1.5 Positioning of PMD sublayer within the IEEE 802.3 architecture

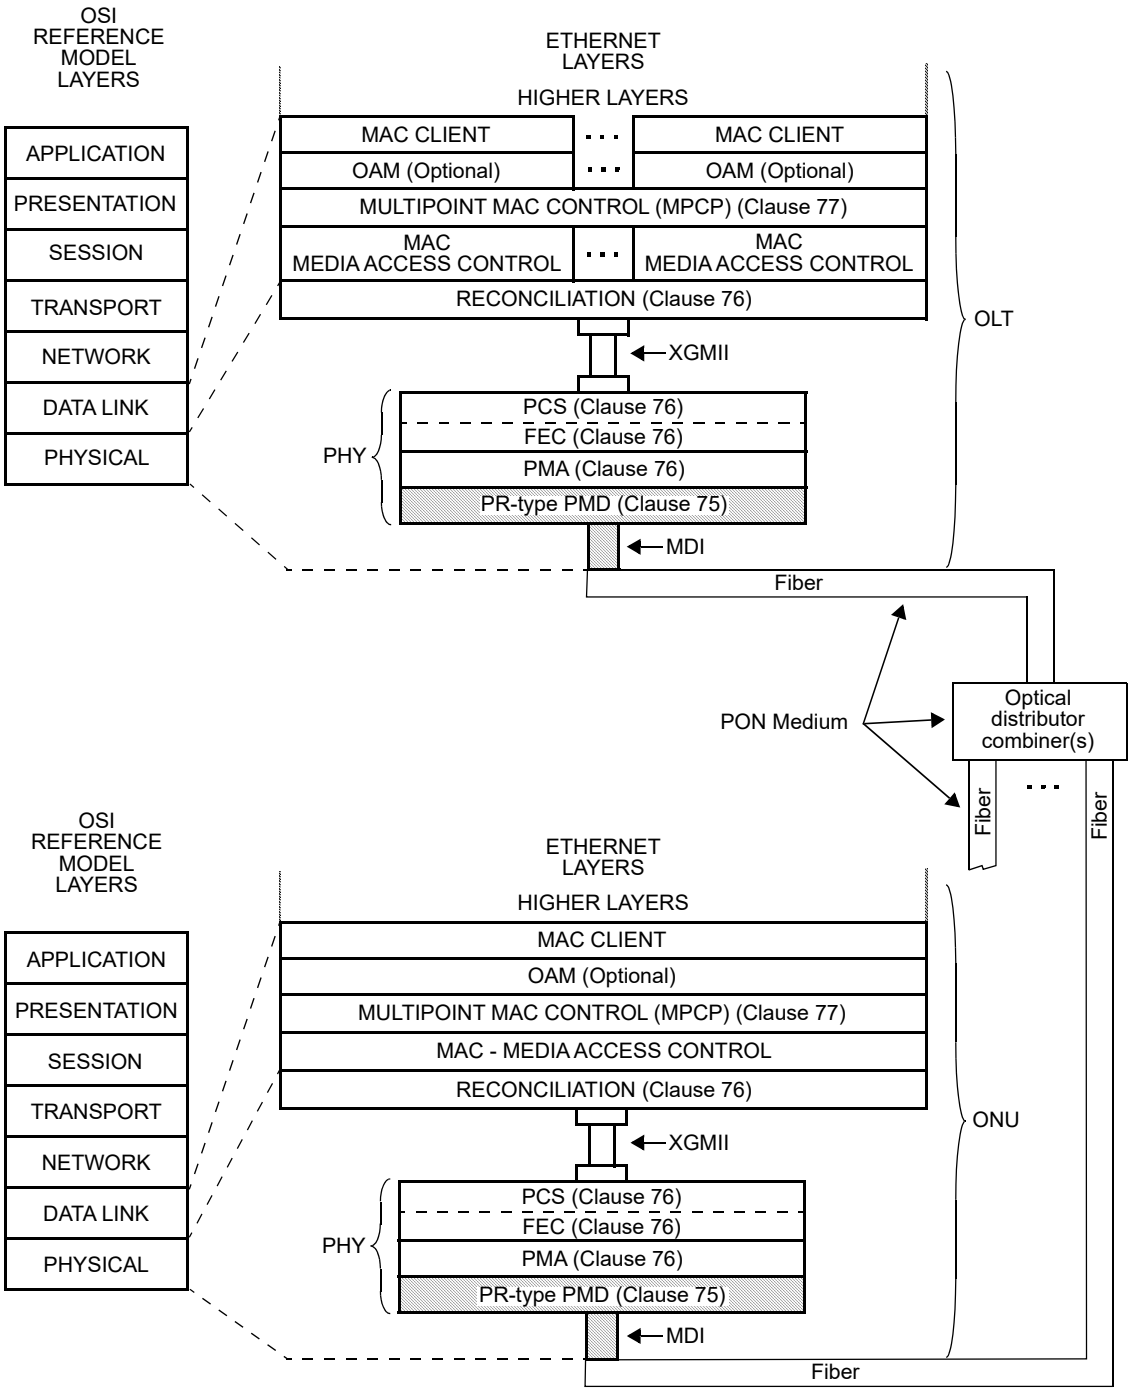

Figure 75–1 and Figure 75–2 depict the relationships of the symmetric-rate (10/10G–EPON) and asymmetric-rate (10/1G–EPON) PMD sublayer (shown hatched) with other sublayers and the ISO/IEC Open System Interconnection (OSI) reference model.

75.2 PMD types

Similarly to power budget classes, asymmetric-rate and symmetric-rate PMDs are identified by PRX and PR designations, respectively.

The characteristics of the P2MP topology result in significantly different ONU and OLT PMDs. For example, the OLT PMD operates in a continuous mode in the transmit direction (downstream), but uses a burst mode in the receive direction (upstream). On the other hand, the ONU PMD receives data in a continuous mode, but transmits in a burst mode. To differentiate OLT PMDs from ONU PMDs, the OLT

PMD name has a suffix “D” appended to it, where D stands for downstream–facing PMD, e.g., 10GBASE–PR–D1. ONU PMDs have suffix “U” for upstream–facing PMD, e.g., 10GBASE–PR–U1.

In the downstream direction, the signal transmitted by the D-type PMD is received by all U-type PMDs. In the upstream direction, the D-type PMD receives data bursts from each of the U-type PMDs.

Clause 75 defines several D-type and several U-type PMDs, that differ in their receive and/or transmit characteristics. Such PMDs are further distinguished by appending a digit after the suffix D or U, e.g., 10GBASE–PR–D1 or 10GBASE–PR–D2.

The following OLT PMDs (D-type) are defined in this subclause:

a) Asymmetric-rate D-type PMDs (collectively referred to as 10/1GBASE–PRX–D), transmitting at 10.3125 GBd continuous mode and receiving at 1.25 GBd burst mode:
   1) 10/1GBASE–PRX–D1
   2) 10/1GBASE–PRX–D2
   3) 10/1GBASE–PRX–D3
   4) 10/1GBASE–PRX–D4
b) Symmetric-rate D-type PMDs (collectively referred to as 10GBASE–PR–D), transmitting at 10.3125 GBd continuous mode and receiving at 10.3125 GBd burst mode:
   1) 10GBASE–PR–D1
   2) 10GBASE–PR–D2
   3) 10GBASE–PR–D3
   4) 10GBASE–PR–D4

The following ONU PMDs (U-type) are defined in this subclause:

c) Asymmetric-rate U-type PMDs (collectively referred to as 10/1GBASE–PRX–U), transmitting at 1.25 GBd burst mode and receiving at 10.3125 GBd continuous mode:
   1) 10/1GBASE–PRX–U1
   2) 10/1GBASE–PRX–U2
   3) 10/1GBASE–PRX–U3
   4) 10/1GBASE–PRX–U4
d) Symmetric-rate U-type PMDs (collectively referred to as 10GBASE–PR–U), transmitting at 10.3125 GBd burst mode and receiving at 10.3125 GBd continuous mode:
   1) 10GBASE–PR–U1
   2) 10GBASE–PR–U3
   3) 10GBASE-PR–U4

A specific power budget is achieved by combining an OLT PMD (D-type) with an ONU PMD (U-type) as shown in 75.2.1. Detailed PMD receive and transmit characteristics for D-type PMDs are given in 75.4 and characteristics for U-type PMDs are presented in 75.5. Every PMD has non-overlapping transmit and receive wavelength bands and operates over a single SMF (see 75B.2).

75.2.1 Mapping of PMDs to power budgets

The power budget is determined by the PMDs located at the ends of the physical media. This subclause describes how PMDs may be combined to achieve the power budgets listed in Table 75–1.

75.2.1.1 Asymmetric-rate, 10 Gb/s downstream and 1 Gb/s upstream power budgets (PRX type)

Table 75–2 illustrates recommended pairings of asymmetric-rate ONU PMDs with asymmetric-rate OLT PMDs to achieve the power budgets shown in Table 75–1.

Table 75–2—PMD – power budget mapping for asymmetric-rate PRX–type power budgets

		OLT PMDs			
		10/1GBASE–PRX–D1	**10/1GBASE–PRX–D2**	**10/1GBASE–PRX–D3**	**10/1GBASE–PRX–D4**
ONU PMDs	**10/1GBASE–PRX–U1**	PRX10	N/A	N/A	N/A
	10/1GBASE–PRX–U2	N/A	PRX20	N/A	N/A
	10/1GBASE–PRX–U3	N/A	N/A	PRX30	N/A
	10/1GBASE–PRX–U4	N/A	N/A	N/A	PRX40

75.2.1.2 Symmetric-rate, 10 Gb/s power budgets (PR type)

Table 75–3 illustrates recommended pairings of symmetric-rate ONU PMDs with symmetric-rate OLT PMDs to achieve the power budgets as shown in Table 75–1.

Table 75–3—PMD – power budget mapping for symmetric-rate PR–type power budgets

		OLT PMDs			
		10GBASE–PR–D1	**10GBASE–PR–D2**	**10GBASE–PR–D3**	**10GBASE–PR–D4**
ONU PMDs	**10GBASE–PR–U1**	PR10	PR20	N/A	N/A
	10GBASE–PR–U3	N/A	N/A	PR30	N/A
	10GBASE–PR–U4	N/A	N/A	N/A	PR40

75.3 PMD functional specifications

The 10GBASE–PR and 10/1GBASE–PRX type PMDs perform the transmit and receive functions that convey data between the PMD service interface and the MDI.

75.3.1 PMD service interface

The following specifies the services provided by Clause 75 PMDs. These PMD sublayer service interfaces are described in an abstract manner and do not imply any particular implementation.

The PMD Service Interface supports the exchange of a continuous stream of bits, representing either 64B/66B blocks (the transmit and receive paths in 10GBASE–PR PMDs, transmit path in 10/1GBASE–PRX–D PMDs) or 8B/10B blocks (transmit path in 10/1GBASE–PRX–U PMDs, receive path in 10/1GBASE–PRX–D PMDs), between the PMA and PMD entities. The PMD translates the serialized data

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

received from the compatible PMA to and from signals suitable for the specified medium. The following primitives are defined:

— PMD_UNITDATA.request
— PMD_UNITDATA.indication
— PMD_SIGNAL.request
— PMD_SIGNAL.indication

75.3.1.1 Delay constraints

The PMD shall introduce a transmit delay of not more than 4 time_quanta with the variability of no more than 0.5 time_quanta, and a receive delay of not more than 4 time_quanta with the variability of no more than 0.5 time_quanta. A description of the overall system delay constraints can be found in 76.1.2 and the definition for the time_quantum can be found in 77.2.2.1.

75.3.1.2 PMD_UNITDATA.request

This primitive defines the transfer of a serial data stream from the Clause 65 or Clause 76 PMA to the PMD.

The semantics of the service primitive are PMD_UNITDATA.request(tx_bit). The data conveyed by PMD_UNITDATA.request is a continuous stream of bits. The tx_bit parameter can take one of two values: ONE or ZERO. The Clause 76 PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal signaling speed of 10.3125 GBd in the case of 10/10G–EPON OLT, 10/10G–EPON ONU, and 10/1G–EPON OLT PMDs. The Clause 65 PMA continuously sends the appropriate stream of bits to the PMD for transmission on the medium, at a nominal signaling speed of 1.25 GBd in the case of 10/1G–EPON ONU PMDs. Upon the receipt of this primitive, the PMD converts the specified stream of bits into the appropriate signals at the MDI.

75.3.1.3 PMD_UNITDATA.indication

This primitive defines the transfer of data from the PMD to the Clause 65 or Clause 76 PMA.

The semantics of the service primitive are PMD_UNITDATA.indication(rx_bit). The data conveyed by PMD_UNITDATA.indication is a continuous stream of bits. The rx_bit parameter can take one of two values: ONE or ZERO. The PMD continuously sends a stream of bits to the Clause 76 PMA corresponding to the signals received from the MDI, at the nominal signaling speed of 10.3125 GBd in the case of 10/10G–EPON OLT, 10/10G–EPON ONU, and 10/1G–EPON ONU PMDs or to the Clause 65 PMA at the nominal signaling speed of 1.25 GBd in the case of 10/1G–EPON OLT PMDs.

75.3.1.4 PMD_SIGNAL.request

In the upstream direction, this primitive is generated by the Clause 76 PMA to turn on and off the transmitter according to the granted time. A signal for laser control is generated as described in 76.4.1.1 for the Clause 76 PCS.

The semantics of the service primitive are PMD_SIGNAL.request(tx_enable). The tx_enable parameter can take on one of two values: ENABLE or DISABLE, determining whether the PMD transmitter is on (enabled) or off (disabled). The Clause 76 PMA generates this primitive to indicate a change in the value of tx_enable. Upon the receipt of this primitive, the PMD turns the transmitter on or off as appropriate.

75.3.1.5 PMD_SIGNAL.indication

This primitive is generated by the PMD to indicate the status of the signal being received from the MDI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The semantics of the service primitive are PMD_SIGNAL.indication(SIGNAL_DETECT). The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL, indicating whether the PMD is detecting light at the receiver (OK) or not (FAIL). When SIGNAL_DETECT = FAIL, PMD_UNITDATA.indication(rx_bit) is undefined. The PMD generates this primitive to indicate a change in the value of SIGNAL_DETECT. If the MDIO interface is implemented, then PMD_global_signal_detect shall be continuously set to the value of SIGNAL_DETECT.

NOTE—SIGNAL_DETECT = OK does not guarantee that PMD_UNITDATA.indication(rx_bit) is known good. It is possible for a poor quality link to provide sufficient light for a SIGNAL_DETECT = OK indication and still not meet the specified bit error ratio. PMD_SIGNAL.indication(SIGNAL_DETECT) has different characteristics for upstream and downstream links, see 75.3.5.

75.3.2 PMD block diagram

The PMD sublayer is defined at the eight reference points shown in Figure 75–3 for 10GBASE–PR and 10/1GBASE–PRX PMDs.

For 10GBASE–PR and 10/1GBASE–PRX PMDs, test points TP1 through TP4 refer to the downstream channel, while test points TP5 through TP8 refer to the upstream channel. In the downstream channel, TP2 and TP3 are compliance points, while in the upstream channel TP6 and TP7 are compliance points. TP1, TP4, TP5, and TP8 are reference points for use by implementers. The optical transmit signal is defined at the output end of a patch cord (TP2 for the downstream channel and TP6 for the upstream channel), between 2 m and 5 m in length, of a fiber type consistent with the link type connected to the transmitter. Unless specified otherwise, all transmitter measurements and tests defined in 75.7 are made at TP2 or TP6, while tests defined in 60.9 are made at TP6. The optical receive signal is defined at the output of the fiber optic cabling (TP3 for the downstream channel and TP7 for the upstream channel) connected to the receiver. Unless specified otherwise, all receiver measurements and tests defined in 75.7 are made at TP3 or TP7.

The electrical specifications of the PMD service interface (TP1 and TP4 for the downstream channel and TP5 and TP8 for the upstream channel) are not system compliance points (these are not readily testable in a system implementation).

75.3.3 PMD transmit function

The PMD Transmit function shall convey the bits requested by the PMD service interface message PMD_UNITDATA.request(tx_bit) to the MDI according to the optical specifications in Clause 75.

In the upstream direction, the flow of bits is interrupted according to PMD_SIGNAL.request(tx_enable). This implies three optical levels, 1, 0, and dark, the latter corresponding to the transmitter being in the OFF state. The higher optical power level shall correspond to tx_bit = ONE.

75.3.4 PMD receive function

The PMD Receive function shall convey the bits received from the MDI according to the optical specifications in Clause 75 to the PMD service interface using the message PMD_UNITDATA.indication(rx_bit). The higher optical power level shall correspond to rx_bit = ONE.

75.3.5 PMD signal detect function

75.3.5.1 ONU PMD signal detect

The PMD Signal Detect function for the continuous mode downstream signal shall report to the PMD service interface, using the message PMD_SIGNAL.indication(SIGNAL_DETECT), which is signaled continuously. PMD_SIGNAL.indication is intended to be an indicator of the presence of the optical signal.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

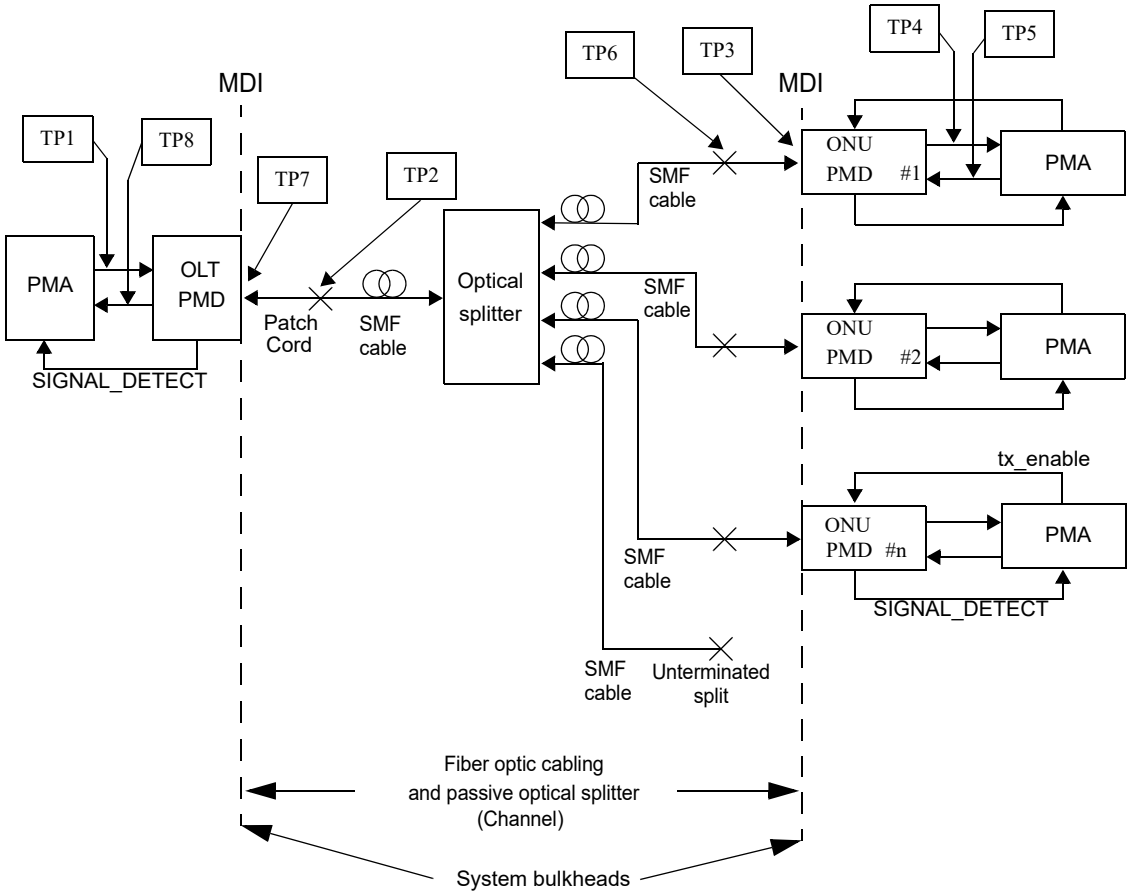

Figure 75–3—10GBASE–PR and 10/1GBASE–PRX block diagram

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 75–4 for 10GBASE–PR and 10/1GBASE–PRX type PMDs. The ONU PMD receiver is not required to verify whether a compliant 10GBASE–PR signal is being received.

75.3.5.2 OLT PMD signal detect

The response time for the PMD Signal Detect function for the burst mode upstream signal may be longer or shorter than a burst length; thus, it may not fulfill the traditional requirements placed on Signal Detect. PMD_SIGNAL.indication is intended to be an indicator of optical signal presence. The signal detect function in the OLT may be realized in the PMD or the Clause 76 PMA sublayer.

The value of the SIGNAL_DETECT parameter shall be generated according to the conditions defined in Table 75–4 for PMDs defined in Clause 75. The 10GBASE–PR–D PMD receiver is not required to verify whether a compliant 10GBASE–PR signal is being received. Similarly, the 10/1GBASE–PRX–D PMD receiver is not required to verify whether a compliant 1000BASE–PX signal is being received.

75.3.5.3 10GBASE–PR and 10/1GBASE–PRX Signal detect functions

The Signal Detect value definitions for Clause 75 PMDs are shown in Table 75–4.

Table 75–4—SIGNAL_DETECT value definitions for Clause 75 PMDs

PMD type	Receive conditions	SIGNAL_DETECT value
10GBASE–PR–D1, 10GBASE–PR–D2, 10GBASE–PR–D3, 10GBASE–PR–D4	Average input optical power ≤ Signal Detect Threshold (min) in Table 75–6 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 75–6 with a compliant 10GBASE–PR signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified
10GBASE–PR–U1, 10GBASE–PR–U3, 10GBASE–PR–U4 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2, 10/1GBASE–PRX–U3, 10/1GBASE–PRX–U4	Average input optical power ≤ Signal Detect Threshold (min) in Table 75–10 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 75–10 with a compliant 10GBASE–PR signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified
10/1GBASE–PRX–D1, 10/1GBASE–PRX–D2, 10/1GBASE–PRX–D3, 10/1GBASE–PRX–D4	Average input optical power ≤ Signal Detect Threshold (min) in Table 75–7 at the specified receiver wavelength	FAIL
	Average input optical power ≥ Receive sensitivity (max) in Table 75–7 with a compliant 1000BASE–PX signal input at the specified receiver wavelength	OK
	All other conditions	Unspecified

75.3.6 PMD transmit enable function for ONU

PMD_SIGNAL.request(tx_enable) is defined for all ONU PMDs specified in Clause 75. PMD_SIGNAL.request(tx_enable) is asserted prior to data transmission by the ONU PMDs.

75.4 PMD to MDI optical specifications for 10/10G–EPON and 10/1G–EPON OLT PMDs

This subclause details the PMD to MDI optical specifications for 10/10G–EPON and 10/1G–EPON OLT PMDs, as specified in 75.2. Specifically, 75.4.1 defines the OLT transmit parameters, while 75.4.2 defines the OLT receive parameters.

The operating ranges for PR and PRX power budget classes are defined in Table 75–1. A PR or PRX compliant transceiver operates over the media types listed in Table 75–14 according to the specifications described in 75.9. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant.

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

75.4.1 Transmitter optical specifications

The signaling speed, operating wavelength, side mode suppression ratio, average launch power, extinction ratio, return loss tolerance, OMA, eye, and Transmitter and Dispersion Penalty (TDP) for transmitters making part of the 10/10G–EPON and 10/1G–EPON OLT PMDs (as specified in 75.2) shall meet the specifications defined in Table 75–5 per measurement techniques described in 75.7. Their $RIN_{15}OMA$ should meet the value listed in Table 75–5 per measurement techniques described in 75.7.8. Note that there are only two groups of transmit parameters. The first group is shared by 10GBASE–PR–D1, 10/1GBASE–PRX–D1, 10GBASE–PR–D3, and 10/1GBASE–PRX–D3. The second group is shared by 10GBASE–PR–D2, 10GBASE–PR–D4, 10/1GBASE–PRX–D2, and 10/1GBASE-PRX-D4.

Average launch power (max)	5	9	dBm
Average launch power (min)[b]	2	5	dBm
Average launch power of OFF transmitter (max)	–39		dBm
Extinction ratio (min)	6		dB
$RIN_{15}OMA$ (max)	–128		dB/Hz
Launch OMA (min)[b]	3.91 (2.46)	6.91 (4.91)	dBm (mW)
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}[c]	{0.25, 0.4, 0.45, 0.25, 0.28, 0.4}		UI
Optical return loss tolerance (max)	15		dB
Transmitter reflectance (max)	–10		dB
Transmitter and dispersion penalty (max)	1.5		dB
Decision timing offset for transmitter and dispersion penalty	±0.05		UI

[a]Transmitter is a single longitudinal mode device. Chirp is allowed such that the total optical path penalty does not exceed that found in Table 75B–1 and Table 75B–2.
[b]Minimum average launch power and minimum launch OMA are valid for ER = 9 dB (see Figure 75–4 for details)
[c]As defined in Figure 75–6.

The relationship between OMA, extinction ratio, and average power is described in 58.7.6 and illustrated in Figure 75–4 for a compliant transmitter. Note that the OMA_{min} and AVP_{min} are calculated for ER = 9 dB, where AVP_{min} represents the Average launch power (min) as presented in Table 75–5. The transmitter specifications are further relaxed by allowing lower ER = 6 dB while maintaining the OMA_{min} and AVP_{min} constant. The shaded area indicates a compliant part.

75.4.2 Receiver optical specifications

The signaling speed, operating wavelength, overload, stressed sensitivity, reflectance, and signal detect for receivers forming part of the 10/10G–EPON and 10/1G–EPON OLT PMDs (as specified in 75.2) shall meet the specifications defined in Table 75–6 for 10/10G–EPON OLT PMDs and in Table 75–7 for 10/1G–EPON OLT PMDs, per measurement techniques defined in 75.7. Their unstressed receive characteristics should meet the values listed in Table 75–6 and Table 75–7 per measurement techniques described in 75.7.11. Either the damage threshold included in Table 75–6 or Table 75–7 shall be met, or the receiver shall be labeled to indicate the maximum optical input power level to which it can be continuously exposed without damage.

The damage threshold included in Table 75–6 and Table 75–7 does not guarantee direct ONU–OLT connection, which may result in damage of the receiver. If direct ONU–OLT connection is necessary, optical attenuators and/or equivalent loss components should be inserted to decrease receive power below the damage threshold.

Table 75–6—PR type OLT PMD receive characteristics *(continued)*

Description	10GBASE–PR–D1	10GBASE–PR–D2, 10GBASE–PR–D3	10GBASE–PR–D4	Unit
Stressed receive sensitivity OMA (max)	–20.22 (9.51)	–24.22 (3.79)	–26.22 (2.39)	dBm (μW)
Vertical eye–closure penalty[d]	2.99			dB
$T_{receiver_settling}$ (max)[e]	800			ns
Stressed eye jitter	0.3			UI pk-pk
Jitter corner frequency for a sinusoidal jitter	4			MHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	(0.05, 0.15)			UI

[a]The BER of 10^{-12} is achieved by the utilization of FEC as described in 76.3.
[b]Direct ONU–OLT connection may result in damage of the receiver.
[c]The stressed receiver sensitivity is mandatory.
[d]Vertical eye closure penalty and the jitter specifications are test conditions for measuring stressed receiver sensitivity. They are not required characteristics of the receiver.
[e]$T_{receiver_settling}$ represents an upper bound. Optics with better performance may be used in compliant implementations, since the OLT notifies the ONUs of its requirements in terms of the $T_{receiver_settling}$ time via the syncTime parameter (see 77.3.3.2).

Table 75–7—PRX type OLT PMD receive characteristics

PMD type	Receive parameters	Reference
10/1GBASE–PRX–D1	same as 1000BASE–PX10–D receive parameters	see Table 60–5
10/1GBASE–PRX–D2	same as 1000BASE–PX20–D receive parameters	see Table 60–8
10/1GBASE–PRX–D3	same as 1000BASE–PX30–D receive parameters[a]	see Table 60–11
10/1GBASE–PRX–D4	same as 1000BASE–PX40–D receive parameters[a]	see Table 60–13

[a]Stressed receive sensitivity (max) is mandatory for 10/1GBASE–PRX–D3 and 10/1GBASE–PRX–D4 PMDs.

75.5 PMD to MDI optical specifications for 10/10G–EPON and 10/1G–EPON ONU PMDs

This subclause details the PMD to MDI optical specifications for 10/10G–EPON and 10/1G–EPON ONU PMDs, as specified in 75.2. Specifically, 75.5.1 defines the ONU transmit parameters, while 75.5.2 defines the ONU receive parameters.

The operating ranges for PR and PRX power budget classes are defined in Table 75–1. A PR or PRX compliant transceiver operates over the media types listed in Table 75–14 according to the specifications described in 75.9. A transceiver which exceeds the operational range requirement while meeting all other optical specifications is considered compliant.

NOTE—The specifications for OMA have been derived from extinction ratio and average launch power (minimum) or receiver sensitivity (maximum). The calculation is defined in 58.7.6.

75.5.1 Transmitter optical specifications

The signaling speed, operating wavelength, spectral width (for 10/1G–EPON ONU PMDs) or side mode suppression ratio (for 10/10G–EPON ONU PMDs), average launch power, extinction ratio, return loss tolerance, OMA, eye and TDP for transmitters forming part of the 10/10G–EPON and 10/1G–EPON ONU PMDs (as specified in 75.2) shall meet the specifications defined in Table 75–8 for 10/10G–EPON ONU PMDs and in Table 75–9 for 10/1G–EPON ONU PMDs, per measurement techniques described in 75.7. Their $RIN_{15}OMA$ should meet the value listed in Table 75–8 or Table 75–9, as appropriate, per measurement techniques described in 75.7.8.

Table 75–8—PR type ONU PMD transmit characteristics

Description	10GBASE –PR–U1	10GBASE –PR–U3	10GBASE –PR–U4	Unit
Signaling speed (range)	10.3125 ± 100 ppm			GBd
Wavelength (range)	1260 to 1280			nm
Side Mode Suppression Ratio (min)[a]	30			dB
Average launch power (max)	4	9	9	dBm
Average launch power (min)[b]	–1	4	6	dBm
Average launch power of OFF transmitter (max)	–45			dBm
Extinction ratio (min)	6			dB
$RIN_{15}OMA$ (max)	–128			dB/Hz
Launch OMA (min)[b]	–0.22 (0.95)	4.78 (3.01)	6.78 (4.77)	dBm (mW)
Transmitter eye mask definition {X1, X2, X3, Y1, Y2, Y3}[c]	{0.25, 0.4, 0.45, 0.25, 0.28, 0.4}			UI
T_{on} (max)	512			ns
T_{off} (max)	512			ns
Optical return loss tolerance (max)	15			dB
Transmitter reflectance (max)	–10			dB
Transmitter and dispersion penalty (max)[d]	3	3	2	dB
Decision timing offset for transmitter and dispersion penalty	±0.0625			UI

[a]Transmitter is a single longitudinal mode device. Chirp is allowed such that the total optical path penalty does not exceed that found in Table 75B–2.
[b]Minimum average launch power and minimum launch OMA are valid for ER = 6 dB (see Figure 75–5 for details).
[c]As defined in Figure 75–6.
[d]If a transmitter has a lower TDP, the minimum transmitter launch OMA (OMA_{min}) and average minimum launch power (AVP_{min}) may be relaxed by the amount 3 dB – TDP for 10GBASE-PR-U1 and 10GBASE-PR-U3 and 2 dB – TDP for 10G-BASE-PR-U4.

The relationship between OMA, extinction ratio and average power is described in 58.7.6 and illustrated in Figure 75–5 for a compliant transmitter. Note that the OMA_{min} and AVP_{min} are calculated for ER = 6 dB. The transmitter average launch power specifications are further relaxed by allowing ER higher than 6 dB while maintaining the OMA_{min} constant. The shaded area indicates a compliant part.

Table 75–9—PRX type ONU PMD transmit characteristics

PMD type	Transmit parameters[a]	Reference
10/1GBASE–PRX–U1	same as 1000BASE–PX10–U transmit parameters	see Table 60–3
10/1GBASE–PRX–U2	same as 1000BASE–PX20–U transmit parameters	see Table 60–6
10/1GBASE–PRX–U3	same as 1000BASE–PX30–U transmit parameters	see Table 60–9
10/1GBASE–PRX–U4	same as 1000BASE–PX40–U transmit parameters	see Table 60–12

[a]Optical return loss of ODN (min) is optional for 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2, 10/1GBASE–PRX–U3, and 10/1GBASE–PRX–U4 PMDs.

The maximum RMS spectral width vs. wavelength for 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2 and 10/1GBASE–PRX–U3 PMDs are shown, respectively, in Table 60–4, Table 60–7, and Table 75–10. The equation used to generate these values is included in 60.9.2.

75.5.2 Receiver optical specifications

The signaling speed, operating wavelength, overload, stressed sensitivity, reflectance, and signal detect for receivers forming part of the 10/10G–EPON ONU and 10/1G–EPON ONU PMDs (as specified in 75.2) shall meet the specifications defined in Table 75–10 for Clause 75 ONU PMDs, per measurement techniques defined in 75.7. Their unstressed receive characteristics should meet the values listed in Table 75–10 per measurement techniques described in 75.7.11. Either the damage threshold included in Table 75–10 shall be met, or the receiver shall be labeled to indicate the maximum optical input power level to which it can be continuously exposed without damage.

The damage threshold included in Table 75–10 does not guarantee direct ONU–OLT connection, which may result in damage of the receiver. If direct ONU–OLT connection is necessary, optical attenuators and/or equivalent loss components should be inserted to decrease receive power below damage threshold.

Table 75–10—PR and PRX type ONU PMD receive characteristics

Description	10GBASE–PR–U1, 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2	10GBASE–PR–U3, 10/1GBASE–PRX–U3	10GBASE–PR–U4, 10/1GBASE–PRX–U4	Unit
Signaling speed (range)	10.3125 ± 100 ppm			GBd
Wavelength (range)	1575 to 1580			nm
Bit error ratio (max)[a]	10^{-3}			—
Average receive power (max)	0	–10	–9	dBm
Damage threshold (max)[b]	1	–9	–8	dBm
Receiver sensitivity (max)	–20.5	–28.5	–29.5	dBm
Receiver sensitivity OMA (max)	–18.59 (13.84)	–26.59 (2.19)	–27.59 (1.74)	dBm (μW)

Table 75–10—PR and PRX type ONU PMD receive characteristics *(continued)*

Description	10GBASE–PR–U1, 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2	10GBASE–PR–U3, 10/1GBASE–PRX–U3	10GBASE–PR–U4, 10/1GBASE–PRX–U4	Unit
Signal detect threshold (min)	–44			dBm
Receiver reflectance (max)	–12			dB
Stressed receive sensitivity (max)[c]	–19	–27	–28	dBm
Stressed receive sensitivity OMA (max)	–17.09 (19.55)	–25.09 (3.1)	–26.09 (2.46)	dBm (μW)
Vertical eye–closure penalty[d]	1.5			dB
Stressed eye jitter (min)	0.3			UI pk-pk
Jitter corner frequency for a sinusoidal jitter	4			MHz
Sinusoidal jitter limits for stressed receiver conformance test (min, max)	(0.05, 0.15)			UI

[a]The BER of 10^{-12} is achieved by the utilization of FEC as described in 76.3.
[b]Direct ONU–OLT connection may result in damage of the receiver.
[c]The stressed receiver sensitivity is mandatory over the entire PR–D transmitter compliance region, as illustrated in Figure 75–4.
[d]Vertical eye closure penalty and the jitter specifications are test conditions for measuring stressed receiver sensitivity. They are not required characteristics of the receiver.

75.6 Dual-rate (coexistence) mode

To support coexistence of 10G–EPON and 1G–EPON ONUs on the same outside plant, the OLT may be configured to use a dual-rate mode. Dual-rate mode supports transmission and/or reception of both 10 Gb/s and 1 Gb/s data rates, and can be introduced as options for 10G–EPON OLTs, functionally combining PMDs supporting 10 Gb/s and 1 Gb/s data rates.

Table 75–11 depicts PMD coexistence mapping for dual-rate mode options.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 75–11—PMD coexistence mapping for dual-rate mode option[a]

Direction of dual-rate operation	OLT PMD combination	ONU PMDs coexisting on the same ODN
Downstream	1000BASE–PX–D 10/1GBASE–PRX–D	(1) 1000BASE–PX–U (2) 10/1GBASE–PRX–U
Upstream	10GBASE–PR–D 10/1GBASE–PRX–D	(1) 10GBASE–PR–U (2) 10/1GBASE–PRX–U
Downstream and upstream	1000BASE–PX–D 10GBASE–PR–D	(1) 1000BASE–PX–U (2) 10/1GBASE–PRX–U (3) 10GBASE–PR–U

[a]Only PMDs with compatible power budgets can be connected to the same ODN.

75.6.1 Downstream dual-rate operation

When the downstream dual-rate operation is enabled, the OLT transmits both 10 Gb/s and 1 Gb/s downstream signals in a WDM manner. The OLT should meet both 10 Gb/s and 1 Gb/s specifications defined in Table 75–5 (10GBASE–PR–D transmit characteristics) and in Table 60–3, Table 60–6, Table 60–9, or Table 60–12 (1000BASE–PX–D transmit characteristics).

75.6.2 Upstream dual-rate operation

When the upstream dual-rate operation is enabled, the OLT receives both 10 Gb/s and 1 Gb/s upstream signals in a TDMA manner. Further implementation details are described in Annex 75A. The OLT should meet both 10 Gb/s and 1 Gb/s specifications defined in Table 75–6 (10GBASE–PR–D receive characteristics), and in Table 60–5, Table 60–8, Table 60–11, and Table 60–13 (1000BASE–PX–D receive characteristics).

NOTE—The damage threshold values in Table 60–5, Table 60–8, Table 60–11, and Table 60–13 are considerably higher than those in Table 75–6; the dual-rate PMD should be labeled appropriately.

75.7 Definitions of optical parameters and measurement methods

When measuring jitter at TP1 and TP5, it is recommended that jitter contributions at frequencies below receiver corner frequencies (i.e., 4 MHz for 10.3125 GBd receiver and 637 kHz for 1.25 GBd receiver) are filtered at the measurement unit. The following subclauses describe definitive patterns and test procedures for certain PMDs of this standard. Implementers using alternative verification methods should ensure adequate correlation and allow adequate margin such that specifications are met by reference to the definitive methods. All optical measurements, except TDP and $RIN_{15}OMA$ shall be made through a short patch cable between 2 m and 5 m in length.

75.7.1 Insertion loss

Insertion loss for SMF fiber optic cabling (channel) is defined at 1270 nm, 1310 nm, or 1577 nm, depending on the particular PMD. A suitable test method is described in ITU–T G.650.1.

75.7.2 Allocation for penalties in 10G–EPON PMDs

All the receiver types specified in Clause 75 are required to tolerate a path penalty not exceeding 1 dB to account for total degradations due to reflections, intersymbol interference, mode partition noise, laser chirp and detuning of the central wavelength, including chromatic dispersion penalty. All the transmitter types specified in Clause 75 introduce less than 1 dB of optical path penalty over the channel. The path penalty is

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a component of transmitter and dispersion penalty (TDP), which is specified in Table 75–5, Table 75–8, and Table 75–9 and described in 58.7.9.

75.7.3 Test patterns

Two types of test patterns are used for testing of 10 Gb/s optical PMDs: square wave (52.9.1.2) and patterns 1, 2, or 3 (52.9.1.1). These 10 Gb/s test patterns for 10GBASE–PR and 10/1GBASE–PRX are in Table 75–12. Two types of test frames [random and jitter (59.7.1)] are used for 1 Gb/s tests relevant to the 10/1GBASE–PRX PHY. All test patterns are listed in Table 75–12.

Table 75–12—Test patterns

Test	10 Gb/s pattern[a]	1 Gb/s pattern	Related subclause
Average optical power	1 or 3	Valid 8B/10B	75.7.5
OMA (modulated optical power)	Square	Idles	75.7.7
Extinction ratio	1 or 3	Idles	75.7.6
Transmit eye	1 or 3	Valid 8B/10B	75.7.7
$RIN_{15}OMA$	Square	Idles	75.7.8
Wavelength, spectral width	1 or 3	Valid 8B/10B	75.7.4
Side mode suppression ratio	1 or 3	Valid 8B/10B	75.7.4
VECP calibration	2 or 3	Jitter frame	75.7.12
Receiver sensitivity	1 or 3	Random frame	75.7.11
Receiver overload	1 or 3	Valid 8B/10B	—
Stressed receive sensitivity	2 or 3	Random frame	75.7.12
Transmitter and dispersion penalty	2 or 3	Random frame	75.7.10
Jitter	2 or 3	Jitter frame	75.7.13
Laser On/Off	1 or 3	Valid 8B/10B	75.7.14
Receiver settling	1 or 3	Valid 8B/10B	75.7.15

[a]Individual 10 Gb/s test patterns are described in 52.9.1.2 for a square wave and 52.9.1.1 for test patterns represented by numbers.

75.7.4 Wavelength, spectral width, and side mode suppression ratio (SMSR) measurement

The center wavelength, spectral width (RMS), and SMSR shall meet the specifications when measured according to the centroidal wavelength, RMS spectral width, and SMSR definitions in IEC 61280-1-3 under modulated conditions using an appropriate PRBS or a valid 10GBASE–PR signal, 1000BASE–X signal, or another representative test pattern.

NOTE—The allowable range of central wavelengths is narrower than the operating wavelength range by the actual RMS spectral width at each extreme.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

75.7.5 Optical power measurements

Optical power shall meet specifications according to the methods specified in IEC 61280-1-1. A measurement may be made with the port transmitting any valid encoded 8B/10B or 64B/66B data stream.

75.7.6 Extinction ratio measurements

The extinction ratio shall meet the specifications when measured according to IEC 61820-2-2 with the port transmitting a repeating idle pattern /I2/ ordered set (see 36.2.4.12) or valid 10GBASE–PR signal, and with minimal back reflections into the transmitter, lower than –20 dB. The test receiver has the frequency response as specified for the transmitter optical waveform measurement.

75.7.7 Optical modulation amplitude (OMA) test procedure

A description of OMA measurements for 1 Gb/s PHYs is found in 58.7.5. The OMA measurements for 10 Gb/s PHYs shall be compliant with the description found in 52.9.5.

75.7.8 Relative intensity noise optical modulation amplitude (RIN_xOMA) measuring procedure

This procedure describes a component test that may not be appropriate for a system level test depending on the implementation. If used, the procedure shall be performed as described in 52.9.6 for 10 Gb/s PHYs and in 58.7.7 for 1 Gb/s PHYs.

75.7.9 Transmit optical waveform (transmit eye)

The required transmitter pulse shape characteristics are specified in the form of a mask of the transmitter eye diagram as shown in Figure 75–5 for upstream direction of 10/1GBASE–PRX PMD and Figure 75–6 for downstream direction of 10/1GBASE–PRX PMD and both directions of 10GBASE–PR PMD.

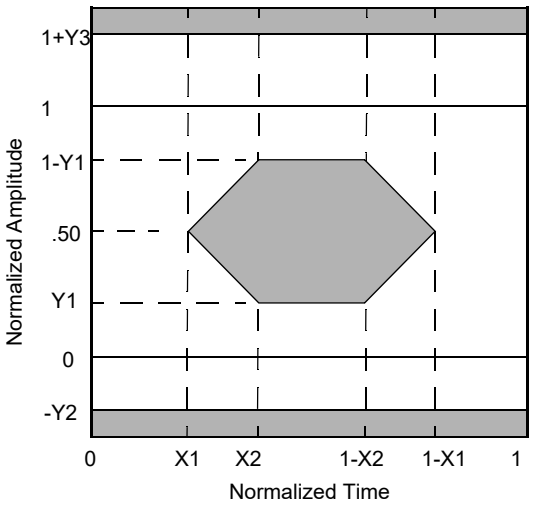

Figure 75–5—Transmitter eye mask definition for upstream direction of 10/1GBASE–PRX PMD

The measurement procedure is described in 58.7.8 for 1 Gb/s PHYs and 52.9.7 for 10 Gb/s PHYs and references therein. The eye shall comply to the mask of the eye using a fourth-order Bessel-Thomson

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

receiver response as defined in 60.9.8 for 1 Gb/s PMD transmitters and 52.9.7 for 10 Gb/s PMD transmitters.

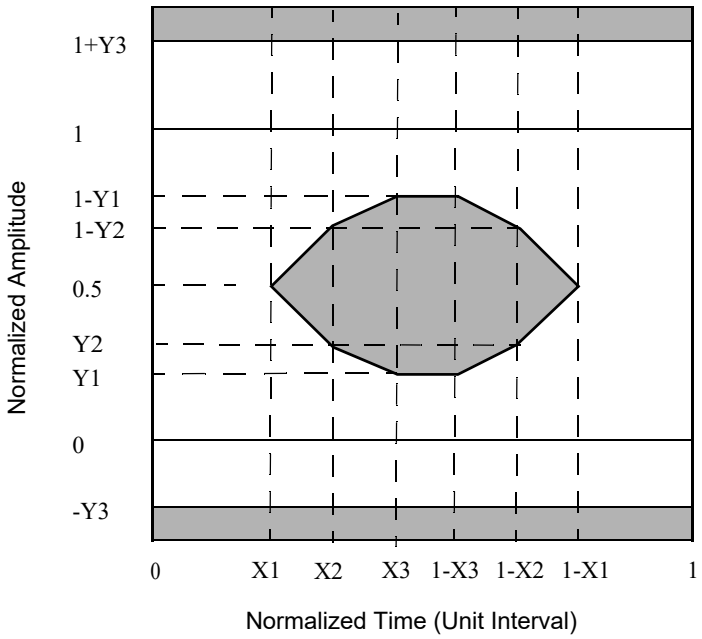

Figure 75–6—Transmitter eye mask definition for downstream direction of 10/1GBASE–PRX PMD and both directions of 10GBASE–PR PMD

75.7.10 Transmitter and dispersion penalty (TDP)

TDP measurement tests transmitter impairments, including chromatic dispersion effects, due to signal propagation in SMF used in PON. Possible causes of impairment include intersymbol interference, jitter, and RIN. Meeting the separate requirements (e.g., eye mask, spectral characteristics) does not in itself guarantee the TDP. The TDP limit shall be met. See 58.7.9 for details of the measurement for 1 Gb/s PHYs. For 10 Gb/s PHYs, TDP is measured as defined in 52.9.10 with an optical channel that meets the requirements listed in Table 75–13.

A 10 Gb/s transmitter is to be compliant with a total dispersion at least as negative as the “minimum dispersion” and at least as positive as the “maximum dispersion” columns specified in Table 75–13 for the wavelength of the device under test. This may be achieved with channels consisting of fibers with lengths chosen to meet the dispersion requirements.

75.7.11 Receive sensitivity

Receiver sensitivity is defined for the random pattern test frame, or test pattern 1, or test pattern 3, and an ideal input signal quality with the specified extinction ratio. The measurement procedure is described in 58.7.10 for 1 Gb/s PHYs and 52.9.8 for 10 Gb/s PHYs. The sensitivity shall be met for the bit error ratio defined in Table 75–6, Table 75–7, or Table 75–10 as appropriate.

75.7.12 Stressed receiver conformance test

Compliance with stressed receiver sensitivity is mandatory for the following PMDs: 10GBASE–PR–D1, 10GBASE–PR–D2, 10GBASE–PR–D3, 10GBASE–PR–D4, 10GBASE–PR–U1, 10GBASE–PR–U3, 10GBASE–PR–U4, 10/1GBASE–PRX–D3, 10/1GBASE–PRX–D4, 10/1GBASE–PRX–U1, 10/1GBASE–

Table 75–13—10 Gb/s transmitter compliance channel specifications

PMD type	Max reach L (km)	Dispersion[a] (ps/nm)		Insertion loss	Optical return loss (dB)
		Minimum	Maximum		
10GBASE–PR–D1 10/1GBASE–PRX–D1	10	0	$0.2325 L\lambda[1–(1300/\lambda)^4]$	Minimum[b]	15
10GBASE–PR–D2 10GBASE–PR–D3 10GBASE–PR–D4 10/1GBASE–PRX–D2 10/1GBASE–PRX–D3 10/1GBASE–PRX–D4	20				
10GBASE–PR–U1	10	$0.2325 L\lambda[1–(1324/\lambda)^4]$	0		
10GBASE–PR–U3 10GBASE–PR–U4	20				

[a]The dispersion is measured for the wavelength of the device under test (λ in nm).
[b]There is no intent to stress the sensitivity of the BERT's optical receiver.

PRX–U2, 10/1GBASE–PRX–U3, and 10/1GBASE–PRX–U4. The stressed receiver conformance test is intended to screen against receivers with poor frequency response or timing characteristics that could cause errors when combined with a distorted but compliant signal. To be compliant with stressed receiver sensitivity, the receiver shall meet the specified bit error ratio at the power level and signal quality defined in Table 75–6, Table 75–7, or Table 75–10 as appropriate, according to the measurement procedures of 58.7.11 for 1 Gb/s PHYs and 52.9.9 for 10 Gb/s PHYs.

75.7.13 Jitter measurements

Jitter measurements for 1 Gb/s are described in 58.7.12. Jitter measurements for 10 Gb/s are described in 52.8.1.

75.7.14 Laser on/off timing measurement

The laser on/off timing measurement procedure is described in 60.9.13.1 with the following changes:

a) T_{on} is defined in 60.9.13.1.1, and its value is less than 512 ns (defined in Table 75–8 and Table 75–9).
b) $T_{receiver_settling}$ is defined in 60.9.13.2.1, and its value is defined in Table 75–6 and Table 75–7.
c) T_{CDR} is defined in 76.4.2.1, and its value is less than 400 ns.
d) $T_{code_group_align}$ is defined in 36.3.2.4, and its value is less than 4 ten bit code–groups for 1 Gb/s PHYs, and is defined as 0 for 10 Gb/s PHYs.
e) T_{off} is defined in 60.9.13.1.1, and its value is less than 512 ns (defined in Table 75–8 and Table 75–9).

75.7.15 Receiver settling timing measurement

75.7.15.1 Definitions

$T_{receiver_settling}$ is denoted as the time beginning from the time that the optical power in the receiver at TP7 reaches the conditions specified in 75.7.12 and ending at the time that the electrical signal after the PMD at

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

TP8 reaches within 15 % of its steady state parameter (average power, jitter) (see Table 75–6 for 10GBASE–PR–D1, 10GBASE–PR–D2, 10GBASE–PR–D3, and 10GBASE–PR–D4, and Table 75–7 for 10/1GBASE–PRX–D1, 10/1GBASE–PRX–D2, 10/1GBASE–PRX–D3, and 10/1GBASE–PRX–D4). $T_{receiver_settling}$ is presented in Figure 75–7. The data transmitted may be any valid 64B/66B symbols (or a specific power synchronization sequence). The optical signal at TP7, at the beginning of the locking, may have any valid 64B/66B pattern, optical power level, jitter, or frequency shift matching the standard specifications.

75.7.15.2 Test specification

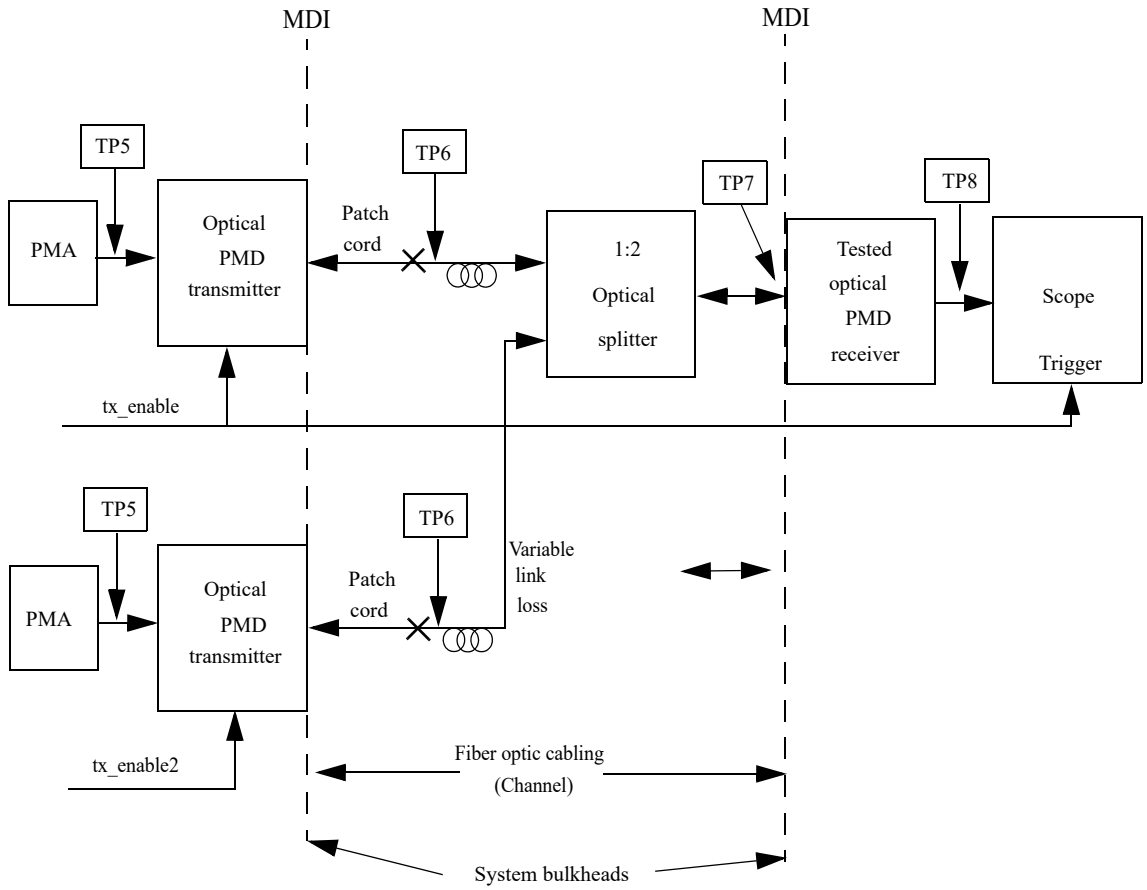

Figure 75–7—Receiver settling time measurement setup

Figure 75–7 illustrates the test setup for the OLT PMD receiver (upstream) $T_{receiver_settling}$ time. The optical PMD transmitter has well–known parameters, with a fixed known T_{on} time. After T_{on} time the parameters of the reference transmitter, at TP6 and therefore at TP7, reach within 15% of its steady state values as specified in Table 75–8 for 10GBASE–PR–U1, 10GBASE–PR–U3, and 10GBASE–PR–U4 and Table 75–9 for 10/1GBASE–PRX–U1, 10/1GBASE–PRX–U2, 10/1GBASE–PRX–U3, and 10/1GBASE–PRX–U4.

Define $T_{receiver_settling}$ time as the time from the tx_enable assertion, minus the known T_{on} time, to the time the electrical signal at TP8 reaches within 15% of its steady state conditions.

Conformance should be assured for an optical signal at TP7 with any level of its specified parameters before the tx_enable assertion. Especially the $T_{receiver_settling}$ time has to be met in the following scenarios:

— Switching from a ‘weak’ (minimal received power at TP7) ONU to a ‘strong’ (maximal received power at TP7) ONU, with minimal guard band between.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— Switching from a ‘strong’ ONU to a ‘weak’ ONU, with minimal guard band between.
— Switching from noise level, with maximal duration interval, to ‘strong’ ONU power level.

The following procedure is a non-rigorous way to verify the declared $T_{receiver_settling}$ time.

a) Use a reference transmitter with a known T_{on}.
b) For the PMD receiver under test, measure all PMD receiver electrical parameters at TP8 after $T_{receiver_settling}$ from the tx_enable trigger minus the reference transmitter T_{on}.
c) Verify the conformance of the measured parameters to within 15% of their specified steady state values.

75.8 Environmental, safety, and labeling

75.8.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

75.8.2 Laser safety

10GBASE–PR and 10/1GBASE–PRX optical transceivers shall conform to Hazard Level 1 laser requirements as defined in IEC 60825–1 and IEC 60825–2, under any condition of operation. This includes single fault conditions whether coupled into a fiber or out of an open bore.

Conformance to additional laser safety standards may be required for operation within specific geographic regions.

Laser safety standards and regulations require that the manufacturer of a laser product provide information about the product’s laser, safety features, labeling, use, maintenance, and service. This documentation explicitly defines requirements and usage restrictions on the host system necessary to meet these safety certifications.

75.8.3 Installation

It is recommended that proper installation practices, as defined by applicable local codes and regulation, be followed in every instance in which such practices are applicable.

75.8.4 Environment

The 10GBASE–PR and 10/1GBASE–PRX operating environment specifications are as defined in 52.11, as defined in 52.11.1 for electromagnetic emission, and as defined in 52.11.2 for temperature, humidity, and handling.

See Annex 67A for additional environmental information. Two optional temperature ranges are defined in Table 60–15. Implementations shall be declared as compliant over one or both complete ranges, or not so declared (compliant over parts of these ranges or another temperature range).

75.8.5 PMD labeling

The 10GBASE–PR and 10/1GBASE–PRX labeling recommendations and requirements are as defined in 52.12.

Defined PMDs are as follows:

— 10/1GBASE–PRX–D1
— 10/1GBASE–PRX–D2

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— 10/1GBASE–PRX–D3
— 10/1GBASE–PRX–D4
— 10GBASE–PR–D1
— 10GBASE–PR–D2
— 10GBASE–PR–D3
— 10GBASE–PR–D4
— 10/1GBASE–PRX–U1
— 10/1GBASE–PRX–U2
— 10/1GBASE–PRX–U3
— 10/1GBASE–PRX–U4
— 10GBASE–PR–U1
— 10GBASE–PR–U3
— 10GBASE–PR–U4

Each field-pluggable component shall be clearly labeled with its operating temperature range over which compliance is ensured.

75.9 Characteristics of the fiber optic cabling

The 10GBASE–PR and 10/1GBASE–PRX fiber optic cabling shall meet the dispersion specifications defined in IEC 60793–2 and ITU–T G.652, or the requirements of Table 75–14 where they differ. The fiber optic cabling consists of one or more sections of fiber optic cable and any intermediate connections required to connect sections together. It also includes a connector plug at each end to connect to the MDI. The fiber optic cabling spans from one MDI to another MDI, as shown in Figure 75–3.

75.9.1 Fiber optic cabling model

The fiber optic cabling model is shown in Figure 75–3.

NOTE—The optical splitter presented in Figure 75–3 may be replaced by a number of smaller 1:n splitters such that a different topology may be implemented while preserving the link characteristics and power budget as defined in Table 75B–1 and Table 75B–2.

The maximum channel insertion losses shall meet the requirements specified in Table 75–1. Insertion loss measurements of installed fiber cables are made in accordance with IEC 61280–4–2:2000. The fiber optic cabling model (channel) defined here is the same as a simplex fiber optic link segment. The term *channel* is used here for consistency with generic cabling standards.

75.9.2 Optical fiber and cable

The fiber optic cable requirements are satisfied by the fibers specified in IEC 60793–2 Type B1.1 (dispersion un–shifted SMF) and Type B1.3 (low water peak SMF), ITU–T G.652 and ITU–T G.657 (bend–insensitive SMF), or by the requirements of Table 75–14 where they differ.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 75–14—Optical fiber and cable characteristics

Description[a]	IEC 60793–2 B1.1, B1.3 SMF, ITU–T G.652, G.657 SMF[b]				Unit
Nominal wavelength[c]	1270	1310	1550	1577	nm
Cable attenuation (max)[d]	0.44	0.4	0.35	0.35	dB/km
Zero dispersion wavelength[e]	$1300 \leq \lambda_0 \leq 1324$				nm
Dispersion slope (max)	0.093				$ps/nm^2 \cdot km$

[a]The fiber dispersion values are normative, all other values in the table are optional
[b]Other fiber types are acceptable if the resulting ODN meets channel insertion loss and dispersion requirements.
[c]Wavelength specified is the nominal wavelength and typical measurement wavelength. Power penalties at other wavelengths are accounted for.
[d]Attenuation for single-mode optical fiber cables for 1310 nm and 1550 nm is defined in ITU–T G.652. The attenuation values in the 1270 nm and 1577 nm windows were calculated using spectral attenuation modelling method (5.4.4) included in G.650.1 and the matrix coefficients included in Appendix III therein. 1310 nm (0.4 dB/km), 1380 nm (0.5 dB/km) and 1550 nm (0.35 dB/km) attenuation values were used as the input for the predictor model.
[e]See IEC 60793 or ITU–T G.652.

75.9.3 Optical fiber connection

An optical fiber connection as shown in Figure 75–3 consists of a mated pair of optical connectors. The 10GBASE–PR or 10/1GBASE–PRX PMD is coupled to the fiber optic cabling through an optical connection and any optical splitters into the MDI optical receiver, as shown in Figure 75–3. The channel insertion loss includes the loss for connectors, splices and other passive components such as splitters, see Table 75B–1 and Table 75B–2.

The channel insertion loss was calculated under the assumption of 14.5 dB loss for a 1:16 splitter/18.1 dB loss for a 1:32 splitter (ITU–T G.671 am 1). Unitary fiber attenuation for particular transmission wavelength is provided in Table 75–14. The number of splices/connectors is not predefined; the number of individual fiber sections between the OLT MDI and the ONU MDI is not defined. The only requirements are that the resulting channel insertion loss is within the limits specified in Table 75–1 and the maximum reach in Table 75–1 is not exceeded. Other fiber arrangements (e.g., increasing the split ratio while decreasing the fiber length) are supported as long as the limits for the channel insertion loss specified in Table 75–1 are observed.

The maximum discrete reflectance for single-mode connections shall be less than –26 dB.

75.9.4 Medium Dependent Interface (MDI)

The 10GBASE–PR or 10/1GBASE–PRX PMD is coupled to the fiber cabling at the MDI. The MDI is the interface between the PMD and the “fiber optic cabling” as shown in Figure 75–3. Examples of an MDI include the following:

a) Connectorized fiber pigtail
b) PMD receptacle

When the MDI is a remateable connection, it shall meet the interface performance specifications of IEC 61753–1. The MDI carries the signal in both directions for 10GBASE–PR or 10/1GBASE–PRX PMD and couples to a single fiber.

NOTE—Transmitter compliance testing is performed at TP2 or TP6 as defined in 75.3.2, not at the MDI.

75.10 Protocol implementation conformance statement (PICS) proforma for Clause 75, Physical Medium Dependent (PMD) sublayer and medium for passive optical networks, type 10GBASE–PR and 10/1GBASE–PRX[138]

75.10.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 75, Physical Medium Dependent (PMD) sublayer and medium for passive optical networks, type 10GBASE–PR and 10/1GBASE–PRX, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

75.10.2 Identification

75.10.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

75.10.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 75, Physical Medium Dependent (PMD) sublayer and medium for passive optical networks, type 10GBASE–PR and 10/1GBASE–PRX
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required?	No [ ] Yes [ ]
(See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[138]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

76. Reconciliation Sublayer, Physical Coding Sublayer, and Physical Media Attachment for 10G-EPON

76.1 Overview

This clause describes the Reconciliation Sublayer (RS), Physical Coding Sublayer (PCS) with FEC, and Physical Medium Attachment (PMA) used with 10GBASE-PR and 10/1GBASE-PRX point-to-multipoint (P2MP) networks. These are passive optical multipoint networks (PONs) that connect multiple DTEs using a single shared fiber. The architecture is asymmetric, based on a tree and branch topology utilizing passive optical splitters. This type of network requires that the Multipoint MAC Control sublayer exists above the MACs, as described in Clause 77.

76.1.1 Conventions

The notation used in the state diagrams in this clause follows the conventions in 21.5. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation ++ after a counter indicates it is to be incremented by 1. The notation −− after a counter indicates it is to be decremented by 1. The notation −= after a counter indicates that the counter value is to be decremented by the following value. The notation += after a counter indicates that the counter value is to be incremented by the following value. Code examples given in this clause adhere to the style of the “C” programming language.

76.1.2 Delay constraints

The MPCP relies on strict timing based on the distribution of timestamps. The actual delay is implementation dependent but an implementation shall maintain a combined delay variation through RS, PCS, and PMA sublayers of no more than 1 time_quantum (see 77.2.2.1) so as not to interfere with the MPCP timing.

76.2 Reconciliation Sublayer (RS) for 10G-EPON

76.2.1 Overview

This subclause extends Clause 46 to enable multiple MACs to interface with a single Physical Layer, and to enable data links with one data rate (e.g., 10 Gb/s) in one direction but another (e.g., 1 Gb/s) in the opposite direction. The number of MACs supported is limited only by the implementation. It is acceptable for only one MAC to be connected to this Reconciliation Sublayer. Figure 76–1 and Figure 76–2 show the relationship between this RS and the ISO/IEC OSI reference model. The mapping of GMII/XGMII signals to PLS service primitives is described in 35.2.1 for GMII and 46.1.7 for XGMII with exceptions noted herein.

76.2.2 Dual-speed Media Independent Interface

In 1G-EPON architectures, the GMII is the interface used to transfer data between the RS and the PCS. For 10/10G-EPON architectures, the XGMII is the interface used to transfer data between the RS and the PCS. When using a 10/1G-EPON architecture, a combination of both GMII and XGMII is needed in order to support transmission and reception at different speeds. Through the parallel use of the GMII and XGMII, the following modes are supported:

— Symmetric-rate 10 Gb/s operation for transmit and receive data paths, utilizing all of the functionality of the XGMII defined in Clause 46.
— Symmetric-rate 1 Gb/s operation for transmit and receive data paths, utilizing all of the functionality of the GMII defined in Clause 35.
— Asymmetric-rate operation for transmit and receive data paths at the OLT, utilizing transmit path functionality of the XGMII defined in Clause 46 and receive path functionality of the GMII defined in Clause 35.
— Asymmetric-rate operation for transmit and receive data paths at the ONU, utilizing transmit path functionality of the GMII defined in Clause 35 and receive path functionality of the XGMII defined in Clause 46.
— Coexistence of various ONU types by utilizing different data paths within the OLT.

76.2.2.1 10/10G-EPON

Figure 76–3(a) depicts the data paths used in 10/10G-EPON.

76.2.2.2 10/1G-EPON

At the OLT, the transmit path uses XGMII signals TXD<31:0>, TXC<3:0> and TX_CLK, while the receive path uses GMII signals RXD<7:0>, RX_ER, RX_CLK, and RX_DV. At the ONU, the transmit path uses GMII signals TXD<7:0>, TX_EN, TX_ER, and GTX_CLK, while the receive path uses XGMII signals RXD<31:0>, RXC<3:0> and RX_CLK.

Figure 76–3(b) depicts the data paths used in 10/1G-EPON.

76.2.2.3 Dual-rate mode

To support coexistence of 10/10G-EPON, 10/1G-EPON, and 1G-EPON ONUs on the same outside plant, the OLT may optionally support dual-rate mode. Dual-rate mode supports transmission and reception at both 10 Gb/s and 1 Gb/s. When operating in a dual-rate mode, a combination of XGMII and GMII data paths are used for transmission and reception. Figure 76–4 depicts the data paths used in an OLT operating in a dual-rate mode.

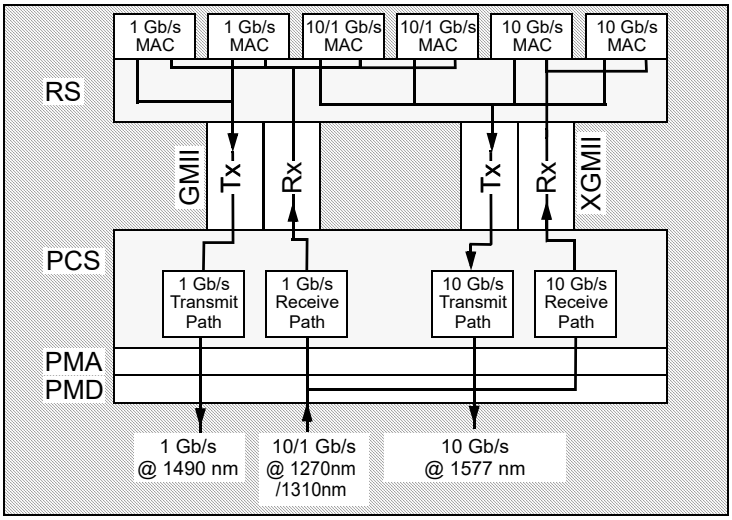

Figure 76–4—PCS and Reconciliation Sublayer for dual rate mode at OLT

76.2.2.4 Mapping of XGMII and GMII primitives

The mapping of XGMII/GMII signals to the PLS_DATA.request and PLS_DATA.indication primitives is described in 76.2.6. Additional details are provided in Table 76–1, which shows the mapping of PLS_-DATA.request primitives to transmit interface signals for different types of OLTs and ONUs. Table 76–2 shows the mapping of PLS_DATA.indication primitives to receive interface signals for different types of OLTs and ONUs.

76.2.3 Summary of major concepts

A successful registration process, described in 77.3.3, results in the assignment of values to the MODE and LLID variables associated with a MAC. This may be one of many MACs in an OLT or a single MAC in an ONU. The MODE and LLID variables are used to identify a packet transmitted from that MAC and how received packets are directed to that MAC. The RS in the OLT shall operate in unidirectional mode as defined in 66.4.

As described in 77.1.2, multiple MACs within an OLT are bound to a single XGMII in the case of a 10/10G-EPON OLT, or to an XGMII transmit path and a GMII receive path in the case of a 10/1G-EPON OLT. Only one PLS_DATA.request primitive is active at any time.

At the ONU, the MAC is either bound to an XGMII in the case of a 10/10G-EPON ONU, or to an XGMII receive path and a GMII transmit path in case the of an 10/1G-EPON ONU.

In the transmit direction, the RS maps the active PLS_DATA.request to either the GMII signals (TXD<7:0>, TX_EN, TX_ER, and GTX_CLK) or the XGMII signals (TXD<31:0>, TXC<3:0>, and TX_CLK) according to the MAC instance generating the request. The RS replaces octets of preamble with the values of the transmitting MAC's MODE and LLID variables.

In the receive direction, the MODE and LLID values embedded within the preamble identify the MAC to which this packet should be directed. The RS establishes a temporal mapping of either the GMII signals (RXD<7:0>, RX_ER, RX_CLK, and RX_DV) or the XGMII signals (RXD<31:0>, RXC<3:0> and RX_CLK) to the correct PLS_DATA.indication and PLS_DATA_VALID.indication primitives.

76.2.3.1 Application

This subclause applies to the interface between the MAC and PHY in an OLT or an ONU. The physical implementation of the interface is primarily intended to be chip-to-chip, but may also be used as a logical interface between ASIC logic modules within an integrated circuit. These interfaces are used to provide media independence, so that an identical media access controller may be used with all 10GBASE-PR and 10/1GBASE-PRX PHY types.

76.2.4 GMII structure

See Clause 35.

76.2.5 XGMII structure

The XGMII structure is discussed in 46.1.6, and Figure 46–2 depicts a schematic view of the RS inputs and outputs.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

76.2.6 Mapping of XGMII and GMII signals to PLS service primitives

Except as noted in Table 76–1 and Table 76–2, the mapping of the signals provided at the XGMII to the PLS service primitives is defined in 46.1.7.

Table 76–1—Mapping of PLS_DATA.request primitive

MAC location	MAC operating speed	Transmit interface	Signals
OLT	1G-EPON (Tx: 1 Gb/s)	GMII	TXD<7:0>, TX_EN, TX_ER, GTX_CLK
OLT	10/10G-EPON (Tx: 10 Gb/s)	XGMII	TXD<31:0>, TXC<3:0>, TX_CLK
OLT	10/1G-EPON (Tx: 10 Gb/s)	XGMII	TXD<31:0>, TXC<3:0>, TX_CLK
ONU	1G-EPON (Tx: 1 Gb/s)	GMII	TXD<7:0>, TX_EN, TX_ER, GTX_CLK
ONU	10/10G-EPON (Tx: 10 Gb/s)	XGMII	TXD<31:0>, TXC<3:0>, TX_CLK
ONU	10/1G-EPON (Tx: 1 Gb/s)	GMII	TXD<7:0>, TX_EN, TX_ER, GTX_CLK

Table 76–2—Mapping of PLS_DATA.indication primitive

MAC location	MAC operating speed	Receive interface	Signals
OLT	1G-EPON (Rx: 1 Gb/s)	GMII	RXD<7:0>, RX_ER, RX_DV, RX_CLK
OLT	10/10G-EPON (Rx: 10 Gb/s)	XGMII	RXD<31:0>, RXC<3:0>, RX_CLK
OLT	10/1G-EPON (Rx: 1 Gb/s)	GMII	RXD<7:0>,RX_ER,RX_DV,RX_CLK
ONU	1G-EPON (Rx: 1 Gb/s)	GMII	RXD<7:0>, RX_ER, RX_DV, RX_CLK
ONU	10/10G-EPON (Rx: 10 Gb/s)	XGMII	RXD<31:0>, RXC<3:0>, RX_CLK
ONU	10/1G-EPON (Rx: 10 Gb/s)	XGMII	RXD<31:0>, RXC<3:0>, RX_CLK

76.2.6.1 Functional specifications for multiple MACs

76.2.6.1.1 Variables

The variables of 65.1.3.1 are inherited except as shown below.

logical_link_id
: Value: 15 bits
This variable shall be set to the broadcast value of 0x7FFE for the unregistered ONU MAC.
Enabled OLT MACs may use any value for this variable. If the optional multicast LLID feature is supported, the OLT may use a multicast_link_id along with the mode bit set to 0.
Registered ONU MACs may use any value other than the reserved values listed in Table 76–4 or a multicast_link_id for this variable.

76.2.6.1.2 RS Transmit function

The transmit function is described in 65.1.3.2 except as noted below in Table 76–3, which shows the replacement mapping for 10G-EPON. The XGMII transmit function is described in 46.3.1.

Copyright © 2022 IEEE. All rights reserved.

Table 76–3—Preamble/SFD replacement mapping

Column	Lane	Field	Preamble/SFD	Modified preamble/SFD
0	0	—	0x55	Same
	1	—	0x55	Same
	2	SLD	0x55	0xD5
	3	—	0x55	Same
1	0	—	0x55	Same
	1	LLID[15:8]	0x55	<mode, logical_link_id[14:8]>[a]
	2	LLID[7:0]	0x55	<logical_link_id[7:0]>[b]
	3	CRC8	0xD5	The 8 bit CRC calculated over column 0 lane 2 through column 1 lane 2

[a]mode maps to TXD[15], logical_link_id[14] maps to TXD[14], logical_link_id[8] maps to TXD[8].
[b]logical_link_id[7] maps to TXD[23], logical_link_id[0] maps to TXD[16].

76.2.6.1.3 RS Receive function

The receive function is described in 65.1.3.3 except as noted below.

Table 65–2 is not applicable to 10G-EPON.

76.2.6.1.3.1 SLD

The 10 Gb/s RS transmit function maintains an alignment for its start control character to lane 0. The SLD is transmitted as the third octet and therefore is aligned to lane 2 in the same column containing the start control character. This is the only possibility considered when parsing the incoming octet stream for the SLD. If the SLD field is not found then the packet shall be discarded. If the packet is transferred, the SLD shall be replaced with a normal preamble octet and the two octets preceding the SLD and the one octet following the SLD are passed without modification. See Table 76–3.

76.2.6.1.3.2 LLID

This subclause supersedes the stipulations of 65.1.3.3.2.

The third and fourth octets following the SLD contain the mode and logical_link_id values. OLTs and ONUs act upon these values in a different manner.

If the device is an OLT, then the following comparison is made:

a) The received mode bit is ignored.
b) If the received logical_link_id value matches 0x7FFF or 0x7FFE and an enabled MAC exists with a logical_link_id variable with the same value, then the comparison is considered a match to that MAC.
c) If the received logical_link_id has a value other than 0x7FFF or 0x7FFE and an enabled MAC exists with a mode variable with a value of 0 and a logical_link_id variable matching the received logical_link_id value, then the comparison is considered a match to that MAC.

If the device is an ONU then the following comparison is made:

d) If the received mode bit is equal to 0 and the received logical_link_id value matches the logical_link_id variable, then the comparison is considered a match.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

e) If the received mode bit is equal to 1 and the received logical_link_id value does not match the logical_link_id variable, or the received logical_link_id matches 0x7FFE, then the comparison is considered a match.
f) If the received logical_link_id value matches one of the assigned multicast LLIDs, then the comparison is considered a match.

If no match is found, then the packet shall be discarded within the RS. If a match is found, then the packet is intended to be transferred. If the packet is transferred, then both octets of the LLID field shall be replaced with normal preamble octets.

If the packet is transferred, the one octet preceding the LLID is passed without modification. A number of LLIDs have been allocated (see Figure 76–4) for various purposes including downstream broadcast, discovery messages, and upstream registration request messages. An additional block of LLIDs has been set aside for future use and definition. A registered ONU shall not transmit frames with one of these reserved LLIDs.

Table 76–4—LLID values

LLID value	Used in RS	Purpose
0x7FFF	1000BASE-PX	Downstream: 1 Gb/s SCB Upstream: ONU registration at 1 Gb/s
0x7FFE	10/1GBASE-PRX	Downstream: 10 Gb/s SCB Upstream: ONU registration at 1 Gb/s
	10GBASE-PR	Downstream: 10 Gb/s SCB Upstream: ONU registration at 10 Gb/s
	10GPASS-XR	Downstream: EPoC SCB Upstream: CNU registration
0x7FFD–0x7F00	—	Reserved for future use

76.2.6.1.3.3 CRC-8

The CRC-8 field is as described in 65.1.3.3.3.

76.3 Physical Coding Sublayer (PCS) for 10G-EPON

76.3.1 Overview

This subclause defines the physical coding sublayers 10GBASE-PR and 10/1GBASE-PRX, supporting burst mode operation over the point-to-multipoint physical medium. The 10GBASE-PR PCS is specified to support 10/10G EPON, where both the receive and transmit paths operate at 10 Gb/s rate. The 10/1GBASE-PRX PCS supports 10/1G-EPON, in which OLT transmit path and ONU receive path operate at 10 Gb/s, while the ONU transmit path and the OLT receive path operate at 1 Gb/s rate.

This subclause also specifies a forward error correction (FEC) mechanism to increase the optical link budget or the fiber distance. Figure 76–1 and Figure 76–2 show the relationship between the PCS sublayer and the ISO/IEC OSI reference model.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

76.3.1.1 10/1GBASE-PRX PCS

Conceptually, the 10/1GBASE-PRX PCS represents a combination of transmit and receive functions defined in the 10GBASE-PR PCS (specified in this clause) and the 1000BASE-PX PCS (specified in Clause 65). At the OLT, the 10/1GBASE-PRX consists of the 10GBASE-PR transmit function and the 1000BASE-PX receive function (see Figure 76–5). Reciprocally, at the ONU, the 10/1GBASE-PRX PCS consists of the 10GBASE-PR receive function and the 1000BASE-PX transmit function (see Figure 76–6).

Deriving a specification for the 10/1GBASE-PRX PCS from the 10GBASE-PR PCS and the 1000BASE-PX PCS specifications as described previously is a straightforward process; therefore, no further explicit specification for the 10/1GBASE-PRX PCS is necessary.

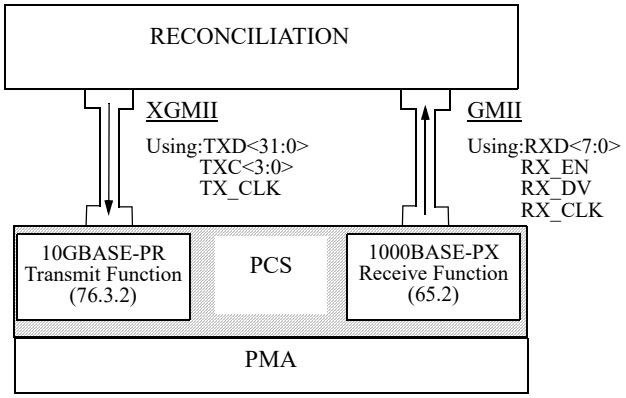

Figure 76–5—Conceptual diagram of 10/1GBASE-PRX PCS, OLT Side

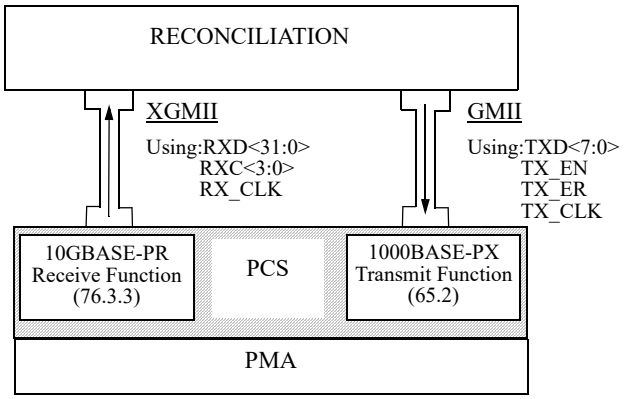

Figure 76–6—Conceptual diagram of 10/1GBASE-PRX PCS, ONU Side

76.3.1.2 10GBASE-PR PCS

The 10GBASE-PR PCS extends the physical coding sublayer described in Clause 49 to support burst mode operation over the point-to-multipoint physical medium. Figure 76–7 illustrates the functional block diagram of the downstream path and Figure 76–8 shows the functional block diagram of the upstream path.

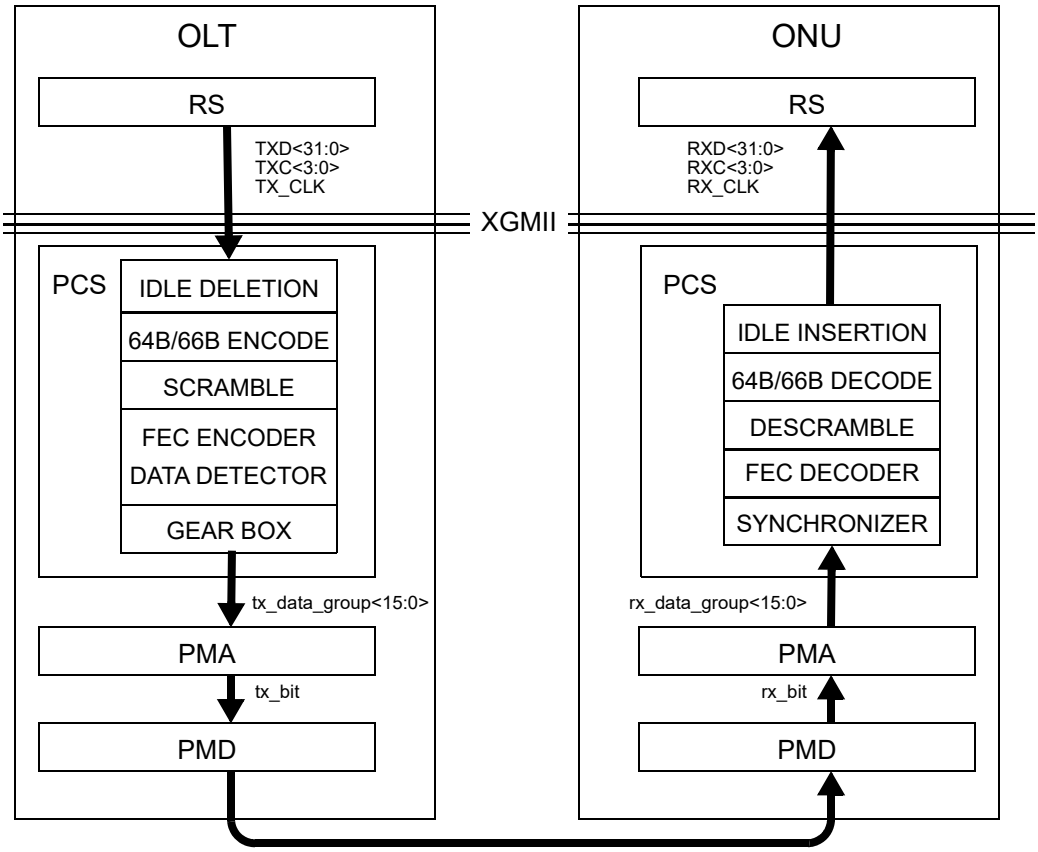

Figure 76–7—PCS functional block diagram, downstream path

76.3.2 PCS transmit function

This subclause defines the transmit direction of the physical coding sublayers for 10GBASE-PR and 10/1GBASE-PRX. In the OLT, the PCS transmit function operates at a 10 Gb/s rate in a continuous mode. In the ONU, the PCS transmit function may operate at a 10 Gb/s rate, as specified herein (10GBASE-PR), or at a 1 Gb/s rate, as specified in Clause 65 (10/1GBASE-PRX). For both 10GBASE-PR and 10/1GBASE-PRX, the ONU PCS always operates in a burst mode in the transmit direction. When operating at the 10 Gb/s rate, the PCS includes a mandatory FEC encoder. Figure 76–7 illustrates the transmit direction of OLT PCS. Figure 76–8 illustrates the transmit direction of the ONU PCS.

76.3.2.1 Idle control character deletion

The Idle Deletion process is responsible for deleting excess Idle characters to allow the parity data to be inserted without increasing the PMD line rate. This process deletes four 72 bit vectors containing Idle characters per every thirty-one 72 bit vectors received from the XGMII. The MPCP function ensures that sufficient Idle characters occur so that the minimum IPG is always preserved between two adjacent packets.

The Idle Deletion process is depicted in Figure 76–9 for OLTs and in Figure 76–10 for ONUs.

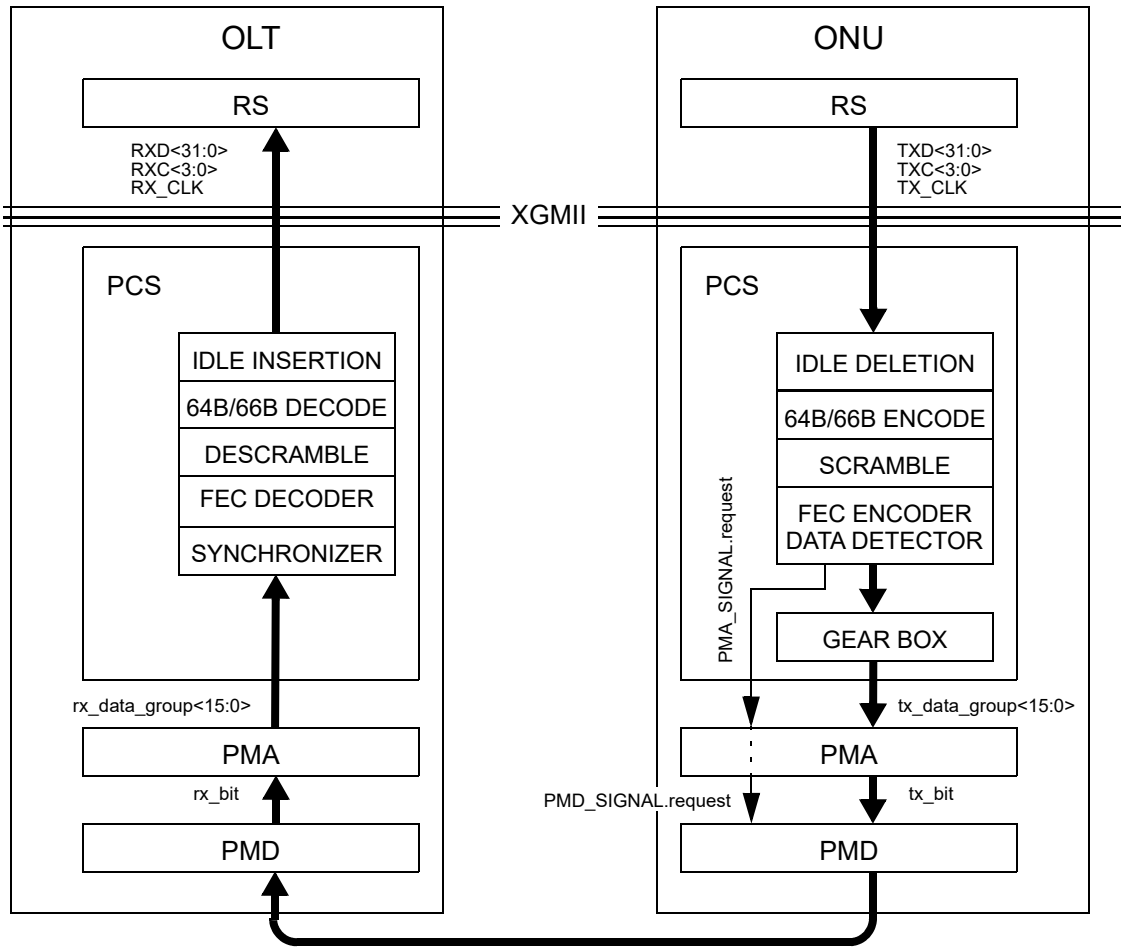

Figure 76–8—PCS functional block diagram, upstream path

76.3.2.1.1 Constants

FEC_DSize

TYPE: 16 bit unsigned

The number of 72 bit vectors constituting a payload of an FEC codeword. To normalize pre-FEC data rate, the Idle Deletion function removes FEC_PSize vectors per every FEC_DSize vectors transferred to the 64B/66B encoder.

Value: 27

FEC_PSize

TYPE: 16 bit unsigned

The number of 72 bit vectors constituting parity portion of an FEC codeword. To normalize pre-FEC data rate, the Idle Deletion function removes FEC_PSize vectors per every FEC_DSize vectors transferred to the 64B/66B encoder.

Value: 4

76.3.2.1.2 Variables

BEGIN

TYPE: Boolean

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This variable is used when initiating operation of the state diagram. It is set to true following initialization and every reset.

DelayBound
TYPE: 16 bit unsigned
This value represents the delay sufficient to initiate the laser and to stabilize the receiver at the OLT (i.e., the maximum FIFO size expressed in 66 bit blocks). The value includes LaserOnTime (77.3.3.2), $T_{receiver_settling}$, T_{CDR}, Burst Delimiter, and the two 66 bit blocks containing Idles, that precede the first packet in the burst. This variable is used only by the ONU.

tx_raw<71:0>
This variable is defined in 49.2.13.2.2.

tx_raw_out<71:0>
72 bit vector sent from the output of the Idle Deletion function to the 64B/66B encoder. The vector contains two XGMII transfers mapped as shown for tx_raw<71:0>.

76.3.2.1.3 Functions

T_TYPE(tx_raw<71:0>)
This function is defined in 49.2.13.2.3.

76.3.2.1.4 Counters

DelCount
TYPE: 16 bit unsigned
Counts the number of 72 bit vectors that need to be deleted.

IdleCount
TYPE: 16 bit unsigned
Counts the number of 72 bit vectors containing Idle control characters or other control vectors.

VectorCount
TYPE: 16 bit unsigned
Counts the number of 72 bit vectors transmitted.

76.3.2.1.5 State diagrams

The OLT PCS shall perform the Idle Deletion process as shown in Figure 76–9. The ONU PCS shall perform the Idle Deletion process as shown in Figure 76–10. Should there be a discrepancy between a state diagrams and descriptive text, the state diagrams prevail.

76.3.2.3 Scrambler

See 49.2.6 Scrambler.

76.3.2.4 FEC encoding

The 10GBASE-PR-D, 10GBASE-PR-U, and 10/1GBASE-PRX-D PCS shall encode the transmitted data stream using Reed-Solomon code (255,223). Annex 76A gives an example of RS(255,223) FEC Encoding.

76.3.2.4.1 FEC Algorithm [RS(255,223)]

The FEC code used for 10GBASE-PR links is a linear cyclic block code—the Reed-Solomon code (255, 223) over the Galois Field of GF(2^8)—a code operating on 8 bit symbols. The code encodes 223 information symbols and adds 32 parity symbols. The code is systematic, meaning that the information symbols are not disturbed in any way in the encoder and the parity symbols are added separately to each block.

The code is based on the generating polynomial shown in Equation (76-1).

$$G(Z) = \prod_{i=0}^{31}(Z - \alpha^i) = A_{32}Z^{32} + A_{31}Z^{31} + \ldots + A_0Z^0 \quad (76\text{–}1)$$

where

α is a root of the binary primitive polynomial $x^8 + x^4 + x^3 + x^2 + 1$ and is represented as 0x02
A is a series representing the resulting polynomial coefficients of $G(Z)$, (A_{32} is equal to 0x01)
Z corresponds to an 8 bit GF(2^8) symbol
x corresponds to a bit position in a GF(2^8) symbol

The parity calculation shall produce the same result as the shift register implementation shown in Figure 76–11. Before calculation begins, the shift register shall be initialized to zero. The contents of the shift register are transmitted without inversion.

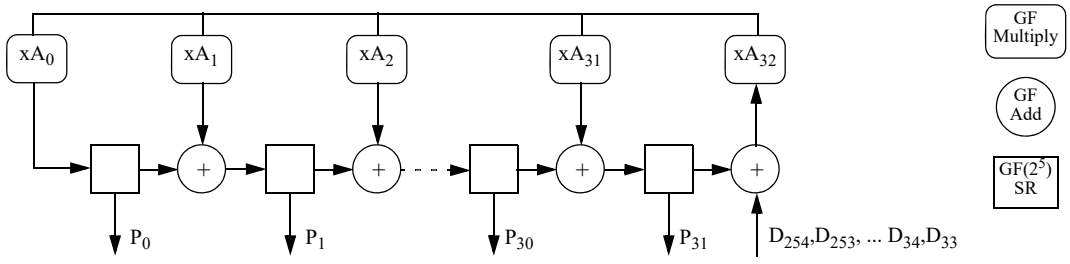

Figure 76–11—Circuit for generating FEC parity vector

An FEC parity vector is represented by Equation (76-2).

$$P(Z) = D(Z) \bmod G(Z) \quad (76\text{–}2)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

where

$D(Z)$ is the data vector $D(Z) = D_{222}Z^{254} + D_{221}Z^{253} + \ldots + D_0Z^{32}$. D_{222} is the first data octet and D_0 is the last.

$P(Z)$ is the parity vector $P(Z) = P_{31}Z^{31} + P_{30}Z^{30} \ldots + P_0Z^0$. P_{31} is the first parity octet and P_0 is the last.

A data octet $(d_7, d_6, \ldots, d_1, d_0)$ is identified with the element: $d_7\alpha^7 + d_6\alpha^6 + \ldots + d_1\alpha^1 + d_0$ in GF(2^8), the finite field with 2^8 elements. The code has a correction capability of up to sixteen symbols.

NOTE—For the (255,223) Reed-Solomon code, the symbol size equals one octet. The d_0 is identified as the LSB and d_7 is identified as the MSB for all octets in accordance with the conventions of 3.1.1.

Bit ordering shall be as illustrated in Figure 76–12.

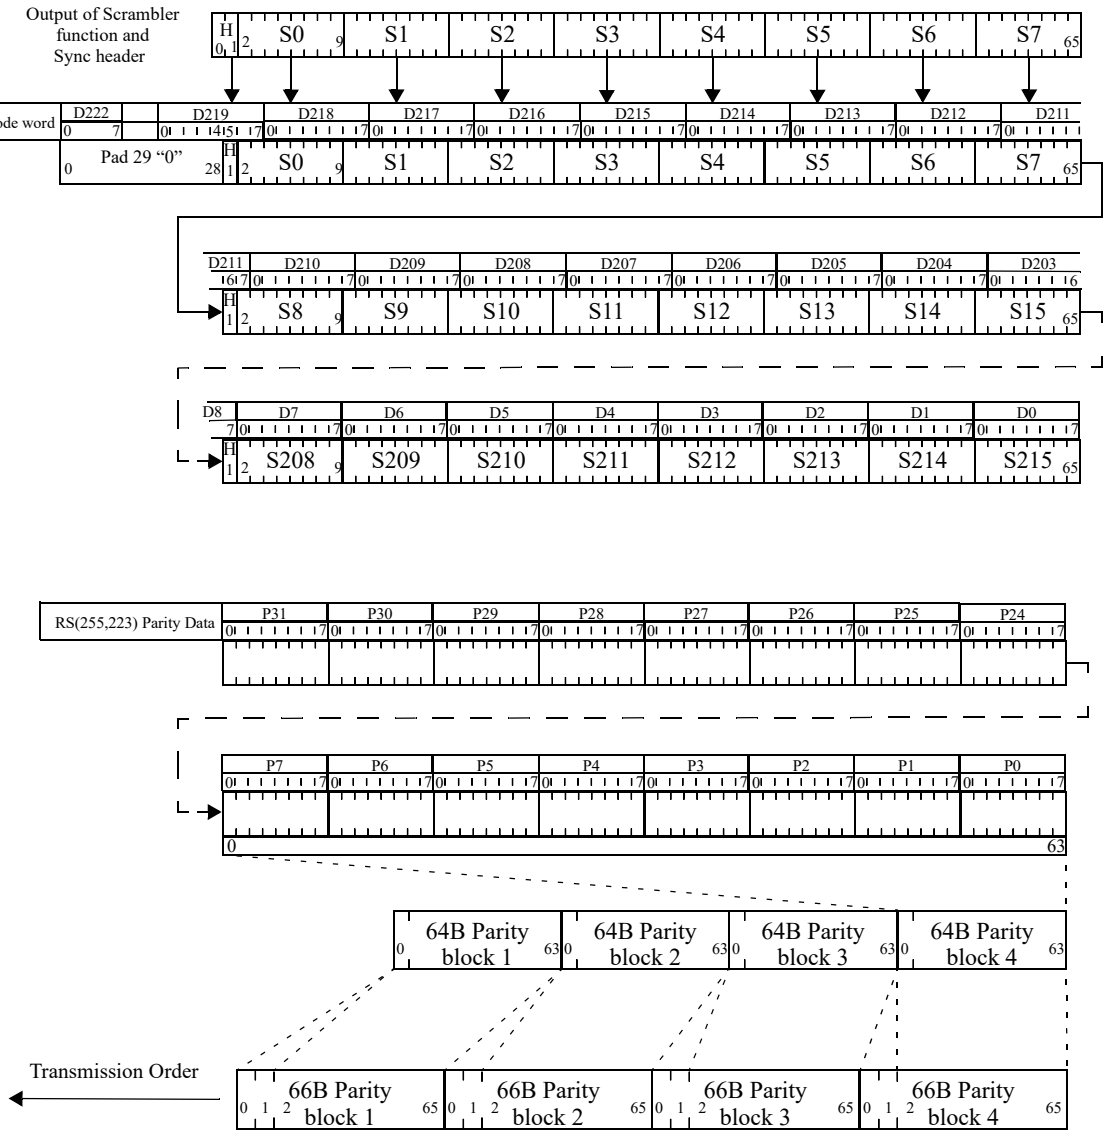

Figure 76–12—Bit ordering in FEC codeword generation

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

76.3.2.4.2 Parity calculation

Padding of FEC codewords and appending FEC parity octets in the 10GBASE-PR and 10/1GBASE-PRX OLT PCS transmitter is illustrated in Figure 76–13. The 64B/66B encoder and scrambler produce 66 bit blocks. The FEC encoder accumulates 27 of these 66 bit blocks to form the basis of an FEC codeword, removing the redundant first bit (i.e., sync header bit <0>) of each block (the first bit is guaranteed to be the complement of the second bit).

The FEC encoder then prepends 29 padding bits (binary 0) to the 27 blocks (65 bits each) to form the 223-octet payload portion of an FEC codeword. This data is then FEC-encoded, resulting in the 32-octet parity portion of the FEC codeword. The 223-octet payload portion and 32-octet parity portion combine to form the 255-octet Reed-Solomon codeword. The padding is used to generate the FEC codeword but is not transmitted.

76.3.2.4.3 FEC Transmission Block Formatting

As shown in Figure 76–13, after the Reed-Solomon codeword has been computed, the FEC encoder constructs the transmittable FEC codeword with the original sequence of twenty-seven 66 bit blocks (including the redundant sync bit, but not including the 29 “0” padding bits). The FEC encoder prepends a 2 bit sync header to each group of 64 parity bits to construct a properly formed 66 bit codeword, according to the predefined sync header pattern for the four 64 bit parity blocks: 00 11 11 00. Finally the four 66 bit parity blocks are appended following the twenty-seven 66 bit data blocks and transmitted to the PMA.

76.3.2.5 Data Detector

The 10GBASE-PR-D, 10GBASE-PR-U, and 10/1GBASE-PRX-D PCS transmit path includes the Data Detector process. This process contains a delay line (FIFO_DD buffer) that stores the 66 bit blocks to allow insertion of the FEC parity data into the transmitted data stream. The length of the FIFO_DD buffer should be large enough to hold the amount of data equal to the maximum amount of parity data that may be inserted within the transmission time of one packet of a maximum length (i.e., at most forty 66 bit blocks of parity data).

76.3.2.5.1 Burst Mode operation (ONU only)

In addition to inserting the parity data into the data stream, the Data Detector process in the 10GBASE-PR-U PCS generates the PMA_SIGNAL.request(tx_enable) primitive to turn the laser on and off at the correct times.

Upon initialization, the laser is turned off. When the first 66 bit block containing data arrives at the buffer, the Data Detector sets the PMA_SIGNAL.request(tx_enable) primitive to the value ON, instructing the PMD sublayer to start the process of turning the laser on.

When the buffer becomes empty (i.e., contains only 66 bit blocks with Idle characters), the Data Detector sends the End of Burst Delimiter and after that sets the PMA_SIGNAL.request(tx_enable) primitive to the value OFF, instructing the PMD sublayer to start the process of turning the laser off. Between packets, Idle blocks arrive at the buffer. If the number of these Idle blocks is insufficient to fill the buffer then the laser is not turned off.

The length of the FIFO_DD buffer at the ONU shall be chosen such that the delay introduced by the buffer together with any delay introduced by the PMA sublayer is long enough to turn the laser on and to allow a laser synchronization pattern, Burst Delimiter pattern, and a predefined number of Idle blocks to be transmitted. The laser synchronization pattern allows the receiving optical detector to adjust its gain ($T_{receiver_settling}$) and synchronize its receive clock (T_{CDR}). The Burst Delimiter allows the receiver to easily identify the beginning of FEC protected portion of the ONU transmission. The Idle control characters are used to synchronize the descrambler and establish start-of-packet delineation.

Figure 76–14 illustrates the details of the ONU burst transmission. In particular, this figure shows the details of the synchronization time and the FEC protected portions of the burst transmission.

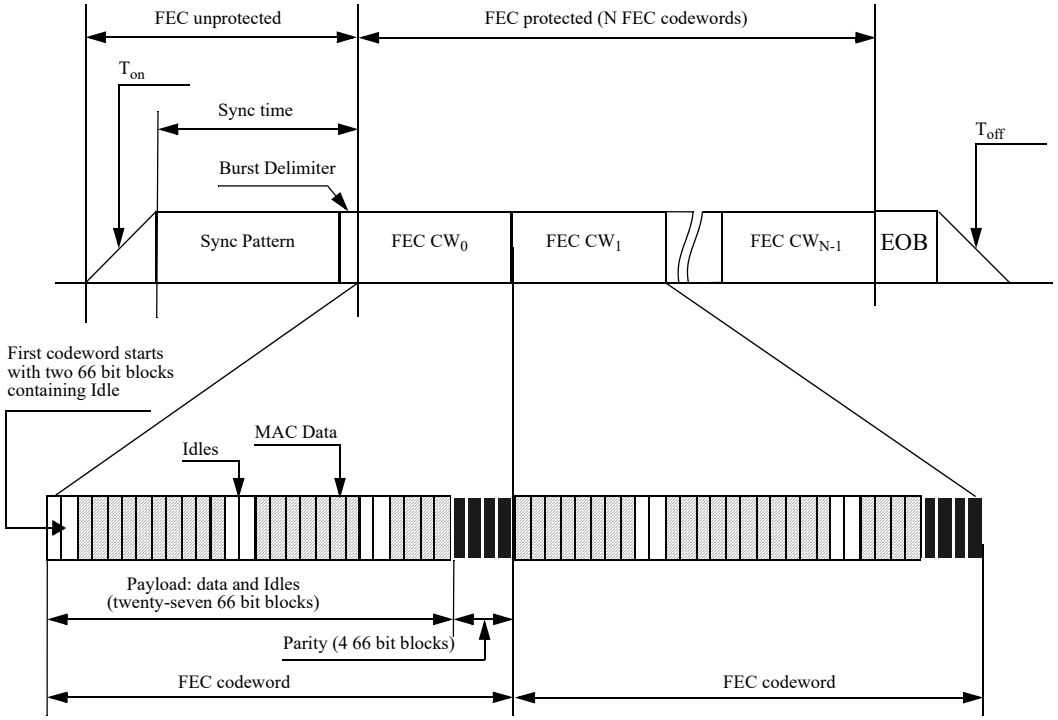

Figure 76–14—Details of burst composition

The ONU burst transmission begins with a Synchronization Pattern (see 76.3.2.5.2), which facilitates receiver clock recovery and gain control at the OLT. To facilitate FEC codeword synchronization, the ONU transmits a 66 bit BURST_DELIMITER (see Figure 76–15). When received at the OLT, the BURST_DELIMITER allows for FEC codeword alignment on the incoming data stream, even in the presence of bit errors. The BURST_DELIMITER is followed by two 66 bit blocks containing Idle codes. The first 66 bit block is used to synchronize the descrambler and a second 66 bit block is needed to provide packet delineation at the RS layer of the OLT. These two 66 bit Idle blocks are part of the first FEC codeword.

The ONU burst transmission ends with an END_BURST_DELIMITER (EOB) pattern of length TERMINATOR_LENGTH (see Figure 76–15). When received at the OLT, the burst terminator allows for the rapid reset of the OLT FEC synchronizer, so that it can search for the next burst. The burst terminator is not part of the last FEC codeword.

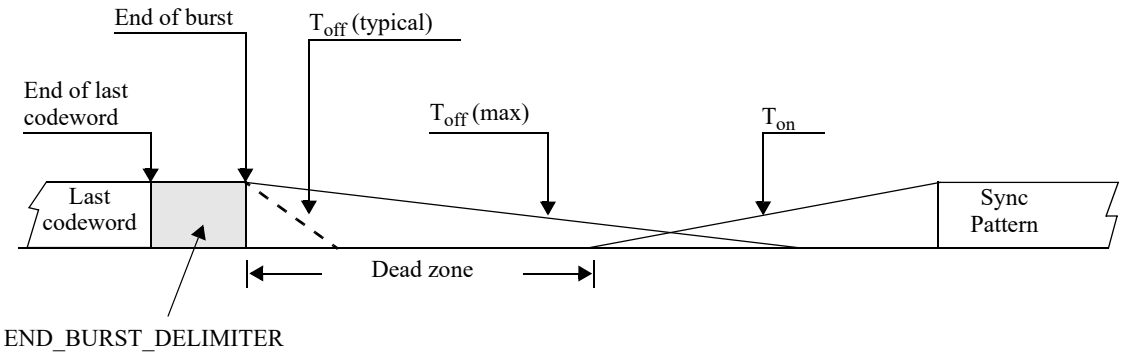

Figure 76–15—ONU burst transmission termination

The body of this subclause comprises state diagrams, including the associated definitions of variables, constants, and functions pertinent to the 10GBASE-PR and 10/1GBASE-PRX OLT PCS transmitters. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams in this clause follows the conventions in 21.5. State diagram variables follow the conventions of 21.5.2 except when the variable has a default value.

76.3.2.5.2 Constants

BURST_DELIMITER
: TYPE: 66 bit unsigned
A 66 bit value used to find the beginning of the first FEC codeword in the upstream burst.
Value: binary 01 followed by 0x 6B F8 D8 12 D8 58 E4 AB (transmission bit sequence: 01 1101 0110 0001 1111 0001 1011 0100 1000 0001 1011 0001 1010 0010 0111 1101 0101)

END_BURST_DELIMITER
: TYPE: 66 bit unsigned
A 66 bit value used to identify the end of the upstream burst transmission.
Value: binary 10 followed by 0x 55 55 55 55 55 55 55 55 (transmission bit sequence of 10 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010 1010)

FEC_DSize
: See 76.3.2.1.1.

FEC_PSize
: See 76.3.2.1.1.

SP
: Type: 66 bit unsigned
A 66 bit value used to for the burst mode synchronization pattern.
Value: binary 10 followed by 0x BF 40 18 E5 C5 49 BB 59 (transmission bit sequence 10 1111 1101 0000 0010 0001 1000 1010 0111 1010 0011 1001 0010 1101 1101 1001 1010)

TERMINATOR_LENGTH
: Type: 8 bit unsigned
Number of END_BURST_DELIMITER blocks that are transmitted at the end of each burst.
Value: 3

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

SH_DATA
Type: 2-bit unsigned
The value of synchronization header indicating that the given 66-bit block is a data block, as defined in 49.2.4.3.
Value: 0x02 (binary representation 10)

SH_CTRL
Type: 2-bit unsigned
The value of synchronization header indicating that the given 66-bit block is a control block, as defined in 49.2.4.3.
Value: 0x01 (binary representation 01)

NOTE—The binary representation of the sync header in here is different than that in Clause 49. In Clause 49, binary values are shown with the first transmitted bit (the LSB) on the left.

76.3.2.5.3 Variables

CLK
TYPE: Boolean
This Boolean is true on every negative edge of TX_CLK (See 46.3.1) and represents instances of time at which a 66 bit block should be passed from Data Detector to the GearBox. This variable is reset to false upon read.

DelayBound
This variable is defined in 76.3.2.1.2.

FIFO_DD
TYPE: Array of 66 bit unsigned elements
A FIFO array used to store tx_coded<65:0> blocks while the parity is inserted and while burst preamble is generated (at the ONU only).

FifoSize
TYPE: 16 bit unsigned
Variable representing a number of elements stored in FIFO_DD.

SyncLength
TYPE: 16 bit unsigned
Required number of sync blocks per burst. The value of this variable is derived from the syncTime (excluding BURST_DELIMITER) and laserOnTime parameters defined in 77.3.3.

Transmitting
TYPE: Boolean
Boolean variable indicating whether the device is transmitting or not. At the ONU, the default value of Transmitting is false. At the OLT, this variable is always set to true.

tx_coded<65:0>
TYPE: 66 bit unsigned
66 bit block containing the output of the scrambler. The format for this vector is shown in Figure 49–7. The left-most bit in the figure is tx_coded<0> and the right-most bit is tx_coded<65>.

tx_coded_out<65:0>
TYPE: 66 bit unsigned

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

66 bit block containing the output of Data Detector being passed to the Gearbox. The format for this vector is shown in Figure 49–7. The left-most bit in the figure is tx_coded<0> and the right-most bit is tx_coded<65>.

76.3.2.5.4 Functions

RemoveFifoHead()

This function removes the first block in FIFO_DD and decrements the variable FifoSize by 1.

```
RemoveFifoHead()
   {
      // shift FIFO_DD forward
      FIFO_DD[0] = FIFO_DD[1]
      FIFO_DD[1] = FIFO_DD[2]
          ...
      FIFO_DD[FifoSize-2] = FIFO_DD[FifoSize-1]
      FifoSize --
   }
```

76.3.2.5.5 Messages

PMA_SIGNAL.request(tx_enable)

This primitive is used to turn the laser on and off at the PMD sublayer. In the OLT, this primitive shall always take the value ON. In the ONU, the value of this variable is controlled by the Data detector state diagram (see Figure 76–17).

SCRAMBLER_UNITDATA.request(tx_coded<65:0>)

A primitive generated by the SCRAMBLER transmit process conveying the next 66 bit block to be transmitted.

SUDR

Alias for SCRAMBLER_UNITDATA.request(tx_coded<65:0>).

76.3.2.5.6 Counters

IdleBlockCount

TYPE: 32-bit signed integer

The number of consecutive non-data blocks ending with the most recently received block. The non-data blocks are represented by sync header 10 (binary).

ParityBlockCount

TYPE: 8 bit unsigned

The number of parity blocks transmitted in a current FEC codeword. After reaching the full parity size (FEC_PSize=4), this counter is reset to 0.

ProtectedBlockCount

TYPE: 8 bit unsigned

The number of blocks added to a payload of a current FEC codeword. After reaching the full payload size (FEC_DSize = 27), this counter is reset to 0.

SyncBlockCount

TYPE: 16 bit unsigned

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The number of synchronization blocks transmitted in current burst.

76.3.2.5.7 State diagrams

The OLT and the ONU shall implement the Data Detector input process as depicted in Figure 76–16. The OLT shall implement the Data Detector output process as depicted in Figure 76–17(a). The ONU shall implement the Data Detector output process as depicted in Figure 76–17(b).

76.3.3 PCS receive Function

This subclause defines the receive direction of physical coding sublayers for 10GBASE-PR and 10/1GBASE-PRX. In the ONU, the PCS operates at a 10 Gb/s rate in a continuous mode. In the OLT, the PCS may operate at a 10 Gb/s rate, as specified herein (10GBASE-PR), or at a 1 Gb/s rate, compliant with Clause 65 (10/1GBASE-PRX). For both 10GBASE-PR and 10/1GBASE-PRX, the OLT PCS always operates in burst mode. When operating at the 10 Gb/s rate, the PCS includes a mandatory FEC decoder. The receive direction of ONU PCS is illustrated in Figure 76–7 and receive direction for the OLT PCS is illustrated in Figure 76–8.

76.3.3.1 OLT synchronizer

The OLT codeword synchronization function receives data via the 16 bit PMA_UNITDATA.indication primitive.

The OLT synchronizer forms a bit stream from the primitives by concatenating requests with the bits of each primitive in order from rx_data-group<0> to rx_data-group<15> (see Figure 76–18). It obtains lock to the thirty-one 66 bit blocks in the bit stream by looking for the burst delimiter. Lock is obtained as specified in the codeword lock state diagram shown in Figure 76–18. While in codeword lock, the synchronizer copies the FEC-protected bits from each data block and the parity bits of the codeword into an input buffer. When the codeword is complete, the FEC decoder is triggered, and the input buffer is freed for the next codeword. When in codeword lock, the state diagram looks for the end of the burst. When this is observed, then the state diagram deasserts codeword lock. The state diagram then goes back to searching for the burst delimiter.

76.3.3.1.1 Variables

BD_valid
: TYPE:Boolean
Indication that is set true if received block rx_coded matches the BURST_DELIMITER with less than 12 bits difference, and de-asserted otherwise.

cword_lock
: TYPE: Boolean
Boolean variable that is set true when receiver acquires codeword delineation.

CurrentBlock<65:0>
: TYPE: 66 bit vector
The last 66 bit block received. This variable has an initial value of 0.

decode_success
: TYPE: Boolean
Indication that is set true if the codeword was successfully decoded by the FEC algorithm, and false otherwise.

EOB_valid
: TYPE: Boolean
Indication that is set true if:

$$\text{DistanceFromEob}(\text{CurrentBlock}) + \text{DistanceFromEob}(\text{PreviousBlock}) < 11$$

It is set to false otherwise.

inbuffer
: TYPE: bit array
An array of 2040 bits that holds the input to the FEC decoder.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

input_buffer_location
TYPE: integer
An integer that points to the next appending location in the input buffer.

persist_dec_fail
TYPE: Boolean
Indication that is set when three consecutive decoding failures have occurred.

PreviousBlock<65:0>
TYPE: 66 bit vector
The 66 bit block received previous to the current block. This variable has an initial value of 0.

reset
This variable is inherited from 49.2.13.2.2.

rx_coded<65:0>
This variable is inherited from 49.2.13.2.2.

signal_ok
This variable is inherited from 49.2.13.2.2.

76.3.3.1.2 Counters

decode_failures
TYPE:
Counter that holds the number of consecutive decoding failures.

sh_wndw_cnt
Count of the number of sync headers checked within the current 62-block window (composed of 2 codewords of 31 blocks each).

76.3.3.1.3 Functions

Append_inbuffer()
Appends the newly arrived 66 bit block into the input buffer of the FEC decoding algorithm, taking care to only insert the bits to be protected, and discarding the unwanted bits.

```
Append_inbuffer()
{
   BlockFromPMA()
   if (sh_wndw_cnt<27)
   {
      inbuffer[input_buffer_location]=rx_coded<1>
      input_buffer_location++
   }
   for(i=2, i<66, i++)
   {
      inbuffer[input_buffer_location]=rx_coded<i>
      input_buffer_location++
   }
}
```

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

BlockFromPMA()

Function that accepts the next received data from the PMA. Conceptually, this function serializes the 16 bit rx_data_group<15:0> to a bit stream at 10.3125 Gb/s, and then deserializes the resulting bit stream into a 66 bit wide rx_coded<65:0> block of data. It does not return until 66 bits have been transferred. Note that the internal design by which this function is accomplished is an implementation choice; however, the design operates such that a new 66 bit block is made available at the regular interval of 6.4 ns, and the transfers are made synchronous to the XGMII clock.

Decode()

Triggers the FEC decoding algorithm to accept the contents of the input buffer, and do its decoding work. Note that this function is not blocking, and returns immediately. It is assumed that the FEC decoding algorithm copies the input buffer contents into its own internal memory, so that the input buffer is released to accept the next codeword.

DecodeWhenReady()

Determines if the inbuffer contains a full codeword, and if so, it triggers the Decode function, and then clears the inbuffer for the next codeword.

```
DecodeWhenReady()
{
   if (sh_wndw_cnt=0 or sh_wndw_cnt=31)
   {
      if (cword_lock)
      {
         Decode();
      }
      Flush_inbuffer();
   }
}
```

DistanceFromEob(block<65:0>)

Returns the Hamming distance between the supplied block and the END_BURST_DELIMITER

Flush_inbuffer()

Flushes the input buffer of the FEC decoding algorithm block.

```
Flush_inbuffer()
{
   for(i=0, i<2040, i++)
   {
      inbuffer[i]=0
   }
   input_buffer_location = 29
}
```

SLIP_One_Bit

Causes the next candidate block sync position to be tested. The next candidate is exactly one bit later than the previous candidate – no burst alignments may be skipped. Following the conceptual model mentioned in “BlockFromPMA,” this function transfers one more bit from the 16 bit serializer to the 66 bit deserializer.

76.3.3.1.4 State diagram

The OLT Synchronizer shall implement the state diagram as depicted in Figure 76–18. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

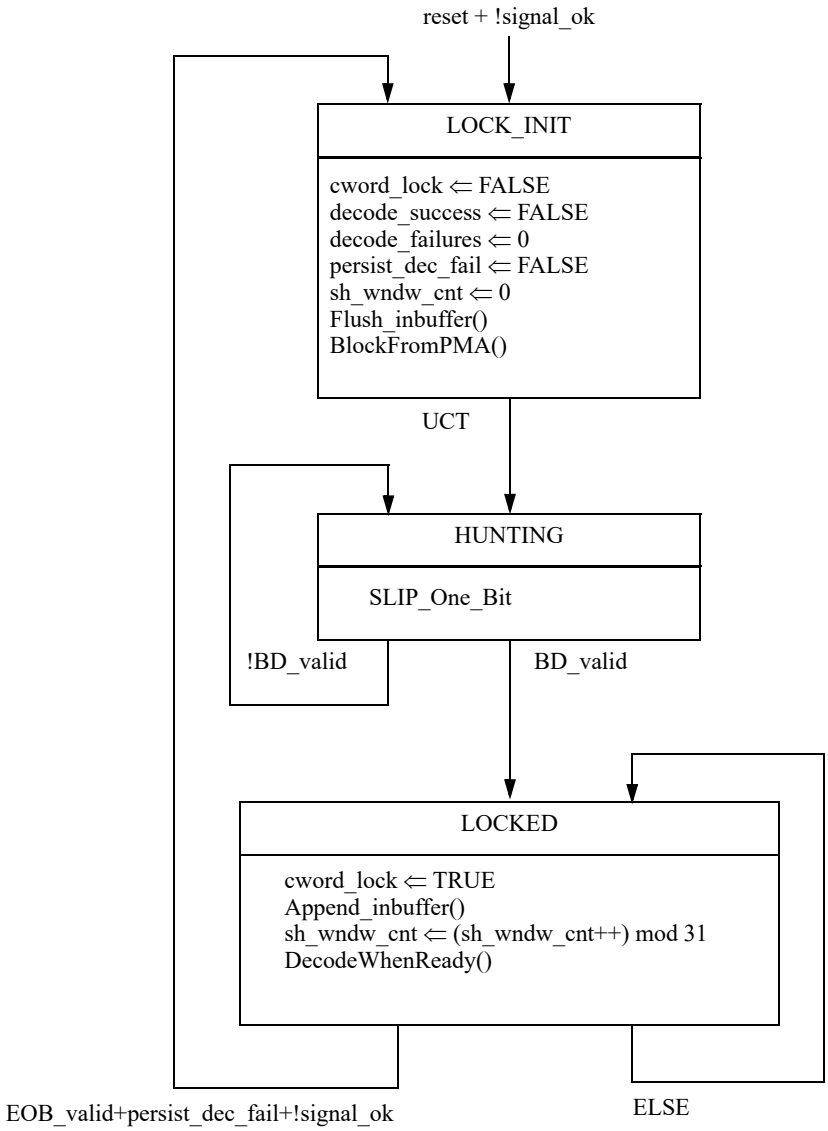

Figure 76–18—OLT Synchronizer state diagram

76.3.3.2 ONU Synchronizer

The codeword synchronization function receives data via the 16 bit PMA_UNITDATA.indication primitive.

The synchronizer forms a bit stream from the primitives by concatenating requests with the bits of each primitive in order from rx_data-group<0> to rx_data-group<15> (see Figure 76–19). It obtains lock to the thirty-one 66 bit blocks in the bit stream using the sync headers and outputs 2040 bit codewords to the FEC decoder function.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

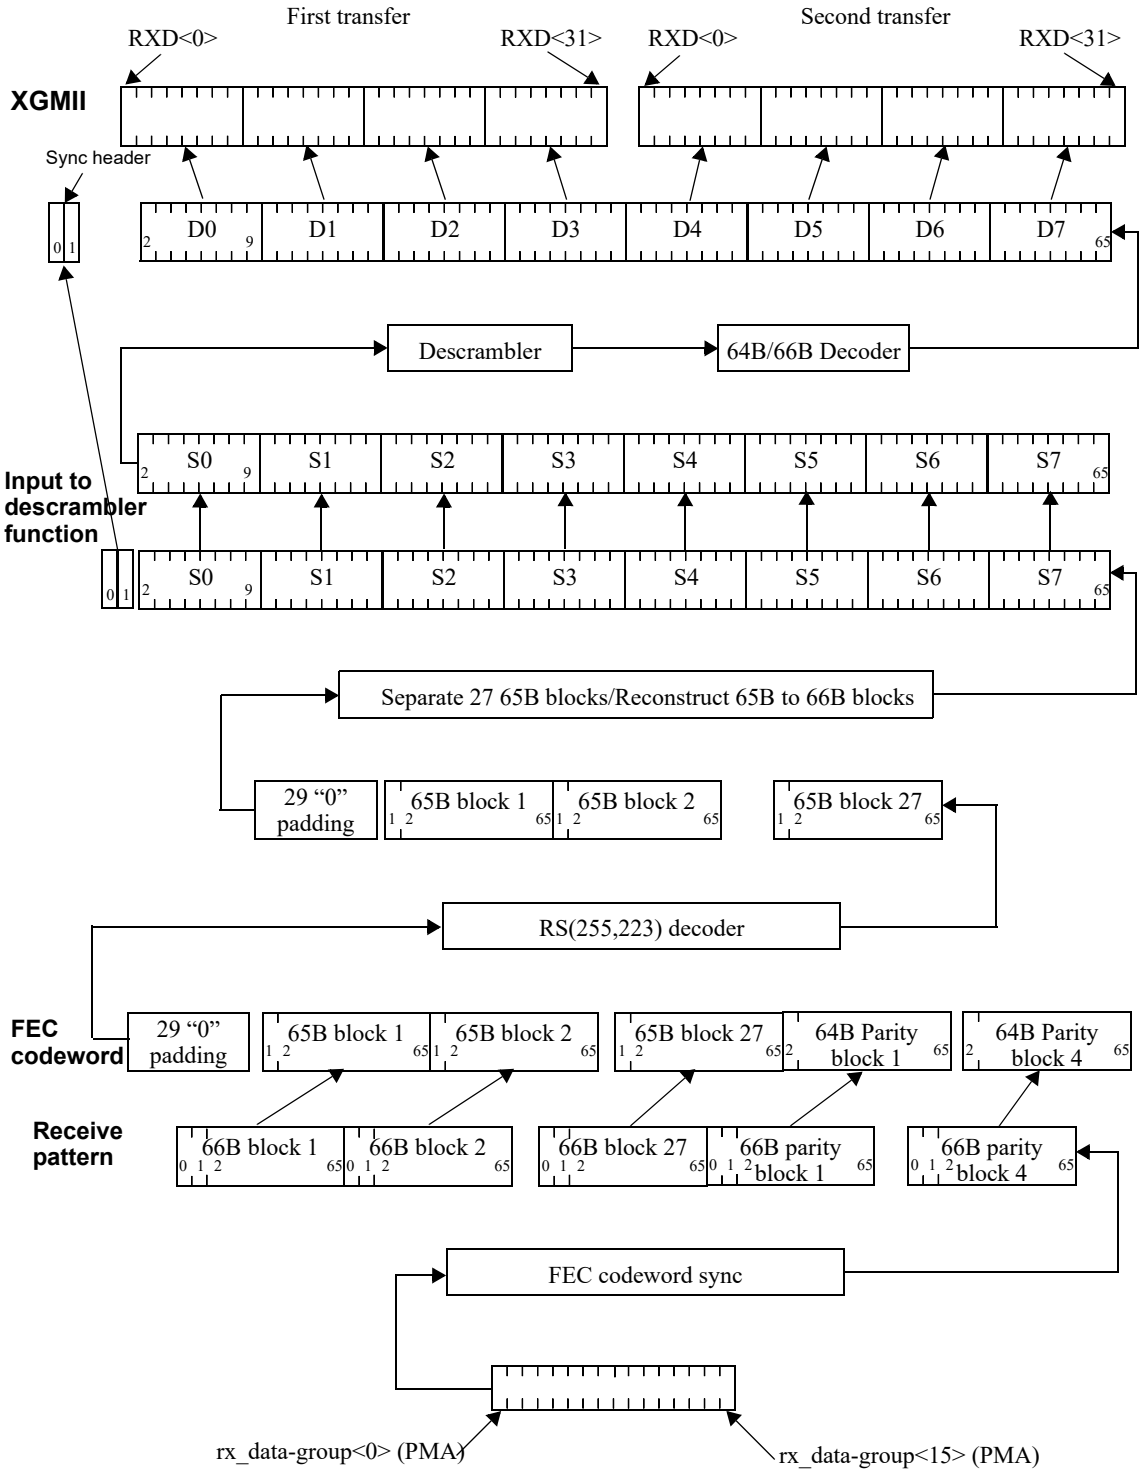

Figure 76–19—PCS Receive bit ordering

The incoming sync header pattern is 27 conventional (Clause 49) sync headers (binary 01 or 10), and then binary 00, 11, 11, and finally binary 00. The ONU synchronizer attempts to match this pattern to the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

received data stream, and when it finds a perfect match of two full codewords (62 blocks), it then asserts codeword lock.

While in codeword lock, the synchronizer copies the FEC-protected bits from each data block and the parity bits of the codeword into an input buffer. When the codeword is complete, the FEC decoder is triggered, and the input buffer is freed for the next codeword.

When in codeword lock, the state diagram continues to check for sync header validity. If 16 or more sync headers in a codeword pair (62 blocks) are invalid, then the state diagram deasserts codeword lock. In addition, if the persist_dec_fail signal becomes set, then codeword lock is deasserted (this check ensures that certain false-lock cases are not persistent.)

76.3.3.2.1 Constants

All the relevant constants defined in 49.2.13.2.1 are inherited. In addition, the following items are defined.

SH_CW_PATTERN
: TYPE: array of 8 bit unsigned
31 element array of codeword sync header bit counts, where each element is set to the value 1 except for:
Value:
SH_CW_PATTERN[27]=0
SH_CW_PATTERN[28]=2
SH_CW_PATTERN[29]=2
SH_CW_PATTERN[30]=0

76.3.3.2.2 Variables

cword_lock
: See 76.3.3.1.1.

decode_success
: See 76.3.3.1.1.

persist_dec_fail
: See 76.3.3.1.1.

reset
: This variable is inherited from 49.2.13.2.2.

sh_valid
: TYPE: Boolean array
Indication that is set true if received block rx_coded has valid sync header bits for the supposed current position in the FEC codeword. That is, sh_valid[i] is asserted if (rx_coded<0> + rx_coded<1>) = SH_CW_PATTERN[i mod 31] and de-asserted otherwise.

signal_ok
: This variable is inherited from 49.2.13.2.2.

slip_done
: This variable is inherited from 49.2.13.2.2.

test_sh
: This variable is inherited from 49.2.13.2.2.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

76.3.3.2.3 Counters

decode_failures
See 76.3.3.1.2.

FEC_cnt
TYPE: 8 bit unsigned
This counter keeps track of the parity sync header index that is currently being tested.

sh_wndw_cnt
See 76.3.3.1.2.

sh_valid_cnt
This counter is inherited from 49.2.13.2.4.

76.3.3.2.4 Functions

Append_inbuffer()
See 76.3.3.1.3.

DecodeWhenReady()
See 76.3.3.1.3.

SLIP
This function is inherited from 49.2.13.2.3.

76.3.3.2.5 State diagram

The ONU Synchronizer shall implement the state diagram as depicted in Figure 76–20. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

76.3.3.3 FEC decoding process

The 10GBASE-PR-D, 10GBASE-PR-U, and 10/1GBASE-PRX-U PCS shall correct errors in the received data stream using Reed-Solomon code (255,223). The FEC decoder corrects or confirms the correctness of the twenty-seven 66 bit blocks contained in the FEC codeword based on the four 66 bit blocks of parity information. The FEC decoding process then forwards the 66 bit data blocks to the descrambler and discards the parity blocks. The FEC decoding process is also responsible for setting bit 0 of the sync header to the inverse of bit 1 of the sync header. The handling of data leaving the FEC decoder and going to the descrambler is specified in the FEC decoding process state diagram shown in Figure 76–21. Implementations shall be capable of correcting up to 16 symbols in a codeword and detecting uncorrectable codewords.

The synchronizer state diagram accumulates a full codeword in a buffer. If the synchronizer is locked, then the FEC decoding process is triggered. The FEC algorithm then processes the buffer. The algorithm produces two outputs: the decode_success signal and (if successful) the corrected buffer. The data portion of the buffer is then read out to the descrambler logic in 66 bit blocks, as normal. Note that the rate of 66 bit transfers here is reduced due to the removal of the FEC parity blocks. This is corrected in the Idle Insertion step (see Figure 76–23).

If decode_success is false, then a counter is incremented (see 45.2.3.42). If there are three decoding failures in a row, then the Persist_dec_fail signal is asserted. This signal then resets the synchronizer.

The FEC decoding process shall provide a user option to indicate an uncorrectable FEC codeword (due to an excess of symbols containing errors) to higher layers. If this option is set to be true, the FEC decoding process checks for the value of decode_success. If the variable decode_success is set to false, then each sync header of the received payload blocks in the FEC codeword is set to a value of binary 00. However, the data blocks are nevertheless passed to the descrambler to maintain descrambling synchronization. When this option is set to FALSE and decode_success is FALSE then each received payload block is passed unchanged.

76.3.3.3.1 Variables

decode_done
: TYPE: Boolean
Indication that is transiently set when the FEC decoder algorithm has completed its processing and the corrected data is present in the output buffer.

decode_success
: See 76.3.3.1.1.

mark_uncorrectable
: TYPE: Boolean
Control variable that is set to true if the uncorrectable errors are to be marked.
Default: TRUE

outbuffer
: TYPE: bit array
An array of 2040 bits that holds the output of the FEC decoder.

persist_dec_fail
: See 76.3.3.1.1.

rx_code_corrected
: Type: 66 bit vector
The next block of data to be sent to the scrambler.

76.3.3.3.2 Counters

decode_failures
: See 76.3.3.1.2.

corrected_FEC_codewords_counter
: A corrected block is an FEC codeword that was received with one or more errored symbols, and that has been corrected by the FEC decoder.
corrected_FEC_codewords_counter counts once for each corrected FEC codeword processed. This is a 32 bit counter. This variable is provided by a management interface that may be mapped to the 45.2.3.41 register (3.76, 3.77).

FEC_uncorrected_blocks_counter
: An uncorrected block is an FEC codeword that was received with 17 or more errored symbols, and that has not been corrected by the FEC decoder.
FEC_uncorrected_blocks_counter counts once for each uncorrected FEC codeword processed. This is a 32 bit counter. This variable is provided by a management interface that may be mapped to the 45.2.3.42 register (3.78, 3.79).

76.3.3.3.3 Functions

All the relevant functions defined in 49.2.13.2.3 are inherited. In addition, the following items are defined.

BlockFromPMA()
See 76.3.3.1.3.

BlockToDescrambler()
Function that sends the next rx_coded_corrected<65:0> block to the descrambler. It does not return until the transfer is completed, and each transfer takes 6.4 ns and is synchronized to the XGMII clock.

Flush_inbuffer()
See 76.3.3.1.3.

Read_outbuffer(i)
Passes output buffer contents to the descrambler, with the appropriate format.

```
Read_outbuffer[i]
{
   int offset = 29+i*65
   for(j=0, j<65, j++)
   {
      rx_coded_corrected<j+1> = outbuffer[j+offset]
   }
   if (!decode_success AND mark_uncorrectable)
   {
      rx_coded_corrected<0> = 0
      rx_coded_corrected<1> = 0
   }
   else
   {
      rx_coded_corrected<0> = !rx_coded_corrected<1>
   }
   BlockToDescrambler()
}
```

SLIP
This function is inherited from 49.2.13.2.3.

76.3.3.3.4 State diagrams

The body of this subclause comprises state diagrams, including the associated definitions of variables, constants, and functions pertinent to the 10GBASE-PR-D, 10GBASE-PR-U, and 10/1GBASE-PRX-U PCS receivers. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams in this clause follows the conventions in 21.5.

The FEC decoding process shall be implemented in the PCS as depicted in Figure 76–21. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

76.3.3.4 BER monitor

The BER monitor is described in Figure 76–22. This BER monitor function operates on the uncorrected incoming data stream.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

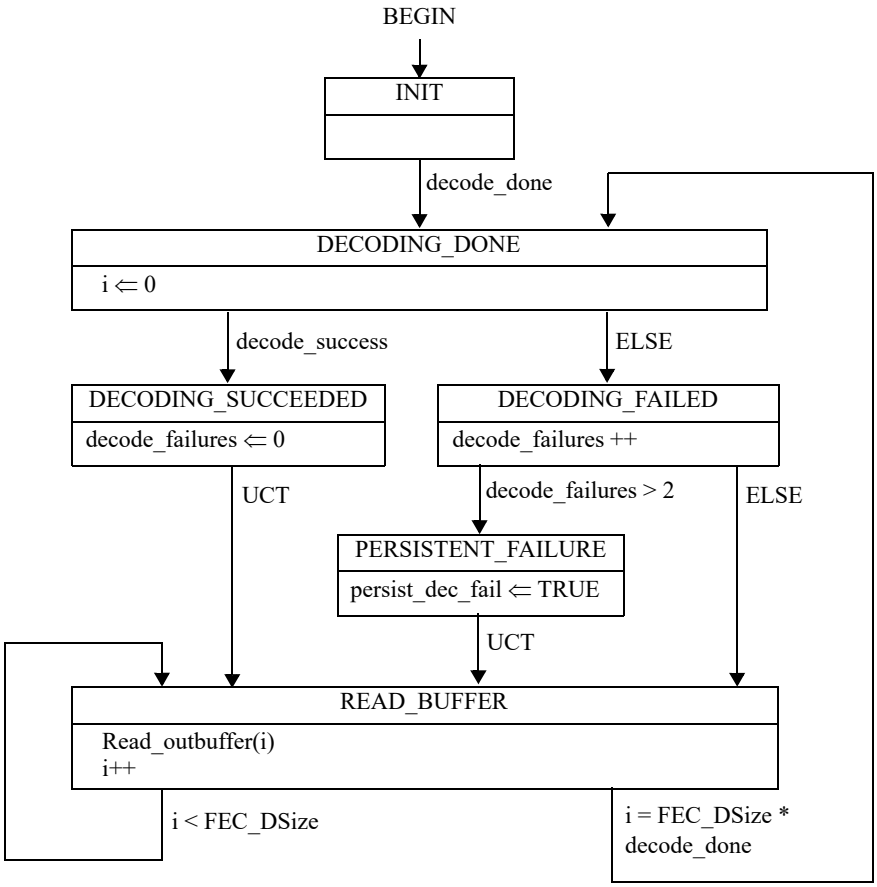

Figure 76–21—FEC decoding process state diagram

76.3.3.4.1 Variables

BER_Monitor_Interval
: Indicates the time window associated with the BER monitor function. The timers in the BER monitor state diagram depend on this configurable variable. This value is reflected in MDIO register 3.80.

ber_test_sh
: This variable is inherited from 49.2.13.2.2.

BER_Threshold
: Indicates the threshold value of invalid sync headers associated with the BER monitor function. When BER_Threshold bad sync headers are encountered within the BER Monitor_Interval period, the BER monitor raises the hi_ber flag. When the number of bad sync headers encountered within the BER_Monitor_interval period less than the BER_Threshold, the hi_ber flag is turned off. This value is reflected in MDIO register 3.82.

hi_ber
: This variable is inherited from 49.2.13.2.2.

reset
: This variable is inherited from 49.2.13.2.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

ber_test_sh
: This variable is inherited from 49.2.13.2.2.

76.3.3.4.2 Timers

State diagram timers follow the conventions of 14.2.3.2.

interval_timer
: Timer that is triggered every BER_monitor_interval μs +1%, –25%.

76.3.3.4.3 Counters

ber_cnt
: This counter is inherited from 49.2.13.2.4.

76.3.3.4.4 State diagrams

The BER monitor state diagram is present only in the ONU. It is shown in Figure 76–22.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

76.3.3.7 Idle Insertion

The receiving PCS inserts the Idle control characters to compensate for the removed FEC parity octets. The Idle Insertion function (see Figure 76–23) receives 72 bit vectors from the 64B/66B decoder and writes them into the Idle Insertion FIFO (called FIFO_II) and reads 72 bit vectors from the FIFO_II and transfers them to the XGMII.

The Idle Insertion process receives 72 bit vectors at a slower rate than the nominal XGMII rate due to the fact that the FEC parity blocks are removed by the FEC decoder and not put through the descrambler and 64B/66B decoder. The Idle Insertion process outputs 72 bit vectors at the nominal XGMII rate. To match the input and output rates, the Idle Insertion process inserts additional 72 bit vectors containing Idle codes. The additional blocks are inserted between packets and not necessarily at the same locations where parity blocks have been removed.

The body of this subclause comprises state diagrams, including the associated definitions of variables, constants, and functions pertinent to the 10GBASE-PR-D, 10GBASE-PR-U and 10/1GBASE-PRX-U PCS receivers. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails. The notation used in the state diagrams in this clause follows the conventions in 21.5.

76.3.3.7.1 Constants

FEC_DSize
: This constant is defined in 76.3.2.1.1.

FEC_PSize
: This constant is defined in 76.3.2.1.1.

FIFO_II_SIZE
: TYPE: 16 bit unsigned
This constant represents the size of Idle Insertion FIFO buffer. This buffer should be able to accommodate the number of 66 bit blocks sufficient to fill the gap introduced by removing the parity blocks from a maximum size MAC frame.
Value: 42

IDLE_VECTOR
: TYPE: 72 bit binary
This constant represents a 72 bit vector containing Idle characters.

LBLOCK_R
: This constant is defined in 49.2.13.2.1.

76.3.3.7.2 Variables

FIFO_II
: TYPE: Array of 72 bit vectors received from 64B/66B decoder.
This FIFO is internal to the Idle Insertion process. Upon initialization, all elements of this array are filled with IDLE_VECTORs. FIFO_II is a zero-based array of size FIFO_II_SIZE (see 76.3.3.7.1).

RX_CLK
: TYPE: Boolean
This variable represents the RX_CLK signal defined in 46.3.2.1.

rx_raw_in<71:0>
: TYPE: 72 bit binary

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Vector received from the output of the 64B/66B decoder. RXD<0> through RXD<31> for the second transfer are placed in rx_raw<40> through rx_raw<71>, respectively.

rx_raw_out<71:0>
TYPE: 72 bit binary
72 bit vector passed from the Idle Insertion process to XGMII. The vector is mapped to two XGMII transfers as follows:
Bits rx_raw<3:0> are mapped to RXC<3:0> for the first transfer;
Bits rx_raw<7:4> are mapped to RXC<3:0> for the second transfer;
Bits rx_raw<39:8> are mapped to RXD<31:0> for the first transfer;
Bits rx_raw<71:40> are mapped to RXD<31:0> for the second transfer.

VectorCount
TYPE: 16 bit unsigned
This variable tracks the number of 72 bit vectors stored in the FIFO_II.

76.3.3.7.3 Functions

T_TYPE(rx_raw)
This function is defined in 49.2.13.2.3.

76.3.3.7.4 Messages

DECODER_UNITDATA.indicate(rx_raw_in<71:0>)
A signal sent by the PCS Receive process conveying the next received 72 bit vector.

DUDI
Alias for DECODER_UNITDATA.indicate(rx_raw_in<71:0>).

76.3.3.7.5 State diagrams

The PCS Idle Insertion function shall implement the state diagram as shown in Figure 76–23. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

76.4 10GBASE-PR and 10/1GBASE-PRX PMA

The 10GBASE-PR PMA is derived from the 10GBASE-R PMA defined in Clause 51. This clause specifies 10GBASE-R extensions necessary to support P2MP operation. The 10/1GBASE-PRX PMA conceptually consists of a combination of transmit and receive functions specified for 10GBASE-PR and 1000BASE-PX defined in 65.3.2, as shown in Table 76–5.

Table 76–5—Derivation of PMA transmit and receive functions for 10GBASE-PR and 10/1GBASE-PRX

PMA	Transmit function	Receive function
10GBASE-PR-U	As specified in Clause 51 with extensions defined in 76.4.1.	
10/1GBASE-PRX-U	Identical to 1000BASE-PX-U. See 65.3.1.	Identical to 10GBASE-PR-U. See 76.4.1.
10GBASE-PR-D	As specified in Clause 51 with extensions defined in 76.4.2.	
10/1GBASE-PRX-D	Identical to 10GBASE-PR-D.	Identical to 1000BASE-PX-D. See 65.3.2.

76.4.1 Extensions for 10GBASE-PR-U and 10/1GBASE-PRX-U

76.4.1.1 Physical Medium Attachment (PMA) sublayer interfaces

In addition to the primitives of Clause 51, the following primitive is defined:

PMA_SIGNAL.request(tx_enable)
: This primitive is mapped to PMD_SIGNAL.request(tx_enable). It is generated by the PCS's Data Detector. The effect of reception of PMD_SIGNAL.request(tx_enable) is defined in 75.3.1.4.

tx_enable
: The tx_enable parameter can take one of two values, ON or OFF.

76.4.1.2 Loop-timing specifications for ONUs

ONUs shall operate at the same time basis as the OLT, i.e., the ONU TX clock tracks the ONU RX clock, which in turn locks to OLT TX clock. Jitter transfer masks are defined in 75.7.

For the 10/1GBASE-PRX-U devices, the received clock PMA_RX_CLK is 644.53125 MHz (10.3125 GBd/16), however, the transmit clock PMA_TX_CLK is 125 MHz (1.25 GBd/10). The loop timing is achieved by multiplying the PMA_RX_CLK by 32 and dividing by 165.

76.4.2 Extensions for 10GBASE-PR-D and 10/1GBASE-PRX-D

76.4.2.1 CDR lock timing measurement for the upstream direction

CDR lock time (denoted T_{CDR}) is defined as a time interval required by the receiver to acquire phase lock on the incoming data stream. T_{CDR} is measured as the time elapsed from the moment when the electrical signal after the PMD at TP8, as illustrated in Figure 75–3, reaches the conditions specified in 75.7.15 for receiver settling time to the moment when the signal phase is recovered and jitter is maintained for a network with BER of no more than 10^{-3}.

A PMA instantiated in an OLT becomes synchronized at the bit level within 400 ns (T_{CDR}) after the appearance of a valid synchronization pattern (as defined in 76.3.2.5.2) at TP8.

76.4.2.1.1 Test specification

The test of the OLT PMA receiver T_{CDR} time assumes that there is an optical PMD transmitter at the ONU with well known T_{on} time as defined in 75.7.14, and an optical PMD receiver at the OLT with well-known $T_{receiver_settling}$ time as defined in 75.7.15. After T_{on} + $T_{receiver_settling}$ time, the parameters at TP8 reach within 15% of their steady state values, measure T_{CDR} as the time from the tx_enable assertion, minus the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

known $T_{on} + T_{receiver_settling}$ time, to the time the electrical signal at the output of the receiving PMA reaches up to the phase difference from the input signal of the transmitting PMA assuring BER of 10^{-3}, and maintaining its jitter specifications. The signal throughout this test is the synchronization pattern, as illustrated in Figure 76–14.

76.5 Protocol implementation conformance statement (PICS) proforma for Clause 76, Reconciliation Sublayer, Physical Coding Sublayer, and Physical Media Attachment for 10G-EPON[139]

76.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 76, Reconciliation Sublayer, Physical Coding Sublayer and Physical Media Attachment for 10G-EPON, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

76.5.2 Identification

76.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

[139]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

76.5.4.3 Preamble mapping and replacement

Item	Feature	Subclause	Value/Comment	Status	Support
PM1	CRC-8 generation	65.1.3.2	CRC calculation produces same result as serial implementation	M	Yes [ ] No [ ]
PM2	CRC-8 initial value	65.1.3.2	CRC shift register initialized to 0x00 before each new calculations	M	Yes [ ] No [ ]
PM3	SLD parsing	76.2.6.1.3.1	If SLD is not found then discard packet	M	Yes [ ] No[ ]
PM4	SLD replacement	76.2.6.1.3.1	Replace SLD with preamble	M	Yes [ ] No [ ]
PM5	LLID matching	76.2.6.1.3.2	If LLID does not match then discard packet	M	Yes [ ] No [ ]
PM6	multicast LLID matching	76.2.6.1.3.2	If multicast LLID matches accept the packet	*FS4 :M	Yes [ ] No [ ]
PM7	LLID replacement	76.2.6.1.3.2	Replace LLID with preamble	M	Yes [ ] No [ ]
PM8	Reserved LLID	76.2.6.1.3.2	Registered ONU shall not transmit frames with a reserved LLID	M	Yes [ ] No [ ]
PM9	CRC-8 checking	65.1.3.3.3	If CRC does not match then discard packet	M	Yes [ ] No [ ]
PM10	CRC-8 replacement	65.1.3.3.3	Replace CRC with preamble	M	Yes [ ] No [ ]

76.5.4.4 Coding Rules

Item	Feature	Subclause	Value/Comment	Status	Support
C1	Encoder implements the code as specified	76.3.2.2		M	Yes [ ] No [ ]
C2	Decoder implements the code as specified	76.3.3.6		M	Yes [ ] No [ ]

76.5.4.5 Data detection

Item	Feature	Subclause	Value/Comment	Status	Support
DD1	Buffer depth	76.3.2.5.1	Depth sufficient to turn on laser and send laser synchronization pattern, Burst Delimiter pattern and a predefined number of Idle control character (receiver settle)	ONU:M	Yes [ ] No [ ]
DD2	OLT laser control	76.3.2.5.5	Always takes the value ON	OLT:M	Yes [ ] No [ ]

77. Multipoint MAC Control for 10G–EPON

77.1 Overview

This clause deals with the mechanism and control protocols required in order to reconcile the 10 Gb/s P2MP topology into the Ethernet framework. The P2MP medium is a passive optical network (PON), an optical network with no active elements in the signal's path from source to destination. The only interior elements used in a PON are passive optical components, such as optical fiber, splices, and splitters. When combined with the Ethernet protocol, such a network is referred to as Ethernet passive optical network (EPON).

P2MP is an asymmetric medium based on a tree (or tree-and-branch) topology. The DTE connected to the trunk of the tree is called optical line terminal (OLT) and the DTEs connected at the branches of the tree are called optical network units (ONU). The OLT typically resides at the service provider's facility, while the ONUs are located at the subscriber premises.

In the downstream direction (from the OLT to an ONU), signals transmitted by the OLT pass through a 1:N passive splitter (or cascade of splitters) and reach each ONU. In the upstream direction (from the ONUs to the OLT), the signal transmitted by an ONU would only reach the OLT, but not other ONUs. To avoid data collisions and increase the efficiency of the subscriber access network, the ONU's transmissions are arbitrated. This arbitration is achieved by allocating a transmission window (grant) to each ONU. An ONU defers transmission until its grant arrives. When the grant arrives, the ONU transmits frames at wire speed during its assigned time slot.

A simplified P2MP topology example is depicted in Figure 77–1. Clause 67 provides additional examples of P2MP topologies.

Topics dealt with in this clause include allocation of upstream transmission resources to different ONUs, discovery and registration of ONUs into the network, and reporting of congestion to higher layers to allow for dynamic bandwidth allocation schemes and statistical multiplexing across the PON.

This clause does not deal with topics including bandwidth allocation strategies, authentication of end-devices, quality-of-service definition, provisioning, or management.

This clause specifies the multipoint control protocol (MPCP) to operate an optical multipoint network by defining a Multipoint MAC Control sublayer as an extension of the MAC Control sublayer defined in Clause 31, and supporting current and future operations as defined in Clause 31and annexes.

Each PON consists of a node located at the root of the tree assuming the role of OLT, and multiple nodes located at the tree leaves assuming roles of ONUs. The network operates by allowing only a single ONU to transmit in the upstream direction at a time. The MPCP located at the OLT is responsible for timing the different transmissions. Reporting of congestion by the different ONUs may assist in optimally allocating the bandwidth across the PON.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Automatic discovery of end stations is performed, culminating in registration through binding of an ONU to an OLT port by allocation of a Logical Link ID (see LLID in 76.2.6.1.3.2), and dynamic binding to a MAC connected to the OLT.

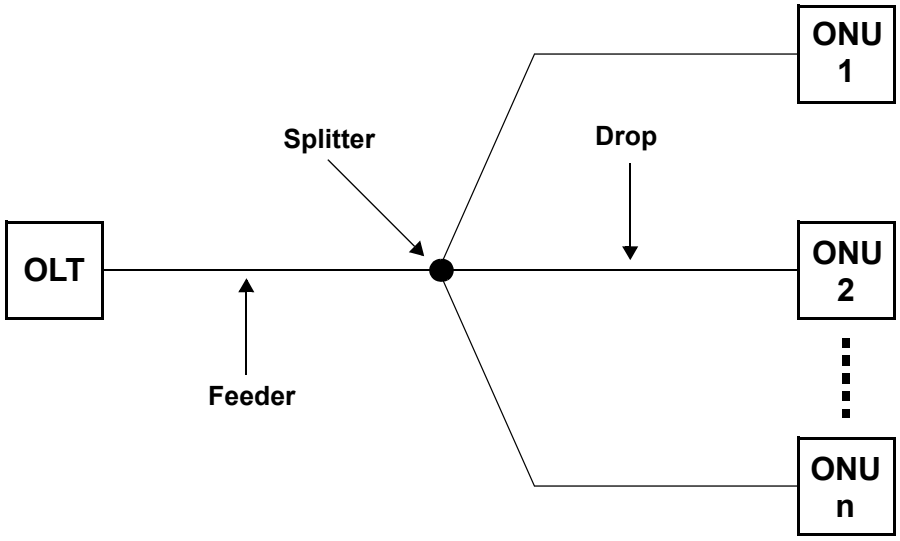

Figure 77–1—PON topology example

The Multipoint MAC Control functionality shall be implemented for subscriber access devices containing point-to-multipoint Physical Layer devices defined in Clause 75.

77.1.1 Goals and objectives

The goals and objectives of this clause are the definition of a point-to-multipoint Ethernet network utilizing an optical medium.

Specific objectives met include the following:

a) Support of point-to-point Emulation (P2PE) as specified
b) Support multiple LLIDs and MAC Clients at the OLT
c) Support a single LLID per ONU
d) Support a mechanism for single copy broadcast
e) Flexible architecture allowing dynamic allocation of bandwidth
f) Use of 32 bit timestamp for timing distribution
g) MAC Control based architecture
h) Ranging of discovered devices for improved network performance
i) Continuous ranging for compensating round trip time variation

77.1.2 Position of Multipoint MAC Control within the IEEE 802.3 hierarchy

Multipoint MAC Control defines the MAC control operation for optical point-to-multipoint networks. Figure 77–2 and Figure 77–3 depict the architectural positioning of the Multipoint MAC Control sublayer with respect to the MAC and the MAC Control client. The Multipoint MAC Control sublayer takes the place of the MAC Control sublayer to extend it to support multiple clients and additional MAC control functionality.

Multipoint MAC Control is defined using the mechanisms and precedents of the MAC Control sublayer. The MAC Control sublayer has extensive functionality designed to manage the real-time control and manipulation of MAC sublayer operation. This clause specifies the extension of the MAC Control

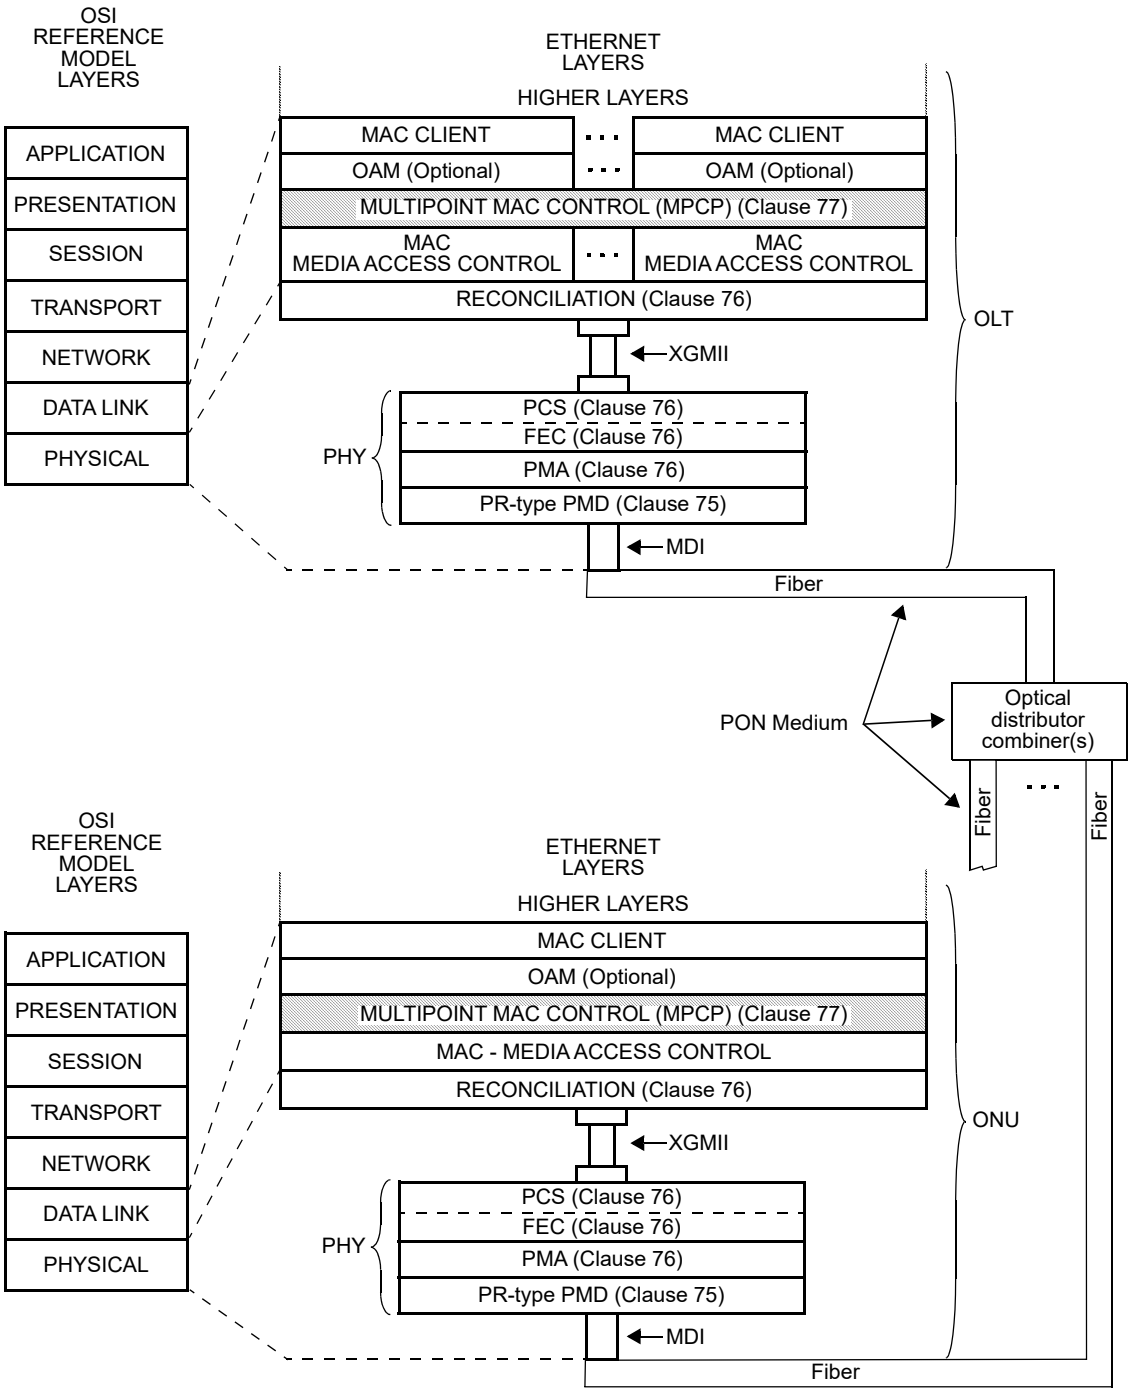
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mechanism to manipulate multiple underlying MACs simultaneously. This clause also specifies a specific protocol implementation for MAC Control.



The Multipoint MAC Control sublayer is specified such that it can support new functions to be implemented and added to this standard in the future. MultiPoint Control Protocol (MPCP), the management protocol for P2MP is one of these protocols. Non-real-time, or quasi-static control (e.g., configuration of MAC operational parameters) is provided by Layer Management. Operation of the Multipoint MAC Control sublayer is transparent to the MAC.

As depicted in Figure 77–2 and Figure 77–3, the layered system instantiates multiple MAC entities, using a single Physical Layer. The individual MAC instances offer a point-to-point emulation service between the OLT and the ONU. An additional MAC is instantiated to communicate to all 10G–EPON ONUs at once. This instance takes maximum advantage of the broadcast nature of the downstream channel by sending a single copy of a frame that is received by all 10G–EPON ONUs. This MAC instance is referred to as Single Copy Broadcast (SCB).

The ONU only requires one MAC instance since frame filtering operations are done at the RS layer before reaching the MAC. Therefore, MAC and layers above are emulation-agnostic at the ONU (see 76.2.6.1.3).

Although Figure 77–2 and Figure 77–3 and supporting text describe multiple MACs within the OLT, a single unicast MAC address may be used by the OLT. Within the EPON Network, MACs are uniquely identified by their LLIDs, which are dynamically assigned by the registration process.

77.1.4 Service interfaces

The MAC Client communicates with the Control Multiplexer using the standard service interface specified in 2.3. Multipoint MAC Control communicates with the underlying MAC sublayer using the standard service interface specified in Annex 4A.3.2. Similarly, Multipoint MAC Control communicates internally using primitives and interfaces consistent with definitions in Clause 31.

77.1.5 State diagram conventions

The body of this standard comprises state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2 augmented as follows:

a) [start x_timer, y] sets expiration of *y* to timer *x_timer*.
b) [stop x_timer] aborts the timer operation for *x_timer* asserting *x_timer_not_done* indefinitely.

The state diagrams use an abbreviation MACR as a shorthand form for MA_CONTROL.request and MACI as a shorthand form for MA_CONTROL.indication.

The vector notations used in the state diagrams for bit vector use 0 to mark the first received bit and so on (for example data[0:15]), following the conventions of 3.1 for bit ordering. When referring to an octet vector, 0 is used to mark the first received octet and so on (for example m_sdu[0..1]).

a < *b:* A function that is used to compare two (cyclic) time values. Returned value is true when *b* is larger than *a* allowing for wrap around of *a* and *b*. The comparison is made by subtracting *b* from *a* and testing the MSB. When MSB(*a*–*b*) = 1 the value true is returned, else false is returned. In addition, the following functions are defined in terms of *a* < *b*:
a > *b* is equivalent to !(*a* < *b* or *a* = *b*)
a ≥ *b* is equivalent to !(*a* < *b*)
a ≤ *b* is equivalent to !(*a* > *b*)

77.2 Multipoint MAC Control operation

As depicted in Figure 77–4, the Multipoint MAC Control functional block comprises the following functions:

a) *Multipoint Transmission Control*. This block is responsible for synchronizing Multipoint MAC Control instances associated with the Multipoint MAC Control. This block maintains the Multipoint MAC Control state and controls the multiplexing functions of the instantiated MACs.
b) *Multipoint MAC Control Instance n*. This block is instantiated for each MAC and respective MAC and MAC Control clients associated with the Multipoint MAC Control. It holds all the variables and state associated with operating all MAC Control protocols for the instance.
c) *Control Parser*. This block is responsible for parsing MAC Control frames, and interfacing with Clause 31 entities, the opcode specific blocks, and the MAC Client.
d) *Control Multiplexer*. This block is responsible for selecting the source of the forwarded frames.
e) *Clause 31 annexes*. This block holds MAC Control actions as defined in Clause 31 annexes for support of legacy and future services.
f) *Discovery, Report, and Gate Processing*. These blocks are responsible for handling the MPCP in the context of the MAC.

77.2.1 Principles of Multipoint MAC Control

As depicted in Figure 77–4, Multipoint MAC Control sublayer may instantiate multiple Multipoint MAC Control instances in order to interface multiple MAC and MAC Control clients above with multiple MACs below. A unique unicast MAC instance is used at the OLT to communicate with each ONU. The individual MAC instances utilize the point-to-point emulation service between the OLT and the ONU as defined in 76.2.

At the ONU, a single MAC instance is used to communicate with a MAC instance at the OLT. In that case, the Multipoint MAC Control contains only a single instance of the Control Parser/Multiplexer function.

Multipoint MAC Control protocol supports several MAC and client interfaces. Only a single MAC interface and Client interface is enabled for transmission at a time. There is a tight mapping between a MAC service interface and a Client service interface. In particular, the assertion of the MAC:MA_DATA.indication primitive in MAC *j* leads to the assertion of the MCF:MA_DATA.indication primitive to Client *j*. Conversely, the assertion of the request service interface in Client *i* leads to the assertion of the MAC:MA_DATA.request primitive of MAC *i*. Note that the Multipoint MAC sublayer need not receive and transmit packets associated with the same interface at the same time. Thus the Multipoint MAC Control acts like multiple MAC Controls bound together with common elements.

The scheduling algorithm is implementation dependent, and is not specified for the case where multiple transmit requests happen at the same time.

The reception operation is as follows. The Multipoint MAC Control instances generate MAC:MA_DATA.indication service primitives continuously to the underlying MAC instances. Since these MACs are receiving frames from a single PHY only one frame is passed from the MAC instances to Multipoint MAC Control. The MAC instance responding to the MAC:MA_DATA.indication is referred to as the enabled MAC, and its service interface is referred to as the enabled MAC interface. The MAC passes to the Multipoint MAC Control sublayer all valid frames. Invalid frames, as specified in 3.4, are not passed to the Multipoint MAC Control sublayer in response to a MAC:MA_DATA.indication service primitive.

The enabling of a transmit service interface is performed by the Multipoint MAC Control instance in collaboration with the Multipoint Transmission Control. Frames generated in the MAC Control are given priority over MAC Client frames, in effect, prioritizing the MA_CONTROL primitive over the MCF:MA_DATA primitive, and for this purpose MCF:MA_DATA.request primitives may be delayed, discarded or modified in order to perform the requested MAC Control function. For the transmission of this frame, the Multipoint MAC Control instance enables forwarding by the MAC Control functions, but the MAC Client interface is not enabled. The reception of a frame in a MAC results in generation of the MAC:MA_DATA.indication primitive on that MAC's interface. Only one receive MAC interface is enabled at any given time since there is only one PHY interface.

The information of the enabled interfaces is stored in the controller state variables, and accessed by the Multiplexing Control block.

The Multipoint MAC Control sublayer uses the services of the underlying MAC sublayer to exchange both data and control frames.

Receive operation (MAC:MA_DATA.indication) at each instance:

a) A frame is received from the underlying MAC
b) The frame is parsed according to Length/Type field
c) MAC Control frames are demultiplexed according to opcode and forwarded to the relevant processing functions
d) Data frames (see 31.5.1) are forwarded to the MAC Client by asserting MCF:MA_DATA.indication primitives

Transmit operation (MAC:MA_DATA.request) at each instance:

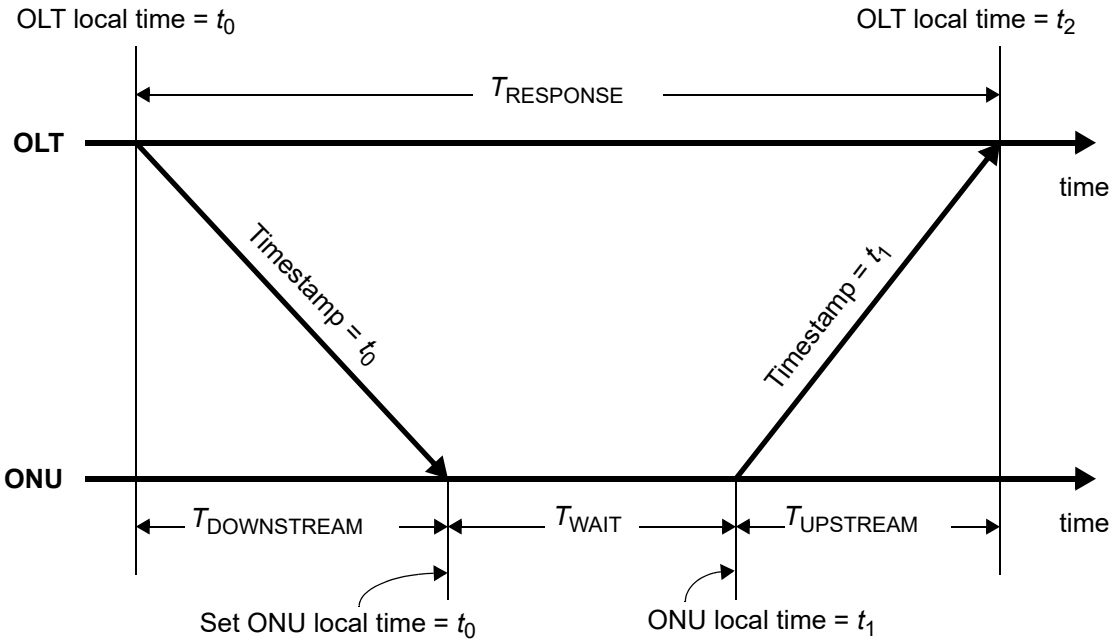
Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

e) The MAC Client signals a frame transmission by asserting MCF:MA_DATA.request, or

f) A protocol processing block attempts to issue a frame, as a result of a previous MA_CONTROL.request or as a result of an MPCP event that generates a frame.

g) When allowed to transmit by the Multipoint Transmission Control block, the frame is forwarded.

77.2.1.1 Ranging and timing process



Both the OLT and the ONU have 32 bit counters that increment every 16 ns. These counters provide a local time stamp. When either device transmits an MPCPDU, it maps its counter value into the timestamp field. The time of transmission of the first octet of the MPCPDU frame from the MAC Control to the MAC is taken as the reference time used for setting the timestamp value.

When the ONU receives MPCPDUs, it sets its counter according to the value in the timestamp field in the received MPCPDU.

When the OLT receives MPCPDUs, it uses the received timestamp value to calculate or verify a round trip time between the OLT and the ONU. The Round Trip Time (RTT) is equal to the difference between the timer value and the value in the timestamp field. The calculated RTT is notified to the client via the MA_CONTROL.indication primitive. The client can use this RTT for the ranging process.

A condition of *timestamp drift error* occurs when the difference between OLT's and ONU's clocks exceeds some predefined threshold. This condition can be independently detected by the OLT or an ONU. The OLT detects this condition when an absolute difference between new and old RTT values measured for a given ONU exceeds the value of guardThresholdOLT (see 77.2.2.1), as shown in Figure 77–11. An ONU detects the timestamp drift error condition when absolute difference between a timestamp received in an MPCPDU and the localTime counter exceeds guardThresholdONU (see 77.2.2.1), as is shown in Figure 77–12.

$T_{DOWNSTREAM}$ = downstream propagation delay

$T_{UPSTREAM}$ = upstream propagation delay

T_{WAIT} = wait time at ONU = $t_1 - t_0$

$T_{RESPONSE}$ = response time at OLT = $t_2 - t_0$

$$RTT = T_{DOWNSTREAM} + T_{UPSTREAM} = T_{RESPONSE} - T_{WAIT} = (t_2 - t_0) - (t_1 - t_0) = t_2 - t_1$$

Figure 77–5—Round trip time calculation

77.2.2 Multipoint transmission control, Control Parser, and Control Multiplexer

The purpose of the multipoint transmission control is to allow only one of the multiple MAC clients to transmit to its associated MAC and subsequently to the RS layer at one time by only asserting one transmitEnable signal at a time.

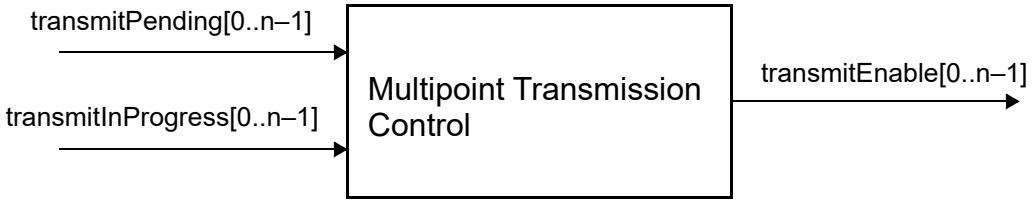

Figure 77–6—Multipoint Transmission Control service interfaces

Copyright © 2022 IEEE. All rights reserved.

Multipoint MAC Control Instance n function block communicates with the Multipoint Transmission Control using transmitEnable[n], transmitPending[n], and transmitInProgress[n] state variables (see Figure 77–4).

The Control Parser is responsible for opcode independent parsing of MAC frames in the reception path. By identifying MAC Control frames, demultiplexing into multiple entities for event handling is possible. Interfaces are provided to existing Clause 31 entities, functional blocks associated with MPCP, and the MAC Client.

The Control Multiplexer is responsible for forwarding frames from the MAC Control opcode-specific functions and the MAC Client to the MAC. Multiplexing is performed in the transmission direction. Given multiple MCF:MA_DATA.request primitives from the MAC Client, and MA_CONTROL.request primitives from the MAC Control Clients, a single MAC:MA_DATA.request service primitive is generated for transmission. At the OLT, multiple MAC instances share the same Multipoint MAC Control, as a result, the transmit block is enabled based on an external control signal housed in Multipoint Transmission Control for transmission overlap avoidance. At the ONU, the Gate Processing functional block interfaces for upstream transmission administration.

77.2.2.1 Constants

FEC_CODEWORD_SIZE
TYPE: integer
This constant represents the size of FEC codeword in octets (FEC_PAYLOAD_SIZE + FEC_PARITY_SIZE).
Value: 248

FEC_PARITY_SIZE
TYPE: integer
This constant represents the size of FEC codeword parity field in octets.
Value: 32

FEC_PAYLOAD_SIZE
TYPE: integer
This constant represents the size of FEC codeword payload in octets.
VALUE: 216

guardThresholdOLT
TYPE: integer
This constant holds the maximum amount of drift allowed for a timestamp received at the OLT. This value is measured in units of time_quantum.
VALUE: 12

guardThresholdONU
TYPE: integer
This constant holds the maximum amount of drift allowed for a timestamp received at the ONU. This value is measured in units of time_quantum.
VALUE: 8

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

MAC_Control_type
TYPE: integer
The value of the Length/Type field as defined in 31.4.1.3.
VALUE: 0x8808

tailGuard
TYPE: integer
This constant holds the value used to reserve space at the end of the upstream transmission at the ONU in addition to the size of last MAC service data unit (m_sdu) in units of octets. Space is allocated for the MAC overheads including: preamble, SFD, DA, SA, Length/Type, FCS, and minimum interpacket gap. The sizes of the above listed MAC overhead items are described in 3.1.1. The size of the minimum IPG is described in 4A.4.2.
VALUE: 38

time_quantum
This variable is defined in 64.2.2.1.

tqSize
TYPE: integer
This constant represents time_quantum in octet transmission times.
VALUE: 20

77.2.2.2 Counters

localTime
TYPE: 32 bit unsigned
This variable holds the value of the local timer used to control MPCP operation. This variable is advanced by a timer at 62.5 MHz, and counts in time_quanta. At the OLT the counter shall track the transmit clock, while at the ONU the counter shall track the receive clock. For accuracy of receive clock see 76.4.1.2. It is reloaded with the received timestamp value (from the OLT) by the Control Parser (see Figure 77–12). Changing the value of this variable while running using Layer Management is highly undesirable and is unspecified.

77.2.2.3 Variables

BEGIN
TYPE: Boolean
This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset.

fecOffset
TYPE: 32 bit unsigned
A variable that advances by 1 after every 8 bit times. After reaching the value of FEC_CODEWORD_SIZE, this variable is reset to zero. In the OLT, this variable is initialized to 0 at system initialization. In the ONU, this variable is assigned in the ONU Control Multiplexer state diagram (see Figure 77–14).
NOTE—Notation fecOffset[1:0] refers to two least significant bits of this variable.

data_rx
TYPE: bit array
This variable represents a 0–based bit array corresponding to the payload of a received MPCPDU. This variable is used to parse incoming MPCPDU frames.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

data_tx

TYPE: bit array

This variable represents a 0-based bit array corresponding to the payload of an MPCPDU being transmitted. This variable is used to access payload of outgoing MPCPDU frames, for example to set the timestamp value.

flags_rx

TYPE: 8-bit unsigned

This variable holds the value of the Flags field from the last received MPCPDU.

grantStart

TYPE: Boolean

This variable indicates beginning of a grant transmission. It is set to true in the GATE Processing ONU Activation state diagram (see Figure 77–30) when a new grant activates. It is reset to false after the transmission of the first frame in the grant (see Figure 77–14). This variable is defined in ONU only.

IdleGapCount

TYPE: 32-bit unsigned

This variable represents length of gap between subsequent frames, expressed in the unit of octet time. This variable advances by 1 after every 8-bit times.

newRTT

TYPE: 16 bit unsigned

This variable temporary holds a newly–measured Round Trip Time to the ONU. The new RTT value is represented in units of time_quanta.

m_sdu_rx

TYPE: bit array

Equal to the concatenation of the Length/Type and data_rx variables.

m_sdu_tx

TYPE: bit array

Equal to the concatenation of the Length/Type and data_tx variables.

m_sdu_ctl

TYPE: bit array

Equal to the concatenation of the MAC_Control_type and data_tx variables.

OctetsRemaining

TYPE: 32 bit unsigned

This variable is an alias for the expression (((stopTime – localTime) × tqSize) – tqOffset). It denotes the number of octets that can be transmitted between the current time and the end of the grant.

OctetsRequired

TYPE: 16 bit unsigned

This variable represents a total transmission time of next packet and is used to check whether the next packet fits in the remainder of ONU's transmission window. The value of OctetsRequired includes packet transmission time, tailGuard defined in 77.2.2.1, and FEC parity data overhead. This variable is measured in units of octets.

opcode_rx

TYPE: 16 bit unsigned

This variable holds an opcode of the last received MPCPDU.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

opcode_tx
: TYPE: 16 bit unsigned
This variable holds an opcode of an outgoing MPCPDU.

packet_initiate_delay
: TYPE: 16 bit unsigned
This variable is used to set the time–out interval for packet_initiate_timer defined in 77.2.2.5. The packet_initiate_delay value is represented in units of octets.

ResetBound
: TYPE: 32-bit unsigned
This variable represents the value of DelayBound (see 76.3.1.2) expressed in units of octet time (i.e., ResetBound = 8 * DelayBound).

RTT
: TYPE: 16 bit unsigned
This variable holds the measured Round Trip Time to the ONU. The RTT value is represented in units of time_quanta.

stopTime
: TYPE: 32 bit unsigned
This variable holds the value of the localTime counter corresponding to the end of the nearest grant. This value is set by the Gate Processing function as described in 77.3.5.

timestamp
: TYPE: 32 bit unsigned
This variable holds the value of timestamp of the last received MPCPDU frame.

timestampDrift
: TYPE: Boolean
This variable is used to indicate whether an error is signaled as a result of uncorrectable timestamp drift.

tqOffset
: TYPE: 8 bit unsigned
This variable denotes the offset (in octet times) of the current actual time from the localTime variable (which maintains the current time in units of time_quanta).

transmitAllowed
: TYPE: Boolean
This variable is used to control PDU transmission at the ONU. It is set to true when the transmit path is enabled, and is set to false when the transmit path is being shut down. transmitAllowed changes its value according to the state of the Gate Processing functional block.

transmitEnable
: TYPE: Boolean array
This array contains one element per each Multipoint MAC Control instance. Elements of this array are used to control the transmit path in the Multipoint MAC Control instance at the OLT. Setting an element to TRUE indicates that the selected instance is permitted to transmit a frame. Setting it to FALSE inhibits the transmission of frames in the selected instance. Only one element of transmitEnable should be set to TRUE at a time.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transmitInProgress
TYPE: Boolean array
This array contains one element per each Multipoint MAC Control instance. The element *j* of this array set to on indicates that the Multipoint MAC Control instance *j* is in the process of transmitting a frame.

transmitPending
TYPE: Boolean array
This array contains one element per each Multipoint MAC Control instance. The element *j* of this array set to on indicates that the Multipoint MAC Control instance *j* is ready to transmit a frame.

77.2.2.4 Functions

abs(n)
This function returns the absolute value of the parameter n.

Opcode–specific function(opcode)
Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

CheckGrantSize(length)
This function calculates the future time at which the transmission of the current frame (including the FEC parity overhead) is completed.

$$\text{CheckGrantSize(length)} = \left\lceil \frac{\text{fecOffset} + \text{length}}{\text{FEC_PAYLOAD_SIZE}} \right\rceil \times \text{FEC_CODEWORD_SIZE} - \text{fecOffset}$$

NOTE—The notation $\lceil x \rceil$ represents a *ceiling* function, which returns the value of its argument *x* rounded up to the nearest integer.

FEC_Overhead(length)
This function calculates the additional amount of time (in octet times) that the MPCP control multiplexer waits following transmission of a frame of size 'length' by the MAC. The additional time is added to allow the insertion of parity data into the frame by the PHY layer. As described in 76.3.2.4, FEC encoder adds 32 parity octets for each block of 216 data or control octets. FEC_Overhead() returns the number of octets that the PHY inserts during transmission of a particular packet and its subsequent IPG. Parameter 'length' represents the size of an entire frame including preamble, SFD, DA, SA, Length/Type, FCS, and IPG. The following formula is used to calculate the overhead:

$$\text{FEC_Overhead(length)} = 12 + \text{FEC_PARITY_SIZE} \times \left\lfloor \frac{\text{fecOffset} + \text{length}}{\text{FEC_PAYLOAD_SIZE}} \right\rfloor$$

NOTE—The notation $\lfloor x \rfloor$ represents a *floor* function, which returns the value of its argument *x* rounded down to the nearest integer.

select()
This function selects the next Multipoint MAC Control instance allowed to initiate transmission of a frame. The function returns an index to the transmitPending array for which the value is not false. The selection criteria in the presence of multiple active elements in the list is implementation dependent.

SelectFrame()
This function enables the interface, which has a pending frame. If multiple interfaces have frames waiting at the same time, only one interface is enabled. The selection criteria is not specified,

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

except for the case when some of the pending frames have Length/Type = MAC_Control. In this case, one of the interfaces with a pending MAC Control frame shall be enabled.

sizeof(sdu)
: This function returns the size of the sdu in octets.

transmissionPending()
: This function returns true if any of the Multipoint MAC Control instances has a frame waiting to be transmitted. The function can be represented as:

```
transmissionPending() =
   transmitPending[0] +
   transmitPending[1] +
   ... +
   transmitPending[n-1]
```

where n is the total number of Multipoint MAC Control instances.

77.2.2.5 Timers

packet_initiate_timer
: This timer is used to delay frame transmission from MAC Control to avoid variable MAC delay while MAC enforces IPG after a previous frame. In addition, this timer increases interframe spacing just enough to accommodate the extra parity data to be added by the FEC encoder.

77.2.2.6 Messages

MAC:MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: The service primitive is defined in 31.3.

MCF:MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: The service primitive is defined in 31.3.

MAC:MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 31.3. The action invoked by this service primitive is not considered to end until the transmission of the frame by the MAC has concluded. The ability of the MAC control layer to determine this is implementation dependent.

MCF:MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 31.3.

77.2.2.7 State diagrams

The Multipoint transmission control function in the OLT shall implement state diagram shown in Figure 77–10. Control parser function in the OLT shall implement state diagram shown in Figure 77–11. Control parser function in the ONU shall implement state diagram shown in Figure 77–12. Control multiplexer function in the OLT shall implement state diagram shown in Figure 77–13. Control multiplexer function in the ONU shall implement state diagram shown in Figure 77–14.

77.3 Multipoint Control Protocol (MPCP)

As depicted in Figure 77–4, the Multipoint MAC Control functional block comprises the following functions:

a) *Discovery Processing*. This block manages the discovery process, through which an ONU is discovered and registered with the network while compensating for RTT.
b) *Report Processing*. This block manages the generation and collection of report messages, through which bandwidth requirements are sent upstream from the ONU to the OLT.
c) *Gate Processing*. This block manages the generation and collection of gate messages, through which multiplexing of multiple transmitters is achieved.

As depicted in Figure 77–4, the layered system may instantiate multiple MAC entities, using a single Physical Layer. Each instantiated MAC communicates with an instance of the opcode specific functional blocks through the Multipoint MAC Control. In addition some global variables are shared across the multiple instances. Common state control is used to synchronize the multiple MACs using MPCP procedures. Operation of the common state control is generally considered outside the scope of this document.

77.3.1 Principles of Multipoint Control Protocol

Multipoint MAC Control enables a MAC Client to participate in a point-to-multipoint optical network by allowing it to transmit and receive frames as if it was connected to a dedicated link. In doing so, it employs the following principles and concepts:

a) A MAC client transmits and receives frames through the Multipoint MAC Control sublayer.
b) The Multipoint MAC Control decides when to allow a frame to be transmitted using the client interface Control Multiplexer.
c) Given a transmission opportunity, the MAC Control may generate control frames that would be transmitted in advance of the MAC Client's frames, utilizing the inherent ability to provide higher priority transmission of MAC Control frames over MAC Client frames.
d) Multiple MACs operate on a shared medium by allowing only a single MAC to transmit upstream at any given time across the network using a time-division multiple access (TDMA) method.
e) Such gating of transmission is orchestrated through the Gate Processing function.
f) New devices are discovered in the network and allowed transmission through the Discovery Processing function.
g) Fine control of the network bandwidth distribution can be achieved using feedback mechanisms supported in the Report Processing function.
h) The operation of P2MP network is asymmetric, with the OLT assuming the role of master, and the ONU assuming the role of slave.

77.3.2 Compatibility considerations

77.3.2.1 PAUSE operation

Even though MPCP is compatible with flow control, optional use of flow control may not be efficient in the case of large propagation delay. If flow control is implemented, then the timing constraints in Annex 31B supplement the constraints found at 77.3.2.4.

NOTE—MAC at an ONU can receive frames from unicast channel and SCB channel. If the SCB channel is used to broadcast data frames to multiple ONUs, the ONU's MAC may continue receiving data frames from SCB channel even after the ONU has issued a PAUSE request to its unicast remote-end.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

77.3.2.2 Optional Shared LAN emulation

By combining P2PE, suitable filtering rules at the ONU, and suitable filtering and forwarding rules at the OLT, it is possible to emulate an efficient shared LAN. Support for shared LAN emulation is optional, and requires an additional layer above the MAC, which is out of scope for this document. Thus, shared LAN emulation is introduced here for informational purposes only.

Specific behavior of the filtering layer at the RS is specified in 76.2.6.1.3.2.

77.3.2.3 Multicast and single copy broadcast support

In the downstream direction, the PON is a broadcast medium. In order to make use of this capability for forwarding broadcast frames from the OLT to multiple recipients without multiple duplication for each ONU, the SCB and multicast LLID support is introduced.

The OLT has at least one MAC associated with every ONU. In addition one more MAC at the OLT is marked as the SCB MAC. Moreover, the OLT has a multicast MAC associated with each defined multicast LLID. The SCB MAC handles all downstream broadcast traffic, but is never used in the upstream direction for client traffic, except for client registration. Similarly, the multicast MACs handle downstream multicast traffic, but are never used in the upstream direction for client traffic. Optional higher layers may be implemented to perform selective broadcast and multicast of frames. Such layers may require additional MACs (multicast MACs) to be instantiated in the OLT for some or all ONUs increasing the total number of MACs beyond the number of ONUs + 1.

When connecting the SCB MAC or a multicast MAC to an IEEE 802.1Q bridge port it is possible that loops may be formed due to the broadcast or multicast nature of the associated LLIDs. Thus it is recommended that this MAC not be connected to an IEEE 802.1Q bridge port.

Configuration of SCB channels as well as filtering and marking of frames for support of SCB is defined in 76.2.6.1.3.2 for 10G–EPON compliant Reconciliation Sublayers.

77.3.2.4 Delay requirements

The MPCP protocol relies on strict timing based on distribution of timestamps. A compliant implementation needs to guarantee a constant delay through the MAC and PHY in order to maintain the correctness of the timestamping mechanism. The actual delay is implementation dependent; however, a complying implementation shall maintain a delay variation of no more than 1 time_quantum through the MAC.

The OLT shall not grant less than 1024 time_quanta into the future, in order to allow the ONU processing time when it receives a gate message. The ONU shall process all messages in less than this period. The OLT shall not issue more than one message every 1024 time_quanta to a single ONU. The unit of time_quantum is defined in 77.2.2.1.

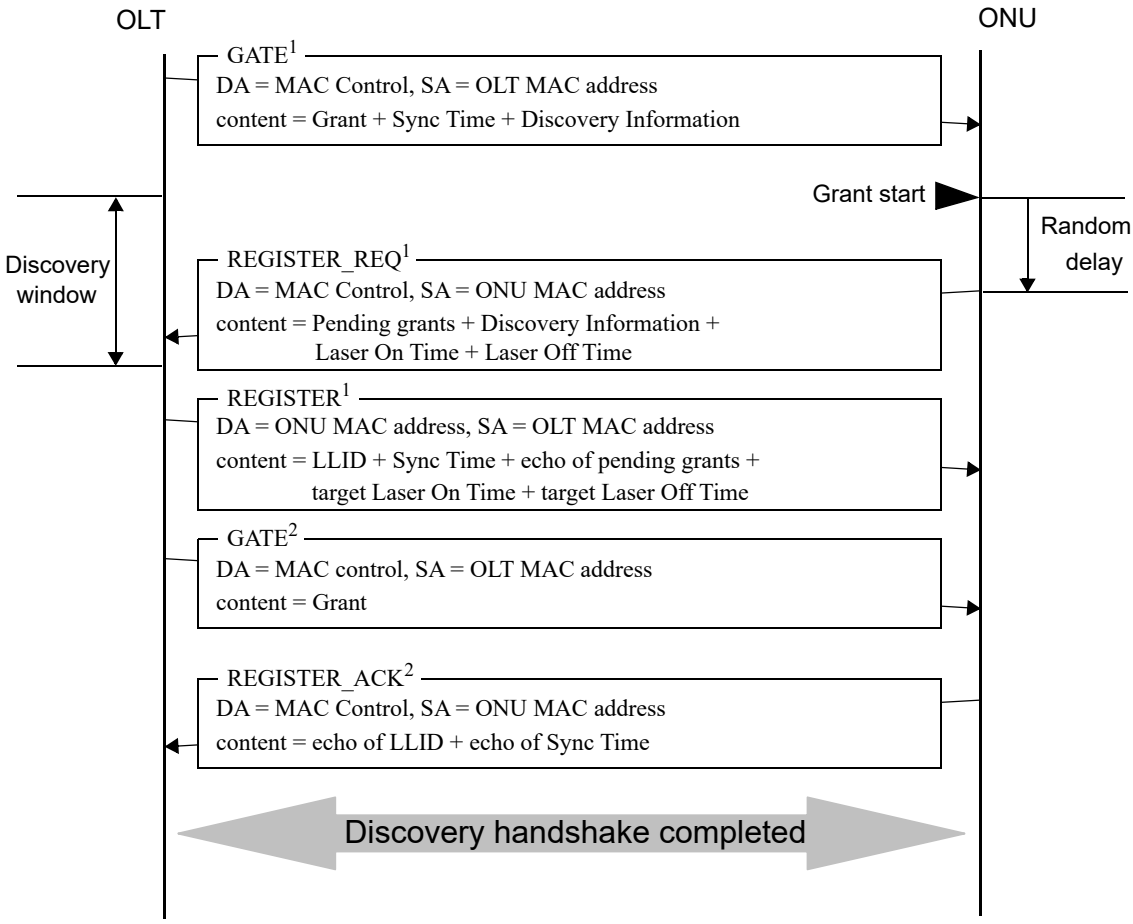
77.3.3 Discovery processing

Discovery is the process whereby newly connected or off-line ONUs are provided access to the PON. The process is driven by the OLT, which periodically makes available Discovery Windows during which off-line ONUs are given the opportunity to make themselves known to the OLT. The periodicity of these windows is unspecified and left up to the implementer. The OLT signifies that a discovery period is occurring by broadcasting a discovery GATE MPCPDU, which includes the starting time and length of the discovery window, along with the Discovery Information flag field, as defined in 77.3.6.1. With the appropriate settings of individual flags contained in this 16 bit wide field, the OLT notifies all the ONUs about its upstream and downstream channel transmission capabilities. Note that the OLT may simultaneously support more than one data rate in the given transmission direction.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Off-line ONUs, upon receiving a Discovery GATE MPCPDU, wait for the period to begin and then transmit a REGISTER_REQ MPCPDU to the OLT. Discovery windows are unique in that they are the only times when multiple ONUs can access the PON simultaneously, and transmission overlap can occur. In order to reduce transmission overlaps, a contention algorithm is used by all ONUs. Measures are taken to reduce the probability for overlaps by artificially simulating a random distribution of distances from the OLT. Each ONU waits a random amount of time before transmitting the REGISTER_REQ MPCPDU that is shorter than the length of the discovery window. It should be noted that multiple valid REGISTER_REQ MPCPDUs can be received by the OLT during a single discovery window. Included in the REGISTER_REQ MPCPDU is the ONU's MAC address and number of maximum pending grants. Additionally, a registering ONU notifies the OLT of its transmission capabilities in the upstream and downstream channels by setting appropriately the flags in the Discovery Information field, as specified in 77.3.6.3.

Note that even though a compliant ONU is not prohibited from supporting more than one data rate in any transmission channel, it is expected that a single supported data rate for upstream and downstream channel is indicated in the Discovery Information field. Moreover, in order to assure maximum utilization of the upstream channel and to decrease the required size of the guard band between individual data bursts, the registering ONU notifies the OLT of the laser on/off times, by setting appropriate values in the Laser On Time and Laser Off Time fields, where both values are expressed in the units of time_quanta.



Upon receipt of a valid REGISTER_REQ MPCPDU, the OLT registers the ONU, allocating and assigning a new port identity (LLID), and bonding a corresponding MAC to the LLID.

The next step in the process is for the OLT to transmit a REGISTER MPCPDU to the newly discovered ONU, which contains the ONU's LLID, and the OLT's required synchronization time. Moreover, the OLT echoes the maximum number of pending grants. The OLT also sends the target value of laser on time and laser off time, which may be different than laser on time and laser off time delivered by the ONU in the REGISTER_REQ MPCPDU.

The OLT now has enough information to schedule the ONU for access to the PON and transmits a standard GATE message allowing the ONU to transmit a REGISTER_ACK. Upon receipt of the REGISTER_ACK, the discovery process for that ONU is complete, the ONU is registered and normal message traffic can begin. It is the responsibility of Layer Management to perform the MAC bonding, and start transmission from/to the newly registered ONU. The discovery message exchange is illustrated in Figure 77–15.

There may exist situations when the OLT requires that an ONU go through the discovery sequence again and reregister. Similarly, there may be situations where an ONU needs to inform the OLT of its desire to deregister. The ONU can then reregister by going through the discovery sequence. For the OLT, the REGISTER message may indicate a value, Reregister or Deregister, that if either is specified forces the receiving ONU into reregistering. For the ONU, the REGISTER_REQ message contains the Deregister bit that signifies to the OLT that this ONU should be deregistered.

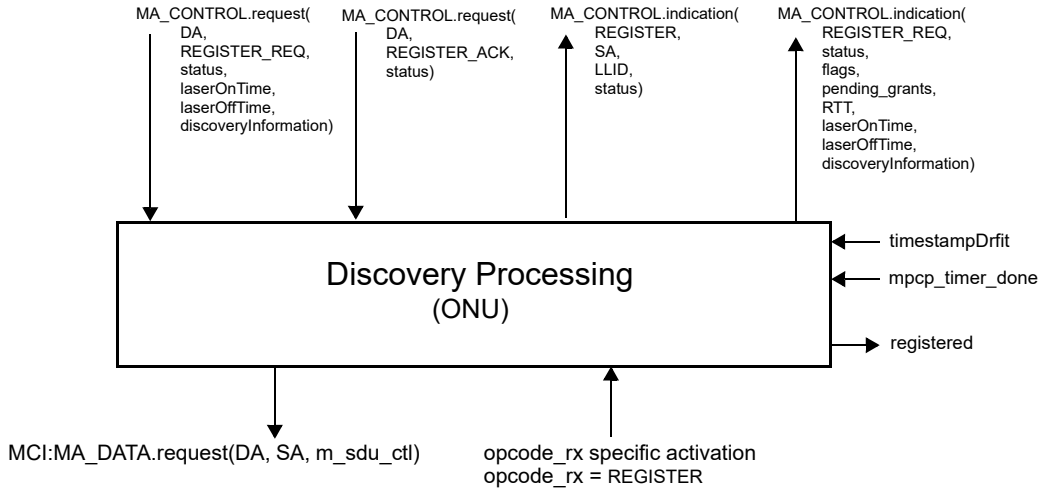

Figure 77–18—Discovery Processing service interfaces (ONU)

77.3.3.1 Constants

laserOffTimeCapability

TYPE: 8 bit unsigned

This constant represents the time required to terminate the laser, in units of time_quantum. While the default value corresponds to a maximum allowed T_{off} (as specified in Table 75–8 and Table 75–9), implementations may set it to the actual value time period required for turning off the PMD, as specified in 75.7.14.

VALUE: 0x20 (512 ns, default value)

laserOnTimeCapability

TYPE: 8 bit unsigned

This constant represents the time required to initialize the laser, in units of time_quantum. While the default value corresponds to a maximum allowed T_{on} (as specified in Table 75–8 and Table 75–9), implementations may set it to the actual value time period required for turning on the PMD, as specified in 75.7.14.

VALUE: 0x20 (512 ns, default value)

77.3.3.2 Variables

BEGIN

This variable is defined in 77.2.2.3.

data_rx

This variable is defined in 77.2.2.3.

data_tx

This variable is defined in 77.2.2.3.

grantEndTime

TYPE: 32 bit unsigned

This variable holds the time at which the OLT expects the ONU grant to complete. Failure of a

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

REGISTER_ACK message from an ONU to arrive at the OLT before grantEndTime is a fatal error in the discovery process, and causes registration to fail for the specified ONU, who may then retry to register. The value of grantEndTime is measured in units of time_quantum.

insideDiscoveryWindow

TYPE: Boolean

This variable holds the current status of the discovery window. It is set to true when the discovery window opens, and is set to false when the discovery window closes.

laserOffTime

TYPE: 8 bit unsigned

This variable holds the time required to terminate the laser. It counts in time_quanta units the time period required for turning off the PMD, as specified by the value of T_{off} in 75.7.14.

VALUE: laserOffTimeCapability (default value)

laserOnTime

TYPE: 8 bit unsigned

This variable holds the time required to initiate the PMD. It counts in time_quanta units the time period required for turning on the PMD, as specified by the value of T_{on} in 75.7.14.

VALUE: laserOnTimeCapability (default value)

localTime

This variable is defined in 77.2.2.2.

m_sdu_ctl

This variable is defined in 77.2.2.3.

opcode_rx

This variable is defined in 77.2.2.3.

pendingGrants

TYPE: 16 bit unsigned

This variable holds the maximum number of pending grants that an ONU is able to queue.

registered

TYPE: Boolean

This variable holds the current result of the Discovery Process. It is set to true once the discovery process is complete and registration is acknowledged.

syncTime

TYPE: 16 bit unsigned

This variable holds the time required to stabilize the receiver at the OLT. It counts time_quanta units from the point where transmission output is stable to the point where synchronization has been achieved. The value of syncTime includes gain adjustment interval ($T_{receiver_settling}$), clock synchronization interval (T_{CDR}), and code–group alignment interval ($T_{code_group_align}$), as specified in 75.7.14. The OLT conveys the value of syncTime to ONUs in Discovery GATE and REGISTER messages. During the synchronization time a 10/1G–EPON ONU transmits only IDLE patterns, and a 10/10G–EPON ONU sends synchronization pattern (SP, see 76.3.2.5.2) followed by burst delimiter pattern (BURST_DELIMITER, see 76.3.2.5.2).

timestampDrift

This variable is defined in 77.2.2.3.

77.3.3.3 Functions

None.

77.3.3.4 Timers

discovery_window_size_timer
: This timer is used to wait for the event signaling the end of the discovery window.
VALUE: The timer value is set dynamically based on the parameters received in a DISCOVERY GATE message.

mpcp_timer
: This timer is used to measure the arrival rate of MPCP frames in the link. Failure to receive frames is considered a fatal fault and leads to deregistration.

77.3.3.5 Messages

MA_DATA.indication(DA, SA, m_sdu, receiveStatus)
: The service primitive is defined in 2.3.2.

MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, GATE, discovery, start, length, discovery_length, sync_time, discoveryInformation)
: The service primitive is used by the MAC Control client at the OLT to initiate the Discovery Process. This primitive takes the following parameters:

DA:	Multicast or unicast MAC address.
GATE:	Opcode for GATE MPCPDU as defined in Table 31A–1.
discovery:	Flag specifying that the given GATE message is to be used for discovery only.
start:	Start time of the discovery window.
length:	Length of the grant given for discovery.
discovery_length:	Length of the discovery window process.
sync_time:	The time interval required to stabilize the receiver at the OLT.
discoveryInformation:	This parameter represents the Discovery Information field in GATE MPCPDU as specified in 77.3.6.1, defining the speed(s) the OLT is capable of receiving and speed(s) at which the discovery window is opened for.

MA_CONTROL.request(DA, GATE, grant_number, start[4], length[4], force_report[4])
: This service primitive is used by the MAC Control client at the OLT to issue the GATE message to an ONU. This primitive takes the following parameters:

DA:	Multicast MAC Control address as defined in Annex 31B.
GATE:	Opcode for GATE MPCPDU as defined in Table 31A–1.
grant_number:	Number of grants issued with this GATE message. The number of grants ranges from 0 to 4.
start[4]:	Start times of the individual grants. Only the first grant_number elements of the array are used.
length[4]:	Lengths of the individual grants. Only the first grant_number elements of the array are used.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

force_report[4]: Flags indicating whether a REPORT message should be generated in the corresponding grant. Only the first grant_number elements of the array are used.

MA_CONTROL.request(DA, REGISTER_REQ, status, laserOnTime, laserOffTime, discoveryInformation)

The service primitive is used by a client at the ONU to request the Discovery Process to perform a registration. This primitive takes the following parameters:

DA: Multicast MAC Control address as defined in Annex 31B.

REGISTER_REQ: opcode for REGISTER_REQ MPCPDU as defined in Table 31A–1.

status: This parameter takes on the indication supplied by the flags field in the REGISTER_REQ MPCPDU as defined in Table 77–5.

laserOnTime: This parameter holds the laserOnTime value, expressed in units of time_quanta, as reported by MAC client and specified in 77.3.6.3.

laserOffTime: This parameter holds the laserOffTime value, expressed in units of time_quanta, as reported by MAC client and specified in 77.3.6.3.

discoveryInformation: This parameter represents the Discovery Information field, as specified in 77.3.6.3, defining the speed(s) the ONU is capable of transmitting and speed(s) at which the registration attempt is made.

MA_CONTROL.indication(REGISTER_REQ, status, flags, pending_grants, RTT, laserOnTime, laserOffTime, discoveryInformation)

The service primitive is issued by the Discovery Process to notify the client and Layer Management that the registration process is in progress. This primitive takes the following parameters:

REGISTER_REQ: Opcode for REGISTER_REQ MPCPDU as defined in Table 31A–1.

status: This parameter holds the values incoming or retry. Value incoming is used at the OLT to signal that a REGISTER_REQ message was received successfully. The value retry is used at the ONU to signal to the client that a registration attempt failed and needs to be repeated.

flags: This parameter holds the contents of the flags field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

pending_grants: This parameter holds the contents of the pending_grants field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

RTT: The measured round trip time to/from the ONU is returned in this parameter. RTT is stated in time_quanta units. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

laserOnTime: This parameter holds the contents of the laserOnTime field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

laserOffTime: This parameter holds the contents of the laserOffTime field in the REGISTER_REQ message. This parameter holds a valid value only when the primitive is generated by the Discovery Process in the OLT.

discoveryInformation: This parameter holds the contents of the Discovery Information field in the REGISTER_REQ MPCPDU. This parameter holds a valid value only when the primitive is generated by the Discovery process in the OLT.

MA_CONTROL.request(DA, REGISTER, LLID, status, pending_grants, laserOnTime, laserOffTime)

The service primitive is used by the MAC Control client at the OLT to initiate acceptance of an ONU. This primitive takes the following parameters:

DA: Unicast MAC address or multicast MAC Control address as defined in Annex 31B.

REGISTER: Opcode for REGISTER MPCPDU as defined in Table 31A–1.

LLID: This parameter holds the logical link identification number assigned by the MAC Control client.

status: This parameter takes on the indication supplied by the flags field in the REGISTER MPCPDU as defined in Table 77–7.

pending_grants: This parameters echoes back the pending_grants field that was previously received in the REGISTER_REQ message.

laserOnTime: This parameter carries the target value of Laser On Time for the given ONU transmitter. This value may be different than the laserOnTime value carried in the REGISTER_REQ MPCPDU received from the corresponding ONU MAC during Discovery stage.

laserOffTime: This parameter carries the target value of Laser Off Time for the given ONU transmitter. This value may be different than the laserOffTime value carried in the REGISTER_REQ MPCPDU received from the corresponding ONU MAC during Discovery stage.

MA_CONTROL.indication(REGISTER, SA, LLID, status)

This service primitive is issued by the Discovery Process at the OLT or an ONU to notify the MAC Control client and Layer Management of the result of the change in registration status. This primitive takes the following parameters:

REGISTER: Opcode for REGISTER MPCPDU as defined in Table 31A–1.

SA: This parameter represents the MAC address of the OLT.

LLID: This parameter holds the logical link identification number assigned by the MAC Control client.

status: This parameter holds the value of accepted / denied / deregistered / reregistered.

MA_CONTROL.request(DA, REGISTER_ACK, status)

This service primitive is issued by the MAC Control clients at the ONU and the OLT to acknowledge the registration. This primitive takes the following parameters:

DA: Multicast MAC Control address as defined in Annex 31B.

REGISTER_ACK: Opcode for REGISTER_ACK MPCPDU as defined in Table 31A–1.

status: This parameter takes on the indication supplied by the flags field in the REGISTER MPCPDU as defined in Table 77–8.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

MA_CONTROL.indication(REGISTER_ACK, SA, LLID, status, RTT)

This service primitive is issued by the Discovery Process at the OLT to notify the client and Layer Management that the registration process has completed. This primitive takes the following parameters:

REGISTER_ACK:	Opcode for REGISTER_ACK MPCPDU as defined in Table 31A–1.
SA:	This parameter represents the MAC address of the reciprocating device (ONU address at the OLT, and OLT address at the ONU).
LLID:	This parameter holds the logical link identification number assigned by the MAC Control client.
status:	This parameter holds the value of accepted/denied/reset/deregistered.
RTT:	The measured round trip time to/from the ONU is returned in this parameter. RTT is stated in time_quanta units. This parameter holds a valid value only when the invoking Discovery Process in the OLT.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

77.3.3.6 State Diagrams

The Discovery Process in the OLT shall implement the discovery window setup state diagram shown in Figure 77–19, request processing state diagram as shown in Figure 77–20, register processing state diagram as shown in Figure 77–21, and final registration state diagram as shown in Figure 77–22. The discovery process in the ONU shall implement the registration state diagram as shown in Figure 77–23.

Instantiation of state diagrams as described in Figure 77–19, Figure 77–20, and Figure 77–21 is performed only at the Multipoint MAC Control instances attached to the broadcast LLID (0x7FFE). Instantiation of state diagrams as described in Figure 77–22 and Figure 77–23 is performed for every Multipoint MAC Control instance, except the instance attached to the broadcast channel.

77.3.4 Report Processing

The Report Processing functional block has the responsibility of dealing with queue report generation and termination in the network. Reports are generated by higher layers and passed to the MAC Control sublayer by the MAC Control clients. Status reports are used to signal bandwidth needs as well as for arming the OLT watchdog timer.

Reports shall be generated periodically, even when no request for bandwidth is being made. This keeps a watchdog timer in the OLT from expiring and deregistering the ONU. For proper operation of this mechanism the OLT shall grant the ONU periodically.

The Report Processing functional block, and its MPCP protocol elements are designed for use in conjunction with an IEEE 802.1P capable bridge.

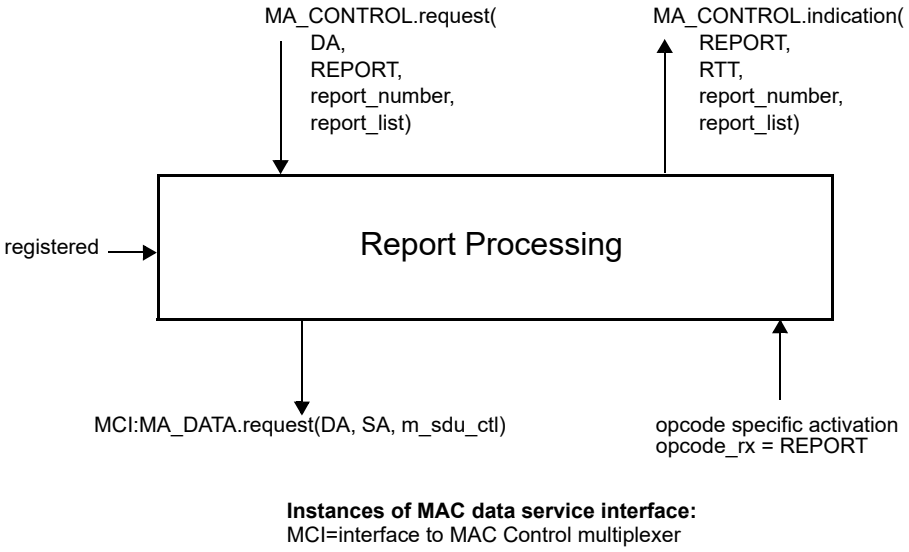

Figure 77–24—Report Processing service interfaces

77.3.4.1 Constants

None.

77.3.4.2 Variables

BEGIN
: TYPE: Boolean
This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset.

data_rx
: This variable is defined in 77.2.2.3.

data_tx
: This variable is defined in 77.2.2.3.

m_sdu_ctl
: This variable is defined in 77.2.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

mpcp_timeout
TYPE: 32 bit unsigned
This variable represents the maximum allowed interval of time between two MPCPDU messages. Failure to receive at least one frame within this interval is considered a fatal fault and leads to deregistration. This variable is expressed in units of time_quanta.
VALUE: 0x03B9ACA0 (1 s, default value)

opcode_rx
This variable is defined in 77.2.2.3.

registered
This variable is defined in 77.3.3.2.

report_timeout
TYPE: 32 bit unsigned
This variable represents the maximum allowed interval of time between two REPORT messages generated by the ONU, expressed in units of time_quanta.
VALUE: 0x002FAF08 (50 ms, default value)

77.3.4.3 Functions

None.

77.3.4.4 Timers

report_periodic_timer
ONUs are required to generate REPORT MPCPDUs with a periodicity of less than report_timeout value. This timer counts down time remaining before a forced generation of a REPORT message in an ONU.

mpcp_timer
This timer is defined in 77.3.3.4.

77.3.4.5 Messages

MA_DATA.request (DA, SA, m_sdu)
The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, REPORT, report_number, report_list)
This service primitive is used by a MAC Control client to request the Report Process at the ONU to transmit a queue status report. This primitive may be called at variable intervals, independently of the granting process, in order to reflect the time varying aspect of the network. This primitive uses the following parameters:

DA:	Multicast MAC Control address as defined in Annex 31B.
REPORT:	Opcode for REPORT MPCPDU as defined in Table 31A–1.
report_number:	The number of queue status report sets located in report list. The report_number value ranges from 0 to a maximum of 13.
report_list:	The list of queue status reports. A queue status report consists of two fields: valid and status. The parameter valid is a Boolean array of length of 8. The index of an element of this array reflects the numbered priority queue in the IEEE 802.1P nomenclature. An element with the value of '0' or false indicates that the corresponding status field is not present (the

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

length of status field is 0),while '1' or true indicates that the corresponding status field is present (the length of status field is 2 octets). The parameter status is an array of 16 bit unsigned integer values. This array consists only of entries whose corresponding bit in field valid is set to true.

MA_CONTROL.indication(REPORT, RTT, report_number, report_list)

The service primitive is issued by the Report Process at the OLT to notify the MAC Control client and higher layers the queue status of the MPCP link partner. This primitive may be called multiple times, in order to reflect the time–varying aspect of the network. This primitive uses the following parameters:

REPORT: Opcode for REPORT MPCPDU as defined in Table 31A–1.

RTT: This parameter holds an updated round trip time value that is recalculated following each REPORT message reception.

report_number: The number of queue status report sets located in report list. The report_number value ranges from 0 to a maximum of 13.

report_list: The list of queue status reports. A queue status report consists of two fields: valid and status. The parameter valid is a Boolean array of length of 8. The index of an element of this array reflects the numbered priority queue in the IEEE 802.1P nomenclature. An element with the value of '0' or false indicates that the corresponding status field is not present (the length of status field is 0),while '1' or true indicates that the corresponding status field is present (the length of status field is 2 octets). The parameter status is an array of 16 bit unsigned integer values. This array consists only of entries whose corresponding bit in field valid is set to true.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

77.3.4.6 State diagrams

The report process in the OLT shall implement the report processing state diagram as shown in Figure 77–25. The report process in the ONU shall implement the report processing state diagram as shown in Figure 77–26. Instantiation of state diagrams as described is performed for Multipoint MAC Control instances attached to unicast LLIDs only.

Figure 77–26—Report Processing state diagram at ONU

77.3.5 Gate Processing

A key concept pervasive in Multipoint MAC Control is the ability to arbitrate a single transmitter out of a plurality of ONUs. The OLT controls an ONU's transmission by the assigning of grants.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The transmitting window of an ONU is indicated in the GATE message where start time and length are specified. An ONU begins transmission when its localTime counter matches the start_time value indicated in the GATE message. An ONU concludes its transmission with sufficient margin to ensure that the laser is turned off before the grant length interval has elapsed.

Multiple outstanding grants may be issued to each ONU. The OLT shall not issue more than the maximum supported maximum outstanding grants as advertised by the ONU during registration (see pending grants in 77.3.6.3).

In order to maintain the watchdog timer at the ONU, grants are periodically generated. For this purpose empty GATE messages may be issued periodically.

When registered, the ONU ignores all gate messages where the Discovery flag is set.

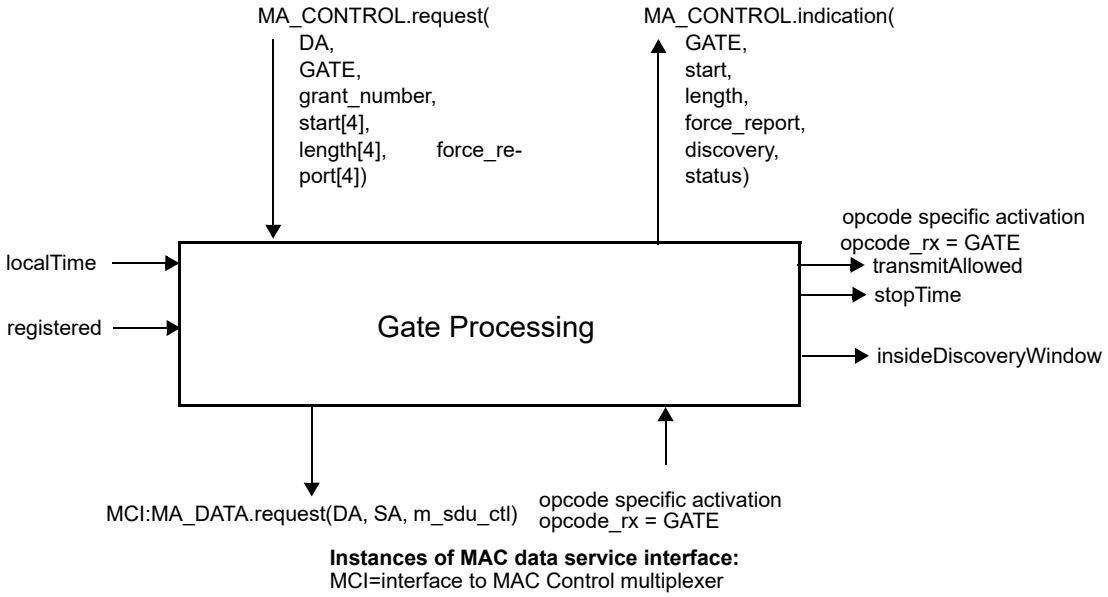

Figure 77–27—Gate Processing service interface

77.3.5.1 Constants

max_future_grant_time
: TYPE: 32 bit unsigned
This constant holds the time limiting the future time horizon for a valid incoming grant.
VALUE: 0x03B9ACA0 (1 s)

min_processing_time
: TYPE: 32 bit unsigned
This constant is the time required for the ONU processing time.
VALUE: 0x00000400 (16.384 μs)

minGrantLength
: TYPE: 32 bit unsigned
This constant represents the minimum data portion of a grant. The minGrantLength is equal to one FEC codeword (see FEC_CODEWORD_SIZE in 77.2.2.1), less the initial 16 idle octets, expressed

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

in units of time_quanta. The minimum grant length accepted by an ONU is equal to minGrantLength + BurstOverhead (see 77.3.5.2).
VALUE: 12

tqSize
This constant is defined in 77.2.2.1.

77.3.5.2 Variables

BEGIN
TYPE: Boolean
This variable is used when initiating operation of the functional block state diagram. It is set to true following initialization and every reset.

BurstOverhead
TYPE: integer
This variable represents the burst overhead and equals the sum of laserOnTime, laserOffTime, syncTime and an additional two time_quanta to account for END_BURST_DELIMITER and two leading IDLE vectors of the payload. This variable is expressed in units of time_quanta.

counter
TYPE: integer
This variable is used as a loop iterator counting the number of incoming grants in a GATE message.

currentGrant
TYPE:

```
structure
{
    DA:           48 bit unsigned, a.k.a MAC address type
    start         32 bit unsigned
    length        16 bit unsigned
    force_report  Boolean
    discovery     Boolean
}
```

This variable is used for local storage of a pending grant state during processing. It is dynamically set by the Gate Processing functional block and is not exposed.
The state is a structure field composed of multiple subfields.

data_rx
This variable is defined in 77.2.2.3.

data_tx
This variable is defined in 77.2.2.3.

effectiveLength
TYPE: 32 bit unsigned
This variable is used for temporary storage of a normalized net time value. It holds the net effective length of a grant normalized for elapsed time, and compensated for the periods required to turn the laser on and off, and waiting for receiver lock.

gate_timeout
TYPE: 32 bit unsigned
This variable represents the maximum allowed interval of time between two GATE messages gen-

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

erated by the OLT to the same ONU, expressed in units of time_quanta.
VALUE: 0x002FAF08 (50 ms, default value)

grantList
TYPE: list of elements having the structure define in currentGrant
This variable is used for storage of the list of pending grants. It is dynamically set by the Gate Processing functional block and is not exposed. Each time a grant is received it is added to the list. The list elements are structure fields composed of multiple subfields. The list is indexed by the start subfield in each element for quick searches.

grantStart
This variable is defined in 77.2.2.3.

insideDiscoveryWindow
This variable is defined in 77.3.3.2.

maxDelay
TYPE: 16 bit unsigned
This variable holds the maximum delay that can be applied by an ONU before sending the REGISTER_REQ MPCPDU. This delay is calculated such that the ONU would have sufficient time to transmit the REGISTER_REQ message and its associated overhead (FEC parity data, end-of-frame sequence, etc.) and terminate the laser before the end of the discovery grant.

m_sdu_ctl
This variable is defined in 77.2.2.3.

nextGrant
TYPE: element having same structure as defined in currentGrant
This variable is used for local storage of a pending grant state during processing. It is dynamically set by the Gate Processing functional block and is not exposed. The content of the variable is the next grant to become active.

nextStopTime
TYPE: 32 bit unsigned
This variable holds the value of the localTime counter corresponding to the end of the next grant.

opcode_rx
This variable is defined in 77.2.2.3.

registered
This variable is defined in 77.3.3.2.

stopTime
This variable is defined in 77.2.2.3.

syncTime
This variable is defined in 77.3.3.2.

transmitAllowed
This variable is defined in 77.2.2.3.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

77.3.5.3 Functions

empty(list)

This function is use to check whether the list is empty. When there are no elements queued in the list, the function returns true. Otherwise, a value of false is returned.

confirmDiscovery(data)

This function is used to check whether the current Discovery Window is open for the given ONU (TRUE) or not (FALSE). This function returns values as shown in Table 77–1.

Table 77–1—Operation of the confirmDiscovery(data) function

OLT Discovery Information: Discovery Window		ONU Tx capability		confirmDiscovery(data) returns
1G	10G	1G	10G	
X	1	0	1	TRUE
1	X	1	0	TRUE
0	1	1	0	FALSE
1	0	0	1	FALSE
0	0	X	X	FALSE[a]

[a]These particular values for the Discovery Window fields should not be normally generated by the OLT.

InsertInOrder(sorted_list, inserted_element)

This function is used to queue an element inside a sorted list. The queuing order is sorted. In the condition that the list is full the element may be discarded. The length of the list is dynamic and it's maximum size equals the value advertised during registration as maximum number of pending grants.

IsBroadcast(grant)

This function is used to check whether its argument represents a broadcast grant, i.e., grant given to multiple ONUs. This is determined by the destination MAC address of the corresponding GATE message. The function returns the value true when MAC address is a global assigned MAC Control address as defined in Annex 31B, and false otherwise.

PeekHead(sorted_list)

This function is used to check the content of a sorted list. It returns the element at the head of the list without dequeuing the element.

Random(r)

This function is used to compute a random integer number uniformly distributed between 0 and r. The randomly generated number is then returned by the function.

RemoveHead(sorted_list)

This function is used to dequeue an element from the head of a sorted list. The return value of the function is the dequeued element.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

77.3.5.4 Timers

gntWinTmr
: This timer is used to wait for the event signaling the end of a grant window.
VALUE: The timer value is dynamically set according to the signaled grant length.

gate_periodic_timer
: The OLT is required to generate GATE MPCPDUs with a periodicity of less than gate_timeout value. This timer counts down time remaining before a forced generation of a GATE message in the OLT.

mpcp_timer
: This timer is defined in 77.3.3.4.

rndDlyTmr
: This timer is used to measure a random delay inside the discovery window. The purpose of the delay is to a priori reduce the probability of transmission overlap during the registration process, and thus lowering the expectancy of registration time in the PON.
VALUE: A random value less than the net discovery window size less the REGISTER_REQ MPCPDU frame size less the idle period and laser turn on and off delays less the preamble size less the IFG size. The timer value is set dynamically based on the parameters passed from the client.

77.3.5.5 Messages

MA_DATA.request (DA, SA, m_sdu)
: The service primitive is defined in 2.3.2.

MA_CONTROL.request(DA, GATE, grant_number, start[4], length[4], force_report[4])
: This service primitive is defined in 77.3.3.5.

MA_CONTROL.indication(GATE, start, length, force_report, discovery, status)
: This service primitive issued by the Gate Process at the ONU to notify the MAC Control client and higher layers that a grant is pending. This primitive is invoked multiple times when a single GATE message arrives with multiple grants. It is also generated at the start and end of each grant as it becomes active. This primitive uses the following parameters:

GATE:	Opcode for GATE MPCPDU as defined in Table 31A–1.
start:	start time of the grant. This parameter is not present when the parameter *status* value is equal to *deactive*.
length:	Length of the grant. This parameter is not present when the parameter *status* value is equal to *deactive*.
force_report:	Flags indicating whether a REPORT message should be transmitted in this grant. This parameter is not present when the parameter *status* value is equal to *deactive*.
discovery:	This parameter holds the value true when the grant is to be used for the discovery process, and false otherwise. This parameter is not present when the parameter *status* value is equal to *deactive*.
status:	This parameter takes the value *arrive* on grant reception, *active* when a grant becomes active, and *deactive* at the end of a grant.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Opcode-specific function(opcode)

Functions exported from opcode specific blocks that are invoked on the arrival of a MAC Control message of the appropriate opcode.

77.3.5.6 State diagrams

The gating process in the OLT shall implement the Gate processing state diagram as shown in Figure 77–28. The gating process in the ONU shall implement the Gate processing state diagram as shown in Figure 77–29 and Figure 77–30. Instantiation of state diagrams as described is performed for all Multipoint MAC Control instances.

Instances of MAC data service interface:
MCI=interface to MAC Control multiplexer

77.3.6 MPCPDU structure and encoding

The MPCPDU structure shall be as shown in Figure 77–31, and is further defined in the following definitions:

a) Destination Address (DA). The DA in MPCPDU is the MAC Control Multicast address as specified in the annexes to Clause 31, or the individual MAC address associated with the port to which the MPCPDU is destined.

b) Source Address (SA). The SA in MPCPDU is the individual MAC address associated with the port through which the MPCPDU is transmitted. For MPCPDUs originating at the OLT end, this can be the address any of the individual MACs. These MACs may all share a single unicast address, as explained in 77.1.2.

c) Length/Type. The Length/Type in MPCPDUs carries the MAC_Control_Type field value as specified in 31.4.1.3.

d) Opcode. The opcode identifies the specific MPCPDU being encapsulated. Values are defined in Table 31A–1.

e) Timestamp. The timestamp field conveys the content of the localTime register at the time of transmission of the MPCPDUs. This field is 32 bits long and counts time in units of time_quanta.

f) Data/Reserved/PAD. These 40 octets are used for the payload of the MPCPDUs. When not used they would be filled with zeros on transmission, and be ignored on reception.

g) FCS. This field is the Frame Check Sequence, typically generated by the underlying MAC.
Based on the MAC instance used to generate the specific MPCPDU, the appropriate LLID shall be generated by the RS.

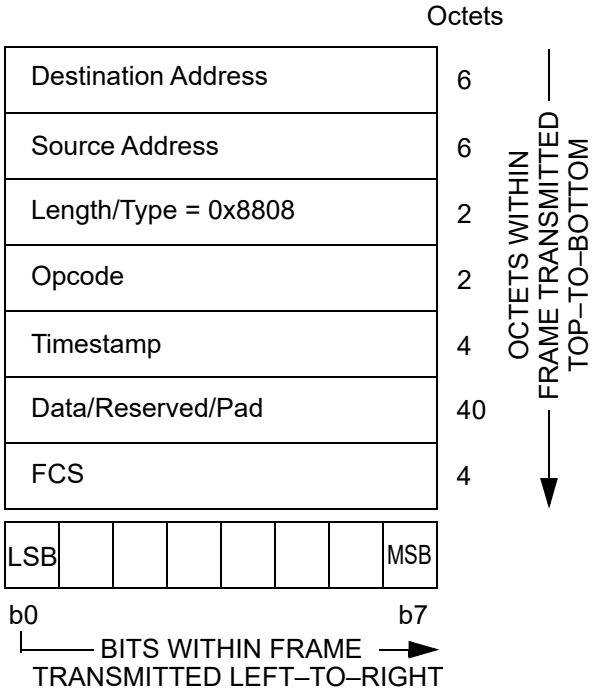

Figure 77–31—Generic MPCPDU

77.3.6.1 GATE description

The purpose of GATE message is to grant transmission windows to ONUs for both discovery messages and normal transmission. Up to four grants can be included in a single GATE message. The number of grants can also be set to zero for using the GATE message as an MPCP keep alive from OLT to the ONU.

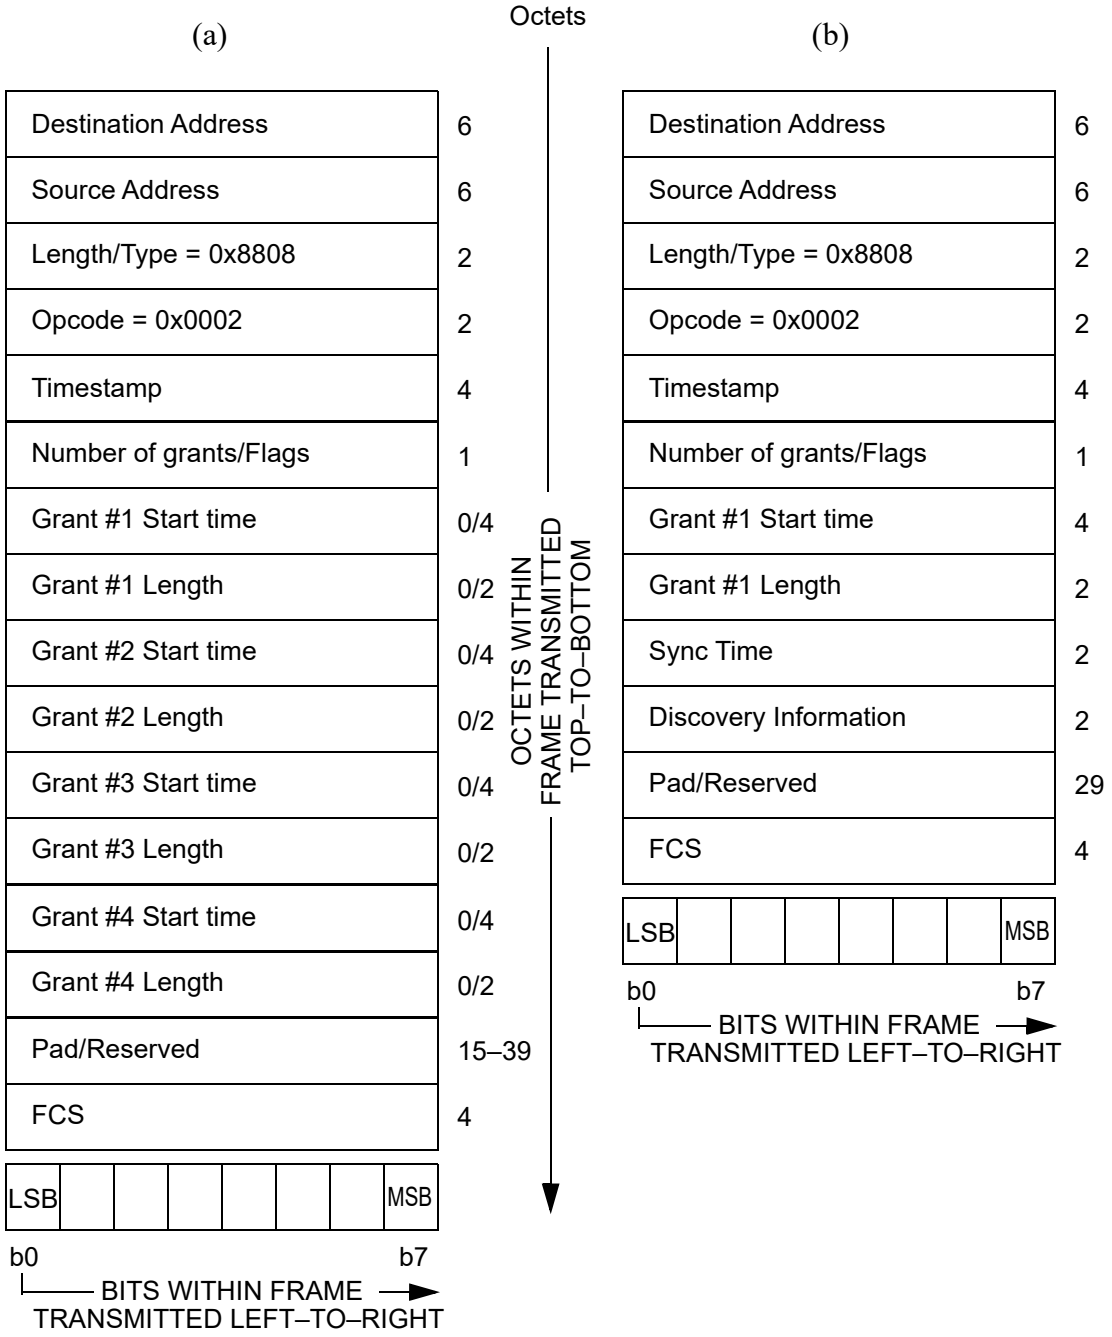

Figure 77–32—GATE MPCPDU: (a) normal GATE MPCPDU, (b) discovery GATE MPCPDU

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The GATE MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the GATE MPCPDU is 0x0002.

b) Flags. This is an 8 bit flag register that holds the following flags: As presented in Table 77–2, the Number of grants field contains the number of grants, composed of valid Length, Start Time pairs in this MPCPDU. This is a number between 0 and 4.

NOTE—When Number of grants is set to 0, sole purpose of message is conveying of timestamp to ONU.

The Discovery flag field indicates that the signaled grants would be used for the discovery process, in which case a single grant shall be issued in the GATE message.
The Force Report flag fields ask the ONU to issue a REPORT message related to the corresponding grant number at the corresponding transmission opportunity indicated in this GATE.

Table 77–2—GATE MPCPDU Number of grants/flags fields

Bit	Flag field	Values
0–2	Number of grants	0 – 4
3	Discovery	0 – Normal GATE 1 – Discovery GATE
4	Force Report Grant 1	0 – No action required 1 – A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 1
5	Force Report Grant 2	0 – No action required 1 – A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 2
6	Force Report Grant3	0 – No action required 1 – A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 3
7	Force Report Grant 4	0 – No action required 1 – A REPORT frame should be issued at the corresponding transmission opportunity indicated in Grant 4

c) Grant #n Start Time. This 32 bit unsigned field represents the start time of the grant. The start time is compared to the local clock, to correlate the start of the grant. Transmitted values shall satisfy the condition Grant #n Start Time < Grant #n+1 Start Time for consecutive grants within the same GATE MPCPDU.

d) Grant #n Length. This 16 bit unsigned field represents the length of the grant. The length is counted in 1 time_quantum increments. There are 4 Grants that are possibly packed into the GATE MPCPDU. The laserOnTime, syncTime, laserOffTime, two initial Idle blocks, FEC parity overhead, and burst terminator sequence (composed of three END_BURST_DELIMITER blocks) are included in and thus consume part of the Grant #n length.

e) Sync Time. This is an unsigned 16 bit value signifying the required synchronization time of the OLT receiver. The ONU calculates the effective grant length by subtracting the syncTime, laserOnTime, laserOffTime and END_BURST_DELIMITER from the grant length it received from the OLT. The value is counted in 1 time_quantum increments. The advertised value includes synchronization requirement on all receiver elements including PMD, PMA and PCS. This field is present only when the GATE is a discovery GATE, as signaled by the Discovery flag and is not present otherwise.

f) Discovery Information. This is a 16 bit flag register. This field is present only when the GATE is a discovery GATE, as signaled by the Discovery flag and is not present otherwise. Table 77–3 presents the internal structure of the Discovery Information flag field.

g) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception. The size of this field depends on the used Grant #n Length/Start Time entry-pairs as well as the presence of the Sync Time and Discovery Information fields, and varies in length from 15–39 accordingly.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The GATE MPCPDU shall be generated by a MAC Control instance mapped to an active ONU, and as such shall be marked with a unicast type of LLID, except when the MPCPDU is a discovery GATE, as indicated by the Discovery flag being set to true. For the discovery procedure, a MAC Control instance is mapped to all ONUs, and therefore, the discovery GATE MPCPDU is marked with the appropriate broadcast LLID (see 77.3.2.3).

Table 77–3—GATE MPCPDU discovery information fields

Bit	Flag field	Values
0	OLT is 1G upstream capable	0 – OLT does not support 1 Gb/s reception 1 – OLT supports 1 Gb/s reception
1	OLT is 10G upstream capable	0 – OLT does not support 10 Gb/s reception 1 – OLT supports 10 Gb/s reception
2–3	Reserved	Ignored on reception
4	OLT is opening 1G discovery window	0 – OLT cannot receive 1 Gb/s data in this window 1 – OLT can receive 1 Gb/s data in this window
5	OLT is opening 10G discovery window	0 – OLT cannot receive 10 Gb/s data in this window 1 – OLT can receive 10 Gb/s data in this window
6–15	Reserved	Ignored on reception

77.3.6.2 REPORT description

REPORT messages have several functionalities. Time stamp in each REPORT message is used for round trip (RTT) calculation. In the REPORT messages ONUs indicate the upstream bandwidth needs they request per IEEE 802.1Q priority queue. REPORT messages are also used as keep–alives from ONU to OLT. ONUs issue REPORT messages periodically in order to maintain link health at the OLT as defined in 77.3.4. In addition, the OLT may specifically request a REPORT message.

The REPORT MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the REPORT MPCPDU is 0x0003.
b) Number of Queue Sets. This field specifies the number of requests in the REPORT message. A REPORT frame may hold multiple sets of Report bitmap and Queue #n as specified in the Number of Queue Sets field.
c) Report bitmap. This is an 8 bit flag register that indicates which queues are represented in this REPORT MPCPDU—see Table 77–4.

Table 77–4—REPORT MPCPDU Report bitmap fields

Bit	Flag field	Values
0	Queue 0	0 – queue 0 report is not present; 1 – queue 0 report is present
1	Queue 1	0 – queue 1 report is not present; 1 – queue 1 report is present
2	Queue 2	0 – queue 2 report is not present; 1 – queue 2 report is present
3	Queue 3	0 – queue 3 report is not present; 1 – queue 3 report is present
4	Queue 4	0 – queue 4 report is not present; 1 – queue 4 report is present
5	Queue 5	0 – queue 5 report is not present; 1 – queue 5 report is present

Table 77–4—REPORT MPCPDU Report bitmap fields *(continued)*

Bit	Flag field	Values
6	Queue 6	0 – queue 6 report is not present; 1 – queue 6 report is present
7	Queue 7	0 – queue 7 report is not present; 1 – queue 7 report is present

d) Queue #n Report. This value represents the length of queue #n at time of REPORT message generation. The reported length shall be adjusted and rounded up to the nearest time_quantum to account for the necessary inter–frame spacing and preamble. FEC parity overhead is not included in the reported length. The Queue #n Report field is an unsigned 16 bit integer representing the transmission request in units of time_quanta. This field is present only when the corresponding flag in the Report bitmap is set.

e) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception. The size of this field depends on the used Queue Report entries, and accordingly varies in length from 0 to 39.

The REPORT MPCPDU shall be generated by a MAC Control instance mapped to an active ONU, and as such shall be marked with a unicast type of LLID.

77.3.6.3 REGISTER_REQ description

The REGISTER_REQ MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the REGISTER_REQ MPCPDU is 0x0004.
b) Flags. This is an 8 bit flag register that indicates special requirements for the registration, as presented in Table 77–5.

Table 77–5—REGISTER_REQ MPCPDU Flags fields

Value	Indication	Comment
0	Reserved	Ignored on reception.
1	Register	Registration attempt for ONU.
2	Reserved	Ignored on reception.
3	Deregister	This is a request to deregister the ONU. Subsequently, the MAC is deallocated and the LLID may be reused.
4–255	Reserved	Ignored on reception.

c) Pending grants. This is an unsigned 8 bit value signifying the maximum number of future grants the ONU is configured to buffer. The OLT should not grant the ONU more than this maximum number of Pending grants vectors composed of {start, length, force_report, discovery} into the future.
d) Discovery Information. This is a 16 bit flag register. Table 77–6 presents the structure of the Discovery Information flag.

Table 77–6—REGISTER_REQ MPCPDU Discovery Information Fields

Bit	Flag field	Values
0	ONU is 1G upstream capable	0 – ONU transmitter is not capable of 1 Gb/s 1 – ONU transmitter is capable of 1 Gb/s
1	ONU is 10G upstream capable	0 – ONU transmitter is not capable of 10 Gb/s 1 – ONU transmitter is capable of 10 Gb/s
2–3	Reserved	Ignored on reception
4	1G registration attempt	0 – 1 Gb/s registration is not attempted 1 – 1 Gb/s registration is attempted
5	10G registration attempt	0 – 10 Gb/s registration is not attempted 1 – 10 Gb/s registration is attempted
6–15	Reserved	Ignored on reception

e) Laser On Time. This field is 1 octet long and carries the Laser On Time characteristic for the given ONU transmitter. The value is expressed in the units of time_quanta.
f) Laser Off Time. This field is 1 octet long and carries the Laser Off Time characteristic for the given ONU transmitter. The value is expressed in the units of time_quanta.
g) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The REGISTER_REQ MPCPDU shall be generated by a MAC Control instance mapped to an undiscovered ONU, and as such shall be marked with a broadcast type of LLID (77.3.2.3).

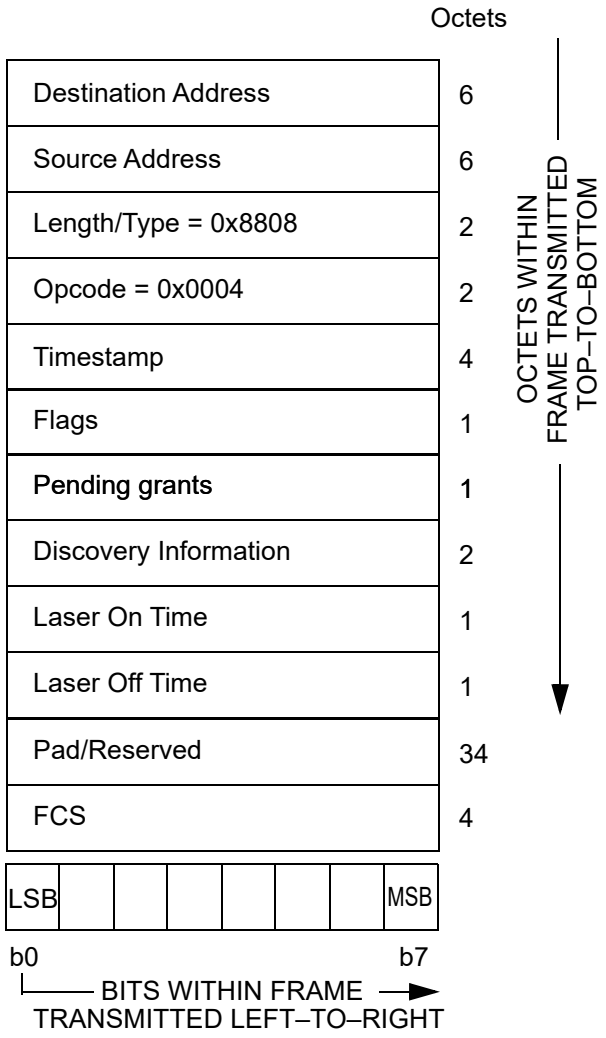

Figure 77–34—REGISTER_REQ MPCPDU

77.3.6.4 REGISTER description

The REGISTER MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) DA. The destination address used shall be an individual MAC address.
b) Opcode. The opcode for the REGISTER MPCPDU is 0x0005.
c) Assigned Port. This field holds a 16 bit unsigned value reflecting the LLID of the port assigned following registration.
d) Flags. this is an 8 bit flag register that indicates special requirements for the registration, as presented in Table 77–7.
e) Sync Time. This is an unsigned 16 bit value signifying the required synchronization time of the OLT receiver. The ONU calculates the effective grant length by subtracting the syncTime, laserOnTime, laserOffTime, and END_BURST_DELIMITER from the grant length it received from the OLT. The value is counted in 1 time_quantum increments. The advertised value includes synchronization requirement on all receiver elements including PMD, PMA, and PCS.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 77–7—REGISTER MPCPDU Flags field

Value	Indication	Comment
0	Reserved	Ignored on reception.
1	Reregister	The ONU is explicitly asked to re-register.
2	Deregister	This is a request to deallocate the port and free the LLID. Subsequently, the MAC is deallocated.
3	Ack	The requested registration is successful.
4	Nack	The requested registration attempt is denied by the MAC Control Client.
5–255	Reserved	Ignored on reception.

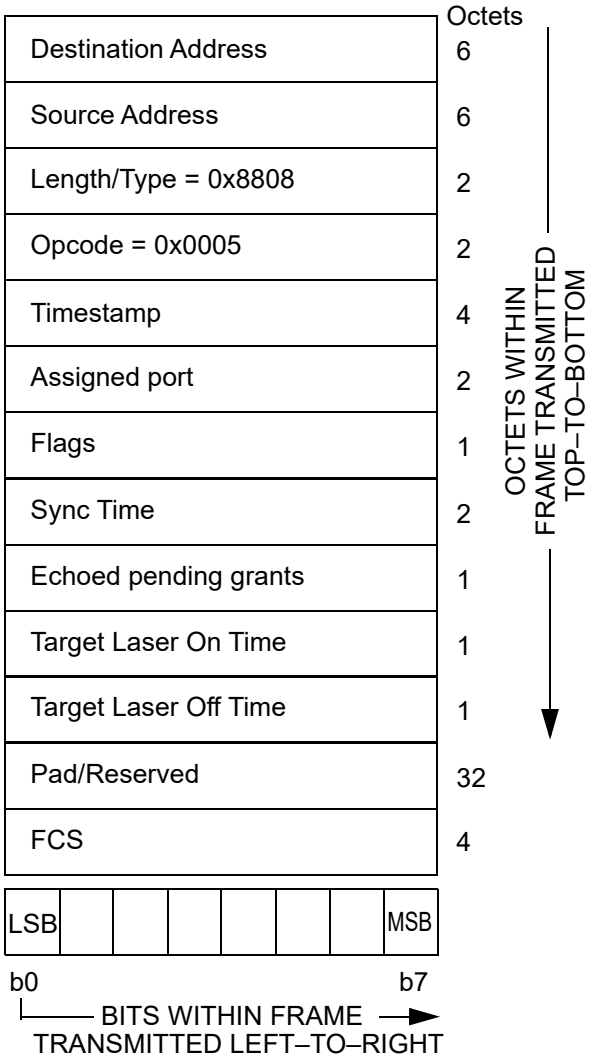

Figure 77–35—REGISTER MPCPDU

f) Echoed pending grants. This is an unsigned 8 bit value signifying the number of future grants the ONU may buffer before activating. The OLT should not grant the ONU more than this number of grants into the future.
g) Target Laser On Time. This is an unsigned 8 bit value, expressed in the units of time_quanta, signifying the Laser On Time for the given ONU transmitter. This value may be different from Laser On Time delivered by the ONU in the REGISTER_REQ MPCPDU during the Discovery process. The ONU updates the local laserOnTime variable per state diagram in Figure 77–23.
h) Target Laser Off Time. This is an unsigned 8 bit value, expressed in the units of time_quanta, signifying the Laser Off Time for the given ONU transmitter. This value may be different from Laser Off Time delivered by the ONU in the REGISTER_REQ MPCPDU during the Discovery process. The ONU updates the local laserOffTime variable per state diagram in Figure 77–23.
i) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored on reception.

The REGISTER MPCPDU shall be generated by a MAC Control instance mapped to all ONUs and such frame is marked by the broadcast LLID (77.3.2.3).

77.3.6.5 REGISTER_ACK description

The REGISTER_ACK MPCPDU is an instantiation of the Generic MPCPDU, and is further defined using the following definitions:

a) Opcode. The opcode for the REGISTER_ACK MPCPDU is 0x0006.
b) Flags. This is an 8 bit flag register that indicates special requirements for the registration, as presented in Table 77–8.
c) Echoed assigned port. This field holds a 16 bit unsigned value reflecting the LLID for the port assigned following registration.
d) Echoed Sync Time. This is an unsigned 16 bit value echoing the required synchronization time of the OLT receiver as previously advertised (77.3.6.4).
e) Pad/Reserved. This is an empty field that is transmitted as zeros, and ignored at reception.

Table 77–8—REGISTER_ACK MPCPDU Flags fields

Value	Indication	Comment
0	Nack	The requested registration attempt is denied by the MAC Control Client.
1	Ack	The registration process is successfully acknowledged.
2–255	Reserved	Ignored on reception.

The REGISTER_ACK MPCPDU shall be generated by a MAC Control instance mapped to an active ONU, and as such shall be marked with a unicast type of LLID.

77.4 Discovery Process in dual-rate systems

The enhancements introduced to the Clause 77 discovery process for EPONs facilitate the coexistence of 10G–EPON with 1G–EPON.

77.4.1 OLT speed-specific discovery

The discovery GATE MPCPDU is defined in Clause 64 for 1 Gb/s operation and in Clause 77 for 10 Gb/s operation. An additional field (Discovery Information field) was added to the 10 Gb/s discovery GATE MPCPDU. This field allows the OLT to relay speed-specific information regarding the discovery window to the different ONUs that may coexist in the same PON. The OLT has the ability to transmit common discovery GATE MPCPDUs on both the 1 Gb/s transmit path and 10 Gb/s transmit path, or it can send

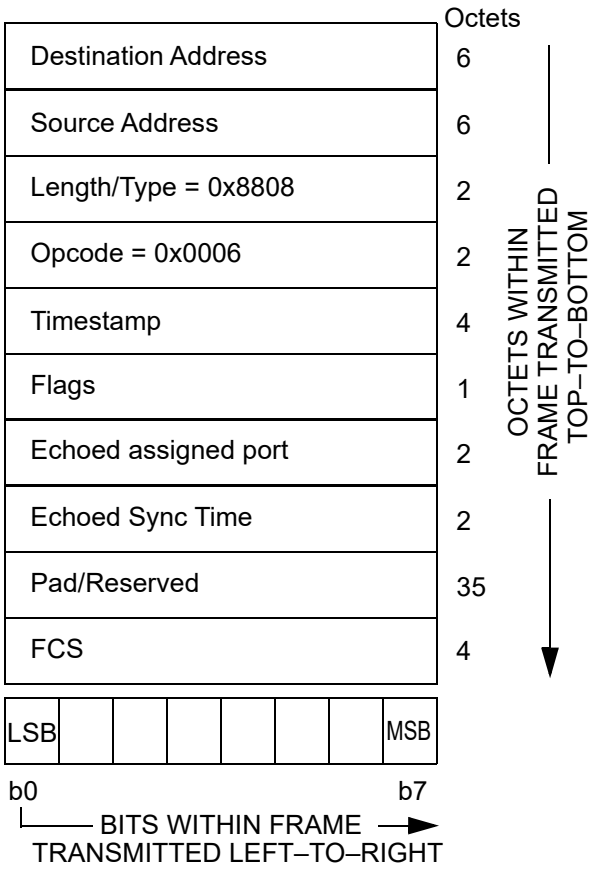

Figure 77–36—REGISTER_ACK MPCPDU

completely separate and independent GATE messages on these different paths. For each discovery window, the OLT is capable of opening windows for individual speeds or multiple speeds.

These different combinations allow the OLT MAC Control Client to open a number of discovery windows for all of the different ONU types. Table 77–9 shows the different types of windows that are possible, along with the necessary LLID and discovery information that also needs to be present in the discovery GATE MPCPDUs. For some combinations, it may be desirable for the OLT MAC Control Client to open overlapping discovery windows. It may do so by sending one discovery GATE MPCPDU on the 1 Gb/s downstream channel and a similar discovery GATE MPCPDU on the 10 Gb/s downstream channel; both discovery GATE MPCPDUs having the same Start Time value.

Figure 77–37 shows the three primary combinations of discovery windows and the different types of REGISTER_REQ MPCPDUs that may be received during the window. Figure 77–37(a) shows reception of messages from 1 Gb/s and 10/1 Gb/s ONUs. Figure 77–37(b) shows reception of messages from 10 Gb/s ONUs. Figure 77–37(c) shows reception of messages from all types of ONUs.

77.4.2 ONU speed-specific registration

A 1G–EPON ONU receives only discovery GATE messages transmitted by the OLT in the 1 Gb/s broadcast channel. Operation and registration of these ONUs is specified in Clause 64.

A 10/1G–EPON ONU is only capable of receiving discovery GATE MPCPDU transmitted by the OLT in the 10 Gb/s broadcast channel. These messages are parsed, and if a 1 Gb/s discovery window is opened, the ONU may attempt to register in the EPON.

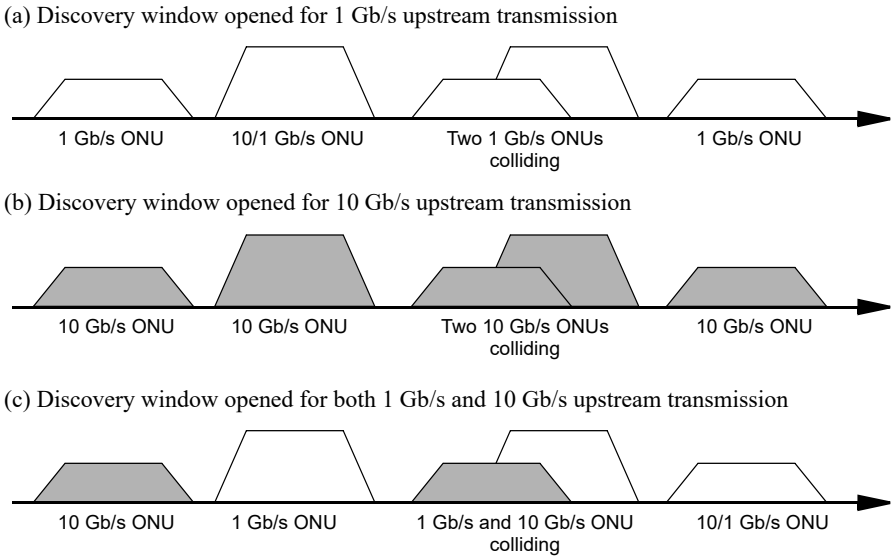

Figure 77–37—Combinations of REGISTER_REQ MPCPDUs during discovery window for 10G–EPON and 1G–EPON coexisting in the same PON

Table 77–9—Discovery GATE MPCPDUs for all ONU types

ONU types targeted by discovery GATE MPCPDU	LLID of discovery GATE(s)	Discovery information			
		Upstream capable		Discovery window	
		1G	10G	1G	10G
1G–EPON	0x7FFF	No Discovery Information field present			
10/1G–EPON	0x7FFE	1	0	1	0
1G–EPON and 10/1G–EPON	0x7FFF[a]	No Discovery Information field present			
	0x7FFE[a]	1	0	1	0
10/10G–EPON	0x7FFE	0	1	0	1
10/1G–EPON and 10/10G–EPON	0x7FFE	1	1	1	1
1G–EPON, 10/1G–EPON, and 10/10G–EPON	0x7FFF[a]	No Discovery Information field present			
	0x7FFE[a]	1	1	1	1

[a]Two discovery GATE MPCPDUs are transmitted in two separate downstream broadcast channels: one with the LLID of 0x7FFF transmitted in the 1 Gb/s downstream broadcast channel and another one the LLID of 0x7FFE transmitted in the 10 Gb/s downstream broadcast channel.

A 10/10G–EPON ONU is only capable of receiving discovery GATE MPCPDU transmitted by the OLT in the 10 Gb/s broadcast channel. These messages are parsed, and if a 10 Gb/s discovery window is opened, the ONU may attempt to register in the EPON.

A dual speed ONU capable of 10/1G–EPON operation or 10/10G–EPON operation is also only capable of receiving discovery GATE MPCPDU transmitted by the OLT in the 10 Gb/s broadcast channel. These messages need to be parsed, and the ONU makes the registration decision based on the available information. The ONU should attempt to register during the discovery window announced as supporting the

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

highest speed common to both the OLT and ONU. Table 77–10 shows the action the ONU should take based on the ONU transmit capabilities and the received discovery information.

Table 77–10—ONU action during discovery window

OLT Discovery information				ONU Tx capability		ONU action
Upstream capable		Discovery window				
1G	10G	1G	10G	1G	10G	
1	0	1	0	1	X	Attempt 1G registration
1	X	1	X	1	0	Attempt 1G registration
X	1	X	1	X	1	Attempt 10G registration
1	1	0	1	1	0	Wait for 1G discovery window
1	1	1	0	X	1	Wait for 10G discovery window

The ONU generates the REGISTER_REQ MPCPDU with the same LLID as the discovery GATE MPCPDU it responds to, i.e., 1G–EPON ONU (per Clause 64) use LLID 0x7FFF, while the 10G–EPON ONUs use LLID 0x7FFE.

77.5 Protocol implementation conformance statement (PICS) proforma for Clause 77, Multipoint MAC Control[140]

77.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 77 Multipoint MAC Control, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

77.5.2 Identification

77.5.2.1 Implementation identification

Supplier	
Contact point for inquiries about the PICS	
Implementation Name(s) and Version(s)	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)	
NOTE 1—Only the first three items are required for all implementations; other information may be completed as appropriate in meeting the requirements for the identification. NOTE 2—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

77.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 77, Multipoint MAC Control
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[140]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

77.5.3 Major capabilities/options

78. Energy-Efficient Ethernet (EEE)

78.1 Overview

The optional EEE capability combines the IEEE 802.3 Media Access Control (MAC) Sublayer with a family of Physical Layers defined to support operation in the Low Power Idle (LPI) mode. When the LPI mode is enabled, systems on both sides of the link can save power during periods of low link utilization.

EEE also provides a protocol to coordinate transitions to or from a lower level of power consumption and does this without changing the link status and without dropping or corrupting frames. The transition time into and out of the lower level of power consumption is kept small enough to be transparent to upper layer protocols and applications.

EEE supports operation over twisted-pair cabling systems, twinaxial cable, electrical backplanes, optical fiber, the XGXS for 10 Gb/s PHYs, the 25GAUI for 25 Gb/s PHYs, the XLAUI for 40 Gb/s PHYs, the LAUI-2 or 50GAUI-n for 50 Gb/s PHYs, the CAUI-n or 100GAUI-n for 100 Gb/s PHYs, the 200GAUI-n and 200GXS for 200 Gb/s PHYs, and the 400GAUI-n and 400GXS for 400 Gb/s PHYs. Table 78–1 lists the supported PHYs and interfaces and their associated clauses.

In addition to the above, EEE defines a 10 Mb/s MAU (10BASE-Te) with reduced transmit amplitude requirements. The 10BASE-Te MAU is fully interoperable with 10BASE-T MAUs over 100 m of class D (Category 5) or better cabling as specified in ISO/IEC 11801:1995. These requirements can also be met by Category 5 cable and components as specified in ANSI/TIA/EIA-568-B-1995. The definition of 10BASE-Te allows a reduction in power consumption.

EEE also specifies means to exchange capabilities between link partners to determine whether EEE is supported and to select the best set of parameters common to both devices. Clause 78 provides an overview of EEE operation. PICS for the optional EEE capability for each specific PHY type are specified in the respective PHY clauses. Normative requirements for Data Link Layer capabilities are contained in 78.4.

78.1.1 LPI Signaling

LPI signaling allows the LPI Client to indicate to the PHY, and to the link partner, that a break in the data stream is expected, and the LPI Client can use this information to enter power-saving modes that require additional time to resume normal operation. LPI signaling also informs the LPI Client when the link partner has sent such an indication.

The definition of LPI signaling assumes the use of the MAC defined in Annex 4A for simplified full duplex operation (with carrier sense deferral). This provides full duplex operation but uses the carrier sense signal to defer transmission when the PHY is in the LPI mode.

The LPI Client connects to the RS service interface. LPI signaling between the RS and PCS is performed by LPI encoding on the Media Independent Interface. The transmit PCS encodes LPI symbols, which are decoded by the link partner receive PCS. The receive and transmit PCS also generate service interface signals, which are passed down to the lower PHY sublayers and indicate when receive and transmit PHY functions may be powered down.

The EEE request signals from the PCS control transitions between quiescent and normal operation. The Clause 49 PCS, Clause 107 PCS, Clause 82 PCS, and Clause 129 PCS also request transmit alert operation to assist the partner device PMD to detect the end of the quiescent state. Additionally the Clause 49 PCS, Clause 107 PCS, and Clause 82 PCS generate the RX_LPI_ACTIVE signal, which indicates to the Clause 74 BASE-R FEC that it can use rapid block lock because the link partner PCS has bypassed scrambling.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Coding defined in 83.5.11 also allows LPI transmit quiet and alert requests from the PCS to be signaled over the 25GAUI, XLAUI, and CAUI-n interfaces. The 25GAUI, XLAUI, and CAUI-n receive interfaces infer the quiet and alert requests from the data received over the interface and use that to recreate the transmit or receive direction signaling.

The receive PCS checks that the link cycles out of the quiescent state at the correct time and that the received signals return to their expected state within the required time. The ENERGY_DETECT indicate signal is passed up from the PMA to the PCS to allow the PCS to monitor the waking process.

78.1.1.1 Reconciliation sublayer service interfaces

Figure 78–1 depicts the LPI Client and the RS interlayer service interfaces.

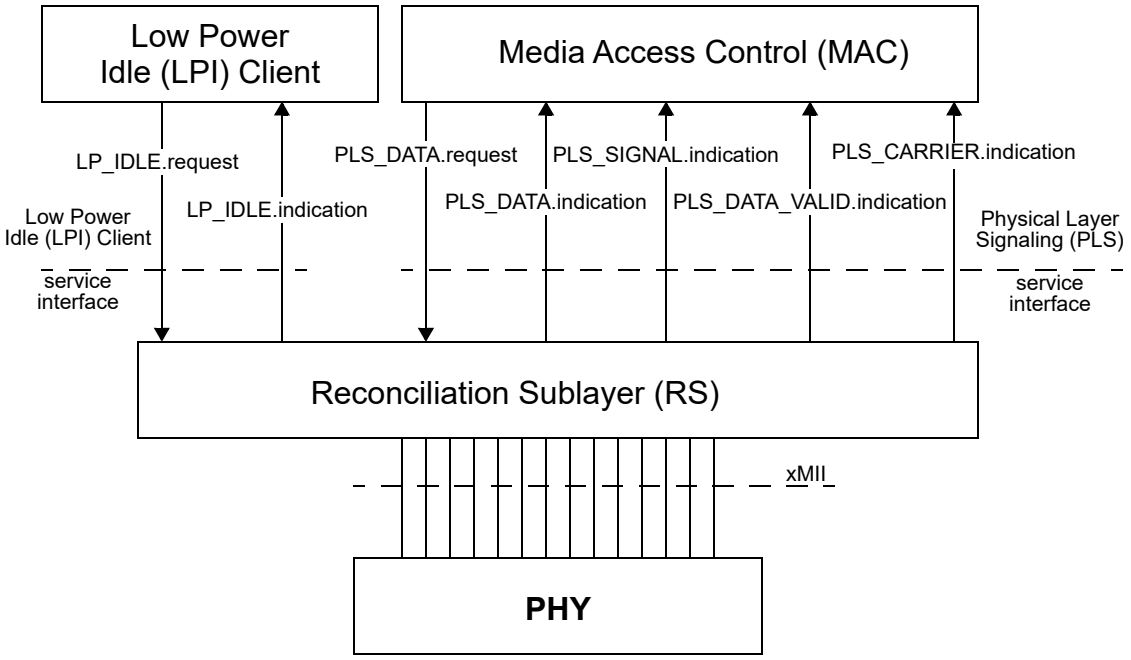

Figure 78–1—LPI Client and RS interlayer service interfaces

78.1.1.2 Responsibilities of LPI Client

The decision on when to signal LPI to the link partner is made by the LPI Client and communicated to the PHY through the RS. The LPI Client is also informed when the link partner is signaling LPI by the RS.

The conditions under which the LPI Client decides to send LPI, and what action are taken by the LPI Client when it receives LPI from the link partner, are implementation specific and beyond the scope of this standard.

78.1.2 LPI Client service interface

The following specifies the service interface provided by the RS to the LPI Client. These services are described in an abstract manner and do not imply any particular implementation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The following primitives are defined:

LP_IDLE.request
LP_IDLE.indication

78.1.2.1 LP_IDLE.request

78.1.2.1.1 Function

A primitive used by the LPI Client to start or stop the signaling of LPI to the link partner.

78.1.2.1.2 Semantics of the service primitive

The semantics of the service primitive are as follows:

LP_IDLE.request (LPI_REQUEST)

The LPI_REQUEST parameter can take one of two values: ASSERT or DEASSERT. ASSERT initiates the signaling of LPI to the link partner. DEASSERT stops the signaling of LPI to the link partner. The effect of receipt of this primitive is undefined in any of the following cases:

a) link_status is not OK (see 28.2.6.1.1)
b) LPI_REQUEST=ASSERT within 1 s of the change of link_status to OK
c) The PHY is indicating LOCAL FAULT
d) The PHY is indicating REMOTE FAULT

78.1.2.1.3 When generated

Specification of the time when this primitive is generated by the LPI client is out of the scope of this standard.

78.1.2.1.4 Effect of receipt

The receipt of this primitive will cause the RS to start or stop signaling LPI to the link partner.

78.1.2.2 LP_IDLE.indication

78.1.2.2.1 Function

A primitive that is used to indicate to the LPI Client that the link partner has started or stopped signaling LPI.

78.1.2.2.2 Semantics of the service primitive

The semantics of the service primitive are as follows:

LP_IDLE.indication (LPI_INDICATION)

The LPI_INDICATION parameter can take one of two values: ASSERT or DEASSERT. ASSERT indicates that the link partner has started signaling LPI. DEASSERT indicates that the link partner has stopped signaling LPI.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

78.1.2.2.3 When generated

This primitive is generated by the RS when it starts or stops receiving Assert LPI encoded on the receive xMII according to the rules defined in 78.1.3.2.

78.1.2.2.4 Effect of receipt

The effect of receipt of this primitive by the LPI client is unspecified.

78.1.3 Reconciliation sublayer operation

LPI assert and detect functions are contained in the Reconciliation Sublayer as shown in Figure 78–2. The xMII in this diagram represents any of the family of medium independent interfaces supported by EEE.

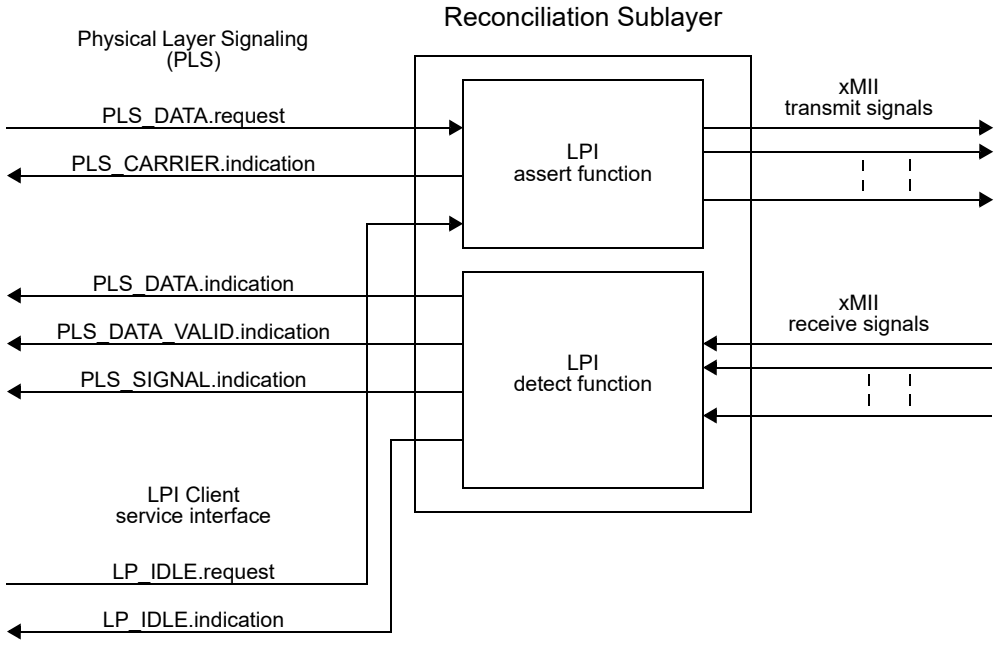

Figure 78–2—RS LPI assert and detect functions

The following provides an overview of RS LPI operation. The actual specification of RS LPI operation can be found in the respective RS clauses.

78.1.3.1 RS LPI assert function

In the absence of an LPI request, indicated by the LPI_REQUEST parameter set to DEASSERT in the LP_IDLE.request primitive of the LPI Client interface, the LPI assert function maps the PLS service interface to the transmit xMII signals as under normal conditions.

When an LPI request is asserted, indicated by the LPI_REQUEST parameter set to ASSERT in the LP_IDLE.request primitive of the LPI Client interface, the LPI assert function starts to transmit the "Assert LPI" encoding on the xMII. The LPI assert function also sets the CARRIER_STATUS parameter to CARRIER_ON in the PLS_CARRIER.indication primitive of the PLS service interface. This will prevent the MAC from transmitting.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When the LPI request is deasserted, indicated by the LPI_REQUEST parameter set to DEASSERT in the LP_IDLE.request primitive of the LPI Client interface, the LPI assert function starts to transmit the normal interframe encoding on the xMII. After a delay, the LPI assert function sets the CARRIER_STATUS parameter to CARRIER_OFF in the PLS_CARRIER.indication primitive of the PLS service interface, allowing the MAC to start transmitting again. This delay is provided to allow the link partner to prepare for normal operation. This delay has a PHY dependent default value but this value can be adjusted using the Data Link Layer capabilities defined in 78.4.

78.1.3.2 LPI detect function

In the absence of LPI, indicated by an encoding other than “Assert LPI” on the receive xMII, the LPI detect function maps the receive xMII signals to the PLS service interface as under normal conditions.

At the start of LPI, indicated by the transition from normal interframe encoding to the “Assert LPI” encoding on the receive xMII, the LPI detect function continues to indicate idle on the PLS service interface, but sets LP_IDLE.indication(LPI_INDICATION) to ASSERT.

At the end of LPI, indicated by the transition from the “Assert LPI” encoding to any other encoding on the receive xMII, LP_IDLE.indication(LPI_INDICATION) is set to DEASSERT and the RS receive function resumes normal decode operation.

78.1.3.3 PHY LPI operation

The following provides an overview of PHY LPI operation. The specification of PHY LPI operation can be found in the respective PHY clauses (see Table 78–1).

78.1.3.3.1 PHY LPI transmit operation

When the start of “Assert LPI” encoding on the xMII is detected, the PHY signals sleep to its link partner to indicate that the local transmitter is entering LPI mode.

The EEE capability in most PHYs requires the local PHY transmitter to go quiet after sleep is signaled.

In the 1000BASE-T LPI mode, the local PHY transmitter goes quiet only after the local PHY signals sleep and receives a sleep signal from the remote PHY. If the remote PHY chooses not to signal LPI, then neither PHY can go into a low power mode; however, LPI requests are passed from one end of the link to the other regardless and system energy savings can be achieved even if the PHY link does not go into a low power mode.

The transmit function of the local PHY is enabled periodically to transmit refresh signals that are used by the link partner to update adaptive filters and timing circuits in order to maintain link integrity.

This quiet-refresh cycle continues until the reception of the normal interframe encoding on the xMII. The transmit function in the PHY communicates this to the link partner by sending a wake signal for a predefined period of time. The PHY then enters the normal operating state.

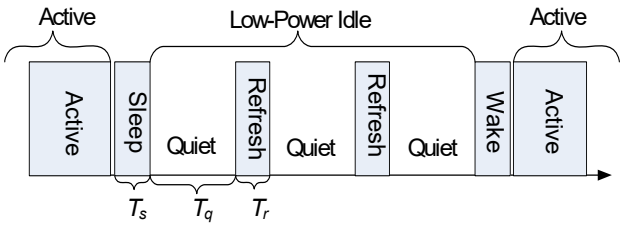
Figure 78–3 illustrates general principles of the EEE-capable transmitter operation.



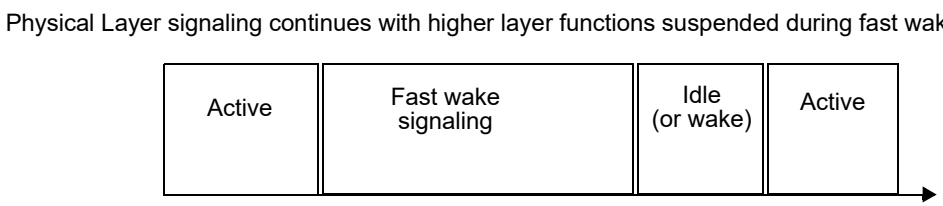


Figure 78–3—Overview of EEE LPI operation

No data frames are lost or corrupted during the transition to or from the LPI mode.

Except for BASE-T, for PHYs with an operating speed of 25 Gb/s or greater that implement the optional EEE capability, two modes of LPI operation may be supported: deep sleep and fast wake. *Deep sleep* refers to the mode for which the transmitter ceases transmission during Low Power Idle (as shown in Figure 78–3) and is equivalent to the only mechanism defined for PHYs with an operating speed of 10 Gb/s or below. Deep sleep support is optional for PHYs with an operating speed of 25 Gb/s or greater that implement EEE with the exception of the PHYs noted in Table 78–1 that do not support deep sleep. *Fast wake* refers to the mode for which the transmitter continues to transmit signals during Low Power Idle so that the receiver can resume operation with a shorter wake time (as shown in Figure 78–4). For transmit, other than the PCS encoding LPI, there is no difference between fast wake and normal operation. Except for BASE-T PHYs, fast wake support is mandatory for PHYs with an operating speed of 25 Gb/s or greater that implement EEE.

NOTE—Fast wake signaling continually indicates LPI in a normally constituted data stream.

Figure 78–4—Overview of fast wake operation

WARNING
The signaling in deep sleep operation precludes transparent mapping of the link over Optical Transport Networks. Only fast wake operation should be enabled for any link that is intended for transparent OTN mapping.

78.1.3.3.2 PHY LPI receive operation

In the receive direction, entering the LPI mode is triggered by the reception of a sleep signal from the link partner, which indicates that the link partner is about to enter the LPI mode. After sending the sleep signal, the link partner ceases transmission if not in fast wake mode. When the receiver detects the sleep signal, the local PHY indicates “Assert LPI” on the xMII and the local receiver can disable some functionality to reduce power consumption.

If not in fast wake mode the link partner periodically transmits refresh signals that are used by the local PHY to update adaptive coefficients and timing circuits. This quiet-refresh cycle continues until the link partner

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

initiates transition back to normal mode by transmitting the wake signal for a predetermined period of time controlled by the LPI assert function in the RS. This allows the local receiver to prepare for normal operation and transition from the "Assert LPI" encoding to the normal interframe encoding on the xMII. After a system specified recovery time, the link supports the nominal operational data rate.

78.1.4 PHY types optionally supporting EEE

EEE defines a low power mode of operation for the IEEE 802.3 PHYs and interfaces listed in Table 78–1. The table also lists the clauses associated with each PHY or sublayer. Normative requirements for the EEE capability for each PHY type and interface are in the associated clauses.

[a]25GAUI/XLAUI/CAUI-n shutdown is supported only when deep sleep is enabled for the associated PHY.
[b]The deep sleep mode of EEE is not supported for this PHY.

78.2 LPI mode timing parameters description

T_s	The period of time that the PHY transmits the sleep signal before turning all transmitters off
T_q	The period of time that the PHY remains quiet before sending the refresh signal
T_r	Duration of the refresh signal
$T_{phy_prop_tx}$	The propagation delay of a given unit of data from the xMII to the MDI
$T_{phy_prop_rx}$	The propagation delay of a given unit of data from the MDI to the xMII

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$T_{phy_shrink_tx}$ Transmitter shrinkage time, defined as the absolute time difference between the following two timing parameters:

—Delay between a transition from the "Assert LPI" to "Normal Idle" at the xMII and the corresponding start of the wake signal at the MDI

—$T_{phy_prop_tx}$

$T_{phy_shrink_rx}$ Receiver shrinkage time, defined as the absolute time difference between the following two timing parameters:

—Delay between start of the wake signal at the MDI and the corresponding transition from "Assert LPI" to "Normal Idle" at the xMII

—$T_{phy_prop_rx}$

T_{w_phy} Parameter employed by the system that corresponds to the behavior of the PHY. It is the period of time between reception of an IDLE signal on the xMII and when the first data codewords are permitted on the xMII. The wake time of a compliant PHY does not exceed T_{w_phy} (min).

$T_{w_sys_tx}$ Parameter employed by the system that corresponds to its requirements. It is the longest period of time the system has to wait between a request to transmit and its readiness to transmit.

$T_{w_sys_rx}$ Parameter employed by the system that corresponds to its requirements. It is the minimum time required by the system between a request to wake and its readiness to receive data.

Table 78–2 summarizes three key EEE parameters (T_s, T_q, and T_r) for supported PHYs.

Table 78–2—Summary of the key EEE parameters for supported PHYs or interfaces

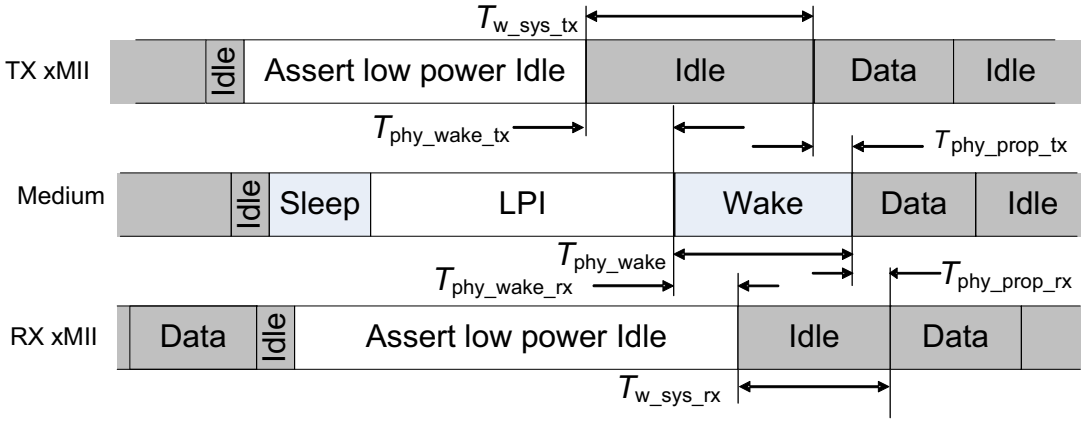

Figure 78–5 illustrates the relationship between the LPI mode timing parameters and the minimum system wake time.

78.3 Capabilities Negotiation

The EEE capability shall be advertised during the Auto-Negotiation stage, except for PHYs that only support fast wake operation or PHYs that exchange EEE capability during link training. Auto-Negotiation provides a linked device with the capability to detect the abilities (modes of operation) supported by the device at the other end of the link, determine common abilities, and configure for joint operation. Auto-Negotiation is performed at power up, on command from management, due to link failure, or due to user intervention. Fast wake capability shall be advertised using L2 protocol frames as described in 78.4. The EEE capability for 2.5GBASE-T and 5GBASE-T shall be advertised during link training according to 126.4.2.5.10. The EEE capability for 2.5GBASE-T1, 5GBASE-T1, and 10GBASE-T1 shall be advertised during link training according to 149.4.2.4.10. The EEE capability for 25GBASE-T and 40GBASE-T shall be advertised during link training according to 113.4.2.5.10.

During Auto-Negotiation, both link partners indicate their EEE capabilities. EEE is supported only if during Auto-Negotiation both the local device and link partner advertise the EEE capability for the resolved PHY type. If EEE is not supported, all EEE functionality is disabled and the LPI client does not assert LPI. EEE deep sleep operation shall not be enabled unless both the local device and link partner advertise deep sleep capability during Auto-Negotiation for the resolved PHY type. If EEE is supported by both link partners for the negotiated PHY type, then the EEE function can be used independently in either direction. The same applies to 2.5GBASE-T, 2.5GBASE-T1, 5GBASE-T, 5GBASE-T1, 10GBASE-T1, 25GBASE-T, and

Copyright © 2022 IEEE. All rights reserved.

$T_{w_sys_tx}$ (min) = $T_{w_sys_rx}$ (min) + $T_{phy_shrink_tx}$ (max) + $T_{phy_shrink_rx}$ (max)
T_{w_phy} (min) = T_{phy_wake} (min) + $T_{phy_shrink_tx}$

$T_{w_sys_res}$ (min) is greater of $T_{w_sys_tx}$ (min) and T_{w_phy} (min)

$T_{phy_shrink_tx}$ (max) = ($T_{phy_wake_tx}$ (max) – $T_{phy_prop_tx}$ (min))
$T_{phy_shrink_rx}$ (max) = ($T_{phy_wake_rx}$(max) – $T_{phy_prop_rx}$ (min))

where

$T_{phy_wake_tx}$ = xMII start of wake to MDI start of wake delay
$T_{phy_prop_tx}$ = xMII to MDI data propagation delay
$T_{phy_wake_rx}$ = MDI start of wake to xMII start of wake delay
$T_{phy_prop_rx}$ = MDI to xMII data propagation delay
T_{phy_wake} = Minimum wake duration required by PHY

Figure 78–5—LPI mode timing parameters and their relationship to minimum system wake time

40GBASE-T except the EEE capabilities are exchanged and resolved during link training instead of during Auto-Negotiation.

Additional capabilities and settings using L2 protocol frames, including the adjustment of the $T_{w_sys_tx}$ parameter, are described in 78.4.

78.4 Data Link Layer capabilities

Additional capabilities and settings are supported using frames based on the IEEE 802.3 Organizationally Specific TLVs are defined in Annex F of IEEE Std 802.1AB™-2009. Devices that require longer wake-up times prior to being able to accept data on their receive paths may use the Data Link Layer capabilities defined in this subclause to negotiate for extended system wake-up times from the transmitting link partner. This mechanism may allow for more or less aggressive energy saving modes.

The Data Link Layer capabilities shall be implemented for devices with an operating speed equal to or greater than 10 Gb/s and may be implemented for all other devices. The use of the EEE Fast Wake TLV shall be interpreted as an indication that the device supports EEE fast wake operation, regardless of the capability advertised during the Auto-Negotiation stage. A device shall not indicate deep sleep capability using the EEE Fast Wake TLV unless both the local device and link partner advertise deep sleep capability during Auto-Negotiation for the resolved PHY type.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Implementations that use the Data Link Layer capabilities shall comply with all mandatory parts of IEEE Std 802.1AB-2009; shall support the EEE Type, Length, Value (TLV) defined in 79.3.5; timing requirement in 78.4.1; and shall support the control state diagrams defined in 78.4.2. Devices with an operating speed equal to or greater than 40 Gb/s shall support EEE Fast Wake TLV as defined in 79.3.6.

The Data Link Layer capabilities are described from a unidirectional perspective on the link between transmitting and receiving link partners. For duplex EEE links that implement the Data Link Layer capabilities, each link partner shall implement the TLV, control and state diagrams for a transmitter as well as a receiver.

For purposes of Data Link Layer capabilities, all values that are negotiated and/or exchanged that have a fractional value shall be rounded up to the nearest integer number in microseconds.

78.4.1 Data Link Layer capabilities timing requirements

An EEE link partner shall send an LLDPDU containing an EEE TLV within 10 s of the Link Layer capability exchange being enabled when both the variables dll_enabled and dll_ready are asserted.

An LLDPDU containing an EEE TLV with an updated value for the "Echo Transmit $T_{w_sys_tx}$" field shall be sent within 10 s of receipt of an LLDPDU containing an EEE TLV where the value of "Transmit $T_{w_sys_tx}$" field is different from the previously communicated value.

An LLDPDU containing an EEE TLV with an updated value for the "Echo Receive $T_{w_sys_tx}$" field shall be sent within 10 s of receipt of an LLDPDU containing an EEE TLV where the value of "Receive $T_{w_sys_tx}$" field is different from the previously communicated value.

78.4.2 Control state diagrams

The control state diagrams for an EEE transmitting link partner and an EEE receiving link partner specify the externally observable behavior of an EEE transmitting link partner and an EEE receiving link partner implementing Data Link Layer capabilities respectively. EEE transmitting link partners implementing Data Link Layer capabilities shall provide the behavior of the state diagram as shown in Figure 78–6. EEE receiving link partners implementing Data Link Layer capabilities shall provide the behavior of the state diagram as shown in Figure 78–7.

78.4.2.1 Conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of state diagrams as described in 21.5.

78.4.2.2 Constants

PHY WAKE VALUE

Integer (2 octets wide) representing the $T_{w_sys_tx}$ (min) defined for the PHY that is in use for the link. This parameter should be rounded up to the nearest integer number when it is calculated and examined according to 78.2 and Table 78–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

78.4.2.3 Variables

Unless otherwise specified, all integers are assumed to be 2 octets wide.

LocTxSystemValue
: Integer that indicates the value of $T_{w_sys_tx}$ that the local system can support. This value is updated by the EEE DLL Transmitter state diagram. This variable maps into the aLldpXdot3LocTxTwSys attribute.

RemTxSystemValueEcho
: Integer that indicates the value Transmit $T_{w_sys_tx}$ echoed back by the remote system. This value maps from the aLldpXdot3RemTxTwSysEcho attribute.

LocRxSystemValue
: Integer that indicates the value of $T_{w_sys_tx}$ that the local system requests from the remote system. This value is updated by the EEE Receiver L2 state diagram. This variable maps into the aLldpXdot3LocRxTwSys attribute.

RemRxSystemValueEcho
: Integer that indicates the value of Receive $T_{w_sys_tx}$ echoed back by the remote system. This value maps from the aLldpXdot3RemRxTwSysEcho attribute.

LocFbSystemValue
: Integer that indicates the value of fallback $T_{w_sys_tx}$ that the local system requests from the remote system. This value is updated by the local system software.

RemTxSystemValue
: Integer that indicates the value of $T_{w_sys_tx}$ that the remote system can support. This value maps from the aLldpXdot3RemTxTwSys attribute.

LocTxSystemValueEcho
: Integer that indicates the remote system's Transmit $T_{w_sys_tx}$ that was used by the local system to compute the $T_{w_sys_tx}$ that it wants to request from the remote system. This value maps into the aLldpXdot3LocTxTwSysEcho attribute.

RemRxSystemValue
: Integer that indicates the value of $T_{w_sys_tx}$ that the remote system requests from the local system. This value maps from the aLldpXdot3RemRxTwSys attribute.

LocRxSystemValueEcho
: Integer that indicates the remote systems Receive $T_{w_sys_tx}$ that was used by the local system to compute the $T_{w_sys_tx}$ that it can support. This value maps into the aLldpXdot3LocRxTwSysEcho attribute.

LocResolvedTxSystemValue
: Integer that indicates the current $T_{w_sys_tx}$ supported by the local system.

LocResolvedRxSystemValue
: Integer that indicates the current $T_{w_sys_tx}$ supported by the remote system.

LPI_FW
: Boolean variable controlling the wake mode for the LPI transmit and receive functions as defined in 82.2.19.2.2.

LocTxSystemFW
: Boolean variable that indicates the state of LPI_FW that the local transmit system can support. This value is updated by the EEE DLL Transmit fast wake state diagram. This variable maps into the aLldpXdot3LocTxFw attribute.

RemTxSystemFWEcho
: Boolean variable that indicates the state of transmit LPI_FW echoed back by the remote system. This value maps from the aLldpXdot3RemTxFwEcho attribute.

LocRxSystemFW
: Boolean variable that indicates the state of LPI_FW that the local receive system requests from the remote system. This value is updated by the EEE DLL Receive fast wake state diagram. This variable maps into the aLldpXdot3LocRxFw attribute.

RemRxSystemFWEcho
: Boolean variable that indicates the state of receive LPI_FW echoed back by the remote system. This value maps from the aLldpXdot3RemRxFwEcho attribute.

RemTxSystemFW
: Boolean variable that indicates the LPI_FW that the remote transmit system requests from the local system. This value maps from the aLldpXdot3RemTxFw attribute.

LocTxSystemFWEcho
: Boolean variable that indicates the remote system's transmit LPI_FW that was used by the local system to decide the LPI_FW that it wants to request from the remote system. This value maps into the aLldpXdot3LocTxFwEcho attribute.

RemRxSystemFW
: Boolean variable that indicates the LPI_FW that the remote receive system requests from the local system. This value maps from the aLldpXdot3RemRxFw attribute.

LocRxSystemFWEcho
: Boolean variable that indicates the remote system's receive LPI_FW that was used by the local system to decide the LPI_FW that it can support. This value maps into the aLldpXdot3LocRxFwEcho attribute.

LocResolvedTxSystemFW
: Boolean that indicates the current LPI_FW supported by the local system.

LocResolvedRxSystemFW
: Boolean variable that indicates the current LPI_FW supported by the remote system.

TempTxFW
: Boolean variable used to store the value of LPI_FW.

TempRxFW
: Boolean variable used to store the value of LPI_FW.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

local_system_FW_change
: An implementation-specific control variable that indicates that the local system wants to change either the Transmit LPI_FW or the Receive LPI_FW.

NEW_TX_FW
: Boolean variable that indicates the value of transmit LPI_FW that the local system can support.

NEW_RX_FW
: Boolean variable that indicates the value of receive LPI_FW that the local system wants the remote system to support.

TempTxVar
: Integer used to store the value of $T_{w_sys_tx}$.

TempRxVar
: Integer used to store the value of $T_{w_sys_tx}$.

local_system_change
: An implementation specific control variable that indicates that the local system wants to change either the Transmit $T_{w_sys_tx}$ or the Receive $T_{w_sys_tx}$.

tx_dll_ready
: Data Link Layer ready: This variable indicates that the tx system initialization is complete and is ready to update/receive LLDPDU containing EEE TLV. This variable is updated by the local system software.

rx_dll_ready
: Data Link Layer ready: This variable indicates that the rx system initialization is complete and is ready to update/receive LLDPDU containing EEE TLV. This variable is updated by the local system software.

NEW_TX_VALUE
: Integer that indicates the value of $T_{w_sys_tx}$ that the local system can support.

NEW_RX_VALUE
: Integer that indicates the value of $T_{w_sys_tx}$ that the local system wants the remote system to support.

78.4.2.4 Functions

examine_Tx_change

This function computes the new value of $T_{w_sys_tx}$ that the local system can support when there is as updated request from the remote system or if local system conditions require a change in the value of the presently supported $T_{w_sys_tx}$.

examine_Rx_change

This function computes the new value of $T_{w_sys_tx}$ that the local system wants the remote system to support. This function is called when the remote system wants to change its presently allocated

$T_{w_sys_tx}$ or if local system conditions require a change in the value of $T_{w_sys_tx}$ presently supported by the remote system.

examine_TxFW_change
: This function decides if the new value of LPI_FW is acceptable by the local transmit system when there is an updated request from the remote system or if local system conditions require a change in the value of the presently supported LPI_FW.

examine_RxFW_change
: This function decides if the new value of LPI_FW is acceptable by the local receive system when there is an updated request from the remote system or if local system conditions require a change in the value of the presently supported LPI_FW.

78.4.2.5 State diagrams

Control for placing data on the medium rests with the transmitting side, hence $T_{w_sys_tx}$ is enforced by the transmitter. For a given path between link partners (i.e., a transmitter and its associated receiver), the transmitting link partner shall wait for the time indicated by the Transmit $T_{w_sys_tx}$ after deasserting LPI (at the xMII) before sending data frames. The receiving link partner shall be ready to accept data based on its echoed value of Transmit link partner's $T_{w_sys_tx}$. This ensures that the link partners transition out of LPI mode and receive frames without loss or corruption.

The general state change procedure for transmitter is shown in Figure 78–6.

78.4.3 State change procedure across a link

The transmitting and receiving link partners utilize the LLDP mechanism to advertise their various attributes to the other entity.

The initial $T_{w_sys_tx}$ defaults governing the EEE operation of the link default to the wake values required by the PHYs. This provides for EEE operation and functionality on initialization and prior to the exchange and processing of the TLVs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The receiving link partner may request a new $T_{w_sys_tx}$ value through the aLldpXdot3LocRxTwSys (30.12.2.1.64) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). The request appears to the transmitting link partner as a change to the aLldpXdot3RemRxTwSys (30.12.3.1.62) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class. The transmitting link partner responds to its receiving partner's request through the aLldpXdot3LocTxTwSys (30.12.2.1.62) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). The transmitting link partner also copies the value of the aLldpXdot3RemRxTwSys (30.12.3.1.62) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class to the aLldpXdot3LocRxTwSysEcho (30.12.2.1.65) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2).

The transmitting link partner may advertise new value of $T_{w_sys_tx}$ through the aLldpXdot3LocTxTwSys (30.12.2.1.62) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). This appears to the receiving link partner as a change to the aLldpXdot3RemTxTwSys (30.12.3.1.60) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class. The receiving link partner responds to a transmitter's request through the aLldpXdot3LocRxTwSys (30.12.2.1.64) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). The receiving link partner also copies the value of the aLldpXdot3RemTxTwSys (30.12.3.1.60) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class to the aLldpXdot3LocTxTwSysEcho (30.12.2.1.63) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). This appears to the transmitting link partner as a change to the aLldpXdot3RemTxTwSysEcho (30.12.3.1.61) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3).

The state diagrams in Figure 78–6 and Figure 78–7 describe the preceding behavior.

The default state of Fast_Wake_Enable is TRUE for all PHYs that support the function. This provides for EEE operation and functionality on initialization and prior to the exchange and processing of the TLVs.

The receiving link partner may request a change of Fast_Wake_Enable through the aLldpXdot3LocRxFw (30.12.2.1.72) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). The request appears to the transmitting link partner as a change to the aLldpXdot3RemRxFw (30.12.3.1.26) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class. The transmitting link partner responds to its receiving partner's request through the aLldpXdot3LocTxFw (30.12.2.1.70) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). The transmitting link partner also copies the value of the aLldpXdot3RemRxFw (30.12.3.1.26) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class to the aLldpXdot3LocRxFwEcho (30.12.2.1.73) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2).

The transmitting link partner may advertise a change of Fast_Wake_Enable through the aLldpXdot3LocTxFw (30.12.2.1.70) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). This appears to the receiving link partner as a change to the aLldpXdot3RemTxFw (30.12.3.1.24) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class. The receiving link partner responds to a transmitter's request through the aLldpXdot3LocRxFw (30.12.2.1.72) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). The receiving link partner also copies the value of the aLldpXdot3RemTxFw (30.12.3.1.24) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3) object class to the aLldpXdot3LocTxFwEcho (30.12.2.1.71) attribute in the LldpXdot3LocSystemsGroup managed object class (30.12.2). This appears to the transmitting link partner as a change to the aLldpXdot3RemTxFwEcho (30.12.3.1.25) attribute in the LldpXdot3RemSystemsGroup managed (30.12.3).

The state diagrams in Figure 78–8 and Figure 78–9 describe the preceding behavior.

78.4.3.1 Transmitting link partner's state change procedure across a link

A transmitting link partner is said to be in sync with the receiving link partner if the presently advertised value of Transmit $T_{w_sys_tx}$ and the corresponding echoed value are equal.

During normal operation, the transmitting link partner is in the RUNNING state. If the transmitting link partner wants to initiate a change to the presently resolved value of $T_{w_sys_tx}$, the local_system_change is asserted and the transmitting link partner enters the LOCAL CHANGE state where NEW_TX_VALUE is computed. If the new value is smaller than the presently advertised value of $T_{w_sys_tx}$ or if the transmitting link partner is in sync with the receiving link partner, then it enters TX UPDATE state. Otherwise, it returns to the RUNNING state.

If the transmitting link partner sees a change in the $T_{w_sys_tx}$ requested by the receiving link partner, it recognizes the request only if it is in sync with the transmitting link partner. The transmitting link partner examines the request by entering the REMOTE CHANGE state where a NEW TX VALUE is computed and it then enters the TX UPDATE state.

Upon entering the TX UPDATE state, the transmitter updates the advertised value of Transmit $T_{w_sys_tx}$ with NEW_TX_VALUE. If the NEW_TX_VALUE is equal to or greater than either the resolved $T_{w_sys_tx}$ value or the value requested by the receiving link partner then it enters the SYSTEM REALLOCATION state where it updates the value of resolved $T_{w_sys_tx}$ with NEW_TX_VALUE. The transmitting link partner enters the MIRROR UPDATE state either from the SYSTEM REALLOCATION state or directly from the TX UPDATE state. The UPDATE MIRROR state then updates the echo for the Receive $T_{w_sys_tx}$ and returns to the RUNNING state.

A transmitting link partner is said to be in sync with the receiving link partner if the presently advertised value of Transmit Fast_Wake_Enable and the corresponding echoed value are equal.

During normal operation, the transmitting link partner is in the RUNNING state. If the transmitting link partner wants to initiate a change to the presently resolved value of Fast_Wake_Enable, the local_system_change is asserted and the transmitting link partner enters the LOCAL CHANGE state where NEW_TX_FW is computed. If the transmitting link partner is in sync with the receiving link partner, then it enters TX UPDATE state. Otherwise, it returns to the RUNNING state.

If the transmitting link partner sees a change in the Fast_Wake_Enable requested by the receiving link partner, it recognizes the request only if it is in sync with the transmitting link partner. The transmitting link partner examines the request by entering the REMOTE CHANGE state where a NEW_TX_FW is computed and it then enters the TX UPDATE state.

Upon entering the TX UPDATE state, the transmitter updates the advertised value of Transmit Fast_Wake_Enable with NEW_TX_FW. If the NEW_TX_FW is different to either the resolved Fast_Wake_Enable value or the value requested by the receiving link partner then it enters the SYSTEM REALLOCATION state where it updates the value of resolved Fast_Wake_Enable with NEW_TX_FW. The transmitting link partner enters the MIRROR UPDATE state either from the SYSTEM REALLOCATION state or directly from the TX UPDATE state. The UPDATE MIRROR state then updates the echo for the Receive Fast_Wake_Enable and returns to the RUNNING state.

78.4.3.2 Receiving link partner's state change procedure across a link

A receiving link partner is said to be in sync with the transmitting link partner if the presently requested value of Receive $T_{w_sys_tx}$ and the corresponding echoed value are equal.

During normal operation, the receiving link partner is in the RUNNING state. If the receiving link partner wants to request a change to the presently resolved value of $T_{w_sys_tx}$, the local_system_change is asserted.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

When local_system_change is asserted or when the receiving link partner sees a change in the $T_{w_sys_tx}$ advertised by the transmitting link partner, it enters the CHANGE state where NEW_RX_VALUE is computed. If NEW_RX_VALUE is less than either the presently resolved value of $T_{w_sys_tx}$ or the presently advertised value by the transmitting link partner, it enters the SYSTEM REALLOCATION state where it updates the resolved value of $T_{w_sys_tx}$ to NEW_RX_VALUE. The receiving link partner ultimately enters the RX UPDATE state, either from the SYSTEM REALLOCATION state or directly from the CHANGE state.

In the RX UPDATE state, it updates the presently requested value to NEW_RX_VALUE, then it updates the echo for the Transmit $T_{w_sys_tx}$ in the UPDATE MIRROR state and finally goes back to the RUNNING state.

A receiving link partner is said to be in sync with the transmitting link partner if the presently requested value of Receive Fast_Wake_Enable and the corresponding echoed value are equal.

During normal operation, the receiving link partner is in the RUNNING state. If the receiving link partner wants to request a change to the presently resolved value of Fast_Wake_Enable, the local_system_change is asserted. When local_system_change is asserted or when the receiving link partner sees a change in the Fast_Wake_Enable advertised by the transmitting link partner, it enters the CHANGE state where NEW_RX_FW is computed. If NEW_RX_FW is different from either the presently resolved value of Fast_Wake_Enable or the presently advertised value by the transmitting link partner, it enters the SYSTEM REALLOCATION state where it updates the resolved value of Fast_Wake_Enable to NEW_RX_FW. The receiving link partner ultimately enters the RX UPDATE state, either from the SYSTEM REALLOCATION state or directly from the CHANGE state.

In the RX UPDATE state, it updates the presently requested value to NEW_RX_FW, then it updates the echo for the Transmit Fast_Wake_Enable in the UPDATE MIRROR state and finally goes back to the RUNNING state.

78.5 Communication link access latency

In the full duplex mode, predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delay through the network. This implies that MAC, MAC Control sublayer, and PHY implementers conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and the concatenation of devices.

The EEE capability adds latency that has to be considered by the network designer. When in the LPI mode, the PHY link is not available immediately for transmission of data. The system has to wake it up by sending the normal IDLE code on the MAC interface. Following the reception of an IDLE code on the MAC interface, the PHY starts the wake-up process. The maximal PHY recovery time, T_{w_phy} is defined for each PHY.

Transmit and/or Receive wait time shrinkage can happen when $T_{phy_shrink_rx}$ or $T_{phy_shrink_tx}$ (as defined in 78.1.3) are not zero. This has to be taken into consideration in designing or configuring the network.

Table 78–4 summarizes critical timing parameters for supported PHYs. These are listed here to assist the system designer in assessing the impact of EEE on the operation of the link.

Case-1 of the 1000BASE-T PHY applies to PHYs in Master mode. Case-2 of the 1000BASE-T PHY applies to PHYs in Slave mode.

NOTE—Annex K defines optional alternative terminology for “master” and “slave”.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Case-1 of the 10GBASE-KR PHY applies to PHYs without FEC. Case-2 of the 10GBASE-KR PHY applies to PHYs with FEC.

Case-1 of the PHY in the MultiGBASE-T set applies when the PHY is requested to transmit the Wake signal before transmission of the Sleep signal to the Link Partner is complete. Case-2 of the PHY in the MultiGBASE-T set applies when the PHY is requested to transmit the Wake signal after transmission of the Sleep signal to the Link Partner is complete and if the PHY has not indicated LOCAL FAULT at any time during the previous 10 ms.

Case-1 of the 25GBASE-CR, 25GBASE-CR-S, 25GBASE-KR, and 25GBASE-KR-S PHYs applies to PHYs in deep sleep without FEC enabled. Case-2 applies to 25GBASE-R PHYs with the BASE-R FEC in deep sleep. Case-3 applies to 25GBASE-R PHYs with the RS-FEC in deep sleep.

Case-1 of the 40GBASE-CR4, 40GBASE-KR4, and 100GBASE-CR10 PHYs applies to PHYs without FEC in deep sleep. Case-2 of these PHYs applies to PHYs with FEC in deep sleep.

Case-1 of the PHY in the MultiGBASE-T1 set applies when the PHY is requested to transmit the alert signal before transmission of the sleep signal to the link partner is complete. Case-2 of the PHY in the MultiGBASE-T1 set applies when the PHY is requested to transmit the wake signal after transmission of the sleep signal to the link partner is complete and if the PHY has not indicated LOCAL FAULT at any time during the previous 10 ms. Case-3 of the PHY in the MultiGBASE-T1 set is the same as Case-1 when Slow Wake is active. Case-4 of the PHY in the MultiGBASE-T1 set is the same as Case-2 when Slow Wake is active.

Table 78–4—Summary of the LPI timing parameters for supported PHYs or interfaces

PHY or interface type	Case	$T_{w_sys_tx}$ (min) (μs)	T_{w_phy} (min) (μs)	$T_{phy_shrink_tx}$ (max) (μs)	$T_{phy_shrink_rx}$ (max) (μs)	$T_{w_sys_rx}$ (min) (μs)
10BASE-T1L		270	250.5	10	240	20

100GBASE-CR10	Case-1	5.5	5.5	2	3	1
	Case-2	7.5	7.5	2	3	1
200GBASE-R fast wake		0.34	0.3	0	0	0.25
200GXS[c]		0.34				
400GBASE-R fast wake		0.34	0.3	0	0	0.25
400GXS[c]		0.34				

[a]All data transmission in 1000BASE-T1 PHY is synchronized to the PHY frame boundary. As such, the EEE function in the 1000BASE-T1 PHY is expected to assert the wake signal only at specific moments of time, aligned to PHY frame boundaries, and no shrinkage or delay at the RX side is expected.

[b] $T_{w_sys_tx}$ is increased by 1 μs for each instance of 25GAUI/XLAUI/CAUI with shutdown enabled on the transmit path.The receiver should negotiate an increase for remote T_{w_sys} for the link partner of 1 μs for each instance of 25GAUI/XLAUI/CAUI with shutdown enabled on the receive path.

[c]The minimum $T_{w_sys_tx}$ of a PHY is increased by the indicated period if there is a 200GXS/400GXS in the transmit path. A PHY that includes a 200GXS/400GXS in the receive path may require an increase of $T_{w_sys_tx}$ on the link partner; this may be negotiated using LLDP (see 79.3.5).

78.5.1 PHY extension using extender sublayers

The XGXS can be inserted between the RS and a 10 Gb/s PHY to transparently extend the physical reach of the XGMII. The LPI signaling can operate through the XGXS with the LPI timing parameters modified as described below.

If the DTE XS XAUI stop enable bit (5.0.9) is asserted, the DTE XS may stop signaling on the XAUI in the transmit direction to conserve energy. If the DTE XS XAUI stop enable bit is asserted, the RS defers sending data following deassertion of LPI by an additional time equal to $T_{w_sys_tx} - T_{w_sys_rx}$ for the XGXS as shown in Table 78–4 (see 46.4.2.1).

If the PHY XS XAUI stop enable bit (4.0.9) is asserted, the PHY XS may stop signaling on the XAUI in the receive direction to conserve energy. The receiver negotiates an additional time for the remote T_{w_sys} equal

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

to $T_{w_sys_tx} - T_{w_sys_rx}$ for the XGXS as shown in Table 78–4 before setting the PHY XS XAUI stop enable bit.

The 200GXS or 400GXS (see Clause 118) can be inserted between the RS and a 200 Gb/s or 400 Gb/s PHY, respectively, to transparently extend the physical reach of the 200GMII or 400GMII. The LPI signaling can operate through the 200GXS or 400GXS with the PHY timing parameters modified as described in Table 78–4.

78.5.2 25 Gb/s 40 Gb/s, and 100 Gb/s PHY extension using 25GAUI, XLAUI, or CAUI-n

25GAUI, XLAUI, CAUI-10, and CAUI-4 may be used as physical instantiations of the inter-sublayer service interface to separate functions between devices. The LPI signaling can operate through these interfaces with the LPI timing parameters modified as described below.

If PMA Egress AUI Stop Enable (PEASE, see 83.3; MDIO register bit 1.7.8) is asserted for any of the PMA sublayers, the PMA may stop signaling on the AUI in the transmit direction to conserve energy. If PEASE is asserted, the RS defers sending data following deassertion of LPI by an additional time equal to $T_{w_sys_tx}$ for the AUI as shown in Table 78–4 for each PMA with PEASE asserted (see 81.4.2).

If PMA Ingress AUI Stop Enable (PIASE, see 83.3; MDIO register bit 1.7.9) is asserted for any of the PMA sublayers, the PMA may stop signaling on the AUI in the receive direction to conserve energy. The receiver should negotiate an additional time for the remote T_{w_sys} equal to $T_{w_sys_tx}$ for the AUI as shown in Table 78–4 for each PMA with PIASE to be asserted before setting the PIASE bits.

78.6 Protocol implementation conformance statement (PICS) proforma for EEE Data Link Layer Capabilities[141]

78.6.1 Introduction

The supplier of a protocol implementation that is claimed to conform to 78.4 shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

78.6.2 Identification

78.6.2.1 Implementation identification

Supplier[a]	
Contact point for inquiries about the PICS[a]	
Implementation Name(s) and Version(s)[a, c]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[b]	
[a]Required for all implementations [b]May be completed as appropriate in meeting the requirements for the identification. [c]The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

78.6.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, 78.4, EEE Data Link Layer Capabilities
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.	
Date of Statement	

[141]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

79. IEEE 802.3 Organizationally Specific Link Layer Discovery Protocol (LLDP) type, length, and value (TLV) information elements

79.1 Overview

The Link Layer Discovery Protocol (LLDP) specified in IEEE Std 802.1AB-2009 is a MAC Client protocol that allows stations attached to an IEEE 802 LAN to advertise to all other stations attached to the same IEEE 802 LAN: the major capabilities provided by the system incorporating that station, the management address or addresses of the entity or entities that provide management of those capabilities, and the identification of the station's point of attachment to the IEEE 802 LAN.

The information fields in each LLDP frame are contained in a Link Layer Discovery Protocol Data Unit (LLDPDU) as a sequence of short, variable length, information elements known as TLVs that each include a type, length, and value field.

Organizationally Specific TLVs can be defined by either the professional organizations or the individual vendors that are involved with the particular functionality being implemented within a system. The basic format and procedures for defining Organizationally Specific TLVs are provided in subclause 9.6 of IEEE Std 802.1AB-2009.

79.1.1 IEEE 802.3 LLDP frame format

The IEEE 802.3 LLDP frame format is illustrated in Figure 79–1.

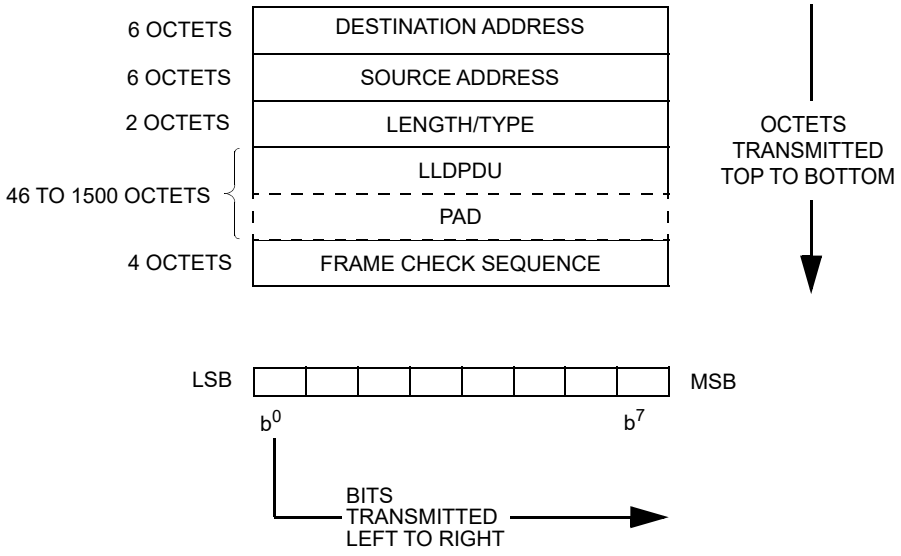

Figure 79–1—IEEE 802.3 LLDP frame format

NOTE—The illustration shows the simplest form of an IEEE 802.3 LLDP frame; i.e., where the frame has no IEEE Std 802.1Q™ tag header, or IEEE Std 802.1AE™ security tag, or any other form of encapsulation applied to it.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.1.1.1 Destination Address field

The Destination Address field of an IEEE 802.3 LLDP frame contains a MAC address specified by 7.1 of IEEE Std 802.1AB-2009 (see 79.2).

79.1.1.2 Source Address field

The Source Address field of an IEEE 802.3 LLDP frame contains the 48-bit individual address of the station sending the frame.

79.1.1.3 Length/Type field

The Length/Type field of an IEEE 802.3 LLDP frame is a 2-octet field that contains 0x88CC. This value carries the Type interpretation (see 3.2.6) and has been universally assigned for LLDP.

79.1.1.4 LLDPDU field

The LLDPDU field of an IEEE 802.3 LLDP frame contains the LLDPDU which is a sequence of short, variable length, information elements known as TLVs that each include type, length, and value fields.

79.1.1.5 Pad field

A minimum MAC frame size is required for correct operation and, if necessary, a Pad field is appended after the LLDPDU field as defined in 3.2.8.

79.1.1.6 Frame Check Sequence field

The Frame Check Sequence (FCS) field contains the Frame Check Sequence, as defined in 3.2.9.

79.2 Requirements of the IEEE 802.3 Organizationally Specific TLV set

All IEEE 802.3 Organizationally Specific TLVs shall conform to the LLDPDU bit and octet ordering conventions of 8.1 of IEEE Std 802.1AB-2009.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3 IEEE 802.3 Organizationally Specific TLVs

The currently defined IEEE 802.3 Organizationally Specific TLVs are listed in Table 79–1. Any additions or changes to these TLVs will be included in this clause.

Table 79–1—IEEE 802.3 Organizationally Specific TLVs

IEEE 802.3 subtype	TLV name	Subclause reference
1	MAC/PHY Configuration/Status	79.3.1
2	Power Via Medium Dependent Interface (MDI)	79.3.2
3	Link Aggregation (deprecated)	79.3.3
4	Maximum Frame Size	79.3.4
5	Energy-Efficient Ethernet	79.3.5
6	EEE fast wake	79.3.6
7	Additional Ethernet Capabilities	79.3.7
8	Power Via MDI Measurements	79.3.8
9 to 255	Reserved	—

79.3.1 MAC/PHY Configuration/Status TLV

The MAC/PHY Configuration/Status TLV is an optional TLV that identifies the following:

a) The duplex and bit-rate capability of the sending IEEE 802.3 LAN node that is connected to the physical medium.
b) The current duplex and bit-rate settings of the sending IEEE 802.3 LAN node.
c) Whether the current duplex and bit-rate settings are the result of auto-negotiation during link initiation or of manual set override action.

Figure 79–2 shows the format of this TLV.

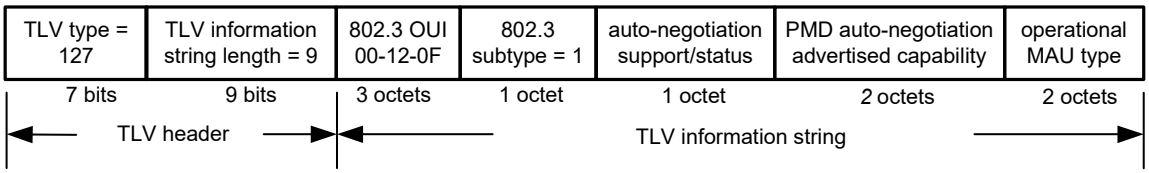

Figure 79–2—MAC/PHY configuration/status TLV format

79.3.1.1 Auto-negotiation support/status

The auto-negotiation support/status field shall contain a bitmap that identifies the auto-negotiation support and current status of the local IEEE 802.3 LAN station as defined in Table 79–2. If the auto-negotiation support bit (bit 0) is one and the auto-negotiation status bit (bit 1) is zero, the IEEE 802.3 physical media dependent sublayer (PMD) operating mode is determined by the operational Medium Attachment Unit (MAU) type field value rather than by auto-negotiation.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 79–2—IEEE 802.3 auto-negotiation support/status

Bit	Function	Value/meaning	IETF RFC 4836 reference
0	Auto-negotiation support	1 = supported 0 = not supported	ifMauAutoNegSupported
1	Auto-negotiation status	1 = enabled 0 = not enabled	ifMauAutoNegAdminStatus
7:2	—	Reserved for future standardization	—

79.3.1.2 PMD auto-negotiation advertised capability field

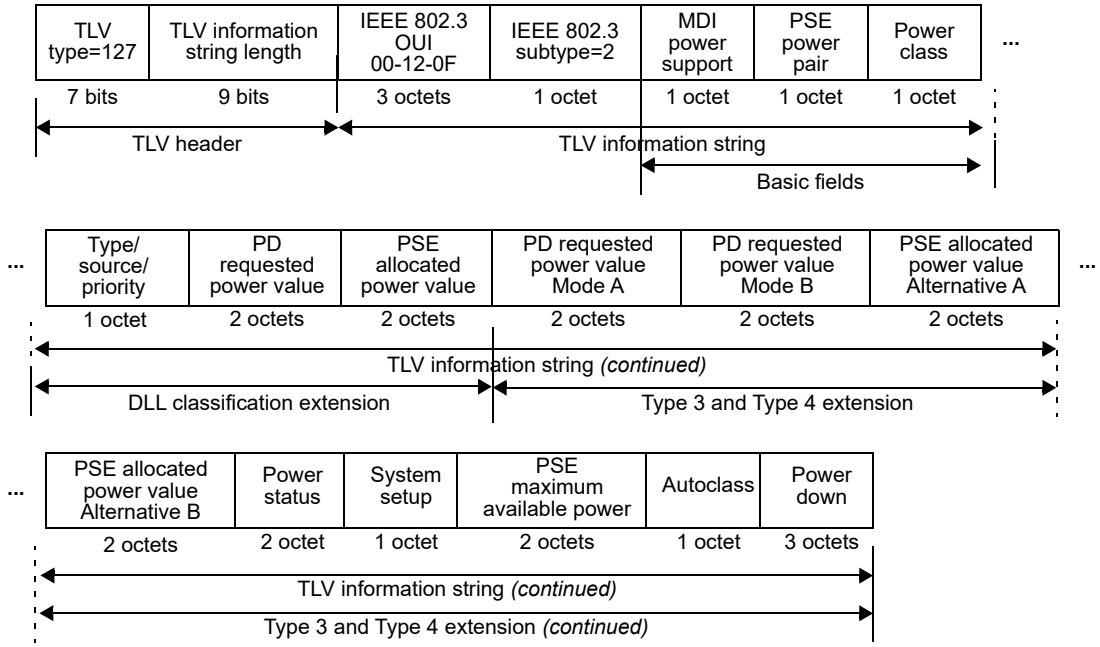
The ‘PMD auto-negotiation capability’ field shall contain a 2-octet value that provides a bitmap of the ifMauAutoNegCapAdvertisedBits object, defined in IETF RFC 4836, of the sending device. Bit zero is the high order (left-most) bit in an octet string.

79.3.1.3 Operational MAU type

The operational MAU type field contains an integer value indicating the MAU type of the sending device. This value shall be derived from the list position of the corresponding dot3MauType as listed in IETF RFC 4836 (or subsequent revisions) and is equal to the last number in the respective dot3MauType Object Identifier (OID). For example, if the ifMauType object is dot3MauType1000BaseTHD which corresponds to {dot3MauType 29}, the numerical value of this field is 29. For MAU types not listed in IETF RFC 4836 (or subsequent revisions), the value of this field shall be set to zero.

79.3.1.4 MAC/PHY Configuration/Status TLV usage rules

An LLDPDU should contain no more than one MAC/PHY Configuration/Status TLV.



79.3.2 Power Via MDI TLV

Clause 33 and Clause 145 define two optional power entities: a Powered Device (PD) and Power Sourcing Equipment (PSE). These entities allow devices to draw/supply power over the sample generic cabling as used for data transmission. The Power Via MDI TLV allows network management to advertise and discover the Power over Ethernet capabilities of the sending IEEE 802.3 LAN station. This TLV is also required to perform Data Link Layer classification as defined in 33.6 and 145.5. Figure 79–3 shows the format of this TLV.

The Power via MDI TLV shown in Figure 79–3 was originally defined in IEEE Std 802.1AB-2005 Annex G.3. This original TLV supported only the first three fields of Figure 79–3, labeled basic fields, enabling discovery and advertisement of Power via MDI capabilities. The Power via MDI TLV was revised by IEEE Std 802.3at-2009 to add a further three fields, labeled DLL classification extension, to provide Data Link Layer (DLL) classification capabilities. The Power via MDI TLV was revised again by IEEE Std 802.3bt-2018 to add a further nine fields, labeled Type 3 and Type 4 extension, to support additional capabilities offered by Type 3 and Type 4 PSEs and PDs.

Power entities may continue to use the Power Via MDI TLV basic fields shown in Figure 79–3 prior to supplying/drawing power to/from the Power Interface (PI), as defined in 1.4.484. The DLL classification extension fields and Type 3 and Type 4 extension fields shown in Figure 79–3 shall not be sent by the PSE unless it is supplying power to a PI encompassed within an MDI and by the PD unless it is drawing power from the PI.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The TLV information string length is

- Basic fields: 7 octets
- Basic fields and DLL classification extension: 12 octets
- Basic fields, DLL classification extension, and Type 3 and Type 4 extension: 29 octets

Figure 79–3—Power Via MDI TLV format

Power entities that implement Data Link Layer classification shall support the Power via MDI TLV DLL classification extension fields shown in Figure 79–3 after the PI has been powered. Type 3 or Type 4 power entities that implement Data Link Layer classification and are connected to another Type 3 or Type 4 power entity shall support the Type 3 and Type 4 extension fields shown in Figure 79–3 after the PI has been powered. Such entities, when connected to a Type 1 or Type 2 power entity, may support the Type 3 and Type 4 extension fields shown in Figure 79–3 after the PI has been powered. Type 1 and Type 2 devices shall not include the Type 3 and Type 4 extension fields in the transmitted Power via MDI TLV.

NOTE—Some implementations of the Power via MDI TLV in Type 1 and Type 2 power entities ignore TLVs that are longer than 12 octets. In order to be interoperable with these implementations, Type 3 and Type 4 power entities are permitted to transmit 12-octet TLVs (without the Type 3 and Type 4 extension) after first transmitting at least one valid 29-octet TLV (including the Type 3 and Type 4 extension). Table 79–3 lists the recommended Power via MDI TLV formats for each combination of power entity Types.

Type 3 and Type 4 PD power entities can determine the PSE Type based on the duration of the first classification event (see 145.3.7) or based on the length of a received Power via MDI TLV (see Figure 79–3). Type 3 and Type 4 PSEs can determine the PD Type based on the PDs Physical Layer requested Class (see 145.2.8 and 145.3.6.1) or based on the length of a received Power via MDI TLV (see Figure 79–3).

79.3.2.1 MDI power support

The MDI power support field shall contain a bitmap of the MDI power capabilities and status as defined in Table 79–4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 79–3—Recommended TLV format

Power entity A	Power entity B	Power entity A sends	Power entity B sends	Recommended TLV format
Type 1, Type 2	Type 1, Type 2	12-octet TLV	12-octet TLV	12-octet TLV
Type 3, Type 4	Type 1, Type 2	29-octet TLV	12-octet TLV	12-octet TLV
Type 1, Type 2	Type 3, Type 4	12-octet TLV	29-octet TLV	12-octet TLV
Type 3, Type 4	Type 3, Type 4	29-octet TLV	29-octet TLV	29-octet TLV

Table 79–4—MDI power support field

Bit	Function	Value/meaning
7:4	Reserved for future standardization	—
3	PSE pairs control ability	1 = pair selection can be controlled 0 = pair selection can not be controlled
2	PSE MDI power state	1 = enabled 0 = disabled
1	PSE MDI power support	1 = supported 0 = not supported
0	Port class	1 = PSE 0 = PD

79.3.2.1.1 Port class

The ‘Port class’ field transmitted shall indicate if the port is a PSE or a PD.

79.3.2.1.2 PSE MDI power support

The ‘PSE MDI power support’ field transmitted by a PSE shall indicate if MDI power is supported. The value of the ‘PSE MDI power support’ field transmitted by a PD is undefined.

79.3.2.1.3 PSE MDI power state

The ‘PSE MDI power state’ field transmitted by a PSE shall indicate if the PSE function is enabled or disabled. When disabled all PSE functions are disabled and behavior is as if there was no PSE functionality. The value of the ‘PSE MDI power state’ field transmitted by a PD is undefined.

79.3.2.1.4 PSE pairs control ability

The ‘PSE pairs control ability’ field transmitted by a PSE shall indicate if the PSE has the capability to control which PSE Pinout Alternative (see 33.2.3 and 145.2.4) is used for PD detection and power. The value of the ‘PSE pairs control ability’ field transmitted by a PD is undefined.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.2.2 PSE power pair

The ‘PSE power pair’ field transmitted by a PSE shall contain an integer value as defined in Table 79–5 based on aPSEPowerPairs (see 30.9.1.1.4). A Type 3 or Type 4 PSE that is supplying power on a single pairset shall use the value that defines that pairset. Either pairset may be indicated when a PSE is detecting or supplying power on both pairsets. The ‘PSE power status value’ field defined in 79.3.2.9 indicates when a PSE is supplying power on both pairsets. The value of the ‘PSE power pair’ field transmitted by a PD is undefined.

Table 79–5—PSE power pair field

Value	Meaning	Alternative
1	signal	Alternative A
2	spare	Alternative B

79.3.2.3 Power class

The ‘Power class’ field transmitted by a PSE shall contain an integer value as defined in Table 79–6 based on aPSEPowerClassification (see 30.9.1.1.8). Class 4 and above is indicated with the same value in this field. Class 5 and above is communicated by the ‘Power Class ext’ field defined in 79.3.2.9.6. The ‘Power class’ field transmitted by a PD is undefined.

Table 79–6—Power class field

Value	Meaning
1	Class 0 PD
2	Class 1 PD
3	Class 2 PD
4	Class 3 PD
5	Class 4 and above PD

79.3.2.4 Power type/source/priority

The ‘Power type/source/priority’ field shall contain a bit-map of the power type, source, and priority defined in Table 79–7 and is reported for the device generating the TLV.

79.3.2.4.1 Power type

This field shall be set according to Table 79–7. Type 3 or Type 4 PSEs shall set this field to the value corresponding with Type 2 PSEs. Type 3 or Type 4 PDs shall set this field to the value corresponding with Type 2 PDs.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 79–7—Power type/source/priority field

Bit	Function	Value/meaning
7:6	Power type	7 6 1 1 = Type 1 PD 1 0 = Type 1 PSE 0 1 = Type 2 PD 0 0 = Type 2 PSE
5:4	Power source	Where Power type = PD 5 4 1 1 = PSE and local 1 0 = Reserved 0 1 = PSE 0 0 = Unknown Where Power type = PSE 5 4 1 1 = Reserved 1 0 = Backup source 0 1 = Primary power source 0 0 = Unknown
3	Reserved	Transmit as zero, ignore on receive
2	PD 4PID	1 = PD supports powering of both Modes simultaneously 0 = PD does not support powering of both Modes simultaneously
1:0	Power priority	1 0 1 1 = low 1 0 = high 0 1 = critical 0 0 = unknown (default)

79.3.2.4.2 Power source

When the power type is PD, this field shall be set to 01 when the PD is being powered only through the PI; to 11 when the PD is being powered from both; and to 00 when this information is not available.

When the power type is PSE, this field shall be set to 01 when the PSE is sourcing its power through the PI from its primary supply; to 10 when the PSE is sourcing its power through the PI from a backup source; and to 00 when this information is not available.

79.3.2.4.3 PD 4PID

This field shall be set according to Table 79–7 when the Power type is PD to indicate whether the PD supports powering of both Modes simultaneously. This field shall be set to ‘0’ when the Power type is PSE.

79.3.2.4.4 Power priority

When the power type is PD, this field shall be set to the power priority configured for the device. If a PD is unable to determine its power priority or it has not been configured, then this field shall be set to 00.

When the power type is PSE, this field reflects the PD priority that the PSE advertises to assign to the PD.

79.3.2.5 PD requested power value

The ‘PD requested power value’ field shall contain the PD’s requested power value defined in Table 79–8. See 33.6.3.3 and Table 145–42 for permitted value ranges.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 79–8—PD requested power value field

Bit	Function	Value/meaning
15:0	PD requested power value	Power expressed in units of 0.1 W Valid values for these bits are decimal 0 through 999.

"PD requested power value" is the maximum input average power (see 33.3.7.2 and 145.3.8.2) the PD is requesting. "PD requested power value" is the power value at the PD PI. A value higher than 713 requires the PSE to support a power level higher than P_{Class_PD} at the PD PI. See 145.2.8 and 145.3.8.2.

79.3.2.6 PSE allocated power value

The 'PSE allocated power value' field shall contain the PSE allocated power value defined in Table 79–9. See 33.6.3.3 and Table 145–41 for permitted value ranges.

Table 79–9—PSE allocated power value field

Bit	Function	Value/meaning
15:0	PSE allocated power value	Power expressed in units of 0.1 W Valid values for these bits are decimal 0 through 999.

"PSE allocated power value" is the maximum input average power (see 33.3.7.2 and 145.3.8.2) the PSE expects the PD to draw. "PSE allocated power value" is the power at the PD PI. The PSE uses this value to compute P_{Class} as defined in 33.2.6 and 145.2.8. A value higher than 713 indicates that the PSE is capable of supporting a power level beyond P_{Class_PD} at the PD PI. This may require an output power level higher than P_{Type} min. See 145.2.8.

79.3.2.7 Dual-signature PD requested power value for Mode A and Mode B

The 'PD requested power value Mode A' field and 'PD requested power value Mode B' field shall contain the PD requested power value defined in Table 79–10 for Mode A and in Table 79–11 for Mode B of a dual-signature PD.

Table 79–10—PD requested power value Mode A field

Bit	Function	Value/meaning
15:0	Dual-signature PD requested power value for Mode A	Power expressed in units of 0.1 W. Valid values for these bits are decimal 0 through 499.

Table 79–11—PD requested power value Mode B field

Bit	Function	Value/meaning
15:0	Dual-signature PD requested power value for Mode B	Power expressed in units of 0.1 W. Valid values for these bits are decimal 0 through 499.

The 'PD requested power value Mode A' field and 'PD requested power value Mode B' field are the maximum input average power levels (see 145.3.8.2) the PD is requesting for the respective Mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.2.8 PSE allocated power value Alternative A and Alternative B

The ‘PSE allocated power value Alternative A’ field and the ‘PSE allocated power value Alternative B’ field shall contain the values in Table 79–12 and Table 79–13 for Type 3 and Type 4 PSEs operating over both pairsets when connected to a dual-signature PD.

Table 79–12—PSE allocated power value Alternative A field

Bit	Function	Value/meaning
15:0	PSE allocated power value for Alternative A	Power expressed in units of 0.1 W. Valid values for these bits are decimal 0 through 499.

Table 79–13—PSE allocated power value Alternative B field

Bit	Function	Value/meaning
15:0	PSE allocated power value for Alternative B	Power expressed in units of 0.1 W. Valid values for these bits are decimal 0 through 499.

The ‘PSE allocated power value Alternative A’ and ‘PSE allocated power value Alternative B’ fields are the maximum input average power levels (see 145.3.8.2) the PSE expects the dual-signature PD to draw on the respective Alternatives when the PSE provides power over 4-pair. These fields are the power levels at the dual-signature PD PI. The PSE uses these values to compute $P_{Class\text{-}2P}$ as defined in 145.2.8.

79.3.2.9 Power status

The ‘Power status’ field contains the PSE's bit-map of the PSE power pair and PSE or PD power class, defined in Table 79–14, and is reported for the device generating the TLV.

Table 79–14—Power status field

Bit	Function	Value/meaning
15:14	PSE powering status	15 14 1 1 = 4-pair powering dual-signature PD 1 0 = 4-pair powering single-signature PD 0 1 = 2-pair powering 0 0 = Reserved/Ignore
13:12	PD powered status	13 12 1 1 = 4-pair powered dual-signature PD 1 0 = 2-pair powered dual-signature PD 0 1 = Powered single-signature PD 0 0 = Reserved/Ignore
11:10	PSE power pairs ext	11 10 1 1 = Both Alternatives 1 0 = Alternative B 0 1 = Alternative A 0 0 = Reserved/Ignore

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 79–14—Power status field *(continued)*

Bit	Function	Value/meaning
9:7	Dual-signature power Class ext Mode A	9 8 7 1 1 1 = Single-signature PD or 2-pair only PSE 1 1 0 = Reserved/Ignore 1 0 1 = Class 5 1 0 0 = Class 4 0 1 1 = Class 3 0 1 0 = Class 2 0 0 1 = Class 1 0 0 0 = Reserved/Ignore
6:4	Dual-signature power Class ext Mode B	6 5 4 1 1 1 = Single-signature PD or 2-pair only PSE 1 1 0 = Reserved/Ignore 1 0 1 = Class 5 1 0 0 = Class 4 0 1 1 = Class 3 0 1 0 = Class 2 0 0 1 = Class 1 0 0 0 = Reserved/Ignore
3:0	Power Class ext	3 2 1 0 1 1 1 1 = Dual-signature PD 1 1 1 0 = Reserved/Ignore 1 1 0 1 = Reserved/Ignore 1 1 0 0 = Reserved/Ignore 1 0 1 1 = Reserved/Ignore 1 0 1 0 = Reserved/Ignore 1 0 0 1 = Reserved/Ignore 1 0 0 0 = Class 8 0 1 1 1 = Class 7 0 1 1 0 = Class 6 0 1 0 1 = Class 5 0 1 0 0 = Class 4 0 0 1 1 = Class 3 0 0 1 0 = Class 2 0 0 0 1 = Class 1 0 0 0 0 = Reserved/Ignore

79.3.2.9.1 PSE powering status

The ‘PSE powering status’ field is used to indicate the existing powering configuration as shown in Table 145–41 and thus to indicate that the PSE is using the ‘PSE allocated power value’ field or is using the ‘PSE allocated power value Alternative A’ field and ‘PSE allocated power value Alternative B’ field as specified in Table 79–12 and Table 79–13. A PSE shall set this field according the current powering status as defined in Table 79–14. A PD shall set the field to 0.

79.3.2.9.2 PD powered status

The ‘PD powered status’ field is used to indicate the existing powered configuration of the PD as shown in Table 145–42 and thus to indicate that the PD is using the ‘PD requested power value’ field or is using the ‘PD requested power value Mode A’ field and the ‘PD requested power value Mode B’ field as specified in Table 79–10 and Table 79–11. A PD shall set this field according to its signature configuration and the current powering status as defined in Table 79–14. A PSE shall set the field to 0.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.2.9.3 PSE power pairs ext

The ‘PSE power pairs ext’ field shall contain the powering status of the PSE, as defined in Table 79–14. A PD shall set the field to 0.

79.3.2.9.4 Dual-signature power Class ext Mode A

A single-signature PD shall set this field to value 7. A dual-signature PD shall set this field per its requested Class on Mode A defined in 145.3.6. A 2-pair only PSE or a PSE connected to a single-signature PD shall set this field to value 7. A PSE connected to a dual-signature PD shall set this field to the PSEs assigned Class for Alternative A as defined in 145.2.8.

79.3.2.9.5 Dual-signature power Class ext Mode B

A single-signature PD shall set this field to value 7. A dual-signature PD shall set this field per its requested Class on Mode B defined in 145.3.6. A 2-pair only PSE or a PSE connected to a single-signature PD shall set this field to value 7. A PSE connected to a dual-signature PD shall set this field to the PSEs assigned Class for Alternative B as defined in 145.2.8.

79.3.2.9.6 Power Class ext

A single-signature PD shall set this field per its requested Class as defined in 145.3.6. A dual-signature PD shall set this field to value 15. A 2-pair only PSE or a PSE connected to a single-signature PD shall set this field to the PSEs assigned Class as defined in 145.2.8. A PSE connected to a dual-signature PD shall set this field to value 15.

79.3.2.10 System setup

The ‘System setup’ field shall contain the device bit-map of the Power Type ext and PD Load defined in Table 79–15 and is reported for the device generating the TLV.

Table 79–15—System setup field

Bit	Function	Value/meaning
7:4	Reserved	Transmit as zero. Ignore on receive.
3:1	Power Type ext	3 2 1 1 1 1 = Reserved / ignore 1 1 0 = Reserved / ignore 1 0 1 = Type 4 dual-signature PD 1 0 0 = Type 4 single-signature PD 0 1 1 = Type 3 dual-signature PD 0 1 0 = Type 3 single-signature PD 0 0 1 = Type 4 PSE 0 0 0 = Type 3 PSE
0	PD Load	1 = PD is dual-signature and power demand on Mode A and Mode B are electrically isolated. 0 = PD is single-signature or dual-signature and power demand on Mode A and Mode B are not electrically isolated.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.2.10.1 Power Type ext

This field shall be set according to Table 79–15.

79.3.2.10.2 PD Load

This field shall be set according to Table 79–15 when the Power type is PD. This field shall be set to 0 when the Power type is PSE. See 145.4.1 for details.

79.3.2.11 PSE maximum available power value

The ‘PSE maximum available power value’ field shall contain the highest power the PSE can grant as defined in Table 79–16. The PSE sets the value of this field taking available power budget and hardware capabilities into account. When connected to a dual-signature PD this value refers to the total amount of power available at the PI, even though power is allocated separately on a per pairset basis. A PD shall set this field to 0.

Table 79–16—PSE maximum available power value field

Bit	Function	Value/meaning
15:0	PSE maximum available power value	Power expressed in units of 0.1 W. Valid values for these bits are 1 through 999.

79.3.2.12 Autoclass

The ‘Autoclass’ field shall contain the bits defined in Table 79–17 to control Autoclass. See 145.2.8.2 and 145.3.6.2 for details on Autoclass. Using the ‘Autoclass’ field to trigger a new Autoclass measurement allows a PD to change maximum power consumption.

Table 79–17—Autoclass field

Bit	Function	Value/meaning
7:3	Reserved	Transmit as zero. Ignore on receive.
2	PSE Autoclass support	1 = PSE supports Autoclass 0 = PSE does not support Autoclass
1	Autoclass completed	1 = Autoclass measurement completed 0 = Autoclass idle
0	Autoclass request	1 = PD requests Autoclass measurement 0 = Autoclass idle

79.3.2.12.1 PSE Autoclass support

When the Power type is PSE, this field shall be set to indicate if the PSE supports Autoclass over DLL according to Table 79–17. When the Power type is PD, this field shall be set to 0.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.2.12.2 Autoclass completed

When the Power type is PSE, this field shall be set to indicate that the PSE has concluded the Autoclass measurement. This happens after a request for Autoclass is made by the PD using the 'Autoclass request' field defined in Table 79–17. When the Power type is PD, this field shall be set to 0.

79.3.2.12.3 Autoclass request

When the Power type is PD, this field may be set to 1 to request a Autoclass measurement by the PSE. The PD sets this field when it is in a state where it consumes its maximum amount of power. In all other cases, the PD sets this field to 0. When the Power type is PSE, this field shall be set to 0.

79.3.2.13 Power down

The 'Power down' field shall contain the bits defined in Table 79–18. The 'Power down' field allows the PD to request power delivery to be terminated, either indefinitely or for a certain period of time.

Table 79–18—Power down field

Bit	Function	Value/meaning
23:18	Power down request	Value = 0x1D requests a power down. Any other value is ignored.
17:0	Power down time	The amount of time in seconds the PD requests to be unpowered. A value of zero means to remain unpowered indefinitely. Valid values are 0 through 262 143.

79.3.2.13.1 Power down request

When the Power type is PD, this field may be set to 0x1D to indicate a request for power down. If power is to be maintained, the field shall be set to 0. When the Power type is PSE, this field shall be set to 0.

79.3.2.13.2 Power down time

This field controls the amount of time in seconds the PD is requesting to be unpowered. When the Power type is PD, this field shall be set per the description in Table 79–18. When the Power type is PSE, this field shall be set to 0.

79.3.2.14 Power Via MDI TLV usage rules

An LLDPDU should contain no more than one Power Via MDI TLV.

79.3.3 Link Aggregation TLV (deprecated)

The Link Aggregation TLV is an optional TLV that indicates whether the link is capable of being aggregated, whether the link is currently in an aggregation, and if in an aggregation, the port identification of the aggregation. Figure 79–4 shows the format for this TLV.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

NOTE—As the Link Aggregation specification has now been removed from IEEE Std 802.3 and is now standardized as IEEE Std 802.1AX, new implementations of this standard are encouraged to make use of the Link Aggregation TLV that is now part of the IEEE 802.1 extension MIB specified in Annex E of IEEE Std 802.1AB-2009.

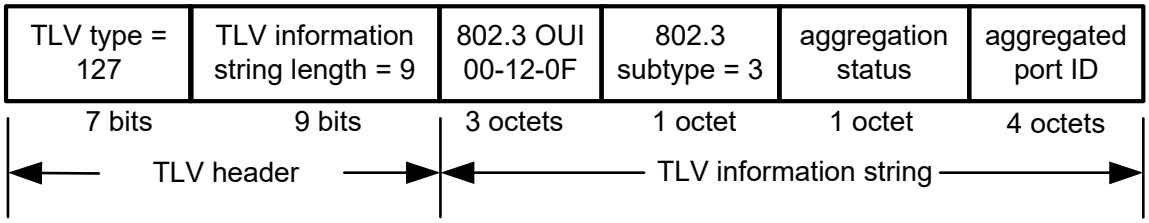

Figure 79–4—Link Aggregation TLV format

79.3.3.1 Aggregation status

The link aggregation status field shall contain a bitmap of the link aggregation capabilities and the current aggregation status of the link as defined in Table 79–19.

Table 79–19—Link aggregation capability/status

Bit	Function	Value/meaning
0	Aggregation capability	0 = not capable of being aggregated 1 = capable of being aggregated
1	Aggregation status	0 = not currently in aggregation 1 = currently in aggregation
7:2	reserved for future standardization	—

79.3.3.2 Aggregated port ID

The aggregated port ID field shall contain the IEEE 802.3 aggregated port identifier, aAggPortID, derived from the ifNumber in the ifIndex for the interface (see 30.7.2.1.1).

79.3.3.3 Link Aggregation TLV usage rules

An LLDPDU should contain no more than one Link Aggregation TLV.

79.3.4 Maximum Frame Size TLV

The Maximum Frame Size TLV is an optional TLV that indicates the maximum frame size capability of the implemented MAC and PHY. Figure 79–5 shows the format of this TLV.

NOTE—MAC and PHY support for a given frame size doesn't necessarily mean that the upper layers support that frame size.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

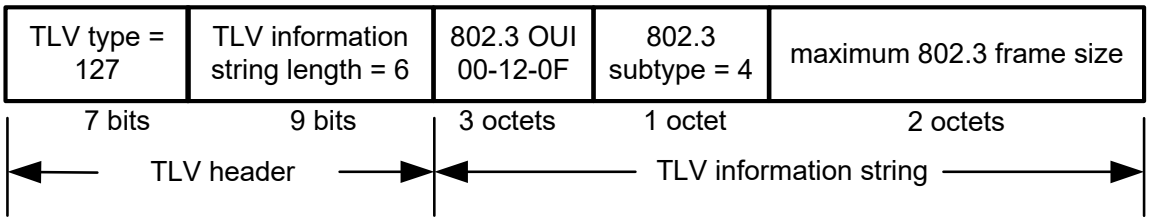

Figure 79–5—Maximum Frame Size TLV format

79.3.4.1 Maximum frame size

The maximum frame size field shall contain an integer value indicating the maximum supported frame size in octets as determined by the following:

a) If the MAC/PHY supports only basic frames (see 3.2.7) the maximum frame size field shall be set to 1518.
b) If the MAC/PHY supports Q-tagged frames (see 3.2.7) the maximum frame size field shall be set to 1522.
c) If the MAC/PHY supports envelope frames (see 3.2.7) the maximum frame size field shall be set to 2000.

79.3.4.2 Maximum Frame Size TLV usage rules

An LLDPDU should contain no more than one Maximum Frame Size TLV.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.5 EEE TLV

The EEE TLV is used to exchange information about the EEE Data Link Layer capabilities. Figure 79–6 shows the format of this TLV.

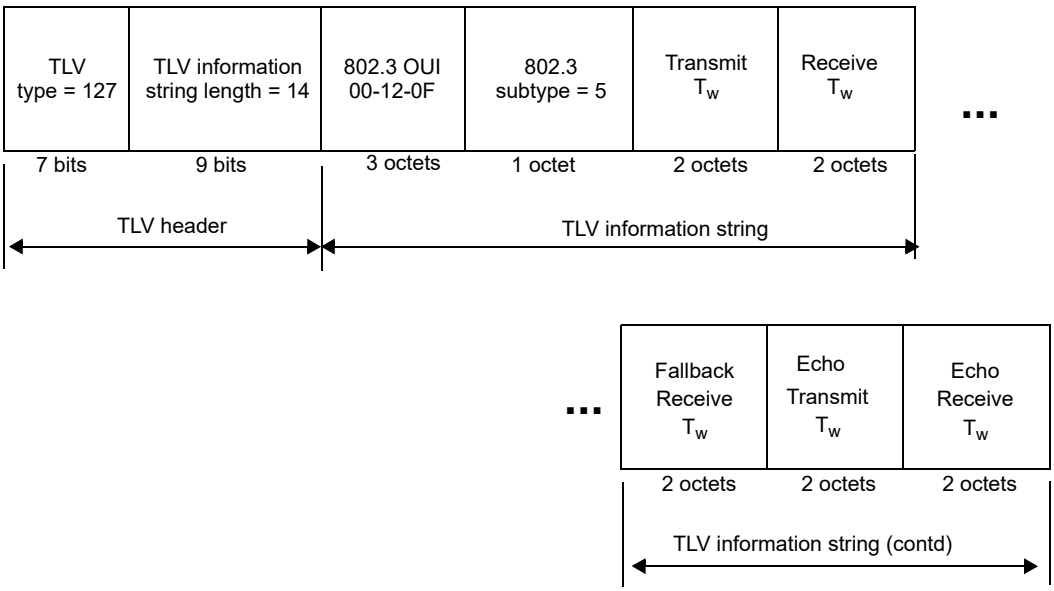

Figure 79–6—EEE TLV format

79.3.5.1 Transmit T_w

Transmit $T_{w_sys_tx}$ (2 octets wide) shall be defined as the time (expressed in microseconds) that the transmitting link partner will wait before it starts transmitting data after leaving the Low Power Idle (LPI) mode. This is a function of the transmit system design and may be constrained, for example, by the transmit path buffering. The default value for Transmit $T_{w_sys_tx}$ is the T_{w_phy} defined for the PHY that is in use for the link. The Transmitting link partner expects that the Receiving link partner will be able to accept data after the time delay Transmit $T_{w_sys_tx}$ (expressed in microseconds).

79.3.5.2 Receive T_w

Receive $T_{w_sys_tx}$ (2 octets wide) shall be defined as the time (expressed in microseconds) that the receiving link partner is requesting the transmitting link partner to wait before starting the transmission data following the LPI. The default value for Receive $T_{w_sys_tx}$ is the T_{w_phy} defined for the PHY that is in use for the link. The Receive $T_{w_sys_tx}$ value can be larger but not smaller than the default. The extra wait time may be used by the receive link partner for power-saving mechanisms that require a longer wake-up time than the PHY-layer definitions.

79.3.5.3 Fallback T_w

A receiving link partner may inform the transmitter of an alternate desired $T_{w_sys_tx}$. Since a receiving link partner is likely to have discrete levels for savings, this provides the transmitter with additional information that it may use for a more efficient allocation. As with the Receive $T_{w_sys_tx}$, this is 2 octets wide. Systems that do not implement this option default the value to be the same as that of the Receive $T_{w_sys_tx}$.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

79.3.5.4 Echo Transmit and Receive T_W

The respective echo values shall be defined as the local link partner's reflection (echo) of the remote link partner's respective values. When a local link partner receives its echoed values from the remote link partner it can determine whether or not the remote link partner has received, registered, and processed its most recent values. For example, if the local link partner receives echoed parameters that do not match the values in its local MIB, then the local link partner infers that the remote link partner's request was based on stale information.

79.3.5.5 EEE TLV usage rules

An LLDPDU should contain no more than one EEE TLV.

79.3.6 EEE Fast Wake TLV

The EEE Fast Wake TLV is used to exchange information about the EEE fast wake capabilities. This TLV is only used by systems with links operating at speeds greater than 10 Gb/s. Figure 79–7 shows the format of this TLV.

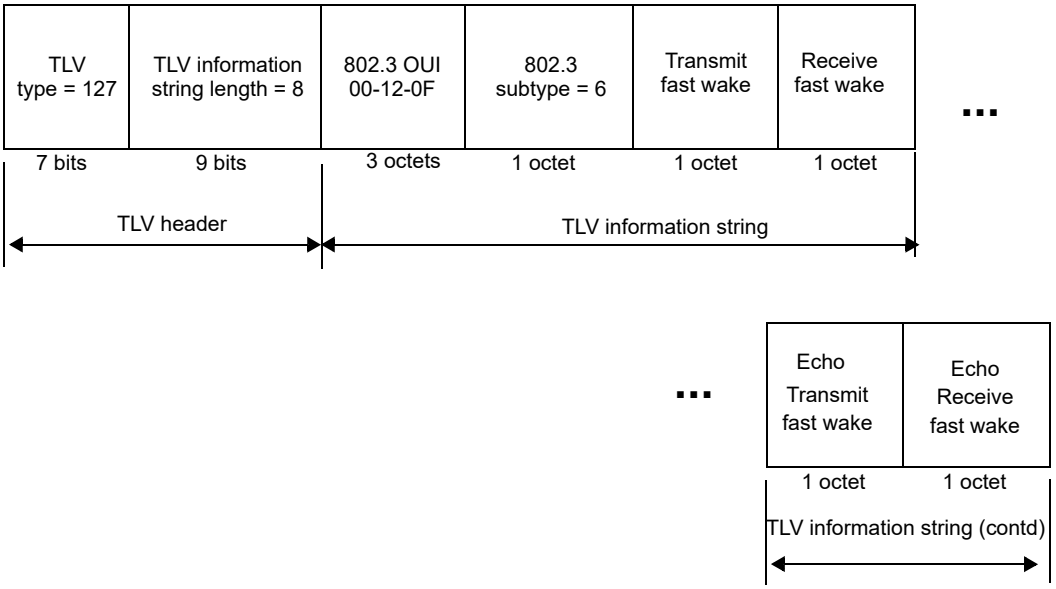

Figure 79–7—EEE Fast Wake TLV format

79.3.6.1 Transmit fast wake

Transmit fast wake (1 octet wide) is a logical indication that the transmit LPI state diagram intends to use the fast wake function (corresponding to the variable LPI_FW in 82.2.19.2.2). Transmit fast wake = 1 corresponds to LPI_FW being TRUE; Transmit fast wake = 0 corresponds to LPI_FW being FALSE. The default value for Transmit fast wake is 1 (TRUE). Transmit fast wake is set to TRUE unless the PHY is capable of deep sleep operation as determined by the PHY type and the results of auto-negotiation.

79.3.6.2 Receive fast wake

Receive fast wake (1 octet wide) is a logical indication that the receive LPI state diagram is expecting its link partner to use the fast wake function (corresponding to the variable LPI_FW in 82.2.19.2.2). Receive fast

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

wake = 1 corresponds to LPI_FW being TRUE; Receive fast wake = 0 corresponds to LPI_FW being FALSE. The default value for Receive fast wake is 1 (TRUE). Receive fast wake is set to TRUE unless the PHY is capable of deep sleep operation as determined by the PHY type and the results of auto-negotiation.

79.3.6.3 Echo of Transmit fast wake and Receive fast wake

The respective echo values are the local link partner's reflection (echo) of the remote link partner's respective values. When a local link partner receives its echoed values from the remote link partner, it can determine whether or not the remote link partner has received, registered, and processed its most recent values. For example, if the local link partner receives echoed parameters that do not match the values in its local MIB, then the local link partner infers that the remote link partner's request was based on stale information.

79.3.6.4 EEE Fast Wake TLV usage rules

An LLDPDU should contain no more than one EEE Fast Wake TLV.

79.3.7 Additional Ethernet Capabilities TLV

The Additional Ethernet Capabilities TLV is an optional TLV that indicates which additional capabilities are supported. Figure 79–8 shows the format of this TLV.

NOTE—MAC and PHY support for a given frame size does not necessarily mean that the upper layers support that frame size.

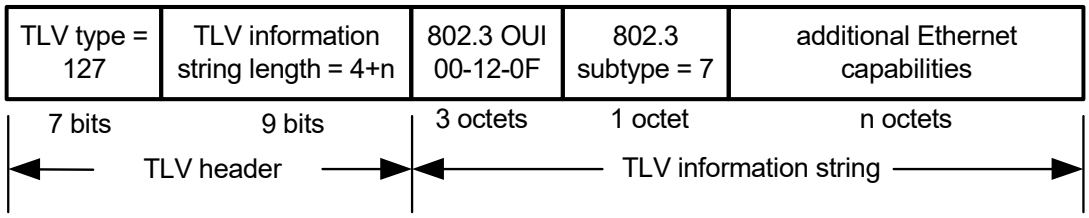

Figure 79–8—Additional Ethernet Capabilities TLV

79.3.7.1 Additional Ethernet capabilities

The additional Ethernet capabilities field shall contain a bitmap that identifies the support and current status of additional Ethernet capabilities on the local IEEE 802.3 LAN station. The first two octets of the field are defined in Table 79–20. Additional octets are reserved.

An implementation shall transmit all Reserved bits as zero and ignore received Reserved bits. Reserved octets shall not be transmitted and if more octets are received than were defined as other than Reserved, the additional octet(s) shall be ignored. If fewer octet(s) are received than defined, the implementation shall act as if the additional octet(s) were received as zero.

79.3.7.2 Additional Ethernet Capabilities TLV usage rules

An LLDPDU should contain no more than one Additional Ethernet Capabilities TLV. Since this TLV is intended to inform a link partner of capabilities, the Additional Ethernet Capabilities TLV should be sent in an LLDPDU addressed to the Nearest Bridge group address (see IEEE Std 802.1Q).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 79–20—Additional Ethernet capabilities

Bit	Function	Value/meaning	Reference
0	preemption capability support	1 = supported 0 = not supported	99.4.2
1	preemption capability status	1 = enabled 0 = not enabled	99.4.2
2	preemption capability active	1 = active 0 = not active	99.4.3
4:3	additional fragment size	A 2-bit integer value indicating, in units of 64 octets, the minimum number of octets over 64 octets required in non-final fragments by the receiver	99.4.4
15:5	Reserved	—	—

79.3.8 Power via MDI Measurements TLV

Clause 33 and Clause 145 define two optional power entities: a Powered Device (PD) and Power Sourcing Equipment (PSE). These entities allow devices to draw/supply power over the same generic cabling as used for data transmission. The Power Via MDI Measurement TLV allows network management to read electrical measurement data from the sending IEEE 802.3 LAN station. Figure 79–9 shows the format of this TLV.

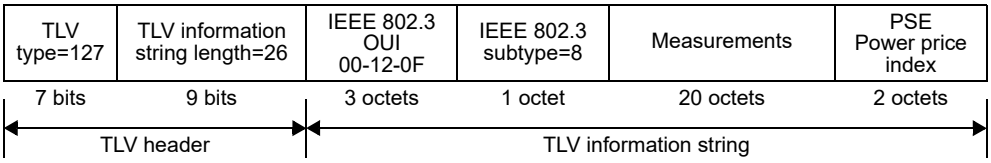

Figure 79–9—Power Via MDI Measurements TLV format for Type 3 and Type 4

79.3.8.1 Measurements

This field shall be set according to Table 79–21.

The ‘Voltage measurement’ field carries the measured voltage value at the PI, the ‘Current measurement’ field carries the measured current value at the PI, the ‘Power measurement’ field carries the measured power value at the PI, and the ‘Energy measurement’ field carries the measured energy consumption value at the PI, as defined in Table 79–21.

Measurement values (voltage, current, power, or energy) shall be set to 0 in case the corresponding request bit is 0. If a device does not support a particular measurement, the corresponding measurement value shall be set to 0.

79.3.8.2 PSE power price index

The ‘PSE power price index’ field shall contain an index of the current price of electricity compared to what the PSE considers the nominal electricity price. The determination of the nominal electricity price is implementation dependent. The field is encoded as defined in Equation (79–1). The PSE sets the value of

Table 79–21—Measurements *(continued)*

Bit	Function	Value/meaning
95:80	Energy uncertainty	Expanded uncertainty (coverage factor k = 2) for the energy measurement, expressed in units of 0.1 kJ. Valid values are 1 through 65 000.
79:64	Voltage measurement	$V_{Port_PD\text{-}2P}$ expressed in units of 1 mV. When the Measurement source is set to 'Port total' this field contains the measurement of the pairset with the highest voltage. Valid values are 0 through 65 000[a].
63:48	Current measurement	I_{Port} or $I_{Port\text{-}2P}$ expressed in units of 0.1 mA. Valid values are 0 through 20 000.
47:32	Power measurement	Power sourced or drawn expressed in units of 10 mW. Valid values are 0 through 10 000.
31:0	Energy measurement	Energy consumed at the port or pairset expressed in units of 0.1 kJ since power on. Valid values are 0 through 4 294 967 295.

[a] The valid range of this field extends beyond the allowed operating range of V_{Port_PD} or $V_{Port_PD\text{-}2P}$; see 33.3.7.1 and 145.3.8.1.

this field taking the availability of power from any external and internal resources, and the relative supply and demand balance, into account. A value of 0xFFFF means that no power price index is available.

$$K_{PPI} = \left(\frac{(\text{Power price index} + 10046) \times 2.512}{75046}\right)^5 \quad (79\text{–}1)$$

where

K_{PPI} is the power price index expressed as a factor ranging from 0.0004 to 100 times the nominal price

Power price index is the value of the 'Power price index' field defined in Table 79–22

Table 79–22—Power price index

Bit	Function	Value/meaning
15:0	Power price index	Valid values for these bits are decimal 0 through 65 000, and hexadecimal value 0xFFFF.

79.3.8.3 Power Via MDI Measurements TLV usage rules

An LLDPDU should contain no more than one Power Via MDI Measurements TLV.

79.4 IEEE 802.3 Organizationally Specific TLV selection management

TLV selection management consists of providing the network manager with the means to select which specific IEEE 802.3 Organizationally Specific TLVs are enabled for inclusion in an LLDPDU. The following LLDP variable cross references the LLDP local systems configuration MIB tables (see Clause 11 of IEEE Std 802.1AB-2009) to indicate which specific TLVs are enabled for the particular port(s) on the system. The specific port(s) through which each TLV is enabled for transmission may be set (or reset) by the network manager:

a) **mibXdot3TLVsTxEnable:** This variable lists the single-instance use IEEE 802.3 Organizationally Specific TLVs, each with a bitmap indicating the system ports through which the referenced TLV is enabled for transmission.

79.4.1 IEEE 802.3 Organizationally Specific TLV selection variable/LLDP Configuration managed object class cross reference

Table 79–23 lists the relationship both between IEEE 802.3 TLV selection variable and the corresponding LLDP Configuration managed object class (see 30.12.1) attribute.

Table 79–23—IEEE 802.3 Organizationally Specific TLV selection variable/LLDP MIB object cross reference

IEEE 802.3 TLV selection variable	LLDP Configuration managed object class attribute
mibXdot3TLVsTxEnable	aLldpXdot3PortConfigTLVsTxEnable

79.4.2 IEEE 802.3 Organizationally Specific TLV/LLDP Local and Remote System group managed object class cross references

The cross references between the IEEE 802.3 TLVs and the LLDP Local System Group managed object class (see 30.12.2) attributes are listed in Table 79–24. The cross references between the IEEE 802.3 TLVs and the LLDP Remote System Group managed object class (see 30.12.3) attributes are listed in Table 79–25.

The cross-references between the EEE TLV, the EEE Fast Wake TLV, and the EEE local (30.12.2) and remote (30.12.3) object class attributes are listed in Table 79–24 and Table 79–25.

79.5 Protocol implementation conformance statement (PICS) proforma for IEEE 802.3 Organizationally Specific Link Layer Discovery Protocol (LLDP) type, length, and value (TLV) information elements[142]

79.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 79, IEEE 802.3 Organizationally Specific Link Layer Discovery Protocol (LLDP) type, length, and value (TLV) information elements, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

79.5.2 Identification

79.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTES 1—Required for all implementations. 2—May be completed as appropriate in meeting the requirements for the identification. 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

79.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 79, IEEE 802.3 Organizationally Specific Link Layer Discovery Protocol (LLDP) type, length, and value (TLV) information elements
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	
Date of Statement	

[142]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

79.5.5 MAC/PHY Configuration/Status TLV

Item	Feature	Subclause	Value/Comment	Status	Support
MPT1	auto-negotiation support/status field	79.3.1.1	Identifies support and current status as defined in Table 79–2	MP:M	Yes [ ] N/A [ ]
MPT2	PMD auto-negotiation capability field	79.3.1.2	Bitmap of the ifMauAutoNeg-CapAdvertisedBits object defined in IETF RFC 4836	MP:M	Yes [ ] N/A [ ]
MPT3	operational MAU type field	79.3.1.3	Derived from the list position of the corresponding dot3Mau-Type as listed in IETF RFC 4836 (or subsequent revisions)	MP:M	Yes [ ] N/A [ ]
MPT4	operational MAU type field	79.3.1.3	Set to zero for MAU types not listed in IETF RFC 4836 (or subsequent revisions)	MP:M	Yes [ ] N/A [ ]
MPT5	Usage rules	79.3.1.4	LLDPDU contains no more than one MAC/PHY Configuration/Status TLV	MP:O	Yes [ ] No [ ] N/A [ ]

79.5.6 EEE TLV

Item	Feature	Subclause	Value/Comment	Status	Support
EET1	Transmit T_w field	79.3.5.1	2 octets representing time (expressed in microseconds) that the transmitting link partner will wait before it starts transmitting data after leaving the LPI mode	EE:M	Yes [ ] N/A [ ]
EET2	Receive T_w field	79.3.5.2	2 octets representing time (expressed in microseconds) that the receiving link partner is requesting the transmitting link partner to wait before it starts transmitting data following the LPI	EE:M	Yes [ ] N/A [ ]
EET3	Fallback field	79.3.5.3	2 octets representing time (expressed in microseconds)	EE:O	Yes [ ] No [ ] N/A [ ]
EET4	Echo Transmit and Receive T_w fields	79.3.5.4	2 octets representing time (expressed in microseconds)	EE:M	Yes [ ] N/A [ ]
EET5	Usage rules	79.3.5.5	LLDPDU contains no more than one EEE TLV	EE:O	Yes [ ] No [ ] N/A [ ]

79.5.7 EEE Fast Wake TLV

Item	Feature	Subclause	Value/Comment	Status	Support
EFW1	Transmit fast wake field	79.3.6.1	1 octet representing fast wake option for transmit LPI function	EEFW: M	Yes [ ] N/A [ ]
EFW2	Receive fast wake field	79.3.6.2	1 octet representing fast wake option for receive LPI function	EEFW: M	Yes [ ] N/A [ ]
EFW3	Echo Transmit and Receive fast wake fields	79.3.6.3	2 octets representing received fast wake options	EEFW: M	Yes [ ] N/A [ ]

79.5.8 Power Via MDI TLV

Item	Feature	Subclause	Value/Comment	Status	Support
PVT1	Not send DLL classification or Type 3 and Type 4 extension fields	79.3.2	Unless supplying or drawing power from the PI	PV:M	Yes [ ] N/A [ ]
PVT2	Type 1 or Type 2 power entity DLL classification extension fields	79.3.2	Support the Power Via MDI TLV DLL classification extension fields shown in Figure 79–3 after the PI has been powered	PV*PT12:M	Yes [ ] N/A [ ]
PVT3	Type 3 or Type 4 power entity DLL classification extension fields	79.3.2	Support the Power Via MDI TLV DLL classification extension fields and Type 3 and Type 4 extension fields shown in Figure 79–3 after the PI has been powered	PV*PT34:M	Yes [ ] N/A [ ]
PVT4	Not support Type 3 and Type 4 power entity DLL Classification	79.3.2	Not include the Type 3 and Type 4 extension fields in Power via MDI TLVs	PV*PT12:M	Yes [ ] N/A [ ]
PVT5	‘Port class’ field	79.3.2.1.1	Indicates if the port is a PSE or a PD when transmitted	PV:M	Yes [ ] N/A [ ]
PVT6	‘PSE MDI power support’ field	79.3.2.1.2	Indicates if MDI power is supported	PV:M	Yes [ ] N/A [ ]
PVT7	‘PSE MDI power state’ field	79.3.2.1.3	Indicates if the PSE function is enabled or disabled	PV:M	Yes [ ] N/A [ ]
PVT8	‘PSE pairs control ability’ field	79.3.2.1.4	Indicates if the PSE has the capability to control which PSE Pinout Alternative is used for PD detection and power	PV:M	Yes [ ] N/A [ ]
PVT9	‘PSE power pair’ field	79.3.2.2	Integer value as defined in Table 79–5 based on aPSEPowerPairs (30.9.1.1.4)	PV:M	Yes [ ] N/A [ ]

80. Introduction to 40 Gb/s and 100 Gb/s networks

80.1 Overview

80.1.1 Scope

This clause describes the general requirements for 40 Gigabit and 100 Gigabit Ethernet. 40 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 40 Gb/s, coupled with any IEEE 802.3 40GBASE Physical Layer implementation. 100 Gigabit Ethernet uses the IEEE 802.3 MAC sublayer operating at a data rate of 100 Gb/s, coupled with any IEEE 802.3 100GBASE Physical Layer implementation. 40 Gb/s and 100 Gb/s Physical Layer devices, such as those specified in Table 80–1, provide a bit error ratio (BER) better than or equal to 10^{-12} at the MAC/PLS service interface.

40 Gigabit and 100 Gigabit Ethernet is defined for full duplex operation only.

80.1.2 Objectives

NOTE—The contents of this subclause have been deleted.

80.1.3 Relationship of 40 Gigabit and 100 Gigabit Ethernet to the ISO OSI reference model

40 Gigabit and 100 Gigabit Ethernet couples the IEEE 802.3 MAC to a family of 40 Gb/s and 100 Gb/s Physical Layers. The relationships among 40 Gigabit and 100 Gigabit Ethernet, the IEEE 802.3 MAC, and the ISO Open System Interconnection (OSI) reference model are shown in Figure 80–1.

While this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience. The only exceptions are as follows:

a) The XLGMII and CGMII, which, when implemented as a logical interconnection port between the MAC sublayer and the Physical Layer device (PHY), uses a 64-bit wide data path as specified in Clause 81. Physical instantiations of this interface may use other data-path widths.
b) The management interface, which, when physically implemented as the MDIO/MDC (Management Data Input/Output and Management Data Clock) at an observable interconnection port, uses a bit-wide data path as specified in Clause 45.
c) The PMA service interface, which, when physically implemented as XLAUI (40 Gb/s Attachment Unit Interface) or CAUI-4 and 100GAUI-4 (100 Gb/s four-lane Attachment Unit Interface) at an observable interconnection port, uses a 4 lane data path as specified in Annex 83A, Annex 83B, Annex 83D, Annex 83E, Annex 135D, or Annex 135E.
d) The PMA service interface, which, when physically implemented as CAUI-10 (100 Gb/s ten-lane Attachment Unit Interface) at an observable interconnection port, uses a 10 lane data path as specified in Annex 83A or Annex 83B.
e) The PMA service interface, which, when physically implemented as 100GAUI-2 (100 Gb/s 2 lane Attachment Unit Interface) at an observable interconnection port, uses a 2 lane data path as specified in Annex 135F or Annex 135G.
f) The PMD service interface, which, when physically implemented as XLPPI (40 Gb/s Parallel Physical Interface) at an observable interconnection port, uses a 4 lane data path as specified in Annex 86A.
g) The PMD service interface, which, when physically implemented as CPPI (100 Gb/s Parallel Physical Interface) at an observable interconnection port, uses a 10 lane data path as specified in Annex 86A.

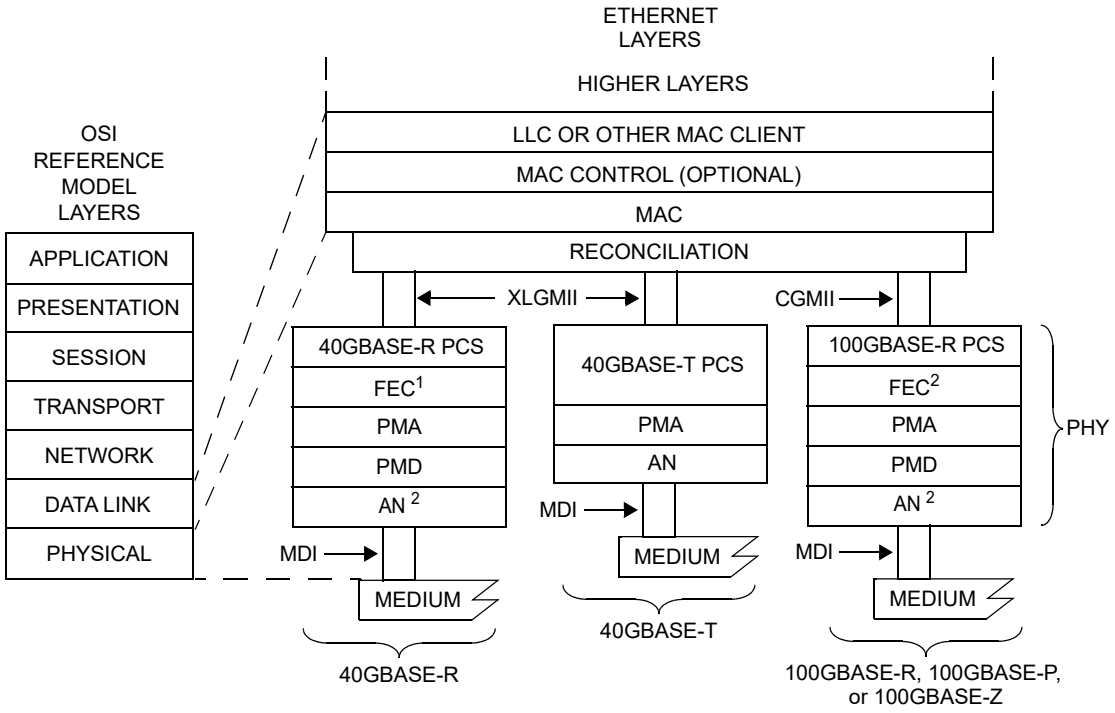
h) The MDIs as specified in:
   — Clause 89 for 40GBASE-FR
   — Clause 140 for 100GBASE-DR, 100GBASE-FR1, and 100GBASE-LR1
   — Clause 154 for 100GBASE-ZR
   use a single lane data path.
i) The MDIs as specified in:
   — Clause 85 for 40GBASE-CR4
   — Clause 86 for 40GBASE-SR4
   — Clause 87 for 40GBASE-LR4 and 40GBASE-ER4
   — Clause 88 for 100GBASE-LR4 and 100GBASE-ER4
   — Clause 92 for 100GBASE-CR4
   — Clause 95 for 100GBASE-SR4
   all use a 4 lane data path.
j) The MDIs as specified in Clause 85 for 100GBASE-CR10, and in Clause 86 for 100GBASE-SR10 use a 10 lane data path.
k) Although there is no electrical or mechanical specification of the MDI for backplane Physical Layers, the PMDs as specified in:
   — Clause 84 for 40GBASE-KR4
   — Clause 93 for 100GBASE-KR4
   — Clause 94 for 100GBASE-KP4
   all use a 4 lane data path.
l) The MDI as specified in Clause 113 for 40GBASE-T uses a 4 lane data path.
m) The MDIs as specified in:
   — Clause 136 for 100GBASE-CR2
   — Clause 137 for 100GBASE-KR2
   — Clause 138 for 100GBASE-SR2
   all use a 2 lane data path.

80.1.4 Nomenclature

The nomenclature employed by the 40 Gb/s and 100 Gb/s Physical Layers is explained as follows.

The alpha-numeric prefix 40GBASE in the port type (e.g., 40GBASE-R) represents a family of Physical Layer devices operating at a speed of 40 Gb/s. The alpha-numeric prefix 100GBASE in the port type (e.g., 100GBASE-R) represents a family of Physical Layer devices operating at a speed of 100 Gb/s.



40GBASE-R represents a family of Physical Layer devices using the Clause 82 Physical Coding Sublayer for 40 Gb/s operation over multiple PCS lanes (see Clause 82). Some 40GBASE-R Physical Layer devices may also use the FEC of Clause 74.

40GBASE-T represents Physical Layer devices using Clause 113 Physical Coding Sublayer (PCS), Physical Medium Attachment (PMA) sublayer, and baseband medium, for data communication at 40 Gb/s over a point-to-point 4-pair balanced twisted-pair medium. 40GBASE-T uses a combination of Reed-Solomon FEC (RS-FEC) and low density parity check (LDPC) FECs in its physical coding sublayer that is mapped to a 128 double-square (DSQ128) constellation for transmission on 4-pair, twisted-pair copper cabling.

100GBASE-R represents a family of Physical Layer devices using the Clause 82 Physical Coding Sublayer for 100 Gb/s operation over multiple PCS lanes (see Clause 82) and a PMD implementing 2-level pulse amplitude modulation (PAM). Some 100GBASE-R Physical Layer devices also use the transcoding and FEC of Clause 91 and some may also use the FEC of Clause 74.

100GBASE-P represents Physical Layer devices using the Clause 82 Physical Coding Sublayer for 100 Gb/s operation over multiple PCS lanes (see Clause 82) and a PMD implementing more than 2-level pulse

AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

NOTE 1—OPTIONAL OR OMITTED DEPENDING ON PHY TYPE
NOTE 2—CONDITIONAL BASED ON PHY TYPE

Figure 80–1—Architectural positioning of 40 Gigabit and 100 Gigabit Ethernet

amplitude modulation (PAM). 100GBASE-P Physical Layer devices also use the transcoding and FEC of Clause 91.

100GBASE-Z represents a family of Physical Layer devices using the Clause 82 Physical Coding Sublayer for 100 Gb/s operation over multiple PCS lanes (see Clause 82), the FEC of Clause 153, and a PMD implementing dual polarization differential quadrature phase shift keying (DP-DQPSK) modulation. Some 100GBASE-Z Physical Layer devices also use the FEC of Clause 91 and the Inverse RS-FEC of Clause 152.

Physical Layer devices listed in Table 80–1 are defined for operation at 40 Gb/s and 100 Gb/s.

Table 80–1—40 Gb/s and 100 Gb/s PHYs

Name	Description
40GBASE-KR4	40 Gb/s PHY using 40GBASE-R encoding over four lanes of an electrical backplane, with reach up to at least 1 m (see Clause 84)
40GBASE-CR4	40 Gb/s PHY using 40GBASE-R encoding over four lanes of shielded balanced copper cabling, with reach up to at least 7 m (see Clause 85)
40GBASE-T	40 Gb/s PHY using RS-FEC and LDPC encoding over balanced twisted-pair structured cabling systems (see Clause 113)

Table 80–1—40 Gb/s and 100 Gb/s PHYs *(continued)*

Name	Description
40GBASE-SR4	40 Gb/s PHY using 40GBASE-R encoding over four lanes of multimode fiber, with reach up to at least 100 m (see Clause 86)
40GBASE-FR	40 Gb/s PHY using 40GBASE-R encoding over one lane on single-mode fiber, with reach up to at least 2 km (see Clause 89)
40GBASE-LR4	40 Gb/s PHY using 40GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 10 km (see Clause 87)
40GBASE-ER4	40 Gb/s PHY using 40GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 40 km (see Clause 87)
100GBASE-KR4	100 Gb/s PHY using 100GBASE-R encoding, Clause 91 RS-FEC and 2-level pulse amplitude modulation over four lanes of an electrical backplane, with a total insertion loss up to 35 dB at 12.9 GHz (see Clause 93)
100GBASE-KP4	100 Gb/s PHY using 100GBASE-R encoding, Clause 91 RS-FEC and 4-level pulse amplitude modulation over four lanes of an electrical backplane, with a total insertion loss up to 33 dB at 7 GHz (see Clause 94)
100GBASE-KR2	100 Gb/s PHY using 100GBASE-R encoding, Clause 91 RS-FEC and 4-level pulse amplitude modulation over two lanes of an electrical backplane, with a total insertion loss up to 30 dB at 13.28 GHz (see Clause 137)
100GBASE-CR2	100 Gb/s PHY using 100GBASE-R encoding and Clause 91 RS-FEC and 4-level pulse amplitude modulation over two lanes of shielded balanced copper cabling, with reach up to at least 3 m (see Clause 136)
100GBASE-CR4	100 Gb/s PHY using 100GBASE-R encoding and Clause 91 RS-FEC over four lanes of shielded balanced copper cabling, with reach up to at least 5 m (see Clause 92)
100GBASE-CR10	100 Gb/s PHY using 100GBASE-R encoding over ten lanes of shielded balanced copper cabling, with reach up to at least 7 m (see Clause 85)
100GBASE-SR4	100 Gb/s PHY using 100GBASE-R encoding over four lanes of multimode fiber, with reach up to at least 100 m (see Clause 95)
100GBASE-SR2	100 Gb/s PHY using 100GBASE-R encoding over two lanes of multimode fiber, with reach up to at least 100 m (see Clause 138)
100GBASE-SR10	100 Gb/s PHY using 100GBASE-R encoding over ten lanes of multimode fiber, with reach up to at least 100 m (see Clause 86)
100GBASE-DR	100 Gb/s PHY using 100GBASE-R encoding over single-mode fiber, with reach up to at least 500 m (see Clause 140)
100GBASE-FR1	100 Gb/s PHY using 100GBASE-R encoding over single-mode fiber, with reach up to at least 2 km (see Clause 140)
100GBASE-LR4	100 Gb/s PHY using 100GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 10 km (see Clause 88)
100GBASE-LR1	100 Gb/s PHY using 100GBASE-R encoding over single-mode fiber, with reach up to at least 10 km (see Clause 140)
100GBASE-ER4	100 Gb/s PHY using 100GBASE-R encoding over four WDM lanes on single-mode fiber, with reach up to at least 40 km (see Clause 88)
100GBASE-ZR	100 Gb/s PHY using 100GBASE-R encoding capable of transmission over a specified channel on a defined DWDM grid in each direction of transmission with reach up to at least 80 km (see Clause 154)

80.1.5 Physical Layer signaling systems

This standard specifies a family of Physical Layer implementations. Table 80–2, Table 80–3, Table 80–4, Table 80–5, and Table 80–6 specify the correlation between nomenclature and clauses. Implementations conforming to one or more nomenclatures meet the requirements of the corresponding clauses.

80.2 Summary of 40 Gigabit and 100 Gigabit Ethernet sublayers

80.2.1 Reconciliation Sublayer (RS) and Media Independent Interface

The Media Independent Interface (Clause 81) provides a logical interconnection between the MAC sublayer and the Physical Layer device (PHY). The Media Independent Interface is not intended to be physically instantiated, rather it can logically connect layers within a device.

The XLGMII supports 40 Gb/s and CGMII supports 100 Gb/s operation through its 64-bit-wide transmit and receive data paths. The Reconciliation Sublayer (RS) provides a mapping between the signals provided at the Media Independent Interface (XLGMII and CGMII) and the MAC/PLS service definition.

While XLGMII and CGMII are optional interfaces, they are used extensively in this standard as a basis for functional specification and provides a common service interface for the physical coding sublayers defined in Clause 82.

80.2.2 Physical Coding Sublayer (PCS)

The terms 40GBASE-R, 100GBASE-R, 100GBASE-P, and 100GBASE-Z refer to a specific family of Physical Layer implementations based upon the 64B/66B data coding method specified in Clause 82 and the PMA specifications defined in Clause 83, Clause 94, Clause 135, or Clause 153. Clause 82 PCSs perform encoding (decoding) of data from (to) the XLGMII/CGMII to 64B/66B code blocks, distribute the data to multiple lanes, and transfer the encoded data to the PMA or FEC.

80.2.3 Forward error correction (FEC) sublayers

A forward error correction sublayer is optional for 40GBASE-KR4, 40GBASE-CR4, and 100GBASE-CR10 PHYs and mandatory for 100GBASE-CR2, 100GBASE-CR4, 100GBASE-KR2, 100GBASE-KR4, 100GBASE-KP4, 100GBASE-SR2, 100GBASE-SR4, 100GBASE-DR, 100GBASE-FR1, 100GBASE-LR1, and 100GBASE-ZR PHYs. The FEC sublayer can be placed in between the PCS and PMA sublayers or between two PMA sublayers.

The BASE-R FEC (see Clause 74) is instantiated for each PCS lane and operates autonomously on a per PCS lane basis. The Reed-Solomon FEC (see Clause 91) is instantiated once and requires 20 PCS lanes and 4 PMA lanes for operation. The SC-FEC (see Clause 153) is instantiated once and requires 20 PCS lanes and 20 PMA lanes for operation.

80.2.4 Physical Medium Attachment (PMA) sublayer

The PMA provides a medium-independent means for the PCS to support the use of a range of physical media. The 40GBASE-R and 100GBASE-R PMAs perform the mapping of transmit and receive data streams between the PCS and PMA via the PMA service interface, and the mapping and multiplexing of transmit and receive data streams between the PMA and PMD via the PMD service interface. In addition, the PMAs perform retiming of the received data stream when appropriate, optionally provide data loopback at the PMA or PMD service interface, and optionally provide test pattern generation and checking.

Clause 83 specifies 40GBASE-R and 100GBASE-R PMAs that may be used with any PHY type of the corresponding rate. Additional PMAs are only applicable to specific PHY types:

a) Clause 94 specifies a PMA that may be used only in a 100GBASE-KP4 PHY.
b) Clause 135 specifies a PMA that may be used in other 100GBASE-P or 100GBASE-ZR PHY types.
c) Clause 153 specifies a PMA that is used in the 100GBASE-ZR PHY.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

80.2.5 Physical Medium Dependent (PMD) sublayer

The Physical Medium Dependent sublayer is responsible for interfacing to the transmission medium. The PMD is located just above the Medium Dependent Interface (MDI). The MDI, logically subsumed within each PMD subclause, is the actual medium attachment for the various supported media.

The 40GBASE-R, 100GBASE-R, 100GBASE-P, and 100GBASE-Z PMDs and their corresponding media are specified in Clause 84 through Clause 89, Clause 92 through Clause 95, Clause 136 through Clause 138, Clause 140, and Clause 154.

80.2.6 Auto-Negotiation

Auto-Negotiation provides a linked device with the capability to detect the abilities (modes of operation) supported by the device at the other end of the link, determine common abilities, and configure for joint operation.

Clause 73 Auto-Negotiation is used by the 40 Gb/s and 100 Gb/s backplane PHYs (40GBASE-KR4, 100GBASE-KR2, 100GBASE-KP4, and 100GBASE-KR4) and the 40 Gb/s and 100 Gb/s copper PHYs (40GBASE-CR4, 100GBASE-CR2, 100GBASE-CR10, and 100GBASE-CR4).

80.2.7 Management interface (MDIO/MDC)

The optional MDIO/MDC management interface (Clause 45) provides an interconnection between MDIO Manageable Devices (MMDs) and Station Management (STA) entities.

80.2.8 Management

Managed objects, attributes, and actions are defined for all 40 Gigabit and 100 Gigabit Ethernet components. These items are defined in Clause 30.

80.3 Service interface specification method and notation

The service interface specification for 40GBASE-R, 100GBASE-R, and 100GBASE-P Physical Layers is as per the definition in 1.2.2. Note that the 40GBASE-R, 100GBASE-R, and 100GBASE-P inter-sublayer service interfaces use multiple scalar REQUEST and INDICATION primitives, to indicate the transfer of multiple independent streams of data units, as explained in 80.3.1 through 80.3.3.

80.3.1 Inter-sublayer service interface

The inter-sublayer service interface is described in an abstract manner and does not imply any particular implementation. The inter-sublayer service interface primitives are defined as follows:

IS_UNITDATA_*i*.request
IS_UNITDATA_*i*.indication
IS_SIGNAL.indication

The IS_UNITDATA_*i*.request (where $i = 0$ to n – 1, and n is the number of streams of data units) primitive is used to define the transfer of multiple streams of data units from a sublayer N to the next lower sublayer N – 1. The IS_UNITDATA_*i*.indication (where $i = 0$ to n – 1, and n is the number of streams of data units) primitive is used to define the transfer of multiple streams of data units from a sublayer N – 1 to the next higher sublayer N. The IS_SIGNAL.indication primitive is used to define the transfer of signal status from a sublayer N – 1 to the next higher sublayer N.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

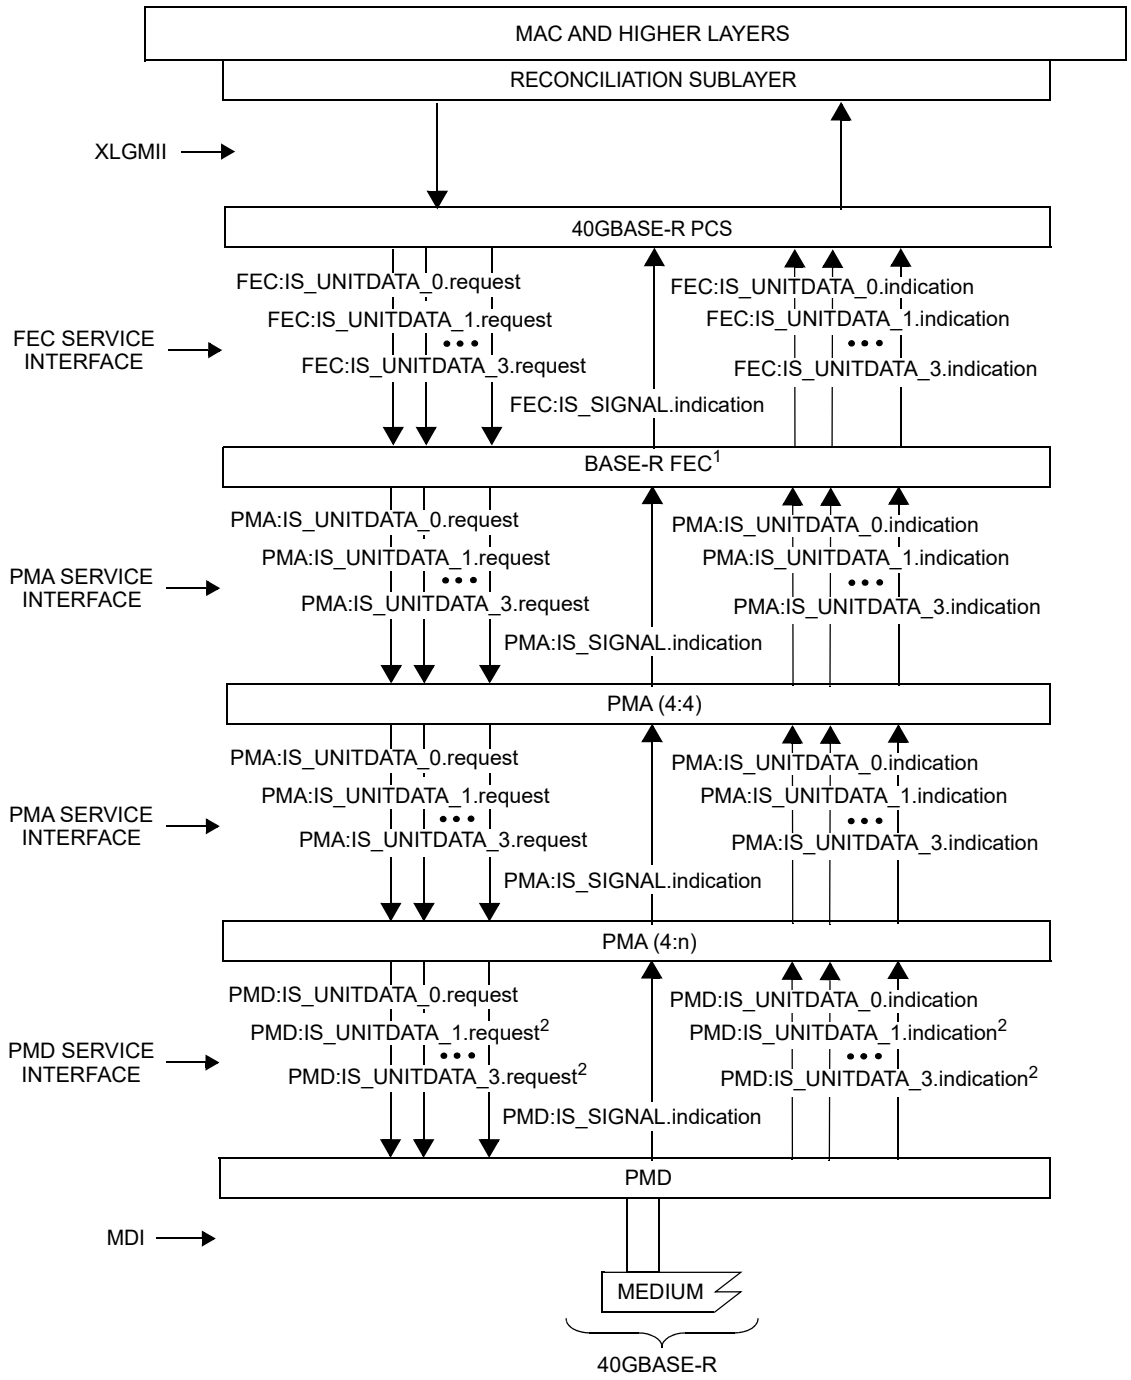
If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78, 78.1.3.3.1), then the inter-sublayer service interface includes five additional primitives defined as follows:

IS_TX_MODE.request
IS_RX_MODE.request
IS_ENERGY_DETECT.indication
IS_RX_LPI_ACTIVE.request
IS_RX_TX_MODE.indication

The IS_TX_MODE.request primitive is used to communicate the state of the PCS LPI transmit function to other sublayers in the PHY. The IS_RX_MODE.request primitive is used to communicate the state of the PCS LPI receive function to other sublayers. The IS_RX_TX_MODE.indication primitive is used to communicate the state of the rx_tx_mode parameter that reflects the inferred state of the link partner's tx_mode parameter from the PMA to other sublayers. The IS_RX_LPI_ACTIVE.request primitive is used to communicate to the BASE-R FEC (see Clause 74) that the PCS has detected LPI signaling. This allows the BASE-R FEC to use rapid block lock; the RS-FEC (see Clause 91) does not use this signal. The IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence.

80.3.2 Instances of the Inter-sublayer service interface

The inter-sublayer interface can be instantiated between different sublayers, hence a prefix notation is defined to identify a specific instance of an inter-sublayer service interface. The following prefixes are defined:



a) PMD:—for primitives issued on the interface between the PMD sublayer and the PMA sublayer called the PMD service interface.
b) PMA:—for primitives issued on the interface between the PMA sublayer and the PCS (or the FEC) sublayer called the PMA service interface.
c) FEC:—for primitives issued on the interface between the FEC sublayer and the PCS (or the PMA) sublayer called the FEC service interface.
d) IFEC:—for primitives issued on the interface between the Inverse FEC sublayer and the PMA sublayer called the Inverse FEC service interface.

Examples of inter-sublayer service interfaces for 40GBASE-R, 100GBASE-R, 100GBASE-P, and 100GBASE-Z with their corresponding instance names are illustrated in Figure 80–2, Figure 80–3, Figure 80–4, Figure 80–5, and Figure 80–6. For example, the primitives for one instance of the inter-sublayer service interface, named the PMD service interface, are identified as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication.

Primitives for other instances, of inter-sublayer interfaces, are represented in a similar manner as described above.

80.3.3 Semantics of inter-sublayer service interface primitives

The semantics of the inter-sublayer service interface primitives for the 40GBASE-R and 100GBASE-R sublayers are described in 80.3.3.1 through 80.3.3.3.

80.3.3.1 IS_UNITDATA_*i*.request

The IS_UNITDATA_*i*.request (where i = 0 to n – 1) primitive is used to define the transfer of multiple streams of data units from a sublayer N to the next lower sublayer N – 1, where n is the number of parallel streams of data units.

80.3.3.1.1 Semantics of the service primitive

```
IS_UNITDATA_0.request(tx_bit)
IS_UNITDATA_1.request(tx_bit)
...
IS_UNITDATA_n–1.request(tx_bit)
```

The data conveyed by IS_UNITDATA_0.request to IS_UNITDATA_n–1.request consists of n parallel continuous streams of encoded bits, one stream for each lane. Each of the tx_bit parameters can take one of two values: one or zero.

80.3.3.1.2 When generated

The sublayer N continuously sends n parallel bit streams IS_UNITDATA_*i*.request(tx_bit) to the next lower sublayer N – 1, each at a nominal signaling rate defined by a specific instance of the inter-sublayer service interface.

80.3.3.1.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

80.3.3.2 IS_UNITDATA_*i*.indication

The IS_UNITDATA_*i*.indication (where i = 0 to n – 1) primitive is used to define the transfer of multiple streams of data units from the sublayer N – 1 to the next higher sublayer N, where n is the number of parallel streams of data units.

80.3.3.2.1 Semantics of the service primitive

```
IS_UNITDATA_0.indication(rx_bit)
IS_UNITDATA_1.indication(rx_bit)
...
IS_UNITDATA_n–1.indication(rx_bit)
```

The data conveyed by IS_UNITDATA_0.indication to IS_UNITDATA_n–1.indication consists of n parallel continuous streams of encoded bits, one stream for each lane. Each of the rx_bit parameters can take one of two values: one or zero.

80.3.3.2.2 When generated

The sublayer N–1 continuously sends n parallel bit streams IS_UNITDATA_*i*.indication(rx_bit) to the next higher sublayer N, each at a nominal signaling rate defined by a specific instance of the inter-sublayer service interface.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

80.3.3.2.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

80.3.3.3 IS_SIGNAL.indication

The IS_SIGNAL.indication primitive is generated by the sublayer N – 1 to the next higher sublayer N to indicate the status of the receive process. This primitive is generated by the receive process to propagate the detection of severe error conditions (e.g., no valid signal being received by the sublayer that generates this primitive) to the next higher sublayer N.

80.3.3.3.1 Semantics of the service primitive

IS_SIGNAL.indication(SIGNAL_OK)

The SIGNAL_OK parameter can take on one of two values: OK or FAIL. A value of FAIL denotes that invalid data is being presented (rx_bit parameters undefined) by the sublayer N – 1 to the next higher sublayer N. A value of OK does not guarantee valid data is being presented by the sublayer N – 1 to the next higher sublayer N.

80.3.3.3.2 When generated

The sublayer N – 1 generates the IS_SIGNAL.indication primitive to the next higher sublayer N whenever there is change in the value of the SIGNAL_OK parameter.

80.3.3.3.3 Effect of receipt

The effect of receipt of this primitive is defined by the sublayer that receives this primitive.

80.3.3.4 IS_TX_MODE.request

The IS_TX_MODE.request primitive communicates the tx_mode parameter generated by the PCS Transmit Process for EEE capability to invoke the appropriate PMA, FEC, and PMD transmit EEE states. Without EEE deep sleep mode capability, the primitive is never invoked and the sublayers behave as if tx_mode = DATA.

80.3.3.4.1 Semantics of the service primitive

IS_TX_MODE.request(tx_mode)

The tx_mode parameter takes on one of up to three values: DATA, QUIET, or ALERT.

80.3.3.4.2 When generated

This primitive is generated to indicate the low power mode of the transmit path.

80.3.3.4.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the sublayer that receives this primitive. In general, when tx_mode is DATA the sublayer operates normally and when tx_mode is QUIET, the sublayer may go into a low power mode.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

80.3.3.5 IS_RX_MODE.request

The IS_RX_MODE.request primitive communicates the rx_mode parameter generated by the PCS LPI receive function to other sublayers. Without EEE deep sleep mode capability, the primitive is never invoked and the sublayers behave as if rx_mode = DATA.

80.3.3.5.1 Semantics of the service primitive

IS_RX_MODE.request(rx_mode)

The rx_mode parameter takes on one of two values: DATA or QUIET.

80.3.3.5.2 When generated

This primitive is generated to indicate the state of the PCS LPI receive function.

80.3.3.5.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the sublayer that receives this primitive. In general, when rx_mode is DATA the sublayer operates normally and when rx_mode is QUIET, the sublayer may go into a low power mode.

80.3.3.6 IS_RX_LPI_ACTIVE.request

The IS_RX_LPI_ACTIVE.request primitive communicates to the FEC that the PCS LPI receive function is active. This primitive may be passed through a PMA sublayer but has no effect on that sublayer. This primitive is only used for a PMA sublayer that is between the PCS and a Clause 74 FEC sublayer; in all other cases the primitive is never invoked and has no effect. Without EEE deep sleep mode capability, the primitive is never invoked and has no effect.

80.3.3.6.1 Semantics of the service primitive

IS_RX_LPI_ACTIVE.request(rx_lpi_active)

The parameter rx_lpi_active is Boolean.

80.3.3.6.2 When generated

This primitive is generated to indicate the state of the PCS LPI receive function. It is FALSE when in the RX_ACTIVE state and TRUE in all other states.

80.3.3.6.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the FEC sublayer that receives this primitive. When rx_lpi_active is true the FEC sublayer uses rapid block lock to reestablish FEC operation following a period of quiescence.

80.3.3.7 IS_ENERGY_DETECT.indication

The IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence. Without EEE deep sleep mode capability, the primitive is never invoked and has no effect.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

80.3.3.7.1 Semantics of the service primitive

IS_ENERGY_DETECT.indication(energy_detect)

The parameter energy_detect is Boolean.

80.3.3.7.2 When generated

This primitive is generated by the PMA, reflecting the state of the signal_detect parameter received from the PMD.

80.3.3.7.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the PCS sublayer that receives this primitive. This parameter is used to indicate that activity has returned on the interface following a period of quiescence.

80.3.3.8 IS_RX_TX_MODE.indication

The IS_RX_TX_MODE.indication primitive communicates the rx_tx_mode parameter. This parameter indicates the value of tx_mode that the PMA sublayer has inferred from the received signal. Without EEE deep sleep capability, the primitive is never generated and the sublayers behave as if rx_tx_mode=DATA.

80.3.3.8.1 Semantics of the service primitive

IS_RX_TX_MODE.indication(rx_tx_mode)

The parameter rx_tx_mode is assigned one of the following values: DATA, QUIET, or ALERT.

80.3.3.8.2 When generated

This primitive is generated whenever there is change in the value of the rx_tx_mode parameter.

80.3.3.8.3 Effect of receipt

The specific effect of receipt of this primitive is defined by the sublayer that receives it.

80.4 Delay constraints

Predictable operation of the MAC Control PAUSE operation (Clause 31, Annex 31B) demands that there be an upper bound on the propagation delays through the network. This implies that MAC, MAC Control sublayer, and PHY implementations conform to certain delay maxima, and that network planners and administrators conform to constraints regarding the cable topology and concatenation of devices. Table 80–7 contains the values of maximum sublayer delay (sum of transmit and receive delays at one end of the link) in bit times as specified in 1.4 and pause_quanta as specified in 31B.2. If a PHY contains an Auto-Negotiation sublayer, the delay of the Auto-Negotiation sublayer is included within the delay of the PMD and medium.

Equation (80–1) specifies the calculation of cable delay in nanoseconds per meter of fiber or electrical cable, based upon the parameter *n*, which represents the ratio of the speed of electromagnetic propagation in the fiber or electrical cable to the speed of light in a vacuum, $c = 3 \times 10^8$ m/s.

$$\text{cable delay} = \frac{10^9}{nc} \text{ ns/m} \quad (80–1)$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The value of *n* should be available from the fiber or electrical cable manufacturer; but if no value is known, then a conservative delay estimate can be calculated using a default value of $n = 0.66$, which yields a default cable delay of 5 ns/m.

See 31B.3.7 for PAUSE reaction timing constraints for stations at operating speeds of 40 Gb/s and 100 Gb/s.

Table 80–7—Sublayer delay constraints

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
40G MAC, RS, and MAC Control	16 384	32	409.6	See 81.1.4.
40GBASE-R PCS	11 264	22	281.6	See 82.5.
40GBASE-R FEC	24 576	48	614.4	See 74.6.

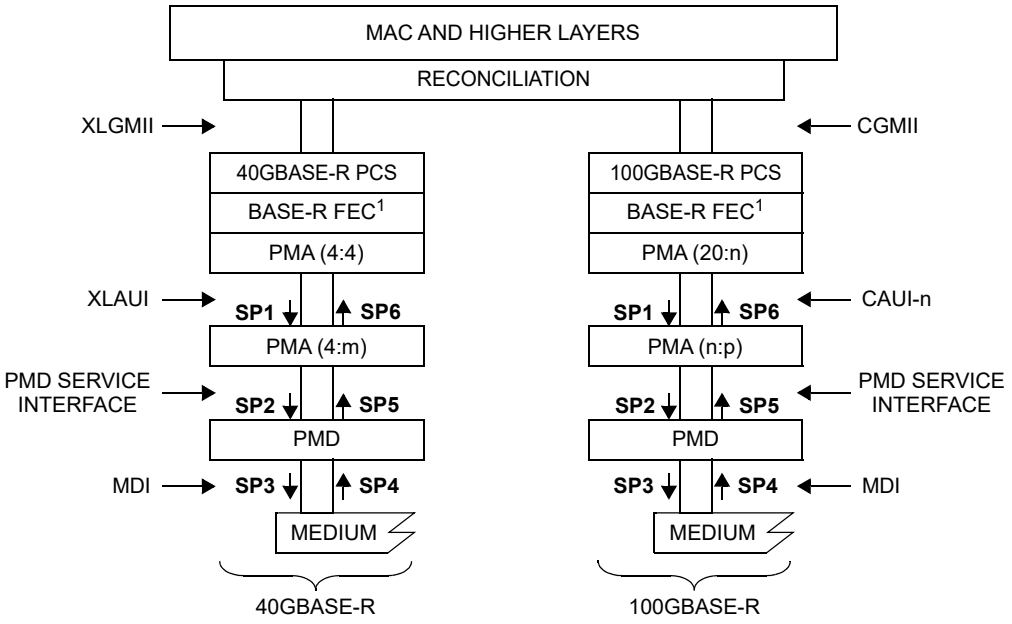
Table 80–7—Sublayer delay constraints *(continued)*

Sublayer	Maximum (bit time)[a]	Maximum (pause_quanta)[b]	Maximum (ns)	Notes[c]
100GBASE-CR2 PMD	4 096	8	40.96	Includes allocation for 20 ns for one direction through cable medium. See 136.5.
100GBASE-CR4 PMD	2 048	4	20.48	Does not include delay of cable medium. See 92.4.
100GBASE-CR10 PMD	9 728	19	97.28	Does not include delay of cable medium. See 85.4.
100GBASE-SR4 PMD	2 048	4	20.48	Includes 2 m of fiber. See 95.3.1.
100GBASE-SR2 PMD	2 048	4	20.48	Includes 2 m of fiber. See 138.3.
100GBASE-SR10 PMD	2 048	4	20.48	Includes 2 m of fiber. See 86.3.1.
100GBASE-DR PMD	2 048	4	20.48	Includes 2 m of fiber. See 140.3.
100GBASE-FR1 PMD	2 048	4	20.48	Includes 2 m of fiber. See 140.3.
100GBASE-LR4 PMD	2 048	4	20.48	Includes 2 m of fiber. See 88.3.1.
100GBASE-LR1 PMD	2 048	4	20.48	Includes 2 m of fiber. See 140.3.
100GBASE-ER4 PMD	2 048	4	20.48	Includes 2 m of fiber. See 88.3.1.
100GBASE-ZR PMD	2 048	4	20.48	Includes 2 m of fiber. See 154.3.1.



[a] For 40GBASE-R, 1 bit time (BT) is equal to 25 ps and for 100GBASE-R, 1 bit time (BT) is equal to 10 ps. (See 1.4.215 for the definition of bit time.)
[b] For 40GBASE-R, 1 pause_quantum is equal to 12.8 ns and for 100GBASE-R, 1 pause_quantum is equal to 5.12 ns. (See 31B.2 for the definition of pause_quanta.)
[c] Should there be a discrepancy between this table and the delay requirements of the relevant sublayer clause, the sublayer clause prevails.

80.5 Skew constraints

Skew (or relative delay) can be introduced between lanes by both active and passive elements of a 40GBASE-R or 100GBASE-R link. Skew is defined as the difference between the times of the earliest PCS lane and latest PCS lane for the one to zero transition of the alignment marker sync bits. The PCS deskew function (see 82.2.13) compensates for all lane-to-lane Skew observed at the receiver. The Skew between the lanes is kept within limits as shown in Table 80–8 so that the transmitted information on the lanes can be reassembled by the receive PCS.

Skew Variation may be introduced due to variations in electrical, thermal or environmental characteristics. Skew Variation is defined as the change in Skew between any PCS lane and any other PCS lane over the entire time that the link is in operation. From the time the link is brought up, Skew Variation is limited to ensure that each PCS lane always traverses the same lane between any pair of adjacent sublayers while the link remains in operation.

PMD = PHYSICAL MEDIUM DEPENDENT
XLAUI = 40 Gb/s ATTACHMENT UNIT INTERFACE
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

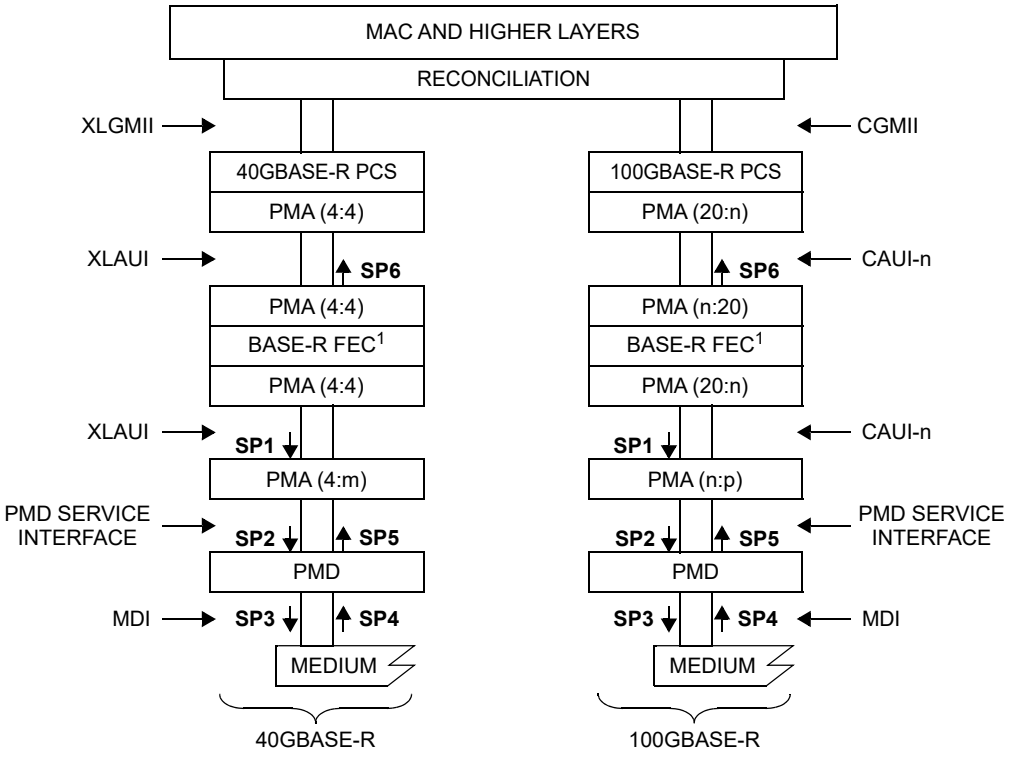
m = 1 or 4
n = 4 or 10
p = 4 or 10
NOTE1—CONDITIONAL BASED ON PHY TYPE

Figure 80–7—40GBASE-R and 100GBASE-R Skew points for single XLAUI or CAUI-n

The maximum Skew and Skew Variation at physically instantiated interfaces is specified at Skew points SP1, SP2, and SP3 for the transmit direction and SP4, SP5, and SP6 for the receive direction as illustrated in Figure 80–7 (single XLAUI or CAUI-n interface) and Figure 80–8 (multiple XLAUI or CAUI-n interfaces).

In the transmit direction, the Skew points are defined in the following locations:

— SP1 on the XLAUI/CAUI-n interface, at the input of the PMA closest to the PMD;
— SP2 on the PMD service interface, at the input of the PMD;
— SP3 at the output of the PMD, at the MDI.



In the receive direction, the Skew points are defined in the following locations:

— SP4 at the MDI, at the input of the PMD;
— SP5 on the PMD service interface, at the output of the PMD;
— SP6 on the XLAUI/CAUI-n interface, at the output of the PMA closest to the PCS.

The allowable limits for Skew are shown in Table 80–8 and the allowable limits for Skew Variation are shown in Table 80–9.

The skew points are similarly illustrated for a PHY incorporating RS-FEC (see Clause 91) in Figure 80–9.

[a]Should there be a discrepancy between this table and the Skew requirements of the relevant sublayer clause, the sublayer clause prevails.
[b]The symbol ≈ indicates approximate equivalent of maximum Skew Variation in UI for 40GBASE-R, based on 1 UI equals 96.969697 ps at PMD lane signaling rate of 10.3125 GBd.
[c]The symbol ≈ indicates approximate equivalent of maximum Skew Variation in UI for 100GBASE-R, based on 1 UI equals 38.787879 ps at PMD lane signaling rate of 25.78125 GBd.
[d]The symbol ≈ indicates approximate equivalent of maximum Skew Variation in UI for 100GBASE-R, based on 1 UI equals 37.64706 ps at PMD lane signaling rate of 26.5625 GBd.
[e]The skew at the RS-FEC receive is the skew between RS-FEC lanes.

80.6 State diagrams

State diagrams take precedence over text.

The conventions of 1.2 are adopted, along with the extensions listed in 21.5.

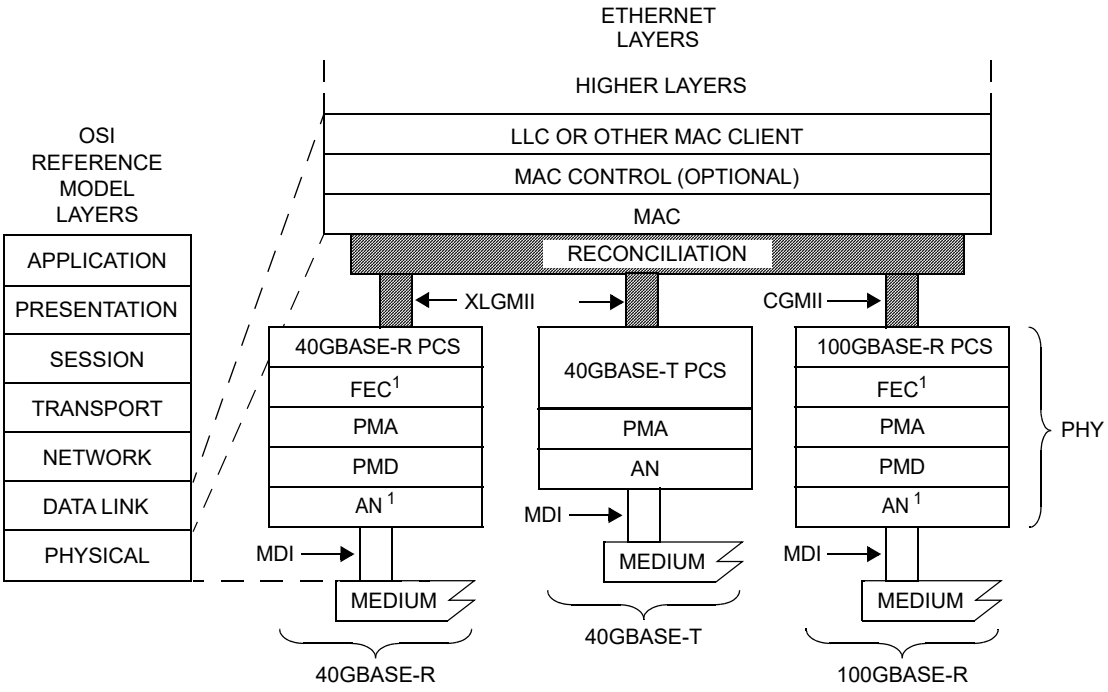
Multiple states of a function that have a transition to a common state utilizing different qualifiers (for example, multiple exit conditions to an IDLE or WAIT state) may be indicated by a shared arrow. An exit

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

transition arrow connects to the shared arrow, and the qualifier is met prior to termination of the transition arrow on the shared arrow. The shared arrow has no qualifier.

80.7 Protocol implementation conformance statement (PICS) proforma

The supplier of a protocol implementation that is claimed to conform to any part of IEEE Std 802.3, Clause 45, Clause 73, Clause 74, Clause 81 through Clause 89, Clause 91 through Clause 95, Clause 135 through Clause 138, Clause 140, Clause 152 through Clause 154, and related annexes demonstrates compliance by completing a protocol implementation conformance statement (PICS) proforma.



A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. A PICS is included at the end of each clause as appropriate. Each of the 40 Gigabit and 100 Gigabit Ethernet PICS conforms to the same notation and conventions used in 21.6.

81. Reconciliation Sublayer (RS) and Media Independent Interface for 40 Gb/s and 100 Gb/s operation (XLGMII and CGMII)

81.1 Overview

This clause defines the characteristics of the Reconciliation Sublayer (RS) and the Media Independent Interface between Ethernet media access controllers and various PHYs. Figure 81–1 shows the relationship of the RS and Media Independent Interface to the ISO/IEC OSI reference model. Note that there are two variants of the Media Independent Interface in this clause, the 40 Gb/s Media Independent Interface (XLGMII) and the 100 Gb/s Media Independent Interface (CGMII).

AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 81–1—RS and MII relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The XLGMII and the CGMII are optional logical interfaces between the MAC sublayer and the Physical Layer device (PHY).

The RS adapts the bit serial protocols of the MAC to the parallel format of the PCS service interface. Though the XLGMII/CGMII is an optional interface, it is used in this standard as a basis for specification. The Physical Coding Sublayer (PCS) is specified to the XLGMII/CGMII, so if not implemented, a conforming implementation shall behave functionally as if the RS and XLGMII/CGMII were implemented.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The XLGMII/CGMII has the following characteristics:

a) The XLGMII supports a speed of 40 Gb/s.
b) The CGMII supports a speed of 100 Gb/s.
c) Data and delimiters are synchronous to a clock reference.
d) It provides independent 64-bit wide transmit and receive data paths.
e) It supports full duplex operation only.

81.1.1 Summary of major concepts

The following are the major concepts of the XLGMII/CGMII:

a) The XLGMII/CGMII is functionally similar to other media independent interfaces that have been defined for lower speeds, as they all define an interface allowing independent development of MAC and PHY logic.
b) The RS converts between the MAC serial data stream and the parallel data paths of the XLGMII/CGMII.
c) The RS maps the signal set provided at the XLGMII/CGMII to the PLS service primitives provided at the MAC.
d) Each direction of data transfer is independent and serviced by data, control, and clock signals.
e) The RS generates continuous data or control characters on the transmit path and expects continuous data or control characters on the receive path.
f) The RS participates in link fault detection and reporting by monitoring the receive path for status reports that indicate an unreliable link, and generating status reports on the transmit path to report detected link faults to the DTE on the remote end of the connecting link.
g) The XLGMII and CGMII may also support Low Power Idle (LPI) signaling for PHY types supporting Energy Efficient Ethernet (EEE) (see Clause 78).

81.1.2 Application

This clause applies to the interface between the MAC and PHY. This logical interface is used to provide media independence so that an identical media access controller may be used with supported PHY types.

81.1.3 Rate of operation

The XLGMII is specified to support 40 Gb/s operation and the CGMII is specified to support 100 Gb/s operation.

81.1.4 Delay constraints

The maximum cumulative MAC Control, MAC, and RS delay (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 81–1. A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

81.1.5 Allocation of functions

The allocation of functions at the XLGMII/CGMII balances the need for media independence with interface simplicity. The XLGMII and CGMII maximize media independence by separating the Data Link and Physical Layers of the OSI seven-layer reference model.

Table 81–1—Delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
40 Gb/s MAC, RS, and MAC Control	16384	32	409.6
100 Gb/s MAC, RS, and MAC Control	24576	48	245.76

81.1.6 XLGMII/CGMII structure

The XLGMII/CGMII is composed of independent transmit and receive paths. Each direction uses 64 data signals (TXD<63:0> and RXD<63:0>), 8 control signals (TXC<7:0> and RXC<7:0>), and a clock (TX_CLK and RX_CLK). Figure 81–2 depicts a schematic view of the RS inputs and outputs.

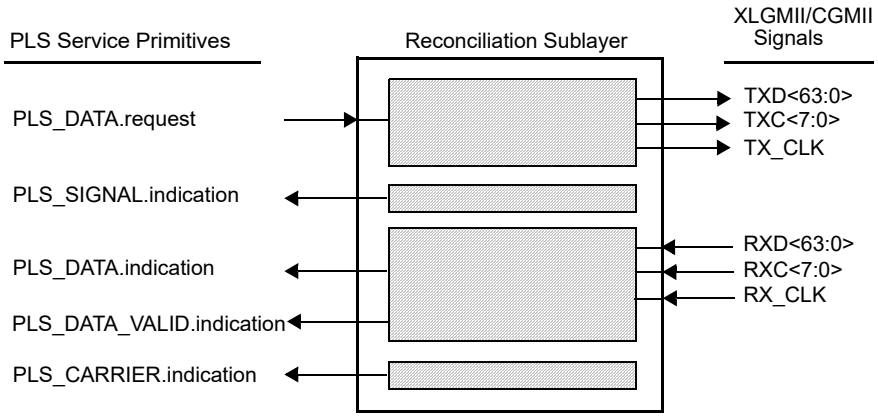

Figure 81–2—Reconciliation Sublayer (RS) inputs and outputs

The 64 TXD and 8 TXC signals shall be organized into eight data lanes, as shall the 64 RXD and 8 RXC signals (see Table 81–2). The eight lanes in each direction share a common clock, TX_CLK for transmit and RX_CLK for receive. The eight lanes are used in round-robin sequence to carry an octet stream. On transmit, each eight PLS_DATA.request transactions represent an octet transmitted by the MAC. The first octet is aligned to lane 0, the second to lane 1, the third to lane 2, the fourth to lane 3, the fifth to lane 4, the sixth to lane 5, the seventh to lane 6 and the eighth to lane 7, then repeating with the ninth to lane 0, etc. Delimiters and interframe idle characters are encoded on the TXD and RXD signals with the control code indicated by assertion of TXC and RXC, respectively.

81.1.7 Mapping of XLGMII/CGMII signals to PLS service primitives

The Reconciliation Sublayer (RS) shall map the signals provided at the XLGMII/CGMII to the PLS service primitives defined in Clause 6. The PLS service primitives provided by the RS and described here behave in exactly the same manner as defined in Clause 6. Full duplex operation only is implemented at 40 Gb/s and 100 Gb/s; therefore, PLS service primitives supporting CSMA/CD operation are not mapped through the RS to the XLGMII/CGMII. This behavior and restrictions are the same as described in 22.7, with the details of the signaling described in 81.3. LPI_REQUEST shall not be set to ASSERT unless the attached link has been operational for at least one second (i.e., link_status = OK, according to the underlying PCS/PMA).

EEE capability requires the use of the MAC defined in Annex 4A for simplified full duplex operation (with carrier sense deferral). This provides full duplex operation but uses the carrier sense signal to defer transmission when the PHY is in its low power state.

Table 81–2—Transmit and receive lane associations

TXD, RXD	TXC, RXC	Lane
<7:0>	<0>	0
<15:8>	<1>	1
<23:16>	<2>	2
<31:24>	<3>	3
<39:32>	<4>	4
<47:40>	<5>	5
<55:48>	<6>	6
<63:56>	<7>	7

Mappings for the following primitives are defined for 40 Gb/s and 100 Gb/s operation:

PLS_DATA.request
PLS_DATA.indication
PLS_CARRIER.indication
PLS_SIGNAL.indication
PLS_DATA_VALID.indication

81.1.7.1 Mapping of PLS_DATA.request

81.1.7.1.1 Function

The RS maps the primitive PLS_DATA.request to the XLGMII/CGMII signals TXD<63:0>, TXC<7:0>, and TX_CLK.

81.1.7.1.2 Semantics of the service primitive

PLS_DATA.request(OUTPUT_UNIT)

The OUTPUT_UNIT parameter can take one of three values: ONE, ZERO, or DATA_COMPLETE. ONE or ZERO represents a single data bit. The DATA_COMPLETE value signifies that the MAC sublayer has no more data to output.

81.1.7.1.3 When generated

This primitive is generated by the MAC sublayer to request the transmission of a single data bit on the physical medium or to stop transmission.

81.1.7.1.4 Effect of receipt

The OUTPUT_UNIT values are conveyed to the PHY by the signals TXD<63:0> and TXC<7:0> on each TX_CLK rising edge. Each PLS_DATA.request transaction shall be mapped to a TXD signal in sequence (TXD<0>, TXD<1>,... TXD<63>, TXD<0>) as described in 81.2, and for every eight transactions, a TXC signal in sequence (TXC<0>, TXC<1>,... TXC<7>, TXC<0>) is generated, as described in 81.3.1.2. After 64 PLS_DATA.request transactions from the MAC sublayer (eight octets of eight PLS_DATA.request transactions each), the RS requests transmission of 64 data bits by the PHY. The first octet of preamble shall

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

be converted to a Start control character and aligned to lane 0. The TXD<63:0> and TXC<7:0> shall be generated by the RS every 64 bit-times of the MAC sublayer.

The DATA_COMPLETE value shall be mapped to a Terminate control character encoded on the next eight TXD signals in sequence after the last data octet; and is transferred to the PHY at the next TX_CLK rising edge. This may be on the same TX_CLK rising edge as the last data octet or the subsequent TX_CLK rising edge. When the Terminate control character is in lane 0, 1, 2, 3, 4, 5, or 6, the lanes following in sequence are encoded with an Idle control character.

81.1.7.2 Mapping of PLS_DATA.indication

81.1.7.2.1 Function

The RS maps the XLGMII/CGMII signals RXD<63:0>, RXC<7:0>, and RX_CLK to the primitive PLS_DATA.indication.

81.1.7.2.2 Semantics of the service primitive

PLS_DATA.indication (INPUT_UNIT)

The INPUT_UNIT parameter can take one of two values: one or zero. It represents a single data bit.

81.1.7.2.3 When generated

The INPUT_UNIT values are derived from the signals RXC<7:0> and RXD<63:0> received from the PHY on each rising edge of RX_CLK. Each primitive generated to the MAC sublayer entity corresponds to a PLS_DATA.request issued by the MAC at the remote end of the link connecting two DTEs. For each RXD<63:0> during frame reception, the RS shall generate 64 PLS_DATA.indication transactions until the end of frame (Terminate control character), where 0, 8, 16, 24, 32, 40, 48, or 56 PLS_DATA.indication transactions will be generated from the RXD<63:0> containing the Terminate. During frame reception, each RXD signal shall be mapped in sequence into a PLS_DATA.indication transaction (RXD<0>, RXD<1>,... RXD<63>, RXD<0>) as described in 81.2.

The RS shall convert a valid Start control character to a preamble octet prior to generation of the associated PLS_DATA.indication transactions. The RS shall not generate any PLS_DATA.indication primitives for a Terminate control character. To assure robust operation, the value of the data transferred to the MAC may be changed by the RS as required by XLGMII/CGMII error indications (see 81.3.3). Sequence ordered sets are not indicated to the MAC (see 81.3.4).

81.1.7.2.4 Effect of receipt

The effect of receipt of this primitive by the MAC sublayer is unspecified.

81.1.7.3 Mapping of PLS_CARRIER.indication

40 Gb/s and 100 Gb/s operation supports full duplex operation only. The RS only generates this primitive when optional EEE capability or the optional detection of Link Interruption is supported.

CARRIER_STATUS is set to CARRIER_ON if the optional EEE capability is supported and LPI_CARRIER_STATUS is TRUE, or if optional detection of Link Interruption is supported and link_fault is Link Interruption (see 81.3.4.1). CARRIER_STATUS is otherwise set to CARRIER_OFF. The deferral mechanism based upon the Link Interruption signal may be enabled or disabled by management.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

81.1.7.4 Mapping of PLS_SIGNAL.indication

40 Gb/s and 100 Gb/s operation supports full duplex operation only. The RS never generates this primitive.

81.1.7.5 Mapping of PLS_DATA_VALID.indication

81.1.7.5.1 Function

The RS maps the XLGMII/CGMII signals RXC<7:0> and RXD<63:0> to the primitive PLS_DATA_VALID.indication.

81.1.7.5.2 Semantics of the service primitive

PLS_DATA_VALID.indication (DATA_VALID_STATUS)

The DATA_VALID_STATUS parameter can take one of two values: DATA_VALID or DATA_NOT_VALID. The DATA_VALID value indicates that the INPUT_UNIT parameter of the PLS_DATA.indication primitive contains valid data of an incoming frame. The DATA_NOT_VALID value indicates that the INPUT_UNIT parameter of the PLS_DATA.indication primitive does not contain valid data of an incoming frame.

81.1.7.5.3 When generated

The PLS_DATA_VALID.indication service primitive shall be generated by the RS whenever the DATA_VALID_STATUS parameter changes from DATA_VALID to DATA_NOT_VALID or vice versa.

DATA_VALID_STATUS shall assume the value DATA_VALID when a PLS_DATA.indication transaction is generated in response to reception of a Start control character on lane 0 if the prior RXC<7:0> and RXD<63:0> contained eight Idle characters, a Sequence ordered set, or a Terminate character. DATA_VALID_STATUS shall assume the value DATA_NOT_VALID when RXC of the current lane in sequence is asserted for anything except an Error control character. In the absence of errors, DATA_NOT_VALID is caused by a Terminate control character. When DATA_VALID_STATUS changes from DATA_VALID to DATA_NOT_VALID because of a control character other than Terminate, the RS shall ensure that the MAC will detect a FrameCheckError prior to indicating DATA_NOT_VALID to the MAC (see 81.3.3.1).

81.1.7.5.4 Effect of receipt

The effect of receipt of this primitive by the MAC sublayer is unspecified.

81.2 XLGMII/CGMII data stream

Packets transmitted through the XLGMII/CGMII shall be transferred within the XLGMII/CGMII data stream. A data stream is a sequence of bytes, where each byte conveys either a data octet or control character. The parts of the data stream are shown in Figure 81–3.

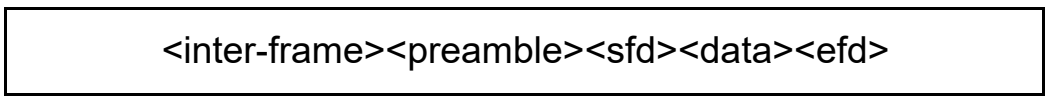

Figure 81–3—XLGMII/CGMII data stream

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

For the XLGMII/CGMII, transmission and reception of each bit and mapping of data octets to lanes shall be as shown in Figure 81–4.

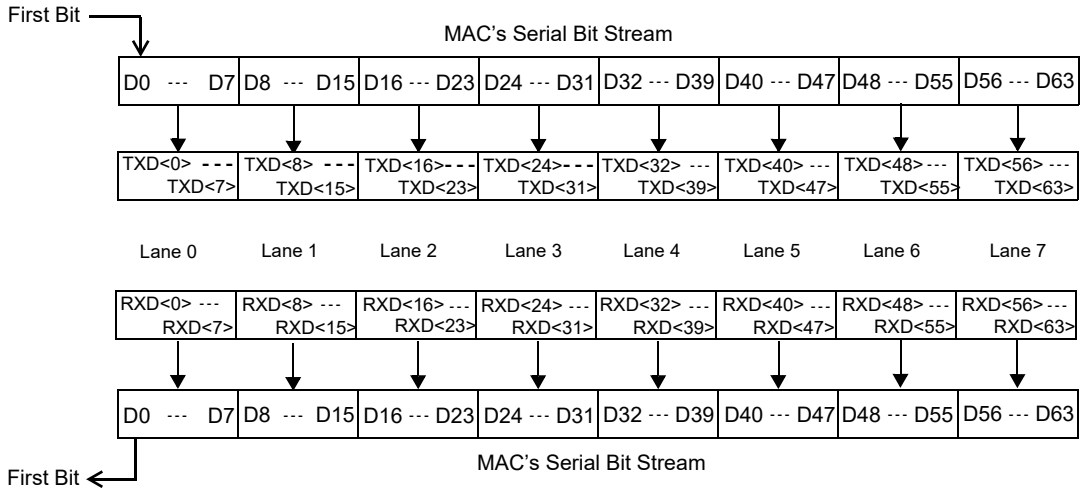

Figure 81–4—Relationship of data lanes to MAC serial bit stream

81.2.1 Inter-frame <inter-frame>

The inter-frame <inter-frame> period on an XLGMII/CGMII transmit or receive path is an interval during which no frame data activity occurs. The <inter-frame> corresponding to the MAC interpacket gap begins with the Terminate control character, continues with Idle control characters and ends with the Idle control character prior to a Start control character. The length of the interpacket gap may be changed between the transmitting MAC and receiving MAC by one or more functions (e.g., RS lane alignment or PHY clock rate compensation). The minimum IPG at the XLGMII/CGMII of the receiving RS is one octet.

The signaling of link status information logically occurs in the <inter-frame> period (see 81.3.4). Frame processing when signaling of link status information is initiated or terminated is described in 81.3.3.

81.2.2 Preamble <preamble> and start of frame delimiter <sfd>

The preamble <preamble> begins a frame transmission by a MAC as specified in 4.2.5 and when generated by a MAC consists of 7 octets with the following bit values:

10101010 10101010 10101010 10101010 10101010 10101010 10101010

The Start control character indicates the beginning of MAC data on the XLGMII/CGMII. On transmit, the RS converts the first data octet of preamble transferred from the MAC into a Start control character. On receive, the RS converts the Start control character into a preamble data octet. The Start control character is aligned to lane 0 of the XLGMII/CGMII by the RS on transmit and by the PHY on receive.

The start of frame delimiter <sfd> indicates the start of a frame and immediately follows the preamble. The bit value of <sfd> at the XLGMII/CGMII is the same as the Start Frame Delimiter (SFD) specified in 4.2.6 and is equal to the following:

10101011

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The preamble and SFD are shown previously with their bits ordered for serial transmission from left to right. As shown, the left-most bit of each octet is the LSB of the octet and the right-most bit of each octet is the MSB of the octet.

The preamble and SFD are transmitted through the XLGMII/CGMII as octets sequentially ordered on the lanes of the XLGMII/CGMII. The first preamble octet is replaced with a Start control character and it is aligned to lane 0, the second octet on lane 1, the third on lane 2, the fourth on lane 3, the fifth on lane 4, the sixth on lane 5, the seventh on lane 6, and the SFD on lane 7, and the eight octets are transferred on the next rising edge of TX_CLK. The ninth octet is assigned to lane 0 with subsequent octets sequentially assigned to the lanes. The XLGMII/CGMII <preamble> and <sfd> are as follows:

Lane 0	**Lane 1**	**Lane 2**	**Lane 3**	**Lane 4**	**Lane 5**	**Lane 6**	**Lane 7**
Start	10101010	10101010	10101010	10101010	10101010	10101010	10101011

81.2.3 Data <data>

The data <data> in a frame shall consist of a set of data octets.

81.2.4 End of frame delimiter <efd>

Assertion of TXC with the appropriate Terminate control character encoding of TXD on a lane constitutes an end of frame delimiter <efd> for the transmit data stream. Similarly, assertion of RXC with the appropriate Terminate control character encoding of RXD constitutes an end of frame delimiter for the receive data stream. The XLGMII/CGMII shall recognize the end of frame delimiter on any of the eight lanes of the XLGMII/CGMII.

81.2.5 Definition of Start of Packet and End of Packet Delimiters

For the purposes of Clause 30, the Start of Packet Delimiter is defined as the Start control character, and the End of Packet delimiter is defined as the end of the last sequential data octet preceding the Terminate control character or other control character causing a change from DATA_VALID to DATA_NOT_VALID (see 81.1.7.5.2 and 30.3.2.1.5).

81.3 XLGMII/CGMII functional specifications

The XLGMII/CGMII is designed to make the differences among the various media and transceiver combinations transparent to the MAC sublayer. The selection of logical control signals and the functional procedures are all designed to this end.

NOTE—No XLGMII/CGMII loopback is defined, but XLGMII/CGMII signals are specified such that transmit signals may be connected to receive signals to create a loopback path. To do this, TXD<0> is connected to RXD<0> ... TXD<63> to RXD<63>, TXC<0> to RXC<0> ... TXC<7> to RXC<7>, and TXCLK to RXCLK. Such a loopback does not test the Link Fault Signaling state diagram, nor any of the error handling functions of the receive RS.

81.3.1 Transmit

81.3.1.1 TX_CLK

TX_CLK is a continuous clock used for operation at the appropriate frequency. TX_CLK provides the timing reference for the transfer of the TXC<7:0> and TXD<63:0> signals from the RS to the PHY. The values of TXC<7:0> and TXD<63:0> shall be sampled by the PHY on the rising edge of TX_CLK. TX_CLK is sourced by the RS.

The TX_CLK frequency shall be one-sixty-fourth of the MAC transmit data rate.

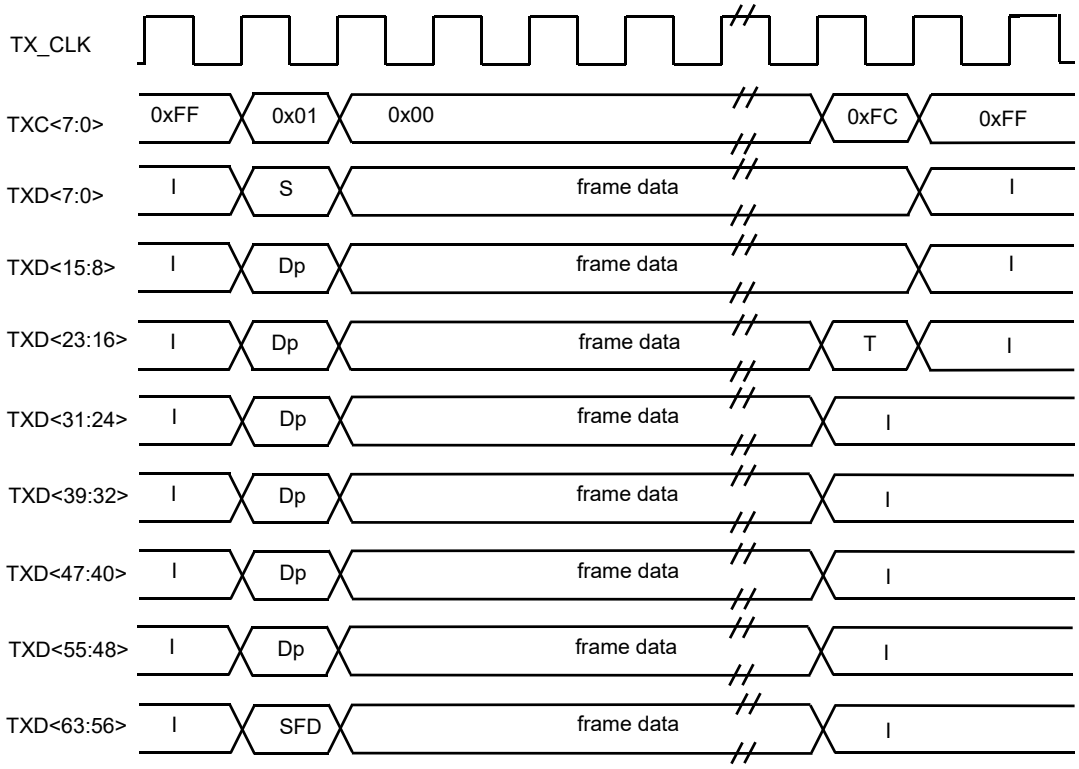
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

81.3.1.2 TXC<7:0> (transmit control)

TXC<7:0> indicate that the RS is presenting either data or control characters on the XLGMII/CGMII for transmission. The TXC signal for a lane shall be deasserted when a data octet is being sent on the corresponding lane and asserted when a control character is being sent. In the absence of errors, the TXC signals are deasserted by the RS for each octet of the preamble (except the first octet that is replaced with a Start control character) and remain deasserted while all octets to be transmitted are presented on the lanes of the XLGMII/CGMII. TXC<7:0> are driven by the RS and shall transition synchronously with respect to the rising edge of TX_CLK. Table 81–3 specifies the permissible encodings of TXD and TXC for an XLGMII/CGMII transmit lane. Additional requirements apply for proper code sequences and in which lanes particular codes are valid (e.g., Start control character is to be aligned to lane 0).

Table 81–3—Permissible encodings of TXC and TXD

TXC	TXD	Description	PLS_DATA.request parameter
0	0x00 through 0xFF	Normal data transmission	Zero, one (eight bits)
1	0x00 through 0x05	Reserved	—
1	0x06	Only valid on all 8 lanes simultaneously to request LPI	No applicable parameter (normal inter-frame)
1	0x07	Idle	No applicable parameter (normal inter-frame)
1	0x08 through 0x9B	Reserved	—
1	0x9C	Sequence (only valid in lane 0)	No applicable parameter (inter-frame status signal)
1	0x9D through 0xFA	Reserved	—
1	0xFB	Start (only valid in lane 0)	No applicable parameter, replaces first eight zero, one of a frame (preamble octet)
1	0xFC	Reserved	—
1	0xFD	Terminate	DATA_COMPLETE
1	0xFE	Error	No applicable parameter
1	0xFF	Reserved	—



A PHY with EEE capability shall interpret the combination of TXC and TXD as shown in Table 81–3 as an assertion of LPI. Transition into and out of the LPI state is shown in Figure 81–7.

81.3.1.3 TXD<63:0> (transmit data)

TXD is a bundle of 64 data signals organized into eight lanes of eight signals each (TXD<7:0>, TXD<15:8>, TXD<23:16>, TXD<31:24>, TXD<39:32>, TXD<47:40>, TXD<55:48>, and TXD<63:56>) that are driven by the RS. Each lane is associated with a TXC signal as shown in Table 81–2 and shall be encoded as shown in Table 81–3. TXD<63:0> shall transition synchronously with respect to the rising edge of TX_CLK. For each high TX_CLK transition, data and/or control are presented on TXD<63:0> to the PHY for transmission. TXD<0> is the least significant bit of lane 0, TXD<8> the least significant bit of lane 1, TXD<16> the least significant bit of lane 2, TXD<24> the least significant bit of lane 3, TXD<32> the least significant bit of lane 4, TXD<40> the least significant bit of lane 5, TXD<48> the least significant bit of lane 6, and TXD<56> the least significant bit of lane 7.

Assertion on a lane of appropriate TXD values when TXC is asserted will cause the PHY to generate code-groups associated with either Idle, Start, Terminate, Sequence, or Error control characters. While the TXC of a lane is deasserted, TXD of the lane is used to request the PHY to generate code-groups corresponding to the data octet value of TXD. An example of normal frame transmission is illustrated in Figure 81–5.

Figure 81–6—Transmit Error Propagation

81.3.1.4 Start control character alignment

On transmit, it may be necessary for the RS to modify the length of the <inter-frame> in order to align the Start control character (first octet of preamble) on lane 0. This shall be accomplished in one of the following two ways:

a) A MAC implementation may incorporate this RS function into its design and always insert additional idle characters to align the start of preamble on an eight byte boundary. Note that this will reduce the effective data rate for certain packet sizes separated with minimum inter-frame spacing.

b) Alternatively, the RS may maintain the effective data rate by sometimes inserting and sometimes deleting idle characters to align the Start control character. When using this method the RS maintains a Deficit Idle Count (DIC) that represents the cumulative count of idle characters deleted or inserted. The DIC is incremented for each idle character deleted, decremented for each idle character inserted, and the decision of whether to insert or delete idle characters is constrained by bounding the DIC to a minimum value of zero and maximum value of seven. Note that this may result in inter-frame spacing observed on the transmit XLGMII/CGMII that is up to seven octets shorter than the minimum transmitted inter-frame spacing specified in Clause 4; however, the frequency of shortened inter-frame spacing is constrained by the DIC rules. The DIC is only reset at initialization and is applied regardless of the size of the IPG transmitted by the MAC sublayer. An equivalent technique may be employed to control RS alignment of the Start control character provided that the result is the same as if the RS implemented the DIC as described.

81.3.1.5 Transmit direction LPI transition

LPI operation and the LPI client are described in 78.1. The RS requests the PHY to transition to the LPI state by asserting TXC and setting TXD to 0x06 (in all lanes). The RS maintains the same state for these signals for the entire time that the PHY is to remain in the LPI state.

The RS asserts TXC and asserts IDLE on lanes 0 to 7 in order to make the PHY transition out of the LPI state. The RS should not present a start code for valid transmit data until after the wake-up time specified for the PHY ($T_{w_sys_tx}$). The wake times are shown in Table 78–4

Figure 81–7 shows the behavior of TXC and TXD<7:0> during the transition into and out of the LPI state.

NOTE—TXC and TXD are shown for one lane, all 8 lanes behave identically during LPI.

Figure 81–7—LPI transition

Table 81–3 summarizes the permissible encodings of TXD<63:0>, TXC<7:0>.

81.3.2 Receive

81.3.2.1 RX_CLK (receive clock)

RX_CLK is a continuous clock that provides the timing reference for the transfer of the RXC<7:0> and RXD<63:0> signals from the PHY to the RS. RXC<7:0> and RXD<63:0> shall be sampled by the RS on the rising edge of RX_CLK. RX_CLK is sourced by the PHY.

The frequency of RX_CLK may be derived from the received data or it may be that of a nominal clock (e.g., TX_CLK). When the received data rate at the PHY is within tolerance, the RX_CLK frequency shall be one-sixty-fourth of the MAC receive data rate.

There is no need to transition between the recovered clock reference and a nominal clock reference on a frame-by-frame basis. If loss of received signal from the medium causes a PHY to lose the recovered RX_CLK reference, the PHY shall source the RX_CLK from a nominal clock reference.

NOTE—This standard neither requires nor assumes a guaranteed phase relationship between the RX_CLK and TX_CLK signals.

81.3.2.2 RXC<7:0> (receive control)

RXC<7:0> indicate that the PHY is presenting either recovered and decoded data or control characters on the XLGMII/CGMII. The RXC signal for a lane shall be deasserted when a data octet is being received on the corresponding lane and asserted when a control character is being received. In the absence of errors, the RXC signals are deasserted by the PHY for each octet of the preamble (except the first octet that is replaced with a Start control character) and remain deasserted while all octets to be received are presented on the

lanes of the XLGMII/CGMII. RXC<7:0> are driven by the PHY and shall transition synchronously with respect to the rising edge of RX_CLK. Table 81–4 specifies the permissible encodings of RXD and RXC for an XLGMII/CGMII receive lane. Additional requirements apply for proper code sequences and in which lanes particular codes are valid (e.g., Start control character is to be aligned to lane 0).

Table 81–4—Permissible lane encodings of RXD and RXC

RXC	RXD	Description	PLS_DATA.indication parameter
0	0x00 through 0xFF	Normal data reception	Zero, one (eight bits)
1	0x00 through 0x05	Reserved	—
1	0x06	Only valid on all 8 lanes simultaneously to indicate LP_IDLE is asserted	No applicable parameter (normal inter-frame)
1	0x07	Idle	No applicable parameter (Normal inter-frame)
1	0x08 through 0x9B	Reserved	—
1	0x9C	Sequence (only valid in lane 0)	No applicable parameter (Inter-frame status signal)
1	0x9D through 0xFA	Reserved	—
1	0xFB	Start (only valid in lane 0)	No applicable parameter, first eight zero, one of a frame (a preamble octet)
1	0xFC	Reserved	—
1	0xFD	Terminate	No applicable parameter (start of inter-frame)
1	0xFE	Error	No applicable parameter
1	0xFF	Reserved	—

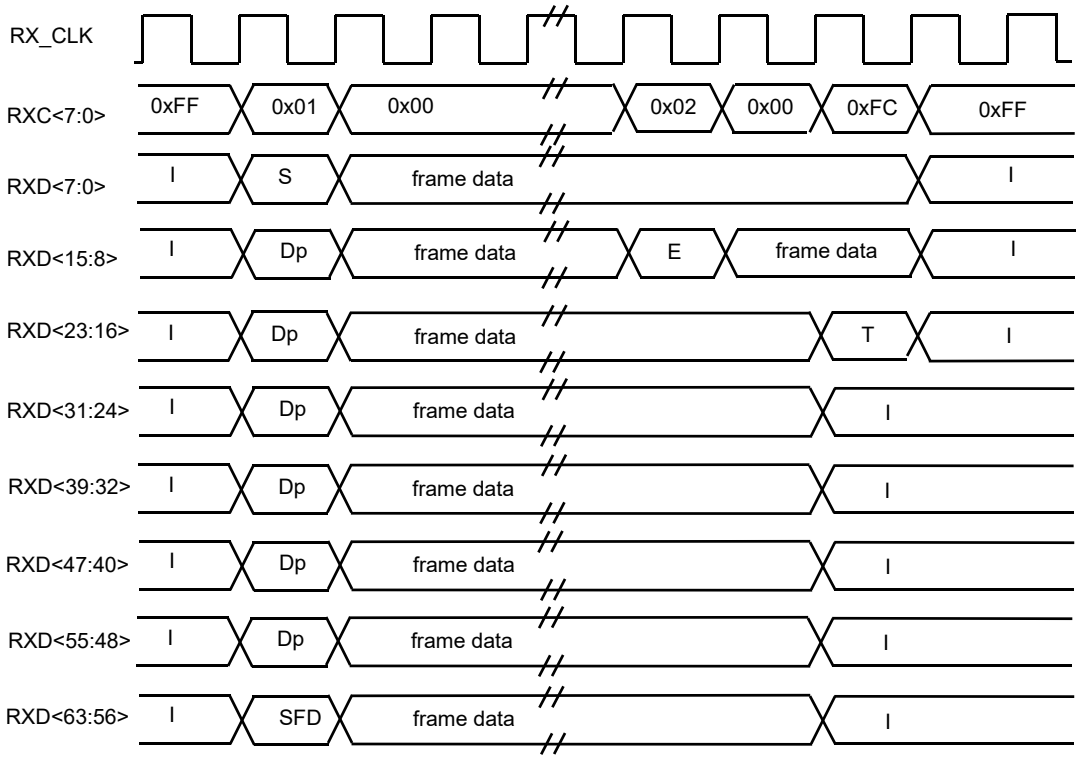
Figure 81–8 shows the behavior of RXC<7:0> during an example frame reception with no errors.

I: Idle control character, S: Start control character, Dp: preamble Data octet, T: Terminate control character, SFD: Start of Frame Delimiter

Figure 81–8—Frame reception without error

81.3.2.3 RXD (receive data)

RXD is a bundle of 64 data signals (RXD<63:0>) organized into eight lanes of eight signals each (RXD<7:0>, RXD<15:8>, RXD<23:16>, RXD<31:24>, RXD<39:32>, RXD<47:40>, RXD<55:48>, and RXD<63:56>) that are driven by the PHY. Each lane is associated with an RXC signal as shown in Table 81–2 and shall be decoded by the RS as shown in Table 81–4. RXD<63:0> shall transition synchronously with respect to the rising edge of RX_CLK. For each rising RX_CLK transition, received data and/or control are presented on RXD<63:0> for mapping by the RS. RXD<0> is the least significant bit of lane 0, RXD<8> the least significant bit of lane 1, RXD<16> the least significant bit of lane 2, RXD<24> the least significant bit of lane 3, RXD<24> the least significant bit of lane 3, RXD<32> the least significant bit of lane 4, RXD<40> the least significant bit of lane 5, RXD<48> the least significant bit of lane 6, and RXD<56> the least significant bit of lane 7. Figure 81–8 shows the behavior of RXD<63:0> during frame reception.



While the RXC of a lane is deasserted, RXD of the lane is used by the RS to generate PLS_DATA.indications. Assertion on a lane of appropriate RXD values when RXC is asserted indicates to the RS the Start control character, Terminate control character, Sequence control character, or Error control character that drive its mapping functions.

RXC of a lane is asserted with the appropriate Error control character encoding on RXD of the lane to indicate that an error was detected somewhere in the frame presently being transferred from the PHY to the

RS (e.g., a coding error, or any error that the PHY is capable of detecting, and that may otherwise be undetectable at the MAC sublayer).

The effect of an Error control character on the RS is defined in 81.3.3.1. Figure 81–9 shows the behavior of RXC and RXD during the reception of an example frame with an error.

I: Idle control character, S: Start control character, Dp: preamble Data octet, T: Terminate control character, E: Error control character, SFD: Start of Frame Delimiter

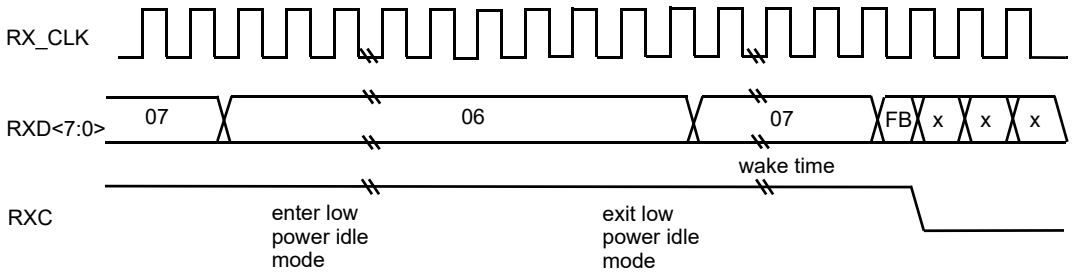

Figure 81–9—Reception with error

81.3.2.4 Receive direction LPI transition

LPI operation and the LPI client are described in 78.1. When the PHY receives signals from the link partner to indicate transition into the low power state, it indicates this to the RS by asserting RXC and setting RXD to 0x06 (in all lanes). The PHY maintains these signals in this state while it remains in the LPI state. When the PHY receives signals from the link partner to indicate transition out of the LPI state, it indicates this to the RS by asserting RXC and asserting idle on all lanes 0 to 7 to return to a normal interframe state. The RS shall interpret the LPI coding as shown in Table 81–4.

Figure 81–10 shows the behavior of RXC and RXD<7:0> during LPI transitions.

NOTE 1—RXC and RXD are shown for one lane, all 8 lanes behave identically during LPI.
NOTE 2—In some instances, LPI may be followed by characters other than IDLE during wake time.

Figure 81–10—LPI transition

81.3.3 Error and fault handling

81.3.3.1 Response to error indications by the XLGMII/CGMII

If, during frame reception (i.e., when DATA_VALID_STATUS = DATA_VALID), a control character other than a Terminate control character is signaled on a received lane, the RS shall ensure that the MAC will detect a FrameCheckError in that frame. This requirement may be met by incorporating a function in the RS that produces a received frame data sequence delivered to the MAC sublayer that is guaranteed to not yield a valid CRC result, as specified by the frame check sequence algorithm (see 3.2.8). This data sequence may be produced by substituting data delivered to the MAC. The RS generates eight PLS_DATA.indication primitives for each Error control character received within a frame, and may generate eight PLS_DATA.indication primitives to ensure FrameCheckError when a control character other than Terminate causes the end of the frame.

Other techniques may be employed to respond to a received Error control character provided that the result is that the MAC sublayer behaves as though a FrameCheckError occurred in the received frame.

81.3.3.2 Conditions for generation of transmit Error control characters

If, during the process of transmitting a frame, it is necessary to request that the PHY deliberately corrupt the contents of the frame in such a manner that a receiver will detect the corruption with the highest degree of probability, then an Error control character may be asserted on a transmit lane by the appropriate encoding of the lane's TXD and TXC signals.

81.3.3.3 Response to received invalid frame sequences

The RS shall not indicate DATA_VALID to the MAC for a Start control character received on any lane other than lane 0. Error free operation will not change the SFD alignment in lane 7. A MAC/RS implementation is not required to process a packet that has an SFD in a position other than lane 7 in the XLGMII/CGMII transfer containing the Start control character.

81.3.4 Link fault signaling

Link fault signaling operates between the remote RS and the local RS. Faults detected between the remote RS and the local RS are received by the local RS as Local Fault. Only an RS originates Remote Fault signals. The behavior of the fault signaling is the same as it is for Clause 46 with the exception that the ordered sets are aligned to eight byte boundaries, padding lanes 4 to 7 with 0x00.

Clause 46 uses the term column when describing data transfers on the XGMII. The eight lanes of data and control transferred per clock cycle on XLGMII/CGMII are equivalent to a column in the following description of link fault signaling.

Sublayers within the PHY are capable of detecting faults that render a link unreliable for communication. Upon recognition of a fault condition, a PHY sublayer indicates Local Fault status on the data path. When this Local Fault status reaches an RS, the RS stops sending MAC data or LPI, and continuously generates a Remote Fault status on the transmit data path (possibly truncating a MAC frame being transmitted). When Remote Fault status is received by an RS, the RS stops sending MAC data or LPI, and continuously generates Idle control characters. When the RS no longer receives fault status messages, it returns to normal operation, sending MAC data or LPI. Note that this behavior only supports bidirectional operation.

Status is signaled in an eight byte Sequence ordered set as shown in Table 81–5. The PHY indicates Local Fault with a Sequence control character in lane 0 and data characters of 0x00 in lanes 1, 2, 4, 5, 6, and 7 plus a data character of 0x01 in lane 3. The RS indicates a Remote Fault with a Sequence control character in lane 0 and data characters of 0x00 in lanes 1, 2, 4, 5, 6, and 7 plus a data character of 0x02 in lane 3. Though most fault detection is on the receive data path of a PHY, in some specific sublayers, faults can be detected on the transmit side of the PHY. This is also indicated by the PHY with a Local Fault status. All other values in lanes 1 to 3 not shown in Table 81–5 are reserved. The link fault signaling state diagram allows future standardization of reserved Sequence ordered sets for functions other than link fault indications.

For operation with links that may be temporarily interrupted, optional detection of a third fault condition, Link Interruption, is provided. Link Interruption is indicated by the PHY receive function by continuously sending the Link Interruption ordered set as defined in Table 81–5.

Table 81–5—Sequence ordered sets

Lane 0	Lane 1	Lane 2	Lane 3	Lane 4	Lane 5	Lane 6	Lane 7	Description
Sequence	0x00	0x00	0x00	0x00	0x00	0x00	0x00	Reserved
Sequence	0x00	0x00	0x01	0x00	0x00	0x00	0x00	Local Fault
Sequence	0x00	0x00	0x02	0x00	0x00	0x00	0x00	Remote Fault
Sequence	0x00	0x00	0x03	0x00	0x00	0x00	0x00	Link Interruption

The RS reports the fault status of the link. Local Fault indicates a fault detected on the receive data path between the remote RS and the local RS. Remote Fault indicates a fault on the transmit path between the local RS and the remote RS. The RS shall implement the link fault signaling state diagram (see Figure 81–11).

81.3.4.1 Variables and counters

The Link Fault Signaling state diagram uses the following variables and counters:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

col_cnt
: A count of the number of columns received not containing a fault_sequence. This counter increments at RX_CLK rate (on the rising clock transitions) unless reset.

fault_sequence
: A new column received on RXC<7:0> and RXD<63:0> comprising a Sequence ordered set of eight bytes and consisting of a Sequence control character in lane 0 and a seq_type in lanes 1, 2, 3, 4, 5, 6, and 7 indicating either Local Fault, Remote Fault, or Link Interruption.

last_seq_type
: The seq_type of the previous Sequence ordered set received
  Values: Local Fault; 0x00 in lane 1, 0x00 in lane 2, 0x01 in lane 3, 0x00 in lane 4, 0x00 in lane 5, 0x00 in lane 6, 0x00 in lane 7.
  Remote Fault; 0x00 in lane 1, 0x00 in lane 2, 0x02 in lane 3, 0x00 in lane 4, 0x00 in lane 5, 0x00 in lane 6, 0x00 in lane 7.
  Link Interruption; 0x00 in lane 1, 0x00 in lane 2, 0x03 in lane 3, 0x00 in lane 4, 0x00 in lane 5, 0x00 in lane 6, 0x00 in lane 7.

link_fault
: An indicator of the fault status.
  Values: OK; No fault.
  Local Fault; fault detected by the PHY.
  Remote Fault; fault detection signaled by the remote RS.
  Link Interruption; link temporarily unavailable, signaled by the PHY.

reset
: Condition that is true until such time as the power supply for the device that contains the RS has reached the operating region.
  Values: FALSE: The device is completely powered and has not been reset (default).
  TRUE: The device has not been completely powered or has been reset.

seq_cnt
: A count of the number of received Sequence ordered sets of the same type.

seq_type
: The value received in the current Sequence ordered set
  Values: Local Fault; 0x00 in lane 1, 0x00 in lane 2, 0x01 in lane 3, 0x00 in lane 4, 0x00 in lane 5, 0x00 in lane 6, 0x00 in lane 7.
  Remote Fault; 0x00 in lane 1, 0x00 in lane 2, 0x02 in lane 3, 0x00 in lane 4, 0x00 in lane 5, 0x00 in lane 6, 0x00 in lane 7.
  Link Interruption; 0x00 in lane 1, 0x00 in lane 2, 0x03 in lane 3, 0x00 in lane 4, 0x00 in lane 5, 0x00 in lane 6, 0x00 in lane 7.

81.3.4.2 State diagram

The Link Fault Signaling state diagram specifies the RS monitoring of RXC<7:0> and RXD<63:0> for Sequence ordered sets. The variable link_fault is set to indicate the value of a received Sequence ordered set when four fault_sequences containing the same fault value have been received with fault sequence separated by less than 128 columns and no intervening fault_sequences of a different fault value. The state diagram is shown in Figure 81–11.

The variable link_fault is set to OK following any interval of 128 columns not containing a Remote Fault, Local Fault, or Link Interruption Sequence ordered set.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

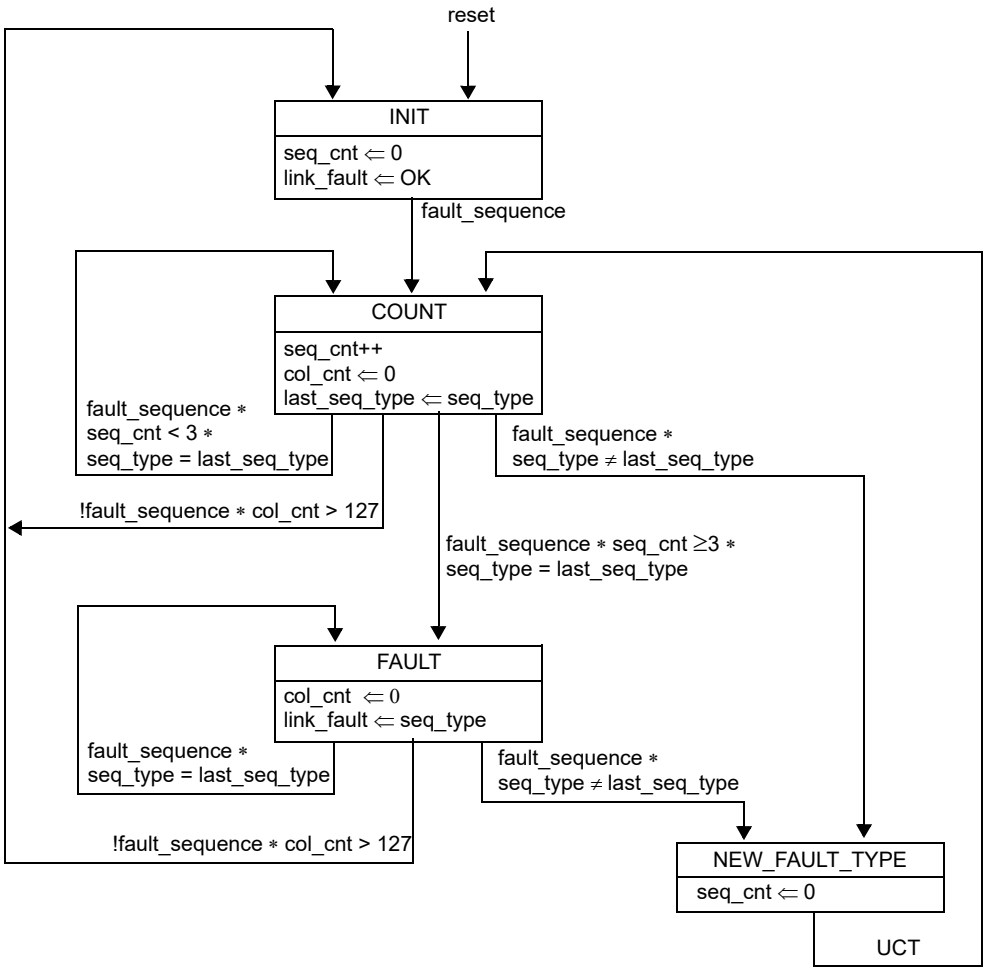

Figure 81–11—Link Fault Signaling state diagram

The RS output onto TXC<7:0> and TXD<63:0> is controlled by the variable link_fault.

a) link_fault = OK
The RS shall send MAC frames as requested through the PLS service interface. In the absence of MAC frames, the RS shall generate Idle control characters.

b) link_fault = Local Fault
The RS shall continuously generate Remote Fault Sequence ordered sets.

c) link_fault = Remote Fault or link_fault = Link Interruption
The RS shall continuously generate Idle control characters.

81.4 LPI assertion and detection

Certain PHYs support Energy Efficient Ethernet (see Clause 78). PHYs with EEE capability support LPI assertion and detection. LPI operation and the LPI client are described in 78.1. LPI signaling allows the RS to signal to the PHY and to the link partner that a break in the data stream is expected and components may use this information to enter power saving modes that require additional time to resume normal operation. Similarly, it allows the LPI client to understand that the link partner has sent such an indication.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The LPI assertion and detection mechanism fits conceptually between the PLS Service Primitives and the XLGMII and CGMII signals as shown in Figure 81–12.

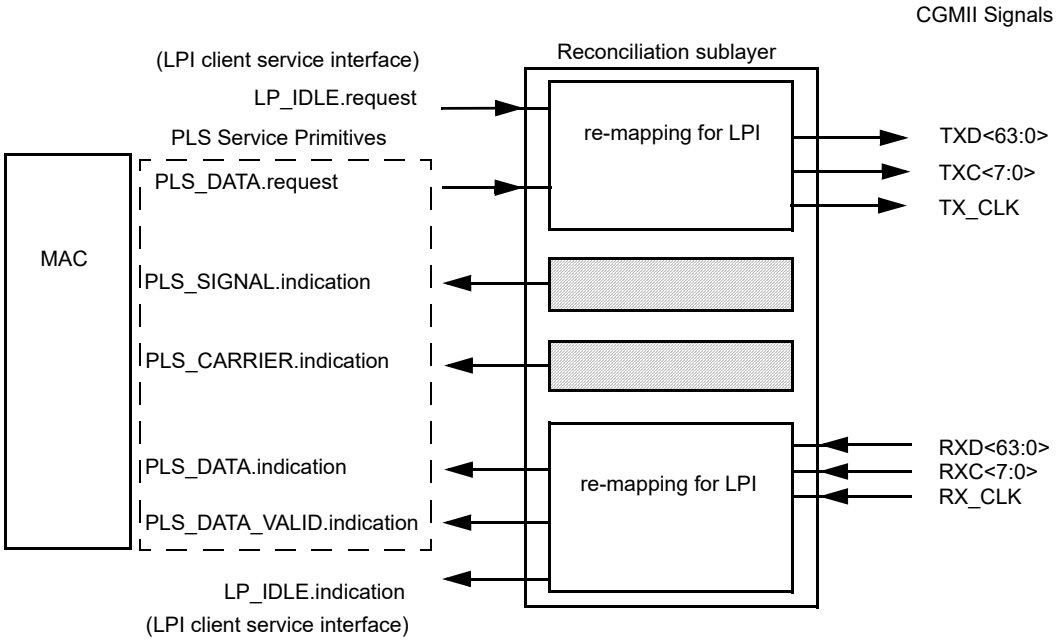

Figure 81–12—LPI assertion and detection mechanism

The definition of TXC<7:0> and TXD<63:0> is derived from the state of PLS_DATA.request (81.1.7), except when it is overridden by an assertion of Remote Fault or LP_IDLE.request.

Similarly, RXC<7:0> and RXD<63:0> are mapped to PLS_DATA.indication except when LP_IDLE is detected.

PLS_CARRIER.indication(CARRIER_STATUS) is set to CARRIER_ON when the link is in LPI mode. See 81.1.7.3.

The timing of PLS_CARRIER.indication when used for the LPI function is controlled by the LPI transmit state diagram.

81.4.1 LPI messages

LP_IDLE.indication(LPI_INDICATION)

A primitive that indicates to the LPI client that the PHY has detected the assertion or deassertion of LPI from the link partner.

Values: DEASSERT: The link partner is operating with normal inter-frame behavior (default).
ASSERT: The link partner has asserted LPI.

LP_IDLE.request(LPI_REQUEST)

The LPI_REQUEST parameter can take one of two values: ASSERT or DEASSERT. ASSERT initiates the signaling of LPI to the link partner. DEASSERT stops the signaling of LPI to the link partner. The effect of receipt of this primitive is undefined if link_status is not OK (see 73.9.1.1) or within 1 s of the change of link_status to OK.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

81.4.2 Transmit LPI state diagram

The operation of LPI in the PHY requires that the MAC does not send valid data for a time after LPI has been deasserted as governed by resolved Transmit T_{w_sys} defined in 78.4.2.3.

This wake-up time is enforced by the transmit LPI state diagram using PLS_CARRIER.indication(CARRIER_STATUS). The implementation shall conform to the behavior described by the transmit LPI state diagram shown in Figure 81–13.

81.4.2.1 Variables and counters

The transmit LPI state diagram uses the following variables and counters:

LPI_CARRIER_STATUS
: The LPI_CARRIER_STATUS variable indicates how the CARRIER_STATUS parameter is controlled by the LPI_REQUEST parameter. The LPI_CARRIER_STATUS is either TRUE or FALSE as determined by the Transmit LPI state diagram in Figure 81–13.

power_on
: Condition that is true until such time as the power supply for the device that contains the RS has reached the operating region.
  Values: FALSE: The device is completely powered (default).
  TRUE: The device has not been completely powered.

reset
: Used by management to control the resetting of the RS.
  Values: FALSE: Do not reset the RS (default).
  TRUE: Reset the RS.

tw_timer
: A timer that counts the time since the deassertion of LPI. The terminal count of the timer is the value of the resolved $T_{w_sys_tx}$ as defined in 78.2. If PMA Ingress AUI Stop Enable (PIASE) bit (1.7.9) is asserted for any of the PMA sublayers, the terminal count of the timer is the value of the resolved $T_{w_sys_tx}$ as defined in 78.2 plus additional time equal to $T_{w_sys_tx}$–$T_{w_sys_rx}$ for the XLAUI and CAUI-n as shown in Table 78–4 for each PMA with PIASE to be asserted. The signal tw_timer_done is asserted when tw_timer reaches its terminal count.

81.4.2.2 State diagram

81.4.3 Considerations for transmit system behavior

The transmit system should expect that egress data flow is halted for at least resolved $T_{w_sys_tx}$ (see 78.2) time after it requests the deassertion of LPI. Buffering and queue management should be designed to accommodate this behavior.

81.4.4 Considerations for receive system behavior

The mapping function of the Reconciliation Sublayer shall continue to signal DATA_NOT_VALID on PLS_DATA_VALID.indication while it is detecting LP_IDLE on the XLGMII and CGMII. The receive system should be aware that data frames may arrive at the XLGMII and CGMII following the deassertion of LPI_INDICATION with a delay corresponding to the link partner's resolved $T_{w_sys_rx}$ (as specified in 78.5) time.

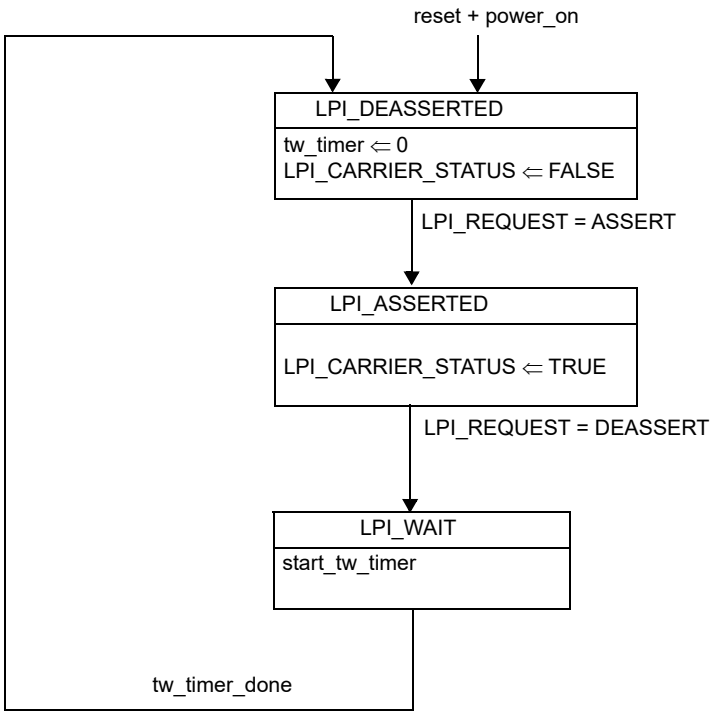

Figure 81–13—Transmit LPI State Diagram

If the PMA Ingress AUI Stop Enable (PIASE) bit (1.7.9) is asserted for any of the PMA sublayers, the PMA may stop signaling on the XLAUI and CAUI-n in the receive direction to conserve energy. The receiver should negotiate an additional time for the remote T_{w_sys} (equal to $T_{w_sys_tx}$–$T_{w_sys_rx}$ for the XLAUI and CAUI-n as shown in Table 78–4) for each PMA with PIASE to be asserted before setting the PIASE bits.

81.5 Protocol implementation conformance statement (PICS) proforma for Clause 81, Reconciliation Sublayer (RS) and Media Independent Interface for 40 Gb/s and 100 Gb/s operation[144]

81.5.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 81, Reconciliation Sublayer (RS) and Media Independent Interface for 40 Gb/s and 100 Gb/s operation, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

81.5.2 Identification

81.5.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

81.5.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 81, Reconciliation Sublayer (RS) and Media Independent Interface for 40 Gb/s and 100 Gb/s operation
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[144]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

82. Physical Coding Sublayer (PCS) for 64B/66B, type 40GBASE-R and 100GBASE-R

82.1 Overview

82.1.1 Scope

This clause specifies the Physical Coding Sublayer (PCS) that is common to two families of (40 Gb/s and 100 Gb/s) Physical Layer implementations, known as 40GBASE-R and 100GBASE-R. The 40GBASE-R PCS is a sublayer of the 40 Gb/s PHYs listed in Table 80–1. The 100GBASE-R PCS is a sublayer of the 100 Gb/s PHYs listed in Table 80–1. The terms 40GBASE-R and 100GBASE-R are used when referring generally to Physical Layers using the PCS defined in this clause.

Both 40GBASE-R and 100GBASE-R are based on a 64B/66B code. The 64B/66B code supports transmission of data and control characters, while maintaining robust error detection. Data distribution is introduced to support multiple lanes in the Physical Layer. Part of the distribution includes the periodic insertion of an alignment marker, which allows the receive PCS to align data from multiple lanes.

82.1.2 Relationship of 40GBASE-R and 100GBASE-R to other standards

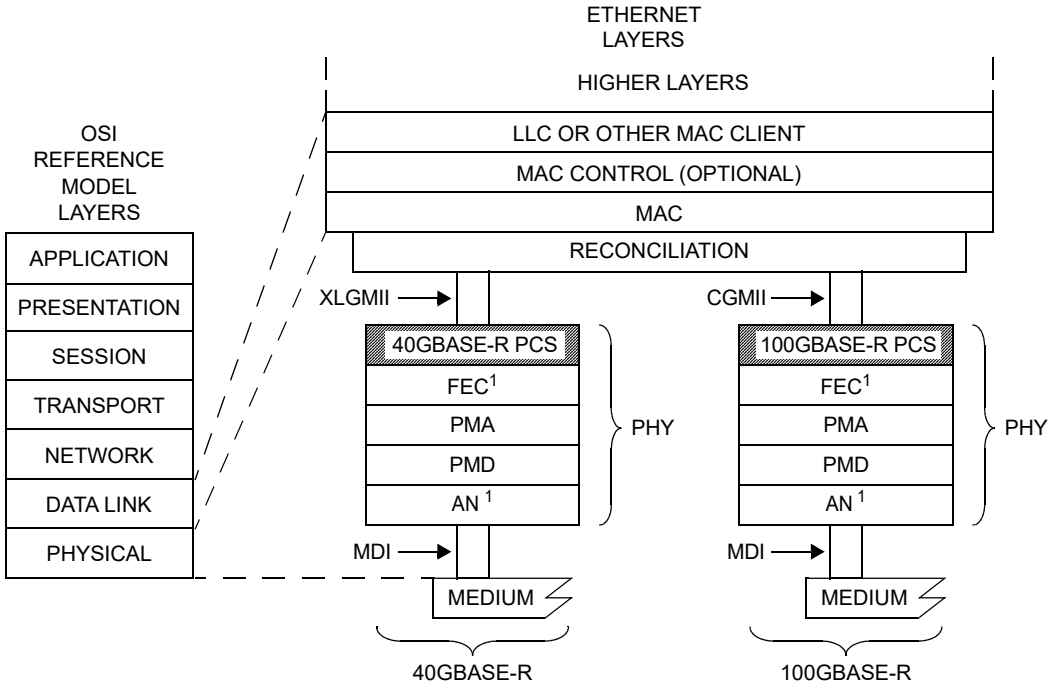

Figure 82–1 depicts the relationships among the 40GBASE-R and 100GBASE-R sublayers (shown shaded), the Ethernet MAC and Reconciliation Sublayers, and the higher layers.

This clause borrows heavily from Clause 49. 64B/66B encoding is reused with appropriate changes made to support 8 byte alignment versus 4 byte alignment in Clause 49. In addition to 64B/66B encoding, there is a methodology to add alignment markers and distribute data to multiple lanes.

82.1.3 Summary of 40GBASE-R and 100GBASE-R sublayers

Figure 82–1 shows the relationship of the 40GBASE-R PCS and 100GBASE-R PCS sublayers (shown shaded) with other sublayers to the ISO Open System Interconnection (OSI) reference model.

AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 82–1—40GBASE-R and 100GBASE-R PCS relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

82.1.3.1 Physical Coding Sublayer (PCS)

The PCS service interface is the Media Independent Interface (XLGMII/CGMII), which is defined in Clause 81. The 40 Gb/s variant of this is called the 40 Gb/s Media Independent Interface (XLGMII) and the 100 Gb/s variant of this interface is called the 100 Gb/s Media Independent Interface (CGMII). The XLGMII/CGMII provides a uniform interface to the Reconciliation Sublayer for all 40 Gb/s and 100 Gb/s PHY implementations.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 40GBASE-R and 100GBASE-R PCSs provide all services required by the XLGMII/CGMII, including the following:

a) Encoding (decoding) of eight XLGMII/CGMII data octets to (from) 66-bit blocks (64B/66B).
b) Transferring encoded data to (from) the PMA.
c) Compensation for any rate differences caused by the insertion or deletion of alignment markers or due to any rate difference between the XLMII/CGMII and PMA through the insertion or deletion of idle control characters.
d) Determining when a functional link has been established and informing the management entity via the MDIO when the PHY is ready for use.

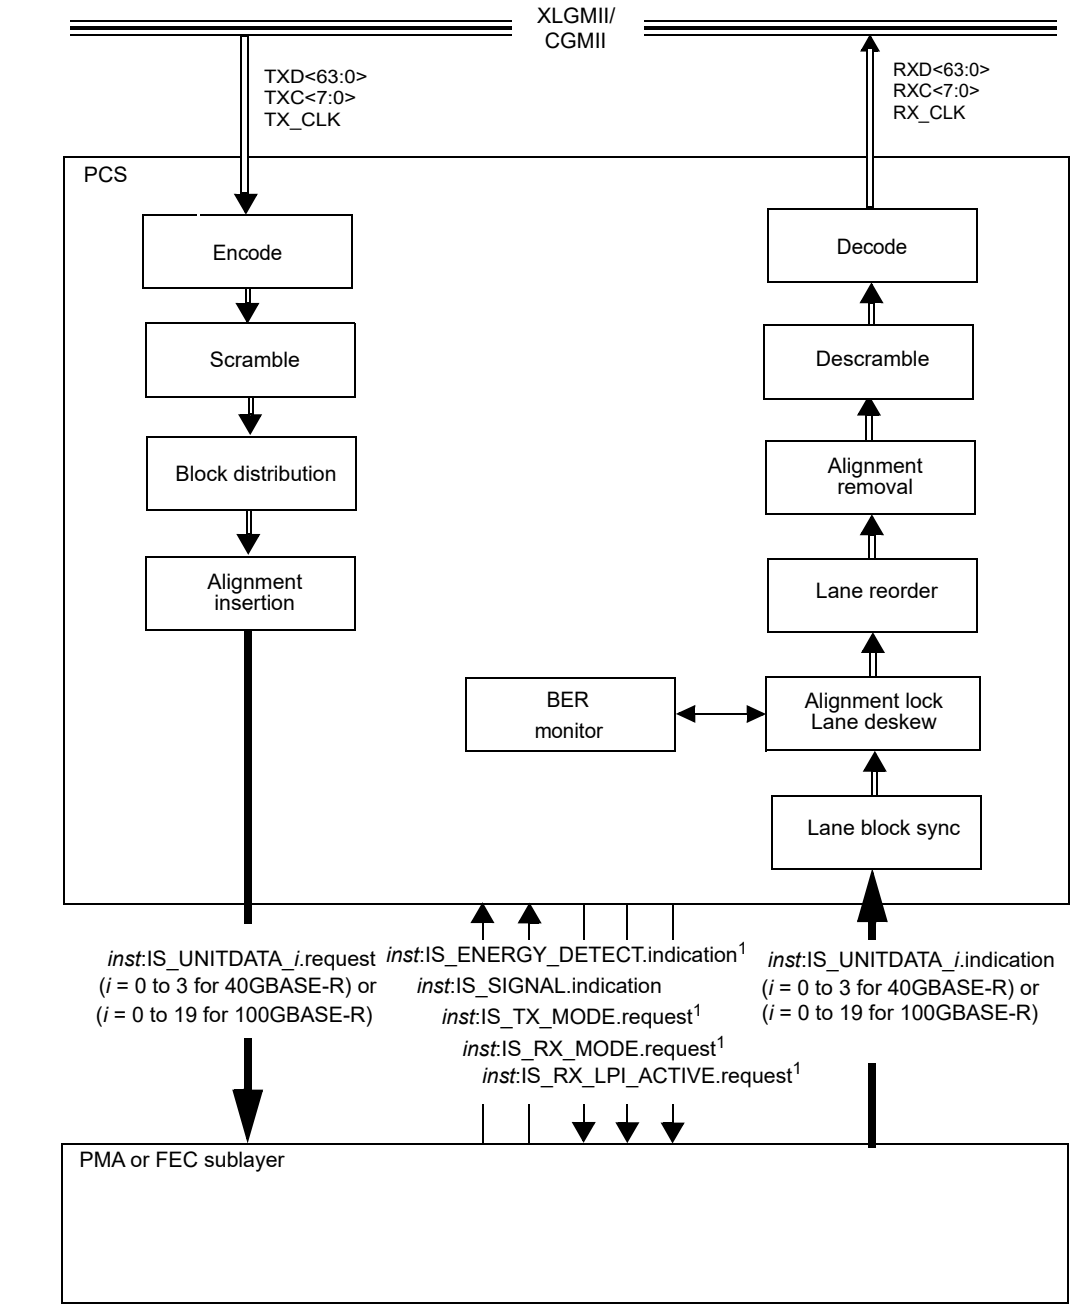
82.1.4 Inter-sublayer interfaces

The upper interface of the PCS may connect to the Reconciliation Sublayer through the XLGMII/CGMII. The lower interface of the PCS connects to the PMA sublayer to support a PMD. If the optional BASE-R FEC sublayer is implemented (see Clause 74) and an optional physical instantiation, i.e., XLAUI or CAUI-n, is not implemented directly below the PCS sublayer, then the lower interface connects to the BASE-R FEC sublayer. For Physical Layers that use Clause 91 RS-FEC, if an optional physical instantiation (i.e., CAUI-n) is not implemented directly below the PCS sublayer, then the lower interface connects to the RS-FEC sublayer. The 40GBASE-R PCS has a nominal rate at the PMA/FEC service interface of 10.3125 Gtransfers/s per PCS lane, which provides capacity for the MAC data rate of 40 Gb/s. The 100GBASE-R PCS has a nominal rate at the PMA/FEC service interface of 5.15625 Gtransfers/s per PCS lane, which provides capacity for the MAC data rate of 100 Gb/s.

It is important to note that, while this specification defines interfaces in terms of bits, octets, and frames, implementations may choose other data-path widths for implementation convenience.

82.1.4.1 PCS service interface (XLGMII/CGMII)

The PCS service interface allows the 40GBASE-R or 100GBASE-R PCS to transfer information to and from a PCS client. The PCS client is the Reconciliation Sublayer. The PCS Service Interface is precisely defined as the Media Independent Interface (XLGMII/CGMII) in Clause 81.



82.1.4.2 Physical Medium Attachment (PMA) or forward error correction (FEC) service interface

The PMA or FEC service interface for the PCS is described in an abstract manner and does not imply any particular implementation. The PMA/FEC Service Interface supports the exchange of encoded data between the PCS and PMA or FEC sublayer. The PMA or FEC service interface is defined in 83.3 or 94.2.1 and is an instance of the inter-sublayer service interface definition in 80.3 or 91.2.

82.2 Physical Coding Sublayer (PCS)

82.2.1 Functions within the PCS

The 40GBASE-R and 100GBASE-R PCSs comprise the PCS Transmit and PCS Receive processes for each rate of operation. The PCS shields the Reconciliation Sublayer (and MAC) from the specific nature of the underlying channel. The PCS transmit channel and receive channel can each operate in normal mode or test-pattern mode.

When communicating with the XLGMII/CGMII, the PCS uses an eight octet-wide, synchronous data path, with packet delimiting being provided by transmit control signals (TXC<n> = 1) and receive control signals (RXC<n> = 1). When communicating with the PMA, the PCS uses multiple serial streams, 4 encoded bit streams for a 40GBASE-R PCS, or 20 encoded bit streams for a 100GBASE-R PCS. Alignment to 64B/66B blocks is performed in the PCS. The PMA sublayer operates independently of block and packet boundaries. The PCS provides the functions necessary to map packets between the XLGMII/CGMII format and the PMA/FEC service interface format.

Note that these serial streams originate from a common clock in each direction, but may vary in phase and Skew dynamically.

When the transmit channel is in normal mode, the PCS Transmit process continuously generates blocks based upon the TXD <63:0> and TXC <7:0> signals on the XLGMII/CGMII. The blocks are scrambled and then distributed to individual PCS lanes. After distribution, alignment marker blocks are periodically added to each PCS lane. Transmit data-units are sent to the service interface via the *inst*:IS_UNITDATA_*i*.request primitive. In these primitives, the *inst* can be either FEC or PMA depending on which sublayer is adjacent to the PCS sublayer.

When the transmit channel is in test-pattern mode, a test pattern is packed into the transmit data-units that are sent to the PMA/FEC service interface via the *inst*:IS_UNITDATA_*i*.request primitive.

When the receive channel is in normal or test-pattern mode, the PCS Synchronization process continuously monitors *inst*:IS_SIGNAL.indication(SIGNAL_OK). When SIGNAL_OK indicates OK, then the PCS Synchronization process accepts data-units via the *inst*:IS_UNITDATA_*i*.indication primitive. It attains block synchronization based on the 2-bit synchronization headers on each one of the PCS lanes. Once block synchronization is found on a PCS lane, then alignment marker lock can be attained by searching for valid alignment markers. After alignment markers are found on all PCS lanes, the PCS lanes can be reordered and deskewed. Note that a particular transmit PCS lane can be received on any receive lane of the service interface due to the Skew and multiplexing that occurs in the path.

The PCS deskew process conveys received blocks to the PCS Receive process. The PCS deskew process deskews and aligns the individual PCS lanes, removes the alignment markers, forms a single stream, and sets the align_status flag to indicate whether the PCS has obtained alignment.

When the PCS deskew process has obtained alignment, the BER monitor process monitors the signal quality asserting hi_ber if excessive errors are detected. When align_status is asserted and hi_ber is deasserted, the PCS Receive process continuously accepts blocks and generates RXD <63:0> and RXC <7:0> on the MII.

When the receive channel is in test-pattern mode, the BER monitor process may be disabled. The Receive process will be held in the RX_INIT state. The received bits will be compared to the test pattern and errors counted.

The PCS shall provide transmit test-pattern mode for the scrambled idle pattern (see 82.2.11), and shall provide receive test-pattern mode for the scrambled idle pattern (see 82.2.11). Test-pattern mode is activated

separately for transmit and receive. The PCS shall support transmit test-pattern mode and receive test-pattern mode operating simultaneously so as to support loopback testing.

82.2.2 Use of blocks

The PCS maps XLGMII/CGMII signals into 66-bit blocks, and vice versa, using a 64B/66B coding scheme. The synchronization headers of the blocks allow establishment of block boundaries by the PCS Synchronization process. The PCS functions ENCODE and DECODE generate, manipulate, and interpret blocks as defined in 82.2.3.

82.2.3 64B/66B transmission code

The PCS uses a transmission code to improve the transmission characteristics of information to be transferred across the link and to support transmission of control and data characters. The encodings defined by the transmission code ensure that sufficient transitions are present in the PHY bit stream to make clock recovery possible at the receiver. The encoding also preserves the likelihood of detecting any single or multiple bit errors that may occur during transmission and reception of information. In addition, the synchronization headers of the code enable the receiver to achieve block alignment on the incoming PHY bit stream. The 64B/66B transmission code specified for use in this standard is a run-length-limited code.[145]

The relationship of block bit positions relative to XLGMII/CGMII, PMA, and other PCS functions is illustrated in Figure 82–3 for transmit and Figure 82–4 for receive. These figures illustrate the processing of a block containing 8 data octets. See 82.2.3.3 for information on how blocks containing control characters are mapped into 66-bit blocks. Note that the sync header is generated by the encoder and bypasses the scrambler.

82.2.3.1 Notation conventions

For values shown as binary, the leftmost bit is the first transmitted bit.

64B/66B encodes 8 data octets or control characters into a block. Blocks containing control characters also contain a block type field. Data octets are labeled D_0 to D_7. The control characters /I/ and /E/ are labeled C_0 to C_7. The control character /Q/ for a sequence ordered set is labeled as O_0 since it is only valid on the first octet of the XLGMII/CGMII. The control character for start is labeled as S_0 for the same reason. The control character for terminate is labeled as T_0 to T_7. The four trailing zero data octets in ordered sets are labeled as Z_4 to Z_7.

One XLGMII/CGMII transfer provides eight characters that are encoded into one 66-bit transmission block. The subscript in the above labels indicates the position of the character in the eight characters from the XLGMII/CGMII transfer.

Contents of block type fields, data octets, and control characters are shown as hexadecimal values. The LSB of the hexadecimal value represents the first transmitted bit. For instance, the block type field 0x1E is sent from left to right as 01111000. The bits of a transmitted or received block are labeled TxB<65:0> and RxB<65:0>, respectively, where TxB<0> and RxB<0> represent the first transmitted bit. The value of the sync header is shown as a binary value. Binary values are shown with the first transmitted bit (the LSB) on the left.

[145]In 10GBASE-R the run length is limited to 66 bits, but in 40GBASE-R and 100GBASE-R, when multiplexing occurs in the PMA, this guaranteed run length limit increases. For example, if two PCS lanes are multiplexed in the PMA, then the possible run length would double.

82.2.3.2 Transmission order

Block bit transmission order shall be as illustrated in Figure 82–3 and Figure 82–4. Note that these figures show the mapping from XLGMII/CGMII to 64B/66B block for a block containing eight data characters.

82.2.3.3 Block structure

Blocks consist of 66 bits. The first two bits of a block are the synchronization header (sync header). Blocks are either data blocks or control blocks. The sync header is 01 for data blocks and 10 for control blocks. Thus, there is always a transition between the first two bits of a block. The remainder of the block contains the payload. The payload is scrambled and the sync header bypasses the scrambler. Therefore, the sync header is the only position in the block that is always guaranteed to contain a transition. This feature of the code is used to obtain block synchronization.

Data blocks contain eight data characters. Control blocks begin with an 8-bit block type field that indicates the format of the remainder of the block. For control blocks containing a Start, Terminate character, or ordered set, that character is implied by the block type field. Other control characters are encoded in a 7-bit control code. Each control block encodes eight characters.

The format of the blocks is as shown in Figure 82–5. In the figure, the column labeled Input Data shows, in abbreviated form, the eight characters used to create the 66-bit block. These characters are either data characters or control characters and, when transferred across the XLGMII/CGMII, the corresponding TXC or RXC bit is set accordingly. Within the Input Data column, D_0 through D_7 are data octets and are transferred with the corresponding TXC or RXC bit set to zero. All other characters are control characters and are transferred with the corresponding TXC or RXC bit set to one. The single bit fields (thin rectangles with no label in the figure) are sent as zero and ignored upon receipt.

All unused values of block type field[146] are invalid; they shall not be transmitted and shall be considered an error if received.

[146]The block type field values have been chosen to have a 4-bit Hamming distance between them. There are five unused values that maintain this Hamming distance: 0x00, 0x2D, 0x33, 0x55, and 0x66.

Figure 82–5—64B/66B block formats

WARNING

The mapping of 40GBASE-R PCS blocks into OPU3 specified in ITU-T G.709 depends on the set of control block types shown in Figure 82–5. Any deviation from the coding specified in Figure 82–5 will break the mapping and may prevent 40GBASE-R PCS blocks from being mapped into OPU3 (see ITU-T G.709 for more details).

82.2.3.4 Control codes

The same set of control characters are supported by the XLGMII/CGMII and the PCS. The representations of the control characters are the control codes. XLGMII/CGMII encodes a control character into an octet (an eight bit value). The 40GBASE-R and 100GBASE-R PCS encode the start and terminate control characters implicitly by the block type field. The 40GBASE-R and 100GBASE-R PCS encode the ordered set control codes using the block type field. The 40GBASE-R and 100GBASE-R PCS encode each of the other control characters into a 7-bit control code.

The control characters and their mappings to 40GBASE-R and 100GBASE-R control codes and XLGMII/CGMII control codes are specified in Table 82–1. All XLGMII/CGMII, 40GBASE-R, and 100GBASE-R control code values that do not appear in the table shall not be transmitted and shall be considered an error if received. The ability to transmit or receive Low Power Idle (LPI) is required for PHYs that support EEE (see Clause 78). If EEE has not been negotiated, LPI shall not be transmitted and shall be treated as an error if received.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

82.2.3.5 Valid and invalid blocks

A block is invalid if any of the following conditions exists:

a) The sync header has a value of 00 or 11.
b) The block type field contains an invalid value (one not included in Figure 82–5).
c) Any control character contains a value not included in Table 82–1.
d) The set of eight XLGMII/CGMII characters does not have a corresponding block format in Figure 82–5.

82.2.3.6 Idle (/I/)

Idle control characters (/I/) are transmitted when idle control characters are received from the XLGMII/CGMII. Idle control characters may be added or deleted by the PCS to adapt between clock rates. /I/ insertion and deletion shall occur in groups of 8. /I/s may be added following idle control characters or ordered sets. They shall not be added while data is being received.

Table 82–1—Control codes

Control character	Notation	XLGMII/ CGMII control code	40/100GBASE-R O code[a]	40GBASE-R and 100GBASE-R control code
idle	/I/	0x07		0x00
LPI	/LI/	0x06		0x06
start	/S/	0xFB		Encoded by block type field
terminate	/T/	0xFD		Encoded by block type field
error	/E/	0xFE		0x1E
Sequence ordered set	/Q/	0x9C	0x0	Encoded by block type 0x4B plus O code, control codes are set to 0x00

[a] INCITS T11 Fibre Channel uses O code 0xF for the signal ordered set. OIF uses O code 0x5 for the FlexE [B59] ordered set. ITU-T uses O code 0xC for the G.8312 [B47] MTN path ordered set.

To communicate LPI, the LPI control character /LI/ is sent continuously in place of /I/. LPI control characters are transmitted when LPI control characters are received from the XLGMII or CGMII. LPI characters may be added or deleted by the PCS to adapt between clock rates in a similar manner to idle control characters. /LI/ insertion and deletion shall occur in groups of 8. /LI/s inserted for clock compensation may only be inserted following other LPI characters.

82.2.3.7 Start (/S/)

The start control character (/S/) indicates the start of a packet. This delimiter is only valid on the first octet of the XLGMII/CGMII (TXD<7:0> and RXD<7:0>). Receipt of an /S/ on any other octet of TXD indicates an error. Block type field values implicitly encode an /S/ as the first character of the block.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

82.2.3.8 Terminate (/T/)

The terminate control character (/T/) indicates the end of a packet. Since packets vary in length, the /T/ can occur on any octet of the XLGMII/CGMII and on any character of the block. The location of the /T/ in the block is implicitly encoded in the block type field. A valid end of packet occurs when a block containing a /T/ is followed by a control block that does not contain a /T/ or an /E/.

82.2.3.9 ordered set (/O/)

Ordered sets are used to extend the ability to send control and status information over the link such as remote fault and local fault status. Ordered sets consist of a control character followed by three data characters followed by four zero data characters on the XLGMII/CGMII. Ordered sets always begin on the first octet of the XLGMII/CGMII. 40 Gigabit and 100 Gigabit Ethernet use one kind of ordered set: the sequence ordered set (see 81.3.4). The ordered set control character /Q/ indicates the start of an ordered set. The block type field plus the O code encode the specific control character for the ordered set. See Table 82–1 for the mapping.

Sequence ordered sets may be deleted by the PCS to adapt between clock rates. Such deletion shall only occur when two consecutive sequence ordered sets have been received and only one of the two ordered sets may be deleted. Only idle control characters may be inserted for clock compensation.

82.2.3.10 Error (/E/)

In both the 64B/66B encoder and decoder, the /E/ is generated whenever an /E/ is detected. The /E/ is also generated when invalid blocks are detected. The /E/ allows the PCS to propagate detected errors. See R_TYPE and T_TYPE function definitions in 82.2.19.2.3 for further information.

82.2.4 Transmit process

The transmit process generates blocks based upon the TXD<63:0> and TXC<7:0> signals received from the XLGMII/CGMII. One XLGMII/CGMII data transfer is encoded into one 66-bit block. It takes 66 *inst*:IS_UNITDATA_*i* transfers to send a 66-bit block of data on each of the PCS lanes. The transmit process may delete idle control characters or sequence ordered sets to accommodate the transmission of alignment markers. If the PCS transmit process spans multiple clock domains, it may also perform clock rate compensation via the deletion of idle control characters or sequence ordered sets or the insertion of idle control characters.

There are sufficient idle control characters to delete in order to make room for alignment markers, in addition to handling clock compensation. Idle control characters or sequence ordered sets are removed, if necessary, to accommodate the insertion of the 66-bit alignment markers. See 82.2.3.6 for more details.

The transmit process generates blocks as specified in the transmit process state diagram. The contents of each block are contained in a vector tx_coded<65:0>, which is passed to the scrambler. tx_coded<1:0> contains the sync header and the remainder of the bits contain the block payload.

82.2.5 Scrambler

The payload, tx_coded<65:2>, is scrambled with a self-synchronizing scrambler. The scrambler is identical to the scrambler used in Clause 49, see 49.2.6 for the definition of the scrambler. The sync bits, tx_coded<1:0>, are not scrambled.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

82.2.6 Block distribution

Once the data is encoded and scrambled, it is distributed to multiple PCS lanes, 66-bit blocks at a time in a round robin distribution from the lowest to the highest numbered PCS lanes. This allows the PCS to support multiple physical lanes in the PMD and XLAUI or CAUI-n interfaces (see Annex 83A, Annex 83B, Annex 83D, and Annex 83E). The 40GBASE-R PCS distributes the 66-bit blocks to 4 PCS lanes, and the 100GBASE-R PCS distributes the blocks to 20 PCS lanes. The distribution process is shown in Figure 82–6.

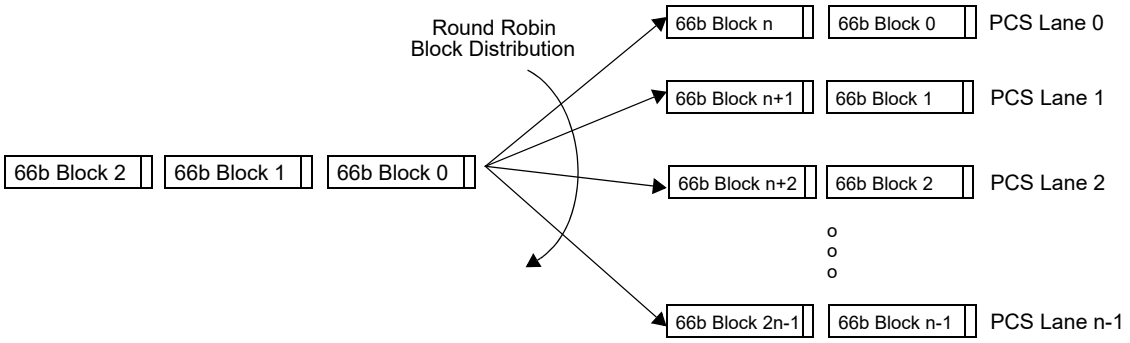

Figure 82–6—PCS Block distribution

82.2.7 Alignment marker insertion

In order to support deskew and reordering of individual PCS lanes at the receive PCS, alignment markers are added periodically to each PCS lane. The alignment marker has the form of a specially defined 66-bit block with a control block sync header. These markers interrupt any data transfer that is already in progress. This allows alignment markers to be inserted into all PCS lanes at the same time. If necessary, room for the alignment markers is created by periodically deleting IPG from the XLGMII/CGMII data stream. Other special properties of the alignment markers are that they are not scrambled and do not conform to the encoding rules as outlined in Figure 82–5. This is possible because the alignment markers are added after encoding is performed in the transmit PCS and the alignment markers are removed before 64B/66B decoding is performed in the receive PCS. The alignment markers are not scrambled in order to allow the receiver to find the alignment markers, deskew the PCS lanes, and reassemble the aggregate stream before descrambling is performed. The alignment markers themselves are formed from a known pattern that is defined to be balanced and with many transitions and therefore scrambling is not necessary for the alignment markers. The alignment markers shall be inserted after every 16383 66-bit blocks on each PCS lane. Alignment marker insertion is shown in Figure 82–7 and Figure 82–8.

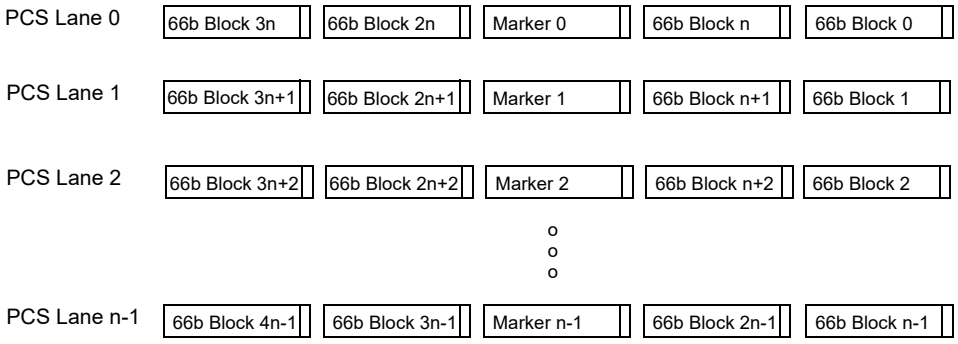

Figure 82–7—Alignment marker insertion

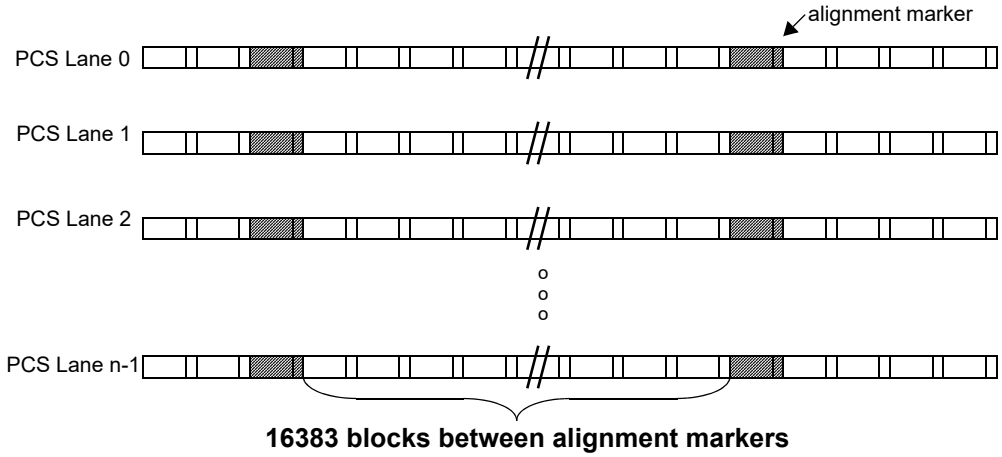

Figure 82–8—Alignment marker insertion period

The format of the alignment markers is shown in Figure 82–9.

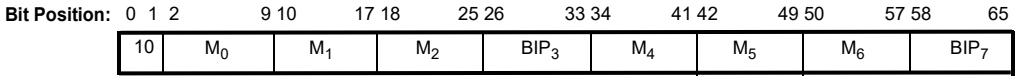

Figure 82–9—Alignment marker format

The content of the alignment markers shall be as shown in Table 82–2 for 100GBASE-R and in Table 82–3 for 40GBASE-R. The contents depend on the PCS lane number and the octet number. Note that M_4 through M_6 are the bit-wise inversion of M_0 through M_2, respectively. Also BIP_7 is the bit-wise inversion of BIP_3. This property allows the alignment markers to be DC-balanced. Lane markers 0 to 19 from Table 82–2 are used for the 100GBASE-R PCS and lane markers 0 to 3 from Table 82–3 are used for the 40GBASE-R PCS. As an example, the lane marker for 100GBASE-R lane number 0 is sent as (left most bit sent first):

Copyright © 2022 IEEE. All rights reserved.

82.2.8 BIP calculations

A PCS lane BIP field is carried in each PCS Lane alignment marker. This allows an accurate and fast measure of the bit error ratio of a given PCS Lane. This information is used to update error counters; no state machines use this information.

Each alignment marker has two Bit Interleaved Parity fields, BIP_3 and BIP_7. BIP_7 is a bit-wise inversion of BIP_3 in order to keep the alignment marker DC-balanced. The BIP_3 field contains the result of a bit interleaved parity calculation. Each bit in the BIP field is an even parity calculation over all of the previous specified bits of a given PCS Lane, from and including the previous alignment marker, but not including the current alignment marker. Using the bit definitions as shown in Figure 82–9, Table 82–4 has the bit assignments for each BIP_3 bit. As an example, BIP_3 bit 0 contains the result of XORing 131072 bits from 16384 66-bit words. BIP_3 bit 3 and bit 4 also include one sync header bit from each 66-bit word. Bit 3 and bit 4 each contain the result of XORing 147456 bits.

Table 82–4—BIP_3 bit assignments

BIP_3 bit number	Assigned 66-bit word bits
0	2, 10, 18, 26, 34, 42, 50, 58
1	3, 11, 19, 27, 35, 43, 51, 59
2	4, 12, 20, 28, 36, 44, 52, 60
3	0, 5, 13, 21, 29, 37, 45, 53, 61
4	1, 6, 14, 22, 30, 38, 46, 54, 62
5	7, 15, 23, 31, 39, 47, 55, 63
6	8, 16, 24, 32, 40, 48, 56, 64
7	9, 17, 25, 33, 41, 49, 57, 65

BIP_3 and BIP_7 are transmitted LSB to MSB. As an example, with BIP_3 = 0x0F, the PCS lane marker for 100GBASE-R lane number 0 is sent as (left most bit sent first):

10 10000011 00010110 10000100 11110000 01111100 11101001 01111011 00001111

If the EEE capability is supported, BIP statistics are only updated when the receiver is in the RX_ACTIVE state (see Figure 82–19). In all other states, the running parity is not calculated. The BIP statistics shall be first updated after transitioning from RAMs to normal AMs on the first received normal AM when LPI_FW is FALSE and on the second received AM after entering the RX_ACTIVE state when LPI_FW is TRUE.

82.2.9 Rapid alignment marker insertion

For the optional EEE capability, an alternate method of alignment is used when operating in the deep sleep low power state. Rapid Alignment Markers (RAMs) function in a similar manner to the alignment markers described in 82.2.7. Normal alignment markers are sent when the transmitter has an LPI transmit state of TX_ACTIVE; RAMs are sent in the TX_WAKE2 state until down_count_done is TRUE and in all the other LPI transmit states. Additionally, the BIP component defined for alignment markers is replaced by a count

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

down field (CD) so that the transition from RAMs to normal alignment markers can be indicated. The RAMs shall be inserted after every 7 66-bit blocks on each 100G PCS lane and every 15 66-bit blocks on each 40G PCS lane. RAM insertion is performed in the same manner as shown in Figure 82–7 and Figure 82–10. The transition from RAMs to normal alignment markers is shown in Figure 82–10. The count down field is also used to communicate some of the states of the tx_mode when it is not being used to coordinate the transition. After the LPI Transmit state diagram transitions from TX_ACTIVE to TX_SLEEP, the first RAM shall be inserted after at least one block of /LI/ has been transmitted on PCS lane 0. In order to force the RAMs to coincide with the start of an FEC block, the distance between the first RAM and preceding normal alignment marker shall be a multiple of 4 66-bit blocks.

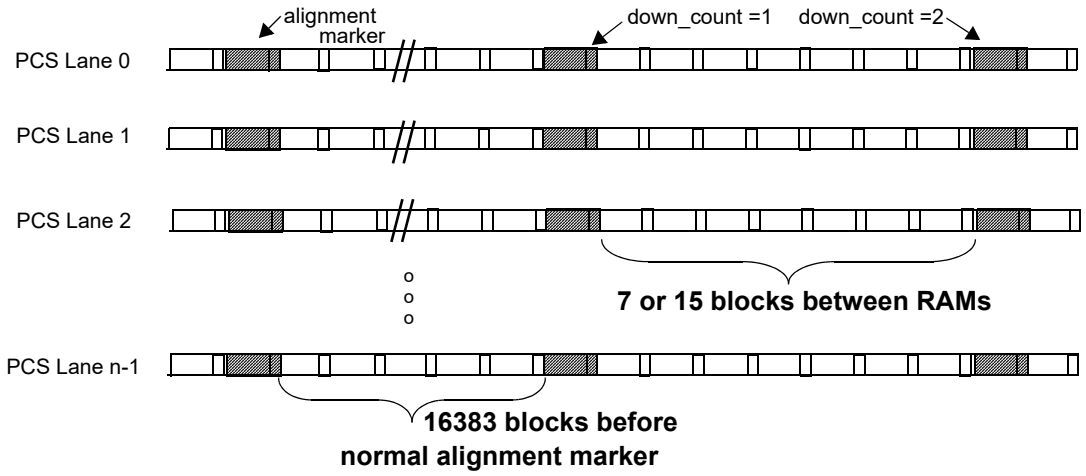

Figure 82–10—RAM transition

The format of the RAMs is shown in Figure 82–11.

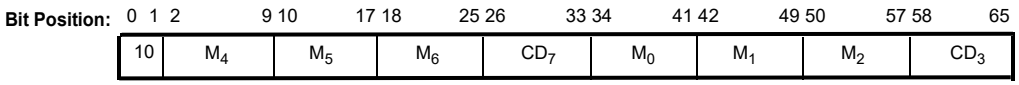

Figure 82–11—RAM format

The content of the RAMs shall be as shown in Table 82–5 for 100GBASE-R or Table 82–6 for 40GBASE-R. Note that these are similar to normal alignment markers, with CD_3 replacing BIP_3 and CD_7 replacing BIP_7, and also M_0 through M_2 and CD_3 swapped with M_4 through M_6 and CD_7, respectively. As an example, the lane marker for 100GBASE-R lane number 0 is sent as (left most bit sent first):

10 01111100 11101001 01111011 CD_7 10000011 00010110 10000100 CD_3

After the RAMs are inserted, data is sent to the PMA or FEC sublayer adjacent to the PCS.

The value of the CD_3 field is derived by the bit-wise XOR of the down_count variable with the M_0 value for the lane (therefore the last 5 RAMs sent by a 100GBASE-R PCS on PCS lane 0 would have CD_3 values: 0xC4, 0xC5, 0xC2, 0xC3, 0xC0; for PCS lane 1 these would be: 0x98, 0x99, 0x9E, 0x9F, 0x9C). The CD_7 field is the bit-wise inversion of CD_3. The CD field is used by the link partner to understand the expected

transition from RAMs to normal AMs. It may also be used by a device with a detached PMA or FEC sublayer to infer the state of the PCS.

Table 82–5—100GBASE-R RAM encodings

PCS lane number	Encoding[a] {M_4, M_5, M_6, CD_7, M_0, M_1, M_2, CD_3}	PCS lane number	Encoding[a] {M_4, M_5, M_6, CD_7, M_0, M_1, M_2, CD_3}

3	0x5D, 0x86, 0xC2, CD_7, 0xA2, 0x79, 0x3D, CD_3

[a]Each octet is transmitted LSB to MSB.

82.2.10 PMA or FEC Interface

When the transmit channel is operating in normal mode, the 40GBASE-R PCS sends four data streams via *inst*:IS_UNITDATA_*i*.request primitives and the 100GBASE-R PCS sends twenty data streams via *inst*:IS_UNITDATA_*i*.request primitives.

The *inst*:IS_UNITDATA_*i*.request primitives are separate serial streams of bits. Since 66-bit blocks were distributed to each lane, that means for the 40GBASE-R PCS: bits 0 to 65 are sent on PCSL 0, bits 66 to 131

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

are sent on PCSL 1; bits 132 to 197 are sent on PCSL 2, bits 198 to 263 are sent on PCSL 3, then bits 264 to 329 are sent on PCSL 0 etc.

For 100GBASE-R it is: bits 0 to 65 on PCSL 0, bits 66 to 131 on PCSL 1, bits 132 to 197 on PCSL 2, bits 198 to 263 on PCSL 3, bits 264 to 329 on PCSL 4, bits 330 to 395 on PCSL 5, bits 396 to 461 on PCSL 6, bits 462 to 527 on PCSL 7, bits 528 to 593 on PCSL 8, bits 594 to 659 on PCSL 9, bits 660 to 725 on PCSL 10, bits 726 to 791 on PCSL 11, bits 792 to 857 on PCSL 12, bits 858 to 923 on PCSL 13, bits 924 to 989 on PCSL 14, bits 990 to 1055 on PCSL 15, bits 1056 to 1121 on PCSL 16, bits 1122 to 1187 on PCSL 17, bits 1188 to 1253 on PCSL 18, bits 1254 to 1319 on PCSL 19, then bits 1320 to 1385 on PCSL 0, etc.

82.2.11 Test-pattern generators

The PCS shall have the ability to generate and detect a scrambled idle test pattern. This test-pattern mode is suitable for receiver tests and for certain transmitter tests.

When a scrambled idle pattern is enabled, the test pattern is generated by the scrambler. No seeding of the scrambler is required during test-pattern operation. The input to the scrambler is a control block (block type=0x1E) with all idles as defined in Figure 82–5. Note that the sync headers and alignment markers are added to the stream so that the receive PCS can align and deskew the PCS lanes.

If a Clause 45 MDIO is implemented, then control of the test-pattern generation is from the BASE-R PCS test-pattern control register (bit 3.42.3).

When the transmit channel is operating in test-pattern mode, the encoded bit stream is distributed to the PCS Lanes as in normal operation (see 82.2.4).

82.2.12 Block synchronization

When the receive channel is operating in normal mode, the block synchronization function receives data via 4 (for 40GBASE-R) or 20 (for 100GBASE-R) IS_UNITDATA_*i*.indication primitives. The PCS forms 4 or 20 bit streams from the primitives by concatenating the bits from the indications of each primitive in order from each *inst*:IS_UNITDATA_0.indication to *inst*:IS_UNITDATA_3.indication or *inst*:IS_UNITDATA_0.indication to *inst*:IS_UNITDATA_19.indication. It obtains lock to the 66-bit blocks in each bit stream using the sync headers and outputs 66-bit blocks. Block lock is obtained as specified in the block lock state diagram shown in Figure 82–12.

If EEE is not supported then block_lock is identical to rx_block_lock. Otherwise the relationship between block_lock and rx_block_lock is given by Figure 82–19.

82.2.13 PCS lane deskew

Once the receiver achieves block lock on a lane, then it begins obtaining alignment marker lock as specified in the alignment marker lock state diagram shown in Figure 82–13. This process identifies the PCS lane number received on a particular lane of the service interface. After alignment marker lock is achieved on all lanes (4 or 20 lanes), then all inter-lane Skew is removed as shown in the PCS deskew state diagram in Figure 82–14. The Skew budget that the PCS receiver shall support is shown in Table 82–7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Note that Skew is defined in 80.5.

Table 82–7—Skew tolerance requirements

PCS	Maximum Skew	Maximum Skew Variation
40GBASE-R	180 ns (~1856 bits)	4ns (~41 bits)
100GBASE-R	180 ns (~928 bits)	4ns (~21 bits)
100GBASE-R with RS-FEC	49 ns (~253 bits)	0.4 ns (~2 bits)

If EEE is not supported then align_status is identical to rx_align_status. Otherwise the relationship between align_status and rx_align_status is given by Figure 82–19.

82.2.14 PCS lane reorder

Transmit PCS lanes can be received on different lanes of the service interface from which they were originally transmitted due to Skew between lanes and multiplexing by the PMA. The receive PCS shall order the received PCS lanes according to the PCS lane number.

82.2.15 Alignment marker removal

After all PCS lanes are aligned and deskewed, the PCS lanes are multiplexed together in the proper order to reconstruct the original stream of blocks and the alignment markers are deleted from the data stream. If necessary, the difference in rate due to deleted alignment markers is compensated for by inserting idle control characters. Note that an alignment marker is always deleted when a given PCS Lane is in am_lock=true even if it does not match the expected alignment marker value (due to a bit error for example). Repeated alignment marker errors will result in am_lock being set to false for a given PCS Lane, but until that happens it is sufficient to delete the block in the alignment marker position.

As part of the alignment marker removal process, the BIP_3 field is compared to the calculated BIP value for each PCS lane. If a Clause 45 MDIO is implemented, then the appropriate BIP error counter register (registers 3.200 through 3.219) is incremented by one each time the calculated BIP value does not equal the value received in the BIP_3 field. The incoming bit error ratio can be estimated by dividing the BIP block error ratio by a factor of 1081344.

82.2.16 Descrambler

The descrambler is identical to that used in Clause 49, see 49.2.10 for the definition.

82.2.17 Receive process

The receive process decodes blocks to produce RXD<63:0> and RXC<7:0> for transmission to the XLGMII/CGMII. One XLGMII/CGMII data transfer is decoded from each block. The receive process may insert idle control characters to compensate for the removal of alignment markers. If the PCS receive process spans multiple clock domains, it may also perform clock rate compensation via the deletion of idle control characters or sequence ordered sets or the insertion of idle control characters.

The receive process decodes blocks as specified in the receive state diagram shown in Figure 82–17.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

82.2.18 Test-pattern checker

When the receive channel is operating in scrambled idle test-pattern mode, the scrambled idle test-pattern checker checks the bits received via *inst*:IS_UNITDATA_*i*.indication primitives.

The scrambled idle test-pattern checker utilizes the block lock state diagram, the alignment marker state diagram, the PCS deskew state diagram, and the descrambler operating as they do during normal data reception. The BER monitor state diagram is disabled during receive test-pattern mode. When align_status is true and the scrambled idle receive test-pattern mode is active, the scrambled idle test-pattern checker observes the sync header and the output from the descrambler. When the sync header and the output of the descrambler is the all idle pattern, a match is detected. When operating in scrambled idle test pattern, the test-pattern error counter counts blocks with a mismatch. Any mismatch indicates an error and shall increment the test-pattern error counter. Because of the error multiplication characteristics of the descrambler, the incoming bit error ratio can be estimated by dividing the 66-bit block error ratio by a factor of 124.

If a Clause 45 MDIO is implemented, then control of the test-pattern reception is from the BASE-R PCS test-pattern control register (bit 3.42.2). In addition errors are counted in the BASE-R PCS test-pattern error counter register (3.43.15:0).

82.2.19 Detailed functions and state diagrams

82.2.19.1 State diagram conventions

The body of this subclause is composed of state diagrams, including the associated definitions of variables, constants, and functions. Should there be a discrepancy between a state diagram and descriptive text, the state diagram prevails.

The notation used in the state diagrams follows the conventions of 21.5. State diagram timers follow the conventions of 14.2.3.2. The notation ++ after a counter or integer variable indicates that its value is to be incremented.

82.2.19.2 State variables

82.2.19.2.1 Constants

EBLOCK_R<71:0>
: 72 bit vector to be sent to the XLGMII/CGMII containing /E/ in all the eight character locations.

EBLOCK_T<65:0>
: 66 bit vector to be sent to the PMA containing /E/ in all the eight character locations.

LBLOCK_R<71:0>
: 72 bit vector to be sent to the XLGMII/CGMII containing one Local Fault ordered set. The Local Fault ordered set is defined in 81.3.4.

LBLOCK_T<65:0>
: 66 bit vector to be sent to the PMA containing one Local Fault ordered set.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

82.2.19.2.2 Variables

align_status
: A variable set by the PCS deskew process to reflect the status of the PCS lane-to-lane alignment. Set true when all lanes are synchronized and aligned, set false when the deskew process is not complete.

NOTE—If the EEE capability is supported, then this variable is affected by the LPI receive state diagram. If the EEE capability is not supported then this variable is identical to rx_align_status controlled according to Figure 82–13.

alignment_valid
: Boolean variable that is set true if all PCS lanes are aligned. It is valid when each lane is in am_lock, with each PCS lane locked to a unique alignment marker from Table 82–2 or Table 82–3, and when all PCS lanes are deskewed. Otherwise, alignment_valid is false.

am_lock<*x*>
: Boolean variable that is set true when receiver acquires alignment marker delineation for a given lane of the service interface, where $x = 0{:}3$ for 40GBASE-R and $x = 0{:}19$ for 100GBASE-R.

am_slip_done
: Boolean variable that is asserted true when the AM_SLIP requested by the alignment marker lock state diagram has been completed indicating that the next candidate 66-bit block position can be tested.

am_status
: A Boolean variable that is true when all lanes are in am_lock and false when at least one lane is not in am_lock.

am_counter_done
: Boolean variable that indicates that the alignment marker counter is done.

am_valid
: Boolean variable that is set true if received block rx_coded is a valid alignment marker. A valid alignment marker matches one of the encodings in Table 82–2, Table 82–3, Table 82–5, or Table 82–6, excluding the BIP_3 and BIP_7 fields.

ber_test_sh
: Boolean variable that is set true when a new sync header is available for testing and false when BER_TEST_SH state is entered. A new sync header is available for testing when the Block Sync process has accumulated enough bits from the PMA to evaluate the header of the next block.

block_lock<*x*>
: Boolean variable that is set true when receiver acquires block delineation for a given lane of the service interface, where $x = 0{:}3$ for 40GBASE-R and $x = 0{:}19$ for 100GBASE-R.

NOTE—If the EEE capability is supported, then this variable is affected by the LPI receive state diagram. If the EEE capability is not supported, then this variable is identical to rx_block_lock controlled according to Figure 82–12.

current_am
: This variable holds the lane number of the current alignment marker. This is compared to the variable first_am to determine if we have alignment marker lock and is always n × 16384 66-bit blocks away from the first_am.

enable_deskew
: A Boolean variable that indicates the enabling and disabling of the deskew process. Blocks may be discarded whenever deskew is enabled. True when deskew is enabled, false when deskew is disabled.

first_am
: A variable that holds the lane number of the first alignment marker that is recognized on a given lane. This is used later to compare to future alignment markers.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

hi_ber
: Boolean variable which is asserted true when the ber_cnt equals 97 indicating a bit error ratio $>10^{-4}$

lane_mapping<*x*>
: This variable indicates which PCS lane is received on lane *x* of the service interface when am_lock<*x*> = true, where *x* = 0:3 for 40GBASE-R and *x* = 0:19 for 100GBASE-R.

PCS_status
: A Boolean variable that is true when align_status is true and hi_ber is false.

r_block_type
: This variable contains the rx_coded<65:0> vector classification results, returned by the R_TYPE function. It can assume one of the following five values {C,S,T,D,E}, as defined by the R_TYPE function.

r_block_type_next
: This variable contains the rx_coded<65:0> vector classification results, returned by the R_TYPE_NEXT function. It can assume one of the following five values {C,S,T,D,E}, as defined by the R_TYPE_NEXT function.

r_test_mode
: Boolean variable that is asserted true when the receiver is in test-pattern mode.

reset
: Boolean variable that controls the resetting of the PCS. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS into low-power mode.

rx_align_status
: Variable used by the PCS lane deskew process to reflect the status of the PCS lane-to-lane alignment. This variable is set true when all lanes are synchronized and aligned, set false when the deskew process is not complete.

rx_block_lock<x>
: Variable used in Figure 82–12 to reflect the status of the code-group delineation for each lane. This variable is set true when the receiver acquires block delineation.

rx_coded<65:0>
: Vector containing the input to the 64B/66B decoder. The format for this vector is shown in Figure 82–5. The leftmost bit in the figure is rx_coded<0> and the rightmost bit is rx_coded<65>.

rx_down_count
: The value that results from the bit-wise exclusive-OR of the Count Down (CD3) byte and the M0 byte of the current received Rapid Alignment Marker (see 82.2.9).

rx_raw<71:0>
: Vector containing one XLGMII/CGMII transfer. RXC<0> through RXC<7> are from rx_raw<0> through rx_raw<7>, respectively. RXD<0> through RXD<63> are from rx_raw<8> through rx_raw<71>, respectively.

sh_valid
: Boolean variable that is set true if received block rx_coded has valid sync header bits. That is, sh_valid is asserted if rx_coded<0> ≠ rx_coded<1> and deasserted otherwise.

signal_ok
: Boolean variable that is set based on the most recently received value of *inst*:IS_SIGNAL.indication(SIGNAL_OK). It is true if the value was OK and false if the value was FAIL.

slip_done
: Boolean variable that is asserted true when the SLIP requested by the Block Lock state diagram has been completed indicating that the next candidate block sync position can be tested.

t_block_type
: This variable contains the tx_raw<71:0> vector classification results, returned by the T_TYPE function. It can assume one of the following five values {C,S,T,D,E}, as defined by the T_TYPE function.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

test_am
: Boolean variable that is set true when a new block is available for testing and false when FIND_1ST state is entered. A new block is available for testing when the Block Sync process has accumulated enough bits from the PMA to evaluate the next block

test_sh
: Boolean variable that is set true when a new sync header is available for testing and false when TEST_SH and TEST_SH2 state are entered. A new sync header is available for testing when the Block Sync process has accumulated enough bits from the PMA to evaluate the header of the next block

tx_coded<65:0>
: Vector containing the output from the 64B/66B encoder. The format for this vector is shown in Figure 82–5. The leftmost bit in the figure is tx_coded<0> and the rightmost bit is tx_coded<65>.

tx_raw<71:0>
: Vector containing one XLGMII/CGMII transfer. TXC<0> through TXC<7> are placed in tx_raw<0> through tx_raw<7>, respectively. TXD<0> through TXD<63> are placed in tx_raw<8> through tx_raw<71>, respectively.

The following variables are used only for the EEE capability.

down_count_done
: Boolean variable that indicates that the down_count counter has reached zero.

down_count_enable
: Boolean variable controlling decrement of the counter down_count. This variable is set by the LPI transmit state diagram.

energy_detect
: A parameter generated by the PMA/PMD sublayer to reflect the state of the received signal. In the PMD this has the same definition as parameter signal_detect and is passed through without modification by the PMA (and FEC).

first_rx_lpi_active
: Boolean variable first_rx_lpi_active is set true when the receiver is in state RX_ACTIVE in the LPI receive state diagram (see Figure 82–19) and R_TYPE(rx_coded) = LI and LPI_FW = FALSE and is otherwise false.

LPI_FW
: Boolean variable controlling the wake mode for the LPI transmit and receive functions. This variable is set true when the link is to use the fast wake mechanism, and false when the link is to use the optional deep sleep mechanism for each direction. This variable defaults true and may only be set to false if the optional deep sleep mode is supported.

rx_lpi_active
: A Boolean variable that is set to true when the receiver is in a low power state and set to false when it is in an active state and capable of receiving data.

Rx LPI indication:
: A Boolean variable indicating the current state of the receive LPI function. This flag is set to true (register bit set to one) when the LPI receive state diagram is in any state other than RX_ACTIVE. This status is reflected in MDIO register 3.1.8. A latch high view of this status is reflected in MDIO register 3.1.10 (Rx LPI received).

rx_mode
: A variable reflecting state of the LPI receive function as defined in Figure 82–19.The parameter has one of two values: DATA and QUIET.

scrambler_bypass
: This Boolean variable indicates whether the Tx PCS scrambler is to be bypassed in order to assist rapid synchronization following low power idle. When set to TRUE, the PCS passes the unscrambled data from the scrambler input rather than the scrambled data from the scrambler output. The scrambler continues to operate normally, shifting input data into the delay line. When scrambler_bypass is set to FALSE the PCS passes scrambled data from the scrambler output.

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

scr_bypass_enable

A Boolean variable used to indicate to the transmit LPI state diagram that the scrambler bypass option is required. The PHY shall set scr_bypass_enable = TRUE if Clause 74 FEC is in use. The PHY shall set scr_bypass_enable = FALSE if this FEC is not in use.

tx_mode

A variable reflecting state of the LPI transmit function as defined in Figure 82–18. When tx_mode is set to QUIET the sublayer may go into a low power state.

82.2.19.2.3 Functions

AM_SLIP

Causes the next candidate block position to be tested. The precise method for determining the next candidate block position is not specified and is implementation dependent. However, an implementation shall ensure that all possible blocks are evaluated.

DECODE(rx_coded<65:0>)

Decodes the 66-bit vector returning rx_raw<71:0>, which is sent to the XLGMII/CGMII. The DECODE function shall decode the block as specified in 82.2.3.

ENCODE(tx_raw<71:0>)

Encodes the 72-bit vector returning tx_coded<65:0> of which tx_coded<65:2> is sent to the scrambler. The two bits of the sync header bypass the scrambler. The ENCODE function shall encode the block as specified in 82.2.3.

R_TYPE(rx_coded<65:0>)

This function classifies the current rx_coded<65:0> vector as belonging to one of the following types, depending on its contents. The classification results are returned via the r_block_type variable.

Values: C; The vector contains a sync header of 10 and one of the following:

a) A block type field of 0x1E and eight valid control characters other than /E/ or /LI/;

b) A block type field of 0x4B.

LI; For EEE capability, the LI type is supported where the vector contains a sync header of 10, a block type field of 0x1E and eight control characters of 0x06 (/LI/).

S; The vector contains a sync header of 10 and the following:

a) A block type field of 0x78.

T; The vector contains a sync header of 10, a block type field of 0x87, 0x99, 0xAA, 0xB4, 0xCC, 0xD2, 0xE1 or 0xFF and all control characters are valid.

D; The vector contains a sync header of 01.

E; The vector does not meet the criteria for any other value.

Valid control characters are specified in Table 82–1.

NOTE—A PCS that does not support EEE classifies vectors containing one or more /LI/ control characters as type E.

R_TYPE_NEXT

This function classifies the 66-bit rx_coded vector that immediately follows the current rx_coded<65:0> vector as belonging to one of the five types defined in R_TYPE, depending on its contents. It is intended to perform a prescient end of packet check. The classification results are returned via the r_block_type_next variable.

SLIP

Causes the next candidate block sync position to be tested. The precise method for determining the next candidate block sync position is not specified and is implementation dependent. However, an implementation shall ensure that all possible bit positions are evaluated.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

T_TYPE = (tx_raw<71:0>)

This function classifies each 72-bit tx_raw vector as belonging to one of the following types depending on its contents. The classification results are returned via the t_block_type variable.

Values: C; The vector contains one of the following:
a) Eight valid control characters other than /O/, /S/, /T/, /LI/, and /E/;
b) One valid ordered set.
LI; For EEE capability, this vector contains eight /LI/ characters.
S; The vector contains an /S/ in its first character, and all characters following the /S/ are data characters.
T; The vector contains a /T/ in one of its characters, all characters before the /T/ are data characters, and all characters following the /T/ are valid control characters other than /O/, /S/ and /T/.
D; The vector contains eight data characters.
E; The vector does not meet the criteria for any other value.

A tx_raw character is a control character if its associated TXC bit is asserted. A valid control character is one containing an XLGMII/CGMII control code specified in Table 82–1. A valid ordered set consists of a valid /O/ character in the first character and data characters in the seven characters following the /O/. A valid /O/ is any character with a value for O code in Table 82–1.

NOTE—A PCS that does not support EEE classifies vectors containing one or more /LI/ control characters as type E.

82.2.19.2.4 Counters

am_counter

This counter counts 66-bit blocks that separate two consecutive alignment markers. If the optional EEE deep sleep capability is supported, when rx_lpi_active is TRUE and LPI_FW is FALSE, the terminal count is 7 for 100GBASE-R PCS and 15 for 40GBASE-R PCS. If the optional EEE deep sleep capability is not supported, or rx_lpi_active is FALSE, the terminal count is 16383.

am_invld_cnt

Count of the number of invalid alignment markers seen in a row. This counter is always reset to all zeros when a valid marker is detected.

ber_count

A 22-bit counter that counts each time BER_BAD_SH state is entered. This counter is reflected in MDIO register bits 3.33.13:8 and 3.44.15:0.

ber_cnt

Count up to a maximum of 97 of the number of invalid sync headers within the current 1.25 ms (40GBASE-R) or 500 μs (100GBASE-R) period.

errored_block_count:

When the receiver is in normal mode, this 22-bit counter counts once for each time RX_E state is entered. This counter is reflected in MDIO register bits 3.33.7:0 and 3.45.13:0.

sh_cnt

Count of the number of sync headers checked within the current 64 or 1024 block window.

sh_invld_cnt

Count of the number of invalid sync headers within the current 64 or 1024 block window.

test_pattern_error_count:

When the receiver is in test-pattern mode, this 16-bit counter counts errors as described in 82.2.18. This counter is reflected in MDIO register bits 3.43.15:0.

The following counters are used only for the EEE capability:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

down_count
: A counter that is used in rapid alignment markers and is decremented each time a RAM is sent while variable down_count_enable = true. The counter initial value is set by the LPI transmit state diagram. When the down_count counter reaches zero, it sets the variable down_count_done = true.

wake_error_counter
: A counter that is incremented each time that the LPI receive state diagram enters the RX_WTF state indicating that a wake time fault has been detected. The counter is reflected in register 3.22 (see 45.2.3.12).

82.2.19.2.5 Timers

State diagram timers follow the conventions of 14.2.3.2.

*x*us_timer
: Timer that is triggered every 1.25 ms +1%, –25% for 40GBASE-R or 500 µs +1%, –25% for 100GBASE-R.

The following timers are used only for the EEE capability.

one_us_timer
: A timer used to count approximately 1 µs intervals. The timer terminal count is set to T_{1U}. When the timer reaches terminal count, it sets one_us_timer_done = true.

rx_tq_timer
: This timer is started when the PCS receiver enters the RX_SLEEP state. The timer terminal count is set to T_{QR}. When the timer reaches terminal count, it sets rx_tq_timer_done = true.

rx_tw_timer
: This timer is started when the PCS receiver enters the RX_WAKE state. The timer terminal count is set to a value no larger than the maximum value given for T_{WR} in Table 82–9. When the timer reaches terminal count, it sets rx_tw_timer_done = true.

rx_wf_timer
: This timer is started when the PCS receiver enters the RX_WTF state, indicating that the receiver has encountered a wake time fault. The rx_wf_timer allows the receiver an additional period in which to synchronize or return to the QUIET state before a link failure is indicated. The timer terminal count is set to T_{WTF}. When the timer reaches terminal count, it sets the rx_wf_timer_done = true.

scr_byp_timer
: This timer is started when the PCS transmitter enters the TX_SCR_BYPASS state. The timer terminal count is set to T_{BYP}. When the timer reaches terminal count, it sets the scr_byp_timer_done = true.

tx_ts_timer
: This timer is started when the PCS transmitter enters the TX_SLEEP state. The timer terminal count is set to T_{SL}. When the timer reaches terminal count, it sets the tx_ts_timer_done = true.

tx_tq_timer
: This timer is started when the PCS transmitter enters the TX_QUIET state. The timer terminal count is set to T_{QL}. When the timer reaches terminal count, it sets the tx_tq_timer_done = true.

tx_tw_timer
: This timer is started when the PCS transmitter enters the TX_WAKE state. The timer terminal count is set to T_{WL}. When the timer reaches terminal count, it sets the tx_tw_timer_done = true.

tx_tw2_timer
: This timer is started when the PCS transmitter enters the TX_WAKE2 state. The timer terminal count is set to T_{WL2}. When the timer reaches terminal count, it sets the tx_tw2_timer_done = true.

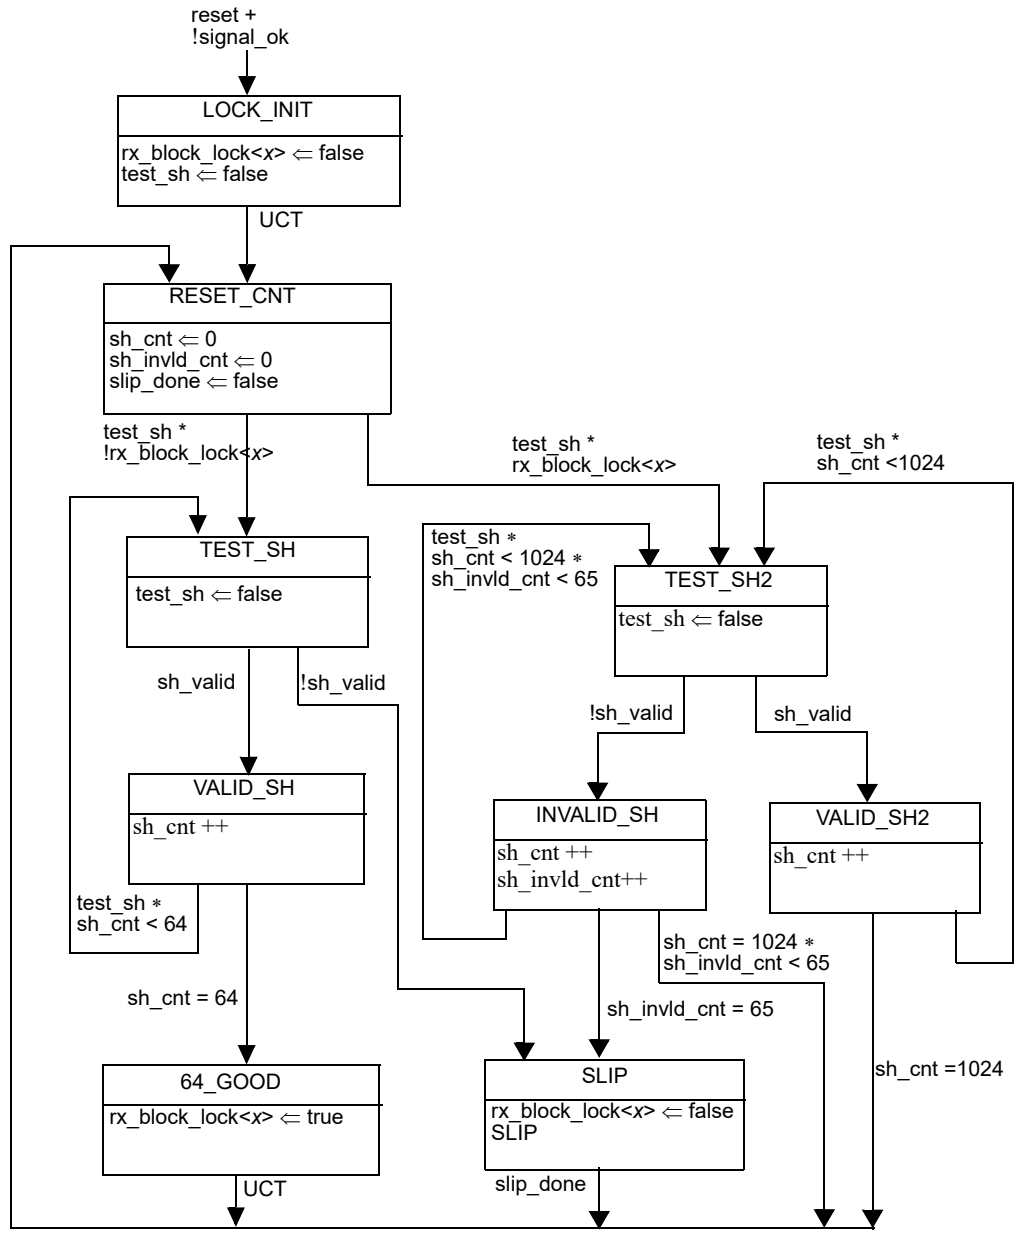
82.2.19.3 State diagrams

The 40GBASE-R PCS shall implement four block lock processes as depicted in Figure 82–12. The 100GBASE-R PCS shall implement twenty block lock processes as depicted in Figure 82–12. A block lock process operates independently on each lane. Each block lock process looks for 64 valid sync headers in a row to declare lock. A valid sync header is either a 01 or a 10. Once in lock, the lock process looks for 65 invalid sync headers within a 1024 sync window to declare out of lock. An invalid sync header is a 11 or 00. Once block lock is achieved on a lane, then the alignment marker process starts.

The 40GBASE-R PCS shall implement four alignment marker lock processes as depicted in Figure 82–13. The 100GBASE-R PCS shall implement twenty alignment marker lock processes as depicted in Figure 82–13. An alignment marker lock process operates independently on each lane. The alignment marker lock state diagram shown in Figure 82–13 determines when the PCS has obtained alignment marker lock to the received bit stream for a given lane of the service interface. Each alignment marker lock process looks for two valid alignment markers 16384 66-bit blocks apart to gain alignment marker lock. On a given lane of the service interface, lane markers have to match each other and an entry from Table 82–2 for 100GBASE-R or Table 82–3 for 40GBASE-R. Note that the BIP_3 and BIP_7 fields are excluded from the markers when making a match to each other or the tables. Once in lock, a lane will go out of alignment marker lock if four markers are received in a row that do not match the alignment marker that the lane is currently locked to. When the alignment marker lock process achieves lock for a lane, and if a Clause 45 MDIO is implemented, the PCS shall record the number of the PCS lane received on that lane of the service interface in the appropriate lane mapping register (3.400 to 3.419).

The PCS shall run the deskew process as depicted in Figure 82–14. The PCS deskew process is responsible for determining if the PCS is capable of presenting coherent data to the XLGMII/CGMII. The deskew process ensures that all PCS lanes have alignment marker lock, are locked to different alignment markers, and that the Skew is within the boundaries of what the PCS can deskew.



The BER Monitor state diagram shown in Figure 82–15 monitors the received aggregate signal for high bit error ratio. The high BER state shall be entered if 97 invalid 66-bit sync headers are detected within a 500 μs window for 100GBASE-R, or a 1.25 ms window for 40GBASE-R. The high BER state is exited once there are less than 97 invalid sync headers in the same window.

The Transmit state diagram shown in Figure 82–16 controls the encoding of transmitted blocks. It makes exactly one transition for each transmit block processed. Though the Transmit state diagram sends Local Fault ordered sets when reset is asserted, the scrambler may not be operational during reset. Thus, the Local Fault ordered sets may not appear on the PMA/FEC service interface.

The Receive state diagram shown in Figure 82–17 controls the decoding of received blocks. It makes exactly one transition for each receive block processed.

The PCS shall perform the functions of block lock, alignment marker lock, PCS deskew, BER Monitor, Transmit, and Receive as specified in the respective state diagrams.

82.2.19.3.1 LPI state diagrams

A PCS that supports the EEE capability shall implement the LPI transmit and receive processes as shown in Figure 82–18 and Figure 82–19. The transmit LPI state diagram controls tx_mode, which disables the transmitter when it is set to QUIET. The receive LPI state diagram controls block_lock during LPI and signals the end of LPI to the receive state diagram.

Following a period of LPI, the receiver is required to achieve block synchronization within the wake-up time specified (see Figure 82–19). The implementation of the block synchronization state diagram should use techniques to ensure that block lock is achieved with minimal numbers of slip attempts. If fast wake is selected then the receiver is expected to maintain sufficient state to allow much faster wake up.

The LPI functions shall use timer values for these state diagrams as shown in Table 82–8 for transmit and Table 82–9 for receive.

Table 82–8—Transmitter LPI timing parameters

Parameter	Description	Min	Max	Units
T_{SL}	Local Sleep Time from entering the TX_SLEEP state to when tx_mode is set to QUIET.	0.9	1.1	μs
T_{QL}	Local Quiet Time from when tx_mode is set to QUIET to entry into the TX_WAKE state.	1.7	1.8	ms
T_{WL}	Time spent in the TX_WAKE state.	1.5	1.6	μs
T_{WL2}	Time spent in the TX_WAKE2 state.	2.4	2.5	μs
T_{BYP}	Time spent in the TX_SCR_BYPASS state, 40 Gb/s operation.	0.9	1.1	μs
T_{BYP}	Time spent in the TX_SCR_BYPASS state, 100 Gb/s operation.	1.9	2.1	μs
T_{1U}	Time spent in the TX_ALERT state.	1.15	1.3	μs

Table 82–9—Receiver LPI timing parameters

Parameter	Description	Min	Max	Units
T_{QR}	Time the receiver waits for energy_detect to be set to true while in the RX_QUIET state before asserting receive fault.	2	3	ms
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault, scr_bypass_enable = FALSE.	—	4.5	μs
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault, scr_bypass_enable = TRUE, 40 Gb/s.	—	5.5	μs
T_{WR}	Time the receiver waits in the RX_WAKE state before indicating a wake time fault, scr_bypass_enable = TRUE, 100 Gb/s.	—	6.5	μs
T_{WTF}	Wake time fault recovery time.	—	10	ms

82.3 PCS Management

The following objects apply to PCS management. If an MDIO Interface is provided (see Clause 45), they are accessed via that interface. If not, it is recommended that an equivalent access be provided.

82.3.1 PCS MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that may provide control and status information for and about the PCS. Mapping of MDIO control variables to PCS control variables is shown in Table 82–10. Mapping of MDIO status variables to PCS status variables is shown in Table 82–11.

Table 82–10—MDIO/PCS control variable mapping

MDIO control variable	PCS register name	Register/ bit number	PCS control variable
Reset	PCS control 1 register	3.0.15	reset
Loopback	PCS control 1 register	3.0.14	Loopback
Transmit test-pattern enable	BASE-R PCS test-pattern control register	3.42.3	tx_test_mode
Receive test-pattern enable	BASE-R PCS test-pattern control register	3.42.2	rx_test_mode
LPI_FW	LPI fast wake enable	3.20.0	LPI_FW

Table 82–11—MDIO/PCS status variable mapping

MDIO status variable	PCS register name	Register/ bit number	PCS status variable
BASE-R and 10GBASE-T receive link status	BASE-R and 10GBASE-T PCS status 1 register	3.32.12	PCS_status
BASE-R and 10GBASE-T PCS high BER	BASE-R and 10GBASE-T PCS status 1 register	3.32.1	hi_ber
Block lock *x*	Multi-lane BASE-R PCS alignment status 1 and 2 registers	3.50.7:0 3.51.11:0	block_lock<*x*>
Lane *x* aligned	Multi-lane BASE-R PCS alignment status 3 and 4 registers	3.52.7:0 3.53.11:0	am_lock<*x*>
PCS lane alignment status	Multi-lane BASE-R PCS alignment status 1 register	3.50.12	align_status
BER	BASE-R and 10GBASE-T PCS status 2 register BER high order counter register	3.33.13:8 3.44.15:0	ber_count
Errored blocks	BASE-R and 10GBASE-T PCS status 2 register Errored blocks high order counter register	3.33.7:0 3.45.13:0	errored_block_count

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Table 82–11—MDIO/PCS status variable mapping *(continued)*

MDIO status variable	PCS register name	Register/ bit number	PCS status variable
Test-pattern error counter	BASE-R PCS test-pattern error counter register	3.43.15:0	test_pattern_error_count
BIP error counter, lane *x*	BIP error counter, lane *x* register	3.200 through 3.219	bip_counter
Lane *x* mapping	Lane *x* mapping register	3.400 through 3.419	lane_mapping
Tx LPI indication	Tx LPI indication	3.1.9	Tx LPI indication
Tx LPI received	Tx LPI received	3.1.11	Tx LPI received
Rx LPI indication	Rx LPI indication	3.1.8	Rx LPI indication
Rx LPI received	Rx LPI received	3.1.10	Rx LPI received
Wake_error_counter	Wake_error_counter	3.22	Wake_error_counter

82.4 Loopback

If a Clause 45 MDIO is implemented, then the PCS shall be placed in the loopback mode when the loopback bit from the PCS control 1 register (bit 3.0.14) is set to a one. In this mode, the PCS shall accept data on the transmit path from the XLGMII/CGMII and return it on the receive path to the XLGMII/CGMII. In addition, the PCS shall transmit what it receives from the XLGMII/CGMII to the PMA/FEC sublayer, and shall ignore all data presented to it by the PMA/FEC sublayer.

82.5 Delay constraints

The maximum delay contributed by the 40GBASE-R PCS (sum of transmit and receive delays at one end of the link) shall be no more than 11264 BT (22 pause_quanta or 281.6 ns). The maximum delay contributed by the 100GBASE-R PCS (sum of transmit and receive delays at one end of the link) shall be no more than 35328 BT (69 pause_quanta or 353.28 ns). A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

82.6 Auto-Negotiation

The following requirements apply to a PCS used with a 40GBASE-KR4 PMD, 40GBASE-CR4 PMD, 100GBASE-CR10, 100GBASE-CR4, 100GBASE-CR2, 100GBASE-KR4, 100GBASE-KP4, or 100GBASE-KR2 PMD where support for the Auto-Negotiation process defined in Clause 73 is mandatory. The PCS shall support the primitive AN_LINK.indication(link_status) (see 73.9). The parameter link_status shall take the value FAIL when PCS_status=false and the value OK when PCS_status=true. The primitive shall be generated when the value of link_status changes.

82.7 Protocol implementation conformance statement (PICS) proforma for Clause 82, Physical Coding Sublayer (PCS) for 64B/66B, type 40GBASE-R and 100GBASE-R[147]

82.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 82, Physical Coding Sublayer (PCS) for 64B/66B, type 40GBASE-R and 100GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma. A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

82.7.2 Identification

82.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1— Required for all implementations. NOTE 2— May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

82.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 82, Physical Coding Sublayer (PCS) for 64B/66B, type 40GBASE-R and 100GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[147] *Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

82.7.4 PICS proforma tables for PCS, type 40GBASE-R and 100GBASE-R

82.7.4.1 Coding rules

Item	Feature	Subclause	Value/Comment	Status	Support
C1	Encoder (and ENCODE function) implements the code as specified	82.2.3 and 82.2.19.2.3		M	Yes [ ]
C2	Decoder (and DECODE function) implements the code as specified	82.2.3 and 82.2.19.2.3		M	Yes [ ]
C3	Only valid block types are transmitted	82.2.3.3		M	Yes [ ]
C4	Invalid block types are treated as an error	82.2.3.3		M	Yes [ ]
C5	Only valid control characters are transmitted	82.2.3.4		M	Yes [ ]
C6	Invalid control characters are treated as an error	82.2.3.4		M	Yes [ ]
C7	Idles do not interrupt data	82.2.3.6		M	Yes [ ]
C8	IDLE control code insertion and deletion	82.2.3.6	Insertion or Deletion in groups of 8 /I/s	M	Yes [ ]
C9	Sequence ordered set deletion	82.2.3.9	Only one whole ordered set of two consecutive sequence ordered sets may be deleted	M	Yes [ ]

82.7.4.2 Scrambler and Descrambler

Item	Feature	Subclause	Value/Comment	Status	Support
S1	Scrambler	82.2.5	Performs as shown in Figure 49–8	M	Yes [ ]
S2	Descrambler	82.2.16	Performs as shown in Figure 49–10	M	Yes [ ]

82.7.4.3 Deskew and Reordering

Item	Feature	Subclause	Value/Comment	Status	Support
DR1	Deskew	82.2.13	Able to deskew up to the value in Table 82–7	M	Yes [ ]
DR2	Reordering	82.2.14	Performs reordering	M	Yes [ ]

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

82.7.4.4 Alignment Markers

Item	Feature	Subclause	Value/Comment	Status	Support
AM1	Alignment marker insertion	82.2.7	Alignment markers are inserted periodically as described in 82.2.7	M	Yes [ ]
AM2	Alignment marker form	82.2.7	Alignment markers are formed as described in 82.2.7	M	Yes [ ]
AM3	Alignment marker removal	82.2.15	Alignment markers are removed as described in 82.2.15	M	Yes [ ]
AM4	Lane mapping	82.2.19.3	PCS lane number is captured	MD:M	Yes [ ] N/A [ ]

82.7.4.5 Test-pattern modes

Item	Feature	Subclause	Value/Comment	Status	Support
JT1	Scrambled idle transmit test-pattern generator is implemented	82.2.11	Performs as in 82.2.11	JTM:M	Yes [ ] N/A[ ]
JT2	Scrambled idle receive test-pattern checker is implemented	82.2.18	Performs as in 82.2.18	JTM:M	Yes [ ] N/A[ ]
JT3	Transmit and receive test-pattern modes can operate simultaneously	82.2.1		JTM:M	Yes [ ] N/A[ ]

82.7.4.6 Bit order

Item	Feature	Subclause	Value/Comment	Status	Support
B1	Transmit bit order	82.2.3.2	Placement of bits into the PCS lanes as shown in Figure 82–3	M	Yes [ ]
B2	Receive bit order	82.2.3.2	Placement of bits into the XLGMII/CGMII as shown in Figure 82–4	M	Yes [ ]

82.7.4.7 Management

Item	Feature	Subclause	Value/Comment	Status	Support
M1	Equivalent access to PCS Management objects is provided	82.3		!MD:O	Yes [ ] No [ ] N/A [ ]

83. Physical Medium Attachment (PMA) sublayer, type 40GBASE-R and 100GBASE-R

83.1 Overview

83.1.1 Scope

This clause specifies the Physical Medium Attachment sublayer (PMA) that is common to two families of (40 Gb/s and 100 Gb/s) Physical Layer implementations, known as 40GBASE-R and 100GBASE-R. The PMA allows the PCS (specified in Clause 82) to connect in a media-independent way with a range of physical media. The 40GBASE-R PMA(s) can support any of the 40 Gb/s PMDs in Table 80–2. The 100GBASE-R PMA(s) can support any of the 100 Gb/s PMDs in Table 80–3 or Table 80–4, but does not provide the PMD service interface for 100GBASE-KP4 (Clause 94). The terms 40GBASE-R and 100GBASE-R are used when referring generally to Physical Layers using the PMA defined in this clause.

40GBASE-R and 100GBASE-R can be extended to support any full duplex medium requiring only that the PMD be compliant with the appropriate PMA interface.

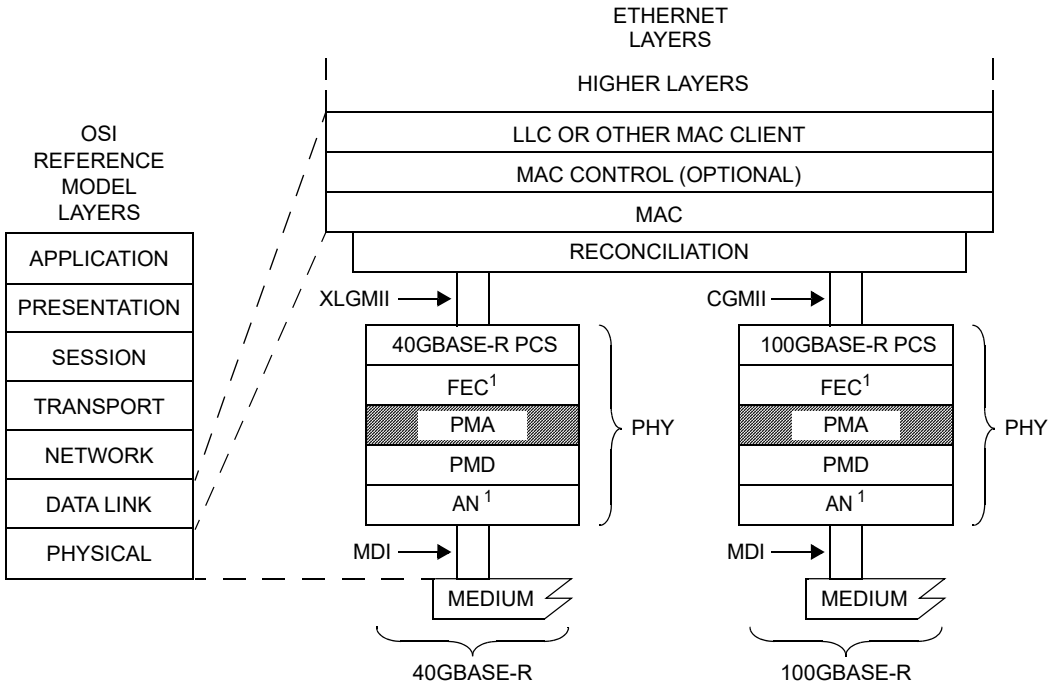
The interfaces for the inputs of the 40GBASE-R and 100GBASE-R PMAs are defined in an abstract manner and do not imply any particular implementation. The optional physical instantiation of the PMD service interfaces for 40GBASE-SR4, 40GBASE-LR4, and 100GBASE-SR10 PMDs, known as XLPPI and CPPI, are defined in Annex 86A. The PMD service interfaces for other PMDs are defined in an abstract manner according to 80.3.1. For 40GBASE-R PMAs, electrical interfaces connecting PMA sublayers, known as XLAUI, are defined in Annex 83A and Annex 83B. For 100GBASE-R PMAs, electrical interfaces connecting PMA sublayers, known as CAUI-n, are defined in Annex 83A, Annex 83B, Annex 83D, and Annex 83E.

83.1.2 Position of the PMA in the 40GBASE-R or 100GBASE-R sublayers

Figure 83–1 shows the relationship of the PMA sublayer (shown shaded) with other sublayers to the ISO Open System Interconnection (OSI) reference model.

83.1.3 Summary of functions

The following is a summary of the principal functions implemented (when required) by the PMA in both the transmit and receive directions:



a) Adapt the PCSL formatted signal to the appropriate number of abstract or physical lanes.
b) Provide per input-lane clock and data recovery.
c) Provide bit-level multiplexing.
d) Provide clock generation.
e) Provide signal drivers.
f) Optionally provide local loopback to/from the PMA service interface.
g) Optionally provide remote loopback to/from the PMD service interface.
h) Optionally provide test-pattern generation and detection.
i) Tolerate Skew Variation.

In addition, the PMA provides receive link status information in the receive direction.

83.1.4 PMA sublayer positioning

An implementation may use one or more PMA sublayers to adapt the number and rate of the PCS lanes to the number and rate of the PMD lanes. The number of PMA sublayers required depends on the partitioning

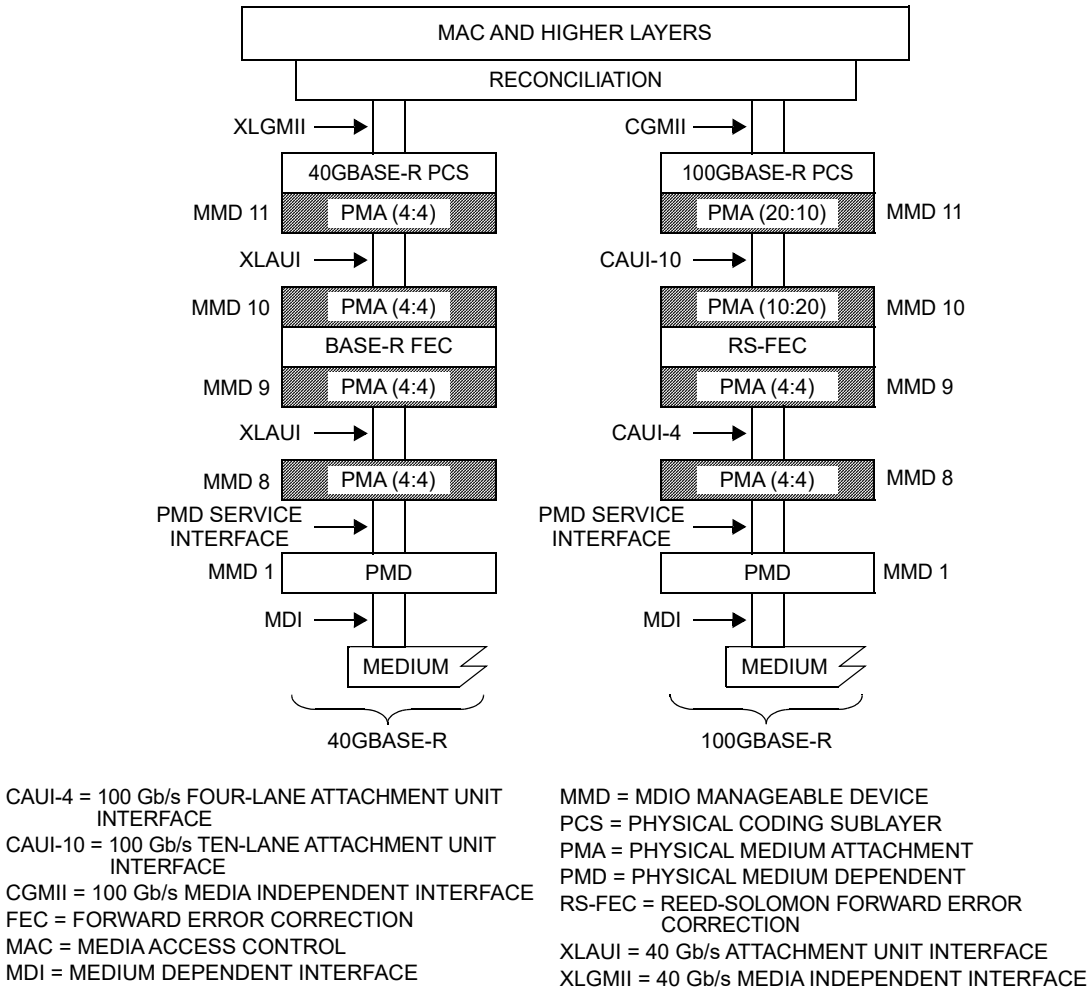
AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE



NOTE 1—CONDITIONAL BASED ON PHY TYPE

Figure 83–1—40GBASE-R and 100GBASE-R PMA relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and IEEE 802.3 Ethernet model

of functionality for a particular implementation. An example is illustrated in Figure 83–2. This example illustrates the partitioning that might arise from use of an FEC device that is separate from the PCS. Additional examples are illustrated in Annex 83C. Each PMA maps the PCSLs from p PMA input lanes to q PMA output lanes in the Tx direction, and from q PMA input lanes to p PMA output lanes in the Rx direction.

Management Data Input/Output (MDIO) Manageable Device (MMD) addresses 1, 8, 9, 10, and 11 are available for addressing multiple instances of PMA sublayers (see Table 45–1 for MMD device addresses). If the PMA sublayer that is closest to the PMD is packaged with the PMD, it shares MMD 1 with the PMD. If the PMD service interface is physically instantiated as nPPI (see Annex 86A), the PMA sublayer that is closest to the PMD will be addressed as MMD 8. More addressable instances of PMA sublayers, each one separated from lower addressable instances by chip-to-chip interfaces, may be implemented and addressed allocating MMD addresses to PMAs in increasing numerical order going from the PMD toward the PCS. The example shown in Figure 83–2 could be implemented with four addressable instances: MMD 8 addressing the lowest PMA sublayer (note that this cannot share MMD 1 with the PMD as they are not packaged together in this example), MMD 9 addressing the PMA sublayer above the XLAUI/CAUI-4 below the FEC, MMD 10 addressing the PMA sublayer below the XLAUI/CAUI-10 above the FEC, and MMD 11 addressing the PMA sublayer closest to the PCS.

MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
MMD = MDIO MANAGEABLE DEVICE
PCS = PHYSICAL CODING SUBLAYER
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
RS-FEC = REED-SOLOMON FORWARD ERROR CORRECTION
XLAUI = 40 Gb/s ATTACHMENT UNIT INTERFACE
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

Figure 83–2—Example 40GBASE-R and 100GBASE-R PMA layering

The number of input lanes and the number of output lanes for a PMA are always divisors of the number of PCSLs. For PMA sublayers supporting 40GBASE-R PMDs, the number of PCSLs is 4, and for PMA sublayers supporting 100GBASE-R PMDs, the number of PCSLs is 20.

The following guidelines apply to the partitioning of PMAs:

a) The inter-sublayer service interface, defined in 80.3, is used for the PMA, FEC, and PMD service interfaces supporting a flexible architecture with optional FEC and multiple PMA sublayers.
   1) An instance of this interface can only connect service interfaces with the same number of lanes, where the lanes operate at the same rate.
b) XLAUI and CAUI-n are physical instantiations of the connection between two adjacent PMA sublayers.
   1) As a physical instantiation, it defines electrical and timing specification as well as requiring a receive re-timing function
   2) XLAUI is a 10.3125 GBd by 4 lane physical instantiation of the respective 40 Gb/s connection
   3) CAUI-10 is a 10.3125 GBd by 10 lane physical instantiation of the respective 100 Gb/s connection
   4) CAUI-4 is a 25.78125 GBd by 4 lane physical instantiation of the respective 100 Gb/s connection

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

c) The abstract inter-sublayer service interface can be physically instantiated as a XLAUI or CAUI-n, using associated PMAs to map to the appropriate number of lanes.
d) Opportunities for optional test-pattern generation, optional test-pattern detection, optional local loopback and optional remote loopback are dependent upon the location of the PMA sublayer in the implementation. See Figure 83–5.
e) A minimum of one PMA sublayer is required in a PHY.
f) A maximum of four PMA sublayers are addressable as MDIO MMDs.

83.2 PMA interfaces

All PMA variants for 40GBASE-R and 100GBASE-R signals are based on a generic specification of a bit mux function that applies to all input/output lane counts and each direction of transmission. Each direction of transmission employs one or more such bit muxes to adapt from the appropriate number of input lanes to the appropriate number of output lanes as illustrated in Figure 83–3.

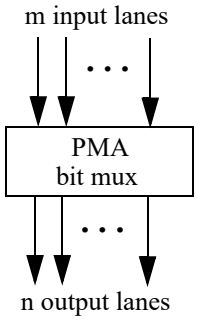

Figure 83–3—PMA bit mux used in both Tx and Rx directions

Conceptually, the PMA bit mux operates in one direction of transmission by demultiplexing PCSLs from m PMA input lanes and remultiplexing them into n PMA output lanes. The mapping of PCSLs from input to output lanes is not specified. See 83.5.2 and Figure 83–4 for details.

Figure 83–5 provides the functional block diagram of a PMA. The parameters of a PMA include the following:

— The aggregate rate supported (40GBASE-R or 100GBASE-R).
— The numbers of input and output lanes in each direction.
— Whether the PMA is adjacent to a physically instantiated interface (XLAUI/CAUI-n above or below, or PMD service interface below).
— Whether the PMA is adjacent to the PCS (or adjacent to FEC when FEC is adjacent to the PCS).
— Whether the PMA is adjacent to the PMD.

83.3 PMA service interface

The PMA service interface for 40GBASE-R and 100GBASE-R is an instance of the inter-sublayer service interface defined in 80.3. The PMA service interface primitives are summarized as follows:

PMA:IS_UNITDATA_*i*.request(tx_bit)
PMA:IS_UNITDATA_*i*.indication(rx_bit)
PMA:IS_SIGNAL.indication(SIGNAL_OK)

For a PMA with p lanes at the PMA service interface, the primitives are defined for $i = 0$ to $p - 1$.

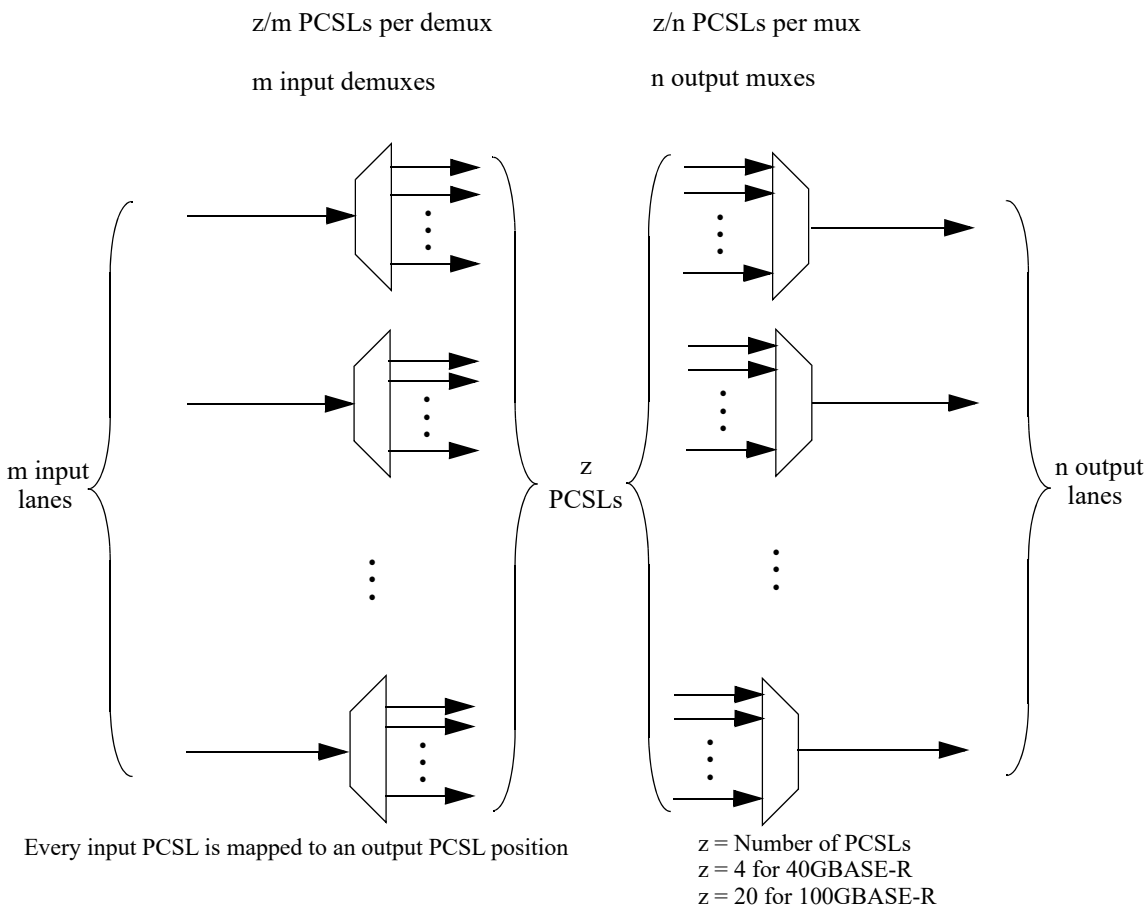
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.



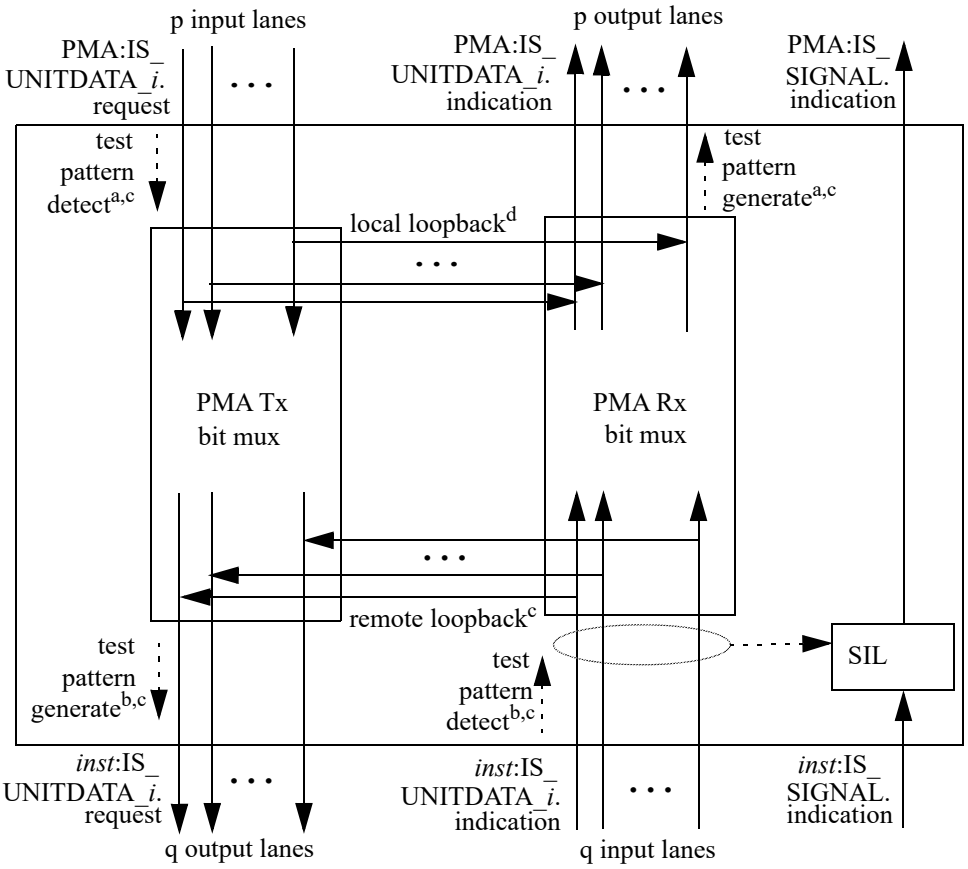


Figure 83–4—PMA bit mux operation used in both Tx and Rx directions

If the PMA client is the PCS or a BASE-R FEC sublayer (see Clause 74), the PMA (or PMA client) continuously sends four (for 40GBASE-R) or twenty (for 100GBASE-R) parallel bit streams to the PMA client (or PMA), each at the nominal signaling rate of the PCSL. If the PMA client is the 100GBASE-R RS-FEC sublayer (see Clause 91), the PMA continuously sends four parallel bit streams to the PMA client (or PMA), each at 25.78125 GBd.

If the PMA client is another PMA, for a PMA supporting a 40GBASE-R PMD, the number of PCSLs z = 4 and for a PMA supporting a 100GBASE-R PMD, the number of PCSLs z = 20. A PMA with p input lanes receives bits on each of its input lanes at z/p times the PCSL rate. Skew may exist between the bits received on each lane even though all lanes originate from the same synchronous source, so there is independence of arrival of bits on each lane.

In the Tx direction, if the bit from a PMA:IS_UNITDATA_*i*.request primitive is received over a physically instantiated interface (XLAUI/CAUI-n), clock and data are recovered on the lane receiving the bit. The bit is routed through the PMA to an output lane through a process that may demultiplex PCSLs from the input, perform any necessary buffering to tolerate Skew Variation across input lanes, and multiplex PCSLs to output lanes. The bit is sent on an output lane to the sublayer below using the *inst*:IS_UNITDATA_*k*.request (*k* not necessarily equal to *i*) primitive (see 83.4).

inst PMD, PMA, or FEC, depending on which sublayer is below this PMA
SIL Signal Indication Logic

[a] If physically instantiated interface (XLAUI/CAUI-n) immediately above this PMA.
[b] If physically instantiated interface (XLAUI/CAUI-n or PMD service interface) immediately below this PMA, or if this is the closest PMA to the PMD.
[c] Optional.
[d] Local loopback is required for PMAs adjacent to some PMDs, and optional for other PMAs. See 83.5.8.

Figure 83–5—PMA Functional Block Diagram

In the Rx direction, when data is being received from every input lane from the sublayer below the PMA that has a PCSL that is routed to a particular output lane at the PMA service interface, and (if necessary), buffers are filled to allow tolerating the Skew Variation that may appear between the input lanes, PCSLs are demultiplexed from the input lanes, remultiplexed to the output lanes, and bits are transferred over each output lane to the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive.

The PMA:IS_SIGNAL.indication primitive is generated through a set of Signal Indication Logic (SIL) that reports signal health based on receipt of the *inst*:IS_SIGNAL.indication from the sublayer below, data being received on all of the input lanes from the sublayer below, buffers filled (if necessary) to accommodate Skew Variation, and bits being sent to the PMA client on all of the output lanes. When these conditions are met, the SIGNAL_OK parameter sent to the PMA client via the PMA:IS_SIGNAL.indication primitive will have the value OK. Otherwise, the SIGNAL_OK primitive will have the value FAIL.

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78, 78.1.3.3.1) then the inter-sublayer service interface includes four additional primitives defined as follows:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

IS_TX_MODE.request
IS_RX_MODE.request
IS_ENERGY_DETECT.indication
IS_RX_TX_MODE.indication

The IS_TX_MODE.request primitive is used to communicate the state of the PCS LPI transmit function to other sublayers in the PHY. The IS_RX_MODE.request primitive is used to communicate the state of the PCS LPI receive function to other sublayers. The IS_RX_TX_MODE.indication primitive is used to communicate the state of the rx_tx_mode parameter, that reflects the inferred state of the link partner's tx_mode parameter, from the PMA to other sublayers. The IS_ENERGY_DETECT.indication primitive is used to communicate that the PMD has detected the return of energy on the interface following a period of quiescence.

A physically instantiated service interface with the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option (see 78.1.3.3.1) may enter a low power state to conserve energy during periods of low link utilization. The ability to support transition to a low power state in the ingress direction is indicated by register 1.1.9 (PMA Ingress AUI Stop Ability, PIASA) and in the egress direction by register 1.1.8 (PMA Egress AUI Stop Ability, PEASA). Transition to the low power state is enabled in the ingress direction by register 1.7.9 (PMA Ingress AUI Stop Enable, PIASE) and in the egress direction by register 1.7.8 (PMA Egress AUI Stop Enable, PEASE). The system shall not assert the enable bit for an interface unless the corresponding ability bit at the other side of the interface is also asserted. If the PIASE bit is TRUE, then the PMA may disable transmitters on the physical instantiation of the ingress AUI when aui_tx_mode is QUIET. If the PEASE bit is TRUE, then the PMA may disable transmitters on the physical instantiation of the egress AUI when tx_mode is QUIET.

83.4 Service interface below PMA

Since the architecture supports multiple PMA sublayers for various PMD lane counts and device partitioning, there are several different sublayers that may appear below a PMA, including FEC, the PMD, or another PMA. The variable *inst* represents whichever sublayer appears below the PMA (e.g., another PMA, FEC, or PMD).

The sublayer below the PMA utilizes the inter-sublayer service interface defined in 80.3. The service interface primitives provided to the PMA are summarized as follows:

inst:IS_UNITDATA_*i*.request(tx_bit)
inst:IS_UNITDATA_*i*.indication(rx_bit)
inst:IS_SIGNAL.indication(SIGNAL_OK)

The number of lanes q for the service interface matches the number of lanes expected by the PMA. The *inst*:IS_UNITDATA_*i* primitives are defined for each lane $i = 0$ to $q - 1$ of the service interface below the PMA. Note that electrical and timing specifications of the service interface are defined if the interface is physically instantiated (e.g., XLAUI/CAUI-n or nPPI), otherwise the service interface is specified only abstractly. The interface between the PMA and the sublayer below consists of q lanes for data transfer and a status indicating a good signal sent by the sublayer below the PMA (see Figure 83–5).

In the Tx direction, when data is being received via the PMA:IS_UNITDATA_*i*.request primitive from every input lane from the PMA client at the PMA service interface (see 83.3) that has a PCSL that is routed to this output lane, and (if necessary), buffers are filled to allow tolerating the Skew Variation that may appear between the input lanes from the PMA client, PCSLs are demultiplexed from the input lanes, remultiplexed to the output lanes, and bits are transferred over each output lane to the sublayer below the PMA.

In the Rx direction, if the bit is received over a physically instantiated interface (XLAUI/CAUI-n or nPPI), clock and data are recovered on the lane receiving the bit. The bit is routed through the PMA to an output

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

lane toward the PMA client through a process that may demultiplex PCSLs from the input, perform any necessary buffering to tolerate Skew Variation across input lanes, and multiplex PCSLs to output lanes, and finally sending the bit on an output lane to the PMA client using the PMA:IS_UNITDATA_*k*.indication (*k* not necessarily equal to *i*) primitive at the PMA service interface.

83.5 Functions within the PMA

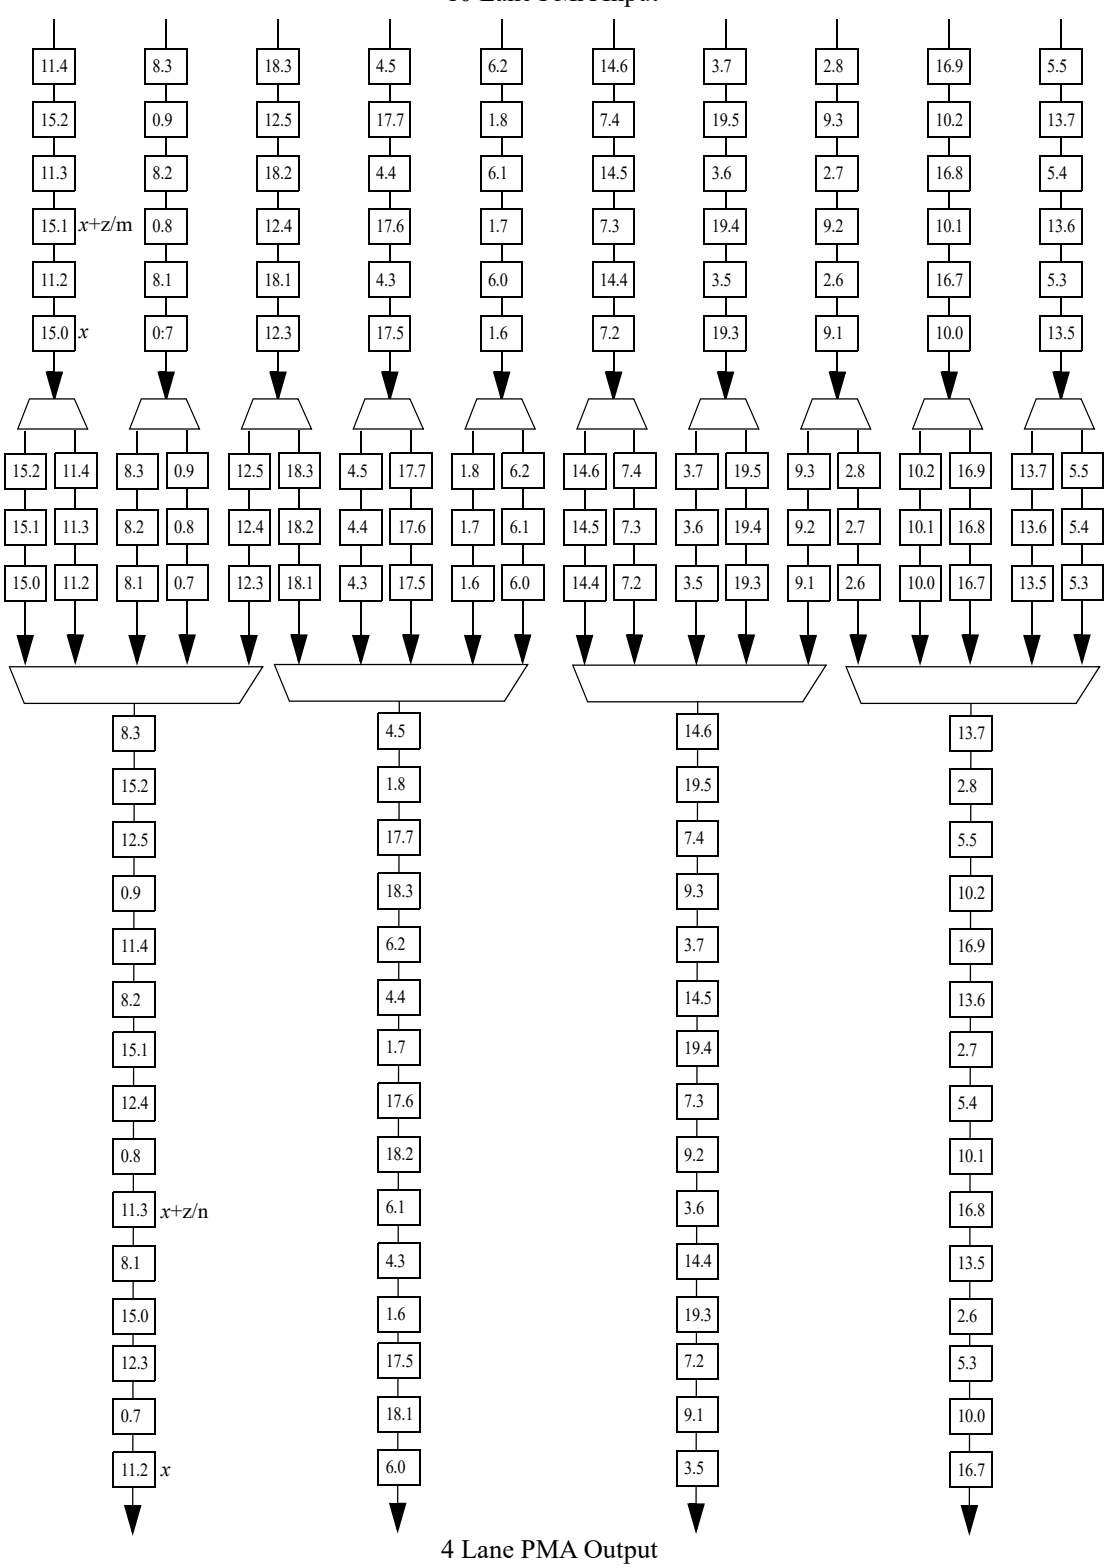
The purpose of the PMA is to adapt the PCSL formatted signal to an appropriate number of abstract or physical lanes, to recover clock from the received signal (if appropriate), and optionally to provide test signals and loopback. Each input (Tx direction) or output (Rx direction) lane between the PMA and the PMA client carries one or more PCSLs that are bit-multiplexed. All input and output lanes between the PMA and the PMA client carry the same number of PCSLs and operate at the same nominal signaling rate. Likewise, each input (Rx direction) or output (Tx direction) lane between the PMA and the sublayer below the PMA carries one or more PCSLs that are bit-multiplexed. All input and output lanes between the PMA and the sublayer below the PMA carry the same number of PCSLs and operate at the same nominal signaling rate. As described in 83.1.4, the number of input lanes and the number of output lanes for a given PMA are divisors of the number of PCSLs for the interface type supported.

83.5.1 Per input-lane clock and data recovery

If the interface between the PMA client and the PMA is physically instantiated as XLAUI/CAUI-n, the PMA shall meet the electrical and timing specifications in Annex 83A, Annex 83B, Annex 83D, or Annex 83E as appropriate. If the interface between the sublayer below the PMA and the PMA is physically instantiated as XLAUI/CAUI-n or nPPI, the PMA shall meet the electrical and timing specifications at the service interface as specified in Annex 83A, Annex 83B, Annex 83D, Annex 83E, or Annex 86A as appropriate.

83.5.2 Bit-level multiplexing

The PMA provides bit-level multiplexing in both the Tx and Rx directions. In the Tx direction, the function is performed among the bits received from the PMA client via the PMA:IS_UNITDATA_*i*.request primitives (for PMA client lanes $i = 0$ to $p - 1$) with the result sent to the service interface below the PMA using the *inst*:IS_UNITDATA_*i*.request primitives (for service interface lanes $i = 0$ to $q - 1$), referencing the functional block diagram shown in Figure 83–5. The bit multiplexing behavior is illustrated in Figure 83–4.



The aggregate signal carried by the group of input lanes or the group of output lanes is arranged as a set of PCSLs. For PMA sublayers supporting 40GBASE-R interfaces, the number of PCSLs z is 4, and the nominal signaling rate R of each PCSL is 10.3125 GBd. For PMA sublayers supporting 100GBASE-R interfaces, the number of PCSLs z is 20, and the nominal signaling rate R of each PCSL is 5.15625 GBd.

For a PMA with m input lanes (Tx or Rx direction), each input lane carries, bit multiplexed, z/m PCSLs. Each input lane has a nominal signaling rate of $R \times z/m$. If bit x received on an input lane belongs to a particular PCSL, the next bit of that same PCSL is received on the same input lane at bit position $x+(z/m)$. The z/m PCSLs may arrive in any sequence on a given input lane.

For a PMA with n output lanes (Tx or Rx direction), each output lane carries, bit multiplexed, z/n PCSLs. Each output lane has a nominal signaling rate of $R \times z/n$. Each PCSL is mapped from a position in the sequence on one of the z/m input lanes to a position in the sequence on one of the z/n output lanes. If bit x sent on an output lane belongs to a particular PCSL, the next bit of that same PCSL is sent on the same output lane at bit position $x + (z/n)$. The PMA shall maintain the chosen sequence of PCSLs on all output lanes while it is receiving a valid stream of bits on all input lanes.

Each PCSL received in any temporal position on an input lane is transferred into a temporal position on an output lane. As the PCS (see Clause 82) has fully flexible receive logic, an implementation is free to perform the mapping of PCSLs from input lanes to output lanes without constraint. Figure 83–6 illustrates one possible bit ordering for a 10:4 PMA bit mux. Other bit orderings are also valid.

83.5.3 Skew and Skew Variation

The Skew (relative delay) between the PCSLs is kept within limits so that the information on the lanes can be reassembled by the PCS.

Any PMA that combines PCSLs from different input lanes onto the same output lane is required to tolerate Skew Variation between the input lanes without changing the PCSL positions on the output. Skew and Skew Variation are defined in 80.5. The limits for Skew and Skew Variation at physically instantiated interfaces are specified at Skew points SP0, SP1, and SP2 in the transmit direction and SP5, SP6, and SP7 in the receive direction as defined in 80.5 and illustrated in Figure 80–7, Figure 80–8, and Figure 80–9.

83.5.3.1 Skew generation toward SP0

In an implementation with one or more physically instantiated CAUI-n interfaces, the PMA that sends data in the transmit direction toward the CAUI-n that is closest to the RS-FEC (SP0 in Figure 80–9) shall produce no more than 29 ns of Skew between PCSLs toward the CAUI-n, and no more than 200 ps of Skew Variation.

83.5.3.2 Skew generation toward SP1

In an implementation with one or more physically instantiated XLAUI/CAUI-n interfaces, the PMA that sends data in the transmit direction toward the XLAUI/CAUI-n that is closest to the PMD (SP1 in Figure 80–7 and Figure 80–8) shall produce no more than 29 ns of Skew between PCSLs toward the XLAUI/CAUI-n, and no more than 200 ps of Skew Variation.

83.5.3.3 Skew tolerance at SP1

In an implementation with one or more physically instantiated XLAUI/CAUI-n interfaces, the PMA service interface that receives data in the transmit direction from the XLAUI/CAUI-n (SP1 in Figure 80–7 and Figure 80–8) shall tolerate the maximum amount of Skew Variation allowed at SP1 (200 ps) between input lanes while maintaining the bit ordering and position of each PCSL on each PMA lane in the transmit direction (toward the PMD).

83.5.3.4 Skew generation toward SP2

In an implementation with a physically instantiated PMD service interface, the PMA adjacent to the PMD service interface shall generate no more than 43 ns of Skew, and no more than 400 ps of Skew Variation between output lanes toward the PMD service interface (SP2 in Figure 80–7 and Figure 80–8). If there is a physically instantiated XLAUI/CAUI-n as well, then the Skew measured at SP1 is limited to no more than 29 ns of Skew and no more than 200 ps of Skew Variation.

83.5.3.5 Skew tolerance at SP5

In an implementation with a physically instantiated PMD service interface, the PMA adjacent to the PMD service interface (SP5) shall tolerate the maximum amount of Skew Variation allowed at SP5 (3.6 ns) between output lanes from the PMD service interface while maintaining the bit ordering and position of each PCSL on each PMA lane in the receive direction (toward the PCS).

83.5.3.6 Skew generation at SP6

In an implementation with one or more physically instantiated XLAUI/CAUI-n interfaces, at SP6 (the receive direction of the XLAUI/CAUI-n closest to the PCS), the PMA or group of PMAs between the PMD and the XLAUI/CAUI-n closest to the PCS shall deliver no more than 160 ns of Skew, and no more than 3.8 ns of Skew Variation between output lanes toward the XLAUI/CAUI-n in the Rx direction.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If there is a physically instantiated PMD service interface as well, the Skew measured at SP5 is limited to no more than 145 ns of Skew and no more than 3.6 ns of Skew Variation. If there is no physically instantiated PMD service interface, the Skew measured at SP4 is limited to no more than 134 ns of Skew, and no more than 3.4 ns of Skew Variation.

83.5.3.7 Skew tolerance at SP6

In an implementation with one or more physically instantiated XLAUI/CAUI-n interfaces, the PMA between the XLAUI/CAUI-n closest to the PCS and the PCS shall tolerate the maximum amount of Skew Variation allowed at SP6 (3.8 ns) between input lanes while maintaining the bit order and position of PCSLs on lanes sent in the receive direction towards the PCS.

83.5.3.8 Skew generation toward SP7

In an implementation with one or more physically instantiated CAUI-n interfaces and RS-FEC, at SP7 (the receive direction of the CAUI-n closest to the PCS), the PMA or group of PMAs between the RS-FEC and the CAUI-n closest to the PCS shall deliver no more than 160 ns of Skew, and no more than 3.8 ns of Skew Variation between output lanes toward the CAUI-n in the Rx direction.

83.5.4 Delay constraints

The maximum cumulative delay contributed by up to four PMA stages in a PHY (sum of transmit and receive delays at one end of the link) shall meet the values specified in Table 83–1. A description of overall system delay constraints and the definitions for bit-times and pause_quanta can be found in 80.4 and its references.

Table 83–1—Delay constraints

Sublayer	Maximum (bit time)	Maximum (pause_quanta)	Maximum (ns)
40GBASE-R PMA	4096	8	102.4
100GBASE-R PMA	9216	18	92.16

83.5.5 Clocking architecture

A PMA with m input lanes and n output lanes shall clock the output lanes at m/n times the rate of the input lanes. This applies in both the Tx and Rx directions of transmission. In the case where the interfaces between the PMA client and the PMA and/or the PMA and the sublayer below the PMA are physically instantiated, the PMA may derive its input clock(s) from the electrical interface on one or more of the input lanes, and generate the output clock(s) with an appropriate PLL multiplier/divider circuit.

There is no requirement that the PMA clock all output lanes in unison. Examples of independent clocking of output lanes include the following:

— The case where the number of input and output lanes are equal (the PMA is provided for retiming and regeneration of the signal). This may be implemented without any rearrangement of PCSLs between input lanes and output lanes (although rearrangements are allowed), and such a PMA may be implemented by driving each output lane using the clock recovered from the corresponding input lane.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

— If the number of input and output lanes have a common factor, the PMA may be partitioned such that PCSLs from a subset of the input lanes are mapped only to a subset of the output lanes (for example, a 10:4 PMA could be implemented as two 5:2 PMAs). The output clock for one subset may be independent of the output clock for other subset(s).

83.5.6 Signal drivers

For cases where the interface between the PMA client and the PMA, or between the PMA and the sublayer below the PMA represent a physically instantiated interface, the PMA provides electrical signal drivers for that interface. The electrical and jitter/timing specifications for these interfaces appear in

— Annex 83A, which specifies the XLAUI/CAUI-10 interface for chip-to-chip applications.
— Annex 83B, which specifies the XLAUI/CAUI-10 interface for chip-to-module applications.
— Annex 83D, which specifies the CAUI-4 interface for chip-to-chip applications.
— Annex 83E, which specifies the CAUI-4 interface for chip-to-module applications.
— 86.2, which specifies the PMD service interface for 40GBASE-SR4 and 100GBASE-SR10 PMDs.
— 87.2, which specifies the PMD service interface for 40GBASE-LR4 and 40GBASE-ER4 PMDs.
— Annex 86A, which specifies the Parallel Physical Interface (XLPPI and CPPI), an optional physical instantiation of the PMD service interface for 40GBASE-SR4, 40GBASE-LR4, and 100GBASE-SR10 PMDs.

83.5.7 Link status

The PMA shall provide link status information to the PMA client using the PMA:IS_SIGNAL.indication primitive. The PMA continuously monitors the link status reported by the service interface below from the *inst*:IS_SIGNAL.indication primitive, and uses this as input to Signal Indication Logic (SIL) to determine the link status to report to the layer above. Other inputs to the SIL may include the status of clock and data recovery on the lanes from the service interface below the PMA and whether buffers/FIFOs have reached the required fill level to accommodate Skew Variation so that data is being sent on the output lanes.

83.5.8 PMA local loopback mode

PMA local loopback shall be provided by the PMA adjacent to the PMD for 40GBASE-KR4, 40GBASE-CR4, 100BASE-CR10, 100GBASE-KR4, and 100GBASE-CR4 PMDs. PMA local loopback mode is optional for other PMDs or for PMAs not adjacent to the PMD. If it is implemented, it shall be as described in this subclause (83.5.8).

The PMA sublayer may provide a local loopback function. The function involves looping back each input lane to the corresponding output lane. Each bit received from the PMA:IS_UNITDATA_*i*.request(tx_bit) primitive is looped back in the direction of the PCS using the PMA:IS_UNITDATA_*i*.indication(rx_bit) primitive.

During local loopback, the PMA performs normal bit muxing of PCSLs per 83.5.2 onto the lanes in the Tx direction toward the service interface below the PMA.

Ability to perform this function is indicated by the Local_loopback_ability status variable. If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.8.0 (45.2.1.7.15). A device is placed in local loopback mode when the Local_loopback_enable control variable is set to one, and removed from local loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD control 1 register (bit 1.0.0, see 45.2.1.1.5).

83.5.9 PMA remote loopback mode (optional)

PMA remote loopback mode is optional. If implemented, it shall be as described in this subclause (83.5.9).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Remote loopback, if provided, should be implemented in a PMA sublayer close enough to the PMD to maintain the bit sequence on each individual PMD lane. When remote loopback is enabled, each bit received over a lane of the service interface below the PMA via *inst*:IS_UNITDATA_*i*.indication is looped back to the corresponding output lane toward the PMD via *inst*:IS_UNITDATA_*i*.request. Note that the service interface below the PMA can be provided by the FEC, PMD, or another PMA sublayer.

During remote loopback, the PMA performs normal bit muxing of PCSLs per 83.5.2 onto the lanes in the Rx direction towards the PMA client.

The ability to perform this function is indicated by the Remote_loopback_ability status variable. If a Clause 45 MDIO is implemented, this variable is accessible through bit 1.13.15 (45.2.1.12.1). A device is placed in remote loopback mode when the Remote_loopback_enable control variable is set to one, and removed from remote loopback mode when this variable is set to zero. If a Clause 45 MDIO is implemented, this variable is accessible through PMA/PMD Control register 1 (bit 1.0.1, see 45.2.1.1.4).

83.5.10 PMA test patterns (optional)

Where the output lanes of the PMA appear on a physically instantiated interface XLAUI/CAUI-n or the PMD service interface (whether or not it is physically instantiated), the PMA may optionally generate and detect test patterns. These test patterns are used to test adjacent layer interfaces for an individual PMA sublayer or to perform testing between a physically instantiated interface of a PMA sublayer and external testing equipment.

The ability to generate each of the respective test patterns in each direction of transmission are indicated by the PRBS9_Tx_generator_ability, PRBS9_Rx_generator_ability, PRBS31_Tx_generator_ability, and PRBS31_Rx_generator_ability status variables, which if a Clause 45 MDIO is implemented are accessible through bits 1.1500.5, 1.1500.4, 1.1500.3, and 1.1500.1, respectively (see 45.2.1.169).

The ability to check PRBS31 test patterns in each direction of transmission are indicated by the PRBS31_Tx_checker_ability and PRBS31_Rx_checker_ability status variables, which, if a Clause 45 MDIO is implemented, are accessible through bits 1.1500.2 and 1.1500.0, respectively (see 45.2.1.169).

If supported, when send Tx PRBS31 test pattern is enabled by the PRBS31_enable and PRBS_Tx_gen_enable control variables, the PMA shall generate a PRBS31 pattern (as defined in 49.2.8) on each of the lanes toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. To avoid correlated crosstalk, it is highly recommended that the PRBS31 patterns generated on each lane be generated from independent, random seeds or at a minimum offset of 20 000 UI between the PRBS31 sequence on any lane and any other lane. When send Tx PRBS31 test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 83.5.2. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Tx_gen_enable control variables are accessible through bits 1.1501.7 and 1.1501.3 (see 45.2.1.170).

If supported, when send Rx PRBS31 test pattern is enabled by the PRBS31_enable and PRBS_Rx_gen_enable control variables, the PMA shall generate a PRBS31 pattern on each of the lanes toward the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive. While this test pattern is enabled, the PMA also generates PMA:IS_SIGNAL.indication(SIGNAL_OK) toward the PMA client independent of the link status at the service interface below the PMA. When send Rx PRBS31 test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 83.5.2. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Rx_gen_enable control variables are accessible through bits 1.1501.7 and 1.1501.1 (see 45.2.1.170).

If supported, when check Tx PRBS31 test pattern mode is enabled by the PRBS31_enable and PRBS_Tx_check_enable control variables, the PMA shall check for the PRBS31 pattern on each of the lanes received from the PMA client via the PMA:IS_UNITDATA_*i*.request primitive. The checker shall

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

increment the test-pattern error counter by one for each incoming bit error in the PRBS31 pattern for isolated single bit errors. Implementations should be capable of counting at least one error whenever one or more errors occur in a sliding 1000-bit window. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Tx_check_enable control variables are accessible through bits 1.1501.7 and 1.1501.2 (see 45.2.1.170). The Tx test-pattern error counters Ln0_PRBS_Tx_test_err_counter through Ln9_PRBS_Tx_test_err_counter count, per lane, errors in detecting the PRBS31 pattern on the lanes from the PMA client. If a Clause 45 MDIO is implemented, these counters are accessible through registers 1.1600 through 1.1609 (see 45.2.1.173). When check Tx PRBS31 test pattern is disabled, the PMA expects normal traffic and test-pattern error counting does not continue. While in check Tx PRBS31 test-pattern mode, bit multiplexing continues as described in 83.5.2. Note that bit multiplexing of per-lane PRBS31 may produce a signal which is not meaningful for downstream sublayers.

If supported, when check Rx PRBS31 test-pattern mode is enabled by the PRBS31_enable and PRBS_Rx_check_enable control variables, the PMA shall check for the PRBS31 pattern on each of the lanes received from the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.indication primitive. If a Clause 45 MDIO is implemented, the PRBS31_enable and PRBS_Rx_check_enable control variables are accessible through bits 1.1501.7 and 1.1501.0 (see 45.2.1.170). The Rx test-pattern error counters Ln0_PRBS_Rx_test_err_counter through Ln9_PRBS_Rx_test_err_counter count, per lane, errors in detecting the PRBS31 pattern on the lanes from the service interface below the PMA. If a Clause 45 MDIO is implemented, these counters are accessible through registers 1.1700 through 1.1709 (see 45.2.1.174). While in check Rx PRBS31 test-pattern mode, the PMA:IS_SIGNAL.indication primitive does not indicate a valid signal. When check Rx PRBS31 test pattern is disabled, the PMA returns to normal operation performing bit multiplexing as described in 83.5.2.

If supported, when send Tx PRBS9 test-pattern mode is enabled by the PRBS9_enable and PRBS_Tx_gen_enable control variables, the PMA shall generate a PRBS9 pattern (as defined in Table 68–6) on each lane toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. If a Clause 45 MDIO is implemented, the PRBS9_enable and PRBS_Tx_gen_enable control variables are accessible through bits 1.1501.6 and 1.1501.3 (see 45.2.1.170). When send Tx PRBS9 test-pattern mode is disabled, the PMA returns to normal operation performing bit multiplexing as described in 83.5.2.

If supported, when send Rx PRBS9 test-pattern mode is enabled by the PRBS9_enable and PRBS_Rx_gen_enable control variables, the PMA shall generate a PRBS9 pattern on each lane toward the PMA client via the PMA:IS_UNITDATA_*i*.indication primitive. The PMA will also generate PMA:IS_SIGNAL.indication(SIGNAL_OK) toward the PMA client independent of the link status at the service interface below the PMA. If a Clause 45 MDIO is implemented, the PRBS9_enable and PRBS_Rx_gen_enable control variables are accessible through bits 1.1501.6 and 1.1501.1 (see 45.2.1.170). When send Rx PRBS9 test-pattern mode is disabled, the PMA returns to normal operation performing bit multiplexing as described in 83.5.2.

Note that PRBS9 is intended to be checked by external test gear, and no PRBS9 checking function is provided within the PMA.

Transmit square wave test-pattern mode optionally applies to each lane of the Tx direction PMA towards a physically instantiated XLAUI/CAUI-n or towards the PMD service interface whether or not it is physically instantiated. The ability to perform this function is indicated by the Square_wave_ability status variable. If a Clause 45 MDIO is implemented, the Square_wave_ability status variable is accessible through the Square wave test ability bit 1.1500.12 (see 45.2.1.169). If implemented, the transmit square wave test-pattern mode is enabled by control variables Square_wave_enable_0 through Square_wave_enable_9. If a Clause 45 MDIO is implemented, these control variables are accessible through the square wave testing control and status register bits 1.1510.0 through 1.1510.9 (limited to the number of lanes of the service interface below the PMA, see 45.2.1.171). When enabled, the PMA shall generate a square wave test pattern (8 ones followed by 8 zeros) on the square wave enabled lanes toward the service interface below the PMA via the *inst*:IS_UNITDATA_*i*.request primitive. Lanes for which square wave is not enabled will transmit normal

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

data resulting from the bit multiplexing operations described in 83.5.2 or test patterns as determined by other registers. When transmit square wave test pattern is disabled for all lanes, the PMA will perform normal operation performing bit multiplexing as described in 83.5.2 or transmit test patterns as determined by other registers.

83.5.11 Energy Efficient Ethernet

When the optional Energy Efficient Ethernet (EEE) deep sleep capability is supported and the PMA service interface is physically instantiated as XLAUI or CAUI-n, the additional functions listed in this subclause are required. These functions enable the communication of service interface parameters that are essential to the operation of the EEE deep sleep capability. The timing parameters for EEE operation are shown in Table 83–2.

Table 83–2—EEE timing parameters

Timer	Symbol	Min.	Max.	Units
PMA quiet signal duration	T_{pq}	200	225	ns
Energy detect hold-off time	T_{ho}	750	800	ns
Time to assert PMA quiet detect	T_{dq}	25	50	ns
Time to assert PMA alert detect	T_{da}	—	25	ns
Time to hold rx_lpi_active = true	T_{ht}	4000	5500	ns

83.5.11.1 PMA quiet and alert signals

The PMA quiet and alert signals are generated on each lane with a self-synchronizing scrambler. The scrambler shall produce the same result as the implementation shown in Figure 83–7. This implements the scrambler polynomial defined by Equation (83–1).

$$G(x) = 1 + x^{28} + x^{31} \tag{83–1}$$

To generate the PMA quiet signal the input to the scrambler shall be 0. To generate the PMA alert signal the input to the scrambler shall be 1.

The initial state the scrambler of a given lane of PMA service interface is chosen to minimize the correlation between lanes.

83.5.11.2 Detection of PMA quiet and alert signals

Each lane detects the PMA quiet and alert signals at the output of a self-synchronizing descrambler that implements the polynomial defined in Equation (83–1). The descrambler shall produce the same result as the implementation shown in Figure 83–8.

The output of the descrambler is considered in consecutive, non-overlapping blocks of 256 bits. If the number of zeros detected in a given 256-bit block is greater than or equal 224, then the lane shall indicate that the PMA quiet signal is detected. If the number of ones detected in a given block is greater than or equal to 224, then the lane shall indicate that the PMA alert signal has been detected. Otherwise, the lane infers

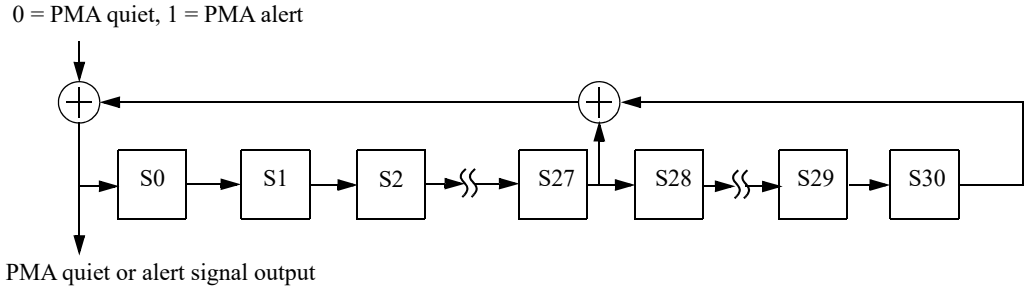

Figure 83–7—Scrambler for PMA quiet and alert signals

that normal data is being received and shall not indicate that either the PMA quiet or PMA alert signal has been detected.

The PMA shall indicate that the quiet signal is detected when all lanes of the PMA service interface have detected the quiet signal. The PMA shall indicate that the alert signal is detected when all lanes of the PMA service interface have detected the alert signal. Otherwise, the PMA infers that normal data is being received and shall not indicate that either the PMA quiet or PMA alert signal has been detected.

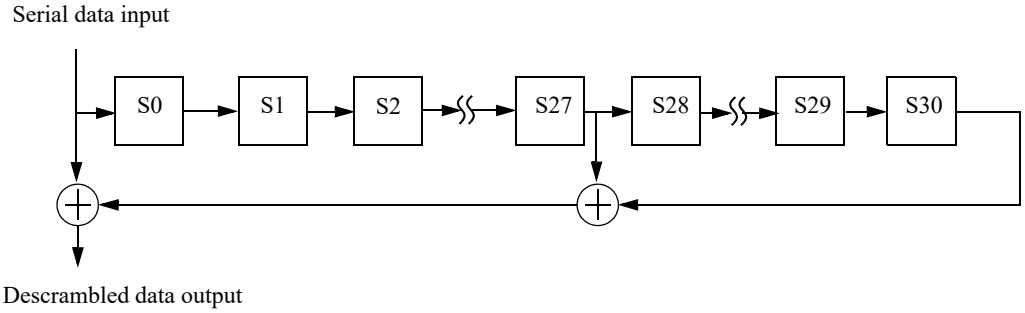

Figure 83–8—Descrambler for PMA quiet and alert signals

83.5.11.3 Additional transmit functions in the Tx direction

If the PMA client is the PCS, BASE-R FEC, or RS-FEC sublayer or is a PMA sublayer where the number of input lanes is not equal to the number of output lanes, then the PMA sublayer shall insert the PMA quiet and alert signals as follows: When the value of tx_mode is QUIET, the PMA inserts the PMA quiet signal defined in 83.5.11.1. When the value of tx_mode is ALERT, the PMA inserts the PMA alert signal defined in 83.5.11.1. For all other values of tx_mode, the PMA output is defined by the bit multiplexing function.

If XLAUI or CAUI-n is permitted to shut down (see 83.3), the variable aui_tx_mode shall be assigned the current value of tx_mode with the following exception. When tx_mode transitions from DATA to QUIET, the value of aui_tx_mode is held at DATA and the timer pma_quiet_timer (T_{pq}) is started. If tx_mode is QUIET when the timer expires, then aui_tx_mode is set to QUIET. If tx_mode is set to a value other than QUIET before the timer expires, then aui_tx_mode is set to DATA.

If XLAUI or CAUI-n is not permitted to shut down, aui_tx_mode shall be assigned the value DATA.

PMA functions in the Tx direction may be disabled in order to conserve energy while aui_tx_mode is QUIET.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

83.5.11.4 Additional receive functions in the Tx direction

For a PMA that is separated from the PCS by XLAUI or CAUI-n, the value of tx_mode shall be assigned as follows: If the PMA quiet signal is detected, the value of tx_mode is set to QUIET. If the PMA alert signal is detected, the value of tx_mode is set to ALERT. Otherwise, the value of tx_mode is DATA.

If XLAUI or CAUI-n is permitted to shut down (see 83.3), then the variable aui_rx_mode shall be assigned as follows: The variable aui_rx_mode is initialized to DATA upon PMA power on or reset. When the PMA quiet signal is detected, the timer hold_off_timer (T_{ho}) is started. If the PMA alert signal is not detected before the timer expires, then aui_rx_mode is set to QUIET and SIGNAL_DETECT is set to FAIL. While aui_rx_mode is QUIET, it shall be set to DATA when SIGNAL_DETECT transitions from FAIL to OK. The value of tx_mode is inferred to be ALERT and the timer alert_timer (T_a) started upon a transition of aui_rx_mode from QUIET to DATA. The value of ALERT shall be held until alert_timer expires after which the value of tx_mode shall be set to DATA.

If XLAUI or CAUI-n is not permitted to shut down, aui_rx_mode shall be assigned the value DATA.

PMA functions in the Tx direction may be disabled in order to conserve energy while aui_rx_mode is QUIET.

83.5.11.5 Additional transmit functions in the Rx direction

For a PMA that is separated from the PCS by XLAUI or CAUI-n, the value of rx_mode shall be assigned as follows. The value of rx_mode is initialized to DATA upon PMA power on or reset. When the PMA quiet signal is detected, the timer hold_off_timer (T_{ho}) is started. If the PMA alert signal is not detected before the timer expires, then rx_mode is set to QUIET. While rx_mode is QUIET, it shall be set to DATA when the PMA alert signal is detected or energy_detect (or SIGNAL_OK) transitions from false to true.

The value of rx_tx_mode may be passed via the PMA:IS_RX_TX_MODE.indication primitive, otherwise it shall be assigned as follows. If the PMA quiet signal is detected, the value of rx_tx_mode is set to QUIET. The value of rx_tx_mode is set to be ALERT and the timer alert_timer (T_a) started upon a transition of the value of rx_mode from QUIET to DATA. The value of ALERT shall be held until alert_timer expires after which the value of rx_tx_mode shall be set to DATA.

If XLAUI or CAUI-n is permitted to shut down (see 83.3), the variable aui_tx_mode shall be assigned the current value of rx_tx_mode with the following exception. When rx_tx_mode transitions from DATA to QUIET, the value of aui_tx_mode is held at DATA and the timer pma_quiet_timer (T_{pq}) is started. If rx_tx_mode is QUIET when the timer expires, then aui_tx_mode is set to QUIET. If rx_tx_mode is set to a value other than QUIET before the timer expires, then aui_tx_mode is set to DATA.

If XLAUI or CAUI-n is not permitted to shut down, aui_tx_mode shall be assigned the value DATA.

PMA functions in the Rx direction may be disabled in order to conserve energy while aui_tx_mode is QUIET.

If the PMA is the client of the BASE-R FEC or RS-FEC sublayer or a PMA sublayer where the number of input lanes is not equal to the number of output lanes, then the PMA sublayer shall insert the PMA quiet and alert signals as follows. When the value of rx_tx_mode is QUIET, the PMA inserts the PMA quiet signal defined in 83.5.11.1. When the value of rx_tx_mode is ALERT, the PMA inserts the PMA alert signal defined in 83.5.11.1. For all other values of rx_tx_mode, the PMA output is defined by the bit multiplexing function.

83.5.11.6 Additional receive functions in the Rx direction

For a PMA that is separated from the PMD by XLAUI or CAUI, the value of energy_detect shall be assigned as follows. The value of energy_detect is initialized to true upon PMA power on or reset. When the value of rx_mode is set to QUIET, the value of energy_detect is set to false. The value of energy_detect is set to true when the PMA alert signal is detected or SIGNAL_DETECT transitions from FAIL to OK.

The value of rx_tx_mode shall be inferred as follows. If the PMA quiet signal is detected, the value of rx_tx_mode is set to QUIET. The value of rx_tx_mode is set to be ALERT and the timer alert_timer (T_a) started upon a transition of the value of rx_mode from QUIET to DATA. The value of ALERT shall be held until alert_timer expires after which the value of rx_tx_mode shall be set to DATA.

If XLAUI or CAUI is permitted to shut down (see 83.3), then the variable aui_rx_mode shall be assigned as follows. The variable aui_rx_mode is initialized to DATA upon PMA power on or reset. When the PMA quiet signal is detected, the timer hold_off_timer (T_{ho}) is started. If the PMA alert signal is not detected before the timer expires, then aui_rx_mode is set to QUIET. While aui_rx_mode is QUIET, it shall be set to DATA when SIGNAL_DETECT transitions from FAIL to OK. The value of tx_mode is assigned to be ALERT and the timer alert_timer (T_a) started upon a transition of aui_rx_mode from QUIET to DATA. The value of ALERT shall be held until alert_timer expires after which the value of tx_mode shall be set to DATA.

If XLAUI or CAUI is not permitted to shut down, aui_rx_mode shall be assigned the value DATA.

PMA functions in the Rx direction may be disabled in order to conserve energy while aui_rx_mode is QUIET.

83.5.11.7 Support for BASE-R FEC

When the PMA is a client of the BASE-R FEC sublayer, the rx_lpi_active parameter of the IS_RX_LPI_ACTIVE.request primitive shall be defined as follows. The value of rx_lpi_active is initialized to false upon PMA power on or reset. The value of rx_lpi_active is set to true and the timer rx_lpi_active_timer (T_{ht}) started upon a transition of the value of rx_mode from QUIET to DATA. When the timer expires, the value of rx_lpi_active is set to false.

83.6 PMA MDIO function mapping

The optional MDIO capability described in Clause 45 describes several variables that provide control and status information for and about the PMA. Since a given implementation may employ more than one PMA sublayer, the PMA control and status information is organized into multiple addressable instances, one for each possible PMA sublayer. See 45.2.1 and 83.1.4 for the allocation of MMD addresses to PMA sublayers. Control and status registers for MMD 8, 9, 10, and 11 will use the Extended PMA control and status registers at identical locations to those for MMD 1.

Mapping of MDIO control variables to PMA control variables is shown in Table 83–3. Mapping of MDIO status variables to PMA status variables is shown in Table 83–4. Mapping of MDIO counter to PMA counters is shown in Table 83–5. These tables provide the register and bit numbers for the PMA addressed as MMD 1. For implementations with multiple PMA sublayers, additional PMA sublayers use the corresponding register and bit numbers in MMDs 8, 9, 10, and 11 as necessary.

83.7 Protocol implementation conformance statement (PICS) proforma for Clause 83, Physical Medium Attachment (PMA) sublayer, type 40GBASE-R and 100GBASE-R[148]

83.7.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 83, Physical Medium Attachment (PMA) sublayer, type 40GBASE-R and 100GBASE-R, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the same, can be found in Clause 21.

83.7.2 Identification

83.7.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

83.7.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 83, Physical Medium Attachment (PMA) sublayer, type 40GBASE-R and 100GBASE-R
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[148]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

84. Physical Medium Dependent sublayer and baseband medium, type 40GBASE-KR4

84.1 Overview

This clause specifies the 40GBASE-KR4 PMD. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 84–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

Table 84–1—Physical Layer clauses associated with the 40GBASE-KR4 PMD

Associated clause	40GBASE-KR4
81—RS	Required
81—XLGMII[a]	Optional
82—PCS for 40GBASE-R	Required
74—BASE-R FEC	Optional
83—PMA for 40GBASE-R	Required
83A—XLAUI	Optional
73—Auto-Negotiation	Required
78—Energy Efficient Ethernet	Optional

[a]The XLGMII is an optional interface. However, if the XLGMII is not implemented, a conforming implementation behaves functionally as though the RS and XLGMII were present.

Figure 84–1 shows the relationship of the 40GBASE-KR4 PMD and MDI (shown shaded) with other sublayers to the ISO/IEC Open System Interconnection (OSI) reference model.

40GBASE-KR4 PHYs with the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78).

84.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 40GBASE-KR4 PMD. The service interface for this PMD is described in an abstract manner and does not imply any particular implementation. The PMD service interface supports the exchange of encoded data. The PMD translates the encoded data to and from signals suitable for the medium.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

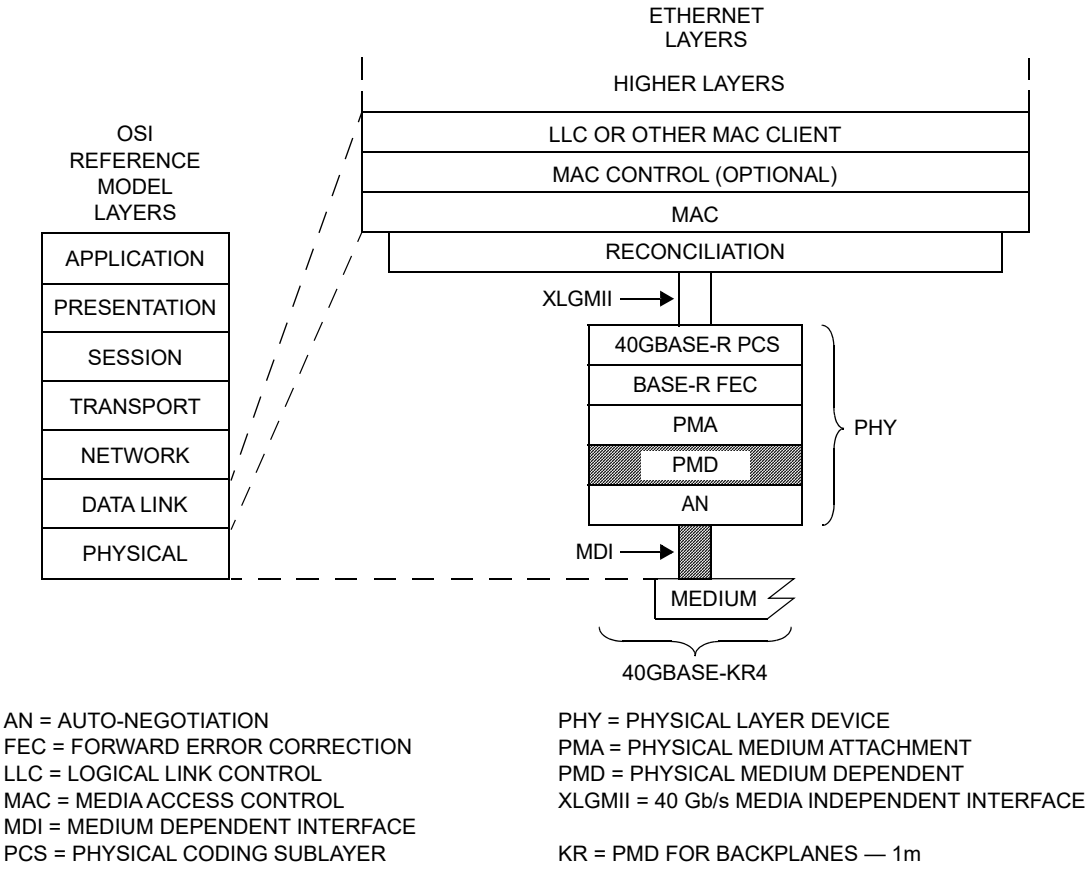

Figure 84–1—40GBASE-KR4 PMD relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

The 40GBASE-KR4 PMD has four parallel bit streams, hence $i = 0$ to 3.

The PMA (or the PMD) continuously sends four parallel bit streams to the PMD (or the PMA), one per lane, each at a nominal signaling rate of 10.3125 GBd.

SIGNAL_DETECT in 40GBASE-KR4 indicates the successful completion of the startup protocol on all four lanes.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the PMD:IS_UNITDATA_*i*.indication parameters are undefined.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The SIGNAL_DETECT parameter maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication primitive.

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78, 78.1.3.3.1), then the inter-sublayer service interface includes two additional primitives defined as follows:

PMD:IS_TX_MODE.request(tx_mode)
PMD:IS_RX_MODE.request(rx_mode)

The tx_mode parameter takes on one of up to three values: DATA, QUIET, or ALERT. When tx_mode = QUIET, transmission is disabled; when tx_mode = ALERT, the alert signal is transmitted (see 84.7.2).

The rx_mode parameter is used to communicate the state of the PCS LPI receive function and takes the value QUIET or DATA.

84.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 82.6.)

The 40GBASE-KR4 PHY may be extended using XLAUI as a physical instantiation of the inter-sublayer service interface between devices. If XLAUI is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

84.4 Delay constraints

The sum of the transmit and the receive delays at one end of the link contributed by the 40GBASE-KR4 PMD, AN, and the medium in one direction shall be no more than 2048 bit times (4 pause_quanta or 51.2 ns). It is assumed that the one way delay through the medium is no more than 320 bit times (8 ns).

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

84.5 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and specified at the points SP1 to SP6 shown in Figure 80–7 and Figure 80–8.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns.

For more information on Skew and Skew Variation see 80.5.

84.6 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. If MDIO is implemented, it shall map MDIO control variables to PMD control variables as shown in Table 84–2, and MDIO status variables to PMD status variables as shown in Table 84–3.

Table 84–2—MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	Global_PMD_transmit_disable
PMD transmit disable 3	PMD transmit disable register	1.9.4	PMD_transmit_disable_3
PMD transmit disable 2	PMD transmit disable register	1.9.3	PMD_transmit_disable_2
PMD transmit disable 1	PMD transmit disable register	1.9.2	PMD_transmit_disable_1
PMD transmit disable 0	PMD transmit disable register	1.9.1	PMD_transmit_disable_0
Restart training	BASE-R PMD control register	1.150.0	mr_restart_training
Training enable	BASE-R PMD control register	1.150.1	mr_training_enable

Table 84–3—MDIO/PMD status variable mapping

MDIO status variable	PMA/PMD register name	Register/ bit number	PMD status variable
Fault	PMA/PMD status 1 register	1.1.7	PMD_fault
Transmit fault	PMA/PMD status 2 register	1.8.11	PMD_transmit_fault

Training failure 0	BASE-R PMD status register	1.151.3	training_failure_0

84.7 PMD functional specifications

84.7.1 Link block diagram

The 40GBASE-KR4 PMD uses the same Link block diagram as 10GBASE-KX4, as defined in 71.6.1.

84.7.2 PMD transmit function

The PMD Transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate electrical signals. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = one.

If the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option is supported (see Clause 78), then when tx_mode is set to ALERT, the PMD transmit function shall transmit a repeating 16-bit pattern, hexadecimal 0xFF00, on each lane. This sequence is transmitted regardless of the value of tx_bit presented by the PMD:IS_UNITDATA_i.request primitive. When tx_mode is ALERT, the transmitter equalizer taps shall be set to the preset state specified in 72.6.10.2.3.1. When tx_mode is QUIET, the transmitter shall be disabled as specified in 84.7.6. For all other states of tx_mode, the driver coefficients are restored to their states resolved during training.

84.7.3 PMD receive function

The PMD Receive function shall convert the four electrical signals from the MDI into four bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

PMD:IS_UNITDATA_3.indication. A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = one.

84.7.4 Global PMD signal detect function

The Global PMD signal detect function shall continuously report the message PMD:IS_SIGNAL.indication (SIGNAL_DETECT) to the PMD service interface. SIGNAL_DETECT, while normally intended to be an indicator of signal presence, is used by 40GBASE-KR4 to indicate the successful completion of the startup protocol on all lanes. When the PHY supports the optional EEE capability with the deep sleep mode, PMD_SIGNAL.indication is also used to indicate when the ALERT signal is detected, which corresponds to the beginning of a refresh or a wake.

When the PHY does not support the EEE capability or if the PHY supports the EEE capability and rx_mode is set to DATA, SIGNAL_DETECT shall be set to FAIL following system reset or the manual reset of the training state diagram. Upon successful completion of training on all lanes, SIGNAL_DETECT shall be set to OK.

When the PHY does not support the EEE capability or if the PHY supports the EEE capability and rx_mode is set to DATA, if training is disabled by management, SIGNAL_DETECT shall be set to OK. When the PHY supports the EEE capability with the deep sleep mode, SIGNAL_DETECT is set to FAIL following a transition from rx_mode = DATA to rx_mode = QUIET. When rx_mode = QUIET, SIGNAL_DETECT shall be set to OK within 500 ns following the application of a signal at the receiver input that corresponds to an ALERT transmission (see 84.7.2) from the link partner. While rx_mode = QUIET, SIGNAL_DETECT shall be held at FAIL as long as the signal at the receiver input corresponds to a QUIET tx_mode (see 84.7.6) of the link partner.

If the MDIO interface is implemented, then Global_PMD_signal_detect (1.10.0) shall be continuously set to the value of SIGNAL_DETECT as described in 45.2.1.9.7.

84.7.5 PMD lane-by-lane signal detect function

If the MDIO interface is implemented, then PMD_signal_detect_0 (1.10.1), PMD_signal_detect_1 (1.10.2), PMD_signal_detect_2 (1.10.3), and PMD_signal_detect_3 (1.10.4) shall be set to one or zero depending on whether a particular lane's signal_detect, as defined by the training state diagram in Figure 72–5, returns true or false (see 45.2.1.9).

84.7.6 Global PMD transmit disable function

The Global_PMD_transmit_disable function is mandatory if EEE with the deep sleep mode option is supported and is otherwise optional. When implemented, it allows all of the transmitters to be disabled with a single variable.

a) When the Global_PMD_transmit_disable variable is set to one, this function shall turn off all of the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage with TX disabled as specified in Table 72–7.
b) If a PMD_fault (84.7.9) is detected, then the PMD may turn off the electrical transmitter in all lanes.
c) Loopback, as defined in 84.7.8, shall not be affected by Global_PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off the transmitter after tx_mode is set to QUIET within a time and voltage level specified in 72.7.1.4. The PMD_transmit_disable function shall turn on the transmitter after tx_mode is set to DATA or ALERT within the time and voltage level specified in 72.7.1.4.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the MDIO interface is implemented, then this function shall map to the Global_PMD_transmit_disable bit as specified in 45.2.1.8.7.

84.7.7 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function is optional and allows the electrical transmitter in each lane to be selectively disabled. When this function is supported, it shall meet the following requirements:

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3) is set to one, this function shall turn off the transmitter associated with that variable such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage with TX disabled as specified in Table 72–7.
b) If a PMD_fault (84.7.9) is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the electrical transmitter in each lane.
c) Loopback, as defined in 84.7.8, shall not be affected by PMD_transmit_disable_*i*.

84.7.8 Loopback mode

Local loopback shall be provided by the adjacent PMA (see 83.5.8) for the 40GBASE-KR4 PMD as a test function to the device. When loopback mode is enabled, transmission requests passed to each transmitter are sent directly to the corresponding receiver, overriding any signal detected by each receiver on its attached link. Note that loopback mode does not affect the state of the transmitter that continues to send data (unless disabled). The method of implementing loopback mode is not defined by this standard.

Control of the loopback function is specified in 45.2.1.1.5.

NOTE 1—The signal paths that are exercised in the loopback mode are implementation specific, but it is recommended that these signal paths encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

84.7.9 PMD_fault function

If the MDIO is implemented, PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault.

84.7.10 PMD transmit fault function

The PMD_transmit_fault function is optional. The faults detected by this function are implementation specific, but should not include the assertion of the Global_PMD_transmit_disable function.

If a PMD_transmit_fault (optional) is detected, then the Global_PMD_transmit_disable function should also be asserted.

If the MDIO interface is implemented, then this function shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

84.7.11 PMD receive fault function

The PMD_receive_fault function is optional. The faults detected by this function are implementation specific.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

If the MDIO interface is implemented, then this function shall contribute to PMA/PMD Receive fault bit as specified in 45.2.1.7.5.

84.7.12 PMD control function

Each lane of the 40GBASE-KR4 PMD shall use the same control function as 10GBASE-KR, as defined in 72.6.10.

The random seed for the training pattern described in 72.6.10.2.6 shall be different for each of the lanes.

The variables rx_trained_*i*, frame_lock_*i*, training_*i,* and training_failure_*i* (where *i* goes from 0 to 3) report status for each lane and are equivalent to rx_trained, frame_lock, training, and training_failure as defined in 72.6.10.3.1.

If the MDIO interface is implemented, then this function shall map these variables to the appropriate bits in the BASE-R PMD status register (register 1.151) as specified in 45.2.1.96.

84.8 40GBASE-KR4 electrical characteristics

84.8.1 Transmitter characteristics

Transmitter electrical characteristics at TP1 for 40GBASE-KR4 shall be the same as 10GBASE-KR, as detailed in 72.7.1.1 through 72.7.1.11.

84.8.1.1 Test fixture

The test fixture defined for 10GBASE-KR in 72.7.1.1 shall be used on all lanes.

84.8.2 Receiver characteristics

Receiver electrical characteristics at TP4 for 40GBASE-KR4 shall be the same as 10GBASE-KR, as detailed in 72.7.2.1 through 72.7.2.5.

84.8.2.1 Receiver interference tolerance

The receiver interference tolerance tests shall be the same as those described for 10GBASE-KR in 72.7.2.1 and Annex 69A.

For 40GBASE-KR4, each lane shall be tested individually using the methodology defined in Annex 69A with the transmitters of the unused lanes active and terminated by the reference impedance.

84.9 Interconnect characteristics

Informative interconnect characteristics for 40GBASE-KR4 are provided in Annex 69B.

84.10 Environmental specifications

84.10.1 General safety

Equipment subject to this clause shall conform to the general safety requirements in J.2.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

84.10.2 Network safety

The designer is urged to consult the relevant local, national, and international safety regulations to ensure compliance with the appropriate requirements.

84.10.3 Installation and maintenance guidelines

It is recommended that sound installation practice, as defined by applicable local codes and regulations, be followed in every instance in which such practice is applicable.

84.10.4 Electromagnetic compatibility

A system integrating the 40GBASE-KR4 PHY shall comply with applicable local and national codes for the limitation of electromagnetic interference.

84.10.5 Temperature and humidity

A system integrating the 40GBASE-KR4 PHY is expected to operate over a reasonable range of environmental conditions related to temperature, humidity, and physical handling (such as shock and vibration). Specific requirements and values for these parameters are considered to be beyond the scope of this standard.

84.11 Protocol implementation conformance statement (PICS) proforma for Clause 84, Physical Medium Dependent sublayer and baseband medium, type 40GBASE-KR4[149]

84.11.1 Introduction

The supplier of a protocol implementation that is claimed to conform to Clause 84, Physical Medium Dependent sublayer and baseband medium, type 40GBASE-KR4, shall complete the following protocol implementation conformance statement (PICS) proforma.

A detailed description of the symbols used in the PICS proforma, along with instructions for completing the PICS proforma, can be found in Clause 21.

84.11.2 Identification

84.11.2.1 Implementation identification

Supplier[1]	
Contact point for inquiries about the PICS[1]	
Implementation Name(s) and Version(s)[1,3]	
Other information necessary for full identification—e.g., name(s) and version(s) for machines and/or operating systems; System Name(s)[2]	
NOTE 1—Required for all implementations. NOTE 2—May be completed as appropriate in meeting the requirements for the identification. NOTE 3—The terms Name and Version should be interpreted appropriately to correspond with a supplier's terminology (e.g., Type, Series, Model).	

84.11.2.2 Protocol summary

Identification of protocol standard	IEEE Std 802.3-2022, Clause 84, Physical Medium Dependent sublayer and baseband medium, type 40GBASE-KR4
Identification of amendments and corrigenda to this PICS proforma that have been completed as part of this PICS	
Have any Exception items been required? No [ ] Yes [ ] (See Clause 21; the answer Yes means that the implementation does not conform to IEEE Std 802.3-2022.)	

Date of Statement	

[149]*Copyright release for PICS proformas:* Users of this standard may freely reproduce the PICS proforma in this subclause so that it can be used for its intended purpose and may further publish the completed PICS.

85. Physical Medium Dependent sublayer and baseband medium, type 40GBASE-CR4 and 100GBASE-CR10

85.1 Overview

This clause specifies the 40GBASE-CR4 PMD and the 100GBASE-CR10 PMD (including MDI) and the baseband medium. When forming a complete Physical Layer, a PMD shall be connected to the appropriate PMA as shown in Table 85–1, to the medium through the MDI and to the management functions that are optionally accessible through the management interface defined in Clause 45, or equivalent.

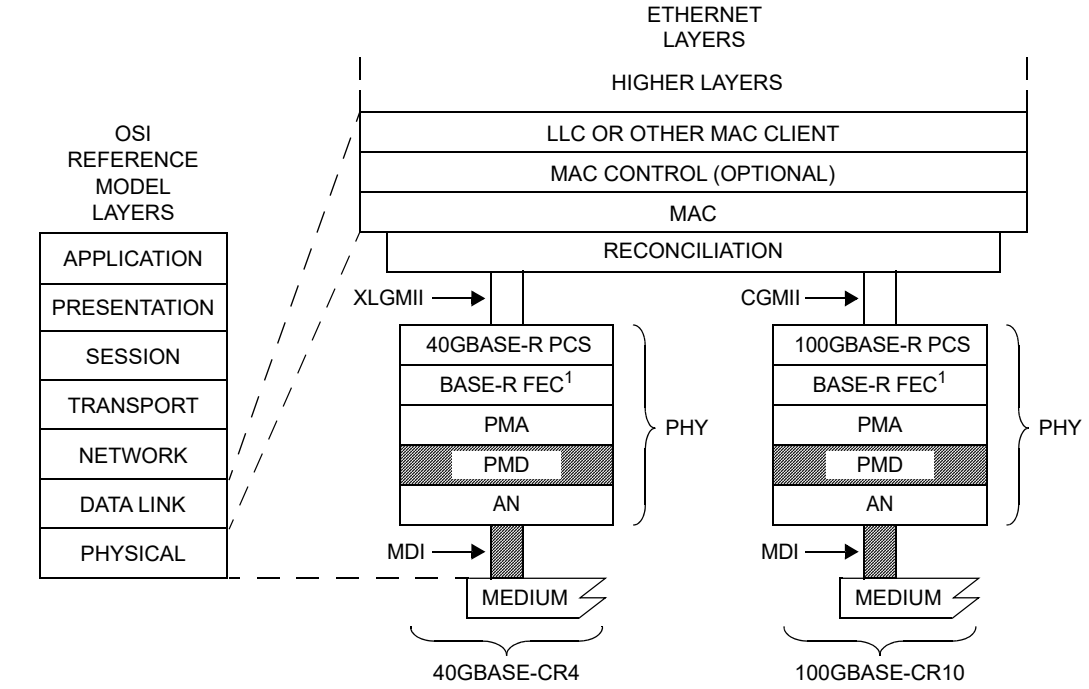

Table 85–1—Physical Layer clauses associated with the 40GBASE-CR4 and 100GBASE-CR10 PMDs

Associated clause	40GBASE-CR4	100GBASE-CR10
81—RS	Required	Required
81—XLGMII[a]	Optional	Not applicable
81—CGMII[b]	Not applicable	Optional
82—PCS for 40GBASE-R	Required	Not applicable
82—PCS for 100GBASE-R	Not applicable	Required
74—BASE-R FEC	Optional	Optional
83—PMA for 40GBASE-R	Required	Not applicable
83—PMA for 100GBASE-R	Not applicable	Required
83A—XLAUI	Optional	Not applicable
83A—CAUI-10	Not applicable	Optional
83D—CAUI-4	Not applicable	Optional
73—Auto-Negotiation	Required	Required
78—Energy Efficient Ethernet	Optional	Optional

[a]The XLGMII is an optional interface. However, if the XLGMII is not implemented, a conforming implementation behaves functionally as though the RS and XLGMII were present.
[b]The CGMII is an optional interface. However, if the CGMII is not implemented, a conforming implementation behaves functionally as though the RS and CGMII were present.

Figure 85–1 shows the relationship of the 40GBASE-CR4 and 100GBASE-CR10 PMD sublayers and MDI to the ISO/IEC Open System Interconnection (OSI) reference model.

AN = AUTO-NEGOTIATION
CGMII = 100 Gb/s MEDIA INDEPENDENT INTERFACE
FEC = FORWARD ERROR CORRECTION
LLC = LOGICAL LINK CONTROL
MAC = MEDIA ACCESS CONTROL
MDI = MEDIUM DEPENDENT INTERFACE
PCS = PHYSICAL CODING SUBLAYER
PHY = PHYSICAL LAYER DEVICE
PMA = PHYSICAL MEDIUM ATTACHMENT
PMD = PHYSICAL MEDIUM DEPENDENT
XLGMII = 40 Gb/s MEDIA INDEPENDENT INTERFACE

CR = PMD FOR COPPER — 7 m
NOTE 1—OPTIONAL

Figure 85–1—40GBASE-CR4 and 100GBASE-CR10 PMDs relationship to the ISO/IEC Open Systems Interconnection (OSI) reference model and the IEEE 802.3 Ethernet model

100GBASE-CR10 and 40GBASE-CR4 PHYs with the optional Energy Efficient Ethernet (EEE) capability with the deep sleep mode option may optionally enter the Low Power Idle (LPI) mode to conserve energy during periods of low link utilization (see Clause 78).

85.2 Physical Medium Dependent (PMD) service interface

This subclause specifies the services provided by the 40GBASE-CR4 and 100GBASE-CR10 PMDs. The service interfaces for these PMDs are described in an abstract manner and do not imply any particular implementation. The PMD service interface supports the exchange of encoded data between the PMA and PMD entities. The PMD translates the encoded data to and from signals suitable for the specified medium.The PMD service interface is an instance of the inter-sublayer service interface defined in 80.3. The PMD service interface primitives are summarized as follows:

PMD:IS_UNITDATA_*i*.request
PMD:IS_UNITDATA_*i*.indication
PMD:IS_SIGNAL.indication

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The 40GBASE-CR4 PMD has four parallel bit streams, hence *i* = 0 to 3 for 40GBASE-CR4, and the 100GBASE-CR10 PMD has ten parallel bit streams, hence *i* = 0 to 9 for 100GBASE-CR10. The PMA (or the PMD) continuously sends four or ten parallel bit streams to the PMD (or the PMA), one per lane, each at a nominal signaling rate of 10.3125 GBd.

For 40GBASE-CR4, SIGNAL_DETECT indicates the successful completion of the startup protocol on all four lanes. For 100GBASE-CR10, SIGNAL_DETECT indicates the successful completion of the startup protocol on all ten lanes.

The SIGNAL_DETECT parameter can take on one of two values: OK or FAIL. When SIGNAL_DETECT = FAIL, the PMD:IS_UNITDATA_*i*.indication parameters are undefined.

The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication primitive.

If the optional EEE capability with the deep sleep mode option is supported (see 78.1.3.3.1) then the inter-sublayer service interface includes two additional primitives defined as follows:

PMD:IS_TX_MODE.request(tx_mode)
PMD:IS_RX_MODE.request(rx_mode)

The tx_mode parameter takes on one of up to three values: DATA, QUIET, or ALERT. When tx_mode = QUIET, transmission is disabled; when tx_mode = ALERT, the alert signal is transmitted (see 85.7.2).

The rx_mode parameter is used to communicate the state of the PCS LPI receive function and takes the value QUIET or DATA.

85.3 PCS requirements for Auto-Negotiation (AN) service interface

The PCS associated with this PMD is required to support the AN service interface primitive AN_LINK.indication defined in 73.9. (See 82.6.)

The 40GBASE-CR4 PHY may be extended using XLAUI, a physical instantiation of the inter-sublayer service interface between devices. Similarly, the 100GBASE-CR10 PHY may be extended using CAUI-n. If XLAUI or CAUI-n is instantiated, the AN_LINK(link_status).indication is relayed from the device with the PCS sublayer to the device with the AN sublayer by means at the discretion of the implementer. As examples, the implementer may employ use of pervasive management or employ a dedicated electrical signal to relay the state of link_status as indicated by the PCS sublayer on one device to the AN sublayer on the other device.

85.4 Delay constraints

A description of overall system delay constraints and the definitions for bit times and pause_quanta can be found in 80.4 and its references.

The sum of the transmit and the receive delays at one end of the link contributed by the 40GBASE-CR4 PMD and AN shall be no more than 4096 bit times (8 pause_quanta or 102.4 ns). The delay through the medium is not included.

The sum of the transmit and the receive delays at one end of the link contributed by the 100GBASE-CR10 PMD and AN shall be no more than 9728 bit times (19 pause_quanta or 97.28 ns). The delay through the medium is not included.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

85.5 Skew constraints

The Skew (relative delay) between the lanes is kept within limits so that the information on the lanes can be reassembled by the PCS. The Skew Variation is also limited to ensure that a given PCS lane always traverses the same physical lane. Skew and Skew Variation are defined in 80.5 and are specified at the points SP1 to SP6 shown in Figure 80–7 and Figure 80–8.

If the PMD service interface is physically instantiated so that the Skew at SP2 can be measured, then the Skew at SP2 is limited to 43 ns and the Skew Variation at SP2 is limited to 400 ps.

The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 shall be less than 600 ps.

The Skew at SP4 (the receiver MDI) shall be less than 134 ns and the Skew Variation at SP4 shall be less than 3.4 ns.

If the PMD service interface is physically instantiated so that the Skew at SP5 can be measured, then the Skew at SP5 shall be less than 145 ns and the Skew Variation at SP5 shall be less than 3.6 ns. For more information on Skew and Skew Variation, see 80.5.

85.6 PMD MDIO function mapping

The optional MDIO capability described in Clause 45 defines several variables that provide control and status information for and about the PMD. Mapping of MDIO control variables to PMD control variables is illustrated in Table 85–2 for 40GBASE-CR4 and 100GBASE-CR10. Mapping of MDIO status variables to PMD status variables is illustrated in Table 85–3 for 40GBASE-CR4 and 100GBASE-CR10.

Table 85–2—40GBASE-CR4 and 100GBASE-CR10 MDIO/PMD control variable mapping

MDIO control variable	PMA/PMD register name	Register/ bit number	PMD control variable
Reset	PMA/PMD control 1 register	1.0.15	PMD_reset
Global PMD transmit disable	PMD transmit disable register	1.9.0	Global_PMD_transmit_disable
PMD transmit disable 9 to PMD transmit disable 0	PMD transmit disable register	1.9.10 to 1.9.1	PMD_transmit_disable_9 to PMD_transmit_disable_0

85.7 PMD functional specifications

85.7.1 Link block diagram

A 40GBASE-CR4 or 100GBASE-CR10 link in one direction is illustrated in Figure 85–2. For purposes of system conformance, the PMD sublayer is standardized at the test points described in this subclause. The electrical transmit signal is defined at TP2. Unless specified otherwise, all transmitter measurements and tests defined in Table 85–5 are made at TP2 utilizing the test fixture specified in 85.8.3.5. Unless specified otherwise, all receiver measurements and tests defined in 85.8.4 are made at TP3 utilizing the test fixture specified in 85.8.3.5. A mated connector pair has been included in both the transmitter and receiver specifications defined in 85.8.3 and 85.8.4. The maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is specified in 85.8.3.4.

The 40GBASE-CR4 and 100GBASE-CR10 channels are defined between the transmitter (TP0) and receiver blocks (TP5) to include the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss as illustrated in Figure 85–2. Annex 85A provides information on parameters associated with test points TP0 and TP5 that may not be testable in an implemented system. All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 85–2. The cable assembly test fixture of Figure 85–14 or its functional equivalent, is required for measuring the cable assembly specifications in 85.10 at TP1 and TP4. Two mated connector pairs and the cable assembly test fixture have been included in the cable assembly specifications defined in 85.10.

Transmitter and receiver differential controlled impedance printed circuit board insertion losses defined between TP0–TP1 and TP4–TP5 respectively are provided informatively in Annex 85A.

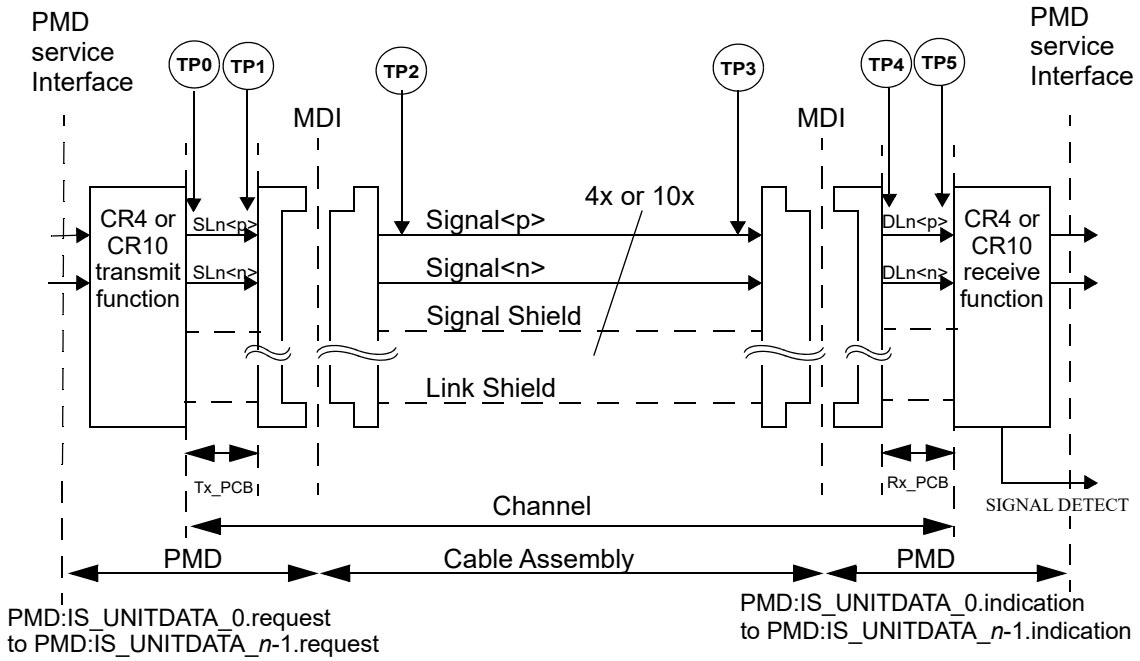

Figure 85–2—40GBASE-CR4 or 100GBASE-CR10 link (half link is illustrated)

Note that the source lanes (SL), signals SLn<p>, and SLn<n> are the positive and negative sides of the transmitters differential signal pairs and the destination lanes (DL) signals, DLn<p>, and DLn<n> are the positive and negative sides of the receivers differential signal pairs for lane n (n = 0, 1, 2, 3 or n = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9).

Table 85–4 describes the defined test points illustrated in Figure 85–2.

Table 85–4—40GBASE-CR4 and 100GBASE-CR10 test points

Test points	Description
TP0 to TP5	The 40GBASE-CR4 and 100GBASE-CR10 channels including the transmitter and receiver differential controlled impedance printed circuit board insertion loss and the cable assembly insertion loss.
TP1 to TP4	All cable assembly measurements are to be made between TP1 and TP4 as illustrated in Figure 85–2. The cable assembly test fixture of Figure 85–14 or its functional equivalent, is required for measuring the cable assembly specifications in 85.10 at TP1 and TP4.
TP0 to TP1 TP4 to TP5	A mated connector pair has been included in both the transmitter and receiver specifications defined in 85.8.3 and 85.8.4. The maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is specified in 85.8.3.4.
TP2	Unless specified otherwise, all transmitter measurements and tests defined in Table 85–5 are made at TP2 utilizing the test fixture specified in 85.8.3.5.
TP3	Unless specified otherwise, all receiver measurements and tests defined in 85.8.4 are made at TP3 utilizing the test fixture specified in 85.8.3.5.

85.7.2 PMD Transmit function

The 40GBASE-CR4 PMD Transmit function shall convert the four bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_3.request into four separate electrical signals. The four electrical signals shall then be delivered to the MDI, all according to the transmit electrical specifications in 85.8.3. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = one. The 100GBASE-CR10 PMD Transmit function shall convert the ten bit streams requested by the PMD service interface messages PMD:IS_UNITDATA_0.request to PMD:IS_UNITDATA_9.request into ten separate electrical signals. The ten electrical signals shall then be delivered to the MDI, all according to the transmit electrical specifications in 85.8.3. A positive output voltage of SL<p> minus SL<n> (differential voltage) shall correspond to tx_bit = one.

If the EEE capability with the deep sleep mode option is supported (see Clause 78) then when tx_mode is set to ALERT, the PMD transmit function shall transmit a repeating 16-bit pattern, hexadecimal 0xFF00, on each lane. This sequence is transmitted regardless of the value of tx_bit presented by the PMD:IS_UNITDATA_i.request primitive. When tx_mode is ALERT, the transmitter equalizer taps are set to the preset state specified in 72.6.10.2.3.1. When tx_mode is QUIET, the transmitter is disabled as specified in 85.7.6. For all other states of tx_mode, the driver coefficients are restored to their states resolved during training.

85.7.3 PMD Receive function

The 40GBASE-CR4 PMD Receive function shall convert the four electrical signals from the MDI into four bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_3.indication. A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = one. The 100GBASE-CR10 PMD Receive function shall convert the ten electrical signals from the MDI into ten bit streams for delivery to the PMD service interface using the messages PMD:IS_UNITDATA_0.indication to PMD:IS_UNITDATA_9.indication. A positive input voltage of DL<p> minus DL<n> (differential voltage) shall correspond to rx_bit = one.

85.7.4 Global PMD signal detect function

The Global PMD signal detect function shall continuously report the message PMD:IS_SIGNAL.indication (SIGNAL_DETECT) to the PMD service interface. SIGNAL_DETECT, while normally intended to be an indicator of signal presence, is used by 40GBASE-CR4 and 100GBASE-CR10 to indicate the successful completion of the startup protocol on all lanes. The SIGNAL_DETECT parameter defined in this clause maps to the SIGNAL_OK parameter in the PMD:IS_SIGNAL.indication primitive. When the PHY supports the optional EEE capability with deep sleep mode, PMD_SIGNAL.indication is also used to indicate when the ALERT signal is detected, which corresponds to the beginning of a refresh or a wake.

When the PHY does not support the EEE capability or if the PHY supports the EEE capability and rx_mode is set to DATA, SIGNAL_DETECT shall be set to FAIL following system reset or the manual reset of the training state diagram. Upon successful completion of training on all lanes, SIGNAL_DETECT shall be set to OK.

When the PHY does not support the EEE capability or if the PHY supports the EEE capability and rx_mode is set to DATA, if training is disabled by management, SIGNAL_DETECT shall be set to OK. When the PHY supports the EEE capability with deep sleep mode, SIGNAL_DETECT is set to FAIL following a transition from rx_mode = DATA to rx_mode = QUIET. When rx_mode = QUIET, SIGNAL_DETECT shall be set to OK within 500 ns following the application of a signal at the receiver input that corresponds to an ALERT transmission (see 85.7.2) from the link partner. While rx_mode = QUIET, SIGNAL_DETECT shall be held at FAIL as long as the signal at the receiver input corresponds to a QUIET tx_mode (see 85.7.6) of the link partner.

If the MDIO interface is implemented, then Global_PMD_signal_detect (1.10.0) shall be continuously set to the value of SIGNAL_DETECT as described in 45.2.1.9.7.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

85.7.5 PMD lane-by-lane signal detect function

When the MDIO is implemented, each PMD_signal_detect_*i* value, where *i* represents the lane number in the range 0:3 for 40GBASE-CR4 and 0:9 for 100GBASE-CR10, shall be continuously updated as described in the following two paragraphs.

For 40GBASE-CR4 PMD_signal_detect_0 (1.10.1), PMD_signal_detect_1 (1.10.2), PMD_signal_detect_2 (1.10.3) and PMD_signal_detect_3 (1.10.4) shall be set to one or zero depending on whether a particular lane's signal_detect, as defined by the training state diagram in Figure 72–5, returns true or false.

For 100GBASE-CR10 PMD_signal_detect_0 (1.10.1), PMD_signal_detect_1 (1.10.2), PMD_signal_detect_2 (1.10.3), PMD_signal_detect_3 (1.10.4), PMD_signal_detect_4 (1.10.5), PMD_signal_detect_5 (1.10.6), PMD_signal_detect_6 (1.10.7), PMD_signal_detect_7 (1.10.8), PMD_signal_detect_8 (1.10.9), and PMD_signal_detect_9 (1.10.10) shall be set to one or zero depending on whether a particular lane's signal_detect, as defined by the training state diagram in Figure 72–5, returns true or false.

85.7.6 Global PMD transmit disable function

The Global_PMD_transmit_disable function is mandatory if EEE with the deep sleep mode option is supported and is otherwise optional. When implemented, it allows all of the transmitters to be disabled with a single variable.

a) When Global_PMD_transmit_disable variable is set to one, this function shall turn off all of the transmitters such that each transmitter drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage in Table 85–5.
b) If a PMD_fault (85.7.9) is detected, then the PMD may turn off the electrical transmitter in all lanes.
c) Loopback, as defined in 85.7.8, shall not be affected by Global_PMD_transmit_disable.
d) For EEE capability, the PMD_transmit_disable function shall turn off the transmitter after tx_mode is set to QUIET within a time and voltage level specified in 72.7.1.4. The PMD_transmit_disable function shall turn on the transmitter after tx_mode is set to DATA or ALERT within the time and voltage level specified in 72.7.1.4.

85.7.7 PMD lane-by-lane transmit disable function

The PMD lane-by-lane transmit disable function is optional and allows the electrical transmitter in each lane to be selectively disabled. When this function is supported, it shall meet the following requirements:

a) When a PMD_transmit_disable_*i* variable (where *i* represents the lane number in the range 0:3 or 0:9) is set to one, this function shall turn off the transmitter associated with that variable such that it drives a constant level (i.e., no transitions) and does not exceed the maximum differential peak-to-peak output voltage specified in Table 85–5.
b) If a PMD_fault (85.7.9) is detected, then the PMD may set each PMD_transmit_disable_*i* variable to one, turning off the electrical transmitter in each lane.
c) Loopback, as defined in 85.7.8, shall not be affected by PMD_transmit_disable_*i*.

85.7.8 Loopback mode

Local loopback mode shall be provided by the adjacent PMA (see 83.5.8) for the 40GBASE-CR4 and 100GBASE-CR10 PMDs as a test function to the device. When loopback mode is enabled, transmission requests passed to each transmitter are sent directly to the corresponding receiver, overriding any signal detected by each receiver on its attached link. Note that loopback mode does not affect the state of the transmitter, which continues to send data (unless disabled).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Control of the loopback function is specified in 45.2.1.1.5.

NOTE 1—The signal path that is exercised in the loopback mode is implementation specific, but it is recommended that this signal path encompass as much of the circuitry as is practical. The intention of providing this loopback mode of operation is to permit diagnostic or self-test functions to test the transmit and receive data paths using actual data. Other loopback signal paths may also be enabled independently using loopback controls within other devices or sublayers.

NOTE 2—Placing a network port into loopback mode can be disruptive to a network.

85.7.9 PMD_fault function

If the MDIO is implemented, PMD_fault is the logical OR of PMD_receive_fault, PMD_transmit_fault, and any other implementation specific fault. The PMD fault function shall be mapped to bit 1.1.7 as listed in Table 85–3.

85.7.10 PMD transmit fault function

The PMD_transmit_fault function is optional. The faults detected by this function are implementation specific, but should not include the assertion of the Global_PMD_transmit_disable function.

If a PMD_transmit_fault (optional) is detected, then the Global_PMD_transmit_disable function should also be asserted.

If the MDIO interface is implemented, then this function shall be mapped to the Transmit fault bit as specified in 45.2.1.7.4.

85.7.11 PMD receive fault function

The PMD_receive_fault function is optional. The faults detected by this function are implementation specific.

If the MDIO interface is implemented, then this function shall contribute to the Receive fault bit as specified in 45.2.1.7.5.

85.7.12 PMD control function

Each lane of the 40GBASE-CR4 or 100GBASE-CR10 PMD shall use the same control function as 10GBASE-KR, as defined in 72.6.10.

The random seed for the training pattern described in 72.6.10.2.6 shall be different for each of the lanes.

85.8 MDI Electrical specifications for 40GBASE-CR4 and 100GBASE-CR10

85.8.1 Signal levels

The 40GBASE-CR4 and 100GBASE-CR10 MDI is a low-swing AC-coupled differential interface. AC-coupling at the receiver, as defined in 85.8.4.5, allows for interoperability between components operating from different supply voltages. Low-swing differential signaling provides noise immunity and improved electromagnetic interference (EMI).

85.8.2 Signal paths

The 40GBASE-CR4 and 100GBASE-CR10 MDI signal paths are point-to-point connections. Each path corresponds to a 40GBASE-CR4 or 100GBASE-CR10 MDI lane and comprises two complementary

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

signals, which form a balanced differential pair. For 40GBASE-CR4, there are four differential paths in each direction for a total of eight pairs, or sixteen connections. For 100GBASE-CR10, there are ten differential paths in each direction for a total of 20 pairs, or forty connections. The signal paths are intended to operate on twinaxial cable assemblies ranging from 0.5 m to 7 m in length, as described in 85.10.

85.8.3 Transmitter characteristics

Transmitter characteristics shall meet specifications summarized in Table 85–5 at TP2 unless otherwise noted. The transmitter specifications at TP0 are provided informatively in Annex 85A, Table 85A–1.

Table 85–5—Transmitter characteristics at TP2 summary

Parameter	Subclause reference	Value	Units
Signaling rate, per lane	85.8.3.9	10.3125 ± 100 ppm	GBd
Unit interval nominal	85.8.3.9	96.969697	ps
Differential peak-to-peak output voltage (max) with Tx disabled		30	mV
Common-mode voltage limits	72.7.1.4	0 to 1.9	V
Differential output return loss (min)	85.8.3.1	See Equation (85–1)	dB
AC common-mode output voltage (max., RMS)		30	mV
Common-mode voltage deviation (max) during LPI	72.7.1.4	150	mV
Amplitude peak-to-peak (max)	72.7.1.4	1200[a]	mV
Transmitter DC amplitude[b]	85.8.3.3	0.34 min, 0.6 max	V
Linear fit pulse (min)[c]	85.8.3.3	0.63 × Transmitter DC amplitude	V

[a]The 40GBASE-CR4 Style-1 connector may support 40GBASE-CR4 or XLPPI interfaces. For implementations that support both interfaces, the transmitter should not exceed the XLPPI voltage maximum until a 40GBASE-CR4 cable assembly has been identified. The 100GBASE-CR10 connector may support 100GBASE-CR10 or CPPI interfaces. For implementations that support both interfaces, the transmitter should not exceed the CPPI voltage maximum until a 100GBASE-CR10 cable assembly has been identified.
[b]The transmitter DC amplitude is the sum of linear fit pulse response $p(k)$ from step 3) divided by M from step 3).
[c]The peak of the linear fit pulse response $p(k)$ from step 3).
[d]Random jitter is specified at a BER of 10^{-12}
[e] See 72.7.1.9 for duty cycle distortion definition.
[f]Total jitter at a BER of 10^{-12} measured per 83A.5.1 excluding data dependent jitter (DDJ). DDJ is a jitter component where jitter that is not correlated to the data pattern has been removed. DDJ is measured with PRBS9 as specified in 83.5.10.

85.8.3.1 Transmitter differential output return loss

The differential output return loss, in dB, of the transmitter shall meet Equation (85–1). This output impedance requirement applies to all valid output levels. The reference impedance for differential return loss measurements shall be 100 Ω.

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 12 - 2\sqrt{f} & 0.05 \leq f < 4.11 \\ 6.3 - 13\log_{10}(f/5.5) & 4.11 \leq f \leq 10 \end{array} \right\} \quad \text{(dB)} \qquad (85\text{–}1)$$

where

f is the frequency in GHz
$Return_loss(f)$ is the return loss at frequency f

The transmitter differential output return loss is illustrated in Figure 85–3.

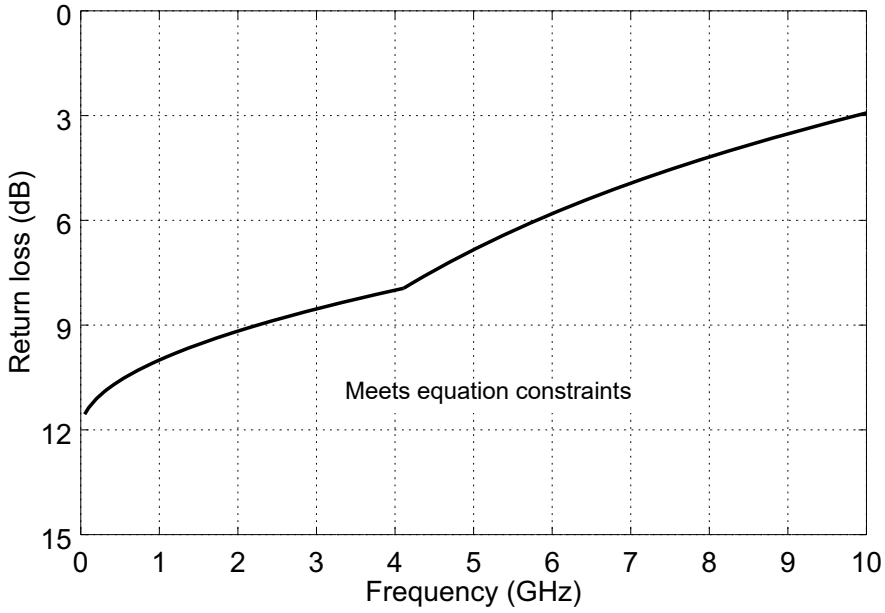

Figure 85–3—Transmitter differential output return loss

85.8.3.2 Transmitter noise parameter measurements

The far-end transmitter output noise is an additional source of noise to the cable assembly's integrated crosstalk noise (ICN) specified in 85.10.7. The far-end transmitter output noise parameter is characterized using two reference channels; a "low-loss" cable assembly with insertion loss on the reference pair of 6 dB ± 1.5 dB at 5.15625 GHz and cable assembly integrated crosstalk noise (ICN) meeting the requirements of 85.10.7 and a "high-loss" cable assembly with insertion loss on the reference pair of 15.7 dB ± 1.5 dB at 5.15625 GHz and cable assembly ICN meeting the requirements of 85.10.7. The far-end transmitter output noise is characterized as a deviation from the cable assembly ICN using the following procedure:

1) Compute the far-end integrated crosstalk noise σ_{fx} into the reference lane of the cable assembly using the methodology of 85.10.7 and the parameters in Table 85–11.
2) Denote σ_l as the far-end ICN for the low-loss cable assembly.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

3) Denote σ_h as the far-end ICN for the high-loss cable assembly.
4) The transmitter under test is connected to one end of the reference cable assembly and the other end is connected to the cable assembly test fixture specified in 85.10.8.
5) All lanes of the cable assembly test fixture are terminated in the reference impedance with the reference lane connected to the measuring instrument.
6) The reference lane of the transmitter under test sends a square wave test pattern as specified in 83.5.10 while all other adjacent transmitter lanes send either scrambled idle or PRBS31.
7) A fixed point on the square wave test pattern is chosen and the RMS deviation from the mean voltage at this observation point is measured. The histogram for RMS noise measurement is 1 UI wide.
8) The measurement should not include the measurement system noise.

For the low-loss cable assembly, the measured RMS deviation from the cable assembly ICN due to the far-end transmitter output noise shall meet the values determined using Equation (85–2).

$$RMSl_{dev} \leq \sqrt{\sigma_l^{\,2} + 2^2} \text{ (mV)} \tag{85–2}$$

For the high-loss cable assembly, the measured RMS deviation from the cable assembly ICN due to the far-end transmitter output noise shall meet the values determined using Equation (85–3).

$$RMSh_{dev} \leq \sqrt{\sigma_h^{\,2} + 1^2} \text{ (mV)} \tag{85–3}$$

85.8.3.3 Transmitter output waveform

The 40GBASE-CR4 and 100GBASE-CR10 transmit function includes programmable equalization to compensate for the frequency-dependent loss of the channel and facilitate data recovery at the receiver. The functional model for the transmit equalizer is the three tap transversal filter shown in Figure 85–4.

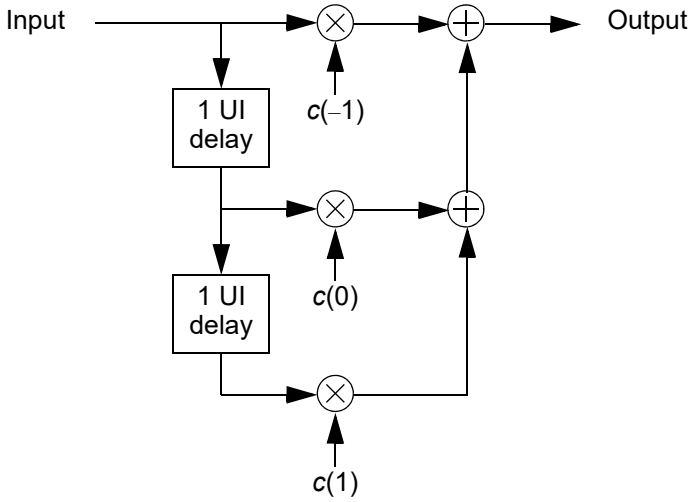

Figure 85–4—Transmit equalizer functional model

The state of the transmit equalizer and hence the transmitted output waveform may be manipulated via the PMD control function defined in 85.7.12 or via the management interface. The transmit function responds to a set of commands issued by the link partner's receive function and conveyed by a back-channel communications path.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

This command set includes instructions to

a) Increment coefficient $c(i)$.
b) Decrement coefficient $c(i)$.
c) Hold coefficient $c(i)$ at its current value.
d) Set the coefficients to a pre-defined value (preset or initialize).

In response, the transmit function relays status information to the link partner's receive function. The status messages indicate that

a1) The requested update to coefficient $c(i)$ has completed (updated).
b1) Coefficient $c(i)$ is at its minimum value.
c1) Coefficient $c(i)$ is at its maximum value.
d1) Coefficient $c(i)$ is ready for the next update request (not_updated).

The requirements for the 40GBASE-CR4 and 100GBASE-CR10 transmit equalizer are intended to be similar to the requirements for 10GBASE-KR specified in 72.7.1.10. However, the signal path from the transmit function to TP2 introduces frequency-dependent loss and phase shift that distorts the signal and makes it difficult to accurately characterize equalizer performance at TP2 using the methodology specified for 10GBASE-KR. The following process enables accurate characterization of the equalizer performance at TP2 by determining and correcting for the frequency-dependent loss and phase shift of the signal path from the transmit function to TP2.

1) The transmitter under test is preset as specified in 72.6.10.2.3.1 such that $c(-1)$ and $c(1)$ are zero and $c(0)$ is its maximum value.
2) Capture at least one complete cycle of the test pattern PRBS9 as specified in 83.5.10 at TP2 per 85.8.3.3.4.
3) Compute the linear fit to the captured waveform and the linear fit pulse response $p(k)$ per 85.8.3.3.5.
4) Define t_x to be the time where the rising edge of the linear fit pulse, p, from step 3) crosses 50% of its peak amplitude.
5) Sample the linear fit pulse, p, at symbol-spaced intervals relative to the time $t_0 = t_x + 0.5$ UI, interpolating as necessary to yield the sampled pulse p_i.
6) Use p_i to compute the vector of coefficients, w, of a N_w-tap symbol-spaced transversal filter that equalizes for the transfer function from the transmit function to TP2 per 85.8.3.3.6.

The parameters of the pulse fit and the equalizing filter are given in Table 85–6. The DC amplitude, the sum of linear fit pulse response, $p(k)$, from step 3) divided by M from step 3), shall be greater than 0.34 V and less than or equal to 0.6 V. The peak of the linear fit pulse response from step 3) shall be greater than 0.63 × DC amplitude. The RMS value of the error between the linear fit from step 3) and the measured waveform, e, normalized to the peak value of the pulse, p, shall be no greater than 0.037.

Table 85–6—Normalized transmit pulse template

Description	Symbol	Value	Units
Linear fit pulse length	N_p	8	UI
Linear fit pulse delay	D_p	2	UI
Equalizer length	N_w	7	UI
Equalizer delay	D_w	1	UI

For each configuration of the transmit equalizer

7) Configure the transmitter under test as required by the test.
8) Capture at least one complete cycle of the test pattern PRBS9 as specified in 83.5.10 at TP2 per 85.8.3.3.4.
9) Compute the linear fit to the captured waveform and the linear fit pulse response p(k) per 85.8.3.3.5.
10) Define t_x to be the time where the rising edge of the linear fit pulse response, p(k), from step 9) crosses 50% of its peak amplitude.
11) Sample the linear fit pulse response, p(k), at symbol-spaced intervals relative to the time $t_0 = t_x + 0.5$ UI, interpolating as necessary to yield the sampled pulse p_i.
12) Equalize the sampled pulse p_i using the coefficient vector, w, computed in step 6) per 85.8.3.3.6 to yield the equalized pulse q_i.

The RMS value of the error between the linear fit from step 9) and the measured waveform, e, normalized to the peak value of the pulse, p, shall be no greater than 0.037.

Coefficient $c(-1)$ is defined to be the value of q_i at time $t_0 + (D_p - 1)$ UI. Coefficient $c(0)$ is defined to be the value of q_i at time $t_0 + D_p$ UI. Coefficient $c(1)$ is defined to be the value of q_i at time $t_0 + (D_p + 1)$ UI.

85.8.3.3.1 Coefficient initialization

When the PMD enters the INITIALIZE state of the Training state diagram (Figure 72–5) or receives a valid request to "initialize" from the link partner, the coefficients of the transmit equalizer shall be configured such that the ratio $(c(0)+c(1)-c(-1))/(c(0)+c(1)+c(-1))$ is 1.29 ±10% and the ratio $(c(0)-c(1)+c(1))/(c(0)+c(1)+c(-1))$ is 2.57 ±10%. These requirements apply upon the assertion a coefficient status report of "updated" for all coefficients.

85.8.3.3.2 Coefficient step size

The change in $c(i)$ corresponding to a request to "increment" that coefficient shall be between 0.0083 and 0.05. The change in $c(i)$ corresponding to a request to "decrement" that coefficient shall be between –0.05 and –0.0083.

The change in the coefficient is defined to be the difference in the value measured prior to the assertion of the "increment" or "decrement" request (e.g., the coefficient update request for all coefficients is "hold") and the value upon the assertion of a coefficient status report of "updated" for that coefficient.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

85.8.3.3.3 Coefficient range

When sufficient "increment" or "decrement" requests have been received for a given coefficient, the coefficient will reach a lower or upper bound based on the range of that coefficient or the combination of coefficients.

With $c(-1)$ set to zero and both $c(0)$ and $c(1)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0) - c(1))/(c(0) + c(1))$ shall be greater then or equal to 4.

With $c(1)$ set to zero and both $c(-1)$ and $c(0)$ having received sufficient "decrement" requests so that they are at their respective minimum values, the ratio $(c(0) - c(-1))/(c(0) + c(-1))$ shall be greater then or equal to 1.54.

Note that a coefficient may be set to zero by first asserting a coefficient preset request and then manipulating the other coefficients as required by the test.

85.8.3.3.4 Waveform acquisition

The transmitter under test repetitively transmits the specified test pattern. The waveform shall be captured with an effective sample rate that is M times the signaling rate of the transmitter under test. The value of M shall be an integer not less than 7. Averaging multiple waveform captures is recommended.

The captured waveform shall represent an integer number of repetitions of the test pattern totaling N bits. Hence the length of the captured waveform should be MN samples. The waveform should be aligned such that the first M samples of waveform correspond to the first bit of the test pattern, the second M samples to the second bit, and so on.

85.8.3.3.5 Linear fit to the waveform measurement at TP2

Given the captured waveform $y(k)$ and corresponding aligned symbols $x(\mathrm{n})$ derived from the procedure defined in 85.8.3.3.4, define the M-by-N waveform matrix Y as shown in Equation (85–4).

$$Y = \begin{bmatrix} y(1) & y(M+1) & \dots & y(M(N-1)+1) \\ y(2) & y(M+2) & \dots & y(M(N-1)+2) \\ \dots & \dots & \dots & \dots \\ y(M) & y(2M) & \dots & y(MN) \end{bmatrix} \tag{85–4}$$

Rotate the symbols vector x by the specified pulse delay D_p to yield x_r as shown in Equation (85–5).

$$x_r = \left[x(D_p+1) \;\; x(D_p+2) \dots x(N) \; x(1) \; \dots \; x(D_p)\right] \tag{85–5}$$

Define the matrix X to be an N-by-N matrix derived from x_r as shown in Equation (85–6).

$$X = \begin{bmatrix} x_r(1) & x_r(2) & \dots & x_r(N) \\ x_r(N) & x_r(1) & \dots & x_r(N-1) \\ \dots & \dots & \dots & \dots \\ x_r(2) & x_r(3) & \dots & x_r(1) \end{bmatrix} \tag{85–6}$$

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

Define the matrix X_1 to be the first N_p rows of X concatenated with a row vector of ones of length N. The M-by-$(N_p + 1)$ coefficient matrix, P, corresponding to the linear fit is then defined by Equation (85–7). The superscript "T" denotes the matrix transpose operator.

$$P = YX_1^T(X_1X_1^T)^{-1} \tag{85–7}$$

The error waveform, $e(k)$, is then read column-wise from the elements of the error matrix E defined by Equation (85–8).

$$E = PX_1 - Y = \begin{bmatrix} e(1) & e(M+1) & \dots & e(M(N-1)+1) \\ e(2) & e(M+2) & \dots & e(M(N-1)+2) \\ \dots & \dots & \dots & \dots \\ e(M) & e(2M) & \dots & e(MN) \end{bmatrix} \tag{85–8}$$

Define P_1 to be a matrix consisting of the first N_p columns of the matrix P as shown in Equation (85–9). The linear fit pulse response, $p(k)$, is then read column-wise from the elements of P_1.

$$P_1 = \begin{bmatrix} p(1) & p(M+1) & \dots & p(M(N_p-1)+1) \\ p(2) & p(M+2) & \dots & p(M(N_p-1)+2) \\ \dots & \dots & \dots & \dots \\ p(M) & p(2M) & \dots & p(MN_p) \end{bmatrix} \tag{85–9}$$

85.8.3.3.6 Transfer function between the transmit function and TP2

Rotate the sampled pulse response p_i by the specified equalizer delay D_w to yield p_r as shown in Equation (85–10).

$$p_r = \left[p_i(D_w+1)\ \ p_i(D_p+2) \dots\ p_i(N_p)\ p_i(1)\ \dots\ p_i(D_w)\right] \tag{85–10}$$

Define the matrix P_2 to be an N_p-by-N_p matrix derived from p_r as shown in Equation (85–11).

$$P_2 = \begin{bmatrix} p_r(1) & p_r(N_p) & \dots & p_r(2) \\ p_r(2) & p_r(1) & \dots & p_r(3) \\ \dots & \dots & \dots & \dots \\ p_r(N_p) & p_r(N_p-1) & \dots & p_r(1) \end{bmatrix} \tag{85–11}$$

Define the matrix P_3 to be the first N_w columns of P_2. Define a unit pulse column vector x_p of length N_p. The value of element $x_p(D_p + 1)$ is 1 and all other elements have a value of 0. The vector of filter coefficients w that equalizes p_i is then defined by Equation (85–12).

$$w = (P_3^TP_3)^{-1}P_3^Tx_p \tag{85–12}$$

Given the column vector of equalizer coefficients, w, the equalized pulse response q_i is determined by Equation (85–13).

$$q_i = P_3w \tag{85–13}$$

85.8.3.4 Insertion loss TP0 to TP2 or TP3 to TP5

Transmitter measurements and tests defined in Table 85–5 are made at TP2 or TP3 using the test fixture of Figure 85–6, or its functional equivalent. The maximum insertion loss from TP0 to TP2 or TP3 to TP5 including the test fixture is determined using Equation (85–14).

$$Insertion_loss(f) \le \left\{ \begin{array}{ll} 0.114 + 0.8914\sqrt{f} + 0.846f & 0.01 \le f < 7 \\ -35.91 + 6.3291f & 7 \le f < 8 \\ 14.72 & 8 \le f \le 10 \end{array} \right\} \text{ (dB)} \quad (85\text{–}14)$$

where

f is the frequency in GHz
$Insertion_loss(f)$ is the insertion loss at frequency f

The maximum insertion loss of TP0 to TP2 or TP3 to TP5 is illustrated in Figure 85–5.

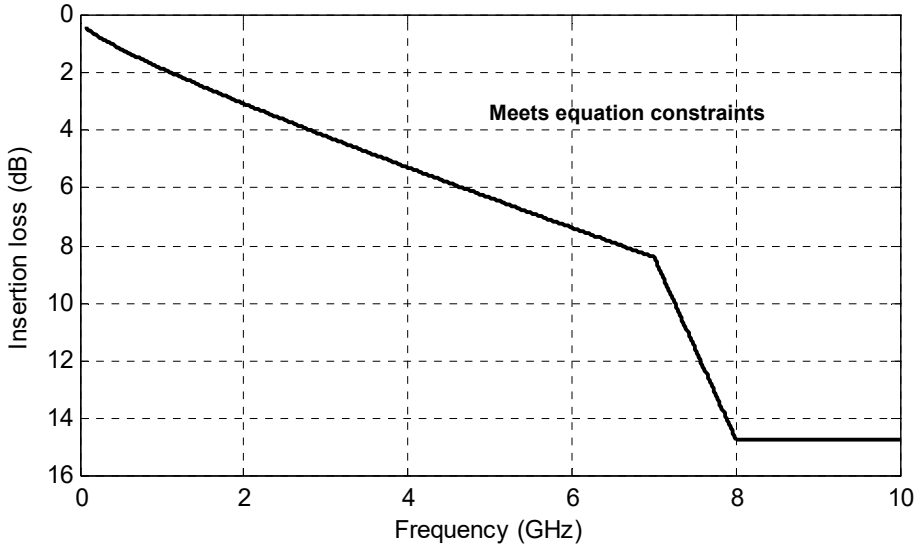

Figure 85–5—Maximum insertion loss TP0 to TP2 or TP3 to TP5

85.8.3.5 Test fixture

The test setup illustrated in Figure 85–6, or its functional equivalent, is required for measuring the transmitter specifications in 85.8.3 at TP2 and the receiver return loss at TP3. TP2 and TP3 are illustrated in Figure 85–2. Figure 85–6 illustrates the test fixture attached to TP2 or TP3.

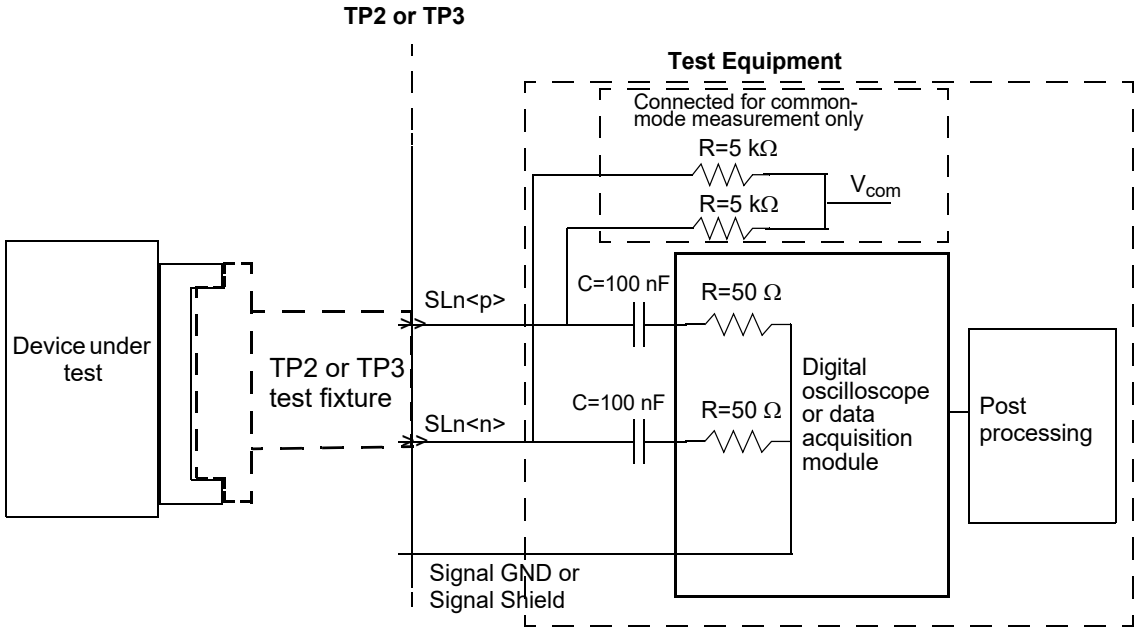

Figure 85–6—Transmitter and receiver test setup

85.8.3.6 Test fixture impedance

The differential return loss, in dB, of the test fixture is specified in a mated state and shall meet the requirements of 85.10.9.2.

85.8.3.7 Test fixture insertion loss

The reference test fixture printed circuit board insertion loss shall meet the values determined using Equation (85–15). The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements.

$$IL_{tfref}(f) = 0.01 + 0.3\sqrt{f} + 0.11f \text{ (dB)} \quad (85–15)$$

for 0.01 GHz $\leq f \leq$ 10 GHz

where

f is the frequency in GHz
$IL_{tfref}(f)$ is the reference test fixture PCB insertion loss at frequency f

85.8.3.8 Data dependent jitter (DDJ)

An oscilloscope, time interval analyzer, or other instrument with equivalent capability may be used to measure DDJ. A repeating PRBS9 pseudo-random test pattern, 511 bits long, is used. For DDJ measurements, the measurement bandwidth should be at least 12 GHz. If the measurement bandwidth affects the result, it can be corrected for by post-processing.

Establish a crossing level equal to the average value of the entire waveform being measured. Synchronize the instrument to the pattern repetition frequency and average the waveforms or the crossing times

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

sufficiently to remove the effects of random jitter and noise in the system. The PRBS9 pattern has 128 positive-going transitions and 128 negative-going transitions. The mean time of each crossing is then compared to the expected time of the crossing, and a set of 256 timing variations is determined. Crossings earlier than expected give a negative variation. Crossings later than expected give a positive variation. DDJ is the range (maximum minus minimum) of the timing variations. Note that it may be convenient to align the expected time of one of the crossings with the measured mean crossing.

Figure 85–7 illustrates the method. The vertical axis is in arbitrary units, and the horizontal axis is plotted in UI. The waveform is AC-coupled to an average value of 0, therefore 0 is the appropriate crossing level. The rectangular waveform shows the ideal crossing times, and the other is the waveform with jitter that is being measured. Only 16 UI are shown (out of 511). The waveforms have been arbitrarily aligned with ($\Delta t_2 = 0$) at 5 UI.

Data dependent jitter is defined as in Equation (85–16).

$$DDJ = max(\Delta t_1, \Delta t_2, \ldots \Delta t_{256}) - min(\Delta t_1, \Delta t_2, \ldots \Delta t_{256}) \quad (85\text{–}16)$$

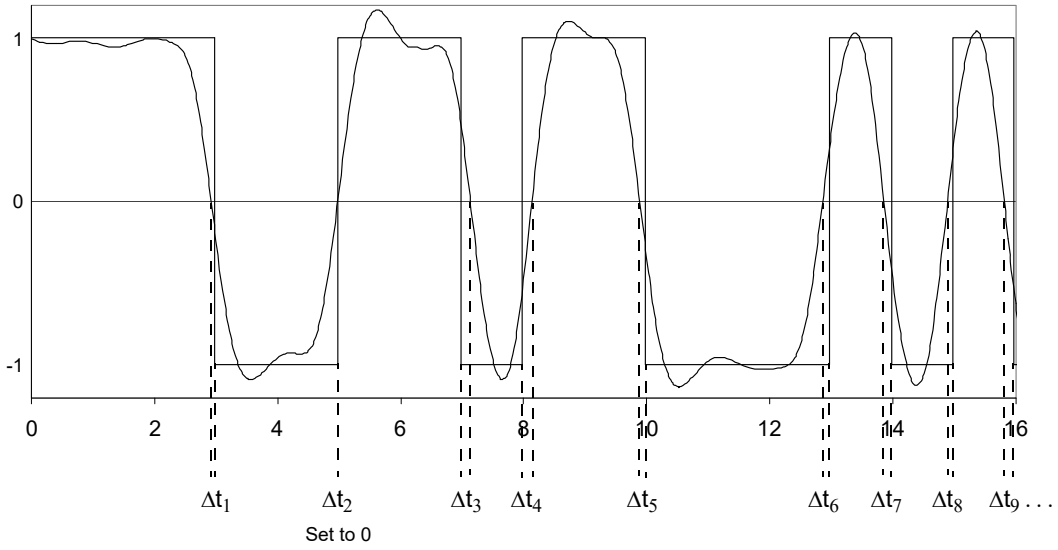

Figure 85–7—Data dependent jitter test method

85.8.3.9 Signaling rate range

The 40GBASE-CR4 and 100GBASE-CR10 MDI signaling rate shall be 10.3125 GBd ±100 ppm per lane. The corresponding unit interval is nominally 96.969697 ps.

85.8.4 Receiver characteristics at TP3 summary

The receiver characteristics shall meet the specifications summarized in Table 85–7 at TP3 unless otherwise noted.

Table 85–7—Receiver characteristics at TP3 summary

Parameter	Subclause reference	Value	Units
Bit error ratio	85.8.4.3	10^{-12} or better	
Signaling rate, per lane	85.8.4.4	10.3125 ± 100 ppm	GBd
Unit interval (UI) nominal	85.8.4.4	96.969697	ps
Differential peak-to-peak input amplitude tolerance (max)	72.7.2.4	1200	mV
Differential input return loss (min)[a]	85.8.4.1	Equation (85–17)	dB
Differential to common-mode input return loss		10 min from 10 MHz to 10 GHz	dB

[a]Relative to 100 Ω differential.

85.8.4.1 Receiver differential input return loss

The differential input return loss, in dB, of the receiver shall meet Equation (85–17). The reference impedance for differential return loss measurements is 100 Ω.

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 12 - 2\sqrt{f} & 0.01 \leq f < 4.11 \\ 6.3 - 13\log_{10}(f/5.5) & 4.11 \leq f \leq 10 \end{array} \right\} \quad \text{(dB)} \qquad (85\text{–}17)$$

where

f is the frequency in GHz
$Return_loss(f)$ is the return loss at frequency f

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

85.8.4.2 Receiver interference tolerance test

The receiver interference tolerance of each lane shall comply with both test 1 and test 2 using the parameters of Table 85–8 when measured according to the requirements of 85.8.4.2.1 to 85.8.4.2.5.

Table 85–8—40GBASE-CR4 and 100GBASE-CR10 interference tolerance parameters

Parameter	Test 1 values	Test 2 values	Units
Maximum BER	10^{-12}	10^{-12}	
Fitted insertion loss coefficients	$a_1 = 2.15$ $a_2 = 0.78$ $a_4 = 0.03$	$a_1 = 6.04$ $a_2 = 0.94$ $a_4 = 0.08$	dB/√GHz dB/GHz dB/GHz^2
Applied SJ[a] (peak-to-peak)	0.115	0.115	UI
Applied RJ[b] (peak-to-peak)	0.13	0.13	UI
Applied DCD (peak-to-peak)	0.035	0.035	UI
Calibrated far-end crosstalk (RMS)	6.3	2.2	mV
Calibrated ICN (RMS) – σ_{nx}	3.7	3.7	mV

[a]Applied SJ frequency >15 MHz, specified at TP0.
[b]Applied random jitter at TP0 is specified at 10^{-12}.

85.8.4.2.1 Test setup

The interference tolerance test is performed with the setup shown in Figure 85–8. The requirements of this subclause are verified at the pattern generator connection (PGC) or test references in Figure 85–8 and Figure 85–9. The lanes under test (LUT) are illustrated in Figure 85–8 and Figure 85–9. The cable assembly receive lanes are terminated in 100 Ω differentially.

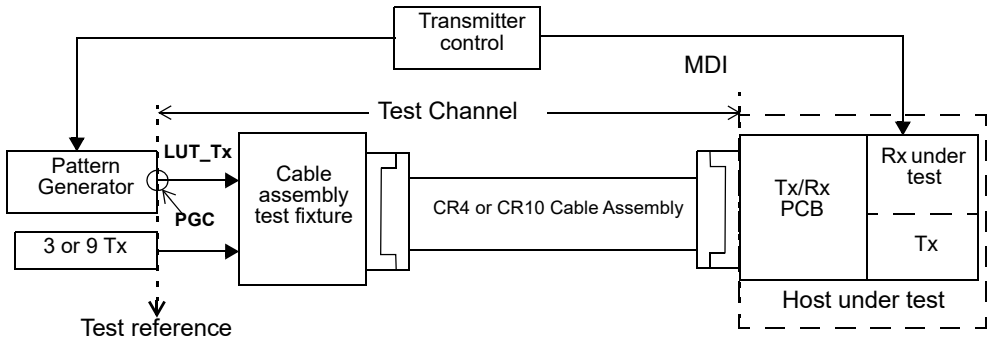

Figure 85–8—Interference tolerance test setup

85.8.4.2.2 Test channel

The test channel consists of the following:

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

a) A cable assembly
b) A cable assembly test fixture
c) A connecting path from the pattern generator to the cable assembly test fixture

85.8.4.2.3 Test channel calibration

The insertion loss, near-end integrated crosstalk noise, and far-end crosstalk of the test channels are characterized at the test references as illustrated in Figure 85–9 using the cable assembly test fixtures specified in 85.10.8.

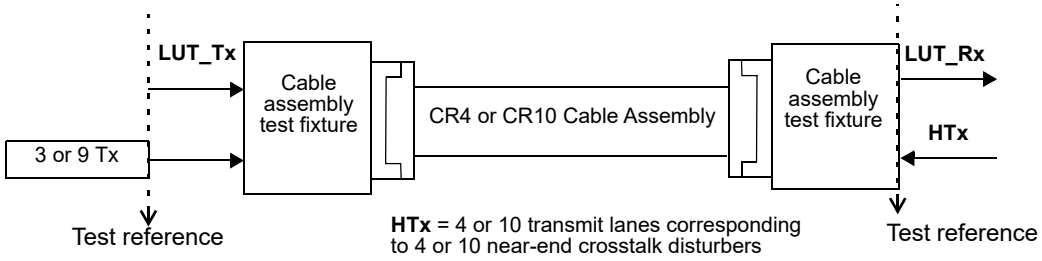

Figure 85–9—Test channel calibration

The fitted insertion loss coefficients of the lane under test (LUT), derived using the fitting procedure in 85.10.2, shall meet the test values in Table 85–8. It is recommended that the deviation between the insertion loss and the fitted insertion loss be as small as practical and that the fitting parameters be as close as practical to the values given in Table 85–8.

The MDNEXT is measured from points HTx to adjacent point LUT_Rx in Figure 85–9. HTx is the set of 4 or 10 transmit lanes of the device under test corresponding to the 4 or 10 near-end crosstalk disturbers with the parameters given in Table 85–11. The RMS value of the integrated MDNEXT crosstalk noise, determined using Equation (85–30) through Equation (85–34), shall meet the test values in Table 85–8.

The far-end crosstalk disturbers consist of 40GBASE-CR4 or 100GBASE-CR10 transmitters. It is recommended that the transition time, equalization setting, and path from the far-end crosstalk disturbers to the cable assembly test fixture emulate the pattern generator as much as practical. For 40GBASE-CR4 test channels, the crosstalk that is coupled into a receive lane is from three transmitters. For 100GBASE-CR10 test channels, the crosstalk that is coupled into a receiver lane is from nine transmitters. The disturber transmitters send either scrambled idle codes or PRBS31. The amplitudes of each of the disturbers should not deviate more than 3 dB from the mean of the disturber amplitudes. The amplitudes of the disturbers should be such that the calibrated far-end crosstalk in Table 85–8 is met in the calibration setup at the LUT point with no signal applied at the PGC, and HTx and PGC terminated in 100 Ω differentially.

85.8.4.2.4 Pattern generator

The pattern generator transmits data to the device under test. Its output amplitude shall be no more than 800 mV peak-to-peak differential when measured on an alternating one zero pattern. The rise and fall times of the pattern generator, as defined in 72.7.1.7, are 47 ps. If the rise and fall times of the pattern generator, T_r, are less than 47 ps the value of a_4 in Table 85–8 is increased by da_4 from Equation (85–18).

$$da_4 = 60.51 \times 10^{-6}(47^2 - T_r^2) \quad (85–18)$$

where T_r is the rise time in ps.

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

The pattern generator shall meet the jitter specification in Table 85–8. The output waveform of the pattern generator shall comply to 72.7.1.11.

85.8.4.2.5 Test procedure

For 40GBASE-CR4 or 100GBASE-CR10 testing, the pattern generator is first configured to transmit the training pattern defined in 72.6.10.2. During this initialization period, the device under test (DUT) configures the pattern generator equalizer, via transmitter control, to the coefficient settings it would select using the protocol described in 72.6.10 and the receiver will be tuned using its optimization method.

After the pattern generator equalizer has been configured and the receiver tuned, the pattern generator is set to transmit test pattern 3 as defined in 86.8.2. The receiver under test shall meet the target BER listed in Table 85–8. During the tests, the disturbers transmit at their calibrated level and all of the transmitters in the device under test transmit either scrambled idle characters or PRBS31, with the maximum compliant amplitude and equalization turned off (preset condition).

85.8.4.3 Bit error ratio

The receiver shall operate with a BER 10^{-12} or better when receiving a compliant transmit signal, as defined in 85.8.3, through a compliant cable assembly as defined in 85.10.

85.8.4.4 Signaling rate range

A 40GBASE-CR4 and 100GBASE-CR10 receiver shall comply with the requirements of 85.8.4.3 for any signaling rate in the range 10.3125 GBd ± 100 ppm. The corresponding unit interval is nominally 96.969697 ps.

85.8.4.5 AC-coupling

The 40GBASE-CR4 and 100GBASE-CR10 receivers are AC-coupled. AC-coupling shall be part of the receive function for Style-2 40GBASE-CR4 connectors. For Style-1 40GBASE-CR4 and 100GBASE-CR10 plug connectors, the receive lanes are AC-coupled; the coupling capacitors shall be within the plug connectors. It should be noted that there may be various methods for AC-coupling in actual implementations. The low frequency 3 dB cutoff of the AC-coupling shall be less than 50 kHz.

It is recommended that the value of the coupling capacitors be 100 nF. This will limit the inrush currents and baseline wander.

85.9 Channel characteristics

The 40GBASE-CR4 and 100GBASE-CR10 channel is defined between TP0 and TP5 to include the transmitter and receiver differential controlled impedance printed circuit board and the cable assembly as illustrated in Figure 85–2. The channel parameters insertion loss, insertion loss deviation (ILD), insertion loss to crosstalk ratio, and the transmitter and receiver differential controlled impedance printed circuit boards for each differential lane are provided informatively in 85A.4 through 85A.7.

85.10 Cable assembly characteristics

The 40GBASE-CR4 and 100GBASE-CR10 cable assembly contains insulated conductors terminated in a connector at each end for use as a link segment between MDIs. This cable assembly is primarily intended as a point-to-point interface of up to 7 m between network ports using controlled impedance cables. All cable assembly measurements are to be made between TP1 and TP4 with cable assembly test fixtures as specified

in 85.10.8 and illustrated in Figure 85–14. These cable assembly specifications are based upon twinaxial cable characteristics, but other cable types are acceptable if the specifications of 85.10 are met.

Table 85–9 provides a summary of the cable assembly differential characteristics at 5.15625 GHz and references to the subclauses addressing each parameter.

Table 85–9—Cable assembly differential characteristics summary

Description	Reference	Value	Unit
Maximum insertion loss at 5.15625 GHz	85.10.2	17.04	dB
Minimum insertion loss at 5.15625 GHz		3	dB
Insertion loss deviation at 5.15625 GHz	85.10.3	max = 1.73 min = –1.73	dB
Minimum return loss at 5.15625 GHz	85.10.4	6.66	dB
MDNEXT loss	85.10.5	Equation (85–26)	dB
MDFEXT loss	85.10.6	Equation (85–27)	dB
Maximum integrated crosstalk noise	85.10.7	Equation (85–33)	mV

85.10.1 Characteristic impedance and reference impedance

The nominal differential characteristic impedance of the cable assembly is 100 Ω. The differential reference impedance for cable assembly specifications shall be 100 Ω.

85.10.2 Cable assembly insertion loss

The fitted cable assembly insertion loss $IL_{fitted}(f)$ as a function of frequency f is defined in Equation (85–19).

$$IL_{\text{fitted}}(f) = a_1\sqrt{f} + a_2 f + a_4 f^2 \quad \text{(dB)} \tag{85–19}$$

where

f is the frequency in GHz
$IL_{\text{fitted}}(f)$ is the fitted cable assembly insertion loss at frequency f

Given the cable assembly insertion loss measured between TP1 and TP4 is at N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 7500 MHz with a maximum frequency spacing of 10 MHz, the coefficients of the fitted insertion loss are determined using Equation (85–20) and Equation (85–21).

Define the frequency matrix F as shown in Equation (85–20).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$F = \begin{bmatrix} \sqrt{f_1} & f_1 & f_1^2 \\ \sqrt{f_2} & f_2 & f_2^2 \\ \cdots & \cdots & \cdots \\ \sqrt{f_N} & f_N & f_N^2 \end{bmatrix} \quad (85–20)$$

The polynomial coefficients a_1, a_2, and a_4 are determined using Equation (85–21). In Equation (85–21), T denotes the matrix transpose operator and IL is a column vector of the measured insertion loss values, IL_n at each frequency f_n.

$$\begin{bmatrix} a_1 \\ a_2 \\ a_4 \end{bmatrix} = (F^T F)^{-1} F^T IL \quad (85–21)$$

The maximum allowed values of the polynomial coefficients a_1, a_2, and a_4 of the fitted cable assembly insertion loss of each pair of the 40GBASE-CR4 and 100GBASE-CR10 in Equation (85–19) and the maximum insertion loss at 5.15625 GHz shall meet the specifications summarized in Table 85–10 unless otherwise noted. The fitted insertion loss corresponding to one example of the maximum insertion loss at 5.15625 GHz and the maximum allowed values of a_1, a_2, and a_4 is illustrated in Figure 85–10.

Table 85–10—Maximum cable assembly insertion loss characteristics

Description	Value	Unit
Maximum insertion loss at 5.15625 GHz	17.04[a]	dB
Maximum fitted insertion loss coefficient a_1	6	dB/√GHz
Maximum fitted insertion loss coefficient a_2	1	dB/GHz
Maximum fitted insertion loss coefficient a_4	0.08	dB/GHz^2

[a]The limit on the maximum insertion loss at 5.15625 GHz precludes the coefficients a_1, a_2, and a_4 from simultaneous maximum values.

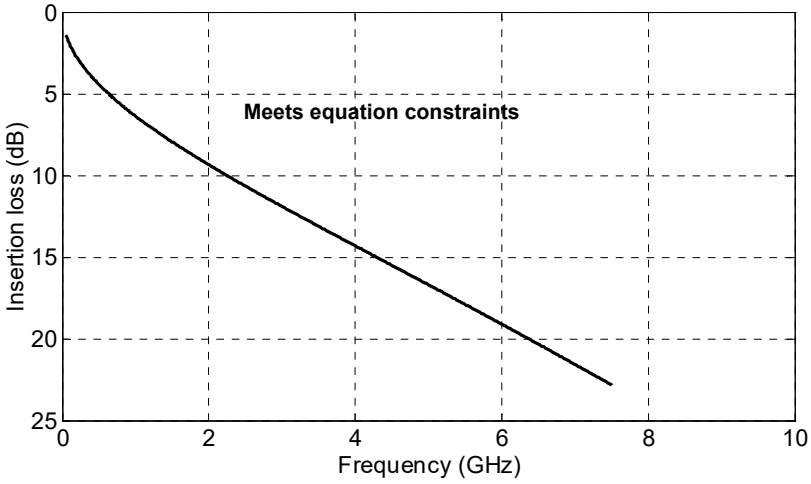

Figure 85–10—Example maximum cable assembly insertion

85.10.3 Cable assembly insertion loss deviation (ILD)

The cable assembly insertion loss deviation is the difference between the cable assembly insertion loss and the fitted cable assembly insertion loss determined using Equation (85–22).

$$ILD(f) = IL(f) - IL_{\text{fitted}}(f) \quad (85–22)$$

where

f	is the frequency in MHz
$ILD(f)$	is the cable assembly insertion loss deviation at frequency f

The *ILD* shall be within the region defined by Equation (85–23) and Equation (85–24). This includes the insertion loss of the differential cabling pairs and the cable assembly connectors.

$$ILD(f) \geq ILD_{\text{min}}(f) = -0.7 - 0.2\times10^{-3} f \text{ (dB)} \quad (85–23)$$

$$ILD(f) \leq ILD_{\text{max}}(f) = 0.7 + 0.2\times10^{-3} f \text{ (dB)} \quad (85–24)$$

for 50 MHz $\leq f \leq$ 7500 MHz

where

f	is the frequency in MHz

The insertion loss deviation limits are illustrated in Figure 85–11.

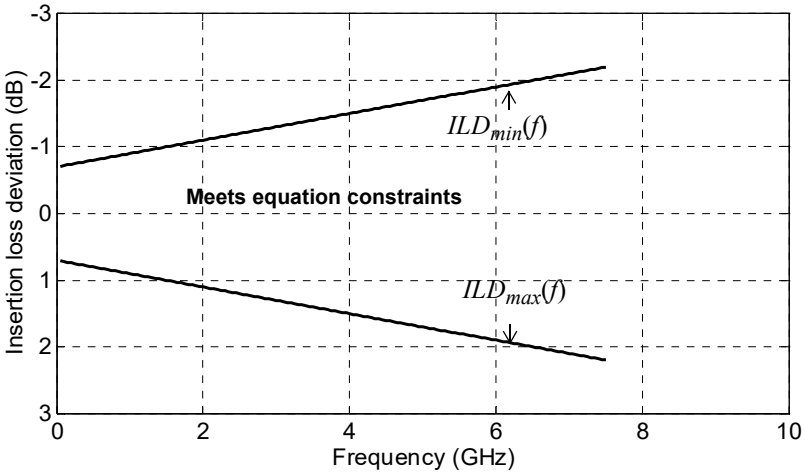

Figure 85–11—Maximum cable assembly insertion loss deviation

85.10.4 Cable assembly return loss

The return loss of each pair of the 40GBASE-CR4 and 100GBASE-CR10 cable assembly shall meet the values determined using Equation (85–25).

$$Return_loss(f) \geq \begin{cases} 12 - 2\sqrt{f} & 0.05 \leq f < 4.1 \\ 6.3 - 13\log_{10}(f/5.5) & 4.1 \leq f \leq 10 \end{cases} \text{ (dB)} \quad (85–25)$$

where

f	is the frequency in GHz
$Return_loss(f)$	is the return loss at frequency f

The minimum cable assembly return loss is illustrated in Figure 85–12.

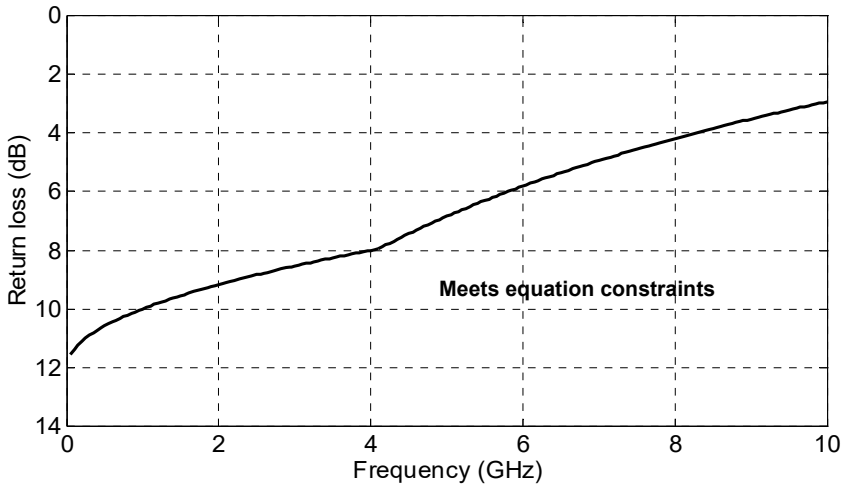

Figure 85–12—Minimum cable assembly return loss

85.10.5 Cable assembly multiple disturber near-end crosstalk (MDNEXT) loss

Since four lanes or ten lanes are used to transfer data between PMDs, the NEXT that is coupled into a receive lane will be from the four or ten transmit lanes. Multiple Disturber Near-End Crosstalk (MDNEXT) loss is determined using the individual NEXT losses.

MDNEXT loss is determined from the four or ten individual pair-to-pair differential NEXT loss values using Equation (85–26).

$$MDNEXT_loss(f) = -10\log_{10}\left(\sum_{i=0}^{i=3\text{or }9} 10^{-NLi(f)/10}\right) \text{(dB)} \quad (85–26)$$

for 50 MHz ≤ f ≤ 10000 MHz

where

$MDNEXT_loss(f)$	is the MDNEXT loss at frequency f
$NL_i(f)$	is the NEXT loss at frequency f of pair combination i, in dB
f	is the frequency in MHz
i	is the 0 to 3 (pair-to-pair combination) or 0 to 9 (pair-to-pair combination)

85.10.6 Cable assembly multiple disturber far-end crosstalk (MDFEXT) loss

Since four lanes or ten lanes are used to transfer data between PMDs, the FEXT that is coupled into a data carrying lane will be from the three other lanes or nine other lanes in the same direction. MDFEXT loss is specified using the individual FEXT losses. MDFEXT loss is determined from the three or nine individual pair-to-pair differential FEXT loss values using Equation (85–27).

$$MDFEXT_loss(f) = -10\log_{10}\left(\sum_{i=0}^{i=2\text{ or }8} 10^{-NLi(f)/10}\right) \text{(dB)} \quad (85–27)$$

for 50 MHz ≤ f ≤ 10000 MHz

where

$MDFEXT_loss(f)$	is the MDFEXT loss at frequency f
$NL_i(f)$	is the FEXT loss at frequency f of pair combination i, in dB
f	is the frequency in MHz
i	is the 0 to 2 (pair-to-pair combination) or 0 to 8 (pair-to-pair combination)

85.10.7 Cable assembly integrated crosstalk noise (ICN)

In order to limit multiple disturber crosstalk noise at a receiver, the cable assembly integrated crosstalk noise (ICN) is specified in relationship to the measured insertion loss. ICN is calculated from the MDFEXT and MDNEXT. Given the multiple disturber near-end crosstalk loss $MDNEXT_loss(f)$ and multiple disturber far-end crosstalk loss $MDFEXT_loss(f)$ measured over N uniformly-spaced frequencies f_n spanning the frequency range 50 MHz to 10000 MHz with a maximum frequency spacing of 10 MHz, the RMS value of the integrated crosstalk noise shall be determined using Equation (85–28) through Equation (85–32). The RMS crosstalk noise is characterized at the output of a specified receive filter utilizing a specified transmitter waveform and the measured multiple disturber crosstalk transfer functions. The transmitter and receiver filters are defined in Equation (85–28) and Equation (85–29) as weighting functions to the multiple disturber crosstalk in Equation (85–30) and Equation (85–31). The sinc function is defined by $\mathrm{sinc}(x) = \sin(\pi x)/(\pi x)$.

Define the weight at each frequency f_n using Equation (85–28) and Equation (85–29).

$$W_{nt}(f_n) = (A_{nt}^2/f_b)\mathrm{sinc}^2(f_n/f_b)\left[\frac{1}{1+(f_n/f_{nt})^4}\right]\left[\frac{1}{1+(f_n/f_r)^8}\right] \quad (85–28)$$

$$W_{ft}(f_n) = (A_{ft}^2/f_b)\mathrm{sinc}^2(f_n/f_b)\left[\frac{1}{1+(f_n/f_{ft})^4}\right]\left[\frac{1}{1+(f_n/f_r)^8}\right] \quad (85–29)$$

where the equation parameters are given in Table 85–11.

Note that the 3 dB transmit filter bandwidths f_{nt} and f_{ft} are inversely proportional to the 20% to 80% rise and fall times T_{nt} and T_{ft} respectively. The constant of proportionality is 0.2365 (e.g., $T_{nt}f_{nt} = 0.2365$; with f_{nt} in hertz and T_{nt} in seconds). In addition, f_r is the 3 dB reference receiver bandwidth, which is set to 7.5 GHz.

The near-end integrated crosstalk noise σ_{nx} is calculated using Equation (85–30).

$$\sigma_{nx} = \left[2\Delta f\sum_n W_{nt}(f_n)10^{-MDNEXT_{loss}(f_n)/10}\right]^{1/2} \quad (85–30)$$

The far-end integrated crosstalk noise σ_{fx} is calculated using Equation (85–31).

$$\sigma_{fx} = \left[2\Delta f\sum_n W_{ft}(f_n)10^{-MDFEXT_{loss}(f_n)/10}\right]^{1/2} \quad (85–31)$$

where Δf is the uniform frequency step of f_n.

The total integrated crosstalk noise σ_x is calculated using Equation (85–32).

Copyright © 2022 IEEE. All rights reserved.
Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

$$\sigma_x = \sqrt{\sigma_{nx}^2 + \sigma_{fx}^2} \quad (85–32)$$

The total integrated crosstalk noise for the cable assembly shall be computed using the parameters shown in Table 85–11.

Table 85–11—Cable assembly integrated crosstalk parameters

Description	Symbol	Value	Units
Symbol rate	f_b	10.3125	GBd
Near-end disturber peak differential output amplitude	A_{nt}	600	mV
Far-end disturber peak differential output amplitude	A_{ft}	600	mV
Near-end disturber 20% to 80% rise and fall times	T_{nt}	24	ps
Far-end disturber 20% to 80% rise and fall times	T_{ft}	24	ps

The total integrated crosstalk RMS noise voltage shall meet the values determined by Equation (85–33) illustrated in Figure 85–13.

$$\sigma_{x,\,\mathrm{ca}} \leq \left\{ \begin{array}{ll} 10 & 3 \leq IL \leq 5.3 \\ 12.4 - 0.45IL & 5.3 < IL \leq 17.04 \end{array} \right\} \quad (\mathrm{mV}) \quad (85–33)$$

where IL is the value of the cable assembly insertion loss in dB at 5.15625 GHz.

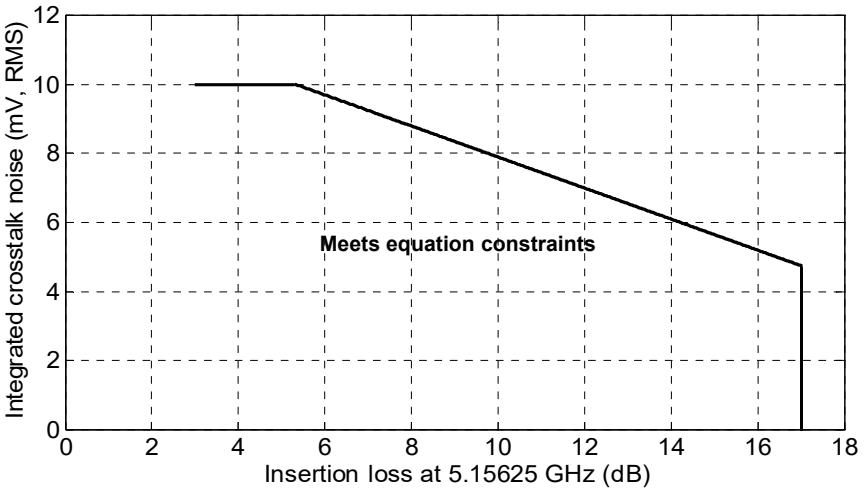

Figure 85–13—Integrated crosstalk noise limits

85.10.8 Cable assembly test fixture

The test fixture of Figure 85–14 or its functional equivalent, is required for measuring the cable assembly specifications in 85.10 at TP1 and TP4. TP1 and TP4 are illustrated in Figure 85–2 and Figure 85–14. The test fixture return loss is equivalent to the test fixture return loss specified in 85.8.3.6. The reference test fixture printed circuit board insertion loss is given in Equation (85–34). The effects of differences between the insertion loss of an actual test fixture and the reference insertion loss are to be accounted for in the measurements.

$$IL_{\text{catf}}(f) = 0.0006 + 0.16\sqrt{f} + 0.0587f \text{ (dB)} \quad (85–34)$$

for 0.01 GHz $\leq f \leq$ 10 GHz

where

f is the frequency in GHz
$IL_{\text{catf}}(f)$ is the reference test fixture printed circuit board insertion loss at frequency f

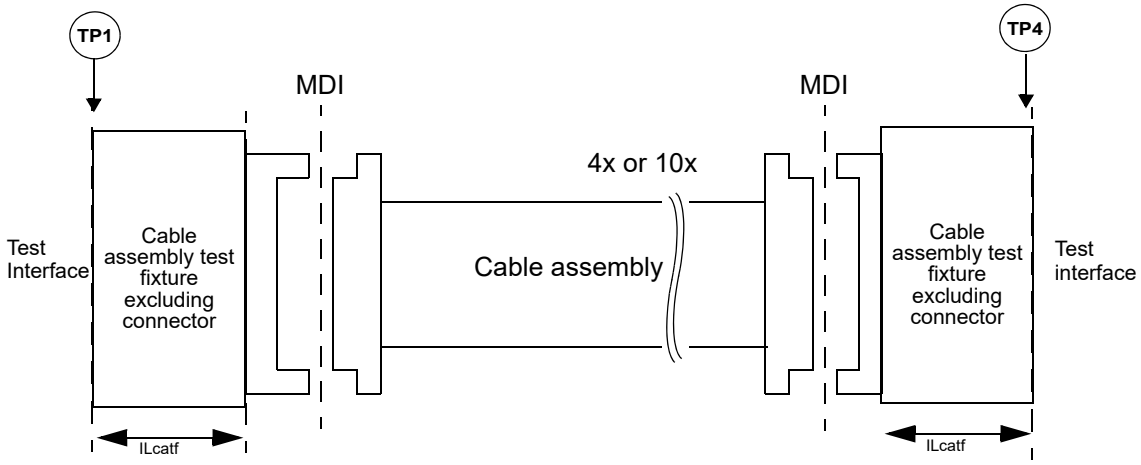

Figure 85–14—Cable assembly test fixtures

85.10.9 Mated test fixtures

The test fixtures of Figure 85–6 and Figure 85–14 are specified in a mated state illustrated in Figure 85–15.

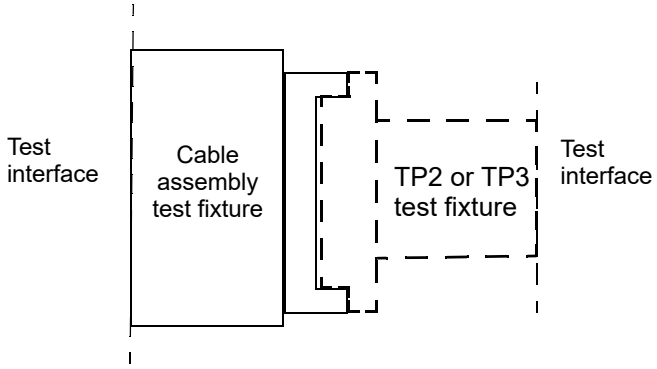

Figure 85–15—Mated test fixtures

Authorized licensed use limited to: IEEE Xplore. Downloaded on November 28,2024 at 03:37:17 UTC from IEEE Xplore. Restrictions apply.

85.10.9.1 Mated test fixtures insertion loss

The insertion loss of the mated test fixtures shall meet the values determined using Equation (85–35) and Equation (85–36).

$$IL(f) \geq IL_{MTFmin}(f) = -0.11 + 0.46\sqrt{f} + 0.16f \qquad 0.01 \leq f \leq 10 \qquad \text{(dB)} \tag{85–35}$$

$$IL(f) \leq IL_{MTFmax}(f) = \left\{ \begin{array}{ll} 0.029 + 0.861\sqrt{f} + 0.158f & 0.01 \leq f < 5.5 \\ 0.2 + 0.65f & 5.5 \leq f \leq 10 \end{array} \right\} \text{(dB)} \tag{85–36}$$

where

f	is the frequency in GHz
$IL(f)$	is the mated test fixture insertion loss at frequency f

The mated test fixtures insertion loss limits are illustrated in Figure 85–16.

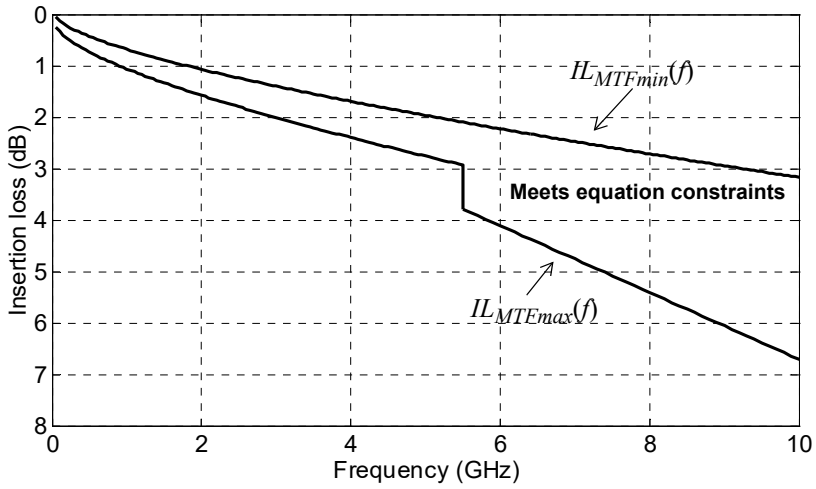

Figure 85–16—Mated test fixtures Insertion loss

85.10.9.2 Mated test fixtures return loss

The return loss of the mated test fixtures measured at either test fixture test interface shall meet the values determined using Equation (85–37).

$$Return_loss(f) \geq \left\{ \begin{array}{ll} 20 - 2f & 0.01 \leq f < 2.5 \\ 15 & 2.5 \leq f < 5 \\ 13.8 - 28.85\log_{10}(f/5.5) & 5 \leq f \leq 10 \end{array} \right\} \text{(dB)} \tag{85–37}$$

where

f	is the frequency in GHz
$Return_loss(f)$	is the return loss at frequency f
